ABSTRACT: In response to the end of the Cold War and changes in the world's political regimes, the United States is not producing new-design nuclear weapons. Instead, the emphasis of the U.S. nuclear weapons program is on reducing the size of the Nation's nuclear stockpile by dismantling existing nuclear weapons. The Department of Energy (DOE) has been directed by the President and Congress to maintain the safety and reliability of the reduced nuclear weapons stockpile in the absence of underground nuclear testing. In order to fulfill that responsibility, DOE has developed a Stockpile Stewardship and Management Program to provide a single highly integrated technical program for maintaining the continued safety and reliability of the nuclear stockpile. The Stockpile Stewardship and Management PEIS describes and analyzes alternative ways to mplement the proposed actions for the Stockpile Stewardship and Management Program.

Stockpile stewardship refers to activities associated with research, design, development and testing of nuclear weapons and the assessment and certification of the safety and reliability. The stockpile stewardship portion of the PEIS evaluates the potential impacts of three proposed facilities: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. The stockpile stewardship alternatives involving these facilities could affect four sites: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and Nevada Test Site (NTS).

Stockpile management refers to activities associated with the production, maintenance, surveillance, refurbishment, and dismantlement of the nuclear weapons stockpile. The stockpile management portion of this PEIS evaluates the potential impacts of carrying out stockpile management alternatives at eight sites: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. The stockpile management alternatives are assessed for nuclear weapons assembly/disassembly and for fabricating pits, secondaries and cases, high explosives, and nonnuclear components.

The Stockpile Stewardship and Management PEIS also evaluates the No Action alternative of relying on existing facilities and continuing the missions at current sites to achieve both the stockpile stewardship and management missions. The No Action alternative assesses the environmental impacts of the on-going Stockpile Stewardship and Management Program and provides a baseline against which alternatives can be evaluated.

DOE has identified the following preferred alternative for the Stockpile Stewardship and Management Program:

Stockpile Stewardship:
- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:
- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL

- Assembly/Disassembly—downsize at Pantex
- High Explosives Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) highly enriched uranium strategic reserve storage at Y-12; and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS*. Decisions on strategic storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the *Stockpile Stewardship and Management Final PEIS* and the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

Evaluation of impacts on land resources, site infrastructure, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, socioeconomics, waste management, environmental justice, as well as radiological and hazardous chemical impacts during normal operation and accidents to workers and the public are included in the assessment. The PEIS presents unclassified information only. A classified appendix has also been prepared to support the PEIS.

PUBLIC COMMENTS: The public comment period on the Draft PEIS was conducted from March 8, 1996 to May 7, 1996. During the comment period, public hearings were held in Los Alamos, NM; Albuquerque, NM; Las Vegas, NV; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. The Draft PEIS was made available through mailings, requests to DOE's Office of Reconfiguration, and at DOE Public Reading Rooms. In preparing the Final PEIS, DOE considered comments received by mail, fax, handed in at hearings, transcribed from messages recorded by telephone, and those transcribed via Internet. In addition, comments and concerns identified during discussions at public hearings were considered.

In response to comments submitted after issuance of the Draft PEIS and due to additional technical details not available at the time of issuance of the Draft, Volumes I, II, and III of the Final PEIS contain revisions and changes. The revisions and changes made since the issuance of the Draft document are indicated by a double underline for minor word changes or by a sidebar in the margin for paragraph or larger changes. In addition, Volume I and each appendix in Volume III provide a unique reference list to enable the reader to further review and research selected topics. Volume IV (Comment Response Document) of the PEIS contains the comments received during public review of the Draft PEIS and the DOE responses to those comments. DOE has public reading rooms near each affected site and in Washington, DC where these referenced documents may be reviewed or obtained for review.

SUMMARY

S.1 INTRODUCTION

The Department of Energy (DOE) is the Federal agency responsible for providing the Nation with nuclear weapons and ensuring that those weapons remain safe and reliable. This programmatic environmental impact statement (PEIS) analyzes the potential consequences to the environment if certain changes to the Nuclear Weapons Complex (Complex) are implemented to support DOE's Stockpile Stewardship and Management Program.

Stockpile stewardship and stockpile management describe DOE's management of the nuclear weapons program. While these terms are not new, DOE has recently redefined them in light of its current roles and responsibilities. Stockpile stewardship comprises the activities associated with research, design, development, and testing of nuclear weapons, and the assessment and certification of their safety and reliability. These activities have been performed at the three DOE weapons laboratories and the Nevada Test Site (NTS). Stockpile management comprises operations associated with producing, maintaining, refurbishing, surveilling, and dismantling the nuclear weapons stockpile. These activities have been performed at the DOE nuclear weapons industrial facilities (see figure S.1–1).

Since the inception of nuclear weapons in the 1940s, DOE and its predecessor agencies have been responsible for stewardship and management of the Nation's stockpile. In response to the end of the Cold War and changes in the world's political regimes, the emphasis of the U.S. nuclear weapons program has shifted dramatically over the past few years from developing and producing new weapons to dismantlement and maintenance of a smaller, enduring stockpile. Accordingly, the nuclear weapons stockpile is being significantly reduced, the United States is no longer manufacturing new-design nuclear weapons, and DOE has closed or consolidated some of its former weapons industrial facilities. Additionally, in 1992 the United States declared a moratorium on underground nuclear testing, and in 1995 President Clinton extended the moratorium and decided to pursue a "zero-yield" Comprehensive Test Ban Treaty (CTBT). Even with these significant changes, DOE's responsibilities for the nuclear weapons stockpile continue, and the President and Congress have directed DOE to continue to maintain the safety and reliability of the enduring nuclear weapons stockpile.

In response to direction from the President and Congress, DOE has developed its Stockpile Stewardship and Management Program to provide a single, highly integrated technical program for maintaining the continued safety and reliability of the nuclear weapons stockpile. It has evolved from predecessor programs that served this mission over previous decades. With no underground nuclear testing, and no new-design nuclear weapons production, DOE expects existing weapons to remain in the stockpile well into the next century. This means that the weapons will age beyond original expectations and an alternative to underground nuclear testing must be developed to verify the safety and reliability of weapons. To meet these new challenges, DOE's science-based Stockpile Stewardship and Management Program has been developed to increase understanding of the basic phenomena associated with nuclear weapons, to provide better predictive understanding of the safety and reliability of weapons, and to ensure a strong scientific and technical basis for future U.S. nuclear weapons policy objectives.

The size and composition of the U.S. nuclear weapons stockpile is determined annually by the President. The Department of Defense (DOD) prepares the Nuclear Weapon Stockpile Plan (NWSP) based on military requirements and coordinates the development of the plan with DOE concerning its ability to support the plan. The NWSP, which is classified, covers the current year and a 5-year planning period. It specifies the types and quantities of weapons required and sets limits on the size and nature of stockpile changes that can be made without additional approval by the President. The Secretaries of Defense and Energy jointly sign the Nuclear Weapon Stockpile Memorandum (NWSM), which includes the NWSP and a long-range planning assessment. As such, the NWSM is the basis for all DOE stockpile support planning.

The Stockpile Stewardship and Management PEIS discusses the relevant factors, such as treaties, that shape the NWSM. Also explained is the fact that

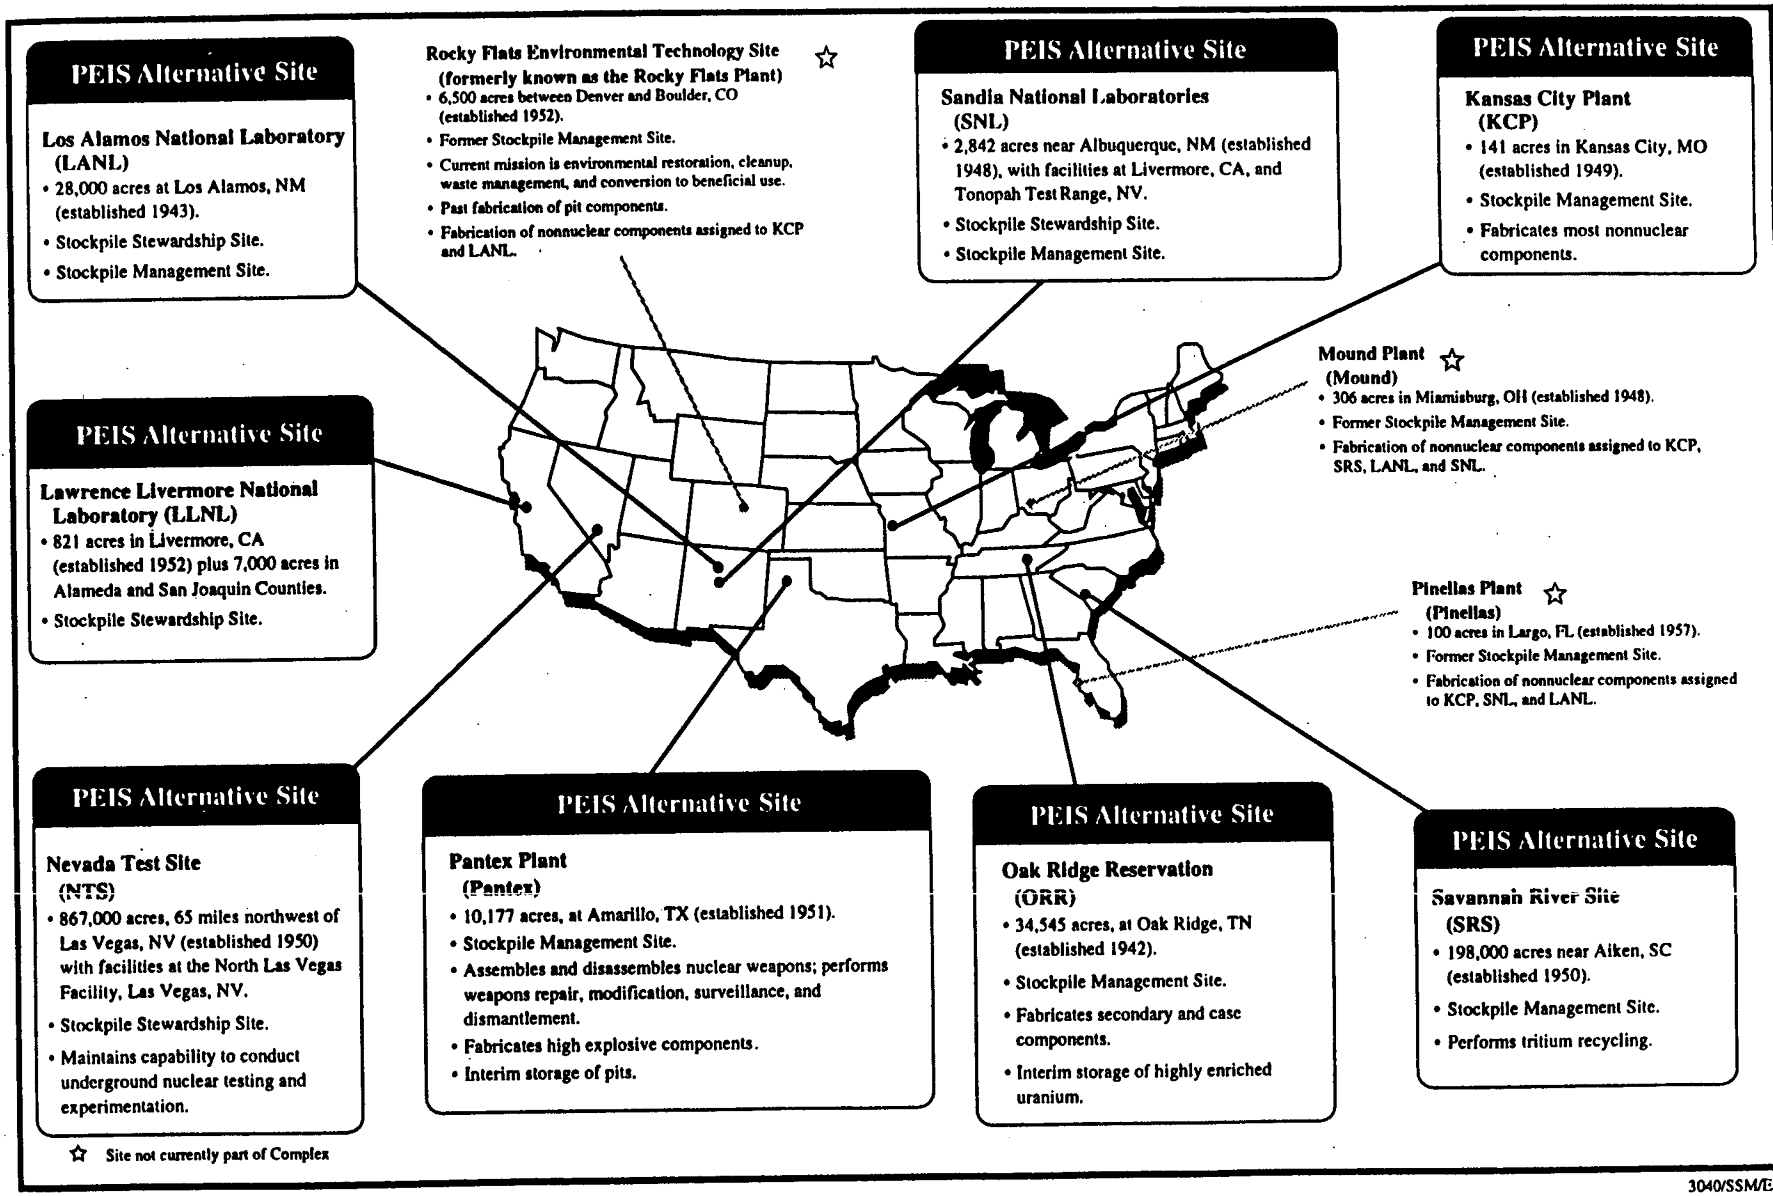

FIGURE S.1–1.—*Current Stockpile Stewardship and Management Sites (Includes Recent Consolidation of Three Former Sites)*.

potential variances in stockpile size, such as a Strategic Arms Reduction Talks (START) I Treaty-sized stockpile versus a START II protocol-sized stockpile, affect only the issue of manufacturing capacity required for the foreseeable future. National security policies in the post-Cold War era require that all the historical capabilities of the weapons laboratories, industrial plants, and NTS be maintained. Capability is the practical ability to perform a basic function or activity. Stockpile stewardship and management capabilities are independent of foreseeable future stockpile sizes. Stockpile management manufacturing capacities are examined in this PEIS, including those required to support a hypothetical low case stockpile size below START II. This was done to examine the sensitivity of potential decisions to transfer manufacturing activities to the weapons laboratories and NTS versus downsizing the industrial plants in place.

S.1.1 Background

A general understanding of nuclear weapons, including the components that make up a weapon and the physical processes involved, helps one understand the scope of the Stockpile Stewardship and Management PEIS and what is to be accomplished by the Stockpile Stewardship and Management Program. Figure S.1.1–1 presents a simplified diagram of a modern nuclear weapon. An actual nuclear weapon produced in the United States is much more complicated, consisting of many thousands of parts.

The nuclear weapon primary is composed of a central core called a pit, which is usually made of plutonium-239 and/or highly enriched uranium (HEU). This is surrounded by a layer of high explosives (HE), which when detonated, compresses the pit, initiating a nuclear reaction. This reaction is generally thought of as the nuclear fission "trigger," which activates the secondary assembly component to produce a thermonuclear fusion reaction. The remaining nonnuclear components consist of everything from arming and firing systems to batteries and parachutes. The production and assembly of many of these components is accomplished at dedicated industrial facilities. Assembly and disassembly (A/D) of nuclear weapons is done only at Pantex.

S.1.2 Alternatives Analyzed in this *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management*

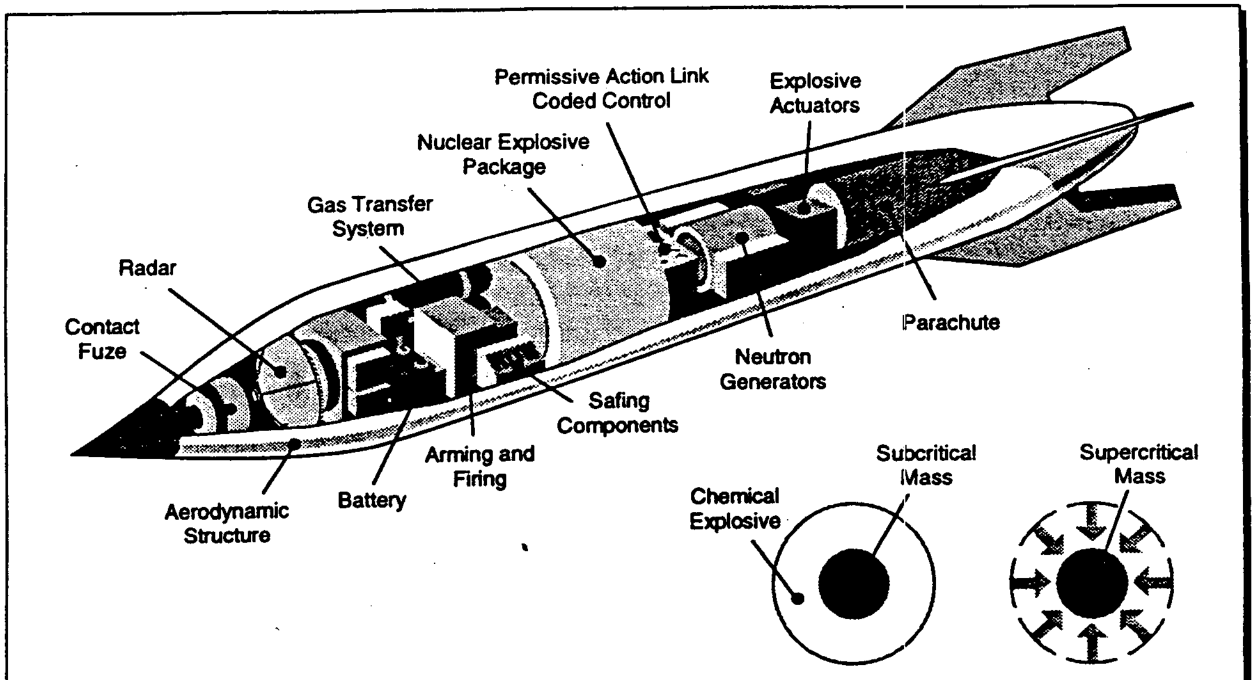
DOE must maintain a Complex with sufficient capability and capacity to meet current and future weapons requirements. For those activities associated with the ongoing stockpile stewardship program, DOE proposes to add enhanced capabilities to existing stockpile stewardship facilities to fulfill requirements. For those activities associated with the ongoing stockpile management program, DOE does not propose to construct any major new weapons industrial facilities. Rather, DOE proposes to "right-size" existing facilities or consolidate them to fulfill expected requirements for manufacture of repair or replacement components for an aging U.S. stockpile.

This PEIS addresses potential changes to the future missions of the three weapons laboratories, the four weapons industrial plants, and NTS. A No Action alternative is also described and analyzed. Figure S.1–1 shows the locations of the eight DOE sites comprising the current Complex. Tables S.3.2–1 and S.3.4–1 show the alternatives analyzed.

To estimate the potential environmental impacts from modifying/constructing and operating the facilities proposed for stockpile management, DOE assumes that facilities would be sized and operated to support a base case stockpile size consistent with the START II protocol. This PEIS also discusses impacts that would be expected for supporting a larger stockpile based on START I Treaty levels, and a hypothetical stockpile smaller than the START II protocol.

With regard to stockpile management facilities, potential environmental impacts from the base case are analyzed quantitatively in the greatest detail, while impacts from the high and low cases are discussed qualitatively. The facilities proposed for stockpile stewardship are independent of projected stockpile size.

The stockpile stewardship portion of this PEIS evaluates the potential environmental impacts of the proposed actions and the reasonable alternatives for carrying out the stockpile stewardship functions. As described in section S.2.4, the three independently



The diagram is a symbolic representation of the design elements of a nuclear weapon. None of the symbols represent actual designs.

Nuclear explosions are produced by initiating and sustaining nuclear chain reactions in highly compressed material which can undergo both fission and fusion reactions. Modern strategic, and most tactical, nuclear weapons use a nuclear explosive package with two assemblies: the primary assembly, which is used as the initial source of energy, and the secondary assembly, which provides additional explosive energy release. The primary assembly contains a central core, called the "pit", which is surrounded by a layer of high explosive. The "pit" is typically composed of plutonium–239 and/or highly enriched uranium (HEU), and other materials. HEU contains large fractions of the isotope uranium–235.

Primary Detonation

The primary nuclear explosion is initiated by detonating the layer of chemical high explosive that surrounds the "pit" which in turn drives the pit material into a compressed mass at the center of the primary assembly. This implosion process is illustrated in the inset of the diagram.

Boosting

In order to achieve higher explosive yields from primaries with relatively small quantities of pit material, a technique called "boosting" is used. Boosting is accomplished by injecting a mixture of tritium (T) and deuterium (D) gas into the pit. The deuterium and tritium are stored in reservoirs until the gas transfer system is initiated. The implosion of the pit along with the onset of the fissioning process heats the D-T mixture to the point that the D-T atoms undergo fusion. The fusion reaction produces large quantities of very high energy neutrons which flow through the compressed pit material and produce additional fission reactions.

Secondary Activation

The energy released by the primary explosion activates the secondary assembly. The secondary assembly is composed of lithium deuteride and other materials. As the secondary implodes, the lithium, in the isotopic form lithium–6, is converted to tritium by neutron interactions, and the tritium product in turn undergoes fusion with the deuterium to create the thermonuclear explosion.

Nonnuclear Components

Nonnuclear components include contact fuzes, radar components, aerodynamic structures, arming and firing systems, gas transfer system, permissive action link coded controls, neutron generators, explosive actuators, safing components, batteries, and parachutes.

2070/SSM/ES

FIGURE S.1.1–1.—*Nuclear Weapons Design.*

justified proposed facilities include the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. Four sites (figure S.1–1) are potentially affected by the stockpile stewardship alternatives: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and NTS (includes NLVF). This PEIS also assesses the No Action alternative of relying on existing experimental facilities and continuing the missions at these four sites to fulfill the stockpile stewardship mission.

The science-based stockpile stewardship program is expected to continuously evolve as better information becomes available and technological advances occur. Additional experimental facilities, such as the Advanced Hydrotest Facility (AHF), the High Explosives Pulsed Power Facility (HEPPF), the Advanced Radiation Source (ARS [X-1]), and the Jupiter Facility are considered to be next generation facilities that may be required in the future to support stockpile stewardship objectives. However, these facilities are not proposed actions in this PEIS because they have not reached the stage of development and definition that is necessary for evaluation and decisionmaking.

The stockpile management portion of this PEIS evaluates the potential environmental impacts of the reasonable alternatives for carrying out the stockpile management functions. Alternatives are assessed for nuclear weapons A/D and for fabricating pit, secondary and case, HE, and nonnuclear components. Eight sites (figure S.1–1) are potentially affected: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. This PEIS also assesses the No Action alternative of relying on existing facilities and continuing the missions at the current sites to fulfill the stockpile management mission.

S.1.3 *National Environmental Policy Act* Strategy for Stockpile Stewardship and Management

This PEIS has been prepared in accordance with section 102(2)(c) of the *National Environmental Policy Act* (NEPA) of 1969, as amended (42 U.S.C. 4321 et seq.), and implemented by regulations promulgated by the Council on Environmental Quality (CEQ) (40 CFR 1500-1508) and DOE regulations (10 CFR 1021). Under NEPA, Federal agencies, such as DOE, that propose major actions that could significantly affect the quality of the human environment are required to prepare an environmental impact statement (EIS) to ensure that environmental information is available to public officials and citizens before decisions are made and before actions are taken. For broad actions, such as the Stockpile Stewardship and Management Program, a PEIS is prepared.

DOE's NEPA compliance strategy for the Stockpile Stewardship and Management Program consists of two phases. The first phase includes the Stockpile Stewardship and Management PEIS and subsequent Records of Decision (ROD). Decisions will be based on relevant factors including economic and technical considerations, DOE statutory mission requirements, policy considerations, and environmental impacts. In addition to the analyses in this PEIS, engineering studies, cost, schedule, and technical feasibility analyses will be considered in the ROD. The ROD is expected to identify the effects of U.S. national security policy changes on Stockpile Stewardship and Management Program missions and determine the configuration (facility locations) necessary to accomplish the Program missions.

During the second phase of the NEPA strategy, which would follow the PEIS ROD, DOE would prepare any necessary project-specific NEPA documents to implement any programmatic decision. However, as explained below, this PEIS also includes project-specific environmental analyses for the experimental facilities proposed for stockpile stewardship.

For the three facilities in the proposed action for stockpile stewardship—NIF, CFF, and the Atlas Facility—the Stockpile Stewardship and Management PEIS is intended to include sufficient project-specific analyses to complete NEPA requirements for siting, construction, and operation, and thus, satisfy both phases of the NEPA compliance strategy. This PEIS supports the programmatic decisions on whether to proceed with the facility and, if so, where to site the facility. The project-specific analysis describes the detailed construction and operational impacts for each facility at the alternative sites. Each proposed facility's project-specific analysis can be found in Volume III of this PEIS.

S.1.4 Related Recently Completed *National Environmental Policy Act* Actions

Two other actions that DOE has already evaluated in separate EISs, in accordance with CEQ regulations for interim actions (40 CFR 1506.1), are within the scope of the Stockpile Stewardship and Management PEIS. These are the *Programmatic Environmental Impact Statement for Tritium Supply and Recycling* and the *Dual-Axis Radiographic Hydrodynamic Test* (DARHT) *Facility Environmental Impact Statement.*

The Tritium Supply and Recycling PEIS evaluated the potential environmental impacts associated with alternatives for siting, constructing, and operating tritium supply and recycling facilities. The purpose of the Tritium Supply and Recycling Program is to provide long-term, assured tritium supply and recycling to support the Nation's nuclear weapons stockpile. The Tritium Supply and Recycling Draft PEIS (DOE/EIS-0161) was issued in March 1995 and was followed by public hearings in April 1995. A Final PEIS was issued in October 1995, followed by the ROD published in the *Federal Register* (60 FR 63878) on December 12, 1995.

The DARHT Facility EIS analyzed the environmental consequences of alternative ways to accomplish enhanced high-resolution radiography for the purposes of performing hydrodynamic tests and dynamic experiments. These tests are used to obtain diagnostic information on the behavior of nuclear weapons primaries and to evaluate the effects of aging on nuclear weapons. The DARHT Facility's construction was about 34 percent complete when construction was halted under a U.S. District Court preliminary injunction issued on January 27, 1995, pending completion of the DARHT Facility EIS and issuance of the ROD. The DARHT Facility EIS evaluated the potential environmental impacts of six alternatives; the preferred approach entailed completing and operating the proposed DARHT Facility at LANL and implementing a phased enhanced containment strategy for testing at the DARHT Facility, so that most tests would be conducted inside steel vessels. The DARHT Facility Draft EIS (DOE/EIS-0228) was issued in May 1995 and was followed by public hearings in May and June 1995. A Final PEIS was issued in August 1995, followed by the ROD published in the *Federal Register* (60 FR 53588) on October 16, 1995.

In the ROD, DOE announced that it will complete and operate the DARHT Facility at LANL while implementing a program to conduct most tests inside steel vessels, with containment to be phased in over 10 years. Following the ROD, DOE filed a motion for dissolution of the injunction. On April 16, 1996, the U.S. District Court concluded that the purpose of the injunction had been satisfied, and therefore lifted the injunction and dismissed the case.

DOE will rely on hydrodynamic testing in the absence of underground nuclear testing to ensure the stockpile's safety and reliability. Under any course of action analyzed in this PEIS, DOE will still need to continue hydrodynamic testing and acquire near-term enhanced radiographic capability such as that provided by the DARHT Facility. DOE determined that implementing the DARHT Facility ROD will not prejudice any decisions in the Stockpile Stewardship and Management Program. The impacts of the DARHT Facility for each resource area are addressed in the No Action impact discussions for LANL in Volume I, section 4.6.3.

S.1.5 Other Department of Energy Ongoing *National Environmental Policy Act* Reviews

In addition to the two completed actions identified above, DOE is currently preparing other programmatic, project-specific, and site-wide NEPA documents. The following major documents have been determined to have potential cumulative effects for the sites being analyzed by this Stockpile Stewardship and Management PEIS, and are described in this PEIS and included in the analysis. This PEIS describes and includes in its analysis the ongoing alternatives being developed by the *Waste Management Programmatic Draft Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste*; the *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement*; the *Site-Wide Draft Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components*; the Site-Wide EIS for the Los Alamos National Laboratory; and the Site-Wide EIS for the Nevada Test Site.

In May 1994, when DOE announced its intention to prepare the Pantex Site-Wide EIS, DOE believed that the Pantex Site-Wide EIS ROD would precede decisionmaking on the long-term storage of pits by at least several years. Accordingly, the Draft Pantex Site-Wide EIS was scoped to address alternative locations for interim pit storage (i.e., until the long-term decisions were made and implemented).

Since May 1994, DOE has initiated two additional NEPA documents that address the storage of pits. This Stockpile Stewardship and Management PEIS will support decisions on the long-term storage of pits that will be needed for national security requirements (strategic reserve pits). The Storage and Disposition PEIS will support decisions on the long-term storage of all pits (strategic reserve and surplus) and the approach for dispositioning pits that are surplus to national security requirements.

Both of these PEISs have progressed to the point where they are scheduled to have their RODs issued by the Fall of 1996, at or about the same time as the ROD for the Pantex Site-Wide EIS, which is scheduled for November 1996. Therefore, DOE is proposing that so long as the RODs of both the PEISs and the Pantex Site-Wide EIS occur within a short period of time of one another, decisions on the long-term storage of pits would be made in the RODs of the PEISs. A decision relating to the interim storage of pits at Pantex would be made in the ROD of the Pantex Site-Wide EIS pending implementation of the selected long-term storage option.

However, if there is a significant delay in the RODs for either of the PEISs, or if DOE does not make a decision on the long-term storage of pits in those RODs, then there would be a need to make a decision on the location of interim storage of pits uninformed by a decision on long-term storage. In any event, the Pantex Site-Wide EIS will be completed with the analysis of interim storage alternatives, including addressing the issues and comments received from the public on that EIS, to support a decision relating to the storage of pits until a long-term storage decision has been made and implemented.

S.1.6 Public Participation

Public participation for this PEIS consisted of two primary activities: the scoping process and the public comment process. CEQ regulations require "an early and open process for determining the scope of issues to be addressed and for identifying the significant issues to be addressed and for identifying the significant issues related to a proposed action (40 CFR 1501.7)." This is usually called the public scoping process. Section 4.1 of the *Implementation Plan Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (DOE/EIS-0236IP, December 1995) describes the scoping process. The following sections describe the public comment process on the Draft EIS.

S.1.6.1 *Public Comment Process on the Draft Programmatic Environmental Impact Statement*

In February 1996, DOE published the Stockpile Stewardship and Management Draft PEIS that evaluated the siting, construction, and operation of the proposed stockpile stewardship facilities and the modification/construction and operation of facilities proposed for stockpile management at eight alternative sites within the Complex. The 60-day public comment period for the Draft PEIS began on March 8, 1996, and ended on May 7, 1996. However, late comments were accepted to the extent practicable.

During the comment period, public hearings were held in Los Alamos, NM; Albuquerque, NM; Las Vegas, NV; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. Five of the public hearings were joint meetings to obtain comments on both the Stockpile Stewardship and Management PEIS and the Storage and Disposition PEIS. Two of the joint meetings (Pantex and SRS) also included the Pantex Site-Wide EIS. In addition, the public was encouraged to provide comments via mail, fax, electronic bulletin board (Internet), and telephone (toll-free 800 number). Figure S.1.6.1–1 shows the dates and locations of the hearings.

The public hearings held for the Draft PEIS were conducted using an interactive workshop-type format. The format chosen allowed for a two-way interaction between DOE and the public and encouraged informed public input and comments on the document. Neutral facilitators were present at the hearings to direct and clarify discussions and comments. Court reporters were also present to

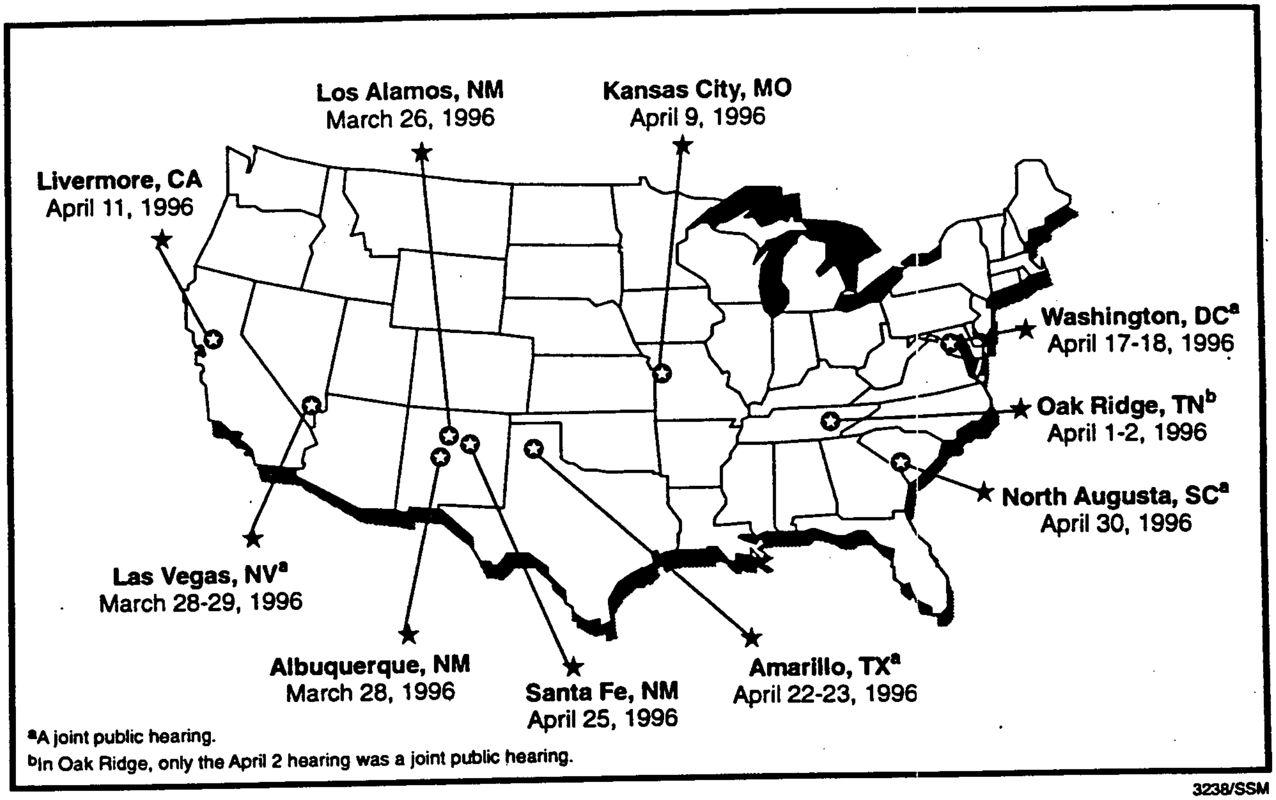


FIGURE S.1.6.1-1.—***Public Hearing Locations and Dates, 1996.***

provide a verbatim transcript of the proceedings and record any formal comments.

All public hearing comment summaries were combined with comments received by mail, fax, Internet, or telephone during the public comment period. Volume IV of this PEIS, the *Comment Response Document*, describes the public comment process in detail, presents comment summaries and responses, and provides copies of all comments received.

S.1.6.2 *Major Comments Received on the Draft Programmatic Environmental Impact Statement*

A large number of the comments received on the Draft PEIS related to concerns that the analysis of particular alternatives and/or alternative sites did not adequately consider such factors as cost and technical feasibility. Although these concerns made up the majority of the comments, many other comments related to the resources analyzed, NEPA and regulatory issues, and DOE and Federal policies as they related to the PEIS. The major issues identified by commentors include the following:

- The potential conflict between the Stockpile Stewardship and Management Program and the Nuclear Nonproliferation Treaty (NPT) goals, and the pursuit of a CTBT
- Using the funds allocated for the Stockpile Stewardship and Management Program for social programs and on research of alternative sources of energy
- The generation, storage, and disposal of radioactive and hazardous wastes and the associated risks
- The impacts of the alternatives on human health (both from radiation and hazardous chemicals) and how these risks were determined and evaluated
- The relationship of this PEIS to other DOE documents and programs, particu-

larly the Pantex and NTS Site-Wide EISs, the Waste Management and the Storage and Disposition PEISs, and the need to make decisions based on all associated programs and activities concurrently

- The need for decisions to be based on many different factors, including environmental, cost, and safety concerns
- The need for DOE to consider a zero-level stockpile, remanufacturing, and denuclearization as alternatives
- Maintaining deterrence with surveillance, curatorship, and remanufacturing without the need for the proposed facilities
- The need for DOE to adequately consider the ongoing stewardship programs
- The need for DOE to perform detailed analysis of future stockpile stewardship facilities.

All of the issues identified above are summarized and responded to in detail in chapter 3 of Volume IV. Substantial revisions to this PEIS resulting from public comments are discussed below.

Revisions in the Final PEIS include additional discussion and analysis in the following areas: alternatives considered but eliminated (section 3.1.2); the No Action alternative (appendix A "Stockpile Stewardship and Management Facilities," sections A.1.5, A.1.6, A.1.7, and A.1.8); socioeconomics at ORR, Pantex, and KCP; accident impacts at Pantex; normal operation impacts for radiological and chemical sections; cumulative impacts (section 4.13); and minor changes to LANL water resources section (4.6.2.4). A new section was also added to appendix F (section F.4, Secondary Impacts of Accidents). Each of these areas is discussed in more detail in the following section.

S.1.6.3 *Changes from the Draft Programmatic Environmental Impact Statement*

As a result of comments received on the Draft PEIS, several changes were incorporated into this PEIS. A brief discussion of the more significant changes is provided in the following paragraphs.

Alternatives Considered but Eliminated from Detailed Study and Related Issues. In response to public comments expressing a concern that DOE had not analyzed a reasonable range of alternatives, section 3.1.2 was expanded. The changes were in response to specific questions concerning compliance with treaties, stockpile size, maintenance and remanufacturing options, and the stockpile stewardship alternatives including No Action. The discussions in section 3.1.2 provide greater detail and more clarification on why alternatives were eliminated from detailed study in this PEIS. Together, chapter 2 and section 3.1.2 explain the framework and the constraints of national security policy that have shaped the proposed actions and reasonable alternatives for this PEIS.

No Action Alternative. Several commentors did not think that the No Action alternative was clearly explained in the Draft PEIS. More specifically, they were not sure which existing facilities at LANL, LLNL, SNL, and NTS were part of the ongoing stockpile stewardship program. As a result, the description of No Action was modified in appendix A to include a listing of major DOE Office of Defense Programs (DP) facilities at LANL, LLNL, SNL, and NTS. Additionally, the discussion of impacts of No Action at LANL (section 4.6.3) was revised as appropriate to include the effects of the DARHT Facility.

Socioeconomics at Oak Ridge Reservation, Kansas City Plant, and Pantex Plant. Based on public comments and revised workforce size estimates, the socioeconomic impact sections for the downsizing alternatives at ORR (section 4.2.3.8), KCP (section 4.4.3.8), and Pantex (section 4.5.3.8) have been revised. The analyses were also expanded to cover the base case single-shift options in greater detail. At these three sites, downsizing of existing facilities is the preferred alternative. For such downsizing, the base case single-shift scenario represents the bounding analysis for the workforce. The change in worker estimates did not cause any of the major indicators in the socioeconomic analysis to change in any significant manner.

Accident Impacts at Pantex Plant. The analyses of impacts due to an aircraft impact and the resulting release of plutonium by a fire or an explosion were modified to include more updated data on probability and source terms developed for the Pantex Site-Wide EIS. Section 4.5.3.9 and appendix sections F.2.1.1 and F.2.1.2 were revised to incorporate the new analytical results. Based on the updated data, the potential impacts and risks to the public from the composite accident presented in this PEIS would be less than previously reported in the Draft PEIS. This change was not significant.

Normal Operation Radiological/Chemical Impacts. The discussion of the normal operation radiological affected environment for LANL, section 4.6.2.9, has been updated to include the latest data from *Environmental Surveillance at Los Alamos During 1993* (LA-12973-ENV, October 1995). The normal operation radiological impact sections 4.2.3.9, 4.3.3.9, and 4.6.3.9 have also been revised to include the contribution of recent facilities at ORR, SRS, and the new environmental surveillance data for LANL. The chemical health effects, section 4.6.3.9 for LANL and section 4.7.3.9 for LLNL, were revised based on new analyses using updated dispersion rates. Tables in appendix section E.3.4 supporting these sections were also updated. The majority of these changes affected the No Action alternative analyses. None of the changes to these sections significantly changed the analysis of impacts for the "action" alternatives.

Cumulative Impacts. The cumulative impact section 4.13 has been modified to incorporate a discussion of normal operation radiological impacts and other changes based on more recent data from NEPA documents and RODs. The changes to this section did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

Los Alamos National Laboratory Water Resources. Changes were incorporated in section 4.6.2.4 (Water Resources) for LANL based on more recent water use and water quality data. The Draft PEIS had erroneously stated that the LANL water allotment would be fully used by about the year 2000. The Final PEIS correctly reports that this allotment would be fully used by about the year 2052. This change did not have a meaningful effect on the analysis/comparative evaluation of alternatives. Minor revisions reflecting the baseline changes, were also made to the LANL water resources impact section 4.6.3.4.

Health Effects Studies. Appendix section E.4, which outlines epidemiological studies at the alternative sites, was rewritten to provide more detail and incorporate more recent and other applicable studies. Although these epidemiology sections do not affect the environmental analysis of future stockpile stewardship and management missions, they do provide relevant information regarding potential health effects from past actions. These changes did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

New Section. A new section has also been added to the Final PEIS (appendix section F.4, Secondary Impacts of Accidents). This section evaluates the secondary impacts of accidents that affect elements of the environment other than humans (e.g., farmland). The section was added because of public comments. The results of this analysis show that secondary impacts from accidents would generally not extend beyond site boundaries, except at Pantex and LLNL, where it is possible that some surface contamination could occur. This new analysis did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

S.2 PURPOSE OF AND NEED FOR THE STOCKPILE STEWARDSHIP AND MANAGEMENT ACTION

The Stockpile Stewardship and Management Program is broad in scope and technically complex. The Program currently involves the integrated activities of three national laboratories, four industrial plants, and a nuclear test site. Further, the Program must be consistent with, and supportive of, U.S. national security policies, which have changed considerably since the end of the Cold War. Therefore, to better understand the Stockpile Stewardship and Management PEIS purpose, need, proposed action, and alternatives, it is useful to view the Program from two different perspectives. One perspective (see section S.2.1) is from the top level of national security policies for nuclear deterrence, arms control, and nonproliferation. These policies include ongoing responsibilities, strategies, and directives. The other perspective (see section S.2.2) focuses on the relevant technical efforts to maintain a safe and reliable U.S. nuclear weapons stockpile. Flow diagrams representing the logic of each perspective are included in figures S.2–1 and S.2–2.

S.2.1 National Security Policy Considerations

There are four principal national security policy overlays and four related treaties that define Program conditions for the reasonably foreseeable future. They are:

- Presidential Decision Directives (PDD)
- *National Defense Authorization Act of 1994* (Pub. L. 103-160)
- DOD Nuclear Posture Review (NPR)
- NWSM
- Proposed CTBT
- NPT
- START I Treaty
- START II protocol

Of the above, the START II protocol is the most useful in helping define a specific time period to bound the reasonably foreseeable future.

Nuclear Posture Review

Beginning in 1991, several Presidential policy decisions, some unilateral and some made in conjunction with international treaties, resulted in DOD conducting the comprehensive NPR, which was approved by the President in 1994. The NPR defines and integrates past and present U.S. policies for nuclear deterrence, arms control, and nonproliferation objectives. The unclassified NPR strategies that pertain to the Stockpile Stewardship and Management Program were presented at the eight public scoping meetings conducted in the summer of 1995. There was general public interest in understanding this complex issue, especially as it relates to treaties, policies, and stockpile size. A summary of how the post-Cold War treaties relate to the NPR strategies and the stockpile follows.

Strategic Arms Reduction Talks. The NPR assumes that the START I Treaty and START II protocol will be fully implemented. However, since the START I Treaty is not yet fully implemented and the START II protocol is not scheduled to be fully implemented until 2003, the NPR strategy protects the U.S. option to reconstitute the stockpile to START I levels should unfavorable events occur in the former Soviet Union. The treaties only control the number of strategic nuclear weapons that can be loaded on treaty-specified and -verified strategic missiles and bombers. These nuclear weapons are limited to 6,000 by the START I Treaty and 3,500 by the START II protocol. The treaties do not control the total stockpile size or the composition of strategic and nonstrategic nuclear weapons of either side. The U.S. stockpile will be larger than 6,000 under START I and 3,500 under START II since the stockpile also includes retaining weapons for nonstrategic nuclear forces, DOD operational spares, and spares to replace weapons attrited by DOE surveillance testing. In the START II case, the stockpile may also include retaining weapons to reconstitute to the START I level. However, the terms "START I-sized stockpile" and "START II-sized stockpile" are relevant to the Stockpile Stewardship and Management PEIS as explained in the discussion of the NWSM.

Comprehensive Test Ban Treaty. It is the declared policy of the United States to seek ratification of a "zero-yield" CTBT as soon as possible. The United States has been observing a moratorium on nuclear testing since 1992. The NPR strategy reflects this policy and the strategy has a significant effect on shaping the Stockpile Stewardship and Management Program. As explained in section S.2.2, it is anticipated that repairs or replacements to an aging U.S. stockpile will be needed. Assessment and certification of the safety and reliability of stockpile repairs or replacements without nuclear testing is a significant challenge to the Stockpile Stewardship and Management Program. In declaring the policy to seek a CTBT, the President also declared that the continued safety and reliability of the U.S. nuclear stockpile is a "supreme national interest" of the United States.

Nuclear Nonproliferation Treaty. Article VI of the NPT obligates the parties "to pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament, and on a treaty on general and complete disarmament under strict and effective international control." However, the NPT does not provide any time period for achieving this goal. Even relatively simple bilateral treaties, such as START I and START II, require more than 10 years to implement, not counting the years of negotiations. In the words of Ambassador Thomas Graham, "Regrettably, none of us is clairvoyant, and so it is unwise to predict with any degree of precision the future international reality and consequently, the complete arms control agenda."[1] For the Stockpile Stewardship and Management PEIS, speculation on the terms and conditions of a "zero level" U.S. stockpile with international verification, as some have suggested during the scoping meetings, goes beyond the bounds of a reasonably foreseeable future. For the same reason, DOE has not chosen to speculate on a return of the nuclear arms race requiring a stockpile larger than START I size. However, in keeping with the NPT goals, the NPR strategy does express the U.S. intent to pursue further reductions in nuclear forces beyond START II. Therefore, the implications of further reductions below the START II-sized stockpile are discussed in this PEIS where they are relevant.

Nuclear Weapon Stockpile Memorandum

Although the NWSM is a classified document, its effect in shaping the Stockpile Stewardship and Management PEIS can be explained in an unclassified context. Without access to the classified NWSM, one might assume that the exact details of the projected stockpile size and composition under START I and START II could have a significant effect on the Stockpile Stewardship and Management PEIS. This is not the case for the following reasons:

- The stockpile composition (i.e., the number of different weapon types), does not vary significantly in either a START I- or START II-sized stockpile. All weapon types are tritium-boosted, thermonuclear weapons that could be affected by the same types of safety and reliability problems requiring repair, replacement, and certification in the absence of nuclear testing. The basic weapons laboratory and industrial capabilities required for the foreseeable future do not vary significantly from planned differences in size or composition of either a START I- or START II-sized stockpile.

- Industrial capacity is only indirectly affected by projected variances in stockpile size and composition. Stockpile size must be linked with historical stockpile data to arrive at estimates of average annual industrial capacity needed to produce components for repair or replacement. Even without the limitations on the use of historical stockpile data described in section S.2.2, this cannot be done with mathematical precision and therefore reasonable technical judgment must be applied. The result is to forecast a need for a smaller industrial base with capacities on a scale of hundreds of weapons per year versus the thousands of weapons per year that existed prior to the end of the Cold War. A range of annual requirements is considered for impact analysis in the Stockpile Stewardship and Management PEIS that bounds potential variances in the NWSM under the START II protocol. In addition, a qualitative sensitivity analysis is performed on the hypothetical low case that is well below the START II-sized stockpile projection and the high case associated with a START I-sized stockpile.

Presidential Decision Directives and Public Law

Over the past few years, there have been several publicly announced PDDs that have shaped the Stockpile Stewardship and Management Program. In the *National Defense Authorization Act of 1994* (Pub. L. 103-160), Congress acted to reinforce many of the same points. A summary of their effect in shaping the Stockpile Stewardship and Management PEIS follows:

- The continued maintenance of a safe and reliable nuclear weapons stockpile will remain a cornerstone of the U.S. nuclear deterrent for the foreseeable future.

- The core intellectual and technical competencies of the United States in nuclear weapons will be maintained. This includes competencies in research,

[1] From a January 1995 speech by Ambassador Graham, Special Representative of the President for Arms Control Non-Proliferation and Disarmament.

design, development, and testing (including nuclear testing); reliability assessment; certification; manufacturing; and surveillance capabilities.

- The United States will develop new ways to maintain a high level of confidence in the safety, reliability, and performance of its nuclear weapons stockpile in the absence of nuclear testing. The strategy for this action will be structured around the use of past nuclear test data in combination with enhanced computational modeling, experimental facilities, and simulators to further comprehensive understanding of the behavior of nuclear weapons and the effects of radiation on military systems.[2]

- The continued vitality of all three DOE nuclear weapons laboratories will be essential in addressing the challenges of maintaining a safe and reliable nuclear weapons stockpile without nuclear testing and without the production of new-design weapons.

S.2.2 Safety and Reliability of the United States Stockpile

This section focuses on the technical effects of national security policy decisions on shaping the purpose, need, proposed actions, and alternatives of the Stockpile Stewardship and Management Program. The stockpile is currently judged to be safe and reliable by DOE. National security policy changes will significantly change the characteristics of the future nuclear weapons stockpile and the manner in which it will need to be certified as safe and reliable.

Stockpile History

Since the beginning of the Cold War, the United States has maintained a nuclear deterrent force as safe and reliable as the evolution of military requirements and technology development would permit. A safe and reliable U.S. nuclear weapons stockpile has been a cornerstone of maintaining a credible nuclear deterrent. The size of the U.S. nuclear weapons stockpile peaked in the 1960s. In the 1970s, it was significantly reduced due to the easing of Cold War tensions with the former Soviet Union. In the late 1970s and through most of the 1980s, Cold War tensions with the former Soviet Union significantly increased and the U.S. nuclear deterrent force was modernized in response. However, the size of the U.S. nuclear weapons stockpile remained stable during the 1980s with the production of new-design weapons replacing dismantled weapons nearly one for one.

The beginning of the 1990s brought the collapse of the Warsaw Pact and the former Soviet Union and a significant effort to end the Cold War. During the first half of the 1990s, many changes occurred in U.S. policy and planning for its nuclear deterrent force. Much has already been accomplished, including the dismantlement, without replacement, of more than 8,000 U.S. nuclear weapons since the end of the Cold War; however, much more will need to be accomplished with the former Soviet Union over the next 10 years to stay the course. Large uncertainties remain concerning the nuclear weapons stockpile of the former Soviet Union, and it is the policy of the United States to protect its national security options for its nuclear deterrent, including the reconstitution of its nuclear forces. The following excerpt is from the President's national security strategy statement in July 1994:

> Even with the Cold War over, our Nation must maintain military forces that are sufficient to deter diverse threats ... We will retain strategic nuclear forces sufficient to deter any future hostile foreign leadership with access to strategic nuclear forces from acting against our vital interests and to convince it that seeking a nuclear advantage would be futile. Therefore we will continue to maintain nuclear forces of sufficient size and capability to hold at risk a broad range of assets valued by such political and military leaders.

Smaller, Aging Stockpile

Until recently there has been no reason to expect that weapons would remain in the stockpile longer than they have in the past. Continuous modernization to improve safety and reliability kept the stockpile

[2] The effects of radiation on nuclear weapons and military systems are referred to as "weapons effects" throughout this PEIS.

young as new-design weapon types replaced old ones. Now, with no new-design weapons being produced, the United States will have a steadily aging stockpile. The average age of the stockpile has never approached the typical lifetime specified in the weapon requirements (approximately 20 years for the most modern U.S. nuclear weapons). The average age of the stockpile is currently about 13 years. The NWSM forecasts the average age will now climb roughly 1 year per year and will reach the 20 year mark by 2005, at which time the oldest weapons will be about 35 years old.

Historical Stockpile Data

The following paragraphs describe the effects of historical stockpile data in shaping the Stockpile Stewardship and Management Program. This information was extracted from an unclassified report, *Stockpile Surveillance: Past and Future* (tri-laboratory report requested by DOE and issued as Sandia Laboratory Report, SAND 95-2751, September 1995), which was co-authored by the three weapons laboratories and is available to the public. The past role of nuclear testing is emphasized because such testing can no longer be relied on to provide unambiguous high confidence in the future safety and reliability of an aging stockpile.

Stockpile Evaluation Program.[3] Continuous evaluation of the safety and reliability of the stockpile has always been a major part of the U.S. nuclear weapons program. Since the introduction of sealed-pit weapons more than 35 years ago, a formal surveillance program of nonnuclear laboratory and flight testing has been in existence. More than 13,800 weapons have been evaluated in this program. The Stockpile Evaluation Program, with its reliance on functional testing, has provided information that can be used in the statistical analysis of nonnuclear component and subsystem reliability. This program has detected about 75 percent of all problems ultimately detected, and it has been the principal mechanism for discovering defects and initiating subsequent repairs and replacements. However, not all aspects of a nuclear weapon can be statistically assessed this way. Weapons research and development (R&D) at the three weapons laboratories and nuclear testing have played an important part in assessing the stockpile and in making corrective changes when needed.

Past Role of Nuclear Testing. Nuclear tests have been a critical part of the nuclear weapons program. They have contributed to a broad range of activities from development of new weapons to stockpile confidence tests to tests that either identified a concern or showed that remedial actions were not needed. However, the United States has not conducted a sufficient number of nuclear tests for any one weapon type to provide a statistical basis of reliability assessment for the nuclear explosive package. This is why the word "performance" instead of "reliability" is used when discussing a nuclear explosive package.

Although nuclear tests were never a part of the formal Stockpile Evaluation Program, they played an important role in maintaining the safety and performance of the weapons in the stockpile. Every advantage was taken of developmental nuclear tests to eliminate potential nuclear explosive problems. In some cases, nuclear testing during development of one weapon type uncovered a problem that was pertinent to a previous design already in the stockpile, which then had to be corrected. Nuclear tests identified certain classes of stockpile problems not observable in the surveillance program. Nuclear tests have been used to resolve issues raised by the Stockpile Evaluation Program, such as whether a particular corrosion problem affected the nuclear yield of a weapon. Nuclear tests have also been used to verify the efficacy of design changes. For example, the adequacy of certain mechanical safing techniques was determined through nuclear testing. In the case of a catastrophic defect, tests have been used to certify totally new designs to replace an existing design. Finally, in some cases, nuclear testing proved that a potential problem did not exist.

Beginning in the late 1970s, DOD and DOE agreed to a formal series of underground nuclear tests of weapons withdrawn from the stockpile. These tests were referred to as Stockpile Confidence Tests. They differed from developmental nuclear tests because the weapons were from actual production, had experienced stockpile conditions, and had minimal changes made to either nuclear or nonnuclear components prior to the test. There have been 17 such confidence tests since 1972, including 4 tests in the early 1970s that were not officially designated as Stockpile Confi-

[3] Other than in specific discussions, the word surveillance is used generically throughout this document in place of the Stockpile Evaluation Program.

dence Tests. Confidence tests have been conducted for each of the weapon types expected to remain in the stockpile well into the next century.

In addition to the 17 confidence tests, at least 51 additional underground nuclear tests have been conducted since 1972 involving nuclear components from the stockpile, components from the actual weapon production line, or components built according to stockpile design specifications and tested after system deployment. The objectives of these tests included weapon effects, weapons R&D, confirmation of a fix, or investigation of safety or performance concerns. Three of these tests (in addition to one confidence test) revealed or confirmed a problem that required corrective action. Four tests (in addition to three confidence tests) confirmed a fix to an identified problem. Additionally, five tests were performed to investigate safety concerns affecting three different weapon types. These five tests verified that a problem did not exist.

The confidence in the performance of the nuclear explosive package has been based on underground nuclear test data, aboveground experiments, computer simulations, surveillance data, and technical judgment. The directors of the three weapons laboratories must certify the nuclear performance of the weapons designed by their laboratory.

In a future without additional nuclear testing, the core capabilities of the weapons laboratories that were developed to eliminate potential problems in new weapon designs must now be employed to assess stockpile problems. However, in the absence of nuclear testing, the ability to assess nuclear components is more difficult; new methods of assessment, discussed later, will have to be developed to help compensate for this loss.

Stockpile Data Summary. The historical stockpile database includes more than 2,400 findings from more than 45 weapon types. Findings are any abnormal conditions pertaining to stockpile weapons, such as out-of-specification data. Findings are then investigated and assessed as to whether or not they are a problem. Excluding multiple occurrences of the same anomalous condition, table S.2.2–1 provides a summary of the distinct findings and actionable findings since 1958. Actionable findings are those that require some form of corrective action. All major components and subsystems have had problems that required corrective actions. The number of findings for nonnuclear components is much larger than that for nuclear components largely because there are so many more nonnuclear components in a nuclear weapon that require testing more frequently. However, the ratio of actionable findings to distinct findings is much greater for the nuclear components. Thus, when a finding has occurred for a nuclear component, it has generally been a serious one requiring corrective action. Often these corrective actions to nuclear components have required changes to all of the weapons comprising the weapon type affected.

For the nuclear explosive package, there were approximately 110 findings on 39 weapon types requiring some remediation either to the entire build of that design or to all weapons produced after the particular finding. In addition to rebuilds and changes in production procedures, other actions included imposing restrictions on the weapon, accepting a performance decrement, and in several cases, conducting a nuclear test to determine that the finding did not require any physical change. There have been other instances not counted as actionable where a material was chemically changing and the weapon was closely monitored to see if further action was necessary or it was an isolated case that did not require remediation.

Certified Repairs or Replacements will be Needed

Based on the age of the planned stockpile over the next 10 years, historical data would project an average of one to two actionable findings per year in

TABLE S.2.2–1.—*Summary of Distinct and Actionable Findings Since 1958*

Type of Components	Distinct Findings	Actionable Findings	
		Findings	Weapon Types
Nuclear	145	110	39
Nonnuclear	703	306	38

Source: SNL 1996a.

the planned stockpile and an average of one to two change proposals approved per year, with one of these resulting in a major change. Even with a START II-sized stockpile, one change can affect thousands of weapons. These projections are most likely minimum numbers. The stockpile they were derived from was, on average, younger than the planned stockpile will be in future years, and the number of components in the weapon types was less than the number of components in weapon types of the planned stockpile. Furthermore, the aging characteristics of some of the materials used in the weapon types remaining in the stockpile are not well understood.

The previous paragraphs describe how problems were identified in stockpile weapons during the period when nuclear testing and active weapons development were being conducted along with the Stockpile Evaluation Program. At the present time, with no anticipated new weapons and no nuclear testing, new approaches are needed to assess weapons for potential problems and anticipate aging concerns, especially in the nuclear explosive package. This is important because the smaller, less diverse U.S. stockpile will be more vulnerable to single-component and common-cause failures (i.e., failures or defects compromising the safety or reliability of, respectively, a single weapon system or several systems sharing a common design feature).

DOE will continue to rely on well-established methods while the weapons laboratories develop new methods of measurement and evaluation to address aging, safety, reliability, and performance issues. As the new methods mature for either nuclear or nonnuclear components, they will be incorporated into the Stockpile Evaluation Program. In the future, for example, DOE will rely on improved experimental capabilities, coupled with an improved computational capability, to address issues associated with the nuclear explosive package. These experimental capabilities, along with enhanced surveillance methods, are now crucial to help assess and predict the state of the stockpile and to provide long lead time information about incipient problems.

S.2.3 Purpose and Need

Broadly stated, changes to U.S. national security policies for nuclear deterrence now place two significant constraints on the way in which DOE has traditionally accomplished its statutory nuclear weapons mission:

- The United States has declared a moratorium on nuclear testing and will seek ratification of a "zero-yield" CTBT.
- The United States has stopped the development and production of new-design nuclear weapons.

With these constraints, U.S. national security policy directs DOE to:

- Maintain the core intellectual and technical competencies of the United States in nuclear weapons including:
  - Research, design, development, testing, reliability assessment, certification, manufacturing, and surveillance
  - All three nuclear weapons laboratories and the capability to resume nuclear testing if needed
- Maintain a safe and reliable U.S. nuclear weapons stockpile

The NPR, PDDs, and Pub. L. 103-160 all address the need to maintain the core competencies of the United States in nuclear weapons without nuclear testing. The NPR strategy adds the expectation of no new-design weapon production; therefore, the NWSM does not currently direct or forecast such a requirement.

The Stockpile Stewardship and Management Program must accomplish these fundamental purposes in a safe, efficient, and environmentally responsible manner. National security policies do not eliminate any of the current or historical core competencies and capabilities of the DOE weapons laboratories, industrial plants, or NTS. They are basic needs that must be maintained for the foreseeable future. These needs are summarized in a focused discussion of their relationship to the development of the PEIS proposed actions and alternatives. A classified appendix has also been prepared to support the PEIS.

Stockpile Stewardship—The Weapons Laboratories and Nevada Test Site

The three weapons laboratories possess most of the core intellectual and technical competencies of the United States in nuclear weapons. These competencies embody more than 50 years of weapons knowledge and experience that cannot be found anywhere else in the United States. Since the end of the Cold War, laboratory staffing in the weapons program has declined significantly due to the effects of policy changes on program and budget. Further significant reductions or consolidations of the weapons laboratories would counter efforts to maintain core competencies and to develop the new technologies necessary to ensure continued high confidence in a safe and reliable stockpile. Current stockpile activities in this regard, such as ongoing retrofits of enduring stockpile weapons and safe dismantlement of weapons no longer required, would also be hampered. For the foreseeable future it would be unreasonable to pursue an alternative course for the weapons laboratories. In addition, because there can be no absolute guarantee of complete success in the development of enhanced experimental and computational capabilities, the United States will maintain the capability to conduct nuclear tests under a "supreme national interest" provision in the anticipated CTBT. DOE will need to maintain the capability for nuclear testing and experimentation at NTS and the necessary technical capabilities at the weapons laboratories to design and conduct such tests.

The science and engineering technology base at the three weapons laboratories controls all DOE technical requirements for a U.S. nuclear weapon. The laboratories perform the basic research, design, system engineering, development testing, reliability assessment, and certification of nuclear performance. In addition, they provide or control all technical specifications that are used by the industrial base for manufacturing and surveillance operations and for maintenance operations conducted by DOD. Data from these operations are provided to the weapons laboratories for assessment and technical resolution of problems.

When stockpile problems develop, all of the core laboratory capabilities may come into play. The cause of the problem is identified and an assessment made of its impact on safety, reliability, or performance. If the problem is to be fixed, alternative solutions are developed. These can range from simple repair of a defective feature to complete redesign of the weapon component or subsystem.

The focus is always on the acquisition of relevant test data to make these judgments. Once a fix is determined, it must be designed, prototyped, and development tested by the laboratories before the design is released for manufacture. This generally includes weapon system-level laboratory and flight tests for nonnuclear features and, in the past, nuclear tests if the changes could affect the weapon's nuclear performance. If the fix is to be manufactured, the laboratories provide the quality assurance test specifications. For nonnuclear components, a significant amount of functional test data is acquired during manufacture and is used to begin building a statistical estimate of component reliability. Subsequent laboratory and flight testing in the surveillance program accumulates additional data that include the effects of aging and exposure to stockpile environments. Thus, over time, high confidence in the safety and statistical reliability of nonnuclear components and subsystems can be established.

The situation is not the same for nuclear components and the assessment of nuclear performance. Nuclear components cannot be functionally tested during manufacture or surveillance. The data acquired during manufacture only show that the component was manufactured as designed. Surveillance data indicate whether the component is changing as a result of aging or exposure to stockpile environments. Manufacturing and surveillance data can identify concerns, but these data do not provide all of the necessary information to assess nuclear performance. Assessment and certification of nuclear performance is a nonstatistical, technical judgment by the weapons laboratories based on scientific theory, experimental data, and computational modeling. The scientific practice of "peer review" has been fundamental to these judgments. Experts from the two nuclear design laboratories review each other's data and conclusions on important issues, thereby providing an independent check and balance.

In the past, nuclear testing filled the gaps in basic understanding of the complex physics phenomena; it provided high confidence in the certification of nuclear safety and performance. Without nuclear testing, science-based stockpile stewardship will focus on obtaining the more accurate scientific and experimental data that will be needed for more accurate computer simulations of nuclear performance. The new experimental data must also be validated against past nuclear test data. Assessment of stockpile problems and certification of repairs or replacements of nuclear components will have to rely on improvements to these tools. The existing tools were used in conjunction with nuclear testing and are inadequate if used alone.

From a broader national security perspective, the core intellectual and technical competencies of the weapons laboratories provide the technical basis for the pursuit of U.S. arms control and nuclear nonproliferation objectives. Their extensive core competencies have provided most of the nuclear weapons arms control technologies developed and employed by the United States. The weapons laboratories will have to continue to provide this essential service in the future. For the same reasons, the weapons laboratories also provide significant technical support for U.S. efforts on nuclear weapons nonproliferation and counter-proliferation programs.

Stockpile Management—The Industrial Base

None of the manufacturing and surveillance capabilities of the current industrial base can be eliminated on the basis of the post-Cold War changes in national security policies. The industrial base also possesses core competencies, such as manufacturing product, process, and quality control know-how. However, with a smaller stockpile and no new-design weapons production, industrial capacity can be reduced to meet anticipated manufacturing requirements for stockpile repair and replacement activities. A summary discussion of each of the major functions needed is provided in this section.

Broadly stated, there are six major manufacturing and surveillance functional areas in the weapons industrial base:

- Weapon A/D
- Pit components
- Secondary and case components
- HE components
- Nonnuclear components
- Tritium supply and recycling

As explained in section S.1.4, tritium supply and recycling was evaluated in a separate PEIS.

Weapon Assembly/Disassembly. Pantex is the only DOE site currently authorized to assemble or disassemble stockpile weapons. Special facilities built to explosives safety criteria are required; in addition, some facilities are designed to limit nuclear material dispersal in case of an HE accident. These facilities exist in large numbers at Pantex, and because they are relatively discrete structures, downsizing-in-place is a viable alternative. NTS has a much smaller set of these special structures that were constructed for use in assembling nuclear test devices. However, NTS has few of the support facilities required for volume assembly or disassembly of stockpile weapons. A major programmatic consideration is the cost of re-creating facilities that already exist at Pantex. Due to ongoing weapon dismantlement requirements, the alternative to transfer this function to NTS would be slow but achievable within a 10-year period.

Pit Components. These components are designed by LANL and LLNL and were formerly produced at the Rocky Flats Plant, which is no longer available for this function. The LLNL facility is not large enough to accommodate both stewardship and management activities; therefore, only LANL is considered to be a reasonable alternative if this function is reestablished at a weapons laboratory. Also, LANL has the more extensive and complete plutonium facility infrastructure. SRS is also considered a viable alternative for reestablishing this function because it has a plutonium processing infrastructure, although it does not have a precision component manufacturing capability. Other than the synergism with maintaining core competencies at the weapons laboratories, a major program consideration would be the scale of manufacturing capacity required for the foreseeable future.

The preceding discussion applies to new pit fabrication as well as both intrusive and nonintrusive modification pit reuse manufacturing capability and capacity. Intrusive modification pit reuse requires handling and processing of the plutonium internal to the pit. Nonintrusive modification pit reuse involves the external features of the pit and does not require an extensive plutonium infrastructure; the risk of contamination and the generation of radioactive waste is very low for nonintrusive modification activities. Therefore, the weapons A/D Facility is also an alternative for nonintrusive modification pit reuse.

Secondary and Case Components. The Y-12 Plant (Y-12) at ORR produces the secondary and case components. These components are designed by LANL and LLNL; therefore, each of those facilities would be reasonable alternative sites if this function is transferred to the weapons laboratories. Both of these laboratories have a uranium technology base and facility infrastructure, although they have only a very limited R&D manufacturing capability. Other than the synergism with maintaining core competencies at the weapons laboratories, a major program consideration would be the cost of transferring product technologies and the re-creation of capital facilities that already exist at Y-12. Due to the complicated nature of nuclear facilities and plans for retrofit of an enduring stockpile weapon involving these components, a transition to either LANL or LLNL would be slow but achievable within a 10-year period. Downsizing Y-12 is considered to be a reasonable alternative.

High Explosive Components. Pantex currently manufactures HE components in special facilities built to explosives safety criteria. Downsizing the facilities at Pantex is a reasonable alternative. Comparable facilities also exist at both LANL and LLNL, and either laboratory has sufficient capacity to meet estimated future manufacturing requirements. Costs for this function are relatively low in any case. If a decision is made to transfer this function to the weapons laboratories, it could be done more quickly than the transfer of other functions. However, Pantex would have to retain disposition and disposal capability for the HE inventories currently onsite and those expected from near-term weapon dismantlement. A major program consideration would be the synergism of this function in maintaining the core competencies of the weapons laboratories.

Nonnuclear Components. KCP currently manufactures the majority of the nonnuclear components. The KCP facilities are not unique in structural design and are amenable to downsizing in place. The manufacturing technologies are complex and varied due to the large number of component types and high reliability requirements. SNL designs most of the components that KCP manufactures; therefore, SNL would become the major nonnuclear component supplier if a decision is made to transfer this function to the weapons laboratories. Other than potential synergism with maintaining core competencies at the weapons laboratories, a major program consideration would be the cost of transferring product technologies and re-creating facilities that already exist at KCP. Requirements for ongoing support of the enduring stockpile would make this a slow transition, but it would be achievable within a 10-year period.

S.2.4 Proposed Action and Alternatives

All of the existing basic capabilities of the laboratory and industrial base continue to be needed even though there have been changes in national security policy since the end of the Cold War. These changes do not affect the standards for stockpile safety and reliability. Therefore, the proposed action concentrates on three major issues that result from the national security policies and constraints placed on the program. The three program elements of the proposed action are:

- Providing enhanced experimental capability
- Rightsizing the industrial base
- Reestablishing manufacturing capability and capacity for pit components

Reasonable alternatives for the proposed action are briefly discussed below. Section S.3 describes these alternatives in more detail.

Enhanced Experimental Capability

Understanding nuclear weapon performance requires knowledge of the performance of the individual elements: the primary (pit and HE), the secondary, and the functional interaction between the primary and the secondary inside the case. Computer model-based validation and certification will be the key to DOE's ability to determine, with confidence, many of the future safety and performance characteristics of the stockpile in the absence of nuclear testing. This requires two principal elements: advanced computational models and facilities to provide experimental data that can be used to adjust (normalize) the computational models in conjunction with past nuclear test data. DOE is proposing three facilities to complement the existing capabilities to provide these data. Two are new facilities and one is the upgrade of an existing facility.

NIF and the Atlas Facility are proposed new facilities. The Atlas Facility would be collocated in TA-35 with the existing Pegasus II Facility at LANL, and the two facilities would use common infrastructures and support facilities. CFF is a proposed environmental and diagnostic upgrade to the existing Flash X-Ray (FXR) Facility at LLNL. As described in section S.3.2, these three new facilities would perform separate functions and provide different types of experimental data. Thus, they are complementary in nature and are not alternatives to one another. In each case, the alternative to constructing and operating the facility is No Action (i.e., relying on existing facilities to provide data). In addition, site alternatives are evaluated for NIF, since it is not associated with an existing facility. Volume III of this PEIS contains project-specific analyses for each of these facilities.

The stockpile stewardship program is expected to continuously evolve as better information becomes available and technological advancements occur. DOE is in the early planning stages for a number of what can be described as "next generation" stewardship facilities. These facilities are discussed in section S.3.2. They will build on the knowledge gained from existing and proposed new facilities. Since these facilities are in the conceptual planning stages, they are not sufficiently defined to be analyzed in this PEIS. When these technologies reach the appropriate level so as to be ripe for decisionmaking, DOE would complete NEPA documentation for them.

Rightsizing the Industrial Base

One of the primary goals of stockpile management is to rightsize functions to provide an effective and efficient manufacturing capability for a smaller stockpile. Such rightsizing must be accomplished in a manner that preserves core competencies in manufacturing and surveillance. This PEIS analyzes two alternative approaches to rightsizing the stockpile management functions described in section S.2.3: (1) transfer manufacturing and surveillance activities from the industrial sites to the weapons laboratories and NTS and (2) downsize the industrial plants in place. Relocation alternatives were selected on the basis of existing technical and facility infrastructure at the laboratories and NTS. Section S.3.4 discusses these alternatives in more detail.

Reestablishing Manufacturing Capability and Capacity for Pit Components

Plutonium pit manufacturing is a special case among those stockpile management functions discussed in section S.2.3. In 1992, DOE ceased plutonium pit manufacturing operations at the Rocky Flats Plant due to concerns about the safety of the plant and national security policy decisions to cease the production of new-design nuclear weapons. Reestablishing pit manufacturing capability and capacity was to be part of the Reconfiguration PEIS. This function is now part of the proposed action in this Stockpile Stewardship and Management PEIS.

Pit manufacturing capability and capacity, like that of all other major weapons components and subsystems, is essential for protecting national security options with regard to the nuclear deterrent. In addition, repair or replacement of pits for existing stockpile weapons may be required in the future. Reasonable alternative sites for reestablishing this function were selected from sites that already possess some measure of the appropriate technical or facility infrastructure.

S.2.5 Nonproliferation

On August 11, 1995, the President announced his commitment to seek a "zero-yield" CTBT. He also established several safeguards that condition the U.S. entry into a CTBT. One of these safeguards is the conduct of science-based stewardship, including the conduct of experimental programs. This safeguard will enable the United States to enter into such a treaty while maintaining a safe and reliable nuclear weapons stockpile consistent with U.S. national security policies.

One benefit of science-based stockpile stewardship is to demonstrate the U.S. commitment to NPT goals; however, the U.S. nuclear posture is not the only factor that might affect whether or not other nations might develop nuclear weapons of their own. Some nations that are not declared nuclear states have the ability to develop nuclear weapons. Many of these nations rely on the U.S. nuclear deterrent for security assurance. The loss of confidence in the safety or reliability of the weapons in the U.S. stockpile could result in a corresponding loss of credibility of the U.S. nuclear deterrent and could provide an incentive to other nations to develop their own nuclear weapons programs.

The United States has halted the development and production of new-design nuclear weapons. The experimental testing program will be used to assess the safety and reliability of the nuclear weapons in the remaining stockpile. Much of this testing is classified and could not lead to proliferation without a breach of security. Use of classified data from past U.S. nuclear tests is also a vital part of the overall process for validation of new experimental data. Most of the component technology used for the proposed enhanced experimental capability is unclassified and is available in open literature, and many other nations have developed a considerable capability.

Proliferation drivers for other states, such as international competition or the desire to deter conventional armed forces, would remain unchanged regardless of whether DOE implemented the proposed action analyzed in this PEIS. In the NPT, the parties agree not to transfer nuclear weapons or other devices, or control over them, and not to assist, encourage, or induce nonnuclear states to acquire nuclear weapons. However, the treaty does not mandate stockpile reductions by nuclear states, and it does not address actions of nuclear states in maintaining their stockpiles.

S.3 ALTERNATIVES

S.3.1 Development of Stockpile Stewardship and Management Program Alternatives

This PEIS evaluates the direct, indirect, and cumulative impacts associated with the Stockpile Stewardship and Management Program alternatives which are summarized in figure S.3.1–1. For the various alternatives, this includes evaluating the applicable impacts of new facility construction or existing facility modification. Also assessed are the operational impacts of long-term stewardship and management activities in support of the base case nuclear weapons stockpile, including transportation of materials and components between sites. This PEIS also provides a sensitivity analysis of differences, when applicable, from the base case alternatives for the high and low case stockpile. However, since it is expected that the annual workload may vary above and below the base case capacity assumptions, the base case is analyzed in the greatest detail.

Planning Assumptions and Basis for Analysis

In the Stockpile Stewardship and Management Program and in this PEIS, DOE will:

- Emphasize compliance with applicable laws and regulations and accepted industrial and weapons safety practices that safeguard the health of workers and the general public, protect the environment, and ensure the security of nuclear material and weapons

- Analyze alternatives that are consistent with, and supportive of, national security policies

- Maximize efficiency and minimize cost and waste consistent with programmatic needs

- Minimize the use of hazardous materials and the number and volume of waste streams consistent with programmatic needs through active pollution prevention programs and measures

DOE is currently preparing site-wide EISs covering continued operations for some of the alternative sites evaluated in the Stockpile Stewardship and Management PEIS. Some of the existing activities covered by these site-specific, site-wide EISs are similar to those of the No Action alternative of the Stockpile Stewardship and Management PEIS. Although the near-term analytical periods for these site-wide EIS analyses are different from that of the Stockpile Stewardship and Management PEIS, which is focused on long-term activities, the preparation of these documents has been closely reviewed and coordinated. As work on these site-wide EISs proceeds, their analyses will continue to be reviewed to ensure consistency. To the extent that the site-wide EIS analyses provide better information, such information has been incorporated. In the preparation of the Stockpile Stewardship and Management Final PEIS, any updated information relating to the sites' affected environment was reviewed and appropriate changes

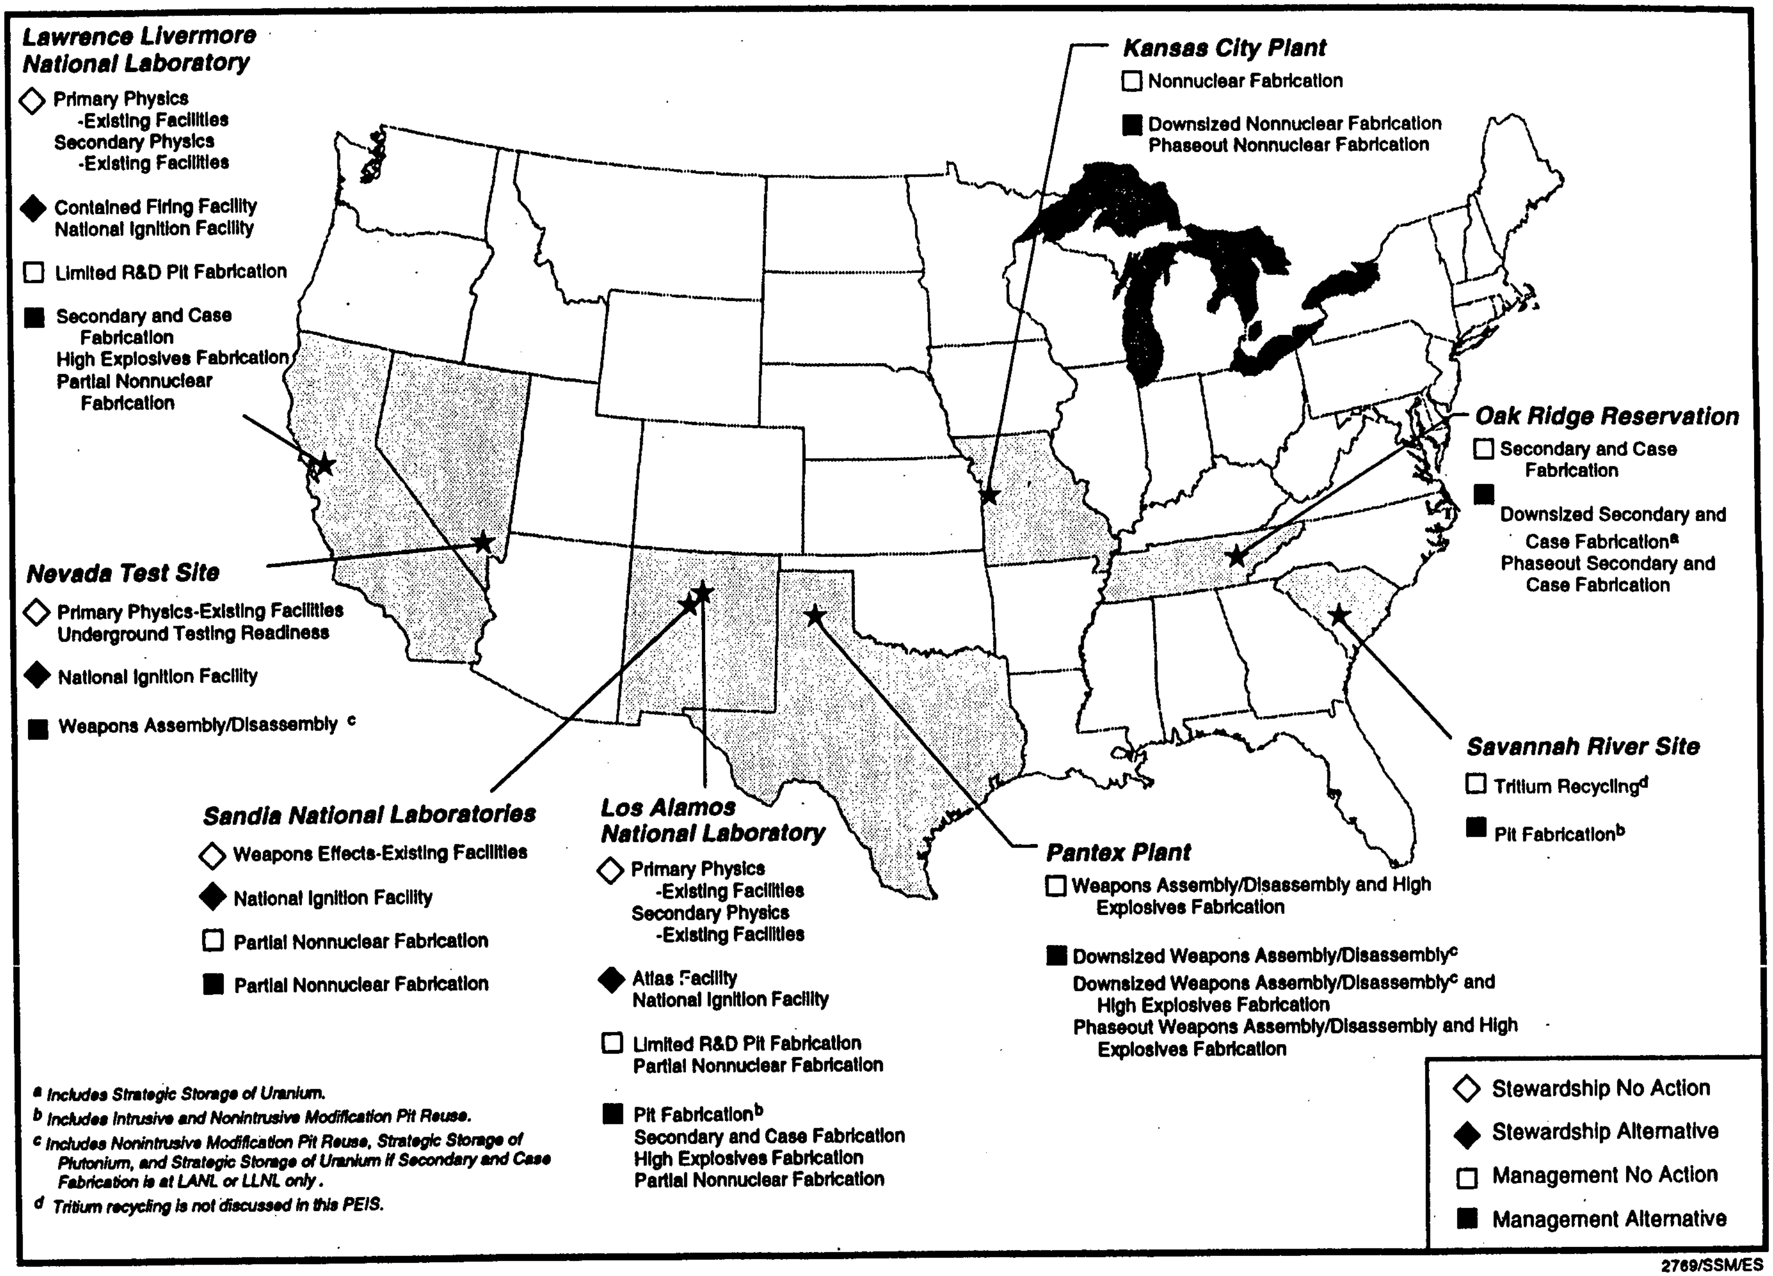

FIGURE S.3.1–1.—*Nuclear Weapons Complex Sites and Stockpile Stewardship and Management Alternatives.*

were made if new information could potentially change results of the impact analyses.

DOE has developed several planning assumptions as the basis of analyses presented in this PEIS. These considerations are summarized below.

No Action Alternative Assumptions

- The No Action alternative for this PEIS is defined in a way that takes into account the fact that DOE for decades has had in place a program for the stewardship and management of the nuclear weapons stockpile. Consistent with CEQ guidance, the No Action alternative consists of those facilities necessary to maintain the status quo in terms of DOE's current program direction. These consist primarily of existing facilities where DOE currently conducts weapons activities, including modifications to those facilities necessary to maintain their current mission capabilities. However, the No Action alternative also includes a small number of minor new facilities that will also be needed simply to maintain current mission capabilities at individual sites. Finally, the No Action alternative includes two major new facilities which are proceeding independent of this PEIS, and for which DOE has prepared separate EISs under the interim action provisions of the CEQ regulations. These EISs are the PEIS for Tritium Supply and Recycling (DOE/EIS-0161) and the EIS for the DARHT Facility (DOE/EIS-0228).

Stockpile Management Assumptions

- Base case stockpile size for the PEIS analysis is consistent with the START II protocol but larger than 3,500 weapons. This PEIS also analyzes a high and a low case stockpile size. The high case consists of maintaining the stockpile at a level consistent with the START I Treaty but larger than 6,000 weapons. The hypothetical low case is a stockpile of approximately 1,000 weapons.

- Impacts from construction, including modifying existing structures, and operation are evaluated. The period of construction or downsizing for each alternative varies; however, for analytical purposes, this PEIS assumes that operations would begin in 2005. A 25-year lifetime was evaluated for operations.

- For plutonium, strategic reserve storage is evaluated at Pantex and NTS. For HEU, strategic reserve storage is evaluated at ORR, Pantex, and NTS. (For purposes of this PEIS, DOE does not intend to move the strategic reserves of HEU to Pantex or NTS if ORR is chosen as the secondary and case fabrication site).

- This PEIS contains an analysis of low-consequence/high-probability accidents (evaluation basis) and high-consequence/low-probability accidents (beyond evaluation basis). A spectrum of both types of accidents is analyzed. For radiological accidents, impacts are evaluated for both the general population residing within an 80-kilometer (km) (50-mile [mi]) radius (including the maximally exposed individual) and for noninvolved workers in collocated facilities. The accident analyses in this PEIS are based upon facility conditions that are expected to exist in 2005. In some cases, facility conditions in 2005 may differ from current facility conditions due to design upgrades.

- Plutonium or uranium would not be introduced into a site that does not currently have a plutonium or uranium infrastructure because of the high cost of new facilities and the complexity of introducing plutonium or uranium operations to sites without current capabilities.

Stockpile Stewardship Assumptions

- The range of stockpile sizes used for analysis of manufacturing capacity-related issues for stockpile management functions is not applicable to stockpile stewardship functions. Capabilities are independent of stockpile size. Stockpile stewardship functions are basic capabilities.

- National security policy requires a safe and reliable stockpile without further nuclear testing and with an aggressive pursuit of enhanced experimental capabilities. Three stockpile stewardship facilities are proposed in this PEIS: NIF, CFF, and the Atlas Facility. These facilities are analyzed as supplements to the facilities and capabilities that currently exist for carrying out the stockpile stewardship mission. Each proposed facility is an independent component of the overall stockpile stewardship program, each has unique value, and, therefore, these proposed facilities are not competing alternatives.

- Assumptions regarding accident analysis are the same as described under stockpile management.

S.3.1.1 *Alternative Sites*

Eight locations (ORR, SRS, KCP, Pantex, LANL, LLNL, SNL, and NTS) are being considered as alternative sites for stockpile stewardship and management missions. All of these sites are currently performing DP activities.

Site Selection

One important strategy of the Stockpile Stewardship and Management Program is to maximize the use of existing infrastructure and facilities as the Complex transitions to be smaller and more efficient in the 21st century. Consequently, only those sites with existing infrastructure or facilities capable of supporting a given stockpile stewardship or stockpile management mission are considered reasonable site alternatives for detailed study in this PEIS. Sites without a technical infrastructure or facilities for a given mission would require significant new construction that would be costly and impractical compared to sites with existing infrastructure and facilities.

For stockpile stewardship, the three existing weapons laboratories (LANL, LLNL, and SNL) and NTS are being considered for new or upgraded stockpile stewardship facilities. This is because the weapons testing mission and stockpile stewardship have always been primary responsibilities of the weapons laboratories and NTS, and existing facilities and capabilities can be built upon to meet the stewardship mission.

Oak Ridge Reservation

ORR, located in Oak Ridge, TN, contains the Oak Ridge National Laboratory, Y-12, and the K-25 Site. DP assignments at ORR are performed at Y-12 and include maintaining the capability to produce secondaries and cases for nuclear weapons, storing and processing uranium and lithium materials and parts, dismantling nuclear weapon secondaries returned from the stockpile, and providing special production support to the DOE weapons laboratories and to other DOE programs.

Savannah River Site

SRS, located near Aiken, SC, contains fuel and target fabrication facilities, nuclear material production reactors, chemical separation plants used for recovery of plutonium and uranium isotopes, a uranium fuel processing area, and the Savannah River Technology Center. SRS is now conducting tritium-recycling operations in support of stockpile requirements using dismantled weapons as the tritium supply source.

Kansas City Plant

KCP, situated on the Bannister Federal Complex in Kansas City, MO, produces and procures nonnuclear electrical, electronic, electromechanical, mechanical, plastic, and nonfissionable metal components for the nuclear weapons program. KCP is currently the principal nonnuclear fabrication facility within the Complex.

Pantex Plant

Pantex, located northeast of Amarillo, TX, fabricates chemical HE for nuclear weapons, assembles and performs maintenance and surveillance of nuclear weapons in the stockpile, disassembles nuclear weapons being retired from the stockpile, and provides interim storage of plutonium components from dismantled weapons.

Los Alamos National Laboratory

LANL, located at Los Alamos, NM, is a multidisciplinary research facility engaged in a variety of programs for DOE and other Government agencies. Its primary mission is the nuclear weapons Stockpile Stewardship and Management Program and related emergency response, arms control, and nonproliferation and environmental activities. It conducts R&D activities including the basic sciences, mathematics and computing with applications to these mission areas and to a broad range of programs including: nonnuclear defense; nuclear and nonnuclear energy; atmospheric, space, and geosciences; bioscience and biotechnology; and the environment.

In regard to nuclear weapons, LANL is responsible for the design of the nuclear explosive package in certain U.S. weapons. In addition, since the end of the Cold War, LANL now conducts the pit surveillance program and some manufacturing of nonnuclear components due to termination of the nuclear weapons missions at the Mound, Pinellas, and Rocky Flats Plants.

Lawrence Livermore National Laboratory

LLNL, located at Livermore, CA, is a multidisciplinary research facility engaged in a variety of programs for DOE and other Government agencies. Its primary mission is the nuclear weapons stewardship program and related emergency response, arms control, and nonproliferation activities. It conducts R&D activities in the basic sciences, mathematics, and computing with applications to these mission areas and to a broad range of programs including: nonnuclear defense; nuclear and nonnuclear energy; atmospheric, space, and geosciences; bioscience and biotechnology; and the environment. In regard to nuclear weapons, LLNL is responsible for the design of the nuclear explosive package in certain U.S. weapons.

Sandia National Laboratories

SNL maintains facilities in three locations in the United States: Albuquerque, NM; Livermore, CA; and Tonopah, NV. The facilities discussed in this document refer only to the Albuquerque location which is located adjacent to the city of Albuquerque, NM. SNL is a multidisciplinary research and engineering facility engaged in a variety of programs for DOE and other Government agencies. Its primary mission is the nuclear weapons Stockpile Stewardship and Management Program and related emergency response, arms control, and nonproliferation activities. In addition, it conducts R&D activities in advanced manufacturing, electronics, information, pulsed power, energy, environment, transportation, and biomedical technologies.

In regard to nuclear weapons, SNL is responsible for the design of nonnuclear components and related system engineering. In addition, since the end of the Cold War, SNL now performs some nonnuclear manufacturing functions due to termination of the nuclear weapons mission at the Mound and Pinellas Plants.

Nevada Test Site

NTS occupies approximately 351,000 hectares (ha) (867,000 acres) in the southeastern part of Nye County in southern Nevada. NTS, located about 104 km (65 mi) northwest of Las Vegas, is a remote, secure facility that maintains the capability for conducting underground testing of nuclear weapons and evaluating the effects of nuclear weapons on military communications systems, electronics, satellites, sensors, and other materials.

North Las Vegas Facility. The North Las Vegas Facility (NLVF), located in the city of North Las Vegas, NV, supports DOE Nevada Operations Office and LANL, LLNL, and SNL weapons test programs, and is considered an adjunct to NTS.

S.3.2 Stockpile Stewardship

Historically, nuclear testing has provided unambiguous high confidence in the safety and reliability of weapons in the stockpile. Without additional underground nuclear testing, DOE must rely on experimental and computational capabilities, especially in weapons physics, to predict the consequences of the complex problems that are likely to occur in an aging stockpile. Without these enhanced capabilities, DOE will lack the ability to evaluate some safety and reliability issues, which could significantly affect the stockpile. It is also possible that, without these enhanced capabilities, DOE could not certify the acceptability of weapons components repaired or modified to address future safety or reliability issues. The nuclear weapons phenomena involved in enhanced experimental capability can be broadly grouped into three categories: physics of nuclear weapons primaries, physics of nuclear weapons secondaries, and weapons effects. Each of these categories are described below, as well as alternatives that are assessed in this PEIS. Table S.3.2–1 depicts the proposed alternatives and facilities under consideration for stockpile stewardship.

TABLE S.3.2–1.—*Stockpile Stewardship Enhanced Experimental Capability Alternatives*

Capability	LANL	LLNL	SNL	NTS
Physics of Nuclear Weapons Primaries				
No Action	X	X		X
Contained Firing Facility[a]		X		
Physics of Nuclear Weapons Secondaries[b]				
No Action	X	X		
National Ignition Facility[a]	X	X	X	X
Atlas Facility[a]	X			
Weapons Effects				
No Action[c]			X	

[a] Proposed facilities. Stockpile Stewardship and Management PEIS includes both a programmatic assessment and a project-specific analysis of these potential experimental facilities.
[b] Facilities used to investigate the physics of nuclear weapons secondaries may also be used to investigate some physics phenomena related to nuclear weapons primaries and weapons effects.
[c] No new facilities solely to investigate weapons effects phenomena are being proposed at this time.

Physics of Nuclear Weapons Primaries

With respect to the physics phenomena from the implosion of the primary, the experimental facilities provide physics validation, material behavior information, improved understanding of the implosion and the ability to assess age related defects. Proposed new facilities and site alternatives under consideration, along with the existing facilities which are part of the No Action alternative, are discussed below.

No Action. The principal diagnostic tools DOE currently uses to study nuclear weapons primaries are hydrodynamic tests and dynamic experiments. Under the No Action alternative, DOE would continue to use the hydrodynamic testing facilities currently available at LANL, LLNL, and NTS, and a new facility planned for LANL. The FXR Facility at LLNL Site 300 uses linear induction accelerator technology for high-speed radiography. The Pulsed High-Energy Radiation Machine Emitting X-Rays Facility has been in continuous operation at LANL since 1963, and uses a radio-frequency accelerator designed for high-speed radiography.

The DARHT Facility at LANL will consist of a new accelerator building with two accelerator halls to provide two perpendicular lines-of-sight which will enable two radiographic images to be captured simultaneously or sequentially and will provide a capability to perform three dimensional diagnostics of a simulated nuclear weapon primary. For the purposes of this PEIS, DOE includes the DARHT Facility in No Action as an existing facility at LANL because DOE has reached an independent decision to construct and operate the facility.

Besides LANL and LLNL, NTS has some hydrodynamic testing facilities in place (e.g., Big Explosive Experimental Facility [BEEF]). BEEF is used to study hydrodynamic motion associated with HE detonations.

Proposed Contained Firing Facility. Both LANL and LLNL are considered necessary for the continued development of a science-based stockpile stewardship program. In this regard, both laboratories will continue to utilize and improve radiographic hydrodynamic testing capability. The proposed CFF would augment and be collocated with the existing FXR Facility at LLNL Site 300. The containment enclosure would provide for containment of hydrodynamic tests and reduce the environmental, safety, and health impacts of current outdoor testing. The enclosure will also improve the quality of diagnostics data derived from testing by better controlling experimental conditions.

Physics of Nuclear Weapons Secondaries

The energy released by the fission of the nuclear weapons primary activates the secondary assembly, creating a thermonuclear (fusion) explosion. With respect to the phenomena of the physics from the thermonuclear explosion of the secondary, the experimental facilities provide improved understanding of thermonuclear ignition, secondary physics validation, and material behavior information. The proposed physics facilities and site alternatives under consideration are discussed below. Some of the facilities may also be useful for investigating physics phenomena related to nuclear weapons primaries and weapon effects. The capabilities that would be provided by the proposed NIF and the Atlas Facility are independent components needed to improve the understanding of the physics of nuclear weapons secondaries. Each proposed facility responds to a different diagnostic need related to nuclear weapons secondaries and they are not competing alternatives.

No Action. Few methods are currently available to study the physics of nuclear weapons secondaries. The principal facilities currently available are the Nova Facility at LLNL and the Pegasus II Facility at LANL. Without improvements to these capabilities, as proposed by the NIF and the Atlas Facility, DOE would lack the ability to evaluate some significant nuclear performance issues, which could adversely affect confidence in the Nation's nuclear deterrent.

Proposed National Ignition Facility. The proposed NIF would make it possible to study radiation physics in the laboratory close to the conditions which would approach that of a thermonuclear detonation. NIF would achieve higher temperatures and pressures, albeit in a very small volume, than any other existing or proposed stockpile stewardship facility. This facility could be located at either LANL, LLNL, SNL, or NTS.

Proposed Atlas Facility. The proposed Atlas Facility at LANL would be used for experiments that would contribute to the development of predictive capabilities related to the aging and performance of secondaries. This facility would build on existing special equipment at LANL.

Weapons Effects

One of the reasons for past underground nuclear testing has been to determine the effects of nuclear weapon radiation outputs of x rays, gamma rays, and neutrons on nuclear weapon subsystems and components. Existing facilities at SNL, such as the Saturn Facility or the Particle Beam Fusion Accelerator Facility, provide a limited capability to investigate these effects, and would continue to operate under No Action. No alternatives for new facilities designed principally for weapons effects testing are being proposed in this PEIS.

Next Generation Stockpile Stewardship Facilities

The science-based stockpile stewardship program will build upon existing information and capabilities. Thus, the program is expected to continuously evolve as better information becomes available and technological advancements occur. In fact, evolution is expected to be an integral part of the science-based stockpile stewardship program. While the proposed NIF, CFF, and Atlas Facility would provide improvements over existing capabilities, and are expected to be important components of science-based stewardship, they do not represent the entire science-based stewardship program that is envisioned for all time.

The next generation of stockpile stewardship facilities have not been defined to the degree necessary for decisionmaking. These anticipated facilities are AHF, HEPPF, ARS (X-1), and the Jupiter Facility. AHF would be a next generation radiographic hydrodynamic test facility featuring multiple pulse and multiple view diagnostic capability. HEPPF would provide experimental capabilities for studying secondary physics at shock pressures and velocities approaching those of actual weapons conditions. ARS (X-1) and Jupiter Facilities would be advanced pulsed-power x-ray sources that would provide enhanced experimental capabilities in the areas of weapons physics and weapons effects.

S.3.2.1 *Stockpile Stewardship Comparison of Alternatives*

To aid the reader in understanding the differences in environmental impacts among the various PEIS stewardship alternatives, this section presents comparisons of the alternatives, concentrating on the major resources assessed in this PEIS.

Proposed National Ignition Facility

The following comparisons have been summarized from the more-detailed comparisons for the NIF alternatives found in Volume III, appendix section I.3.5. The NIF project-specific analysis addresses the impacts of constructing and operating NIF at four alternative sites: LLNL (preferred), LANL, SNL, and NTS (includes NLVF). A No Action alternative is also assessed.

Under No Action, DOE would rely on existing aboveground experimental facilities, predominantly the

Nova Facility at LLNL, to study the physics of nuclear weapons secondaries. No construction impacts are associated with the No Action alternative and the operational impacts of the Nova Facility have been accounted for in the overall environmental baseline presented for LLNL.

For the action alternative, the analysis indicates that there would be few significant differences in environmental impacts at the candidate sites. The maximum 24-hour concentration of particulate matter 10 microns or smaller (PM_{10}) in the air during site clearing would exceed applicable standards at LLNL and NLVF. However, the ambient air quality impacts would be localized and of short duration. Uncommitted land requirements would be greatest at NTS (18.2 ha [45.0 acres]), although this acreage is less than 1 percent of the uncommitted land at NTS. Conversely, the least amount of uncommitted land that would be required for NIF would be 3.2 ha (7.9 acres) at NLVF. However, this acreage represents the largest percentage of uncommitted land at a candidate site (56 percent). Of greater significance would be the quality of the habitat of the uncommitted land that would be affected by NIF construction. The highest-quality habitats that would be affected would be forest (4.0 ha [9.9 acres]) at LANL or desert (18.2 ha [45 acres]) at NTS. At the other candidate sites, habitat disturbance would occur to grassland (LLNL and SNL) or to an area of sparse vegetation (NLVF). No significant biotic or cultural impacts are expected at any of the NIF alternative sites.

At each NIF alternative site, beneficial socioeconomic impacts associated with construction and operation would occur. During construction, 270 to 470 direct new jobs would be created in the peak year of activity. These direct jobs would create indirect jobs such that the total jobs during the peak year would be: 2,870 at LLNL; 1,130 at LANL; 1,640 at NTS; and 1,770 at SNL. Once operations begin, NIF would employ 330 direct workers. The total number of jobs (direct plus indirect) during operation would be 890 at LLNL, 600 at LANL, 620 at NTS, and 670 at SNL.

Over the 30-year operational life of NIF, the public would be exposed to a very small dose of radiation. No cancer fatalities would be expected to occur from exposures associated with routine NIF operations under either the Conceptual Design or Enhanced options. A radiological accident at NIF would not cause any cancer fatalities to the public except possibly at NLVF and SNL. Under postulated accident conditions, radiological impacts to the public and workers would be minor. The highest calculated radiation dose is 4,900 person-rem. At most, two cancer fatalities could occur if an accidental release occurred. Because of the extremely low accidental release frequency ($2x10^{-8}$/yr), the risk of radiation-caused cancer fatalities from the postulated accident at any site is essentially zero. The cancer fatality risk associated with radiological exposure from an accident involving the transport of NIF tritium targets would range from $1x10^{-8}$ to $8x10^{-10}$ fatalities per year, whereas the nonradiological fatality risks associated with vehicular emissions and accidents would be in the range of 10^{-3} to 10^{-4} fatalities per year.

Although each candidate site would implement waste minimization practices, the generation of additional wastes would be unavoidable. All candidate sites have current or planned capacity to handle wastes associated with construction and operation of NIF; however, this would entail offsite shipment of some of the wastes for all sites except LANL.

NIF would comply with all applicable Federal, state, and local environmental regulatory requirements, including the *California Environmental Quality Act* if NIF is sited in the state of California. Such compliance functions as a general form of mitigation. The candidate sites have also established several mitigative measures for construction actions that would also be applicable to NIF construction. While each of these mitigative measures may be minor, in combination they could significantly reduce impacts to the environmental resources of the selected site.

With regard to unavoidable impacts, land clearing and construction activities for NIF would eliminate habitat and destroy or displace wildlife. Construction of new facilities could result in short-term disturbances of previously undisturbed biological habitats. These disturbances could cause long-term reductions in the biological productivity of an area. Construction of NIF would replace natural habitat with areas of pavement and buildings. Depending upon the candidate site selected, this conversion could extend the influence of urbanized/industrial habitats into natural areas, increase fragmentation of natural habitat, and cause minor loss of habitat used by rare species. However, no critical habitat for Federal threatened or endangered species would be affected.

Radiological doses to the general public from NIF operation would be no more than 20 percent of the dose from all other candidate site operations and no more than one-millionth of the dose to the population from normal background radiation. NIF would be considered a low-hazard, radiological facility. Such a facility uses radionuclides (for nonreactor purposes) and has other hazards (such as chemicals needed at the facility). Low hazard implies that there are minor onsite and negligible offsite consequences.

Cumulative impacts would result from the addition of the incremental effects of the construction and operation of NIF to the effects of other past, present, and reasonably foreseeable future actions at the selected site. Fugitive dust emissions from construction of NIF would be an incremental addition to the already existing environmental impact of dust emissions to the atmosphere. Minor changes in stormwater runoff are expected due to removal of grass cover during NIF construction and increased runoff from pavement during facility operation.

Proposed Contained Firing Facility

The following comparisons have been summarized from the more-detailed information for CFF found in Volume III, appendix J.

Under No Action, DOE would rely on existing aboveground experimental facilities, predominantly the existing hydrotest facilities at LLNL, LANL, and NTS to study the physics of nuclear weapons primaries. No construction impacts are associated with those existing facilities, and the operational impacts of those facilities have been accounted for in the overall environmental baseline presented for LLNL, LANL, and NTS.

Because the proposal for CFF involves modification to the existing FXR Facility, construction impacts are expected to be small. Very little land would be disturbed and the construction activities would largely involve internal modifications to the existing facility. Wastes and socioeconomic impacts from construction would be negligible.

Impacts associated with operation would also be negligible. CFF would not utilize any significant quantities of resources, would not cause any significant socioeconomic changes at LLNL, and would not generate large quantities of hazardous or low-level wastes. LLNL has adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by CFF. Impacts to human health from CFF operation are expected to be extremely small and within regulatory limits.

Proposed Atlas Facility

The following comparisons have been summarized from the more-detailed information for the Atlas Facility found in Volume III, appendix K.

Under No Action, DOE would rely on existing aboveground experimental facilities, predominantly the Pegasus Facility at TA-35 at LANL, to study the physics of nuclear weapon secondaries. No construction impacts are associated with that facility, and the operational impacts from Pegasus have been accounted for in the overall environmental baseline presented for LANL.

Because the proposal for the Atlas Facility involves modification to the existing facilities within TA-35, construction impacts are expected to be small. Very little land would be disturbed and the construction activities would largely involve internal modifications to the existing facility. Wastes and socioeconomic impacts from modification activities would be negligible.

Impacts associated with operations would also be negligible. The Atlas Facility would not utilize any significant quantities of resources, would not cause any significant socioeconomic changes at LANL, and would not generate large quantities of hazardous or low-level wastes. LANL has adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by the Atlas Facility. Impacts to human health from Atlas Facility operations are expected to be small and within regulatory limits.

S.3.3 Underground Nuclear Testing

One of the primary purposes of the Stockpile Stewardship and Management PEIS is to evaluate ways of maintaining a continued safe and reliable nuclear deterrent in the absence of nuclear testing. Thus, the proposal described in this PEIS does not include nuclear testing. However, because it is possible—although not probable—that the United States might one day exercise its "supreme national interests" rights and conduct underground nuclear testing to certify the safety and reliability of its nuclear weapons, this PEIS and the NTS Site-Wide EIS include an analysis of the environmental impacts of underground nuclear testing at NTS.

S.3.4 Stockpile Management

Stockpile management comprises operations associated with producing, maintaining, refurbishing, surveilling, and dismantling the nuclear weapons stockpile. The individual stockpile management functions can be grouped into five major categories: weapons A/D, nonnuclear components fabrication, pit fabrication, secondary and case fabrication, and HE fabrication. Specific alternatives that would enable DOE to maintain its stockpile management responsibilities are shown in table S.3.4–1 and are discussed below.

Weapons Assembly/Disassembly Alternatives

Weapons A/D provides the capability to dismantle retired weapons, assemble nuclear and nonnuclear components into nuclear weapons, and perform weapons surveillance. In addition, the capability to conduct nonintrusive modification pit reuse would be a mission of the weapons A/D Facility. This alternative also includes an option to store strategic reserves of nuclear components (pits and secondaries).

The alternatives for A/D are: 1) to continue in current facilities at Pantex with only those changes that are currently scheduled and budgeted (No Action), 2) to downsize and consolidate facilities and operations at Pantex, or 3) to relocate operations to NTS.

No Action. The No Action alternative for these activities, except nonintrusive modification pit reuse, is presently located at Pantex. Current plutonium R&D

TABLE S.3.4–1.—*Stockpile Management Alternatives*

Capability[a]	Y-12	SRS	KCP	Pantex	LANL	LLNL	SNL	NTS
Weapons Assembly/Disassembly[b]								
No Action				X				
Downsize existing capability				X				
Relocate capability								X
Nonnuclear Fabrication								
No Action			X		X		X	
Downsize existing capability			X					
Relocate capability					X[c]	X[c]	X[c]	
Pit Fabrication and Intrusive Modification Pit Reuse[d]								
No Action[e]					X	X		
Reestablish capability		X			X			
Secondary and Case Fabrication[d]								
No Action	X[f]							
Downsize existing capability	X[f]							
Relocate capability					X	X		
High Explosives Fabrication								
No Action				X				
Downsize existing capability				X				
Relocate capability					X	X		

[a] Surveillance is included in all capabilities.
[b] Includes nonintrusive modification pit reuse and the option of strategic reserve storage of plutonium and HEU.
[c] KCP functions would be distributed among two or three of the laboratories.
[d] Staging and storage of working inventories of nuclear materials and components are included.
[e] Research and development capability only.
[f] Includes strategic storage of HEU reserve.

facilities at LANL and LLNL have limited capability and capacity to perform nonintrusive modification pit reuse.

Downsize at Pantex Plant. This alternative would downsize and consolidate facilities and operations including strategic reserve storage at Pantex. Downsizing of the A/D operation at Pantex could consist of an in-place decrease in facility footprint and relocation into modern, existing facilities, mostly within Zone 12. No new construction would be required at Pantex; however, relocation and reinstallation of equipment would be required.

Relocate to Nevada Test Site. This alternative is based on the use of the current Device Assembly Facility and balance of plant infrastructure available and required to maintain the capability for underground nuclear testing. Additional new construction would be required and would be designed and sized to meet the specific needs of the reduced program.

Nonnuclear Fabrication

Nonnuclear fabrication consists of the following general functions:

- Fabrication of electrical, electronic, electro-mechanical, and mechanical components (plastics, metals, and composites) and assembly of arming, fuzing, and firing systems
- Surveillance inspection and testing of nonnuclear components

The alternatives considered for nonnuclear fabrication include the No Action alternative of continuing in current facilities, downsizing and consolidating existing facilities at KCP, or closing KCP and sharing nonnuclear fabrication functions among LANL, SNL, and/or LLNL.

No Action. The No Action alternative for these activities is presently located at KCP, SNL, and LANL. KCP manufactures nonnuclear weapon components and conducts surveillance testing on and makes repairs to nonnuclear weapons components. SNL conducts system engineering of nuclear weapons, designs and develops nonnuclear components, conducts field and laboratory nonnuclear testing, manufactures some nonnuclear weapons components, and provides safety and reliability assessments of the stockpile. LANL also manufactures a few nonnuclear weapons components and conducts surveillance on certain nonnuclear weapons components.

Downsize at Kansas City Plant. The downsized nonnuclear fabrication alternative consists of three major factory segments designed around electronics, mechanical, and engineered materials product lines, procuring some components from outside sources, and reducing the KCP footprint for DP activities about 45 percent. This alternative consists of downsizing and consolidating existing facilities and would require facility modification but no new construction.

Relocate to Los Alamos National Laboratory. The basis for this alternative would be to use the existing infrastructure at LANL to provide for production requirements of the Complex. Nonnuclear fabrication missions considered for transfer to LANL include plastics, which might also be transferred to LLNL; detonator inert components and pilot plant; and reservoirs and valves, which might also be transferred to SNL.

Relocate to Lawrence Livermore National Laboratory. This alternative calls for LLNL to provide support for nuclear system plastic components that might also go to LANL. This alternative would build on LLNL's established plastics fabrication mission with no new facility construction required.

Relocate to Sandia National Laboratories. This alternative would transfer the majority of current KCP missions to the Albuquerque, NM facility of SNL, except for nuclear system plastic components which would go to either LANL or LLNL and high energy detonator inert components, which would go to LANL. In addition, there is the option of moving the reservoir mission to either LANL or SNL. This alternative would require construction of a new stand-alone production site at SNL, directly east of Technical Area I consisting of six new buildings and renovations or minor modifications to some existing buildings.

Pit Fabrication and Intrusive Modification Pit Reuse Alternatives

This capability, hereafter referred to as pit fabrication, includes all activities necessary to fabricate new pits, to modify the internal features of existing pits (intrusive modification), and to recertify or requalify pits. There are two alternative sites for pit fabrication: SRS and LANL. Nonintrusive modification pit reuse, which is an inherent capability of the Pit Fabrication Facility, includes the processes and systems necessary to make modifications to the external features of a pit, if necessary, and to recertify the pit for reuse in a weapon.

No Action. Under the No Action alternative, DOE would continue to use existing R&D capabilities at LANL and LLNL. LANL maintains a limited capability to fabricate plutonium components using its plutonium R&D facility and performs surveillance operations on plutonium components returned from the stockpile. In addition, less extensive capabilities would continue at LLNL to support material and process technology development.

Reestablish at Los Alamos National Laboratory. This alternative would reconfigure the Plutonium Facility at LANL to fulfill the pit fabrication mission and the intrusive modification pit reuse mission. This alternative would locate pit manufacturing in existing facilities within five technical areas. Existing equipment would be retained as much as possible, but some equipment would be upgraded.

Reestablish at Savannah River Site. This alternative would establish a pit fabrication and reuse facility at SRS within existing hardened facilities, but with new equipment and systems. Facilities are available at the SRS separation areas, F- and H-Area, which could house all the process functions required for the manufacture of plutonium pits. Pit fabrication would be located in Building 232-H and plutonium processing would be located in the F-Canyon facilities. New equipment and systems would be required for the Pit Fabrication Facility.

Secondary and Case Fabrication

The secondary and case fabrication mission includes all activities to support fabrication, surveillance, inspection, and testing of secondaries and components. Functional capabilities for these services include operations to physically and chemically process, machine, inspect, assemble, and disassemble secondary and case materials. Materials include depleted uranium, enriched uranium, uranium alloys, isotopically enriched lithium hydride and lithium deuteride, and other materials. Alternative sites considered for stockpile management secondary activities are ORR, LANL, and LLNL.

No Action. Under No Action, ORR would continue secondary and case fabrication. Y-12 maintains the capability to produce and assemble secondaries, cases, and related nonnuclear weapon components.

Downsize at Oak Ridge Reservation. This alternative would be based on downsizing the existing secondary and case fabrication facilities at Y-12 on ORR. The downsized facilities would only require approximately 14 percent of the existing Y-12 floor space and there would be no new facility construction at Y-12 to support the secondary and case fabrication mission. Modifications to the existing buildings would be required for implementation of the alternative secondary and case fabrication mission and to upgrade the buildings to meet natural phenomena requirements.

Relocate to Los Alamos National Laboratory. This alternative would establish a secondary and case fabrication capability using the processes proven at Y-12 and would use facilities in 11 existing buildings. Modifications to the LANL facilities would be required to perform the stockpile management secondary and case fabrication mission.

Relocate to Lawrence Livermore National Laboratory. This alternative would establish a secondary and case fabrication capability using the processes proven at Y-12, and would use facilities in existing buildings. The secondary and case fabrication facilities at LLNL would principally involve minor modifications to six buildings at the Livermore Site.

High Explosives Fabrication

The HE fabrication mission is described in two functional areas: HE main charge fabrication and small HE component fabrication. The HE fabrication mission includes activities needed to provide HE, binders, main charge formulations, initiation HE, and mock HE formulations.

The HE fabrication mission supports the production aspect of stockpile management and also supports HE surveillance and some stockpile stewardship activities.

No Action. Under No Action, Pantex would continue fabrication and surveillance of HE components for nuclear weapons. LANL and LLNL would continue to perform weapons HE R&D, surveillance, and HE safety studies.

Downsize at Pantex Plant. The Pantex HE fabrication alternative would downsize and consolidate current HE operations and facilities. Only minor modifications to existing facilities within Zones 11 and 12 would be required. This alternative would be considered only in conjunction with maintaining the weapons A/D mission at Pantex.

Relocate to Los Alamos National Laboratory. This alternative would transfer HE operations from Pantex to LANL. This alternative would use existing LANL R&D facilities, which have sufficient capacity for stockpile management requirements. There would be no new building construction and no significant modifications required.

Relocate to Lawrence Livermore National Laboratory. The LLNL HE fabrication alternative would transition HE fabrication activities from Pantex. The LLNL HE fabrication alternative would require construction of 1 new facility for storage of HE and would use 23 existing buildings, 66 existing magazines, and various utilities and services at Site 300.

Relocate to both Los Alamos National Laboratory and Lawrence Livermore National Laboratory. This option would involve splitting the mission between the two laboratories. Since its impact is bounded by the previous two options, this option is not analyzed further.

S.3.4.1 *Stockpile Management Comparison of Alternatives*

To aid the reader in understanding the differences in environmental impacts among the various PEIS management alternatives, this section presents comparisons of the alternatives, concentrating on the major resources assessed in this PEIS.

Assembly/Disassembly

In addition to the No Action alternative, two alternatives are being considered that would meet the needs of the Program: (1) downsizing the existing A/D facilities at Pantex and (2) transferring the A/D mission to NTS by expanding the Device Assembly Facility. Under No Action, the A/D mission would remain at Pantex. No downsizing or modification of facilities would occur, and there would be no construction impacts. Downsizing existing facilities at Pantex would involve internal modifications to the existing facility. Transferring the A/D mission to NTS would entail upgrading and expanding the Device Assembly Facility.

Socioeconomic Impacts. Because of the reduced workload associated with completing the weapon dismantlement backlog, significant employment reductions will occur at Pantex for all alternatives. There would be a decrease from the current total of 3,437 workers to about 1,644 workers. Of the current workforce, 3,002 are associated with A/D operations. Under No Action only 915 A/D workers would be required. The downsized Pantex facility would be optimally configured for the reduced future workload, and would operate more efficiently than the No Action Pantex facility. The downsized Pantex facility would require 800 workers for single-shift operation. To perform operations in the downsized Pantex facility in a three-shift mode, 1,266 workers would be required.

If the A/D mission were transferred to NTS, 1,093 direct jobs (based on three-shift operation) would be created at that site, along with 1,160 indirect jobs. The 2,253 total new jobs would cause the regional economic area unemployment rate to decrease by approximately 0.1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. If the A/D mission were transferred to NTS, there would be socioeconomic impacts associated with phasing out the A/D mission at Pantex. The phaseout would result in 1,644 direct jobs lost at the Pantex site, and another 1,905 indirect jobs would be lost in the regional economic area. The loss of 3,549 total jobs would cause the regional economic area unemployment rate to increase from 4.8 to 6.2 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

Socioeconomic impacts at NTS associated with a peak construction workforce of 662 would produce small positive economic benefits. The 662 direct workers would also generate 622 indirect jobs. The 1,284 total new jobs during peak construction would cause no change in the regional economic area unemployment rate. Housing rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

Resource Impacts. Due to the reduced workload expected in the future at Pantex, impacts from operations are expected to be less than current impacts. Air quality would remain within regulatory limits, and water requirements would be met without increased aquifer drawdowns. In addition, downsizing existing facilities at Pantex would involve internal modifications to the existing facility. No land would be disturbed.

Transferring the A/D mission to NTS would entail upgrading and expanding the Device Assembly Facility, with associated increases in land disturbance. An estimated 7.5 ha (18.5 acres) of additional land would be disturbed, which is less than 1 percent of the land available at NTS for development. This land disturbance would increase the potential to impact cultural and biotic resources; however, the impact to cultural resources is not expected to be significant because the proposed A/D site has been previously disturbed during construction activities associated with the Device Assembly Facility. Impacts to biotic resources are expected to be minor; however, the presence of the desert tortoise at NTS would require a site survey to determine any impacts. With mitigation measures already in place at NTS to minimize impacts to the Federal-listed desert tortoise, significant impacts due to the proposed project are not expected.

Because both alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, both alternatives would produce similar operational environmental impacts for most resource areas. Impacts to air quality were modeled, and results indicate minimal impacts for both alternatives. Water use for the NTS alternative is projected to be less than for the Pantex alternative because continued operations at Pantex would rely on existing, older, site-wide infrastructure. At both sites, water requirements could be adequately met without substantial aquifer drawdown. At Pantex, downsizing would reduce groundwater withdrawals by 21 percent compared to No Action. At NTS, water requirements to support the A/D mission would be approximately 4 percent more than projected usage. Groundwater withdrawals at NTS would be less than the recharge rates for the aquifer.

Radiation and Waste Management Impacts. The average radiological dose to workers at Pantex would not be expected to change, although the total worker dose would change due to the reduced number of workers associated with a reduction in workload. Worker exposure to radiation is expected to be about equal (approximately 10 mrem/year) for both alternatives and well within regulatory limits. Because of the small difference in the workforce for this mission at the two sites, this would result in a total worker dose of 3.0 person-rem/year at Pantex and 2.6 person-rem/year at NTS. The added risk to the workforce due to these levels of radiation exposure is extremely small.

Radiation exposure to the public from normal operation would be well within regulatory limits at both sites. At Pantex, the incremental dose to the population within 80 km (50 mi) would be $4.0x10^{-4}$ person-rem/year. At NTS, the incremental dose to the public within 80 km (50 mi) resulting from operation of the A/D Facility would be $3.1x10^{-6}$ person-rem/year. The added risk to the public due to these levels of radiation exposure is extremely small.

Both sites have adequate waste management facilities to treat, store, and/or dispose of wastes from the A/D mission, although LLW at Pantex would continue to be shipped offsite to NTS. The impacts of transporting LLW are similar to the impacts of transporting nonradiological materials, which are small. Transferring the A/D mission to NTS would eliminate the need to ship LLW from Pantex to NTS. Transferring the A/D mission to NTS by expanding the Device Assembly Facility would also increase the overall amount of eventual decontamination and decommissioning (D&D) activities and wastes.

Accident Impacts. Potential impacts from accidents would not be expected to change significantly due to reduced workload. Accident impacts were determined using computer modeling. For the composite accident, less than one fatal cancer would be expected for the surrounding 80-km (50-mi) population at either Pantex or NTS. Based on a weighted averaging of the postulated accidents, at Pantex there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 43,000 years from accidents. At NTS, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 500,000 years from accidents.

Other. The A/D mission also includes an option to store strategic reserves of plutonium and/or uranium. At Pantex, which presently stores both strategic reserves and surplus quantities of plutonium, no additional facilities would be needed, and no significant new environmental impacts or risks would result. Storing the strategic reserve would not produce any additional air emissions, require any additional water withdrawals, generate any wastes, or require additional workers. At NTS, however, the Device Assembly Facility would be further expanded to accomplish the strategic reserve storage. The additional construction would have smaller impacts (less than 10 percent) than the construction associated with the Device Assembly Facility upgrade for the A/D mission. Radiation exposure to the public in the event of an accident would be significantly less than for the A/D mission for either alternative.

Pit Fabrication

For pit fabrication, a capability that no longer exists due to the closure of the Rocky Flats Plant, two alternatives are being considered that would reestablish this mission and meet the needs of the Program: (1) upgrading the existing plutonium R&D fabrication capability at LANL and (2) upgrading existing H-Area and F-Canyon facilities at SRS. Both alternatives involve relatively minor (though costly) upgrades to existing facilities. Under the No Action alternative, DOE would not reestablish this mission, but would rely on the existing R&D capabilities at LANL and LLNL.

Socioeconomic Impacts. During operation, both alternatives would have small positive socioeconomic impacts. Based on the socioeconomic modeling, impacts would be higher at SRS because of the indirect jobs that would be created due to this mission. Modeling results indicate no indirect jobs for this mission at LANL. At SRS, up to 813 direct jobs would be created for surge operations, along with 1,594 indirect jobs. These 2,407 total new jobs would cause the regional economic area unemployment rate to decrease from 6.7 to 6.0 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. At LANL, up to 260 new direct jobs would be created for surge operations, but no indirect jobs would be created. The 260 total new jobs would cause the regional economic area unemployment rate to decrease from 6.2 to 6.0 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Because the SRS alternative has less of an infrastructure in place for plutonium fabrication, the SRS alternative would require more direct workers (288 versus 138) during construction. At both sites, however, the socioeconomic impacts during construction would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. Construction activities would involve internal modifications to existing facilities, no land would be disturbed, and thus, no impacts to cultural and biotic resources would result. Because both alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, both alternatives would result in similar operational environmental impacts for most resource areas. Impacts to air quality were modeled, and results indicate minimal impacts to air quality for both alternatives. Water requirements at SRS would be provided from surface water, which is plentiful, and no adverse impacts would be expected. At LANL, groundwater would be used. Water requirements for this mission, which would be less than 1 percent of projected No Action uses, could be adequately met without exceeding the groundwater allotment at LANL.

Radiation and Waste Management Impacts. Worker exposure to radiation is expected to be about equal for both alternatives and well within regulatory limits. At either SRS or LANL, the average workforce dose from this mission would be approximately 380 mrem/year. Because of a difference in workforce for this mission at the two sites, this would result in a total worker dose of 156 person-rem/year at SRS and 55 person-rem/year at LANL. Statistically, this would equate to one fatal cancer every 16 years at SRS, and every 45 years at LANL, from operation of the Pit Fabrication Facility. Radiation exposure to the public from normal operation would be well within regulatory limits at both sites. At SRS and LANL, the incremental dose to the public within 80 km (50 mi) would be 5.9×10^{-4} person-rem/year and 8.6x10^{-5} person-rem/year, respectively. The added risk to the public due to these levels of radiation exposure is extremely small. Both site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Accident Impacts. Potential impacts from accidents were determined using computer modeling. For the composite accident, less than one fatal cancer would be expected for the surrounding 80-km (50-mi) population at both SRS and LANL. Based on a weighted averaging of the postulated accidents, at SRS there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 360,000 years from accidents. At LANL, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 160,000 years from accidents.

Secondary and Case Fabrication

In addition to the No Action alternative, three alternatives being considered would meet the needs of the Program: (1) downsizing facilities that presently perform this mission at ORR, (2) transferring the secondary and case fabrication mission to LANL by upgrading the existing R&D secondary and case fabrication capabilities of LANL, and (3) transferring the secondary and case fabrication mission to LLNL by upgrading the existing R&D secondary and case fabrication capabilities of LLNL. Under No Action, the secondary and case fabrication mission would remain at Y-12 at ORR, and no downsizing or modification of facilities would occur.

Socioeconomic Impacts. Under No Action, there would be a decrease in the number of workers at Y-12 from the current total of 5,152 workers to 4,721 workers. Of the 5,152 workers, 3,126 workers are currently associated with the core stockpile management mission. Under No Action, only 2,741 core stockpile management workers would be required. The downsized Y-12 would be optimally configured for the reduced future workload, operate more efficiently, and require 784 workers for single-shift operation, a reduction of 1,957 workers. To perform operations in the downsized Y-12 in a three-shift mode, 1,376 core stockpile management workers would be required, a reduction of 1,365 workers. A reduction of 1,365 direct jobs represents approximately 9 percent of the projected No Action workforce at the entire ORR site, and less than 1 percent of the regional economic area. Another 3,490 indirect jobs would also be lost.

Mitigating the workforce reductions would be the fact that downsizing would require 1,152 new jobs associated with landlord activities in preparation for D&D activities. Another 1,600 indirect jobs would be created by these D&D jobs. The net effect for the three-shift mode of operation would be a loss of a total of 213 direct jobs at Y-12, which would represent less than 1 percent of the projected No Action workforce at ORR.

Transferring the secondary and case fabrication mission to either LANL or LLNL would have small positive socioeconomic impacts at those sites, and negative socioeconomic impacts at ORR due to the phaseout of this mission. At LANL, 321 direct jobs (based on three-shift operation) would be created, but no indirect jobs would be created for this industry. The 321 new jobs would cause the regional economic area unemployment rate to decrease from 6.2 to 6.0 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. At LLNL, 290 new direct jobs (based on three-shift operation) would be created, along with 722 indirect jobs. The 1,012 new jobs would cause the regional economic area unemployment rate to decrease by less than 1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

Transferring the secondary and case fabrication mission from ORR to either LANL or LLNL would result in the loss of 3,336 jobs projected for this mission under No Action at Y-12, and the closure and D&D of the Y-12 facilities previously involved in this mission. Another 10,134 indirect jobs could also be lost. It is expected that 1,385 new jobs would be created by a direct transfer of responsibilities from DP to the DOE Office of Environmental Management. Additionally, because the D&D of facilities at ORR would be a relatively long-term process, any initial negative socioeconomic impacts resulting from the transfer of the secondary and case fabrication mission to LANL or LLNL would be minimized by the additional workforce associated with D&D activities at ORR. These 1,385 new D&D jobs would also create 1,937 new indirect jobs. The net effect would be a loss of a total of 13,470 total jobs (direct plus indirect) in the ORR regional economic area. This would cause the regional economic area unemployment rate to increase from 4.9 to 7.4 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

During construction activities, socioeconomic impacts would result, but would be small. The number of peak workers would be 14 at ORR, 55 at LANL, and 130 at LLNL, which has the least extensive existing infrastructure for secondary and case fabrication. At all three sites, the socioeconomic impacts during construction would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. Impacts from continued operation at Y-12 are expected to be similar to current impacts. Air quality would remain within regulatory limits and water requirements would be adequately met by surface water withdrawals. For the three "action" alternatives, no previously undisturbed land would be disturbed, and thus, no impacts to biotic resources would result. Minimal impacts to cultural resources may result from building modifications to facilities eligible for the National Register of Historic Places. Because each of the alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, each of the alternatives would produce similar operational environmental impacts for most resource areas. Impacts to air quality were modeled for each alternative and results indicate minimal impacts to air quality for each of the alternatives. Water requirements at ORR would be met from surface water, which is plentiful, and no adverse impacts would be expected. At LANL, groundwater would be used. Groundwater withdrawals would increase by less than 1 percent over projected No Action water requirements, and LANL's groundwater allotment would not be exceeded. At LLNL, public water supply would be used, and usage would be approximately 20-percent higher than projected No Action water requirements. No adverse impacts to water resources are expected.

Radiation and Waste Management Impacts. Radiation worker exposure to radiation is expected to be about equal for all three alternatives and well within regulatory limits. At each of the three sites, the average workforce dose from this mission would be approximately 2.2 mrem/year. Because of differences in projected workforces, this would result in a total worker dose of 0.38 person-rem/year at ORR, 0.33 person-rem/year at LANL, and 0.55 person-rem/year at LLNL. The added risk to the workforce due to these levels of radiation exposure is extremely small. Radiation exposure to the public from normal operation would be well within regulatory limits at these sites. At ORR, the incremental dose to the population within 80 km (50 mi) would be 0.6 person rem/year. The probability of a member of the public dying from cancer would be $3x10^{-4}$/year. At LANL, the incremental dose to the population within 80 km (50 mi) would be 0.5 person-rem/year. The probability of a member of the public dying from cancer would be $2.5x10^{-4}$/year. At LLNL, the incremental dose to the population within 80 km (50 mi) would be 0.84 person-rem/year. The probability of a member of the public dying from cancer would be $4.2x10^{-4}$/year. The added risk to the public due to these levels of radiation exposure is extremely small. All three site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Accident Impacts. Potential impacts from accidents were determined using computer modeling. For all postulated accidents, less than one fatal cancer would be expected for the surrounding 80-km (50-mi) population at each of the sites. Based on a weighted averaging of the postulated accidents, at ORR and LANL there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 830,000 years from accidents. At LLNL, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 260,000 years from accidents.

Other. If the secondary and case fabrication mission were transferred from ORR, storage of the strategic reserves of HEU would be transferred to the A/D Facility (or a consolidated storage facility being assessed in the Storage and Disposition PEIS). The potential impacts associated with the one-time transfer of the strategic reserves of HEU to the A/D Facility are expected to be minor, even in the event of an accident, due to the robust shipping containers.

High Explosives Fabrication

In addition to the No Action alternative, three alternatives are being considered that would meet the needs of the Program: (1) downsizing facilities that presently perform this mission at Pantex, (2) transferring the HE fabrication mission to LANL by upgrading the existing R&D HE fabrication capabilities of LANL, and/or (3) transferring the HE fabrication mission to LLNL by upgrading the existing R&D HE fabrication capabilities of LLNL. Transferring the HE fabrication from Pantex to LANL and/or LLNL would result in the closure and D&D of Pantex facilities previously involved in this activity. Under No Action, the HE fabrication mission would remain at Pantex. No downsizing or modification of facilities would occur.

Socioeconomic Impacts. Downsizing the HE fabrication mission at Pantex would reduce the number of direct workers associated with this mission to 37, compared to 105 for No Action. Transferring the HE fabrication mission to either LANL or LLNL would create small positive socioeconomic impacts at either of those sites, and small negative socioeconomic impacts at Pantex, due to the phaseout of this mission. For surge operations at LANL, 67 new direct jobs would be created, but no indirect jobs would be created by this industry. The 67 new jobs would cause the regional economic area unemployment rate to decrease from 6.2 to 6.1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. For surge operations at LLNL, 100 new direct jobs would be created, along with 155 indirect jobs. The 255 total new jobs would cause the regional economic area unemployment rate to decrease by less than 1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Phasing out the HE fabrication mission at Pantex would cause the loss of 105 direct jobs, which would be approximately 3 percent of the projected No Action workforce at Pantex. The direct plus indirect jobs lost would cause no observable change to the Pantex regional economic area unemployment rate, housing/rental vacancies, and public finance expenditures/revenues.

During construction activities, socioeconomic impacts would result, but they would be small. The number of peak workers would be 29 at Pantex, 46 at LANL, and 19 at LLNL. At all three sites, the socioeconomic impacts during construction would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. For the three "action" alternatives, construction impacts are expected to be minor and would involve internal modifications to existing facilities. No land would be disturbed at Pantex or LANL, and thus, no impacts to cultural or biotic resources would result. At LLNL, a small area of land (less than 1 ha) would be disturbed to construct an HE and parts storage building, but impacts to biotic and cultural resources are not expected.

Because each of the alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, each of the alternatives would result in similar operational environmental impacts for most resource areas. Impacts to air quality were modeled for each alternative, and results indicate minimal impacts to air quality for each of the alternatives. At all sites, water requirements would be met from groundwater. At Pantex, this alternative applies only in conjunction with the downsize A/D alternative at Pantex discussed earlier. Downsizing both missions would reduce groundwater withdrawals by 16 percent compared to No Action. At LANL, groundwater withdrawals would increase by less than 1 percent over projected No Action water requirements, and LANL's groundwater allotment would not be exceeded. At LLNL, groundwater and/or the public water supply could be used to support the HE fabrication mission. If public water were used, it would require approximately 21 percent of the design capacity of the public water tap line. If groundwater were used, withdrawals would increase by approximately 65 percent from No Action, but they would not have any adverse impacts to aquifer levels.

Radiation and Waste Management Impacts. There are no radiological risks to workers or the public associated with the HE fabrication mission and no adverse impacts associated with normal operation. All three site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Accident Impacts. Potential impacts from chemical accidents or explosions were determined using modeling. Impacts from these types of accidents could include death or bodily damage. Due to proximity, workers would be most susceptible to any potential impacts. For all postulated accidents, impacts to the public were much less than to workers. In the event of an accident involving HE fabrication, due to the higher population surrounding LLNL, public impacts could be higher at LLNL compared to LANL and Pantex. Transferring the HE fabrication mission from Pantex to LANL and/or LLNL would require HE components to be shipped from the fabrication site to the A/D Facility. HE is a nonradioactive, hazardous material. There are no impacts associated with the incident-free transportation of HE. In the event of an accident, HE transportation impacts would be no greater than those encountered by the public from industry's transportation of similar explosives. Potential accidents could include both explosive and nonexplosive roadway accidents, with potential impacts of death, lesser bodily injury, and property damage.

Nonnuclear Fabrication

In addition to the No Action alternative, two alternatives are being considered that would meet the needs of the Program: (1) downsizing the facilities that presently perform this mission at KCP and (2) transferring the KCP nonnuclear fabrication mission to LANL, LLNL, and SNL by upgrading existing nonnuclear fabrication capabilities at LANL and LLNL, and constructing new nonnuclear fabrication facilities at SNL. Under No Action, the nonnuclear fabrication mission would remain at current locations; primarily at KCP, with small workloads at LANL and SNL.

Socioeconomic Impacts. At KCP, workforce downsizing consistent with a reduced workload has already taken place; therefore, the projected No Action workforce (3,179 workers) is equal to the current workforce. Of these 3,179 workers, 2,508 workers perform core stockpile management missions. The downsized KCP facility would be optimally configured for the reduced future workload, would operate more efficiently, and would require 1,669 core stockpile management workers for single-shift operation. To perform operations in the downsized KCP facility in a three-shift mode, 2,257 workers would be required. This is 251 workers less than the No Action single-shift number of workers. Another 443 indirect jobs would also be lost. The loss of a total of 694 jobs (direct plus indirect jobs) would not cause the regional economic area unemployment rate to change.

Transferring the nonnuclear fabrication mission to the laboratories would create small positive socioeconomic impacts at both LANL and LLNL, with increases of 240 and 131 total (direct plus indirect) jobs, respectively. At each of these sites, socioeconomic indicators would change by less than 1 percent. At SNL, 1,160 direct jobs would be created, along with 1,350 indirect jobs. The 2,510 new jobs would cause the regional economic area unemployment rate to decrease from 5.7 to 5.2 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Phasing out the nonnuclear fabrication mission from KCP would cause the loss of 3,179 direct jobs and the loss of 5,609 indirect jobs in the regional economic area. The loss of 8,788 total jobs from KCP would cause the regional economic area unemployment rate to increase from 4.9 to 5.6 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Some socioeconomic impacts could be mitigated by employing personnel for D&D of the KCP facility, although that is not expected to last more than 5 years.

During construction activities, socioeconomic impacts would result, but would be small. At KCP, 187 direct jobs would be created during downsizing activities, plus another 262 indirect jobs. The 449 total jobs created during construction at KCP would represent less than a 1 percent increase in the regional economic area, and would cause no observable change to the regional economic area unemployment rate, housing/rental vacancies, and public finance expenditures/revenues. If the nonnuclear fabrication mission is transferred to the three laboratories, no observable socioeconomic impacts would occur at LANL or LLNL. At SNL, 379 direct jobs would be created during construction activities, plus another 421 indirect jobs. The 800 total jobs created during construction at SNL would represent less than a 1 percent increase in employment in the regional economic area, and would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. Due to the reduced workload expected in the future, impacts from operations are expected to be less than current impacts. Air quality would remain within regulatory limits at each of the sites, and water requirements would be adequately met.

For the alternative that would downsize KCP, the construction activities would involve internal modifications to the existing facility. No land would be disturbed. For the alternative that would transfer the KCP mission to the laboratories, construction impacts would involve internal facility modifications at LANL and LLNL. At SNL, approximately 9 ha (22 acres) of land would be disturbed to construct a new facility. This represents approximately 6 percent of the undisturbed land at SNL. Potential impacts to cultural and biotic resources would exist, but they would be mitigated to the extent practicable during follow-on, site-specific studies.

Because each of the alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, each of the alternatives would result in similar operational environmental impacts for most resource areas. Impacts to air quality were modeled for each alternative. Modeling results indicate minimal impacts to air quality for each of the alternatives. Water requirements for nonnuclear fabrication are relatively minor at each of the sites. At KCP, water requirements, which are publicly provided, would be reduced by approximately 31 percent compared to No Action. At LANL, groundwater withdrawals would increase by less than 1 percent over projected No Action water requirements, and LANL's groundwater allotment would not be exceeded. At LLNL, there would also be a less than 1 percent increase in water requirements to support nonnuclear fabrication. At SNL, groundwater would be used. Groundwater withdrawals would increase by approximately 64 percent over projected No Action withdrawals, but would still represent only 29 percent of the Kirtland Air Force Base groundwater rights. Thus, no adverse impacts are expected.

Radiation, Waste Management, and Accident Impacts. There are no radiological risks to workers or the public associated with the nonnuclear fabrication mission, and there are no adverse impacts associated with normal operation. Accident profiles at the sites would not change as a result of downsizing KCP or transferring the nonnuclear fabrication mission to the laboratories. Phaseout of the nonnuclear mission from KCP would eliminate any potential accidents at that site. All three site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Stockpile Management Top-Level Comparison

Based upon the reasonable alternatives for the five major missions that make up the stockpile management program, one could construct a matrix with a large number of discrete alternatives for the entire Complex. Analyzing such a large number of alternatives is neither practical nor useful. What is useful, however, is to look at the two extreme configurations for the entire Complex in order to compare environmental impacts for a bounding case analysis. Based on the alternatives that are reasonable for the individual missions, the bounding configurations and environmental impacts for the Complex are a relatively unconsolidated Complex that is downsized/rightsized in place or a relatively consolidated Complex that is rightsized by upsizing the laboratories and NTS.

For the first configuration (referred to as Downsize/Rightsize-in-Place), the Complex would consist of A/D at Pantex, HE fabrication at Pantex, pit fabrication at LANL (or SRS), secondary and case fabrication at ORR, and nonnuclear fabrication at KCP. This is essentially the preferred alternative for stockpile management. For the second configuration (referred to as Maximum Consolidation), the Complex would consist of A/D at NTS, HE fabrication at LANL (or LLNL), pit fabrication at LANL, secondary and case fabrication at LANL (or LLNL), and nonnuclear fabrication at SNL, LANL, and LLNL. Major differences in environmental impacts between these two configurations are presented below.

Socioeconomic Impacts. It is worthy to note that some of the reductions in workforce at the various stockpile management facilities are associated with reduced workloads expected in the future, while additional reductions in workforce could occur due to the physical downsizing of facilities. For the A/D and HE missions at Pantex, under No Action, the core stockpile management workforce would be reduced from the current level of 3,107 workers (3,002 for A/D and 105 for HE) to 1,020 workers (915 for A/D and 105 for HE) for single-shift operation. The physical downsizing of the facility would also improve efficiency such that the workforce could be reduced even further, to 831 workers for single-shift operation (800 for A/D and 31 for HE). Three-shift operation of the downsized Pantex facility would require 1,303 core stockpile management workers (1266 for A/D and 37 for HE).

For the secondary and case fabrication mission at ORR, under No Action, the workforce would be reduced from the current level of 3,126 core stockpile management workers to 2,741 workers for single-shift operation. The physical downsizing of Y-12 (essentially an 86-percent reduction in facility size) would also improve efficiency such that the core stockpile management workforce could be reduced even further, to 784 workers for single-shift operation. Three-shift operation of the downsized Y-12 facility would require 1,376 core stockpile management workers. The adverse socioeconomic impacts associated with the Y-12 downsizing would be mitigated by the creation of 1,152 new jobs associated with landlord activities in preparation for the D&D of the facilities no longer needed.

At KCP, workforce reductions consistent with a reduced workload have already taken place; therefore, the projected No Action workforce (2,508 core stockpile management workers) is equal to the current workforce. Downsizing the KCP facility would improve efficiency such that the workforce could be reduced to 1,669 workers for single-shift operation. Three-shift operation of the downsized KCP facility would require 2,257 workers.

Overall, socioeconomic impacts from construction for the Maximum Consolidation configuration would be minimal, except at NTS and SNL. Socioeconomic impacts from construction for the Downsize/Rightsize-in-Place configuration would also be minimal.

Resource Impacts. Construction impacts associated with the Downsize/Rightsize-in-Place configuration would be minimal. All construction activities would be modifications to existing facilities, with no new construction. Consequently, no significant land disturbance at any sites would result, and no potential impacts to biota or cultural resources would occur.

Construction impacts associated with the Maximum Consolidation configuration would be small overall; only the Device Assembly Facility upgrade at NTS and the Nonnuclear Facility at SNL involve any land disturbance greater than 1 ha (2.47 acres). Most construction activities would be modifications to existing facilities, with no significant land disturbance, and no potential impacts to biota or cultural resources.

During operation, because each of the two configurations would utilize similar facilities, procedures, resources, and numbers of workers, each would result in similar operational environmental impacts for most resource areas. For the Maximum Consolidation configuration, the greatest potential for any significant environmental impacts would occur at LANL, which would be the site for pit fabrication, secondary and case fabrication, HE fabrication, and a portion of nonnuclear fabrication. For each of the resources evaluated in this PEIS, no significant impacts are expected from such consolidation. Modeling results for air quality indicate minimal impacts to air quality. Water requirements would increase at LANL by 2.5 percent, but would still be less than the LANL allotment.

Radiation, Waste Management, and Accident Impacts. Cumulative doses to the population from normal operation would be less than regulatory limits. Impacts from accidents are independent of other missions (e.g., accident risks are additive, not multiplicative). Thus, the potential accident would be the sum of the risks from each mission. For maximum consolidation at LANL, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 135,000 years from accidents. LANL would have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by these missions.

A difference in the operation of the Downsize/Rightsize-in-Place configuration and the Maximum Consolidation configuration would involve the transportation of nuclear and hazardous materials. The Downsize/Rightsize-in-Place configuration would result in transporting plutonium components between LANL (or SRS) and Pantex, and transporting secondary and case components between ORR and Pantex. Incident-free impacts associated with this transportation are small, while accident impacts are minor. The Maximum Consolidation configuration would also result in transporting plutonium components and secondary and case components.

Transportation would occur between LANL and NTS. Relative to the Downsize/Rightsize-in-Place configuration, any transportation impacts would be less due to shorter distances and less populated roadways. The Maximum Consolidation configuration would also result in transporting HE components between LANL and NTS, but no significant impacts are expected.

S.3.5 Alternatives Considered but Eliminated from Detailed Study and Related Issues

This section of the PEIS has been revised in response to comments received on the Draft PEIS concerning its scope and the alternatives considered. To begin, it is important to review the basic logic used in constructing this PEIS and to restate the nature of the decisions expected to be made based on the contents of the PEIS.

Section S.2 describes the national security policy framework that defines the purpose and need for DOE's nuclear weapons mission for the foreseeable future. It also describes the development of proposed actions and reasonable alternatives in response to recent changes in national security policy. Section S.2 also puts those changes in broad technical perspective. Successive levels of technical detail are provided in chapters 3 and 4 of Volume I, and in Volumes II and III. The discussions that follow refer to the appropriate sections of this PEIS to avoid unnecessary repetition.

As stated in the Notice of Intent (60 FR 31291) published on June 14, 1995, DOE intends that the ROD on this PEIS will:

- Identify the future missions of the Stockpile Stewardship and Management Program; and
- Determine the configuration (facility locations) of the Complex necessary to accomplish the Program missions

While the terms "stockpile stewardship" and "stockpile management" are relatively new, the Program is not new when considered in terms of its substructure capabilities (section S.1). What the terms are meant to convey is a change in Program focus away from large-scale development and production of new-design nuclear weapons with nuclear testing, to one that focuses on the safety and reliability of a smaller, aging stockpile without nuclear testing. Even with this change in focus, however, national security policies require DOE to maintain the capabilities of the ongoing Program. The proposed actions flow logically from the mission purpose and need, given the policy constraints placed on the Program. Enhanced experimental capability is proposed because it is the surrogate source of experimental data that are needed to continually assess and certify a safe and reliable stockpile constrained by the absence of nuclear testing. Rightsizing manufacturing capacities is proposed in direct response to the reduced requirements of a smaller, aging stockpile constrained by the absence of new-design weapon production. Reestablishing pit manufacturing capability is proposed because it restores a required capability of the Program that was temporarily lost as a consequence of the closure of the Rocky Flats Plant.

In developing this PEIS, DOE judged the above three proposed actions to be significant at the programmatic level. Some additional strategies of the Stockpile Stewardship and Management Program, such as enhanced computational capability, were judged not to have significance for this PEIS because they did not have the potential for significant environmental impacts relative to the ongoing Program at a site, nor was the mission capability being considered for transfer to another site. The programmatic level environmental impacts of the ongoing Program at each of the eight sites in the Complex are described in chapter 4 of Volume I. Projects and facilities to support the ongoing Program are subject to site-specific NEPA review.

The issue of Stockpile Stewardship and Management Program alternatives is complex because nuclear weapons require a complete integrated set of technical capabilities and an appropriately sized manufacturing capacity. The technical capabilities are generally characterized as research, design, development, and testing; reliability assessment and certification; and manufacturing and surveillance operations (section S.2.1 and figure S.2–2). From a technical point of view, none of these capabilities can be deleted if DOE is to maintain a safe and reliable stockpile (section S.2.3). In addition, DOE has been directed to maintain these capabilities by national security policy from the President and Congress (section S.2.3).

S.3.5.1 *Alternatives in General*

Commentors questioned the different treatment of stewardship and management alternatives, mainly the lack of stewardship alternatives. Stewardship and management alternatives are treated differently in the PEIS because they address fundamentally different problems. Stockpile stewardship capabilities form the basis of U.S. judgments about the safety, reliability, and performance of U.S. nuclear weapons, and in a larger context, U.S. judgments about the nuclear weapons capabilities of others (section S.2.3). DOE did not consider it reasonable to propose stewardship alternatives that would diminish stewardship capabilities, particularly given the fact that historic confidence in the safety and performance of the stockpile was derived from nuclear testing that is no longer part of the ongoing stewardship program. National security policy requires DOE to maintain, and in some areas enhance, the stewardship capabilities of the three weapons laboratories and NTS (section S.2.1). The PEIS also explains the basis for this in a technical context, including the need for two independent nuclear design laboratories (section S.2.3). Therefore, this PEIS has no proposed actions that transfer ongoing stockpile stewardship missions from one site to another, or that would otherwise diminish ongoing stewardship missions.

National security policy also requires DOE to maintain stockpile management capabilities and appropriate manufacturing capacity for a smaller stockpile. Unlike stockpile stewardship capabilities, the smaller stockpile does permit some reasonable siting alternatives for stockpile management capabilities and capacities to accomplish the mission purpose and need within the current national security policy framework (section S.2.3).

S.3.5.2 *Enhanced Experimental Capability*

DOE has considered that there are differing opinions on the technical merit of DOE's proposed actions with regard to enhanced experimental capability. Nuclear weapons design information, including the complex physics of nuclear weapon explosions, is classified for reasons of national security and nonproliferation. Even if this information were unclassified, the physics problems remain daunting; hence, the reason why nuclear testing was so important to the past program. Both the classification of information and technical complexity of the issues form natural barriers to public communication. The technical complexity alone engenders significant debate among qualified experts, especially in the area of high energy density physics. This PEIS attempts to explain the weapon physics issues in an unclassified, comprehensible manner regarding its relation to mission purpose and need (section S.2), proposed actions and alternatives (section 3.3 of Volume I), and project-specific technical detail (Volume III). In the absence of nuclear testing, there are two basic alternatives: (1) rely on existing facilities as sources of experimental data described by the No Action alternative, and (2) pursue the enhanced capability of the proposed facilities to provide the sources of experimental data needed.

Role of Existing Experimental Facilities. In DOE's technical judgment, the existing facilities described by the No Action alternative are inadequate to meet the challenge of assessing and certifying a safe and reliable stockpile over the longer term. It is also DOE's technical judgment that it is impossible to speculate at this time whether any of the existing facilities could be retired, because they would be obsolete or redundant, as a result of a decision to construct and operate any or all of the three proposed new stewardship facilities. The uncertainties inherent in the R&D nature of the stewardship program would make that kind of exercise essentially guesswork. The development of machines to simulate the intricacies of a nuclear detonation requires a highly sophisticated scientific R&D program. It very likely will take 5 to 10 years to begin obtaining reliable data from the new facilities. Until those facilities are operational, DOE cannot reliably predict how the additional capabilities they provide will mesh with the capabilities of previously existing machines to further the goals of the Program. It is only through incremental advances in the state of the science that decisions can eventually be made regarding the retirement of obsolete or redundant facilities.

DOE is committed to making maximum efficient use of the stewardship capabilities at its disposal. However, it is not reasonable to speculate at this time about how future stewardship requirements might affect existing facilities and capabilities.

Next Generation Experimental Facilities. Commentors suggested that potential next generation experimental facilities be analyzed as part of the proposed action. This PEIS includes a discussion of potential next-generation experimental facilities and the reasons why they are not proposed actions or alternatives (section S.2.4 and section 3.3.4 of Volume I). These facilities, while contemplated on the basis of anticipated technical need, have not reached the stage of design maturity through R&D for DOE to include a decisionmaking analysis at this time. However, this PEIS does broadly describe, in general terms or by reference, what is known today about their potential environmental impacts. The environmental impacts from these facilities as contemplated today would not be significantly different from existing "similar" facilities. By characterizing the potential impacts in this way, the decisionmaker will be aware of the potential program-level cummulative impacts of the next-generation facilities when deciding whether to pursue a program of enhanced experimental capability. If DOE proposes to construct and operate such facilities in the future, appropriate NEPA review will be performed.

New Weapon Design. Commentors have suggested that the proposal for enhanced experimental capabilities is directed more at the capability to design new weapons in the absence of nuclear testing than at maintaining the safety and reliability of the existing stockpile and that stewardship alternatives could be different if the facilities were directed only at maintaining the existing stockpile. This PEIS explains why these capabilities are needed to maintain the safety and reliability of a smaller, aging stockpile in the absence of nuclear testing (section S.2). The existing U.S. stockpile of nuclear weapons is highly engineered and technically sophisticated in its design for safety, reliability, and performance. The stewardship capabilities required to make technical judgments about the existing stockpile are likewise technically sophisticated; therefore, it would be unreasonable to say that these stewardship capabilities could not be applied to the design of new weapons, albeit with less confidence than if new weapons could be nuclear tested.

However, the development of new weapon designs requires integrated nuclear testing such as occurs in nuclear explosive tests. Short of nuclear testing, no single stockpile stewardship activity, nor any combination of activities, could confirm that a new-design weapon would work. In fact, a key effect of a "zero-yield" CTBT would be to prevent the confident development of new-design weapons. National security policy requires DOE to maintain the capability to design and develop new weapons, and it will be a national security policy decision to use or not use that capability. Choosing not to use enhanced experimental capability for new weapons designs would not change the technical issues for the existing stockpile and, therefore, the stewardship alternatives would not change.

The issue of new-design weapons is separate from DOE's need to perform modifications to existing weapons that require research, design, development, and testing. The phrase used in this PEIS, "without the development and production of new-design weapons," is meant to convey the fact that the historical continuous cycle of large scale development and production of new weapons designs replacing older weapon designs has been halted. For example, during the 1980s, about a dozen new-design weapons were in full-scale development or production. Over the decade, production of new-design weapons replaced dismantled weapons nearly one for one. Today, only modifications to parts of existing weapons are being performed or planned; dismantlement has continued. This results in a smaller, aging stockpile that must be assessed and certified without nuclear testing. This is now the primary focus of the stewardship program.

Nonproliferation. Commentors have suggested that enhanced experimental capability is a proliferation risk. The national security policy framework discussed in this PEIS seeks a new balance between U.S. arms control and nonproliferation objectives and U.S. national security requirements for nuclear deterrence while pursuing these objectives (section S.2.1). In addition, a discussion is provided on some of the more difficult issues that must be considered in determining the balance, including a discussion of experimental capability (section S.2.5). In particular, the issue of nonproliferation and the proposed NIF was studied in detail. The study, prepared by the DOE Office of Arms Control and Nonproliferation, has been the subject of extensive public involvement, interagency review, and review by outside experts. The study concluded that the technical proliferation concerns of NIF are manageable and can therefore be made acceptable and that NIF can contribute positively to U.S. arms control and nonproliferation policy goals (appendix section I.2.1 of Volume III). NIF is a proliferation concern because of its broader scientific applications and expected frequent use by researchers worldwide, and, like the other proposed enhanced experimental facilities because of its possible relevance to the development of new weapon designs. However, the development of new weapon designs requires integrated testing. None of the proposed facilities, either alone or together, could perform such integrated testing of new concepts, and therefore cannot replace nuclear testing for the development of new weapon designs. The role of these facilities will be to help assess and certify the safety and reliability of the nuclear weapons remaining in the stockpile in the absence of nuclear testing. The national security policy framework and the technical issues that drive the proposed action for enhanced experimental capability remain the same.

Subcritical Experiments. With regard to the treatment of ongoing stewardship activities or enhanced experimental capability, subcritical experiments are an example of how changes in terminology have caused some confusion about what is evaluated in this PEIS under the No Action alternative. Subcritical experiments have been conducted at NTS over many years. Historically, operations at NTS have included tests or experiments that included both HE and special nuclear materials that were intended to produce no nuclear yield or negligible nuclear energy releases. These experiments frequently remained subcritical (i.e., they did not achieve self-sustaining fission chain reactions). The term "subcritical experiments" does not define a new form of activity or mission. It is intended to underscore the fact that in the future such experiments will be configured to ensure that the condition of criticality cannot be achieved. This issue has been clarified in the NTS Site-Wide EIS.

S.3.5.3 *Safe and Reliable Stockpile*

Some commentors have suggested that nuclear weapon reliability is not important in the post-Cold War era. National security policy as established by the President and Congress requires a safe and reliable stockpile. In order for the nuclear deterrent to be credible within the current national security policy framework, it must be reliable in a militarily effective way. A program designed to ensure the safety but not the reliability of the stockpile would require DOE to speculate on an alternate concept of nuclear deterrence and a national security policy framework to support it. See also the discussion of denuclearization in section S.3.5.4.

Commentors have also suggested acceptance of lower standards of reliability as an alternative to enhanced stewardship capabilities. This PEIS explains how the assessment and certification of nuclear performance is carried out, and how this process differs from the more conventional statistical methods used for assessing reliability of the nonnuclear portion of the weapon. Assessment and certification of nuclear performance is a technical judgment by the weapons laboratories based on scientific theory, experimental data, and computational modeling (sections S.2.2 and S.2.3). The question is not whether to accept a lower standard of nuclear performance (less nuclear explosive yield), but whether or not there is a technical basis to confidently know how well the weapon will perform at all. Enhanced stewardship capability is focused on the technical ability to confidently judge nuclear safety and performance in the absence of nuclear testing.

Aside from being inconsistent with national security policy, attempting to separate weapon safety and reliability is more technically complex than it sounds. A modern nuclear weapon is highly integrated in its design for safety, reliability, and performance. It contains electrical energy sources and many explosive energy sources in addition to the main charge HE. The principal safety concern is accidental detonation of the HE causing dispersal of radioactive materials (plutonium and uranium). Modern weapons are designed and system-engineered to provide a predictable response in accident environments (e.g., fire, crush, or drop). However, because of the technical complexity of potential accident scenarios (i.e., combined environments) and the fact that complete nuclear weapons cannot be used for experimental data, assessment of the design and the effect of changes that might be occurring due to stockpile environments must rely on other sources of experimental data and complex computer modeling. Enhanced experimental capability specifically related to the weapon secondary is a nuclear performance concern. Enhanced computational capability in general, and enhanced experimental capability related to the weapon primary in particular, are both nuclear safety and performance concerns.

S.3.5.4 *Description of Alternative Approaches*

Commentors have suggested that DOE consider alternative forms of stewardship. While their comments are responded to in Volume IV, this section discusses DOE's consideration of the broad range of views on this issue. The Congressional Research Service report, *Nuclear Weapons Stockpile Stewardship: Alternatives for Congress*, December 14, 1995, provides a reasonable description of the various viewpoints on alternatives and a framework for discussion. (The report uses the term stockpile stewardship generically to describe the Stockpile Stewardship and Management Program.) The following discussion of alternative approaches is taken from the summary of that report.

> **Denuclearizers** would eliminate nuclear weapons worldwide in the foreseeable future, perhaps one to two decades. Until then, they would have a minimal U.S. stewardship program whose personnel, as curators of weapons knowledge, would monitor weapons. **Restorers** would maintain nuclear weapons with the only proven method, an ongoing program of research, development, design, testing, and production, downsized to meet post-Cold War needs. Three intermediate positions seek to maintain weapons indefinitely without nuclear testing. **Remanufacturers** believe that since current weapons have been tested and certified as meeting military requirements, this Nation can maintain them indefinitely by "remanufacturing"—reproducing them to the exact specifications of the originals. Remanufacturers would go to great lengths to do so in order to avoid risks that even slight changes to warheads might introduce. **Enhancers**, who take the Administration's position on stewardship, see identical remanufacture as impossible. They believe some changes in design, process, and materials are unavoidable and others are desirable. A robust science program, they hold, is the best that can be done without testing to monitor warheads, anticipate problems, modify warheads when problems arise, and revalidate stockpile effectiveness on an ongoing basis. They would have a small manufacturing program. **Maintainers** fall between remanufacturers and enhancers. They focus on how to maintain warheads. They prefer to avoid changes to warheads but would not go to great lengths to do so. They view a strong science program as essential, but only to the extent that its elements connect directly to maintaining weapons. They emphasize manufacturing as the ultimate guarantor of U.S. ability to solve warhead problems. They, along with enhancers, favor some link to testing if confidence cannot be maintained in any other way.

Beyond the broad overview of alternative approaches to stockpile stewardship and management, the main text of the report discusses variations within each of the five points of view. Given the political and technical complexity of the Program, many approaches can appear to be distinct or reasonable alternatives for detailed study. In fact, while the enhancer's viewpoint as described above most closely resembles the Program described in this PEIS, the Program actually embraces elements of all five viewpoints. The following discussion illustrates this point and focuses on the main issue(s) that, in DOE's view, eliminate the other approaches as distinct or reasonable alternatives for this PEIS.

Denuclearization. This approach is reflected in this PEIS to the extent that national security policy is pointed toward the goals of denuclearization. Since the end of the Cold War, more than 8,000 U.S. nuclear weapons have been dismantled, no new-design weapons are being produced, three former nuclear weapons industrial plants have been closed, and the United States is observing a nuclear test moratorium and seeking a "zero-yield" CTBT. Maintenance of a safe and reliable stockpile is not inconsistent with working toward the NPT goal of eliminating nuclear weapons worldwide at some unspecified time in the future. However, denuclearization is not a reasonable alternative for this PEIS because it is not feasible based on current national security policy.

The main issue discussed in this section is consideration of an alternative with a very small (10s or 100s) or zero stockpile. Two of the stockpile sizes analyzed in this PEIS, a START I Treaty- and START II protocol-sized stockpile, are the only ones currently defined and directed by national security policy. The PEIS also analyzes a hypothetical 1,000 weapon stockpile for the purpose of a sensitivity analysis for manufacturing capacity decisions. The NWSM specifies the types of weapons and quantities of each weapon type by year (section S.1). The NWSM is developed based on DOD force structure requirements necessary to maintain nuclear deterrence and comply with existing arms control treaties while pursuing further arms control reductions. This PEIS explains the complexity of this process and why DOE does not believe it reasonable to speculate using a large number of arbitrary assumptions (section S.2.1). DOE has considered that a future national security policy framework could define a path to a smaller stockpile. However, DOE has the following perspective on this issue.

Stockpile stewardship capabilities are currently viewed by the United States as a means to further U.S. nonproliferation objectives in seeking a "zero-yield" CTBT. Likewise, it would be reasonable to assume that U.S. confidence in its stewardship capabilities would remain as important, if not more important, in future arms control negotiations to reduce its stockpile further. The path to a very small (10s or 100s) or zero stockpile would require the negotiation of complex international treaties, most likely with provisions that require intrusive international verification inspections of nuclear weapons related facilities. Therefore, DOE believes it reasonable to assume that complex treaty negotiations, when coupled with complex implementation provisions, would likely stretch over several decades. On a gradual path to a very small or zero stockpile, stockpile size alone would not change the purpose and need, proposed actions, and alternatives in this PEIS as they relate to stewardship capabilities. The issues of maintaining the core competencies of the United States in nuclear weapons, and the technical problems of a smaller, aging stockpile in the absence of nuclear testing, remain the same.

On a gradual path to a very small or zero stockpile, this PEIS evaluates reasonable approaches to stockpile management capability and capacity. At some point on this path, further downsizing of existing industrial plants or the alternative of consolidating manufacturing functions at stewardship sites would become more attractive as manufacturing capacity becomes a less important consideration. However, in the near term, the preferred alternative of downsizing the existing industrial plants would still be a reasonable action because the projected downsizing investment pays back within a few years through reduced operating expense; in addition, the downsizing actions are consistent with potential future decisions regarding plant closures. In regard to the proposed action of reestablishing pit manufacturing capability, DOE does not propose to establish higher manufacturing capacities than are inherent in the reestablishment of the basic manufacturing capability. In developing the criteria for reasonable stockpile management alternatives, DOE was careful not to propose the introduction of significant new types of environmental hazards to any prospective site. On a gradual path to a very small or zero stockpile, stockpile size alone would not change the purpose and need, proposed actions, and alternatives in this PEIS with regard to stockpile management capabilities and capacities.

To achieve eventual denuclearization, some commentors have asserted that DOE should adopt a passive curatorship approach to maintaining the declining nuclear weapons stockpile. The concept of curatorship is already being implemented at the existing sites in the form of knowledge preservation programs. While not necessary in an era of continuous development and production of new-design weapons and nuclear testing, knowledge preservation is now part of DOE's overall effort to maintain core competency in the weapons complex. However, as an inherently imperfect reconstruction, this effort can never ensure completeness of information nor relevance to future stockpile problems. More importantly, knowledge preservation does not address the fundamental issue of confidence in future technical judgments about issues that are yet to arise regarding the safety and performance of the stockpile. In highly technical matters, confidence arises from having appropriate data to support conclusions. In the absence of nuclear testing, the science-based approach to stockpile stewardship is focused on achieving the capability to acquire appropriate data.

From an environmental impact point of view, this PEIS displays the environmental impacts of each site's ongoing Program operations on an annual basis. The impacts of alternatives for proposed actions are displayed individually on the same basis. If one assumes that denuclearization leads to eventual site closure, then this PEIS, together with the Tritium Supply and Recycling PEIS, presents the environmental impacts of closing the four remaining industrial plants. While this PEIS does not directly consider the closure of the weapons laboratories and NTS, it is not at all clear what nuclear weapons capabilities the U.S. would retain even if it decided on a zero stockpile. However, the environmental impacts of the ongoing Program (No Action alternative) are essentially what would be phased out, with or without the proposed actions. DOE does not believe that speculative combinations of this data on speculative time lines provides any useful information for decisionmaking.

Restoration. The restorer's point of view is reflected in this PEIS to the extent that current national security policy requires DOE to maintain all the historical capabilities of the Program, including the capability for new-design weapons and nuclear testing. However, restoration is not a reasonable alternative for this PEIS because it requires a national security policy decision to reverse the constraints placed on the Program, namely, by resuming nuclear testing and new-design weapons production.

The environmental impacts of the restoration approach would be the same as those described in this PEIS to the extent that such a decision did not require manufacturing capacities higher than analyzed in this PEIS. In addition, this PEIS includes a brief description of the environmental impacts of nuclear testing (section 4.12 of Volume I); the Site-Wide EIS for NTS contains detailed information.

Remanufacturing. The remanufacturer's point of view is reflected in this PEIS by the fact that remanufacturing to specification will be attempted when possible and when appropriate to the problem being solved. With more than a half dozen different weapon types projected to remain in the stockpile, and with each weapon type containing thousands of parts, remanufacturing will undoubtedly occur for a significant number of repair and replacement activities. However, remanufacturing is not reasonable as a distinct exclusive alternative to the ongoing stockpile stewardship program or the proposed action of enhanced experimental capability for the technical reasons discussed below. In addition, it would not be a reasonable alternative because it does not fully support national security policies that require the conduct of a science-based stockpile stewardship and maintenance of the capability to design and produce new weapons.

Remanufacturing weapon components to their original specification, or maintaining weapons to their original design specifications, would superficially appear to be a reasonable approach to maintaining the safety and reliability of the stockpile in the absence of nuclear testing. Precise replication, however, is often not possible. Subtle changes in materials, processing, and fabrication techniques are an ever-present problem. In some cases, specialty materials and components become unavailable for commercial or environmental reasons. Implicit in the remanufacturing assumption is that the design blueprint, manufacturing process, and the materials used are specified in exact detail in every way. However, there is an unwritten element of "know how" that knowledgeable and experienced personnel contribute to any complicated manufacturing process (for this reason, controlling the acquisition of "know-how" is a major nuclear weapons nonproliferation objective). Materials and processes are not always specified in important ways because, at the time, they were not known to be important. The problem is illustrated by the following hypothetical example:

A material produced for a critical weld has a specification for a trace impurity; the manufacturing process consistently produced the material with a trace impurity less than the maximum allowed and the welds were satisfactory; the manufacturing process is changed for some reason, such as cost or environmental concerns; the material is now being produced with less trace impurity than before the process was changed; the material is still within specification; however, the welds are no longer satisfactory; it was unknown at the time that the higher level of the trace impurity was necessary to produce a satisfactory weld.

While remanufacturing sounds simple in principle, it is likely in fact to present complex issues of design, manufacturing process, and material variables. A simplified view of remanufacturing cannot serve as a "stand alone" manufacturing approach, let alone an alternative approach to enhanced stewardship capability. In the absence of underground nuclear testing, nuclear components (pits and secondaries) cannot be functionally tested. Stewardship capabilities provide the analytical tools (experimental and computational) to assess the significance of a problem observed during surveillance and to decide if the problem should be fixed; and if fixed, to certify that the fix will work (section S.2.3). In the past, the decision to fix or not fix an observed problem could be made with nuclear testing (section S.2.2). Stockpile stewardship strategies focus on the basic material science and the enhanced experimental and computational tools necessary to better predict age-related defects and to make sound technical judgments on nuclear safety and performance in the absence of nuclear testing.

The DARHT EIS (DOE/EIS-0228, section 2.3.2) provides an additional discussion of the limitations of a remanufacturing-to-specification approach. It discusses, as an example, the actions taken to evaluate and resolve unanticipated deterioration of HE in the now-retired W68 warhead for a submarine-launched ballistic missile. In that case it was necessary to replace the HE with a more chemically stable formulation. In addition, some other materials were no longer commercially available, requiring changes in the rebuilt weapons. Nuclear testing was ultimately used to verify that the necessary changes were acceptable. DOE does not consider it feasible to maintain all potentially obsolescent commercial sources and processes used for materials in existing weapons; aging would still occur in stored reserves of such materials.

With regard to stockpile management, remanufacturing without enhanced stewardship capability would also have notable drawbacks. DOE plans to maintain the capability to produce secondaries, and proposes to reestablish the capability to produce pits, by producing small quantities (10s) of each annually to maintain capability. This capacity should be sufficient to replace components attrited from the stockpile by surveillance testing. Remanufacturing these components, without the enhanced stewardship analytical capability to determine if and when replacement is necessary, is likely to require higher levels of production than DOE believes necessary to maintain production capability. Also, remanufacturing a nuclear component to the original specifications will not prevent age-related problems related to those specifications from recurring. Since these components use plutonium and uranium, radiation exposure to personnel and generation of radioactive waste would also be higher than necessary. If repeated remanufacturing were required, further unnecessary risks would result from additional weapon A/D operations and additional transport of nuclear components between sites.

From an environmental impact point of view, the remanufacturing concept would have greater impacts for the proposed action of reestablishing pit capability because DOE proposes to use a cleaner, less waste-generating process than was used at the Rocky Flats Plant. All other environmental impacts would not be distinguishable from those described in this PEIS because existing manufacturing processes form the Program baseline.

Maintenance. The maintainer's point of view is reflected in this PEIS to the extent that it is consistent with the No Action alternative. Under this approach, weapons maintenance would be the focus of stockpile stewardship. This approach would rely on enhanced surveillance and dual revalidation, whereby the weapons laboratories would conduct independent technical examinations of weapons to validate their safety and reliability. Any problems that arose would be solved through either remanufacture or "fixes" proposed by the weapons laboratories. These attributes are all part of the ongoing Program that will continue into the future. The principal difference between the Program as presented in this PEIS and this point of view is differing judgment on how much enhanced experimental capability would be needed to assess and certify a safe and reliable stockpile over the long term. The maintainers believe that less (or no) additional experimental capability would be required if DOE placed more emphasis on enhanced surveillance and dual revalidation.

DOE believes that this approach would not provide a sufficient basis for assessing and certifying the safety and reliability of the stockpile. Although enhanced surveillance will play an important role in the future of the Program, it serves a limited purpose. Surveillance activities identify stockpile problems through the examination and analysis of weapons sampled from the stockpile. An enhanced surveillance program would serve to identify problems with greater confidence and increased warning time. However, it would not provide a sole basis for assessing the significance of the problem or determining its solution. The ability of the laboratories to validate that the problem has been corrected, in the absence of nuclear testing, depends on their experimental and computational capabilities. In DOE's judgment, as explained in section S.2.3, those capabilities are inadequate. Therefore, to the extent that maintainance would not provide sufficient enhanced experimental capability, it is not a reasonable alternative.

From an environmental impact point of view, the maintenance concept is not distinguishable from the impacts of the No Action alternative for stockpile stewardship and the proposed actions for stockpile management.

S.4 PREFERRED ALTERNATIVE

CEQ regulations require an agency to identify its preferred alternative(s) in the Final EIS (40 CFR 1502.14[e]). The preferred alternative is the alternative that the agency believes would best fulfill its statutory mission, considering environmental, economic, technical, and other factors. This PEIS provides information on the environmental impacts. Cost, schedule, and technical analyses have also been prepared and are presented in the *Analysis of Stockpile Management Alternatives* report and the *Stockpile Management Preferred Alternatives Report*, which are available in the appropriate DOE Public Reading Rooms for public review.

DOE has identified the following preferred alternatives of the Stockpile Stewardship and Management Program:

Stockpile Stewardship:

- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:

- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL
- A/D—downsize at Pantex
- HE Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) HEU strategic reserve storage at Y-12 and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the Storage and Disposition PEIS. Decisions on strategic reserve storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the Stockpile Stewardship and Management PEIS and the Storage and Disposition PEIS are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

The preferred PEIS alternatives do not represent decisions by DOE. Rather, they reflect DOE's current preferences based on existing information. The ROD, when issued, will describe DOE's decisions for the Stockpile Stewardship and Management PEIS proposed actions.

ABSTRACT: In response to the end of the Cold War and changes in the world's political regimes, the United States is not producing new-design nuclear weapons. Instead, the emphasis of the U.S. nuclear weapons program is on reducing the size of the Nation's nuclear stockpile by dismantling existing nuclear weapons. The Department of Energy (DOE) has been directed by the President and Congress to maintain the safety and reliability of the reduced nuclear weapons stockpile in the absence of underground nuclear testing. In order to fulfill that responsibility, DOE has developed a Stockpile Stewardship and Management Program to provide a single highly integrated technical program for maintaining the continued safety and reliability of the nuclear stockpile. The Stockpile Stewardship and Management PEIS describes and analyzes alternative ways to implement the proposed actions for the Stockpile Stewardship and Management Program.

Stockpile stewardship refers to activities associated with research, design, development and testing of nuclear weapons and the assessment and certification of the safety and reliability. The stockpile stewardship portion of the PEIS evaluates the potential impacts of three proposed facilities: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. The stockpile stewardship alternatives involving these facilities could affect four sites: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and Nevada Test Site (NTS).

Stockpile management refers to activities associated with the production, maintenance, surveillance, refurbishment, and dismantlement of the nuclear weapons stockpile. The stockpile management portion of this PEIS evaluates the potential impacts of carrying out stockpile management alternatives at eight sites: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. The stockpile management alternatives are assessed for nuclear weapons assembly/disassembly and for fabricating pits, secondaries and cases, high explosives, and nonnuclear components.

The Stockpile Stewardship and Management PEIS also evaluates the No Action alternative of relying on existing facilities and continuing the missions at current sites to achieve both the stockpile stewardship and management missions. The No Action alternative assesses the environmental impacts of the on-going Stockpile Stewardship and Management Program and provides a baseline against which alternatives can be evaluated.

DOE has identified the following preferred alternative for the Stockpile Stewardship and Management Program:

Stockpile Stewardship:
- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:
- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL

- Assembly/Disassembly—downsize at Pantex
- High Explosives Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) highly enriched uranium strategic reserve storage at Y-12; and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS*. Decisions on strategic storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the *Stockpile Stewardship and Management Final PEIS* and the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

Evaluation of impacts on land resources, site infrastructure, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, socioeconomics, waste management, environmental justice, as well as radiological and hazardous chemical impacts during normal operation and accidents to workers and the public are included in the assessment. The PEIS presents unclassified information only. A classified appendix has also been prepared to support the PEIS.

PUBLIC COMMENTS: The public comment period on the Draft PEIS was conducted from March 8, 1996 to May 7, 1996. During the comment period, public hearings were held in Los Alamos, NM; Albuquerque, NM; Las Vegas, NV; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. The Draft PEIS was made available through mailings, requests to DOE's Office of Reconfiguration, and at DOE Public Reading Rooms. In preparing the Final PEIS, DOE considered comments received by mail, fax, handed in at hearings, transcribed from messages recorded by telephone, and those transcribed via Internet. In addition, comments and concerns identified during discussions at public hearings were considered.

In response to comments submitted after issuance of the Draft PEIS and due to additional technical details not available at the time of issuance of the Draft, Volumes I, II, and III of the Final PEIS contain revisions and changes. The revisions and changes made since the issuance of the Draft document are indicated by a double underline for minor word changes or by a sidebar in the margin for paragraph or larger changes. In addition, Volume I and each appendix in Volume III provide a unique reference list to enable the reader to further review and research selected topics. Volume IV (Comment Response Document) of the PEIS contains the comments received during public review of the Draft PEIS and the DOE responses to those comments. DOE has public reading rooms near each affected site and in Washington, DC where these referenced documents may be reviewed or obtained for review.

CHAPTER 1

Chapter 1

CHAPTER 1: INTRODUCTION

Chapter 1 begins with an overview of the Stockpile Stewardship and Management Program and the Department of Energy's roles and responsibilities. This chapter also includes a discussion of the background of the Program, a brief description of the organization of the document, and the Department of Energy's National Environmental Policy Act *of 1969 strategy for stockpile stewardship and management. Chapter 1 concludes with a discussion of related* National Environmental Policy Act *actions and other programmatic, project-specific, and site-wide reviews that are currently being prepared.*

1.1 OVERVIEW

The Department of Energy (DOE) is the Federal agency responsible for providing the Nation with nuclear weapons and ensuring that those weapons remain safe and reliable. This programmatic environmental impact statement (PEIS) analyzes the potential consequences to the environment if certain changes to the Nuclear Weapons Complex (Complex) are implemented to support DOE's Stockpile Stewardship and Management Program.

Stockpile stewardship and stockpile management describe DOE's management of the nuclear weapons program. While these terms are not new, DOE has recently redefined them in light of its current roles and responsibilities. Stockpile stewardship comprises the activities associated with research, design, development, and testing of nuclear weapons, and the assessment and certification of their safety and reliability. These activities have been performed at the three DOE weapons laboratories and the Nevada Test Site (NTS). Stockpile management comprises operations associated with producing, maintaining, refurbishing, surveilling, and dismantling the nuclear weapons stockpile. These activities have been performed at the DOE nuclear weapons industrial facilities.

Since the inception of nuclear weapons in the 1940s, DOE and its predecessor agencies have been responsible for stewardship and management of the Nation's stockpile. In response to the end of the Cold War and changes in the world's political regimes, the emphasis of the U.S. nuclear weapons program has shifted dramatically over the past few years from developing and producing new weapons to dismantlement and maintenance of a smaller, enduring stockpile. Accordingly, the nuclear weapons stockpile is being significantly reduced, the United States is no longer manufacturing new-design nuclear weapons, and DOE has closed or consolidated some of its former weapons industrial facilities. Additionally, in 1992 the United States declared a moratorium on underground nuclear testing, and in 1995 President Clinton extended the moratorium and decided to pursue a "zero yield" Comprehensive Test Ban Treaty (CTBT). Even with these significant changes, DOE's responsibilities for the nuclear weapons stockpile continue, and the President and Congress have directed DOE to continue to maintain the safety and reliability of the enduring nuclear weapons stockpile.

In response to direction from the President and Congress, DOE has developed its Stockpile Stewardship and Management Program to provide a single, highly integrated technical program for maintaining the continued safety and reliability of the nuclear weapons stockpile. It has evolved from predecessor programs that served this mission over previous decades. With no underground nuclear testing, and no new-design nuclear weapons production, DOE expects existing weapons to remain in the stockpile well into the next century. This means that the weapons will age beyond original expectations and an alternative to underground nuclear testing must be developed to verify the safety and reliability of weapons. To meet these new challenges, DOE's science-based Stockpile Stewardship and Management Program has been developed to increase understanding of the basic phenomena associated with nuclear weapons, to provide better predictive understanding of the safety and reliability of weapons, and to ensure a strong scientific and technical basis for future U.S. nuclear weapons policy objectives.

The size and composition of the U.S. nuclear weapons stockpile is determined annually by the President. The Department of Defense prepares the Nuclear Weapon Stockpile Plan (NWSP) based on military requirements and coordinates the development of the plan with DOE concerning its ability to support the plan. The NWSP, which is classified, covers the current year and a 5-year planning period. It specifies the types and quantities of weapons required and sets limits on the size and nature of stockpile changes that can be made without additional approval by the President. The Secretaries of Defense and Energy jointly sign the Nuclear Weapon Stockpile Memorandum (NWSM), which includes the NWSP and a long-range planning assessment. As such, the NWSM is the basis for all DOE stockpile support planning. Figure 1.1–1 depicts the NWSM process.

Chapter 2 discusses the relevant factors, such as treaties, that shape the NWSM. Also explained is the fact that potential variances in stockpile size, such as a Strategic Arms Reduction Talks (START) I Treaty-sized stockpile versus a START II protocol-sized stockpile, affect only the issue of manufacturing capacity required for the foreseeable future. National security policies in the post-Cold War era require that all the historical capabilities of the weapons laboratories, industrial plants, and NTS be maintained. Capability is the practical ability to perform a basic function or activity. Stockpile stewardship and management capabilities are independent of foreseeable future stockpile sizes. Stockpile management manufacturing capacities are examined in this PEIS, including those required to support a hypothetical low case stockpile size below START II. This was done to examine the sensitivity of potential decisions to transfer manufacturing activities to the weapons laboratories and NTS versus downsizing the industrial plants in place.

DOE must maintain a Complex with sufficient capability and capacity to meet current and future weapons requirements. For those activities associated with the ongoing stockpile stewardship program, DOE proposes to add enhanced capabilities to existing stockpile stewardship facilities to fulfill requirements. For those activities associated with the ongoing stockpile management program, DOE does not propose to construct any major new weapons industrial facilities. Rather, DOE proposes to "right-size" existing facilities or consolidate them to fulfill expected requirements for manufacture of repair or replacement components for an aging U.S. stockpile.

This *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* addresses potential changes to the future missions of the three weapons laboratories, the four weapons industrial plants, and NTS. A No Action alternative is also described and analyzed. Figure 1.1–2 shows the locations of the eight DOE sites comprising the current Complex.

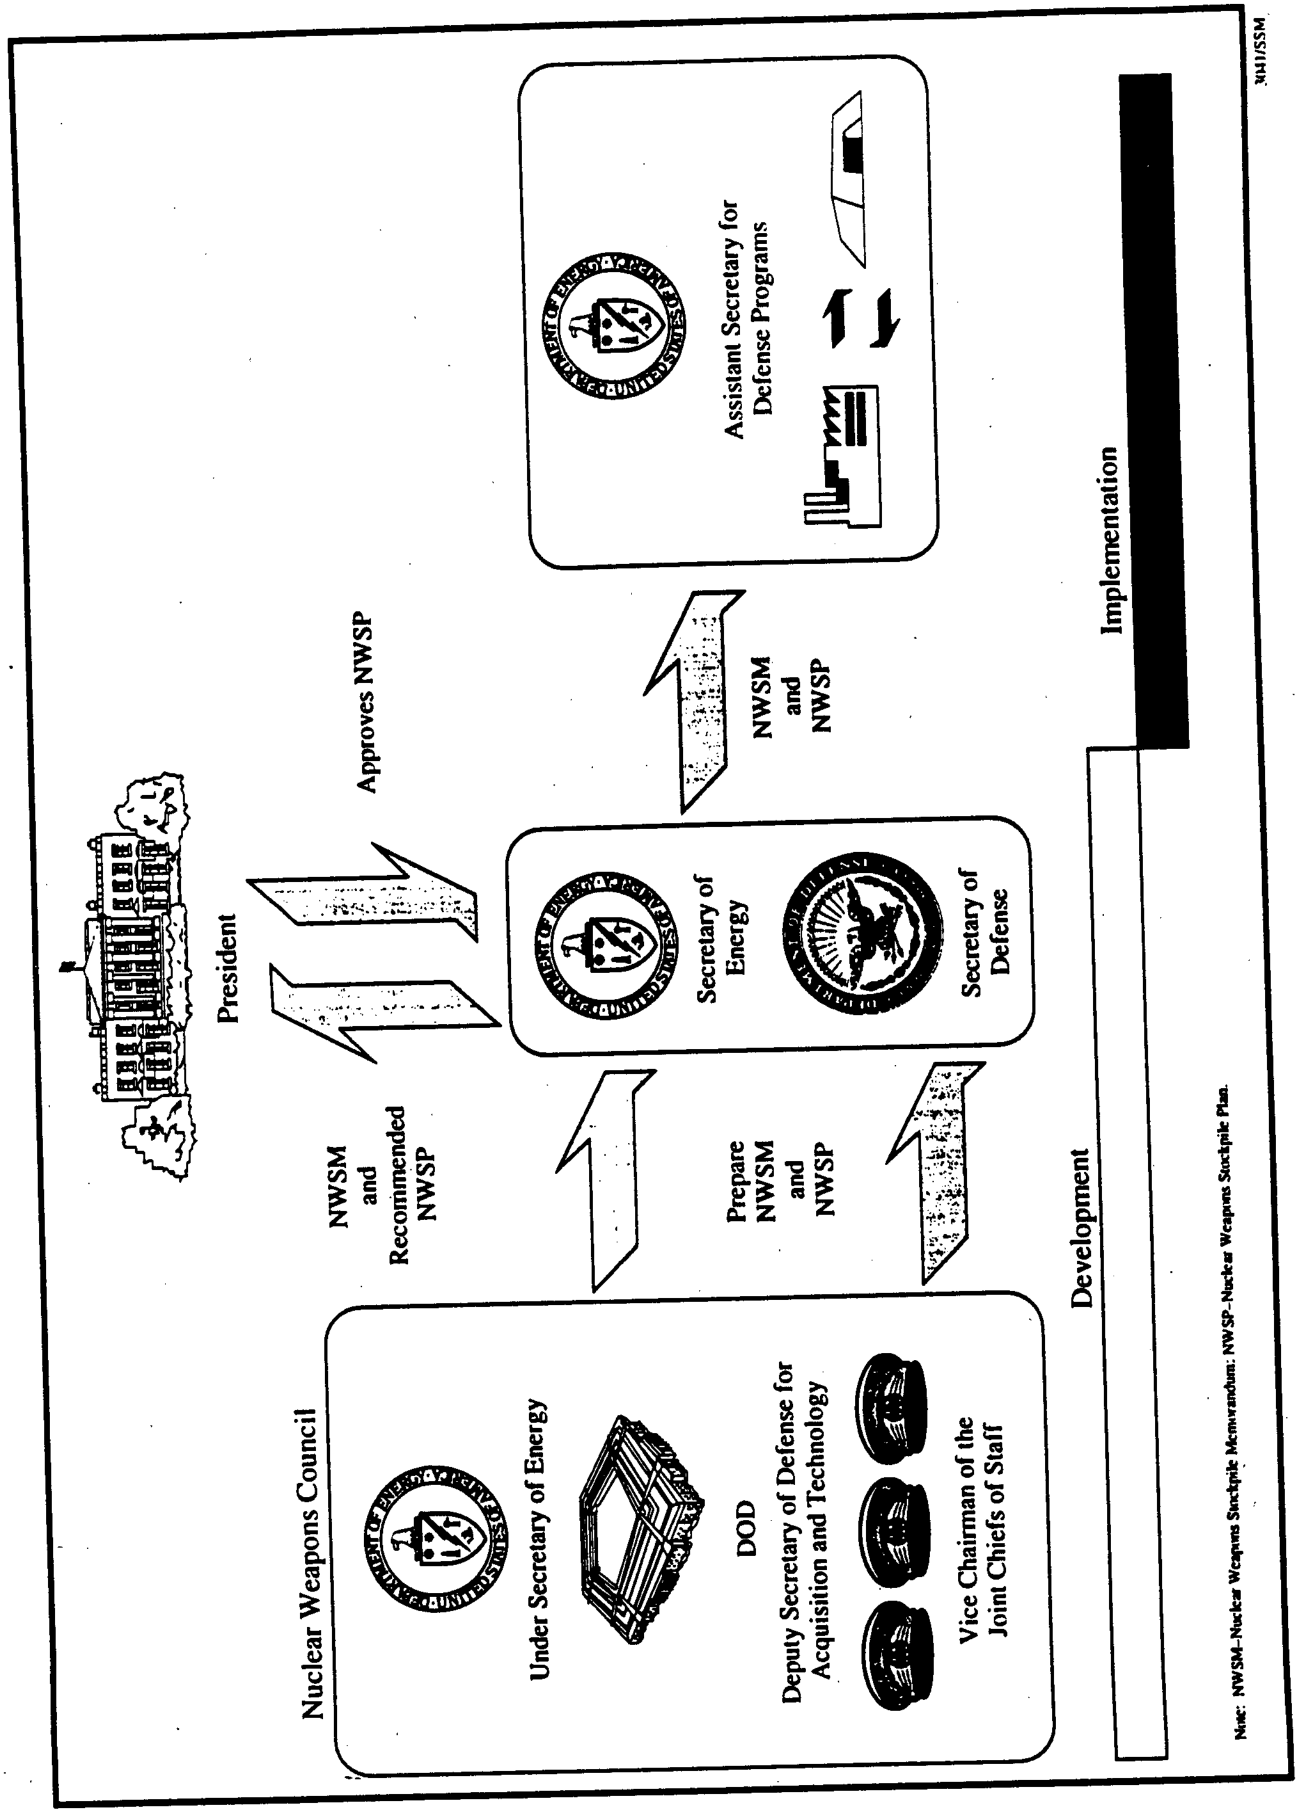
To estimate the potential environmental impacts from modifying/constructing and operating the facilities proposed for stockpile management, DOE assumes that facilities would be sized and operated to support a base case stockpile size consistent with the START II protocol. This PEIS also discusses impacts that would be expected for supporting a larger stockpile based on START I Treaty levels, and a hypothetical stockpile smaller than the START II protocol.

With regard to stockpile management facilities, potential environmental impacts from the base case are analyzed quantitatively in the greatest detail, while impacts from the high and low cases are discussed qualitatively. The facilities proposed for stockpile stewardship are independent of projected stockpile size.

1.2 ALTERNATIVES ANALYZED IN THE *PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT FOR STOCKPILE STEWARDSHIP AND MANAGEMENT*

The alternatives analyzed in this PEIS are described in detail in chapter 3 and summarized in this section. Alternatives are analyzed for both stockpile stewardship and stockpile management.

The stockpile stewardship portion of this PEIS evaluates the potential environmental impacts of the proposed actions and the reasonable alternatives for carrying out the stockpile stewardship functions. As described in section 3.3, the three independently justified proposed facilities include: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. Four sites (figure 1.1–2) are potentially affected by the stockpile stewardship alternatives: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and NTS (includes NLVF). This PEIS also assesses the No



Note: NWSM–Nuclear Weapons Stockpile Memorandum; NWSP–Nuclear Weapons Stockpile Plan.

FIGURE 1.1-1.—*Nuclear Weapons Stockpile Memorandum Process.*

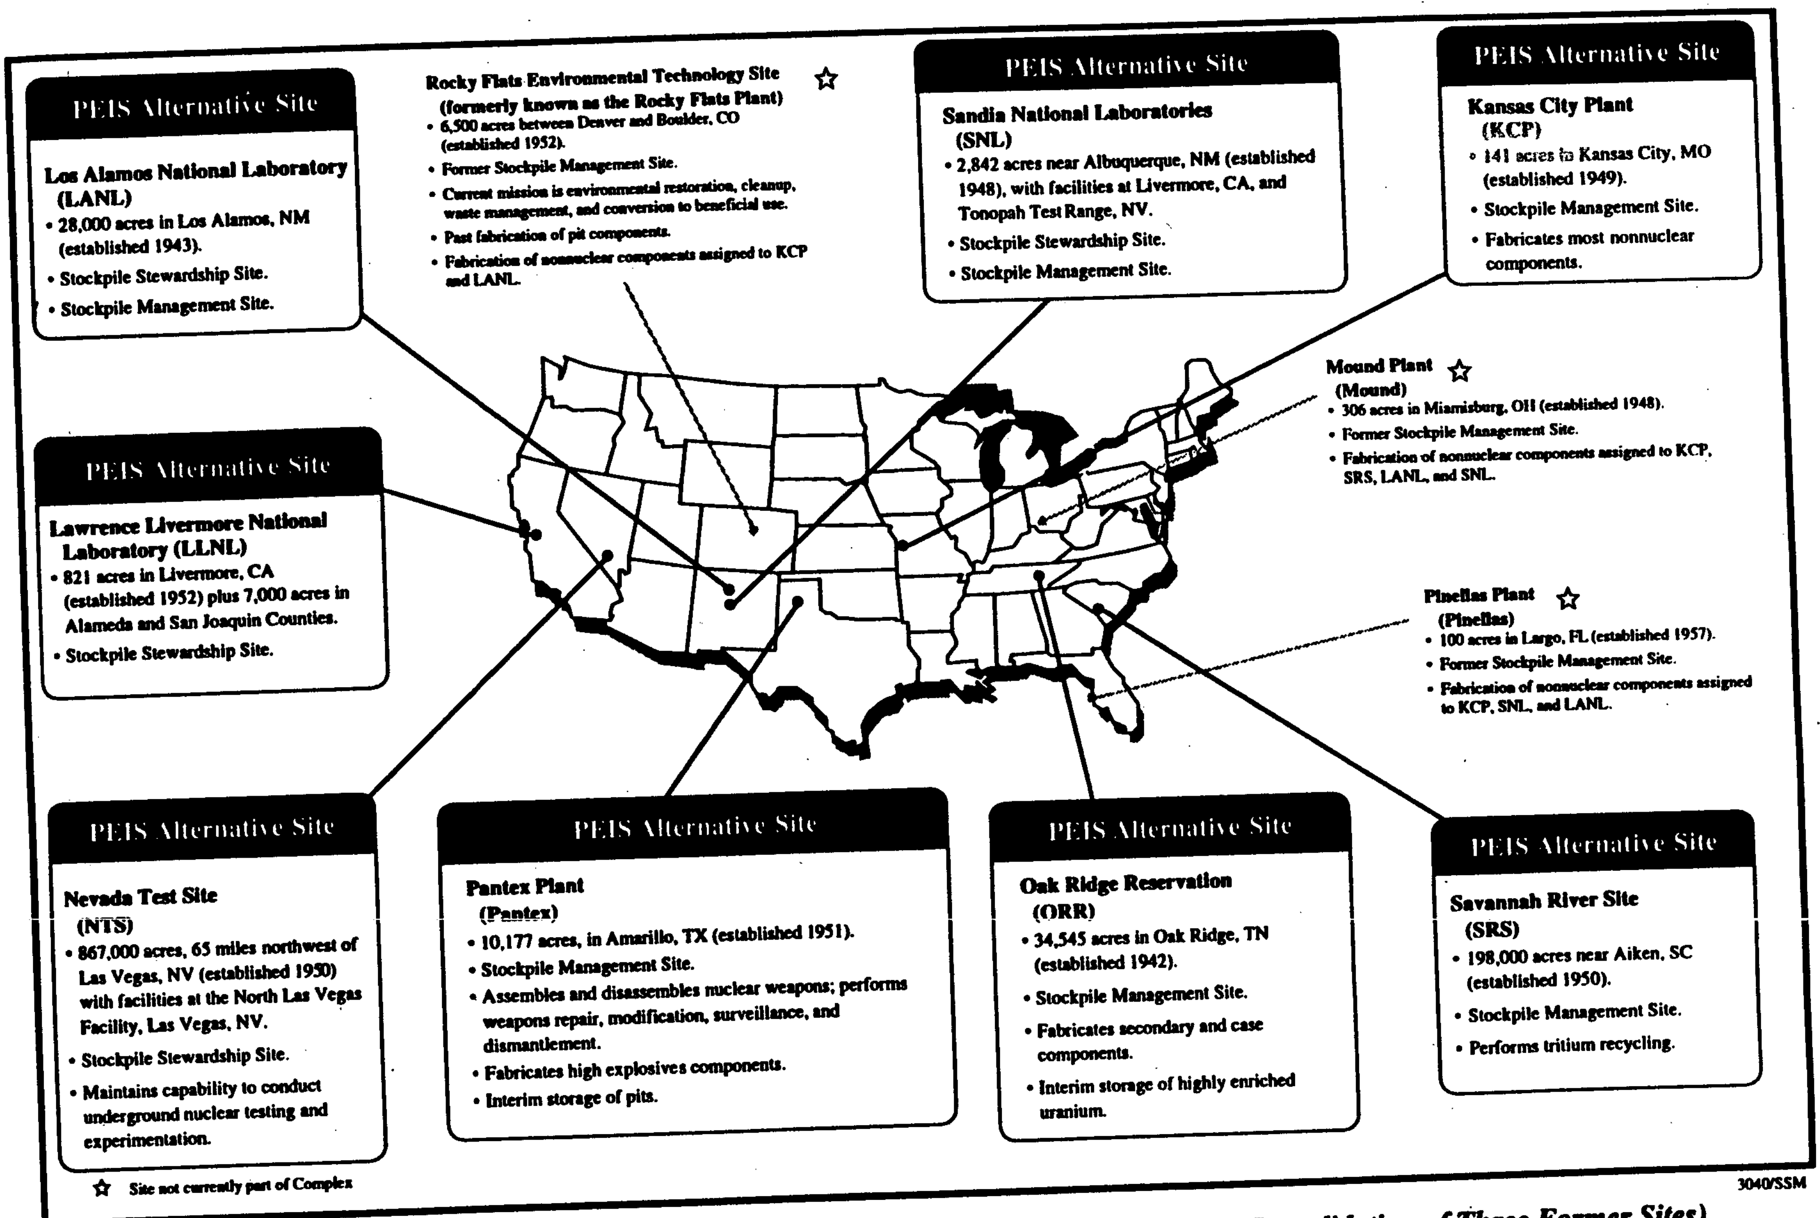


FIGURE 1.1–2.—*Current Stockpile Stewardship and Management Sites (Includes Recent Consolidation of Three Former Sites).*

Action alternative of relying on existing experimental facilities and continuing the missions at these four sites to fulfill the stockpile stewardship mission.

The science-based stockpile stewardship program is expected to continuously evolve as better information becomes available and technological advancements occur. Additional experimental facilities, such as the Advanced Hydrotest Facility, the High Explosives Pulsed Power Facility, the Advanced Radiation Source, and the Jupiter Facility, are considered to be next generation facilities (see section 3.3.4) that may be required in the future to support stockpile stewardship objectives. However, these facilities are not proposed actions in this PEIS because they have not reached the stage of development and definition that is necessary for evaluation and decisionmaking.

The stockpile management portion of this PEIS evaluates the potential environmental impacts of the reasonable alternatives for carrying out the stockpile management functions. As described in section 3.4, alternatives are assessed for nuclear weapons assembly/disassembly (A/D) and for fabricating pit, secondary and case, high explosives (HE), and nonnuclear components. Eight sites (figure 1.1–2) are potentially affected: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. This PEIS also assesses the No Action alternative of relying on existing facilities and continuing the missions at the current sites to fulfill the stockpile management mission.

1.3 BACKGROUND

To aid the reader's understanding of this PEIS, background information on the evolution of this PEIS and an unclassified description of a nuclear weapon follow.

1.3.1 Evolution of the *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management*

Stockpile stewardship and management responsibilities have been ongoing for decades and the Program now reflects the cumulative effects of relatively recent U.S. national security policy changes. This PEIS experienced three general stages of evolution.

The first stage of evolution began in January 1991, when the Secretary of Energy announced that DOE would prepare a PEIS examining alternatives for reconfiguring the Complex. The framework for the Reconfiguration PEIS was described in the January 1991 *Nuclear Weapons Complex Reconfiguration Study* (DOE/DP–0083), a detailed examination of alternatives for the future Complex. This Reconfiguration Study contemplated large, stand-alone replacement facilities for the plutonium fabrication capability of the Rocky Flats Plant, as well as possible replacement and relocation of other Complex missions.

During the 1992 through 1994 timeframe, the second stage of the evolution reflected changes in DOE's thinking due to the reduction in weapons resulting from the end of the Cold War, unilateral stockpile reductions, and the START II protocol. Because of the planned significant stockpile reductions, the scope of the Reconfiguration Study changed to reflect a smaller and more integrated Complex than previously envisioned. Additionally, DOE placed increased importance on the stewardship of special nuclear materials that were determined to be in excess of the Nation's weapons needs.

DOE concluded in October 1994 that the framework described in the Reconfiguration Study no longer fit current circumstances or supported any realistic proposal for reconfiguring the Complex. Contributing factors to that conclusion included public comments from Reconfiguration Study scoping meetings, the fact that production of new-design nuclear weapons was not required for the foreseeable future, and DOE's decision to prepare a separate *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement* (DOE/EIS–0229-D, draft published in February 1996).

As a result of these changed circumstances, the third stage evolved, whereby DOE separated the previously planned Reconfiguration PEIS into two new PEISs: the *Programmatic Environmental Impact Statement for Tritium Supply and Recycling* and this Stockpile Stewardship and Management PEIS. As explained in section 1.6, the Tritium Supply and Recycling PEIS has been completed and this Stockpile Stewardship and Management PEIS has been revised to better reflect current and expected Program requirements.

1.3.2 Nuclear Weapons

A general understanding of nuclear weapons, including the components that make up a weapon and the physical processes involved, helps one understand the scope of the Stockpile Stewardship and Management PEIS and what is to be accomplished by the Program. Figure 1.3.2–1 presents a simplified diagram of a modern nuclear weapon. An actual nuclear weapon produced in the United States is much more complicated, consisting of many thousands of parts.

The nuclear weapon primary is composed of a central core called a pit, which is usually made of plutonium-239 and/or highly enriched uranium (HEU). This is surrounded by a layer of HE, which when detonated, compresses the pit, initiating a nuclear reaction. This reaction is generally thought of as the nuclear fission "trigger," which activates the secondary assembly component to produce a thermonuclear fusion reaction. The remaining nonnuclear components consist of everything from arming and firing systems to batteries and parachutes. The production and assembly of many of these components is accomplished at dedicated industrial facilities. The A/D of nuclear weapons is done only at Pantex.

1.4 Organization of this Programmatic Environmental Impact Statement

This PEIS consists of four volumes. Volume I contains the main text; Volume II contains technical appendixes that support the analyses in Volume I and additional project information; and Volume III contains the project-specific environmental analyses for the proposed NIF, CFF, and Atlas Facility. Volume IV contains the comments received on the Draft PEIS during the public review period and the DOE responses. The Summary is a separate publication.

Volume I contains 10 chapters, which include the following information:

Chapter 1—Introduction. Stockpile Stewardship and Management Program background and the environmental analysis process.

Chapter 2—Purpose and Need. Reasons why DOE needs to take action and the objectives DOE proposes to achieve.

Chapter 3—Proposed Action and Alternatives. How DOE proposes to meet the specified need and achieve the objectives. This chapter also includes a summary comparison of the potential environmental impacts of the PEIS alternatives.

Chapter 4—Affected Environment and Environmental Impacts. Aspects of the environment (i.e., natural, built, and social) that might be affected by the PEIS alternatives and analyses of the potential impacts on the environment. Impacts are compared to the projected environmental conditions that would be expected to support the base case if no action were taken (the No Action alternative).

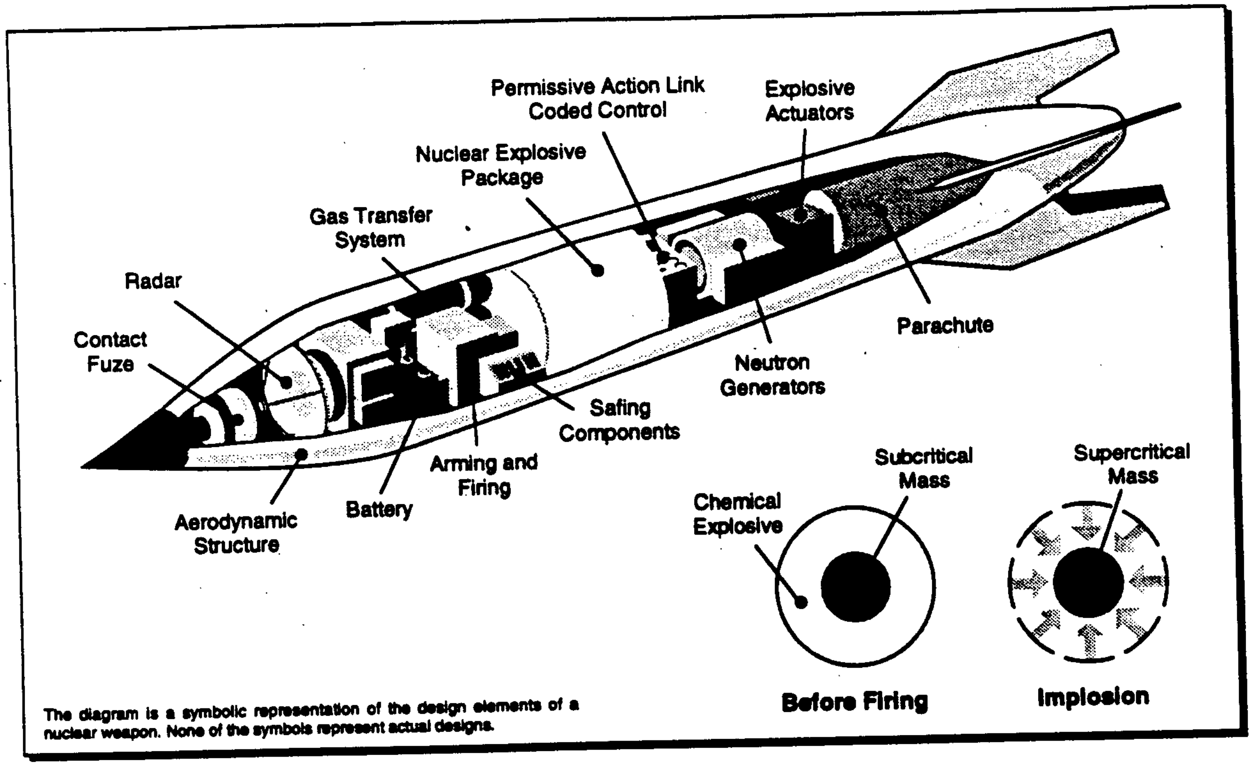
Chapter 5—Regulatory Requirements. Environmental, safety, and health regulations that would apply to the PEIS alternatives and agencies consulted for their expertise.

Chapters 6 through 10. A list of references; a list of preparers; a list of agencies, organizations, and persons to whom copies of this PEIS were sent; a glossary; and an index.

Volume II contains eight appendixes of technical information supporting the environmental analyses presented in Volume I. These appendixes contain the following information: Stockpile Stewardship and Management Program facilities; air quality; threatened, endangered, and special status species; socioeconomics; human health; facility accidents; intersite transportation; and environmental management.

Volume III contains three appendixes that comprise the project-specific environmental analyses for the NIF, CFF, and Atlas Facility proposed actions.

Volume IV (Comment Response Document) contains a description of the public hearing process, information on the document's organization and instructions for its use, a brief summary of changes to the Draft PEIS, and all comments received and DOE responses.



Nuclear explosions are produced by initiating and sustaining nuclear chain reactions in highly compressed material which can undergo both fission and fusion reactions. Modern strategic, and most tactical, nuclear weapons use a nuclear explosive package with two assemblies: the primary assembly, which is used as the initial source of energy, and the secondary assembly, which provides additional explosive energy release. The primary assembly contains a central core, called the "pit", which is surrounded by a layer of high explosives. The "pit" is typically composed of plutonium–239 and/or highly enriched uranium (HEU), and other materials. HEU contains large fractions of the isotope uranium–235.

Primary Detonation

The primary nuclear explosion is initiated by detonating the layer of chemical high explosive that surrounds the "pit" which in turn drives the pit material into a compressed mass at the center of the primary assembly. This implosion process is illustrated in the inset of the diagram.

Boosting

In order to achieve higher explosive yields from primaries with relatively small quantities of pit material, a technique called "boosting" is used. Boosting is accomplished by injecting a mixture of tritium (T) and deuterium (D) gas into the pit. The deuterium and tritium are stored in reservoirs until the gas transfer system is initiated. The implosion of the pit along with the onset of the fissioning process heats the D-T mixture to the point that the D-T atoms undergo fusion. The fusion reaction produces large quantities of very high energy neutrons which flow through the compressed pit material and produce additional fission reactions.

Secondary Activation

The energy released by the primary explosion activates the secondary assembly. The secondary assembly is composed of lithium deuteride and other materials. As the secondary implodes, the lithium, in the isotopic form lithium–6, is converted to tritium by neutron interactions, and the tritium product in turn undergoes fusion with the deuterium to create the thermonuclear explosion.

Nonnuclear Components

Nonnuclear components include contact fuzes, radar components, aerodynamic structures, arming and firing systems, a gas transfer system, permissive action link coded controls, neutron generators, explosive actuators, safing components, batteries, and parachutes.

1.5 NATIONAL ENVIRONMENTAL POLICY ACT STRATEGY FOR STOCKPILE STEWARDSHIP AND MANAGEMENT

This PEIS has been prepared in accordance with Section 102(2)(c) of the *National Environmental Policy Act* (NEPA) of 1969, as amended (42 U.S.C. 4321 et seq.), and implemented by regulations promulgated by the Council on Environmental Quality (CEQ) (40 CFR 1500-1508) and DOE regulations (10 CFR 1021). Under NEPA, Federal agencies, such as DOE, that propose major actions that could significantly affect the quality of the human environment are required to prepare an environmental impact statement (EIS) to ensure that environmental information is available to public officials and citizens before decisions are made and before actions are taken. For broad actions, such as the Stockpile Stewardship and Management Program, a PEIS is prepared.

DOE's NEPA compliance strategy for the Stockpile Stewardship and Management Program consists of two phases. The first phase includes the Stockpile Stewardship and Management PEIS and subsequent Record(s) of Decision (ROD). Decisions will be based on relevant factors including economic and technical considerations, DOE statutory mission requirements, policy considerations, and environmental impacts. In addition to the analyses in this PEIS, engineering studies, cost, schedule, and technical feasibility analyses will be considered in the ROD. The ROD is expected to identify the effects of U.S. national security policy changes on Program missions and determine the configuration (facility locations) necessary to accomplish the Program missions.

During the second phase of the NEPA strategy, which would follow this PEIS ROD, DOE would prepare any necessary project-specific NEPA documents to implement any programmatic decision. However, as explained below, this PEIS also includes project-specific environmental analyses for the experimental facilities proposed for stockpile stewardship.

For the three facilities in the proposed action for stockpile stewardship—NIF, CFF, and the Atlas Facility—the Stockpile Stewardship and Management PEIS is intended to include sufficient project-specific analyses to complete NEPA requirements for siting, construction, and operation, and thus, satisfy both phases of the NEPA compliance strategy. This PEIS supports the programmatic decisions on whether to proceed with the facility and, if so, where to site the facility. The project-specific analysis describes the detailed construction and operational impacts for each facility at the alternate sites. Each proposed facility's project-specific analysis can be found in Volume III of this PEIS.

1.6 RELATED RECENTLY COMPLETED *NATIONAL ENVIRONMENTAL POLICY ACT* ACTIONS

Two other actions that DOE has already evaluated in separate EISs, in accordance with CEQ regulations for interim actions (40 CFR 1506.1), are within the scope of the Stockpile Stewardship and Management PEIS. These are the Tritium Supply and Recycling PEIS and the *Dual Axis Radiographic Hydrodynamic Test* (DARHT) *Facility Environmental Impact Statement*. These two actions, and their relationship to the Stockpile Stewardship and Management PEIS, are described below.

1.6.1 *Programmatic Environmental Impact Statement for Tritium Supply and Recycling*

The Tritium Supply and Recycling PEIS evaluated the potential environmental impacts associated with alternatives for siting, constructing, and operating tritium supply and recycling facilities. The purpose of the Tritium Supply and Recycling Program is to provide long-term, assured tritium supply and recycling to support the Nation's nuclear weapons stockpile. The Tritium Supply and Recycling Draft PEIS (DOE/EIS–0161) was issued in March 1995 and was followed by public hearings in April 1995. A Final PEIS was issued in October 1995, followed by the ROD, published in the *Federal Register* (60 FR 63878), on December 12, 1995.

In the ROD, DOE announced that it will embark on a dual track strategy for acquiring a new tritium production capability that involves the use of existing commercial light water reactors via the purchase of a reactor or purchase of irradiation services (with the option to purchase the reactor), and the development of a linear accelerator. DOE will seek to fully prove the feasibility of both approaches over the next 3 years, then implement the most promising approach, while completing the design and necessary procedures (e.g., regulatory approval) for the other path to allow it to serve as a backup to the preferred path. If an accelerator is built, it will be located at SRS.

Tritium, a radioactive gas that decays at a rate of more than 5 percent per year, is a necessary component of every nuclear weapon in the existing stockpile and must be replenished periodically in order for the weapons to operate as designed. No new tritium has been produced since 1988, when the last of the DOE's tritium production reactors at SRS was shut down. Currently, tritium recycled from weapons retired from the stockpile is used to meet stockpile requirements. However, based on a START II protocol stockpile size, even with tritium recycling, new tritium will be needed by 2011. Because it could take up to 15 years for a tritium source, once selected, to begin producing tritium, it was necessary for DOE to make a decision on tritium supply in advance of this Stockpile Stewardship and Management PEIS. The decision resulting from the Tritium Supply and Recycling PEIS is accounted for in the No Action alternative of this PEIS.

1.6.2 *Dual Axis Radiographic Hydrodynamic Test Facility Environmental Impact Statement*

The DARHT Facility EIS analyzed the environmental consequences of alternative ways to accomplish enhanced high-resolution radiography for the purposes of performing hydrodynamic tests and dynamic experiments. These tests are used to obtain diagnostic information on the behavior of nuclear weapons primaries and to evaluate the effects of aging on nuclear weapons. The DARHT Facility's construction was about 34 percent complete when construction was halted under a U.S. District Court preliminary injunction issued on January 27, 1995, pending completion of the DARHT Facility EIS and issuance of the ROD. The DARHT Facility EIS evaluated the potential environmental impacts of six alternatives; the preferred approach entailed completing and operating the proposed DARHT Facility at LANL and implementing a phased enhanced containment strategy for testing at the DARHT Facility, so that most tests would be conducted inside steel vessels. The DARHT Facility Draft EIS (DOE/EIS-0228) was issued in May 1995 and was followed by public hearings in May and June 1995. A Final PEIS was issued in August 1995, followed by the ROD, published in the *Federal Register* (60 FR 53588) on October 16, 1995.

In the ROD, DOE announced that it will complete and operate the DARHT Facility at LANL while implementing a program to conduct most tests inside steel vessels, with containment to be phased in over 10 years. Following the ROD, DOE filed a motion for dissolution of the injunction. On April 16, 1996, the U.S. District Court concluded that the purpose of the injunction has been satisfied, and therefore lifted the injunction and dismissed the case.

DOE will rely on hydrodynamic testing in the absence of underground nuclear testing to ensure the stockpile's safety and reliability. Under any course of action analyzed in this Stockpile Stewardship and Management PEIS, DOE will still need to continue hydrodynamic testing and acquire near-term enhanced radiographic capability such as that provided by the DARHT Facility. DOE determined that implementing the DARHT Facility ROD will not prejudice any decisions in the Stockpile Stewardship and Management Program. The impacts of the DARHT Facility for each resource area are addressed in the No Action impact discussions for LANL in section 4.6.3.

1.7 OTHER *NATIONAL ENVIRONMENTAL POLICY ACT* REVIEWS

In addition to the two interim actions identified above, DOE is currently preparing other programmatic, project-specific, and site-wide NEPA documents. These documents, and their relationship to the Stockpile Stewardship and Management PEIS, are discussed below.

1.7.1 Waste Management Programmatic Environmental Impact Statement

Alternatives for managing radioactive, hazardous, and mixed (radioactive and hazardous) wastes are analyzed in the *Waste Management Programmatic Draft Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DOE/EIS-0200-D), issued in August 1995. When completed, the Waste Management PEIS will support DOE decisions on the management of, and facilities for, the treatment, storage, and/or disposal of radioactive, hazardous, and mixed wastes.

Wastes would be generated by the Stockpile Stewardship and Management Program. Although there may be changes from site to site, for the Complex as a whole, the wastes will be similar in form and quantity to wastes currently generated by DOE facilities and analyzed in the Waste Management PEIS. Wastes generated by the Program would be managed in accordance with decisions made as a result of the Waste Management PEIS. Nonetheless, for the purposes of thoroughly analyzing the impacts of the proposed action, the treatment, storage, and/or disposal of these wastes in existing facilities is analyzed in the Stockpile Stewardship and Management PEIS.

Both the Stockpile Stewardship and Management PEIS and the Waste Management PEIS consider national strategies. The Waste Management PEIS considers alternatives that include local, regional, and/or consolidated waste management facilities. This Stockpile Stewardship and Management PEIS addresses alternatives that could result in the relocation of current missions and/or closure of existing sites. These two strategies are mutually consistent; however, the RODs will require coordination.

1.7.2 *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The Storage and Disposition PEIS will analyze alternatives for the long-term storage of all weapons-usable fissile materials, primarily HEU and plutonium, and the disposition of weapons-usable fissile materials, primarily plutonium the President has declared to be surplus to national defense needs. The *Implementation Plan for the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement* was issued in March 1995, and the Draft PEIS was issued in February 1996.

Both this Stockpile Stewardship and Management PEIS and the Storage and Disposition PEIS analyze reasonable alternatives for the long-term storage of strategic reserves of plutonium and HEU. Because the overall scope of each PEIS is significantly different, different long-term strategic reserve storage alternatives are reasonable for each PEIS. For example, the Stockpile Stewardship and Management PEIS evaluates alternatives for strategic reserve storage (in the form of pits and secondaries) at the weapons A/D Facility, which is where these strategic reserves might be first used. The Storage and Disposition PEIS has a relatively broader scope regarding fissile material storage, which will include the storage of all surplus material, naval reactor fuel, and naval reactor fuel feed stock, as well as nonweapons research and development materials. It analyzes alternatives, among others, that would collocate strategic reserves with surplus fissile materials.

Preparation of these two PEISs is being closely coordinated to ensure that all reasonable alternatives for long-term strategic reserve storage are assessed. Decisions on strategic storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the Stockpile Stewardship and Management Final PEIS and the Storage and Disposition Final PEIS are completed.

1.7.3 *Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components*

The *Draft Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (Pantex Site-Wide EIS) (DOE/EIS-0225D), which was issued in March 1996, analyzes the alternatives and environmental impacts associated with conducting nuclear weapons operations at Pantex for approximately the next 5 to 10 years. Included in the Pantex Site-Wide Draft EIS is an analysis of a plan to increase the interim storage of plutonium pits from 12,000 to 20,000 pits. The EIS also analyzes alternative locations to Pantex for interim pit storage operations.

In May 1994, when DOE announced its intention to prepare the Pantex Site-Wide EIS, DOE believed that the Pantex Site-Wide EIS ROD would precede decisionmaking on the long-term storage of pits by at least several years. Accordingly, the Pantex Site-Wide Draft EIS was scoped to address alternative locations for interim pit storage (i.e., until the long-term decisions were made and implemented).

Since May 1994, DOE has initiated two additional NEPA documents that address the storage of pits. This Stockpile Stewardship and Management PEIS will support decisions on the long-term storage of pits that will be needed for national security requirements (strategic reserve pits). As discussed above, the Storage and Disposition PEIS will support decisions on the long-term storage of all pits (strategic reserve and surplus) and the approach for dispositioning pits that are surplus to national security requirements.

Both of these PEISs have progressed to the point where they are scheduled to have their RODs issued by the fall of 1996, at or about the same time as the ROD for the Pantex Site-Wide EIS, which is scheduled for November 1996. Therefore, DOE is proposing that as long as the RODs of both PEISs and the Pantex Site-Wide EIS occur within a short period of time of one another, decisions on the long-term storage of pits would be made in the RODs of the PEISs. A decision relating to the interim storage of pits at Pantex would be made in the ROD of the Pantex Site-Wide EIS pending implementation of the selected long-term storage option.

However, if there is a significant delay in the RODs for either of the PEISs, or if DOE does not make a decision on the long-term storage of pits in those RODs, then there would be a need to make a decision on the location of interim storage of pits uninformed by a decision on long-term storage. In any event, the Pantex Site-Wide EIS will be completed with the analysis of interim storage alternatives, including addressing the issues and comments received from the public on that EIS, to support a decision relating to the storage of pits until a long-term storage decision has been made and implemented.

This PEIS includes Pantex as an alternative site for the following stockpile management missions: HE fabrication, weapons A/D, and strategic reserve storage. Programmatic decisions on these alternatives will be identified in the ROD for this PEIS; however, a decision on storage may occur later than decisions on the other two missions.

1.7.4 *Site-Wide Environmental Impact Statement for the Los Alamos National Laboratory*

The LANL Site-Wide Draft EIS is currently being prepared and analyzes alternatives for LANL's operation over the next 5 to 10 years. The Stockpile Stewardship and Management PEIS includes LANL as an alternative site for two stockpile stewardship facilities (NIF and Atlas) and the following stockpile management missions: pit fabrication, secondary and case fabrication, HE fabrication, and nonnuclear fabrication. Programmatic decisions on these alternatives will be identified in the ROD for this PEIS.

1.7.5 *Final Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada*

The NTS Site-Wide EIS (DOE/EIS 0243), analyzes alternatives for NTS's operation over the next 5 to 10 years. The Stockpile Stewardship and Management PEIS includes NTS as an alternative site for both a stockpile stewardship facility (NIF) and two stockpile management missions: weapons A/D and strategic reserve storage. Programmatic decisions on these alternatives will be identified in the ROD for this PEIS; however, a decision on storage may occur later than a decision on weapons A/D.

1.8 PUBLIC PARTICIPATION

Public participation for the PEIS consisted of two primary activities: the scoping process and the public comment process. CEQ regulations require "an early and open process for determining the scope of issues to be addressed and for identifying the significant issues to be addressed and for identifying the significant issues related to a Proposed Action (40 CFR 1501.7)." This is usually called the public scoping process. Section 4.1 of the *Implementation Plan Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (DOE–EIS–0236IP, December 1995) describes the scoping process. The following sections describe the public comment process on the Draft PEIS.

1.8.1 Public Comment Process on the Draft Programmatic Environmental Impact Statement

In February 1996, DOE published the Stockpile Stewardship and Management Draft PEIS that evaluated the siting, construction, and operation of the proposed stockpile stewardship facilities and the modification/construction and operation of facilities proposed for stockpile management at eight alternative sites within the Complex. The 60-day public comment period for the Draft PEIS began on March 8, 1996, and ended on May 7, 1996. However, late comments were considered to the extent practical.

During the comment period, public hearings were held in Los Alamos, NM; Albuquerque, NM; Las Vegas, NV; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. Five of the public hearings were joint meetings to obtain comments on both the Stockpile Stewardship and Management PEIS and the Storage and Disposition PEIS. Two of the joint meetings (Pantex and SRS) also included the Pantex Site-Wide EIS. In addition, the public was encouraged to provide comments via mail, fax, electronic bulletin board (Internet), and telephone (toll-free 800 number). Figure 1.8.1–1 shows the dates and locations of the hearings.

The public hearings held for the Draft PEIS were conducted using an interactive workshop-type format. The format chosen allowed for a two-way interaction between DOE and the public and encouraged informed public input and comments on the document. Neutral facilitators were present at the hearings to direct and clarify discussions and comments. Court reporters were also present to provide a verbatim transcript of the proceedings and record any formal comments.

All public hearing comment summaries were combined with comments received by mail, fax, Internet, or telephone during the public comment period. Volume IV of this PEIS, the Comment Response Document, describes the public comment process in detail, presents comment summaries and responses, and provides copies of all comments received.

1.8.2 Major Comments Received on the Draft Programmatic Environmental Impact Statement

A large number of the comments received on the Draft PEIS related to concerns that the analysis of particular alternatives and/or alternative sites did not adequately consider such factors as cost and technical feasibility. Although these concerns made up the majority of the comments, many other comments related to the resources analyzed, NEPA and regula-

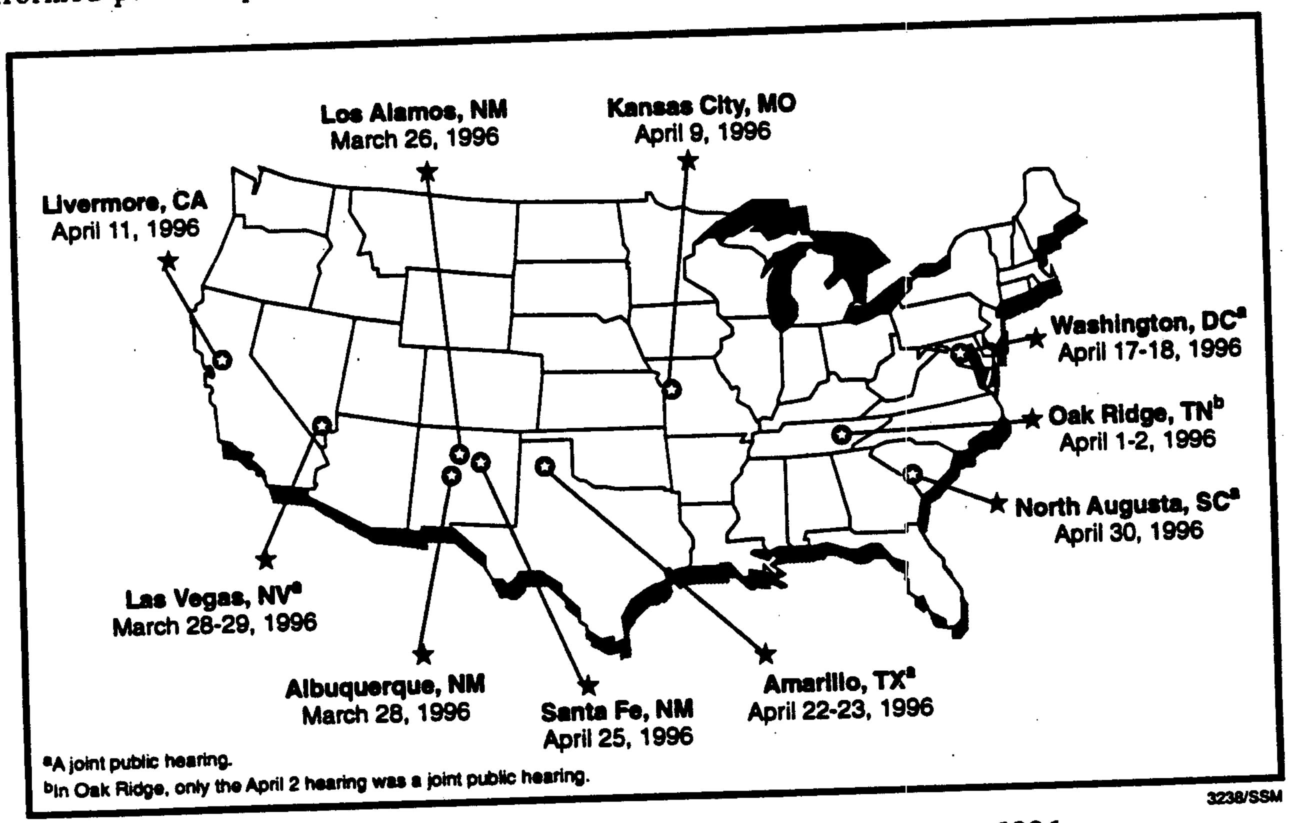

FIGURE 1.8.1–1.—*Public Hearing Locations and Dates, 1996.*

tory issues, and DOE and Federal policies as they related to this PEIS. The major issues identified by commentors include the following:

- The potential conflict between the Stockpile Stewardship and Management Program and the Nuclear Nonproliferation Treaty goals, and the pursuit of a CTBT
- Using the funds allocated for the Stockpile Stewardship and Management Program for social programs and on research of alternative sources of energy
- The generation, storage, and disposal of radioactive and hazardous wastes and the associated risks
- The impacts of the alternatives on human health (both from radiation and hazardous chemicals) and how these risks were determined and evaluated
- The relationship of this PEIS to other DOE documents and programs, particularly the Pantex and NTS Site-Wide EISs, the Waste Management and the Storage and Disposition PEISs, and the need to make decisions based on all associated programs and activities concurrently
- The need for decisions to be based on many different factors, including environmental, cost, and safety concerns
- The need for DOE to consider a zero-level stockpile, remanufacturing, and denuclearization as alternatives
- Maintaining deterrence with surveillance, curatorship, and remanufacturing without the need for the proposed facilities
- The need for DOE to adequately consider the ongoing stewardship program
- The need for DOE to perform detailed analysis of future stockpile stewardship facilities

All of the issues identified above are summarized and responded to in detail in chapter 3 of Volume IV. Substantial revisions to this PEIS resulting from public comments are discussed below.

Revisions in the Final PEIS include additional discussion and analysis in the following areas: alternatives considered but eliminated (section 3.1.2); the No Action alternative (appendix A, Stockpile Stewardship and Management Facilities, sections A.1.5, A.1.6, A.1.7, and A.1.8); socioeconomics at ORR, Pantex, and KCP; accident impacts at Pantex; normal operation impacts for radiological and chemical sections; cumulative impacts (section 4.13); and minor changes to LANL water resources section (section 4.6.2.4). A new section was also added to appendix F (section F.4, Secondary Impacts of Accidents). Each of these areas is discussed in more detail in the following section.

1.8.3 Changes from the Draft Programmatic Environmental Impact Statement

In response to comments submitted after issuance of the Draft PEIS and due to additional technical details not available at the time of issuance of the Draft, Volumes I, II, and III of the Final PEIS contain revisions and changes. The revisions and changes made since the issuance of the Draft PEIS are indicated by a double underline for minor word changes or by a sidebar in the margin for paragraph or larger changes. In addition, Volume I and each appendix in Volume III provide a unique reference list to enable the reader to further review and research selected topics. Volume IV (Comment Response Document) of the PEIS contains the comments received during public review of the Draft PEIS and the DOE responses to those comments. DOE has public reading rooms near each affected site and in Washington, DC, where these referenced documents may be reviewed or obtained for review. A brief discussion of the more significant changes is provided in the following paragraphs.

Alternatives Considered but Eliminated from Detailed Study and Related Issues. In response to public comments expressing a concern that DOE had not analyzed a reasonable range of alternatives, section 3.1.2 was expanded. The changes were in response to specific questions concerning compliance with treaties, stockpile size, maintenance and remanufacturing options, and the stockpile stewardship alternatives including No Action. The discussions in section 3.1.2 provide greater detail and more clarification on why alternatives were eliminated from detailed study in this PEIS. Together, chapter 2 and section 3.1.2 explain the framework and the constraints of national security policy that have shaped the proposed actions and reasonable alternatives for this PEIS.

No Action Alternative. Several commentors did not think that the No Action alternative was clearly explained in the Draft PEIS. More specifically, they were not sure which existing facilities at LANL, LLNL, SNL, and NTS were part of the ongoing stockpile stewardship program. As a result, the description of No Action was modified in appendix A to include a listing of major DOE Office of Defense Programs function facilities at LANL, LLNL, SNL, and NTS. Additionally, the discussion of impacts of No Action at LANL (section 4.6.3) was revised as appropriate to include the effects of the DARHT Facility.

Socioeconomics at Oak Ridge Reservation, Kansas City Plant, and Pantex Plant. Based on public comments and revised workforce size estimates, the socioeconomic impact sections for the downsizing alternatives at ORR (section 4.2.3.8), KCP (section 4.4.3.8), and Pantex (section 4.5.3.8) have been revised. The analyses were also expanded to cover the base case single-shift option in greater detail. At these three sites, downsizing of existing facilities is the preferred alternative. For such downsizing, the base case single-shift scenario represents the bounding analysis for the workforce. The change in worker estimates did not cause any of the major indicators in the socioeconomic analysis to change in any significant manner.

Accident Impacts at Pantex Plant. The analyses of impacts due to an aircraft impact and resulting release of plutonium by a fire or an explosion were modified to include more updated data on probability and source terms developed for the Pantex Site-Wide EIS. Section 4.5.3.9 and appendix sections F.2.1.1 and F.2.1.2 were revised to incorporate the new analytical results. Based on the updated data, the potential impacts and risks to the public from the composite accident presented in this PEIS would be less than previously reported in the Draft PEIS. This change was not significant.

Normal Operation Radiological/Chemical Impacts. The discussion of the normal operation radiological affected environment for LANL, section 4.6.2.9, has been updated to include the latest data from *Environmental Surveillance at Los Alamos During 1993 (LA-12973-ENV, October 1995)*. The normal operation radiological impact sections 4.2.3.9, 4.3.3.9, and 4.6.3.9 have also been revised to include the contribution of recent facilities at ORR, SRS, and the new environmental surveillance data for LANL. The chemical health effects, section 4.6.3.9 for LANL and section 4.7.3.9 for LLNL, were revised based on new analyses using updated dispersion rates. Tables in appendix section E.3.4 supporting these sections were also updated. The majority of these changes affected the No Action alternative analyses. None of the changes to these sections significantly changed the analysis of impacts for the "action" alternatives.

Cumulative Impacts. The cumulative impact section, 4.13, has been modified to incorporate a discussion of normal operation radiological impacts and other changes based on more recent data from NEPA documents and RODs. The changes to this section did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

Los Alamos National Laboratory Water Resources. Changes were incorporated in section 4.6.2.4 (Water Resources) for LANL based on more recent water use and water quality data. The Draft PEIS had erroneously stated that the LANL water allotment would be fully used by about 2000. The Final PEIS correctly reports that this allotment would be fully used by about 2052. This change did not have a meaningful effect on the analysis/comparative evaluation of alternatives. Minor revisions reflecting the baseline changes were also made to the LANL water resources impact section, 4.6.3.4.

Health Effects Studies. Appendix section E.4, which outlines epidemiological studies at the alternative sites, was rewritten to provide more detail and incorporate more recent and other applicable studies. Although these epidemiology sections do not affect the environmental analysis of future stockpile stewardship and management missions, they do provide relevant information regarding potential health effects from past actions. These changes did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

New Section. A new section has also been added to the Final PEIS (appendix section F.4, Secondary Impacts of Accidents). This section evaluates the secondary impacts of accidents that affect elements of the environment other than humans (e.g., farmland). The section was added because of public comments. The results of this analysis show that secondary impacts from accidents would generally not extend beyond site boundaries, except at Pantex and LLNL, where it is possible that some surface contamination could occur. This new analysis did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

CHAPTER 2

Chapter 2

CHAPTER 2: PURPOSE OF AND NEED FOR THE STOCKPILE STEWARDSHIP AND MANAGEMENT ACTION

Chapter 2 describes the purpose of and need for the Stockpile Stewardship and Management Program. It includes a discussion of national security policy considerations and the technical effects of national security policy on shaping the Program's purpose and need. The proposed action and alternatives are also discussed. The final section summarizes the chapter and introduces the logic flow diagrams that depict the framework of the Program from national policy and stockpile perspectives.

2.1 INTRODUCTION

The Stockpile Stewardship and Management Program is broad in scope and technically complex. The Program currently involves the integrated activities of three national laboratories, four industrial plants, and a nuclear test site. Further, the Program must be consistent with, and supportive of, U.S. national security policies, which have changed considerably since the end of the Cold War. Therefore, to better understand the *Programmatic Environmental Impact Statement* (PEIS) *for Stockpile Stewardship and Management* purpose, need, proposed action, and alternatives, it is useful to view the Program from two different perspectives. One perspective (see section 2.2) is from the top level of national security policies for nuclear deterrence, arms control, and nonproliferation. These policies include ongoing responsibilities, strategies, and directives. The other perspective (see section 2.3) focuses on the relevant technical efforts to maintain a safe and reliable U.S. nuclear weapons stockpile. Flow diagrams representing the logic of each perspective are referenced in the chapter summary (see section 2.7) and appear at the end of chapter 2.

2.2 NATIONAL SECURITY POLICY CONSIDERATIONS

There are four principal national security policy overlays and four related treaties that define Program conditions for the reasonably foreseeable future. They are:

- Presidential Decision Directives (PDDs)
- *National Defense Authorization Act of 1994* (Pub. L. 103-160)
- The Department of Defense (DOD) Nuclear Posture Review (NPR)
- Nuclear Weapon Stockpile Memorandum (NWSM)
- Proposed Comprehensive Test Ban Treaty (CTBT)
- Nuclear Nonproliferation Treaty (NPT)
- Strategic Arms Reduction Talks (START) I Treaty
- START II protocol

Of the above, the START II protocol is the most useful in helping define a specific time period to bound the reasonably foreseeable future.

2.2.1 Nuclear Posture Review

Beginning in 1991, several Presidential policy decisions, some unilateral and some made in conjunction with international treaties, resulted in DOD conducting the comprehensive NPR, which was approved by the President in 1994. The NPR defines and integrates past and present U.S. policies for nuclear deterrence, arms control, and nonproliferation objectives. The unclassified NPR strategies that pertain to the Stockpile Stewardship and Management Program were presented at the eight public scoping meetings conducted in the summer of 1995. There was general public interest in understanding this complex issue, especially as it relates to treaties, policies, and stockpile size. A summary of how the post-Cold War treaties relate to the NPR strategies and the stockpile follows.

Strategic Arms Reduction Talks. The NPR assumes that the START I Treaty and START II protocol will be fully implemented. However, since the START I Treaty is not yet fully implemented and the START II protocol is not scheduled to be fully implemented until 2003, the NPR strategy protects the U.S. option to reconstitute the stockpile to START I levels should unfavorable events occur in the former Soviet Union. The treaties only control the number of strategic nuclear weapons that can be loaded on treaty-specified and -verified strategic missiles and bombers. These nuclear weapons are limited to 6,000 by the START I Treaty and 3,500 by the START II protocol. The treaties do not control the total stockpile size or the composition of strategic and nonstrategic nuclear weapons of either side. The U.S. stockpile will be larger than 6,000 under START I and 3,500 under START II since the stockpile also includes weapons retained for nonstrategic nuclear forces, DOD operational spares, and spares to replace weapons attrited by Department of Energy (DOE) surveillance testing. In the START II case, the stockpile may also include weapons retained to reconstitute to the START I level. However, the terms "START I-sized stockpile" and "START II-sized stockpile" are relevant to the Stockpile Stewardship and Management PEIS as explained in section 2.2.2 and chapter 3.

Comprehensive Test Ban Treaty. It is the declared policy of the United States to seek ratification of a "zero yield" CTBT as soon as possible. The United States has been observing a moratorium on nuclear testing since 1992. The NPR strategy reflects this policy and the strategy has a significant effect on shaping the Stockpile Stewardship and Management Program. As explained in section 2.3.4, it is anticipated that repairs or replacements to an aging U.S. stockpile will be needed. Assessment and certification of the safety and reliability of stockpile repairs or replacements without nuclear testing is a significant challenge to the Program. In declaring the policy to seek a CTBT, the President also declared that the continued safety and reliability of the U.S. nuclear stockpile is a "supreme national interest" of the United States.

Nuclear Nonproliferation Treaty. Article VI of the NPT obligates the parties "to pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament, and on a treaty on general and complete disarmament under strict and effective international control." However, the NPT does not provide any time period for achieving this goal. Even relatively simple bilateral treaties, such as START I and START II, require more than 10 years to implement, not counting the years of negotiations. In the words of Ambassador Thomas Graham, "Regrettably, none of us is clairvoyant, and so it is unwise to predict with any degree of precision the future international reality and consequently, the complete arms control agenda."[1] For the Stockpile Stewardship and Management PEIS, speculation on the terms and conditions of a "zero level" U.S. stockpile with international verification, as some have suggested during the scoping meetings, goes beyond the bounds of the reasonably foreseeable future. For the same reason, DOE has chosen not to speculate on a return of the nuclear arms race requiring a stockpile larger than START I size. However, in keeping with the NPT goals, the NPR strategy does express the U.S. intent to pursue further reductions in nuclear forces beyond START II. Therefore, the implications of further reductions below the START II-sized stockpile are discussed in this PEIS where they are relevant.

2.2.2 Nuclear Weapon Stockpile Memorandum

Although the NWSM is a classified document, its effect in shaping the Stockpile Stewardship and Management PEIS can be explained in an unclassified context. Without access to the classified NWSM, one might assume that the exact details of the projected stockpile size and composition under START I and START II could have a significant effect on the Stockpile Stewardship and Management PEIS. This is not the case for the following reasons:

- The stockpile composition (i.e., the number of different weapon types), does not vary significantly in either a START I- or START II-sized stockpile. All weapon types are tritium-boosted, thermonuclear weapons that could be affected by the same types of safety and reliability problems requiring repair, replacement, and certification in the absence of nuclear testing. The basic weapons laboratory and industrial capa-

[1]From a January 1995 speech by Ambassador Graham, Special Representative of the President for Arms Control Non-Proliferation and Disarmament.

bilities required for the foreseeable future do not vary significantly from planned differences in size or composition of either a START I- or START II-sized stockpile.

- Industrial capacity is only indirectly affected by projected variances in stockpile size and composition. Stockpile size must be linked with historical stockpile data to arrive at estimates of average annual industrial capacity needed to produce components for repair or replacement. Even without the limitations on the use of historical stockpile data described in section 2.3.3, this cannot be done with mathematical precision and, therefore, reasonable technical judgment must be applied. The result is to forecast a need for a smaller industrial base with capacities on a scale of hundreds of weapons per year versus the thousands of weapons per year that existed prior to the end of the Cold War. A range of annual requirements is considered for impact analysis in the Stockpile Stewardship and Management PEIS that bounds potential variances in the NWSM under the START II protocol. In addition, a qualitative sensitivity analysis is performed on the hypothetical low case that is well below the START II-sized stockpile projection and the high case associated with a START I-sized stockpile (see section 3.1.1.2).

2.2.3 Presidential Decision Directives and Public Law

Over the past few years, there have been several publicly announced PDDs that have shaped the Stockpile Stewardship and Management Program. In the *National Defense Authorization Act of 1994* (Pub. L. 103-160), Congress acted to reinforce many of the same points. A summary of their effect in shaping the Stockpile Stewardship and Management PEIS follows:

- The continued maintenance of a safe and reliable nuclear weapons stockpile will remain a cornerstone of the U.S. nuclear deterrent for the foreseeable future.

- The core intellectual and technical competencies of the United States in nuclear weapons will be maintained. This includes competencies in research, design, development, and testing (including nuclear testing); reliability assessment; certification; manufacturing; and surveillance capabilities.

- The United States will develop new ways to maintain a high level of confidence in the safety, reliability, and performance of the U.S. nuclear weapons stockpile in the absence of nuclear testing. The strategy for this action will be structured around the use of past nuclear test data in combination with enhanced computational modeling, experimental facilities, and simulators to further comprehensive understanding of the behavior of nuclear weapons and the effects of radiation on military systems.[2]

- The continued vitality of all three DOE nuclear weapons laboratories will be essential in addressing the challenges of maintaining a safe and reliable nuclear weapons stockpile without nuclear testing and without the production of new-design weapons.

2.3 Safety and Reliability of the United States Stockpile

This section focuses on the technical effects of national security policy decisions on shaping the purpose, need, proposed actions, and alternatives of the Stockpile Stewardship and Management Program. The stockpile is currently judged to be safe and reliable by DOE. National security policy changes will significantly change the characteristics of the future nuclear weapons stockpile and the manner in which it will need to be certified as safe and reliable.

2.3.1 Stockpile History

Since the beginning of the Cold War, the United States has maintained a nuclear deterrent force as safe and

[2]The effects of radiation on nuclear weapons and military systems are referred to as "weapon effects" throughout this PEIS.

reliable as the evolution of military requirements and technology development would permit. A safe and reliable U.S. nuclear weapons stockpile has been a cornerstone of maintaining a credible nuclear deterrent. The size of the U.S. nuclear weapons stockpile peaked in the 1960s. In the 1970s, it was significantly reduced due to the easing of Cold War tensions with the former Soviet Union. In the late 1970s and through most of the 1980s, Cold War tensions with the former Soviet Union significantly increased and the U.S. nuclear deterrent force was modernized in response. However, the size of the U.S. nuclear weapons stockpile remained stable during the 1980s with the production of new-design weapons replacing dismantled weapons nearly one for one.

The beginning of the 1990s brought the collapse of the Warsaw Pact and the former Soviet Union and a significant effort to end the Cold War. During the first half of the 1990s, many changes occurred in U.S. policy and planning for its nuclear deterrent force. Much has already been accomplished, including the dismantlement, without replacement, of more than 8,000 U.S. nuclear weapons since the end of the Cold War; however, much more will need to be accomplished with the former Soviet Union over the next 10 years to stay the course. Large uncertainties remain concerning the nuclear weapons stockpile of the former Soviet Union, and it is the policy of the United States to protect its national security options for its nuclear deterrent, including the reconstitution of its nuclear forces. The following excerpt is from the President's national security strategy statement in July 1994:

> Even with the Cold War over, our Nation must maintain military forces that are sufficient to deter diverse threats. . . . We will retain strategic nuclear forces sufficient to deter any future hostile foreign leadership with access to strategic nuclear forces from acting against our vital interests and to convince it that seeking a nuclear advantage would be futile. Therefore we will continue to maintain nuclear forces of sufficient size and capability to hold at risk a broad range of assets valued by such political and military leaders.

2.3.2 Smaller, Aging Stockpile

Until recently there has been no reason to expect that weapons would remain in the stockpile longer than they have in the past. Continuous modernization to improve safety and reliability kept the stockpile young as new-design weapon types replaced old ones. Now, with no new-design weapons being produced, the United States will have a steadily aging stockpile. The average age of the stockpile has never approached the typical lifetime specified in the weapon requirements (approximately 20 years for the most modern U.S. nuclear weapons). The average age of the stockpile is currently about 13 years. The NWSM forecasts the average age will now climb roughly 1 year per year and will reach the 20 year mark by 2005, at which time the oldest weapons will be about 35 years old.

2.3.3 Historical Stockpile Data

The following paragraphs describe the effects of historical stockpile data in shaping the Stockpile Stewardship and Management Program. This information was extracted from an unclassified report, *Stockpile Surveillance: Past and Future* (tri-laboratory report requested by DOE and issued as Sandia Laboratory Report, SAND 95-2751, September 1995), which was co-authored by the three weapons laboratories and is available to the public. The past role of nuclear testing is emphasized because such testing can no longer be relied on to provide unambiguous high confidence in the future safety and reliability of an aging stockpile.

Stockpile Evaluation Program.[3] Continuous evaluation of the safety and reliability of the stockpile has always been a major part of the U.S. nuclear weapons program. Since the introduction of sealed-pit weapons more than 35 years ago, a formal surveillance program of nonnuclear laboratory and flight testing has been in existence. More than 13,800 weapons have been evaluated in this program. The Stockpile Evaluation Program, with its reliance on functional testing, has provided information that can be used in the statistical analysis of nonnuclear component and subsystem reliability. This program has detected about 75 percent of all problems ultimately detected, and has been the principal

[3]Other than in specific discussions, the word surveillance is used generically throughout this document in place of the Stockpile Evaluation Program.

mechanism for discovering defects and initiating subsequent repairs and replacements. However, not all aspects of a nuclear weapon can be statistically assessed this way. Weapons research and development (R&D) at the three weapons laboratories and nuclear testing have played an important part in assessing the stockpile and in making corrective changes when needed.

Past Role of Nuclear Testing. Nuclear tests have been a critical part of the nuclear weapons program. They have contributed to a broad range of activities from development of new weapons to stockpile confidence tests to tests that either identified a concern or showed that remedial actions were not needed. However, the United States has not conducted a sufficient number of nuclear tests for any one weapon type to provide a statistical basis of reliability assessment for the nuclear explosive package. This is why the word "performance" instead of "reliability" is used when discussing a nuclear explosive package.

Although nuclear tests were never a part of the formal Stockpile Evaluation Program, they played an important role in maintaining the safety and performance of the weapons in the stockpile. Every advantage was taken of developmental nuclear tests to eliminate potential nuclear explosive problems. In some cases, nuclear testing during development of one weapon type uncovered a problem that was pertinent to a previous design already in the stockpile, which then had to be corrected. Nuclear tests identified certain classes of stockpile problems not observable in the surveillance program. Nuclear tests have been used to resolve issues raised by the Stockpile Evaluation Program, such as whether a particular corrosion problem affected the nuclear yield of a weapon. Nuclear tests have also been used to verify the efficacy of design changes. For example, the adequacy of certain mechanical safing techniques was determined through nuclear testing. In the case of a catastrophic defect, tests have been used to certify totally new designs to replace an existing design. Finally, in some cases, nuclear testing proved that a potential problem did not exist.

Beginning in the late 1970s, DOD and DOE agreed to a formal series of underground nuclear tests of weapons withdrawn from the stockpile. These tests were referred to as Stockpile Confidence Tests. They differed from developmental nuclear tests because the weapons were from actual production, had experienced stockpile conditions, and had minimal changes made to either nuclear or nonnuclear components prior to the test. There have been 17 such confidence tests since 1972, including 4 tests in the early 1970s that were not officially designated as Stockpile Confidence Tests. Confidence tests have been conducted for each of the weapon types expected to remain in the stockpile well into the next century.

In addition to the 17 confidence tests, at least 51 additional underground nuclear tests have been conducted since 1972 involving nuclear components from the stockpile, components from the actual weapon production line, or components built according to stockpile design specifications and tested after system deployment. The objectives of these tests included weapon effects, weapons R&D, confirmation of a fix, or investigation of safety or performance concerns. Three of these tests (in addition to one confidence test) revealed or confirmed a problem that required corrective action. Four tests (in addition to three confidence tests) confirmed a fix to an identified problem. Additionally, five tests were performed to investigate safety concerns affecting three different weapon types. These five tests verified that a problem did not exist.

The confidence in the performance of the nuclear explosive package has been based on underground nuclear test data, aboveground experiments, computer simulations, surveillance data, and technical judgment. The directors of the three weapons laboratories must certify the nuclear performance of the weapons designed by their laboratory.

In a future without additional nuclear testing, the core capabilities of the weapons laboratories that were developed to eliminate potential problems in new weapon designs must now be employed to assess stockpile problems. However, in the absence of nuclear testing, the ability to assess nuclear components is more difficult; new methods of assessment, discussed later, will have to be developed to help compensate for this loss.

Stockpile Data Summary. The historical stockpile database includes more than 2,400 findings from more than 45 weapon types. Findings are any abnormal conditions pertaining to stockpile weapons, such as out-of-specification data. Findings are then investigated and assessed as to whether or not they are a problem. Excluding multiple occurrences of the

TABLE 2.3.3–1.—*Summary of Distinct and Actionable Findings Since 1958*

Type of Components	Distinct Findings	Actionable Findings	
		Findings	Weapon Types
Nuclear	145	110	39
Nonnuclear	703	306	38

Source: SNL 1996a.

same anomalous condition, table 2.3.3–1 provides a summary of the distinct findings and actionable findings since 1958. Actionable findings are those that require some form of corrective action. All major components and subsystems have had problems that required corrective actions. The number of findings for nonnuclear components is much larger than that for nuclear components largely because there are so many more nonnuclear components in a nuclear weapon that require testing more frequently. However, the ratio of actionable findings to distinct findings is much greater for the nuclear components. Thus, when a finding has occurred for a nuclear component, it has generally been a serious one requiring corrective action. Often these corrective actions to nuclear components have required changes to all of the weapons comprising the weapon type affected.

For the nuclear explosive package, there were approximately 110 findings on 39 weapon types requiring some remediation either to the entire build of that design or to all weapons produced after the particular finding. In addition to rebuilds and changes in production procedures, other actions included imposing restrictions on the weapon, accepting a performance decrement, and in several cases, conducting a nuclear test to determine that the finding did not require any physical change. There have been other instances not counted as actionable where a material was chemically changing and the weapon was closely monitored to see if further action was necessary or it was an isolated case that did not require remediation.

2.3.4 Certified Repairs or Replacements Will be Needed

Based on the age of the planned stockpile over the next 10 years, historical data would project an average of one to two actionable findings per year in the planned stockpile and an average of one to two change proposals approved per year, with one of these resulting in a major change. Even with a START II-sized stockpile, one change can affect thousands of weapons. These projections are most likely minimum numbers. The stockpile they were derived from was, on average, younger than the planned stockpile will be in future years, and the number of components in the weapon types was less than the number of components in weapon types of the planned stockpile. Furthermore, the aging characteristics of some of the materials used in the weapon types remaining in the stockpile are not well understood.

The previous paragraphs describe how problems were identified in stockpile weapons during the period when nuclear testing and active weapons development were being conducted along with the Stockpile Evaluation Program. At the present time, with no anticipated new weapons and no nuclear testing, new approaches are needed to assess weapons for potential problems and anticipate aging concerns, especially in the nuclear explosive package. This is important because the smaller, less diverse U.S. stockpile will be more vulnerable to single-component and common-cause failures (i.e., failures or defects compromising the safety or reliability of, respectively, a single weapon system or several systems sharing a common design feature).

DOE will continue to rely on well-established methods while the weapons laboratories develop new methods of measurement and evaluation to address aging, safety, reliability, and performance issues. As the new methods mature for either nuclear or nonnuclear components, they will be incorporated into the Stockpile Evaluation Program. In the future, for example, DOE will rely on improved experimental capabilities, coupled with an improved computational capability, to address issues associated with the nuclear explosive package. These experimental capabilities, along with enhanced surveillance methods, are now crucial to help assess and predict the state of the stockpile and to provide long lead time information about incipient problems.

2.4 Purpose and Need

Broadly stated, changes to U.S. national security policies for nuclear deterrence now place two significant constraints on the way in which DOE has traditionally accomplished its statutory nuclear weapons mission:

- The United States has declared a moratorium on nuclear testing and will seek ratification of a "zero yield" CTBT.
- The United States has stopped the development and production of new-design nuclear weapons.

With these constraints, U.S. national security policy directs DOE to:

- Maintain the core intellectual and technical competencies of the United States in nuclear weapons including:
  - Research, design, development, testing, reliability assessment, certification, manufacturing, and surveillance
  - All three nuclear weapons laboratories and the capability to resume nuclear testing if needed
- Maintain a safe and reliable U.S. nuclear weapons stockpile

The NPR, PDDs, and Pub. L. 103-160 all address the need to maintain the core competencies of the United States in nuclear weapons without nuclear testing. The NPR strategy adds the expectation of no new-design weapon production; therefore, the NWSM does not currently direct or forecast such a requirement.

The Stockpile Stewardship and Management Program must accomplish these fundamental purposes in a safe, efficient, and environmentally responsible manner. National security policies do not eliminate any of the current or historical core competencies and capabilities of the DOE weapons laboratories, industrial plants, or the Nevada Test Site (NTS). They are basic needs that must be maintained for the foreseeable future. These needs are summarized in a focused discussion of their relationship to the development of the PEIS proposed actions and alternatives. A classified appendix has also been prepared to support this PEIS.

2.4.1 Stockpile Stewardship—The Weapons Laboratories and Nevada Test Site

The three weapons laboratories possess most of the core intellectual and technical competencies of the United States in nuclear weapons. These competencies embody more than 50 years of weapons knowledge and experience that cannot be found anywhere in the United States. Since the end of the Cold War, laboratory staffing in the weapons program has declined significantly due to the effects of policy changes on program and budget. Further significant reductions or consolidations of the weapons laboratories would counter efforts to maintain core competencies and to develop the new technologies necessary to ensure continued high confidence in a safe and reliable stockpile. Current stockpile activities in this regard, such as ongoing retrofits of enduring stockpile weapons and safe dismantlement of weapons no longer required, would also be hampered. For the foreseeable future it would be unreasonable to pursue an alternative course for the weapons laboratories. In addition, because there can be no absolute guarantee of complete success in the development of enhanced experimental and computational capabilities, the United States will maintain the capability to conduct nuclear tests under a "supreme national interest" provision in the anticipated CTBT. DOE will need to maintain the capability for nuclear testing and experimentation at NTS and the necessary technical capabilities at the weapons laboratories to design and conduct such tests.

The science and engineering technology base at the three weapons laboratories controls all DOE technical requirements for a U.S. nuclear weapon. The laboratories perform the basic research, design, system engineering, development testing, reliability assessment, and certification of nuclear performance. In addition, they provide or control all technical specifications that are used by the industrial base for manufacturing and surveillance operations and for maintenance operations conducted by DOD. Data from these operations are provided to the weapons laboratories for assessment and technical resolution of problems.

When stockpile problems develop, all of the core laboratory capabilities may come into play. The cause of the problem is identified and an assessment made of its impact on safety, reliability, or performance. If the problem is to be fixed, alternative solutions are developed. These can range from simple repair of a defective feature to complete redesign of the weapon component or subsystem.

The focus is always on the acquisition of relevant test data to make these judgments. Once a fix is determined, it must be designed, prototyped, and development tested by the laboratories before the design is released for manufacture. This generally includes weapon system-level laboratory and flight tests for nonnuclear features and, in the past, nuclear tests if the changes could affect the weapon's nuclear performance. If the fix is to be manufactured, the laboratories provide the quality assurance test specifications. For nonnuclear components, a significant amount of functional test data is acquired during manufacture and is used to begin building a statistical estimate of component reliability. Subsequent laboratory and flight testing in the surveillance program accumulates additional data that include the effects of aging and exposure to stockpile environments. Thus, over time, high confidence in the safety and statistical reliability of nonnuclear components and subsystems can be established.

The situation is not the same for nuclear components and the assessment of nuclear performance. Nuclear components cannot be functionally tested during manufacture or surveillance. The data acquired during manufacture only show that the component was manufactured as designed. Surveillance data indicate whether the component is changing as a result of aging or exposure to stockpile environments. Manufacturing and surveillance data can identify concerns, but these data do not provide all of the necessary information to assess nuclear performance. Assessment and certification of nuclear performance is a nonstatistical, technical judgment by the weapons laboratories based on scientific theory, experimental data, and computational modeling. The scientific practice of "peer review" has been fundamental to these judgments. Experts from the two nuclear design laboratories review each other's data and conclusions on important issues, thereby providing an independent check and balance.

In the past, nuclear testing filled the gaps in basic understanding of the complex physics phenomena; it provided high confidence in the certification of nuclear safety and performance. Without nuclear testing, science-based stockpile stewardship will focus on obtaining the more accurate scientific and experimental data that will be needed for more accurate computer simulations of nuclear performance. The new experimental data must also be validated against past nuclear test data. Assessment of stockpile problems and certification of repairs or replacements of nuclear components will have to rely on improvements to these tools. The existing tools were used in conjunction with nuclear testing and are inadequate if used alone.

From a broader national security perspective, the core intellectual and technical competencies of the weapons laboratories provide the technical basis for the pursuit of U.S. arms control and nuclear nonproliferation objectives. Their extensive core competencies have provided most of the nuclear weapons arms control technologies developed and employed by the United States. The weapons laboratories will have to continue to provide this essential service in the future. For the same reasons, the weapons laboratories also provide significant technical support for U.S. efforts on nuclear weapons nonproliferation and counter-proliferation programs.

2.4.2 Stockpile Management—The Industrial Base

None of the manufacturing and surveillance capabilities of the current industrial base can be eliminated on the basis of the post-Cold War changes in national security policies. The industrial base also possesses core competencies, such as manufacturing product, process, and quality control know-how. However, with a smaller stockpile and no new-design weapons production, industrial capacity can be reduced to meet anticipated manufacturing requirements for stockpile repair and replacement activities. A summary discussion of each of the major functions needed is provided in this section. A more detailed discussion can be found in section 3.4.

Broadly stated, there are six major manufacturing and surveillance functional areas in the weapons industrial base:

- Weapons assembly/disassembly (A/D)
- Pit components
- Secondary and case components
- High explosives (HE) components
- Nonnuclear components
- Tritium supply and recycling

As explained in chapter 1, tritium supply and recycling was evaluated in a separate PEIS.

Weapons Assembly/Disassembly. The Pantex Plant (Pantex) is the only DOE site currently authorized to assemble or disassemble stockpile weapons. Special facilities built to explosives safety criteria are required; in addition, some facilities are designed to limit nuclear material dispersal in case of an HE accident. These facilities exist in large numbers at Pantex, and because they are relatively discrete structures, downsizing-in-place is a viable alternative. NTS has a much smaller set of these special structures that were constructed for use in assembling nuclear test devices. However, NTS has few of the support facilities required for volume assembly or disassembly of stockpile weapons. A major programmatic consideration is the cost of re-creating facilities that already exist at Pantex. Due to ongoing weapon dismantlement requirements, the alternative to transfer this function to NTS would be slow but achievable within a 10-year period.

Pit Components. These components are designed by Los Alamos National Laboratory (LANL) and Lawrence Livermore National Laboratory (LLNL) and were formerly produced at the Rocky Flats Plant, which is no longer available for this function. The LLNL facility is not large enough to accommodate both stewardship and management activities; therefore, only LANL is considered to be a reasonable alternative if this function is reestablished at a weapons laboratory. Also, LANL has the more extensive and complete plutonium facility infrastructure. Savannah River Site is also considered a viable alternative for reestablishing this function because it has a plutonium processing infrastructure, although it does not have a precision component manufacturing capability. Other than the synergism with maintaining core competencies at the weapons laboratories, a major program consideration would be the scale of manufacturing capacity required for the foreseeable future.

The preceding discussion applies to new pit fabrication as well as both intrusive and nonintrusive modification pit reuse manufacturing capability and capacity. Intrusive modification pit reuse requires handling and processing of the plutonium internal to the pit. Nonintrusive modification pit reuse involves the external features of the pit and does not require an extensive plutonium infrastructure; the risk of contamination and the generation of radioactive waste is very low for nonintrusive modification activities. Therefore, the weapons A/D Facility is also an alternative for nonintrusive modification pit reuse.

Secondary and Case Components. The Y-12 Plant (Y-12) at the Oak Ridge Reservation produces the secondary and case components. These components are designed by LANL and LLNL; therefore, each of those facilities would be reasonable alternative sites if this function is transferred to the weapons laboratories. Both of these laboratories have a uranium technology base and facility infrastructure, although they have only a very limited R&D manufacturing capability. Other than the synergism with maintaining core competencies at the weapons laboratories, a major Program consideration would be the cost of transferring product technologies and the re-creation of capital facilities that already exist at Y-12. Due to the complicated nature of nuclear facilities and plans for retrofit of an enduring stockpile weapon involving these components, a transition to either LANL or LLNL would be slow but achievable within a 10-year period. Downsizing Y-12 is considered to be a reasonable alternative.

High Explosives Components. Pantex currently manufactures HE components in special facilities built to explosives safety criteria. Downsizing the facilities at Pantex is a reasonable alternative. Comparable facilities also exist at both LANL and LLNL, and either laboratory has sufficient capacity to meet estimated future manufacturing requirements. Costs for this function are relatively low in any case. If a decision is made to transfer this function to the weapons laboratories, it could be done more quickly than the transfer of other functions. However, Pantex would have to retain disposition and disposal capability for the HE inventories currently onsite and those expected from near-term weapon dismantlement. A major Program consideration would be the synergism of this function in maintaining the core competencies of the weapons laboratories.

Nonnuclear Components. Kansas City Plant (KCP) currently manufactures the majority of the nonnuclear components. The KCP facilities are not unique in structural design and are amenable to downsizing in place. The manufacturing technologies are complex and varied due to the large number of component types and high reliability requirements. Sandia National Laboratories (SNL) designs most of the components that KCP manufactures; therefore, SNL would become the major nonnuclear component supplier if a decision is made to transfer this function to the weapons laboratories. Other than potential synergism with maintaining core competencies at the weapons laboratories, a major program consideration would be the cost of transferring product technologies and re-creating facilities that already exist at KCP. Requirements for ongoing support of the enduring stockpile would make this a slow transition, but it would be achievable within a 10-year period.

2.5 Proposed Action and Alternatives

All of the existing basic capabilities of the laboratory and industrial base continue to be needed even though there have been changes in national security policy since the end of the Cold War. These changes do not affect the standards for stockpile safety and reliability. Therefore, the proposed action concentrates on three major issues that result from the national security policies and constraints placed on the Program. The three program elements of the proposed action are:

- Providing enhanced experimental capability
- Rightsizing the industrial base
- Reestablishing manufacturing capability and capacity for pit components

Reasonable alternatives for the proposed action are briefly discussed below. Chapter 3 describes these alternatives in more detail.

2.5.1 Providing Enhanced Experimental Capability

Understanding nuclear weapon performance requires knowledge of the performance of the individual elements: the primary (pit and HE), the secondary, and the functional interaction between the primary and the secondary inside the case. Computer model-based validation and certification will be the key to DOE's ability to determine, with confidence, many of the future safety and performance characteristics of the stockpile in the absence of nuclear testing. This requires two principal elements: advanced computational models and facilities to provide experimental data that can be used to adjust (normalize) the computational models in conjunction with past nuclear test data. DOE is proposing three facilities to complement the existing capabilities to provide these data. Two are new facilities and one is the upgrade of an existing facility.

The National Ignition Facility (NIF) and the Atlas Facility are proposed new facilities. The Atlas Facility would be collocated in TA-35 with the existing Pegasus II Facility at LANL, and the two facilities would use common infrastructures and support facilities. The Contained Firing Facility is a proposed environmental and diagnostic upgrade to the existing Flash X-Ray Facility at LLNL. As described in section 3.3, these three new facilities would perform separate functions and provide different types of experimental data. Thus, they are complementary in nature and are not alternatives to one another. In each case, the alternative to constructing and operating the facility is No Action (i.e., relying on existing facilities to provide data). In addition, site alternatives are evaluated for NIF, since it is not associated with an existing facility. Volume III of this PEIS contains project-specific analyses for each of these facilities.

The stockpile stewardship program is expected to continuously evolve as better information becomes available and technological advancements occur. DOE is in the early planning stages for a number of what can be described as "next generation" stewardship facilities. These facilities are discussed in section 3.3.4. They will build on the knowledge gained from existing and proposed new facilities. Since these facilities are in the conceptual planning stages, they are not sufficiently well defined to be analyzed in this PEIS. When these technologies reach the appropriate level so as to be ripe for decisionmaking, DOE would complete *National Environmental Policy Act* (NEPA) documentation for them.

2.5.2 Rightsizing the Industrial Base

One of the primary goals of stockpile management is to rightsize functions to provide an effective and efficient manufacturing capability for a smaller stockpile. Such rightsizing must be accomplished in a manner that preserves core competencies in manufacturing and surveillance. This PEIS analyzes two alternative approaches to rightsizing the stockpile management functions described in section 2.4.2: (1) transfer manufacturing and surveillance activities from the industrial sites to the weapons laboratories and NTS and (2) downsize the industrial plants in place. Relocation alternatives were selected on the basis of existing technical and facility infrastructure at the laboratories and NTS. Section 3.4 discusses these alternatives in detail.

2.5.3 Reestablishing Manufacturing Capability and Capacity for Pit Components

Plutonium pit manufacturing is a special case among those stockpile management functions discussed in section 2.4.2. In 1992, DOE ceased plutonium pit manufacturing operations at the Rocky Flats Plant due to concerns about the safety of the plant and national security policy decisions to cease the production of new-design nuclear weapons. Reestablishing pit manufacturing capability and capacity was to be part of the Reconfiguration PEIS discussed in chapter 1. This function is now part of the proposed action in this Stockpile Stewardship and Management PEIS.

Pit manufacturing capability and capacity, like that of all other major weapons components and subsystems, is essential for protecting national security options with regard to the nuclear deterrent. In addition, repair or replacement of pits for existing stockpile weapons may be required in the future. Reasonable alternative sites for reestablishing this function were selected from sites that already possess some measure of the appropriate technical or facility infrastructure.

2.6 NONPROLIFERATION

On August 11, 1995, the President announced his commitment to seek a "zero yield" CTBT. He also established several safeguards that condition U.S. entry into a CTBT. One of these safeguards is the conduct of science-based stewardship, including the conduct of experimental programs. This safeguard will enable the United States to enter into such a treaty while maintaining a safe and reliable nuclear weapons stockpile consistent with U.S. national security policies.

One benefit of science-based stockpile stewardship is to demonstrate U.S. commitment to NPT goals; however, the U.S. nuclear posture is not the only factor that might affect whether or not other nations might develop nuclear weapons of their own. Some nations that are not declared nuclear states have the ability to develop nuclear weapons. Many of these nations rely on the U.S. nuclear deterrent for security assurance. The loss of confidence in the safety or reliability of the weapons in the U.S. stockpile could result in a corresponding loss of credibility of the U.S. nuclear deterrent and could provide an incentive to other nations to develop their own nuclear weapons programs.

The United States has halted the development and production of new-design nuclear weapons. The experimental testing program will be used to assess the safety and reliability of the nuclear weapons in the remaining stockpile. Much of this testing is classified and could not lead to proliferation without a breach of security. Use of classified data from past U.S. nuclear tests is also a vital part of the overall process for validation of new experimental data. Most of the component technology used for the proposed enhanced experimental capability is unclassified and is available in open literature, and many other nations have developed a considerable capability.

Proliferation drivers for other states, such as international competition or the desire to deter conventional armed forces, would remain unchanged regardless of whether DOE implemented the proposed action analyzed in this PEIS. In the NPT, the parties agree not to transfer nuclear weapons or other devices, or control over them, and not to assist, encourage, or induce nonnuclear states to acquire nuclear weapons. However, the treaty does not mandate stockpile reductions by nuclear states, and it does not address actions of nuclear states in maintaining their stockpiles.

2.7 SUMMARY

National security policies require DOE to maintain the historical nuclear weapon competencies and capabilities of three weapons laboratories, the industrial plants, and NTS. In addition, DOE must maintain an appropriately sized industrial capacity to manufacture repair and replacement components for weapons that remain in the stockpile. The environmental impacts of maintaining these historical capabilities will be established by the No Action characterization of the sites. With this baseline, the proposed actions and alternatives are analyzed incrementally for each relevant site. In this manner, the broad cumulative impact of the Program and the specific impacts of the proposed actions and alternatives can be displayed and discussed.

In preparation for the Stockpile Stewardship and Management PEIS public scoping process, DOE published a document entitled *The Stockpile Stewardship and Management Program* in May 1995. This document supplements this chapter with a broader discussion of Program strategies to address the major issues and policy constraints placed on the Program. There are five strategies discussed:

- Enhanced experimental and computational capabilities
- Enhanced weapon and materials surveillance technologies
- Effective and efficient production complex
- Long-range stockpile support
- Tritium production

In developing the Stockpile Stewardship and Management PEIS proposed actions, the significant aspects of "enhanced experimental capability" and "effective and efficient production complex" are directly addressed. As explained in chapter 1, the enhanced experimental capability of the Dual Axis Radiographic Hydrodynamic Test Facility and tritium production are addressed as related interim actions in separate environmental impact statements. The remaining elements of these strategies are primarily a redirection of R&D efforts at the weapons laboratories away from the design of new weapons toward the development of appropriate technologies to address the needs of a safe, reliable, and smaller, aging stockpile. As such, they are not judged to be significant NEPA issues and do not have broad environmental impacts beyond what is analyzed in this PEIS.

Figure 2.7–1 presents the framework used for discussing the Stockpile Stewardship and Management Program from a U.S. national security policy perspective. Figure 2.7–2 presents a view of the complete Stockpile Stewardship and Management Program from a stockpile perspective, integrating all aspects of the proposed action.

CHAPTER 3

Chapter 3

CHAPTER 3: STOCKPILE STEWARDSHIP AND MANAGEMENT PROGRAM ALTERNATIVES

Chapter 3 provides descriptions of the alternative sites and the program alternatives for meeting the Nation's nuclear weapons stockpile stewardship and management requirements. The chapter begins with a summary of the development of the alternatives, followed by descriptions of the alternative sites and their current missions. The stockpile stewardship discussion provides a description of the three basic stewardship areas, along with the associated alternatives, including a brief description of concepts for next-generation stewardship facilities. The stockpile management discussion provides a description of the various management functions and their associated alternatives. Brief discussions of emerging technologies that may affect stockpile management facilities and functions in the future and a discussion of a potential next-generation plutonium fabrication facility follow. The chapter concludes with a comparison of the stockpile stewardship and management alternatives and a discussion of the preferred alternatives.

3.1 Development of Stockpile Stewardship and Management Program Alternatives

This programmatic environmental impact statement (PEIS) evaluates the direct, indirect, and cumulative impacts associated with the Stockpile Stewardship and Management Program alternatives that are summarized in figure 3.1–1. For the various alternatives, this includes evaluating the applicable impacts of new facility construction or existing facility modification. Also assessed are the operational impacts of long-term stewardship and management activities in support of the base case nuclear weapons stockpile, including transportation of materials and components between sites. This PEIS also provides a sensitivity analysis of differences, when applicable, from the base case alternatives for the high and low case stockpile. However, since it is expected that the annual workload may vary above and below the base case capacity assumptions, the base case is analyzed in the greatest detail.

3.1.1 Planning Assumptions and Basis for Analysis

In the Stockpile Stewardship and Management Program and in this PEIS, the Department of Energy (DOE) will:

- Emphasize compliance with applicable laws and regulations and accepted industrial and weapons safety practices that safeguard the health of workers and the general public, protect the environment, and ensure the security of nuclear material and weapons
- Analyze alternatives that are consistent with, and supportive of, national security policies
- Maximize efficiency and minimize cost and waste, consistent with programmatic needs
- Minimize the use of hazardous materials and the number and volume of waste streams consistent with programmatic needs through active pollution prevention programs and measures

As explained in section 1.7, DOE is currently preparing site-wide environmental impact statements (EIS)s covering continued operations for some of the alternative sites evaluated in this PEIS. Some of the existing activities covered by these site-specific, site-wide EISs are similar to those of the No Action alternative of this PEIS. Although the near-term analytical periods for the site-wide EIS analyses are different from those of the *Programmatic Environmental Impact Statement for Stockpile Stewardship and Management*, which is focused on long-term activities, the preparation of these documents has been closely reviewed and coordinated. As work on these site-wide EISs proceeds, their analyses will continue to be reviewed to ensure consistency. To the

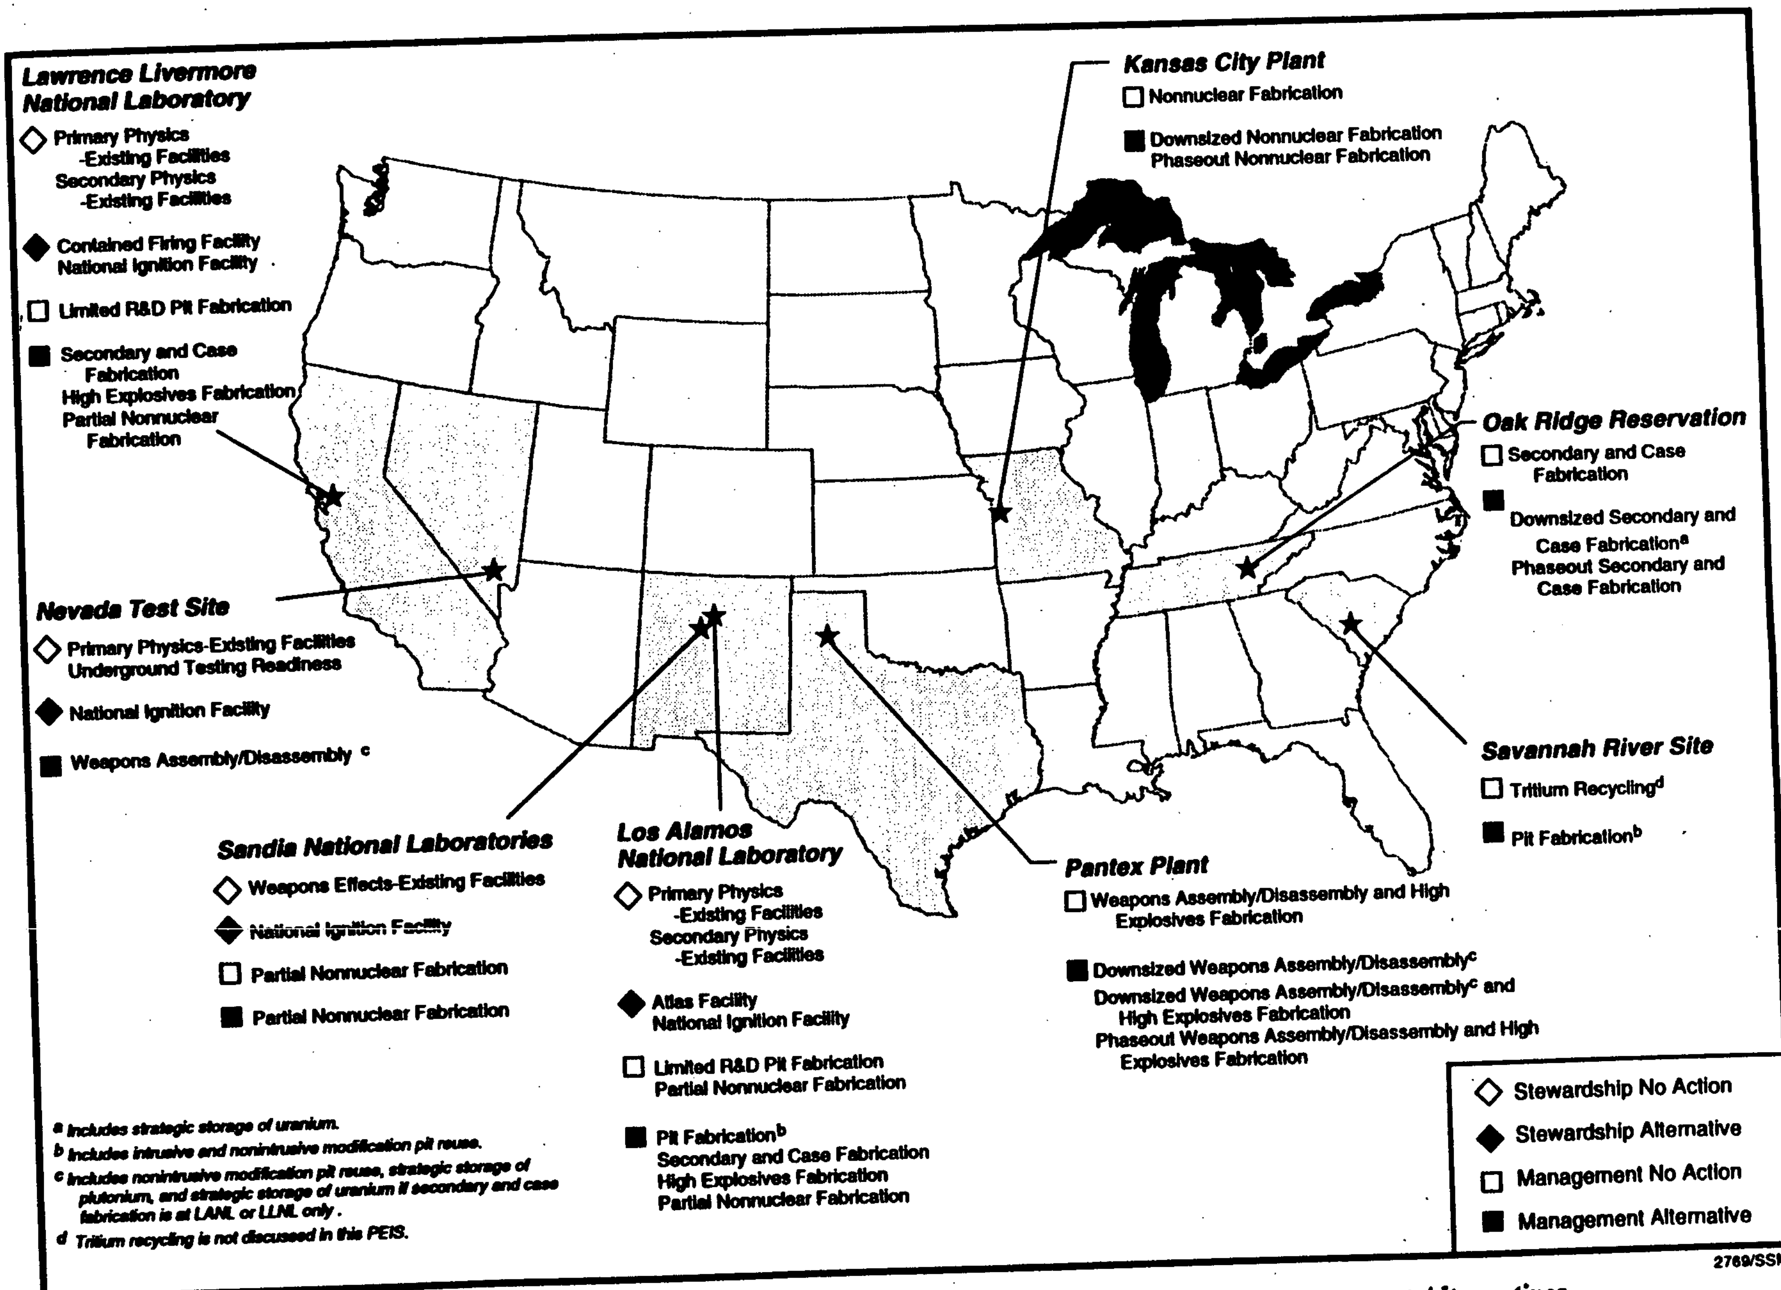

FIGURE 3.1–1.—*Nuclear Weapons Complex Sites and Stockpile Stewardship and Management Alternatives.*

extent that the site-wide EIS analyses provide better information, such information has been incorporated, as appropriate. In the preparation of the Stockpile Stewardship and Management Final PEIS, any updated information relating to the sites' affected environment was reviewed and appropriate changes were made if new information could potentially change results of the impact analyses.

DOE has developed several planning assumptions as the basis of analyses presented in this PEIS. These considerations are summarized below.

3.1.1.1 *No Action Alternative Assumptions*

- The No Action alternative for this PEIS is defined in a way that takes into account the fact that DOE for decades has had in place a program for the stewardship and management of the nuclear weapons stockpile. Consistent with CEQ guidance, the No Action alternative consists of those facilities necessary to maintain the status quo in terms of DOE's current program direction. These consist primarily of existing facilities where DOE currently conducts weapons activities, including modifications to those facilities necessary to maintain their current mission capabilities. However, the No Action alternative also includes a small number of minor new facilities that will also be needed simply to maintain current mission capabilities at individual sites. Finally, the No Action alternative includes two major new facilities which are proceeding independent of this PEIS, and for which DOE has prepared separate EISs under the interim action provisions of the CEQ regulations. These EISs are the Programmatic Environmental Impact Statement for Tritium Supply and Recycling (DOE/EIS-0161) and the EIS for the Dual Axis Radiographic Hydrodynamic Test (DARHT) Facility (DOE/EIS-0228).

3.1.1.2 *Stockpile Management Assumptions*

- Base case stockpile size for the PEIS analysis is consistent with the Strategic Arms Reduction Talks (START) II protocol, but larger than 3,500 weapons. This PEIS also analyzes a high and a low case stockpile size to determine how the environmental impacts may change due to changes in the stockpile size. The high case consists of maintaining the stockpile at a level consistent with the START I Treaty, but larger than 6,000 weapons. The hypothetical low case is a stockpile of approximately 1,000 weapons.

- Analysis is provided for facilities that would be sized to support estimated average annual manufacturing requirements resulting from the base case stockpile size assuming single-shift operation, 5 days per week. This PEIS analyzes environmental impacts of the base case quantitatively, including an evaluation of three-shift operation, 5 days per week (surge operation), to provide a bounding analysis. For stockpile management, this PEIS assesses alternatives that would downsize or modify existing facilities. With the exception of one nonnuclear facility at Sandia National Laboratories (SNL) and the expansion of the Device Assembly Facility at Nevada Test Site (NTS), there would be no greenfield construction of new facilities for any of the stockpile management alternatives. Existing facilities that would be downsized or modified have inherent differences in capacities when operated in the base case three-shift surge mode. For a given stockpile management mission, the downsize alternatives generally have a greater inherent capacity than other alternatives. For the downsize alternatives, therefore, a portion of the environmental impacts are due to the higher output associated with the three-shift surge mode of operation.

- This PEIS also qualitatively assesses each stockpile management alternative against identical low and high case single-shift workloads. Differences in environmental impacts for these single-shift workloads are attributable primarily to inherent differences in the existing facility and support infrastructure of the different sites.

- The facility sizing assumptions for the various stockpile management facilities,

TABLE 3.1.1.2–1.—***Stockpile Management Facility Sizing Assumptions (Annual Activity on Single Operating Shift)***

Function	Low Case	Base Case	High Case
Weapons Assembly/Disassembly			
Rebuilds			
(disassemblies)	50	150	300
(assemblies)	50	150	300
Evaluation			
(disassemblies)	120	120	140
(rebuilds)	110	110	140
High Explosives Fabrication	50	150	300
Nonnuclear Fabrication			
Field and factory retrofits	up to 100	up to 300	up to 600
Nuclear Fabrication			
Pit fabrication	50[a]	50[a]	100
Pit reuse (nonintrusive modification)	50	100	200
Secondary and case fabrication	50[a]	50[a]	100

[a] Capability based capacity - the facility capacity (up to 50 per year) inherent with the facilities and equipment required to manufacture one component for any stockpile system.

Source: DOE 1996j.

based on the above assumptions, are shown in table 3.1.1.2–1.

- Impacts from construction, including modifying existing structures, and operation are evaluated. The period of construction or downsizing for each alternative varies; however, for analytical purposes, this PEIS assumes that operations would begin in 2005. A 25-year lifetime was evaluated for operations.

- Proven technologies are presented in this PEIS as a baseline for the various management alternatives. Section 3.5 discusses emerging technologies that have the potential to offer even greater environmental advantages. The design goal of all facilities includes consideration of waste minimization and pollution prevention to minimize facility and equipment contamination, and to make the future decontamination and decommissioning (D&D) of facilities as simple and inexpensive as possible. This PEIS includes a general discussion of environmental impacts from D&D, including a discussion of the D&D process, the types of actions associated with D&D, and the general types of impacts associated with D&D. Any discussion of specific impacts would be too speculative because the extent of contamination, the degree of decontamination, and the environmental impacts associated with performing D&D cannot be known without performing a detailed study of the facility. Such analyses are more appropriate for tiered project-specific *National Environmental Policy Act* (NEPA) documents.

- Designs of facilities for the fabrication of nuclear components include provisions for handling and storing working inventories of nuclear materials. For plutonium, working inventories would be stored at Savannah River Site (SRS) or Los Alamos National Laboratory (LANL). For highly enriched uranium (HEU), working inventories would be stored at Oak Ridge Reservation (ORR), LANL, or Lawrence Livermore National Laboratory (LLNL).

- For plutonium, strategic reserve storage is evaluated at the Pantex Plant (Pantex) and NTS. For HEU, strategic reserve storage is evaluated at ORR, Pantex, and NTS. For the purposes of this PEIS, DOE does not intend to move the strategic reserves of HEU to Pantex or NTS if

ORR is chosen as the secondary and case fabrication site.

- This PEIS contains an analysis of low-consequence/high-probability accidents (evaluation basis) and high-consequence/low-probability accidents (beyond evaluation basis). A spectrum of both types of accidents is analyzed. For radiological accidents, impacts are evaluated both for the general population residing within an 80-kilometer (km) (50-mile [mi]) radius (including the maximally exposed individual) and for noninvolved workers in collocated facilities. The accident analyses in this PEIS are based upon facility conditions that are expected to exist in 2005. In some cases, facility conditions in 2005 may differ from current facility conditions due to design upgrades.

In developing alternatives for pit components, the following additional assumptions were used for new pit fabrication and intrusive modification pit reuse:

- Plutonium would not be introduced into a site that does not currently have a plutonium infrastructure because of the high cost of new plutonium facilities and the complexity of introducing plutonium operations into sites without current plutonium capabilities.

- The plutonium research and development (R&D) mission and functions would remain at LANL and LLNL, and the plutonium pit surveillance mission would remain at LANL. Both sites would store the materials required to support these missions.

In developing alternatives for secondaries and cases, the following additional assumptions were used:

- HEU would not be introduced into a site that does not currently have an infrastructure because of a desire to use suitable existing structures where possible and because of the high cost of new facilities.

- The uranium R&D mission and functions would remain at LANL and LLNL. If the Y-12 Plant (Y-12) at ORR is selected to retain the secondary and case fabrication mission, these R&D missions would be undertaken in partnership with Y-12. These sites would store the materials required to support this mission.

3.1.1.3 *Stockpile Stewardship Assumptions*

- The range of stockpile sizes used for analysis of manufacturing capacity-related issues for stockpile management functions is not applicable to stockpile stewardship functions. As explained in chapter 2, national security policies require all the historical stockpile stewardship and management capabilities to be maintained. Capabilities are independent of stockpile size. Stockpile stewardship functions are basic capabilities. For the same reason it is not reasonable to assume a "zero level" stockpile for the foreseeable future (sections 2.2.1 and 3.1.2), it is also not reasonable to assume the United States would eliminate the basic capabilities it needs to maintain a safe and reliable stockpile within the same foreseeable future.

- National security policy requires a safe and reliable stockpile without further nuclear testing and with an aggressive pursuit of enhanced experimental capabilities (section 2.5.1). Three stockpile stewardship facilities are proposed in this PEIS: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. These facilities are analyzed as supplements to the facilities and capabilities that currently exist for carrying out the stockpile stewardship mission. Each proposed facility is an independent component of the overall stockpile stewardship program, each has unique value, and, therefore, these proposed facilities are not competing alternatives.

- Assumptions, regarding accident analyses are the same as described under stockpile management.

3.1.2 Alternatives Considered but Eliminated from Detailed Study and Related Issues

This section of the PEIS has been revised in response to comments received on the Draft PEIS concerning its scope and the alternatives considered. To begin, it is important to review the basic logic used in constructing this PEIS and to restate the nature of the decisions expected to be made based on the contents of the PEIS.

Chapter 2 describes the national security policy framework that defines the purpose and need for DOE's nuclear weapons mission for the foreseeable future. It also describes the development of proposed actions and reasonable alternatives in response to recent changes in national security policy. Chapter 2 also puts those changes in broad technical perspective. Successive levels of technical detail are provided in chapters 3 and 4, and in Volumes II and III. The discussions that follow refer to the appropriate sections of this PEIS to avoid unnecessary repetition.

As stated in the Notice of Intent (60 FR 31291) published on June 14, 1995, DOE intends that the ROD on this PEIS will:

- Identify the future missions of the Stockpile Stewardship and Management Program; and
- Determine the configuration (facility locations) of the Complex necessary to accomplish the Program missions

While the terms "stockpile stewardship" and "stockpile management" are relatively new, the Program is not new when considered in terms of its substructure capabilities (section 1.1). What the terms are meant to convey is a change in Program focus away from large-scale development and production of new-design nuclear weapons with nuclear testing, to one that focuses on the safety and reliability of a smaller, aging stockpile without nuclear testing. Even with this change in focus, however, national security policies require DOE to maintain the capabilities of the ongoing Program. The proposed actions flow logically from the mission purpose and need, given the policy constraints placed on the Program. Enhanced experimental capability is proposed because it is the surrogate source of experimental data that are needed to continually assess and certify a safe and reliable stockpile constrained by the absence of nuclear testing. Rightsizing manufacturing capacities is proposed in direct response to the reduced requirements of a smaller, aging stockpile constrained by the absence of new-design weapon production. Reestablishing pit manufacturing capability is proposed because it restores a required capability of the Program that was temporarily lost as a consequence of the closure of the Rocky Flats Plant.

In developing this PEIS, DOE judged the above three proposed actions to be significant at the programmatic level. Some additional strategies of the Stockpile Stewardship and Management Program, such as enhanced computational capability, were judged not to have significance for this PEIS because they did not have the potential for significant environmental impacts relative to the ongoing Program at a site, nor was the mission capability being considered for transfer to another site. The programmatic level environmental impacts of the ongoing Program at each of the eight sites in the Complex are described in chapter 4. Projects and facilities to support the ongoing Program are subject to site-specific NEPA review.

The issue of Stockpile Stewardship and Management Program alternatives is complex because nuclear weapons require a complete integrated set of technical capabilities and an appropriately sized manufacturing capacity. The technical capabilities are generally characterized as research, design, development, and testing; reliability assessment and certification; and manufacturing and surveillance operations (section 2.2 and figure 2.7–2). From a technical point of view, none of these capabilities can be deleted if DOE is to maintain a safe and reliable stockpile (section 2.4). In addition, DOE has been directed to maintain these capabilities by national security policy from the President and Congress (section 2.4).

3.1.2.1 *Alternatives in General*

Commentors questioned the different treatment of stewardship and management alternatives, mainly the lack of stewardship alternatives. Stewardship and management alternatives are treated differently in the PEIS because they address fundamentally different problems. Stockpile stewardship capabilities form the basis of U.S. judgments about the safety, reliability, and performance of U.S. nuclear weapons, and in a larger context, U.S. judgments about the nuclear weapons capabilities of others (section 2.4.1). DOE did not consider it reasonable to propose stewardship alternatives that would diminish stewardship capabilities, particularly given the fact that historic confidence in the safety and performance of the stockpile was derived from nuclear testing that is no longer part of the ongoing stewardship program. National security policy requires DOE to maintain, and in some areas enhance, the stewardship capabilities of the three weapons laboratories and NTS (section 2.2). The PEIS also explains the basis for this in a technical context, including the need for two independent nuclear design laboratories (section 2.4.1). Therefore, this PEIS has no proposed actions that transfer ongoing stockpile stewardship missions from one site to another, or that would otherwise diminish ongoing stewardship missions.

National security policy also requires DOE to maintain stockpile management capabilities and appropriate manufacturing capacity for a smaller stockpile. Unlike stockpile stewardship capabilities, the smaller stockpile does permit some reasonable siting alternatives for stockpile management capabilities and capacities to accomplish the mission purpose and need within the current national security policy framework (section 2.4.2).

3.1.2.2 *Enhanced Experimental Capability*

DOE has considered that there are differing opinions on the technical merit of DOE's proposed actions with regard to enhanced experimental capability. Nuclear weapons design information, including the complex physics of nuclear weapon explosions, is classified for reasons of national security and nonproliferation. Even if this information were unclassified, the physics problems remain daunting; hence, the reason why nuclear testing was so important to the past program. Both the classification of information and technical complexity of the issues form natural barriers to public communication. The technical complexity alone engenders significant debate among qualified experts, especially in the area of high energy density physics. This PEIS attempts to explain the weapon physics issues in an unclassified, comprehensible manner regarding its relation to mission purpose and need (chapter 2), proposed actions and alternatives (section 3.3), and project-specific technical detail (Volume III). In the absence of nuclear testing, there are two basic alternatives: (1) rely on existing facilities as sources of experimental data described by the No Action alternative, and (2) pursue the enhanced capability of the proposed facilities to provide the sources of experimental data needed.

Role of Existing Experimental Facilities. In DOE's technical judgment, the existing facilities described by the No Action alternative are inadequate to meet the challenge of assessing and certifying a safe and reliable stockpile over the longer term. It is also DOE's technical judgment that it is impossible to speculate at this time whether any of the existing facilities could be retired, because they would be obsolete or redundant, as a result of a decision to construct and operate any or all of the three proposed new stewardship facilities. The uncertainties inherent in the R&D nature of the stewardship program would make that kind of exercise essentially guesswork. The development of machines to simulate the intricacies of a nuclear detonation requires a highly sophisticated scientific R&D program. It very likely will take 5 to 10 years to begin obtaining reliable data from the new facilities. Until those facilities are operational, DOE cannot reliably predict how the additional capabilities they provide will mesh with the capabilities of previously existing machines to further the goals of the Program. It is only through incremental advances in the state of the science that decisions can eventually be made regarding the retirement of obsolete or redundant facilities.

DOE is committed to making maximum efficient use of the stewardship capabilities at its disposal. However, it is not reasonable to speculate at this time about how future stewardship requirements might affect existing facilities and capabilities.

Next Generation Experimental Facilities. Commentors suggested that potential next generation experimental facilities be analyzed as part of the proposed action. This PEIS includes a discussion of potential next-generation experimental facilities and the reasons why they are not proposed actions or alternatives (sections 2.5 and 3.3.4). These facilities, while contemplated on the basis of anticipated technical need, have not reached the stage of design maturity through R&D for DOE to include a decisionmaking analysis at this time. However, this PEIS does broadly describe, in general terms or by reference, what is known today about their potential environmental impacts. The environmental impacts from these facilities as contemplated today would not be significantly different from existing "similar" facilities. By characterizing the potential impacts in this way, the decision-maker will be aware of the potential program-level cumulative impacts of the next-generation facilities when deciding whether to pursue a program of enhanced experimental capability. If DOE proposes to construct and operate such facilities in the future, appropriate NEPA review will be performed.

New Weapon Design. Commentors have suggested that the proposal for enhanced experimental capabilities is directed more at the capability to design new weapons in the absence of nuclear testing than at maintaining the safety and reliability of the existing stockpile and that stewardship alternatives could be different if the facilities were directed only at maintaining the existing stockpile. This PEIS explains why these capabilities are needed to maintain the safety and reliability of a smaller, aging stockpile in the absence of nuclear testing (chapter 2). The existing U.S. stockpile of nuclear weapons is highly engineered and technically sophisticated in its design for safety, reliability, and performance. The stewardship capabilities required to make technical judgments about the existing stockpile are likewise technically sophisticated; therefore, it would be unreasonable to say that these stewardship capabilities could not be applied to the design of new weapons, albeit with less confidence than if new weapons could be nuclear tested.

However, the development of new weapon designs requires integrated nuclear testing such as occurs in nuclear explosive tests. Short of nuclear testing, no single stockpile stewardship activity, nor any combination of activities, could confirm that a new-design weapon would work. In fact, a key effect of a "zero-yield" CTBT would be to prevent the confident development of new-design weapons. National security policy requires DOE to maintain the capability to design and develop new weapons, and it will be a national security policy decision to use or not use that capability. Choosing not to use enhanced experimental capability for new weapons designs would not change the technical issues for the existing stockpile and, therefore, the stewardship alternatives would not change.

The issue of new-design weapons is separate from DOE's need to perform modifications to existing weapons that require research, design, development, and testing. The phrase used in this PEIS, "without the development and production of new-design weapons," is meant to convey the fact that the historical continuous cycle of large scale development and production of new weapons designs replacing older weapon designs has been halted. For example, during the 1980s, about a dozen new-design weapons were in full-scale development or production. Over the decade, production of new-design weapons replaced dismantled weapons nearly one for one. Today, only modifications to parts of existing weapons are being performed or planned; dismantlement has continued. This results in a smaller, aging stockpile that must be assessed and certified without nuclear testing. This is now the primary focus of the stewardship program.

Nonproliferation. Commentors have suggested that enhanced experimental capability is a proliferation risk. The national security policy framework discussed in this PEIS seeks a new balance between U.S. arms control and nonproliferation objectives and U.S. national security requirements for nuclear deterrence while pursuing these objectives (section 2.2). In addition, a discussion is provided on some of the more difficult issues that must be considered in determining the balance, including a discussion of experimental capability (section 2.6). In particular, the issue of nonproliferation and the proposed NIF was studied in detail. The study, prepared by the DOE Office of Arms Control and Nonproliferation, has been the subject of extensive public involvement, interagency review, and review by outside experts. The study concluded that the technical proliferation concerns of NIF are manageable and can therefore be made acceptable and that NIF can contribute positively to U.S. arms control and nonproliferation policy goals (appendix section I.2.1 of Volume III). NIF is a proliferation concern because of its broader scientific applications and expected frequent use by researchers worldwide, and, like the other proposed enhanced experimental facilities because of its possible relevance to the development of new weapon designs. However, the development of new weapon designs requires integrated testing. None of the proposed facilities, either alone or together, could perform such integrated testing of new concepts, and therefore cannot replace nuclear testing for the development of new weapon designs. The role of these facilities will be to help assess and certify the safety and reliability of the nuclear weapons remaining in the stockpile in the absence of nuclear testing. The national security policy framework and the technical issues that drive the proposed action for enhanced experimental capability remain the same.

Subcritical Experiments. With regard to the treatment of ongoing stewardship activities or enhanced experimental capability, subcritical experiments are an example of how changes in terminology have caused some confusion about what is evaluated in this PEIS under the No Action alternative. Subcritical experiments have been conducted at NTS over many years. Historically, operations at NTS have included tests or experiments that included both HE and special nuclear materials that were intended to produce no nuclear yield or negligible nuclear energy releases. These experiments frequently remained subcritical (i.e., they did not achieve self-sustaining fission chain reactions). The term "subcritical experiments" does not define a new form of activity or mission. It is intended to underscore the fact that in the future such experiments will be configured to ensure that the condition of criticality cannot be achieved. This issue has been clarified in the NTS Site-Wide EIS.

3.1.2.3 *Safe and Reliable Stockpile*

Some commentors have suggested that nuclear weapon reliability is not important in the post-Cold War era. National security policy as established by the President and Congress requires a safe and reliable stockpile. In order for the nuclear deterrent to be credible within the current national security policy framework, it must be reliable in a militarily effective way. A program designed to ensure the safety but not the reliability of the stockpile would require DOE to speculate on an alternate concept of nuclear deterrence and a national security policy framework to support it. See also the discussion of denuclearization in section 3.1.2.4.

Commentors have also suggested acceptance of lower standards of reliability as an alternative to enhanced stewardship capabilities. This PEIS explains how the assessment and certification of nuclear performance is carried out, and how this process differs from the more conventional statistical methods used for assessing reliability of the nonnuclear portion of the weapon. Assessment and certification of nuclear performance is a technical judgment by the weapons laboratories based on scientific theory, experimental data, and computational modeling (sections 2.4.1 and 2.3). The question is not whether to accept a lower standard of nuclear performance (less nuclear explosive yield), but whether or not there is a technical basis to confidently know how well the weapon will perform at all. Enhanced stewardship capability is focused on the technical ability to confidently judge nuclear safety and performance in the absence of nuclear testing.

Aside from being inconsistent with national security policy, attempting to separate weapon safety and reliability is more technically complex than it sounds. A modern nuclear weapon is highly integrated in its design for safety, reliability, and performance. It contains electrical energy sources and many explosive energy sources in addition to the main charge HE. The principal safety concern is accidental detonation of the HE causing dispersal of radioactive materials (plutonium and uranium). Modern weapons are designed and system-engineered to provide a predictable response in accident environments (e.g., fire, crush, or drop). However, because of the technical complexity of potential accident scenarios (i.e., combined environments) and the fact that complete nuclear weapons cannot be used for experimental data, assessment of the design and the effect of changes that might be occurring due to stockpile environments must rely on other sources of experimental data and complex computer modeling. Enhanced experimental capability specifically related to the weapon secondary is a nuclear performance concern. Enhanced computational capability in general, and enhanced experimental capability related to the weapon primary in particular, are both nuclear safety and performance concerns.

3.1.2.4 *Description of Alternative Approaches*

Commentors have suggested that DOE consider alternative forms of stewardship. While their comments are responded to in Volume IV, this section discusses DOE's consideration of the broad range of views on this issue. The Congressional Research Service report, *Nuclear Weapons Stockpile Stewardship: Alternatives for Congress*, December 14, 1995, provides a reasonable description of the various viewpoints on alternatives and a framework for discussion. (The report uses the term stockpile stewardship generically to describe the Stockpile Stewardship and Management Program.) The following discussion of alternative approaches is taken from the summary of that report.

> **Denuclearizers** would eliminate nuclear weapons worldwide in the foreseeable future, perhaps one to two decades. Until then, they would have a minimal U.S. stewardship program whose personnel, as curators of weapons knowledge, would monitor weapons. **Restorers** would maintain nuclear weapons with the only proven method, an ongoing program of research, development, design, testing, and

production, downsized to meet post-Cold War needs. Three intermediate positions seek to maintain weapons indefinitely without nuclear testing. **Remanufacturers** believe that since current weapons have been tested and certified as meeting military requirements, this Nation can maintain them indefinitely by "remanufacturing"—reproducing them to the exact specifications of the originals. Remanufacturers would go to great lengths to do so in order to avoid risks that even slight changes to warheads might introduce. **Enhancers**, who take the Administration's position on stewardship, see identical remanufacture as impossible. They believe some changes in design, process, and materials are unavoidable and others are desirable. A robust science program, they hold, is the best that can be done without testing to monitor warheads, anticipate problems, modify warheads when problems arise, and revalidate stockpile effectiveness on an ongoing basis. They would have a small manufacturing program. **Maintainers** fall between remanufacturers and enhancers. They focus on how to maintain warheads. They prefer to avoid changes to warheads but would not go to great lengths to do so. They view a strong science program as essential, but only to the extent that its elements connect directly to maintaining weapons. They emphasize manufacturing as the ultimate guarantor of U.S. ability to solve warhead problems. They, along with enhancers, favor some link to testing if confidence cannot be maintained in any other way.

Beyond the broad overview of alternative approaches to stockpile stewardship and management, the main text of the report discusses variations within each of the five points of view. Given the political and technical complexity of the Program, many approaches can appear to be distinct or reasonable alternatives for detailed study. In fact, while the enhancer's viewpoint as described above most closely resembles the Program described in this PEIS, the Program actually embraces elements of all five viewpoints. The following discussion illustrates this point and focuses on the main issue(s) that, in DOE's view, eliminate the other approaches as distinct or reasonable alternatives for this PEIS.

Denuclearization. This approach is reflected in this PEIS to the extent that national security policy is pointed toward the goals of denuclearization. Since the end of the Cold War, more than 8,000 U.S. nuclear weapons have been dismantled, no new-design weapons are being produced, three former nuclear weapons industrial plants have been closed, and the United States is observing a nuclear test moratorium and seeking a "zero-yield" CTBT. Maintenance of a safe and reliable stockpile is not inconsistent with working toward the NPT goal of eliminating nuclear weapons worldwide at some unspecified time in the future. However, denuclearization is not a reasonable alternative for this PEIS because it is not feasible based on current national security policy.

The main issue discussed in this section is consideration of an alternative with a very small (10s or 100s) or zero stockpile. Two of the stockpile sizes analyzed in this PEIS, a START I Treaty- and START II protocol-sized stockpile, are the only ones currently defined and directed by national security policy. The PEIS also analyzes a hypothetical 1,000 weapon stockpile for the purpose of a sensitivity analysis for manufacturing capacity decisions. The NWSM specifies the types of weapons and quantities of each weapon type by year (section 1.1). The NWSM is developed based on DOD force structure requirements necessary to maintain nuclear deterrence and comply with existing arms control treaties while pursuing further arms control reductions. This PEIS explains the complexity of this process and why DOE does not believe it reasonable to speculate using a large number of arbitrary assumptions (section 2.2). DOE has considered that a future national security policy framework could define a path to a smaller stockpile. However, DOE has the following perspective on this issue.

Stockpile stewardship capabilities are currently viewed by the United States as a means to further U.S. nonproliferation objectives in seeking a "zero-yield" CTBT. Likewise, it would be reasonable to assume that U.S. confidence in its stewardship capabilities would remain as important, if not more important, in future arms control negotiations to reduce its stockpile further. The path to a very small (10s or 100s) or zero stockpile would require the negotiation of complex international treaties, most likely with provisions that require intrusive international verification inspections of nuclear weapons related facilities. Therefore, DOE believes it reasonable to assume that complex treaty negotiations, when coupled with complex implementation provisions, would likely stretch over several decades. On a gradual path to a very small or zero stockpile, stockpile size alone would not change the purpose and need, proposed actions, and alternatives in this PEIS as they relate to stewardship capabilities. The issues of maintaining the core competencies of the United States in nuclear weapons, and the technical problems of a smaller, aging stockpile in the absence of nuclear testing, remain the same.

On a gradual path to a very small or zero stockpile, this PEIS evaluates reasonable approaches to stockpile management capability and capacity. At some point on this path, further downsizing of existing industrial plants or the alternative of consolidating manufacturing functions at stewardship sites would become more attractive as manufacturing capacity becomes a less important consideration. However, in the near term, the preferred alternative of downsizing the existing industrial plants would still be a reasonable action because the projected downsizing investment pays back within a few years through reduced operating expense; in addition, the downsizing actions are consistent with potential future decisions regarding plant closures. In regard to the proposed action of reestablishing pit manufacturing capability, DOE does not propose to establish higher manufacturing capacities than are inherent in the reestablishment of the basic manufacturing capability. In developing the criteria for reasonable stockpile management alternatives, DOE was careful not to propose the introduction of significant new types of environmental hazards to any prospective site. On a gradual path to a very small or zero stockpile, stockpile size alone would not change the purpose and need, proposed actions, and alternatives in this PEIS with regard to stockpile management capabilities and capacities.

To achieve eventual denuclearization, some commentors have asserted that DOE should adopt a passive curatorship approach to maintaining the declining nuclear weapons stockpile. The concept of curatorship is already being implemented at the existing sites in the form of knowledge preservation programs. While not necessary in an era of continuous development and production of new-design weapons and nuclear testing, knowledge preservation is now part of DOE's overall effort to maintain core competency in the weapons complex. However, as an inherently imperfect reconstruction, this effort can never ensure completeness of information nor relevance to future stockpile problems. More importantly, knowledge preservation does not address the fundamental issue of confidence in future technical judgments about issues that are yet to arise regarding the safety and performance of the stockpile. In highly technical matters, confidence arises from having appropriate data to support conclusions. In the absence of nuclear testing, the science-based approach to stockpile stewardship is focused on achieving the capability to acquire appropriate data.

From an environmental impact point of view, this PEIS displays the environmental impacts of each site's ongoing Program operations on an annual basis. The impacts of alternatives for proposed actions are displayed individually on the same basis. If one assumes that denuclearization leads to eventual site closure, then this PEIS, together with the Tritium Supply and Recycling PEIS, presents the environmental impacts of closing the four remaining industrial plants. While this PEIS does not directly consider the closure of the weapons laboratories and NTS, it is not at all clear what nuclear weapons capabilities the U.S. would retain even if it decided on a zero stockpile. However, the environmental impacts of the ongoing Program (No Action alternative) are essentially what would be phased out, with or without the proposed actions. DOE does not believe that speculative combinations of this data on speculative time lines provides any useful information for decisionmaking.

Restoration. The restorer's point of view is reflected in this PEIS to the extent that current national security policy requires DOE to maintain all the historical capabilities of the Program, including the capability for new-design weapons and nuclear testing. However, restoration is not a reasonable alternative for this PEIS because it requires a national security policy decision to reverse the constraints placed on the Program, namely, by resuming nuclear testing and new-design weapons production.

The environmental impacts of the restoration approach would be the same as those described in this PEIS to the extent that such a decision did not require manufacturing capacities higher than analyzed in this PEIS. In addition, this PEIS includes a brief description of the environmental impacts of nuclear testing (section 4.12); the Site-Wide EIS for NTS contains detailed information.

Remanufacturing. The remanufacturer's point of view is reflected in this PEIS by the fact that remanufacturing to specification will be attempted when possible and when appropriate to the problem being solved. With more than a half dozen different weapon types projected to remain in the stockpile, and with each weapon type containing thousands of parts, remanufacturing will undoubtedly occur for a significant number of repair and replacement activities. However, remanufacturing is not reasonable as a distinct exclusive alternative to the ongoing stockpile stewardship program or the proposed action of enhanced experimental capability for the technical reasons discussed below. In addition, it would not be a reasonable alternative because it does not fully support national security policies that require the conduct of a science-based stockpile stewardship and maintenance of the capability to design and produce new weapons.

Remanufacturing weapon components to their original specification, or maintaining weapons to their original design specifications, would superficially appear to be a reasonable approach to maintaining the safety and reliability of the stockpile in the absence of nuclear testing. Precise replication, however, is often not possible. Subtle changes in materials, processing, and fabrication techniques are an ever-present problem. In some cases, specialty materials and components become unavailable for commercial or environmental reasons. Implicit in the remanufacturing assumption is that the design blueprint, manufacturing process, and the materials used are specified in exact detail in every way. However, there is an unwritten element of "know how" that knowledgeable and experienced personnel contribute to any complicated manufacturing process (for this reason, controlling the acquisition of "know-how" is a major nuclear weapons nonproliferation objective). Materials and processes are not always specified in important ways because, at the time, they were not known to be important. The problem is illustrated by the following hypothetical example:

A material produced for a critical weld has a specification for a trace impurity; the manufacturing process consistently produced the material with a trace impurity less than the maximum allowed and the welds were satisfactory; the manufacturing process is changed for some reason, such as cost or environmental concerns; the material is now being produced with less trace impurity than before the process was changed; the material is still within specification; however, the welds are no longer satisfactory; it was unknown at the time that the higher level of the trace impurity was necessary to produce a satisfactory weld.

While remanufacturing sounds simple in principle, it is likely in fact to present complex issues of design, manufacturing process, and material variables. A simplified view of remanufacturing cannot serve as a "stand alone" manufacturing approach, let alone an alternative approach to enhanced stewardship capability. In the absence of underground nuclear testing, nuclear components (pits and secondaries) cannot be functionally tested. Stewardship capabilities provide the analytical tools (experimental and computational) to assess the significance of a problem observed during surveillance and to decide if the problem should be fixed; and if fixed, to certify that the fix will work (section 2.4.1). In the past, the decision to fix or not fix an observed problem could be made with nuclear testing (section 2.3). Stockpile stewardship strategies focus on the basic material science and the enhanced experimental and computational tools necessary to better predict age-related defects and to make sound technical judgments on nuclear safety and performance in the absence of nuclear testing.

The DARHT EIS (DOE/EIS-0228, section 2.3.2) provides an additional discussion of the limitations of a remanufacturing-to-specification approach. It discusses, as an example, the actions taken to evaluate and resolve unanticipated deterioration of HE in the now-retired W68 warhead for a submarine-launched ballistic missile. In that case it was necessary to replace the HE with a more chemically stable formulation. In addition, some other materials were no longer commercially available, requiring changes in the rebuilt weapons. Nuclear testing was ultimately used to verify that the necessary changes were acceptable. DOE does not consider it feasible to maintain all potentially obsolescent commercial sources and processes used for materials in existing weapons; aging would still occur in stored reserves of such materials.

With regard to stockpile management, remanufacturing without enhanced stewardship capability would also have notable drawbacks. DOE plans to maintain the capability to produce secondaries, and proposes to reestablish the capability to produce pits, by producing small quantities (10s) of each annually to maintain capability. This capacity should be sufficient to replace components attrited from the stockpile by surveillance testing. Remanufacturing these components, without the enhanced stewardship analytical capability to determine if and when replacement is necessary, is likely to require higher levels of production than DOE believes necessary to maintain production capability. Also, remanufacturing a nuclear component to the original specifications will not prevent age-related problems related to those specifications from recurring. Since these components use plutonium and uranium, radiation exposure to personnel and generation of radioactive waste would also be higher than necessary. If repeated remanufacturing were required, further unnecessary risks would result from additional weapon assembly/disassembly (A/D) operations and additional transport of nuclear components between sites.

From an environmental impact point of view, the remanufacturing concept would have greater impacts for the proposed action of reestablishing pit capability because DOE proposes to use a cleaner, less waste-generating process than was used at the Rocky Flats Plant. All other environmental impacts would not be distinguishable from those described in this PEIS because existing manufacturing processes form the Program baseline.

Maintenance. The maintainer's point of view is reflected in this PEIS to the extent that it is consistent with the No Action alternative. Under this approach, weapons maintenance would be the focus of stockpile stewardship. This approach would rely on enhanced surveillance and dual revalidation, whereby the weapons laboratories would conduct independent technical examinations of weapons to validate their safety and reliability. Any problems that arose would be solved through either remanufacture or "fixes" proposed by the weapons laboratories. These attributes are all part of the ongoing Program that will continue into the future. The principal difference between the Program as presented in this PEIS and this point of view is differing judgment on how much enhanced experimental capability would be needed to assess and certify a safe and reliable stockpile over the long term. The maintainers believe that less (or no) additional experimental capability would be required if DOE placed more emphasis on enhanced surveillance and dual revalidation.

DOE believes that this approach would not provide a sufficient basis for assessing and certifying the safety and reliability of the stockpile. Although enhanced surveillance will play an important role in the future of the Program, it serves a limited purpose. Surveillance activities identify stockpile problems through the examination and analysis of weapons sampled from the stockpile. An enhanced surveillance program would serve to identify problems with greater confidence and increased warning time. However, it would not provide a sole basis for assessing the significance of the problem or determining its solution. The ability of the laboratories to validate that the problem has been corrected, in the absence of nuclear testing, depends on their experimental and computational capabilities. In DOE's judgment, as explained in section 2.4, those capabilities are inadequate. Therefore, to the extent that maintenance would not provide sufficient enhanced experimental capability, it is not a reasonable alternative.

From an environmental impact point of view, the maintenance concept is not distinguishable from the impacts of the No Action alternative for stockpile stewardship and the proposed actions for stockpile management.

3.1.3 Underground Nuclear Testing

The last underground nuclear test conducted by the United States was in 1992. Since then, the United States has observed a moratorium on underground nuclear testing while pursuing a CTBT. On August 11, 1995, the President announced that, "one of my Administration's highest priorities is to negotiate a Comprehensive Test Ban Treaty to reduce the danger posed by nuclear weapons proliferation." In this announcement, the President also stated that he would seek a "zero yield" CTBT, which would "ban any nuclear weapon test explosion or any other nuclear explosion immediately upon entry into force." The President declared his commitment "to do everything possible to conclude the Comprehensive Test Ban Treaty negotiations as soon as possible so that a treaty can be signed next year."

As part of this announcement, the President also stated that he had been assured "that we can meet the challenge of maintaining our nuclear deterrent under a Comprehensive Test Ban Treaty through a science-based stockpile stewardship program without nuclear testing." However, the President cautioned that "while I am optimistic that the stockpile stewardship program will be successful, as President, I cannot dismiss the possibility, however unlikely, that the program will fall short of its objectives." The President went on to say further: "In the event that I were informed by the Secretary of Defense and Secretary of Energy ... that a high level of confidence in the safety or reliability of a nuclear weapons type which the Secretaries consider to be critical to our nuclear deterrent could no longer be certified, I would be prepared, in consultation with Congress, to exercise our 'supreme national interests' rights under the Comprehensive Test Ban Treaty in order to conduct whatever testing might be required."

One of the primary purposes of the Stockpile Stewardship and Management PEIS is to evaluate ways of maintaining a continued safe and reliable nuclear deterrent in the absence of nuclear testing. Thus, the proposal described in this PEIS does not include nuclear testing. However, because it is possible—although not probable—that the United States might one day exercise its "supreme national interests" rights and conduct underground nuclear testing to certify the safety and reliability of its nuclear weapons, this PEIS and the NTS Site-Wide EIS include an analysis of the environmental impacts of underground nuclear testing at NTS.

3.1.4 No Action Alternative

Under the No Action alternative, DOE would not take the actions proposed in this PEIS. Activities associated with stockpile stewardship and management would continue at the Complex sites using existing facilities, and no significant changes would occur.

With regards to stockpile stewardship, under the No Action alternative, activities at the three weapons laboratories (LANL, LLNL, and SNL) and NTS would continue using existing experimental facilities, but the proposed new experimental facilities would not be constructed. The major No Action facilities for the various stockpile stewardship functions include: the DARHT Facility and the Pulsed High Energy Machine Emitting X-Rays (PHERMEX) Facility at LANL, the Flash X-Ray (FXR) Facility at LLNL, and the Big Explosives Experimental Facility (BEEF) at NTS for studying the physics of the weapons primary; the Nova Facility at LLNL and the Pegasus II Facility at LANL for studying physics of the weapons secondary; and the Saturn and Particle Beam Fusion Accelerator (PBFA) Facilities at SNL for studying weapon effects. These facilities are more fully described in section 3.3, while the major activities at sites involved with stockpile stewardship are described in section 3.2.

Under the No Action alternative, stockpile management functions would remain at their current locations, no further rightsizing or consolidation beyond currently planned initiatives would take place, and pit manufacturing capability would not be reestablished. The major No Action facilities for the various stockpile management functions include: A/D and HE fabrication at Pantex; secondary and case fabrication at Y-12; nonnuclear fabrication facilities primarily at Kansas City Plant (KCP), with smaller capabilities at LANL and SNL; R&D plutonium fabrication capabilities at LANL and LLNL; and tritium supply and recycling facilities at SRS per the decisions in the Tritium Supply and Recycling ROD. These facilities are more fully described in section 3.4, while the major activities at sites involved with stockpile management are described in section 3.2.

From a programmatic perspective, the No Action alternative would not ensure DOE's ability to maintain core U.S. competencies in nuclear weapons in the long term while also maintaining a safe and reliable, smaller, aging U.S. stockpile. Because this is not acceptable, the No Action alternative is not considered to be reasonable. However, in accordance with the CEQ regulations, the No Action alternative is presented and assessed in this PEIS.

3.2 Alternative Sites

Eight locations (ORR, SRS, KCP, Pantex, LANL, LLNL, SNL, and NTS) are being considered as alternative sites for stockpile stewardship and management missions. All of these sites are currently performing DOE Office of the Assistant Secretary for Defense Programs (DP) activities.

3.2.1 Site Selection

One important strategy of the Stockpile Stewardship and Management Program is to maximize the use of existing infrastructure and facilities as the Complex transitions to be smaller and more efficient in the 21st century. Consequently, only those sites with existing infrastructure or facilities capable of supporting a given stockpile stewardship or stockpile management mission are considered reasonable site alternatives for detailed study in this PEIS. Sites without a technical infrastructure or facilities for a given mission would require significant new construction that would be costly and would create excessive technical risk compared to sites with existing infrastructure and facilities.

For stockpile stewardship, the three existing weapons laboratories and NTS are being considered for new or upgraded stockpile stewardship facilities. This is because the weapons testing mission and stockpile stewardship have always been primary responsibilities of the weapons laboratories and NTS, and existing facilities and capabilities can be built upon to meet the stewardship mission.

For stockpile management, all of the eight current Complex sites could be considered for one or more stockpile management functions. The three weapons laboratories and NTS have various production and manufacturing capabilities and infrastructure that could be improved upon to meet the stockpile management missions. As an example, for the A/D mission there are two reasonable site alternatives: Pantex, which currently performs this mission and has facilities that could be downsized for the future A/D mission; and NTS, which has a relatively new facility known as the Device Assembly Facility that could be upgraded and expanded to perform the A/D mission. Other sites, such as SRS or ORR, that do not have existing facilities or experience necessary to perform the A/D mission, are unreasonable options relative to the sites that have existing A/D facilities. This same logic is similarly applied for the other stockpile management missions.

3.2.2 Oak Ridge Reservation

ORR covers approximately 13,980 hectares (ha) (34,545 acres) in Oak Ridge, TN. ORR contains the Oak Ridge National Laboratory (ORNL), Y-12, and the K-25 Site (K-25). The primary focus of ORNL is on conducting basic and applied scientific research and technology development. Y-12 engages in national security activities, which are included in this PEIS. The Oak Ridge Gaseous Diffusion Plant, which has been shut down, is located at K-25. K-25 now serves as an operations center for environmental restoration and waste management programs.

Y-12 receives, processes, and provides interim storage for unirradiated enriched uranium returned from dismantled weapons and DOE sites as described in the *Environmental Assessment and Finding of No Significant Impact, Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Level at the Y-12 Plant, Oak Ridge, Tennessee* (DOE/EA-0929). The capacity of existing processing and storage facilities is sufficient to accommodate all of the forecasted amounts of enriched uranium that would be placed in interim storage. The current missions and functions are described in table 3.2.2-1.

Defense Program Activities. The ORR DP assignments are performed at Y-12 and include maintaining the capability to produce secondaries and cases for nuclear weapons, storing and processing uranium and lithium materials and parts, dismantling nuclear weapons secondaries returned from the stockpile, and providing special production support to DOE weapons laboratories and to other DOE programs. To accomplish its storage mission, some processing of special nuclear materials may be required to recover materials from the returned secondaries. In addition, Y-12 performs stockpile surveillance activities on the components it produces.

3.2.3 Savannah River Site

SRS, located on approximately 80,130 ha (198,000 acres) near Aiken, SC, was established in 1950. The major nuclear facilities at SRS have included fuel and target fabrication facilities, nuclear material production reactors, chemical separation plants used for recovery of plutonium and uranium isotopes, a uranium fuel processing area, and the Savannah River Technology Center, which provides process support. Historically, DOE has produced tritium at SRS; however, DOE has not produced new tritium since 1988. Plutonium and spent nuclear fuel processing to produce material for nuclear weapons at SRS, have been terminated. DOE is currently preparing a separate EIS to explore the use of these facilities to stabilize existing quantities of plutonium residues as well as other nuclear materials. Tritium recycling operations will continue at SRS with the Replacement Tritium Facility conducting the majority of these operations. Tritium decays and must be replaced periodically to meet weapons spec-

TABLE 3.2.2–1.—*Current Major Missions at Oak Ridge Reservation*

Mission	Description	Sponsor
Weapon Components	Maintain capability to fabricate uranium and lithium components and parts for nuclear weapons	Defense Programs (DP)
Stockpile Surveillance	Evaluation of components and subsystems returned from the stockpile	Defense Programs (DP)
Uranium and Lithium Storage	Store enriched uranium, depleted uranium, and lithium materials and parts	Defense Programs (DP)
Dismantlement	Dismantle nuclear weapon secondaries returned from the stockpile	Defense Programs (DP)
Special Nuclear Material	Process uranium	Defense Programs (DP); Nuclear Energy (NE)
Test Devices	Provide support to weapons laboratories	Defense Programs (DP)
Environmental Restoration and Waste Management	Waste management and decontamination and decommissioning activities at Oak Ridge National Laboratory and K-25	Environmental Management (EM)
Research and Development	Oak Ridge National Laboratory basic research and development in energy, health, and environment	Energy Research (ER); Environment, Safety, and Health (EH); Nuclear Energy (NE)
Isotope Production	Oak Ridge National Laboratory produces radioactive and stable isotopes not available elsewhere	Nuclear Energy (NE)

ifications. Tritium recycling facilities empty tritium from weapons reservoirs, purify it to eliminate the helium decay product, and fill replacement reservoirs with specification tritium for nuclear stockpile weapons. Filled reservoirs are delivered to Pantex for weapons assembly and directly to the Department of Defense as replacements for weapons reservoirs. As part of the previous nonnuclear consolidation, SRS is also in the process of receiving some of the tritium processing and reservoir surveillance functions previously performed at the Mound Plant in Miamisburg, OH. The current missions at SRS are shown in table 3.2.3–1.

Defense Program Activities. In the past, the SRS complex for the production of nuclear materials consisted of five reactors (the C-, K-, L-, P-, and R-Reactors) in addition to a fuel and target fabrication

TABLE 3.2.3–1.—*Current Major Missions at Savannah River Site*

Mission	Description	Sponsor
Tritium Recycling and Reservoir Surveillance	Operate H-Area tritium facilities	Defense Programs (DP)
Stockpile Surveillance	Evaluation of reservoir components returned from stockpile	Defense Programs (DP)
Research and Development	Savannah River Technology Center technical support of Defense Programs, Environmental Management, and Nuclear Energy programs	Defense Programs (DP); Environmental Management (EM); Nuclear Energy (NE)
Stabilize Targets, Spent Nuclear Fuels, and Other Nuclear Materials	Operate F- and H-Canyons	Environmental Management (EM)
Waste Management	Operate waste processing facilities	Environmental Management (EM)
Environmental Monitoring and Restoration	Operate remediation facilities	Environmental Management (EM)
Space Program Support	Provide plutonium-238 for space program missions	Nuclear Energy (NE)

plant, two target and spent nuclear fuel chemical separation plants, a tritium-target processing facility, a heavy water rework facility, and waste management facilities.

The K-Reactor, the last operational reactor, was put into cold standby status in 1992 with no planned provision for restart. SRS is now conducting tritium-recycling operations in support of stockpile requirements using dismantled weapons as the tritium supply source.

3.2.4 Kansas City Plant

KCP is situated on approximately 57 ha (141 acres) of the 121-ha (300-acre) Bannister Federal Complex, which is located within incorporated city limits 19 km (12 mi) south of the downtown center of Kansas City, MO. The plant shares the Bannister Federal Complex site with other Federal agencies: the General Services Administration, the U.S. Marine Corps, the Federal Aviation Administration, the National Archives, and the Internal Revenue Service, among others.

KCP produces and procures nonnuclear electrical, electronic, electromechanical, mechanical, plastic, and nonfissionable metal components for the nuclear weapons program. Current missions at KCP are shown in table 3.2.4–1.

Defense Program Activities. KCP is currently the principal nonnuclear fabrication facility within the Complex. As such, KCP produces a variety of nonnuclear components and provides surveillance testing and repair services for these components.

3.2.5 Pantex Plant

Pantex is located about 27 km (17 mi) northeast of Amarillo, TX, on approximately 4,119 ha (10,177 acres) of DOE-owned land. Pantex missions are the fabrication of chemical HE for nuclear weapons, assembly, disassembly, maintenance, and surveillance of nuclear weapons in the stockpile, dismantlement of nuclear weapons being retired from the stockpile, and interim storage of plutonium components from dismantled weapons. Weapons activities involve the handling (but not processing) of uranium, plutonium, and tritium components, as well as a variety of nonradioactive hazardous or toxic chemicals. The current Pantex missions and functions are listed in table 3.2.5–1.

In the near term, weapons dismantlement and plutonium pit storage activities will dominate activities at Pantex. Although analysis in the *Environmental Assessment for Interim Storage of Plutonium Components* (DOE/EA-0812) found that Pantex has a sufficient number of storage magazines to safely accommodate 20,000 pits, Pantex only has authority to provide interim storage for up to 12,000 pits as described in a Finding of No Significant Impact (59 FR 3674) on January 26, 1994. Decisions regarding additional pit storage beyond 12,000 pits are being

TABLE 3.2.4–1.—*Current Major Missions at Kansas City Plant*

Mission	Description	Sponsor
Nonnuclear Component Fabrication	Manufacture electrical, electronic, electromechanical, plastic, and metallic components; fuzing and firing systems; and composite structures	Defense Programs (DP)
Telemetry Assembly	Manufacture telemetry assemblies and neutron detectors for flight test assemblies	Defense Programs (DP)
Test Equipment Design and Fabrication	Manufacture test equipment capable of performing electrical and mechanical tests on nonnuclear weapon components	Defense Programs (DP)
Stockpile Surveillance	Evaluation of components and subsystems returned from stockpile	Defense Programs (DP)

considered in the *Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (DOE/EIS-0225).

Defense Program Activities. The main mission of Pantex is the A/D of nuclear weapons. Other than HE, virtually all other components of the weapons come from other DOE or DOD sites. Modification, maintenance, and repair activity at Pantex involves the disassembly of nuclear weapons so that one or more of the components can be repaired, replaced, or modified. After replacing components, the weapons are reassembled and returned to the stockpile. Pantex surveillance activities involve weapon disassembly, laboratory testing of various components, and rebuilding weapons for shipment back to the stockpile. Production of HE components includes processing and machining main charge subassemblies and fabrication of mock components for use in weapon test assemblies, manufacturing small HE components, producing a variety of explosive materials from chemical reactants and commercially produced explosives, and evaluating explosive materials and components through a variety of analytical, mechanical, and explosive tests. Retired weapon dismantlement is the predominant current activity at Pantex. Weapons are returned from DOD, disassembled, and components are either destroyed, reclaimed, or returned to the original manufacturer. The exception is plutonium pits, which are stored onsite on an interim basis.

3.2.6 Los Alamos National Laboratory

LANL was established as a nuclear weapons design laboratory in 1943 and was formerly known as the Los Alamos Scientific Laboratory. Its facilities are located on about 11,300 ha (28,000 acres) about 40 km (25 mi) northwest of Santa Fe, NM.

LANL is a multidisiciplinary research facility engaged in a variety of programs for DOE and other Government agencies. Its primary mission is the nuclear weapons Stockpile Stewardship and Management Program and related emergency response, arms control, and nonproliferation and environmental activities. It conducts R&D activities in the basic sciences, mathematics, and computing with applications to these mission areas and to a broad range of programs including: nonnuclear defense; nuclear and nonnuclear energy; atmospheric, space, and geosciences; bioscience and biotechnology; and the environment. Table 3.2.6–1 illustrates current missions at LANL. A more detailed discussion of the complete spectrum of laboratory activities can be found in the current LANL Institutional Plan, which is unclassified and available to the public.

In regard to nuclear weapons, LANL is responsible for the design of the nuclear explosive package in certain U.S. weapons (LLNL has this responsibility for other weapons.) LANL maintains research, design, development, testing (including nuclear testing), surveillance, assessment, and certification capabilities in

support of the Stockpile Stewardship and Management Program. In addition, since the end of the Cold War, LANL now conducts the pit surveillance program and some manufacturing of nonnuclear components due to termination of the nuclear weapons mission at the Mound, Pinellas, and Rocky Flats Plants.

3.2.7 Lawrence Livermore National Laboratory

LLNL was established as a nuclear weapons design laboratory in 1952 and was formerly known as the Lawrence Radiation Laboratory. Its facilities are located on about 332 ha (821 acres) in Livermore, CA. A 2,800-ha (7,000-acre) auxiliary testing range known as Site 300 is located about 29 km (18 mi) east of the Livermore Site. Site 300 is used primarily for HE testing and other experimentation, such as particle beam research.

LLNL is a multidisiciplinary research facility engaged in a variety of programs for DOE and other Government agencies. Its primary mission is the nuclear weapons stewardship program and related emergency response, arms control, and nonproliferation activities. It conducts research and development activities in the basic sciences, mathematics, and computing, with applications to these mission areas and to a broad range of programs including: nonnuclear defense; nuclear and nonnuclear energy; atmospheric, space, and geosciences; bioscience and biotechnology; and the environment. Table 3.2.7–1 illustrates current missions at LLNL. A more detailed discussion of the complete spectrum of laboratory activities can be found in the current LLNL Institutional Plan which is unclassified and available to the public. In regard to nuclear weapons, LLNL is responsible for the design of the nuclear explosive package in certain U.S. weapons (LANL has this responsibility for other weapons). LLNL maintains research, design, development, testing (including nuclear testing), surveillance, assessment, and certification capabilities in support of the Stockpile Stewardship and Management Program.

3.2.8 Sandia National Laboratories

SNL was established as a nuclear weapons design laboratory in 1945. Its facilities are in three locations in the continental United States: Albuquerque, NM; Livermore, CA; and Tonopah, NV. The facilities discussed in this document refer only to the main Albuquerque site, which is located on about 1,150 ha (2,842 acres) of DOE property on Kirtland Air Force Base and an additional 6,072 ha (15,003 acres) provided to DOE through ingrant land from Kirtland Air Force Base, the State of New Mexico, and Isleta Pueblo.

SNL is a multidisiciplinary research and engineering facility engaged in a variety of programs for DOE and other Government agencies. Its primary mission is the nuclear weapons Stewardship and Management Program and related emergency, arms control, and nonproliferation activities. In addition, it conducts R&D activities in advanced manufacturing, electronics, information, pulsed power, energy, environment, transportation, and biomedical technologies. Table 3.2.8–1

illustrates current missions at SNL. A more detailed discussion of the complete spectrum of laboratory activities can be found in the current SNL Institutional Plan, which is unclassified and available to the public.

In regard to nuclear weapons, SNL is responsible for the design of nonnuclear components and related system engineering. It maintains research, design, development, testing (including nuclear testing), surveillance, assessment, and certification capabilities in support of the Program. In addition, because of the end of the Cold War, SNL now performs some nonnuclear manufacturing functions due to termination of the nuclear weapons mission at the Mound and Pinellas Plants.

3.2.9 Nevada Test Site

NTS occupies approximately 351,000 ha (867,000 acres) in the southeastern part of Nye County in southern Nevada. NTS is located about 104 km (65 mi) northwest of Las Vegas. It is a remote, secure facility that maintains the capability for conducting underground testing of nuclear weapons and evaluating the effects of nuclear weapons on military communications systems, electronics, satellites, sensors, and other materials. The first nuclear test at NTS was conducted in January 1951. Since the signing of the Threshold Test Ban Treaty in 1974, it has been the only U.S. site used for nuclear weapons testing. Approximately one-third of the land (located in the eastern and northwestern portions of the site) has been used for nuclear weapons testing, one-third (located in the western portion of the site) has been reserved for future missions, and one-third has been reserved for R&D and other facility requirements. Facilities include nuclear device assembly, diagnostic canister assembly, hazardous liquid spill, and the radioactive waste management site. In addition, Yucca Mountain, an area on the southwestern boundary of the site, is being evaluated by DOE for siting of a spent nuclear fuel and high-level waste (HLW) repository. While the primary purpose of Yucca Mountain

is for commercial HLW, it is also slated to receive some defense HLW.

Activities at NTS are concentrated in several general areas. Most of the onsite work is related to DP activities, although there are DOE Office of Environmental Management (EM), other DOE, and non-DOE activities as well. NTS is a unique facility because it is a large open area into which access is tightly controlled, it has a substantial infrastructure, and it has the capability to handle and run tests with hazardous or radioactive materials. Because of these factors, activities other than nuclear testing, such as mobile missile transporter tests and nuclear rocket tests, have been carried out for other Federal departments and agencies. The current missions and functions of NTS are shown in table 3.2.9–1.

Defense Program Activities. The primary DP mission at NTS is to help ensure the safety and reliability of the Nation's nuclear weapons stockpile. This stewardship program includes maintaining the readiness and capability to conduct underground nuclear weapons tests and conducting such tests if so directed by the President. Other aspects of stockpile stewardship also include conventional HE tests, dynamic experiments, and hydrodynamic testing. The Nuclear Emergency Search Team based at NTS maintains the readiness to respond to any type of nuclear emergency, including search and identification for lost or stolen weapons, and training exercises related to nuclear bomb and radiation dispersal threats.

NTS has also been a key site for past efforts in the areas of nuclear nonproliferation and verification of international treaties. This work was exemplified recently by the Joint Treaty Verification Project, a cooperative effort between the United States and the former Soviet Union.

North Las Vegas Facility. Located on a 32-ha (80-acre) site in the city of North Las Vegas, NV, the North Las Vegas Facility supports the DOE Nevada Operations Office and LLNL, LANL, and SNL weapons test programs and is considered an adjunct to NTS. The facility supports test prestaging activities and fabrication, assembly, and testing of field diagnostic systems that collect data from NTS weapons testing activities. This facility is being considered as an alternative location for NIF and is described more fully in appendix I.

3.3 STOCKPILE STEWARDSHIP ENHANCED EXPERIMENTAL CAPABILITY

Historically, nuclear testing has provided unambiguous high confidence in the safety and reliability of weapons in the stockpile. Without additional underground nuclear testing, DOE must rely on experimental and computational capabilities, especially in weapons physics, to predict the consequences of the complex problems that are likely to occur in an aging stockpile. Without these enhanced capabilities, DOE will lack the ability to adequately evaluate some safety and reliability issues, which could significantly affect the Nation's confidence in the stockpile. It is also possible that, without these enhanced capabili-

Work for Others	Provides for the use of NTS areas and facilities by other groups and agencies for activities such as military training exercises	DOD and various other agencies

ties, DOE could not certify the acceptability of certain weapons components repaired or modified to address future safety or reliability issues.

The physical principles involved in nuclear weapons call for a range of experimental capabilities to provide data. These capabilities differ in time and energy density (related to temperature and pressure), and they are complementary rather than duplicative, because they serve different needs. These aboveground sources of experimental data can be categorized most easily by time; that is, by the duration of the output pulse of the data. Thermonuclear processes vary in time down to the nanosecond range.[1] For example, powerful lasers do the best job of producing experimental data at the highest temperatures (millions of degrees) in the laboratory, but only for very short time intervals. Multi-nanosecond pulsed-power sources do the best job of producing very energetic pulses of x radiation in that time period, but at moderate temperatures. And microsecond pulsed-power sources and HE do the best job of providing an energetic but controlled hydrodynamic "push" in that time period for simulation and study of complex hydrodynamic phenomena.[2] The three weapons laboratories are also complementary in providing these technologies. The powerful laser capability is centered at LLNL, the nanosecond pulsed-power capability is centered at SNL, and the microsecond pulsed-power capability is centered at LANL.

As discussed in chapter 2, the historical stockpile data indicate that problems are likely to develop in the aging stockpile that will require certified repairs or replacements without nuclear testing. Thus, U.S. national security policy in pursuit of a "zero yield" CTBT calls for the aggressive pursuit of enhanced experimental capabilities to help ensure a safe and reliable stockpile without additional nuclear testing. Therefore, DOE has included the detailed project-specific analyses for the proposed facilities (NIF, CFF, and Atlas) in this PEIS. Enhanced experimental facilities considered in this PEIS are those that either require or may require budget "line item" authorization from Congress. Next generation facilities are discussed in section 3.3.4. Within the next several years, it is expected that the weapons laboratories may request DOE authorization to begin the formal Congressional budget "line item" process for these facilities. NEPA documentation would be completed as a normal part of this process.

The nuclear weapons phenomena involved in enhanced experimental capability can be broadly grouped into three categories: physics of nuclear weapons primaries, physics of nuclear weapons secondaries, and weapons effects. Table 3.3–1 depicts the proposed alternatives and facilities for enhanced experimental capability.

3.3.1 Physics of Nuclear Weapons Primaries

Primary implosion is initiated by detonating a layer of chemical HE that surrounds the plutonium pit. The HE drives the pit material into a compressed mass at the center of the primary assembly, resulting in a fission reaction. With respect to the physics phenomena from the implosion of the primary, the experimental facilities provide physics validation, material behavior information, improved understanding of the implosion, and the ability to assess age-related defects. LANL and LLNL have been conducting basic work in these areas for many years. However, in the absence of additional nuclear testing, new and improved capabilities are needed. Proposed new facilities and site alternatives under consideration, along with the existing facilities which are part of the No Action alternative, are discussed below.

3.3.1.1 *No Action*

The principal diagnostic tools DOE currently uses to study nuclear weapons primaries are hydrodynamic tests and dynamic experiments. Hydrodynamic tests examine interactions among parts of the weapons primary. Dynamic experiments explore broader issues regarding materials science. Under the No Action alternative, DOE would continue to use the hydrodynamic testing facilities currently available at LANL, LLNL, and NTS, and a new facility planned for LANL. The FXR Facility at LLNL Site 300 has been in continuous operation since 1983. The FXR Facility uses linear induction accelerator technology for high-speed radiography. DOE does not perform dynamic experiments with plutonium at LLNL because the necessary infrastructure is not in place at Site 300. The PHERMEX Facility has been in continuous operation at LANL since 1963. The PHERMEX Facility uses a radio-frequency accelerator designed

[1] Nanoseconds are billionths of a second; microseconds are millionths of a second.

[2] Under extreme temperatures and pressures, the dynamics (motion) of solids, such as metals, behave more like fluids, thus the term hydrodynamic.

[a] Proposed facilities. The Stockpile Stewardship and Management PEIS includes both a programmatic assessment and a project-specific analysis of these potential experimental facilities.

[b] Facilities used to investigate the physics of nuclear weapons secondaries may also be used to investigate some physics phenomena related to nuclear weapons primaries and weapons effects.

[c] No new facilities solely to investigate weapons effects phenomena are being proposed at this time.

for high-speed radiography at LANL. Because neither the FXR Facility nor the PHERMEX Facility is capable of providing the degree of resolution, intensity, rapid time sequencing, or three-dimensional views that are now needed to provide answers to current questions regarding weapons condition or performance, DOE has decided to construct and operate a new facility (DARHT) at LANL.

The DARHT Facility will consist of a new accelerator building with two accelerator halls to provide two perpendicular lines-of-sight, which will enable two radiographic images to be captured simultaneously or sequentially and will provide a capability to perform three-dimensional diagnostics of a simulated nuclear weapon primary. Most tests and experiments at the DARHT Facility would be conducted inside of modular steel containment vessels. In the future, DOE may perform dynamic experiments with plutonium at the DARHT Facility; these experiments would be conducted in specially designed double-walled containment vessels. DOE has analyzed the environmental impacts of this proposal; the DARHT Facility Final EIS (DOE/EIS-0228) was published in August 1995 and on October 10, 1995, DOE issued its ROD to proceed with the facility. Construction of the facility was enjoined by the U.S. District Court for the District of New Mexico on January 27, 1995, pending completion of the EIS and ROD. Following the ROD, DOE filed motion for dissolution of the injunction. On April 16, 1996, the U.S. District Court concluded that the purpose of the injunction had been satisfied, and therefore lifted the injunction and dismissed the case.

For the purposes of this PEIS, DOE includes DARHT as an existing facility at LANL because DOE has reached an independent decision to construct and operate the facility. Under all alternatives considered in this PEIS, including the No Action alternative, DOE would complete construction and operate both axes of the DARHT Facility. When DARHT becomes operational, DOE would phase out operation of the PHERMEX Facility. Modular steel containment vessels would be used at the DARHT Facility firing site to contain emissions and debris from selected hydrodynamic tests and dynamic experiments; any experiments involving plutonium would always be conducted inside a specially designed double-walled steel vessel.

Besides LANL and LLNL, NTS has some hydrodynamic testing facilities in place. In addition to its past underground nuclear testing program, DOE has conducted underground and aboveground hydrodynamic tests at NTS. For example, BEEF is used to study hydrodynamic motion associated with HE detonations; however, BEEF does not include a high resolution radiographic diagnostic capability.

3.3.1.2 *Proposed Contained Firing Facility*

As discussed previously, both LANL and LLNL are considered necessary for the continued development of the science-based stockpile stewardship program. In this regard both laboratories will continue to utilize and improve radiographic hydrodynamic test capability.

The proposed CFF would augment and upgrade the existing FXR Facility at LLNL's Site 300. The containment enclosure would provide for containment of hydrodynamic tests and reduce the environmental, safety, and health impacts of current outdoor testing. The enclosure will also improve the quality of diagnostics data derived from testing by better controlling experimental conditions. Tables 3.3.1.2–1 through 3.3.1.2–3 show CFF construction and operating requirements and waste volumes. More detailed information about CFF can be found in appendix section A.2.2 and in the project-specific analysis presented in appendix J.

3.3.2 Physics of Nuclear Weapons Secondaries

The energy released by the fission of the nuclear weapons primary activates the secondary assembly, creating a thermonuclear (fusion) explosion. The physics of nuclear weapons secondaries deals with the interaction of many dynamic physics processes, including hydrodynamics, thermodynamics, fission, and fusion. With respect to the phenomena of the physics from the thermonuclear explosion of the secondary, the experimental facilities provide improved understanding of thermonuclear ignition, secondary physics validation, and material behavior information. LANL and LLNL have been conducting basic work in these areas for many years. However, without additional nuclear testing, new and improved capabilities are needed. The proposed new facilities and site alternatives under consideration are discussed below. Some of the facilities may also be useful for investigating physics phenomena related to nuclear weapons primaries and weapons effects. The capabilities that would be provided by the proposed NIF and the Atlas Facility are independent components needed to improve the understanding of the physics of nuclear weapons secondaries. Each proposed facility responds to a different diagnostic need related to nuclear weapons secondaries and is not competing with other alternatives.

3.3.2.1 *No Action*

Few methods are currently available to study the physics of nuclear weapons secondaries. The principal facilities currently available are the Nova Facility at LLNL and the Pegasus II Facility at LANL. The Nova Facility and the Pegasus II Facility do not provide conditions sufficiently close to those in a nuclear weapon secondary to improve our understanding of these important concepts and processes. Without improvements to these capabilities, as proposed by NIF and the Atlas Facility, DOE would lack the ability to evaluate some significant nuclear performance issues, which could adversely affect confidence in the Nation's nuclear deterrent.

3.3.2.2 *Proposed National Ignition Facility*

The proposed NIF would make it possible to study radiation physics in laboratory experiments that would approach certain conditions of a thermonuclear detonation. NIF would achieve higher temperatures and pressures, albeit in a very small volume, than any other existing or proposed stockpile stewardship facility. This facility could be located at either LANL, LLNL,SNL, or NTS. Tables 3.3.2.2–1 through 3.3.2.2–3 show generic

NIF construction, operating requirements, and waste volumes. The data in these three tables reflect nonsite-specific estimates developed prior to site-specific analyses. More detailed and site-specific information about NIF can be found in the project-specific analysis presented in appendix I.

3.3.2.3 *Proposed Atlas Facility*

The proposed Atlas Facility at LANL would be used for experiments that would contribute to the development of predictive capabilities related to the aging and performance of secondaries. This facility would build on existing special equipment at LANL, SNL, or NTS. Tables 3.3.2.3–1 through 3.3.2.3–3 show Atlas Facility construction and operating requirements and waste volumes. Although principally considered as a stewardship facility for study of the physics of nuclear weapons secondaries, the proposed Atlas Facility at LANL could also be used for hydrodynamic experiments to resolve issues related to material properties, mixing and other physics aspects of weapons primaries. More detailed information about the Atlas Facility can be found in the project-specific analysis presented in appendix K.

3.3.3 Weapons Effects

One of the reasons for past underground nuclear testing has been to determine the effects of nuclear weapon radiation outputs of x rays, gamma rays, and neutrons on nuclear weapon subsystems and components. Of particular importance is the ability to certify

TABLE 3.3.2.3–2.—*Atlas Facility Annual Operation Requirements*

that crucial nuclear weapons components meet military requirements to withstand radiation. Additionally, underground nuclear testing has been used to establish, with high confidence, adherence to military requirements for nonweapons systems such as satellites. Existing facilities at SNL, such as the Saturn Facility or the PBFA Facility, provide a limited capability to investigate these effects, and would continue to operate under the No Action alternative. No alternatives for new facilities designed principally for weapons effects testing are being proposed in this PEIS.

3.3.4 Next Generation Stockpile Stewardship Facilities

The science-based stockpile stewardship program will build upon existing information and capabilities and the program is expected to continuously evolve as better information becomes available and technological advancements occur. Today, because of limitations on data and technology, only the first steps to a fully capable science-based stockpile stewardship program can be taken. Thus, DOE is only in a position to propose NIF, CFF, and Atlas Facility for decisionmaking analysis in this PEIS. These three facilities are described in detail in appendixes I, J, and K, respectively. The goal is to provide a sufficiently detailed analysis for these three facilities in this PEIS to allow for their construction and operation if the decision is made to do so.

While these three proposed facilities would provide improvements over existing capabilities, and are expected to be important components of science-based stewardship, they do not represent the entire science-based stewardship program that is envisioned for all time. The next generation of potential stockpile stewardship facilities cannot be defined to the degree necessary to perform detailed environmental impact analysis. However, these next generation facilities can be described in general terms such that a consideration of cumulative impacts that might be related to the ultimate science-based stockpile stewardship program can be qualitatively assessed. Next generation facilities anticipated for science-based stockpile stewardship are the Advanced Hydrotest Facility (AHF), the High Explosive Pulsed Power Facility (HEPPF), the Advanced Radiation Source (ARS [X-1]), and the Jupiter Facility. The following sections provide a broad description of what these three facilities might look like. Section 4.11 describes the general impacts of constructing and operating these types of facilities.

3.3.4.1 *Advanced Hydrotest Facility*

AHF would be the next generation hydrodynamic test facility following the DARHT Facility at LANL. AHF would be an improved radiographic facility that would provide for imaging on more than two axes, each with multiple time frames, though the number of axes and time frames is still subject to requirements definition and design evolution. The facility would be used to better reveal the evolution of weapon primary implosion symmetry and boost-cavity shape under normal conditions and in accident scenarios. Due to the nature of the dynamic experiments and hydrodynamic testing to be conducted with the facility, AHF would probably be considered for location at NTS and LANL only.

At this point, the feasibility and definition of an AHF is still insufficiently determined for DOE to propose such a facility. For example: performance requirements and specifications for such a facility (i.e., determination of what capabilities should be required of an AHF for assessment of stockpile aging and related effects, beyond those of the DARHT Facility) have not been fully established. In addition, the type of technology to provide the basis for the facility has not been determined, and concepts for the resultant physical plant would accordingly vary significantly. Three basic technology approaches are currently being examined. These include linear induction accelerators of a type similar to that in the baseline DARHT Facility design (DOE/EIS-0228), an inductive-adder pulsed-power technology based on technology now in use for other purposes at SNL and elsewhere, and high-energy proton accelerators similar to technology in use at LANSCE and a number of facilities in the United States and internationally. The first two are different approaches to accelerating a high-current burst of electrons, which when stopped in a dense target produce x rays for radiography. This is the approach used in the existing PHERMEX (LANL) and FXR (LLNL) Facilities, and which will be used in the DARHT Facility. The third approach would use bursts of very energetic protons, magnetic lenses, and particle detectors to produce the radiographic image. These technologies still require development and validation.

3.3.4.2 *High Explosives Pulsed Power Facility*

This facility would provide experimental capabilities for studying secondary physics at shock pressures and velocities approaching those of actual weapon conditions. Explosive pulsed power is the most economically feasible means of providing aboveground experimental capability at energies above 100 megajoules. While current explosives testing facilities can probably test explosives systems using up to 500 kilograms (kg) (1,100 pounds [lb]) of HE, future systems may require up to 3,000-kg (6,600-lb) explosive charges. Systems so large cannot be tested at current laboratory facilities; therefore, BEEF at NTS is a likely candidate site.

For some years, DOE has pursued both capacitor bank facilities and HE experiments in pulsed power. HE generators offered a means to explore higher energy (higher current) frontiers without major capital investment, albeit at a relatively low data rate, and capacitor banks offered the advantages of repeatable (and indoor) experimental facilities with higher data rates, for broad experimental use. Data from HE experiments, for example, has helped provide validation of technical issues used in the Atlas Facility design concept.

An HE pulsed-power generator, such as Procyon at LANL, is basically an assembly of HE and metal (e.g., copper) and other components which is explosively and destructively detonated a single time, resulting in a brief pulse of high electrical current being delivered to the experimental configuration. High magnetic fields result from the high current pulse and may either be directly used to study materials phenomena or may be used to produce high pressures and implosions of (typically) cylindrical shells. (See the discussion in the Atlas Facility site-specific analysis, appendix sections K.1 and K.2.1.)

As distinct from an explosive generator, a firing site is a facility typically consisting of a firing location, associated hardened bunkers, and related equipment, in an area from which personnel can be excluded. Many different HE experiments (including those in which pulsed electrical power is produced) can be performed at an HE firing site, as long as the explosive blast, and other experiment parameters, do not exceed the designed or permitted capabilities of the firing site. Currently most of the largest-scale HE pulsed-power experiments in the United States, whether for technology development or weapons stockpile stewardship, are conducted at a pulsed-power firing point at TA-39 at LANL. As noted, this experimental capability has a limit of approximately 500 kg (1,100 lb) of HE. Therefore a potential need for a new HEPPF was postulated to support generators using much larger explosive charges, which though not yet demonstrated could produce higher pressures in larger masses and volumes than can be accessed at the LANL site. Existing laboratory sites cannot readily support experiments with much larger charges.

3.3.4.3 *Advanced Radiation Source (X-1) and Jupiter Facility*

The ARS (X-1) and Jupiter Facilities would have advanced pulsed-power x-ray sources to provide enhanced experimental capabilities in the areas of weapons physics and weapon effects.

Conceptually, the ARS(X-1) Facility would be a new facility containing a pulsed-power accelerator capable of producing intense bursts of x rays and high temperature and density plasmas. ARS (X-1) would be a technological advance over the current PBFA II Facility and would provide about 8 megajoules of x-ray energy in contrast to 2 megajoules expected from PBFA II in the near term. ARS (X-1) would be an interim step to the conceptual Jupiter Facility, which limits the risk involved in developing a new facility that requires a much larger investment. Conceptually, the Jupiter Facility would provide about 32 megajoules of x-ray energy.

ARS (X-1) would be used to study the physics of radiation flow, opacities, high energy densities, the effects of radiation on weapons, and potentially, inertial confinement fusion relevant physics. Section 3.3 describes the complementary nature of experimental facilities required to perform weapon assessment and certification functions in the absence of nuclear testing. ARS (X-1) would provide greatly improved capability over the current Saturn and PBFA II Facilities with regard to higher temperatures, higher densities, and longer pulse widths in the multi-nanosecond range. ARS (X-1) would thereby add to the complement of fast pulsed power, slow pulsed power, and laser facilities needed to begin addressing the full spectrum of weapons physics and weapon-effects science in the absence of nuclear testing.

Although other stewardship sites would be considered, if ARS (X-1) were constructed at SNL, the conceptual design would use some of the pulsed-power facility infrastructure existing in Technical Area IV. Various accelerator architecture concepts are being explored which present different performance, cost, and risk options. The ARS (X-1) accelerator is conceived of as a 24-module machine which would store approximately 56 megajoules of electrical energy in capacitors. This electrical energy would be released and compressed to produce an output pulse on the order of 100 nanoseconds long. This pulse may be used to generate an intense burst of x rays and high temperature and density plasmas. Supporting facilities for the accelerator, such as storage and circulation systems for insulating oil and de-ionized water, would also be required to supplement the already present capacity used by the other major facilities collocated in Technical Area IV. About 4,645 m^2 (50,000 ft^2) of space available in Technical Area IV would be needed to construct the facility which would be operated and maintained by a staff of about 20 people.

3.4 STOCKPILE MANAGEMENT

Stockpile management activities include dismantlement, maintenance, surveillance, and repair or replacement of weapons and weapons components in the existing stockpile. In the past, a large Complex provided the capability and capacity to rapidly fix any problems found in the stockpile. One of the primary goals of stockpile management is to rightsize functions to provide an effective and efficient manufacturing capability for the smaller stockpile. The individual stockpile management functions can be grouped into five major categories: weapons A/D, nonnuclear components fabrication, pit fabrication, secondary and case fabrication, and HE fabrication. Both intrusive and nonintrusive modification pit reuse are considered inherent capabilities of pit fabrication and nonintrusive modification pit reuse is always considered to be collocated with A/D. Specific alternatives that would enable DOE to maintain its stockpile management responsibilities are shown in table 3.4–1 and are discussed below.

3.4.1 Weapons Assembly/Disassembly Alternatives

Weapons A/D provides the capability to dismantle retired weapons, assemble nuclear and nonnuclear components into nuclear weapons, perform weapons surveillance, store strategic reserves of nuclear components (pits and secondaries), and recertify and requalify pits. In addition, nonintrusive modification pit reuse capabilities would be collocated with the weapons A/D Facility.

To maintain confidence in the safety and reliability of the stockpile, DOE conducts surveillance operations on a statistically significant number of weapons annually. Surveillance operations consist primarily of disassembly and inspection of stockpile weapons

[a] Surveillance is included in all capabilities.
[b] Includes nonintrusive modification pit reuse and the option of strategic reserve storage of plutonium and HEU.
[c] KCP functions would be distributed among two or three of the laboratories.
[d] Staging and storage of working inventories of nuclear materials and components are included.
[e] Research and development capability only.
[f] Includes strategic storage of HEU reserve.

returned to DOE from DOD. Most of these weapons are rebuilt and returned to the stockpile during what is called the "protected period." Extra components are built at the end of the production run to replace components attrited by surveillance testing for a specified protected period established by DOD. When the replacement components are exhausted, the weapon is not rebuilt and the stockpile is reduced.

The nonintrusive modification pit reuse alternative would provide a capability to perform nonintrusive modification of pits for reuse in the stockpile. Nonintrusive modification is modification to the external surfaces and features of a pit. For example, to add safety features such as fire resistant cladding, there is little risk of contamination, and the generation of radioactive waste is very low.

Operation. The weapons A/D process consists of five main functions and nonintrusive modification pit reuse, which are described below.

Weapons Assembly. Weapons assembly is performed to produce a new weapon, rebuild a weapon that has been disassembled for surveillance, repair a weapon, or modify or replace components. The assembly steps for a rebuild are the same as for a new weapon, except that the starting point varies depending on the extent of disassembly.

Complete weapons assembly is accomplished in three stages: nuclear explosive package assembly, mechanical assembly, and final package assembly. Nuclear explosive package assembly entails bonding or mating HE main charge subassemblies to a pit and then enclosing this subassembly in a case along with other components such as the secondary. Mechanical weapons assembly entails placing the nuclear explosive package in a warhead or bomb case, then installing the arming, fusing and firing system; neutron generator; and gas transfer system components. Numerous quality control inspections and tests of electrical and mechanical systems are performed throughout the process. Final package assembly involves installing some additional components and packaging the weapons for shipment.

Weapons Disassembly. Weapons disassembly is similar to the reverse of the assembly process and is performed to dismantle, modify, repair, or evaluate a weapon. The operations conducted for each type of disassembly are similar, but the extent of the disassembly and the procedures used vary. Many of the facilities used for various disassembly and testing operations are the same as facilities used for weapons assembly.

Joint Test Assembly and Post-Mortem. As part of the ongoing stockpile surveillance program, weapons are randomly selected from the stockpile or from new production for conversion into a joint test assembly. The nuclear explosive package is removed and replaced with a mock assembly that includes telemetry components. After flight tests by DOD, joint test assemblies are often recovered and returned to the A/D Facility for post-mortem disassembly and evaluation.

Test Bed Assembly and Disassembly. A test bed is an apparatus used for bench testing weapons systems, subsystems, and components. Testing is generally conducted at Pantex in the Weapons Evaluation Test Laboratory operated by SNL. Test beds are disassembled at the A/D Facility after testing.

Optional Storage of Plutonium and Highly Enriched Uranium Strategic Reserve. Storage of the plutonium strategic reserve could occur at the weapons A/D Facility. If Y-12 is selected as the site for the secondary and case fabrication mission, HEU strategic reserve storage would remain at ORR. If Y-12 is not selected, then the HEU strategic reserve could also be stored at the weapons A/D Facility. The strategic reserve provides pits and secondaries which could be used for replacement in the enduring stockpile or as feedstock for nuclear fabrication. The quantities associated with strategic reserve storage are classified. If the decision is made that strategic reserves will be stored with nonstrategic reserves, then consolidated storage could occur at one of the five sites being considered in the *Storage and Disposition of Weapons Usable Fissile Materials Programmatic Environmental Impact Statement*, rather than at the weapons A/D Facility.

Nonintrusive Modification Pit Reuse. This alternative supports three major operations: pit recertification, pit requalification, and nonintrusive modification. Nonintrusive modification pit reuse includes the operations, inspections, and evaluations that are required to change design features by the addition of shells or other nonnuclear components for the incorporation of fire safety or security improvements. Pits received from strategic reserve storage or weapon disassembly for surveillance or maintenance may be used as feed stock for nonintrusive modification.

The alternatives for A/D are to continue in current facilities at Pantex with only those changes that are currently scheduled and budgeted (No Action), to downsize and consolidate facilities and operations at Pantex, or to relocate operations to NTS.

3.4.1.1 *No Action*

The No Action alternative for these activities, except nonintrusive modification pit reuse, is presently located at Pantex. Pantex dismantles retired weapons, assembles nuclear and nonnuclear components into nuclear weapons, repairs and modifies weapons, evaluates weapons, and performs nonnuclear testing of nuclear weapons. Current plutonium R&D facilities at LANL and LLNL have limited capability and capacity to perform nonintrusive modification pit reuse.

3.4.1.2 *Downsize at Pantex Plant*

This alternative would downsize and consolidate facilities and operations including strategic reserve storage at Pantex primarily into Zone 12 (figure 3.4.1.2–1), using existing modern structures. This alternative is described in more detail in appendix section A.3.1.1.

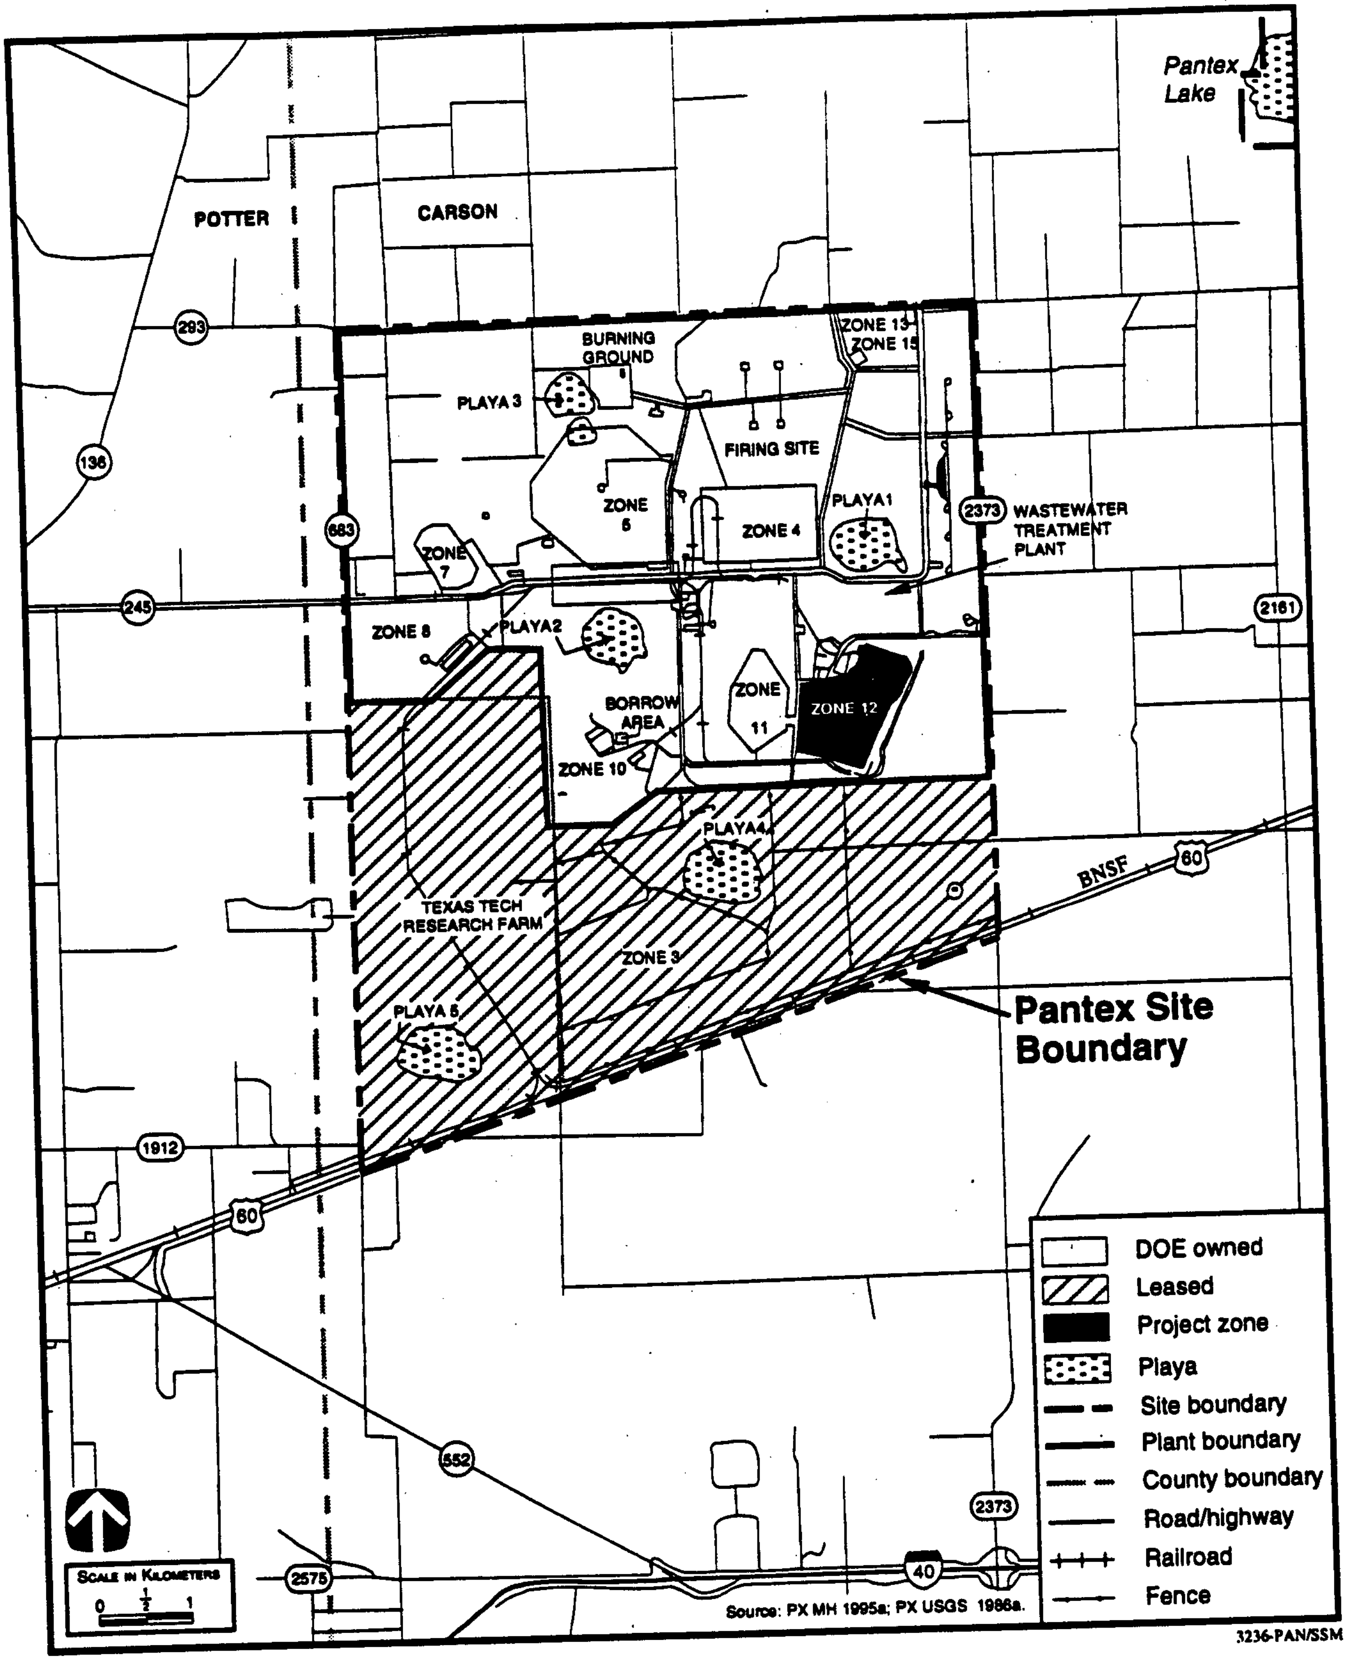
Downsizing of the A/D operation at Pantex would consist of an in-place decrease in facility footprints and relocation into modern, existing facilities, mostly within Zone 12. The facilities primarily used are cells and bays that were specifically designed and constructed for A/D operations. The consolidation of the site would not require modification of these structures, but would require relocation and installation of equipment within them. Support functions would remain within the currently established facilities, some of which are outside Zone 12. No new construction would be required at Pantex; however, relocation and reinstallation of equipment would be required.

The capabilities for nonintrusive modification pit reuse would be established in existing facilities within Zone 12. This would require modification of some of the bays to install glove boxes; redesign of the heating, ventilation, and air conditioning; and improvement of the fire detection and suppression systems. These facilities would also have the capability to support pit recertification and requalification operations.

Construction. There would be no new construction anticipated at Pantex for this alternative. The A/D mission would be consolidated primarily into Zone 12 with some supporting operations in Zones 13, 15, and 16. Figure 3.4.1.2–2 shows the weapons A/D site plan for Zone 12 and the facilities included in the proposed downsized and consolidated A/D mission at Pantex. Strategic reserve storage would be in Zone 12 for both plutonium and HEU. The nonintrusive modification pit reuse alternative would require modification of four bays in Building 12-104. The capability to perform recertification, requalification, and nonintrusive modification pit reuse activities currently exists at Pantex except for processes that are needed for pit tube replacement, welding on the pit, and inspection of internal pit surfaces. The existing capabilities would be upgraded and relocated within Building 12-116.

Building 12-116 is a new building that was constructed in accordance with the requirements for a safety class (Category 2) vault-type nuclear facility. This facility would support consolidation of the activities that involve processing of components that contain special nuclear material. Recertification, requalification, and reuse activities would use almost the entire facility.

Building 12-104 is a new building that was also constructed in accordance with the requirements for a safety class (Category 2) nuclear explosives A/D Facility. To fulfill the pit reuse mission, one module (four bays) of the building would be modified to meet nonreactor nuclear facility requirements. These requirements include improvements to the fire detection and suppression system; a capture system for fire water runoff; the addition of control, change out, and decontamination areas; security improvements to provide facility control; and complete redesign of the heating, ventilation, and air conditioning system to provide the progressive negative pressure scenario required for containment of radionuclide contamination. Three of the four bays would



3236-PAN/SSM

FIGURE 3.4.1.2–1.—*Weapons Assembly and Disassembly Zones at Pantex Plant.*

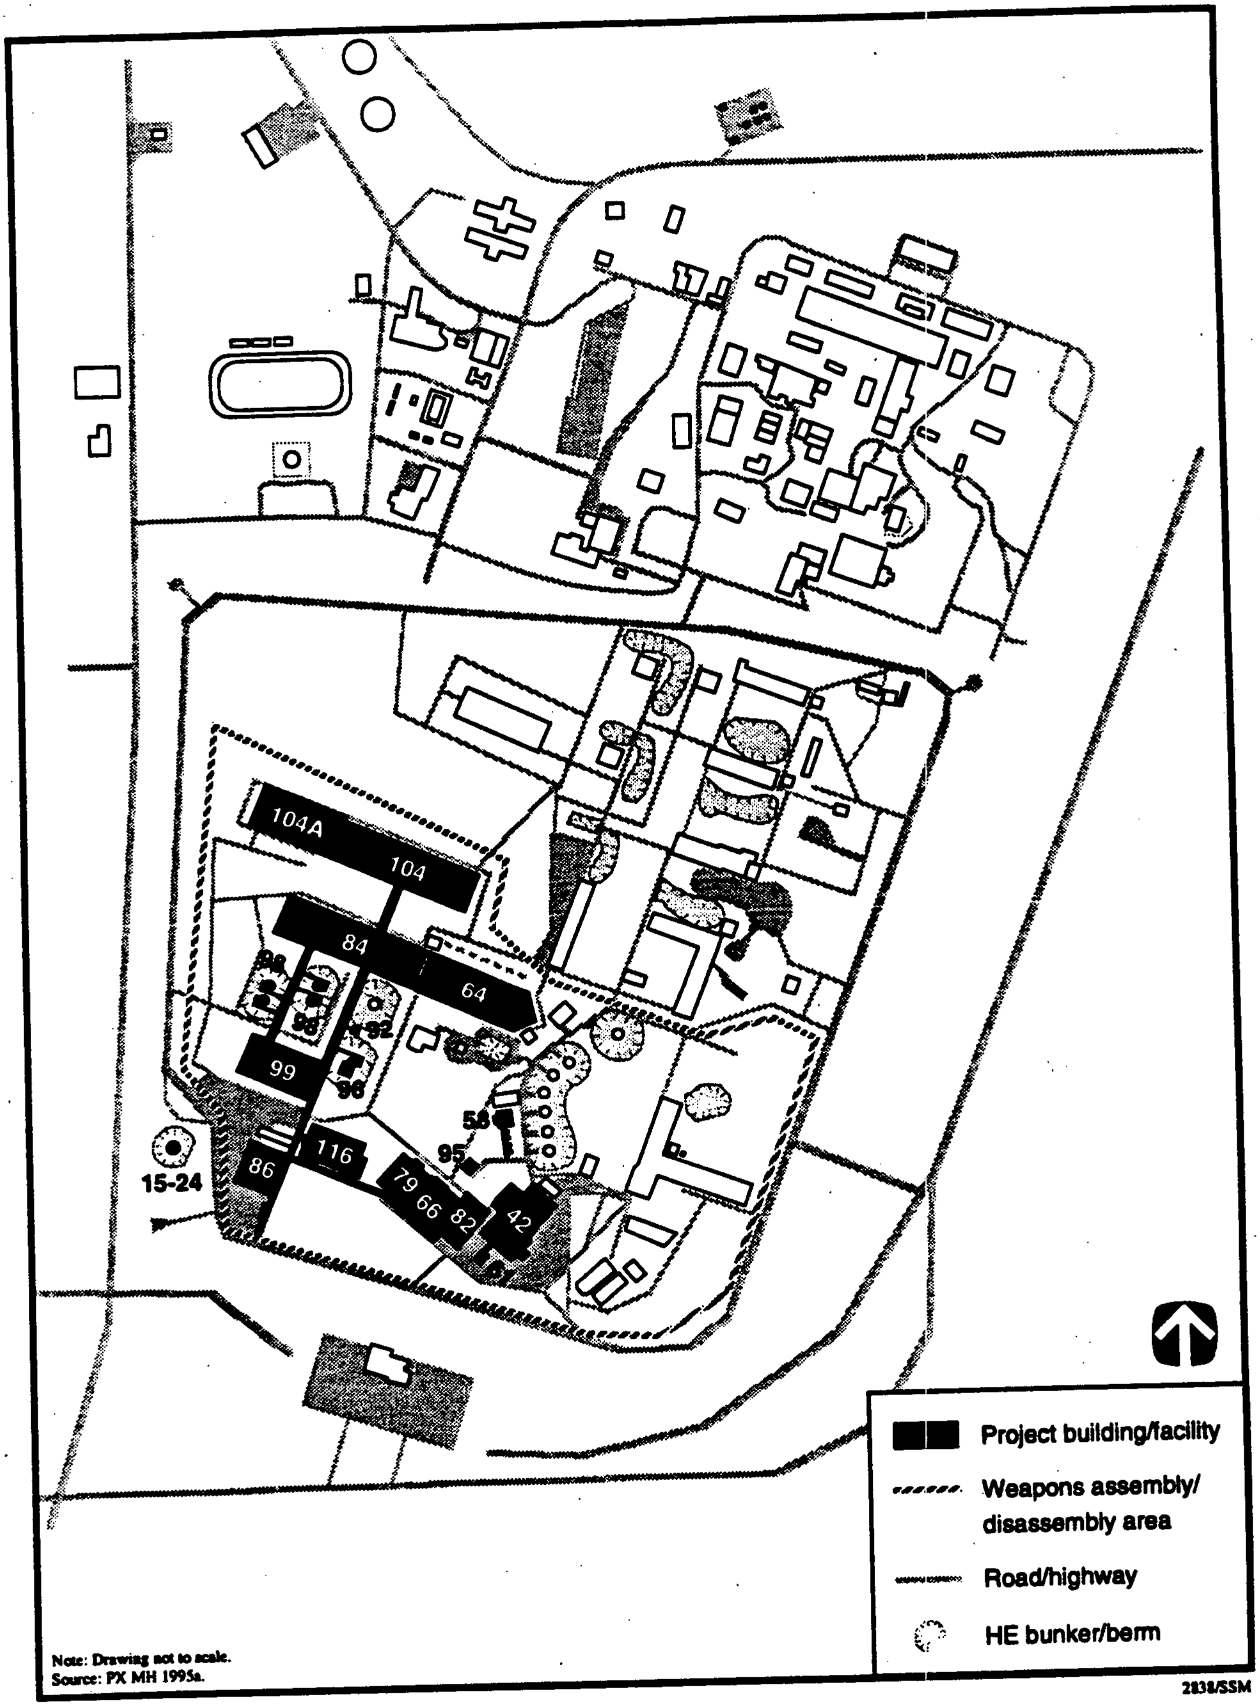


FIGURE 3.4.1.2–2.—*Weapons Assembly/Disassembly Site Plan at Pantex Plant (Zone 12).*

be fitted with pit reuse process equipment to provide the minimum capability required to support recertification, requalification, and nonintrusive modification activities. The fourth bay would be available for installation of additional equipment if workload requirements increase. The pit reuse facility would have the capability to support all recertification, requalification, and nonintrusive modification pit reuse activities. Table 3.4.1.2–1 shows building modification construction requirements for downsizing and consolidating into existing facilities.

Operation. Operation requirements for surge operation of the downsized/consolidated weapons A/D facilities are shown in table 3.4.1.2–2.

Process Support Systems. Process support systems include systems, equipment, and procedures that support the weapons A/D processes. The process support systems are described in more detail in appendix section A.3.1.1.

Waste Management. Pantex's existing waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous, radioactive, and mixed wastes generated at Pantex facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workloads would not require significant modification of the existing Pantex waste management infrastructure. Waste generation for construction and operation of the Pantex A/D alternative is shown in table 3.4.1.2–3.

3.4.1.3 *Relocate to Nevada Test Site*

This alternative is based on the use of the current Device Assembly Facility and balance of plant infrastructure available and required to maintain the capability for underground nuclear testing. The alternative is discussed in more detail in appendix section A.3.1.2. Additional new construction would be required and would be designed and sized to meet the specific needs of the reduced program and enhanced safety and environmental objectives.

Construction. This alternative would require modification of existing facilities and new construction. Nonintrusive modification pit reuse would require construction of a new pit reuse facility as an adjunct to the existing Device Assembly Facility. Equipment for the facility would be purchased or transferred from existing Complex facilities. The new facility would be classified as a nonreactor nuclear facility. Though new construction would be required, the

existing NTS infrastructure would be sufficient to support the facility.

The facility would be placed in the backfill area north of the Device Assembly Facility, with a specific location to be developed in conjunction with the A/D effort. The current Device Assembly Facility would be used for a secure shipping and receiving station with no additional construction requirements.

A site map of the proposed A/D plant is shown in figure 3.4.1.3–1. This map shows the overall plant, including associated support facilities, the plant protected area, and limited area. A site plan of the material access area is shown in figure 3.4.1.3–2. The size, number, and arrangement of the plant building and support areas are conceptual and can change as design progresses. The site plans are included to convey general layout information only.

The existing Device Assembly Facility would form the cornerstone of the A/D plant, but additional facilities to handle the workload, pit reuse, and strategic storage (if appropriate) would have to be added. All plant facilities located within the material access area either occupy existing buildings inside the Device Assembly Facility or are located in hardened new construction connected to the Device Assembly Facility. All plant facilities located within the limited area, at the plant site (adjacent to the Device Assembly Facility), would require new construction. Approximately 11 percent of this construction is needed to support the option of storing strategic reserves of nuclear components (pits and secondaries). Table 3.4.1.3–1 shows construction requirements for the NTS weapons A/D alternative.

Operation. Operating requirements for surge operation of the NTS weapons A/D Facility are shown in table 3.4.1.3–2. The water usage at NTS is somewhat lower than at Pantex since Pantex has a larger plant population and uses more water for supporting operations such as steam heat.

Waste Management. NTS's existing waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alterna-

3.4.2 Nonnuclear Fabrication Alternatives

Nonnuclear fabrication consists of the following general functions:

- Fabrication of electrical, electronic, electromechanical and mechanical components (plastics, metals, and composites), and assembly of arming, fuzing, and firing systems
- Surveillance inspection and testing of nonnuclear components

The nonnuclear components alternatives provide for the nonnuclear fabrication missions currently residing at KCP. Production requirements for nonnuclear components, in terms of factory and field retrofits to weapons, are shown in table 3.1.1.2–1.

The alternatives considered for nonnuclear fabrication included downsizing and consolidating existing facilities at KCP, or closing KCP and sharing nonnuclear fabrication functions among SNL, LANL, and/or LLNL. These alternatives are discussed below.

3.4.2.1 *No Action*

The No Action alternative facilities for these activities are presently located at KCP, SNL, and LANL. KCP manufactures nonnuclear weapons components and conducts surveillance testing on, and makes repairs to, nonnuclear weapons components. SNL conducts system engineering of nuclear weapons, designs and develops nonnuclear components, conducts field and laboratory nonnuclear testing, manufactures some nonnuclear weapons components, and provides safety and reliability assessments of the stockpile. LANL also manufactures a few nonnuclear weapons components and conducts surveillance on certain nonnuclear weapons components.

3.4.2.2 *Downsize at Kansas City Plant*

The downsized nonnuclear fabrication alternative consists of three major factories designed around electronic, mechanical, and engineered materials product lines; procuring some components from outside sources; and reducing the KCP footprint for DP activities to 167,000 square meters (m^2) (1.8 million square feet [ft^2]) from the current

297,000 m^2 (3.2 million ft^2). This alternative is discussed in more detail in appendix section A.3.6.1.

Construction. This alternative consists of downsizing and consolidating existing facilities and would require facility modification but no new construction. Currently, KCP occupies approximately 297,000 m^2 (3.2 million ft^2) contained in three buildings: the Main Manufacturing Building, the Manufacturing Support Building, and the Technology Transfer Center (figure 3.4.2.2–1). The downsized and consolidated KCP would reduce the size of the plant to approximately 167,000 m^2 (1.8 million ft^2) for DP activities. The Technology Transfer Center and Manufacturing Support Building facilities would be totally vacated of DP activities. All operations and support functions required for the nonnuclear fabrication mission would be accomplished within the reduced floor space of the Main Manufacturing Building. Vacated floor space would be returned to the General Services Administration or retained for Work for Others use, if appropriate. The downsized KCP facility would consist of the following major factories and product-oriented departments: Electronics Factory, Mechanical Factory, Engineered Materials Factory, Joint Test Assembly and Special Electronic Assembly Department, Reservoir Fabrication and Assembly Department, and Transportation Safeguards Department.

Facilities modification to establish the downsized and consolidated KCP configuration would take approximately 4 years. During this time, major interior building modification would occur. Table 3.4.2.2–1 shows construction requirements for the KCP nonnuclear fabrication alternative.

Operation. The operation of the downsized and consolidated KCP is based on current KCP facilities and missions, downsized and reorganized for efficiency into several modules and product departments.

Electronics Factory. Existing separate departments for electronics products would be combined into the electronics factory and would be designed around three common process modules: microelectronics, interconnects, and final assembly.

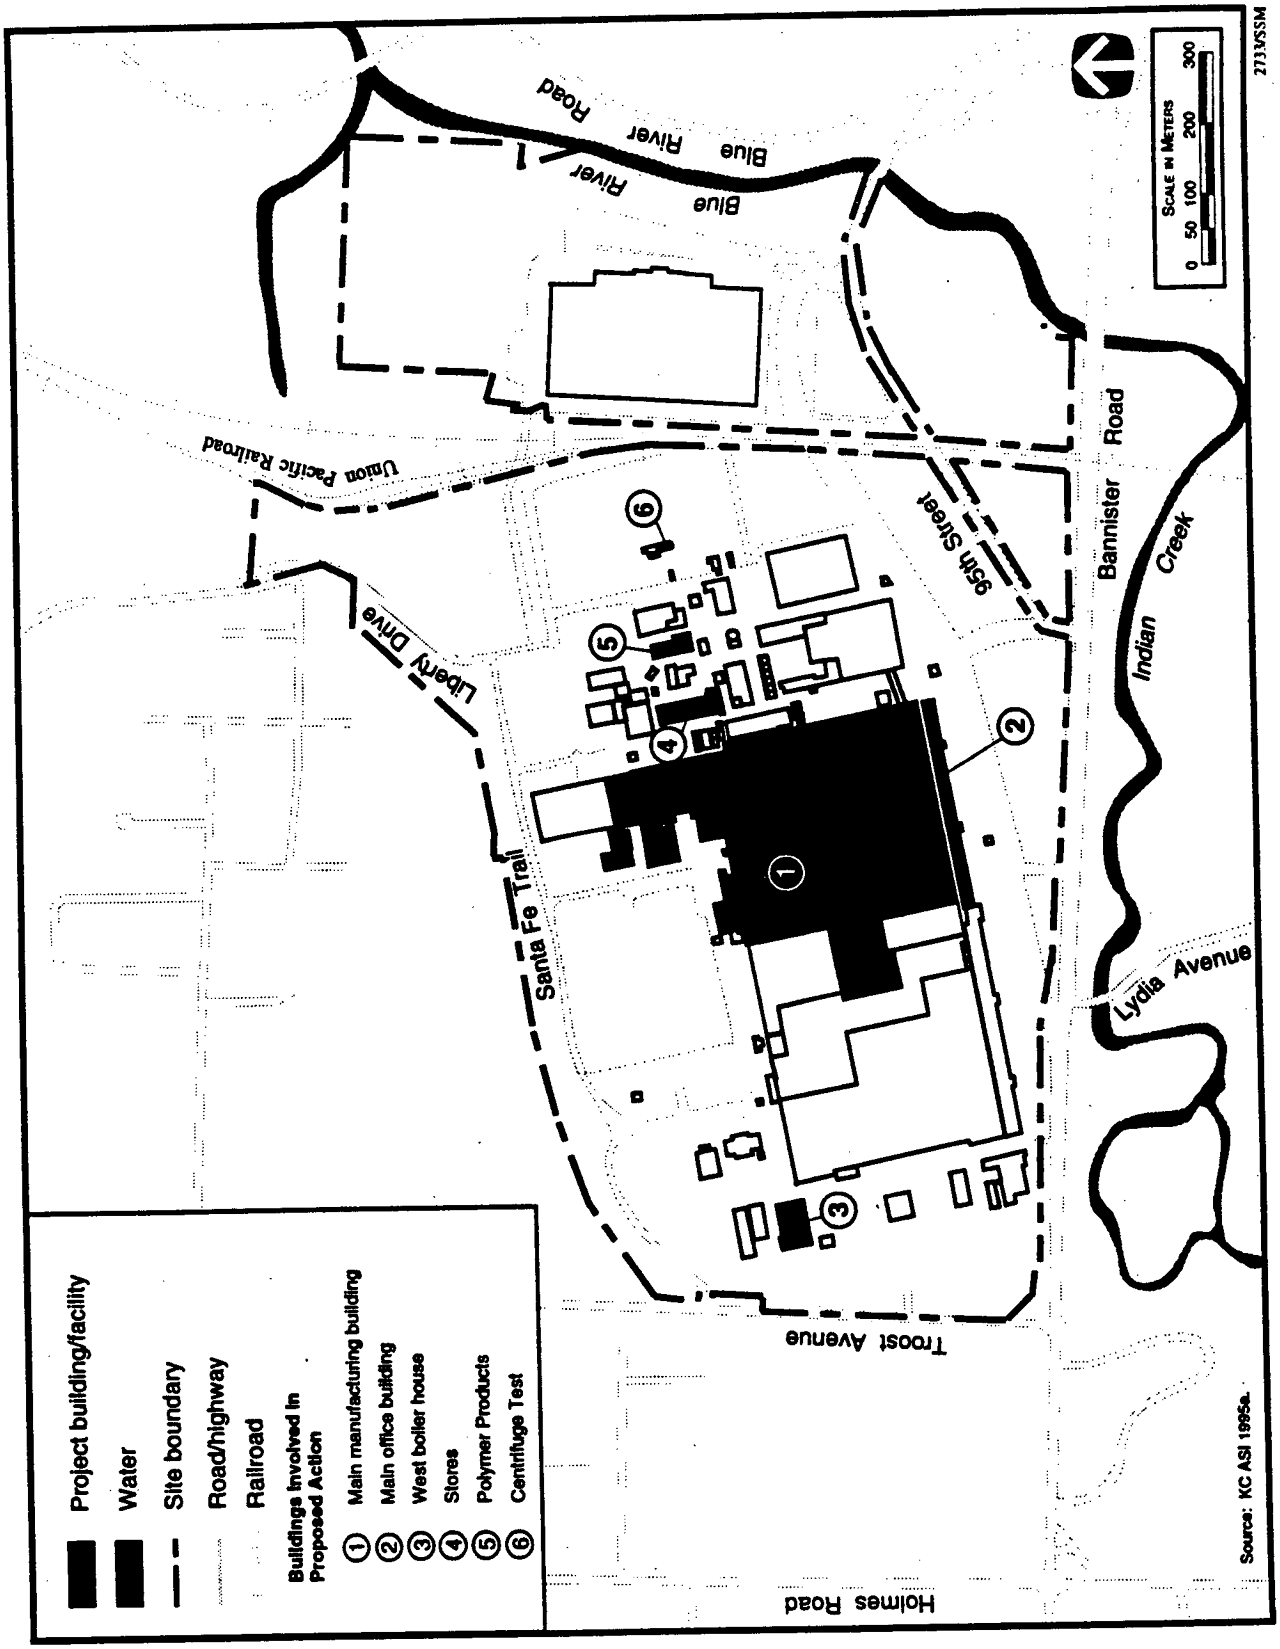

FIGURE 3.4.2.2–1.—*Location of Downsized Nonnuclear Fabrication Facilities at the Bannister Federal Complex/Kansas City Plant.*

Source: KC ASI 1995a.

Mechanical Factory. KCP has already implemented a process-based approach for most mechanical technologies. The alternative would achieve substantial downsizing in processing areas to maximize efficiency and cost savings. The mechanical factory would be organized around three process modules: mechanical assembly, mechanical welding, and sheet metal and special processing.

Engineered Materials Factory. This factory would manufacture products that depend on special materials (foams, polymers, and composites) for unique performance or functional characteristics. These products include cushions, desiccants, getters, and composite cases. The engineered materials factory would consist of four generic processing modules (machining, pressing, molding, and compounding), one assembly module, and the Polymer Production Facility. The processing and assembly areas would be consolidated, but the Polymer Production Facility would remain unchanged. The facility is a stand-alone facility that produces materials not available from commercial industry. The consolidation of facilities for the engineered materials factory would reduce floor space requirements for these operations by approximately 50 percent.

Joint Test Assembly and Special Electronics Assembly. Even though these products are electronic assemblies similar to the products fabricated in the electronics factory, they would be built in separate areas because of their unique production and security requirements. These production operations would be combined into one organizational unit. This would provide savings in indirect support, yet allow the unique operations practices and security considerations to be maintained.

Reservoir Fabrication and Assembly. Reservoir production, a relatively new responsibility at KCP, was transferred from the Rocky Flats Plant through the previously authorized nonnuclear consolidation program. The new reservoir production area is correctly sized to support the ongoing workload associated with limited-life component exchanges and would not be changed for this alternative.

Transportation Safeguards. Trailer production and escort vehicle modification would continue to be managed and operated as a separate unit. Floor space requirements would be reduced by relocation of the escort vehicle modification operations so they would be contiguous with the trailer operations.

Table 3.4.2.2–2 shows the KCP Nonnuclear Fabrication Facility annual surge operating requirements.

Waste Management. The KCP waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All wastes generated at KCP facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workload would not require significant modification of the existing KCP waste management infrastructure. Waste generation for construction and operation of the KCP nonnuclear fabrication alternative is shown in table 3.4.2.2–3.

3.4.2.3 *Relocate to Los Alamos National Laboratory*

Historically, LANL has maintained a prototyping capability in support of R&D for nearly all of the components in nuclear weapons that are designed at LANL. The basis for this alternative would be to use the existing infrastructure at LANL to provide for production requirements of the Complex. Figures 3.4.2.3–1 through 3.4.2.3–5 show the technical areas (TAs) involved and the detailed facility layout for key project TAs. Nonnuclear fabrication missions considered for transfer to LANL fall into the following categories: plastics, detonator inert components, and pilot plant; and reservoirs and valves. The LANL nonnuclear fabrication alternative is discussed in more detail in appendix section A.3.6.2.

Construction

Plastics, Detonator Inert Components, and Pilot Plant. In the areas of plastics production and high energy detonator inert components, existing facilities contain nearly all required processing equipment and facilities to provide for the production mission. LANL facilities currently used for plastics processing and polymer synthesis activities include the Weapons Plastics and Adhesives Facility at TA-16, the Detonator Production Facility at TA-22, Reservoir and Valve Production at TA-3, and a Polymer Synthesis, Processing, and Characterization Facility at TA-35. Additional floor space is available at TA-16 for production and two bays are available in the DX-16 Pilot Processing Facility for large-scale pilot processes. The following facilities, with the specified installations/upgrades, would be used for nonnuclear production activities at LANL: plastics production would be located in TA-16, Buildings 302, 303, 304, 305, 306, and 307; detonator inert

components would be manufactured in TA-22, Building 91; and large-scale pilot plant polymer synthesis would occur in TA-16, Building 340. Electrical system upgrades and the installation of new and/or transferred equipment would be required in most of these facilities. Small-scale pilot plant polymer synthesis operations and mold storage, which require no installations or upgrades, would be located in TA-35, Building 213, and TA-16, Building 332, respectively.

Reservoirs and Valves. The basis for the reservoir alternative is to construct a Boost System Production Facility and establish a nuclear-grade material mission. The alternative would dedicate 2,300 m^2 (25,000 ft^2) in TA-3, Building SM-39 (Main Shops) for boost system production and the nuclear grade materials mission. Building modification activities would include removal of existing machine tools and replacement with new or transferred machine tools. No other upgrades would be necessary. The proposed installations and modifications would occur over a 2-year period.

Table 3.4.2.3–1 shows construction requirements to install 50 pieces of equipment and to upgrade electrical systems for the LANL nonnuclear fabrication alternative.

Operation

Plastics, Detonator Inert Components, and Pilot Plant. LANL currently has process equipment and capabilities in place to support much of this mission. Additional processing capability would be transferred from KCP in the areas of polyurethane foam dispensing, intensive mixing, extruding and leaching of cellular silicone, flame spraying, and parylene coating. The proposed plastics production activities would use equipment such as mixers, extruders, roll mills, presses, coaters, screeners, testing equipment, and quality assurance equipment. For pilot plant operations, additional processing capability would be required for large-scale processing of up to 379 liters (L) (100 gallons [gal]). The proposed pilot plant production activities would use reactor vessels, mixer heaters, pulverizers, and solvent recovery equipment during operation. All detonator flat cable processing capability is currently available; however, upgraded equipment would be used to better meet production requirements. Detonator inert component manufacture and assembly operations would use several types of equipment including drills, cleaners, etchers, strippers, developers, scanners, laminators, presses, lasers, and welders.

Reservoirs and Valves. Process equipment and capabilities exist at LANL to support small-scale reservoir and valve production. Operation activities would consist of metal machining, inspection, packaging, and storage functions. Typical production equipment would include lathes, mills, drills, grinders, welders, and inspections/testing equipment. Table 3.4.2.3–2 shows the LANL Nonnuclear Fabrication Facility surge operating requirements.

Waste Management. The LANL existing waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous and nonhazardous wastes generated at LANL facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workload would not require significant modification of the existing LANL waste management infrastructure. Waste generation for construction and operation of the LANL nonnuclear fabrication alternative is shown in table 3.4.2.3–3.

3.4.2.4 *Relocate to Lawrence Livermore National Laboratory*

This alternative calls for LLNL to provide support for nuclear system plastic components. The LLNL Nonnuclear Fabrication Facility would provide the plastic components and polymers currently produced at KCP. These products include filled and unfilled molded parts; syntactic, rigid, and flexible foam parts; composite structures and specialty polymers currently produced at the KCP pilot plant. All processes would be identical to those currently used at KCP, except for the scaling down of the cellular silicone process and one polymer synthesis process.

This alternative would build on LLNL's established plastics fabrication mission. Over half of the equipment to be used is currently operational at LLNL. The laboratory has used this equipment to provide components for prototypes, underground test devices, and hydrotest devices to the weapons program, and numerous other components to other DOE programs. As a result of this established mission, LLNL has developed a site infrastructure that would support this alternative at the Livermore Site (figure 3.4.2.4–1). All facilities meet the current Federal and state environment, safety, and health requirements. The LLNL nonnuclear fabrication alternative is discussed in more detail in appendix section A.3.6.3.

Construction. The LLNL Nonnuclear Fabrication Facility would consist of 15 departments with facilities located primarily in Building B231 and 4 other buildings nearby. No new facility construction is

Waste Management. LLNL's existing waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous and nonhazardous wastes generated at LLNL facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workloads would not require significant modification of the existing LLNL waste management infrastructure. Waste generation for construction and operation of the LLNL nonnuclear fabrication alternative is shown in table 3.4.2.4–3.

3.4.2.5 *Relocate to Sandia National Laboratories*

This alternative would transfer the majority of current KCP missions to the Albuquerque, NM facility of SNL, except for nuclear system plastic components that would go to either LANL or LLNL, and high energy detonator inert components that would go to LANL. In addition, there is the option of moving the reservoir mission to either SNL or LANL.

Only major assemblies or those components requiring special security considerations would be planned for in-house fabrication. SNL production would consist primarily of assembly of procured piece parts. The technologies that have been traditionally retained in-house at KCP, but under this alternative would be produced commercially, include the following: printed wiring boards, interconnect/junction boxes, lasers and electro-optics, interconnect cables, and molded plastic parts. Additionally, SNL would outsource metal machining, hybrid microcircuit substrates, and sheet metal forming. A more detailed dis-

[a] With the exception of sanitary wastes, the data for a multiple shift were determined by multiplying the single-shift values by 2.5.

[b] Data were provided as 2,500 lb of acetone, 3,500 lb of toluene/methanol, 250 lb of toluene, and 270 lb of dimethyl formamide. Assuming a density of 1,000 kg/cubic meter, these were converted to cubic meters.

[c] Assumes toluene/methanol wastewaters would be recycled by a distillation process. Five percent of the toluene/methanol volume is assumed for the distillation bottoms, which appear as a solid waste effluent.

[d] No data provided for liquid sanitary wastes such as sewage. Assumed 50 gal/day per person, 250 days/yr operation. Number of employees used is 60. The urea waste stream was multiplied by 2.5. for three shifts.

[e] LLNL does not treat sanitary wastewater. It goes to the municipal sanitary sewer system; thus, the effluent is the same as generated.

[f] No data provided for solid sanitary wastes such as housekeeping trash. Assumed 0.3 ft^3/day per person, 250 days/yr operation. Number of employees used is 60.

[g] Assumes that two-thirds of the solid waste is compactible by a factor of 4:1.

Source: LLNL 1995f; LLNL 1995i:2.

cussion of this alternative is provided in appendix section A.3.6.4.

Construction. This alternative would require construction of a new stand-alone production site at SNL, directly east of Technical Area I (figure 3.4.2.5–1). The alternative includes six new buildings and renovation or minor modifications to some existing buildings. The site would have four new production facilities, an office structure, and a central utilities building, all surrounded by a security fence with guards. The facility plot plan is shown in figure 3.4.2.5–2.

The new site would be independent of the existing Technical Area I, but would be connected to the area's utility network. The new construction would total approximately 58,060 m^2 (625,000 ft^2), which would be located on 9 ha (22 acres) of available land. In addition to renovation projects, some existing buildings would undergo minor modifications to accept the new workload. These minor modifications would yield an additional 5,110 m^2 (55,000 ft^2) of work space.

The new or modified facilities are Office Facility; Distribution Center Facility, Electronic Assembly Facility, Mechanical Assembly Facility, Special Products Facility, Central Utility Building, and modifications to existing buildings (820, 860, 894, 905, 913, and others). Table 3.4.2.5–1 shows construction requirements for the SNL Nonnuclear Fabrication Facility.

Operation. The nonnuclear fabrication alternative at SNL would operate processes and manufacturing functions similar to those of KCP. Manufacturing activities would be designed to fabricate the numerous electrical and mechanical components of nuclear weapons not proposed to be secured commercially. Fabrication activities would involve a precision machine shop with forges, presses, ovens, other metal-forming and metal-treating equipment, mechanical assembly areas, and clean rooms. Table 3.4.2.5–2 shows the surge operating requirements for the SNL Nonnuclear Fabrication Facility.

Waste Management. The SNL existing waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous and nonhazardous wastes generated and any radioactive or mixed wastes generated under upset conditions at SNL facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workload would not require significant modification of the existing SNL waste management infrastructure. Waste generation for construction and operation of the SNL Nonnuclear Fabrication Facility is shown in table 3.4.2.5–3.

3.4.3 Pit Fabrication and Intrusive Modification Pit Reuse Alternatives

This capability, hereafter referred to as pit fabrication, includes all activities necessary to fabricate new pits, to modify the internal features of existing pits (intrusive modification), and to recertify or requalify pits. Processes for fabrication of replacement pits and modification of existing pits may involve handling, storing, and shipping HEU components. It is assumed that HEU components for assembly into replacement pits will be fabricated at Y-12 and shipped to LANL. Uranium components removed from pits that are to be replaced would be processed to remove residual plutonium, packaged, and shipped to Y-12.

For the base case analysis, workload requirements are assumed to be at a level necessary to maintain competence and to replace components destroyed during surveillance testing. This base case production rate is approximately 20 pits per year. In order to ensure that DOE is able to support the national security mission, equipment would be installed to provide the capability to fabricate one each of every pit type in the post-2005 stockpile. This concept is called capability-based capacity. Operating this array of equipment 5 days per week, on a single shift, provides an annual capacity of approximately 50 pits of, at most, 2 different types.

There are two alternative sites for pit fabrication: SRS and LANL. Nonintrusive modification pit reuse, which is an inherent capability of the pit fabrication facility, includes the processes and systems necessary to make modifications to the external features of a pit, if necessary, and to recertify the pit for reuse in a weapon.

3.4.3.1 *No Action*

Under the No Action alternative, DOE would continue to use existing R&D capabilities at LANL and LLNL. LANL maintains a limited capability to fabricate plutonium components using its Plutonium Research and Development Facility and performs surveillance operations on plutonium components returned from the stockpile. In addition, less extensive capabilities would continue at LLNL to

[a] The data for a multiple shift were determined by multiplying single-shift data by 2.
[b] LLW or mixed LLW would not be generated during normal operation. However, upset conditions may result in the generation of minimal quantities of LLW or mixed LLW.
[c] No data provided. Assumes 25 gal/day per construction worker for 250 days/yr and 260 construction workers. Construction toilets are trucked offsite for servicing.
[d] SNL sanitary wastewater goes to the city of Albuquerque sanitary sewer system; thus the effluent is the same as generated.
[e] Assumes that two-thirds of the solid waste is compactible by a factor of 4:1.
[f] Includes washing from flushing mechanical systems, dust control water, and blockwork, cementitious coatings.

support material and process technology development. Under No Action, DOE would not have the capability to perform pit fabrication to meet the requirements described in section 3.1 for the base case.

3.4.3.2 *Reestablish at Los Alamos National Laboratory*

This alternative would reconfigure the Plutonium Facility at LANL to fulfill the pit fabrication mission and the intrusive modification pit reuse mission. Pit manufacturing would consist of the following functions: pit fabrication, plutonium processing, waste processing, analytical chemistry, physical vapor deposition coatings, and storage. A more detailed discussion of this alternative is provided in appendix section A.3.3.1.

Construction. This alternative would locate pit manufacturing in existing facilities within five technical areas (TAs -55, -3, -8, -50, and -54). Figure 3.4.3.2–1 shows the LANL TAs. The pit fabrication/modification and plutonium processing activities would be located in the existing Plutonium Facility (PF-4), which is situated within the controlled access area of TA-55. The 300 Area of PF-4 would be used to fabricate plutonium components and to assemble those components into pits. Existing equipment would be retained as much as possible, but some equipment would be upgraded to production quality. Other TAs would provide waste processing, analytical chemistry, and other support functions. Figure 3.4.3.2–2 shows the plot plan for the pit fabrication/modification and plutonium processing facilities in TA-55. Table 3.4.3.2–1 shows construction requirements for the LANL Pit Fabrication Facility.

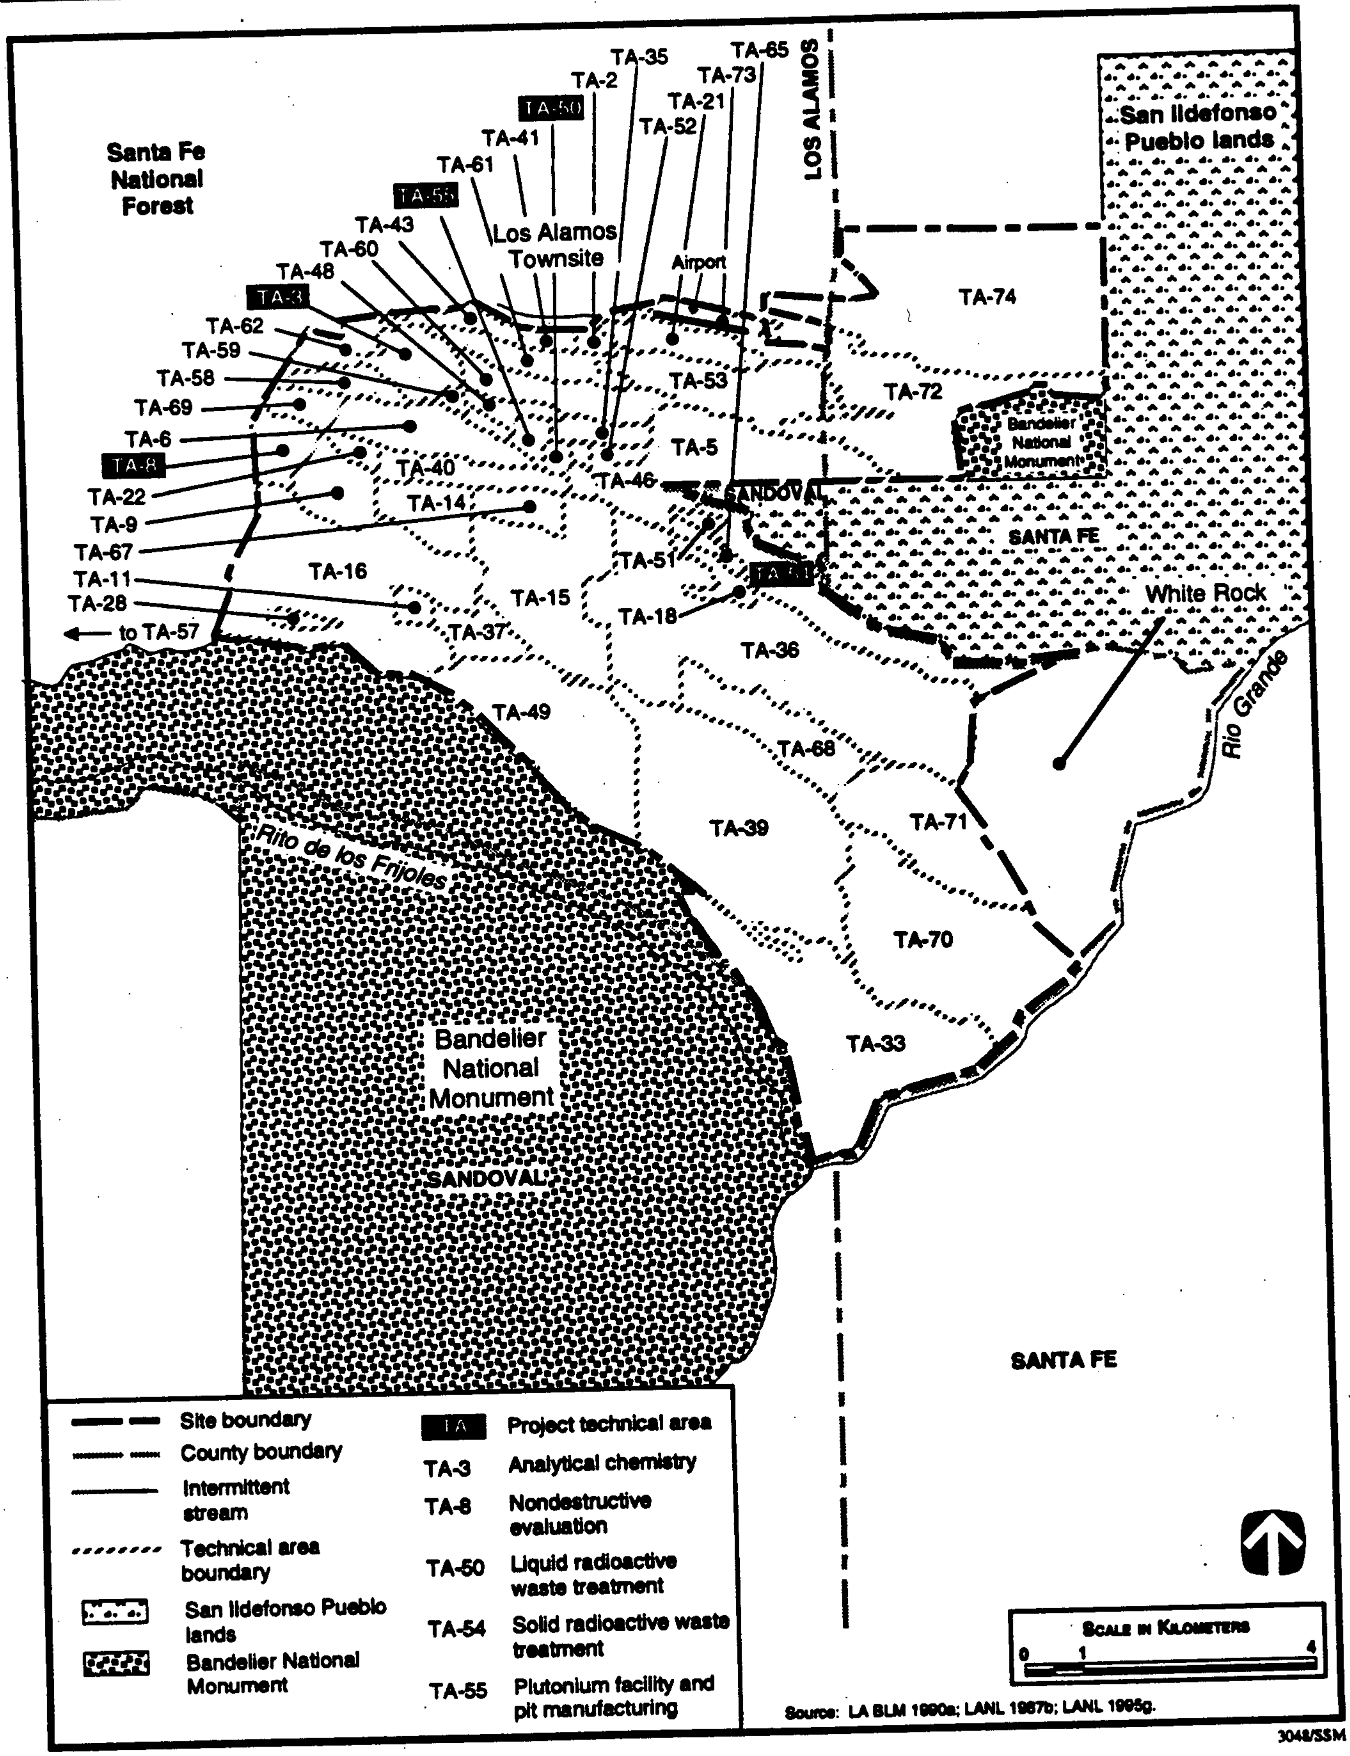

FIGURE 3.4.3.2–1.—*Pit Fabrication Technical Areas at Los Alamos National Laboratory.*

Source: LANL 1995g.

Operation. This alternative would consolidate the pit fabrication and modification processes, receiving pits from offsite and shipping new or rebuilt pits to the Weapons Assembly Facility. The pits received from offsite would be routed to a disassembly area. The plutonium metal from disassembled pits would be purified before transfer to the fabrication area. Residues generated in the disassembly/metal purification areas would primarily consist of chloride salts, crucibles, and chloride-contaminated scrap. The bulk of the residual plutonium would be purified and converted to plutonium metal in the chloride recovery area. Recovered plutonium metal would also be sent to the fabrication area. During fabrication, plutonium metal would be cast into the desired near-net shape and machined to the final shape with desired tolerances. The finished components would be assembled with other nonplutonium materials into the new pit component. These new pits would be sent to the Weapons Assembly Facility. During the casting and machining operations, a number of residues would be generated that require processing and would subsequently undergo nitrate aqueous recovery operations. In nitrate aqueous recovery, the residues are purified and converted to oxide for return to the reduction operations. Solid and liquid wastes from processing areas would be routed to waste management facilities for processing into a disposable waste form. Analytical laboratories provide chemical analyses of plutonium metal, oxides, solutions, and wastes. Table 3.4.3.2–2 shows the surge operating requirements for the LANL Pit Fabrication and Intrusive Modification Pit Reuse Facility.

Waste Management. The existing LANL waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous, radioactive, and mixed waste generated at LANL facilities would be managed in accordance with all applicable Federal and state regulation. The wastes anticipated from the estimated workloads would not require significant modifications of the existing LANL waste management infrastructure. Waste generation for construction and operation of the LANL Pit Fabrication Facility is shown in table 3.4.3.2–3.

3.4.3.3 *Reestablish at Savannah River Site*

This alternative would establish a pit fabrication and reuse facility at SRS within existing hardened facilities, but with new equipment and systems. The facility would fulfill the replacement pit fabrication mission and the intrusive and nonintrusive modification pit reuse missions. This alternative would consolidate all pit fabrication and modification

[a] Over 3-year construction period a total of 27 t (30 tons) of associated piping and ventilation ductwork from glove boxes would be generated. For volume conversion 1500 kg/m^3 was assumed.

[b] Over 3-year construction period a total of 41 t (45 tons) of glove boxes and 14 t (15 tons) of associated piping ventilation and ductwork, would be generated. For volume conversion, 1500 kg/m^3 was assumed.

[c] Assumes 50 gal/day/person/shift with the parameters of 250 days/yr and 260 total additional employees for three shifts.

[d] Assumes 0.3 ft^3/day/person/shift with the parameters of 250 days/yr and 260 total additional employees for three shifts.

[e] Includes 0.15 t (0.17 tons) of steel assuming density of 0.127 m^3/t.

Source: LANL 1995g; LANL 1996e:1.

processes, receiving pits from offsite and shipping new or rebuilt pits off site to the Weapons Assembly Facility. Nonnuclear pit components would be manufactured at other DOE sites and shipped to SRS for assembly into pits. The receiving, handling, and disposition of surplus plutonium could also be consolidated with the plutonium processing facilities. A more detailed discussion of this alternative is provided in appendix section A.3.3.2.

Construction. Facilities are available at the SRS separation areas, F-Area, and H-Area, which could house, in hardened structures, all the process functions required for the manufacture of plutonium pits (figure 3.4.3.3–1). Pit fabrication would be located in Building 232-H, and plutonium processing would be located in the F-Canyon facilities.

Building 232-H is primarily a hardened facility that is used for tritium processing and handling operations that are being relocated to the Replacement Tritium Facility. Adequate space would be available for the Pit Fabrication Facility following removal of some existing equipment and piping systems. New equipment and systems would be required for the Pit Fabrication Facility.

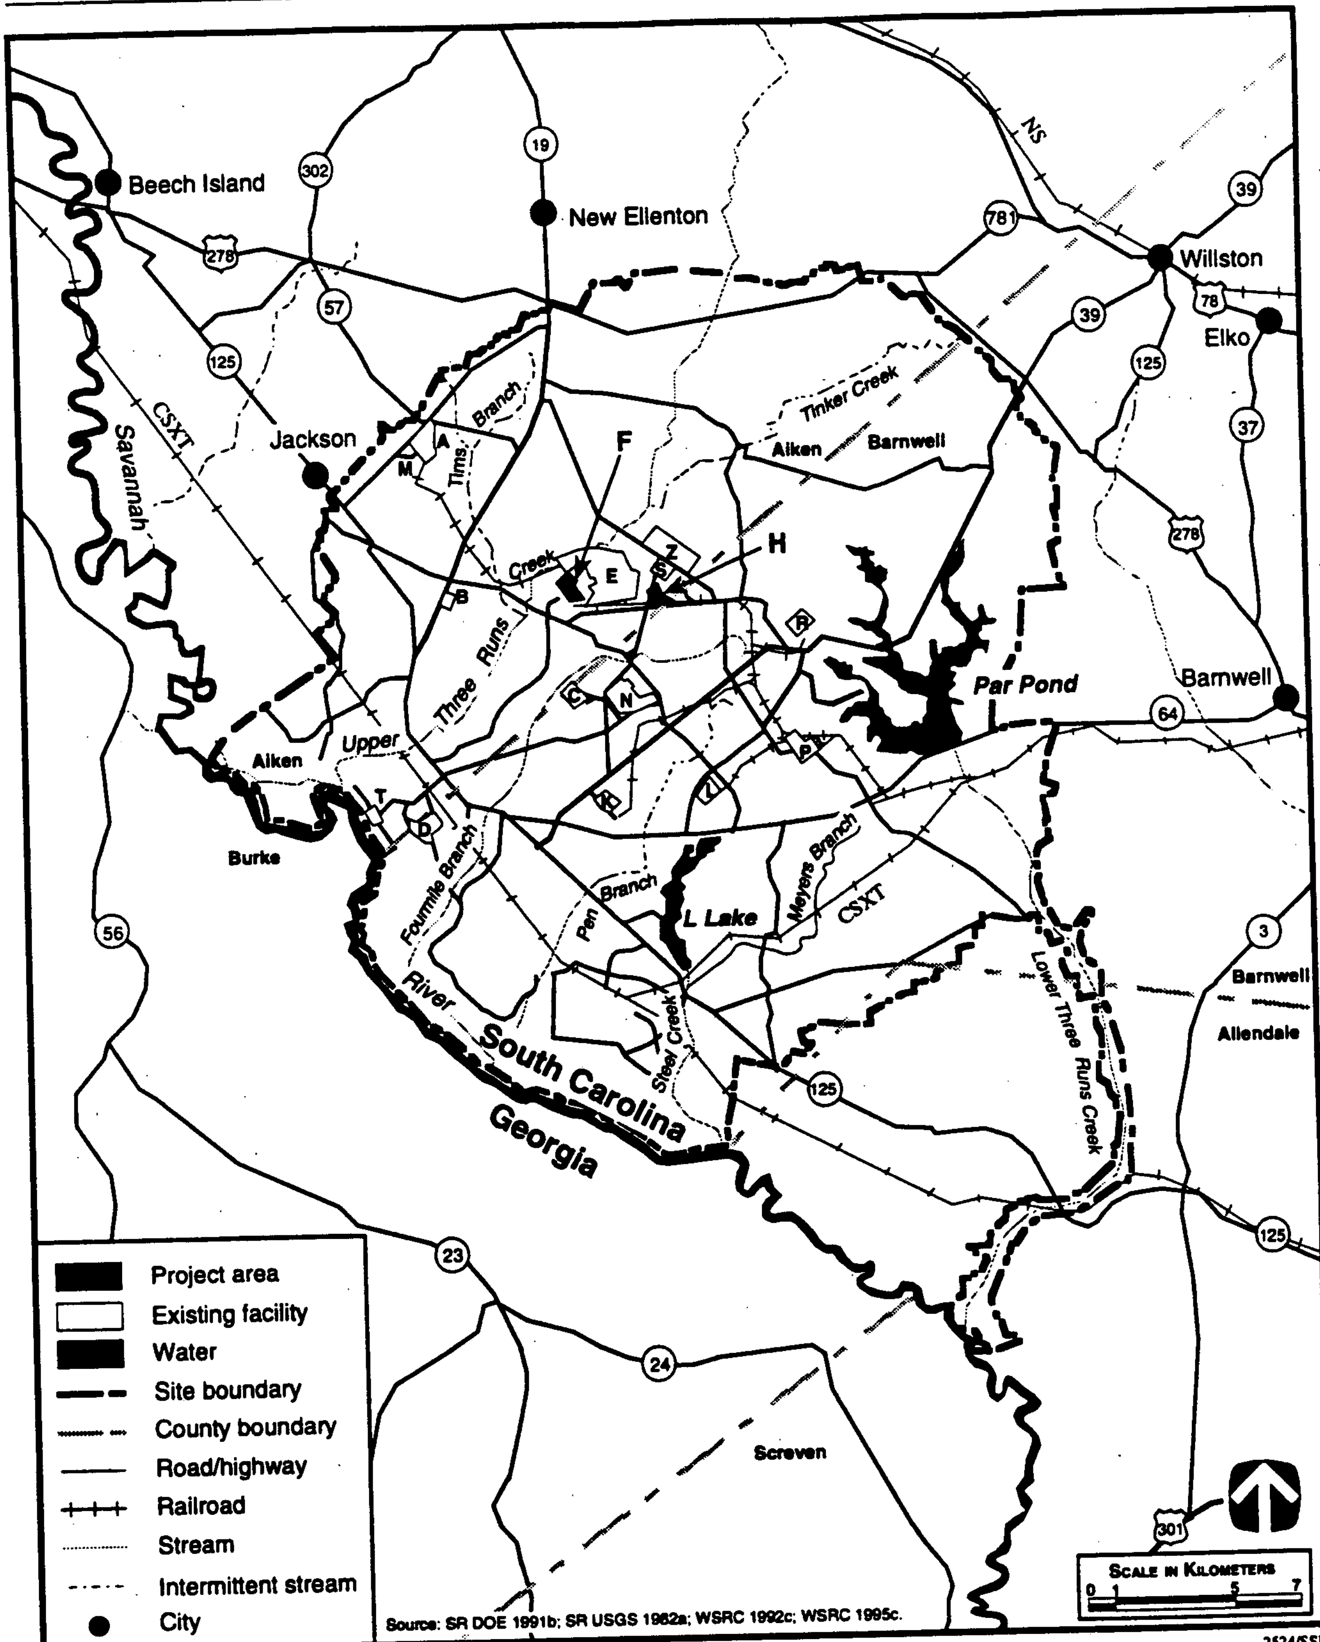

FIGURE 3.4.3.3–1.—*Pit Fabrication Areas at Savannah River Site.*

F-Canyon facilities have adequate noncontaminated hardened areas to house the plutonium processing functions. The Plutonium Storage Facility and the New Special Recovery Facility, which have never been started up, would be used in addition to a third level F-Canyon building production space that has been decontaminated. Many of the unused glove boxes in these facilities could be used as is or with minor modifications. Table 3.4.3.3–1 shows construction requirements, and figure 3.4.3.3–2 provides a site plan for the SRS Pit Fabrication and Intrusive Modification Pit Reuse Facility.

Operation. Table 3.4.3.3–2 shows the surge operating requirements for the SRS Pit Fabrication and Intrusive Modification Pit Reuse Facility. Specific processes required for pit fabrication are discussed in appendix section A.3.3.2.

Pit disassembly, plutonium purification, and residue processing would be performed in existing hardened facilities in the F-Area. These facilities include New Special Recovery, which is equipped to dissolve and purify plutonium, a new reduction (metal preparation) facility in Building 221-F, and the Plutonium

TABLE 3.4.3.3–2.—*Savannah River Site Pit Fabrication Facility Surge Operation Annual Requirements*

Requirement	Consumption
Resource	
Electrical energy (MWh)	9,700
Peak electrical demand (MWe)	1.6
Liquid fuel (L)	28,400
Natural gas[a] (m^3)	None
Water (L)	46,200,000
Coal (t)	1,090
Plant Footprint (m^2)	NA[b]
Employment (Workers)	813

[a] Cubic meters at standard temperature and pressure.
[b] Contained within existing facilities.
Note: NA - not applicable.

Storage Facility. Existing facilities in the F-Area are sized for a large yearly throughput (2 to 5 metric tons [t] [2.2 to 5.5 short tons {tons}]), if required. Also available onsite is the Defense Waste Processing Facility, which would be used for disposal of americium that is a byproduct of plutonium purification. Analytical laboratories in the F-Canyon Area are available to support process control requirements. These facilities in F-Area are operated by the DOE Environmental Management Program.

The plutonium fabrication process in Building 232-H would be an abbreviated version of the process used by the Rocky Flats Plant. Though there are several pit types, the process for each pit type is basically the same. The process consists of casting parts to the near-net shape, machining the surfaces of the casting to achieve the final shape, and performing tests on the completed parts to ensure suitability. After this inspection, the plutonium components are cleaned and assembled with the nonnuclear components to be built into the pit and then welded together into one unit. With the plutonium encapsulated, it may then be safely removed from the glove box, certified, and stored or shipped offsite, as needed.

Nonnuclear components used in the new pits would be received from offsite. After inspection, these parts would be stored in Building 704-55H until needed for either newly fabricated or reused pits.

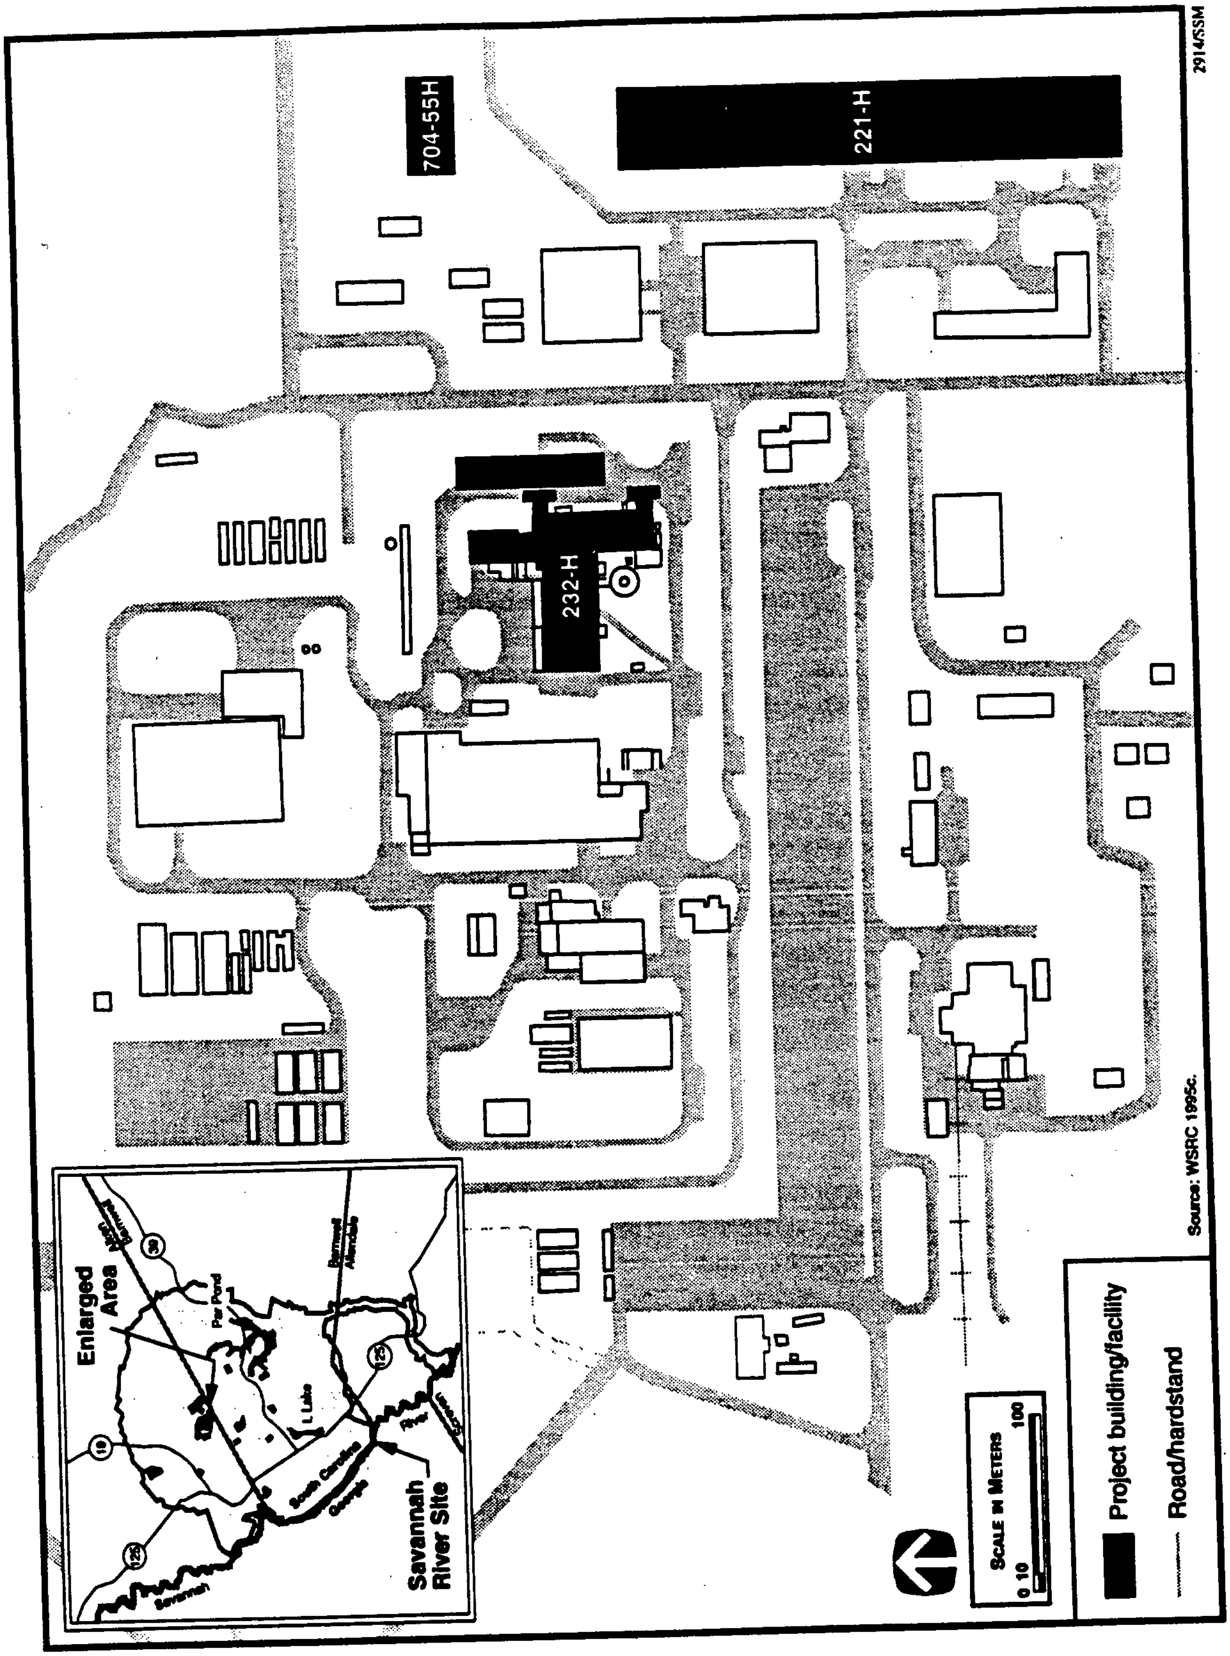

FIGURE 3.4.3.3–2.—*Pit Fabrication Facility Site Plan at Savannah River Site.*

For the nonintrusive modification pit reuse function, the pit is not disassembled. The entire pit is received through the weapons retirement/disassembly process. The pit is then cleaned, inspected and, if necessary, the exterior of the pit is modified. No plutonium is exposed in the nonintrusive modification pit reuse function.

Waste Management. The existing SRS waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous, radioactive, and mixed waste generated at SRS facilities would be managed in accordance with all applicable Federal and state regulations. The wastes anticipated from the estimated workloads would not require significant modifications of the existing SRS waste management infrastructure. The plutonium recovery process would generate a liquid transuranic (TRU) waste that SRS would manage as a high-specific activity waste. This waste would be managed in accordance with the SRS HLW management plan and would result in HLW glass logs and LLW saltstone. Radiographic inspection would generate a low-specific activity waste stream that would include development chemicals such as silver. This stream would be treated as mixed LLW. Waste generation for construction and operation of the SRS Pit Fabrication Facility is shown in table 3.4.3.3–3.

3.4.4 Secondary and Case Fabrication Alternatives

The secondary and case fabrication mission includes all activities to support fabrication, surveillance, inspection, and testing of secondaries and components. Functional capabilities for these services include operations to physically and chemically process, machine, inspect, assemble, and disassemble secondary and case materials. Materials include depleted uranium, enriched uranium, uranium alloys, isotopically enriched lithium hydride and lithium deuteride, and other materials. The concept of capability-based capacity discussed in section 3.4.3 applies to this section. Alternative sites considered for stockpile management secondary activities are ORR, LANL, and LLNL.

When comparing data between site alternatives, it is important to note that there are differences in the facility designs. The Y-12 alternative includes all the necessary support facilities to conduct the missions, not just the production and storage facilities. The LANL and LLNL alternatives only consider the incremental changes for operating the production facilities. The actual production footprint size of each alternative is almost identical; however, the production capacities vary between site alternatives. For example, base case, multiple-shift capacities at Y-12 and LANL are about 150 units, whereas at LLNL the equivalent production capability would be about 50 units. This creates significant differences in some of the data.

3.4.4.1 *No Action*

Under No Action, ORR would continue secondary and case fabrication. Y-12 maintains the capability to produce and assemble uranium and lithium components, to recover uranium and lithium materials from the component fabrication process and disassembled weapons, and to produce secondaries, cases, and related nonnuclear weapons components.

3.4.4.2 *Downsize at Oak Ridge Reservation*

This alternative would be based on downsizing the existing secondary and case fabrication facilities at Y-12 (figure 3.4.4.2–1) consistent with future requirements. The downsized facilities would only require approximately 14 percent of the existing Y-12 floor space for the DP mission, while EM missions would assume the majority of the remaining area. The Y-12 secondary and case fabrication facilities would be divided into the following four factories:

- Enriched uranium factory for processing enriched uranium
- Depleted uranium factory for processing depleted uranium and uranium alloys
- Special materials factory for processing lithium compounds and other materials
- Nonnuclear factory for processing nonnuclear secondary and case parts and materials

This alternative is discussed in more detail in appendix section A.3.2.1.

TABLE 3.4.3.3–3.—*Savannah River Site Pit Fabrication Waste Volumes (120 Pits Per Year)*

Nonhazardous (Other)			
Liquid	None	None	None
Solid	500[h]	1,450[i]	None

[a] At SRS, this would be managed as high-specific activity liquid waste, which would be combined with HLW at the Tank Farm and then processed in accordance with the High-Level Waste Management Plan as described in appendix section H.2.2. The resultant waste forms include 0.61 glass logs composed of comingled TRU waste from pit fabrication and legacy HLW, and LLW saltstone. Based on aqueous alternative process for Complex 21; denitrated water=49.3 L/kg plutonium metal processed and discarded filtrates=6.9 L/kg plutonium metal. Neutralized with 0.2 L of 50-percent caustic per kilogram of waste.

[b] One-half of this volume is considered intermediate-level waste at SRS and would be disposed of in the intermediate-level waste vaults in E-Area. It is managed as TRU waste because it contains beta or gamma emitters that produce a dose equal to or greater than 200 millirem/hr at 5 cm (2 in) from an unshielded container.

[c] Based on aqueous alternative process for Complex 21; 166 L of recycle water per kilogram of plutonium metal processed. Assume "recycle" water sent to Effluent Treatment Facility; recovered acid recycled.

[d] Incinerable=58 m^3, nonincinerable=30 m^3.

[e] Includes 7.6 m^3 (9.9 yd^3) of D&D wastes such as wall material contaminated with asbestos.

[f] Treatment of liquid hazardous wastes results in solid hazardous ash. Volume reduction is 200:1.

[g] Assumes 350:1 wastewater to sludge ratio for treatment of liquid sanitary waste.

[h] Includes 1.5 m^3 (2 yd^3) of concrete and 0.18 t (0.2 tons) of steel. Includes 498 m^3 (651 yd^3) of D&D wastes such as ductwork, concrete, electrical wiring, and equipment.

[i] Recyclable wastes.

Source: SRS 1996a:2; WSRC 1995c.

Construction. This alternative consists of five principal production buildings, one shared production facility, and a number of office, utility, and change-house facilities. Buildings 9204-2 and 9201-5W would be placed in cold standby for potential activation should unforeseen capacity needs arise. Re-activation of these buildings would require separate NEPA evaluation. Figure 3.4.4.2–2 shows the location of the Y-12 secondary and case fabrication facilities. There would be no new facility construction at Y-12 to support the secondary and case fabrication mission. Modifications to the existing buildings would be required for implementation of the alternate secondary and case fabrication mission and to upgrade the

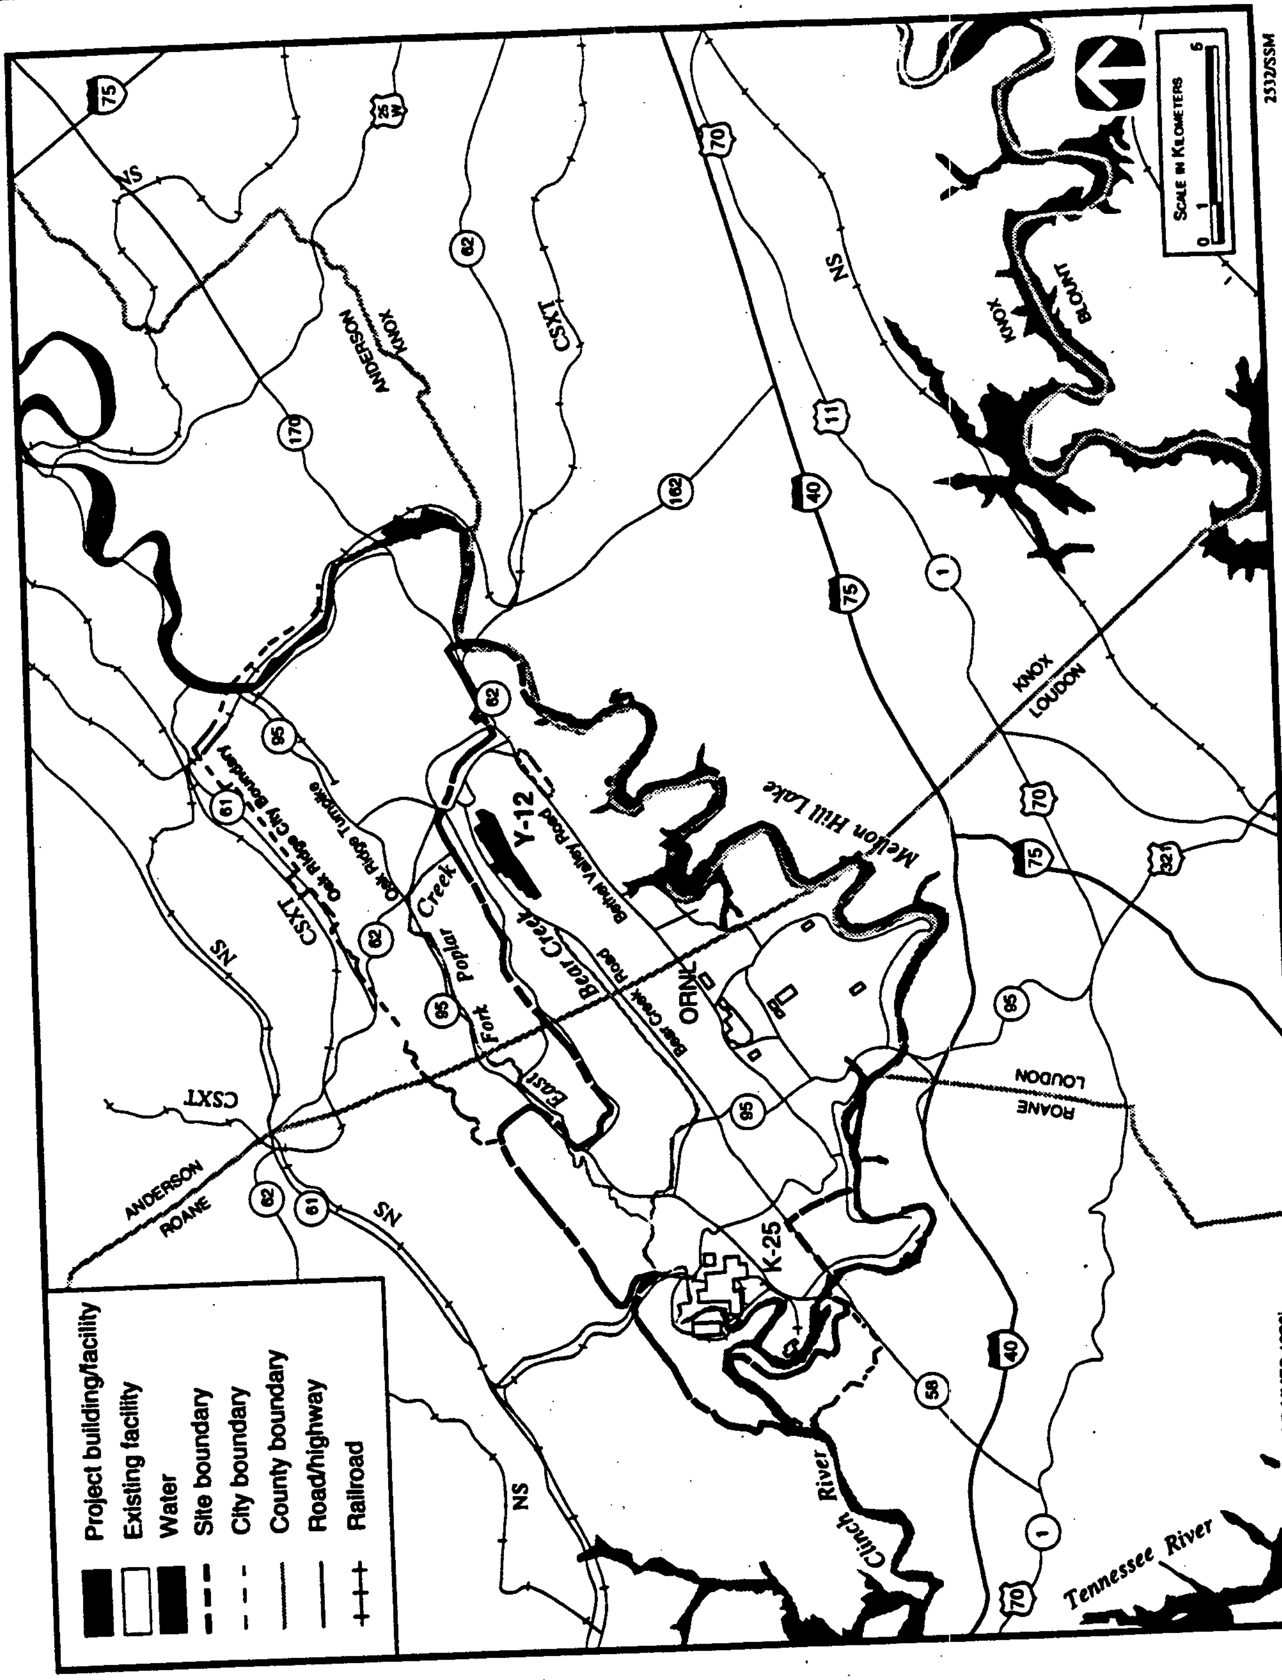

FIGURE 3.4.4.2–1.—*Secondary and Case Fabrication Area at Oak Ridge Reservation.*

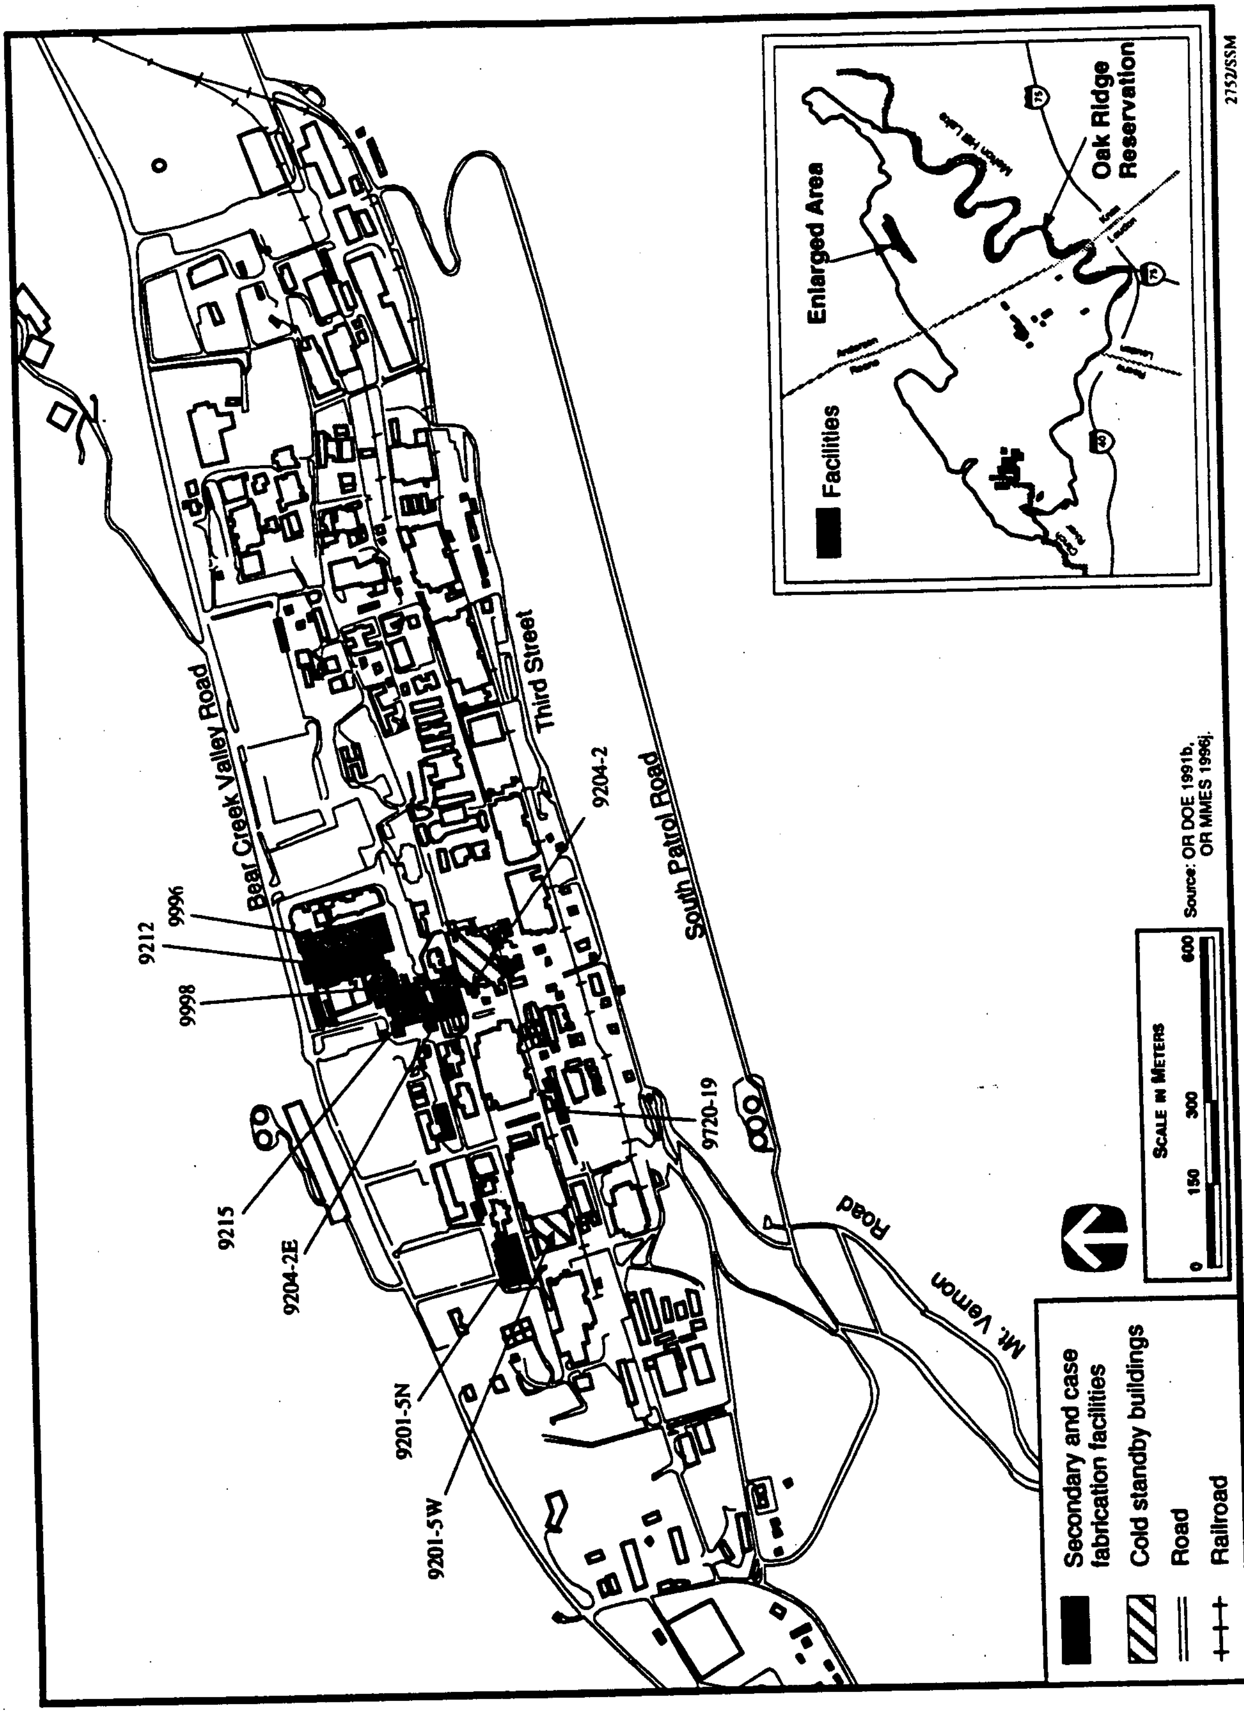

FIGURE 3.4.4.2-2.—*Secondary and Case Fabrication and Materials Management Areas Plot Plan at Y-12 Plant.*

buildings to meet natural phenomena requirements. The modifications would be as follows:

- Building 9996: Connections between the building and the A-2 Wing of Building 9212 complex would be strengthened.

- Building 9212: Modifications would be made to numerous columns, knee braces, and cross braces to provide proper stiffness and load distribution.

- Buildings 9215: The M-Wing area of this building would be converted primarily for enriched uranium storage. The high case would require some machine tools to be in cold standby. The F-Wing area would house the can shop, to be relocated from Building 9201-1. The roof deck would be tack welded to existing purlins, additional corner supports would be added to this area of the roof, and four new scuppers would be added.

- Building 9998: This building houses the depleted uranium/binary foundry area. The installation of a 3,175-t (3,500-ton) press would be required in F-Area. Enriched uranium machining and the associated dimensional inspection would be relocated to the H2-Area. Other additions include the plasma-spray coating and ceramic machining operations to be located in the G3-Area. Some new equipment for special materials processing would also be installed in the G3-Area. Four steel columns and two steel girders would be strengthened by adding additional steel. Roof bracing would be added and additional tack welding of the roof support steel would be done.

- Building 9201-5N: Tack weld roof deck to roof, provide additional roof corner support, and install scuppers.

- Building 9204-2E: The first floor of this building would have a lithium processing, forming, and machining area installed. The metal room deck would be tack welded to existing purlins, and additional roof scuppers would be added.

- Building 9201-5W: The placement of this building in cold standby would be accomplished by installation of a new east wall that would separate the 5W-Area from the rest of the building.

- Building 9204-2: Isolation of most of this building would be required to put the building in cold standby. The only portion of the building that would be used for the base case secondary and case fabrication plant would be the isostatic press area in the northwest corner of the building. Additional roof scuppers would be added and the metal roof deck would be tack welded to the existing purlins. Major structural upgrading would be required on the eastern portion of the building.

Table 3.4.4.2–1 shows construction requirements for the Y-12 Secondary and Case Fabrication Facility.

3.4.4.3 *Relocate to Los Alamos National Laboratory*

This alternative would establish a secondary and case fabrication capability using the processes proven at Y-12 and would use facilities in 11 existing buildings. The LANL Secondary and Case Fabrication Facility operations would fall into the following four categories:

- Enriched uranium operations
- Depleted uranium and uranium alloy operations
- Special materials fabrication for lithium compounds and other materials
- Nonnuclear fabrication and processing for nonnuclear secondary and case parts and materials

This alternative is discussed in more detail in appendix section A.3.2.2.

Construction. Secondary and case fabrication at LANL would utilize existing facilities within the boundaries of TAs -3, -8, -50, -55, and -54. Facilities within each of these TAs include the TA-3 Sigma complex (Buildings SM-35, SM-66, and SM-141), the TA-3 Chemistry and Metallurgy Research Building (Building SM-29), the TA-3 Main Machine Shop (Buildings SM-39 and SM-102), the TA-8 Nondestructive Evaluation Facility (Buildings 22 and 23), the TA-55 Nuclear Material Storage Facility for overflow capacity, the TA-50 Liquid Radioactive Waste Management Facility, and the TA-54 Solid Radioactive Waste Management Area. These areas are shown in figure 3.4.4.3–1.

Figure 3.4.4.3–2 shows the major structures located in TA-3. The buildings shown on this plot plan for use in stockpile stewardship and management operations are SM-29, SM-35, SM-39, SM-66, SM-102, and SM-141. Modifications would be required for the following facilities:

- Renovations to Wings 2, 4, and 9 of the Chemistry and Metallurgy Research Building
- Main machine shop change room and ventilation upgrades
- Sigma complex lithium forming, machining, and inspection
- Sigma complex lithium purification and storage

Modification to the LANL facilities to perform the stockpile management secondary and case fabrication mission would require approximately 7 years for design, construction, mission transfer, and operational startup. Table 3.4.4.3–1 shows construction requirements for the LANL Secondary and Case Fabrication Facility.

waste regulations. The wastes anticipated from the estimated workloads would not require significant modification of the existing LANL waste management infrastructure. Waste generation for construction and operation of the LANL secondary and case fabrication alternative is shown in table 3.4.4.3–3.

3.4.4.4 *Relocate to Lawrence Livermore National Laboratory*

This alternative would establish a secondary and case fabrication capability using the processes proven at Y-12, and would use facilities in existing buildings. The LLNL Secondary and Case Fabrication Facility operations are the same as those described in section 3.4.4.3. This alternative is discussed in more detail in appendix section A.3.2.3.

Construction. Manufacturing and assembly of the secondaries and cases would take place at the Livermore Site (figure 3.4.4.4–1) in the buildings shown on the LLNL site plan, figure 3.4.4.4–2. The

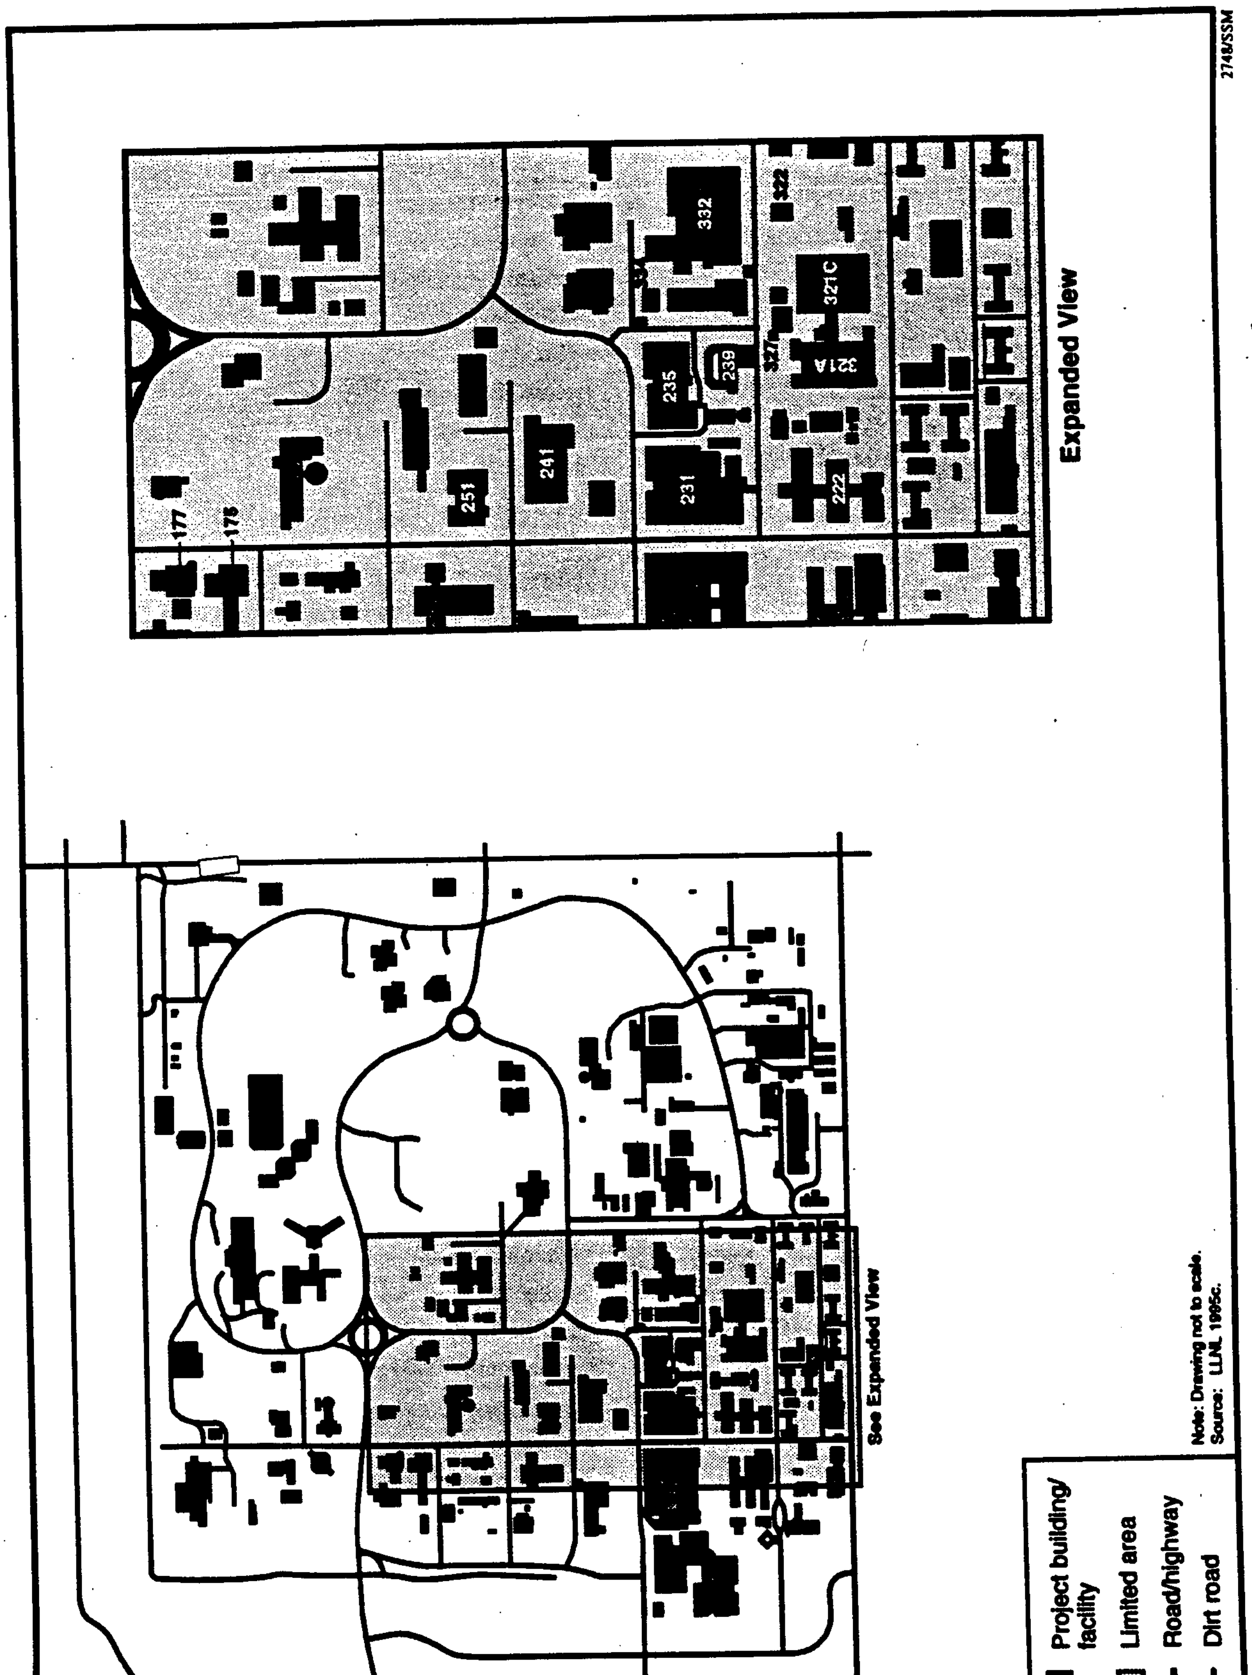

FIGURE 3.4.4.4–2.—*Secondary and Case Fabrication Site Plan at Lawrence Livermore National Laboratory.*

secondary and case fabrication facilities at LLNL would principally involve the following buildings with minor modifications:

- Building 175 for E-beam melt facility for uranium alloy billets
- Building 231 for uranium foundry and metal working for uranium alloys
- Building 241 for special material fabrication (lithium and other special materials)
- Building 321 for machining of depleted uranium and uranium alloys and fabrication of nonnuclear components
- Building 332 as the Main Enriched Uranium Piece Part Fabrication Facility and the Main A/D Quality Evaluation Facility
- Building 334 as an extension to Building 332

In addition, the secondary and case fabrication functions would share facilities in several buildings with other LLNL programs for sample test activities. While this alternative would not require new building construction, it would require some modifications and building renovations, and the construction of a 167 m^2 (1,800 ft^2) steel frame covered space within the Superblock protected area to house the enriched uranium inventory. Table 3.4.4.4–1 shows construction requirements for the LLNL Secondary and Case Fabrication Facility.

Operation. Table 3.4.4.4–2 shows the surge operating requirements for the LLNL Secondary and Case Fabrication Facility.

Waste Management. The LLNL existing waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous, radioactive, and mixed wastes generated at LLNL facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workload would not require significant modifications to the existing LLNL waste management infrastructure. Waste generation for construction and operation of the LLNL secondary and case fabrication alternative is shown in table 3.4.4.4–3.

include manufacturing process development, formulation, synthesis, main charge manufacturing (pressing, machining, subassembly, receiving/storage, quality assurance, and disposition), and energetic component manufacture. The HE fabrication mission supports the production aspect of stockpile management and also supports HE surveillance and some stockpile stewardship activities.

3.4.5.1 *No Action*

Under No Action, Pantex would continue, in its current configuration, the fabrication and surveillance of HE components for nuclear weapons. LANL and LLNL would continue to perform weapons HE R&D, surveillance, and HE safety studies.

3.4.5.2 *Downsize at Pantex Plant*

The Pantex HE fabrication alternative would downsize and consolidate current HE operations and facilities. This alternative would be considered only in conjunction with maintaining the weapons A/D mission at Pantex. Although there is no requirement for collocation of weapons A/D and HE fabrication, it would not be practical to maintain Pantex operations solely for HE fabrication. This alternative is discussed in more detail in appendix section A.3.5.1.

Construction. Figures 3.4.5.2–1, 3.4.5.2–2, and 3.4.5.2–3 show Zones 11 and 12 and the existing facilities within these zones that are part of the HE fabrication proposal. Only minor modifications to existing facilities within Zones 11 and 12 would be required. The Pantex HE fabrication alternative would use existing buildings and facilities within Zones 4, 11, 12, FS-11, FS-22, FS-24, and the Burning Ground. Table 3.4.5.2–1 shows construction requirements for the Pantex HE Fabrication Facility.

Operation. The HE fabrication process comprises HE main charge fabrication, small HE component fabrication, HE formulation and synthesis, and HE testing and characterization. Processes used include isostatic pressing, machining, mechanical punch and die pressing, laser welding, explosive-extrusion, mechanical assembly, dimensional checking, and a variety of testing methodologies. There would be no change in processes or operations for HE fabrication from existing Pantex operations. Table 3.4.5.2–2 shows the annual Pantex HE Fabrication Facility surge operating requirements.

Waste Management. The existing Pantex waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous, nonhazardous, and a minimal quantity of radioactive waste generated at Pantex facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workloads would not require significant modification of the existing Pantex waste management infrastructure. Waste generation for construction and operation of the Pantex HE fabrication alternative is shown in table 3.4.5.2–3.

3.4.5.3 *Relocate to Los Alamos National Laboratory*

This alternative would transfer HE operations to LANL from Pantex during a 2-year transition period, during which Pantex would continue to support the stockpile. This alternative would use existing LANL R&D facilities, which have sufficient capacity to accommodate the required workload. This alternative is discussed in more detail in appendix section A.3.5.2. The option to share the HE mission with LLNL is bounded by this analysis and is not discussed further.

Construction. LANL HE fabrication process capability is already established. HE fabrication and storage functions would be supported in existing facilities at LANL TAs -9, -16, and -37 (figure 3.4.5.3–1). Since LANL HE plant facilities already exist and have sufficient capacity for stockpile management requirements, no new building construction and no significant modifications would be required. As indicated in table 3.4.5.3–1, there would be minimal resource requirements other than personnel for modification and transition, and no waste would be generated. Figure 3.4.5.3–2 shows the existing major HE fabrication facilities at TA-16. Additional TAs would provide production support and testing functions.

Operation. The HE fabrication alternative at LANL would operate in the same manner as current HE fabrication processes and operations. HE processing facilities at LANL were designed and built for production-scale operations and were operated as production facilities for many years. The current baseline production technologies in use at Pantex would be used at LANL. HE processing at LANL includes HE storage; HE synthesis; HE formulations, pressing, machining, assembly, and subassembly of HE devices; quality assurance activities; and HE disposal. Operations would also continue to provide environmental, safety, and performance testing of HE and HE assemblies. Table 3.4.5.3–2 shows the annual LANL HE Fabrication Facility surge operating requirements.

Waste Management. The existing LANL waste management infrastructure can be applied to manage and treat all anticipated waste streams from this alternative. All hazardous, nonhazardous, and a minimal quantity of radioactive waste generated at LANL facilities would be managed in accordance with all applicable Federal and state waste regulations. The wastes anticipated from the estimated workloads would not require significant modification of the existing LANL waste management infrastructure. Waste generation for construction and operation of the LANL HE fabrication alternative is shown in table 3.4.5.3–3.

3.4.5.4 *Relocate to Lawrence Livermore National Laboratory*

The LLNL HE fabrication alternative would transfer HE fabrication activities from Pantex over a 2-year transition period, during which Pantex would continue to support the stockpile. The LLNL HE Fabrication Facility would consist of the HE technology functional area with four main functions: HE main charge fabrication, small HE component fabrication, HE formulation and synthesis, and HE testing and characterization. This alternative would use existing R&D facilities, with some minor enhancements and modifications. The LLNL HE fabrication alternative is discussed in more detail in appendix section A.3.5.3. The option to share the HE mission with LANL is bounded by this analysis and is not discussed further.

Construction. The LLNL HE fabrication alternative would require construction of 1 new facility and would use 23 existing buildings, 66 existing magazines, and various utilities and services at Site 300 (figure 3.4.5.4–1). The one new facility would be for storage of HE. This building would have 11,350 kg (25,000 lb) of conventional HE bulk and parts storage for a 116 m^2 (1,250 ft^2) staging capacity. Table 3.4.5.4–1 shows construction requirements for the LLNL HE Fabrication Facility.

Operation. The LLNL HE fabrication alternative activities would continue using the same facilities,

3.5 Emerging Technologies

DOE is planning to maintain the weapons stockpile using technologies that are in many cases more cost effective with less environmental impact than those used in the past. In addition to these proven baseline technologies planned for the downsized weapons complex, there are newer technologies under consideration that have the potential to offer even greater cost and environmental advantages. However, these technologies have not matured sufficiently to be included with confidence within the current baseline design. In most cases, new technologies that reduce waste and scrap generation and raw material usage concurrently reduce processing steps and operating costs. However, installing new technology requires capital construction and in nuclear facilities may require substantial additional cost to decontaminate and remove old equipment. These construction and decontamination operations also generate waste. Nevertheless, it is foreseeable that the future Complex could include some of these emerging technologies. This section discusses the major emerging technologies under consideration and their potential to further reduce future environmental impacts.

In the design of the Complex, there is a common waste management approach that emphasizes four areas of concern: the reduction of environmental impacts by avoiding environmentally offensive substances; process improvements that minimize waste generation; recycling, in order to minimize waste and raw material use; and the treatment of generated wastes. For some of the major processes, the following sections identify the significant benefits from emerging technologies that could reduce plant effluent, emissions, wastes, worker exposures, and operating cost.

3.5.1 Plutonium Fabrication and Processing

The plutonium facility includes a fabrication area where the plutonium is shaped into usable geometric shapes called pits and a processing area where the supporting chemical operations are performed. Plutonium from dismantled weapons may also be recovered. An amount of plutonium sufficient for carrying out fabrication and processing operations would be stored at the facility. The facility would be supported by activities such as analytical laboratories and waste management operations.

The emerging technologies for plutonium fabrication and processing are directed at minimizing waste at the source, reducing the amount of emissions, reducing the exposure of personnel to radiation, reducing the operational cost of the facility, improving recovery efficiencies, and improving safety. The following specific emerging technologies could affect the characteristics of the Plutonium Fabrication and Processing Facility and further reduce its environmental impact on the public and the safety and health of its workers.

For fabrication of plutonium parts, a near-net shape casting process is part of the baseline design. The casting undergoes additional machining, cleaning, and certification steps. This fabrication process is vastly superior to fabrication processes used in the past because the amount of scrap, waste, residue, and worker radiation dose are greatly reduced. Near-net shape casting technology development is continuing toward a goal of producing precision castings that require no additional machining and associated handling and material recycling. Even if the final goal is not met, any additional progress toward the goal allows for reduced machining, which results in reduced scrap, waste, residue, and worker radiation exposure.

An important fabrication step is a density measurement of the plutonium part. The baseline design measurement process requires that the part be immersed in a brominated hydrocarbon fluid. Hazardous residue is left in the fluid and from the cleaning step that follows. An emerging technology would use a nonreactive gas as the density measurement medium. If this technology is able to provide the required precision, then no residue would be left from the measurement and no follow-up cleaning step would be required.

3.5.2 Uranium Fabrication and Processing

The production of nuclear weapons requires parts fabrication and supporting chemical operations for enriched uranium, depleted uranium, and depleted uranium alloys. Uranium from dismantled weapons may also be processed. An amount of uranium in its various forms would be stored at the facility sufficient for carrying out uranium fabrication and processing operations. The facility would be supported by activities such as analytical laboratories and waste management operations.

The emerging technologies for uranium fabrication and processing are directed at minimizing waste at the source, reducing the amount of emissions, reducing the operational cost of the facility, improving recovery efficiencies, improving safety, and reducing the exposure of personnel to radiation. Radiation exposure is not as big an issue for uranium operations as for plutonium operations, but there will always be an operational goal to reduce exposures consistent with an as-low-as-reasonably-achievable philosophy. The following specific emerging technologies could affect the characteristics of the Uranium Fabrication and Processing Facility and further reduce its environmental impact on the public and the impact to the safety and health of its workers.

The baseline technology for enriched uranium parts fabrication largely continues to rely on the same technologies that have been in use for many years. Some enriched uranium parts are produced by a wrought process that includes casting, rolling, forming, and machining. This process produces a substantial amount of scrap that must be recycled. Other parts are produced directly from a casting to a near-net shape, but these require a substantial amount of final machining. Advances in technology should improve the near-net shape casting process so that final machining is greatly reduced. The improved near-net shape casting process has fewer steps and generates far less scrap that must be recycled. The full implementation of this process would reduce cost, worker radiation exposure, and waste and residue production.

Baseline technology for depleted uranium and uranium alloy parts involves casting, rolling, forming, and machining operations in which the finished part is much smaller than the starting material. An emerging technology is spin forming of some or all of these parts. Although conceptually simple, it is very difficult to spin form to the proper specifications because of the metallurgical properties of uranium. After spin forming, a machining step would still be required, but the final part would have a substantial portion of the metal contained in the starting blank. Spin forming has far fewer process steps than the current process and generates far less scrap that must be processed. The full implementation of this process would reduce cost, worker radiation exposure, and waste and residue.

All uranium and uranium alloy products, whether using the baseline technology or emerging technologies, require a casting step. Currently, the crucibles and molds for casting are made of graphite. In some cases, the graphite is coated with rare earth oxides to extend its life and to reduce carbon contamination of the parts. Graphite molds and crucibles are expensive, have a short life even when coated, and become contaminated with uranium. There is ongoing development to improve coatings, to extend the life of molds and crucibles, and to reduce carbon contamination of parts and uranium contamination of the molds and crucibles. There is also development in alternative materials for molds and crucibles. If improved coating or metal molds and crucibles prove to be feasible, their use in a production environment could reduce cost, and reduce or eliminate substantial quantities of contaminated graphite that must be processed.

Advanced uranium chemical processing technologies are currently under development. These technologies allow high-efficiency recovery and waste and residue processing with reduced worker and environmental radiation exposure. The chemicals used for processing, and the resulting emissions and effluents, are largely benign. These emerging processing technologies have been successfully tested in the laboratory, but have not been scaled up to the pilot plant level. This technology, if successful, could result in reductions in plant emissions and effluents as well as improvements in worker and public health and safety.

3.5.3 Lithium Hydride Fabrication and Processing

The basic steps of producing lithium hydride parts are hydriding lithium metal, grinding hydrided lithium into powder, pressing the powder into blanks, and machining the blanks into the final part. Near-net shape pressing technology has the potential to produce blanks that require less machining and therefore generate less material that must be recycled or stored. This process, if successful, could reduce the cost of operations. Environmental and waste impacts from current operations are very small.

Scrap and parts from old weapons are converted to a hydroxide, then to lithium chloride. The lithium chloride is converted to lithium metal in an electrolytic cell. This process poses hazards for workers and is an environmental emission hazard. The next step is to hydride the metal so it can serve as the feed material for the fabrication process. An emerging technology proven on a laboratory scale uses a bipolar electrolytic cell to convert lithium hydroxide directly to lithium metal. This avoids the lithium chloride step and its associated emission and worker safety hazards.

3.5.4 High Explosives

The HE processes formulate, press, machine, and inspect main charges required for nuclear weapons and related research, development, and testing programs. Also included are explosive material recycling and disposition of explosives from disassembled weapons. Currently, excess explosive materials are disposed of by open burning or detonation. Alternative disposal technologies are being reviewed or developed for possible application. These alternative technologies include biodegradation, base hydrolysis, and reaction in a molten salt solution. Each of these technologies, if proved feasible, would be capable of reducing explosive materials to environmentally benign gases and chemicals.

3.6 Next Generation Stockpile Management Facilities

Stockpile management facilities have been sized in this analysis based on the planned and expected workload to support a START II-sized nuclear weapons stockpile. In addition, stockpile sizes larger and smaller than the START II protocol stockpile have been analyzed to assess the sensitivity of the analysis and the ultimate decision to pursue alternative stockpile sizes.

For all parts of nuclear weapons, except the plutonium pits, an existing large manufacturing capacity exists. Alternatives are considered for downsizing this large capacity at the manufacturing site or transferring the mission to a laboratory or test site where a smaller development and test capability could be expanded to accommodate the production mission. The pit manufacturing capability and capacity was located at the DOE Rocky Flats Plant, which is no longer available for this mission. Therefore, only alternatives that build on an R&D plutonium infrastructure or, in the case of SRS, build on a plutonium infrastructure established for a different purpose, are considered in this analysis.

In sizing pit fabrication for the foreseeable future, consideration was given to establishing a larger fabrication capacity in line with the capacity planned for other portions of the Complex. However, after review of historical pit surveillance data, larger capacity was rejected because of the expected small demand for the fabrication of new replacement pits for the foreseeable future covered in this PEIS.

Construction and operation of a larger pit production capacity at this time would be expensive and would not have sufficient workload requirements for the foreseeable future to justify its maintenance and operation. DOE believes that significant advances are possible in facility design, construction, and operation which would significantly affect new plutonium facility size, cost, and environmental impact. DOE further believes that development and demonstration work should be performed on alternative facility concepts prior to making large financial and programmatic commitments, particularly in light of the expected small near-term requirement for pit production. DOE will perform development and demonstration work at its operating plutonium facilities over the next 5 years to study alternative modular facility concepts that could be utilized in the future in the construction of a larger fabrication capacity. Should a larger pit production capacity be required in the future, appropriate environmental and siting analyses would be performed at that time.

3.7 Comparison of Alternatives

To aid the reader in understanding the differences in environmental impacts among the various PEIS alternatives, this section presents comparisons of the alternatives, concentrating on the major resources assessed in this PEIS. In section 3.7.1, alternatives for each stockpile management mission (e.g., A/D, pit fabrication, secondary and case fabrication, nonnuclear fabrication, and HE fabrication) are compared with one another and the No Action alternative. Tables 3.7.1–1 through 3.7.1–4 contain the quantitative data to support these comparisons.

Section 3.7.1 also contains a top-level comparison of the entire stockpile management program. That comparison assesses the major differences in environmental impacts between a Complex that is downsized/rightsized in-place (the preferred alternative) and a Complex that is consolidated to the maximum extent practicable.

In section 3.7.2, the three proposed stockpile stewardship facilities are compared with the No Action alternative. The quantitative data to support the comparisons for the proposed stockpile stewardship facilities are in the project-specific analyses found in appendixes I, J, and K.

3.7.1 Stockpile Management

To aid the reader in understanding the differences in environmental impacts among the various PEIS alternatives, this section presents comparisons of the alternatives, concentrating on the major resources assessed in this PEIS.

Assembly/Disassembly. In addition to the No Action alternative, two alternatives are being considered that would meet the needs of the Program: (1) downsizing the existing A/D facilities at Pantex and (2) transferring the A/D mission to NTS by expanding the Device Assembly Facility. Under No Action, the A/D mission would remain at Pantex. No downsizing or modification of facilities would occur, and there would be no construction impacts. Downsizing existing facilities at Pantex would involve internal modifications to the existing facility. Transferring the A/D mission to NTS would entail upgrading and expanding the Device Assembly Facility.

Socioeconomic Impacts. Because of the reduced workload associated with completing the weapon dismantlement backlog, significant employment reductions will occur at Pantex for all alternatives. There would be a decrease from the current total of 3,437 workers to about 1,644 workers. Of the current workforce, 3,002 are associated with A/D operations. Under No Action only 915 A/D workers would be required. The downsized Pantex facility would be optimally configured for the reduced future workload, and would operate more efficiently than the No Action Pantex facility. The downsized Pantex facility would require 800 workers for single-shift operation. To perform operations in the downsized Pantex facility in a three-shift mode, 1,266 workers would be required.

If the A/D mission were transferred to NTS, 1,093 direct jobs (based on three-shift operation) would be created at that site, along with 1,160 indirect jobs. The 2,253 total new jobs would cause the regional economic area unemployment rate to decrease by approximately 0.1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. If the A/D mission were transferred to NTS, there would be socioeconomic impacts associated with phasing out the A/D mission at Pantex. The phaseout would result in 1,644 direct jobs lost at the Pantex site, and another 1,905 indirect jobs would be lost in the regional economic area. The loss of 3,549 total jobs would cause the regional economic area unemployment rate to increase from 4.8 to 6.2 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

Socioeconomic impacts at NTS associated with a peak construction workforce of 662 would produce small positive economic benefits. The 662 direct workers would also generate 622 indirect jobs. The 1,284 total new jobs during peak construction would cause no change in the regional economic area unemployment rate. Housing rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

Resource Impacts. Due to the reduced workload expected in the future at Pantex, impacts from operations are expected to be less than current impacts. Air quality would remain within regulatory limits, and water requirements would be met without increased aquifer drawdowns. In addition, downsizing existing facilities at Pantex would involve internal modifications to the existing facility. No land would be disturbed.

Transferring the A/D mission to NTS would entail upgrading and expanding the Device Assembly Facility, with associated increases in land disturbance. An estimated 7.5 ha (18.5 acres) of additional land would be disturbed, which is less than 1 percent of the land available at NTS for development. This land disturbance would increase the potential to impact cultural and biotic resources; however, the impact to cultural resources is not expected to be significant because the proposed A/D site has been previously disturbed during construction activities associated with the Device Assembly Facility. Impacts to biotic resources are expected to be minor; however, the presence of the desert tortoise at NTS would require a site survey to determine any impacts. With mitigation measures already in place at NTS to minimize impacts to the Federal-listed desert tortoise, significant impacts due to the proposed project are not expected.

Because both alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, both alternatives would produce similar operational environmental impacts for most resource areas. Impacts to air quality were modeled, and results indicate minimal impacts for both alternatives. Water use for the NTS alternative is projected to be less than for the Pantex alternative because continued operations at Pantex would rely on existing, older, site-wide infrastructure. At both sites, water requirements could be adequately met without substantial aquifer drawdown. At Pantex, downsizing would reduce groundwater withdrawals by 21 percent compared to No Action. At NTS, water requirements to support the A/D mission would be approximately 4 percent more than projected usage. Groundwater withdrawals at NTS would be less than the recharge rates for the aquifer.

Radiation and Waste Management Impacts. The average radiological dose to workers at Pantex would not be expected to change, although the total worker dose would change due to the reduced number of workers associated with a reduction in workload. Worker exposure to radiation is expected to be about equal (approximately 10 mrem/year) for both alternatives and well within regulatory limits. Because of the small difference in the workforce for this mission at the two sites, this would result in a total worker dose of 3.0 person-rem/year at Pantex and 2.6 person-rem/year at NTS. The added risk to the workforce due to these levels of radiation exposure is extremely small.

Radiation exposure to the public from normal operation would be well within regulatory limits at both sites. At Pantex, the incremental dose to the population within 80 km (50 mi) would be 4.0×10^{-4} person-rem/year. At NTS, the incremental dose to the public within 80 km (50 mi) resulting from operation of the A/D Facility would be 3.1×10^{-6} person-rem/year. The added risk to the public due to these levels of radiation exposure is extremely small.

Both sites have adequate waste management facilities to treat, store, and/or dispose of wastes from the A/D mission, although LLW at Pantex would continue to be shipped offsite to NTS. The impacts of transporting LLW are similar to the impacts of transporting nonradiological materials, which are small. Transferring the A/D mission to NTS would eliminate the need to ship LLW from Pantex to NTS. Transferring the A/D mission to NTS by expanding the Device Assembly Facility would also increase the overall amount of eventual D&D activities and wastes.

Accident Impacts. Potential impacts from accidents would not be expected to change significantly due to reduced workload. Accident impacts were determined using computer modeling. For the composite accident, less than one fatal cancer would be expected for the surrounding 80-km (50-mi) population at either Pantex or NTS. Based on a weighted averaging of the postulated accidents, at Pantex there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 43,000 years from accidents. At NTS, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 500,000 years from accidents.

Other. The A/D mission also includes an option to store strategic reserves of plutonium and/or uranium. At Pantex, which presently stores both strategic reserves and surplus quantities of plutonium, no additional facilities would be needed, and no significant new environmental impacts or risks would result. Storing the strategic reserve would not produce any additional air emissions, require any additional water withdrawals, generate any wastes, or require additional workers. At NTS, however, the Device Assembly Facility would be further expanded to accomplish the strategic reserve storage. The additional construction would have smaller impacts (less than 10 percent) than the construction associated with the Device Assembly Facility upgrade for the A/D mission. Radiation exposure to the public in the event of an accident would be significantly less than for the A/D mission for either alternative.

Pit Fabrication. For pit fabrication, a capability that no longer exists due to the closure of the Rocky Flats Plant, two alternatives are being considered that would reestablish this mission and meet the needs of the Program: (1) upgrading the existing plutonium R&D fabrication capability at LANL and (2) upgrading existing H-Area and F-Canyon facilities at SRS. Both alternatives involve relatively minor (though costly) upgrades to existing facilities. Under the No Action alternative, DOE would not reestablish this mission, but would rely on the existing R&D capabilities at LANL and LLNL.

Socioeconomic Impacts. During operation, both alternatives would have small positive socioeconomic impacts. Based on the socioeconomic modeling, impacts would be higher at SRS because of the indirect jobs that would be created due to this mission. Modeling results indicate no indirect jobs for this mission at LANL. At SRS, up to 813 direct jobs would be created for surge operations, along with 1,594 indirect jobs. These 2,407 total new jobs would cause the regional economic area unemployment rate to decrease from 6.7 to 6.0 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. At LANL, up to 260 new direct jobs would be created for surge operations, but no indirect jobs would be created. The 260 total new jobs would cause the regional economic area unemployment rate to decrease from 6.2 to 6.0 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Because the SRS alternative has less of an infrastructure in place for plutonium fabrication, the SRS alternative would require more direct workers (288 versus 138) during construction. At both sites, however, the socioeconomic impacts during construction would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. Construction activities would involve internal modifications to existing facilities, no land would be disturbed, and thus, no impacts to cultural and biotic resources would result. Because both alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, both alternatives would result in similar operational environmental impacts for most resource areas. Impacts to air quality were modeled, and results indicate minimal impacts to air quality for both alternatives. Water requirements at SRS would be provided from surface water, which is plentiful, and no adverse impacts would be expected. At LANL, groundwater would be used. Water requirements for this mission, which would be less than 1 percent of projected No Action uses, could be adequately met without exceeding the groundwater allotment at LANL.

Radiation and Waste Management Impacts. Worker exposure to radiation is expected to be about equal for both alternatives and well within regulatory limits. At either SRS or LANL, the average workforce dose from this mission would be approximately 380 mrem/year. Because of a difference in workforce for this mission at the two sites, this would result in a total worker dose of 156 person-rem/year at SRS and 55 person-rem/year at LANL. Statistically, this would equate to one fatal cancer every 16 years at SRS, and every 45 years at LANL, from operation of the Pit Fabrication Facility. Radiation exposure to the public from normal operation would be well within regulatory limits at both sites. At SRS and LANL, the incremental dose to the public within 80 km (50 mi) would be 5.9×10^{-4} person-rem/year and 8.6×10^{-5} person-rem/year, respectively. The added risk to the public due to these levels of radiation exposure is extremely small. Both site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Accident Impacts. Potential impacts from accidents were determined using computer modeling. For the composite accident, less than one fatal cancer would be expected for the surrounding 80-km (50-mi) population at both SRS and LANL. Based on a weighted averaging of the postulated accidents, at SRS there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 360,000 years from accidents. At LANL, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 160,000 years from accidents.

Secondary and Case Fabrication. In addition to the No Action alternative, three alternatives being considered would meet the needs of the Program: (1) downsizing facilities that presently perform this mission at ORR, (2) transferring the secondary and case fabrication mission to LANL by upgrading the existing R&D secondary and case fabrication capabilities of LANL, and (3) transferring the secondary and case fabrication mission to LLNL by upgrading the existing R&D secondary and case fabrication capabilities of LLNL. Under No Action, the secondary and case fabrication mission would remain at Y-12 at ORR, and no downsizing or modification of facilities would occur.

Socioeconomic Impacts. Under No Action, there would be a decrease in the number of workers at Y-12 from the current total of 5,152 workers to 4,721 workers. Of the 5,152 workers, 3,126 are currently associated with the core stockpile management mission. Under No Action, only 2,741 core stockpile management workers would be required. The downsized Y-12 would be optimally configured for the reduced future workload, operate more efficiently, and require 784 workers for single-shift operation, a reduction of 1,957 workers. To perform operations in the downsized Y-12 in a three-shift mode, 1,376 core stockpile management workers would be required, a reduction of 1,365 workers. A reduction of 1,365 direct jobs represents approximately 9 percent of the projected No Action workforce at the entire ORR site, and less than 1 percent of the regional economic area. Another 3,490 indirect jobs would also be lost.

Mitigating the workforce reductions would be the fact that downsizing would require 1,152 new jobs associated with landlord activities in preparation for D&D activities. Another 1,600 indirect jobs would be created by these D&D jobs. The net effect for the three-shift mode of operation would be a loss of a total of 213 direct jobs at Y-12, which would represent less than 1 percent of the projected No Action workforce at ORR.

Transferring the secondary and case fabrication mission to either LANL or LLNL would have small positive socioeconomic impacts at those sites, and negative socioeconomic impacts at ORR due to the phaseout of this mission. At LANL, 321 direct jobs (based on three-shift operation) would be created, but no indirect jobs would be created for this industry. The 321 new jobs would cause the regional economic area unemployment rate to decrease from 6.2 to 6.0 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. At LLNL, 290 new direct jobs (based on three-shift operation) would be created, along with 722 indirect jobs. The 1,012 new jobs would cause the regional economic area unemployment rate to decrease by less than 1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

Transferring the secondary and case fabrication mission from ORR to either LANL or LLNL would result in the loss of 3,336 direct jobs projected for this mission under No Action at Y-12, and the closure and D&D of the Y-12 facilities previously involved in this mission. Another 10,134 indirect jobs could also be lost. It is expected that 1,385 new jobs would be created by a direct transfer of responsibilities from DP to EM. Additionally, because the D&D of facilities at ORR would be a relatively long-term process, any initial negative socioeconomic impacts resulting from the transfer of the secondary and case fabrication mission to LANL or LLNL would be minimized by the additional workforce associated with D&D activities at ORR. These 1,385 new D&D jobs would also create 1,937 new indirect jobs. The net effect would be a loss of a total of 13,470 total jobs (direct plus indirect) in the ORR regional economic area. This would cause the regional economic area unemployment rate to increase from 4.9 to 7.4 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent.

During construction activities, socioeconomic impacts would result, but would be small. The number of peak workers would be 14 at ORR, 55 at LANL, and 130 at LLNL, which has the least extensive existing infrastructure for secondary and case fabrication. At all three sites, the socioeconomic impacts during construction would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. Impacts from continued operation at Y-12 are expected to be similar to current impacts. Air quality would remain within regulatory limits and water requirements would be adequately met by surface water withdrawals. For the three "action" alternatives, no previously undisturbed land would be disturbed, and thus, no impacts to biotic resources would result. Minimal impacts to cultural resources may result from building modifications to facilities eligible for the National Register of Historic Places. Because each of the alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, each of the alternatives would produce similar operational environmental impacts for most resource areas. Impacts to air quality were modeled for each alternative and results indicate minimal impacts to air quality for each of the alternatives. Water requirements at ORR would be met from surface water, which is plentiful, and no adverse impacts would be expected. At LANL, groundwater would be used. Groundwater withdrawals would increase by less than 1 percent over projected No Action water requirements, and LANL's groundwater allotment would not be exceeded. At LLNL, public water supply would be used, and usage would be approximately 20-percent higher than projected No Action water requirements. No adverse impacts to water resources are expected.

Radiation and Waste Management Impacts. Radiation worker exposure to radiation is expected to be about equal for all three alternatives and well within regulatory limits. At each of the three sites, the average workforce dose from this mission would be approximately 2.2 mrem/year. Because of differences in projected workforces, this would result in a total worker dose of 0.38 person-rem/year at ORR, 0.33 person-rem/year at LANL, and 0.55 person-rem/year at LLNL. The added risk to the workforce due to these levels of radiation exposure is extremely small. Radiation exposure to the public from normal operation would be well within regulatory limits at these sites. At ORR, the incremental dose to the population within 80 km (50 mi) would be 0.6 person rem/year. The probability of a member of the public dying from cancer would be 3×10^{-4}/year. At LANL, the incremental dose to the population within 80 km (50 mi) would be 0.5 person-rem/year. The probability of a member of the public dying from cancer would be 2.5×10^{-4}/year. At LLNL, the incremental dose to the population within 80 km (50 mi) would be 0.84 person-rem/year. The probability of a member of the public dying from cancer would be 4.2×10^{-4}/year. The added risk to the public due to these levels of radiation exposure is extremely small. All three site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Accident Impacts. Potential impacts from accidents were determined using computer modeling. For all postulated accidents, less than one fatal cancer would be expected for the surrounding 80-km (50-mi) population at each of the sites. Based on a weighted averaging of the postulated accidents, at ORR and LANL there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 830,000 years from accidents. At LLNL, there would be a statistical risk that one fatal cancer to a member of the public would result approximately every 260,000 years from accidents.

Other. If the secondary and case fabrication mission were transferred from ORR, storage of the strategic reserves of HEU would be transferred to the A/D Facility (or a consolidated storage facility being assessed in the Storage and Disposition PEIS). The potential impacts associated with the one-time transfer of the strategic reserves of HEU to the A/D Facility are expected to be minor, even in the event of an accident, due to the robust shipping containers.

High Explosives Fabrication. In addition to the No Action alternative, three alternatives are being considered that would meet the needs of the Program: (1) downsizing facilities that presently perform this mission at Pantex, (2) transferring the HE fabrication mission to LANL by upgrading the existing R&D HE fabrication capabilities of LANL, and/or (3) transferring the HE fabrication mission to LLNL by upgrading the existing R&D HE fabrication capabilities of LLNL. Transferring the HE fabrication from Pantex to LANL and/or LLNL would result in the closure and D&D of Pantex facilities previously involved in this activity. Under No Action, the HE fabrication mission would remain at Pantex. No downsizing or modification of facilities would occur.

Socioeconomic Impacts. Downsizing the HE fabrication mission at Pantex would reduce the number of direct workers associated with this mission to 37, compared to 105 for No Action. Transferring the HE fabrication mission to either LANL or LLNL would create small positive socioeconomic impacts at either of those sites, and small negative socioeconomic impacts at Pantex, due to the phaseout of this mission. For surge operations at LANL, 67 new direct jobs would be created, but no indirect jobs would be created by this industry. The 67 new jobs would cause the regional economic area unemployment rate to decrease from 6.2 to 6.1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. For surge operations at LLNL, 100 new direct jobs would be created, along with 155 indirect jobs. The 255 total new jobs would cause the regional economic area unemployment rate to decrease by less than 1 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Phasing out the HE fabrication mission at Pantex would cause the loss of 105 direct jobs, which would be approximately 3 percent of the projected No Action workforce at Pantex. The direct plus indirect jobs lost would cause no observable change to the Pantex regional economic area unemployment rate, housing/rental vacancies, and public finance expenditures/revenues.

During construction activities, socioeconomic impacts would result, but they would be small. The number of peak workers would be 29 at Pantex, 46 at LANL, and 19 at LLNL. At all three sites, the socioeconomic impacts during construction would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. For the three "action" alternatives, construction impacts are expected to be minor and would involve internal modifications to existing facilities. No land would be disturbed at Pantex or LANL, and thus, no impacts to cultural or biotic resources would result. At LLNL, a small area of land (less than 1 ha) would be disturbed to construct an HE and parts storage building, but impacts to biotic and cultural resources are not expected.

Because each of the alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, each of the alternatives would result in similar operational environmental impacts for most resource areas. Impacts to air quality were modeled for each alternative, and results indicate minimal impacts to air quality for each of the alternatives. At all sites, water requirements would be met from groundwater. At Pantex, this alternative applies only in conjunction with the downsize A/D alternative at Pantex discussed earlier. Downsizing both missions would reduce groundwater withdrawals by 16 percent compared to No Action. At LANL, groundwater withdrawals would increase by less than 1 percent over projected No Action water requirements, and LANL's groundwater allotment would not be exceeded. At LLNL, groundwater and/or the public water supply could be used to support the HE fabrication mission. If public water were used, it would require approximately 21 percent of the design capacity of the public water tap line. If groundwater were used, withdrawals would increase by approximately 65 percent from No Action, but they would not have any adverse impacts to aquifer levels.

Radiation and Waste Management Impacts. There are no radiological risks to workers or the public associated with the HE fabrication mission and no adverse impacts associated with normal operation. All three site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Accident Impacts. Potential impacts from chemical accidents or explosions were determined using modeling. Impacts from these types of accidents could include death or bodily damage. Due to proximity, workers would be most susceptible to any potential impacts. For all postulated accidents, impacts to the public were much less than to workers. In the event of an accident involving HE fabrication, due to the higher population surrounding LLNL, public impacts could be higher at LLNL compared to LANL and Pantex. Lastly, transferring the HE fabrication mission from Pantex to LANL and/or LLNL would require HE components to be shipped from the fabrication site to the A/D Facility. HE is a nonradioactive, hazardous material. There are no impacts associated with the incident-free transportation of HE. In the event of an accident, HE transportation impacts would be no greater than those encountered by the public from industry's transportation of similar explosives. Potential accidents could include both explosive and nonexplosive roadway accidents, with potential impacts of death, lesser bodily injury, and property damage.

Nonnuclear Fabrication. In addition to the No Action alternative, two alternatives are being considered that would meet the needs of the Program: (1) downsizing the facilities that presently perform this mission at KCP and (2) transferring the KCP nonnuclear fabrication mission to LANL, LLNL, and SNL by upgrading existing nonnuclear fabrication capabilities at LANL and LLNL and constructing new nonnuclear fabrication facilities at SNL. Under No Action, the nonnuclear fabrication mission would remain at current locations; primarily at KCP, with small workloads at SNL and LANL.

Socioeconomic Impacts. At KCP, workforce downsizing consistent with a reduced workload has already taken place; therefore, the projected No Action workforce (3,179 workers) is equal to the current workforce. Of these 3,179 workers, 2,508 workers perform core stockpile management missions. The downsized KCP facility would be optimally configured for the reduced future workload, would operate more efficiently, and would require 1,669 core stockpile management workers for single-shift operation. To perform operations in the downsized KCP facility in a three-shift mode, 2,257 workers would be required. This is 251 workers less than the No Action single-shift number of workers. Another 443 indirect jobs would also be lost. The loss of a total of 694 jobs (direct plus indirect jobs) would not cause the regional economic area unemployment rate to change.

Transferring the nonnuclear fabrication mission to the laboratories would create small positive socioeconomic impacts at both LANL and LLNL, with increases of 240 and 131 total (direct plus indirect) jobs, respectively. At each of these sites, socioeconomic indicators would change by less than 1 percent. At SNL, 1,160 direct jobs would be created, along with 1,350 indirect jobs. The 2,510 new jobs would cause the regional economic area unemployment rate to decrease from 5.7 to 5.2 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Phasing out the nonnuclear fabrication mission from KCP would cause the loss of 3,179 direct jobs and the loss of 5,609 indirect jobs in the regional economic area. The loss of 8,788 total jobs from KCP would cause the regional economic area unemployment rate to increase from 4.9 to 5.6 percent. Housing/rental vacancies and public finance expenditures/revenues would change by less than 1 percent. Some socioeconomic impacts could be mitigated by employing personnel for D&D of the KCP facility, although that is not expected to last more than 5 years.

During construction activities, socioeconomic impacts would result, but would be small. At KCP, 187 direct jobs would be created during downsizing activities, plus another 262 indirect jobs. The 449 total jobs created during construction at KCP would represent less than a 1 percent increase in the regional economic area, and would cause no observable change to the regional economic area unemployment rate, housing/rental vacancies, and public finance expenditures/revenues. If the nonnuclear fabrication mission is transferred to the three laboratories, no observable socioeconomic impacts would occur at LANL or LLNL. At SNL, 379 direct jobs would be created during construction activities, plus another 421 indirect jobs. The 800 total jobs created during construction at SNL would represent less than a 1 percent increase in employment in the regional economic area, and would not cause any socioeconomic indicator to change by more than 1 percent.

Resource Impacts. Due to the reduced workload expected in the future, impacts from operations are expected to be less than current impacts. Air quality would remain within regulatory limits at each of the sites, and water requirements would be adequately met.

For the alternative that would downsize KCP, the construction activities would involve internal modifications to the existing facility. No land would be disturbed. For the alternative that would transfer the KCP mission to the laboratories, construction impacts would involve internal facility modifications at LANL and LLNL. At SNL, approximately 9 ha (22 acres) of land would be disturbed to construct a new facility. This represents approximately 6 percent of the undisturbed land at SNL. Potential impacts to cultural and biotic resources would exist, but they would be mitigated to the extent practicable during follow-on, site-specific studies.

Because each of the alternatives would utilize similar facilities, procedures, resources, and numbers of workers during operation, each of the alternatives would result in similar operational environmental impacts for most resource areas. Impacts to air quality were modeled for each alternative. Modeling results indicate minimal impacts to air quality for each of the alternatives. Water requirements for nonnuclear fabrication are relatively minor at each of the sites. At KCP, water requirements, which are publicly provided, would be reduced by approximately 31 percent compared to No Action. At LANL, groundwater withdrawals would increase by less than 1 percent over projected No Action water requirements, and LANL's groundwater allotment would not be exceeded. At LLNL, there would also be a less than 1 percent increase in water requirements to support nonnuclear fabrication. At SNL, groundwater would be used. Groundwater withdrawals would increase by approximately 64 percent over projected No Action withdrawals, but would still represent only 29 percent of the Kirtland Air Force Base groundwater rights. Thus, no adverse impacts are expected.

Radiation, Waste Management, and Accident Impacts. There are no radiological risks to workers or the public associated with the nonnuclear fabrication mission, and there are no adverse impacts associated with normal operation. Accident profiles at the sites would not change as a result of downsizing KCP or transferring the nonnuclear fabrication mission to the laboratories. Phaseout of the nonnuclear mission from KCP would eliminate any potential accidents at that site. Lastly, all three site alternatives have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by this mission.

Stockpile Management Top-Level Comparison. Based upon the reasonable alternatives for the five major missions that make up the stockpile management program, one could construct a matrix with a large number of discrete alternatives for the entire Complex. Analyzing such a large number of alternatives is neither practical nor useful. What is useful, however, is to look at the two extreme configurations for the entire Complex in order to compare environmental impacts for a bounding case analysis. Based on the alternatives that are reasonable for the individual missions, the bounding configurations and environmental impacts for the Complex are a relatively unconsolidated Complex that is downsized/rightsized in place or a relatively consolidated Complex that is rightsized by upsizing the laboratories and NTS.

For the first configuration (referred to as Downsize/Rightsize-in-Place), the Complex would consist of A/D at Pantex, HE fabrication at Pantex, pit fabrication at LANL (or SRS), secondary and case fabrication at ORR, and nonnuclear fabrication at KCP. This is essentially the preferred alternative for stockpile management. For the second configuration (referred to as Maximum Consolidation), the Complex would consist of A/D at NTS, HE fabrication at LANL (or LLNL), pit fabrication at LANL, secondary and case fabrication at LANL (or LLNL), and nonnuclear fabrication at SNL, LANL, and LLNL. Major differences in environmental impacts between these two configurations are presented below.

Socioeconomic Impacts. It is worthy to note that some of the reductions in workforce at the various stockpile management facilities are associated with reduced workloads expected in the future, while additional reductions in workforce could occur due to the physical downsizing of facilities. For the A/D and HE missions at Pantex, under No Action, the core stockpile management workforce would be reduced from the current level of 3,107 workers (3,002 for A/D and 105 for HE) to 1,020 workers (915 for A/D and 105 for HE) for single-shift operation. The physical downsizing of the facility would also improve efficiency such that the workforce could be reduced even further, to 831 workers for single-shift operation (800 for A/D and 31 for HE). Three-shift operation of the downsized Pantex facility would require 1,303 core stockpile management workers (1266 for A/D and 37 for HE).

For the secondary and case fabrication mission at ORR, under No Action, the workforce would be reduced from the current level of 3,126 core stockpile management workers to 2,741 workers for single-shift operation. The physical downsizing of Y-12 (essentially an 86-percent reduction in facility size) would also improve efficiency such that the core stockpile management workforce could be reduced even further, to 784 workers for single-shift operation. Three-shift operation of the downsized Y-12 facility would require 1,376 core stockpile management workers. The adverse socioeconomic impacts associated with the Y-12 downsizing would be mitigated by the creation of 1,152 new jobs associated with landlord activities in preparation for the D&D of the facilities no longer needed.

At KCP, workforce reductions consistent with a reduced workload have already taken place; therefore, the projected No Action workforce (2,508 core stockpile management workers) is equal to the current workforce. Downsizing the KCP facility would improve efficiency such that the workforce could be reduced to 1,669 workers for single-shift operation. Three-shift operation of the downsized KCP facility would require 2,257 workers.

Overall, socioeconomic impacts from construction for the Maximum Consolidation configuration would be minimal, except at NTS and SNL. Socioeconomic impacts from construction for the Downsize/Rightsize-in-Place configuration would also be minimal.

Resource Impacts. Construction impacts associated with the Downsize/Rightsize-in-Place configuration would be minimal. All construction activities would be modifications to existing facilities, with no new construction. Consequently, no significant land disturbance at any sites would result, and no potential impacts to biota or cultural resources would occur.

Construction impacts associated with the Maximum Consolidation configuration would be small overall; only the Device Assembly Facility upgrade at NTS and the Nonnuclear Facility at SNL involve any land disturbance greater than 1 ha (2.47 acres). Most construction activities would be modifications to existing facilities, with no significant land disturbance, and no potential impacts to biota or cultural resources.

During operation, because each of the two configurations would utilize similar facilities, procedures, resources, and numbers of workers, each would result in similar operational environmental impacts for most resource areas. For the Maximum Consolidation configuration, the greatest potential for any significant environmental impacts would occur at LANL, which would be the site for pit fabrication, secondary and case fabrication, HE fabrication, and a portion of nonnuclear fabrication. For each of the resources evaluated in this PEIS, no significant impacts are expected from such consolidation. Modeling results for air quality indicate minimal impacts to air quality. Water requirements would increase at LANL by 2.5 percent, but would still be less than the LANL allotment.

Radiation, Waste Management, and Accident Impacts. Cumulative doses to the population from normal operation would be less than regulatory limits. Impacts from accidents are independent of other missions (e.g., accident risks are additive, not multiplicative). Thus, the potential accident would be the sum of the risks from each mission. For maximum consolidation at LANL, there would be a statistical risk that one fatal cancer to a member of the public would result aproximately every 135,000 years from accidents. LANL would have adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by these missions.

A difference in the operation of the Downsize/Rightsize-in-Place configuration and the Maximum Consolidation configuration would involve the transportation of nuclear and hazardous materials. The Downsize/Rightsize-in-Place configuration would result in transporting plutonium components between LANL (or SRS) and Pantex, and transporting secondary and case components between ORR and Pantex. Incident-free impacts associated with this transportation are small, while accident impacts are minor. The Maximum Consolidation configuration would also result in transporting plutonium components and secondary and case components. Transportation would occur between LANL and NTS. Relative to the Downsize/Rightsize-in-Place configuration, any transportation impacts would be less due to shorter distances and less populated roadways. The Maximum Consolidation configuration would also result in transporting HE components between LANL and NTS, but no significant impacts are expected.

3.7.2 Stockpile Stewardship

Proposed National Ignition Facility. The following comparisons have been summarized from the more-detailed comparisons for the NIF alternatives found in appendix section I.3.5.

The NIF project-specific analysis addresses the impacts of constructing and operating NIF at four alternative sites: LLNL (preferred), LANL, SNL, and NTS (including NLVF). A No Action alternative is also assessed.

Under No Action, DOE would rely on existing aboveground experimental facilities, predominantly the Nova Facility at LLNL, to study the physics of nuclear weapons secondaries. No construction impacts are associated with the No Action alternative and the operational impacts of the Nova Facility have been accounted for in the overall environmental baseline presented for LLNL.

For the action alternative, the analysis indicates that there would be few significant differences in environmental impacts at the candidate sites. The maximum 24-hour concentration of particulate matter 10 microns or smaller (PM_{10}) in the air during site clearing would exceed applicable standards at LLNL and NLVF. However, the ambient air quality impacts would be localized and of short duration. Uncommitted land requirements would be greatest at NTS (18.2 ha [45.0 acres]), although this acreage is less than 1 percent of the uncommitted land at NTS. Conversely, the least amount of uncommitted land that would be required for NIF would be 3.2 ha (7.9 acres) at NLVF. However, this acreage represents the largest percentage of uncommitted land at a candidate site (56 percent). Of greater significance would be the quality of the habitat of the uncommitted land that would be affected by NIF construction. The highest-quality habitats that would be affected would be forest (4.0 ha [9.9 acres]) at LANL or desert (18.2 ha [45 acres]) at NTS. At the other candidate sites, habitat disturbance would occur to grassland (LLNL and SNL) or to an area of sparse vegetation (NLVF). No significant biotic or cultural impacts are expected at any of the NIF alternative sites.

At each NIF alternative site, beneficial socioeconomic impacts associated with construction and operation would occur. During construction, 270 to 470 direct new jobs would be created in the peak year of activity. These direct jobs would create indirect jobs such that the total jobs during the peak year would be: 2,870 at LLNL; 1,130 at LANL; 1,640 at NTS; and 1,770 at SNL. Once operations begin, NIF would employ 330 direct workers. The total number of jobs (direct plus indirect) during operation would be 890 at LLNL, 600 at LANL, 620 at NTS, and 670 at SNL.

Over the 30-year operational life of NIF, the public would be exposed to a very small dose of radiation. No cancer fatalities would be expected to occur from exposures associated with routine NIF operations under either the Conceptual Design or Enhanced options. A radiological accident at NIF would not cause any cancer fatalities to the public except possibly at NLVF and SNL. Under postulated accident conditions, radiological impacts to the public and workers would be minor. The highest calculated radiation dose is 4,900 person-rem. At most, two cancer fatalities could occur if an accidental release occurred. Because of the extremely low accidental release frequency ($2x10^{-8}$/yr), the risk of radiation-caused cancer fatalities from the postulated accident at any site is essentially zero. The cancer fatality risk associated with radiological exposure from an accident involving the transport of NIF tritium targets would range from $1x10^{-8}$ to $8x10^{-10}$/yr; whereas the nonradiological fatality risks associated with vehicular emissions and accidents would be in the range of 10^{-3} to 10^{-4}/yr.

Although each candidate site would implement waste minimization practices, the generation of additional wastes would be unavoidable. All candidate sites have current or planned capacity to handle wastes associated with construction and operation of NIF; however, this would entail offsite shipment of some of the wastes for all sites but LANL.

NIF would comply with all applicable Federal, state, and local environmental regulatory requirements, including the *California Environmental Quality Act* if NIF is sited in the State of California. Such compliance functions as a general form of mitigation. The candidate sites have also established several mitigative measures for construction actions that would also be applicable to NIF construction. While each of these mitigative measures may be minor, in combination they could significantly reduce impacts to the environmental resources of the selected site.

With regard to unavoidable impacts, land clearing and construction activities for NIF would eliminate habitat and destroy or displace wildlife. Construction of new facilities could result in short-term disturbances of previously undisturbed biological habitats. These disturbances could cause long-term reductions in the biological productivity of an area. Construction of NIF would replace natural habitat with areas of pavement and buildings. Depending upon the candidate site selected, this conversion could extend the influence of urbanized/industrial habitats into natural areas, increase fragmentation of natural habitat, and cause minor loss of habitat used by rare species. However, no critical habitat for federally threatened or endangered species would be affected.

Radiological doses to the general public from NIF operation would be no more than 20 percent of the dose from all other candidate site operations and no more than one-millionth of the dose to the population from normal background radiation. NIF would be considered a low-hazard, radiological facility. Such a facility uses radionuclides (for nonreactor purposes) and has other hazards (such as chemicals needed at the facility). Low hazard implies that there are minor onsite and negligible offsite consequences.

Cumulative impacts would result from the addition of the incremental effects of the construction and operation of NIF to the effects of other past, present, and reasonably foreseeable future actions at the selected site. Fugitive dust emissions from construction of NIF would be an incremental addition to the already existing environmental impact of dust emissions to the atmosphere. Minor changes in stormwater runoff are expected due to removal of grass cover during NIF construction and increased runoff from pavement during facility operation.

Proposed Contained Firing Facility. The following comparisons have been summarized from the more-detailed information for CFF found in appendix J.

Under No Action, DOE would rely on existing aboveground experimental facilities, predominantly the existing hydrotest facilities at LLNL, LANL, and NTS to study the physics of nuclear weapons primaries. No construction impacts are associated with those existing facilities, and the operational impacts of those facilities have been accounted for in the overall environmental baseline presented for LLNL, LANL, and NTS.

Because the proposal for CFF involves modification to the existing FXR Facility, construction impacts are expected to be small. Very little land would be disturbed and the construction activities would largely involve internal modifications to the existing facility. Wastes and socioeconomic impacts from construction would be negligible.

Impacts associated with operations would also be negligible. CFF would not utilize any significant quantities of resources, would not cause any significant socioeconomic changes at LLNL, and would not generate large quantities of hazardous or low-level wastes. LLNL has adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by CFF. Impacts to human health from CFF operations are expected to be extremely small and within regulatory limits.

Proposed Atlas Facility. The following comparisons have been summarized from the more-detailed information for the Atlas Facility found in appendix K.

Under No Action, DOE would rely on existing aboveground experimental facilities, predominantly the Pegasus Facility at TA-35 at LANL, to study the physics of nuclear weapon secondaries. No construction impacts are associated with that facility, and the operational impacts from Pegasus have been accounted for in the overall environmental baseline presented for LANL.

Because the proposal for the Atlas Facility involves modification to the existing facilities within TA-35, construction impacts are expected to be small. Very little land would be disturbed and the construction activities would largely involve internal modifications to the existing facility. Wastes and socioeconomic impacts from modification activities would be negligible.

Impacts associated with operations would also be negligible. The Atlas Facility would not utilize any significant quantities of resources, would not cause any significant socioeconomic changes at LANL, and would not generate large quantities of hazardous or low-level wastes. LANL has adequate existing waste management facilities to treat, store, and/or dispose of wastes that would be generated by the Atlas Facility. Impacts to human health from Atlas Facility operations are expected to be small and within regulatory limits.

3.8 Preferred Alternative

CEQ regulations require an agency to identify its preferred alternative(s) in the Final Environmental Impact Statement (40 CFR 1502.14[e]). The preferred alternative is the alternative which the agency believes would best fulfill its statutory mission, considering environmental, economic, technical, and other factors. This PEIS provides information on the environmental impacts. Cost, schedule, and technical analyses have also been prepared, and are presented in the *Analysis of Stockpile Management Alternatives* report (DOE 1996j) and the *Stockpile Management Preferred Alternatives Report* (DOE 1996k), which are available in the appropriate DOE Public Reading Rooms for public review.

DOE has identified the following preferred alternatives for the Stockpile Stewardship and Management Program:

Stockpile Stewardship:

- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:

- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL
- Assembly/Disassembly—downsize at Pantex
- High Explosives Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) HEU strategic reserve storage at Y-12 and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the Storage and Disposition PEIS. Decisions on strategic reserve storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the Stockpile Stewardship and Management PEIS and the Storage and Disposition PEIS are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

The preferred PEIS alternatives do not represent decisions by DOE. Rather, they reflect DOE's preferences based on existing information. The ROD, when issued, will describe DOE's decisions for the Stockpile Stewardship and Management PEIS proposed actions.

HE fabrication D&D would require 579 shipments of LLW to NTS during HE phaseout period. Additional treatment capacity at Pantex would be needed for liquid LLW and Mixed LLW generated from D&D activities.	Existing facilities adequate	Existing facilities adequate	Eliminates future shipments of Pantex LLW to NTS. D&D would require 1,006 shipments of LLW to NTS during phaseout period. Additional treatment capacity at Pantex would be needed for liquid LLW and Mixed LLW.	Existing facilities adequate	Existing facilities adequate	Existing facilities adequate

[a] A/D mission includes impacts from strategic reserve storage.
[b] Data shown is for transfer of entire HE fabrication mission to LANL or LLNL. HE fabrication could be shared at LANL and LLNL.
[c] All data for operations are based on three shift except for No Action, which is based on one shift.
[d] Percent groundwater allotment only applies to LANL.
[e] Three-shift operation; single-shift operation would be 800 A/D direct workers and 624 support workers.
[f] Three-shift operation; single-shift operation would be 31 HE direct workers.
[g] At LANL, 67 of the 200 jobs would be new jobs.
[h] At LLNL, 100 of the 232 jobs would be new jobs.
[i] Three-shift operation; single-shift operation would result in a loss of 408 (189 direct and 219 indirect) jobs.
[j] Three-shift operation; single-shift operation would result in a loss of 475 (220 direct and 255 indirect) jobs.
[k] Impacts to population out to 80 km (50 mi).
[l] Appendix F provides reference to existing documents of No Action accidents. Appendix section F.3 describes a comparison of accidents for No Action versus accidents associated with downsizing.

Note: NA - not applicable; EBA - evaluation basis accident; BEBA - beyond evaluation basis accident.

	No Action	Downsize KCP	Relocate Nonnuclear and Phaseout KCP[a] LANL	LLNL	SNL	Phaseout KCP
Operation[b] (continued)						
Waste Management	Small quantities of LLW would continue to be generated. Mixed waste would no longer be generated.	Existing facilities adequate; the generation of LLW and hazardous waste would be reduced.	Waste generation volumes would increase slightly. LANL has adequate existing waste management facilities.	Waste generation volumes would increase slightly. LLNL has adequate existing waste management facilities.	Waste generation volumes would increase slightly. SNL has adequate existing waste management facilities.	Hazardous wastes from operations would no longer be generated, but D&D activities during phaseout would generate some hazardous wastes.

[a] If nonnuclear fabrication were transferred to LANL, LLNL, and SNL, impacts of phaseout at KCP would also occur.
[b] All data for operations are based on three-shift except for No Action, which is based on single-shift.
[c] This number represents 29-percent of the Kirtland Air Force Base groundwater rights. SNL can obtain water from other groundwater sources.
[d] Three-shift operation, single-shift operation would be 1,669 nonnuclear direct workers and 671 support workers.
[e] At LANL, 194 of the 315 jobs would be new jobs.
[f] At LLNL, 60 of the 114 jobs would be new jobs.
[g] Three-shift operation; single-shift operation would result in a loss of 2,319 (839 direct and 1480 indirect) jobs.
Note: NA - not applicable.

• Annual worker dose (mrem/yr) (total)	2.2	2.2	2.2	2.2	0
• 25-year fatal cancer risk (total)	2.2×10^{-5}	2.2×10^{-5}	2.2×10^{-5}	2.2×10^{-5}	0

TABLE 3.7.1–4.—*Summary Comparison of Impacts for the Secondary and Case Fabrication Mission* [Page 2 of 2]

	No Action	Downsize ORR	Transfer to LANL[a]	Transfer to LLNL[a]	Phaseout at Y-12
Operation[b] (continued)					
Complete Set (EBAs and BEBAs)[i]					
• Expected consequences (fatalities)	j	0.02	0.02	0.063	NA
• Expected risk (fatalities per year)	j	1.2×10^{-6}	1.2×10^{-6}	3.8×10^{-6}	NA
Waste Management	Spent nuclear fuel, TRU, LLW, mixed waste, hazardous waste, and nonhazardous waste would continue to be generated.	All waste generation would decrease. Existing and planned waste management facilities would be adequate.	Waste generation volumes would increase slightly. Existing waste management facilities are adequate.	Waste generation volumes would increase slightly. Existing waste management facilities are adequate.	Wastes generated by operation of the mission would be eliminated. Existing and planned waste treatment facilities are adequate.

[a] If secondary and case fabrication mission were transferred to LANL or LLNL, impacts of phase-out at Y-12 would also result.

[b] All data for operations based on three shift except for No Action, which is based on one shift.

[c] Percent groundwater allotment only applies to LANL.

[d] Total site workforce is for Y-12 only.

[e] Three-shift operation, single-shift operation would be 784 secondary and case direct workers and 1,980 support and other workers. 1,152 workers would support D&D of the facilities vacated by downsizing.

[f] At LANL, 321 of the 523 jobs would be new jobs.

[g] At LLNL, 290 of the 760 jobs would be new jobs.

[h] Three-shift operation; single-shift operation would result in a loss of 4,200 (805 direct and 3,395 indirect) jobs.

[i] Impacts to population out to 80 km (50 mi).

[j] Appendix F provides reference to existing documents for No Action accidents. Section F.3 describes a comparison of accidents for No Action versus accidents associated with downsizing.

Note: NA - not applicable; EBA - Evaluation Basis Accident; BEBA - Beyond Evaluation Basis Accident.

CHAPTER 4

Chapter 4

CHAPTER 4: AFFECTED ENVIRONMENT AND ENVIRONMENTAL IMPACTS

Chapter 4 describes the affected environment and the environmental impacts associated with stockpile stewardship and management alternatives. The chapter begins with an overview of applicable environmental assessment methodologies. The affected environment and environmental impacts of stockpile stewardship and management facilities are then discussed for each of the following sites: Oak Ridge Reservation, Savannah River Site, Kansas City Plant, Pantex Plant, Los Alamos National Laboratory, Lawrence Livermore National Laboratory, Sandia National Laboratories, and Nevada Test Site. Each discussion begins with a brief site description and the stockpile stewardship and management alternatives being considered for that site, continues with a description of the affected environment at the site, and concludes with a description of environmental impacts, a sensitivity analysis for management alternatives, and potential mitigation measures. The general potential environmental impacts of next generation stockpile stewardship facilities and underground nuclear testing are discussed in separate sections. Following the sections that address individual sites, are discussions of potential impacts from intersite transportation, cumulative impacts, and several issues that are common to all sites: unavoidable adverse environmental impacts, the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity, irreversible and irretrievable commitments of resources, and facility transition.

Discussions of the environment that may be affected at each alternative site, and the associated environmental impacts that would result from the Stockpile Stewardship and Management Program make up the core of this chapter. In accordance with Council on Environmental Quality (CEQ) regulations, the affected environment is "interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment" (40 CFR 1508.14). The environmental impacts sections provide the analytical basis for the comparisons of potential impacts of the various stockpile stewardship and management facilities and the No Action alternative that are presented in chapter 3.

Affected Environment. The descriptions of the affected environment provide a basis for understanding the direct, indirect, and cumulative effects of the proposed Program and alternatives. The localities and characteristics of each potentially affected environmental resource are described for each site. The scope of the discussions varies by resource to ensure that all relevant issues are included.

For land resources, geology and soils, biotic resources, and cultural and paleontological resources, discussions of each Department of Energy (DOE) site and its surroundings are included along with descriptions of the representative area within that site that could be affected by the Program alternatives. This information provides a basis for understanding both direct effects and the overall resource base that could be affected by ancillary activities that may be defined in later stages of Program development.

Ambient conditions are described for air and water resources. Discussions focus on air conditions at site boundaries and the surface water bodies and groundwater aquifers that could be affected. This information serves as a basis for analyzing key air and water quality parameters to obtain results that can then be compared to regulatory standards.

Socioeconomic conditions are described for the counties and communities that could be affected by regional population changes associated with the proposed stockpile stewardship and management facilities. The affected environment discussions include projections of regional growth and related socioeconomic indicators. Each region is large enough to account for growth related to direct project employment as well as secondary jobs that may be created by the project.

In addition to those natural and human environmental resources discussed above, the affected environment sections include a number of issues related to ongoing DOE activities at each site. These issues involve facility operations and site infrastructure, intersite transport of nuclear materials, waste management, and radiological and hazardous chemical impacts during normal operation and from accidents. Where reasonably foreseeable changes to any of these factors can be predicted, they are discussed.

Environmental Impacts. In accordance with CEQ regulations, the environmental consequences discussions provide the analytical detail for comparisons of environmental impacts associated with the various stockpile stewardship and management facilities. Discussions are provided for each DOE site and each environmental resource and relevant issues that could be affected.

For comparison purposes, environmental concentrations of emissions and other potential environmental effects are presented with appropriate regulatory standards or guidelines. However, compliance with regulatory standards is not necessarily an indication of the significance or severity of the environmental impact for purposes of the *National Environmental Policy Act* (NEPA) of 1969.

The purpose of the analysis of environmental consequences is to identify the potential for environmental impacts. The environmental assessment methods used and the factors considered in assessing environmental impacts are discussed in section 4.1 and in the appropriate appendixes. The potential for impacts to a given resource or relevant issue is described in the introduction to each section within the site discussions (sections 4.2 through 4.9) that follow.

4.1 ENVIRONMENTAL RESOURCE/ISSUE METHODOLOGIES

4.1.1 Land Resources

This section considers land use plans and policies, zoning regulations, specially protected lands, and existing land use as appropriate for all sites. The potential impacts associated with changes to land use as a result of the alternatives are discussed.

Land use changes associated with upgraded and/or experimental stockpile stewardship facilities could occur in both rural and urban settings and could affect both developed and undeveloped land. The analysis of land use considers impacts that could result from the modification of existing facilities or the construction of new facilities on or adjacent to each site. Potential changes in land use are expected to occur within the existing boundaries of most, if not all, DOE sites. However, the use of lands adjacent to or in the vicinity of DOE sites (i.e., non-DOE land) could be affected by these changes, including new or expanded safety zones.

The degree to which the alternatives affect future use or development of land at each DOE site is considered. Land use impacts are assessed based on the extent and type of land that would be affected. The land use analysis also considers potential direct impacts resulting from the conversion of, or the incompatibility of, land use changes with special status lands such as prime and unique farmlands, and other protected lands such as Federal- and state-controlled lands (e.g., public land administered by the Bureau of Land Management or other Government agencies).

4.1.2 Site Infrastructure

Changes to site infrastructure are assessed by overlaying the support requirements of the respective stockpile stewardship and management facilities upon the projected site infrastructure capacities. These assessments focus upon electrical power and fuel requirements. Projections of electricity availability, site development plans, and other DOE mid- and long-range planning documents are utilized to project site infrastructure conditions. Tables are presented that depict the additional infrastructure requirements resulting from the alternatives. Mitigation considerations that could reduce impacts due to changes in infrastructure are identified on a site-by-site basis.

4.1.3 Air Quality

The air quality assessment evaluates the consequences of criteria and hazardous/toxic air pollutants associated with each alternative at each site. The criteria pollutants are specified in 40 CFR 50, Environmental Protection Agency (EPA) Regulations on National Primary and Secondary Ambient Air Quality Standards. The hazardous/toxic air pollutants are listed in Title III of the 1990 *Clean Air Act* (CAA) *Amendments*, the National Emissions Standards for Hazardous Air Pollutants (NESHAPs)

(40 CFR 61), and standards or guidelines proposed or adopted by the respective states.

Air quality concentrations from modeling site emission rates projected to 2005 define No Action concentrations of pollutants. This programmatic environmental impact statement (PEIS) presents the estimated impacts on air quality based on No Action air quality conditions at each site and the projected impacts resulting from the alternatives and compares the total concentrations to the most restrictive Federal and/or state ambient air quality standards and guidelines.

The modeling of site-specific emissions was performed in accordance with EPA's Guideline on Air Quality Models. The EPA-recommended Industrial Source Complex Short-Term (ISCST) Model (Version 2) (EPA 1992f) was chosen as the most appropriate model to perform the air dispersion modeling analysis for this PEIS because it allows for the estimation of dispersion from a combination of point, area, and volume sources. Input data for the model was provided by DOE sites. For source characteristics that are not available, characteristics were estimated based on similar source configurations at sites employing similar processes.

EPA guidelines are conservatively applied in the air quality assessment. The "highest-high" was selected for comparison to applicable standards and guidelines for all averaging times, instead of the EPA-recommended "highest-high" and "highest second highest" concentration for long-term and short-term averaging times, respectively. The concentrations evaluated are the maximum occurring at or beyond the site boundary or public access roads. It was also assumed that the toxic/hazardous emissions for DOE sites with incomplete source characteristics originate from a single point source. This assumption generally results in higher concentrations than would actually occur since emission sources are commonly geographically separated from one another.

A more detailed and quantitative assessment will be performed in site-specific NEPA documents designed to support a construction-level siting decision. This PEIS assessment of impacts from the No Action alternative and the other alternatives uses a screening level analysis and is based on conservative assumptions for modeling of potential impacts. The screening level modeling analysis presented in this document is a programmatic approach intended to provide a comparison of the air quality among each of the DOE sites. Modeled concentrations of air pollutants presented in this document that exceed the Federal or state air quality standards provide an indication of a potential problem, not a de facto exceedance. Detailed modeling and/or monitoring at each site would be required in order to obtain more accurate estimates of pollutant concentrations. The assessment in site-specific NEPA documents would be more refined with detailed design, source characteristics, and exact source locations.

Uncertainties. The performance of the ISCST Model has been evaluated with field data for its point source submodel (EPA 1977a; EPRI 1983a; EPRI 1985a; EPRI 1988a) and for its special features, such as gravitational settling/dry deposition option (EPA 1981a; EPA 1982a) and building downwash option (APCA 1986a; EPA 1981a). The ISCST Model is an extended version of the Single Source (CRSTER) Model; based on field data measured at four large power plants, it was concluded that the model was acceptable for predicting the upper percentile of the frequency distributions of 1-hour concentrations and of the corresponding distributions of 24-hour concentrations. The highest second-highest 1-hour concentrations were predicted within a factor of two at two-thirds of the field sampling sites for elevated power plant plumes. The ratio of the highest second-highest 24-hour concentration tended to be underpredicted by the model, with the ratio of predicted concentration to measured concentration ranging from about 0.2 to 2.7 at about 90 percent of the sampling sites (EPA 1977a:F-31).

In other validation studies for the Point Source Model, the CRSTER Model predicted peak short-term (i.e., 1-, 3-, and 24-hour) concentration values within 30 to 70 percent at a plain site (EPRI 1983a:7-1). The CRSTER Model predicted peak 1-hour concentrations within 2 percent and underpredicted peak 3-hour concentrations by about 30 percent at a moderately complex terrain site (EPRI 1985a:7-1). The ISCST Model overpredicts 1-hour concentrations by about 60 percent with better predictions for longer time periods at an urban site (EPRI 1988a:5-2). Uses of gravitational settling/dry deposition and building downwash options were found to improve the model performance significantly over that of the model without such features (APCA 1986a; EPA 1981a; EPA 1982a). The concentrations presented in this document are the highest concentrations predicted by the model in order to present conservative estimates of pollutant concentrations.

4.1.4 Water Resources

The quality and quantity of surface water and groundwater resources are described using available data. Potential effects on surface water and groundwater availability and quality are assessed.

Surface Water. Local surface water resources in the project region, flow characteristics and relationships, and stream classifications are used to describe current conditions. Data used for impact assessments include rates of water consumption and wastewater discharge for both construction and operation phases. Changes in the annual low flows of surface water resulting from proposed withdrawals and discharges are determined. In cases where low flow data are unavailable, average flow data are used. The existing water supply is evaluated to determine if sufficient quantities are available to support an increased demand by comparing projected increases with the capacity of the supplier and existing water rights, agreements, or allocations.

The water quality of potentially affected receiving waters is determined by reviewing current monitoring data for nonradiological parameters. Potential impacts from radiological parameters are discussed in the radiological and hazardous chemical impacts sections of the normal operation and accidents sections. Focus is given to parameters that exceed applicable water quality criteria, as determined by the individual states. Monitoring reports for discharges permitted under the National Pollutant Discharge Elimination System (NPDES) program are examined for compliance with permit limits and requirements. The performance of each candidate DOE site in complying with the permit requirements is presented. In most cases, current design data do not include information on the constituents present or the rate of discharge. The assessment of water quality impacts from wastewater (sanitary and process) and stormwater runoff qualitatively addresses potential impacts to the receiving waters' minimum or average flow, as available and appropriate. Suitable mitigation measures for potential impacts such as stream channel erosion and sedimentation, stream bank flooding, and thermal changes are identified. Water quality management practices are also reviewed. If effluent constituent data are available, parameters with the potential to further degrade existing receiving water quality along with parameters exceeding existing NPDES permit limits are identified.

Floodplains are identified to determine whether any of the proposed stockpile stewardship and management facilities are located within a floodplain. Where possible, the proposed location is compared with the 500-year floodplain.

Groundwater. Groundwater resources are analyzed for effects on aquifers, groundwater usage, and groundwater quality within the regions. Groundwater resources are defined as the aquifers underlying the site and their extensions down the hydraulic gradients to, and including, discharge points. The affected environment discussion includes a description of the potentially affected groundwater basins. The local aquifers are described in terms of the extent, thickness, character of rock formations, and quality of the groundwater. Recharge areas are also noted. Total baseline groundwater use at the facility is compiled using the best available data. Groundwater usage is described and projections of future usage are made based on changing patterns of usage and anticipated growth patterns, whenever site-specific groundwater availability issues are identified.

Drawdown estimates are made both onsite and offsite. Short- and long-term impacts associated with construction withdrawals are estimated. Both proposed facilities and existing facilities are considered in determining cumulative impacts.

Available data on existing groundwater quality conditions are compared to Federal and state groundwater quality standards, effluent limitations, and safe drinking water standards. Additionally, Federal and state permitting requirements for groundwater withdraw and discharge are identified. Impacts of groundwater withdrawals on existing contaminant plumes due to construction and facility operation are assessed to determine the potential for changes in their rates of migration and the effects of any changes in the plumes on groundwater users. Impacts are assessed by the degree to which groundwater quality, drawdown of groundwater levels, and groundwater availability to other users would be affected. Impacts on groundwater quality are presented when effluent constituent data are available.

4.1.5 Geology and Soils

Geology. Impacts to the geological environment considers destruction of or damage to unique geological features, subsidence caused by groundwater withdrawal, and landslides or shifting caused by loading or removal of supporting rock or soil. The local geology that could affect the alternatives, including geomorphology, stratigraphy, structural attitude of rocks, faults and seismicity, general foundation, and boring conditions, are described as appropriate for each alternative site. The locations of faults are identified and an overview of the seismicity of the site areas, including the history and significance of earthquakes, along with their intensity and ground acceleration, is presented. Areas of potentially unstable slopes and impacts to the stability of slopes by the removal or addition of large volumes of earth in construction are characterized.

Soils. Soil types at the proposed project sites are described and the capability of supporting construction of the proposed facilities is assessed. Shrinking or swelling of ground as a result of landscaping, irrigation, or construction dewatering and soil erosion susceptibility associated with construction are also addressed.

4.1.6 Biotic Resources

During construction, impacts to biotic resources, including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species, may result from land-clearing activities, erosion and sedimentation, and human disturbance and noise. Operations may affect biotic resources as a result of changes in land use, emission of radionuclides, water withdrawal, wastewater discharge, and human disturbance and noise. In general, potential impacts are assessed based on the degree to which various habitats or species could be affected by an alternative. Where appropriate, impacts are evaluated with respect to Federal and state protection regulations and standards.

The analysis of impacts of project alternatives to biological resources is addressed at a level that is appropriate to the specificity of available information. In general, the analysis of impacts to biological resources presented in this PEIS is qualitative rather than quantitative. Quantitative analyses would be performed in site- and project-specific NEPA documentation.

Terrestrial Resources. Impacts of the proposed alternatives on terrestrial plant communities are evaluated by comparing data on site vegetation communities to proposed land requirements for construction and operation. The analysis of impacts to wildlife is based to a large extent on plant community loss or modification, which directly affects animal habitat. The loss of important or sensitive habitats and species is considered more important than the loss of regionally abundant habitats or species. Where appropriate, the disturbance, displacement, or loss of wildlife is evaluated in accordance with wildlife protection laws such as the *Migratory Bird Treaty Act*. Impacts on biotic resources from the release of radionuclides are not evaluated. Radiological releases associated with the various alternatives would generally be at or below natural background levels and would be within limits established to protect workers and the public. Since humans have generally been shown to be the most sensitive organism to radiation release these levels should also be protective of biota (AEC 1968a:220; NAS 1972a:34). Radiological effects on humans are addressed in the human health sections.

Wetlands. The potential direct loss of wetlands resulting from construction and operation of the proposed alternatives is addressed in a way similar to the evaluation of impacts on terrestrial plant communities; that is, by comparing data on site or regional wetlands to proposed land requirements. Sedimentation impacts are evaluated based on the proximity of wetlands to project areas and with the knowledge that an erosion control and sedimentation plan would be required. Impacts resulting from wastewater discharge into a wetland system are evaluated, recognizing that effluents would be required to meet Federal and state standards.

Aquatic Resources. Impacts to aquatic resources resulting from sedimentation and wastewater discharge are evaluated as described for wetlands. Potential impacts from radionuclides are not addressed for the same reasons described for terrestrial resources. Where appropriate, impingement and entrainment impacts are evaluated as is compliance with protective measures, such as the *Anadromous Fish Conservation Act*.

Threatened and Endangered Species. Impacts on threatened and endangered species are determined in a manner similar to that used to describe terrestrial and aquatic resources since the sources of potential impacts are similar. A list of species potentially present on each site or in proximity to the site or region (appendix C) was developed using information obtained from the U.S. Fish and Wildlife Service (USFWS) and appropriate state agencies. This list, along with consideration of site environmental and engineering data, and provisions of the *Endangered Species Act*, are used to evaluate whether the various alternatives could impact any threatened or endangered plant or animal (or its habitat).

Species that are Federal proposed or candidates for listing as threatened or endangered species do not receive legal protection under the *Endangered Species Act*. However, the USFWS recommends that impacts to these species be considered in project planning since their status can be changed to threatened or endangered in the foreseeable future. The USFWS has recently changed the classification of species under review for listing as threatened or endangered (61 FR 7596). Proposed species include those plants and animals for which a proposed rule to list as threatened or endangered has been published. Candidate species include those plants and animals for which the USFWS has on file sufficient information on biological vulnerability and threat to support issuance of a proposed rule for listing as threatened or endangered. Candidate species previously included Category 1 (species appropriate for listing as protected) and Category 2 (species possibly appropriate for listing as protected). Due to the recent rule change, candidate species include only those which are appropriate for listing as protected species (i.e., species formerly listed as Category 1). The Category 2 designation has been omitted. Some of the species previously identified as Federal candidate Category 2 in the Draft PEIS also have a state status and continue to be evaluated for potential impacts. However, due to the change in candidate classification described above, many species have been eliminated from proposed site threatened and endangered species lists.

4.1.7 Cultural and Paleontological Resources

Included in these sections are evaluations of the impacts of the Stockpile Stewardship and Management Program alternatives on prehistoric, historic, Native American, and paleontological resources. The effects considered include those resulting directly from land disturbance during construction, visual intrusion to the settings or environmental context of historic structures, visual and audio intrusions on Native American sacred sites, reduced access to Native American traditional use areas, unauthorized artifact collecting, and vandalism. Laws, regulations, Executive orders, and DOE orders mandating protection of cultural and paleontological resources are described for each site in chapter 5.

Prehistoric Resources. Prehistoric resources are physical properties resulting from human activities that predate written records. They are generally identified as either isolated artifacts or sites. Sites may contain concentrations of artifacts (e.g., stone tools and ceramic sherds), features (e.g., remains of campfires and houses), and plant and animal remains. Depending on their age, complexity, integrity, and relationship to one another, sites may be important for and capable of yielding information about past populations and adaptive strategies. The affected environment section for prehistoric resources includes a brief overview of the number and types of prehistoric sites in the project areas, if known, and their status on the National Register of Historic Places (NRHP). The overview consists of a summary of existing information about prehistoric resources in the region and a discussion of types of sites that are likely to occur.

Impact assessments for prehistoric resources focus mainly on those properties likely to be eligible for the NRHP. Impacts are assessed by considering whether or not the proposed action could substantially add to an existing disturbance of resources in the project areas, adversely affect NRHP-eligible resources, or cause loss of or destruction to important prehistoric resources.

Historic Resources. Historic resources consist of physical properties that postdate the existence of written records. In the United States, historic resources are generally considered to be those that date from 1492 onward. Historic resources include architectural structures or districts (e.g., buildings, dams, and bridges), objects, and archaeological features (e.g., foundations of mills or residences, trails, and trash dumps). Ordinarily, sites less than 50 years old are not considered historic for analytical purposes, but exceptions can be made for younger properties if they are of exceptional importance (e.g., structures associated with Cold War themes [36 CFR 60]). The affected environment section for historic resources includes a brief overview of the number and types of historic sites in the project areas, if known, and their status on the NRHP. The overview consists of a summary of existing information about historic resources in the region and a discussion of the types of sites that are likely to exist.

Impact assessments for historic resources focus mainly on those properties likely to be eligible for the NRHP. Impacts are assessed by considering whether or not the proposed action could substantially add to an existing disturbance of resources in the project areas, could adversely affect NRHP-eligible resources, or could cause loss of or destruction to important historic resources.

Native American Resources. Native American resources are sites, areas, or materials important to Native Americans for religious or heritage reasons. In addition, cultural values are placed on natural resources such as plants, which have multiple purposes within various Native American groups. Of primary concern are concepts of sacred space that create the potential for land-use conflicts. Native American concerns would be identified through direct consultation with tribal representatives and field visits with tribal religious specialists during preparation of project-specific tiered NEPA documents. Contacts would be identified by reference to the ethnographic literature, by state and national pantribal organizations, and by agency and academic anthropologists.

The individual resource type, the proximity of impact areas to the resources, and the likely duration of impacts are considered in the analysis of Native American resources. Specific concerns include the relative importance of the resource in the Native American physical universe or religion, the distance at which activities in the vicinity of a sacred area constitute a disturbance, the extent to which affected resources may be restored, and the extent to which alternative sources for raw materials are available and/or suitable. Impacts to Native American resources are assessed by considering whether or not the proposed action has the potential to affect sites important for their position in the Native American physical universe or belief system, or the possibility of reducing access to traditional use areas or sacred sites.

Paleontological Resources. Paleontological resources are the physical remains, impressions, or traces of plants or animals from a former geological age. They include casts, molds, and trace fossils such as burrows or tracks. Fossil localities typically include surface outcrops, areas where subsurface deposits are exposed by ground disturbance, and special environments favoring preservation, such as caves, peat bogs, and tar pits. Paleontological resources are important mainly for their potential to provide scientific information on paleoenvironments and the evolutionary history of plants and animals. The affected environment section for paleontological resources includes a description of known paleontological localities and geological formations in the project areas that may be fossil bearing.

Impact assessments for paleontological resources are based on the numbers and kinds of resources that could be affected, as well as the quality of fossil preservation in a given deposit, particularly in deposits with high research potential. Such deposits include poorly known fossil forms; well-preserved terrestrial vertebrates; unusual depositional contexts; assemblages containing a variety of fossil forms, particularly associations of vertebrates, invertebrates, and plants; or deposits recovered from poorly studied regions or in unusual concentrations.

4.1.8 Socioeconomics

These sections describe and assess impacts on local and regional socioeconomic conditions and factors including employment, economy, population, housing, and public finance. This PEIS assesses the socioeconomic impacts of both the gains and losses of missions at each site. The potential for socioeconomic impacts on population, housing, and local government finance is greatest in those local jurisdictions immediately adjacent to each site and those that are the residential locations of the majority of DOE site employees. Potential socioeconomic impacts on the economy (employment and income) are not bounded by local government jurisdictions but rather by industrial linkages to a regional market. Therefore, potential socioeconomic impacts are assessed using two geographic regions, a regional economic area, and a region of influence (ROI). Regional economic areas are used to assess potential effects on the economy. ROIs are used to assess effects which are more localized in political jurisdictions surrounding the sites.

The regional economic area for each site encompasses a broad market that involves trade among and between regional industrial and service sectors. It is characterized by strong economic linkages between the communities located in the region. These linkages determine the nature and magnitude of multiplier effects on economic activity (i.e., purchases, earnings, and employment) at each candidate site. Regional economic areas are defined by the U.S. Bureau of Economic Analysis as consisting of an economic node that serves as the center of economic activity and the surrounding counties that are economically related and include the places of work and residences of its labor force.

The U.S. Bureau of Economic Analysis measures multiplier effects of interindustry linkages with the Regional Input-Output Modeling System (RIMS II). RIMS II is based on an accounting framework called an input-output table. An input-output table shows, for each industry, industrial distributions of inputs purchased and outputs sold. RIMS II Total Direct-Effect Multipliers are used in this PEIS to estimate additional regional employment and income generated by employment and income directly associated with the proposed alternatives. RIMS II is also used to estimate the effects of jobs and income lost in a region due to downsizing or phaseout.

Additional potential demographic impacts were assessed on a smaller geographic area (ROI) where the housing market and community public finances could be most affected. Proposed Program alternatives at alternative sites were assessed using a site-specific ROI, comprising those local jurisdictions likely to experience the greatest socioeconomic impacts. The ROI is defined as those counties where approximately 90 percent of the current DOE and contractor employees reside. This residential distribution reflects existing commuting patterns and attractiveness of area communities for people employed at each site, and is used to estimate the future distribution of direct workers with the proposed alternative. The evaluation of impacts is based on the degree to which changes in employment and population affect the regional economy, housing market, and public finance. It is assumed that most new or lost jobs would occur within the ROI where the majority of DOE and contractor employees live. The changes to these factors are projected to 2030 because the projected life of the DOE facilities for the alternatives under study is 25 years starting in 2005. The following sections discuss each of the socioeconomic conditions and factors considered.

Employment. The construction and operation of stewardship and management technologies and facilities could affect employment at DOE sites. Changes in site employment would, in turn, directly affect local and regional populations, economies, housing, and public finance. Current employment at each site is described, as well as projected employment associated with other planned DOE initiatives. Socioeconomic trends and the relationship of site employment to these trends are examined for each potentially affected socioeconomic region. Emphasis is placed on evaluating total direct and indirect employment changes and impacts associated with potential mission relocations.

Economy. The regional economies surrounding each site are characterized. Emphasis is placed on the measurement of the relative contribution and importance of each site's employment payroll and purchases to the economy. Changes to regional economic conditions are evaluated based on each site's relative contribution and changes to employment. Emphasis is placed on the economic effects of mission changes associated with the operation of stewardship and management technologies and facilities.

Population. The demographic changes in the ROI surrounding each site are described and assessed. Demographic characteristics are presented for the site's ROI to support the assessment of socioeconomic impacts. Trends are identified and used to project demographic changes over the environmental baseline period. Cumulative population impacts include the population impacts of other DOE actions under consideration, including planned environmental restoration activities.

Housing. Changes in employment at each site would affect the demand and supply of housing units, including the need for temporary housing (e.g., rental units) to support in-migrating construction workers. Trends in the housing availability within each site's socioeconomic ROI are characterized and evaluated. Numbers of in-migrating and out-migrating site employees associated with each of the alternatives are then used to evaluate housing impacts.

Public Finance. Each site is located on land owned by the Federal Government, which exempts these lands from state and local taxation. However, all employee income, property, and purchases are subject to applicable Federal, state, and local taxation requirements.

The additional workforce associated with any of these alternatives is small, and would require few in-migrating workers. For that reason, there would be little increased demand on specific community services. However, there would be fiscal impacts associated with additional missions or the phaseout of existing missions which could affect the community's ability to provide basic infrastructure and services. Therefore, the fiscal impacts on each site's ROI are assessed for counties, cities, and school districts, rather than the change in demand for specific community services. For a more detailed discussion of public finance, see appendix D.

4.1.9 Radiation and Hazardous Chemical Environment

4.1.9.1 *Normal Operation*

Public Health Risks. The risks to the general public during the 25-year operational interim are determined in three ways. Radiological releases/doses, which are conveyed in site-specific reports, are used to calculate risks associated with predicted baseline (No Action) operations in 2005. Incremental radiological/chemical doses and respective subsequent risks for management alternatives associated with each applicable site examined in this PEIS are calculated (modeled) via predicted release quantities supplied by "technology-specific" data reports and from site-dependent parameters. Incremental radiological/chemical doses and respective subsequent risks associated with certain proposed stewardship alternatives (on a per site basis) pursuant to this PEIS, are directly referenced from technology-specific or site-specific data reports.

Radiological Impacts. The assessment of incremental (or decremental) impacts incurred at each of the DOE sites are performed using the GENII computer code. This type of assessment uses such site-dependent factors as meteorology, population distributions, agricultural production, and an assumed facility location on a given site. Health risks to the maximally exposed individual and population within 80 kilometers (km) (50 miles [mi]) at Oak Ridge Reservation (ORR), Savannah River Site (SRS), Pantex Plant (Pantex), Sandia National Laboratories (SNL), and Nevada Test Site (NTS) are analyzed for each management and/or stewardship alternative, with the assumption that any two or more alternatives (with the exception of No Action) are not concurrently existing. At Los Alamos National Laboratory (LANL) and Lawrence Livermore National Laboratory (LLNL) however, a cumulative calculation is provided which includes all possible alternatives simultaneously existing at each respective site.

Resulting doses are compared with regulatory limits, and for perspective, are also compared with background radiation levels in the area of the site. These doses are then converted into the projected number of fatal cancers using a dose-to-risk conversion factor of 500 fatal cancers per 1,000,000 person-rem ($5x10^{-4}$ fatal cancers per person-rem) derived from data presented in a report prepared by the National Research Council's Committees on the Biological Effects of Ionizing Radiations (BEIR V) and also cited in the *1990 Recommendations of the International Commission on Radiological Protection.* The calculated health effects from each of the alternatives are then compared to one another (including the No Action alternative).

Hazardous Chemical Impacts. Public health risks from hazardous chemical releases during normal operation at the respective DOE sites are assessed by essentially the same analytical approach using conservative assumptions. This conservative approach is applied uniformly to all alternative sites using guidance provided under the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA). The initial assessment in risk analysis is considered a screening step that was determined to be the appropriate level of analysis for this

PEIS. Under this guidance, if the Hazard Index (HI) is ≤ 1.0, all noncancer exposure values meet Occupational Safety and Health Administration (OSHA) standards; if the cancer risk is $\leq 1 \times 10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $\leq 1 \times 10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the general population.

Engineering designs used for the stockpile stewardship and management process and/or storage facilities include the anticipated emissions of hazardous chemicals. From emission data, concentrations at the site boundary are assumed to represent the maximum that any member of the public will encounter; therefore, the site boundary concentrations are derived through the ISCST Model (version 2) recommended by EPA. The noncancer risks of the maximally exposed individual of the public will consist of hazard quotients (HQs) that compare chemical exposure levels to the reference concentration values published by EPA in the Integrated Risk Information System. The cancer risk to the maximally exposed individual is calculated from the doses derived from modeling exposure levels, using slope factors or unit risks for individual chemicals published in the Integrated Risk Information System or the health effects summary tables. The health effects summary tables are the yearly summary of EPA's regulatory toxicity data. The HI values (i.e., the sum of the HQs) and cancer risks are conservative because a single source and a single point at the site boundary are chosen for the calculations. The cancer risks are also conservative due to the single point concentration and the position where the exposure is assumed to occur. The HI is independent of the cancer risk.

The HIs and cancer risks are used as screening tools to identify potential health concerns that may require further analysis. If the HI meets OSHA standards and cancer risks are within the default value, then further analysis is most likely not warranted. However, if in the conservative approach, there are sites or activities wherein the HI and/or cancer risk exceed acceptable limits, then these sites or activities become candidates for further in-depth analysis. The in-depth analysis should identify the individual chemicals that contribute to substantial adverse HI and/or cancer risk impacts, starting with those chemicals showing the highest HQs and/or cancer risk and grouping them according to their specific health effects. These chemicals then may be identified for inclusion in more specific site analyses. It should be noted that when the OSHA standards for HIs and/or the cancer risk default value are exceeded, a health concern may not necessarily exist. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging whether the sites have a health concern. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among different sites. The baseline is then used to determine the extent to which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

Information pertaining to OSHA-regulated permissible exposure limits, reference concentrations, reference doses, cancer slope factors (if any), and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b.)

Occupational Health Risks. Health risks are assessed for two types of workers. The first type is the involved worker who would be located inside a facility that is involved with any of the given alternatives being examined. The second type is the noninvolved worker who would be located somewhere else on a given site but is not involved with occupational tasks associated with any of the given alternatives.

Radiological Impacts. Involved worker exposures are either based on values reported in technology-specific data reports or in occupational dose histories for similar operations. The doses to noninvolved workers at each respective site are determined based on occupational dose histories; in most cases for these workers, impacts associated with normal operation for each management and/or stewardship alternative are assumed to be negligible compared with those associated with their primary onsite activities. Worker impacts associated with each alternative at ORR, SRS, Pantex, SNL, and NTS are analyzed with the assumption that any two or more alternatives (with the exception of No Action) are not concurrently existing. At LANL and LLNL however, a cumulative calculation is reported that includes all possible alternatives simultaneously existing at each respective site.

The worker doses are converted into the number of projected fatal cancers using the dose-to-risk conversion factor of 400 fatal cancers per 1,000,000 person-rem ($4x10^{-4}$ fatal cancers per person-rem) given in ICRP Publication 60. This lower risk estimator, compared with that for members of the public, reflects the absence of children in the workforce.

Hazardous and Toxic Chemical Impacts. Since direct chemical monitoring data on worker exposure is not available for specific operations, the onsite worker is assumed to receive the maximum exposure any involved or noninvolved onsite person will receive. OSHA-regulated levels (i.e., permissible exposure levels) are applied to all hazardous chemicals that are released at the site. This includes both the project-specific releases as well as those that are a result of other site operations. All onsite exposures are assumed to occur at a distance of 100 meters (m) (330 feet [ft]) from a centralized point of release, which will yield a conservative concentration level for each chemical. The concentrations are derived through the ISCST Model recommended by EPA. The noncancer risks to the onsite worker consist of HQs that compare chemical exposure levels to the permissible exposure level values established by OSHA. The HI for each alternative is the sum of all HQs for the alternative. The cancer risks to the onsite worker are calculated from doses derived from modeled exposure level, using slope factors or unit risks for individual chemicals published in the Integrated Risk Information System or the health effects summary tables. The worker exposure is based on an 8-hour day and 52 weeks of 40 hours each (i.e., 0.237 fractional year). The HI values and cancer risks are conservative because a single point at 100 m (330 ft) from a centralized source term is chosen for the calculations. The cancer risks are conservative due to the single point concentration and the position where the exposure is assumed. The HI is independent of cancer risk. The cancer risks to the facility worker for each chemical are computed from the dose (converted from air concentrations) and the unit risk or slope factors to yield a probable risk. The risks are also conservative because a single point at or near the maximum onsite concentration is selected for calculating the exposure of the facility worker. Actual risks are likely lower than estimated risks.

As described for public health risks, this conservative approach is applied uniformly to workers at all sites using guidance under CERCLA. Under this guidance, if the HI is ≤ 1.0, all noncancer exposure values meet OSHA standards. If the cancer risk is $\leq 1 \times 10^{-6}$ (the default value, not a regulatory limit), no further analysis is indicated. If the HI exceeds the OSHA standards and/or the cancer risk exceeds the default value, a need for a more in-depth analysis of the data is indicated. It should be noted that when the OSHA standards for HIs and/or the cancer risk default value are exceeded, a health concern may not necessarily exist. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among different sites. The baseline is then used to determine the extent to which each alternative adds or subtracts from the No Action HI and cancer risk for workers at each site.

Information pertaining to OSHA-regulated permissible exposure limits, reference concentration, reference doses, cancer slope factors (if any), and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

Epidemiological Studies. In March 1990, the Secretary of Energy announced that DOE would turn over responsibility for analytical epidemiologic research on long-term health effects on workers at DOE facilities and the public in surrounding communities to the Department of Health and Human Services. Further, DOE directed that this worker and public health and exposure data be released. A Memorandum of Agreement with the Department of Health and Human Services was signed in January 1991. The Department of Health and Human Services is now conducting the ongoing health effects research program. The National Institute for Occupational Safety and Health also initiated a study in 1994 but does not expect the results before 1997. Discussions are presented of past and ongoing health studies for each site.

4.1.9.2 *Facility Accidents*

Accident Analysis for Postulated Accident Scenarios. The relative consequences of postulated accidents in the evaluation of each alternative are considered. In evaluating the magnitude and consequences of each alternative, a suitable accident analysis is performed to produce results for decision-making purposes. Although the concepts used are analogous to a formal Probabilistic Risk Assessment, which would be appropriate for a project-level analysis, the accident analysis involves considerably less detail and only addresses a representative spectrum of beyond design-basis accidents (high-consequence, low-probability) and a representative spectrum of possible operational accidents (low-consequence but high-probability of occurrence). The technical approach for the selection of accidents is consistent with the DOE Office of NEPA Oversight *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements* (May 1993), which recommends consideration of two major categories of accidents: within design-basis accidents and beyond design-basis accidents.

For the purpose of this assessment, risk is defined as the mathematical product of the probability and consequences of an accident. Both probability and consequences are presented in this PEIS. The risk-contributing scenarios consider both design-basis and severe accidents. The specific accidents consider the types of facilities. Examples of accidents include those resulting from operator errors, spills, criticalities, fires, explosions, airplane crashes, common-cause failures, collocated facilities, severe weather, earthquakes, and transportation. Information on potential accidents includes those that have been postulated and analyzed for similar facilities. The risks of the various stockpile stewardship and management facilities are evaluated in terms of the incremental increase in risk and the cumulative effect of that risk with respect to normal day-to-day risks to which the general population is exposed.

For each alternative, a number of evaluation and beyond evaluation accidents have been identified and are generally referred to as the composite set of accidents. Two subsets of the composite set are also referred to as the composite set of evaluation basis accidents (EBAs) and the composite set of beyond evaluation basis accidents (BEBAs). Impacts are presented for the composite set of accidents to reflect the combined impacts of EBAs and BEBAs. The impacts for the composite set of EBAs are also provided to reflect the impacts of high-frequency/low-consequence accidents. Impacts for the composite set of BEBAs are provided to show the impacts of low-frequency/high-consequence accidents. EBAs are generally in a frequency range greater than 10^{-6} per year, while BEBAs are generally in a frequency range of 10^{-7} to 10^{-6} per year. In some cases, accidents less than 10^{-7} are included in the composite set of BEBAs.

Accident risk to collocated workers was calculated for a hypothetical worker at 1,000 m (3,281 ft) from the facility, or at the site boundary, whichever is closer. For distances less than 1,000 m (3,281 ft), the screening model techniques used in the programmatic level analyses are less effective because of the effects of buildings on meteorology and dispersion. For purposes of this analysis, all workers associated with a specific stockpile management function are assumed to be at risk for the various accident scenarios addressed in this PEIS. Where information is available, risks to involved workers from accidents are presented. It should be noted that the purpose of this PEIS is to assist the decisionmaker in making programmatic site selection decisions. Since the activities are the same for a given stockpile management function regardless of location, the risk to involved workers would be independent of site location and would not be a discriminating factor for programmatic siting decisions. Risk to workers from radiological accidents would be addressed in greater detail in site-specific tiered NEPA documents when more detailed information is available.

Sensitivity Analysis. Adequate data is not available to support a quantitative sensitivity analysis for accident impacts; therefore, a discussion of the subject is not presented in the accident discussion for the management alternatives in this PEIS. However, it is expected that higher case workloads could increase the quantity of hazardous materials at risk in an accident and the accident frequency. Therefore, this could result in a corresponding increase in accident impacts.

Uncertainties. The sequence of analyses performed to generate the radiological impact estimates from normal operation and facility accidents include selection of normal operational modes and accident sequences, estimation of source terms, estimation of environmental transport and uptake of radionuclides, calculation of radiation doses to exposed individuals, and estimation of health effects. There are uncertainties associated with each of these steps. Uncertainties exist in the way the physical systems being analyzed are represented by the computational models and in the data required to exercise the models due to measurement errors, sampling errors, or natural variability.

The analysis is designed to ensure—through judicious selection of release scenarios, models, and parameters—that the results represent the potential risks, and that there is a consistent basis for comparing alternatives. This is accomplished by making conservative assumptions in the calculations at each step.

The risk analysis presented in this PEIS is not a complete risk assessment in the sense of identifying and analyzing all physically possible accidents including those high consequence accidents whose probability is so remote as to render them not reasonably foreseeable. The accident analyses do include, however, a spectrum of reasonably foreseeable accidents including high consequence accidents and their associated risks for the technologies and facilities. These severe accidents have low accident frequencies, often less than 1.0×10^{-6} per year. The accident analyses also include higher frequency accidents (evaluation-basis and other operational accidents) that typically have lower consequences. These evaluation-basis and other operational accidents have accident frequencies that are greater than 1.0×10^{-6} per year.

In summary, the radiological and hazardous chemical impact estimates presented in this document were obtained by:

- Using the best available data
- Considering the processes, events, and accidents that are reasonably foreseeable for the facilities described in this study and the environment
- Making conservative assumptions when there is doubt about the exact nature of the processes and events taking place
- Ensuring the consistency of analysis across alternatives

Emergency Preparedness. Emergency preparedness and planning has the effect of mitigating the consequences of facility accidents. Emergency preparedness plans exist for all sites and are summarized for each site.

4.1.10 Waste Management

A major effort of the Stockpile Stewardship and Management Program has been and would continue to be the minimization of waste generation. The proposed alternatives would incorporate waste minimization and pollution prevention practices to the maximum extent practicable. Waste minimization efforts and the management of Program-related wastes are discussed for each DOE site. Waste management facilities that would support stockpile stewardship and management facilities would treat and package waste into forms that would enable long-term storage or disposal. For sites under consideration that do not have existing or planned onsite low-level waste (LLW) disposal, the number of additional shipments required to transport LLW from the site to a DOE LLW disposal facility is estimated. For example, for purposes of this analysis it is assumed that Pantex would ship its LLW to NTS as per current practice. The risks associated with additional shipments are addressed as part of the intersite transport assessment (section 4.10). Waste management activities that would support the Program are assumed to be per current site practice and are contingent upon decisions to be made through the *Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DOE/EIS-0200-D, August 1995). Any future waste management facilities that may be required to support the Program would be coordinated with any decisions resulting from the Waste Management PEIS and any respective site-specific NEPA documentation.

The construction and operation of stockpile stewardship and management facilities would generate several types of wastes. Generation points are in some cases different among alternative sites depending upon specific siting of various facilities. Construction wastes are similar to those generated by any construction project of comparable scale. Wastes generated during the operation of stockpile stewardship and management facilities consist of five primary types: transuranic (TRU), low-level, mixed, hazardous, and nonhazardous wastes. The types and amounts of waste vary according to the alternative and facility. For example, the Pit Fabrication Facility is the only facility projected to generate any TRU waste.

The nuclear weapons facilities provide for the short-term stabilization, staging, storage, and management of waste, including the means to minimize waste generation, until DOE either disposes of the waste or places it in long-term storage. To provide a framework for addressing the impacts of waste management for stockpile stewardship and management facilities, descriptive information is presented on the waste management activities anticipated for each DOE site. The volumes of each type of waste generated are estimated by facility and DOE site. These estimates have included waste minimization provisions. The impact assessment addresses the waste types and projected waste volumes from the various stockpile stewardship and management facilities at each site compared to No Action. Impacts are assessed in the context of existing site practices for treatment, storage, and disposal, including the applicable regulatory setting and requirements. Existing permits, compliance agreements, and other site-specific waste management practices were reviewed and analyzed to assess the ability to conduct the required activities.

Decontamination and decommissioning (D&D) activities are also addressed. Such activities depend upon the historic use of the facility and the final disposition of a facility. D&D activities could range from performing a simple radiological survey to completely dismantling and removing a radioactively contaminated facility. The D&D waste volumes from transition facilities no longer required for stockpile stewardship and management missions are estimated.

4.1.11 Environmental Justice

This PEIS assesses the potential for disproportionately high and adverse human health or environmental effects on minority and low-income populations in accordance with Executive Order 12898, *Federal Action to Address Environmental Justice in Minority Populations and Low Income Populations*. Because both the Federal Working Group on Environmental Justice and DOE are still in the process of developing guidance on criteria for identifying effects to these populations, the approach taken in this PEIS analysis may differ somewhat from whatever guidance may be issued.

This PEIS environmental justice analysis addressed selected demographic characteristics of the ROI (80 km [50 mi]) for each of the eight alternative sites. The analysis identified census tracts where racial or ethnic minorities comprise 50 percent, or a simple majority, of the total population in the census tract, or where racial or ethnic minorities comprise less than 50 percent but greater than 25 percent of the total population in the census tract. The analysis also identified low-income communities where 25 percent or more of the population is characterized as living in poverty (yearly income of less than $8,076 for a family of two). Impacts are assessed based on the analysis presented for each resource and issue area for each of the proposed alternatives at each site. Any disproportionately high and adverse human health or environmental effects on minority and low-income populations are discussed.

4.1.12 Cumulative Impacts

Cumulative impacts address the incremental effects of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions (43 FR 55978; 40 CFR 1500-1508).

Other DOE programs (including environmental management missions) and other Federal, state, and local development programs all have the potential to contribute to cumulative effects on DOE sites. "Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time" (40 CFR 1508.7). To the extent information was available for these other actions at a given site, the cumulative impacts are presented.

Continuing Department of Energy Missions. Continuing DOE missions and any reasonably foreseeable changes to these missions are addressed as part of the affected environment baseline. Continuing missions at each site are discussed in the site infrastructure section of the affected environment discussion for each DOE site. These missions provide the baseline against which the stockpile stewardship and management facilities are compared. For example, water requirements for the proposed stockpile stewardship and management facilities are combined with requirements of continuing missions to assess the total impact to water resources.

Environmental Management Missions. Any planned and reasonably foreseeable new or modified waste handling facilities are discussed in the waste management section for each site. In addition, to the extent that other environmental management missions or strategies are planned and defined, they are also discussed as bounding environmental impacts of waste management actions. Specific waste management activities are being addressed in the Waste Management PEIS being prepared by the DOE Office of the Assistant Secretary for Environmental Management (EM).

Other Federal and State Programs. Other Federal and state programs are identified, but only planned, reasonably foreseeable programs are considered. Typical programs in this category include public works projects and military base closures and reuse projects. Potential consequences of any major programs that increase impacts when combined with the stockpile stewardship and management alternatives are presented.

Local Development Programs. Local development programs are not specifically identified. However, socioeconomic projections take into account anticipated regional growth. Local development programs are a part of this growth and are addressed collectively using growth as a substitute. Socioeconomic projections form the baseline for much of the environmental analysis presented in this document.

Approach for Cumulative Impact Assessments. There is no generic methodology for the assessment of cumulative impacts. Therefore, the following approach represents a design for analyzing programmatic cumulative impacts relative to past, present, and probable future activities. It incorporates a wide ranging view of DOE defense programs, environmental management, and other outside interactions. This strategy is integrated with detailed resource-specific assessment methods where appropriate, and can be developed further in site-specific tiered NEPA documentation to ensure compatibility across the DOE Office for the Assistant Secretary for Defense Programs (DP), EM, and other programs.

The rationale for this approach is that this PEIS is a programmatic document. The reference condition for cumulative effects is the No Action alternative. The strategy has four major components:

- Focus analysis primarily on the impacts at each stockpile stewardship and management site where other DP and/or EM activities are reasonably anticipated. Past, baseline, and future DP and EM activities are more clearly defined and have a higher degree of certainty than offsite activities. These activities tend to be much more speculative the further into the future they are planned.

- Address quantitatively cumulative impact analyses associated with offsite activities in site-specific, tiered NEPA documentation.

- Coordinate efforts between DP and EM activities through the Memorandum of Agreement between DP and EM activities.

- Focus on site-specific cumulative effects from stockpile stewardship and management, addressing them in terms of both the temporal and spatial aspects of DP activities, as well as the level, phasing, and site-specific locations of proposed EM facilities and activities. This is appropriate due to the uncertainty and lack of specificity associated with offsite activities that could result in significant incremental, indirect, or synergistic cumulative impacts; these activities are more effectively addressed in site-specific, tiered NEPA documentation.

This method is flexible and allows for the assessment of cumulative impacts to regulated resources at a lower level of analysis due to the protection afforded to them through applicable regulations. In addition, the method recognizes that the focus on a given resource may vary according to site-specific characteristics of the local environment. Where these types of variations are identified, a level of analysis would be performed commensurate to the importance of the potential cumulative impacts on that resource.

4.2 Oak Ridge Reservation

ORR is a Government-owned, contractor-operated reservation located in the State of Tennessee. The regional location of ORR is shown in figure 4.2–1 and the principal facilities at ORR are shown in figure 4.2–2. The prime contractor manages the Y-12 Plant (Y-12), Oak Ridge National Laboratory (ORNL), the K-25 Site (K-25), and most other properties on the reservation. The facilities began operation in 1943 as part of the World War II Manhattan Project. The primary missions at each facility have changed over the past 50 years, with the current missions described in section 3.2.2. Although Y-12 is the main focus area with respect to the proposed actions, baseline environmental information and impact assessment are presented for ORR due to the proximity and potential impacts of nearby facilities, both present and future.

4.2.1 Description of Alternatives

No Action. ORR would continue to perform the missions described in section 3.2.2.

Stockpile Management Alternatives. The secondary and case fabrication mission could be consolidated and downsized, and remain at Y-12. In this scenario, storage of the strategic reserve of uranium would remain at Y-12. The Y-12 secondary and case fabrication mission could also be transferred to either LANL or LLNL. In the event the secondary and case fabrication mission is transferred to the laboratories, the DP missions at Y-12 would be phased out and the facilities transitioned to EM for disposition. In addition, the strategic reserve of uranium in the form of canned subassemblies would be relocated to the weapons assembly/disassembly (A/D) Facility at either Pantex or NTS.

Stockpile Stewardship Alternatives. There are no stockpile stewardship alternatives that include ORR.

4.2.2 Affected Environment

The following sections describe the affected environment at ORR for land resources, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure at ORR, the radiation and hazardous chemical environment, and the waste management conditions are described.

4.2.2.1 *Land Resources*

ORR is located on approximately 13,980 hectares (ha) (34,545 acres) within the corporate limits of the city of Oak Ridge, approximately 19 km (12 mi) west of Knoxville, TN. All the land within ORR is owned by the Federal Government and is administered, managed, and controlled by DOE. Generalized land uses at ORR and in the vicinity are shown in figure 4.2.2.1–1.

Land uses within ORR can be grouped into four major land use classifications: industrial, forest/undeveloped, public/quasi-public, and water. The industrial areas account for approximately 4,700 ha (11,700 acres) or approximately 33 percent of the total site area. An additional 490 ha (1,200 acres) are used for a security buffer zone around various facilities. About 320 ha (800 acres) of ORR's land is classified as public land and consists mainly of the 36-ha (90-acre) Clark Center Recreational Park, numerous small public cemeteries, and an onsite public road (OR DOE 1989a:5-10). The remaining area, about 8,700 ha (21,600 acres), consists of forest/undeveloped land, some of which is managed as pine plantations for production of pulpwood and saw timber. The DOE Water Treatment Facility, which provides water to many ORR facilities and the city of Oak Ridge, is located just north of Y-12. There are no prime farmlands on ORR.

In 1980, DOE designated approximately 5,500 ha (13,600 acres) of ORR undeveloped land as a National Environmental Research Park. The park is used by the national scientific community as an outdoor laboratory for environmental science research on the impact of human activities on the eastern deciduous forest ecosystem (DOE 1985a:3,27).

Land bordering ORR is predominately rural and used largely for residences, small farms, forest land, and pasture land. The city of Oak Ridge, along the northeast portion of the site, has a typical urban mix of residential, public, commercial, and industrial land uses. There are four residential areas along the northern boundary of ORR; each has several houses within approximately 30 m (98 ft) of the boundary.

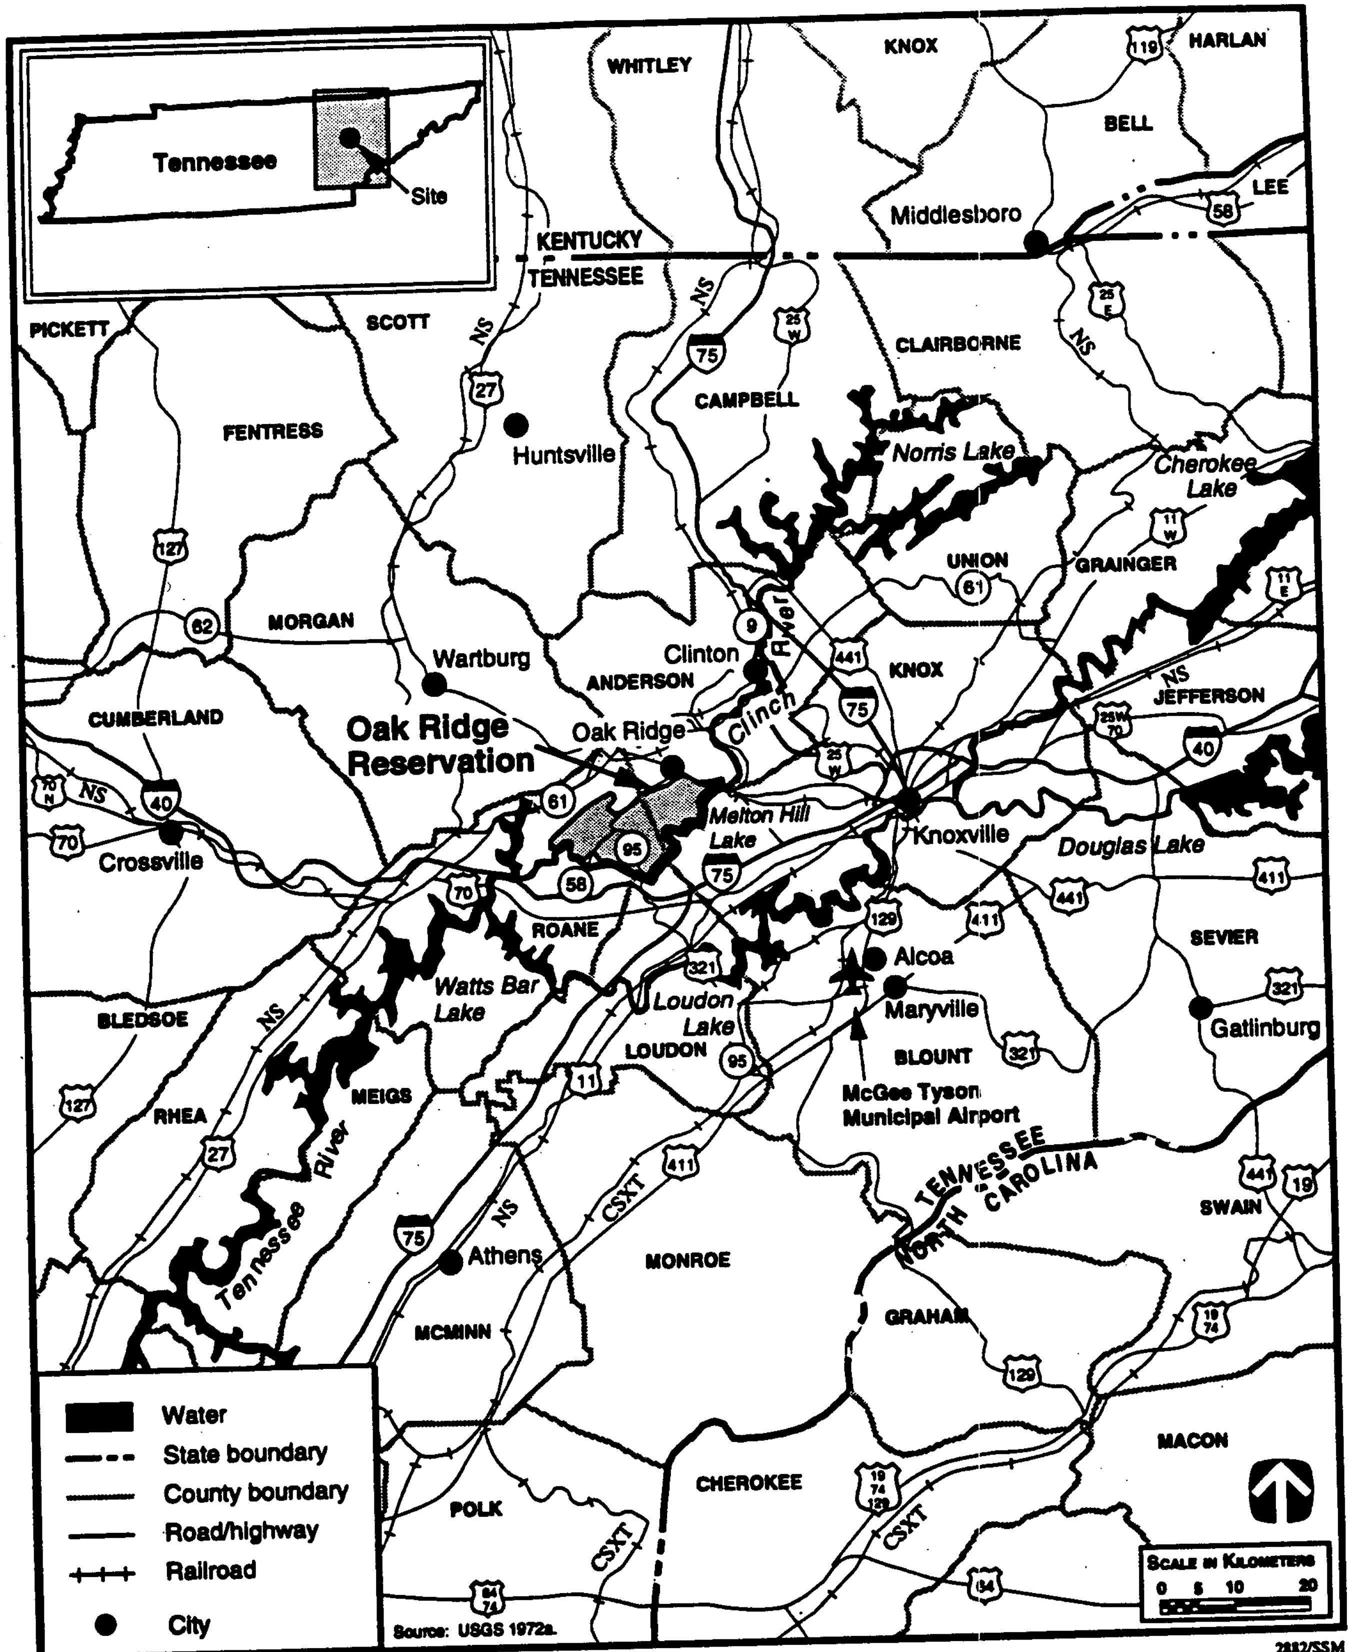

FIGURE 4.2–1.—*Oak Ridge Reservation, Tennessee, and Region.*

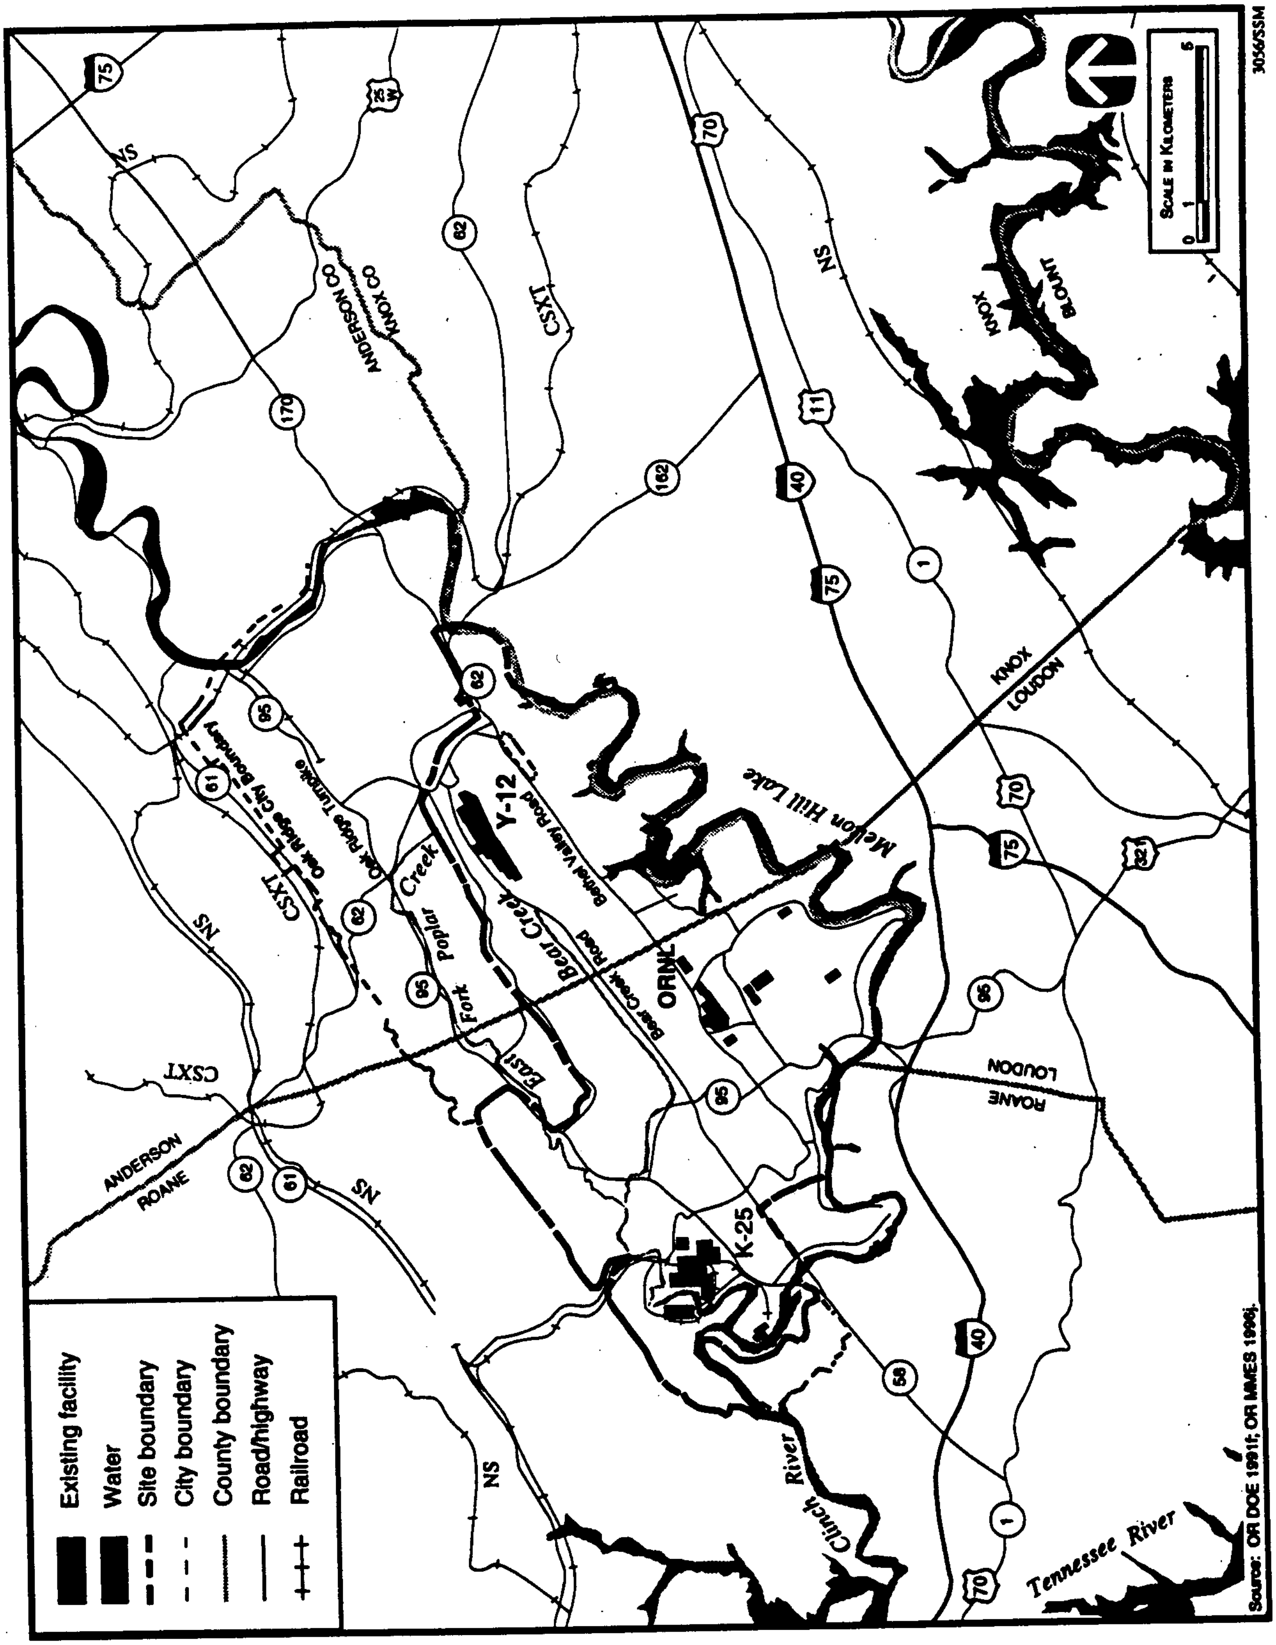

FIGURE 4.2–2.—*Principal Facilities at Oak Ridge Reservation.*

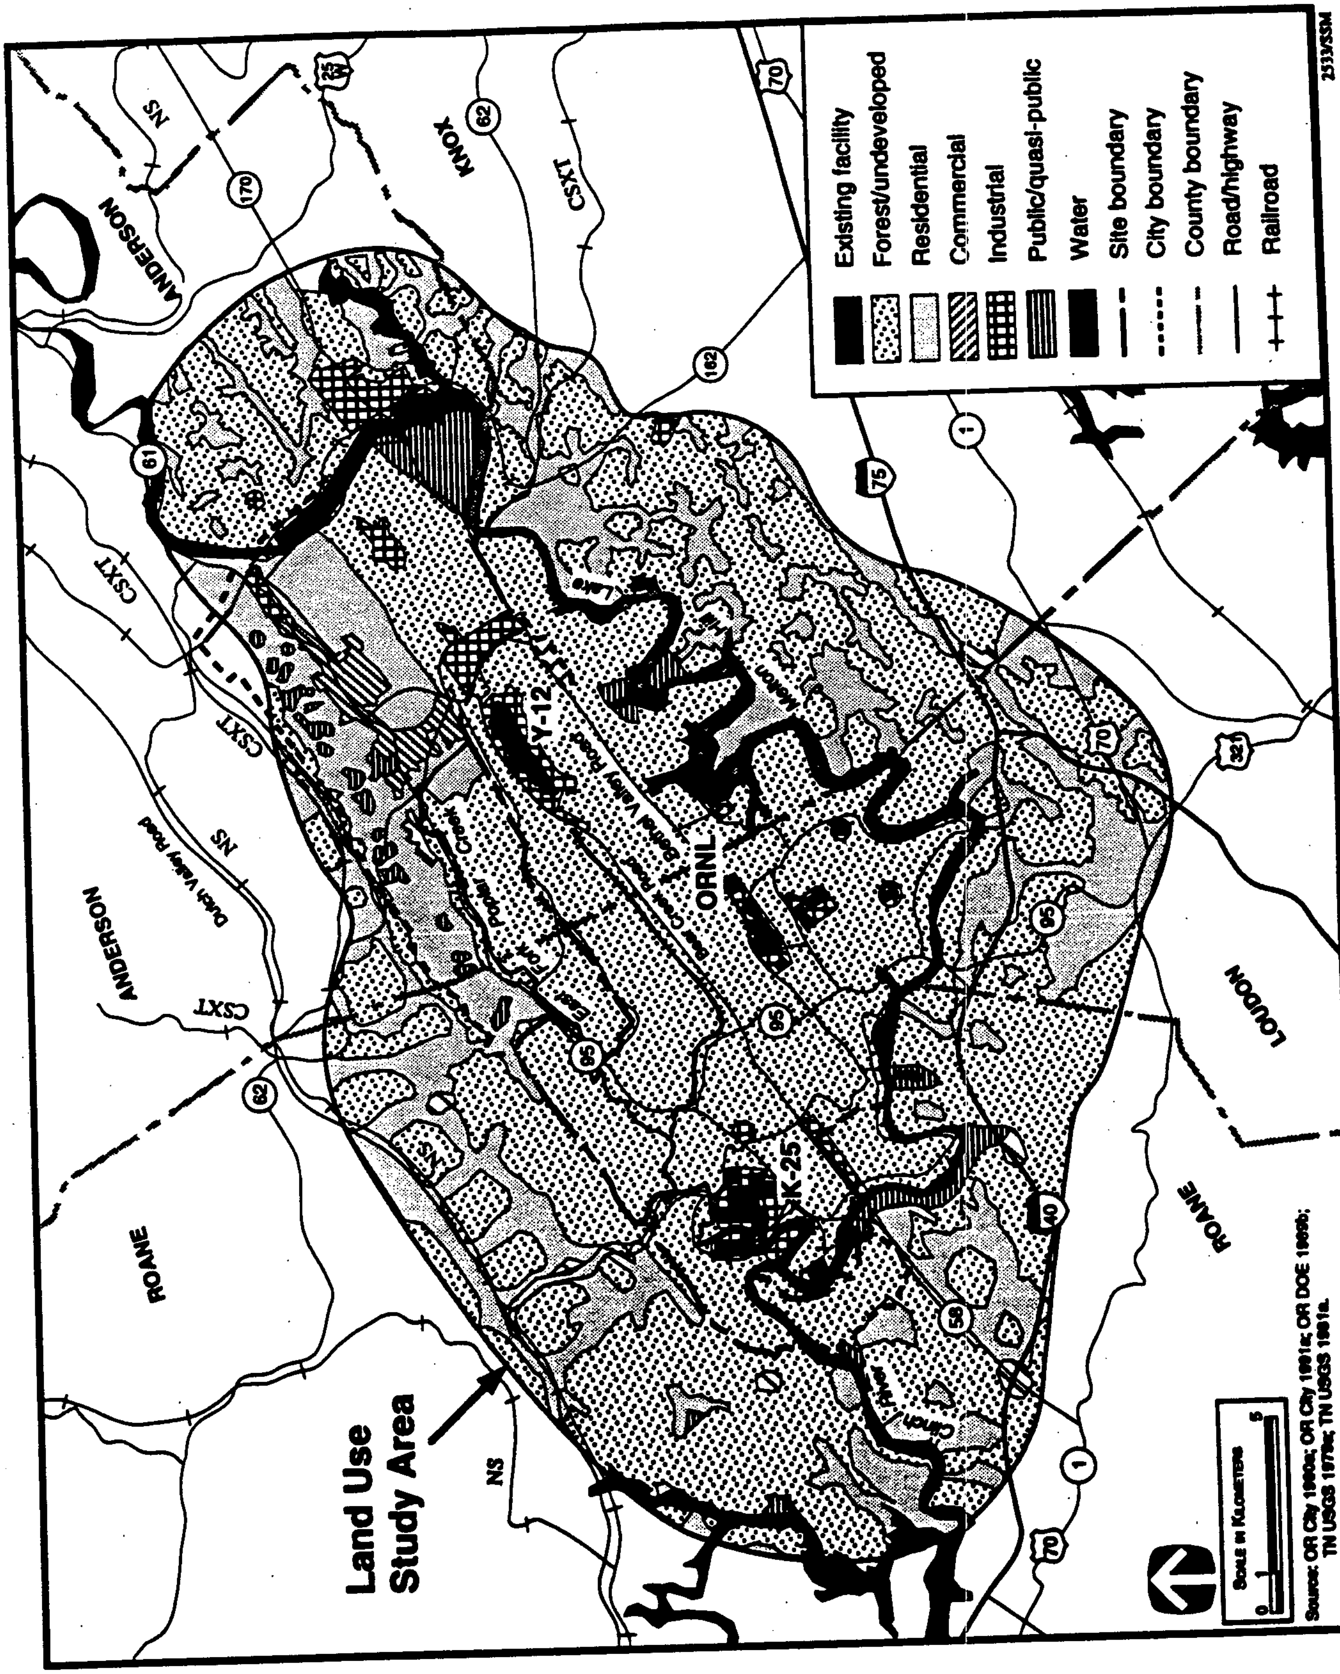

FIGURE 4.2.2.1-1.—*Generalized Land Use at Oak Ridge Reservation and Vicinity.*

Y-12 is largely developed and encompasses 328 ha (811 acres) of which 255 ha (630 acres) are enclosed by security fencing. Y-12 is the primary location used for supporting DP missions, including nuclear components production and surveillance and nuclear production mission assignments. These activities are housed in approximately 425 buildings containing 152,911 square meters (m^2) (5.4 million square feet [ft^2]) of floor space. Y-12 also has approximately 20 buildings, containing 8,495 m^2 (300,000 ft^2) of floor space, that house support activities and several organizations of the DOE Oak Ridge Field Office.

4.2.2.2 *Site Infrastructure*

To support the current missions at ORR, as described in section 3.2.2, an extensive infrastructure exists as shown in table 4.2.2.2–1. These resources support operations at Y-12, ORNL, and K-25.

TABLE 4.2.2.2–1.—*Baseline Characteristics for Oak Ridge Reservation*

Characteristics	Current Value
Land	
Area (ha)	13,980
Roads (km)	71
Railroads (km)	27
Electrical	
Energy consumption (MWh/yr)	726,000
Peak load (MWe)	110
Fuel	
Natural gas (m^3/yr)	95,000,000
Liquid (L/yr)	416,000
Coal (t/yr)	16,300
Steam	
Generation (kg/hr)	150,000
Water	
Usage (MLY)	14,210

4.2.2.3 *Air Quality*

The following section describes existing air quality and reviews the meteorology and climatology in the vicinity of ORR. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.2.

Meteorology and Climatology. The Cumberland and Great Smoky Mountains have a moderating influence on the climate at ORR. Winters are generally mild and summers warm, with no noticeable extremes in precipitation, temperature, or winds.

The annual average temperature at ORR is 13.7 °Celsius (C) (56.6 °Fahrenheit [F]); the average daily minimum temperature in January is -3.8 °C (25.1 °F), and the average daily maximum temperature in July is 30.4 °C (86.7 °F). The average annual precipitation is approximately 136.6 centimeters (cm) (53.77 inches [in]). Prevailing wind directions at ORR tend to follow the orientation of the valley; up valley, from west to southwest; or down valley, from east to northeast. The average annual wind speed is approximately 2.0 meters per second (m/s) (4.5 miles per hour [mph]) (NOAA 1994c:3). Additional information related to meteorology and climatology at ORR is presented in appendix section B.3.2.

Ambient Air Quality. ORR is located in Anderson and Roane Counties in the eastern Tennessee and southwestern Virginia Interstate Air Quality Control Region (AQCR) 207. As of 1995, the areas within this AQCR were designated by EPA as attainment areas with respect to all National Ambient Air Quality Standards (NAAQS) for criteria pollutants (40 CFR 81.343). Applicable NAAQS and Tennessee State ambient air quality standards are presented in appendix table B.3.1–1.

One Prevention of Significant Deterioration Class I area can be found in the vicinity of ORR. This area, the Great Smoky Mountains National Park, is located approximately 48 km (30 mi) southeast of ORR. Since the promulgation of regulations, no Prevention of Significant Deterioration permits have been required for any emissions source at ORR.

The primary emission sources of criteria pollutants are the steam plants at Y-12, K-25, and ORNL. Other emission sources include fugitive particulates from coal piles, the *Toxic Substances Control Act* (TSCA) incinerator, other processes, vehicles, and temporary emissions from various construction activities (OR DOE 1987a:33-49). Appendix table B.3.2–1 presents emission rates of pollutants from ORR.

Table 4.2.2.3–1 presents the baseline ambient air concentration for criteria pollutants and other pollutants of concern at ORR. As shown in the table, baseline concentrations are in compliance with applicable guidelines and regulations.

4.2.2.4 *Water Resources*

This section describes the surface and groundwater resources at ORR.

Surface Water. The major surface water body in the immediate vicinity of ORR is the Clinch River, which borders the site to the south and west. There are four major subdrainage basins on ORR that flow into the Clinch River and are affected by site operations: Poplar Creek, East Fork Poplar Creek, Bear Creek, and White Oak Creek. Drainage from Y-12 enters both Bear Creek and East Fork Poplar Creek; K-25 drains predominantly into Poplar Creek and Mitchell Branch; and ORNL drains into the White Oak Creek drainage basin (OR DOE 1992c:1-16). Several smaller drainage basins, including Ish Creek, Grassy Creek, Bearden Creek, McCoy Branch, Kerr

TABLE 4.2.2.3–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Oak Ridge Reservation, 1992*

Pollutant	Averaging Time	Most Stringent Regulation or Guideline ($\mu g/m^3$)	Baseline Concentration ($\mu g/m^3$)
Criteria Pollutant			
Carbon monoxide	8-hour	10,000 [a]	5
	1-hour	40,000 [a]	11
Lead	Calendar quarter	1.5 [a]	0.05 [b]
Nitrogen dioxide	Annual	100 [a]	3
Ozone	1-hour	235 [a]	[c]
Particulate matter	Annual	50 [a]	1
	24-hour	150 [a]	2
Sulfur dioxide	Annual	80 [a]	2
	24-hour	365 [a]	32
	3-hour	1,300 [a]	80
Mandated by Tennessee			
Gaseous fluoride (as hydrogen fluoride)	30-day	1.2 [d]	0.2
	7-day	1.6 [d]	0.3
	24-hour	2.9 [d]	<0.6
	12-hour	3.7 [d]	<0.6
	8-hour	250 [d]	0.6
Total suspended particulates	24-hour	150 [d]	2
Hazardous and Other Toxic Compounds			
Chlorine	8-hour	150 [d]	4.1
Hydrogen chloride	8-hour	750 [d]	57
Mercury	8-hour	5 [d]	0.06 [e]
Nitric acid	8-hour	[f]	78
Sulfuric acid	8-hour	100 [d]	20

Hollow Branch, and Raccoon Creek, drain directly to the Clinch River. Each drainage basin takes the name of the major stream flowing through the area. Within each basin are a number of small tributaries. The natural surface water bodies in the vicinity of ORR are shown in figure 4.2.2.4–1.

The Clinch River and connected waterways supply all raw water for ORR. The Clinch River has an average flow of 132 cubic meters (m^3)/s (4,647 cubic feet [ft^3]/s) as measured at the downstream side of Melton Hill Dam at mile 23.1. The average flow of Bear Creek near Y-12 is 0.11 m^3/s (3.9 ft^3/s). The average flow at East Fork Poplar Creek is 1.3 m^3/s (45 ft^3/s) (OR USGS 1986a:161,168-169). Y-12 uses approximately 7,530 million liters per year (MLY) (1,989 million gallons per year [MGY]) of water, while ORR uses approximately twice as much (14,760 MLY [3,900 MGY]). The ORR water supply system, which includes the DOE treatment facility and the K-25 treatment facility, has a capacity of 44,347 MLY (11,716 MGY).

At Y-12, there are six treatment facilities with NPDES-permitted discharge points to East Fork Poplar Creek. Y-12 is also permitted to discharge wastewater to the City of Oak Ridge Wastewater Treatment Facility. At ORNL, three NPDES-permitted wastewater treatment facilities discharge into White Oak Creek basin. K-25 operates one sanitary sewage system which discharges to Poplar Creek (OR DOE 1994c:4-17–4-19).

Clinch River water levels in the vicinity of ORR are regulated by a system of dams operated by the Tennessee Valley Authority. Melton Hill Dam controls the flow of the Clinch River along the northeast and southeast sides of ORR. Watts Bar Dam, located on the Tennessee River downstream of the lower end of the Clinch River, controls the flow of the Clinch River along the southeast side of ORR (ORNL 1986a:1-17).

The Tennessee Valley Authority has conducted flood studies along Clinch River, Bear Creek, and East Fork Poplar Creek. Portions of Y-12 lie within the 100- and 500-year floodplains of East Fork Poplar Creek; however, proposed alternative facilities are located outside the 500-year floodplain (ORR 1995a:6).

Surface Water Quality. The streams and creeks of Tennessee are classified by the Tennessee Department of Environment and Conservation and defined in the State of Tennessee Water Quality Standards. Classifications are based on water quality, designated uses, and resident aquatic biota. The Clinch River is the only surface water body on ORR classified for domestic water supply. Most of the streams at ORR are classified for fish and aquatic life, livestock watering, and wildlife (OR DOE 1992c:1-16). White Oak Creek and Melton Branch are the only streams not classified for irrigation. Portions of Poplar Creek, East Fork Poplar Creek, and Melton Branch are not classified for recreation.

Both routine and NPDES-required surface water monitoring programs (over 225 sites) are performed at Y-12 to assess the impacts of the plant effluents upon natural receiving water and to estimate the impacts of these effluents on human health and the environment. At Y-12, Bear Creek, McCoy Branch, Rogers Quarry, and East Fork Poplar Creek receive effluent from treated sanitary wastewater, industrial discharges, cooling water blowdown, stormwater, surface water runoff, and groundwater. The chemical water quality of Bear Creek has been affected by the infiltration of contaminated groundwater. Contaminants included high concentrations of dissolved salts, several metals, chlorinated solvents, and polychlorinated biphenyls (PCBs) (OR DOE 1994d:5-9). DOE is currently involved with remediation of East Fork Poplar Creek under CERCLA because the creek was contaminated by past releases from Y-12. Significant cleanup activities are required onsite and offsite. Contaminants present in East Fork Poplar Creek included mercury, organics, PCBs, and radionuclides (OR DOE 1994d:5-9).

There are 455 NPDES-permitted outfalls associated with the three major facilities at ORR; many of these are stormwater outfalls. Approximately 57,000 NPDES laboratory analyses were completed in 1993, with a compliance rate of over 99 percent. Most excursions were associated with precipitation runoff (OR DOE 1994c:2-13).

As shown in table 4.2.2.4–1, all parameters were below state water quality criteria where the Clinch River leaves ORR. Monitoring data from this sampling site are compared with monitoring data from the Melton Hill Dam sampling site, located

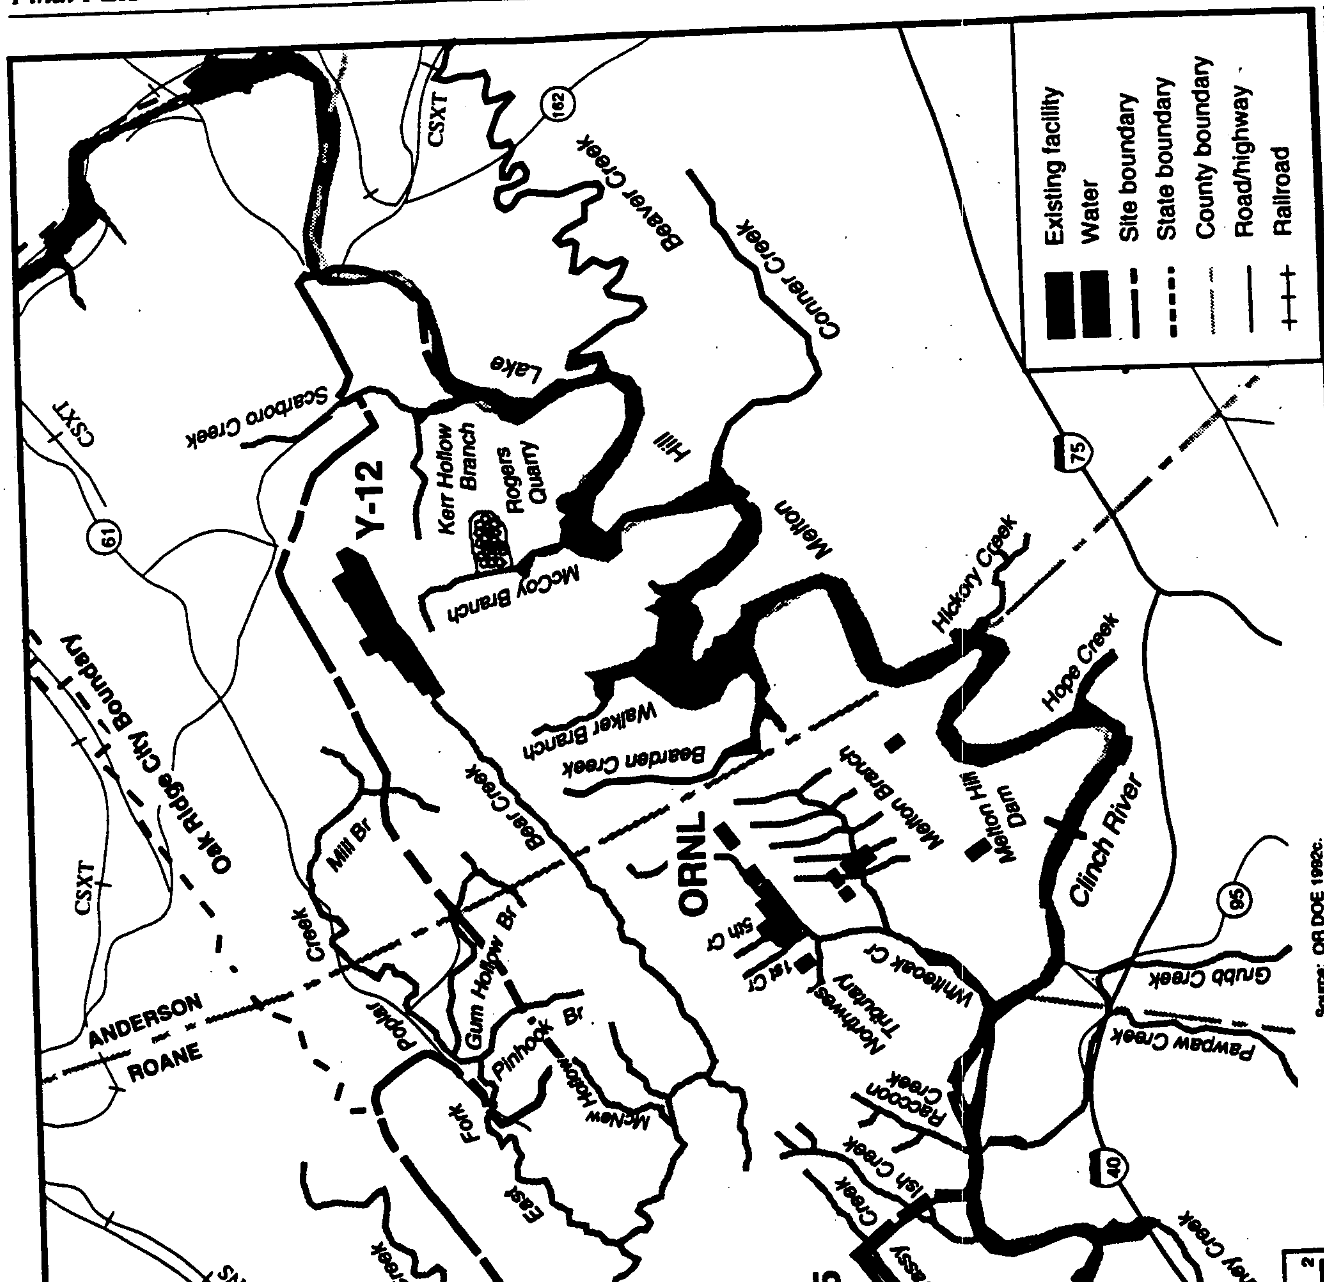

FIGURE 4.2.2.4-1.—*Surface Water Features at Oak Ridge Reservation.*

TABLE 4.2.2.4–1.—*Summary of Surface Water Quality Monitoring of the Clinch River, 1993*

Parameter	Unit of Measure	Water Quality Criteria[a]	Average Water Body Concentration: Downstream from all DOE Inputs	Average Water Body Concentration: Melton Hill Reservoir Above City of Oak Ridge Water Intake
Radiological				
Alpha (gross)	pCi/L	15[b]	0.85 (0.30)	1.7 (0.46)
Beta (gross)	pCi/L	50[c]	4.8 (0.54)	2.9 (0.32)
Cesium-137	pCi/L	120[d]	0.65 (1.2)	NST
Technetium-99	pCi/L	4,000[d]	2.9 (1.1)	NST
Uranium, Total[e]	pCi/L	20[d]	1.6 (0.97)	1.0 (0.50)
Nonradiological				
Chemical oxygen demand	mg/L	NA	~8.2[f]	15
Fluoride	mg/L	4.0[b], 2.0[g]	~0.10[f]	NST
Manganese	mg/L	0.05[h]	0.036	0.91
Nitrate	mg/L	10.0[b]	3.3	
pH	pH units	6.5-8.5[g]	8.0	8.0
Sodium	mg/L	NA	4.1	4.8
Sulfate	mg/L	250[g]	21.0	22.0
Suspended solids	mg/L	NA	~11.0[f]	~6.6

upstream of all ORR discharges, and therefore are representative of background water quality. The concentrations downstream of ORR discharges were lower than concentrations upstream in all cases except gross beta and total suspended solids. Concentrations at Melton Hill Dam were also well below applicable water quality criteria.

Surface Water Rights and Permits. In Tennessee, the state's water rights laws are codified in the *Water Quality Control Act*. In effect, the water rights are similar to riparian rights in that the designated usages of a water body cannot be impaired. The only requirement to withdraw water from available supplies would be a U.S. Army Corps of Engineers permit to construct intake structures.

Groundwater. ORR is located in an area of sedimentary rocks of widely varying hydrological characteristics. However, because of the topographic relief and a decrease in bedrock fracture density with depth, groundwater flow is restricted primarily to shallow depths of the saturated zone in the aquitards, and groundwater discharges primarily to nearby surface waters within ORR (OR DOE 1994c:7-5). Depth to groundwater is generally 6 to 9 m (19.7 to

29.5 ft) but is as little as 1.5 m (4.9 ft) in the area of Bear Creek Valley near Highway 95.

Aquifers at ORR include a surficial soil and regolith unit and bedrock aquifers. The surficial aquifer consists of manmade fill, alluvium, and weathered bedrock. Bedrock aquifers occur in carbonates and low-yield sandstones, siltstones, and shales.

There are no Class I sole-source aquifers that lie beneath ORR. All aquifers are considered Class II aquifers (current potential sources of drinking water). Because of the abundance of surface water and its proximity to the points of use, very little groundwater is used at ORR. Only one water supply well exists on ORR; it provides a supplemental water supply to an aquatics laboratory during extended droughts.

Recharge occurs over most of the area but is most effective where overburdened soils are thin or permeable. In the area near Bear Creek Valley, recharge into the carbonate rocks occurs mainly along Chestnut Ridge (OR DOE 1992c:5-5). Shallow groundwater generally flows from the recharge areas to the center of Bear Creek Valley and discharges into Bear Creek and its tributaries.

Groundwater Quality. Groundwater samples are collected quarterly from a representative number of the more than 1,000 monitoring wells throughout ORR. Groundwater samples collected from the monitoring wells are analyzed for a standard suite of parameters and constituents, including trace metals, volatile organic compounds (VOCs), radioactive materials, and pH. Background groundwater quality at ORR is generally good in the near surface aquifer zones and poor in the bedrock aquifer at depths greater than 300 m (984 ft) due to high total dissolved solids.

Groundwater in Bear Creek Valley near Y-12 has been contaminated by hazardous chemicals and radionuclides (mostly uranium) from past weapons production process activities. The contaminated sources include past waste disposal sites, waste storage tanks, spill sites, and contaminated inactive facilities (OR DOE 1994c:7-11,7-16,7-33–7-36).

Groundwater Availability, Use, and Rights. Industrial and drinking water supplies in the area are primarily taken from surface water sources. However, single-family wells are common in adjacent rural areas not served by the public water supply system. Most of the residential supply wells in the immediate area of ORR are south of the Clinch River (OR DOE 1992c:1-15). Most wells used for potable water are located in the deeper principal carbonate aquifer (305 m [1,000 ft]), while the groundwater contamination at Y-12 is primarily found at a depth of approximately 84 m (276 ft).

Groundwater rights in the State of Tennessee are traditionally associated with the Reasonable Use Doctrine (VDL 1990a:725). Under this doctrine, landowners can withdraw groundwater to the extent that they must exercise their rights reasonably in relation to the similar rights of others.

4.2.2.5 *Geology and Soils*

Geology. ORR lies in the Valley and Ridge province of east-central Tennessee. The topography consists of alternating valleys and ridges that have a northeast-southwest trend, with most ORR facilities occupying the valleys. Y-12 is in the Bear Creek Valley. Bear Creek Valley and the adjacent Pine and Chestnut Ridges are underlain by rocks composed of siltstone, silty limestone, and shale with some sandstone. The present topography of the valleys is the result of stream erosion of the softer shales and limestones. The ridges are underlain by the more resistant sandstones and dolomites.

ORR is cut by many inactive faults formed during the late Paleozoic Era. The Oak Ridge area lies at the boundary between seismic Zones 1 and 2 (appendix figure A.1–1). Since the New Madrid earthquakes of 1811 to 1812, at least 26 other earthquakes with a modified Mercalli intensity of III to VI have been felt in the Oak Ridge area. Most of these seismic events have occurred in the Valley and Ridge province. The nearest seismic event occurred in 1930, 8 km (5 mi) from ORR. It had a modified Mercalli intensity of V at the site (OR EG&G 1991a: 3-4). The magnitude of the largest recorded earthquake in eastern Tennessee was 4.6 on the Richter scale. This earthquake occurred in 1973 in Maryville, TN, 34 km (21 mi) southeast of ORR, and had an estimated modified Mercalli intensity of V to VI in the Oak Ridge area (DOE 1996h:4.55). There is no volcanic hazard at ORR. The area has not experienced volcanism within the last 230 million years. Therefore, future volcanism is not expected (DOE 1995i:4-200).

Soils. Bear Creek Valley lies on well to moderately well-drained soils underlain by shale, siltstone, and sandstone. Developed portions of the valley are designated as urban land. Soil erosion from past land uses has ranged from slight to severe. Erosion potential is very high in those areas with slopes greater than 25 percent that have been severely eroded in the past. Erosion potential is lowest in nearly flat-lying permeable soils that have a loamy texture (ORNL 1988b:69). Additionally, wind erosion is slight, shrink-swell potential is low to moderate, and the soils are acceptable for standard construction techniques. There are no prime farmlands on ORR (DOE 1995i:4-188).

4.2.2.6 *Biotic Resources*

The following section describes biotic resources at ORR including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. A list of the threatened and endangered species that may be found on or in the vicinity of ORR is presented in appendix C.

Terrestrial Resources. Plant communities at ORR are characteristic of the intermountain regions of central and southern Appalachia. Approximately 10 percent of ORR has been developed since it was withdrawn from public access; the remainder of the site has reverted to or been planted with natural vegetation (OR DOE 1989a:3-5). The vegetation of ORR has been categorized into seven plant communities (figure 4.2.2.6–1). Pine and pine-hardwood forest and oak-hickory forest are the most extensive plant communities on ORR, while northern hardwood forest and hemlock-white pine-hardwood forest are the least common forest community types. Nine-hundred eighty-three species, subspecies, and varieties of plants have been identified on ORR (OR NERP 1993b:2).

Animal species found on ORR include 26 species of amphibians, 33 species of reptiles, 169 species of birds, and 39 species of mammals (OR NERP nda:10-17). Animals commonly found on ORR include the American toad (*Bufo americanus*), eastern garter snake (*Thamnophis sirtalis*), Carolina chickadee (*Parus carolinensis*), northern cardinal (*Cardinalis cardinalis*), white-footed mouse (*Peromyscus leucopus*), and raccoon (*Procyon lotor*). Although the whitetail deer (*Odocoileus virginianus*) is the only species hunted onsite (OR DOE 1991c:4-6), other game animals are also present. Raptors, such as the northern harrier (*Circus cyaneus*) and great horned owl (*Bubo virginianus*), and carnivores, such as the gray fox (*Urocyon cinereoargenteus*) and mink (*Mustela vison*), are ecologically important groups on ORR. A variety of migratory birds has been found at ORR. Migrating birds present onsite, as well as their nests and eggs, are protected by the *Migratory Bird Treaty Act*.

Terrestrial habitat within the Y-12 area is dominated by buildings, parking lots, and lawns; thus, little natural vegetation is present. A few small forested areas do exist within the plant boundary along the slope of Chestnut Ridge. Fauna within the Y-12 area are limited by the lack of large areas of natural habitat (OR DOE 1994d:5-13).

Wetlands. Wetlands on ORR include emergent, scrub/shrub, forested wetlands associated with embayments of the Melton Hill and Watts Bar Reservoirs, riparian areas bordering major streams and their tributaries, old farm ponds, and groundwater seeps. Well-developed communities of emergent wetland plants in the shallow embayments of the two reservoirs typically intergrade into forested wetland plant communities, which extend upstream through riparian areas associated with streams and their tributaries. Old farm ponds on ORR vary in size and support diverse plant communities and fauna. Although most riparian wetlands on ORR are forested, areas within utility rights-of-way, such as those in Bear Creek and Melton Valleys, support emergent wetland vegetation (OR NERP 1991a:18,26,41). Two small wetland areas are located near the west end of Y-12 (OR DOE 1994d:5-14). Y-12 is drained by Bear Creek and East Fork Poplar Creek; wetlands occur along portions of both streams.

Aquatic Resources. Aquatic habitat on or adjacent to ORR ranges from small, free-flowing streams in undisturbed watersheds to larger streams with altered flow patterns due to dam construction. These aquatic habitats include tailwaters, impoundments, reservoir embayments, and large and small perennial streams.

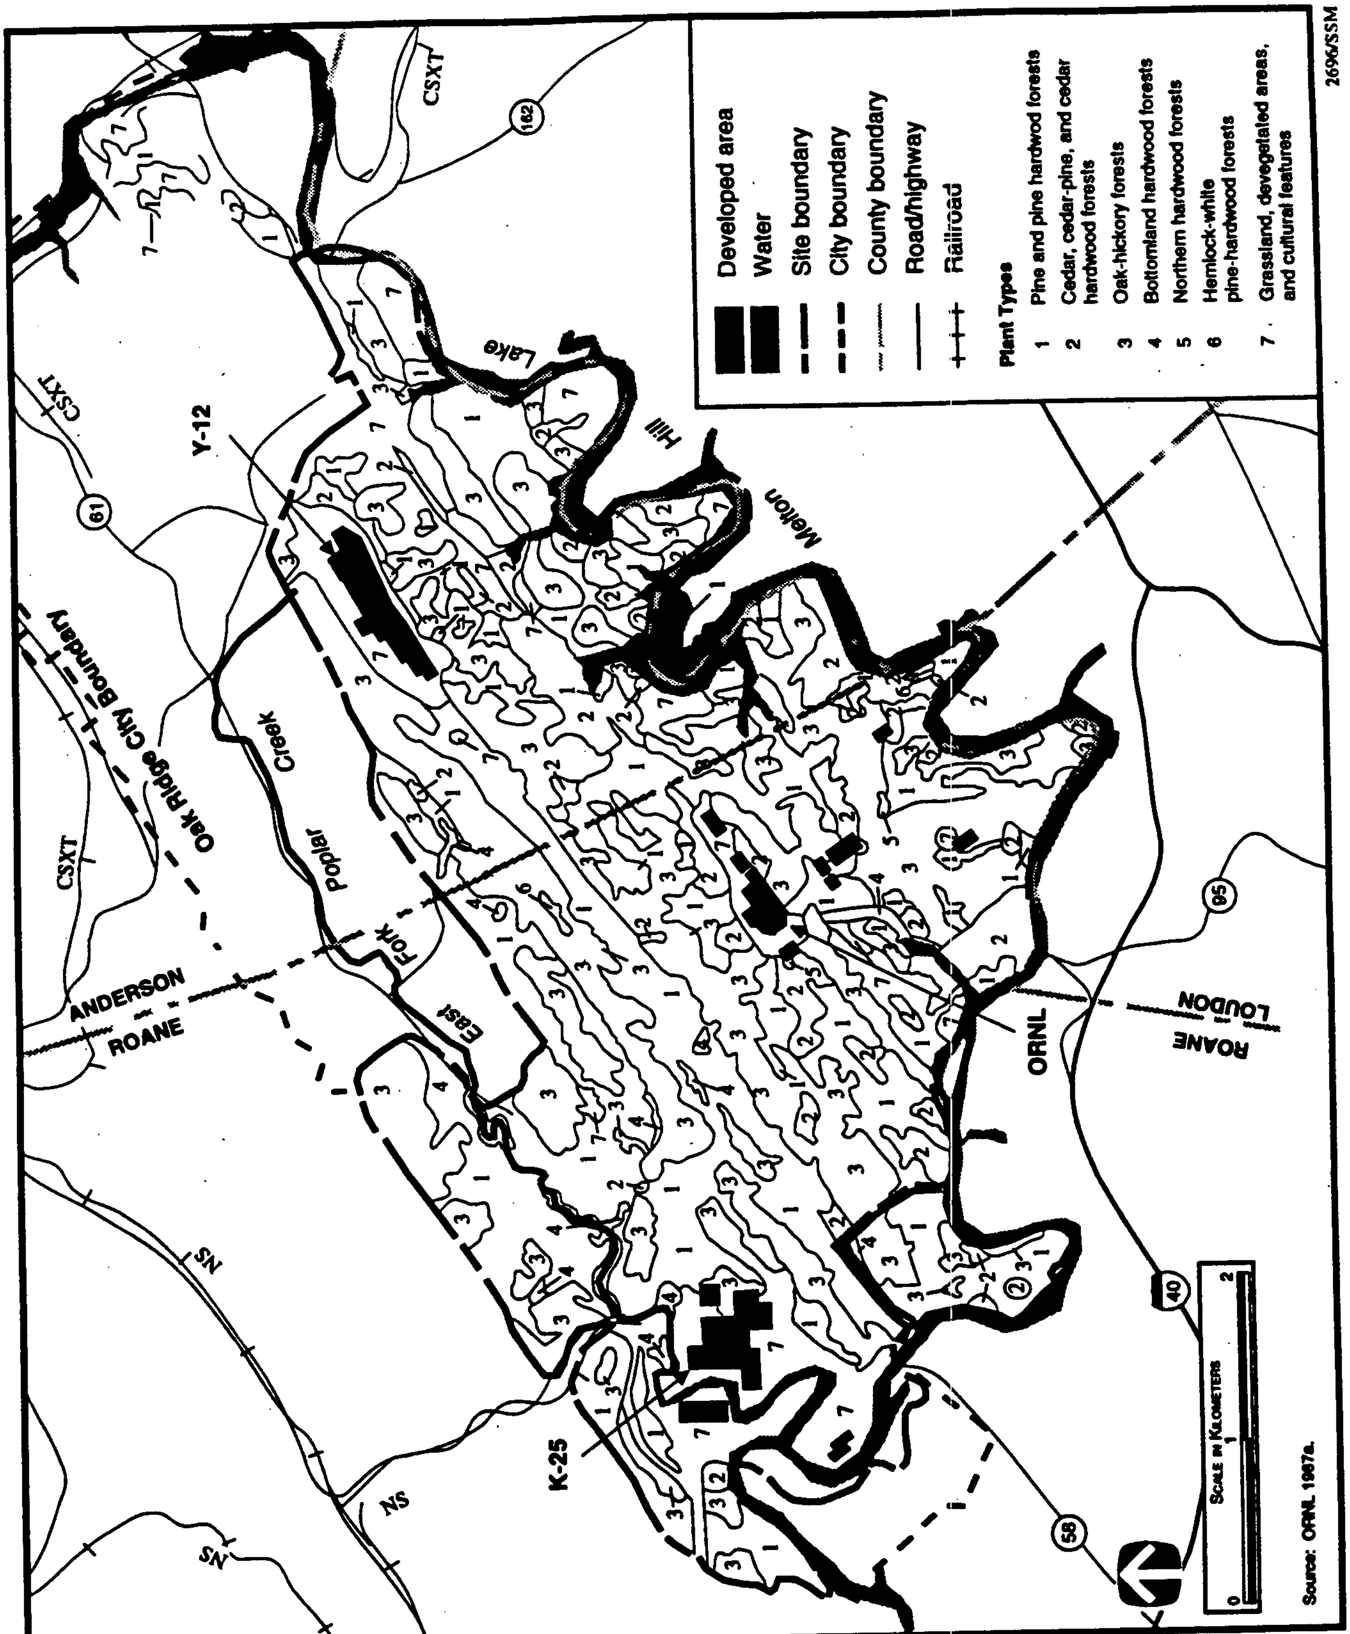

FIGURE 4.2.2.6–1.—*Distribution of Plant Communities at Oak Ridge Reservation.*

Aquatic areas within ORR also include seasonal and intermittent streams.

Sixty-four fish species have been collected on or adjacent to ORR. The minnow family has the largest number of species and is numerically dominant in most streams (ORNL 1988c:O-43). Fish species representative of the Clinch River in the vicinity of ORR are shad and herring (*Clupeidae*), common carp (*Cyprinus carpio*), catfish (*Ictaluridae*), bluegill (*Lepomis macrochirus*), crappie (*Pomoxis spp.*), and drum (*Aplodinotus grunniens*) (ORNL 1981b:138-139). The most important fish species taken commercially in the ORR area are common carp and catfish. Commercial fishing is permitted on the Clinch River downstream from Melton Hill Dam (TN WRA 1995a:1-5). Recreational species consist of crappie, largemouth bass (*Micropterus salmoides*), sauger (*Stizostedion canadense*), sunfish (*Lepomis spp.*), and catfish. Sport fishing is not permitted within ORR.

Y-12 is drained by Bear Creek and East Fork Poplar Creek. While both streams contain adequate physical habitat to maintain and propagate aquatic life throughout their length, species abundance and diversity within both streams have been affected by past Y-12 operation (OR DOE 1994d:5-13).

Threatened and Endangered Species. Eighty-four Federal- and state-listed threatened, endangered, and other special status species may be found on and in the vicinity of ORR (appendix table C–1). Twenty-six of these species have been identified on the site, 17 of which are Federal- and/or state-listed as threatened or endangered. The bald eagle (*Haliaeetus leucocephalus*) is the only Federal-listed species observed on the site (i.e., foraging on Melton Hill and Watts Bar Lakes). The additional state-listed species observed include 14 plant, 1 hawk, and 1 salamander species. No critical habitat for threatened or endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on ORR.

Y-12 does not contain any special status species (OR DOE 1994d:5-14). However, Bear Creek, which drains the western portion of the plant area, contains the Tennessee dace (*Phoxinus tennesseensis*).

4.2.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. More than 20 cultural resources surveys have been conducted on ORR. About 90 percent of ORR has received at least reconnaissance-level studies; however, less than 5 percent of ORR has been intensively surveyed. Most cultural resources studies have occurred along the Clinch River and adjacent tributaries. Prehistoric sites recorded at ORR include villages, burial mounds, camps, quarries, chipping stations, limited activity locations, and shell scatters. To date, over 45 prehistoric sites have been recorded at ORR, 13 of which may be considered potentially eligible for the NRHP. Most of these sites however have not yet been evaluated.

One site (40RE86), which is located on the Clinch River near K-25, has been determined to be eligible for inclusion on the NRHP. No NRHP-eligible prehistoric sites have been identified at Y-12. One site (40AN6), a lithic scatter, was identified near Scarboro Road east of Y-12, outside the fences. A field review of Y-12 indicated that much of the area had been disturbed and that the potential for NRHP-eligible prehistoric sites was low. Additional prehistoric sites may be identified in the unsurveyed portions of ORR. On May 6, 1994, a Programmatic Agreement concerning the management of historical and cultural properties at ORR was executed among the Oak Ridge Operations Office, the Tennessee State Historic Preservation Officer (SHPO), and the Advisory Council on Historic Preservation. This agreement was administered to satisfy DOE's responsibilities regarding sections 106 and 110 of the *National Historic Preservation Act*, and requires DOE to develop a cultural resources management plan for ORR and to conduct cultural resources surveys as required.

Historic Resources. Historic resources identified at ORR include both archaeological remains and standing structures. Documented log, wood frame, or fieldstone structures include cabins, barns, churches, gravehouses, springhouses, storage sheds, smokehouses, log cribs, privies, henhouses, and garages. Archaeological remains consist primarily of foundations, roads, and trash scatters. Sixty-nine pre-1942 cemeteries were located within the original ORR site (OR Robinson 1950a:130). Because the size of the reservation has been reduced, today there are 32 known cemeteries within ORR. More than 240 historic resources have been recorded at ORR, and 38 of those sites may be considered potentially NRHP eligible.

All structures at ORR have been surveyed for historic significance, and all pre-World War II structures have been evaluated for NRHP eligibility. Freel's Cabin and two church structures, George Jones Memorial Baptist Church and the New Bethel Baptist Church, are listed on the NRHP. These structures date from before the establishment of the Manhattan Project. NRHP sites associated with the Manhattan Project include the Graphite Reactor at ORNL, listed on the NRHP as a National Historic Landmark, and three traffic checkpoints, Bear Creek Road, Bethel Valley Road, and Oak Ridge Turnpike Checking stations. None of these sites is located at Y-12. Many other buildings and facilities at ORR are associated with the Manhattan Project and may be potentially eligible for the NRHP.

Historic building surveys were completed during fiscal year 1994 at K-25 and ORNL. A similar survey was completed at Y-12 in fiscal year 1995. The final document should be finished in fiscal year 1996. Based on this survey, approximately 100 buildings at Y-12 may be NRHP eligible. The secondary and case fabrication alternative involves modifications to 17 buildings at Y-12 (appendix section A–3.2.1). Through consultation with the Tennessee SHPO, Buildings 9215, 9401-3, 9706-2, 9996, 9998, and 9212 have been determined NRHP eligible as contributing properties to the proposed Y-12 Plant National Register Historic District. In addition, Building 9710-2 has been determined to be NRHP eligible. The remaining buildings involved do not possess architectural or historical significance to meet National Register Criteria and therefore are not considered to be contributing properties to the proposed historic district. Additional historic sites may be anticipated in the unsurveyed portions of ORR.

Native American Resources. The Overhill Cherokee occupied portions of the Tennessee, Hiwassee, Clinch, and Little Tennessee River Valleys by the 1700s. Overhill Cherokee villages consisted of a large townhouse, a summer pavilion, and a plaza. Residences had both summer and winter structures. Subsistence was based on hunting, gathering, and horticulture. Most of the Cherokee people were relocated to the Oklahoma territory in 1838; some Cherokee later returned to the area from Oklahoma. Resources that may be sensitive to Native American groups include remains of prehistoric and historic villages, ceremonial lodges, cemeteries, burials, and traditional plant gathering areas. No Native American resources have been identified at Y-12. The Eastern Band of the Cherokee has been consulted concerning activities at ORR.

Paleontological Resources. The majority of geological units with surface exposures at ORR contain paleontological materials. All paleontological materials consist of invertebrate remains, and these assemblages have relatively low research potential (NRC 1987c:122).

4.2.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at ORR include employment and regional economy, population and housing, and public finance. Statistics for employment and regional economy are presented for the regional economic area that encompasses 15 counties in Tennessee around ORR. Statistics for population and housing, and public finance are presented for the ROI, a four-county area in which 91.3 percent of all ORR employees reside: Anderson County (33.1 percent), Knox County (36 percent), Loudon County (5.6 percent), and Roane County (16.6 percent) (appendix table D.1–1). Figure 4.2.2.8–1 presents a map of the counties and selected cities composing the ORR regional economic area and ROI. Supporting data is presented in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the ORR regional economic area are summarized in figure 4.2.2.8–2. Between 1980 and 1990, the civilian labor force in the regional economic area increased from 355,353 to 412,803 persons, a 16-percent increase (an annual average increase of 1.6 percent). In 1994, unemployment in the regional economic area was 4.9 percent, about the same as for Tennessee (4.8 percent). The region's per capita income of $17,652 in 1993 was approximately 4.3 percent less than the statewide per capita income of $18,439.

As shown in figure 4.2.2.8–2, the composition of the regional economic area economy parallels that of the statewide economy of Tennessee. During 1993, the

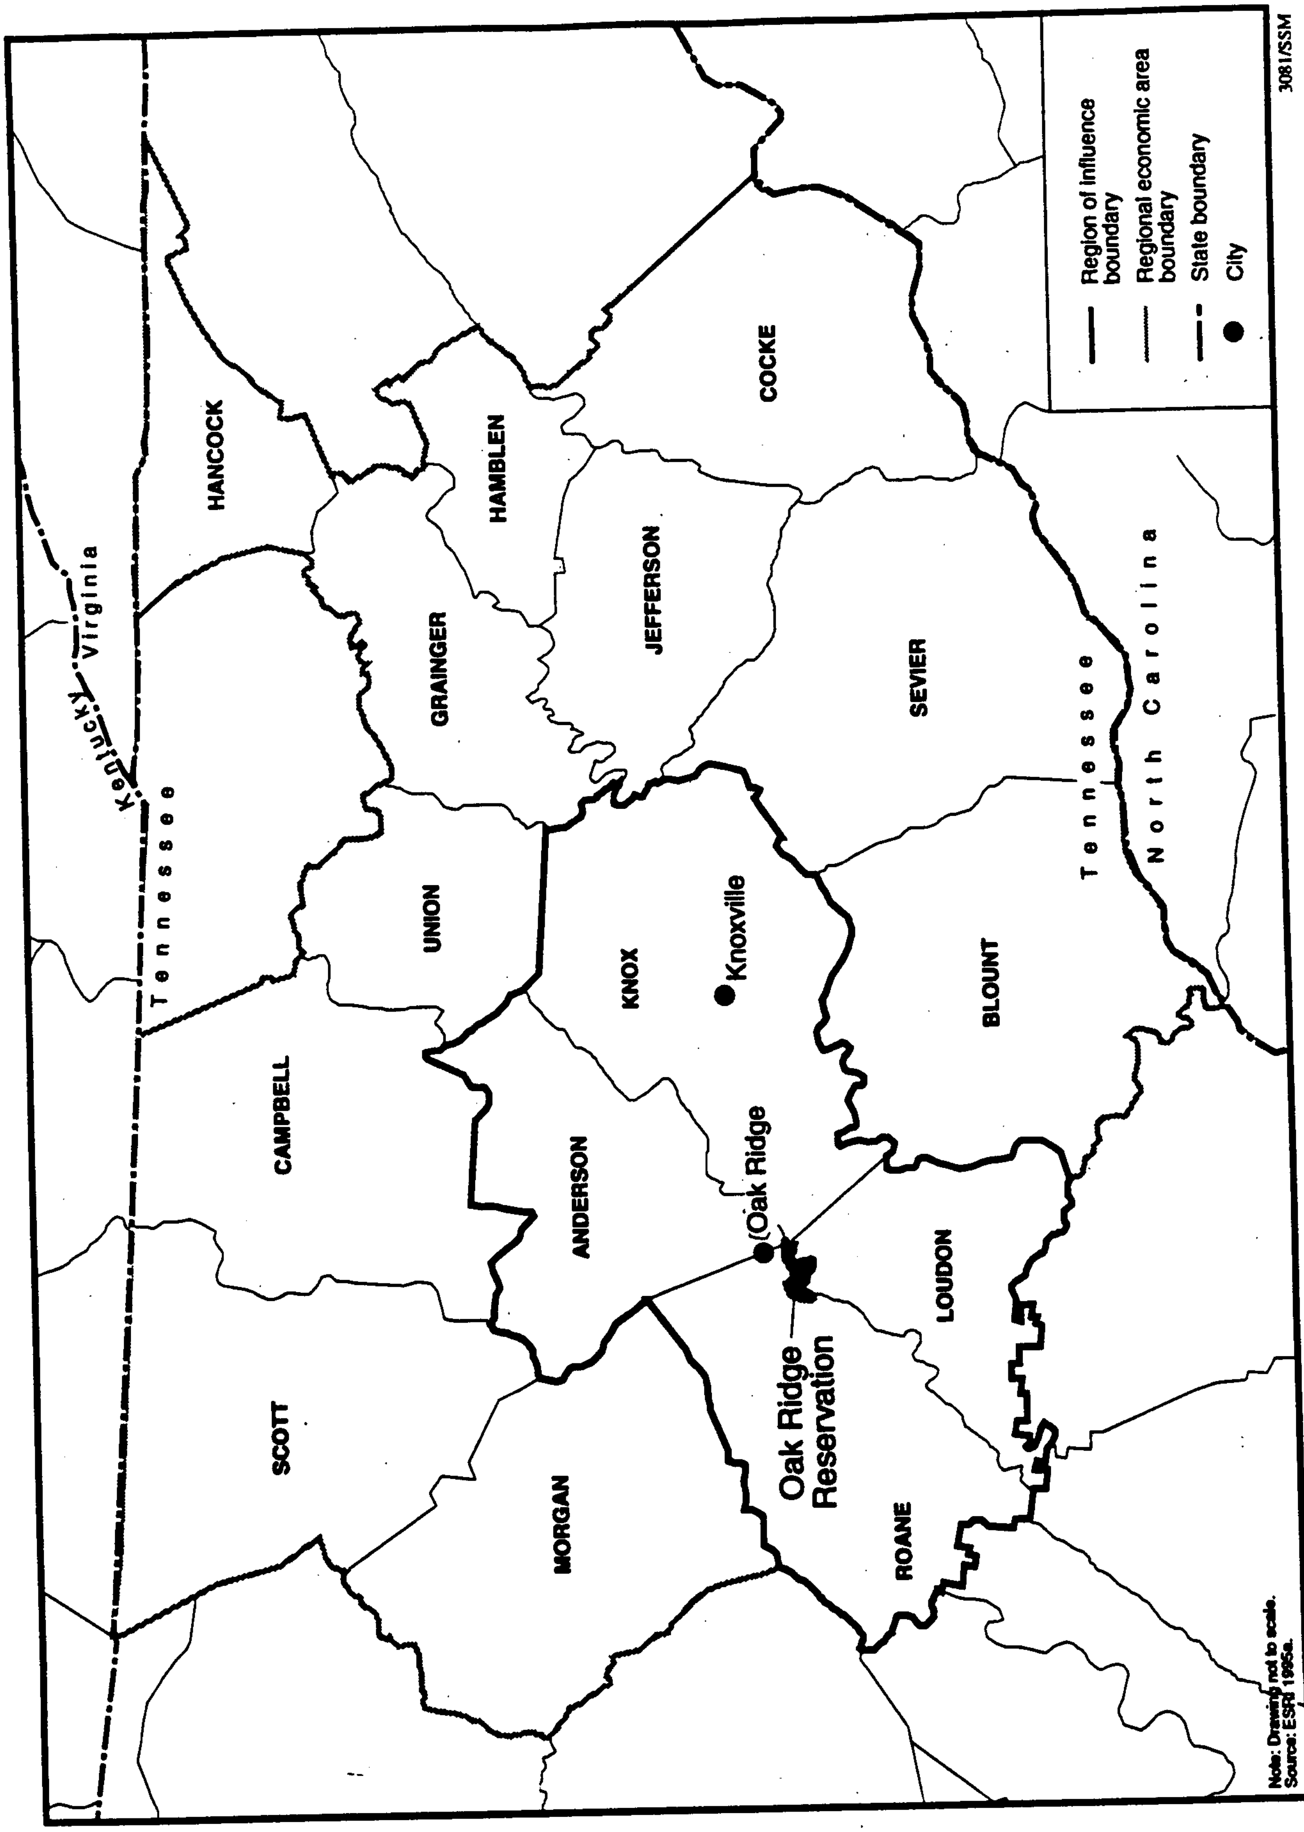

FIGURE 4.2.2.8–1.—*Regional Economic Area and Region of Influence for Oak Ridge Reservation.*

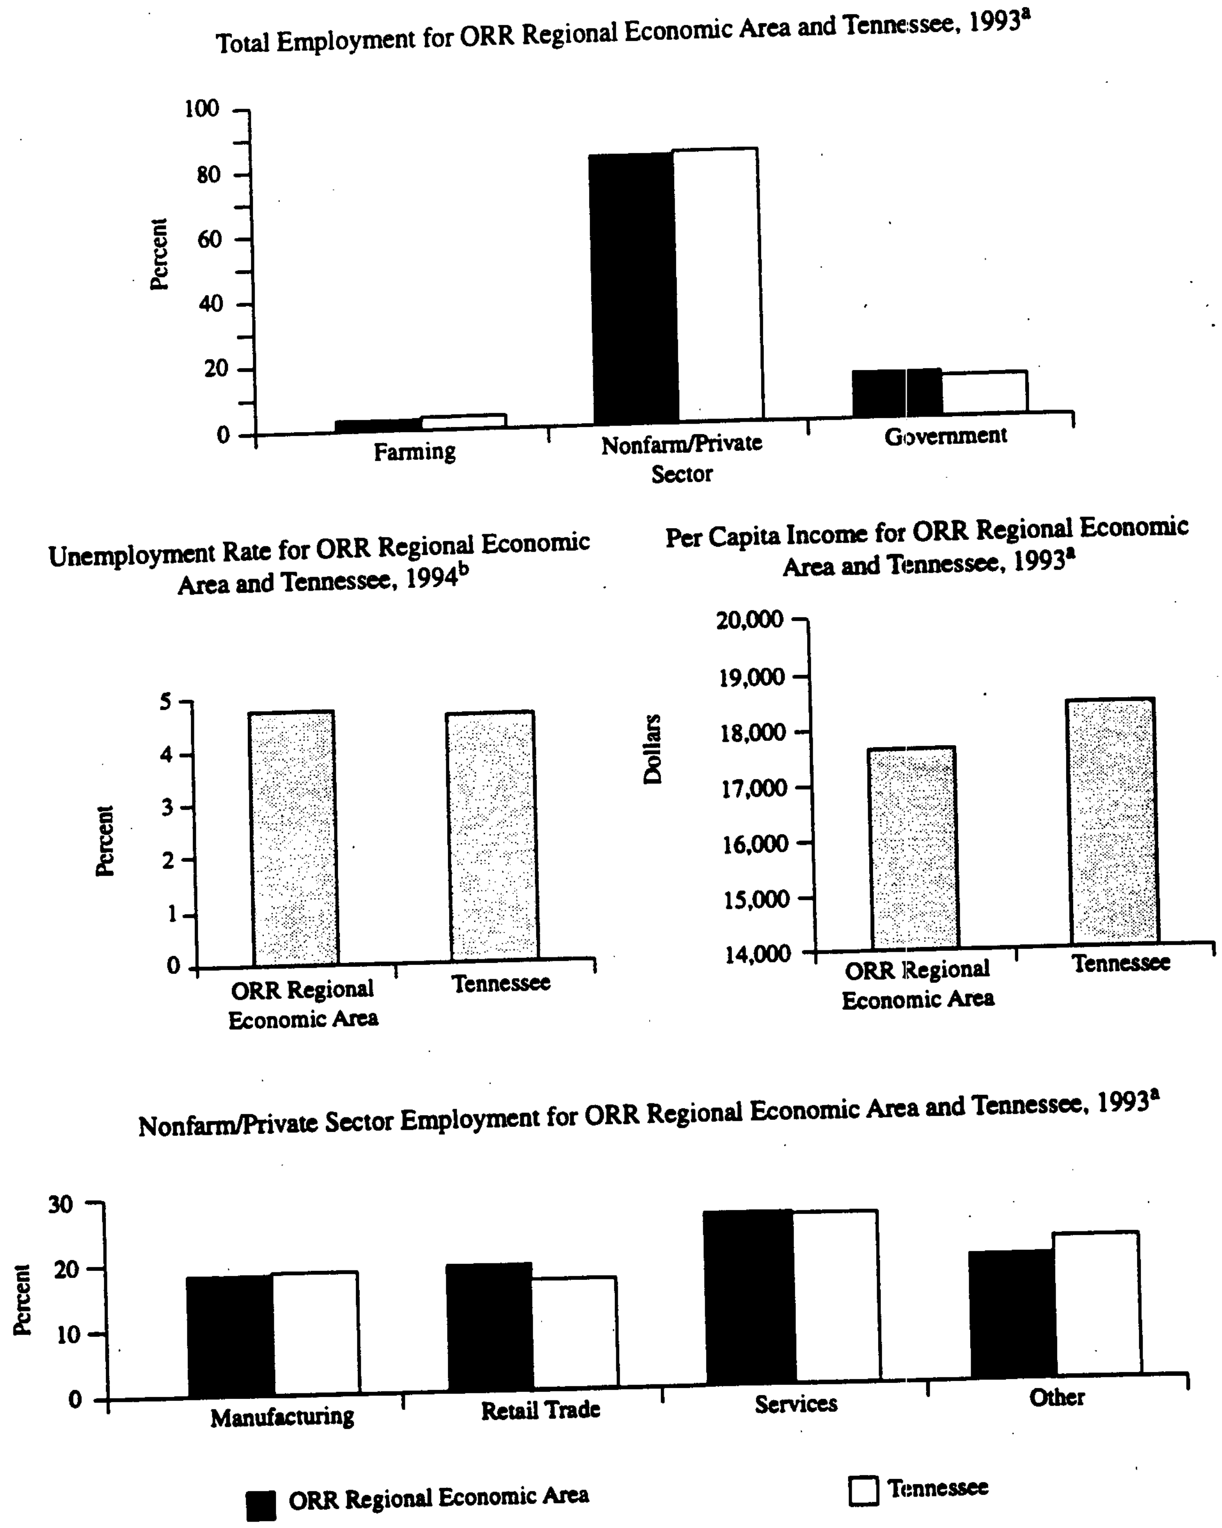

[a]DOC 1995a.
[b]DOL 1995a.

FIGURE 4.2.2.8–2.—*Economy for the Oak Ridge Reservation Regional Economic Area and Tennessee.*

service sector constituted over 26 percent of the region's total employment, followed by retail trade (19 percent) and manufacturing (18 percent). For the entire state, the service sector comprised 26 percent of total employment, manufacturing comprised 19 percent, and retail trade, 17 percent.

Population and Housing. Between 1980 and 1992, the ROI population increased from 464,018 to 499,444. This was an increase of about 7.6 percent (an annual average increase of less than 1 percent). Within the ROI, Loudon County experienced the greatest population increase at 16.4 percent (an annual average increase of a little over 0.7 percent), while Roane County's population decreased by about 0.7 percent (much less than 1 percent annually).

Between 1980 and 1990, the total number of housing units in the ROI increased from 181,299 to 206,067. The 13.8-percent increase (1.4-percent annual average increase) in housing units between 1980 and 1990 was slightly less than the annual average increase for the entire state. The total number of housing units in the ROI for 1992 was estimated to be 213,500. The 1990 ROI homeowner and rental vacancy rates were 1.7 and 8.5 percent, respectively. These rates were comparable to the statewide rates. Population and housing trends are summarized in figure 4.2.2.8–3.

Public Finance. Financial characteristics of the local jurisdictions in the ORR ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. Funding for schools in the ROI is provided by the county or city in which they are located. Major revenue and expenditure fund categories for counties and cities are presented in appendix table D.2.3–1. Figure 4.2.2.8–4 summarizes 1994 local governments' revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.2.2.8–4. All jurisdictions assessed had positive fund balances.

4.2.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at ORR. Also included are discussions of health effects studies, a brief accident history, and emergency preparedness considerations.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of ORR are shown in table 4.2.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. Accordingly, the incremental total dose to the population would result only from changes in the size of the population. Background radiation doses are unrelated to ORR operations.

Radionuclides released into the environment from ORR operations provide another source of radiation exposure to individuals in the vicinity of ORR. The radionuclides and quantities released from operations in 1993 are listed in the *Oak Ridge Reservation Environmental Report for 1993* (ES/ESH-47). The doses to the public resulting from these releases and direct radiation are presented in table 4.2.2.9–2. These doses fall within radiological limits (DOE Order 5400.5, *Radiation Protection of the Public and the Environment*) and are small in comparison to background radiation. The releases listed in the 1993 report were used in developing the reference environment (No Action) radiological releases at ORR in 2005 (section 4.2.3.9).

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem ($5x10^{-4}$ fatal cancer per person-rem) to the public (appendix E), the fatal cancer risk to the maximally exposed member of the public due to radiological releases from ORR operations in 1993 is estimated to be approximately $1.5x10^{-6}$. That is, the estimated probability of this person dying of cancer at some point in the future from radiation exposure associated with 1 year of ORR operations is less than 2 chances in 1 million. (Note that it takes several to many years from the time of exposure to radiation for a cancer to manifest itself.)

Based on the same conversion factor, 0.014 excess fatal cancers are projected in the population living within 80 km (50 mi) of ORR from normal operation in 1993. To place this number in perspective, it can be compared with the numbers of fatal cancers expected in this population from all causes. The 1990 mortality rate associated with cancer for the entire U.S. population was 0.2 percent per year

FIGURE 4.2.2.8–4.—*Local Government Public Finance for the Oak Ridge Reservation Region of Influence.*

(Almanac 1993a:839). Based on this national rate, the number of fatal cancers from all causes expected to occur during 1993 was 1,760 for the population living within 80 km (50 mi) of ORR. This number of expected fatal cancers is much higher than the estimated 0.014 fatal cancers that could result from ORR operations in 1993. Workers at ORR receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities. Table 4.2.2.9–3 presents the average, maximum, and total occupational doses to ORR workers from operations in 1992. These doses fall within radiological limits (10 CFR 835). Based on a dose-to-risk conversion factor of 400 fatal cancers per 1 million person-rem ($4x10^{-4}$ fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to workers from operations in 1992 is estimated to be 0.027. A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in the *Oak Ridge Reservation Annual Site Environmental Report for 1993* (ES/ESH-47). The concentrations of radioactivity in various environmental media (e.g., air, water, and soil) in the site region (onsite and offsite) are also presented in the same report.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are presented in previous sections of this PEIS, particularly sections 4.2.2.3 and 4.2.2.4.

TABLE 4.2.2.9–1.—*Sources of Radiation Exposure to Individuals in the Vicinity, Unrelated to Oak Ridge Reservation Operations*

Source	Committed Effective Dose Equivalent (mrem/yr)
Natural Background Radiation	
Cosmic and cosmogenic radiation[a]	27
External terrestrial radiation[a]	28
Internal terrestrial radiation[b]	40
Radon in homes (inhaled)[b]	200
Other Background Radiation[b]

[b] NCRP 1987a. Value for radon is an average for the United States.

TABLE 4.2.2.9–2.—*Doses to the General Public from Normal Operation at Oak Ridge Reservation, 1993 (Committed Effective Dose Equivalent)*

Affected Environment	Atmospheric Releases		Liquid Releases		Total	
	Standard[a]	Actual	Standard[a]	Actual	Standard[a]	Actual
Maximally exposed individual (mrem)	10	1.4	4	0.6[b]	100	3.0[c]
Population within 80 kilometers[d] (person-rem)	None	26	None	2.0	100	28.0
Average individual within 80 kilometers[e] (mrem)	None	0.030	None	$2.3x10^{-3}$	None	0.032

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem per year limit from airborne emissions is required by the CAA, the 4 mrem per year limit is required by the SDWA, and the total dose of 100 mrem per year is the limit from all pathways combined. The 100 person-rem value for the population is given in proposed 10 CFR 834 (58 FR 16268).
[b] Includes a dose of 0.20 mrem from drinking water.
[c] Includes an annual direct radiation dose of 1 mrem to an individual at Poplar Creek or the Clinch River shoreline.
[d] In 1993, this population was approximately 880,000.
[e] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.
Source: OR DOE 1994c.

Adverse health impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and achieve compliance with permit requirements (e.g., air emissions and NPDES permit requirements). The effectiveness of these controls is verified by using monitoring information and inspecting mitigation measures. Health impacts to the public may occur during normal operation via inhalation of air containing hazardous chemicals released to the atmosphere by ORR operations. Risks to public health from ingesting contaminated drinking water or direct exposure are also potential pathways.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.2.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. These concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to ORR workers during normal operation may include inhaling the workplace atmosphere, drinking ORR potable water, and other possible contacts with hazardous materials associated with work assignments. The potential health impacts vary from facility to facility and from worker to worker, and there is not enough information available to allow a meaningful estimation and summation of these impacts. However, workers are protected from workplace-specific hazards through appropriate training, protective equipment, monitoring, and management controls. Workers are also protected by ORR's adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals in the workplace. Appropriate monitoring, which reflects the frequency and amounts of chemicals used in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm; therefore, workers' health conditions at ORR are expected to be substantially better than required by the standards.

TABLE 4.2.2.9–3.—*Doses to the Onsite Worker from Normal Operation at Oak Ridge Reservation, 1992*

	Onsite Releases and Direct Radiation	
Affected Environment	**Standard**[a]	**Actual**[b]
Average worker (mrem)	None	4.0
Maximally exposed worker (mrem)	5,000	2,000
Total workers (person-rem)	None	68

[a] 10 CFR 835. DOE's goal is to maintain radiological exposure as low as reasonably achievable.

[b] DOE 1993n:7. The number of badged workers in 1992 was approximately 17,000.

Health Effects Studies. Two epidemiologic studies were conducted to determine whether or not ORR contributed to any excess cancers in the communities surrounding the facility. One study found no excess cancer mortality in the population living in counties surrounding ORR when compared to the control populations located in other nearby counties and elsewhere in the United States. The other study found a slight increase in several types of cancers in the counties near ORR, but none of the increases were statistically significant.

More epidemiologic studies have been conducted to assess the health effects of the population working at ORR than at any other site reviewed for this PEIS. Increased cancer mortalities have been reported and linked to specific job categories, age, and length of employment, as well as the levels of radiation exposure. For a more detailed description of the studies reviewed and the findings, refer to appendix section E.4.

Accident History. There have been no accidents with a measurable impact on the offsite population during nearly 50 years of Y-12 operation at ORR. The most noteworthy accident in Y-12 history was the 1958 criticality accident. The impact from this accident resulted in radiation sickness for a few ORR employees. In 1989, there was a one-time accidental release of xylene into ORR's sewer system with no adverse offsite impacts. Accidental releases of anhydrous hydrogen fluoride occurred in 1986, 1988, and 1992, with few onsite and negligible offsite impacts. The hydrogen fluoride system where these accidents occurred is being modified to reduce the probability of future releases and to minimize the potential consequences if a release does occur (ORR 1992a:6).

Emergency Preparedness. Each DOE site has established an emergency management program. This program has been developed and maintained to ensure adequate response for most accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with emergency planning, preparedness, and response.

DOE has overall responsibility for emergency planning and operations at ORR; however, DOE has delegated primary authority for event response to the operating contractor. Although the contractor's primary response is onsite, it does provide offsite assistance, if requested, under the terms of existing mutual aid agreements. If a hazardous materials event with offsite impacts occurs at a DOE ORR facility, elected officials and local governments are responsible for the state's response efforts. The Governor's Executive Order No. 4 established the Tennessee Emergency Management Agency as the agency responsible for coordinating state emergency services. When a hazardous materials event occurring at DOE facilities is beyond the capability of local government and assistance is requested, the Tennessee Emergency Management Agency Director may direct state agencies to provide assistance to the local governments. To accomplish this task and ensure prompt initiation of emergency response actions, the director may activate the State Emergency Operations Center and Field Coordination Center. City or county officials may activate local emergency operations centers in accordance with existing emergency plans.

4.2.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and ongoing waste management activities for ORR. A more detailed discussion of the ongoing waste management operations is provided in appendix section H.2.1.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operations at ORR and is engaged in several activities to bring its operations into full regulatory compliance. These activities are set forth in negotiated agreements that contain schedules for achieving compliance with applicable requirements and financial penalties for nonachievement of agreed upon milestones. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

EPA placed ORR on the National Priorities List (NPL) on November 21, 1989. DOE, EPA Region IV, and the Tennessee Department of Environment and Conservation completed a Federal Facility Agreement effective January 1, 1992, coordinating ORR inactive site assessment and remedial action. Portions of the Federal Facility Agreement are applicable to operating waste management systems. Existing actions being conducted under the *Resource Conservation and Recovery Act* (RCRA) and applicable state laws minimize duplication, expedite response actions, and achieve a comprehensive remediation of the site.

ORR manages a small quantity of spent nuclear fuel and five broad waste categories: TRU, low-level, mixed, hazardous, and nonhazardous. Because there is no spent nuclear fuel or TRU waste associated with any of the proposed activities at ORR, there is no discussion in this PEIS of spent nuclear fuel or TRU waste generation and management at ORR.

Low-Level Waste. LLW generated at Y-12 and K-25 is primarily contaminated with uranium; whereas, at ORNL, LLW consists primarily of mixed fission products. During 1993, Y-12, ORNL, and K-25 generated approximately 1,030 m^3 (272,000 gallon [gal]), 1,540 m^3 (407,000 gal), and 6 m^3 (1,540 gal) of liquid LLW, respectively (OR MMES 1995c:5-12). At Y-12, the Central Pollution Control Facility treats and discharges nonnitrate dilute wastewater, acidic and caustic waste, and plating rinse waters. This facility can also perform pretreatment of nitrate bearing waste streams. The West End Treatment Facility processes nitrate bearing wastewater consisting of nitric acid, nitrate bearing rinse waters, waste coolants, and bio-nitrification sludge. At ORNL, liquid LLW is collected in storage tanks and routed through underground transfer lines to central evaporators for concentration. The concentrate is sent to the Milton Valley storage tanks for storage and the condensate is sent to the Process Waste Treatment

Plant for further treatment prior to further management actions.

During 1993, Y-12, ORNL, and K-25 generated approximately 2,400 m^3 (3,130 cubic yards [yd^3]), 1,720 m^3 (2,250 yd^3), and 1,540 m^3 (2,030 yd^3) of solid LLW, respectively (OR MMES 1995c:5-12). Solid LLW consists primarily of radioactively contaminated construction debris, wood, paper, asbestos, trapping media, personal protection equipment, and process equipment. In addition, Y-12, ORNL, and K-25 also generated 2,335 m^3, 0.3 m^3, and 42 m^3 of contaminated scrap metal, respectively. Depleted and natural uranium machine chips, after oxidation to a stable uranium oxide, are transported to the depleted uranium oxide storage vaults. Uranium sawfines are blended with uranium oxide and placed in the oxide vaults as a short-term storage method. The only LLW disposal facility on ORR is located at ORNL; however, it only accepts LLW generated at ORNL. The declining disposal capacity has created a significant increase in storage requirements. Currently, LLW is shipped to commercial treatment facilities for volume reduction (incineration or supercompaction) or recycle (metal smelting). The resulting residuals are returned to K-25 for storage and shipment to a disposal site.

The management of LLW at ORR has been affected by three recent events: declines in ORR disposal capacity, changes in regulatory and operational conditions, and evolution of the radioactive waste disposal-class concept. The previous strategy classified LLW according to its isotopic content, concentration, and the performance of a disposal facility. In some instances, these classifications are used to describe the type of LLW or a disposal technology. For example, L-I refers to low concentration LLW or a landfill disposal facility, while L-II refers to low-to-moderate concentration LLW or a tumulus disposal facility. A revised classification system has been proposed. Exempt LLW would have contaminant levels sufficiently low to be disposed of in a sanitary or industrial landfill with state concurrence. Disposable LLW would be suitable for disposal at ORR as determined by facility performance assessments. Offsite LLW would be waste which would not meet the criteria of exempt or disposable. The long-range strategy is to rely on the combination of onsite and offsite facilities. Plans for a replacement onsite disposal facility will continue to be pursued with the most likely candidate site for a tumulus disposal facility being Bear Creek Valley. That portion of the LLW that cannot be disposed of onsite consistent with DOE Order 5820.2A, *Radioactive Waste Management*, will be stored until disposal offsite becomes available.

Mixed Low-Level Waste. RCRA mixed, radioactive land disposal-restricted waste is in storage at Y-12, ORNL, and K-25. Because prolonged storage of these wastes exceeded the 1-year limit imposed by RCRA, ORR entered into a Federal Facility Compliance Agreement for RCRA land disposal restriction wastes with EPA on June 12, 1992. The Federal Facility Compliance Agreement recognizes that DOE will continue to generate and store such mixed wastes subject to land disposal restrictions. A Tennessee Department of Environment and Commissioner's Order was issued on September 26, 1995, that requires DOE to comply with the site treatment plan that was developed pursuant to the *Federal Facility Compliance Act* of 1992. The plan contains milestones and target dates for DOE to characterize and treat its inventory of mixed wastes.

In 1993, Y-12, ORNL, and K-25 generated 334,016 kilograms (kg) (736,372 pounds [lb]), 176,925 kg (390,049 lb), and 928,948 kg (2,047,959 lb) of mixed LLW, respectively (OR MMES 1995c:7-7). Liquid mixed wastes at Y-12 consist primarily of nonnitrate bearing wastewaters, contaminated groundwaters, nitrate-bearing wastes, cyanide wastes, contaminated waste oils, acidic wastes, caustic wastes, and contaminated solvents. Solid wastes include both RCRA- and TSCA-mixed wastes. The Central Pollution Control Facility and Plating Rinsewater Treatment Facility treat the nonnitrate bearing wastewaters; whereas, the West End Treatment Facility treats nitrate bearing wastes. Other treatment facilities include the Groundwater Treatment Facility, Waste Coolant Processing Facility, Cyanide Treatment Unit, Uranium Treatment Unit, and Biodenitrification Unit.

Mixed waste at K-25 includes liquids, sludges, and soil contaminated with hazardous and PCB constituents (including waste, oils, spent solvents, paints, and cyanide- or sulfide-bearing reactive wastes), and corrosive and toxic wastes from laboratory processes. Treatment facilities at K-25 include the Central Neutralization Facility and the TSCA Incinerator. The primary waste streams treated at the Central Neutralization Facility include the scrubber effluent from the TSCA Incinerator and process wastewaters from the K-1501 Steam Plant. The K-25 TSCA incinerator has a design capacity to incinerate 907 kg/hour (hr) (2,000 lb/hr) of mixed liquid waste and up to 454 kg/hr (1,000 lb/hr) of solids and sludge (91 kg/hr [200 lb/hr] maximum sludge content). The TSCA incinerator is capable of incinerating both TSCA- and RCRA-mixed waste. DOE guidance currently does not allow incineration of solids or sludges. Because of permit limits (i.e., TSCA, RCRA, and the State of Tennessee), the incinerator is not running at full capacity. In 1993, approximately 2,309 m^3 (610,000 gal) of mixed liquid waste was incinerated (OR MMES 1995c:7-9).

ORNL has no facilities specifically designed for the treatment of mixed wastes. Generators currently neutralize many corrosives before discharge to process drains. Organic mixed wastes are scheduled to be treated at the TSCA Incinerator.

Uranium-contaminated PCB wastes (mixed wastes) are being stored in excess of the 1-year limit imposed by TSCA because of the lack of treatment and disposal capacities. DOE and EPA have signed a Federal Facility Compliance Agreement, effective February 20, 1992, to bring the K-25 site associated with the Uranium Enrichment Program into compliance with TSCA regulations for use, storage, and disposal of PCBs. It also addressed the approximately 10,000 pieces of nonradioactive PCB-containing dielectric equipment associated with the shutdown of diffusion plant operations. An additional Federal Facility Compliance Agreement related to TSCA compliance is currently being discussed by DOE and EPA for ORR.

Hazardous Waste. RCRA-regulated wastes are generated by ORR in laboratory research, electroplating operations, painting operations, descaling, demineralizer regeneration, and photographic processes. Certain other wastes (e.g., spent photographic processing solutions) are processed onsite into a nonhazardous state. Those wastes that are safe to transport and are certified as having no radioactivity added are shipped offsite to RCRA-permitted commercial treatment or disposal facilities. Small amounts of reactive chemical explosives that would be dangerous to transport offsite, such as aged picric acid, are processed onsite in the Chemical Detonation Facility at ORNL.

Y-12 generated approximately 9,920 m^3 (13,000 yd^3) of hazardous waste in 1993 (OR MMES 1995c:6-4). Of this amount approximately 8,840 m^3 (11,600 yd^3) was liquid hazardous waste that was managed as mixed LLW and treated at the Plating Rinsewater Treatment Facility and the Steam Plant Wastewater Treatment Facility. The solid waste was treated offsite. Liquid and solid hazardous waste streams include steam plant wastewaters for treatment, mineral oil contaminated with PCBs, and sludges. All hazardous waste generated at K-25, including all wastes subject to RCRA and TSCA regulations, is managed as mixed LLW.

At ORNL approximately 23,800 m^3 (31,200 yd^3) of liquid hazardous waste was generated in 1993. Bulk nonnitrate acids previously neutralized at the Nonradiological Wastewater Treatment Plant are now sent to the Central Neutralization Facility. No treatment is performed for the approximately 354 m^3 (464 yd^3) of solid hazardous waste at ORNL (OR MMES 1995c:6-5). Some waste is sent to K-25 for storage or incineration, while the remainder (non-RCRA) is sent to a landfill at Y-12. Hazardous waste at K-25 is managed as mixed waste. Hazardous waste is collected and stored until it can be certified under the "no rad added" policy, at which time it is shipped offsite.

Nonhazardous Waste. Nonhazardous wastes are generated from ORR maintenance and utilities. For example, the steam plant produces a nonhazardous sludge. Scrap metals are discarded from maintenance and renovation activities and are recycled, when appropriate. Construction and demolition projects also produce nonhazardous industrial wastes. All nonradioactive medical wastes are autoclaved to render them noninfectious and are sent to the Y-12 sanitary landfill. Remedial action projects also produce wastes requiring proper management. The State of Tennessee-permitted landfill (Construction Demolition Landfill VI) receives nonhazardous industrial materials such as fly ash and construction debris. Asbestos and general refuse are managed in the Industrial and Sanitary Landfill V located at Y-12.

Approximately 52,800 m^3 (69,100 yd^3) of solid industrial and sanitary wastes were generated on

ORR in 1993 (OR MMES 1995c:8-4). Y-12 is the single largest generator of this waste category with 43,900 m^3 (57,600 yd^3). ORNL and K-25 generated approximately 11 and 6 percent, respectively, of the total nonhazardous waste.

4.2.3 Environmental Impacts

4.2.3.1 *Land Resources*

No Action. Under No Action, DOE would continue current and planned activities at ORR as described in section 3.2.2. No additional land-use impacts are anticipated at ORR beyond the effects of existing and future activities that are independent of the proposed action.

Management Alternatives

Downsize Secondary and Case Fabrication. The proposed alternative to downsize and consolidate secondary and case fabrication at Y-12 would involve the modification of existing facilities. The downsize secondary and case fabrication alternative would not impact land use outside the existing Y-12 boundary. Equipment and material laydown and warehousing would be short term and within existing building space or Y-12 developed areas. The proposed activities would be compatible with land-use plans and policies. Impacts to land use are not expected.

The movement of the strategic reserve of highly enriched uranium (HEU) at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have no adverse impact on ORR land use plans and policies. Vacated storage facilities would be transferred to EM for D&D and disposition.

Phaseout of Secondary and Case Fabrication. The proposed alternative would not affect land use in the short term. Facilities and infrastructure supporting the secondary and case fabrication mission and the strategic reserve of HEU would transition to EM for D&D before disposition. A future scenario may be the potential for the site to accommodate industrial type activities. The subsequent use of the vacated Y-12 secondary and case fabrication facilities and land would be developed in the transition plan prepared by EM. Any potential future use would be required to be compatible with remaining ORR missions and consistent with site development plans.

Sensitivity Analysis. Y-12 would be able to accommodate all operations and support functions for downsizing secondary and case fabrication within existing facilities. The use of those facilities would be sufficient to maintain capacity for the low case. In order to support the high case, additional equipment and floor space in existing buildings would be required. There would be no additional land required.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.2.3.2 *Site Infrastructure*

The ORR site infrastructure resources are capable of accommodating any of the proposed alternatives for which ORR is a candidate, with relatively minor changes in the existing electrical and fuel resources. Table 4.2.3.2–1 presents a comparison of the annual operating infrastructure resource requirements for the alternatives of No Action, secondary and case fabrication, and phaseout of secondary and case fabrication. Existing facilities would only be modified, as required, to accommodate mission objectives; therefore, construction-related impacts would be minimal.

No Action. The No Action alternative would continue to satisfy the secondary and case fabrication mission objectives in the existing Y-12 facilities without modification. The DP missions and functions that would continue under this alternative include dismantling nuclear weapon components, maintaining production capability and stockpile support, storing uranium and lithium materials, processing special nuclear materials, and providing support to design agencies, as requested. Continuing the secondary and case fabrication mission with existing facilities would result in a 13-percent increase in electrical energy consumption and a 4.2-percent increase in energy equivalent fuel consumption relative to current usage. This increase is well within ORR's historic usage and existing infrastructure capacity. No adverse site infrastructure-related effects are anticipated with this alternative.

Management Alternatives

Downsize Secondary and Case Fabrication. The secondary and case fabrication alternative at Y-12 would result in a downsized and consolidated manufacturing operation consisting of five primary production buildings, one shared production facility, and a number of office, utility, and changehouse facilities.

TABLE 4.2.3.2–1.—*Site Infrastructure Requirements and Changes for Stockpile Management Alternatives at Oak Ridge Reservation*

Alternative	Electrical: Energy (MWh/yr)	Electrical: Peak Load (MWe)	Fuel: Liquid (L/yr)	Fuel: Gas (m^3/yr)	Fuel: Coal (t/yr)
Current Resources[a]	726,000	110	416,000	95,000,000	16,300
No Action					
Total site requirement	820,000	124	379,000	99,000,000	17,100
Change from current resources	94,000	14	-37,000	4,000,000	800
Downsize Secondary and Case Fabrication					
Total site requirement	791,000	121.2	629,000	93,000,000	16,600
Change from No Action	-29,000	-2.8	250,000	-6,000,000	-500
Phaseout Secondary and Case Fabrication					
Total site requirement	673,000	102.2	379,000	76,000,000	16,100
Change from No Action	-147,000	-21.8	0	-23,000,000	-1,000

[a] Current resources reflect 1993 usage. ORR available capacity is 13,880,000 MWh/yr for electrical energy with a peak load capability of 2,100 MWe and 250,760,000 m^3/yr for natural gas.

Source: OR LMES 1996i; OR MMES 1996j; ORR 1995a:1; ORR 1995a:3.

This downsizing and consolidation effort would result in a facility that occupies approximately 11 percent of the historical area utilized in support of DP functions. The downsizing would be accomplished by preproducing and purchasing certain materials and services, moving processes, and relocating equipment to facilitate consolidation, and the efficient utilization of resources to maximize the number of buildings that could be vacated and turned over to other programs.

Continuing to perform the secondary and case manufacturing operations at Y-12 with the new production requirements and with downsized and consolidated facilities would not affect onsite or offsite corridors for road, rail, pipelines, transmission, and communication services. However, when compared to the No Action alternative site requirements, the consumptive usage of electrical energy with the downsized facility would decrease by about 3.5 percent, and fuel consumption would decrease by approximately 5.4 percent on an equivalent energy basis. These changes reflect facility operating conditions for the production of a base case, multiple-shift, stockpile size. Since these changes are well within the existing ORR site resource capacity, no adverse site infrastructure related environmental impacts are expected to result from this action.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would make available additional storage facilities for transition to EM for D&D and disposition. Impacts to site infrastructure would be negligible because these types of facilities require little infrastructure support and resources.

Phaseout of Secondary and Case Fabrication. The phaseout of the secondary and case fabrication mission at Y-12 would result in an 18-percent decrease in electrical energy consumption and about a 21-percent decrease in fuel consumption (energy equivalent) relative to No Action usage at ORR. No adverse site infrastructure-related environmental effects would result from the phaseout of secondary and case fabrication at ORR.

Sensitivity Analysis. For a high case, stockpile size (multiple-shift) workload, the secondary and case fabrication utility requirements would double, whereas low case (single-shift) facility operation would result in utility resource usage of approximately one-fifth that of base case surge usage.

Potential Mitigation Measures. The downsizing and consolidation or phaseout of secondary and case manufacturing would minimize adverse environmental effects. Facilities vacated by these actions would be decontaminated and decommissioned and released for uses that would potentially be less environmentally intrusive.

4.2.3.3 *Air Quality*

No Action. The No Action air quality analysis utilizes estimated air emissions data from operations at ORR in 2005, assuming continuation of current site missions, to calculate pollutant concentrations at or beyond the ORR site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in appendix table B.3.2–1. Table 4.2.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards.

TABLE 4.2.3.3–1.—*Estimated Concentrations of Pollutants from No Action and Stockpile Management Alternatives at Y-12 Plant*

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines (μg/m³)	2005 No Action (μg/m³)	Downsize Secondary and Case Fabrication (μg/m³)	Phaseout of Secondary and Case Fabrication (μg/m³)

Management Alternatives

Downsize Secondary and Case Fabrication. The downsize secondary and case fabrication mission at Y-12 would generate criteria and toxic/hazardous emissions resulting from the operation of the plant boiler, component manufacturing, and chemical processes. Reasonably available control technology would be used to minimize pollutant emissions. This would include using high efficiency particulate air (HEPA) filters to contain particulate emissions and providing liquid scrubbing prior to HEPA filtration to remove chemical vapors such as nitric acid. Downsizing of the secondary and case fabrication mission at Y-12 would result in a net reduction of atmospheric pollutants. The emission rates for criteria and toxic/hazardous pollutants for the downsize secondary and case fabrication mission are presented in table B.3.2–1. Table 4.2.3.3–1 presents the resulting concentrations of criteria and toxic/hazardous pollutants from No Action and the downsize secondary and case fabrication mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on air quality because storage facilities and strategic reserve activities have no measurable air emissions.

Phaseout of Secondary and Case Fabrication. Phaseout of the secondary and case fabrication mission at Y-12 would result in a net reduction of criteria and toxic/hazardous emissions. The emission rates for criteria and toxic/hazardous pollutants for the phaseout of the secondary and case fabrication at Y-12 are presented in table B.3.2–1. Table 4.2.3.3–1 presents the resulting concentrations of criteria and toxic/hazardous pollutants from No Action and the phaseout of the secondary and case fabrication mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the downsize secondary and case fabrication alternative would result in higher and lower concentrations of criteria and toxic/hazardous pollutants for the high and low cases respectively. The concentrations of pollutants for both cases are expected to remain within applicable Federal and state regulations and guidelines.

Potential Mitigation Measures. No mitigation measures are required for the downsize secondary and case fabrication and phaseout of secondary and case fabrication alternatives at Y-12.

4.2.3.4 *Water Resources*

Environmental impacts associated with the management alternatives at ORR could affect both surface and groundwater resources. The proposed project facilities are located outside any 100- and 500-year floodplain zone (ORR 1995a:6). At ORR, surface water resources, primarily the Clinch River, would be used to meet all construction and operation water requirements. The Clinch River has sufficient flow to support the downsize secondary and case fabrication alternative. A description of the activities that would continue at ORR is provided in section 3.2.2. Table 4.2.3.4–1 presents existing surface water and groundwater resources and the potential changes to water resources at ORR resulting from the proposed alternatives. The total site water resource requirements for each alternative including No Action (base case single-shift operation) are displayed in this table.

Surface Water

No Action. No construction would occur under No Action; therefore, no additional construction water would be used or discharged. Under No Action, surface water withdrawals from the Clinch River are estimated to be 14,760 MLY (3,900 MGY) because of increased operating requirements of existing secondary and case fabrication facilities at ORR. This is an increase of 550 MLY (145 MGY) from the current usage of 14,210 MLY (3,754 MGY). Wastewater discharges to East Fork Poplar Creek from Y-12 would increase to 2,277 MLY (601 MGY), an increase of 71 percent over current discharges. No adverse impacts to surface waters or surface water quality are expected because all discharges would be monitored to comply with the NPDES permit limits. The discharges are also well below historic Y-12 discharge volumes to East Fork Poplar Creek.

TABLE 4.2.3.4–1.—*Potential Changes to Water Resources from Stockpile Management Alternatives at Oak Ridge Reservation*

Affected Resource Indicator	No Action Single-Shift Operation 2005	Downsize Secondary and Case Fabrication Three-Shift Operation	Phaseout Secondary and Case Fabrication
Construction

Actions in 100-year floodplains	None	None	NA
Actions in 500-year floodplains	None	None	NA

[a] Total water requirements for construction at Y-12 are based on a 6-year period for secondary and case fabrication.
[b] No construction water would be used and no construction wastewater would be generated. Total site water use and wastewater discharge would be the same as No Action operation.
[c] All discharges to natural drainages require NPDES permits.
Note: NA - not applicable; MLY - million liters per year.
Source: OR LMES 1996i; OR MMES 1996j; ORR 1995a:1.

Management Alternatives

Downsize Secondary and Case Fabrication. Surface water withdrawals and discharges during modification activities to downsize and consolidate secondary and case fabrication activities at ORR would increase by 0.27 MLY (0.07 MGY) and would not adversely affect flow or downstream users. Treated wastewater effluent discharged to surface streams would be monitored to comply with NPDES permit and other discharge requirements. To minimize soil erosion impacts, stormwater management and erosion control measures would be implemented. To support downsize secondary and case fabrication three-shift surge operations, approximately 13,820 MLY (3,651 MGY) would be required for total site operation. This water requirement would support operations to produce surge quantities of secondaries. Production of base case quantities of secondaries and cases would not require any additional water above the amount needed under the No Action alternative. Total site wastewater discharges with downsize secondary and case fabrication would be 2,147 MLY (567 MGY). All discharges would be monitored to comply with NPDES permit limits. Stormwater runoff from the main plant area would be collected in detention ponds, monitored, and, if acceptable, discharged to nearby streams. Stormwater runoff from outside the main plant area would be discharged to nearby streams. No adverse impacts to surface waters or surface water quality are expected.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on surface or groundwater resources at Y-12.

Phaseout of Secondary and Case Fabrication. Phaseout activities for secondary and case fabrication at Y-12 would decrease water usage at ORR by 2,450 MLY (647 MGY) from No Action. The phaseout would reduce Y-12 discharges from secondary and case fabrication by 100 percent and ORR discharges to approximately 1,827 MLY (482 MGY). The phaseout of the secondary and case fabrication mission at ORR would have no adverse impacts on surface water quality.

Groundwater

No Action. Under No Action, no additional impacts to groundwater resources are anticipated beyond the effects of existing and future activities, which are independent of and not affected by the proposed action. As discussed in section 4.2.2.4, one well currently supplies a small amount of water for a laboratory. Groundwater use is expected to remain constant in 2005.

Groundwater quality data obtained from wells located near the Y-12 facility indicate that groundwater quality has been improved by ongoing restoration activities. Under No Action, current restoration programs would continue. Process and wastewater would continue to be treated at either the Y-12 Centralized Pollution Control Facility or at the Y-12 West End Treatment Facility before being discharged to surface waters. Minimal impacts on groundwater quality are expected due to wastewater releases.

Management Alternatives

Downsize Secondary and Case Fabrication. All water for modification activities and operation of the downsized and consolidated secondary and case fabrication facilities would be taken from the Clinch River, with no plans for withdrawal from groundwater resources. All process, utility, and sanitary wastewater would be treated prior to discharge into East Fork Poplar Creek in accordance with NPDES permits. Minimal impact to groundwater quality is expected.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on surface or groundwater resources at Y-12.

Phaseout of Secondary and Case Fabrication. By phasing out the secondary and case fabrication mission at Y-12, no adverse impact to groundwater resources is expected. Spill protection systems and plans exist to contain and minimize effects of releases of hazardous substances during transition and D&D activities. Given normal safeguards and precautions, no adverse impacts to groundwater quality are expected to result from secondary and case fabrication phaseout activities. Current environmental restoration programs would not be adversely impacted.

Sensitivity Analysis. The surface water requirements and discharges needed for the high stockpile case are expected to be similar to the low case surge three-shift operation, downsize secondary and case fabrication alternative. The low case scenario would require a slightly smaller amount of surface water (less than 1 percent) than No Action to meet stockpile production requirements. Impacts to surface water or surface water quality would be similar to the downsize secondary and case fabrication alternative for the high case scenario and less for the low case scenario. Groundwater or groundwater quality would not be affected by the high or low case stockpile requirement at ORR.

Potential Mitigation Measures. No mitigation measures beyond standard engineering design have been identified.

4.2.3.5 *Geology and Soils*

The alternatives proposed for ORR would have no impact on geological resources described in section 4.2.2.5. Hazards posed by geological conditions are expected to be minor. Land requirements to support building modification activity would be minimal, and existing Y-12 developed land area in the immediate vicinity of the project would be used. Potential changes to geology and soils associated with the proposed alternatives at ORR are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at ORR. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Downsize Secondary and Case Fabrication. The downsizing and/or consolidation of secondary and case fabrication at Y-12 would not affect geological conditions. Activities required to modify project facilities would not be adversely affected by geological conditions.

No known active faults exist within the boundaries of ORR, and ground rupture as a result of an earthquake is unlikely. Based on the seismic history of the area, a low seismic risk exists at ORR and should not preclude safe modification and operation of the secondary and case fabrication facilities. All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1, Facility Safety and accompanying safety guidelines.

Volcanic activity has not occurred in the area for over 200 million years and is extremely unlikely to impact project activities. Landslides or other nontectonic events are highly unlikely to affect project facilities. Slopes and underlying foundation materials are generally stable. Potential health impacts from accidents associated with geological hazards are discussed in section 4.2.3.9.

Building material laydown and warehousing land requirements would be minimal. Space within existing buildings and existing developed Y-12 areas would be used. Project-related parking requirements can be satisfied by existing parking facilities. The properties and conditions of soils place no limitations on modification activities or the safe operation of project facilities.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have no impacts on geology and soils at Y-12.

Phaseout of Secondary and Case Fabrication. The phaseout of secondary and case fabrication at Y-12 would not affect geology and soils. The D&D of vacated facilities would be carried out within the interior sections of the buildings.

Sensitivity Analysis. The high or low case operation scenario would not affect geology and soils.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.2.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species on ORR. In general, impacts to these resources are not expected from the proposed alternatives; however, noise and human presence could temporarily disturb wildlife.

No Action. Under No Action, the secondary and case fabrication mission described in section 3.2.2 would continue at Y-12. There would be no changes to current biotic resource conditions at Y-12 or ORR as described in section 4.2.2.6.

Management Alternatives

Downsize Secondary and Case Fabrication. Downsizing and consolidating the Y-12 secondary and case fabrication mission at ORR is not expected to impact biological resources. All activities, including alterations to existing buildings, would take place within developed portions of the Y-12 area. There would be no increase over existing water consumption or discharge.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on biotic resources at Y-12.

Phaseout of Secondary and Case Fabrication. Phaseout of secondary and case fabrication at Y-12 would not result in adverse impacts to biotic resources. During the phaseout period additional human activity could temporarily disturb wildlife living nearby; however, disturbance would be minimal since Y-12 is presently a heavily used industrial area and nearby wildlife populations have already adapted to its presence. Once all phaseout activities are complete, wildlife use of the area would depend on subsequent land use. Phaseout of DP missions at Y-12 could lessen impacts to the Tennessee dace population in Bear Creek since effluent discharges to the stream would decrease.

Sensitivity Analysis. Implementation of either a low or high case workload would not affect biological resources.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.2.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly through ground disturbance, building modification, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. On May 6, 1994, a Programmatic Agreement concerning the management of historical and cultural properties at ORR was executed among the Oak Ridge Operations Office, the Tennessee SHPO, and the Advisory Council on Historic Preservation. This agreement was administered to satisfy DOE's responsibilities regarding Sections 106 and 110 of the *National Historic Preservation Act*, and requires DOE to develop a cultural resources management plan for ORR and to conduct cultural resources surveys, as required.

The area affected by the proposed alternatives is limited to Y-12. No NRHP prehistoric sites have been identified at Y-12. A field review of the area indicated that most of the land was disturbed, making the identification of NRHP-eligible archaeological resources unlikely. A historic buildings survey was conducted across Y-12 in 1995, and approximately 100 structures were identified as being potentially NRHP-eligible. The associated report is currently under preparation and will be finished in the fall 1996. Native American resources of concern to Cherokee tribes in Oklahoma and Tennessee may be affected by some of the proposed alternatives. Fossils present at ORR are of fairly common invertebrates and therefore have low research potential.

No Action. Under No Action, DOE would continue the existing and planned missions at ORR described in section 3.2.2. Any impacts to cultural and paleontological resources from these missions would be independent of and unaffected by the proposed action.

Management Alternatives

Downsize Secondary and Case Fabrication. This alternative involves the use and modification of existing buildings at Y-12. Because all of Y-12 is either developed or disturbed and minimal space would be required for equipment and material laydown and parking during building modification, no impacts to prehistoric, Native American, or paleontological resources are expected. Seven of the facilities (Buildings 9215, 9401-3, 9706-2, 9996, 9998, 9212, and 9710-2) to be modified (appendix section A.3.2.1) under this alternative are NRHP eligible. Any project-related effects would be addressed in tiered NEPA documentation. Impacts to cultural and paleontological resources under the proposed alternative are independent of strategic reserve storage.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would not affect cultural and paleontological resources at Y-12.

Phaseout of Secondary and Case Fabrication. The phaseout of secondary and case fabrication at Y-12 may affect some cultural or paleontological resources. The subsequent use of Y-12 would determine potential future impacts to these resources. NRHP-eligible resources would be identified through project-specific inventories and evaluations. Specific concerns about Native American resources would be addressed through consultation with the potentially affected tribes. Any project-related effects would be addressed in tiered NEPA documentation. No impacts to scientifically important paleontological resources are expected.

Sensitivity Analysis. The high and low case production scenarios would have the same impacts to cultural and paleontological resources. The high case scenario would require additional buildings over the base case scenario, but these buildings are currently assigned to the secondary and case mission. Cultural resources would therefore not be affected.

Potential Mitigation Measures. If adverse impacts to NRHP-eligible sites cannot be avoided through project design or siting, then a Memorandum of Agreement may need to be negotiated among DOE, the Tennessee SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the Tennessee SHPO and the Advisory Council on Historic Preservation in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific NRHP-eligible sites would be identified during tiered NEPA documentation.

If adverse impacts to Native American resources cannot be avoided through project design or siting, then acceptable mitigation measures to reduce project effects on them would be determined in consultation with the affected Native American groups. In accordance with the *Native American Graves Protection and Repatriation Act* and the *American Indian Religious Freedom Act*, such mitigations may include, but may not be limited to, appropriate relocation of human remains, planting vegetation screens to reduce visual or noise intrusion, increasing access to traditional use areas, or transplanting or harvesting important Native American plant resources.

4.2.3.8 *Socioeconomics*

No Action. Under the No Action alternative, the existing missions at Y-12 would continue to operate, but with a somewhat smaller workforce. The current total Y-12 workforce of 5,152 would decline to 4,721 by 2005. The composition of the Y-12 workforce in 2005 would include 2,741 employees associated with core stockpile management activities and 1,980 performing support and other nonstockpile management tasks. The Y-12 workforce would remain relatively stable at this level for the duration of the missions. Figure 4.2.3.8–1 presents a breakdown of the Y-12 workforce under the No Action alternative. Projections for the regional economy, employment rates, population and housing, and public finance characteristics are presented in appendix D.

Regional Economy and Employment. Total employment in the regional economic area is projected to grow approximately 1 percent annually between 1995 and 2000, reaching approximately 488,700 in the latter year. After 2001, employment is expected to increase by less than 1 percent annually, reaching approximately 572,100 in 2030. Unemployment in the regional economic area was 4.9 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $18,198 in 1995 to $22,494 in 2030. No Action employment for ORR is expected to reach 15,171 persons by 2005.

Population and Housing. Annual ROI county and city population and housing increases are projected to average slightly less than 1 percent between 1995 and 2005. Between 2006 and 2030, the annual rate of increase is expected to be much less than 1 percent. Population in the ROI is estimated to increase from 519,300 in 1995 to 641,800 in 2030. The total number of housing units in the ROI is projected to increase from 215,100 in 1995 to 265,700 in 2030.

Public Finance. Funding for school districts is provided by the county or city in which the school district is located. Between 2000 and 2005, all ROI county and city total revenues are projected to increase at an annual average of 1.1 percent or less. Total expenditures are projected to increase an annual average of less than 1 percent during the same period. These rates of increase should continue until 2030.

Management Alternatives

Downsize Secondary and Case Fabrication

Under this alternative, the secondary and case fabrication mission would remain at ORR but operate at reduced capacity and with a smaller workforce. Downsizing Y-12 would require some modification to the existing facilities and would involve 14 workers during the peak construction period. The size of the operational workforce would vary over time and would depend on whether DOE implements a single-shift or three-shift operation.

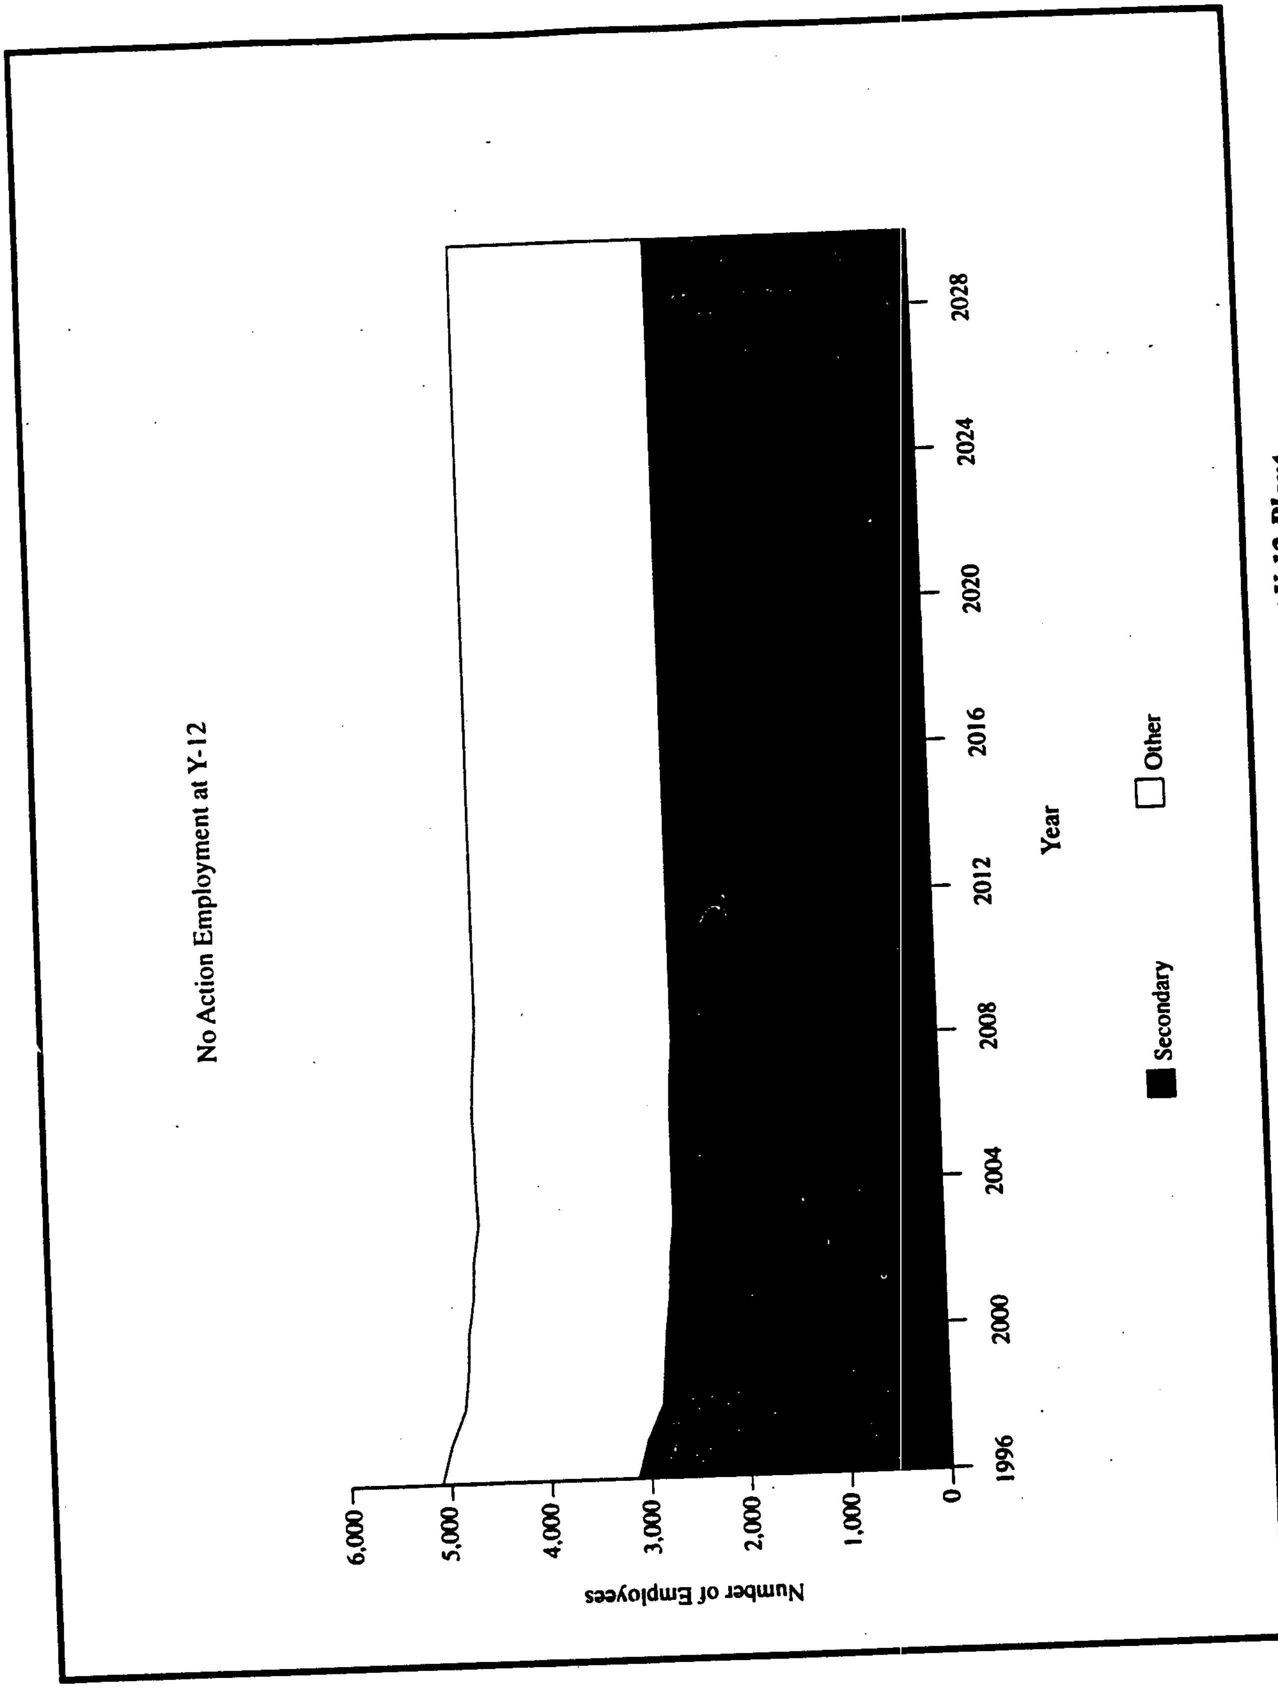

FIGURE 4.2.3.8–1.—*No Action Employment at Y-12 Plant.*

Base Case Single Shift. Under the base case single shift the total Y-12 workforce would decrease in 2005 from the No Action level of 4,721 to 3,916. The composition of the workforce would also change significantly, as shown in figure 4.2.3.8–2. Because the base case single-shift workforce would result in the greatest number of job losses, it serves as the bounding scenario for the socioeconomic analysis. Although the number of workers conducting nonstockpile management activities would remain constant (1,980), the number of core stockpile management workers employed would decrease from 2,741 to 784. In addition, 1,152 workers would be employed to perform landlord responsibilities in preparation for D&D of the facilities vacated by downsizing. Over the period 2005 to 2030, the number of D&D workers would range from a high of 1,522 in 2016 to a low of 557 in 2030. When D&D activities reach a peak in 2016, Y-12 would employ 435 fewer workers than under the No Action alternative.

Base Case Surge (Three Shift). Under the base case surge scenario, the total Y-12 workforce would decrease in 2005 from the No Action level of 4,721 to 4,508. Although the number of nonstockpile management workers and D&D personnel would be the same as under the base case single-shift scenario, a total of 1,376 workers would be required to perform core stockpile management functions in 2005. The core stockpile management workforce would remain relatively stable at this level for the duration of the mission. D&D activities would increase over time such that during the period from 2014 to 2017, the total Y-12 workforce would be slightly larger than the No Action workforce. The total Y-12 workforce size would peak in the year 2016 at 4,807, an increase of 157 over No Action. Figure 4.2.3.8–3 presents a breakdown of the Y-12 workforce under base case surge.

The transfer of HEU strategic reserve from ORR to another DOE site (an alternative in the Storage and Disposition PEIS) would have no impact on site employment. Strategic reserve HEU storage operations are integrated into the secondary and case fabrication mission; therefore, worker numbers would not change if the secondary and case fabrication mission is retained at Y-12, but without the strategic reserve HEU.

Regional Economy and Employment. Modification of the facility would require a total of 14 workers during the peak construction period. An additional 15 jobs would be generated in related industries in the regional economy. Available labor within the region would be sufficient to fill both the direct and indirect jobs generated by the modification activities. Total employment and per capita income would increase slightly from the No Action level projections. Unemployment would remain at the No Action level of 4.9 percent.

Base Case Single Shift. Operations-related employment changes at ORR would begin as the facility modification reaches completion. The workforce at Y-12 would decrease by 805 in the year 2005. Because secondary and case fabrication activities generate more indirect jobs in related industries than do D&D activities, the indirect jobs generated by D&D would be overshadowed by the indirect jobs lost from downsizing. The downsizing of the facility to the base case single-shift mode would, in 2005, result in a loss of approximately 4,200 jobs in the regional economy (805 at Y-12 and about 3,395 offsite indirect jobs).

Total employment in the ORR regional economic area would fall by less than 1 percent as a result of the reduction in workforce. Unemployment would increase from the No Action level of 4.9 percent to 5.6 percent. Per capita income would decrease by less than 1 percent. Changes in total employment and per capita income from the No Action levels are shown in figure 4.2.3.8–4.

Base Case Surge (Three Shift). In 2005, base case surge operations would require 213 fewer workers than would the No Action alternative. As described earlier, many core stockpile management jobs would be replaced by D&D jobs. However, because secondary and case fabrication activities generate more indirect jobs in related industries than do D&D activities, the indirect jobs generated by D&D would be overshadowed by the indirect jobs lost from downsizing. The downsizing of the facility to base case three-shift production in 2005 would eliminate approximately 2,103 jobs in the regional economy (213 at Y-12 and about 1,890 offsite indirect jobs). Even in 2016, when onsite employment would

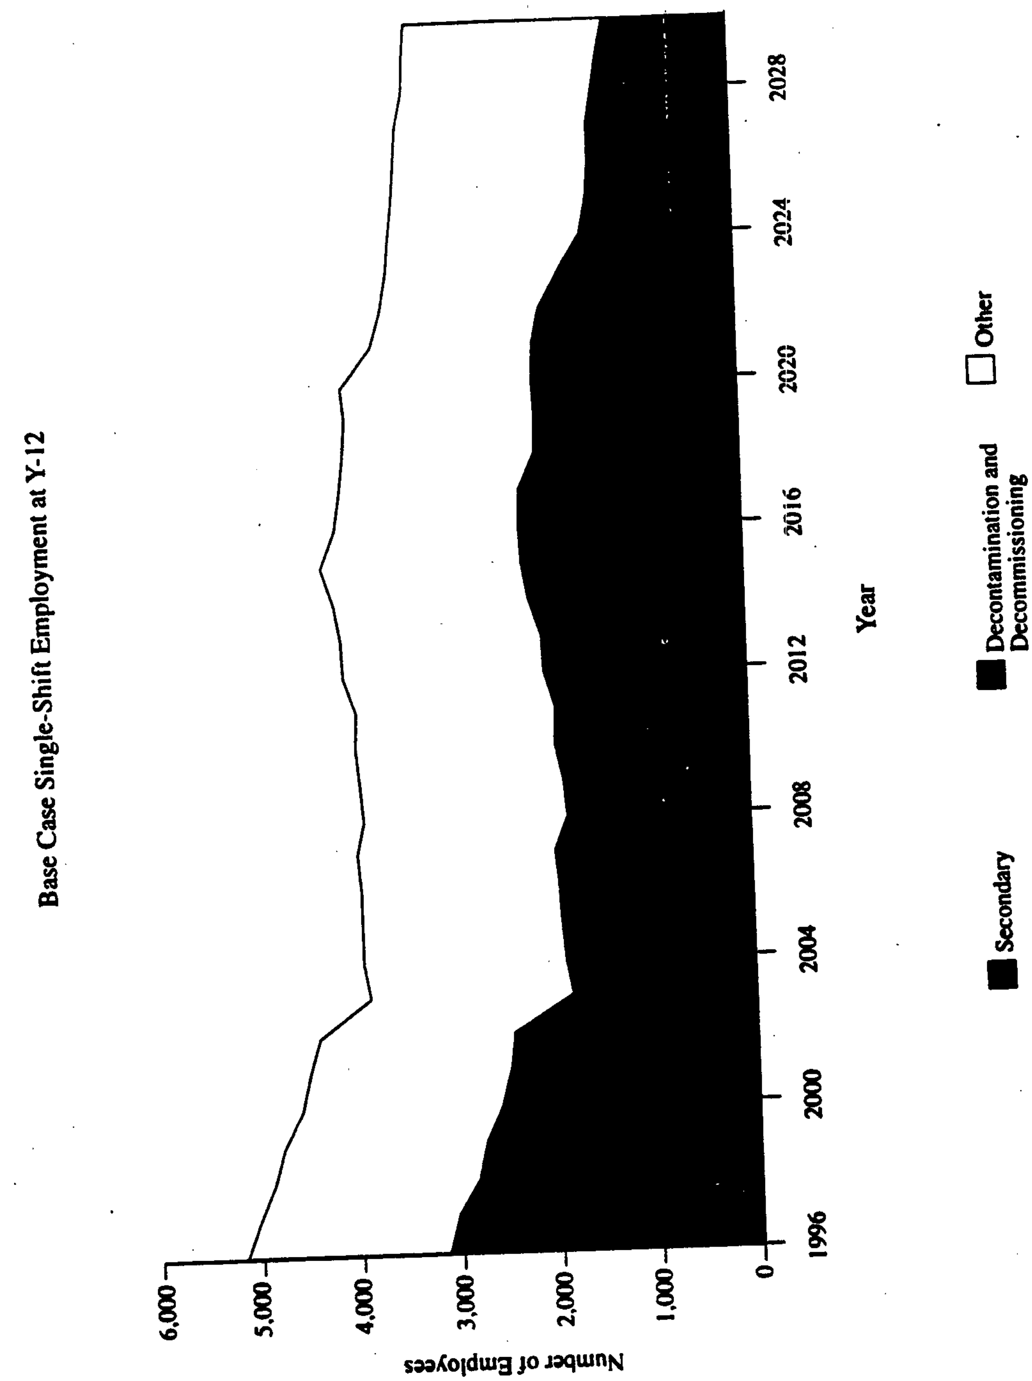

FIGURE 4.2.3.8–2.—*Base Case Single-Shift Employment at Y-12 Plant.*

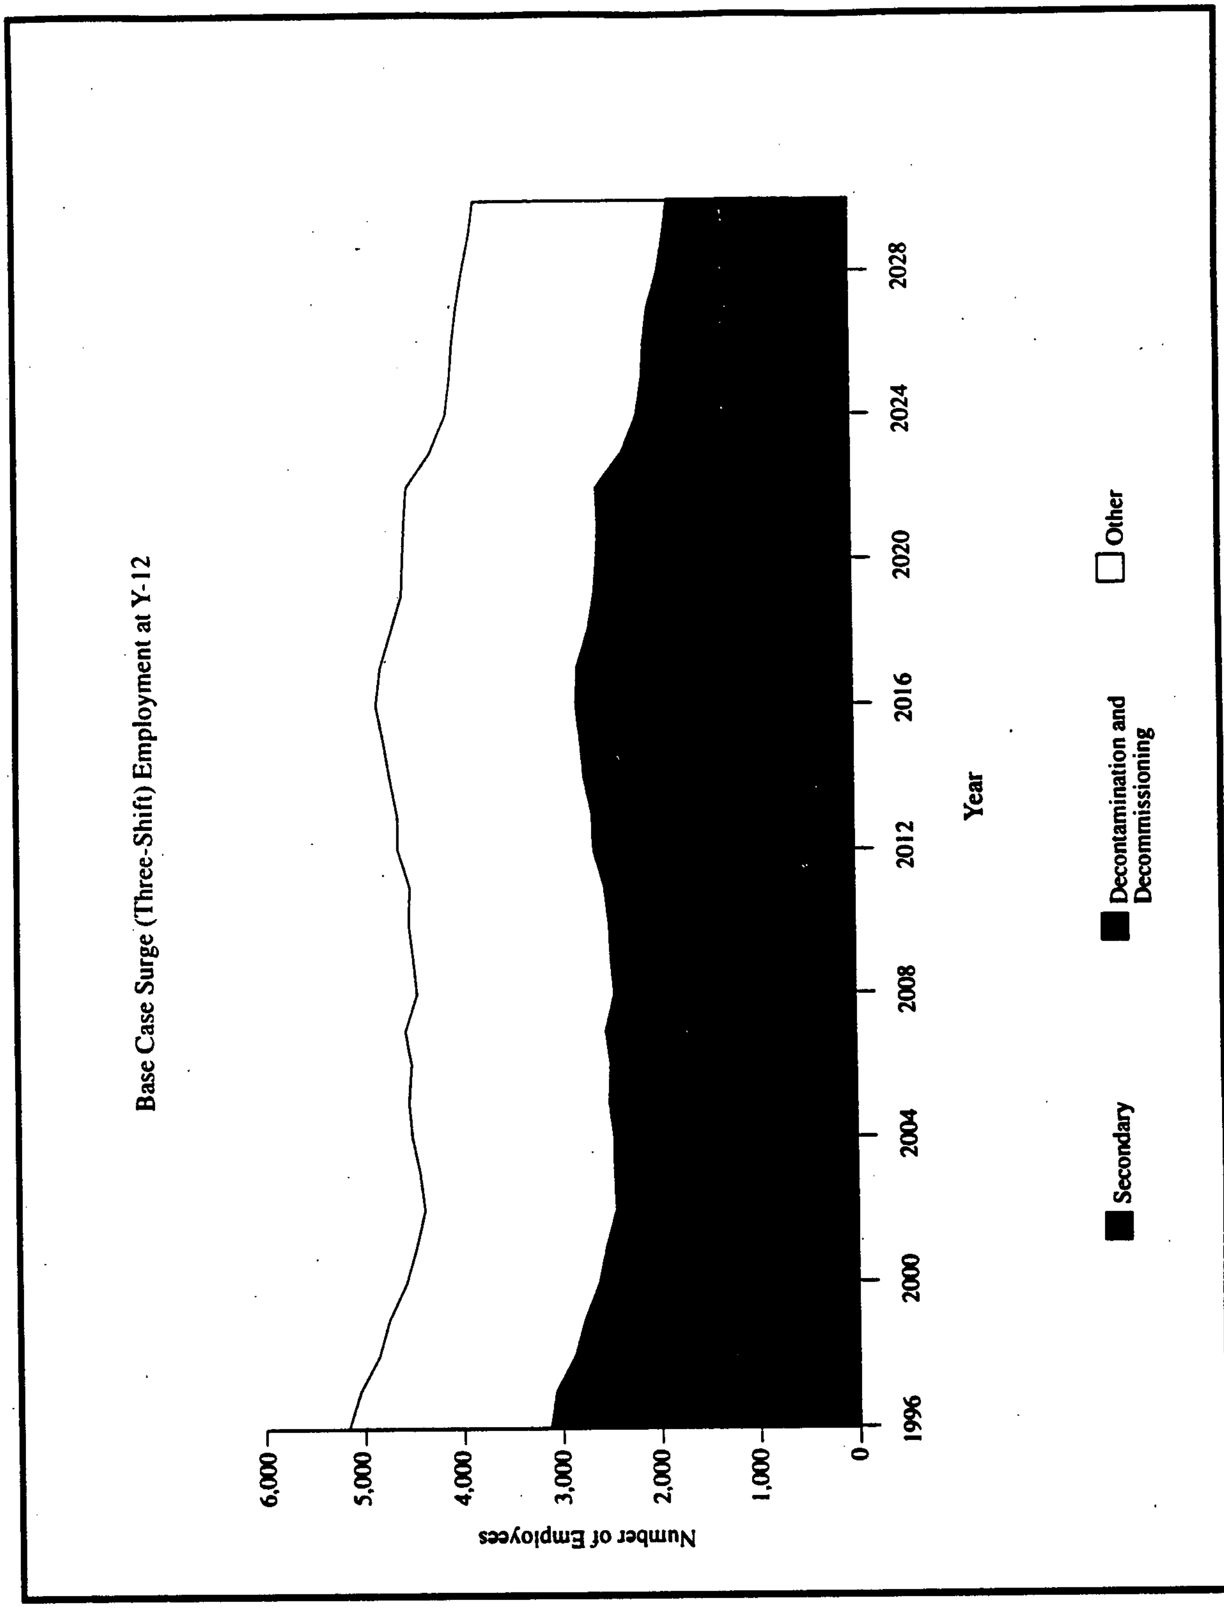

FIGURE 4.2.3.8–3.—*Base Case Surge Employment at Y-12 Plant.*

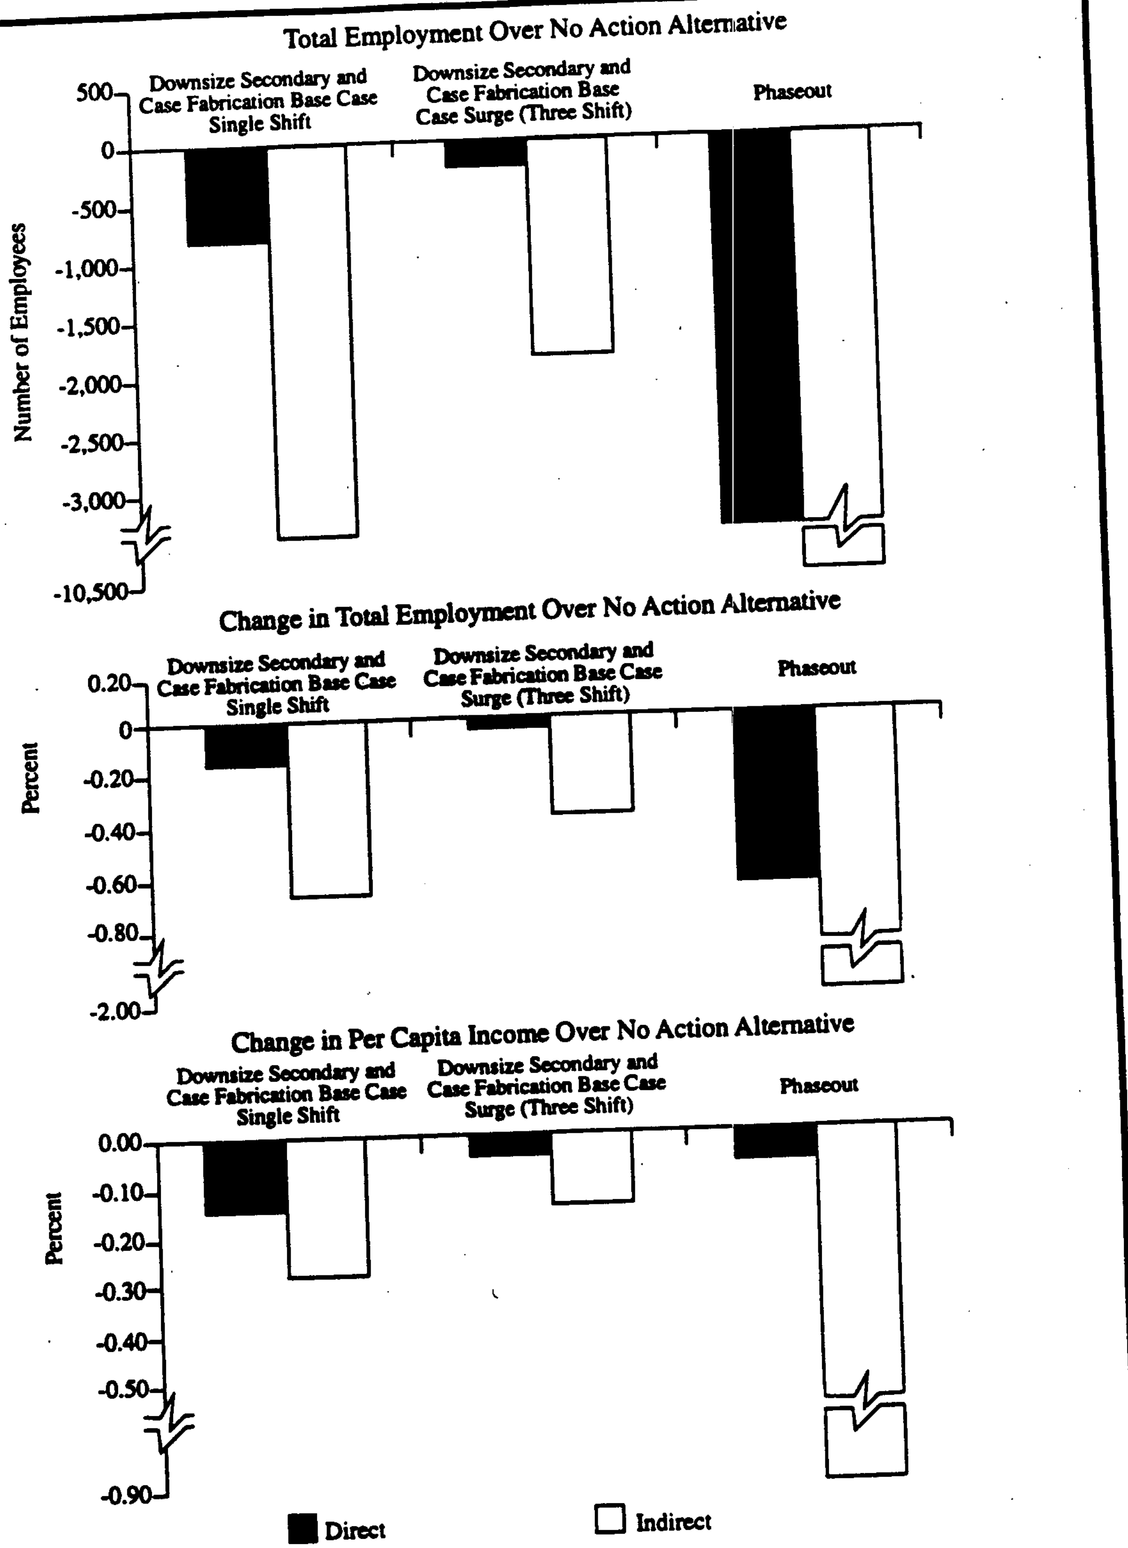


Note: No Action projections are baseline for comparing proposed alternatives.

Source: Socio 1996b.

FIGURE 4.2.3.8–4.—*Employment and Income Changes Resulting from Management Alternatives in the Oak Ridge Reservation Regional Economic Area, 2005.*

exceed the No Action alternative workforce, there would be a net loss of approximately 1,210 jobs to the regional economy.

Total employment for the ORR regional economic area would fall by less than 1 percent under this alternative. Unemployment would increase from the No Action level of 4.9 percent to 5.2 percent. Per capita income would decrease by less than 1 percent. Changes in total employment and per capita income from the No Action levels are shown in figure 4.2.3.8–4.

Population and Housing. Population in the ORR ROI during peak modification activities for Secondary and Case Fabrication Facility base case single shift and base case surge (three shift) would not increase over No Action projections. There would be enough workers available in the region to fill the direct and indirect jobs generated by the modifications to the facilities.

Base Case Single Shift. There could be some change in population and housing as a result of the downsizing of the facility. Some workers and their families might out-migrate from the ROI. This would result in, at most, slightly less than a 2-percent decrease in the ROI population. Some currently occupied housing units would become vacant or the housing construction rate would decrease as a result of the out-migration. Estimates of ROI population and required housing vacancies for full operation at ORR are shown in figure 4.2.3.8–5.

Base Case Surge (Three Shift). There could be some change in population and housing as a result of the downsizing of the facility. Some workers and their families might out-migrate from the ROI. This would result in, at most, slightly less than a 1-percent decrease in the ROI population. Some currently occupied housing units would become vacant or the housing construction rate would decrease as a result of the out-migration. Estimates of ROI population and required housing vacancies for full operation at ORR are shown in figure 4.2.3.8–5.

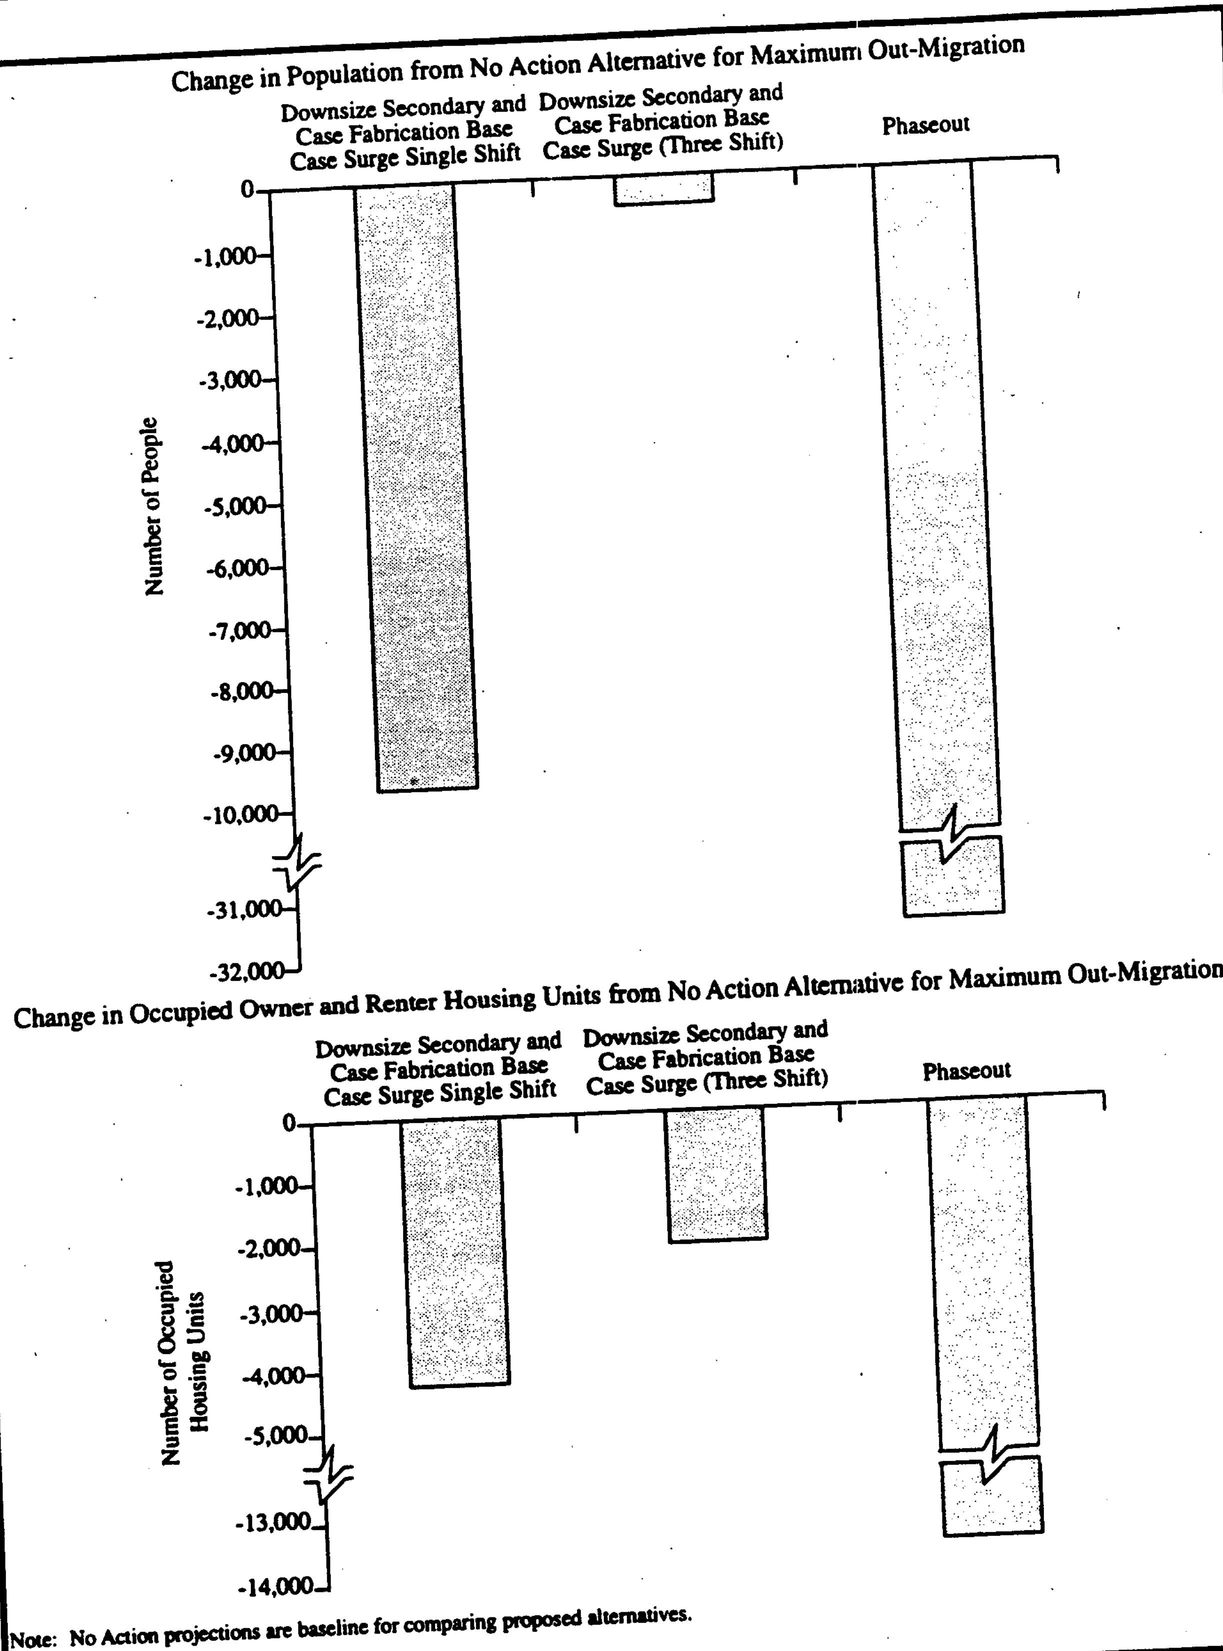
Public Finance. Modifications required to downsize the secondary and case fabrication facility base case single shift and base case surge (three shift) would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Base Case Single Shift. Downsizing the facility could result in the out-migration of workers from the ROI, which would cause a loss of income and population that would affect revenues and expenditures in the ROI. Changes in revenues and expenditures compared to No Action projections due to downsizing of the facility for single-shift operation are shown in figure 4.2.3.8–6. In 2005, the percent decrease in total ROI revenues and expenditures from No Action projections would be approximately 1.9 and 1.1 percent, respectively.

Base Case Surge (Three Shift). Downsizing the facility could result in the out-migration of workers from the ROI, which would cause a loss of income and population that would affect revenues and expenditures in the ROI. Changes in revenues and expenditures compared to No Action projections due to downsizing of the facility for three-shift operation are shown in figure 4.2.3.8–7. In 2005, the percent decrease in total ROI revenues and expenditures from No Action projections would be approximately 0.9 and 0.5 percent, respectively.

Phaseout of Secondary and Case Fabrication. Phaseout of the stockpile management mission at Y-12 would eliminate all core stockpile management and support jobs at Y-12. The only remaining jobs would be those associated with D&D activities. Consequently, Y-12 employment in 2005 would total 1,385 compared to the No Action level of 4,721, a loss of 3,336 jobs. Figure 4.2.3.8–8 shows the breakdown of Y-12 employment under phaseout.

Regional Economy and Employment. By 2005, all of the core stockpile management jobs would be eliminated and the workforce would decrease by 3,336. Because secondary and case fabrication activities generate more indirect jobs in related industries than do D&D activities, the indirect jobs generated by D&D would be overshadowed by the indirect jobs lost from phaseout. Accordingly, the phaseout of secondary and case fabrication at Y-12 in 2005 would result in a loss of about 13,470 jobs in the regional economy (3,336 at Y-12 and about 10,134 offsite indirect jobs). It should be noted that under the phaseout alternative in 2017, the D&D workforce would increase to 2,307 and stabilize at approxi-



Note: No Action projections are baseline for comparing proposed alternatives.

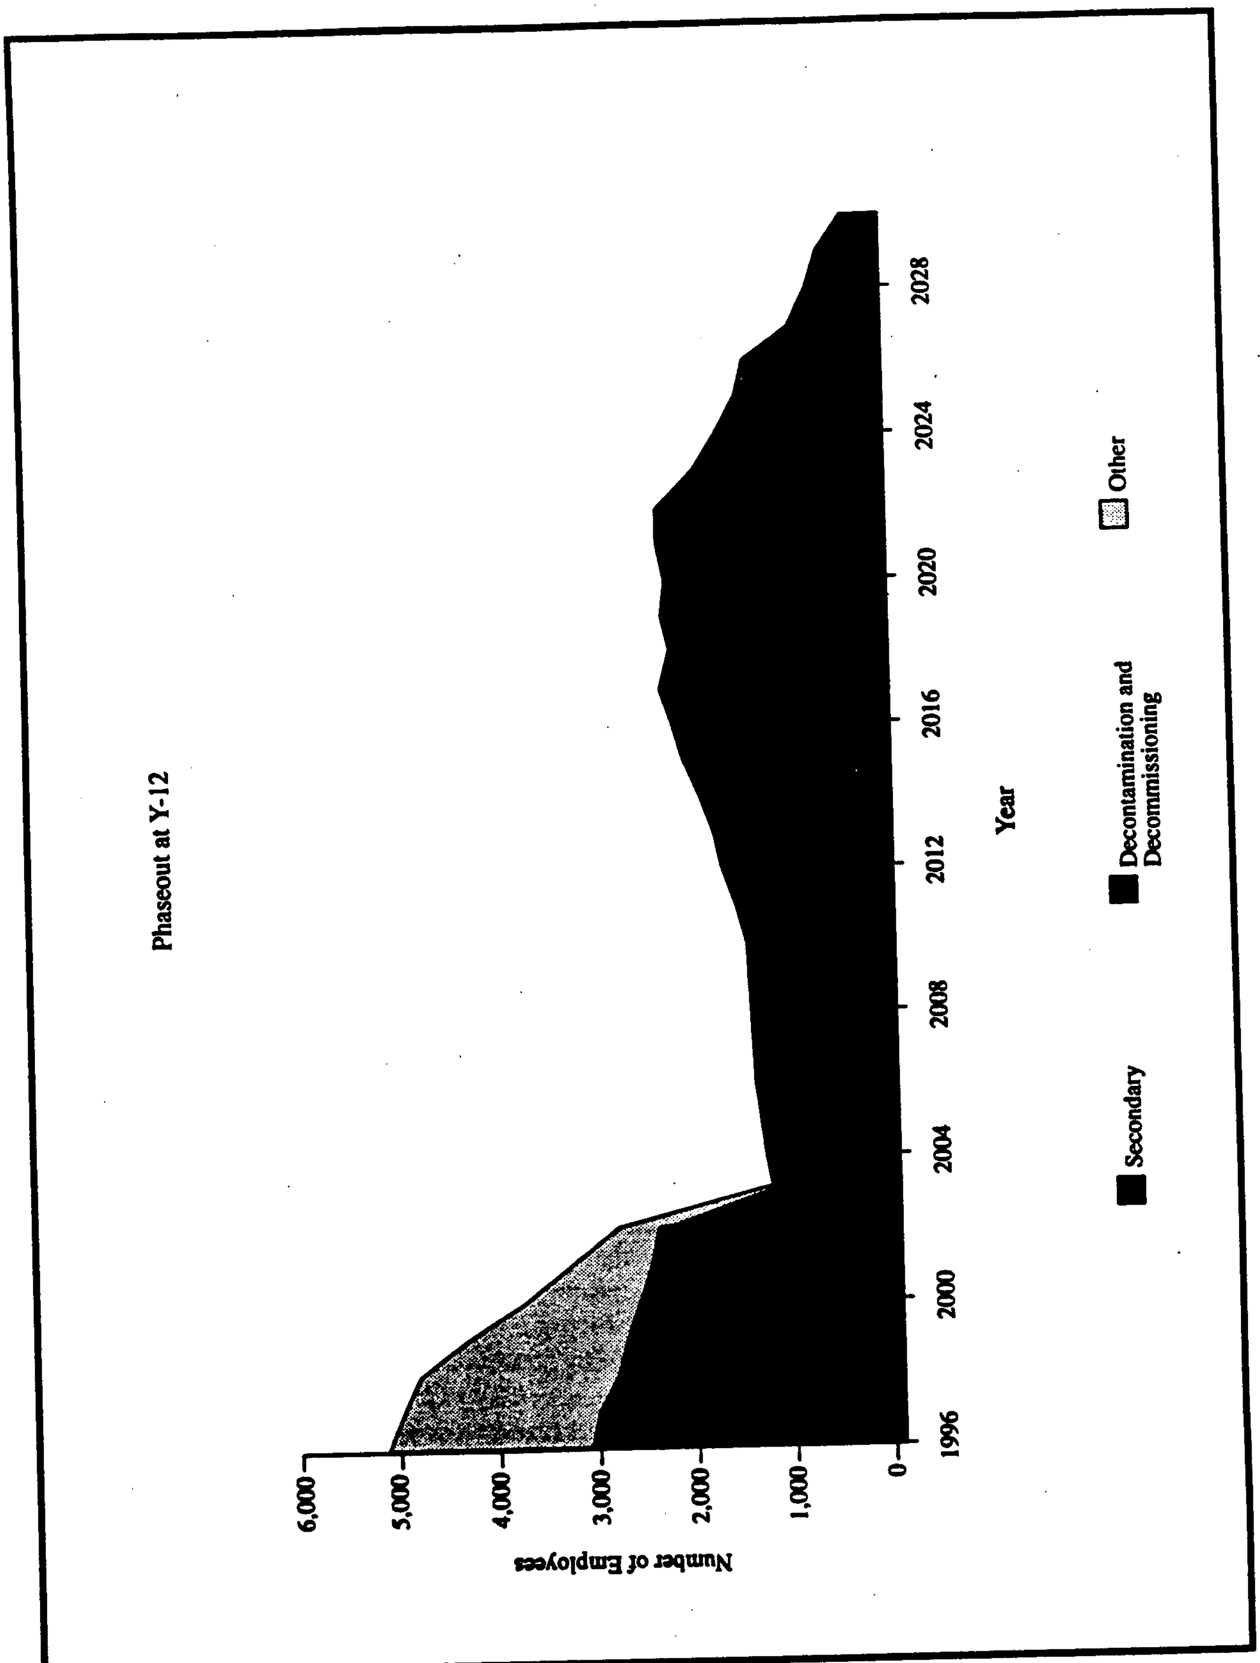

FIGURE 4.2.3.8–8.—*Phaseout at Y-12 Plant.*

mately 2,300 workers through the year 2022. During the period from 2023 to 2030, the workforce would be gradually phased out as D&D tasks are completed.

The reduction in workforce in 2005, would decrease total employment in the ORR regional economic area by less than 3 percent. Unemployment would increase from the No Action level of 4.9 percent to 7.4 percent. Per capita income would decrease by a little over 1 percent. Changes in total employment and per capita income from the No Action levels are shown in figure 4.2.3.8–4.

Population and Housing. There could be some changes in population and housing as a result of the phaseout. Some displaced workers and their families might out-migrate from the ROI. This would result in, at most, a decrease of about 5.5 percent in the ROI population. Some currently occupied housing units would become vacant as a result of the out-migration and the housing construction rate would be reduced. ROI population projections and owner and renter housing units for phaseout of the secondary and case fabrication mission at ORR are shown in figure 4.2.3.8–5.

Public Finance. Phaseout of the secondary and case fabrication mission would cause a loss of income and population that would affect ROI revenues and expenditures. In 2005, the total ROI revenues and expenditures would be reduced below No Action projections by approximately 6.2 and 3.6 percent, respectively. Revenue decreases for communities in the ORR ROI would range from 2.8 percent in Loudoun County to 16.3 percent in Oak Ridge. Decreases in expenditures would range from 2.5 percent in Knoxville to 13.7 percent in Oak Ridge. Changes for each ROI county and city are shown in figure 4.2.3.8–9.

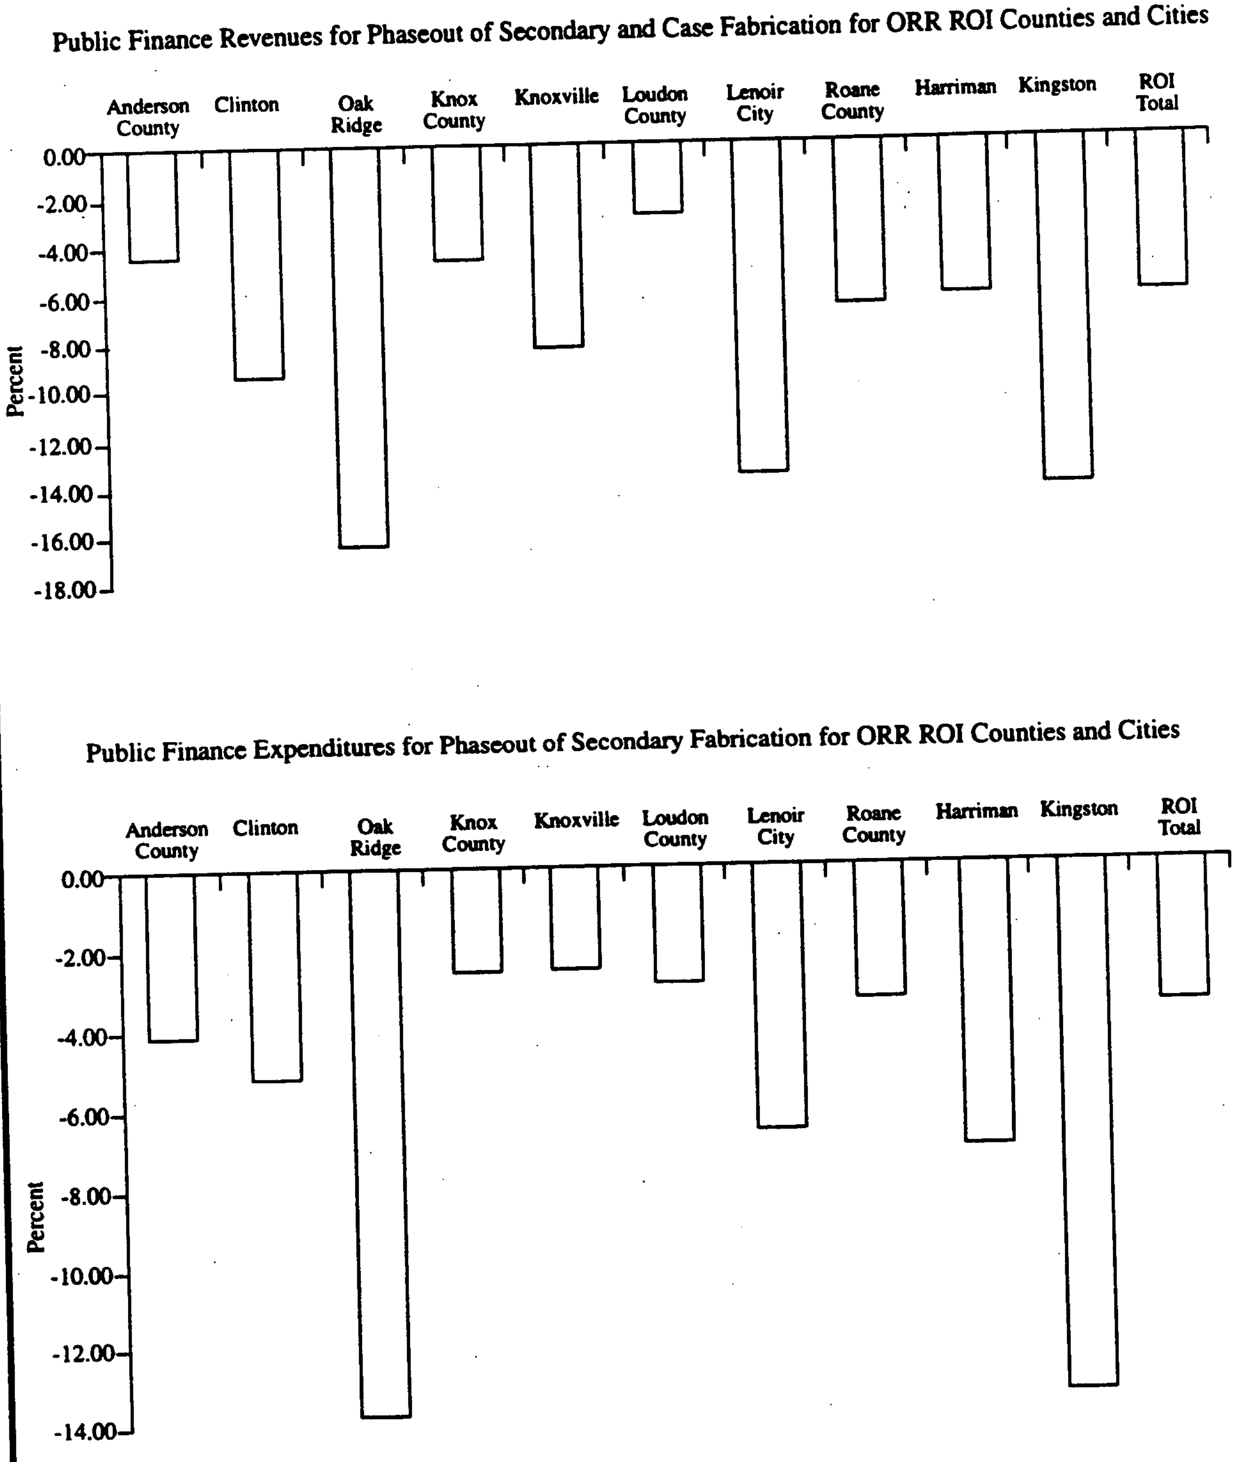
Sensitivity Analysis. The number of construction workers required to modify the Secondary and Case Fabrication Facility for the high and low case would be the same as the other scenarios. Operation of the Secondary and Case Fabrication Facility for the high case mode would require fewer core stockpile management workers than for the base case surge mode, but more than for the base case single-shift operation. Accordingly, more jobs would be phased out under the high case scenario than under the base case surge scenario, but fewer than under base case single-shift mode. The magnitude of socioeconomic impacts would fall between the base case surge and the base case single-shift options. The workforce size for the low case would be the same as for the base case single-shift mode. Therefore, the socioeconomic impacts would be the same.

Potential Mitigation Measures. In the event of a phaseout of DP activities at ORR, adverse socioeconomic impacts could result in the affected regional economic region. To mitigate potential socioeconomic impacts, Section 3161 of the *National Defense Authorization Act* (Public Law 102-484) requires DOE to develop a plan for restructuring the workforce for a defense nuclear facility whenever a change in workforce is necessary. The legislation also directs DOE to consult with local, state, and national stakeholders in developing the plan.

DOE has initiated a number of actions to respond to the legislative requirements, including the creation of the Office of Worker and Community Transition. In February 1996, the Office issued interim planning guidance in developing plans to help mitigate unavoidable impacts from workforce restructuring. Although the guidance is not prescriptive, it sets forth DOE policy on mitigating economic impacts of restructuring. For example, the guidance states that whenever possible, the impacts of workforce reductions should be minimized through the use of early retirement and normal attrition. Where appropriate, employees should be retrained for work in environmental restoration and waste management. The guidance also recommends that terminated employees receive assistance in obtaining reemployment through out-placement services, appropriate retraining, and educational services. To the extent practical, DOE and its contractor should offer a hiring preference to terminated employees. The DOE guidance also suggests that the affected communities should receive assistance to mitigate impacts to the public infrastructure and finances.

4.2.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the radiological and hazardous chemical releases and their associated impacts that could result from No Action and the proposed alternatives at ORR. Within this section, impacts resulting from the base case scenario are quantitatively



Source: Socio 1996b.

FIGURE 4.2.3.8–9.—*Percent Change from No Action Alternative in County and City Total Revenues and Expenditures in the Oak Ridge Reservation Region of Influence with Phaseout of Secondary and Case Fabrication, 2005.*

discussed and a sensitivity analysis of the high and low case scenarios is qualitatively discussed.

Summaries of radiological impacts at ORR to the public and to workers associated with normal operation are presented in tables 4.2.3.9–1 and 4.2.3.9–2, respectively. Radiological and chemical accident impacts are given in figure 4.2.3.9–1 and tables 4.2.3.9–3 and 4.2.3.9–4. The impact assessment methodology is described in section 4.1.9 and further supplementary methodological information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the modification of any facilities to support the Stockpile Stewardship and Management Program. However, limited hazardous chemical releases (e.g., small spills of diesel fuel from equipment refueling) may occur due to building modification activities for the base case scenario and may increase slightly for the high case scenario. The concentrations of these releases are expected to be well within the regulated exposure limits and would not result in any adverse health effects.

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge. Furthermore, discharges of wastewater through NPDES-permitted outfalls that can be attributed to the activities associated with the secondary and case fabrication mission at ORR are expected to be below NPDES limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at ORR, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). The HI is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all management alternative (secondary and case fabrication) chemicals emitted at the site. An HI of ≤ 1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is $\leq 1 \times 10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $\leq 1 \times 10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the population. Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

No Action

Radiological Impacts. Potential radiological impacts to the public resulting from the No Action alternative are presented in table 4.2.3.9–1. These impacts are representative of the aggregate total that is estimated to exist from ORR remaining site contributions (such as K-25, ORNL, and other non-DP Y-12 activities) and from single-shift base case operations at Y-12. Total impacts are provided for comparison with applicable regulations governing total site operations. To place doses to the public from the No Action alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.2.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 3.0 mrem for the No Action alternative. The annual population dose within 80 km (50 mi) in 2030 would be 40.2 person-rem. The incremental impacts incurred from three-shift base case operation are small when compared to those existing for the normal baseline site operation (see table 4.2.3.9–1).

Total site doses to onsite workers from normal operation for the No Action alternative are presented in table 4.2.3.9–2. The average annual dose to involved workers for this alternative would be 2.2 mrem. The dose to the entire facility workforce (involved workforce) would be 2.2 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database, which report doses from similar types of operations; the presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information.

Based on the radiological impacts associated with normal operation under the No Action alternative, all

TABLE 4.2.3.9–1.—*Potential Radiological Impacts to the Public Resulting from Normal Operation of Stockpile Management Alternatives at Oak Ridge Reservation*

Affected Environment	No Action Single-Shift Operation	Downsize Secondary and Case Fabrication Three-Shift Operation	Secondary and Case Fabrication Phaseout
	Total Site[a]	Total Site[a]	Total Site[a]
Maximally Exposed Individual (Public)			
Atmospheric Release			
Dose[b] (mrem/yr)	1.4	1.6	1.4
Percent of natural background[c]	0.47	0.54	0.47
25-year fatal cancer risk	1.7×10^{-5}	2.0×10^{-5}	1.7×10^{-5}
Liquid Release			
Dose[b] (mrem/yr)	0.6	0.6	0.6
Percent of natural background[c]	0.20	0.20	0.20
25-year fatal cancer risk	7.4×10^{-6}	7.4×10^{-6}	7.4×10^{-6}
Atmospheric and Liquid Releases[d]			
Dose[b] (mrem/yr)	3.0	3.2	3.0
Percent of natural background[c]	1.0	1.1	1.0
25-year fatal cancer risk	3.7×10^{-5}	3.9×10^{-5}	3.7×10^{-5}
Population Within 80 Kilometers			
Atmospheric and Liquid Releases in 2030			
Dose (person-rem)	40.2[e]	40.8[e]	40.0[e]
Percent of natural background[c]	1.3×10^{-2}	1.3×10^{-2}	1.3×10^{-2}
25-year fatal cancers	0.51	0.52	0.51

[a] Includes impacts from K-25, ORNL, and other non-DP Y-12 activities.
[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem per year from the air pathways, 4 mrem from the drinking water pathway, and 100 mrem per year from all pathways combined (DOE Order 5400.5).
[c] Natural background radiation levels to the average individual is 295 mrem per year; to the population within 80 km in 2030 is estimated to be 315,300 person-rem.
[d] Includes an annual direct radiation dose of 1 mrem to an individual at Poplar Creek or the Clinch River shoreline.
[e] Includes Y-12 Interim Storage.
Source: OR DOE 1994c; OR DOE 1994d.

resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from normal operation under the No Action base case one-shift operation at ORR are presented below. Analyses to support the values presented in this section are provided in appendix table E.3.4–1. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging the sites as having a hazardous chemical health concern. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among sites. This baseline is then used to determine the extent to which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed member of the public at ORR resulting from normal onsite operation under the No Action alternative would be 0.0395, and the cancer risk would be zero. The HI to the onsite worker would be 0.154 and the cancer risk would be zero.

TABLE 4.2.3.9–2.—*Potential Radiological Impacts to Workers Resulting from Normal Operation of Stockpile Management Alternatives at Oak Ridge Reservation*

Affected Environment	No Action Single-Shift Operation	Downsize Secondary and Case Fabrication Three-Shift Operation	Secondary and Case Fabrication Phaseout
Involved Workforce[a]			
Average worker dose[b] (mrem/yr)	2.2	2.2	0
25-year fatal cancer risk	$2.2x10^{-5}$	$2.2x10^{-5}$	0
Total dose (person-rem/yr)	2.2	0.38	0
Noninvolved Workforce[c]			
Average worker dose[b] (mrem/yr)	5.1	5.1	5.1
25-year fatal cancer risk	$5.1x10^{-5}$	$5.1x10^{-5}$	$5.1x10^{-5}$
Total dose (person-rem/yr)	72	72	72
Total Site Workforce[d]			
Dose (person-rem/yr)	75	73	72
25-year fatal cancers	0.75	0.73	0.72

[a] The involved worker is a worker associated with operation of the secondary and case fabrication facilities. The estimated numbers of involved workers are 174 for the downsize alternative and 1,000 for the No Action alternative, respectively.

[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835). The dose presented for the involved workforce is only that incremental dose received from the secondary and case fabrication mission. The total dose received by the involved workforce would be higher than that received by the noninvolved workforce from these operations.

[c] The noninvolved worker is a worker on site but not associated with operations of the secondary and case fabrication facilities in question. The estimated number of noninvolved workers is 14,200 at ORR.

[d] The total site workforce is the sum of the numbers of involved and noninvolved workers. The estimated number of workers at ORR in the total site workforce is 14,400 for the downsize alternative and 15,200 for the No Action alternative, respectively.

Management Alternatives

Downsize Secondary and Case Fabrication

Radiological Impacts. Radiological impacts to the public resulting from the downsize secondary and case fabrication alternative are presented in table 4.2.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from ORR remaining site contributions (i.e., K-25, ORNL, and other non-DP Y-12 activities) and from three-shift base case operation at Y-12. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.2.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 3.2 mrem for this alternative. The annual dose to the population within 80 km (50 mi) in 2030 would be 40.8 person-rem. The incremental impacts incurred from three-shift base case operations are very small when compared to those existing for the normal site operation (see table 4.2.2.9–2). Total site doses to onsite workers from normal operation for the downsize secondary and case fabrication alternative are presented in table 4.2.3.9–2. The average annual dose to involved workers for this alternative would be 2.2 mrem. The dose to the entire facility workforce (i.e., involved workforce) would be 0.38 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which report doses for similar types of operations; the presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks for construction workers involved with downsizing activities that involve performing tasks in close proximity to potentially contaminated areas. The estimated reduction in impacts from not storing the secondary and case strategic reserve at Y-12 would be negligible.

The contribution to radiological impacts from the storage of the HEU strategic reserve at ORR is included within the downsize secondary and case fabrication mission. Radiological impacts incurred from storage of the strategic reserve are extremely small, therefore total site impacts would not be affected if the strategic reserve was not located at Y-12.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from normal operation due to downsizing and/or consolidating the secondary and case fabrication mission at Y-12 are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–2.

The incremental HI for the maximally exposed member of the public would be 0.056, and the incremental cancer risk would be zero as a result of downsizing and/or consolidating the secondary and case fabrication mission at ORR. The incremental HI for the onsite worker would be 0.178, and the incremental cancer risk would be zero as a result of downsizing and/or consolidating the secondary and case fabrication mission.

The HIs for the public and onsite worker are within acceptable health levels. The cancer risks to the public and onsite worker are within the default value level of 1×10^{-6}.

Phaseout of Secondary and Case Fabrication

Radiological Impacts. Radiological impacts to the public resulting from the phaseout of secondary and case fabrication mission at Y-12 are presented in table 4.2.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from ORR remaining site contributions (i.e., K-25, ORNL, and other non-DP Y-12 activities). Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.2.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 3.0 mrem for this alternative. The dose to the annual population within 80 km (50 mi) dose in 2030 would be 40.0 person-rem.

Total site doses to onsite workers from normal operation after the phaseout of the secondary and case fabrication mission at Y-12 are presented in table 4.2.3.9–2. The annual dose to the entire facility workforce is estimated to be 72 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced from Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which report doses for similar types of operations; the presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks for construction workers involved with phaseout activities from performing tasks in close proximity to potentially contaminated areas.

Based on the radiological impacts associated with normal site operations, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. The HIs for the public and the onsite worker would be reduced to 0, and the cancer risks to the public and the onsite worker would remain at zero as a result of the phaseout of the secondary and case fabrication mission (see appendix table E.3.4–3). Therefore, there are no adverse health effects or cancer risks to the public or the onsite worker due to this alternative.

Sensitivity Analysis. Radiological impacts may be subject to certain degrees of variance resulting from either high or low case operations. For the high case scenario, impacts to both the public and worker would be similar to the three-shift base case operations. For the low case scenario, impacts to the public and workers would be similar to the single-shift base case operations.

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Operation under the high case scenario may increase emissions of hazardous chemicals. Since HIs for the public and onsite workers are well within acceptable health levels and cancer risks are zero, increased emissions with high case operations are not expected to be sufficient to adversely effect HI and cancer risks at ORR. The low case scenario would not have any appreciable effect on hazardous chemical emissions at ORR and would not have any impact upon HI and cancer risks to the public and onsite worker.

Potential Mitigation Measures. Radioactive and chemical airborne emissions to the general population and onsite exposures to workers could be reduced by implementing the latest technology for process and design improvements. For example, to reduce public exposure to emissions, improved building and work area control methods could be used to remove radioactivity from releases to the environment. Similarly, the use of remote, automated, and robotic production methods are examples of techniques that are being developed which would reduce worker exposure (see section 3.5.2).

Facility Accidents. The proposed actions have the potential for accidents that may impact the health and safety of workers and the public. The potential for reasonably foreseeable accidents and associated consequences that have been evaluated are summarized in this section and described in more detail in appendix F. The methodology used in the assessment is described in section 4.1.9. A list of documents reviewed for applicable accident data is provided in appendix table F.1.1–1. The potential impacts from accidents, ranging from high-consequence/low-probability to low-consequence/high-probability events, have been evaluated in terms of potential cancer fatalities that may result for noninvolved workers and the public. The risk of cancer fatalities has also been evaluated to provide an overall measure of accident impacts and is calculated by multiplying the accident annual frequency (or probability) of occurrence by the consequences (number of cancer fatalities). Figure 4.2.3.9–1 shows the risk of latent cancer fatalities in the population within 80 km (50 mi) that may result from accidents. Specifically, the curves in the figure show the probability (vertical axis) that the number of cancer fatalities in the offsite population within 80 km (50 mi) (horizontal axis) will be exceeded. The curves reflect the probability of the accident. For example, the probability that an HEU accident will result in more than one cancer fatality is 10^{-6} per year.

In addition to the potential impacts to noninvolved workers and the offsite population, there are potential

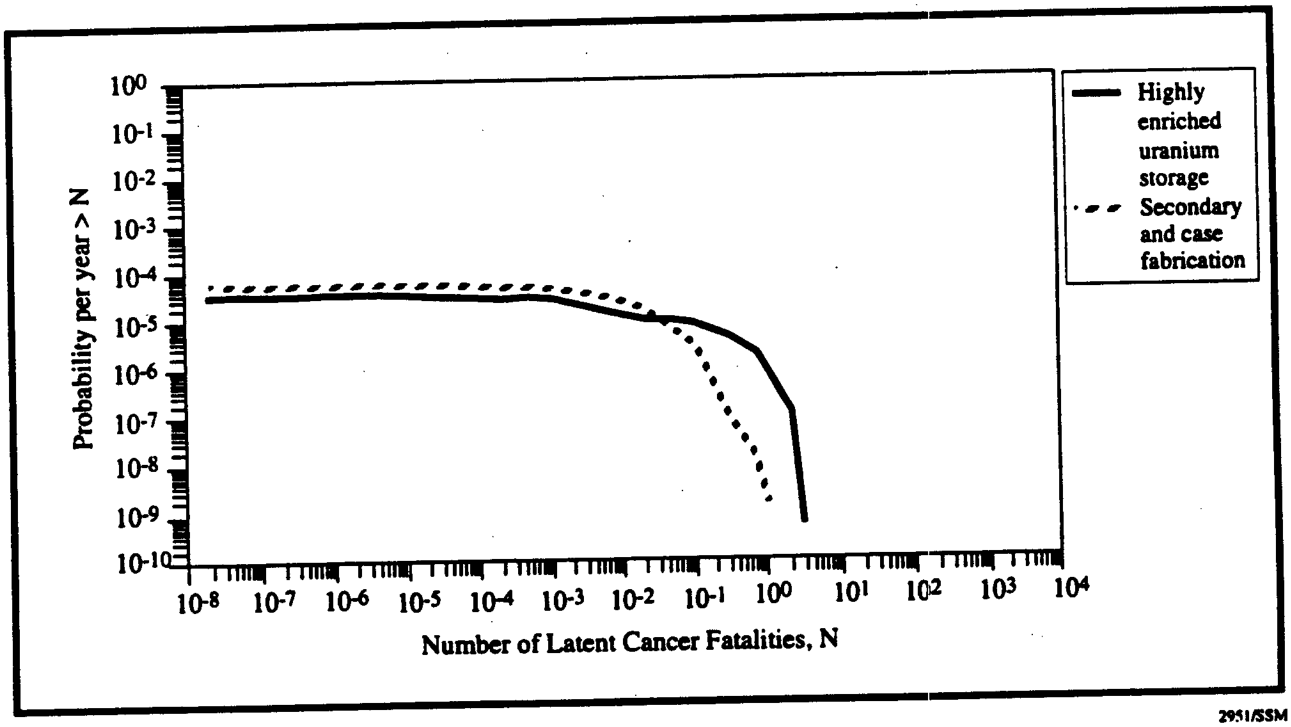

FIGURE 4.2.3.9–1.—*Combined Evaluation Basis Accidents and Beyond Evaluation Basis Accidents—Cancer Fatalities Complementary Cumulative Distribution Functions for Stockpile Management Alternatives at Oak Ridge Reservation.*

impacts to involved workers who would be located in the facilities associated with the proposed action. Quantitative statements of these impacts cannot be made until design details are developed further, at which time the number and location of facility workers, and protective and mitigating features can be estimated to support accident impact analyses. However, depending on the type of accident, facility workers in close proximity to the point of the accident could receive high levels of exposure to radiation, hazardous chemicals, and potentially fatal impacts.

The movement of the strategic reserve of HEU at ORR to another DOE site location (an alternative in the Storage and Disposition Program) would have the effect of eliminating all risks of accidents at ORR associated with these reserves over the long term. However, over the short term, there would exist risks of accidents to workers and the public during handling and transportation operations for the movement of the reserves. These short term risks of accidents would be addressed in tiered safety documentation, such as a safety analysis report, that would be prepared prior to the movement of the reserves.

No Action. Under the No Action alternative, secondary and case fabrication would continue to be performed at the ORR site with no changes to facilities and operations. Potential accidents and their consequences under existing conditions have previously been addressed in facility safety documentation according to requirements in DOE orders.

Management Alternatives

Downsize Secondary and Case Fabrication. A set of potential accidents has been postulated for the downsize secondary and case fabrication alternative for which there may be releases of radioactive materials that may impact onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.2.3.9–1. The curve reflects the probability of the accidents occurring. The impacts for the composite set of EBAs and BEBAs are shown in table 4.2.3.9–3. If an accident were to occur, there would be an estimated 0.02 cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 619 m (2,030 ft) (at the site boundary) from the accident would have an increased likelihood of cancer fatality of 1.1×10^{-4}. For the maximally exposed individual located at the site boundary, there would be an increased likelihood of cancer fatality of 1.3×10^{-4}. The risk for the combined EBA and BEBA composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.2.3.9–3. For the same worker, the maximally exposed individual, and the population, the risks, taking into account the probability of accidents, would be 6.4×10^{-9}, 8.0×10^{-9}, and 1.2×10^{-6} cancer fatalities per year, respectively. Table 4.2.3.9–3 also shows the impacts for EBAs and BEBAs only. There is also a potential for chemical accidents and impacts as shown in table 4.2.3.9–4.

Storage of Strategic Uranium Reserves. A set of potential accidents has been postulated for the storage of strategic uranium reserves for which there may be releases of radioactive materials that may impact workers and the offsite population. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.2.3.9–1. The curve reflects the probability of the accidents occurring. The impacts for the composite set of EBAs and BEBAs are shown in table 4.2.3.9–3. If an accident were to occur, there would be an estimated 0.14 cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 619 m (2,030 ft) (at the site boundary) from the accident would have an increased likelihood of cancer fatality of 7.3×10^{-4}. For the maximally exposed individual located at the site boundary, there would be an increased likelihood of cancer fatality of 9.1×10^{-4}. The risks for the composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.2.3.9–3. For the same worker, the maximally exposed individual, and the population, the risks would be 2.2×10^{-8}, 2.7×10^{-8}, and 4.1×10^{-6} fatalities per year, respectively. No BEBAs have been identified for storage of strategic uranium reserves. Table 4.2.3.9–3 also shows the impacts for EBAs and BEBAs only.

TABLE 4.2.3.9–3.—*Impacts of Accidents for Downsize Secondary and Case Fabrication and Storage of Uranium Strategic Reserves at Oak Ridge Reservation*

Parameter	Downsize Secondary and Case Fabrication			Storage of Uranium Strategic Reserves		
	EBA	BEBA	EBA and BEBA Combined	EBA	BEBA	EBA and BEBA Combined
Composite Accident Frequency (Per Year)	$6.0x10^{-5}$	$5.0x10^{-7}$	$6.0x10^{-5}$	$4.0x10^{-5}$	[a]	$4.0x10^{-5}$
Consequences						
Noninvolved Worker						
Cancer fatality[b]	$1.0x10^{-4}$	$9.7x10^{-4}$	$1.1x10^{-4}$	$7.3x10^{-4}$	[a]	$7.3x10^{-4}$
Risk (cancer fatality per year)	$5.9x10^{-9}$	$4.9x10^{-10}$	$6.4x10^{-9}$	$2.2x10^{-8}$	[a]	$2.2x10^{-8}$
Maximally Exposed Individual						
Cancer fatality[b]	$1.2x10^{-4}$	$1.2x10^{-3}$	$1.3x10^{-4}$	$9.1x10^{-4}$	[a]	$9.1x10^{-4}$
Risk (cancer fatality per year)	$7.4x10^{-9}$	$6.0x10^{-10}$	$8.0x10^{-9}$	$2.7x10^{-8}$	[a]	$2.7x10^{-8}$
Population Within 80 Kilometers[c]						
Cancer fatality[d]	0.018	0.18	0.02	0.14	[a]	0.14
Risk (cancer fatalities per year)	$1.1x10^{-6}$	$9.1x10^{-8}$	$1.2x10^{-6}$	$4.1x10^{-6}$	[a]	$4.1x10^{-6}$

[a] There are no BEBAs for storage of uranium strategic reserves.

[b] Probability (increased likelihood) of cancer fatality to a hypothetical member of the public located at the site boundary or to a noninvolved worker as a result of exposure to the indicated dose if an accident occurred.

[c] For the offsite population of 1,096,144, the average probability of cancer fatality/risk of cancer fatality (per year) for the combined EBA and BEBA is $1.8x10^{-8}/1.1x10^{-12}$ and $1.3x10^{-7}/3.7x10^{-12}$, respectively, for the listed alternative(s), downsized secondary fabrication, and storage of strategic uranium reserves.

[d] Number of cancer fatalities in the population within 80 km (50 mi) as a result of exposure to the indicated dose if the accident occurs.

Note: All values are mean values; BEBA - beyond evaluation basis accidents; EBA- evaluation basis accidents.

Source: Results shown are derived from accident analyses in appendix F.

TABLE 4.2.3.9–4.—*Impacts of Chemical Accidents for Downsize Secondary and Case Fabrication at Oak Ridge Reservation*

Accident Description	Accident Frequency (Per Year)	IDLH	TLV-STEL	TLV-TWA	Concentration to: Noninvolved Worker (mg/m³)	Concentration to: Individual at Site Boundary (mg/m³)	Potential Impacts of Exceeding: IDLH Limits[a]	Potential Impacts of Exceeding: TLV Limits[a]

Phaseout of Secondary and Case Fabrication. A phaseout of the secondary and case fabrication mission at ORR would have the effect of eliminating any potential for accidents over the long term related to secondary and case fabrication and uranium storage activities. However, there would be a potential for accidents during the phaseout process that could impact workers and the public. These potential accidents and their consequences are addressed in each affected facility's safety analysis report and/or safety documentation applicable to the phaseout process.

4.2.3.10 *Waste Management*

This section summarizes the impacts on waste management at ORR under No Action and for each of the proposed alternatives that would include the phaseout of secondary and case fabrication. There is no spent nuclear fuel, high-level waste (HLW), or TRU waste associated with the fabrication of secondaries and cases. Table 4.2.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for ORR. Projections for No Action are based on single-shift operation and were derived from 1994 environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities.

Table 4.2.3.10–2 provides the total estimated operational waste volumes projected to be generated at ORR as a result of both downsizing and consolidating, and phasing out the secondary and case fabrication mission. The net increase/decrease over No Action is provided below in parentheses. The waste volumes generated and the resultant waste effluent from the downsized Secondary and Case Fabrication Facility can be found in table 3.4.4.2–3 and are based on surge operations (three shifts). Facilities that would support the Stockpile Stewardship and Management Program would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act*, RCRA, and other applicable statutes as outlined in appendix section H.1.2.

The waste volumes given in table 4.2.3.10–2 include the storage of the strategic reserve of HEU. The volume of waste associated with the storage of the strategic reserve HEU is very small (less than 0.01 percent) in relation to the total amount of wastes generated from the secondary and case fabrication mission and is an even smaller percentage of the total ORR waste generation volume. Therefore, the continued storage of the strategic reserve HEU would have a negligible impact on waste management at ORR. The impact of continuing to store the strategic reserve HEU as part of the total inventory of nonsurplus HEU at ORR is also addressed in the Storage and Disposition PEIS (DOE/EIS-0229-D). In addition, the Storage and Disposition PEIS analyzes moving the HEU to another DOE site location. Since the HEU is already packaged, it is expected that any waste generated from repackaging, health physics, and analytical chemistry activities would be very small in comparison to the total wastes generated at ORR. Therefore, the moving of HEU would also have a minimal impact on ORR waste management.

No Action. Under No Action, spent nuclear fuel, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at ORR from the missions outlined in section 3.2.2. ORR would continue to store HEU, and treat, store, and dispose of its waste legacy and newly generated wastes in current and planned facilities.

Liquid LLW would be solidified, neutralized, and allowed to evaporate in existing and planned facilities as described in appendix section H.2.1. Some liquid waste would also be incinerated. Solid LLW would be compacted and stored onsite at K-25 and ORNL. Contaminated scrap metal would be processed by smelting by a commercial vendor for beneficial reuse where possible, including the DOE Shielding Block Program or be size-reduced for disposal. Liquid hazardous wastes would continue to be treated onsite with any hazardous residuals sent offsite to a RCRA-permitted disposal facility. Solid hazardous waste would continue to be shipped offsite to a RCRA-permitted disposal facility. Limited onsite treatment of solid hazardous waste may occur in the future at the K-1435 TSCA Incinerator.

Solid mixed waste would be treated and disposed of according to the ORR Site Treatment Plan which was developed pursuant to the *Federal Facility Compliance Act* of 1992. Liquid mixed wastes would also be incinerated at the TSCA Incinerator. The resulting

[a] The No Action volumes are from table 4.2.3.10–1 and are based on single-shift operation.
[b] Waste generation volumes for secondary and case fabrication at Y-12 are from table 3.4.4.2–3 and are based on surge operations (three shifts).
[c] Includes 10,000 m^3 of recyclable wastes.
Note: Waste generation volumes have been rounded to three significant figures. Waste effluent volumes (i.e., after treatment and volume reduction), which are used in the narrative description of the impacts, are also found in table 3.4.4.2–3.
Source: OR LMES 1996i; OR MMES 1996j.

waste would then be stored in a RCRA-permitted facility in Department of Transportation (DOT)-approved containers until it is shipped to an offsite DOE disposal facility. Some of this waste would be placed in interim storage until new technologies for treatment and disposal are identified and evaluated.

A new industrial pretreatment facility for liquid discharges from Y-12 to the city of Oak Ridge sanitary system would be constructed under the terms of their Industrial Pretreatment Permit. Nonhazardous sanitary and nonradioactive process waste liquids would be treated in conventional sewage treatment plants. The resultant solids would be disposed of with solid nonhazardous waste in a permitted landfill to handle projected future waste volumes.

Management Alternatives

Downsize Secondary and Case Fabrication. Modification activities and operation of a downsized or consolidated Secondary and Case Fabrication Facility would have an impact on existing and planned ORR waste management activities by decreasing the generation of low-level, mixed low-level, hazardous, and nonhazardous wastes from the amounts projected for No Action. There are adequate existing and planned waste treatment and storage facilities at ORR to manage all wastes generated from the fabrication of secondaries and cases.

Waste generated during the 6-year modification period would consist of approximately 8.2 m^3/yr (10.7 yd^3/yr) of solid LLW from contaminated steel and concrete, solid mixed low-level, solid hazardous, and nonhazardous wastes. Liquid and solid nonhazardous wastes generated during modification activities would include concrete and steel waste construction materials, sanitary wastewater, and other solid nonhazardous wastes. The low-level contaminated concrete would be placed in appropriate containers and shipped to a DOE LLW disposal facility. The low-level contaminated steel would go to the Contaminated Scrap Metal Yard where it would be shipped to an offsite contractor for processing for beneficial reuse where possible, including use in the DOE Shielding Block Program. An estimated 1 m^3/yr (1.3 yd^3/yr) of solid mixed LLW would be managed in accordance with the ORR Site Treatment Plan. Approximately 2 m^3/yr (2.7 yd^3/yr) of solid hazardous wastes would be packaged in DOT-approved containers and shipped offsite to commercial RCRA-permitted treatment and disposal facilities. Twenty seven cubic meters per year (7,040 gal/yr) of sanitary wastewater would be disposed of through the use of portable toilets of the existing sanitary system. The steel construction material, 4.1 t/yr (4.5 tons/yr), would be tested to ensure that no hazardous or radioactive contamination is present, and then recycled as scrap material before completing construction. The 3.4 m^3/yr (4.4 yd^3/yr) of concrete, 2.6 m^3/yr (3.4 yd^3/yr) of solid sanitary wastes, and 2.1 m^3/yr (2.7 yd^3/yr) of other solid nonhazardous wastes would be disposed of by the construction contractor.

Approximately 320 m^3 (84,500 gal) of liquid LLW from contaminated wastewater and spent coolant from operation of the downsized or consolidated Secondary and Case Fabrication Facility would be treated at the West End Treatment Facility and the Central Pollution Control Facility (OR MMES 1995j:7-6). The Waste Feed Preparation Facility would reduce the volume of and package for offsite treatment solid LLW composed of contaminated scrap metal; depleted uranium oxide, sawfines, and chips; air filters; HEPA filters; and uranium-contaminated graphite. Contracts are already in place with private vendors to incinerate or supercompact the waste. Approximately 572 m^3 (749 yd^3) of ash and supercompacted bales would be stored at K-25 while awaiting disposal. Assuming a land usage factor of 3,300 m^3/ha (1,750 yd^3/acre), this would require 0.2 ha/yr (0.4 acres/yr) of LLW disposal area at ORR. If onsite disposal at ORR is not possible, approximately 34 LLW shipments to a DOE disposal facility would be required.

The 3,400 m^3 (898,000 gal) of liquid mixed LLW from spent coolant and mopwater, machine coolant, nitric acid solutions, waste oil, wastewater, miscellaneous acids, and plating rinsewater would be managed in accordance with the ORR Site Treatment Plan, which was developed to comply with the *Federal Facility Compliance Act* of 1992. Approximately 92 m^3 (120 yd^3) of solid mixed LLW, to include sludge from chemical recovery, gloves and wipes, floor sweepings, oily sludge, and salt from salt baths, would also be managed in accordance with the ORR Site Treatment Plan. The ORR Site Treatment Plan currently includes the use of the TSCA Incinerator at K-25, the Plating Rinsewater Treatment Facility, the Waste Coolant Processing Facility, and private vendors.

Miscellaneous organics, waste oil, miscellaneous chemicals, washdown water, plating solutions, dye penetrant water, used mineral oil, sodium hypochlorite, spent coolant and mopwater, waste nitric acid, plating rinsewater, dirty motor oil, solvents, and photographic wastes would be the sources of liquid hazardous wastes. Sources of solid hazardous wastes would include miscellaneous solid chemicals, gloves, floor sweepings, filters, oily sludge, air filters, shop waste, rags and wipes, and medical waste. Hazardous waste would be stabilized and packaged in DOT-approved containers for shipment to RCRA-permitted facilities using DOT-registered transporters. As shown in table 4.2.3.10–2, hazardous waste quantities for Y-12 are included with mixed LLW quantities.

Wastewater would not be discharged offsite. Sanitary wastewater treated effluent would be used as makeup to the cooling tower. Utility wastewater final blowdown would be evaporated to dry waste. Solid nonhazardous wastes would consist primarily of trash, waste paper, scrap metal, air filters, personnel respirators, plastic bags, medical wastes, and gloves. Nonrecyclable portions, 7,670 m^3 (10,000 yd^3) of

TABLE 4.2.3.10–3.—*Estimated Decontamination and Decommissioning Wastes at Oak Ridge Reservation*

Category	Downsize Secondary and Case Fabrication (m^3)	Phaseout of Secondary and Case and Fabrication (m^3)

Source: ORR 1995a:3.

this waste would be sent to one of the Y-12 sanitary/industrial landfills. A new state-permitted landfill at Y-12 has a life expectancy of 40 years. Nonhazardous classified wastes would be disposed of at Industrial Landfill IV.

Waste would be generated from D&D activities associated with the downsizing and consolidation of the secondary and case fabrication mission. Total waste volumes from these activities over a 30-year period are shown in table 4.2.3.10–3.

Phaseout of Secondary and Case Fabrication. The phaseout of the secondary and case fabrication mission at Y-12 would have a small positive impact on ORR waste management activities by ultimately reducing the generation of low-level, mixed, and nonhazardous wastes. Approximately 530 m^3 (140,000 gal) of liquid and 1,840 m^3 (2,410 yd^3) of solid LLW would no longer be generated. An estimated 5,700 m^3 (1,510,000 gal) of liquid mixed and 150 m^3 (196 yd^3) of solid mixed LLW would no longer be generated and treated according to the ORR Site Treatment Plan. The decrease in nonhazardous waste generation would occur over time as facilities that are no longer needed are deactivated. As with the downsize secondary and case fabrication alternative, wastes would be generated from D&D activities associated with the phaseout of the secondary and case fabrication mission. Total waste volumes from these activities over a 30-year period are also shown in table 4.2.3.10–3.

Sensitivity Analysis. The waste volumes generated from the downsized and consolidated Secondary and Case Fabrication Facility required to support a larger stockpile level (high case) operating on a single-shift basis are bounded by the base case under surge operations. Thus, there are no additional waste management impacts associated with the Secondary and Case Fabrication Facility that would support a high case stockpile operating at single shift. The volumes generated from the Secondary and Case Fabrication Facility required to support a low case stockpile would be reduced by a factor of at least three.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies, thereby further reducing or mitigating impacts. Pollution prevention and waste minimization would be considered in determining the final actions of the Stockpile Stewardship and Management Program at ORR. Utilization of existing and planned treatment and storage facilities would be maximized to further reduce impacts.

4.2.3.11 *Environmental Justice*

As discussed in section 4.14, impacts, if any, to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.2.3.9, which describes public and occupational health impacts from normal operation, shows that potential radiological and chemical air emissions and releases are lower than regulatory limits. However, the cumulative effect of continuous (or intermittent over time) very low exposures could have some impact on human health or the environment. Any adverse human health or environmental impacts that may occur would affect people living within communities located near ORR. The analysis of the demographics data presented in appendix D for the communities surrounding ORR indicates that even if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.3 SAVANNAH RIVER SITE

SRS was established in 1950 as a nuclear materials production site and occupies approximately 80,130 ha (198,000 acres) south of Aiken, SC. The current DP mission at SRS is to process tritium and conduct tritium recycling and filling in support of nuclear weapons stockpile requirements. Section 3.2.3 provides a description of all the DOE missions and support facilities at SRS. The location of SRS within the South Carolina and Georgia region is illustrated in figure 4.3–1, and the principal facilities at SRS are shown in figure 4.3–2.

4.3.1 Description of Alternatives

No Action. SRS would continue to perform the missions described in section 3.2.3.

Stockpile Management Alternatives. The pit fabrication and intrusive modification pit reuse mission (hereafter referred to as pit fabrication) could be located at SRS. Nonintrusive modification pit reuse is an inherent capability of this mission. No facilities at SRS would be phased out as a result of any of the proposed alternatives discussed in the PEIS.

Stockpile Stewardship Alternatives. There are no stockpile stewardship alternatives that include SRS.

4.3.2 Affected Environment

The following sections describe the affected environment at SRS for land resources, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure, radiation and hazardous chemical environment, waste management conditions, and current intersite transportation issues at SRS are described.

4.3.2.1 *Land Resources*

SRS occupies approximately 80,130 ha (198,000 acres) in portions of Aiken, Allendale, and Barnwell Counties in southwestern South Carolina, approximately 20 km (12 mi) southeast of Augusta, GA. All of the land within SRS is owned by the Federal Government and is administered, managed, and controlled by DOE. Generalized land uses at SRS and in the vicinity are shown in figure 4.3.2.1–1.

SRS land uses can be grouped into three major categories: forest/undeveloped, water, and developed facility locations. Approximately 77,300 ha (191,000 acres) of SRS (approximately 96 percent) are undeveloped. Of this undeveloped area, approximately 72 percent is forested. A forest management program has been in effect at SRS since 1952, when it was formed through an interagency agreement between DOE (then the Atomic Energy Commission) and the U.S. Forest Service (WSRC 1993a:317). The majority of the woodlands area (53 percent of the total site) is in revenue producing, managed timber production. There are no prime farmlands on SRS.

In 1972, DOE designated all of SRS as a National Environmental Research Park. The National Environmental Research Park is used by the national scientific community to study the impact of human activities on the cypress swamp and southeastern pine and hardwood forest ecosystems (DOE 1985a:1).

Land use bordering SRS is primarily forest and agricultural, although there is a substantial amount of open water and nonforested wetland along the Savannah River Valley. Incorporated and industrial areas are the only other significant land uses in the vicinity. There is a small amount of urban and residential development bordering SRS. The closest residences include several located to the west, north, and northeast that, while within 61 m (200 ft) of the site boundary, are 13 to 16 km (8 to 10 mi) from the center of the site where the majority of SRS industrial activity is located.

SRS has been divided into several operating areas based on the type of production process occurring within an area. Facilities proposed to support the pit fabrication alternative at SRS are located in the F- and H-Areas. The 232-H Building in the H-Area would house pit fabrication, while plutonium processing would be housed in F-Canyon facilities in F-Area. Both areas are largely developed with many facilities historically associated with chemical and physical processes used to separate uranium, plutonium, and fission products. The F-Area chemical separations facilities are located near the center of SRS between Upper Three Runs Creek to the north and Fourmile Branch to the south. The H-Area facilities are also located near the center of SRS, approx-

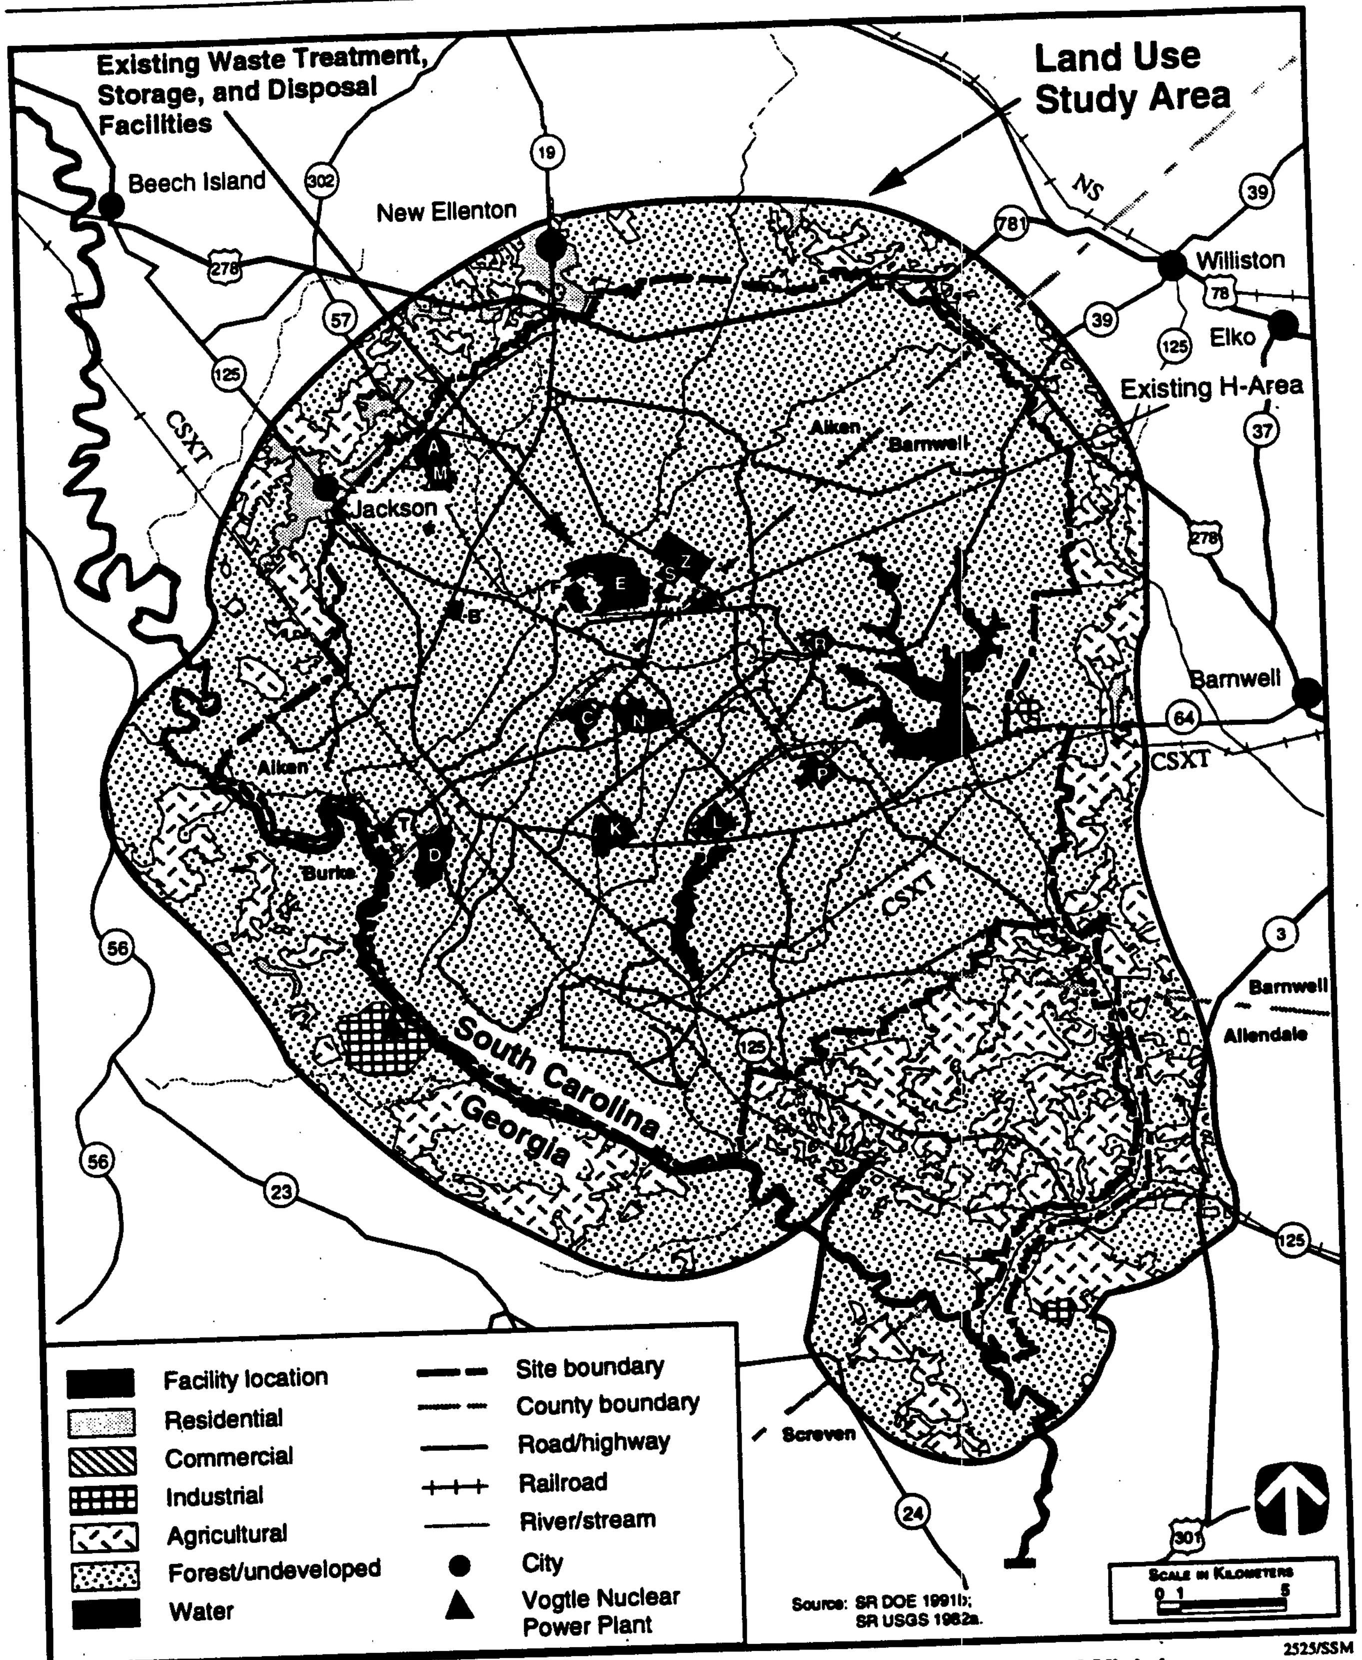

FIGURE 4.3.2.1–1.—*Generalized Land Use at Savannah River Site and Vicinity.*

imately 8 km (5 mi) southeast of the 700 Administration Area.

4.3.2.2 *Site Infrastructure*

SRS contains extensive production, service, and research facilities. Not all of these facilities are in operation or are needed today. To support current missions and functions, an infrastructure exists as shown in table 4.3.2.2–1. The road infrastructure is needed for extensive intrasite transportation requirements. The railroad infrastructure is required to support large-volume deliveries of coal and oversized structural components. SRS does not have a connection to the local natural gas lines.

TABLE 4.3.2.2–1.— ***Baseline Characteristics for Savannah River Site***

Characteristics	Current Value

Generation (kg/hr)	85,000

Source: DOE 1995p.

4.3.2.3 *Air Quality*

The following section describes existing air quality including a review of the meteorology and climatology in the vicinity of SRS. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.3.

Meteorology and Climatology. The SRS region has a temperate climate with short, mild winters and long, humid summers. Throughout the year, the region is frequently affected by the warm and moist maritime air masses. The annual average temperature at SRS is 17.3 °C (63.2 °F); the average daily minimum temperature in January is 0.0 °C (32.0 °F); the average daily maximum temperature is 33.2 °C (91.7 °F) in July. The average annual precipitation at SRS is 113.4 cm (44.66 in) (NOAA 1994c:3). Precipitation is distributed fairly evenly throughout the year, with the highest precipitation in summer and the lowest in autumn. There is no predominant wind direction at SRS. The average annual wind speed at Augusta National Weather Service Station is 2.9 m/s (6.5 mph) (NOAA 1994c:3).

Ambient Air Quality. SRS is located near the center of the Augusta-Aiken Interstate AQCR 153. As of 1995, the areas within SRS and its surrounding counties were in attainment with respect to the NAAQS for criteria pollutants (40 CFR 50; 40 CFR 81.311; 40 CFR 81.341). Applicable NAAQS and the ambient air quality standards for South Carolina and Georgia are presented in appendix table B.3.1–1.

Since the promulgation of Prevention of Significant Deterioration regulations (40 CFR 52.21) in 1977, Prevention of Significant Deterioration permits have not been required for any new SRS emission sources nor modifications required to existing permits. There are no Prevention of Significant Deterioration Class I areas within 100 km (62.1 mi) of SRS.

The emissions inventory from sources at SRS for criteria pollutants is presented in appendix table B.3.3–1. Historically, the primary emission sources of criteria air pollutants at SRS are the nine coal-burning and four fuel oil-burning boilers that produce steam and electricity (A-, D-, H-, K-, and P-Areas), the fuel and target fabrication facilities (M-Area), and processing facilities (F- and H-Areas). Other emissions and sources include fugitive particulates from coal piles and coal-processing facilities, vehicles, and temporary emissions from various construction-related activities.

Hazardous/toxic air pollutant standards have been adopted by the State of South Carolina Department of Health and Environmental Control. No ambient standards for hazardous/toxic air pollutants have been proposed or established by the State of Georgia.

Table 4.3.2.3–1 presents the baseline ambient air concentration for criteria pollutants and other pollutants of concern at SRS. As shown in the table,

TABLE 4.3.2.3–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Savannah River Site, 1990*

baseline concentrations are in compliance with applicable guidelines and regulations.

4.3.2.4 *Water Resources*

This section describes the surface and groundwater resources at SRS.

Surface Water. The most prominent hydrologic feature at SRS is the Savannah River, which borders the southwest portion of the site for 32 km (19.9 mi) (figure 4.3.2.4–1). Six major streams flow through SRS to the Savannah River: Upper Three Runs Creek, Beaver Dam Creek, Fourmile Branch, Pen Branch, Steel Creek, and Lower Three Runs Creek. Upper Three Runs has two tributaries, Tims Branch and Tinker Creek; Pen Branch has one tributary, Indian Grave Branch; and Steel Creek has one tributary, Meyers Branch (SR DOE 1990a:3-14). Surface water run-off in the vicinity of the H-Area flows into Upper Three Runs Creek and Fourmile Branch.

SRS withdraws surface water from Savannah River mainly for industrial cooling purposes. A small quantity is also removed for drinking water supplies. In 1994, 140,000 MLY (36,984 MGY) of surface water was supplied from the Savannah River. Most of the water withdrawn is eventually returned to the Savannah River through its onsite tributaries. Streams, especially Fourmile Branch, that received discharges from reactors in the past are still recovering from scouring or erosion impacts. The Fourmile Branch drainage basin also receives effluents from C-, F-, and H-Areas. The average flow of the Savannah River is 283 m^3/s (9,990 ft^3/s). The lowest recorded flow, 183 m^3/s (6,500 ft^3/s), occurred during a drought period from 1985 to 1988 (SR DOE 1990a:3-18).

The Savannah River supplies potable water to several municipalities (SR DOE 1995e:3-8). Upstream from SRS, the river supplies domestic and industrial water to Augusta, GA, and North Augusta, SC. Approximately 130 river mi (209 km) downstream from SRS, the river supplies domestic and industrial water needs for the Cherokee Hill Waste Treatment Plant at Port Wentworth, GA, and for Beaufort and Jasper Counties in South Carolina.

There are two manmade water bodies on SRS: L-Lake, which discharges to Steel Creek; and Par Pond, which empties into Lower Three Runs Creek (SR DOE 1995b:3-15-3-21). There are approximately 190 Carolina bays scattered throughout the site. Carolina bays are naturally occurring closed depressions that may hold water (SR NERP 1989a:9). There are no direct discharges to the bays; however, they do receive some stormwater runoff.

Average annual treated sanitary discharge volume from SRS to the Savannah River is approximately 700 MLY (185 MGY), which is approximately 50 percent of the new Centralized Sanitary Wastewater Treatment Facility capacity. Wastewater from the treatment plant is discharged to Fourmile Branch. The F/H Effluent Treatment Facility treats industrial wastewater generated in the F- and H-Areas, where the proposed alternative activities would be located. The treated wastewater is released to Upper Three Runs Creek in accordance with NPDES regulations. The design capacity of the F/H Effluent Treatment Facility is 600 MLY (159 MGY). However, the maximum permitted treatment capacity is 400 MLY (106 MGY). Currently, the facility treats approximately 16 MLY (4.23 MGY).

The proposed alternative activities would be located in the F- and H-Areas, which are located outside of the 100-year floodplain zones (SR DOE 1995b:3-17). Information on the location of 500-year floodplains at SRS is currently not available. A site-specific floodplain assessment would be required before implementing any Program alternatives at SRS.

Surface Water Quality. In the vicinity of SRS, the Savannah River and onsite streams are classified as freshwater suitable for primary and secondary contact recreation and drinking water (after conventional treatment in accordance with the requirements of the South Carolina Department of Health and Environmental Control), fishing and the survival and propagation of a balanced indigenous and aquatic community of fauna and flora, and industrial and agricultural uses (SC DHEC 1992a:29). Table 4.3.2.4–1 lists the 1993 surface water monitoring results for the Savannah River.

SRS has two NPDES permits which regulate industrial wastewater discharge from 81 outfalls and 1 general stormwater discharge permit that covers 48 outfalls. SRS collects and analyzes water from these outfalls to ensure compliance with NPDES permit

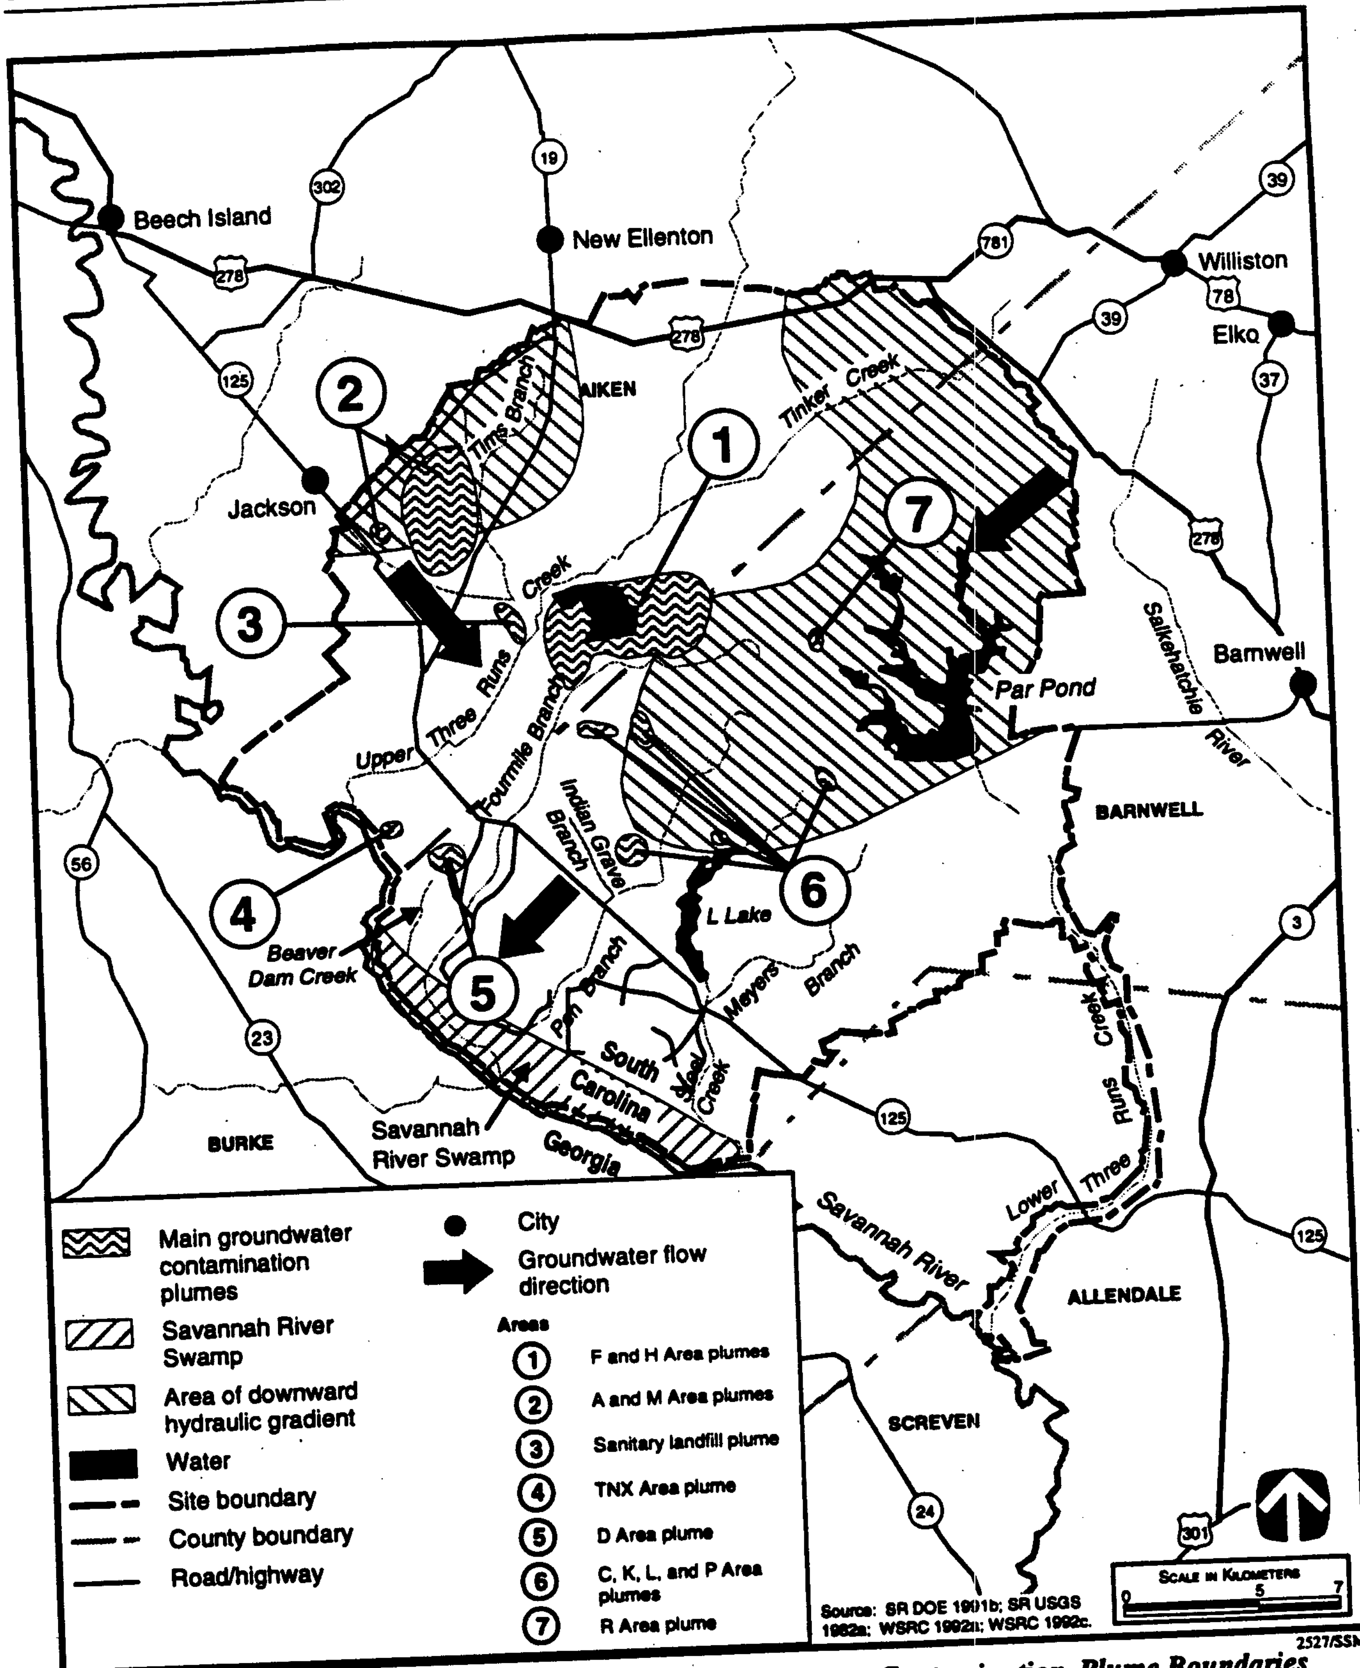

FIGURE 4.3.2.4–1.—*Surface Water Features and Groundwater Contamination Plume Boundaries at Savannah River Site.*

TABLE 4.3.2.4–1.—***Summary of Surface Water Quality Monitoring at Savannah River Site, 1993***

Parameter	Unit of Measure	Water Quality Criteria[a]	Minimum and Maximum Water Body Concentration
Radiological			
Alpha (gross)	pCi/L	15[b]	ND – 0.325
Beta (nonvolatile)	pCi/L	50[c]	0.959 – 3.12
Plutonium-238	pCi/L	1.6[d]	ND – 0.00174
Plutonium-239	pCi/L	1.2[d]	ND – 0.0012
Strontium-89, 90	pCi/L	400[d]	0.009 – 0.22
Tritium	pCi/L	80,000[d]	66 – 1,920
Nonradiological			
Alkalinity	mg/L	NA	13 – 24
Aluminum	mg/L	0.05-0.2[e]	0.182 – 0.838
Ammonia nitrogen	mg/L	NA	0.02 – 0.11
Calcium	mg/L	NA	3.25 – 5.09
Chemical oxygen demand	mg/L	NA	ND
Chromium	mg/l	0.1[b, f]	ND
Conductivity	µmhos/cm	NA	54 – 106
Dissolved oxygen	mg/L	>5[f]	6.2 – 10.5
Iron	mg/L	0.3[e]	0.516 – 1.15
Lead	mg/L	0.015[b]	ND – 0.003
Magnesium	mg/L	NA	1.11 – 1.34
Manganese	mg/L	0.05[e]	0.04 – 0.064
Nitrogen (as NO_2/NO_3)	mg/L	NA	0.18 – 0.31
pH	pH units	6.5-8.5[e]	6.0 – 6.7
Phosphate P	mg/L	NA	ND
Sodium	mg/L	NA	5.28 – 12.7
Sulfate	mg/L	250[e]	4 – 9
Suspended solids	mg/L	NA	5 – 16
Temperature	°C	<32.2[f]	9.1 – 25.7
Total dissolved solids	mg/L	500[e]	49 – 90
Zinc	mg/L	5[e]	ND – 0.012[g]

[a] For comparison only, except for parameters which have South Carolina water quality criteria.
[b] National Primary Drinking Water Regulations (40 CFR 141).
[c] Proposed National Primary Drinking Water Regulation, Radionuclides (56 FR 33050).
[d] DOE's Derived Concentration Guides for water (DOE Order 5400.5). Values are based on a committed effective dose equivalent of 100 mrem per year; however, because the drinking water maximum contaminant level is based on 4 mrem per year, the number listed is 4 percent of the Derived Concentration Guides.
[e] National Secondary Drinking Water Regulations (40 CFR 143).
[f] South Carolina State water quality criteria.
[g] Average concentrations were not calculated because of an insufficient amount of sampling. The maximum concentration is listed.

Note: NA - not applicable; ND - none detected; all nonradiological data from station R-10, downstream of SRS; all radiological data from station R-3B (below Vogtle Electric Generating Plant).

Source: SR DOE 1995c.

limits. Of the 8,000 analyses performed at the industrial outfalls in 1993, 10 exceeded permit limits, for a compliance rate of 99.9 percent. Noncompliances were noted mainly for pH and total suspended solids, with one noncompliance each for oil and grease and biological oxygen demand. In all cases, either corrective actions or administrative reviews were undertaken in an effort to prevent future noncompliances (WSRC 1994d:4-75).

Surface Water Rights and Permits. Surface water rights for the Savannah River are determined by the Doctrine of Riparian Rights. Under this doctrine, users of water must not adversely impact quantity or quality of water availability for downstream users.

Groundwater. Several aquifer system naming schemes have been used at SRS. For this document, the shallowest aquifer will be called the water table. The water table is underlain by a leaky "Green Clay" aquitard, which separates the water table from the Congaree aquifer. Below the Congaree aquifer is the leaky Ellenton aquitard, below which is the Cretaceous (also known as the Tuscaloosa) aquifer. In general, groundwater beneath the site flows slowly laterally towards streams and swamps and into the Savannah River at rates ranging from centimeters to several hundred meters per year. The depth to which onsite streams cut into the soils controls the horizontal movement of groundwater. The valleys of the smaller perennial streams receive discharge from the shallow saturated geologic formations. The valleys of major tributaries of the Savannah River (such as Three Runs Creek) drain formations of intermediate depth. The valley of the Savannah River drains deep formations.

Groundwater flow at some locations on the site (such as F- and H-Areas and certain sections of K-Area) is predominantly upward through the aquitard from the deeper aquifer to the shallow aquifer (figure 4.3.2.4–1). In other areas including A-, M-, L-, and P-Areas the vertical component of groundwater flow is downward. Horizontal groundwater flow occurs at the M-Area (to the west-northwest in the shallow aquifer and subsequent flow to the south toward Upper Three Runs Creek in the intermediate aquifer), K-Area disassembly basin (toward Pen Branch and L-Lake), P-Area disassembly basin (toward Steel Creek), F-Canyon Building (toward Upper Three Runs Creek and Fourmile Branch), and H-Canyon Building (toward Upper Three Runs Creek and its tributaries).

The Cretaceous aquifer is an abundant and important water resource for the SRS region. Some of the local cities (e.g., Aiken) also obtain groundwater from the Cretaceous aquifer, but most of the rural population in the SRS region obtains its water from either the Congaree or water table. All groundwater at SRS is classified by the EPA as a Class II water source (i.e., a current potential source of drinking water). Depth to groundwater ranges from at or near ground surface (near streams) to 46 m (151 ft).

Groundwater Quality. Groundwater data have been obtained from SRS monitoring wells for the past several years. Groundwater quality at SRS ranges from excellent (soft and slightly acidic) to below EPA drinking water standards for several constituents in the vicinity of some waste sites. Industrial solvents, metals, tritium, and other constituents used or generated at SRS are present at elevated levels in the shallow aquifers beneath 5 to 10 percent of SRS (SR DOE 1995c:3-13). These aquifers are not used for SRS operations or drinking water; however, they do discharge to site streams and eventually enter the Savannah River. Most contaminated groundwater at SRS flows beneath facilities; the sources of the contaminants reflect the operations and chemical processes performed at those facilities. At F- and H-Areas, contaminants in the groundwater include tritium and other radionuclides, metals, nitrates, and chlorinated and volatile organics. Area plumes are shown in figure 4.3.2.4–1. At A- and M-Areas, groundwater contaminants include chlorinated volatile organics, radionuclides, metals, and nitrates. At the reactors (C-, K-, L-, and P-Areas), tritium, other radionuclides, and lead are present in the groundwater. At the D-Area, groundwater contaminants include VOCs, chromium, nickel, lead, zinc, iron, sulfate and tritium. At the TNX Area, VOCs, lead, nitrate, and uranium are present in the groundwater (SR DOE 1995c:3-13).

Radioactive constituents (tritium, cesium-137, iodine-131, ruthenium-106, and strontium-89 and -90) above drinking water standards have been detected in F-Area monitoring wells (SR DOE 1995c:3-13). Studies of flow directions, infiltration rates, and operating history indicate that the source of the contamination is from an isolated incident that occurred more than 35 years ago. Groundwater contamination found beneath the H-Canyon reflects the widespread use of tritium in the H-Area. The tritium present in the groundwater is not directly from H-Canyon activities, but rather results from past use of the nearby H-Area seepage basins and the subsequent migration of contaminants beneath the H-Canyon. Results of groundwater quality measurements from wells located in the H-Area and comparison with standards or criteria for selected quality parameters are presented in table 4.3.2.4–2.

As shown in table 4.3.2.4–2, when compared to national primary and secondary maximum contaminant levels, parameter concentrations are within acceptable limits except for pH in one of the wells. The elevated pH is most likely due to the well completion with grout and not from actual groundwater impacts.

Groundwater Availability, Use, and Rights. Groundwater is a domestic, municipal, and industrial water source throughout the Upper Coastal Plain. Most municipal and industrial water supplies in Aiken County are from the Cretaceous aquifer. Domestic water supplies are primarily from the Congaree aquifer and the water table. In Barnwell and Allendale Counties, the Congaree aquifer supplies some municipal users. At SRS, most groundwater is obtained from the Cretaceous aquifer, with a few wells pumping from the Congaree aquifer. Every major operating area at SRS has groundwater supply wells; total groundwater production from these wells is approximately 13,300 MLY (3,500 MGY), similar to the volume pumped for industrial and municipal production within 16 km (9.9 mi) of the site (SRS 1995a:1).

Groundwater rights in South Carolina are traditionally associated with the absolute ownership rule.

TABLE 4.3.2.4–2.—*Groundwater Quality Monitoring at Savannah River Site, 1994*

Parameter	Unit of Measure	Water Quality Criteria and Standards[a]	Well Number HAA-4B	Well Number HCA-4C
Radiological				
Alpha (gross)	pCi/L	15[b]	2.1	<0.5
Beta (nonvolatile)	pCi/L	50[c]	0.2	0.7
Tritium	pCi/L	80,000[d]	6,300	1,600
Nonradiological				
Barium	mg/L	2[b]	0.0397	0.0695
Chloride	mg/L	250[e]	2.69	1.75
Iron	mg/L	0.3[e]	0.004	0.0057
Lead	mg/L	0.015[b]	0.003	0.003
Manganese	mg/L	0.05[e]	0.002	0.0052
Nitrate	mg/L	10[b]	0.333	0.74
pH	pH units	6.5-8.5[e]	8.1	9.03

Source: SRS 1995a:11.

Originating in English common-law doctrine, the owners of land overlying a groundwater resource are allowed to withdraw from their wells all the water they wish for whatever purpose they desire. The water withdrawn can be used for any purpose on or off the owner's land (VDL 1990a:725). However, the *Water Use Reporting and Coordination Act* requires all users of 379,000 L or more per day (100,000 gal or more per day) (136 MLY [35.9 MGY]) of water to report their withdrawal rates to the South Carolina Water Resources Commission. SRS exceeds this amount of groundwater use, and must report its withdrawal rates to the commission.

4.3.2.5 *Geology and Soils*

Geology. SRS is located in the Aiken Plateau portion of the Upper Atlantic Coastal Plain east of the Fall Line, a major physiographic and structural feature that separates the Piedmont and the Coastal Plain, in southeastern South Carolina.

The plateau is highly dissected, with narrow, steep-sided valleys separated by broad flat areas. There is evidence from subsurface mapping and seismic surveys that suggests the presence of faults beneath SRS. The largest of these faults is the Pen Branch fault. However, there is no evidence of movement within the last 38 million years along this fault.

SRS lies within seismic Zone 2 (appendix figure A.1–1). Since 1985 only three earthquakes, all of Richter magnitude 3.2 or less, have occurred in the immediate area of SRS. None of these earthquakes produced any damage at SRS. Historically, two large earthquakes occurred within 300 km (186 mi) of SRS. The larger of these two earthquakes, the Charleston earthquake of 1886, had a magnitude in the 6.5 to 7.5 range. Earthquakes capable of producing structural damage to any buildings are not likely to occur in the vicinity of SRS (SR duPont 1988a:9). There is no volcanic hazard at SRS. The area has not experienced volcanism within the last 230 million years (DOE 1995i:4-383).

Soils. The soils of the F- and H-Areas are mainly well drained and somewhat excessively drained with a loamy subsoil. They have a thick, sandy surface layer and subsurface layer and a loamy subsoil that is 1 to 2 m (3.3 to 6.6 ft) below the surface in some areas (SR USDA 1990a:6,7,128). Many of the soils are subject to erosion, flooding, ponding, and cutbank caving. The soils at SRS are considered acceptable for standard construction techniques. There are no prime farmlands on SRS (DOE 1995i:4-372).

4.3.2.6 *Biotic Resources*

The following section describes biotic resources at SRS including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. A list of the threatened or endangered species that may be found on or in the vicinity of SRS is presented in appendix C.

Terrestrial Resources. Most of SRS has remained undeveloped since it was established in 1950. Only about 5 percent of the site is occupied by DOE facilities. Five major plant communities have been identified at SRS (figure 4.3.2.6–1). Of these, the largest plant community is the loblolly-longleaf-slash pine community, which covers approximately 65 percent of the site. This community type, as well as upland hardwood-scrub oak, is found primarily in upland areas. Swamp forests and bottomland hardwood forests are found along the Savannah River and the numerous streams that traverse SRS. More than 1,300 taxa of vascular plants have been identified on the site (DOE 1992e:4-126; DOE 1995p:4-47).

Because of the variety of plant communities on the site, as well as the region's mild climate, SRS supports a diversity and abundance of wildlife including 43 amphibian, 58 reptile, 213 bird, and 54 mammal species. Common species at SRS include the slimy salamander (*Plethodon glutinosus*), eastern box turtle (*Terrapene carolina*), Carolina chickadee (*Parus carolinensis*), common crow (*Corvus brachyrhynchos*), eastern cottontail (*Sylvilagus floridanus*), and gray fox (*Urocyon cinereoargenteus*) (DOE 1992e:4-128; WSRC 1993b:3-5,3-39). A number of game animals are found on SRS; however, only the whitetail deer (*Odocoileus virgineanus*) and feral hog (*Sus scrofa*) are hunted onsite. Raptors, such as the Cooper's hawk (*Accipiter cooperii*) and black vulture (*Coragyps atratus*), and carnivores, such as the gray fox and raccoon (*Procyon lotor*), are ecologically important groups on SRS. A variety of migratory birds has been found at SRS. Migratory birds and their nests and eggs are protected by the *Migratory Bird Treaty Act*. Eagles are similarly protected by the *Bald and Golden Eagle Protection Act*.

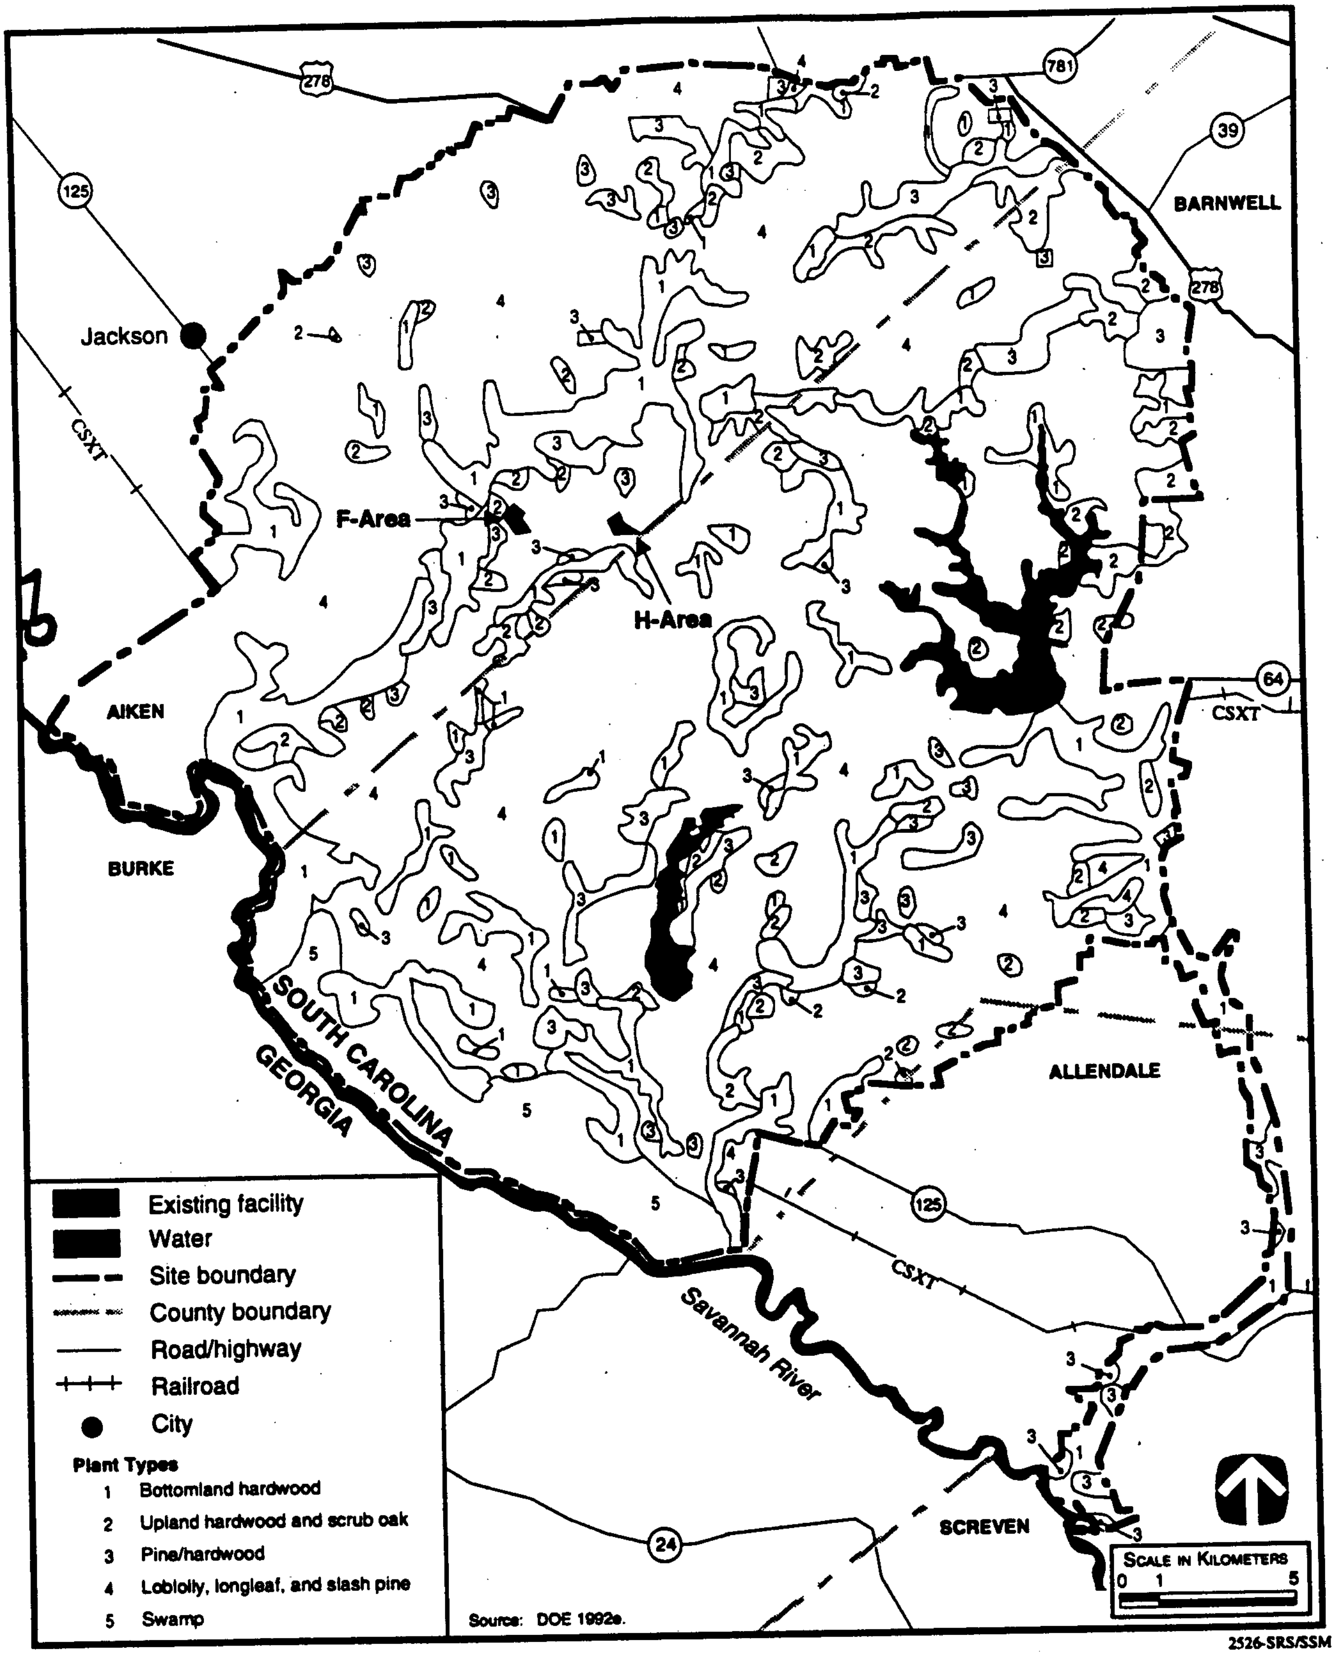

FIGURE 4.3.2.6–1.—*Distribution of Plant Communities at Savannah River Site.*

The F- and H-Areas are industrialized areas. They are surrounded primarily by evergreen forests with areas of grassland, scrub-shrub, and barren land also present. Bottomland hardwood forest is located along Fourmile Branch and Upper Three Runs Creek (and their tributaries) located to the south and north of these areas, respectively (WSRC 1993b:2-14). While wildlife associated with these areas would include species tolerant of human disturbance, animals found in surrounding areas would be expected to be similar to those animals found in comparable habitats elsewhere on SRS.

Wetlands. SRS contains 19,800 ha (49,000 acres) of wetlands, most of which are associated with flood plains, streams, and impoundments. Wetland cover types on the site may be divided into the following categories: bottomland hardwoods, cypress-tupelo, scrub-shrub, emergent, and open water (WSRC 1993b:4-6). The most extensive wetland type on SRS is swamp forest (3,800 ha [9,390 acres]) associated with the Savannah River floodplain. Past releases of cooling water effluent into site streams and the Savannah River swamp have resulted in shifts in plant community composition. Changes have included the replacement of bald cypress by scrub-shrub and emergent vegetation in the swamp and the reduction in bottomland forests along streams (WSRC 1989e:3-4).

Carolina bays, a type of wetland unique to the southeastern United States, are also found on SRS. Approximately 190 Carolina bays have been identified on the site. These natural shallow depressions occur on interstream areas of SRS and range from lakes to shallow marshes, herbaceous bogs, shrub bogs, or swamp forests (SR NERP 1989a:9).

Wetlands found in the vicinity of the F- and H-Areas are primarily associated with Fourmile Branch and Upper Three Runs Creek and their tributaries. These wetlands have been classified as bottomland hardwood (WSRC 1993b:4-12).

Aquatic Resources. Aquatic habitat on SRS includes manmade ponds, Carolina bays, reservoirs, and the Savannah River and its tributaries. There are more than 50 manmade impoundments located throughout the site that mainly support populations of bass (*Centrarchidae*) and sunfish (*Lepomis spp.*) (SR DOE 1982a:4-22). Fewer than 20 Carolina bays have permanent fish populations. Species present in these bays include redfin pickerel (*Esox americanus americanus*), mud sunfish (*Acantharchus pomotis*), lake chubsucker (*Erimyzon sucetta*), and mosquitofish (*Gambusia affinis*) (SR NERP 1989a:37). Par Pond and L-Lake support similar fish populations, including largemouth bass (*Micropterus salmoides*), black crappie (*Pomoxis nigromaculatus*), and various species of pan fish. Sport and commercial fishing are not allowed on SRS (DOE 1992e:4-132).

The Savannah River is used for both commercial and sport fishing. Important commercial species are American shad (*Alosa sapidissima*), hickory shad (*Alosa mediocris*), and striped bass (*Morone saxatilis*), all of which are anadromous. The most important warm water game fish species of the Savannah River are bass, pickerel (*Esox spp.*), crappie (*Pomoxis spp.*), bream (*Lepomis spp.*), and catfish (*Ictaluridae*). In the past, water intake structures for the C- and K-Reactors and D-Area power house caused an annual estimated entrainment of about 10 percent of the fish eggs and larvae passing the intake canals during the spawning season. In addition, estimated impingement losses were about 7,600 fish per year (SR DOE 1987b:3-31,C-61). There are no longer any major water withdrawals for the reactors, and entrainment and impingement have dropped accordingly.

Streams in the vicinity of the F- and H-Areas include Fourmile Branch and Upper Three Runs Creek and their tributaries. Fish species present in Fourmile Branch near these areas include dusky shiner (*Notropis cummingsae*), creek chubsucker (*Erimyzon oblongus*), yellow bullhead (*Ictalurus natalis*), and spotted sunfish (*Lepomis punctatus*). Recent studies found that the outcropping of groundwater from the F- and H-Area seepage basins has not resulted in adverse changes in the structure of the aquatic community below the outcropping zone (WSRC 1993b:12-53,12-56).

Fish species present in Upper Three Runs Creek in the vicinity of the F- and H-Areas include dusky shiner, yellowfin shiner (*Notropis lutipinnis*), redbreast sunfish (*Lepomis auritus*), and bluegill (*Lepomis macrochirus*). Recent studies of fish communities above and below the stream in the vicinity of the F- and H-Areas indicated that no measurable community level impacts were associated with contaminants outcropping from these areas (WSRC 1993b:10-59,10-60).

Threatened and Endangered Species. Sixty-one Federal- and state-listed threatened, endangered, and other special status species may be found on and in the vicinity of SRS (appendix table C–2). Fifty-seven of these species have records of occurrence on the site, 12 of which are Federal- and/or state-listed as threatened or endangered. The Federal-listed species recorded onsite include both subspecies of the peregrine falcon (*Falco peregrinus anatum* and *F.p. tundrius*), bald eagle (*Haliaeetus leucocephalus*), red-cockaded woodpecker (*Picoides borealis*), wood stork (*Mycteria americana*), Kirtland's warbler (*Dendroica kirtlandii*), American alligator (*Alligator mississippiensis*), shortnose sturgeon (*Acipenser brevirostrum*), and smooth coneflower (*Echinacea laevigata*). Additional state-listed species observed onsite include the Rafinesque's big-eared bat (*Plecotus rafinesquii*), Appalachian Bewick's wren (*Thryomanes bewickii altus*), and common ground dove (*Columbina passerina*). No critical habitat for threatened or endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on SRS.

The F- and H-Areas contain no habitat for any of the Federal-listed threatened or endangered species found on SRS. Smooth coneflower could exist in open woodlands or roadbanks in the vicinity. None of the special status plant species listed in appendix table C–2 have been recorded near the F- and H-Areas. Although the pine forest adjacent to these areas could provide habitat for certain special status species, no such species are known to be present, and field surveillance would be required to verify the presence of any sensitive species.

4.3.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. An extensive archaeological survey program began at SRS in 1974 consists of numerous field studies such as reconnaissance surveys, shovel test transects, and intensive site tests and excavations. More than 60 percent of SRS has received some level of cultural resources evaluation involving both prehistoric and historic resources. More than 800 prehistoric sites or sites with prehistoric components have been identified; however, fewer than 8 percent have been evaluated for NRHP eligibility. To date, 67 prehistoric and historic sites are considered potentially eligible for listing on the NRHP. Prehistoric site types at SRS consist of villages, base camps, limited activity sites, quarries, and workshops.

All activities at SRS associated with the proposed pit fabrication mission would occur in the F- and H-Areas. Portions of both have been surveyed for cultural resources. Both contain potentially NRHP-eligible prehistoric sites. Both areas have tracts which are disturbed as a result of grading and construction. A Programmatic Agreement was signed by the Savannah River Operations Office, DOE, the South Carolina SHPO, and the Advisory Council on Historic Preservation on August 24, 1990. The purpose of the agreement is to ensure that appropriate measures are taken to inventory, evaluate, protect, and enhance archaeological sites at SRS. In addition, an Archaeological Resource Management Plan for SRS is in place.

Historic Resources. Types of historic sites include farmsteads, tenant dwellings, mills, plantations and slave quarters, rice farming dikes, dams, cattle pens, ferry locations, towns, churches, schools, cemeteries, commercial building locations, and roads. Approximately 400 historic sites or sites with historic components have been identified within SRS; approximately 10 percent have been evaluated for NRHP eligibility.

Systematic historic building surveys have not yet been conducted at SRS. As part of the Cold War mission, SRS has been involved with tritium operations and other nuclear material production for more than 30 years. As such, some of the facilities at SRS may be eligible for listing on the NRHP.

Native American Resources. Native American groups with traditional ties to the area include the Apalachee, Cherokee, Chickasaw, Creek, Shawnee, Westo, and Yuchi. At different times, each of these Native American groups was encouraged by the English to settle in the area to provide protection from the French, Spanish, or other Native American groups. Main villages of both the Cherokee and Creek were located southwest and northwest of SRS, but both groups may have used the area for hunting and gathering activities. During the early 1800s, most of the remaining Native Americans residing in the region were relocated to the Oklahoma territory.

Native American resources in the region include remains of villages or townsites, ceremonial lodges, burials, cemeteries, and areas containing traditional plants used for religious ceremonies. Literature reviews and consultations with Native American representatives reveal that there are some concerns related to the *American Indian Religious Freedom Act* within the central Savannah River Valley; however, no specific sites at SRS have been identified. The Yuchi Tribal Organization, the National Council of the Muskogee Creek, the Indian People's Muskogee Tribal Town Confederate, the Pee Dee Indian Association, the Ma Chis Lower Alabama Creek Indian Tribe, and the United Keetoowah Band of the Cherokees have expressed concerns for sensitive Native American resources at SRS. The Yuchi and the Muskogee Creek expressed concern for areas containing several plants traditionally used in ceremonies (SR DOE 1991e:19,21).

Paleontological Resources. Paleontological materials at SRS include fossil plants, numerous invertebrate fossils, deposits of giant oysters (*Crassostrea gigantissima*), mollusks, and bryozoa. All paleontological materials from SRS are marine invertebrate deposits and, with the exception of the giant oysters, are relatively common fossils; therefore, the assemblages have relatively low research potential.

4.3.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at SRS include employment and regional economy, population and housing, and public finance. Statistics for employment and regional economy are presented for the regional economic area that encompasses 15 counties around SRS in Georgia and South Carolina. Statistics for population and housing and public finance are presented for the ROI, a four-county area in which 87.3 percent of all SRS employees reside: Aiken County (51.9 percent) and Barnwell County (7.3 percent) in South Carolina, and Columbia County (10.6 percent) and Richmond County (17.5 percent) in Georgia (appendix table D.1–2). Figure 4.3.2.8–1 presents a map of the counties and selected cities comprising the SRS regional economic area and ROI. Supporting data are presented in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the SRS regional economic area are summarized in figure 4.3.2.8–2. Between 1980 and 1990, the civilian labor force in the regional economic area increased from 204,563 to 248,239, a 21.4-percent increase (annual average of 2.1 percent). In 1994, unemployment in the regional economic area was 6.7 percent, which was slightly higher than South Carolina's and more than 1 percent higher than in Georgia. The region's per capita income of $17,212 in 1993 was approximately 2.1 percent greater than South Carolina's per capita income of $16,861 and 10.6 percent lower than Georgia's per capita income of $19,249.

As shown in figure 4.3.2.8–2, the regional economic area, South Carolina, and Georgia have similar employment patterns. The service sector accounts for the largest share of total employment in the region (22 percent), Georgia (25 percent), and South Carolina (22 percent). Manufacturing employment, however, accounted for 20 percent of the total employment in the region and South Carolina, but only accounted for 15 percent of the total employment in Georgia.

Population and Housing. Between 1980 and 1992, the ROI population grew from 347,241 to 425,100. The 22.4-percent increase (annual average of 2.2 percent) was lower than the 24.0-percent increase in Georgia's population, but higher than the 15.4-percent increase in South Carolina's population. Within the ROI, the Columbia County population increased by 82.0 percent, while Barnwell County's population only increased by 6.2 percent.

The 25.5-percent increase in housing units between 1980 and 1990, was about 2 percent greater than South Carolina, and was approximately 5 percent less than the increase in Georgia. The total number of housing units estimated for 1992 was 160,500. The 1990 homeowner vacancy rate in the ROI, 2.2 percent, was comparable to the homeowner vacancy rates experienced by South Carolina and Georgia. The rental vacancy rate for the ROI counties, nearly 10 percent, was approximately 2 percent less than the

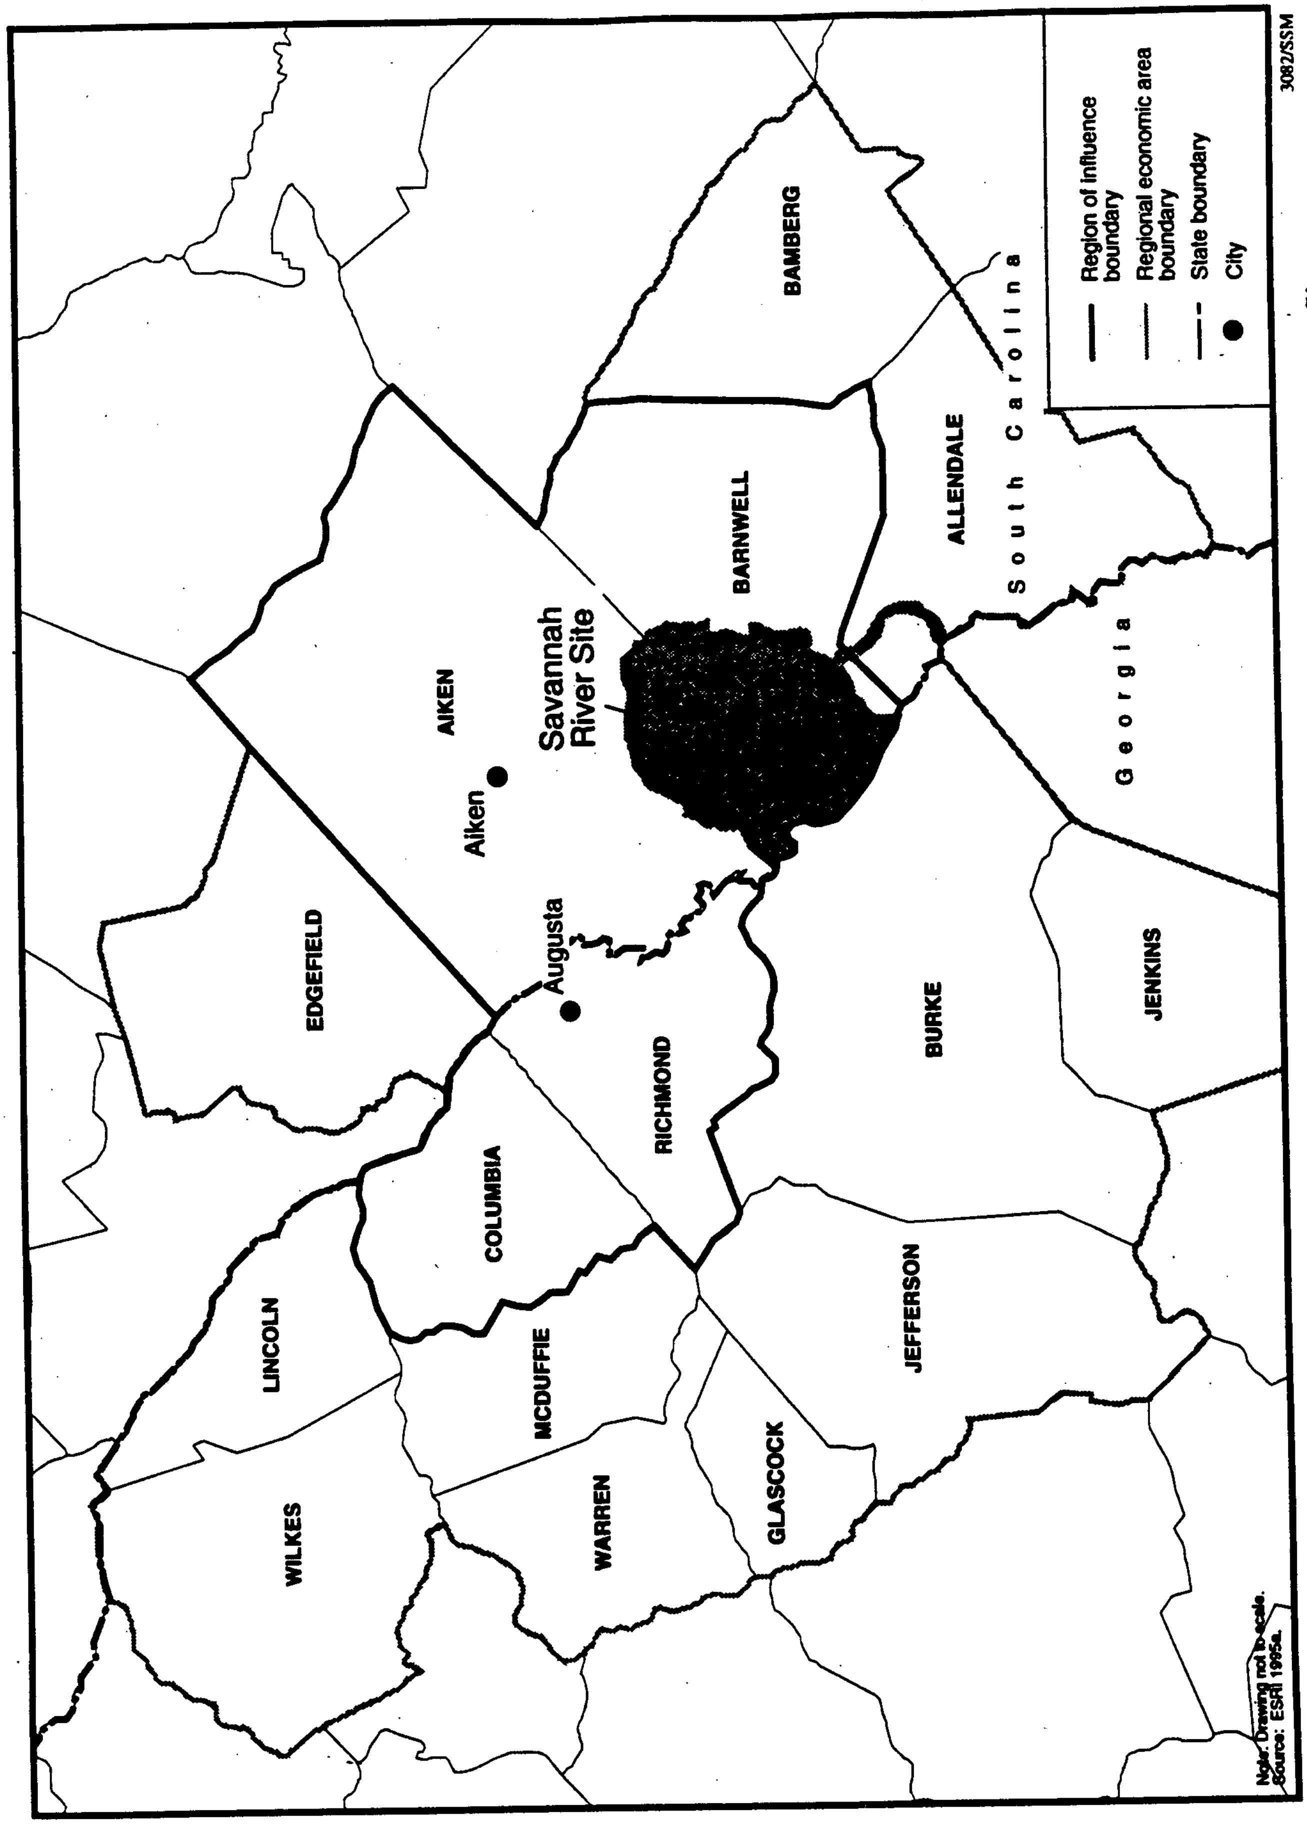

FIGURE 4.3.2.8–1.—*Regional Economic Area and Region of Influence for Savannah River Site.*

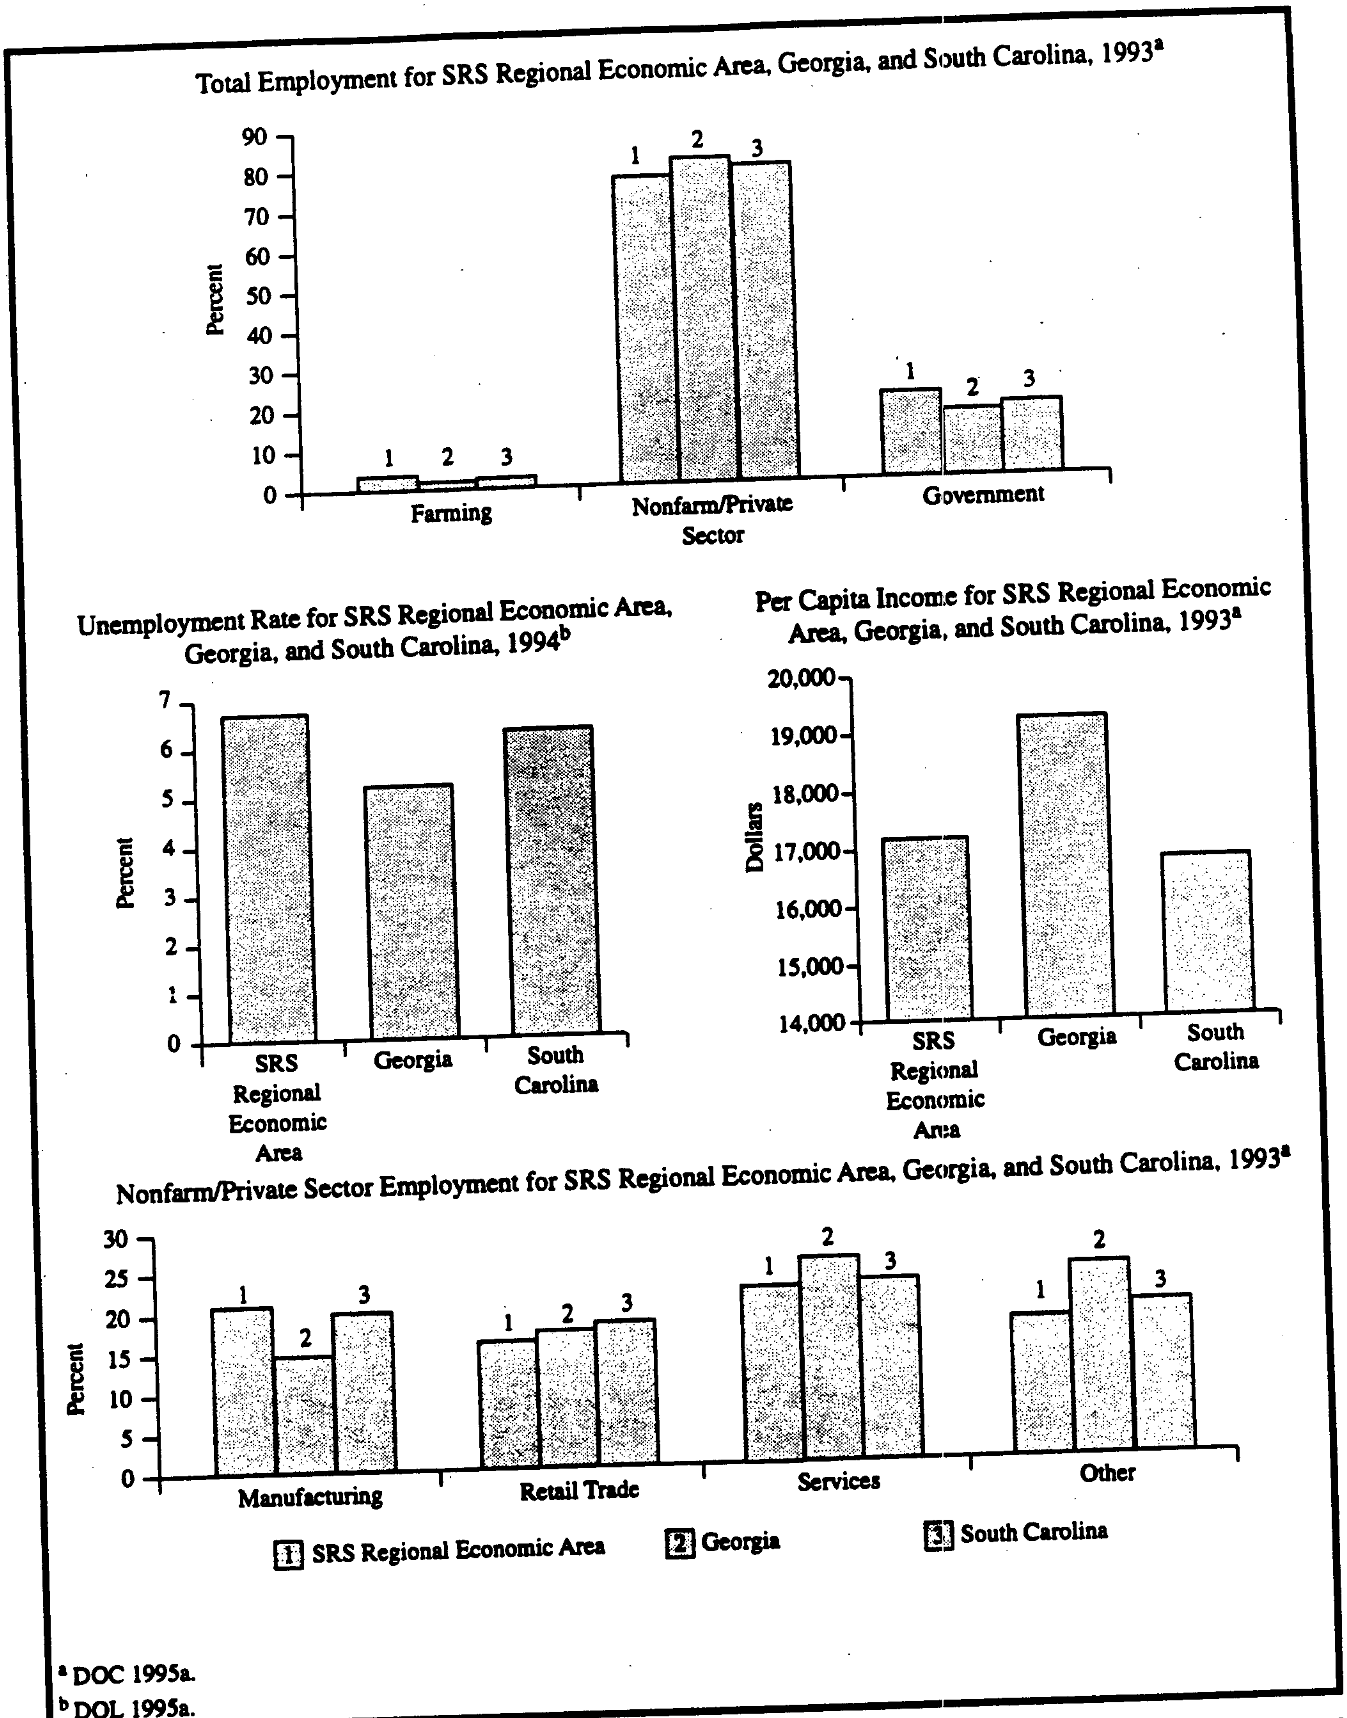

FIGURE 4.3.2.8–2.—*Economy for the Savannah River Site Regional Economic Area, Georgia, and South Carolina.*

rental vacancy rates for both states. Population and housing trends are summarized in figure 4.3.2.8–3.

Public Finance. Financial characteristics of the local jurisdictions in the SRS ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure fund categories for counties, cities, and school districts are presented in appendix tables D.2.3–2 and D.2.3–3. Figure 4.3.2.8–4 summarizes 1994 local governments' revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.3.2.8–4. All jurisdictions assessed had positive fund balances.

4.3.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at SRS. Also included are discussions of health effects studies, emergency preparedness considerations, and a brief accident history.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of SRS are shown in table 4.3.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. The incremental total dose to the population would result only from changes in the size of the population. Background radiation doses are unrelated to SRS operations.

Releases of radionuclides to the environment from SRS operations provide another source of radiation exposure to individuals in the vicinity of SRS. The radionuclides and quantities released from SRS operations in 1993 are listed in the *Savannah River Site Environmental Report for 1993* (WSRC-TR-94-075). The doses to the public resulting from these releases are presented in table 4.3.2.9–2. These doses fall within radiological limits (DOE Order 5400.5) and are small in comparison to background radiation. The releases listed in the 1993 report were used to develop the reference environment (No Action) radiological releases at SRS in 2005 (section 4.3.3.9).

TABLE 4.3.2.9–1.—*Sources of Radiation Exposure to Individuals in the Vicinity, Unrelated to Savannah River Site Operations*

Source	Committed Effective Dose Equivalent (mrem/yr)
Natural Background Radiation	
Cosmic and cosmogenic radiation[a]	29
External terrestrial radiation[a]	29
Internal terrestrial radiation[b]	40
Radon in homes (inhaled)[b]	200
Other Background Radiation[b]	
Diagnostic x rays and nuclear medicine	53
Weapons test fallout	<1
Air travel	1
Consumer and industrial products	10
Total	363

[a] Derived from information given in WSRC 1994d.
[b] NCRP 1987a. Value for radon is an average for the United States.

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem (5.0×10^{-4} fatal cancer per person-rem) to the public (appendix E), the fatal cancer risk to the maximally exposed member of the public from radiological releases from SRS operations in 1993 is estimated to be approximately 1.6×10^{-7}. That is, the estimated probability of this person dying of cancer at some point in the future from radiation exposure associated with 1 year of SRS operations is less than 2 chances in 10 million. (Note that it takes several to many years from the time of exposure to radiation for a cancer to manifest itself.)

Based on the same conversion factor, 1.1×10^{-2} excess fatal cancers are projected in the population living within 80 km (50 mi) of SRS from normal operation in 1993. To place this number into perspective, it can be compared with the number of fatal cancers expected in this population from all causes. The 1990 mortality rate, associated with cancer, for the entire

TABLE 4.3.2.9–2.—*Doses to the General Public from Normal Operation at Savannah River Site, 1993 (Committed Effective Dose Equivalent)*

Affected Environment	Atmospheric Releases		Liquid Releases		Total	
	Standard[a]	Actual	Standard[a]	Actual[b]	Standard[a]	Actual
Maximally exposed individual (mrem)	10	0.18	4	0.14	100	0.32
Population within 80 kilometers[c] (person-rem)	None	20.0	None	1.5	100	21.5
Average individual within 80 kilometers[d] (mrem)	None	0.032	None	0.003	None	0.035

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem per year limit from airborne emissions is required by the CAA, the 4 mrem per year limit is required by the SDWA, and the total dose of 100 mrem per year is the limit from all pathways combined. The 100 person-rem value for the population is given in proposed 10 CFR 834 (58 FR 16268).

[b] The actual dose value conservatively includes all water pathways, not just the drinking water pathway. The population dose includes contributions to Savannah River users downstream of SRS to the Atlantic Ocean.

[c] In 1993, this population was approximately 620,100.

[d] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.

Source: WSRC 1994d.

U.S. population was 0.2 percent per year (Almanac 1993a:839). Based on this national mortality rate, the number of fatal cancers from all causes expected during 1993 in the population living within 80 km (50 mi) of SRS was 1,240. This number of expected fatal cancers is much higher than the estimated 1.1×10^{-2} fatal cancers that could result from SRS operations in 1993.

Workers at SRS receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities. Table 4.3.2.9–3 includes the average, maximum, and total occupational doses to SRS workers from operations in 1993. These doses fall within radiological limits (10 CFR 835). Based on a dose-to-risk conversion factor of 400 fatal cancers per 1 million person-rem (4.0×10^{-4} fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to SRS workers from operations in 1992 is estimated to be 0.14.

A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in the *Savannah River Site Environmental Report for 1993* (WSRC-TR-94-075). The concentrations of radioactivity in various environmental media (e.g., air, water, and soil) in the onsite and offsite regions are also presented in this reference.

TABLE 4.3.2.9–3.—*Doses to the Onsite Worker from Normal Operation at Savannah River Site, 1993*

Affected Environment	Onsite Releases and Direct Radiation	
	Standard[a]	Actual[b]
Average worker (mrem)	None	17.9
Maximally exposed worker (mrem)	5,000	3,000
Total workers (person-rem)	None	350

[a] 10 CFR 835. DOE's goal is to maintain radiological exposures as low as reasonably achievable.

[b] DOE 1993n:7. The number of badged workers in 1992 was approximately 19,500.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain toxic chemicals that can be inhaled; drinking water, which may contain toxic chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are presented in sections 4.3.2.3 and 4.3.2.4.

Adverse health impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and to achieve compliance with permit requirements (i.e., air emissions and NPDES permit requirements). The effectiveness of these controls is verified by using monitoring information and inspecting mitigation measures. Health impacts to the public may occur during normal operation at SRS via inhalation of air containing hazardous chemicals released to the atmosphere by SRS operations. Contaminated drinking water and direct exposure may also put public health at risk.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.3.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. These concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to SRS workers during normal operation may include inhaling the workplace atmosphere, drinking SRS potable water, and other possible contacts with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and there is not enough information available to allow a detailed estimation and summation of these impacts. However, the workers receive appropriate training, protective equipment, monitoring, and management controls to protect them from workplace-specific hazards. Workers are also protected by SRS adherence to OSHA and EPA occupational standards that limit concentrations of potentially hazardous chemicals in the workplace atmosphere and drinking water. Appropriate monitoring, which reflects the frequency and amounts of chemicals used in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm. Therefore, worker health conditions at SRS are expected to be substantially better than required by the standards.

Health Effects Studies. Two published epidemiological studies have been conducted on the general population in communities surrounding SRS. A study conducted in 1984 of the population living within 80 km (50mi) of SRS found no excess risk of any type of cancer or other diseases compared with the reference population. A statistically significant excess in leukemia deaths was observed among hourly workers at SRS employed at least 5 years, but less than 15 years. For a more detailed description of the studies reviewed and the findings, refer to appendix section E.4.

Accident History. From 1974 to 1988, there was a series of releases from the tritium facilities at SRS. These releases have been traced to aging equipment in the tritium processing facility and are one of the reasons for constructing a replacement tritium facility at SRS. A detailed description and study of these incidents and their consequences to the offsite population has been documented by SRS. Between 1974 and 1988, there were 13 inadvertent tritium releases. The most significant releases were in 1981, 1984, and 1985 when 32,934; 43,800; and 19,403 curies of tritiated water vapor, respectively, were released (WSRC 1991a:4). In the period between 1989 and 1992, there were 20 inadvertent releases, all with little or no offsite dose consequences. The largest of these recent releases occurred in 1992 when 12,000 curies (Ci) of tritium were released. In 1993, an inadvertent release of plutonium-238 and -239 took place. Westinghouse Savannah River Corporation emergency response models estimated a hypothetical exposure of 0.0019 mrem at the site boundary (WSRC 1994d:182).

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for most accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with emergency planning, preparedness, and response. The Emergency Preparedness Facility at SRS provides overall direction and control for onsite responses to emergencies and coordinates with Federal, state, and local agencies and officials on the technical aspects of the emergency.

The SRS Emergency Operations Facility consists of several centers, described below, that provide distinct emergency response support functions. The SRS Operations Center coordinates the initial response to all SRS emergencies and is equipped to function as the heart of SRS's emergency response communications network. The Technical Support Center provides command and control of emergency response activities for the affected facility or operational area. The Emergency Operations Center provides command and control of emergency response activities for SRS locations outside of the affected area. The Security Management Center coordinates activities relating to the security and safeguarding of materials by providing security staff in the affected area and contractor management in the Emergency Operations Center. The Dose Assessment Center is responsible for assessing the health and environmental consequences of any airborne or aqueous releases of radioactive or toxic chemicals and recommends onsite and offsite protective actions to other centers.

4.3.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and ongoing waste management activities at SRS. A more detailed discussion of ongoing waste management operations is provided in appendix section H.2.2.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operations at SRS. DOE is engaged in several activities to bring its operations into full regulatory compliance. These activities are set forth in negotiated agreements that contain schedules for achieving compliance with applicable requirements and financial penalties for nonachievement of agreed upon milestones. These agreements have been reviewed to assure the proposed action is allowable under the terms of these agreements.

EPA has placed SRS on the NPL and has identified approximately 150 potential operable units. In accordance with CERCLA, DOE entered into a Federal Facility Agreement with EPA and the State of South Carolina, effective January 15, 1993, to coordinate cleanup activities at SRS under one comprehensive strategy. The Federal Facility Agreement, titled the RCRA Facility Investigation Remedial Investigation Program Plan, combines the RCRA Facility Investigation Program Plan under RCRA with a CERCLA cleanup program.

SRS has an aggressive waste minimization program in progress to vastly improve the operation of existing and planned liquid and solid waste generation, treatment, and storage facilities. A disciplined approach to these activities is being developed based on technology and experience from the commercial nuclear industry. This approach has already reduced the generation of TRU waste by 48 percent, LLW by 13 percent, mixed waste by 96 percent, and hazardous waste by 58 percent (DOE 1993e:I-18). SRS generates and manages the following waste categories: high-level, TRU, low-level, mixed, hazardous, and nonhazardous. A discussion of the waste management operations associated with each of these categories follows.

High-Level Waste. Liquid HLW at SRS is made up of many waste streams generated during the recovery and purification of TRU products and unburned fissile material from spent reactor fuel elements. In 1993, SRS generated approximately 1,561 m^3 (412,400 gal) of liquid HLW (SR DOE 1994c:4). As illustrated in appendix figure H.2.2–1, these wastes are separated by waste form, radionuclide, and heat content prior to their transfer to underground storage tanks in F- and H-Area tank farms. Processes that treat liquid HLW include separation, evaporation, and ion exchange. Evaporation produces a cesium-contaminated condensate. Cesium is removed from the condensate, resulting in a LLW stream which is treated in the F/H-Area Effluent Treatment Facility. The remaining HLW stream salts are precipitated, and some can be decontaminated. The resulting decontaminated salt solution is sent with residues from the F/H-Area Effluent Treatment Facility to the Defense Waste Processing Z-Area Saltstone Facility where it is mixed with a blend of cement, fly ash, and blast furnace slag to form grout. The grout is pumped into disposal vaults where it hardens for permanent disposal as solid LLW. The remaining high-level salt and sludge will be permanently immobilized as a glass solid cast in stainless steel containers at the Defense Waste Processing Facility Vitrification Plant. The stainless-steel containers will be decontaminated to DOT standards, welded closed, and temporarily stored onsite for eventual transport to and disposal in a permanent Federal repository.

Future HLW generation would result from processing and stabilization of spent fuel sent to SRS for long-term storage as a result of 61 FR 9441 (published in the *Federal Register* on March 8, 1996), or from remediation or material recovery activities performed in F- and H-Canyons.

Transuranic Waste. Under the Federal Facility Compliance Agreement on RCRA Land Disposal Restrictions signed by EPA and DOE on March 13, 1991, SRS is required to prepare TRU waste for shipment. SRS will begin discussions with the South Carolina Department of Health and Environmental Control on alternative treatment options in January 1998 if the Secretary of Energy does not decide to operate the Waste Isolation Pilot Plant (WIPP) by that time. If a delayed opening date for WIPP is determined, DOE will propose modifications to the SRS Site Treatment Plan for approval by the State of South Carolina. Status on the WIPP readiness schedule will be included in these modifications. Certified TRU waste is stored on TRU waste storage pads until it can be shipped to WIPP, once that facility can demonstrate compliance with the requirements of 40 CFR 191 and 40 CFR 268, or to another TRU waste disposal facility should WIPP prove unsatisfactory. Should additional treatment be necessary for disposal at WIPP, SRS would develop the appropriate treatment capability. In 1993, SRS generated no liquid TRU and 391 m^3 (511 yd^3) of solid TRU waste (SR DOE 1994c:4). All TRU waste currently generated is stored in containers on aboveground pads.

The Experimental TRU Waste Assay Certification Facility began operation in 1986 to certify newly generated TRU waste. It since has been shut down. A new TRU Waste Characterization/Certification Facility is planned and would provide extensive containerized waste processing and certification capabilities. The facility is needed to prepare TRU waste for treatment and to certify TRU waste for disposal at WIPP. Drums that can be certified for shipment to WIPP are placed in interim storage on concrete pads in E-Area. Buried and stored wastes containing concentrations of TRU nuclides between 10 and 100 nCi/g are referred to as alpha-contaminated LLW. This alpha-contaminated LLW is managed like TRU waste because its physical and chemical properties are similar, and because similar procedures will be used to determine its final disposition. Because all of the TRU waste placed on the aboveground pads prior to January 1990 is suspected of having hazardous constituents, a RCRA Part B permit application has been submitted for the TRU waste storage pads and the Experimental TRU Waste Assay/Certification Facility. The waste is currently being stored under RCRA interim status.

Low-Level Waste. The bulk of liquid LLW is aqueous process waste including effluent cooling water, decontaminated salt solutions, purge water, water from storage basins for irradiated reactor fuel or target elements, distillate from the evaporation of process waste streams, and surface water runoff from areas where there is a potential for radioactive contamination. Liquids are processed to remove and solidify the radioactive constituents and to release the balance of the liquids to permitted discharge points within standards established by the regulatory permit. Solid LLW includes operating plant and laboratory waste, contaminated equipment, reactor and reactor fuel hardware, irradiated targets, and spent deionizer resin from reactor coolant treatment. For 1993, SRS generated approximately 14,100 m^3 (18,440 yd^3) of solid LLW (SR DOE 1994c:4). Solid LLW is separated by radiation levels into low and intermediate categories. Solid LLW that radiates less than 200 mrem/hr at 5 cm (1.97 in) from the unshielded container is considered low-activity waste. If it radiates greater than 200 mrem/hr at 5 cm (1.97 in), it is considered intermediate-activity waste. Intermediate activity tritium waste is intermediate-activity waste with greater than 10 Ci of tritium per container. The disposal mode for solid LLW is disposal in earthen trenches and concrete vaults. Saltstone generated in the solidification of decontaminated salts extracted from HLW is disposed of as LLW in separate vaults, and is the highest volume of solid LLW disposed of at SRS. Disposal facilities are projected to meet solid LLW storage requirements, including LLW from offsite DOE facilities such as Pinellas, for the next 20 years.

Mixed Low-Level Waste. In 1993, SRS generated an estimated 115 m^3 (30,380 gal) of liquid mixed and 18 m^3 (24 yd^3) of solid mixed LLW (SR DOE 1994c:4). The Federal Facility Compliance Agreement signed by EPA and DOE on March 13, 1991, addresses SRS compliance with RCRA land disposal restrictions pertaining to past, ongoing, and future generation of mixed LLW (mostly solvents, dioxin, and California List wastes contaminated with tritium). SRS is allowed to continue to operate, generate, and store mixed wastes subject to land disposal restrictions. In return, SRS will report to EPA the characterization of all solid waste streams disposed of in land disposal units at SRS and has submitted its waste minimization plan to EPA for review. Schedules for measures to provide compliance through construction of the Consolidated Incineration Facility and the Hazardous Waste/Mixed Waste Storage Facility are included in the Federal Facility Compliance Agreement.

The Consolidated Incineration Facility will treat mixed LLW and hazardous waste. The hazardous waste/mixed waste disposal vaults are scheduled to be available in 2002. Mixed waste is currently placed in interim storage in the E-Area Solid Waste Disposal Facility and in two buildings in G-Area. These RCRA-permitted facilities will be used until completion of the Consolidated Incineration Facility and the Hazardous Waste/Mixed Waste Storage Facility. The *Federal Facility Compliance Act* of 1992 requires DOE facilities storing mixed wastes to develop site-specific treatment plans and to submit the plans for approval. The Federal Facility Compliance Agreement formed the basis for the SRS proposed site treatment plan.

Hazardous Waste. In 1993, SRS generated approximately 74 m^3 (97 yd^3) of hazardous wastes (SR DOE 1994c:4). Lead, mercury, cadmium, 1,1,1-trichloroethane, leaded oil, trichlorotrifluoroethane, benzene, and paint solvents are typical additional hazardous wastes generated at SRS. All hazardous wastes are stored onsite in RCRA- and DOT-approved containers in three RCRA-permitted hazardous waste storage buildings on three interim status storage pads in B- and N-Areas. Most of the waste is shipped offsite to commercial RCRA-permitted treatment and disposal facilities using DOT-certified transporters. Eight to 9 percent of the hazardous waste (organic liquids, sludge, and debris) will be incinerated in the Consolidated Incineration Facility. Hazardous chemicals are stripped from aqueous liquids collected during groundwater monitoring in the M-Area Air Stripper, with the treated wastewater discharged in accordance with NPDES criteria.

Nonhazardous Waste. In 1993, SRS generated an estimated 700,000 m^3 (184,900,000 gal) of liquid and 6,670 m^3 (8,720 yd^3) of solid sanitary wastes (SR DOE 1994c:4). In 1994, the centralization and upgrading of the sanitary wastewater collection and treatment systems at Savannah River were completed. The program included the replacement of 14 of 20 aging treatment facilities scattered across the site with a new 3,975 m^3/day (1.05 million gallons per day [MGD]) central treatment facility connecting them with a new 28.9-km (18-mi) primary sanitary collection system. The collection system intercepts wastewater at points prior to discharge into old sanitary wastewater treatment facilities.

The new Central Treatment Facility treats sanitary wastewater by the extended aeration activated sludge process utilizing the oxidation ditch method. The treatment facility separates the wastewater into two forms, clarified effluent and sludge. The liquid effluent is further treated by nonchemical methods of ultraviolet light disinfection to meet NPDES discharge limitations. The sludge goes through a volume reduction process to reduce pathogen levels to meet proposed land application criteria (40 CFR 503). The remaining existing sanitary wastewater treatment facilities are being upgraded as necessary to meet demands by replacing existing chlorination treatment systems with nonchemical ultraviolet light disinfection systems to meet NPDES limitations. Municipal solid waste generated at SRS is sent to a permitted offsite disposal facility. DOE is evaluating a proposal to participate in an interagency effort to establish a regional solid waste management center at SRS.

SRS addressed the offsite shipments in *Environmental Assessment for the Transportation and Disposal of Savannah River Site Generated Municipal Solid Waste at an Off-Site Disposal Facility* (DOE/EA-0989, August 1994) and described the environmental impacts of a regional center in *Environmental Assessment for the Construction and Operation of the Three Rivers Authority Waste Management Center at the Savannah River Site* (DOE/EA-1079, October 1995).

4.3.3 Environmental Impacts

4.3.3.1 *Land Resources*

No Action. Under No Action, DOE would continue current and planned activities at SRS as described in section 3.2.3. No additional land use impacts are anticipated at SRS beyond the effects of existing and future activities which are independent of the proposed action.

Management Alternatives

Pit Fabrication. Existing facilities at H- and F-Areas, would be modified to support the pit fabrication mission at SRS. The total facility building space affected during modification would be approximately 23,226 m^2 (250,002 ft^2). No additional land would be used to implement the new mission at SRS. The temporary use of approximately 2 ha (5 acres) for equipment and material laydown and construction worker parking would be needed. Existing vacant building space and developed areas would be used for these activities. Operation of the pit fabrication facilities would be compatible with and would not affect existing or proposed future land use at SRS. No land use impacts are expected.

Sensitivity Analysis. SRS would be able to accommodate all operations and support functions for pit fabrication with modification of existing facilities. Modification of the existing facilities would be sufficient to maintain capacity for both the high and low case production scenarios.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.3.3.2 *Site Infrastructure*

The pit fabrication mission at SRS would require modifications to existing facilities in H- and F-Areas. The existing SRS infrastructure would be capable of supporting the new mission without major modifications. A comparison of site infrastructure and facilities resource changes for the No Action and the pit fabrication alternative is shown in table 4.3.3.2–1.

No Action. SRS would continue current operations as described in section 3.2.3. Site infrastructure requirements under No Action are not expected to change from current usage. Additional impacts to the site infrastructure from No Action are not expected.

Management Alternatives

Pit Fabrication. Existing buildings in H- and F-Areas would be modified to support the pit fabrication activities. The SRS infrastructure would be capable of supporting the pit fabrication activities without major modifications. Adequate electrical energy is available at the site and from the regional power grid. The pit fabrication activities would increase electric power, oil, and coal use by 2 percent or less over No Action and be well within available resource supplies for the site.

Sensitivity Analysis. For the high stockpile size case, the size of the facility would have to be increased

TABLE 4.3.3.2–1.—*Site Infrastructure Requirements and Changes for Stockpile Management Alternatives at Savannah River Site*

Alternative	Electrical: Energy (MWh/yr)	Electrical: Peak Load (MWe)	Fuel: Liquid (L/yr)	Fuel: Gas (m^3/yr)	Fuel: Coal (t/yr)
Current Resources	659,000	130	28,400,000	NA	210,000
No Action (2005)					
Total site requirement	659,000	130	28,400,000	NA	210,000
Change from current resources	0	0	0	NA	0
Pit Fabrication					
Total site requirement	668,700	131.6	28,428,400	NA	211,090
Change from No Action	9,700	1.6	28,400	NA	1,090

Note: NA - not applicable.
Source: DOE 1995p; WSRC 1995c.

slightly, resulting in a minor impact to the SRS infrastructure. The low stockpile case is adequately covered by the capability-based capacity of the base case facility.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.3.3.3 *Air Quality*

No Action. No Action air quality utilizes estimated air emissions data from operations at SRS in 2005, assuming continuation of current site missions, to calculate pollutant concentrations at or beyond the SRS site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in appendix table B.3.3–1. Table 4.3.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards.

Management Alternatives

Pit Fabrication. Gaseous emissions of criteria air pollutants would be generated from the pit fabrication mission. These emissions would result from the combustion of fossil fuel for generation of electricity and steam. The emission rates for criteria pollutants for the pit fabrication mission are presented in appendix section B.3.3. Table 4.3.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action combined with those generated from operation of the pit fabrication mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the pit fabrication alternative would result in higher and lower concentrations of criteria and toxic/hazardous pollutants for the high and low cases, respectively. The concentrations of pollutants for both cases are expected to remain within applicable Federal and state regulations and guidelines.

Potential Mitigation Measures. No mitigation measures are required for the pit fabrication alternative at SRS.

4.3.3.4 *Water Resources*

Environmental impacts associated with the construction and operation of the potential stockpile management facilities at SRS could affect surface and groundwater resources. The proposed facilities would be located outside the 100-year floodplain. The location of the 500-year floodplain at SRS is undefined; however, a site-specific assessment would be required before implementing the pit fabrication mission at SRS. Groundwater would be used for construction and operation of the facilities. A description of the functions to be transferred to SRS is presented in section 3.2.3. Table 4.3.3.4–1 presents existing surface and groundwater resources and the potential impact of the alternatives. The total site water resource requirements for each alternative including No Action are displayed in this table.

Surface Water

No Action. Under No Action, no additional impacts to surface water resources are anticipated beyond the effects of existing and future activities, which are independent of and unaffected by the proposed action. No construction or modification activities would occur; therefore, no additional construction water would be required or discharged. During operation, wastewater discharged to surface waters would decrease 3 MLY (0.79 MGY) from the current discharge rate of 703 MLY (186 MGY). The No Action discharges listed in table 4.3.3.4–1 include projected wastewater discharges from the proposed tritium supply facility. As a result of a reduction in discharges to site streams, water quality may improve.

Management Alternatives

Pit Fabrication. Due to the location of the proposed pit fabrication and intrusive modification pit reuse mission, the stream most likely to receive surface water discharge during modification activities and operation is Fourmile Branch. Figure 4.3.2.4–1 shows

TABLE 4.3.3.3–1.—***Estimated Concentrations of Pollutants from No Action and Stockpile Management Alternatives at Savannah River Site***

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines (μg/m³)	2005 No Action (μg/m³)	Pit Fabrication (μg/m³)

Floodplain		
Actions in 100-year floodplain	NA	None
Actions in 500-year floodplain	NA	Uncertain

[a] Total water requirements for construction at SRS are based on a 5-year time period for pit fabrication.
[b] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharged would be the same as No Action operation.
[c] All discharges to natural drainages require NPDES permits.
Note: NA - not applicable; MLY - million liters per year.
Source: SRS 1995a:1; WSRC 1995c.

F- and H-Areas and their location with respect to Fourmile Branch. During both modification and operation periods, the new Central Sanitary Treatment Facility at SRS would treat wastewater. During modification activities of the Pit Fabrication Facility, no surface water withdrawals would be made. Approximately 3 MLY (0.79 MGY) of treated sanitary wastewater would be released to surface water during the modification phase. During operation, approximately 46 MLY (12 MGY) of treated wastewater would be discharged. All discharges would be monitored to comply with NPDES permit limits and other discharge requirements. Impacts from runoff during construction and operation would be temporary and manageable.

Groundwater

No Action. Under No Action, no additional impacts to groundwater resources are anticipated beyond the effects of existing and future activities which are independent of and not affected by the proposed action. A description of the activities that would continue at SRS is discussed in section 3.2.3. No construction would occur under No Action; therefore, no additional groundwater for construction would be used. Groundwater withdrawals for operation of existing facilities and the proposed tritium supply facility at SRS are expected to increase from 12,490 MLY (3,300 MGY) to 13,249 MLY (3,500 MGY) by 2005.

Section 4.3.2.4 describes existing groundwater conditions at SRS.

Management Alternatives

Pit Fabrication. Approximately 6 MLY (1.58 MGY) of groundwater would be required for the 5-year building modification period. The additional construction water would represent less than a 0.05-percent increase over the projected SRS No Action groundwater withdrawal of 13,249 MLY (3,500 MGY). This amount, compared to the projected SRS No Action level, is not expected to cause a significant increase in drawdown. Groundwater required for modification activities and operation and the percent increase in projected water use are shown in table 4.3.3.4–1. Groundwater required for operation (13,295 MLY [3,512 MGY]) would represent a 0.35-percent increase over the projected groundwater withdrawal.

Groundwater Quality. During modification and operation of the pit fabrication facilities, there are no plans for direct discharge to groundwater. All discharges to surface waters would be monitored to comply with NPDES permit limits and other discharge requirements. As a result, impacts to groundwater quality at SRS are not expected.

Sensitivity Analysis. The effluent discharges to surface water resulting from the high case are expected to be similar to the volumes generated by the base case surge three-shift pit fabrication operation. The low case scenario would discharge a slightly higher volume of treated effluent compared to the No Action volume. Additional impacts to surface and groundwater quality from the high and low case production scenarios would be negligible.

Potential Mitigation Measures. The use of surface water instead of groundwater for potable water and operation of support facilities would reduce groundwater use.

4.3.3.5 *Geology and Soils*

Modification of existing facilities at SRS for pit fabrication would have no impact on geological resources. Hazards posed by geological conditions at SRS are minor. Building material laydown would use approximately 2 ha (5 acres) within existing developed areas in the immediate vicinity of the building modification activities. Potential changes to geology and soils associated with the pit fabrication alternative at SRS are discussed below.

No Action. Under No Action, DOE would continue existing and planned activities at SRS. Any impacts to geology and soils from No Action activities would be independent of and unaffected by the proposed action.

Management Alternatives

Pit Fabrication. No potential project impacts to geological conditions would be expected. Modification of existing facilities would be compatible with existing geological conditions. Based on the seismic history of the area, a low seismic risk exists at SRS and should not preclude safe modification and operation of the project facilities. All modifications to facilities would meet standards for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides.

Volcanic activity is not a factor anywhere in the region and is extremely unlikely to impact project activities. It is also highly unlikely that landslides, sinkhole development, or other nontectonic movements would affect project activities. Slopes and underlying foundation materials are stable. Potential health impacts from accidents associated with geological hazards are discussed in section 4.3.3.9.

Because modification activities would occur within existing structures, no adverse impacts to soils are anticipated. Although stormwater runoff could occur occasionally during building modification activities, soil impacts are not anticipated with standard construction erosion and sediment control measures. The properties and conditions of soils in the project area place no limitation on modification activities. No soil disturbance during operation is expected.

Sensitivity Analysis. The high or low case operation scenario would not affect geology and soils.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.3.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species on SRS. Impacts to these resources are not expected from the proposed alternatives; however, noise and human presence could temporarily disturb wildlife.

No Action. Under No Action, the missions described in section 3.2.3 would continue at SRS. There would be no changes to current biotic resource conditions at the site as described in section 4.3.2.6.

Management Alternatives

Pit Fabrication. The pit fabrication mission at SRS would utilize existing facilities within the boundaries of the F- and H-Areas. Wastewater would be released through existing NPDES-permitted discharges. Operation of pit fabrication facilities at SRS would not be expected to impact biotic resources.

Sensitivity Analysis. Implementation of either a low or high case workload would not affect biological resources.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.3.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly though ground disturbance, building modifications, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. The proposed alternatives involve only modifications to existing facilities and no ground disturbance. Some NRHP-eligible historic structures may be affected by the proposed action. Site-specific surveys and evaluations would be conducted in conjunction with tiered NEPA documentation. Because the proposed alternative involves only modifications to existing facilities, no impacts to prehistoric, Native American, or paleontological resources are anticipated. DOE has a Programmatic Agreement with the South Carolina SHPO and the Advisory Council on Historic Preservation to ensure that appropriate measures are taken to inventory, evaluate, protect, and enhance archaeological resources at SRS. An Archaeological Resources Management Plan is also in place.

No Action. Under No Action, DOE would continue the existing and planned missions at SRS described in section 3.2.3. Any impacts to cultural and paleontological resources from these missions would be independent of and unaffected by the proposed action.

Management Alternatives

Pit Fabrication. This alternative involves the modification of existing facilities in the F- and H-Areas. Existing developed areas would be used for equipment and material laydown and parking. None of the buildings to be modified under this alternative have been evaluated for NRHP eligibility. NRHP resources would be identified through project-specific surveys and evaluations. Any project-related effects to historic resources would be addressed in tiered NEPA documentation. No impacts to prehistoric, Native American, or paleontological resources are anticipated.

Sensitivity Analysis. The high and low case scenarios would have the same impacts to cultural and paleontological resources. The base case pit fabrication production facilities can accommodate both high and low case scenarios.

Potential Mitigation Measures. If NRHP-eligible sites cannot be avoided through project design or siting, and would be adversely affected, then a Memorandum of Agreement would need to be negotiated among DOE, the South Carolina SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the South Carolina SHPO and the Advisory Council on Historic Preservation in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific

NRHP-eligible sites would be identified during tiered NEPA documentation.

4.3.3.8 *Socioeconomics*

No Action. Under No Action, the existing missions at SRS, as described in section 3.2.3, would continue. No new employment or in-migration of workers would be required. Projections for regional economy and employment rates, population and housing changes, and public finance characteristics are presented in appendix D.

Regional Economy and Employment. Total employment in the regional economic area is projected to grow approximately 1 percent annually between 1995 and 2000, reaching approximately 259,400 persons in the latter year. Between 2001 and 2020, employment is expected to increase by less than 1 percent annually, reaching approximately 315,800 persons. Site employment at SRS is expected to be 19,288 in 2005. Unemployment in the regional economic area was 6.7 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $17,789 to $23,041 between 1995 and 2030.

Population and Housing. Annual ROI county and city population and housing growth is projected to average about 1 percent between 1995 and 2000, and then slow to less than 1 percent. Annual increases between 2006 and 2030 are expected to be less than 1 percent. The ROI population is projected to increase from 447,300 in 1995 to 579,400 in 2030. The total number of housing units in the ROI is projected to increase from 168,900 in 1995 to 218,600 in 2030.

Public Finance. Between 2000 and 2005, all ROI county, city, and school district total revenues and expenditures are projected to increase at an annual average of 1 percent or less. These rates of increase should continue until 2030.

Management Alternatives

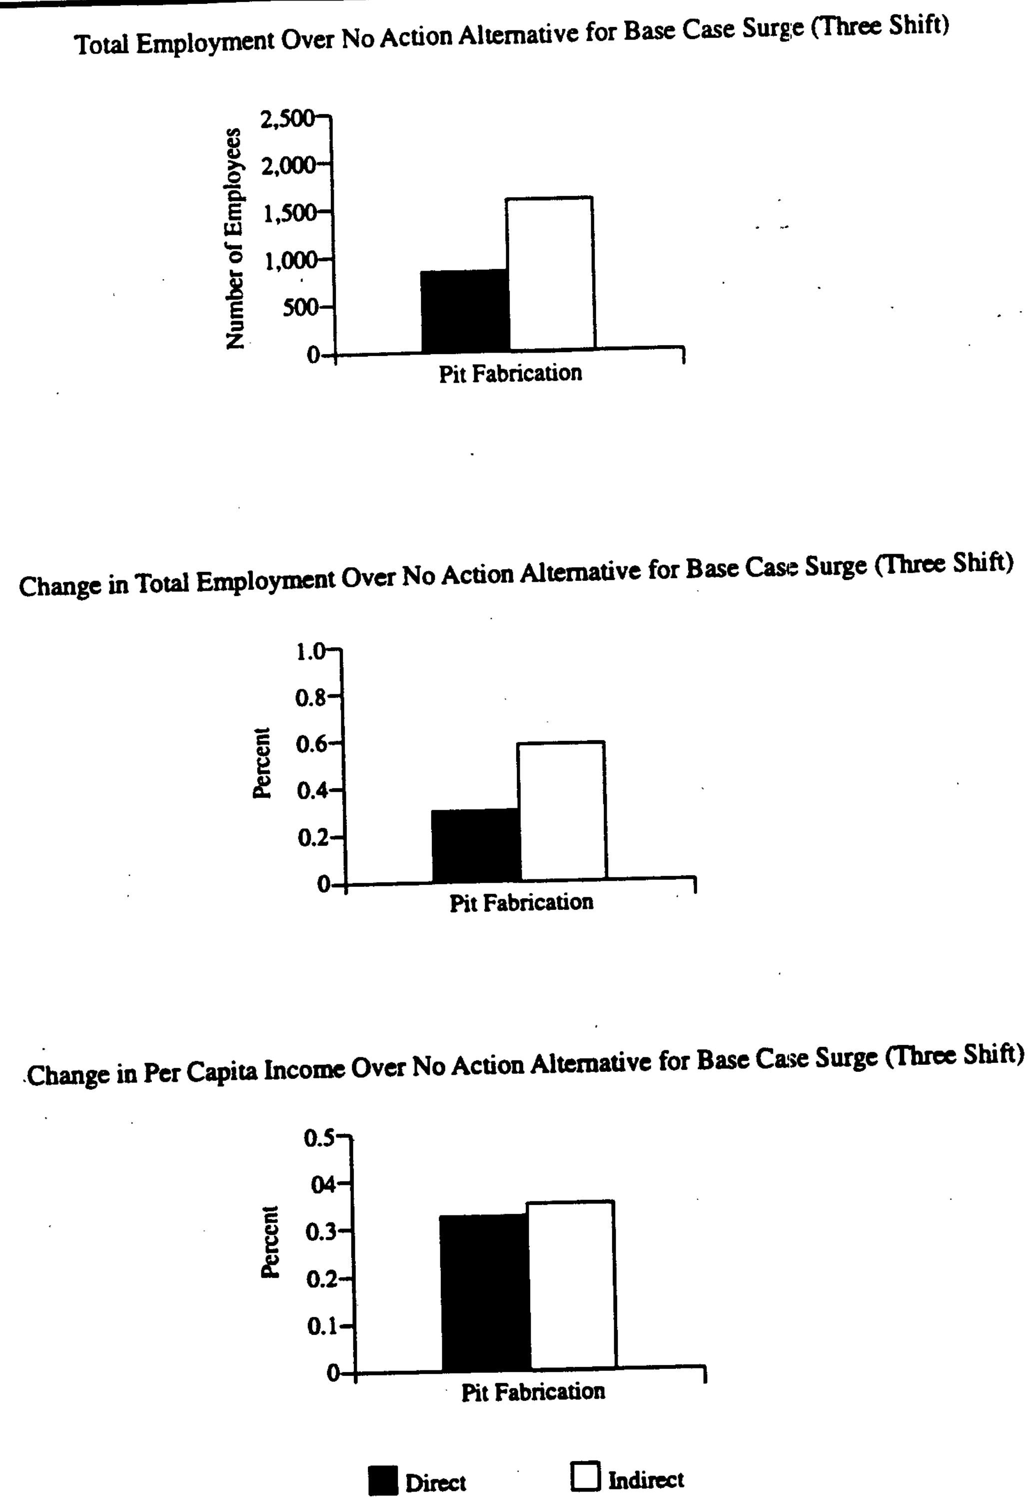
Pit Fabrication

Regional Economy and Employment. Modification-related activities for the Pit Fabrication Facility would require 288 direct workers during the peak construction year and would generate 228 additional indirect jobs in the regional economic area. Total employment for the SRS regional economic area would increase by less than 1 percent. This increase would reduce regional unemployment from 6.7 percent under No Action estimates to approximately 6.5 percent. Per capita income for the SRS regional economic area would increase very slightly over No Action projections as a result of modification activities for the Pit Fabrication Facility.

Facility operation-related employment at SRS would begin phasing in as the modification phase neared completion. Operation of the facility in the base case surge mode would require about 813 direct workers and would generate 1,594 additional indirect jobs in the regional economic area. As a result of the operation of the Pit Fabrication Facility, total employment for the SRS regional economic area would increase annually by slightly less than 1 percent. This increase would reduce unemployment from 6.7 percent under No Action estimates to approximately 6 percent. Per capita income for the SRS regional economic area would increase by less than 1 percent over No Action projections. Changes in employment and per capita income resulting from operation of the facility are shown in figure 4.3.3.8–1.

Population and Housing. Population in the SRS ROI during peak construction would not increase over No Action projections. Enough workers would be available in the regional economic area and ROI to fill all of the direct and indirect jobs created by the modification phase of the facility.

Projections indicate that there would not be enough available workers to fill all of the direct operation jobs. Up to 360 workers would in-migrate to fill vacant positions at the Pit Fabrication Facility. However, the actual number of in-migrating workers would likely be much lower due to downsizing activities at SRS that would make available some current SRS employees who might qualify for transfer to the Pit Fabrication Facility. ROI population and total housing units over No Action for full operation at SRS are shown in figure 4.3.3.8–2. If the maximum number of in-migrating workers were needed for full operation, about 240 additional housing units would however, need to be constructed over the No Action estimates. Based on past con-



Note: No Action projections are baseline for comparing proposed alternatives.

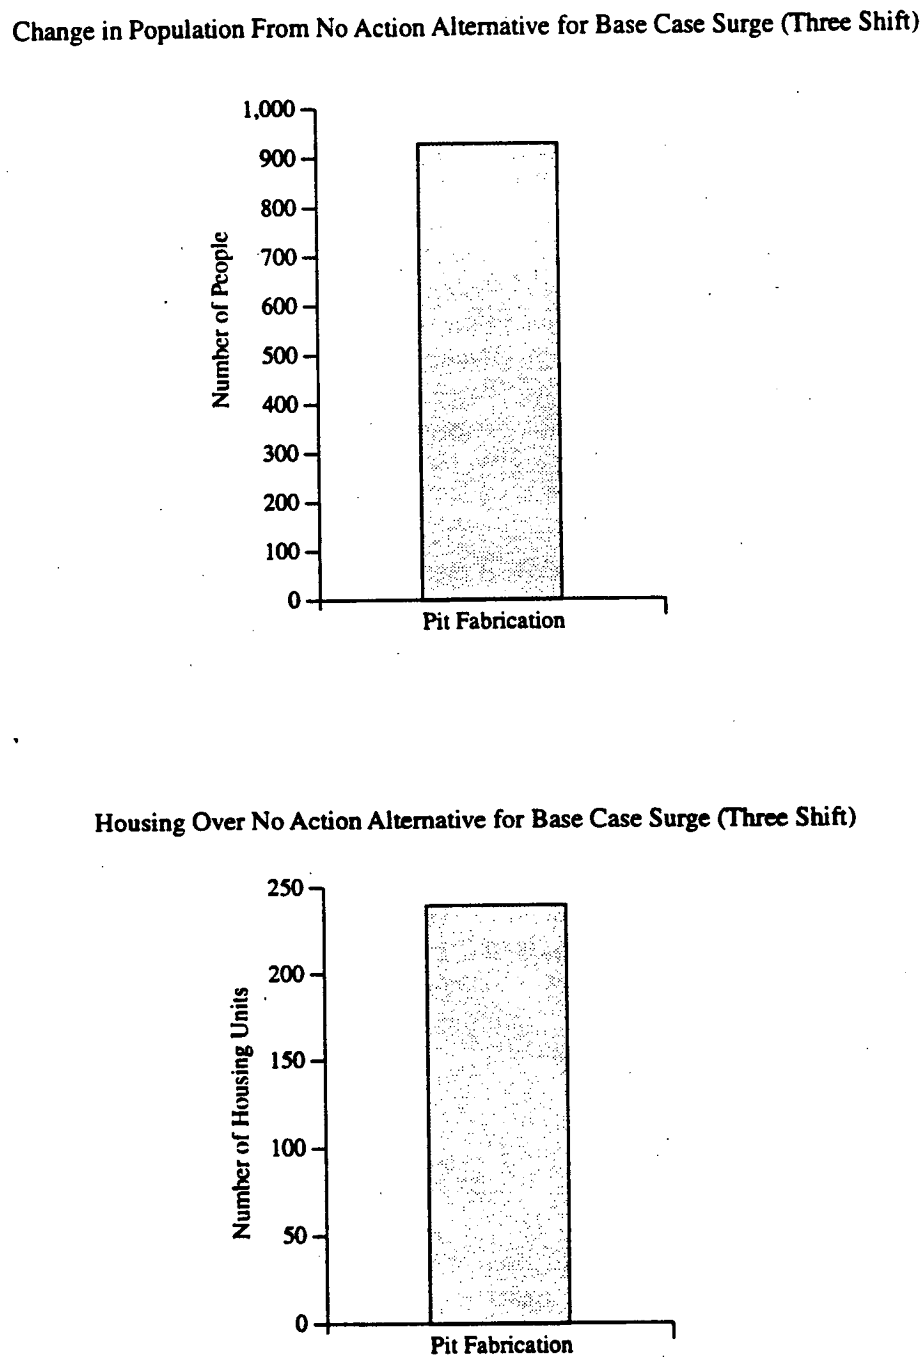
FIGURE 4.3.3.8–1.—***Employment and Income Changes Resulting from Management Alternatives in the Savannah River Site Regional Economic Area, 2005.***



Note: No Action projections are baseline for comparing proposed alternatives.
Source: Socio 1996b.

FIGURE 4.3.3.8–2.—*Population and Housing Changes Resulting from Management Alternatives in the Savannah River Site Region of Influence, 2005.*

struction rates, new construction would be sufficient to meet this demand.

Public Finance. Modification of the Pit Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Changes in revenues and expenditures compared to No Action projections due to operation of the Pit Fabrication Facility are shown in figure 4.3.3.8–3. At full operation, the percent increase in total ROI revenues and expenditures would increase above No Action projections by approximately 0.2 and 0.14 percent, respectively.

Sensitivity Analysis. There would be no change in the number of construction workers required to complete the Pit Fabrication Facility for either the high or low case. Operation of the Pit Fabrication Facility for high case production would require fewer workers than would base case surge production. This decrease in workers would generate fewer additional indirect jobs. For the low case, worker requirements would decrease further resulting in slightly smaller increases in regional economy, population and housing, and public finance than in either the base case surge or high case levels. These changes would be negligible.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.3.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the radiological and hazardous chemical releases and their associated impacts that could result from No Action and the proposed alternatives at SRS. Within this section, impacts resulting from the base case scenario are quantitatively discussed, and a sensitivity analysis of the high and low case scenarios is qualitatively discussed.

Summaries of the prevailing radiological impacts at SRS to the public and to workers associated with normal operation are presented in tables 4.3.3.9–1 and 4.3.3.9–2, respectively; radiological and chemical accident impacts are presented in figure 4.3.3.9–1 and tables 4.3.3.9–3 and 4.3.3.9–4. The impact assessment methodology is described in section 4.1.9 and further supplementary methodological information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the construction/modification of any facilities to support the pit fabrication mission. However, limited hazardous chemical releases (e.g., small spills of diesel fuel from equipment refueling) may occur due to building modification activities for the low and base case scenarios and may increase slightly for the high case scenario. The concentrations of these releases are expected to be well within the regulated exposure limits and would not result in any adverse health effects.

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge. Furthermore, discharges of wastewater through NPDES-permitted outfalls, which can be attributed to the activities associated with the pit fabrication mission at ORR, are expected to be below NPDES limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at SRS, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). The HI is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all management alternative (secondary fabrication) chemicals emitted at the site. An HI of ≤ 1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is $\leq 1 \times 10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $\leq 1 \times 10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the population. Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals

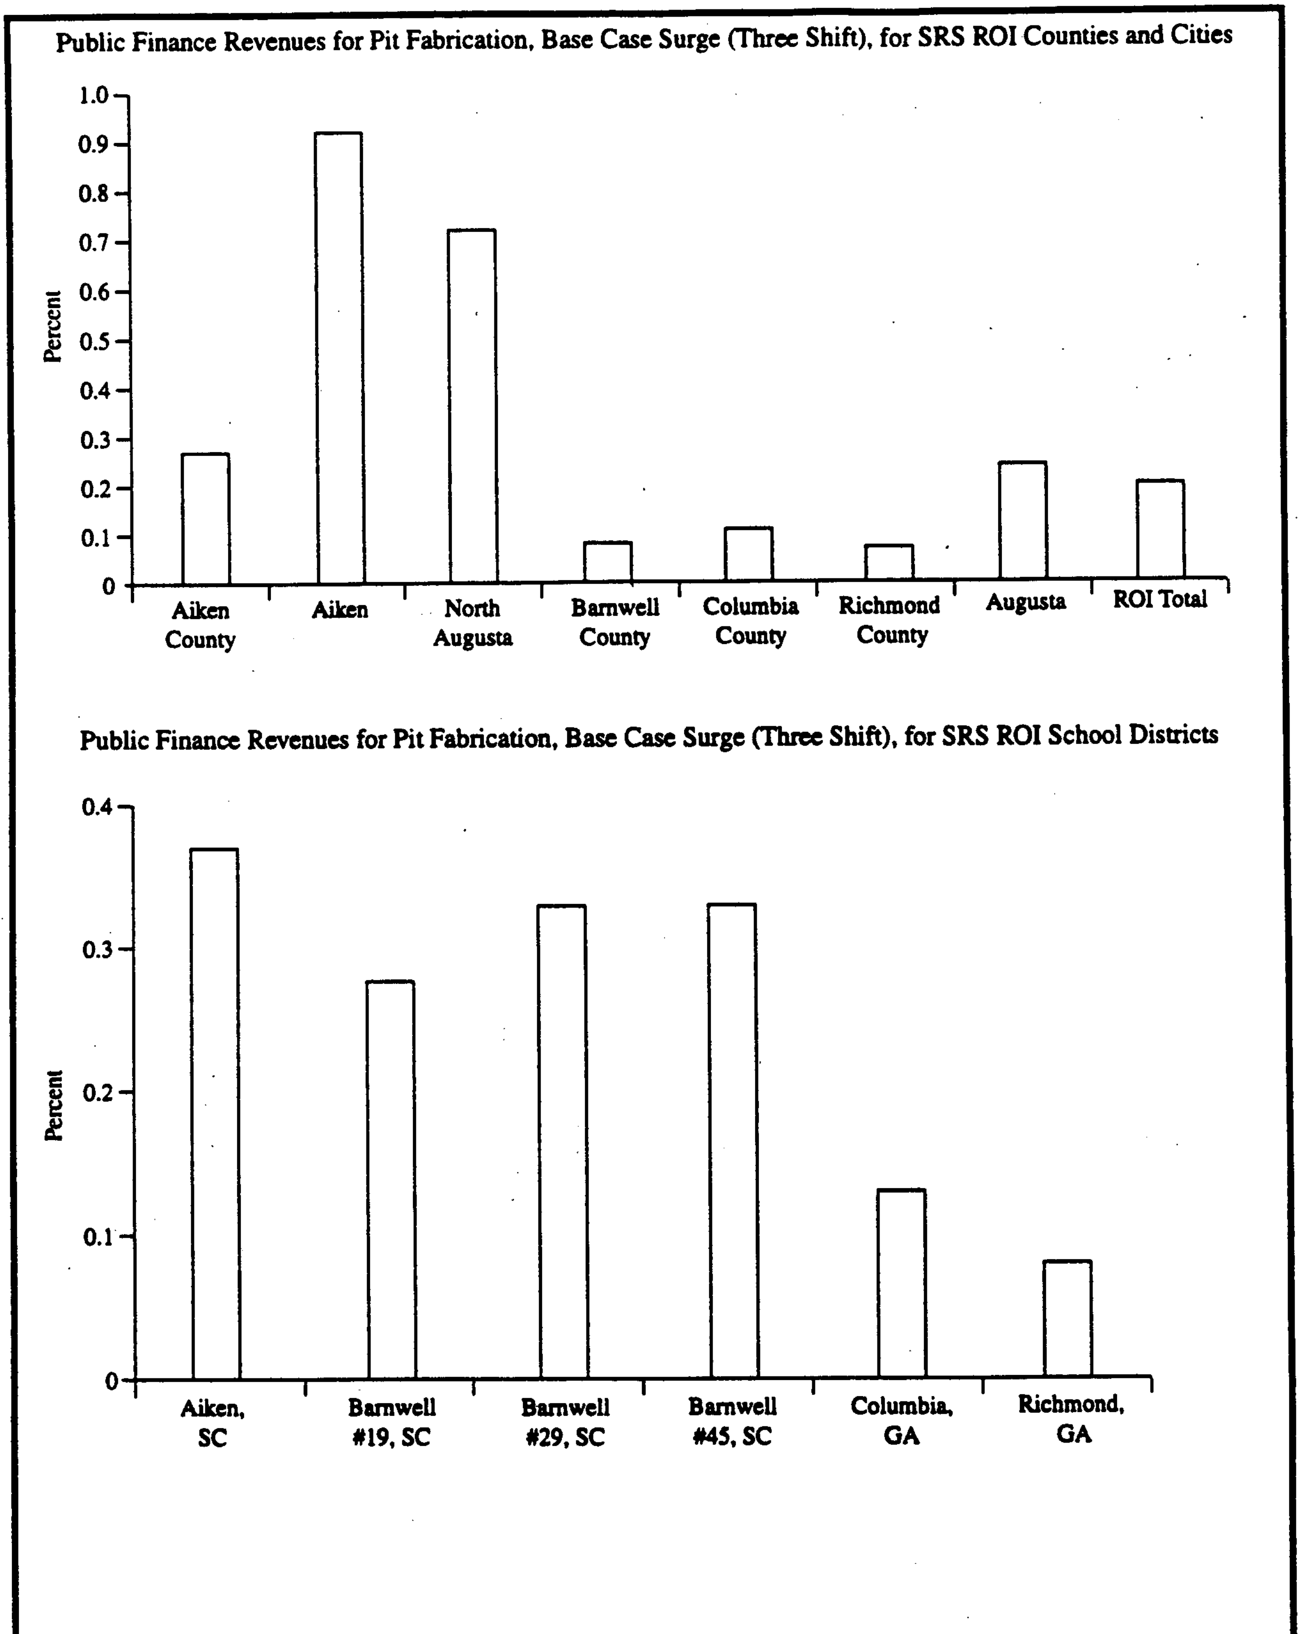


FIGURE 4.3.3.8–3.—***Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Savannah River Site Region of Influence with Pit Fabrication, Base Case Surge, 2005*** **[Page 1 of 2].**

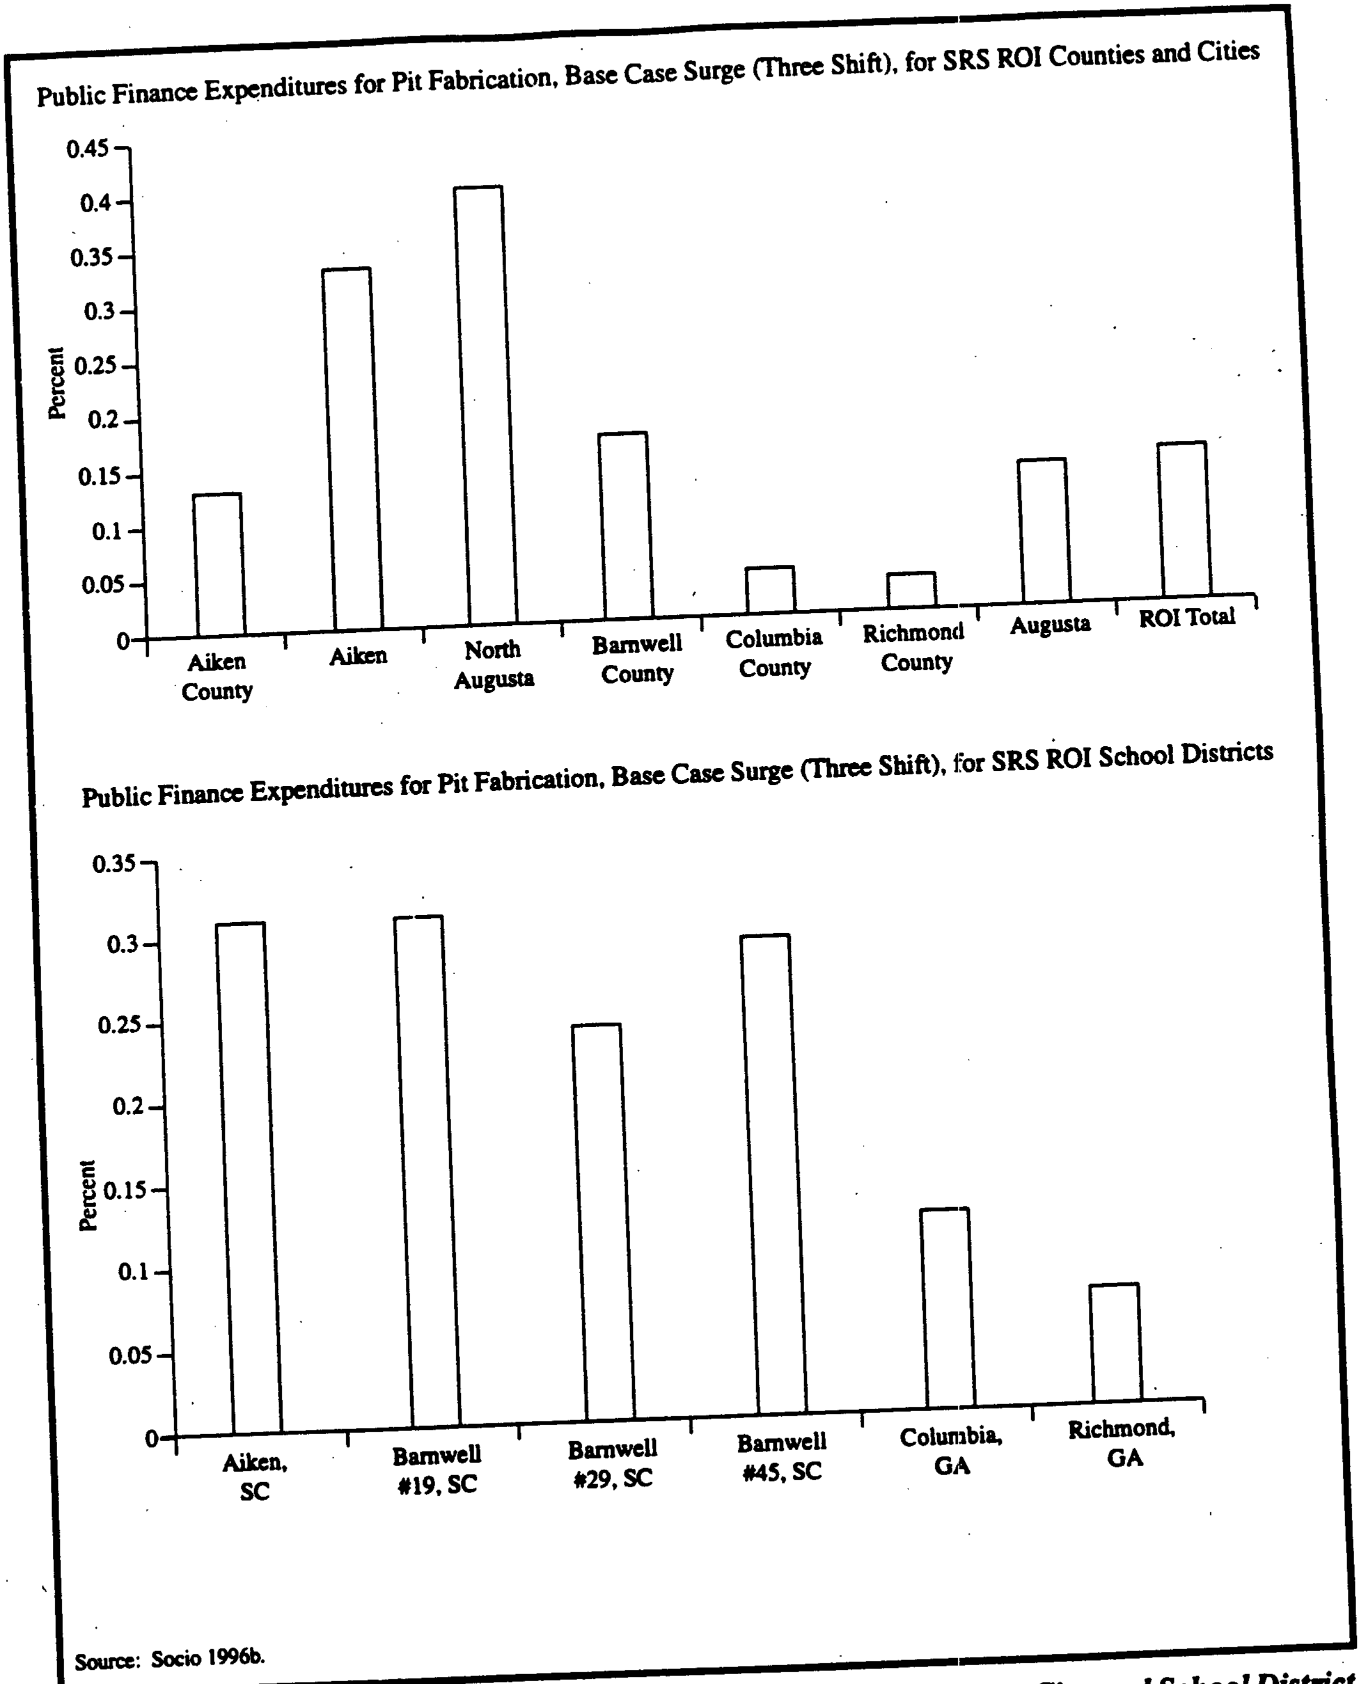

FIGURE 4.3.3.8–3.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Savannah River Site Region of Influence with Pit Fabrication, Base Case Surge 2005* [Page 2 of 2].

described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

No Action

Radiological Impacts. Radiological impacts to the public resulting from the No Action alternative are presented in table 4.3.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational SRS contributions. Total impacts are provided to compare to applicable regulations governing total site operations. To place doses to the public incurred from the No Action alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.3.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 0.32 mrem for the No Action alternative. The annual population dose (within 80 km [50 mi]) in 2030 would be 21.6 person-rem.

Total site doses to onsite workers from normal operation for the No Action alternative are presented in table 4.3.3.9–2. The estimated annual dose to the entire facility for this alternative would be 349 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database, which reports doses for similar types of operations. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information.

Based on the radiological impacts associated with normal operation under the No Action alternative, all

TABLE 4.3.3.9–1.—*Potential Radiological Impacts to the Public Resulting from Normal Operation of Stockpile Management Alternatives at Savannah River Site*

Affected Environment	No Action Total Site[a]	Pit Fabrication Three-Shift Operation Total Site[a]
Maximally Exposed Individual (Public)		
Atmospheric Release		
Dose[b] (mrem/yr)	0.18	0.18
Percent of natural background[c]	0.062	0.062
25-year fatal cancer risk	2.3×10^{-6}	2.3×10^{-6}
Liquid Release		
Dose[b] (mrem/yr)	0.14	0.14
Percent of natural background[c]	0.045	0.045
25-year fatal cancer risk	1.7×10^{-6}	1.7×10^{-6}
Atmospheric and Liquid Releases		
Dose[b] (mrem/yr)	0.32	0.32
Percent of natural background[c]	0.10	0.10
25-year fatal cancer risk	4.0×10^{-6}	4.0×10^{-6}
Population Within 80 Kilometers		
Atmospheric and Liquid Releases in 2030		
Dose (person-rem)	21.6[d]	21.6[d]
Percent of natural background[c]	9.6×10^{-3}	9.6×10^{-3}
25-year fatal cancers	0.27	0.27

[a] Includes impacts from all site operations.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem/yr from the air pathways, 4 mrem/yr from the drinking water pathway, 100 mrem/yr from all pathways combined (DOE Order 5400.5).

[c] Natural background radiation levels to average individual is 298 mrem/yr; to the population within 80 km (50 mi) in 2030 is 216,700 person-rem.

[d] Includes Defense Waste Processing Facility and Foreign Reactor Spent Fuel.

Note: Annual incremental doses of 1.0×10^{-5} mrem to the maximally exposed individual and 5.9×10^{-4} person-rem to the population are incurred from the pit fabrication alternative.

Source: WSRC 1994d; WSRC 1995c.

TABLE 4.3.3.9–2.—***Potential Radiological Impacts to Workers Resulting from Normal Operation of Stockpile Management Alternatives at Savannah River Site***

Affected Environment	No Action	Pit Fabrication Three-Shift Operation
Involved Workforce[a]		
Average worker dose[b] (mrem/yr)	NA	380
25-year fatal cancer risk	NA	3.8×10^{-3}
Total dose (person-rem/yr)	NA	156
Noninvolved Workforce[c]		
Average worker dose[b] (mrem/yr)	17.9	17.9
25-year fatal cancer risk	1.8×10^{-4}	1.8×10^{-4}
Total dose (person-rem/yr)	349	349
Total Site Workforce[d]		
Dose (person-rem/yr)	349	505
25-year fatal cancers	3.5	5.0

[a] The involved worker is a worker associated with operation of the pit fabrication facilities. The estimated number of involved workers is 411 for the pit fabrication alternative.

[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835).

[c] The noninvolved worker is an onsite worker unassociated with operation of the pit fabrication facilities in question. The estimated number of noninvolved workers is 19,500 for the pit fabrication alternative at SRS.

[d] The total site workforce is the sum of the number of involved and noninvolved workers. The estimated number of workers in the total site workforce is 19,911 for the pit fabrication alternative and 19,500 for No Action at SRS.

Note: NA - not applicable.

Source: DOE 1993n:7; LANL 1995b:6; WSRC 1995a.

resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from normal operation under No Action at SRS are presented below. Analyses to support the values presented in this section are provided in appendix table E.3.4–4. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging if sites have a hazardous chemical health concern. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among sites. This baseline is then used to determine the extent to which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed member of the public at SRS resulting from normal operation under the No Action alternative would be 5.16×10^{-3} and the cancer risk would be 1.31×10^{-7}. The HI for the onsite worker would be 1.16, and the cancer risk would be 1.94×10^{-4}.

The HI for the public is within acceptable health levels. The HI for onsite workers (1.16) exceeds the cumulative HQ screening level (the HI) of 1.0, but not necessarily the individual OSHA standards for specific effects. The cancer risk to the public is within the acceptable EPA default level of 1×10^{-6}. The cancer risk to the onsite worker (1.94×10^{-4})is not within the acceptable EPA default level of 1.0×10^{-6}.

The HI for the onsite worker is due to the high emissions from 5 of the 13 hazardous chemicals listed in appendix table E.3.4–4 under the No Action alternative at SRS. To determine the actual potential impacts, an analysis according to organ/tissue specific effects (i.e., second tier analysis) was performed. Preliminary analysis according to affected tissues/organs shows that only two noncancer endpoints: respiratory (the HI is equal to approximately 0.72) and central nervous system (the HI is equal to approximately 0.30) effects exceed the default level. Cancer risks for leukemia, lung, and kidney exceed the acceptable range of 10^{-4} to 10^{-6} based on specific chemicals and applications based on the initial second tier screen. However, all of these effects are localized to not more than three areas on SRS (G-, H-, and T-areas) and the relevant emissions come mostly from five point sources (buildings). Only the H-Area (Building WG-2) appears to have an HI for workers that exceeds the default level. There appears to be only one noncancer adverse effect associated with the exceedance: the HI is equal to approximately 4.71 for respiratory system effects. However, the potential chemical health effects and cancer risks to workers presented here does not take into consideration the OSHA and DOE operations health and safety measures required to be followed by workers in these areas. Chemicals identified as principal contributors for the noncancer and cancer risks are nitric acid, bis-chloromethyl ether, benzene, and chloroform.

To protect site workers, the SRS Industrial Hygiene Program is implementing the program requirements identified in DOE O 440.1, *Worker Protection Management for DOE Federal and Contractor Employees*, which provides for identification, evaluation, and control of chemical hazards within the workplace. Compliance with the SRS Industrial Hygiene Program requirements of WRSC 4Q, *Industrial Hygiene Manual*, ensure that facility workers are adequately protected against chemical, physical, or biological agents that cause or are likely to cause sickness, impaired health, or significant discomfort. The Industrial Hygiene Program requires that occupational exposures to hazardous substances remain below the public exposure limits set by OSHA. Compliance with this requirement is assured by a combination of engineering and workplace controls as well as the use of personal protective equipment.

Since 1990, SRS has implemented a number of programs designed to reduce the use of products that have hazardous components. For example, SRS has centralized efforts to find substitutes for products containing hazardous constituents and to ensure that those substitutes are purchased whenever possible.

Management Alternatives

Pit Fabrication

Radiological Impacts. Radiological impacts to the public resulting from the pit fabrication alternative are presented in table 4.3.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational SRS contributions and from three-shift base case operations for pit fabrication at the site. Total impacts are provided to demonstrate compliance with applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.3.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 0.32 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 21.6 person-rem. The incremental impacts incurred from three-shift base case operations are negligible when compared to those existing for the normal baseline site operations (see table 4.3.3.9–1).

Total site doses to onsite workers from normal operation for the pit fabrication alternative are presented in table 4.3.3.9–2. The average annual dose to involved workers for this alternative would be 380 mrem. The total annual dose to the entire facility workforce (involved workforce) would be 156 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced either from alternative-specific data reports or from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations; the presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and to the onsite worker resulting from normal operation due to the pit fabrication mission, which includes intrusive and nonintrusive modification of pit reuse, are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–5.

The incremental HI for the maximally exposed member of the public would be 1.83×10^{-6}, and the incremental cancer risk would be zero as a result of the pit fabrication alternative at SRS. The incremental HI for the onsite worker would be 2.99×10^{-4}, and the incremental cancer risk would be zero as a result of the pit fabrication alternative.

The incremental effects of the pit fabrication alternative would not change the No Action hazardous chemical impacts. The total HI for the maximally exposed member of the public would be 5.16×10^{-3} and the cancer risk would be 1.31×10^{-7}. The total HI for the onsite worker would be 1.16 and the cancer risk would be 1.94×10^{-4}.

Sensitivity Analysis. Radiological impacts may be subject to certain degrees of variance resulting from either high or low case operations. For the high case scenario, impacts to both the public and worker would be similar to the three-shift base case operations. For the low-case scenario, impacts to the public and workers would be expected to fall within the increment (range) projected between that of No Action and the pit fabrication alternative (i.e., an increase of approximately zero mrem/year to the maximally exposed individual, an increase of approximately zero person-rem/year to the population within 80 km (50 mi), and an increase of less than 156 person-rem/year to the total site workforce).

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Based on workload requirements at SRS, operations under the low case scenario are similar to the base case scenario and would not have any appreciable effect on hazardous chemical emissions. Therefore, operations under the low case scenario would not have any impact upon the HI and cancer risks to the public and onsite workers.

Based on workload requirements at SRS, operations under the high case scenario would be five-fold greater than the base case scenario and may substantially increase emissions of hazardous chemicals. Increases in hazardous chemical emissions under the high case scenario would have an adverse impact on the HI and cancer risks to the onsite worker.

Potential Mitigation Measures. Radioactive airborne emissions to the general population and onsite exposures to workers could be reduced by implementing the latest technology for process and design improvements. For example, to reduce public exposure from emissions, improved building and work area control methods could be used to remove radioactivity from releases to the environment. Similarly, the use of remote, automated, and robotic production methods are examples of techniques that are being developed to reduce worker exposure (see section 3.5.1). Mitigation measures needed to reduce or eliminate the emissions of all hazardous chemicals due to pit fabrication alternative operations would be the same as those described for No Action.

Facility Accidents. The proposed actions have the potential for accidents that may impact the health and safety of workers and the public. The potential for, and associated consequences of, reasonably foreseeable accidents that have been evaluated are summarized in this section and described in more detail in appendix F. The methodology used in the assessment is described in section 4.1.9. A list of documents reviewed for applicable accident data is provided in appendix table F.1.1–1. The potential impacts from accidents, ranging from high-consequence/low-probability to low-consequence/high-probability events, have been evaluated in terms of potential cancer fatalities that may result for noninvolved workers and the public. The risk of cancer fatalities has also been evaluated to provide an overall measure of accident impacts and is calculated by multiplying the accident annual frequency (or probability) of occurrence by the consequences (number of cancer fatalities). Figure 4.3.3.9–1 shows the risk of latent cancer fatalities in the population within 80 km (50 mi) that may result from accidents for the alternatives. Specifically, the curve in the figure shows the probability (vertical axis) that the number of cancer fatalities in the offsite population within 80 km (50 mi) (horizontal axis) will be exceeded. The curve does reflect the probability of the accident.

In addition to the potential impacts to noninvolved workers and the offsite population, there are potential impacts to involved workers who would be located in the facilities associated with the proposed action. Quantitative statements of these impacts cannot be made until design details are developed further at which time the number and location of facility workers can be estimated to support accident impact analyses. However, depending on the type of accident, facility workers in close proximity to the point of the accident could receive high levels of exposure to radiation and hazardous chemicals, with potentially fatal impacts.

No Action. Under the No Action alternative all existing conditions would continue at SRS with no changes to facilities and operations. For existing conditions, potential accidents and their consequences have previously been addressed in facility safety documentation according to requirements in DOE orders.

Management Alternatives

Pit Fabrication. A set of potential accidents has been postulated for the pit fabrication alternative for which there may be releases of radioactive materials or other hazardous effects that may impact onsite workers and the offsite population. The accident impacts of greatest interest are those associated with pit fabrication and/or intrusive modification. Any potential accident impacts associated with nonintrusive modification would be bounded by the pit fabrication and intrusive modification accident impacts. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.3.3.9–1. For example, the probability of a pit fabrication accident causing more than 0.1 cancer fatality is approximately 10^{-8} per year. The curve reflects the probability of the accidents occurring. The consequences of the composite set of accidents are shown in table 4.3.3.9–3.

If an accident were to occur, there would be an estimated 5.4×10^{-5} cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 1,000 m (3,281 ft) from the accident on the site would have an increased likelihood of cancer fatality of 3.5×10^{-7}. A maximally exposed individual located at the site boundary would have an increased likelihood of cancer fatality of 7.3×10^{-9}. The risks for the combined EBA and BEBA composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.3.3.9–3. For the same worker, maximally exposed individual, and population, the risks would be 1.8×10^{-8}, 3.8×10^{-10}, and 2.8×10^{-6} cancer fatalities per year, respectively. Table 4.3.3.9–3 also shows the impacts of EBAs and BEBAs only. There is also a potential of chemical accident impacts as shown in table 4.3.3.9–4.

4.3.3.10 *Waste Management*

This section summarizes the impacts on waste management at SRS under No Action and for the pit fabrication alternative. There is no spent nuclear fuel or

TABLE 4.3.3.9–3.—*Impacts of Accidents for Pit Fabrication and Intrusive and Nonintrusive Modification Pit Reuse at Savannah River Site*

Parameter	Pit Fabrication		
	EBA	BEBA	EBA and BEBA Combined
Composite Accident Frequency (Per Year)	0.05	$1.0x10^{-6}$	0.05
Consequences			
Noninvolved Worker			
Cancer fatality[a]	$3.4x10^{-7}$	$3.3x10^{-5}$	$3.5x10^{-7}$
Risk (cancer fatality per year)	$1.8x10^{-8}$	$3.3x10^{-11}$	$1.8x10^{-8}$
Maximally Exposed Individual			
Cancer fatality[a]	$7.3x10^{-9}$	$4.4x10^{-7}$	$7.3x10^{-9}$
Risk (cancer fatality per year)	$3.8x10^{-10}$	$4.4x10^{-13}$	$3.8x10^{-10}$
Population Within 80 Kilometers[b]			
Cancer fatalities[c]	$5.4x10^{-5}$	$3.2x10^{-3}$	$5.4x10^{-5}$
Risk (cancer fatalities per year)	$2.8x10^{-6}$	$3.2x10^{-9}$	$2.8x10^{-6}$

[a] Probability (increased likelihood) of cancer fatality to a hypothetical member of the public located at the site boundary or to a noninvolved worker as a result of exposure to the indicated dose if the accident occurred.

[b] For the offsite population of 747, 836, the average probability of cancer fatality/risk of cancer fatality (per year) for the combined EBA and BEBA is $7.2x10^{-11}/3.7x10^{-12}$ for the listed alternative.

[c] Number of cancer fatalities in the population within 80 km (50 mi) of the site as a result of exposure to the indicated dose if the accident occurs.

Note: All values are mean values; BEBA - beyond evaluation basis accidents; EBA - evaluation basis accidents.

Source: Results shown are derived from accident analyses in appendix F.

HLW associated with pit fabrication, which includes intrusive and nonintrusive modification pit reuse. However, the liquid TRU waste, categorized as high-specific activity waste at SRS, would be treated in accordance with the SRS HLW management plan. As illustrated in appendix figure H.2.2–1, this would result in solid HLW glass logs and solid LLW in the form of saltstone. Table 4.3.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action. Projections for No Action were derived from 1994 environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities.

Table 4.3.3.10–2 provides the total estimated operational waste volumes projected to be generated at SRS as a result of the pit fabrication alternative. The net increase over No Action is provided in parentheses. The waste volumes generated and the resultant waste effluent from pit fabrication can be found in table 3.4.3.3–3 and are based on surge operations (three shifts). Facilities that would support the pit fabrication mission would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act*, RCRA, and other applicable statutes as outlined in appendix section H.1.2.

No Action. Under No Action, high-level, TRU, low-level, mixed, hazardous, and nonhazardous wastes, and spent nuclear fuel would continue to be managed from the missions outlined in section 3.2.3. SRS would continue to store its inventory of plutonium, and treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities. The processing of legacy wastes would require new facilities, since the necessary treatment, storage, and disposal facilities either do not exist or are nearing capacity. Spent nuclear fuel is not discussed because there is no spent nuclear fuel associated with pit fabrication.

TRU waste already packaged to WIPP waste acceptance criteria would either be stored or would have been shipped. Vitrification is planned to reduce waste

TABLE 4.3.3.9–4.—*Impacts of Chemical Accidents for Pit Fabrication at Savannah River Site*

Accident Description	Accident Frequency (Per Year)	IDLH	TLV-STEL	TLV-TWA	Concentration to: Noninvolved Worker (mg/m³)	Concentration to: Individual at Site Boundary (mg/m³)	Potential Impacts of Exceeding: IDLH Limits[a]	Potential Impacts of Exceeding: TLV Limits[a]

[a] The No Action volumes are from table 4.3.3.10–1.
[b] Waste generation volumes were derived from table 3.4.3.3–3 and are based on surge operations (three shifts).
[c] Includes 65 m^3 of intermediate LLW managed as TRU but disposed of as LLW in the intermediate-level LLW vaults onsite.
[d] Recyclable wastes.
Note: Waste generation volumes were rounded to three significant figures. Waste effluent volumes (i.e., after treatment and volume reduction) that are used in the narrative description of the impacts are also found in table 3.4.3.3–3.

volume. SRS TRU waste is expected to occupy 3 percent of the WIPP capacity. If shipments to WIPP are delayed, additional storage facilities would be designed and constructed as needed. Should WIPP prove to be an unacceptable facility, TRU wastes would be stored in accordance with all applicable requirements until a new repository becomes available. Mixed waste which has been incinerated and stabilized would be disposed of onsite as LLW, according to the SRS Site Treatment Plan which was developed to comply with the *Federal Facility Compliance Act* of 1992.

Liquid LLW would be sent to collection tanks that would be batch transferred to treatment and storage facilities onsite, such as the Effluent Treatment Facility or the Tank Farm. Liquid LLW concentrate would be processed into saltstone. Solid LLW would continue to be compacted and disposed of by burial onsite in engineered trenches or vaults, depending on the LLW category. The planned burial ground expansion in the E-Area is expected to accommodate the current waste disposal requirements through 2024. Additional waste disposal facilities would be constructed as needed to ensure compliance. The Consolidated Incineration Facility would also be utilized to reduce the volume of LLW requiring disposal.

The majority (85 to 89 percent) of SRS hazardous wastes would be sent offsite for treatment and disposal. SRS does not plan to construct facilities solely for the treatment of hazardous wastes. However, facilities planned for the treatment of mixed wastes would be utilized to the extent capacity is available. Some selected organic hazardous wastes would be incinerated in the Consolidated Incineration Facility. A facility would be constructed to provide containment for the decontamination of debris and metals to be recycled onsite or sold as scrap.

Liquid sanitary waste would be conveyed to existing domestic wastewater treatment facilities. The treated sanitary and process wastewater would be discharged through NPDES outfalls, and the resultant solids would be disposed of with solid nonhazardous waste in an onsite or offsite permitted landfill.

Management Alternatives

Pit Fabrication. Construction and operation of a Pit Fabrication Facility would impact existing and planned SRS waste management facilities and activities by increasing the generation of TRU, low-level, mixed, hazardous, and nonhazardous wastes. An optional plutonium recovery process would generate high-specific activity liquid waste at SRS that would be treated in accordance with the SRS HLW management plan. The resultant waste forms include 0.61 glass logs composed of comingled TRU waste from pit fabrication and legacy HLW, and LLW saltstone.

Approximately 65 m^3/yr (84 yd^3/yr) of TRU waste and 11 m^3/yr (15 yd^3/yr) of mixed TRU waste would be packaged and placed on concrete pads for interim storage where it would await shipment to WIPP, once that facility can demonstrate compliance with requirements of 40 CFR 191 and 40 CFR 268, or to another TRU waste disposal facility should WIPP prove unsatisfactory. Nine additional trucks per year, or if applicable, five regular train shipments per year or two dedicated train shipments per year, would be required to transport the additional project-related wastes.

An additional 65 m^3/yr (84 yd^3/yr) of intermediate-level (LLW) waste (appendix section A.3.3.2) would be generated and managed as TRU waste because it presents similar handling characteristics. However, it would be disposed of onsite in the Intermediate-Level Vaults. Assuming a land usage factor of 8,600 m^3/ha (4,500 yd^3/acres), this would require 0.008 ha/yr (0.02 acres/yr) of disposal area.

A small quantity of liquid mixed LLW containing silver may be generated from the radiography process. The silver would be removed and stored as mixed waste for further processing or recovery. The liquid would then be treated in the F/H-Area Effluent Treatment Facility and discharged.

An estimated 80 m^3 (21,000 gal) of liquid LLW would be generated from glove box operations and in the separation of plutonium recovery liquids. This waste would be processed through the F/H-Area Effluent Treatment Facility, or evaporated and the resultant concentrate processed into saltstone. Incinerable portions of solid LLW would be treated in the Consolidated Incineration Facility before disposal onsite. After treatment and volume reduction, 34 m^3 (44 yd^3) of solid LLW would require 0.004 ha/yr (0.01 acres/yr) of LLW disposal area in the E-Area disposal facility.

A small amount of hazardous waste would be generated, accumulated onsite, and shipped offsite to a RCRA-permitted treatment and disposal facility. While SRS has not planned new facilities for hazardous waste treatment, the option exists to treat these wastes in the mixed waste treatment facilities where excess capacity is available.

Nonhazardous wastes would be recycled where feasible. Liquid sanitary waste could be treated in the centralized liquid sanitary waste treatment facility. Solid wastes would be shipped offsite to a commercial disposal facility.

Sensitivity Analysis. The impact of the high case single-shift operation would not be significantly different from that of the base case multiple-shift operation. Liquid TRU waste generation would be unchanged and solid TRU and mixed-TRU waste would increase somewhat. LLW generation would be similar, and hazardous and solid sanitary waste would be unchanged. Liquid sanitary waste generation would decrease slightly. Operating at the low case would decrease liquid TRU, liquid LLW, and liquid sanitary waste. Generation rates would be unchanged for the other waste categories.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies. Pollution prevention and waste minimization would be incorporated in determining the final actions of the Stockpile Stewardship and Management Program at SRS.

4.3.3.11 *Environmental Justice*

As discussed in section 4.14, any impacts to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.3.3.9, which describes public and occupational health impacts from normal operation, shows that potential chemical air emissions and releases are not within the generally accepted threshold of regulatory concern. This information is based on the conservative programmatic assumptions and modeling detailed in appendix E. Any adverse human health or environmental impacts that may occur would affect people living within communities located near SRS. The analysis of the demographic data presented in appendix D for the communities surrounding SRS indicate that if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.4 KANSAS CITY PLANT

Kansas City Plant (KCP) is situated on approximately 57 ha (141 acres) of the 121-ha (300-acre) Bannister Federal Complex located within incorporated city limits, 19 km (11.8 mi) south of the downtown center of Kansas City, MO (figure 4.4–1). Of this area, 49 ha (121 acres) are allocated to DOE, and 8 ha (19.8 acres) are on loan from the General Services Administration. Figure 4.4–2 shows the principal DOE facilities at the Bannister Federal Complex. The plant shares the Bannister Federal Complex site with other Federal agencies: the General Services Administration, the Department of Defense (DOD) Finance and Accounting Service, the Federal Aviation Administration, the National Archives and Records Center, and the Internal Revenue Service, among others. Section 3.2.4 provides a description of the DOE missions and support facilities at KCP.

4.4.1 Description of Alternatives

No Action. KCP would continue to perform the missions described in section 3.2.4.

Stockpile Management Alternatives. The nonnuclear fabrication mission could be consolidated and downsized and remain at KCP. The KCP nonnuclear fabrication mission could also be split up and transferred to SNL, LANL, and LLNL. In the event the nonnuclear fabrication mission was transferred to the laboratories, the DP missions at KCP would be phased out and the facilities turned over to EM for disposition.

Stockpile Stewardship Alternatives. There are no stockpile stewardship alternatives that include KCP.

4.4.2 Affected Environment

The following sections describe the affected environment at KCP for land resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure, radiation and hazardous chemical environment, waste management conditions, and current intersite transportation issues at KCP are described.

4.4.2.1 *Land Resources*

KCP consists of 57 ha (141 acres) and is located within the boundaries of the 121 ha (300 acre) Bannister Federal Complex. The Bannister Federal Complex is located approximately 19 km (12 mi) south of the downtown area of Kansas City, MO. Generalized land uses at the Bannister Federal Complex (including KCP) and in the vicinity are shown in figure 4.4.2.1–1. KCP currently contains approximately 297,000 m^2 (3.2 million ft^2) of floorspace, with approximately 82 percent located within the large Federal office/industrial building that dominates the site. KCP, as well as the remainder of the Bannister Federal Complex, is compactly developed with limited open space.

No residential structures are within the Bannister Federal Complex. The General Services Administration operates a child care center onsite just north of the main DOE building and west of the DOE-controlled parking area.

Land use within a 3.2 km (2 mi) radius of the Bannister Federal Complex is urban. Of this land, 41 percent is residential (containing approximately 14,200 dwelling units), 42 percent is open space (25 percent consists of city-owned recreational lands; the remainder is vacant property), 6 percent is commercial, 6 percent is publicly owned (Federal, state, and local government), and 5 percent is industrial. The closest residence to the Bannister Federal Complex is approximately 6 m (20 ft) away at its northernmost boundary; however, this residence is approximately 165 m (0.10 mi) northwest of the closest DOE-controlled property. A multi-family development west of the Bannister Federal Complex is approximately 125 m (410 ft) away from the nearest DOE-controlled property.

Future city land use plans call for expanding the Indian Creek Greenway through future acquisition of vacant private property, which would increase the amount of permanent open space around the Bannister Federal Complex. There are no prime farmlands on the Bannister Federal Complex. The Bannister Federal Complex does not contain any public recreation facilities. A U.S. Marine Corps baseball diamond and the General Services Administration child care center playground are located at the northwest corner.

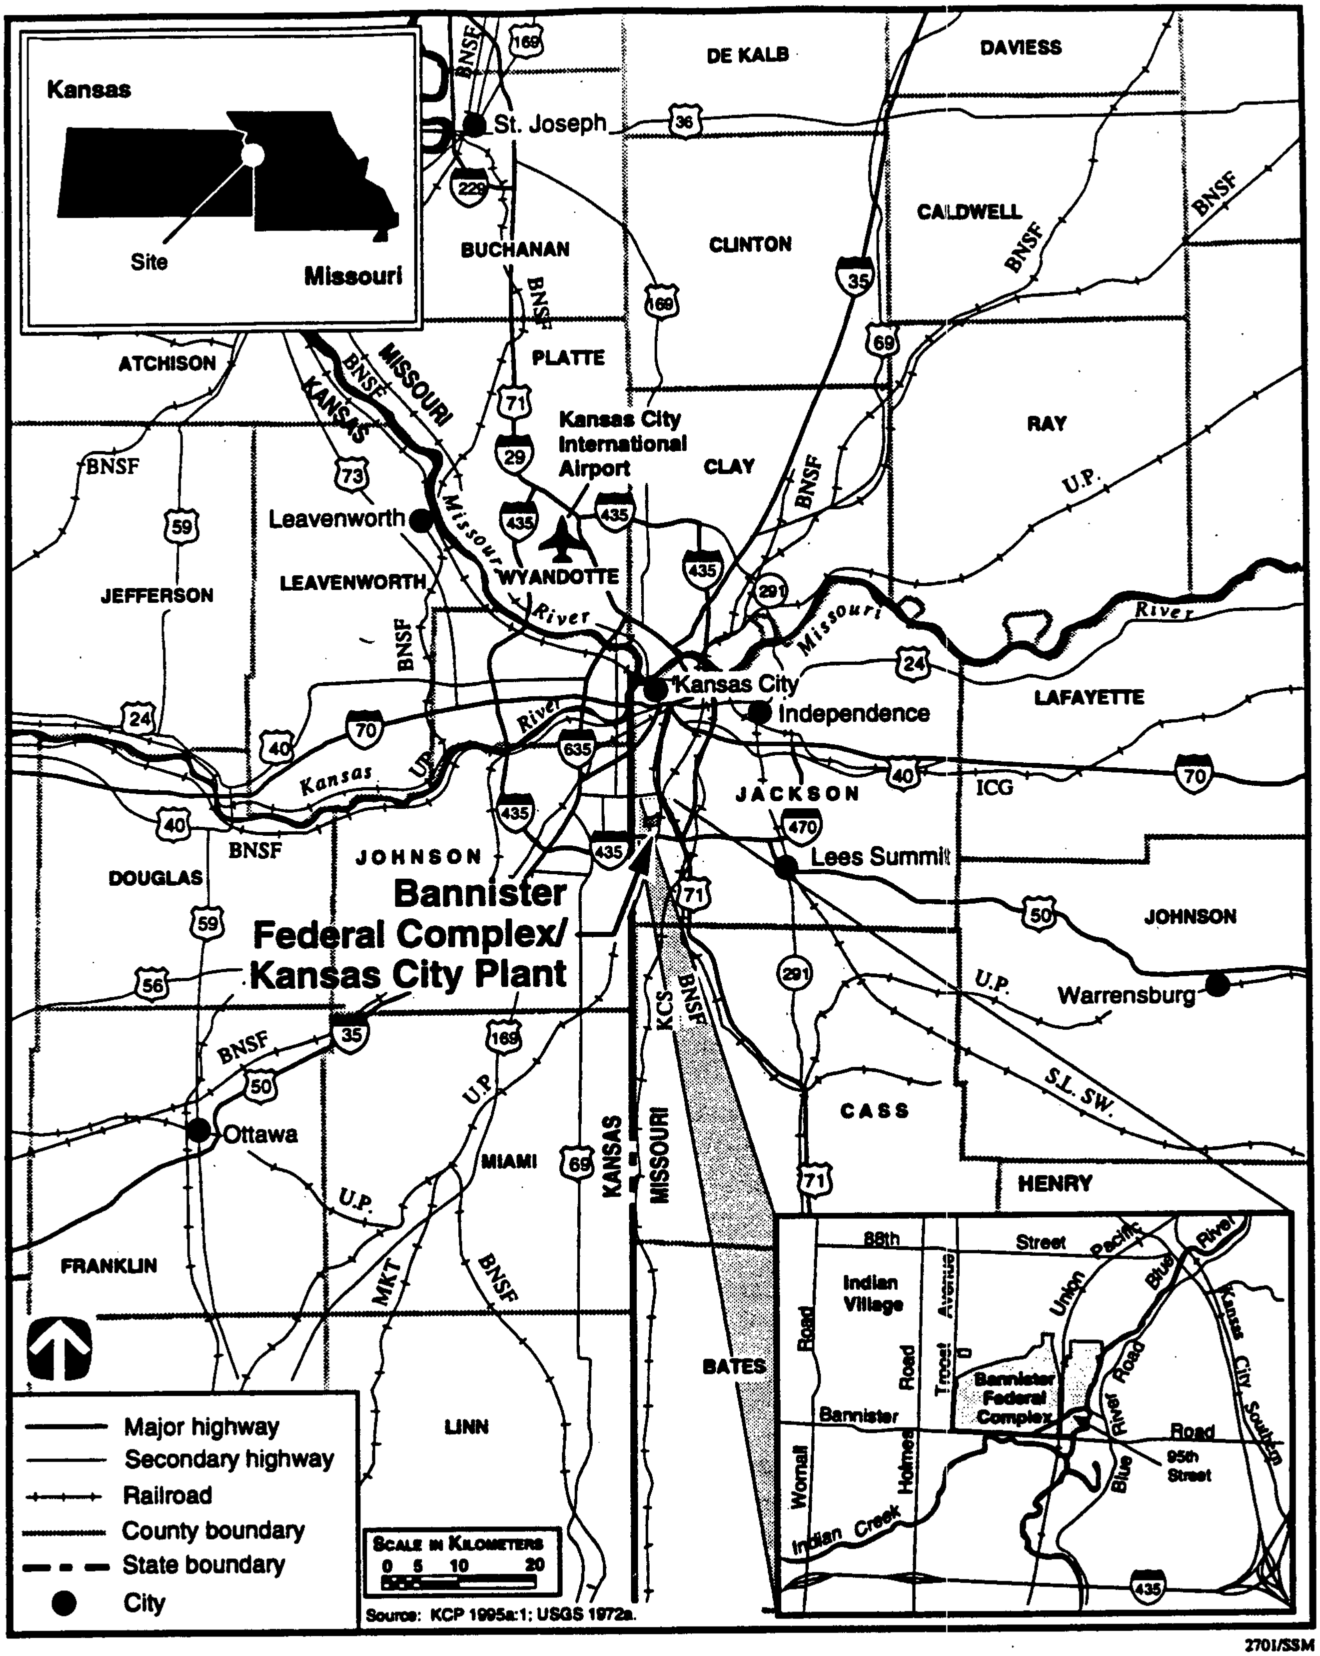

FIGURE 4.4–1.—*Bannister Federal Complex/Kansas City Plant, Missouri, and Region.*

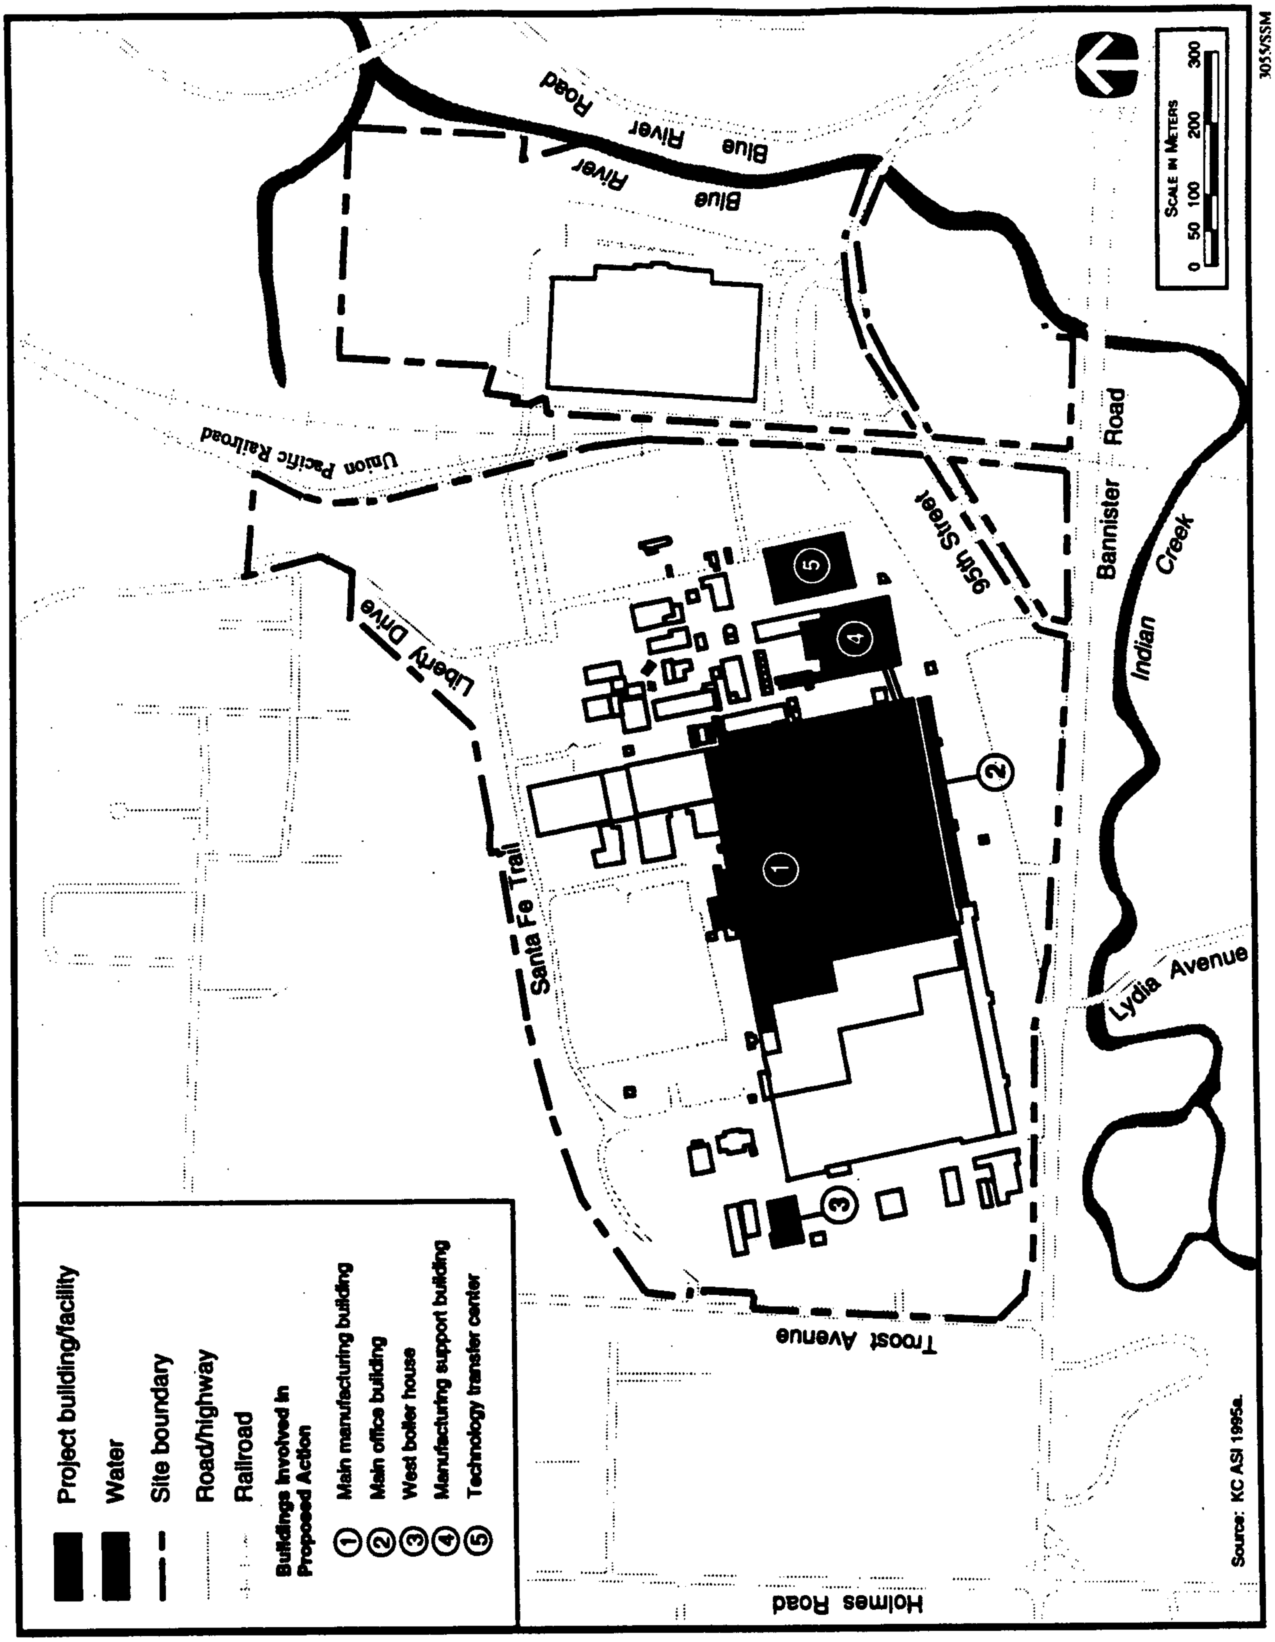

FIGURE 4.4–2.—*Principal Facilities at the Bannister Federal Complex/Kansas City Plant.*

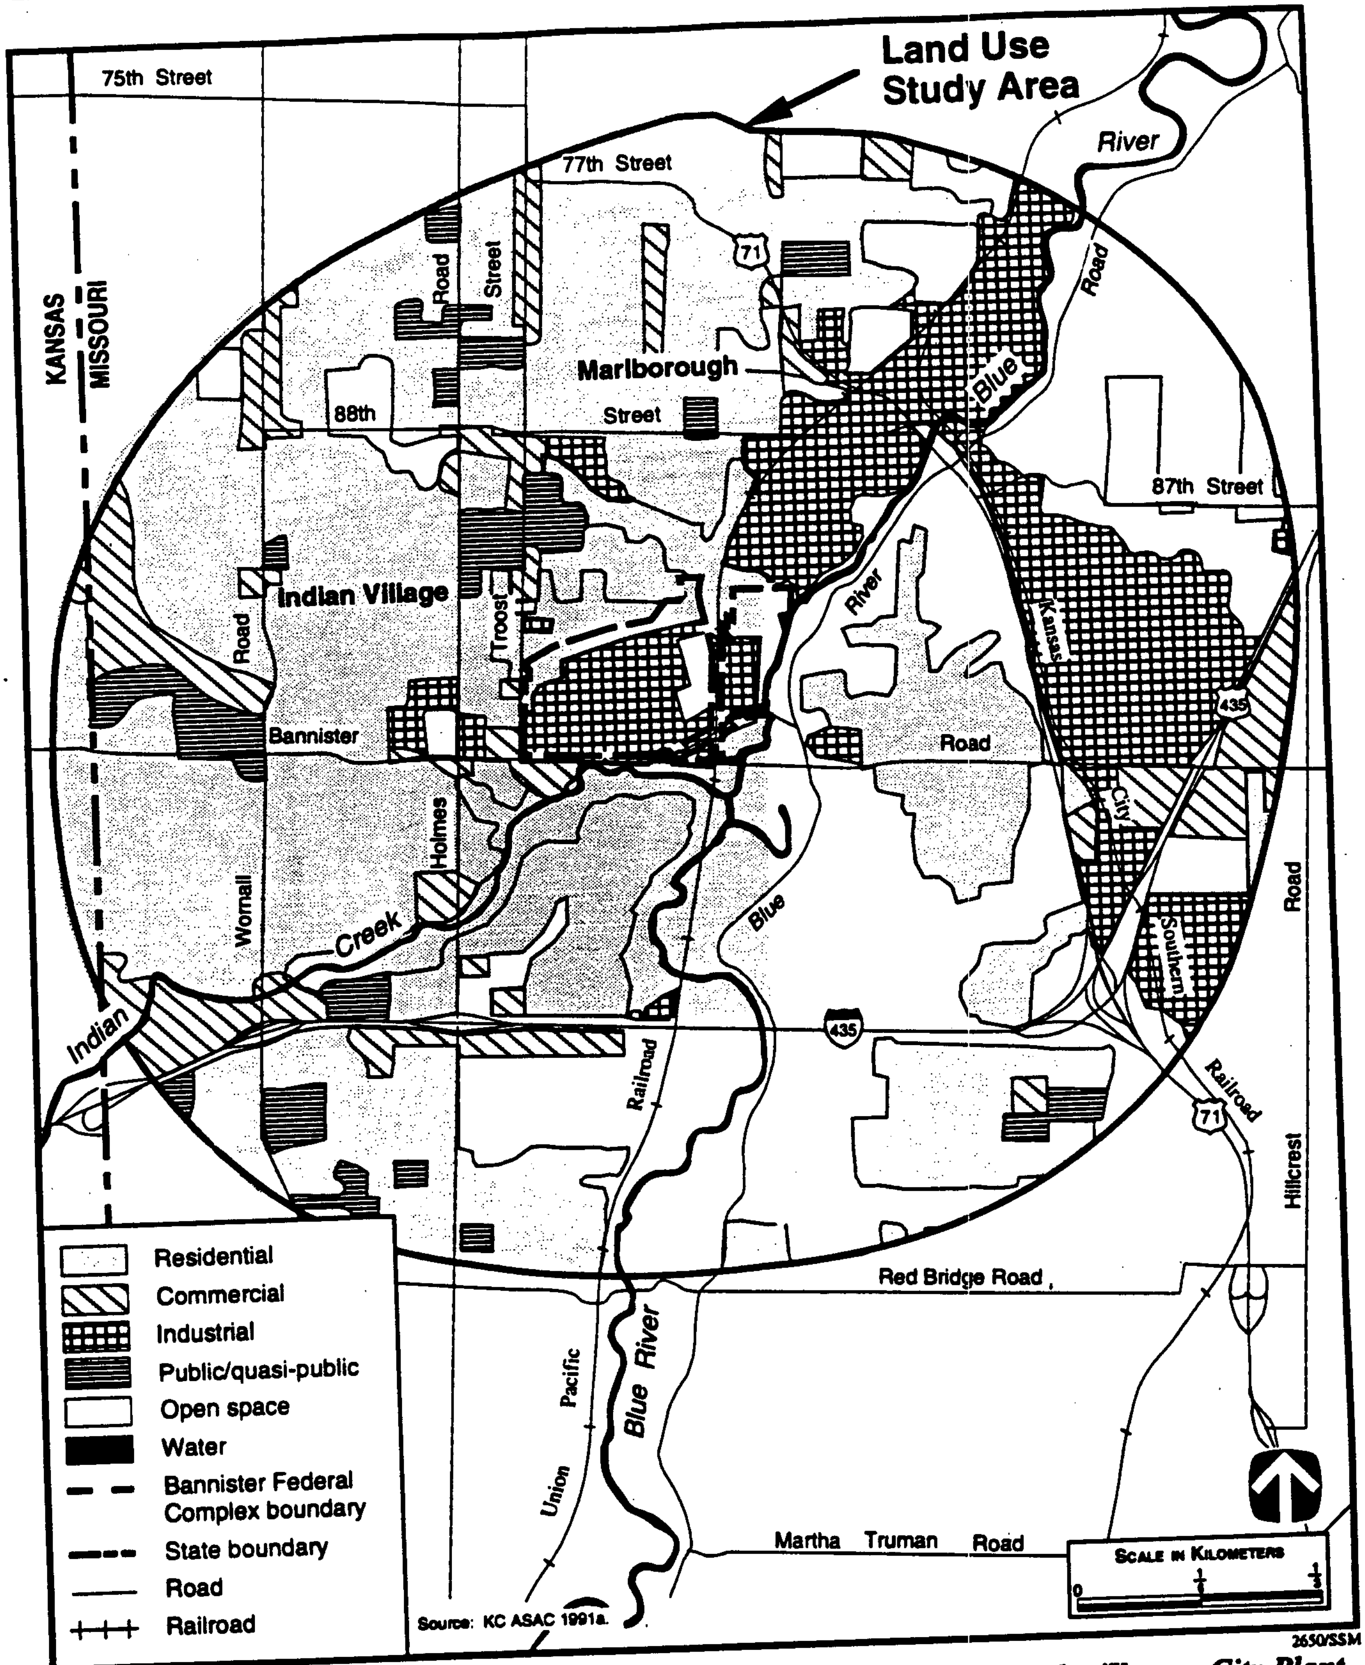

FIGURE 4.4.2.1–1.—*Generalized Land Use at the Bannister Federal Complex/Kansas City Plant and Vicinity.*

4.4.2.2 *Site Infrastructure*

Section 3.2.4 describes the current missions at KCP. To support these missions, an infrastructure exists as shown in table 4.4.2.2–1.

TABLE 4.4.2.2–1.—*Baseline Characteristics for Kansas City Plant*

Characteristics	Current Value

4.4.2.3 *Air Quality*

The following section describes existing air quality, including a review of the meteorology and climatology in the vicinity of KCP. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.4.

Meteorology and Climatology. The climate at the Bannister Federal Complex and in the surrounding region is characterized as humid and continental, with warm summers, moderately cold winters, and moderate annual precipitation. The annual average temperature in the area, as measured at the Kansas City National Weather Service station, is 12.0 °C (53.6 °F); temperatures vary from an average daily minimum of -8.5 °C (16.7 °F) in January to an average daily maximum of 31.5 °C (88.7 °F) in July. Annual average precipitation is 95.6 cm (37.62 in) with most precipitation occurring between April and October. About 51 cm (20.1 in) of snowfall are typically recorded per year. Maximum monthly precipitation measured at the Kansas City National Weather Service station ranged from 6.8 cm (2.66 in) in January to 39.3 cm (15.47 in) in July. The annual average windspeed is approximately 4.8 m/s (10.8 mph) (NOAA 1994a:3).

Ambient Air Quality. The Bannister Federal Complex is located in the Metropolitan Kansas City Intrastate AQCR 94. This AQCR is designated as attainment by the EPA for all criteria pollutants (40 CFR 81.326). The Missouri State ambient air quality standards for criteria pollutants, which are the same as the NAAQS, are listed in appendix table B.3.1–1.

Missouri has been delegated authority by EPA to enforce standards for the hazardous air pollutants regulated under NESHAP. The Missouri Department of Natural Resources uses guidelines for acceptable ambient air levels for air toxic pollutants in evaluating new sources and modifications to sources. The hazardous/toxic air pollutants described in this section are those currently emitted at KCP.

The principal sources of criteria air pollutants are four boilers serving the Bannister Federal Complex. Appendix table B.3.4–1 presents an emissions inventory of these sources. Hazardous/toxic air pollutants are emitted from various process sources at the Bannister Federal Complex. Complex emissions data are summarized in appendix table B.3.4–1.

Ambient air quality conditions at KCP for 1994 are shown in table 4.4.2.3–1. With the exception of the ozone (1-hour) standard and the annual particulate matter standard, ambient air quality concentrations in the Bannister Federal Complex area do not exceed applicable guidelines or regulations. The maximum measured ozone background concentration is approximately 103 percent of the 1-hour standard. The majority of the ozone concentration is attributed to chemical reactions involving vehicular traffic and not emissions from KCP. The maximum measured particulate matter background concentration is approximately 170 percent of the annual standard.

4.4.2.4 *Water Resources*

This section describes the surface and groundwater resources at KCP.

Surface Water. KCP is located near the confluence of the Blue River and Indian Creek (figure 4.4.2.4–1).

TABLE 4.4.2.3–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Kansas City Plant, 1994*

Pollutant	Averaging Time	Most Stringent Regulation or Guideline (μg/m³)	Baseline Concentration (μg/m³)
Criteria Pollutant			
Carbon monoxide	8-hour	10,000[a]	4,872

Source: 40 CFR 50; KC ASI 1995a; MO DNR 1992a.

Individual drainage basins exist for each, but both the Blue River and Indian Creek are included in the Blue River basin. KCP lies on the divide between the two drainage basins, both of which receive surface runoff and cooling water discharge from the plant. Flow in Indian Creek during the summer is primarily effluent from the sewage treatment plant located on Indian Creek upstream of KCP (KC ABA 1986a:II-25). No surface water is withdrawn at KCP. The Kansas City, MO, municipal water supply system provides all drinking and process water for KCP. The water usage at KCP averages approximately 1,934 MLY (511 MGY).

Four NPDES outfalls at KCP, numbered 001 through 004, discharge a combination of stormwater and one-pass cooling water. Outfall 001 discharges to the Blue River and outfalls 002, 003, and 004 discharge into Indian Creek. There are six unpermitted stormwater outfalls at the Federal complex under the

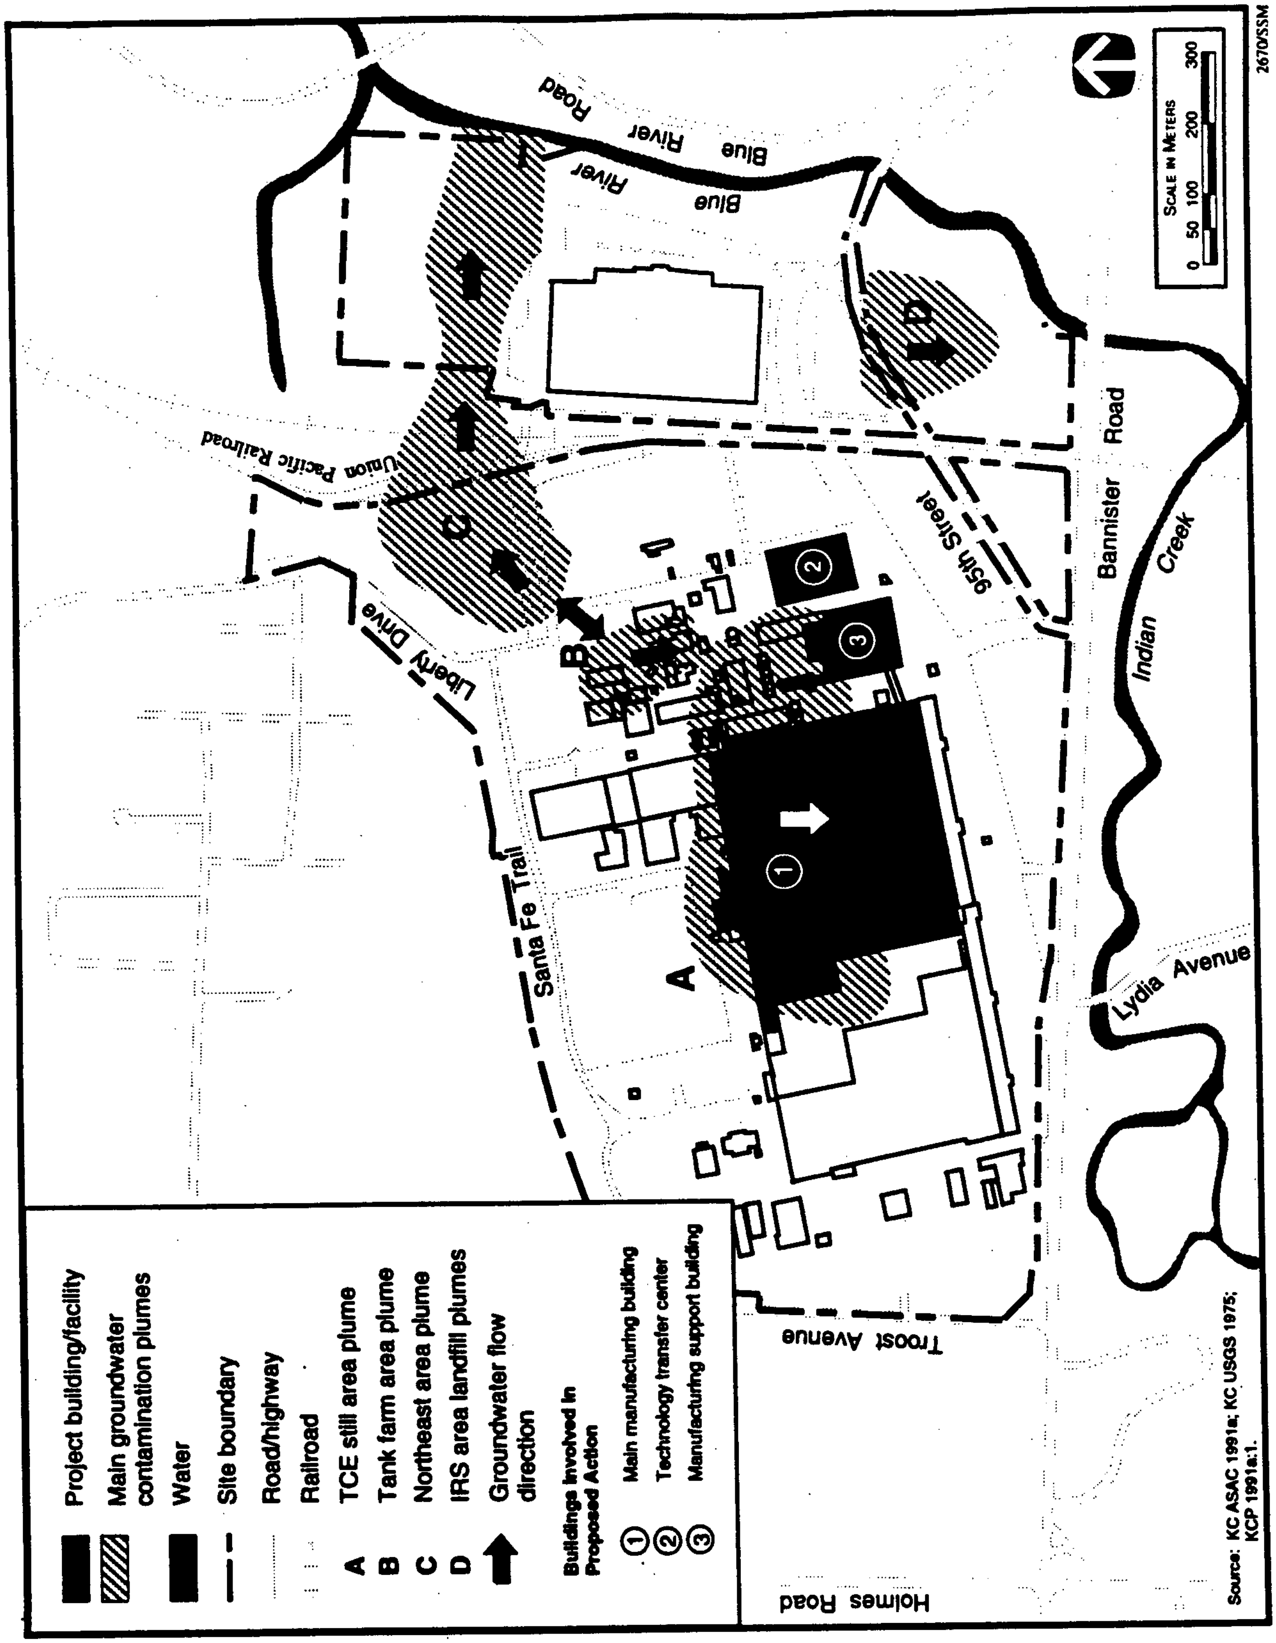

FIGURE 4.4.2.4–1.—*Surface Water Features and Groundwater Contamination Plume Boundaries at Kansas City Plant.*

responsibility of the General Services Administration: two discharge stormwater to the Blue River, and four discharge stormwater from nonindustrial areas of the Bannister Federal Complex to Indian Creek.

Industrial wastewater is pretreated onsite at the 2,080 MLY (550 MGY) capacity Industrial Wastewater Processing Facility. In 1994, KCP discharged approximately 884 MLY (233.5 MGY) to the Industrial Wastewater Processing Facility. Following pretreatment, effluent is monitored and discharged in combination with KCP sanitary wastewater to the Kansas City Municipal Wastewater Treatment Plant. In 1994, sanitary wastewater generation from KCP was estimated at 429 MLY (113.3 MGY).

The quality of the effluent discharged from KCP to the Kansas City Municipal Wastewater Treatment Plant is regulated by a Kansas City, MO, Discharge Permit; city ordinances administered by the Kansas City, MO, Water and Pollution Control Department; and U.S. EPA Pretreatment Standards for the metal-finishing category (40 CFR 433.17). Regulatory compliance is monitored at the Industrial Wastewater Processing Facility. Table 4.4.2.4–1 presents a summary of the parameters monitored, a comparison

TABLE 4.4.2.4–1.—*Combined Sanitary Sewer Effluent Monitoring at Kansas City Plant*

[a] Metal finishing standards are recalculated every 6 months (40 CFR 433). Therefore, four different standards are applied to each parameter. The limits provided are the average of the four standards applicable to KCP during 1993 and 1994.

[b] Limits referenced in the ordinance as generally acceptable as provided in *Missouri Effluent Guidelines for Municipal Control of Industrial Wastes*.

[c] Standard has not been established.

Note: ND - no data; NA - not applicable; (G) - grab sample; (T) - total; (H) - hexavalent.

of the average concentrations discharged between 1993 and 1994 with regulatory standards, and the estimated total quantity of each parameter discharged from KCP to the Municipal Wastewater Treatment Plant, during both 1993 and 1994. As indicated in the table, the estimated quantity of constituents discharged from the plant has remained essentially unchanged or has decreased between 1993 and 1994.

As part of KCP's Waste Minimization and Pollution Prevention Program, a design was prepared for an Organics Treatment System. Implementation of this system began in September 1995 and will consist of new piping to route all chlorinated solvent and total toxic organics-contaminated groundwater at KCP to a new organics treatment facility, which will treat the organics prior to discharge to the Kansas City, MO, publicly owned treatment works.

KCP lies within the 500-year floodplain of the Blue River and Indian Creek; however, flood control works, providing KCP with protection against a 500-year flood, are now completed.

Surface Water Quality. Water quality in Indian Creek and Blue River is affected by effluent introduced upstream of KCP from the Leawood, KS, Sewage Treatment Plant on Indian Creek, and runoff from the urbanized Blue River watershed. Water quality in Blue River and Indian Creek is monitored at six locations. KCP's four NPDES-permitted outfalls are monitored on a monthly basis. Water quality monitoring results during 1994 for the Blue River and Indian Creek near KCP are presented in tables 4.4.2.4–2 and 4.4.2.4–3. Drinking water standards are provided for comparison purposes.

The maximum concentrations of cyanide downstream of KCP outfalls on Indian Creek and the Blue River exceed Missouri chronic water quality standards. Upstream of KCP discharges, cyanide concentrations on the same date were similarly elevated and are noted as the source of the elevated readings. The maximum concentrations for aluminum, nitrate, total dissolved solids, and iron were above Federal drinking water regulations in both the Blue River and Indian Creek. Chloride was also above Federal drinking water regulations in Indian Creek. Similarly, upstream concentrations were also elevated for each of these parameters on corresponding dates, indicating the source of these elevated levels is upstream of KCP.

NPDES-permitted outfall 001, which discharges to the Blue River, has a flow of approximately 949 MLY (250 MGY). In the past, contaminated groundwater infiltrated this outfall, resulting in the detection of 1,2-dichloroethylene at an average of 4 micrograms (μg)/L during 1992. A groundwater interceptor drain, referred to as the outfall 001 interceptor system, was installed beneath the portion of outfall 001 into which contaminated groundwater migrated. Groundwater collected in this system is pumped to the KCP Groundwater Treatment Unit which treats groundwater flows from other areas of the plant. Since installation of the outfall 001 interceptor system, 1,2-dichloroethylene has not been detected in outfall 001.

All average effluent concentrations were within NPDES limits in 1994. Past exceedances for PCB led to the reconstruction of outfall 002. Approximately 10,703 m^3 (14,000 yd^3) of PCB-contaminated soil were removed from a former outfall location where the present-day outfall pipe traverses. Zinc concentrations exceeded notification levels three times in 1994, although concentrations in the receiving water bodies remained within applicable standards (table 4.4.2.4–1). It is important to note that exceeding a notification level is not considered a permit violation (KC ASAC 1991a:9). A zinc source report was prepared and issued in March 1991. This report associated elevated levels of zinc with rainwater runoff from vehicle parking areas and from galvanized equipment and fencing on roofs and grounds of the facility (KCP 1993a:1).

Surface Water Rights and Permits. KCP facilities do not withdraw surface water for use. The Kansas City, MO, municipal water supply system provides all drinking and process water for KCP. All industrial wastewater is pretreated on site and then discharged in combination with KCP sanitary wastewater to the Kansas City Municipal Wastewater Treatment Plant.

Groundwater. KCP lies on alluvium, consisting of a complex mix of continuous and discontinuous layers/lenses of clayey silt, sand, and gravel. Two permeable water-bearing zones are present within the alluvium: an upper sand-clay-silt zone and a basal gravel zone with a sand-silt-clay matrix. The two

Source: KCP 1995a:1.

zones are separated in certain areas by a layer of olive to blue-green clayey silt. The two permeable water-bearing zones and the intervening clayey silt all transmit water and constitute the alluvium aquifer. The alluvial aquifer is considered a Class II aquifer having current and potential sources of drinking water and water having other beneficial uses. There are, however, no current uses of groundwater associated with the aquifer underlying KCP.

Groundwater Quality. Background groundwater quality in the alluvial aquifer is considered poor due to high iron and manganese concentrations. Additionally, three separate groundwater contaminant plumes have been identified within the KCP boundaries (figure 4.4.2.4–1). These contaminant plumes are due to past activities at several sites including the Trichloroethylene Still Area, the Underground Tank Farm, and the Northeast Area. In addition, an abandoned landfill south of the Internal Revenue Service parking lot is a contributing source of contamination to the groundwater. This landfill is not under the authority or control of DOE.

The primary contaminants present in the groundwater are trichloroethylene and its degradation products: 1,2-dichloroethylene and vinyl chloride. The contamination exists solely in the alluvial aquifer. The 1994 monitoring test results for the two plumes, referred to as the Blue River and Indian Creek groundwater flow system plumes, are summarized in table 4.4.2.4–4. Remediation activities include treating an average of approximately 151,000 L (39,900 gal) of solvent-contaminated groundwater per day (KCP 1993a:1).

Groundwater Availability, Use, and Rights. No groundwater is withdrawn for water supply use at KCP. Water is supplied to KCP from the city of Kansas City, MO, potable water distribution system, which currently supplies its users with approximately 158,775 MLY (41,948 MGY). This water is obtained from the Missouri River and from a field of wells in the Missouri River alluvium 24 km (15 mi) north of the plant (KCP 1991a:2). Water use at KCP averages about 1,934.5 MLY (511 MGY). The capacity of the KCP system is approximately 44,165 MLY (11,668 MGY). KCP is able to purchase unlimited amounts of water from Kansas City, MO. Missouri operates under the Riparian Doctrine where landowners have unrestricted rights to use water contained on their land.

4.4.2.5 *Geology and Soils*

Geology. KCP is located on the Central Stable Interior Platform of the Great Plains Province and rests on the southeastern flank of the Forest City Basin as it rises toward the Ozark Uplift. The plant lies on approximately 14 m (46 ft) of alluvium of the Blue River floodplain, which is bordered by outcrops of Pennsylvanian limestones and shales (DOE 1993j:4-29).

Source: KCP 1995a:1.

The Kansas City area is seismically stable and located in seismic Zone 2 (figure A.1-1). Since 1811, Kansas has experienced 13 earthquakes of intensity V or above on the modified Mercalli scale (approximately 4.5 on the Richter scale). Missouri has experienced 45 earthquakes with intensity V or above during the same period (DOC 1982a:191,195,198, 47a, 48a).

Several large earthquakes greater than magnitude 8 occurred in 1811 and 1812 along the New Madrid Fault Zone, 563 km (350 mi) southeast of Kansas City. The Kansas City area was affected by modified Mercalli intensity values estimated at VII or less during these events (Nuttli 1990a:2,3). No geological hazards are known in the immediate area of KCP. The plant does not lie within areas of subsidence, landsliding, active volcanism, rapid erosion, or sedimentation (DOE 1993j:4-29).

Soils. KCP is underlain by urban bottomland and udifluvents. Urban bottomland consists of areas where more than 85 percent of the surface is covered by concrete, asphalt, buildings, or other impervious material. Udifluvents consist of nearly level fill areas located adjacent to the Blue River. These soils present no erosion hazard or shrink-swell problems. No agricultural or prime farmland soils are present (DOE 1993j:4-29).

4.4.2.6 *Biotic Resources*

The following section describes biotic resources at KCP including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species.

Terrestrial Resources. KCP is located in an area of mixed residential and industrial development in a region of former oak-hickory forest. The plant itself occupies 57 ha (141 acres) of the 121-ha (299-acre) Bannister Federal Complex site. The site is almost exclusively occupied by buildings, parking lots, lawns, and lawns with ornamental trees. The Bannister Federal Complex is bordered on the north by a bluff supporting a relatively undisturbed oak-hickory woodland designated as Legacy Park. Riparian forests, dominated by cottonwoods (*Populus spp.*) and willow (*Salix spp.*), and disturbed by human activities, border the Blue River and Indian Creek east and south of the complex (KC DOE 1989a:3-21).

Wildlife in the KCP area is dominated by human-tolerant species (KC DOE 1989a:3-21). Animal species found on the site would be limited to species such as American robins (*Turdus migratorius*), house sparrows (*Passer domesticus*), and squirrels (*Sciuridae*). A more diversified fauna would be expected within Legacy Park and the riparian forests bordering the Blue River and Indian Creek. With the exception of squirrels, no game species would be expected within the Bannister Federal Complex. While raptors could occasionally fly over the site, none would be expected to nest or forage there. Due to the developed nature of the site, carnivores would not be expected.

Wetlands. No wetlands exist within DOE-controlled areas in the Bannister Federal Complex. An area of potential wetlands supporting a cover of narrow-leafed cattail (*Typha augustifolia*) and a mixture of bulrushes (*Scirpus spp.*) and sedges (*Carex spp.*) is located in a low area north of the Internal Revenue Service building near the northeastern corner of the Bannister Federal Complex (KC DOE 1990a:13).

Aquatic Resources. No aquatic habitats exist within the Bannister Federal Complex. Beyond the KCP boundary, aquatic habitats associated with the Blue River and Indian Creek receive discharges of stormwater and one-pass cooling water generated on the Bannister Federal Complex. Four fish kills have occurred in the Blue River in the 5 years preceding 1992; however, the Missouri Department of Conservation has not attributed any of those kills to activities conducted at KCP (KCP 1991a:3). A 1980 census of fish in the Blue River indicated 29 species were present including gar (*Lepisosteus spp.*), shad (*Clupeidae*), common carp (*Cyprinus carpio*), minnows (*Cyprinidae*), suckers (*Catostomidae*), catfish (*Ictaluridae*), bass (*Centrarchidae*), sunfish (*Lepomis spp.*), and perch (*Percidae*) (KC DOE 1989a:3-19,3-21).

Threatened and Endangered Species. The USFWS has indicated that the bald eagle (*Haliaeetus leucocephalus*) is the only Federal-protected, threatened, or endangered species present in the vicinity of the Bannister Federal Complex (KC DOE 1990a:13).

Because of the nearly complete development of the Bannister Federal Complex, suitable habitat for the bald eagle does not exist. The Missouri Department of Conservation's records do not indicate that any sensitive species or communities exist within the Bannister Federal Complex or the surrounding area (KC DOE 1989a:3-22). No critical habitat for threatened or endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on KCP.

4.4.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. The prehistoric chronology of the KCP area consists of five broad time periods: Paleo-Indian (12,000 to 8,000 B.C.), Dalton (8,000 to 7,000 B.C.), Archaic (7,000 to 1,000 B.C.), Woodland (1,000 B.C. to A.D. 900), and Mississippian (A.D. 900 to 1700). Site types that may exist in the area include villages, campsites, limited-activity sites, and burial mounds. Two prehistoric sites and a multicomponent site have been previously recorded along the terraces of the Blue River. All of the KCP area has been either developed or disturbed, mainly as a result of flood protection construction. No surveys have been conducted at KCP. However, one cultural resources survey was conducted on areas adjacent to KCP and no prehistoric resources were identified.

Historic Resources. The history of the KCP region has been previously documented. The main building was built in 1942 for the manufacture of Pratt & Whitney aircraft engines for the U.S. Navy. After World War II, production ceased, and the plant was declared excess. The Atomic Energy Commission began production at the plant in 1949. Some of the facilities at KCP lack architectural integrity, are not representative of a particular style, and are not considered contributing features to the broad themes of World War II defense production, the Manhattan Project, or initial nuclear production. Consequently, these facilities are not likely to be considered eligible for the NRHP. However, some of the facilities at KCP may be NRHP eligible based on their association with the Cold War.

Native American Resources. Three Native American groups occupied or traversed the KCP area: the Osage, the Missouri, and the Kansas. The Great and Little Osage Indians occupied the region when French explorers and trappers arrived in the early 1700s. The Missouri Indians occupied the area along the Missouri River between the Grand and Chariton Rivers in central Missouri. The Kansas moved along the Missouri River from St. Louis toward St. Joseph, MO, from the late 1600s to around 1800. By 1827, they were living along the Kansas River in northern Kansas. Native American resources in the KCP area may include remains of villages, trails, springs, vision quest sites, and burial sites. However, most of the historic Indian villages were not located in the KCP area, but south on the Osage River or north and east along the Missouri River.

Paleontological Resources. KCP is located on alluvium from the Blue River floodplain, which is bordered by outcrops of Pennsylvanian limestones and shale. Some fossils may exist in the limestones and shale.

4.4.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at KCP include employment, regional economy, population, housing, and public finance. Statistics for employment and regional economy are presented for the regional economic area that encompasses 49 counties surrounding KCP in Kansas and Missouri. Population, housing, and public finance statistics are presented for the ROI, a four-county area where 93 percent of the KCP employees lived in 1991. The ROI includes Cass (14 percent) and Jackson (60 percent) Counties in Missouri and Wyandotte (2 percent) and Johnson (17 percent) Counties in Kansas. Figure 4.4.2.8–1 presents a map of the counties and selected cities composing the KCP regional economic area and ROI. Supporting data are presented in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the KCP regional economic area are summarized in figure 4.4.2.8–2. The civilian labor force in the regional economic area grew 13 percent between 1980 and 1990 (1.3 percent annual growth). Total regional employment numbered 1,160,522 persons in 1994. The unemployment rate in the region was 4.9 percent, comparable to the 5.3 and 4.9 percent unemployment rates in Kansas and Missouri, respectively. Per capita income in the region was $19,629 in

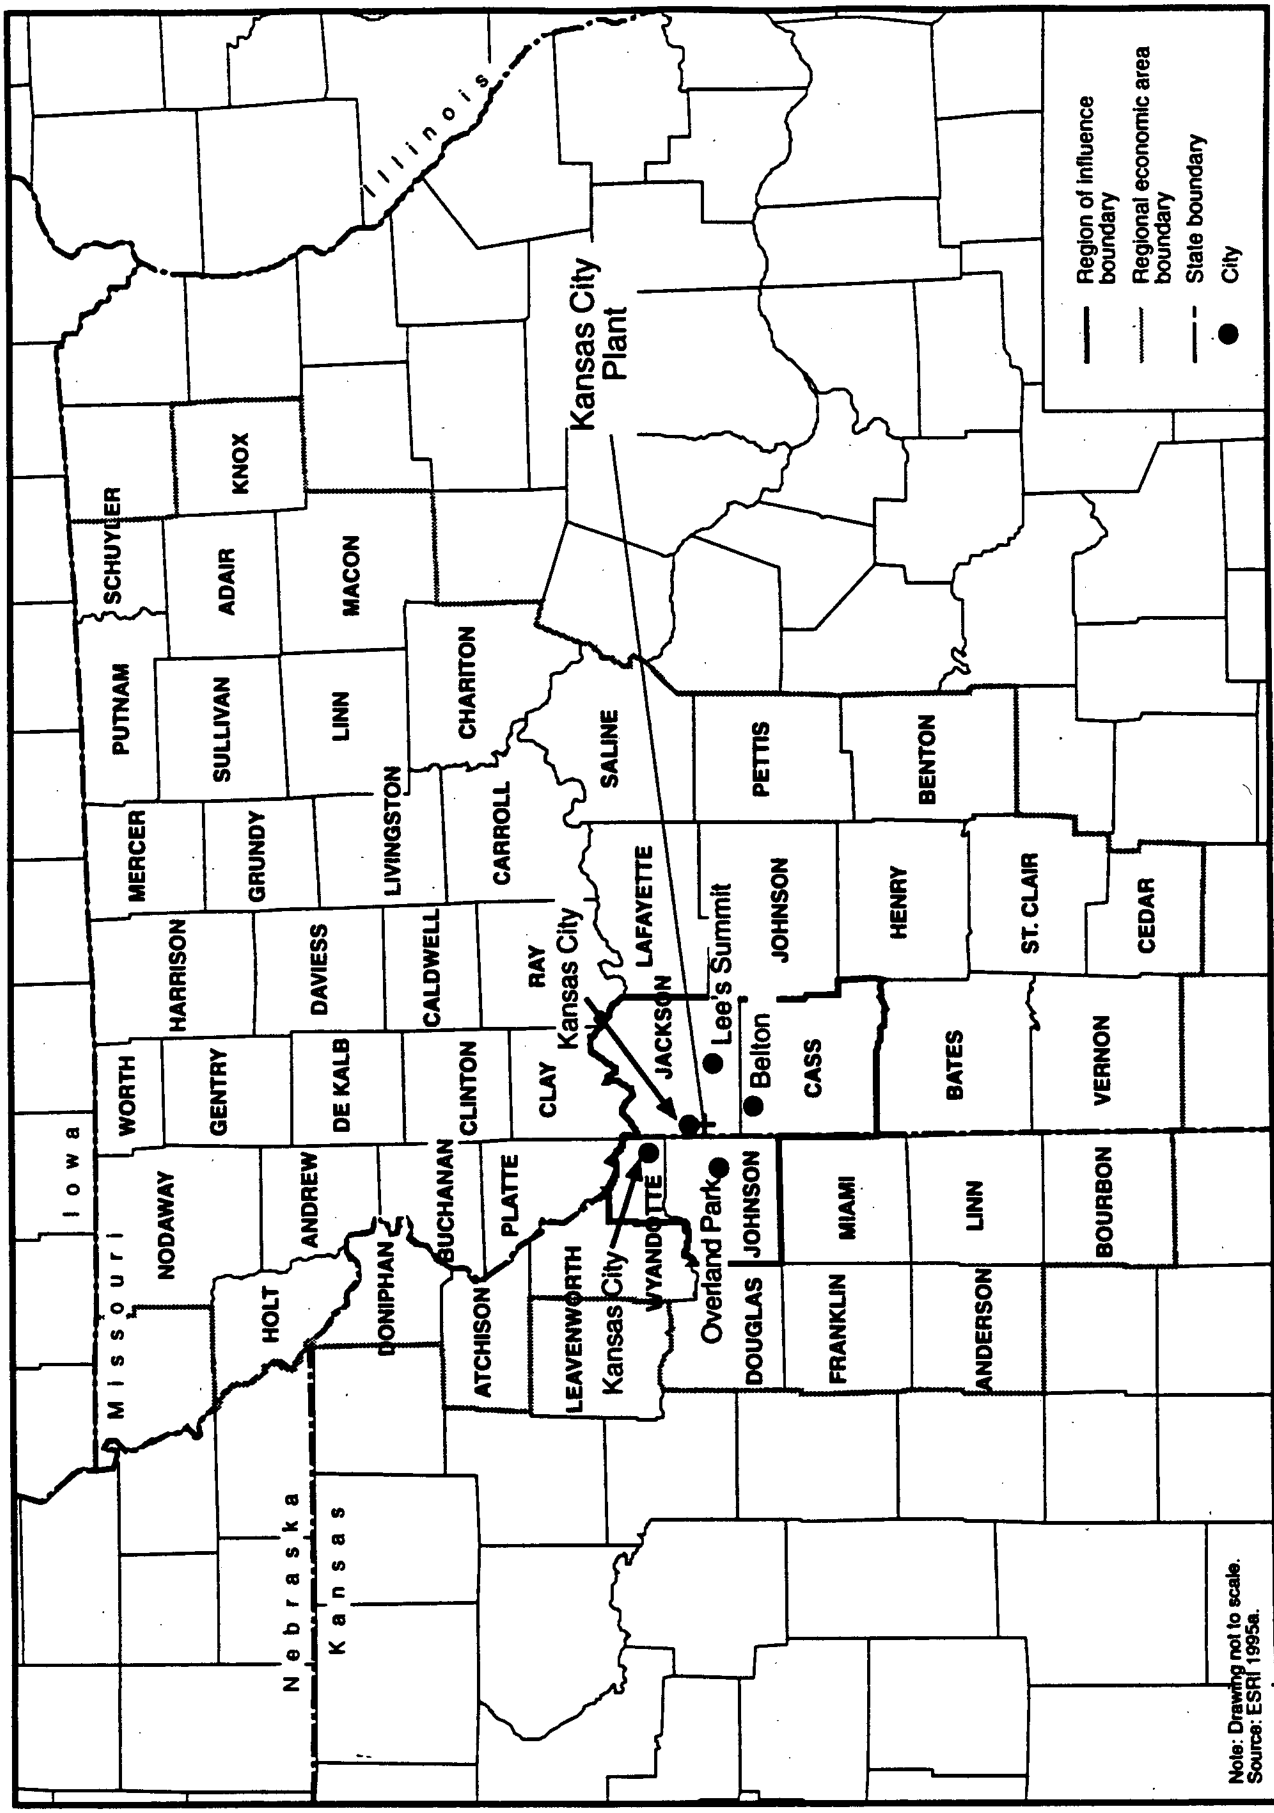

FIGURE 4.4.2.8–1.—*Regional Economic Area and Region of Influence for Kansas City Plant.*

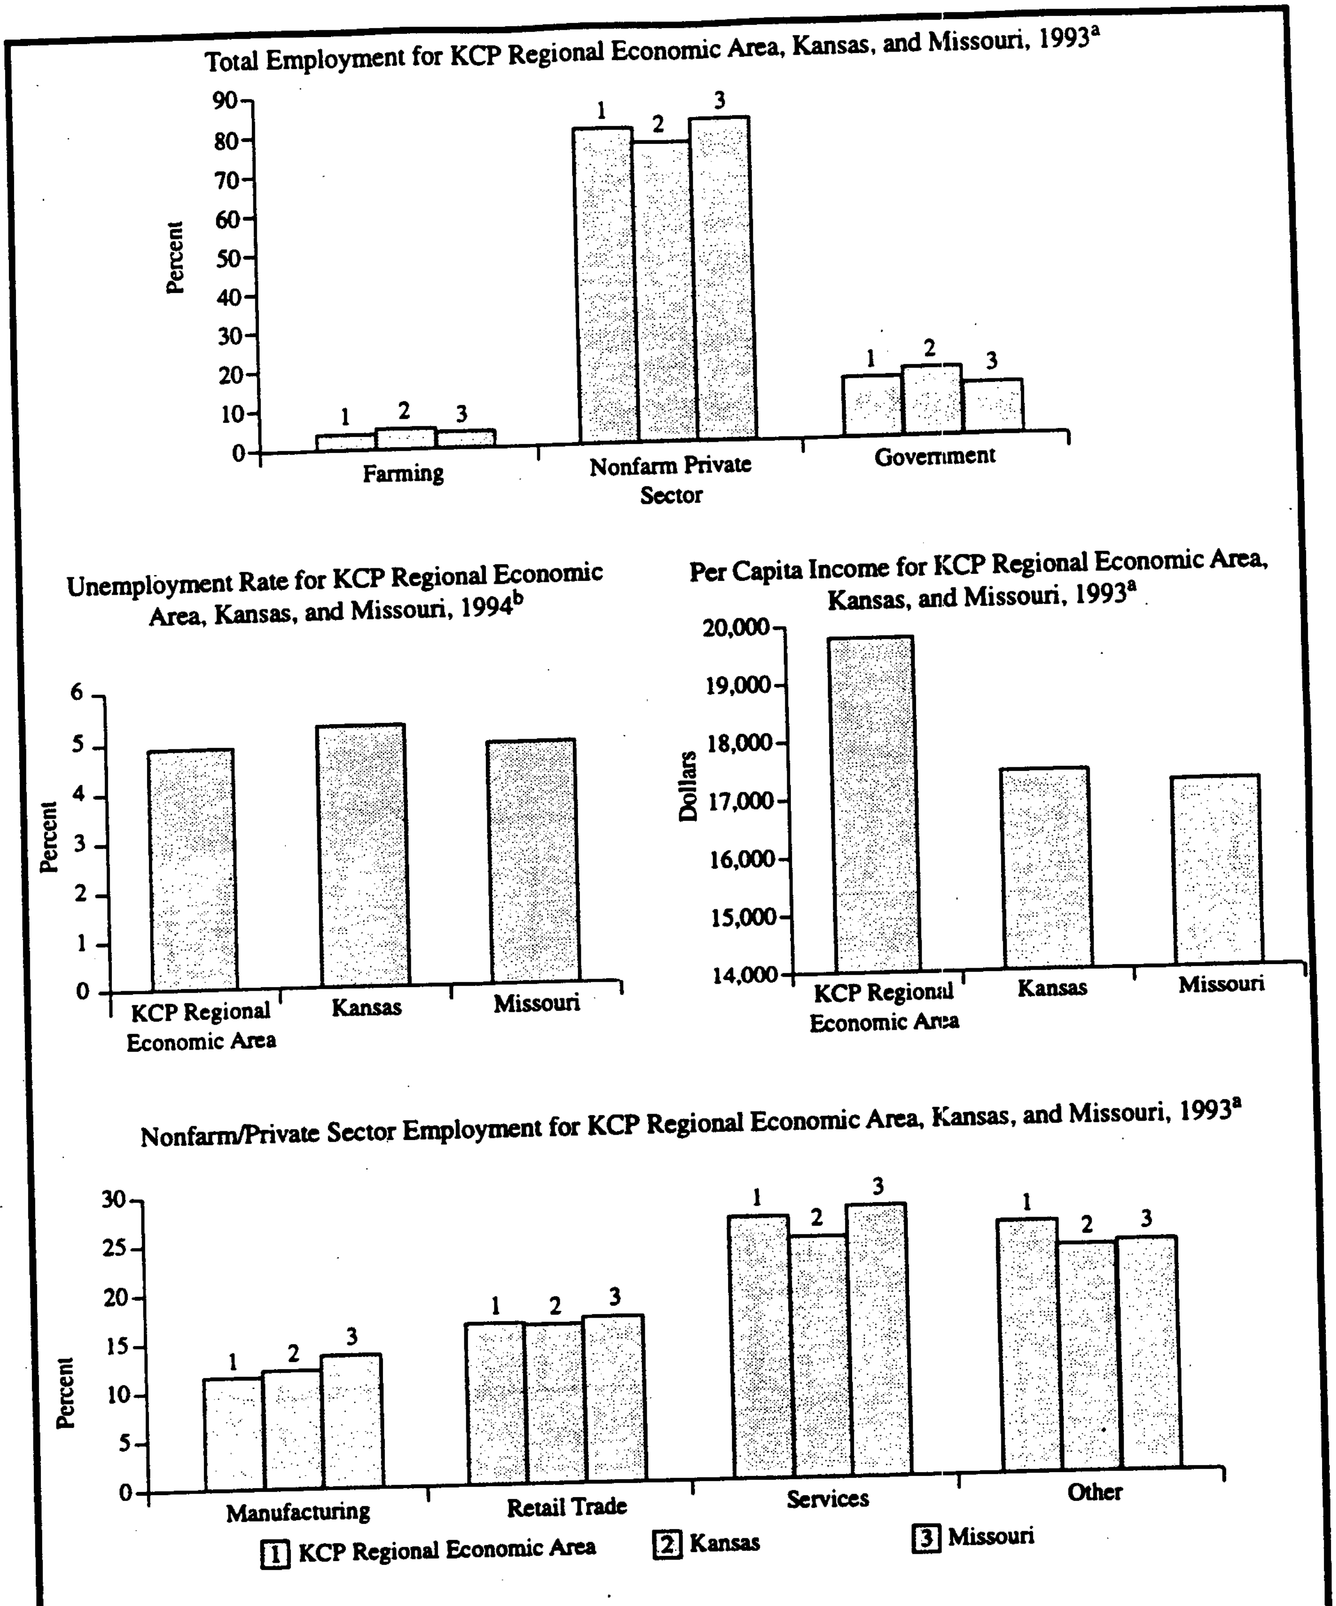

[a] DOC 1995a.
[b] DOL 1995a.

FIGURE 4.4.2.8–2.—*Economy for the Kansas City Plant Regional Economic Area, Kansas, and Missouri.*

1993. The 1993 state per capita income was $17,213 in Missouri and $17,440 in Kansas.

As shown in figure 4.4.2.8–2, Kansas, Missouri, and the regional economic area have similar employment patterns. The service sector accounts for the largest share of total employment in both Kansas and Missouri (25 percent and 28 percent, respectively) and in the KCP region (27 percent).

Population and Housing. The ROI population, which totalled 1,235,369 in 1992, increased by about 10 percent (0.8 percent annually) between 1980 and 1992. This increase significantly exceeded the population growth rate for Kansas and Missouri (approximately 0.5 percent annually) during the same period. Within the ROI, the Cass County population increased by a total of 39 percent (3 percent annually), while the population in Wyandotte County fell by approximately 8 percent during the same period.

The increases in the number of housing units averaged approximately 1 percent annually in the ROI between 1980 and 1990, when the total reached 504,197. During this period however, the housing stock in Johnson County expanded by about 40 percent, an increase of almost 4 percent annually. In 1990, the homeowner vacancy rates averaged 3 percent in the ROI and rental vacancies averaged 12 percent. Population and housing statistics for the ROI are summarized in figure 4.4.2.8–3.

Public Finance. Financial characteristics of the local jurisdictions in the KCP ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure fund categories for counties, cities, and school districts are presented in appendix tables D.2.3–4 and D.2.3–5. Figure 4.4.2.8–4 summarizes local governments' revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.4.2.8–4. All jurisdictions assessed had positive fund balances.

4.4.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at KCP. Also included are discussions of health effects studies, a brief accident history, and emergency preparedness considerations.

Radiation Environment. Major sources of background radiation exposure to individuals (public and workers) in the vicinity of KCP are shown in table 4.4.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. The total dose to the population changes as population size changes. There are no releases of radioactive material at KCP (KC ASAC 1991a:33); therefore, background radiation doses are unrelated to KCP operations.

TABLE 4.4.2.9–1.—*Sources of Radiation Exposure to Individuals in the Vicinity, Unrelated to Kansas City Plant Operations*

Source	Committed Effective Dose Equivalent (mrem/yr)
Natural Background Radiation	
Cosmic and external terrestrial radiation[a]	57
Internal terrestrial radiation[b]	39
Radon in homes[b] (inhaled)	200
Other Background Radiation[b]	
Diagnostic x rays and nuclear medicine	53
Weapons test fallout	<1
Air travel	1
Consumer and industrial products	10
Total	361

[a] Derived from information given in EPA 1981b.
[b] NCRP 1987a. Value for radon is an average for the United States.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which

FIGURE 4.4.2.8–4.—*Local Government Public Finance for the Kansas City Plant Region of Influence* **[Page 2 of 2].**

may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in sections 4.4.2.3 and 4.4.2.4.

Adverse health impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and to achieve compliance with permit requirements. The effectiveness of these controls is verified through the use of monitoring information and inspection of mitigation measures. Health impacts to the public may occur during normal operation at KCP via inhalation of air containing hazardous chemicals released to the atmosphere by KCP operations. Risks to public health from other possible pathways such as ingestion of contaminated drinking water or direct exposure are low relative to the inhalation pathway.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.4.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. These concentrations are in compliance with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to KCP workers during normal operation may include inhaling the workplace atmosphere, drinking KCP potable water, and possible other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. KCP workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm. Therefore, worker health conditions at KCP are expected to be substantially better than required by standards.

Health Effects Studies. No known epidemiological studies have been conducted in the surrounding communities to date. Karches et al., conducted a health hazard evaluation of the plant that manufactured nonnuclear hardware for weapons systems (NIOSH 1972a). The survey revealed concentrations of toluene-diisocyanate that exceeded the ceiling standard in mixing and molding operations and levels of methyl-ethyl-ketone used in cleaning operations that exceeded the excursion limits. Employee complaints include respiratory symptoms and recurrent dermatitis from epoxy resins. For information on DOE's Epidemiological Surveillance Program at KCP, refer to appendix section E.4.4.

Accident History. A review of recent KCP annual environmental and accident reports indicates that there have been no significant adverse impacts to workers, the public, or the environment. This review was performed to provide an indication of the site's accident history.

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for most accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with emergency planning, preparedness, and response. The KCP Emergency Preparedness Plan is designed to minimize or mitigate the impact of any emergency upon the health and safety of employees and the public.

4.4.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and ongoing waste management activities at KCP. A more detailed discussion of the ongoing waste management activities is provided in appendix section H.2.3.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operations at KCP. DOE is engaged in several activities to bring its operations into full regulatory compliance. These activities are set forth in negotiated agreements that contain schedules for achieving compliance with applicable requirements, and financial penalties for nonachievement of agreed upon milestones. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

KCP does not dispose of waste onsite, although onsite disposal, and leaks and discharges have occurred in the past. On March 6, 1989, EPA requested that DOE enter into a RCRA Section 3008(h) Administrative Order of Consent. On June 23, 1989, DOE and EPA Region VII signed the order. The provisions of the order require that DOE conduct all assessment and remediation activities regulated under the order in accordance with approved environmental restoration remediation schedules.

KCP manages four broad waste categories: low-level, mixed, hazardous, and nonhazardous. A discussion of the waste management activities associated with each of these categories follows.

Low-Level Waste. KCP generates small quantities of LLW (<1 m^3) (KCP 1995a:1). Activities that generate LLW are the assembly, disassembly, and testing of irradiated components, scheduled replacement of tritium exit signs, disposal of x-ray sources, and small amounts of contaminated cleanup towels, disposable gloves, and packing materials. Periodically, the liquid LLW (≤1 gal) is solidified and mixed into concrete or plaster of Paris for final handling and disposal.

The solid LLW (≤1 m^3) is accumulated and stored in one controlled access facility used to store both LLW and mixed waste. LLW is stored onsite temporarily using DOT-approved containers until sufficient quantities accumulate to warrant shipment to a DOE disposal facility.

Mixed Low-Level Waste. Through process changes that have been made, KCP no longer routinely generates mixed waste. However, the potential exists for the generation of mixed waste from shielded equipment sources and future clean-up debris. Any KCP mixed waste generated in the future would be stored with LLW in a controlled access, RCRA-permitted storage facility pending the contract award to an offsite commercial RCRA-permitted mixed waste treatment and disposal facility. Once a contract is awarded, the mixed LLW would be transported to the commercial facility for treatment and disposal.

Hazardous Waste. In 1994, KCP generated 130 m^3 (34,340 gal) of RCRA-regulated and 80 m^3 (21,130 gal) of TSCA-regulated liquid wastes. In addition, 175 m^3 (229 yd^3) of RCRA-regulated and 500 m^3 (654 yd^3) of TSCA-regulated solid wastes were also generated (KCP 1995a:1). Hazardous waste is generated by a number of activities at KCP and consists of wastes such as acidic and alkaline liquids, solvents, oils, and coolants. Processes such as plating, etching, electronic assembly, metals and plastics machining and forming, and wastewater treatment are the principal generators. Waste stream residues generated at KCP that are not reclaimed, treated onsite at the Industrial Wastewater Pretreatment Facility, or recycled, are manifested and shipped under contract with DOT-certified transporters to RCRA-permitted offsite treatment and disposal facilities.

Hazardous wastes are managed in compliance with RCRA requirements as delineated in the Operating Permit issued by the Missouri Department of Natural Resources under the provisions of 40 CFR 270-272. KCP currently operates 10 RCRA interim status waste storage areas for containerized nonradioactive hazardous wastes, and 6 bulk storage tanks for nonradioactive hazardous wastes. These facilities are for temporary storage of wastes prior to disposal using offsite RCRA-permitted commercial facilities. The container storage and tank storage facilities have total design capacities of 167 m^3 (44,000 gal) for liquid and 2,350 m^3 (3,070 yd^3) for solid hazardous/toxic wastes (KCP 1993a:1).

The KCP Environmental Restoration Program serves to identify the nature and extent of environmental contamination at inactive waste sites. The site investigations conducted to date have indicated that hazardous waste constituents found in soil and groundwater at KCP are associated with past operations and are found at or near units now considered regulated hazardous waste management and solid waste management units.

Hazardous waste generated at KCP is manifested and shipped under contracts with DOT-registered transporters to RCRA- or TSCA-permitted incineration, reclamation, or disposal facilities. In addition, procedures have been developed by KCP to evaluate all prospective treatment, storage, and disposal sites to ensure that the facilities are operating in accordance with all applicable regulations. An annual reevaluation site visit is conducted by KCP environmental and waste management personnel for all treatment, storage, or disposal facilities utilized by KCP.

Waste that requires disposal under TSCA continues to decrease. The primary generation source of PCB wastes over the past 15 years has been equipment upgrades and electrical substation replacement (i.e., replacement of transformers). These projects are now complete and this category of waste is now primarily generated from restoration and remediation projects.

Nonhazardous Waste. Nonhazardous wastes are generated routinely and include general plant refuse such as paper, cardboard, glass, wood, plastics, scrap, and metal containers. Nonhazardous wastes are segregated and recycled whenever possible. The wastes are transported to a sanitary landfill. Approximately 8,300 t (9,150 tons) of solid sanitary waste were generated in 1994 (KC DOE 1995a:7). Sanitary wastewaters are discharged to the sanitary sewer in compliance with Kansas City, MO, sewer-use ordinance provisions and permit discharge limits. In 1994, about 249,000 m^3 (65,778,800 gal) of sanitary wastewater were generated (KC DOE 1995a:10). Biomedical waste is incinerated offsite at an incinerator permitted and approved by the Kansas Department of Health and Environment.

4.4.3 Environmental Impacts

4.4.3.1 *Land Use*

No Action. Under No Action, DOE would continue current and planned activities at KCP as described in section 3.2.4. No additional land use impacts are anticipated at KCP beyond the effects of existing and future activities that are independent of the proposed action.

Management Alternatives

Downsize Nonnuclear Fabrication. Since 1990, KCP has been undergoing a restructuring of the physical plant to reduce its size under nonnuclear manufacturing consolidation of the Complex. Modification of existing facilities as a result of the downsizing effort would continue and appropriate measures would be taken to further consolidate nonnuclear fabrication at KCP. No additional land would be used to downsize the nonnuclear fabrication mission. Impacts to land use or land use plans are not expected.

Phaseout of Nonnuclear Fabrication. The phaseout of nonnuclear fabrication at KCP would not affect land resources. The proposed alternative would not affect land use in the short term. Facilities and infrastructure would transition to EM for D&D before disposition. A future scenario may be the potential for the site to accommodate industrial type activities. The subsequent use of KCP would be addressed in the transition plan prepared by EM.

Sensitivity Analysis. All operations and support functions for nonnuclear fabrication can be accomplished within the restructured KCP. The downsized facility (167,000 m^2 [1.8 million ft^2]) would be sufficient to maintain capacity for the low case production scenario. Approximately 5,760 m^2 (62,000 ft^2) of unallocated floor space would be rearranged in order to support the high case production scenario.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.4.3.2 *Site Infrastructure*

A comparison of site infrastructure and facilities resource needs for the nonnuclear fabrication alternatives at KCP is shown in table 4.4.3.2–1.

No Action. This alternative continues the nonnuclear fabrication mission in current facilities as described in section 3.4.2. Reductions in site infrastructure

TABLE 4.4.3.2–1.—***Site Infrastructure Requirements and Changes for Stockpile Management Alternatives at Kansas City Plant***

	Electrical		Fuel		
Alternative	**Energy (MWh/yr)**	**Peak Load (MWe)**	**Liquid (L/yr)**	**Gas (m^3/yr)**	**Coal (t/yr)**
Current Resources	129,886	24.2	9,058	15,151,078	NA
No Action (2005)					
Total site requirement	119,150	24.2	9,058	13,449,774	NA
Change from current resources	-10,736	0	0	-1,701,304	NA
Downsize Nonnuclear Fabrication					
Total site requirement	225,000	30	0[a]	18,900,000	NA
Change from No Action	105,850	5.8	-9,058	5,450,226	NA
Phaseout Nonnuclear Fabrication					
Total site requirement	0	0	0	0	NA
Change from No Action	-119,150	-24.2	-9,058	-13,449,774	NA

[a] Oil consumption is reduced to 0 L/yr after facility downsize.
Note: NA - not applicable.
Source: KC ASI 1995a; KCP 1995a:1.

would be minimal, consistent with reduced output requirements.

Management Alternatives

Downsize Nonnuclear Fabrication. The nonnuclear fabrication alternative for KCP would downsize and consolidate facilities at KCP to more efficiently support the reduced mission. The KCP infrastructure would be capable of supporting the reduced nonnuclear fabrication mission without major modifications to the existing infrastructure. For normal operation, the modified production facilities would require fewer resources compared to the current site-wide requirements, except for peak electrical load, which would increase slightly. Construction impacts would be minimal since downsizing consists of minor modifications to existing facilities. As indicated in table 4.4.3.2–1, electrical energy requirements for three-shift surge operation in the base case facility would be almost double compared to No Action.

Phaseout of Nonnuclear Fabrication. Phaseout of the nonnuclear fabrication mission at KCP would result in a substantial reduction in site infrastructure resource requirements. During facility transition activities to prepare for turnover to EM, site resource requirements would remain approximately the same as No Action. After transfer to EM and after D&D, facilities would remain in a caretaker status until final disposition.

Sensitivity Analysis. To support high case production levels, a modest increase in factory floor space size to 172,985 m^3 (1,862,000 ft^2) would be necessary. The majority of additional space would be in the electronics factory along with a smaller increase in the utility reservoir area. Utility requirements would change moderately to accommodate the additional production and floor space. There would be little difference in the site infrastructure impacts associated with high case production compared to base case surge operation. The low case scenario could easily be handled in the base case facility without modification.

Potential Mitigation Measures. No additional mitigation measures are anticipated.

4.4.3.3 Air Quality

No Action. Impacts to air quality under No Action are estimated using air emissions data from operations at KCP in 2005, assuming continuation of current site missions, to calculate pollutant concentrations at or beyond the KCP site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in table B.3.4–1. Table 4.4.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Pollutant concentrations in the vincinity of KCP are expected to remain within applicable Federal and state regulations and guidelines except for the 1-hour concentration for ozone and the annual concentration for particulate matter, which may be the result of offsite contributions.

Management Alternatives

Downsize Nonnuclear Fabrication. The primary impact of downsizing and/or consolidating the nonnuclear fabrication function at KCP would be to reduce the fugitive emissions of numerous small amounts of solvents in the nonnuclear component fabrication processes. These solvents include acetone, isopropyl alcohol, methyl ethyl ketone, toluene, and trichloroethylene. Table 4.4.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from downsizing and/or consolidating the nonnuclear fabrication mission. Emission rates of criteria and toxic/hazardous pollutants for this option are presented in table B.3.4–1. Concentrations of pollutants resulting from downsizing and/or consolidating nonnuclear fabrication are expected to be within Federal and state regulations except for the 1-hour concentration of ozone and the annual concentration of particulate matter, which are above their applicable standards.

Phaseout of Nonnuclear Fabrication. Phaseout of nonnuclear fabrication at KCP would result in cessation of air pollutant emissions from the facility. The air quality in and around KCP is expected to improve as a result of the phaseout of the nonnuclear fabrication mission.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the downsize nonnuclear fabrication alternative would result in higher and lower concentrations of criteria and toxic-hazardous pollutants for the high and low cases, respectively. The concentrations of pollutants for both cases are expected to be within applicable

TABLE 4.4.3.3–1.—*Estimated Concentrations of Pollutants from No Action and Stockpile Management Alternatives at Kansas City Plant*

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines (μg/m³)	2005 No Action (μg/m³)	Downsize Nonnuclear Fabrication (μg/m³)	Phaseout Nonnuclear Fabrication (μg/m³)

Federal and state regulations and guidelines, except the 1-hour concentration of ozone and the annual concentration of particulate matter.

Potential Mitigation Measures. The reduction of emissions of nitrogen oxides and VOCs from KCP using reasonably available control technology may contribute to the reduction of concentrations of ozone. Installation of additional HEPA filters may contribute to the reduction of annual particulate matter concentrations. In general, however, these concentrations of pollutants are an area-wide phenomenon closely linked to urban concentrations of automobile exhaust which are not linked to the KCP site mission.

4.4.3.4 *Water Resources*

Environmental impacts associated with the modification and operation of the potential nonnuclear fabrication facilities at KCP could affect surface and groundwater resources. All water required for modification and operations would be supplied from the Kansas City Municipal Water Supply System. Process and sanitary wastewater generated from the modification and operation activities would be discharged to the Kansas City Wastewater Treatment Plant. With improved flood control, all KCP operations are protected from flooding events up to and including a 500-year flood. Modification would take place within existing facilities to achieve the downsizing and consolidation of nonnuclear fabrication. A description of the functions to be included in the nonnuclear fabrication process and the facility locations selected to house these activities is presented in section 3.4.2. Table 4.4.3.4–1 presents existing surface and groundwater resources and the potential changes to water resources at KCP resulting from the proposed alternatives. The total site water resource requirements for each alternative including No Action are displayed in this table.

Surface Water

No Action. No construction would occur under No Action; therefore, no additional construction water would be used or discharged. Under No Action, because of reduced operating requirements of existing facilities at KCP, treated wastewater volume is estimated to decrease to 702 MLY (185 MGY) by 2005. No adverse impacts to surface water or surface water quality are expected.

Management Alternatives

Downsize Nonnuclear Fabrication. No surface water would be required to modify the nonnuclear fabrication facilities, nor would modification activities generate wastewater.

Approximately 1,340 MLY (354 MGY) of municipal water would be required for three-shift surge operation of the downsize nonnuclear fabrication facilities. The water usage would represent approximately a 31-percent decrease from the projected No Action use of 1,930 MLY (509 MGY) and would not affect other users of the Kansas City Municipal Water Supply System.

No added or special wastewater handling capability would be required. Existing capabilities would be used to handle the generated wastewater. Most of the process wastewater is acidic and alkaline wastewater requiring pH adjustment, and is readily amenable to treatment at the wastewater pretreatment facility prior to discharge to the Kansas City Municipal Sewer System. The KCP Industrial Wastewater Pretreatment Facility, with a design capacity of approximately 1,788.5 MLY (472.5 MGD), has sufficient available capacity to treat the wastewater from the proposed alternative.

Surface Water Quality. There would be no impact to surface water quality due to sanitary or process wastewater because these discharges go to city treatment facilities. There would be no increase in cooling water discharges from the operations. In addition, significant changes in stormwater runoff from KCP are not anticipated.

Phaseout of Nonnuclear Fabrication. Phaseout activities for KCP would end all current DP operations. The phaseout of DP activities would cease industrial discharges to the wastewater pretreatment facility and cooling water discharges to Blue River and Indian Creek. This would have a minor beneficial impact to water quality in Blue River and Indian Creek.

TABLE 4.4.3.4–1.—*Potential Changes to Water Resources from Stockpile Management Alternatives at Kansas City Plant*

Affected Resource Indicator	No Action Single-Shift Operation 2005	Downsize Nonnuclear Fabrication Three-Shift Operation	Phaseout of Nonnuclear Fabrication
Construction			
Water Availability and Use			
Water source	Municipal supply	Municipal supply	Municipal supply
Total site water operation requirement (MLY)[a]	0[b]	1,930	0
Percent change from No Action water use (1,930 MLY)	NA	0	0
Water Quality			
Wastewater discharge to Kansas City Wastewater Treatment Plant (MLY)	0[b]	702	0
Percent change from No Action wastewater discharge (702 MLY)	NA	0	0
Operation			
Water Availability and Use			
Water source	Municipal water supply	Municipal water supply	Municipal water supply
Total site water operation requirement (MLY)	1,930	1,340	0
Percent change from No Action water use (1,930 MLY)	NA	-31	-100
Percent change from current water use (1,934.5 MLY)	-0.2	-31	-100
Water Quality			
Wastewater discharge to Kansas City Wastewater Treatment Plant (MLY)	702	794	0
Percent change from No Action wastewater discharge (702 MLY)	NA	13	-100

Actions in 100-year floodplain	None	None	None
Actions in 500-year floodplain	None	None	None

[a] Total water requirements for construction at KCP are based on a 4-year time period for nonnuclear fabrication.
[b] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharged would be the same as No Action operation.
Note: NA - not applicable; MLY - million liters per year.
Source: KC ASI 1995a; KCP 1995a:1.

Groundwater

No Action. Under No Action, no additional impacts to groundwater resources are anticipated beyond the effects of existing and future activities that are independent of and unaffected by the proposed action. Under No Action, current restoration programs described in section 4.4.2.4 would continue. Process and sanitary wastewater would continue to be treated prior to release.

Management Alternatives

Downsize Nonnuclear Fabrication. No groundwater would be used for modification of buildings and operating the downsize and consolidation of nonnuclear fabrication mission at KCP.

Groundwater Quality. Plumes of organic solvents and VOCs are present beneath the buildings proposed to contain downsized and consolidated nonnuclear fabrication functions (section 4.4.2.4). Groundwater corrective actions are in progress and should not affect future nonnuclear fabrication activities. Because no groundwater beneath KCP would be used and no discharge of waste materials to groundwater is planned, no additional impacts to groundwater quality are expected to result from this alternative.

Phaseout of Nonnuclear Fabrication. By phasing out the nonnuclear fabrication mission at KCP, water demand on the Kansas City Municipal Water Supply System would decrease. No adverse impacts on water supplies are expected.

Spill protection systems and plans exist to contain and minimize effects of releases of hazardous substances. Given normal safeguards and precautions, no adverse impacts to groundwater quality are expected to result from phaseout activities. Current environmental restoration programs would not be adversely impacted.

Sensitivity Analysis. Surface water, surface water quality, groundwater, and groundwater quality would not be affected by the high or low case stockpile requirement at KCP.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.4.3.5 *Geology and Soils*

The proposed alternatives for KCP would have no impact on geological resources as described in section 4.4.2.5. Due to low seismic and volcanic risk, the proposed action would not be affected by geological conditions. Potential changes to geology and soils associated with alternatives at KCP are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at KCP. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Downsize Nonnuclear Fabrication. Downsizing and/or consolidating the nonnuclear fabrication mission at KCP would not affect geological conditions. Designs of the project facilities would ensure that they would not be adversely affected by geological conditions.

Building modification activities at KCP would be limited to rearrangements and modifications within the confines of existing plant floor space. Existing parking areas are sufficient to accommodate construction workers. Building material laydown areas would be within the space being modified.

The properties and conditions of the soils underlying the proposed site place no limitations on modification and renovation activities. Soil conditions would not adversely affect the safe operation of downsized and/or consolidated project facilities. The proposed action would have no adverse impacts on KCP soils because the entire area has been disturbed to accommodate existing facilities and operations.

Renovation and facility modifications would be performed in accordance with DOE O 420.1 and accompanying safety guides. Seismic hazards would not increase. Landslides, sinkhole development, rapid erosion, sedimentation, or other nontectonic events are unlikely.

Phaseout of Nonnuclear Fabrication. The phaseout of the nonnuclear fabrication mission at KCP would not affect geology and soils. The D&D of vacated facilities would take place within the buildings.

Sensitivity Analysis. The high or low case operation scenario would not affect geology and soils.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.4.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. In general, impacts to these resources are not expected from the proposed alternatives; however, noise and human presence could temporarily disturb wildlife.

No Action. Under No Action, the nonnuclear fabrication mission described in section 3.2.4 would continue at KCP. This would result in no changes to current biotic resource conditions at the site as described in section 4.4.2.6.

Management Alternatives

Downsize Nonnuclear Fabrication. Downsizing the nonnuclear fabrication mission at KCP would involve consolidating all functions into the main manufacturing building and a number of outlying buildings. Stormwater and some cooling wastewaters would continue to be discharged to the Blue River via NPDES permitted outfalls. This alternative would not be expected to impact biotic resources.

Phaseout of Nonnuclear Fabrication. Phaseout of the nonnuclear fabrication mission at KCP is unlikely to result in adverse impacts to biotic resources. During the phaseout period, additional human activity could temporarily disturb wildlife living nearby; however, disturbance would be minimal since the facility is presently a heavily used industrial area and nearby wildlife populations have already adapted to its presence. Once all phaseout activities are complete, wildlife use of the area would depend on future use of the facilities.

Sensitivity Analysis. Implementation of either a low or high case workload would not affect biological resources.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.4.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly through ground disturbance, building modifications, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusion into Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. To date, no surveys have been conducted at KCP. All of the area has been either developed or disturbed; consequently, the probability for locating NRHP-eligible archaeological resources at KCP is low. Because the facility was designed and organized around the mission of the Cold War era, some of the existing buildings may be eligible for the NRHP. Site-specific surveys and evaluations would be conducted in conjunction with tiered NEPA documentation. No Native American resources have been identified at KCP. Geological strata at KCP may be fossil bearing.

No Action. Under No Action, DOE would continue the existing and planned missions of KCP described in section 3.2.4. Any impacts to cultural or paleontological resources from these missions would be independent of and unaffected by the proposed action.

Management Alternatives

Downsize Nonnuclear Fabrication. This alternative would involve reducing the operating size of the facility and its support infrastructure. Because KCP is developed and disturbed, it is unlikely to contain NRHP-eligible archaeological resources. This alternative is not expected to affect prehistoric, Native American, or paleontological resources. KCP was designed and organized around the mission of the Cold War and, as such, some of the buildings may be NRHP eligible. NRHP-eligible resources would be identified through project-specific inventories and evaluations, and any project-related effects would be addressed in tiered NEPA documentation.

Phaseout of Nonnuclear Fabrication. The phaseout of nonnuclear fabrication at KCP may affect some cultural resources. The subsequent use of KCP would determine potential future impacts to these resources. NRHP-eligible resources would be identified through project-specific surveys and evaluations. Specific concerns about Native American resources would be addressed through consultation with the potentially affected tribes. Any project-related effects would be addressed in tiered NEPA documentation. No impacts to paleontological resources are expected.

Sensitivity Analysis. The high and low case scenarios have the same impacts to cultural and paleontological resources. The base case production facility for downsize nonnuclear fabrication would accommodate both the high and low case production scenarios.

Potential Mitigation Measures. If NRHP-eligible sites cannot be avoided through project design or siting, and would be adversely affected, then a Memorandum of Agreement would need to be negotiated among DOE, the Missouri SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the Missouri SHPO and the Advisory Council on Historic Preservation in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific NRHP-eligible sites would be identified during tiered NEPA documentation.

If Native American resources cannot be avoided through project design or siting, then acceptable mitigation measures to reduce project effects on them would be determined in consultation with the affected Native American groups. In accordance with the *Native American Graves Protection and Repatriation Act* and the *American Indian Religious Freedom Act*, such mitigations may include, but would not be limited to, appropriately relocating human remains, planting vegetation screens to reduce visual or noise intrusion, increasing access to traditional use areas, or transplanting or harvesting important Native American plant resources.

4.4.3.8 *Socioeconomics*

No Action. Under No Action, the existing Nonnuclear Fabrication Facility at KCP would remain operational with its current staffing requirements. The facility would continue to employ a total of 3,179 workers. Of these workers, 2,508 would be core stockpile management workers involved in the process of nonnuclear fabrication, while the remaining 671 workers would be support staff or other employees not involved in the mission. Projected regional economy and employment levels, population, housing, and public finance characteristics are presented in appendix D.

Regional Economy and Employment. Total employment in the regional economic area is projected to increase by less than 1 percent annually between 1995 and 2030, reaching approximately 1,194,400 in 2000 and 1,373,300 in 2030. Unemployment in the regional economic area was 4.9 percent in 1994 and is expected to remain near that level into the near future. Per capita income is projected to increase from approximately $20,004 in 1995 to $23,759 in 2030.

Population and Housing. Annual ROI county and city population and housing growth is projected to average less than 1 percent between 1995 and 2030. The ROI population is projected to grow from 1,257,600 in 1995 to 1,493,700 in 2030. The total number of housing units is projected to increase from 525,200 in 1996 to 619,700 in 2030.

Public Finance. Between 2000 and 2005, all ROI county, city, and school district total revenues and expenditures are projected to increase at an annual average of less than 1 percent. This rate of increase should continue until 2030.

Management Alternatives

Downsize Nonnuclear Fabrication. Downsizing and consolidating the nonnuclear fabrication mission at KCP would initially require some construction workers to reconfigure the facility, but would result in a reduced operations workforce. Under this alternative, nonnuclear fabrication would be organized into three modules: mechanical, electronics, and engineered materials. The size of the operational workforce would depend on whether DOE implements a single-shift or three-shift operation.

Base Case Single Shift. Under the base case single shift, the total KCP workforce would decrease from the No Action level of 3,179 to 2,340. The composition of the workforce would also change. The number of support and other workers would remain at the same level as for No Action; however, the number of workers associated with the nonnuclear fabrication mission would decrease from 2,508 to 1,669.

Base Case Surge (Three Shift). Under the base case surge scenario the total KCP workforce would decrease from the No Action level of 3,179 to 2,928. As with the base case single-shift operation, the number of support and other workers would remain at the same level as for No Action. The number of workers associated with the nonnuclear fabrication mission would decrease from 2,508 to 2,257. It should be noted that the number of workers employed for high case production would be the same as for base case surge. Therefore, the socioeconomic impacts would be identical for both cases.

Regional Economy and Employment. Modification of the existing facility for downsized operation would employ 187 workers during peak construction in 2000 and generate an additional 262 indirect jobs in related industries. Changes in the regional economic area's employment would be less than 1 percent, and there would be no perceptible change in the unemployment rate.

Base Case Single Shift. Base case single-shift operation would employ fewer workers than the No Action alternative, and would result in employment and income losses to the region. A total of 2,319 jobs (839 direct and 1,480 indirect), would be lost, and regional unemployment would increase from 4.9 to 5.1 percent. Per capita income would decrease by less than 1 percent. These employment and income effects are shown in figure 4.4.3.8–1.

Base Case Surge (Three Shift). The base case surge operation would employ fewer workers than under No Action and would result in employment and income losses to the region. A total of 694 jobs (251 direct and 443 indirect) would be lost, although there would be no perceptible change to the region's unemployment rate. Per capita income would decrease by less than 1 percent. These changes are shown in figure 4.4.3.8–1.

Population and Housing. Modifying the facility for base case single-shift operation would cause no change in the region's population from the No Action projections because available labor in the region would fill any jobs generated during construction.

Base Case Single Shift. Operation of the downsized facility for base case single-shift production could lead to out-migration of the displaced workers seeking employment outside the region. Although this scenario is less probable for KCP than for other, more rural DOE installations, out-migration of displaced workers would lead to a decrease in population and an increase in housing vacancies. If all displaced direct and indirect workers were to out-migrate with their families, the regional population would decrease by about 5,937 or 0.2 percent of the projected population under the No Action alternative. These changes are shown in figure 4.4.3.8–2. The largest loss in population would occur in Jackson County and Kansas City, MO, where the majority of the current workforce resides. Housing vacancies would increase, but the change would be too small to significantly affect the market for either rental or nonrental housing.

Base Case Surge (Three Shift). Operation of the facility for base case surge production could lead to out-migration of the displaced workers seeking employment outside of the region. If all of the displaced direct and indirect workers and their families were to out-migrate, the regional population would decrease by about 1,811, a decrease of less than 0.1 percent of the projected population under the No Action alternative. As with the base case single shift operation, the largest population losses would occur in Jackson County and Kansas City, MO, where the majority of current KCP workers reside. Housing vacancies would increase, but the change would be too small to significantly affect the market for either rental or nonrental housing. These changes are shown in figure 4.4.3.8–2.

Public Finance. Modification of the Nonnuclear Fabrication Facility for base case single-shift operation would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Base Case Single Shift. Downsizing the facility for base case single-shift operation could result in the out-migration of workers from the ROI, causing a loss of income that would affect ROI revenues and expenditures. Changes in revenues and expenditures compared to No Action projections due to downsizing the Nonnuclear Fabrication Facility at KCP are shown in figure 4.4.3.8–3. In 2005, the total ROI revenues and expenditures would be reduced below No Action projections by approximately 0.5 and 2.0 percent, respectively. The Center School District would experience the greatest decreases in revenues (nearly 0.6 percent) and expenditures (approximately 0.4 percent).

Base Case Surge. Downsizing the facility could result in the out-migration of workers from the ROI, which would cause a loss of income that would affect

FIGURE 4.4.3.8–2.—*Population and Housing Changes Resulting from Management Alternatives in the Kansas City Plant Region of Influence, 2005.*

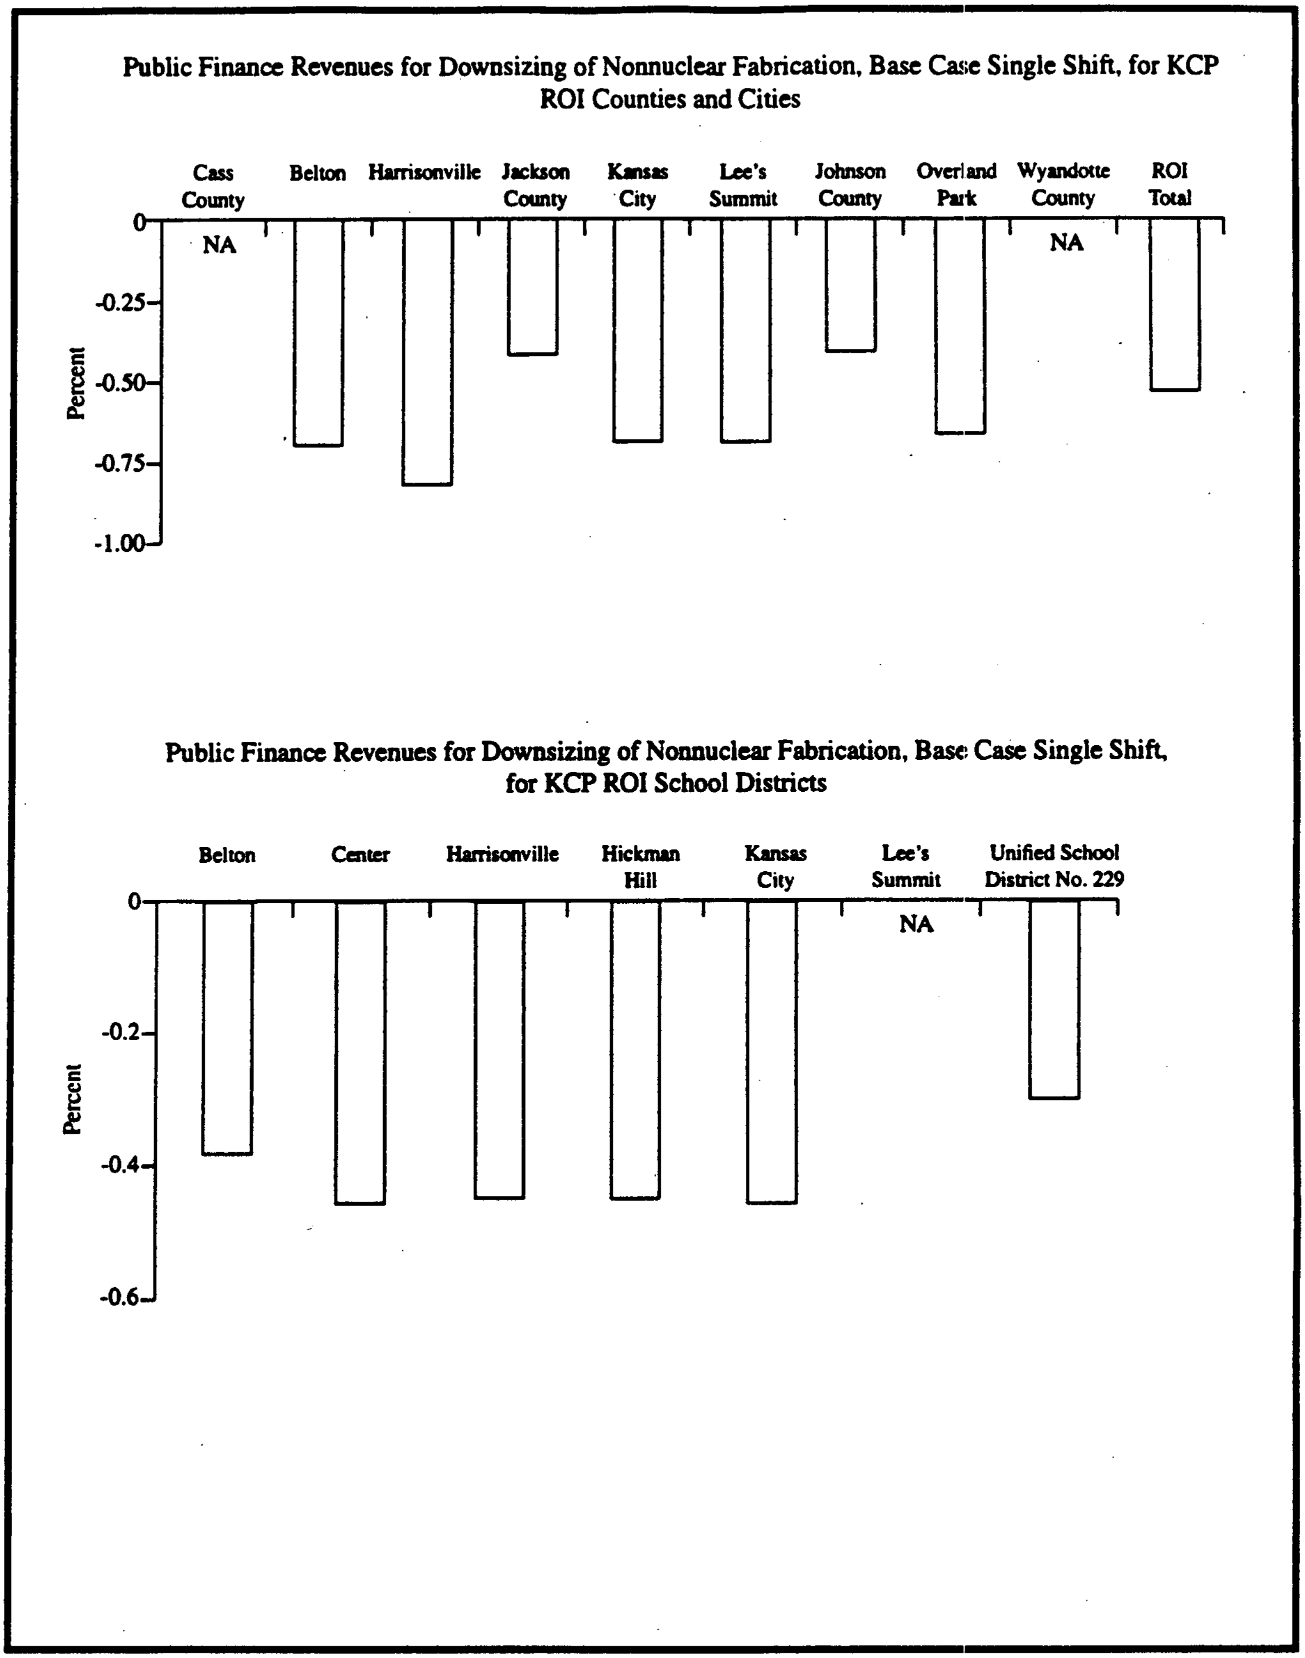

FIGURE 4.4.3.8–3.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Kansas City Plant Region of Influence with Downsizing of Nonnuclear Fabrication, Base Case Single Shift, 2005* [Page 1 of 2].

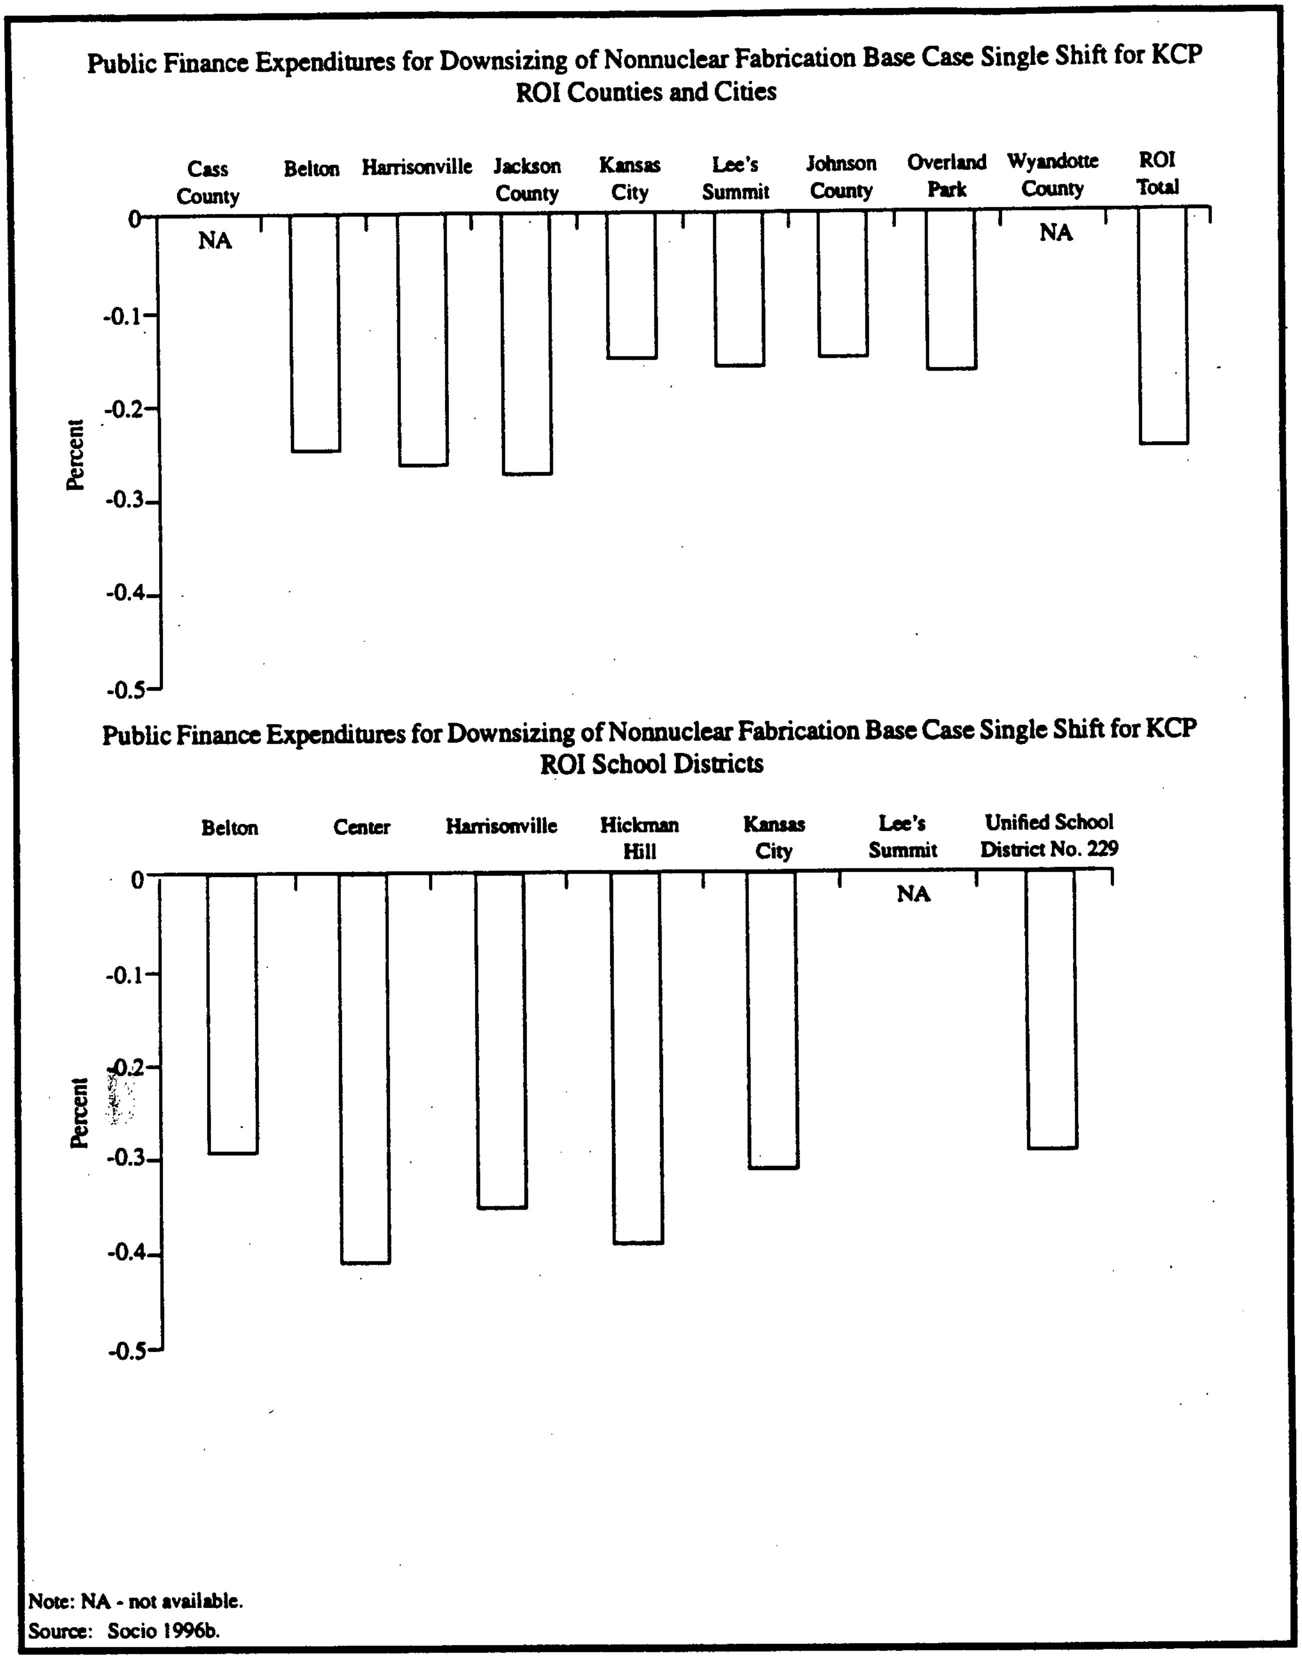

FIGURE 4.4.3.8–3.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Kansas City Plant Region of Influence with Downsizing of Nonnuclear Fabrication, Base Case Single Shift, 2005* [Page 2 of 2].

ROI revenues and expenditures. Changes in revenues and expenditures compared to No Action projections due to downsizing the nonnuclear facility for surge operation at KCP are shown in figure 4.4.3.8–4. In 2005, the total ROI revenues and expenditures would be reduced below No Action projections by approximately 0.16 and 0.07 percent, respectively.

Phaseout of Nonnuclear Fabrication. Under this alternative, the nonnuclear fabrication mission at KCP would be transferred to other existing DOE installations, and the KCP workforce would decrease from 3,179 under the No Action alternative to zero in 2005, when the phaseout would be completed. Termination of the KCP mission would generate additional losses in related industries in the region.

Regional Economy and Employment. Termination of the KCP nonnuclear fabrication mission would lead to both direct and indirect employment and income losses to the regional economy, which are shown in figure 4.4.3.8–1. Total job loss in 2005 is estimated at 8,788 (3,179 direct and 5,609 indirect), about 0.7 percent of projected employment for the regional economic area. Unemployment in the region would increase from 4.9 percent to 5.6 percent and per capita income would decrease from approximately $21,330 to $21,174.

Population and Housing. Phaseout of KCP could result in displaced workers leaving the region to seek employment elsewhere. However, this scenario is less probable for KCP than for other DOE installations, because of its location in a large urban economy where a diverse industrial base provides a greater abundance of alternative employment opportunities than at more rural sites.

If all of the displaced direct and indirect workers leave the area with their families, total out-migration would number 22,497, a 0.9-percent reduction from the projected No Action population. These changes are shown in figure 4.4.3.8–2. The largest population loss would occur in Jackson County and Kansas City, MO, where the majority of KCP employees currently reside. Housing vacancies would also increase as a result of out-migration. However, the change would be too small to significantly affect either the rental or nonrental housing market.

Public Finance. Phaseout of the Nonnuclear Fabrication Facility could result in the out-migration of workers from the ROI that would affect ROI revenues and expenditures. Changes in revenues and expenditures compared to No Action projections due to phaseout of the nonnuclear fabrication mission are shown in figure 4.4.3.8–5. In 2005, the percent decrease in total ROI revenues and expenditures below No Action would be approximately 2.0 and 0.9 percent, respectively. The city of Harrisonville would experience the greatest decrease in revenues (nearly 31 percent) and the Center School District would experience the greatest decrease in expenditures (1.6 percent).

Sensitivity Analysis. Construction employment requirements for the low-case nonnuclear fabrication mission at KCP are the same as discussed above. Therefore, the socioeconomic impacts on the region from construction for low case production would also be the same. Construction for high-case production, however, would require additional workers above base case requirements. There would be slightly greater benefits to the regional area as a result, but the change in the regional economy would still be extremely small.

Employment requirements for low case production would be slightly smaller than for base case single shift. This option would result in greater employment losses to the regional economy than would the base case single-shift option, when compared to No Action. The high case option or the base case surge (three-shift) operation would require 2,257 core stockpile management workers and the same 671 support workers required under No Action or base case single-shift operation, for a total of 2,928 workers. There would be fewer jobs lost in the region and therefore any negative socioeconomic impacts would be decreased.

Potential Mitigation Measures. In the event of a phaseout of DP activities at KCP, adverse socioeconomic impacts could result in the affected economic region. To mitigate potential socioeconomic impacts, Section 3161 of the *National Defense Authorization Act* (Public Law 102-484) requires DOE to develop a plan for restructuring the workforce for a defense nuclear facility whenever a change in workforce is

necessary. The legislation also directs DOE to develop the plan in consultation with local, state, and national stakeholders.

DOE has initiated a number of actions to respond to the legislative requirements, including the creation of the Office of Worker and Community Transition. In February 1996, the office issued interim planning guidance in developing plans to help mitigate unavoidable impacts from workforce restructuring. Although the guidance is not prescriptive, it sets forth DOE policy on mitigating economic impacts of restructuring. For example, the guidance states that whenever possible, the impacts of workforce reductions should be minimized through the use of early retirement and normal attrition. Where appropriate, employees should be retrained for work in environmental restoration and waste management. The guidance also recommends that terminated employees receive assistance in obtaining reemployment through out-placement services, appropriate retraining, and educational services. To the extent practical, DOE and its contractor should offer a hiring preference to terminated employees. The DOE guidance also suggests that the affected communities should receive assistance to mitigate impacts to the public infrastructure and finances.

4.4.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the hazardous chemical releases and their associated impacts that could result from No Action and proposed alternatives at KCP. There would be no radiological health impacts to the public or to workers from KCP operations resulting from potential alternatives. Within this section, impacts resulting from the base case scenario are quantitatively discussed and the high and low case scenarios are qualitatively discussed. Further supplementary information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the modification of any facilities to support the proposed alternatives. However, limited hazardous chemical releases (e.g., small spills of diesel fuel from equipment refueling) would be anticipated due to building modification activities for the base case and may increase slightly for the high case scenario. The concentration of these releases is expected to be well within the regulated exposure limits and would not result in any adverse health effects.

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge to the city sewer system and further treated at the public-owned treatment plant. Furthermore, discharges of water through NPDES-permitted outfalls that can be attributed to the activities associated with the nonnuclear fabrication mission at KCP are expected to be below NPDES limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at KCP, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). It is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all management alternative (nonnuclear fabrication) chemicals emitted at the site. An HI of ≤ 1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is $\leq 1\text{x}10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $1\text{x}10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinuiguished from the cancer risk for an individual member of the population. Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

No Action

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from normal operation under No Action at KCP are presented below. Analyses to support the values presented in this section are provided in appendix table E.3.4–6. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging the sites as having a hazardous health concern. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among sites. The baseline is then used to determine the extent by which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed member of the public at KCP resulting from normal operation under the No Action alternative would be 0.019, and the cancer risk would be 1.13×10^{-6}. The HI to the onsite worker would be 1.08×10^{-2}, and the cancer risk would be 7.99×10^{-6}.

The HIs to the public and onsite worker are within acceptable health levels. The cancer risks to the public (1.13×10^{-6}) and to the onsite worker (7.99×10^{-6}) slightly exceed EPA default value of 1×10^{-6}. Cancer risk exceeds the EPA default value due to the emissions of perchloroethylene and trichloroethylene associated with normal site operation.

Potential mitigation measures such as substituting less toxic solvents or modifying production processes are proposed to reduce or eliminate the emissions of perchloroethylene and trichloroethylene due to normal site operation associated with the No Action alternative at KCP.

Management Alternatives

Downsize Nonnuclear Fabrication

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation due to downsizing and/or consolidating the nonnuclear fabrication mission at KCP are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–7.

The HI for the maximally exposed member of the public would be 1.02×10^{-3}, and the cancer risk would be 1.65×10^{-6} as a result of downsizing and/or consolidating the nonnuclear fabrication mission at KCP. The HI for the onsite worker would be 1.70×10^{-4} and the cancer risk would be 1.16×10^{-5}.

The HIs to the public and the onsite worker are within acceptable health regulatory levels. The cancer risks to the public (1.65×10^{-6}) and the onsite worker (1.16×10^{-5}) marginally exceed the acceptable threshold of regulatory concern of 1×10^{-6}. Cancer risks exceed the default value due to the emission of trichloroethylene with operation of the downsize nonnuclear fabrication alternative at KCP. Cancer risks for the public and onsite worker would increase slightly from the No Action values as a result of this management alternative.

Phaseout of Nonnuclear Fabrication

Hazardous Chemical Impacts. There are no hazardous chemical emissions associated with the phaseout of nonnuclear fabrication at KCP. The HIs for the public and the onsite worker would be reduced to zero, and the cancer risks for the public and the onsite worker would remain at zero as a result of the phaseout (see appendix table E.3.4–8). Therefore, there are no adverse health effects or cancer risks to the public or onsite workers due to this alternative.

Sensitivity Analysis. Operations under the high case scenario substantially increase emissions of hazardous chemicals. However, since the HIs to the public and the onsite workers are well within acceptable health levels, there are no expected adverse impacts as a result of the high case scenario at KCP. However, any additional emissions of hazardous chemicals, particularly trichloroethylene, may increase cancer risks for the public and the onsite worker.

Operations under the low case scenario are not expected to have any appreciable effect on hazardous chemical emissions. Therefore, no increase in the HI for the public or onsite worker, or cancer risks for the public and onsite worker are expected.

Facility Accidents

No Action. Under the No Action alternative, nonnuclear fabrication would continue to be performed at KCP with no changes to facilities and operations. Potential accidents, under existing conditions, and their consequences have previously been addressed in facility safety documentation according to requirements in DOE orders.

Management Alternatives. Accident information on the two management alternatives under consideration at KCP, nonnuclear fabrication and phaseout of the nonnuclear fabrication mission, is provided in this section.

Downsize Nonnuclear Fabrication. The impacts of potential accidents associated with nonnuclear fabrication activities at KCP were previously addressed in the *Nonnuclear Consolidation Environmental Assessment* (DOE/EA-0792, June 1993) where it was determined that the then current accident profile would not change as a result of the relocation of nonnuclear fabrication functions to KCP. The present proposed action to downsize and/or consolidate the nonnuclear fabrication mission at KCP is not expected to change the accident profile that presently exists at the site.

Phaseout of Nonnuclear Fabrication. A phaseout of the nonnuclear fabrication mission at KCP would have the effect of eliminating any potential for accidents over the long term related to nonnuclear fabrication activities. However, there would be a potential for accidents during the phaseout process that could impact workers and the public. These potential accidents and their consequences are generally addressed in each affected facility's safety analysis report and/or safety documentation applicable to the phaseout process.

Potential Mitigation Measures. No mitigation measures are anticipated to be needed with the nonnuclear fabrication phaseout alternative.

4.4.3.10 *Waste Management*

This section summarizes the impacts on waste management at KCP under No Action and for each of the alternatives, including the phaseout of nonnuclear fabrication. There is no spent nuclear fuel, high-level, or TRU waste associated with the fabrication of nonnuclear components. Table 4.4.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for KCP. Projections for No Action are based on base case single-shift operation and were derived from 1994 environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated is identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities.

Table 4.4.3.10–2 provides the total estimated operational waste volumes projected to be generated at KCP as a result of the various alternatives. The net increase or decrease over No Action is provided in parentheses. The waste volumes generated and the resultant waste effluent for the nonnuclear fabrication mission can be found in table 3.4.2.2–3 and are based on surge operations (three shifts). KCP facilities that would support nonnuclear fabrication would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act*, RCRA, and other applicable statutes as outlined in appendix section H.1.2.

No Action. Under No Action, generation of all waste types at KCP is expected to decrease as production workload operations are reduced from the missions outlined in section 3.2.4. The Pollution Prevention Program would systematically reduce waste generation through specific waste minimization projects and the use of process waste assessments. There are no significant changes expected in waste stream types or handling other than possible reduced quantities due to the smaller workload.

KCP would continue to generate small quantities of LLW, which would be accumulated onsite and stored in DOE-approved containers in a controlled-access facility until sufficient quantities accumulate to warrant shipment to an approved DOE disposal facility. Due to process changes, KCP would no longer expect to generate any mixed waste, but the potential to generate a small quantity of mixed LLW would exist under upset conditions such as a leaking commercial source or contamination of a segregating medium used to recover radioactive gap tubes from weapon components. In the event any mixed waste is generated, it would be stored in a RCRA-permitted facility until shipped to a RCRA-permitted commercial mixed waste treatment and disposal facility.

PCB and asbestos wastes would be managed and stored in compliance with all applicable TSCA requirements. All hazardous waste stream residue generated at KCP that is not reclaimed or recycled on

TABLE 4.4.3.10–1.—*Projected Waste Management Under No Action at Kansas City Plant*

[a] The No Action volumes are from table 4.4.3.10–1 and are based on single-shift operations.
[b] Generated waste volumes from table 3.4.2.2–3 and are based on surge operations (three shifts).
Note: Waste generation volumes were rounded to three significant figures. Waste effluent volumes (i.e., after treatment and volume reduction) which are used in the narrative description of the impacts can also be found in table 3.4.2.2–3.

site would be manifested and shipped under contract with RCRA-permitted transporters to RCRA-permitted offsite treatment and disposal facilities. KCP industrial wastewater would be treated onsite to meet effluent standards prior to discharge to the Kansas City, MO, wastewater treatment plant.

Solid refuse waste streams would be segregated and recycled whenever possible. Solid refuse not recycled would be disposed of in the local sanitary landfill by a commercial contractor. Sanitary wastewaters would be discharged to the industrial wastewater processing facility or to the sanitary sewer system.

Management Alternatives

Downsize Nonnuclear Fabrication. Downsizing and consolidating nonnuclear fabrication would result in a decrease in the generation of low-level and hazardous wastes. The generation of nonhazardous waste would increase due to the use of multiple worker shifts as compared to No Action operations.

Waste generated during construction would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of by the construction contractor, and the hazardous wastes would be shipped to a commercial RCRA-permitted treatment and disposal facility.

The downsized and consolidated nonnuclear fabrication facilities would not expect to generate LLW or mixed LLW. The approximately 60 m^3 (15,960 gal) of liquid hazardous wastes and 61 m^3 (80 yd^3) of solid hazardous wastes would not impact waste management activities at KCP.

Approximately 793,900 m^3 (209,700,000 gal) of liquid nonhazardous wastes, to include sanitary and utility/process wastewaters, would be treated to meet the discharge permit requirement for the Kansas City publicly owned treatment facilities. Existing facilities and the available technologies are adequate to accommodate the volume from a multiple-shift operation. The 11,900 m^3 (15,500 yd^3) of solid nonhazardous wastes would be shipped to the currently utilized offsite landfill. The reduced nonhazardous waste volumes would not impact onsite or offsite waste treatment and disposal facilities.

Phaseout of Nonnuclear Fabrication. With the phaseout of nonnuclear fabrication, 210 m^3 (55,500 gal) of liquid and 675 m^3 (883 yd^3) of solid hazardous wastes would no longer be generated from operations. Liquid and solid nonhazardous wastes would decrease over time as the facilities were deactivated and employment decreased to a caretaker level. D&D activities associated with the closure of KCP would generate 71,112 m^3 (93,000 yd^3) of liquid and 3,397 m^3 (4,440 yd^3) of solid hazardous waste, as well as 837 m^3 (1,090 yd^3) of solid sanitary waste over the 5-year period of D&D activities.

Sensitivity Analysis. The waste volumes generated from the Nonnuclear Fabrication Facility required to support a large stockpile level (high case) operating on a single-shift basis are bounded by the base case under surge operations. Thus, there are no additional waste management impacts associated with the Nonnuclear Fabrication Facility that would support a high case stockpile. The volumes generated from the Nonnuclear Fabrication Facility required to support a low case stockpile would be reduced by a factor of at least three.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies. Pollution prevention and waste minimization would be incorporated in determining the final proposed actions of the Stockpile Stewardship and Management Program at KCP.

4.4.3.11 *Environmental Justice*

As discussed in section 4.14, any impacts to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.4.3.9, which describes public and occupational health impacts from normal operation, shows that potential chemical air emissions and releases are marginally not within the generally acceptable threshold of regulatory concern. This information is based on the conservative programmatic assumptions and modeling detailed in appendix E. Any adverse human health or environmental impacts that may occur would affect people living within communities located near KCP. The analysis of the demographic data presented in appendix D for the communities surrounding KCP indicates that if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.5 PANTEX PLANT

Pantex was established in 1951 and currently occupies approximately 4,119 ha (10,177 acres) of DOE-owned land near Amarillo, TX. The current DP mission at Pantex is to assemble and disassemble nuclear weapons; perform HE manufacturing; perform weapons repair, modification, and disposal; conduct stockpile evaluation and testing; and provide interim storage for plutonium. Section 3.2.5 provides a description of all the DOE missions and support facilities at Pantex. The location of Pantex is illustrated in figure 4.5–1, and the principal facilities and zones at Pantex are shown in figure 4.5–2.

4.5.1 Description of Alternatives

No Action. Pantex would continue to perform the missions described in section 3.2.5.

Stockpile Management Alternatives. The A/D and the high explosives (HE) fabrication missions could be downsized and consolidated and remain at Pantex. If the A/D mission remains at Pantex, the nonintrusive modification pit reuse mission and the option of storing the strategic reserve of pits could be located there. In addition, if Y-12 does not retain the secondary and case fabrication mission, the storage of the strategic reserve of secondaries could be located at Pantex.

The HE fabrication mission could be phased out at Pantex and transferred to either LANL, LLNL, or both. In the event that the HE fabrication mission was transferred, those facilities associated with this mission would be phased out and Pantex downsized to accommodate just the A/D mission. The nonintrusive modification pit reuse and strategic storage options would also be located at Pantex.

The A/D mission could either stay at Pantex without the HE fabrication mission or it could be phased out at Pantex and transferred to NTS. If the A/D mission was also transferred, then all of the DP missions at Pantex would be phased out and the entire plant could be turned over to EM for disposition.

Stockpile Stewardship Alternatives. There are no tockpile stewardship alternatives that include antex.

4.5.2 Affected Environment

4.5.2.1 *Land Resources*

Pantex is located within Carson County in the Panhandle region of Texas, 27 km (17 mi) east-northeast of downtown Amarillo. Pantex covers 6,466 ha (15,978 acres) of land, of which 4,119 ha (10,177 acres) are owned by the Federal Government, and 2,347 ha (5,800 acres) immediately south of the main plant area are leased from Texas Tech for use as a safety and security buffer zone. DOE-owned land at the plant facility includes 3,683 ha (9,100 acres) in the main plant area and 436 ha (1,077 acres) around Pantex Lake, 4 km (2.5 mi) northeast of the main plant area. The undeveloped land at Pantex Lake is held by DOE to retain water rights. All owned and leased buildings on the Pantex site are administered, managed, and controlled by DOE. Generalized land uses at Pantex and in the vicinity are shown in figure 4.5.2.1–1.

Industrial operations at Pantex are currently located on approximately 809 ha (2,000 acres) of DOE-owned property, excluding the Burning Ground, firing sites, and other outlying areas. The Burning Ground and firing sites occupy approximately 198 ha (489 acres).

Texas Tech Agriculture Research operations use DOE-leased land that is not actively used by Pantex operations for agricultural use. Agricultural activities generally consist of dry farming and livestock grazing. A limited amount of crop irrigation occurs. Except for the playas, the Natural Resources Conservation Service (formerly the Soil Conservation Service) considers these lands prime farmland when irrigated. Texas Tech land also contains four dwelling units located approximately 5 km (3 mi) southwest of the weapons A/D and HE production core.

The land surrounding Pantex is rural private property. The closest offsite residences are approximately 31 m (102 ft) west of the plant boundary along Farm-to-Market Road 683. Most of the surrounding land is prime farmland when irrigated, with the exception of the area northwest of the plant site, which is rangeland. The majority of the surrounding land is cultivated. The packing plant of Iowa Beef Packers, Inc., is the only industrial facility within 3 km (2 mi) of the plant.

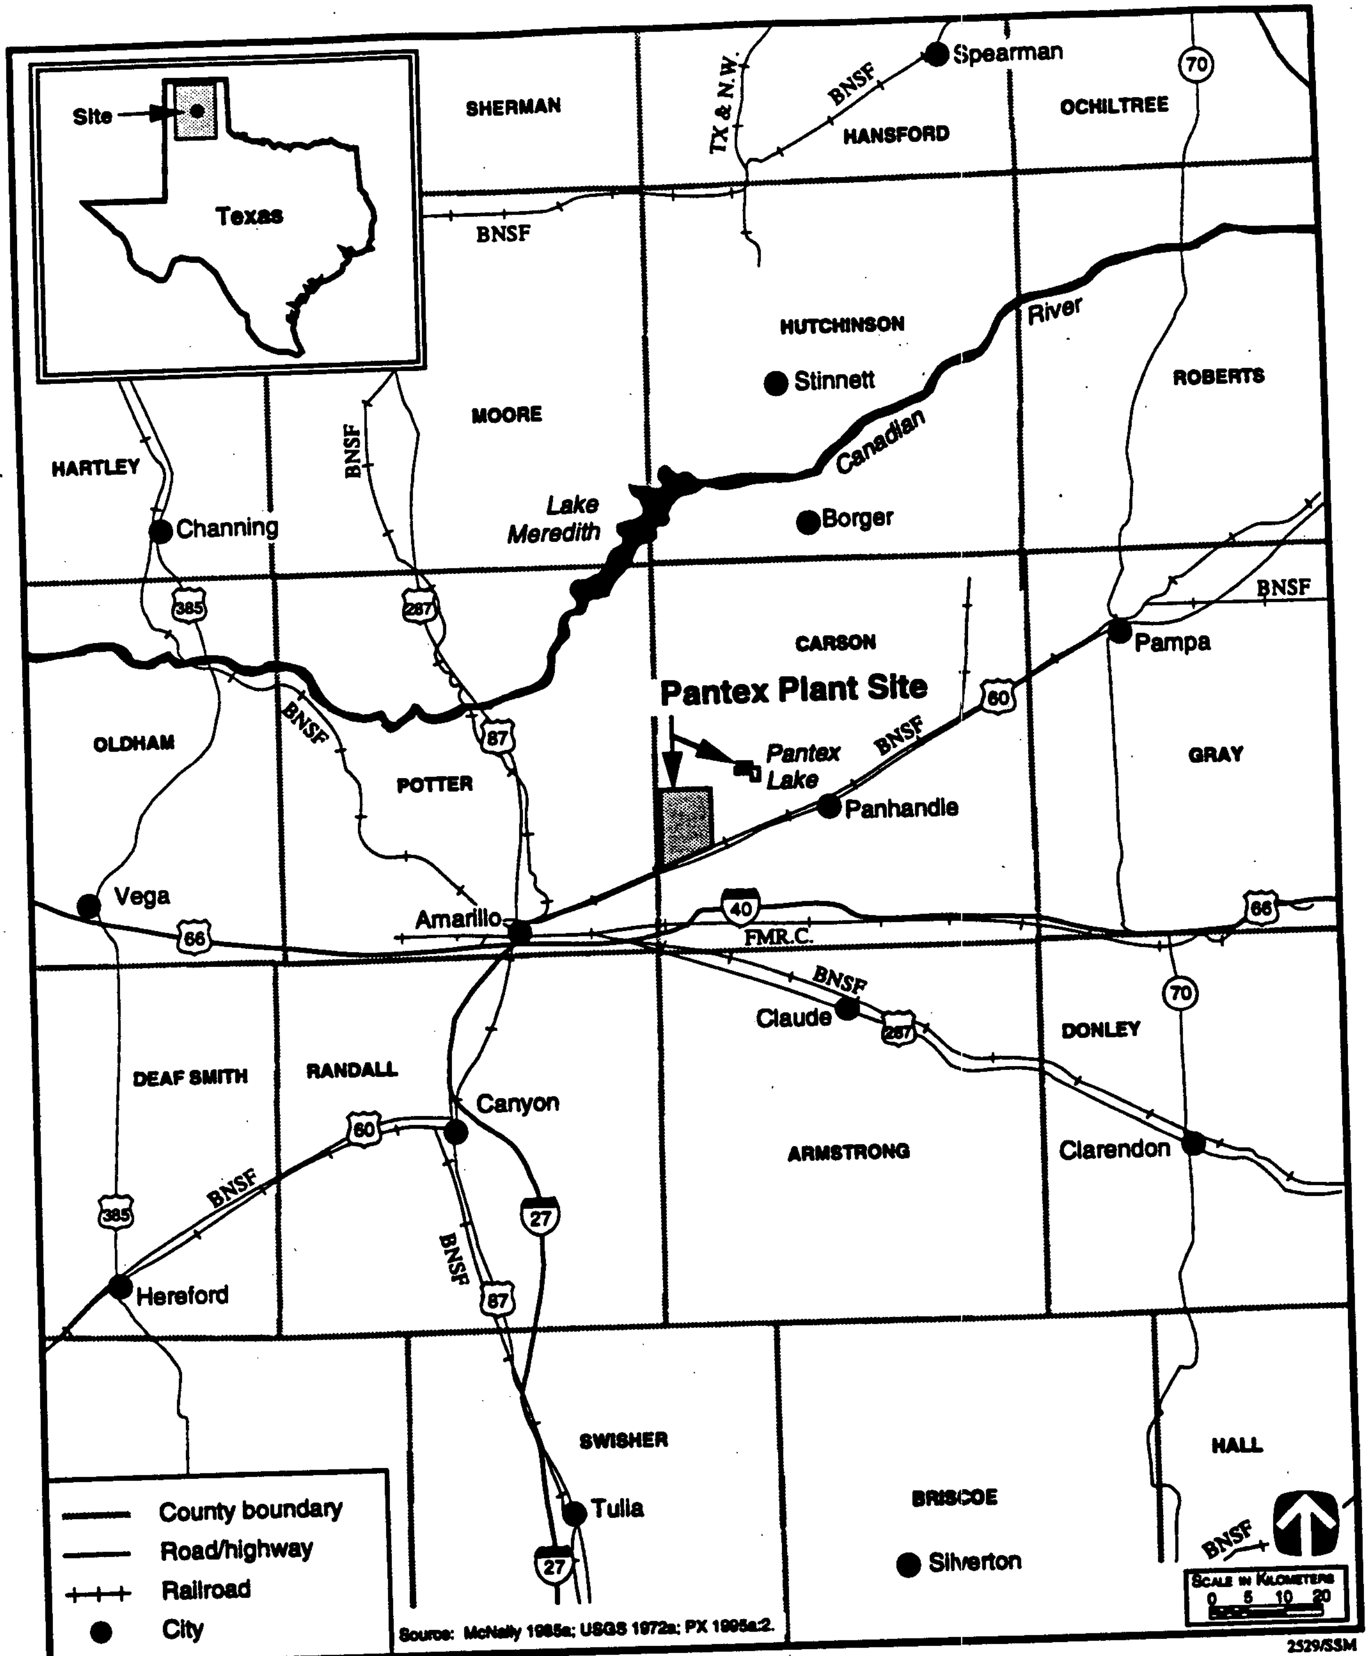

FIGURE 4.5–1.—*Pantex Plant Site, Texas, and Region.*

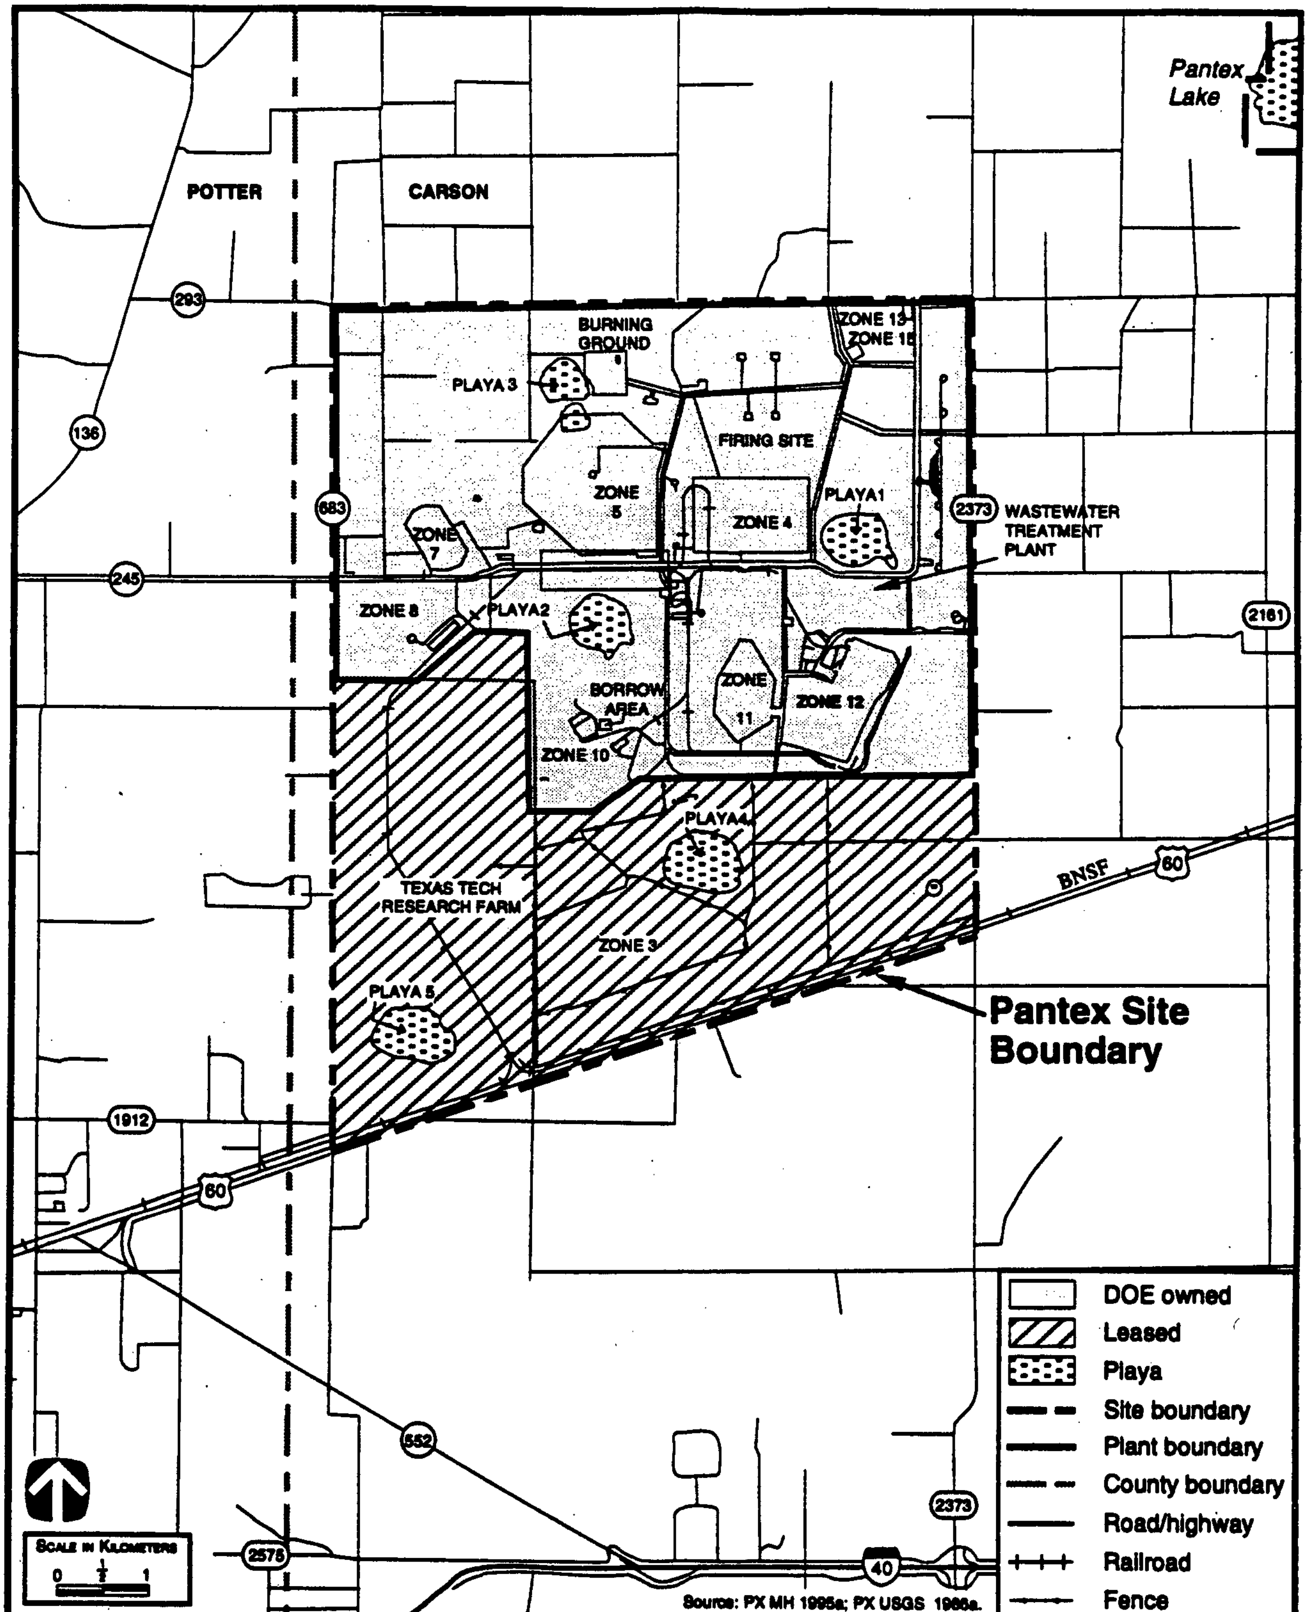

FIGURE 4.5–2.—*Principal Facilities and Zones at Pantex Plant.*

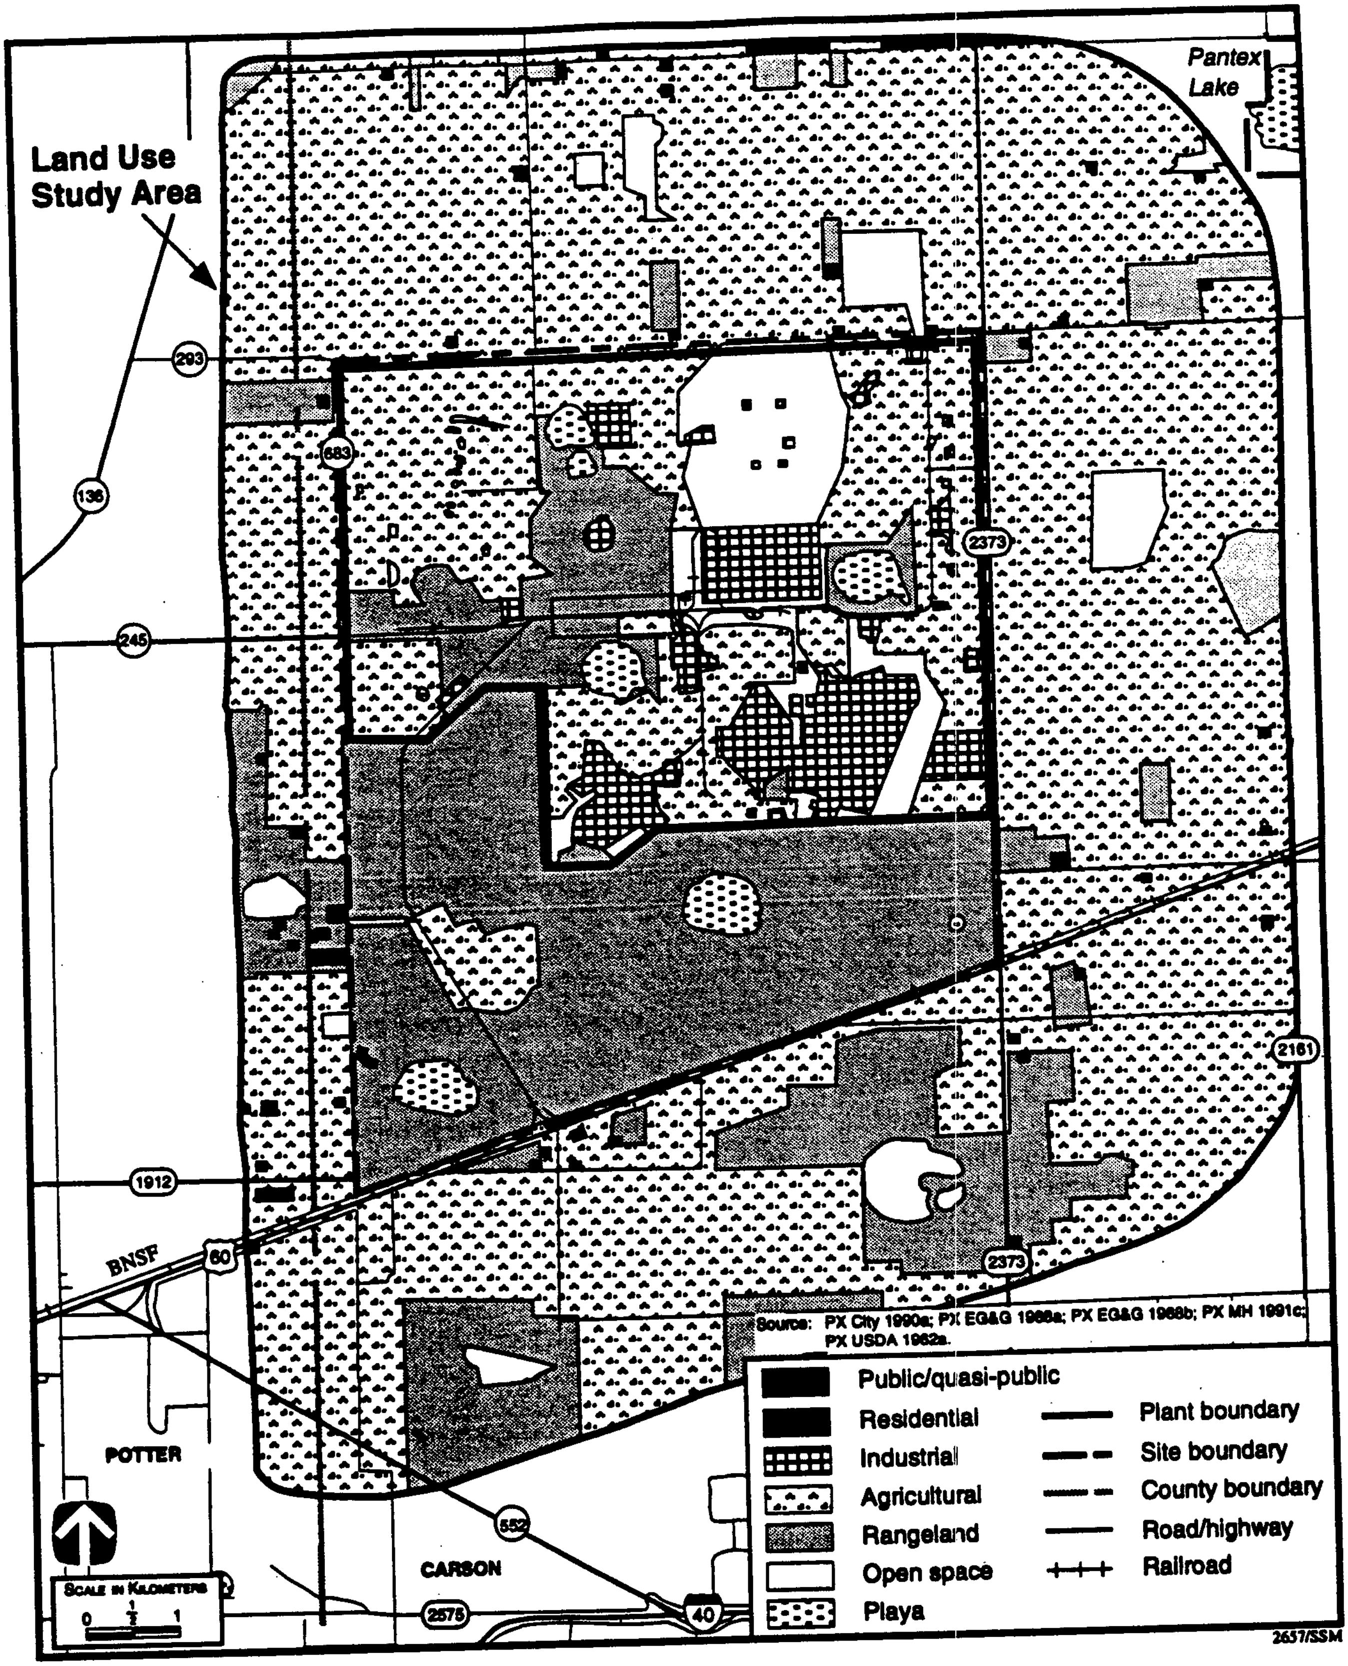

FIGURE 4.5.2.1–1.—*Generalized Land Use at Pantex Plant and Vicinity.*

Four low-altitude Federal airways used by the Amarillo International Airport for aircraft landings and takeoffs cross or come near Pantex. The runway is located approximately 11 km (7 mi) southwest of the site boundary.

It is anticipated that future residential development in the area will occur toward the southwest, away from the plant. The East Planning Area of the city, which extends to within 3.2 km (2 mi) of the plant site, has historically been one of the slower growing residential areas. Because of the presence of the airport, an important industrial use in this area, the Amarillo Comprehensive Plan encourages compatible use rather than residential use. The largest residential area, located approximately 8 km (5 mi) southwest of the plant boundary, is the site of the former Amarillo Air Force Base housing, which has been converted to rental housing.

4.5.2.2 *Site Infrastructure*

Section 3.2.5 describes the current missions at Pantex. To support these missions, infrastructure exists as shown in table 4.5.2.2–1.

TABLE 4.5.2.2–1.—***Baseline Characteristics for Pantex Plant***

Characteristics	Current Value

4.5.2.3 *Air Quality*

This section describes existing air quality including a review of the meteorology and climatology in the vicinity of Pantex. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.5.

Meteorology and Climatology. The climate at Pantex and in the surrounding region is characterized as semi-arid with hot summers and relatively cold winters. The average annual temperature in the Amarillo region is 13.8 °C (56.9 °F); average daily temperatures vary from a mean daily minimum of -5.7 °C (21.8 °F) in January to a mean daily maximum of 32.8 °C (91.1 °F) in July. The annual average precipitation is approximately 49.7 cm (19.6 in). Prevailing wind directions at Pantex are from the south to southwest. The annual average wind speed is 6.0 m/s (13.5 mph) (NOAA 1994c:3).

Ambient Air Quality. Pantex is located within the Amarillo-Lubbock Intrastate AQCR 211, which is currently designated as "attainment" or "unclassified" by EPA (40 CFR 81.344) with respect to the NAAQS for criteria pollutants (40 CFR 50). Appendix table B.3.1–1 lists the NAAQS for these criteria pollutants. These standards have been adopted by the State of Texas (TX ACB 1993a). There are no Prevention of Significant Deterioration (40 CFR 52.21) Class I areas within 100 km (62.1 mi) of Pantex.

The primary emission sources of criteria pollutants at Pantex are the steam plant boilers, the explosives burning operation, and diesel and gasoline engines. Potential emission sources of hazardous/toxic air pollutants include the HE Synthesis Facility, the explosives burning operation, miscellaneous laboratories, and other small operations. With the exception of open burning of HE at the Burning Ground, most stationary points of nonradioactive atmospheric releases are from fume hoods and building exhaust systems with HEPA filters.

Table 4.5.2.3–1 presents the baseline ambient air concentrations for criteria pollutants and other pollutants of concern at Pantex. As shown in the table, baseline concentrations are in compliance with applicable guidelines and regulations.

TABLE 4.5.2.3–1.—***Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Pantex Plant, 1993*** **[Page 1 of 3]**

4.5.2.4 *Water Resources*

This section describes the surface and groundwater resources at Pantex.

Surface Water. There are no streams or rivers at Pantex, and all site water requirements are currently met by groundwater. All surface water drains to playas, natural closed depressions that collect runoff to form ephemeral lakes. There are six playas associated with Pantex. Playas 1 through 3 are located on the main site, Playas 4 and 5 are located south and southwest, respectively, of the main site, and Pantex Lake (the sixth playa) is located approximately 4 km (2.5 mi) northeast of the main site (figure 4.5.2.4–1).

Playa 1 receives continuous wastewater discharges from the Pantex Wastewater Treatment Facility. Treated industrial wastewater discharges from buildings, and stormwater runoff are directed to Playas 1, 2, and 4. Playa 3 receives stormwater runoff from the Pantex Burning Ground. Playa 5 has received wastewater from numerous sources other than Pantex. Past Pantex activities included discharge of treated effluents to Pantex Lake. There are also a number of playas adjacent to Pantex that receive drainage from perimeter portions of the site. Playas provide a source of groundwater recharge through infiltration, although the rate of recharge is unknown. A study to determine this infiltration rate is currently being conducted (PX DOE 1996b:4-55).

Because there are no onsite or nearby flowing streams, floodplains exist only in association with the playas. The U.S. Army Corps of Engineers delineated 100- and 500-year floodplains and concluded that the only incidence of flooding would occur at Playa 3. The 500-year flood runoff at Playa 3 would overflow out of the drainage basin creating shallow (less than 30 cm [1 ft]) flooding of the drainage basins for Playas 1 and 2. This limited flooding would not affect the operations of Pantex (PX DOE 1996b:4-57).

Surface Water Quality. Surface water monitoring is conducted at all five playas at the main plant and Pantex Lake as well as at Bushland Playa, an offsite control playa (50 km [30 mi] west of Pantex) used for comparative purposes. Bushland Playa was dry during 1994. With the exception of a June 1994 high water level in Playa 1, due to a rainfall event, the Texas Natural Resources Conservation Commission's annual wastewater inspection in 1993 and 1994 did not note any deficiencies with permit requirements; however, the plant reported 16 excursions of the pH limitation during 1993. A treatment to adjust the effluent pH was installed in September 1993.

Surface Water Rights and Permits. Pantex submitted an NPDES permit application for industrial discharge on November 5, 1990, and a stormwater discharge permit application in October 1991. EPA

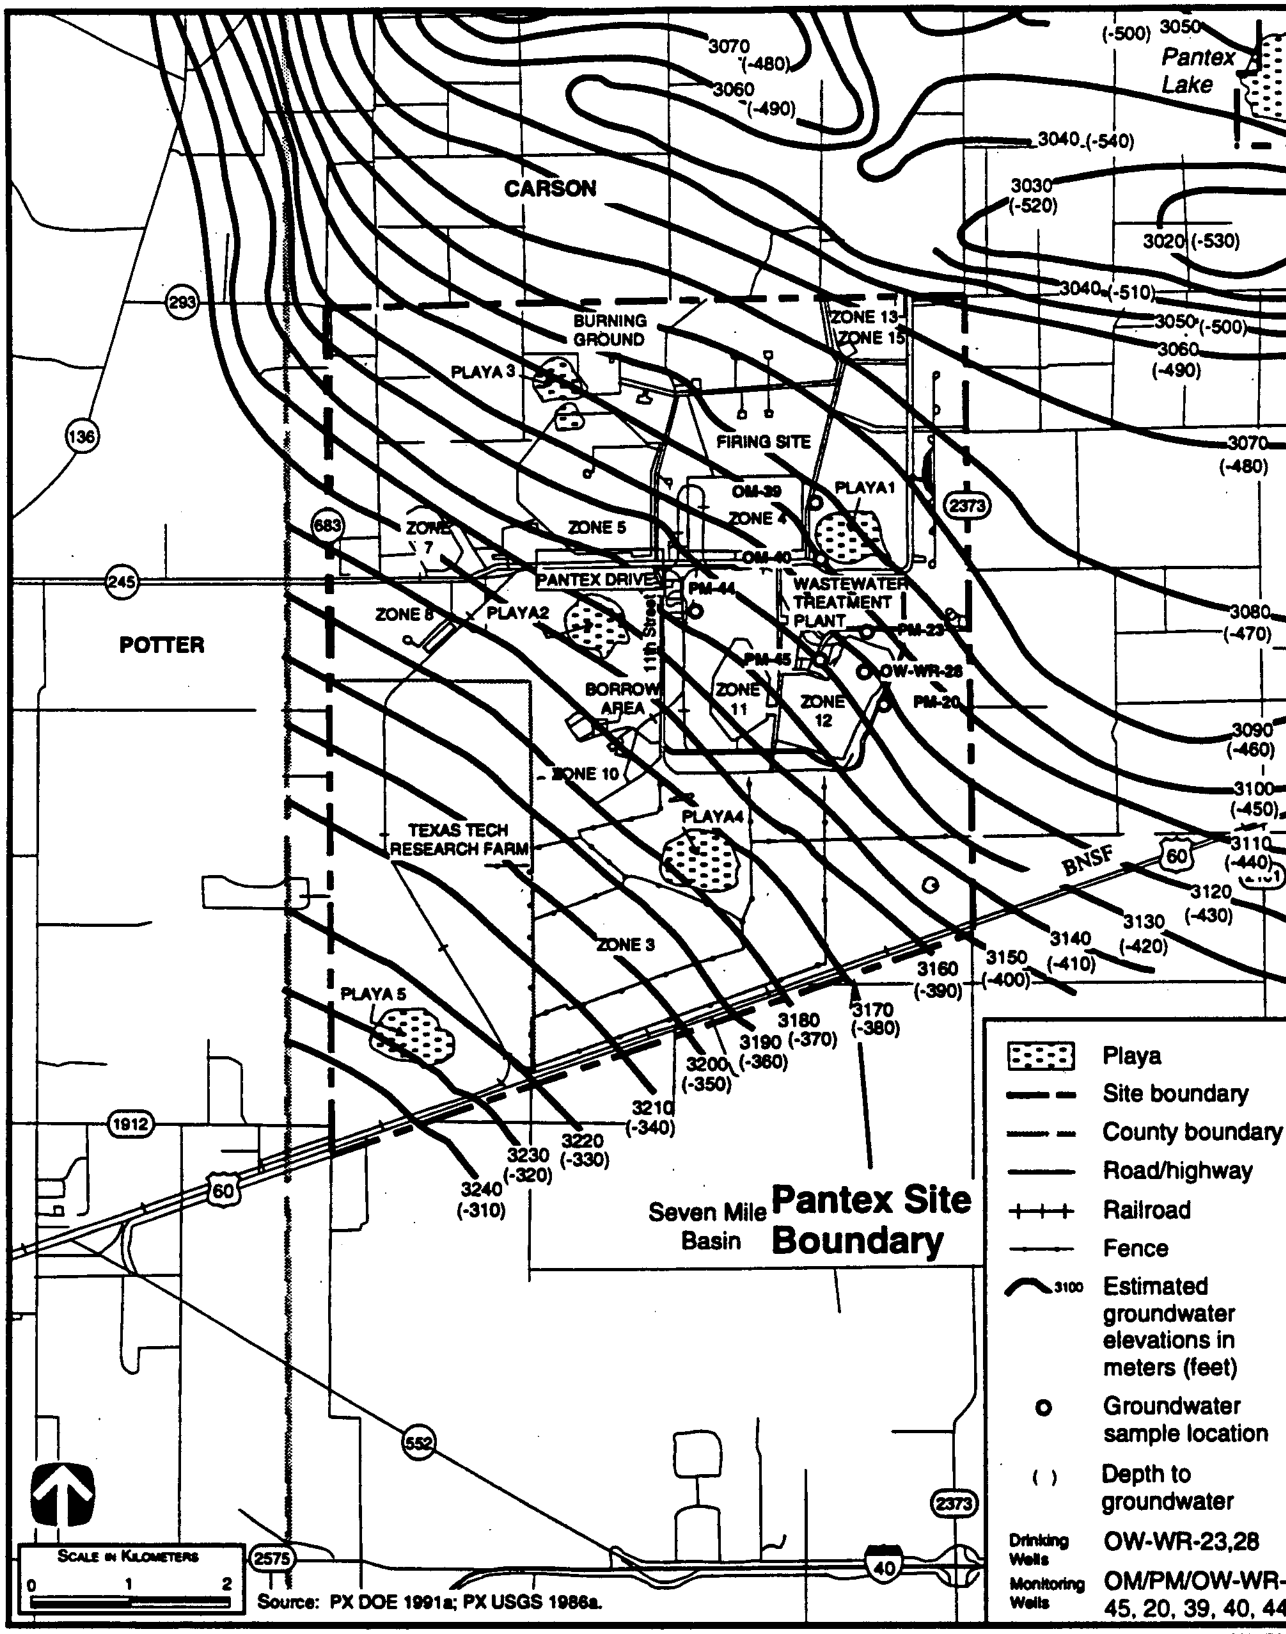

Figure 4.5.2.4–1.—*Potentiometric Surface of the Ogallala Aquifer at Pantex Plant.*

classified the playa lakes as jurisdictional wetlands and not "waters of the U.S." and therefore did not issue either permit. EPA requested on February 16, 1994, that Pantex resubmit modified NPDES permit applications for industrial discharge to Playas 1, 2, and 4. The application was submitted to EPA on August 26, 1994. A Notice of Intent to discharge stormwaters associated with nonconstruction industrial activities into Playas 1, 2, 3, and 4 via outfalls 007 through 030 was submitted to EPA on September 30, 1994. A stormwater permit was issued by EPA in February 1995. A draft NPDES industrial discharge permit was issued on December 31, 1994. Comments followed the issuance of the permit, and additional information was requested. A revised draft NPDES permit was issued on August 12, 1995; issuance of a final permit is still pending (PX DOE 1996b:4-61).

Treated domestic and industrial wastewater from Pantex is discharged into Playas 1 and 2 under the Texas Natural Resource Conservation Commission Wastewater No-Discharge Permit No. 02296. This permit was issued on May 19, 1980, and renewed and modified on May 3, 1988. This permit allows wastewater disposal by evaporation and onsite irrigation on Texas Tech University farmland. A modified renewal application was submitted on December 26, 1990. This application was protested, and the existing permit expired on May 6, 1993, without renewal. A settlement was reached on November 6, 1995, between Pantex and the local citizens. Issuance of the final permit is still pending. Until a decision is made by the Texas Natural Resource Conservation Commission, the plant continues to operate under the terms and conditions of the expired permit (PX DOE 1996b:4-61).

Water rights in Texas fall under the Doctrine of Prior Appropriations. Under this doctrine, the user who first appropriated water for a beneficial use has priority to use available water supply over a user claiming rights at a later time. Courts also recognize riparian rights legally granted from Spanish-American Agreements. The Texas Natural Resources Conservation Commission is the administrator for water rights and is the permit-issuing authority.

Groundwater. Pantex is located on the Texas High Plains aquifer system, which is the southernmost extension of a regional aquifer that extends from Texas to South Dakota (PX WDB 1993a:1). The two principal water-bearing units beneath Pantex and adjacent areas are the Ogallala aquifer and the underlying Dockum Group aquifer (PX DOE 1983a). Deep wells in the northeast corner of Pantex, completed at depths of 183 to 259 m (600 to 850 ft) into the Ogallala Formation, have provided the water supply at Pantex for over 40 years. A discontinuous perched aquifer is present at 66 to 88 m (217 to 290 ft) below ground surface; it is best defined under the eastern portion of Pantex, particularly under Zones 11 and 12. The perched groundwater is capable of yielding 2 to 5 gallons per minute, but is not used as a source for drinking water for any plant operations (PX DOE 1996b:4-65).

The Ogallala aquifer beneath Pantex has not been classified by EPA; however, it is the only source of drinking water at Pantex. Depth to water in the Ogallala aquifer ranges from 104 m (341 ft) at the southern boundary of Pantex to 140 m (459 ft) at the northern boundary. The saturated thickness of the Ogallala Formation ranges from 15 m (49.2 ft) to more than 120 m (394 ft) and in some areas is capable of producing yields in excess of 4,000 L per minute (1,050 gal per minute). Estimates of annual recharge rates to the Ogallala aquifer vary from 0.02 to 4.1 cm/yr (0.0079 to 1.6 in/yr) (PX DOE 1996b:4-69) based on earlier studies that investigated slow regional infiltration of precipitation and recent studies that explored percolation of water through playa lakes and leakage from the Dockum Group aquifer into the Ogallala aquifer (PX WDB 1993a:2).

The withdrawal of water from the Ogallala aquifer continues to exceed recharge, causing water levels to decline in the Pantex area at a rate of approximately 0.6 to 2 m/yr (1.97 to 6.56 ft/yr). From 1980 to 1990, the city of Amarillo well field north of Pantex experienced up to 20 m (60 ft) of water-level decline, causing a depression in the groundwater surface northeast of Pantex (PX WDB 1993a:11). In 1990, the recoverable volume of water in storage and available for use in the Ogallala aquifer was estimated at 5.15×10^{14} L (1.36×10^{14} gal) (PX DOE 1996b:4-71). Figure 4.5.2.4–1 shows the groundwater surface of the Ogallala aquifer beneath Pantex.

Groundwater Quality. Pantex's groundwater monitoring program includes monitoring wells and onsite Ogallala production wells distributed throughout the facility. Wells located in the vicinity of the plant are shown in figure 4.5.2.4–1. Groundwater samples collected from the wells are analyzed for a standard suite of parameters and constituents, including volatile organics, semi-volatile organics, pesticides, herbicides, trace metals, radionuclides (gross alpha and gross beta), and field parameters (total dissolved solids and pH). Limited metal concentrations have been found in some of the groundwater samples from the wells monitoring the Ogallala aquifer, including iron which was above the drinking water regulation.

Table 4.5.2.4–1 shows the most recent groundwater analytical data from the Ogallala aquifer. Past groundwater samples from the perched zone have been found to contain a variety of constituents that are either above background levels or drinking water standards or are not naturally occurring. These include 1,2-dichloroethane; chromium; iron; total dissolved solids; and trichloroethane. Table 4.5.2.4–2 shows the groundwater quality from three wells completed in the perched zone.

Groundwater Availability, Use, and Rights. Five production wells in the northeast corner of Pantex serve the plant's industrial and potable water needs. During the 1994 water year, the plant pumped 836 million L (221 million gal) of water from the Ogallala aquifer, while the city of Amarillo pumped 23,900 million L (6,320 million gal) from its Carson County well field located immediately north and northeast of the plant (PX DOE 1996b:4-77). The capacity of Pantex well field is approximately 1,990 MLY (526 MGY). Pantex Lake, located adjacent to the Amarillo water-well field, is available for drilling additional water wells if needed for future Pantex operations.

Groundwater is controlled by the individual landowner in Texas. The Texas Department of Health and the Texas Water Development Board are the two state agencies with major involvement in groundwater fact finding, data gathering, and analysis. Local groundwater management is the responsibility of local jurisdictions through Groundwater Management Districts. The Pantex facility is located in Panhandle Groundwater District 3, which has the authority to require permits and limit the quantity of water pumped. Presently, the Panhandle Groundwater District does not limit the quantity of water pumped.

4.5.2.5 *Geology and Soils*

Geology. Pantex is located on the southern High Plains of the Texas panhandle. The topography at Pantex consists of flat to gently rolling plains. There are no unique landforms, and the only distinctive features are playas that are spaced more or less uniformly over the site. The playas are about 500 to 1,000 m (1,640 to 3,280 ft) across with clay bottoms and depths to 9 m (30 ft).

The site itself is underlain by the Blackwater Draw Formation. At Pantex this geologic formation consists of a sequence of buried soils with an upper unit of mostly silt, clay, and caliche and a 12- to 23-m (40- to 75-ft) thick lower unit of silty sand with caliche. The Ogallala Formation, one of two principal water-bearing units beneath Pantex and adjacent areas, underlies the Blackwater Draw Formation.

The plant is located at the edge of a large Permian fault block, but there is no indication of faulting in the immediate area in the last 250 million years. Pantex lies on the boundary between seismic Zones 0 and 1 (figure A.1–1). Since 1906, only nine earthquakes of Richter magnitude 3.0 or greater have been recorded in the more seismically active Amarillo Uplift region 20 km (12 mi) northeast of Pantex. Seismicity in the Palo Duro Basin and at Pantex is low. There is no volcanic hazard at Pantex (DOE 1995i:4-298).

In the High Plains area, salt dissolution in Permian formations is an active process which can lead to sinkholes and fractures. Such surficial expressions have not been identified in Carson County, where Pantex is located. Sinkholes and fractures have been identified, however, in adjacent Armstrong County to the south and Hutchinson County to the north (PX DOE 1996b:4-29, 4-31).

Soils. Pantex is underlain by soils of the Pullman-Randall association. These soils are typically deep, very low permeability clay loams and clays. Pullman soils underlie most of the plant area, but Randall soils occur in the vicinity of the playas and depressions. Areas of Estacado, Lofton, and Pep clay loams are found in sloping areas surrounding playa bottoms (PX DOE 1995d:5-3). Water and wind erosion and shrink-swell potential are moderate to severe for most of the soil units (PX USDA 1962a:1,2; PX USDA 1980a:31,32). However, the soils are acceptable for standard construction techniques. DOE-leased land at Pantex that is used for agricultural purposes by

Texas Tech is considered prime farmland when irrigated (DOE 1995i:4-282).

4.5.2.6 *Biotic Resources*

The following section describes biotic resources at Pantex including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. A list of threatened and endangered species that may be found on or in the vicinity of Pantex is presented in appendix C.

Terrestrial Resources. Pantex is located within a treeless portion of the High Plains that is classified as mixed prairie. The primary vegetation of the High Plains includes short-grasses (buffalo-grass [*Buchloe dactyloides*] and blue grama [*Bouteloua gracilis*]) and mid-grasses (little bluestem [*Schizachyrium scoparium*], sideoats grama [*Bouteloua curtipendula*], and western wheatgrass [*Agropyron smithii*]) (PX DOE 1991a:2). Approximately 23 percent of the site, including land leased from Texas Tech University, has been developed. Much of the remainder of the site has been disturbed by past agricultural practices and is being managed as native and improved pasture, or is being cultivated by the university or its tenant farmers (PX DOE 1983a:3-20,3-23). Small areas of relatively undisturbed vegetation exist around playas. Some protection for native habitat is also provided at Pantex where plant operations preclude agricultural activities. Vegetation within these areas consists primarily of grasses and herbs, although barrel cactus (*Ferocactus sp.*) is also present (PX DOE 1995d;5-3, 5-4). Plant communities on the site have not been mapped. A total of 229 plant species has been identified at Pantex (PX DOE 1993c:2).

Terrestrial wildlife species identified on Pantex include 7 amphibians, 8 reptiles, 43 birds, and 19 mammals (PX DOE 1994c:4-5; PX DOE 1994d:7-11). Common animal species known to exist in the vicinity of Pantex include the upland chorus frog (*Pseudacris triseriata*), common bullsnake (*Pituophis melanoleucus*), western meadowlark (*Sturnella neglecta*), mourning dove (*Zenaida macroura*), black-tailed jackrabbit (*Lepus californicus*), and black-tailed prairie dog (*Cynomys ludovicianus*). Among the game animals existing onsite are cottontails (*Sylvilagus spp.*), scaled quail (*Callipepla squamata*), northern bobwhite (*Colinus virginianus*), mourning dove, and numerous waterfowl species (PX DOE 1994b:2,3; PX DOE 1994d:8,11). Hunting is not permitted at Pantex. Common raptors on Pantex include the Swainson's hawk (*Buteo swainsoni*) and burrowing owl (*Athene cunicularia*). Carnivores present include the American badger (*Taxidea taxus*) and coyote (*Canis latrans*). A variety of migratory birds has been found at Pantex. Migratory birds and their nests and eggs, are protected by the *Migratory Bird Treaty Act*. Eagles are similarly protected by the *Bald and Golden Eagle Protection Act*.

Wetlands. Wetlands at Pantex are associated with the five playa basins existing on the site and Pantex Lake (also a playa), located approximately 4 km (2.5 mi) northeast of the site. The National Wetland Inventory map identifies Playas 1 through 5 and part of Pantex Lake as wetlands. Playas 1, 2, and 3 are classified by the USFWS as palustrine (nontidal wetlands dominated by trees, shrubs, and emergent vegetation) systems. The larger Playas, 4 and 5, and Pantex Lake are classified as lacustrine (lakes, ponds, and other enclosed open waters at least 8 ha [20 acres] in extent and not dominated by trees, shrubs, or emergent vegetation) systems. Playas 1, 2, and 4 currently receive treated industrial discharges and stormwater runoff, while Playa 3 receives only stormwater runoff. Playa 5 and the Pantex Lake do not receive site discharges. National Wetland Inventory maps identify a number of smaller palustrine wetlands, approximately 4 ha (10 acres) or less, located on the western and southwestern parts of Pantex in areas that are largely grazed or farmed. Situated along the Central Flyway Migratory Route, the Pantex playas are important to migratory birds and provide valuable habitat for nesting and wintering birds, as well.

Aquatic Resources. Aquatic habitat at Pantex is limited to four ephemeral playas, one permanent playa, and several ditches. Although the playas and ditches located on the Pantex site proper may provide habitat for amphibians and macroinvertebrates, they do not support any fish populations. However, a small pond associated with Pantex Lake does support a small population of minnows (*Cyprinidae*) (PX DOE 1996b:4-139).

Threatened and Endangered Species. Ten Federal- or state-listed threatened, endangered, and other special status species may be found on and in the vicinity of Pantex (appendix table C–3). Five of these species have records of occurrence on the site, four of which are Federal- and/or state-listed as threatened or endangered. The Federal-listed bald eagle (*Haliaeetus leucocephalus*) is a winter resident that has been observed foraging at playas on the site each year, while the whooping crane (*Grus americana*) is considered a very infrequent migrant, last observed in 1990. The state-listed Texas horned-lizard (*Phrynosoma cornutum*) resides on site, while the white-faced ibis (*Plegadis chihi*) may forage at site playas. The Federal candidate swift fox (*Vulpes velox*) has also been observed onsite. No critical habitat for threatened and endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on Pantex.

4.5.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. Archaeological surveys at Pantex have systematically covered approximately one-half of the facility. To date, 63 prehistoric sites have been recorded on DOE and Texas Tech University property. Prehistoric site types identified at Pantex include small temporary campsites and limited activity locations characterized by surface scatters of artifacts. Some of the sites contain heat-altered rock that suggests food processing. Consistent with a Pantex prehistoric site location model, these prehistoric campsites tend to be clustered near the Pantex playa drainages. In this model, prehistoric sites would be located only within 0.4 km (0.25 mi) of playas or their drainages. Of 22 prehistoric sites tested, only one, a late prehistoric bison kill site north of Pantex Lake, has been determined potentially eligible for the NRHP. To date, no activity is planned that would affect this potentially significant site. Other identified sites are thought to be ineligible based on their lack of contextual integrity. A cultural resources management plan is being developed for Pantex. Implementation of this plan is scheduled for 1997. An interim programmatic agreement is in place to ensure regulatory compliance, and potential adverse impacts are evaluated on a case-by-case basis.

Historic Resources. The Pantex facility was originally constructed in 1942 as a World War II bomb-loading plant on land claimed from local farmers. Remains of eight of these farmsteads have been recorded as historic archaeological sites; these sites have minimal integrity and are highly unlikely to be eligible for the NRHP.

The entire Pantex site has been surveyed for World War II-era structures and foundations, and all such properties have been systematically recorded. The Texas SHPO has listed 45 of these structures as potentially eligible for the NRHP. The Cold War historic context has not yet been fully defined for Pantex. When completed, it is probable that a number of plant structures will be determined NRHP eligible.

Native American Resources. Native Americans known to have traditional interests in Pantex include the Comanche Tribe of Oklahoma, the Kiowa Tribe of Oklahoma, the Apache Tribe of Oklahoma, the Mescalero Apache Tribe, the Jicarilla Apache Tribe, the Cheyenne-Arapaho Tribe of Oklahoma, the Wichita and Affiliated Tribes, the Caddo Tribe of Oklahoma, the Delaware Tribe of Western Oklahoma, and the Fort Sill Apache Tribe. DOE is performing a historic treaties search and a public outreach program to involve Native American stakeholders in decisionmaking related to the use of plant land and the protection of cultural resources. Traditional cultural properties have not been identified at Pantex, but the remains of temporary historic campsites and hunting locations are possible.

Paleontological Resources. The surficial geology of the Pantex area consists of silts, clays, and sands of the Blackwater Draw Formation. In other areas of the High Plains, this formation contains Late Pleistocene vertebrate remains, including bison, camel, horse, mammoth, and mastodon, with occasional and significant evidence of their use by early humans. Evidence of woolly mammoths has been found north of Pantex near the Canadian River.

4.5.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at Pantex include employment, regional economy, population, housing, and public finance. Statistics for employment and regional economy are presented for the regional economic area that encompasses 32 counties surrounding Pantex in Texas and New Mexico. Statistics for population, housing, and public finance are presented for the ROI, a four-county area in which approximately 96 percent of all Pantex employees reside: Armstrong County (1 percent), Carson County (11 percent), Potter County (34 percent), and Randall County (50 percent). Site employment at Pantex totalled 3,555 in 1994 and is projected to decrease to 1,644 by 2005. Figure 4.5.2.8–1 presents a map of the counties and selected cities composing the Pantex regional economic area and ROI. Supporting data are shown in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the Pantex regional economic area are summarized in figure 4.5.2.8–2. The civilian labor force in the regional economic area grew approximately 9 percent between 1980 and 1990 (about 1 percent annually). Total employment in the region was 219,504 in 1994. In 1994, unemployment in the regional economic area was 4.8 percent, significantly lower than 6.4 and 6.3 percent unemployment in Texas and New Mexico, respectively. The 1993 per capita income in the regional economic area was $19,310, approximately 1.5 percent higher than the per capita income in Texas ($19,023) and 19 percent higher than New Mexico's per capita income of $16,346.

As shown in figure 4.5.2.8–2, the Pantex regional economic area, Texas, and New Mexico have similar employment patterns. The service sector accounts for the largest share of total employment in both Texas and New Mexico (28 percent in both states), as well as in the region (22 percent). Manufacturing, however, accounts for a greater share of employment in Texas (11 percent) than in the region (9 percent) or New Mexico (6 percent).

Population and Housing. The ROI population, which totalled 200,052 in 1992, increased by approximately 10 percent (less than 1 percent annually) between 1980 and 1992, less than half the growth rate of Texas during the same period. Furthermore, population growth was uneven among the ROI counties; Randall County grew about 22 percent (an annual rate of almost 2 percent) while the populations of Carson and Armstrong Counties decreased slightly.

Increases in the number of housing units averaged approximately 1 percent annually in the ROI from 1980 to 1990, less than the almost 3 percent annual increase for Texas. Within the ROI, the number of housing units increased at a rate of almost 3 percent in Randall County, while the number of units decreased slightly in both Carson and Potter Counties. Homeowner and rental vacancy rates in the Pantex ROI in 1990 were comparable to those in Texas. Population and housing statistics for the ROI are summarized in figure 4.5.2.8-3.

Public Finance. Financial characteristics of the local jurisdictions in the Pantex ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure fund categories for counties, cities, and school districts are presented in appendix tables D.2.3–6 and D.2.3–7. Figure 4.5.2.8–4 summarizes local governments' revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.5.2.8–4. All jurisdictions assessed had positive fund balances.

4.5.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at Pantex. Also included are discussions of health effects studies, emergency preparedness considerations, and a brief accident history.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of Pantex are shown in table 4.5.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. The incremental total dose to the population would result only from changes in the size of the population. Background radiation doses are unrelated to Pantex operations.

Releases of radionuclides to the environment from Pantex operations provide another source of radiation exposure to people in the vicinity of Pantex. The radionuclides and quantities released from Pantex

operations in 1994 are listed in the *1994 Environmental Report for Pantex Plant* (DOE/AL/65030-9506). The doses to the public resulting from these releases are given in table 4.5.2.9–2. These doses fall within radiological limits (DOE Order 5400.5) and are small in comparison to background radiation. The releases listed in the 1994 report were used in the development of the reference environment (No Action) radiological releases at Pantex in 2005 (section 4.5.3.9).

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem ($5x10^{-4}$ fatal cancer per person-rem) to the public (appendix E), the fatal cancer risk to the maximally exposed member of the public due to radiological releases from Pantex operations in 1994 is estimated to be approximately $2.9x10^{-11}$. That is, the estimated probability of this person dying of cancer at some point in the future from radiation exposure associated with 1 year of Pantex operations is less than 3 chances in 100 billion. (Note that it takes several to many years from the time of exposure to radiation for a cancer to manifest itself.)

Based on the same conversion factor, $7.0x10^{-8}$ excess fatal cancers are projected in the population living within 80 km (50 mi) of Pantex from normal operation in 1994. To place this number into perspective, it can be compared with the number of fatal cancers expected in this population from all causes. The 1990 mortality rate associated with cancer for the U.S. population was 0.2 percent per year (Almanac 1993a:839). Based on this mortality rate, the number of fatal cancers from all causes expected to occur during 1994 in the population living within 80 km (50 mi) of Pantex was 550. This number of expected fatal cancers is much higher than the

TABLE 4.5.2.9–2.—*Doses to the General Public from Normal Operation at Pantex Plant, 1994 (Committed Effective Dose Equivalent)*

Affected Environment	Atmospheric Releases		Liquid Releases		Total	
	Standard[a]	Actual	Standard[a]	Actual	Standard[a]	Actual
Maximally exposed individual (mrem)	10	$5.8x10^{-5}$	4	0.0	100	$5.8x10^{-5}$
Population within 80 kilometers[b] (person-rem)	None	$1.4x10^{-4}$	None	0.0	100	$1.4x10^{-4}$
Average individual within 80 kilometers[c] (mrem)	None	$5.0x10^{-7}$	None	0.0	None	$5.0x10^{-7}$

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem/yr limit from airborne emissions is required by the CAA, the 4 mrem/yr limit is required by the SDWA, and the total dose of 100 mrem/yr is the limit from all pathways combined. The 100 person-rem value for the population is given in proposed 10 CFR 834 (58 FR 16268).

[b] In 1994, this population was approximately 275,000.

[c] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.

TABLE 4.5.2.9–3.—*Doses to the Onsite Worker from Normal Operation at Pantex Plant, 1994*

Affected Environment	Onsite Releases and Direct Radiation	
	Standard[a]	Actual[b]
Average worker (mrem)	None	10
Maximally exposed worker (mrem)	5,000	660
Total workers (person-rem)	None	30

[a] 10 CFR 835. DOE's goal is to maintain radiological exposure as low as reasonably achievable.

[b] PX DOE 1995d. The number of badged workers in 1994 was approximately 2,980.

estimated 7.0×10^{-8} fatal cancers that could result from Pantex operations in 1994.

Workers at Pantex receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities. Table 4.5.2.9–3 includes the average, maximum, and total occupational doses to Pantex workers from operations in 1994. These doses fall within radiological limits (10 CFR 835). Based on a dose-to-risk conversion factor of 400 fatal cancers per 1 million person-rem (4×10^{-4} fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to Pantex workers from operations in 1994 is estimated to be 0.012.

A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in the *Pantex Plant Site Report for Calendar Year 1994*. In addition, the concentrations of radioactivity in various environmental media (e.g., air, water, and soil) in the onsite and offsite site regions are presented in the same reference. Pantex operations contribute only small amounts of radioactivity to all these media.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in sections 4.5.2.3 and 4.5.2.4.

Adverse health impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and to achieve compliance with permit requirements. The effectiveness of these controls is verified through the use of monitoring information and inspection of mitigation measures. Health impacts to the public may occur during normal operation at Pantex via inhalation of air containing hazardous chemicals released to the atmosphere by Pantex operations. Risks to the public health from ingestion of contaminated drinking water or by direct exposure are also potential pathways.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.5.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. All annual concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous/toxic chemicals is presented in appendix E.

Exposure pathways to Pantex workers during normal operation may include inhaling the workplace atmosphere, drinking Pantex potable water, and possible other contact with hazardous materials associated with particular work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. Pantex workers are also protected by adherence to OSHA and EPA occupational standards that limit workplace atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operating processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm. Therefore, worker health conditions at Pantex are expected to be substantially better than required by standards.

Health Effects Studies. Only one mortality study and one cancer incidence epidemiological study of the general population in communities surrounding Pantex has been performed, and only one study of workers has been done. Significant increases in prostate cancer mortalities among males in Potter and Randall Counties and leukemia mortalities among Carson County males were observed between 1981 and 1992. The analysis on excess cancer incidence found no statistically significant excesses in males. Workers were reported to show a nonstatistically significant excess of brain cancer and leukemia in the one study conducted, but the small number of cases could be attributed to chance alone. For a more detailed description of the studies reviewed and the findings, refer to appendix section E.4.5.

Accident History. There have been no plutonium-dispersing detonation accidents during nuclear weapons operations at Pantex. In 1989, during a weapon disassembly and retirement operation, a release of tritium in the assembly cell occurred. As a result, four workers received negligible doses and a fifth worker received a dose of 1.4 mrem.

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response to accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with planning, preparedness, and response.

Pantex has an emergency management plan, with guidance on implementation provided by a series of Emergency Preparedness Procedures manuals, to protect life and property within the facility, the health and welfare of surrounding areas, and the defense interests of the Nation during any credible emergency situation. Formal mutual assistance agreements have been made with Federal, State of Texas, and local governments. Federal agreements include Interagency Agreements with the Federal Bureau of Investigation for security-based events requiring its efforts, Veteran's Administration for maintenance of an Emergency Radiation Treatment Facility, LLNL for plume modeling information and data from the Atmospheric Release Advisory Center, and the U.S. Army for Explosives Ordnance Disposal. The DOE/State of Texas Agreement-in-Principle contains both DOE and State activities to mutually improve and integrate both Pantex and State of Texas emergency preparedness programs for potential Pantex-generated emergencies. Memoranda of Understanding among the city of Amarillo, Carson County, and Randall County are in place for mutual assistance and aid in the event of a Pantex-generated emergency. Under accident conditions, an emergency coordinating team of DOE and Pantex contractor management personnel would initiate the Pantex Emergency Plan and coordinate all onsite actions.

If offsite areas could be affected, the Texas Department of Public Safety would be notified immediately, and would make emergency announcements to the public and local governmental agencies in accordance with Annex R of the State of Texas Emergency Management Plan. Pantex has radiological assistance teams with a total of 46 personnel who are equipped and trained to respond to an accident involving radioactive contamination either onsite or offsite.

In addition, the Joint Nuclear Accident Coordination Center in Albuquerque, NM, can be called upon should the need arise. This would mobilize radiation emergency response teams from DOE, DOD, and other participating Federal agencies.

4.5.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and ongoing waste management activities for Pantex. A more detailed discussion of the ongoing waste management operation is provided in appendix section H.2.4.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operations at Pantex. The activities DOE is engaged in to bring its operations into full regulatory compliance are set forth in negotiated agreements that contain schedules for achieving compliance with applicable requirements and financial penalties. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

EPA Region 6 on July 29, 1991, proposed Pantex for listing on the NPL of Superfund cleanup sites. Independent evaluations questioned this proposed listing and DOE dissented on the proposal. In September 1991, DOE submitted to EPA its technical comments regarding the proposed listing. EPA placed Pantex on the NPL on May 31, 1994. The DOE Amarillo Area office is currently negotiating a tri-party Federal Facility Agreement with the EPA and the State of Texas. Currently all environmental restoration activities are conducted in compliance with an RCRA permit issued in April 1991. Environmental restoration activities are expected to be completed in 2000.

Pantex's waste management goals are to avoid waste generation or minimize the volume of waste generated to the extent that is technologically and economically practicable, reduce the hazard of waste through substitution or process modification, minimize contamination of existing or proposed real property and facilities, minimize exposure and associated risks to human health and the environment to as low as reasonably achievable levels, and ensure safe, efficient, and compliant long-term management of all wastes. Pantex manages four broad waste categories: low-level, mixed, hazardous, and nonhazardous. Pantex does not generate or manage spent nuclear fuel or HLW. Pantex does not generate TRU waste as a result of normal operation. In the unlikely event that any TRU waste is generated, it would be stabilized and packaged in an appropriate container until shipment to a DOE-approved storage site. A discussion of the waste management operations associated with the remaining categories follows.

Low-Level Waste. LLW generated at Pantex consists of radioactive waste materials associated with weapons A/D, such as protective clothing, cleaning materials, filters, and other similar materials. In 1994, Pantex generated 33 m^3 (8,720 gal) of liquid and 122 m^3 (160 yd^3) of solid LLW (PX 1995a:2). Liquid LLW is being stored onsite awaiting a treatment process. Compactible wastes are processed at Pantex's Solid Waste Compaction Facility and staged along with the noncompactible wastes for shipment to a DOE-approved disposal site and/or a commercial vendor. Pantex's LLW is currently shipped to NTS for disposal.

Mixed Low-Level Waste. Mixed LLW is generated during various production, maintenance, modification, and dismantlement functions. For 1994, Pantex generated approximately 1 m^3 (264 gal) of liquid and 15 m^3 (20 yd^3) of solid mixed LLW (PX 1995a:2). These wastes consist primarily of small quantities of material such as radioactively contaminated solvents and wipes contaminated by organic solvents and radioactive scrap metal. Mixed LLW is currently stored onsite in RCRA-permitted facilities. Pantex has received exemptions to DOE Order 5820.2A, *Radioactive Waste Management* for mixed waste shipments to two RCRA-permitted commercial facilities. Pantex developed the *Pantex Plant Compliance Plan* to provide mixed waste treatment capability for all mixed waste streams in accordance with the *Federal Facility Compliance Act* of 1992. This plan was approved by the Texas Natural Resources Conservation Commission and adopted through an Agreed Order on September 27, 1995. The Agreed Order signed by the State of Texas on October 2, 1995, requires implementation of this plan.

Hazardous Waste. Pantex received an RCRA Part B hazardous waste permit from EPA and the Texas Natural Resources Conservation Commission on April 25, 1991. This permit authorizes Pantex to manage hazardous and industrial solid wastes listed in the permit. The permit also requires Pantex to notify the Texas Natural Resources Conservation Commission of the discovery of any release of hazardous waste or hazardous constituents that may have occurred from any solid waste management unit. The hazardous waste permit specifically excluded the 17 RCRA units at the HE Burning Ground that are currently operated under interim status with a written grant of authority for air emissions from the Texas Natural Resources Conservation Commission. Pantex has submitted a request to the Texas Natural Resources Conservation Commission for an RCRA Part B permit modification to add these units at the Burning Ground. A decision on this modification has not been reached.

Most of the hazardous waste generated by Pantex results from HE operations; however, electroplating and photographic and various other operations also generate additional hazardous waste streams. In 1994, Pantex generated 16 m^3 (4,230 gal) of solvent-contaminated wastewater, explosives-contaminated wastewater, and spent organic solvents contaminated with explosives. Solid hazardous wastes included approximately 177 m^3 (232 yd^3) of RCRA-regulated and 8 m^3 (10 yd^3) of TSCA-regulated wastes (PX 1995a:2). HE, HE support material, HE-contaminated materials, and HE-contaminated solid wastes are burned under controlled conditions at Pantex's Burning Ground. Ash, debris, and residue resulting from this burning are transported offsite for approved disposal at a commercial RCRA-permitted facility. All other hazardous waste generated at Pantex, including various chemicals, solvents, heavy metals, and other hazardous constituents, are manifested and shipped offsite by DOT-certified transporters for recycling or disposal at a commercial RCRA-permitted facility.

Nonhazardous Waste. Nonhazardous solid and liquid sanitary wastes are generated at Pantex. An estimated 476,000 m^3 (125,700,000 gal) of sewage wastewater and 4,190 m^3 (1,107,000 gal) of other wastewater was generated in 1994 (PX 1995a:2). Sewage and some pretreated industrial wastewater are treated by the sanitary sewage wastewater treatment system. The liquid effluent from the system is discharged into a playa, where it then either evaporates or filtrates into the ground. Liquid industrial waste is also treated in a tank system that removes metals from plating solutions and then neutralizes this solution. The effluent from this process is discharged to a playa, which is permitted by the Texas Natural Resources Conservation Commission. Stormwater discharges are regulated by a NPDES permit. A proposed upgrade to the sanitary wastewater sewer treatment system would permit all industrial wastewater and sewage to be treated at one location.

Nonhazardous solid waste generated onsite consists primarily of paper, cardboard, construction waste, and cafeteria waste. For 1994, Pantex generated approximately 824,400 kg (1,817,500 lb) of solid sanitary waste (PX 1995a:2). Seventy percent of the solid sanitary waste was disposed of at the City of Amarillo Landfill. The remainder was shipped offsite to other treatment/disposal facilities. In addition, 47,400 m^3 (62,000 yd^3) of construction debris were generated (PX 1995a:2). Only construction wastes are disposed of onsite. Prior to late 1989, sanitary waste was disposed of onsite. Since then, sanitary waste has been transported to the City of Amarillo Landfill for disposal. Waste asbestos is sent to an offsite permitted landfill.

4.5.3 Environmental Impacts

4.5.3.1 *Land Use*

No Action. Under No Action, DOE would continue current and planned activities at Pantex. No additional land use impacts are anticipated at Pantex beyond the effects of existing and future activities which are independent of the proposed action.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. The downsizing and consolidating of the A/D and HE fabrication activities at Pantex would occur within existing buildings. Modification of existing buildings would require the short-term use of approximately 0.4 ha (1 acre) for equipment laydown and parking. These activities would be accommodated within vacant building space or developed areas near the modification sites. No additional land would be used to implement the downsize A/D and HE fabrication mission. The proposed activities would be compatible with existing land use plans. Impacts to land use are not expected.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no adverse impact on Pantex land-use plans and policies. Vacated storage facilities would be transferred to EM for D&D and disposition.

Downsize Assembly/Disassembly. The downsizing and consolidating of A/D activities at Pantex would occur within existing buildings. Modification of existing buildings would require the short-term use of approximately 0.2 ha (0.4 acres) for equipment laydown and parking. These activities would be accommodated within vacant building space or developed areas near the modification sites. No additional land would be used to implement the downsize A/D mission. The phaseout of HE fabrication would make more of the Pantex site available for other use but would not adversely affect land use at Pantex. The proposed activities would be compatible with existing land use plans and activities. Impacts to land use are not expected.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. This alternative would not affect land use in the short term. Facilities and infrastructure would transition to EM for D&D before disposition. A future scenario may be the potential for the site to accommodate industrial-type activities. The subsequent use of Pantex facilities and land would be addressed in the transition plan prepared by EM.

Sensitivity Analysis. All operations and support functions and facilities for the downsize A/D and HE fabrication activities at Pantex would be sufficient to accommodate the high and lower production cases with no change.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.5.3.2 *Site Infrastructure*

The Pantex infrastructure would be capable of supporting the downsizing and consolidation of the A/D and HE fabrication missions or A/D mission alone without major modifications. A comparison of site infrastructure and facility requirements for the proposed alternatives is shown in table 4.5.3.2–1. Site infrastructure construction impacts would be minimal since existing Pantex facilities would be used with only minor modifications.

No Action. This alternative would continue the A/D and HE fabrication missions described in section 3.2.5 in essentially the same facilities. The significant reduction in required site infrastructure resources shown in table 4.5.3.2–1 reflects the reduced workload after current nuclear weapons stockpile dismantlement actions are complete. Because of the reduced production workload, the need for site infrastructure resources would be less than the current requirements for electrical energy, liquid fuel, and natural gas. Peak electrical load would be 74 percent of current demand.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. This alternative would downsize and consolidate the A/D and HE fabrication missions with nonintrusive modification pit reuse and the option of storing the strategic reserve of pits and canned subassemblies at Pantex. The action would result in a 6-percent increase in natural gas consumption compared to the No Action alternative. There

TABLE 4.5.3.2–1.—***Site Infrastructure Requirements and Changes for Stockpile Management Alternatives at Pantex Plant***

Alternative	Electrical		Fuel		
	Energy (MWh/yr)	Peak Load (MWe)	Liquid (L/yr)	Gas (m^3/yr)	Coal (t/yr)
Current Resources (1994)	84,420[a]	13.6[b]	1,775,720	14,600,000[c]	NA
No Action (2005)					
Total site requirement	46,266	10	795,166	7,200,000	NA
Change from current resources	-38,154	-3.6	-980,554	-7,400,000	NA
Downsize Weapons Assembly/Disassembly and High Explosives Fabrication					
Total site requirement	46,250	11	795,600	7,650,000	NA
Change from No Action	-16	1	434	450,000	NA
Downsize Weapons Assembly/Disassembly					
Total site requirement	43,000	10	740,000	7,150,000	NA
Change from No Action	-3,266	0	-55,166	-50,000	NA
Phaseout Weapons Assembly/Disassembly and High Explosives Fabrication					
Total site requirement	0	0	0	0	NA
Change from No Action	-46,266	-10	-795,166	-7,200,000	NA

[a] System capacity is 201,480 MWh/yr.
[b] System capacity is 22.5 MWe.
[c] System capacity is 289,000,000 m^3/yr.
Note: NA - not applicable.
Source: PX 1995a:2; PX 1996e:1; PX DOE 1995g; PX DOE 1996b; PX MH 1995a.

would be only a slight change from No Action requirements in the other site infrastructure resources.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would cause a negligible change in these requirements because these types of facilities require little infrastructure support and resources. Moving the strategic reserve would make available additional storage facilities for transition to EM for D&D and disposition.

Downsize Assembly/Disassembly. The weapons A/D alternative would downsize and consolidate the A/D mission with nonintrusive modification pit reuse, and the option of storing the strategic reserve of pits and canned subassemblies at Pantex. Under this alternative, HE fabrication at Pantex would also be phased out. This alternative would reduce the requirements for electrical energy by 7 percent, liquid fuel by 7 percent, and natural gas by 1 percent compared to the No Action alternative. Storing strategic reserve pits at another site instead of Pantex would result in a minimal change in site infrastructure requirements.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. This alternative would phase out the A/D and HE fabrication missions. Site infrastructure would continue to operate and resources would continue to be consumed during transition of the buildings to EM for D&D.

Sensitivity Analysis. To support high case production output with single-shift operation, more facilities would be required. Specifically, Pantex would retain 48 operational assembly bays instead of 31, 6 operational assembly cells instead of 4, and a small number of additional cells for strategic reserve storage. Also, several other functions, including weapon staging and pit laser sampling, would be relocated to provide more capability. The only increased facility requirement for HE fabrication would be activating additional operating bays in the HE Machining Building. Very small differences exist between the base and low or high case options in the site infrastructure variables considered in this analysis. There would be little or no difference in the site infrastructure impacts associated with high case operations.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.5.3.3 *Air Quality*

No Action. No Action air quality utilizes estimated air emissions data from operations at Pantex in 2005, assuming continuation of current site missions, to calculate pollutant concentrations at or beyond the Pantex site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in appendix table B.3.5–1. Table 4.5.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rate. In this table, pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. Gaseous emissions of criteria and toxic/hazardous air pollutants would be generated from the downsized and/or consolidated A/D and HE fabrication mission. These emissions would result from open burn/open detonation of nonradioactive scrap HE and HE-contaminated waste, plant boiler operation, cleaning operations using solvents, and formulation and synthesis operations. Emission rates for the HE fabrication mission for criteria and toxic/hazardous pollutants are presented in table appendix B.3.5–1. Table 4.5.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from downsizing and/or consolidating the A/D and HE mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on air quality because storage facilities and strategic reserve activities have no measurable air emissions.

Downsize Assembly/Disassembly. Gaseous emissions of criteria and toxic/hazardous air pollutants would be generated from operation of the downsized and/or consolidated A/D mission. These emissions would result from plant boiler operation and cleaning operations using solvents (PX MH 1995a:H-17). Emission rates for criteria and toxic/hazardous pollutants from the downsized and/or consolidated A/D mission are presented in appendix table B.3.5–1. Table 4.5.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from operation of the downsized and/or consolidated A/D mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. Phaseout of the A/D and HE fabrication mission at Pantex would result in a net reduction of criteria and toxic/hazardous emissions. Table 4.5.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from phaseout of the A/D and HE fabrication mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the downsize A/D and HE fabrication or downsize A/D alternative would result in higher and lower concentrations of criteria and toxic/hazardous pollutants for the high and low cases, respectively. The concentrations of pollutants for the high case are expected to be within applicable Federal and state regulations and guidelines.

Potential Mitigation Measures. No mitigation measures are anticipated for the downsize A/D and HE fabrication, downsize A/D, or phaseout of A/D and HE fabrication alternatives at Pantex.

4.5.3.4 *Water Resources*

Environmental impacts associated with building modification activities and operation of the proposed A/D and HE facilities at Pantex could affect surface

[a] Federal standard.
[b] No air pollutants will be emitted from Pantex after phaseout of A/D and HE fabrication.
[c] No sources indicated.
[d] State standard. The effect screening levels are used in evaluation of hazardous and other toxic compounds.
[e] No Standard.
[f] No data available, concentration assumed less than applicable standard.
Note: 30-minute concentrations are represented by 1-hour predicted concentrations; concentrations for downsized alternatives represent the alternative only.
Source: 40 CFR 50; PX 1996e:1; PX DOE 1996b; PX MH 1995a; PX MH 1995b; TX ACB 1987a; TX ACB1993a; TX NRCC 1992a; TX NRCC 1995a.

and groundwater resources. All water required for modification or operation would be supplied from groundwater. The facilities affected by the alternatives are located outside the 100- and 500-year floodplains. A description of the activities that would continue at Pantex is provided in section 3.2.5. Table 4.5.3.4–1 presents existing surface and groundwater resources and the potential changes to water resources at Pantex resulting from the proposed alternatives. The total site water resource requirements for each alternative including No Action (base case, single-shift operation) are displayed in this table.

Surface Water

No Action. No construction would take place under No Action; therefore, no additional construction water or wastewater would be used or discharged. During operation under No Action, no surface water would be used. However, current wastewater discharges to Playas 1, 2, and possibly 4, would decrease by approximately 339 MLY (89.6 MGY) by 2005. No additional impacts to surface water quality are expected since treated water discharges would be reduced.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. No surface water would be used for any building modification or operation activities associated with downsizing and consolidating A/D and HE fabrication. No additional impacts to surface water availability or surface water quality are expected. Downsizing modifications would take approximately 3 years. The estimated 141.5 MLY (37 MGY) of nonhazardous wastewater, including sanitary wastewater, generated during the modification of the facilities would be discharged to playas. Discharging the wastewater would not result in an exceedance of the Texas Natural Resources Conservation Commission-permitted discharge volume limit.

During operation, approximately 148 MLY (39 MGY) of treated effluent would be discharged from utility processes and facility sanitary wastewater. All treated effluent would be required to meet NPDES permit requirements. No adverse impacts to surface water or surface water quality are expected. The estimated volume of wastewater discharged to the playas would be within the Texas Natural Resources Conservation Commission-permitted discharge volume limit.

Stormwater runoff would be collected in detention ponds. Runoff from site support facilities outside the main plant would be discharged directly to natural drainage channels. Uncontaminated stormwater would be released to natural drainage channels. Contaminated runoff would be retained, treated, and released. All discharges to playas would be monitored and subject to NPDES permit requirements.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on surface or groundwater resources at Pantex.

Downsize Assembly/Disassembly. No surface water would be used for any modification or operation activities associated with downsizing and consolidating A/D facilities. The estimated 141 MLY (37 MGY) of nonhazardous wastewater generated while modifying the facilities would either be recycled or treated and discharged to the playas. Potential impacts to surface waters during the 3-year modification phase for any of the facilities are not expected. During modification activities, wastewater discharged to the playas would not cause an exceedance of the Texas Natural Resources Conservation Commission-permitted discharge volume limit. During operation, no additional wastewater would be discharged.

Stormwater runoff would be collected in detention ponds. Runoff from site support facilities would be discharged directly to natural drainage channels. Uncontaminated stormwater would also be released to natural drainage channels. Contaminated runoff would be retained and treated before being discharged. All discharges to playas would be monitored and subject to NPDES permit requirements.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. The phaseout of DP missions at Pantex would reduce surface water discharges to the playas. The playas would continue to collect precipitation through natural drainage channels. Water

TABLE 4.5.3.4–1.—*Potential Changes to Water Resources from Stockpile Management Alternatives at Pantex Plant*

[a] Total water requirements for construction at Pantex are based on a 3-year time period for A/D and HE fabrication.
[b] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharged would be the same as No Action operation.
[c] All discharges to natural drainages require NPDES permits.
Note: NA - not applicable; MLY - million liters per year.
Source: PX MH 1995a.

quality in the playas may improve slightly with the reduction in treated effluent from Pantex.

Groundwater

No Action. No construction would take place under No Action; therefore, no additional construction water would be used. Current groundwater use of 836 MLY (221 MGY) would decrease to 249 MLY (65.8 MGY) by 2005 because current weapons disassembly activities would end. Groundwater would continue to be withdrawn from the Ogallala aquifer through wells located on the Pantex property. No additional impacts to groundwater quality from operation are anticipated since water use and discharges would be reduced, and there are no direct discharges to groundwater.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. Water requirements for the downsized and consolidated A/D and HE fabrication facilities would be small relative to total aquifer storage, but still represent an amount greater than the annual recharge for the aquifer in the area. As shown in table 4.5.3.4–1, water use during modification of the facilities of 249.7 MLY (65.9 MGY) would represent an increase of approximately 0.3 percent over the projected Pantex groundwater usage of 249 MLY (65.8 MGY). Operating the A/D and HE fabrication facilities would require 209 MLY (55.2 MGY) of groundwater, a decrease of 16 percent from the No Action water requirements of 249 MLY (65.8 MGY). The amount of water used for operations would represent approximately 11 percent of the total Pantex well capacity of 1,900 MLY (502 MGY). As mentioned previously, although Pantex water use would decrease, operation water use would still contribute to the overall decline of the Ogallala aquifer because the area groundwater withdrawal rate would exceed the recharge rate.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on surface or groundwater resources at Pantex.

Downsize Assembly/Disassembly. Water requirements for downsizing and consolidating A/D facilities would be small relative to total aquifer storage, but would still represent an amount greater than the annual recharge for the area. As shown in table 4.5.3.4–1, approximately 0.5 MLY (0.13 MGY) would be used to modify the existing facilities at Pantex. This would represent approximately a 0.2-percent increase over the projected groundwater usage of 249 MLY (65.8 MGY) and would increase the total projected amount to be pumped in Carson County by less than 1 percent.

Approximately 196 MLY (51.8 MGY) would be used for operating the facilities. This would represent a 21-percent decrease from No Action water use. The operation water use represents approximately 10 percent of the total Pantex well capacity of 1,900 MLY (502 MGY). Because of the overall negative recharge to withdrawal rate of the Ogallala aquifer, the operation water used by Pantex would still contribute to the overall continued depletion of the Ogallala aquifer.

Groundwater Quality

Downsize Assembly/Disassembly and High Explosives Fabrication. As discussed in the surface water section, modification activities and operation of the facilities would not result in direct discharges to groundwater. However, treated wastewater discharged to playas could percolate into the groundwater. Any contaminants that might enter the aquifer would be expected to move down gradient to the north, away from existing facilities. Water withdrawal from the aquifer would have little effect on plume migration.

Downsize Assembly/Disassembly. As discussed in the surface water section, modification activities and operation of the facilities would not result in direct discharges to groundwater. However, treated wastewater discharged to playas could percolate into the groundwater. Any contaminants that might enter the aquifer would be expected to move down gradient to the north, away from existing facilities. Water withdrawal from the aquifer would have little effect on plume migration.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. The phaseout of DP missions at Pantex would reduce the amount of groundwater withdrawal at the Pantex well field by 249 MLY

(65.8 MGY) and the discharge of treated effluent to the playas by 141 MLY (37.3 MGY). The decrease in groundwater use would benefit the Ogallala aquifer. The reduction in treated plant effluent to the playas would have no effect on groundwater quality.

Sensitivity Analysis. The effluent discharges to playas resulting from the high stockpile case are expected to be similar to the volumes generated by the surge three-shift operation downsize A/D or downsize A/D HE mission. The low case scenario would discharge a slightly smaller volume of treated effluent compared to the No Action volume. Additional impacts to surface water quality from the high and low case production scenarios would be negligible. The groundwater use resulting from the high stockpile case is expected to be similar to low case surge three-shift operation downsize A/D or the downsize A/D HE mission. The low case scenario would require a slightly smaller amount of groundwater compared to the No Action volume. Impacts to groundwater quality from the high and low case production scenarios would be negligible.

Potential Mitigation Measures. Water use could be further reduced by including engineering design measures into the downsized facilities and remaining supporting infrastructure. These design measures could include equipment to enable reuse of process and cooling water to the maximum extent practical.

4.5.3.5 *Geology and Soils*

The proposed alternatives for Pantex would have no impact on geological resources described in section 4.5.2.5. Hazards posed by geological conditions are negligible at Pantex. Potential changes to geology and soils associated with the alternatives at Pantex are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at Pantex. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. Downsizing and/or consolidating A/D and HE fabrication at Pantex would require approximately 0.4 ha (1 acre) of existing buildings and developed areas for equipment laydown, warehousing, and parking. Soil disturbance would not be expected. No adverse soil impacts are anticipated.

There are no known active faults within the boundaries of Pantex; therefore, there is little chance for ground rupture as a result of an earthquake. All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides.

Volcanic activity has not occurred in the area for millions of years and is extremely unlikely to impact project facilities. It is also unlikely that landslides, sinkhole development, or other nontectonic events would affect project facilities. Slopes and underlying foundation materials are stable. Potential subsidence impacts resulting from salt dissolution are considered negligible at Pantex because salt dissolution is a slow process relative to human activities (PX DOE 1996b: 4-52, 4-53). Potential health impacts from accidents associated with geological hazards are discussed in section 4.5.3.9.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no impacts on geology and soils at Pantex.

Downsize Assembly/Disassembly. Downsizing and/or consolidating A/D would require approximately 0.1 ha (0.3 acre) for equipment laydown and warehousing, and an additional 0.04 ha (0.1 acre) for parking. Soil disturbance would not be expected. Seismic, volcanic, and other nontectonic risks would be the same as described for the downsize A/D and HE fabrication alternative.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. The phaseout of A/D and HE fabrication at Pantex would have no effect on geology and soils. The D&D of vacated facilities would be carried out inside the buildings.

Sensitivity Analysis. The high or low case operation scenario would not affect geology or soils.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.5.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species at Pantex. In general, impacts to these resources are not expected from the proposed alternatives; however, noise and human presence could temporarily disturb wildlife. Also, a reduction in discharges due to DP mission phaseout would reduce the area of open water in playas.

No Action. Under No Action, the A/D and HE fabrication missions described in section 3.2.5 would continue at Pantex. This would result in no changes to current biotic resource conditions at the site as described in section 4.5.2.6.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. A downsized and/or consolidated A/D and HE fabrication mission with nonintrusive pit reuse and storage of the strategic reserve of plutonium and uranium at Pantex would utilize existing facilities. Modification of existing buildings would require about 0.4 ha (1 acre) for temporary parking and equipment laydown. Except for some temporary disturbance to wildlife during modification activities, and a slight decrease in wastewater discharge which could reduce open water areas within receiving playas, this alternative is not expected to affect site biotic resources.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on biotic resources at Pantex.

Downsize Assembly/Disassembly. Impacts to biotic resources from downsizing and/or consolidating the A/D mission with nonintrusive pit reuse and storage of the strategic reserve of plutonium and uranium at Pantex would be similar to those described for the downsize A/D and HE fabrication alternative. However, this alternative would require slightly less area (0.2 ha [0.4 acres]) for temporary parking and equipment laydown. As in the case for the A/D alternative, the options of not storing strategic reserves of secondaries (HEU) or strategic reserves of plutonium and HEU would not impact biological resources.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. Phaseout of the A/D and HE fabrication missions at Pantex is unlikely to result in adverse impacts to biotic resources. During the phaseout period, additional human activity could disturb wildlife living nearby; however, disturbance would be minimal since the facility is presently a heavily used industrial area and nearby wildlife populations have already adapted to its presence. Once all phaseout activities are completed, wildlife use of the area would depend upon future use of the facilities. Phaseout would result in a decrease of effluent discharge to site playas which may alter the currently existing habitat.

Sensitivity Analysis. Implementation of either a low or high case workload would not affect biological resources.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.5.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly through ground disturbance, building modifications, visual intrusion of the project to the historic setting or environmental context of historic sites, visual or audio intrusion to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting or vandalism. A cultural resources management plan is being developed for Pantex. An interim programmatic agreement is in place to ensure regulatory compliance and potential adverse impacts are evaluated on a case-by-case basis. Zones 11 and 12 at Pantex are the areas to be affected under the alternatives. Because the areas are developed and disturbed and the proposed alternatives involve no new building construction, the potential for impacts to prehistoric, Native American, and paleontological resources is low. There are 12 buildings in Zone 12 that are considered NRHP eligible based on their Cold War era affiliation. None of these structures would be affected by the proposed alternatives. Zone 11 contains a number of historic structures from a World War II era bomb manufacturing line. The Texas SHPO has declared that 34 buildings in Zone 11 are NRHP eligible, as contributing properties to a potential historic district. Some of these structures, or the integrity of their spatial arrangement, may be affected by the alternatives.

No Action. Under No Action, DOE would continue the existing and planned missions at Pantex described in section 3.2.5. Any impacts to cultural and paleontological resources from these missions would be independent of and unaffected by the proposed action.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. A downsized and/or consolidated A/D mission with nonintrusive pit reuse and HE fabrication with or without the storage of the strategic reserve of plutonium and/or uranium would utilize existing Pantex facilities. No modifications or upgrades to NRHP-eligible facilities and infrastructure would be necessary. No new construction or ground disturbance would occur that would affect cultural or paleontological resources.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would not affect cultural and paleontological resources at Pantex.

Downsize Assembly/Disassembly. A downsized and/or consolidated A/D mission with nonintrusive pit reuse with or without the storage of strategic reserve of plutonium and/or uranium at Pantex would utilize existing facilities. No modifications or upgrades to NRHP-eligible facilities and infrastructure would be necessary. No new construction or ground disturbance would occur that would affect cultural or paleontological resources. The phaseout of HE fabrication may affect some NRHP-eligible structures.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. The phaseout of A/D and HE fabrication may affect some cultural or paleontological resources. The subsequent use of Pantex would determine potential future impacts to these resources. NRHP-eligible prehistoric and historic resources would be identified through project-specific inventories and evaluations. Specific concerns about Native American resources would be addressed through consultation with the potentially affected tribes. Any project-related effects would be addressed in tiered NEPA documentation.

Sensitivity Analysis. The high and low case scenarios have the same impacts to cultural and paleontological resources. The base case facilities to support the downsize A/D or A/D and HE fabrication operations mission would accommodate the high and low case production scenarios.

Potential Mitigation Measures. If NRHP-eligible sites cannot be avoided through project design or siting, and would result in adverse impacts, then a Memorandum of Agreement may need to be negotiated among DOE, the Texas SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the Texas SHPO and the Advisory Council on Historic Preservation in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific NRHP-eligible sites would be identified during tiered NEPA documentation.

If Native American resources cannot be avoided through project design or siting, then acceptable mitigation measures to reduce project effects on them would be determined in consultation with the affected Native American groups. In accordance with the *Native American Graves Protection and Repatriation Act* and the *American Indian Religious Freedom Act*, such mitigations may include, but would not be limited to, appropriately relocating human remains, planting vegetation screens to reduce visual or noise intrusion, increasing access to traditional use areas, or transplanting or harvesting important Native American plant resources.

4.5.3.8 *Socioeconomics*

No Action. Under No Action, the existing A/D and HE fabrication missions at Pantex would remain operational. As Pantex downsizes to fill the post-Cold War mission needs, total plant employment is estimated to decrease from the current level of 3,437 to 1,644 workers in 2005. A/D operations would employ 915 workers and the HE fabrication mission would employ 105 workers. The remaining 624 employees would be support staff or other workers not employed by either of the missions. The size of the Pantex workforce would remain stable from 2005 to 2030. Projected regional economy and employment rates, population and housing changes, and public finance characteristics are presented in appendix D.

Regional Economy and Employment. Total employment in the regional economic area is projected to increase approximately 1.1 percent annually between 1995 and 2000, when total employment reaches approximately 235,800. Long-range projections indicate slower growth after 2000. Total employment is projected to increase by less than 1 percent annually and reach 287,400 in 2030. The unemployment rate was 4.8 percent in 1994 and is expected to remain at that level into the near future. Per capita income is projected to increase from approximately $19,987 in 1995 to $25,719 in 2030.

Population and Housing. Annual ROI county and city population and housing growth is projected to average about 0.8 percent between 1995 and 2030. The ROI population is projected to increase from 210,600 in 1995 to 271,000 in 2030. The total number of housing units is projected to increase from 87,100 to 112,100 during the same period.

Public Finance. Between 2000 and 2005, all ROI county, city, and school district total revenues are projected to increase at an annual average of approximately 1 percent. Total expenditures are projected to increase at an annual average of approximately 1 percent or less during the same period. These rates of increase should continue until 2030.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. Under this alternative, both the A/D and HE missions would remain at Pantex. For all cases, some construction workers would be required to modify the existing facility. Changes to the plant workforce required for each production case are described below.

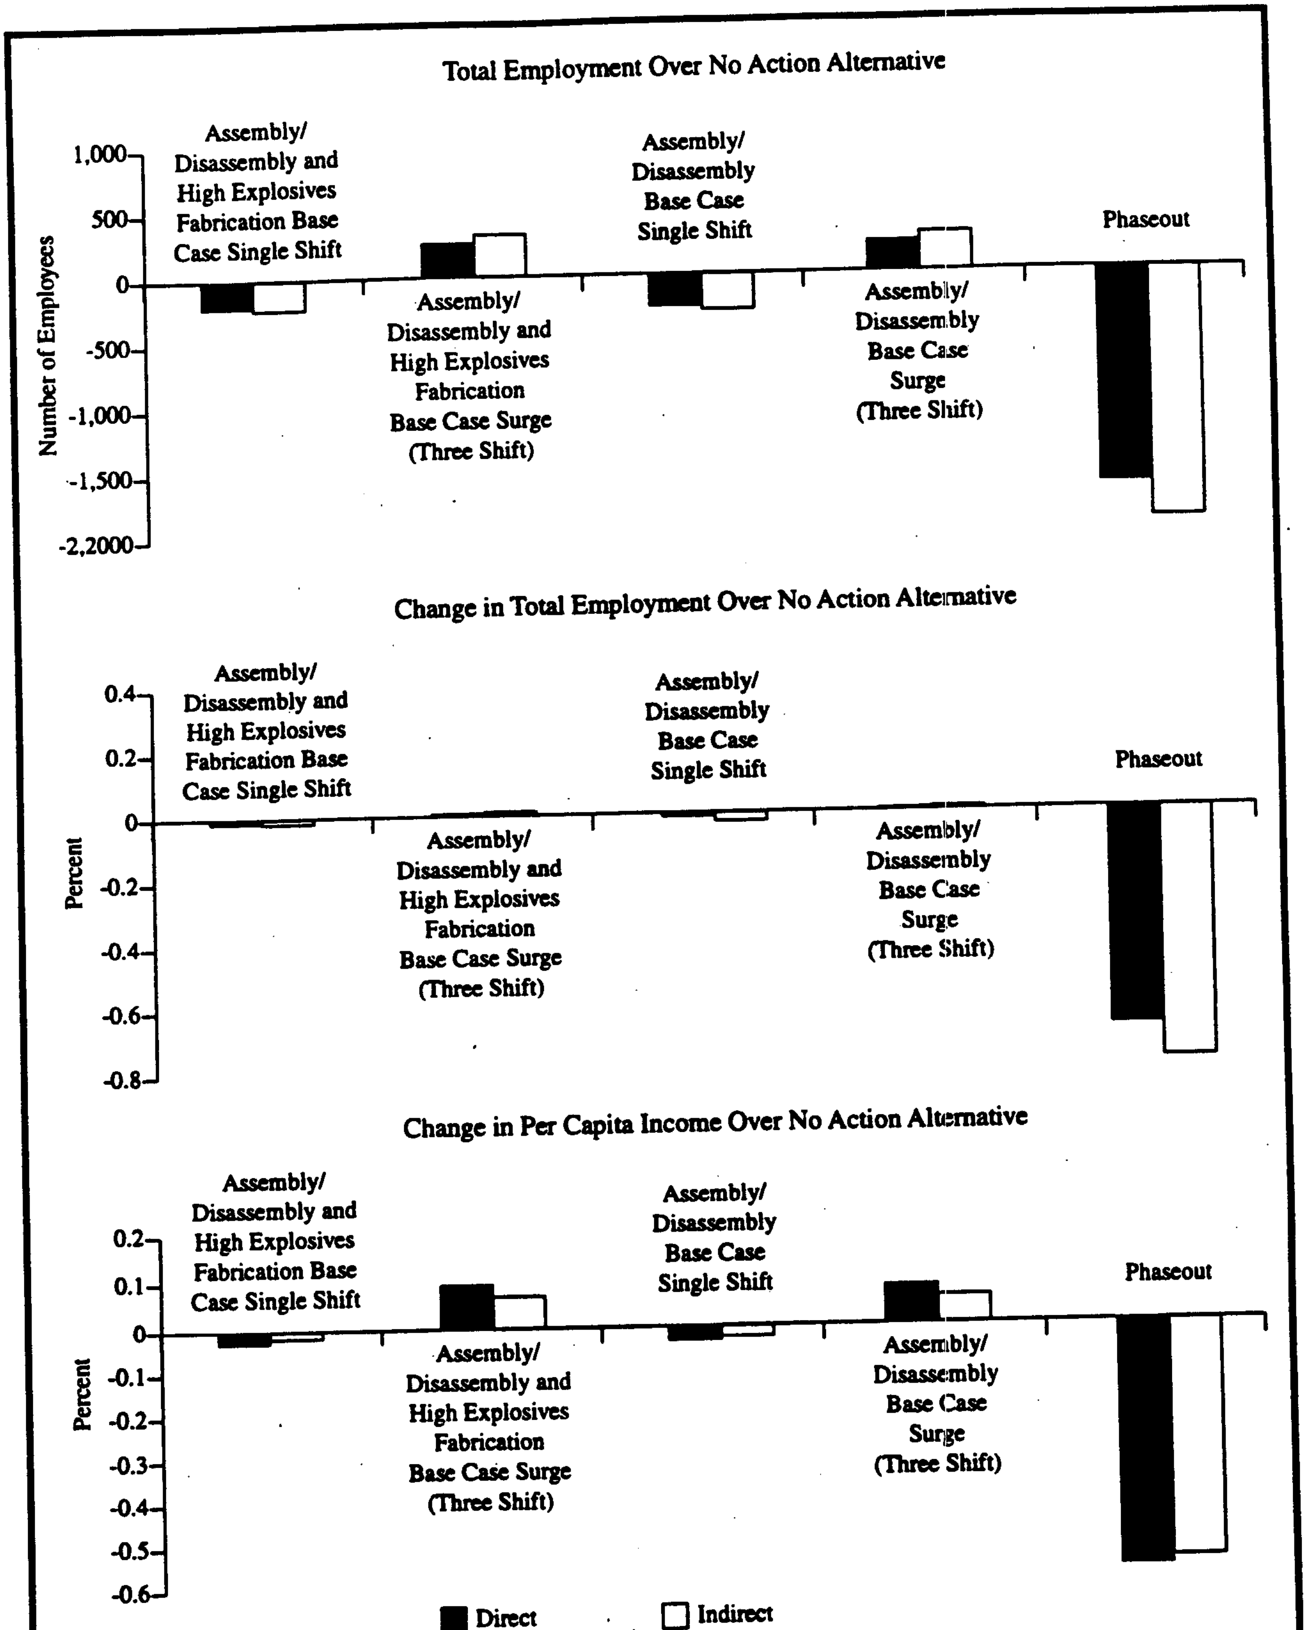
Base Case Single Shift. Under base case single-shift production, the facility would operate at reduced capacity and employ a smaller workforce than under the No Action alternative. The operational workforce would fall from the No Action level of 1,644 to 1,455. The workforce would include the same 624 support and other employees required under the No Action alternative, but a smaller core stockpile management workforce: 780 workers for A/D, 20 workers for pit reuse, and 31 for HE fabrication. The workforce would remain stable from 2005 to 2030.

Base Case Surge. Under base case surge production, the facility would be configured to operate at increased capacity as needed. The operational workforce would increase from the No Action level of 1,644 to 1,927, an increase of 283 workers. The workforce would include the same 624 support and other employees required under the No Action alternative, but a larger core stockpile management workforce: 1,244 workers for A/D, 22 workers for pit reuse, and 37 for HE fabrication.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have minimal impact on site employment and the regional economy beyond the downsize A/D and HE fabrication alternative. Strategic reserve pit storage operations are integrated into the A/D mission; therefore, worker numbers would remain essentially unchanged if the pits were moved and the A/D mission remained at Pantex.

Regional Economy and Employment. During peak modification activities, a total of 173 jobs (96 direct and 77 indirect) would be generated. Changes in the regional economic area's employment would be less than 1 percent. There would be no perceptible change in per capita income or in the regional unemployment rate. Impacts to the regional economy during operations for each of the production cases are described below.

Base Case Single Shift. Because fewer workers would be employed than for the No Action alternative, some losses to regional employment and income would result. A total of 408 jobs (189 direct and 219 indirect) would be lost, and regional unemployment would increase from 4.8 to 5.0 percent. Per capita income would decrease by less than 1 percent. These changes are shown in figure 4.5.3.8–1.



Source: Socio 1996b.

FIGURE 4.5.3.8–1.—***Employment and Income Changes Resulting from Management Alternatives in the Pantex Plant Regional Economic Area, 2005.***

Base Case Surge (Three Shift). Under base case surge, a total of 611 jobs (283 direct and 328 indirect) would be generated and unemployment would decrease from 4.8 to 4.5 percent. Per capita income would increase by less than 1 percent. These changes are shown in figure 4.5.3.8–1.

Population and Housing. Because available labor within the regional economic area would be sufficient to fill any direct or indirect jobs created during modification of the facility, the population would remain as projected under the No Action alternative.

Under the base case single-shift scenario, reductions in the workforce could lead to out-migration as displaced workers leave the region to seek employment opportunities. If all of the displaced direct and indirect workers would leave the region with their families, the population would fall by 1,065. Housing vacancies would increase slightly. These changes are shown in figure 4.5.3.8–2. Under base case surge, the additional jobs that would be generated would be filled by workers currently residing in the region. Therefore, there would be no change in the population over the No Action alternative.

Public Finance. Modification of the A/D and HE fabrication facilities or base case surge operation would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Downsizing the facilities for base case single-shift operation could result in the out-migration of workers from the ROI, which would affect ROI revenues and expenditures. Changes in revenues and expenditures compared to No Action projections due to downsizing the A/D and HE facilities at Pantex are shown in figure 4.5.3.8–3. If all displaced workers and their families left the ROI, total revenues and expenditures would be reduced below No Action projections by approximately 0.5 and 0.3 percent, respectively.

Downsize Assembly/Disassembly. Under this alternative, the A/D mission would remain at Pantex but the HE fabrication operations would be phased out and transferred to another DOE facility. To implement this alternative, modifications would be made to the facility which would generate some construction employment during the modification. Changes to the plant operational workforce for each of the cases is described below.

Base Case Single Shift. The total plant workforce would fall from the No Action level of 1,644 to 1,424. The resulting workforce would include 780 workers involved in A/D, 20 workers for pit reuse, and 624 in support or other non-core stockpile management positions.

Base Case Surge (Three Shift). Under base case surge, the total plant workforce would increase from the No Action level of 1,644 to 1,890. The workforce would include 1,244 workers involved in A/D, 22 workers for pit reuse, and 624 in support or other non-core stockpile management positions.

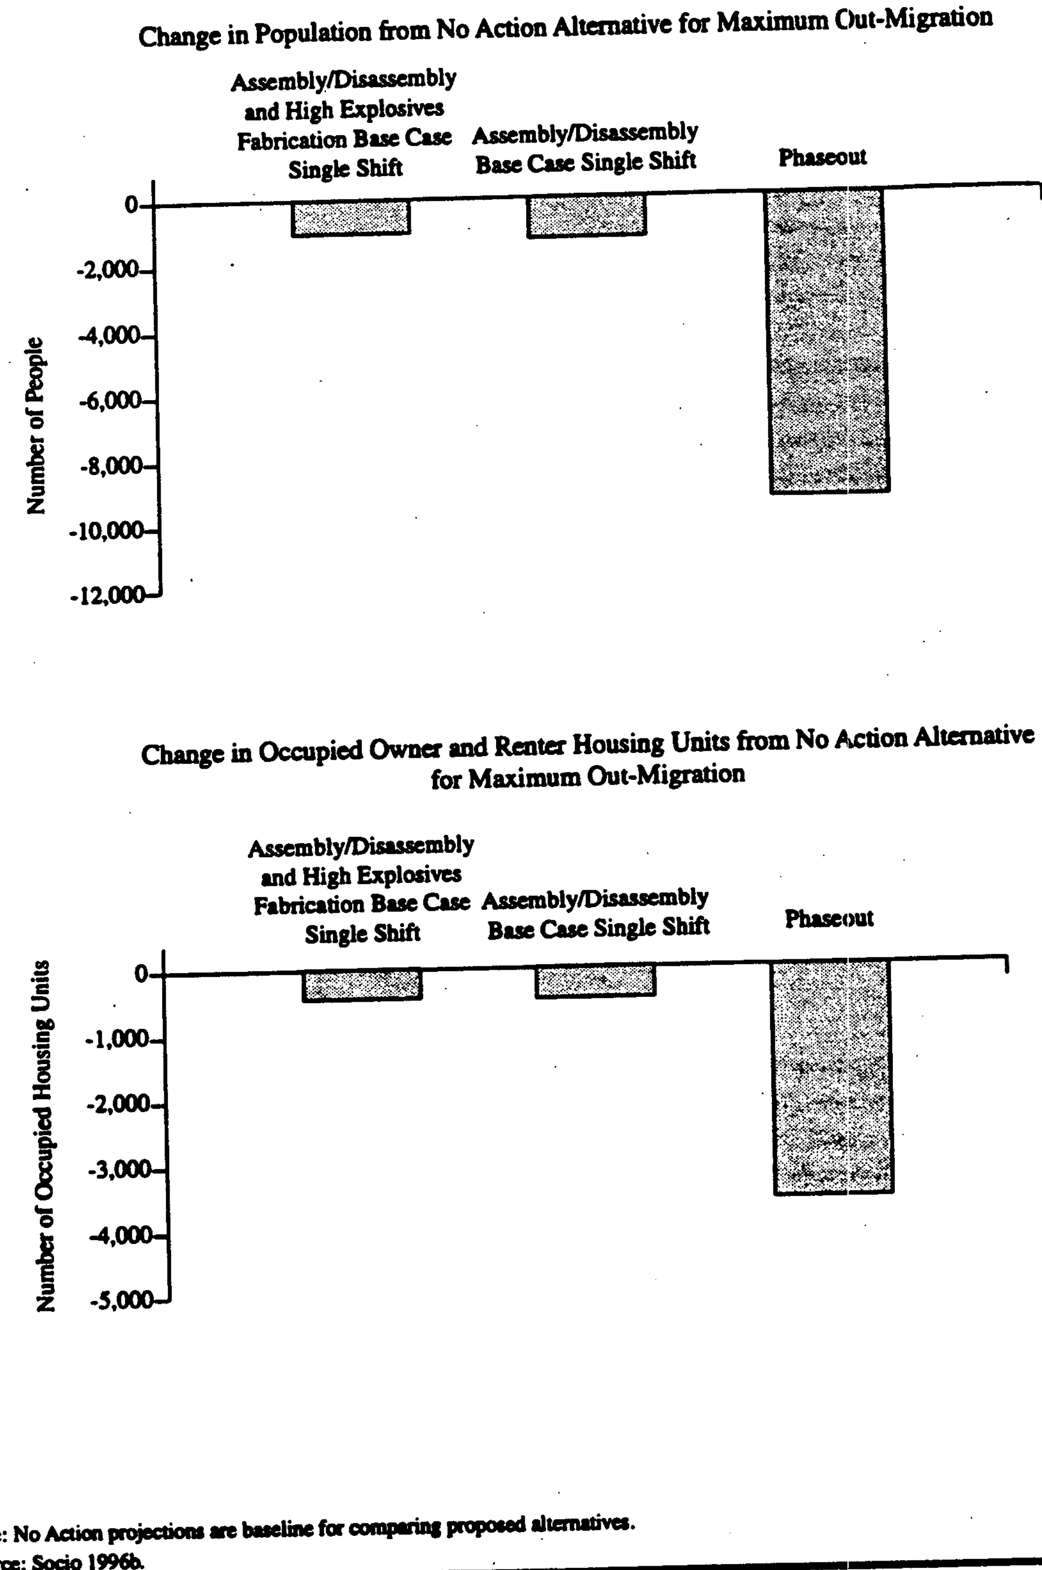
Regional Economy and Employment. For all cases, during peak construction, a total of 121 jobs (67 direct and 54 indirect) would be generated. Employment in the regional economic area would increase by less than 1 percent. There would be no perceptible change in per capita income or in the unemployment rate in the region. Changes to the regional economy during operation is described below for each of the cases.

Base Case Single Shift. Reducing the workforce for the A/D mission would result in a total loss of 475 jobs (220 direct and 255 indirect) in the regional economic area. Unemployment would increase from 4.8 to 5.0 percent. The regional per capita income would fall less than 1 percent. These changes are shown in figure 4.5.3.8–1.

Base Case Surge (Three Shift). Under base case surge, a total of 531 jobs (246 direct and 285 indirect) would be generated and unemployment would decrease from 4.8 to 4.6 percent. Per capita income would increase by less than 1 percent. These changes are shown in figure 4.5.3.8–1.

Population and Housing. There would be no change in the region's population during modification of the facility. Therefore, the housing market would also remain as projected under the No Action alternative.

Under the base case and high case single-shift scenario, the reduction in workforce could lead to out-migration as displaced workers leave the region to seek employment opportunities. If all of the displaced direct and indirect workers would leave the region



Note: No Action projections are baseline for comparing proposed alternatives.

FIGURE 4.5.3.8–3.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures, in the Pantex Plant Region of Influence, with Downsizing of Assembly/Disassembly and High Explosives Fabrication, Base Case Single Shift, 2005* **[Page 2 of 2].**

with their families, the population would fall by 1,240. Housing vacancies would increase slightly. These changes are shown in figure 4.5.3.8–2. Under base case surge, the additional jobs that would be generated would be filled by workers currently residing in the region. Therefore, there would be no change in the population over the No Action alternative.

Public Finance. Neither modification of the A/D Fabrication Facility nor base case surge operation would require in-migrating workers. Therefore, changes to public finances compared to No Action projections would be due to income increases and would be negligible.

Downsizing the facility for base case single-shift operation could result in the out-migration of workers from the ROI, causing a loss of income that would affect ROI revenues and expenditures. Changes in revenues and expenditures compared to No Action projections due to downsizing the A/D Facility for base case single-shift operation at Pantex are shown in figure 4.5.3.8–4. In 2005, revenues and expenditures would fall below No Action projections by approximately 0.6 and 0.4 percent, respectively. There would be less out-migration as a result of high case single-shift production. Therefore, any changes to public finance would be smaller.

Effects of High Explosives Phaseout. The HE fabrication operation requires 105 workers under the No Action alternative (downsizing to lower production levels would involve 31 workers under base case single shift and 37 workers under base case surge) Because HE fabrication generates an additional 122 jobs in related industries, the phaseout of this mission would result in the loss of 227 jobs to the regional economy. These impacts are included in the previous downsize A/D discussion.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. Under this alternative, both the A/D and HE fabrication missions would be transferred to other existing DOE installations. The total workforce at Pantex, projected to be 1,644 under the No Action alternative, would decrease to zero in 2005.

Regional Economy and Employment. Termination of the A/D and HE fabrication missions at Pantex would lead to both direct and indirect job losses in the regional economy. A total of 3,549 jobs (1,644 direct and 1,905 indirect) would be lost. Unemployment rates for the regional economic area would increase from a projected rate of 4.8 percent to 6.2 percent in 2005, the year the phaseout would be implemented. Per capita income would decrease slightly to $22,022 from the projected No Action level of $22,235. Changes in regional employment and income from No Action projections are shown in figure 4.5.3.8–1.

Population and Housing. Population in the ROI could decrease by more than 9,260 if all displaced workers and their families were to leave the ROI to seek employment opportunities elsewhere, a decrease of 3.9 percent from the No Action level projections. This out-migration would create additional housing vacancies in both rental and nonrental housing as shown in figure 4.5.3.8–2. However, the effects to the regional housing market would be minor.

Public Finance. Phaseout of the A/D and HE fabrication missions could lead to the out-migration of workers from the ROI, that would affect ROI revenues and expenditures. Changes in revenues and expenditures compared to No Action projections due to phaseout of operations at Pantex are shown in figure 4.5.3.8–5. In 2005, the percent decrease in total ROI revenues and expenditures below No Action projections would be approximately 4.4 and 2.7 percent, respectively. The greatest decrease would occur in the Claude School District where revenues could decrease by approximately 4.1 percent and in the Panhandle School District where expenditures would be expected to decrease by 3.7 percent.

Sensitivity Analysis. The number of construction workers required to modify the A/D and HE facilities for high case production is the same as for base case single-shift or base case surge production. Therefore, the socioeconomic impacts from construction would be the same.

Operation of the facilities for the high case mode would require more workers than base case single shift, but less than base case surge operation. The size of the site workforce would fall below the No Action levels, but would still be larger than the base case single-shift workforce. Therefore, any negative socioeconomic impacts in the region would be less than would result from base case single-shift operation.

Potential Mitigation Measures. In the event of a phaseout of DP activities at Pantex, adverse socioeconomic impacts could result in the affected economic region. To mitigate potential socioeconomic impacts, Section 3161 of the *National Defense Authorization Act* (Public Law 102-484) requires DOE to develop a plan for restructuring the workforce for a defense nuclear facility whenever a change in workforce is necessary. The legislation also directs DOE to consult with local, state, and national stakeholders in developing the plan.

DOE has initiated a number of actions to respond to the legislative requirements, including the creation of the Office of Worker and Community Transition. In February 1996, the office issued interim planning guidance in developing plans to help mitigate unavoidable impacts from workforce restructuring. Although the guidance is not prescriptive, it sets forth DOE policy on mitigating economic impacts of restructuring. For example, the guidance states that whenever possible, the impacts of workforce reductions should be minimized through the use of early retirement and normal attrition. Where appropriate, employees should be retrained for work in environmental restoration and waste management. The guidance also recommends that terminated employees receive assistance in obtaining reemployment through out-placement services, appropriate retraining, and educational services. To the extent practical, DOE and its contractor should offer a hiring preference to terminated employees. The DOE guidance also suggests that the affected communities should receive assistance to mitigate impacts to the public infrastructure and finances.

4.5.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the radiological and hazardous chemical releases and their associated impacts, which could result from No Action and the proposed alternatives at Pantex. Within this section, impacts resulting from the base case scenario are quantitatively discussed, and a sensitivity analysis of the high and low cases is qualitatively discussed.

Summaries of the prevailing radiological impacts to the public and to workers associated with normal operation at Pantex are presented in tables 4.5.3.9–1 and 4.5.3.9–2, respectively; radiological accident impacts are presented in tables 4.5.3.9–3 and 4.5.3.9–4. The impact assessment methodology is described in section 4.1.9 and further supplementary methodological information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the construction/modification of any new facilities; however, limited hazardous chemical releases (e.g., small spills of diesel fuel from equipment refueling) may occur due to building modification activities for the base case scenario and may be somewhat larger if the high case scenario is implemented. The concentration of these releases is expected to be well within the regulated exposure limits and would not result in any adverse health effects.

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge. Furthermore, discharges of wastewater through NPDES-permitted outfalls, which can be attributed to the activities associated with normal operation at Pantex, are expected to be below NPDES limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at Pantex, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). It is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all management alternative chemicals proposed to be emitted at the site. Using EPA guidance, an HI of ≤ 1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is $\leq 1 \times 10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $<1 \times 10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the population.

Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

No Action

Radiological Impacts. Radiological impacts to the public resulting from the No Action alternative are presented in table 4.5.3.9–1. HE fabrication has not been included in the analysis because activities associated with this fabrication mission do not result in radiological releases. The applicable impacts are representative of the aggregated total which is estimated to exist from all future baseline operational Pantex contributions. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from the No Action alternative into perspective, comparisons are made with natural background radiation. As shown in table 4.5.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 5.8×10^{-5} mrem for the No Action alternative. The annual population dose within 80 km (50 mi) in 2030 would be 1.4×10^{-4} person-rem.

Total site doses to onsite workers from normal operation for the No Action alternative are presented in table 4.5.3.9–2. The estimated annual dose to involved workers for this alternative would be 10 mrem. The dose to the entire facility workforce (involved workforce) would be 10.7 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations; there are no doses incurred to the noninvolved workers since their job tasks are limited to HE fabrication.

TABLE 4.5.3.9–1.—*Potential Radiological Impacts to the Public Resulting from Normal Operation of Stockpile Management Alternatives at Pantex Plant*

Affected Environment	No Action Single-Shift Operation Total Site[a]	Downsize Assembly/Disassembly Three-Shift Operation Total Site[a]	Phaseout Assembly/Disassembly and High Explosives Fabrication Total Site[a]
Maximally Exposed Individual (Public)			
Atmospheric Release			
Dose[b] (mrem/yr)	5.8×10^{-5}	9.8×10^{-5}	0
Percent of natural background[c]	1.7×10^{-5}	2.9×10^{-5}	0
25-year fatal cancer risk	7.2×10^{-10}	1.2×10^{-9}	0
Liquid Release			
Dose[b] (mrem/yr)	0	0	0
Percent of natural background[c]	0	0	0
25-year fatal cancer risk	0	0	0
Atmospheric and Liquid Releases			
Dose[b] (mrem/yr)	5.8×10^{-5}	9.8×10^{-5}	0
Percent of natural background[c]	1.7×10^{-5}	2.9×10^{-5}	0
25-year fatal cancer risk	7.2×10^{-10}	1.2×10^{-9}	0
Population Within 80 Kilometers			
Atmospheric and Liquid Releases in 2030			
Dose (person-rem)	1.4×10^{-4}	5.4×10^{-4}	0
Percent of natural background[c]	1.5×10^{-7}	5.7×10^{-7}	0
25-year fatal cancers	1.8×10^{-6}	6.8×10^{-6}	0

[a] Includes impacts from all site operations.

[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem/yr from the air pathways, 4 mrem/yr from the drinking water pathway, and 100 mrem/yr from all pathways combined (DOE Order 5400.5).

[c] Natural background radiation levels to the average individual is 334 mrem/yr; to the population within 80 km (50 mi) in 2030 is 95,300 person-rem.

TABLE 4.5.3.9–2.—***Potential Radiological Impacts to Workers Resulting from Normal Operation of Stockpile Management Alternatives at Pantex Plant***

Affected Environment	No Action Single-Shift Operation	Downsize Assembly/Disassembly Three-Shift Operation	Phaseout Assembly/Disassembly and High Explosives Fabrication
Involved Workforce[a]			
Average worker dose[b] (mrem/yr)	10	10	0
25-year fatal cancer risk	$1.0x10^{-4}$	$1.0x10^{-4}$	0
Total dose (person-rem/yr)	10.7	3.0	0
Noninvolved Workforce[c] **(HE Fabrication)**			
Average worker dose[b] (mrem/yr)	0	0	0
25-year fatal cancer risk	0	0	0
Total dose (person-rem/yr)	0	0	0
Total Site Workforce[d]			
Dose (person-rem/yr)	10.7	3.0	0
25-year fatal cancers	0.11	0.030	0

[a] The involved worker is a worker associated with operations of the A/D facilities. The estimated number of involved workers considered at risk for exposure is 300 for the downsize/consolidate alternative. The 1,070 workers for the No Action alternative are all considered at risk for exposure.

[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835).

[c] The noninvolved worker is an onsite worker unassociated with operation of the A/D facilities in question. The estimated number of noninvolved workers is 50.

[d] The total site workforce is the sum of the number of involved and noninvolved workers. The estimated number of workers in the total site workforce is 350 for the downsize/consolidate alternative and 1,070 for the No Action alternative.

Source: DOE 1993n:7; PX MH 1995a.

Based on the radiological impacts associated with normal operation under the No Action alternative, all resulting doses are within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from normal operation under No Action at Pantex are presented below. Analyses to support the values presented in this section are provided in appendix table E.3.4–9. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging the sites as having a hazardous chemical health concern. The model used in this PEIS to calculate HI and cancer risk only establishes a baseline for comparison of alternatives among sites. The baseline is then used to determine the extent by which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed member of the public at Pantex resulting from normal operation under the No Action alternative would be $5.56x10^{-3}$ and the cancer risk would be $1.10x10^{-8}$. The HI to the onsite worker would be $6.14x10^{-3}$, and the cancer risk would be $4.48x10^{-7}$.

The HIs for the public and onsite worker are within acceptable health levels. The cancer risks to the public and the onsite worker are within the EPA default value of $1.0x10^{-6}$.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication

Radiological Impacts. Radiological impacts to the public resulting from downsizing the A/D mission are presented in table 4.5.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational Pantex contributions and from three-shift base case A/D operations at the site. HE fabrication has not been included in the analysis because activities associated with this fabrication mission do not result in radiological releases. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.5.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be $9.8x10^{-5}$ mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be $5.4x10^{-4}$ person-rem. The impacts incurred from three-shift base case operations are very small, as is the case for normal baseline site operations.

Total site doses to onsite workers from normal operation for the downsize A/D mission are presented in table 4.5.3.9–2. The average annual dose to involved workers for this alternative would be 10 mrem. The dose to the entire facility workforce (involved workforce) would be 3.0 person-rem. As stated in the methodology section 4.1.9, worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations; there are no doses incurred to noninvolved workers since their job tasks only entail HE fabrication. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

The contribution to radiological impacts from the storage of the strategic reserve at Pantex is included within the downsize A/D and HE fabrication mission. Radiological impacts incurred from storage of the strategic reserve are extremely small, therefore total site impacts would not be affected if the strategic reserve was not located at Pantex.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation due to downsizing and/or consolidating the A/D and HE fabrication mission with nonintrusive pit reuse and storage of the strategic reserve of plutonium and uranium at Pantex are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–10.

The HI for the maximally exposed member of the public would be $4.82x10^{-5}$ and the cancer risk would be $8.37x10^{-10}$ as a result of operation of the A/D and HE fabrication alternative in 2005. The HI to the onsite worker would be $1.30x10^{-4}$ and the cancer risk would be $3.40x10^{-8}$ as a result of operation of the A/D and HE fabrication alternative in 2005. Operation of the downsize A/D and HE fabrication mission would result in HIs to the public and onsite worker that are within acceptable health regulatory levels. The cancer risks to the public and the onsite worker are within the EPA default value of $1.0x10^{-6}$.

The options of not including the storage of the strategic reserve of uranium and/or the strategic reserve of plutonium would not increase, and may slightly decrease hazardous chemical emissions with operation of the downsized/consolidated A/D and HE fabrication mission. Therefore, the HI and cancer risk for the public and the onsite worker would not increase if the strategic reserves are not stored at Pantex.

Downsize Assembly/Disassembly

Radiological Impacts. Radiological impacts to the public resulting from downsizing the A/D mission are presented in table 4.5.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational Pantex contributions and from three-shift base case A/D operations at the site. Total impacts are provided to compare with applicable regulations governing total site operation. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.5.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be $9.8x10^{-5}$ mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be $5.4x10^{-4}$ person-rem. The impacts incurred from three-shift base case operations are very small, as is the case for normal baseline site operations.

Total site doses to onsite workers from normal operation for the downsize A/D mission are presented in table 4.5.3.9–2. The average annual dose to involved workers for this alternative would be 10 mrem. The dose to the entire facility workforce (involved workforce) would be 3.0 person-rem. As stated in the methodology section 4.1.9, all worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations; there are no doses incurred to noninvolved workers since their job tasks only entail HE fabrication. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

The contribution to radiological impacts from the storage of the strategic reserve at Pantex is included within the downsize A/D mission. Radiological impacts incurred from storage of the strategic reserve are extremely small, therefore total site impacts would not be affected if the strategic reserve was not located at Pantex.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation due to downsizing and/or consolidating the A/D mission with nonintrusive pit reuse and storage of the strategic reserve of plutonium and uranium at Pantex are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. This alternative includes phaseout of HE fabrication. Analyses to support the values presented in this section are provided in appendix table E.3.4–11.

The HI for the maximally exposed member of the public would be 2.42×10^{-3} and the cancer risk would be 8.06×10^{-10} as a result of operation of the downsize A/D mission in 2005. The HI for the onsite worker would be 1.57×10^{-3} and the cancer risk would be 3.28×10^{-8} as a result of downsize A/D operation in 2005. The HIs for the public and onsite worker are within acceptable health regulatory levels. The cancer risks to the public and onsite worker are within the EPA default value of 1.0×10^{-6}.

The options of not including the storage of the strategic reserve of uranium and/or the strategic reserve of plutonium would not increase, and may slightly decrease hazardous chemical emissions with operation of the downsized/consolidated A/D mission. Therefore, the HI and cancer risk for the public and the onsite worker would not increase if the strategic reserves are not stored at Pantex.

Phaseout of Assembly/Disassembly and High Explosives Fabrication

Radiological Impacts. Radiological impacts to the public resulting from the phaseout of the A/D mission at Pantex are presented in table 4.5.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational Pantex contributions. Total impacts are provided to compare with applicable regulations governing total site operation. To place doses to the public from this alternative into perspective, comparisons are made with natural background radiation. As shown in table 4.5.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 0 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 0 person-rem. If A/D operations are eliminated, there would be no other radiological contribution from any other site operation (i.e., HE fabrication).

Total site doses to onsite workers from normal operation for the phaseout of the A/D mission are presented in table 4.5.3.9–2. The average annual dose to involved workers for this alternative would be 0 mrem. The dose to the entire facility workforce (involved workforce) would be 0 person-rem. As stated in the methodology section 4.1.9, there are no doses incurred to noninvolved workers because their job tasks only entail HE fabrication. There may be small risks to construction/demolition workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Radiological impacts incurred from the storage of the strategic reserve at Pantex are extremely small, therefore total site impacts would not be affected if the strategic reserve was not located at Pantex. Based on the radiological impacts associated with normal operation, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be extremely small.

Hazardous Chemical Impacts. There are no hazardous chemical emissions associated with the phaseout of A/D and HE fabrication at Pantex. The HIs for the public and the onsite worker would be reduced to zero and the cancer risks to the public and the onsite worker would be reduced to zero as a result of the phaseout (see appendix table E.3.4–12). Therefore, there are no adverse health effects or cancer risk to the public or the onsite worker due to this alternative.

Sensitivity Analysis. Small differences are expected to exist between operation at the base and low and high case scenarios. Since the HIs are well within the acceptable health regulatory limits and the cancer risks are below the EPA default value, no adverse HI or cancer risk impacts are expected due to low or high case scenarios.

Radiological impacts may be subject to certain degrees of variance resulting from either high or low case operations. For the high case scenario, impacts to both the public and workers would be similar to the three-shift base case operations. For the low-case scenario, impacts to the public would be expected to fall within the increment (range) projected between the No Action and the downsize A/D mission alternatives (i.e., less than a 4.0×10^{-5} mrem/yr increase to the maximally exposed individual, and less than a 4.0×10^{-4} person-rem/yr increase to the population within 80 km [50 mi]). Impacts to the total site workforce would be expected to fall below those associated with three-shift base case operations (i.e., less than 3.0 person-rem/yr).

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be extremely small.

Potential Mitigation Measures. Radioactive airborne emissions to the general population and onsite exposures to workers could be reduced by implementing the latest technology for process and design improvements. For example, to reduce public exposure from emissions, improved building and work area control methods could be used to remove radioactivity from emissions to the environment. Similarly, the use of remote, automated, and robotic production methods are examples of techniques that are being developed which would reduce worker exposure (see section 3.5.4). There would be no additional mitigative measures anticipated for chemical hazards.

Facility Accidents. The proposed actions have the potential for accidents that may impact the health and safety of workers and the public. The potential for and associated consequences of reasonably foreseeable accidents that have been evaluated are summarized in this section and described in more detail in appendix F. The methodology used in the assessment is described in section 4.1.9. A list of documents reviewed for applicable accident data is provided in appendix table F.1.1–1. The potential impacts from accidents, ranging from high-consequence/low-probability to low-consequence/high-probability events, have been evaluated in terms of potential cancer fatalities that may result for noninvolved workers and the public. The risk of cancer fatalities has also been evaluated to provide an overall measure of accident impacts and is calculated by multiplying the accident annual frequency (or probability) of occurrence by the consequences (number of cancer fatalities). A figure is also provided showing the risk of latent cancer fatalities in the population within 80 km (50 mi) that may result from accidents for the alternatives. Specifically, the curves in each figure show the probability (vertical axis) that the number of cancer fatalities in the offsite population within 80 km (50 mi) (horizontal axis) will be exceeded. The curves reflect the probability of the accident.

In addition to the potential impacts to noninvolved workers and the offsite population, there are potential impacts to involved workers who would be located in the facilities associated with the proposed action. Quantitative statements of these impacts cannot be made until design details are developed further, at which time the number and location of facility workers, protective and mitigating features can be estimated to support detailed accident impact analyses; however, depending on the type of accident, facility workers in close proximity to the point of the accident could receive high levels of exposure to radiation and potentially fatal impacts.

The accident analyses in this PEIS have been closely coordinated with the Pantex Site-Wide EIS to ensure consistency. The Pantex Site-Wide EIS is a more detailed evaluation of Pantex operations than this PEIS. Consequently, if there are any differences between the two documents, this PEIS defers to the Pantex Site-Wide EIS as the more accurate analysis of potential impacts from accidents.

No Action. Under the No Action alternative, A/D, storage of strategic plutonium reserves, and HE fabrication would continue to be performed at Pantex with no changes to facilities and operations. Under existing conditions, potential accidents and their consequences have been addressed in facility safety documentation according to requirements in DOE orders.

Management Alternatives

Accident information on the management alternatives under consideration at Pantex (downsize A/D and HE fabrication, storage of strategic plutonium reserves, and phaseout of A/D and HE fabrication) is provided in this section.

Downsize of Assembly/Disassembly. A set of potential accidents has been postulated for the downsize A/D alternative for which there may be releases of radioactive materials or other hazardous effects that may impact onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of probable cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.5.3.9–1. For example, the probability of a weapons A/D accident causing more than 10 cancer fatalities is approximately 10^{-6} per year. The curves reflect the probability of the accidents occurring. The consequences for the composite set of accidents and their risks are shown in table 4.5.3.9–3.

If an accident were to occur, there would be an estimated $5.2x10^{-4}$ cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 1,000 m (3,281 ft) from the accident would have an increased likelihood of cancer fatality of $2.0x10^{-6}$. A maximally exposed individual located at the site boundary would have an increased likelihood of cancer fatality of $2.0x10^{-6}$. The risks for the combined EBA and BEBA composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.5.3.9–3. For the same worker, the maximally exposed individual, and the population, the risks are $5.6x10^{-8}$, $5.6x10^{-8}$, and $1.5x10^{-5}$ cancer fatalities per year, respectively. Table 4.5.3.9–3 also shows the impacts for EBA and BEBA only.

Nonintrusive Modification Pit Reuse. A set of potential accidents can be postulated for the nonintrusive pit reuse for which there may be releases of radioactive materials or other hazardous effects that may impact onsite workers and the offsite popula-

TABLE 4.5.3.9–3.—*Impacts of Accidents for Downsize Assembly/Disassembly at Pantex Plant*

Parameter	Downsize Weapons Assembly/Disassembly			Storage of Plutonium Strategic Reserves		
	EBA	BEBA	EBA and BEBA Combined	EBA	BEBA	EBA and BEBA Combined
Composite Accident Frequency (Per Year)	0.028	$1.1x10^{-6}$	0.028	$6.0x10^{-4}$	$5.0x10^{-8}$	$6.0x10^{-4}$
Consequences						
Noninvolved Worker						
Cancer fatality[a]	$1.7x10^{-6}$	$6.2x10^{-3}$	$2.0x10^{-6}$	$2.3x10^{-6}$	$6.4x10^{-4}$	$2.3x10^{-6}$
Risk (cancer fatality per year)	$4.8x10^{-8}$	$7.4x10^{-9}$	$5.6x10^{-8}$	$1.4x10^{-9}$	$3.2x10^{-11}$	$1.4x10^{-9}$
Maximally Exposed Individual						
Cancer fatality[a]	$1.7x10^{-6}$	$8.0x10^{-3}$	$2.0x10^{-6}$	$9.0x10^{-7}$	$2.6x10^{-4}$	$9.2x10^{-7}$
Risk (cancer fatality per year)	$4.6x10^{-8}$	$9.7x10^{-9}$	$5.6x10^{-8}$	$5.4x10^{-10}$	$1.3x10^{-11}$	$5.5x10^{-10}$
Population Within 80 Kilometers[b]						
Cancer fatalities[c]	$4.8x10^{-4}$	0.94	$5.2x10^{-4}$	$1.0x10^{-4}$	0.03	$1.1x10^{-4}$
Risk (cancer fatalities per year)	$1.3x10^{-5}$	$1.1x10^{-6}$	$1.5x10^{-5}$	$6.2x10^{-8}$	$1.5x10^{-9}$	$6.4x10^{-8}$

[a] Probability (increased likelihood of cancer fatality to a hypothetical member of the public located at the site boundary or to a noninvolved worker as a result of exposure to the indicated dose) if the accident occurred.

[b] For the offsite population of 285,409, the average probability of cancer fatality/risk of cancer fatality (per year) for the combined EBA and BEBA is $1.8x10^{-4}/5.3x10^{-11}$ and $2.1x10^{-10}/1.4x10^{-12}$ respectively, for the listed alternative(s), downsize weapons A/D and storage of plutonium strategic reserves.

[c] Number of cancer fatalities in the population out to 80 km (50 mi) as a result of exposure to the indicated dose if the accident occurs.

Note: All values are mean values; BEBA - beyond evaluation basis accidents; EBA - evaluation basis accidents.

Source: Results shown are derived from accident analyses (see appendix F).

tion. Any such impacts, however, would be bounded by the impacts of accidents associated with the downsize A/D and/or plutonium storage activities and are therefore not addressed further.

High Explosives Fabrication. A set of potential accidents has been postulated for the HE fabrication mission for which there may be hazardous effects that may impact onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The chemical accident impacts are shown in table 4.5.3.9–4.

In addition to the chemical accident impacts, the potential physical effects from a catastrophic explosion of the entire contents of a process-related building was also considered. This accident would have a probability of occurrence less than the explosion considered above (i.e., less than $1.0x10^{-6}$ per year). The quantity of HE detonated could range up to 2.4 t (2.6 tons); the blast pressure could result in death (up to 20 m [66 ft]), lung damage (20 to 40 m [66 to 131 ft]), thoracic injury (40 to 60 m [131 to 197 ft]), and eardrum rupture (60 to 80 m [197 to 262 ft]), depending on an individual's distance from the accident. Injuries could also be caused by glass breakage and building debris.

Storage of Plutonium Strategic Reserves. A set of potential accidents has been postulated for the storage of plutonium strategic reserves for which there may be releases of radioactive materials that may impact collocated onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of potential cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.5.3.9–1. For example, the probability that a plutonium storage accident causes more than one cancer fatality is approximately $5x10^{-9}$ per year.

The curve reflects the probability of the accidents occurring. The consequences of the composite set of accidents and their risks are shown in table 4.5.3.9–3.

Source: Results derived from accident analysis (see appendix F).

If an accident were to occur, there would be an estimated 1.1×10^{-4} cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 1,000 m (3,281 ft) from the accident would have an increased likelihood of cancer fatality of 2.3×10^{-6}. A maximally exposed individual located at the site boundary would have an increased likelihood of cancer fatality of 9.2×10^{-7}. The risks for the combined EBA and BEBA composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.5.3.9–3. For the same worker, the maximally exposed individual, and the population, the risks are 1.4×10^{-9}, 5.5×10^{-10}, and 6.4×10^{-8} cancer fatalities per year, respectively. Table 4.5.3.9–3 also shows the impacts for EBA and BEBA only.

Storage of Uranium Strategic Reserves. A set of potential accidents has been postulated for the storage of uranium strategic reserves for which there may be releases of radioactive materials or other hazardous effects that may impact collocated onsite workers and the offsite population. Any such impacts, however, are expected to be bounded by the impacts of accidents associated with A/D, or storage of strategic plutonium reserves at Pantex and are therefore not addressed further.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. A phaseout of both the A/D and HE fabrication missions at Pantex would have the effect of eliminating any potential for accidents over the long term related to A/D and HE fabrication activities. However, there would be a potential for accidents during the phaseout process that could impact workers and the public. These potential accidents and their consequences are addressed in each affected facility's safety analysis report and/or safety documentation applicable to the phaseout process.

4.5.3.10 *Waste Management*

This section summarizes the impacts on waste management at Pantex under No Action and for each of the proposed alternatives. There is no spent nuclear fuel or HLW associated with weapons A/D (which includes nonintrusive modification pit reuse and storage of strategic reserves of plutonium and uranium) or HE fabrication. Table 4.5.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action. Projections for No Action are based on single-shift operations and were derived from 1994 environmental data, with appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include waste from future, yet uncharacterized, environmental restoration activities.

Table 4.5.3.10–2 provides the total estimated operational waste volumes projected to be generated at Pantex as a result of the various alternatives. The net increase or decrease over No Action is provided below in parentheses. The waste volumes generated and the resultant waste effluent can be found in table 3.4.1.2–3 for A/D and table 3.4.5.2–3 for HE fabrication. Both tables are based on surge operations (three shifts). Facilities that would support the Stockpile Stewardship and Management Program would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act*, RCRA, and other applicable statutes as outlined in appendix section H.1.2.

The movement of the strategic reserve pits at Pantex to another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on waste management at Pantex because storage of strategic reserve pits generates minimal waste. Waste generated during transition activities to EM and D&D of strategic reserve storage facilities would be negligible.

No Action. Under No Action, LLW, mixed LLW, hazardous, and nonhazardous wastes would continue to be generated at Pantex from the missions described in section 3.2.5. Pantex could also store, over the long term, certain quantities of plutonium pits; however, no impact on waste management is expected since such storage generates minimal additional waste.

Compactible portions of solid LLW would continue to be processed at the onsite solid waste compaction facility. Mixed waste would be treated and disposed of according to the Pantex Site Treatment Plan that was developed in accordance with the *Federal Facility Compliance Act* of 1992. Although the predominant workload in 1994 was disassembly operations, the activities were assumed to be representative of projected A/D and HE levels that characterize No Action operations. It is expected that generation

[a] No Action volumes are from table 4.5.3.10–1 and are based on single-shift operations.

[b] Waste volumes for the increment due to HE fabrication are from table 3.4.5.2–3 and are based on surge operations (three shifts), which were added to downsize A/D volumes.

[c] Waste generation volumes for the downsize A/D Facility are from table 3.4.1.2–3.

Note: Waste generated volumes were rounded to three significant figures. Waste effluent volumes (i.e., after treatment and volume reduction), which are used in the narrative description of the impacts, are also found in tables 3.4.5.2–3 and 3.4.1.2–3.

Source: Appendix A.

rates would decrease through waste minimization efforts.

Management Alternatives

Downsize Assembly/Disassembly and High Explosives Fabrication. Downsizing and consolidating the A/D Facility with HE fabrication would impact existing and planned Pantex waste management activities by decreasing the generation of low-level, mixed, and hazardous wastes. The amount of waste generated from storage of the strategic reserve of plutonium and HEU is minimal. Waste generated during construction activities to modify existing buildings would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of by the contractor, as part of the construction project. The hazardous wastes would be shipped to a commercial RCRA-permitted treatment and disposal facility.

Following treatment and volume reduction, approximately 10 m^3 (14 yd^3) of LLW from sanitized and demilitarized weapons parts, lead shielding, desiccants, foam, and residue from decontamination and cleaning operations would require disposal. Assuming a land usage of 6,000 m^3/ha (3,200 yd^3/acres), this would require approximately 0.002 ha/yr (0.004 acres/yr) of LLW disposal area at NTS. Assuming 16.6 m^3 (21.7 yd^3) of LLW per shipment, one additional shipment to NTS every 2 years would be required.

The small amount of mixed LLW waste contains hazardous constituents or is contaminated with HE and/or solvents. This mixed LLW could be treated and disposed of through the use of existing and planned facilities in accordance with the Pantex Site Treatment Plan. HE residual materials, such as bulk HE-machining scrap and off-spec HE components and HE-contaminated materials (e.g., gloves, wipes and rags) and process water generated during HE fabrication operations, are the source of most of the waste material that must be processed. Currently, thermal treatment of HE material and HE-contaminated materials is the preferred permitted technique used to dispose of and decontaminate solid materials. HE-contaminated process water, generated by synthesis and formulation processes, vacuum pump seal water, and HE machining processes is collected in tanks and then treated with activated carbon filters to remove residual HE solids and solvents. Waste minimization and recycling would be used to reduce the amount of material that ultimately must be subjected to waste treatment processes. Scrap HE material and HE-contaminated process water that are recycled are not considered waste and are handled as in-plant operations. Existing and planned facilities are adequate to handle the 2.3 m^3 (601 gal) of liquid and 30 m^3 (39 yd^3) of solid hazardous wastes.

Approximately 148,000 m^3 (39,100,000 gal) of liquid nonhazardous waste that includes sanitary, utility and process wastewaters, and cooling tower blowdown would be processed using existing and planned waste facilities. Following volume reduction, 178 m^3 (233 yd^3) of solid nonhazardous wastes such as clean nonplutonium metals, packing materials, office trash, defective and damaged equipment, and industrial waste from utility and maintenance operations would be shipped to the currently utilized offsite landfill.

Downsize Assembly/Disassembly. Downsizing and consolidating the A/D Facility would impact existing and planned Pantex waste management activities by decreasing the generation of low-level, mixed low-level, hazardous, and nonhazardous wastes. Waste generated during construction activities to modify existing buildings would consist of wastewater, nonhazardous solids, and hazardous wastes. The nonhazardous wastes would be disposed of by the contractor, as part of the construction project, and the hazardous wastes would be shipped to a commercial RCRA-permitted treatment and disposal facility.

The impacts for LLW and mixed LLW are identical to those described above. The 2 m^3 (540 gal) of liquid and 0.05 m^3 (0.07 yd^3) of solid hazardous wastes such as rags, wipes, and cleaning solvents would have no impact on waste management activities at Pantex. Approximately 141,000 m^3 (37,200,000 gal) of liquid nonhazardous waste that includes sanitary, utility and process wastewaters, and cooling tower blowdown would be processed using existing and planned waste facilities. Following volume reduction, 170 m^3 (222 yd^3) of solid nonhazardous waste would be shipped to a currently utilized offsite landfill.

The phaseout of the HE Fabrication Facility would only occur as a part of the downsize A/D alternative at Pantex. This would decrease the generation of low-level, mixed, hazardous, and nonhazardous wastes from operations. However, waste would be generated from D&D activities associated with the phaseout of the HE fabrication mission. Total waste volumes from these activities over a 6-year period are shown in table 4.5.3.10–3.

Liquid LLW would be generated during the characterization phase and decontamination phase of the D&D process. The decontamination wash process for sampling equipment, personnel protective equipment, other equipment, and facilities would be the major sources. The estimated volumes of waste would require additional treatment capacity at Pantex. The solid LLW would require approximately 579 shipments to NTS and 1.6 ha (4 acres) of disposal area at NTS. Mixed LLW would be managed in accordance with the Pantex Site Treatment Plan and might require additional onsite treatment to handle the waste volume from D&D activities. Hazardous wastes would be packaged and shipped offsite to

TABLE 4.5.3.10–3.—*Estimated Decontamination and Decommissioning Wastes at Pantex Plant*

Category	Phaseout of High Explosives Fabrication (m^3)	Phaseout of Assembly/Disassembly and High Explosives Fabrication (m^3)
Low-Level		
Liquid	1,000	1,700
Solid	9,600	16,700
Mixed Low-Level		
Liquid	2,400	4,200
Solid	23,900	41,700
Hazardous		
Liquid	13,600	21,000
Solid	143,200	220,000
Nonhazardous (Sanitary)		
Liquid	596,000	1,175,000
Solid	None	None
Nonhazardous (Other)		
Liquid	None	None
Solid	2,367,000	4,660,000

Note: Waste generation volumes have been rounded to three significant figures.
Source: PX 1995a:5.

RCRA-permitted facilities using DOT-certified transporters. Additional temporary storage capacity may be required. Liquid sanitary waste would be collected from all buildings by the existing underground sewer pipe system and routed to the sanitary wastewater sewer treatment system. Solid nonhazardous waste such as rock, brick, glass, dirt, and certain plastics and rubber would be sent offsite for disposal.

Phaseout of Assembly/Disassembly and High Explosives Fabrication. With the phaseout of the A/D and HE fabrication missions, approximately 1 m^3 (323 gal) of liquid and 19 m^3 (25 yd^3) of solid LLW, 0.14 m^3 (38 gal) of liquid and 4 m^3 (5 yd^3) of solid mixed LLW, and 2 m^3 (601 gal) of liquid and 31 m^3 (41 yd^3) of solid hazardous wastes would no longer be generated from operations. Liquid and solid nonhazardous waste would decrease over time as facilities are deactivated and employment decreases to a caretaker level. However, waste would be generated from D&D activities associated with the phaseout of the HE fabrication and assembly missions. Total waste volumes from these activities over a 6-year period are shown in table 4.5.3.10–3.

Liquid LLW would be generated during the characterization phase and decontamination phase of the D&D process. The decontamination wash process for sampling equipment, personnel protective equipment, other equipment, and facilities would be the major sources of waste. The estimated volume of waste would require additional treatment capacity at Pantex. The solid LLW would require approximately 1,006 shipments to NTS and 2.8 ha (6.9 acres) of disposal area at NTS. Mixed LLW would be managed in accordance with the Pantex Site Treatment Plan and might require additional onsite treatment to handle the volume from D&D activities. Hazardous wastes would be packaged and shipped offsite to RCRA-permitted facilities using DOT-certified transporters. Additional temporary storage capacity may be required. Liquid sanitary waste would be collected from all buildings by the existing underground sewer pipe system and routed to the sanitary wastewater sewer treatment system. Solid nonhazardous waste such as rock, brick, glass, dirt, and certain plastics and rubber would be sent offsite for disposal.

Sensitivity Analysis. The waste volumes generated from the downsized and consolidated A/D or the downsized and consolidated A/D and HE fabrication facilities required to support a larger stockpile level (high case), operating on a single-shift basis, are bounded by the base case under surge operations. There would be no additional waste management impacts associated with the A/D or A/D and HE Fabrication Facility that would support a high case stockpile operating at a single shift. The volumes generated from the A/D or A/D and HE fabrication facilities required to support a low case stockpile would be reduced by a factor of at least three.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies, thereby further reducing or mitigating impacts. Pollution prevention and waste minimization would be incorporated in the final actions of the Stockpile Stewardship and Management Program at Pantex.

4.5.3.11 *Environmental Justice*

As discussed in section 4.14, any impacts to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.5.3.9, which describes public and occupational health impacts from normal operation, shows that potential radiological and chemical air emissions and releases are lower than regulatory limits. However, the cumulative effect of continuous, (or intermittent over time) very low exposures could have some impact on human health or the environment. Any adverse human health or environmental impacts that may occur would affect people living within communities located near Pantex. The analysis of the demographics data presented in appendix D for the communities surrounding Pantex indicates that even if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.6 Los Alamos National Laboratory

LANL was established in 1943 and currently occupies approximately 11,300 ha (28,000 acres) near Los Alamos, NM, in support of missions as discussed in section 3.2.6. The DOE property boundaries for the site are illustrated in figure 4.6–1, and the technical areas (TA)s are illustrated in figure 4.6–2.

4.6.1 Description of Alternatives

There are no facilities at LANL that would be phased out as a result of any of the proposed alternatives discussed in this PEIS.

No Action. LANL would continue to perform the missions described in section 3.2.6.

Stockpile Management Alternatives. The pit fabrication and intrusive and nonintrusive modification pit reuse missions (referred to hereafter as pit fabrication), the secondary and case fabrication mission, the HE fabrication mission, and a portion of the nonnuclear fabrication mission could be located at LANL. The HE fabrication mission could also be shared with LLNL, and the nonnuclear fabrication mission could be shared with SNL and LLNL.

Stockpile Stewardship Alternatives. The proposed Atlas Facility would be located at LANL and the proposed National Ignition Facility (NIF) could be located at LANL.

4.6.2 Affected Environment

The following sections describe the affected environment at LANL for land resources, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure, radiation and hazardous chemical environment, and waste management conditions at LANL are described.

4.6.2.1 *Land Resources*

LANL is located in north-central New Mexico, 97 km (60 mi) north-northeast of Albuquerque, 40 km (25 mi) northwest of Santa Fe, and 32 km (20 mi) southwest of Española in Los Alamos and Santa Fe Counties. The associated communities of Los Alamos and White Rock are in Los Alamos County. Figure 4.6–1 shows the geographical location of LANL. The 11,300-ha (28,000-acre) LANL site and adjacent communities are situated on the Pajarito Plateau, which consists of a series of finger-like mesas separated by deep canyons that run from the Jemez Mountains on the west toward the Rio Grande Valley on the east. Mesa tops range in elevation from approximately 2,400 m (7,800 ft) on the west to about 1,900 m (6,200 ft) on the east (LANL 1994a: II-1, II-2).

The developed acreage of LANL consists of 30 active TAs (see figure 4.6–2). The TAs potentially affected by the program are identified in figure 4.6–2. These TAs consist of laboratory facilities and support infrastructure. They account for only a small portion of the total land area at LANL. Most of LANL is undeveloped to provide security, safety, and expansion possibilities for future mission requirements. There are no agricultural activities present at LANL nor are there any prime farmlands. In 1977, DOE designated LANL as a National Environmental Research Park, which is used by the national scientific community as an outdoor laboratory to study the impacts of human activities on the pinyon-juniper woodland ecosystems (DOE 1985a:3,21).

Most developments within Los Alamos County are confined to mesa tops. Generalized land uses are shown in figure 4.6.2.1–1. The surrounding land is largely undeveloped with large tracts north, west, and south of the LANL site administered by the U.S. Forest Service (Santa Fe National Forest), the National Park Service (Bandelier National Monument), and Los Alamos County. The San Ildefonso Pueblo borders the LANL site to the east (LANL 1994a: II-1, II-2). The closest offsite residences to LANL are approximately 3 m (10 ft) from the northern boundary.

4.6.2.3 *Air Quality*

The discussion of existing air quality includes a review of the meteorology and climatology in the vicinity of LANL. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.6.

Meteorology and Climatology. Los Alamos has a semiarid, temperate mountain climate. The climate averages for atmospheric variables such as temperature, pressure, moisture, and precipitation are based on observations made at the TA-59 LANL weather station from 1961 through 1993. The meteorological conditions described here are representative of conditions on the Pajarito Plateau at an elevation of approximately 2,250 m (7,400 ft) above sea level (LANL 1995s: II-8). In July, the average daily high temperature is 27.2 °C (81 °F), and the average nighttime low temperature is 12.8 °C (55 °F). The average January daily high is 4.4 °C (40 °F), and the average nighttime low is -8.3 °C (17 °F). The highest recorded temperature is 35 °C (95 °F), and the lowest recorded temperature is -27.8 °C (-18 °F). The large daily range in temperature of approximately 13 °C (23 °F) results from the site's relatively high elevation and dry, clear atmosphere, which allows high insolation during the day and rapid radiative losses at night (LANL 1995s: II-8).

The average annual precipitation is 47.6 cm (18.7 in) but is quite variable from year to year. The lowest recorded annual precipitation is 17.3 cm (6.8 in), and the highest is 77 cm (30.3 in). The maximum precipitation recorded for a 24-hour period is 8.8 cm (3.5 in) (LANL 1995s:II-11.) Because of the eastward slope of the terrain, there is a large east-to-west gradient in precipitation across the plateau. White Rock often receives about 13 cm (5 in) less annual precipitation than the TA-59 weather station, and the eastern flanks of the Jemez Mountains often receive about 13 cm (5 in) more (LANL 1994a:II-11).

Los Alamos winds are generally light, averaging 2.8 m/s (6.3 mph). Strong winds are most frequent during the spring when peak gusts often exceed 22 m/s (50 mph). The highest recorded wind gust was 34.4 m/s (77 mph). The semiarid climate promotes strong surface heating by day and strong radiative cooling by night. Because the terrain is complex, heating and cooling rates are uneven over the LANL area, which results in local thermally generated winds (LANL 1995s:II-11).

Ambient Air Quality. LANL is located within the New Mexico Intrastate AQCR 157. None of the areas within LANL and its surrounding counties are designated as nonattainment areas with respect to any of the NAAQS (40 CFR 81.332). A nonattainment area is an area that has air quality worse than designated by NAAQS for one or more criteria pollutants. Applicable NAAQS and New Mexico State ambient air quality standards are presented in appendix table B.3.1–1.

The criteria pollutants—nitrogen dioxide, carbon monoxide, hydrocarbons, particulate matter, and sulfur dioxide—make up approximately 79 percent of the stationary source emissions at LANL. The source of these criteria pollutants is combustion in power plants, steam plants, asphalt plants, and local space heaters. Toxic and other hazardous pollutants represent the remaining 21 percent of emissions from stationary sources at LANL. These emissions are generated by equipment surface cleaning, coating processes, and acid baths, and include gases, vapors, metal dusts, and miscellaneous emissions such as wood dust, hazardous gases, and plastics (LANL 1994a:VI-3, VII-1).

One Prevention of Significant Deterioration Class I Area, the Bandelier National Monument's Wilderness Study Area, borders LANL to the south. To date, LANL has not been subject to Prevention of Significant Deterioration requirements (LANL 1993b:III-20).

Ambient concentration limits for hazardous/toxic air pollutants (to be used by the state as one of the criteria in evaluating construction permit applications for a new emission source) have been approved by the New Mexico Environmental Improvement Board. The estimated 2005 No Action annual emission rates from LANL facilities are listed in appendix table B.3.6–1. Estimates of maximum ground-level concentrations at or beyond the LANL boundary are listed in table 4.6.2.3–1. Concentrations of criteria and hazardous/toxic air pollutants are in compliance with applicable guidelines and regulations. The hazardous/toxic air pollutant limits are one-hundredth of the recognized occupational exposure levels (e.g., 8-hour time-weighted threshold limit values).

Table 4.6.2.3–1 presents the baseline ambient air concentrations for criteria pollutants for 1992 and other pollutants of concern for 1990 at LANL. As shown in the table, baseline concentrations are in compliance with applicable guidelines and regulations.

4.6.2.4 *Water Resources*

This section describes the surface and groundwater resources at LANL.

Surface Water. The Rio Grande is the major surface water feature in north-central New Mexico. All surface water drainage and groundwater discharge from the Pajarito Plateau ultimately arrives at the Rio

TABLE 4.6.2.3–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Los Alamos National Laboratory, 1990 and 1992* [Page 1 of 2]

Grande. The Rio Grande at Otowi, just east of Los Alamos, has a drainage area of 37,037 square kilometers (km^2) (14,300 square miles [mi^2]) in southern Colorado and northern New Mexico (DOE 1995hh:4-26).

The major canyons that contain reaches of ephemeral streams inside LANL are Pajarito, Water, Ancho, and Chaquehui Canyons (figure 4.6.2.4–1) (DOE 1995hh:4-26).

Ephemeral streams in the lower portions of Ancho and Chaquehui Canyons extend to the Rio Grande without being depleted. In lower Water Canyon, the ephemeral stream is very short and does not extend to the Rio Grande. In Pajarito Canyon, Homestead Spring feeds an ephemeral stream 2- to 3-miles long (DOE 1995hh:4-26).

Springs between 2,408- and 2,713-m (7,900- and 8,900-ft) elevation on the eastern slope of the Jemez Mountains supply base flow throughout the year to the upper reaches of Cañon de Valle, Los Alamos, Pajarito, and Water Canyons. These springs discharge water perched in the Bandelier Tuff and Tschicoma Formation at rates from 0.0001 to 0.0085 m^3/s (0.0035 to 0.30 ft^3/s). The volume of flow from the springs is insufficient to maintain surface flow within more than the western third of the canyons before it is depleted by evaporation, transpiration, and infiltration (DOE 1995hh:4-26).

Eleven drainage areas, with a total area of 212 km^2 (82 mi^2) pass through the eastern boundary of LANL. Runoff from heavy thunderstorms and heavy snowmelt reaches the Rio Grande several times a year from some drainages. Los Alamos, Pajarito, and Water Canyons have drainage areas greater than 26 km^2 (10 mi^2). Pueblo Canyon has a drainage area of 21 km^2 (8 mi^2), while all others have less than 13 km^2 (5 mi^2). The overall flood risk to LANL is low because nearly all the structures are located on the mesa tops, from which runoff drains rapidly into the deep canyons (DOE 1995hh:4-26). The hydrological features at LANL are depicted in figure 4.6.2.4–1. No surface water is withdrawn at LANL for either drinking water or facility operations (DOE 1993j:4-76).

Los Alamos, Sandia, and Mortandad Canyons currently receive treated-industrial or sanitary effluent. Pueblo Canyon does not receive LANL effluents. Surface waters in these canyons are not a source of municipal, industrial, or agricultural water supply. Several times during the year heavy precipitation or snowmelt would cause waters from Pueblo, Los Alamos, or Sandia Canyons to extend beyond LANL boundaries and reach the Rio Grande (LANL 1995s:2-7).

In Mortandad Canyon, no surface runoff to LANL's boundary has occurred since studies were initiated in 1960. Pueblo Canyon received both untreated and treated industrial effluents from 1944 to 1964. It currently receives treated sanitary effluents from Los Alamos County treatment plants in its upper and middle reaches (DOE 1993j:4-76).

Existing wastewater generation from LANL is approximately 693 MLY (183 MGY) (DOE 1993j:4-76). Permitted effluent discharges at LANL emerge from 2 sanitary wastewater treatment facilities and 130 industrial outfalls. These outfalls include power plant discharges (1 outfall), boiler blowdown (2 outfalls), treated cooling water (38 outfalls), noncontact cooling wastewater (51 outfalls), radioactive waste treatment plant (1 outfall), HE wastewater (21 outfalls), photographic laboratory rinse wastewater (13 outfalls), printed circuit board process wastewater (1 outfall), and sanitary wastewater (2 outfalls) (LANL 1995s:D-3).

Surface Water Quality. The 1993 surface water quality monitoring results for the five onsite canyons are presented in table 4.6.2.4–1. The overall compliance for sanitary and industrial discharges during 1993 was 100 percent and 99.1 percent, respectively.

Water Rights and Permits. Water rights in New Mexico fall under the Doctrine of Prior Appropriations. Under this doctrine, the user who first appropriated water for a beneficial use has priority to use available water supply over a user claiming rights at a later time. All natural water flowing in streams and water courses in New Mexico is considered to be public and subject to appropriation for beneficial use. Beneficial use is the basis, measure, and limit of the right to use water. No water right, therefore, may be granted or claimed for more than the amount that can be beneficially used. DOE owns combined surface and groundwater rights. These rights include the withdrawal of 5,541.3 acre-ft/yr from a variety of

[a] For comparison purposes only.
[b] Mean of multiple samples.
[c] Surface water is monitored at two location in Acid-Pueblo Canyon. The monitoring results presented are from Pueblo 3.
[d] Two locations are normally monitored in Los Alamos Canyon; however, one location was dry at the time of sampling. Results are reported for location DPS-1.
[e] Three locations are monitored in Sandia Canyon. The monitoring results presented are from the sampling location with the highest concentration of the given parameter.
[f] Only one location in Mortandad Canyon is sampled (GS-1).
[g] DOE Derived Concentration Guides for drinking water (DOE Order 5400.5). Values are based on a committed effective dose of 100 mrem per year; however, because the drinking water Maximum Contaminant Level is based on 4 mrem per year, the number listed is 4 percent of the Derived Concentration Guide. All concentrations of radionuclides are determined by subtracting the instrument background environmental level from the monitored concentrations. A negative or zero incremental concentration means that the concentration at the sampling location is equivalent to the environmental level and that there is no significant impact from the facility.
[h] Proposed National Primary Drinking Water regulation (56 FR 33050).
[i] National Secondary Drinking Water regulation (40 CFR 143).

wells and surface diversions under licenses RG–485 through RG–488, 1503, 1802, and 1802–B. DOE also owns a contract for 1,200 acre-ft/yr (1,480 MLY) of San Juan/Chama Diversion water.

Groundwater. Groundwater in the LANL area exists in three modes—in shallow alluvium in canyons, perched groundwater and in the main aquifer. The main aquifer consists mostly of clastic sediments within the Santa Fe Group and the Puye Formation. Nearly all groundwater at LANL is obtained from deep wells that produce water from this aquifer. A minor amount of groundwater at LANL is obtained from springs. Most aquifers that lie beneath LANL, with the exception of perched zones, are considered Class II aquifers, having current sources of drinking water and other beneficial uses (DOE 1993j:4-77).

The Santa Fe Group consists of, in ascending order, the Tesuque Formation, Puye Conglomerate, and basaltic rocks of Chino Mesa. The Tesuque Formation contains thin, jointed, interbedded basalt flows that may yield large amounts of water. Some units have lower permeabilities that restrict the movement of water within the formation. The Puye Conglomerate overlies the Tesuque Formation and is highly permeable. When saturated, it yields large amounts of water to wells (LANL 1984a:3).

The depth to the top of the aquifer ranges from about 366 m (1,200 ft) on the west to about 183 m (600 ft) on the east (LANL 1984a:8). The total saturated thickness penetrated by production wells ranges up to approximately 518 m (1,700 ft). The most productive area lies in the central portion of the Pajarito Plateau and includes the Pajarito well field. The average drawdown for these wells is 12 m (39.4 ft). The rate of movement of water in the aquifer is approximately 12 to 29 m (39.4 to 95.1 ft) per year (LANL 1984a:7,8).

Groundwater Quality. Most of the wells in the Pajarito Plateau yield fresh water (total dissolved solids less than 500 mg/L), although some wells east of the site have a higher total dissolved solids content (1,000 mg/L or more). The primary, secondary, and radiochemical groundwater quality, as measured from wells and springs in the main aquifer were below the DOE derived concentration guides or the New Mexico standards applicable to a DOE drinking water system (DOE 1993j:4-77). As shown in table 4.6.2.4–2, all parameters were below the applicable water quality criteria or standard in the main aquifer in 1993.

Groundwater Availability and Use. LANL, the nearby communities of Los Alamos and White Rock, and Bandelier National Monument are entirely dependent on groundwater for their water supply. The water supply is primarily obtained from well fields. During 1993, total production from the wells for potable and nonpotable use was 5,519 MLY (1,458 MGY) (LANL 1995r:4). LANL's water system had an average demand equal to about 81 percent of its current allotment of 6,800 MLY (1,800 MGY).

Two new wells have been drilled recently at LANL, one of which began pumping in the summer of 1992. The new wells are expected to supplant the now abandoned Los Alamos field. Water is taken from depths of 245 to 550 m (804 to 1,805 ft).

Over the next 50 years, increases in water use may require one of the following: use of the 1,500 MLY (396 MGY) of San Juan-Chama water (releasing the water in exchange for excess pumping) and/or establishment of credit for return flow (DOE 1993j:4-79).

Based on No Action projections, the net growth in overall use is about 0.4 percent per year. Based on this growth rate, the present allotment would be fully used by about 2052. If San Juan-Chama water is added, the limit to the total available supply would be reached by about 2072.

4.6.2.5 *Geology and Soils*

Geology. LANL is located on the Pajarito Plateau. The surface of the plateau is dissected by deep, southeast-trending canyons separated by long, narrow mesas. The Pajarito Plateau is capped by the Bandelier Tuff, a geologic unit comprising a massive pumiceous tuff breccia of ash-flow origin and a succession of cliff-forming welded ash flows. The tuff is underlain by sedimentary and volcanic rocks of the Santa Fe Group (LA DOE 1979a:3-9).

LANL lies within seismic Zone 2 (appendix figure A.1–1). The strongest earthquake in the last 100 years within an 80-km (50-mi) radius was estimated to have a magnitude of 5.5 to 6 and a modified Mercalli intensity of VII. Studies suggest

that several faults have produced seismic events with a magnitude of 6.5 to 7.8 in the last 500,000 years (LANL 1987c:ix). LANL operates a seismic hazards program which monitors seismicity through a seismic network and conducts studies in paleoseismology. Major faults at LANL include the Pajarito, Rendija Canyon, and Guaje Mountain faults (figure 4.6.2.5–1). The Guaje Mountain fault had movement on it between 4,000 and 6,000 years ago. There is no evidence of movement along the Pajarito fault system during historical times (DOE 1995hh:4-19). The 100-year earthquake at Los Alamos is regarded as having a magnitude of 5, with an event of magnitude 7 being the maximum credible earthquake. These values are currently used in design considerations at LANL (LANL 1987c:43,53,54,58).

Geological concerns associated with the LANL area include potential downslope movements in association with regional seismic activity. Although isolated rockfalls commonly occur from the canyon rims, landslides are an unlikely hazard at Los Alamos because of the dry climate, deep water table, and the rock characteristics. Although the area has the potential for future volcanic eruptions, the periodicity and structural development of past eruptions indicate a very low probability of an event occurring within the next 1,000 years (LA DOE 1979a:3-17).

Soils. LANL is underlain by soil types varying in texture from clay and clay loam to gravel. Over 95 percent of the soils are developed on acidic volcanic rocks (LANL 1978a:6,7). Because of the topographic relief of the Pajarito Plateau, rock outcrops occur on greater than 50 percent of the site area.

Water and wind erosion of these soils varies from slight to severe depending on slope, soil grain size, amount of disturbance, and degree of protection. Shrink-swell potential ranges from low to high, correlating with the amount of swelling clays present (LANL 1978a:80). The soils are acceptable for standard construction techniques. No soils in Los Alamos County have been designated prime farmland or Soil of Statewide Importance for New Mexico.

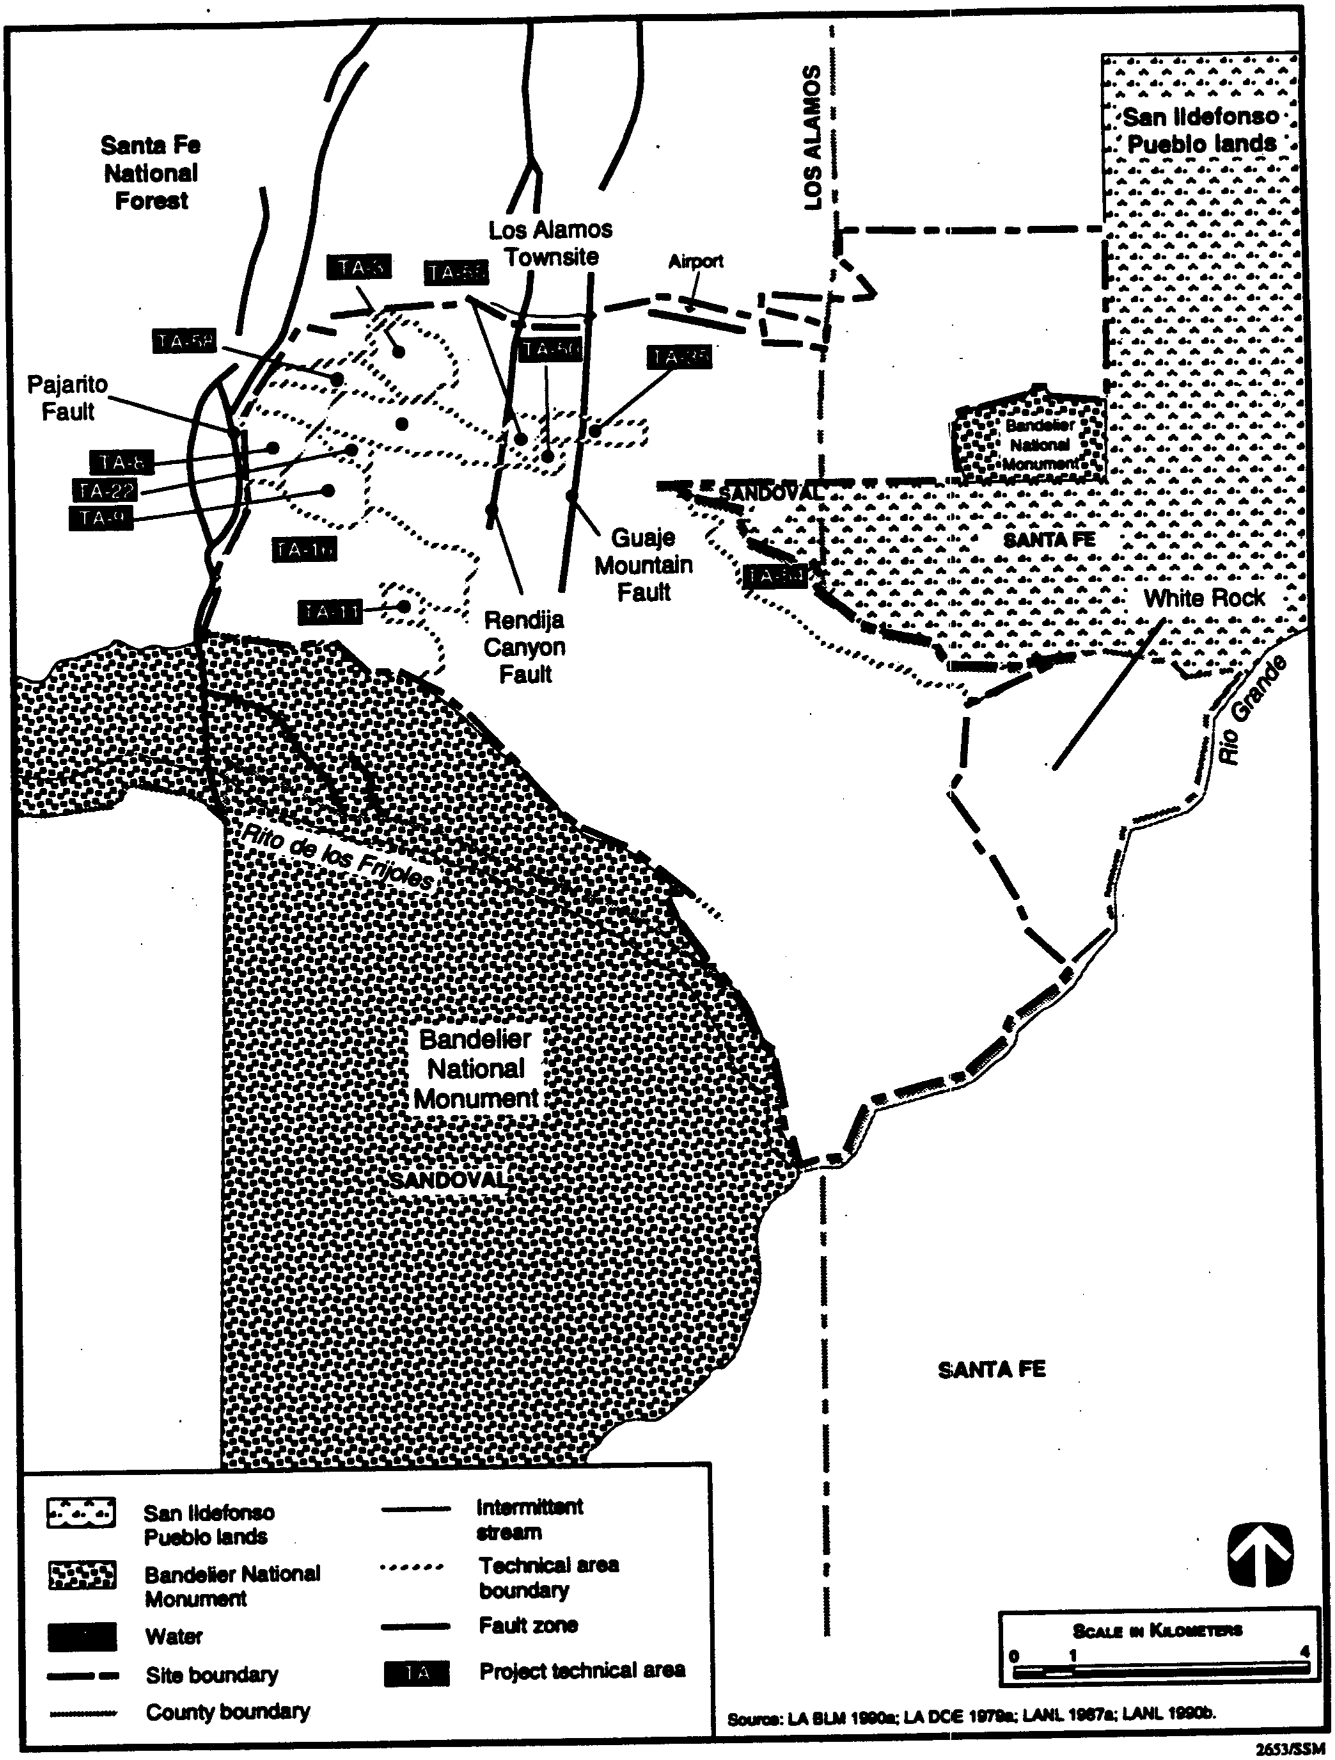

FIGURE 4.6.2.5–1.—*Major Fault Systems Near the Los Alamos National Laboratory Region.*

4.6.2.6 *Biotic Resources*

The following section describes biotic resources at LANL including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. A list of threatened and endangered species that may exist on or near LANL is presented in appendix C.

Terrestrial Resources. LANL lies within the Colorado Plateau Province. Ecosystems within the laboratory site itself are quite diverse due partly to the 1,500-m (5,000-ft) elevational gradient from the Rio Grande on the southeastern boundary to the Jemez Mountains, 20 km (12.4 mi) to the west, and to the many canyons with abrupt slope changes that dissect the site. Only a small portion of the total land area at LANL has been developed. The remaining land has been classified into six major vegetative communities as shown in figure 4.6.2.6–1. Within LANL, the predominant community types are juniper grassland in the eastern one-third, pinyon-juniper in the central one-third, and ponderosa pine in the western one-third. The juniper-grassland community is found along the Rio Grande on the eastern border of the Pajarito plateau and extends upward on the south-facing sides of the canyons at 1,700 to 1,900 m (5,600 to 6,200 ft). The pinyon-juniper community, generally found in the 1,900- to 2,100-m (6,200- to 6,900-ft) elevation range, includes large portions of the mesa tops and north-facing slopes at the lower elevations. The ponderosa pine community is found in the western portion of the plateau and on mesa tops in the 2,100- to 2,300 m (6,900- to 7,500-ft) elevation range. Coniferous trees are the dominant vegetation in the LANL environs, with pinyon pine (*Pinus edulis*) and one-seed juniper (*Juniperus monosperma*) predominant below 2,100 m (6,900 ft), and ponderosa pine (*Pinus ponderosa*) and Douglas fir (*Pseudotsuga menziesii*) predominant above that elevation (DOE 1995hh:4-39-4-42). Almost 350 vascular plant species have been found, or are likely to be found, on LANL (LA DOE 1979a:3-39).

Terrestrial animal species that can be found on or near LANL include 1 amphibian, 9 reptile, 189 bird, and 45 mammal species (LA DOE 1979a:3-46, C-1 to C-3). Undeveloped areas within LANL provide habitat for a diversity of terrestrial wildlife. Species lists have been compiled from observational data and published data, but the occurrence of some species has not been verified (LANL 1995i:f-1). Among vertebrates, the collared lizard (*Crotaphytus collaris*), eastern fence lizard (*Sceloporus undulatus*), and whiptail lizard (*Cnemidophorus spp.*) are some of the reptiles found at LANL. Typically, these are found at elevations between 1,910 and 2,134 m (6,265 and 7,000 ft). Bird species that nest in the area include the Mexican spotted owl (*Strix occidentalis lucida*), great-horned owl (*Bubo virginianus*), and red-tailed hawk (*Buteo jamaicensis*) among the raptors, and Say's phoebe (*Sayornis saya*), lesser goldfinch (*Carduelis psaltria*), and American robin (*Turdus migratorius*) among other types. Overwintering species include the scrub jay (*Aphelocoma coerulescens*), common raven (*Corvus corax*), and house finch (*Carduelis mexicanus*) (LANL 1992c; LANL 1995j).

Some of the larger mammals at LANL are the American black bear (*Ursus americanus*), coyote (*Canis latrans*), and raccoon (*Procyon lotor*), while the smaller species include the Mexican woodrat (*Neotoma mexicana*), deer mouse (*Peromyscus maniculatus*), Abert's squirrel (*Sciurus aberti*), and mountain cottontail (*Sylvilagus nuttalli*) (LANL 1995i:4-42). The most important and prevalent big game species at LANL are mule deer (*Odocoileus hemionus*) and elk (*Cervus canadensis*). LANL lands have traditionally been a transitional area for wintering elk and mule deer. More recently, these two species have been using LANL property on a year-round basis. Migratory birds and their nests and eggs are protected by the *Migratory Bird Treaty Act*. Eagles are similarly protected by the *Bald and Golden Eagle Protection Act*.

Throughout LANL's history, developments within various TAs have caused significant alterations in the terrain and the general landscape of the Pajarito Plateau. These alterations have resulted in significant changes in land use by most groups of wildlife species, particularly birds and larger mammals that have large seasonal and/or daily ranges. Certain projects required the segregation of large areas, such as mesa tops and, in some cases, project areas were secured by virtually impenetrable fences around their perimeters. These alterations have undoubtedly caused some species of wildlife, such as elk and deer, to alter their land use patterns by cutting off or altering seasonal and/or daily travel corridors to wintering areas, breeding habitat, foraging habitat,

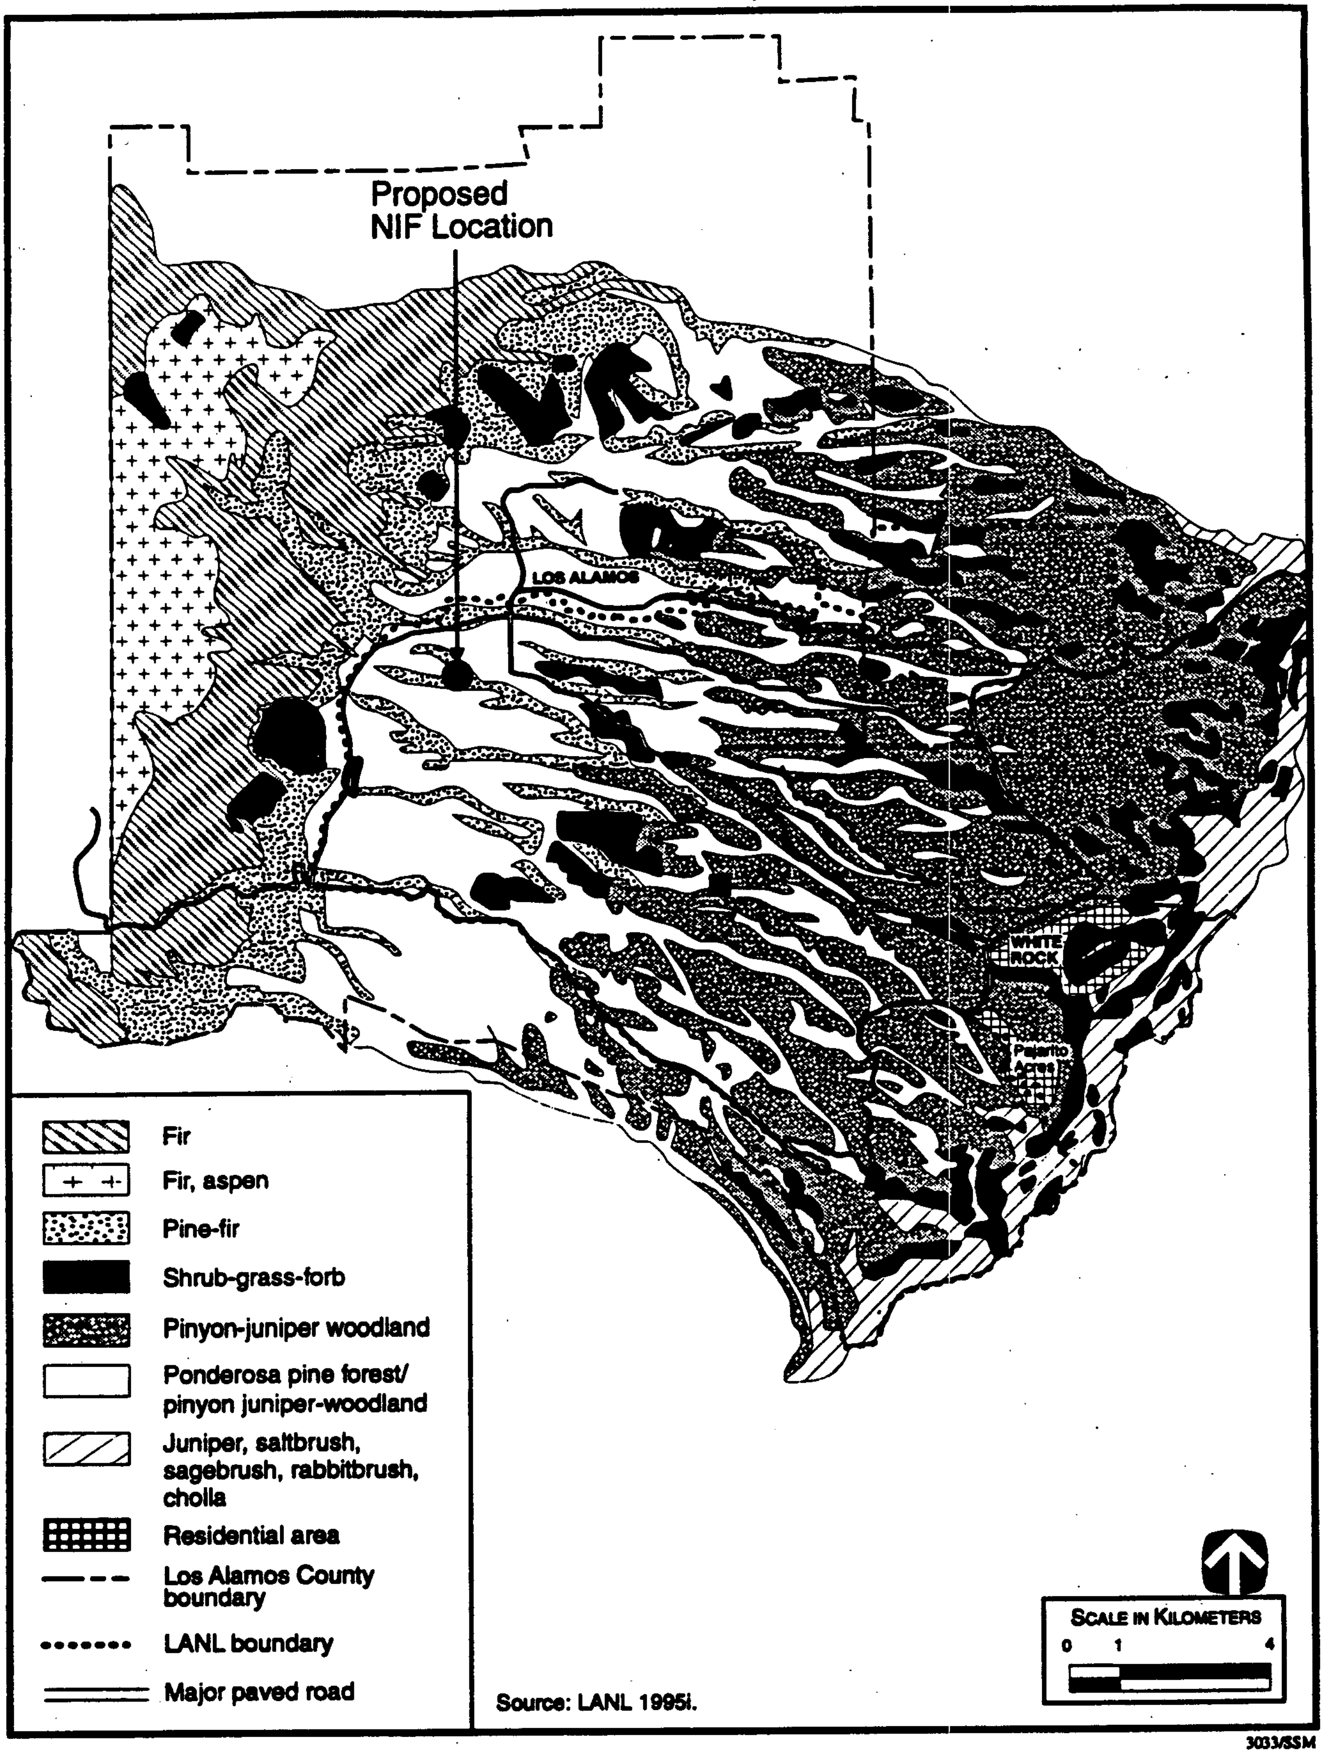

FIGURE 4.6.2.6–1.—*Distribution of Plant Communities at Los Alamos National Laboratory.*

and bedding areas, as well as other necessary habitats.

In 1980, elk were primarily using the southwestern portion of LANL (LA NERP 1981a). In addition, critical calving areas and important high-use areas were identified, all of which were primarily in the west and southwest part of LANL. Since 1980, the number of elk using LANL lands increased significantly. Studies of elk conducted from 1991 to 1993 (LANL 1995i:4-43) revealed increased use of habitats north and northeast of previously documented high-use areas (LA NERP 1981a). There have also been recent concerns about increases in motor vehicle accidents involving elk and deer in the LANL area (LANL 1995i:4-43). In general, however, little is known of habitat use patterns, population trends, and characteristics of elk on the Pajarito Plateau.

The proposed NIF would be located within an undeveloped portion of TA-58 that contains ponderosa pine. Wildlife present in the area would include those species typical of this forest type. A herd of elk and signs of black bears have been identified in the general site area (appendix I).

Wetlands. National Wetland Inventory maps show that most LANL wetlands occur in canyons that drain to the Rio Grande. Wetlands are found in most of the canyons on the laboratory site including Pueblo, Los Alamos, Sandia, Mortendad, Pajarito, Water, Ancho, Chaquchi, and White Rock (Rio Grande) Canyons. Wetlands have also developed in the vicinity of outfalls from LANL facilities. Most wetlands are classified as riverine intermittent, meaning they may contain flowing water part of the year and may contain pooled water or be dry the remainder of the year. Palustrine emergent and/or scrub-shrub wetlands are also indicated in sections of Pueblo, Los Alamos, Sandia, Pajarito, and Ancho Canyons. Most of the riverine and Palustrine wetlands known to exist at LANL are designated as temporary or seasonal by the National Wetlands Inventory maps. No wetlands exist in the immediate NIF site area (appendix I; DOE 1995hh:4-43).

Aquatic Resources. Aquatic habitats at LANL are limited to the Rio Grande and several springs and intermittent streams in the canyons. Some of these habitats currently receive NPDES-permitted wastewater discharges. The springs and streams at LANL do not support fish; however, many other aquatic species thrive in these waters (DOE 1995hh:4-43). No aquatic resources exist in the immediate NIF site area (appendix I).

The Rio Grande is located along the southeastern property boundary and supports populations of common carp (*Cyprinus Carpio*), chub (*Cyprinidae*), white sucker (*Catostomus commersoni*), and carpsucker (*Carpiodes spp.*). Game fish inhabiting the Rio Grande in the vicinity of LANL include the channel catfish (*Ictalurus punctatus*) and brown trout (*Salmo trutta*).

Threatened and Endangered Species. Twenty Federal- or state-listed threatened, endangered, and other special status species may be found on and in the vicinity of LANL (appendix table C–4). Four of these species have been observed on LANL. The Federal-listed species recorded onsite include the Mexican spotted owl (*Strix occidentalis lucida*), which has recently been observed nesting near TA-15 (two young were fledged from this nest during the 1995 breeding season) (DOE 1995hh:4-45), the bald eagle *(Haliaeetus leucocephalus)*, which winters along the Rio Grand River, and peregrine falcon *(Falco peregrinus)*, which historically nested onsite and occasionally still forages there. The state-threatened Jemez Mountain salamander (*Plethodon neomexicanus*) has also been observed onsite. LANL canyons provide suitable nesting, roosting, and foraging habitats for the Mexican spotted owl. No critical habitat for threatened or endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on LANL; however, critical habitat for the Mexican spotted owl has been designated in areas bordering the northern and western boundaries of LANL (60 FR 29914).

Suitable habitat exists within the proposed NIF location that could attract several of the special status species that potentially occur on LANL. These species include the Mexican spotted owl, gray vireo *(Vireo vicinior)*, southwestern willow flycatcher *(Empidonax traillii extimus)*, spotted bat *(Euderma maculatum)*, New Mexican meadow jumping mouse *(Zapus hudsonius luteus)*, and plant species such as giant helleborine orchid. Site-specific surveys would be required to verify the occurrence of these or any other sensitive species.

4.6.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. Prehistoric site types identified in the vicinity of LANL include large multiroom pueblos, field houses, talus houses, shrines, rock shelters, animal traps, hunting blinds, water control features, agricultural fields and terraces, quarries, rock art, trails, campsites, windbreaks, rock rings, and limited activity sites. Approximately 75 percent of LANL has been inventoried for cultural resources. Coverage for many inventories has been less than 100 percent; however, approximately 60 percent of LANL has received 100-percent coverage. More than 1,300 prehistoric sites have been recorded at LANL, and approximately 95 percent of these sites are considered eligible or potentially eligible for the NRHP. Two areas in the vicinity of LANL have been established as NRHP sites or districts: Bandelier National Monument (named as a monument in 1916) and Puye Cliffs Historical Ruins.

The 11 TAs potentially affected by project alternatives are shown in figure 4.6–2. Of these areas, all of TA-35 has been surveyed, while the other TAs have been partially surveyed. NRHP-eligible prehistoric resources have been identified in TAs -3, -8, -9, -16, -28, -37, -50, and -54 (LANL 1996e:1). New facility construction would occur only in TA-58, one third of which has been surveyed. The survey of TA-58 located no prehistoric resources. The unsurveyed two thirds of TA-58 may contain prehistoric resources. Prehistoric resources also may occur in areas needed for construction laydown, materials storage, and parking.

Historic Resources. Historic resources consist of homesteads, corrals, ditches, trash scatters, roads and trails, railroads, ranches, mines, remains of commercial ventures, and buildings associated with the Manhattan Project and the Cold War era. More than 80 historic resources have been recorded at LANL, and about 90 percent of the resources are considered eligible or potentially eligible for the NRHP.

The existing LANL facilities have been extensively modified and refurbished since 1943 when major construction occurred after World War II. The existing facilities are not likely to be considered NRHP eligible because they lack architectural integrity and may not be representative of a particular style. However, some of the facilities may be NRHP eligible based on their association with the broad historic theme of the Manhattan Project and initial nuclear production.

Portions of the proposed TA project areas have been surveyed. NRHP-eligible buildings exist in TAs -3, -8, -9, -16 (74 individual buildings); TA-22 (TA-22-1); TA-28; and TA-55. Structures at the front and back gates are also eligible for the NRHP. Additional NRHP-eligible historic resources may exist in other involved TAs. Some of the buildings requiring modification under the proposed alternatives may potentially be NRHP eligible.

Native American Resources. Native Americans in the area with concerns include the six Tewa-speaking Pueblos of the northern Rio Grande Valley (San Ildefonso, San Juan, Santa Clara, Nambe, Tesuque, and Pojoaque) and the Cochiti and Jemez Pueblos.

Cultural resources are of special importance to Native Americans. These resources located on the LANL site may consist of prehistoric sites with ceremonial features such as kivas, village shrines, petroglyphs, or burials, or traditional cultural properties with no observable manmade features. Consultations with local Native Americans to identify any such cultural resources have been conducted in the past and are ongoing. An ethnographic study is currently being conducted to identify traditional cultural properties in the area as part of the LANL site-wide EIS.

Paleontological Resources. Pajarito Plateau consists primarily of Pleistocene volcanic tuffs and compacted pumice and ashfalls of the Bandelier Formation. None of the formations within LANL are known to be fossiliferous.

4.6.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at LANL include employment and regional economy, population and housing, and public finance. Statistics for employment and local economy are based on the regional economic area that encompasses seven counties in New Mexico around LANL. Statistics for population and housing, and public finance are presented for the ROI, a three-county area in which 88.1 percent of all LANL employees reside: Los Alamos County (48.3 percent), Rio Arriba County (20.8 percent), and Santa Fe County (19.0 percent) (appendix table D.1–5). More than half of the Los Alamos County employees reside in the unincorporated communities of Los Alamos and White Rock. Figure 4.6.2.8–1 presents a map of the counties and selected cities composing the LANL regional economic area and ROI. Supporting data is presented in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the LANL regional economic area are summarized in figure 4.6.2.8–2. Between 1980 and 1990, the civilian labor force in the regional economic area increased from 74,759 to 100,257, a 34-percent increase (annual average increase of 3.4 percent). In 1994 unemployment in the regional economic area was 6.2 percent compared to 6.3 percent for New Mexico. The region's per capita income of $17,689 in 1993 was approximately 8.2 percent higher than New Mexico's per capita income of $16,346.

As shown in figure 4.6.2.8–2, the regional economic area and New Mexico have similar employment patterns. The service sector accounts for the largest share of total employment in both the region (31 percent) and in New Mexico (28 percent). Manufacturing employment accounted for 4 percent of the total regional employment but 6 percent of the total state employment.

Population and Housing. Between 1980 and 1992, the ROI population grew from 122,241 to 158,249, an increase of 29.5 percent (annual average increase of 2.5 percent). Within the ROI, however, Santa Fe County, increased by 39.6 percent (annual average increase of 3.3 percent). Population growth in Los Alamos was nearly stagnant during the same period. The unincorporated communities of Los Alamos and White Rock in Los Alamos County are included in the county population and housing analysis.

The number of housing units increased from 46,006 in 1980 to 63,386 units in 1990; an increase of 37.8 percent (annual average increase of 3.8 percent). The 1990 homeowner vacancy rate in the ROI was 2.3 percent. The rental vacancy rate for the ROI counties was 7.7 percent. Population and housing trends are summarized in figure 4.6.2.8–3.

Public Finance. Financial characteristics of the local jurisdictions in the LANL ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure categories for counties, cities, and school districts are presented in appendix tables D.2.3–8 and D.2.3–9. Figure 4.6.2.8–4 summarizes 1994 local governments' revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.6.2.8–4. All jurisdictions assessed had positive fund balances.

4.6.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at LANL. Also included are descriptions of health effects studies, a brief accident history, and emergency preparedness considerations.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of LANL are shown in table 4.6.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. The total dose to the population changes as the population size changes. Background radiation doses are unrelated to LANL operations.

Releases of radionuclides to the environment from LANL operations provide another source of radiation exposure to individuals in the vicinity of LANL. The radionuclides and quantities released from LANL operations in 1993 are listed in *Environmental Surveillance at Los Alamos During 1993* (LA-12973-ENV). The doses to the public resulting from these releases and direct radiation are presented in table 4.6.2.9–2. These doses fall within regulatory limits (DOE Order 5400.5) and are small in comparison to background radiation. The releases were used in the development of the reference environment's (No Action) radiological releases in 2005.

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem ($5x10^{-4}$ fatal cancers person-rem) to the public (appendix E), the

FIGURE 4.6.2.8–4.—*Local Government Public Finance for Los Alamos National Laboratory Region of Influence* [Page 2 of 2].

fatal cancer risk to the maximally exposed member of the public due to radiological releases from LANL operations in 1993 is estimated to be $3.3x10^{-6}$. That is, the estimated probability of this person dying of cancer at some point in the future from radiation exposure associated with 1 year of LANL operations is about 3 chances in 1 million. (Note that it takes several to many years from the exposure to radiation for a cancer to manifest itself).

Based on the same conversion factor, $1.5x10^{-3}$ excess fatal cancers were estimated from normal operation in 1993 to the population living within 80 km (50 mi) of LANL. The 1990 mortality rate, associated with cancer, for the entire U.S. population was 0.2 percent per year (Almanac 1993a:839). Based on the national rate, the number of fatal cancers expected during 1990 in the population living within 80 km (50 mi) of LANL was 438. This number of expected fatal cancers is much higher than the estimated $1.5x10^{-3}$ fatal cancers that could result from LANL operations in 1993.

Workers at LANL receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities. Table 4.6.2.9–3 includes the average, maximum, and total occupational doses to LANL workers from operations in 1992. Except for the dose of less than 7,000 mrem to one worker, all other doses fall within regulatory limits (10 CFR 835). Based on a dose-to-risk conversion factor of

TABLE 4.6.2.9–1.—*Sources of Radiation Exposure to Individuals in the Vicinity, Unrelated to Los Alamos National Laboratory Operations*

Source	Committed Effective Dose Equivalent (mrem/yr)
Natural Background Radiation[a]	
Cosmic radiation	48
External terrestrial radiation	44
Neutron cosmic radiation	10
Internal terrestrial radiation	40

TABLE 4.6.2.9–2.—*Doses to the General Public from Normal Operation at Los Alamos National Laboratory, 1993 (Committed Effective Dose Equivalent)*

Affected Environment	Atmospheric Releases		Liquid Releases		Total	
	Standard[a]	Actual	Standard[a]	Actual[b]	Standard[a]	Actual
Maximally exposed individual (mrem)	10	5.7	4	0.8	100	6.5
Population within 80 kilometers[c] (person-rem)	None	3.0	None	~0[d]	100	3.0
Average individual within 80 kilometers[e] (mrem)	None	0.014	None	~0[d]	None	0.014

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem/yr limit for airborne emissions is required by the *Clean Air Act*, the 4 mrem/yr limit is required by the *Safe Drinking Water Act*, and the total dose of 100 mrem/yr is the limit from all pathways combined. The 100 person-rem value for the population is found in proposed 10 CFR 834 (58 FR 16268).
[b] The actual dose values given in this column conservatively include all water pathways, not just the drinking water pathway.
[c] In 1993, this population was approximately 219,000.
[d] Although the maximally exposed individual receives a dose, no population groups are exposed to any liquid pathways.
[e] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.
Source: LANL 1995s.

400 fatal cancers per 1 million person-rem ($4x10^{-4}$ fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to LANL workers from operations in 1992 is estimated to be 0.077.

TABLE 4.6.2.9–3.—*Doses to the Onsite Worker from Normal Operation at Los Alamos National Laboratory, 1992*

Affected Environment	Onsite Releases and Direct Radiation	
	Standard[a]	Actual[b]
Average worker (mrem)	None	34
Maximally exposed worker (mrem)	5,000	~7,000[c]
Total workers (person-rem)	None	194

[a] 10 CFR 835. DOE's goal is to maintain radiological exposure as low as reasonably achievable.
[b] DOE 1993n:7; the number of badged workers in 1992 was approximately 5,700.
[c] Only one worker exceeded the worker dose standard.

A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in *Environmental Surveillance at Los Alamos During 1993* (LA-12973-ENV). In addition, the concentrations of radioactivity in various environmental media (e.g., air, water, and soil) in the onsite and offsite regions are presented in the same reference.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in previous sections of this PEIS, particularly sections 4.6.2.3 on air quality and 4.6.2.4 on surface and groundwater quality.

Adverse impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and to achieve compliance with permit requirements. The effectiveness of these controls is verified through the use of monitoring information and inspection of mitigation measures. Health impacts to the public may occur during normal operation at LANL via inhalation of air containing hazardous chemicals released to the atmosphere from LANL operations. Risks to public health from ingestion of contaminated drinking water or direct exposure are also potential pathways.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.6.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. These concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to LANL workers during normal operation may include inhaling the workplace atmosphere, drinking LANL potable water, and possible other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. LANL workers are also protected by adherence to OSHA and EPA occupational standards that limit workplace atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm.

Health Effects Studies. Recent epidemiological studies have been conducted in the LANL area. One study, by Athas and Key (NM DOH 1993a), reported elevations in brain cancer incidence during the mid- to late-1980s, compared to state and national reference populations, but random fluctuation could not be ruled out. Breast cancer incidence rates in Los Alamos from 1970 to 1990 have remained level, but higher than New Mexico rates. Reproductive and demographic factors known to increase the risk of breast cancer have been prevalent in the county. Ovarian cancer incidence in the county from 1986 to 1990 was approximately two-fold greater than that observed in a New Mexico State reference population. In the mid- to late-1980s, a two-fold excess risk of melanoma was observed in Los Alamos County compared with a New Mexico State Reference population. A more recent study by Athas (NM DOH 1996a) observed a four-fold increase in thyroid cancer incidence during the late 1980s and early 1990s compared with the state as a whole, but the rate began to decline in 1994 and 1995. No statistically significant excess cancers were reported for male workers exposed to plutonium. However, statistically significant excesses in kidney cancer and lymphomatic leukemia were observed in male workers exposed to external radiation (HP 1994a: 577-588). An excess of death from suicides was reported among female radiation workers (LA Wiggs1987a). For a more detailed description of the studies reviewed and the findings, refer to appendix section E.4.7.

Accident History. A review of recent LANL annual environmental and accident reports indicates that there have been no significant adverse impacts to workers, the public, or the environment. This review was performed to provide an indication of the site's accident history. During the review period, from 1986 to 1990, site operations were much higher than in previous years and also higher than what is anticipated for the future.

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for most accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with emergency planning, preparedness, and response. The LANL Emergency Preparedness Plan is designed to minimize or mitigate the impact of any emergency upon the health and safety of employees and the public.

4.6.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and waste management activities for LANL. A more detailed discussion of the ongoing waste management operation and the regulatory setting is provided in appendix section H.2.5.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operation of LANL and is engaged in several activities to bring its current operations into full regulatory compliance. These activities are set forth in permits and negotiated agreements that contain schedules for achieving compliance with applicable requirements and financial penalties for nonachievement of agreed upon milestones. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

LANL is not listed on the NPL. As a function of obtaining a RCRA permit, however, the *Hazardous and Solid Waste Amendments* of 1984 mandate that permits for treatment, storage, and disposal facilities include provisions for corrective action to mitigate releases from solid and hazardous waste facilities in operation and to clean up contamination in areas designated as solid waste management units at LANL. By the end of 1995, over 60 of the approximately 2,100 potential release sites identified had been remediated, no further action was proposed for 575 sites, and 1,100 sites were slated for investigation or cleanup; for the remaining sites, action is still pending. All cleanup activities are expected to be completed by 2010 (LANL 1996e:1).

Through its research activities, LANL manages a small quantity of spent nuclear fuel and five broad waste categories: TRU, low-level, mixed, hazardous, and nonhazardous wastes. Because there is no spent nuclear fuel or HLW associated with any of the proposed activities at LANL, there is no discussion in this PEIS of spent nuclear fuel or HLW generation and management at LANL. A discussion of the waste management activities associated with each of these categories follows.

Transuranic Waste. In 1993, LANL generated approximately 54 m^3 (70 yd^3) of TRU waste (LANL

1994b:6). The Plutonium Facility (TA-55) is the principal generator of liquid TRU waste at LANL. Process acidic and caustic wastewaters, evaporator distillates from the nitrate recovery area, cooling water from glove boxes, and wet vacuum seal water are the principal sources. Sludges that remain after treatment through filtration and residual evaporator bottoms are loaded into 208-L (55-gal) drums, solidified, and transported to Area G for storage. The liquid wastes remaining after filtration are transferred from TA-55 to the Radioactive Liquid Waste Treatment Facility (TA-50) by gravity drain in double-wall pipelines. After treatment at TA-50 involving sedimentation, clarification, and flocculation, the residual radioactive sludge is loaded into drums, solidified, and transported to Area G for storage. Most of LANL's TRU waste is currently stored on four asphalt pads. TRU wastes are currently being stored, until they can be shipped to WIPP if that facility can demonstrate compliance with the requirements of 40 CFR 191 and 40 CFR 268, or to another TRU waste disposal facility should WIPP prove unsatisfactory. Should additional treatment be necessary for disposal at WIPP, LANL would develop the appropriate treatment to meet the WIPP waste acceptance criteria and package the wastes in accordance with DOE, NRC, and DOT requirements for transport to WIPP for disposal. LANL is presently upgrading TRU waste storage facilities to comply with RCRA requirements under the terms of a consent order with the State of New Mexico.

LANL generates mixed TRU wastes. Newly generated mixed TRU wastes are identified, characterized, and stored in compliance with RCRA. In 1993, LANL generated approximately 255 m^3 (334 yd^3) of mixed TRU wastes (LANL 1994b:6). The *Federal Facility Compliance Act* of 1992 requires DOE to provide specific information to EPA and the State of New Mexico on LANL's mixed TRU waste streams, treatment facilities, and technology development activities. This waste category covers a broad range of physical matrix categories for LANL. The Federal Facility Compliance Order for the Site Treatment Plan requires treatment of all mixed wastes not in compliance with the land disposal provisions of RCRA. This compliance order is the implementation of the *Federal Facility Compliance Act* at LANL. The WIPP waste acceptance criteria specifies limiting parameters for waste containers, waste form, waste packaging, accompanying data, and miscellaneous requirements for packaging and RCRA. It is anticipated that some technology required for additional treatment of TRU wastes to attain additional treatment standards can be adapted from the technologies that must be brought online for mixed LLW. If DOE is successful in obtaining a no-migration petition for the disposal of mixed TRU wastes at WIPP, adherence with treatment standards under the land disposal restrictions would not be required.

Low-Level Waste. Both liquid and solid LLW are generated and managed by LANL. In 1993, LANL generated approximately 21,400 m^3 (5,653,000 gal) of liquid and 2,693 m^3 (3,523 yd^3) of solid LLW (LANL 1994b:6,9). Liquid LLW is generated from many areas throughout LANL: there are two wastewater treatment facilities used for treatment of aqueous LLW, one of which utilizes ion-exchange technology. As part of a new radioactive liquid waste treatment facility project, a facility for the solidification and subsequent volume reduction of the radioactive liquid waste treatment plant sludge containing plutonium, americium, and other radionuclides is proposed, but not funded at LANL.

Solid LLW is generated from many areas throughout LANL. Solid LLW such as paper, plastic, glassware, and rags are separated into compactible and noncompactible materials by the waste generators. Compactible bales are banded, wrapped and sealed in plastic, and moved to Area G for disposal in landfill pits, located at TA-54 (figure 4.6–2). LLW noncompactible items, such as large equipment and much of the D&D waste, generally are not packaged but delivered to the burial site in covered or enclosed vehicles. Continued construction at Area G is dependent on decisions made in conjunction with the LANL sitewide EIS being prepared by LANL.

Mixed Low-Level Waste. In 1993, LANL generated approximately 45 m^3 (59 yd^3) of mixed LLW (LANL 1994b:6). Mixed LLW includes solvents, pyrophoric substances, spray cans, scintillation vials, uranium-contaminated lithium hydride, miscellaneous reagent chemicals, vacuum pump oil contaminated with mercury, gas cylinders, and other contaminated material. It is stored at TA-54 Areas L and G. Currently, LANL does not dispose of mixed LLW. In accordance with the *Federal Facility Compliance Act* of 1992, LANL has developed a site treatment plan which covers management of all mixed waste at LANL. The State of New Mexico Environment Department issued a Compliance Order in the Site Treatment Plan for Mixed Waste in October 1995. The compliance order addresses land disposal restricted mixed waste. For mixed waste with identified treatment technologies, the plan provides a schedule for submitting permit applications, entering into contracts, initiating construction, conducting systems testing, starting operations, and processing mixed wastes. For mixed waste without an identified treatment technology, the plan includes a schedule for identifying and developing technologies, identifying the funding requirements for research and development (R&D), submitting treatability study notifications, and submitting R&D permit applications.

Mixed waste treatment skids are being designed to treat onsite hazardous and mixed waste streams that are not amenable to offsite treatment. Examples of the waste streams potentially amenable to skid treatment are reactive metals, plating wastes, acids, bases, ignitable liquids, spent solvents, and decontamination debris. Not all of the technologies to be included have been chosen. The mixed waste treatment skids would be housed in an existing LANL structure. An environmental restoration high-energy plasma technology is being tested as a technique for total destruction of mixed LLW that has been treated to land disposal restrictions standards. This technique will allow LANL to stay in compliance with the *Federal Facility Compliance Act* of 1992.

Hazardous Waste. LANL received a permit for treatment, storage, and disposal of hazardous waste under RCRA in November 1989, and for the *Hazardous and Solid Waste Amendments* of 1984 provisions from EPA on March 8, 1990. All hazardous waste treatment and storage facilities at LANL are either fully permitted or are operating under interim status, while other waste management facilities are being developed.

LANL produces a wide variety of hazardous wastes. In 1993, LANL generated approximately 84 t (93 tons) of RCRA-regulated, 460 t (507 tons) of state-regulated, and 124 t (137 tons) of TSCA-regulated solid hazardous wastes (LANL 1994b:6). Small volumes of almost all wastes listed under 40 CFR 261 are generated as a result of a wide variety of ongoing research. HE waste is generated during the processing and testing of various HE materials. All HE hazardous waste and potentially contaminated HE waste is picked up from the generating facility and treated by open detonation, open burning, or incineration at TAs -14, -15, -16, -36, and -39. Ash residue is then treated and, when its hazardous characteristic can be removed and it is determined that this residue does not contain radioactive constituents, it is disposed of onsite in the landfill, TA-54, Area J. The HE wastewater is treated by gravity settlement in a sump and discharged from NPDES-permitted outfalls. LANL is developing a HE wastewater treatment facility that will collect and treat these wastewaters with stepped filtration.

LANL does not landfill RCRA-hazardous waste onsite, but contracts with certified transporters to deliver hazardous waste to commercial offsite RCRA-permitted treatment, storage, and disposal facilities. Before waste is sent offsite, the potential treatment or disposal facility is inspected by LANL personnel. Operating records and permits are also reviewed. LANL has an EPA Letter of Authorization allowing disposal of solid PCB-contaminated articles at the TA-54, Area G landfill. Other PCB waste and liquid PCB-contaminated articles are sent offsite to TSCA-regulated disposal facilities. Asbestos mixed waste is buried at TA-54, Area G. Asbestos waste is shipped offsite to an approved disposal site in accordance with TSCA and NESHAP regulations. Infectious wastes are managed according to State of New Mexico regulations.

Nonhazardous Waste. In 1993, LANL generated 8,180 t (9,017 tons) of solid sanitary wastes (LANL 1994b:6). Solid sanitary wastes are generated routinely and include general facility refuse such as paper, cardboard, glass, wood, plastic, scrap, metal containers, dirt, and rubble. Solid sanitary wastes are segregated and recycled whenever possible. Trash is accumulated onsite in dumpsters, which are emptied on a regular basis by a commercial waste disposal firm and taken to the county sanitary landfill. The Los Alamos County landfill is located on property owned by DOE and is operated under a special-use permit. Approximately one-third of the solid sanitary waste disposed of at the county landfill originates from LANL. The Area J special waste landfill, which is operated by and is under the administrative control of LANL, receives only administratively controlled solid sanitary waste. Solid sanitary waste will be managed and disposed of at LANL until 2007, the year the existing sanitary landfill is expected to reach the end of its useful life. At that time, either a new landfill will have to be constructed or provisions made for offsite disposal.

LANL generates approximately 693,000 m^3 (183,000,000 gal) of liquid sanitary waste (DOE 1993j:3-54). A new sanitary wastewater treatment plant and collection system to replace 7 existing wastewater treatment facilities and 30 existing septic tanks have been completed. The new treatment plant will enable reuse of the treated wastewater for non-drinking water uses such as cooling and irrigation. The plant and collection system is designed to meet the requirements of LANL's existing Federal Facility Compliance Agreement and is expected to meet all of LANL's needs for the next 20 years.

4.6.3 Environmental Impacts

4.6.3.1 *Land Use*

No Action. Under No Action, DOE would continue current and planned activities at LANL as described in section 3.2.6. No additional land use impacts are anticipated at LANL beyond the effects of the existing and future activities that are independent of the proposed action.

Management Alternatives

Pit Fabrication. The existing plutonium facility at LANL would be modified to support this alternative. Additional land would not be used to implement the new mission. The proposed activity would be compatible and consistent with land use plans and policies. Impacts to land use are not expected.

Secondary and Case Fabrication. The secondary and case fabrication alternative at LANL would use existing facilities, equipment, and infrastructure to support production requirements for the secondary fabrication mission. Only minimal modifications to existing facilities at LANL would be required. Additional land would not be used to implement the new mission. These activities would be compatible and consistent with land use plans and policies. Impacts to land use are not expected.

High Explosives Fabrication. The proposed HE fabrication activities would be conducted in existing LANL facilities. No new facilities or structures would be required to support HE fabrication. Additional land would not be used to implement the mission. The proposed activity would be compatible and consistent with land use plans and policies. Impacts to land use are not expected.

Nonnuclear Fabrication. LANL would use existing facilities to support nonnuclear fabrication activities. Additional land would not be used to implement the mission. The proposed activity would be compatible and consistent with land use plans and policies. Impacts to land use are not expected.

Sensitivity Analysis. LANL would be able to accommodate the high and low case production operations for all management alternatives with base case production facilities. No land-use impacts are expected.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed location of NIF at LANL is within TA-58. An estimated 4 ha (10 acres) of land for buildings, walkways, building access, and buffer space would be required to construct and operate NIF. The land required for the proposed NIF would represent approximately 1 percent of the land currently available for development within LANL. However, 4 ha (10 acres) represents an extremely small proportion of LANL's total land area of 111 km^2 (43 mi^2). The proposed NIF is compatible and consistent with land-use plans for this area. No impacts to LANL land-use plans or policies are expected.

Proposed Atlas Facility. The proposed Atlas Facility would include existing buildings located in a developed area within TA-35 at LANL. Modification activities would involve renovating the existing buildings for use in performing pulsed-power experiments. The area is currently used for similar types of activities. The proposed Atlas Facility activity would be compatible and consistent with land use plans for the area. Impacts to LANL land-use plans and policies are not expected.

Combined Program Impacts. Of the six potential Stockpile Stewardship and Management Program alternatives proposed for LANL, existing facilities would be modified for five of the alternatives. No additional land would be used to implement the mission. The proposed NIF would require clearing 4 ha (10 acres) of undeveloped land for buildings, walkways, and buffer space. The total land use impact from placing all potential Program alternatives at LANL would be the use of 4 ha (10 acres) of undeveloped land in TA-58 for the new NIF mission.

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives at LANL are anticipated.

4.6.3.2 *Site Infrastructure*

This section discusses site infrastructure at LANL for No Action and the modifications needed for actions due to construction and operation of stockpile stewardship and management facilities. A comparison of site infrastructure and facility resource needs for No

Action and the proposed alternatives is presented in table 4.6.3.2–1.

No Action. This alternative continues the management missions, described in section 3.2.6, of limited pit fabrication and selected nonnuclear fabrication, and the stewardship R&D missions. As stated in section 1.6.2, the Dual Axis Radiographic Hydrodynamic Test (DARHT) Facility is considered part of No Action. Impacts on site infrastructure would be minimal since the Pulsed High Energy Radiation Machine Emitting X-Rays (PHERMEX) Facility would be phased out as the DARHT Facility becomes operational. As shown in table 4.6.3.2–1, the site infrastructure would continue to adequately supply facility requirements.

Management Alternatives

Pit Fabrication. As shown in table 4.6.3.2–1, site infrastructure would require slight facility improvements to meet pit fabrication requirements. Only a slight increase over No Action requirements in electrical energy and natural gas use is expected. No other impacts to site infrastructure are expected.

Secondary and Case Fabrication. Site infrastructure would require slight facility improvements to meet secondary and case fabrication requirements. Table 4.6.3.2–1 shows the total site requirement with secondary and case fabrication and the change from No Action. Impacts to site infrastructure include a 9-percent increase in electrical energy use over No Action requirements. The electric power pool has sufficient capacity margins to accommodate the secondary and case fabrication mission. There would also be an increase in liquid fuel use.

High Explosives Fabrication. Site infrastructure would require minor facility improvements to meet HE fabrication requirements. Impacts to site infrastructure include an increase in liquid fuel use over No Action requirements. An 8-percent increase in natural gas use would occur, but there would be only a slight increase in electrical energy use over No Action requirements. This analysis assumes the entire HE mission is relocated to LANL. If it is shared with LLNL, the impact would be proportionately less.

Nonnuclear Fabrication. Minor site infrastructure facility improvements would be needed to meet nonnuclear fabrication requirements. As shown in table 4.6.3.2–1, only a slight increase in energy use is expected. No other impacts to site infrastructure are expected.

Sensitivity Analysis. No change in site infrastructure impacts are expected for the high and low production case for pit, secondary and case, and HE fabrication. For nonnuclear fabrication, the high production case would require using additional facilities, namely Buildings 300 and 301 at S-Site. Also, additional capital equipment would need to be added to increase processing, storage, and inventory control capability. No additional site infrastructure changes would be needed to meet the low production case.

Stewardship Alternatives

Proposed National Ignition Facility. As shown in table 4.6.3.2–1, site infrastructure would require slight facility improvements to meet the proposed NIF requirements. Impacts to site infrastructure include a 11-percent increase in electrical energy use, a 22-percent increase in peak electrical loads, and a 2-percent increase in natural gas use over No Action requirements. The electric power pool has sufficient capacity margins to accommodate the proposed NIF.

Proposed Atlas Facility. The LANL site infrastructure would require minor facility improvements to meet the proposed Atlas Facility requirements. Table 4.6.3.2–1 shows the expected change in site requirements to support the Atlas Facility. Impacts to site infrastructure include no increase in peak electrical load requirements due to utilization of existing generators currently used for other experiments and only a slight increase in electrical energy use over No Action requirements. No other impacts to site infrastructure are expected.

Combined Program Impacts. If all of the alternatives applicable to LANL were to be located there, the combined impacts would exceed current site infrastructure resources. The largest impact would be a 25-percent increase in electrical energy use with an associated 31-percent increase in peak electrical load. Natural gas use would increase by 10 percent. Consumption of liquid fuel, which is currently used for standby power only and shows no amount in table 4.6.3.2–1, would increase to about 197,400 L per year.

TABLE 4.6.3.2–1.—*Site Infrastructure Requirements and Changes for Stockpile Stewardship and Management Alternatives at Los Alamos National Laboratory*

Alternative	Electrical		Fuel		
	Energy (MWh/yr)	Peak Load (MWe)	Liquid (L/yr)	Gas (m^3/yr)	Coal (t/yr)

Potential Mitigation Measures. No mitigation measures are anticipated.

4.6.3.3 *Air Quality*

No Action. No Action air quality utilizes estimated air emissions data from operations at LANL in 2005, assuming continuation of current site missions, to calculate pollutant concentrations at or beyond the LANL site boundary. Included in the criteria and toxic/hazardous emissions from LANL are those emissions estimated for operation of the DARHT Facility currently under construction. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in appendix table B.3.6–1. Table 4.6.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards.

Management Alternatives

Pit Fabrication. Operation of the Pit Fabrication Facility would generate criteria and toxic/hazardous pollutants resulting from the combustion of fossil fuels for space heating and manufacturing processes. The emissions consist of particulate matter, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and

VOCs. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the Pit Fabrication Facility are presented in appendix table B.3.6–1. Table 4.6.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the Pit Fabrication Facility. Concentrations of pollutants resulting from operation of this facility added to No Action concentrations are expected to remain within Federal and state regulations.

Secondary and Case Fabrication. The Secondary and Case Fabrication Facility would generate criteria and toxic/hazardous emissions resulting from operation of the plant boiler, component manufacturing, and chemical processes. Reasonably available control technology would be used to minimize pollutant emissions. This would include using HEPA filters to contain particulate emissions and providing liquid scrubbing prior to HEPA filtration to remove chemical vapors such as nitric acid. Emission rates for criteria and toxic/hazardous pollutants for the secondary and case fabrication mission are presented in appendix table B.3.6–1. Table 4.6.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the secondary and case fabrication mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to remain within Federal and state regulations and guidelines. Modeled estimates for the 24-hour concentration of nitrogen dioxide, however, are above the applicable standard.

High Explosives Fabrication. Gaseous emissions of criteria and toxic/hazardous air pollutants would be generated from HE fabrication. These emissions would result from open burn/open detonation of nonradioactive scrap HE and HE-contaminated waste, plant boiler operation, cleaning operations using solvents, and formulation and synthesis operations. Emission rates for criteria and toxic/hazardous pollutants for HE fabrication are presented in appendix table B.3.6–1. Table 4.6.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from HE fabrication. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

Nonnuclear Fabrication. Aerial emissions of combustion by-products from the slight increase in process steam usage would result in an increase of 159 kg (350 lb) of VOCs. This emission rate is based upon the increase of natural gas combustion needed to generate an additional 1 million British thermal units of energy. Pollutant emissions of combustion by-products for steam and gas heating systems for normal building operations are not considered, as the facilities are existing and no increases in emissions would occur as a result of the proposed activity. Table 4.6.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and nonnuclear fabrication. Concentrations of pollutants resulting from operation of nonnuclear fabrication added to No Action concentrations are expected to remain within Federal and state regulations.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the program alternative would result in higher and lower concentrations of criteria and toxic/hazardous pollutants for the high and low case, respectively. The concentrations of pollutants for the high case pit fabrication, HE, and nonnuclear fabrication missions are expected to be within applicable Federal and state regulations and guidelines. The 24-hour concentration of nitrogen dioxide for the high case secondary and case fabrication mission is above applicable standards and guidelines.

Stewardship Alternatives

Proposed National Ignition Facility. Operation of the proposed NIF would generate criteria and toxic/hazardous pollutants resulting from the combustion of boiler fuel for heating, operation of diesel generators, and solvent cleaning processes. The emissions consist of particulate matter, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and VOCs. Boiler fuel is assumed to be natural gas. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the proposed NIF are presented in appendix table B.3.6–1. Table 4.6.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the proposed NIF. Concentrations of pollutants resulting from operation of the proposed NIF added to No Action concentrations are expected to remain within Federal and state regulations.

Proposed Atlas Facility. Operation of the Atlas Facility would not typically generate criteria pollutants; however, for purposes of this analysis it is anticipated that small amounts of lead or other similar heavy metals might be released as a volatilized metal from the target chamber following certain occasional experiments. Toxic/hazardous emissions would be generated by the Atlas Facility following each experiment due to the evaporation of solvents used to clean the inside of the target chamber. The quantity of air emissions resulting from each experiment are small and therefore require no facility air filtration or scrubbers. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the proposed Atlas Facility are presented in appendix table B.3.6–1. Table 4.6.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the proposed Atlas Facility. Concentrations of pollutants resulting from operation of the proposed Atlas Facility added to No Action concentrations are expected to remain within Federal and state regulations.

Combined Program Impacts. The combined Program impacts to air quality, assuming that each of the proposed stewardship and management alternatives are located at LANL, are presented in table 4.6.3.3–1. The table presents total program concentrations of criteria and toxic/hazardous pollutants derived by adding the contribution from each alternative. The contribution to air pollutants was determined for each alternative independently from each of the other alternatives. Therefore, adding the respective contributions presents a conservative estimate of the combined impacts to air quality since the maximum pollutant concentration for each alternative would not occur at the same time or location at or beyond the site boundary.

Using this conservative estimate of the combined impacts to air quality at LANL, the data indicate that the 24-hour concentration of nitrogen dioxide may result in a concentration above the applicable State of New Mexico ambient air quality standard. All other criteria and/or toxic/hazardous air pollutants are expected to be within applicable standards.

Potential Mitigation Measures. The use of reasonably available control technology may contribute to the reduction of concentrations of nitrogen dioxide.

4.6.3.4 *Water Resources*

Environmental impacts associated with the construction and operation of the potential stockpile stewardship and management facilities at LANL could affect surface and groundwater resources. All water required for construction or operation would be supplied from groundwater. The proposed sites for the new or modified facilities would be outside the 100- and 500-year floodplains. A description of the activities that would continue at LANL is provided in section 3.2.6. Table 4.6.3.4–1 presents existing surface water and groundwater resources and the potential changes to water resources at LANL resulting from the proposed alternatives. The total site water resources requirements for each alternative including No Action are displayed in this table. Combined program impacts if all alternatives were implemented at LANL are also listed.

Surface Water

No Action. Since there would be no construction under No Action, no additional construction water would be required or discharged. Current wastewater discharge would remain at 693 MLY in the No Action year 2005.

Management Alternatives

Pit Fabrication. Existing facilities would be modified at TA-55 to accept the pit fabrication mission. Modification activities would take place in TAs atop mesas and would not be affected by a 500-year flood. No surface water would be withdrawn for stockpile stewardship and management activities. Impacts to surface water resources associated with runoff and wastewater discharged during the modification phase would be negligible.

During operation, sanitary and other liquid wastes would be treated at the Los Alamos Sanitary Treatment Facility. Treated wastewater would then be discharged to the canyons. The additional sanitary wastewater generated by the processes would be approximately 12.3 MLY (3.2 MGY). This repre-

TABLE 4.6.3.4–1.—*Potential Changes to Water Resources from Stockpile Stewardship and Management Alternatives at Los Alamos National Laboratory* [Page 2 of 2]

Affected Resource Indicator	No Action Single-Shift Operation 2005	Pit Fabrication Three-Shift Operation	Secondary and Case Fabrication Three-Shift Operation	High Explosives Fabrication Three-Shift Operation	Nonnuclear Fabrication Three-Shift Operation	National Ignition Facility	Atlas Facility	Combined Program Impacts
Floodplain								
Actions in 100-year floodplain	NA	None	None	None	None	None	None	None
Actions in 500-year floodplain	NA	None	None	None	None	None	None	None

[a] Total water requirements for construction at LANL are based on a 4-year period for Atlas Facility, a 2-year period for nonnuclear fabrication and HE fabrication, a 4-year period for secondary and case fabrication, and a 5-year period for the proposed NIF.

[b] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharged would be the same as No Action operation.

[c] NPDES permit is required for stormwater discharges.

Note: NA - not applicable; MLY - million liters per year.

Source: LANL 1995b:1; LANL 1995c; LANL 1995d; LANL 1995e; LANL 1995g; LANL 1996e:1; appendix I; appendix K.

sents an increase of approximately 1.8 percent over the projected sanitary wastewater generation rate of 693 MLY (183 MGY).

Secondary and Case Fabrication. During operation, nonhazardous sanitary liquid wastes would be disposed of by a sanitary collection system. Sanitary process and support liquids are sent by drain to the sanitary wastewater treatment plant (TA-46) and treated similarly to municipal sewage. The additional sanitary wastewater generated by the processes would be approximately 20.4 MLY (5.4 MGY). This represents an increase of approximately 2.9 percent over the projected sanitary wastewater generation rate of 693 MLY (183 MGY). No additional impacts to surface water are anticipated.

While brief downpours can cause local flash flooding, especially in canyons, streams, and other low spots, most of the LANL TAs, including TA-55, are located atop the finger mesas near drainage ditches and are not subject to flooding.

High Explosives Fabrication. During modification activities, no additional sanitary liquid waste or other liquid wastes would be generated. During operation, sanitary liquid and other liquid wastes would be treated at the Los Alamos Sanitary Treatment Facility before being discharged to the canyons. The HE fabrication processes would generate approximately 12.8 MLY (3.38 MGY) of additional sanitary wastewater. This represents an increase of approximately 1.8 percent over the projected sanitary wastewater generation rate of 693 MLY (183 MGY). Treated effluent would be monitored to comply with NPDES-permitted and other applicable discharge requirements. No adverse impacts to surface water or surface water quality are expected.

All proposed HE facilities and buildings at the Los Alamos HE Facility are located above the critical flood elevation of the potential flood source (i.e., river, dam, levee, and precipitation).

Nonnuclear Fabrication. An additional 0.005 MLY (0.001 MGY) of wastewater would be discharged during construction. Sanitary and other liquid wastes would be treated at the Los Alamos Sanitary Treatment Facility and then discharged to the canyons. The processes associated with nonnuclear fabrication would generate approximately 0.57 MLY (0.151 MGY) of additional sanitary wastewater. This represents approximately a 0.08-percent increase in the annual projected sanitary wastewater generation rate of 693 MLY (183 MGY). Treated effluent would be monitored to comply with NPDES permits and with applicable discharge requirements. No adverse impacts to surface water or surface water quality are expected.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed NIF is expected to generate an additional 17.8 MLY (4.7 MGY) of sanitary wastewater. This amount would represent a 2.6-percent increase in the annual projected sanitary wastewater generation rate of 693 MLY (183 MGY). Consolidation of LANL's sewer system was completed in 1994 to bring all treatment systems into compliance with Federal and state regulations. Capacity of the consolidated sewer system would be sufficient to meet project requirements.

Because the canyons south and north of the NIF location are more than 20 m (65.6 ft) deep, the 100-year floodplain is contained within the canyons. Because of the depth of the canyons, impacts from a 500-year flood event are unlikely.

Proposed Atlas Facility. Existing buildings at TA-35 would be renovated for the proposed Atlas Facility. During modification activities and operations, a minimal amount of wastewater would be generated. Current wastewater capacities would be able to meet the additional requirements for the Atlas Facility. Additional information regarding the Atlas Facility at LANL is presented in appendix K. No additional wastewater would be discharged to surface water during construction, modification, or operation activities.

Groundwater

No Action. Water supply at LANL is provided by three DOE-owned well fields. Springs in the area produce approximately 1 percent of the water supply. Approximately 5,760 MLY (1,522 MGY) of water is produced.

Since there would be no construction or modifications under No Action, no additional groundwater for construction would be required. Baseline conditions and operations, described in section 4.6.2.4, would continue, and groundwater withdrawal would remain at 5,760 MLY (1,522 MGY) in 2005. No additional impacts to groundwater quality are anticipated since there are no direct discharges to groundwater.

Management Alternatives

Pit Fabrication. Water requirements for both the building modification activities and operation phase would be supplied from local groundwater sources. Minimal water would be needed during the building modification activities.

During operation, an additional 30.2 MLY (7.98 MGY) of water would be required to support pit fabrication activities, which is a 0.52-percent increase over the No Action groundwater withdrawal of 5,760 MLY (1,522 MGY). The projected water requirements for modification activities and operation would not constitute significant increases in the total amount of groundwater currently withdrawn by LANL and would not affect water supply in the area. The additional amount would still be below the LANL maximum allotment of 6,800 MLY (1,796 MGY).

Secondary and Case Fabrication. Approximately 1 MLY (0.26 MGY) of groundwater would be required for construction and modification activities.

Operation of the secondary and case fabrication facilities would require approximately 55 MLY (14.5 MGY), which is less than a 1-percent increase over the projected groundwater withdrawal of 5,760 MLY (1,522 MGY). The projected water requirements during operation would not constitute significant increases in the total amount of groundwater currently withdrawn by LANL and would not affect water supply in the area. The additional amount would still be below the LANL maximum allotment of 6,800 MLY (1,796 MGY).

High Explosives Fabrication. No additional groundwater would be needed for HE fabrication building modification activities. During modification, no wastewater would be discharged to groundwater. Adverse impacts to groundwater are not expected.

Operation of the HE fabrication facilities would require approximately 13 MLY (3.4 MGY), which is an increase of less than 1 percent over the projected groundwater withdrawal of 5,760 MLY (1,522 MGY). The projected water requirements during operation would not constitute significant increases in the total amount of groundwater currently withdrawn by LANL and would not affect water supply in the area. The additional amount of water would still be below the LANL maximum allotment of 6,800 MLY (1,796 MGY).

Nonnuclear Fabrication. Approximately 0.004 MLY of additional groundwater would be needed for building modification activities for nonnuclear fabrication. Operation of the nonnuclear fabrication facilities would require approximately 48.3 MLY (12.76 MGY), which is a 0.8-percent increase in the projected groundwater use of 5,760 MLY (1,522 MGY). The projected water requirements during operation would not constitute significant increases in the total amount of groundwater currently withdrawn by LANL, and would not affect water supply in the area.

Groundwater Quality. No process wastes from the proposed management alternatives would be discharged directly to the groundwater, and all treated wastewater discharges to the canyons would be monitored to comply with NPDES permit and other applicable discharge requirements. Given normal safeguards and precautions, no adverse impacts to groundwater quality are expected.

Sensitivity Analysis. The effluent discharges to surface waters resulting from the high stockpile case are expected to be similar or slightly greater than the volumes generated by the surge three-shift operation alternatives. The low case scenario would discharge a slightly larger volume of treated effluent compared to the No Action volume. Additional impacts to surface water quality would be negligible. Groundwater quality is not expected to be impacted by the low or high case production scenario at LANL.

Stewardship Alternatives

Proposed National Ignition Facility. During the proposed NIF's 5-year construction period, approximately 3 MLY (0.8 MGY) of water would be required. This amount is a 0.05-percent increase in the (2005) projected groundwater withdrawal of 5,760 MLY (1,522 MGY). Operation of the proposed NIF would require approximately 152 MLY (40.2 MGY), of which 17.8 MLY (4.7 MGY) would be for domestic use. This amount is a 2.6-percent increase in the projected groundwater withdrawal of 5,760 MLY (1,522 MGY). The projected water requirements during operation would not constitute significant increases in the total amount of groundwater projected to be withdrawn by LANL and would not affect water supply in the area. This additional amount would still be below the LANL maximum allotment of 6,800 MLY (1,800 MGY).

Proposed Atlas Facility. Existing buildings at TA-35 would require renovation for the proposed Atlas Facility. During modification activities and operation, a minimal amount of water would be required. Current water capacities would be able to meet the additional requirements for the proposed Atlas Facility. Additional information regarding the Atlas Facility at LANL is presented in appendix K.

Groundwater Quality. No process wastes from the proposed stewardship alternative would be discharged directly to the groundwater, and all treated wastewater discharges to the canyons would be monitored to comply with NPDES permit and other applicable discharge requirements. Given normal safeguards and precautions, no adverse impacts to groundwater quality are expected.

Combined Program Impacts. The combined Program impacts to water resources if each proposed alternative were implemented at LANL are shown in table 4.6.3.4–1. A negligible amount of water would be required for modification activities. Approximately 6,059 MLY (1,600 MGY) of groundwater would be required to operate the facilities; this represents a 5.2-percent increase in projected groundwater use and 89 percent of the current groundwater allotment at LANL. Wastewater discharges during construction and operation of the facilities would total approximately 0.6 MLY (0.2 MGY) and 64 MLY (17 MGY), respectively. All wastewater would be discharged to surface waters and would be monitored to comply with NPDES permit and other applicable discharge requirements. Given normal safeguards and precautions, no adverse impacts to surface water or groundwater quality are expected.

Potential Mitigation Measures. Because appropriate erosion and runoff management measures would be implemented during construction to comply with NPDES stormwater management regulations, no mitigation measures should be necessary. Stormwater measures include erosion control measures such as silt fences, dikes, and sediment traps to divert runoff away from disturbed areas and stabilization practices that cover soils with materials such as riprap or mulch in order to prevent direct exposure of soils to runoff.

4.6.3.5 *Geology and Soils*

The proposed alternatives for LANL would have no adverse impact on the geological resources described in section 4.6.2.5. Although a moderate seismic risk exists at LANL, this would be considered during design, construction, and operation of any new functions. The existing seismic risk does not preclude safe implementation and operation of the new functions. The LANL stockpile management alternatives and the proposed Atlas Facility would use existing structures within their current footprints. There would be a nominal amount of area required for equipment staging, material laydown, and parking. Existing facility space or developed areas would be used for these activities. Modification activities, with the exception of the erection of seismic reinforcement, would be within the existing building structures. There is sufficient parking for construction workers in lots adjacent to work areas.

The proposed NIF would require additional acreage, but would not adversely affect geological resources. Control measures would be used to minimize any soil erosion. Potential changes to geology and soils associated with the proposed alternatives at LANL are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at LANL. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Pit Fabrication. All new functions would be accommodated within existing structures; therefore, modification and operation activities would not affect geological conditions. Soil disturbance is not expected. The properties and conditions of the soils underlying the proposed site place no limitations on modification activities and operation. Soils would not adversely affect the safe operation of project facilities.

During implementation and operation of the new functions, seismic activity in the area could pose a potential hazard to the facilities and personnel at LANL. Modifications of site facilities to accommodate new pit fabrication functions would take into account the moderate seismic risk in the LANL area. All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides. Secondary effects from seismic activities, such as soil liquefaction or landslides, are not expected because of the depth of groundwater and relatively stable topography on top of the mesas. Hazards resulting from the return of volcanism during implementation or operation are unlikely (see section 4.6.2.5). Potential health impacts from accidents associated with geological hazards are discussed in section 4.6.3.9.

Secondary and Case Fabrication. Impacts to geology and soils from secondary and case fabrication at LANL would be similar to those described above for pit fabrication.

High Explosives Fabrication. Impacts to geology and soils from HE fabrication at LANL would be similar to those described above for pit fabrication.

Nonnuclear Fabrication. Impacts to geology and soils from nonnuclear fabrication at LANL would be similar to those described above for pit fabrication.

Sensitivity Analysis. The high or low case operation scenario for the proposed stockpile management alternatives at LANL would not affect geology or soils.

Stewardship Alternatives

Proposed National Ignition Facility. The construction and operation of the proposed NIF at LANL would not adversely affect geological resources. NIF would require the clearing of an estimated 4 ha (10 acres) of land for buildings, walkways, building access, and buffer space. Soil impacts during construction would be short term and minor with appropriate erosion and sediment control measures. Net soil disturbance during operation would be less than for construction because areas temporarily used for equipment and material laydown would be restored. Seismic risks would be taken into account during construction and operation of the proposed NIF (see appendix I).

Proposed Atlas Facility. The design, installation, and operation of the Atlas Facility in existing buildings at LANL would have no impact on geological resources. Seismic risks would be taken into account during design, implementation, and operation of the Atlas Facility (see appendix K).

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives at LANL are anticipated.

4.6.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species at LANL. Although most alternatives would not impact these resources, the proposed NIF would result in a loss of terrestrial habitat and possible impacts to threatened and endangered species.

No Action. Under No Action, the limited replacement pit fabrication, selected nonnuclear fabrication, and stewardship R&D missions described in section 3.2.6 would continue at LANL. There would be no changes to current biotic resource conditions at the site as described in section 4.6.2.6.

Management Alternatives

Pit Fabrication. The pit fabrication and intrusive and nonintrusive modification pit reuse mission at LANL would utilize existing facilities within the boundaries of a number of the site's TAs. No new construction would be required and wastewater would be released through existing NPDES-permitted discharges. The operation of pit manufacturing facilities at LANL is not expected to impact biotic resources.

Secondary and Case Fabrication. The secondary and case fabrication mission, would take place in existing structures located within a number of the site's TAs. No new construction would be required and wastewater would be released through existing NPDES permitted discharges. The operation of the secondary and case fabrication mission facilities at LANL is not expected to impact biotic resources.

High Explosives Fabrication. The HE fabrication mission would take place in existing structures located within a number of the site's TAs. No new construction would be required and wastewater would be released through existing NPDES-permitted discharges. The operation of HE fabrication mission facilities at LANL is not expected to impact biotic resources.

Nonnuclear Fabrication. Nonnuclear fabrication mission elements that would be moved to LANL would be located in existing buildings within a number of the site's TAs. No new construction would be required and wastewater would be released through existing NPDES-permitted discharges. The relocation of the nonnuclear fabrication mission to LANL is not expected to impact biotic resources.

Sensitivity Analysis. Implementation of either a low or high case workload for the stockpile management alternatives would not affect biological resources at LANL.

Stewardship Alternatives

Proposed National Ignition Facility

Terrestrial Resources. The proposed NIF would be located within TA-58, an undeveloped area containing ponderosa pine. Construction of new facilities would result in the disturbance of approximately 4 ha (10 acres) of habitat. This would cause a fragmentation of the wooded habitat present on the site. Proper erosion and sediment control measures would reduce the potential for disturbance of habitat adjacent to the construction area. During construction, animal species within the disturbed area would be either destroyed or displaced depending upon whether they were able to move from the area.

During construction and operation, fencing around the proposed NIF could cause a localized constraint on the movement of the resident elk herd in the area of the site. Wildlife may also be disturbed by the increased level of human activity associated with the project.

Wetlands. Construction and operation of the proposed NIF is not expected to affect wetlands since this resource is not located on or near the proposed site.

Aquatic Resources. Construction and operation of the proposed NIF is not expected to affect aquatic resources since this resource is not located on or near the proposed site.

Threatened and Endangered Species. The construction of the proposed NIF at LANL would disturb a small amount of habitat suitable for several special status species which potentially exist onsite. If present, less mobile species such as the New Mexican meadow jumping mouse *(Zapus hudsonius luteus)* and plant species could be lost during construction. Construction could also disturb potential foraging or nesting habitat for the Mexican spotted owl (*Strix occidentalis lucida*), gray vireo *(Vireo vicinior)*, southwestern willow flycatcher *(Empidonox traillii extimus)*, and spotted bat *(Euderma maculata)*. Some species such as the spotted owl may be further disturbed by the increased level of human activity (i.e., noise and lighting) associated with the project. Informal consultation under the *Endangered Species Act* may be necessary regarding the Mexican spotted owl.

Proposed Atlas Facility. The proposed Atlas Facility would be located at TA-35, located near the center of Pajarito Mesa, which is immediately north and east of Pajarito Canyon. The facility would be placed in existing TA-35 buildings, with the exception of a limited number of associated structures (e.g., storage tanks and a concrete pad), which would be constructed adjacent to existing buildings. No natural habitat would be disturbed and runoff volumes would not change appreciably from present levels; thus, impacts to biotic resources from construction and operation of the proposed Atlas Facility would not be expected.

Potential Mitigation Measures. Limiting the area to be disturbed, revegetating with native species, and implementing a soil erosion and sediment control plan would help to lessen short- and long-term impacts to terrestrial species and habitats. Disturbance to wildlife living in areas adjacent to new facilities may be minimized by preventing workers from entering undisturbed areas. It may be necessary to survey the site for the nests of migratory birds prior to construction and to avoid clearing operations during the breeding season. If any threatened or endangered species exist on the site, specific mitigation measures would be developed in conjunction with the USFWS.

4.6.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly through ground disturbance, building modification, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. Cultural resources surveys have been conducted in portions of the involved TAs. Some NRHP-eligible prehistoric and historic resources may be affected by the proposed actions. Site-specific surveys and evaluations would be conducted in conjunction with the *National Historic Preservation Act* and tiered NEPA documents. No impacts to Native American resources are anticipated. Geological strata at LANL are not known to be fossiliferous.

No Action. Under No Action, DOE would continue existing and planned missions at LANL as described in section 3.2.6. Any impacts to cultural or paleontological resources would be independent of and unaffected by the proposed action.

Management Alternatives

Pit Fabrication. Pit fabrication and intrusive modification pit reuse would necessitate reconfiguring and upgrading existing facilities within TAs -3, -8, -35, -50, -54, and -55. A nominal area would be required for equipment staging, material laydown, and parking during the modification of the facilities. All of TA-35 has been surveyed, and no cultural resources were identified. Portions of TAs -3, -8, -50, -54, and -55 have been surveyed and contain NRHP-eligible prehistoric and/or historic resources. Additional prehistoric and historic resources may exist on unsurveyed portions of the involved TAs. NRHP-eligible resources would be identified through project-specific inventories and evaluations, and any project-related effects would be addressed in tiered NEPA documentation. Impacts to Native American resources are not expected as a result of the alternative but would be identified through consultation with the potentially affected tribes. None of the geological formations at LANL are known to be fossiliferous.

Secondary and Case Fabrication. Replacing secondary and case fabrication would use existing facilities within the boundaries of TAs -3, -8, -50, -54, and -55. Some of these buildings would need modifications. A nominal area within existing buildings and developed areas would be required for equipment staging, material laydown, and parking during the facilities modification. Portions of each of the involved TAs have been surveyed and contain NRHP-eligible prehistoric and/or historic resources. Some additional NRHP-eligible sites may exist in unsurveyed portions of the involved TAs. Some prehistoric and historic resources may be affected by the proposed action. NRHP-eligible resources would be identified through project-specific surveys, inventories, and evaluations, and any project-related effects would be addressed in tiered NEPA documentation. Impacts to Native American resources are not expected but would be identified through consultation with potentially affected tribes. None of the geological formations at LANL are known to be fossiliferous.

High Explosives Fabrication. HE fabrication would take place in TAs -9, -16, -28, and -37. Only minimal new equipment is needed; no facility construction or modification is necessary to conduct the HE fabrication mission at LANL. No impacts to cultural or paleontological resources are anticipated. Sharing this mission with LLNL would have no impact on cultural and paleontological resources at LANL.

Nonnuclear Fabrication. Nonnuclear fabrication would use existing facilities within TAs -3, -16, -22, and -35. Additional equipment and building modifications would be necessary. These modifications largely involve electrical upgrades, and no ground disturbance is expected. Impacts to prehistoric, Native American, or paleontological resources are not anticipated. Some of the facilities to be modified under this alternative have been declared eligible for inclusion in the NRHP. Any project-related effects to historic resources would be addressed in tiered NEPA and *National Historic Preservation Act* documentation.

Sensitivity Analysis. The high and low case scenarios for the proposed stockpile management alternatives at LANL would have the same impacts to cultural and paleontological resources as the base case production facilities.

Stewardship Alternatives

Proposed National Ignition Facility. Surveys indicate that no prehistoric or historic archaeological sites or structures exist on the proposed NIF location in TA-58. Paleontological remains are unlikely to exist in the proposed location because the Pajarito Plateau, comprised of Pleistocene volcanic tuffs and the Bandelier Formation, does not contain fossiliferous deposits. No Native American resources have been identified to date in the proposed location but some may be identified through consultation with the potentially affected tribes.

Proposed Atlas Facility. Existing buildings in TA-35 would be renovated to implement the proposed Atlas Facility. Some additional land would be required for the placement of concrete pads, storage tanks, and transportable office and diagnostic space. All of TA-35 has been surveyed for cultural resources and none were identified. All of the involved buildings were constructed in either 1980 or 1990 (appendix K) and are not NRHP eligible. No impacts to Native American or paleontological resources are expected.

Potential Mitigation Measures. If NRHP-eligible sites cannot be avoided though project design or siting, and the facility would cause adverse impacts, then a Memorandum of Agreement would need to be negotiated among DOE, the New Mexico SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the New Mexico SHPO and the Advisory Council on Historic Preservation in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific NRHP-eligible sites would be identified during tiered NEPA documentation.

If Native American resources could not be avoided through project design or siting, then acceptable mitigation measures to reduce project impacts on them would be determined in consultation with the affected Native American groups. In accordance with the *Native American Graves Protection and Repatriation Act* and the *American Indian Religious Freedom Act*, such mitigations may include, but would not be limited to, appropriately relocating human remains, planting vegetation screens to reduce visual or noise intrusion, increasing access to traditional use areas during operation, or transplanting or harvesting important Native American plant resources.

4.6.3.8 *Socioeconomics*

No Action. Under No Action, the existing missions at LANL as described in section 3.2.6 would continue with no new employment or in-migration of workers. Projections for regional economy and employment rates, population and housing changes, and public finance characteristics are presented in appendix D.

By 2002, the DAHRT Facility would be operational at LANL. A total of 80 jobs would be generated as a result of operation of this facility. This increase in workers has been considered in the No Action analysis for LANL.

Regional Economy and Employment. Total employment in the regional economic area is projected to grow slightly less than 2 percent annually between 1995 and 2000, reaching approximately 122,700 in the latter year. Long-range projections show employment growth averaging slightly more than 1 percent annually between 1995 and 2000 and then slowing to less than 1 percent between 2021 and 2030, reaching approximately 164,400 persons. Site employment at LANL is expected to total 6,546 in 2005. The unemployment rate in the regional economic area was 6.2 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $18,314 in 1995 to $26,801 in 2030.

Population and Housing. Annual ROI county and city population and housing growth is projected to be less than 2 percent over the period 1995 to 2005 and then is expected to slow to about 1 percent in the period 2006 to 2030. Annual increases between 2006 and 2030 are expected to be a little more than 1 percent. Population in the ROI is projected to increase from 167,400 in 1995 to 245,100 by 2030. The total number of housing units in the ROI is projected to increase from 70,100 in 1995 to 102,700 in 2030.

Public Finance. Between 2000 and 2005, all ROI county, city, and school district total revenues are projected to increase at an annual average of less than 1.6 percent. Total expenditures are projected to increase at an annual average of less than 1.5 percent during the same period. These rates of increase should continue until 2030.

Management Alternatives

Pit Fabrication

Regional Economy and Employment. Modification-related activities for the Pit Fabrication Facility would require 138 direct workers during the peak construction year and would generate approximately an additional 90 indirect jobs in the regional economic area. As a result of the modification activities, total employment for the LANL regional economic area would increase by much less than 1 percent. This increase would reduce the unemployment rate from 6.2 percent under the No Action alternative to approximately 6 percent. Per capita income for the LANL regional economic area would increase very slightly over No Action projections.

Operation employment at LANL would begin phasing in as the modification phase nears completion. Operation of the facility in the base case surge mode would generate 260 new direct jobs, but would generate no indirect jobs because there are no closely related industries in the regional economic area. As a result of the operation of the facility, total employment for the LANL regional economic area would increase by much less than 1 percent. This increase would reduce regional unemployment from the 6.2 percent No Action estimate to approximately 6.0 percent. Per capita income for the LANL regional economic area would increase by much less than 1 percent over No Action projections. Changes in employment and per capita income resulting from the operation of the Pit Fabrication Facility are shown in figure 4.6.3.8–1.

Population and Housing. Population in the LANL ROI during peak construction would not increase over No Action projections. Available workers in the regional economic area and ROI would be sufficient to fill all of the direct and indirect jobs generated by the modification activities for the facility.

There would not be enough available workers to fill all of the direct operation jobs. Approximately 20 workers would in-migrate to fill positions at the Pit Fabrication Facility. The ROI population over No Action for full operation at LANL is shown in figure 4.6.3.8–2. Vacant housing in the ROI is sufficient to house the in-migrating workers and their families.

Public Finance. Modification of the Pit Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be attributed to income increases and would be negligible.

Changes in revenues and expenditures compared to No Action projections due to operation of the facility at LANL are shown in figure 4.6.3.8–3. In 2005 the percent increase in total ROI revenues and expenditures over No Action projections would be negligible with the exception of the Los Alamos school district which would be expected to experience increases of approximately 1 percent.

Secondary and Case Fabrication

Regional Economy and Employment. Modification-related activities for the Secondary and Case Fabrication Facility would generate a total of 55 direct jobs during the peak construction year and would generate an additional 36 indirect jobs in the regional economic area. As a result of the modification activities, total employment for the LANL regional economic area would increase by less than 1 percent. This increase would reduce regional unemployment from the 6.2 percent No Action estimate to approximately 6.1 percent. Per capita income for the LANL regional economic area would increase very slightly over No Action projections as a result of modification activities for the Secondary and Case Fabrication Facility.

Facility operation-related employment at LANL would begin phasing in as the modification phase nears completion. Operation of the facility in the base

case surge mode would require 321 new direct workers but would generate few additional indirect jobs in the regional economic area because there are no closely related industries in the regional economic area. As a result of the operation of the facility, total employment for the LANL regional economic area would increase by less than 1 percent. This increase would reduce regional unemployment from the 6.2 percent No Action estimates to approximately 6.0 percent. Per capita income for the LANL regional economic area would increase by less than 1 percent over No Action projections. Changes in employment and per capita income resulting from the operation of the Secondary and Case Fabrication Facility are shown in figure 4.6.3.8–1.

Population and Housing. Population in the LANL ROI during construction or operation of the Secondary and Case Fabrication Facility would not increase over No Action projections. Available workers in the regional economic area and ROI would be sufficient to fill all of the jobs generated by construction and operation of the facility.

Public Finance. Construction and operation of the Secondary and Case Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

High Explosives Fabrication

Regional Economy and Employment. Modification-related activities for the facility would require 46 direct workers during the peak construction year and would generate an additional 30 indirect jobs in the regional economic area. As a result of the modification activities, total employment for the LANL regional economic area would increase by less than 1 percent. Unemployment would decrease from the 6.2 percent No Action estimates to approximately 6.1 percent. Per capita income for the LANL regional economic area would increase very slightly over No Action projections as a result of modification activities for the HE Facility.

Facility operation-related employment at LANL would begin phasing in as the modification phase nears completion. Operation of the facility in the base case surge mode would require 67 new direct workers but would generate only a few indirect jobs because there are no closely related industries in the regional economic area. As a result of the operation of the HE Facility, total employment for the LANL regional economic area would increase by much less than 1 percent. The No Action regional unemployment of 6.2 percent would decrease to 6.1 percent. Per capita income for the LANL regional economic area would increase slightly over No Action projections. Changes in employment and per capita income resulting from the operation of the HE Facility are shown in figure 4.6.3.8–1.

Population and Housing. Population in the LANL ROI during peak construction would not increase over No Action projections. Available workers in the regional economic area and ROI would be sufficient to fill all of the direct and indirect jobs generated by construction of the HE Facility.

There would not be enough available workers in the regional economic area and ROI to fill all of the jobs generated by operation of the facility. Approximately 10 additional workers would have to in-migrate into the ROI to fill the new direct jobs. Population in the LANL ROI during full operation would increase by approximately 30 people over No Action projections. The ROI population over No Action for full operation at LANL is shown in figure 4.6.3.8–2. No additional housing units would be needed to meet such a small population increase.

Public Finance. Modification of the HE Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Changes in revenues and expenditures compared to No Action projections due to operation of the HE Facility at LANL are shown in figure 4.6.3.8–4. In 2005, the percent increase in total ROI revenues and expenditures over No Action projections would be negligible.

Nonnuclear Fabrication

Regional Economy and Employment. Modification-related activities for the facility would require a total of six workers during the peak construction year and would generate an additional four indirect jobs in

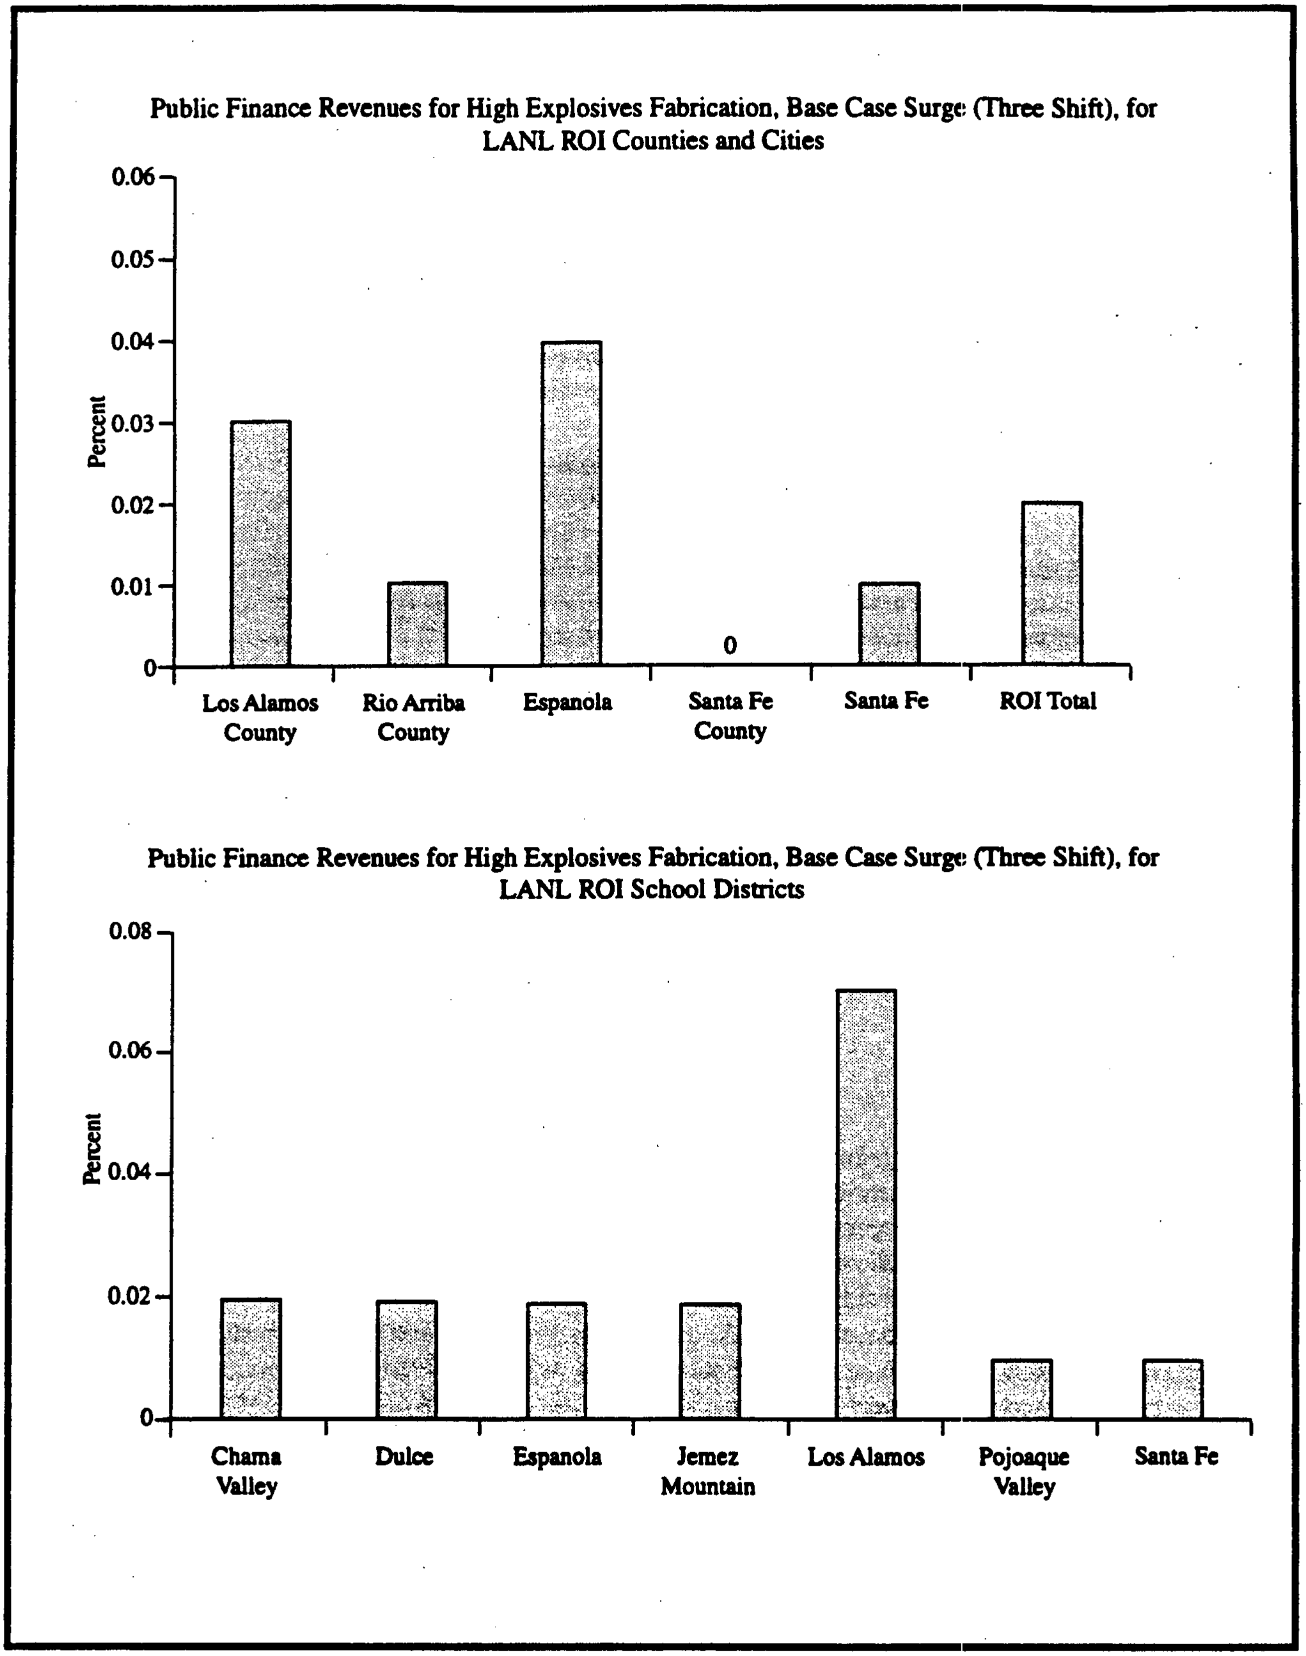

FIGURE 4.6.3.8–4.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Los Alamos National Laboratory Region of Influence with High Explosives Fabrication, Base Case Surge, 2005* [Page 1 of 2].

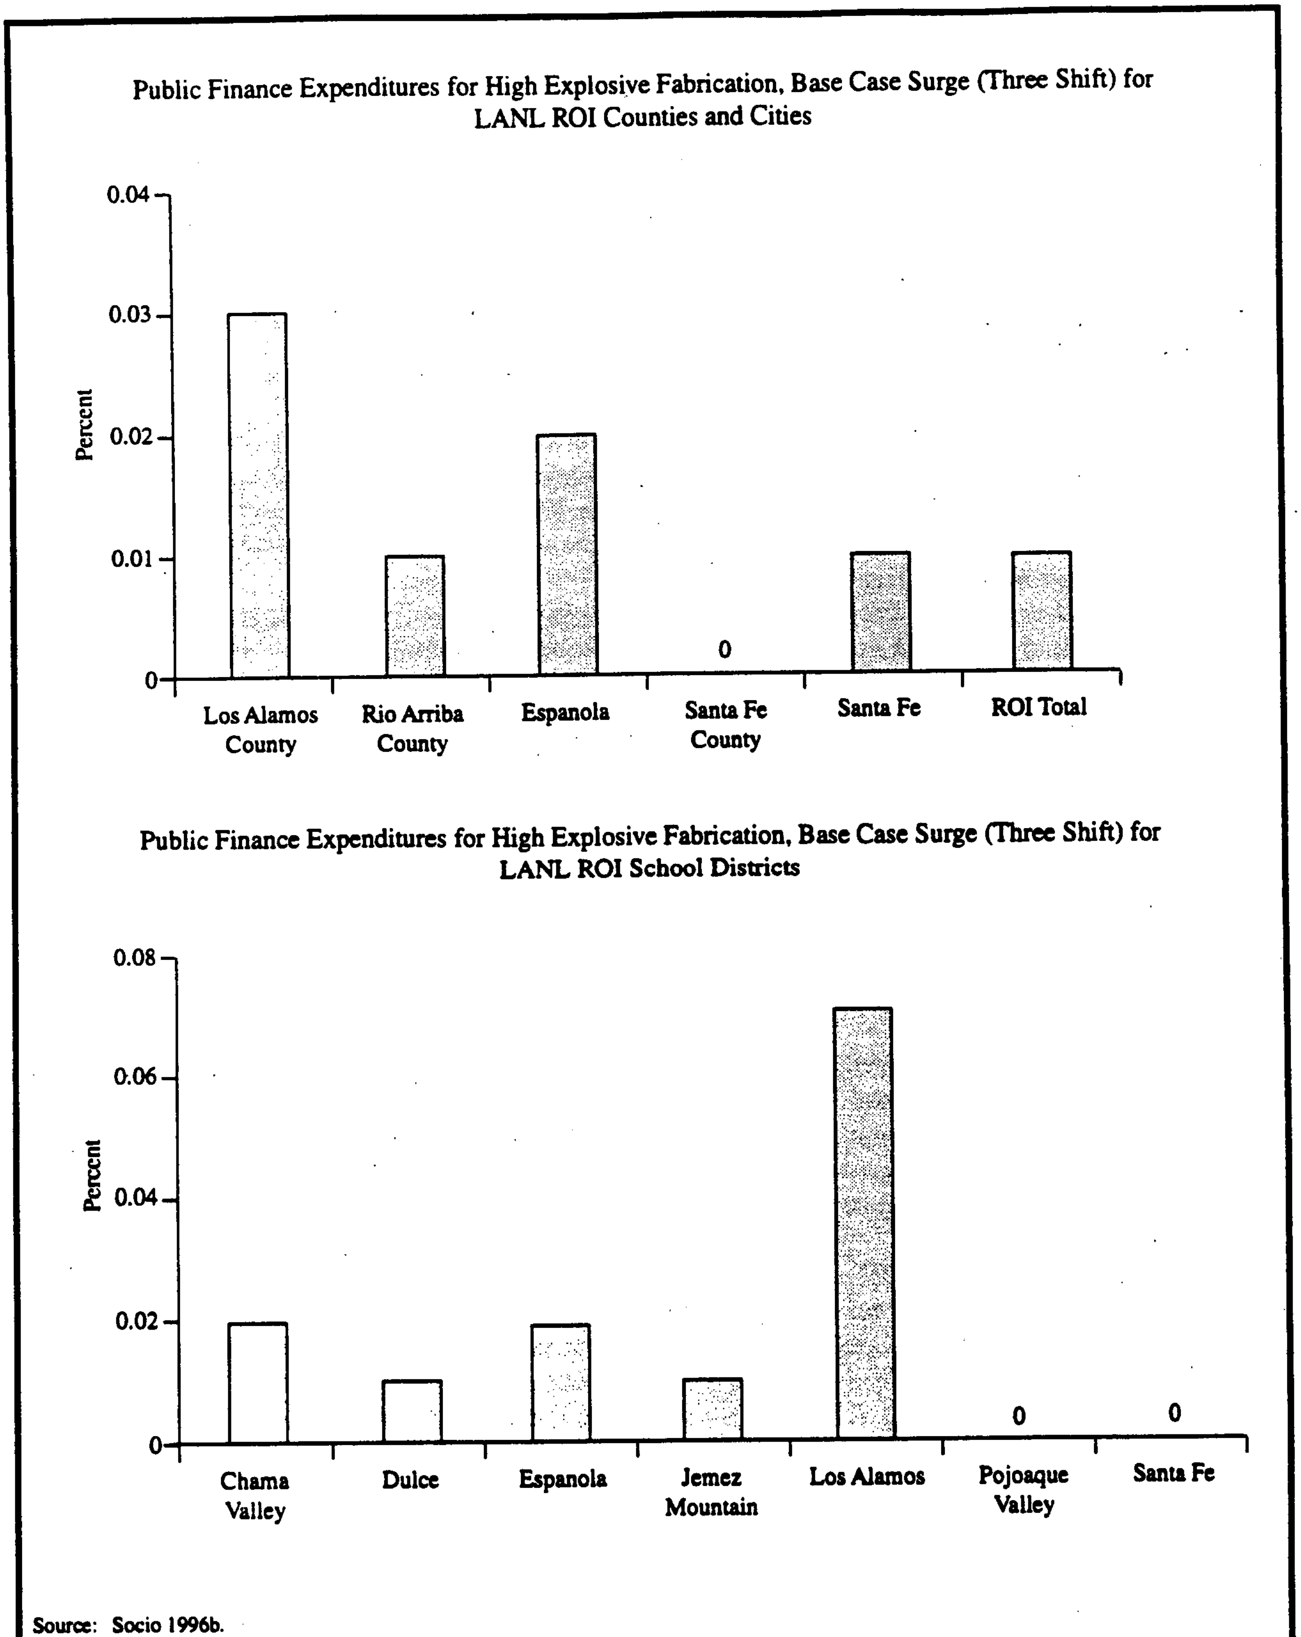

FIGURE 4.6.3.8–4.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Los Alamos National Laboratory Region of Influence with High Explosives Fabrication, Base Case Surge, 2005* [Page 2 of 2].

the regional economic area. As a result of the modification activities, total employment and per capita income would not noticeably increase. The unemployment rate would remain unchanged.

Facility operation-related employment at LANL would begin phasing in as the modification phase nears completion. Operation of the facility in the base case surge mode would require 194 new direct workers and would generate approximately 46 indirect jobs in the regional economic area. As a result of the operation of the facility, total employment for the LANL regional economic area would increase by less than 1 percent. Unemployment would decrease from 6.2 percent under the No Action alternative to 6.0 percent. Per capita income for the LANL regional economic area would increase by less than 1 percent over No Action projections. Changes in employment and per capita income resulting from the operation of the Nonnuclear Fabrication Facility are shown in figure 4.6.3.8–1.

Population and Housing. Population in the LANL ROI during peak construction and full operation would not increase over No Action projections. There would be enough workers available in the regional economic area and ROI to fill all of the direct and indirect jobs generated by the modification and operation of the Nonnuclear Fabrication Facility.

Public Finance. Construction and operation of the Nonnuclear Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Partial Nonnuclear Fabrication. LANL may not receive the entire nonnuclear mission. Reservoirs and/or plastics may be excluded from the mission. If this occurs, the full operation employment increment would range from 57 to 232 direct jobs. For these options, in-migration would not be required. Socioeconomic effects on regional economy, employment, population, and housing would be less than for the full nonnuclear mission. These changes would be minimal.

Sensitivity Analysis. There would be no change in the number of construction workers required to complete any of the facilities for LANL (pit manufacturing, secondary and case fabrication, HE or nonnuclear fabrication) for either the high or low case. Operation of any of the facilities for the high case level would require fewer workers than would the base case surge operation. For the low case, worker requirements would decrease further causing slightly smaller increases in regional economy, population and housing, and public finance than occurred in either the base case surge or high case levels. These changes would be negligible.

Stewardship Alternatives

Proposed National Ignition Facility. The following is a summary of the socioeconomic effects of construction of the proposed NIF at LANL. See appendix I for a more detailed, project-specific discussion.

Regional Economy and Employment. Construction of NIF would require 270 construction workers during the peak year of construction and would generate approximately 860 additional indirect jobs in the regional economic area. Employment for operation would begin phasing in as the construction phase nears completion. Operation of the facility would require 330 direct workers and would generate 270 additional indirect jobs in the regional economic area. Construction and operation of NIF would have only minimal affects on the regional economy and employment.

Population and Housing. Both construction and operation of the facility would require workers and their families to in-migrate to the ROI. This in-migration would cause a slight increase in the population of the ROI. Vacant housing in the ROI is sufficient to handle these increases.

Public Finance. Both revenues and expenditures would increase as a result of the construction and operation of NIF. Increases due to construction would peak in 1998 and then decline as construction nears completion in 2002. Increases due to operation of the facility would peak in 2003 and continue through the duration of NIF operations.

Proposed Atlas Facility. The Atlas Facility at LANL would not have any identified socioeconomic impact over No Action.

Combined Program Impacts. If the pit fabrication, secondary and case fabrication, HE, and nonnuclear fabrication missions and the NIF were all located at LANL, the resulting benefits to the regional economy would be greater than from any one mission. Increases in total employment would be about 1 percent while per capita income would increase less than 1 percent. There would be sufficient available labor in the projected labor force to fill any construction-related employment requirements, but not enough to fill operation-related employment requirements. Approximately 1,349 people (workers and their families) would in-migrate into the LANL ROI to fill the available operation jobs. Although there would be a small population increase in the ROI, vacant housing would not be sufficient to house all in-migrating workers during full operation. Approximately 250 houses would need to be constructed over the No Action estimates. However, based on past building rates, new construction would be able to meet this demand. As shown in figure 4.6.3.8–5, the increase in ROI total revenues and expenditures over No Action projections would be approximately 0.7 and 0.6 percent, respectively. The Los Alamos School District would experience the greatest revenue and expenditure increases at approximately 3.1 percent.

Potential Mitigation Measures. No mitigation measures are anticipated for the stockpile stewardship and management alternatives at LANL.

4.6.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the radiological and hazardous chemical releases and their associated impacts which could result from No Action and proposed alternatives at LANL. Within this section, impacts resulting from the base case scenario are quantitatively discussed, and a sensitivity analysis of the high and low case scenarios is qualitatively discussed.

Summaries of the prevailing radiological impacts at LANL to the public and to workers associated with normal operation are presented in tables 4.6.3.9–1 and 4.6.3.9–2, respectively; accident radiological impacts are presented in figure 4.6.3.9–1 and tables 4.6.3.9–3 through 4.6.3.9–7. The impact assessment methodology is described in section 4.1.9, and further supplementary methodological information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the construction or modification of any facilities to support the Stockpile Stewardship and Management Program. However, limited hazardous chemical releases (e.g., small spills of diesel fuel from equipment refueling) may occur due to construction activities for the base case scenario and may increase slightly for the high case scenario. The concentration of these releases is expected to be well within the regulated exposure limits and would not result in any adverse health effects.

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge. Furthermore, discharges of wastewater through NPDES-permitted outfalls which can be attributed to the activities associated with normal operations and operations of the stockpile stewardship and management alternatives at LANL are expected to be below NPDES limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at LANL, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). It is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all alternative chemicals proposed to be added (the increment) at the site to yield cumulative levels for the site. An HI of ≤1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is $\leq 1 \times 10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of 1×10^{-6} is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the population. Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

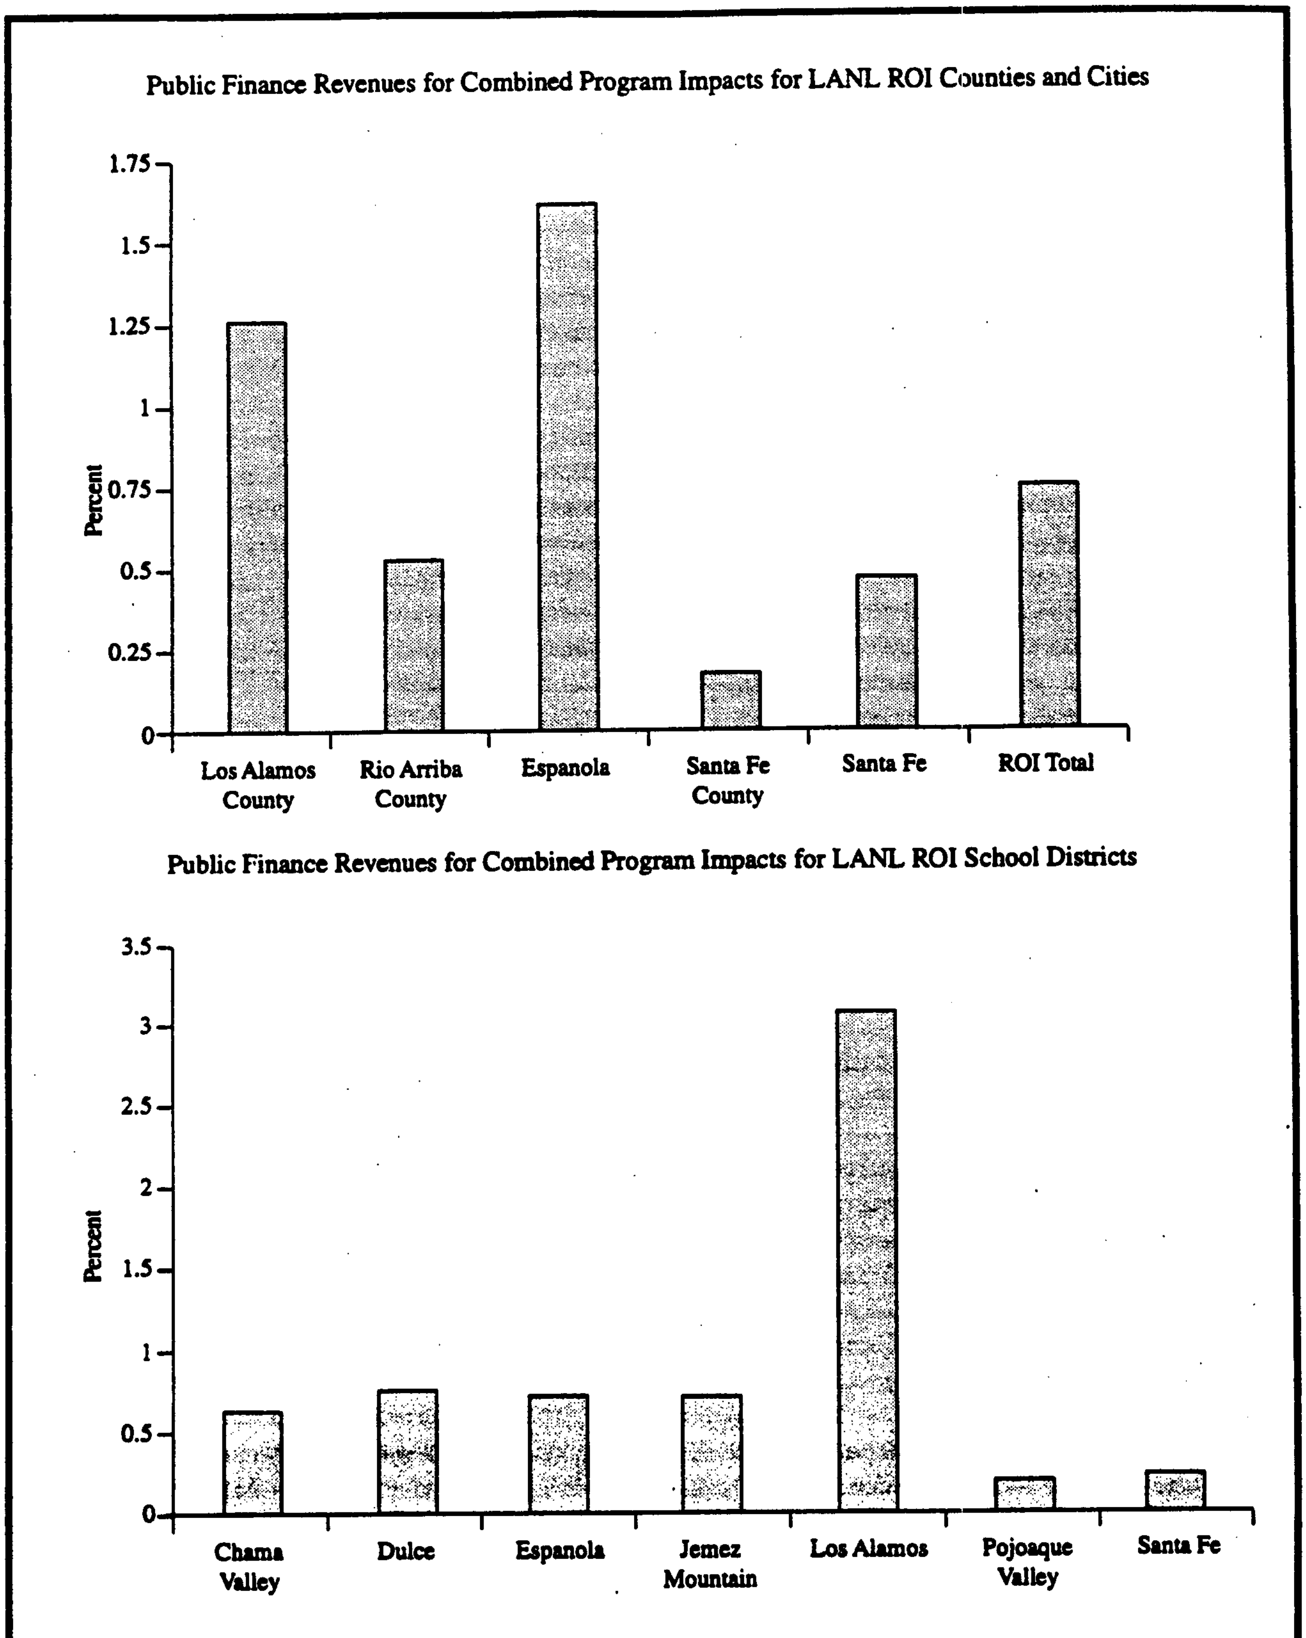

FIGURE 4.6.3.8–5.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Los Alamos National Laboratory Region of Influence with Combined Program Impacts, 2005* [Page 1 of 2].

FIGURE 4.6.3.8–5.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Los Alamos National Laboratory Region of Influence with Combined Program Impacts, 2005* [Page 2 of 2].

No Action

Radiological Impacts. Radiological impacts to the public resulting from the No Action alternative are presented in table 4.6.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational contributions (including pit fabrication R&D). Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from the No Action alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.6.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 6.5 mrem for the No Action alternative. The annual population dose within 80 km (50 mi) in 2030 would be 2.7 person-rem.

Total site doses to onsite workers from normal operation for the No Action alternative are presented in table 4.6.3.9–2. The estimated annual dose to the entire facility workforce for this alternative would be 196 person-rem. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information.

Potential radiological impacts to the public and workers in tables 4.6.3.9–1 and 4.6.3.9–2 include the addition of the phased containment option (preferred alternative) representing the DARHT Facility and the phaseout of the PHERMEX Facility at LANL. Based on the radiological impacts associated with normal operation under the No Action alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from normal operation under No Action at LANL are presented below. Analyses to support the values presented in this section are provided in appendix table E.3.4–13. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging the sites as having a hazardous health concern of alternatives among sites. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among sites. The baseline is then used to determine the extent to which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed individual of the public at LANL resulting from normal operation under the No Action alternative would be 3.01×10^{-2}, and the cancer risk would be 5.15×10^{-6}. The HI for the onsite worker would be 4.65×10^{-2} and the cancer risk would be 1.54×10^{-4}. The HIs for the public and onsite worker are within acceptable health levels.

Cancer risks to the public and to the onsite worker exceed the EPA default value as a result of the emissions of methylene chloride; 1,1,2-trichloroethane; and trichloroethylene associated with operations under the No Action alternative at LANL.

Mitigation measures such as substituting less toxic solvents or modifying processes are proposed to reduce or eliminate the emissions of all hazardous chemicals due to operations under the No Action alternative with particular attention to methylene chloride; 1,1,2-trichloroethane; and trichloroethylene.

Management Alternatives

Pit Fabrication

Radiological Impacts. Radiological impacts to the public resulting from the pit fabrication alternative are presented in table 4.6.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational LANL contributions and from three-shift base case operations for pit fabrication at the site. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.6.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 6.5 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 2.7 person-rem. The impacts incurred from three-shift base case operations are negligible when compared to those existing for the normal baseline site operations (see table 4.6.3.9–1).

[a] Assumes operations are located at TA-3.

[b] Conservative assumption poses existence of maximally exposed individual at multiple locations simultaneously.

[c] Includes impacts from No Action.

[d] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem/yr from the air pathways, 4 mrem/yr from the drinking water pathway, 100 mrem/yr from all pathways combined (DOE Order 5400.5).

[e] Natural background radiation levels to average individual is 342 mrem/yr; to the population within 80 km (50 mi) in 2030 is 95,200 person-rem.

Note: Impacts from the Phased Containment Option (preferred alternative) representing the DARHT Facility are included within the No Action values presented in the table. However, PHERMEX Facility operations at LANL will be phased out and are therefore not included. Annual incremental doses of $1.7x10^{-5}$ mrem to the maximally exposed individual and $8.6x10^{-5}$ person-rem to the population are incurred from the pit fabrication alternative.

Noninvolved Workforce[d]						
Average worker dose[c] (mrem/yr)	34	34	34	34	34	NA
25-year fatal cancer risk	3.4×10^{-4}	3.4×10^{-4}	3.4×10^{-4}	3.4×10^{-4}	3.4×10^{-4}	NA
Total dose (person-rem/yr)	196	196	196	196	196	196
Total Site Workforce[e]						
Dose (person-rem/yr)	196	252	196	204	196	260
25-year fatal cancers	2.0	2.5	2.0	2.0	2.0	2.6

[a] Assumes operations are located at TA-3.

[b] The involved worker is a worker associated with operation of the pit fabrication, secondary and case fabrication, NIF, and other facilities. The dose presented for the involved workforce is only that incremental dose received from the pit fabrication, secondary and case fabrication, NIF, and Atlas Facility. The total dose received by the involved workforce would be higher than that received by the noninvolved workforce from these operations. The estimated number of involved workers is 267 at the proposed NIF, 146 for pit fabrication, and 151 for secondary and case fabrication.

[c] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835).

[d] The noninvolved worker is an onsite worker not associated with operation of the proposed stockpile stewardship and management facilities. The maximum estimated number of noninvolved workers is 5,770 for each of the stockpile stewardship and management alternatives.

[e] The total site workforce is the sum of the number of involved and noninvolved worker impacts. The estimated numbers of badged workers in the total site workforce for each of the radiologically concerned alternatives are 5,916 for pit fabrication, 5,921 for secondary and case fabrication, 6,037 for the proposed NIF, and 5,770 for No Action.

Note: Impacts to workers presented in this table include the addition of the Phased Containment Option (preferred alternative) representing the DARHT Facility and the phasing out of the PHERMEX Facility at LANL; NA - not applicable.

Source: DOE 1993n:7; DOE 1995hh; LANL 1995b:6; LANL 1995e; LANL 1995g; appendix I; appendix K.

Total site doses to onsite workers from normal operation for the pit fabrication mission are presented in table 4.6.3.9–2. The average annual dose to involved workers for this alternative would be 380 mrem. The dose to the entire facility workforce (involved workforce) would be 55.6 person-rem. As stated in the methodology section 4.1.9, all worker doses were referenced either from alternative-specific working group data reports or from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation of the pit fabrication alternative at LANL are presented below. The pit fabrication alternative includes intrusive and nonintrusive modification pit reuse. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–14.

The incremental HI for the maximally exposed member of the public would be 2.10×10^{-4}, and the incremental cancer risk would be zero as a result of operation of the pit fabrication mission in the year 2005. The incremental HI for the onsite worker would be 1.75×10^{-4}, and the incremental cancer risk would be zero as a result of operation of the pit fabrication mission in 2005.

The total site operation and the increment associated with the pit fabrication alternative would result in HIs for the public (0.030) and onsite worker (0.047) that are within acceptable health levels. The cancer risks to the public (5.15×10^{-6}) and to the onsite worker (1.54×10^{-4}) slightly exceed the EPA default value of 1×10^{-6}.

Cancer risks to the public and to the onsite worker exceed the EPA default value as a result of the No Action emissions of chloroform; methylene chloride; 1,1,2-trichloroethane; and trichloroethylene. Incremental emissions due to the pit fabrication mission cause only a minimal increase in the HI for the public and onsite worker and, therefore, this alternative is not expected to increase the cancer risk for the public and the onsite worker.

Secondary and Case Fabrication

Radiological Impacts. Radiological impacts for the public resulting from the secondary and case fabrication alternative are presented in table 4.6.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational LANL contributions and from three-shift base case operation for secondary and case fabrication at the site. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses for the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.6.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 6.7 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 3.2 person-rem. The impacts incurred from three-shift base case operations are small when compared to those existing for the normal baseline site operations (see No Action column in table 4.6.3.9–1).

Total site doses to onsite workers from normal operation for the secondary and case fabrication mission are presented in table 4.6.3.9–2. The average annual dose to involved workers for this alternative would be 2.2 mrem. The dose to the entire facility workforce (involved workforce) would be 0.33 person-rem. As stated in the methodology section 4.1.9, all worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from the normal operation of the secondary and case fabrication alternative at LANL are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–15.

The incremental HI for the maximally exposed member of the public would be 9.43×10^{-4} and the incremental cancer risk would be zero as a result of operation of the secondary and case fabrication mission in 2005. The incremental HI for the onsite worker would be 7.89×10^{-4} and the incremental cancer risk would be zero as a result of operation of the secondary and case fabrication mission in 2005.

Total site operations of the secondary and case fabrication mission would result in HIs (HI is applicable only to noncarcinogenic risks) for the public (0.031) and the onsite worker (0.047) that are within acceptable health levels. The cancer risks for the public (5.15×10^{-6}) and the onsite worker (1.54×10^{-4}) slightly exceed the EPA default value of 1×10^{-6} using extremely conservative stack assumptions (i.e., a stack flow of 0.1 ft/sec). Using the same emissions values and average LANL stack flow, the cancer risk values drop by 2 to 3 orders of magnitude (i.e., 100 to 1,000 times lower).

Cancer risks for the public and for the onsite worker exceed the EPA default value as a result of the No Action emissions of methylene chloride; 1,1,2-trichloroethane; and trichloroethylene. When average LANL stack flows are used, the cancer risk for the public and the onsite worker do not exceed the default value for any alternative. Incremental emissions due to the secondary and case fabrication mission cause only a minimal increase in HI (noncarcinogenic risks) for the public and onsite worker and no additional cancer risk for the public and the onsite worker.

High Explosives Fabrication

Radiological Impacts. There are no radiological impacts associated with this alternative.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation of the HE fabrication alternative at LANL are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–16.

The incremental HI for the maximally exposed individual of the public would be 3.99×10^{-3} and the incremental cancer risk would be zero as a result of operation of the HE fabrication mission in 2005. The incremental HI for the onsite worker would be 3.33×10^{-3} and the incremental cancer risk would be zero as a result of operation of the HE fabrication mission in 2005.

Total site operations of the HE fabrication mission would result in HIs for the public (0.034) and the onsite worker (0.05) that are within acceptable health levels. The cancer risks for the public (5.15×10^{-6}) and the onsite worker (1.54×10^{-4}) slightly exceed the EPA default value of 1×10^{-6}. Incremental emissions due to the HE fabrication mission cause only a minimal increase in HI for the public and onsite worker and no additional cancer risk for the public and the onsite worker.

Cancer risks for the public and for the onsite worker exceed the EPA default value as a result of the No Action emissions of chloroform, methylene chloride; 1,1,2-trichloroethane; and trichloroethylene.

Sharing of the HE Fabrication alternative mission with LLNL would be expected to reduce emissions of hazardous chemicals by up to 50 percent. Therefore, HI and cancer risk impacts may be reduced up to 50 percent as a result of HE fabrication mission sharing with LLNL. This would bring the cancer risk to an acceptable level of 1×10^{-6}.

Nonnuclear Fabrication

Radiological Impacts. There are no radiological impacts associated with this alternative.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation of the nonnuclear fabrication alternative at LANL are presented below. The nonnuclear fabrication alternative includes detonators and the option of adding reservoirs, plastics, or both to this mission. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–17.

The incremental HI to the maximally exposed member of the public would be 2.61×10^{-5} and the incremental cancer risk would be zero as a result of operation of the nonnuclear fabrication mission in 2005. The incremental HI for the onsite worker would be 3.15×10^{-6}, and the incremental cancer risk would be zero as a result of operation of the nonnuclear fabrication mission in 2005.

Total site operations and the incremental effect of the nonnuclear fabrication mission would result in HIs for the public (0.03) and the onsite worker (0.047) that are within acceptable health levels. The cancer risks for the public (5.15×10^{-6}) and the onsite worker (1.54×10^{-4}) slightly exceed the EPA default value of 1×10^{-6}.

Cancer risks for the public and for the onsite worker exceed the EPA default value due to the No Action emissions of chloroform methylene chloride; 1,1,2-trichloroethane; and trichloroethylene. Incremental emissions due to the nonnuclear fabrication mission cause only a minimal increase in HI for the public and onsite worker and no additional cancer risk for the public and the onsite worker.

The emissions of hazardous chemicals may not increase, and may slightly decrease if the options of not including reservoirs, plastics, or both in the nonnuclear fabrication alternative is implemented. Therefore, it is not expected that there would be any increase in HI or cancer risk for the public or for the onsite worker by not including reservoirs, plastics, or both in the nonnuclear fabrication alternative at LANL.

Sensitivity Analysis. Radiological impacts may be subject to certain degrees of variance resulting from either high or low case operations. For the high case scenario, impacts to both the public and worker would be similar to the three-shift base case operations. For the low-case scenario, impacts to the total workforce would be expected to fall within the increment (range) projected between that of No Action and the pit fabrication alternative (less than 55.6 person-rem/year increase to the total site workforce). Impacts for the public would be expected to fall within the increment (range) projected between that of No Action and the secondary and case fabrication alternative (less than 0.2 mrem/year to the maximally exposed individual, and less than 0.5 person-rem/year for the population).

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects for the public and to workers would be small.

Operations under the low case scenario for pit, secondary and case, HE, and nonnuclear fabrication are not expected to increase the emissions of hazardous chemicals at LANL. Since the HIs are well within the acceptable health limits, there are no adverse HI impacts for the public and the onsite worker expected. The low case scenario probably would not contribute to the expected adverse effects of cancer risk for the public and onsite worker.

Operations under the high case scenario for pit and secondary and case fabrication may increase the emissions of hazardous chemicals at LANL. Since the HIs are well within the acceptable health limits, there are no expected adverse HI impacts for the public and the onsite worker. The high case scenario probably would also not increase cancer risk for the public and onsite worker above the EPA default value.

Operations under the high case scenario for HE fabrication may result in up to a two-fold increase in the emissions of hazardous chemicals at LANL. Since the HIs are well within the acceptable health limits, no adverse HI impacts for the public and the onsite worker are expected. The high case scenario probably would not increase the cancer risk for the public and onsite worker above the EPA default value.

Operations under the high case scenario for nonnuclear fabrication may result in up to a three-fold increase in the emissions of hazardous chemicals at LANL. Since the HIs are well within the acceptable health limits, no adverse HI impacts for the public and the onsite worker are expected. The high case scenario may, however, contribute to the adverse effects of cancer risk for the public and onsite worker unless mitigation steps are implemented.

Stewardship Alternatives

Proposed National Ignition Facility

Radiological Impacts. Radiological impacts for the public resulting from normal operation of the proposed NIF for the enhanced option scenario are presented in table 4.6.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational LANL contributions and from enhanced option operations of the proposed NIF at the site. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses for the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.6.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 6.5 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 2.8 person-rem. The impacts incurred from proposed NIF operations are small when compared to those existing for the normal baseline site operations (see No Action column in table 4.6.3.9–1).

Total site doses to onsite workers from normal operation for the proposed NIF are presented in table 4.6.3.9–2. The average annual dose to involved workers for this alternative would be 30 mrem. The dose to the entire facility workforce (involved workforce) would be 8.0 person-rem. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects for the public and to workers would be small.

Hazardous Chemical Impacts. No hazardous chemical impacts are expected from operation of the NIF (see appendix I). Therefore, HIs and cancer risks for the public and onsite workers were not calculated nor assessed.

Proposed Atlas Facility

Radiological Impacts. There are no radiological impacts associated with this alternative. Total site doses and impacts characteristic of this alternative are equal to the No Action alternative.

Hazardous Chemical Impacts. Minimal hazardous chemical impacts are expected from operation of the Atlas Facility (see appendix K). Therefore, HIs and cancer risks for the public and onsite workers were not calculated nor assessed.

Combined Program Impacts

Radiological Impacts. Radiological impacts to the public and to workers from the simultaneous operation of all LANL site alternatives (both management and stewardship) would result in very small increases over the No Action or the largest individual alternative. All Program totals would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Combined Program impacts due to hazardous chemical emissions from operation of the No Action alternative and the incremental chemical emissions incurred by the management alternatives (pit fabrication, secondary and case fabrication, HE fabrication, and nonnuclear fabrication) would result in a cumulative HI for the public of 0.035 and a cumulative cancer risk of $5.15x10^{-6}$. The cumulative HI for the onsite worker would be 0.051 and the cumulative cancer risk would be $1.54x10^{-4}$.

The cumulative Program HIs (noncarcinogenic effects) for the public and the onsite worker are within acceptable health levels since the HIs do not exceed the value of 1. Concern for potential health effects is heightened when the HI exceeds 1. Cumulative cancer risks for the public and the onsite worker exceed the cancer risk default value of $1x10^{-6}$ under No Action when extremely conservative stack parameters are used. When average LANL stack flows are used, the cancer risk for the public and the onsite workers do not exceed this default value for any alternatives. The incremental chemical emissions due to operations associated with all of the management alternatives did not increase the cancer risks.

Potential Mitigation Measures. Radioactive airborne emissions to the general population and onsite exposures to workers could be reduced by implementing the latest technology for process and design improvements. For example, to reduce public exposure from emissions, improved building and work area control methods could be used to remove radioactivity from the releases to the environment. Similarly, the use of remote, automated and robotic production methods are examples of techniques that are being developed which would reduce worker exposure (see section 3.5).

Measures such as substituting less-toxic solvents or modifying processes are proposed to reduce or eliminate the emissions of all hazardous chemicals due to site operations, with particular attention to methylene chloride; 1,1,2-trichloroethane; and trichloroethylene.

Facility Accidents. The proposed actions have the potential for accidents that may impact the health and safety of workers and the public. The potential for and associated consequences of reasonably foreseeable accidents that have been evaluated are summarized in this section and described in more detail in appendix F. The methodology used in the assessment is described in section 4.1.9. A list of documents reviewed for applicable accident data is provided in appendix table F.1.1–1. The potential impacts from accidents, ranging from high-consequence/low-probability to low-consequence/high-probability events, have been evaluated in terms of potential cancer fatalities that may result for noninvolved workers and the public. The risk of cancer fatalities has also been evaluated to provide an overall measure of accident impacts and is calculated by multiplying the accident annual frequency (or probability) of occurrence by the consequences (number of cancer fatalities). A figure is also provided showing the risk of latent cancer fatalities in the population within 80 km (50 mi) that may result from accidents for the alternatives. Specifically, the curves in each figure show the probability (vertical axis) that the number of cancer fatalities in the offsite population within 80 km (50 mi) (horizontal axis) will be exceeded. The curves reflect the probability of the accident.

In addition to the potential impacts to noninvolved workers and the offsite population, there are potential impacts to involved workers who would be located in the facilities associated with the proposed action. Quantitative statements of these impacts cannot be made until design details are developed further, at which time the number and location of facility workers protective and mitigating features can be estimated to support accident impact analyses. However, depending on the type of accident, facility workers in close proximity to the point of the accident could receive high levels of exposure to radiation, with potentially fatal impacts.

No Action. Under the No Action alternative, limited pit fabrication, nonnuclear fabrication, and stewardship R&D would continue to be performed at LANL with no changes to facilities and operations. Under existing conditions, potential accidents and their consequences have been addressed in facility safety documentation according to requirements in DOE orders.

Management Alternatives. This section provides accident information on the four management alternatives under consideration at LANL: pit fabrication, secondary and case fabrication, HE fabrication, and nonnuclear fabrication.

Pit Fabrication. A set of potential accidents has been postulated for the pit fabrication and intrusive and nonintrusion modification pit reuse alternative for which there may be releases of radioactive materials or other hazardous effects that may impact onsite workers and the offsite population. The accident impacts of greatest interest are those associated with pit fabrication and/or intrusive modification. Any potential accident impacts associated with nonintrusive modification would be bounded by the intrusive modification activity impacts. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of probable cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.6.3.9–1. For example, the probability of a pit fabrication accident causing more than 0.1 cancer fatalities is approximately 10^{-6} per year. The curve reflects the probability of the accidents occurring. The impacts for the composite set of accidents are shown in table 4.6.3.9–3. If an accident were to occur, there would be an estimated 1.2×10^{-4} cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 1,000 m (3,281 ft) from the accident would have an increased likelihood of cancer fatality of 6.4×10^{-7}. A

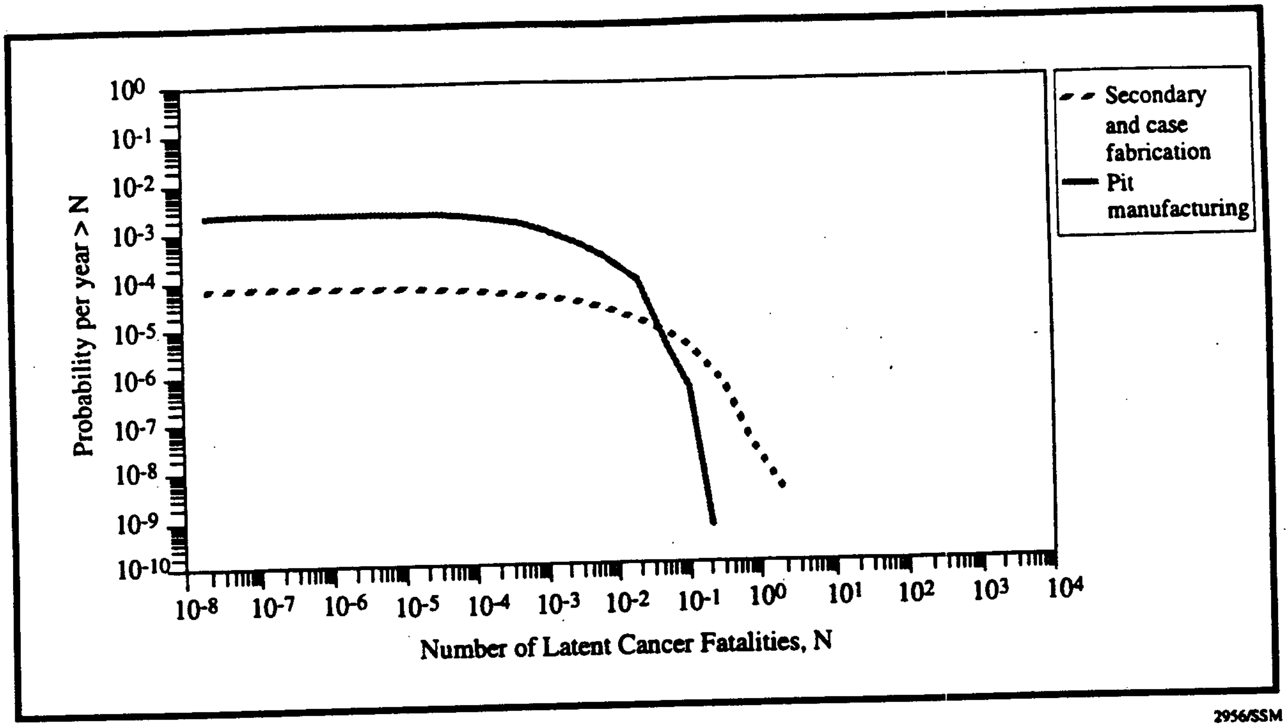

FIGURE 4.6.3.9–1.—*Combined Evaluation Basis Accidents and Beyond Evaluation Basis Accidents—Cancer Fatalities Complementary Cumulative Distribution Functions for Stockpile Management Alternatives at Los Alamos National Laboratory.*

maximally exposed individual located at the site boundary would have an increased likelihood of cancer fatality of 4.3×10^{-7}. The risks for the composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.6.3.9–3. For the same worker, maximally exposed individual, and population, the risks would be 3.3×10^{-8}, 2.2×10^{-8}, and 6.2×10^{-6} cancer fatalities per year, respectively. There is also a potential for chemical accident impacts as shown in table 4.6.3.9–4.

Secondary and Case Fabrication. A set of potential accidents has been postulated for the secondary and case fabrication alternative for which there may be releases of radioactive materials or other hazardous effects that may impact onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of probable cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.6.3.9–1. For example, the probability of a secondary and case fabrication accident causing more than one cancer fatality is approximately 10^{-8} per year. The curve reflects the probability of the accidents occurring. The impacts of the composite set of accidents are shown in table 4.6.3.9–3. If an accident were to occur, there would be an estimated 0.02 cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 862 m (2,828 ft) from the accident would have an increased likelihood of cancer fatality of 6.8×10^{-5}. For a maximally exposed individual located at the site boundary, there would be an increased likelihood of cancer fatality of 8.4×10^{-5}. The risks for the combined EBA and BEBA composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.6.3.9–3. For the same worker, maximally exposed individual and population, the risks would be 4.1×10^{-9}, 5.1×10^{-9}, and 1.2×10^{-6} cancer fatalities per year, respectively. Table 4.6.3.9–3 also shows the impacts for EBAs only and BEBAs only. There is also a potential for chemical accidents and impacts as shown in table 4.6.3.9–5.

High Explosives Fabrication. A set of potential accidents has been postulated for the HE fabrication alternative for which there may be hazardous effects that may impact onsite workers and the offsite popula-

TABLE 4.6.3.9–3.—*Impacts of Accidents for Pit and Secondary and Case Fabrication and Intrusive and Nonintrusive Modification Pit Reuse at Los Alamos National Laboratory*

Parameter	Pit Fabrication and Intrusive Modification Pit Reuse			Secondary and Case Fabrication		
	EBA	BEBA	EBA and BEBA Combined	EBA	BEBA	EBA and BEBA Combined
Composite Accident Frequency (Per Year)	0.0152	$1.0x10^{-6}$	0.0152	$6.0x10^{-5}$	$5.0x10^{-7}$	$6.0x10^{-5}$
Consequences						
Noninvolved Worker						
Cancer fatality[a]	$6.4x10^{-7}$	$3.8x10^{-5}$	$6.4x10^{-7}$	$6.3x10^{-5}$	$6.2x10^{-4}$	$6.8x10^{-5}$
Risk (cancer fatality per year)	$3.3x10^{-8}$	$3.8x10^{-4}$	$3.3x10^{-8}$	$3.8x10^{-9}$	$3.1x10^{-10}$	$4.1x10^{-9}$
Maximally Exposed Individual						
Cancer fatality[a]	$4.3x10^{-7}$	$2.6x10^{-5}$	$4.3x10^{-7}$	$7.9x10^{-5}$	$7.7x10^{-4}$	$8.4x10^{-5}$
Risk (cancer fatality per year)	$2.2x10^{-8}$	$2.6x10^{-11}$	$2.2x10^{-8}$	$4.7x10^{-9}$	$3.9x10^{-10}$	$5.1x10^{-9}$
Population Within 80 Kilometers [b]						
Cancer fatality[c]	$1.2x10^{-4}$	$7.1x10^{-3}$	$1.2x10^{-4}$	0.018	0.18	0.02
Risk (cancer fatalities per year)	$6.2x10^{-6}$	$7.1x10^{-9}$	$6.2x10^{-6}$	$1.1x10^{-6}$	$8.9x10^{-8}$	$1.2x10^{-6}$

[a] Probability (increased likelihood) of cancer fatality to a hypothetical member of the public located at the site boundary or to a noninvolved worker as a result of exposure to the indicated dose if the accident occurred.

[b] For the offsite population of 287,977 for pit fabrication and 281,812 for secondary fabrication, the average probability of cancer fatality/risk of cancer fatality (per year) for the combined EBA and BEBA is $4.2x10^{-10}/2.2x10^{-11}$ and $7.1x10^{-8}/4.3x10^{-12}$ respectively, for the listed alternative(s), pit fabrication, and secondary and case fabrication.

[c] Number of cancer fatalities in the population out to 80 km (50 mi) as a result of exposure to the indicated dose if the accident occurs.

Note: All values are mean values; BEBA - beyond evaluation basis accidents; EBA - evaluation basis accidents.

Source: Results shown are derived from accident analyses in appendix F.

tion. The potential accidents analyzed are described in appendix F. The consequences of the accidents are shown in table 4.6.3.9–6.

In addition to the chemical accident impacts, there are the potential physical effects from a catastrophic explosion of the entire contents of a process related building, which would have a probability of occurrence less than the explosion considered above (i.e., less than 1.0×10^{-6} per year). The quantity of HE detonated could range up to 18 t (19.8 tons); the blast pressure could result in death (at up to 40 m [131 ft]), lung damage (at 80 m [262 ft]), thoracic injury (at 130 m [420 ft]), and eardrum rupture (at 160 m [525 ft]), depending on an individual's distance from the accident. Injuries could also be caused by glass breakage and building debris.

Nonnuclear Fabrication. The impacts of potential accidents associated with nonnuclear fabrication activities at LANL were previously addressed in *Nonnuclear Consolidation Environmental Assessment* (DOE/EA-0792, June 1993) where it was determined that the then current accident profile would not change as a result of the relocation of nonnuclear fabrication functions to LANL. The present proposed action to transfer the nonnuclear fabrication mission to LANL is not expected to change the accident profile that presently exists at the site.

Stewardship Alternatives. Accident information on the two proposed stewardship alternatives under consideration at LANL, the NIF and the Atlas Facility, is provided in this section.

Proposed National Ignition Facility. Studies of potential accidents associated with the proposed NIF have been performed. A bounding accident was postulated based on a preliminary hazard analysis. The bounding accident assumes a severe earthquake of 1 G horizontal ground acceleration occurring during a maximum-credible-yield fusion experiment. Beamlines streaking into the target chamber and building structures other than the target area building would fail during the postulated earthquake. The collapsed beamlines and building structures would provide a pathway for acute atmospheric releases of tritium in the tritium processing system, activated gases in the air, and activated material in the target chamber.

The frequency of this severe earthquake is estimated at 1×10^{-4} per year. The joint frequency of the severe earthquake during the maximum-credible-yield fusion experiment would be less than 2×10^{-8} per year. The radiological impacts of the accident, presented in table 4.6.3.9–7, were estimated using the GENII computer code.

Proposed Atlas Facility. Studies of potential accidents associated with the proposed Atlas Facility have been performed. The results of the studies indicate that the bounding case accident for a site worker involves electrocution from a high energy power source or mechanical collapse of the overhead crane. Both scenarios have an equal likelihood of occurrence. The impact to a site worker in these scenarios could be death. However, the likelihood of occurrence is less than once in 100 years of operation. The most likely accident that could result in an impact to collocated workers involves exposure to emissions and effluents from a capacitor bank fire. In this scenario, a collocated worker would receive minimal exposure to smoke and sprinkler system water containing mineral oil from a Marx module. The impact to a collocated worker in this scenario would be temporary irritation and discomfort; however, the likelihood of occurrence is less than once in 10,000 years of operation. In the event of a fire, all site and collocated workers would be evacuated.

The most likely accident scenario that could result in an impact to the public involves exposure to emissions and effluents from a capacitor bank fire. In this scenario, a member of the public could receive minimal exposure to smoke. The impact to a member of the public in this scenario would be less than that experienced by a collocated worker. Exposure to the smoke could result in very mild and temporary irritation and discomfort. There are no probable accidents which would result in an adverse impact to the public.

4.6.3.10 *Waste Management*

This section summarizes the impacts on waste management at LANL under No Action as well as for each of the proposed alternatives. There is no spent nuclear fuel or HLW associated with pit fabrication, secondary and case fabrication, HE fabrication, nonnuclear fabrication, the proposed Atlas Facility, or the proposed NIF; therefore, there is no further discussion of these wastes for LANL. Table 4.6.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action. Projections for

No Action were derived from 1993 environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated is identifiable. The projection does not include wastes from future, as yet uncharacterized, environmental restoration activities.

Table 4.6.3.10–2 provides the total estimated operational waste volumes projected to be generated at LANL as a result of the various proposed alternatives. The net increase over No Action is provided below in parentheses. The waste volumes generated from the various alternatives and the resultant waste effluent used in the impact analysis can be found in section 3.3 for the stewardship alternatives and section 3.4 for the management alternatives. The waste volumes for the management alternatives are based on surge operations (three shifts). Facilities that would support the Stockpile Stewardship and Management Program at LANL would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act*, RCRA, and other applicable statutes as outlined in appendix section H.1.2.

No Action. Under No Action, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at LANL from the missions outlined in section 3.2.6. The decrease in solid LLW is due to the phase out of the PHERMEX Facility as the new DARHT Facility with contained firing becomes operational. LANL would continue to treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

Liquid TRU waste would continue to be generated by the Plutonium Facility (TA-55). The residual TRU waste sludge that remains after treatment would continue to be loaded into 208-L (55-gal) steel drums, solidified, and transported to Area G for storage. Solid TRU waste would be characterized, certified to meet the criteria for acceptance at WIPP, and placed in storage at Area G while awaiting shipment to WIPP or an alternate facility. Plans are to develop a new facility for characterizing and processing solid TRU waste. This new facility is projected to be operational in 2006.

Liquid LLW would be neutralized and solidified in two onsite treatment facilities. Solid LLW would be compacted, packaged, and stored for disposal either in an onsite, expanded Area G LLW burial site or through other disposal options. Liquid mixed waste would undergo neutralization/pH adjustment, oxidation/reduction, precipitation, chelation/flocculation, and filtration. Both liquid and solid mixed waste would be treated and disposed of according to the LANL Site Treatment Plan, which was developed pursuant to the *Federal Facility Compliance Act* of 1992. The resulting waste would then be stored in a RCRA-permitted facility in DOT-approved containers until it is shipped to an offsite DOE disposal facility. Some of this waste would be placed in interim storage until new technologies for treatment and disposal are identified and evaluated. Liquid sanitary wastes would be treated by a consolidation and collection system and discharged to NPDES-permitted sanitary tile fields. Solid nonhazardous waste would be disposed of in a regional commercial disposal facility.

[g] NIF volumes are from table 3.3.2.2–3 and are based on conceptual designs.
[h] Treated process water.
[i] Recyclable wastes.
Note: Waste generation volumes were rounded to three significant figures. Waste effluent volumes are shown in section 3.3 and 3.4 tables for each alternative.

Management Alternatives

Pit Fabrication. Over the 3-year construction period, it is estimated that approximately 27 t (30 tons) of TRU waste and 54 t (60 tons) of LLW would be generated. These numbers assume that about 20 glove boxes from the 300 Area and 10 glove boxes from the 400 Area would be removed. The glove boxes should meet the definition of LLW; whereas, approximately two-thirds of the associated piping and ventilation ductwork would be considered TRU waste. Assuming a density of 1,500 kg/m^3, this is a volume of 6 m^3/yr (8 yd^3/yr) of TRU waste and 12 m^3/yr (16 yd^3/yr) of LLW. The TRU waste would be packaged to meet the WIPP Waste Acceptance Criteria and stored until it is shipped to WIPP for disposal. This would require two additional truck shipments over the entire construction period. The LLW would be packaged to meet the Area G waste disposal criteria. This would require approximately 0.003 ha (0.007 acres) of LLW disposal area for the entire construction project. Liquid and solid hazardous waste generated during construction would be packaged and shipped offsite to RCRA-permitted treatment and disposal facilities.

Treatment and processing of liquid and solid TRU, and solid mixed TRU wastes to meet the WIPP Waste Acceptance Criteria would result in 60 m^3 (78 yd^3) of TRU waste and 2 m^3 (3 yd^3) of solid mixed TRU waste to be packaged in accordance with DOE and NRC requirements for transport to WIPP for disposal. Seven additional truck shipments per year would be required to transport this waste to WIPP. There is adequate excess capacity at LANL liquid radwaste treatment facilities to handle the 15 m^3 (3,940 gal) of liquid LLW. Following treatment and processing, 393 m^3 (514 yd^3) of solid LLW would require disposal at the Area G LLW disposal site. Assuming a land usage factor of 12,500 m^3/ha (6,630 yd^3/acres), approximately 0.03 ha/yr (0.08 acres/yr) of LLW disposal area at LANL would be required.

The LANL Site Treatment Plan for mixed waste was developed pursuant to the *Federal Facility Compliance Act*. The mixed waste streams identified at LANL have been combined into 30 treatability groups, each with a preferred treatment option. The type of mixed wastes generated by pit fabrication would fit into 1 of the established 30 treatability groups and would not create new treatability groups or new preferred treatment options. Minimal impacts would result from the 2 m^3 (555 gal) of liquid hazardous waste that would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Minimal impacts would result from the 12,300 m^3 (3.25 million gal) of liquid sanitary waste that would be routed to the TA-46 sanitary wastewater treatment facilities. Minimal impacts would result from the 552 m^3 (722 yd^3) of solid nonhazardous waste that would be disposed of in offsite industrial and sanitary landfills.

Secondary and Case Fabrication. The Secondary and Case Fabrication Facility would not generate any TRU waste. The 192 m^3 (50,700 gal) of liquid LLW would have little impact on LANL radwaste treatment facilities as there is adequate capacity to handle the increase. After treatment and volume reduction, 349 m^3 (456 yd^3) of solid LLW would require disposal in the Area G LLW disposal site. Assuming a land usage factor of 12,500 m^3/ha (6,630 yd^3/acres), approximately 0.03 ha/yr (0.07 acres/yr) of LLW disposal area would be required.

The type of mixed wastes generated by secondary and case fabrication would fit into 1 of the established 30 treatability groups and would not require the creation of new treatability groups or new preferred treatment options. The 30 m^3 (7,930 gal) of liquid mixed wastes and 108 m^3 (141 yd^3) of solid mixed wastes generated annually may impact the available storage capacity of the main areas for future mixed waste storage in RCRA-permitted hazardous waste management units. Minimal impacts would result from the 60 m^3 (15,900 gal) of liquid hazardous waste and 216 m^3 (283 yd^3) of solid hazardous waste that would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Minimal impacts would result from the 20,200 m^3 (5.35 million gal) of liquid sanitary waste that would be routed to septic tanks or sanitary wastewater treatment facilities. After volume reduction, minimal impacts would result from the 639 m^3 (836 yd^3) of solid nonhazardous waste that would be disposed of in offsite industrial and sanitary landfills.

High Explosives Fabrication. The HE Fabrication Facility would not generate any TRU waste, or mixed

LLW. Minimal quantities of solid LLW would be generated annually either from handling depleted uranium parts during subassembly operations or from processing of materials returned from the stockpile with slight contamination. The operational life of the Area G LLW disposal site would not be impacted. Minimal impacts would result from the 4 m^3 (925 gal) of liquid hazardous waste and 13 m^3 (16 yd^3) of solid hazardous waste that would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Minimal impacts would result from the 5,900 m^3 (1.56 million gal) of liquid sanitary waste that would be routed to septic tanks or sanitary wastewater treatment facilities. Minimal impacts would result from the 17 m^3 (22 yd^3) of solid nonhazardous waste that would be disposed of in offsite industrial and sanitary landfills.

Nonnuclear Fabrication. The Nonnuclear Fabrication Facility would not generate any TRU, low-level, or mixed low-level wastes. Minimal impacts would result from the 11 m^3 (3,000 gal) of liquid hazardous waste and 0.1 m^3 (0.13 yd^3) of solid hazardous waste that would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Minimal impacts would result from the 568 m^3 (150,000 gal) of liquid sanitary waste that would be discharged to the sanitary wastewater system and the 11 m^3 (15 yd^3) of solid nonhazardous waste that would be disposed of in offsite industrial and sanitary landfills.

Sensitivity Analysis. The waste volumes generated from the pit, secondary and case, HE, and nonnuclear fabrication alternatives required to support a larger stockpile level (high case) operating on a single-shift basis are bounded by the base case under surge operations. There would be no additional waste management impacts associated with the alternatives that would support a high case stockpile operating at a single shift. The volumes generated from the proposed alternatives required to support a low case stockpile would be reduced by a factor of at least 3.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed NIF would not generate any TRU waste. The 0.6 m^3 (159 gal) of liquid LLW could be treated with existing onsite capabilities with no impact. The 3 m^3 (4 yd^3) of solid LLW would have a minimal impact on the operational life of the Area G LLW disposal site. Assuming a land usage factor of 12,500 m^3/ha (6,630 yd^3/acres), 0.0002 ha/yr (0.0006 acres/yr) of LLW disposal area would be required.

The LANL Site Treatment Plan for mixed waste was developed pursuant to the *Federal Facility Compliance Act*. The mixed waste streams identified at LANL have been combined into 30 treatability groups, each with a preferred treatment option. The type of mixed wastes generated by the proposed NIF would fit into 1 of the established 30 treatability groups and would not require the creation of new treatability groups or new preferred treatment options. The 2 m^3 (528 gal) of liquid mixed LLW and the 0.3 m^3 (0.4 yd^3) of solid mixed LLW generated would not impact the available storage capacity of the main areas for future mixed waste storage in RCRA-permitted hazardous waste management units. Minimal impacts would result from the 2 m^3 (608 gal) of liquid hazardous waste and 8 m^3 (10 yd^3) of solid hazardous waste that would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. The 17,900 m^3 (4.72 million gal) of liquid sanitary waste would not be expected to impact the existing sanitary wastewater treatment system. Minor impacts would result from the 6,050 m^3 (7,910 yd^3) of solid nonhazardous waste that would be disposed of in offsite industrial and sanitary landfills.

Proposed Atlas Facility. For purposes of this analysis it is assumed that a small amount (<1 m^3 annually) of liquid or solid hazardous waste would be generated by occasional experiments involving lead or other simulant materials. This waste would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Minimal impacts would result from the generation of 710 m^3 (188,000 gal) of liquid sanitary waste as there is adequate capacity within the existing sanitary wastewater treatment system to handle the increase. Minimal impacts would result from the 9 m^3 (12 yd^3) of solid nonhazardous waste that would be disposed of at the Los Alamos County landfill.

Combined Program Impacts. If all the proposed stockpile stewardship and management alternatives listed in table 4.6.3.10–2 were located at LANL, the impacts from TRU and mixed TRU wastes would be identical to those discussed for the pit fabrication alternative. Following treatment and volume reduction, approximately 745 m^3 (925 yd^3) of solid LLW would require disposal at the Area G LLW disposal site. An estimated 0.06 ha (0.15 acres) of LLW disposal area would be required. The impacts from mixed low-level and hazardous wastes are identical to those discussed for the secondary and case fabrication alternative. The 57,600 m^3 (15.2 million gal) of liquid sanitary wastes would not be expected to impact the sanitary wastewater treatment system since adequate capacity exists to handle this increase. After volume reduction, approximately 7,270 m^3 (9,510 yd^3) of solid sanitary waste would require disposal. This increase could require the construction of a new sanitary landfill sooner than currently planned.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies, thereby further reducing or mitigating impacts. Pollution prevention and waste minimization would be considered in determining the final actions of the Stockpile Stewardship and Management Program at LANL.

4.6.3.11 *Environmental Justice*

As discussed in section 4.14, any impacts to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.6.3.9, which describes public and occupational health impacts from normal operation, shows that potential chemical air emissions and releases are not within the generally acceptable threshold of regulatory concern. This information is based on the conservative programmatic assumptions and modeling detailed in appendix E. However, the cumulative effect of continuous (or intermittent over time) very low exposures could have some impact on human health or the environment. Any adverse human health or environmental impacts that may occur would affect people living within communities located near LANL. The analysis of the demographic data presented in appendix D for the communities surrounding LANL indicates that if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.7 Lawrence Livermore National Laboratory

LLNL was established in 1952 and currently occupies approximately 332 ha (821 acres) next to Livermore, CA (Livermore Site), and 2,800 ha (7,000 acres) at Site 300, approximately 29 km (18 mi) southeast of Livermore in support of missions discussed in section 3.2.7. The locations of the sites are illustrated in figure 4.7–1. Figure 4.7–2 shows the DOE property boundaries for the Livermore Site.

4.7.1 Description of Alternatives

No Action. LLNL would continue to perform the missions described in section 3.2.7.

Stockpile Management Alternatives. The secondary and case fabrication mission, the HE fabrication mission, and a portion of the nonnuclear fabrication mission could be located at LLNL. The HE fabrication mission could also be shared with LANL.

Stockpile Stewardship Alternatives. The Contained Firing Facility (CFF) would be located at Site 300 and the proposed NIF could be located at the Livermore Site.

4.7.2 Affected Environment

The following sections describe the affected environment at the LLNL main site (Livermore Site) and Site 300 for land resources, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure, radiation and hazardous chemical environment, waste management conditions, and current intersite transport issues are described.

4.7.2.1 *Land Resources*

LLNL consists of two sites: the main facility (approximately 332 ha [821 acres]) at Livermore, and Site 300 (approximately 2,800 ha [7,000 acres]) in the Tracy Hills, approximately 29 km (18 mi) east of the Livermore Site. Both sites are owned by the Federal Government and administered, managed, and controlled by DOE.

Livermore Site. Generalized land uses within the Livermore Site and in the immediate vicinity are shown in figure 4.7.2.1–1. The site itself is categorized into a variety of land uses, with the vast majority dedicated to R&D. The R&D designation includes office facilities, light and heavy laboratories, and light industrial facilities in direct support of programmatic endeavors. A significant portion of the site is classified as undeveloped and industrial uses occupy a substantial amount of land. There are no prime farmlands on the Livermore Site.

The Livermore Site is bordered on the east by Greenville Road. Land use on the east is primarily agricultural. The South Bay Aqueduct, a branch of the California Aqueduct, crosses Greenville Road just south of the Livermore Site. Patterson Pass Road borders the Livermore Site on the north. Land to the immediate north of Patterson Road is light industrial and vacant land. The Patterson Reservoir and filtration plant, part of the South Bay Aqueduct system, are located northeast of the site. The Livermore Site is bordered on the west by South Vasco Road. Land use to the west is primarily urban residential, with some vacant land.

The Livermore Site is bordered on the south by East Avenue. Sandia National Laboratories, Livermore, is located immediately adjacent and south of East Avenue. A small light-industrial park is located on the southwest corner of East Avenue and South Vasco Road. The remainder of lands south of the Livermore Site and Sandia National Laboratories, Livermore, are primarily agricultural, comprised of vineyards and rangeland primarily used for grazing. There are also some rural residences in these areas. The closest residences to the boundaries of the Livermore Site are 0.4 km (0.25 mi) to the east, 0.56 km (0.35 mi) to the west, 2.0 km (1.2 mi) to the north, and 0.8 km (0.50 mi) to the south.

Site 300. Generalized land uses within Site 300 and in the immediate vicinity are shown in figure 4.7.2.1–2. The site itself consists of a large percentage of undeveloped territory and land dedicated to both R&D and industrial functions. There are no prime farmlands on Site 300. No significant land use changes are projected for Site 300 at present (LLNL 1995k:16-19).

The majority of the land surrounding Site 300 is agricultural and is primarily used for grazing sheep and

cattle. There are two, privately operated, research and testing facilities located near Site 300. Physics International is located adjacent to the east boundary, and Stanford Research Institute International is approximately 0.97 km (0.60 mi) south of the site. Both of these facilities conduct HE testing similar to that conducted at Site 300 (LL DOE 1992c:4-6). Corral Hollow Road borders Site 300 on the south. Adjacent to the western portion of Site 300, across Corral Hollow Road, is the Carnegie State Vehicular Recreation Area. This area covers approximately 6,483 ha (16,020 acres) and is operated by the California Department of Parks and Recreation, Off-Highway Motor Vehicle Recreation Division, for the exclusive use of off-road vehicles. Several rural residences are located along Corral Hollow Road, west of Site 300 and the Carnegie State Vehicular Recreation Area. The closest residences to the boundaries of Site 300 are 0.48 km (0.3 mi) to the east, 0.16 km (0.1 mi) to the west, 3.5 km (2.2 mi) to the north, and 0.72 km (0.45 mi) to the south. The nearest urban area is the city of Tracy, approximately 13 km (8.1 mi) to the northeast.

4.7.2.2 *Site Infrastructure*

Section 3.2.7 describes the current missions at LLNL. To support these missions an infrastructure exists as shown in table 4.7.2.2–1.

TABLE 4.7.2.2–1.—*Baseline Characteristics for Lawrence Livermore National Laboratory*

Characteristics	Current Value	
Land	**Main Site**	**Site 300**
Area (ha)	332	2,800
Roads (km)	24	40
Railroads (km)	0	0
Electrical		
Energy consumption (MWh/yr)	327,716	15,661
Peak Load (MWe)	57.2	2.6
Fuel		
Natural Gas (m^3/yr)	14,160,000	NA
Liquid (L/yr)	31,688	43,527
Coal (t/yr)	0	0

4.7.2.3 *Air Quality*

This section describes existing air quality, including a review of the meteorology and climatology in the vicinity of the Livermore Site and Site 300. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.7.

Meteorology and Climatology. The climate at the Livermore Site, Site 300, and the surrounding region is classic Mediterranean with hot dry summers and cold wet winters. The average annual temperature at the Livermore Site is 12.5 °C (54.5 °F); the normal seasonal temperature range is defined by winter nighttime lows in the vicinity of 0 °C (32 °F) and summer daytime highs around 38 °C (100.4 °F). The highest and lowest annual precipitation on record are 78.2 cm (30.8 in) and 13.8 cm (5.4 in), respectively. Prevailing winds at the Livermore Site are from the west and southwest. The climate at Site 300, while similar to the Livermore Site, is modified by higher elevation and more pronounced relief. The temperature range is somewhat more extreme than the Livermore Site. Topography significantly influences surface wind patterns at Site 300 with prevailing winds from the west-southwest (LLNL 1993b:1-2,1-3).

Ambient Air Quality. The Livermore Site is located within the San Francisco Bay Area Air Quality Management District. With respect to attainment of the NAAQS (40 CFR 50), this area has been designated as follows: A part of Alameda County, which is in the San Francisco Bay Area Air Quality Management District, is designated as nonattainment for carbon monoxide (with a classification of moderate ≤12.7 ppm) and ozone (with a classification of moderate) (40 CFR 81.305). Site 300 is located within the San Joaquin Valley Unified Air Pollution Control District. The area is classified as a nonattainment area for ozone (with a classification of serious) and PM_{10} (with a classification of serious) (40 CFR 81.305). Applicable NAAQS and California State ambient air quality standards are presented in appendix table B.3.1–1.

The primary emission sources of criteria air pollutants at the Livermore Site and Site 300 are numerous boilers, solvent cleaning operations, emergency generators, and various experimental, testing, and process sources. Emission estimates for these sources are presented in appendix table B.3.7–1.

Several PSD Class I areas have been designated in the vicinity of the Livermore Site, including Point Reyes National Wilderness Area, approximately 89 km (55 mi) to the northwest; and Desolation National Wilderness Area, Mokelumne National Wilderness Area, Emigrant National Wilderness Area, Hoover National Wilderness Area, and Yosemite National Park, approximately 160 to 190 km (100 to 120 mi), respectively, to the east and northeast. Since the promulgation of the PSD regulations (40 CFR 52.21) in 1977, no PSD permits have been required for any emission sources at the Livermore Site.

The State of California employs a health-risk based program for toxic air pollutants. As required by the *California Air Toxic "Hot Spots" Information and Assessment Act* of 1987 (AB2588), the Bay Area Air Quality Management District and the San Joaquin Valley Unified Air Pollution Control District requested that the Livermore Site and Site 300 assess the impact of toxic air emissions on the surrounding area. The risks at the Livermore Site were found to be below the threshold values that are used to determine need for further evaluation. The Site 300 toxic air pollutant inventory has been completed and will be submitted to the San Joaquin Valley Unified Air Pollution Control District for review to determine if a risk assessment is required (LLNL 1993b:2-24).

The "Hot Spots" program, however, is not applicable to the other stockpile stewardship and management candidate sites. To compare with the other stockpile stewardship and management candidate sites, the predicted maximum 8-hour concentrations for toxic air pollutants are provided. Table 4.7.2.3–1 presents the baseline ambient air concentrations for criteria pollutants and other hazardous/toxic air pollutants of concern at the Livermore Site and Site 300. As shown in the table, criteria pollutant baseline concentrations are in compliance with applicable guidelines and regulations, with the exception of 1-hour nitrogen dioxide at the Livermore Site.

4.7.2.4 *Water Resources*

This section describes the surface and groundwater resources at LLNL. This site includes the facilities in the Livermore Valley and at Site 300, referred to here as Livermore Site and Site 300, respectively.

Surface Water

Livermore Site. The main surface water features at the Livermore Site are the Arroyo Las Positas and Arroyo Seco. Arroyo Las Positas drains in the hills directly east and northeast of the Livermore Site and usually flows only after storms (figure 4.7.2.4–1). This channel enters the Livermore Site from the east, is diverted along a storm ditch around the northern edge of the site, and exits the site at the northwest corner. Arroyo Seco flows through the very southwest corner of the Livermore Site. Arroyo Las

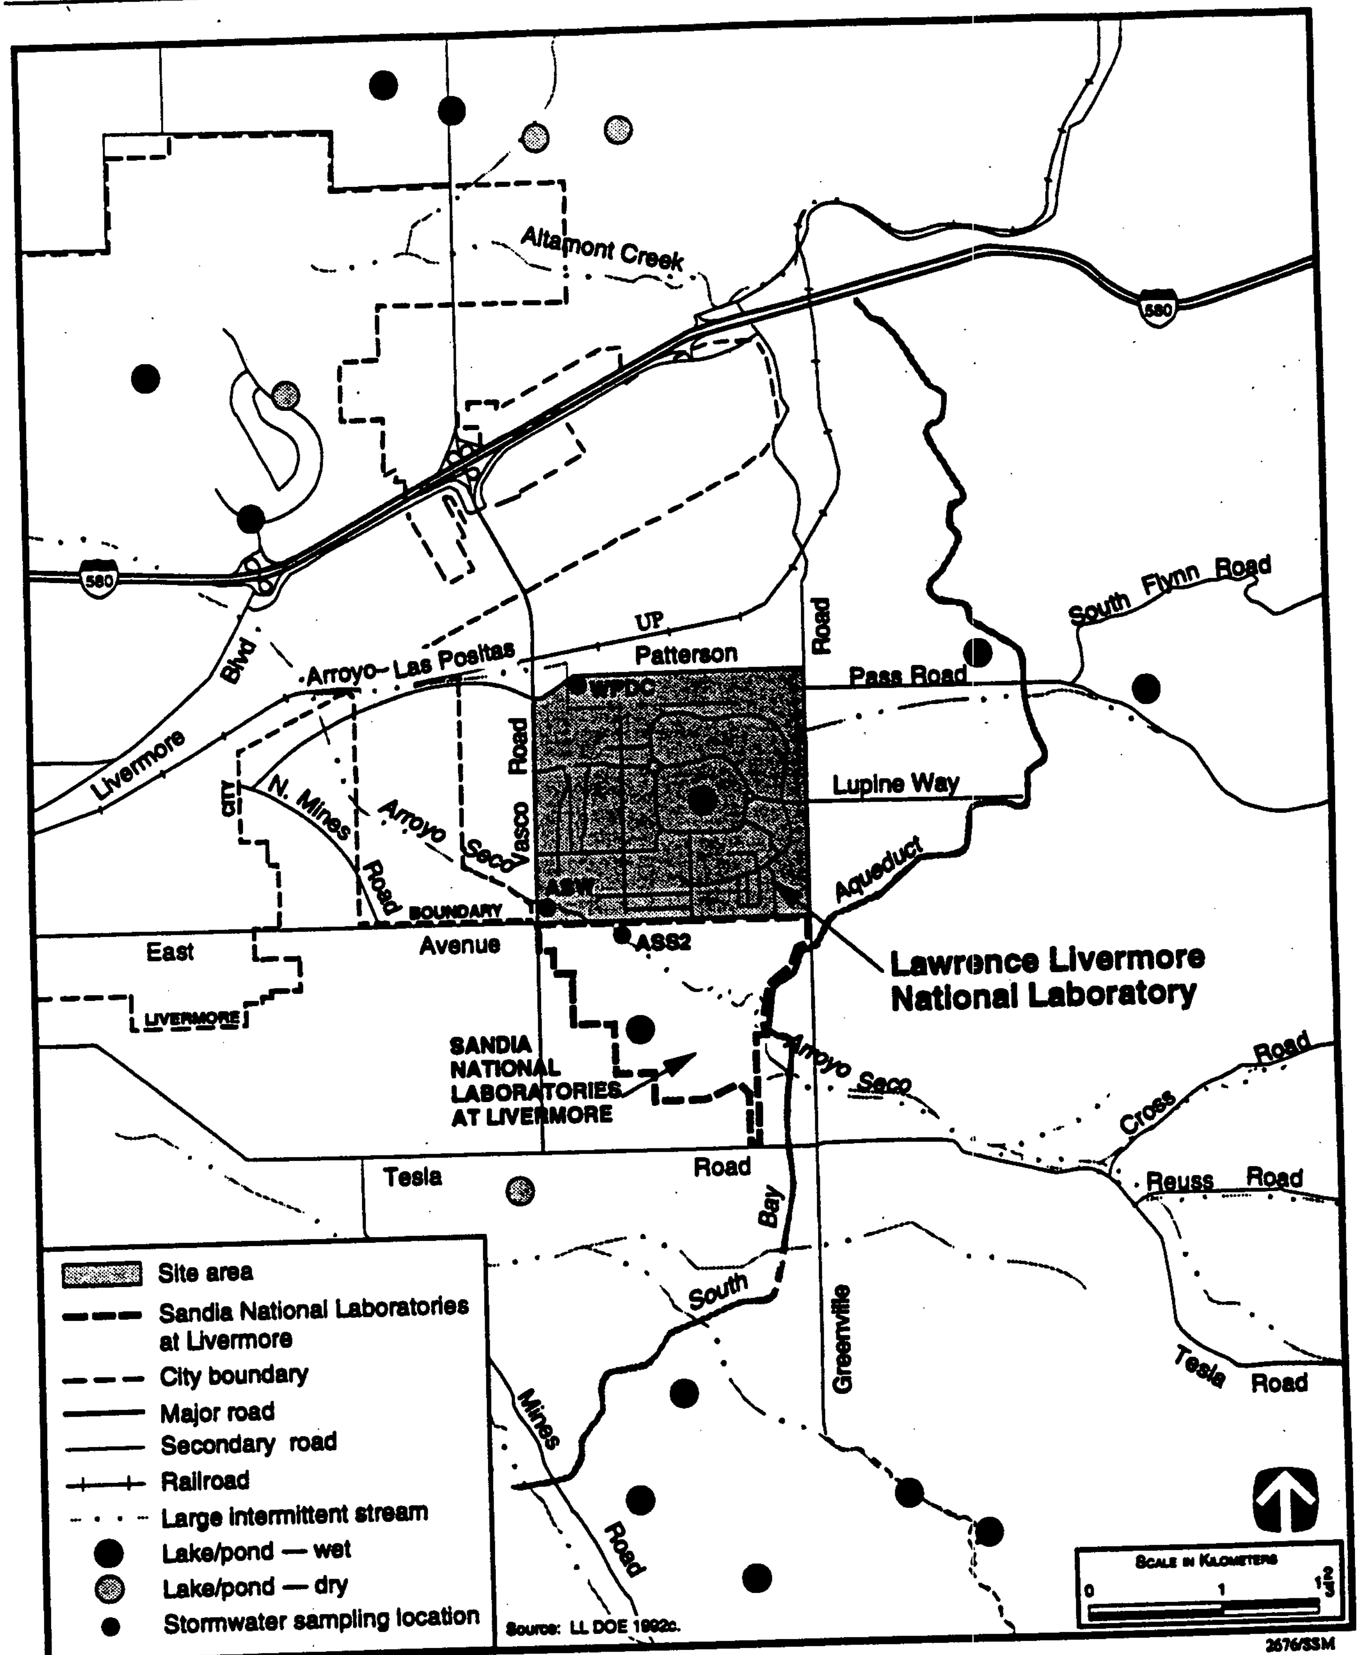

FIGURE 4.7.2.4–1.—*Surface Water Features Near Lawrence Livermore National Laboratory, Livermore Site, and Vicinity.*

Positas flows into Arroyo Seco west of the site. Both stream channels are dry for most of the year.

Nearly all surface water runoff at the Livermore Site is discharged into Arroyo Las Positas; only surface water runoff along the southern boundary and some storm drains in the southwest corner of the Livermore Site drain into Arroyo Seco (LL DOE 1992c:4-147). The locations of hydrological features are shown in figure 4.7.2.4–1.

Two areas on the Livermore Site are within the 100-year floodplains of the Arroyo Las Positas and Arroyo Seco. However no existing onsite structures are within the 100-year floodplain. The channels routing Arroyo Las Positas and Arroyo Seco through the Livermore Site would be able to contain a 100-year flood. The 500-year flood levels have not been delineated.

The total annual water use at the Livermore Site is currently 968 MLY (256 MGY). LLNL receives water from two suppliers. During the summer months, June through August, deliveries are taken primarily from the Alameda County Flood Control and Water Quality Conservation District Zone 7. This water is a mixture of groundwater and water from the South Bay Aqueduct of the State Water Project. For the remainder of the year, LLNL's water usually is supplied from the Hetch-Hetchy Aqueduct.

Approximately 400 MLY (106 MGY) of wastewater from the Livermore Site is discharged to the city of Livermore sewer system and processed at the Livermore Water Reclamation Plant (LLNL 1994a:5-1). This wastewater includes sanitary and industrial discharges from the Livermore Site and Sandia National Laboratories. The discharges are permitted by the city of Livermore and monitored for pH, selected metals, and radioactivity (LLNL 1994a:5-2). LLNL also monitors the waters of the Livermore Site, Site 300, and surrounding areas, as well as stormwater runoff.

Site 300. There are no perennial streams at or near Site 300. The canyons that dissect the hills and ridges at Site 300 drain into intermittent streams. The majority of these onsite streams drain to the south into Corral Hollow Creek, also intermittent, which flows east along the southern boundary of Site 300 in the San Joaquin Valley. In addition to these streams, 24 springs and 2 vernal pools exist onsite. Some surface water discharge occurs from cooling towers and other process runoff areas.

A tapline from the Hetch-Hetchy Aqueduct has been constructed with a capacity of 1.9 MLD (0.502 MGD) or 693 MLY (183 MGY). However, Site 300 has not been connected to the service as of yet. Site 300 is planning to use a new water supply from the San Francisco Water Department via the Aqueduct and the Coast Ridge Tunnel (LLNL 1991b:6).

At Site 300, stormwater, cooling tower water, and groundwater that has been treated to remove contaminants are discharged to onsite or adjacent drainages in accordance with NPDES permit conditions. Approximately 4.8 MLY (1.3 MGY) of wastewater is discharged to the wastewater sewage pond. The maximum capacity of the sanitary wastewater sewage pond in the General Services Area is 12 MLY (3.2 MGY).

Based on the flow and stream channel widths, 100-year flood events would be contained within the channels except for portions of Greenville Road (LL DOE 1992c:6-9). There is no information available for delineating the 500-year floodplain at Site 300. The lined drainage retention basin at Site 300 mitigates effects from significant flooding.

Surface Water Quality

Livermore Site. Offsite surface water bodies in the vicinity of the Livermore Site are routinely monitored for radioactive parameters. In addition, stormwater runoff at the Livermore Site is routinely monitored for radioactive and nonradioactive parameters. Approximately 25 percent of the stormwater runoff generated within the site drains into the lined Central Drainage Retention Basin, and the remainder drains either directly, or via a system of storm sewers and ditches, into Arroyo Seco or Arroyo Las Positas. Table 4.7.2.4–1 summarizes the monitoring results at the Livermore Site for 1993. Maximum concentrations of gross beta were above their comparison criteria at least once in 1993. There was one instance of noncompliance with wastewater permit limits in 1994: a discharge of methylene chloride. This event was reported to the city of Livermore Water Reclamation Plant. Table 4.7.2.4–2 summarizes the surface water monitoring results from the Arroyo Seco at the Livermore Site.

Site 300. At Site 300, surface water samples analyzed in 1994 for gross beta and tritium showed concentrations below maximum contaminant levels for drinking water, except for gross alpha radiation for one sampling event. No concentrations were above comparison criteria in 1993.

Surface Water Rights and Permits. LLNL holds several permits pertaining to local, state, and Federal regulations: NPDES permits; Waste Discharge Requirements permits for any discharge of wastes that could adversely affect the beneficial uses of water; a city of Livermore Water Reclamation Plant permit for wastewater discharges to the city sanitary sewer system; and California Department of Fish and Game permits for streambed alteration for any work that may disturb or impact rivers, streams, or lakes.

Groundwater

Livermore Site. Groundwater at the Livermore Site occurs in an upper unconfined zone overlying a series of semiconfined aquifers. The two geologic units containing the most important aquifers are the surface valley-fill deposits (shallow alluvial aquifer) and the Livermore Formation (semi-confined aquifer).

The Livermore Site is located within the Spring subbasin of the Livermore Valley groundwater basin. The aquifers are locally recharged by the stream runoff from precipitation and controlled releases from the South Bay Aqueduct, direct rainfall, irrigation, and treated groundwater infiltration. In addition, stream channels and ditches, and gravel pits west of the city of Livermore also recharge the shallow alluvial aquifer. Groundwater is also naturally discharged from the basin at Arroyo de la

TABLE 4.7.2.4–1.—***Stormwater Quality Monitoring at the Livermore Site, 1993***

Laguna located 18 km (11 mi) southwest of the Livermore Site (LL DOE 1992c:4-151). Depth to the shallow alluvial aquifer beneath the Livermore Site ranges from approximately 9 to 34 m (30 to 110 ft). Groundwater generally flows westward throughout much of the site and southwest in the southeast area of the Livermore Site.

Site 300. At Site 300, there are two regional aquifers or major waterbearing zones: an aquifer in the sandstones and conglomerates of the Neroly Formation and a deep confined aquifer also located in the Neroly Formation. The deep confined aquifer (122 to 152 m deep [400 to 499 ft]), beneath the southern part of the site within the Neroly Formation, provides the water supply for Site 300. In addition, there are a number of local perched groundwater zones. These are not significant aquifers, because water quality is poor and yields are low. Groundwater flow in the deep confined aquifer is controlled by the sandstone beds (LLNL 1995n:E.2.4-27). North of the Patterson Anticline, which is roughly in the center of Site 300, (figure 4.7.2.4–2) water moves to the northeast, and south of the Anticline it moves to the southeast (LLNL 1994a:8-5). Runoff that has concentrated in Elk Ravine and Corral Hollow Creek recharges local bedrock aquifers. No aquifers in the Site 300 area are considered sole source aquifers under the *Safe Drinking Water Act* (SDWA).

Groundwater Quality

Livermore Site. Groundwater in the vicinity of the Livermore Site is generally suitable as a domestic, municipal, agricultural, and industrial supply, with the exception of groundwater less than 91 m (300 ft) deep (LL DOE 1992c:4-164). A network of groundwater monitoring and extraction wells at the Livermore Site is routinely monitored for radioactive and nonradioactive parameters. Maximum concentrations of gross alpha, nitrate/nitrite, trichloroethylene, and tritium were above their water quality criteria/standard in 1993. The maximum concentrations for tritium are found in one localized well within the Livermore Site boundary (LLNL 1994a:7-14), and pose no threat to water supplies.

VOCs have been detected in the onsite groundwater and in the area around the Livermore Site. All site practices known to contribute VOCs to groundwater have been discontinued. Investigations, however, have determined that VOC-contaminated water is present under 85 percent of the Livermore Site. The

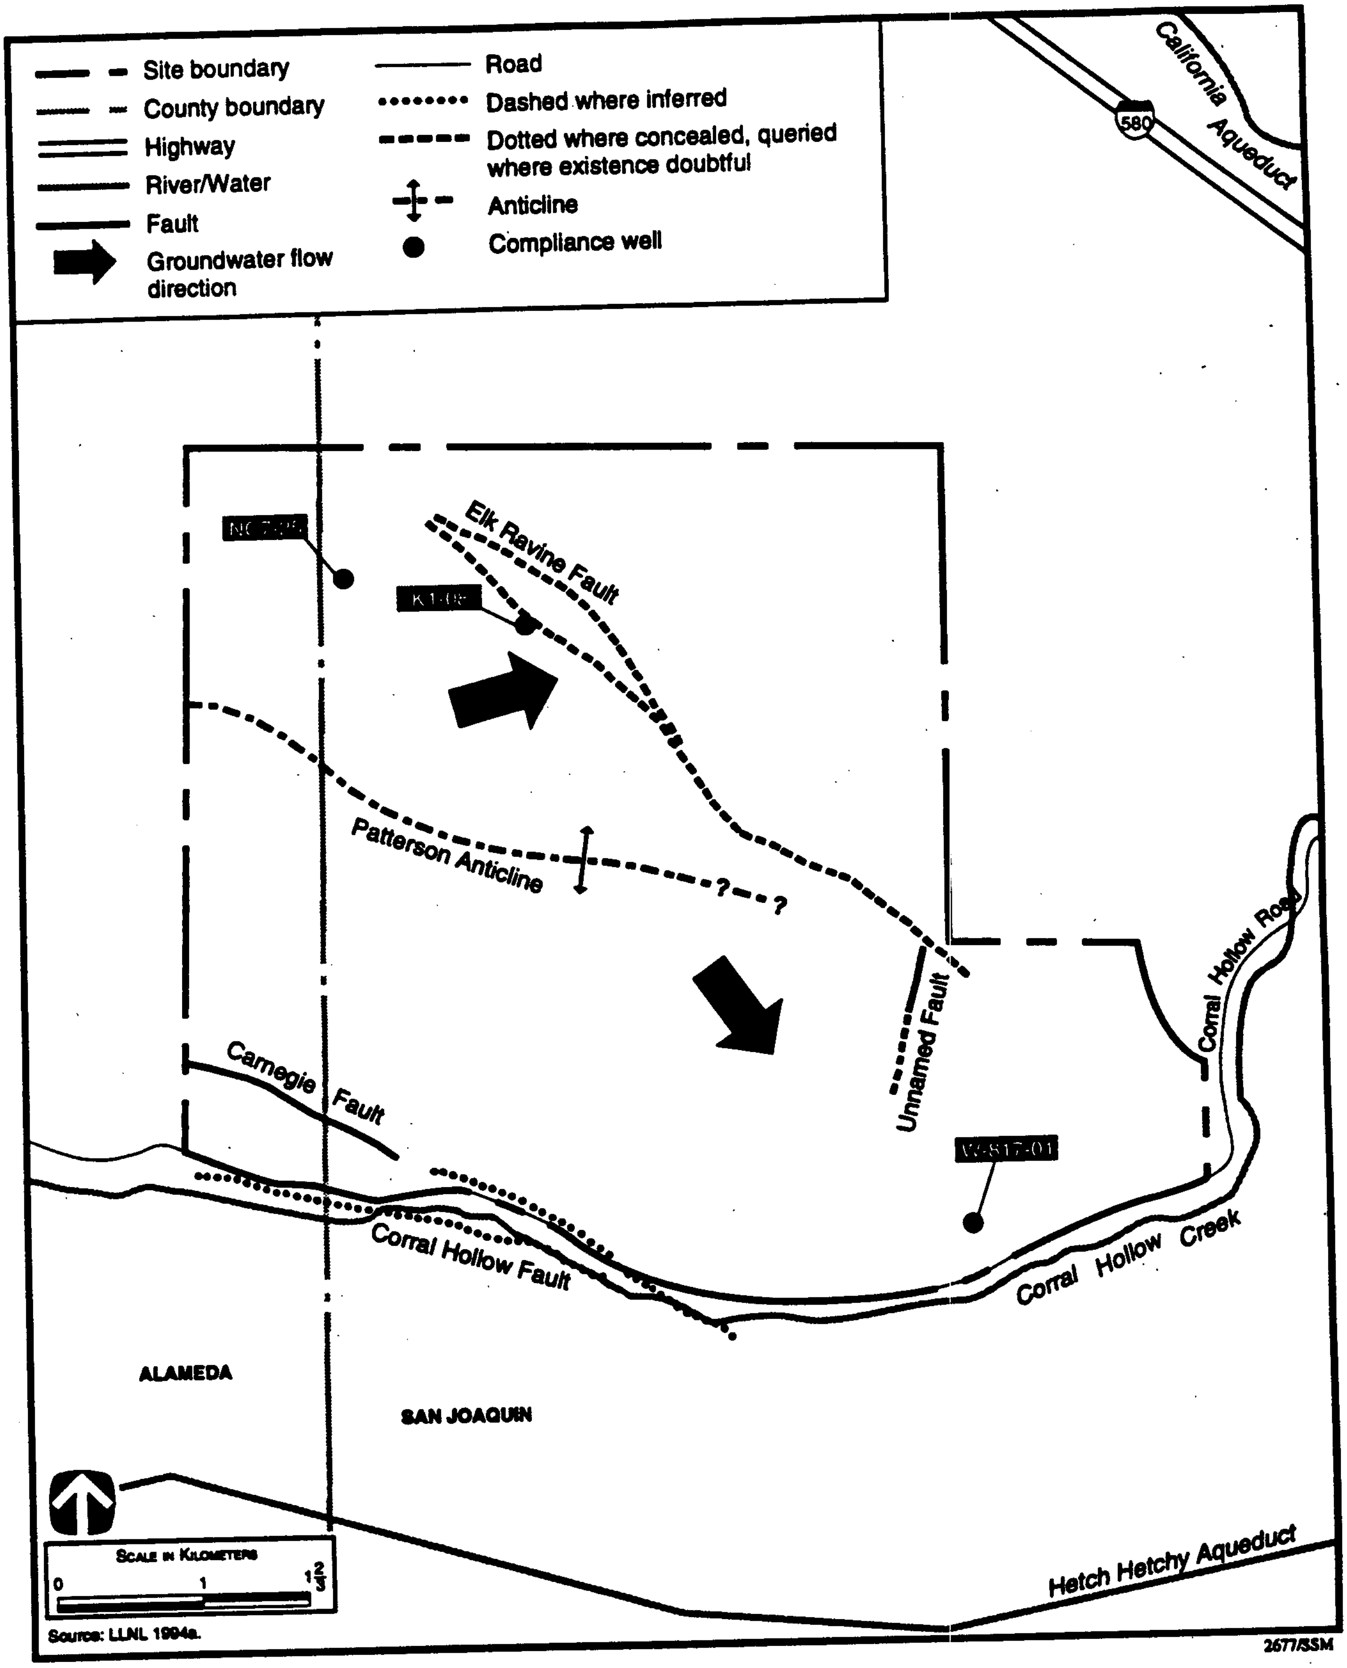

FIGURE 4.7.2.4–2.—*Groundwater Flow Direction and Structural Features at Lawrence Livermore National Laboratory, Site 300.*

contaminant plumes have migrated off site in two areas. One plume containing mainly tetrachloroethylene extends from the southwest corner of the Livermore Site about 762 m (2,500 ft) west of Vasco Road under private property. It is migrating to the northwest at a rate of about 21 m (68.9 ft) per year. Three municipal supply wells are situated within about 4.4 km (2.4 mi) of this plume. The other plume, which contains primarily trichloroethylene, extends about 244 m (800 ft) south onto DOE property administered by Sandia National Laboratories, Livermore. LLNL is working with EPA and the State of California to identify appropriate remedial measures.

Approximately 150 million L (34.3 million gal) of groundwater in the southwest corner of the facility have been treated to remove VOCs. The treated water is discharged either to a recharge basin south of the site or to stream channels in accordance with NPDES permit limitations.

Site 300. At Site 300, groundwater is sampled quarterly from inactive and active water supply wells and monitoring wells. Samples are analyzed for radioactive and nonradioactive parameters (table 4.7.2.4–3). Maximum concentrations of arsenic, gross alpha, nitrate/nitrite, trichloroethylene, tritium, and uranium were above their water quality criteria/standard at least once in 1993 (LLNL 1994a: 7-17-7-18). Currently, LLNL is investigating and identifying characteristics of the groundwater contamination at Site 300. Several plumes of VOCs and tritium have been identified in shallow and deeper bedrock aquifers in this and adjacent offsite areas (LLNL 1994a:7-16–7-17). LLNL is working with the EPA and California to remediate these plumes.

Groundwater Availability and Use

Livermore Site. The Livermore Site relies on imported surface water for its municipal, commercial, residential, and agricultural uses, supplemented only by a relatively small amount of treated groundwater used for irrigation and cooling tower makeup. The water from the supply wells is blended with imported surface water before distribution to the public.

Site 300. At Site 300, approximately 90 MLY (23.8 MGY) of water are extracted from two groundwater supply wells located in the southeast portion of the site. Other water supply wells located near Site 300 are used for recreation, stock watering, and potable purposes.

Groundwater Rights and Permits. Groundwater rights in the State of California are traditionally associated with Correlative Rights, which are derived from the concept that water users will share the resource during droughts, based on the relative areal extent of the land owned by the competing landowners. If no competition for water exists, then landowners can withdraw groundwater to the extent that they exercise their rights reasonably in relation to the similar rights of others. Because the majority of the water supply at Site 300 is from onsite wells, the present water restriction is the capacity and recharge of the wells.

4.7.2.5 *Geology and Soils*

Geology

Livermore Site. The Livermore Site is located within the California Coast Ranges, an area of north-northwest trending ranges and valleys. Livermore Valley, an exception to this trend, forms an east-west structural basin defined by branches of the San Andreas fault system. The Livermore Site occupies a smooth land surface that slopes gently to the northwest.

The Livermore Site is underlain by late Tertiary and Quaternary rocks that lie on basement rocks of the Franciscan assemblage, which consist of severely deformed sandstone, shale, and chert. In the Livermore area, this unit is mainly sandstone. The Livermore Valley topographic and structural basin was formed in Pliocene time by movements along faults to the east and west. The basin is filled with 1,219 m (4,000 ft) of Pliocene to Holocene alluvial gravels, sands, and lacustrine clays of the Livermore Formation. Late Quaternary alluvial deposits immediately underlie the Livermore Site.

The historically active, northwest-trending Calaveras fault zone, the easternmost branch of the San Andreas fault system in the San Francisco Bay area, traverses the western margin of Livermore Valley. The Concord-Green Valley fault and parallel trending Greenville fault zone define the eastern boundary of Livermore Valley. In addition, two other capable

[f] Proposed National Primary Drinking Water Regulations; Radionuclides (56 FR 33050).
[g] DOE Derived Concentration Guide for drinking water (DOE Order 5400.5). Values are based on a committed effective dose of 100 mrem per year; however, because the drinking water maximum contaminant level is based on 4 mrem per year, the number listed is 4 percent of the Derived Concentration Guide.

Note: NA - not applicable; mg/L - milligrams per liter; pCi/L - picocuries per liter. Well locations are shown in figure 4.7.2.4–1.

Source: LLNL 1994a.

faults, the Las Positas and Verona faults, as well as several inactive faults, cut the southern part of Livermore Valley. The Livermore Site lies in an area of historically inactive faulting, 1.6 km (1.0 mi) north of the Las Positas fault zone and less than 3.2 km (2.0 mi) west of the Greenville fault zone (figure 4.7.2.5–1).

The Livermore Site lies within seismic Zone 4 (figure A.1–1). The Calaveras fault has had several earthquakes of Richter magnitude 5.0 or greater in the last 150 years. A maximum probable earthquake greater than magnitude 7.0 is possible. In 1980, an earthquake sequence on the Greenville fault produced two earthquakes of magnitude 5.5 and 5.6. There are also surface indications of other recent seismic events, and the maximum credible earthquake estimated for this fault zone is magnitude 6.6±0.2. Although the Las Positas fault zone has no recorded historical movement, a portion of the Las Positas fault from northeast of Arroyo Mocho to a point 229 m (751 ft) east of Greenville Road lies in a special studies zone under the *Alquist-Priolo Act*. This act requires that active fault location studies be performed before building permits can be issued for most classes of construction (LLNL 1984a:49). The maximum credible

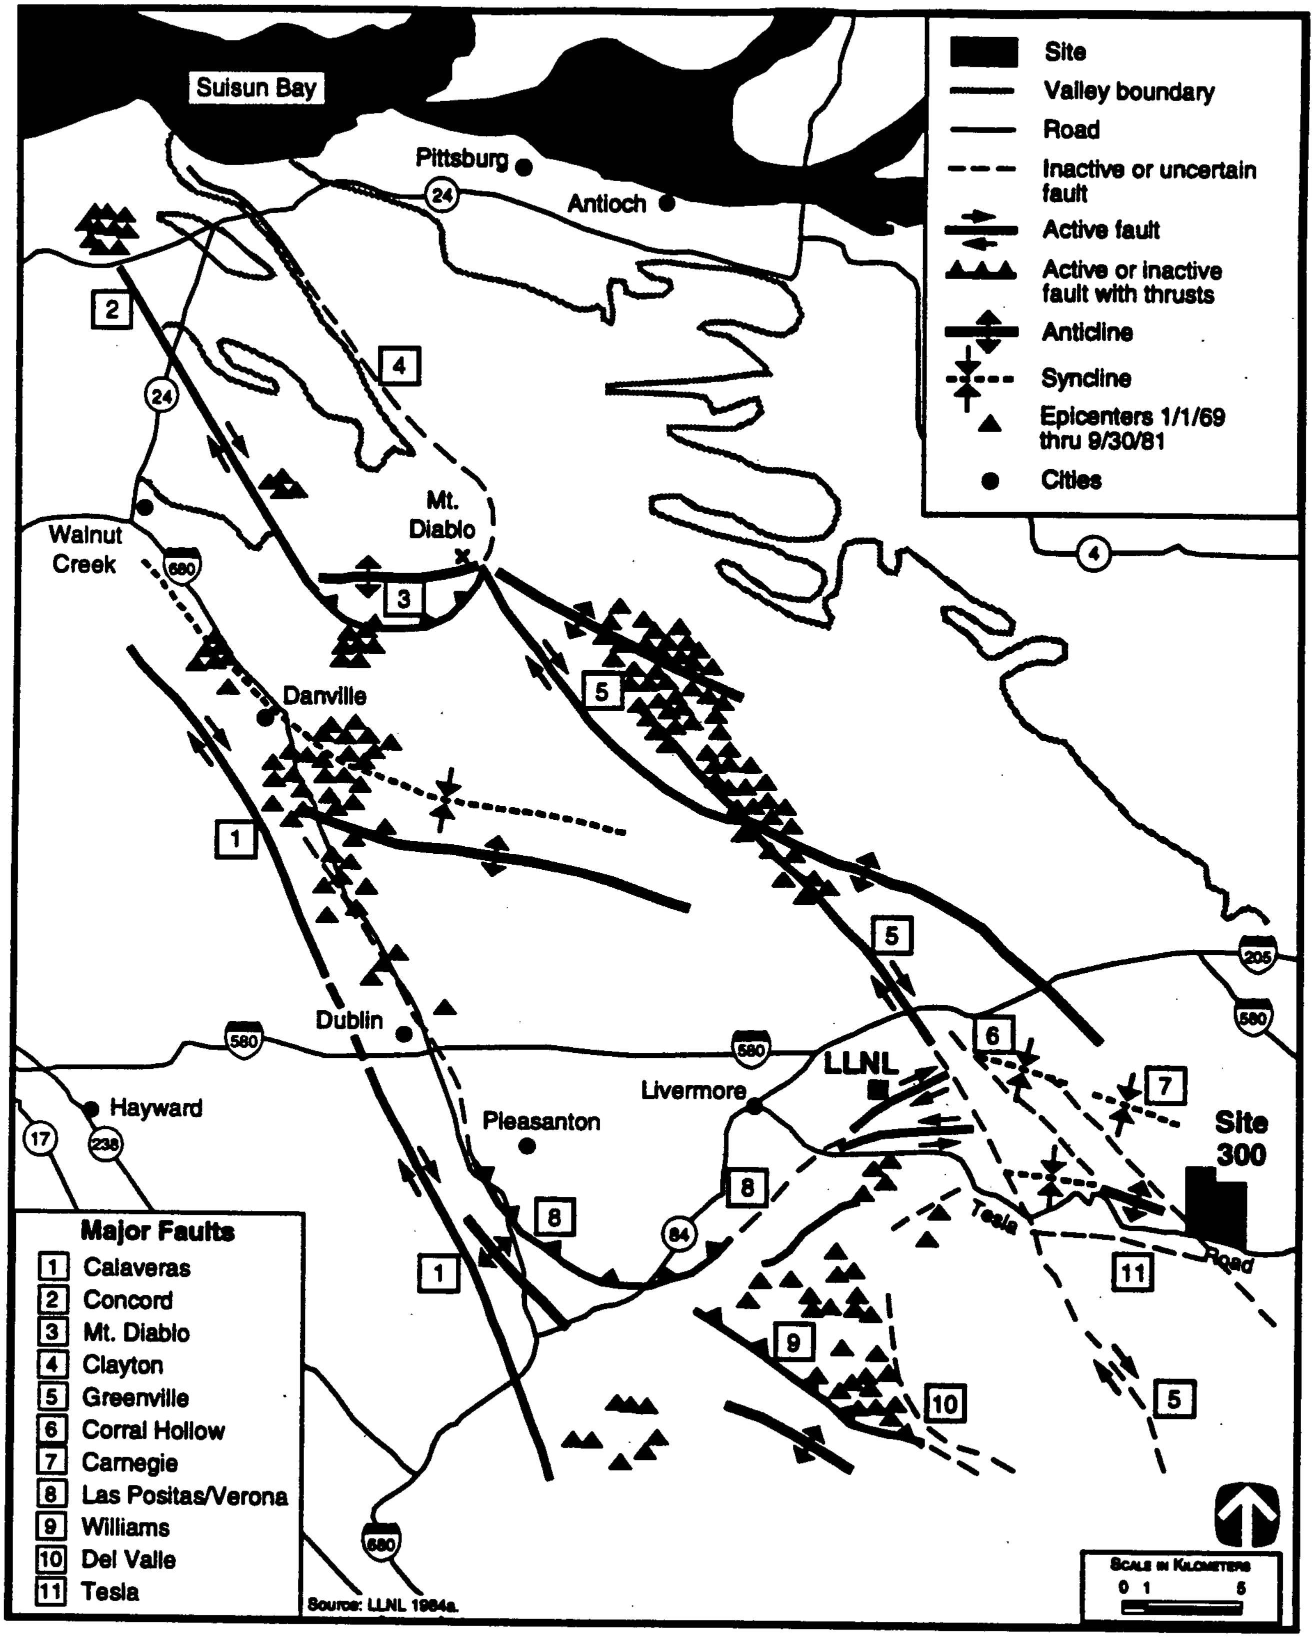

FIGURE 4.7.2.5–1.—*Major Faults and Earthquake Epicenters of Livermore Valley, California.*

earthquake for this fault zone is magnitude 6.0±0.5 (modified Mercalli intensity VI or greater) (LLNL 1984a:52). The potentials for surface faulting, damage from liquefaction, and slope instability at the Livermore Site are all low (LL DOE 1992c:4-84,4-86). The potential for volcanic activity is low as well (DOE 1995cc:4-66).

Site 300. Site 300 is located at the eastern margin of the California Coast Ranges, 16 km (10 mi) east of Livermore Valley. The site lies in an area of northwest-trending steep hills and ridges separated by ravines and is underlain by Eocene to Pliocene sedimentary rocks that rest on a basement of the Cretaceous Great Valley Sequence. Late Miocene to Pliocene interbedded sandstones, siltstones, and claystones are exposed in much of the site. Cretaceous, Eocene, and Early Miocene rocks are also present along the northern and southern borders of the site. These rocks are locally overlain by Quaternary alluvial and terrace deposits and Holocene colluvium, alluvium, and valley fill deposits.

Site 300 lies within seismic Zone 4 (appendix figure A.1–1). Two major faults cut Site 300. The Carnegie and Corral Hollow faults cross the southern boundary of the site; Holocene movement has occurred along these faults (LLNL 1991d:1). The combined Corral Hollow-Carnegie fault zone may be capable of generating an earthquake of Richter magnitude 6.5 to 7.1. The inactive northwest-trending Elk Ravine fault cuts across the northeast section of the site. Site 300 facilities are not within a special studies zone. The principal seismic hazard would be the ground shaking associated with movement along either the Corral Hollow-Carnegie fault or Greenville fault, 8 km (5 mi) to the west of Site 300 (LLNL 1983a:49-52). Surface faulting at Site 300 in areas adjacent to the active Carnegie fault is possible, while the potential for liquefaction at Site 300 is low. The potential for seismically induced landslides at Site 300 still exists (LL DOE 1992c:4-87,4-89).

Soils

Livermore Site. The Livermore Site is located on soils originally classified as the Rincon-San Ysidro association. These soils are nearly level, loamy textured, shallow to very deep soils on older fans and floodplains. The hazard of erosion is slight to moderate. Several of these soils, including the Rincon, San Ysidro, and Zamora Series soils, have moderate to high shrink-swell potential (LL USDA 1966a:17). Recently, the entire area under the Livermore Site has been redesignated as urban and built-up land. There are no prime or unique farmland soils located at the Livermore Site.

Site 300. Site 300 soils in Alameda County belong to the Altamont-Diablo association. Soils in San Joaquin County have different designations than Alameda County soils, but the properties of these soils are identical. The water erosion hazard of these soils is slight to severe; the wind erosion hazard is slight. Many soils have a high shrink-swell potential. There is no prime or unique farmland on Site 300.

4.7.2.6 *Biotic Resources*

The following section describes biotic resources at the Livermore Site and Site 300 including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. A list of the threatened and endangered species that may be found on or in the vicinity of the Livermore Site and Site 300 is presented in appendix C.

Terrestrial Resources. The Livermore Site and Site 300 are located in the California Chaparral Province. The U.S. Forest Service has classified the general vegetation type of the region as annual grasslands (USDA 1977a).

Livermore Site. The Livermore Site includes developed areas surrounded by security zones of mostly grassland. Developed land area includes approximately 78 percent of the site. The undeveloped land in the security zones is grassland dominated by nonnative grasses such as ripgut brome (*Bromus diandrus*) and slender oat (*Avena barbata*). Arroyo Seco, a stream bed which runs across the southwestern corner of the site, is steep-sided and forms a relatively undisturbed habitat. Both native trees (such as red willow [*Salix spp.*] and California walnut [*Juglans hindsii*]) and introduced species (such as black locust [*Robinia pseudo-acacia*] and almond [*Prunus amygdalus*]) are present (LL DOE 1992c:4-91).

Five species of amphibians, 2 species of reptiles, 31 species of birds, and 10 species of mammals have been reported at the Livermore Site (LL DOE

1992d:F-33,F-36,F-39). Wildlife at the site includes species that are found in the grassland habitat of the security zones and those that live in the developed areas or along the arroyos. Species found in the security zones include the western fence lizard (*Sceloporus occidentalis*), western meadowlark (*Sturnella neglecta*), black-tailed jackrabbit (*Lepus californicus*), and California ground squirrel (*Spermophilus beecheyi*). Nesting birds within the laboratory complex include the American crow (*Corvus brachyrhynchos*), American robin (*Turdus migratorius*), Anna's hummingbird (*Calypte anna*), white-throated swift (*Aeronautes saxatalis*), California quail (*Callipepla californica*), and house sparrow (*Passer domesticus*). Bird species observed along Arroyo Seco include the mourning dove (*Zenaida macroura*), acorn woodpecker (*Melanerpes formicivorus*), sharp-shinned hawk (*Accipiter striatus*), and turkey vulture (*Cathartes aura*) (LL DOE 1992c:4-95). Game animals include the California quail and desert cottontail (*Sylvilagus auduboni*). Raptors present on site include the red-tailed hawk (*Buteo jamaicensis*), Cooper's hawk (*Accipiter cooperii*), and golden eagle (*Aquila chrysaetos*), while carnivores present include the coyote (*Canus latrans*) and red fox (*Vulpes vulpes*). Migrating birds present on site, as well as their nests and eggs, are protected by the *Migratory Bird Treaty Act*. Eagles are similarly protected by the *Bald and Golden Eagle Protection Act*.

Site 300. Five plant communities are found on Site 300 (figure 4.7.2.6–1). In addition, approximately 5 percent of the site has been disturbed. Introduced grassland is the largest community, covering 81 percent of the site. Native grassland, which covers 10 percent of the site, is the second most abundant community type. Coastal sage scrub and oak woodland plant communities occupy about 2 percent of the Site 300 area. Northern riparian woodland is considered rare on Site 300. Grazing has not been permitted on the site since 1953; thus, the area has more native grasses and herbs than neighboring property. Controlled burning of about 810 ha (2,000 acres) each year is conducted as a means of wildfire control and to aid in maintaining native grass communities. A total of 342 species of plants has been recorded on Site 300 (LL DOE 1992c:4-92; LL DOE 1992d:F-4).

Studies of Site 300 have identified 21 species of amphibians and reptiles, 79 species of birds, and 27 species of mammals (appendix J). Because of the abundance of grassland communities, species favoring this habitat type are most abundant on the site. Common animals found at Site 300 include the gopher snake (*Pituophis melanoleucus*), western meadowlark, savannah sparrow (*Passerculus sandwichensis*), California ground squirrel, and deer mouse (*Peromyscus maniculatus*). In addition, springs and the surrounding vegetation provide important habitat for a number of song birds and game animals (LL DOE 1992c:4-96,4-97). Game animals at Site 300 include the mule deer (*Odocoileus hemionus*), desert cottontail, and California quail. Hunting is not permitted onsite (LLNL 1992a:3). Additional important species found at Site 300 include raptors, such as the great-horned owl (*Bubo virginianus*) and northern harrier (*Circus cyaneus*), and carnivores, such as the coyote and bobcat (*Lynx rufus*). As is the case for the Livermore Site, migratory birds and eagles are protected by Federal legislation.

Wetlands

Livermore Site. Wetlands at the Livermore Site are limited to several small areas along Arroyo Las Positas, located at and downstream from culverts that channel runoff from surrounding areas. Two areas, totaling 0.12 ha (0.3 acres), are dominated by saltgrass (*Distichlis spicata*). A species of sedge (*Carex spp.*) is also common. One saltgrass wetland has both standing and flowing water and areas of very wet soil. The other saltgrass wetland is drier, with sandy soil. A third, smaller wetland (0.04 ha [0.1 acres]) is located in a culvert. Cattail (*Typha spp.*) is the dominant plant in this wetland with other species such as sedge and saltgrass also commonly observed. Both standing and flowing water have been observed in this area, and the soil is sandy (LL DOE 1992d:G-16).

Site 300. Wetlands at Site 300 were delineated according to methods contained in the *Federal Manual for Identifying and Delineating Jurisdictional Wetlands* (January 10, 1989). Site 300 contains 2.7 ha (6.7 acres) of wetlands. The wetland areas are small and scattered on the site in approximately 16 locations. Many of the wetlands are associated with natural springs, although one is

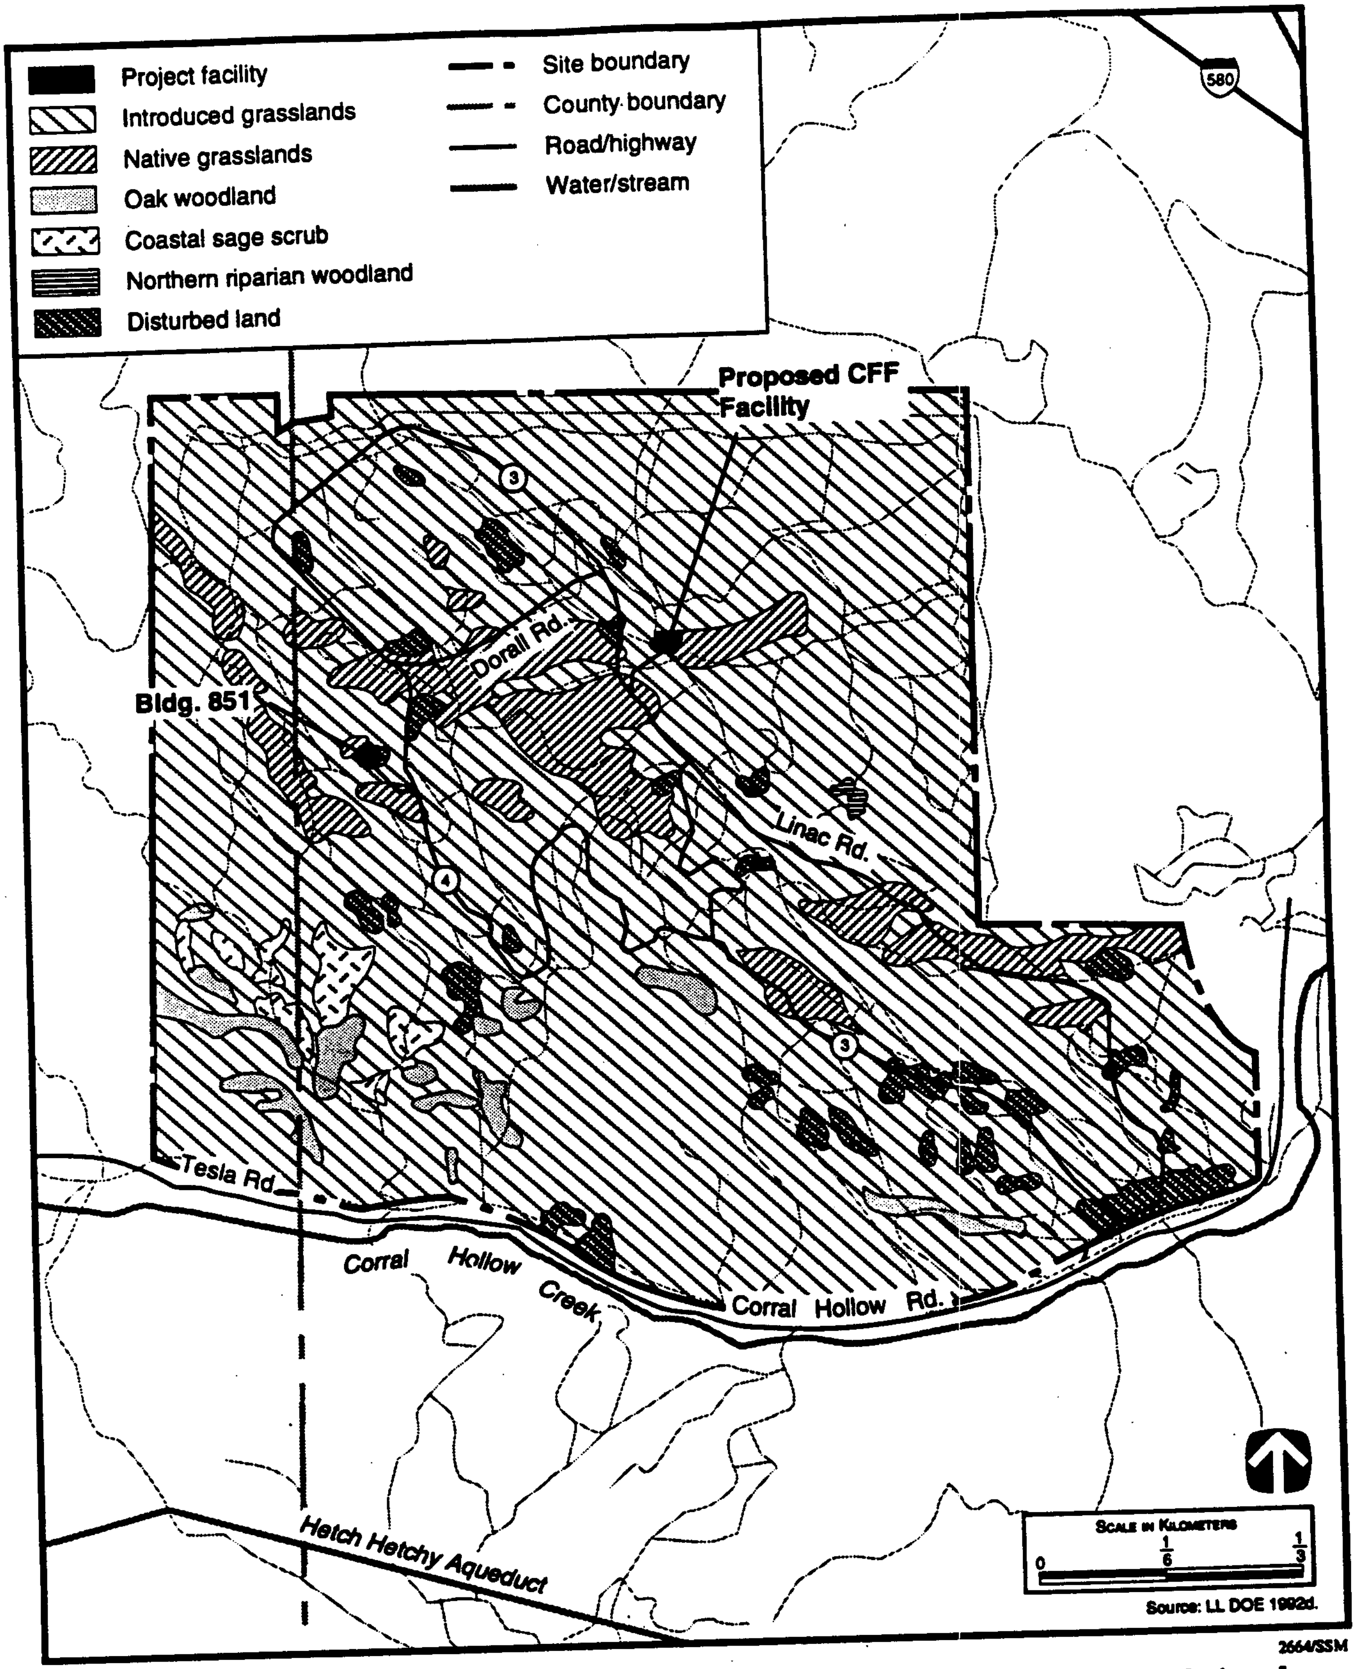

FIGURE 4.7.2.6–1.—*Distribution of Plant Communities at Lawrence Livermore National Laboratory, Site 300.*

associated with a vernal pool, and several have been artificially created from Site 300 runoff. Many of the wetlands associated with springs are at the bottom of deep canyons. Typical wetland vegetation associated with these springs include cattail, rush (*Juncus spp.*), willow, and cottonwood (*Populus spp.*) (LL DOE 1992c:4-112; LL DOE 1992d:G-19,G-46-G-48).

Aquatic Resources

Livermore Site. Potential aquatic habitat on the Livermore Site consists of an intermittent drainage system, seeps, springs, ditches, and a groundwater retention basin. The intermittent drainage system comprises westward-flowing arroyos that contain water during the winter months. Arroyos on the site include Arroyo Las Positas, located along the northern edge of the Livermore Site, and Arroyo Seco, which crosses the southwest corner of the site. Because of their temporary nature, the arroyos do not support fish. The seeps, springs, and ditches also do not support fish; however, the groundwater retention basin contains a population of mosquito fish (*Gambusia affinis*) (LLNL 1995i:3).

Site 300. Potential aquatic habitat on Site 300 consists of vernal pools, ponds, springs, and drainages. There is one perennial stream on the site. A sewage lagoon is located on the property, but it does not support any fish populations (LL DOE 1992c:4-95). Ponds located in the southeast-central portion of the site, and springs and drainages located throughout the site, do not support fish populations (LLNL 1992a:1).

Threatened and Endangered Species

Livermore Site. Forty-six Federal- and state-listed threatened, endangered, and other special status species may be found on and in the vicinity of the Livermore Site (appendix table C–5). Eleven of these species have been observed on the Livermore Site, including the Federal-listed bald eagle (*Haliaeetus leucocephalus*). The other observed species include state special concern species. Although suitable habitat for several listed species exists onsite, potential occurrence of most of the species in appendix table C–5 is minimal due to the lack of suitable habitat and negative survey results. Site surveillance would be required to verify the occurrence of any listed species. No critical habitat for threatened and endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on the Livermore Site.

Site 300. Forty-eight Federal- and state-listed threatened, endangered, and other special status species may be found on and in the vicinity of Site 300 (appendix table C–5). Twenty-four of these species have been observed on Site 300. These species include the Federal-listed American peregrine falcon (*Falco peregrinus anatum*) and large-flowered fiddleneck (*Amsinckia grandiflora*), and Federal-proposed endangered Alameda whipsnake (*Masticophis lateralis euryxanthus*) and California red-legged frog (*Rana aurora draytoni*). The other observed species include the state-listed Swainson's hawk and state special concern species. Potential occurrence of most of the other species listed in table C–5 is minimal due to lack of suitable habitat and negative survey results. Site surveillance would be required to verify their occurrence. No critical habitat for threatened and endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on Site 300.

4.7.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. The Livermore Site covers 332 ha (820 acres), 259 ha (640 acres) of which have been developed. Four cultural resources surveys have been conducted for undeveloped areas of the facility. No prehistoric resources were identified, and records searches indicated that no prehistoric resources had been previously recorded on or near the Livermore Site. Prehistoric sites identified in the vicinity of the Livermore Site and Site 300 include villages, campsites, rockshelters, and limited activity locations, including lithic scatters, hearths, and concentrations of fire-affected rocks. A cultural resources management plan is being developed to address issues of resource identification and maintenance.

A 1981 survey of Site 300 identified a quarry site, two prehistoric rockshelters, and one prehistoric rockshelter/historic graffiti site (LL DOE 1981a:2F.58). These sites were recorded but have not been evaluated to determine their eligibility for the NRHP.

Historic Resources. No historic sites have been recorded for the Livermore Site; however, buildings and facilities associated with the World War II-era Livermore Naval Air Station and themes in nuclear weapons development and other research projects may still be present. Because the Livermore Site was established in 1952, existing structures are not associated with the Manhattan Project or initial nuclear production. A formal NRHP evaluation of the buildings and facilities is currently being initiated.

The 1981 survey for parts of Site 300 resulted in 21 recorded historic sites, including historic graffiti, trash scatters, cabins, a foundation, a mine tunnel, a power/telegraph pole, and a townsite. The townsite, Carnegie, is a state-registered landmark. Most of the sites are associated with an industrial mining and manufacturing complex built in Corral Hollow Canyon between 1891 and 1918. Additional archival research is being conducted to clarify the characteristics of the Carnegie townsite. Site 300 was established in 1953; existing structures are not associated with the Manhattan Project or initial nuclear production.

Native American Resources. Native American groups known to have used Alameda and San Joaquin counties include the Costanoans (or Ohlone), Northern Yokuts, and Eastern Miwok. These groups were hunters and gatherers who relied on a variety of resources including deer, elk, antelope, fish, birds, nuts, and fruits. Individual tribes usually had a permanent village and occupied smaller campsites on a seasonal basis. The Northern Valley Yokuts and Eastern Miwok were decimated after European contact due to disease and acculturation, and no longer exist as a group. It is estimated that there are approximately 130 people of Costanoan (Ohlone) descent still living in the San Francisco Bay region.

Sacred and important Native American resources that might be found in the vicinity of the Livermore Site and Site 300 include burials, cremations, vision quest sites, and traditional use areas. Initial consultation with identified local Native American groups to determine important resources has begun.

Paleontological Resources. Most of the surficial and near-surface sediments of the Livermore Site are alluvial deposits of the Livermore Formation. They range in age from latest Pleistocene (15,000 to 20,000 years) to 100,000 years or greater and are not known to be fossiliferous. The only vertebrate fossil deposits in the vicinity of the Livermore Site are in the Quaternary deposits of the surrounding low hills of the east Livermore Valley, but the fossils are few in number and quite scattered. They have been tentatively identified as Rancholabrean and Blancan in age (Pleistocene) and consist of bone fragments of mammoth and giant ground sloth.

Geological formations with paleontological materials at Site 300 are the Franciscan Complex and the Cierbo and Neroly Formations. The Franciscan Complex gravels are known to contain Icthyosaurus fossils; however, no known localities have been recorded within Site 300. The Cierbo Formation outcrops extensively in the northwest quarter of Site 300 and contains Miocene oyster shells. Because these paleontological materials are relatively common, marine invertebrate assemblages are considered to have relatively low research potential.

More than 75 percent of Site 300 is Neroly Formation. Miocene (Caledonian age) mammal fossil deposits have been found within the Neroly Formation in the vicinity of Site 300 and Corral Hollow. Plant leaf and stem fossils have been recovered from the lower Neroly Formation. An assortment of vertebrate taxa are also represented, including camelids, mastodon, early horses, beavers, squirrels, and shrews. Fossil finds are generally widely scattered and consist of no more than several bone fragments. Numerous fossil bones and bone fragments from the Neroly Formation have been found on the south side of Corral Hollow Creek, adjacent to the facility and along a fire trail and road improvement areas within Site 300. The Neroly Formation paleontological locality within Site 300 is being assessed. The paleontological resources on Site 300 may have moderate research potential and may contribute data to aid paleoenvironmental reconstruction.

4.7.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at LLNL include employment and regional economy, population, housing, and public finance. Employment and regional economy statistics are presented for the regional economic area that encompasses 22 counties in California around LLNL. Statistics for the remaining socioeconomic characteristics are presented for the ROI, a three-county area in which approximately 86 percent of all LLNL employees reside: Alameda County (57 percent), Contra Costa County (13 percent), and San Joaquin County (16 percent). There are no other counties where more than 3 percent of LLNL employees reside. Figure 4.7.2.8–1 presents a map of counties and selected cities composing the LLNL regional economic area and ROI. Supporting data are presented in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the LLNL regional economic area are summarized in figure 4.7.2.8–2. The civilian labor force in the regional economic area grew a total of 26 percent between 1980 and 1990, an average annual growth rate of 2.6 percent. Total regional economic area employment in 1994 was 4,068,974, and the unemployment rate was 7.6 percent. In comparison, state unemployment was 8.6 percent. Total personal income in the regional economic area in 1993 was $454 billion, and per capita income was $25,179. State per capita income in 1993 was $21,894.

As shown in figure 4.7.2.8–2, the LLNL regional economic area and the State of California have similar employment patterns with the manufacturing, retail trade, and services sector providing almost the same proportion of nonfarm employment in both regions. The service sector accounts for the largest share of nonfarm private sector employment in both California (32 percent) and the region (38 percent).

Population and Housing. In 1992, population in the ROI totalled 2,652,248. The ROI population increased 26 percent between 1980 and 1992 (about 2 percent annually), a somewhat slower rate of increase than the state population growth of 31 percent (approximately 2.5 percent annually) during the same period. Total population increases within the ROI ranged from over 18 percent (about 1.5 percent annually) in Alameda County to about 45 percent (3.8 percent annual growth) in San Joaquin County during the same period.

The number of housing units in the ROI increased 18 percent during the 1980s (1.8 percent annually). Increases in the number of housing units in the ROI counties ranged from 13 percent (1.3 percent annually) in Alameda County to 25 percent (2.5 percent annually) in Contra Costa County. These growth rates compare to the 21-percent increase in housing units in California during the same period. In 1990, the regional homeowner vacancy rate averaged 1.6 percent, and the rental vacancy rate averaged 5.6 percent. These vacancy rates were comparable to the homeowner and rental vacancy rates for the entire state. Figure 4.7.2.8–3 summarizes population and housing trends for the LLNL ROI.

Public Finance. Financial characteristics of the local jurisdictions in the LLNL ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure fund categories for counties, cities, and school districts are presented in appendix tables D.2.3–10 and D.2.3–11. Figure 4.7.2.8–4 summarizes 1994 local government revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.7.2.8–4. All jurisdictions assessed had positive fund balances.

4.7.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at LLNL. Also included are descriptions of health effects studies, a brief accident history, and emergency preparedness considerations.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of LLNL are shown in table 4.7.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. The total dose to the population would result only from changes in the size of the population. Background radiation doses are unrelated to LLNL operations.

Weapons test fallout	<1
Air travel	1
Consumer and industrial products	10
Total	365

[a] LLNL 1994a. Value for radon is an average for the United States.
[b] NCRP 1987a.

Releases of radionuclides to the environment from LLNL operations provide another source of radiation exposure to individuals in the vicinity of LLNL. The radionuclides and quantities released from LLNL operations in 1994 are listed in the *Environmental Report 1994* (UCRL-50027-94). The doses to the public resulting from these releases are presented in table 4.7.2.9–2. These doses fall within regulatory limits (DOE Order 5400.5) and are small in comparison to background radiation. The releases listed in the 1994 report were used in the development of the reference environment's (No Action) radiological releases at LLNL in 2005.

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem ($5x10^{-4}$ fatal cancers per person-rem) to the public (appendix E), the fatal cancer risk to the maximally exposed member of the public due to radiological releases from LLNL operations in 1994 is estimated to be $3.3x10^{-8}$. That is, the estimated probability of this person dying of cancer from radiation exposure associated with 1 year of LLNL operations is slightly greater than 3 chances in 100 million. (Note that it takes several years from the time of exposure to radiation for cancer to manifest itself.)

Based on the same conversion factor, $3.8x10^{-4}$, excess fatal cancers are projected in the population living within 80 km (50 mi) of LLNL from normal operation in 1994. To place this number into perspective, it can be compared with the number of fatal cancers expected in this population from all causes. The 1990 mortality rate associated with cancer for the entire U.S. population was 0.2 percent per year (Almanac 1993a:839). Based on this national rate, the number of fatal cancers from all causes expected during 1994 in the population living within 80 km (50 mi) of LLNL was 12,000. This number of expected fatal cancers is much higher than the

TABLE 4.7.2.9–2.—*Doses to the General Public from Normal Operation at Lawrence Livermore National Laboratory, 1994 (Committed Effective Dose Equivalent)*

Affected Environment	Atmospheric Releases		Liquid Releases		Total	
	Standard[a]	Actual	Standard	Actual	Standard[a]	Actual
Maximally exposed individual (mrem)	10	0.065	4	0.0	100	0.065
Population within 80 kilometers[b] (person-rem)	None	0.76	None	0.0	100	0.76
Average individual within 80 kilometers[c] (mrem)	None	$1.3x10^{-4}$	None	0.0	None	$1.3x10^{-4}$

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem/yr limit from airborne emissions is required by the CAA, the 4 mrem/yr limit is required by the SDWA, and the total dose of 100 mrem/yr is the limit from all pathways combined. The 100 person-rem value for the population is given in proposed 10 CFR 834 (58 FR 16268).
[b] In 1994, this population was approximately 6 million.
[c] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.
Source: LLNL 1994a.

estimated 3.8×10^{-4} fatal cancers that could result from LLNL operations in 1994.

Workers at LLNL receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities.

Table 4.7.2.9–3 includes the average, maximum, and total occupational doses to LLNL workers from operations in 1994. These doses fall within radiological limits (10 CFR 835). Based on a dose-to-risk conversion factor of 400 fatal cancers per 1 million person-rem (4×10^{-4} fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to LLNL workers from operations in 1994 is estimated to be 0.0073.

A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in the *Lawrence Livermore National Laboratory Environment Report-1994* (UCRL-50027-94). The concentrations of radioactivity in various environmental media (e.g., air and water) and in animal tissue in the site region (onsite and offsite) are also presented in the same reference.

TABLE 4.7.2.9–3.—***Doses to the Onsite Worker from Normal Operation at Lawrence Livermore National Laboratory, 1994***

	Onsite Releases and Direct Radiation	
Affected Environment	**Standard**[a]	**Actual**[b]
Average worker (mrem)	None	2.1
Maximally exposed worker (mrem)	5,000	1,300
Total workers (person-rem)	None	18.3

[a] 10 CFR 835. DOE's goal is to maintain radiological exposure as low as reasonably achievable.

[b] LLNL 1994a. The number of badged workers in 1994 was approximately 8,700.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in sections 4.7.2.3 and 4.7.2.4.

Adverse health impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and to achieve compliance with permit requirements. The effectiveness of these controls is verified through the use of monitoring information and inspection of mitigation measures. Health impacts to the public may occur during normal operation at LLNL via inhalation of air containing hazardous chemicals released to the atmosphere by LLNL operations. Risks to public health from ingestion of contaminated drinking water or direct exposure are also potential pathways.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.7.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. These concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to LLNL workers during normal operation may include inhaling the workplace atmosphere, drinking LLNL potable water, and possible other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. LLNL workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm. Therefore, worker health conditions at LLNL are expected to be substantially better than required by standards.

Health Effects Studies. A study involving two groups of children and young adults under the age of 25 who were born in Livermore between 1960 and 1990 and lived in Livermore between 1960 and 1991 found no increased risk of leukemia or non-Hodgkins lymphoma. The study found a 2.4-fold increase in the risk of malignant melanoma in the children and young adults who lived in Livermore between 1960 and 1991 and a 6.4-fold increased risk of malignant melanoma for children born in Livermore between 1960 and 1991. No increased risk of any other type of cancer was found.

A joint study conducted by the California Department of Public Health and LLNL reported 19 cases of malignant melanoma between 1972 and 1977 among LLNL employees (Lancet 1981a: 712-716). No other cancers were increased among LLNL employees from 1969 to 1980 (WJM 1985a:214-218).

Hiatt and Fireman investigated the hypothesis that the increased incidence of malignant melanoma was due to a difference in medical care received by LLNL employees compared to non-LLNL employees of the same geographic area belonging to the same prepaid health plan (LLNL 1984c). The authors concluded that the sustained increase in melanoma incidence at LLNL is associated with an increased likelihood of being biopsied for pigmented skin lesions because the physicians caring for LLNL employees may be more aware of the potential malignancy of pigmented lesions than those caring for non-LLNL employees.

The most recent case-control study of malignant melanoma concluded that there was no association between occupational factors and the increased melanoma diagnosis among LLNL employees (LLNL 1994e). No clear explanation for the increased melanoma among LLNL workers has been provided. Increased awareness and enhanced surveillance are currently suspected. For a more detailed description of the studies and the findings, refer to appendix section E.4.7.

Accident History. Prior to 1960, there were no accidents at LLNL that had offsite impacts. Since 1960, there have been a number of accidents that have resulted in only negligible exposures to the public.

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for most accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with emergency planning, preparedness, and response. The LLNL Emergency Preparedness Plan is designed to minimize or mitigate the impact of any emergency upon the health and safety of employees and the public.

4.7.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and waste management activities for the Livermore Site and Site 300. A more detailed discussion of the ongoing Livermore Site and Site 300 waste management operations and the regulatory setting is provided in appendix section H.2.6.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operation at the Livermore Site and Site 300, and is engaged in several activities to bring its operations into full regulatory compliance. These activities are set forth in negotiated agreements that contain schedules for compliance with applicable requirements and financial penalties for nonachievement of agreed-upon milestones. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

EPA included the Livermore Site on the NPL on July 21, 1987, because of groundwater contamination primarily by solvents containing VOC and fuel hydrocarbons. DOE, EPA, and the State of California entered into a Federal Facility Agreement to serve as the interagency agreement required under CERCLA and *Superfund Amendments and Reauthorization Act* (SARA), Section 120. This Federal Facility

Agreement applies to the Livermore Site only and establishes a procedural framework and schedule for conducting source investigations, continued sampling, monitoring, and remediation of groundwater at the site. The Federal Facility Agreement enhances interagency coordination and cooperation, minimizes duplication of analysis and documentation, expedites remedial actions with a minimum of administrative delays, and establishes a basis for a determination that DOE has completed the CERCLA, RCRA, and state requirements.

Site 300 was placed on the NPL in 1990 because VOCs were discovered in the regional aquifer underlying the site and because of the proximity of the contamination to private drinking water supplies. The EPA and Site 300 authorities agreed to combine RCRA and CERCLA restoration requirements under a single Federal Facility Agreement for Site 300. A Federal Facility Agreement covering cleanup activities at Site 300 was executed on June 29, 1992. This agreement addresses the presence of trichloroethylene (TCE) in soil, rock, and groundwater; HE compounds in the HE Process Area; and tritium in the Pit 7 complex and in the Building 850 Area.

Through its research activities at the Livermore Site and Site 300, LLNL manages five broad waste categories: TRU, low-level, mixed, hazardous, and nonhazardous wastes, some of which are classified. Because there is no TRU waste associated with any of the proposed activities at LLNL, there is no discussion in this PEIS of TRU waste generation and management at LLNL. A discussion of the waste management activities associated with each of these waste categories follows.

Low-Level Waste. In 1994, the Livermore Site generated approximately 181 m^3 (47,800 gal) of liquid and 307 m^3 (403 yd^3) of solid LLW (LLNL 1995i:1). Solid LLW at the Livermore Site consists of gloves, absorbent paper, plastics, glass, and other solid materials contaminated with low-level radioactive materials. Wastewater from retention tank systems that exceeds site radiological discharge limits or any special limits established for that tank, and cannot be treated for discharge or released to the sanitary sewer, is treated as LLW. Smaller quantities of contaminated liquids may be accumulated in various sizes and types of containers. Nonreleasable wastewater in generator retention tank systems is pumped into portable tanks for treatment at the Wastewater Treatment Tank Farm at the Building 514 Facility. At the Area 514 Waste Treatment Facility, containerized and bulk radioactive liquid wastes are transferred into one of the six 7,003 L (1,850 gal) treatment tanks to be treated chemically. These tanks are used to treat both radioactive and mixed waste liquids. Following treatment, a sample is gathered by hazardous waste management personnel and analyzed by a certified analytical laboratory for pH, metals, gross alpha and beta activity, tritium, and other possible contaminants, as necessary (depending on the waste's description). If the review indicates that the contents of a treatment tank are below established sewer discharge limits, the liquid is released to the sanitary sewer.

The precipitate wastes from tank farm chemical treatments are filtered in the Dorr-Oliver unit by creating a filter cake (coating a rotating drum with a slurry of diatomaceous earth), depositing the precipitate on the absorbent filter cake, capturing the filtrate in a tank, removing and packaging the contaminated cake, and then either discharging the liquid filtrate to the sanitary sewer or retreating it. The filter cake is then stabilized. Liquid and solid radioactive wastes are processed or stored at Building 514 and 612 complexes.

In 1994, Site 300 generated approximately 463 m^3 (606 yd^3) of solid LLW (LLNL 1995i:1). Site 300 generates solid LLW from the detonation of test assemblies on firing tables. The debris from the detonation is contaminated with depleted uranium and, in some instances, thorium or tritium. LLW is packaged in approved waste containers and transported for staging on site, pending shipment to the Livermore Site or shipment directly to NTS for disposal.

Mixed Low-Level Waste. In 1994, the Livermore Site generated approximately 51 m^3 (13,470 gal) of liquid and 20 m^3 (26 yd^3) of solid mixed LLW (LLNL 1995i:1). Some of the generated liquid mixed LLW is treated at the Area 514 Wastewater Treatment Tank Farm prior to discharge to the sanitary sewer so that hazardous constituents and radionuclides are removed, and this wastewater can be discharged within the allowable limits of the sewer discharge permit. The residual solids from this treatment process contain such hazardous constituents as coolants and solvents used in machining operations, toxic metals, decontamination solutions, and dyes. Mixed LLW is treated or stored at the Area 514 Wastewater Treatment Tank Farm and Building 612 complexes located in the southeast corner of the Livermore Site. Mixed wastes generated by Site 300 are currently stored and will continue to be stored at the Livermore Site until DOE-approved disposal options are available. These options are outlined in the LLNL Site Treatment Plan. In 1994, Site 300 generated approximately 8 m^3 (2,100 gal) of liquid and 0.37 m^3 (0.48 yd^3) of solid mixed LLW.

Hazardous Waste. The Livermore Site and Site 300 presently operate five hazardous waste management facilities: Area 514, Area 612, Building 693, and Building 233 container storage unit are at the Livermore Site. Building 883 is at Site 300. The Area 514 and Area 612 facilities contain treatment and storage units for hazardous and mixed wastes. The Building 693 facility is currently a container storage unit for hazardous waste and limited flammable mixed waste, pending analysis. The Building 233 container storage unit is currently used to store mixed, low-level, and TRU waste. Building 883 is used for hazardous wastes only.

In 1994, approximately 342 m^3 (90,350 gallons) of liquid and 237 m^3 (310 yd^3) of solid hazardous wastes were generated at the Livermore Site (LLNL 1995i:1). Waste Management Facility operations at the Livermore Site are subject to Federal, state, regional, and local environmental requirements. Hazardous waste operations at the Livermore Site include the safe and proper handling, treatment, packaging, storage, and shipment of all hazardous waste generated by the site. The Livermore Site hazardous waste management units operate under RCRA interim status with an approved Part A Permit that was submitted December 16, 1991. A revised Part A Permit has been submitted to the state, while the Part B application submitted on January 17, 1992, undergoes processing by the State of California. Hazardous wastes are generated by the numerous R&D activities conducted throughout the facilities. Storage areas for nonradioactive and radioactive (or mixed) wastes are located at the Area 612 Facility yard. Wastes that contain PCBs and other wastes regulated by the TSCA are stored in Building 625. The nonradiological hazardous waste consists of ignitable, reactive, corrosive, toxic, and biohazardous waste (such as very dilute carcinogens and small animal carcasses) generated in biomedical and environmental research. Liquid hazardous waste contained in carboys may be pumped into drums that are stored, pending offsite transportation. The solid chemical wastes are packaged in drums and temporarily stored. The waste is then packaged according to DOT regulations. A commercial waste handler transports the liquid and solid hazardous waste drums to RCRA-permitted treatment, storage, and disposal facilities.

Building 693 was constructed in 1987. The California Department of Toxic Substances Control approved operation of this chemical waste storage facility in early 1991 under interim status standards. Building 693 began operation in 1992 and is used to store containerized RCRA-, TSCA-, and California-only regulated waste and limited flammable mixed waste, pending safety analysis.

Liquid waste and wastewaters are accumulated in retention tanks, carboys, or drums at the respective source locations throughout the Livermore Site. There, the materials are sampled and analyzed, and the determined waste contaminant levels are compared to the Livermore Site and city of Livermore discharge limits. If the levels of contaminants are below the regulatory limits, the material is released to the sanitary sewer. Industrial wastewater that contains constituents at concentrations greater than allowed by the city of Livermore discharge limits is managed as hazardous waste.

In 1994, Site 300 generated 111 m^3 (29,320 gal) of liquid and 46 m^3 (60 yd^3) of solid hazardous wastes (LLNL 1995i:1). Hazardous waste generated at Site 300 can be broken down into three general categories: explosives, analytical chemicals, and industrial wastes. The generation of solid and liquid hazardous waste varies with the number and type of experiments being conducted at any given time at Site 300. HE wastes are treated at the Building 829 complex, an open burn facility used for thermal treatment of these wastes. This facility will be operated until a new explosives waste treatment facility is permitted and operational as stated in a 1993 compliance order between LLNL, DOE, and the State of California. Site 300 hazardous wastes are stored in Building 883, a RCRA-permitted storage facility, before transfer to the Livermore Site waste management facilities.

Generally, wastes are stored up to 1 year before shipment to the Livermore Site. Hazardous wastes are shipped through licensed commercial transporters to various offsite commercial RCRA-permitted treatment, storage, and disposal facilities.

The newly redesigned Decontamination and Waste Treatment Facility will replace and upgrade current waste management facilities presently used to process, treat, and store hazardous, radioactive, and mixed wastes. The Decontamination and Waste Treatment Facility would receive Livermore Site-generated medical, hazardous, LLW, and mixed LLW for consolidation, processing, treatment, and packaging before shipment and disposal offsite at commercial RCRA-permitted facilities.

The explosives waste storage facility project will convert five existing explosives storage magazines for the storage of explosives wastes. A new prefabricated metal building, to be located in a previously paved area, will be used for storing explosives-contaminated solid wastes (including packing material, discarded paper, and plastic labware) and ash from thermal treatment processes. Each of the five earth-covered magazines will be capable of storing specified weight limits of explosives, depending on the explosives waste types present.

Nonhazardous Waste. In 1994, the Livermore Site generated approximately 6,425 t (7,082 tons) of solid nonhazardous wastes (LLNL 1995i:1). Solid, nonhazardous wastes generated consisted of paper, plastics, glass, organic, and other wastes. The Livermore Site does not have onsite solid waste disposal facilities. Solid wastes are collected in dumpsters and other similar containers in such a manner as to assure that they do not contain hazardous or radioactive wastes and are transported to the Vasco Road Landfill for disposal.

In 1994, Site 300 generated approximately 315 m^3 (412 yd^3) of solid nonhazardous wastes (LLNL 1995i:1). The sources of solid, nonhazardous waste on Site 300 include office and laboratory refuse, construction debris, and landscape clippings. Solid, nonhazardous waste generated at Site 300 is transported to the Corral Hollow Sanitary Landfill, approximately 4 km (2.49 mi) east of Site 300 on Corral Hollow Road.

Medical wastes generated at the Livermore Site consist of biohazardous waste and sharps wastes. In 1994, approximately 2 m^3 (3 yd^3) of solid medical wastes were generated. Infectious wastes from the Biomedical Sciences Division are autoclaved in Building 365 to sterilize prior to disposal as sanitary waste, while sharps (e.g., needles, blades, and glass slides) waste is sent to an offsite commercial RCRA-permitted incinerator following sterilization.

Medical wastes at Site 300 are generated at the Medical Facility, Building 877. In 1994, approximately 2 m^3 (528 gal) of liquid and 2 m^3 (3 yd^3) of solid medical wastes were generated (LLNL 1995i:1). These wastes are managed in accordance with established LLNL procedures for handling medical wastes and are transported to the Livermore Site, where they are autoclaved at Building 365. The sterilized materials are then disposed of as sanitary waste.

For 1994, the Livermore Site generated approximately 456,000 m^3 (120,460,000 gal) of sanitary wastewater (LLNL 1995i:2). If sanitary wastewater generated by operations exceed permissible discharge limits and is treatable using permitted Livermore Site waste treatment units, the water is processed to meet the release criteria and then monitored as it is discharged to ensure that permissible discharge limits are not exceeded. These wastes enter the city of Livermore's sewer system and are then processed at the city of Livermore Water Reclamation Plant. The treated sanitary wastewater is piped to San Francisco Bay for discharge, except for a small volume that is used for summer irrigation of the municipal golf course adjacent to the Livermore Water Reclamation Plant. Sludge from the treatment plant is disposed of in offsite landfills.

When wastewater is discharged to the sewer system, it combines with sewage from SNL, Livermore. To protect the Livermore Water Reclamation Plant and to minimize any cleanup that might become necessary, the Livermore Site has an onsite sewage diversion and retention system that is capable of containing approximately 775,000 L (200,000 gal) of potentially contaminated sewage until it can be analyzed and appropriate handling methods implemented. If the liquids cannot be processed for discharge, they are packaged for treatment or disposal at an offsite facility. Treatment residues, or solids generated from the treatment process, are also packaged for treatment or disposal at an offsite facility.

In 1994, Site 300 generated approximately 4,420 m^3 (1,167,600 gal) of sanitary wastewater (LLNL 1995i:2). Sanitary wastewater generated within the General Services Area at Site 300 is discharged to an onsite sewer lagoon. Other more remotely located buildings on Site 300 are serviced by septic systems and leach fields. Industrial wastewaters are contained in retention tanks and analyzed, and their proper disposition determined. These wastewaters may be shipped to the Livermore Site for treatment, then discharged to the sanitary sewer system or shipped directly to an offsite treatment and disposal facility. The nonhazardous rinsewater from the HE machining, pressing, and formulation processes are disposed of by surface evaporation from two ponds.

4.7.3 Environmental Impacts

4.7.3.1 *Land Use*

No Action. Under No Action, DOE would continue current and planned activities at LLNL as described in section 3.2.7. No additional land-use impacts are anticipated at LLNL beyond the effects of existing and future activities that are independent of the proposed action.

Management Alternatives

Secondary and Case Fabrication. The secondary and case fabrication alternative at the Livermore Site would use existing facilities, equipment, and infrastructure to support production requirements for the secondary and case fabrication mission. Facilities for this proposed action would require approximately 21,739 m^2 (234,000 ft^2) of floor space, and all operations would be carried out within those facilities. Additional land would not be used to implement the new mission. The proposed secondary and case fabrication activities would be compatible and consistent with existing operations, and LLNL land-use plans and policies. No land-use impacts are expected.

High Explosives Fabrication. The HE fabrication alternative at the Livermore Site would use existing facilities and infrastructure to support the HE feedstock, main charge, and component procurement and fabrication activities. Additional land would not be used to implement the mission. The proposed HE fabrication activities would be compatible and consistent with existing operation and LLNL land-use plans and policies. Land-use impacts are not expected.

Nonnuclear Fabrication. Nonnuclear fabrication and assembly activities for nonnuclear components would be incorporated into existing buildings with mission modification. Modification activities would be limited to upgrades within existing facilities. Additional land would not be used to implement the mission. The proposed nonnuclear fabrication activities would be compatible and consistent with existing operations and LLNL land-use plans and policies. Impacts to land-use are not expected.

Sensitivity Analysis. LLNL would be able to accommodate the high and low case operation for all proposed management alternatives with the base case production facilities. No land-use impacts are expected.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed site for NIF would occupy an estimated 8.1 ha (20 acres) of vacant undeveloped land in the northeast corner of the Livermore Site. The site acreage would account for 11 percent of the land currently designated as available for development inside the Livermore Site boundaries. The project would be located in an area where similar types of research and experimentation activities occur. The proposed NIF would be compatible and consistent with LLNL land-use plans and policies. No impacts to land-use are expected.

Proposed Contained Firing Facility. The proposed CFF would be a modification to the existing B801 Flash X-Ray (FXR) Facility located at Site 300. Approximately 1.2 ha (3 acres) of hillside land adjacent to the present B801 complex would be disturbed during construction of the proposed CFF. The proposed action would be compatible and consistent with existing operations at Site 300 and LLNL land-use plans and policies. Construction and operation of CFF would not result in land-use impacts.

Combined Program Impacts

Livermore Site. Of the four stockpile stewardship and management alternatives proposed for the Livermore Site, existing facilities would be used for three of the alternatives. Additional land would not be used to implement these three missions. The proposed NIF would require clearing 8.1 ha (20 acres) of land for buildings, walkways, and buffer space. An additional 2 ha (4.9 acres) would be temporarily required for a construction laydown area. The total land-use impact from placing all potential Program alternatives at the Livermore Site would be the use of 8.1 ha (20 acres) of undeveloped land for the new NIF mission.

Site 300. Combined Program impacts would be limited to land-use impacts from construction and operation of CFF, which are expected to be negligible.

Potential Mitigation Measures. Additional mitigation measures are not anticipated.

4.7.3.2 *Site Infrastructure*

This section discusses site infrastructure at LLNL for No Action and the modifications needed for actions due to construction and operation of new stockpile stewardship and management facilities. A comparison of site infrastructure and facilities resources needs for No Action and the proposed alternatives is presented in table 4.7.3.2–1.

No Action. This alternative continues the LLNL missions described in section 3.2.7. As shown in table 4.7.3.2–1, the site infrastructure would continue to adequately supply facility requirements. There would be a 12-percent increase in petrochemical (oil) use and a 13-percent increase in natural gas use over current site requirements.

Management Alternatives

Secondary and Case Fabrication. The site infrastructure would require facility improvements to implement this alternative. Table 4.7.3.2–1 shows the total site requirements and the changes over No Action for electricity and fuel to support the secondary and case fabrication mission. Impacts to site energy infrastructure include a 108-percent increase in liquid fuel use and a 4-percent increase in electrical energy and natural gas use over No Action requirements.

High Explosives Fabrication. The site infrastructure would require slight facility improvements to implement this alternative. The changes in LLNL site infrastructure requirements are shown in table 4.7.3.2–1. Impacts to site infrastructure include a 67-percent increase in liquid fuel use over No Action requirements. No other impacts to site infrastructure are expected. This analysis assumes the entire mission is relocated to LLNL. If it is shared with LANL, the impact would be appropriately less.

Nonnuclear Fabrication. As shown in table 4.7.3.2–1, the site infrastructure requirement changes would be small to implement this alternative. Impacts to site infrastructure are not expected.

Sensitivity Analysis. No change in site infrastructure impacts are expected for the high and low production cases for the nonnuclear and HE fabrication alternatives. For secondary and case fabrication, facility upgrades and utility improvements would be required to support the high production case. No changes are expected to meet the low case production scenario.

Stewardship Alternatives

Proposed National Ignition Facility. Table 4.7.3.2–1 shows the energy requirement to support the proposed NIF at LLNL. The LLNL site infrastructure would require slight facility improvements to implement this alternative. Impacts to site infrastructure include a 9-percent increase in electrical energy use, a 33-percent increase in peak electrical load, and a 4-percent increase in natural gas use over No Action requirements. The electric power pool has sufficient capacity margins to accommodate the proposed NIF.

Proposed Contained Firing Facility. As shown in table 4.7.3.2–1, the site infrastructure would require slight facility improvements to implement this alternative. Impacts to site infrastructure include slight increases in electrical energy and liquid fuel use over No Action requirements.

Combined Program Impacts. If all applicable alternatives were to be located at LLNL, the combined impacts would exceed current site resources. The largest impact would be a 179-percent increase in liquid fuel use. Electrical peak load would increase by 40 percent with an associated increase in electrical energy use of 14 percent. Consumption of natural gas would increase by about 8 percent.

Potential Mitigation Measures. No additional mitigation measures for proposed stockpile stewardship and management alternatives at LLNL are anticipated.

4.7.3.3 *Air Quality*

No Action. No Action air quality utilizes estimated air emissions data from operations at the Livermore Site and Site 300 in 2005 assuming continuation of current site missions to calculate pollutant concentrations at or beyond the Livermore Site and Site 300 boundaries. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in appendix table B.3.7–1. Tables 4.7.3.3–1 and 4.7.3.3–2 present the No Action

TABLE 4.7.3.2–1.—***Site Infrastructure Requirements and Changes for Stockpile Stewardship and Management Alternatives at Lawrence Livermore National Laboratory***

Alternative	Electrical: Energy (MWh/yr)	Electrical: Peak Load (MWe)	Fuel: Liquid (L/yr)	Fuel: Gas (m^3/yr)	Fuel: Coal (t/yr)

pollutant concentrations calculated from the 2005 emission rates for the Livermore Site and Site 300, respectively. In this table pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards. Modeled estimates for the 1-hour nitrogen dioxide concentration at the Livermore Site, however, result in a concentration above the applicable standard.

Management Alternatives

Secondary and Case Fabrication. The secondary and case fabrication mission would generate criteria and toxic/hazardous emissions resulting from the operation of the plant boiler, component manufacturing, and chemical processes. Reasonably available control technology would be used to minimize pollutant emissions. This would include using HEPA filters to contain particulate emissions and providing liquid scrubbing prior to HEPA filtration to remove chemical vapors such as nitric acid. Emission rates for criteria and toxic/hazardous pollutants from secondary and case fabrication are presented in appendix table B.3.7–1. Table 4.7.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of secondary and case fabrication.

TABLE 4.7.3.3–1.—*Estimated Concentrations of Pollutants from No Action and Stockpile Stewardship and Management Alternatives at the Livermore Site* [Page 1 of 2]

Pollutant	Averaging Time	Most Stringent Regulations or Guidelines (μg/m³)	2005 No Action (μg/m³)	Secondary and Case Fabrication (μg/m³)	Nonnuclear Fabrication (μg/m³)	National Ignition Facility (μg/m³)	Combined Program Impacts (μg/m³)

[f] No standard.
Source: 40 CFR 50, CA EPA 1993a; LLNL 1995i:1; LLNL 1995j; appendix J.

The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines. Modeled estimates for 1-hour nitrogen dioxide concentration at the Livermore Site, however, are above the applicable standard.

High Explosives Fabrication. Gaseous emissions of criteria and toxic/hazardous air pollutants would be generated from the HE fabrication mission. These emissions would result from open burn/open detonation of nonradioactive scrap HE and HE-contaminated waste, plant boiler operation, cleaning operations using solvents, and formulation and synthesis operations. Emission rates for criteria and toxic/hazardous pollutants from HE fabrication are presented in appendix table B.3.7–1. Table 4.7.3.3–2 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the HE mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

Nonnuclear Fabrication. The primary source of emissions would be fugitive emissions of numerous small amounts of solvents from nonnuclear component fabrication processes. These solvents include acetone, isopropyl alcohol, methyl ethyl ketone, and toluene. Table 4.7.3.3–1 presents the concentrations of toxic/hazardous pollutants resulting from No Action and nonnuclear fabrication. Emission rates of toxic/hazardous pollutants for annual operation of nonnuclear fabrication are presented in appendix table B.3.7–1. Concentrations of pollutants resulting from operation of nonnuclear fabrication added to No Action concentrations are expected to be within Federal and state regulations. Modeled estimates for the 1-hour concentration of nitrogen dioxide at the Livermore Site, however, are above the applicable standard.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the program alternatives at the Livermore Site and Site 300 would result in higher and lower concentrations of criteria and toxic/hazardous pollutants for the high and low case, respectively. The concentrations of pollutants for both cases are expected to be within applicable Federal and state regulations and guidelines. The 1-hour concentrations of nitrogen dioxide at the Livermore Site may result in a concentration above the applicable standard.

Stewardship Alternatives

Proposed National Ignition Facility. Operation of the proposed NIF would generate criteria and toxic/hazardous pollutants resulting from the combustion of boiler fuel for heating, operation of diesel generators, and solvent cleaning processes. The emissions consist of particulate matter, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and volatile organic compounds. Boiler fuel is assumed to be natural gas. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the proposed NIF are presented in appendix table B.3.7–1. Table 4.7.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the proposed NIF. Concentrations of pollutants resulting from operation of the proposed NIF added to No Action concentrations are expected to be within Federal and state regulations. Modeled estimates for the 1-hour concentration of nitrogen dioxide at the Livermore Site, however, are above the applicable standard.

Proposed Contained Firing Facility. It is expected that emissions (such as particulate metal oxides and soot, acid gases, and VOCs) from the proposed CFF operations would be below regulatory limits because of the extensive air scrubbing, filtration, and absorption systems that would be operated in conjunction with the proposed CFF. Resulting emissions from the air control system should then be limited to those such as carbon dioxide, nitrogen, water, and, when tritium is used in the chamber, tritiated water as well as very minor amounts of activated air gas molecules (appendix J).

Combined Program Impacts. The combined impacts to air quality assuming that each of the proposed stockpile stewardship and management alternatives is located at the Livermore Site and Site 300 are small. Tables 4.7.3.3–1 and 4.7.3.3–2 present the Program total concentrations of criteria and toxic/hazardous pollutants derived by adding the contribution from each alternative at each site. The contribution to air pollutants was determined for each alternative independently from each of the other alternatives. Therefore, adding the respective contributions presents a conservative estimate of the combined impacts to air quality since the maximum pollutant concentration for each alternative would not occur at the same time or location at or beyond the site boundary.

Using this conservative estimate of the combined impacts to air quality at the Livermore Site and Site 300, the data indicate that the 1-hour concentration of nitrogen dioxide may result in a concentration above the applicable State of California ambient air quality standard at the Livermore Site. All other criteria and/or toxic/hazardous air pollutants are expected to be within applicable standards.

Potential Mitigation Measures. The reduction of emissions of nitrogen dioxide from the Livermore Site using reasonable available control technology would contribute to the reduction of concentrations of nitrogen dioxide at or beyond the site boundary.

4.7.3.4 *Water Resources*

Environmental impacts associated with the construction and operation of the proposed stockpile stewardship and management facilities at LLNL could affect surface and groundwater resources. The proposed sites for the facilities would be outside the 100-year floodplain. An assessment of the 500-year floodplain would be performed before construction began. A description of the functions to be transferred to LLNL and the facility locations selected to house these activities is presented in sections 3.3 and 3.4. Tables 4.7.3.4–1 and 4.7.3.4–2 present existing surface and groundwater resources and the potential changes to water resources at the Livermore Site and Site 300 resulting from the proposed alternatives. The total site water resource requirements for each alternative, including No Action, are displayed in this table.

Surface Water

No Action. At the Livermore Site, water would continue to be obtained from county and state suppliers described in section 4.7.2.4. No construction would occur under No Action; therefore, no additional construction water would be required or discharged. Current public water usage of 968 MLY (256 MGY) would decrease to 967 MLY (255 MGY) by 2005. Current wastewater discharges to the city of Livermore are expected to increase 56 MLY (14.8 MGY) by 2005.

At Site 300, current wastewater discharges of 4.8 MLY (1.3 MGY) are anticipated to decrease 0.4 MLY (0.1 MGY) by 2005. Adverse impacts to surface water or surface water quality at the Livermore Site or Site 300 are not expected under the No Action alternative.

Management Alternatives

Secondary and Case Fabrication. The estimated 3.0 MLY (0.79 MGY) of public water withdrawals during modifications of the secondary and case fabrication facilities at the Livermore Site would compose no more than a 0.3-percent increase over the projected water use of 967 MLY (255 MGY). The 461 MLY (122 MGY) of treated wastewater effluent would be released to the city of Livermore Water Reclamation Plant during construction; this would be approximately a 15-percent increase over current Livermore Site wastewater discharges of 400 MLY (106 MGY). All discharges would be monitored to comply with NPDES permit and other discharge requirements. To minimize soil erosion impacts, stormwater management and erosion control measures would be implemented. With appropriate controls, adverse impacts to surface water are not expected.

An additional 194 MLY (51.2 MGY) would be required to support three-shift surge operations of the secondary and case fabrication facilities. This is approximately a 20-percent increase over the projected amount of water use. Approximately 102 MLY (27 MGY) of treated wastewater would be released to the city of Livermore Water Reclamation Plant during operations, resulting in a 40-percent increase over projected Livermore Site wastewater discharges. All discharges would be to the city of Livermore sewer system and would be monitored to comply with NPDES permit and other discharge requirements. Adverse impacts to surface water are not expected.

Nonnuclear Fabrication. Public water use of 0.02 MLY (0.005 MGY) during modification of the nonnuclear fabrication facilities at the Livermore Site would comprise less than a 0.1-percent increase over the projected water use of 967 MLY (255 MGY).

TABLE 4.7.3.4–1.—*Potential Changes to Water Resources from Stockpile Stewardship and Management Alternatives at the Livermore Site*

[a] Total water requirements for construction at Site 300 are based on a 1-year time period for HE fabrication and a 2-year time period for CFF.

[b] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharged would be the same as No Action operation.

[c] NPDES permit is required for stormwater.

Note: NA - not applicable; MLY - million liters per year.

Source: LLNL 1995i:1; LLNL 1995j; appendix J.

Approximately 0.02 MLY (0.005 MGY) of treated wastewater effluent would be released to the city of Livermore Water Reclamation Plant during the modification phase. All discharges would be to the city of Livermore sewer system and monitored to comply with NPDES permits and other requirements.

An additional 3.8 MLY (1 MGY) of public water is needed for operating the nonnuclear fabrication facilities. The estimated 462 MLY (122 MGY) of treated wastewater released to the city of Livermore Water Reclamation Plant during operations would be a 1.2-percent increase over projected wastewater discharges. All discharges would be to the city of

Livermore sewer system and monitored to comply with NDPES permit and other discharge requirements. Adverse impacts to surface water are not expected.

High Explosives Fabrication. During construction and operations of these facilities at Site 300, surface, groundwater, public water supply (Hetch Hetchy Reservoir), or a combination of both, could be used to meet water requirements. If reservoir water is used, withdrawals of 91.2 MLY (24.1 MGY) during construction and modifications of the HE facilities would compose no more than 13 percent of the 693 MLY (183 MGY) capacity of the newly constructed tap line to the Hetch Hetchy Aqueduct. The 5.8 MLY (1.5 MGY) of treated wastewater effluent released to the General Service Area leach fields and septic systems during construction would be 48 percent of the wastewater leach fields and septic systems capacity of 12 MLY (3.2 MGY). All discharges would be monitored to comply with NPDES permit and other discharge requirements. To minimize soil erosion impacts to surface waters, stormwater management and erosion control measures would be implemented. Adverse impacts to surface waters are not expected.

An additional 12.2 MLY (3.2 MGY) of treated wastewater would be released to the General Service Area leach fields and septic systems during operations. The additional wastewater represents a 178-percent increase over current wastewater discharges and exceeds the capacity of the leach fields and septic systems by 2 percent. Additional leach fields or modifications to the septic systems would have to be planned to meet the projected discharges. All discharges would be monitored to comply with permit and other discharge requirements.

Stewardship Alternatives

Proposed National Ignition Facility. Constructing the proposed NIF at the Livermore Site would require approximately 3 MLY (0.79 MGY) of water over the 5-year construction period or a 0.3-percent increase in the projected water requirements of 967 MLY (255 MGY). NIF's construction would require a California General Construction Activity Stormwater Permit, which satisfies the requirements of both the NPDES and State of California stormwater regulations. Construction activities would be expected to have minor to negligible effects on water quality, assuming that a stormwater pollution prevention plan is prepared and implemented to minimize soil erosion, sedimentation, and contamination of stormwater. During construction, the additional 0.4 MLY (0.1 MGY) of wastewater generated would be handled by the existing city of Livermore sewer and treatment system. During operation, the proposed NIF would require approximately 152 MLY (40.2 MGY) of additional water, of which 17.9 MLY (4.7 MGY) would be used for domestic purposes. This amount is approximately 16 percent of the projected amount of the Livermore Site's water use. The proposed NIF operation would not exceed water and wastewater utility capacities.

Proposed Contained Firing Facility. Constructing the proposed CFF would require some excavation and terrain sloping. The direction and volume of existing runoff would not be altered by the proposed site work because all earth work would be accomplished within the same micro-drainage area below the division for adjacent watersheds. To minimize soil erosion impacts, stormwater management and erosion control measures would be implemented. Appendix J provides more detailed analyses of the proposed CFF.

Groundwater

No Action. Under No Action, the relatively small amount of groundwater used for irrigation and cooling tower makeup at the Livermore Site would remain the same. At Site 300, projected water use is expected to remain at the current 90 MLY (23.8 MGY) level. The two existing groundwater supply wells in the southeastern portion of the site are the sole source of this water; however, a tap line from the Hetch Hetchy Aqueduct has been constructed with a capacity of 693 MLY (183 MGY) and is expected to be in operation in the near future. It is not known at this time how much Site 300 will rely on this additional water source. No additional impacts to groundwater quality are anticipated since there are no direct discharges to groundwater.

Management Alternatives

Secondary and Case Fabrication. During modification activities and operation of the secondary and case fabrication facilities at the Livermore Site, water would be obtained from the public suppliers described in section 4.7.2.4. There are no plans for withdrawal from groundwater resources. All process, utility, and sanitary wastewater would be discharged to the city of Livermore sewer systems for treatment at the Livermore Water Reclamation Plant. No adverse impacts to groundwater or groundwater quality are expected.

Nonnuclear Fabrication. During modification activities and operation of the nonnuclear fabrication facilities at the Livermore Site, water would be obtained from the public suppliers described in section 4.7.2.4. There are no plans for withdrawal from groundwater resources. All process, utility, and sanitary wastewater would be discharged to the city of Livermore sewer system for treatment at the Livermore Water Reclamation Plant. No adverse impacts to groundwater or groundwater quality are expected.

High Explosives Fabrication. The groundwater used while constructing and modifying the HE facilities would be approximately equal to current groundwater withdrawals of 90 MLY (23.8 MGY) from Site 300. During construction, no wastewater would be discharged directly to the ground. Adverse impacts to groundwater or groundwater quality are not expected.

Operating the facilities would require an additional 58.2 MLY (15.4 MGY), an approximate 65-percent increase over the projected amount of groundwater withdrawn from the aquifer. As previously mentioned, water could also be obtained from the newly constructed tap line connecting Site 300 to the Hetch Hetchy Aqueduct. This new tap line has a supply capacity of 693 MLY (183 MGY). No wastewater would be discharged directly to groundwater. All discharges to the leach fields and septic systems would be monitored to comply with permit and other discharge requirements. Adverse impacts to groundwater or groundwater quality are not expected.

Sensitivity Analysis. Surface water or surface water quality would not be affected by either the low or high case production scenario for stockpile management alternatives at the Livermore Site and Site 300. Groundwater or groundwater quality is not expected to be impacted by the high or low case production scenario for stockpile management alternatives at the Livermore Site or Site 300.

Stewardship Alternatives

Proposed National Ignition Facility. During construction and operation of the proposed NIF facilities at the Livermore Site, water would be obtained from the public suppliers described in section 4.7.2.4. There would be no withdrawal from groundwater resources. All process, utility, and sanitary wastewater would be discharged to the city of Livermore sanitary sewer system for treatment at the Livermore Water Reclamation Plant. No adverse impacts to groundwater or groundwater quality are expected. Appendix I provides a more detailed analysis of the proposed NIF.

Proposed Contained Firing Facility. During construction and operation of the proposed CFF at Site 300, water would either be obtained from groundwater via the two onsite groundwater supply wells or from public water supply (Hetch Hetchy Aqueduct). An additional 1.9 MLY (0.5 MGY) would be required for construction activities and 2.3 MLY (0.60 MGY) for operation of the proposed CFF. These requirements compose less than a 3-percent increase from projected groundwater use. No adverse impacts to groundwater or groundwater quality are expected. Appendix J provides a more detailed analysis of the proposed CFF.

Combined Program Impacts. The combined Program impacts to water resources if each proposed alternative was implemented at the Livermore Site are shown in table 4.7.3.4–1. During construction approximately 973 MLY (257 MGY) of public supply water would be used. Approximately 1,317 MLY (348 MGY) of public supply water would be required for operation of the facilities; this represents a 36-percent increase from the projected water use. Wastewater discharges during construction and operation of the facilities would total 458 MLY (121 MGY) and 582 MLY (154 MGY), respectively. All wastewater would be discharged to the city of Livermore sewer systems. Adverse impacts to both surface water and groundwater quality are not anticipated.

Potential Mitigation Measures. Additional leach fields or modifications to the septic systems would have to be planned in order to meet the projected HE fabrication wastewater discharges. Reclaiming or recycling wastewater would reduce sanitary discharges and minimize the impact on the existing Site 300 sanitary treatment system.

4.7.3.5 *Geology and Soils*

The alternatives proposed for LLNL would have no adverse impact on geological resources described in section 4.7.2.5. Although a relatively high seismic risk exists at LLNL, this would be considered in the design of any new structures. The existing seismic risk does not preclude safe construction, modification, or operation of any proposed facilities. All new functions, with the exceptions of the proposed NIF and CFF, would be accommodated in existing structures. For the management alternatives, LLNL has sufficient warehousing space, parking space, and yard area to accommodate construction area requirements. Control measures would be used to minimize any soil erosion. Potential changes to geology and soils associated with the proposed alternatives at LLNL are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at LLNL. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Secondary and Case Fabrication. Soil disturbance is not expected during modification of existing buildings for the secondary and case fabrication mission at the Livermore Site. Since facilities needed for the secondary and case fabrication mission already exist, only laydown areas for receiving and staging equipment and construction materials are needed. The Livermore Site has sufficient warehousing space and developed yard area to accommodate this requirement. Offices for construction engineering and management would be provided by plant engineering, or trailers would be located adjacent to facilities undergoing modification. Parking for construction workers is available onsite. Adverse soil impacts are not expected. The construction of a 167-m^2 (1,800-ft^2) steel-framed Butler-type building that is needed to provide covered space within the Superblock protected area would not affect geology or soils.

The potential for surface faulting at the Livermore Site is very low (LL DOE 1992c:4-84). Ground shaking is more likely. Based on the seismic history of the area, a high seismic risk exists but should not preclude safe modification and operation of the proposed facilities. Potential sources of future ground motion at LLNL include the major regional faults and the local faults: Greenville, Las Positas, Verona, Corral Hollow, Carnegie, and Williams (LL DOE 1992c:4-83,4-84). The location of the proposed facilities would be evaluated at the Livermore Site during project-specific studies so that these faults and any associated potential ground rupture would be considered in facilities design. All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides. Potential health impacts from accidents associated with geological hazards are discussed in 4.7.3.9.

High Explosives Fabrication. No significant upgrades to either the HE Applications Facility at the Livermore Site or to Site 300 are anticipated should LLNL receive the HE fabrication mission for the Complex. All production operations would be housed within existing buildings, with the exception of a 116-m^2 (1,250-ft^2) facility for conventional HE storage. Soil disturbances during construction of the new storage facility would be minimal with standard construction erosion control measures.

Based on the seismic history of the area, a high seismic risk exists but should not preclude safe modification and operation of the proposed facilities. Potential sources of future ground motion at Site 300 include the major regional faults and the local faults: Greenville, Las Positas, Corral Hollow, Carnegie, Black Butte, and Midway (LL DOE 1992c:4-87). The location of the proposed facilities would be evaluated at LLNL during project-specific studies so that these faults and any associated potential ground rupture would be considered in facilities design. Surface faulting at Site 300 in areas adjacent to the active Carnegie fault is possible (LL DOE 1992c:4-87). However, no HE facilities are located in these areas. The potential for seismically induced ground deformation at Buildings 826, 851, and 854, located on landslide deposits, is considered to be moderate to high (LL DOE 1992c:4-89). All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides.

Nonnuclear Fabrication. All production operations can be housed within existing buildings at the Livermore Site. Material and equipment laydown and parking areas exist, and no additional areas would be required. Adverse soil impacts are not expected. Seismic risks would be similar to the risks associated with the secondary and case fabrication mission.

Sensitivity Analysis. The high or low case operation scenario for the proposed stockpile management alternatives at LLNL would not affect geology or soils.

Stewardship Alternatives

Proposed National Ignition Facility. The construction and operation of the proposed NIF at the Livermore Site would not adversely affect geological resources. The proposed NIF would require the clearing of an estimated 8.1 ha (20 acres) of land for structures, walkways, building access, and buffer space. Soil impacts during construction would be short term and minor with appropriate standard construction erosion and sediment control measures. Net soil disturbance during operation would be less than for construction because areas temporarily used for material and equipment laydown would be restored. Seismic risks would be taken into account during construction and operation of NIF (see appendix I).

Proposed Contained Firing Facility. Construction of the proposed CFF at LLNL would result in minor soil impacts at Site 300 in the vicinity of the B801 complex. About 36,700 m^3 (48,000 yd^3) of soil surrounding the current facility would be excavated and removed to provide space for the new portion of the facility. Approximately 1.2 ha (3 acres) would be permanently disturbed immediately around the B801 complex as a result of necessary slope contouring and construction of the proposed CFF. Soils exposed by project construction, especially on the hillsides, are considered to be moderately vulnerable to erosion; their clay content provides slightly more resistance to erosion than does the high loam content of entisols, which dominate Site 300 soil types. Erosion, if it occurs, would be minor and short term. Erosion of the small hillsides surrounding the proposed project would not be expected beyond one growing season. Cut hillsides would be sloped and, where local geology allows, revegetated (using hydroseeding) to prevent erosion. The direction and volume of existing runoff would not be altered by the proposed site work because all earthwork would be accomplished within the same micro-drainage area below the division for adjacent watersheds. Dust suppression and stormwater pollution prevention (runoff) mitigation technologies would be applied to reduce these impacts (see appendix J).

Existing B801 site slopes are stable. Unconsolidated overburden is only a few feet thick in the area and bedrock dips at a shallow angle (about 5 degrees) to the northeast. However, a recently active landslide deposit has been observed east of the site within about 244 m (800 ft). This landslide is reported to have generated a mudflow that reached the vicinity of the B801 site during a 15-year period prior to 1983. This mudflow appears to have been mitigated by placement of an earthen fill between the flow and the B801 site. Appropriate slope stabilization measures would be taken in the design and construction of graded slopes (see appendix J).

A number of active faults are considered capable of causing strong ground motion at Site 300. The nearest of these faults to Site 300 is the Carnegie-Corral Hollow fault, which crosses the southwest portion of the site. No significant recorded earthquakes have occurred on any of the local faults. The effect of seismic activity at Site 300 is likely to be confined to ground shaking with no surface displacement. Raber and Carpenter have identified the principal seismic hazard at Site 300 as being the potential for strong ground shaking caused by an earthquake on the Greenville fault, located about 8 km (5 mi) west of Site 300 (see appendix J). Facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides.

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives at LLNL are anticipated.

4.7.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species at LLNL. Construction and operation of the HE Fabrication Facility, proposed CFF, and proposed NIF would result in loss of terrestrial habitat and possible impacts to threatened and endangered species. Temporary impacts to wildlife due to noise and human presence during construction are also possible for most of these alternatives.

No Action. Under No Action, the stockpile stewardship missions described in section 3.2.7 would continue at LLNL. There would be no changes to current biotic resource conditions at the site as described in section 4.7.2.6.

Management Alternatives

Secondary and Case Fabrication. The secondary and case fabrication mission at the Livermore Site would require modification of some existing structures and construction of one Butler-style building. New construction would take place within an area of the Livermore Site that is already developed. Temporary construction laydown and parking would utilize existing warehousing and yard area. Wastewater would be discharged to the sanitary sewer system. Except for some temporary disturbance to wildlife during construction of the new building, no adverse impacts to site biotic resources are expected.

High Explosives Fabrication. Most operations associated with the HE fabrication mission at LLNL would be housed within existing buildings within the B827 Area of Site 300. However, an HE storage area would need to be developed. This facility would be located just southeast of the B827 Area. Impacts to biotic resources are not expected from modification activities conducted at existing buildings. The HE storage area would result in the disturbance of about 0.8 ha (2 acres) of grassland. Proper erosion and sediment control measures would reduce the potential for disturbance of habitat adjacent to the construction area. Construction and operation would result in some disturbance to wildlife living in adjacent areas due to noise and human presence. Impacts to wetlands and aquatic resources would not be expected due to the general lack of these resources in the area. The presence of threatened and endangered species in the area to be disturbed is unknown. Preactivity surveys would be required to determine the occurrence of any special status species including the San Joaquin kit fox *(Vulpes macrotis mutica)*, San Joaquin pocket mouse *(Perognathus inoratus)*, western burrowing owl, *(Athene cunicularia hypugea)*, California horned lizard *(Phrynosoma coronatum frontale)*, and American badger *(Taxidea taxus)*.

Nonnuclear Fabrication. Nonnuclear fabrication mission functions would be located in existing buildings at the Livermore Site. No new construction would be required and wastewater would be released through existing NPDES-permitted discharges. The relocation of the nonnuclear fabrication mission to the Livermore Site would not impact biotic resources.

Sensitivity Analysis. Implementation of either a low or high case workload for the stockpile management alternatives would not effect biological resources of LLNL with the exception of those already described for the proposed HE Fabrication Facility.

Stewardship Alternatives

Proposed National Ignition Facility

Terrestrial Resources. The proposed NIF would be sited on an 8.1-ha (20-acre) area of disturbed grassland located within the Livermore Site. Proper erosion and sediment control measures would reduce the potential for disturbance of habitat adjacent to the construction area. Animal species within the disturbed area would be either destroyed or displaced depending upon whether they were able to move from the area. Wildlife may also be disturbed by the increased level of human activity associated with the project.

Wetlands. The proposed NIF site does not contain, nor is it located near, wetlands. Construction and operation of the proposed NIF is not expected to adversely impact this resource. Proper erosion and sediment control measures would reduce the potential of impacting site wetlands.

Aquatic Resources. Because there are no aquatic resources on the proposed NIF site, this resource would not be disturbed by construction. Proper erosion and sediment control measures would reduce the potential of sediment-laden runoff from reaching site arroyos.

Threatened and Endangered Species. Adverse impacts to special status species would not be expected from construction or operation of the proposed NIF due to the lack of suitable habitat and the disturbed nature of the proposed site.

Proposed Contained Firing Facility

Terrestrial Resources. Construction of the proposed CFF would result in the disturbance of approximately 1.2 ha (3.0 acres) of hillside land adjacent to the present Site 300 B801 complex. While some of the area to be developed has been previously disturbed, some land adjacent to B801 would be impacted. Erosion and sediment control measures would reduce the potential for disturbance of habitat adjacent to the construction area. Animal species within the disturbed area would be either destroyed or displaced depending upon whether they were able to move from the area. Wildlife may also be disturbed by the increased level of human activity associated with the project.

Wetlands. Direct disturbance to wetlands from construction would not occur since there are no wetlands located on the site. However, a cattail wetland (resulting from cooling tower discharge), located about 60 m (197 ft) south-southwest of B801, could be affected by sediment runoff. Erosion and sediment control measures would be used to reduce the risk of indirect impacts to this wetland.

Aquatic Resources. There are no aquatic resources on or near the B801 area; therefore, aquatic resources would not be affected by construction or operation of the proposed CFF.

Threatened and Endangered Species. No known Federal- or state-listed endangered plant or animal species are present within the immediate vicinity of the B801 complex. The potential for impacts to the western burrowing owl and American badger from construction and operation of the proposed CFF are considered minimal. Western burrowing owl dens have become established during periods of road construction south of B801 and during long periods of outdoor explosives testing at the present B801 complex; thus, it is unlikely that construction and operation of the new facility would adversely affect this species. American badgers should not be affected due to the relatively small portion of the species' home range (less than 1 percent) that would be occupied by the project, the large amount of unrestricted land at Site 300, and the transient nature of American badgers. Preactivity surveys for special status species (i.e., San Joaquin kit fox, western burrowing owl, and American badger) would be conducted prior to the start of the project and, if found, appropriate mitigation measures would be implemented.

Potential Mitigation Measures. Minimization of the area to be disturbed, revegetation with native species, and implementation of a soil erosion and sediment control plan would help to lessen short- and long-term impacts to terrestrial species and habitats, as well as wetlands in the vicinity of the proposed CFF. Disturbance to wildlife living adjacent to facilities may be minimized by preventing workers from entering undisturbed areas. It may be necessary to survey the site for the nests of migratory birds prior to construction and to avoid clearing operations during the breeding season. If any threatened or endangered species occur on the site, specific mitigation measures would be developed in conjunction with the USFWS.

4.7.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly through ground disturbance, building modifications, visual intrusion of the project to the historic setting or environmental context of historic sites, visual and audio intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. Some cultural and paleontological resources may be affected by the proposed alternatives.

No Action. Under No Action, DOE would continue the existing and planned missions of the Livermore Site and Site 300. Any impacts to cultural or paleontological resources from these missions would be independent of and unaffected by the proposed action.

Management Alternatives

Secondary and Case Fabrication. The secondary and case fabrication mission at the Livermore Site would involve equipment movement, installation, building modification, and the construction of one 167 m^2 (1,800 ft^2) steel framed Butler-style building within the Superblock protected area. No cultural or paleontological resources are known to exist within the proposed area; however, some resources may be affected by the proposed alternative. NRHP-eligible resources would be identified through project-specific surveys, inventories, and evaluations, and any project-related effects would be addressed in tiered NEPA documentation.

High Explosives Fabrication. LLNL maintains most of the facilities necessary for HE fabrication within the B827 area of Site 300. An HE storage area would need to be developed. The proposed facility would be located to the southeast of the B827 area. About 0.8 ha (2 acres) would be disturbed during construction. Site 300 has been surveyed and does contain prehistoric and historic resources. Additional resources may exist in the acreage to be disturbed during construction. Some Native American and paleontological resources may also be affected. Project-specific evaluations and any project-related effects would be addressed in tiered NEPA documentation. No impacts to cultural or paleontological resources are expected. Sharing this mission with LANL would have no effects on cultural or paleontological resources at LLNL.

Nonnuclear Fabrication. The nonnuclear fabrication mission at LLNL would involve equipment movement, installation, and some modification to existing buildings. Some NRHP-eligible historic buildings may be affected under this alternative. NRHP-eligible resources would be identified through project-specific inventories and evaluations, and any project-related effects would be addressed in tiered NEPA documentation. No impacts are expected to prehistoric, Native American, or paleontological resources.

Sensitivity Analysis. The secondary and case, HE, and nonnuclear alternatives high and low case production scenarios would have the same impacts to cultural and paleontological resources as the base case production facilities.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed alternative would require the construction of two buildings and the development of 8.1 ha (20 acres) of currently undeveloped land at the Livermore Site. No prehistoric or historic resources exist on the proposed location for NIF at the Livermore Site. Six to 13 m (2 to 4 ft) of fill cover the proposed location, which is underlain by soils deposited approximately 15,000 years ago. These soils predate the earliest documented human settlement in the area, and it is unlikely that these soils contain prehistoric materials. Paleontological remains have not been recovered from the soils. Consultation is in progress with Native American groups to identify any important cultural resources on the Livermore Site (appendix I).

Proposed Contained Firing Facility. Under this alternative, 36,701 m^3 (48,000 yd^3) of soils surrounding the existing B801 facility at Site 300 would be excavated. A surface survey conducted in 1981 recorded one prehistoric site 394 m (1,300 ft) from the proposed project area. Additional NRHP-eligible prehistoric and historic sites may exist in the area. Should culturally significant materials be encountered during construction, work would stop until the discovery could be evaluated by a qualified archaeologist. Some paleontological resources with moderate research potential exist within Site 300 and may be affected by the proposed action. Consultation is in progress with Native American groups to identify any important cultural resources on Site 300 (appendix J).

Potential Mitigation Measures. If NRHP-eligible resources cannot be avoided through project design or siting, and would result in adverse impacts, then a Memorandum of Agreement would need to be negotiated between DOE, the California SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the California SHPO and the Advisory Council on Historic Preservation, in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific NRHP-eligible sites would be identified during tiered NEPA documentation.

If Native American resources cannot be avoided through project design or siting, then acceptable mitigation measures to reduce project effects on them would be determined in consultation with the affected Native American groups. In accordance with the *Native American Graves Protection and Repatriation Act* and the *American Indian Religious Freedom Act*, such mitigations may include, but would not be limited to, appropriately relocating human remains, planting vegetation screens to reduce visual or noise intrusion, increasing access to traditional use areas during operations, or transplanting or harvesting important Native American plant resources.

Because scientifically important buried paleontological materials could be affected, paleontological monitoring of construction activities and data recovery of fossil remains would be appropriate mitigation measures.

4.7.3.8 *Socioeconomics*

No Action. Under No Action, the existing stewardship R&D missions would remain operational at LLNL. No new employment or in-migration of workers would be required. Projected regional economy and employment levels, population and housing changes, and public finance characteristics are presented in appendix D.

Regional Economy and Employment. Total employment in the regional economic area is projected to increase by about 2 percent annually between 1996 and 2000, and reach approximately 4,621,900 in 2000. Long-range projections show employment growth continuing at this rate until 2020 when annual growth falls to less than 1 percent. Total employment is projected to number 6,555,300 in 2030. No Action employment at LLNL is projected to reach 8,189 by 2005. Unemployment in the regional economic area was 7.6 percent in 1994 and is expected to remain near that level into the near future. Per capita income is projected to increase from approximately $27,215 to $41,570 between 1996 and 2030.

Population and Housing. Annual ROI county and city population and housing growth is projected to average about 2 percent from 1995 to 2000, but then slow to 1 percent between 2000 and 2030. The ROI population is projected to increase from 2,841,200 in 1995 to 4,421,000 in 2030. The total number of housing units is projected to increase from 1,074,200 to 1,671,600 during the same period.

Public Finance. Between 2000 and 2005, all ROI county, city, and school district total revenues are projected to increase at an annual average of less than 1.8 percent. Total expenditures are projected to increase at an annual average of less than 1.4 percent during the same period. These rates of increase should continue until 2030.

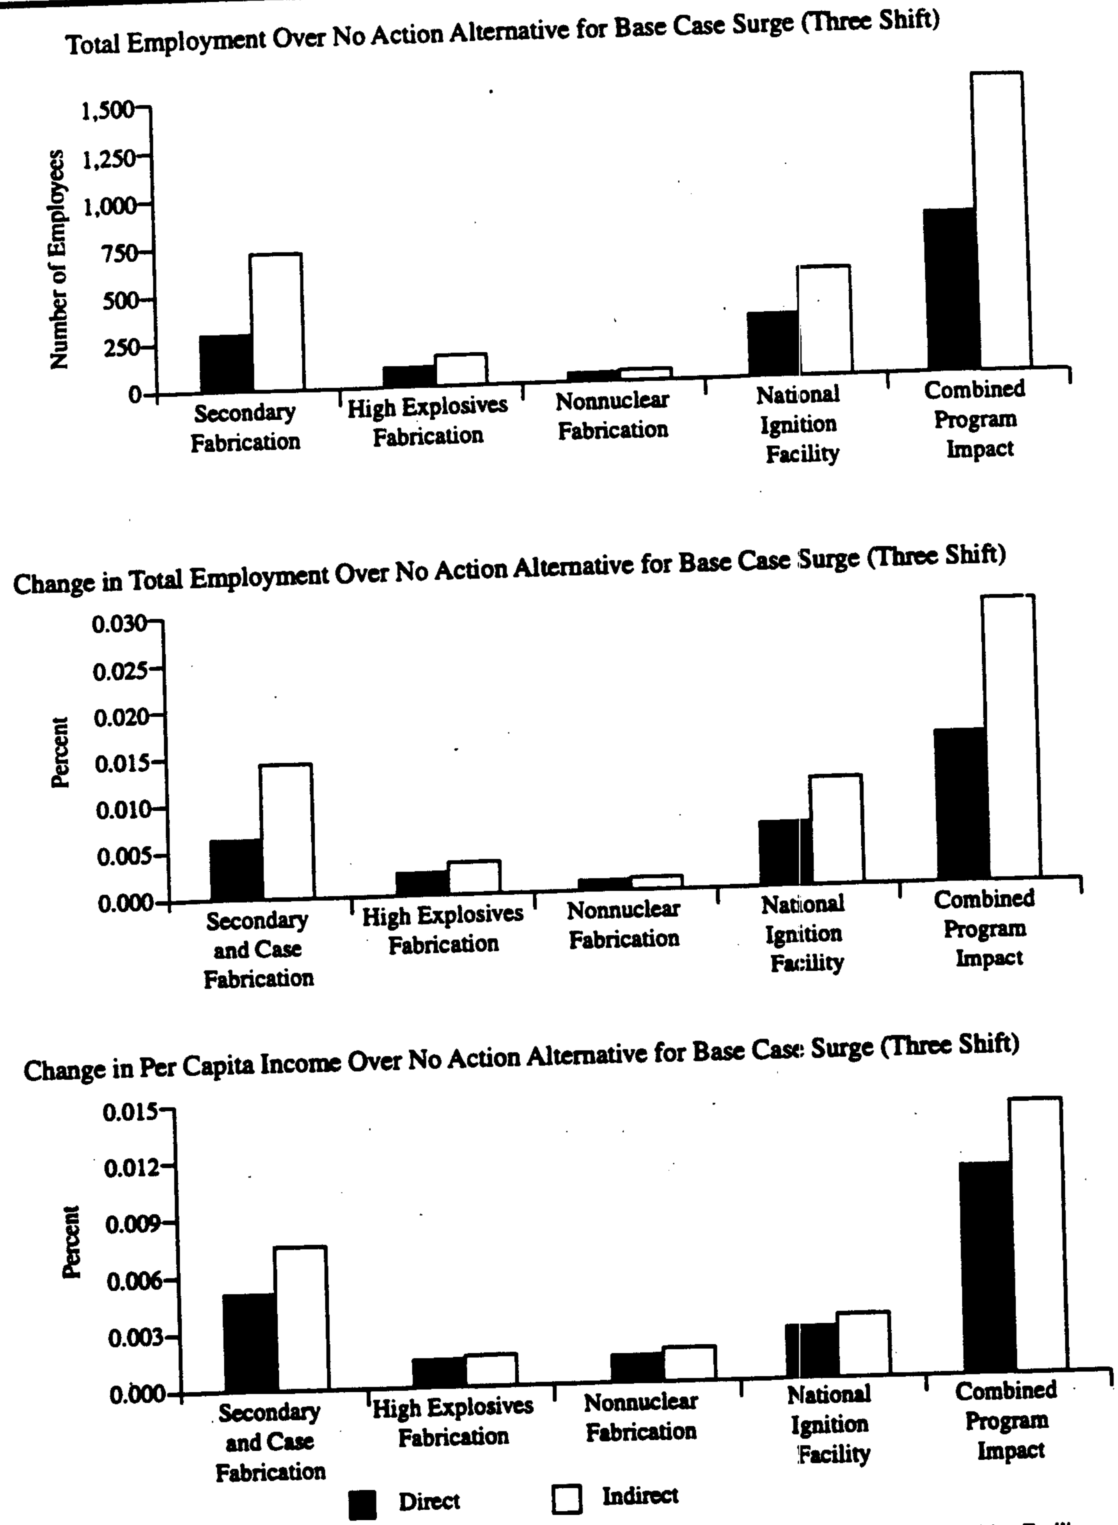
Management Alternatives

Secondary and Case Fabrication

Regional Economy and Employment. During peak construction, the modification and renovation of these facilities would employ 130 workers during 2000, the peak year of construction, and generate an additional 194 indirect jobs in the regional economy. Total employment in the regional economic area would increase by less than 1 percent from the No Action projections. There would be no perceptible change in either the regional economic area per capita income or the unemployment rate.

Although operation of the facility would require a larger and more permanent workforce than construction, resulting increases to the regional economic area's employment and income would still be less than 1 percent. During operation of the facility, the creation of 290 direct jobs at LLNL would generate 722 indirect jobs in other industries in the region. Because so few jobs are generated relative to the large regional economic area, the unemployment rate would remain unchanged from the No Action level of 7.6 percent. See figure 4.7.3.8–1.

Population and Housing. Sufficient available labor within the region eliminates the need for any in-migrant workers to fill direct or indirect jobs created as a result of this alternative; therefore, housing and population would remain the same as under the No Action alternative.



Note: No Action projections are baseline for comparing proposed alternatives; base case surge does not apply to National Ignition Facility operation.

Source: Socio 1996b.

FIGURE 4.7.3.8–1.—*Employment and Income Changes Resulting from Stewardship and Management Alternatives in the Lawrence Livermore National Laboratory Regional Economic Area, 2005.*

Public Finance. Construction and operation of the Secondary and Case Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be attributed to income increases and would be negligible.

High Explosives Fabrication. The HE fabrication alternative would involve the transfer of HE fabrication functions from Pantex to LLNL. A variation of this alternative would divide the HE mission between LANL and LLNL. This latter option would require a smaller workforce at each of the receiving sites than if the entire mission were transferred to one laboratory. The regional economy would still benefit, but on a smaller scale than described below.

Regional Economy and Employment. During peak construction a total of 47 jobs (19 direct and 28 indirect) would be generated in the region. Total employment in the regional economic area would increase by less than 1 percent. There would be no perceptible change in either the regional economic area per capita income or unemployment rate.

Although operation of the facility would have a greater impact on the regional economic area's employment and income because of a larger required workforce, the resulting increases would still constitute a less than 1 percent increase from the No Action alternative. Operations would generate a total of approximately 255 jobs (100 direct and 155 indirect) in the region, too small a number to affect the unemployment rate in such a large urban regional economic area. See figure 4.7.3.8–1.

Population and Housing. Because all direct and indirect jobs created as a result of transferring the HE fabrication mission to LLNL would be filled by the available labor force within the regional economic area, housing and population would remain the same as in the No Action alternative.

Public Finance. Construction and operation of the HE Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Nonnuclear Fabrication

Regional Economy and Employment. During peak modification activities a total of 15 jobs (6 direct and 9 indirect) would be generated. Changes in the regional economic area's employment would be less than 1 percent. There would be no perceptible change in either the regional economic area per capita income or the unemployment rate.

Although operations would have a greater impact on the regional economic area's employment, because of the larger workforce, the resulting increases in both employment and income would still be less than 1 percent. Operation of the facility would generate a total of about 131 jobs (60 direct and 71 indirect) in the region, too small a number to affect unemployment in such a large urban regional economic area. This is shown in figure 4.7.3.8–1.

Population and Housing. Projections indicate that available labor within the regional economic area would be sufficient to fill all direct and indirect jobs created by both modification and operation of the facility. Therefore, housing demand and population growth would remain unchanged from No Action projections.

Public Finance. Construction and operation of the Nonnuclear Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be due to income increases and would be negligible.

Sensitivity Analysis. Construction employment requirements for the low case secondary and case fabrication mission at LLNL are the same as for the base case surge discussed above. Therefore, the socioeconomic impacts on the region from the construction would also be the same. Construction to meet the high case production scenario would require 10 additional workers. However, the socioeconomic effects on the region would remain essentially unchanged from the base case surge level. Employment requirements for operation under the low case production scenario would be less than for the base case surge. Accordingly, the economic benefits would also be smaller than projected for the base case surge level.

High case operation of the Secondary and Case Fabrication Facility would require more workers than base case surge operation. However, the expected changes to the total regional economic area employment would still be less than 1 percent. Some of these additional workers would have to in-migrate to the regional economic area to fill specific employment requirements. Population would increase slightly, as would housing demand. However, these population increases would also be less than 1 percent and would be readily accommodated by projected vacancies within the housing stock.

Construction employment requirements for the high or low case HE fabrication and nonnuclear fabrication missions at LLNL are the same as for the base case surge level discussed above. Therefore, the socioeconomic impacts on the region from construction would also be the same.

During full operation, employment requirements for the base case surge of these alternatives would equal or exceed employment needs for the high and low cases. The region would still benefit economically from the high or low case, but on a smaller scale than from the base case surge due to a smaller workforce.

Stewardship Alternatives

Proposed National Ignition Facility. The following is a summary of the socioeconomic effects of construction of the proposed NIF at LLNL. See appendix I for a more detailed, project-specific discussion.

Regional Economic Impacts. Construction of the proposed NIF would require 470 construction workers during the peak year of construction and would generate an additional 2,400 indirect jobs in the regional economic area. Employment for operation would begin phasing in as the construction phase neared completion. Operation of the facility would require 330 direct workers and would generate an additional 560 indirect jobs in the regional economic area. Construction and operation of the proposed NIF would have only minimal affects on the regional economy and employment. During both phases there would be no perceptible change in the unemployment rate attributable to the proposed project, and changes to per capita income would be less than 1 percent.

Population and Housing. Both construction and operation of the facility would require workers and their families to in-migrate to the ROI. Population increases would total about 1,600 during construction and 350 during operation. This in-migration would cause a slight increase in the housing demand during both periods. However, the demand for additional housing during construction would absorb less than 2 percent of the projected vacant housing stock in the ROI. The increase in demand during operations would be much smaller and have no effect in the housing market.

Public Finance. Both revenues and expenditures would increase as a result of the construction and operation of the proposed NIF. Increases due to construction would peak in 1998 and then decline as construction nears completion in 2002. Increases due to operation of the facility would peak in 2003 and continue through the duration of NIF operation.

Proposed Contained Firing Facility. There are no identified effects over No Action to the socioeconomics of the LLNL regional economic area as a result of the modification activities or operation of CFF.

Combined Program Impacts. If the secondary and case fabrication, HE fabrication, nonnuclear fabrication, and NIF missions were all located at LLNL, the resulting benefits to the regional economy would be greater than from any one mission. However, the changes in regional total employment and per capita income would still be less than 1 percent. This is shown in figure 4.7.3.8–1. There would be sufficient labor available in the projected labor force to fill any employment requirements, and population and housing would remain as projected in the No Action alternative.

Potential Mitigation Measures. Adding any new missions to LLNL would create new jobs and generally benefit the local economy through increased earnings in the ROI. Because the effects on population and housing markets are so slight relative to the size of the region, and are generally perceived to be beneficial, no mitigation measures would be necessary.

4.7.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the radiological and hazardous chemical releases and their associated impacts, which could result from No Action and the proposed alternatives at LLNL. Within this section, impacts resulting from the base case scenario are quantitatively discussed, and a sensitivity analysis of the high and low case scenarios is qualitatively discussed.

Summaries of the prevailing radiological impacts to the public and to workers associated with normal operation at LLNL are presented in tables 4.7.3.9–1 through 4.7.3.9–4. Radiological accident impacts are presented in figure 4.7.3.9–1 and in tables 4.7.3.9–5 through 4.7.3.9–9. The impact assessment methodology is described in section 4.1.9 and further supplementary methodological information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the construction or modification of any facilities to support the Stockpile Stewardship and Management Program. However, limited hazardous chemical releases (e.g., small spills of diesel fuel and from equipment refueling) may occur because of construction activities for the base case scenario and may increase slightly for the high case scenario. The concentration of these releases is expected to be well within the regulated exposure limits and would not result in any adverse health effects.

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge. Furthermore, discharges of wastewater through NPDES-permitted outfalls, which can be attributed to the activities associated with normal operation and operation of the stockpile stewardship and management alternatives at LLNL are expected to be below NPDES limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at LLNL, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). It is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all alternative chemicals, proposed to be added (the increment) at the site, to yield cumulative levels for the site. An HI of ≤1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is ≤ $1x10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $1x10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the population. Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effect Technical Reference* (TTI 1996b).

No Action

Radiological Impacts. Radiological impacts to the public resulting from the No Action alternative are presented in tables 4.7.3.9–1 and 4.7.3.9–2 for the Livermore Site and Site 300, respectively. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational contributions. Total impacts are provided to compare to applicable regulations governing total site operations. To place doses to the public from the No Action alternative into perspective, comparisons are made to natural background radiation. As shown in tables 4.7.3.9–1 and 4.7.3.9–2, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 0.065 mrem for the No Action alternative at the Livermore Site and 0.080 mrem at Site 300. The annual population dose within 80 km (50 mi) in 2030 would be 0.76 person-rem at the Livermore Site and 0.17 person-rem at Site 300.

Total site doses to onsite workers from normal operation for the No Action alternative are presented in table 4.7.3.9–3 for the Livermore Site and table 4.7.3.9–4 for Site 300. The estimated annual dose to the entire facility workforce for this alternative would be 18 person-rem at the Livermore Site and 0.42 person-rem at Site 300.

TABLE 4.7.3.9–1.—*Potential Radiological Impacts to the Public Resulting from Normal Operation of Stockpile Stewardship and Management Alternatives at the Livermore Site*

Affected Environment	No Action Total Site	Secondary and Case Fabrication Three-Shift Operation Total Site[b]	National Ignition Facility Total Site[b]	Combined Program Impacts[a] Total Site[b]

[a] Conservative assumption poses existence of maximally exposed individual at multiple locations simultaneously.
[b] Includes impacts from No Action.
[c] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem/yr from the air pathways, 4 mrem/yr from the drinking water pathway, and 100 mrem/yr from all pathways combined (DOE Order 5400.5).
[d] Natural background radiation levels to average individual is 300 mrem/yr; to the population within 80 km (50 mi) in 2030 it is 2,353,000 person-rem.
Source: LLNL 1994a; LLNL 1995c; appendix I.

Based on the radiological impacts associated with normal operation under the No Action alternative, all resulting doses are within radiological limits and would be well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public resulting from normal operation under No Action at LLNL are presented below. Analyses to support the values presented in this section are provided in appendix table E.3.4–20. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging the sites as having a hazardous chemical health concern. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among sites. The baseline is then used to determine the extent by which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed member of the public at LLNL resulting from normal operation under the No Action alternative would be 1.34, and the cancer risk would be 4.55×10^{-7}. The HI for the onsite worker would be 2.39, and the cancer risk would be 4.53×10^{-6}.

The HIs for the public (1.34) and the onsite worker narrowly exceed the cumulative HQ screening level of 1.0 (the HI) as a result of the total emissions of over 100 of 130 hazardous chemicals listed in appendix table E.3.4–20 under the No Action alternative. Individual OSHA standards for specific effects were not necessarily exceeded. However, if reanalyzed according to organ/tissue specific effects (i.e.,

[a] Conservative assumption poses existence of maximally exposed individual at multiple locales simultaneously.
[b] Includes impacts from No Action.
[c] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem/yr from the air pathways, 4 mrem/yr from the drinking water pathway, and 100 mrem/yr from all pathways combined (DOE Order 5400.5).
[d] Natural background radiation levels: to average individual is 300 mrem/yr; to the population within 80 km (50 mi) in 2030 it is 2,353,000 person-rem.
Source: LLNL 1994a; appendix J.

after second stage analysis), it is very likely that the HIs would prove acceptable. The cancer risks for the onsite worker (4.53×10^{-6}) narrowly exceed the EPA default value as a result of the emissions of 1,1-dichloroethylene, 1,4-dioxane, arsenic, benzene, cadmium, carbon tetrachloride, chloroform, chromium VI, epichlorohydrin, folpet, methylene chloride, nickel, and trichloroethylene.

Management Alternatives

Secondary and Case Fabrication

Radiological Impacts. Radiological impacts to the public resulting from the secondary and case fabrication alternative are presented in table 4.7.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational Livermore Site contributions and from three-shift base case operations for secondary and case fabrication at the site. Total impacts are provided to compare to applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.7.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 1.3 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030

TABLE 4.7.3.9–3.—***Potential Radiological Impacts to Workers Resulting from Normal Operation of Stockpile Stewardship and Management Alternatives at the Livermore Site***

Affected Environment	No Action	Secondary and Case Fabrication Three-Shift Operation	National Ignition Facility	Combined Program Impacts
Involved Workforce[a]				
Average worker dose[b] (mrem/yr)	NA	2.2	30	NA
25-year fatal cancer risk	NA	2.2×10^{-5}	3.0×10^{-4}	NA
Total dose (person-rem/yr)	NA	0.55	8.0	8.6
Noninvolved Workforce[c]				
Average worker dose[b] (mrem/yr)	2.1	2.1	2.1	2.1
25-year fatal cancer risk	2.1×10^{-5}	2.1×10^{-5}	2.1×10^{-5}	2.1×10^{-5}
Total dose (person-rem/yr)	18	18	18	18
Total Site Workforce[d]				
Dose (person-rem/yr)	18	19	26	27
25-year fatal cancers	0.18	0.19	0.26	0.27

[a] The involved worker is a worker associated with operation of the secondary and case fabrication or NIF. The dose presented for the involved workforce is only that incremental dose received from the secondary and case fabrication mission or NIF. The total dose received by the involved workforce would be higher than that received by the noninvolved workforce from these operations. The estimated number of involved workers is 250 for secondary and case fabrication and 267 for NIF.

[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835).

[c] The noninvolved worker is an onsite worker onsite but not associated with operation of the secondary and case fabrication or NIF facilities. The estimated number of noninvolved workers at the Livermore Site is 8,200 for secondary and case fabrication, and for NIF.

[d] The total site workforce is the sum of the number of involved and noninvolved workers. The estimated number of badged workers in the total site workforce at the Livermore Site is 8,200 for No Action, 8,467 for NIF, and 8,450 for secondary and case fabrication.

Note: NA - not applicable.

25-year fatal cancers	4.2×10^{-3}	<0.018	<0.023

[a] The involved worker is a worker associated with operation of CFF. The estimated number of involved workers is three for the proposed CFF.

[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835). The average worker is assumed to receive the same dose at Site 300 as at the Livermore Site complex.

[c] The noninvolved worker is an onsite worker not associated with operation of CFF. The estimated number of noninvolved workers at Site 300 is 200.

[d] The total site workforce is the sum of the number of involved and noninvolved workers. The estimated number of badged workers in the total site workforce at Site 300 is 203.

Note: NA - not applicable.

Source: DOE 1993n:7; appendix J.

would be 1.6 person-rem. Total site doses to onsite workers from normal operation for the secondary and case fabrication mission are presented in table 4.7.3.9–3. The average annual dose to involved workers for this alternative would be 2.2 mrem. The dose to the entire facility workforce (involved workforce) would be 0.55 person-rem. As stated in the methodology section 4.1.9, all worker doses were referenced from the Radiation Exposures for DOE and DOE Contractor Employees 1992 Database which reports doses for similar types of operations. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation of the secondary and case fabrication alternative at the Livermore Site are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–21.

The incremental HI for the maximally exposed member of the public would be 8.97×10^{-3}, and the incremental cancer risk would be zero as a result of the secondary and case fabrication mission at the Livermore Site. The incremental HI for the onsite worker would be 6.16×10^{-3}, and the incremental cancer risk would be zero as a result of the secondary and case fabrication mission.

Total site operations and the incremental effects of the secondary and case fabrication mission would result in the HIs for the public (1.35) and the onsite worker (2.40) narrowly exceeding the cumulative HQ screening level of 1.0 (the HI), but not necessarily exceeding the individual OSHA standards for specific effects. The cancer risks for the public (3.80×10^{-7}) are within the EPA default value of concern of 1×10^{-6}. The cancer risks to the onsite worker (4.53×10^{-6}) narrowly exceed the EPA default value.

The HI for the public and the onsite worker exceeds the cumulative HQ screening level of 1.0 (the HI) as a result of the total emissions of over 100 of 130 hazardous chemicals due to No Action total site operations at LLNL. The individual OSHA standards for specific effects were not necessarily exceeded. However, if reanalyzed according to organ/tissue specific effects (i.e., after second stage analysis), it is very likely that the HIs would prove acceptable. The cancer risks for the onsite worker exceed the EPA default value as a result of the No Action emissions of 1,1-dichloroethylene; 1,4-dioxane; arsenic; benzene; cadmium; carbon tetrachloride; chloroform; chromium VI; epichlorohydrin; folpet; methylene chloride; nickel; and trichloroethylene.

High Explosives Fabrication

Radiological Impacts. There are no radiological impacts associated with this alternative.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation of the HE fabrication alternative at LLNL are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–22.

The incremental HI for the maximally exposed member of the public would be 1.42×10^{-3}, and the incremental cancer risk would be 8.47×10^{-10} as a result of the HE fabrication mission at LLNL. The incremental HI for the onsite worker would be 5.62×10^{-4}, and the incremental cancer risk would be 8.43×10^{-9} as a result of the HE fabrication mission.

Total site operations and the incremental effect of the HE fabrication mission would result in the HIs for the public (1.34) and the onsite worker (2.39) narrowly exceeding the cumulative HQ screening level of 1.0 (the HI), but not necessarily exceeding the individual OSHA standards for specific effects. The cancer risk for the public is within the EPA default value of 1×10^{-6}. The cancer risk to the onsite worker (1.79×10^{-6}) narrowly exceeds the EPA default value.

The HI for the public and the onsite worker exceeds the cumulative HQ screening level of 1.0 (the HI) as a result of the total emissions of over 100 of 130 hazardous chemicals due to No Action total site operations at LLNL. Individual OSHA standards for specific effects were not necessarily exceeded. However, if reanalyzed according to organ/tissue specific effects (i.e., after second stage analysis), it is very likely that the HIs would prove acceptable. The cancer risk for the onsite worker exceeds the EPA default value as a result of the No Action emissions of 1,1-dichloroethylene; 1,4-dioxane; arsenic; benzene; cadmium; carbon tetrachloride; chloroform; chromium VI; epichlorohydrin; folpet; methylene chloride; nickel; and trichloroethylene.

Sharing of the HE fabrication mission with LANL would be expected to reduce emissions of hazardous chemicals by up to 50 percent. Therefore, HI and cancer risk impacts may be reduced up to 50 percent, and the cancer risk could drop to approximately 1×10^{-6}.

Nonnuclear Fabrication

Radiological Impacts. There are no radiological impacts associated with this alternative.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from the normal operation of the nonnuclear fabrication alternative at the Livermore Site are presented below. The HI and cancer risk would remain constant over 25 years of operation provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–23.

The incremental HI for the maximally exposed member of the public would be 4.94×10^{-5}, and the incremental cancer risk is zero as a result of the nonnuclear fabrication alternative at the Livermore Site. The incremental HI for the onsite worker would be 1.20×10^{-6}, and the incremental cancer risk would be zero as a result of the nonnuclear fabrication mission.

Total site operations and the incremental effects of the nonnuclear fabrication mission would result in the HIs for the public (1.34) and the onsite worker (2.39) narrowly exceeding the cumulative HQ screening level of 1.0 (the HI), but not necessarily exceeding individual OSHA standards for specific effects. The cancer risk for the public (4.55×10^{-7}) is within the EPA default value of 1×10^{-6}. The cancer risk for the onsite worker (4.53×10^{-6}) narrowly exceeds the EPA default value.

The HIs for the public and the onsite worker exceed the cumulative HQ screening level of 1.0 (the HI) as a result of the total emissions of over 100 of 130 hazardous chemicals due to No Action and total site operations at the Livermore Site. However, if reanalyzed according to organ/tissue specific effects (i.e., after second stage analysis), it is very likely that the HIs would prove acceptable. The cancer risk to the onsite worker exceeds the EPA default value as a result of the No Action emissions of 1,1-dichloroethylene; 1,4-dioxane; arsenic; benzene; cadmium; carbon tetrachloride; chloroform; chromium VI; epichlorohydrin; folpet; methylene chloride; nickel; and trichloroethylene.

Sensitivity Analysis. Radiological impacts may be subject to certain degrees of variance resulting from either high or low case operations for secondary and case fabrication. For the high case scenario, total impacts to both the public and worker would be similar to the three-shift base case operations. For the low case scenario, impacts to the public and site workforce would be expected to fall within the increment (range) projected between the No Action and the secondary and case fabrication alternatives (less than 1.2 mrem/year to the maximally exposed individual, less than 0.84 person-rem/year to the population, and less than 1 person-rem/year to the total site workforce).

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Operations under the low case scenario for secondary and case, HE, and nonnuclear fabrication are not expected to appreciably affect hazardous chemical emissions at LLNL and, therefore, would not adversely affect the HI impacts and cancer risks for the public and the onsite worker.

Operations under the high case scenario for secondary and case fabrication may result in up to a two- to four-fold increase in the emission of hazardous chemicals at LLNL. Chemical emissions under the high case scenario may substantially increase the HI impact to the public and raise the HI for the onsite worker above the cumulative HQ screening level of 1.0 (the HI), but not necessarily the individual OSHA standards for specific effects. Cancer risks for the public are below the EPA default value, but operations under the high case scenario may increase cancer risks above the EPA default value. Since cancer risks for the onsite worker already exceed the EPA default value, operations under the high case scenario would further contribute to the adverse cancer risk impacts.

Operations under the high case scenario for HE fabrication may result in up to a two-fold increase in the emission of hazardous chemicals at LLNL. Chemical emissions under the high case scenario may increase the HI impact for the public and raise the HI for the onsite worker above the cumulative HQ screening level of 1.0 (the HI), but not necessarily the individual OSHA standards for specific effects. Cancer risks for the public are below the EPA default value, but operations under the high case scenario may increase cancer risks above the EPA default value. Since cancer risks for the onsite worker already exceed the EPA default value, operations under the high case scenario would further contribute to the adverse cancer risk impacts.

Operations under the high case scenario for nonnuclear fabrication may result in up to a 2.5-fold increase in the emissions of hazardous chemicals at LLNL. Chemical emissions under the high case scenario would further adversely affect the HI impact for the public and raise the HI for the onsite worker above the cumulative HQ screening level of 1.0 (the HI), but not necessarily the individual OSHA standards for specific effects. The HI might still be acceptable upon reanalysis according to organ/tissue specific effects. Cancer risks for the public are below the EPA default value, but operations under the high case scenario may adversely affect cancer risks. Since cancer risks for the onsite worker already exceed the EPA default value, operations under the high case scenario would contribute to the adverse cancer risk impacts.

Stewardship Alternatives

Proposed National Ignition Facility

Radiological Impacts. Radiological impacts to the public resulting from normal operation of the proposed NIF for the enhanced option scenario are presented in table 4.7.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational Livermore Site contributions and from enhanced option operations of the proposed NIF at the site. Total impacts are provided to compare to applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.7.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 0.17 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 0.96 person-rem.

Total site doses to onsite workers from normal operation for the proposed NIF are presented in table 4.7.3.9–3. The average annual dose to involved workers for this alternative would be 30 mrem. The dose to the entire facility workforce (involved workforce) would be 8.0 person-rem. The presented noninvolved worker impacts were not modeled due to the unavailability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. No hazardous chemical impacts are expected from the operation of the proposed NIF (see appendix I). Therefore, the HI and cancer risks for the public and the onsite worker were not calculated nor assessed.

Proposed Contained Firing Facility

Radiological Impacts. Radiological impacts to the public resulting from normal operation of the proposed CFF alternative are presented in table 4.7.3.9–2. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational Site 300 contributions and from operations for the proposed CFF at the site. Total impacts are provided to compare to applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.7.3.9–2, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 0.12 mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 0.49 person-rem.

Total site doses to onsite workers from normal operation of the proposed CFF are presented in table 4.7.3.9–4. The average annual dose to involved workers for this alternative would be less than 250 mrem. The dose to the entire facility workforce (involved workforce) would be less than 0.75 person-rem. The presented noninvolved worker impacts were modeled for this alternative due to the availability of certain site-specific information. There may also be small risks to construction workers who are involved with tasks that are in close proximity to potentially contaminated areas.

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. No hazardous chemical impacts are expected from the proposed CFF (see appendix J). Therefore, the HI and cancer risks for the public and the onsite worker were not calculated nor assessed.

Combined Program Impacts. Radiological impacts to the public and to workers from the simultaneous operation of all Livermore Site (and all Site 300) proposed alternatives, respectively, would result in very small increases over the No Action or the largest contributing individual alternative. All Program totals would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Combined Program impacts due to hazardous chemical emissions with operation of the No Action alternative and the incremental emissions incurred by the management alternatives (secondary and case fabrication, HE fabrication, and nonnuclear fabrication) result in a combined HI for the public of (1.13) and a cancer risk of (4.55x10^{-7}). The combined HI for the onsite worker is (2.40), and the combined cancer risk is (4.53x10^{-6}).

The combined Program HI for the public narrowly exceeds the acceptable health level; the HI for the onsite worker increases slightly, but remains narrowly within the acceptable health level. Cancer risks to the public would not increase above the acceptable level of regulatory concern. Cancer risks to the onsite worker would not increase, but would remain narrowly above the EPA default value.

Potential Mitigation Measures. Radioactive airborne emissions to the general population and onsite exposures to workers could be reduced by implementing the latest technology for process and design improvements. For example, to reduce public exposure from emissions, improved building and work area control methods could be used to remove radioactivity from the releases to the environment. Similarly, the use of remote, automated, and robotic production methods are examples of techniques that are being developed which would reduce worker exposure (see section 3.5).

Mitigation measures, such as substituting less toxic solvents and chemicals or modification processes, are proposed to reduce or eliminate the emissions of all hazardous chemicals due to operations under the No Action alternative. Particular attention would be given to 1,1-dichloroethylene, 1,4-dioxane, arsenic, benzene, cadmium, carbon tetrachloride, chloroform, chromium VI, epichlorohydrin, folpet, methylene chloride, nickel, and trichloroethylene.

Facility Accidents. The proposed actions have the potential for accidents that may impact the health and safety of workers and the public. The potential for and associated consequences of reasonably foreseeable accidents that have been evaluated are summarized in this section and are described in more detail in appendix F. The methodology used in the assessment is described in section 4.1.9. A list of documents reviewed for applicable accident data is provided in table F.1.1–1. The potential impacts from accidents, ranging from high-consequence/low-probability to low-consequence/high-probability events, have been evaluated in terms of potential cancer fatalities that may result for noninvolved workers and the public. The risk of cancer fatalities has also been evaluated to provide an overall measure of accident impacts and is calculated by multiplying the accident annual frequency (or probability) of occurrence by the consequences (number of cancer fatalities). Figure 4.7.3.9–1 shows the risk of latent cancer fatalities in the population within 80 km (50 mi) that may result from accidents for the alternatives. Specifically, the curve in the figure shows the probability (vertical axis) that the number of cancer fatalities in the offsite population within 80 km (50 mi) (horizontal axis) will be exceeded. The curve does show the probability of the accident.

In addition to the potential impacts to noninvolved workers and the offsite population, there are potential impacts to involved workers who would be located in the facilities associated with the proposed action. Quantitative statements of these impacts cannot be made until design details are developed further, at which time the number and location of facility workers protective and mitigating features can be estimated to support detailed accident impact analyses. However, depending on the type of accident, facility workers in close proximity to the point of the accident could receive high levels of exposure to radiation with potentially fatal impacts.

No Action. Under the No Action alternative, stewardship would continue to be performed at LLNL with no changes to facilities and operations. Under existing conditions, potential accidents and their consequences have been addressed in facility safety documentation according to requirements in DOE orders.

Management Alternatives

Secondary and Case Fabrication. A set of potential accidents have been postulated for the secondary and case fabrication alternative for which there may be releases of radioactive materials or other hazardous effects that may impact onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The probability distribution showing the range of probable cancer fatalities that may result for the composite set of accidents identified in appendix F is shown in figure 4.7.3.9–1. For example, the probability of a secondary and case fabrication accident causing more than one cancer fatality is approximately 10^{-6} per year. The curve reflects the probability of the accidents occurring. The impacts for the composite set of accidents and their consequences are shown in table 4.7.3.9–5. If an accident were to occur, there would be an estimated 0.063 cancer fatalities in the population within 80 km (50 mi) of the site. A noninvolved worker located 247 m (810 ft) (site boundary) from the accident would have an increased likelihood of cancer fatality of 1.5×10^{-4}. A maximally exposed individual located at the site boundary would have an increased likelihood of cancer fatality of 1.8×10^{-4}. The risks for the combined EBA and BEBA composite set of accidents, reflecting both the probability of the accident occurring and the consequences, are also shown in table 4.7.3.9–5. For the same worker, maximally exposed individual and population, the risks are 8.9×10^{-9}, 1.1×10^{-8}, and 3.8×10^{-6} cancer fatalities per year, respectively. Table 4.7.3.9–5 shows the impacts for EBAs and BEBAs only. There is also a potential for chemical accidents as shown in table 4.7.3.9–6.

High Explosives Fabrication. A set of potential accidents have been postulated for the HE fabrication alternative for which there may be hazardous effects that could impact onsite workers and the offsite population. The potential accidents analyzed are described in appendix F. The chemical impacts of the accidents are shown in table 4.7.3.9–7. The threshold limit value-time weighted average (TLV-TWA) limits represent a time-weighted average limit to a worker for a 40-hour work week. Exposures exceeding these limits could result in a suite of symptoms including liver damage, cyanosis, sore throat, muscular pain, kidney damage, and anemia. Note that the toxic exposures considered here are of a much shorter duration, on the order of minutes.

In addition to the chemical accident impacts, the potential for physical effects from a catastrophic explosion of the entire contents of a process-related

Consequences			
Noninvolved Worker			
Cancer fatality[a]	$1.4x10^{-4}$	$1.4x10^{-3}$	$1.5x10^{-4}$
Risk (cancer fatality per year)	$8.2x10^{-9}$	$6.8x10^{-10}$	$8.9x10^{-9}$
Maximally Exposed Individual			
Cancer fatality[a]	$1.7x10^{-4}$	$1.7x10^{-3}$	$1.8x10^{-4}$
Risk (cancer fatality per year)	$1.0x10^{-8}$	$8.5x10^{-10}$	$1.1x10^{-8}$
Population Within 80 Kilometers [b]			
Cancer fatality[c]	0.06	0.6	0.063
Risk (cancer fatalities per year)	$3.5x10^{-6}$	$2.9x10^{-7}$	$3.8x10^{-6}$

[a] Probability (increased likelihood) of cancer fatality to hypothetical member of the public located at the site boundary or to a noninvolved worker if the accident occurred as a result of exposure to the indicated dose.

[b] For the offsite population of 7,843,061, the average probability of cancer fatality/risk of cancer fatality (per year) for the combined EBA and BEBA is $8.0 x10^{-9}/4.8x10^{-13}$ for the listed alternative.

[c] Number of cancer fatalities in the population out to 80 km (50 mi) as a result of exposure to the indicated dose if the accident occurs.

Note: All values are mean values; BEBA - beyond evaluation basis accidents; EBA - evaluation basis accidents.

Source: Results shown are derived from model accident analyses.

TABLE 4.7.3.9–6.—*Impacts of Chemical Accidents for Secondary and Case Fabrication at Lawrence Livermore National Laboratory*

Accident Description	Accident Frequency (Per Year)	IDLH	TLV-STEL	TLV-TWA	Concentration to: Noninvolved Worker (mg/m^3)	Concentration to: Individual at Site Boundary (mg/m^3)	Potential Impacts of Exceeding: IDLH Limits[a]	Potential Impacts of Exceeding: TLV Limits[a]

[c] Offsite individual exposed to concentration exceeding limit.
[d] Individual at 560 meters from boundary (individual at boundary is exposed to concentrations of roughly 3 times lower).
Note: TLV - threshold limit value; TWA - time-weighted average; TATB - triaminotrinitrobenzene; TNT - trinitrotoluene.
Source: Derived from accident analyses (see appendix F).

building, which would have a probability of occurrence less than the explosion considered above (i.e., less than 1.0×10^{-6} per year), was also considered. The quantity of HE detonated could range up to 18 t (19.8 tons); the blast pressure could result in death (up to 40 m [131 ft]), lung damage (80 m [262 ft]), thoracic injury (130 m [427 ft]), and eardrum rupture (160 m [525 ft]) depending on an individual's distance from the accident. Injuries could also result from glass breakage and building debris

Nonnuclear Fabrication. The impacts of potential accidents associated with nonnuclear fabrication activities at LLNL were previously addressed in *Nonnuclear Consolidation Environmental Assessment* (DOE/EA-0792, June 1993) where it was determined that the then current accident profile would not change as a result of the relocation of nonnuclear fabrication functions to LLNL. The present proposed action to transfer the nonnuclear fabrication mission to LLNL is not expected to change the accident profile that presently exists at the site.

Stewardship Alternatives

Proposed National Ignition Facility. Studies of potential accidents associated with the proposed NIF have been performed. A bounding accident was postulated based on a preliminary hazard analysis. The bounding accident assumes a severe earthquake of 1 g horizontal ground acceleration occurring during a maximum-credible-yield fusion experiment. Beamlines leaking into the target chamber and building structures other than the target area building would fail during the postulated earthquake. The collapsed beamlines and building structures would provide a pathway for acute atmospheric releases of tritium in the tritium processing system, activated gases in the air, and activated material in the target chamber.

The frequency of this severe earthquake is estimated at 1×10^{-4} per year. The joint frequency of the severe earthquake during the maximum-credible-yield fusion experiment would be less than 2×10^{-8} per year. The radiological impacts of the accident, presented in table 4.7.3.9–8, were estimated using the GENII computer code.

Proposed Contained Firing Facility. Studies of potential accidents associated with the proposed CFF have been performed. The reasonably foreseeable accident scenarios that could produce the greatest potential impacts are the following:

TABLE 4.7.3.9–8.—***Consequences and Risk of the Bounding Proposed National Ignition Facility Accident at the Livermore Site***

Health Impact	Conceptual Designs	Enhanced Baseline Option
Workers Onsite		
Dose (person-rem)	29	49
Fatal cancers	0	0
Risk (cancer fatalities per year)	2×10^{-10}	4×10^{-10}
Maximally Exposed Individual		
Dose (person-rem)	0.1	0.2
Fatal cancers	5×10^{-5}	8×10^{-5}
Risk (cancer fatality per year)	1×10^{-13}	2×10^{-13}
Population Within 80 Kilometers		
Dose (person-rem)	260	440
Fatal cancers	1.3×10^{-1}	0
Risk (cancer fatalities per year)	3×10^{-9}	4×10^{-9}

Source: Appendix I.

- Scenario 1: Accidental detonation of a test of a 60-kg (132-lb) charge of explosives at the B801 firing table. (Applicable to the No Action alternative.)

- Scenario 2: Accidental detonation of a 60-kg (132-lb) test that could contain up to 20 mg (200 curies) of tritium with dispersal through an unsecured blast door during final preparation. No neutron generation potential would exist because blast doors would be closed before any accident scenario that would involve neutron generation (misfire). (Applicable to either B801 or B851 alternatives.)

One beyond design basis accident configuration is considered as follows:

- Scenario 3: Same test configuration as Scenario 2, but the planned detonation takes place yielding the potential for neutron generation: accidental rupture of the CFF Firing Chamber occurs. (Applicable to either B801 or B851 alternatives.)

The impacts to involved workers for each accident scenario would probably be fatal injuries from blast effects due to peak overpressure and debris, but there would be no injury offsite to members of the public. No damage to current buildings offsite or in other areas of Site 300 would be expected. Projected radiation effects for the three scenarios are shown in table 4.7.3.9–9.

4.7.3.10 *Waste Management*

This section summarizes the impacts on waste management at the Livermore Site and Site 300 under No Action and for each of the stockpile stewardship and management alternatives. There is no spent nuclear fuel, HLW, or TRU waste associated with secondary and case fabrication, HE fabrication, nonnuclear fabrication, the proposed CFF, or the proposed NIF; therefore, there is no further discussion of these wastes at LLNL. Table 4.7.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for the Livermore Site. Table 4.7.3.10–2 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action for Site 300. Projections for No Action were derived from 1994 environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated is identifiable. The projection does not include wastes from future, as yet uncharacterized, environmental restoration activities.

Table 4.7.3.10–3 provides the total estimated operational waste volumes projected to be generated at LLNL as a result of the secondary and case fabrication, nonnuclear fabrication, and the proposed NIF alternatives. Table 4.7.3.10–4 provides the total estimated operational waste volumes projected to be generated at Site 300 as a result of the HE fabrication and proposed CFF alternatives. The net increase or decrease over No Action is provided in the table in parentheses. The waste volumes generated from the various alternatives and the resultant waste effluent used in the impact analysis can be found in table 3.4.4.4–3 for secondary and case fabrication, table 3.4.2.4–3 for nonnuclear fabrication, table 3.4.5.4–3 for HE fabrication, table 3.3.2.2–3 for NIF, and table 3.3.1.2–3 for CFF. Facilities that would support the Stockpile Stewardship and Management Program would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act*, RCRA, and other applicable statutes as outlined in appendix section H.1.2.

No Action. Under No Action, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at LLNL from the missions outlined in section 3.2.7. LLNL would continue to treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

Liquid LLW would be neutralized and solidified and the treated wastewater discharged to the city of

Liquid	2[d]	570 (+568)	2[d] (+0)	570 (+568)
Solid	2[d]	38 (+36)	2[d] (+0)	38 (+36)

[a] No Action volumes are from table 4.7.3.10–2 and are based on 50 tests per year at the current B801 Complex.

[b] Volumes for HE fabrication are from table 3.4.5.4–3 and are based on surge operations (three shifts).

[c] Volumes for CFF are from table 3.3.1.2–3 and are based on 100 tests per year. Wastes generated from the B801 Complex, appendix table J.5.2.2–1, were subtracted since this facility would not operate if CFF was constructed.

[d] Medical waste.

Note: Waste generation volumes were rounded to three significant figures. Waste effluent volumes are found in sections 3.3 and 3.4.

Livermore sanitary sewer. Solid LLW would be compacted, packaged, and stored for shipment to NTS. Hazardous waste would be packaged and shipped offsite to RCRA-permitted treatment, storage, and disposal facilities. Liquid mixed waste would undergo neutralization/pH adjustment, oxidation/reduction, precipitation, chelation/flocculation, and filtration in the Area 514 Wastewater Treatment Tank Farm, Area 514 Wastewater Filtration Unit, and Building 513 Solidification Unit. Both liquid and solid mixed waste would be treated and disposed of according to the LLNL Site Treatment Plan, which was developed pursuant to the *Federal Facility Compliance Act* of 1992. The resulting waste would then be stored in a RCRA-permitted facility in DOT-approved containers until it is shipped to an offsite DOE disposal facility. Some of this waste would be placed in interim storage until new technologies for treatment and disposal are identified and evaluated. Liquid nonhazardous sanitary wastes would be pretreated and discharged to the city of Livermore sanitary sewer system. Solid nonhazardous sanitary waste would be disposed of in a permitted offsite sanitary landfill sized to handle projected future waste volumes.

Under No Action, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at Site 300 from the missions outlined in section 3.2.7. Site 300, in conjunction with LLNL, would continue to treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities.

LLNL does not anticipate the future generation of mixed waste at Site 300. If mixed waste is generated at Site 300, the mixed waste would be limited to storage periods of 90 days or less. The mixed waste would then be taken either to LLNL for treatment and/or long-term storage or sent to commercial facilities for treatment and/or disposal. Site 300 LLW, including the gravel from firing table operations, would be packaged in approved waste containers and transported to Building 804 for staging, pending shipment to LLNL or shipment directly to NTS for disposal. Site 300 would hold hazardous waste before it is transferred to the Area 612 facility at LLNL for treatment, storage, and disposal or send it directly offsite to RCRA-permitted treatment, storage, and disposal facilities. Sanitary wastewater generated within the General Services Area at Site 300 would be discharged to an onsite sewer lagoon. Other more remotely located buildings on Site 300 would be serviced by septic systems and leach fields. Site 300 industrial wastewaters would be contained in retention tanks and analyzed to determine their proper disposition. These wastewaters could be shipped to LLNL for treatment and discharged to the sanitary sewer system or shipped directly to an offsite treatment and disposal facility. Solid waste generated at Site 300 would be transported to a permitted offsite sanitary landfill.

Management Alternatives

Livermore Site

Secondary and Case Fabrication. The Secondary and Case Fabrication Facility would not generate any TRU waste. Following treatment and volume reduction, 304 m^3 (398 yd^3) of solid LLW would be packaged in approved waste containers for staging, pending shipment directly to NTS for disposal. With no onsite LLW disposal capability, LLNL would require approximately 18 additional LLW shipments per year to NTS. Assuming a land usage factor of 6,000 m^3/ha (3,180 yd^3/acres), 0.05 ha/yr (0.13 acres/yr) of LLW disposal area at NTS would be required.

The LLNL Site Treatment Plan for mixed waste was developed pursuant to the *Federal Facility Compliance Act*. The mixed waste streams identified at LLNL have been combined into 10 treatability groups, each with a preferred treatment option. The type of mixed wastes generated by secondary and case fabrication would fit into one of the established 10 treatability groups and would not require the creation of new treatability groups or new preferred treatment options. The 550 m^3 (145,000 gal) annual generation of liquid mixed wastes and 12 m^3 (16 yd^3) annual generation of solid mixed wastes may impact the available storage capacity of the main areas for future mixed waste storage in RCRA-permitted hazardous waste management units. Existing and planned mixed waste treatment at LLNL would be adequate to handle the increased volume. Additional staging capacity for 540 m^3 (143,000 gal) of liquid and 18 m^3 (24 yd^3) of solid hazardous wastes while awaiting shipment to offsite RCRA-permitted treatment and disposal facilities may be needed. Minimal impacts would result from the 102,000 m^3 (26.9 million gal) of liquid nonhazardous sanitary waste, which would be collected and routed to the sanitary and industrial waste treatment plant prior to discharge to the city of Livermore sanitary sewer system. Minimum impacts would result from the 4,320 m^3 (5,650 yd^3) of solid nonhazardous sanitary waste that would be disposed of in offsite industrial and sanitary landfills.

Nonnuclear Fabrication. The Nonnuclear Fabrication Facility would not generate any TRU waste, LLW, or mixed LLW. The generation of 7 m^3 (1,950 gal) of liquid hazardous wastes would have a small impact on LLNL's waste management infrastructure. The toluene/methanol waste stream would be recycled by distillation. The distillation bottoms (0.2 m^3 [0.26 yd^3]) would be shipped offsite to a RCRA-permitted disposal facility as solid hazardous waste. The remaining 3 m^3 (905 gal) of liquid hazardous waste would be staged in the onsite hazardous waste accumulation area and shipped to offsite RCRA-permitted treatment, storage, and disposal facilities. Minimal impacts would result from the 5,770 m^3 (1,530,000 gal) of liquid sanitary waste that would be collected and routed to the sanitary and industrial waste treatment plant. Minimal impacts would result from the 64 m^3 (83 yd^3) of solid nonhazardous sanitary waste that would be disposed of in offsite industrial and sanitary landfills after volume reduction.

Site 300

High Explosives Fabrication. The HE Fabrication Facility at Site 300 would not generate any TRU or mixed LLW. Minimal to zero quantities of LLW would be generated. If generated, these wastes would be packaged in approved waste containers and transported to Building 804 for staging, pending shipment to LLNL, or they would be shipped directly to NTS for disposal. Minimal impacts would result from the 3 m^3 (920 gal) of liquid hazardous waste and 54 m^3 (70 yd^3) of solid hazardous waste, which could be staged in the onsite hazardous waste accumulation area up to 1year before being shipped to LLNL or to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Existing infrastructure should be able to handle the 7,270 m^3 (1,920,000 gal) of liquid sanitary waste. Minimal impacts would result from the 55 m^3 (72 yd^3) of solid nonhazardous sanitary waste that would be disposed of in offsite industrial and sanitary landfills.

Sensitivity Analysis. The waste volumes generated from the secondary and case, nonnuclear, and HE fabrication facilities required to support a larger stockpile level (high case) operating on a single-shift basis are bounded by the base case under surge operations. There would be no additional waste management impacts associated with these fabrication facilities that would support a high case stockpile operating at a single shift. The volumes generated from these fabrication facilities required to support a low case stockpile would be reduced by a factor of at least three.

Stewardship Alternatives

Livermore Site

Proposed National Ignition Facility. The proposed NIF would not generate any TRU waste. The 0.7 m^3 (185 gal) of liquid LLW could be batch treated in the Area 514 Wastewater Treatment Tank Farm with minimal impact. The 3 m^3 (4 yd^3) of solid LLW would be packaged in approved waste containers and staged, pending shipment directly to NTS for disposal. Assuming a land usage factor of 6,000 m^3/ha (3,180 yd^3/acres), less than 0.0005 ha/yr (0.001 acres/yr) of LLW disposal area at NTS would be required.

The LLNL Site Treatment Plan for mixed waste was developed pursuant to the *Federal Facility Compliance Act*. The mixed waste streams identified at LLNL have been combined into 10 treatability groups, each with a preferred treatment option. The type of mixed wastes generated by NIF would fit into one of the established 10 treatability groups and would not require the creation of new treatability groups or new preferred treatment options. The annual generation of 2 m^3 (528 gal) of liquid and 0.3 m^3 (0.4 yd^3) of solid mixed wastes would have a negligible impact on the available storage capacity of the main areas for future mixed waste storage in RCRA-permitted hazardous waste management units. Minimal impacts would result from the 2 m^3 (528 gal) of liquid hazardous waste and 8 m^3 (10 yd^3) of solid hazardous waste, which would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Additional sanitary wastewater treatment capacity may be required to accommodate the 17,900 m^3 (4.72 million gal) of liquid nonhazardous sanitary waste that would be routed to sanitary wastewater treatment facilities prior to discharge to existing municipal sanitary wastewater systems. Minimal impacts would result from the 6,050 m^3 (7,910 yd^3) of solid nonhazardous sanitary waste that would be disposed of in offsite industrial and sanitary landfills after volume reduction.

Site 300

Proposed Contained Firing Facility. The proposed CFF would not generate any TRU waste. CFF would reduce the annual generation of solid LLW from the No Action alternative by 16 m^3 (21 yd^3). The 90 m^3 (117 yd^3) of solid LLW from CFF would be packaged in approved waste containers and staged, pending shipment directly to NTS for disposal. Six LLW shipments per year to NTS and 0.016 ha/yr (0.04 acres/yr) of LLW disposal area at NTS would be required.

The LLNL Site Treatment Plan for mixed waste was developed to comply with the *Federal Facility Compliance Act*. The mixed waste streams identified at LLNL have been combined into 10 treatability groups, each with a preferred treatment option. The type of mixed wastes generated by CFF would fit into one of the established 10 treatability groups and would not require the creation of new treatability groups or new preferred treatment options. The 10 m^3 (14 yd^3) annual generation of solid mixed waste would have a negligible impact on the available storage capacity of the main areas for future mixed waste storage in RCRA-permitted hazardous waste management units.

CFF would reduce the generation of solid hazardous wastes by 4 m^3 (5 yd^3) from the No Action alternative. The 6-m^3 (1,560-gal) increase in the generation of liquid hazardous wastes would have a minimal impact. Hazardous wastes would be stored in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. The additional 284 m^3 (75,000 gal) of liquid sanitary wastes would have a negligible impact on the existing sanitary wastewater system. Negligible impacts would also result from the 13 m^3 (17 yd^3) of additional solid sanitary wastes.

Combined Program Impacts

Livermore Site. If all the stockpile stewardship and management alternatives listed in table 4.7.3.10–3 were located at the Livermore Site, the impacts from LLW, mixed LLW, and hazardous wastes would be similar to those discussed for the secondary and case fabrication alternative. The 126,000 m^3 (33.2 million gal) of liquid sanitary wastes would not be expected to impact the sanitary wastewater treatment system, as adequate capacity exists to handle this increase. After volume reduction, approximately 10,400 m^3 (13,600 yd^3) of solid sanitary waste would require disposal. This increase could require the construction of a new sanitary landfill sooner than currently planned.

Site 300. If all the stockpile stewardship and management alternatives listed in table 4.7.3.10–4 were located at Site 300, the impacts from LLW, and mixed LLW would be identical to those identified for the CFF alternative. The impacts from hazardous and nonhazardous wastes would be similar to the HE fabrication alternative.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies, thereby further reducing or mitigating waste and waste management impacts. Pollution prevention and waste minimization would be considered in determining the final actions of the Stockpile Stewardship and Management Program at the Livermore Site and Site 300.

4.7.3.11 *Environmental Justice*

As discussed in section 4.14, any impacts to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.7.3.9, which describes public and occupational health impacts from normal operation, shows that potential chemical air emissions and releases narrowly exceed the generally accepted threshold of regulatory concern. This information is based on the conservative programmatic assumptions and modeling detailed in appendix E. Any adverse human health or environmental impacts that may occur would affect people living within communities located near LLNL. The analysis of the demographic data presented in appendix D for the communities surrounding LLNL indicates that if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.8 Sandia National Laboratories

SNL is headquartered in Albuquerque, NM, and maintains facilities in other locations. The facilities discussed in this document refer only to the Albuquerque location, which is adjacent to the city of Albuquerque as shown in figure 4.8–1. The site shown in figure 4.8–2 is approximately 10.5 km (6.5 mi) east of downtown Albuquerque. SNL consists of 1,150 ha (2,842 acres) on Kirtland Air Force Base. An additional 6,072 ha (15,003 acres) are provided to DOE through ingrant land from Kirtland Air Force Base, the State of New Mexico, and the Isleta Pueblo to conduct operations.

4.8.1 Description of Alternatives

There are no facilities at SNL that would be phased out as a result of any of the proposed alternatives discussed in the PEIS.

No Action. SNL would continue to perform the missions described in section 3.2.8.

Stockpile Management Alternatives. The majority of the nonnuclear fabrication mission could be located at SNL. A portion of the nonnuclear fabrication mission would also be shared with LANL and possibly LLNL.

Stockpile Stewardship Alternatives. The proposed NIF could be located at SNL.

4.8.2 Affected Environment

The following sections describe the affected environment at SNL for land resources, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure, radiation and hazardous chemical environment, and waste management conditions, at SNL are described.

4.8.2.1 *Land Resources*

SNL is located approximately 10.5 km (6.5 mi) east of downtown Albuquerque, NM (figure 4.8–1). Generalized land uses at SNL and in the vicinity are shown in figure 4.8.2.1–1. There are no prime farmlands on SNL. The affected environment consists of two technical areas at the northern end of the site, designated Technical Area I and Technical Area II (figure 4.8–2).

Technical Area I is the most intensively developed of the SNL technical areas, containing administrative and support facilities; project engineering, research, and component development activities; neutron generator production; and special laboratories and shops.

The Kirtland Air Force Base cantonment, the most heavily developed area on the base, is adjacent to Technical Area I. U.S. Air Force-accompanied base housing is located west and north of Technical Area I. Various Kirtland Air Force Base facilities and operations, including flight operations, are located west of Technical Area I. U.S. Air Force flight operations are collocated with the civilian commercial aircraft operations of Albuquerque International Airport. The runway and taxiways are owned and managed by the city of Albuquerque (SN USAF 1990a:3.6-1). The airport Accident Potential Zone 1 extends east beyond the runway clear zone to the edge of the Technical Area I boundary, with Accident Potential Zone 2 extending across Technical Area I. Flight operations of the airport are regulated by the Federal Aviation Administration, which does not use Accident Potential Zones.

The U.S. Air Force granted an exemption for the development of an all new Air Installation Compatible Use Zone study at Kirtland Air Force Base. The base, however, monitors all development in its vicinity to ensure compatibility with base flying missions. The U.S. Air Force Air Installation Compatible Use Zone Land Use Guidelines do not recommend uses within Zone 1 and Zone 2 that are highly labor intensive; that involve explosive, fire, toxic, corrosive, or other hazardous characteristics; or that occupy high-density offices.

Except for vacant land on both sides of Tijeras Canyon east of Technical Area I and some unmanned utility facilities, the land north of SNL is part of the urbanized city of Albuquerque. The urban land use consists of a mixture of residential, commercial, industrial, institutional, and various supporting public uses. The closest residence to the Kirtland Air Force Base boundary is approximately 6 m (20 ft) to the north. An industrial park is currently being developed immediately east of the Eubank Gate and

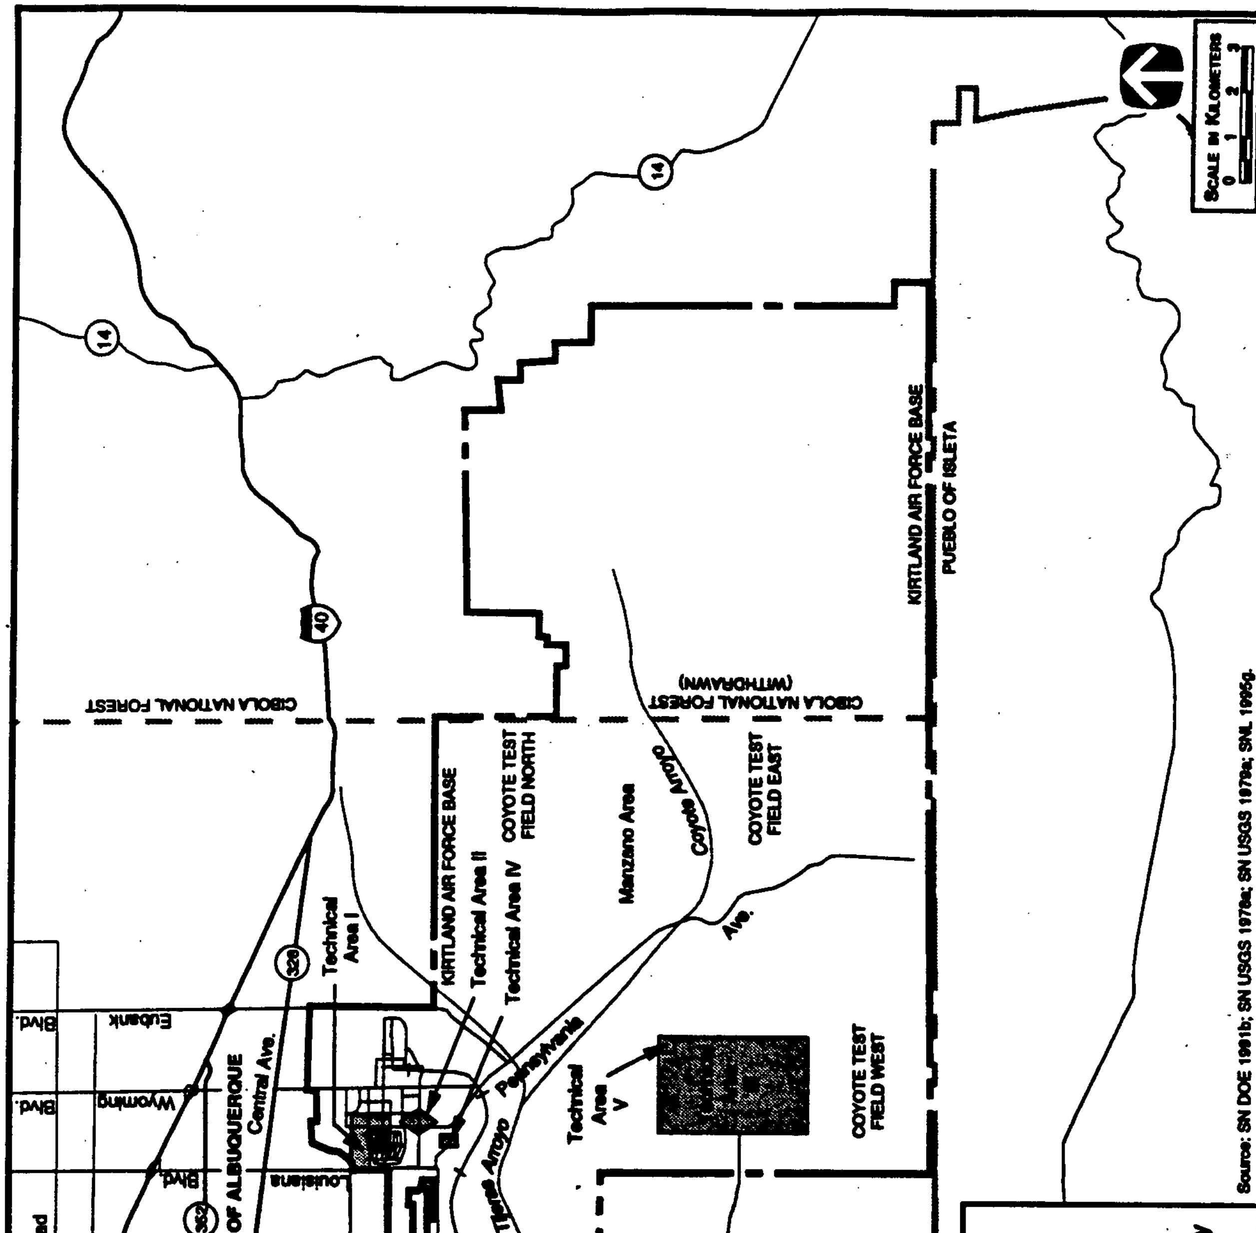

FIGURE 4.8–2.—*Location of Technical Areas I through V at Sandia National Laboratories, New Mexico.*

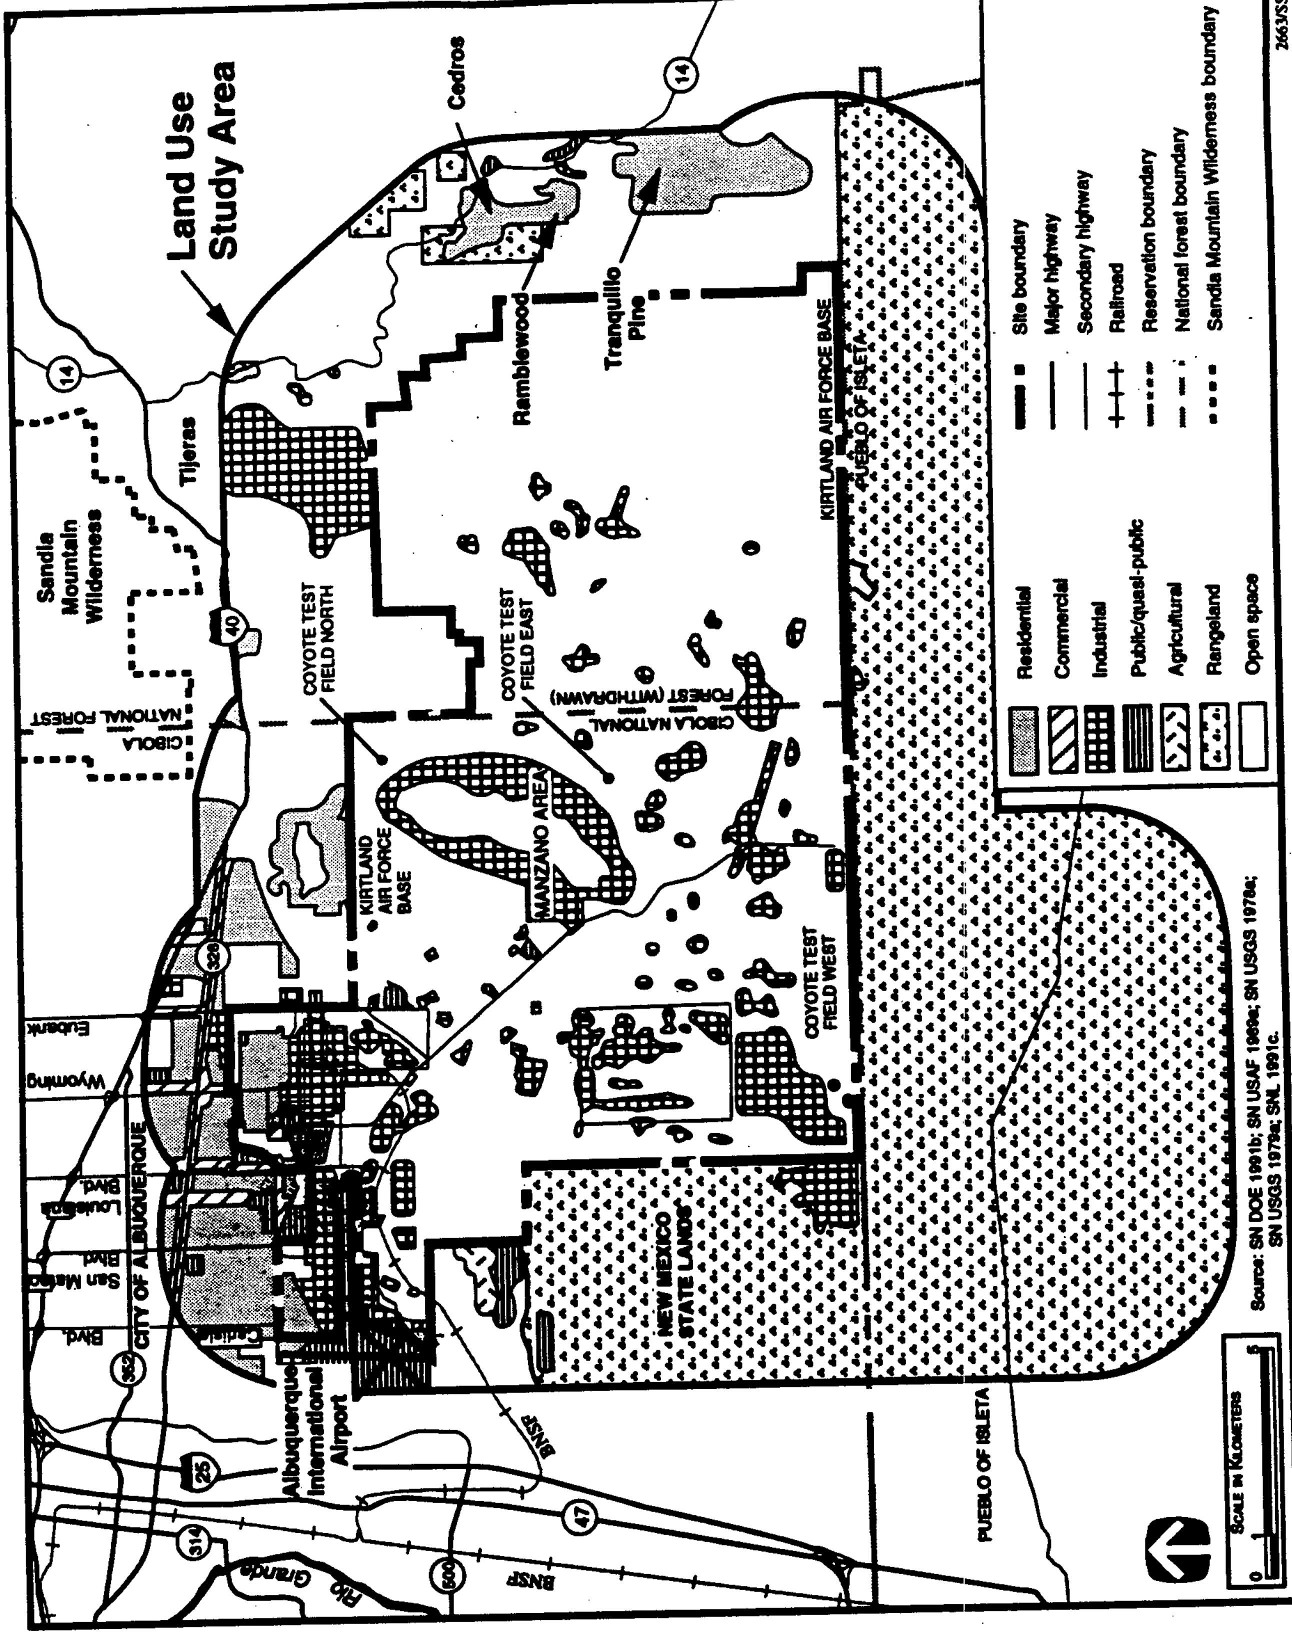

FIGURE 4.8.2.1-1.—*Generalized Land Use at Sandia National Laboratories, New Mexico, and Vicinity.*

Technical Area I. Commercial uses are primarily concentrated north of the site along Central Avenue and Gibson Boulevard (SN USAF 1990a:3.6-4–3.6-6). SNL does not contain any public recreation facilities.

4.8.2.2 *Site Infrastructure*

The site infrastructure characteristics that exist to support the current SNL missions described in section 3.2.8 are summarized in table 4.8.2.2–1.

TABLE 4.8.2.2–1.—*Baseline Characteristics for Sandia National Laboratories*

Characteristics	Current Value
Land	
Area (ha)	1,150
Roads (km)	40
Railroads (km)	8
Electrical	
Energy consumption (MWh/yr)	186,944
Peak load (MWe)	32
Fuel	
Natural gas (m^3/yr)	15,773,761
Liquid (L/yr)	1,301,598
Coal (t/yr)	0
Steam	
Generation (kg/hr)	29,287
Water	
Usage (MLY)	1,387[a]

4.8.2.3 *Air Quality*

The following section describes existing air quality including a review of the meteorology and climatology in the vicinity of SNL. More detailed discussions of the air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.8.

Meteorology and Climatology. The climate at SNL and in the surrounding region is characteristic of a semiarid steppe. The annual average temperature in the area is 13.4 °C (56.2 °F); temperatures vary from an average daily minimum of -5.7 °C (21.7 °F) in January to an average daily maximum of 33.6 °C (92.5 °F) in July. The average annual precipitation is 22.6 cm (8.88 in). The annual average wind speed is 4.0 m/s (9.0 mph) (NOAA 1994c:3).

Ambient Air Quality. SNL is located within the Albuquerque-Mid Rio Grande New Mexico Intrastate AQCR 152. Portions of the AQCR are designated nonattainment for carbon monoxide and total suspended particulates (40 CFR 81.332). The NAAQS and the State of New Mexico ambient air quality standards are given in appendix table B.3.1–1.

The principal sources of criteria air pollutants at SNL are the steam plant and the emergency diesel generator plant (SNL 1994a:5-19,5-20). Other emissions include fugitive particulate emissions from waste-burial activities, other process emissions, vehicular emissions, and temporary emissions from various construction activities. Hazardous/toxic air pollutant emissions at SNL occur from laboratories and miscellaneous operations and consist primarily of hydrogen chloride, methyl chloroform, toluene, and xylene. The emission inventories are included in appendix table B.3.8–1.

Ambient air quality conditions at SNL are shown in table 4.8.2.3–1. Ambient air quality concentrations at SNL are in compliance with applicable guidelines and regulations.

4.8.2.4 *Water Resources*

This section describes the surface and groundwater resources at SNL.

Surface Water. SNL is located within Kirtland Air Force Base on the Albuquerque East Mesa. The mesa slopes gently southwest to the Rio Grande, the primary drainage channel for the area. The Rio Grande is located 10 km (6 mi) west of Kirtland Air Force Base and flows north to south. No perennial streams flow through the SNL area. The major surface water feature at SNL is the Arroyo Seco, an intermittent stream that enters the site on the eastern boundary and exits on the northwestern corner. The channel is dry at least 6 months out of the year. Two other primary surface channels at SNL are Tijeras Arroyo and the smaller Arroyo del Coyote (figure 4.8–2). The Arroyo del Coyote joins the Tijeras Arroyo to discharge into the Rio Grande approximately 8 km (5 mi) from the western edge of Kirtland

TABLE 4.8.2.3–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Sandia National Laboratories, 1994* [Page 1 of 2]

Air Force Base. Both arroyos flow intermittently during spring snowmelt or following thunderstorms. Springs in the eastern mountains provide a perennial flow in the upper reaches of Tijeras Arroyo. Most of this flow evaporates or percolates into the soil before reaching Kirtland Air Force Base.

Tijeras Arroyo separates Technical Areas I, II, and IV from Technical Areas III, V, and the Coyote Test Field. Stormwater runoff is drained from the SNL Technical Areas by a combination of overland flow, natural channels, open drainage ditches, culverts, and storm sewers.

High peak flows of short duration characterize floods in the area. High-intensity summer thunderstorms produce the greatest flows, but flooding is not considered a high probability at SNL. The proposed stockpile stewardship and management activities would be located outside the 100- and 500-year floodplain zones (SNL 1995g:1-7).

SNL contains over 24 km (15 mi) of sewer lines interconnected with those of Kirtland Air Force Base. In 1994, SNL had two categorical pretreatment operations and four general wastewater streams discharging to the city of Albuquerque wastewater treatment plant. Discharges by SNL are regulated by the city of Albuquerque Public Works Department, Liquid Waste Division, under the authority of the city's Sewer Use and Wastewater Control Ordinance. The city's ordinance is approved by EPA in accordance with the *Clean Water Act* (CWA), as amended (SNL 1995g:6-1). Total flow from SNL is estimated to be 757 MLY (200 MGY).

To comply with EPA regulations, the city of Albuquerque has implemented an industrial wastewater pretreatment program. This program requires SNL to obtain permits for wastewater discharges to the city's wastewater treatment plant. These permits specify the required quality of discharges and the frequency of reporting the results of the monitoring (SNL 1995g:6-1). In 1994, SNL did not meet permit limits on four different occasions. Noncompliances were for excursions of lead, nickel, pH, oil, and grease (SNL 1995g:6-5).

SNL has one active permitted discharge plan from the state to discharge stormwater from oil storage tank areas and building basements to two surface impoundments (lagoons) permitted under the New Mexico Water Quality Control Commission Regulations as implemented by the New Mexico Environmental Improvement Board.

Surface Water Quality. As a part of the annual surface water monitoring program, samples are obtained from stations upstream and downstream of SNL in the Rio Grande and from Coyote Springs. The upstream station on the Rio Grande is at Corrales Bridge, and the downstream station is at the Isleta Indian Reservation, considerably downstream of the influent point of Tijeras Arroyo. Stormwater flowing into Tijeras Arroyo is the only significant surface water flow into the Rio Grande from the site. Stormwater monitoring is conducted twice a year at SNL. Rio Grande water samples are analyzed for gross alpha, gross beta, total uranium, and tritium. Results from the 1994 annual monitoring are presented in table 4.8.2.4–1. Concentrations of radionuclides in surface waters in 1994 did not exceed applicable standards. No nonradiological monitoring is conducted in Tijeras Arroyo or in the Rio Grande.

Groundwater. SNL lies within the north-south trending Albuquerque basin. The principal aquifer of the Albuquerque basin is the Valley Fill aquifer. The Valley Fill consists of unconsolidated and semiconsolidated sands, gravels, silts, and clays that vary in thickness from a few meters adjacent to the mountain ranges to over 6,400 m (21,000 ft) at a point 8 km (5 mi) southwest of the Kirtland Air Force Base airfield. The Valley Fill aquifer is considered a Class IIa aquifer, having a current source of drinking water and waters having other beneficial uses.

The regional water table is separated by a fault complex that divides the area into a deep region on the west side of the complex and a shallower region on the east side. The depth to groundwater ranges from 15 m to 30 m (49 ft to 98 ft) on the east side of the fault complex and from 116 m (380 ft) to 153 m (500 ft) on the west side (SNL 1995g:1-5). Based on available data, the apparent direction of groundwater flow west of the fault complex is generally to the north and northwest. The direction of groundwater flow east of the fault complex typically is west toward the fault system.

Sources of recharge to the aquifer include precipitation, snowmelt along the margins of the basin, underflow from adjacent areas such as the Hagen Basin, and seepage from streams, canal drains, surface reservoirs, and applied crop irrigation water.

Groundwater Quality. Groundwater monitoring at SNL has been conducted since 1985. Overall, the groundwater in this region has been classified as a calcium bicarbonate chemical type with a pH ranging from 6.08 to 8.84 and an alkalinity range of 0.40 to 49 mg/L. The east side wells are characterized by lower pH than the west side wells. Currently, no monitoring wells are in the proposed project area. The closest well, located approximately 0.4 km (0.25 mi) southeast of the area, had an August 1990 depth-to-water reading of 152 m (499 ft).

The chemical waste landfill has been identified as a source of groundwater contamination. In 1994, concentrations of nickel and chromium were found above the water quality criteria established by the New Mexico Water Quality Regulations in the groundwater at the chemical waste landfill. No Target Analyte Metals or radionuclides were detected above background levels in groundwater samples collected in 1994. The groundwater contamination areas are not located near buildings that house proposed DP activities.

TABLE 4.8.2.4–1.—*Surface Water Quality Monitoring of the Rio Grande at Sandia National Laboratories, 1994*

Parameter	Unit of Measure	Water Quality Criteria[a]	Water Body Concentration Range[b]
Alpha (gross)	pCi/L	15[c]	2-3
Beta (gross)	pCi/L	50[d]	3-7
Tritium	pCi/L	80,000[e]	20-100
Uranium, total	μg/L	NA	1.6-2.6

[a] For comparison only.
[b] Samples were collected from station 11 located on the Rio Grande at the Isleta Pueblo down gradient of SNL. Samples are collected biannually: in May and August.
[c] National Primary Drinking Water Regulations (40 CFR 141).
[d] Proposed National Primary Drinking Water Regulations, Radionuclides (56 FR 33050).
[e] DOE's Derived Concentration Guides for water (DOE Order 5400.5). Values are based on a committed effective dose equivalent of 100 mrem per year; however, because the drinking water maximum contaminant level is based on 4 mrem per year, the number listed is 4 percent of the Derived Concentration Guides.

Note: NA - not applicable.
Source: SNL 1995g.

Groundwater Availability, Use, and Rights. SNL uses approximately 1,387 MLY (366 MGY) of water. Thirty percent of the water used at SNL is purchased from the city of Albuquerque, and the rest is pumped from Kirtland Air Force Base wells.

The city of Albuquerque has annual consumptive water rights of 27,300 MLY (7,210 MGY). The city receives a 50-percent return flow credit for sanitary wastewater discharged to the Rio Grande. In addition, the city of Albuquerque also has 56,800 MLY (15,000 MGY) consumptive water rights to the San Juan/Chama Diversion.

Kirtland Air Force Base has groundwater rights of 7,900 MLY (2,090 MGY). It also has the option of purchasing 10 percent of its water from the city of Albuquerque. Currently, it is operating at a 50-percent capacity.

Groundwater rights in New Mexico are traditionally associated with the appropriation doctrine. In this system, all water is declared to be public and subject to appropriation on the basis "first in time, first in right" principle (VDL 1990a:725). Control of well use is regulated by permits.

4.8.2.5 *Geology and Soils*

Geology. SNL lies on a sequence of sedimentary, igneous, and Precambrian basement rocks. The northern and western sections rest on Miocene to Quaternary gravels, sands, silts, and clays deposited in the basin formed by uplift of the mountains to the east. The eastern portion of SNL is primarily underlain by Precambrian rocks.

SNL is located in seismic Zone 2 (figure A.1–1). The eastern portion of SNL is cut by the Tijeras, Hubble Springs, Sandia, and Manzano faults. The facility is situated in a region of high seismic activity but low magnitude and intensity (SN ERDA 1977a:82). Available records indicate that more than 1,100 earthquakes have occurred during the past 127 years. Intensities have been as high as a modified Mercalli intensity of VII. However, during the past century, only three earthquakes have caused damage at Albuquerque, which is located approximately 10.5 km (6.5 mi) from SNL.

Possible geological concerns include potential ground shaking and rupturing associated with regional seismic activity and the faults intersecting on the site. Statistical studies indicate that a non-damaging earthquake of modified Mercalli intensity less than III may be expected every 2 years, with a damaging event every 100 years. The potential for damage from volcanic activity is small (DOE 1995cc:4-112).

Soils. SNL is located on soils of the Bluepoint-Kokan, Madurez-Wink, Tijeras-Embudo, Kolob-Rock outcrop, and the Seis-Orthids associations (SN USDA 1977a:31,32,41,42). The Bluepoint-Kokan soils are excessively drained, sandy, and gravelly. The Madurez-Wink soils are well-drained and loamy. The Tijeras-Embudo soils are well-drained, loamy, and gravelly. The Kolob-Rock outcrop association in the eastern portion of SNL includes deep, moderately to very steep, well-drained, loamy, and stony soils, and basalt, sandstone, and limestone rock outcrops. The Seis-Orthids association includes shallow to moderately deep soils on level to very steep slopes that are well-drained, very cobbly, stony and very stony, and loamy.

The hazard of blowing soils on the terraces and pediments is severe. Future water erosion hazards are moderate on the alluvial fans, foothills, and highlands. No soils are classified prime farmland at SNL. The soils at SNL are acceptable for standard construction techniques.

4.8.2.6 *Biotic Resources*

The following section describes biotic resources at SNL including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. A list of threatened and endangered species that may be found on or in the vicinity of SNL is presented in appendix C.

Terrestrial Resources. SNL is located at the juncture of four major North American physiographic and biotic provinces: the Great Basin, the Rocky Mountains, the Great Plains, and the Chihuahuan Desert. The biotic communities of the area exhibit influences from each of these provinces, with the Great Basin influence generally dominating.

SNL occupies about 1,150 ha (2,842 acres) within the larger Kirtland Air Force Base which totals 21,319 ha (52,700 acres). Approximately 39 percent of SNL-controlled land is developed. Vegetation of the area can be classified into four major plant communities: pinyon pine-juniper, grassland, riparian woodland, and riparian scrubland. The pinyon pine-juniper and grassland communities dominate the area, while the riparian woodland and riparian scrubland are limited to the surface drainage courses of canyons and arroyos, respectively (SNL 1992c:5-1). In total, 379 species have been identified that exist or could exist within the area (SNL 1990a:27-37).

At least 10 amphibian, 46 reptile, 124 bird, and 68 mammal species exist, or could exist, in the area of SNL (SNL 1990a:14,16,17,19-22,24-26). Common species include the short-horned lizard *(Phrynosoma douglassi)*, prairie rattlesnake *(Crotalus viridis viridis)*, mourning dove *(Zenaida macroura)*, horned lark *(Eremophila alpestris)*, black-tailed jackrabbit *(Lepus californicus)*, and black-tailed prairie dog *(Cynomys ludovicianus)*. A number of game animals are found on SNL; however, hunting is not permitted. Raptors, such as the Cooper's hawk *(Accipiter cooperii)* and golden eagle *(Aquila chrysaetos)*, and carnivores, such as the coyote *(Canis latrans)* and bobcat *(Lynx rufus)*, are ecologically important groups on the site. A variety of migratory birds has been found at SNL. Migratory birds and their nests and eggs are protected by the *Migratory Bird Treaty Act*. Eagles are similarly protected by the *Bald and Golden Eagle Protection Act*.

Wetlands. National Wetland Inventory maps of SNL have not been prepared nor have site wetlands been delineated. Springs exist at Lurance Canyon, Sol se Mate, and the outlet of Coyote Canyon. Sole se Mate Spring has a small area of permanent water below it that supports wetland plants such as cattails *(Typha spp.)* and rushes *(Juncus spp.)*. A swampy area exists at Coyote Springs that supports wetland vegetation (SN ERDA 1977a: 94-95). These springs can be considered an important source of water for wildlife.

Aquatic Resources. Potential aquatic resources found on SNL include Arroyo del Coyote and Tijeras Arroyo (located in the west and central portions of the site, respectively). The Rio Grande River is located about 10 km (6.2 mi) west of the site. There are no continuously flowing streams on the site. Site arroyos flow intermittently during heavy thundershowers (SNL 1994a:1-7). The arroyos do not support any permanent fish population.

Threatened and Endangered Species. The 18 Federal- and state-listed threatened, endangered, and other special status species that could be found on or in the vicinity of SNL are listed in appendix table C–6. No Federal-listed threatened or endangered species are known to exist on SNL. However, potential breeding habitat exists on SNL for the Mexican spotted owl *(Strix occidentalis lucida)*, southwestern willow flycatcher *(Empidonax traillii extimus)*, and the Federal-candidate mountain plover *(Charadrius montanus)*. The only special status species known to exist onsite is the state-threatened gray vireo *(Vireo vicinior)* (SNL 1992c:5-10,5-11). No critical habitat, as defined in the *Endangered Species Act* (50 CFR 17.11 and 17.12), exists on SNL.

4.8.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. The prehistoric chronology for the SNL area consists of three broad time periods: Paleo-Indian (10,000 to 5,500 B.C.), Archaic (5,500 B.C. to A.D. 1), and Anasazi (A.D. 1 to 1600) (SN NPS 1988a:132). All DOE-owned properties under SNL control have been surveyed or assessed for cultural resources (SNL 1993c:1-6). All five Technical Areas have been intensively surveyed; no prehistoric sites were recorded. However, because techniques and procedures varied greatly between projects in these areas, most surveys prior to 1985 are not considered adequate, and buried sites or archaeological remains may exist. Prehistoric site types may include pueblos, pithouse villages, rockshelters, hunting blinds, agricultural terraces, quarries, lithic and ceramic scatters, and hearths. Similar sites have been found at nearby locations. A systematic walkover survey was completed at the proposed site locations and no cultural resources were identified.

Historic Resources. Historic resources identified in the vicinity of SNL are associated with early mining, ranching and sheepherding activities, commercial ventures, or transportation routes. All five DOE Technical Areas have been intensively inventoried for resources; two historic sites were recorded. These sites were small historic trash scatters and are not eligible for the NRHP. Twenty-three historic resources have been recorded on DOE-owned or -controlled lands outside of the five Technical Areas, and about 65 percent are considered eligible or potentially eligible for the NRHP.

SNL was established in 1945 as the Z Division of the Los Alamos Scientific Laboratory. Technical Area I originally consisted of temporary World War II structures and wooden framed buildings; more permanent buildings were constructed in 1948. Construction in Technical Area II was initiated in 1948, including two buildings (Buildings 904 and 907) used to assemble the first hydrogen bomb. Test facilities were developed in Technical Area III from 1954 through 1960 (SNL 1993c:2-12,2-13). Numerous buildings and structures in Technical Areas I, II, and III were built between 1945 and 1960; most are associated with the AEC, and, as such, may be considered NRHP eligible. Buildings in Technical Areas III, IV, and V may also qualify for eligibility for the NRHP when they are 50 years old. The New Mexico SHPO has requested that buildings in these areas be evaluated at that time. Buildings 904 and 907 may be considered potentially NRHP eligible because of their association with the assembly of the first hydrogen bomb.

Native American Resources. Native Americans with concerns in this area include the Sandia Pueblo, north of Albuquerque, and the Isleta Pueblo, south of Kirtland Air Force Base (SNL 1993c:1-9). Native American resources on SNL/DOE-controlled lands may consist of prehistoric sites with ceremonial features such as kivas, village shrines, petroglyphs, or burials; all of these site types or features would be of concern to local groups. Consultation with the Isleta and Sandia Pueblos has been initiated by DOE for this project, and no Native American cultural resources have been identified within SNL, including the proposed NIF location.

Paleontological Resources. The geology at SNL consists of sedimentary and volcanic rocks. Uppermost is a sequence of gravel, sand, silt, clay, and caliche. Underneath are sedimentary rocks, and, beneath them, Precambrian rocks. Some fossils have been discovered near SNL. These fossils include vertebrate remains 5 to 8 km (3 to 5 mi) west-northwest of Technical Area III, and an ankle bone from an extinct Pleistocene camel and two teeth from a horse on the south side of Tijeras Arroyo. A fossilized horse skull and some hare teeth were recovered near the mouth of Tijeras Arroyo. These fossils may have been transported to their site of discovery. However, it is possible fossils are present at SNL beneath the alluvial fan deposits from the Sandia Mountains.

4.8.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at SNL include employment and local economy, population and housing, and public finance. Statistics for employment and local economy are based on the regional economic area that encompasses nine counties around SNL located in Arizona and New Mexico. Statistics for population and housing, and public finance are presented for the ROI, a three-county area in which 97 percent of all SNL employees (7,341 persons in 1993) reside: Bernalillo County (88.0 percent), Valencia County (4.5 percent), and Sandoval County (4.5 percent) in New Mexico (appendix table D.1–7). Figure 4.8.2.8–1 presents a map of the counties and selected cities composing the SNL regional economic area and ROI. Supporting data is presented in appendix D.

Regional Economy Characteristics. Selected employment and regional economy statistics for the SNL regional economic area are summarized in figure 4.8.2.8–2. The civilian labor force in the regional economic area increased from 279,186 in 1980 to 344,309 in 1990. This is an increase of 23 percent (annual average increase of 2.3 percent). The 1994 unemployment rate in the regional economic area was 5.7, which was less than 1 percent lower than the rates in Arizona and New Mexico. The region's per capita income of $17,003 in 1993 was approximately 4 percent greater than New Mexico's per capita income of $16,346 and 6 percent lower than Arizona's per capita income of $18,085.

In 1993, as shown in figure 4.8.2.8–2, the percentage of total employment involving the private sector activity of retail trade in the regional economic area (18 percent) was comparable to the economies of Arizona and New Mexico. Service activities in the region (31 percent of the total employment) were also comparable to Arizona and New Mexico. Manufacturing was similar in both the regional economic area (7 percent) and New Mexico, but represented a 2-percent larger share of total employment in Arizona.

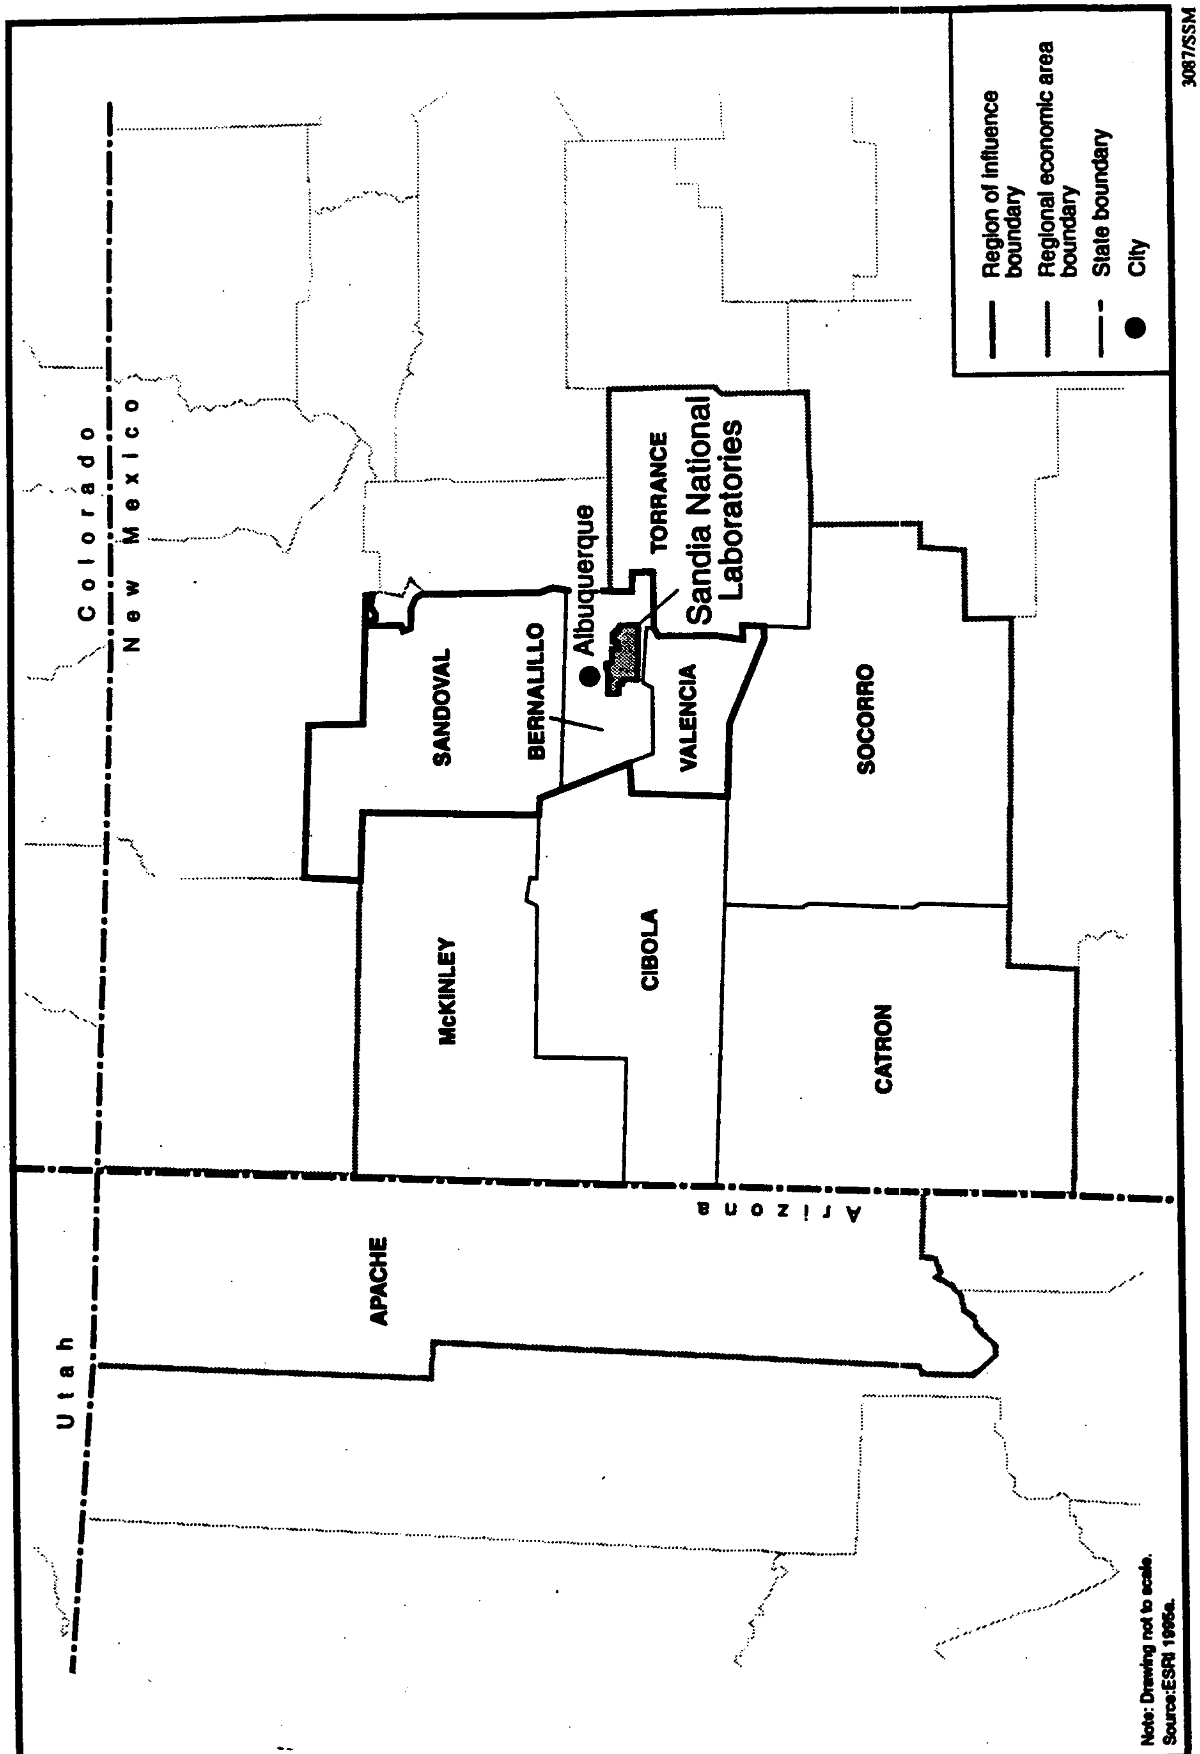

FIGURE 4.8.2.8–1.—*Regional Economic Area and Region of Influence for Sandia National Laboratories.*

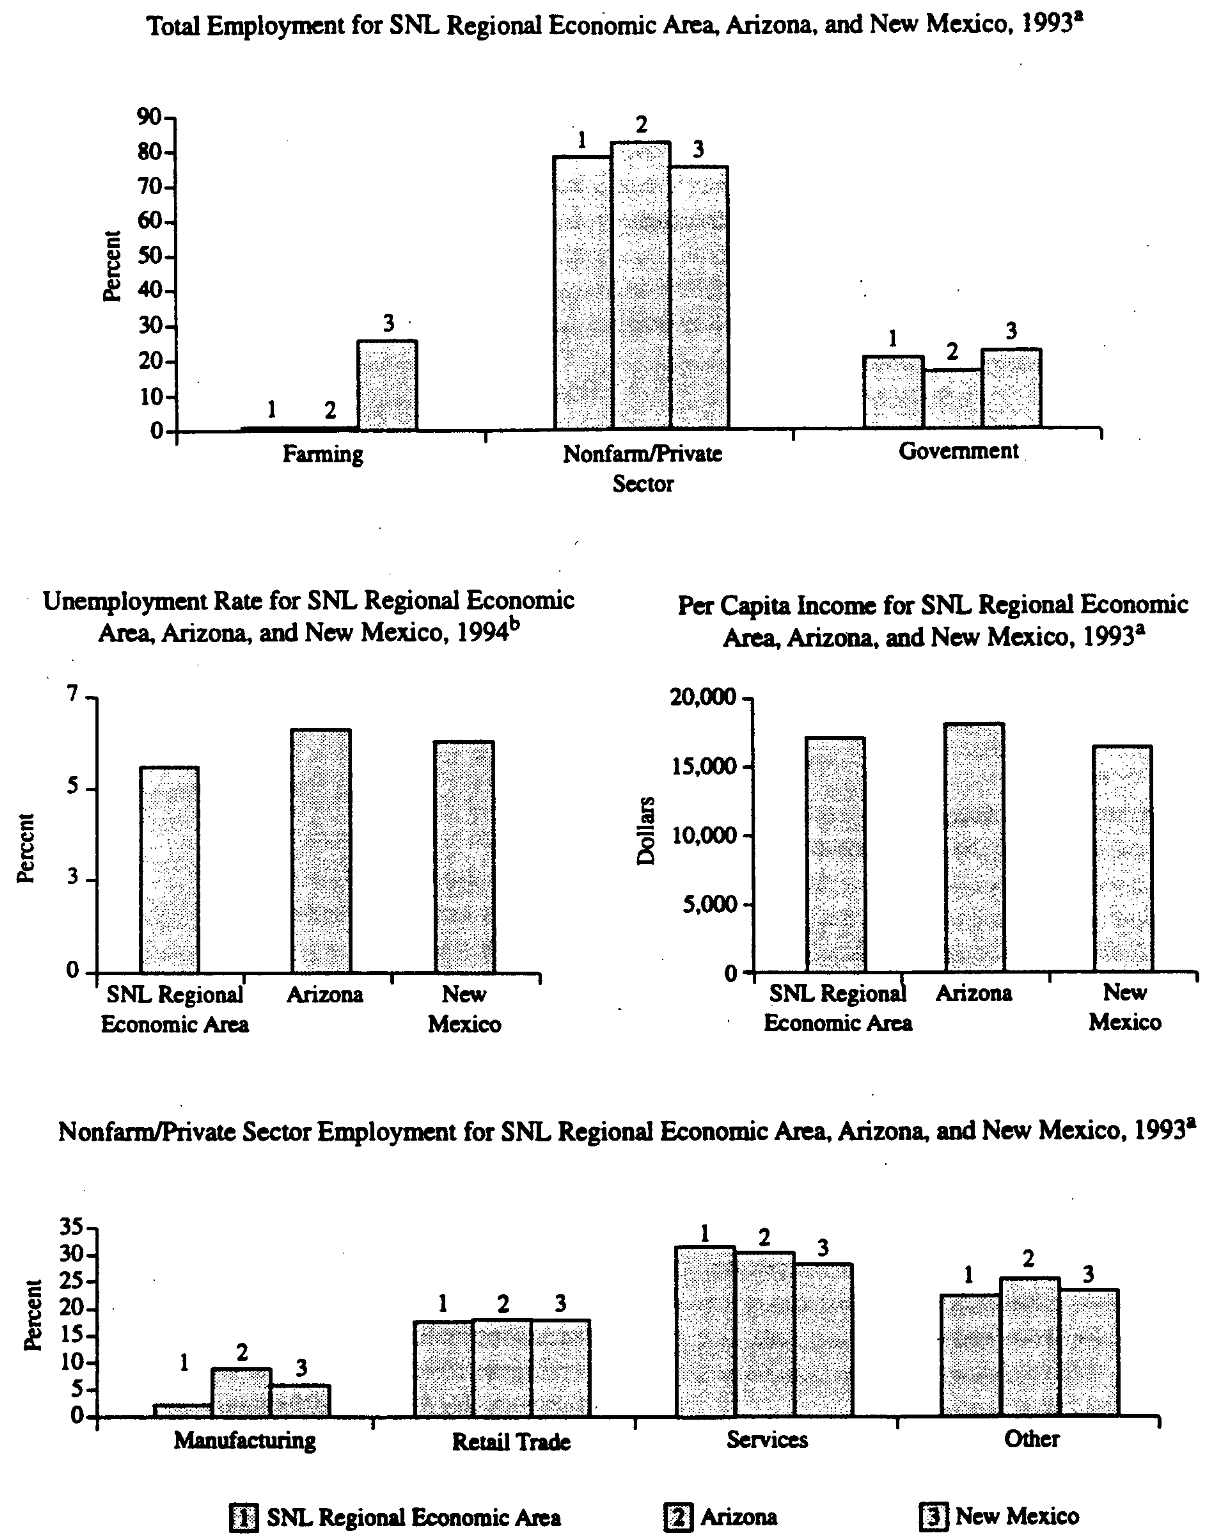

[a]DOC 1995a.
[b]DOL 1995a.

FIGURE 4.8.2.8–2.—*Economy for the Sandia National Laboratories Regional Economic Area, Arizona, and New Mexico.*

Population and Housing. Between 1980 and 1992, the ROI population grew from 515,614 to 616,346. This is an increase of 19.5 percent (annual average increase of 1.6 percent). Within the ROI, Sandoval County experienced the largest increase at 97.7 percent, while Valencia County's population decreased by 21.0 percent. This decrease was due to the formation of Cibola County that was created entirely from the western portion of Valencia County shortly after the 1980 census. If the 1992 Cibola County population was added to Valencia's, the result would be an 18-percent increase from 1980 to 1992.

Between 1980 and 1990, housing units increased from 196,765 to 241,683. This is a 22.8-percent increase (annual average increase of 2.3 percent), which is similar to the percent increase for New Mexico. The total number of housing units estimated for 1992 is 244,900. The 1990 homeowner vacancy rate in the ROI was 1.8 percent. The rental vacancy rate for the ROI counties was 10.2 percent. Population and housing trends are summarized in figure 4.8.2.8–3.

Public Finance. Financial characteristics of the local jurisdictions in the SNL ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure fund categories for counties, cities, and school districts are presented in appendix tables D.2.3–12 and D.2.3–13. Figure 4.8.2.8–4 summarizes 1994 local governments' revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.8.2.8–4. All jurisdictions assessed had positive fund balances.

4.8.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environment at SNL. Also included are discussions of health effects studies, emergency preparedness considerations, and a brief accident history.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of SNL are shown in table 4.8.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time. The incremental total dose to the population would result only from changes in the size of the population. Background radiation doses are unrelated to SNL operations.

TABLE 4.8.2.9–1.—*Sources of Radiation Exposure to Individuals in the Vicinity, Unrelated to Sandia National Laboratories Operations*

Source	Committed Effective Dose Equivalent (mrem/yr)
Natural Background Radiation	
Cosmic and external terrestrial radiation[a]	95
Internal terrestrial radiation[b]	39
Radon in homes (inhaled)[b]	200
Other Background Radiation[b]	
Diagnostic x rays and nuclear medicine	53
Weapons test fallout	<1
Air travel	1
Consumer and industrial products	10
Total	399

[a] SNL 1994a.
[b] NCRP 1987a.

Releases of radionuclides to the environment from SNL operations provide another source of radiation exposure to people in the vicinity. The radionuclides and quantities released from operations in 1993 are listed in the *1993 Site Environmental Report Sandia National Laboratories, Albuquerque, New Mexico* (SAND94-1293). The doses to the public resulting from these releases are given in table 4.8.2.9–2. These doses fall within radiological limits (DOE Order 5400.5) and are small in comparison to background radiation. The releases listed in the 1993 report were used in the development of the reference

FIGURE 4.8.2.8–4.—***Local Government Public Finance for the Sandia National Laboratories Region of Influence*** **[Page 2 of 2].**

TABLE 4.8.2.9–2.—*Doses to the General Public from Normal Operation at Sandia National Laboratories, 1993 (Committed Effective Dose Equivalent)*

	Atmospheric Releases		Liquid Releases		Total	
Affected Environment	Standard[a]	Actual	Standard[a]	Actual	Standard[a]	Actual
Maximally exposed individual (mrem)	10	$1.6x10^{-3}$	4	0.0	100	$1.6x10^{-3}$
Population within 80 kilometers[b] (person-rem)	None	0.027	None	0.0	100	0.027
Average individual within 80 kilometers[c] (mrem)	None	$4.7x10^{-5}$	None	0.0	None	$4.7x10^{-5}$

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem/yr limit from airborne emissions is required by the CAA, the 4 mrem/yr limit is required by the SDWA, and the total dose of 100 mrem/yr is the limit from all pathways combined. The 100 person-rem value for the population is given in proposed 10 CFR 834 (58 FR 16268).

[b] In 1993, this population was approximately 578,000.

[c] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.

Source: SNL 1994a.

environment (No Action) radiological releases at SNL in 2005 (section 4.8.3.9).

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem ($5x10^{-4}$ fatal cancer per person-rem) to the public (appendix E), the fatal cancer risk to the maximally exposed member of the public due to radiological releases from SNL operations in 1993 was estimated to be approximately $8.0x10^{-10}$. That is, the estimated probability of this person dying of cancer at some point in the future from radiation exposure associated with 1 year of operations is less than 1 in 1 billion. (Note that it takes several to many years from the time of exposure to radiation for a cancer to manifest itself.)

Based on the same conversion factor, $1.4x10^{-5}$ excess fatal cancers are projected in the population living within 80 km (50 mi) of SNL from normal operation in 1993. To place this number into perspective, it can be compared with the number of fatal cancers expected in this population from all causes. The 1990 mortality rate associated with cancer for the U.S. population was 0.2 percent per year (Almanac 1993a:839). Based on this mortality rate, the number of fatal cancers from all causes expected to occur during 1993 in the population living within 80 km (50 mi) of SNL is 1,156. This number of expected fatal cancers is much higher than the estimated $1.4x10^{-5}$ fatal cancers that could result from SNL operations in 1993.

Workers at SNL receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities. Table 4.8.2.9–3 includes the average, maximum, and total occupational doses to workers from operations in 1992. These doses fall within radiological limits (10 CFR 835). Based on a dose-to-risk conversion factor of 400 fatal cancers per 1 million person-rem ($4x10^{-4}$ fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to SNL workers from operations in 1992 is estimated to be $4.4x10^{-3}$.

TABLE 4.8.2.9–3.—*Doses to the Onsite Worker from Normal Operation at Sandia National Laboratories, 1992*

	Onsite Releases and Direct Radiation	
Affected Environment	Standard[a]	Actual[b]
Average worker (mrem)	None	3.2
Maximally exposed worker (mrem)	5,000	1,000
Total workers (person-rem)	None	11

[a] 10 CFR 835. DOE's goal is to maintain radiological exposure as low as reasonably achievable.

[b] DOE 1993n:7. The number of badged workers in 1992 was approximately 3,420.

A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in *1993 Site Environmental Report Sandia National Laboratories, Albuquerque, New Mexico* (SAND 94-1293). In addition, the concentrations of radioactivity in various environmental media (e.g., air, water, and soil) in the onsite and offsite regions are presented in the same reference.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., surface waters during swimming and soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in sections 4.8.2.3 and 4.8.2.4.

Adverse health impacts to the public can be minimized through administrative and design controls that decrease hazardous chemical releases to the environment and achieve compliance with permit requirements (e.g., air emissions and NPDES permit requirements). The effectiveness of these controls is verified through the use of monitoring information and inspection of mitigation measures. Health impacts to the public may occur during normal operation at SNL via inhalation of air containing hazardous chemicals released to the atmosphere by operations. Risks to public health from ingestion of contaminated drinking water or by direct exposure are also potential pathways.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.8.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. All annual concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to SNL workers during normal operation may include inhaling the workplace atmosphere, drinking SNL potable water, and possible other contact with hazardous materials associated with particular work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. SNL workers are also protected by adherence to OSHA and EPA occupational standards that limit workplace atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amount of chemicals utilized in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm. Therefore, worker health conditions at SNL are expected to be substantially better than required by the standards.

Health Effects Studies. There are no known epidemiological studies that have been conducted which examine the impact of SNL on the health of the surrounding communities.

Broadwell and others reported on 25 workers currently or formerly involved in the manufacture of hybrid microcircuits (AJIM 1995a:677-698). Clinical narratives and retrospective exposure assessments in the study group suggested chronic low-level exposure to solvents, with intermittent acute excursions. Solvent exposures linked to a clinical syndrome were intermittent, and symptoms were reversible after cessation of what were reported as "high-level" exposures. Several exposed workers showed clinical evidence of an acquired toxic encephalopathy supporting an association between long-term solvent exposure and depressed mood, with increased somatic symptoms. Attention to engineering controls, chemical fume hood ventilation, work practices, safety training, and personal protective gear was markedly improved when the lab was moved in the fall of 1990. For a more detailed description of the studies and the findings, refer to appendix section E.4.8.

Accident History. A review of the recent SNL annual environmental and accident reports indicates that there have been no significant adverse impacts to workers, the public, or the environment. This review was performed to provide an indication of the site's accident history. The period of review, from 1986 to 1990, was a time during which plant operations were much higher than in previous years and also higher than what is anticipated for the future.

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response to accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with planning, preparedness, and response.

4.8.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and ongoing waste management activities for the Albuquerque location of SNL. A more detailed discussion of the ongoing waste management operation is provided in appendix section H.2.7.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operations at SNL. DOE is also engaged in several activities to bring its operations into full regulatory compliance. These activities are set forth in negotiated agreements that contain schedules for achieving compliance with these applicable requirements and financial penalties for nonachievement of agreed upon milestones. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

SNL is not on the NPL for sites requiring environmental restoration in accordance with CERCLA and *Superfund Amendments and Reauthorization Act* (SARA). The assessment of environmental contamination at SNL began formally in 1984, when DOE started to identify, assess, and remediate potentially hazardous waste sites in response to CERCLA. This program identified 117 sites with potential contamination. A similar investigation was conducted by EPA in 1987. These programs ultimately defined a working inventory of potential "solid waste management units." Current investigations are intended to determine the nature and extent of hazardous and radioactive contamination and to restore any sites where such materials pose a threat to human health or the environment. It is assumed that remediation at all sites will be completed by 2011.

SNL has a Waste Minimization and Pollution Awareness Plan to document projections for present and future waste generation rates. This program tracks the amount of waste generated at the site and encourages the use of waste reduction methods. In the future, it will assess opportunities for preventing pollution from priority waste streams, increasing recycling efforts, and ensuring the procurement of recycled products.

SNL manages a small quantity of spent nuclear fuel and five broad waste categories: TRU, low-level, mixed, hazardous, and nonhazardous. Because there is no spent nuclear fuel or TRU waste associated with any of the proposed activities at SNL, there is no discussion in this PEIS of spent nuclear fuel or TRU waste generation and management at SNL. A discussion of the waste management operations associated with low-level, mixed, hazardous, and nonhazardous wastes follows.

Low-Level Waste. In 1994, SNL generated approximately 0.9 m^3 (241 gal) of liquid and 53 m^3 (70 yd^3) of solid LLW (SNL 1995f:7). SNL generates LLW in both technical and remote test areas as a result of R&D activities. Most of the LLW consists of contaminated equipment and combustible decontamination materials and cleanup debris. All generated LLW is temporarily stored at generator sites or aboveground in transportation containers at the Technical Area III disposal site. All LLW packages are currently onsite pending approval of transport by commercial carriers to NTS for disposal.

Mixed Low-Level Waste. In 1994, SNL generated approximately 0.007 m^3 (2 gal) of liquid and 1.9 m^3 (2.5 yd^3) of solid mixed LLW (SNL 1995f:7). Mixed waste includes radioactively contaminated oils and solvents and radioactively contaminated or activated lead, or other heavy metals. Other mixed waste may be generated as a result of weapons tests. The 557-m^2 (666-yd^2) Radioactive and Mixed Waste Management Facility will have a centralized packaging and storage function for LLW and mixed waste. Mixed waste will be stored at the facility until accepted for disposal at NTS once it is permitted.

Processing at the Radioactive and Mixed Waste Management Facility will include activities required to comply with the waste acceptance criteria and Federal regulations. Pursuant to the *Federal Facility Compliance Act,* SNL developed a site treatment plan for mixed wastes at SNL. The site treatment plan is intended to bring SNL into compliance with Land Disposal Restrictions storage prohibitions under the *New Mexico Hazardous Waste Act* and RCRA. On March 31, 1995, DOE submitted its proposed site treatment plan to the New Mexico Environment Department for review, public comment, and approval. On October 6, 1995, a Compliance Order was issued by the State of New Mexico requiring SNL to comply with the site treatment plan for the treatment of mixed wastes at SNL. The Compliance Plan Volume of the site treatment plan provides overall schedules for achieving compliance with the land disposal restrictions storage and treatment requirements, a schedule for the submittal of applications for permits, construction of treatment facilities, technology development, offsite transportation for treatment, and the treatment of mixed wastes in full compliance with the *New Mexico Hazardous Waste Act* and RCRA. An annual update to the site treatment plan is required.

Hazardous Waste. In 1994, SNL generated approximately 342 m^3 (90,530 gal) of liquid, and 81.9 t (90.3 tons) of RCRA-regulated and 647 t (713 tons) of state-regulated solid hazardous wastes (SNL 1995f:7). Hazardous/toxic chemical waste is generated at SNL by the numerous R&D activities conducted throughout the facilities. The Hazardous Waste Management Facility can store 265 m^3 (70,000 gal) of liquid and solid hazardous wastes at one time. There are no active onsite disposal facilities for hazardous/toxic wastes at SNL. All RCRA-regulated wastes are packaged, manifested, and shipped offsite by DOT-registered transporters for disposal at RCRA-permitted treatment, storage, and disposal facilities.

Nonhazardous Waste. For 1994, SNL generated approximately 75,700 m^3 (19,998,000 gal) of liquid sanitary and industrial wastewater (SNL 1995b:1). SNL contains over 24 km (15 mi) of sewer lines interconnected with those of Kirtland Air Force Base. Pretreated industrial wastewater effluent and sanitary sewage are discharged to the city of Albuquerque sewer system in compliance with NPDES permit discharge limits. In 1994, SNL generated approximately 13,600 t (14,990 tons) of solid sanitary waste (SNL 1995f:7). Solid sanitary waste is collected and taken to the Albuquerque sanitary landfill on a regular basis.

4.8.3 Environmental Impacts

4.8.3.1 *Land Resources*

No Action. Under No Action, DOE would continue current and planned activities at SNL as described in section 3.2.8. No additional land-use impacts are anticipated at SNL beyond the effects of existing and future activities which are independent of the proposed action.

Management Alternatives

Nonnuclear Fabrication. The Nonnuclear Fabrication Facility at SNL would require no additional land acquisition. Modification of existing facilities and new construction at Technical Area I would be required to accommodate the new proposed activities. The new facilities at SNL would provide approximately 58,060 m^2 (625,000 ft^2) of work space and would be located within an undeveloped 9-ha (22-acre) area. The land to be developed represents approximately 6 percent of the land currently identified as available for development at SNL, but it is only a small portion of the land available for future development within SNL. An additional 5,110 m^2 (55,000 ft^2) of support facility space would be located in existing buildings. The proposed nonnuclear fabrication activities would be compatible and consistent with current operations in the area and SNL land-use plans and policies. Impacts to land use or land use plans are not expected.

Sensitivity Analysis. SNL would be able to accommodate all operations and support functions for nonnuclear fabrication with modification of existing facilities. Modification of existing facilities to support base case production would be sufficient to maintain capacity for both the high and low production cases.

Stewardship Alternatives

Proposed National Ignition Facility. Impacts to land use at and around SNL from the proposed NIF project would be limited to the clearing of land, minor and temporary disruptions to contiguous land parcels south of the proposed site from construction activities, and a slight increase in vehicular traffic. The proposed site for NIF would occupy a large parcel of flat, vacant land on the southern end of Technical Area II between East Ordinance Road and "R" Boulevard, and a small plot of land for temporary construction staging on the northern edge of Technical Area IV just south of "R" Boulevard. The proposed NIF project would require the clearing of an estimated 11 ha (28 acres) of land for buildings, walkways, building access and buffer space. Such acreage would account for approximately 7 percent of the land currently identified as available for development at SNL, but it represents only a small portion of the land available for future development within SNL. The project would be located in an area dedicated to similar land uses. No impacts to land use or land-use plans and policies at SNL, in Bernalillo County, the city of Albuquerque, or nearby communities would be expected.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.8.3.2 *Site Infrastructure*

The SNL site infrastructure resources are capable of accommodating any of the alternatives for which it is a candidate with only moderate changes in the existing electrical and fuel resources. Table 4.8.3.2–1 presents a comparison of the annual operating infrastructure resource requirements for the alternatives of No Action, nonnuclear fabrication, and the proposed NIF. The No Action alternative would continue SNL's current mission objectives in the existing facilities without modification as described in section 3.2.8. Under the No Action alternative, the required site infrastructure resources would be unchanged relative to current resource consumption.

Management Alternatives

Nonnuclear Fabrication. SNL is being considered for the alternative of nonnuclear fabrication. Under this alternative, the majority of the ongoing nonnuclear production activities at KCP would be reconfigured and transferred to SNL, with a small portion going to LANL and possibly LLNL.

The nonnuclear fabrication alternative at SNL would result in a new stand-alone production site with four new production facilities, an office structure, and a central utilities building surrounded by a security fence. In addition, some existing buildings would

TABLE 4.8.3.2–1.—***Site Infrastructure Requirements and Changes for Stockpile Stewardship and Management Alternatives at Sandia National Laboratories***

Alternative	Electrical		Fuel		
	Energy (MWh/yr)	Peak Load (MWe)	Liquid (L/yr)	Natural Gas (m^3/yr)	Coal (t/yr)
Current Resources (1994)	186,944	32	1,301,598	15,773,761	NA
No Action (2005)					
Total site requirements	186,944	32	1,301,598	15,773,761	NA
Change from current resources	0	0	0	0	NA
Nonnuclear Fabrication					
Total site requirement	226,644	38.2	1,301,598	19,043,761	NA
Change from No Action	39,700	6.2	0	3,270,000	NA
National Ignition Facility					
Total site requirement	228,944	42	1,304,398	16,583,761	NA
Change from No Action	42,000	20	2,800	810,000	NA
Combined Program Impacts					
Total site requirement	268,644	58.2	1,304,398	19,853,761	NA
Change from No Action	81,700	26.2	2,800	4,080,000	NA

Note: NA - not applicable.
Source: SNL 1995b:1; SNL 1995b:4; SNL 1995b:5; SNL 1995e; appendix I.

require minor modifications to accept some functions associated with this action. The nonnuclear fabrication mission at SNL would increase electrical energy usage and fuel (natural gas) consumption by approximately 20 percent relative to the No Action alternative.

SNL's electrical power distribution is by underground 15 kV (nominal) feeder loops. Dual feeders, each capable of carrying the entire load, would be run in new ductbanks and manholes to new double-ended unit substations in a new central plant on the site. The required power for the nonnuclear mission is greater than is usually available from the existing site loops and would most likely require a separate, dedicated, feeder loop from the utility substation. Natural gas is supplied by Kirtland Air Force Base and would be distributed, as required, to the nonnuclear fabrication facilities from the existing underground gas main.

The effect of not including reservoirs in the nonnuclear fabrication mission would not result in any significant reduction in the site infrastructure-related impacts at SNL since this activity only involves final reservoir assembly; primarily welding, along with final inspection, testing, packaging, and shipping. The only machining to be performed would be post-weld dressing. Final certification would include volume measurement and proof testing.

Sensitivity Analysis. The site infrastructure requirements given in table 4.8.3.2–1 reflect facility operating conditions for the production of a base case, multiple-shift, stockpile size. For the reduced stockpile size associated with the low case scenario, there would be a small (10-percent) reduction in the required floorspace and operating personnel. Transition to a high case stockpile size would result in about a 30- to 50-percent increase in these requirements. These deviations in the stockpile size would result in comparable changes in site infrastructure resource requirements.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed NIF alternative at SNL would result in the construction of six new buildings and ancillary facilities (i.e., access roads, parking facilities, and utility extensions). Infrastructure requirements would not exceed any utility resources available at SNL. The NIF mission would increase SNL's electrical energy consumption by approximately 22 percent, whereas the increase in fuel usage would be less than 1 percent relative to the No Action alternative.

Potential Mitigation Measures. No mitigation measures are anticipated.

4.8.3.3 *Air Quality*

No Action. No Action air quality utilizes estimated air emissions data from operations at SNL in 2005 assuming continuation of current site missions to calculate pollutant concentrations at or beyond the SNL site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in table B.3.8–1. Table 4.8.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared with applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards.

Management Alternatives

Nonnuclear Fabrication. No new air pollutant waste streams will be generated by the nonnuclear fabrication mission at SNL. Emissions from the additional nonnuclear fabrication missions at SNL will include exhausts from vehicles and small quantities of aromatic hydrocarbon solvents, alcohols, and related chemistry. Process gases will be vented, but these consist only of naturally occurring atmospheric gases and vapors (i.e., nitrogen, argon, carbon dioxide, helium, hydrogen, and water) and are not considered to be pollutants. Table 4.8.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and nonnuclear fabrication. Concentrations of pollutants resulting from operation of nonnuclear fabrication added to No Action concentrations are expected to be within Federal and state regulations.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the nonnuclear fabrication alternative would result in the same concentrations of criteria and toxic/hazardous pollutants for the high and low case. The concentrations of pollutants for both cases are expected to be within applicable Federal and state regulations and guidelines.

Stewardship Alternatives

Proposed National Ignition Facility. Operation of the proposed NIF would generate criteria and toxic/hazardous pollutants resulting from the combustion of boiler fuel for heating, operation of diesel generators,

and solvent cleaning processes. The emissions consist of PM_{10}, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and VOCs. Boiler fuel is assumed to be natural gas. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the proposed NIF are presented in table B.3.8–1. Table 4.8.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the proposed NIF. Concentrations of pollutants resulting from operation of the proposed NIF added to No Action concentrations are expected to be within Federal and state regulations.

Potential Mitigation Measures. No mitigation measures are anticipated for the nonnuclear fabrication and the proposed NIF at SNL.

4.8.3.4 *Water Resources*

Environmental impacts associated with the construction and operation of the potential stockpile stewardship and management facilities at SNL could affect surface and groundwater resources. All water required for construction or operation would be supplied from local groundwater resources at Kirtland Air Force Base. The proposed sites for the facilities would be outside the 100- and 500-year floodplains. A description of the proposed functions to be transferred to SNL is presented in sections 3.3 and 3.4. Table 4.8.3.4–1 presents existing surface and groundwater resources and the potential changes to water resources at SNL resulting from the proposed alternatives. The total site water resource requirement for each alternative including No Action are displayed in this table.

Surface Water

No Action. Under No Action, no impacts to surface water resources are anticipated because there are no surface water withdrawals or demands. No construction would occur under No Action; therefore, no additional construction water would be used or discharged. Current operation wastewater discharges of 757 MLY (200 MGY) are expected to remain the same in 2005. Treated wastewater effluent would be monitored to comply with the city of Albuquerque's Sewer Use and Wastewater Control Ordinance. No impacts to surface or surface water quality are expected.

Management Alternatives

Nonnuclear Fabrication. No surface water would be used for construction and modification activities or operation. An additional 6.5 MLY (1.7 MGY) of wastewater would be generated by the construction and modification activities of the nonnuclear fabrication facilities. This wastewater increase represents less than 1 percent over the projected sanitary wastewater generation rate. During operation an additional 291 MLY (76.9 MGY) of wastewater would be generated. This wastewater discharge represents a 38.5-percent increase over projected sanitary wastewater generation. A stormwater pollution prevention plan would be prepared and implemented to minimize soil erosion, sedimentation, and contamination of stormwater. During construction and operation, all wastewater would be collected, treated, and discharged to the city of Albuquerque sewer systems. Treated wastewater would be monitored to meet or exceed standards of the city of Albuquerque's Sewer Use and Wastewater Control Ordinance. There would be no new wastewater streams added or special waste handling capability required. There would be no impacts to surface water quality because all wastewater would be discharged to the city of Albuquerque's sewer systems. There would be no change in stormwater runoff due to this alternative. Adverse impacts to surface water are not expected. Nonnuclear fabrication facilities would be located in portions of Technical Areas I and II that are determined to be above the 500-year floodplain.

Stewardship Alternatives

Proposed National Ignition Facility. Construction of the proposed NIF would be expected to have minor to negligible effects on water quality. A stormwater pollution prevention plan would be prepared and implemented to minimize soil erosion, sedimentation, and contamination of stormwater. During operation of NIF, wastewater discharge would be expected to increase by about 18 MLY (4.8 MGY). Wastewater discharges would have to meet all Kirtland Air Force Base and the city of Albuquerque discharge requirements. Appropriate measures would be taken to

TABLE 4.8.3.4–1.—*Potential Changes to Water Resources from Stockpile Stewardship and Management Alternatives at Sandia National Laboratories*

Actions in 100-year floodplain	NA	None	None
Actions in 500-year floodplain	NA	None	None

[a] Total water requirements for construction at SNL are based on a 3-year period for nonnuclear fabrication and a 5-year period for NIF.

[b] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharged would be the same as No Action operation.

[c] All discharges to natural drainages require NPDES permits.

Note: NA - not applicable; MLY - million liters per year.

Source: SNL 1995b:1; SNL 1995e; appendix I.

comply with stormwater discharge regulations associated with construction activities under the CWA.

Groundwater

No Action. Under No Action, baseline conditions and operations, described in section 4.8.2.4, would continue at SNL, and the current groundwater amount of 970 MLY (256 MGY) would increase to 1,390 MLY (367 MGY) by 2005. Groundwater would continue to be withdrawn from local groundwater sources, but no additional impacts to groundwater quality are anticipated because there are no direct discharges to groundwater.

Management Alternatives

Nonnuclear Fabrication. Water requirements for the modification, construction, and operation of the nonnuclear fabrication facilities would be supplied from local groundwater sources at Kirtland Air Force Base. During the modification and construction phase, approximately 0.7 MLY (0.18 MGY) of groundwater would be required. This amount is less than 0.1 percent of the projected SNL groundwater withdrawal of 1,390 MLY (367 MGY) from the Kirtland Air Force Base wells. It is anticipated that an additional 893 MLY (236 MGY) of water would be required to operate the facilities. This amount is an increase of approximately 64-percent over No Action water requirements, but only comprises 29 percent of the Kirtland Air Force Base groundwater rights of 7,900 MLY (2,090 MGY). Adverse impacts to groundwater are not expected.

Groundwater Quality. No process wastes would be discharged directly to the groundwater and all wastewater discharges would be monitored to comply with NPDES permit and other applicable discharge requirements. Given normal safeguards and precautions, no adverse impacts to groundwater quality are expected.

Sensitivity Analysis. All effluent is discharged to the city of Albuquerque; therefore, both the high and low case production scenario for nonnuclear fabrication would have no impacts to surface water quality. Groundwater or groundwater quality would not be affected by the high or low case stockpile requirement for nonnuclear fabrication at SNL.

Stewardship Alternatives

Proposed National Ignition Facility. During construction of the proposed NIF, approximately 3 MLY (0.8 MGY) of additional groundwater would be required. Approximately 152 MLY (40.2 MGY) of additional groundwater would be required during operation of NIF, increasing the water use at SNL by 11 percent over No Action.

Groundwater Quality. No process wastes would be discharged directly to the groundwater, and all wastewater discharges would be monitored to comply with NPDES permit and other applicable discharge requirements. Given normal safeguards and precautions, no adverse impacts to groundwater quality are expected.

Potential Mitigation Measures. No mitigation measures for the stockpile stewardship and management alternatives at SNL are anticipated.

4.8.3.5 *Geology and Soils*

The proposed alternatives for SNL would have no adverse impact on geological resources described in section 4.8.2.5. Although a moderate seismic risk exists for new facilities, this would be considered in the design of the structures. The existing seismic risk does not preclude safe construction and operation of the proposed project facilities. Control measures would be used to minimize any soil erosion. Impacts would depend on the extent of land disturbing activities and the amount of soil disturbed. Potential changes to geology and soils associated with the proposed alternatives at SNL are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at SNL. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Nonnuclear Fabrication. Construction activities would not affect geologic conditions. Designs of the new 58,060 m^2 (625,000 ft^2) facility would ensure that it would not be adversely affected by geologic conditions. The properties and conditions of the soils in the proposed project area place no limitations on the construction or safe operation of project facilities.

The area of land disturbance for nonnuclear fabrication at SNL is approximately 9 ha (22 acres). Part of the construction required for the new Nonnuclear Fabrication Facility includes parking spaces in the form of ground-level, uncovered, paved lots. SNL's practice is to use parking lots as construction staging areas for both material and office trailers and to pave the lots as one of the last construction activities. Further, the new buildings are proposed to be slab-on-grade for the first level, and the proposed construction site is relatively flat and unobstructed, which would minimize the amount of land required for cut-and-fill operations during construction. For modification and renovation of existing buildings, staging activities would use the same operations and staging areas that were used during previous renovations.

Disturbance could occur at building, parking, and construction laydown areas, leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil losses would depend on frequency of storms; wind velocities; size and location of the facilities with respect to drainage and wind patterns; slopes, shape, and area of the tracts of ground disturbed; and whether the soil is bare, particularly during the construction period. Appropriate erosion and sediment control measures would be used to minimize any soil loss.

Net soil disturbance during operations would be less than for construction, because areas temporarily used for laydown would be paved. Although erosion from stormwater runoff and wind action could occur occasionally during operation, it is anticipated to be minimal.

There are no known active faults that cross the area of the proposed facilities. The Tijeras and Sandia faults, located in the eastern portion of SNL, are regarded as the most probable sources for seismic activity in the vicinity of the proposed facilities. The location of active faults and the associated potential ground rupture would be considered in the design of facilities. All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1, and accompanying safety guides. Major seismic activity and associated mass movement and subsidence are unlikely to occur during the construction or operational phases, because seismic activity in the region is generally of low intensity and magnitude (see section 4.8.2.5). Hazards resulting from the return of volcanism are unlikely (see section 4.8.2.5). Potential health impacts from accidents associated with geological hazards are discussed in section 4.8.3.9.

Sensitivity Analysis. The high or low case operation scenario would not affect geology and soils.

Stewardship Alternatives

Proposed National Ignition Facility. The construction and operation of the proposed NIF at SNL would not adversely affect geological resources. NIF would require the clearing of an estimated 11 ha (28 acres) of land for buildings, walkways, building access, and buffer space (see appendix I). Soil impacts during construction would be short term and minor with appropriate standard construction erosion and sediment control measures. Net soil disturbance during operation would be less than for construction because areas temporarily used for laydown would be restored. Seismic risks would be taken into account during construction and operation of NIF.

Potential Mitigation Measures. No mitigation measures for the stockpile stewardship and management alternatives at SNL are anticipated.

4.8.3.6 *Biotic Resources*

The following section addresses impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. Construction and operation of nonnuclear fabrication mission facilities and the proposed NIF would result in a loss of terrestrial habitat. Nonnuclear fabrication mission facilities may also impact special status species.

No Action. Under No Action, the selected nonnuclear fabrication and stewardship R&D missions described in section 3.2.8 would continue at SNL. This would result in no changes to current biotic resource conditions at the site as described in section 4.8.2.6.

Management Alternatives

Nonnuclear Fabrication

Terrestrial Resources. While the nonnuclear fabrication mission at SNL would use some space in existing buildings, approximately 9 ha (22 acres) would be required for construction of new facilities. The area to be developed is located just east of Technical Area I and is characterized as grassland. Grassland is a common plant community type in the area. Animal species within the disturbed area would be either destroyed or displaced depending upon whether they were able to move from the area. For example, many reptiles and small mammals, as well as nests and young birds, would likely be destroyed, while larger mammals and birds would be able to leave the area. Wildlife may also be disturbed by the increased level of human activity associated with the project.

Wetlands. There are no wetlands on or near the proposed site for the location of the nonnuclear fabrication mission at SNL. Wetlands would not be affected by construction or operation of new nonnuclear fabrication facilities.

Aquatic Resources. There is no natural aquatic habitat on or near the proposed site for the location of the nonnuclear fabrication mission at SNL. Aquatic resources would not be affected by construction or operation of new nonnuclear fabrication facilities.

Threatened and Endangered Species. There would be no Federal-listed threatened or endangered species affected by construction and operation of new nonnuclear fabrication facilities at SNL. Considering that grassland habitat is the prevalent plant community type in the site area, the Federal-candidate mountain plover (*Charadrius montanus*) could potentially exist onsite. This bird species could lose possible nesting and foraging habitat as a result of site development. Preactivity surveys would need to be conducted prior to construction in order to determine if any special status species are present on or near the site.

Sensitivity Analysis. While implementation of a low case workload would not alter impacts to biological resources, the high case workload would result in a slight increase in the disturbed grassland area.

Stewardship Alternatives

Proposed National Ignition Facility

Terrestrial Resources. The proposed NIF would be located within a disturbed grassland area of Technical Area II. Construction of new facilities would require 11 ha (28 acres). Proper erosion and sediment control measures would reduce the potential for disturbance of habitat adjacent to the construction area. Animal species within the disturbed area would be either destroyed or displaced, depending upon whether they were able to move from the area. For example, many reptiles and small mammals, as well as nests and young birds, would likely be destroyed, while larger mammals and birds would be able to leave the area. Wildlife may also be disturbed by the increased level of human activity associated with the project.

Wetlands. The proposed NIF site does not contain, nor is it located near, wetlands. The construction and operation of the proposed NIF is not expected to adversely impact this resource.

Aquatic Resources. The proposed NIF site does not contain, nor is it located near, aquatic resources. The construction and operation of the proposed NIF is not expected to adversely impact this resource.

Threatened and Endangered Species. Adverse impacts to special status species are not expected from the construction or operation of the proposed NIF at SNL due to the lack of suitable habitat and the disturbed nature of the proposed site. A site survey may be required to determine the presence of any special status species.

Potential Mitigation Measures. Minimization of the area to be disturbed, revegetation with native species, and implementation of a soil erosion and sediment control plan would help to lessen short- and long-term impacts to terrestrial species and habitats. Disturbance to wildlife living in areas adjacent to management and stewardship facilities may be minimized by preventing workers from entering undisturbed areas. It may be necessary to survey the site for the nests of migratory birds prior to construction and to avoid clearing operations during the breeding season. If any threatened or endangered species occur on the site, specific mitigation measures would be developed in conjunction with the USFWS.

4.8.3.7 *Cultural and Paleontological Resources*

For the discussion of impacts, the term cultural resources includes prehistoric, historic, and Native American resources. Cultural and paleontological resources may be affected directly through ground disturbance, building modifications, visual intrusion of the project to the historic setting, or environmental context of historic sites, visual and noise intrusions to Native American resources, reduced access to traditional use areas, and unauthorized artifact collecting and vandalism. Some NRHP-eligible historic sites may be affected by the proposed action. All of the undisturbed DOE-owned properties at SNL were surveyed for cultural resources between 1989 and 1991. No significant resources were found. However, it is possible that buried archaeological remains are present and that some of the SNL facilities may be NRHP eligible based on their historical or architectural significance (SNL 1993c:1-6). The SNL Sitewide Hydrogeologic Characterization project reports that no important paleontological remains have been recovered from deposits on SNL (apendix I).

No Action. Under No Action, DOE would continue existing and planned missions at SNL as described in section 3.2.8. Any impacts to cultural or paleontological resources would be independent of and unaffected by the proposed action.

Management Alternatives

Nonnuclear Fabrication. This alternative would involve renovation and modification of existing facilities at SNL and the construction of a new stand alone production facility. New construction would be located on available undeveloped land directly east of Technical Area I. Although no NRHP-eligible resources were identified during a pedestrian survey of the proposed nonnuclear fabrication area, the potential for subsurface prehistoric and historic resources exists. In 1989, the Quivira Research Center identified two prehistoric lithic and ceramic scatters in a Kirtland Air Force Base management area adjacent to the proposed project area. Both of these sites are on the southern bank of the Tijeras Arroyo. It is also possible that some of the buildings involved may be NRHP eligible. NRHP-eligible resources would be identified during project-specific surveys and evaluations. Some important Native American and paleontological resources may be affected by the proposed alternative. Any project related effects would be addressed in tiered NEPA documentation.

Sensitivity Analysis. The high and low case scenarios have the same impacts to cultural and paleontological resources. The base case production facilities for the nonnuclear fabrication mission operation would accommodate the high and low case production scenarios.

Stewardship Alternatives

Proposed National Ignition Facility. If the proposed NIF were to be located at SNL, it would require the construction of six buildings on a currently undeveloped tract of 11 ha (28 acres) in Technical Area II. Pedestrian surveys indicate that no prehistoric or historic sites or standing structures exist within the proposed NIF location. The Isleta Pueblo has not identified any important Native American resources nor have important paleontological remains been recovered from deposits in the proposed NIF location. No impacts to cultural or paleontological resources are anticipated from construction and operation of the proposed NIF.

Potential Mitigation Measures. If project design or siting would result in adverse effects to NRHP-eligible sites, then a Memorandum of Agreement would need to be negotiated among DOE, the New Mexico SHPO, and the Advisory Council on Historic Preservation. The Memorandum of Agreement would formalize mitigation measures agreed to by these consulting parties. Mitigation measures could include describing and implementing intensive inventory and evaluation studies, data recovery plans, site treatments, and monitoring programs. The appropriate level of data recovery for mitigation would be determined through consultation with the New Mexico SHPO and the Advisory Council on Historic Preservation, in accordance with Section 106 of the *National Historic Preservation Act*. Mitigation measures for specific NRHP-eligible sites would be identified during tiered NEPA documentation.

If Native American resources cannot be avoided through project design or siting, then acceptable mitigation measures to reduce project effects on them would be determined in consultation with the affected Native American groups. In accordance with the *Native American Graves Protection and Repatriation Act* and the *American Indian Religious Freedom Act*, such mitigations may include, but would not be limited to, appropriately relocating human remains, planting vegetation screens to reduce visual or noise intrusion, increasing access to traditional use areas during operation, or transplanting or harvesting important Native American plant resources.

Because scientifically important buried paleontological materials could be affected, paleontological monitoring of construction activities and data recovery of fossil remains would be appropriate mitigation measures.

4.8.3.8 *Socioeconomics*

No Action. Under No Action, the existing missions at SNL, as described in section 3.2.8, would continue. No new employment or in-migration of workers would be required. Projections of regional economy and employment rates, population and housing statistics, and public finance characteristics are presented in appendix D.

Regional Economy and Employment. Total employment in the regional economic area is projected to increase by less than 2 percent annually between 1995 and 2000, reaching approximately 420,900 in the latter year. Long-range projections show employment growth averaging slightly above 1 percent annually between 2001 and 2020, and then slowing to less than 1 percent between 2021 and 2030 when total employment reaches 563,880. Site employment for SNL is expected to be 7,341 in 2005. The unemployment rate in the regional economic area was 5.7 percent in 1994 and is expected to remain at this level into the near future. Per capita income is projected to increase from approximately $17,676 in 1995 to $25,867 in 2030.

Population and Housing. Annual ROI county and city population and housing increases are projected to average about 2 percent between 1996 and 2005. Annual increases between 2006 and 2030 are expected to average approximately 1 percent. Population in the ROI is estimated to increase from 653,100 in 1995 to 955,600 in 2030. The total number of housing units in the ROI is projected to increase from 267,700 to 391,800 during the same period.

Public Finance. Between 2000 and 2005, all ROI county, city, and school district total revenues are projected to increase at an annual average of less than 1.6 percent. Total expenditures are projected to increase at an annual average of less than 1.5 percent during the same period. These rates of increase should continue until 2030.

Management Alternatives

Nonnuclear Fabrication

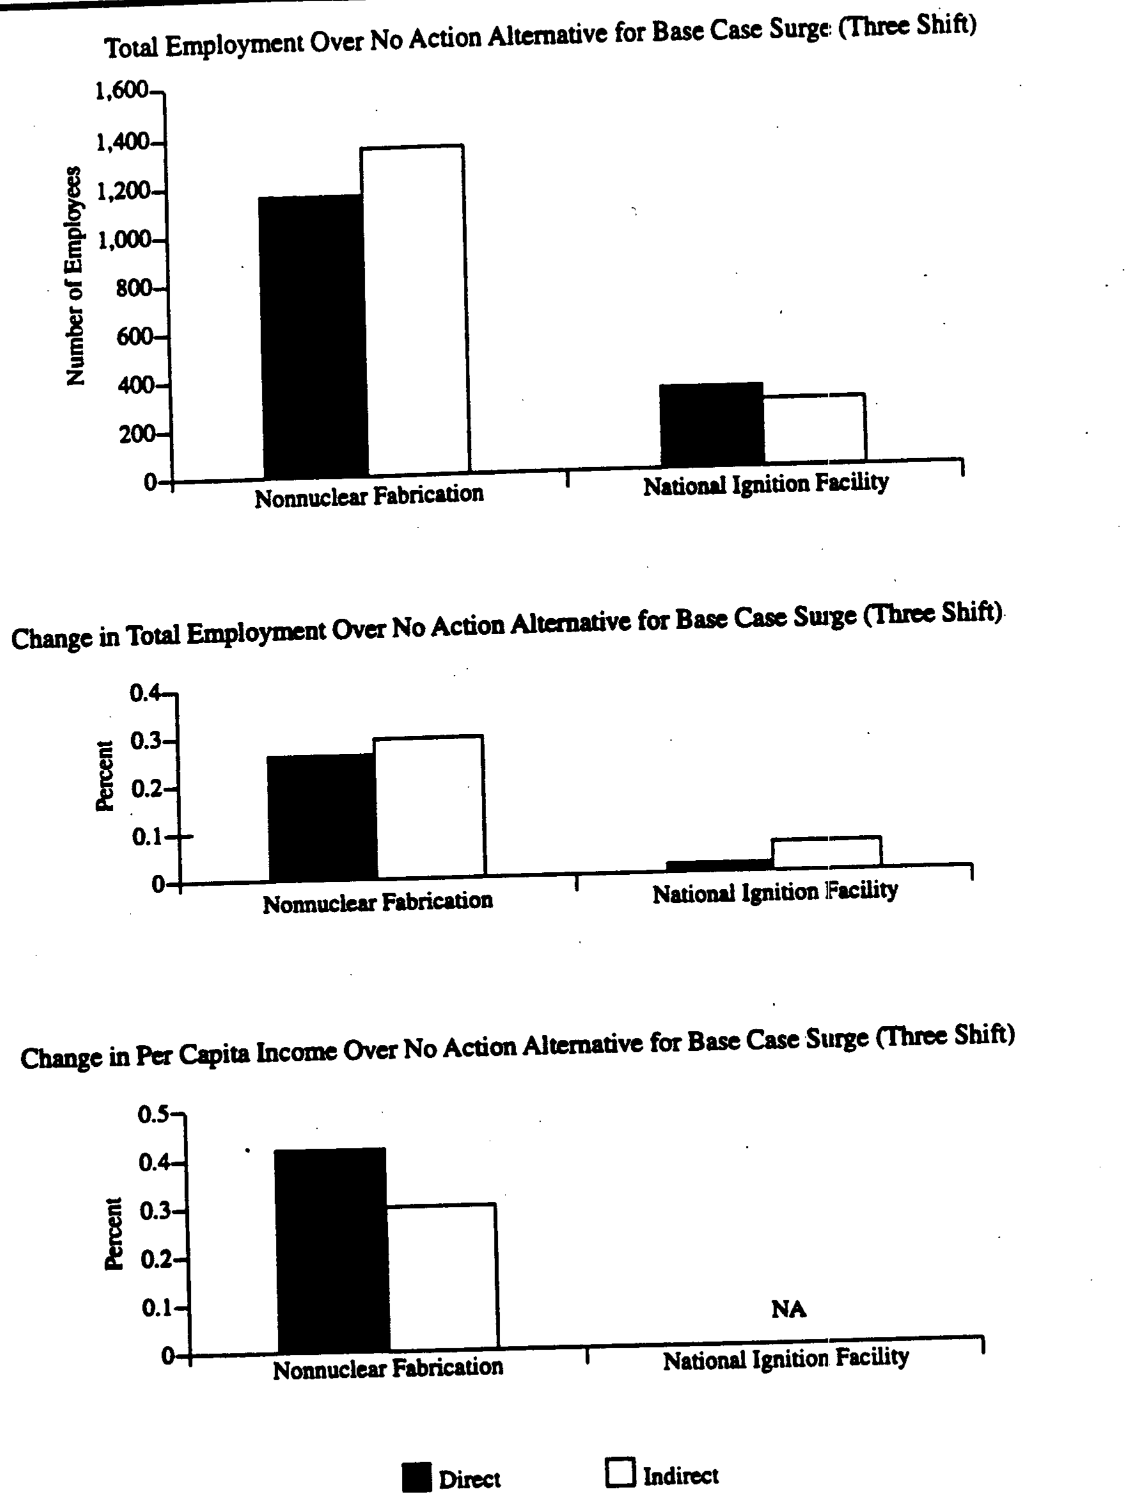
Regional Economy and Employment. Construction-related activities for the Nonnuclear Fabrication Facility would require 379 direct workers during the peak construction year, and would generate 421 indirect jobs in the regional economic area. As a result of the construction and modification activities, total employment in the SNL regional economic area would increase by less than 1 percent. Regional unemployment would fall from the No Action estimate of 5.7 percent to approximately 5.5 percent. Per capita income in the SNL regional economic area would increase very slightly over No Action projections as a result of constructing the facility.

Facility operation-related employment at SNL would begin phasing in as the construction phase neared completion. Operation of the facility in the base case surge mode would require 1,160 direct jobs, and would generate 1,350 additional indirect jobs in the regional economic area. As a result of the operation of the Nonnuclear Fabrication Facility, total employment in the SNL regional economic area would increase by less than 1 percent. Regional unemployment would fall from the 5.7 percent No Action estimate to approximately 5.2 percent. Per capita income for the SNL regional economic area would increase by less than 1 percent over No Action projections. Changes in employment and per capita income resulting from the operation of the Nonnuclear Fabrication Facility are shown in figure 4.8.3.8–1.

Population and Housing. Population in the SNL ROI during peak construction would not increase over No Action projections. Enough workers would be available in the regional economic area and ROI to fill all of the direct and indirect jobs generated by the construction of the facility.

There are not enough available workers to fill all of the direct operation jobs. Approximately 145 workers would in-migrate to fill new positions at the Nonnuclear Fabrication Facility. Changes in the ROI population over No Action during full operation at SNL are shown in figure 4.8.3.8–2. Vacant housing would be sufficient to house in-migrating workers and their families.

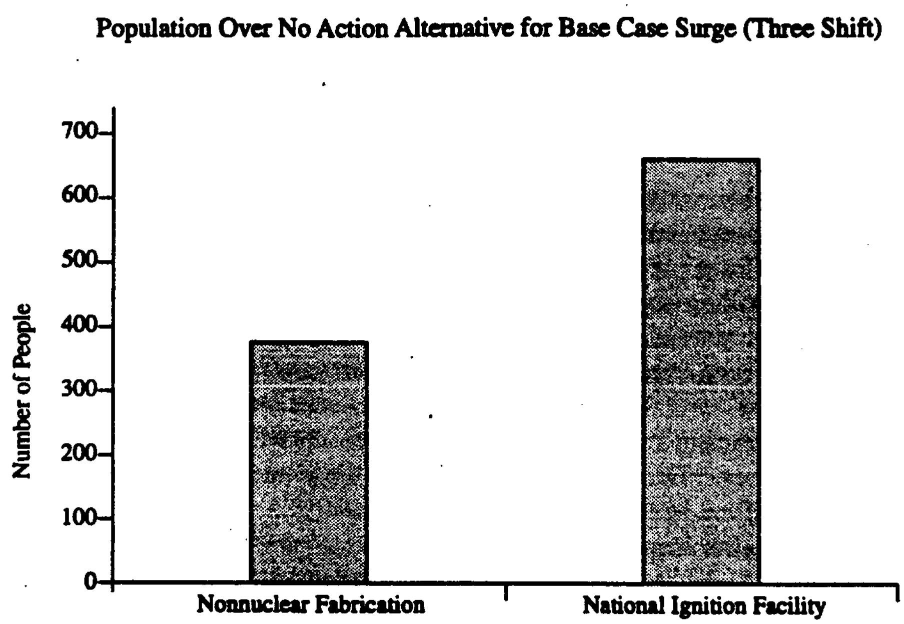
Public Finance. Construction of the Nonnuclear Fabrication Facility would not require in-migrating workers. Therefore, changes to local finances compared to No Action projections would be attributed to income increases and would be negligible.



Note: No Action projections are baseline for comparing proposed alternatives; base case surge does not apply to NIF operation; NA - not applicable.

Source: Socio 1996b.

FIGURE 4.8.3.8–1.—***Employment and Income Changes Resulting from Stewardship and Management Alternatives in the Sandia National Laboratories Regional Economic Area, 2005.***



Note: No Action projections are baseline for comparing proposed alternatives; base case surge does not apply to NIF operation.
Source: Socio 1996b.

FIGURE 4.8.3.8–2.—*Population Changes Resulting from Stewardship and Management Alternatives in the Sandia National Laboratories Region of Influence, 2005.*

Changes in revenues and expenditures compared to No Action projections due to operation of the Nonnuclear Fabrication Facility with reservoirs at SNL are shown in figure 4.8.3.8–3. In 2005, the percent increase in total ROI revenues and expenditures over No Action projections would be negligible (less than 0.1 percent).

Nonnuclear Fabrication Without Reservoirs

The option of terminating the reservoir production mission at SNL would result in 56 fewer direct operations jobs. There would be less in-migration than in the nonnuclear fabrication with reservoirs alternative. This would result in slightly smaller increases in regional economy, population and housing, and public finance than occurred in the nonnuclear fabrication with reservoirs base case surge alternative.

Sensitivity Analysis. There would be no change in the number of construction workers required to complete the Nonnuclear Fabrication Facility for either the high or low case. Operation of the facility at the high case level, would require the same number of workers and would have the same socioeconomic effects as the base case surge level. For the low case, worker requirements would decrease, causing slightly lower increases in regional economy, population and housing, and public finance than occurred in the base case surge level. These changes would be negligible.

Stewardship Alternatives

Proposed National Ignition Facility. The following is a summary of the socioeconomic effects of construction of the proposed NIF at SNL. See appendix I for a more detailed, project-specific discussion.

Regional Economy and Employment. Construction of the proposed NIF would require 280 construction workers during the peak year of construction, and would generate approximately 1,490 additional indirect jobs in the regional economic area. Employment for operation would begin phasing in as the construction phase neared completion. Operation of the facility would require 330 direct workers, and would generate 340 additional indirect jobs in the regional economic area. Construction and operation of NIF would have only minimal effects on the regional economy and employment.

Population and Housing. Both construction and operation of the facility would require workers and their families to in-migrate to the ROI. This in-migration would cause a slight increase in the population of the ROI. Vacant housing in the ROI is sufficient to handle these increases.

Public Finance. Both revenues and expenditures would increase as a result of the construction and operation of the proposed NIF. Increases due to construction would peak in 1998 and then decline as construction neared completion in 2002. Increases due to operation of the facility would peak in 2003 and continue through the duration of NIF operation.

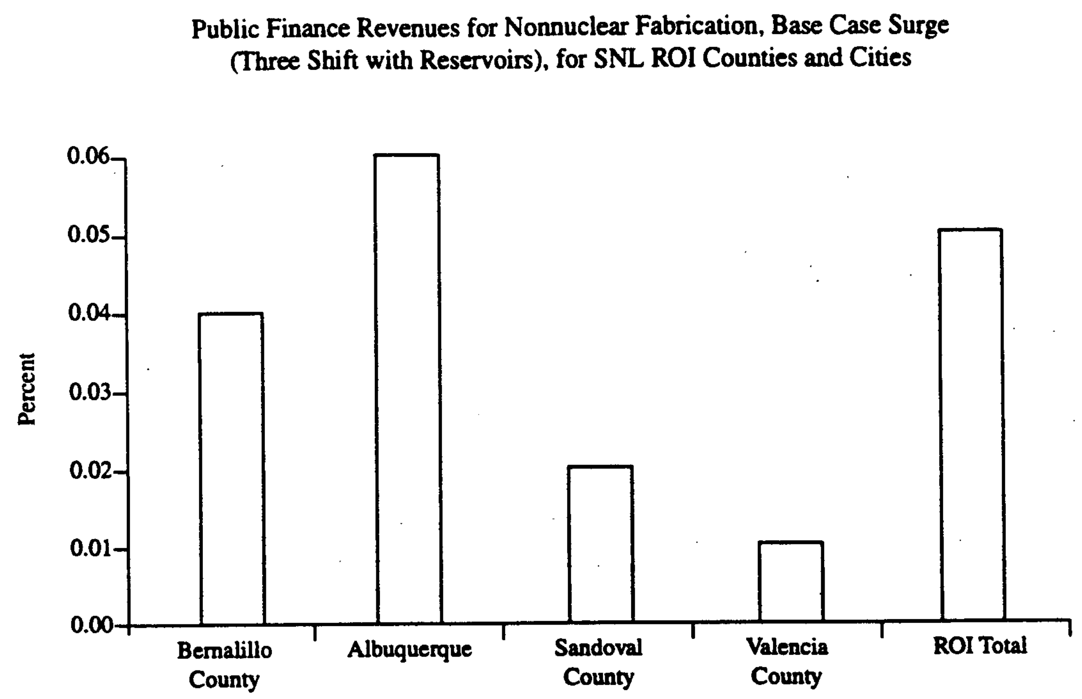
Potential Mitigation Measures. No mitigation measures are anticipated.

4.8.3.9 *Radiation and Hazardous Chemical Environment*

This section describes the radiological and hazardous chemical releases and their associated impacts, which could result from No Action and the proposed alternatives at SNL. Within this section, impacts resulting from the base case scenario are quantitatively discussed, and a sensitivity analysis of the high and low case scenarios is qualitatively discussed.

Summaries of the prevailing radiological impacts at SNL to the public and to workers associated with normal operation are presented in tables 4.8.3.9–1 and 4.8.3.9–2, respectively. Accident impacts are given in table 4.8.3.9–3. The impact assessment methodology is described in section 4.1.9, and further supplementary methodological information is presented in appendixes E and F.

Normal Operation. There would be no radiological releases during the construction or modification of any facilities to support the Stockpile Stewardship and Management Program. However, limited hazardous chemical releases (e.g., small spills of diesel fuel from equipment refueling) may occur due to construction activities for the base case scenario and may increase slightly for the high case scenario. The concentration of these releases is expected to be well within the regulated exposure limits and would not result in any adverse health effects.



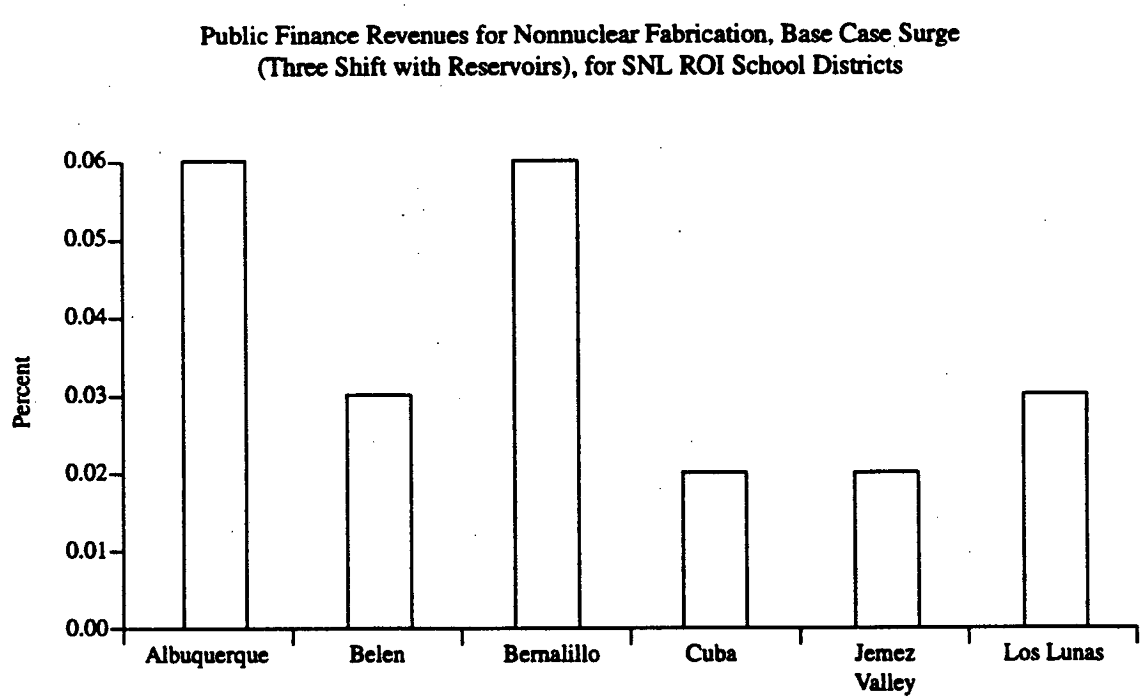


FIGURE 4.8.3.8–3.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Sandia National Laboratories Region of Influence with Nonnuclear Fabrication, 2005* [Page 1 of 2].

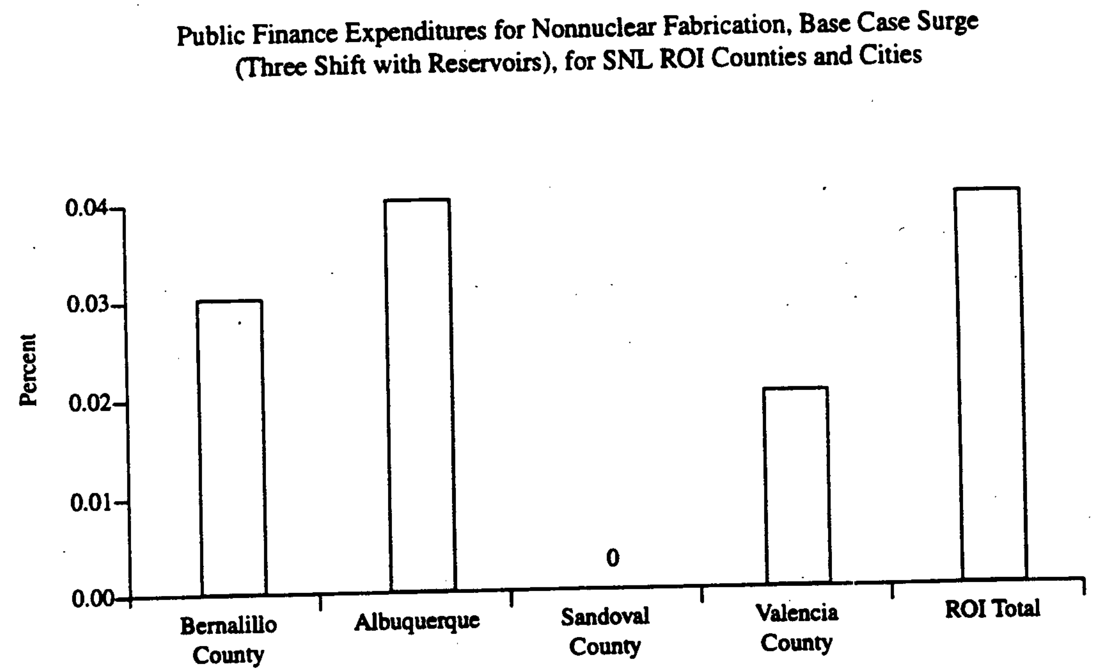

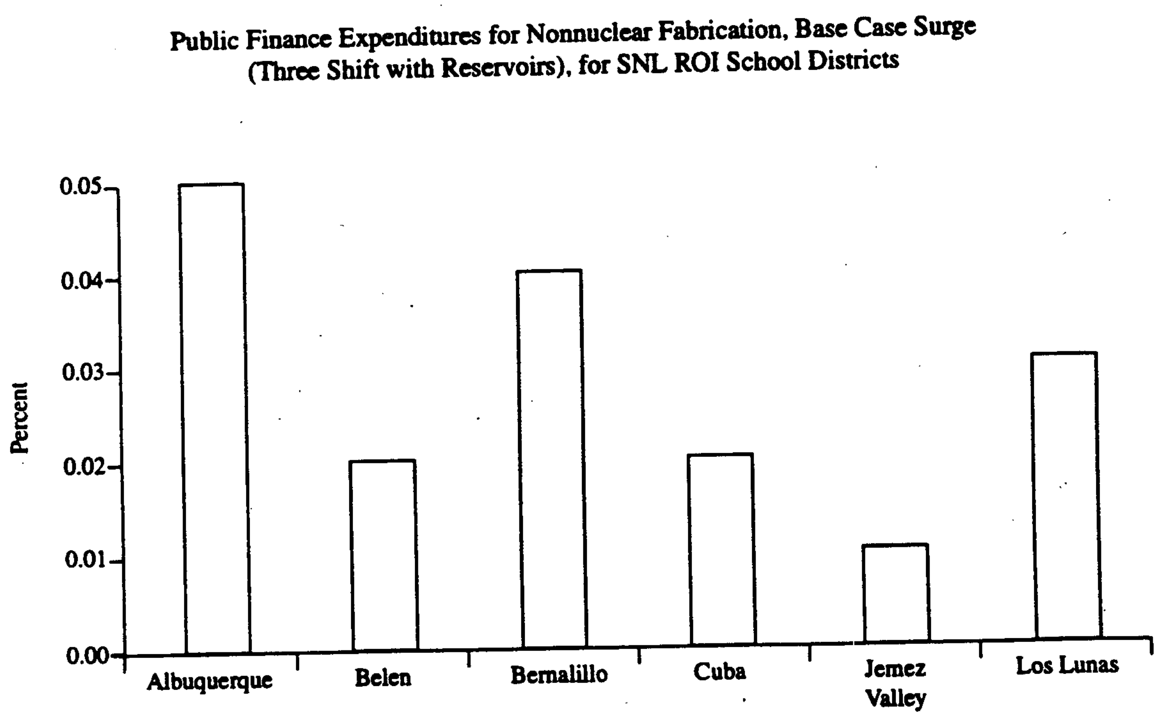

Source: Socio 1996b.

FIGURE 4.8.3.8–3.—*Percent Change from No Action Alternative in County, City, and School District Total Revenues and Expenditures in the Sandia National Laboratories Region of Influence with Nonnuclear Fabrication, Base Case Surge, 2005* [Page 2 of 2].

Water from processes containing hazardous chemicals is not discharged directly into surface water or groundwater that serves as potable water. Process water that may contain hazardous chemicals is treated before discharge to the city of Albuquerque sewer system. Furthermore, state-permitted discharges of stormwater to surface impoundment (lagoons) which can be attributed to the activities associated with normal operation and operation of the stockpile stewardship and management alternatives at SNL are expected to be below New Mexico Water Quality Control Commission Regulations limits. Water quality would not be adversely affected. Thus, the primary pathway considered for the public and the onsite worker is the air pathway.

For normal operation at SNL, all possible hazardous chemicals were examined for further analysis based on their toxicity, concentration, and frequency of use. The HI is a summation of the HQ for all chemicals. The HQ is the value used as an assessment of noncancer toxic effects of chemicals (e.g., kidney or liver dysfunction). It is independent of cancer risk, which is calculated only for those chemicals identified as carcinogens. The HI was calculated for the No Action chemicals and all alternative chemicals proposed to be added (the increment) at the site to yield cumulative levels for the site. An HI of ≤1.0 indicates that all noncancer exposure values meet OSHA standards; if the cancer risk is $\leq 1\times10^{-6}$ (the default value, not a regulatory standard), no further analysis is indicated. A cancer risk of $\leq 1\times10^{-6}$ is considered acceptable by EPA (40 CFR 300.430) because this incidence of cancers cannot be distinguished from the cancer risk for an individual member of the population. Information pertaining to OSHA-regulated exposure limits and toxicity profiles for all hazardous chemicals described in this PEIS may be found in the *Chemical Health Effects Technical Reference* (TTI 1996b).

No Action

Radiological Impacts. Radiological impacts to the public resulting from the No Action alternative are presented in table 4.8.3.9–1. These impacts are representative of the aggregated total which is estimated to exist from all future baseline operational contributions. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from the No Action alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.8.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 1.6×10^{-3} mrem for the No Action alternative. The annual population dose within 80 km (50 mi) in 2030 would be 0.027 person-rem.

Total site doses to onsite workers from normal operation for the No Action alternative are presented in table 4.8.3.9–2. The estimated average annual dose to the entire facility workforce for this alternative would be 11 person-rem. The presented noninvolved worker values were not modeled due to the unavailability of certain site-specific information.

Based on the radiological impacts associated with normal operation under the No Action alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. Hazardous chemical impacts to the public and onsite workers resulting from normal operation under No Action at SNL are presented below. Analyses used to support the values presented in this section are provided in appendix table E.3.4–26. This PEIS does not purport to provide the level of detail needed to go beyond a conservative screening process for hazardous chemicals. As such, the analysis in this PEIS for the No Action alternative should not be relied upon as a basis for judging the sites as having a hazardous health concern. The model used to calculate HI and cancer risk in this PEIS only establishes a baseline for comparison of alternatives among sites. The baseline is then used to determine the extent to which each alternative adds or subtracts from the No Action HI and cancer risk to the public at each site.

The HI for the maximally exposed member of the public at SNL resulting from normal operation under the No Action alternative would be 2.31×10^{-3} and the cancer risk would be zero. The HI for the onsite worker would be 1.04×10^{-5} and the cancer risk would be zero.

The HIs for the public and for the onsite worker are within the acceptable health levels. The cancer risks to the public and the onsite worker are within the EPA default value of 1×10^{-6}.

TABLE 4.8.3.9–1.—*Potential Radiological Impacts to the Public Resulting from Normal Operation of Stockpile Stewardship Alternatives at Sandia National Laboratories*

Affected Environment	No Action Total Site	National Ignition Facility Total Site[a]
Maximally Exposed Individual (Public)		
Atmospheric Release		
Dose[b] (mrem/yr)	1.6×10^{-3}	5.6×10^{-3}
Percent of natural background[c]	4.8×10^{-4}	1.7×10^{-3}
25-year fatal cancer risk	2.0×10^{-8}	7.1×10^{-8}
Liquid Release		
Dose[b] (mrem/yr)	0	0
Percent of natural background[c]	0	0
25-year fatal cancer risk	0	0
Atmospheric and Liquid Releases		
Dose[b] (mrem/yr)	1.6×10^{-3}	5.6×10^{-3}
Percent of natural background[c]	4.8×10^{-4}	1.7×10^{-3}
25-year fatal cancer risk	2.0×10^{-8}	7.1×10^{-8}
Population Within 80 Kilometers		
Atmospheric and Liquid Releases in 2030		
Dose (person-rem)	0.027	0.23
Percent of natural background[c]	1.0×10^{-5}	8.9×10^{-5}
25-year fatal cancers	3.3×10^{-4}	2.8×10^{-3}

[a] Includes impacts from No Action.
[b] The applicable radiological limits for an individual member of the public from total site operations are 10 mrem/yr from the air pathways, 4 mrem/yr from the drinking water pathway, and 100 mrem/yr from all pathways combined (DOE Order 5400.5).
[c] Natural background radiation levels to an average individual are 334 mrem/yr and to the population within 80 km (50 mi) in 2030 are 259,500 person-rem.

Management Alternatives

Nonnuclear Fabrication

Radiological Impacts. There are no radiological impacts associated with this alternative.

Hazardous Chemical Impacts. Hazardous chemical impacts for the public and for the onsite worker resulting from normal operation due to the nonnuclear fabrication mission at SNL are presented below. The HI and cancer risk would remain constant over 25 years of operation, provided exposures remain the same. Analyses to support the values presented in this section are provided in appendix table E.3.4–27.

The incremental HI for the maximally exposed member of the public would be 1.02×10^{-4} and the incremental cancer risk would be 1.65×10^{-7} as a result of the nonnuclear fabrication mission at SNL. The incremental HI for the onsite worker would be 1.60×10^{-4} and the incremental cancer risk would be 1.10×10^{-5} as a result of the nonnuclear fabrication alternative.

Total site operations of the nonnuclear fabrication mission would result in HIs for the public (2.41×10^{-3}) and the onsite worker (1.70×10^{-4}) that are within acceptable health levels. The cancer risks for the public (1.65×10^{-7}) are within the default value. The cancer risks to the onsite worker (1.10×10^{-5}) somewhat exceed the default value of 1×10^{-6} due to emissions of trichloroethylene under the nonnuclear fabrication mission at SNL.

It is likely that emissions of hazardous chemicals would not increase, and may slightly decrease, as a result of implementing the option of not including

TABLE 4.8.3.9–2.—*Potential Radiological Impacts to Workers Resulting from Normal Operation of Stockpile Stewardship Alternatives at Sandia National Laboratories*

Affected Environment	No Action	National Ignition Facility
Involved Workforce[a]		
Average worker dose[b] (mrem/yr)	NA	30
25-year fatal cancer risk	NA	3.0×10^{-4}
Total dose (person-rem/yr)	NA	8.0
Noninvolved Workforce[c]		
Average worker dose[b] (mrem/yr)	3.2	3.2
25-year fatal cancer risk	3.2×10^{-5}	3.2×10^{-5}
Total dose (person-rem/yr)	11	11
Total Site Workforce[d]		
Dose (person-rem/yr)	11	19
25-year fatal cancers	0.11	0.19

[a] The involved worker is a worker associated with operation of NIF. The estimated number of involved workers is 267 for NIF.
[b] The radiological limit for an individual worker is 5,000 mrem/yr (10 CFR 835).
[c] The noninvolved worker is an onsite worker not associated with operation of NIF. The estimated number of noninvolved workers is 3,400 for NIF.
[d] The total site workforce is the sum of the number of involved and noninvolved workers. The estimated number of workers in the total site workforce is 3,400 for No Action and 3,667 for NIF.
Note: NA - not applicable.
Source: DOE 1993n:7; appendix I.

reservoirs in the nonnuclear fabrication alternative at SNL. Therefore, no effects on the existing HI and cancer risk impacts for the public and onsite workers are expected.

Sensitivity Analysis. Operations under the low case scenario for nonnuclear fabrication are expected to reduce hazardous chemical emissions by up to 50 percent at SNL and, therefore, would likely reduce the HIs and cancer risks for the public and the onsite worker.

Operations under the high case scenario for nonnuclear fabrication may result in up to a 4-fold increase in the emissions of hazardous chemicals at SNL. The HI for the public and the onsite worker should remain within the cumulative HQ screening level of 1.0 (the HI). Cancer risks for the public are well within the default value of 1×10^{-6} and would not exceed this level under the high case scenario. Since cancer risk impacts for the onsite workers already exceed the EPA default value, operations under the high case scenario would further contribute to the adverse cancer risk impacts.

Stewardship Alternatives

Proposed National Ignition Facility

Radiological Impacts. Radiological impacts to the public resulting from normal operation of the proposed NIF for the enhanced option scenario are presented in table 4.8.3.9–1. These impacts are representative of the aggregate total which is estimated to exist from all future baseline operational SNL contributions and from enhanced option operations of the proposed NIF at the site. Total impacts are provided to compare with applicable regulations governing total site operations. To place doses to the public from this alternative into perspective, comparisons are made to natural background radiation. As shown in table 4.8.3.9–1, the total dose to the maximally exposed member of the public from annual total site operations is within radiological limits and would be 5.6×10^{-3} mrem for this alternative. The annual population dose within 80 km (50 mi) in 2030 would be 0.23 person-rem.

Total site doses to onsite workers from normal operation of the proposed NIF are presented in table

4.8.3.9–2. The average annual dose to involved workers for this alternative would be 30 mrem. The dose to the entire facility workforce (involved workforce) would be 8.0 person-rem. The presented total dose to noninvolved workers was not modeled due to the unavailability of certain site-specific information.

Based on the radiological impacts associated with normal operation of this alternative, all resulting doses would be within radiological limits and are well below levels of natural background radiation. The associated risks of adverse health effects to the public and to workers would be small.

Hazardous Chemical Impacts. No hazardous chemical impacts are expected from operation of the proposed NIF (see appendix I). Therefore, the HI and cancer risk to the public and the onsite worker were not calculated nor assessed.

Potential Mitigation Measures. Mitigation measures such as substituting less toxic solvents and chemicals or modifying processes are proposed to reduce or eliminate the emissions of trichloroethylene due to site operations. Radioactive airborne emissions to the general population and onsite exposures to workers could be reduced by implementing the latest technology for process and design improvements. For example, to reduce public exposure from emissions, improved building and work area control methods could be used to remove radioactivity from the releases to the environment. Similarly, the use of remote, automated, and robotic production methods are examples of techniques that are being developed that would reduce worker exposure (see section 3.5).

Facility Accidents. The proposed actions have the potential for accidents that may impact the health and safety of workers and the public. The potential for and associated consequences of reasonably foreseeable accidents that have been assessed are summarized in this section.

No Action. Under the No Action alternative, nonnuclear fabrication and stewardship R&D would continue to be performed at SNL with no changes to facilities and operations. Under existing conditions, potential accidents and their consequences have been addressed in facility safety documentation according to requirements in DOE orders. In addition, there are other facilities at SNL besides those for nonnuclear fa brication and stewardship R&D. The potential for accidents at these other facilities has been similarly addressed and documented.

Management Alternatives. This section provides accident information on the nonnuclear fabrication alternative for SNL.

Nonnuclear Fabrication. The impacts of potential accidents associated with nonnuclear fabrication activities at SNL were previously addressed in *Nonnuclear Consolidation Environmental Assessment* (DOE/EA-0792, June 1993) where it was determined that the then current accident profile would not change as a result of the relocation of nonnuclear fabrication functions to SNL. The present proposed action to transfer the nonnuclear fabrication mission to SNL is not expected to change the accident profile that presently exists at the site.

Stewardship Alternatives

Proposed National Ignition Facility. Studies of potential accidents associated with the proposed NIF have been performed. A bounding accident was postulated based on a preliminary hazard analysis. The bounding accident assumes a severe earthquake of 1 G horizontal ground acceleration occurring during a maximum-credible-yield fusion experiment. Beamlines streaking into the target chamber and building structures other than the target area building would fail during the postulated earthquake. The collapsed beamlines and building structures would provide a pathway for acute atmospheric releases of tritium from the tritium processing system, activated gases in the air, and activated material in the target chamber.

The frequency of this severe earthquake is estimated at $1x10^{-4}$ per year. The joint frequency of the severe earthquake during the maximum-credible-yield fusion experiment would be less than $2x10^{-8}$ per year. The radiological impacts of the accident, presented in table 4.8.3.9–3, were estimated using the GENII computer code.

TABLE 4.8.3.9–3.—***Consequences and Risk of the Bounding Proposed National Ignition Facility Accident at Sandia National Laboratories***

Parameter	Conceptual Design	Enhanced Baseline Option
Workers Onsite		
Dose (person-rem)	20	33
Fatal cancers	0	0
Risk (cancer fatalities per year)	2×10^{-10}	3×10^{-10}
Maximally Exposed Individual

4.8.3.10 *Waste Management*

This section summarizes the impacts on waste management at the Albuquerque location of SNL under No Action and for each of the proposed alternatives. There is no spent nuclear fuel, HLW, or TRU waste associated with nonnuclear fabrication or the proposed NIF; therefore, there is no further discussion of these wastes at SNL. Table 4.8.3.10–1 lists the projected waste generation rates and treatment, storage, and disposal capacities under No Action. Projections for No Action were derived from 1994 environmental data, with the appropriate adjustments made for those changing operational requirements where the volume of wastes generated are identifiable. The projection does not include wastes from future, yet uncharacterized, environmental restoration activities.

Table 4.8.3.10–2 provides the total estimated operational waste volumes projected to be generated at SNL as a result of the nonnuclear fabrication alternative and the NIF alternative. The net increase over No Action is shown in the table in parentheses. The waste volumes generated from the alternatives and the resultant waste effluent used in the impact analysis can be found in table 3.4.2.5–3 for nonnuclear fabrication and table 3.3.2.2–3 for NIF. Facilities that would support the Stockpile Stewardship and Management Program would treat and package all waste generated into forms that would enable long-term storage and/or disposal in accordance with the *Atomic Energy Act,* RCRA, and other applicable statutes as outlined in appendix section H.1.2.

No Action. Under No Action, TRU, low-level, mixed, hazardous, and nonhazardous wastes would continue to be generated at SNL from the missions described in section 3.2.8. SNL would continue to treat, store, and dispose of its legacy and newly generated wastes in current and planned facilities. Liquid LLW would be neutralized and solidified. Solid LLW would be compacted, packaged, and stored at the Technical Area III storage site for shipment to NTS. Both liquid and solid mixed waste would be treated in the Technical Area III Radioactive and Mixed Waste Management Facility and disposed of according to the SNL Site Treatment Plan which was developed pursuant to the *Federal Facility Compliance Act* of 1992. The resulting waste would be stored in a RCRA-permitted facility in DOT-approved containers until shipped to an offsite DOE disposal facility. Some of this waste would be placed in interim storage until new technologies for treatment and disposal are identified and evaluated. Hazardous waste would be packaged and shipped offsite to RCRA-permitted treatment storage and disposal facilities. Liquid sanitary waste would continue to be sent to the City of Albuquerque Municipal Sanitary Sewer System. Solid nonhazardous sanitary waste would be disposed of at the Albuquerque Sanitary Landfill.

Management Alternatives

Nonnuclear Fabrication. The Nonnuclear Fabrication Facility at SNL would not generate any TRU waste, LLW, or mixed LLW. Minimal impacts would result from the 15 m^3 (3,840 gal) of liquid hazardous waste and 17 m^3 (22 yd^3) of solid hazardous waste, which would be packaged and stored onsite in RCRA-permitted facilities prior to shipment offsite to commercial RCRA-permitted treatment, storage, and disposal facilities. The estimated 291,000 m^3 (77,000,000 gal) of sanitary waste would be

[a] No Action volumes are from table 4.8.3.10–1.
[b] Volumes for nonnuclear fabrication are from table 3.4.2.5–3 and are based on surge operations (three shifts).
[c] Volumes for NIF are from table 3.3.2.2–3 and are based on the conceptual design.
Note: Waste generation volumes were rounded to three significant figures. Waste effluent volumes are found in sections 3.3 and 3.4.

conveyed to the City of Albuquerque Municipal Sanitary Sewer System. Additional treatment in accordance with site practice and discharge permits may be required. Following volume reduction, 3,940 m^3 (5,150 yd^3) per year of solid nonhazardous waste would be disposed of at the Albuquerque Sanitary Landfill. Minimal impacts to the remaining capacity of the landfill are expected.

Sensitivity Analysis. The waste volumes generated from the Nonnuclear Fabrication Facility required to support a larger stockpile level (high case) operating on a single-shift basis are bounded by the base case under surge operations. Thus, there are no additional waste management impacts associated with the Nonnuclear Fabrication Facility that would support a high case stockpile operating at a single shift. The volumes generated from the Nonnuclear Fabrication Facility required to support a low case stockpile would be reduced by a factor of at least three.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed NIF would not generate any TRU waste. The 0.6 m^3 (159 gal) of liquid LLW would require treatment prior to disposal. Liquid LLW is currently stored at the point of generation. Treatability studies are being conducted prior to applying for a RCRA permit for treating and storing liquid LLW and mixed waste. The 3 m^3 (4 yd^3) of solid LLW would be packaged in approved waste containers and staged in the Technical Area III storage site pending shipment directly to NTS for management. Assuming a land usage factor of 6,000 m^3/ha (3,180 yd^3/acres), less than 0.0005 ha/yr (0.0001 acres/yr) of LLW disposal area would be required.

The SNL Site Treatment Plan for Mixed Waste was developed to comply with the *Federal Facility Compliance Act.* The mixed waste streams identified at SNL have been combined into 16 treatability groups, each with a preferred treatment option. The type of mixed wastes generated by NIF would fit into one of the established 16 treatability groups and would not require the creation of new treatability groups or new preferred treatment options. The annual generation of 2 m^3 (528 gal) of liquid mixed wastes and the annual generation of 0.3 m^3 (0.4 yd^3) of solid mixed waste would have a negligible impact on the available storage capacity of the main areas for future mixed waste storage: the seven Manzano bunkers, the Radioactive and Mixed Waste Management Facility, and Building 6596.

Minimal impacts would result from the 2 m^3 (608 gal) of liquid hazardous waste and 8 m^3 (10 yd^3) of solid hazardous waste, which would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. There are no adverse impacts expected from the annual volume of 17,900 m^3 (4.72 million gal) of liquid nonhazardous sanitary waste discharged to the City of Albuquerque Municipal Sanitary Sewer System. Additional treatment in accordance with site practice and discharge permits may be required. Minimal impacts to the Albuquerque Sanitary Landfill would result from the 6,050 m^3 (7,910 yd^3) of solid nonhazardous waste.

Combined Program Impacts. If all the stockpile stewardship and management alternatives listed in table 4.8.3.10–2 were located at SNL, the impacts from low-level and mixed LLW would be identical to those discussed for NIF. Minimal impacts would result from the program total of 17 m^3 (4,450 gal) of liquid and 25 m^3 (33 yd^3) of solid hazardous wastes. Adequate facilities exist to package and stage these wastes in onsite RCRA-permitted facilities prior to shipment offsite to commercial RCRA-permitted treatment and disposal facilities. There are no adverse impacts expected from the program total of 309,000 m^3 (81.7 million gal) annual volume liquid sanitary wastes discharged to the City of Albuquerque Sanitary Sewer System. Additional treatment in accordance with site practice and discharge permits may be required. After volume reduction, approximately 9,990 m^3 (13,100 yd^3) of solid sanitary waste would require disposal at the Albuquerque Sanitary Landfill. Minimal impacts to the landfill are expected.

Potential Mitigation Measures. Waste quantities or waste forms could undergo additional reductions by utilizing emerging technologies, thereby further reducing or mitigating impacts. Pollution prevention and waste minimization would be considered in determining the final actions of the Stockpile Stewardship and Management Program at SNL. Utilization of existing and planned treatment and storage facilities would be maximized to further reduce impacts.

4.8.3.11 *Environmental Justice*

As discussed in section 4.14, any impacts to surrounding communities would most likely result from toxic or hazardous air pollutants and radiological emissions. Section 4.8.3.9, which describes public and occupational health impacts from normal operation, shows that potential chemical air emissions and releases are not within the generally accepted threshold of regulatory concern. This information is based on the conservative programmatic assumptions and modeling detailed in appendix E. Any adverse human health or environmental impacts that might occur would affect people living within communities located near SNL. The analysis of the demographic data presented in appendix D for the communities surrounding SNL indicates that if there were any adverse health impacts to these communities, they would not appear to disproportionately affect minority or low-income populations.

4.9 Nevada Test Site

NTS was established in 1950 and currently occupies approximately 351,000 ha (867,000 acres) located 105 km (65 mi) northwest of Las Vegas, NV. The site has conducted underground testing of nuclear weapons and evaluation of the effects of nuclear weapons on military communications systems, electronics, satellites, sensors, and other materials. In October 1992, underground nuclear testing was halted, yet the site maintains the capability to resume testing if authorized by the President. Section 3.2.9 provides a description of all DOE missions and support facilities at NTS. The location of NTS within the state of Nevada is illustrated in figure 4.9–1, and the principal facilities at NTS are shown in figure 4.9–2.

4.9.1 Description of Alternatives

There are no facilities at NTS that would be phased out as a result of any of the proposed alternatives discussed in this PEIS.

No Action. NTS would continue to perform the mission described in section 3.2.9.

Stockpile Management Alternatives. The A/D mission, including the nonintrusive modification pit reuse mission (hereafter referred to as A/D), and the option of storage of strategic reserves of plutonium and uranium could be located at NTS.

Stockpile Stewardship Alternatives. NIF could be located at NTS (at the main site or at NLVF).

4.9.2 Affected Environment

The following sections describe the affected environment at NTS and NLVF for land resources, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, and socioeconomics. In addition, the infrastructure, radiation and hazardous chemical environment, and waste management conditions are described.

4.9.2.1 *Land Resources*

Land Use. NTS occupies approximately 351,000 ha (867,000 acres) in southern Nye County in southern Nevada, with the southwestern boundary located approximately 16 km (10 mi) from California. The town of Indian Springs and the Indian Springs Air Force Auxiliary Field, in northeast Clark County, NV, are 39 km (24.2 mi) southeast of the closest NTS boundary. All of the land within NTS is owned by the Federal Government and is administered, managed, and controlled by DOE. NTS is also entirely bordered by Federal land: the land to the west, north, and east consists of the Nellis Air Force Range; the land to the south is administered by the Bureau of Land Management.

Generalized land uses at NTS and its vicinity are shown in figure 4.9.2.1–1. NTS is divided into 3 major regions consisting of 26 areas. The northern region of NTS is the underground nuclear weapons test area. Nuclear test ranges are located at Yucca Flats, Pahute Mesa, Rainier Mesa, and Buckboard Mesa. The southwest region of NTS (Area 25) provides support for nonweapons and nonnuclear weapons programs, such as the proposed HLW repository at the Yucca Mountain Project Site. Area 25 also provides support for short-term activities such as the nuclear weapons accident exercises conducted by the Nuclear Emergency Search Team. The southeastern region is the nonnuclear test area and primary administrative and support area of NTS.

Land areas not used for missions or other purposes have been designated in the *Nevada Site Development Plan* as reserve areas, available for future development (NT DOE 1994d:7-8). Approximately 4,050 ha (10,000 acres) of reserve areas are present within Areas 5 and 6, which are located in Frenchman and Yucca Flats. Figure 4.9.2.1–2 identifies the primary facilities, A/D area, and testing areas at NTS.

The Device Assembly Facility, undergoing final construction, is designed to conduct all nuclear assembly operations at NTS in support of the Nuclear Weapons

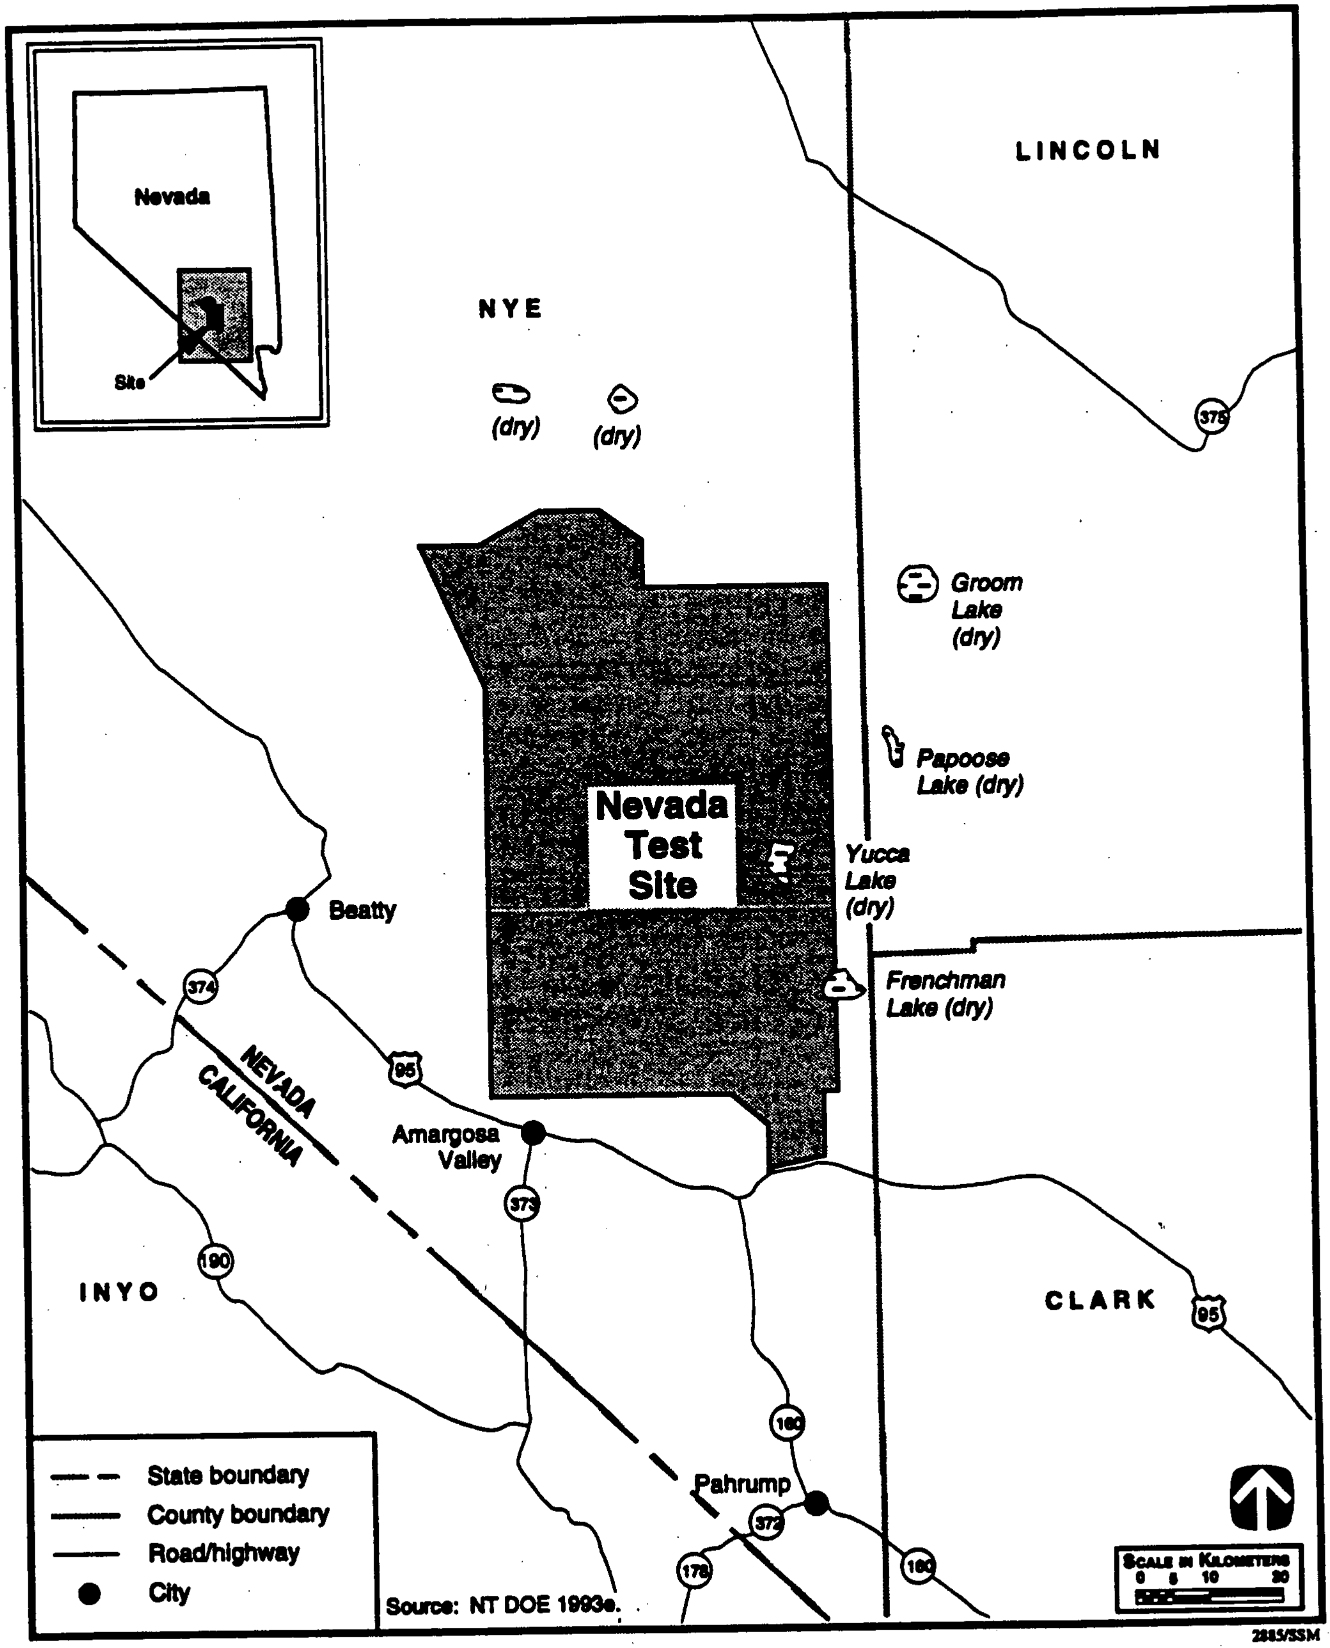

FIGURE 4.9–1.—*Nevada Test Site, Nevada, and Region.*

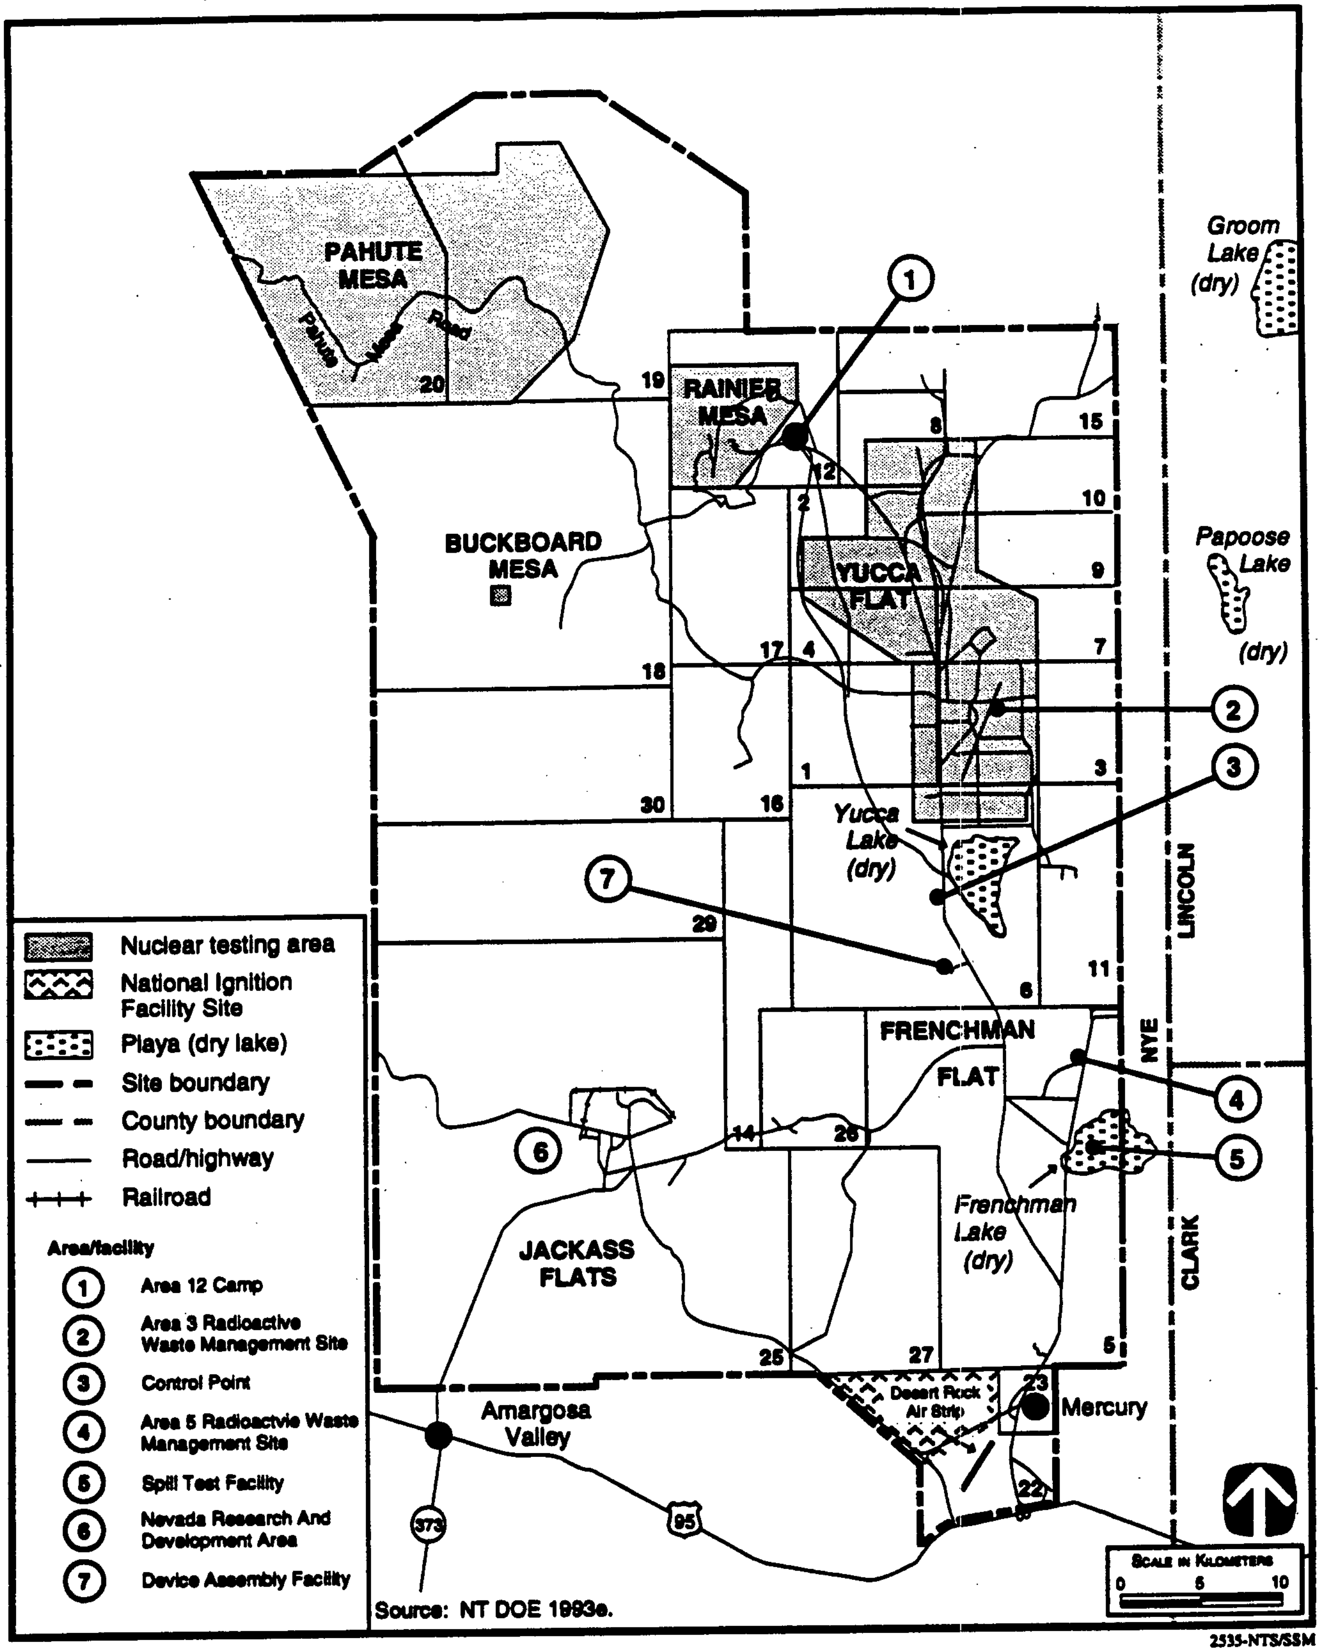

Figure 4.9–2.—*Principal Facilities and Testing Areas at Nevada Test Site.*

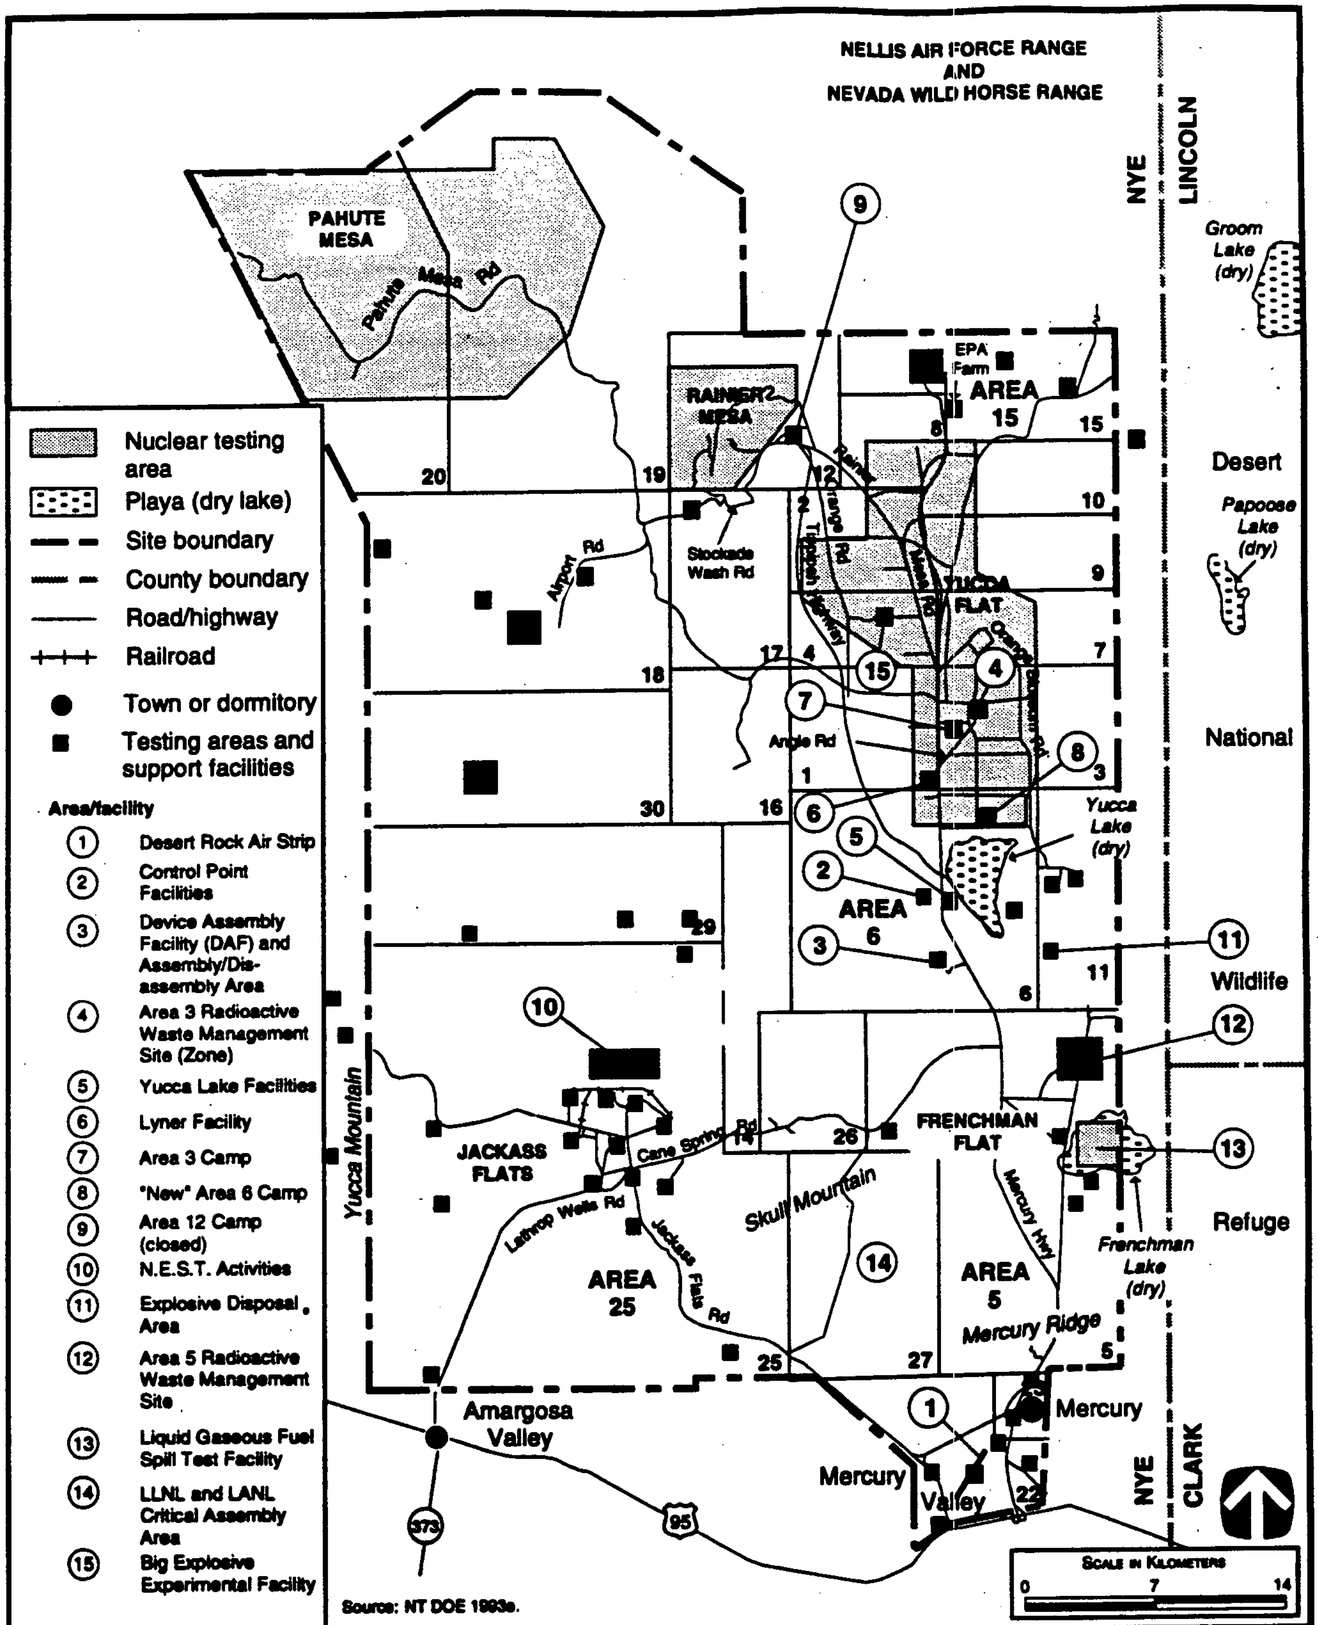

FIGURE 4.9.2.1–2.—*Primary Facilities, Assembly/Disassembly Area, and Testing Areas at Nevada Test Site.*

Test Program. Other nearby facilities include the DOD test area, explosives disposal area, radioactive waste management site, and the Spill Test Facility.

In 1992, DOE designated the entire NTS as a National Environmental Research Park. The park is used by the national scientific community as an outdoor laboratory for research on the effects of human activities on the desert ecosystem. There is no prime farmland present on NTS. Offsite agricultural activity occurs on the south side of U.S. Route 95, consisting of a cattle allotment granted by the Bureau of Land Management.

The Timber Mountain Caldera National Natural Landmark is located approximately 11 km (6.8 mi) north-northwest of the Device Assembly Facility, separated by mountains to the west. A wilderness study area located within the Desert National Wildlife Refuge, which has been recommended for inclusion in the National Wilderness System, is approximately 12 km (7.5 mi) to the east. This part of the refuge is also a part of the Nellis Air Force Range; it is jointly managed by the U.S. Air Force and USFWS. Public entry to this portion of the refuge is generally prohibited by the Air Force. The closest offsite residence to the NTS boundary is approximately 2 km (1.2 mi) south, at the unincorporated town of Amargosa Valley.

North Las Vegas Facility

Land Use. NLVF occupies 32 ha (80 acres) in the city of North Las Vegas, NV, as shown in figure 4.9.2.1–3. NLVF is zoned for general industrial use and is bordered on the north, south, and east by general industrial zoning. The western border of the site is adjacent to Commerce Street, which separates the property from fully developed, single-family residential-zoned property (figure 4.9.2.1–4).

NLVF is divided into three distinct areas: the A, B, and C Complexes. Complex A covers 8 ha (20 acres) and houses support for the LLNL nuclear test program. Complex B covers 8 ha (20 acres) just south of Complex A and houses support for the LANL test program. Complex C, located west of A and B Complexes, covers 15.5 ha (38.3 acres) and houses a computer center and administrative and engineering support functions (appendix I).

4.9.2.2 *Site Infrastructure*

As shown in figure 4.9.2.1–1, activities at NTS are concentrated in facilities in several general areas. Section 3.2.9 describes the current NTS missions. To support these missions an infrastructure exists as shown in table 4.9.2.2–1.

TABLE 4.9.2.2–1.—***Baseline Characteristics for Nevada Test Site***

Characteristics	Current Value
Land	
Area (ha)	351,000
Roads (km)	640
Railroads (km)	0
Electrical	
Energy consumption (MWh/yr)	121,460
Peak load (MWe)	27.4
Fuel	
Natural gas (m^3/yr)	0
Liquid (L/yr)	5,716,000
Coal (t/yr)	0

4.9.2.3 *Air Quality*

The following section describes the existing air quality at NTS and NLVF and includes a review of meteorology and climatology in the vicinity. More detailed discussions of air quality methodologies, input data, and atmospheric dispersion characteristics are presented in appendix section B.3.9 and appendix I.

Meteorology and Climatology. The climate at NTS and in the surrounding region is characterized by limited precipitation, low humidity, and large diurnal temperature ranges. The lower elevations are characterized by hot summers and mild winters, which are typical of other Great Basin desert areas. As elevation increases, precipitation amounts increase and temperatures decrease (NT DOE 1986b:3-46).

The annual average temperature is 19.5 °C (67.1°F); the average daily minimum temperature is 0.9 °C (33.6°F) in January; and the average daily maximum temperature is 41.1 °C (105.9°F) in July. The average annual precipitation at NTS is 10.5 cm (4.13 in) (NOAA 1994d:3). Prevailing winds at NTS vary

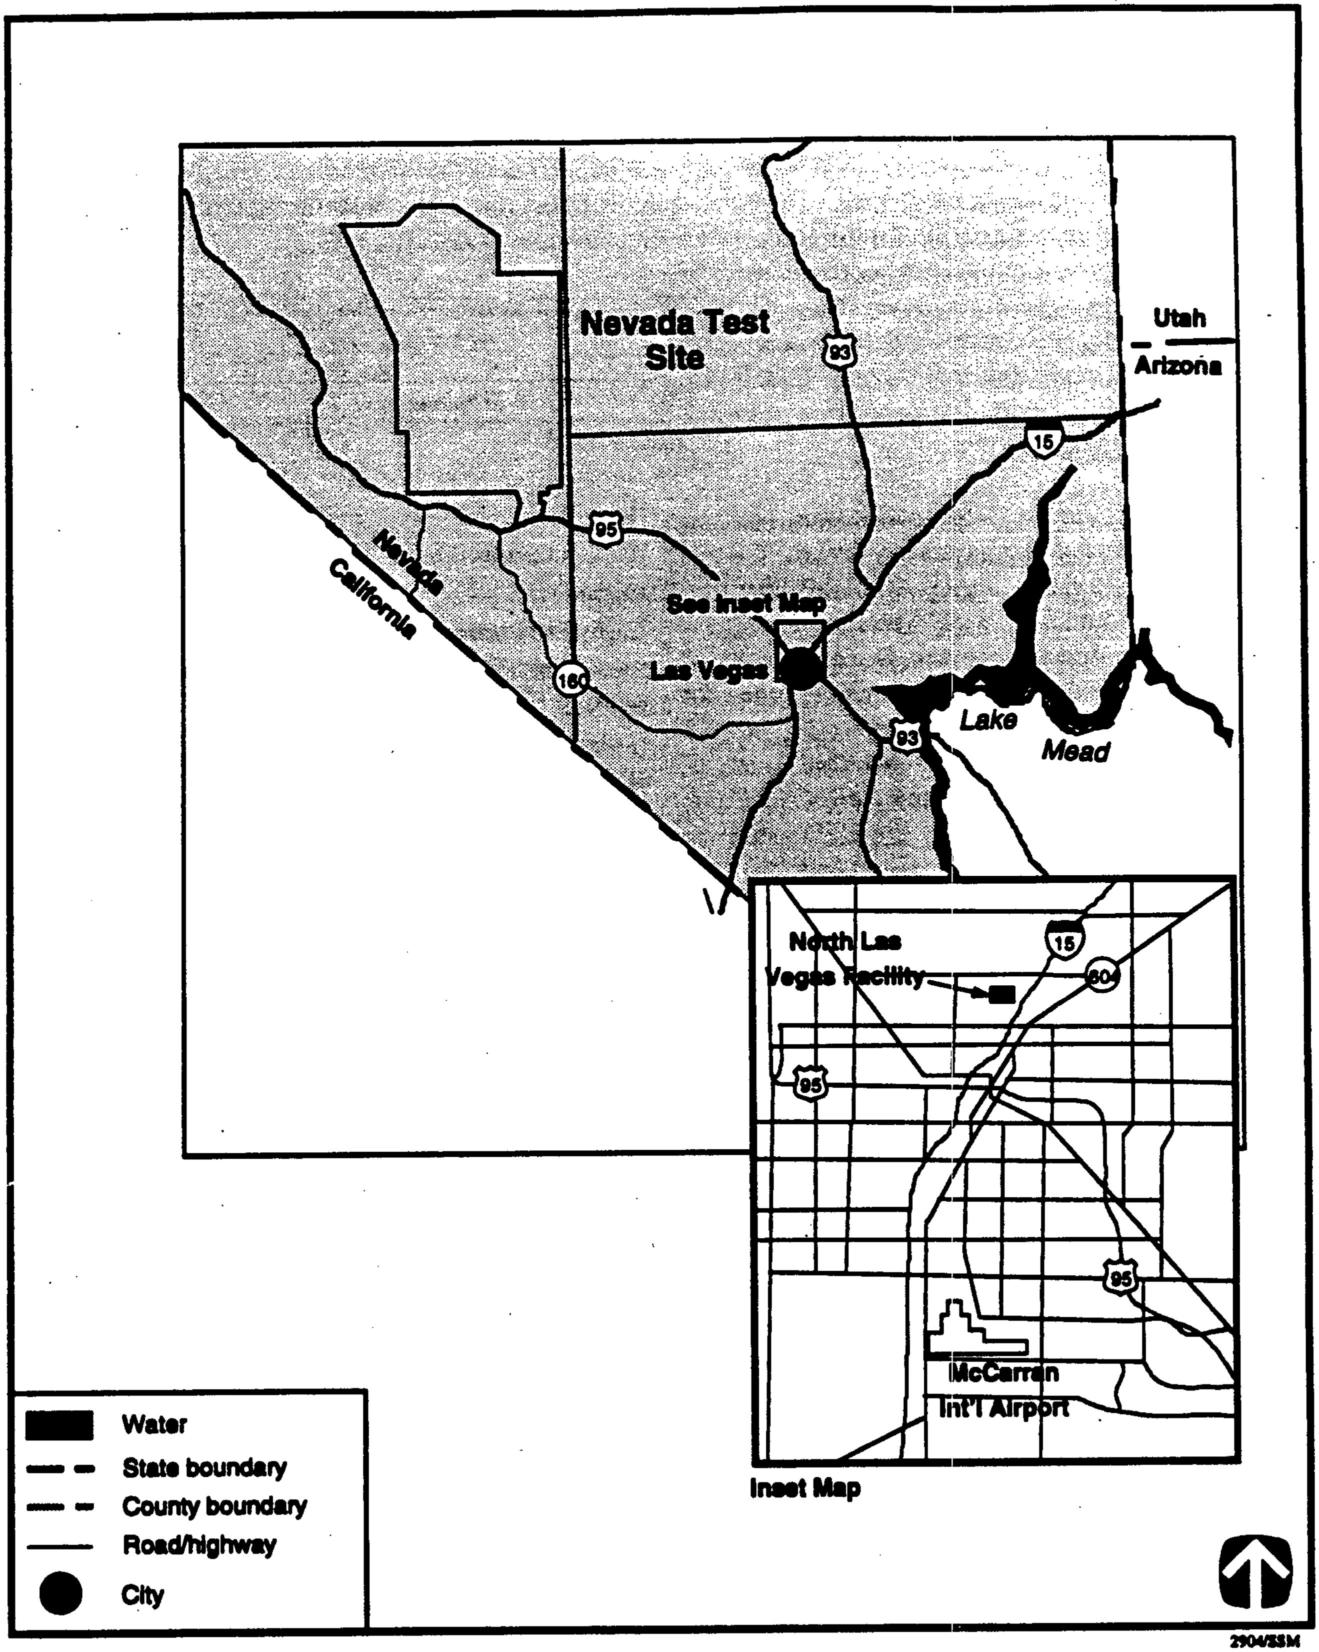

FIGURE 4.9.2.1–3.—*Regional Location of the North Las Vegas Facility.*

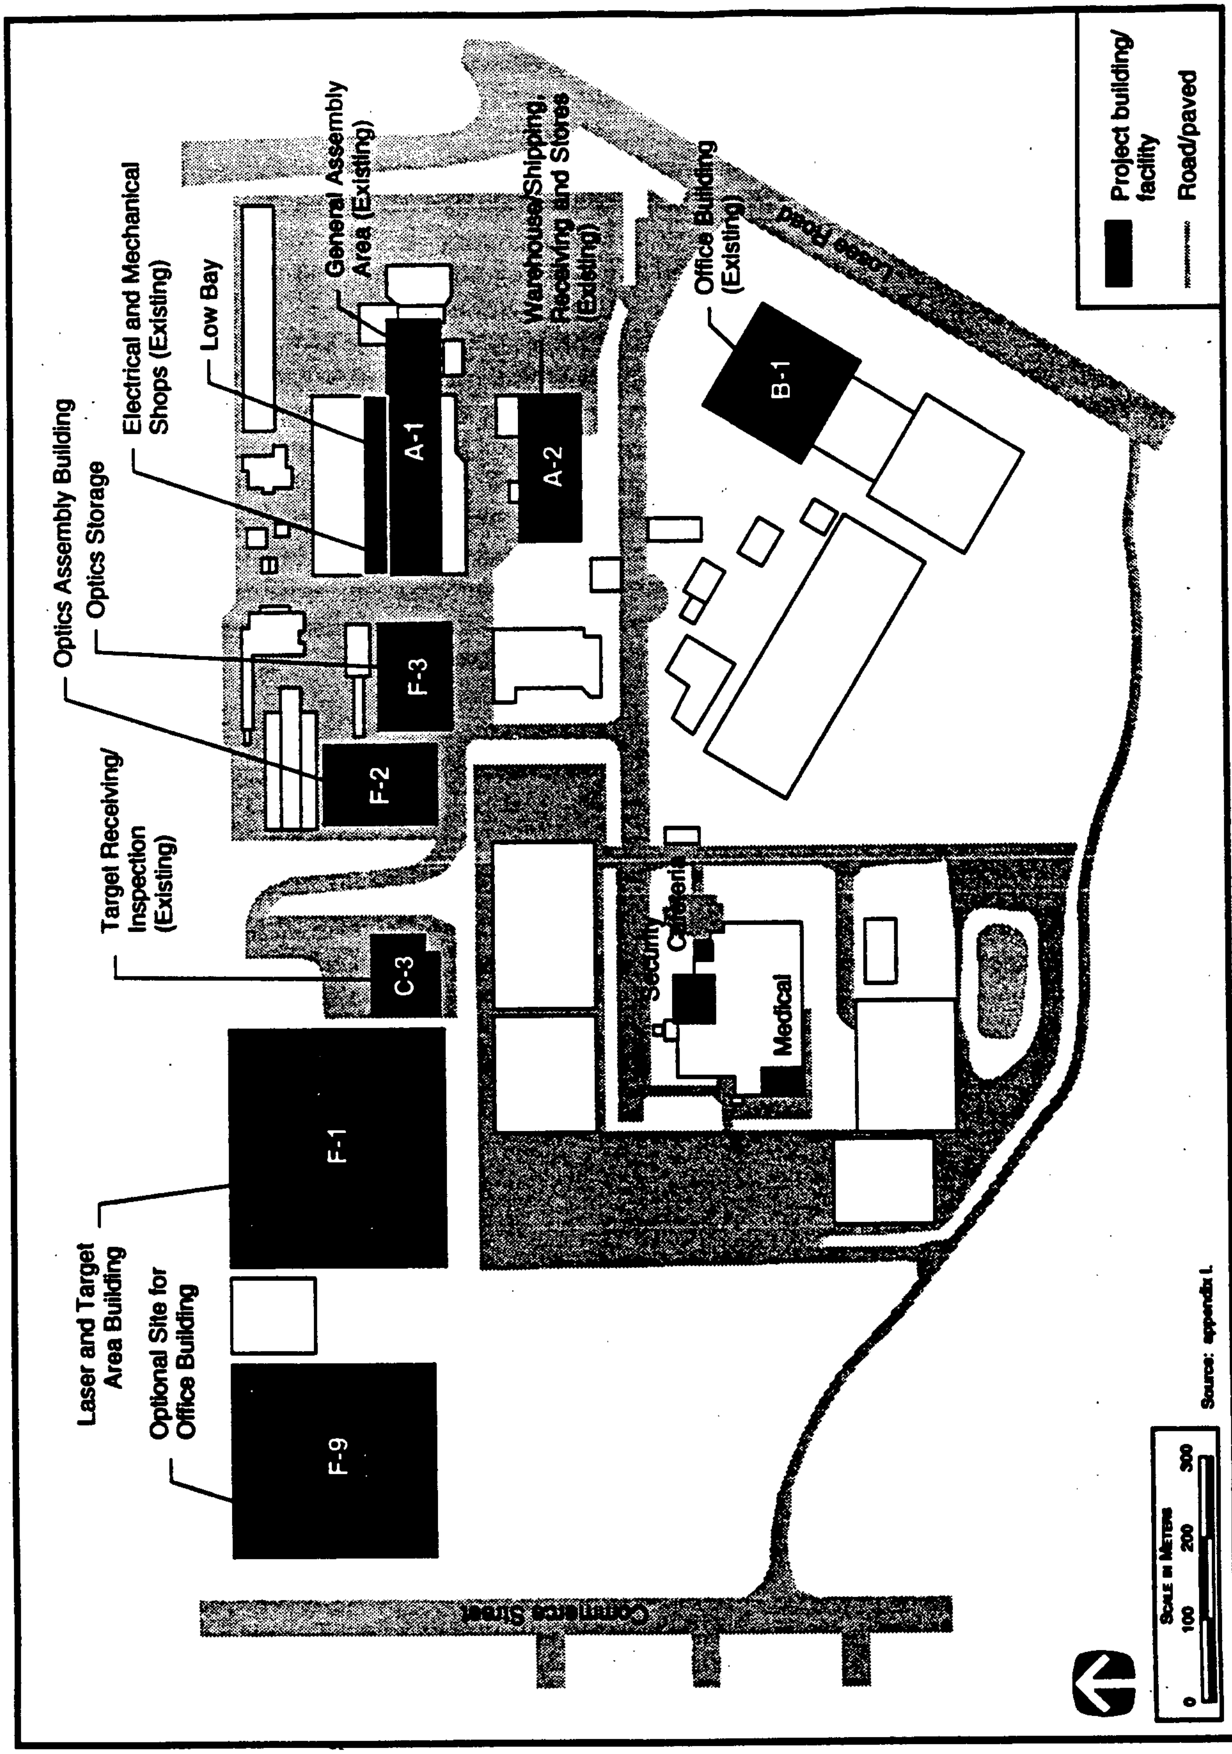

FIGURE 4.9.2.1–4.—*North Las Vegas Facility.*

by location. The annual average wind speed is 4.2 m/s (9.3 mph).

Ambient Air Quality. NTS is located within the Nevada AQCR 147. The region is designated as an attainment or unclassified area (40 CFR 81.329) with respect to the NAAQS. Applicable NAAQS and Nevada State ambient air quality standards are presented in appendix table B.3.1–1.

Two Prevention of Significant Deterioration Class I areas in the vicinity of NTS are Grand Canyon National Park, approximately 193 km (120 mi) to the southeast, and Sequoia National Park, California, approximately 169 km (105 mi) to the west-southwest of the site. Since the promulgation of Prevention of Significant Deterioration regulations (40 CFR 52.21) in 1977, no permits have been required for any emissions source at NTS.

The primary emission sources of criteria air pollutants at NTS include particulates from construction and other surface disturbances, fugitive dust from unpaved roads, various pollutants from fuel burning equipment, incineration, open burning, and volatile organics from fuel storage facilities. A summary of emission estimates for sources at NTS is presented in appendix table B.3.9–1.

Table 4.9.2.3–1 shows the site baseline ambient air concentrations for criteria pollutants and other pollutants of concern at NTS. No hazardous air pollutant or other toxic compound sources are indicated. Baseline concentrations are in compliance with applicable guidelines and regulations. Elevated levels of ozone or particulate matter may occur occasionally because of pollutants transported into the area by wind or because of local sources of fugitive particulates (NT DOE 1983a:30). Concentrations of other criteria pollutants (sulfur dioxide, nitrogen dioxide, carbon monoxide, and lead) are low because there are no large emission sources nearby. The nearest significant emission source for criteria pollutants is the Las Vegas area, which is about 105 km (65 mi) southeast of NTS.

North Las Vegas Facility

Meteorology and Climatology. The climate at NLVF and the surrounding region has four well-defined

TABLE 4.9.2.3–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Nevada Test Site, 1990 to 1992*

Pollutant	Averaging Time	Most Stringent Regulation or Guideline ($\mu g/m^3$)	Baseline Concentration ($\mu g/m^3$)
Criteria Pollutant			
Carbon monoxide	8-hour	10,000[a]	2,290
	1-hour	40,000[a]	2,748
Lead	Calendar quarter	1.5[a]	[b]

seasons. Summers display desert conditions, with maximum temperatures usually in the 38 °C (100 °F) range. Winter daytime temperatures average near 15.5 °C (60 °F). Rainy days average less than one in June to three per month in the winter. The annual average temperature at NLVF is 19.1 °C (66.3 °F); average daily temperatures range from 6.9°C (44.5 °F) in January to 32.1 °C (89.8 °F) in July. The average annual precipitation is 106 millimeters (4.19 in). The prevailing winds are from the southwest at an annual average wind speed of 4.2 m/s (9.3 mph) (GRI 1992a). Additional information related to meteorology and climatology at NLVF is presented in appendix I.

Ambient Air Quality. NLVF is located within the Las Vegas Intrastate AQCR 13, which only includes Clark County. Portions of Clark County, including the NLVF site, are in nonattainment with the NAAQS for carbon monoxide, particulate matter, and TSPs (40 CFR 81.329). The Clark County Health District is responsible for air pollution control and attainment of air quality standards in Clark County. Applicable NAAQS and Clark County ambient air quality standards are presented in table 4.9.2.3–2. In addition to NAAQS for criteria pollutants, NLVF is subject to ambient air quality standards adopted by the Clark County Health District.

The Clark County Health District operates a network of ambient air monitoring stations in Clark County. The county monitor closest to NLVF is at the McDaniel Post Office at 1414 East Lake Mead Drive, approximately 1.9 km (1.2 mi) east of the proposed NIF location. Data for this and other monitors near NLVF are provided in appendix I. Table 4.9.2.3–2 presents the 1994 baseline ambient air concentrations for criteria pollutants and other pollutants at NLVF. As the table shows, all of the baseline concentrations are in compliance with the NAAQS.

4.9.2.4 *Water Resources*

This section describes the surface and groundwater resources at NTS and NLVF.

TABLE 4.9.2.3–2.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at North Las Vegas Facility, 1994*

Surface Water. Surface water is not used at NTS. There are no perennial streams on NTS. The most noticeable natural hydrologic features are the playas (lake beds) that collect stormwater runoff. Runoff in the eastern half of the site ultimately collects in the playas of Yucca Flat and Frenchman Flat. In the northeastern portion, the runoff drains outside the test site and onto the Nellis Air Force Range Complex. In the western half and southernmost part, runoff is carried offsite towards the Amargosa Desert. Figure 4.9.2.4–1 shows the locations of the playas and flats. A few natural springs can be found at NTS.

Because there are no continuously flowing surface waters, there are no studies to assess 500-year floodplain boundaries. Two 100-year flood analyses have been conducted. These analyses show no runoff from a 100-year storm adversely affecting the proposed project areas. However, the proposed project areas are in a region where flash flooding occurs due to locally isolated intense convection storms. These floods normally last less than 6 hours.

Surface Water Quality. There are no NPDES permits for the site because there are no wastewater discharges to onsite or offsite surface waters. However, the state has issued sewage discharge permits for sewage lagoons and ponds for NTS facilities. Because there are no surface waters at or near the proposed project areas, and because there will be no withdrawal or discharge to natural surface waters at NTS, the assessment of surface water quality is not applicable.

Surface Water Rights and Permits. Surface water rights are not an issue because NTS facilities do not withdraw surface water for use, nor do they discharge effluents directly to natural surface waters.

Groundwater. NTS is located within three groundwater subbasins of the Death Valley Groundwater Basin (NT DOE 1994b:9-2). Groundwater beneath the eastern portion of NTS is located in the Ash Meadows Subbasin; the western portion is located in the Alkali Flat Furnace Creek Ranch Subbasin; and a small part of the northwestern corner is located in the Oasis Valley Subbasin (figure 4.9.2.4–1). The proposed project area is situated over the Ash Meadows Subbasin. Three primary aquifers are present within the Ash Meadows Subbasin: the Lower Carbonate (the deepest), the Volcanic, and the Valley-Fill (the shallowest) (NT DOE 1994b:2-13). Other aquifers are present to a limited extent under the area, but their water bearing potential has not been thoroughly investigated. Limited aquifers may occur in other volcanic units, including lava flows and bedded tuffs.

The Lower Carbonate is the regional aquifer and comprises carbonate rocks of Middle Cambrian through Devonian age. The saturated thickness ranges from 100 to over 1,000 m (328 to over 3,280 ft). This aquifer drains in a south-southwest direction, under Yucca and Frenchman Flat, toward Ash Meadows (NT USGS 1975a:C1). The Volcanic and Valley-Fill aquifers range in thickness from zero to about 610 m (2,000 ft) and are confined to their respective drainage basin (such as Frenchman and Yucca Flats) (NT DOE 1992d).

Depth to groundwater at NTS ranges from 160 m (515 ft) beneath Frenchman Flat to over 700 m (2,300 ft) at Pahute Mesa. There are, however, areas of perched water that lie at considerably shallower depths.

Estimates of the perennial yield of the NTS aquifers (i.e., the total amount that can be removed on an annual basis without depleting the groundwater reservoir) include 57,000 MLY (15,058 MGY) (NT USGS 1988a) and 38,000 MLY (10,039 MGY) (NT DOE 1992b:41-43). Groundwater recharge occurs from infiltration of precipitation in the northern and eastern mountain ranges and from underflow from upgradient areas. Natural discharge from the aquifers primarily occurs from evaporation and transpiration in the Amargosa Valley (including Ash Meadows) and Death Valley areas (figure 4.9.2.4–1).

Groundwater pumping at Ash Meadows was curtailed by order of the U.S. Supreme Court to protect the endangered pupfish *Cyprinodon* by maintaining water levels at Devils Hole. Devils Hole is a water-filled cavern near Ash Meadows, approximately 48 km (29.8 mi) southwest of NTS (latitude 36°25'40", longitude 116°18'13"). Studies show that historical pumping on NTS at rates that exceed current rates was probably unrelated to observed declines at Devils Hole (NT LVVWD 1994a). Springs at Ash Meadows nearby contain a large concentration of rare, endangered, and threatened indigenous species which depend upon adequate spring

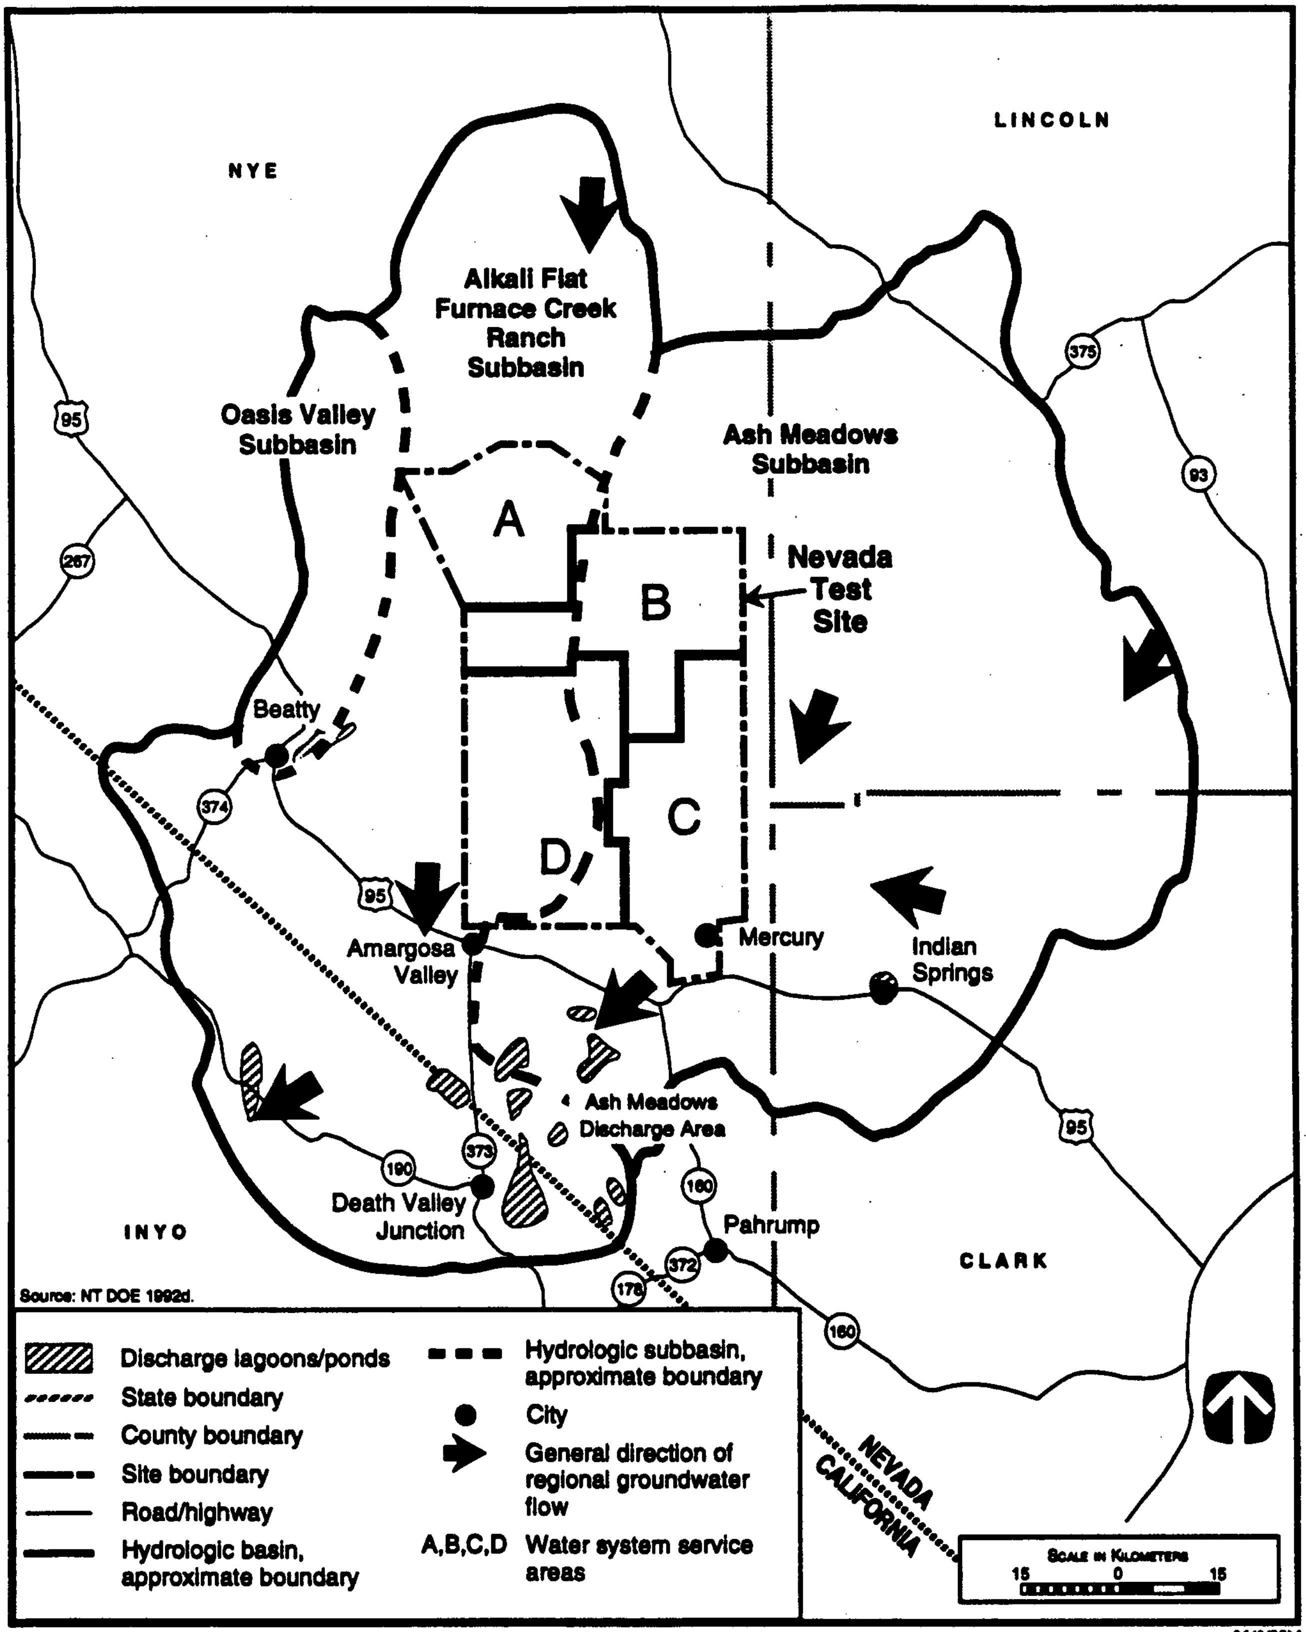

FIGURE 4.9.2.4–1.—*Groundwater Hydrologic Units at Nevada Test Site and Vicinity.*

flow for their survival. Substantially increased pumping at NTS is unlikely to lower spring levels but might reduce spring discharge rates (NTS 1995a:1).

Groundwater Quality. Currently, aquifers beneath NTS have not been classified by EPA. However, during an independent study (NT DOE 1989a:ii-v) the aquifers beneath NTS were classified as Class IIa and Class IIb (groundwater currently used for drinking water). In 1972, the Nevada Operations Office instituted a long-term hydrological monitoring program to be operated by EPA under an Interagency Agreement. Groundwater is monitored at and in the vicinity of NTS to detect any radioactivity that may be related to previous nuclear testing activities. Only wells drilled previously for water supply or exploratory purposes are being used in the existing monitoring program. In compliance with the SDWA and a State of Nevada Drinking Water Supply System Permit, drinking water wells and industrial use distribution systems are sampled and analyzed on a monthly basis. Groundwater samples collected are analyzed for a standard suite of parameters and constituents, including radioactive materials, nonradioactive materials, and other field parameters (pH and total dissolved solids).

Groundwater at portions of NTS has been affected by nuclear testing activities conducted during the last 43 years. Approximately 20 percent of the total underground nuclear tests have been conducted below the water table or have been close enough that effects have extended below it. Table 4.9.2.4–1 shows the 1993 groundwater quality in the vicinity of the proposed project site. In general, tritium is the only radionuclide that appears at significant levels in sampled groundwater. Samples collected in 1993 show tritium concentrations ranging from 120 pCi/L

TABLE 4.9.2.4–1.—*Groundwater Quality Monitoring at Nevada Test Site, 1993*

Parameter	Unit of Measure	Water Quality Criteria and Standards[a]	Potable Water Distribution System High	Potable Water Distribution System Low
Radiological				
Alpha (gross)	pCi/L	15[b]	11	0.62
Beta (gross)	pCi/L	50[c]	13	3.2
Tritium	pCi/L	80,000[d]	120	0.93
Nonradiological				
Alkalinity	mg/L	NA	270	64
Arsenic	mg/L	0.05[b]	0.012	<0.003
Barium	mg/L	2.0[b]	0.15	0.00
Chromium	mg/L	0.1[b]	<0.005[e]	<0.005[e]

Note: NA - not applicable.
Source: NT DOE 1994b.

in a nonpotable supply well located in the northwestern part of NTS to 0.93 pCi/L in a potable supply well located in the southeastern part of NTS. It is speculated that the Lower and Upper Carbonate aquifers would most likely be the aquifers in which tritium might migrate to offsite areas.

Groundwater Availability, Use, and Rights. Groundwater is the only local source of industrial and drinking water supplies in the NTS area. Numerous production wells are located on NTS and distributed among various areas of the site. Figure 4.9.2.4–1 shows how the NTS water system has been divided into four water service areas (A, B, C, and D) based on the location of the water supply system and support facilities. Water usage on NTS is largely for potable, construction, and dust control purposes. Water supply wells at NTS draw water from the Lower and Upper Carbonate, the Volcanic, and the Valley Fill aquifers. The total water usage in 1994 was 2,400 MLY (634 MGY), of which 1,300 MLY (343 MGY) were withdrawn from the Ash Meadows Subbasin, and 1,100 MLY (290 MGY) were withdrawn from the Alkali Flat Furnace Creek Ranch Subbasin (figure 4.9.2.4–1). The pumping capacity for all the water supply wells at NTS is estimated at 14,800 MLY (3,910 MGY).

The State of Nevada strictly controls all surface and groundwater withdrawals. The Appropriation Doctrine governs the acquisition and use of water rights. NTS has been withdrawn from public use and thus possesses an unquantified water right sufficient to meet the purposes of NTS land withdrawal, subject to water rights that existed at the time land for NTS was withdrawn.

<u>North Las Vegas Facility</u>

NLVF is located in the Las Vegas Valley, which is a desert between sharp, rugged mountain ranges on a gently sloping alluvial fan piedmont. At the lowest point of the alluvial fan is the Las Vegas Wash, which drains an area of 2,280 km^2 (880 mi^2) toward Lake Mead. Stormwater from NLVF is discharged into local flood control systems (appendix I).

The water supply for NLVF is provided by the city of North Las Vegas. Current water usage by NLVF is about 69 MLY (18.2 MGY) (appendix I). Industrial wastewater and sanitary sewage from NLVF are discharged into the city of North Las Vegas sewer system, which is connected to the city of Las Vegas treatment plant. The treated wastewater is discharged into Lake Mead under an NPDES permit issued by the Nevada Division of Environmental Protection (appendix I). NLVF discharges an average of 55 MLY (14.5 MGY) of wastewater. Wastewater quality has historically met the permit requirement established by the city to protect the treatment processes and ultimately the water quality of Lake Mead (appendix I).

4.9.2.5 *Geology and Soils*

Geology. NTS is located in the southern part of the Great Basin section of the Basin and Range Province in an intermediate position between the high, topographically closed basins in central Nevada and the low, connected basins of the Amargosa Desert-Death Valley region to the southwest. NTS consists of three flats (Yucca, Jackass, and Frenchman) surrounded by mountains (NT DOE 1988a:3-116). The general geology of the test site comprises three major rock units: complexly folded and faulted sedimentary rocks of Paleozoic age overlain at many places by volcanic tuffs and lavas of Tertiary age, which in the valleys are covered by an alluvium of late Tertiary and Quaternary age that was derived from erosion of the nearby hills of Tertiary and Paleozoic rocks (NT ERDA 1977a:2-40).

The general region has been tectonically active in the near past and has numerous faults (figure 4.9.2.5–1). NTS lies in an area of moderate historic seismicity on the southern margin of the Southern Nevada East-West Seismic Belt in seismic Zones 2 and 3 (figure A.1–1). Since about 1848, more than 4,000 earthquakes have been recorded within a 241-km (150-mi) radius of NTS. Most of these earthquakes were minor events with Richter magnitudes of less than 5.5. The largest event on record, which took place 161 km (100 mi) west in Owens Valley, CA, had an estimated magnitude of 8.3. In 1992, an earthquake of 5.6 magnitude occurred in the southwest corner of the site under Little Skull Mountain. The maximum acceleration from this earthquake was approximately 0.21 G (G is the acceleration due to gravity) at Amargosa Valley (DOE 1995i:4-117).

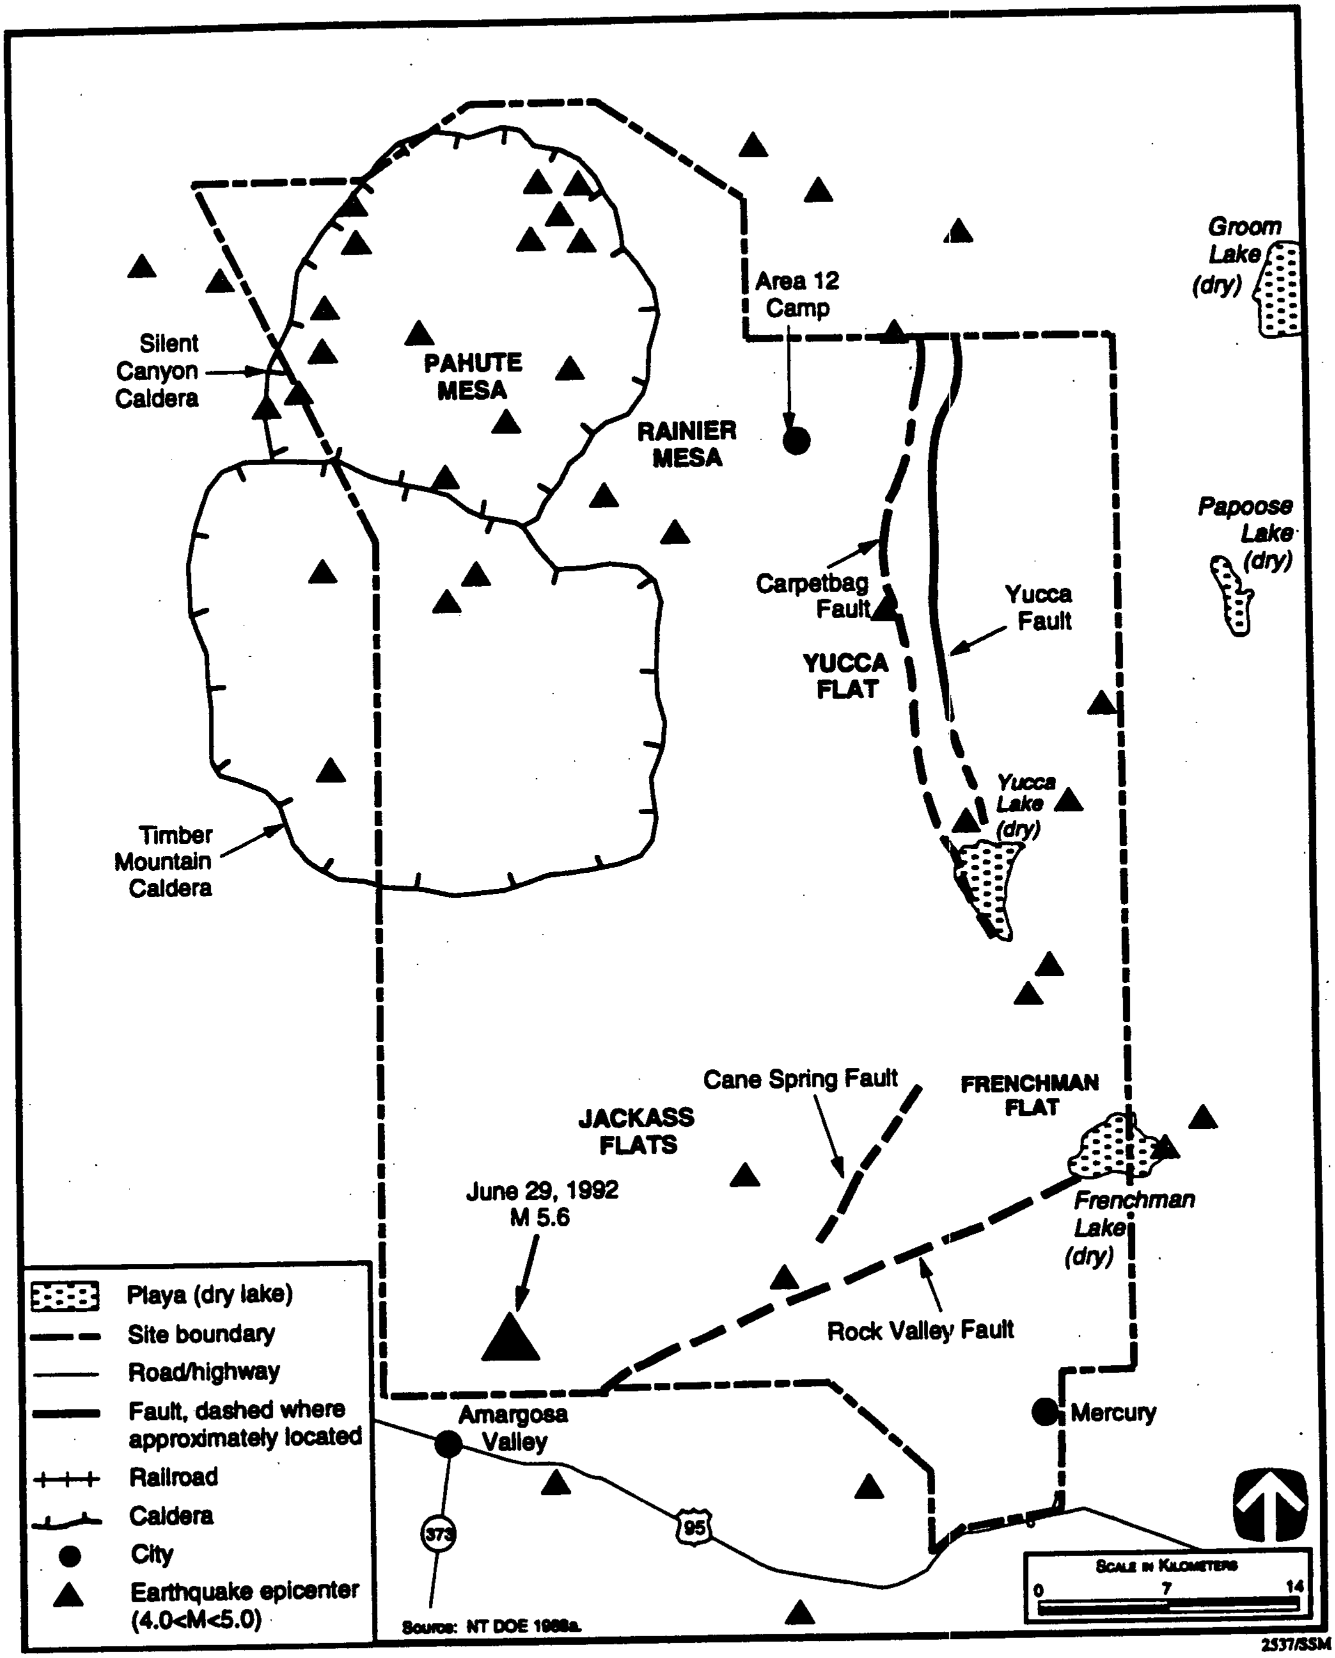

FIGURE 4.9.2.5–1.—*Major Fault Systems and Historic Earthquakes in Nevada Test Site Region.*

The Yucca and Carpetbag faults were active during the late Quaternary. The Yucca fault has undergone surface rupture within the past few thousand to tens of thousands of years. Some earthquakes can be directly associated with the fault trace and the area beyond the southern end of the mapped section in the Yucca Pass, suggesting that the fault may continue in that direction. No significant vertical surface displacement has occurred on the Carpetbag fault system during the past 150,000 years, but there is evidence of episodes of fracturing and possible minor faulting from 30,000 to 240,000 years ago, with average recurrence intervals at about 25,000 years for the last 125,000 years (NT DOE 1988e:30-31). The Carpetbag fault has been mapped in the subsurface beyond the southern end of Yucca Basin and may project to the northeast of the proposed project area. Possible magnitude, intensity, and acceleration of earthquakes along the Yucca and Carpetbag faults have not been estimated (DOE 1995i:4-117).

The Cane Spring fault, which lies approximately 8 km (5 mi) south of the proposed project area, does not show Holocene displacement but is thought to have been the source of a magnitude 4.3 earthquake in 1971. The maximum credible earthquake associated with the Cane Spring fault is expected to produce a peak acceleration of 0.67 G with a 6.7 magnitude (DOE 1995i:4-117). The recurrence interval is estimated at 10,000 to 30,000 years.

The most recent volcanic activity in the immediate area was 3.7 million years ago, and the likelihood for renewed activity in the next 10,000 years is slight (DOE 1995i:4-117). NTS lies approximately 241 km (150 mi) southeast of the Long Valley area of California, an area with potential volcanic eruption of the Mount St. Helens type.

Soils. Limited soil studies have been performed at NTS. Soil studies (borings) were done for the Device Assembly Facility. Studies in adjacent areas have divided soils into three major types: shallow soils developed in the uplands and mountains; soils on valley fill and nearly level to moderately sloping outwash plains, alluvial fans, and fan aprons; and playas and soils on nearly level flats and basins. Possible erosion hazards range from slight to severe, while the shrink-swell potential ranges from low to high for these soils. The potential for wind erosion and shrink-swell increases into the playas and basins. The potential for water erosion increases with increasing slope. The soils at NTS are considered acceptable for standard construction techniques. There is no prime farmland at NTS.

North Las Vegas Facility

NLVF is located within the Las Vegas Valley. Rugged mountain ranges surround the low lying alluvial filled valley. The valley consists primarily of fine grained Miocene and Pliocene sedimentary rocks. NLVF is located within seismic Zone 2 (figure A.1–1). The soils on NLVF range from stiff to very stiff silty and sandy clay and clay with interbedded medium-dense to dense clayey and silty sand. The soils at NLVF are considered acceptable for standard construction techniques.

4.9.2.6 *Biotic Resources*

The following section describes biotic resources at NTS and NLVF including terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. Also presented in appendix C is a list of the threatened and endangered species that may be found onsite or in the vicinity of NTS.

Terrestrial Resources. NTS lies in a transition area between the Mojave and Great Basin deserts. As a result, flora and fauna characteristic of both deserts are found within the site boundaries (NT ERDA 1976a:34). Approximately 33 km^2 (12.7 mi^2) of NTS have been developed, which represent less than 1 percent of the site; thus, natural plant communities are found across most of NTS (NT DOE 1988d:3,4,6,7). The site has been divided into nine major communities as shown in figure 4.9.2.6–1. Of the communities present onsite, the mountains, hills and mesas, sagebrush, creosote bush, and hopsage-desert thorn communities are the most extensive. Saltbush and desert thorn communities occupy more limited areas adjacent to the playas in Frenchman and Yucca Flats. Introduced plants such as red brome (*Bromus rubens*), cheatgrass (*Bromus tectorum*), and Russian thistle (*Salsola kali*) have become important species in some areas. These plants rapidly invade disturbed areas and delay revegetation of areas by native species (NT ERDA 1976a:40; NT Hunter 1991a:1). A total of 711 taxa of vascular plants has been identified on or near NTS (NT ERDA 1976a:34).

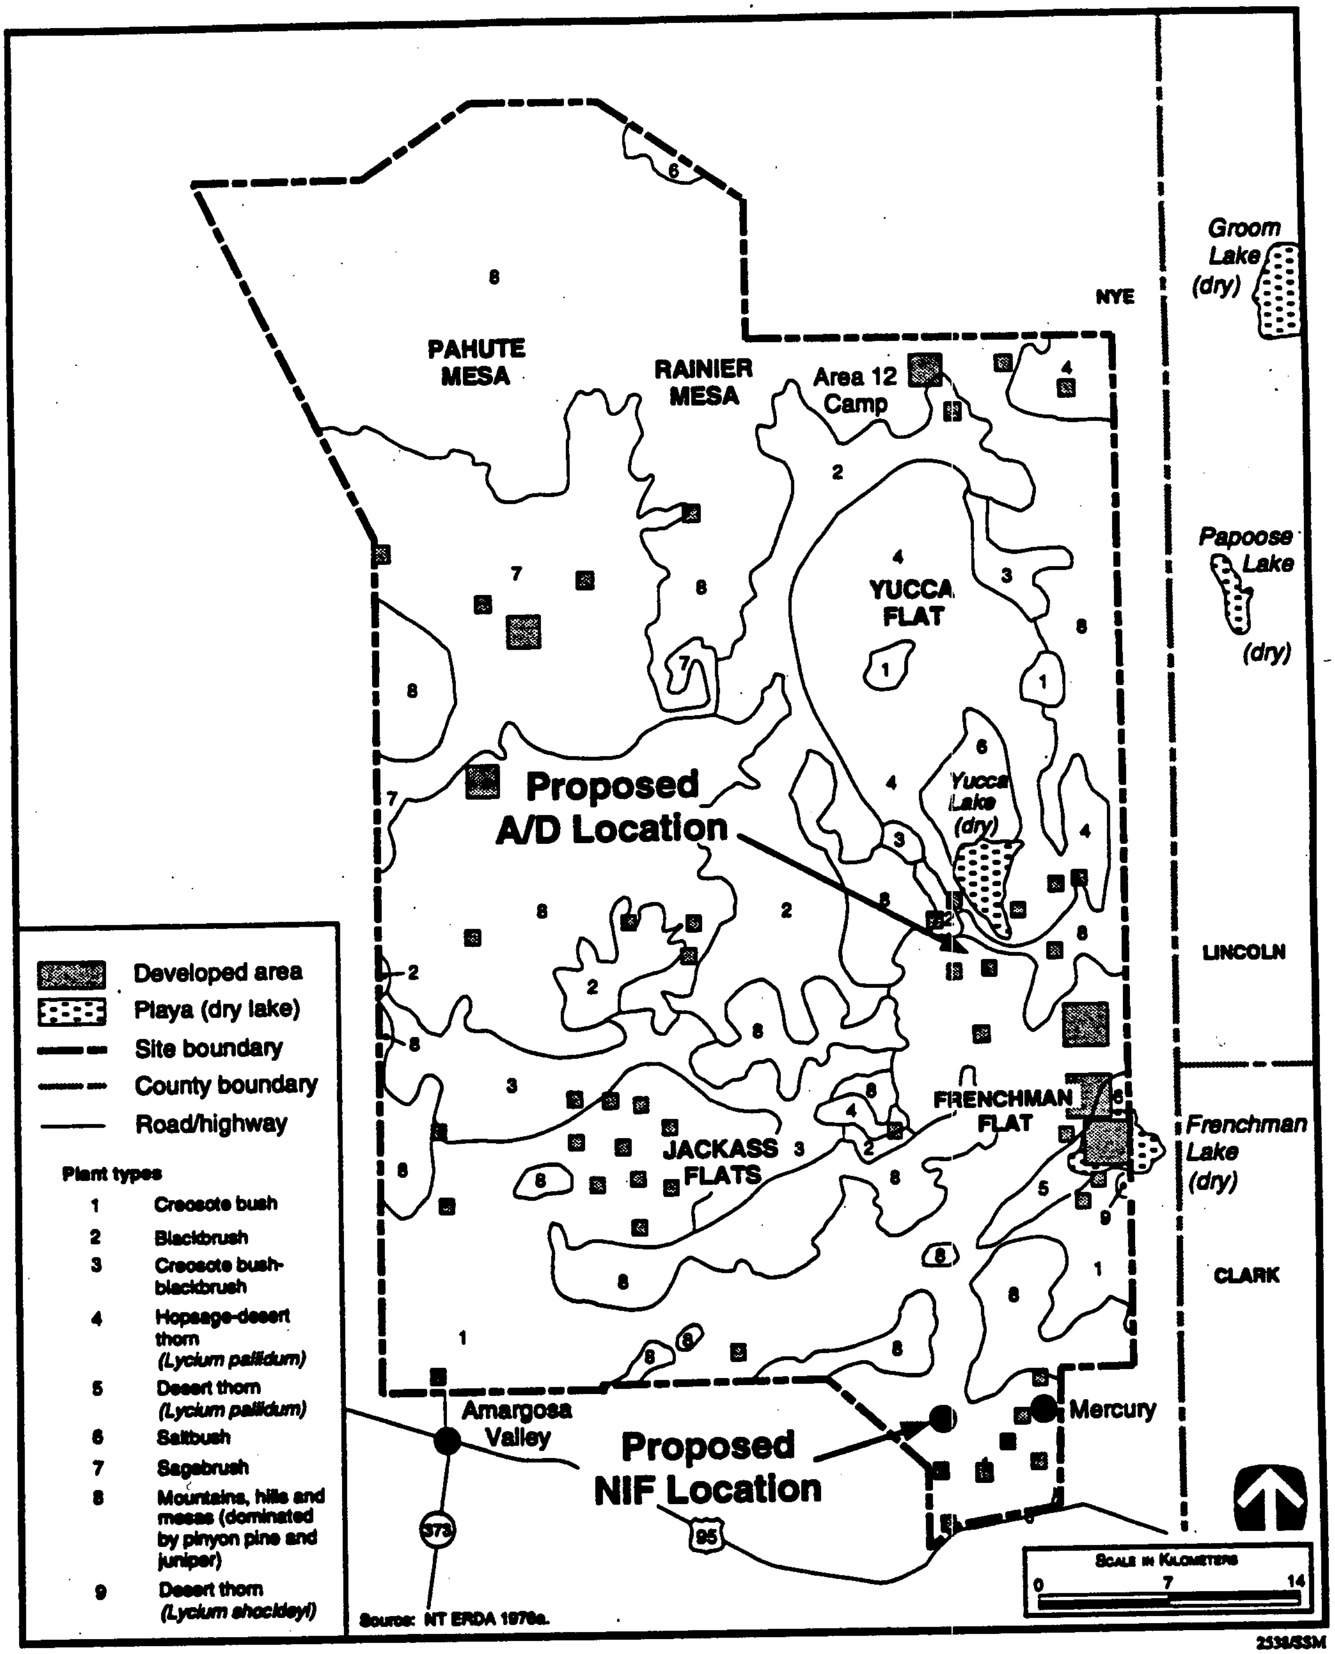

Figure 4.9.2.6–1.—*Distribution of Plant Communities at Nevada Test Site.*

Terrestrial wildlife found on NTS includes 33 species of reptiles, 222 species of birds, and 49 species of mammals (NT Greger 1992a; NTS 1990a:1; NTS 1990a:2). Species common to NTS include the side-blotched lizard (*Uta stansburiana*), western shovel-nosed snake (*Chionactis occipitalis*), blackthroated sparrow (*Amphispiza bilineata*), red-tailed hawk (*Buteo jamaicensis*), Merriam's kangaroo rat (*Dipodomys merriami*), and Great Basin pocket mouse (*Perognathus parvus*). Water holes, both natural and manmade, are important to many species of wildlife, including game animals such as pronghorn (*Antilocapra americana*) and mule deer (*Odocoileus hemionus*) (NT Greger nda). Hunting is not permitted anywhere on NTS. Raptors and carnivores are two ecologically important groups on NTS and are represented by species such as the turkey vulture (*Cathartes aura*) and rough-legged hawk (*Buteo lagopus*), and long-tailed weasel (*Mustela frenata*) and bobcat (*Lynx rufus*), respectively. A variety of migratory birds has been found at NTS. Migratory birds and their nests and eggs are protected by the *Migratory Bird Treaty Act*. Eagles are similarly protected by the *Bald and Golden Eagle Protection Act*.

The proposed NIF site would be located in an area of creosote bush habitat to the west of the Mercury Base Camp (figure 4.9.2.6–1). Wildlife present in the site area would include that associated with the Mojave desert and could include Merriam's kangaroo rat, Le Conte's thrasher (*Toxostoma lecontei*), and desert iguana (*Dipsosaurus dorsalis*).

Wetlands. National Wetland Inventory maps of NTS have not been prepared nor have wetlands been delineated on the site. However, small riparian areas (less than 0.4 ha [1.0 acres]) may be associated with site springs. There are no wetlands on or near the proposed NIF site (appendix I).

Aquatic Resources. Potential aquatic habitat on NTS includes surface drainages, playas, springs, and manmade reservoirs. There are no continuously flowing streams on the site, and permanent surface water sources are limited to a few small springs. These surface drainages, playas, and springs are unable to support permanent fish populations (DOE 1995w:2.4-61). Manmade construction water reservoirs located throughout the site support three introduced species of fish: bluegill (*Lepomis macrochirus*), goldfish (*Carassius auratus*), and golden shiners (*Notemigonus crysoleucas*) (NTS 1992a:6). There are no aquatic resources on or near the proposed NIF site (appendix I).

Threatened and Endangered Species. Nine Federal- and state-listed threatened, endangered, and other special status species may be found in the vicinity of NTS (appendix table C–7). Eight of these species have been observed on NTS, seven of which are listed as either Federal- or state-threatened or endangered species. No critical habitat for threatened or endangered species, as defined in the *Endangered Species Act* (50 CFR 17.11; 50 CFR 17.12), exists on NTS.

The Federal-listed bald eagle (*Haliaeetus leucocephalus*) and peregrine falcon (*Falco peregrinus*) have been recorded as rare migrants on NTS, but the desert tortoise (*Gopherus agassizii*) is the only resident Federal-listed species known to inhabit NTS. The range of the desert tortoise lies in the southern third of NTS. Tortoises on NTS are most commonly found in the areas shown in figure 4.9.2.6–2. Further surveys may reveal other areas of concentration. The abundance of tortoises on NTS is considered low to very low relative to other areas within this species' geographic range. Densities of tortoises on NTS range from 0 to 17 individuals per square km (0 to 45 individuals per square mile), with most habitats probably having densities of 0 to 8 individuals per square km (0 to 20 individuals per square mile) (NT DOE 1991b:3-23).

The only known population of the Devils Hole pupfish (*Cyprinodon diabolis*) lives in a single, spring-fed sinkhole pool in Ash Meadows, approximately 48 km (29.8 mi) southwest of the proposed project area. There is concern over the survival of the pupfish and other sensitive species found in the Ash Meadows area due to the threat of declining water levels (NT DOI 1991a:1,4-6). Several additional state-listed species have been recorded on NTS. These species include the spotted bat (*Euderma maculatum*), Beatley milkvetch (*Astragalus beatleyae*), and Mojave fishhook cactus (*Sclerocactus polyancistrus*). The Federal-candidate mountain plover has also been observed on NTS (appendix table C–7).

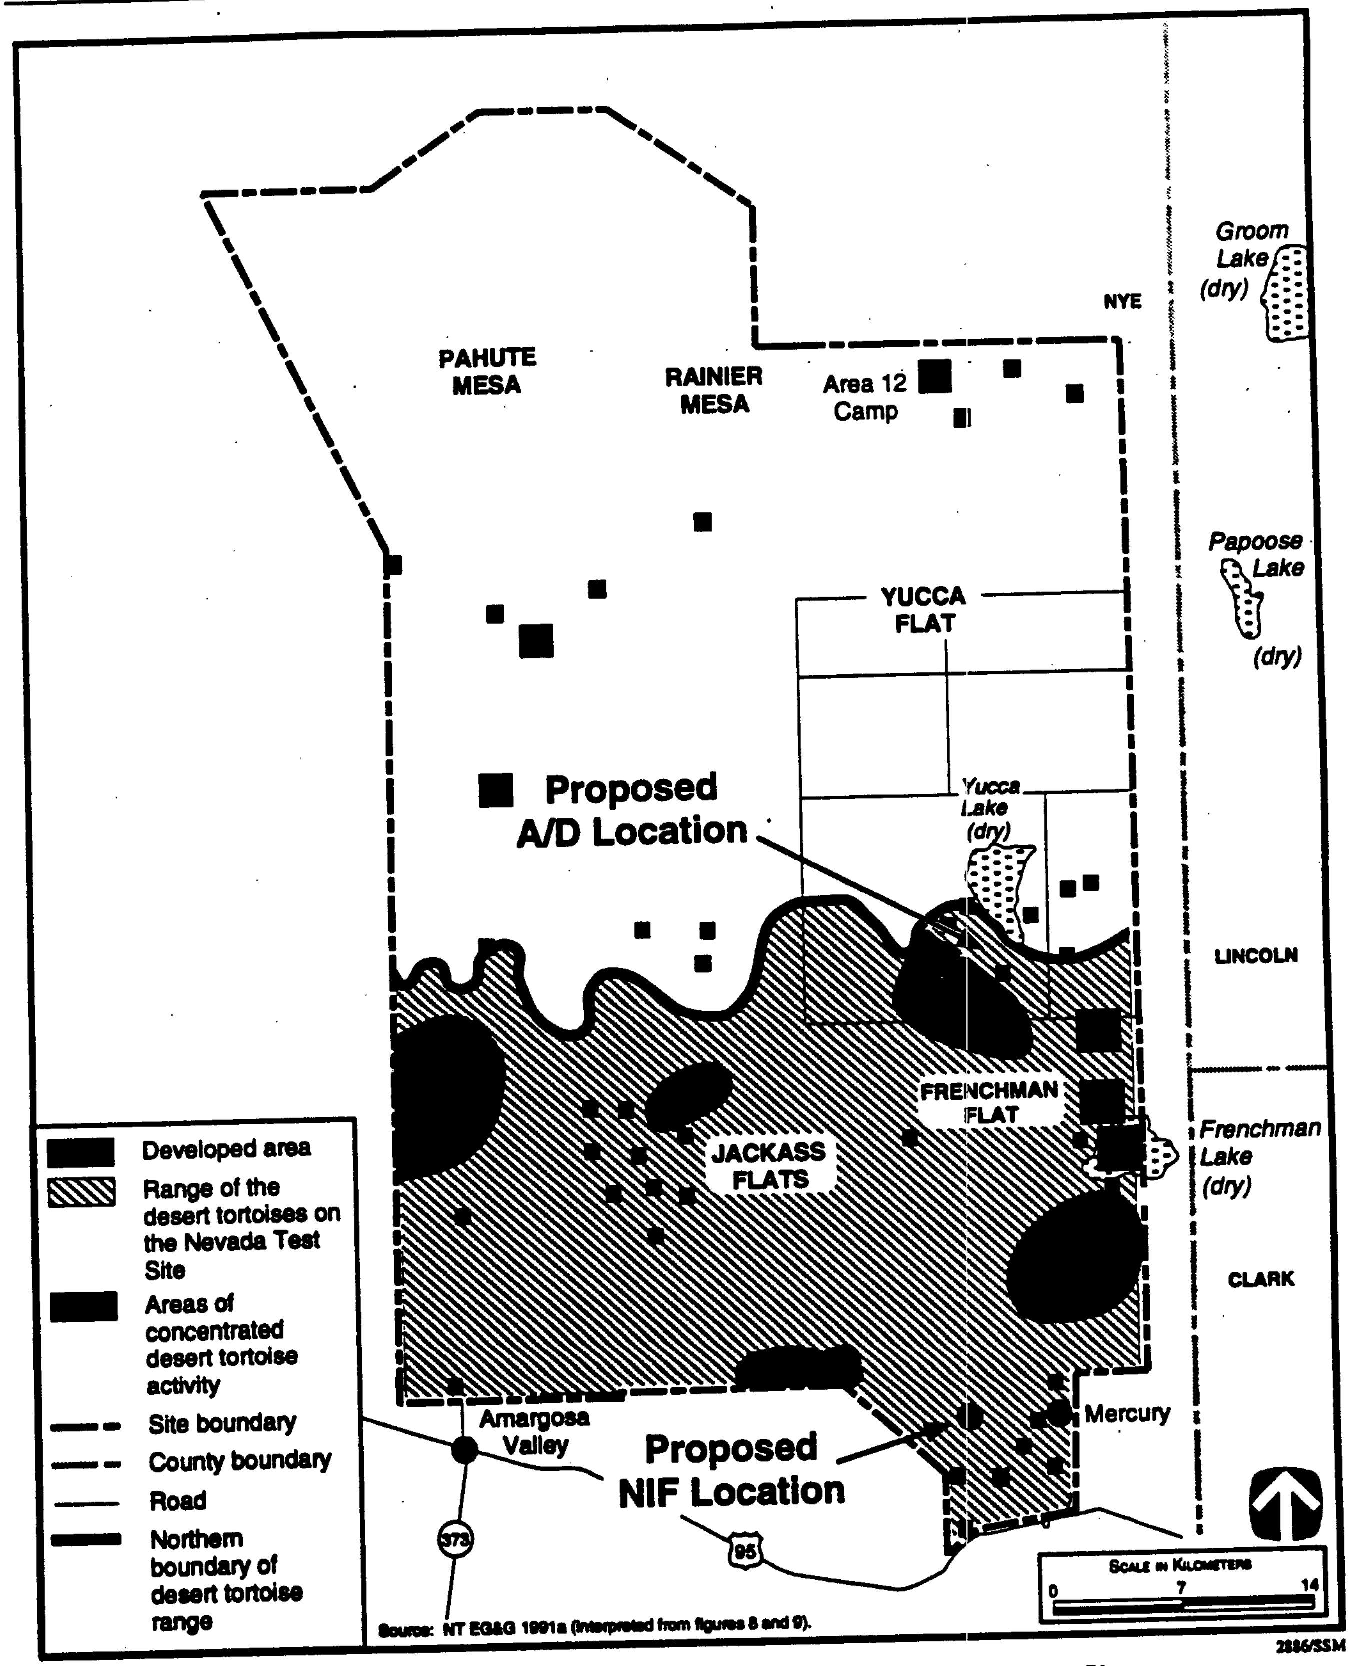

Figure 4.9.2.6–2.—*Distribution of Desert Tortoise at Nevada Test Site.*

The proposed NIF location contains habitat suitable for several special status species. The desert tortoise is the only Federal-listed species known to inhabit the area. A site-specific survey may be required to verify the existence of special status species.

North Las Vegas Facility

Terrestrial Resources. NLVF is in the Southern Basin and Range Ecoregion (see appendix I). NLVF was built on cleared, previously disturbed land that is now mostly covered by buildings, pavement, or landscaping. Exceptions include about 4.5 ha (11 acres) of undeveloped land at the western end of the facility (designated area for proposed new construction associated with NIF), the open area west of the Building C-3, and the stormwater detention basin south of the Building C-1. No original undisturbed native vegetation remains on the site (see appendix I).

Because NLVF is located in an urbanized area and contains little vegetation, few wildlife species exist. The only species that exist are those adapted to urban habitats which may include small mammals such as house mouse (*Mus musculus*) and Norway rat (*Rattus norvegicus*); and ubiquitous bird species such as American robin (*Turdus migratorius*), European starling (*Sturnus vulgaris*), house finch (*Carpodacus mexicanus*), house sparrow (*Passer domesticus*), and rock dove (*Columba livia*) (see appendix I).

Threatened and Endangered Species. Because NLVF is located within urban Las Vegas, and on previously disturbed land within a fenced site, it is not expected that any threatened, endangered, or rare species exist. No designated critical habitats for Federal-listed species exist at NLVF. The facility is within the range of the Federal-listed desert tortoise; however, urbanized areas of Clark County are not considered tortoise habitat. No desert tortoises were found during an offsite survey of undeveloped land located near the western boundary of NLVF (see appendix I).

4.9.2.7 *Cultural and Paleontological Resources*

Prehistoric Resources. Approximately 6 percent of NTS has been inventoried for cultural resources including all lands managed through a Memorandum of Agreement with Nellis Air Force Base. Excluding sites in the Yucca Mountain project area, over 1,600 prehistoric sites have been recorded at NTS. Prehistoric site types identified on NTS include habitation sites with wood and brush structures, windbreaks, rock rings, and cleared areas; rockshelters; petroglyphs (rock art); hunting blinds; rock alignments; quarries; temporary camps; milling stations; roasting ovens or pits; water caches; and limited activity locations. Milling stations are especially prevalent near the Yucca Lake playa margins. Several prehistoric rockshelters have been identified on Hogback Ridge.

At Frenchman Flat, in which the proposed A/D site would be located, 99 archaeological sites have been identified to date, including 2 historic sites and 2 sites related to nuclear testing (NT DOE 1996c:4-190). Forty-nine of these sites have been determined to be NRHP eligible, and a historic district composed of structures related to the development of nuclear weapons has also been proposed. Cultural resources surveys were conducted around the A/D site in 1984. No significant archaeological sites were found.

The proposed NIF would be located in Area 22. Only three prehistoric sites have been identified in Area 22, or Mercury Valley, and none are NRHP eligible. An archaeological survey was conducted at the proposed location and several scatters of debris were identified on the surface. These are not considered eligible for the NRHP.

Historic Resources. Historic site types on NTS include mines and prospects, trash dumps, settlements, campsites, ranches, homesteads, developed spring heads, trails, and roads. Nuclear test site structures and associated debris, including instrumentation stands and temporary storage bunkers, are also located within NTS. The test site area at Frenchman Flat, which includes the remains of many of these structures, has been recommended to the SHPO as a Historic District. Excluding the Yucca Mountain project area, 63 historic sites, including 7 associated with nuclear testing, have been recorded. One historic site was identified in Mercury Valley, but is not NRHP eligible. The only site currently listed on the NRHP is Sedan Crater. The Crater, located in Yucca Flat, was created in 1962 as part of the Plowshare Program, whose aim was to identify peaceful uses for nuclear explosions. The Emigrant Trail used by the "49ers" that traverses the southwestern corner of NTS is considered NRHP eligible.

Additional historic sites may occur on unsurveyed portions of NTS.

Native American Resources. At the time of European American contact, southern Nevada was inhabited by the Western Shoshone, the Southern Paiute, and the Owens Valley Paiute. Families lived in small groups from the spring through the fall. During winter, relatively stable villages of several families were established in relatively warm places, close to reserves of pine nuts, seeds, and dried meats.

Native American resources include burials, ceremonial sites, musical stones, medicine rocks, petroglyphs, and traditional use areas. Local plants important in traditional and religious activities include jimsonweed, juniper, greasewood, creosote, Indian tobacco, piñon pine, buckbush, and scrub oak. Concern has been expressed about the availability and accessibility of such resources. It is worth noting that many natural resources at NTS are viewed as cultural resources by Native Americans. As an example, sagebrush is used as a tool and for clothing and medicinal purposes. Both Mercury Valley and Frenchman Flat contain a wide variety of plants and animals significant to Native Americans.

Consultation with Native American cultural and religious leaders has been conducted for other projects at or near NTS to identify traditional cultural resources that may be affected by Federal actions, and to obtain Native American recommendations for mitigating potential adverse impacts on traditional cultural resources. DOE has established ongoing consultation with 17 Native American tribal organizations with cultural ties to NTS. According to these groups, no Native American resources have been identified in the proposed NIF location.

Paleontological Resources. The surface geology of NTS is characterized by alluvium-filled valleys surrounded by ranges composed of Paleozoic sedimentary rocks and Tertiary volcanic tuffs and lavas. The Pre-Cambrian and Paleozoic rocks at NTS represent relict deposits made in shallow water at the submerged edge of a continental platform which ran from Mexico to Alaska and existed throughout most of the Paleozoic. Although the Pre-Cambrian sedimentary deposits contain no fossils or only a few poorly preserved fossils, the Paleozoic marine limestones are moderately to abundantly fossiliferous. Marine fossils found in the same Paleozoic formations on Nellis Air Force Range, adjacent to NTS to the north, include trilobites, conodonts, ostracods, solitary and colonial corals, brachiopods, algae, gastropods, and archaic fish. These fossils, however, are relatively common and have low research potential.

Tertiary volcanic deposits are not expected to contain fossils; however the Late Pleistocene terrestrial vertebrate fossils of the Rancholabrean Land Mammal Age could be expected in the Quaternary deposits. The possibility of finding mammoth, horse, camel, and bison remains might be expected because such fossils have been found at Tule Springs, 56 km (34.8 mi) from the southern edge of NTS and in Nye Canyon. Fossils found at Tule Springs include bison, deer, a small donkey-like horse, camel, Columbia mammoth, ground sloth, giant jaguar, bobcat, coyote, muskrat, and a variety of rabbits, rodents, and birds. This paleontological assemblage has high research potential. Although Quaternary deposits with paleontological materials may occur on NTS, no known fossil localities have been recorded to date.

Other Pleistocene resources include pack rat middens, which are studied by scientists at the University of Nevada, Reno, the Desert Research Institute, and New Mexico Tech, to investigate paleoclimatic regimes. No paleontological resources are expected to exist within the area proposed for the NIF, as the geology in that area does not contain fossiliferous deposits.

North Las Vegas Facility

Although a historic site (Kyle Ranch) is located less than 1.6 km (1 mi) southwest of the proposed NIF location, no archaeological remains (prehistoric or historic) are likely to be present because of the heavy past disturbance of the surface and near-surface sediment (NT DOE 1996c:4-746). Lower lying deposits that are relatively undisturbed are too ancient to contain archaeological remains. No historic structures exist in the proposed NIF location. No Native American cultural resources have been identified at NLVF in the course of past consultation with potentially affected tribal organizations.

4.9.2.8 *Socioeconomics*

Socioeconomic characteristics addressed at NTS and NLVF include employment and regional economy, population, housing, and public finance. Statistics for employment and regional economy are presented for the regional economic area that encompasses 11 counties around NTS and NLVF in Arizona, Nevada, and Utah. Statistics for population, housing, and public finance are presented for the ROI, a two-county area in which 97 percent of all NTS employees reside: Clark County (82 percent) and Nye County (15 percent). The residential distribution of NLVF employees follows a similar pattern, with the vast majority of employees residing in these two counties. As a result, both DOE facilities occupy the same ROI and regional economic area. Figure 4.9.2.8–1 presents a map of the counties and selected cities that comprise the NTS and NLVF regional economic area and ROI. Supporting data are presented in appendix D.

Regional Economy Characteristics. Selected employment and economic statistics for the NTS and NLVF regional economic area are summarized in figure 4.9.2.8–2. The civilian labor force grew 64 percent between 1980 and 1990, an annual average of 6.4 percent. Total employment in the region was 587,533 in 1994. During 1994, unemployment in the regional economic area was 6.1 percent, comparable to state unemployment in Arizona (6.4 percent) and Nevada (6.2 percent), but higher than in Utah (3.7 percent). The 1993 regional economic area per capita income of $20,561 was almost 9 percent lower than Nevada's per capita income of $22,727, but significantly higher than the per capita income in Arizona ($18,085) and Utah ($16,354).

As shown in figure 4.9.2.8–2, the NTS regional economic area and Nevada have similar employment patterns. In both the region and the state, the service sector accounts for over 40 percent of the total employment. In Utah and Arizona, services account for about a third of employment, with manufacturing providing a greater source of employment in these states than in Nevada.

Population and Housing. The ROI population, which totalled 865,144 in 1992, increased by about 83 percent (6.9 percent annually) from the 1980 level, a rate of increase that exceeded the state annual population growth rate of about 5 percent during the same period. Some cities within the ROI grew at even faster rates; the city of Henderson, for example, increased at an average annual rate of over 20 percent between 1980 and 1992.

Increases in housing units averaged approximately 7 percent annually in the ROI between 1980 and 1990, greater than the approximately 3-percent annual increase for Nevada. The homeowner vacancy rate in the ROI averaged 3 percent in 1990, while the vacancy rate for rental units averaged 10 percent. Both rates were comparable to Nevada's vacancy rates. Population and housing statistics for the ROI are summarized in figure 4.9.2.8–3.

Public Finance. Financial characteristics of the local jurisdictions in the NTS ROI that are most likely to be affected by the proposed action are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expendable trust funds. School district boundaries may or may not coincide with county or city boundaries, but the districts are presented under the county where they primarily provide services. Major revenue and expenditure fund categories for counties, cities, and school districts are presented in appendix tables D.2.3–14 and D.2.3–15. Figure 4.9.2.8–4 summarizes 1994 local government revenues and expenditures. Fund balances, which are dollars carried over from previous years, are not included in figure 4.9.2.8–4. All jurisdictions assessed had positive fund balances.

4.9.2.9 *Radiation and Hazardous Chemical Environment*

The following section provides a description of the radiation and hazardous chemical environments at NTS and NLVF. Also included are discussions of health effects studies, emergency preparedness considerations, and an accident history.

Radiation Environment. Major sources of background radiation exposure to individuals in the vicinity of NTS are shown in table 4.9.2.9–1. All annual doses to individuals from background radiation are expected to remain constant over time.

Consumer and industrial products	10
Total	378

[a] Derived from information given in EPA 1981b.
[b] NCRP 1987a.

Releases of radionuclides to the environment from NTS operations provide another source of radiation exposure to individuals in the vicinity of NTS. The radionuclides and quantities released from NTS operations in 1993 are listed in the *U.S. Department of Energy Nevada Operations Office Annual Site Environment Report-1993* (DOE/NV/11432-123). The doses to the public resulting from these releases are presented in table 4.9.2.9–2. These doses fall within radiological limits (DOE Order 5400.5) and are small in comparison to background radiation. The releases listed in the 1993 report were used in the development of the reference environment's (No Action) radiological releases at NTS in 2005 (section 4.9.3.9).

Based on a dose-to-risk conversion factor of 500 cancer deaths per 1 million person-rem ($5x10^{-4}$ fatal cancers per person-rem) to the public (appendix E), the fatal cancer risk to the maximally exposed member of the public due to radiological releases from NTS operations in 1993 is estimated to be $2.4x10^{-9}$. That is, the estimated probability of this person dying of cancer at some point in the future from radiation exposure associated with 1 year of NTS operations is about 2 chances in 1 billion. (Note that it takes several to many years from the time of exposure to radiation for a cancer to manifest itself.)

Based on the same conversion factor, $6.0x10^{-6}$ excess fatal cancers are projected in the population living within 80 km (50 mi) of NTS from normal operation in 1993. To place this number into perspective, it can be compared with the number of fatal cancers expected in this population from all causes. The 1990 mortality rate associated with cancer for the

TABLE 4.9.2.9–2.—*Doses to the General Public from Normal Operation at Nevada Test Site, 1993 (Committed Effective Dose Equivalent)*

Affected Environment	Atmospheric Releases		Liquid Releases		Total	
	Standard[a]	Actual	Standard[a]	Actual	Standard[a]	Actual
Maximally exposed individual (mrem)	10	0.0048	4	0.0	100	0.0048
Population within 80 kilometers[b] (person-rem)	None	0.012	None	0.0	100	0.012
Average individual within 80 kilometers[c] (mrem)	None	$5.5x10^{-4}$	None	0.0	None	$5.5x10^{-4}$

[a] The standards for individuals are given in DOE Order 5400.5. As discussed in that order, the 10 mrem/yr limit from airborne emissions is required by the CAA, the 4 mrem/yr limit is required by the SDWA, and the total dose of 100 mrem/yr is the limit from all pathways combined. The 100 person-rem value for the population is given in proposed 10 CFR 834 (58 FR 16268).
[b] In 1993, this population was approximately 21,750.
[c] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.
Source: NT DOE 1994b.

entire U.S. population was 0.2 percent per year (Almanac 1993a:839). Based on this national rate, the number of fatal cancers from all causes expected during 1993 in the population living within 80 km (50 mi) of NTS was 44. This number of expected fatal cancers is much higher than the estimated 6.0×10^{-6} fatal cancers that could have resulted from NTS operations in 1993.

Workers at NTS receive the same dose as the general public from background radiation, but also receive an additional dose from working in the facilities. Table 4.9.2.9–3 includes the average, maximum, and total occupational doses to NTS workers from operations in 1992. These doses fall within radiological limits (10 CFR 835). Based on a dose-to-risk conversion factor of 400 fatal cancers per 1 million person-rem (4×10^{-4} fatal cancers per person-rem) among workers (appendix E), the number of excess fatal cancers to NTS workers from operations in 1992 is estimated to be 0.0008.

A more detailed presentation of the radiation environment, including background exposures and radiological releases and doses, is presented in the *U.S. Department of Energy Nevada Operations Office Annual Site Environment Report-1993* (DOE/NV/11432-123). The concentrations of radioactivity in various environmental media (e.g., air and water) and in animal tissue in the site region (onsite and offsite) are also presented in the same reference.

TABLE 4.9.2.9–3.—*Doses to the Onsite Worker from Normal Operation at Nevada Test Site, 1992*

	Onsite Releases and Direct Radiation	
Affected Environment	**Standard[a]**	**Actual[b]**

Total workers (person-rem)	None	2.0

[a] 10 CFR 835. DOE's goal is to maintain radiological exposure as low as reasonably achievable.

[b] DOE 1993n:7. The number of badged workers in 1992 was approximately 780.

Chemical Environment. The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through direct contact or via the food pathway). The baseline data for assessing potential health impacts from the chemical environment are those presented in sections 4.9.2.3 and 4.9.2.4.

Adverse health impacts to the public can be minimized through administrative and design controls to decrease hazardous chemical releases to the environment and to achieve compliance with permit requirements. The effectiveness of these controls is verified through the use of monitoring information and inspection of mitigation measures. Health impacts to the public may occur during normal operations at NTS via inhalation of air containing hazardous chemicals released to the atmosphere by NTS operations. Risks to public health from ingestion of contaminated drinking water or direct exposure are also potential pathways.

Baseline air emission concentrations for hazardous air pollutants and their applicable standards are presented in section 4.9.2.3. These concentrations are estimates of the highest existing offsite concentrations and represent the highest concentrations to which members of the public could be exposed. These concentrations are compared with applicable guidelines and regulations. Information about estimating health impacts from hazardous chemicals is presented in appendix E.

Exposure pathways to NTS workers during normal operation may include inhaling the workplace atmosphere, drinking NTS potable water, and possible other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. NTS workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded. Additionally, DOE requirements ensure that conditions in the workplace are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm. Therefore, worker health conditions at NTS are expected to be substantially better than required by standards.

Health Effects Studies. Several epidemiological studies have been conducted to investigate possible adverse health effects of low-level radioactive fallout on residents of Nevada and Utah. A mortality study of Utah children conducted by Lyon et al. investigated the relationship between childhood leukemia and radioactive fallout and found a significant excess of leukemia among children who died during the high fallout period (between 1951 and 1958) compared to those who died during the low fallout periods (between 1944 and 1950 and between 1959 and 1975). A followup to the Lyon et al. study conducted by Beck and Krey found that bone doses of southern Utah residents were too low to account for the excess leukemia deaths.

A nonstatistically significant excess of thyroid neoplasm was reported among children living near the nuclear testing sites (Utah/Nevada) when compared to a group living in Arizona (HP 1990c:739-746).

An excess number of leukemia cases were observed among men who participated in military maneuvers in August 1957. No excess in "total cancers" was observed but four cases of polycythemia vera were reported where 0.2 were expected (JAMA 1984a:662-664). For a more detailed description of the studies and the findings, refer to appendix section E.4.7.

Accident History. Nuclear testing began at NTS in 1951. There were some 100 atmospheric nuclear explosions before the Limited Test Ban Treaty was implemented in 1973. Since then, all nuclear tests have been conducted underground.

Since 1970, there have been 126 nuclear tests that released approximately 54,000 Ci (2,000 TBq) of radioactivity to the atmosphere. Of this amount, 11,500 Ci (430 TBq) were accidental due to containment failure (massive releases or seeps) and late-time seeps. (Seeps are small releases after a test when gases diffuse through pore spaces of the overlying rock.) The remaining 42,500 Ci (1,600 TBq) were operational releases. From the perspective of human health risk, if the same person had been standing at the boundary of NTS in the area of maximum concentration of radioactivity for every test since 1970, that person's total exposure would be equivalent to 32 extra minutes of normal background exposure, or the equivalent of one-thousandth of a single chest x ray (OTA 1989a).

Emergency Preparedness. Each DOE site has established an emergency management program that would be activated in the event of an accident. This program has been developed and maintained to ensure adequate response for most accident conditions and to provide response efforts for accidents not specifically considered. The emergency management program incorporates activities associated with emergency planning, preparedness, and response. The NTS Emergency Preparedness Plan is designed to minimize or mitigate the impact of any emergency upon the health and safety of employees and the public. The plan integrates all emergency planning into a single entity to minimize overlap and duplication and to ensure proper responses to emergencies not covered by a plan or directive. The manager of the Nevada Operations Office has the responsibility to manage, counter, and recover from an emergency occurring at NTS.

The plan provides for identification and notification of personnel for any emergency that may develop during operational and nonoperational hours. The Nevada Operations Office receives warnings, weather advisories, and any other communications that provide advance warning of a possible emergency. The plan is based upon current Nevada Operations Office vulnerability assessments, resources, and capabilities regarding emergency preparedness.

<u>North Las Vegas Facility</u>

NLVF provides calibration services using specialized radiation fields for a variety of instrument test packages in support of DOE Nevada operations. A detailed discussion of the radiation environment, including background, radiological releases, and doses to members of the public are presented in the

U.S. Department of Energy Nevada Field Office Annual Site Environmental Report-1993 (DOE/NV/11432-123, September 1994). The concentrations of radioactivity in various environmental media (i.e., air, water, and soil) in the site region and the dose to onsite workers at NLVF are also presented in that reference.

Calculated radiological doses are used to estimate the potential health impacts to the public and onsite workers at NLVF from any releases of radioactivity. Small atmospheric releases occurred on July 12 and August 14, 1995. The dose to a maximally exposed individual and to the surrounding population from these releases is expected to be negligible. The actual dose to these receptors will be quantified upon receipt of monitoring data. The annual doses to workers and the public are summarized in table 4.9.2.9–4; corresponding health risks are also presented in the table. These doses are in addition to those from natural background radiation, consumer products, and medical sources, which total about 360 mrem/yr. The onsite worker doses are within regulatory limits. Background radiation doses are unrelated to NLVF operations.

Chemical Environment. Exposure pathways to NLVF workers during normal operation may include inhaling the workplace atmosphere, drinking NLVF potable water, and possible other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a

TABLE 4.9.2.9–4.—*Annual Doses to the General Public and Onsite Workers from Normal Operation at North Las Vegas Facility, 1993*

Receptor	Atmospheric Releases		Liquid Releases		Total		
	Regulatory Limit[a]	Calculated	Regulatory Limit[a]	Calculated	Regulatory Limit[a]	Calculated	Risk[b]
Individual Dose

Maximally exposed individual (mrem)	10	0.0[d]	4	0.0	100	0.0	0.0
Population Dose							
Population within 80 kilometers (person rem)	d	0.0[c]	d	0.0	d	0.0	0.0
Worker Dose							
Average worker (mrem)	NA[e]	0.0	NA[e]	0.0	5,000	82	$3.3x10^{-5}$
Maximally exposed worker (mrem)	NA[e]	0.0	NA[e]	0.0	5,000	440	$1.8x10^{-4}$
Total workers[f] (person-rem)	NA[e]	0.0	NA[e]	0.0	None	0.57	$2.3x10^{-4}$

[a] The regulatory limits for individuals are given in DOE Order 5400.5. The 10 mrem/yr limit from airborne emissions is required by the CAA. The 4 mrem/yr limit is required by the SDWA, and the total dose of 100 mrem/yr is the limit from all pathways combined. The regulatory limit for workers is 5,000 mrem (10 CFR 835).

[b] Based on latent fatal cancer risk factors of $5x10^{-4}$/mrem for individuals, $5x10^{-4}$/person-rem for population, and $4x10^{-4}$/mrem for workers (ICRP 1991a).

[c] Two very small atmospheric releases occurred on July 12 and August 14, 1995. Dose to any offsite individual is expected to be a fraction of a mrem (monitoring data is not yet available from all stations).

[d] No regulatory limits exist for population doses.

[e] NA - not applicable; worker doses were estimated on the basis of readings from monitoring devices called thermoluminescent dosimeters.

[f] The number of badged workers in 1994 was approximately seven.

Source: NTS 1995a:5.

meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. NLVF workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded. The maximum daily quantities of NIF-related hazardous materials stored at NLVF are presented in appendix table I.4.4.1.7.2–1. NLVF stores and uses few hazardous materials in amounts greater than the threshold planning quantities that require reporting under 40 CFR 370 (NT DOE 1995g).

4.9.2.10 *Waste Management*

This section outlines the major environmental regulatory structure and ongoing waste management activities for NTS, including NLVF. A more detailed discussion of the ongoing waste management operations is provided in appendix section H.2.8.

DOE is working with Federal and state regulatory authorities to address compliance and cleanup obligations arising from its past operations at NTS. DOE is engaged in several activities to bring its operations into full regulatory compliance. These activities are set forth in negotiated agreements that contain schedules for achieving compliance with applicable requirements and financial penalties for nonachievement of agreed upon milestones. These agreements have been reviewed to assure the proposed actions are allowable under the terms of these agreements.

DOE has decided that underground testing areas should be governed pursuant to the provisions of CERCLA. Preliminary assessment/site investigation reports and a hazardous ranking system package were provided to EPA for their use in determining whether NTS should be included on the NPL. In May 1993, the state of Nevada issued a letter to DOE indicating it did not appear that EPA would make a decision on the NPL status of NTS in the near future.

DOE has published the Nevada Test Site Treatment Plan and *Federal Facility Compliance Act* consent order addressing environmental restoration and waste management on NTS. A mutual consent agreement between the state of Nevada and DOE, updated in June 1995, permits NTS to use the available capacity of the TRU waste storage pad for the storage of onsite generated mixed LLW that does not meet the land disposal provisions of RCRA.

The Nevada Operations Office completed a waste minimization plan for NTS in 1991 and created an organization whose mission is to promote waste minimization and pollution prevention and to ensure compliance with DOE requirements. NTS currently generates waste from ongoing operations and remediation associated with past activities and receives waste from other DOE facilities. NTS manages the following waste categories: TRU, LLW, mixed, hazardous, and nonhazardous. A discussion of the waste management operations associated with each of these categories follows.

Transuranic Waste. Although NTS does not currently generate any TRU wastes, from 1974 to 1990, 612 m^3 (800 yd^3) of mixed TRU waste was received from LLNL and is stored on a 8,300-m^2 (89,300-ft^2) asphalt storage pad at Area 5 of NTS (NT REECO 1995a:21). DOE and the State of Nevada signed a Settlement Agreement on July 23, 1992, allowing the Nevada Operations Office to retain this inventory of mixed TRU waste subject to an appropriate permitting process. None of these waste packages is WIPP certified. They will have to be certified before shipment to WIPP. These wastes have been moved to a 1,995-m^2 (21,470-ft^2) polyvinyl chloride-coated polyester fabric covered building for storage until WIPP is determined to be a suitable disposal facility, pursuant to the requirements of 40 CFR 191 and 40 CFR 268, or until another suitable repository is found (NT DOE 1996b:30-38). NTS has areas of plutonium-contaminated soil, for which treatment technology is being developed. This activity may produce additional volumes of TRU or mixed TRU waste. Limited quantities of TRU waste were also disposed of in trench 4C and in greater confinement units in Area 5.

Low-Level Waste. In 1993, NTS generated approximately 178 m^3 (233 yd^3) of solid LLW onsite (NT DOE 1994f:4). LLW has been generated and disposed of in eight areas at NTS, but currently only Areas 3 and 5 are active for disposal. Bulk waste is disposed of in Area 3, and packaged classified and unclassified waste is disposed of in Area 5. Disposal of onsite waste began in 1971, and in 1978 operations expanded to receive wastes generated offsite. In 1995, 15 generators shipped LLW to NTS for disposal. An additional nine generators are applying for or awaiting approval (NT DOE 1996c:4-61, 4-62). As of October 1994, approximately 301,667 m^3 (394,600 yd^3) of LLW in Area 3 (NT DOE 1996c:4-43) and as of December 1993 approximately 167,400 m^3 (218,900 yd^3) of LLW in Area 5 (NT REECO 1994a:12) have been disposed of. Standard shallow land burial techniques have been employed.

Mixed Low-Level Waste. In 1993, NTS did not generate any mixed waste. Disposal of mixed waste received from the Rocky Flats Environmental Technology Site has taken place at NTS. Mixed waste disposal at NTS ceased, pending issuance by the state of Nevada of a RCRA Part B Permit for NTS. environmental restoration at NTS could generate additional volumes of mixed waste which would require some form of treatment. A liquid waste treatment system is being designed to process these mixed wastes. Mixed waste generated in the state of Nevada that meets land disposal restrictions of RCRA can be disposed of in the Area 5 mixed waste disposal unit, Pit 3. Pit 3 currently has an inventory of 8,024 m^3 (10,500 yd^3) (NT DOE 1996c:4-46). Other units in Areas 3 and 5 where mixed waste was previously disposed of will be closed in conformance with RCRA. The Nevada Division of Environmental Protection provides RCRA oversight for NTS. The 1992 revised RCRA Part B Permit application to include a separate mixed waste storage and disposal unit at NTS, in accordance with the provisions of the *Federal Facility Compliance Act* of 1992, has been submitted to the state of Nevada. A mutual consent agreement between the state of Nevada and DOE permits the storage of mixed LLW that do not meet RCRA land disposal restrictions on the TRU waste storage pads. DOE has published the NTS Site Treatment Plan and *Federal Facility Compliance Act* Consent Order that establishes the basis for treatment, storage and disposal of mixed LLW at NTS.

Hazardous Waste. For 1993, NTS generated approximately 34.6 m^3 (45 yd^3) of hazardous wastes (NT DOE 1994f:4). Hazardous wastes result from ongoing operations that utilize solvents, lubricants, fuel, lead, metals, motor oil, and acids. Hazardous wastes are accumulated at satellite areas, stored at the Area 5 RCRA-permitted hazardous waste storage unit, and shipped offsite by truck to a commercial RCRA-permitted facility using DOT-approved transporters. Additional accumulation areas and new equipment are planned to prevent the possibility of cross contamination with radioactive wastes (creating mixed wastes) in handling these materials. PCB-contaminated waste is accumulated and stored in the Area 6 TSCA waste accumulation unit. Accumulated PCB waste is shipped offsite to a commercial TSCA-permitted treatment, storage, and disposal facility. Hazardous waste generation is decreasing as the result of an aggressive waste minimization program, and will substantially decrease in the future due to the present moratorium on nuclear testing.

NLVF generated about 8.2 m^3 (2,180 gal) of liquid and 3.5 m^3 (4.6 yd^3) of solid hazardous wastes in 1994. All hazardous wastes are treated, stored, or disposed of offsite at RCRA-permitted facilities. Spills or releases of hazardous materials have historically been minor in nature and have been promptly cleaned up upon discovery.

A Waste Minimization and Pollution Prevention Awareness Implementation Plan submitted to DOE on December 20, 1991, is in place for NLVF. A formalized system of waste minimization was developed through the implementation of EG&G/EM Policy No. 31-70, Waste Minimization and Pollution Prevention, and Standard Operating Procedure 31-006.A, Hazardous Waste Minimization Plan. Hazardous waste generation from various processes has already been reduced through product substitution or by permanently discontinuing the hazardous waste generating process.

There are no underground storage tanks for hazardous or petroleum substances at NLVF. All aboveground tanks employ either secondary containment or a double-walled tank with continuous leak detection. There are no hazardous waste treatment, storage, or disposal facilities requiring state or Federal permits at NLVF (NT DOE 1995g).

Nonhazardous Waste. Nonhazardous sanitary wastes are expected to be generated at the current rates for several years, then decline assuming the present moratorium on underground weapons testing continues. Liquid nonhazardous wastes are disposed of in septic tanks, sumps, or in ponds. Solid wastes are disposed of in landfills at various locations on the site. Recycling of paper, metals, glass, plastics, and cardboard has already resulted in some decreases in waste quantities. NTS generated 7,170 t (7,900 tons) of solid sanitary wastes in 1993 (NT DOE 1994f:4). Solid waste landfills located in Areas 6, 9, and 23 are in use for the disposal of solid nonhazardous wastes.

The Area 6 landfill is a Class III landfill that accepts hydrocarbon-burdened soil and debris. The Area 9 landfill is a Class II landfill because it accepts less than 18 t (20 tons) of solid waste per day. The Area 9 landfill is allowed to receive all types of nonhazardous solid waste, excluding radioactive waste, free liquids, and asbestos. Its current capacity is approximately 993,883 m^3 (1.3 million yd^3). Due to changes in state regulatory requirements, the Area 9 landfill will undergo partial closure and reopen as a Class III construction and demolition landfill. The Area 23 landfill receives all types of nonhazardous solid waste with nonpathogenic hospital waste, dead animals, and asbestos-containing materials being buried in separate cells that are identified by concrete markers. The current capacity is approximately 449,541 m^3 (588,000 yd^3). The Area 23 landfill is scheduled to remain in operation as a Class II landfill after modification to comply with the new state regulations (NT DOE 1996c:4-47).

Policies and procedures are in place at NLVF that promote recycling and resource recovery. Physical and administrative measures implemented at NLVF minimize or prevent the introduction of pollutants into stormwater. Stormwater from the NLVF site is discharged by concentrated conveyance or sheet flow onto Losee Road. Industrial wastewater and sanitary sewage from NLVF are discharged into city of North Las Vegas sewer lines, which are connected to the city of Las Vegas publicly owned treatment works. The publicly owned treatment works discharges treated wastewater directly into Lake Mead under a NPDES permit issued by the Nevada Division of Environmental Protection. NLVF discharges an average of 147,303 L (38,888 gal) of wastewater per day into the publicly owned treatment works, with a peak maximum of 369,318 L (97,000 gal) of wastewater per day. Approximately 32 to 35 percent of the total wastewater originates from industrial processes, while the remaining 65 percent is predominantly sanitary wastes. Wastewater quality historically has been in compliance with permit conditions established by the city of North Las Vegas to protect the publicly owned treatment works treatment processes and ultimately the water quality in Lake Mead (NT DOE 1995g).

4.9.3 Environmental Impacts

4.9.3.1 *Land Resources*

No Action. Under No Action, DOE would continue current and planned activities at NTS as described in section 3.2.9. No additional land-use impacts are anticipated at NTS beyond the effects of existing and future activities which are independent of the proposed action.

Management Alternatives

Assembly/Disassembly. The A/D mission at NTS would require construction of a new A/D Facility within Area 6. Construction of the A/D mission would disturb up to 3.2 ha (8 acres) of land. The required acreage represents a small portion of the land available for future development at NTS. The existing Device Assembly Facility would form the cornerstone of the proposed A/D Facility. The Pit Reuse Facility would serve as an adjunct to the Device Assembly Facility, which would require modification to support the Pit Reuse Facility. Construction of the new facility would not impact NTS land-use plans and would be compatible and consistent with existing activities performed at the site.

The movement of strategic reserve pits and HEU apart from the A/D mission at NTS at another DOE site location (an alternative in the Storage and Disposition Program) would result in fewer facilities being constructed. NTS has no existing facilities for strategic reserve storage, therefore no impact on NTS land-use plans and policies are expected.

Sensitivity Analysis. NTS would be able to accommodate all operations and support functions for A/D with the proposed construction of the new A/D Facility and existing facilities. Those facilities would be sufficient to support the low production case. In order to support the high production case, additional floor space within existing buildings would be required.

Stewardship Alternatives

Proposed National Ignition Facility. Approximately 18.2 ha (45 acres) within Area 22 would be required for buildings, walkways, building access, and buffer space. The required acreage represents a small portion of the total land available on NTS for future development. The proposed NIF would occupy approximately 34,344 m^2 (369,675 ft^2) and would be compatible and consistent with existing operations in the area. No impacts to land use outside Area 22 or to land-use plans or policies at NTS are expected.

North Las Vegas Facility

The principal impact of the proposed NIF project on land use at NLVF would be the conversion of limited open space. The proposed NIF would require about 3.2 open ha (8 acres), which represents approximately 10 percent of NLVF's total land area and 56 percent of land available for development at NLVF. The impact of this conversion would be reduced somewhat by the existence of other areas on the site (i.e., F-4, F-5, and F-6) that would remain open for future development. Potential onsite impacts to land use could also result from required waste and water system upgrades, but the presence of NIF should not preclude future land uses or development in the city of North Las Vegas or Clark County.

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives are anticipated.

4.9.3.2 *Site Infrastructure*

This section discusses site infrastructure for No Action and the modification and construction of facilities necessary for stockpile stewardship and management alternatives at NTS. The additional facilities will affect the site primarily by increasing electrical power use. A comparison of site infrastructure and facilities resource needs for No Action and the proposed alternatives is presented in table 4.9.3.2–1. Currently, NTS does not use natural gas; therefore, the equivalent amount of liquid fuel is used for determining the fuel requirements as shown in the table.

No Action. The missions discussed earlier in section 3.2.9 would continue under No Action. The infrastructure at NTS would continue to be maintained so that underground nuclear testing could be resumed in the event it is again required for national security. Facility improvements around the site would continue in a staged manner through 2014; however, overall operations would not increase.

Management Alternatives

Assembly/Disassembly. The A/D mission with non-intrusive modification pit reuse and an option to store strategic reserves of plutonium and uranium would add a new A/D Facility and several other associated facilities. A nonintrusive modification pit reuse facility, which would be an adjunct facility to the Device Assembly Facility, would take weapon components from the disassembled weapons, make modifications to them, and assemble the modified components into new weapons. For storing the strategic reserve of plutonium and uranium, an adjunct facility to the Device Assembly Facility would also be needed. For the potential A/D complex to support stockpile management, the peak electrical power load is estimated to be 7 MWe. This alternative would be within the site's current electrical capacity but above the No Action energy load.

Plutonium and HEU strategic reserves are not currently stored in any facilities at NTS. Therefore, if the strategic reserve were located at another DOE site (an alternative in the Storage and Disposition Program) fewer facilities would be constructed. The change in site infrastructure requirements would be negligible.

To connect the NTS road network with the A/D complex, approximately 2 km (1.24 mi) of additional secondary access roads would be required. Interconnection requirements for the A/D complex are not expected to add or change appreciably when specific site adaptions are completed.

Sensitivity Analysis. The high or low case production scenario would not substantially affect the site's operational infrastructure. The electrical use would change slightly; however, the peak load would remain the same. Oil use would also change slightly, affecting only the scheduling of oil deliveries. Construction of additional facilities would be required for

TABLE 4.9.3.2–1.—*Site Infrastructure Requirements and Changes for Stockpile Stewardship and Management Alternatives at Nevada Test Site*

	Electrical		Fuel		
Alternative	Energy (MWh/yr)	Peak Load (MWe)	Liquid (L/yr)	Gas[a] (m^3/yr)	Coal (t/yr)
Current Resources	121,460[b]	27.4	5,716,000	0	NA
No Action (2005)					
Total site requirement	124,940	24.7	5,716,000	0	NA
Change from current resources	0	-2.7	0	0	NA
Weapons Assembly/Disassembly					
Total site requirement	169,940	31.7	9,386,000	0	NA
Change from No Action	45,000	7	3,670,000	0	NA
National Ignition Facility					
Total site requirement	162,940	44.7	6,378,000	0	NA
Change from No Action	38,000	20	662,000	0	NA
Combined Program Impacts					
Total site requirement	207,940	51.7	10,048,000	0	NA
Change from No Action	83,000	27	4,332,000	0	NA

[a] Liquid fuel is the primary utility fuel at NTS. The weapons A/D Facility and NIF fuel requirements have been converted to liquid fuel equivalents; natural gas is assumed to be 1,000 British thermal units per ft^3, and liquid fuel (8 lb/gal) is assumed to be 19,000 British thermal units per pound.

[b] Current electrical usage is below site capacity. The electrical capacity is 176,844 MWh with a peak load capacity of 45 MW.

Note: NA - not applicable.

Source: NT DOE 1995b; NTS 1993a:4; NTS 1995a:1; NTS 1995a:2; NTS 1996a:1; appendix I.

the high case while the low case would require much less modification of the Device Assembly Facility.

Stewardship Alternatives

Proposed National Ignition Facility. The proposed NIF is the only stockpile stewardship alternative facility proposed for NTS. Support facilities to accommodate research, testing, and material requirements would cover 18.2 ha (45 acres). For the proposed NIF complex, the peak electrical power load is estimated to be 20 MWe. This power requirement would require additional high-voltage transmission lines from Las Vegas and electrical distribution and transmission equipment onsite. The proposed NIF would use less than 0.1 percent of the regional power pool capacity margin. The additional power for the proposed NIF could be supplied by the Nevada Power Company. An alternative for the supplying power would be to use the 100 MW solar facility proposed for NTS.

To connect the NTS road network with the proposed NIF complex, approximately 2 km (1.24 mi) of additional secondary access roads would be required. Interconnection requirements for the complex are not expected to add or change appreciably when specific site adaptions are completed.

North Las Vegas Facility

NLVF has adequate site infrastructure to support the proposed NIF without major modifications.

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives at NTS are anticipated.

4.9.3.3 *Air Quality*

No Action. No Action air quality utilizes estimated air emissions data from operations at NTS in 2005, assuming continuation of current site missions to calculate pollutant concentrations at or beyond the NTS site boundary. The emission rates for criteria and toxic/hazardous pollutants for No Action are presented in appendix table B.3.9–1. Table 4.9.3.3–1 presents the No Action pollutant concentrations calculated from the 2005 emission rates. In this table, pollutant concentrations are compared to applicable Federal and state regulations and guidelines. Concentrations are expected to remain within these standards.

Management Alternatives

Assembly/Disassembly. Gaseous emissions of criteria and toxic/hazardous air pollutants would be generated from the A/D mission. These emissions would result from open burn/open detonation of non-radioactive scrap HE and HE-contaminated waste, plant boiler operation, cleaning operations using solvents, and small-scale synthesis operations. Emission rates for criteria and toxic/hazardous pollutants for the A/D mission are presented in appendix table B.3.9–1. Table 4.9.3.3–1 presents the concentrations of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the A/D mission. The resulting concentrations of criteria and toxic/hazardous pollutants are expected to be within Federal and state regulations and guidelines.

The storage of strategic reserve pits and HEU apart from the A/D mission at NTS at another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on air quality because NTS has no existing strategic reserve storage facilities.

Sensitivity Analysis. Impacts to air quality from either the low or high case scenario of the A/D alternative would result in higher and lower concentrations of criteria and toxic/hazardous pollutants for the high and low case, respectively. The concentrations of pollutants for both cases are expected to be within applicable Federal and state regulations and guidelines.

Stewardship Alternatives

Proposed National Ignition Facility. Operation of the proposed NIF would generate criteria and toxic/hazardous pollutants resulting from the combustion of boiler fuel for heating, operation of diesel generators, and solvent cleaning processes. The emissions consist of particulate matter, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and VOCs. Boiler fuel is assumed to be liquefied petroleum gas. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the proposed NIF are presented in appendix table

TABLE 4.9.3.3–1.—*Estimated Concentrations of Pollutants from No Action and Stockpile Stewardship and Management Alternatives at Nevada Test Site*

B.3.9–1. Table 4.9.3.3–1 presents the concentration of criteria and toxic/hazardous pollutants resulting from No Action and those generated from operation of the proposed NIF. Concentrations of pollutants resulting from operation of the proposed NIF added to No Action concentrations are expected to be within Federal and state regulations.

North Las Vegas Facility

Operation of the proposed NIF would generate criteria and toxic/hazardous pollutants resulting from the combustion of boiler fuel for heating, operation of diesel generators, and solvent cleaning processes. The emissions consist of particulate matter, carbon monoxide, nitrogen dioxide, sulfur dioxide, lead, and VOCs. Boiler fuel is assumed to be liquefied petroleum gas. Emission rates of criteria and toxic/hazardous pollutants for annual operation of the proposed NIF are presented in appendix table

B.3.9–1. Appendix table I.4.4.2.2.1–2 presents the emissions of criteria pollutants resulting from No Action and those generated from operation of the proposed NIF. Concentrations of pollutants resulting from operation of the proposed NIF added to No Action concentrations are expected to be within Federal and state regulations.

Construction Emissions. Estimated construction emissions, including site-clearing emissions and emissions associated with facility construction, are listed in table 4.9.3.3–2. The construction emission estimates are based on characteristics of the proposed NLVF location and on construction vehicle exhaust and fugitive emissions. Site clearing would occur in the first year, followed by facility construction for 4 years.

Detailed emission inventories associated with site clearing and facility construction, meteorological data used, air quality model assumptions, model input parameters, and potential project-specific mitigation measures are presented in appendix I.

TABLE 4.9.3.3–2.—*Estimated National Ignition Facility Construction Emissions for North Las Vegas Facility*

Pollutant	Total Emissions (t/yr)
Carbon monoxide	1.23
Lead	Negligible
Nitrogen dioxide	3.76
Particulate matter	6.89
Sulfur dioxide	0.43
Volatile organic compounds	0.44

Source: Appendix I.

With conventional dust control, maximum 24-hour average particulate matter concentrations of 156 $\mu g/m^3$ over background are predicted at the site boundary (10 m [32 ft] north of the proposed NIF location). These levels would be above the NAAQS and state standard for particulate matter. Additional dust-control measures, such as use of a calcium-based dust suppressant, reduction of activity, or use of intensified dust control measures should be implemented to comply with the NAAQS for particulate matter. Site clearing at NLVF would be expected to last less than a month, so ambient air quality impacts associated with site clearing would be minor, local, and temporary.

Operating Emissions. Air pollutant emissions from operation of the proposed NIF at NLVF are expected to be primarily due to fuel combustion and cleaning of the debris shields. Emissions of VOCs from debris shield cleaning is estimated at approximately 0.5 t/yr (0.45 tons/yr). Other potential air pollutant emission sources not considered significant are target destruction by either the direct drive or enhanced indirect drive options, emissions from vehicles used for freight shipments and employee commuting, and emissions from welding operations at the Fabrication Facility. The annual energy requirements for the proposed NIF are listed in appendix I. These energy requirements are assumed applicable to all sites. Fuel usage to meet these energy requirements is specific to NLVF.

Table 4.9.3.3–3 lists estimated annual air pollutant emissions based on the anticipated NIF annual energy requirements. External combustion units (boilers) would have to comply with best available control technology for carbon monoxide and nitrogen oxides for nonmajor sources (APCR sections 12.2.10.1, 12.2.11.1). Emissions of VOCs at the stated annual rate of 0.5 t/yr (0.45 tons/yr) may require additional controls depending on the type of solvent used (APCR Section 60.1.1). More detailed information on emission estimates and potential impacts is provided in appendix I.

TABLE 4.9.3.3–3.—*North Las Vegas Facility Annual Emission Increase with the Proposed National Ignition Facility Operation*

Pollutant	1990 Emissions (t/yr)	Projected National Ignition Facility Emissions (t/yr)	1990 Emissions Plus National Ignition Facility (t/yr)	National Ignition Facility Percent of 1990 Emissions
Carbon monoxide	0.23	0.56	0.79	241.56
Lead	Negligible	Negligible	Negligible	Negligible
Nitrogen dioxide	1.07	2.28	3.35	213.17
Particulate matter	0.78	0.21	0.99	27.00
Sulfur dioxide	0.07	0.04	0.11	50.96
Volatile organic compounds	3.45	0.57	4.02	16.56

Note: Percentages are calculated prior to rounding off emissions.
Source: Appendix I.

Potential Mitigation Measures. Mitigation measures to reduce emissions of particulate matter from site activities would probably not reduce the 24-hour particulate matter concentration below the regulatory limit due to the high naturally occurring background particulate concentrations in the desert environment in which NTS is located. Site-specific mitigation measures that would reduce particulate concentrations include paving unpaved roads and parking areas; watering to reduce dust emissions; applying nontoxic soil stabilizers to all inactive construction areas; covering, watering, or applying nontoxic soil binders to exposed piles (i.e., gravel, sand, and dirt); and suspending all excavation and grading operations when wind speeds warrant.

4.9.3.4 *Water Resources*

Environmental impacts associated with the construction and operation of the potential stockpile stewardship and management facilities at NTS could affect surface and groundwater resources. Potential water resource impacts at NLVF from the proposed NIF are discussed at the end of this section. All water required for construction or operation would be supplied from groundwater. The proposed sites for stewardship and management facilities do not lie within areas historically prone to flooding. There are no continuous flowing streams at NTS and no designated flood plains. Although a floodplain survey has not been conducted at NTS, such an analysis would be conducted before construction began. A description of the functions to be transferred to NTS and the facility locations selected to house these activities is presented in sections 3.3 and 3.4. Table 4.9.3.4–1 presents existing surface and groundwater resources and the potential changes to water resources at NTS and NLVF resulting from the proposed alternatives. The total site water resource requirements for each alternative including No Action are displayed in this table.

Surface Water

No Action. Under No Action, no impacts to surface water resources are anticipated because there are no surface water withdrawals, liquid discharges to streams, offsite surface drainage system, or publicly owned treatment works. A description of the mission and activities that would continue at NTS is provided in section 3.2.9.

Management Alternatives

Assembly/Disassembly. Surface water would not be used for any construction or operation activities associated with the A/D mission with nonintrusive pit reuse and storage of strategic reserves of plutonium and HEU at NTS. Consequently, impacts to surface water availability are not expected. The potential impacts to surface waters during construction would be erosion of disturbed land and sedimentation in drainage channels. To minimize soil erosion impacts, stormwater management and standard erosion control measures would be employed. The estimated 6.7 MLY (1.8 MGY) of nonhazardous wastewater generated during construction would either be recycled or treated and released to sewage or containment ponds that would be designed to minimize seepage. During operation, 53 MLY (14 MGY) of sanitary wastewater would be discharged to lagoons or evaporation ponds. Impacts to surface water quality are not expected. The existing lagoons and evaporation ponds just south of the Device Assembly Facility may have to be decommissioned and new facilities constructed due to the present system's proximity to the proposed A/D Facility.

The storage of strategic reserve pits and HEU apart from the A/D mission at NTS at another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on surface or groundwater resources at NTS.

Stewardship Alternatives

Proposed National Ignition Facility. Floodplain maps are not available for the proposed NTS Area 22 location for NIF. Preliminary calculations indicate that the 500-year flood depth for the nearest drainage channel is about 0.09 m (0.3 ft). NIF facilities could be protected from potential floods by raising foundations above the projected flood elevation.

A total of 2.1 MLY (0.55 MGY) of nonhazardous wastewater generated during construction would either be recycled or treated and released to sewage or containment ponds that would be designed to minimize seepage. During operation, 19 MLY (5 MGY) of sanitary wastewater would be discharged to lagoons or evaporation ponds. Sewage treatment and disposal facilities would have to be constructed for the project. There are no NPDES

Actions in 100-year floodplain	NA	Uncertain	Uncertain	None
Actions in 500-year floodplain	NA	Uncertain	Uncertain	None

[a] No Action water requirements and wastewater discharge for NLVF are 69.4 MLY and 54.8 MLY, respectively.
[b] Total water requirements for construction at NTS are based on a 6-year time period for A/D and a 5-year time period for NIF.
[c] No construction water would be used or construction wastewater generated. Total site water use and wastewater discharge would be the same as No Action operation.
[d] Wastewater discharge to city of North Las Vegas public wastewater treatment plant.
Note: NA - not applicable; MLY - million liters per year.
Source: NT DOE 1995b; NTS 1995a:1.

permits for the NTS site because there are no wastewater discharges to onsite or offsite surface waters; however, a state of Nevada permit for sewage discharge to sewage lagoons and ponds for NIF wastewater disposal would be required. Adverse impacts to surface water are not expected.

Groundwater

No Action. Under No Action, no additional impacts to groundwater availability or quality are anticipated beyond the effects of existing and future activities that are independent of and not affected by the proposed action. Baseline conditions and operations, described in section 4.9.2.4, would continue at NTS. No construction would occur under No Action; therefore, no additional construction groundwater would be used under No Action. Current groundwater usage of 2,400 MLY (634 MGY) is expected to remain the same in 2005 and would continue to be withdrawn from local groundwater sources. No additional impacts to groundwater quality are anticipated since there are no direct discharges to groundwater.

Management Alternatives

Assembly/Disassembly. Approximately 16.4 MLY (4.3 MGY) of groundwater is required for construction of facilities for the A/D mission with nonintrusive pit reuse and the option of storage of strategic reserves of plutonium and uranium. This amount represents a maximum increase of approximately 0.7 percent over projected groundwater withdrawal. The estimated 98.4 MLY (26 MGY) of groundwater required for operations would be an increase of less than 4.1 percent in projected water use, and would not be expected to cause depletion of the aquifer. The existing NTS water system supporting the proposed project area would have to be expanded to include one additional water well, treatment facilities, and an additional storage tank to provide for potable, fire, and process water.

As discussed in section 4.9.2.4, estimated perennial yields of the NTS aquifers range from 38,000 MLY (10,040 MGY) to 53,000 MLY (14,000 MGY). Based on these yields, total groundwater withdrawals required for the operation of the A/D alternative would remain below the lower rate. No adverse impacts on aquifer levels are expected.

The storage of strategic reserve pits and HEU apart from the A/D mission at NTS at another DOE site location (an alternative in the Storage and Disposition Program) would have no impact on surface or groundwater resources at NTS.

Sensitivity Analysis. Surface water and surface water quality would not be affected by either the low or high case production scenarios for the A/D mission at NTS. Groundwater and groundwater quality would not be affected by either the A/D mission low or high case production scenario.

Stewardship Alternatives

Proposed National Ignition Facility. Approximately 3 MLY (0.8 MGY) of groundwater is required for construction of NIF, which would represent a 0.13-percent increase over the projected groundwater withdrawal. The estimated 152 MLY (40.2 MGY) of groundwater required for operations would be a 6.3-percent increase in projected water use and would be well below the low estimate for recharge of the aquifer. Adverse impacts to groundwater supply are not expected.

Groundwater Quality. Under normal construction and operating conditions, sanitary wastewater disposed to the sewage or containment ponds would be the only discharge that could potentially reach the Valley-Fill aquifer. The wastewater would not have a measurable affect on groundwater quality because of the combined effects of a deep water table, low discharge volumes, high evaporation rates, and a composition and concentration consistent with treated and monitored sanitary wastewater. Adverse impacts to groundwater resources from A/D or NIF operations are not expected.

North Las Vegas Facility

Groundwater would not be used for construction or operation of the proposed NIF at NLVF; all water would be purchased from public suppliers. The proposed NIF location at NLVF is outside the 500-year floodplain of the local drainage (FEMA 1983a). Construction of NIF at NLVF would be expected to have minor to negligible affects on water quality with the implementation of a stormwater pollution and prevention plan to minimize soil erosion, sedimentation, and contamination of stormwater. Measures would be taken to comply with stormwater discharge regulations associated with construction activities under the CWA.

About 3 MLY (0.8 MGY) of water would be required for construction (LLNL 1995m). The total raw water supply required for NIF operation would be about 152 MLY (40.2 MGY), of which 18 MLY (4.8 MGY) would be for domestic use. The water required for NIF operation would be equivalent to an increase of 219 percent over the current usage of 69 MLY (18 MGY) (NT DOE 1995g; NTS 1995a:4). Sanitary wastewater volume is estimated to be 72.55 MLY (17.7 MGY). Water supply and sanitary wastewater treatment are provided by the city of North Las Vegas (NT DOE 1994g). Current water and wastewater utility capacity would be adequate to meet the additional requirement for the proposed NIF. Additional information regarding water and wastewater utility capacity at NLVF are presented in appendix I.

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives at NTS or NLVF are anticipated.

4.9.3.5 *Geology and Soils*

The proposed alternatives for NTS would have no adverse impact on geological resources described in section 4.9.2.5. Although a moderate seismic risk exists at NTS, it does not preclude safe construction and operation of the new facilities and would be considered in the design of any new structures. The hazard of volcanic activity is improbable and is not expected to impact the proposed facilities. Construction laydown and parking for the A/D mission would disturb up to 3.2 ha (8 acres) of land. Control measures would be used to minimize construction-related soil erosion. Potential impacts to geology and soils associated with the proposed alternatives at NTS are discussed below.

No Action. Under No Action, DOE would continue current and planned activities at NTS. Any impacts to geology and soils would be independent of and unaffected by the proposed action.

Management Alternatives

Assembly/Disassembly. Construction activities would not affect geological conditions. Designs of the facilities would ensure that they would not be adversely affected by geological conditions.

There are no known active faults that cross the proposed facilities. Based on the seismic history of the area, a moderate seismic risk exists at NTS but should not preclude safe construction and operation of the proposed facilities. The Cane Spring Fault, located approximately 8 km (5 mi) south of the Device Assembly Facility, is regarded as the most probable source for seismic activity in the vicinity of the proposed facilities, although a number of smaller faults are inferred in the alluvial areas of the site and in the Massachusetts Mountain area (DOE 1995i:4-148). The Yucca and Carpetbag Faults, which are located to the north of the proposed facilities, are also potential sources of seismic activity. The location of the proposed facilities would be evaluated at NTS during project-specific studies so that these faults and any associated potential ground rupture would be considered in facilities design. All facilities would be designed for earthquake-generated ground acceleration in accordance with DOE O 420.1 and accompanying safety guides.

Although there is a history of volcanism in the NTS area, volcanic eruptions are improbable (section 4.9.2.5). The most likely danger is from possible ash fall eruptions from the Long Valley area, 241 km (150 mi) to the west-northwest. Lava extrusion from sources at NTS could recur but is highly unlikely. Precursors, such as shallow earthquakes, fumarole activity, and higher groundwater temperatures, provide advance warning of most eruptions; no such activity is currently indicated at NTS or in the immediate vicinity. It is highly unlikely that landslides, sinkhole development, or other nontectonic events would affect project facilities. Slopes and underlying foundation materials are stable (DOE 1995i:4-148). Potential health impacts from accidents associated with geological hazards are discussed in section 4.9.3.9.

The properties and conditions of the soils underlying the proposed project site place no limitations on construction. These same soils would not adversely affect the safe operation of project facilities.

Soils would be impacted by construction and operation of the facilities. The soil disturbance from construction laydown and parking for the new facilities could be as much as 3.2 ha (8 acres). Also, the new building footprint would occupy approximately 4.3 ha (10.6 acres). Disturbance would occur at building, parking, and construction laydown areas, resulting in destruction of the soil profile, and leading to a possible temporary increase in erosion as a result of stormwater runoff and wind action. Soil losses would depend on frequency of storms; wind velocities; size and location of the facilities with respect to drainage and wind patterns; slope, shape, and area of the tracts of ground disturbed; and whether the soil is bare, particularly during the construction period. Appropriate erosion and sediment control measures would be used to minimize soil loss.

Net soil disturbance during operation would be less than for construction, because areas temporarily used for laydown would be restored. Although erosion from stormwater runoff and wind action could occur occasionally during operation, it is anticipated to be minimal.

The storage of strategic reserve pits and HEU apart from the A/D mission at NTS at another DOE site location (an alternative in the Storage and Disposition Program) would have less impacts on geology and soils at NTS because new facilities would not be constructed for storage.

Sensitivity Analysis. The high or low case operation scenario would not affect geology or soils.

Stewardship Alternatives

Proposed National Ignition Facility. The construction and operation of the proposed NIF at NTS would have no adverse impact on geological resources. An estimated 18.2 ha (45 acres) of land in Area 22 would be required for buildings, walkways, building access, and buffer space (see appendix I). Soil impacts during construction would be short term and minor with appropriate standard construction erosion and sediment control measures. Net soil disturbance during operation would be less than for construction because areas temporarily used for laydown would be restored. Seismic risks would be taken into account during construction and operation of NIF.

North Las Vegas Facility

The construction and operation of the proposed NIF at NLVF would have no adverse impact on geological resources. NIF would require about 3.2 ha (8 acres) of open land (see appendix I). Soil impacts during construction would be short term and minor with appropriate standard construction erosion and sediment control measures. The site has been disturbed in the past; therefore the impact due to the construction of NIF would be minor. Net soil disturbance during operation would be less than for construction because areas temporarily used for laydown would be restored. Seismic risks would be taken into account during construction and operation of NIF.

Potential Mitigation Measures. No mitigation measures for stockpile stewardship and management alternatives are anticipated.

4.9.3.6 *Biotic Resources*

The following sections address impacts to terrestrial resources, wetlands, aquatic resources, and threatened and endangered species at NTS. While the A/D Facility would not likely impact biotic resources, construction and operation of the proposed NIF would lead to a loss of terrestrial habitat and could impact the desert tortoise *(Gopherus agassizii)*.

No Action. Under No Action, the stewardship R&D missions described in section 3.2.9 would continue at NTS. This would result in no changes to current biotic resource conditions at the site as described in section 4.9.2.6.

Management Alternatives

Assembly/Disassembly. The existing Device Assembly Facility site would be used for A/D with nonintrusive pit reuse and storage of the strategic reserves of plutonium and uranium. Although some construction would be required, new structures would be built within areas that have already been disturbed. Existing wastewater facilities would be used for the disposal of nonhazardous liquid waste. This includes sewage settling ponds constructed for the Device Assembly Facility that have increased bird use of the Device Assembly Facility area (NT DOE 1995j:1). Direct impacts to the desert tortoise are unlikely; however, traffic associated with A/D has the potential to indirectly impact this species. Mitigation measures would be developed in consultation with the USFWS and could include reducing speed limits on roadways.

The storage of strategic reserve pits and HEU apart from the A/D mission at NTS at another DOE site location (an alternative in the Storage and Disposition Program) would have less impact on biotic resources at NTS because new facilities would not be constructed for storage.

Sensitivity Analysis. Implementation of either the low or high case workload would not change direct impacts to biological resources from those noted above. Indirect impacts to the desert tortoise could change in response to variations in the volume of traffic.

Stewardship Alternatives

Proposed National Ignition Facility

Terrestrial Resources. The proposed NIF would be located within an undeveloped portion of the creosote bush community (figure 4.9.2.6–1). Construction of new facilities would result in the disturbance of 18.2 ha (45 acres) of habitat. Proper erosion and sediment control measures would reduce the potential for disturbance of habitat adjacent to the construction area. Areas disturbed by construction, such as laydown areas and temporary construction parking lots, would be of minimal value to wildlife because of the difficulty in reestablishing a vegetative cover in a desert environment. In addition, introduced plants such as red brome, cheatgrass, and Russian thistle readily invade disturbed areas and delay vegetation by native plants. During construction, animal species within the disturbed area would be either destroyed or displaced depending upon whether they were able to move from the area. For example, reptiles and small mammals, as well as nests and young birds, would likely be destroyed, while larger mammals and birds would be able to leave the area. Wildlife may also be disturbed by the increased level of human activity associated with the project.

Wetlands. The proposed NIF site does not contain, nor is it located near, wetlands; therefore, construction and operation of the proposed facility would not adversely impact this resource.

Aquatic Resources. The proposed NIF site does not contain, nor is it located near, aquatic resources; therefore, construction and operation of the proposed facility would not adversely impact this resource.

Threatened and Endangered Species. Since the proposed NIF site is located in the southern portion of NTS, the potential exists for the desert tortoise to be impacted by construction and operation of the proposed facility and the associated 3.2-km (2.0-mi) underground water supply pipeline. Vehicular traffic associated with construction and operation could also pose a threat to the tortoise. Groundwater levels in Devils Hole are not expected to change due to operation of the proposed NIF; thus, no impacts to the Devils Hole pupfish (*Cyprinodon diabolis*) are expected.

North Las Vegas Facility

Terrestrial Resources. An environmental assessment conducted for the Nevada Support Facility (that would be located in the same general area as the proposed NIF at NLVF) concluded that no significant impacts to ecological resources would occur from construction and operation of that facility (see appendix I). That conclusion would also be applicable to the proposed NIF if it should be located at NLVF.

Construction of the proposed NIF at NLVF would occur within a 3.2-ha (8-acre) area of disturbed soil with scattered grasses and forbs. This area is of negligible value to wildlife. Landscaping around the new NIF buildings could add a minor amount of lawn with scattered shrubs and trees that could provide habitat for wildlife species adapted to suburban or industrial conditions. The general types of impacts that could result from proposed NIF construction at NLVF would be similar to those discussed for LLNL (see appendix I).

Wetlands and Aquatic Resources. The proposed NIF location at NLVF does not contain, nor is it located near, wetlands or surface water resources; therefore, construction and operation of the proposed NIF at NLVF would not be expected to adversely affect such resources.

Threatened and Endangered Species. Although NLVF is located within the range of the desert tortoise, it is not expected that tortoises would occur at the site of the proposed NIF. The proposed location is within a fenced area and does not contain adequate cover habitat for tortoises; therefore, no impacts to desert tortoises would be expected. Impacts to other listed species would not be expected because NLVF does not contain suitable habitat for listed species whose ranges encompass the facility.

Potential Mitigation Measures. For facilities located at NTS, certain mitigation measures would help lessen impacts to biotic resources. Minimization of the area to be disturbed and implementation of a soil erosion and sediment control plan would help to lessen short- and long-term impacts to terrestrial species and habitats. Disturbance to wildlife living in areas adjacent to facilities may be minimized by preventing workers from entering undisturbed areas. It may be necessary to survey disturbed areas for the nests of migratory birds prior to construction and to avoid clearing operations during the breeding season.

If any threatened or endangered species appear in disturbed areas, specific mitigation measures would be developed in conjunction with the USFWS. A Biological Opinion concerning the desert tortoise has been issued by the USFWS covering current projects (NT DOI 1992b). Recommended mitigation measures included providing worker training, putting restrictions on vehicle speeds and off-road movement, conducting clearance surveys prior to surface disturbance, providing stop work authority if tortoises are found within work areas, removing tortoises from trenches, landfills, and treatment ponds, inspecting trenches, and having biologists present when heavy equipment is in use. Similar recommendations would be considered for the proposed NIF. No mitigation measures would be required if the proposed NIF was located at the NLVF site.

4.9.3.7 *Cultural and Paleontological Resources*
