Nonhazardous Waste. SNL liquid sanitary waste is sent to municipal treatment facilities. SNL contains over 24 km (15 mi) of sewer lines interconnected with those of Kirtland Air Force Base. In June 1994, SNL activated the liquid effluent control system to retain process wastewater for radiological screening prior to disposal into the sanitary sewer. SNL's policy prohibits the disposal of radiological material above regulatory levels into the sanitary sewer system. Discharges by SNL to the publicly owned treatment works are regulated by the city of Albuquerque Public Works Department, Liquid Waste Division, under the authority of the city's Sewer Use and Wastewater Control Ordinance (SNL 1995g:6-1). Solid sanitary waste is collected and taken to the Albuquerque Sanitary Landfill on a regular basis. The total solid sanitary waste generated in 1994 as packaged for disposal was 13,600 t (14,990 tons) (SNL 1995f:7).

The classified waste landfill at SNL is a Class D landfill located in Technical Area III. The unit is an outdoor facility, 0.983 ha (2.43 acres) in size, used for the disposal of classified solid waste generated at SNL R&D facilities. The landfill currently operates under a notice of intent, submitted annually to the State of New Mexico Solid Waste Bureau. The industrial wastes (called classified solid waste) disposed of at this landfill originate from the classified reapplication yard. The waste stream consists of toner cartridges, computer tapes, crates and pallets, weapon components, and related hardware. The remaining capacity of this landfill is 9,635 m^3 (12,600 yd^3) (DOE 1994k).

H.2.8 Nevada Test Site

After underground nuclear tests, radioactive and hazardous materials were extracted and analyzed. These activities have resulted in the accumulation of low-level, hazardous, and mixed wastes that must be treated, stored, and disposed of. The *Site Book for Waste Management* (May 1994), the *Waste Management Plan for the Nevada Test Site* (February 1995), and the *NTS Site Treatment Plan* and Federal Facility Compliance Act Consent Order (March 1996) and the NTS EIS (Draft, December 1995) detail waste management activities at NTS.

Radioactive and hazardous wastes (according to the current definition of hazardous wastes) generated from past nuclear testing activities were disposed of at Areas 2, 3, 5, 6, 8, 9, 12, and 23. These were mixed wastes and LLW composed of debris, drilling mud, decontamination wastes, laboratory, and classified wastes. Areas 3 and 5 are still currently active for waste storage and disposal. Area 3 receives offsite and onsite bulk waste for disposal in subsidence craters. A RCRA closure plan has been submitted to the Nevada Division of Environmental Protection for this facility. The Radioactive Waste Management Site in the north of Area 5 contains LLW management units and receives packaged classified and unclassified LLW. It also has TRU wastes from LLNL in storage, and a hazardous waste accumulation site. The NTS is not currently accepting mixed wastes from any locations. Mixed waste could be accepted from defense related generators within the State of Nevada; however, there is no mixed waste ready for disposal that meets the land disposal restrictions of RCRA. Mixed waste has been disposed of from out-of-state generators, and this practice is planned for the future contingent upon approval and permitting (RCRA Part B) of future mixed waste disposal units and on actions resulting from the Record of Decision (ROD) on the Waste Management PEIS.

In the past, waste disposal at NTS was accomplished through landfills, underground injection and leachfields on NTS, and through offsite disposal of hazardous wastes. A goal of the NTS Environmental Restoration Project is to remove or immobilize hazardous substances, pollutants, and contaminants, while achieving compliance with environmental laws and regulations. Environmental restoration activities will be guided by the ROD from the NTS EIS and be in accordance with the Site Treatment Plan.

Pollution Prevention. The Nevada Operations Office is an active participant in DOE's National Waste Minimization and Pollution Prevention Program. A comprehensive Waste Minimization Plan for NTS was completed in 1991, which defines specific goals, methods, responsibilities, and achievements for organizations. A waste minimization organization promotes waste minimization and pollution prevention and assures compliance with DOE orders at NTS. A report on waste generation and waste minimization is published annually. DOE publishes site-wide plans and guidance, and each contractor develops its own implementation plan. Plans and procedures have been developed, limiting the number and types of hazardous materials used on the site.

Since the initiation of the waste minimization program, several steam-cleaning operations have been eliminated, and half of the hazardous solvents used at NTS have been replaced with nonhazardous solvents. Recycling and reclamation activities have been established to reuse lead, silver, lubricating oil, and trichlorotrifluoroethane. Automatic decontamination equipment, recycling fabrication tool coolant systems, and continuous oil change and reburn systems have been placed in service to reduce hazardous waste generation. Closed loop effluent recycling for steam cleaning has eliminated the production of 17.8 million L (4.7 million gal) of wastewater annually and has reduced hazardous waste generation by 90 percent. Two solvent waste stills recycle 85 percent of all solvents and thinners used. Nonhazardous aqueous solution parts cleaners have eliminated the need for parts cleaning solvents.

The procurement of all materials is also reviewed for the opportunity to reduce the purchase of hazardous materials for NTS operations. In addition, an education and training program for all site personnel and for the surrounding community is helping to increase awareness of best practices and lessons learned in waste reduction.

Transuranic Waste. TRU and mixed TRU waste is stored at NTS on the TRU waste storage pad in Area 5. This waste was generated at LLNL and shipped to NTS between 1974 and 1990. All NTS TRU and mixed TRU waste is expected to be certified for disposal at WIPP in Carlsbad, NM, or another suitable repository should WIPP prove to be unsatisfactory. The Nevada Operations Office has the option to construct a TRU Waste Certification Building for breaching, sampling, and certifying containers of TRU waste to meet the WIPP Waste Acceptance Criteria which is expected to be finalized by June 1997 (NT DOE 1996b:4-61, 4-62). Other technologies, such as mobile characterization capabilities, are also being considered. This waste inventory consists of 612 m^3 (800 yd^3) of heterogeneous debris. The TRU waste is stored in the TRU Pad Cover Building on the TRU Waste Storage Pad to protect the containers from the environment. In addition, TRU and suspected TRU waste from weapons tests were emplaced in boreholes. Decisions to retrieve this waste or leave it in place will be based on performance assessments required by 40 CFR 191 and/or risk assessments required by CERCLA or RCRA. Table H.2.8–1 lists the mixed TRU waste storage units at NTS.

Low-Level Waste. Contaminated soils, created from past atmospheric nuclear weapons tests, occur at various locations on NTS. Some of this surface contamination has been and is planned to be removed and disposed of as waste. Although the debris from underground weapons tests remain underground, samples of this debris are brought to the surface for analysis and then must be disposed of as waste. The majority of LLW generated at NTS is disposed of in subsidence craters in Area 3. This area also receives substantial quantities of containerized bulk waste from other offsite DOE facilities. Some waste disposal units are being closed in this area, while others are being readied for future use. Area 5 receives low-level radioactive waste from both onsite and offsite generators. New disposal capacity is planned for this area, and the offsite generators will be required to meet the NTS Waste Acceptance Criteria (which includes periodic reviews by the Nevada Operations Office) to permit them to ship LLW for disposal at NTS.

Historically, the volume of waste received from offsite is approximately equal to or slightly greater than the volume of waste generated onsite. Recently onsite waste generation (other than environmental restoration waste) has declined due to cessation of nuclear testing. Offsite receipts currently dominate waste disposal activities at NTS. Remediation activities at NTS will produce waste streams that will have to be treated, stored, and disposed of. Offsite waste shipments must meet NTS Waste Acceptance Criteria that require that the waste be approved for disposal at NTS. Fifteen generators currently ship LLW to NTS, and an additional nine are applying for or are awaiting approval (NT DOE 1996c:4-61, 4-62). The LLW disposal capacity in use or planned at NTS is listed in table H.2.8–2.

Mixed Low-Level Waste. Mixed LLW is generated by DP-related support activities, environmental restoration activities, and activities supporting TRU waste disposal at WIPP or another suitable repository should the WIPP prove to be unacceptable. Wastes

TABLE H.2.8–1.—*Mixed Transuranic Waste Storage at Nevada Test Site*

Storage Unit	Input Capability	Total Area (m^2)	Comment
Asphalt storage pad (covered building)	Mixed TRU solid, mixed LLW	8,300 (1,995 in TRU pad cover building)	Available storage capacity on the TRU pad to be used for storage of future, onsite generated mixed LLW that does not meet RCRA land disposal restriction provisions.

TABLE H.2.8–2.—*Low-Level and Mixed Low-Level Waste Storage and Disposal at Nevada Test Site*

Disposal Unit	Input Capability	Total Capacity[a] (m^3)	Comment
Mixed waste, P03U management unit	Mixed LLW solid	118,908	Interim status. Onsite use only. RCRA Part A 1988. EA published, withdrawn. Will be considered in site-specific EIS.
LLW disposal, P04U	LLW solid, wood, metal, rubble, debris	66,946	Operational. Additional 616,300 m^3 capacity available for expansion
LLW disposal, P06U	LLW solid	27,002	Operational, reserved for future use
Classified shallow land burial, T02C	LLW solid, metal in approved containers	1,698	Operational, no remaining capacity
Shallow land burial, T03U	LLW solid, metal, debris, unclassified	7,086	Reserved for LLW disposal
Classified shallow land burial, T04C	LLW solid, metal in approved containers	1,518	Operational
Mixed waste storage pad	Mixed LLW solid	6,040[b]	Planned. RCRA Part B submitted in 1992
Bulk LLW disposal, U3AHAT	LLW solid, wood, metal, soil, biological	424,800	Operational

[a] Schedules and capacity for facilities under design or construction are subject to changes such as availability of funds and permit issuance.
[b] Estimated assuming no aisle space and containers stacked 2 m (6.6 ft) high.
Source: NT DOE 1996b; NT REECO 1994a.

were generated by the analytical activities supporting weapons tests and consisted of drilling muds and debris generated from tunnel reentry and rehabilitation. Additional wastes result from radiochemical analysis and decontamination of equipment and facilities used in sample extraction and analysis. NTS has received mixed wastes from other DOE sites and may receive additional waste in the future, pending the completion of the site treatment plans for all DOE sites and once proper permits are obtained. Mixed waste generated in the State of Nevada that meets the land disposal restrictions of RCRA can be disposed of in the Area 5 mixed waste disposal unit, Pit 3. Mixed waste not meeting land disposal restrictions can be stored on the TRU waste storage pad. A RCRA Part B permit application for a new mixed waste storage unit was submitted in January 1995.

Mixed LLW streams are being characterized to determine what technologies and capabilities are required for safe, environmentally sound, and compliant disposal. Construction of the Liquid Waste Treatment System, a central facility for treating liquid LLW and mixed LLW (contaminated effluents from environmental restoration and DP activities), has been funded and is being designed. Receiving/holding and evaporation reservoirs and associated mixed waste processes will be RCRA-permitted.

Table H.2.8–2 lists mixed LLW storage and disposal facilities at NTS. Table H.2.8–3 lists the mixed LLW streams inventory and 5-year projected generation at NTS. The total volume is 296 m^3 (388 yd^3), including a 20,425-kg (45,000-lb) empty spent shipping cask. Table H.2.8–3 lists mixed LLW waste streams at NTS.

Hazardous Waste. Hazardous wastes are generated from ongoing operations at NTS. Wastes consist of solvents, lubricants, fuel, lead, metals, and acids. Hazardous wastes are accumulated at various sites around NTS while they await shipment offsite to a RCRA-permitted facility. Over the next 5 years, additional satellite storage locations are planned. A separate accumulation site across the road from Area 5 is provided to avoid potential cross-contamination with radioactive waste. The generation of hazardous wastes at NTS is expected to decrease significantly because of the cessation of nuclear testing, the completion of environmental restoration activities, and the impact of waste minimization activities. Hazardous waste is stored on a 279-m^2 (3,000-ft^2) covered pad in Area 5 (NT REECO 1995a:33).

Nonhazardous Waste. Nonhazardous sanitary wastes are expected to be generated at the current rates for several years into the future, then decline due to the cessation of nuclear weapons testing. Recycling of paper, metals, glass, plastics, and cardboard has already resulted in some decreases in waste quantities.

TABLE H.2.8–3.—*Mixed Low-Level Waste Streams at Nevada Test Site*

Waste Matrix	Number of Waste Streams	Inventory Reported March 1996 (m^3)	Five-Year Projection	
			Number of Waste Streams	Total Generation
PCB contaminated soil	1	0.11	0	0
Lead contaminated soil	1	29.8	0	0
Bulk lead waste	4	2.49	0	0
Solvent sludge (Area 12)	1	0.11	0	0
Shipping cask	1	2.2	0	0
Treatability test facility solvent	1	0.21	0	0
Pico fluor	1	0	1	0.3
Analytical services solvent	1	<0.1	0	0

ABSTRACT: In response to the end of the Cold War and changes in the world's political regimes, the United States is not producing new-design nuclear weapons. Instead, the emphasis of the U.S. nuclear weapons program is on reducing the size of the Nation's nuclear stockpile by dismantling existing nuclear weapons. The Department of Energy (DOE) has been directed by the President and Congress to maintain the safety and reliability of the reduced nuclear weapons stockpile in the absence of underground nuclear testing. In order to fulfill that responsibility, DOE has developed a Stockpile Stewardship and Management Program to provide a single highly integrated technical program for maintaining the continued safety and reliability of the nuclear stockpile. The Stockpile Stewardship and Management PEIS describes and analyzes alternative ways to implement the proposed actions for the Stockpile Stewardship and Management Program.

Stockpile stewardship refers to activities associated with research, design, development and testing of nuclear weapons and the assessment and certification of the safety and reliability. The stockpile stewardship portion of the PEIS evaluates the potential impacts of three proposed facilities: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. The stockpile stewardship alternatives involving these facilities could affect four sites: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and Nevada Test Site (NTS).

Stockpile management refers to activities associated with the production, maintenance, surveillance, refurbishment, and dismantlement of the nuclear weapons stockpile. The stockpile management portion of this PEIS evaluates the potential impacts of carrying out stockpile management alternatives at eight sites: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. The stockpile management alternatives are assessed for nuclear weapons assembly/disassembly and for fabricating pits, secondaries and cases, high explosives, and nonnuclear components.

The Stockpile Stewardship and Management PEIS also evaluates the No Action alternative of relying on existing facilities and continuing the missions at current sites to achieve both the stockpile stewardship and management missions. The No Action alternative assesses the environmental impacts of the on-going Stockpile Stewardship and Management Program and provides a baseline against which alternatives can be evaluated.

DOE has identified the following preferred alternative for the Stockpile Stewardship and Management Program:

Stockpile Stewardship:
- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:
- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL

- Assembly/Disassembly—downsize at Pantex
- High Explosives Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) highly enriched uranium strategic reserve storage at Y–12; and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS*. Decisions on strategic storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the *Stockpile Stewardship and Management Final PEIS* and the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

Evaluation of impacts on land resources, site infrastructure, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, socioeconomics, waste management, environmental justice, as well as radiological and hazardous chemical impacts during normal operation and accidents to workers and the public are included in the assessment. The PEIS presents unclassified information only. A classified appendix has also been prepared to support the PEIS.

PUBLIC COMMENTS: The public comment period on the Draft PEIS was conducted from March 8, 1996 to May 7, 1996. During the comment period, public hearings were held in Los Alamos, NM; Albuquerque, NM; Las Vegas, NV; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. The Draft PEIS was made available through mailings, requests to DOE's Office of Reconfiguration, and at DOE Public Reading Rooms. In preparing the Final PEIS, DOE considered comments received by mail, fax, handed in at hearings, transcribed from messages recorded by telephone, and those transcribed via Internet. In addition, comments and concerns identified during discussions at public hearings were considered.

In response to comments submitted after issuance of the Draft PEIS and due to additional technical details not available at the time of issuance of the Draft, Volumes I, II, and III of the Final PEIS contain revisions and changes. The revisions and changes made since the issuance of the Draft document are indicated by a double underline for minor word changes or by a sidebar in the margin for paragraph or larger changes. In addition, Volume I and each appendix in Volume III provide a unique reference list to enable the reader to further review and research selected topics. Volume IV (Comment Response Document) of the PEIS contains the comments received during public review of the Draft PEIS and the DOE responses to those comments. DOE has public reading rooms near each affected site and in Washington, DC where these referenced documents may be reviewed or obtained for review.

SUMMARY

I-S.1 INTRODUCTION

The U.S. Department of Energy (DOE) proposes to construct and operate the National Ignition Facility (NIF). The goals of NIF are to achieve fusion ignition in the laboratory for the first time by using inertial confinement fusion (ICF) technology based on an advanced design solid-state laser and to conduct high-energy-density experiments in support of national security and civilian applications.

The purpose of this project-specific analysis is to assess the environmental impacts of construction and operation of NIF. This document describes the project and its purpose and need, considers site alternatives and project design options, delineates the affected environments, assesses potential environmental impacts, and suggests mitigation measures. This analysis, as an appendix to the *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management*, is equivalent to a stand-alone environmental impact statement on the proposed NIF.

I-S.2 PURPOSE AND NEED

NIF would provide a unique capability for DOE's science-based stewardship of the nuclear weapons stockpile. The goal of obtaining fusion ignition and burn would attract and challenge top scientific and engineering talent with a problem containing many of the same elements of physical understanding as those necessary for stewardship of the nuclear stockpile. Planned experiments with NIF, at temperatures and pressures near those that occur in nuclear weapon detonations, would provide the data needed to verify certain aspects of sophisticated computer models. These models are needed to simulate weapons physics and to provide insights on the reliability of the Nation's nuclear weapons stockpile. Specially designed NIF experiments could also address specific issues of modeling or physics that are of concern because of changes in weapons due to aging or remanufacture. Finally, NIF experiments could provide a unique source of radiation for studies on nuclear weapon effects.

NIF experiments could address, to various degrees, certain weapons issues connected with fusion ignition and boosting; weapon effects; radiation transport; and secondary implosion, ignition, and output. Most of these processes occur at very high energy density (i.e., at high temperatures and pressures) and are relevant to a weapon's reliability. NIF would achieve higher temperatures and pressures, albeit in a very small volume, than any other existing or proposed stockpile stewardship facility. It is also the only facility that would achieve fusion ignition. Safety issues principally connected with the high explosive and fissile material implosion in a weapon would not be addressed by NIF.

Present computer codes are not adequate to calculate all the high-energy-density phenomena that occur in an exploding nuclear weapon. The high temperatures and pressures achievable with NIF would be used to measure properties of matter at the extreme conditions expected and, thus, verify aspects of advanced computer models. If an unanticipated change relevant to the high-energy-density phase of weapon operation is observed in the weapon surveillance program, specially designed NIF experiments could aid weapons scientists in validating aspects of their integrated computer models to assess whether that change would adversely impact the weapon's reliability. It is important to have NIF operating well before the period 2005 to 2010, as weapons age beyond their original design lifetime.

As a multipurpose facility, NIF would also be important to the Nation's energy, basic science, and technology missions. Its data would determine whether ICF can be a viable source of electric power in the future. Achieving ignition, optimizing the various target gain curves, and providing initial data on fusion reactor materials would allow sound decisions to be made concerning inertial fusion energy development.

NIF experiments would also achieve the same temperatures and pressures that exist in the sun and other stars, providing new laboratory capabilities for exploring basic high-energy-density sciences such as astrophysics and plasma physics. As the world's largest optical instrument, NIF could spur high technology industries in such areas as optics, lasers, materials, high-speed instrumentation, semiconductors, and precision manufacturing.

Achievement of fusion ignition at NIF would fulfill a major goal of the ICF program. Both the National Academy of Sciences in 1990 and the Inertial Confinement Fusion Advisory Committee have recommended proceeding with an ignition facility based upon solid-state laser technology.

I-S.3 PROJECT DESCRIPTION

Conventional construction techniques would be used to build NIF. The extent and exact nature of such activities as site clearing, infrastructure improvements, and support facility construction required would depend on the specific location selected for NIF. Construction of NIF would be organized in the following sequential phases: (1) initial building construction, (2) special equipment structures installation, (3) final building construction, (4) final installation preparation, (5) clean component installation, and (6) final laser/target systems installation.

Once operational, NIF would provide the capability to perform the full range of target physics experiments leading up to and including ignition and burn. It would also allow researchers to design experiments studying weapons effects, weapons physics, fusion energy, and the basic sciences. NIF would consist of two main components: a collection of 192 laser generation and transport systems and a target area including a target chamber and associated equipment. An advanced, integrated sensor and computer system would control the lasers and collect data from diagnostic equipment. These elements would all be housed in one central facility. Required support facilities, such as assembly areas, maintenance areas, machine and mechanical shops, and offices would be located nearby. General site requirements would include control by DOE Office of the Assistant Secretary for Defense Programs (DP), significant ICF infrastructure, protection of the public and the environment, hazardous and radioactive waste management capability, and transportation services. The total land area requirement for NIF, including direct-support buildings, would be about 20 hectares (ha) (50 acres). Depending on the site selected, many of the NIF needs may be served by existing facilities, reducing the requirements of new land area to 3.2 to 18.2 ha (7.9 to 45 acres).

I-S.4 ALTERNATIVES

The alternatives considered in this analysis consist of five candidate locations at four DP sites (Lawrence Livermore National Laboratory [LLNL], Los Alamos National Laboratory [LANL], Nevada Test Site [NTS] - Area 22 main site location, North Las Vegas Facility [NLVF] location near NTS, and Sandia National Laboratories [SNL]), the No Action alternative, and two design capabilities. The designs under consideration consist of two operational capabilities, the Conceptual Design Option and the Enhanced Option.

I-S.4.1 Alternative Sites

DOE has selected one preferred (LLNL) and three alternative (LANL, NTS, and SNL) NIF sites that meet most of the following site criteria: DP-controlled Federal site, significant ICF infrastructure, adequate protection of the public and the environment, hazardous and radioactive waste management capability, and adequate transportation services for transport of targets. While the two NTS locations, Area 22 and NLVF, do not currently have ICF infrastructure, they have been included to ensure that DOE examines any potential lost efficiencies that might arise by taking advantage of the infrastructure that must be maintained at these sites in accordance with the presidential mandate to maintain a test-readiness posture.

Lawrence Livermore National Laboratory. LLNL is located about 64 kilometers (km) (40 miles [mi]) east of San Francisco in southern Alameda County. LLNL occupies 332 ha (821 acres). NIF would be situated on an 8.1-ha (20-acre) disturbed grassland area in the northeastern quadrant of LLNL, adjacent to existing ICF facilities.

Los Alamos National Laboratory. LANL is located in Los Alamos County, in north-central New Mexico, approximately 97 km (60 mi) north-northeast of Albuquerque. LANL occupies 11,300 ha (28,000 acres). NIF would be located on a 4-ha (10-acre) area in Technical Area (TA) 58, an undeveloped forested area adjacent to TA-3, the hub for LANL administration and support activities.

Nevada Test Site. Area 22 at NTS is located in southern Nye County in southern Nevada, about 105 km (65 mi) northwest of Las Vegas. NTS occupies about 350,000 ha (867,000 acres). NIF would be located on an 18.2-ha (45-acre) area within Area 22 in undeveloped creosote bush habitat, southwest of Mercury Base Camp in the southeastern portion of the NTS. NLVF is located in the city of North Las Vegas, Nevada, and occupies 32 ha (80 acres) zoned for general industry within the city. NIF would be located within a 3.2-ha (8.0-acre) previously disturbed, sparsely vegetated area in the northwestern portion of NLVF.

Sandia National Laboratories/New Mexico. DOE SNL site is located 11 km (6.5 mi) east of downtown Albuquerque in Bernalillo County, New Mexico. DOE owns 1,150 ha (2,842 acres) within the boundaries of the Kirtland Air Force Base military reservation and uses additional property through land withdrawals and land-use permits from Kirtland Air Force Base, the State of New Mexico, and the Isleta Pueblo. NIF would be located in an 11-ha (28-acre) disturbed grassland portion of the southern side of Technical Area II. The site is near SNL facilities that would be required for NIF support.

I-S.4.2 No Action

Under the No Action alternative, DOE would not construct and operate NIF. Without the facility, the Stockpile Stewardship and Management Program mission and the Nation's sustainable energy policy mission, as defined in the *National Energy Policy Act* of 1992, would be adversely affected. Key support elements of Stockpile Stewardship and Management, such as the goals of producing ignition and energy gain in ICF targets and performing fusion and high-energy-density physics or weapons-effects experiments in support of the Stockpile Stewardship and Management Program, would not be achieved.

The Stockpile Stewardship and Management Program would continue to use Nova and other facilities for a time, but fusion ignition and the much higher temperatures and pressures of NIF would not be available. Alternatives to achieve higher temperatures and pressures than are presently available may eventually be proposed, but they would not be available when several of the remaining types of nuclear weapons age beyond their original design lifetime, between 2005 and 2010. Thus, issues may arise that decrease confidence in the reliability of these weapons and increase the probability that the United States may need to invoke "supreme National interest" and withdraw from any Comprehensive Test Ban Treaty in effect (based on *Statement by the President on Goal for a Comprehensive Test Ban Treaty*, White House Office of the Press Secretary, August 11, 1995).

Without NIF, efforts to obtain the critical data needed to determine if the ICF approach, based on the neodymium glass solid-state laser design, would be a viable and practical energy source for electric power production would be delayed or abandoned. Other ICF-based methods proposed for achieving ignition (such as heavy ion acceleration, light ion diodes, krypton-fluoride lasers) are not developed to the point of being able to propose an ignition facility. As a result, these potential alternatives for ICF energy source demonstrations would have longer lead times and a higher integrated cost to achieve the mission proposed for NIF.

I-S.4.3 Operational Capability Options

Two operational capability options (Conceptual Design and Enhanced) have been proposed for NIF. The Conceptual Design Option would use an ICF approach called "indirect drive." In indirect drive, laser beams would illuminate and heat the interior surfaces of a small metal case (hohlraum) containing a deuterium-tritium-filled capsule. The beams would cause the case to emit x rays that would strike the fusion target capsule, resulting in compression and heating of the capsule to conditions igniting the fusion reaction. This option also includes basic experiments for weapons physics, nuclear weapons effects on other systems, and other user community needs.

The Enhanced Option would include the indirect drive operations of the Conceptual Design Option and a second approach called "direct drive." The Enhanced Option would provide the capability to perform an increased number of both yield and non-yield experiments to accommodate greater user needs. No hohlraum would be used in the direct drive approach. Instead, a large number of laser beams would be employed to ensure good uniformity of the driving force (laser light) over the face of the target. The laser beams would impinge directly on the deuterium-tritium-filled capsule to drive the fusion reaction. Because it is possible that NIF would be used for direct-drive experiments in its lifetime, operating conditions for both indirect- and direct-drive experiments have been developed and are being assessed.

I-S.5 Environmental Consequences

Table I-S.5–1 compares the potential environmental consequences of the No Action alternative with those of construction and operation of NIF at the alternative candidate sites. The comparison is based on the assessments in section I.4 of this analysis. Factors analyzed include land use and visual resources; air quality and noise; water resources; biotic resources; cultural and paleontological resources; socioeconomics; and radiological and chemical health, safety, and risk. Where they would differ, the potential impacts of the two operational scenarios (Conceptual Design Option and Enhanced Option), are also compared in table I-S.5–1. Table I-S.5–2 compares waste management issues for each candidate site.

The analyses in this appendix indicate that there would be few significant differences in the adverse environmental impacts among the candidate sites analyzed. The maximum 24-hour particulate matter 10 microns or smaller (PM_{10}) concentration in the air during site clearing would exceed applicable standards at LLNL and NLVF (table I-S.5–1). However, the ambient air quality impacts would be localized and of short duration. Uncommitted land requirements would be greatest at NTS (18.2 ha [45.0 acres]), although this acreage is less than 1 percent of the uncommitted land at NTS. Conversely, the least amount of uncommitted land that would be required for NIF would be 3.2 ha (7.9 acres) at NLVF. However, this acreage represents the largest percentage of uncommitted land at a candidate site (56 percent). Of greater significance would be the quality of the habitat of the uncommitted land that would be affected by NIF construction. The highest-quality habitats that would be affected would be forest (4.0 ha [9.9 acres]) at LANL or desert (18.2 ha [45 acres]) at NTS. At the other candidate sites, habitat disturbance would occur to grassland (LLNL and SNL) or to an area of sparse vegetation (NLVF) (table I-S.5–1). The risk of cancer to members of the public from a facility accident involving the release of radioactive material would be greatest at NLVF and SNL (table I-S.5–1), although the potential for the actual occurrence of such an accident would be extremely low.

NIF will comply with all applicable Federal, state, and local environmental regulatory requirements, including the *California Environmental Quality Act* if NIF is sited in the State of California. The candidate sites have also enacted several mitigative measures for construction actions that would also be applicable to NIF construction. While each of these mitigative measures may be minor, in combination they could significantly reduce impacts to the environmental resources of the selected site. The evaluations of environmental consequences of NIF construction and operation summarized in tables I-S.5–1 and I-S.5–2 are based on the assumption that the mitigative measures would be carried out if the proposed action were undertaken.

Even with mitigation, construction and operation of NIF could result in unavoidable residual adverse effects. These effects would include the disturbance of up to 18.2 ha (45 acres) of land to construct NIF and provide additional supporting infrastructure and access roads (table I-S.5–1). However, land required for NIF at any of the candidate sites would not conflict with site development or land use plans. Concentrations of PM_{10} and total suspended particulates in the air are expected to be close to or exceed the 24-hour ambient PM_{10} and total suspended particulates standards during peak construction periods under dry and windy conditions. Such exceedances are not uncommon for large construction projects. Loss of wildlife habitat within the disturbed areas would be unavoidable, thus resulting in some localized effects on biota. Few unavoidable adverse socioeconomic impacts would occur in any of the regions of influence for NIF candidate sites. No adverse disproportionate environmental justice concerns would be expected at any of the candidate sites, except for a minor potential to disproportionately impact minority populations in the region of influence for NLVF.

Over the 30-year operational life of NIF, the public would be exposed to a very small dose of radiation (table I-S.5–1). No cancer fatalities would be expected to occur from exposures associated with routine NIF operations under either the Conceptual Design or Enhanced options. A radiological accident at NIF would not cause any cancer fatalities to the public except possibly at NLVF (1 and 2 estimated cancer fatalities for the conceptual design option and enhanced option, respectively) and SNL (1 estimated cancer fatality for the enhanced option) (table I-S.5–1). The cancer fatality risk (cancer fatality per year) associated with radiological exposure from an accident involving transport of NIF tritium targets would range from 1×10^{-8} to 8×10^{-10}; whereas the nonradiological fatality risks associated with vehicular emissions and accidents would be in the range of 10^{-3} to 10^{-4} (table I-S.5–1).

Although each candidate site would implement waste minimization practices, the generation of additional wastes would be unavoidable. All candidate sites have

TABLE I-S.5-1.—*Comparison of Alternatives for the Proposed National Ignition Facility* [Page 4 of 4]

Environmental Resource Parameter	No Action	LLNL[a]	LANL[a]	NTS[a]	NLVF[a]	SNL[a]
Transportation Impacts (Nonradiological) (Fatalities/Year)[o]						
Vehicular emissions	None	$1x10^{-3}$ ($2x10^{-3}$)	$8x10^{-4}$ ($2x10^{-3}$)	$8x10^{-4}$ ($2x10^{-3}$)	$8x10^{-4}$ ($2x10^{-3}$)	$2x10^{-3}$ ($4x10^{-3}$)
Accidents	None	$2x10^{-3}$ ($4x10^{-3}$)	$2x10^{-3}$ ($4x10^{-3}$)	$2x10^{-3}$ ($6x10^{-3}$)	$2x10^{-3}$ ($5x10^{-3}$)	$2x10^{-3}$ ($4x10^{-3}$)

[a] Value for Enhanced Option is given in parentheses only for parameters that differ from the Conceptual Design Option.

[b] Uncommitted land, as defined by each of the sites, is land that is currently open and available for NIF development. An additional 2 hectares would be temporarily required for a construction laydown area at LLNL. Construction laydown areas for the other sites would be located within the area designated for NIF.

[c] Estimated by combining baseline concentrations and NIF contributions based on dust control measures using water spray twice a day (with continuous water spraying and/or chemical dust suppressants for LLNL and NLVF sites).

[d] The 24-hour California state standards for particulate matter (50 $\mu g/m^3$) are more stringent than the national standards (150 $\mu g/m^3$).

[e] No action emissions would be equivalent to baseline emissions provided under the candidate site columns.

[f] Noise levels may be annoying during the peak construction activity associated with site clearing but would not require a hearing conservation plan.

[g] Current water supply capacity would be adequate to meet the additional requirements for NIF.

[h] Areas would be maximum habitat loss assuming total site clearing before any site revegetation or landscaping. An additional 2 hectares would be temporarily cleared for the construction laydown area at LLNL.

[i] Qualitative estimate of wildlife disturbance based on quality of habitat at and surrounding NIF location, which influences the number of wildlife species that may be present and the habituation of wildlife to human activities.

[j] Values provided are for the peak construction year only.

[k] The No Action alternative would not have measurable impacts on socioeconomics at the NTS or NLVF sites. However, at LLNL, LANL, and SNL, No Action could result in slightly reduced employment and associated effects. No Action could result in a reduction of 153 jobs (direct and indirect) and 190 fewer trips generated per day at LLNL; a reduction of 27 jobs and 38 fewer trips generated at LANL; and 29 fewer jobs and 38 fewer trips generated at SNL.

[l] Higher public dose for NLVF is due to higher population density near NLVF.

[m] The hazard zone refers to the area downwind of an accident where concentrations would be above emergency planning levels.

[n] Risks are presented from the manufacturing site yielding the largest risks.

[o] Collective population fatalities were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Design). For example, a reported value of $4x10^{-3}$ fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

Note: ND – No data available; NA – Not applicable.

current or planned capacity to handle wastes associated with construction and operation of NIF; however, this would entail offsite shipment of some of the wastes for all sites but LANL (table I-S.5–2).

Resources that would be committed irreversibly or irretrievably during construction and operation of NIF include concrete, steel, fuel, and power. Land set aside at disposal facilities to accommodate radiological and hazardous chemical wastes from NIF represents an irreversible commitment of resources because wastes in belowground disposal areas may not be completely removed at the end of the project. This land could be perpetually unusable because the substrata would not be available for other potential intrusive uses, such as mining, utilities, or foundations for other facilities. However, the surface area appearance and biological habitat lost during construction and operation of the disposal facilities could, to a large extent, be restored. Consumption of operating supplies, miscellaneous chemicals, and gases, while irreversible, would not constitute a permanent drain on local resources or involve any material in critically short supply in the United States as a whole. Materials consumed or reduced to unrecoverable forms of waste, such as radioactive waste, are also irretrievable.

Adequate land exists at each of the five candidate location sites to support ongoing programs and other foreseeable short-term uses of undeveloped areas. The use of land for NIF would enhance the long-term productivity of the selected site in two ways. First, NIF represents long-term research and development functions compatible with historic nuclear weapons support and would require a technically competent, skilled, and stable workforce. Second, in light of current reductions in the nuclear weapons stockpile, the lack of new weapons development or production, the moratorium on nuclear testing, and concerns about safety and reliability in the aging stockpile, DOE plans to downsize or consolidate existing facilities and provide upgraded or new experimental and computational capabilities that would enhance the long-term productivity of the selected sites.

Land clearing and construction activities for NIF would eliminate habitat and destroy or displace wildlife. Construction of new facilities could result in short-term disturbances of previously undisturbed biological habitats. These disturbances could cause long-term reductions in the biological productivity of an area.

Cumulative impacts would result from the addition of the incremental effects of the construction and operation of NIF to the effects of other past, present, and reasonably foreseeable future actions at the selected site. PM_{10} emissions from construction of NIF would be an incremental addition to the already existing environmental impact of dust emissions to the atmosphere. Minor changes in stormwater runoff are expected due to removal of grass cover during NIF construction and increased runoff from pavement during facility operations. Construction of NIF would replace natural habitat with areas of pavement and buildings. Depending upon the candidate site selected, this conversion could extend the influence of urbanized/industrial habitats into natural areas, increase fragmentation of natural habitat, and cause minor loss of habitat used by rare species. However, no critical habitat for federally threatened or endangered species would be affected. Radiological doses to the general public from NIF operations would be no more than 20 percent of the dose from all other candidate site operations and no more than one-millionth of the dose to the population from normal background radiation. The risk of a NIF accident-related cancer fatality occurring to a member of the public over the 30-year lifetime of the facility would be less than 1 in 700,000. NIF would be considered a low-hazard, radiological facility. Such a facility uses radionuclides (for nonreactor purposes) and has other hazards (such as chemicals needed at the facility). Low hazard implies that there are minor onsite and negligible offsite consequences.

I-S.6 U.S. Department of Energy's Preferred Alternative

Council on Environmental Quality regulations require that an agency identify the preferred alternative for a proposed Federal action in a final environmental impact statement (40 *Code of Federal Regulations* 1502.14[e]). The preferred alternative is the alternative that DOE believes would best fulfill its statutory mission, giving consideration to environmental, economic, technical, and other factors. The preferred operational option for NIF is the Enhanced Option (indirect and direct drive). The preferred NIF siting alternative is at LLNL. The Record of Decision will describe DOE's decision on the operational capability and siting of NIF.

APPENDIX I: NATIONAL IGNITION FACILITY PROJECT-SPECIFIC ANALYSIS

I.1 INTRODUCTION

I.1.1 The National Ignition Facility Proposal

As part of its Stockpile Stewardship and Management Program, the U.S. Department of Energy (DOE) proposes to construct and operate the National Ignition Facility (NIF) (DOE 1995b). NIF would contain the world's largest solid-state laser system, which would be used to achieve ignition of nuclear fusion in the laboratory for the first time. NIF would perform fusion, high-energy-density, and radiation-effects experiments in support of stewardship of the Nation's stockpile of nuclear weapons and other basic and applied science objectives.

NIF would consist of 192 laser beams that would be focused into a small target containing a spherical capsule of fusion fuel, positioned in the center of a large spherical target chamber. The energy of the lasers would be deposited into the target in a few billionths of a second, causing the fuel capsule inside the target to implode, thereby compressing and heating the fuel. This process would force atomic nuclei sufficiently close together so that the rate of fusion reactions would become very large. This reaction rate would, in fact, be so rapid that a significant fraction of the fuel would burn up before the target flew apart in a miniature explosion; that is, while the target was held together only by its own inertia. This method for achieving fusion ignition and energy gain is called inertial confinement fusion (ICF). Ignition occurs when the fusion reactions become self sustained; i.e., a significant portion of the fusion reactions result from self heating of the fuel beyond that achievable by the lasers alone. Energy gain occurs when the amount of fusion energy produced by the target exceeds the amount of laser energy supplied to ignite the target. The NIF capsule's fusion yield is expected to be up to 10 times the laser driver energy required to produce fusion ignition.

In January 1993, the Secretary of Energy confirmed the need for NIF and authorized a collaborative effort by the three DOE defense laboratories and the University of Rochester's Laboratory for Laser Energetics to produce the Conceptual Design Report for NIF. The Conceptual Design Report was completed in April 1994. In October 1994, the Secretary of Energy approved initiation of the next phase of the NIF Project, including preliminary design, safety analysis, cost and schedule validation, and *National Environmental Policy Act* (NEPA) analysis preparation that would include public involvement. This NIF Project-Specific Analysis (PSA), prepared as part of the *Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (PEIS), represents that NEPA analysis. This PSA is equivalent to a project-specific EIS. However, it is referred to as a PSA to avoid confusion with the term PEIS. As a part of the Stockpile Stewardship and Management PEIS, this PSA shares certain elements (such as data) common to the main document. However, some of the data described in this PSA are necessarily more detailed than some of the data cited in the Stockpile Stewardship and Management PEIS analysis.

I.1.2 History and Background

Three decades of research and development by U.S. laboratories and private industry has led to the design of NIF. Soon after the invention of the laser in the early 1960s, scientists recognized that the laser might be used to drive an ICF capsule to ignition and that this technology could be used to achieve some of the high-energy-density conditions (such as high temperatures and pressures) that occur in the detonation of nuclear weapons. It was also recognized that if more energy could be produced than that required to ignite a target, such fusion technology might one day also be used to generate electrical power.

Since then, a series of laser systems, each several times more powerful than its predecessor, have been constructed and operated. The first of these laser systems, a single beam system called Longpath, was completed in 1970 and was used experimentally for 5 years, until a two-beam system called Janus was completed in 1974. Janus demonstrated laser-driven compression, heating, and thermonuclear burn of fusion fuel for the first time. Although neither Janus nor any of the subsequent lasers were large enough to produce target ignition, each advanced the state of the art in solid-state laser technology, and each contributed significantly to a sounder understanding of how ICF targets work.

Experimentation on the most recent of these systems, the 10-beam Nova laser, has led to an even greater understanding of ICF targets. Nova has been used not only for target physics experiments, but also for weapons physics experiments of the type that would be done at NIF, although the NIF experiments would be done at much larger energies (a factor of 40 to 50 times more energy available). Thus, the Nova experiments have established the principles and measurement techniques that would be used at NIF. More than 10,000 experiments have been conducted with Nova during its 10 years of operation. DOE is also now conducting target physics research at the Omega Upgrade Facility located at the University of Rochester. This new laser system is similar in energy to Nova but has a larger number of beams and can better address issues of directly driven laser targets than can Nova, which specializes in indirectly driven targets (see chapter 3). In its Enhanced Option mode, NIF would be capable of performing experiments with both types of targets.

During the 1980s, a program to study the physics of ICF capsules with the much larger energies available from underground nuclear explosions was successfully conducted. The very positive results of the Nova program, combined with the positive results from underground nuclear tests in the Halite/Centurion program, have led to the development of specifications for a future system to create target ignition and energy gain, i.e., for NIF. A 1990 study by the National Academy of Sciences (NAS 1990), which reviewed both the laboratory and the underground nuclear test data, recommended proceeding with an ignition facility based on a solid-state laser as the next step in the ICF program. NIF is proposed as that next step.

Achievement of fusion ignition at NIF would fulfill a major goal of the ICF program. The ICF program was initiated in 1971 to develop capabilities that would support the Nation's nuclear weapons deterrent and that have longer-term potential for commercial energy. Confidence in ignition at NIF is based on 24 years of ICF research and major program reviews, most recently the continuous monitoring of ICF progress by the ICF Advisory Committee. That panel of independent experts tracked the successful accomplishment of the objectives set out by the National Academy of Sciences recommendations in 1990 and advised DOE that the program was technologically ready to proceed with NIF, both from the standpoint of the understanding of target physics and from the standpoint of the readiness of the laser technology (DOE 1990). In 1994, the Beamlet laser, a full-scale prototype NIF beamline, demonstrated that the laser technology selected for NIF would perform as specified.

The ability to predict the performance of ignition capsules is based on similar calculations of physics that predict some aspects of nuclear weapons performance. Ignition is a "first-level" test of our weapons analysis capability. Achieving laboratory ignition with laser-driven inertial fusion is widely recognized as a major scientific challenge that will attract and stimulate highly capable scientists. While much of the science is useful to nuclear weapons analyses, NIF is not a weapon, and the ICF approach cannot be directly extended to become a weapon. Much of the research at NIF can be open to the broad scientific community. Thus, NIF experiments can advance both our weapons analysis capability and civilian science and energy interests.

I.1.3 Environmental Review Process

DOE's NEPA compliance for the Stockpile Stewardship and Management Program includes preparation of the Stockpile Stewardship and Management PEIS. Because NIF would be an integral part of a science-based Stockpile Stewardship and Management Program, the NEPA process for NIF is being conducted as part of the NEPA process for Stockpile Stewardship and Management. This NIF PSA is, therefore, included as an appendix to the Stockpile Stewardship and Management PEIS. The PSA was prepared according to the Council on Environmental Quality's "Regulations for Implementing the Procedural Provisions of the *National Environmental Policy Act*" (40 CFR 1500-1508) and DOE's NEPA implementing procedures and guidelines (10 CFR 1021). The purpose of this NIF PSA is to provide an environmental evaluation of the impacts of construction and operation of NIF as a basis for DOE's decision on whether or not to proceed with such a facility. As discussed in section I.1.1, this document is in the strictest sense a project-specific EIS, but it is referred to as a PSA to avoid confusion with the term PEIS.

The first step in the Stockpile Stewardship and Management PEIS process was to publish a Notice of Intent to prepare an EIS in the *Federal Register* (60 FR 31291, June 14, 1995). The Notice of Intent described the project and solicited comments on preliminary plans for the scope of the Stockpile Stewardship and Management PEIS. The Notice of Intent also announced DOE's plan for gathering scoping comments on the significant issues and concerns related to the proposed action and alternatives that should be addressed in the PEIS. To ensure public input to the planning and preparation of the PEIS, public scoping meetings were held during July and August 1995. At each meeting, representatives of DOE explained the purpose of the meeting, the role of the Federal Government, and the PEIS process. During the remainder of each meeting, DOE received comments from agencies, groups, and individuals and invited interested parties to submit any additional comments by August 11, 1995, the close of the PEIS scoping period. Concerns and suggestions resulting from the scoping process are summarized and evaluated in the Stockpile Stewardship and Management PEIS Implementation Plan, which states how the comments are to be incorporated into the scope of the Stockpile Stewardship and Management PEIS. The Implementation Plan also summarizes the proposed action and alternatives (designs, sitings, and No Action), outlines issues to be addressed in the PEIS, and discusses the subsequent procedures for the PEIS preparation. The Stockpile Stewardship and Management Draft PEIS was subsequently prepared and published in February 1996.

The publication of, and call for comments on, the Stockpile Stewardship and Management Draft PEIS were announced in the Notice of Availability published in the *Federal Register*. DOE invited comments from all interested parties to correct factual errors or to provide insights on any matter related to this environmental analysis. The 60-day public comment period for the Draft PEIS began on March 8, 1996 and ended on May 7, 1996. However, late comments were accepted to the extent practicable.

After considering the comments received, DOE revised the Stockpile Stewardship and Management Draft PEIS, as appropriate. This Final PEIS was distributed to those who received the Stockpile Stewardship and Management Draft PEIS, those who commented on the Draft PEIS, and any other interested parties.

Following completion of the Stockpile Stewardship and Management Final PEIS, but at least 30 days after it is issued, DOE will issue a Record of Decision (ROD). The ROD will explain all factors, including environmental impacts, that DOE considered in reaching its decisions regarding Stockpile Stewardship and Management, including NIF. The ROD will specify the alternatives that are considered to be environmentally preferable. This NIF PSA is a critical element in the ROD and the basis for the environmental comparison of alternatives related to NIF. DOE anticipates that, in addition to considering the environmental impacts as presented in the PEIS, the ROD will be based on cost, national security, and infrastructure considerations. If mitigation measures, monitoring, or other conditions are adopted as part of the agency's decision, they will be summarized in the ROD as applicable and included in a Mitigation Action Plan that would accompany the ROD. The Mitigation Action Plan would explain how and when mitigation measures would be implemented and how DOE would monitor the mitigation measures to judge their effectiveness.

I.1.4 Organization of the National Ignition Facility Project-Specific Analysis

This NIF PSA consists of eight chapters. Chapter I.1 (Introduction) describes the NIF background and the environmental review process. Chapter I.2 (Purpose and Need for the National Ignition Facility) describes mission-related reasons why DOE needs to construct and operate NIF. Chapter I.3 (Proposed Action and Alternatives) describes the facilities required for NIF and the operations that would be associated with NIF. Chapter I.3 also includes a discussion of the No Action alternative and an overview of the four DOE sites, providing five alternate locations for NIF.

Chapter I.4 (Affected Environment and Environmental Impacts) describes the natural and human resources at the alternate NIF locations and identifies the impacts that could occur to these resources from construction and operation of NIF and from the No Action alternative. This chapter also addresses mitigation commitments and recommendations, adverse effects that cannot be avoided, irreversible and irretrievable commitments of resources, the relationship between short-term uses and long-term productivity, and cumulative impacts. Chapter I.5 (Environmental, Occupational Safety and Health Permits, and Compliance Requirements) discusses environmental regulations, Executive Orders, permits, and laws applicable to NIF construction and operation.

Chapter I.6 (List of Preparers) includes a list (including credentials) of the technical staff who prepared the NIF PSA. Chapter I.7 (Glossary) defines selected technical terms used within this PSA. Chapter I.8 includes a list of references.

I.2 Purpose and Need for the National Ignition Facility

I.2.1 General Background

Under the *Atomic Energy Act* of 1954, as amended (42 *United States Code* 2011 et seq.), the U.S. Department of Energy (DOE) is charged with providing nuclear weapons to support the Nation's nuclear deterrent policy. Thus, DOE must maintain a Complex with sufficient capabilities and capacity to meet current and future weapons requirements. This mission is accomplished in a way that protects the environment and the health and safety of workers and the public.

Recent changes in the global political situation and in national security needs have necessitated corresponding changes in the way DOE must meet its responsibilities regarding the Nation's nuclear weapons. As a result of international arms control agreements (the Strategic Arms Reduction Talks [START I] Treaty and the START II protocol and unilateral decisions by the U.S. Government), the Nation's stockpile will be significantly reduced by 2003. Consequently, the Nation has halted the development of new nuclear weapons, begun closing portions of the DOE weapons complex, and is considering further consolidation and downsizing of the remaining elements in the Complex. In addition, the Nation is observing a moratorium on nuclear testing and is pursuing a *Comprehensive Test Ban Treaty* (CTBT). However, international nuclear dangers remain and, as the President has emphasized, nuclear deterrence will continue to be an important element of the U.S. national security posture. Thus, DOE's responsibilities for ensuring the safety and reliability of the Nation's nuclear stockpile and for maintaining expertise in nuclear weapons generally will continue for the foreseeable future.

In announcing the indefinite extension of the nuclear test moratorium in July 1993, President Clinton reaffirmed the importance of maintaining confidence in the enduring U.S. stockpile by alternative means and the need to ensure that the Nation's nuclear deterrent remains safe, secure, and reliable during a test ban. In 1994, by Presidential Decision Directive and Act of Congress (Public Law 103-160), DOE was directed to establish a Stockpile Stewardship and Management Program to ensure the continued safety and reliability of the remaining weapons and the preservation of the core intellectual and technical competencies of the United States in nuclear weapons in the absence of nuclear testing. Subsequent Presidential decisions established that the United States would seek a "zero-yield" CTBT (August 1995) and that all three of the Nation's nuclear weapons laboratories would be required to ensure the highest continued confidence in the stockpile.

Thus, DOE was required to develop a Stockpile Stewardship and Management Program that would not include any level of nuclear testing but would support the following objectives:

- Full support at all times of the Nation's nuclear deterrent with safe and reliable nuclear weapons while transforming the current Complex (laboratories and production facilities) to one that is more appropriate for a smaller stockpile

- Preservation of the core of intellectual and technical competencies of the weapons laboratories. Without nuclear testing, confidence in the Nation's nuclear stockpile will depend largely on the continued availability of competent people who must make the scientific and technical judgments related to the safety and reliability of nuclear weapons

- Ensurance that the activities needed to maintain the Nation's nuclear deterrent are consistent with the Nation's arms-control and nonproliferation objectives

The purpose and need section that follows (section I.2.2) discusses the National Ignition Facility's (NIF) role in supporting objectives 1 and 2 above. Objective 3 (nonproliferation) was evaluated for NIF in a recent DOE study—*The National Ignition Facility and the Issue of Nonproliferation* (DOE 1995a). That study, prepared by the Office of Arms Control and Nonproliferation of DOE, has been the subject of extensive public involvement, interagency review, and review by outside experts. The study concludes that (1) the technical proliferation concerns at NIF are manageable and therefore can be made acceptable, and (2) NIF can contribute positively to U.S. arms control and nonproliferation policy goals.

To ensure the continued safety and reliability of the enduring stockpile while achieving a CTBT, the President and the Department of Defense have emphasized the importance of a strong science-based stockpile stewardship program, including NIF. It is important to establish a firm commitment to this program before the issue of ratification of a CTBT arises.

I.2.2 Purpose and Need

I.2.2.1 *Stockpile Stewardship and Management Program*

Although DOE is confident today that the Nation's nuclear weapons stockpile is safe and reliable, it is expected that problems could develop in the future. A recent interlaboratory study, *Stockpile Surveillance: Past and Future* (Johnson et al. 1995), documents the historical evidence. Nuclear weapons, of necessity, contain materials that react with one another slowly even when the weapon is simply being stored. These slow interactions can and have, over time, caused defects in weapons that adversely affect safety and/or reliability. These processes are called "aging." Also, design or manufacturing defects have been found after a weapon enters the stockpile or is remanufactured. The DOE historical database on such incidents shows that there have been hundreds of cases that have necessitated some kind of corrective action because of safety or reliability concerns. Because nuclear weapons in the future will be expected to remain in the stockpile beyond their designed lifetimes, it is to be expected that such incidents will increase.

The Stockpile Stewardship and Management Program (DOE 1995b) defines a science-based program intended to satisfy the three program objectives stated in section I.2.1. Science-based stockpile stewardship would provide the expert judgment, underpinned by scientific understanding, advanced calculations, and modern experimental facilities, to predict, identify, evaluate, and render solutions to problems that affect safety and reliability of the remaining stockpile in the absence of underground testing. The stockpile stewardship program would not replace nuclear testing completely because complex interactions between processes cannot be experimentally simulated. However, for weapons that have been tested before (and all the weapons expected to remain in the stockpile have been tested), the previous nuclear test database will provide a benchmark that can be used to evaluate future problems with the stockpile.

Building upon existing capabilities, the DOE science-based stockpile stewardship program includes an accelerated strategic computing initiative and several new experimental facilities that are required to provide the data needed to verify the models and help assess specific problems that arise. The stewardship program consists of three major components that are used to evaluate stockpile surveillance data: (1) experimental capabilities and facilities, (2) scientific evaluation by competent scientists of the information from the experimental capabilities and facilities, and (3) validation of the computer models using the accelerated strategic computing initiative. These three components lead to the development of a corrective action to resolve the identified problem.

I.2.2.2 *Physical Processes in Nuclear Weapons*

Because nuclear tests would not be available, more sophisticated and comprehensive computer models would be needed to conduct essential evaluations. For confidence to be established in these new models, experimental facilities must be able to provide data on all processes in the relevant physical regimes that occur in weapons. The relevant physical regimes may be divided into the following groups:

1. Detonation of high explosive and implosion of fissile material
2. Conditions for criticality of fissile material
3. Fusion ignition and boosting
4. Radiation transport
5. Secondary implosion
6. Secondary ignition, burn, and output
7. Nuclear weapon effects on other systems

The DOE program proposes a set of experimental facilities, each designed to address one or more of these areas in a complementary fashion.

A general understanding of a nuclear weapon would be helpful to better understand these seven categories and their relationship to stockpile stewardship and management and NIF. Modern thermonuclear weapons consist of two stages: a primary stage (fission trigger) and a secondary stage (fusion). The purpose of the primary is to produce x rays to implode the secondary, thereby causing ignition. The secondary is the stage that produces high yields for modern U.S. strategic weapons–typically hundreds of kilotons. The primary contains a subcritical pit of fissile material, generally plutonium, surrounded by a layer of chemical high explosive. The high explosive is detonated, burns rapidly, and compresses the pit. The implosion of the pit increases the density of the fissile material to super criticality, leading to a fission chain reaction and rapid heating. X rays from the hot exploding primary are then channeled by a radiation case to the secondary, where they implode the secondary, creating temperatures and pressures great enough to ignite a fusion reaction in the secondary.

To increase their efficiency, modern primaries can employ a process called boosting. In boosted primaries, the pit contains the hydrogen isotopes deuterium and tritium gas that is compressed and heated. The deuterium and tritium gas undergoes fusion, producing copious quantities of energetic neutrons that flood the compressed pit. The extra burst of neutrons causes significant additional fission reactions that "boost" the primary yield to a much higher value. If the primary fails to boost properly, its yield may be inadequate to drive the secondary, resulting in weapon failure.

I.2.2.3 *The National Ignition Facility as Part of the Stockpile Stewardship and Management Program*

NIF would provide an essential capability for the DOE's science-based stewardship of the nuclear weapons stockpile. The basic goal of NIF is to achieve ignition of thermonuclear fusion in the laboratory by imploding and igniting a small capsule containing a mixture of deuterium and tritium. The goal of obtaining fusion ignition and burn at NIF would attract and challenge top scientific and engineering talent with a problem containing many of the same elements of physical understanding as those necessary for stewardship of the nuclear stockpile. Achieving fusion ignition and conducting experiments at such high temperatures and densities in NIF would make it possible to study the properties of material under conditions close to those they would be subjected to in a nuclear weapon detonation. Thus, specific experiments can be conducted with weapons materials to measure relevant equations of state (what pressures are created at high temperature), opacity (how a material absorbs and emits radiation), and hydrodynamics (how a material moves in response to forces applied). These experiments apply to several of the regimes of interest listed in section I.2.2.2. The following discussion focuses on how NIF can be used to evaluate weapons concerns relevant to the physical regimes in that list.

NIF experiments could examine the growth and control of hydrodynamic instabilities, which are important both in making inertial confinement fusion (ICF) targets ignite and burn and in making nuclear weapons perform reliably. Hydrodynamic instabilities ultimately lead to mixing of some quantity of one material with another. This mix can affect both ignition and burn processes (regimes 3 and 6). NIF experiments can determine how fusion fuels ignite and what helps and what hinders the ignition process (such as how much mix is tolerable).

High-temperature transport of radiation in complex geometries and materials (regime 4) can be examined to test the ability of computer models to predict this transport. Deposition and re-emission of radiation and the general transport problem constitute a very complex process. This process must be understood in order to predict the transport of radiation necessary to ignite ICF targets. In addition, radiation transport experiments can be designed to simulate weapons radiation transport conditions more closely than those in the basic ICF ignition target.

Output calculations must be done on the ICF ignition targets so that the performance of the target can be properly measured. Again, however, specific targets can be designed to alter the output radiation. These experiments can be used to test the computer codes used to calculate the output of weapons.

NIF targets, either the basic type for ignition or specially altered ones, would produce copious x rays, neutrons, gamma rays, and other radiation. These emissions can be used to assess the consequences of nuclear effects (regime 7) in electronic systems or other hardware intentionally exposed to these radiations. The survivability of military hardware subjected to various nuclear effects is an important factor in assuring reliability of that hardware.

In addition to its role in attracting and maintaining core scientific and engineering capability and in helping to verify the calculational capability of the more sophisticated computer models, NIF would also play a role in evaluating specific problems that arise in the stockpile, as mentioned in section I.2.2.2. As the stockpile surveillance program reveals an unanticipated change due to aging or remanufacture, a weapons expert will estimate which of the weapons physics processes listed in section I.2.2.3 could be affected. If any of the high-energy-density process (regimes 3 through 7) could be affected, then a NIF experiment may be designed to measure the physical properties of the change. For example, if the chemical composition of a material (such as a glue joint) has changed for some reason, it may be necessary to determine the opacity (how a material absorbs and emits radiation) of the changed material. Computer models are not able to predict the opacity of all materials under all temperatures and pressures. Thus, it may be necessary to put some of the changed material into a NIF target, raise its temperature and pressure to near those that would occur when the weapon is exploded, and measure its opacity (regime 4). These measurements would then be compared with the computer model predictions, and the physics model would be refined until an agreement was reached. The computer model could then be used to evaluate whether the given change in properties causes an integrated change in performance that adversely affects the reliability of the weapon. This evaluation would determine whether the altered weapon could remain in the stockpile (or be placed in the stockpile in the case of a remanufactured weapon).

In conclusion, NIF would address, to some degree, weapons processes that occur in physical regimes 3 through 7 in the list in section I.2.2.2. These processes are the ones that occur at very high energy density (high temperatures and pressures). These processes are very important in assessing a weapon's reliability. NIF would achieve higher temperatures and pressures, albeit in a very small volume, than any other proposed stockpile stewardship facility. It would also be the only facility that would achieve fusion ignition. The principal safety issues for a nuclear weapon that involve the high explosive and fissile material implosion, relevant physical regimes 1 and 2, could not be addressed in NIF.

The nuclear weapons expected to remain in the stockpile will age beyond their original design lifetime between the years 2005 and 2010. It is important to have NIF in place and operating successfully well before this period so that the facility can be used to help verify the new computer models before problems may begin arising more rapidly. The goals of completing construction of NIF in 2002 and achieving ignition by 2005 would allow this to happen, first with nonignition target experiments and later with ignition experiments.

I.2.3 Other Benefits of the National Ignition Facility

NIF would be a multipurpose facility used for both national security and civilian applications. The most significant potential long-term civilian application of ICF is the generation of electric power. DOE is pursuing two distinct approaches to fusion energy: magnetic fusion energy and inertial fusion energy. Development of inertial fusion as a source of electrical power depends upon achieving ignition in NIF. This approach to inertial fusion energy is consistent with the recommendations of the National Academy of Science's *Second Review of the Department of Energy's Inertial Confinement Fusion Program* (NAS 1990) and the *Fusion Policy Advisory Committee Report* (DOE 1990). Many studies (such as Meier 1994; Moir 1994) have described viable power plant designs that could be developed once high-gain targets are understood. Furthermore, the International Atomic Energy Agency report, *Energy from Inertial Fusion* (IAEA 1995), describes possible engineering development paths to a demonstration fusion power plant once ignition is established on NIF. These development paths are most efficiently accomplished if NIF can first be used to (1) determine the beam energy required for ignition, (2) map out the target gain curves, and (3) understand the post-ignition dynamics of the environment inside a reaction chamber. Thus, early achievement of ignition in NIF is needed to allow the pursuit of an efficient, timely, inertial fusion energy development program.

NIF would also establish new capabilities for the basic sciences. Because fusion targets would provide temperatures and pressures similar to those found in the sun and other stars, data from NIF high-energy-density experiments would interest scientists working in such fields as astrophysics, material sciences, nonlinear optics, x-ray sources, plasma physics, and computational physics. For example, astrophysicists could do experiments that study some of the processes that occur during primordial nucleosynthesis (the original formation of all elements), stellar evolution, and spectacular events such as a supernova explosion.

As the world's largest optical instrument, NIF could spur high-technology industries in the areas of optics, lasers, materials, high-speed instrumentation, semiconductors, and precision manufacturing. Past ICF developments, for example, have led to manufacturing capabilities for precision optics that enabled the development of correcting optics to fix the initial problem of the Hubble space telescope. The ICF need for high-speed target diagnostics led to the development of a low-cost micro-impulse radar that has many commercial applications (12 industrial licenses have already been granted). Commercial applications derived from NIF could include flexible, low-cost, laser-based manufacturing; advanced x-ray lithography for integrated circuit manufacturing; high-density information storage; improved flat-panel display technology; advanced health care technologies; new materials; and new scientific instrumentation.

NIF would play a major role in U.S. science and technology early in the next century. Its civilian and defense missions would maintain weapons technology and expertise for continuing national security objectives, assess a new energy option, contribute to the basic high-energy-density sciences, and enhance industrial competitiveness through numerous technology advances.

I.2.4 Relationship of the National Ignition Facility to Other Department of Energy Environmental Impact Statements

DOE prepared this programmatic environmental impact statement (PEIS) to assess the alternatives for conducting the Stockpile Stewardship and Management Program, including the action described in this NIF Project-Specific Analysis (PSA). The PEIS also evaluates the No Action alternative and provide an assessment of environmental impacts to support programmatic and siting decisions.

However, for NIF and certain other facilities, the PEIS includes both a programmatic assessment and site-specific assessments of the construction and operation impacts at the reasonable candidate sites. The site-specific assessments consider the environmental impacts associated with siting of these facilities and provide a basis for deciding whether or not to proceed with construction.

DOE is currently preparing site-wide EISs for two of the five sites proposed as alternative locations for NIF: the Nevada Test Site (NTS) and the Los Alamos National Laboratory (LANL). The projected completion dates for these EISs are late 1996 for LANL and NTS. A site-wide EIS for the Lawrence Livermore National Laboratory, the preferred NIF location, was issued in 1992. The site-wide EISs address the continued operation of the sites, including near-term (within 5 to 10 years) proposed projects. The site-wide EISs provide an opportunity to address the cumulative impacts of all reasonably-foreseeable activities and provide a mechanism for coordinating site and agency planning for complex facilities by providing an opportunity for review of the potential collective environmental effects associated with large, diverse facilities. The EISs evaluate a range of different alternatives, including the alternative of continuing current operations.

DOE's *Draft Waste Management Programmatic Environmental Impact Statement*, issued in August 1995, addresses the long-term management and safe treatment, storage, and disposal of radioactive, hazardous, and mixed wastes. NIF would generate these types of wastes, and the treatment, disposal, and storage of NIF wastes would be compatible with any decisions resulting from the waste management PEIS.

DOE is proceeding with two other actions related to the Stockpile Stewardship and Management Program: the Dual-Axis Radiographic Hydrodynamic Test Facility EIS (DOE 1995c) and the Tritium Supply and Recycling PEIS (DOE 1995d). DOE determined that implementing the ROD on these two facilities will not prejudice any decisions in the Stockpile Stewardship and Management Program.

I.3 Proposed Action and Alternatives

I.3.1 Overview

This chapter describes the alternatives analyzed in this Project-Specific Analysis (PSA) for the construction and operation of the National Ignition Facility (NIF) at one of five candidate locations at four alternate sites: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Nevada Test Site (NTS) Area 22 main site location and North Las Vegas Facility (NLVF) location near NTS, or Sandia National Laboratories (SNL). The NIF Conceptual Design Report (LLNL 1994b) describes the proposed action in detail and establishes the technical feasibility of the project. Section I.3.2 describes the proposed action and includes a description of NIF and its operations. Section I.3.3 describes the No Action alternative. Section I.3.4 describes the five locations at the four alternative sites, including their selection, location, infrastructure requirements, and site-specific aspects of NIF construction and operations. Section I.3.5 discusses other alternatives not considered in detail. Section I.3.6 summarizes and compares the impacts of construction and operation of NIF at the four alternative sites.

I.3.2 Proposed Action

The proposed action is to construct and operate NIF, which would be capable of achieving fusion ignition by the inertial confinement fusion (ICF) process. Two options for NIF operations have been proposed. The Conceptual Design Option would use an ICF approach called indirect drive. The current research program on ICF has emphasized development of the indirect drive approach, and the experimental program currently planned for NIF uses that approach. In indirect drive, laser beams would illuminate and heat the interior surfaces of a metal case (hohlraum) containing a deuterium-tritium-filled capsule. The beams would cause the case to emit x rays that would in turn strike the fusion target capsule and drive the fusion reaction (figure I.3.2–1). Targets used for indirect drive would contain sub-milligram levels of tritium.

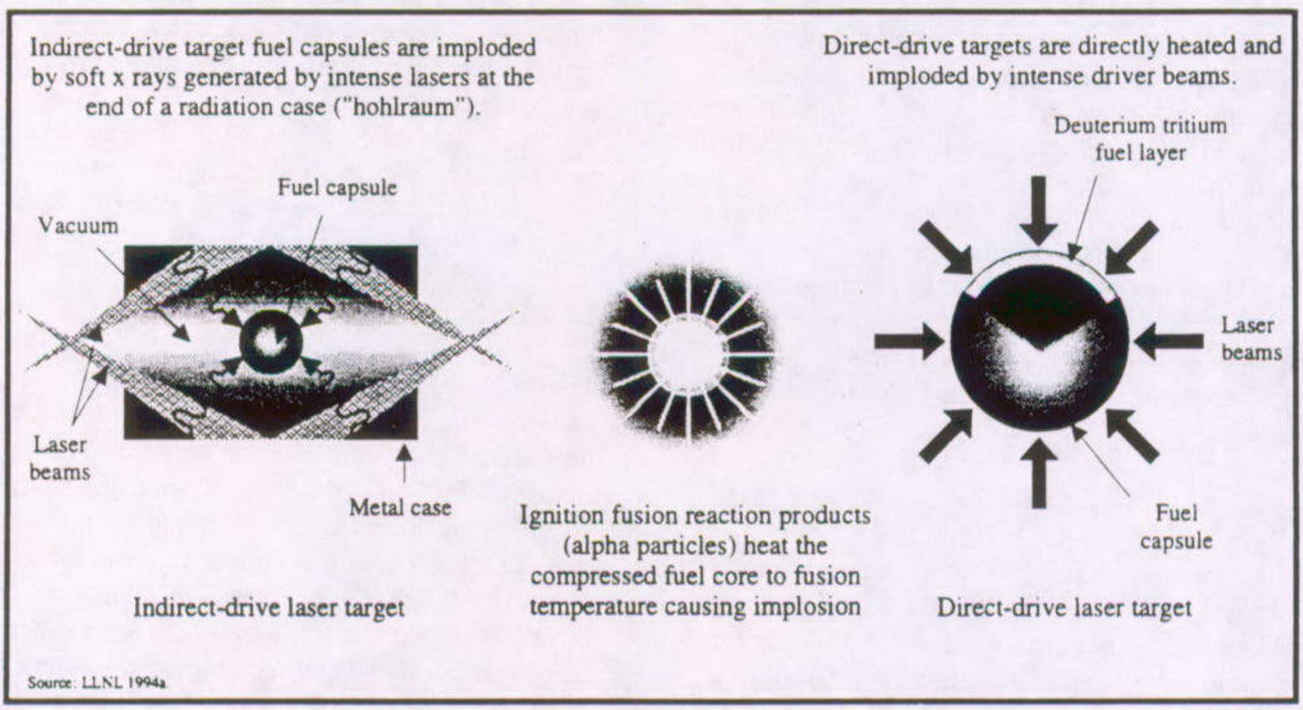

Figure I.3.2–1.—*Schematic Diagram of Indirect Drive and Direct Drive Methods of Achieving Inertial Confinement Fusion.*

An Enhanced Option would include the above indirect drive operations and a second approach called direct drive. The Enhanced Option would also include the ability to perform an increased number of experiments to accommodate greater user needs. No hohlraum would be used in the direct drive ICF method. Instead, a large number of laser beams would impinge directly on the outer surface of the capsule containing the tritium and deuterium (figure I.3.2.–1). Targets for direct drive would contain milligram levels of tritium. Achieving ICF by direct drive is theoretically possible, and an experimental feasibility program is currently underway at the Omega Upgrade Facility at the University of Rochester Laboratory for Laser Energetics in New York and at the Naval Research Laboratory in Washington, D.C. Because it is possible that NIF would be used for direct-drive experiments in its lifetime, operating conditions for both indirect- and direct-drive experiments have been developed and are assessed in this PSA.

I.3.2.1 *National Ignition Facility Components*

NIF would consist of three main elements: a laser system and optical components, a target chamber placed within a target area, and an advanced integrated computer system to control the lasers and diagnostic equipment. These three elements would be housed in a single environmentally controlled building called the Laser and Target Area Building (figure I.3.2.1–1). The entire NIF complex (figure I.3.2.1–2) would require a maximum area of about 20 hectares (ha) (50 acres). Depending on the site selected, many of the NIF needs may be served by existing facilities (see section I.3.4), reducing the requirements for a full 20 ha (50 acres) of new land area.

I.3.2.1.1 Laser and Target Area Building

The Laser and Target Area Building would be an environmentally controlled facility housing the laser and target area systems and the integrated computer system. The majority of the building would contain laser optics. This reinforced concrete and structural steel building would be constructed to be vibration isolated, provide radiation confinement and control, and include all necessary machine control and diagnostic systems. It would consist of two laser bays, two optical switchyards, a target chamber in a target area, target diagnostic facilities, capacitor areas, control rooms, and operations support areas (figure I.3.2.1–1). The floor plan would have a U-shaped layout, with the laser bays forming the legs of the "U" and the optical switchyards and target room forming the connection (LLNL 1994b).

I.3.2.1.1.1 *Laser System*

A laser is a device that produces a beam of monochromatic (single-color) "light" in which the waves of light are all in phase. This condition creates a beam that has relatively little divergence (scattering) and has a high concentration of energy per unit area of the beam. The NIF laser system would generate and deliver high-power optical pulses to a target suspended in the target chamber. Multiple laser beams would be used to uniformly irradiate the required target surface area.

The NIF laser would contain 192 independent laser beams, or beamlets. Each beamlet would have a square aperture of slightly less than 40-centimeter (cm) (16-inch [in]) beam width. Beamlets, each of which would have a unique beam path, or beamline, to the chamber, would be grouped in 48 2x2 groupings at the target chamber. The 192 beamlines would require more than 10,000 discrete optical components. Figure I.3.2.1.1.1–1 illustrates a schematic diagram of the path of one beamlet from origin to the target.

I.3.2.1.1.2 *Target Area*

The NIF target area (figure I.3.2.1.1.2–1) would provide confinement of tritium and activation products by providing physical barriers and by controlling air flow. In addition shielding would provide protection from neutron and gamma radiation. The target area would consist of the following major subsystems: target chamber, target emplacement positioner, target diagnostics, target diagnostic control room, support structures, environmental protection, and vacuum and other auxiliary systems (LLNL 1994b). The primary tritium confinement would be provided by the target (vacuum) chamber and tritium collection system, which would be designed to capture tritium exhausted from the test

chamber. The secondary tritium confinement would be the Target Area Building structure, which would be provided with a heating, ventilation, and air conditioning system capable of operating at a negative pressure during and immediately after shots of greater than 1 megajoule (MJ). The building structure would act as the confinement for air activation products. The final exhaust release point from the heating, ventilation, and air conditioning system would be elevated. The airborne radiation releases at the building release points would be measured and the target area would have monitors to allow detection of conditions requiring corrective or protective actions.

Environmental protection systems, including tritium-handling systems, target storage, and decontamination equipment used to clean the target chamber components, would be located adjacent to the target chamber and target chamber room. X-ray, optical, and neutron measurement instruments would be arranged around the chamber to help evaluate the success of each target experiment. Structural support of the target diagnostics, as well as of the target positioner, final optic assemblies, and turning mirrors, would be provided by target area structures. The target area would also provide the following subsystems: the target area auxiliary systems, material handlers, the chamber personnel transporter, and the diagnostics and classified control rooms.

I.3.2.1.1.3 *Target Chamber*

The NIF target chamber would be a 10-meter (m) (33-feet [ft]) internal-diameter spherical aluminum shell with walls 10 cm (4 in) thick (figure I.3.2.1.1.3–1), and the exterior of the chamber would be encased in 40 cm (16 in) of concrete to provide neutron shielding. The target chamber would be supported vertically by a hollow concrete pedestal and horizontally by radial joints connected to the cantilevered floors. The aluminum wall of the chamber would provide a vacuum barrier and mounting surface for the first wall panels, which protect the aluminum from soft x rays and shrapnel. The vacuum system would provide a 10^{-6} torr vacuum level for target experiments (LLNL 1994b).

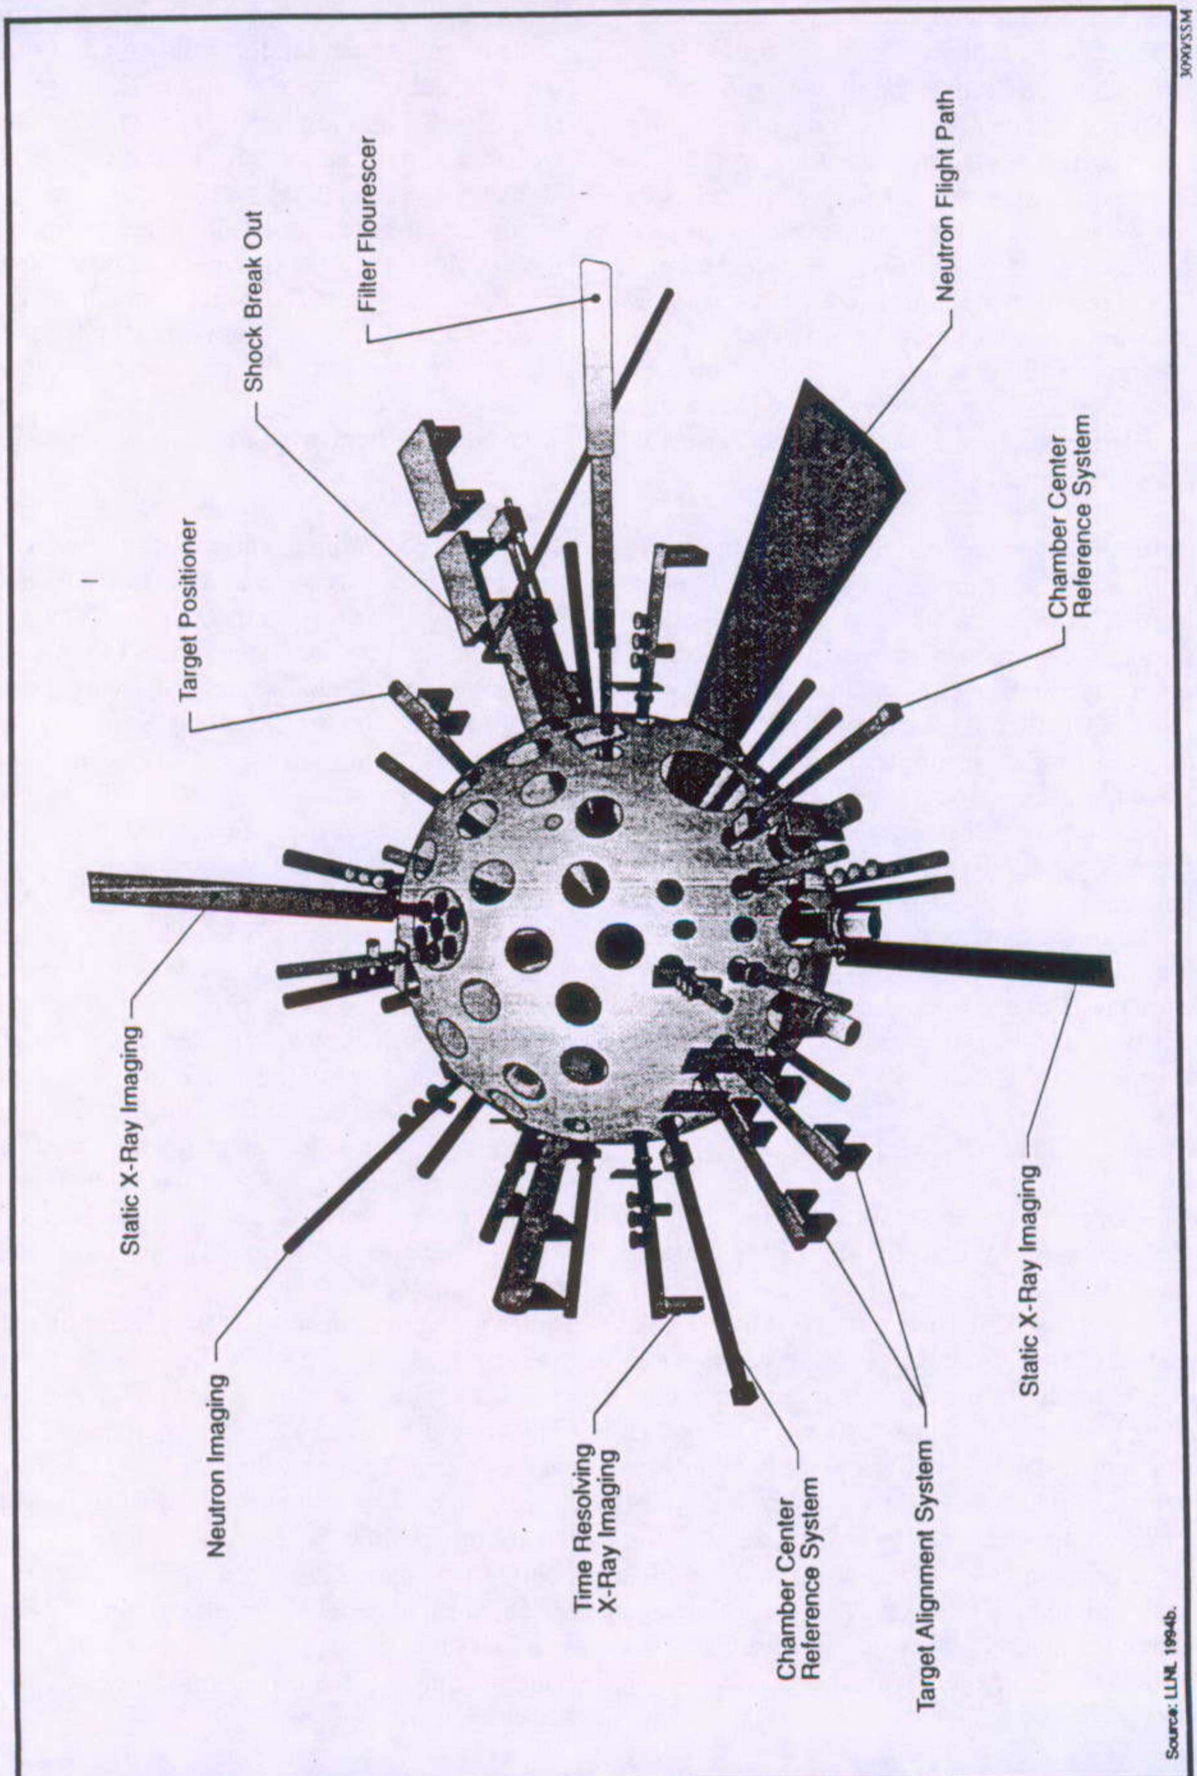
The laser beams would enter the chamber in two conical arrays from the top and two conical arrays from the bottom. At the poles and in the equatorial regions of the chamber, diagnostic equipment would be inserted through the chamber wall. Unconverted laser light that hit the opposite wall would be absorbed by the light-absorbing panels located adjacent to and slightly smaller than the opposing beam port. The target chamber would also include the target emplacement and positioning/alignment systems and planned diagnostics.

I.3.2.1.1.4 *Integrated Computer Control System*

The computer control system would be an integrated network of conventional computer systems providing the hardware and software needed to support full operational activities. The system would include the computer controls to manage the complex laser optical system and would have to meet security requirements to handle classified information.

I.3.2.1.1.5 *Sequence of Events During an Ignition Shot*

A shot would begin as weak laser pulses at four separate frequencies (or colors of light) in the master oscillator room (figure I.3.2.1–1). Each pulse is launched into an optical fiber system that amplifies and splits the pulse into 192 separate fibers, 48 of each color. The four colors are used to smooth the intensity (power per unit area) of the laser spot on the target. The power in the laser pulse at this point is a little less than a watt. Typical pulses are a few nanoseconds long, so the energy is a few nanojoules. The optical fibers carrying the pulses then spread out to 192 preamplifiers. The preamplifiers are located beneath the focal plane at the center of the large transport spatial filters, which are located between the laser components and the target chamber (figure I.3.2.1.1.1–1). Within the preamplifier, the pulse is amplified by a factor of about one million, to about a millijoule. The laser pulse then enters spatial beam-shaping optics and a flashlamp-pumped, four-pass rod amplifier, which converts it to about a 1-joule pulse with the spatial intensity profile needed for injection into the main laser cavity.



Source: LLNL 1994b.

FIGURE I.3.2.1.1.3–1.—*Target Chamber with Typical Diagnostic Equipment.*

The pulse of laser light from the preamplifier reflects from a small mirror (labeled LM0, figure I.3.2.1.1.1–1). The laser light comes to a focus at the focal plane of the transport spatial filter, and passes through booster amplifier 3, reflects from the polarizer, is amplified further in cavity amplifier 2, goes through a second spatial filter (the cavity spatial filter), then passes through cavity amplifier 1, and reflects from the deformable mirror (mirror LM1, figure I.3.2.1.1.1–1). The beam then reflects back through cavity amplifier 1, the cavity spatial filter, and cavity amplifier 2.

In the interim, the Pockels cell (figure I.3.2.1.1.1–1) is energized. This component rotates the plane of polarization of the laser light from horizontal to vertical. Therefore, the laser light pulse passes through the polarizer and strikes cavity mirror LM2, which redirects the pulse back to the Pockels cell, which rotates the polarization back to horizontal. The pulse then continues towards the deformable mirror LM1. It then reflects back from LM1, through cavity amplifier 1, the cavity spatial filter, and cavity amplifier 2 again. By this time the Pockels cell has been de-energized so that it no longer rotates the polarization of the pulse. Thus, the laser pulse reflects from the polarizer and is further amplified by booster amplifier 3 to an energy of about 17 kilojoules for a typical ignition target pulse shape. The pulse then passes through the transport spatial filter on a path slightly displaced from the input path, thus just missing the injection mirror LM0.

The laser pulse then travels through a long beam path reflecting from several transport mirrors (LM 4 through 8) until it reaches the target chamber. (For simplicity, figure I.3.2.1.1.1–1 does not show all of these mirrors.) Mounted on the target chamber is a frequency converter that changes the infrared laser pulses to ultraviolet light. The focusing lens then brings the four color pulses (192 separate fibers or 48 for each color pulse) to a focus at a single spot at the center of the target chamber. The debris shield/phases plate (figure I.3.2.1.1.1–1) protects the focusing lens from any target fragments, and it may also have a pattern etched into its surface to reshape the distribution of laser intensity in the focal spot on the target.

The target would be a small spherical capsule whose hollow interior would contain a thin annular layer of liquid or solid DT fuel (a mixture of deuterium and tritium isotopes of hydrogen). The outer surface of the capsule is rapidly heated and evaporated, either by the absorption of soft x rays under indirect drive or by direct heating by lasers under direct drive (see figure I.3.2.–1). The rocket effect caused by the evaporated outer capsule creates an inward pressure causing the capsule to implode in about 4 nanoseconds. The implosion heats the DT fuel in the core of the capsule to about 50 million degrees Celsius (90 million degrees Fahrenheit), sufficient to cause the innermost core of the DT fuel to undergo fusion. The fusion reaction products deposit energy in the capsule, further increasing the fuel temperature and the fusion reaction rate. Core fuel ignition occurs when the self-heating of the core DT fuel due to the fusion reaction product deposition becomes faster than the heating due to compression. The ignition of the core would then propagate the fusion burn into the compressed fuel layer around the core. This will result in the release of much more fusion energy than the energy required to compress and implode the core.

The energy in one pulse would be about equal to the caloric energy in one candy bar (1.8 MJ, or 400 food calories). However, the peak power for a few nanoseconds would be equal to about 500 terawatts (500×10^{12} watts), instantaneously exceeding the steady-state power capacity in the entire United States by about a factor of 1,000 (LLNL 1994a).

I.3.2.1.2 Target Receiving/Inspection Area

NIF would require a facility at which to receive and inspect targets fabricated at another site (LLNL 1995b). This area would require several Class 100 (Airborne Particulate Cleanliness Class) clean rooms and inspection laboratories in a vibration-free environment. This facility would also include cryogenic laboratories and a central chemical waste system. The facility would have to meet security requirements to handle classified equipment.

I.3.2.1.3 Other Areas

Optics Assembly Area/Clean Room. The optics assembly area/clean room would be used to clean, coat (for example, with Sol-gel as an optics dielectric), inspect, and assemble the NIF's optics and crystals (LLNL 1995b).

General Assembly Area. The general assembly area would be used to assemble mechanical and electrical components not requiring a clean-room environment (LLNL 1995b). The facility would be equipped to handle large and heavy assemblies. This area would also be used for assembly welding.

Optics Maintenance Area. The optics maintenance area would be used for refurbishing, cleaning, and coating of both laser glass and optical components (LLNL 1995b). This specialized area would require vibration isolation, temperature and humidity controls, and Class 100 clean rooms.

Optics Storage Area. During the NIF operational phase, spare parts would be stored in the optics storage area. Because of the size and mass of many of these components the storage area would provide for truck and forklift access (LLNL 1995b).

Radioactive Storage Area. The radioactive storage area would be an intermediate storage area used to store components that come out of the target area before they can be decontaminated.

Electrical and Mechanical Shops. The electrical and mechanical shops would house the machine tools to be used for repairs, maintenance, and special fabrication required for daily operations of the NIF laser and its auxiliary systems (LLNL 1995b).

Support Facilities. NIF would require the following additional support facilities (LLNL 1995b): (1) shipping, receiving, and central stores; (2) medical building; (3) cafeteria; (4) garage and gas station; (5) fire station; and (6) security and badging. All of these services currently exist within the infrastructures of the candidate sites and could be used by NIF.

I.3.2.1.4 Facility Construction

Conventional construction techniques would be used to build NIF. The extent and exact nature of such activities as site clearing, infrastructure improvements, and support facility construction required would depend on the specific location selected for NIF. Construction of NIF would be organized in the following sequential phases: (1) initial building construction, (2) special equipment structures installation, (3) final building construction, (4) final installation preparation, (5) clean component installation, and (6) final laser/target systems installation.

As conceptually designed, about 20 ha (50 acres) of land area would be required for NIF. Figure I.3.2.1–2 shows an overall conceptual plan of a generic NIF site, including all required buildings and improvements. Within this area, all direct and support buildings for NIF would require 4.7 ha (11.6 acres). There would also be 4.1 ha (10.1 acres) of access roads and 1.9 ha (4.7 acres) of parking space (LLNL 1995b). The remaining 9.3 ha (23.0 acres) would consist of open space (e.g., landscaped lawns). The actual amount of land required at the selected host site would be less, as all of the candidate sites have existing facilities that could meet some of the infrastructure requirements for NIF (see section I.3.4). During construction, about 2.0 ha (4.9 acres) of land would be required for a construction laydown area. The laydown area would be located within or near the location designated for the NIF (see section I.3.4). Following construction, the laydown area would be restored to its preconstruction condition or incorporated into the landscaping design selected for the site.

I.3.2.2 *Facility Operations*

The NIF experimental plan comprises several stages:

- Start-up experiments to activate core diagnostics and to validate laser performance
- Hohlraum tuning experiments to attain minimum asymmetry in x-ray drive

(indirect-drive approach only, laser symmetry experiments for direct drive)

- Cryogenic pre-ignition experiments for detailed study of capsule implosions
- User experiments for weapons physics, weapons effects, and other user groups
- Ignition experiments
- Ignited burn experiments to obtain basic data for inertial confinement energy development, basic scientific research on high-density plasmas, and research relative to various military-related applications

When the laser "fires" on a target, all 192 laser beams are synchronized such that after grouping in 48 2x2 groupings at the chamber, they simultaneously "hit" the target. The target is compressed and heated, creating intense fusion reactions. Ignition is defined as occurring when heating of the compressed target by fusion products is just adequate to create an advancing front, or wave, of fusion reactions across the target, heating or "igniting" the entire fuel in the target to reaction conditions.

The numbers and types of "shots" needed to achieve ignition have been estimated on the basis of experience with other large laser systems–such as Nova (many of the activities for NIF would have parallels with Nova, such as hohlraum symmetry and plasma diagnostic activation) and the NIF Beamlet Demonstration Project. Relatively low laser energies would be required for most of the early shots; shaped pulses greater than 1 MJ would be required for very few shots before the demonstration of ignition. It is estimated that approximately 1,600 target shots, in addition to approximately three months of downtime for installation of a cryogenic target positioner, would be required to attain ignition (LLNL 1994b). Concurrently, other target experiments would be carried out for various user communities.

I.3.2.2.1 Conceptual Design Operations

It is expected that once ignition is achieved, NIF would be operated within the constraints specified for an operational baseline in the Conceptual Design. This baseline, or Conceptual Design Option, is the 192-beam, indirect drive operation mode for NIF. The estimated parameters for the Conceptual Design Option are as follows:

- Maximum design yield: 20 MJ
- Annual total yield: 385 MJ/year (yr)
- Tritium throughput: 600 Curies (Ci)/yr
- Maximum tritium inventory: 300 Ci
- Tritium effluent: 10 Ci/yr

I.3.2.2.2 Enhanced Option Operations

The enhanced NIF operational capabilities, or Enhanced Option, would include the indirect drive and user capabilities described above plus direct-drive capabilities and additional test-specific capabilities that might be desired by the user communities. In addition, the Enhanced Option would include the ability to perform an increased number of yield experiments per year to accommodate greater user needs. Enhanced capability operations would involve some design changes to the Conceptual Design Option Facility. By diverting the 24 beamlines (96 beamlets) from the indirect-drive configuration for direct drive, an additional 24 beam ports would be placed evenly spaced half above and half below the chamber equator. Final optics assemblies already modified for direct drive would be placed permanently at these ports. The final turning mirrors that direct the laser beams to their final optics assemblies would be adjusted with motors to direct the selected beams away from their usual final optics assemblies and toward another final mirror that would send the beams through the new final optics assemblies in a direct-drive mode. A different target positioner would be required for direct-drive target insertion and positioning. A new target shroud that could be removed much more quickly than that for indirect drive would also be required. Equipment decontamination systems would also be upgraded for the Enhanced Option. The Enhanced Option Facility would use the same utilities and consumables (for example, electricity, water, fuel, and oil) as the Conceptual Design Option Facility.

Under the Enhanced Option, NIF would have the capability to do both direct and indirect drive target experiments (although several days would be necessary to switch from one mode to another). The facility would also have the capacity to handle more experiments per year (both yield and no-yield types) to accommodate greater user needs than permitted by the Conceptual Design Option operations. The estimated operating parameters for the Enhanced Option are as follows:

- Maximum design yield: 20 MJ[1]
- Annual total yield: 1,200 MJ/yr
- Tritium throughput: 1,750 Ci/yr
- Maximum tritium inventory: 500 Ci
- Tritium effluent: 30 Ci/yr

I.3.2.2.3 Security

Both classified and unclassified activities would be conducted at NIF, and appropriate security and badging requirements would be implemented. Because many uncleared visitors are expected to use the facility, security features would be designed to allow easy access for visitors while at the same time maintaining effective physical and technical security where necessary.

Security requirements would include those for physical protection of classified matter; physical protection of Department of Energy (DOE) property and unclassified facilities; protective program operations; and personnel security, including issuance, control, and use of badges, passes, and credentials. In addition, telecommunication services would be designed to be capable of handling both classified and unclassified information.

I.3.3 No Action Alternative

Under the No Action alternative, NIF would not be constructed or operated. NIF's experiments related to science-based stockpile stewardship (see section I.2.2) would not be realized. If NIF were not built, the ability of the Stockpile Stewardship and Management Program to obtain the fusion and high-temperature/density data that would have been available with NIF would be hampered or delayed. The Stockpile Stewardship and Management Program would continue to use Nova and other facilities for as long as they produced useful data, but the existing facilities are not capable of reaching the temperatures and pressures that are anticipated for NIF. If other technologies were proposed to obtain higher temperatures and pressures than those available from existing facilities, such technologies would not be operational by the period 2005 to 2010. When enduring stockpile weapons age beyond their original design lifetimes, confidence in the reliability of such weapons may decrease significantly, and the probability would increase that the United States might have to invoke "supreme National interest" and withdraw from any test moratorium or *Comprehensive Test Ban Treaty*.

Under the No Action alternative, many operations at LLNL, LANL, SNL, and NTS would continue as described in the existing environment subsections of chapter I.4. However, all existing NIF-dependent functions of the ICF program would be discontinued at LLNL, LANL, and SNL. The number of employees at each of these sites would decrease somewhat as a result. For the purposes of the socioeconomic analysis in this PSA, it is assumed that employment at LLNL would decrease by 100, employment at LANL would decrease by 20, and employment at SNL would decrease by 20. There would be no change in employment at NTS or NLVF related to the No Action alternative.

[1] Maximum credible yield is 45 MJ for bounding accident evaluation.

I.3.4 Alternative Sites

This PSA evaluates the impacts of construction and operations of NIF at five locations at four alternative sites: LLNL in California, LANL in New Mexico, Area 22 and NLVF associated with NTS in Nevada, and SNL in New Mexico. The selection of these four sites was based on a two-step process. Three alternative sites were identified on the basis of the following primary site criteria (LLNL 1995b):

- Federal site controlled by the U.S. Department of Energy Office of the Assistant Secretary for Defense Programs (DP)
- Significant ICF programs consisting of ICF-related experimental facilities and personnel working on ICF studies (also called ICF infrastructure)
- Adequate protection of the public and the environment
- Hazardous and radioactive waste management capability
- Adequate transportation services for transportation of targets

Three sites met the first two criteria: LLNL, LANL, and SNL. Significant ICF infrastructure exists at LANL, LLNL, and SNL and the University of Rochester; however, the latter is not a DP facility. All three DP sites have locations that could accommodate NIF; all three sites have the capabilities to construct and operate NIF with adequate protection of the public and environment; all three sites manage both hazardous and radioactive wastes; and all three sites have adequate transportation services for transporting targets. No other sites within the DOE system meet these criteria.

In her October 1994 approval letter for Key Decision 1, Energy Secretary Hazel O'Leary announced LLNL as the preferred NIF site and LANL, NTS, and SNL as alternative sites. NTS meets four of the above five criteria, lacking only a significant ICF infrastructure. However, NTS has a long history of nuclear weapons testing and was added as an alternative site, on the basis of the presidential mandate to maintain a test readiness posture. NTS has proposed two possible locations for NIF. One is NTS Area 22 in the southeastern area of the site, and the other is NLVF, located in the city of North Las Vegas. These two locations, one remote and one within an urban area, well represent alternatives for locating NIF at NTS. The other alternative sites do not have such diversity of alternative locations, and each has selected one proposed location for NIF.

LLNL has been selected as the preferred site because of its prominence as a leading center for laser science, engineering, and technology. The laboratory has been in the forefront of laser and fusion technology, having constructed several large lasers and fusion experiments, including Shiva, Nova, the Atomic Vapor Laser Isotope Separation project, and the Magnetic Fusion Test Facility. LLNL has the required combination of existing facilities, equipment, infrastructure, and technical and management personnel required to build and operate NIF (LLNL 1994c).

Final site selection will result from this PSA and the Record of Decision (ROD), which will also include consideration of the information and evaluations presented in the *Stockpile Stewardship and Management Programmatic Environmental Impact Statement*. For clarity, the following terminology is used in this document: the word site refers to a DOE-controlled Federal site, such as LANL or NTS; the word location refers to the proposed location of NIF within the larger DOE-controlled Federal site. Table I.3.4–1 lists the facilities required for NIF operations at each site.

I.3.4.1 *Lawrence Livermore National Laboratory*

I.3.4.1.1 Location Description

LLNL is a multipurpose scientific engineering research facility operated by the University of California for DOE. LANL was founded on the site of a former U.S. Navy maintenance base in 1952. LLNL's mission is to serve as a national resource of scientific, technical, and engineering capability with a special focus on national security. Over the years, this mission has evolved to include a wide variety of activities, including ICF, laser isotope separation, magnetic fusion energy, biomedical and environmen-

tal research, environmental restoration, and waste management.

The LLNL site is about 64 kilometers (km) (40 miles [mi]) east of San Francisco in southern Alameda County, California. Figure I.3.4.1.1–1 shows the regional location of LLNL. The site occupies an area of 332 ha (821 acres), including land that serves as a buffer zone around the northern and western borders of the site.

As proposed at LLNL, NIF would require construction of two buildings—the Laser and Target Area Building and the Optics Assembly Area—with the remaining building requirements met with existing facilities (see table I.3.4–1). Figure I.3.4.1.1–2 shows the proposed location for the Laser and Target Area Building and the Optics Assembly Building within the existing LLNL complex. The location was selected because it is accessible to the support facilities and functions that would be required to operate and maintain the NIF systems (LLNL 1995b).

The two new buildings would be situated on an 8.1-ha (20-acre) area in the northeastern quadrant of the LLNL site, adjacent to existing ICF facilities (figure I.3.4.1.1–2). The buildings would be constructed in an area where large laser and optical systems have been operating for several years.

Several existing facilities would be modified as necessary, and used to perform supporting functions for NIF. These facilities include: B166 (ICF High Bay), B298 (ICF Target Development, Receiving, and Inspection), B321 (Optics Fabrication), B331 (Tritium Facility), B381 (High Bay), B391 (Nova and High Bay), and B392 (ICF R&D and Storage Area). The current operation of these facilities is covered in the LLNL sitewide Environmental Impact Statement/Environmental Impact Report (DOE and UC 1992). The impacts of any modifications and operation of these facilities have also been evaluated in this PSA. The main impact of these facilities is the inventories of hazardous chemicals used for optics processing. These have been considered in the generation of wastes, effluents, and the postulated accidents for NIF described in chapter 4 of this PSA. The general use facilities (i.e., office building, electrical and mechanical shops, warehouses, shipping and receiving, stores, medical facility, garage, cafeteria, fire station, security, and badge office) serve LLNL as a whole and require no modification to accommodate the addition of NIF.

The LLNL site is located within the California Coast Ranges, an area of north-northwest trending ranges and valleys. The Livermore Valley, an exception to this trend, forms an east-west structural basin defined by branches of the San Andreas fault system. LLNL occupies a smooth land surface that slopes gently to the northwest. Several fault zones traverse the Livermore Valley. LLNL lies within Seismic Zone 4, and the area's seismicity makes earthquake-resistant construction a necessity (LLNL 1995a). The proposed NIF location has been subjected to geological, soil, and vibrational studies, and the site characteristics were determined to be sufficient for the proposed NIF building and equipment designs (LLNL 1994d, 1995b).

I.3.4.1.2 Infrastructure Requirements

Existing utilities at LLNL include electrical power, natural gas, domestic water, cooling water, demineralized water, sewer, compressed air, life-safety alarms, and a voice/data communications system. Most of the utility systems are configured as loops to provide increased reliability and isolation for repair and maintenance. All utilities meet the requirements of current LLNL missions and have the capacity to support NIF (LLNL 1995c).

I.3.4.1.3 Construction and Operations

The construction of the Laser and Target Area Building and the Optics Assembly Building at LLNL would require the relocation of an underground storm drain; currently no other buildings or structures exist at the proposed NIF location. Construction would not require decontamination and decommissioning (D&D) of existing structures, and the area contains no known contaminated soils or previous waste dumps that would require remediation. It is anticipated that the small, incremental amounts of waste that would be generated during construction would be handled by the existing waste treatment and management systems.

During construction a staging area of about 2 ha (4.9 acres) would be required. There are three siting options for this staging area. The staging area would be graded and covered with a chip seal over an

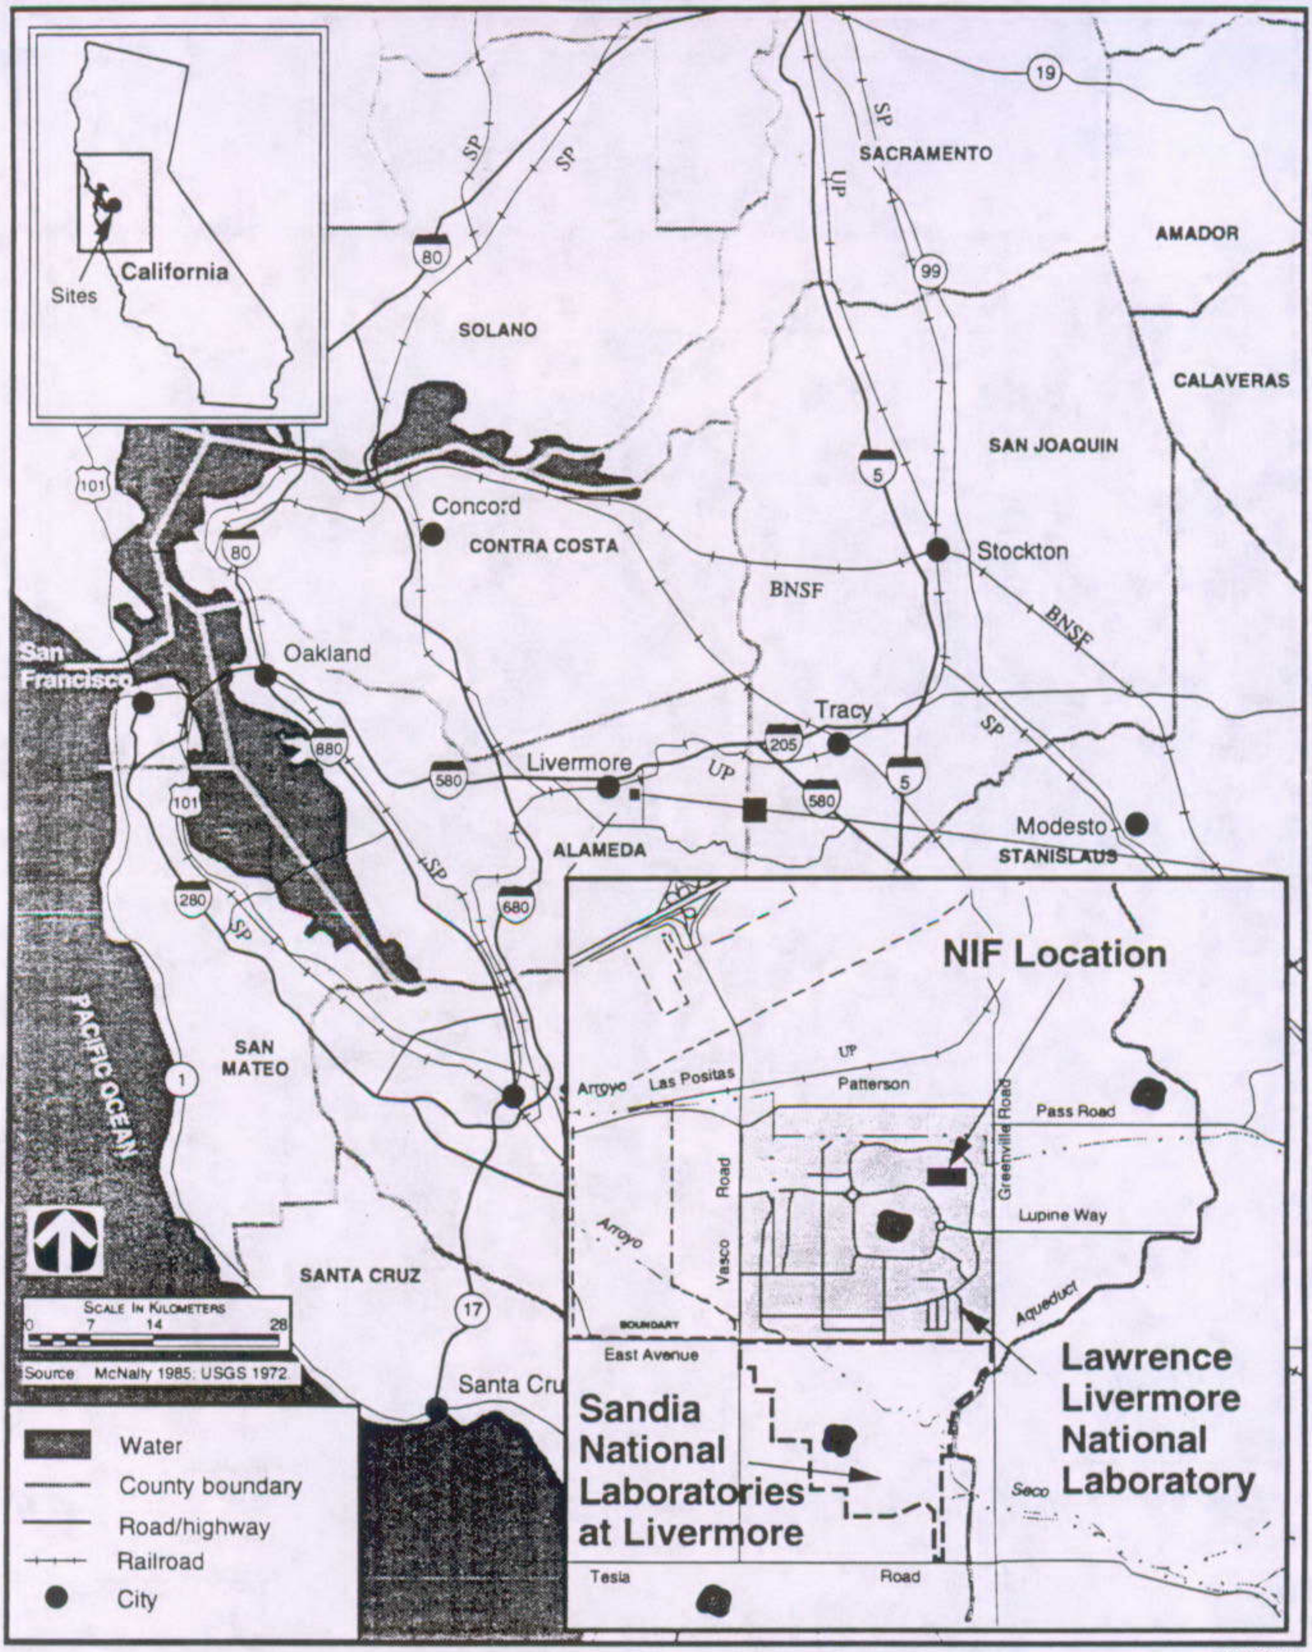

FIGURE I.3.4.1.1–1.—*Regional Location of Lawrence Livermore National Laboratory.*

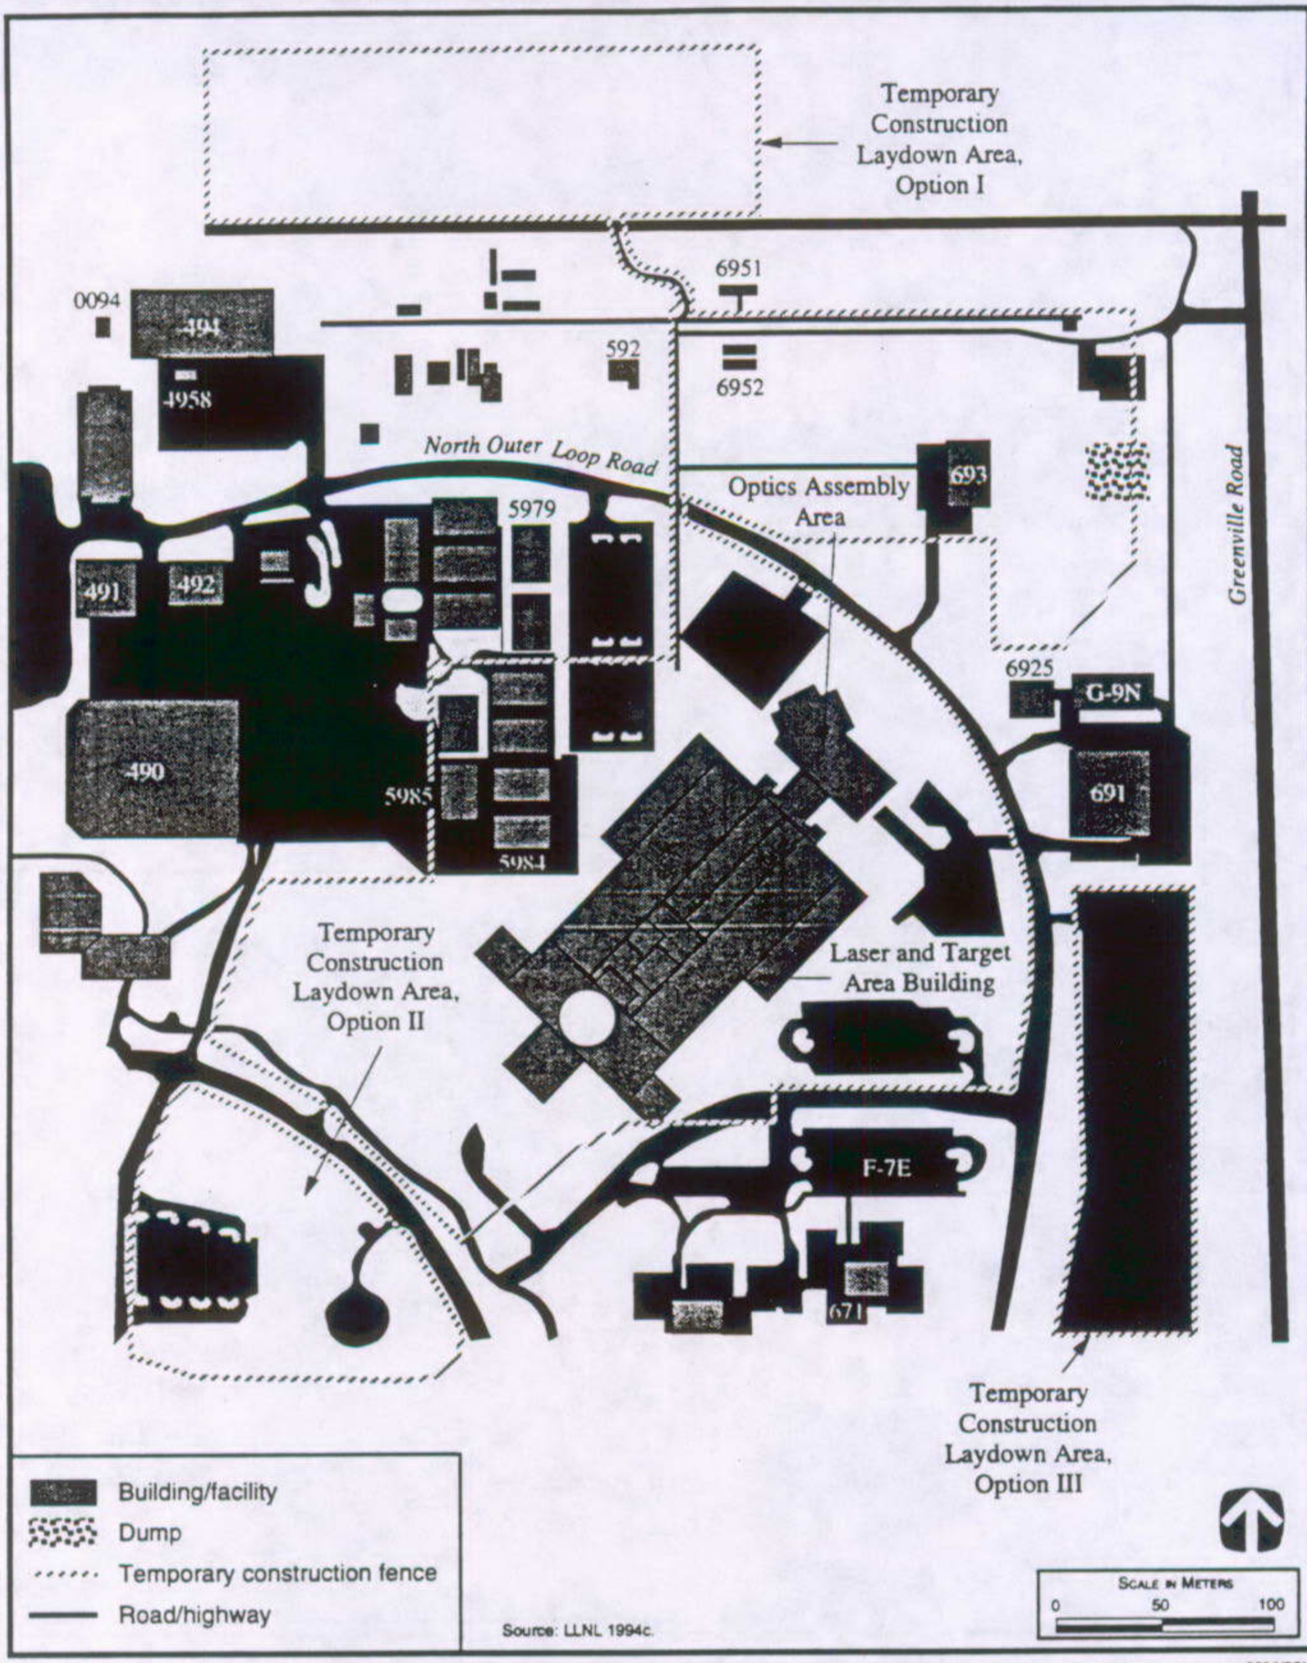

FIGURE I.3.4.1.1–2.—*Proposed Location for the National Ignition Facility at Lawrence Livermore National Laboratory.*

aggregate base. The selected staging area would be cleared and fenced during the construction period. Staging Area option I is across Arroyo Las Positas from the proposed NIF location. A temporary access road, including a bridge across the arroyo, would also be required for movement of construction materials between the option I laydown area and the NIF site. The proposed access road would connect the county's Patterson Pass Road with LLNL's existing Avenue T. Avenue T and other existing LLNL roadways would also be improved to handle the increased traffic. A security post would be installed along the access road. The proposed access road would be 7.3 m (24 ft) wide with 1 m (3 ft) shoulders, and would be about 152 m (500 ft) long. It would be constructed using asphalt over an aggregate base. The bridge would be about 12-18 m (40-60 ft) long and 7.3 m (24 ft) wide. All supporting structures would be located on the tops of the channel banks, out of Arroyo Las Positas. The bridge would be designed so as not to reduce the capacity of the arroyo or increase the risk of flooding. The 100-year floodplain is contained within the channel of the arroyo which is approximately 12-18 m (40-60 ft) wide. Option II would require the removal of a small helipad, while option III would require elimination of a recreational field. The chip seal and fencing at the staging area would be removed upon completion of NIF construction, and the area would be returned to its pre-project condition. If option I is selected, the present plans are to remove the bridge and access road. However, they are being designed as permanent structures so that they could be left in place and used as another entrance to LLNL. The security post would also be removed unless needed for continued use. The arroyo channel banks would be restored to their pre-project condition after the bridge is removed.

I.3.4.2 *Los Alamos National Laboratory*

I.3.4.2.1 Location Description

LANL is a DOE research and technology development facility operated under contract by the University of California. LANL was established in 1943 to provide facilities for research, design, and testing of nuclear weapons and nuclear materials. Over the past 50 years, LANL's mission has evolved in response to national policy to include research in energy, materials science, nuclear safeguards and security, biomedical science, computational science, environmental protection and cleanup, and other basic science research (DOE 1995c).

LANL and the associated residential areas of Los Alamos and White Rock are located in Los Alamos County, in north-central New Mexico, approximately 97 km (60 mi) north-northeast of Albuquerque, 40 km (25 mi) northwest of Santa Fe, and 32 km (20 mi) southwest of Espanola, New Mexico (figure I.3.4.2.1–1).

The proposed LANL location for NIF is Technical Area (TA)-58, which is an undeveloped area adjacent to TA-3, the hub for LANL administration and support activities (figure I.3.4.2.1–2). The new construction proposed at this location includes the Laser and Target Area Building, the Optics Assembly Area, the General Assembly Area, and office space required for NIF.

Table I.3.4–1 lists the existing LANL facilities that satisfy NIF space requirements. Two of the existing facilities listed, TA-3-287 and TA-3-105, would be adequate to support additional NIF functions after significant modification and upgrading. These two buildings, the Scyllac Building (TA-3-287) and the Sherwood Building (TA-3-105), would be designated for use as the Optics Maintenance Area and the Optics Storage Area, respectively. Both of these facilities are in fair to good condition, have been well maintained, and contain no contamination or other environmental hazards (ICF Kaiser Engineers and LANL 1994a). An existing facility in TA-54 could serve as the Radiological Storage Area.

LANL lies within Seismic Zone 2. LANL operates a seismic hazards program that monitors seismicity through a seismic network and conducts studies in paleoseismology. Potential earthquake magnitude and intensity values are used in design considerations at the site.

I.3.4.2.2 Infrastructure Requirements

LANL's existing utility network includes 600 km (400 mi) of lines for six primary utilities: electricity, telecommunications, water, sanitary sewer, radioactive liquid waste, and natural gas. LANL's Long Range Utilities Development Plan includes several proposed upgrades and improvements that would bring the system up to the standards required for the NIF systems. A utility corridor now extends along the

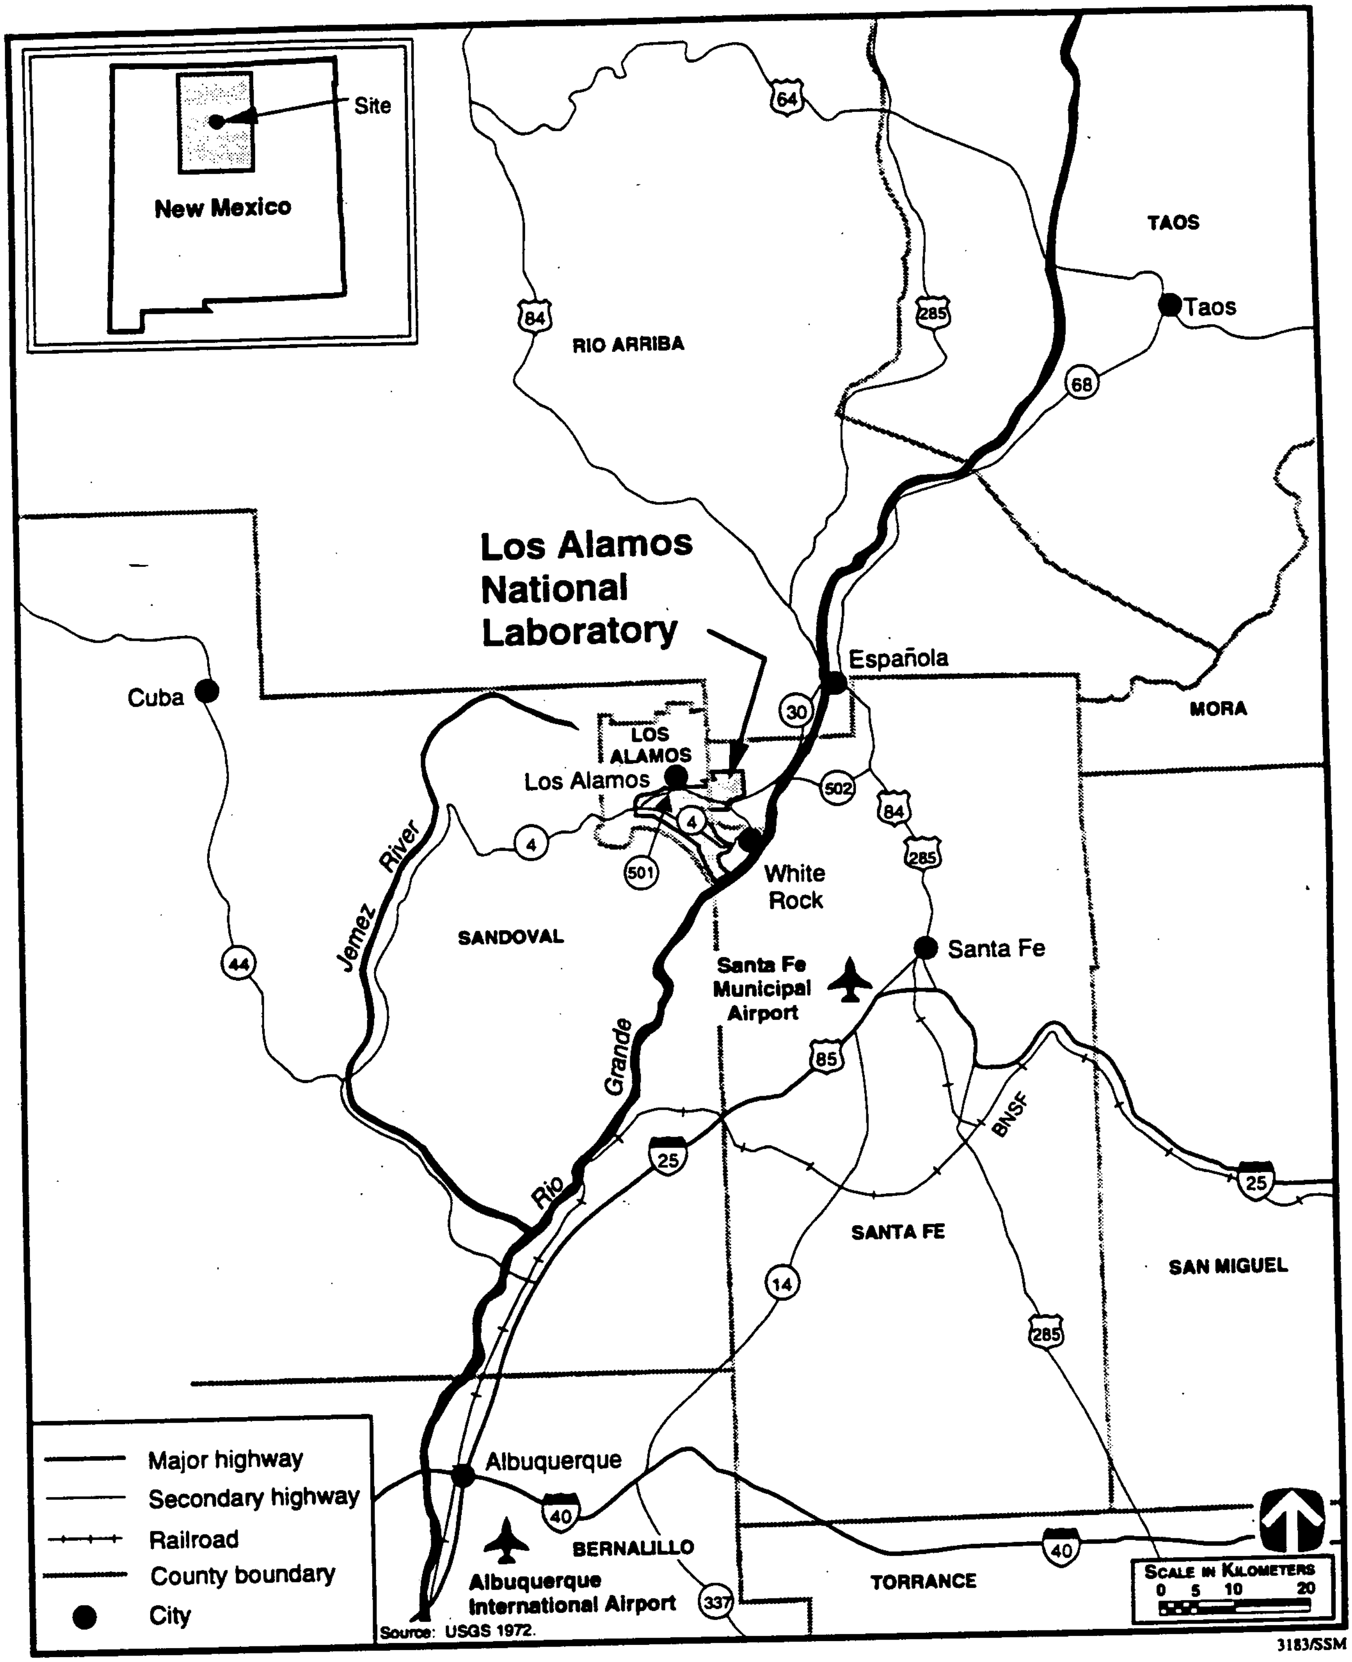

FIGURE I.3.4.2.1-1.—*Regional Location of Los Alamos National Laboratory.*

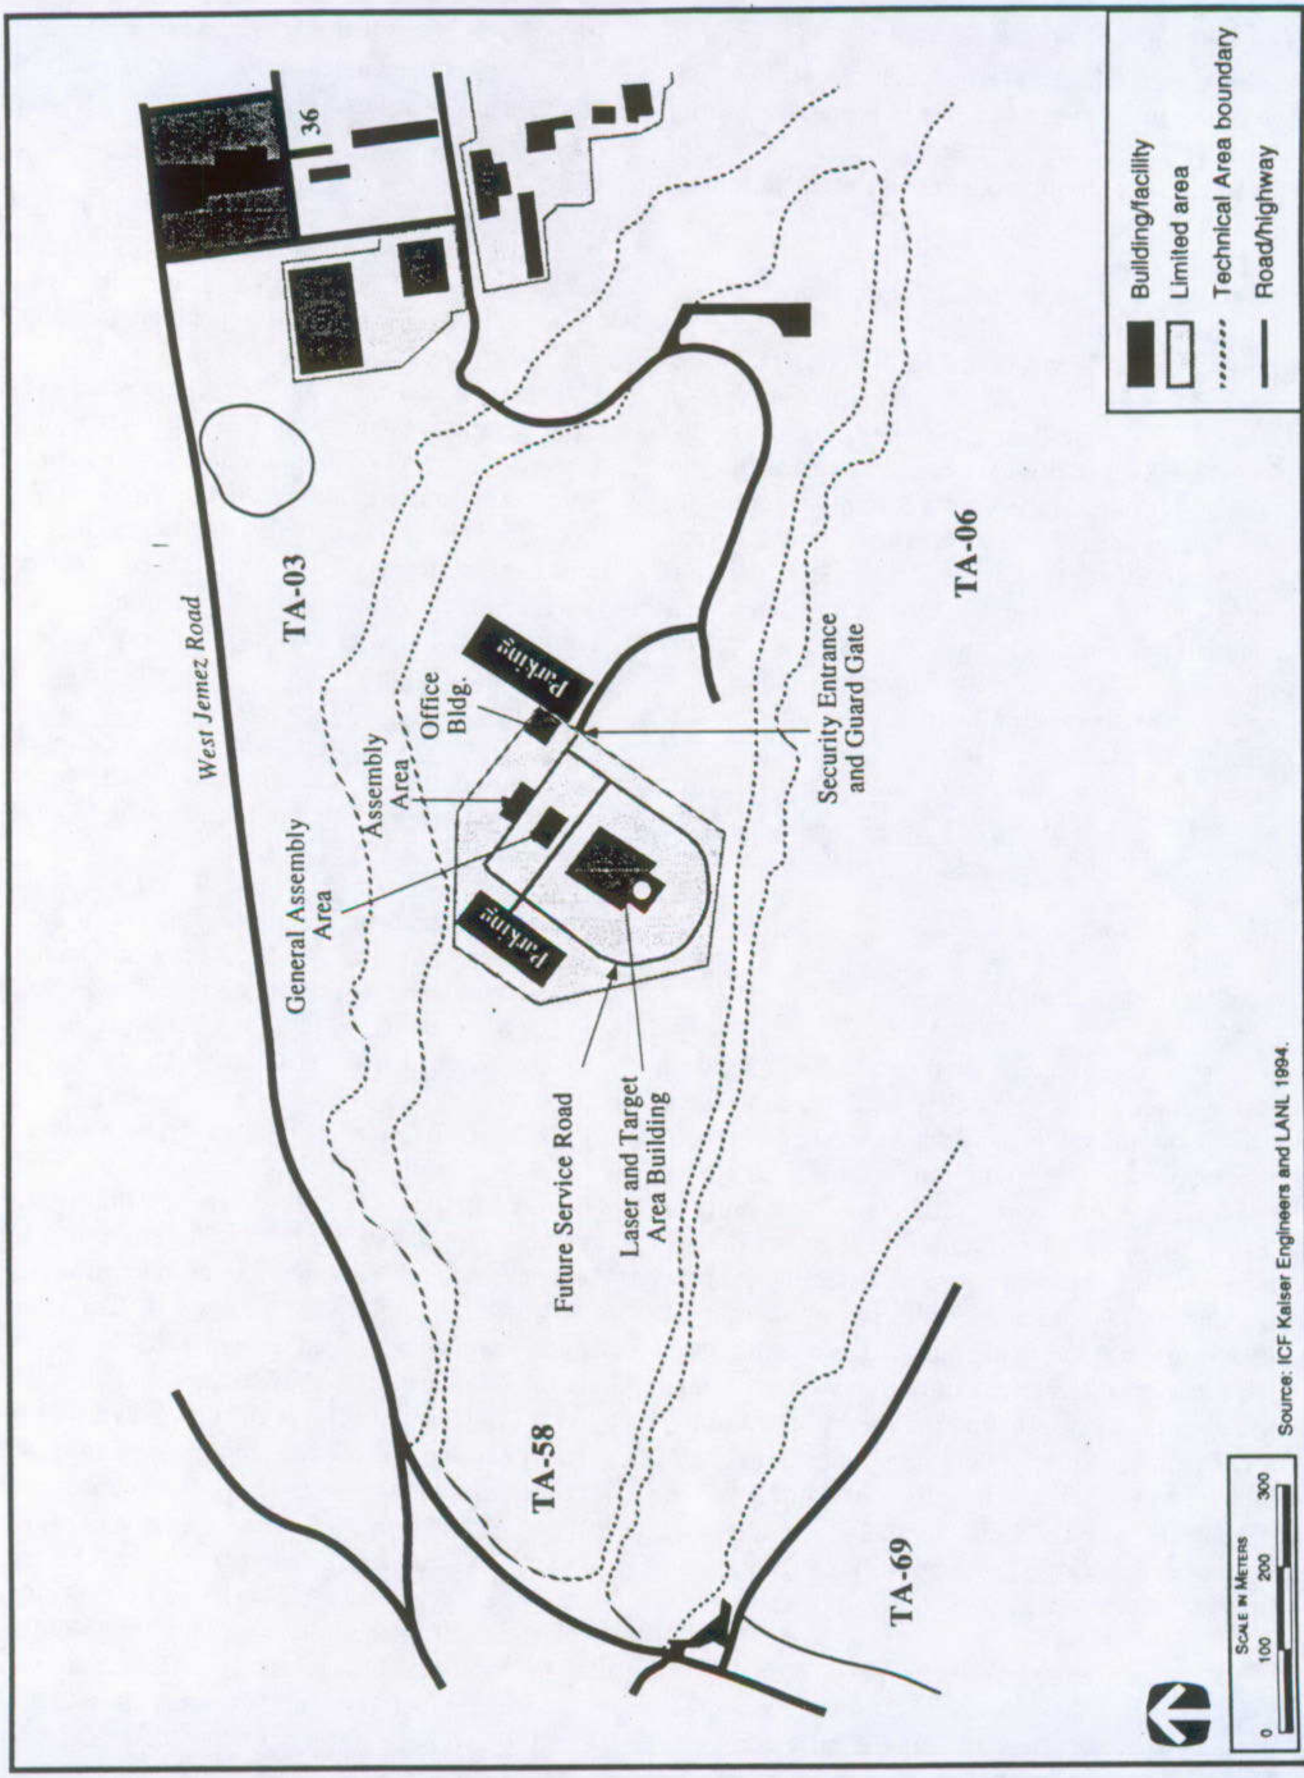

FIGURE I.3.4.2.1–2.—*Proposed Location for the National Ignition Facility at Los Alamos National Laboratory.*

eastern boundary of the proposed NIF location and, with some modifications and conditions noted below, would be sufficient to support NIF project requirements. This corridor presently includes lines for water, telecommunications, electricity, and natural gas (LANL 1990a).

I.3.4.2.3 Construction and Operations

The proposed NIF location at LANL is a large, undeveloped tree-covered area. Preparation of the TA-58 location would require tree removal and clearing and some leveling and filling to create a construction site suitable for NIF. The TA-58 location has no known solid waste management units that would require remediation. Because the volcanic Bandelier tuff underlying the area is an unusually strong foundation material, NIF buildings could be constructed entirely with concrete slabs on grade rather than with piers to stabilize the foundation of the target area. Present solid waste management facilities are adequate to handle the wastes generated during construction activities. The construction laydown area would be located within the area designated for NIF.

I.3.4.3 *Nevada Test Site*

I.3.4.3.1 Location Description

NTS was established in 1950 and has been used for underground testing of nuclear weapons and evaluation of the effects of nuclear weapons on military communications systems, electronics, satellites, sensors, and other items. Underground nuclear testing was halted in October 1992, but the site maintains the capability to resume testing if authorized by the President. In addition to maintaining underground nuclear testing program capabilities, NTS maintains nuclear emergency search team program capabilities, supports the Yucca Mountain Site Characterization Program, supports arms control and treaty verification activities, and provides support to other DOE and non-DOE missions. NTS is operated for DOE by several management and operating contractors.

NTS occupies approximately 350,000 ha (867,000 acres) in southern Nye County in southern Nevada, approximately 105 km (65 mi) northwest of Las Vegas, NV (figure I.3.4.3.1–1). The town of Indian Springs and the Indian Springs Air Force Auxiliary Field, in northwestern Clark County, NV, are 39 km (24 mi) southeast of the closest NTS boundary.

The proposed NTS location for NIF is Area 22, located southwest of Mercury Base Camp (figure I.3.4.3.1–2). This proposed location is a remote, flat desert setting with sparse vegetation. It is directly accessible by Jackass Flats Highway. Table I.3.4–1 lists the facilities that would be constructed at NTS Area 22 and those existing facilities that would be converted to meet NIF requirements. The Laser and Target Area Building, Optics Assembly Area, Target Receiving and Inspection, Optics Maintenance Area, and Optics Storage Area would be constructed as new facilities. Most other NIF requirements would be met by converting existing facilities at Mercury Base Camp. Building 610, located about 3.2 km from the NIF location, would be used for the Radiological Storage Area. In addition, two existing buildings in Area 6 (about 52 km [32 mi] from the NIF location) would be used for general maintenance (Raytheon Services Nevada 1995).

The region has been tectonically active in the near past and has numerous faults. NTS lies in an area of moderate historic seismicity on the southern margin of the Southern Nevada East-West Seismic Belt in Seismic Zones 2 and 3 (DOE 1995d).

I.3.4.3.2 Infrastructure Requirements

Major utilities, including telecommunications, natural gas, water, and electricity, are accessible to the proposed NIF location from Mercury Base Camp, located 3.2 km (2.0 mi) away. A 138-kilovolt overhead power line passes within 0.4 km (0.25 mi) of the NIF location, and adequate commercial power to NTS is available from the Nevada Power Company and the Valley Electric Association. A new electrical substation would have to be constructed for the project (Raytheon Services Nevada 1995). Water supply and storage are adequate to meet NIF requirements; supply is from six wells on NTS. An underground pipeline about 3.2 km (2 mi) long would have to be constructed to connect the NIF facilities to the site water supply system. Sewage disposal facilities would also have to be constructed for the project; adequate space exists for ponds or a sewage plant.

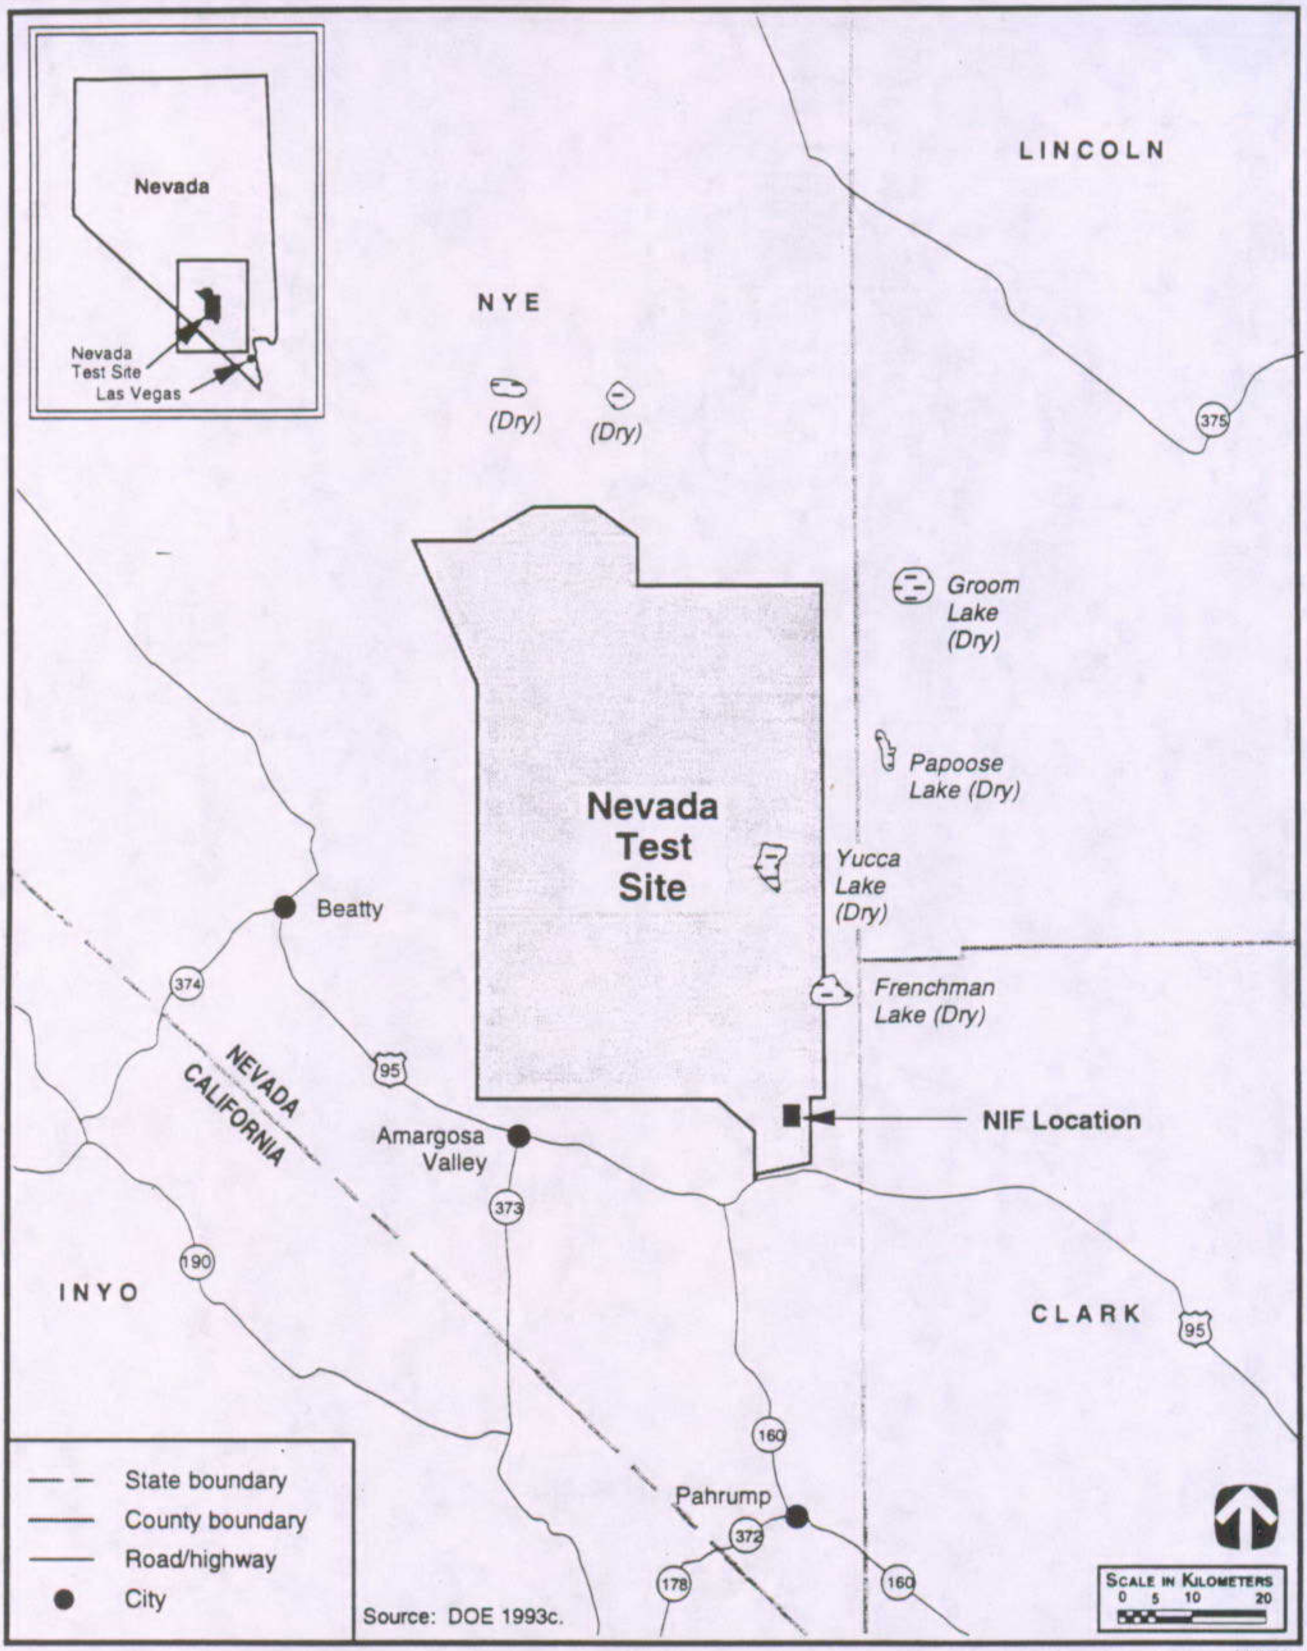

FIGURE I.3.4.3.1–1.—*Regional Location of Nevada Test Site.*

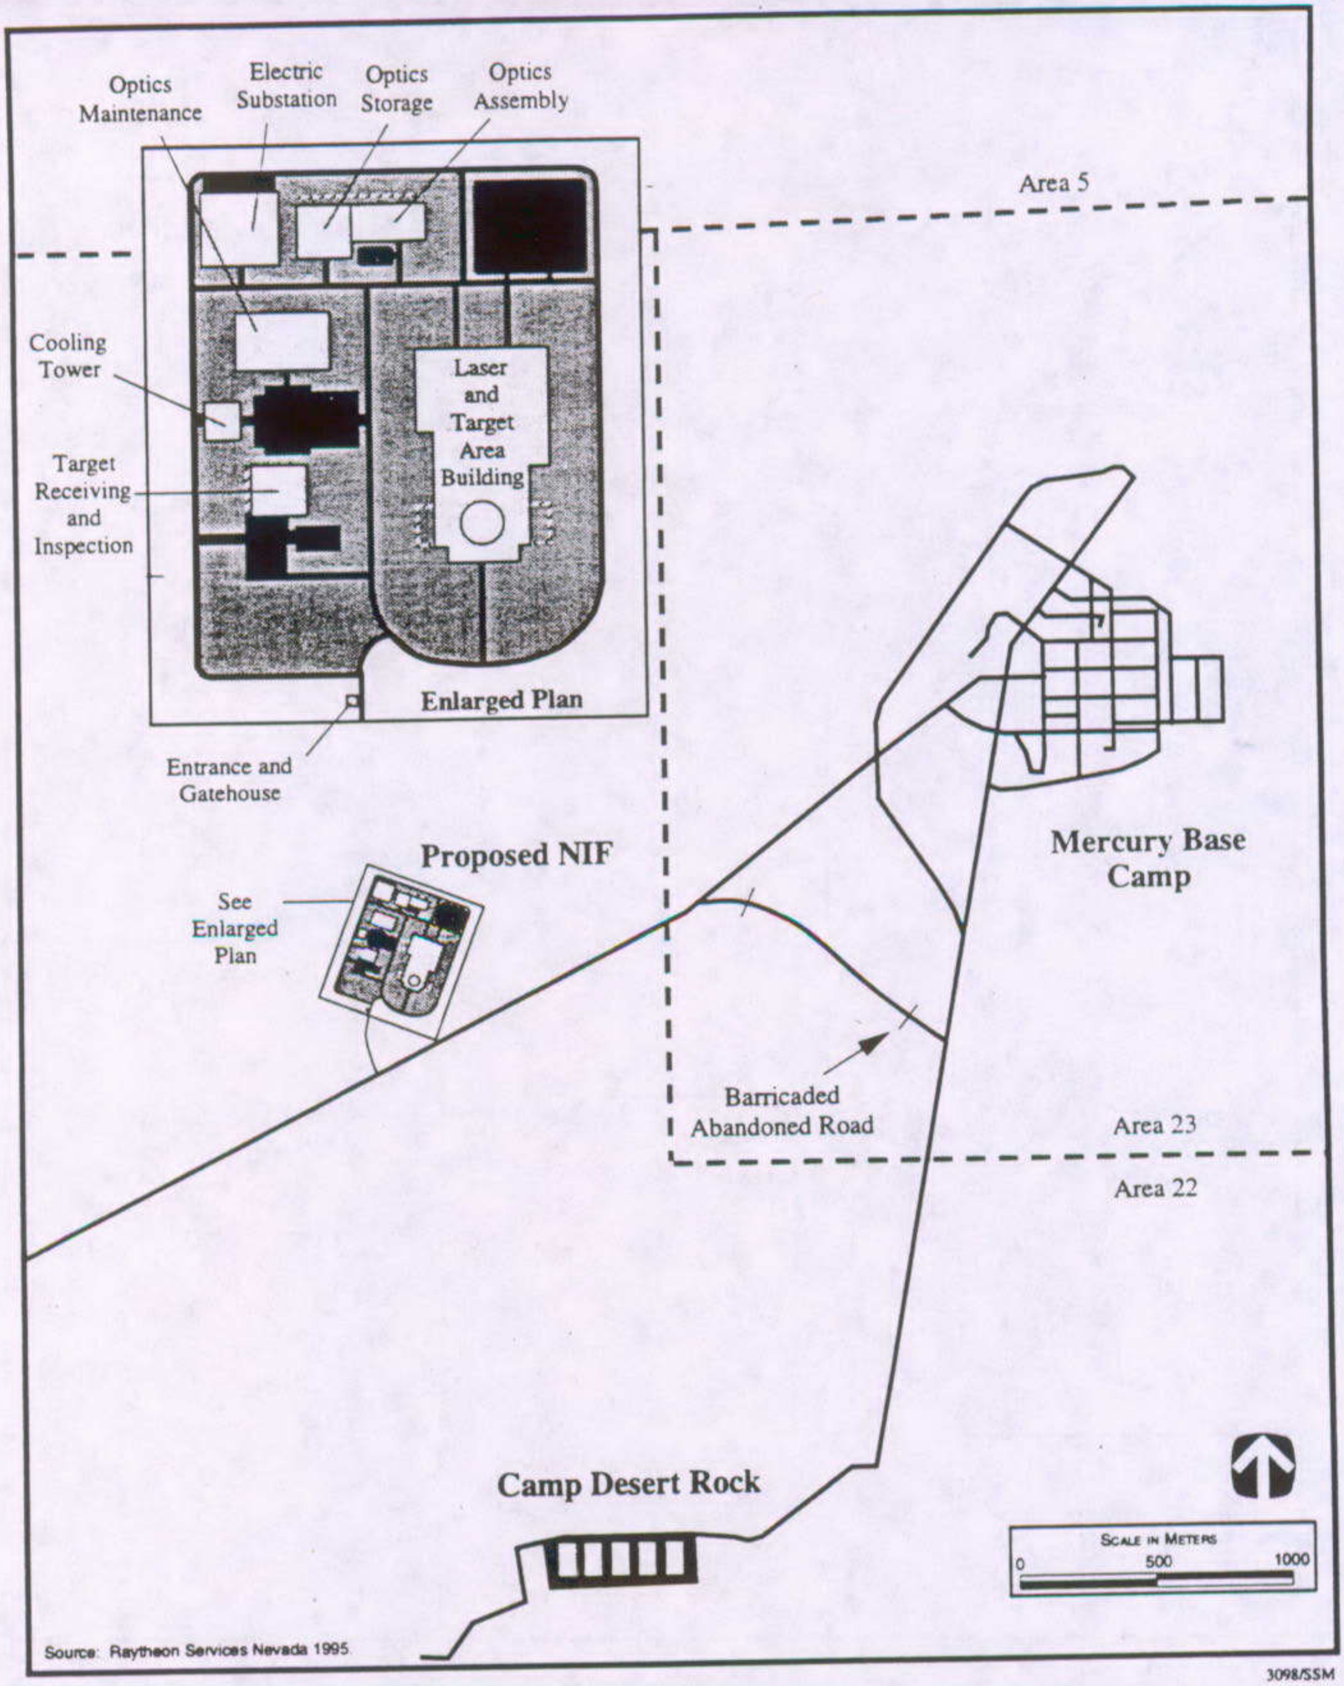

FIGURE I.3.4.3.1–2.—*Proposed Location for the National Ignition Facility at Nevada Test Site Area 22.*

I.3.4.3.3 Construction and Operations

During site preparation, the ground at Area 22 would have to be cleared of existing vegetation. The site is relatively level, undisturbed desert land and would require minimal site preparation. Currently, no buildings or other facilities are located in the vicinity. Construction would not require D&D of existing structures and there are no known contaminated soils or previous waste dumps in the area that would require remediation. Small amounts of waste generated during construction would be handled by the existing waste treatment and management systems. A cement batch plant would be set up in the area to accommodate construction needs and reduce transportation requirements. The construction laydown area would be located within the area designated for NIF.

I.3.4.4 *North Las Vegas Facility*

I.3.4.4.1 Location Description

The overall mission of NLVF is to support the Nevada Operations Office and the LLNL, LANL, and SNL weapons test programs. The mission includes prestaging activities, as well as fabrication, assembly, and testing of field diagnostic systems that collect data from underground nuclear detonations at NTS (DOE 1994b). NLVF is located in the city of North Las Vegas, NV, which is part of the three-city metropolitan area encompassing Las Vegas, Henderson, and North Las Vegas (figure I.3.4.4.1–1).

The proposed NIF location is within the NLVF perimeter, west of Losee Road, north of Carey Avenue, east of Commerce Street, and south of Brooks Road within the city limits of North Las Vegas, NV. New facilities that would be required at the NLVF for NIF include the Laser and Target Area Building, the Optics Assembly Area, the Optics Maintenance Area, the Optics Storage Area, Target Receiving and Inspection Area, Radiological Storage Area, and possibly office facilities (table I.3.4–1). As shown in figure I.3.4.4.1–2, the proposed layout would use a large portion of the existing open space to position NIF buildings (DOE 1992, 1995e). The immediate area is zoned for general industrial activity. The proposed location for NIF consists of previously graded land with sparse vegetation.

The NLVF is within the Las Vegas Valley. Rugged mountain ranges surround the low-lying alluvial filled valley. The valley consists primarily of fine-grained Miocene and Pliocene sedimentary rocks. NLVF is located within Seismic Zone 2.

I.3.4.4.2 Infrastructure Requirements

The proposed NIF location at NLVF is readily accessible to all utilities. Existing electrical, wastewater, and water supply capacities are adequate to meet NIF requirements, but connections would be necessary for the project. The nearest water supply is a city of Las Vegas well about 0.16 km (0.25 mi) south of the site. Although domestic water supplies appear to be adequate, a source of low-conductivity cooling water would have to be developed at the site. Connections with local sewer lines would also be necessary (DOE 1995e).

I.3.4.4.3 Construction and Operations

During site preparation for new facilities, the ground would have to be cleared of vegetation. Construction would not require D&D of existing structures, and there are no known contaminated soils or previous waste dumps in the area that would require remediation. Small amounts of waste generated during construction would be handled by the existing waste treatment and management systems in the city of Las Vegas. The construction laydown area would be located within the area designated for NIF.

I.3.4.5 *Sandia National Laboratories*

I.3.4.5.1 Location Description

SNL is a DOE research and development (R&D) facility at Albuquerque, NM. SNL was established in 1949. During more than four decades of existence, its mission has expanded from an original focus on nuclear weapons R&D to include research on other advanced military technologies, energy programs, arms verification, and applied research in numerous scientific fields, including an extensive program in materials research (IT Corporation 1992).

SNL is located 10.5 km (6.5 mi) east of downtown Albuquerque in Bernalillo County (figure I.3.4.5.1–1), within the boundaries of the 21,044-ha (52,000-acre)

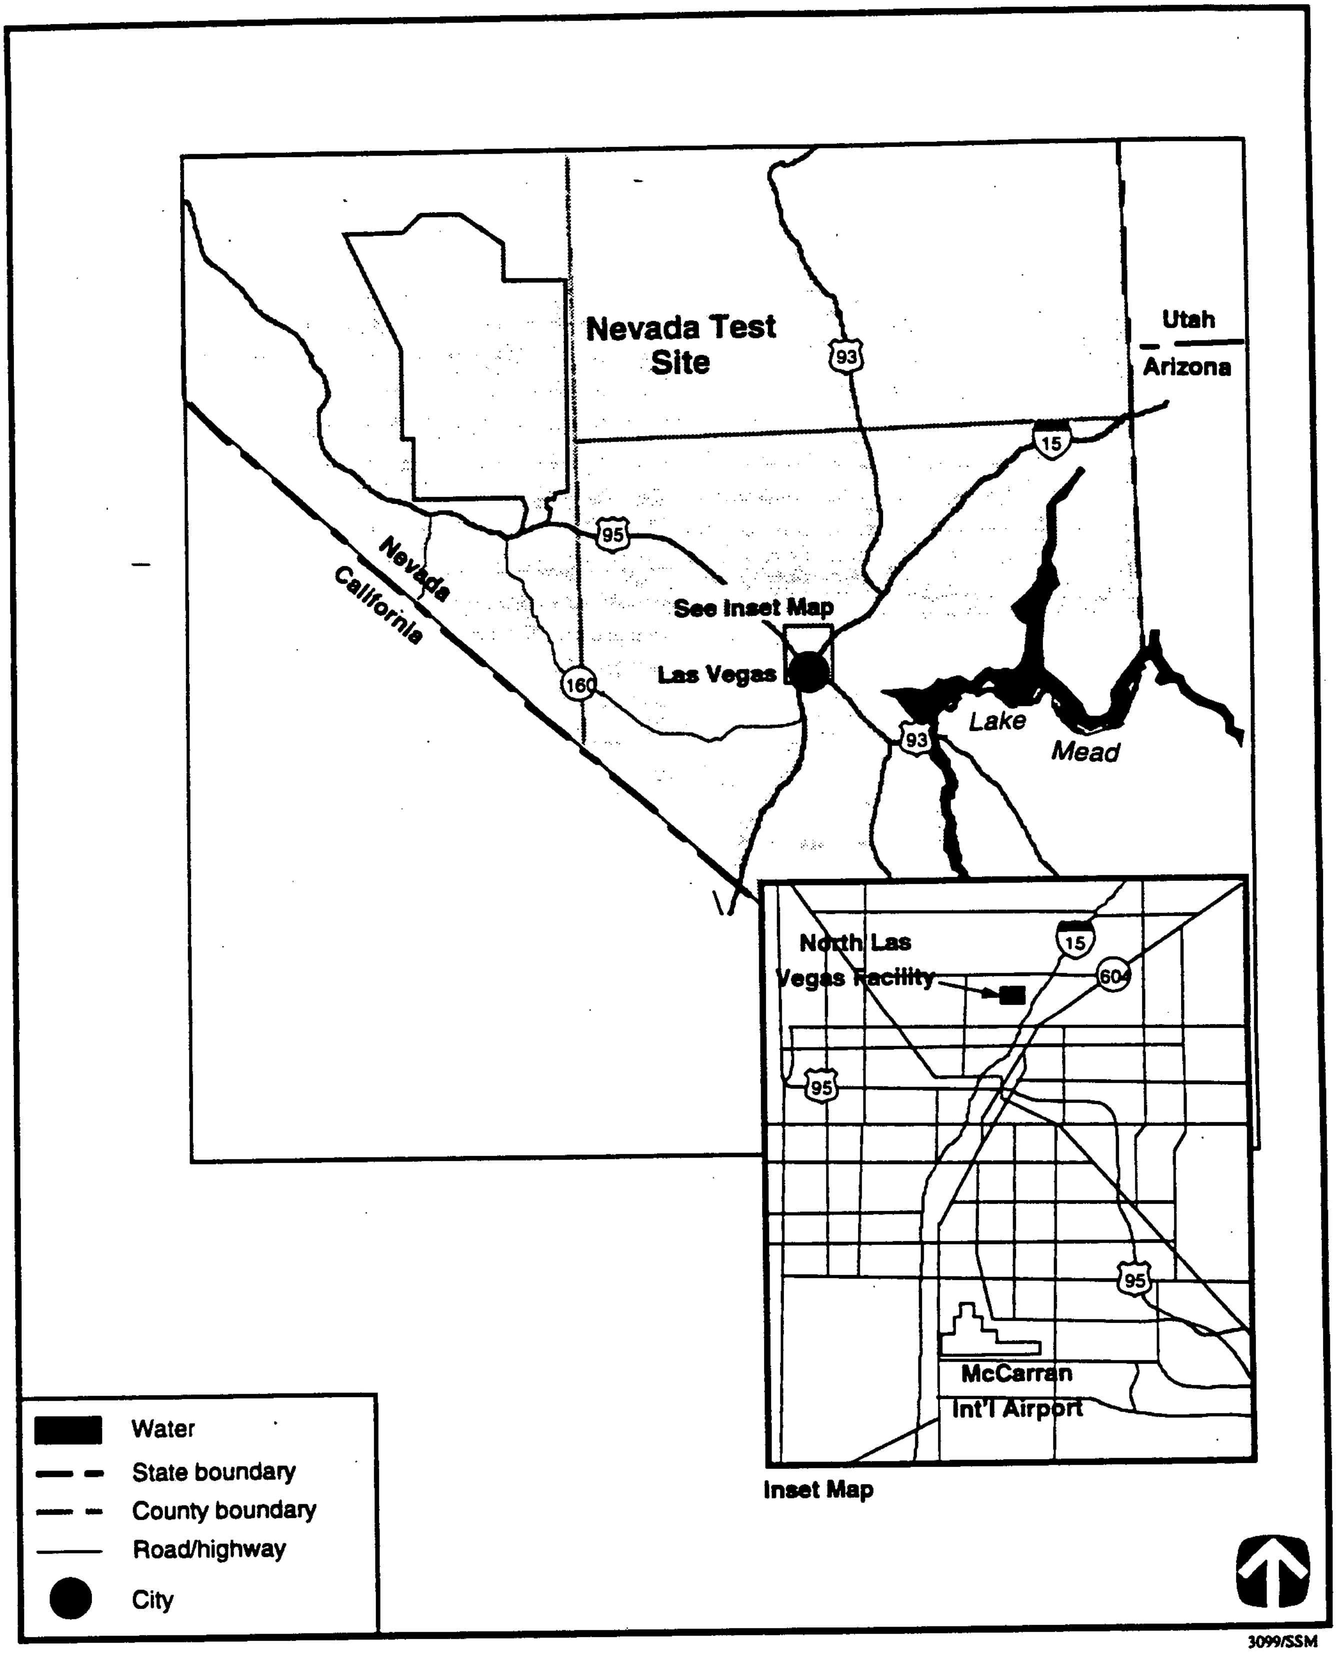

FIGURE I.3.4.4.1–1.—*Regional Location of the North Las Vegas Facility.*

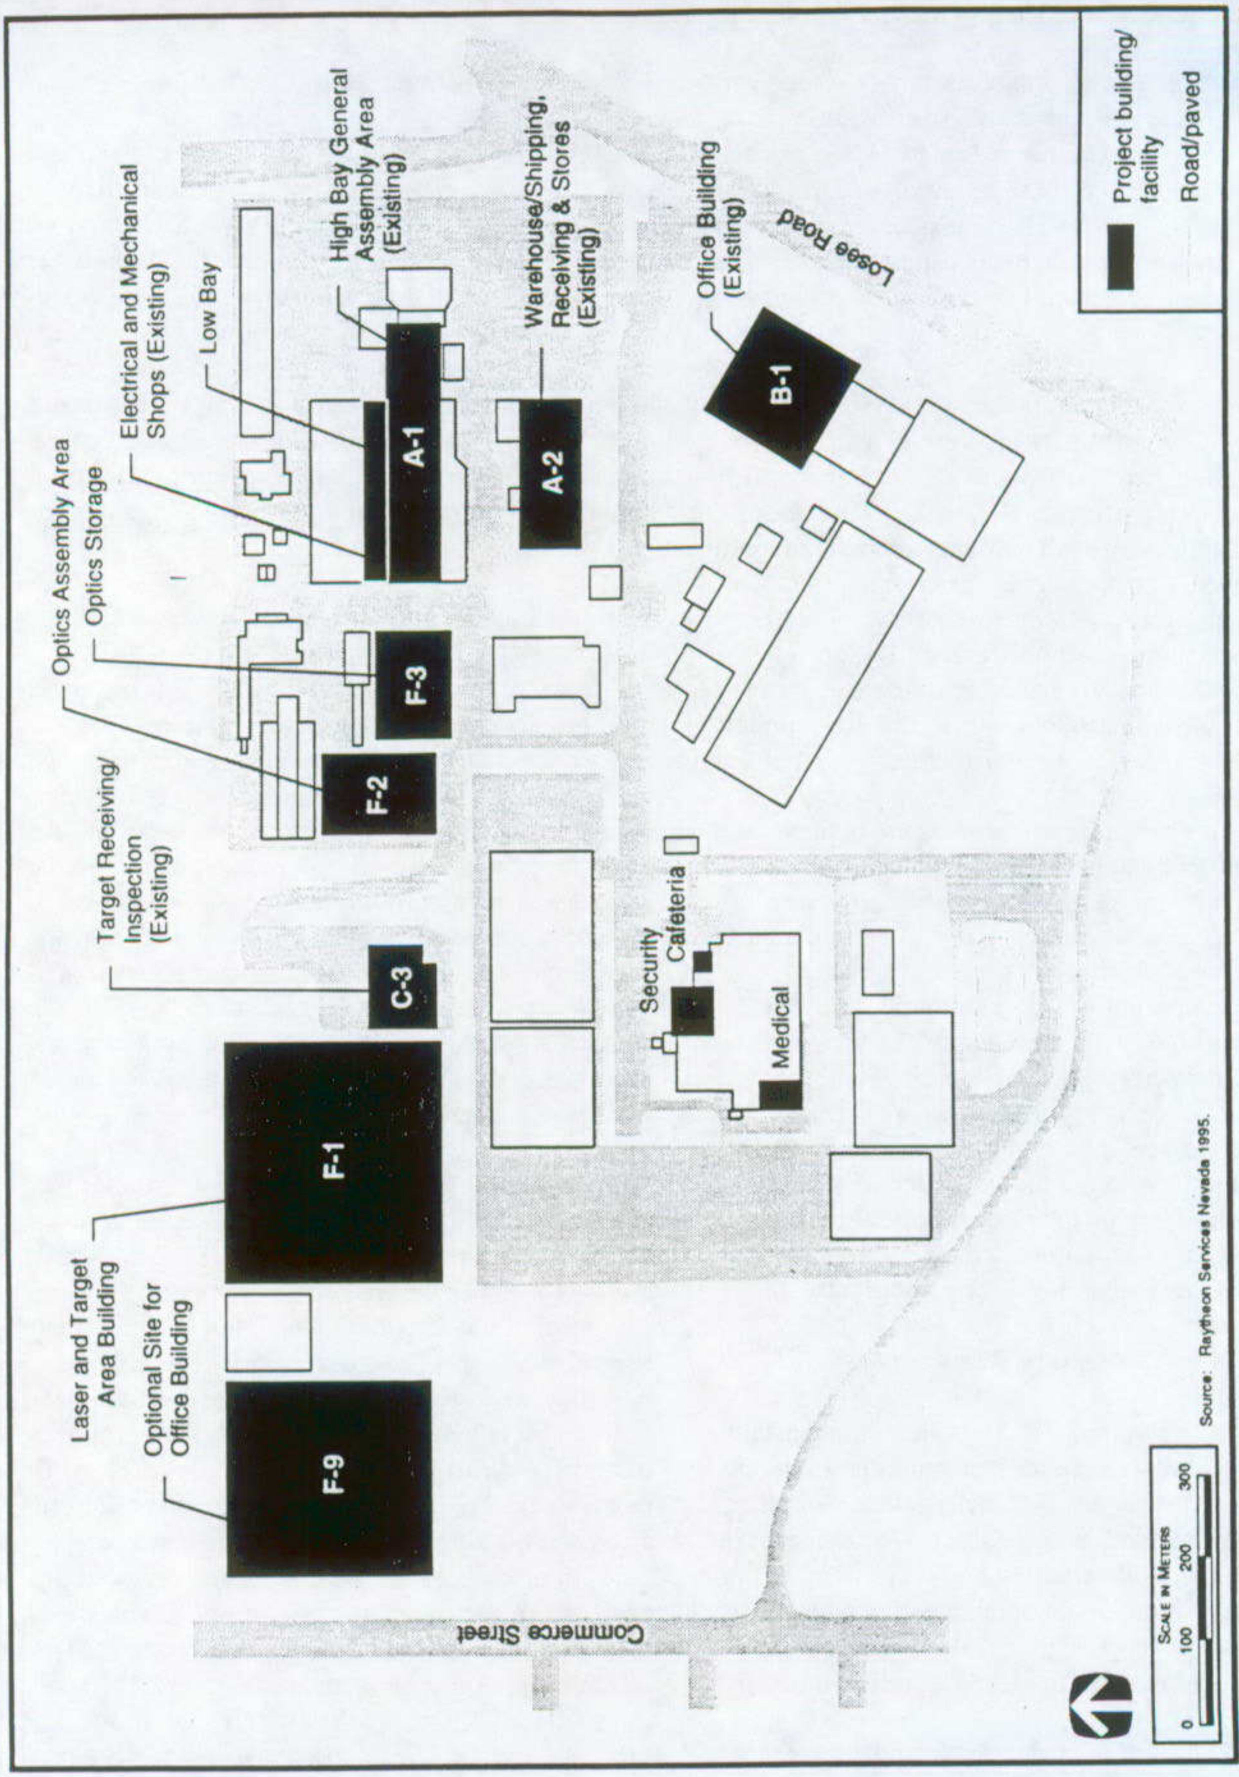

FIGURE I.3.4.4.1–2.—*Proposed Location for the National Ignition Facility at North Las Vegas Facility.*

Kirtland Air Force Base military reservation. DOE owns 1,150 ha (2,842 acres), and additional areas are provided to DOE primarily for testing and safety buffers through land withdrawals and land-use permits from Kirtland Air Force Base, the State of New Mexico, and the Isleta Pueblo. Laboratory operations are conducted at five TAs and several remote test areas situated in the eastern part of Kirtland Air Force Base.

The preliminary location proposed for NIF at SNL is an 11-ha (27.5-acre) plot of level, largely cleared, undeveloped property on the southern side of Technical Area II (figure I.3.4.5.1–2). This location has sufficient space for all new construction proposed for NIF at SNL, including the Laser and Target Area Building, Optics Assembly Area, Target Receiving, Optics Maintenance and Storage, Radiological Storage Area, and warehouse facilities. This location is near all SNL facilities required for NIF support (table I.3.4–1) (Boyes 1995; SNL 1995a).

SNL lies on a sequence of sedimentary, igneous, and Precambrian basement rocks. The northern and western sections rest on Miocene to Quaternary gravels, sands, silts, and clays deposited in the basin that was formed by uplift of the mountains to the east. The eastern portion of SNL is primarily underlain by Precambrian rocks. This portion of the site is cut by the Tijeras, Hubble Springs, Sandia, and Manzano faults. SNL is located in Seismic Zone 2. The facility is situated in a region of high seismic activity, but the activity is of low magnitude and intensity. Possible geologic concerns include potential ground shaking and rupturing associated with regional seismic activity and the faults intersecting on the site.

I.3.4.5.2 Infrastructure Requirements

Existing utility systems at SNL include electricity, domestic water, wastewater treatment, telecommunications, and natural gas. Electricity, water, and natural gas are supplied to SNL by Kirtland Air Force Base. Although the SNL utilities show signs of aging, recent efforts to upgrade components of the system have improved service (SNL 1995a). Current supply capacities are adequate to meet the projected requirements for NIF.

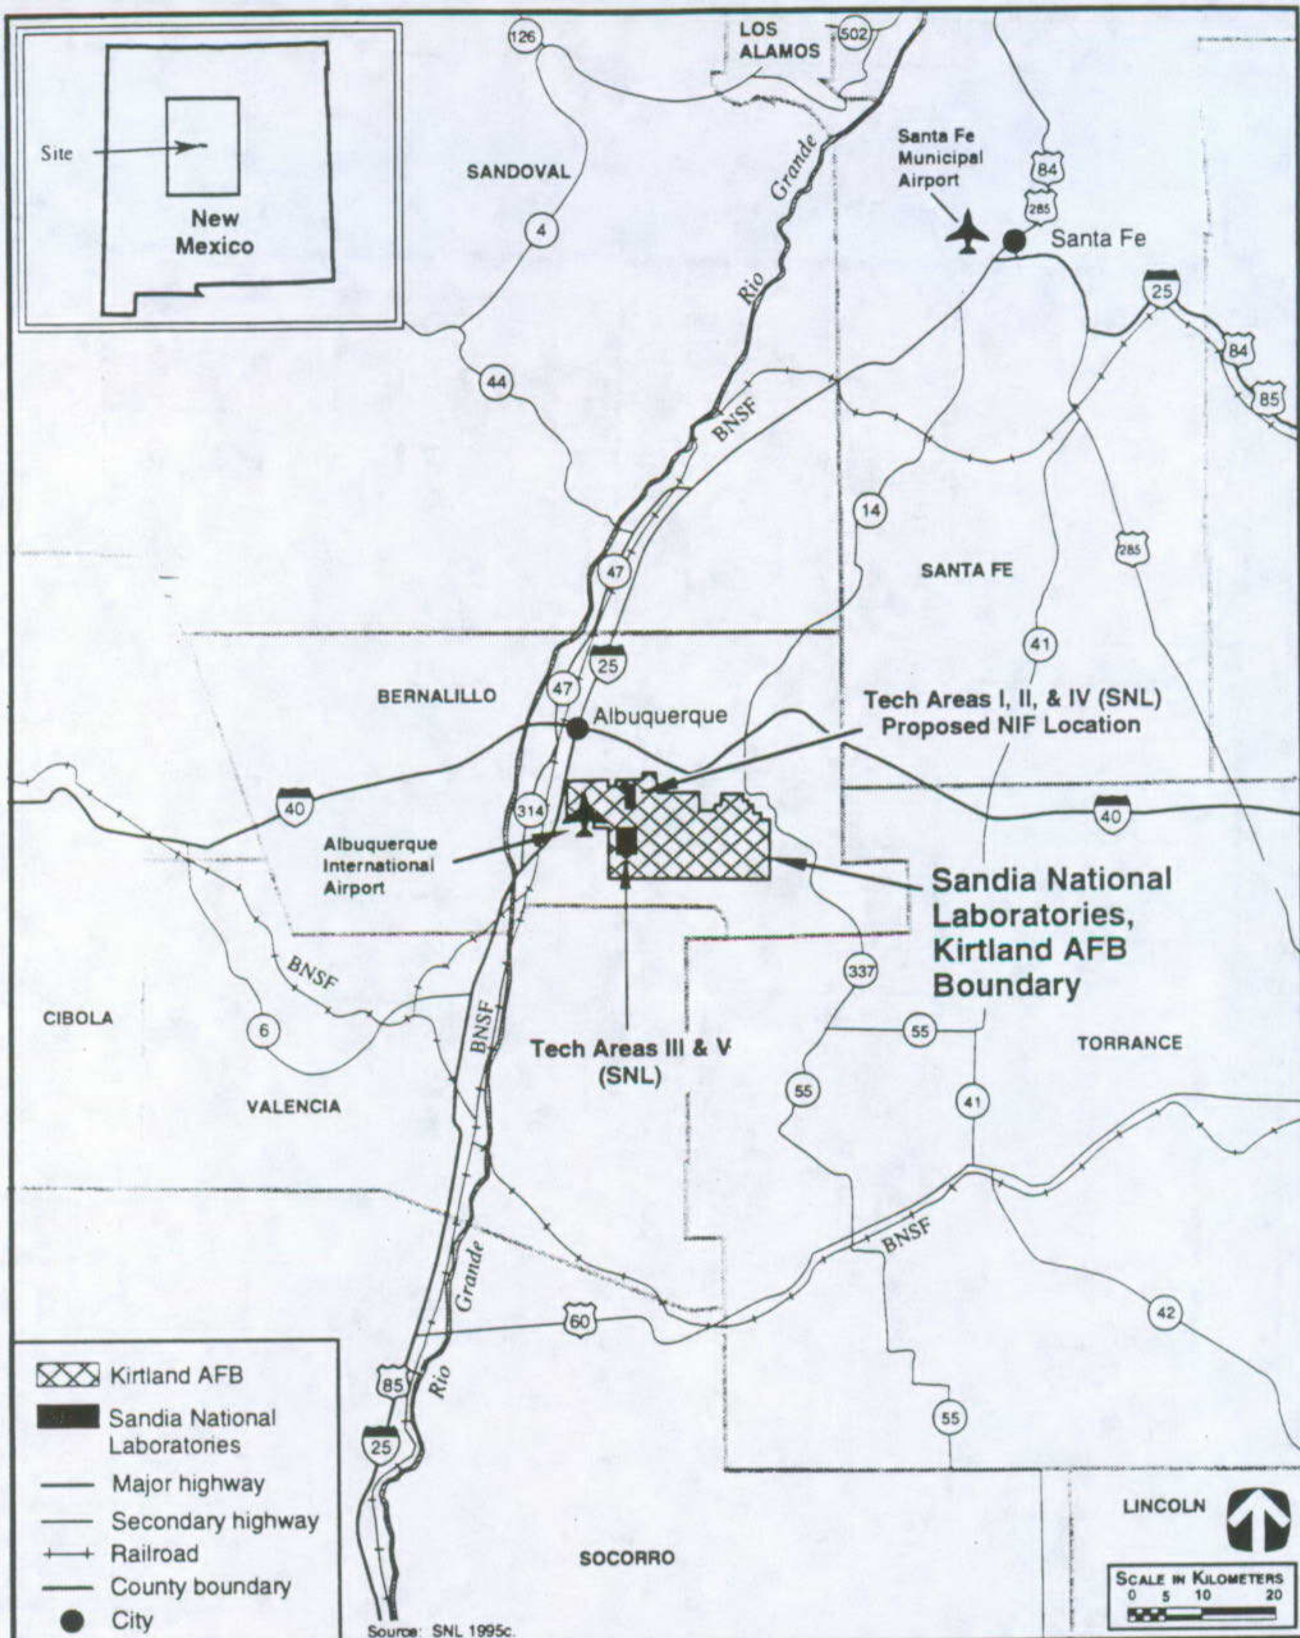
I.3.4.5.3 Construction and Operations

The proposed SNL location is relatively cleared and would require little preparation before construction activities. Several drainage ditches would be rerouted before construction began. Construction would not require D&D of existing structures, and there are no known contaminated soils or previous waste dumps in the area that would require remediation. Small amounts of waste generated during construction would be handled by the existing waste treatment and management systems. The construction laydown area would be located within the area designated for NIF.

I.3.5 Alternatives Not Considered in Detail

NIF is an advanced-design, solid-state laser facility in the preliminary design phase of engineering. As a result, there are ongoing discussions of possible design alternatives that might maximize facility performance, reduce cost, or better meet the needs of users. An example of such a set of alternatives would be the arrangement of laser beams in the laser arrays. Most of these alternatives are suggestions as to the design and arrangement of internal machine components, and they would not affect the performance of the facility in a way that relates to the assessment of environmental consequences. For this reason, these types of alternatives have not been addressed in this PSA.

Several technologies are under development as drivers for ICF targets. The major programs in the United States are solid-state lasers, heavy-ion accelerators, light-ion diodes (pulsed power technology), and gaseous krypton-fluoride lasers. Design studies have been conducted for all these technologies showing how they could be used as drivers for inertial fusion power plants and for ICF research facilities. For example, point designs for each driver were developed for the study of the Laboratory Microfusion Facility (a high-target-gain facility considered by DOE in the late 1980s). Such studies revealed that each driver has advantages and disadvantages over the others for the power plant application, and, as yet, no clear choice can be made among them. However, for the Ignition Facility, the 1990 review of the ICF program by the National Academy of Sciences examined the status and rate of progress of each of the driver technologies.



3155/SSM

FIGURE I.3.4.5.1–1. *Regional Location of Sandia National Laboratories.*

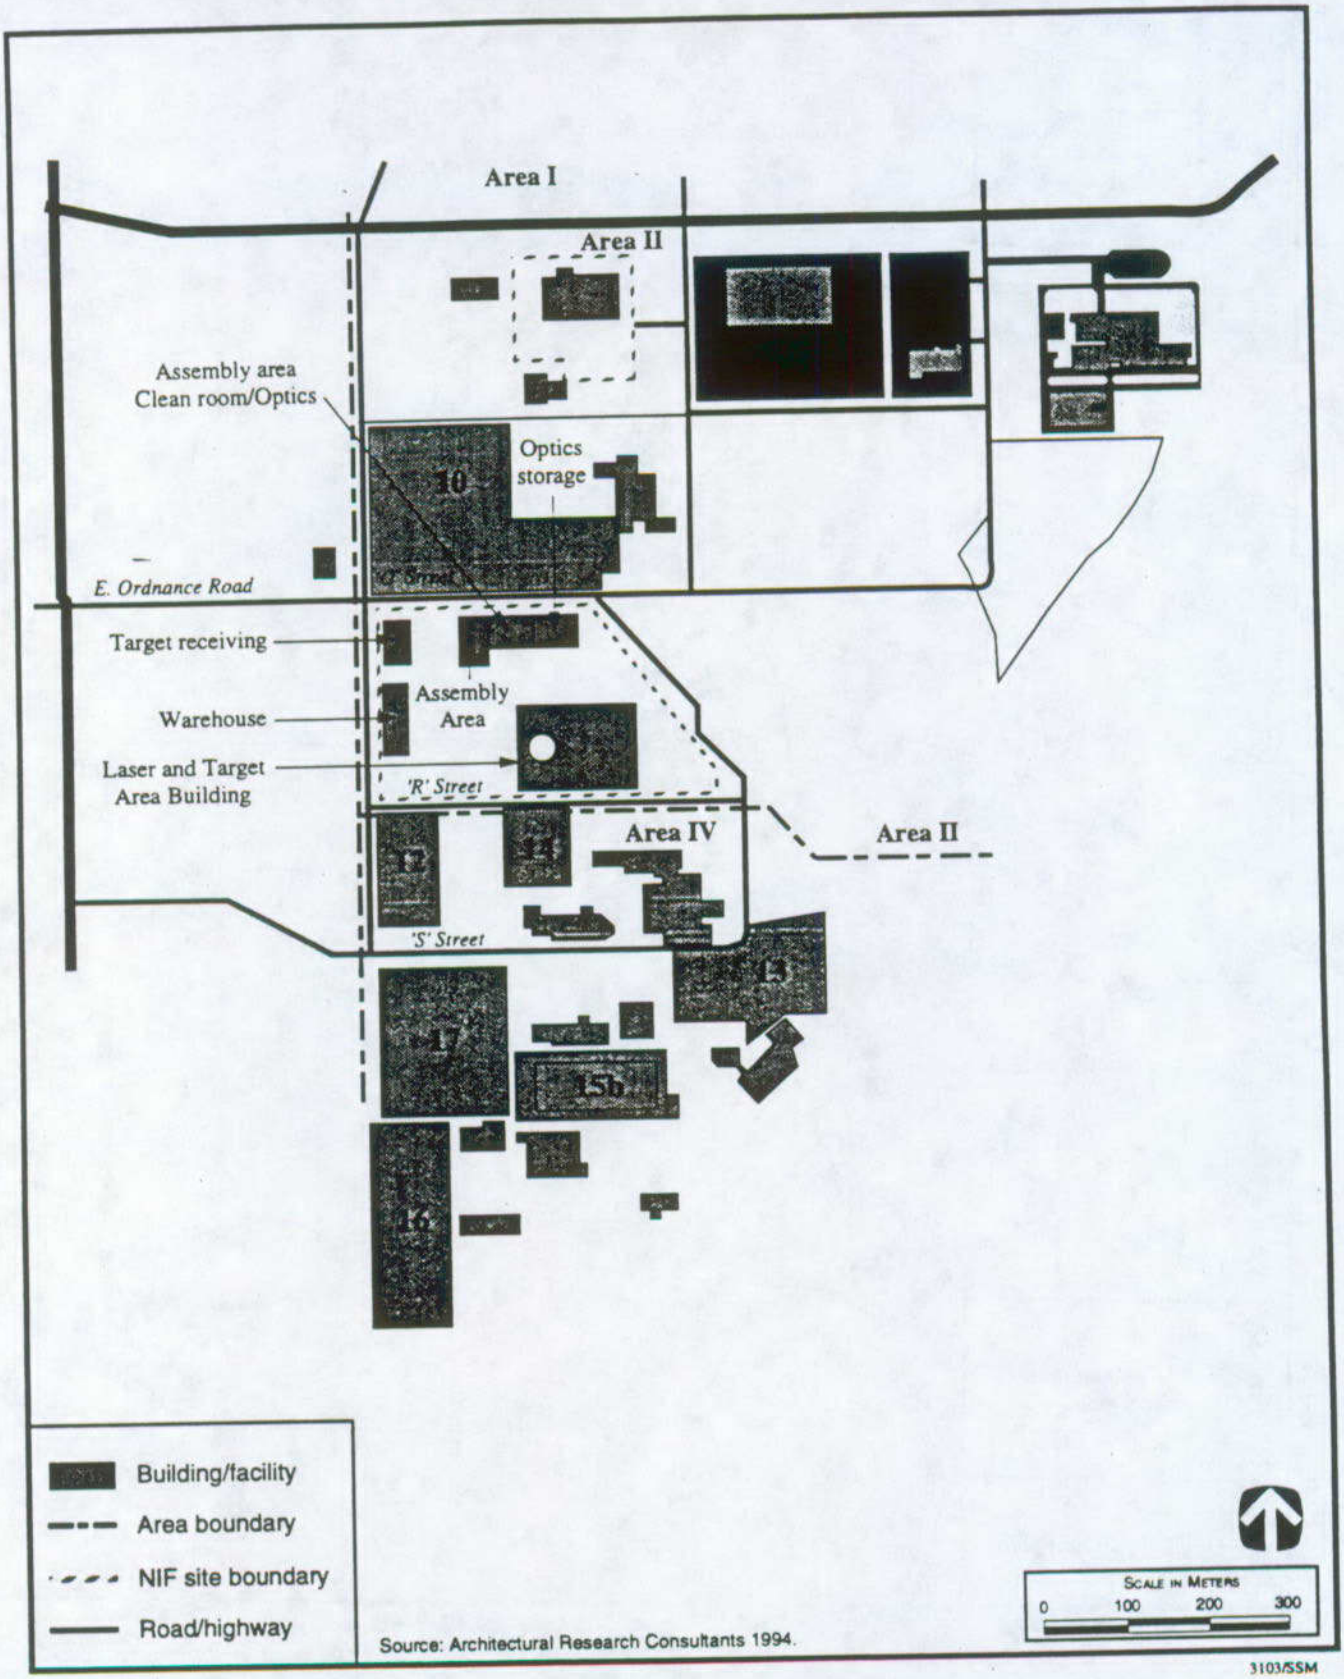


FIGURE I.3.4.5.1–2.—*Proposed Location for the National Ignition Facility at Sandia National Laboratories.*

The National Academy of Sciences recommended that DOE focus the ICF program on achieving an Ignition Facility within about 10 years and concluded that the only driver technology capable of accomplishing that objective within that time period was the solid-state laser. It is also clear that because of the longer required development times and the earlier comparisons between drivers for the Laboratory Microfusion Facility, the integrated cost of the program up to the ignition experiment would be larger for the alternatives than for NIF as designed. The present NIF design incorporates that recommendation. Because of these recommendations and conclusions, the alternative drivers were not considered in detail in this PSA.

Several NIF user proposals for future tests using heavy materials have been identified, but lack sufficient definition to determine if they are feasible or even possible. These proposals include suggestions for tests with fissionable materials (isotopes such as uranium-238 and thorium-232), and users are preparing papers describing these postulated experiments. Initial evaluations indicate that NIF would retain its classification as a low-hazard, radiological facility for postulated experiments with small amounts of these identified fissionable materials. However, at this time, the feasibility of such experiments remains highly speculative, and experiments of this type are not reasonably foreseeable. Thus, such tests are not considered in this document. Furthermore, postulated experiments that use fissile materials (isotopes such as uranium-232, uranium-235, and plutonium-239) are even less defined; no experiments of this type are foreseen in planned NIF operations; and thus they are not considered in this document. DOE recognizes and acknowledges that any future determination to conduct experiments that have implications beyond the currently defined operational envelope and safety analysis would require both additional safety analysis and *National Environmental Policy Act* (NEPA) action, in addition to possible facility modifications.

NIF has been designed to achieve a very large step in development of ICF. When and whether this step of indirectly driven fusion ignition with hydrogen (deuterium and tritium targets) will actually be achieved is not certain. If experiments on the Omega Upgrade Facility are successful in the later 1990s, the next reasonable step is to attempt ignition using directly driven targets on NIF. Both indirectly and directly driven target experiments have been assessed in this PSA in the Enhanced Option mode. NIF, as described in the Conceptual Design Report (LLNL 1994b) and in this PSA, relies on a U-shaped building configuration. Evaluations of costs and engineering of the laser components of NIF have considered other configurations for the Laser and Target Area Building. One such suggestion is for an in-line building. Such a change in building configuration would require realignment of the building at its proposed locations. This realignment would primarily affect the distance of the target chamber to the site boundary. It is likely that such a building configuration would position the target chamber at the same distance or farther from the site boundary, resulting in no change or slightly reduced radiological impact to the public for both normal operations and accident conditions. Because alternative building configuration bounds the upper limits of these impacts, other building configurations are not evaluated in further detail in this PSA.

I.3.6 Summary and Comparison of Impacts

This section summarizes and compares the environmental impacts that would occur from the construction and operation of NIF at the five candidate sites and from the No Action alternative. A comparison of the Conceptual Design Option (indirect drive) with the Enhanced Option (indirect and direct drives) is also provided. Tables I.3.6.1–1 and I.3.6.8–1 compare impacts from the construction and operation of NIF at the candidate sites under both operational scenarios. The following sections supplement the impacts and comparisons summarized in those tables.

I.3.6.1 *Land Use and Visual Resources*

Construction and operation of NIF would be consistent with existing land uses at all of the candidate sites. Table I.3.6.1–1 presents the acreage and percentage of a candidate site's uncommitted land required for NIF and the number of buildings that would have to be constructed at each candidate site. With the exception of foreground view impacts at LANL, only minor visual impacts from NIF construction would occur at the candidate sites.

Facility Accidents (Chemical)						
Distance to end of hazard zone from accident[m] (m)	None	237 (778)	237 (778)	239[l] (784)	237 (778)	237 (778)
Transportation accidents[n] (Radiological)						
Public dose risk (person-rem/yr)	None	$2.2x10^{-6}$ ($1.8x10^{-5}$)	$2.6x10^{-6}$ ($2x10^{-5}$)	$2.4x10^{-6}$ ($1.9x10^{-5}$)	$2.4x10^{-6}$ ($1.9x10^{-5}$)	$1.6x10^{-6}$ ($1.2x10^{-5}$)
Cancer fatalities risk	None	$1x10^{-9}$ ($9x10^{-9}$)	$1x10^{-9}$ ($1x10^{-8}$)	$1x10^{-9}$ ($9x10^{-9}$)	$1x10^{-9}$ ($9x10^{-9}$)	$8x10^{-10}$ ($6x10^{-9}$)
Transportation Impacts (Nonradiological) (Fatalities/Year)[o]						
Vehicular emissions	None	$1x10^{-3}$ ($2x10^{-3}$)	$8x10^{-4}$ ($2x10^{-3}$)	$8x10^{-4}$ ($2x10^{-3}$)	$8x10^{-4}$ ($2x10^{-3}$)	$2x10^{-3}$ ($4x10^{-3}$)
Accidents	None	$2x10^{-3}$ ($4x10^{-3}$)	$2x10^{-3}$ ($4x10^{-3}$)	$2x10^{-3}$ ($6x10^{-3}$)	$2x10^{-3}$ ($5x10^{-3}$)	$2x10^{-3}$ ($4x10^{-3}$)

[a] Value for Enhanced Option is given in parentheses only for parameters that differ from the Conceptual Design Option.

[b] Uncommitted land, as defined by each of the sites, is land that is currently open and available for NIF development. An additional 2 hectares (acres) would be temporarily required for a construction laydown area at LLNL. Construction laydown areas for the other sites would be located within the areas designated for NIF.

[c] Estimated by combining baseline concentrations and NIF contributions based on dust control measures using water spray twice a day (with continuous water spraying and/or chemical dust suppressants for LLNL and NLVF sites).

[d] The 24-hour California state standards for particulate matter 10 microns or smaller (50 $\mu g/m^3$) are more stringent than the national standards (150 $\mu g/m^3$).

[e] No action emissions would be equivalent to baseline emissions provided under the candidate site columns.

[f] Noise levels may be annoying during the peak construction activity associated with site clearing but would not require a hearing conservation plan.

[g] Current water supply capacity would be adequate to meet the additional requirements for NIF.

[h] Areas would be maximum habitat loss assuming total site clearing before any site revegetation or landscaping. An additional 2 hectares (acres) would be temporarily cleared for the construction laydown area at LLNL.

[i] Qualitative estimate of wildlife disturbance based on quality of habitat at and surrounding the NIF location, which influences the number of wildlife species that may be present and the habituation of wildlife to human activities.

[j] Values provided are for the peak construction year only.

[k] The No Action alternative would not have measurable impacts on socioeconomics at the NTS or NLVF sites. However, at LLNL, LANL, and SNL, No Action could result in slightly reduced employment and associated effects. No Action could result in a reduction of 153 jobs (direct and indirect) and 190 fewer trips generated per day at LLNL; a reduction of 27 jobs and 38 fewer trips generated at LANL; and 29 fewer jobs and 38 fewer trips generated at SNL.

[l] Higher public dose for NLVF is due to higher population density near NLVF.

[m] The hazard zone refers to the area downwind of an accident where concentrations would be above emergency planning levels.

[n] Risks are presented from the manufacturing site yielding the largest risks.

[o] Collective population fatalities were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Design). For example, a reported value of $4x10^{-3}$ fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

Note: ND – No data available; NA – Not applicable.

Source: Derived from tables and text contained in appendix I.

I.3.6.2 *Air Quality and Noise*

Short-term (i.e., 24-hour) fugitive dust emissions of particulate matter 10 microns or smaller (PM_{10}) during construction would vary among the candidate sites (table I.3.6.1–1). The PM_{10} from each construction site activity would depend on the local meteorology, soil conditions, and the amount of land disturbed during construction. Windy conditions, dry loose soil, and large area disturbance of land would result in the highest PM_{10} emissions. The construction activity contribution of ambient PM_{10} concentration is additive to the background concentration of PM_{10} when compared to the ambient air quality standard. Thus, the higher the background concentration for the same source contribution, the higher the total concentration. The maximum percent of the Federal or state standard that would occur at the candidate sites would range from a low of 35 percent at SNL to a high of 260 percent at LLNL (table I.3.6.1–1). The latter case is for the more stringent California state standard. Emissions for LLNL would be 87 percent of the Federal standard for PM_{10}.

Annual air pollutant emissions from NIF operations would be primarily from fuel combustion, which is assumed to be the same for all candidate sites. Boiler fuel, the primary source of air pollutant emissions, was assumed to be natural gas for all sites except NTS, which would use liquefied petroleum gas. The effect that NIF operations would have on air pollutant emissions would depend on the candidate site's level of emissions before NIF operations (table I.3.6.1–1). No difference in air quality impacts would exist between the Conceptual Design and Enhanced options.

For all candidate sites, noise impacts would be minor. During construction, localized impacts would be greater for those areas with lower ambient noise values. A high ambient value at NLVF would counteract the short distance from construction activities, leading to no annoying noise at the nearest public residences. At NTS, the ambient noise level is very low, and the distance to the nearest residence is very far; therefore, no noticeable noise impacts from construction would occur. Site clearing would cause minor noise impacts at the other candidate sites (LLNL, LANL, and SNL). Impacts during construction for either the Conceptual Design or Enhanced options would be very minor at nearby site buildings or offsite public residences.

I.3.6.3 *Water Resources*

Operation of NIF would require 152 million liters per year (MLY) (40 million gallons per year) of water under either the Conceptual Design or Enhanced options. This water need would range from 2.8 percent of current water use at LANL to 220 percent of current water use at NLVF (table I.3.6.1–1). The current water supply and wastewater treatment capacities at LLNL are expected to be sufficient to meet the requirements of NIF. Planned utility upgrades would be required at LANL to meet water and wastewater needs. At NTS, a 3.2-km (2.0-mi) underground water pipeline would be required to provide water to the NIF location, and sewage treatment and disposal facilities would have to be constructed. At NLVF, current water supply capacity would be adequate to meet the 220-percent increase in water demand. For SNL, agreement with Kirtland Air Force Base and the city of Albuquerque would be required to obtain additional water supply and to discharge additional wastewater.

I.3.6.4 *Biotic Resources*

The maximum amount of land (and percentage of uncommitted land) that would be required for NIF at each candidate site is summarized under Land Resources in table I.3.6.1–1. These areas can be conservatively viewed as the maximum amount of habitat that would be lost or modified for NIF. The relative disturbance to wildlife from construction of NIF would be related to the quality of habitat that would be impacted by construction. Quality, in turn, is related to the type of habitat within which NIF would be constructed and to the degree of development within the immediate area of NIF at the candidate site.

The NLVF site has the most disturbed habitat, and it is also the most developed among the candidate sites. Expected impacts to biota at NLVF would be negligible, with no impacts expected to rare, threatened, or endangered species. The vegetative communities at LLNL and SNL are more developed than at NLVF, but are still indicative of formerly disturbed sites. The areas surrounding these two sites have also been partially developed. Thus, impacts to biota at these two candidate sites would be minor. Because habitats at these two sites could be used by rare, threatened, or endangered species (but are not preferred habitats), the potential for negligible impacts to listed species exists at these sites. NIF locations at LANL and NTS would be within higher-quality habitats (forested and desert habitats, respectively) than occur at the other candidate sites. Also, these two sites do not have extensive developments in the immediate area. Thus, impacts to biota at these two sites would be considered moderate, with a minor chance of impacts to rare, threatened, or endangered species. There would be no difference in impacts to biotic resources between the Conceptual Design and the Enhanced options.

I.3.6.5 *Cultural and Paleontological Resources*

No impacts would be expected to archaeological sites, historic structures, important paleontological remains, or Native American cultural resources at any of the candidate sites. However, a field survey is in progress at NTS to determine if prehistoric or historic archaeological sites occur in the area proposed for NIF. If any significant sites are found, mitigation measures would be developed in consultation with the Nevada State Historic Preservation Officer.

I.3.6.6 *Socioeconomics*

Data on the peak number of jobs, in-migrating population, number of housing units required, increase in local jurisdiction (revenues and expenditures), and number of daily vehicle trips associated with the construction of NIF at the candidate sites are provided in table I.3.6.1–1. Traffic congestion increases would be expected at LLNL, LANL, NLVF, and SNL.

Slight disproportionate effects could occur to minority populations at LANL and NLVF. No other disproportionate affects to minority and/or low-income populations due to NIF construction and operation would be expected. The construction and operation of NIF is not projected to cause major adverse environmental or human health impacts at four of the five candidate sites. Consequently, no environmental justice issues would be likely at those four sites. However, a cancer fatality is projected within the impact zone for the NLVF site under accident conditions (table I.3.6.1–1). The minority population within the impact zone and close to NLVF site is disproportionately large compared with the population of Nevada as a whole. Thus, there would be a potential environmental justice issue for the NLVF site should NIF be constructed and operated there.

I.3.6.7 *Radiation and Hazardous Chemicals*

NIF would be considered a low-hazard, radiological facility. Such a facility uses radionuclides (for nonreactor purposes) and has other hazards (such as chemicals needed at the facility). Being low-hazard implies that there are minor on site and negligible offsite consequences. Potential radiological impacts from normal NIF operations to the general public surrounding all candidate sites would be inconsequential. Estimated radiation doses vary among sites. The greatest calculated radiation dose for the entire operational life of NIF is 18 person-rem to the general public. No cancer fatalities would be expected to occur. Radiological impacts from the Conceptual Design Option would be about one-third of those from the Enhanced Option.

Under postulated accident conditions, radiological impacts to the public and workers would be minor. The highest calculated radiation dose is 4,900 person-rem. At most, two cancer fatalities could occur if an accidental release occurred. Because of the extremely low accidental release frequency ($2x10^{-8}$/yr), the risk of radiation-caused cancer fatalities from the postulated accident at any site is essentially zero. Radiological impacts from the postulated accident under the Conceptual Design Option would be about one-half of those under the Enhanced Option.

During transportation of the targets, there would be essentially no radiological impacts to the public. The risk of fatality due to physical trauma from transportation accidents would also be negligible. Impacts would be similar among all target manufacturing sources to target use site pairs because the risks would be dominated by truck transportation from the sites to the nearest airports. The larger variable distance between airports would not contribute significantly to the risk because of lower accident probabilities associated with flying compared with driving.

A wide range of nonradiological chemical releases were considered from operation of NIF. Four release scenarios were identified as having the potential for the greatest worker and offsite consequences. The modeling of each of the scenarios for each candidate site revealed that no offsite nonradiological impacts would occur. Concentration values above the level that would cause irreversible health effects would only occur within about 200 m (655 ft) from a release point. For the most part, workers inside other buildings within the 200-m (655-ft) radius from a nonradiological chemical release would be protected by the building structures themselves. Protective action distances would be only slightly less for the Conceptual Design Option than for the Enhanced Option.

I.3.6.8 *Waste Management*

Table I.3.6.8–1 compares waste management at the candidate sites. The low-level solid radioactive wastes generated by NIF would be handled in a similar manner at LLNL, NLVF, and SNL. It is currently planned that low-level solid radioactive waste would be treated and disposed of at an onsite treatment facility that is planned for completion in 1997. The mixed wastes would be disposed of at the mixed waste disposal unit currently being planned at NTS for wastes that meet *Resource Conservation and Recovery Act* (RCRA) land disposal requirements. If these two treatment facilities are not available when needed, the wastes could be stored onsite for up to one year or shipped to offsite facilities capable of treating and disposing of low-level radioactive wastes and mixed wastes. Hazardous wastes would be sent offsite to a permitted treatment, storage, and disposal facility. Wastes at these three sites would be shipped to and disposed of at NTS and low-level liquid radioactive wastes and mixed wastes generated by NIF at NLVF would be treated and disposed of at treatment and disposal facilities currently being planned to be built at NTS. The State of Nevada has filed a lawsuit objecting to the acceptance of radioactive (mixed and low-level) wastes at NTS without DOE developing a site-wide EIS under NEPA (*State of Nevada* v. *Hazel R. O'Leary, United States Department of Energy*, Docket: CV-S-94-00576-PMP [RLH]). DOE issued a Draft EIS for NTS and offsite locations in the State of Nevada (DOE/EIS 0243) in January 1996 (see section 1.7.5.). DOE expects to issue an ROD by the time any NIF-generated waste would be available for shipment to NTS. NTS is currently accepting low-level radioactive waste streams from certain existing shippers. Also under an agreement between DOE and the State of Nevada, no mixed waste from offsite is currently being accepted for storage or disposal at NTS. NTS has submitted a revised Part B Permit application to include a separate storage and disposal unit for solid mixed wastes. Such application is currently pending action by the Nevada Division of Environmental Protection.

The following discussions on environmental impacts of waste management assume that NTS will accept offsite waste shipments from NIF. If these facilities are not available when needed, the wastes from NIF could be shipped to offsite commercial facilities. The hazardous wastes generated by NIF operations at the three sites would be sent to an offsite commercial disposal facility.

The majority of low-level radioactive waste generated at LANL would be managed and disposed of onsite. Some of the mixed wastes would be treated onsite in a hazardous waste treatment facility that is planned for LANL. The mixed waste that could not be treated onsite would be transported to NTS for treatment and disposal when NTS has received an appropriate permit from the State of Nevada. The hazardous waste generated by NIF at LANL would be treated, stored, and disposed of at facilities currently in operation or being constructed at LANL.

At NTS, solid low-level radioactive wastes would be disposed of onsite. Low-level radioactive liquid waste would be treated and disposed of at an onsite treatment facility that is planned for completion in 1997. The mixed wastes would be disposed of at the mixed waste disposal unit currently being planned at NTS for wastes that meet RCRA land disposal requirements. If these two treatment facilities are not available when needed, the wastes could be stored onsite for up to one year or shipped to offsite facilities capable of treating and disposing of low-level radioactive wastes and mixed wastes. Hazardous wastes would be sent offsite to a permitted treatment, storage, and disposal facility.

I.4 AFFECTED ENVIRONMENT AND ENVIRONMENTAL IMPACTS

I.4.1 Lawrence Livermore National Laboratory

I.4.1.1 *Affected Environment*

The following sections describe the affected environment associated with the construction and operation of the National Ignition Facility (NIF) at Lawrence Livermore National Laboratory (LLNL). Land use, air quality and acoustics, water resources, biotic resources, cultural and paleontological resources, socioeconomics, radiation and hazardous chemicals, and waste management are described.

I.4.1.1.1 Location and Land Use

The LLNL 332-hectare (ha) (821-acre) site is east of the city of Livermore, California; immediately to the south is Sandia National Laboratories (SNL), Livermore (figure I.3.4.1.1–1). Although their primary missions are similar, LLNL and SNL are separate facilities. Also located south of LLNL are agricultural areas devoted to grazing, orchards and vineyards, some low-density residential areas, and a business park to the southwest. A very small amount of low-density residential development lies east of LLNL, and a business park is located to the north. A parcel of open space to the northeast has been rezoned to allow development of a center for heavy industry (LLNL 1994d). A high-density residential area lies west of the site. Figure I.4.1.1.1–1 shows generalized land use at LLNL and vicinity.

The majority of the LLNL site is designated "industrial," and the perimeter areas on the western and northern portions of the site are designated "industrial" or "agricultural." The southwestern and southeastern quadrants of the site are the most crowded. The proposed location for NIF at LLNL is in the northeastern quadrant of the site adjacent to existing inertial confinement fusion (ICF) facilities (figure I.3.4.1.1–2).

Slopes at the LLNL site are nearly level. Soils are loamy textured, shallow to very deep soils occur on older fans and floodplains. The erosion potential is slight to moderate. No prime or unique farmland soils are located at LLNL.

I.4.1.1.2 Air Quality and Acoustics

This discussion of existing air quality and acoustics includes a review of the meteorology, climatology, and atmospheric dispersion characteristics near LLNL. No meteorological data were available for the proposed NIF location, so the nearest local and regional monitoring information was used to describe expected site conditions.

I.4.1.1.2.1 *Meteorology and Climatology*

The climate at LLNL and the surrounding region is characterized by mild, rainy winters and warm, dry summers. The annual average temperature at LLNL is 15.0 degrees Celsius (°C) (59.0 degrees Fahrenheit [°F]); average daily temperatures range from 7.9 °C (46.2 °F) in January to 21.0 °C (69.8 °F) in July. The average annual precipitation is 37.8 centimeters (cm) (14.9 inches [in]) (LLNL 1995a). The prevailing winds are from the southwest to west at an annual average wind speed of 3.3 meters per second (m/s) (7.4 miles [mi] per hour [hr] [mph]) (LLNL 1992). The 1994 annual wind rose for LLNL is shown in figure I.4.1.1.2.1–1. During 1994, unstable conditions occurred approximately 29 percent of the year, neutral conditions occurred about 35 percent of the year, and stable conditions occurred the remaining 36 percent (LLNL 1995d). Atmospheric dispersion improves as the wind speed increases and atmospheric conditions become more unstable.

I.4.1.1.2.2 *Ambient Air Quality*

National Ambient Air Quality Standards (NAAQS) exist for the criteria air pollutants ozone, carbon monoxide, nitrogen dioxide, sulfur oxides (measured as sulfur dioxide), particulate matter with a diameter of less than 10 microns (PM_{10}), and lead (40 *Code of Federal Regulations* [CFR] 50). California has established state ambient air quality standards for these pollutants, as well as standards for suspended sulfates, hydrogen sulfide, vinyl chloride (chloroethene), and visibility reducing particles. In addition, the Bay Area Air Quality Management District (BAAQMD) has established a monthly ambient concentration limit for beryllium (LLNL 1994d), which is the same as the National Emission Standard for Hazardous Air Pollutants for beryllium (40 CFR 61.32). Applicable NAAQS and California state and BAAQMD ambient air quality standards are presented in table I.4.1.1.2.2–1.

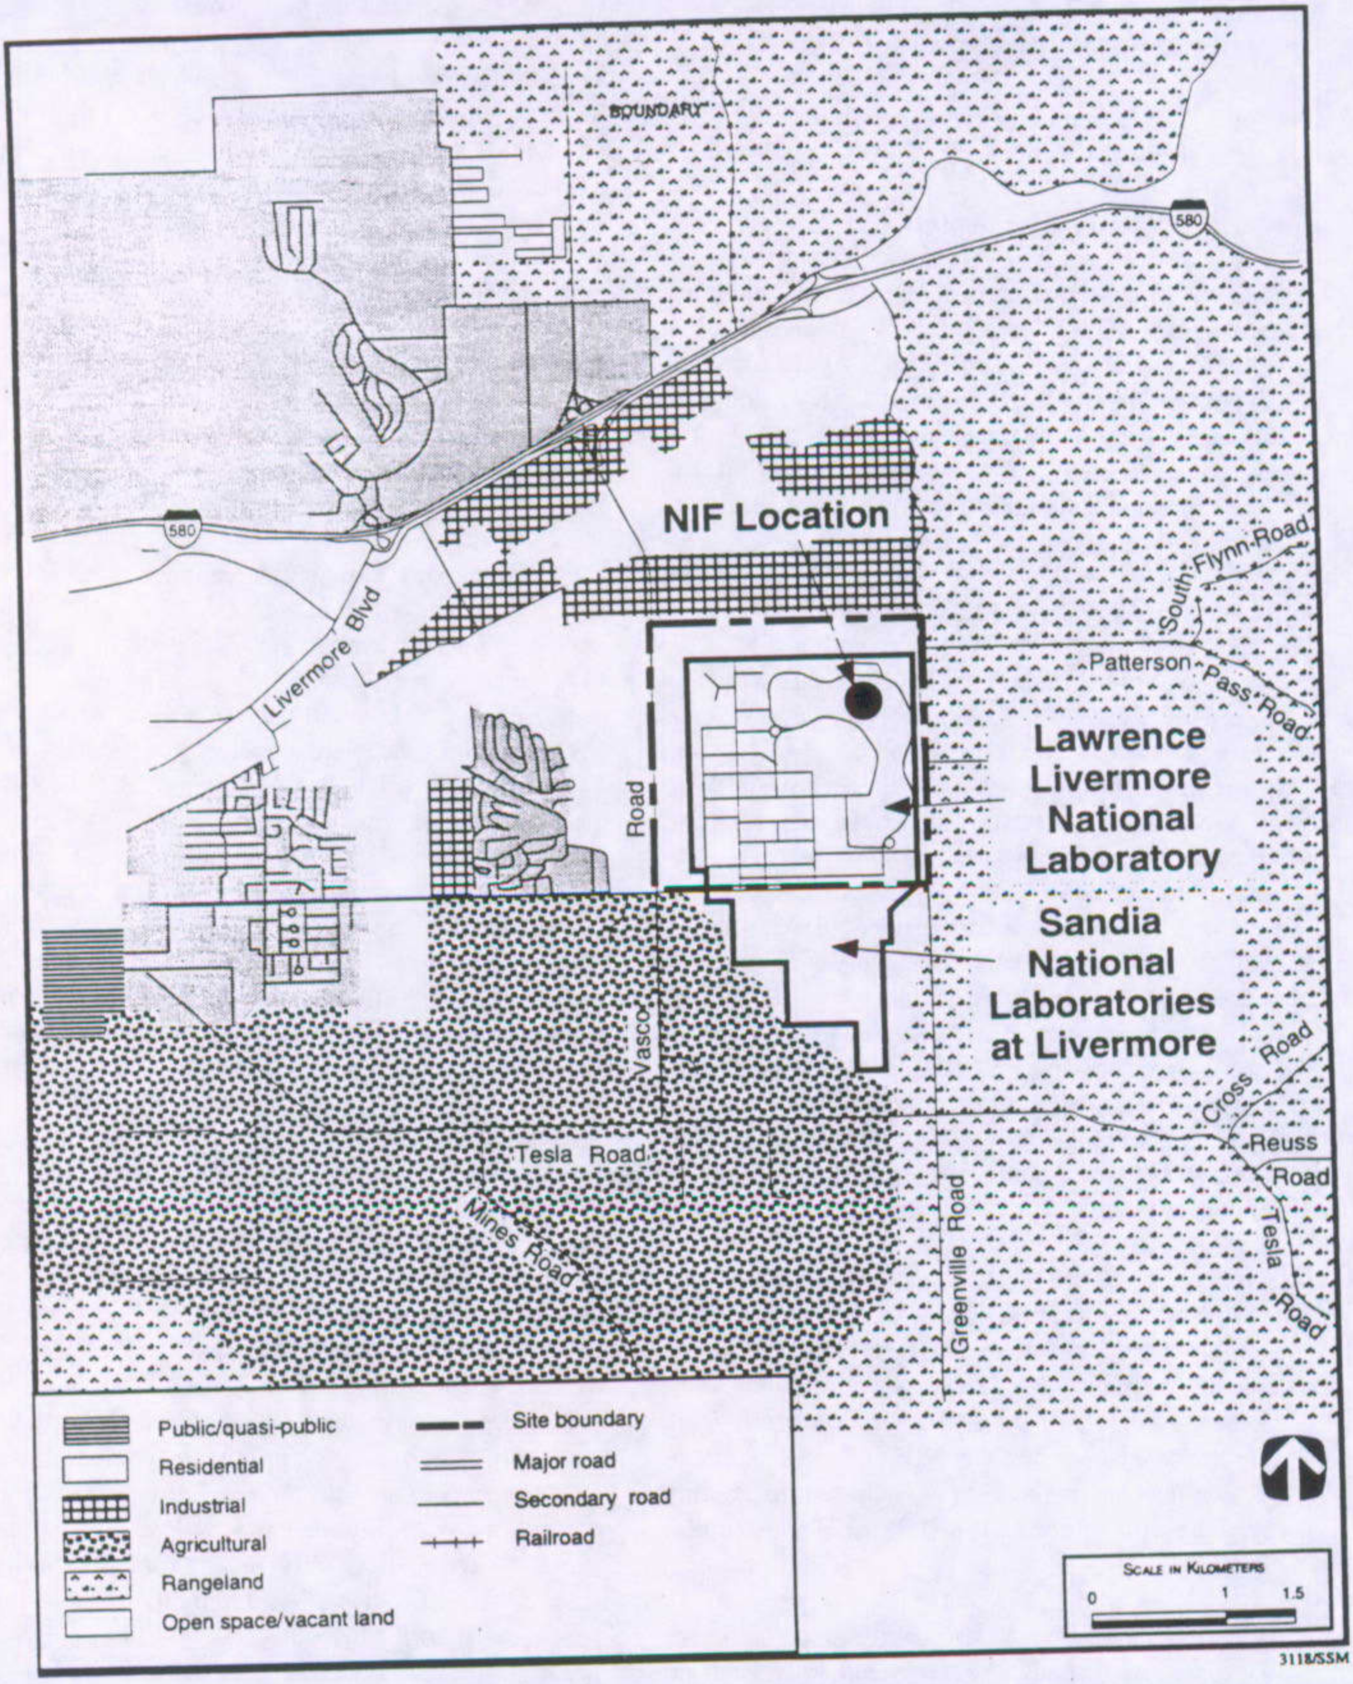

FIGURE I.4.1.1.1–1.—*Generalized Land Use at Lawrence Livermore National Laboratory and Vicinity.*

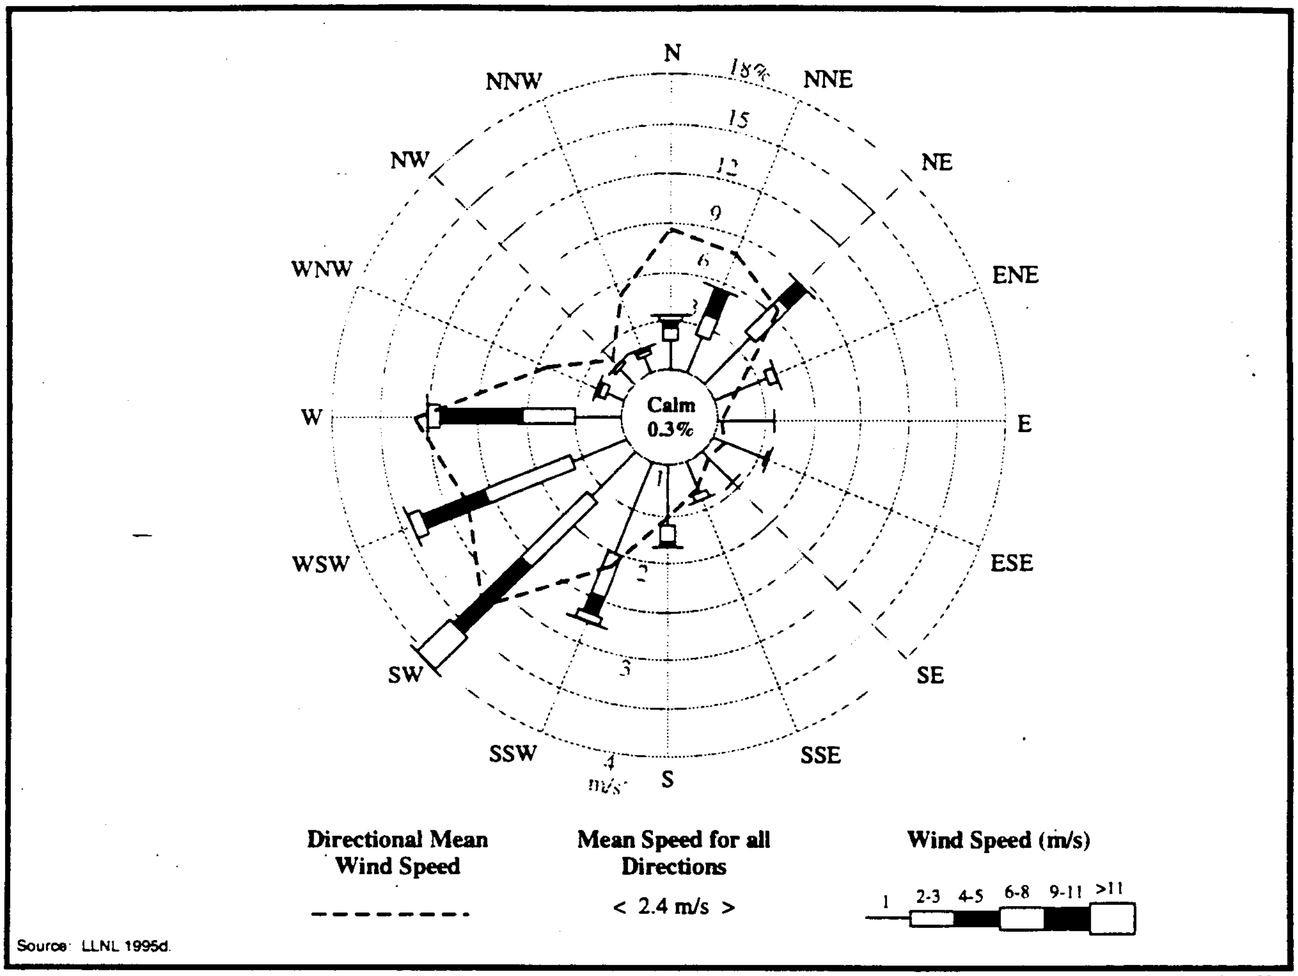

FIGURE I.4.1.1.2.1–1.—*Wind Distribution at Lawrence Livermore National Laboratory, 1994.*

LLNL is located within the San Francisco Bay Area Basin, designated by the Federal Government as the San Francisco Bay Intrastate Air Quality Control Region (AQCR 30). The Bay Area Basin is in attainment for all national ambient air quality standards except carbon monoxide in an urban area that includes the northern tip of Alameda County (40 CFR 81.305). This nonattainment area does not include LLNL. The Bay Area Basin is designated nonattainment for the state ozone and PM_{10} and has an unclassified state designation for hydrogen sulfide and visibility reduction (CARB 1994). (With the exception of one county designated as attainment and four counties and part of a fifth county designated as unclassified, all of California is designated as nonattainment for the state 24-hour PM_{10}.) In general, pollutant emission increases in an area designated nonattainment for a specific pollutant are subject to more stringent permitting requirements than if the area is designated as attainment.

The BAAQMD is responsible for air pollution control from stationary sources and attainment of air quality standards in the San Francisco Bay Area, including Alameda County. The district operates ambient air monitors throughout the San Francisco Bay Area Air Basin to determine compliance with national and state ambient air quality standards. The BAAQMD monitor closest to LLNL is the Livermore Old First Street Station located in downtown Livermore. In addition, LLNL maintains 8 onsite and 11 offsite particulate monitors that measure airborne beryllium concentrations. The most recently published data show violations in calendar year 1993 of the state and national ozone standards and the state 24-hour PM_{10} standard (see table I.4.1.1.2.2–1 and Lazaro et al. 1996).

Federal Prevention of Significant Deterioration (PSD) regulations limit increases in criteria pollutant concentrations resulting from emissions from new

TABLE I.4.1.1.2.2–1.—***Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Lawrence Livermore National Laboratory***

Pollutant	Averaging Time	Most Stringent Regulation or Guideline ($\mu g/m^3$)	1993 Baseline Concentration[a] ($\mu g/m^3$)
Criteria Pollutant			
Carbon monoxide	8-hour	10,000[b,c]	4,600
	1 hour	23,000[c]	7,000
Lead	Calendar quarter	1.5[b]	0.01
	30-day	1.5[c]	0.01
Nitrogen dioxide	Annual	100[b]	36
	1 hour	470[c]	210
Ozone	1 hour	180[c]	250 [d]
Particulate matter 10 microns or smaller	Annual arithmetic mean	50[c]	24.3
	Annual geometric mean	30[c]	20.9
	24-hour	50[c]	84 [d]
Sulfur dioxide	Annual	80[b]	ND [e]
	24-hour	105[c]	ND
	3-hour	1,300[b]	ND
	1 hour	655[c]	ND
Mandated by State			
Hydrogen sulfide	1 hour	42	ND
Suspended sulfates	24-hour	25	6.9
Vinyl chloride (chloroethene)	24-hour	26	ND
Visibility-reducing particles	8-hour (10 a.m.-6 p.m. PST)	[f]	ND
Mandated by BAAQMD			
Beryllium	30-day	0.01	0.000137
Other Air Pollutants			
Particulate ammonium-10μm	24-hour	NS[g]	1.50
Particulate chloride-10μm	24-hour	NS	3.61
Particulate nitrate-10μm	24-hour	NS	20.8
Particulate sulfate-10μm	24-hour	NS	4.7
Suspended nitrates	24-hour	NS	22.5
Total suspended particulates	24-hour	NS	93.0

[a] For short-term standards, baseline concentration is highest concentration for year for state standards, second highest for Federal standards.
[b] Federal standard (40 CFR 50).
[c] State standard.
[d] Exceeds most stringent regulation or guideline.
[e] ND - no data available.
[f] In sufficient amount to produce an extinction coefficient of 0.23 per km due to particles when the relative humidity is less than 70 percent.
[g] NS - no data available.

Source: CARB 1993; Lazaro et al. 1996; LLNL 1994a.

sources above a baseline concentration. The allowable concentration increases (called increments and presented in Lazaro et al. 1996), depend on the PSD classification of the area. Class I areas allow the smallest increases. The area surrounding LLNL contains several PSD Class I areas. The closest such areas are Point Reyes National Wilderness Area, approximately 90 kilometers (km) (55 miles) to the west-northwest; Desolation National Wilderness Area and Mokelumme National Wilderness Areas (160 to 180 km [100 to 110 mi]) to the northeast; and Emigrant National Wilderness Area, Hoover National Wilderness Area, and Yosemite National Park (215 to 230 km [135 to 145 mi]) to the east-northeast and east.

The primary emission sources of criteria pollutants at LLNL are numerous boilers, solvent cleaning operations, stand-by electric generators, and various experimental, testing, and process sources. Emissions estimates for these sources are presented in section I.4.1.2.2.

I.4.1.1.2.3 *Acoustic Conditions*

Major noise emission sources within LLNL include various experimental facilities, equipment, and machines. LLNL is bordered by highways along its entire boundary. In the vicinity of a highway, traffic contributes to ambient noise levels, especially during peak hours. Across the highways bordering the site, the main land uses are light industrial to the north and south, urban residential to the west, agricultural to the southwest, and open rangeland to the east. The acoustic environment along the LLNL boundary is generally assumed to be that of an urban location, with typical average daytime sound levels of 55 to 65 decibel A-weighted (dBA).

I.4.1.1.3 Water Resources

The LLNL site is in the eastern Livermore Valley. Only intermittent streams flow into the eastern Livermore Valley from the surrounding uplands and low hills. Two intermittent streams flow through the LLNL site: Arroyo Las Positas and Arroyo Seco (figure I.4.1.1.3.–1). The proposed NIF location is in the drainage of Arroyo Las Positas. Arroyo Las Positas drains an area of 13.3 square kilometers (km^2) (5.16 square miles [mi^2]) east of the LLNL site. The channel is not well defined and usually carries only storm runoff. The channel enters the site from the east, is diverted along a ditch around the northern edge of the site, and exits the site at the northwestern corner. Arroyo Seco has a drainage area of 36.3 km^2 (14.0 mi^2) upstream of Sandia National Laboratories, Livermore. The headwaters of the arroyo are in the hills southeast of the LLNL site. The channel is well defined in the LLNL area and is dry for at least six months of the year.

Surface drainage and infiltration at LLNL are generally good, but infiltration decreases locally with increasing clay content in soils (U.S. Department of Energy [DOE] and University of California [UC] 1992). About one-fourth of stormwater runoff within the LLNL site drains into the Central Drainage Basin (figure I.4.1.1.3.–1), which collects runoff from the southeastern quadrant of the LLNL site. During extreme wet weather, the basin can overflow through culverts into storm drains that discharge into Arroyo Las Positas. The remainder of the site drains either directly or indirectly into the two arroyos through storm sewers and ditches (DOE and UC 1992; LLNL 1994d).

Groundwater at the LLNL site occurs in an unconfined zone overlying a series of semiconfined aquifers. The two geologic units containing the most important aquifers are the surface valley-fill deposits and the Livermore Formation. The aquifers in the Livermore Valley are locally recharged by precipitation, irrigation, stream runoff from precipitation, and controlled releases from the South Bay Aqueduct and gravel pits west of the city of Livermore. Groundwater withdrawal from the Livermore Valley is mainly for agricultural use, municipal use, and gravel quarrying. In the vicinity of the LLNL site, agricultural withdrawal is still a major source of groundwater drawdown. Depth to groundwater at the LLNL site varies from about 34 m (110 feet [ft]) in the southeast corner to 9 m (30 ft) in the northwest corner (DOE and UC 1992).

Water used at LLNL (including Sandia National Laboratories, Livermore) is primarily surface water purchased from the city of San Francisco Hetch Hetchy Aqueduct and from the Alameda County Flood and Water Conservation District, Zone 7. A small amount of treated groundwater is used for irrigation and cooling tower makeup. In 1990, 983 million liters (L) (260 million gallons [gal]) and

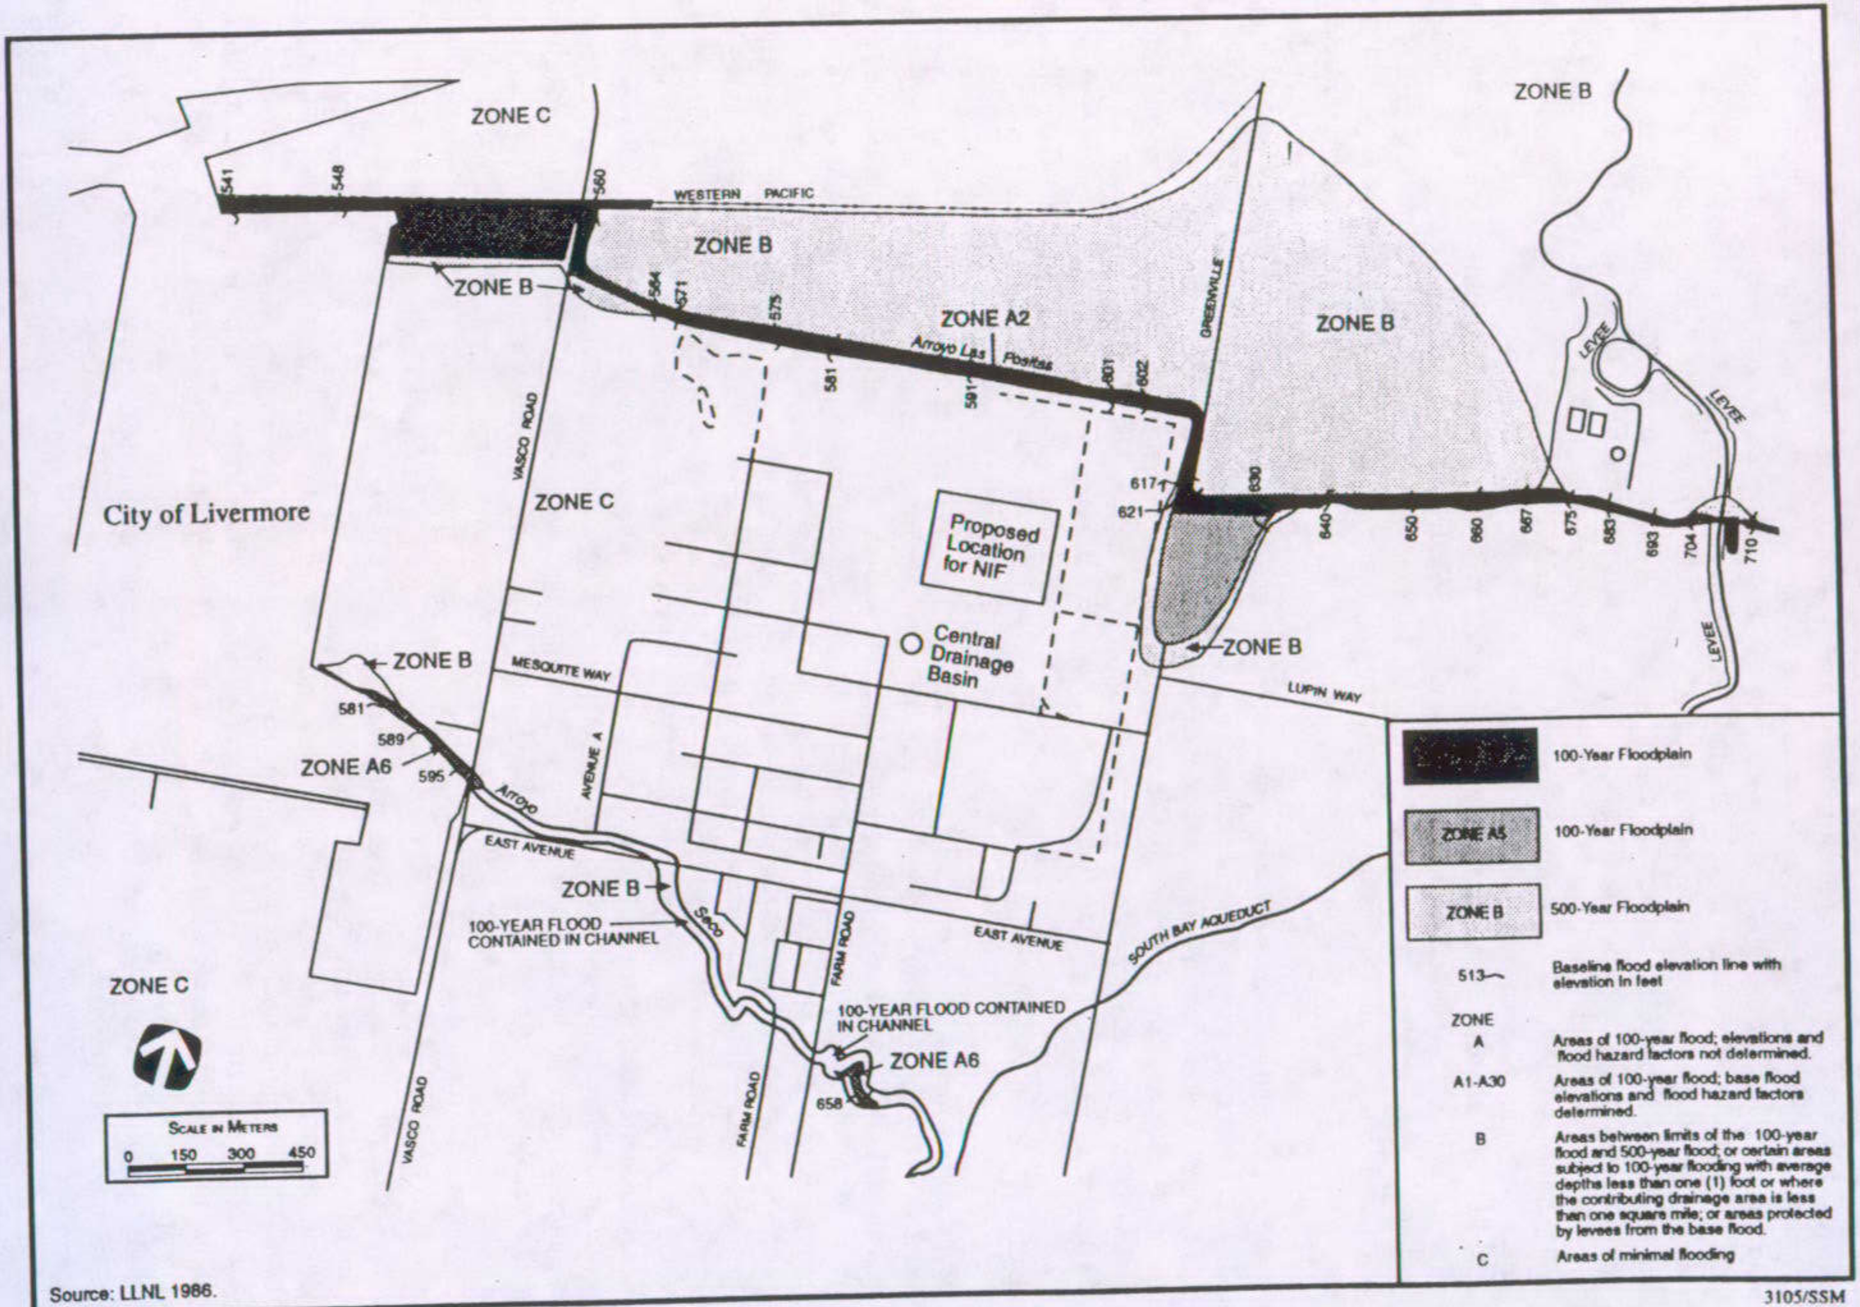

FIGURE I.4.1.1.3–1.—*Surface Water Features, Including Floodplain Map, of the Lawrence Livermore National Laboratory Area.*

74.1 million L (19.6 million gal) of water were obtained from the two sources, respectively. The water is primarily used for industrial cooling processes, the sanitary system, and irrigation. The LLNL site (excluding Sandia National Laboratories, Livermore) currently uses 970 million liters per year (MLY) (256 million gallons per year [MGY]) annually (LLNL 1995c) and used an average of 990 MLY (262 MGY) from 1986 through 1990 (DOE and UC 1992).

Beginning in 1988, LLNL started implementing water conservation measures such as (1) reducing landscape watering by 35 percent below the projected 1989 level, (2) reducing blowdown from cooling towers to minimal operable levels, (3) limiting use of water for car washes, and (4) eliminating the washing of sidewalks and driveways (DOE and UC 1992).

The city of Livermore Water Reclamation Plant handles sewage from the LLNL site and Sandia National Laboratories, Livermore. The plant currently receives an average of 6.205 MLY (1.643 MGY). The facility is being expanded to treat 11.753 MLY (3.103 MGY) (DOE and UC 1992). LLNL discharges about 402 MLY (110 MGY) of wastewater to the city of Livermore sewer system. This volume includes wastewater from Sandia National Laboratories, Livermore, which is discharged into the LLNL sewer system. LLNL tests and pretreats all wastewater before it leaves the site.

I.4.1.1.4 Biotic Resources

LLNL is within the Southern and Central California Plains and Hills Ecoregion (Omernik 1986). This ecoregion is dominated by annual grasslands. A generalized overview of the habitats and biota that occur at LLNL are provided by DOE and UC (1992). Agricultural, industrial, and residential developments have limited the diversity of wildlife in the area of LLNL. About 259 ha (640 acres) (78 percent) of the 332-ha (821-acre) LLNL site is developed. The developed portions of LLNL are planted with ornamental vegetation and lawns; the undeveloped lands in the security areas (including the proposed NIF and laydown locations) are primarily dominated by nonnative grasses and forbs. Common plant species include ripgut brome, slender oat, star thistle, Russian thistle, turkey mullein, sweet fennel, and Italian ryegrass (DOE and UC 1992). Relatively small areas of other habitats at LLNL hold a special significance, either because of their uniqueness or because of their importance as habitat to biota. These areas are primarily limited to remnant riparian habitats in Arroyo Seco along the southwestern corner of LLNL. These areas contain native tree species such as red willow and California walnut and introduced species such as black locust and almond (DOE and UC 1992). No wildlife refuges or sanctuaries occur at LLNL.

The wildlife of LLNL consists primarily of species adapted to habitats that have been disturbed by humans and that are tolerant of human presence (DOE and UC 1992). Common species at LLNL include the western fence lizard, western meadowlark, American crow, American robin, Anna's hummingbird, white-throated swift, California quail, house sparrow, scrub jay, European starling, house finch, house sparrow, desert cottontail, black-tailed jackrabbit, feral house cat, and California ground squirrel. Raptors that have been observed at LLNL include the red-tailed hawk, Cooper's hawk, sharp-shinned hawk, ferruginous hawk, red-shouldered hawk, black-shouldered kite, American kestrel, burrowing owl, turkey vulture, and golden eagle. Red and gray foxes, coyotes, and raccoons are also known to exist throughout LLNL (DOE and UC 1992).

Wetlands at LLNL are limited to three small areas totaling 0.15 ha (0.36 acre) located at, and downstream from, culverts (DOE and UC 1992). Saltgrass and sedge dominate the two wetlands that exist along Arroyo Las Positas; the other wetland is dominated by cattails, with saltgrass and sedge also existing. Other plant species existing in these wetlands include willow, curly dock, ryegrass, and Hooker's evening primrose. These wetlands are located 300 m (1,000 ft) and more from the proposed NIF construction area.

Aquatic habitats are limited to intermittent drainages (in the two arroyos that cross the site), ditches, and a 1.6-ha (4-acre) water retention basin at LLNL. The water retention basin, located southwest of the proposed NIF location near the center of LLNL, is the only water body that contains fish (mosquito fish). It also could provide habitat suitable for waterfowl, tricolored blackbirds, sensitive amphibians, and sensitive aquatic invertebrates. Runoff from this basin could eventually increase riparian habitat within Arroyo Las Positas (DOE and UC 1992). Kingfishers and pied-billed grebes have been observed at the basin (LLNL 1994d).

A list of rare, threatened, and endangered Federal and state species that could exist at LLNL is provided in Lazaro et al. (1996). Most of the listed species would be more likely to exist in the less disturbed habitats of LLNL, although several of the species could forage or inhabit the grassland habitat identified for NIF and/or laydown locations (such as western burrowing owls). During detailed surveys conducted in 1991, no sensitive species were encountered at LLNL (DOE and UC 1992). During the summer of 1994, a nesting pair of white-tailed kites, a state-protected species, was noted in a stand of eucalyptus trees near the East Gate (LLNL 1994a). No designated critical habitats for federally listed species exist at LLNL.

I.4.1.1.5 Cultural and Paleontological Resources

No prehistoric or historic archaeological sites or historic structures exist on the proposed locations for NIF at LLNL. The uppermost 0.6 to 1.2 m (2 to 4 ft) of sediment at the proposed site is composed of redeposited fill that would not contain any undisturbed archaeological remains. Results of an intensive pedestrian survey (employing 15 m [50 ft] transects) conducted in July 1990 noted the disturbed character of the surficial sediment and absence of archaeological remains (Bennett 1994). The fill unit overlies alluvium of Pleistocene age that was deposited at least 15,000 years ago (Dresen and Weiss 1985) and thus antedates the earliest documented human settlement in the region (therefore, has little or no probability of containing archaeological remains). Paleontological remains (which would represent late Quaternary fauna) have not been recovered from the alluvium (Dresen and Weiss 1985). Consultation is in progress with Native American groups to identify any important cultural resources on LLNL.

I.4.1.1.6 Socioeconomics

Socioeconomic characteristics discussed here include the regional economy, population and housing, public finance and public service infrastructure, and local transportation. Regional economic statistics are based on a regional economic study area that encompasses 22 counties around LLNL, as defined by the U.S. Bureau of Economic Analysis (BEA). The economic study area is a broad labor and product market-based region linked by trade among economic sectors within the region. Statistics for population and housing, public finance, and public service infrastructure are based on the region of influence (ROI), a three-county area (Alameda, Contra Costa, and San Joaquin counties) in which nearly 93 percent of all LLNL employees reside. Lazaro et al. (1996) lists counties included in the economic study region and the counties included in the ROI. Assumptions, assessment methodologies, and supporting data for each technical area are also presented in Lazaro et al. (1996).

I.4.1.1.6.1 *Regional Economy*

The regional economic study area for LLNL includes the San Francisco-Oakland-San Jose Consolidated Metropolitan Statistical Area, consisting of the following Primary Metropolitan Statistical Areas: Oakland, San Francisco, San Jose, Santa Cruz, Santa Rosa-Petaluma, and Vallejo-Fairfield-Napa. Between 1988 and 1995, employment in the economic study area was projected to increase from 4,555,600 to 5,117,400. BEA projects a compounded average annual rate of growth of 1.2 percent from 1995 to 2003 (527,124 jobs) (BEA 1990). The unemployment rate in the area is expected to decrease from 6.5 percent in 1995 to 4.4 percent in 2010 (Association of Bay Area Governments 1993).

In 1995, LLNL employed approximately 8,300 people, accounting for 0.2 percent of employment in the regional economic study area. The distribution of LLNL employees by place of residence in the ROI is presented in Lazaro et al. (1996).

I.4.1.1.6.2 *Population and Housing*

The ROI has experienced significant population growth between 1980 and 1990, with an average annual increase of about 2 percent, bringing the 1990 total to about 2.5 million. By the year 2000, population in the ROI is expected to grow to approximately 2.9 million (U.S. Department of Commerce 1994; BEA 1990).

Between 1980 and 1990, the number of housing units in the ROI increased approximately 19 percent, from

832,559 to 986,553 (see table I.4.1.1.6.2–1). The number of housing units in Alameda County increased from 444,607 units in 1980 to 504,109 units in 1990 (13.4 percent). Housing units in Contra Costa County increased from 251,917 units in 1980 to 316,170 units in 1990 (25.5 percent). Housing units in San Joaquin County increased from 136,001 units in 1980 to more than 166,274 units in 1990 (22.3 percent). The number of housing units in the ROI is expected to increase about 16 percent over the period 1990 to 2000. The rental vacancy rate in the ROI is approximately 5 percent (U.S. Department of Commerce 1994; Urban Land Institute [ULI] 1995).

The residential building permit volume within the ROI remained strong between the mid- to late-1980s; however, with the national and local recession and a slowing of new household formation, permit volume in the region dropped between 1990 and 1993. The market rebounded somewhat in 1994. The largest percent of new construction within the ROI since 1989 has been within Contra Costa County, where most NIF employees would reside (ULI 1995).

Contra Costa County has historically been the Bay Area's strongest market for residential development, followed by Alameda County. Most new construction has been within southern Alameda County and eastern Contra Costa County, a trend that is likely to continue. Substantial new construction is also planned within central Contra Costa County east of San Roman and north of Dublin (ULI 1995).

The rental apartment market, which experienced some overbuilding in the 1980s, has improved in the 1990s. Production has declined sharply since 1989, reflecting a market adjustment to overbuilding and changes in the Federal tax code. Because of the public construction volume during the 1980s and the subsequent slow economy, rental rate increases since 1985 have generally been lower than the rate of inflation. With high land and construction costs, rental rates do not justify new construction. Despite the lack of new construction, vacancy rates remained about 5 percent in 1993 and 1994. Vacancy rates have not declined because of the doubling up that has occurred in the depressed economy and the large number of renters who have taken advantage of favorable prices and interest rates to purchase homes.

The counties within the ROI are far more receptive to residential development than the San Francisco area on the western side of the bay. The ROI is likely to continue to experience strong residential development activity. Substantial inventories of suitable land remain, particularly in the southern portion of Alameda County and the eastern portion of Contra Costa County near LLNL (ULI 1995).

I.4.1.1.6.3 *Public Finance and Public Services Infrastructure*

Public financial characteristics of the local jurisdictions in the ROI that are most likely to be affected by construction and operation of NIF at LLNL are summarized in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and (as applicable) debt service, capital project, and expenditure trust funds. Major revenue and expenditure categories and revenues less expenditures for counties and cities are presented in table I.4.1.1.6.3–1. Table I.4.1.1.6.3–2 summarizes public service levels for community services, health care, and education.

I.4.1.1.6.4 *Local Transportation*

Vehicular access to LLNL is primarily from Interstate 580 by the Vasco Road and Greenville Road interchanges. LLNL can be entered through security gates along Vasco Road, East Avenue, and Greenville Road. Specific access points include Westgate Drive, Mesquite Way, Southgate Drive, Avenue J, and East Gate Drive (DOE and UC 1992). Table I.4.1.1.6.4–1 lists the site access roads at LLNL, the average daily traffic volumes for each route, and the estimated levels of service at key local intersections.

Traffic concerns in the ROI have reinforced attempts to restrict residential development. However, these restrictions have pushed residential development to the urban fringes, worsening traffic congestion. Among the solutions being instituted for the region's transportation problems are numerous improvements now under way or planned for the region's public transit systems. Several extensions of the Bay Area Rapid Transit (BART) system are currently under construction, including a new line of Dublin and Pleasanton and an extension of the Concord line to Pittsburgh (ULI 1995).

TABLE I.4.1.1.6.2–1.—*Population and Housing Data for the Lawrence Livermore National Laboratory Area*

Category	1980	1990	1996	1997	1998	1999	2000	2001	2002	2003
Estimated ROI population	2,109,052	2,538,312	2,767,679	2,795,646	2,823,903	2,852,453	2,881,300	2,905,074	2,929,049	2,953,227

[a] If reporting body did not distinguish between state and Federal revenue sources, the total for all intergovernmental revenue was combined and reported under the "State sources" heading.

Source: Alameda County 1994; Contra Costa County 1994; San Joaquin County 1994; city of Livermore 1994; city of Pleasanton 1994; city of Tracy 1994; city of Manteca 1994.

TABLE I.4.1.1.6.3-2.—*Public Services—Lawrence Livermore National Laboratory Area*

Part I: Education

County/School District	Enrollment	Pupil-Teacher Ratio	Per Pupil Expenditure ($)
Alameda County	188,076	28.4:1[a]	4,538
Contra Costa County	132,951	22.9:1[a]	4,192
San Joaquin County	119,115	NA	4,347

Part II: Level of Service per 1,000 Population

County/Jurisdiction	Police Protection	Fire Protection	General Government	Physicians
Alameda County	0.5	0.1	7.9	2.7
City of Livermore	1.0	0.8	5.5	NA
City of Pleasanton	1.2	0.8	6.6	NA
Contra Costa County	0.6	0.4[b]	7.7	2.6
San Joaquin County	0.3	NA[c]	12.8	1.6
City of Manteca	1.0	0.6	5.9	NA
City of Tracy	1.1	0.6	5.1	NA

[a] Pupil-teacher ratio is for grades 1–8.

[b] Contra Costa Fire Protection District is the largest fire protection district in Contra Costa County; however, other districts also provide service throughout the county.

[c] General Government number includes firefighters. Fire services in San Joaquin County are provided by approximately 27 fire protection districts, including city fire departments.

Note: NA - not applicable.

Source: Contra Costa County 1994; Alameda County 1994; Contra Costa County School Districts 1994; American Medical Association 1994; Federal Bureau of Investigation 1993; San Joaquin County Schools 1995a; San Joaquin County Schools 1995b; city of Pleasanton Personnel Department 1995; city of Manteca Personnel Department 1995; city of Manteca Fire Department 1995; Contra Costa Fire Protection Department 1995; Alameda County Fire Department 1995.

Freeway improvements are also under way in the region, including replacement of Cypress Freeway, improvements to major interchanges in Walnut Creek, and construction of a high-occupancy vehicle ramp from Interstate 80 to the Bay Bridge. There are numerous ongoing seismic retrofit projects (California Department of Transportation 1995). With general political resistance to infill housing development, most affordable housing is being produced in remote locations within the region and beyond in Solano and San Joaquin counties. These areas are poorly served by public transportation and are located along increasingly congested traffic arteries, such as Interstate 205. With the focus of new housing development likely to continue in these areas, traffic congestion is projected to worsen (ULI 1995).

LLNL is served by several public transportation providers. San Joaquin County provides bus access to LLNL from the San Joaquin Valley, Wheels Transit Service serves LLNL from the Tri-Valley region, and BART provides express buses during peak commuting hours (ULI 1995).

Major railroads in the ROI are the Atchison, Topeka, and Santa Fe Railroad, the Southern Pacific Transportation Company, and the Union Pacific Railroad. The Union Pacific passes within 1.6 km (1 mi) of LLNL; however, there is no direct rail access to LLNL.

The ROI is served by several airports, including Oakland International, San Jose International, Stockton Metropolitan, and San Francisco International Airport. The Livermore Municipal Airport serves local air traffic.

I.4.1.1.6.5 *Environmental Justice*

Environmental justice concerns the potential for high and adverse environmental or human health impacts to disproportionately affect minority or low-income populations. For this assessment, environmental justice is evaluated for impacts within the site region, defined as an 80 km (50 mi) radius around the site, and within the local area. Lazaro et al. (1996) presents the demographic analysis of minority and low-income population distributions on a regional and local basis.

In the LLNL site region in 1990, 7 percent of the population was low income and 41 percent was minority. These values are lower percentages of both low-income and minority persons than the California state averages (12 percent low income and 43 percent minority). However, within that area, census tracts closer to LLNL tend to have a higher proportion of minority population but a lower proportion of low-income population than do census tracts farther from the site.

TABLE I.4.1.1.6.4–1.—*Baseline Traffic on Lawrence Livermore National Laboratory Access Roads*

Route	From	To	Estimated 1995 AADT	Estimated 1995 LOS
Patterson Pass Road	Vasco Road	Greenville Road	1,040	A
East Avenue	Vasco Road	Greenville Road	11,250	A

I.4.1.1.7 Radiation and Hazardous Chemicals

I.4.1.1.7.1 *Radiation Environment*

Many of the activities that take place at LLNL involve handling radioactive materials and operating radiation-producing equipment. A detailed discussion of the radiation environment, including background, radiological releases, and doses to members of the public is presented in the publication *Environmental Report 1993* (LLNL 1994d). The concentrations of radioactivity in various environmental media (air, water, soil) in the site region are also presented in that report.

Calculated radiological doses were used to estimate the potential health impacts to the public and onsite workers at LLNL from any releases of radioactivity. The annual doses to an individual, the surrounding population (within 80 km [50 mi]), and workers are summarized in table I.4.1.1.7.1–1; corresponding health risks are also presented in the table. These values are in addition to those from natural background, consumer products, and medical sources, which total about 365 millirems (mrem) per year. Background radiation doses are unrelated to LLNL operations. Regulatory limits that specify the maximum effective dose equivalent to individual members of the public and occupational workers are also presented in table I.4.1.1.7.1–1. The doses to the public presented in table I.4.1.1.7.1–1 are within regulatory limits (DOE 1990) and are small compared to background radiation. The onsite worker doses are also within regulatory limits.

I.4.1.1.7.2 *Hazardous Chemical Environment*

The background chemical environment important to human health consists of the atmosphere, which may contain hazardous particulates or vapors that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (for example, soil through contact or via the food pathway). Exposure pathways to LLNL workers during normal operation may include inhaling the workplace atmosphere, drinking LLNL potable water, and possibly other contact with hazardous materials associated with work assignments. The maximum daily quantities of hazardous materials stored in 1992 are listed in table I.4.1.1.7.2–1. The potential for health impacts varies from facility to facility and from worker to worker, and depends on the operations performed, as well as the materials handled. However, workers are protected from hazards specific to the workplace through (1) appropriate training, (2) engineering controls, (3) work practices, (4) administrative controls, (5) monitoring, and (6) protective equipment. LLNL workers are also protected by adherence to Occupational Safety and Health Administration (OSHA) and U.S. Environmental Protection Agency (EPA) standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded.

TABLE I.4.1.1.7.2–1.—*Maximum Daily Quantities of National Ignition Facility-Related Hazardous Materials Stored at Lawrence Livermore National Laboratory*

Hazardous Material	Quantity
Acetone	3,577 kg
Alumina	3,345 kg
Ammonium hydroxide	2.23 kg
Copper	55.8 kg
Ethyl alcohol	13,244 L
Hafnium oxide	1,115 kg
Mercury	1,238 kg
Sodium hydroxide	9,455 kg
Tetraethyl orthosilicate	1,904 kg

Note: kg - kilograms; L - liters.
Source: DOE and UC 1992.

I.4.1.1.8 Waste Management

LLNL currently operates four waste management facilities. The Area 514 and Area 612 facilities contain treatment and storage units for hazardous and mixed wastes. The Building 693 facility is currently a container storage unit for mixed hazardous waste, *Toxic Substances Control Act* (TSCA)-regulated waste (such as polychlorinated biphenyls), and radioactive waste. The Building 233 container storage unit is currently used to store mixed waste, low-level waste (LLW), and transuranic (TRU) waste.

TABLE I.4.1.1.7.1–1.—*Annual Radiation Doses to the General Public and Onsite Workers from Normal Operations at Lawrence Livermore National Laboratory*

Receptor	Atmospheric Releases		Liquid Releases		Total		
	Regulatory Limit[a]	Calculated	Regulatory Limit[a]	Calculated[b]	Regulatory Limit[a]	Calculated	Risk[c]
Individual Dose							
Average exposed individual[d] (mrem)	10	$1.3x10^{-4}$	4	0.0	100	$1.3x10^{-4}$	$6.5x10^{-11}$
Maximally exposed individual (mrem)	10	$6.5x10^{-2}$	4	0.0	100	$6.5x10^{-2}$	$3.3x10^{-7}$
Population Dose[e]							
Population within 80 kilometers (person-rem)	f	$7.6x10^{-1}$	f	0.0	f	$7.6x10^{-1}$	$3.8x10^{-4}$
Worker Dose[g]							
Average worker (mrem)	NA	NA	NA	NA	5,000	2.1	$8.4x10^{-7}$
Maximally exposed worker (mrem)	NA	NA	NA	NA	5,000	1,300	$5.2x10^{-4}$
Total worker[h] (person-rem)	NA	NA	NA	NA	None	18.3	$7.3x10^{-3}$

[a] The regulatory limits for individuals are given in DOE Order 5400.5. The 10 mrem/yr limit from airborne emissions is required by the *Clean Air Act*. The 4 mrem/yr limit is required by the *Safe Drinking Water Act*, and the total dose of 100 mrem/yr is the limit from all pathways combined. The occupational limit for workers is 5,000 mrem/yr (10 CFR 835).
[b] The calculated dose values listed in this column conservatively include all water pathways, not just the drinking water pathway.
[c] Based on latent fatal cancer risk factors of $5x10^{-7}$/mrem for individuals, $5x10^{-4}$ /person-rem for population, and $4x10^{-7}$/mrem for workers (ICRP 1991).
[d] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.
[e] Estimated for a population of approximately 6 million.
[f] No regulatory limit exists for population doses; however, a 100 person-rem value for the population is found in proposed 58 FR 16268 (10 CFR 834).
[g] Worker doses were estimated on the basis of readings from monitoring devices called thermoluminescent dosimeters.
[h] The number of badged workers in 1994 was approximately 8,700.

Note: NA - not applicable.

Source: LLNL 1994d.

The current waste management practices at LLNL are outlined in table I.4.1.1.8–1. Wastes relevant to NIF that are managed at LLNL from research activities include LLW, mixed wastes, and hazardous and nonhazardous wastes. The exact nature of some of the LLNL waste is classified information. The NIF project is expected to generate low-level, mixed, hazardous, and nonhazardous wastes during operation; none of these wastes would be classified.

I.4.1.1.8.1 *Low-Level Waste*

Both liquid and solid LLW are generated and managed by LLNL. LLW solids at LLNL consist of gloves, absorbent paper, plastics, glass, and other solid materials contaminated with low-level radioactive materials. Liquid and solid LLW are processed or stored at the Building 514 and 612 complexes. Wastewater from retention-tank systems that exceed site radiological discharge limits or any special limits established for that tank, and that cannot be adjusted for discharge or released to the sanitary sewer, is treated as LLW. Smaller quantities of liquids may be accumulated in containers of various sizes and types. Nonreleasable wastewater is pumped into portable tanks for treatment at the Wastewater Treatment Tank Farm at the Building 514 Facility, where it is containerized and transferred into one of six 7,003-L (1,850-gal) treatment tanks for chemical treatment. These tanks are used to treat both radioactive and mixed liquid wastes. After treatment, if the analysis indicates that the contents of a treatment tank are within established sewer discharge limits, the liquid is discharged to the sanitary sewer. If the contents are not within discharge limits, they are retreated.

I.4.1.1.8.2 *Mixed Low-Level Waste*

Some of the generated mixed liquid LLW is treated at the Area 514 Wastewater Treatment Tank Farm before discharge to the sanitary sewer system so that hazardous constituents and radionuclides can be removed and this wastewater can be discharged within the allowable limits of the National Pollutant Discharge Elimination System (NPDES) permit. The residual solids from this treatment process may contain hazardous constituents such as oils and solvents, toxic metals, decontamination solutions, and dyes. Mixed LLW is treated or stored at the Area 514 Wastewater Treatment Tank Farm and Building 612 complexes.

I.4.1.1.8.3 *Hazardous Waste*

Hazardous wastes are generated by the numerous research and development (R&D) activities conducted at LLNL. Storage areas for nonradioactive and radioactive (or mixed) wastes are located at Area 612, Area 514, Building 233, and Building 833. Wastes that contain polychlorinated biphenyls and other wastes regulated by the TSCA are stored in Building 693. Nonradioactive, hazardous liquid waste may be stored in drums and portable tanks, pending consolidation and/or offsite transportation. A commercial waste handler transports the nonradioactive solid and liquid hazardous waste drums to an appropriately permitted disposal, treatment, or recycle facility. LLNL hazardous waste management units operate under *Resource Conservation and Recovery Act* (RCRA) interim status with an approved Part A Permit. Building 693 operates under interim standards and is used to store containerized RCRA-, TSCA-, and California-only regulated waste.

Wastewater may be accumulated in retention tanks, carboys, or drums at the various source locations throughout LLNL. The materials are then analyzed, and the determined waste contaminant levels are compared to LLNL and city of Livermore discharge limits. If the contaminant levels are below the regulatory limits, the material is released to the sanitary sewer. Industrial wastewater that contains constituents at concentrations greater than allowed by the city of Livermore discharge limits is managed as hazardous waste.

Hazardous wastes may be shipped through licensed commercial transporters to various offsite commercial RCRA-permitted treatment, storage, and disposal facilities.

The newly redesigned Decontamination and Waste Treatment Facility is planned to replace and upgrade current facilities used to process, treat, and store hazardous, radioactive, and mixed wastes. The Decontamination and Waste Treatment Facility would receive LLNL and other Oakland, California, generated medical waste, hazardous waste, LLW, and mixed LLW for consolidation, processing, treatment, and packaging before shipment and disposal offsite at a commercial RCRA-permitted facility.

TABLE I.4.1.1.8–1.—*Current Waste Management at Lawrence Livermore National Laboratory*

Category	1994 Generation (m^3)	Treatment Method	Treatment Capacity (m^3/yr)	Storage Method	Storage Capacity[a] (m^3)	Disposal Method	Disposal Capacity (m^3)
Low-Level							
Liquid	181	Neutralization, filtration, solidification, precipitation, oxidation, flocculation, blending	3,736 (34.1/ treatment episode)	Hazardous Waste Management Division Facilities	627	Treated wastewater discharged to city of Livermore sanitary sewer if within approved limits	None
Solid	307	Shredding, drum crushing, compaction	NA	Hazardous Waste Management Division Facilities	2,297	Shipped to Nevada Test Site	NA
Mixed Low-Level							
Liquid	51	Neutralization, filtration, solidification, precipitation, oxidation, flocculation, blending	8,750	Hazardous Waste Management Division Facilities	627	Treated wastewater discharged to city of Livermore sanitary sewer if within approved limits	NA
Solid	20	Shredding, drum crushing, compaction	11,800	Hazardous Waste Management Division Facilities	2,297	None	None
Hazardous							
Liquid	342	Shipped to offsite RCRA-permitted treatment, storage, and disposal facility, except for silver recovery	97	Hazardous Waste Management Division Facilities	76.9	Shipped to offsite RCRA-permitted treatment, storage, and disposal facility	NA
Solid	237	Shipped to offsite RCRA-permitted treatment, storage, and disposal facility, except for silver recovery	NA	Hazardous Waste Management Division Facilities	98	Shipped to offsite RCRA-permitted treatment, storage, and disposal facility	NA
Nonhazardous (Sanitary)							
Liquid	456,000	None	NA	Retention tanks	829 (spill control capacity 882,622 L)	Discharged to city of Livermore sanitary sewer system	NA

I.4.1.1.8.4 *Nonhazardous Waste*

Solid nonhazardous wastes generated by LLNL consist of paper, plastics, glass, organic, and other wastes. LLNL does not have onsite solid waste disposal facilities. Solid wastes are collected in dumpsters and similar containers in such a manner as to ensure that they do not contain hazardous or radioactive wastes and transported to the Vasco Road Landfill for disposal.

If industrial wastewater generated by LLNL operations exceeds permissible discharge limits and is treatable by permitted LLNL waste treatment units, the water is processed to meet the release criteria and then monitored as it is discharged to ensure that permissible discharge limits are not exceeded. These wastes enter the city of Livermore's sewer system and are then processed at the city's Water Reclamation Plant. The treated wastewater is piped to San Francisco Bay for discharge, except for a small volume that is used for summer irrigation of the municipal golf course adjacent to the Livermore Water Reclamation Plant. Sludge from the treatment plant is disposed of in offsite landfills.

LLNL has an onsite sewage diversion and retention system that is capable of containing approximately 757 cubic meters (m^3) (26,700 cubic feet [ft^3]) of potentially contaminated sewage until it can be analyzed and appropriate handling methods implemented. If the liquids cannot be processed for discharge, they are packaged for treatment or disposal at an offsite facility. Treatment residues, or solids generated from the treatment process, are also packaged for treatment or disposal at an offsite facility.

I.4.1.2 *Environmental Impacts*

The following sections describe the potential environmental impacts for land use and visual resources, air quality and noise, water resources, ecological resources, cultural and paleontological resources, and socioeconomics from constructing and operating NIF at LLNL. In addition, impacts associated with radiation, hazardous chemicals, and waste management are described.

I.4.1.2.1 Land Use and Visual Resources

I.4.1.2.1.1 *Land Use*

Impacts to land use at LLNL from construction and operation of NIF would be limited to the clearing of land, minor and temporary disruptions to contiguous land parcels, and a slight increase in vehicular traffic. No significant impacts to onsite or offsite land uses are anticipated from the project. The proposed location for the two buildings requiring construction for NIF would occupy a large parcel of relatively flat, vacant land in the northeastern corner of LLNL (figure I.3.4.1.1–2). The proposed location is in a section of LLNL where similar types of research and experimentation already occur. Therefore, no conversion of existing land use would result. The NIF buildings would require the clearing of an estimated 8 ha (20 acres) of land for structures, walkways, building access, and buffer space. Such acreage would account for approximately 11 percent of the land currently available for development inside the LLNL site boundaries (Gawronski 1995). An additional 2.0 ha (4.9 acres) would be cleared for a construction laydown area (figure I.3.4.1.1–2). This area would be restored after NIF construction is completed. No impacts to land use (including zoning) on land outside of LLNL or in nearby communities would be expected.

With appropriate erosion and sediment control measures, soil impacts during construction of NIF would be short term and minor. Seismic risks would be taken into account during construction and operation of NIF.

I.4.1.2.1.2 *Visual Resources*

With the exception of minor, temporary impacts (fugitive dust, equipment exhaust, etc.) associated with construction activities, no impacts to the visual character of LLNL or to surrounding visual resources would be expected. The Laser and Target Area and the Optics Assembly buildings would be constructed in a sector of LLNL that has similar structures. The plot that would contain the two new facilities consists of grassland and a few trees that are visually uniform and not distinct or unique. Because so much of LLNL is developed, views into the installation from surrounding points would not be altered by the two new buildings.

I.4.1.2.2 Air Quality and Acoustics

I.4.1.2.2.1 *Air Quality*

The potential air quality impacts resulting from construction and operation of NIF are discussed separately because the air pollutant emissions generated during construction would not occur during NIF operations.

Construction Emissions. Estimated construction emissions, including site-clearing emissions and emissions associated with facility construction, are listed in table I.4.1.2.2.1–1. The construction emission estimates are based on characteristics of the proposed LLNL location and on construction vehicle exhaust and fugitive emissions. Site clearing would occur the first year, followed by facility construction during the next four years (LLNL 1995b).

TABLE I.4.1.2.2.1–1.—*Estimated National Ignition Facility Construction Emissions for the Lawrence Livermore National Laboratory Location*

Pollutant	Total Emissions (t/yr)[a]
Particulate matter 10 microns or smaller	14.51[b]
Volatile organic compounds	0.44
Carbon monoxide	1.23
Nitrogen dioxide	3.76
Sulfur dioxide	0.43
Lead	Negligible

[a] Metric tons (1,000 kg) per year.

[b] Includes 4.17 t/yr (4.60 ton/yr) of fugitive emissions for site clearing, using water spray control that occurs during a 30-day period in the first year and 10 t/yr (11.02 ton/yr) of facility construction emissions that occur for 11 months during the first year of construction.

Source: Lazaro et al. 1996.

The site-clearing phase of construction, which would continue for about one month, would produce the greatest amount of fugitive dust (particulate matter of 10 microns or less [PM_{10}]) emissions. The Industrial Source Complex, Short-Term Model, Version 2 (ISCST2, Version 93109 [EPA 1992a-b]) was used to determine the impact of site-clearing activities on ambient air quality. The Industrial Source Complex dispersion model is the EPA's preferred regulatory modeling tool for most applications in simple terrain (EPA 1995a). The ISCST2 Model was chosen because the general area from NIF location to nearby receptors of concern is relatively flat and is characterized as simple terrain. The data selected for modeling air quality were 1994 surface meteorological data from the LLNL site (LLNL 1995d). The surface wind speeds and directions are summarized in an annual wind rose (see figure I.4.1.1.2.1–1). In addition, a constant mixing height of 600 m (1,970 ft) was used throughout the year (LLNL 1995d). Detailed emission inventories associated with site clearing and facility construction; meteorological data used; and air quality model, assumptions, and model input parameters are presented in Lazaro et al. (1996).

The national and state 24-hour PM_{10} standards are 150 and 50 micrograms (μg)/m^3, respectively. The 24-hour average PM_{10} background concentration of 84 μg/m^3 is already above the State Ambient Air Quality Standard (SAAQS) of 50 μg/m^3 (see table I.4.1.1.2.2–1). Accordingly, site clearing should be conducted so as to minimize further impacts on ambient air quality. With a conventional water-spraying dust control system (that is, 50-percent control for excavation and 60-percent control for traffic on unpaved roads), maximum 24-hour average PM_{10} concentrations of 104 μg/m^3 over background are predicted at the site boundary (about 350 m [1,150 ft] east of the proposed NIF location). Operation with additional dust control measures that involve continuous water spraying and/or use of a chemical dust suppressant, would reduce PM_{10} dust emissions from excavation by 75 percent and PM_{10} emissions from traffic on unpaved roads by 90 percent. These measures would bring maximum 24-hour average PM_{10} concentrations down to 46 μg/m^3 over the background concentration. Including background concentration, maximum 24-hour concentrations would still be higher than the SAAQS for PM_{10}. The ambient air quality impacts associated with site clearing would be limited to the area just outside the site boundary, which the general public is expected to occupy infrequently. In addition, site clearing at LLNL would be expected to last for only a month, so ambient air quality impacts associated with site clearing would be local and temporary.

Modeling efforts showed that over a year, the six highest 24-hour PM_{10} concentration levels in descending order would be 62, 50, 43, 43, 43, and 36 μg/m^3 above the background concentration. These levels were predicted for an area near the eastern boundary, which is the closest to the NIF location. In addition, annual average PM_{10} concentrations were estimated for the entire one-year construction period, which consists of one month for site clearing, followed by facility construction. The estimated highest annual arithmetic mean PM_{10} concentration level of 5 μg/m^3 above the background concentration is well below the state standard of 30 μg/m^3 in terms of geometric mean. (Note that the arithmetic mean is greater than or equal to the geometric mean.) As a consequence, long-term ambient air quality impacts associated with NIF construction would be minor. However, short-term ambient air quality impacts resulting from site clearing could be moderate, although local and temporary in extent. Additional regulatory information is provided in section I.5.2.1.

Emissions During Operations. Air pollutant emissions from operation of NIF at LLNL are expected to occur primarily from fuel combustion and solvent cleaning of the debris shields. Emissions of solvent volatile organic compounds (VOCs) (ethanol) from debris shield cleaning are estimated at about 0.50 metric tons per year (t/yr) (0.55 ton/yr) (LLNL 1995b). Other potential air pollutant emission sources not considered significant are target destruction under either the Conceptual Design or Enhanced options, emissions from vehicles used for freight shipments and employee commuting, and emissions from welding operations at the Fabrication Facility.

As indicated in table I.4.1.2.2.1–2, estimated air pollutant emissions due to NIF operation are well below 1 t/yr (1.1 ton/yr), except for nitrogen dioxide, which is below 2 t/yr (2.2 ton/yr). Estimated air pollutant emissions from NIF operations are less than 10 percent of LLNL 1994 emissions, except for carbon monoxide, which is approximately 11 percent of 1994 emissions. Existing ambient concentrations for these pollutants (see section I.4.1.1.2.2, table-I.4.1.2.2.1–1) are well below the ambient air quality standards except for PM_{10} and ozone. The increase of 0.16 t/yr (0.18 ton/yr) PM_{10} is less than 5 percent of LLNL 1994 emissions and is not expected to cause a measurable increase in the 24-hour and annual average ambient concentrations. VOC emissions related to NIF operations are estimated to increase by less than 5 percent for the existing emissions at LLNL. Estimated NIF VOC operating emissions at LLNL are 0.56 t/yr (0.61 tons/yr). Total 1995 VOC emissions for the BAAQMD are 269,248 t/yr (296,173 tons/yr) and from fuel combustion are 6,654 t/yr (7,319 tons/yr). Therefore, NIF contribution of VOCs to production of ozone would be almost insignificant (Mangat 1995). On the basis of this information, it can be concluded that NIF operations would have no adverse impact on air quality and would not contribute to a violation of the ambient air quality standards.

The NIF annual energy requirements based on heat and hot water demand for the Laser and Target Area Building and all necessary support facility buildings are listed in table I.4.1.2.2.1–3. All candidate sites would require construction of the Laser and Target

TABLE I.4.1.2.2.1–2.—*Annual Emission Increases with National Ignition Facility Operation at Lawrence Livermore National Laboratory*

Pollutant	1994 Emissions[a] (t/yr)	Projected NIF Emissions (t/yr)[a]	1994 Emissions Plus NIF (t/yr)	NIF Percent of 1994 Emissions
Particulate matter 10 microns or smaller	3.36	0.16	3.52	8.8
Volatile organic compound	13.10	0.56	13.66	4.3
Carbon monoxide	3.99	0.43	4.42	11
Nitrogen dioxide	23.50	1.79	25.29	7.61
Sulfur dioxide	0.37	0.03	0.40	9
Lead	<0.01	Negligible	<0.01	Negligible

[a] Emissions based on site-estimated natural gas external combustion, diesel internal combustion, and volatile organic compound solvent cleaning (0.5 t/yr [0.55 ton/yr]) and emission factors (EPA 1995c; Lazaro et al. 1996).

Source: EPA 1993; Zahn 1995.

Area Building. None of the candidate sites would require construction of the full complement of support facilities that are represented by the annual support facilities energy demand in table I.4.1.2.2.1–3. Therefore, NIF annual energy demand and resulting air pollutant emissions differ among sites based on the area of new buildings required. The ratio of the sum of new support building construction area to the sum of the area for all NIF required support buildings was used to adjust support building energy demand for each candidate site (see table I.3.4–1 for a listing of new buildings required by NIF for each candidate site).

Table I.4.1.2.2.1–2 lists the estimated LLNL annual air pollutant emissions on the basis of the anticipated NIF annual energy requirements provided in table I.4.1.2.2.1–3, adjusted to recognize that at LLNL only one new support building (area of 1,858 square meters [m^2] [20,000 square feet {ft^2}]) would be required out of the total complement of support buildings (area of 26,722 m^2 [287,643 ft^2]) indicated in table I.3.4–1. Published emission factors (EPA 1995b) were used to estimate the emissions. Emissions of VOCs from solvent cleaning are included. For comparative purposes, table I.4.1.2.2.1–2 includes the LLNL 1994 site-wide emissions. More detailed information on emission estimates is provided in Lazaro et al. (1996).

The BAAQMD may require that NIF external combustion facilities (boilers) be equipped with the best available control technology (BACT) for criteria and organic pollutants (Regulation 2, Rule-301) (BAAQMD 1995). BACT will be determined by the permitting process. EPA New Source Performance Standards would limit boiler nitrogen oxide air pollutant emissions according to the boiler-rated heat input. Gas-fired boilers with rated heat input greater than 105,600 megajoules per hour (MJ/hr) (100 million British thermal units per hour [Btu/hr]), but not over 264,000 MJ/hr (250 million Btu/hr), are limited to New Source Performance Standard nitrogen oxide emissions ranging from 43 to 86 nanograms per joule (ng/J) (depending on the heat release rate, which is a function of the furnace volume [40 CFR 60.44b]). There are no New Source Performance Standard emission limits for gas-fired boilers with a rated heat input at or less than 105,600 MJ/hr (40 CFR 60.40c).

VOC emissions, primarily ethanol (see Lazaro et al. 1996), from solvent cleaning of debris shields and treatment/refurbishment of optics and laser components would require no controls but might require emission offsets from the Small Facility Banking Account (Regulation 2, Rule 2-302). The Small Facility Banking Account was established by BAAQMD to provide emission offsets for small air pollutant emission facilities such as NIF. Additional regulatory information is presented in section I.5.2.1.

I.4.1.2.2.2 *Acoustics*

During the site-clearing phase of construction of NIF at the LLNL site, noise from construction equipment would cause an increase of 14 decibels (dB) (from 55-dBA to 69 dBA) in the average outdoor daytime sound level at the location of the maximally exposed individual 800 m (2,600 ft) east-northeast of the NIF target chamber room location on the eastern side of Greenville Road. The Composite Noise Rating

TABLE I.4.1.2.2.1–3.—*Estimated Annual Energy Requirements for the National Ignition Facility*

Facility	Use	Fuel Type	Annual Energy Consumption
NIF Laser and Target Area Building	Heating, ventilation, and air conditioning	Natural gas	2.11×10^7 MJ
	Domestic hot water	Natural gas	3.11×10^5 MJ
	Stand-by power	Diesel	320 L
NIF Support Facilities[a]	Heating, ventilation, and air conditioning and hot water	Natural gas	1.95×10^7 MJ
	Stand-by power	Diesel	5,500 L

[a] Represents energy consumption for all required NIF support facilities. See table I.3.4–1 for a list of NIF support facilities.

Note: MJ - megajoule(s); L -liter(s).

Source: LLNL 1995b; White 1995e.

(CNR) rank, adjusted for the estimated preexisting background level and for temporal and conceptual characteristics of the sound, is expected to be "F." Noise with CNR ranks "A" through "D" is generally considered to be acceptable, with "A" representing essentially no impacts. Rankings above "D" are usually addressed with mitigative measures unless the source is temporary.

The average outdoor daytime sound level at the nearest laboratory building would be expected to increase by 4 dB, to 59 dBA. The adjusted CNR rank for the resulting sound would be "B." This "B" rating for modified CNR refers to general activity outside the nearest laboratory building, as compared to ambient background levels. Noise from NIF construction is not included in the "B" rating. The average daytime sound level at the residential area approximately 1.6 km (1.0 mi) west of the construction site would not be expected to increase over the existing average daytime sound level, estimated to be 61 dBA.

These noise level predictions are estimates based on the assumptions given in Lazaro et al. (1996). The noise levels produced during construction are not expected to have a significant impact on LLNL employees or on staff working inside the veterinary hospital (nearest offsite public receptor). Complaints of annoyance may be expected from hospital employees working outside the hospital during heavy construction periods. However, noise levels are not expected to result in hearing loss or interference with speech.

I.4.1.2.3 Water Resources

Construction of NIF at LLNL would be expected to have minor to negligible effects on water quality. The current water supply and wastewater treatment capacities are expected to be sufficient to meet the requirements of NIF.

During construction, about 2.95 MLY (0.78 MGY) of water would be required (LLNL 1995b). The wastewater generated during construction would be handled by the existing sewer and treatment systems. The wastewater volume would be less than the water requirement of consumptive uses, such as incorporation into concrete and evaporation. Sanitary sewer discharges from LLNL go to the city of Livermore wastewater collection system, which is currently being renovated to reduce infiltration and inflow experienced during periods of heavy rainfall.

Water and wastewater utility requirements for NIF operations at LLNL are shown in table I.4.1.2.3–1. The total raw water supply required for NIF would be about 152 MLY (40 MGY), of which about 18 MLY (4.7 MGY) would be for domestic use. The additional sanitary wastewater volume from NIF operations is estimated to be 18 MLY (4.7 MGY). A sewer diversion facility protects against accidental release of contaminants not usually associated with sewage into the Livermore treatment plant (LLNL 1994d). The wastewater volume at the LLNL site would increase about 4.5 percent as a result of NIF operations. The sewer diversion facility is capable of handling the projected increase. Wastewater containing nonsewage-related contaminants would be pretreated before release to the Livermore treatment plant.

Potential impacts of stormwater runoff from both the NIF and construction laydown locations on surface water quality are expected to be minor because NIF would be operated under the Livermore Site Industrial Activity Stormwater Pollution Prevention Plan

TABLE I.4.1.2.3–1.—*Water and Wastewater Utility Capacity at Lawrence Livermore National Laboratory*

Utility System	Current Usage	NIF Requirement[a]	Projected Usage, Including NIF[b]	Current Capacity[b]
Water supply (MLY)	967[b]	152	1,119	3,980
Wastewater treatment (MLY)	402[c]	18	420	2,340

[a] From LLNL 1995b.
[b] From LLNL 1995b and Paisner 1995.
[c] From LLNL 1994d.

to be developed in accordance with California Department of Transportation specification Section 7–1.0G and LLNL's General Construction Activity Stormwater Permit. The proposed bridge spanning Arroyo Las Positas to the staging area (option I) would be constructed so that its structure and supports would not increase the risk of a 100-year flood breaching the banks of the arroyo. The proposed NIF location has minimal flooding potential because it is outside the 500-year floodplain of Arroyo Las Positas although the staging area (option I) would be within the 500-year floodplain (figure I.4.1.1.3.–1). The staging area (option I) would not be used to store highly volatile, toxic, or water reactive materials. Therefore, locating the staging area in the 500-year floodplain would pose no environmental risk.

However, the proposed NIF location is within the 2000-year floodplain for Arroyo Los Positas. Nevertheless, severe flooding at NIF due to overflow of the arroyo would be relatively slow to develop. This would allow the opportunity to secure radioactive and hazardous material inventories and move them to a safe location. A severe flood could result in facility and equipment damage, but the likelihood of such an event would be small over the 30-year operational lifetime of NIF.

Potential effects of NIF on groundwater would be minor to negligible. No groundwater would be used for NIF, and no wastewater would be discharged to aquifers. Groundwater recharge at the LLNL site might be slightly reduced because of additional paved surface areas. Potential impacts of stormwater runoff on groundwater quality are expected to be negligible because NIF would be operated under the Industrial Activity Stormwater Pollution Prevention Plan.

I.4.1.2.4 Biotic Resources

I.4.1.2.4.1 *Terrestrial Resources*

The NIF location at LLNL would occupy a 8.1-ha (20.0-acre) parcel of grassland. The 2.0 ha (4.9 acres) areas designated as optional sites for the temporary staging area contain grassland (option I) or maintained lawns (options II and III) (figure I.3.4.1.1–2). Vegetation within these areas would be eliminated by construction and spoils disposal, resulting in a minor loss of habitat. This loss would be considered a slight adverse impact. Construction could also affect nearby vegetation through the deposition of dust and other particulates from soil disturbance and from the operation of vehicles and large machinery. This deposition could inhibit photosynthesis and, if chronic, result in a limited amount of plant mortality. In addition, soil compaction caused by heavy machinery could destroy the plants and indirectly damage roots of plants from adjacent areas by reducing soil aeration and altering soil structure. However, impacts from dust and compaction would be temporary, localized, and limited to common species that are found in disturbed areas. The quality of the vegetative community at the proposed NIF location is marginal, and since construction would occur in an area of previous disturbance, potential impacts are considered negligible.

Impacts to wildlife from NIF construction would include (1) loss and alteration of habitat and (2) disturbance of individual animals by noise and human activity. Suitable alternative habitats, and escape pathways to those habitats, exist for displaced individuals. However, these animals could face stronger competitive pressures, potentially resulting in the loss of individual animals. It is unlikely that construction activities would be a threat to the continued survival of any local wildlife populations.

The areas occupied by NIF buildings, equipment, access roads, and parking lots would be unavailable to wildlife for the life of the project. The construction laydown area would be unavailable to wildlife during the construction period. It would be restored to existing conditions following construction. Vegetation should be reestablished within a few growing seasons. Some portions of the NIF site, particularly those around the main buildings, would be landscaped with lawns and scattered bushes and trees. Such habitat currently exists around other LLNL facilities and is of limited use to many wildlife species. Nevertheless, species adapted to suburban areas would readily inhabit or utilize these areas.

Few impacts would occur to terrestrial biota during operation of NIF. Increased traffic and local disturbances could lead to increased losses of road-killed individuals of some species, but this impact is not considered significant.

I.4.1.2.4.2 *Wetlands and Aquatic Resources*

It is DOE policy (10 CFR 1022) to avoid impacts to wetlands to the maximum extent practicable, in compliance with Section 404 of the *Clean Water Act* and Executive Order 11990 (*Protection of Wetlands*). Because the proposed NIF location is nearly 300 m (1,000 ft) from the nearest wetland, the construction and operation of NIF would not be expected to affect wetlands at LLNL. The location of the temporary access bridge across Arroyo Las Positas for the option I staging area would be about 100 m (328 ft) east of the nearest wetland, and, thus, would not impact wetland habitat. The option I staging area would be the closest alternate laydown area to the wetland. It would be at least 23 m (75 ft) from the nearest wetland. Temporary barriers would be used to prevent inadvertent impacts to the wetland.

The potential for adverse impacts to aquatic resources would be extremely low because no waterbodies are located in the immediate vicinity of the construction area. Generally, impacts to surface waters from construction activities occur as a result of (1) habitat destruction or modification from construction activities within the waterbody or (2) increases in turbidity, sedimentation, or chemical contamination from runoff. Overall, construction impacts to aquatic resources at LLNL would not be considered significant because (1) critical habitats (such as spawning or rearing areas) for important species (recreational, commercial, or listed species) do not occur at the proposed NIF location and therefore would not be affected and (2) increased sedimentation, habitat removal or modification, or potential spills (such as of fuel) would be localized, short term, and mitigable. The increase in impervious land surface associated with NIF could increase runoff, which could accelerate erosion of unstable soils and add to the contaminant load entering nearby waterbodies. However, a stormwater pollution prevention plan would be implemented to control such events (section I.4.1.2.3). Landscaping around new NIF buildings would also minimize surface erosion and site runoff.

I.4.1.2.4.3 *Rare, Threatened, and Endangered Species*

No deleterious impacts to listed species would be expected from construction or operation of NIF. NIF would be located on previously disturbed grassland habitat that is surrounded primarily by developed laboratory facilities. Thus, NIF location does not provide suitable habitat for the listed species that could exist at LLNL. White-tailed kites have nested near the East Gate of LLNL. Mitigative measures that would be taken so that NIF construction traffic would not affect this species (that is, rerouting traffic during nesting) are discussed in section I.4.7. However, construction of the option I staging area and its access road could impact the western burrowing owls by reducing potential foraging habitat or disrupting resident individuals. Nevertheless, loss of foraging area is not expected to adversely affect this species, and burrows of this species would be avoided during construction.

I.4.1.2.5 Cultural and Paleontological Resources

Construction and operation of NIF would have no effects on archaeological sites or historic structures listed on or eligible for the *National Register of Historic Places* (NRHP) or important paleontological remains because these resources are absent in the affected area. Consultation is in progress to determine whether the proposed project could affect Native American cultural resources.

I.4.1.2.6 Socioeconomics

Locating NIF at LLNL would have a minor impact on socioeconomic conditions in the economic study region and in the ROI described in section I.4.1.1.6. This is because LLNL is located in a diverse regional economy with extensive inter- and intraregional, national, and global economic interactions and linkages. Also, because the NIF partnership would include representatives from government, industry, and the academic sectors throughout the United States, procurement and investment would be dispersed over a number of different regions, damping the concentration of economic effects of the program.

The following sections describe the effects of constructing and operating NIF on the host region's economy and employment, and on population and housing, public finances, public services, and local transportation in the ROI.

I.4.1.2.6.1 *Regional Economic Impacts*

Slight changes in employment and levels of economic activity in the economic study region would occur from local spending of employee wages, procurement of goods and services (including construction materials), and other local investment associated with constructing and operating NIF. In addition to creating new jobs (direct) at the site, indirect job opportunities, such as community support services, would also be created in the economic study area as a result of these new direct jobs. The total new jobs created (direct and indirect) would contribute slightly to reduce unemployment and increase income and economic output in the regional economy during both the construction and operation of NIF. Table I.4.1.2.6.1–1 presents the potential impacts to the regional economy if NIF were located at LLNL.

The construction force for NIF at LLNL would peak at approximately 470 direct jobs in 1998. Construction-related procurement would indirectly create nearly 2,400 additional jobs in the economic study area. Employment for operation would begin phasing in as construction neared completion. Direct employment related to operations is projected at 330, with more than 560 indirect jobs created throughout the economic study area. As a result of constructing and operating NIF, the baseline compounded average annual growth rate from 1995 to 2003 would increase by 0.002-percentage points.

Peak earnings associated with the 470 direct jobs created in 1998 are projected at approximately 27.1 million dollars. Construction-related procurement would indirectly create more than 60 million dollars in regional earnings. Direct earnings related to operations are projected to reach nearly 14 million dollars, with 16.5 million dollars in indirect earnings added to the regional economy.

I.4.1.2.6.2 *Population and Housing*

Construction. Population in-migration resulting from NIF construction phase demands would begin in 1996 and peak in 1998, with a projected cumulative total of nearly 1,600 people moving into the ROI over the 3-year period (table I.4.1.2.6.1–1). This population increase would result in demand for an additional 580 housing units in the ROI. Baseline projections of the ROI housing market from 1996 (NIF construction start date) through 1998 indicate that nearly 54,000 housing units would be available over the 3-year period. The demand for additional housing units in the LLNL region for NIF-related in-migration would absorb approximately 1 percent of the estimated supply of vacant housing stock in the ROI. Most of this housing demand would be temporary and would primarily affect the renter segment of the ROI housing market. The NIF project would stimulate little demand for new housing construction because of the number of vacant housing units within the ROI and the proximity of LLNL to many communities in northern California with the ability to provide both temporary and permanent housing for in-migrating workers.

Operations. Population in-migration resulting from NIF operation phase demands could result in an additional 360 people moving into the ROI. While additional demand for housing would be longer term relative to construction, no perceptible strain on the market is expected, assuming that the general conditions associated with the housing market continue.

I.4.1.2.6.3 *Public Finance*

Construction. Given the population and economic growth associated with NIF during the construction phase, fiscal balances (revenues and expenditures) are expected to increase slightly for all the jurisdictions within the ROI. Short-term public financial impacts would peak during 1998 and would then decline as construction neared completion in 2002. Since the largest percentage of socioeconomic impacts are expected to occur in Alameda County (assuming current residential patterns), that county would experience larger fiscal impacts than elsewhere in the ROI (table I.4.1.2.6.1–1).

Operations. The increase in population and economic growth as a result of NIF operations would slightly increase fiscal balances (revenues and expenditures) for all counties within the ROI, with the greatest impact in Alameda County. Fiscal impacts would remain relatively stable from the initial impact in 2003 through the duration of NIF operations.

I.4.1.2.6.4 *Public Services*

By 1998, Alameda County would need to hire five additional teachers and three additional doctors to maintain its current level of service. By 2003, when operations start, Alameda County would only need

Source: Model results.

one additional teacher and one additional doctor over the baseline conditions to maintain their level of service (table I.4.1.2.6.1–1).

I.4.1.2.6.5 *Local Transportation*

In 1995, LLNL employed about 8,300 persons. Direct employment generated by the NIF project at LLNL for the life cycle of the project (1996 to 2033) would range from a maximum of 470 new jobs in 1998 to a minimum of 80 new jobs in 2001. The 470 new jobs at LLNL have the potential to generate up to 902 new vehicle trips per day (table I.4.1.2.6.1–1). These additional trips could increase congestion on roads around LLNL, particularly East Avenue (table I.4.1.2.6.5–1).

Indirect jobs could affect traffic flow within the LLNL region, depending on where those jobs were located. However, if the new indirect jobs were sufficiently dispersed, the road network in the San Francisco metropolitan area would likely handle new trips generated by indirect jobs associated with NIF.

I.4.1.2.6.6 *Environmental Justice*

Minorities, but not low-income persons, are clustered disproportionately in the local vicinity of the LLNL site (section I.4.1.1.6.5). Thus, the local area impacts from the construction and operation of NIF could disproportionately affect minorities. However, none of the local area environmental or health impacts from the construction and operation of NIF would be highly adverse or significant. Therefore, no environmental justice issues for local area impacts have been identified for this site.

For the population in the region within 80 km (50 mi) of LLNL, both minorities and low-income populations are in lower proportion to other populations than in California as a whole (section I.4.1.1.6.5). Thus, no environmental justice issues for regional impacts are identified for this site.

I.4.1.2.7 Radiation and Hazardous Chemicals

This section describes potential radiological and hazardous chemical impacts that could result from normal operations and postulated accidents of NIF at LLNL. Methods, data, and assumptions used in estimating these impacts are presented in Lazaro et al. (1996).

I.4.1.2.7.1 *Normal Operations*

The general public living in areas surrounding the LLNL site and workers at LLNL may be exposed to small quantities of radionuclides released and radiation emitted from routine NIF operations; however, the expected level of radioactive releases and radiation emissions would be well within regulatory limits. No impacts from hazardous chemicals should occur because only minute quantities of hazardous VOCs are expected to be emitted during routine NIF operations. Impacts from routine transportation of tritium targets would also not be expected, because there would be no detectable levels of radiation outside the packages carrying the low-energy beta-emitting tritium targets.

Table I.4.1.2.7.1–1 summarizes the potential impacts of radiation exposures from the Conceptual Design and the Enhanced options of NIF operations at LLNL.

TABLE I.4.1.2.7.1–1.—*Potential Radiological Impacts from Normal Operations of the National Ignition Facility at Lawrence Livermore National Laboratory*

maximally exposed member of the public located about 400 m (1,300 ft) east of NIF is 0.1 mrem/yr, which is much less than the dose limit of 100 mrem/yr resulting from all pathways combined (DOE 1990). The likelihood of the maximally exposed individual contracting a fatal cancer would be 1 in 500,000 for the entire operational life of NIF (dose/yr x 30-yr x fatal cancer risk factor of $5x10^{-4}$/rem). The estimated radiation dose to the surrounding public is 0.2 person-rem/yr; no cancer fatalities would be expected to occur in the public for the entire NIF operations at LLNL. For the Conceptual Design Option, estimated radiation impacts would be about one-third the impacts of the Enhanced Option; therefore, no adverse health effects would result.

Impacts to Workers. In addition to exposure to the radionuclides, the general LLNL workers outside NIF could be exposed to direct radiation resulting from high-yield experiments at NIF. For the Enhanced Option, the estimated radiation dose to these non-NIF workers at LLNL is 0.2 person-rem/yr. No cancer fatalities would be expected to occur among workers for the entire NIF operations at LLNL. For the Conceptual Design Option, estimated radiation impacts would be about one-third the impacts for the Enhanced Option and would carry extremely low risk of adverse health effects.

Potential radiation exposures inside NIF would be kept as low as reasonably achievable through facility design, material selection, shielding, and administrative controls. The design objective is to keep the individual radiation worker dose equivalent to or less than 500 mrem/yr. On average, it is estimated that a NIF worker would receive approximately 30 mrem/yr.

I.4.1.2.7.2 *Postulated Accidents*

Radionuclides and hazardous chemicals could be released by accidents either at NIF or during the transportation of tritium targets from the site of production to NIF. Tables I.4.1.2.7.2–1 and I.4.1.2.7.2–2 summarize potential radiological and transportation impacts to the public and workers from postulated facility and transportation accidents, respectively. A description of each accident scenario evaluated is provided in Lazaro et al. (1996).

TABLE I.4.1.2.7.2–1.—***Potential Radiological Impacts from Postulated Bounding Accident Involving the National Ignition Facility at Lawrence Livermore National Laboratory***

Risk (cancer fatalities/yr)	$2x10^{-10}$	$4x10^{-10}$

Source: Model results.

Radiological Impacts

Impacts to the Public. The public could be exposed to radionuclides released from a postulated accident at NIF. The bounding accident assumes an earthquake occurring at the time of a maximum-yield experiment with an accidental release frequency of $2x10^{-8}$/yr. For the Enhanced Option, the estimated radiation dose to the maximally exposed member of the public is 0.2 rem. The likelihood of the maximally exposed individual contracting a fatal cancer from this exposure is 1 in 12,000. The estimated radiation dose to the surrounding public is 440 person-rem. No cancer fatalities would be expected to occur among the public following an accident at NIF. For the Conceptual Design Option, estimated radiation impacts are about one-half the impacts from the Enhanced Option. No adverse health effects would be expected to result.

Table I.4.1.2.7.2–1 also indicates that the risk of radiation-caused cancer fatalities from the postulated accident at LLNL would be essentially zero when the anticipated extremely low accident frequency during NIF operations is taken into account. The risk is the product of the estimated radiation dose, fatal cancer risk factor of $5x10^{-4}$, and accident release frequency of $2x10^{-8}$/yr.

TABLE I.4.1.2.7.2-2.—*Potential Radiological Risks and Consequences of Transporting Tritium Targets from Manufacturing Facilities to Lawrence Livermore National Laboratory*

Fatal cancers	2×10^{-4}	2×10^{-3}
Maximally Exposed Individual[b,d]		
Dose (rem)	1.2×10^{-4}	1.2×10^{-3}
Fatal cancer probability	6×10^{-8}	6×10^{-7}

[a] Collective population fatalities were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Option). For example, a reported value of 4×10^{-3} fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

[b] The most severe accidents assume that 100 percent of the target tritium is released in an oxide form during an accident. Accident consequences results were determined using RISKIND computer program which is described in Yuan et al. 1993. Stable weather conditions (Pasquill stability class F) with a wind speed of 1 m/s (2.2 mph) were assumed.

[c] The maximum consequences would result from an accident occurring in an urban environment. The population was assumed to extend at a uniform density of 3,861 persons/km^2 (10,000 person/mi^2) to a radius of 80 km (50 mi) from the accident site. The population exposure pathways for urban environments include inhalation and resuspended inhalation. Urban environments were not assumed to produce food for local use or export, hence no ingestion dose was included.

[d] The maximally exposed individual was assumed to be at the location of maximum exposure. The location of the maximally exposed individual was assumed to be 380 m (1,247 ft) from the accident under stable weather conditions. Individual exposure pathways include acute inhalation during passage of the plume. No ingestion dose was considered.

Note: The transportation risk assessment assumed 100 percent of the tritium targets are manufactured and transported to NIF from each site. In practice, tritium targets would be produced and transported from more than one manufacturer. The transportation risk assessment was performed for offsite transportation only. Transportation risks from onsite tritium targets were assumed to be negligible compared with risks from offsite transportation.

Source: Model results.

Impacts to Workers. For the Enhanced Option, the estimated radiation dose to all workers at LLNL is 49 person-rem. No cancer fatalities would be expected to occur to workers following the postulated accident at LLNL. For the Conceptual Design Option, the estimated radiation impacts are about one-half the impacts of the Enhanced Option. No adverse health effects would be expected. The risk of radiation-caused cancer fatalities would be essentially zero considering the extremely low frequency potential for the postulated accident to occur. LLNL has a comprehensive emergency plan, which would be expanded to incorporate NIF, to ensure protection of workers in case of an accident or natural disaster.

Transportation Impacts. Radiological impacts associated with the transportation of tritium targets would result from a release of tritium into the environment following a transportation accident. Since tritium is a pure beta emitter with no associated gamma radiation, radiological risks associated with routine (incident-free) transportation operations are considered to be negligible. The potential radiological impacts of transporting tritium targets were calculated for truck and air travel. Trucks were assumed to be used to transport the tritium targets from the manufacturing sites to the nearest major airport, while cargo aircraft were assumed to be used to transport the targets to Oakland International Airport. After arriving at the airport, the targets would be transferred to a truck for shipment to NIF at LLNL.

Table I.4.1.2.7.2–2 presents the risks associated with the transportation of tritium targets from each of the tritium manufacturing facilities to NIF at LLNL. Radiological risk from transportation activities is defined as the product of the accident consequence (dose) and the probability of the accident occurring, and is calculated by considering a wide range of accidents, from high-probability, low-consequence events to low-probability, high-consequence events (see Lazaro et al. 1996). Estimated latent cancer fatality risks are obtained by multiplying the dose risk by 0.0005 latent cancer fatalities per person-rem (International Commission on Radiological Protection [ICRP] 1991). Latent cancer fatality risks range from $5x10^{-10}$ to $9x10^{-9}$ per year for all cases. Nonradiological impacts associated with the ground transport of tritium targets are calculated under both routine (incident-free) and accident conditions. Nonradiological population risks for routine operations are calculated by multiplying the distance traveled by truck in urban population density zones by a risk factor for latent mortality from pollutant inhalation (Rao et al. 1982). Nonradiological population risks resulting from vehicular accidents are calculated in a similar manner by multiplying the state-specific accident fatality rate by the distance traveled by truck in the state.

Maximally exposed individual and population doses were calculated for a transportation accident involving the release of the entire tritium cargo (assumed to be five tritium targets). Radiological impacts resulting from a potential maximum consequence accident were assessed for a general population located in an urban population density zone. Maximally exposed individuals were assumed to be exposed and unshielded as the plume passed at a distance resulting in the largest dose to the individual. Radiological consequences were assessed using worst-case weather conditions (Pasquill Stability Class F) for both the collective population and the maximally exposed individual. For assessment purposes, it was assumed that the entire tritium cargo was released to the environment in oxide form. The estimated number of latent cancer fatalities from the maximum-severity transportation accident was calculated by multiplying the population-committed effective dose equivalent by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Table I.4.1.2.7.2–2 summarizes the impacts resulting from a maximum-consequence accident involved in the transportation of tritium targets.

Hazardous Chemical Impacts. A number of possible chemical accidents were studied in terms of their potential impacts on workers and the public outside the LLNL site boundaries. The four possible accidents likely to have the greatest impacts were studied in detail. The range of accidents considered (including an aircraft crash) and the four selected for more detailed study are discussed in Lazaro et al. (1996). The four accident scenarios considered in detail were as follows:

- A mercury release from the ignitron switches
- A combined alumina/silica release from the target chamber
- A carbonyl fluoride release from the optics treatment area

- A hydrogen fluoride release from the optics treatment area

The nearest public facility to the release points for accidents 1 and 2 is the veterinary hospital to the east. The nearest public facility to the release points for accidents 3 and 4 is the industrial park to the north.

A modeling study was conducted for each of the four release scenarios. More details, including predicted concentrations, are provided in Lazaro et al. (1996). The modeling study applied a dispersion model to each of the releases and used a health criterion representative of acute impacts from an exposure that might happen once in a lifetime. The health criterion (Emergency Response Planning Guidelines-2 [ERPG-2] level) was the concentration below which, if exposure occurred for an hour, would still allow the exposed individual to avoid irreversible health effects by taking emergency action. The results of the modeling yield the following conclusions:

- The threat zone from each of the four accidents would not extend to the boundary with the public under either typical or extreme meteorological conditions

- Nearby buildings and personnel outside would be at risk if any of the four accidents occurred. The assumption was made that the release would not be inhibited by walls of the NIF Laser and Target Area Building, and the wind would take the plume away from the building. The distances beyond which concentrations would fall below the ERPG-2 level for each of the accidents are as follows:

  - Mercury scenario—237 m (778 ft) for both the Conceptual Design and Enhanced options
  - Alumina/silica scenario—171 m (561 ft) for Conceptual Design Option and 231 m (758 ft) for Enhanced Option
  - Carbonyl fluoride scenario—99 m (325 ft) for both the Conceptual Design and Enhanced options
  - Hydrogen fluoride scenario—101 m (331 ft) for both the Conceptual Design and Enhanced options

The personnel in nearby buildings would likely be protected because the release (typically lasting 15 minutes) would pass by the buildings with little infiltration. Personnel in the Laser and Target Area Building and those outside in the immediate vicinity might be affected.

I.4.1.2.8 Waste Management Impacts

This section evaluates potential effects of wastes that would be generated by NIF on current waste management practices at LLNL during construction, normal operation, and the decommissioning of NIF at LLNL.

I.4.1.2.8.1 *Waste Generation and Management During Construction and Operation*

The estimated amounts and types of wastes that would be generated during construction of NIF are listed in table I.4.1.2.8.1–1. Most construction wastes would be nonhazardous and would be handled under conventional construction regulations. Adequate capacity exists at LLNL to handle these wastes. Any hazardous wastes would be handled accordingly, as discussed below.

TABLE I.4.1.2.8.1–1.—*Estimated Amounts and Types of Wastes Generated During Construction of the National Ignition Facility at Lawrence Livermore National Laboratory*

Waste Type	Amount Generated (m^3)
Nonhazardous (sanitary liquid)	14,000
Nonhazardous (sanitary solid)	500
Other nonhazardous (liquid)	900
Other nonhazardous (solid)	900

Source: LLNL 1994b.

Table I.4.1.2.8.1–2 lists the quantities of wastes generated by category for both the Conceptual Design and Enhanced options (Andrews and Tobin 1995). The following discussions describe the proposed disposition of the wastes (using current practices) shown in that table. During operation, various low-level, mixed, hazardous, and nonhazardous wastes would be handled at NIF. Treatment or storage of NIF waste stream would not affect current treatment and/or storage capacities. The quantities of these waste streams at LLNL are presented in tables I.4.1.2.8.1–2 and I.4.1.2.8.1–3. Waste handling

[a] Articles cleaned by wiping, carbon dioxide blasting, and other decontamination methods. These materials would be handled as solid low-level radioactive wastes.

Note: Numbers in bold italics refer to waste estimates for the Enhanced Option; LATB - Laser and Target Area Building; OAB - Optics Assembly Building; HEPA - high-efficiency particulate air.

Source: Andrews and Tobin 1995; Bowers 1995.

methods would be the same for both the Conceptual Design and Enhanced options. While total waste quantities would be somewhat higher for the Enhanced Option, no changes in handling methods would be necessary. Successive sections cover how developing technologies might be applied to minimize waste streams and, finally, disposition of wastes from decommissioning.

Low-Level Waste. The solid LLW processed during NIF operations would be disposed of at the Nevada Test Site (NTS). LLNL presently generates waste streams similar to those that would be produced by NIF, and those wastes are currently approved for disposal at NTS. Further details and a discussion of low-level liquid waste handling are presented in section I.4.1.1.8.1.

Mixed Waste. Solid mixed wastes would be sent to an appropriately licensed commercial mixed waste disposal site. LLNL presently has a contract with a commercial handler for disposal of certain mixed waste streams that meet the waste acceptance criteria, and this agreement would be extended to include NIF mixed wastes.

If an acceptable mixed waste stream contained only "characteristic" hazards (non-listed hazards specific to NIF) and it met the appropriate treatment standards listed in 40 CFR 268, the waste would be approved for shipment to NTS. However, if the mixed waste stream contained a listed hazard, it would be shipped to an approved commercial handler after being stabilized and meeting land requirements. The mixed aqueous waste from cleaning the debris shield would be neutralized, stabilized, and shipped to NTS for disposal as an approved waste stream. If this waste were found to be contaminated with listed solvents not approved for NTS disposal, the stabilized waste would be sent to a commercial handler instead.

Hazardous Waste. LLNL currently disposes of large quantities of hazardous waste by a well-established system using onsite consolidation and shipment to commercial handlers. Capacitors and general chemicals are currently disposed of under this procedure. Under this approach, NIF solid hazardous wastes would be shipped to an approved commercial RCRA treatment, storage, and disposal facility.

Nonhazardous Waste. Storm drains would be available in the NIF site with a capacity adequate for local rainfall at a design-basis flood level. This capacity would be based on a low-hazard-use building under DOE Standard 1020-94, Section 6.1.3. Nonhazardous solid waste generation at the NIF site is estimated to total 6,000 m^3/yr (7,848-yd^3/yr). This solid waste would be handled following general regulations.

Possible Waste Minimization During Operation. Several actions or technologies have been identified that, if successfully implemented, could significantly reduce or even eliminate certain forms of waste now projected for NIF (Andrews and Tobin 1995). In addition, some steps might be taken to reuse or recycle waste material. The proposed technology and procedures are briefly described here, and an estimate of the possible reduced waste streams is shown in table I.4.1.2.8.1–3. These estimates assume successful development of various new methodologies that are proposed to minimize the waste streams. As such, they represent an optimistic lower limit of waste generation at NIF. Comparing these projections to those in table I.4.1.2.8.1–2 indicates that wastes might be reduced significantly (by a factor of 2 to 10). The following discussion identifies some important aspects of the minimization plan.

The lifespan of a molecular sieve could be extended if subatmospheric chamber flushing were employed. The use of lower flushing pressure would reduce vapor loading. Further reductions might be achieved if chamber tritium (following laser beam target strikes) were pumped directly to liquid helium cryo panels.

Minimizing the scrap hardware removed from the chamber would be accomplished by concentrating on three design areas: utilizing activation-resistant materials, minimizing weight and volume of structures, and discouraging the use of temporary setups.

Implementation of an oil-less vacuum roughing pump system would eliminate 200 L (52.8 gal) of liquid mixed waste. Such pumps have only recently become available and would be evaluated for use at NIF; however, their cost and dependability remain uncertain.

Cleaning of the debris shields with carbon dioxide pellets could remove the anti-reflective coating and activated particulate matter. If successful, this procedure could significantly reduce or even eliminate the production of radioactive sodium hydroxide, which is currently listed as liquid mixed waste.

A large fraction of the general chemical waste from the Optics Assembly Area would involve the anti-reflective coating solution. One method for reducing this waste would be to distill the ethanol from the waste solution and reuse it as a cleaner.

Capacitors in the Laser and Target Area Building would be the predominant source of hazardous waste. This source could be reduced by purchasing advanced capacitor units with a longer service life. This decision, however, would depend on the development and cost of such capacitors.

In addition to reducing or eliminating the liquid LLW from debris shield cleaning, carbon dioxide cleaning might also further reduce solid LLW. Far fewer wipes would be needed for general decontamination purposes if a "general decontamination carbon dioxide station" were developed and functional. Other liquid LLW streams, as well as solid mixed and liquid mixed streams, might also be reduced with such a system because carbon dioxide could possibly remove activated particulates, as well as tritium contamination, and eliminate the need for solvents.

Existing Waste Management Capabilities at LLNL. Comparison of the waste volumes that would be generated by NIF (see table I.4.1.2.8.1–2) with current waste handling at LLNL provides an indication of the capability of the existing facilities at LLNL to accommodate the various waste management tasks associated with NIF.

For reference, table I.4.1.1.8–1 shows the current waste management capacity at LLNL. Table I.4.1.2.8.1–4 summarizes, in broad categories, the total yearly NIF waste generation estimates for the Conceptual Design and Enhanced options. Table I.4.1.2.8.1–4 is a condensed version of the earlier detailed flows given in table I.4.1.2.8.1–2.

Table I.4.1.2.8.1–4 shows the potential impact of NIF on waste storage at LLNL. Existing storage capacity (except for hazardous waste) appears to be adequate to handle NIF waste for a number of years. Table I.4.1.2.8.1–5 compares the NIF waste generation rate to the annual handling/treatment capacity at LLNL. This table indicates that NIF waste could generally be treated by current LLNL facilities without a large adverse impact.

In summary, the information presented in tables I.4.1.2.8.1–4 and I.4.1.2.8.1–5 indicates that the added NIF wastes would not represent a significant impact on the existing waste storage capacity nor on the waste treatment capacity at LLNL, since the management of NIF wastes at LLNL would not represent a significant extension of current practices or capabilities. The added impact of NIF wastes on the environment would be minimal and would fall within present regulatory requirements.

I.4.1.2.8.2 *Waste Management at Lawrence Livermore National Laboratory During National Ignition Facility Decommissioning*

The decontamination and decommissioning (D&D) activities for NIF would not add a significant burden to operations at LLNL. This type of activity is common throughout the DOE complex, and LLNL has experienced staff capable of carrying out these types of activities. The procedures proposed by LLNL for decommissioning NIF after its projected 30 years of operation are summarized below (Tobin and Latkowski 1995). The major activated/contaminated components would be located in the target area, so this facility would pose the most complex operation.

Decommissioning of NIF Laser. All assemblies and equipment would be removed from the laser bays, pulse power bays, master oscillator room, and control room. The support systems, piping, and wiring in the laser bays would also be removed. Minimum disassembly would be done on laser components. Glass would be stored in the simplest, least costly manner. Detached assemblies or subassemblies would fall into three categories: those immediately transferable to other DOE projects, those of possible use in the future, and those not likely to be reused. The items in the first category would be reassigned; the items in the second category would be packaged and stored; and the items in the third category would be disposed of through salvage. Several components, namely ignitrons and capacitors, would be handled as wastes. As shown in table I.4.1.2.8.2–1 the volume of the resulting waste would total about 313 m^3 (409 yd^3).

TABLE I.4.1.2.8.1–4.—*Impact of Estimated National Ignition Facility-Generated Waste on Waste Storage at Lawrence Livermore National Laboratory*

Category	NIF-Generated Waste/Year (m^3)		Years to Fill Storage with NIF Flow Alone[a]		Is Existing or Planned Storage Capacity Adequate
	Solid	Liquid	Solid	Liquid	
Low-Level[b]					
Conceptual design total	2.98	0.60	2,000	500	Yes
Enhanced total	7.25	1.56	800	200	Yes
Mixed					
Conceptual design total	0.34	2.0	7,000	300	Yes
Enhanced total	0.88	4.98	2,600	100	Yes
Hazardous[c]					
Conceptual design total	8.0	2.3	12,250	30	Yes, Marginally (liquid)
Enhanced total	8.0	4.6	12,250	20	Yes, Marginally (liquid)

[a] In order to translate the solid waste mass into an expression of volume and to calculate the values shown for the number of years to fill storage capacity with NIF flow alone, the following values for the densities of the materials were assumed: molecular sieves: density of diatomaceous earth (0.22 g/cm^3); personal protective equipment and wipes: density of paper (0.4 g/cm^3); pre- and high-efficiency particulate air filters: density of charcoal (1.8 g/cm^3); paper capacitors: density of paper (0.4 g/cm^3); hardware from the chamber: density of 50 percent aluminum and 50 percent stainless steel (5.3 g/cm^3).

[b] The total amount of the low-level waste was found by adding the values in the column "Cleaned" of table I.4.1.2.8.1–2 to the column "Low-Level" of the same table. The density of the debris shield was assumed to be the density of iron (7.87 g/cm^3). The density of low-level liquid waste was assumed equal to 1.0 g/cm^3. The amount of the "cleaned" personal protection equipment and wipes/general cleaning was added to the solid low-level radioactive waste.

[c] The values for the hazardous waste are the sum of the Laser and Target Area Building and Target Area Building and Optics Assembly Area values.

Decommissioning of NIF Target Area. Two issues dominate the complexity or ease with which structures in the target area would be decommissioned at the end of NIF operation: (1) the extent of tritium contamination and (2) the contact dose due to long-lived activation products induced in large structures such as the target chamber, space frame/mirror support frames, and concrete.

Semipermanent facility features that contain materials of concern for neutron activation, such as cable runs and diagnostics, would be maintained during NIF operations in such a way that contact dose rates would allow their reuse in other facilities. This condition would be achieved through a combination of periodic change-out, radioactive decay time, and shielding. If proven successful, the carbon dioxide system proposed for waste minimization would be adapted to meet NIF decontamination needs. As proposed, frequent cleaning of equipment and inner chamber surfaces exposed to tritium and activated debris would significantly reduce (if not virtually eliminate) the need for major end-of-life decontamination. NIF operations would be designed both to minimize the quantity and extent of contamination and to reduce the hazard level of wastes. NIF decom-

TABLE I.4.1.2.8.1–5.—*Comparison of National Ignition Facility Waste to Annual Treatment Capacity at Lawrence Livermore National Laboratory*

Category	Ratio of NIF Waste Generation to Annual Treatment Capacity[a]	Treatment Capacity (m^3/yr)	Is Treatment Capacity Adequate

missioning operations would be designed to maximize reuse and recycle of all components of the target area. For present estimates, it is conservatively assumed that the tritium decontamination levels required to allow material to be reused in uncontrolled areas or to be scrapped is 10-disintegrations per minute per square centimeter (dpm/cm^2) (62.5-dpm/square inches [in^2]) of removable tritium or 50-dpm/cm^2 (312.5-dpm/in^2) of removable and fixed tritium (generally in compliance with DOE 1990). Material from NIF would be decontaminated to this level before being disposed of or reused in an uncontrolled area. It is assumed that items useful for other DOE facilities that contain or use tritium would be packaged and shipped to those locations rather than undergo extensive decontamination, pending cost/benefit safety analysis. LLNL assumed that the contact dose rate level required to allow material with induced radioactivity to be reused in uncontrolled areas or to be scrapped is the level permitted by DOE O 441.1. Such material would be held in storage at the NIF site until the contact dose rate level decayed to this level or until it could be disposed of as radioactive waste. The waste quantities are listed in table I.4.1.2.8.2–2. Values are provided for both a minimal case, which assumes a 385-MJ annual release over the projected 30-year operational period, and an expanded case, with a 1,200-MJ annual release. The chamber support structures represent the largest volume (3,058 m^3 [4,000 yd^3]) to be handled, with a total volume of all components being about 4,400 m^3 (5,755 yd^3).

TABLE I.4.1.2.8.2–2.—*National Ignition Facility Target Area Low-Level Radioactive Waste Quantities from Decommissioning*

Item	Volume (m³)	Mass (t)
Vacuum system	34	54
Tritium system	16	36
Diagnostics manipulators	12	3.6
Target positioner	2 (4)	1 (2)
Chamber shielding	282 (567)	310 (620)
Chamber plates	6.3	8.5
Laser light absorbers	1.3 (2.0)	1.9 (3.0)
Chamber support structures	3,058	3,364
Target area beam transport	220 (330)	111 (161)
Final optics hardware	754 (1,204)	545 (815)
Total	4,386 (5,233)	4,425 (5,057)

Note: Values shown assume a 30-year life with 385-megajoule yields. Values in parentheses assume 1,200-megajoule annual yields.

Source: Tobin and Latkowski 1995.

Handling of these components would require careful application of as low as reasonably achievable practices. Estimated dose rates encountered during decommissioning for these components are shown in table I.4.1.2.8.2–3. Assuming careful planning and handling of the disassembly, it is estimated that the occupational exposure involved would be on the order of background rates (table I.4.1.2.8.2–4). The operations required would be unique, but would be within the capability of LLNL personnel, considering LLNL's prior experience with decommissioning large facilities and LLW handling.

TABLE I.4.1.2.8.2–3.—*Estimated Contact Dose Rates of Key National Ignition Facility Components*

Component	30-day Dose Rate (mrem/hr) (385 MJ/1,200 MJ)	3-year Dose Rate (mrem/hr) (385 MJ/1,200 MJ)

I.4.2 Los Alamos National Laboratory

I.4.2.1 *Affected Environment*

The following sections describe the affected environment associated with the construction and operation of NIF at Los Alamos National Laboratory (LANL). Land use, air quality and acoustics, water resources, biotic resources, cultural and paleontological resources, socioeconomics, radiation and hazardous chemicals, and waste management are described.

I.4.2.1.1 Location and Land Use

The 11,300-ha (28,000-acre) LANL site is situated on Pajarito Plateau, which consists of a series of finger-like mesas separated by deep east-to-west oriented canyons cut by intermittent streams. Mesa tops range in elevation from approximately 2,400 m (7,800 ft) mean sea level (MSL) on the flanks of the Jemez Mountains to the west to about 1,900 m (6,200 ft) MSL at their eastern termination above the Rio Grande Valley to the east (LANL 1994).

The land surrounding LANL is largely undeveloped, with large tracts of land north, west, and south of the site being held by the Santa Fe National Forest, Bureau of Land Management, Bandelier National Monument, and Los Alamos County. San Ildefonso Pueblo borders LANL to the east (LANL 1994) (figure I.4.2.1.1–1).

Most LANL developments are confined to mesa tops, and most functions are concentrated in eight development areas, each of which is composed of various technical areas (TAs). Most of the land at LANL is very difficult to develop given the significant physical constraints. For example, over half the area consists of slopes that exceed 20 percent (LANL 1990a). Most land provides isolation for security and safety and is held in reserve for future use (LANL 1994).

The proposed NIF location at LANL is within TA-58 (figure I.3.4.2.1–2), which is part of the "Core Area and Two-Mile Mesa North" development area of LANL. The temporary construction laydown area would be located within the location designated for NIF. This development area houses approximately 57 percent of the LANL population and encompasses about 4 percent of the total LANL area. TA-58 is an undeveloped TA west of TA-3, the central hub of administration and support activities. TA-58 is characterized by gradual to moderate forested slopes. Several dirt and gravel roads cross the area. Initial surveys of the proposed TA-58 greenfield site indicate that there are no solid waste management unit locations at the site (ICF Kaiser and LANL 1994). Current access to TA-58 is provided by the existing canyon crossing from TA-3.

The topography of LANL affords spectacular views of the surrounding landscape of forested mountains, deep canyons, and the Rio Grande Valley. The mountain scenery, unusual geology, and archaeological heritage create a diverse visual environment. The scenery contrasts greatly with the functional industrial facilities of LANL. A majority of LANL's parking lots, security gates, and service and storage yards are visible to employees and visitors using public roads (DOE 1995c).

LANL is underlain by soil types varying in texture from clay and clay loam to gravel. Because of the topographic relief of the Pajarito Plateau, rock outcrops occur on greater than 50 percent of the site area. Soils on the mesas in the TA-58 area can vary widely in thickness and are typically thinnest near the edges of the mesas, where bedrock is often exposed. The walls of the canyons often consist of steep rock outcrops and patches of shallow undeveloped soils. Soils near the center of the mesa are more likely to be deeper and more stable, indicating less erosion than soils near the edges of the mesa (LANL 1993). The soils at LANL are acceptable for standard construction techniques, and none have been designated prime farmland or soil of statewide importance for New Mexico.

I.4.2.1.2 Air Quality and Acoustics

This discussion of existing air quality and acoustics includes a review of meteorology and climatology, and ambient air quality characteristics near LANL.

I.4.2.1.2.1 *Meteorology and Climatology*

LANL and the surrounding region have a semiarid, temperate mountain climate. The annual average temperature at LANL is 8.8 °C (47.8 °F); average daily temperatures range from -2.0 °C (28.5 °F) in January to 20.0 °C (68.0 °F) in July. The average annual precipitation at LANL is 47.5 cm (18.7 in) (Bowen 1992). Prevailing winds at LANL are from

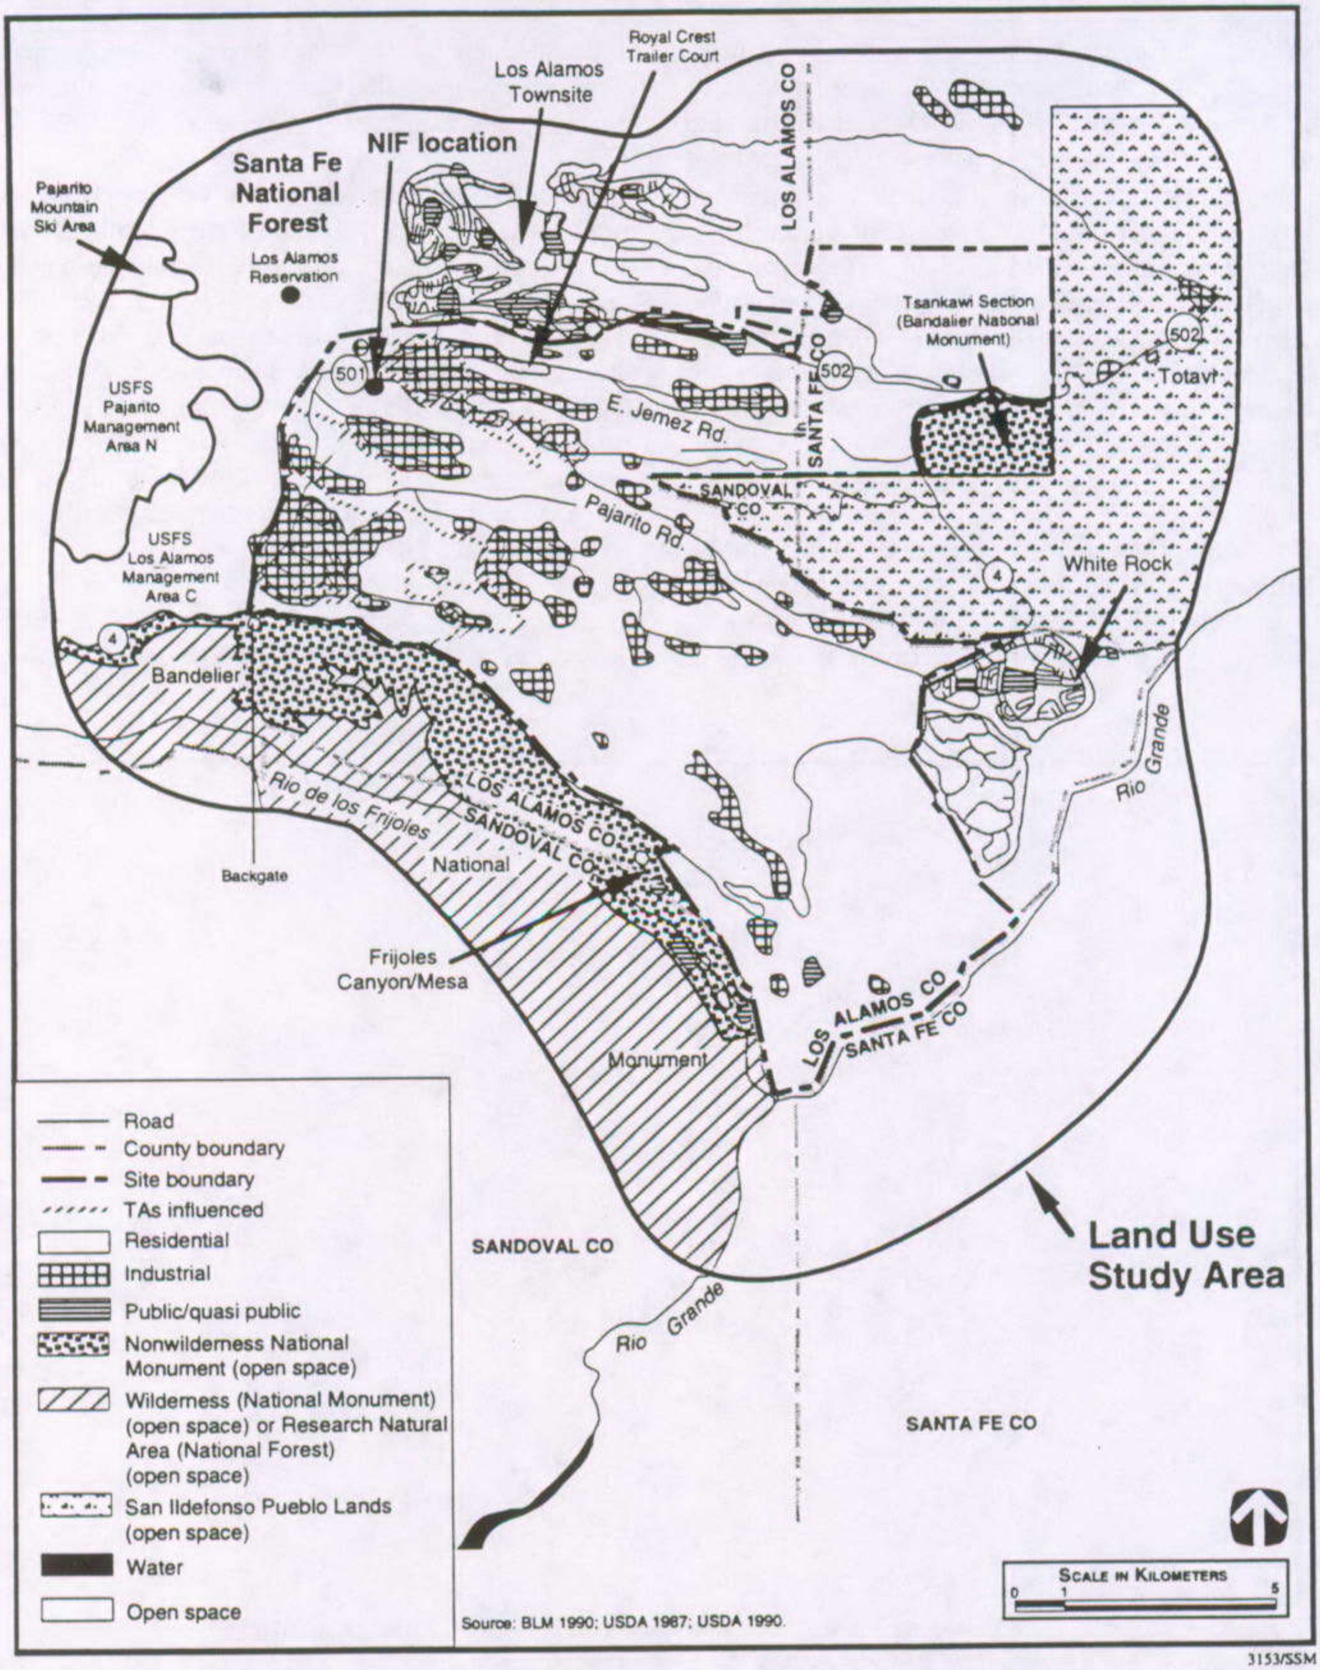

FIGURE I.4.2.1.1–1.—*Generalized Land Use at Los Alamos National Laboratory and Vicinity.*

the south during the day and from the west-northwest at night. The annual average wind speed is 2.8 m/s (6.3 mph) (Bowen 1989). The 1994 annual wind rose for LANL is shown in figure I.4.2.1.2.1–1. From 1990 to 1994, unstable atmospheric conditions occurred approximately 33 percent of the time, neutral conditions occurred about 36 percent of the time, and stable conditions occurred the remaining 31 percent of the time (Kreiner 1995). Atmospheric dispersion improves as the wind speed increases and as atmospheric conditions become more unstable.

I.4.2.1.2.2 *Ambient Air Quality*

The State of New Mexico is responsible for air pollution control and attainment of air quality standards in Los Alamos County. In addition to NAAQS for criteria pollutants, LANL is subject to ambient air quality standards adopted by New Mexico. Applicable NAAQS and New Mexico state ambient air quality standards are presented in table I.4.2.1.2.2–1.

LANL is located within the Upper Rio Grande Valley Intrastate AQCR 157. None of the areas within LANL and its surrounding counties are designated as nonattainment areas for any of the NAAQS (40 CFR 81.332). The nearest nonattainment area, for carbon monoxide and total suspended particulates, is in Bernalillo County, about 65 km (40 mi) south. In general, pollutant emission increases in an area designated nonattainment for a specific pollutant are subject to more stringent permitting requirements than if the area is designated attainment.

The New Mexico Environment Department monitor closest to LANL is adjacent to the Bandelier National

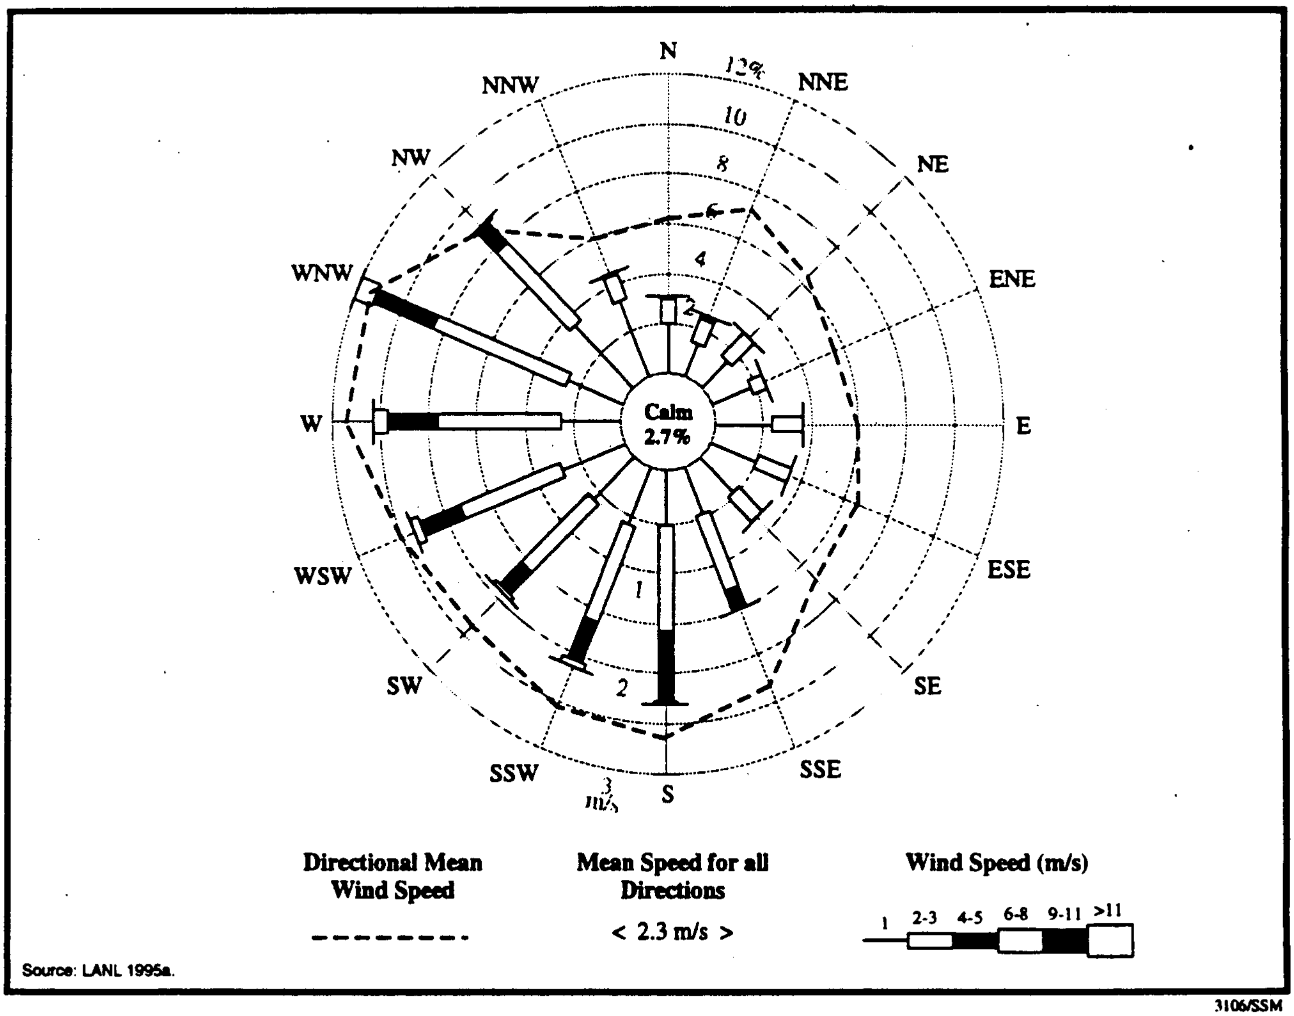

FIGURE I.4.2.1.2.1–1.—*Wind Distribution at Los Alamos National Laboratory, 1994.*

Monument at the southern LANL site boundary, approximately 8 km (5 mi) south-southeast of the proposed NIF location. In addition, LANL maintains eight onsite and nine offsite particulate monitors that measure airborne beryllium concentrations. The most recently published monitoring data show no violations of the NAAQS (see table I.4.2.1.2.2–1).

One Prevention of Significant Deterioration (PSD) Class I Area, the Bandelier National Monument's Wilderness Area, borders LANL to the south. To date, LANL has not been subject to PSD requirements (LANL 1990b; LANL 1994).

The primary emission sources of criteria pollutants at LANL are the steam plants, powerplant, beryllium operations, asphalt plant, burning of explosive wastes, and experimental detonation of conventional explosives (LANL 1994). Other emission sources include fugitive particulates from waste-burial activities, industrial processes, vehicles, and construction activities. Emission estimates for these sources are presented in section I.4.2.2.2.

Table I.4.2.1.2.2–1 presents the baseline ambient air concentrations for criteria pollutants for 1992 to 1993. The baseline concentrations are in compliance with applicable regulations and guidelines.

I.4.2.1.2.3 *Acoustic Conditions*

Major noise emission sources within LANL include various industrial facilities, equipment, and machines. At the site boundary, away from most of the industrial facilities at LANL, noise emitted from the site is barely distinguishable from background noise levels. However, some noise from detonation of explosives can be heard at residences adjacent to the site.

Background noise levels of 31 to 35 dBA have been measured near the Bandelier National Monument entrance and State Route 4 (Vigil 1995) and 38 to 51 dBA at White Rock (Burns 1995). The higher background noise levels at White Rock result from a greater amount of traffic (DOE 1995c).

Peak noise sources at LANL include explosive experiments at several TAs. An onsite peak noise level of 140 to 148 dBA has been measured 230 m (750 ft) from a 9-kg (20-lb) trinitrotoluene (TNT) test. Offsite peak noise levels measured from a 70-kg (150-lb) TNT test were 71 dBA at the site boundary and 60 to 70 dBA at permanent residences (DOE 1995c).

The acoustic environment along the LANL boundary is typical of a rural location, with residual noise levels of 35 to 50 dBA (EPA 1974). Near highways, traffic contributes to ambient noise levels, especially during peak hours, resulting in significantly higher noise levels than at remote locations.

The State of New Mexico has not established specific numerical environmental noise standards applicable to LANL. The Los Alamos County Code, Chapter 8.28.060(d), prohibits propagated noise levels in residential areas above 65 dBA between 7:00 a.m. and 9:00 p.m. and above 53 dBA at other times. Noise between 65 and 75 dBA for more than 10 minutes in a given hour is allowed between 7:00 a.m. and 9:00 p.m. Permits can be requested for temporary activities that exceed these standards (DOE 1995c).

I.4.2.1.3 Water Resources

Proposed new facilities for NIF would be located at the mesa top between Twomile Canyon and one of its tributaries (figure I.3.4.2.1–2). Streamflow in Twomile Canyon and its tributaries is ephemeral. Most runoff results from summer thunderstorms, and occasionally from intermittent springs (LANL 1993).

Groundwater in the LANL area occurs in three modes: (1) water in shallow alluvium in canyons, (2) perched groundwater, and (3) the main aquifer of the Los Alamos area. The main aquifer is the only aquifer in the area capable of serving as a municipal water supply. The main aquifer is separated from the alluvial and perched groundwater by about 110 to 190 m (350 to 620 ft) of tuff and volcanic sediments with low moisture content (LANL 1994).

The water supply for LANL comes from three DOE-owned well fields. Some surface water is used for boiler makeup and lawn watering, but this source accounts for only about 1 percent of the total water use. Average annual production for the entire system is about 5,600 MLY (1,480 MGY), of which about one third (1,900 MLY [502 MGY]) is used at

TABLE I.4.2.1.2.2–1.—***Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Los Alamos National Laboratory***

Pollutant	Averaging Time	Most Stringent Regulation or Guideline (mg/m^3)	Baseline Concentration[a] (mg/m^3)
Criteria Pollutant			
Carbon monoxide	8 hours	7,689[b]	115
	1 hour	11,578[b]	630
Lead	Calendar quarter	1.5[c]	ND[d]
Nitrogen dioxide	Annual	73[b]	3.8[e]
	24 hours	145[b]	ND[d]
Ozone	1 hour	235[c]	139[e]
Particulate matter 10 microns or smaller	Annual	50[c]	8[e]
	24 hours	150[c]	21[e]
Sulfur dioxide	Annual	40[b]	1.3[f]
	24 hours	202[b]	ND[d]
	3 hours	1,300[c]	ND[d]
	1 hour	NS[g]	23[f]
Mandated by State			
Hydrogen sulfide	1 hour	11[b]	ND[d]
Soiling index	-	0.4[h]	ND[d]
Total reduced sulfur	30 minutes	3[b]	ND[d]
Total suspended particulates	Annual	60[b]	8
	30 days	90[b]	<21
	7 days	110[b]	<21
	24 hours	150[b]	21

[a] For short-term standards, baseline concentration is second highest concentration for year for Federal standards and for 1-hour hydrogen sulfide state standard; highest concentration for other short-term standards.

[b] State standard.

[c] Federal standard (40 CFR 50).

LANL. The annual consumption, without the proposed NIF, is expected to increase to 2,300 MLY (608 MGY) in the year 2005. Most water consumption is for industrial use (LANL 1990a; Purtymun et al. 1994; Richardson 1995c).

Most recent water quality monitoring data available for drinking water at LANL indicate that all parameters regulated under the *Safe Drinking Water Act* were in compliance with the maximum contaminant levels established by the regulation (LANL 1994).

I.4.2.1.4 Biotic Resources

LANL is located at the transition between the Arizona/New Mexico Plateau and Southern Rockies ecoregions (Omernik 1986). The predominant habitat in the western portion of LANL (including the proposed NIF area) is the ponderosa pine community (2,100 to 2,300 m [6,900 to 7,500 ft] elevation range). This community is dominated by ponderosa pine, with Douglas fir, Gambel oak, mountain muhly, and little bluestem also being common. The pinyon-juniper community (1,900 to 2,100 m [6,200 to 6,900 ft] elevation range) also occurs in the area. This habitat consists of stands of pinyon pine and one-seeded juniper, as well as grasses such as blue grama and galleta (DOE 1995c). NIF site is located west of a developed area of LANL (figure I.3.4.2.1–2).

Reptiles common to the LANL area include the collared lizard, eastern fence lizard, and whiptail lizard (DOE 1995c). Bird species that nest in the northwestern portion of LANL include the American robin, black-headed grosbeak, chipping sparrow, common raven, Hammond's flycatcher, lesser goldfinch, Steller's jay, white-breasted nuthatch, and western tanager (Travis 1992). LANL has traditionally been a wintering area for elk and mule deer. However, these two species have recently been using LANL on a year-round basis (DOE 1995c). This use has prompted concerns about increases in vehicular accidents with elk and deer at LANL (Kirk 1995, as cited in DOE 1995c). A herd of elk is resident at Two-Mile Mesa, and signs of black bear have been observed in Operational Unit 1111 (which includes TA-58). Raccoons, coyotes, porcupines, and skunks frequent the area (LANL 1993). Smaller mammal species include the Mexican woodrat, deer mouse, Abert's squirrel, and Nuttall's cottontail.

Wetlands at LANL are limited to the canyons, where riverine intermittent wetlands exist in most of the canyons and palustrine emergent and/or scrub-shrub wetlands exist in sections of Pueblo, Los Alamos, Sandia, Pajarito, and Ancho canyons. No wetlands exist in the immediate area proposed for NIF.

Aquatic habitats on LANL are primarily limited to springs and intermittent streams that flow through the 14 major canyons that pass throughout LANL. Releases of treated industrial and sanitary wastewaters allow portions of the intermittent streams in Los Alamos, Sandia, and Mortandad canyons to maintain more permanent flows. No aquatic habitats exist on the immediate NIF location area.

A list of the Federal and state rare, threatened, and endangered species that could exist at LANL is provided in Lazaro et al. (1996). Habitats that could attract several of the species (for example, Mexican spotted owl, northern goshawk, loggerhead shrike, gray vireo, and spotted bat) are present within Operational Unit 1111 (within which the proposed NIF location occurs) (LANL 1993). However, no designated critical habitats for Federal-listed species exist at LANL.

I.4.2.1.5 Cultural and Paleontological Resources

More than 1,300 prehistoric sites have been recorded on LANL; however, no archaeological sites or historic structures are recorded for the proposed NIF location in TA-58. Preliminary assessment of the proposed NIF location indicates that it is unlikely to contain archaeological remains; a field survey will be conducted to verify this assessment (ICF Kaiser Engineers and LANL 1994). Paleontological remains are unlikely to exist on the proposed NIF location because the Pajarito Plateau, composed of Pleistocene volcanic tuffs and the Bandelier Formation, does not contain fossiliferous deposits. No Native American cultural resources have been identified in the proposed NIF location by the six potentially affected tribes.

I.4.2.1.6 Socioeconomics

Socioeconomic characteristics described for LANL include regional economy, population and housing, public finance and public service infrastructure, and local transportation. Regional economic statistics are based on a regional economic study area that encompasses seven counties around LANL as defined by the Bureau of Economic Analysis. The economic study area is a broad labor and product market-based region linked by trade among economic sectors within the region. Statistics for population and housing, public finance, and public service infrastructure are based on the ROI, a three-county area in which more than 90 percent of all LANL employees reside. The ROI includes the counties of Los Alamos (with 48.3 percent of LANL employees), Rio Arriba (20.8 percent), and Santa Fe (19.0 percent). Counties included in the economic study region and counties included in the ROI are listed in Lazaro et al. (1996). Assumptions, assessment methodologies, and supporting data for each TA are also presented in Lazaro et al. (1996).

I.4.2.1.6.1 *Regional Economy*

The regional economic study area for LANL includes the Santa Fe Metropolitan Statistical Area. Between 1988 and 1995, employment in the economic study region was projected to increase from 66,800 to 75,900. BEA (1990) projects a compounded average annual growth rate of 1.26 percent from 1995 to 2003 (8,018 jobs). In 1995, LANL employed approximately 6,200 persons, accounting for 10.8 percent of employment in the regional economic study area. The distribution of LANL employees by place of residence in the ROI are presented in Lazaro et al. (1996).

I.4.2.1.6.2 *Population and Housing*

The ROI has experienced steady population growth between 1980 and 1990, with an average annual increase of about 2 percent, bringing the 1990 total to about 150,000 persons. Population growth has been strongest in Santa Fe County (approximately 30 percent between 1980 and 1990). By the year 2000, population in the ROI is expected to grow to approximately 169,900 persons (BEA 1995; U.S. Department of Commerce 1994).

Between 1980 and 1990 the number of housing units in the ROI increased by over 37 percent, from 46,006 units to 63,386 units (see table I.4.2.1.6.2–1). Housing in Los Alamos County increased from 6,585 units in 1980 to 7,565 units in 1990 (15 percent). Housing in Rio Arriba County increased from 11,107 units in 1980 to 14,357 units in 1990 (29 percent). Housing in Santa Fe County increased from 28,314 units to 41,464 units in 1990 (46 percent). The number of housing units in the ROI is expected to increase about 27 percent between 1990 and 2000 (BEA, 1995; U.S. Department of Commerce, 1994; ULI 1995).

The number of vacant owner units in the ROI has increased from approximately 3,100 units in 1980 to about 5,000 in 1990. It is estimated that in the year 2000 there will be approximately 7,000 vacant owner units if current construction and economic trends continue in the ROI.

In 1980 there were approximately 4,400 vacant housing units in the ROI. The number of vacant housing units increased to about 7,000 in 1990. It is estimated that by 2000 there will be approximately 9,000 vacant housing units if current construction and economic trends continue in the ROI.

I.4.2.1.6.3 *Public Finance and Public Services Infrastructure*

Public financial characteristics of the local jurisdictions in the ROI that would most likely be affected by construction and operation of NIF at LANL are summarized in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund; special revenue funds; and, as applicable, debt service, capital project, and expenditure trust funds. Major revenue and expenditure categories and total revenues less expenditures for counties and cities are presented in table I.4.2.1.6.3–1. Table I.4.2.1.6.3–2 summarizes levels of service for education, community services, and health care.

TABLE I.4.2.1.6.3–1.—*Public Finance—Los Alamos National Laboratory Area*

Revenues and Expenditures[a]	Los Alamos County	Rio Arriba County	Santa Fe County	Santa Fe City	Espanola
Local sources (percent)	56	80	88	82	11
State sources (percent)	44	20	12	17	89
Federal sources (percent)	0	0	0	0	0
Total revenues (dollars)	19,825,220	10,662,842	29,528,335	16,175,431	6,679,263
General government (percent)	26	36	25	44	24
Public safety, health and community services (percent)	74	59	65	51	57
Debt service (percent)	0	4	9	5	7
Other (percent)	0	1	1	0	12
Total expenditures (dollars)	16,085,523	9,280,844	27,221,324	6,454,442	7,015,513
End-of-year fund balance (dollars)	7,190,875	5,570,366	17,676,743	61,911,387	2,851,826

[a] If reporting body did not distinguish between state and Federal revenue sources, the total for all intergovernmental revenue was combined and reported under the "State sources" heading.

I.4.2.1.6.4– *Local Transportation*

Vehicular access to LANL is provided by Pajarito Road; East Jemez Road; U.S. Route 84; and New Mexico Routes 4, 501, and 502 (DOE 1993a). Table I.4.2.1.6.4–1 shows the average daily traffic volumes for the site access roads at LANL. No major road improvements are scheduled for those segments providing immediate access to LANL (DOE 1993a)

Estimated traffic along segments providing access to LANL is projected to contribute to differing service level conditions in accordance with population growth. New Mexico State Route 4 (NMSR 4) would generally support congestion-free traffic flow. NMSRs 501 and 502 would support stable flow. NMSR 501 (between NMSR 4 East and NMSR 502), NMSR 502 (from NMSR 501 at Los Alamos to NMSR 40), and NMSR 502 (between NMSR 4 and NMSR 30) have all reached "level of service C" during the peak commuting hour. This level of service supports stable traffic flow but is approaching congested levels. Along these roadways, a motorist's speed and ability to maneuver could be restricted during the peak hour.

Although there is no public bus service that serves Los Alamos County, a nonprofit bus service provides regular scheduled runs between White Rock, LANL, and the Los Alamos townsite. The closest railroad to LANL is the Atchison, Topeka, and Santa Fe Railroad (DOE 1993a) (Montoya 1995).

The LANL ROI is served by the Albuquerque International Airport, which provides jet passenger service from both national and local carriers. The

Source: DOE 1993a.

Santa Fe Municipal Airport and Los Alamos Airport serve local air traffic (DOE 1993a; DOT 1992).

I.4.2.1.6.5 *Environmental Justice*

Environmental justice concerns the potential for high and adverse environmental or human health impacts to disproportionately affect minority or low-income populations. In this project-specific analysis (PSA), environmental justice is evaluated for impacts within the site region, defined as an 80-km (50-mi) radius around the site, and for the local area. Lazaro et al. (1996) presents the demographic analysis of minority and low-income population distributions on a regional and local basis.

In the LANL site region in 1990, 14 percent of the population was low income and 52 percent was minority. This value represents a lower percentage of the population that is low income, but a slightly higher percent that is minority, than the New Mexico state averages (21 percent low income and 49 percent minority). Within that area, census tracts closer to the LANL site tend not to have significantly higher or lower proportions of minority or low-income populations than tracts farther from the site.

I.4.2.1.7 Radiation and Hazardous Chemicals

I.4.2.1.7.1 *Radiation Environment*

LANL's radiological activities include testing of weapons for the Nation's nuclear arsenal, space nuclear systems, controlled thermonuclear fusion, and nuclear safeguards. A detailed discussion of the radiation environment, including background, radiological releases, and doses to members of the public is presented in *Environmental Surveillance at Los Alamos During 1992* (LANL 1994). The concentrations of radioactivity in various environmental media (air, water, soil) in the site region are also presented in that report.

Calculated radiological doses were used to estimate the potential health impacts to the public and onsite workers at LANL from any releases of radioactivity. The annual doses to individuals, the surrounding population (within 80 km [50 mi]), and workers are summarized in table I.4.2.1.7.1–1; corresponding health risks are also presented in the table. These values are in addition to those from natural background, consumer products, and medical sources, which total about 405 mrem. Background radiation doses are unrelated to LANL operations. Regulatory limits that specify the maximum effective dose equivalent to individual members of the public and occupational workers are also presented in table I.4.2.1.7.1–1.

The doses to the public presented in table I.4.2.1.7.1–1 are within regulatory limits (DOE 1990) and are small in comparison with background radiation. The onsite worker doses are all within regulatory limits, with the exception of the maximally exposed worker dose received by one worker.

I.4.2.1.7.2 *Hazardous Chemical Environment*

The background chemical environment important to human health has been discussed in section I.4.1.1.7.2. The inventories of hazardous materials stored at LANL are presented in table I.4.2.1.7.2–1. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. LANL workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded.

I.4.2.1.8 Waste Management

The current waste management practices at LANL are outlined in table I.4.2.1.8–1. Wastes managed at LANL from research activities include spent nuclear fuel, TRU, low-level, mixed, hazardous, and nonhazardous wastes.

I.4.2.1.8.1 *Low-Level Waste*

Both liquid and solid LLW are generated and managed at LANL. Liquid LLW is generated from many areas throughout the site. LANL has two onsite liquid LLW treatment facilities, one of which uses ion-exchange technology. A new Radioactive Liquid Waste Treatment Facility is planned for LANL. Con-

TABLE I.4.2.1.7.1–1.—*Annual Radiation Doses to the General Public and Onsite Workers from Normal Operations at Los Alamos National Laboratory*

Receptor	Atmospheric Releases: Regulatory Limit[a]	Atmospheric Releases: Calculated	Liquid Releases: Regulatory Limit[a]	Liquid Releases: Calculated[b]	Total: Regulatory Limit[a]	Total: Calculated	Total: Risk[c]
Individual Dose							
Average exposed individual[d] (mrem)	10	6.3×10^{-3}	4	0[e]	100	6.3×10^{-3}	3.2×10^{-9}
Maximally exposed individual (mrem)	10	7.9	4	0.8	100	8.7	4.4×10^{-6}
Population Dose							
Population within 80 km (person-rem)	f	1.4	f	0[g]	f	1.4	7.0×10^{-4}
Worker Dose[h]							
Average worker (mrem)	NA	NA	NA	NA	5,000	34	1.4×10^{-5}
Maximally exposed worker (mrem)	NA	NA	NA	NA	5,000	7,000[i]	2.8×10^{-3}
Total workers[j] (person-rem)	NA	NA	NA	NA	None	194	7.7×10^{-2}

[a] The regulatory limits for individuals are given in DOE Order 5400.5. The 10 mrem/yr limit from airbome emissions is required by the *Clean Air Act*, the 4 mrem/yr limit is required by the *Safe Drinking Water Act*, and the total dose of 100 mrem/yr is the limit from all pathways combined. The occupational limit for workers is 5,000 mrem (10 CFR 835).
[b] The calculated dose values given in the column under Liquid Releases conservatively includes all water pathways, not just the drinking water pathway.
[c] Based on a risk factor of 5×10^{-7}/mrem for individuals, 5×10^{-4} /person-rem for population, and 4×10^{-7}/mrem for workers (ICRP 1991).
[d] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.
[e] Estimated for a population of approximately 224,000.
[f] No regulatory limits exist for population doses; however, a 100 person-rem value for the population is found in proposed 10 CFR834 (58 FR 16268).
[g] Although the maximally exposed individual receives a dose, no population groups are exposed to any liquid pathways.
[h] Worker doses were estimated on the basis of readings from monitoring devices called thermoluminescent dosimeters.
[i] Only one worker exceeded the worker dose regulatory limit.
[j] The number of badged workers in 1992 was approximately 5,700.
Note: NA - not applicable.

struction is expected to be complete in the year 2009. LANL also has an evaporation lagoon for the disposal of tritium-contaminated aqueous wastes at TA-53. The primary user of this facility is the Los Alamos Meson Physics Facility.

Solid LLW is generated from many areas throughout LANL and is disposed of onsite at TA-54, Area G. Solid LLW waste, such as paper, plastic, glassware, and rags, is separated into compactivel and noncompactivel materials by the waste generators. A 181-t (200-ton) compactor currently in the permitting stage will be used in the future to compact solid waste before it is placed in the landfill. Noncompactible LLW items, such as large equipment and much

of the D&D wastes, generally are wrapped in plastic and delivered to the burial site in covered or enclosed vehicles. A portion of the existing landfill has been contaminated by a chemical plume from the hazardous chemical disposal site. This contamination will partially restrict development of the landfill area. An expansion of disposal sites is planned and is currently being reviewed through the *National Environmental Policy Act* (NEPA) process.

I.4.2.1.8.2 *Mixed Low-Level Waste*

Mixed LLW includes solvents, pyrophoric substances, spray cans, scintillation vials, uranium-contaminated lithium hydride, miscellaneous reagent chemicals, vacuum pump oil contaminated with mercury, gas cylinders, and other contaminated material. It is stored onsite at TA-54 in Areas L and G. Currently LANL does not dispose of mixed LLW. The *Federal Facility Compliance Act* of 1992 requires LANL to develop a site treatment plan that will cover all mixed LLW at LANL. For mixed waste with identified treatment technologies, the plan must provide a schedule for submitting permit applications, entering into contracts, initiating construction, conducting system testing, starting operations, and processing mixed wastes. For mixed waste without an identified treatment technology, the plan must include a schedule for identifying and developing technologies, identifying the funding requirements for R&D, submitting treatability study exemptions, and submitting R&D permit applications.

A Hazardous Waste Treatment Facility planned for LANL is designed to treat hazardous and mixed waste streams that are not amenable to offsite treatment. Not all of the technologies to be included in the Hazardous Waste Treatment Facility have been chosen, but the facility will be able to treat reactive metals, plating wastes, acids, bases, ignitable liquids, spent solvents, and decontamination debris. An environmental restoration high-energy plasma technology is being tested as a technique for total destruction of mixed LLW. Another facility that will have the capability to treat mixed waste will be the Mixed Waste Disposal Facility. The treatment facilities will include a plant for treating leachate wastewater, a thermal desorption plant, a plant for stabilizing metals, and a landfill. Some mixed LLW packages are planned to be transported by commercial carriers in closed vans to NTS for burial after NTS is permitted. This procedure will allow LANL to stay in compliance with the *Federal Facility Compliance Act* of 1992.

I.4.2.1.8.3 *Hazardous Waste*

LANL received a permit for treatment, storage, and disposal of hazardous waste under RCRA in November of 1989 and under the Hazardous and Solid Waste Amendments of 1984 provisions from EPA on March 8, 1990. All hazardous waste treatment, storage, and disposal facilities at LANL are either fully permitted or are operating under interim status while other waste management facilities are being developed. Small volumes of almost all wastes listed under 40 CFR 261 are generated as a result of a wide variety of ongoing research. LANL does no landfilling of RCRA-hazardous waste onsite, but contracts with certified transporters to deliver hazardous waste to commercial RCRA-permitted treatment and disposal facilities offsite.

I.4.2.1.8.4 *Nonhazardous Waste*

Nonhazardous wastes are generated routinely and include general facility refuse such as paper, cardboard, glass, wood, plastics, scrap, metal containers, dirt and rubble. Nonhazardous wastes are segregated and recycled whenever possible. Trash is accumulated onsite in dumpsters, which are transported to the county sanitary landfill by commercial firms. The Los Alamos County Landfill is located on property owned by DOE and is operated under a special use permit.

I.4.2.2 *Environmental Impacts*

The following sections describe the potential environmental impacts for land use and visual resources, air quality and noise, water resources, ecological resources, cultural and paleontological resources, and socioeconomics from constructing and operating NIF at LANL. In addition, impacts associated with radiation and hazardous chemicals and waste management are described.

I.4.2.2.1 Land Use and Visual Resources

I.4.2.2.1.1 *Land Use*

Impacts to land use at LANL from NIF would be limited to land cleared and leveled for the Laser and Target Area Building, Optics Assembly Area, General Assembly Area, and office space associated with NIF. The proposed location for NIF (figure I.3.4.2.1–2) consists principally of second-growth woodlands located in TA-58. NIF would require the clearing of an estimated 4 ha (10 acres) of land for buildings, walkways, building access, temporary construction laydown area, and buffer space. The 4 ha (10 acres) would account for approximately 1 percent of the land currently available for development within LANL (Richardson 1995b). However, 4 ha (10 acres) represents an extremely small proportion of LANL's total land area of 111 km^2 (43 mi^2). The project would be located in an area designated as an experimental science land-use zone in LANL's Site Development Plan (LANL 1990a).

With appropriate erosion and sediment control measures, soil impacts during construction of NIF would be short term and minor. Seismic risks would be taken into account during construction and operation of NIF.

I.4.2.2.1.2 *Visual Resources*

New buildings for NIF would be located in the eastern portion of TA-58, in the middle of a young mixed forest of pinyon and Ponderosa pine with typical heights of about 23 m (75 ft) that rises above and to the west of the developed portion of TA-03. In addition to minor and short-term impacts associated with construction activities (fugitive dust, equipment exhaust, etc.), negative visual impacts would occur in the immediate vicinity of the new buildings in the eastern portion of TA-58. The visual character of the woodland would be altered by the presence of large structures, particularly the Laser and Target Area Building, which is expected to exceed 37 m (120 ft) in height. Because of the proximity of the NIF location to highly developed TA-3 and the LANL core area, longer-range views (greater than 1 km [0.5 mi] from the source) would not be adversely affected by NIF.

I.4.2.2.2 Air Quality and Acoustics

I.4.2.2.2.1 *Air Quality*

Construction Emissions. Estimated construction emissions, including emissions from site clearing and emissions associated with building construction, are listed in table I.4.2.2.2.1–1. The construction emission estimates are based on characteristics of the proposed LANL location and on construction vehicle exhaust and fugitive emissions.

Site clearing, which would continue for about two weeks, would produce the greatest amount of fugitive dust PM_{10} emissions compared with other phases of construction (which would occur over four years) and operation. The ISCST2, Version 93109 (EPA 1992a-b) was used to determine the impact of site-clearing activities on ambient air quality (see section I.4.1.2.2.1). The data selected for modeling air quality were 1994 surface meteorological data from the LANL site (LANL 1995a). The surface wind speeds and directions are summarized in an annual wind rose (see figure I.4.2.1.2.1–1). In addition, seasonal average morning mixing height data for Albuquerque (Holzworth 1972) were used throughout the corresponding months (LANL 1995a). Detailed emission inventories associated with site clearing and facility construction, meteorological data used, air quality model assumptions, and model input parameters are presented in Lazaro et al. (1996).

TABLE I.4.2.2.2.1–1.—*Estimated National Ignition Facility Construction Emissions for the Los Alamos National Laboratory Location*

Pollutant	Total Emissions (t/yr)[a]
Particulate matter 10 microns or smaller	8.16[b]
Volatile organic compounds	0.44
Carbon monoxide	1.23
Nitrogen dioxide	3.76
Sulfur dioxide	0.43
Lead	Negligible

[a] Metric tons (1,000 kg) per year.

[b] Includes 2.18 t/yr (2.4 ton/yr) of fugitive emissions for site clearing, using water-spray control that would occur during an approximate 16-day period in the first year and 5.62 t/yr (6.2 ton/yr) of facility construction emissions that would occur for the remainder of the year.

Source: Lazaro et al. 1996.

The national 24-hour particulate matter standard is 150 μg/m^3 (see table I.4.2.1.2.2–1). The 24-hour average particulate matter background concentration representative of the LANL site was 21 μg/m^3 (table I.4.2.1.2.2–1). With conventional dust control (that is, 50 percent control for excavation and 60 percent control for traffic on unpaved roads), maximum 24-hour average PM_{10} concentrations of 94 μg/m^3 over background are predicted at the public access road (West Jemez Road, which runs north of NIF location at the closest distance of 460 m [1,500 ft]). The maximum PM_{10} concentration of 115 μg/m^3, including background concentration, would be below the 24-hour NAAQS of 150 μg/m^3 for PM_{10}. Site clearing at LANL would be expected to last for approximately one-half month, so ambient air quality impacts associated with site clearing would be minor, local, and temporary.

Emissions During Operations. Air pollutant emissions from operation of NIF at LANL would be primarily due to fuel combustion and cleaning of the debris shields. Emissions of solvent VOCs (ethanol) from debris shield cleaning are estimated at approximately 0.5 t/yr (0.55 ton/yr) (LLNL 1995b). Other potential air pollutant emission sources not considered significant would be target destruction during operation under either the Conceptual Design or Enhanced options, exhaust emissions from vehicles used for freight shipments and employee commuting, and emissions from welding operations at the Fabrication Facility.

Table I.4.2.2.2.1–2 lists the estimated LANL annual air pollutant emissions on the basis of the anticipated NIF annual energy requirements provided in table I.4.1.2.2.1–3, adjusted to recognize that at LANL only three new support buildings (area of 4,645 m^2 [50,000 ft^2]) would be required out of the total complement of support buildings (area of 26,722 m^2 [287,643 ft^2]) as indicated in table I.3.4–1. Published emission factors (EPA 1993) were used in the calculations. Emissions of VOCs from solvent cleaning are included. For comparative purposes, table I.4.2.2.2.1–2 includes the LANL 1990 sitewide emissions. More detailed information on emission estimates is provided in Lazaro et al. (1996).

As indicated in table I.4.2.2.2.1–2, estimated air pollutant emissions from NIF operation at LANL are well below 1 t/yr (1.1 ton/yr), except for nitrogen dioxide, which is below 2 t/yr (2.2 ton/yr). Air pollutant emissions from NIF operations are less than 10 percent of LANL 1990 emissions except for VOC, which is approximately 20 percent of 1990 emissions. Existing ambient concentrations for these pollutants (see section I.4.2.1.2.2, table I.4.2.1.2.2–1) are well below the ambient air quality standards for all pollutants. On the basis of this information, it can be concluded that NIF operation would have no adverse impact on air quality and would not contribute to violation of ambient air quality standards.

Under New Mexico Air Quality regulations, a permit would be required before installation of NIF external

TABLE I.4.2.2.2.1–2.—*Annual Emission Increases with National Ignition Facility Operation at Los Alamos National Laboratory*

Pollutant	1990 Emissions[a] (t/yr)	Projected NIF Emissions[b] (t/yr)	1990 Emissions Plus NIF (t/yr)	NIF percent of 1990 Emissions
Particulate matter 10 microns or smaller	2.56[c]	0.18	2.74	6.8
Volatile organic compounds	2.89[d]	0.56	3.45	20
Carbon monoxide	21.58	0.46	22.04	2.2
Nitrogen dioxide	53.88	1.91	55.79	3.55
Sulfur dioxide	0.70	0.03	0.73	5
Lead	0.03	Negligible	0.03	Negligible

[a] Only pollutants with 1990 emissions of 11.35 kilograms/year (kg/yr) (25 lb/yr) or more are reported here.
[b] Emissions based onsite estimated natural gas external combustion, diesel internal combustion, and VOC solvent cleaning (0.5 t/yr [0.55 ton/yr]) and emission factors (EPA 1995c; Lazaro et al. 1996).
[c] Reported as particulate matter and assumed equivalent to particulate matter (PM_{10}).
[d] Reported as nonmethane hydrocarbons and assumed equivalent to VOC.
Source: EPA 1993; LANL 1994.

combustion units (boilers) if the boilers were subject to New Source Performance Standards (New Mexico Environment Improvement Board/Air Quality Control Regulations 702) (NMEIB/AQCR 702) (NMEIB 1994). Gas-fired boilers with rated heat input greater than 105,600 MJ/hr (100 million British thermal units [Btu/hr]), but not over 264,000 MJ/hr (250 million Btu/hr), are limited to New Source Performance Standards nitrogen oxide emissions ranging from 43 to 86 ng/J (depending on the heat release rate, which is a function of the furnace volume [40 CFR 60.44b]). There are no New Source Performance Standards emission limits for gas-fired boilers with a rated heat input at or less than 105,600 MJ/hr (40 CFR 60.40c).

Emissions of VOC at the stated annual rate of about 0.5 t/yr (0.55 ton/yr) would not have a significant impact on local air quality and would not require any additional controls (NMEIB/AQCR 702, Part 2). Additional regulatory information is presented in section I.5.2.1.

I.4.2.2.2.2 *Acoustics*

During the clearing phase of construction for NIF at the LANL site, noise from construction equipment would increase the average outdoor sound level by 6 dB at the location of the nearest public residence. That point corresponds to the location of the maximally exposed individual 1,670 m (5,480 ft) north-northeast of the proposed NIF location. The average outdoor sound level at this location would be expected to increase from 40 to 46 dBA when the clearing equipment was operating. The CNR rank, adjusted for the estimated preexisting background level and for temporal and conceptual characteristics of the sound, would be expected to be "C." Noise with CNR ranks of "A" through "D" is generally considered to be acceptable, with "A" being the least annoying. At a rank of "C," sporadic complaints from the public are expected. However, the possibility of complaints might be lessened if it were explained to the public beforehand that the noise would occur over a period of only about two weeks, and only during daylight hours.

The average outdoor daytime sound level at the nearest laboratory building at LANL would be expected to increase by 14 dB, from 40 dBA to 54 dBA. The adjusted CNR rank for the resulting sound is "D." This sound level would occur outside the laboratory buildings. Unless windows and doors were open, the increase in sound level would not be expected to interfere with any activities that were not sensitive to sound at the level of normal speech.

The average daytime sound level at the nearest Los Alamos townsite residential area, about 1.6 km (1 mi) northwest of the construction site, would be expected to increase by 4 dB, from 45 to 49 dBA. The adjusted CNR rank for the increased level is "B."

These estimates are based on the assumptions given in Lazaro et al. (1996). It is possible that actual noise levels might be either slightly higher or lower than these estimates.

I.4.2.2.3 Water Resources

Construction of NIF at LANL would be expected to have minor to negligible effects on water quality. Utility upgrades under LANL's long-range utilities development plan are expected to meet future projected water requirements and wastewater treatment needs, including those for NIF.

During construction, about 2.95 MLY (0.80 MGY) of water would be required for NIF (LLNL 1995b). NIF operations would require about 152 MLY (40 MGY) of raw water. About 18 MLY (4.7 MGY) of that total would be for domestic use (table I.4.2.2.3–1).

TABLE I.4.2.2.3–1.—*Water and Wastewater Utility Capacity at Los Alamos National Laboratory*

Utility System	Current Usage[a,b]	NIF Requirement[c]	Projected Usage, Including NIF[a]	Current Capacity[a]
Water supply (MLY)	5,519	152	5,671	6,800
Wastewater treatment (MLY)	693	18	711	829

[a] LANL 1990a; LANL 1995b; Richardson 1995c.
[b] DOE 1993b.
[c] LLNL 1995a.

Sanitary wastewater generated by operation of NIF is estimated to total about 18 MLY (4.7 MGY). Consolidation of LANL's existing sewer system was completed in 1992, bringing all treatment systems into compliance with Federal and state regulations. Wastewater treatment capacity in the new consolidated facility is sufficient to meet NIF requirements.

Because the canyons south and north of the NIF location are more than 20 m (65 ft) deep, the 100-year floodplain is contained within the canyons (Dunham 1995). No floodplain map for the 500-year flood is available, but because of the depth of the canyons, flooding of the NIF location from the 500-year flood is unlikely.

I.4.2.2.4 Biotic Resources

I.4.2.2.4.1 *Terrestrial Resources*

NIF (including the temporary construction laydown area) would be constructed within a mix of ponderosa pine and pinyon pine-juniper habitats and would eliminate up to 4.0 ha (9.9 acres) of these habitats. The general types of impacts that could result from NIF construction at LANL would be similar to those discussed for LLNL (e.g., destruction or displacement of wildlife within construction areas) (section I.4.1.2.4). However, the ponderosa pine and pinyon-juniper habitats that would be affected at LANL are of a higher quality than is the disturbed grassland at LLNL. Construction of NIF at LANL would extend the influence of an urbanized/industrial area into more natural habitat and increase fragmentation of the wooded habitat. Operation of NIF is not expected to have significant adverse impacts on terrestrial resources. Fencing around NIF may have a localized affect on the movement of the elk herd and localized disturbance of wildlife could occur from the increased level of human activity.

I.4.2.2.4.2 *Wetlands and Aquatic Resources*

The proposed NIF location at LANL does not contain, nor is it located near, wetlands or surface water resources. Therefore, construction and operation of NIF at LANL would not be expected to adversely affect such resources.

I.4.2.2.4.3 *Rare, Threatened, and Endangered Species*

No significant adverse impacts to rare, threatened, or endangered species from construction or operation of NIF at LANL would be expected. Several of the listed species that exist at LANL could exist in the area proposed for NIF (section I.4.2.1.4.3). Construction of NIF facilities could result in a minor loss of habitat that could be utilized by some species (e.g., New Mexican jumping mouse, northern goshawk, gray vireo, southwestern willow flycatcher, spotted bat, and occult little brown bat). However, no habitat designated as critical would be affected. Lights associated with the NIF project could affect the availability of prey base for the Mexican spotted owl (Risberg 1995).

I.4.2.2.5 Cultural and Paleontological Resources

Construction and operation of the proposed NIF at LANL would have no effect on archaeological sites or historic structures listed on or eligible for NRHP because these resources are absent in the affected area. The proposed NIF would have no effect on important paleontological remains or Native American cultural resources.

I.4.2.2.6 Socioeconomics

Locating NIF at LANL would have a minor impact on socioeconomic conditions in the economic study region and in the ROI described in section I.4.2.1.6. Because NIF partnership includes representatives from government, industry, and the academic sector throughout the United States, procurement and investment required for NIF would be dispersed over a number of different regions, damping the concentration of economic effects of the program in the LANL area.

The following sections describe the effects of constructing and operating NIF on the host region's economy and employment, and on population, housing, public finances and services, and local transportation in the ROI.

I.4.2.2.6.1 *Regional Economic Impacts*

Slight changes in employment and economic activity levels in the economic study region would occur from local spending of employee wages, procurement of goods and services (including construction materials), and other local investments associated with constructing and operating NIF. In addition to creating new jobs (direct) at the site, indirect job opportunities, such as community-support services, would also be created in the economic study region as a result of NIF construction and operation. The total new jobs created (direct and indirect) would contribute slightly to unemployment reduction, income increases, and economic output in the regional economy during construction and operation of NIF (table I.4.2.2.6.1–1). Constructing NIF at LANL would result in a peak of approximately 270 direct jobs in 1998. This construction-related procurement would indirectly create nearly 860 jobs in the economic study area. Employment for operation would begin phasing in as construction neared completion. Direct employment related to operations is projected at 330, with nearly 270 indirect jobs created throughout the economic study region. As a result of construction and operation of NIF, the baseline compounded average annual growth rate from 1995 to 2003 would increase by 0.03 percentage points.

Peak earnings associated with the 270 direct jobs created in 1998 are projected at approximately 15.3 million dollars. Construction-related procurement would indirectly create more than 16 million dollars in regional earnings. Direct earnings related to operations are projected to reach nearly 14 million dollars, with 5.5 million dollars in indirect earnings added to the regional economy.

I.4.2.2.6.2 *Population and Housing*

Construction. Population in-migration resulting from the NIF construction phase demands would begin in 1996 and peak in 1998, with a projected cumulative total of 2,200 people moving into the ROI (table I.4.2.2.6.1–1) over the three-year period. This population increase would result in demand for an additional 800 housing units in the ROI. Baseline projections of the LANL ROI housing market from 1996 (NIF construction start date) through 1998 indicate that nearly 8,800 housing units would be available. The introduction of 2,200 new workers and their families could affect the housing market in the ROI. Additional housing demand could absorb approximately 800 homes or 9 percent of the 8,800 vacant housing units in the LANL region. Such a high demand for housing could stimulate new housing starts and affect housing costs in the region. However, most of this housing demand would be temporary and would primarily affect the renter segment of the ROI housing market.

Operations. Population in-migration resulting from the NIF operation phase demands could result in an additional 610 people moving into the ROI. While this demand for housing would be longer term relative to construction, no perceptible strain on the market is expected, assuming that the general conditions associated with the housing market continue.

I.4.2.2.6.3 *Public Finance*

Construction. Given the population and economic growth associated with NIF during the construction phase, fiscal balances (revenues and expenditures) are expected to increase for all jurisdictions within the ROI. Short-term public impacts would peak during 1998 and would then decline as construction neared completion in 2002. Since the largest percentage of socioeconomic impacts are expected to occur in Los Alamos County (assuming current residential patterns), that county would experience the largest fiscal impact in the ROI (table I.4.2.2.6.1–1).

Operations. The increase in population and economic growth as a result of NIF operations would increase fiscal balances for all counties within the ROI, with greatest impact in Los Alamos County. Fiscal impacts would remain relatively stable throughout the operational period.

I.4.2.2.6.4 *Public Services*

By 1998, the county of Los Alamos would need to hire 13 additional teachers and two additional doctors to maintain its current level of service. By 2003, when operations would start, the county would need only four additional teachers over the baseline conditions to maintain the current level of service.

I.4.2.2.6.5 *Local Transportation*

In 1995, LANL employed approximately 6,200 persons (DOE 1993a). Direct employment generated by NIF at LANL for the life cycle of the project (1996 to 2033) would range from a minimum of 28 new jobs in 1996 to a maximum of 270 new jobs in 1998.

TABLE I.4.2.2.6.1-1.—*Potential Socioeconomic Impacts in the Los Alamos National Laboratory Area*

Parameters	NIF Alternative Change Over Reference Baseline		Reference Baseline	
	Peak Construction 1998[a]	Operations 2003[b]	1996 to 2002[a]	2003[b]
Regional Employment				
Direct jobs	270	330		
Indirect jobs	860	270		
Total jobs	1,130	600	1,760 additional jobs projected annually	2,250 additional jobs projected
Regional Aggregate Earnings[c]				
Direct earnings	15.29	13.81		
Indirect earnings	16.27	5.48		
Total earnings	31.56	19.29		
Regional Population Migration				
ROI in-migrating population	2,200	610	1,700 additional people annually	1,360 additional people
Regional Housing Demand				
Number of housing units in the ROI	800	220	9,080 vacant housing units (annual average)	10,080 vacant housing units
Local Transportation				
Number of trips generated at site per day	518	630		
Public Finance				
Percent change over 1995 fund balance	4.40	0.71	NA[d]	NA
Public Services (LOS)				
Change in service demand (Los Alamos County)				
Police	2	1	48[d]	50
Fire	5	2	130[d]	136
General	28	8	566[d]	585
Physicians	2	0	55[d]	56
Teachers	13	4	260[d]	268

[a] Construction period would be 1996 to 2002, with peak construction projected to occur in 1998.
[b] Operating period would be 2003 to 2033, with impacts throughout the period projected to remain stable.
[c] Regional earnings are in millions of constant 1994 dollars.
[d] Projected 1998 fund balance for Public Finance, and projected 1998 level of service (LOS) for Public Services.

Note: LOS - level of service.

Source: Model results.

The peak number of direct jobs created by NIF at LANL would be approximately 270 in 1998. These direct jobs could generate up to 518 new daily trips on LANL access roads (table I.4.2.2.6.5–1). Depending on where the new workforce resided, congestion on NMSR 4 from NMSR 126 to NMSR 501 could increase in Los Alamos County. The level of service on NMSRs 501 and 502 near LANL are currently approaching congested levels during peak periods; new trips generated from NIF construction and operation could aggravate congestion on these roads (table I.4.2.2.6.5–1).

A peak of approximately 860 indirect jobs in 1998 could impact traffic flow within the region, depending on where these jobs were located. If all indirect employment was concentrated in either Los Alamos or Santa Fe, increased congestion could occur on that city's roads. However, if indirect jobs were dispersed throughout the region, the regional road system would likely be able to handle the additional trips generated from the operation of NIF.

I.4.2.2.6.6 *Environmental Justice*

For the population in the region within 80 km (50 mi) of LANL, minorities are in a higher proportion and low-income populations are in lower proportion to other populations than in New Mexico as a whole (section I.4.2.1.6.5). Socioeconomic impacts within this region would be beneficial. Health impacts from radiological doses in this region would not be expected to result in any cancer fatalities. Because these two impacts would not be highly adverse, no environmental justice issues for regional impacts have been identified.

Neither minority nor low-income populations are clustered disproportionately in the local vicinity of the LANL site (section I.4.2.1.6.5). Thus, the local area impacts from construction and operation of NIF would not disproportionately affect either minority or low-income populations at this site. Consequently, no environmental justice issues related to local area impacts from the construction and operation of NIF have been identified.

I.4.2.2.7 Radiation and Hazardous Chemicals

This section describes potential radiological and hazardous chemical impacts resulting from normal operations and postulated accidents at NIF at LANL. Methods, data, and assumptions used in estimating impacts are presented in Lazaro et al. (1996).

I.4.2.2.7.1 *Normal Operations*

The general public surrounding the LANL site and workers at LANL may be exposed to small quantities of radionuclides released and radiation emitted from routine NIF operations; however, these levels of radioactive releases and radiation emissions would be expected to be well within regulatory limits. No impacts from hazardous chemicals should occur, because only minute quantities of hazardous VOCs would be expected to be emitted during routine NIF operations. Impacts from routine transportation of tritium targets would also not be expected, because there would be no detectable levels of radiation outside the packages carrying the low-energy beta-emitting tritium targets.

Table I.4.2.2.7.1–1 summarizes the potential impacts of radiation exposures resulting from the Conceptual Design and the Enhanced options of NIF operations at LANL.

TABLE I.4.2.2.7.1–1.—*Potential Radiological Impacts from Normal Operations of the National Ignition Facility at Los Alamos National Laboratory*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (mrem/yr)	0.003	0.009
Percent of natural background	$7x10^{-4}$	0.002
30-year fatal cancer probability	$4x10^{-8}$	$1x10^{-7}$

Impacts to the Public. For the Enhanced Option, the estimated radiation dose to a maximally exposed member of the public located about 1.6 km (1 mi) north-northeast of NIF would be 0.01 mrem/yr, which would be much less than the dose limit of 100 mrem/yr resulting from all pathways combined (DOE 1990). The likelihood of the maximally exposed individual contracting a fatal cancer would be 1 in 10 million for the entire operational life of NIF (dose/yr x 30 yr x fatal cancer risk factor of $5x10^{-4}$/rem). The estimated radiation dose to the surrounding public is 0.06 person-rem/yr; no cancer fatalities would be expected to occur in the public for the entire NIF operations at LANL. For the Conceptual Design Option, estimated radiation impacts are about one-third the impacts from the Enhanced Option. No adverse health effects would result.

Impacts to Workers. In addition to potential exposure to radionuclides, the general LANL workers outside NIF could be exposed to direct radiation resulting from high-yield experiments at NIF. For the Enhanced Option, the estimated radiation dose to these non-NIF workers at LANL is 0.05 person-rem/yr. No cancer fatalities would be expected to occur to workers for the entire NIF operations at LANL. For the Conceptual Design Option, estimated radiation impacts are about one-third the impacts from the Baseline Option, posing an extremely low risk of adverse health effects.

Potential radiation exposures inside NIF would be kept as low as reasonably achievable through facility design and administrative controls. The design objective of NIF would be to keep the individual radiation worker dose to less than 500 mrem/yr. On average, it is estimated that a NIF worker would receive a dose of approximately 30 mrem/yr.

I.4.2.2.7.2 *Postulated Accidents*

Radionuclides and hazardous chemicals could be released by accidents postulated at NIF and during the transport of tritium targets. Tables I.4.2.2.7.2–1 and I.4.2.2.7.2–2 summarize potential impacts to the public and workers from postulated facility and transportation accidents. A description of each accident scenario evaluated is provided in Lazaro et al. (1996).

Radiological Impacts

Impacts to the Public. The public could be exposed to radionuclides released from a postulated accident at NIF. The bounding accident assumes an earthquake would occur at the time of a maximum-yield experiment, with an accidental release frequency of $2x10^{-8}$/yr. For the Enhanced Option, the estimated radiation dose to the maximally exposed member of the public is 0.1 rem. The likelihood that the maximally exposed individual would contract a fatal cancer from this exposure is 1 in 16,000. The estimated radiation dose to the surrounding public is 490 person-rem. No cancer fatalities would be expected to occur in the public following such an accident at NIF. For the Conceptual Design Option, estimated radiation impacts are about half the impacts calculated for the Enhanced Option. No adverse health effects would be expected.

TABLE I.4.2.2.7.2–1.—*Potential Radiological Impacts from Postulated Bounding Accident Involving the National Ignition Facility at Los Alamos National Laboratory*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (rem)	0.08	0.1
Fatal cancer probability	$4x10^{-5}$	$7x10^{-5}$
Risk (cancer fatalities/yr)	$8x10^{-13}$	$1x10^{-12}$
Population Within 80 Km		
Dose (person-rem)	290	490
Fatal cancers	0	0
Risk (cancer fatalities/yr)	$3x10^{-9}$	$5x10^{-9}$
Workers Onsite		
Dose (person-rem)	14	23
Fatal cancers	0	0
Risk (cancer fatalities/yr)	$1x10^{-10}$	$2x10^{-10}$

Source: Model results.

Table I.4.2.2.7.2–1 also indicates that the risk of radiation-caused cancer fatalities from the postulated accident at LANL would be essentially zero, considering the extremely low probability of the accident occurring during NIF operations. The risk would be the product of the estimated radiation dose, fatal

TABLE I.4.2.2.7.2–2.—*Potential Radiological Risks and Consequences of Transporting Tritium Targets from Manufacturing Facilities to Los Alamos National Laboratory*

Manufacturing Facility	Conceptual Design Option	Enhanced Option
General Atomics

Nonradiological vehicular emissions (fatalities/yr)	4×10^{-4}	9×10^{-4}
Savannah River		
Dose risk (person-rem/yr)	2.4×10^{-6}	1.9×10^{-5}
Fatality risk (cancer fatalities/yr)	1×10^{-9}	1×10^{-8}
Nonradiological accidents[a] (fatalities/yr)	2×10^{-3}	4×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	4×10^{-4}
University of Rochester		
Dose risk (person-rem/yr)	2.6×10^{-6}	2.0×10^{-5}
Fatality risk (cancer fatalities/yr)	1×10^{-9}	1×10^{-8}
Nonradiological accidents[a] (fatalities/yr)	2×10^{-3}	4×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	4×10^{-4}
Maximum Consequence Accident		
Population[b,c]		
Dose (person-rem)	0.33	3.3
Fatal cancers	2×10^{-4}	2×10^{-3}
Maximally Exposed Individual[b,d]		
Dose (rem)	1.2×10^{-4}	1.2×10^{-3}
Fatal cancer probability	6×10^{-8}	6×10^{-7}

[a] Collective population fatalities causes were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Option). For example, a reported value of 4×10^{-3} fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

[b] The most severe accidents assumed that 100 percent of the target tritium was released in an oxide form during an accident. Accident consequence results were determined using the RISKIND computer program which is described in Yuan et al. 1993. Stable weather conditions (Pasquill Stability Class F) with a wind speed of 1 m/s (2.2 mph) were assumed.

[c] The maximum consequences would result from an accident occurring in an urban environment. The population was assumed to extend at a uniform density of 3,861 persons/km^2 (10,000 persons/mi^2) to a radius of 80 km (50 mi) from the accident site. The population exposure pathways for urban environments included inhalation and resuspended inhalation. Urban environments were not assumed to produce food for local use or export, hence no ingestion dose was included.

[d] The maximally exposed individual was assumed to be at the location of maximum exposure. The location of the maximally exposed individual was assumed to be 380 m (1,247 ft) from the accident under stable weather conditions. Individual exposure pathways include acute inhalation during passage of the plume. No ingestion dose was considered.

Note: The transportation risk assessment assumed 100 percent of the tritium targets would be manufactured and transported to NIF from each site. In practice, tritium targets would be produced and transported from more than one manufacturer.
The transportation risk assessment was performed for offsite transportation only. Transportation risks from onsite transport of tritium targets were assumed to be negligible compared with risks from offsite transportation.

Source: Model results.

cancer risk factor of $5x10^{-4}$/rem, and accident release frequency of $2x10^{-8}$/yr.

Impacts to Workers. For the Enhanced Option, the estimated radiation dose to all workers at LANL from the postulated accident is 23 person-rem. No cancer fatalities would be expected to occur to workers following the postulated accident. For the Conceptual Design Option, estimated radiation impacts are about half the impacts calculated for the Enhanced Option. No adverse health effects would be expected. The risk of radiation-caused cancer fatalities would essentially be zero, considering the extremely low potential for the postulated accident to occur. LANL has a comprehensive emergency plan, which would be expanded to incorporate NIF to ensure protection of workers in case of an accident or natural disaster.

Transportation Impacts. Radiological impacts associated with the transportation of tritium targets would result from a release of tritium into the environment following a transportation accident. Since tritium is a pure beta emitter with no associated gamma radiation, radiological risks associated with routine (incident-free) transportation operations are considered to be negligible. The potential radiological impacts of transporting tritium targets were calculated for truck and air travel. For this analysis, it was assumed that the tritium targets would be transported by truck from the manufacturing sites to the nearest major airport and then by cargo aircraft to Albuquerque International Airport. After arriving at Albuquerque, the targets would be transferred to a truck for shipment to NIF at LANL.

Table I.4.2.2.7.2–2 presents the risks associated with the transportation of tritium targets from each of the tritium manufacturing facilities to NIF at LANL. Radiological risk from transportation activities is defined as the product of the accident consequence (dose) and the probability of the accident occurring, and was calculated by considering a wide range of accidents, from high-probability, low-consequence events to low-probability, high-consequence events (see Lazarro et al. 1996). Latent cancer fatality risks were obtained by multiplying the dose risk by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Latent cancer fatality risks range from $1x10^{-9}$ to $1x10^{-8}$ per year for all cases.

Nonradiological impacts associated with the ground transport of tritium targets were calculated under both routine (incident-free) and accident conditions. Nonradiological population risks for routine operations were calculated by multiplying the distance traveled by truck in urban population density zones by a risk factor for latent mortality from pollutant inhalation (Rao et al. 1982). Nonradiological population risks resulting from vehicular accidents were calculated in a similar manner by multiplying the state-specific accident fatality rate by the distance traveled by truck in the state.

The maximally exposed individual and population doses were calculated for a transportation accident involving release of the entire tritium cargo (assumed to be five tritium targets). Radiological impacts from a potential maximum-consequence accident were assessed for a general population located in a zone of urban population density. Maximally exposed individuals are assumed to be exposed unshielded as the plume passed at a distance resulting in the largest dose to the individual. Radiological consequences were assessed using worst-case weather conditions (Pasquill Stability Class F) for both the collective population and the maximally exposed individual. For assessment purposes, it was assumed that the entire tritium cargo was released to the environment in oxide form. The estimated number of latent cancer fatalities from the maximum-severity transportation accident was calculated by multiplying the population committed effective dose equivalent by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Table I.4.2.2.7.2–2 summarizes the impacts resulting from a maximum-consequence accident during the transport of tritium targets.

Hazardous Chemical Impacts. A number of possible chemical accidents were studied in terms of their potential impacts on workers and the public outside the LANL site boundaries. The range of accidents considered (including an aircraft crash) and the four possible accidents likely to have the greatest impacts were studied in detail (see Lazaro et al. 1996). These four accidents are as follows:

- A mercury release from the ignitron switches
- A combined alumina/silica release from the target chamber

- A carbonyl fluoride release from the optics treatment area

- A hydrogen fluoride release from the optics treatment area

These accidents would occur within the NIF Laser and Target Area Building, and people at nearby buildings and members of the public would be potentially at risk for inhalation effects. The nearest location of members of the public would be 1.6 km (1.0 mi) north-northeast of the proposed NIF.

A modeling study was conducted for each of the four release scenarios. More details, including predicted concentrations, are provided in Lazaro et al. (1996). The modeling study applied a dispersion model to each of the releases and used a health criterion representative of acute impacts from an exposure that might happen once in a lifetime. The health criterion (ERPG-2 level) was the concentration below which, if exposure occurred for an hour, the exposed individual could still avoid irreversible health effects by taking emergency action. The results of the modeling yield the following conclusions:

- The threat zone from each of the four accidents would not extend to the boundary with the public under either typical or extreme meteorological conditions

- Nearby buildings and personnel outside would be at risk if any of the four accidents occurred. The assumptions were made that the release would not be inhibited by walls of NIF Laser and Target Area Building and that the wind would take the plume away from the building. The distances beyond which concentrations would fall below the ERPG-2 level for each of the accidents are as follows:

  - Mercury scenario—237 m (778 ft) for both the Conceptual Design and Enhanced options

  - Alumina/silica scenario—171 m (561 ft) for the Conceptual Design Option and 231 m (758 ft) for the Enhanced Option

  - Carbonyl fluoride scenario—70 m (230 ft) for both the Conceptual Design and Enhanced options

  - Hydrogen fluoride release—101 m (331 ft) for both the Conceptual Design and Enhanced options

The personnel in nearby buildings would likely be protected because the release (typically lasting 15 minutes) would pass by the buildings with little infiltration. Personnel outside in the immediate vicinity of the NIF building may be affected.

I.4.2.2.8 Waste Management Impacts

This section evaluates wastes that would be generated by NIF that might affect the current waste management practices of LANL during construction, operation, and decommissioning of NIF if it were to be located at LANL.

I.4.2.2.8.1 *Waste Generation and Management During Construction and Operation*

All construction wastes would be nonhazardous and would be handled under conventional construction regulations. Site capacity is adequate to handle these wastes, or arrangements would be made with offsite disposal facilities if necessary.

Table I.4.1.2.8.1–2 (section I.4.1.2.8.1) describes the quantities of wastes generated during operations by category for both the Conceptual Design and Enhanced options (Bowers and Crawford 1995). The following discussions describe current practices and the proposed disposition of NIF operational wastes shown in table I.4.1.2.8.1–2 for LANL.

During operation, various low-level, mixed, hazardous, and nonhazardous wastes would be handled at NIF. The quantities of these wastes and their proposed management at LANL are discussed below. Technologies that might be employed to minimize waste streams are also discussed. Waste handling methods would be the same for both the Conceptual Design and Enhanced options. Waste quantities would be somewhat higher for the Enhanced Option; however, no changes in waste handling would be necessary.

Aqueous LLW would be treated at TA-50 (radioactive Liquid Waste Treatment Facility) if the tritium concentration was low enough in the TA-53 lagoon or would be treated using equipment and techniques developed by LANL's Tritium Systems and Engineering Group (Richardson 1995d). Molecular sieves would be disposed of at TA-54, Area G. Personal protective equipment and cleaned wipes would be reused, as is common practice at other laboratories. Solid LLW would be disposed of at TA-54, Area G. High-efficiency particulate air filters are currently sampled and characterized at LANL by the Chemical Science and Technology Division, which has a program to dispose of high-efficiency particulate air filters at TA-54. Solid LLW material that is discarded is an approved waste for disposal at TA-54.

Solid mixed wastes generated by NIF would be stored at Area G of TA-54 in inspectable arrays until characterization and selection of an appropriate disposal facility (for example, Hazardous Waste Treatment Facility or NTS). The tritiated vacuum pump oil could be stabilized. Liquid mixed waste would be treated onsite or stabilized.

Hazardous Waste. Disposal of capacitors and general chemicals would be handled as outlined in section I.4.2.1.8.3.

Nonhazardous Waste. Nonhazardous wastes generated by NIF would be handled similarly to current procedures at LANL (section I.4.2.1.8.4). The incremental waste generated by NIF would not be expected to significantly affect the volume of wastes that would be disposed of at the Los Alamos County Landfill located on property owned by DOE (Richardson 1995e).

Potential Waste Minimization During Operations. During operations, waste minimization would be handled as described in section I.4.1.2.8 for LLNL.

Existing Waste Management Capabilities at LANL. The estimated waste that would be generated by NIF is listed in table I.4.1.2.8.1–2. Table I.4.2.2.8.1–1 compares the NIF waste generation rate to the annual handling/treatment capacity at LANL. Table I.4.2.2.8.1–2 details the impacts that NIF would have on existing storage capacities at LANL.

I.4.2.2.8.2 *Waste Management at Los Alamos National Laboratory During National Ignition Facility Decommissioning*

LANL proposes that decommissioning NIF after the projected 30 years of operation would follow the procedures for handling the laser, target area, and associated equipment as described in section I.4.1.2.8 for LLNL.

TABLE I.4.2.2.8.1–1.—*Comparison of National Ignition Facility Waste to Annual Treatment Capacity at Los Alamos National Laboratory* [Page 1 of 2]

Hazardous[c]						
Conceptual design total	8.0	2.30	63	200	Yes	Yes
Enhanced total	8.0	4.60	63	100	Yes	Yes

[a] The following values for the densities of the materials were assumed: molecular sieves: density of diatomaceous earth (0.27 g/cm^3); personal protective equipment and wipes: density of paper (0.4 g/cm^3); pre- and high-efficiency particulate air filters: density of charcoal (1.8 g/cm^3); paper capacitors: density of paper (0.4 g/cm^3); hardware from the chamber: density of 50 percent aluminum and 50 percent stainless steel (5.3 g/cm^3).

[b] The total amount of the low-level waste was found by adding the values in the column "Cleaned" of table I.4.1.2.8.1–2 to the column "Low-Level" of the same table. The density of the debris shield was assumed to be the density of iron (7.87g/cm^3). The density of the low-level liquid waste was assumed equal to 1.0 g/cm^3. The amount of the "cleaned" personal protective equipment and wipes/general cleaning was added to solid low-level radioactive waste.

[c] The values for the hazardous waste were calculated by adding the hazardous waste from the Laser and Target Area Building and the Optics Assembly Area.

Source: Calculated from tables I.4.1.2.8.1–2 and I.4.2.1.8–1.

I.4.3 Nevada Test Site

I.4.3.1 *Affected Environment*

The following sections describe the affected environment associated with the construction and operation of NIF at Area 22 of Nevada Test Site (NTS). Land use, air quality and acoustics, water resources, biotic resources, cultural and paleontological resources, socioeconomics, radiation and hazardous chemicals, and waste management are described.

I.4.3.1.1 Location and Land Use

The 350,000-ha (867,000-acre) NTS site is located east of U.S. Route 95 in Nye County, Nevada. All of the land within NTS is owned by the Federal Government and is administered, managed, and controlled by DOE. NTS is also entirely bordered by Federal land—the land to the west, north, and east consists of the Nellis Air Force Range, and Federal land to the south is administered by the Bureau of Land Management. There is no prime farmland at NTS. Offsite agricultural activity occurs on the southern side of U.S. Route 95 and consists of a cattle allotment granted by the Bureau of Land Management (DOE 1995c). Figure I.4.3.1.1–1 shows generalized land uses at NTS and vicinity.

NTS is divided into three major regions consisting of 26 areas. The northern region is the underground nuclear weapons test area. The southwestern region (Area 25) provides support primarily for DOE's proposed high-level waste repository at the Yucca Mountain Project Site. The southeastern region is the nonnuclear explosives test area and the primary administrative and support area of NTS. Mercury Base Camp, in the southeastern region is the main base camp for worker housing and administrative operations for the site (DOE 1995c).

The proposed location for NIF is in Area 22, which is an undeveloped area approximately 3.2 km (2.0 mi) southwest of the Mercury Base Camp (figure I.3.4.3.1–2). New buildings required for NIF would be constructed in Area 22, while most other NIF requirements would be met through conversion of existing facilities located within the Mercury Base Camp. General maintenance would use two existing buildings in Area 6, approximately 52 km (32 mi) from the proposed NIF location. The temporary construction laydown area would be located within the location designated for NIF.

NTS is in the southern Great Basin Region of the Basin and Range Physiographic Province, which is characterized by a series of north-south trending mountain ranges separated by broad alluvial valleys. The higher elevations on NTS are on Pahute Mesa, about 2,205 m (7,235 ft), and Rainer Mesa, about 2,345 m (7,649 ft) above sea level. The lowest elevations are in Frenchman Flat and Jackass Flats, both at approximately 910 m (3,000 ft) above sea level (DOE 1995d).

The visible facilities of NTS are scattered within this setting. Public viewpoints of NTS are located in the Amargosa Valley and Mercury Valley along U.S. Route 95. At the principal view point in the Mercury Valley, the main base camp at Mercury is well defined at night by facility lighting (DOE 1995c).

Limited soil studies have been performed at NTS. Studies in adjacent areas have classified soils into three major types: shallow soils developed in the uplands and mountains; soils on valley fill and nearly level to moderately sloping outwash plains, alluvial fans, and fan aprons; and playas and soils on nearly level flats and basins. Possible erosion hazards range from slight to severe, while the shrink-swell potential ranges from low to high for these soils. The potential for wind erosion and shrink-swell increases into the playas and basins. The soils at NTS are considered acceptable for standard construction techniques. There is no prime farmland at NTS (DOE 1995c).

I.4.3.1.2 Air Quality and Acoustics

This discussion of existing air quality and acoustics includes a review of the meteorology, climatology, and atmospheric dispersion characteristics near NTS.

I.4.3.1.2.1 *Meteorology and Climatology*

The climate at NTS and in the surrounding region is characterized by limited precipitation, low humidity, and large diurnal temperature ranges. The lower elevations are characterized by hot summers and mild winters. As elevation increases on the site, precipitation increases and temperature decreases (DOE 1986). The annual average temperature at Desert Rock, NV, near the proposed NIF location at NTS is

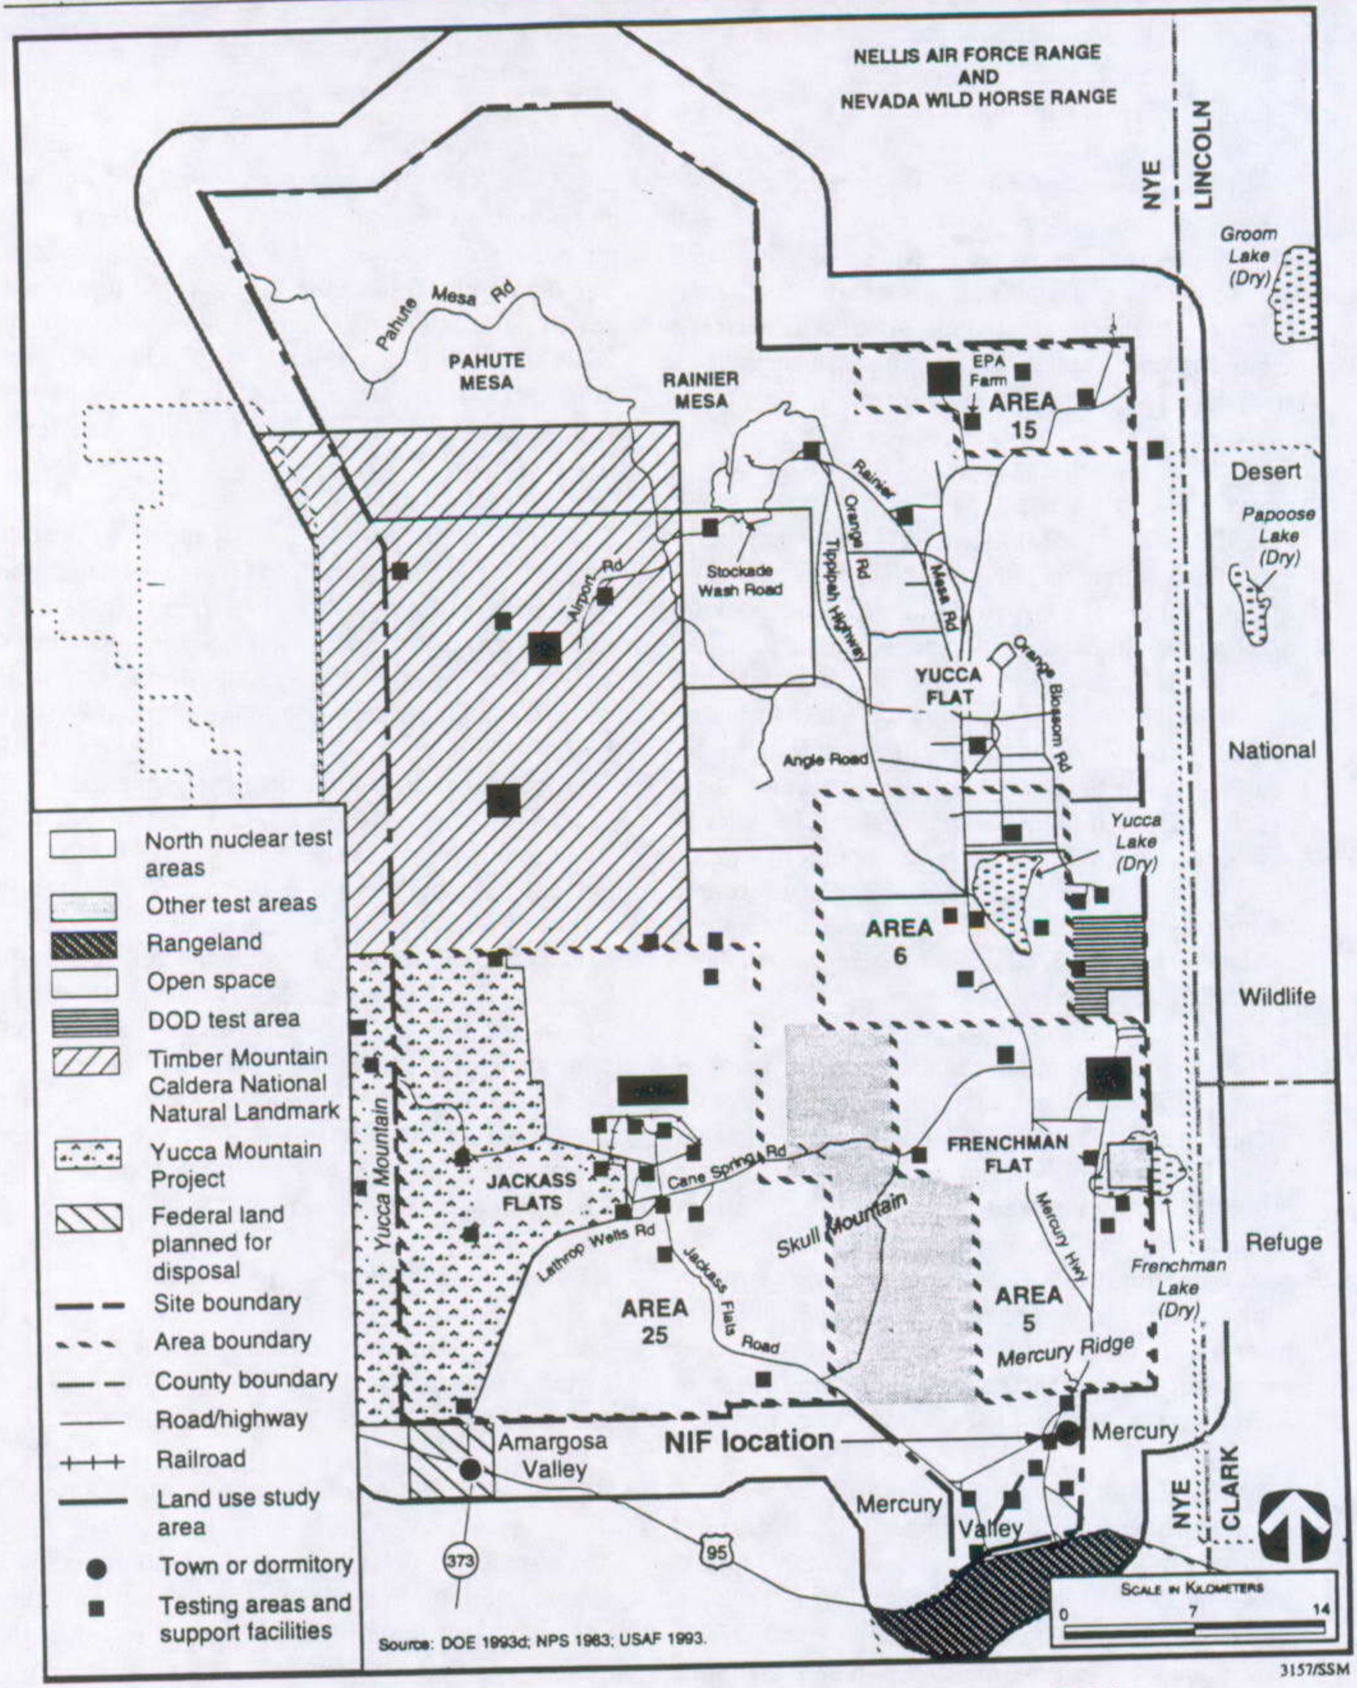

FIGURE I.4.3.1.1–1.—*Generalized Land Use at Nevada Test Site and Vicinity.*

16.5 °C (62 °F); average daily temperatures range from 6.5 °C (44 °F) in January to a maximum of 29.0 °C (84 °F) in July. The average annual precipitation is 17.1 cm (6.72 in). The prevailing winds are from the south-southwest during the day and east-northeast at night at an annual average wind speed of 15 km/hr (kph) (9.2 mph) (White 1995a). The 5-year wind rose for NTS (based on measurements at Desert Rock Air Strip) is shown in figure I.4.3.1.2.1–1. During 1987 to 1991, unstable atmospheric conditions occurred approximately 22 percent of the time, neutral conditions about 38 percent of the time, and stable conditions the remaining 40 percent (EPA 1995b). In general, atmospheric dispersion improves as the wind speed increases and as atmospheric conditions become more unstable.

The limited precipitation and warm temperatures characteristic of the region create an arid climate that limits the growth of ground-covering vegetation, resulting in large areas of exposed soil that are potential sources of windborne particulate matter (dust). Atmospheric particulate matter concentrations are reduced if the exposed soil is wetted or if the particulate matter is "washed out" of the atmosphere by precipitation. However, the area's precipitation and temperature seldom provide these beneficial mechanisms. This condition increases the particulate matter background concentration and increases the likelihood that the area's PM_{10} and total suspended particulates (TSP) ambient air concentrations will approach or exceed regulatory standards.

I.4.3.1.2.2 *Ambient Air Quality*

The State of Nevada is responsible for air pollution control and attainment of air quality standards in Nye County. Federal air quality standards exist for the criteria air pollutants ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, PM_{10}, and lead

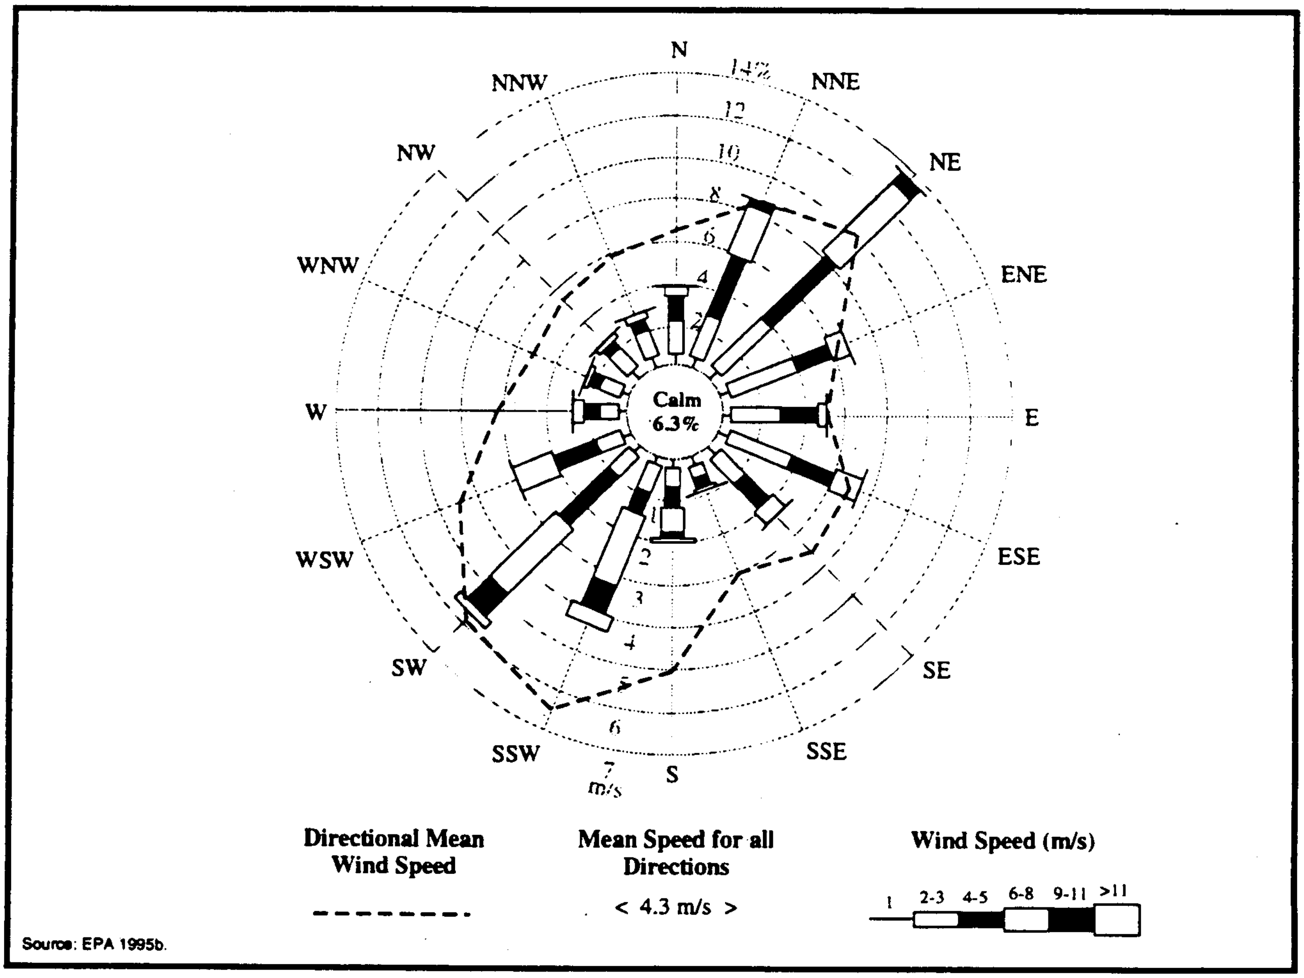

FIGURE I.4.3.1.2.1–1.—*Wind Distribution at Nevada Test Site, 1987-1991.*

(40 CFR 50). Nevada has also established state ambient air quality standards for these pollutants, as well as for hydrogen sulfide and visibility. The state and national ambient air quality standards for criteria pollutants are the same for Nye County (NBAQ 1988-1992). Applicable NAAQS and Nevada State ambient air quality standards are presented in table I.4.3.1.2.2–1.

Nye County, located in the Nevada Interstate AQCR 147, is in attainment or unclassified with regard to the NAAQS (40 CFR 81.329). In general, pollutant emission increases in an area designated nonattainment for a specific pollutant are subject to more stringent permitting requirements than if the area is designated attainment or unclassified.

The monitoring data available for NTS are very limited. Carbon monoxide data were collected for one month at three NTS sites in 1990. Onsite monitoring data have also been collected for PM_{10} and sulfur dioxide. The closest state-operated air monitoring station, located in the North Las Vegas area (AQCR 13) about 105 km (65 mi) southeast of NTS, is not representative of NTS. Table I.4.3.1.2.2–1 shows that, except for the 24-hour PM_{10}, baseline concentrations are in compliance with applicable national and Nevada ambient air quality standards. The PM_{10} is exceeded because of moderate background concentrations attributable to the desert terrain and contributions from operations at the site (DOE 1995c).

The area surrounding NIF location at NTS contains two PSD Class I areas: the Grand Canyon National Park, approximately 193 km (120 mi) to the east-southeast in Arizona, and Sequoia National Park, approximately 169 km (105 mi) to the west in California.

The primary criteria pollutant emission sources at NTS include particulates from construction, unpaved roads, and other ground surface disturbances; various pollutants from operation of fuel-burning equipment, incineration, and open burning; and VOCs from fuel

TABLE I.4.3.1.2.2–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Nevada Test Site*

Pollutant	Averaging Time	Most Stringent Regulation or Guideline (μg/m^3)	Baseline Concentration (μg/m^3)
Criteria Pollutant			
Carbon monoxide	8 hours	10,000[a,b]	2,300
	1 hour	40,000[a,b]	2,700
Lead	Calendar quarter	1.5[a,b]	ND[c]
Nitrogen dioxide	Annual	100[a,b]	ND
Ozone	1 hour	235[a,b]	ND
Particulate matter	Annual	50	8.4

storage facilities (DOE 1995c). Emission estimates for these sources are listed in section I.4.3.2.2.

I.4.3.1.2.3 *Acoustic Conditions*

Major sources of noise within NTS include various industrial facilities, equipment, and machines, and aircraft operations. No noise survey data for NTS are available. At the site boundary, away from most of the industrial facilities at NTS, noise emitted from the site is barely distinguishable from background noise levels.

The acoustic environment along the NTS boundary can be classified as either uninhabited desert or small rural communities and is assumed to be that of a rural location with residual noise levels of 35 to 50 dBA (EPA 1974). Near highways, traffic contributes to ambient noise levels, especially during peak hours, resulting in significantly higher noise levels than at remote locations. Except for the prohibition of nuisance noise, neither the State of Nevada nor its local governments have established specific numerical environmental noise standards applicable to NTS (DOE 1995c).

I.4.3.1.3 Water Resources

No perennial streams exist in the proposed NIF location at NTS (figure I.3.4.3.1–2). Rainfall quickly evaporates or infiltrates the normally dry soil; flows in stream channels occur only after significant precipitation events. Flowing water in the normally dry channels, if it occurs, also evaporates or seeps into permeable sand and gravel channel beds (DOE 1995d). During extreme storm events, sheet flooding may occur. The 500-year floodplain has not been delineated for the proposed NTS Area 22 location for NIF. Preliminary calculations indicate that the broad, flat plain that includes the proposed NIF location may experience a sheet flow reaching a depth of 0.09 m (0.3 ft) during a 500-year flood event (White 1995f).

Groundwater beneath the eastern portion of NTS, which includes the proposed NIF location, is part of the Ash Meadows groundwater sub-basin. Three primary aquifers are present within this subbasin: the Lower Carbonate (the deepest), the Volcanic, and the Valley-Fill (the shallowest). Other aquifers are present to a limited extent under the area, but their water-yielding potential has not been thoroughly investigated. The Lower Carbonate, the regional aquifer, has a saturated thickness ranging from about 100 to 1,000 m (328 to 3,280 ft). The groundwater in this aquifer flows in a south-southwest direction toward Ash Meadows. The Volcanic and Valley-Fill aquifers range in thickness from 0 to about 600 m (0 to 1,970 ft) and are confined within local drainage basins. The depth to the groundwater table is about 220 m (722 ft) beneath valleys in the southern part of NTS (DOE 1995c-d). NTS water supply system consists of 17 wells, 11 of which are currently active (White 1995b).

I.4.3.1.4 Biotic Resources

NTS occurs within the Southern Basin and Range Ecoregion (Omernik 1986). The site is in a transition area between the Mojave and Great Basin deserts and, thus, contains species characteristic of both deserts. Less than one percent of the 350,000 ha (867,000 acres) of NTS is developed; thus, natural plant communities are found across most of NTS. The areas designated for use for NIF are within the creosote bush community (one of nine major plant communities occurring at NTS). Introduced plants such as red brome, cheatgrass, and Russian thistle are common in some areas (DOE 1995c).

Common wildlife species at NTS include the side-blotched lizard, western shovel-nosed snake, black-throated sparrow, red-tailed hawk, Merriam's kangaroo rat, and Great Basin pocket mouse. Raptors common to NTS include the turkey vulture and rough-legged hawk. Carnivores that exist at NTS include the long-tailed weasel and bobcat, and big-game species include the pronghorn antelope and mule deer. Hunting is not permitted on NTS.

Wetlands are associated with the playas and springs on NTS. However, no potential wetlands exist in the area designated for NIF. Natural aquatic resources at NTS are limited to two playas and a few natural springs. In addition, sewage lagoons and ponds are associated with existing NTS facilities, and man-made water reservoirs are located throughout NTS. The water reservoirs support introduced bluegill, goldfish, and golden shiners. None of the aquatic resources exist in the area designated for NIF.

A list of Federal and state rare, threatened, and endangered species that could potentially exist at NTS is provided in Lazaro et al. (1996). The desert tortoise is the only Federal-listed (threatened) species known to inhabit NTS, and no designated critical habitats for Federal-listed species exist at NTS. Habitats that could attract several of the species (e.g., chuckwalla, desert tortoise, and loggerhead shrike) are present. The distribution of the desert tortoise includes the southern third of NTS, which includes the location designated for NIF (figure I.4.3.1.4–1). Urbanization, roadways, habitat fragmentation, grazing, wildfires, disease, and other perturbations have caused decreases in desert tortoise populations (Bury et al. 1994; Corn 1994). The occurrence of the desert tortoise on NTS is $\leq 17/km^2$ ($44/mi^2$). They occur mostly in the lowland desert community dominated by creosote bush and burro bush (Bury et al. 1994).

I.4.3.1.5 Cultural and Paleontological Resources

An intensive archaeological field survey (employing 15-m [50-ft] transects) was conducted at the proposed NIF location and access road on NTS during August 1995 (Jones 1995). The survey documented an isolated artifact (stone flake) that does not meet eligibility criteria for NRHP and is not considered significant (Hattori 1995). Paleontological remains are unlikely to occur on the proposed NIF location on the basis of its geologic setting, which lacks fossiliferous deposits. No Native American cultural resources have been identified in the proposed NIF location in the course of consultation with potentially affected tribes.

I.4.3.1.6 Socioeconomics

Socioeconomic characteristics summarized here for the NTS area include the regional economy, population and housing, public finance and public service infrastructure, and local transportation. Regional economic statistics are based on a regional economic study area that encompasses 11 counties around NTS as defined by BEA. The economic study area is a broad labor and product market-based region linked by trade among economic sectors within the region. Statistics for population, housing, public finance, and public service infrastructure are based on the ROI, a two-county area in which 97 percent of all NTS employees reside. These counties are Clark County (containing 82 percent of NTS employees) and Nye County (15 percent). Lazaro et al. (1996) lists counties and cities included in the economic study region and the counties included in the ROI. Assumptions, assessment methodologies, and supporting data for each TA are also presented in Lazaro et al. (1996).

I.4.3.1.6.1 *Regional Economy*

The regional economic study area for NTS includes the Las Vegas Metropolitan Statistical Area (Clark County). Employment in the economic study region was projected to increase from 412,300 in 1988 to 496,700 in 1995. BEA projects a compounded average annual rate of growth of 1.9 percent from 1995 to 2003 (79,522 jobs) (BEA 1990).

In 1995, NTS employed about 8,600 persons (DOE 1995), accounting for 2.0 percent of employment in the regional economic study area. The distribution of NTS employees by place of residence in the ROI is presented in Lazaro et al. (1996).

I.4.3.1.6.2 *Population and Housing*

The ROI has experienced significant population growth between 1980 and 1990, with an average annual increase of about 4.5 percent, bringing the 1990 total to approximately 683,000 persons. Population growth has been strongest in Clark County. By the year 2000, population in the ROI is projected to grow to approximately 860,000 (U.S. Department of Commerce 1994; BEA 1990).

Between 1980 and 1990, the number of housing units in the ROI increased from 194,899 to 325,261, an increase of 67 percent (see table I.4.3.1.6.2–1). Housing in Clark County increased from approximately 190,607 units in 1980 to 317,188 units in 1990. Housing in Nye County increased from 4,292 units in 1980 to approximately 8,073 units in 1990. Assuming a continuation of current construction and economic trends, the number of housing units in the ROI is projected to increase to approximately 455,000 units by the year 2000.

The number of vacant owner units in the ROI has increased from approximately 11,000 in 1980 to about 17,000 in 1990. It is estimated that in the year

Source: Historical data from U.S. Department of Commerce 1994; projections by Halliburton-NUS 1995.

2000 there will be approximately 24,000 vacant owner units if current construction and economic trends continue in the ROI.

In 1980 there were approximately 7,000 vacant rental units in the ROI. The number of vacant rental units increased to about 15,000 in 1990. It is estimated that in the year 2000 there will be approximately 22,000 vacant rental units if current construction and economic trends continue in the ROI.

Between 1993 and 1994, within the Las Vegas Metropolitan Statistical Area, single-family development experienced a sharp increase of about 30 percent in new housing units. Multifamily housing construction increased by 44 percent between 1993 and 1994. The number of new housing units sold increased as well, rising 11 percent over 1993 levels. In spite of the growing supply of houses in the Las Vegas market, new housing prices continue to climb (ULI 1995).

I.4.3.1.6.3 *Public Finance and Public Services Infrastructure*

Public financial characteristics of the local jurisdictions in the ROI that are most likely to be affected by construction and operation of NIF at NTS are summarized in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expenditure trust funds. Major revenue and expenditure categories and total revenues less expenditures for counties and cities are presented in table I.4.3.1.6.3–1.

Table I.4.3.1.6.3–2 summarizes public service levels for education, community services, and health care.

I.4.3.1.6.4 *Local Transportation*

Vehicular access to NTS is provided by U.S. 95 to the south, with access to the northeast provided by State Route 373. State Route 160 provides site access from the south and east. Road segments providing access to NTS experience little traffic congestion outside of the Las Vegas metropolitan area. Although traffic is generally heavier on U.S. 95 than on State Route 373, both roads are projected to remain at level of service A (DOE 1995a). Table I.4.3.1.6.4–1 lists the site access roads at NTS and the average daily traffic volumes for each route. No major road improvements are scheduled for road segments providing immediate access to NTS (DOE 1995c). Although no public transportation system serves NTS, a contract bus service for workers is available at a nominal cost (DOE 1995c). The major railroad in the ROI is the Union Pacific Railroad located approximately 80 km (50 mi) east of NTS near the city of Las Vegas. McCarran International Airport in the city of Las Vegas provides jet passenger service from both national and local carriers.

I.4.3.1.6.5 *Environmental Justice*

Environmental justice concerns the potential for high and adverse environmental or human health impacts to disproportionately affect minority or low-income populations. In this PSA, environmental justice is evaluated for impacts within the site region, defined as the area within an 80-km (50-mi) radius around the site, and for the local area. Lazaro et al. (1996) presents the demographic analysis of minority and low-income population distributions on a regional and local basis.

TABLE I.4.3.1.6.3–1.—*Public Finance—Nevada Test Site Area*

Revenues and Expenditures[a]	Clark County	City of Henderson	City of Las Vegas	City of North Las Vegas	Nye County
Local sources (percent)	63	39	46	44	53
State sources (percent)	37	61	54	56	47
Federal sources (percent)	0	0	0	0	0
Total revenues (dollars)	295,686,362	44,838,156	165,281,174	33,422,607	12,348,383
General government (percent)	22	25	19	15	37
Public safety, health, and community services (percent)	66	75	80	85	63
Debt service (percent)	0	0	0	0	0
Other (percent)	11	0	0	0	0
Total expenditures (dollars)	241,422,802	42,164,384	155,307,893	33,027,839	12,511,908
End-of-year fund balance (dollars)	77,826,604	1,140,575	13,712,536	3,656,142	1,374,364

[a] If reporting body did not distinguish between state and Federal revenue sources, the total for all intergovernmental revenue was combined and reported under "state sources."

TABLE I.4.3.1.6.4–1.—*Baseline Traffic on Nevada Test Site Access Roads*

NTS Access Road	1993 Average Daily Traffic
U.S. 95 (6.1 km north of Mercury Interchange)	2,715
U.S. 95 (In Searchlight, 0.16 km south of SR-164)	6,115
SR 160 (In Pahrump Valley, 61 m south of SR 372 to Ash Meadows)	10,600
SR 160 (Pahrump Valley at Clark/Nye County line)	2,970
SR 160 (145 m south of U.S. 95)	655
U.S. 95/6 (In Tonopah, 0.3 km north of U.S. 6 north of St. Patrick Street)	7,635
SR 160 (In Pahrump Valley, 0.16 km north of SR 372 to Ash Meadows)	6,670

Source: Nevada Department of Transportation 1993.

In the NTS site region in 1990, 10 percent of the population was low income and 14 percent was minority, compared with the Nevada state average of 10 percent low income and 21 percent minority. Within the area, census tracts closer to the NTS site tend not to have significantly higher or lower proportions of minority or low-income populations than tracts farther from the site.

I.4.3.1.7 Radiation and Hazardous Chemicals

I.4.3.1.7.1 *Radiation Environment*

Both aboveground and underground tests of nuclear weapons and test devices have been conducted at NTS. In addition, weapons effects tests have been conducted on military communications, electronics, satellites, sensors, and other materials. In October 1992, underground nuclear testing was halted. The site maintains the capability of resuming testing if directed by the President. A detailed discussion of the radiation environment, including background, radiological releases, and doses to members of the public, is presented in *U.S. Department of Energy Nevada Operations Office Annual Site Environment Report–1993, Volume 1* (DOE 1994a). The concentrations of radioactivity in various environmental media (air, water, soil) in the site region are also presented in that reference.

Calculated radiological doses were used to estimate the potential health impacts to the public and onsite workers at NTS from any releases of radioactivity. The annual doses to individuals, to the surrounding population (within 80 km [50 mi]), and to workers are summarized in table I.4.3.1.7.1–1; corresponding health risks are also presented in this table. These doses are in addition to those from natural background, consumer products, and medical sources, which total about 378 mrem. Background radiation doses are unrelated to NTS operations. Regulatory limits that specify the maximum effective dose equivalent to individual members of the public and occupational workers are also presented in table I.4.3.1.7.1–1. The doses to the public listed in the table are within regulatory limits (DOE 1990) and are small in comparison to background radiation. The onsite worker doses are also within regulatory limits.

I.4.3.1.7.2 *Hazardous Chemical Environment*

The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (for example, soil through contact or via the food pathway). Exposure pathways to NTS workers during normal operation may include inhaling the workplace atmosphere, drinking NTS potable water, and possibly other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. NTS workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals used in NTS operation processes, ensures that these standards are not exceeded. The quantities of NIF-related hazardous materials purchased for use at NTS in 1994 are listed in table I.4.3.1.7.2–1.

TABLE I.4.3.1.7.1-1.—*Annual Radiation Doses to the General Public and Onsite Workers from Normal Operations at Nevada Test Site*

Receptor	Atmospheric Releases: Regulatory Limit[a]	Atmospheric Releases: Calculated	Liquid Releases: Regulatory Limit[a]	Liquid Releases: Calculated[b]	Total: Regulatory Limit[a]	Total: Calculated	Total: Risk[c]
Individual Dose							
Average exposed individual[d] (mrem)	10	5.5×10^{-4}	4	0.0	100	5.5×10^{-4}	2.8×10^{-10}
Maximally exposed individual (mrem)	10	4.8×10^{-3}	4	0.0	100	4.8×10^{-3}	2.4×10^{-9}
Population Dose[e]							
Population within 80 km (person-rem)	f	1.2×10^{-2}	f	0.0	f	1.2×10^{-2}	6.0×10^{-6}
Worker Dose[g]							
Average worker (mrem)	NA	NA	NA	NA	5,000	2.6	1.0×10^{-6}
Maximally exposed worker (mrem)	NA	NA	NA	NA	5,000	750	3.0×10^{-4}
Total workers (person-rem)[h]	NA	NA	NA	NA	None	2	8.0x1

[a] The regulatory limits for individuals are given in DOE Order 5400.5. The 10 mrem/yr limit from airborne emissions is re ired by the *Clean Air Act*, the 4 mrem/yr limit is required by the *Safe Drinking Water Act*, and the total dose of 100 mrem/yr is th imit from all pathways combined. The occupational limit for workers is 5,000 mrem (10 CFR 835).

[b] The calculated dose values given in the column under Liquid Releases conservatively includes all water pathways, not ju the drinking water pathway.

[c] Based on latent fatal cancer risk factors of 5×10^{-7}/mrem for individuals, 5×10^{-4} /person-rem for population, and 4×10^{-7}/mr n for workers (ICRP 1991).

[d] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.

[e] Estimated for a population of approximately 21,750 people.

[f] No regulatory limits exist for population doses; however, a 100 person-rem value for the population is found in proposed 5 FR 16268 (10 CFR 834).

[g] Worker doses were estimated on the basis of readings from monitoring devices called thermoluminescent dosimeters.

[h] The number of badged workers in 1992 was approximately 780.

Note: NA - not applicable.

I.4.3.1.8 Waste Management

The current waste management practices at NTS are outlined in table I.4.3.1.8-1. Wastes generated by research activities at NTS include TRU wastes, LLW, mixed, hazardous, and nonhazardous wastes.

I.4.3.1.8.1 *Low-Level Waste*

LLW has been generated and disposed of in eight areas at NTS, but currently only Areas 3 and 5 are active for LLW treatment, storage, and disposal.

Bulk waste is disposed of in Area 3, and packaged classified and unclassified waste is disposed of in Area 5. Disposal of onsite waste began in 1971, and in 1978 operations expanded to receive wastes generated offsite. The offsite generators are currently revising their procedures to meet NTS waste acceptance criteria. Standard shallow land burial techniques have been employed for disposal.

I.4.3.1.8.2 *Mixed Low-Level Waste*

Mixed waste received from Rocky Flats Environmental Technology Site (formerly known as the Rocky Flats Plant) has been disposed of at NTS. This mixed waste disposal at NTS ceased in 1990, pending issuance by the State of Nevada of a RCRA Part B Permit for NTS. No mixed waste has been accepted from offsite generators for disposal since 1990. The existing mixed waste disposal unit, P03U, has interim status and may be used for disposal of DOE mixed waste generated in the State of Nevada. Environmental restoration could generate additional volumes of mixed wastes that would require some form of treatment. The Nevada Division of Environmental Protection provides RCRA oversight for NTS. A 1992 revised RCRA Part B Permit application to include a separate mixed waste storage and disposal unit at NTS, in accordance with the provisions of the *Federal Facility Compliance Act* of 1992, has been submitted to the state. The Site Treatment Plan was finalized with the state in March 1996. The Site Treatment Plan and Compliance Order do not contain provisions for accepting offsite wastes. Negotiations concerning waste streams that are not included will be dealt with on a case-by-case basis.

If a permit for the proposed mixed waste disposal units is denied, DOE/NV will have to deal with mixed waste generated at NTS in the same manner as at other DOE facilities across the country. The mixed waste will be properly characterized and managed, and a disposal location will have to be identified.

I.4.3.1.8.3 *Hazardous Waste*

Hazardous wastes result from ongoing operations that use solvents, lubricants, fuel, lead, metals, motor oil, and acids. Hazardous wastes are accumulated at satellite areas and shipped offsite to a commercial RCRA-permitted facility. Additional accumulation areas are planned, and new equipment is planned to prevent the possibility of cross contamination with radioactive wastes (creating mixed wastes) in handling these materials. Hazardous waste generation is decreasing as the result of an aggressive waste minimization program and will substantially decrease in the future due to the present moratorium on nuclear testing.

I.4.3.1.8.4 *Nonhazardous Waste*

Nonhazardous sanitary wastes are expected to be generated at the current rates for the next several years and then decline, assuming the present moratorium on underground weapons testing continues. Liquid nonhazardous wastes are disposed of in septic tanks, sumps, or in ponds; solid nonhazardous wastes are disposed of in landfills at various locations on the site. Recycling of paper, metals, glass, plastics, and cardboard has resulted in some decreases in waste quantities.

I.4.3.2 *Environmental Impacts*

The following sections describe the potential environmental impacts for land use and visual resources, air quality and noise, water resources, ecological resources, cultural and paleontological resources, and socioeconomics from constructing and operating NIF at NTS. In addition, impacts associated with radiation, hazardous chemicals, and waste management are described.

I.4.3.2.1 Land Use and Visual Resources

I.4.3.2.1.1 *Land Use*

Land-use impacts resulting from siting the NIF project at NTS would be limited to clearing and leveling of land for the Laser and Target Area Building, the Optics Assembly Area, the Optics Maintenance Area, Optics Storage Area, and Target Receiving and Inspection Area. Minor, short-term disturbance of the land containing NIF facilities could also result from installation of necessary water and wastewater systems. The proposed location for NIF would be in Area 22,

Source: NTS 1996; White 1995g.

about 3.2 km (2 mi) southwest of the Mercury Base Camp in an isolated part of Nye County (figure I.3.4.3.1–2). An estimated 18 ha (45 acres) of land in Area 22 would be required for buildings, walkways, building access, temporary construction laydown area, and buffer space. However, the required acreage represents a small fraction of total land available on NTS for future development (White 1995d). The project would be located on a large tract of vacant land that has at least an additional 80 ha (200 acres) available for future expansion. No impacts to land use outside of Area 22 would be expected.

With appropriate erosion and sediment control measures, soil impacts during construction of NIF would be short term and minor. Seismic risks would be taken into account during construction and operation of NIF.

I.4.3.2.1.2 *Visual Resources*

Although structures erected for the NIF project would alter the visual landscape of the proposed location, no adverse visual impacts are expected. The proposed NIF location at NTS is remotely located in a part of Nevada that has a population density of less than 1.0 person/km^2 (2.6 persons/mi^2). The area is relatively flat, dominated by desert vegetation, and not visually diverse. NIF structures, particularly the Laser and Target Area Building, would be visible to persons using U.S. Highway 95, but the distance of the site from the highway (about 6.5 km [4 mi]) would lessen its visual domination of the horizon. Other manmade structures, such as the Mercury Base Camp and Desert Rock Air Strip, already exist in the vicinity of the proposed NIF site.

I.4.3.2.2 Air Quality and Acoustics

I.4.3.2.2.1 *Air Quality*

Construction Emissions. Estimated air pollutant emissions from site clearing and facility construction are listed in table I.4.3.2.2.1–1. The construction emission estimates are based on characteristics of the proposed NTS location for NIF and on construction vehicle exhaust and fugitive emissions.

Site clearing would continue for about 2.5 months, followed by facility construction for four years (LLNL 1995b). Site clearing would produce the greatest amount of fugitive dust PM_{10} emissions. The ISCST2, Version 93109 [EPA 1992a-b] was used to determine the impact of site-clearing activities on ambient air quality (see section I.4.1.2.2.1). The data selected for modeling air quality were surface meteorological data and twice-daily mixing height data from the nearby Desert Rock National Weather Service Station for 1987-91 (EPA 1995b). The surface wind speeds and directions are summarized in an annual wind rose (see figure I.4.3.1.2.1–1). Detailed emission inventories associated with site clearing and facility construction, meteorological data used, air quality model assumptions, and model input parameters are presented in Lazaro et al. (1996).

TABLE I.4.3.2.2.1–1.—*Estimated National Ignition Facility Construction Emissions for the Nevada Test Site Location*

Pollutant	Total Emissions (t/yr)[a]
Particulate matter	31.93[b] (35.20)
Volatile organic compounds	0.44 (0.49)
Carbon monoxide	1.23 (1.36)
Nitrogen dioxide	3.73 (4.11)
Sulfur dioxide	0.43 (0.47)
Lead	Negligible

[a] Metric tons (1,000 kg) per year.
[b] Includes 10.43 t/yr (11.50 ton/yr) of fugitive emissions for site clearing using water-spray control that would occur during an approximate 73-day period in the first year and 21.14 t/yr (23.30 ton/yr) of facility construction emissions that would occur for the remainder of the first year of construction.

Note: See Lazaro et al. (1996) for details.
Source: Lazaro et al. 1996.

Because of the arid conditions typical of the region, the 24-hour average PM_{10} background concentration representative of NTS site is 173 μg/m^3 (table I.4.3.1.2.2–1), which is already over the national and state standard of 150 μg/m^3 (see table I.4.3.1.2.2–1). Therefore, site clearing should be carried out so as to minimize additional impacts on ambient air quality. With conventional dust control (that is, 50 percent control for excavation and 60 percent control for traffic on unpaved roads), a maximum 24-hour average PM_{10} concentration of 2 μg/m^3 over background is predicted at the site boundary. This value is so small because the site boundary is approximately 4.5 km (2.8 mi) east of the proposed NIF location. Although the maximum PM_{10} concentration of 175 μg/m^3, including background concentration, would be above the 24-hour NAAQS, the impact on ambient air quality from site clearing alone would be insignificant. Site clearing at NTS would be expected to last for 2.5 months, so any associated air quality impacts would be local and temporary.

Emissions During Operations. Sources of air pollutant emissions from NIF operation at NTS would include fuel combustion and solvent cleaning of the debris shields. Emissions of solvent VOCs (ethanol) from debris shield cleaning would total approximately 0.5 t/yr (0.55 ton/yr) (LLNL 1995b). Other potential air pollutant emission sources that would not be considered significant would include the target destruction, under either the Conceptual Design or Enhanced options, emissions from vehicles used for freight shipments and employee commuting, and emissions from welding operations at the Fabrication Facility.

Table I.4.3.2.2.1–2 lists the estimated NTS annual air pollutant emissions on the basis of the anticipated NIF annual energy requirements provided in table I.4.1.2.2.1–3. These values were adjusted to recognize that at NTS, only four new support buildings (with a total area of 5,341 m^2 [57,492 ft^2]) would be required out of the total complement of support buildings (area of 26,722 m^2 [287,643 ft^2]). Also, fuel usage to meet these energy requirements would be specific to NTS. Liquid petroleum gas would be used rather than natural gas (White 1995e). Published emission factors (EPA 1995) were used in the calculations. Emissions of VOCs from solvent cleaning are included. For comparative purposes, table I.4.3.2.2.1–2 includes NTS 1992 sitewide emissions. More detailed information on emission estimates is provided in Lazaro et al. (1996).

As indicated in table I.4.3.2.2.1–2, estimated air pollutant emissions due to NIF operation at NTS are well below 1 t/yr (1.1 ton/yr) except for nitrogen dioxide, which is less than 3 t/yr (3.3 ton/yr). Estimated air pollutant emissions from NIF operations, are less than 1 percent of NTS 1992 emissions Existing ambient concentrations for these pollutants (see section I.4.3.1.2.2, table I.4.3.1.2.2–1) are well below the ambient air quality standards, except for PM_{10}. The predicted increase of 0.08 t/yr (0.09 ton/yr) in PM_{10} is equivalent to less than 1 percent of NTS 1992 emissions and is not expected to cause a measurable increase in the 24-hour and annual average ambient concentrations at the site boundary. On the basis of this information, it can be concluded that NIF operations would have no adverse impact on air quality and would not contribute to violation of the ambient air quality standards.

TABLE I.4.3.2.2.1–2.—***Annual Emission Increases with National Ignition Facility Operation at Nevada Test Site***

Pollutant	1992 Emissions[a] (t/yr)	Projected NIF Emissions[a] (t/yr)	1992 Emissions Plus NIF (t/yr)	NIF Percent of 1992 Emissions
Particulate matter	86.8[b]	0.08	86.9	0.09
Volatile organic compounds	ND	0.56	NA	NA
Carbon monoxide	ND	0.37	NA	NA
Nitrogen dioxide	ND	2.21	NA	NA
Sulfur dioxide	71.1	0.004	71.1	0.006
Lead	ND	Negligible	NA	NA

[a] 1992 emissions are the most current data available. Emissions are based on site-estimated liquid petroleum gas external combustion, diesel internal combustion, and VOC solvent cleaning (0.5 t/yr [0.55 ton/yr]) and emission factors (EPA 1995c; ANL 1995).

[b] Based on boiler and incinerator emissions.

Note: ND - no data available; NA - not applicable.

Source: EPA 1993; DOE 1995c.

NTS must comply with the Nevada State Air Pollution Control regulations. Construction activities at NTS would require an operating permit for any surface area disturbance of more than 2.02 ha (5 acres) of land (that is, clearing, excavating, and leveling the land) (Nevada Administrative Code [NAC] Section 445.365). Therefore, a construction permit would be required for NIF. Construction fugitive dust air pollutant emissions must be controlled by using the best practical methods to prevent particulate matter from becoming airborne (NAC Section 445B.365 [NSEC 1995]).

External combustion units (boilers) must have a state air pollution permit before construction (NAC Sections 445B.291, 445B.287). Liquid petroleum gas-fired boilers with rated heat input greater than 105,600 MJ/hr (100 million Btu/hr) but not over 264,000 MJ/hr (250 million Btu/hr) are limited to New Source Performance Standards (NSPS) nitrogen oxide emissions of from 43 to 86 ng/J, depending on the heat release rate, which is a function of the furnace volume (40 CFR 60.44b). There are no NSPS emission limits for liquid petroleum gas-fired boilers with a rated heat input at or less than 105,600 MJ/hr (40 CFR 60.40c).

Emissions of VOC at the stated annual rate of 0.5 t/yr (0.55 ton/yr) would not have a significant impact on local air quality and would not require any additional controls (NAC 445B.395). Additional air quality regulatory information is presented in section 5.2.

I.4.3.2.2.2 *Acoustics*

During the clearing phase of construction of NIF at NTS, there would be no increase in the average outdoor daytime sound level at the nearest private residence, 20 km (12.4 mi) south-southwest of the NIF site. The average outdoor daytime sound level at this point would remain at 28 dBA or less during hours the clearing equipment was operating. The CNR rank, adjusted for the estimated preexisting background level, would not be expected to change from its normal level.

The residual outdoor daytime sound level at the nearest laboratory building (the gate house/security office) is expected to increase by 12 dB, to 40 dBA. The existing average daytime sound level at this point is estimated to be 28 dBA. The adjusted CNR rank for the resulting sound is "C." These estimates are based on the assumptions given in Lazaro et al. (1996). It is possible that the actual noise levels might be higher or lower than those estimated.

I.4.3.2.3 Water Resources

About 2.95 MLY (0.78 MGY) of water would be required for NIF construction (LLNL 1995b). Water and wastewater utility requirements for NIF operations at NTS are shown in table I.4.3.2.3–1. The raw water supply required for NIF operations would total about 152 MLY (40 MGY), of which 18 MLY (4.7 MGY) would be for domestic use. NTS water supply system has adequate production and storage capacity to meet the needs of NIF. The water would be obtained from six existing wells on NTS. An underground water pipeline about 3.2-km (2-mi) long would have to be constructed to the NIF location. Sewage treatment and disposal facilities would also have to be constructed for the project. Adequate land area exists for such facilities (White 1995e). The foundations for NIF buildings would be above the depth of the 500-year flood and project facilities would be designed to withstand any flood. Materials that might cause water pollution would not be stored within reach of the 500-year flood.

TABLE I.4.3.2.3–1.—*Water and Wastewater Utility Capacity at Nevada Test Site*

Utility System	Current Usage	NIF Requirement	Projected Usage, Including NIF	Current Capacity
Water supply[a] (MLY)	2,400	152	2,552	14,800
Wastewater treatment (MLY)	0	18	18	0

[a] Represents pumping capacity for all the water supply wells for NTS water services area, which includes NIF location.
Source: White 1995e.

I.4.3.2.4 Biotic Resources

I.4.3.2.4.1 *Terrestrial Resources*

At NTS Area 22, NIF (including the temporary construction laydown area) would be constructed within undeveloped creosote bush habitat, eliminating up to 18.2 ha (45.0 acres) of that habitat. The general types of impacts that could result from NIF construction at NTS would be similar to those discussed for LLNL (section I.4.1.2.4–1). Areas disturbed by construction but not occupied by a building, parking lot, or access road would be of minimal value to wildlife because of the difficulty of reestablishing a vegetative cover in a desert environment (DOE 1995c). Additionally, introduced plants such as red brome, cheatgrass, and Russian thistle readily invade disturbed areas and delay revegetation by native plants.

I.4.3.2.4.2 *Wetlands and Aquatic Resources*

The proposed NIF location at NTS does not contain, nor is it located near, wetlands or surface water resources. Therefore, construction and operation of NIF at NTS would not be expected to adversely affect such resources.

I.4.3.2.4.3 *Rare, Threatened, and Endangered Species*

No habitat designated as critical to threatened or endangered species would be affected by construction of NIF. Construction and operation of NIF (including the 3.2-km [2-mi] underground water supply pipeline) at NTS Area 22 location could pose a threat to individual desert tortoises and their habitat. Vehicular traffic associated with NIF construction and operation would also be a threat to tortoises. The ferruginous hawk would be discouraged from using areas near NIF because of human disturbance, but the loggerhead shrike could use the fence that would surround NIF for perching and hunting sites (DOE 1995c).

I.4.3.2.5 Cultural and Paleontological Resources

Construction and operation of the proposed NIF at Area 22 would have no effect on archaeological sites or historic structures listed on or eligible for the NRHP, or on important paleontological remains or Native American cultural resources.

I.4.3.2.6 Socioeconomics

Locating NIF at NTS would have a minor impact on the economic study region and in the ROI described in section I.4.3.1.6 because the site is in a somewhat diverse regional economy with extensive inter- and intraregional, national, and global economic interactions and linkages. None of the average annual increases in any of the socioeconomic variables would constitute a major difference from the region-specific average annual increases expected without NIF. Also, because the NIF partnership includes representatives of government, industry, and the academic sector throughout the United States, procurement and investment would be dispersed over a number of different regions, thus dampening the concentration of economic effects of the program.

The following sections describe the effects of constructing and operating NIF on the host region's economy and employment, and on population, housing, public finances and services, and local transportation in the ROI.

I.4.3.2.6.1 *Regional Economic Impacts*

Slight changes in employment and economic activity levels in the economic study region would occur from local spending of employee wages, procurement of goods and services including construction materials, and other local investment associated with constructing and operating NIF. In addition to creating new jobs (direct) at the site, indirect job opportunities, such as community support services, would also be created in the economic study region as a result of these new direct jobs. The total new jobs created (direct and indirect) would contribute slightly to unemployment reduction and would increase income and economic output in the regional economy during construction and operation of NIF. Table I.4.3.2.6.1–1 presents the potential impacts to the regional economy if NIF is located at NTS.

Constructing NIF at NTS would result in a peak of approximately 280 direct jobs in 1998. This construction-related procurement would indirectly create 1,360 jobs in the economic study area.

TABLE I.4.3.2.6.1–1.—*Potential Socioeconomic Impacts in the Nevada Test Site Area*

Parameters	NIF Alternative Change Over Reference Baseline		Reference Baseline	
	Peak Construction 1998[a]	Operations 2003[b]	1996 to 2002[a]	2003[b]
Regional Employment				
Direct jobs	280	330		
Indirect jobs	1,360	290		
Total jobs	1,640	620	14,600 jobs projected annually	12,900 additional jobs projected
Regional Aggregate Earnings [c]				
Direct earnings	16.19	13.81		
Indirect earnings	27.22	6.29		
Total earnings	43.41	20.10		
Regional Population Migration				
ROI in-migrating population	2,340	440		13,300 additional people
Regional Housing Demand				
Number of housing units in the ROI	850	160	44,400 vacant housing units (annual average)	50,000 vacant housing units
Local Transportation				
Number of trips generated at site per day	538	630		
Public Finance	0.21	0.04	NA[d]	NA
Percent change over 1995 fund balance (Clark County)				
Public Services				
Change in service demand				
Police[e]	9	1	1,436[d]	7,839
Fire[e]	2	0	379[d]	909
General[e]	15	2	2,240[d]	2,349
Physicians[f]	3	1	1,455[d]	2,096
Teachers[f]	18	3	9,530[d]	13,725

[a] Construction period would be 1996 to 2002, with peak construction projected to occur in 1998.
[b] Operating period would be 2003 to 2033, with impacts throughout the period projected to remain stable.
[c] Regional earnings are millions of constant 1994 dollars.
[d] Projected 1998 fund balance for Public Finance, and projected 1998 level of service (LOS) for Public Services.
[e] Las Vegas.
[f] Clark County.
Note: NA - not applicable.
Source: Model results.

Employment for NIF operation would begin phasing in as construction neared completion. Direct employment related to operations is projected at 330, with nearly 290 indirect jobs created throughout the economic study region. As a result of constructing and operating NIF, the baseline compound average annual growth rate from 1995 to 2003 would increase by 0.01 percentage points.

Peak earnings associated with the 280 direct jobs created in 1998 are projected at approximately 16.2 million dollars. Construction-related procurement would indirectly create more than 27 million dollars in regional earnings. Direct earnings related to operations are projected to reach nearly 14 million dollars, with 6.3 million dollars in earnings added to the regional economy.

I.4.3.2.6.2 *Population and Housing*

Construction. Population in-migration resulting from NIF construction phase demands would peak in 1998 with a projected cumulative total of 2,340 people moving into the ROI (table I.4.3.2.6.1–1). This population increase would result in demand for an additional 850 housing units on the ROI. Baseline projections of the NTS ROI housing market from 1996 (NIF construction start date) through 1998 indicate that nearly 43,000 housing units will be available. The demand for approximately 850 vacant housing units in the ROI would use approximately 2 percent of the available housing stock in the ROI. NIF would generate little demand for new housing construction because of the number of vacant housing units within the ROI and the proximity of NTS to Las Vegas. Most of this housing demand would be temporary and would primarily affect the renter segment of the ROI housing market.

Operation. Population in-migration resulting from NIF operation phase demands could result in an additional 440 people moving into the ROI. While additional demand for housing would be longer term relative to construction, no perceptible strain on the market is expected, assuming that the general conditions associated with the housing market continue.

I.4.3.2.6.3 *Public Finance*

Construction. Given the projected population and economic growth associated with NIF during the construction phase, fiscal balances (revenues and expenditures) would be expected to increase for all the jurisdictions within the ROI. Short-term public finance impacts would peak during the year 1998 and would then decline as construction neared completion in 2002. Since the largest percentage of socioeconomic impacts are expected to occur in Clark County (assuming current residential patterns), that county would experience the greatest fiscal impacts in the ROI (table I.4.3.2.6.1–1).

Operation. The increase in population and economic growth as a result of NIF operations would increase fiscal balances for all counties within the ROI, with the greatest impact in Clark County. Fiscal impacts would remain relatively stable from the initial impact in 2003 throughout the duration of NIF operations.

I.4.3.2.6.4 *Public Services*

By the year 1998, Clark County would need to hire 9 additional police officers, and Nye County would need 18 additional teachers and 3 additional doctors to maintain its current level of service. By 2003, when operations would start, Nye County would need only three additional teachers and one additional doctor over the baseline conditions to maintain the current level of service.

I.4.3.2.6.5 *Local Transportation*

In 1995, NTS employed approximately 8,600 persons (DOE 1995c). Direct employment generated by NIF at NTS for the life cycle of the project (1996-2033) would range from a minimum of 21 new jobs in 1996 to a maximum of 280 new jobs in 1998. Peak direct employment would be approximately 280 workers in 1998. These direct jobs would generate additional trips on NTS access roads (table I.4.3.2.6.1–1); however, these additional trips should not significantly increase congestion of NTS local transportation network (table I.4.3.2.6.5–1).

A peak of nearly 1,360 indirect jobs in 1999 could be generated within the ROI if NIF was located at NTS. It is likely that the major share of these jobs would be located within Clark and Nye counties. The road network in Clark County and the city of Las Vegas is well developed and expanding and would be capable of handling the additional trips generated from operation of NIF. Because the indirect jobs would be

dispersed in both Clark and Nye counties, adverse impacts to the regional transportation network are unlikely.

I.4.3.2.6.6 *Environmental Justice*

For the region within 80 km (50 mi) of NTS, both minorities and low-income populations are in the same or lower proportion to other populations compared with the state of Nevada as a whole (section I.4.3.1.6.5). Thus, no environmental justice issues associated with regional impacts have been identified.

Neither minority nor low-income persons are clustered disproportionately in the local vicinity of NTS (section I.4.3.1.6.5). Thus, the local area impacts from construction and operation of NIF would not disproportionately affect either minority or low-income populations.

I.4.3.2.7 Radiation and Hazardous Chemicals

This section describes potential radiological and hazardous chemical impacts that could result from normal operations and postulated accidents at NIF at NTS. Methods, data, and assumptions used in estimating these impacts are presented in Lazaro et al. (1996).

I.4.3.2.7.1 *Normal Operations*

The general public surrounding, and workers at, NTS might be exposed to small quantities of radionuclides released and radiation emitted from routine NIF operations; however, the expected level of radioactive releases and radiation emissions would be well within regulatory limits. No impacts from hazardous chemicals should occur because only minute quantities of hazardous VOCs would be emitted during routine NIF operations. Impacts from routine transportation of tritium targets also would not be expected because there would be no detectable levels of radiation outside the package carrying the low-energy beta-emitting tritium targets.

Table I.4.3.2.7.1–1 summarizes the potential impacts of radiation exposures from operations consistent with the Conceptual Design Option and the Enhanced Option of NIF at NTS.

Impacts to the Public. For the Enhanced Option, the estimated radiation dose to a maximally exposed member of the public located about 20 km (12.5 mi) south-southeast of NIF is 4×10^{-4} mrem/yr, which is much less than the dose limit of 100 mrem/yr resulting from all pathways combined (DOE 1990). The likelihood of the maximally exposed individual contracting a fatal cancer is 1 in 170 million for the entire operational life of NIF (dose/yr x 30 yr x fatal cancer risk factor of 5×10^{-4}/rem). The estimated radiation dose to the surrounding public is 1×10^{-3} person-rem/yr; no cancer fatalities would be expected to occur in the public for the entire NIF operations at NTS. For the Conceptual Design Option, estimated radiation impacts are about one-third the impacts of the Enhanced Option. No adverse health effects would result.

Impacts to Workers. In addition to their potential exposure to radionuclides, the general NTS workers outside NIF could be exposed to direct radiation resulting from high-yield experiments at NIF. For the Enhanced Option, the estimated radiation dose to these non-NIF workers at NTS is 9×10^{-4} person-rem/yr. No cancer fatalities would be expected to occur in workers for the entire NIF operations at NTS. For the Conceptual Design Option, estimated radiation impacts are about one-third the impacts of the Enhanced Option and carry extremely low risk of adverse health effects.

TABLE I.4.3.2.7.1–1.—*Potential Radiological Impacts from Normal Operations of the National Ignition Facility at Nevada Test Site*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (mrem/yr)	1×10^{-4}	4×10^{-4}
Percent of natural background	4×10^{-5}	1×10^{-4}
30-year fatal cancer probability	2×10^{-9}	6×10^{-9}
Population Within 80 Km		
Dose (person-rem/yr)	3×10^{-4}	1×10^{-3}
Percent of natural background	5×10^{-6}	2×10^{-5}
30-year fatal cancers	0	0
Workers Onsite		
Dose (person-rem/y)		
Non-NIF workers	3×10^{-4}	9×10^{-4}
NIF workers	10	10
30-year fatal cancers	0	0

Source: Model results.

Potential radiation exposures inside NIF would be kept as low as reasonably achievable through facility design and administrative controls. The design objective of NIF is to keep the individual radiation worker dose to less than 500 mrem/yr. On average, it is estimated that a NIF worker would receive approximately 30 mrem/yr.

I.4.3.2.7.2 *Postulated Accidents*

Radionuclides and hazardous chemicals could be released from accidents postulated at NIF and during the transportation of tritium targets. Tables I.4.3.2.7.2–1 and I.4.3.2.7.2–2 summarize potential radiological impacts to the public and workers from postulated facility and transportation accidents, respectively. A description of each accident scenario evaluated is provided in Lazaro et al. (1996).

Radiological Impacts

Impacts to the Public. The public could be exposed to radionuclides released from a postulated accident at NIF. The bounding accident assumed that an earthquake would occur at the time of a maximum-yield experiment, with an accidental release frequency of $2x10^{-8}$/yr. For the Enhanced Option, the estimated radiation dose to the maximally exposed member of the public is 0.05 rem. The likelihood of the maximally exposed individual contracting a fatal cancer from this exposure would be 1 in 5,000. The estimated radiation dose to the surrounding public would be 70 person-rem. No cancer fatalities would be expected to occur among members of the public following an accident at NIF. For the Conceptual Design Option, estimated radiation impacts are about one-half the impacts from the Enhanced Option. No adverse health effects would be expected to result.

Table I.4.3.2.7.2–1 also indicates that the risk of radiation-caused cancer fatalities from the postulated accident at NTS is essentially zero when the extremely low frequency of the accident occurring during NIF operations is taken into account. The risk is the product of the estimated radiation dose, a fatal cancer risk factor of $5x10^{-4}$, and an accident release frequency of $2x10^{-8}$/yr.

TABLE I.4.3.2.7.2–1.—*Potential Radiological Impacts from Postulated Bounding Accident Involving the National Ignition Facility at Nevada Test Site*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (rem)	0.03	0.05
Fatal cancer probability	$2x10^{-5}$	$2x10^{-5}$

Risk (cancer fatalities/yr)	$2x10^{-11}$	$3x10^{-11}$

Source: Model results.

Impacts to Workers. For the Enhanced Option, the estimated radiation dose to all workers at NTS is 4 person-rem. No cancer fatalities would be expected to occur among workers following the postulated accident at NTS. For the Conceptual Design Option, estimated radiation impacts are about half the impacts of the Enhanced Option. No adverse health effects would be expected to result. The risk of radiation-caused cancer fatalities would essentially be zero considering the extremely low potential for the postulated accident to occur. NTS has a comprehensive emergency plan, which would be expanded to incorporate NIF, to ensure protection of workers in case of an accident or natural disaster.

Transportation Impacts. Radiological impacts associated with the transportation of tritium targets would result from a release of tritium into the environment following a transportation accident. Because tritium is a pure beta emitter with no associated gamma radiation, radiological risks associated with routine (incident-free) transportation operations would be considered negligible. The potential radiological impacts of transporting tritium targets were calculated for truck and air travel. Trucks were assumed to be used to transport the tritium targets from the manufacturing sites to the nearest major airport, with cargo aircraft then used to transport the targets to McCarran International Airport. After arriving at McCarran, the targets were assumed to be transferred to a truck for shipment to NIF at NTS.

Table I.4.3.2.7.2–2 summarizes the risks associated with the transportation of tritium targets from each of the tritium manufacturing facilities to NIF at NTS. Radiological risk from transportation activities is defined as the product of the accident consequence (dose) and the probability of the accident occurring, and was calculated by considering a wide range of accidents, from high-probability, low-consequence events to low-probability, high-consequence events (see Lazaro et al. 1996). Estimated latent cancer fatality risks were obtained by multiplying the dose risk by $5x10^{-4}$ latent cancer fatalities per person-rem (ICRP 1991). Estimated latent cancer fatality risks range from $6x10^{-10}$ to $9x10^{-9}$ per year for all cases.

Nonradiological impacts associated with the ground transport of tritium targets were calculated for both routine (incident-free) and accident conditions. Nonradiological population risks for routine operations were calculated by multiplying the distance traveled by truck in urban population density zones by a risk factor for latent mortality from pollutant inhalation (Rao et al. 1982). Nonradiological population risks resulting from vehicular accidents were calculated in

TABLE I.4.3.2.7.2–2.—*Potential Radiological Risks and Consequences of Transporting Tritium Targets from Manufacturing Facilities to Nevada Test Site*

Manufacturing Facility	Conceptual Design Option	Enhanced Option
General Atomics		
Dose risk (person-rem/yr)	$1.2x10^{-6}$	$9.5x10^{-6}$
Fatality risk (cancer fatalities/yr)	$6x10^{-10}$	$5x10^{-9}$
Nonradiological accidents[a] (fatalities/yr)	$1x10^{-3}$	$3x10^{-3}$
Nonradiological vehicular emissions (fatalities/yr)	$8x10^{-4}$	$2x10^{-3}$
Lawrence Livermore National Laboratory		
Dose risk (person-rem/yr)	$1.2x10^{-6}$	$9.3x10^{-6}$
Fatality risk (cancer fatalities/yr)	$6x10^{-10}$	$5x10^{-9}$
Nonradiological accidents[a] (fatalities/yr)	$1x10^{-3}$	$3x10^{-3}$
Nonradiological vehicular emissions (fatalities/yr)	$4x10^{-4}$	$1x10^{-3}$
Los Alamos		
Dose risk (person-rem/yr)	$2.4x10^{-6}$	$1.9x10^{-5}$
Fatality risk (cancer fatalities/yr)	$1x10^{-9}$	$9x10^{-9}$
Nonradiological accidents[a] (fatalities/yr)	$2x10^{-3}$	$6x10^{-3}$
Nonradiological vehicular emissions (fatalities/yr)	$2x10^{-4}$	$5x10^{-4}$
Savannah River		
Dose risk (person-rem/yr)	$2.0x10^{-6}$	$1.6x10^{-5}$
Fatality risk (cancer fatalities/yr)	$1x10^{-9}$	$8x10^{-9}$
Nonradiological accidents[a] (fatalities/yr)	$1x10^{-3}$	$3x10^{-3}$
Nonradiological vehicular emissions (fatalities/yr)	$2x10^{-4}$	$5x10^{-4}$
University of Rochester		
Dose risk (person-rem/yr)	$2.1x10^{-6}$	$1.6x10^{-5}$
Fatality risk (cancer fatalities/yr)	$1x10^{-9}$	$8x10^{-9}$
Nonradiological accidents[a] (fatalities/yr)	$9x10^{-4}$	$2x10^{-3}$
Nonradiological vehicular emissions (fatalities/yr)	$2x10^{-4}$	$5x10^{-4}$
Maximum Consequence Accident		
Population[b,c]		
Dose (person-rem)	0.33	3.3
Fatal cancers	$2x10^{-4}$	$2x10^{-3}$
Maximally Exposed Individual[b,d]		
Dose (rem)	$1.2x10^{-4}$	$1.2x10^{-3}$
Fatal cancer probability	$6x10^{-8}$	$6x10^{-7}$

[a] Collective population fatalities were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Option). For example, a reported value of $4x10^{-3}$ fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

[b] The most severe accidents assumed that 100 percent of the target tritium was released in an oxide form during an accident. Accident consequence results were determined using the RISKIND computer program which is described in Yuan et al. 1993. Stable weather conditions (Pasquill Stability Class F) with a wind speed of 1 m/s (2.2 mph) were assumed.

[c] The maximum consequences would result from an accident occurring in an urban environment. The population was assumed to extend at a uniform density of 3,861 persons/km^2 (10,000 persons/mi^2) to a radius of 80 km (50 mi) from the accident site. The population exposure pathways for urban environments included inhalation and resuspended inhalation. Urban environments were not assumed to produce food for local use or export, hence no ingestion dose was included.

[d] The maximally exposed individual was assumed to be at the location of maximum exposure. The location of the maximally exposed individual was assumed to be 380 m (1,247 ft) from the accident under stable weather conditions. Individual exposure pathways included acute inhalation during passage of the plume. No ingestion dose was considered.

Note: The transportation risk assessment assumed 100 percent of the tritium targets would be manufactured and transported to NIF from each site. In practice, tritium targets would be produced and transported from more than one manufacturer. The transportation risk assessment was performed for offsite transportation only. Transportation risks from onsite transport of tritium targets were assumed to be negligible compared to risks from offsite transportation.

Source: Model results.

a similar manner by multiplying the state-specific accident fatality rate by the distance traveled by truck in the state.

The maximally exposed individual and population doses were calculated for a transportation accident involving the entire release of the tritium cargo (assumed to be five tritium targets). Radiological impacts resulting from a potential maximum-consequence accident were assessed for a general population located in an urban population density zone. Maximally exposed individuals were assumed to be exposed and unshielded as the plume passed at a distance, resulting in the largest dose to the individual. Radiological consequences were assessed for worst-case weather conditions (Pasquill Stability Class F) for both the collective population and the maximally exposed individual. For assessment purposes, it was assumed that the entire tritium cargo was released to the environment in oxide form. The estimated number of latent cancer fatalities from the maximum-severity transportation accident was calculated by multiplying the population-committed effective dose equivalent by $5x10^{-4}$ latent cancer fatalities per person-rem (ICRP 1991). Table I.4.3.2.7.2-2 summarizes the impacts of a maximum-consequence accident during transportation of tritium targets.

Hazardous Chemical Impacts. A number of possible chemical accidents (including one caused by an aircraft crash) were studied in terms of their potential impacts on workers and the public outside NTS boundaries (Lazaro et al. 1996). The five accidents likely to have the greatest impacts were studied in detail. Four of these five accidents would occur at NIF location, and the fifth accident would occur elsewhere on NTS. The four release scenarios occurring at NIF are as follows:

- A mercury release from the ignitron switches
- A combined alumina/silica release from the target chamber
- A carbonyl fluoride release from the optics treatment area
- A hydrogen fluoride release from the optics treatment area

All four accidents at NIF would occur far from workers in other buildings and very far from the public. The fifth accident is unique to NTS because of the presence of propane storage tanks for fuel on the site near NIF. The two largest tanks hold 28,400 L (7,500 gal) each and are positioned side by side. The worst-case scenario assumes that both tanks would simultaneously leak from a 5-cm (2-in) diameter hole 0.3 m (1 ft) from the tank bottom as a continuous release over one hour.

A modeling study was conducted for each of the five release scenarios. More details, including predicted concentrations, are provided in Lazaro et al. (1996). The modeling study applied a dispersion model to each of the releases and used a health criterion (ERPG-2 level) representative of acute impacts from an exposure that might happen once in a lifetime. The health criterion was the concentration below which, if exposure occurred for an hour, the exposed individual could still avoid irreversible health effects by taking emergency action. The results of the modeling yielded the following conclusions:

- The threat zone from each of the four accidents would not extend to the boundary with the public under either typical or extreme meteorological conditions
- Personnel in other buildings on the site are so far away that they would not be affected. The assumptions made for the four accidents in the NIF Laser and Target Area Building were that the release would not be inhibited by the walls of the NIF building and that the wind would take the plume away from the building. The distances beyond which concentrations would fall below the ERPG-2 level for each of the five accidents are as follows:
  - Mercury scenario—239 m (784 ft) for both the Conceptual Design and Enhanced options.
  - Alumina/silica scenario—231 m (758 ft) for the Conceptual Design Option and 171 m (561 ft) for the Enhanced Option.

–Carbonyl fluoride scenario—75 m (246 ft) for both the Conceptual Design and Enhanced options.

–Hydrogen fluoride release—101 m (331 ft) for both the Conceptual Design and Enhanced options.

–Propane release—755 m (2,477 ft) for both the Conceptual Design and Enhanced options.

Personnel in NIF Laser and Target Area Building and those outside in the immediate vicinity might be affected.

I.4.3.2.8 Waste Management Impacts

This section describes the proposed management of wastes generated during construction, normal operation, and the ultimate decommissioning of NIF if it were located at NTS.

I.4.3.2.8.1 *Waste Generation and Management During Construction and Operation*

During construction, waste management would be performed as described in section I.4.1.2.8 for LLNL. No water permits would be needed for withdrawal of groundwater for activities occurring on NTS. A RCRA Part B Permit would be required for the construction of hazardous and mixed waste management facilities, and a state-issued permit would be required for the construction of nonhazardous waste landfills. All construction activity would be performed in compliance with requirements identified in DOE O 47001.1. NTS has adequate capacity to handle (or contract for offsite disposal of) this waste stream.

Table I.4.1.2.8.1–2 (section I.4.1.2.8.1) describes the quantities of various low-level, mixed, hazardous, and nonhazardous wastes that would be generated during NIF operation for both the Conceptual Design Option and Enhanced Option. The following paragraphs describe how the wastes shown in that table would be managed if NIF were located at NTS.

Successive sections cover how developing technologies might be applied to minimize waste streams. Waste handling methods would be the same for both the Conceptual Design and Enhanced options. While, as shown in various tables, total estimated waste quantities are somewhat higher for the Enhanced Option, no changes in handling methods would be necessary.

Low-Level Waste. Solid LLW produced during NIF operations would be disposed of onsite. NTS currently disposes of solid LLW onsite, in compliance with NVO-325 waste acceptance criteria.

Waste that does not meet the waste acceptance criteria requirements of NVO-325 may not be disposed of at NTS. The waste must be certified to meet the requirements whether that creates the need for further treatment or characterization or whatever the area of deficiency by which the waste or the management program governing the waste was deemed unacceptable. There is and has been waste that has been unapproved or disapproved. DOE's Nevada Operations Office conducts an audit on the program managing the waste and is the approval authority for all waste streams to be disposed of on NTS.

Aqueous LLW would be treated onsite to eliminate free liquids. Currently, there are no existing facilities at NTS for the treatment of liquid radioactive waste. However, there are plans to develop this capability at NTS in the near future (FY 1997) (see next section on mixed liquid waste).

Mixed Waste. Current plans are to permit mixed solid waste disposal units on NTS for mixed waste generated both on and offsite that meets RCRA land disposal requirements. A permit application has been submitted to the State of Nevada, and it is estimated that the units will be available in fiscal year 1997, well before NIF operations would begin. NTS currently has the capability, under interim status, to dispose of mixed waste generated onsite at the Area 5 Radioactive Waste Management Site. The current remaining capacity for mixed waste disposal at NTS is over 90,000 m^3 (117,000 yd^3) and will be much greater (approximately 250,000 m^3 [325,000 yd^3]), assuming that approval and construction of permitted mixed waste disposal units takes place as anticipated. The small amount of mixed waste generated at NIF would not significantly affect mixed waste operations. In the event the mixed waste was generated before development of acceptable NTS disposal capacity, the waste could be stored, pending approval by the State of Nevada, at a storage pad onsite at the Area 5 Radioactive Waste Management Site or could be sent to a mixed waste disposal site out of state.

Low-level mixed liquid waste would be treated to eliminate free liquids before disposal at NTS. Free liquids are not allowed for disposal, per requirements identified in the NTS Waste Acceptance Criteria, NVO-325. As with solid mixed waste, the requirements identified in the RCRA land disposal restrictions would also be met. No facilities currently exist at NTS for the treatment of liquid mixed waste; however, there are plans to develop such capability in the near future. The liquid waste treatment system, which is designed to treat large volumes of liquid waste (both radioactive and mixed) is expected to be available in fiscal year 1997. This system would use evaporation as the primary treatment method for the anticipated waste. A second mixed waste treatment facility, which is still in the preliminary planning stages, is also expected to be operational in fiscal year 1997. This facility will use stabilization as the primary method of treatment and might be more appropriate for the liquid mixed waste from NIF. This facility should be online by the time any waste would be generated by NIF operations. Therefore, upon approval of a permit modification, this planned facility would be available for the treatment of NIF liquid mixed waste.

If necessary, NIF liquid mixed waste could be stored onsite at the Area 5 Radioactive Waste Management Site until a treatment facility was available. This waste would be stored on a mixed-waste storage pad that is planned for construction in the near future. If the mixed waste storage pad were not available at the time of generation, the waste could be stored on the TRU pad with approval from the State of Nevada. The TRU pad is currently used for the storage of mixed waste (Ortego and Johnston 1995). The waste containers are protected from the environment in a covered building. Monitoring already exists and could be modified to detect hazards specific to NIF waste.

The mixed aqueous waste from the debris shield cleaning would be neutralized, stabilized, and disposed of at NTS as an approved waste stream.

Hazardous Waste. NTS has a well-established system for management of large quantities of hazardous waste. Both liquid and solid hazardous wastes are sent offsite to permitted treatment, storage, or disposal facilities located outside Nevada. Hazardous waste generated at NTS is accumulated and stored at the RCRA-permitted hazardous waste storage unit located near the Area 5 Radioactive Waste Management Site. NTS generates approximately 300,000 L (79,250 gal) of hazardous waste annually, based on fiscal year 1994 volumes. The addition of an estimated 8.0 m^3 (280 ft^3) of solid and 4,500 L (1,190 gal) of liquid hazardous waste from NIF could be handled by the existing waste management system and would not cause a significant adverse impact. A subcontractor typically removes waste from the hazardous waste storage unit on a monthly basis under an existing approved EPA identification number for NTS. There are no plans to construct a hazardous waste disposal unit at NTS. Precious metals, such as silver and mercury, and used oils are sent to approved recycling and recovery centers. Most hazardous waste from NIF would be shipped to an approved commercial RCRA treatment, storage, and disposal facility.

Nonhazardous Waste. Sanitary wastewater would be treated at a new sewage lagoon system dedicated to NIF. There are a number of these sewage lagoons in existence at NTS because this is the customary method for managing this type of waste. Resources would be available to construct this system for NIF.

The development of a storm drain would depend on the siting for NIF. Because of the vast availability of usable land at NTS, it is unlikely that extensive storm drain development would be necessary. Siting of the facility and its subsequent design would allow for alluvial flood protection. There are no public structures in the vicinity of NTS that would require the diversion of flood waters. The only potentially affected structures would be the other DOE facilities in the vicinity of NIF.

Disposal of nonhazardous solid waste would be handled by onsite DOE/NV contractors. NTS maintains the capability to dispose of nonhazardous solid waste at onsite disposal units. Landfills are available for sanitary waste, construction debris, and hydrocarbon-contaminated soil. The onsite contractor maintains a collection schedule for the removal of nonhazardous waste and can be called for supplementary pickups as needed.

Possible Waste Minimization During Operation. Waste minimization would be handled as described in section I.4.1.2.8 for LLNL. A pollution prevention opportunity assessment will be conducted on proposed NIF operations to optimize their efficiency and minimize waste generation.

Existing Waste Management Capabilities at Nevada Test Site. Based on the estimated waste generation by NIF (table I.4.3.2.8.1–1) and on information on current waste handling practices at NTS, comparison tables were developed that indicate the capability of the existing NTS facilities to undertake the various waste managements tasks associated with NIF.

For reference, table I.4.3.1.8–1 shows the current waste management capacity at NTS. Table I.4.3.2.8.1–1 shows the impact of estimates for NIF on waste storage at NTS. Table I.4.3.2.8.1–2 is a comparison of NIF waste-generation rate to the annual handling/treatment capacity at NTS. There are currently no treatment capabilities on NTS applicable to the waste that would be generated at NIF.

I.4.3.2.8.2 *Waste Management at Nevada Test Site During National Ignition Facility Decommissioning*

NTS proposes that decommissioning NIF after 30 years of operation includes removal of the laser and associated equipment from the laser building (Ortego 1995). The D&D activities would not add a significant burden to operations at NTS. This type of activity is common throughout the DOE complex at

TABLE I.4.3.2.8.1–1.—***Impact of Estimated National Ignition Facility-Generated Waste on Waste Storage at Nevada Test Site***

Category	NIF-Generated Waste/Year[a] (m^3)		Years to Fill with NIF Flow Alone		Is Existing or Planned Storage Capacity Adequate	
	Solid	Liquid	Solid	Liquid	Solid	Liquid
Low-Level						
Conceptual Design total	2.98	0.60	Unknown	Unknown	Yes[b]	Yes[b]
Enhanced total	7.25	1.56	Unknown	Unknown	Yes[b]	Yes[b]
Mixed						
Conceptual Design total	0.34	2.00	3.3×10^3	0.57	Yes	Yes[c]
Enhanced total	0.88	4.98	1.3×10^3	0.22	Yes	Yes
Hazardous[d]						
Conceptual Design total	8.0	2.30	13[e]	45.2	Yes[f]	Yes[f]
Enhanced total	8.0	4.60	13[e]	22.6	Yes[f]	Yes[f]

[a] The total amount of the low-level waste was found by adding the values in the column "Cleaned" of table I.4.1.2.8.1–2 to the column "Low-Level" of the same table. The mass of the debris shield was translated into volume by assuming the density of iron (7.87 g/cm^3). The density of the low-level liquid waste was assumed equal to 1.0 g/cm^3.

[b] The storage capacity is unknown; however, the capacity is easily larger than 1,600 L/yr (426 gal/yr). Storage could be accomplished with 208-L (55-gal) drums at numerous locations.

[c] Planned.

[d] The values for the hazardous waste were found by adding the hazardous waste from the Laser and Target Area Building and the Optics Assembly Area.

[e] The following values for the densities of the materials were assumed: molecular sieves: density of diatomaceous earth (0.27 g/cm^3); personal protective equipment and wipes: density of paper (0.4 g/cm^3); pre- and high-efficiency particulate air filters: density of charcoal (1.8 g/cm^3); paper capacitors: density of paper (0.4 g/cm^3); hardware from the chamber: density of 50 percent aluminum and 50 percent stainless steel (5.3 g/cm^3).

[f] Shipped offsite.

the present time. Experienced waste-handling and radiation safety personnel working at NTS would be employed for decommissioning.

A wide variety of decommissioning projects similar to those required for NIF are currently under way at NTS. All radiation-related work practices at NTS comply with the three primary requirements and guidance documents for radiation safety: 10 CFR 835, Radiation Control Manual, and DOE N 441.1. A fully implemented program has been established with complex guidelines and procedures, which forms a site-specific Radiation Safety and Control Manual. As low as reasonably achievable programs have been established and are implemented based on the above-noted program documents. All work that would present the potential for exposure or contamination would receive special consideration and planning, including, but not limited to, dry-run practices, condition monitoring experiments, and personal protective equipment upgrade analysis. Decontamination systems designed specifically for equipment in NIF would be established to optimize efficiency and reduce the amount of waste residuals from the decontamination process. A wide variety of radiation safety and decontamination resources and experience exist at NTS. These resources would be made available, as necessary, for the development and implementation of NIF systems. Existing equipment, such as anticontamination clothing and personal protective equipment, would be available for use at NIF. This type of reusable equipment would be decontaminated onsite at the laundering and cleaning facilities available at NTS. Residual materials from the decontamination process would be disposed of at NTS.

The following sections discuss specifics of decommissioning of NIF laser and associated components, followed by a discussion of decommissioning of equipment in the target area. The major activated/contaminated components would be located in the target area, so this facility would pose the most complex operation.

Decommissioning of National Ignition Facility Laser by Nevada Test Site. The decommissioning of the NIF laser would be handled similar to the manner described in section I.4.1.2.8 for LLNL. Mercury wastes from the ignitron switches would be sent to a permitted mercury recycling center, as is the current practice for other mercury wastes. The mixed waste from the capacitors would have to meet the requirements of NVO-325 before disposal on NTS at the Area 5 Radioactive Waste Management Site, as indicated in the discussion above on mixed wastes.

If the mixed waste from capacitors did not meet the physical requirements mandated under NVO-325, the waste might be treated to meet these requirements. If the characterization information on the capacitor mixed waste was deemed unacceptable, the characterization documentation must be redone and/or improved to meet the requirements. If the quality assurance on the capacitor mixed waste was inadequate, the management of the waste would have to be improved to meet the requirements. If the generators did not wish to achieve compliance with the requirements of NVO-325 they might wish to pursue other locations for disposal of the waste.

There should be no reason the mixed waste from the capacitors would not meet the waste acceptance criteria of NVO-325 as long as the waste was managed, treated and/or characterized properly, in compliance with the applicable requirements.

Decommissioning of National Ignition Facility Target Area. The decommissioning of the NIF target area would be handled similar to the manner described in section I.4.1.2.8 for LLNL. DOE/NV and associated contractors have experience dealing with tritium contamination in virtually all phases of operations. Routine carbon dioxide cleaning during operations of NIF would be the primary process for reducing the total amount of contamination on components at the end of life of NIF. NTS waste management operations have disposed of millions of curies of tritium during the history of Radioactive Waste Management Site operations, especially in Area 5. This disposal site, as well as operational sites throughout NTS, is equipped with tritium monitoring and detection systems. The Analytical Services Laboratory at NTS (in Area 23) can perform a variety of analyses for tritium and can carry out personnel decontamination.

Radioactive and mixed waste could be disposed of at NTS, assuming it could be managed and processed in accordance with NVO-325. Large structures that could not easily be containerized could be disposed of at the Area 3 Radioactive Waste Management Site, which is used for the disposal of bulk LLW containers.

NIF would be decommissioned according to standard engineering practices. The project would be handled in a manner similar to construction projects, per the requirements of DOE O 430.1. This planning would optimize all phases of decommissioning and provide the most efficient method for completing the work. Efficient work would lead to a reduction in time for exposure of workers, which would in turn reduce the overall exposure projections.

I.4.4 North Las Vegas Facility

I.4.4.1 *Affected Environment*

The following sections describe the affected environment associated with the construction and operation of NIF at the North Las Vegas Facility (NLVF). Land use, air quality and acoustics, water resources, biotic resources, cultural and paleontological resources, socioeconomics, radiation and hazardous chemicals, and waste management are described.

I.4.4.1.1 Location and Land Use

NLVF is located in the city of North Las Vegas, west of Losee Road, north of Carey Avenue, east of Commerce Street, and south of Brooks Avenue (figure I.3.4.4.1–2). The 32-ha (80-acre) NLVF is zoned general industrial and is bordered on the north, south, and east by general industrial zoning. The western border of the site is adjacent to Commerce Street, which separates the property from fully developed, single-family residential-zoned property. Figure I.4.4.1.1–1 shows the generalized land use in the vicinity of NLVF. NLVF is divided into three distinct areas: the A, B, and C complexes. The A complex covers 8 ha (20 acres) and housed support for the LLNL nuclear test program. The B complex covers 8 ha (20 acres) just south of A complex and housed support for the LANL nuclear test program. The C complex, located west of A and B complexes, covers 15.5 ha (38.3 acres) and housed a computer center and administrative and engineering support functions (DOE 1995h). The open space in C complex would be the primary location for NIF and for the temporary construction laydown area. Existing facilities in C complex and A complex would also be used (figure I.3.4.4.1–2).

The entire NLVF is built on cleared, previously disturbed land, and most of it is covered by buildings, pavement, concrete, or landscaping, except for the open space in C complex. That open space is void of most vegetation. The soils on NLVF range from relatively thick layers of cemented to noncemented soils, and from stiff to very stiff silty and sandy clay, and clay with interbedded medium-dense to dense clayey and silty sand.

I.4.4.1.2 Air Quality and Acoustics

This discussion of existing air quality and acoustics includes a review of the meteorology, climatology, and ambient air quality characteristics near NLVF.

I.4.4.1.2.1 *Meteorology and Climatology*

The climate at NLVF and the surrounding region has four well-defined seasons. Summers display desert conditions, with maximum temperatures usually near 38 °C (100 °F). Winters are mild, with daytime temperatures near 15.5 °C (60 °F). Rainy days average less than one in June to three per month in the winter. Severe thunderstorms occasionally occur in the summer. The spring and fall are generally considered the most ideal seasons, although sharp temperature changes can occur during these months. The annual average temperature at NLVF is 19.1 °C (66.3 °F); average daily temperatures range from 6.9 °C (44.5 °F) in January to 32.1 °C (89.8 °F) in July. The average annual precipitation is 10.6 cm (4.19 in). The prevailing winds are from the southwest at an annual average speed of 15.2 kph (9.3 mph) (Gale Research 1992). The 5-year wind rose for NLVF (based on measurements at McCarran International Airport in Las Vegas) is shown in figure I.4.4.1.2.1–1. From 1987 to 1991, unstable conditions occurred approximately 28 percent of the time, neutral conditions about 37 percent of the time, and stable conditions the remaining 35 percent of the time (NOAA 1995b). In general, atmospheric dispersion improves as the wind speed increases and as the atmospheric conditions become more unstable.

The limited precipitation and warm temperatures create an arid climate that limits the growth of ground-covering vegetation. This condition results in large areas of exposed soil that are potential sources of windborne particulate matter (dust). Ambient particulate matter concentrations are reduced if the exposed soil is wetted or if the airborne particulate matter is "washed out" of the atmosphere by precipitation. However, the area's precipitation and temperature seldom provide these beneficial mechanisms. This situation worsens the particulate matter background concentration and increases the likelihood of the area's PM_{10} and TSP ambient air concentrations approaching or exceeding regulatory standards.

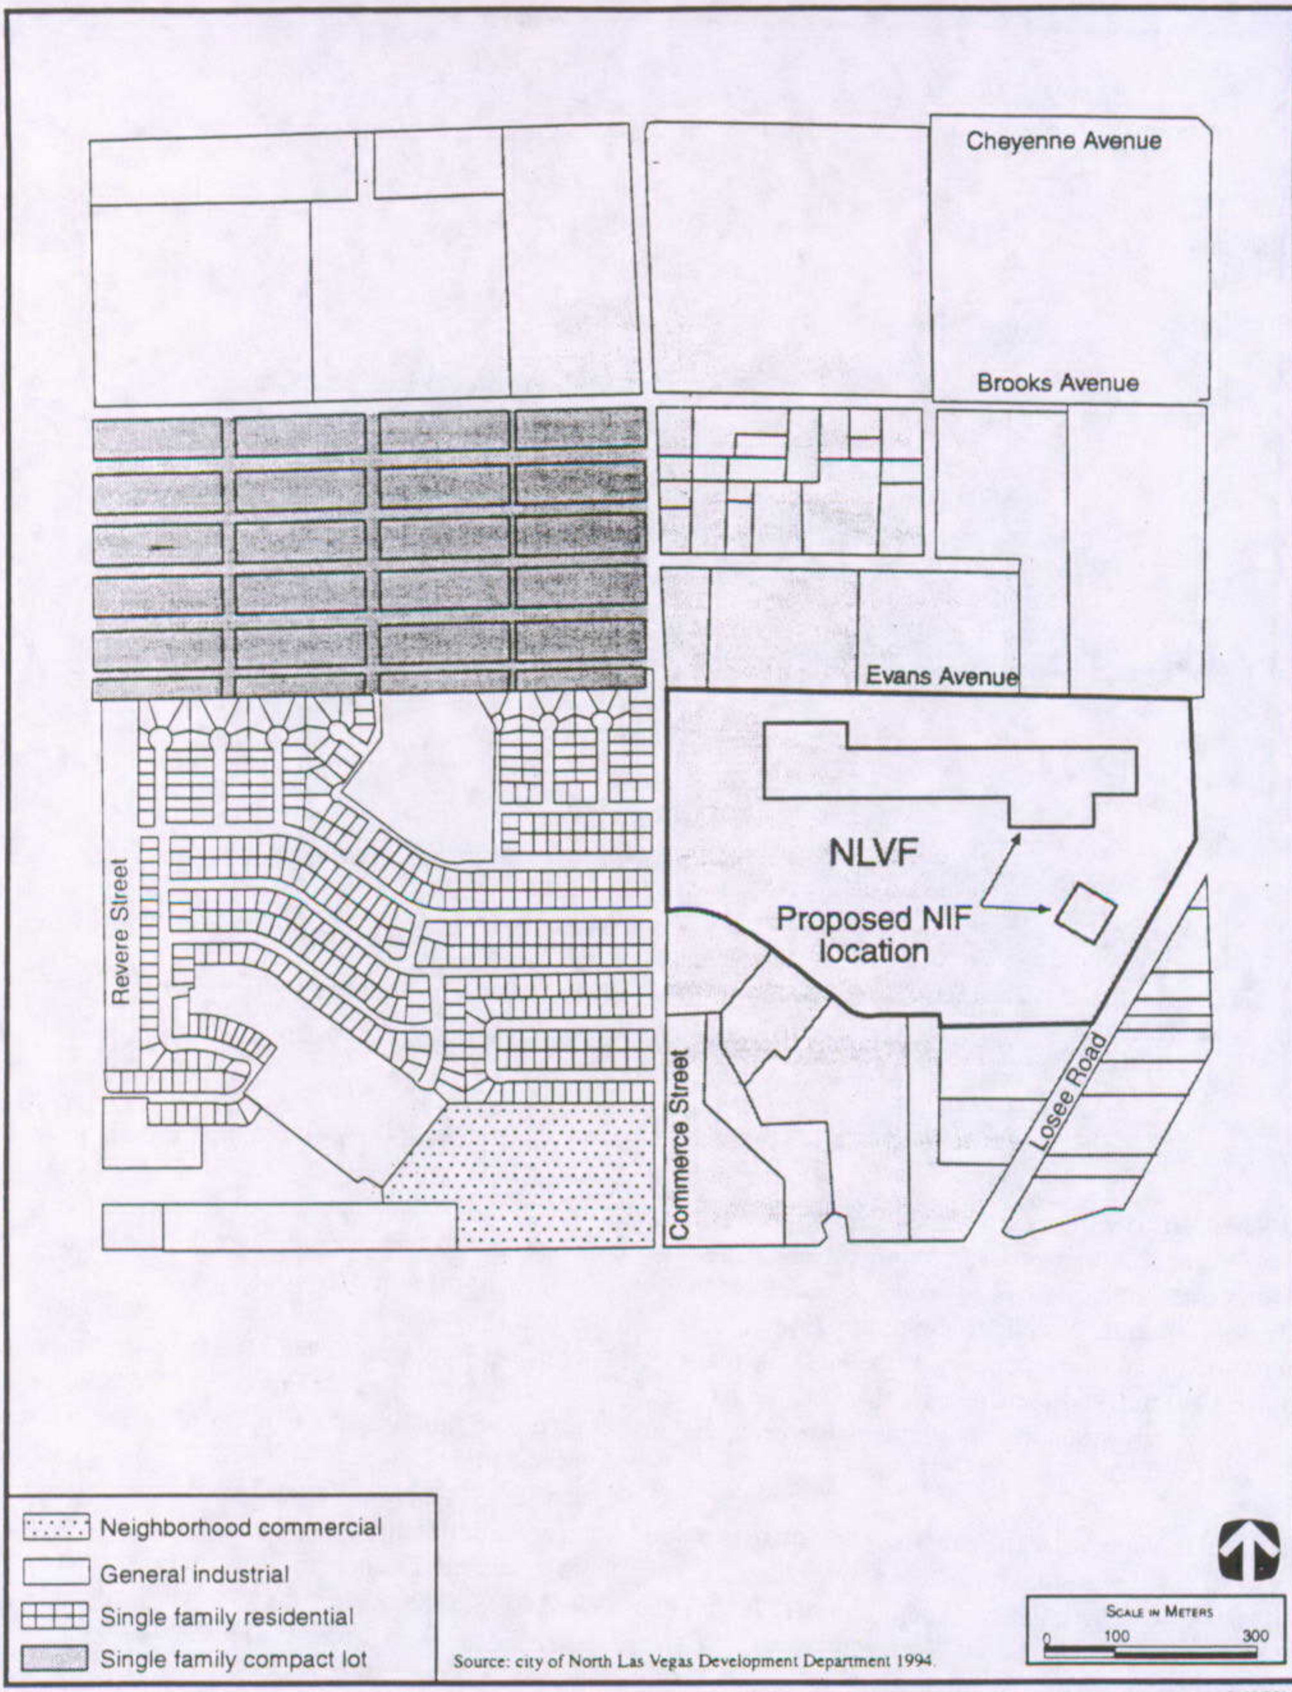

FIGURE I.4.4.1.1–1.—*Generalized Land Use at North Las Vegas Facility and Vicinity.*

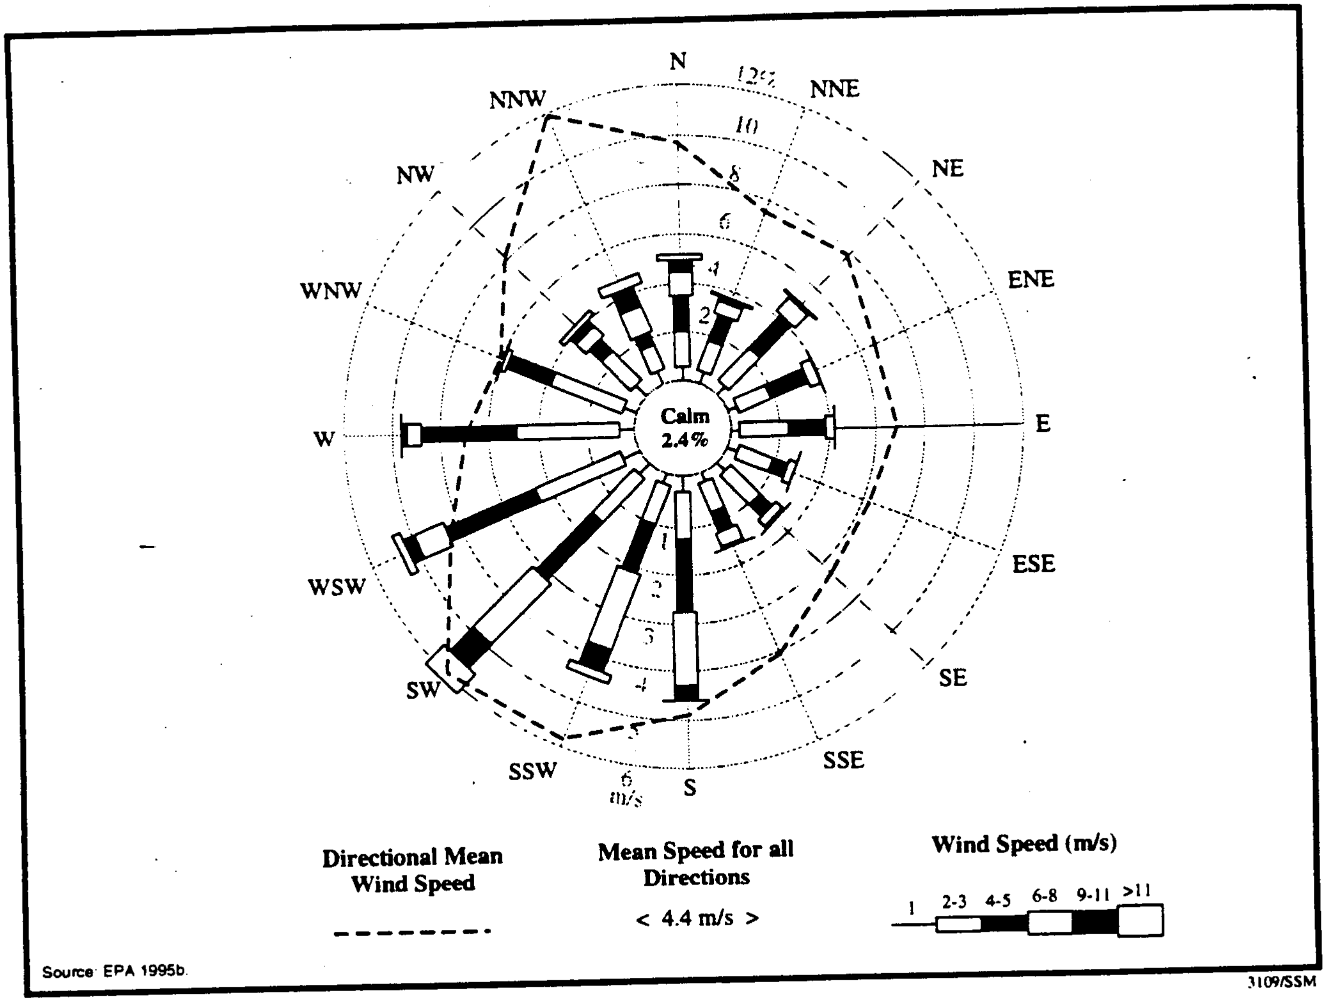

FIGURE I.4.4.1.2.1-1.—*Wind Distribution at North Las Vegas Facility, 1987-1991.*

I.4.4.1.2.2 *Ambient Air Quality*

The Clark County Health District is responsible for air pollution control and attainment of air quality standards in Clark County. In addition to NAAQS for criteria pollutants, NLVF is subject to ambient air quality standards adopted by the Clark County Health District. Applicable NAAQS and Clark County ambient air quality standards are presented in table I.4.4.1.2.2-1.

The NLVF site is in the Las Vegas Intrastate AQCR 13, which includes only Clark County. Portions of Clark County, including the NLVF site, are classified as nonattainment areas for the NAAQS for carbon monoxide, PM_{10}, and TSP (40 CFR 81.339). In general, pollutant emission increases in an area designated as nonattainment for a specific pollutant are subject to more stringent permitting requirements than if the area is designated as attainment.

The Clark County Health District operates a network of air monitoring stations in Clark County. The monitor closest to NLVF is at the McDaniel Post Office at 1414 East Lake Mead Drive, approximately 1.9 km (1.2 mi) east of the proposed NIF location. Data for this and other monitors near NLVF are provided in Lazaro et al. (1996). Table I.4.4.1.2.2-1 lists the 1994 baseline ambient air concentrations for criteria pollutants and other pollutants at NLVF. All of the baseline concentrations are in compliance with NAAQS. The emissions of criteria pollutants at NLVF are discussed in section I.4.4.2.2.

The area surrounding NLVF contains two PSD Class I areas: Grand Canyon National Park, approximately 110 km (65 mi) to the east in Arizona, and

TABLE I.4.4.1.2.2–1.—***Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at North Las Vegas Facility***

Pollutant	Averaging Time	Most Stringent Regulation or Guideline ($\mu g/m^3$)	1994 Baseline Concentration[a] ($\mu g/m^3$)
Criteria Pollutant			
Carbon monoxide	8 hours	10,000[b,c,d]	8,635
	1 hour	40,000[b,c,d]	13,456
Lead	Calendar quarter	1.5[b,c,d]	ND[e]
Nitrogen dioxide	Annual	100[c,d]	53
Ozone	1 hour	235[b,c,d]	192
Particulate matter 10 microns or smaller	Annual	50[b,c,d]	47
	24 hours	150[b,c,d]	114
Sulfur dioxide	Annual	60[c,d]	ND
	24 hours	260[c,d]	ND
	3 hours	1,300[b,c,d]	ND
Mandated by State			
Hydrogen sulfide	1 hour	112[c]	ND
Visibility	-	f	ND

[a] For short-term standards, baseline concentration is the highest concentration for the year.
[b] Federal standard (40 CFR 50).
[c] State standard.
[d] County standard.
[e] ND - No data available.
[f] In sufficient amount to reduce the prevailing visibility to less than 48 km (30 mi) when the humidity is less than 70 percent.

Joshua Tree National Monument, approximately 250 km (155 mi) to the south-southwest in California.

I.4.4.1.2.3 *Acoustic Conditions*

Major noise emission sources within NLVF include motor vehicles and various industrial facilities and equipment. The site is bordered by highways along the eastern and western NLVF boundaries. Near highways, traffic contributes to ambient noise levels, especially during peak hours. The adjacent main land uses in the vicinity of NLVF are light industrial to the north, east, and south, and urban residential to the west. The acoustic environment along the NLVF boundary is generally assumed to be that of an urban location, with typical average daytime sound noise levels of 55 to 65 dBA (EPA 1974).

I.4.4.1.3 Water Resources

NLVF is located in the Las Vegas Valley, which is a desert between sharp, rugged mountain ranges on a gently sloping alluvial fan piedmont. At the lowest point of the alluvial fan is the Las Vegas Wash, which drains an area of 2,280 km^2 (880 mi^2) toward Lake Mead. Stormwater from NLVF is discharged into local flood control systems (DOE 1995h).

The depth to groundwater at NLVF varies seasonally from 5 to 45 m (17 to 150 ft). Groundwater is the source of water supply for the city of North Las Vegas, which in turn provides water to NLVF. The nearest water well to NLVF is about 0.40 km (0.25 mi) south (DOE 1995h). Current water usage by NLVF is about 69.4 MLY (18.3 MGY) (Lazaroff 1995a). Industrial wastewater and sanitary sewage from NLVF are discharged into the city of North Las Vegas sewer system, which is connected to the city of

Las Vegas treatment plant. The treated wastewater is discharged into Lake Mead under an NPDES permit issued by the Nevada Division of Environmental Protection (DOE 1995h). NLVF discharges an average of 54.8 MLY (14.5 MGY) of wastewater. Wastewater quality has historically met the permit requirement established by the city to protect the treatment processes and ultimately the water quality of Lake Mead (DOE 1995h). The proposed NIF location at NLVF is outside the 500-year floodplain of the local drainage (FEMA 1993).

I.4.4.1.4 Biotic Resources

NLVF is in the Southern Basin and Range Ecoregion (Omernik 1986). NLVF was built on cleared, previously disturbed land that is now mostly covered by buildings, pavement, or landscaping. Exceptions include about 4.5 ha (11 acres) of undeveloped land at the western end of the facility (designated area for NIF), the open area west of Building C-3, and the stormwater detention basin south of Building C-1. No undisturbed native vegetation remains on the site (DOE 1995h). No wetlands or natural aquatic habitats occur at NLVF.

Because NLVF is located in an urbanized area and contains little vegetation, few native wildlife species are present. No surveys for onsite biota have been conducted. However, species adapted to urban habitats (e.g., small mammals such as house mouse and Norway rat; and ubiquitous bird species such as American robin, European starling, house finch, house sparrow, and rock dove) would be expected to exist at NLVF.

Because NLVF is located within urban Las Vegas on previously disturbed land within a fenced site, no threatened, endangered, or rare species are expected to exist there. No designated critical habitats for Federal-listed species exist at NLVF. The facility is within the range of the federal-threatened desert tortoise, but urbanized areas of Clark County are not considered tortoise habitat (DOE 1995h). No desert tortoises were found during an offsite survey of undeveloped land near the western boundary of NLVF (Knowles and Gulash 1989).

I.4.4.1.5 Cultural and Paleontological Resources

Although prehistoric and historic remains (sites 26CK1185 and 26CK1527) are located within 1.6 km (1 mi) of the proposed NIF location, no archaeological remains (prehistoric or historic) are likely to be present at that location because of the heavy past disturbance of the surface and near-surface sediment (DOE 1995h; Jones 1995). Lower-lying deposits that are relatively undisturbed are too ancient to contain archaeological remains. No historic structures occur in the proposed NIF location. No Native American cultural resources have been identified at NLVF in the course of past consultation with potentially affected tribal organizations.

I.4.4.1.6 Socioeconomics

Socioeconomic characteristics described for NLVF area include the regional economy, population and housing, public finance and public service infrastructure, and local transportation. Regional economic statistics are based on a regional economic study area that encompasses 11 counties around NLVF as defined by the Bureau of Economic Analysis. The economic study area is a broad labor and product market-based region linked by trade among economic sectors within the region. Statistics for population, housing, public finance, and public service infrastructure are based on the ROI, a two-county area in which 95 percent of NLVF employees reside. Lazaro et al. (1996) lists counties included in the economic study region and counties included in the ROI. Assumptions, assessment methodologies, and supporting data for each TA are also presented in Lazaro et al. (1996).

I.4.4.1.6.1 *Regional Economy*

The regional economic study area for NLVF includes the Las Vegas Metropolitan Statistical Area (Clark County). Employment in the economic study region is projected to increase from 412,300 in 1988 to 496,700 in 1995. BEA projects the compounded annual rate of growth at 19 percent from 1995 to 2018 (79,522 jobs) (BEA 1990).

In 1995, NLVF employed approximately 1,000 people, accounting for less than 1 percent of employment in the regional economic study area. The distribution of NLVF employees by place of residence in the ROI is presented in Lazaro et al. (1996).

I.4.4.1.6.2 *Population and Housing*

The ROI experienced significant population growth between 1980 and 1990, with an average annual increase of about 4.5 percent, bringing the 1990 total to approximately 683,000 persons. Population growth has been strongest in Clark County. By the year 2000, population in the ROI is projected to grow to approximately 860,000 persons (BEA 1990; U.S. Department of Commerce 1994).

Between 1980 and 1990, the number of housing units in the ROI increased from 194,899 to 325,261, an increase of 67 percent (see table I.4.4.1.6.2–1). Housing in Clark County increased from approximately 190,607 units in 1980 to 317,188 in 1990. Housing in Nye County increased from 4,292 units in 1980 to approximately 8,073 in 1990. Assuming a continuation of current construction and economic trends, the number of housing units in the ROI is projected to increase to approximately 455,000 by the year 2000.

The number of vacant owner units in the ROI has increased from approximately 11,000 units in 1980 to 17,000 in 1990. It is estimated that in the year 2000 there will be approximately 25,000 vacant owner units if current construction and economic trends continue in the ROI.

In 1980 there were approximately 7,000 vacant rental units in the ROI. The number of vacant rental units increased to about 15,000 in 1990. It is estimated that in the year 2000 there will be approximately 22,000 vacant rental units if current construction and economic trends continue in the ROI.

Between 1993 and 1994, the Las Vegas Metropolitan Statistical Area experienced a sharp increase of about 30 percent in new single-family housing units. Multifamily housing construction increased by 44 percent between 1993 and 1994. The number of new housing units sold increased as well, rising 11 percent over 1993 levels. In spite of the growing supply of houses in the Las Vegas market, new housing prices continue to climb (ULI 1995).

I.4.4.1.6.3 *Public Finance and Public Services Infrastructure*

Public financial characteristics of the local jurisdictions in the ROI that are most likely to be affected by construction and operation of NIF at NLVF are summarized in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expenditure trust funds. Major revenue and expenditure categories and revenues less expenditures for counties and cities are presented in table I.4.4.1.6.3–1. Table I.4.4.1.6.3–2 summarizes public service levels for community services, health care, and education.

I.4.4.1.6.4 *Local Transportation*

The existing roadway network in the vicinity of NLVF includes Losee Road, Carey Avenue, Cheyenne Avenue, Interstate 15, Commerce Street, Brooks Avenue, and Lake Mead Boulevard. Direct access to NLVF is via Brooks Avenue, Carey Avenue, Commerce Street, Losee Road, and North 5th Street (Omni-Means 1990).

Losee Road is generally a north-south oriented roadway adjacent to the eastern boundary of NLVF. It currently begins at a signalized intersection with Lake

Mead Boulevard and continues north, intersecting Carey Avenue at a four-way-stop intersection and Cheyenne Avenue at a signalized intersection. Both the Atlas Gate and the South Gate provide access to Losee Road (Omni-Means 1990).

Cheyenne Avenue is an east-west roadway to the north of the project site. Except for the first 300 m (1,000 ft) west of Losee Road, Cheyenne Avenue is a two-lane roadway. Carey Avenue is a four-lane roadway that provides east-west circulation south of the project site. It includes a grade-separated crossing of Interstate 15 but does not provide access to the freeway. Lake Mead Boulevard is another important east-west road south of NLVF. It is a four-lane roadway from its interchange with Interstate 15 west to H Street. Interstate 15 is a four-lane limited access interstate freeway oriented north-south through the area. In the vicinity of the project, access is provided to Interstate 15 at interchanges with Lake Mead Boulevard and Cheyenne Avenue. Commerce Street is a two-lane street running north-south along the western edge of NLVF. It begins at Cheyenne Avenue and terminates just north of Lake Mead Boulevard. Another short portion acts as a continuation of Losee Road south of Lake Mead Boulevard for a few blocks. Brooks Avenue is a minor two-lane street running east-west between Losee Road and Martin Luther King Boulevard north of the site (Omni-Means 1990). Table I.4.4.1.6.4–1 provides 1990 levels of service for roads around NLVF.

Road improvements within the NLVF vicinity include repaving of Carey Avenue, resurfacing of Cheyenne Street, and future improvements of the Interstate 15 and Cheyenne Avenue interchange. The major transportation project in the region is the "spaghetti bowl" expansion at the Interstate 15 and U.S. 95 interchange. The first phase of this project is scheduled to begin within the next 12 months (Burke 1995).

The primary railroad in the region is the Union Pacific Railroad, which is located approximately 1.6 km (1 mi) east of NLVF. McCarran International Airport in the city of Las Vegas provides jet passenger service from both national and local carriers.

I.4.4.1.6.5 *Environmental Justice*

Environmental justice concerns the potential for high and adverse environmental or human health impacts to disproportionately affect minority or low-income populations. In this PSA, environmental justice is evaluated for impacts within the site region, defined as the area within an 80-km (50-mi) radius around the site, and for the local area. Lazaro et al. (1996) presents the demographic analysis of minority and low-income population distributions on a regional and local basis.

In the NLVF site region in 1990, 10 percent of the population was low income and 25 percent was minority. These values represent an equal percentage of low-income and a higher percentage of minority persons than the Nevada state average (10 percent low income and 21 percent minority). Within the area, census tracts closer to the NLVF site tend to have significantly higher proportions of minority, but not low-income, populations than tracts farther from the site.

TABLE I.4.4.1.6.4–1.—*Baseline Traffic on North Las Vegas Facility Access Roads*

Route	From	To	Estimated 1995 AADT	Estimated 1995 LOS
Carey Ave	300 ft east of M.L. King Blvd	NA	7,730	A

I.4.4.1.7 Radiation and Hazardous Chemicals

I.4.4.1.7.1 *Radiation Environment*

NLVF provides calibration services using specialized radiation fields for a variety of instrument test packages in support of DOE Nevada Operations. A detailed discussion of the radiation environment, including background, radiological releases, and doses to members of the public, is presented in *U.S. Department of Energy Nevada Operations Office Annual Site Environment Report–1993, Volume 1* (1994). The concentrations of radioactivity in various environmental media (air, water, soil) in the site region are also presented in this reference.

Calculated radiological doses were used to estimate the potential health impacts to the public and onsite workers at NLVF from any releases of radioactivity. The annual doses to the workers are summarized in table I.4.4.1.7.1–1; corresponding health risks are also presented in the table (also see Lazaro et al. 1996). These doses are in addition to those from natural background, consumer products, and medical sources, which total about 360 mrem/yr. The onsite worker doses are within regulatory limits. Background radiation doses are unrelated to NLVF operations. Regulatory limits that specify the maximum effective dose equivalent to individual members of the public and occupational workers are also presented in table I.4.4.1.7.1–1.

I.4.4.1.7.2 *Hazardous Chemical Environment*

The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through contact or via the food pathway). Exposure pathways to NLVF workers during normal operation may include inhaling the workplace atmosphere, drinking NLVF potable water, and possible other contact with hazardous materials associated with work assignments. The potential for health impacts varies from facility to facility and from worker to worker, and available information is not sufficient to allow a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls. NLVF workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded. The maximum daily quantities of NIF-related hazardous materials stored at NLVF are presented in table I.4.4.1.7.2–1. NLVF stores and uses few hazardous materials in amounts greater than the threshold planning quantities that require reporting under the Federal regulations at 40 CFR 370–Hazardous Chemical Reporting: Community Right-to-Know (DOE 1995h).

TABLE I.4.4.1.7.2–1.—*Maximum Daily Quantities of National Ignition Facility-Related Hazardous Materials Stored at North Las Vegas Facility*

Hazardous Material	Quantity
Acetone	37.8 L
Alumina	2,063 kg
Ammonia	275 kg
Ammonium hydroxide	37.84 L
Boron	20 kg
Copper	<4.5 kg
Ethanol	1,514 L
Hydrofluoric acid	208 L
Lead	<5.6 kg
Mercury	6,333 kg
Methylene chloride	18.9 L
Stainless steel	<1.1 kg
Tetraethylorthosilicate	378.4 L

Source: Lazaroff 1995b.

I.4.4.1.8 Waste Management

The current waste management practices at NLVF are outlined in table I.4.4.1.8–1. Wastes managed at NLVF from research activities include hazardous and nonhazardous wastes. The NIF project is expected to generate low-level, mixed, hazardous, and nonhazardous wastes during operation.

TABLE I.4.4.1.7.1–1.—***Annual Radiation Doses to the General Public and Onsite Workers from Normal Operations at North Las Vegas Facility***

Receptor	Atmospheric Releases: Regulatory Limit[a]	Atmospheric Releases: Calculated	Liquid Releases: Regulatory Limit[a]	Liquid Releases: Calculated[b]	Total: Regulatory Limit[a]	Total: Calculated	Total: Risk[c]
Individual Dose							
Average exposed individual (mrem)	10	0.0[d]	4	0.0	100	0.0	0.0
Maximally exposed individual (mrem)	10	0.0[d]	4	0.0	100	0.0	0.0
Population Dose							
Population within 80 km (person-rem)	e	0.0[d]	e	0.0	e	0.0	0.0
Worker Dose[f]							
Average worker (mrem)	NA	NA	NA	NA	5,000	82	3.3×10^{-5}
Maximally exposed worker (mrem)	NA	NA	NA	NA	5,000	440	1.8×10^{-4}
Total workers (person-rem)[g]	NA	NA	NA	NA	None	0.57	2.3×10^{-4}

[a] The regulatory limits for individuals are given in DOE Order 5400.5. The 10 mrem/yr limit from airborne emissions is required by the *Clean Air Act*; the 4 mrem/yr limit is required by the *Safe Drinking Water Act*, and the total dose of 100 mrem/yr is the limit from all pathways combined. The occupational limit for workers is 5,000 mrem (10 CFR 835)

[b] The calculated dose values given in the column under Liquid Releases conservatively includes all water pathways, not just the drinking water pathway.

[c] Based on latent fatal cancer risk factors of 5×10^{-7}/mrem for individuals, 5×10^{-4} /person-rem for population, and 4×10^{-7}/mrem for workers (ICRP 1991).

[d] Two very small atmospheric releases occurred on July 12 and August 14, 1995. The dose to any offsite individual is expected to be a fraction of a mrem (monitoring data is not yet available from all stations).

[e] No regulatory limits exist for population doses; however, a 100 person-rem value for the population is found in the proposed 10 CFR 834 (58 FR 16268).

[f] Worker doses were estimated on the basis of readings from monitoring devices called thermoluminescent dosimeters.

[g] The number of badged workers in 1994 was approximately seven.

Note: NA - not applicable.

Source: White 1995g.

I.4.4.1.8.1 *Hazardous Waste*

NLVF generated about 17,920 kg (39,500 lb) of hazardous wastes in 1992. All hazardous wastes are treated, stored, or disposed of offsite at EPA-permitted facilities. Spills or releases of hazardous materials have historically been minor and were promptly cleaned up upon discovery.

A Waste Minimization and Pollution Prevention Awareness Implementation Plan submitted to DOE/NV on December 20, 1991, is in place for NLVF. A formalized system of waste minimization was developed through the implementation of EG&G/EM Policy No. 31-70, *Waste Minimization and Pollution Prevention;* and Standard Operating Procedure 31-006.A, *Hazardous Waste Minimization Plan*. Hazardous waste generation from various processes has already been reduced through product substitution or by permanently discontinuing the hazardous waste generating process.

There are no underground storage tanks for hazardous or petroleum substances at NLVF. All aboveground tanks are protected against accidental releases by use of either secondary containment or a double-walled tank with continuous leak detection. There are no hazardous waste treatment, storage, or disposal facilities requiring state or Federal permits at NLVF (DOE 1995h).

TABLE I.4.4.1.8–1.—*Current Waste Management at North Las Vegas Facility*

I.4.4.1.8.2 *Nonhazardous Waste*

Policies and procedures are in place at NLVF that promote recycling and resource recovery. In 1992, a total of 9 t (9.9 tons) of office paper, 227 t (250 tons) of scrap metals, and 425 laser printer cartridges from NLVF were recycled.

Physical and administrative measures implemented at NLVF minimize or prevent the introduction of pollutants into stormwater. Stormwater from the NLVF site is discharged by concentrated conveyance or sheet flow onto Losee Road. Industrial wastewater and sanitary sewage from NLVF are discharged into city of North Las Vegas sewer lines, which are connected to the city of Las Vegas publicly owned treatment works. The publicly owned treatment works discharges treated wastewater directly into Lake Mead under an NPDES permit issued by the Nevada Division of Environmental Protection. NLVF discharges an average of 147,303 L (38,888 gal) of wastewater per day into the publicly owned treatment works, with a peak maximum of 369,318 L (97,000 gal) of wastewater per day. Approximately 32 to 35 percent of the wastewater originates from industrial processes; the remaining 65 percent is predominantly sanitary wastes. Wastewater quality historically has been in compliance with permit conditions established by the city of North Las Vegas to protect the publicly owned treatment works treatment processes and ultimately the water quality in Lake Mead (DOE 1995h).

I.4.4.2 *Environmental Impacts*

The following sections describe the potential environmental impacts for land use and visual resources, air quality and noise, water resources, ecological resources, cultural and paleontological resources, and socioeconomics for constructing and operating NIF at NLVF. In addition, impacts associated with radiation, hazardous chemicals, and waste management are described.

I.4.4.2.1 Land Use and Visual Resources

I.4.4.2.1.1 *Land Use*

Other than temporary impacts associated with construction activities, the principal impact of NIF on land use at NLVF would be the conversion of limited open space. NLVF occupies 32 ha (80 acres) (figure I.3.4.4.1–2), and although NIF (including the temporary construction laydown area) would only require about 3.2 ha (8 acres) of open space, that area represents approximately 10 percent of NLVF's total land area and 56 percent of NLVF's developable land (Lazaroff 1995c). However, the impact of this conversion would be reduced somewhat by the existence of other areas on the site (F-4, F-5, F-6) that remain open for future development. Potential onsite impacts to land use could also result from required waste and water system upgrades, but the presence of NIF should not preclude future land uses or development in the city of North Las Vegas or Clark County.

With appropriate erosion and sediment control measures, soil impacts during construction of NIF would be short term and minor. Seismic risks would be taken into account during construction and operation of NIF.

I.4.4.2.1.2 *Visual Resources*

With the exception of short-term minor impacts associated with construction (fugitive dust, equipment exhaust, etc.), NIF-related impacts to visual resources in and around NLVF would be limited to an intrusion on the visual landscape by the Laser and Target Area Building. The structure would exceed 37 m (120 ft) in height and would be visible above the horizon to most viewers in the residential areas located just beyond the western and southeastern boundaries of NLVF. However, visual impacts would be negligible because of a general lack of competing or unique visual landscape features for the residential area viewers. For onsite viewers, NIF would be located in an area that is characterized by industrial-type structure forms, little or no variety in vegetation, and virtually no visual diversity.

I.4.4.2.2 Air Quality and Acoustics

I.4.4.2.2.1 *Air Quality*

Construction Emissions. Estimated construction emissions of air pollutants, including those from site clearing and those associated with facility construction, are listed in table I.4.4.2.2.1–1. These emission estimates are based on characteristics of the proposed NLVF location and on projected construction vehicle exhaust and fugitive emissions. Site clearing would occur for about two weeks, followed by facility construction for four years (LLNL 1995b).

The site-clearing phase of construction would produce the greatest amount of fugitive dust PM_{10} emissions of the construction process. The ISCST2, Version 93109 (EPA 1992a-b) was used to determine the impact of site-clearing activities on ambient air quality (see section I.4.1.2.2.1). The data selected for modeling air quality were surface meteorological data from nearby Las Vegas McCarran International Airport and twice-daily mixing height data from the Desert Rock National Weather Service Station for 1987-91 (EPA 1995b). The surface wind speeds and directions are summarized in an annual wind rose (see figure I.4.4.1.2.1–1). Detailed emission inventories associated with site clearing and facility construction, meteorological data used, air quality model assumptions, and model input parameters are presented in Lazaro et al. (1996).

The 24-hour average PM_{10} background concentration representative of the NLVF site is 114 $\mu g/m^3$, which is very close to the national and state standard of 150 $\mu g/m^3$ (table I.4.4.1.2.2–1). This condition is due to arid soil conditions typical of the region. Accordingly, site clearing should be carried out so as to minimize impact on ambient air quality.

With conventional dust control (such as 50 percent control for excavation and 60 percent control for traffic on unpaved roads), maximum 24-hour average PM_{10} concentrations of 156 $\mu g/m^3$ over background are predicted at the site boundary (10 m [32 ft] north of the proposed NIF location). These levels would be above the NAAQS and State Ambient Air Quality Standard for PM_{10}, resulting in significant short-term impacts to air quality at the site boundary during the two weeks of site clearing. Operation with additional dust-control measures that involve continuous water spraying or use of a chemical dust suppressant would reduce dust emissions from excavation by 75 percent and from traffic on unpaved roads by 90 percent. These measures would bring maximum 24-hour average concentrations down to 69 μg/m^3 over background concentration. A maximum concentration of 183 μg/m^3, including background concentration, would still be higher than the national and state standards for PM_{10}. Thus, other approaches (such as reduction of activity or use of intensified dust control measures) should be implemented to comply with the national and state standards for PM_{10}. For example, by reducing the workload by half (which would increase the site-clearing period to one month), the maximum PM_{10} concentration over background is predicted to be 35 μg/m^3. Including background concentration, the cumulative concentration would be 149 μg/m^3, which would comply with the NAAQS for PM_{10}. Site clearing at NLVF would be expected to last for less than one month, so air quality impacts associated with site clearing would be local and temporary, assuming that proper mitigation measures were employed.

TABLE I.4.4.2.2.1–1.—*Estimated National Ignition Facility Construction Emissions for the North Las Vegas Facility Location*

Pollutant	Total Emissions (t/yr)[a]
Particulate matter 10 microns or smaller	6.89[b]
Volatile organic compound	0.44
Carbon monoxide	1.23
Nitrogen dioxide	3.76
Sulfur dioxide	0.43
Lead	Negligible

[a] Metric tons (1,000 kg) per year.

[b] Includes 1.91 t/yr (2.11 ton/yr) of fugitive emissions for site clearing using water-spray control that would occur during an approximate 13-day period in the first year and 4.63 t/yr (5.10 ton/yr) of facility construction emissions that would occur for the remainder of the first year of construction.

Source: Lazaro et al. 1996.

Emissions During Operations. Sources of air pollutant emissions from operation of NIF at NLVF are expected to be primarily fuel combustion and cleaning of the debris shields. Emissions of VOCs (ethanol) from debris shield cleaning are estimated to total about 0.5 t/yr (0.55 ton/yr) (LLNL 1995b). Other potential air pollutant emission sources not considered significant are target destruction under either the direct drive or indirect drive options, emissions from vehicles used for freight shipments and employee commuting, and emissions from welding operations at the Fabrication Facility.

As indicated in table I.4.4.2.2.1–2, air pollutant emissions due to NIF operation are projected to be well below 1 t/yr (1.1 ton/yr) except for nitrogen dioxide, which is projected at approximately 2 t/yr (2.2 ton/yr). Estimated air pollutant emissions from NIF operations would constitute significant increases over 1990 emission levels, ranging from an increase of 27 percent for PM_{10} to 241 percent for carbon monoxide. However, existing ambient concentrations for these pollutants (see section I.4.4.1.2.2, table I.4.4.1.2.2–1) are well below the ambient air quality standards, and it can be concluded that NIF operation would have no adverse impact on air quality and would not contribute to a violation of the ambient air quality standards.

Table I.4.4.2.2.1–2 includes the estimated NLVF annual air pollutant emissions based on the anticipated NIF annual energy requirements provided in table I.4.1.2.2.1–3, adjusted to recognize that at NLVF, only four new support buildings (total area of 13,006 m^2 [140,000 ft^2]) would be required out of the total complement of support buildings (area of 26,722 m^2 [287,643 ft^2]).

Published emission factors (EPA 1995b) were used in the calculations. Emissions of VOCs resulting from shield cleaning with solvents are included. For comparative purposes, table I.4.4.2.2.1–2 also includes NLVF 1990 sitewide emissions. More detailed information on emission estimates is provided in Lazaro et al. (1996).

NLVF must comply with the Clark County Air Pollution Control regulations (APCR) (DBHCC 1995). Abatement of visible fugitive dust emissions would be required for construction activities at NLVF. Construction activities specifically addressed include general site; haul roads; and material handling, storage, and transport (APCR, section 41).

External combustion units (boilers) would have to comply with BACT for carbon monoxide and nitrogen oxide for nonmajor sources (APCR, sec-

TABLE I.4.4.2.2.1-2.—***Annual Emission Increases with National Ignition Facility Operation at North Las Vegas Facility***

Pollutant	1990 Emissions (t/yr)	Projected NIF Emissions[a] (t/yr)	1990 Emissions Plus NIF (t/yr)	NIF Percent of 1990 Emissions
Particulate matter	0.78	0.21	0.99	27
Volatile organic compound	3.45	0.57	4.02	17
Carbon monoxide	0.23	0.56	0.79	241
Nitrogen oxide	1.07	2.28	3.35	213
Sulfur dioxide	0.07	0.04	0.11	50
Lead	Negligible	Negligible	Negligible	Negligible

Source: DOE 1995h; EPA 1993.

tions 12.2.10.1, 12.2.11.1). In addition, emission offset credits might be required at more than twice the potential to emit for these boiler emissions (APCR, section 12.2.11.4). Gas-fired boilers with rated heat input greater than 105,600 MJ/hr (100 million Btu/hr) but not over 264,000 MJ/hr (250 million Btu/hr) are limited to NSPS nitrogen oxide emissions from 43 to 86 ng/J, depending on the heat release rate, which is a function of the furnace volume (40 CFR 60.44b). There are no NSPS emission limits for gas-fired boilers with a rated heat input at or less than 105,600 MJ/hr (40 CFR 60.40c).

Emissions of VOCs at the stated annual rate of 0.5 t/yr (0.55 ton/yr) might require additional controls, depending on the type of solvent used (APCR, section 60.1.1). Additional regulatory information is presented in section I.5.2.

I.4.4.2.2.2 *Acoustics*

During the clearing phase of NIF construction at NLVF, equipment noise would cause an increase of 8 dB in the average outdoor sound level at the nearest residence, which is in a neighborhood on the western side of Commerce Avenue, west of the site. Because of traffic noise from the street that runs along the east side of this residential area, the average daytime sound level is already high, thus reducing the effect of the added noise.

The point modeled was 210 m (690 ft) west of the facility. The results show that the average sound level at this point is expected to increase from 66 dBA to 74 dBA during hours that the clearing equipment is operating. The CNR rank, adjusted for the estimated preexisting background level, is expected to be "A." (Noise with CNR ranks "A" through "D" is generally considered to be acceptable, with "A" essentially leading to no impacts.) At the level of "D," the Modified CNR method predicts sporadic complaints from the public. The likelihood of such complaints can be lessened if the public is notified in advance that the noise will occur only over a period of approximately a month and only during daylight hours.

Because the residential area is so close to the construction area, the average daytime sound level would vary with changes in the locations of the various pieces of construction equipment as they moved about in the course of site clearing.

To illustrate the effect of equipment movement, a second point, also at the edge of the residential area, was modeled. This second point was 134 m (440 ft) south of the first residential point and immediately across Commerce Avenue from the construction site. The results showed that the average outdoor daytime sound level is expected to increase 17 dB, from 66 dBA to 83 dBA, for the same deployment of equipment. The adjusted CNR rank for this level is "C," which is not expected to elicit more than sporadic complaints.

The average outdoor daytime sound level at the nearest laboratory building at NLVF is expected to increase by 10 dB, from 60 dBA to 70 dBA. The adjusted CNR rank for the resulting sound is "A." This level would occur outside the laboratory buildings; unless windows and doors were open, the increase in sound level would not be expected to interfere with any activities that were not sensitive to sound at the level of normal speech. These are estimates based on the assumptions given in Lazaro et al. (1996).

I.4.4.2.3 Water Resources

Construction of NIF at NLVF would be expected to have minor to negligible effects on water quality in the area. Current water and wastewater utility capacities would be adequate to meet the additional requirements for NIF.

About 2.95 MLY (0.78 MGY) of water would be required for construction (LLNL 1995b). Water and wastewater utility requirements for NIF operations at NLVF are shown in table I.4.4.2.3–1. The total raw water supply required for NIF operation would be about 152 MLY (40 MGY), of which 18.0 MLY (4.7 MGY) would be for domestic use. This water requirement for NIF operation would be equivalent to an increase of 220 percent over the current NLVF usage of 69.4 MLY (18.3 MGY) (DOE 1995h; Lazaroff 1995a). The NIF sanitary wastewater volume is estimated to be 18.0 MLY (4.7 MGY). Water supply and sanitary wastewater treatment are provided by the city of North Las Vegas (DOE 1994b). Current water and wastewater utility capacity would be adequate to meet the additional requirement for NIF.

The proposed NIF location at NLVF has minimal flooding potential because it is outside the 500-year floodplain of the local drainage (FEMA 1983).

I.4.4.2.4 Biotic Resources

I.4.4.2.4.1 *Terrestrial Resources*

An environmental assessment (DOE 1995h) conducted for the Nevada Support Facility (that would be located in the same general area proposed for NIF at NLVF) concluded that no significant impacts to ecological resources would occur from construction and operation of that facility. That conclusion would also be applicable to NIF if it should be located at NLVF.

The general types of impacts that could result from NIF construction at NLVF would be similar to those discussed for LLNL (section I.4.1.2.4). Construction of NIF (including the temporary construction laydown area) at NLVF would occur within a 3.2-ha (7.9-acre) area of disturbed soil with scattered grasses and forbs that occurs within the 4.5 ha (11 acres) of undeveloped land at the western end of NLVF. This area is of negligible value to wildlife. Landscaping around the new NIF buildings could add a minor amount of lawn with scattered shrubs and trees that could provide habitat for wildlife species adapted to suburban or industrial conditions.

I.4.4.2.4.2 *Wetlands and Aquatic Resources*

The proposed NIF location at NLVF does not contain, nor is it located near, wetlands or surface water resources. Therefore, construction and operation of NIF at NLVF would not be expected to adversely affect such resources.

I.4.4.2.4.3 *Rare, Threatened, and Endangered Species*

Although NLVF is located within the range of the desert tortoise (federally threatened), it is not

TABLE I.4.4.2.3–1.—*Water and Wastewater Utility Capacity at North Las Vegas Facility*

Utility System	Current Usage	NIF Requirement	Projected Usage, Including NIF	Current Capacity
Water supply (MLY)	69.4	152	221	2,993
Wastewater treatment (MLY)	54.8	17.9	73	402

Source: DOE 1995h; Lazaroff 1995a.

expected that tortoises would exist at the proposed location for NIF. That location is within a fenced area and does not contain adequate cover habitat required for tortoises. Therefore, no impacts to desert tortoises would be expected at NLVF. Impacts to other listed species would not be expected because NLVF does not contain suitable habitat for listed species whose ranges encompass the facility.

I.4.4.2.5 Cultural and Paleontological Resources

Construction and operation of the proposed NIF would have no effect on archaeological sites or historic structures that are listed on or eligible for NRHP, important paleontological remains, or Native American cultural resources.

I.4.4.2.6 Socioeconomics

Construction and operation of NIF at NLVF would have a minor impact on socioeconomic conditions in the economic study region and in the ROI described in section I.4.4.1.6, because NLVF would be located in a somewhat diverse regional economy with extensive inter- and intraregional, national, and global economic interactions and linkages. None of the average annual increases in any of the socioeconomic variables would constitute a major difference from the region-specific base line average annual increases. Also, because the NIF partnership includes representatives from government, industry, and the academic sector throughout the United States, NIF-related procurement and investment would be dispersed over a number of different regions, dampening the concentration of economic effects of the program.

The following sections describe the effects on the host region's economy and employment, and on population, housing, public finances, public services infrastructure, and local transportation in the ROI.

I.4.4.2.6.1 *Regional Economic Impacts*

Slight changes in employment and economic activity levels in the economic study region would occur from local spending of employee wages, procurement of goods and services (including construction materials), and other local investment associated with constructing and operating NIF. In addition to creating new jobs (direct) at the site, the project would create indirect job opportunities, such as community support services, in the economic study area. The total new jobs created (direct and indirect) would contribute to unemployment reduction and increased income and economic output in the regional economy during construction and operation of NIF. Table I.4.4.2.6.1–1 presents the potential impacts to the regional economy if NIF were located at NLVF.

Constructing NIF at NLVF would result in a peak of approximately 280 direct jobs in 1998. This construction-related procurement would indirectly create nearly 1,360 jobs in the economic study region. Employment for operation would begin phasing in as construction neared completion. Direct employment related to operations is projected at 330, with more than 290 indirect jobs created throughout the economic study region. As a result of constructing and operating NIF, the baseline compounded annual growth rate from 1995 to 2003 would increase by 0.01 percentage points.

Peak earnings associated with the 280 direct jobs created in 1998 are projected at approximately 16.7 million dollars. Construction-related procurement would indirectly create more than 27 million dollars in regional earnings.

I.4.4.2.6.2 *Population and Housing*

Construction. Population in-migration resulting from NIF construction phase demands would peak in 1998, with a projected cumulative total of 2,340 people moving into the ROI (table I.4.4.2.6.1–1). This population increase would result in demand for an additional 850 housing units in the ROI. Baseline projections of the NLVF ROI housing market from 1996 (NIF construction start date) through 1998 indicate that nearly 43,000 housing units would be available. It has been estimated that more than 50,000 vacant housing units would be available in the ROI in 1998 and 1999. The NIF-related demand for approximately 850 housing units in the ROI would absorb approximately 2 percent of the available housing stock in the ROI. The NIF project would generate little demand for new housing construction because of the number of vacant housing units within the ROI and the proximity of NLVF to Las Vegas. Most of the housing demand would be temporary and would primarily affect the renter segment of the ROI housing market.

TABLE I.4.4.2.6.1–1.—*Potential Socioeconomic Impacts in the North Las Vegas Facility Area*

Parameters	NIF Alternative Change Over Reference Baseline		Reference Baseline	
	Peak Construction 1998[a]	Operations 2003[b]	1996 to 2002[a]	2003[b]
Regional Employment				
Direct jobs	280	330		
Indirect jobs	1,360	290		
Total jobs	1,640	620	14,600 jobs projected annually	12,900 additional jobs
Regional Aggregate Earnings[c]				
Direct earnings	16.19	13.81		
Indirect earnings	27.22	6.29		
Total earnings	43.41	20.10		
Regional Population Migration				
ROI in-migrating population	2,340	440		13,300 additional people
Regional Housing Demand				
Number of housing units in the ROI	850	160	44,000 vacant housing units (annual average)	50,000 vacant housing units
Local Transportation				
Number of trips generated at site per day	538	630		
Public Finance	0.21	0.04	NA[d]	NA
Percent change over 1995 fund balance (Clark County)				
Public Services (LOS)				
Change in service demand				
Police[e]	9	1	1,436[d]	7,839
Fire[e]	2	0	379[d]	909
General[e]	15	2	2,240[d]	2,349
Physicians[f]	3	1	1,455[d]	2,096
Teachers[f]	18	3	9,530[d]	13,725

[a] Construction period would be 1996 to 2002, with peak construction projected to occur in 1998.
[b] Operating period would be 2003 to 2033, with impacts throughout the period projected to remain stable.
[c] Regional earnings are millions of constant 1994 dollars.
[d] Projected 1998 fund balance for Public Finance, and projected 1998 level of service (LOS) for Public Services.
[e] Las Vegas.
[f] Clark County.
Source: Model results.

Operations. Population in-migration resulting from NIF operation phase demands could result in an additional 440 people moving into the ROI. While this demand for housing would be longer term relative to construction, no perceptible strain on the market is expected, assuming that the general conditions associated with the housing market continue.

I.4.4.2.6.3 *Public Finance*

Construction. Given the anticipated population and economic growth associated with NIF during the construction phase, fiscal balances (revenues and expenditures) are expected to increase for all jurisdictions within the ROI. Short-term public finance impacts would peak during 1998 and would then decline as construction neared completion in 2002. Since the largest percentage socioeconomic impacts are expected to occur in Clark County (assuming current residential patterns), the county would experience the greatest fiscal impacts in the ROI (table I.4.4.2.6.1–1).

Operations. The increase in population and economic growth as a result of NIF operations would increase both revenues and expenditures for all counties within the ROI, with the greatest impact in Clark County. Fiscal impacts would remain stable from the initial impact in 2003 through the duration of NIF operations.

I.4.4.2.6.4 *Public Services*

By the year 1998, Clark County would need to hire nine additional police officers, and Nye County would need 18 additional teachers and 3 additional doctors to maintain its current level of service. By 2003, when operations would start, Nye County would need only 3 additional teachers and 1 additional doctor over the baseline conditions to maintain the current level of service.

I.4.4.2.6.5 *Local Transportation*

In 1995, NLVF employed approximately 1,000 persons. Direct employment generated by the NIF project at NLVF for the life cycle of the project (1996-2033) would range from a minimum of 21 new jobs in 1996 to a maximum of 280 new jobs in 1998. Peak direct employment would total approximately 280 workers in 1998. These direct jobs would generate additional trips on NLVF access roads (table I.4.4.2.6.5–1); however, these additional trips should not significantly increase congestion to the NLVF transportation network (table I.4.4.2.6.5–1).

A peak of nearly 1,360 indirect jobs in 1999 could be generated within the ROI if NIF were located at NLVF. It is likely that the major share of these jobs would be located within Clark County. The road network associated with Clark County and the city of Las Vegas is well developed and expanding, and it would be capable of handling the additional trips generated from the operation of NIF. Because the indirect jobs would be dispersed across Clark County, adverse impacts to the regional transportation network are unlikely.

I.4.4.2.6.6 *Environmental Justice*

For the population in the region within 80 km (50 mi) of NLVF, minorities are in a higher proportion and low-income populations are in an equal proportion to other populations relative to Nevada as a whole (section I.4.4.1.6.5). Thus, minorities—but not low-income populations—could experience disproportionate regional socioeconomic impacts, which would be beneficial. The regional health impact of radiological doses to the population over the lifetime of NIF might result in one cancer fatality. This impact would occur to the population within the region, which is disproportionately minority. Thus, an environmental justice issue exists with the construction and operation of NIF at this site.

Minorities, but not low-income persons, are clustered disproportionately in the local vicinity of the NLVF site (section I.4.4.1.6.5). Thus, the local area impacts from the construction and operation of NIF could disproportionately affect minorities but not low-income populations. None of these local area environmental or health impacts have been judged to be highly adverse or significant.

I.4.4.2.7 Radiation and Hazardous Chemicals

This section describes potential radiological and hazardous chemical impacts resulting from normal operations and postulated accidents at NIF at NLVF. Methods, data, and assumptions used in estimating impacts are presented in Lazaro et al. (1996).

I.4.4.2.7.1 *Normal Operations*

The general public around NLVF and workers at NLVF might be exposed to small quantities of radionuclides released and radiation emitted from routine NIF operations; however, the expected level of radioactive releases and radiation emissions is well within regulatory limits. No impacts from hazardous chemicals should occur because only minute quantities of hazardous VOCs are expected to be emitted during routine NIF operations. Impacts from routine transportation of tritium targets are also not expected because there would be no detectable levels of radiation outside the packages carrying the low-energy, beta-emitting tritium targets. Table I.4.4.2.7.1–1 summarizes the potential impacts of radiation exposures from the Conceptual Design Option and the Enhanced Option for NIF operations at NLVF.

Impacts to the Public. For the Enhanced Option, the radiation dose to a maximally exposed member of the public located about 210 m (689 ft) west of NIF is estimated to be 0.6 mrem/yr, which is much less than the dose limit of 100 mrem/yr resulting from all pathways combined (DOE 1990). The likelihood of the maximally exposed individual contracting a fatal cancer is 1 in 130,000 for the entire operational life of NIF (dose/yr x 30 yr x fatal cancer risk factor of $5x10^{-4}$/rem). The radiation dose to the surrounding public is estimated at 0.6 person-rem/yr; no cancer fatalities would be expected to occur in the public for the entire NIF operations at NLVF. For the Conceptual Design Option, it is estimated that radiation impacts would be one-third the impacts of the Enhanced Option. No adverse health effects would result.

Impacts to Workers. In addition to the potential for their exposure to radionuclides, the general NLVF workers outside NIF could be exposed to direct radiation resulting from high-yield experiments at NIF. For the Enhanced Option, the estimated radiation dose to these non-NIF workers at NLVF is 0.07 person-rem/yr. No cancer fatalities would be expected to occur among workers for the entire NIF operations at NLVF. For the Conceptual Design Option, estimated radiation impacts are about one-third of those of the Enhanced Option, and the risk of adverse health effects would be extremely low.

TABLE I.4.4.2.7.1–1.—*Potential Radiological Impacts from Normal Operations of the National Ignition Facility at North Las Vegas Facility*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (mrem/yr)	0.2	0.6
Percent of natural background	0.06	0.2
30-year fatal cancer probability	$2x10^{-6}$	$8x10^{-6}$
Population Within 80 Km		
Dose (person-rem/yr)	0.2	0.6
Percent of natural background	$7x10^{-5}$	$2x10^{-4}$
30-year fatal cancers	0	0
Workers Onsite		
Dose (person-rem/yr)		
Non-NIF workers	0.02	0.07
NIF workers	10	10
30-year fatal cancers	0	0

Source: Model results.

Potential radiation exposures inside NIF would be kept as low as reasonably achievable through facility design and administrative controls. The design objective of NIF is to keep the individual radiation worker dose to less than 500 mrem/yr. It is estimated that on average, a NIF worker would receive approximately 30 mrem/yr. No adverse health effects are anticipated to workers inside NIF at this exposure level.

I.4.4.2.7.2 *Postulated Accidents*

Radionuclides and hazardous chemicals could be released from accidents at NIF and during the transportation of tritium targets. Tables I.4.4.2.7.2–1 and I.4.4.2.7.2–2 summarize potential impacts to the public and workers from postulated facility and transportation accidents. A description of each accident scenario evaluated is provided in Lazaro et al. (1996).

TABLE I.4.4.2.7.2–1.—*Potential Radiological Impacts from Postulated Bounding Accident Involving the National Ignition Facility at North Las Vegas Facility*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (rem)	6	10
Fatal cancer probability	$3x10^{-3}$	$5x10^{-3}$
Risk (cancer fatalities/yr)	$6x10^{-11}$	$1x10^{-10}$
Population Within 80 Km		
Dose (person-rem)	3,000	4,900
Fatal cancers	1	2
Risk (cancer fatalities/yr)	$3x10^{-8}$	$5x10^{-8}$
Workers Onsite		
Dose (person-rem)	30	50
Fatal cancers	0	0
Risk (cancer fatalities/yr)	$2x10^{-10}$	$4x10^{-10}$

Source: Model results.

Radiological Impacts

Impacts to the Public. The public could be exposed to radionuclides released from a postulated accident at NIF. The bounding accident assumes that an earthquake would occur at the time of a maximum-yield experiment, with an accidental release frequency of $2x10^{-8}$/yr. For the Enhanced Option, the estimated radiation dose to the maximally exposed member of the public is 10 rem. The likelihood of the maximally exposed individual contracting a fatal cancer from this exposure would be 1 in 200. The estimated radiation dose to the surrounding public from the postulated accident is 4,900 person-rem. At this dose level, two cancer fatalities would be expected to occur in the public.

However, as indicated in table I.4.4.2.7.2–1, the actual risk of radiation-caused cancer fatalities from the postulated accident is essentially zero when the extremely low frequency of the accident occurring during NIF operations is taken into account. The risk is the product of the estimated radiation dose, fatal cancer factor of $5x10^{-4}$/rem, and accident release frequency of $2x10^{-8}$/yr. For the Conceptual Design Option, it is estimated that radiation impacts would be about half the impacts from the Enhanced Option. One cancer fatality would be expected to result within the surrounding population if the accident did occur.

Impacts to Workers. For the Enhanced Option, the estimated radiation dose to all workers at NLVF is 50 person-rem from the postulated accident. No cancer fatalities would be expected to occur among workers following the accident. For the Conceptual Design Option, the estimated radiation impacts are about half the impacts from the Enhanced Option. No adverse health effects would be expected. The risk of radiation-caused cancer fatalities would essentially be zero, considering the extremely low potential for the postulated accident to occur. NLVF has a comprehensive emergency plan, which would be expanded to incorporate NIF to ensure protection of workers in case of an accident or natural disaster.

Transportation Impacts. Radiological impacts associated with the transportation of tritium targets would result from a release of tritium into the environment following a transportation accident. Since tritium is a pure beta emitter with no associated gamma radiation, radiological risks associated with routine (incident-free) transportation operations would be considered negligible. The potential radiological impacts of transporting tritium targets were calculated for truck and air travel. The targets were assumed to be transported by truck from the manufacturing sites to the nearest major airport and then by cargo aircraft to McCarran International Airport in Las Vegas. It was further assumed that after arriving at the Las Vegas airport, the targets would be transferred to a truck for shipment to NLVF.

Table I.4.4.2.7.2–2 summarizes the risks associated with the transportation of tritium targets from each of the tritium manufacturing facilities to NIF at NLVF. Radiological risk from transportation activities is defined as the product of the accident consequence (dose) and the probability of the accident occurring, and was calculated by considering a wide range of accidents, from high-probability, low-consequence events to low-probability, high-consequence events (see ANL 1995). Latent cancer fatality risks were obtained by multiplying the dose risk by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Latent cancer fatality risks are estimated to range from $6x10^{-10}$ to $9x10^{-9}$ per year for all cases.

TABLE I.4.4.2.7.2–2.—*Potential Radiological Risks and Consequences of Transporting Tritium Targets from Manufacturing Facilities to North Las Vegas Facility*

Manufacturing Facility	Conceptual Design Option	Enhanced Option
General Atomics		
Dose risk (person-rem/yr)	1.2×10^{-6}	9.4×10^{-6}
Fatality risk (cancer fatalities/yr)	6×10^{-10}	5×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	8×10^{-4}	2×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	8×10^{-4}	2×10^{-3}
Lawrence Livermore National Laboratory		
Dose risk (person-rem/yr)	1.2×10^{-6}	9.3×10^{-6}
Fatality risk (cancer fatalities/yr)	6×10^{-10}	5×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	9×10^{-4}	2×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	4×10^{-4}	1×10^{-3}
Los Alamos		
Dose risk (person-rem/yr)	2.4×10^{-6}	1.9×10^{-5}
Fatality risk (cancer fatalities/yr)	1×10^{-9}	9×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	2×10^{-3}	5×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	5×10^{-4}
Savannah River		
Dose risk (person-rem/yr)	2.0×10^{-6}	1.6×10^{-5}
Fatality risk (cancer fatalities/yr)	1×10^{-9}	8×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	8×10^{-4}	2×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	5×10^{-4}
University of Rochester		
Dose risk (person-rem/yr)	2.1×10^{-6}	1.6×10^{-5}
Fatality risk (cancer fatalities/yr)	1×10^{-9}	8×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	6×10^{-4}	1×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	5×10^{-4}
Maximum Consequence Accident		
Population[b,c]		
Dose (person-rem)	0.33	3.3
Fatal cancers	2×10^{-4}	2×10^{-3}
Maximally Exposed Individual[b,d]		
Dose (rem)	1.2×10^{-4}	1.2×10^{-3}
Fatal cancer probability	6×10^{-8}	6×10^{-7}

[a] Collective population fatalities were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Option). For example, a reported value of 4×10^{-3} fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

[b] The most severe accidents assumed that 100 percent of the target tritium would be released in an oxide form during an accident. Accident consequence results were determined using the RISKIND computer program which is described in Yuan et al. 1993. Stable weather conditions (Pasquill Stability Class F) with a wind speed of 1 m/s (2.2 mph) were assumed.

[c] The maximum consequences would result from an accident occurring in an urban environment. The population was assumed to extend at a uniform density of 3,861 persons/km^2 (10,000 persons/mi^2) to a radius of 80 km (50 mi) from the accident site. The population exposure pathways for urban environments include inhalation and resuspended inhalation. Urban environments were not assumed to produce food for local use or export, hence no ingestion dose was included.

[d] The maximally exposed individual was assumed to be at the location of maximum exposure. The location of the maximally exposed individual was assumed to be 380 m (1,247 ft) from the accident under stable weather conditions. Individual exposure pathways included acute inhalation during passage of the plume. No ingestion dose was considered.

Note: The transportation risk assessment assumes 100 percent of the tritium targets would be manufactured and transported to NIF from each site. In practice, tritium targets would be produced and transported from more than one manufacturer. The transportation risk assessment was performed for offsite transportation only. Transportation risks from onsite transport of tritium targets were assumed to be negligible compared to risks from offsite transportation.

Source: Model results.

radiological population risks for routine operations were calculated by multiplying the distance traveled by truck in zones of urban population density by a risk factor for latent mortality from pollutant inhalation (Rao et al. 1982). Nonradiological population risks resulting from vehicular accidents were calculated in a similar manner by multiplying the state-specific accident fatality rate by the distance traveled by truck in the state.

The maximally exposed individual and population doses were calculated for a transportation accident involving the entire release of the tritium cargo (assumed to be five tritium targets). Radiological impacts resulting from a potential maximum-consequence accident were assessed for a general population in an urban population density zone. Maximally exposed individuals were assumed to be exposed unshielded as the plume passed at a distance resulting in the largest dose to the individual. Radiological consequences were assessed using worst-case weather conditions (Pasquill Stability Class F) for both the collective population and the maximally exposed individual. For assessment purposes, it was assumed that the entire tritium cargo was released to the environment in oxide form. The estimated number of latent cancer fatalities from the maximum-severity transportation accident was calculated by multiplying the population committed effective dose equivalent by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Table I.4.4.2.7.2–2 summarizes the impacts of a maximum-consequence accident during transportation of tritium targets.

Hazardous Chemical Impacts. A number of possible chemical accidents were studied in terms of their potential impacts on workers and the public outside the NLVF site boundaries (Lazaro et al. 1996). The four possible accidents likely to have the greatest impacts were studied in detail. The accidents considered (including an aircraft crash) and the four selected for more detailed study are discussed in Lazaro et al. (1996). The four accident scenarios considered in detail were as follows:

- A mercury release from the ignitron switches
- A combined alumina/silica release from the target chamber
- A carbonyl fluoride release from the optics treatment area
- A hydrogen fluoride release from the optics treatment area

The nearest site boundary (to a residential area) is 210 m (689 ft) west of the proposed NIF location. Potential impacts at that area and at the nearest onsite buildings are of principal interest.

A modeling study was conducted for each of the four release scenarios. More details, including predicted concentrations, are provided in Lazaro et al. (1996). The modeling study applied a dispersion model to each of the releases and used a health criterion representative of acute impacts from an exposure that might happen once in a lifetime. The health criterion (ERPG-2 level) was the concentration below which, if exposure occurred for an hour, the exposed individual could still avoid irreversible health effects by taking emergency action. The results of the modeling yielded the following conclusions:

- The threat zone from each of the four accidents would not extend to the boundary with the public under either typical or extreme meteorological conditions except for the mercury release. The nearest members of the public would be 210 m (689 ft) west of the facility, and the maximum threat zone for the mercury release would be 239 m (784 ft). Houses there are more than 19 m (62 ft) from the street, so people in those houses should be protected. However, people outdoors and within the 239-m (784-ft) threat zone could be adversely affected by inhalation of released mercury.
- Nearby buildings and personnel outside would be at risk if any of the four accidents occurred. The assumption was made that the release would not be inhibited by walls of the NIF Laser and Target Area Building and that the wind would take the plume away from the building. The distances beyond which concentrations would fall below the ERPG-2 level for each of the accidents are as follows:

- Mercury scenario—237 m (778 ft) for both the Conceptual Design and Enhanced options

- Alumina/silica scenario—171 m (561 ft) for the Conceptual Design Option and 231 m (758 ft) for the Enhanced Option

- Carbonyl fluoride scenario—75 m (246 ft) for both the Conceptual Design and Enhanced options

- Hydrogen fluoride release—101 m (331 ft) for both the Conceptual Design and Enhanced options

The personnel in nearby buildings would likely be protected because the release (typically lasting 15 minutes) would pass by the buildings with little infiltration. Personnel in the NIF Laser and Target Area Building and those outdoors in the immediate vicinity might be affected.

I.4.4.2.8 Waste Management Impacts

This section evaluates wastes generated by NIF that might impact current waste management at NLVF during construction, normal operation, and the ultimate decommissioning of NIF if it were located at NLVF.

I.4.4.2.8.1 *Waste Generation and Management During Construction and Operation*

Waste management during construction would be performed as described in section I.4.1.2.8 for LLNL. All construction activities would be performed in compliance with requirements identified in DOE Order 430.1. Table I.4.1.2.8.1–2 (section I.4.1.2.8.1) describes the quantities of wastes generated by category for both the Conceptual Design Option and Enhanced Option. NLVF has no onsite capacity to treat or dispose of low-level, mixed, or hazardous wastes.

During operation, various low-level, mixed, hazardous, and nonhazardous wastes would be generated at NIF. The quantities of these waste streams and their proposed management at NLVF are discussed below. Successive sections cover how developing technologies might be applied to minimize waste streams and, finally, the disposition of wastes from decommissioning.

Waste handling methods would be the same under both the Conceptual Design Option and the Enhanced Option. While total waste quantities would be somewhat higher for the Enhanced Option, no changes in handling methods would be necessary.

Low-Level Waste. Solid LLW would be disposed of at NTS. Hardware from the NIF chamber is an example of the type of solid LLW that would be discarded. Aqueous LLW would be treated at NTS to eliminate free liquids. Currently, no facilities exist at NLVF or at NTS for treatment of liquid radioactive waste. However, as discussed below, there are plans to develop this capability at NTS in the near future.

Mixed Waste. Current plans are to permit mixed solid waste disposal units at NTS for mixed waste generated both on and offsite that meets RCRA land disposal requirements. A permit application has been submitted to the State of Nevada, and it is estimated that the units will be available in fiscal year 1997, well before NIF would begin operations. NTS currently has the capability, under interim status, to dispose of mixed waste generated onsite at the Area 5 Radioactive Waste Management Site. This availability could conceivably be extended, if approved by the State of Nevada, to mixed waste generated at NLVF as well. The current remaining capacity for mixed waste disposal at NTS is over 90,000 m^3 (117,700 yd^3) and will be much greater (about 250,000 m^3 [327,000 yd^3]), assuming that approval and construction of permitted mixed waste disposal units takes place as anticipated. The small amount of mixed waste generated at NIF would not significantly affect mixed waste operations. In the event the mixed waste were generated before the development of acceptable NTS disposal capacity, the waste could be stored pending approval by the State of Nevada at a storage pad at the Area 5 Radioactive Waste Management Site or sent to a mixed waste disposal site out of state.

Mixed liquid waste would be treated to eliminate free liquids before disposal at NTS. Free liquids are not allowed for disposal, and must be stabilized according to the requirements stipulated in the NTS Waste Acceptance Criteria, NVO-325. As with solid mixed waste, the requirements identified in the RCRA for the land disposal restrictions would also be met. Currently, no facilities exist at NLVF or NTS for treatment of liquid mixed waste; however, there are plans to develop this capability in the near future. The liquid waste treatment system, which is designed to treat large volumes of liquid waste (both radioactive and mixed) is expected to be available in fiscal year 1997. This system would use evaporation as the primary treatment method for the anticipated waste. A second NTS mixed waste treatment facility that is still in the preliminary planning stages is also expected to be operational in fiscal year 1997. This facility will use stabilization as the primary method of treatment and might be more appropriate for the liquid mixed waste from NIF. This facility should be online by the time any waste could be generated by NIF operations. Therefore, upon approval of a permit modification, this planned facility would be available for the treatment of NIF liquid mixed waste. If necessary, the NIF liquid mixed waste could be stored at the NTS Area 5 Radioactive Waste Management Site until a treatment facility was available. The mixed aqueous waste from debris shield cleaning would be neutralized, stabilized, and transported to NTS for disposal as an approved waste stream.

Hazardous Waste. Most hazardous waste would be shipped to an approved commercial RCRA treatment, storage, and disposal facility. Scheduled pickup and removal of hazardous waste is now done by a subcontractor. The subcontractor can be called for nonscheduled removal, if necessary.

Nonhazardous Waste. Sanitary wastewater would be handled with the existing facility sewage removal outlets connected to the city of Las Vegas wastewater treatment system. NLVF operates under an NPDES permit. The addition of an estimated 18 MLY (5 MGY) of nonhazardous liquid waste from NIF operations would not have major effects on the existing removal system at the facility or on the Las Vegas treatment system.

All facilities within NLVF are, or will soon be, provided with adequate stormwater runoff protection. The development of enhanced stormwater drainage channels is planned for fiscal year 1995 at NLVF to divert runoff flow to city flood protection channels. The primary channels diverting flow from NLVF run along the road east and adjacent to the site. These primary diversion channels feed into a large storm drain channel near NLVF and are designed to protect Interstate 15, which is located approximately 200 m (656 ft) to the east. A soil stabilization project is also planned for undeveloped land within NLVF. The existing storm drain network is capable of handling the expected floodwaters from a storm occurring on or near NLVF. The design-basis-flood-level local rainfall, based on a low-hazard-use building at this location, would not be considered a significant risk because of the low probability of flooding. NLVF encompasses 33 ha (80 acres) and is not located within a 100-year floodplain.

Disposal of solid nonhazardous wastes would be handled through the city of North Las Vegas waste removal contractor. That contractor operates a transfer location less than 1 km (0.6 mi) northwest of NLVF. Waste from this transfer station is taken to a landfill outside the city limits. The transfer station handles a large portion of the waste from the city of Las Vegas, and the estimated volume of 6,000 m^3 (8,000 yd^3) per year from NIF would not have a significant impact on the transfer station operations. Waste would be regularly removed in bulk waste collection bins provided by the city contractor. At times of unusually heavy generation of nonhazardous solid waste, the city contractor could be called for supplementary pickups.

Possible Waste Minimization During Operation. Waste minimization for NIF operations at NLVF would be handled as described in section I.4.1.2.8 for LLNL. The operation process would be subjected to a pollution prevention opportunity assessment to optimize efficiency and minimize waste generation.

Existing Waste Management Capabilities at NLVF. On the basis of the anticipated waste volume generation by NIF (table I.4.1.2.8.1–2) and on information on current waste handling practices at NLVF, comparison tables were developed that indicate the capability of the existing NLVF facilities to undertake the various waste managements tasks associated with NIF. Table I.4.4.2.8.1–1 shows the estimated impacts of the NIF operations on waste storage at NLVF and compares the NIF waste generation rate to the annual handling/treatment capacity at NLVF.

The management of NIF wastes at NLVF would represent a significant extension of current practices

TABLE I.4.4.2.8.1–1.—*Comparison of the National Ignition Facility Waste to Annual Treatment Capacity at North Las Vegas Facility*

Category	Amount of NIF-Generated Waste/Year[a] (m^3)	Ratio of NIF Waste Generation to Annual Treatment Capacity	Treatment Capacity (m^3/yr)	Is the Treatment Capacity Adequate	Is Existing or Planned Storage/ Disposal Capacity Adequate
Low-Level					
Liquid (m^3)					
Conceptual design total	0.60	NA	None	No	Yes[b]
Enhanced total	1.56	NA	None	No	Yes[b]
Solid (m^3)					
Conceptual design total	2.98	NA	None	No	Yes[b]
Enhanced total	7.25	NA	None	No	Yes[b]
Mixed					
Liquid (m^3)					
Conceptual design total	2.0	NA	None	No	Yes[b]
Enhanced total	4.98	NA	None	No	Yes[b]
Solid (m^3)					
Conceptual design total	0.34	NA	None	No	Yes[b]
Enhanced total	0.88	NA	None	No	Yes[b]
Hazardous[c]					
Liquid (m^3)					
Conceptual design total	2.30	NA	None	No	Yes[d]
Enhanced total	4.60	NA	None	No	Yes[d]
Solid (m^3)					
Conceptual design total	8.0	NA	None	No	Yes[d]
Enhanced total	8.0	NA	None	No	Yes[d]

[a] The total amount of the low-level waste was found by adding the values in the column "Cleaned" of table I.4.1.2.8–2 to the column "Low-Level" of the same table. The mass of the debris shield was assumed to be the density of iron (7.87 g/cm^3). The density of the low-level liquid was assumed equal to 1.0 g/cm^3. The amount of the "cleaned" personal protective equipment and wipes/general cleaning was added to solid low-level radioactive waste.

[b] Shipped offsite to NTS.

[c] The hazardous waste values are the sum of the values for the Laser and Target Area Building and the Optics Assembly Area.

[d] Shipped offsite to RCRA treatment, storage, and disposal facility.

Note: NA - not applicable.

Source: Calculated from table I.4.1.2.8.1–2 and Ortego 1995.

or capability. Thus, the impact of NIF waste on waste management operations at NLVF would be significant. Maximum efforts would have to be made to ensure compliance with regulatory requirements. Treatment processes for mixed and hazardous wastes would be investigated and coordinated with the State of Nevada in order to obtain appropriate permits. Radioactive and mixed waste would be managed in accordance with NVO-325 requirements and disposed of at NTS.

I.4.4.2.8.2 *Waste Management at North Las Vegas Facility During National Ignition Facility Decommissioning*

The procedures proposed by NLVF for decommissioning NIF after 30 years of operation are summarized here. The general approach is that at the end of the life of the NIF Laser Facility, the laser and associated equipment would be removed from the laser building. D&D activities for NIF would not add a significant burden to operations at NLVF. This type of activity is common throughout the DOE complex at the present time. Experienced waste handling and radiation safety personnel working at NTS would be used for decommissioning NIF. A wide variety of decommissioning projects are currently in progress at NTS.

All radiation-related work practices at NTS comply with the three primary requirements and guidance documents for radiation safety: 10 CFR 835, Radiation Control Manual, and DOE N 441.1. A fully implemented program has been established with complete procedures and guidance from a site-specific Radiation Safety and Control Manual. As low as reasonably achievable programs have been established and are implemented on the basis of the above-noted program documents. All work that would present the potential for exposure or contamination would receive special consideration and planning, including (but not limited to) dry-run practices, condition monitoring experiments, and personal protective equipment upgrade analysis. Decontamination systems would be established specifically for equipment in NIF to optimize efficiency and reduce the amount of waste residuals from the decontamination process. A wide variety of radiation safety and decontamination resources and experience exist at NTS. These resources would be made available, as necessary, for the development and implementation of NIF systems. Existing equipment, such as anticontamination clothing and personal protective equipment, would be available for use at NIF. This type of reusable equipment would be decontaminated onsite at the laundering and cleaning facilities available at NTS. Residual materials from the decontamination process would be disposed of at NTS.

The following sections discuss decommissioning of the NIF laser and associated components, followed by a discussion of decommissioning of equipment in the target area. The major activated/contaminated components would be located in the target area, so this facility would be the most complex operation.

Decommissioning of the NIF Laser by NLVF. The decommissioning of the NIF laser would be handled as described in section I.4.1.2.8 for LLNL. Mercury wastes from the ignitron switches would be sent to a permitted mercury recycling center, as is the current practice. The mixed waste from the capacitors would have to meet the requirements of NVO-325 before disposal on the NTS at the Area 5 Radioactive Waste Management Site.

Decommissioning of the NIF Target Area. The decommissioning of the NIF target area would be handled similar to the manner described in section I.4.1.2.8 for LLNL. DOE/NV and associated contractors have experience dealing with tritium contamination in virtually all phases of operations. Routine carbon dioxide cleaning during operations of NIF is indicated as the primary process for reducing the total amount of contamination on components at the end-of-life of NIF. Waste management operations at NTS have included disposal of millions of curies of tritium, especially as part of Area 5 Radioactive Waste Management Site operations. The disposal site, and operational sites throughout NTS, are equipped for tritium monitoring and detection. The Analytical Services Laboratory at NTS (in Area 23) can perform a variety of analyses for tritium, including personnel contamination determinations.

Radioactive and mixed waste could be disposed of at NTS assuming it could be managed and processed in accordance with NVO-325. Large structures that could not easily be containerized could be disposed of at the Area 3 Radioactive Waste Management Site, which is used for the disposal of bulk LLW containers.

NIF would be decommissioned according to standard engineering practices. The project would be handled similarly to construction projects per requirements of DOE O 430.1. This planning would optimize all phases of decommissioning and provide the most efficient method for completing the work. Efficient work would lead to a reduction in time for exposure of workers, which would in turn reduce the overall exposure projections.

I.4.5 Sandia National Laboratories

I.4.5.1 *Affected Environment*

The following sections describe the affected environment associated with the construction and operation of NIF at Sandia National Laboratories (SNL). Land use, air quality and acoustics, water resources, biotic resources, cultural and paleontological resources, socioeconomics, radiation and hazardous chemicals, and waste management are described.

I.4.5.1.1 Location and Land Use

The 1,150-ha (2,842-acre) SNL site is located east of Albuquerque, New Mexico, within the boundaries of the 21,044-ha (52,000-acre) Kirtland Air Force Base military reservation. The land north of SNL, with the exception of a few vacant parcels, is part of the urbanized city of Albuquerque. Areas to the west and south, by agreements with the State of New Mexico and the Isleta Pueblo, serve as buffer zones for certain test operations. Figure I.4.5.1.1–1 shows SNL Technical Areas and surrounding Kirtland Air Force Base land use.

The proposed NIF location at SNL is in an undeveloped area in Technical Area II, north of R Street, east of 9th Avenue and south of East Ordnance Road (figure I.3.4.5.1-2). The temporary construction laydown area would be located within the location designated for NIF. Areas east of the proposed NIF location in Technical Area II have been used for testing explosive components, and the immediate vicinity of NIF location was until recently part of an extensive operational safety zone. With the completion of the Explosives Component Facility in 1995, Technical Area II will be increasingly used for laboratory service functions (SNL 1995a). To the south of the proposed NIF location is Technical Area IV, which consists of several Inertial Confinement Fusion (ICF) and pulsed-power research facilities. In the area immediately north is located an SNL facilities storage yard, and to the west is a DOE arms control treaty verification rail and truck terminal mock-up. Approximately 2.4 km (1.5 mi) to the west is the runway for Kirtland Air Force Base, which is also shared with commercial planes landing at Albuquerque International Airport. A residential development at Kirtland Air Force Base containing approximately 100 housing units is located approximately 1.5 km (0.9 mi) north of the proposed NIF location. Well-drained, gravelly soils dominate the area. No soils at SNL are classified as prime farmland.

I.4.5.1.2 Air Quality and Acoustics

This discussion of existing air quality and acoustics includes a review of the meteorology, climatology, and ambient air quality characteristics near SNL.

I.4.5.1.2.1 *Meteorology and Climatology*

The climate at SNL and the surrounding region is arid continental with abundant sunshine, low humidity, scant precipitation, and a wide seasonal range of temperatures. The annual average temperature at SNL is 13.4 °C (56.2 °F); average daily temperatures range from 1.6 °C (34 8 °F) in January to 26.0 °C (78.8 °F) in July. The average annual precipitation at SNL is 20.6 cm (8.12 in). Prevailing winds much of the year are from the southeast; however, prevailing winter and spring winds are from the north and south, respectively. The annual average wind speed is 14.5 kph (9.0 mph) (NOAA 1990). Figure I.4.5.1.2–1 shows the 5-year wind rose for SNL based on measurements at Albuquerque International Airport. During the years 1987 to 1991, unstable atmospheric conditions occurred approximately 27 percent of the time, neutral conditions about 36 percent of the time, and stable conditions the remaining 37 percent of the time (EPA 1995b). In general, atmospheric dispersion improves as the wind speed increases and as the atmospheric conditions become more unstable.

The limited precipitation and warm temperatures of the area create an arid climate that limits the growth of ground-covering vegetation, resulting in the presence of large areas of exposed soil that are a potential source of windborne particulate matter (dust). These particulate matter concentrations are reduced if the exposed soil is wetted or if the dust is "washed out" of the atmosphere by precipitation. However, the area's precipitation and temperature seldom provide these beneficial mechanisms. This condition worsens the background particulate matter concentrations and increases the likelihood of the area's particulate matter (PM_{10}) and TSP ambient air concentration approaching or exceeding regulatory standards.

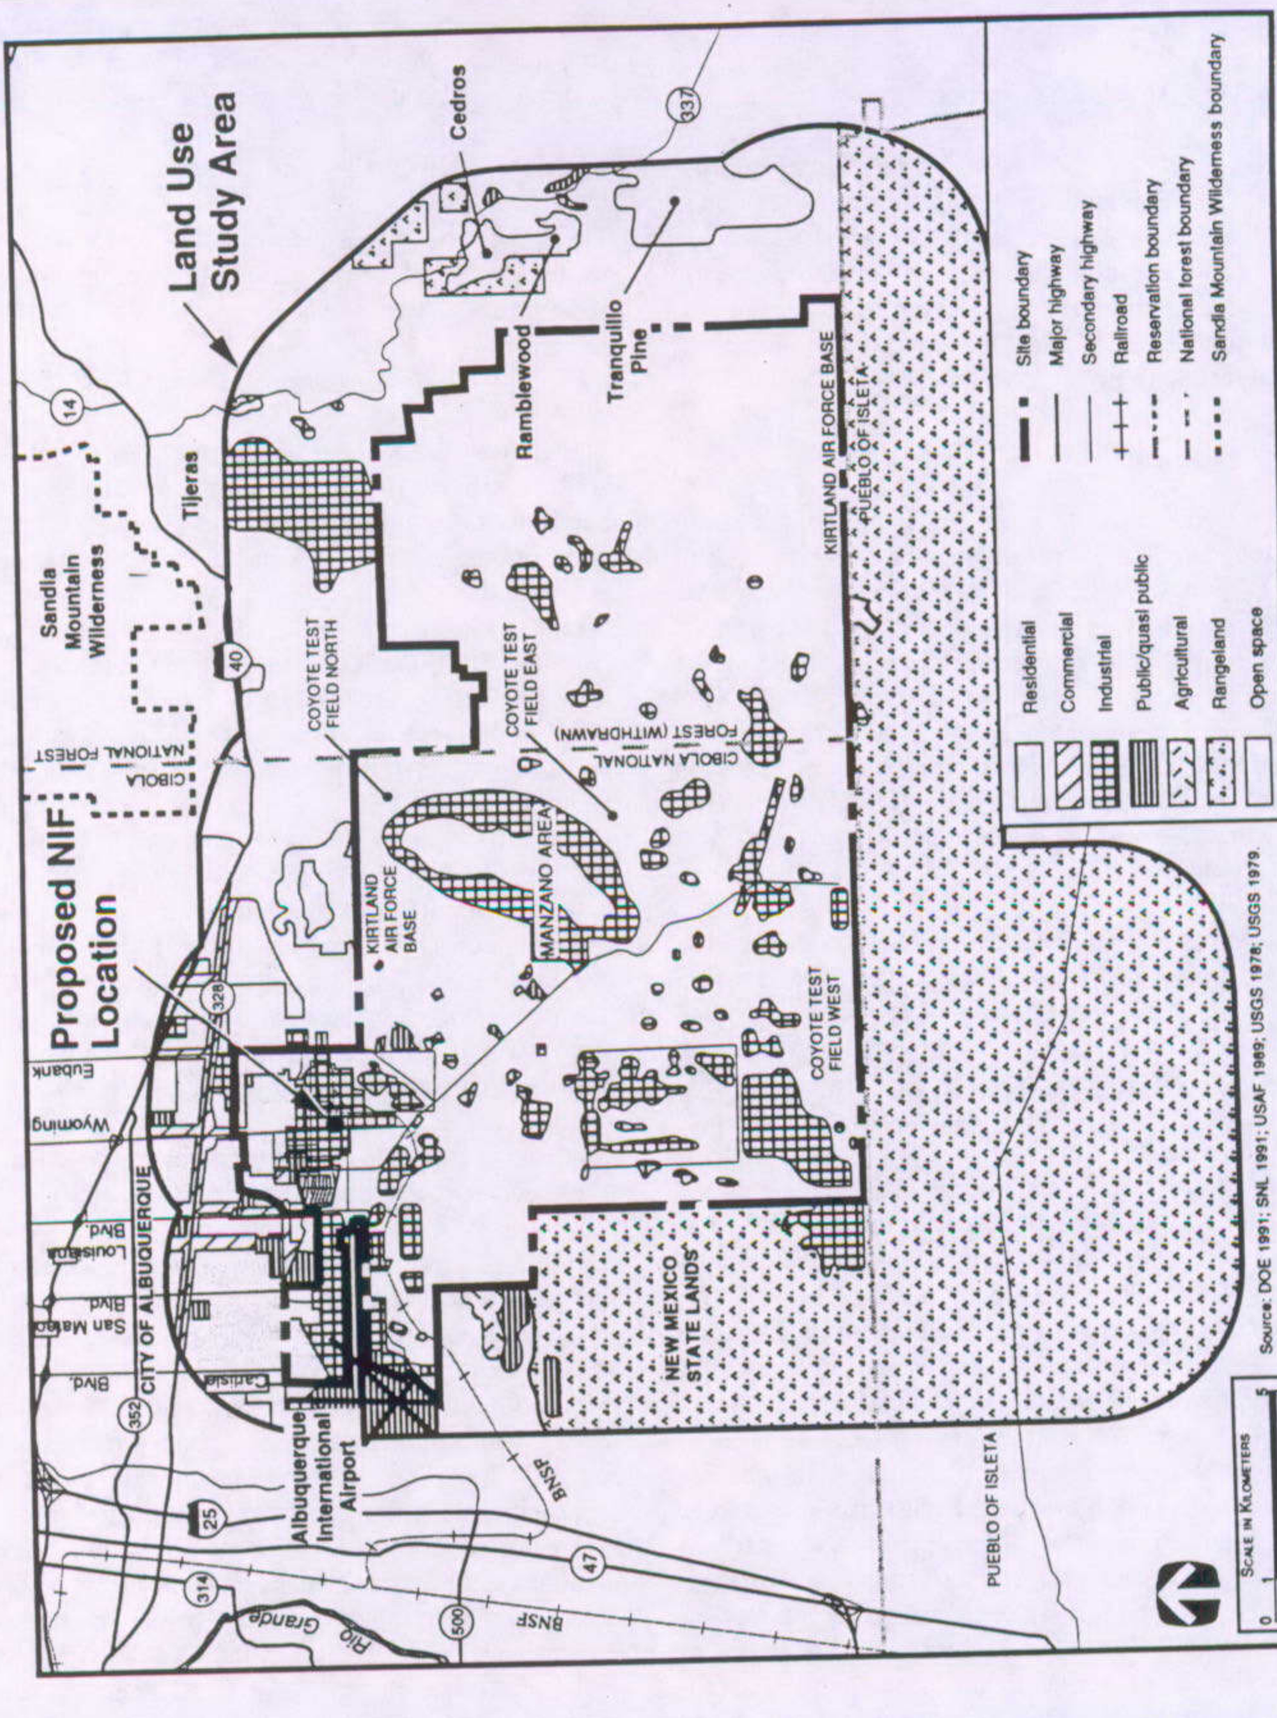

FIGURE I.4.5.1.1-1.—*Generalized Land Use at Sandia National Laboratories and Vicinity.*

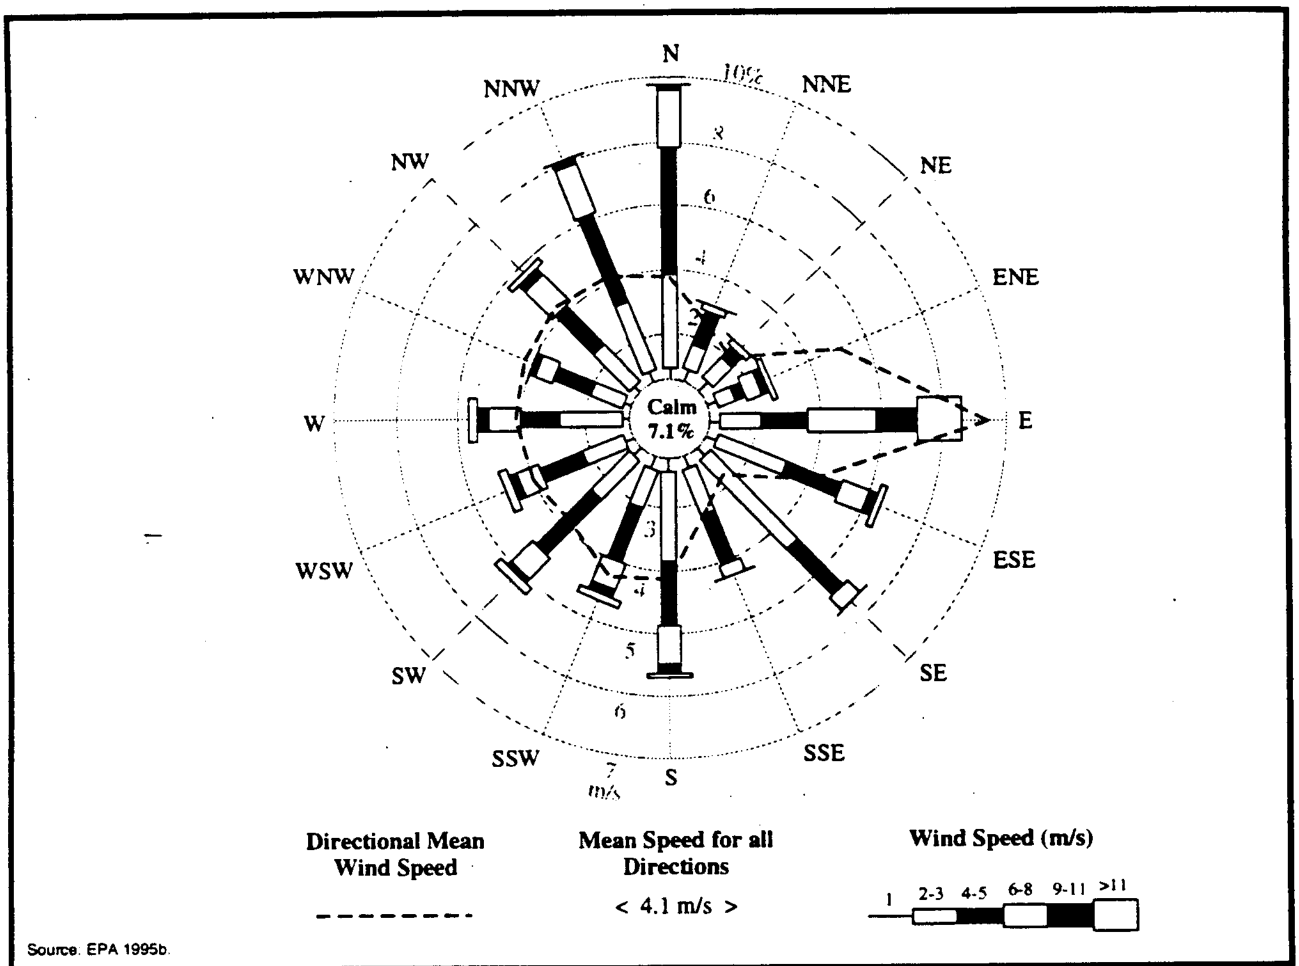

FIGURE I.4.5.1.2–2.—*Wind Distribution at Sandia National Laboratories, 1987-1991.*

I.4.5.1.2.2 *Ambient Air Quality*

The Albuquerque-Bernalillo County Air Quality Control Board is responsible for air pollution control and attainment of air quality standards in the city of Albuquerque and Bernalillo County. In addition to being subject to NAAQS for criteria pollutants, SNL is subject to ambient air quality standards adopted by the Albuquerque-Bernalillo County Air Quality Control Board. Applicable NAAQS and Albuquerque-Bernalillo County ambient air quality standards are listed in table I.4.5.1.2.2–1.

SNL is located within the Albuquerque-Mid Rio Grande New Mexico Intrastate AQCR 152. Portions of the AQCR are designated as nonattainment for carbon monoxide and TSP (40 CFR 81.332). In general, pollutant emission increases in an area designated as nonattainment for a specific pollutant are subject to more stringent permitting requirements than if the area is designated as attainment.

The New Mexico Environment Department operates a network of air quality monitors in the Albuquerque area. The state monitor closest to SNL is at the city water tank on Mesilla (Site ID 2ZE), approximately 8 km (5 mi) north-northwest of the proposed NIF location. Data for this and other monitors near SNL are shown in Lazaro et al. (1996). Table I.4.5.1.2.2–1 presents the 1993 baseline ambient air concentrations for criteria pollutants and other pollutants at SNL. All of the baseline concentrations are in compliance with the NAAQS. The 1-hour photochemical oxidant concentration exceeds the county standard, which is common in urban areas.

The nearest PSD Class I Area is the Bandelier National Monument Wilderness Area, which is

TABLE I.4.5.1.2.2–1.—*Comparison of Baseline Ambient Air Concentrations with Most Stringent Applicable Regulations and Guidelines at Sandia National Laboratories*

Pollutant	Averaging Time	Most Stringent Regulation or Guideline (μg/m³)	1993 Baseline Concentration[a] (μg/m³)
Criteria Pollutant

located about 70 km (45 mi) north-northeast of SNL (NMAQB 1994).

The primary emission sources of criteria pollutants at SNL are the steam plant, paint shops, toxic machine shop, process development laboratory, and diesel generator plant at Technical Area I, and the explosive testing at Technical Area II (DOE 1988). Other emission sources include fugitive particulates from waste-burial activities, other processes, vehicles, and construction activities.

I.4.5.1.2.3 *Acoustic Conditions*

SNL is within Kirtland Air Force Base, which borders the Albuquerque International Airport. Commercial and military aircraft operations are the dominant source of noise at SNL because of the presence of the major east/west runway of the International Airport to the west of the northern portion of the SNL site. Military aircraft from Kirtland Air Force Base share the International Airport runways with commercial aircraft. Aircraft operations are a periodic noise source, and maximum levels are associated with aircraft takeoffs and landings (DOE 1993b). Other noise emission sources within SNL include motor vehicles and various industrial facilities and equipment.

Studies have recorded intermittent noise levels of 54 to 102 dBA for the northern portion of SNL near Technical Areas I, II, and IV east of the International Airport east/west runway. Daytime noise levels in Technical Area III, in the southern portion of SNL remote from the runway, have been measured at 64 to 72 dBA, with an average of 66 dBA (DOE 1993b). These noise levels contribute to the ambient background noise in these areas.

I.4.5.1.3 Water Resources

The major surface water feature in the area is the Rio Grande, which flows north to south through Albuquerque and lies about 10 km (6 mi) west of SNL. There are no perennial streams on the SNL site. The two primary surface channels at SNL are Tijeras Arroyo and Arroyo del Coyote. Tijeras Arroyo is directly southeast of Technical Area II and has a drainage area of about 208 km^2 (80 mi^2) above the confluence with Arroyo del Coyote. Arroyo del Coyote has a drainage area of about 70 km^2 (27 mi^2). Both arroyos flow intermittently during heavy summer thundershowers (SNL 1994). Technical Area II has no stormsewer system. Storm runoff drains into Tijeras Arroyo, which flows west to the Rio Grande. Except for the southeast corner, Technical Area II (including the proposed NIF location) is outside the 100- and 500-year floodplains of Tijeras Arroyo (figure I.4.5.1.3–1).

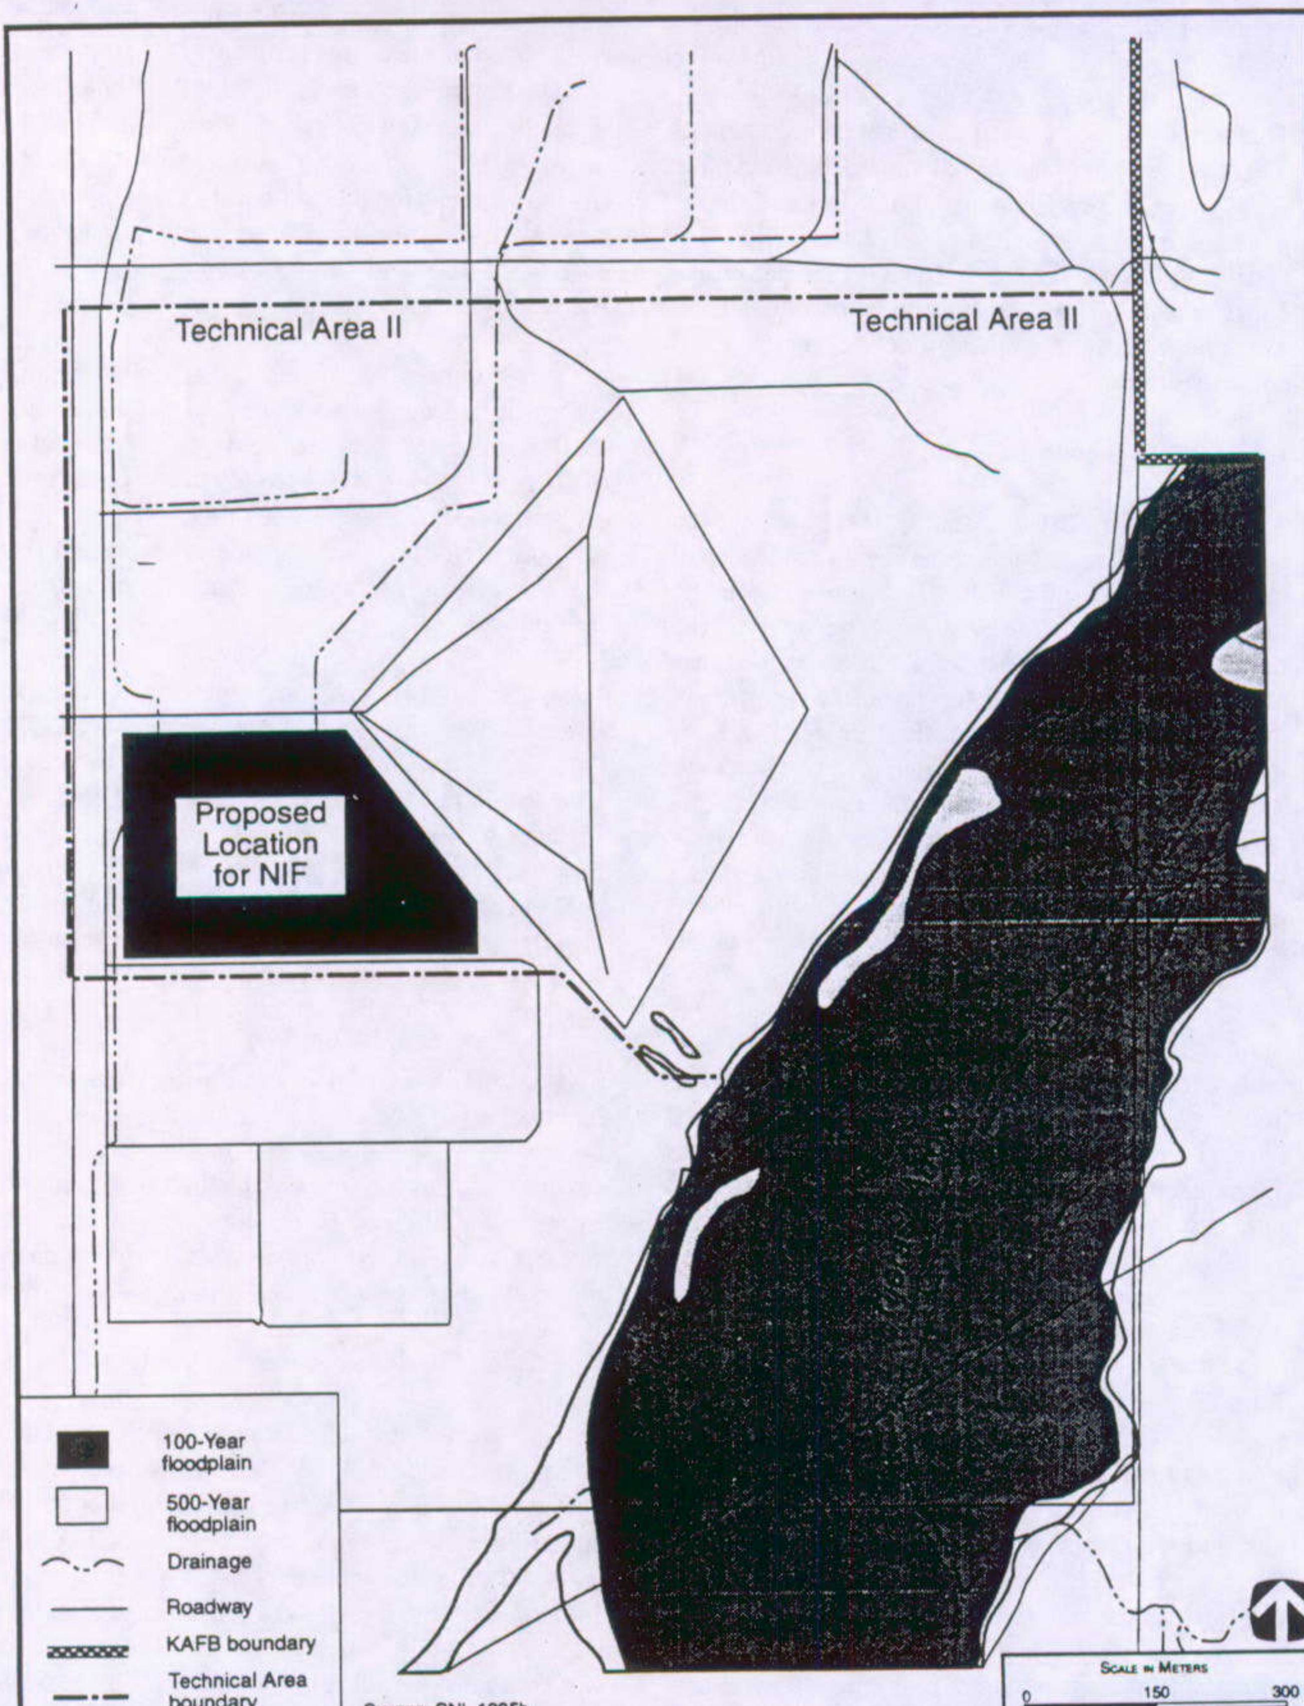
A fault complex separates the regional aquifer system into a deeper zone west of the fault and a shallower zone to the east. The depth to groundwater at SNL varies from 15 to 30 m (49 to 98 ft) east of the fault and 120 to 150 m (394 to 492 ft) west of the fault. Most SNL facilities, including Technical Area II where NIF would be located, are located west of the fault system.

The water supply for SNL is provided by Kirtland Air Force Base and the city of Albuquerque. Kirtland Air Force Base draws water from a system of wells, with a backup from the city of Albuquerque. In 1990, Kirtland Air Force Base pumped an average of over 5,840 MLY (1,533 MGY) of water from its production wells. SNL uses about 1,387 MLY (365 MGY) of water, of which 70 percent is provided by Kirtland Air Force Base and the rest by the city of Albuquerque (SNL 1995a; IT Corporation 1992).

SNL contains over 24 km (15 mi) of sewer lines interconnected with those of Kirtland Air Force Base. During 1993, SNL had four general wastewater streams discharging to the Albuquerque wastewater treatment plant and three industrial wastewater streams that required pretreatment before discharging to the sewer system (SNL 1994).

I.4.5.1.4 Biotic Resources

SNL is located in the Arizona, Livermore Plateau Ecoregion (Omernik 1986). Most of the undeveloped spaces located at and near the area designated for NIF support grassland vegetation. Common plant species include galleta, sand dropseed, ring muhly, and Indian ricegrass. Grassland vegetation dominates in Technical Area II, with arroyo banks occurring along the southeastern margin of that area. The arroyo banks generally contain a drought-adapted grassland community, dominated by species such as club



3111/SSM

FIGURE I.4.5.1.3–1.—*Floodplain Map for Technical Area-II at Sandia National Laboratories.*

cholla, prickly pear, soapweed yucca, and four-wing saltbush (IT Corporation 1992).

The size and diversity of the wildlife populations at SNL are limited by lack of available water (IT Corporation 1992). Amphibians and reptiles that could occur in Technical Area II include the western spadefoot toad, plains spadefoot toad, Woodhouse's toad, Great Plains toad, many-lined skink, Great Plains skink, whiptail lizard, side-blotched lizard, short-horned lizard, bullsnake, and coachwhip. The western diamondback rattlesnake and western rattlesnake also occur in grassland communities of the area (IT Corporation 1992).

Raptors that may use grassland habitats of SNL for hunting include northern harrier, red-tailed hawk, Swainson's hawk, ferruginous hawk, American kestrel, prairie falcon, barn owl, long-eared owl, great horned owl, burrowing owl, and turkey vultures. Other common grassland birds that may nest in the area include scaled quail, mourning dove, greater roadrunner, horned lark, American crow, northern mockingbird, crissal thrasher, loggerhead shrike, lark sparrow, black-throated sparrow, western meadowlark, brown-headed cowbird, and house finch (IT Corporation 1992).

Common mammals in the grassland areas include desert cottontail, black-tailed jackrabbit, spotted ground squirrel, Gunnison's prairie dog, Botta's pocket gopher, silky pocket mouse, Ord's kangaroo rat, banner-tailed kangaroo rat, Merriam's kangaroo rat, western harvest mouse, deer mouse, white-footed mouse, and northern grasshopper mouse. Coyote, kit fox, long-tailed weasel, badger, striped skunk, and bobcat are among the predatory mammals within the grassland habitats. Mule deer infrequently make use of such habitats (IT Corporation 1992).

No National Wetland Inventory maps have been prepared for SNL. If wetlands do exist on SNL, they would be in the area of the springs and intermittent drainages associated with the canyons and arroyos of Kirtland Air Force Base. These areas do not occur within the area designated for NIF.

Aquatic resources of SNL include intermittent stream channels within Arroyo del Coyote and Tijeras Arroyo. Several springs exist on Kirtland Air Force Base, including Sol de Mete Spring, Coyote Springs, and G Spring, associated with canyons and arroyos. There are also drainage ditches, Lake Christian (a 0.8-ha [2.0-acre] permanent pond in the southern portion of Kirtland Air Force Base), and golf course ponds. None of these resources occur within the area designated for NIF.

A list of Federal and state rare, threatened, and endangered species that could potentially exist at SNL is provided in Lazaro et al. (1996). Habitats that could attract several of the species (such as loggerhead shrike and New Mexico jumping mouse) are present. However, no designated critical habitats for Federal-listed species exist at SNL.

I.4.5.1.5 Cultural and Paleontological Resources

No prehistoric or historic archaeological sites or structures exist on the proposed NIF location in Technical Area II. An intensive pedestrian field survey (employing 6- to 12-m [20- to 50-ft] transects) was conducted during August 1990; no artifacts or features were encountered on or near the proposed NIF location (Hoagland 1990). The SNL Sitewide Hydrogeologic Characterization Project reports that no important paleontological remains have been recovered from deposits on SNL, including the alluvial and colluvial sediments that exist on the proposed NIF location (Wheeler 1995a). Consultation with the Isleta Pueblo indicates that no Native American cultural resources exist within the boundaries of SNL, including the proposed NIF location (Wheeler 1995a).

I.4.5.1.6 Socioeconomics

Socioeconomic characteristics described here for the SNL area include the regional economy, population and housing, public finance and public service infrastructure, and local transportation. Regional economic statistics are based on a regional economic study area that encompasses nine counties around SNL, as defined by the BEA. The economic study area is a broad labor and product market-based region linked by trade among economic sectors within the region. Statistics for population and housing, public finance, and infrastructure are based on the ROI, a three-county area in which more than 95 percent of SNL employees reside. The three counties are Bernalillo (containing 88.0 percent of the workforce), Sandoval (4.5 percent), and Valencia (4.5 percent). The counties and cities included in the economic study region and the counties included in the ROI are listed in Lazaro et al. (1996). Assumptions, assessment methodologies. and supporting data are also presented in Lazaro et al. (1996).

I.4.5.1.6.1 *Regional Economy*

The economic study area for SNL includes the Albuquerque Metropolitan Statistical Area (Bernalillo County) and eight surrounding counties. Between 1988 and 1995, employment in the economic study region was projected to increase from 291,600 to 331,500. BEA (1990) projects a compounded average annual growth rate of 1.3 percent from 1995 to 2003 (34,646 jobs).

In 1995, SNL employed approximately 8,500 persons, accounting for 2.8 percent of employment in the regional economic study area. In 1995, employment at SNL dropped to 7,543. Data on historical and projected employment at SNL and the distribution of employees by place of residence in the ROI are presented in Lazaro et al. (1996).

I.4.5.1.6.2 *Population and Housing*

The ROI experienced steady population growth between 1980 and 1990, with an average annual increase of about 3.2 percent, bringing the 1990 total to about 605,000 persons. Population growth has been strongest in Sandoval County (84 percent between 1980 and 1990). By the year 2000, population in the ROI is expected to grow to approximately 672,000 persons (U.S. Department of Commerce 1994; BEA 1990).

Between 1980 and 1990, the number of housing units in the ROI increased by over 22 percent, from 196,765 to 241,683 units (see table I.4.5.1.6.2–1). Housing in Bernalillo County increased from 162,126 units in 1980 to 201,235 in 1990 (24 percent). Housing in Sandoval County increased from 12,286 units in 1980 to 23,667 in 1990 (93 percent), and housing in Valencia County decreased from 22,352 units in 1980 to 16,781 in 1990 (minus 25 percent). The number of housing units in the ROI is expected to increase about 19 percent between 1990 and 2000 (U.S. Department of Commerce 1994; BEA 1990; ULI 1995).

The number of vacant owner units in the ROI increased from about 11,000 units in 1980 to about 13,000 in 1990. It is estimated that by the year 2000 there will be approximately 16,000 vacant owner units if current construction and economic trends continue in the ROI.

In 1980 there were approximately 5.000 vacant rental units in the ROI. The number of vacant units increased to about 7,000 by 1990. It is estimated that by the year 2000 there will be approximately 9,000 vacant rental units if current construction and economic trends continue in the ROI.

In 1994, the residential market within the ROI continued a four-year upward trend, both in terms of

TABLE I.4.5.1.6.2–1.—*Population and Housing Data for the Sandia National Laboratories Area*

	1980	1990	1996	1997	1998	1999	2000	2001	2002	2003
Estimated ROI population	458,430	605,088	642,577	649,734	656,973	664,295	671,700	677,689	683,733	689,833
Estimated total housing units	196,765	241,683	268,634	273,126	277,617	282,109	286,601	291,093	295,585	300,076
Estimated vacant owner units	11,123	13,053	14,372	14,592	14,811	15,031	15,251	15,471	15,691	15,910

Estimated total vacant housing units in ROI[a]	16,151	20,064	22,412	22,803	23,194	23,586	23,977	24,386	24,760	25,151

[a] Vacancy rate - 8 percent.
Source: Historical data from U.S. Department of Commerce (1994); projections by Haliburton-NUS (1995).

construction activity and sales of existing houses. Construction of single-family houses increased by 20 percent. Single-family development continued to be concentrated in the northwest and northeast Albuquerque submarkets, as well as in the city of Rio Rancho. The northwest and northeast submarkets contain more upscale housing, with more affordable housing in the city of Rio Rancho. After four years of declining vacancy rates, the region appears poised for a surge in new construction. Multifamily permits have increased sharply since 1993, and several residential projects are planned. In light of current economic conditions in the Albuquerque housing market, residential construction activity is expected to continue at a brisk pace (ULI 1995).

I.4.5.1.6.3 *Public Finance and Public Services Infrastructure*

Public financial characteristics of the local jurisdictions in the ROI that are most likely to be affected by NIF at SNL are presented in this section. The data reflect total revenues and expenditures of each jurisdiction's general fund, special revenue funds, and, as applicable, debt service, capital project, and expenditure trust funds. Major revenue and expenditure categories and total revenues less expenditures for counties and cities are presented in table I.4.5.1.6.3–1. Table I.4.5.1.6.3–2 summarizes public service levels for education, community service, and health care.

I.4.5.1.6.4 *Local Transportation*

Vehicular access to SNL is provided by Broadway Boulevard, Eubank Boulevard, Louisiana Boulevard, Wyoming Boulevard, and Gibson Boulevard in Albuquerque. Interstate 40 and Interstate 25 provide regional access to SNL. Table I.4.5.1.6.4–1 shows the site access roads at SNL and the average daily traffic volumes for each route.

There currently are two major road improvement projects within the SNL vicinity. These projects are (1) the Eubank Road and Interstate 40 interchange overpass project and (2) the Four Hills Road, Tramway Boulevard, and Interstate 40 interchange project. Future road improvement projects that will begin before 2000 include the Juan Tabo Road and Interstate 40 interchange project, the Wyoming Boulevard and Interstate 40 interchange project, and the Gibson Street reconstruction project (Fegan 1995).

Traffic along road segments providing access to SNL is projected to contribute to differing service level conditions in accordance with population growth. Eubank, Gibson, Louisiana, Wyoming, and, to a lesser extent, Broadway would typically experience traffic congestion, with volumes approaching or exceeding the design capacity of each roadway. Along these roadways, a motorist's speed and ability to maneuver would be restricted, and potential disruptions to traffic flow could be caused by accidents

TABLE I.4.5.1.6.3–1.—*Public Finance—Sandia National Laboratories Area*

Revenues and Expenditures[a]	Bernalillo County	City of Albuquerque	Valencia County	Sandoval County
Local sources (percent)	70	55	NA	85

or maintenance activities, resulting in considerable congestion (DOE 1993a).

Major planned improvements to roads that provide access to SNL include future construction of a limited-access, six-lane freeway from Interstate 40 on the west to Interstate 25 on the north. Construction of additional capacity for Interstate 40 east may include one lane in each direction from Tramway Boulevard to the intersection between Interstate 25 and Interstate 40 (the Big I). A transportation corridor study of a potential roadway from Tramway, Eubank, and Juan Tabo along the Tijeras Arroyo (to intersect with Interstate 25 between Rio Bravo and the Pajarito Study Corridor and provide access to Kirtland Air Force Base and Mesa Del Sol) is being pursued. The study is expected to determine the number of lanes and functional classification for the facility (Middle Rio Grande Council of Governments 1995). Public transportation within the ROI is provided by Sun Tran. The Albuquerque Aviation Department owns and operates the Albuquerque International Airport, which provides jet service from both national and local carriers.

I.4.5.1.6.5 *Environmental Justice*

Environmental justice concerns the potential for high and adverse environmental or human health impacts to disproportionately affect minority or low-income

TABLE I.4.5.1.6.4–1.—*Baseline Traffic on Sandia National Laboratories Access Roads*

Route	From	To	1995 ADT	1995 PHV	1995 LOS	2000 ADT	2000 PHV	2000 LOS

Note: ADT - average daily traffic; PHV - peak hour volume; LOS - level of service.

Source: DOE 1993a.

populations. In this PSA, environmental justice is evaluated for impacts within the site region, defined as the area within an 80-km (50-mi) radius around the site, and within the local area. Lazaro et al. (1996) presents the demographic analysis of minority and low income population distributions on a regional and local basis.

In the SNL site region in 1990, 15 percent of the population was low income and 45 percent was minority. These values are lower percentages of both low-income and minority persons than the New Mexico state averages (21 percent low income and 49 percent minority). Within the area, census tracts closer to the SNL site tend not to have significantly higher or lower proportions of minority or low-income populations than tracts farther from the site.

I.4.5.1.7 Radiation and Hazardous Chemicals

I.4.5.1.7.1 *Radiation Environment*

A detailed discussion of the radiation environment at SNL, including background, radiological releases, and doses to members of the public, is presented in 1993 *Site Environmental Report*, Sandia National Laboratories (SNL 1994). The concentrations of radioactivity in various environmental media (air, water, soil) in the site region are also presented in that reference.

Calculated radiological doses were used to estimate the potential health impacts to the public and onsite workers at SNL from any releases of radioactivity. The annual doses to individuals, the surrounding population (within 80 km [50 mi]), and workers are summarized in table I.4.5.1.7.1–1; corresponding health risks are also presented in this table. These doses are in addition to those from natural background, consumer products, and medical sources, which total about 399 mrem.

Background radiation doses are unrelated to SNL operations. Regulatory limits that specify the maximum effective dose equivalent to individual members of the public and occupational workers are also presented in table I.4.5.1.7.1–1.

The doses to the public are within regulatory limits (DOE 1990) and are small in comparison to background radiation. The onsite worker doses are also within regulatory limits.

I.4.5.1.7.2 *Hazardous Chemical Environment*

The background chemical environment important to human health consists of the atmosphere, which may contain hazardous chemicals that can be inhaled; drinking water, which may contain hazardous chemicals that can be ingested; and other environmental media with which people may come in contact (e.g., soil through contact or the food pathway). Exposure pathways to SNL workers during normal operation may include inhaling the workplace atmosphere, drinking SNL potable water, and possible other contact with hazardous materials associated with work assignments.

The existing inventory of hazardous chemicals at SNL of the types that may be used by NIF is listed in table I.4.5.1.7.2–1. The potential for health impacts from these chemicals varies from facility to facility and from worker to worker, and available information is not sufficient to permit a meaningful estimation and summation of these impacts. However, workers are protected from hazards specific to the workplace through appropriate training, protective equipment, monitoring, and management controls.

TABLE I.4.5.1.7.2–1.—*1994 Inventory of National Ignition Facility-Related Hazardous Materials Stored at Sandia National Laboratories*

Hazardous Material	Quantity
Acetone	7,069 L
Aluminum	27,092 kg

Average worker (mrem)	NA	NA	NA	NA	5,000	3.2	$1.3x10^{-6}$
Maximally exposed worker (mrem)	NA	NA	NA	NA	5,000	1,000	$4.0x10^{-4}$
Total workers[h] (person-rem)	NA	NA	NA	NA	None	11	$4.4x10^{-3}$

[a] The regulatory limits for individuals are given in DOE Order 5400.5. The 10 mrem/yr limit from airborne emissions is required by the *Clean Air Act*, the 4 mrem/yr limit is required by the *Safe Drinking Water Act*, and the total dose of 100 mrem/yr is the limit from all pathways combined. The occupational limit for workers is 5,000 mrem (10 CFR 835).

[b] The calculated dose values given in the Liquid Releases column conservatively include all water pathways, not just the drinking water pathway.

[c] Based on latent fatal cancer risk factors of $5x10^{-7}$/mrem for individuals, $5x10^{-4}$/person-rem for population, and $4x10^{-7}$/mrem for workers (ICRP 1991).

[d] Obtained by dividing the population dose by the number of people living within 80 km (50 mi) of the site.

[e] Dose for the population in an 80-km (50-mi) radius surrounding SNL, including the population on Kirtland Air Force Base; estimated for a population of approximately 578,313 people.

[f] No regulatory limits exist for population doses; however, a 100 person-rem value for the population is found in proposed 58 FR 16268 (10 CFR 834).

[g] Worker doses were estimated on the basis of readings from monitoring devices called thermoluminescent dosimeters.

[h] The number of badged workers in 1992 was approximately 3,420.

Note: NA - not applicable.

Source: SNL 1994.

SNL workers are also protected by adherence to OSHA and EPA occupational standards that limit atmospheric and drinking water concentrations of potentially hazardous chemicals. Appropriate monitoring, which reflects the frequency and amounts of chemicals utilized in the operation processes, ensures that these standards are not exceeded.

The chemical pollutant levels from SNL operations to which the public is exposed meet all applicable permit, regulatory, and DOE operational requirements. A review of the SNL annual environmental and accident reports indicates that there have been no significant adverse impacts to workers, the public, or the environment from hazardous chemicals.

I.4.5.1.8 Waste Management

The current waste management practices at SNL are outlined in table I.4.5.1.8–1. Wastes generated at SNL from research activities include low-level, mixed, hazardous, and nonhazardous wastes. NIF is expected to generate these same categories of wastes during operation.

I.4.5.1.8.1 *Low-Level Waste*

LLW at SNL is generated in both technical and remote test areas as a result of R&D activities. Most of LLW consists of contaminated equipment and combustible decontamination materials and cleanup

debris. All generated LLW is temporarily stored at generator sites or aboveground in transportation containers at the location of the closed Technical Area III LLW disposal site. All LLW packages currently onsite are being stored, pending approval for transport by commercial carriers to NTS for burial.

I.4.5.1.8.2 *Mixed Low-Level Waste*

Mixed wastes managed at SNL include radioactively contaminated oils and solvents and radioactively contaminated or activated lead or other heavy metals. Other mixed wastes may be generated as a result of weapons tests. The 557-m^2 (6,000-ft^2) Radioactive and Mixed Waste Management Facility will have a centralized packaging and storage function for LLW and mixed waste. Mixed waste will be stored at the facility until a decision has been made on an acceptable waste disposal site. Waste processing at the Radioactive and Mixed Waste Management Facility will include activities required to comply with the waste acceptance criteria and Federal regulations. SNL is aiding DOE in developing a compliance agreement to be negotiated with EPA Region VI Field Office. DOE and SNL are assessing their responsibilities as outlined in the FFCA and may enter into similar agreements with the State of New Mexico.

I.4.5.1.8.3 *Hazardous Waste*

Hazardous wastes are generated at SNL by the numerous R&D activities conducted throughout the Laboratory. The Hazardous Waste Management Facility can store 265,000 L (70,000 gal) of liquid and solid hazardous wastes at one time. There are no active onsite disposal facilities for hazardous/toxic wastes at SNL. All RCRA-regulated wastes are packaged, manifested, and shipped offsite by DOT-registered carriers for disposal at RCRA-permitted treatment and disposal facilities.

I.4.5.1.8.4 *Nonhazardous Waste*

SNL contains over 24 km (15 mi) of sewer lines interconnected with those of Kirtland Air Force Base. Pretreated industrial wastewater effluent and sanitary sewage are discharged to the city of Albuquerque sewer system in compliance with NPDES permit discharge limits. Solid sanitary waste is collected and taken to the municipal solid waste landfills of the city of Albuquerque and the city of Rio Rancho.

At SNL, waste minimization and pollution prevention programs have been implemented with programmatic controls such as source reduction, inventory control, product substitution, and waste exchange programs.

I.4.5.2 ***Environmental Impacts***

The following sections describe the potential environmental impacts for land use and visual resources, air quality and noise, water resources, ecological resources, cultural and paleontological resources, and socioeconomics for constructing and operating NIF at SNL. In addition, impacts associated with radiation, hazardous chemicals, and waste management are described.

I.4.5.2.1 Land Use and Visual Resources

I.4.5.2.1.1 *Land Use*

Impacts to land use at and around SNL from NIF would be limited to the clearing of land, minor and temporary disruptions from construction activities at contiguous land parcels south of the proposed location, and a slight increase in vehicular traffic. The proposed location for NIF at SNL (figure I.3.4.5.1–2) is a large parcel of flat, vacant land on the southern end of Technical Area II between East Ordnance Road and R Boulevard, and a small plot of land for construction staging on the northern edge of Technical Area IV just south of R Boulevard. NIF would require the clearing of an estimated 10.5 ha (25.9 acres) of land for buildings, walkways, building access, temporary construction laydown area, and buffer space. Such acreage would account for approximately 7 percent of the land currently available for development at SNL (Wheeler 1995b). NIF would be located in an area dedicated to similar land uses (SNL 1995a). No impacts to land use in Bernalillo County, the city of Albuquerque, or nearby communities would be expected.

With appropriate erosion and sediment control measures, soil impacts during construction of NIF would be short term and minor. Seismic risk would be taken into account during construction and operation of NIF.

I.4.5.2.1.2 *Visual Resources*

Other than short-term construction effects (from fugitive dust, equipment exhaust, etc.), no impacts to visual resources would result from siting and operation of the proposed facilities. NIF would be located in an area that is flat, has little variety in vegetation, and has virtually no visual diversity. Structures erected for NIF would be consistent with the industrial-type building form that can be found on contiguous and nearby parcels of land. Although the Laser and Target Area Building would exceed 37 m (120 ft) in height, it would not appreciably alter the visual character of Technical Area II and its environs. The visual impact of NIF would be further reduced by its remoteness from public access roads.

I.4.5.2.2 Air Quality and Acoustics

I.4.5.2.2.1 *Air Quality*

Construction Emissions. Estimated emissions from site-clearing and construction of the facilities are listed in table I.4.5.2.2.1–1. The estimates are based on characteristics of the proposed SNL location and on construction vehicle exhaust and fugitive emissions. Site clearing would occur over a period of about 5 weeks, and would produce the greatest amount of fugitive dust (PM_{10}) emissions during the construction process. ISCST2, Version 93109 [EPA 1992a-b] was used to determine the impact of site-clearing activities on ambient air quality (see section I.4.1.2.2.1). The data selected for modeling air quality were surface meteorological data and twice-daily mixing height data from nearby Albuquerque International Airport for 1987 to 1991 (EPA 1995b). The surface wind speeds and directions are summarized in an annual wind rose (see figure I.4.5.1.2–1). Detailed emission inventories associated with site clearing and facility construction; meteorological data used; and air quality model, assumptions, and input parameters are presented in Lazaro et al. (1996).

The national 24-hour PM_{10} standard is 150 $\mu g/m^3$; the 24-hour average PM_{10} background concentration representative of the SNL site is 40 $\mu g/m^3$ (table I.4.5.1.2.2–1). With conventional dust control (i.e., 50-percent control for excavation and 60-percent control for traffic on unpaved roads), maximum 24-hour average PM_{10} concentrations of 12 $\mu g/m^3$ over background are predicted at the closest site boundary (1.0 km [0.6 mi] north-northeast of NIF location).

TABLE I.4.5.2.2.1–1.—*Estimated National Ignition Facility Construction Emissions for the Sandia National Laboratories Location*

Pollutant	Total Emissions (t/yr)[a]
Particulate matter volatile organic compound	18.33[b]
Volatile organic compound	0.44
Carbon monoxide	1.23
Nitrogen dioxide	3.76
Sulfur dioxide	0.43
Lead	Negligible

[a] Metric tons (1,000 kg) per year.
[b] Includes 5.26 t/yr of fugitive emissions for site clearing using water-spray control that would occur during an approximate 39-day period in the first year and 12.7 t/yr of facility construction emissions that would occur for the remainder of the year.
Source: Lazaro et al. 1996.

Maximum PM_{10} concentrations of 52 $\mu g/m^3$, including background concentration, are considerably below the 24-hour NAAQS of 150 $\mu g/m^3$ for PM_{10}. Site clearing at SNL would be expected to last for about a month, so ambient air quality impacts associated with site clearing would be negligible, local, and temporary. Additional regulatory information is presented in section I.5.2.

Emissions During Operations. Air pollutant emissions from operation of NIF at SNL are expected to be primarily from fuel combustion and cleaning of debris shields. Emissions of solvent VOCs (ethanol) from debris shield cleaning are expected to total about 0.5 t/yr (0.55 tons/yr) (LLNL 1995b). Other potential air pollutant emission sources not considered significant are target destruction under either the direct-drive or enhanced indirect-drive options, emissions from vehicles used for freight shipments and employee commuting, and emissions from welding operations at the Fabrication Facility.

Table I.4.5.2.2.1–2 lists the estimated SNL annual air pollutant emissions based on the anticipated NIF annual energy requirements provided in table I.4.1.2.2.1–3, adjusted to recognize that at SNL, six new support buildings (with a total area of 9,988 m^2 [107,513 ft^2]) would be required out of the total complement of support buildings area of 26,722 m^2 [287,643 ft^2]).

Published emission factors (EPA 1993) were used in the calculations. Emissions of VOCs from solvent cleaning are included. For comparative purposes, table I.4.5.2.2.1–2 includes SNL 1993 site-wide emissions. More detailed information on emission estimates is provided in Lazaro et al. (1996). As indicated in table I.4.5.2.2.1–2, estimated air pollutant emissions due to NIF operation at SNL are well below 1 t/yr (1.1 tons/yr) except for nitrogen dioxide, which is about 2 t/yr (2.2 tons/yr). Estimated air pollutant emissions from NIF operations would constitute increases over SNL 1993 emission levels, ranging from an increase of 5.3 percent for PM_{10} to 227 percent for carbon monoxide. Existing ambient concentrations for these pollutants (see section I.4.5.1.2.2, table I.4.5.1.2.2–1) are well below the ambient air quality standards except for the Albuquerque County 8-hour standard for carbon monoxide. The additional emission of 0.52 t/yr (0.57 ton/yr) carbon monoxide from NIF operations might pose a problem in attainment of this standard.

SNL must comply with the Albuquerque-Bernalillo County Air Quality Control Board (1995) regulations. Construction activities would require a permit because 0.30 ha (0.74 acre) of land surface would be disturbed. As part of the permit, SNL would have to specify mitigation measures that would prevent the escape from the site of airborne particulate matter that would have more than 10 percent opacity relative to the surrounding background.

Installation of NIF external combustion units (boilers) would require a county permit before construction (Regulation No. 22). Gas-fired boilers with rated heat input greater than 105,600 MJ/hr (100 million Btu/hr) but not over 264,000 MJ/hr (250 million Btu/hr) are limited to New Source Performance Standard nitrogen oxides (NOx) emissions from 43 to 86 ng/J, depending on the heat release rate, which is a function of the furnace volume (40 CFR 60.44b). There are no New Source Performance Standard emission limits for gas-fired boilers with a rated heat input at or less than 105,600 MJ/hr (40 CFR 60.40c). VOC emissions without

TABLE I.4.5.2.2.1–2.—*Annual Emission Increases with National Ignition Facility Operation at Sandia National Laboratories*

Pollutant	1993 Emissions[a] (t/yr)	Projected National Ignition Facility Emissions[b] (t/yr)	1993 Emissions with National Ignition Facility (t/yr)	NIF Percent of 1993 Emissions

controls would be limited to less than 45.4 kg (100 lb) in any single 24-hour day or 4.54 kg/hr (10 lb/hr) (Regulation No. 11.07). Additional regulatory information is presented in section I.5.2.

I.4.5.2.2.2 *Acoustics*

During site clearing for NIF at the SNL site, noise from construction equipment would increase the average daytime outdoor sound level by 1 dB at the location of the nearest residence. The point modeled is 1,864 m (6,116 ft) north-northwest of NIF. The average sound level at this point would be expected to increase from 64 dBA to 65 dBA during hours that clearing equipment would be operating. The CNR rank, adjusted for the estimated preexisting background level and for temporal and conceptual characteristics of the sound, is expected to be "A." Noise with CNR ranks "A" through "D" is generally considered to be acceptable, with "A" representing essentially no impacts. At the "A" level, the Modified CNR method predicts no complaints from the public. The noise would occur only over a period of approximately one month and only during daylight hours.

The average outdoor daytime sound level at the nearest laboratory building would not be expected to increase. The existing average daytime sound level at this point is estimated to be 64 dBA. The adjusted CNR rank for the resulting sound is "A."

The average daytime sound level at the residential area approximately 1.6 km (1 mi) west of the construction site would not be expected to increase. The existing average daytime sound level at this point is estimated to be 63 dBA. The adjusted CNR rank for the resulting sound is "A." This sound level is not expected to result in complaints from residents in the area.

These noise level estimates are based on the assumptions given in Lazaro et al. (1996). It is possible that actual noise levels could be lower or higher than the estimates.

I.4.5.2.3 Water Resources

About 2.95 MLY (0.78 MGY) of water would be required for NIF construction (LLNL 1995b). Water requirements for NIF operations (152 MLY [40 MGY]) would increase the water use at SNL by 11 percent. Wastewater discharge would be expected to increase by about 18 MLY (4.7 MGY), which is less than 2 percent of the current wastewater volume of 1,280 MLY (336 MGY) (Wheeler 1995c). Agreement with Kirtland Air Force Base and the city of Albuquerque would have to be reached to obtain additional water supply and to discharge additional wastewater.

The proposed location for NIF has minimal flooding potential because it is outside the 500-year floodplain of Tijeras Arroyo (figure I.4.5.1.3–1) (SNL 1995b).

I.4.5.2.4 Biotic Resources

I.4.5.2.4.1 *Terrestrial Resources*

NIF (including the temporary construction laydown area) at SNL would be constructed within 10.5 ha (25.9 acres) of previously disturbed grassland habitat. The general types of impacts that could result from NIF construction at SNL would be similar to those discussed for LLNL (section I.4.1.2.4).

I.4.5.2.4.2 *Wetlands and Aquatic Resources*

The proposed NIF location at SNL does not contain, nor is it located near, any wetlands or surface water resources. Therefore, construction and operation of NIF at SNL would not be expected to adversely affect such resources.

I.4.5.2.4.3 *Rare, Threatened, and Endangered Species*

The only impacts to rare, threatened, or endangered species that might occur from construction of NIF at SNL would be displacement or avoidance of the NIF location because of human presence and noise. No impacts from operation of NIF would be anticipated.

I.4.5.2.5 Cultural and Paleontological Resources

Construction and operation of the proposed NIF would have no effect on archaeological sites or historic structures that are listed on or eligible for the NRHP, important paleontological remains, or Native American cultural resources.

I.4.5.2.6 Socioeconomics

Construction and operation of NIF at SNL would have a minor impact on the socioeconomic conditions in the economic study region and ROI described in section I.4.5.1.6. This is because the SNL is located in a somewhat diverse regional economy with extensive inter- and intraregional, national, and global economic interactions and linkages. Also, because the NIF partnership includes representatives of government, industry, and the academic sector throughout the United States, procurement and investment would be dispersed over a number of different regions, dampening the concentration of economic effects of the program.

The following sections describe the effects of construction and operation of NIF on the host region's economy and employment, and on population, housing, public finances, public services, and local transportation in the ROI.

I.4.5.2.6.1 *Regional Economic Impacts*

Slight changes in employment and economic activity levels in the economic study region would occur from local spending of employee wages, procurement of goods and services including construction materials, and other local investment associated with constructing and operating NIF. In addition to creating new jobs (direct) at the site, indirect job opportunities, such as community support services, would also be created in the economic study area as a result of these new direct jobs. The total new jobs created (direct and indirect) would contribute slightly to unemployment reduction and increased income and economic output in the regional economy during construction and operation of NIF. Table I.4.5.2.6.1–1 summarizes the potential impacts to the regional economy if NIF were located at SNL. Construction of NIF at SNL would result in a peak of more than 280 direct jobs in 1998. This construction-related procurement would indirectly create more than 1,490 jobs in the economic study area. Employment for operation would begin phasing in as construction neared completion. Direct employment related to operations is estimated at 330, with more than 340 indirect jobs created throughout the economic study area. As a result of constructing and operating NIF, the baseline compounded average annual growth rate from 1995 to 2003 would increase by 0.02 percentage points.

Peak earnings associated with the 280 direct jobs created in 1998 are projected at approximately 16.4 million dollars. Construction-related procurement would indirectly create more than 24 million dollars in regional earnings. Direct earnings related to operations are projected to reach nearly 14 million dollars, with 7.3 million dollars in indirect earnings added to the regional economy.

I.4.5.2.6.2 *Population and Housing*

Construction. Population in-migration resulting from NIF construction phase demands would peak in 1998 with a projected cumulative total of 3,065 people moving into the ROI (table I.4.5.2.6.1–1).

This population increase would result in demand for an additional 1,120 housing units in the ROI. Baseline projections of the SNL ROI housing market from 1996 (NIF construction start date) through 1998 indicate that nearly 54,000 housing units would be available. NIF-related demand for approximately 1,120 housing units in 1998 in the ROI would absorb approximately 5 percent of the vacant housing supply in the ROI. NIF would generate little demand for new housing construction because of the number of vacant housing units within the SNL region and the proximity of SNL to many communities in the Middle Rio Grande Valley that could provide both temporary and permanent housing for in-migrating workers. Most of this housing demand would be temporary and would primarily affect the renter segment of the ROI housing market.

Operations. Population in-migration resulting from NIF operation phase demands could result in an additional 660 people moving into the ROI. While the demand for housing would be longer term relative to construction, no perceptible strain on the market is expected, assuming that the general conditions associated with the housing market continue.

I.4.5.2.6.3 *Public Finance*

Construction. Given the anticipated population and economic growth associated with NIF during the construction phase, fiscal balances (revenues and expenditures) would be expected to increase for all the

TABLE I.4.5.2.6.1-1.—*Potential Socioeconomic Impacts in the Sandia National Laboratories Area*

Parameters	NIF Alternative Change Over Reference Baseline		Reference Baseline

Teachers[f]	24	5	4,895[e]	5,303

[a] Construction period would be 1996 to 2002, with peak construction projected to occur in 1998.
[b] Operating period would be 2003 to 2033, with impacts throughout the period projected to remain stable.
[c] Regional earnings are millions of constant 1994 dollars.
[d] Albuquerque.
[e] Projected 1998 fund balances for Public Finances, and projected 1998 level of service (LOS) for public services.
[f] Bernalillo County.
Source: Model results.

jurisdictions within the ROI. Short-term fiscal impacts would peak during 1998 and would then decline as construction neared completion in 2002. Since the largest percentage of socioeconomic impacts are expected to occur in Bernalillo County and the city of Albuquerque (assuming current residential patterns), these jurisdictions would experience the greatest fiscal impacts in the ROI (table I.4.5.2.6.1–1).

Operations. The increase in population and economic growth as a result of NIF operations would increase fiscal balances for all counties within the ROI, with the greatest impact in Bernalillo County and the city of Albuquerque. Fiscal impacts are projected to remain stable from the initial impact in 2003 through the duration of NIF operations.

I.4.5.2.6.4 *Public Services*

By 1998, Albuquerque would require 24 additional teachers and 10 additional doctors to maintain its current level of service. By 2003, when operations would start, 5 additional teachers and 2 additional doctors would be required over baseline conditions to maintain the current level of service.

I.4.5.2.6.5 *Local Transportation*

In 1995, SNL employed approximately 8,500 persons. Direct employment generated by NIF at SNL for the life of the project (1996-2033) would range from a minimum of 21 new jobs in 2001 to a maximum of 280 new jobs in 1998. The 280 direct jobs in 1998 could generate up to 538 new trips daily on SNL access roads (table I.4.5.2.6.1–1). Many roads near SNL have reached capacity and experience some congestion. Any additional trips generated by NIF would have the potential to aggravate the existing congestion on SNL access roads, particularly on Eubank, Gibson, Wyoming, and Louisiana Boulevards (table I.4.5.2.6.5–1).

A peak of approximately 1,490 new indirect jobs in 1998 could affect traffic flow within the Albuquerque region, depending on where these jobs are located. However, if the new indirect jobs associated with operation of NIF were sufficiently dispersed, the road network in the Albuquerque metropolitan area would likely be able to handle additional traffic generated by indirect jobs associated with NIF.

Source: DOE 1993a.

I.4.5.2.6.6 *Environmental Justice*

For the region within 80 km (50 mi) of SNL, both minorities and low-income populations constitute smaller proportions of the population than in New Mexico as a whole (section I.4.5.1.6.5). Thus, no environmental justice issues associated with regional impacts have been identified.

Neither minorities nor low-income persons are clustered disproportionately in the local vicinity of the SNL site (section I.4.5.1.6.5). Thus, local area impacts from the construction and operation of NIF would not disproportionately affect either minority or low-income populations.

I.4.5.2.7 Radiation and Hazardous Chemicals

This section describes potential radiological and hazardous chemical impacts resulting from normal operations and postulated accidents at NIF at SNL. Methods, data, and assumptions used in estimating impacts are presented in Lazaro et al. (1996).

I.4.5.2.7.1 *Normal Operations*

The general public surrounding the SNL site and workers at SNL might be exposed to small quantities of radionuclides released and radiation emitted from routine NIF operations; however, the expected levels of radioactive releases and radiation emissions are well within regulatory limits. No impacts from hazardous chemicals should occur because only minute quantities of hazardous VOCs are expected to be emitted during routine NIF operations. No impacts are expected from routine transportation of tritium targets because there would be no detectable levels of radiation outside the packages carrying the targets. Table I.4.5.2.7.1–1 summarizes the potential impacts of radiation exposures for the Conceptual Design Option and the Enhanced Option for NIF operations at SNL.

Impacts to the Public. For the Enhanced Option, the estimated radiation dose to a maximally exposed member of the public located about 1.9 km (1.2 mi) north of NIF is 0.004 mrem/yr, which is much less than the dose limit of 100 mrem/yr resulting from all pathways combined (DOE 1990). The likelihood of the maximally exposed individual contracting a fatal cancer is 1 in 17 million for the entire operational life of NIF (dose/yr x 30 yr x fatal cancer risk factor of 5×10^{-4}/rem). The estimated radiation dose to the surrounding public is 0.2 person-rem/yr; no cancer fatalities would be expected to occur in the public for the entire NIF operations at SNL.

TABLE I.4.5.2.7.1–1.—***Potential Radiological Impacts from Normal Operations of the National Ignition Facility at Sandia National Laboratories***

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (mrem/yr)	0.001	0.004
Percent of natural background	3×10^{-4}	0.001
30-year fatal cancer probability	2×10^{-8}	6×10^{-8}
Population Within 80 Km		
Dose (person-rem/yr)	0.07	0.2
Percent of natural background	3×10^{-5}	9×10^{-5}
30-year fatal cancers	0	0
Workers Onsite		
Dose (person-rem/yr)		
Non-NIF workers	0.02	0.08
NIF workers	10	10
30-year fatal cancers	0	0

Source: Model results.

For the Conceptual Design Option, radiation impacts are estimated to be about one-third of those for the Enhanced Option. No health effects would result.

Impacts to Workers. In addition to potential exposure to radionuclides, the general SNL workers outside NIF could be exposed to direct radiation resulting from high-yield experiments at NIF. For the Enhanced Option, the estimated radiation dose to these non-NIF workers at SNL is 0.08 person-rem/yr. No cancer fatalities would be expected to occur in workers for the entire NIF operations at SNL. For the Conceptual Design Option, radiation impacts are estimated to be about one-third the impacts from the Enhanced Option but still carry no risk of adverse health effects.

Potential radiation exposures inside NIF would be kept as low as reasonably achievable through facility design and administrative controls. The design objective of NIF is to keep the individual radiation worker dose to less than 500 mrem/yr. On average, it is estimated that a NIF worker would receive approximately 30 mrem/yr. No adverse health effects to workers inside NIF would be expected at this exposure level.

I.4.5.2.7.2 *Postulated Accidents*

Radionuclides and hazardous chemicals could be released from accidents postulated at NIF and during the transportation of tritium targets. Tables I.4.5.2.7.2–1 and I.4.5.2.7.2–2 summarize estimated impacts to the public and workers from postulated accidents. A description of each accident scenario evaluated is provided in Lazaro et al. (1996).

TABLE I.4.5.2.7.2–1.—*Potential Radiological Impacts Resulting from Postulated Bounding Accident Involving the National Ignition Facility at Sandia National Laboratories*

Receptor	Conceptual Design Option	Enhanced Option
Maximally Exposed Individual		
Dose (rem)	0.07	0.1
Fatal cancer probability	$4x10^{-5}$	$6x10^{-5}$
Risk (cancer fatalities/yr)	$7x10^{-13}$	$1x10^{-12}$
Population Within 80 Km		
Dose (person-rem)	1,100	1,800
Fatal cancers	0	1
Risk (cancer fatalities/yr)	$1x10^{-8}$	$2x10^{-8}$
Workers Onsite		
Dose (person-rem)	20	33
Fatal cancers	0	0
Risk (cancer fatalities/yr)	$2x10^{-10}$	$3x10^{-10}$

Source: Model results.

<u>Radiological Impacts</u>

Impacts to the Public. The public could be exposed to radionuclides released from a postulated accident at NIF. The bounding accident assumes that an earthquake would occur at the time of a maximum-yield experiment with an accidental release frequency of $2x10^{-8}$/yr. For the Enhanced Option, the estimated radiation dose to the maximally exposed member of the public is 0.1 rem. The likelihood of the maximally exposed individual contracting a fatal cancer from this exposure would be 1 in 17,000. The estimated radiation dose to the surrounding public is 1,800 person-rem. At this level of dose, one cancer fatality would be expected within the surrounding population if the accident were to occur. However, as indicated in table I.4.5.2.7.2–1, the actual risk of radiation-caused cancer fatalities from the postulated accident at SNL is essentially zero when the extremely low probability of the accident occurring during NIF operations is taken into account. The risk is the product of the estimated radiation dose, fatal cancer risk factor of $5x10^{-4}$/rem, and accident release frequency of $2x10^{-8}$/yr.

For the Conceptual Design Option, estimated radiation impacts would be about one-half the impacts from the Enhanced Option. No cancer fatalities would be expected to occur in the public if the postulated accident occurred at NIF.

Impacts to Workers. For the Enhanced Option, the estimated radiation dose to all workers at SNL is 33 person-rem. No cancer fatalities would be expected to occur among workers following the postulated accident at SNL. For the Conceptual Design Option, the estimated radiation impacts are about half the impacts from the Enhanced Option. No adverse health effects would be expected to result. The risk of radiation-caused cancer fatalities among workers would essentially be zero considering the extremely low potential for the postulated accident to actually occur. SNL has a comprehensive emergency plan, which would be expanded to incorporate NIF to ensure protection of workers in case of an accident or natural disaster.

<u>Transportation Impacts</u>. Radiological impacts associated with the transportation of tritium targets would result from a release of tritium into the environment following a transportation accident. Because tritium is a low-energy beta emitter with no associated gamma rays, there would be no radiological risks associated with incident-free (routine) transportation operations. The potential radiological impacts of transporting tritium targets were calculated for truck and air travel. It was assumed that trucks would be used to transport the tritium targets from the manufacturing sites to the nearest major airport and that cargo aircraft would be used to

TABLE I.4.5.2.7.2-2.—*Potential Radiological Risks and Consequences of Transporting Tritium Targets from Manufacturing Facilities to Sandia National Laboratories*

Manufacturing Facility	Conceptual Design Option	Enhanced Option
General Atomics		
Dose risk (person-rem/yr)	1.1×10^{-6}	8.9×10^{-6}
Fatality risk (cancer fatalities/yr)	6×10^{-10}	4×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	5×10^{-4}	1×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	8×10^{-4}	2×10^{-3}
Lawrence Livermore National Laboratory		
Dose risk (person-rem/yr)	1.2×10^{-6}	9.4×10^{-6}
Fatality risk (cancer fatalities/yr)	6×10^{-10}	5×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	6×10^{-4}	1×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	4×10^{-4}	9×10^{-4}
Los Alamos		
Dose risk (person-rem/yr)	1.5×10^{-6}	1.2×10^{-5}
Fatality risk (cancer fatalities/yr)	8×10^{-10}	6×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	2×10^{-3}	4×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-3}	4×10^{-3}
Savannah River		
Dose risk (person-rem/yr)	1.4×10^{-6}	1.1×10^{-5}
Fatality risk (cancer fatalities/yr)	7×10^{-10}	6×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	5×10^{-4}	1×10^{-3}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	5×10^{-4}
University of Rochester		
Dose risk (person-rem/yr)	1.6×10^{-6}	1.2×10^{-5}
Fatality risk (cancer fatalities/yr)	8×10^{-10}	6×10^{-9}
Nonradiological accidents[a] (fatalities/yr)	3×10^{-4}	7×10^{-4}
Nonradiological vehicular emissions (fatalities/yr)	2×10^{-4}	5×10^{-4}
Maximum Consequence Accident		
Population[b,c]		
Dose (person-rem)	0.33	3.3
Fatal cancers	2×10^{-4}	2×10^{-3}
Maximally Exposed Individual[b,d]		
Dose (rem)	1.2×10^{-4}	1.2×10^{-3}
Fatal cancer probability	6×10^{-8}	6×10^{-7}

[a] Collective population fatalities were calculated for 145 shipments (Conceptual Design Option) and 335 shipments (Enhanced Option). For example, a reported value of 4×10^{-3} fatalities suggests that no fatalities are expected for the proposed action. However, one single fatality out of the entire affected population might be expected over the course of 250 years if the same number of shipments were to continue for that length of time.

[b] The most severe accidents assumed that 100 percent of the target tritium would be released in an oxide form during an accident. Accident consequence results were determined using the RISKIND computer program which is described in Yuan et al. 1993. Stable weather conditions (Pasquill Stability Class F) with a wind speed of 1 m/s (2.2 mph) were assumed.

[c] The maximum consequences would result from an accident occurring in an urban environment. The population was assumed to extend at a uniform density of 3,861 persons/km^2 (10,000 persons/mi^2) to a radius of 80 km (50 mi) from the accident site. The population exposure pathways for urban environments included inhalation and resuspended inhalation. Urban environments were not assumed to produce food for local use or export, hence no ingestion dose was included.

[d] The maximally exposed individual was assumed to be at the location of maximum exposure. The location of the maximally exposed individual was assumed to be 380 m (1,247 ft) from the accident under stable weather conditions. Individual exposure pathways included acute inhalation during passage of the plume. No ingestion dose was considered.

Note: The transportation risk assessment assumed that 100 percent of the tritium targets would be manufactured and transported to NIF from each site. In practice, tritium targets would be produced and transported from more than one manufacturer. The transportation risk assessment was performed for offsite transportation only. Transportation risks from onsite transport of tritium targets were assumed to be negligible compared to risks from offsite transportation.

Source: Model results.

transport the tritium targets to Albuquerque International Airport. After arriving at the Albuquerque airport, the targets would be transferred to a truck for shipment to NIF at SNL.

Table I.4.5.2.7.2–2 summarizes the risks associated with the transportation of tritium targets from each of the tritium manufacturing facilities to NIF at SNL. Radiological risk from transportation activities is defined as the product of the accident consequence (dose) and the probability of the accident occurring, and was calculated by considering a wide range of accidents, from high-probability, low-consequence events to low-probability, high-consequence events (see Lazaro et al. 1996). Latent cancer fatality risks were obtained by multiplying the dose risk by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Estimated latent cancer fatality risks range from $6x10^{-10}$ to $6x10^{-9}$ per year for all cases.

Nonradiological impacts associated with the ground transport of tritium targets were calculated for both routine (incident-free) and accident conditions. Nonradiological population risks for routine operations were calculated by multiplying the distance traveled by truck in urban population density zones by a risk factor for latent mortality from pollutant inhalation (Rao et al. 1982). Nonradiological population risks resulting from vehicular accidents were calculated in a similar manner by multiplying the state-specific accident fatality rate by the distance traveled by truck in the state.

The maximally exposed individual and population doses were calculated for a transportation accident involving the release of the entire tritium cargo (assumed to be five tritium targets). Radiological impacts resulting from a potential maximum-consequence accident were assessed for a general population located in an urban population density zone. The maximally exposed individual was assumed to be exposed unshielded as the plume passed at a distance resulting in the largest dose to the individual. Radiological consequences were assessed for worse-case weather conditions (Pasquill Stability Class F) for both the collective population and the maximally exposed individual. For assessment purposes, it was assumed that the entire tritium cargo would be released to the environment in oxide form. The estimated number of latent cancer fatalities from the maximum-severity transportation accident was calculated by multiplying the population committed effective dose equivalent by 0.0005 latent cancer fatalities per person-rem (ICRP 1991). Table I.4.5.2.7.2–2 summarizes the impacts of a maximum-consequence accident during transportation of tritium targets.

Hazardous Chemical Impacts. A number of chemical accidents (including one caused by an aircraft crash) were considered in evaluating potential impacts on members of the public or nearby workers at NIF (Lazaro et al. 1996). The four accidents likely to have the greatest impacts were selected for more detailed study. These four accident scenarios are as follows:

- A mercury release from the ignitron switches
- A combined alumina/silica release from the target chamber
- A carbonyl fluoride release from the optics treatment area
- A hydrogen fluoride release from the optics treatment area

A modeling study was conducted for each of the four release scenarios. More details, including predicted concentrations, are provided in Lazaro et al. (1996). The modeling study applied a dispersion model to each of the releases and used a health criterion representative of acute impacts from an exposure that might happen once in a lifetime. The health criterion (ERPG-2 level) was the concentration below which, if exposure occurred for an hour, the exposed individual could still avoid irreversible health effects by taking emergency action. The results of the modeling yielded the following conclusions:

- The threat zone from each of the four accidents would not extend to the boundary with the public under either typical or extreme meteorological conditions.
- Nearby buildings and personnel outside would be at risk if any of the four accidents occurred. The assumptions were made that the release would not be inhibited by walls of NIF Laser and Target Area Buildings and that the wind

would take the plume away from the building. The distances beyond which concentrations would fall below the ERPG-2 level from each of the accidents are as follows:

- Mercury scenario—237 m (778 ft) for both the Conceptual Design and Enhanced options
- Alumina/silica scenario—174 m (571 ft) for the Conceptual Design Option and 231 m (758 ft) for the Enhanced Option
- Carbonyl fluoride scenario—70 m (230 ft) for both the Conceptual Design and Enhanced options
- Hydrogen fluoride release—101 m (331 ft) for both the Conceptual Design and Enhanced options

The hazard zones for the Conceptual Design Option and Enhanced Option are the same for accidents 1, 3, and 4. These zones are for persons outdoors. People in nearby buildings would likely be protected because the release (typically lasting for 15 minutes) would pass by the buildings with little infiltration. Typically, the concentrations experienced inside single-story structures are a factor of five or more lower than the outdoor levels. Personnel in the Laser and Target Area Building and those outside in the immediate vicinity might be affected.

I.4.5.2.8 Waste Management Impacts

This section evaluates wastes generated by NIF that might affect current waste management practices at SNL during construction, normal operation, and the ultimate decommissioning of NIF if it were located at SNL.

I.4.5.2.8.1 *Waste Generation and Management During Construction and Operation*

The contractor would be required to remove construction-related wastes, including fill generated by site foundation work, from SNL for disposal by the contractor.

During operation, various low-level, mixed, hazardous, and nonhazardous wastes would be generated at NIF. The same waste-handling methods would be used for both the Conceptual Design Option and the Enhanced Option. Although total waste quantities would be somewhat higher for the Enhanced Option, no changes in handling methods would be necessary. Table I.4.1.2.8.1–2 (section I.4.1.2.8.1) lists the quantities of wastes that would be generated (by category) for both the Conceptual Design Option and Enhanced Option, and the following sections describe the proposed disposition of those wastes.

Low-Level Waste. Onsite disposal of LLW at SNL was terminated in December 1988. Currently, all newly generated LLW is stored temporarily above ground at generator sites or in transportation containers at the inactive Technical Area III disposal site.

The Radioactive and Mixed Waste Management Facility at SNL was completed in 1990. Because of changes in regulations during construction, some facility upgrades are required before operations can begin. This 730-m^2 (7,858-ft^2) facility will serve as a centralized packaging and storage facility for LLW and LLW-mixed waste that meet the facility waste acceptance criteria. It is projected that the Radioactive and Mixed Waste Management Facility will be operational in 1996.

Additionally, SNL has an approved program for the NVO-325 "Nevada Test Site Defense Waste Acceptance Criteria, Certification and Transfer Requirements." All NIF solid LLW could be added to the program and disposed of at the NTS LLW disposal site. Liquid radioactive waste could be solidified and disposed of at NTS as well.

Mixed Waste. As was the case for LLW, onsite disposal of mixed waste at SNL was also terminated in December 1988, and all newly generated mixed wastes are stored temporarily above ground at generator sites or in transportation containers at the inactive Technical Area III disposal site. The Radioactive and Mixed Waste Management Facility is expected to be operational in 1996 and would be able to accept NIF-generated mixed wastes. When the treatment of the hazardous portion of the mixed waste is not feasible, the waste would be stored onsite until DOE determined the appropriate disposal option for mixed waste.

Hazardous Waste. All RCRA-regulated wastes generated by SNL (except mixed waste) are transported offsite for disposal at EPA-permitted treatment, storage, and disposal facilities. Chemical wastes generated by SNL R&D activities are collected from generator locations, segregated according to DOT hazard class, and transported to the RCRA-permitted Hazardous Waste Management Facility for storage. At Hazardous Waste Management Facility, the wastes are consolidated and packaged according to EPA-permitted treatment, storage, and disposal facilities or recyclers for final disposition. Packaged wastes are transported by EPA-permitted carriers to EPA-permitted treatment, storage, and disposal facilities or recyclers for final disposition. The same procedure would be used for NIF-generated hazardous wastes.

During 1993, 484 t (533 tons) of chemical waste were managed by SNL's chemical waste management program, including 141 t (155 tons) of RCRA-regulated hazardous waste and 343 t (378 tons) of nonregulated industrial waste. NIF-generated hazardous waste would not adversely affect SNL's capacity to manage this waste stream.

Nonhazardous Wastes. SNL nonhazardous wastes are managed by the Waste Operations Department of the Environmental Operations Center and are disposed of at the solid waste landfills of two local cities of Albuquerque and Rio Rancho. NIF-generated, nonhazardous waste streams would be incorporated into the existing procedures.

Possible Waste Minimization During Operation. A formal Waste Minimization and Pollution Prevention Awareness Program was initiated in 1989. The program addresses waste reduction activities for all media (air, water, and solid) for nonhazardous, hazardous, mixed, and radioactive wastes. The program's objective is to foster a philosophy to conserve resources and make pollution prevention an integral part of design, operations, and maintenance.

If NIF were to be sited at SNL, the Waste Minimization and Pollution Prevention Awareness Program staff would work with NIF design and operations staff to identify opportunities for waste minimization and pollution prevention. Strategies for achieving these opportunities would be designed by the program staff in conjunction with NIF staff.

Impacts on Existing Waste Management Capabilities at SNL. Data on the estimated waste generation by NIF (table I.4.1.2.8.1–2) and on current waste management capacities at SNL have been used to evaluate the capability of the existing SNL facilities to undertake the various waste management tasks associated with NIF. For reference, table I.4.5.1.8–1 lists the current waste management capacity at SNL, and table I.4.5.2.8.1–1 shows the anticipated impact of NIF wastes on that capacity. Table I.4.5.2.8.1–2 compares the NIF waste generation rate to the annual handling/treatment capacity at SNL.

As discussed above, SNL waste management operations are focused around two facilities, the Hazardous Waste Management Facility for hazardous waste management, and the Radioactive and Mixed Waste Management Facility for radioactive and mixed waste management. All hazardous wastes are staged, processed, and packaged for shipment to RCRA-permitted commercial treatment, storage, and disposal facilities at the Hazardous Waste Management Facility. All mixed and radioactive wastes are currently stored at the generator sites throughout SNL or in transportation containers at SNL's inactive disposal site in Technical Area III. These wastes will be transferred to the Radioactive and Mixed Waste Management Facility when it is opened for operations. At the Radioactive and Mixed Waste Management Facility, LLW will be temporarily stored and then packaged for shipment to offsite disposal facilities to be selected by DOE. Mixed wastes will be processed and treated, then packaged for shipment to offsite facilities approved for either treatment or disposal.

I.4.5.2.8.2 *Waste Management at Sandia National Laboratories During National Ignition Facility Decommissioning*

NIF would be decommissioned after 30 years of operation. The major activated/contaminated components would be located in the target area, so decommissioning of this component poses the most complex operation. The procedures would be similar to those discussed in previous sections for NIF decommissioning at other candidate sites.

Decommissioning of NIF Laser. During decommissioning of the laser systems, the waste quantities

TABLE I.4.5.2.8.1–1.—*Impact of Estimated National Ignition Facility-Generated Waste on Waste Storage at Sandia National Laboratories*

Category	NIF-Generated Waste/Year (m^3)		Years to Fill Storage with NIF Flow Alone[a]		Is Existing or Planned Storage Capacity Adequate	
	Solid[b]	Liquid[b]	Solid	Liquid	Solid	Liquid
Low-Level						
Conceptual design total	2.98	0.60	$0.3x10^3$	NA[c]	Yes	Yes
Enhanced total	7.25	1.56	$0.1x10^3$	NA[c]	Yes	Yes
Mixed						
Conceptual design total	0.34	2.00	297	NA[c]	Yes	Yes
Enhanced total	0.88	4.98	114	NA[c]	Yes	Yes
Hazardous[d]						
Conceptual design total	8.0	2.3	NA[e]	NA[e]	NA[e]	Yes[f]
Enhance total	8.0	4.6	NA[e]	NA[e]	NA[e]	Yes[f]

[a] The following values for the densities of the materials were assumed: molecular sieves: density of diatomaceous earth (0.27 g/cm^3); personal protective equipment and wipes: density of paper (0.4 g/cm^3); pre- and high-efficiency particulate air filters: density of charcoal (1.8 g/cm^3); paper capacitors: density of paper (0.4 g/cm3); hardware from chamber: density of 50 percent aluminum and 50 percent stainless steel (5.3 g/cm^3).

[b] The total amount of the low-level waste was found by adding the values in the column "Cleaned" of table I.4.1.2.8.1–2 to the column "Low-Level" of the same table. The density of the debris shield was assumed to be the density of iron (7.87 g/cm^3). The density of the low-level liquid waste was assumed equal to 1.0 g/cm^3. The amount of the "cleaned" personal protective equipment and wipes/general cleaning was added to he solid low-level radioactive waste.

[c] All liquid low-level waste and mixed waste are currently stored temporarily at the site of generation. SNL is conducting treatability studies before applying for RCRA permit for treating and storage of liquid low-level waste and mixed waste.

[d] The values for the hazardous waste are the sum of Laser and Target Area Building and Optics Assembly Area values.

[e] Hazardous waste is stored temporarily and then shipped offsite to a commercial RCRA waste disposal facility.

[f] Temporarily stored, then shipped offsite to RCRA-permitted storage/disposal facility.

Note: NA - not applicable.

listed in table I.4.1.2.8.2–1 would be handled as discussed in the sections on hazardous, nonhazardous, radioactive, and mixed waste management above.

Decommissioning of NIF Target Area. The waste quantities listed in table I.4.1.2.8.2–2 from target area decommissioning would be handled as discussed in the sections on hazardous, nonhazardous, radioactive, and mixed waste management above. There are no special issues related to any waste topics, including tritium handling. All waste handling would be done in accordance with the waste management procedures outlined above. Quantities and dose rates listed in tables I.4.1.2.8.2–3 and I.4.1.2.8.2–4 do not present any special problems.

I.4.6 No Action

Under the No Action alternative, NIF would not be constructed or operated. Without the facility, the missions to be accomplished by operation of NIF (sections I.2.2 and I.2.3) would be adversely affected. Any other course of action could have its own unique set of environmental impacts that would differ from those of NIF. Thus, while the No Action alternative would avoid the direct impacts of NIF, it might also result in other impacts. The nature and extent of such impacts would depend on the ultimate course of action taken to ensure the Nation's nuclear deterrent and cannot be analyzed at this time.

If NIF were not constructed and operated, the impacts of these activities would not occur at any of the alternative sites. Land use, air quality, noise, water resources, biotic resources, cultural and paleontological resources, radiological and hazardous chemical environments, and waste management would remain as described in the affected environment sections for each of the alternative sites (sections I.4.1.1, I.4.2.1, I.4.3.1, I.4.4.1, and I.4.5.1). Current land use would continue. There would be no changes in the visual environments. Other programs at the alternative sites would continue to generate air pollutants, use water, and produce wastes.

If NIF were not constructed and operated, a number of socioeconomic and operational impacts could occur at several of the candidate sites. At LLNL, the Nova Facility would continue to operate, but with a changed mission to support stockpile stewardship (section I.3.3). All NIF-dependent functions of the ICF program would be discontinued at LLNL, LANL, and SNL. For the purpose of this PSA, it was assumed that no NIF would directly result in the loss of approximately 100 full-time equivalent employees at LLNL, 20 employees at LANL, and 20 employees at SNL. Reductions in personal consumption expenditures by laboratory personnel and in program-related operational procurement expenditures would result in additional indirect effects on the regional economy surrounding each of these sites because the demand for capital investment, commodities, and services would decline. These additional indirect effects would include the loss of approximately 53 additional jobs in the economic study region for LLNL, 7 jobs in the economic study region for LANL, and 9 jobs in the economic study region for SNL. Overall, the loss of jobs as a result of NIF not being constructed would cause a decrease in projected average annual employment growth in the economic study region of the three candidate sites. Although the loss of jobs in the economic study region might lead to some out-migration from the ROI at each site under the No Action alternative, the extent of out-migration is not known. The impact of the No Action alternative on population, housing, public finance, and public services in the ROI at each site cannot, therefore, be estimated. The No Action alternative would slightly reduce the average number of daily trips to each site (100 at LLNL, 20 at LANL, and 20 at SNL).

No change in socioeconomic conditions would occur at NTS and NLVF under the No Action alternative. Baseline conditions would continue as described in sections I.4.3.1 and I.4.4.1.

I.4.7 Mitigation

I.4.7.1 *Summary of Mitigation Commitments*

The following section addresses specific mitigative measures that the candidate sites have enacted for any construction action, including potential NIF construction. While each of these mitigative measures may be minor, their overall combined contribution would significantly reduce impacts to the environmental resources of the candidate sites. The evaluations of environmental consequences of NIF construction and operation addressed in sections I.4.1.2, I.4.2.2, I.4.3.2, I.4.4.2, and I.4.5.2 are based on the assumption that the mitigative measures would be carried out if the proposed action was undertaken.

I.4.7.1.1 Biotic Resources

No more than 60 days before the start of construction at LLNL, a preconstruction survey for protected and sensitive biological resources would be conducted within the proposed NIF and laydown locations, as well as the access routes and bridge that would connect these locations. Exclusion or buffer zones would be established around any sensitive locations in these areas. Appropriate mitigation measures would be implemented to avoid or minimize potential adverse impacts to protected and sensitive resources, such as Federal- or state-listed species.

Reclamation plans for the staging area, bridge, and access road are to be developed. Reclamation activities would include removal of all temporary construction features, stabilization of soils to prevent erosion, and reseeding with appropriate plant species.

At LANL, an ecological studies team (see DOE 1995b) would be consulted for the following:

- To conduct a preconstruction site-specific survey
- To determine whether any raptor nesting sites were present in or around the construction area (if nesting sites were discovered, an ecological studies team would recommend spatial and/or temporal restrictions on construction activities)
- To approve all tree removal (live or snag)
- To recommend mitigation measures before construction disturbance
- To help determine plant species for revegetation activities

At LANL, all light sources during construction and operation of NIF would have to be arranged so that light is not directed toward LANL canyons in order to protect habitat that might be used by the Mexican spotted owl (Risberg 1995). Because fencing could affect wildlife movements, an ecological studies team would be contacted to determine whether fencing around NIF would need to be minimized.

At NTS, preconstruction surveys would be required to determine the occurrence of listed plant species in the area to be disturbed (DOE 1995c). Mitigative measures required for the desert tortoise would include (1) conducting surveys for the tortoise and removing any tortoises found in affected areas; (2) conducting periodic inspections and eventual backfilling, covering, or installing of tortoise-proof fencing around open construction trenches and excavations; and (3) reducing vehicle speed limits on site roadways (DOE 1995c).

I.4.7.1.2 Cultural and Paleontological Resources

No archaeological sites or historic structures currently listed on or eligible for the NRHP, or paleontological resources, are present within the areas proposed for NIF at the five candidate sites. Thus, mitigation measures would not be necessary.

I.4.7.2 Potential Mitigation

The candidate sites have committed to a broad spectrum of mitigative measures that would minimize adverse environmental impacts from the construction and operation of NIF. The following are additional mitigative measures that may be adopted at one or more of the candidate sites.

I.4.7.2.1 Land Use

During construction at the LLNL site, traffic should be monitored along Greenville Road between Interstate 580 and East Avenue. A road directly accessing the proposed site from Greenville Road could reduce traffic congestion if monitoring indicated a problem. If the option I staging area is selected, the temporary access road from Patterson Pass Road could also serve as access to NIF during operations. For NLVF, traffic on Commerce Avenue along the western edge of the installation and on Losee Road near the facility's south gate should be monitored during and after the construction phase. At all sites, construction traffic should be encouraged to avoid essential gates and other site access points during morning traffic peaks.

I.4.7.2.2 Visual Resources

Fugitive dust suppression techniques during the construction phase of the NIF project would be impacted. While landscaping could improve the visual quality of any buildings constructed for NIF, landscaping is particularly recommended for the proposed site at LANL. Tree removal on the proposed NIF location at LANL should be monitored to ensure that the fewest trees possible are taken.

I.4.7.2.3 Air Quality

Generation of fugitive particulate (PM_{10}) emissions (dust) during site clearing and facility construction could be mitigated with the use of appropriate dust control measures. With conventional dust control methods using water spray, an estimated 50 percent control can be achieved during earthmoving activities, and 60 percent control can be achieved for traffic on unpaved roads (EPA 1989). The addition of dust suppressants such as calcium to the water can decrease unpaved road traffic emissions by up to 90 percent of uncontrolled levels (Nalco 1987). Additives can also decrease earthmoving dust emissions by up to 65 percent (EPA 1989). Uncontrolled nitrogen oxide air pollutant emissions from gas- or liquid petroleum gas-fired external-combustion (boiler) sources can be reduced by best available control technology (for example, by use of boilers equipped with nitrogen oxide controls). Boilers above a specific size are required by regulation to install best available control technology, which defines the amount of reduction of nitrogen oxide emissions required.

The public should be notified in advance that elevated noise levels would occur during daylight hours for up to several months (depending on the candidate site selected) during the construction period.

I.4.7.2.4 Biotic Resources

To ensure compliance with the *Migratory Bird Treaty Act*, a determination should first be made as to whether protected migratory birds nest in the areas to be cleared for NIF (this activity would include conducting site surveys to locate any nests of migratory birds). If nests or eggs of migratory birds were present, the U.S. Department of the Interior would be consulted regarding the appropriate precautions that might be necessary during construction. This consultation should occur as far in advance of construction as practicable.

Additionally, the following mitigation measures might be needed:

- If migratory birds were nesting at the proposed NIF construction areas, clearing operations would be avoided during the breeding season, where practicable.
- To minimize disturbance of wildlife, construction workers would be prevented from entering undisturbed areas adjacent to any construction sites.
- The area around NIF (and the staging area at LLNL) would be revegetated with native plants, in keeping with the spirit of the Presidential Memorandum of April 26, 1994 (*Environmentally and Economically Beneficial Practices on Federal Landscaped Grounds*).
- Construction crews would receive environmental briefings as appropriate to alert them to specific areas of concern and to explain the reasons for such concerns.
- Passive reminders (such as signs) to warn work crews to use only designated access roads or to inform them that they are working in an environmentally sensitive area should be considered (particularly at LANL and NTS). Passive reminders should also be considered for the option I staging area and its access road at LLNL to avoid potential impacts to wetlands in the Arroyo Las Positas. Use of temporary physical barriers (such as fencing) to remind crews to avoid short cuts across sensitive areas should also be considered.
- Construction traffic would be restricted to existing roads, whenever possible.
- Parking and equipment storage areas would be limited to as few designated sites as possible, in order to limit unnecessary disturbance of vegetation.
- Pre-construction surveys of the NIF location would be made to determine if any rare, threatened, or endangered species were present. If listed species are found, specific mitigation measures would be developed in conjunction with the U.S. Fish and Wildlife Service and/or appropriate state agencies entrusted with natural resources management authorities to minimize impacts to the species from construction of NIF.

I.4.7.2.5 Pollution Prevention and Waste Minimization During Operation

Several actions or technologies have been identified that, if successfully implemented, could significantly reduce or even eliminate certain forms of pollution or waste now projected for generation by NIF. In addition, some steps might be taken to reuse or recycle waste material. The proposed technology and procedures are briefly described here and in section I.4.1.2.8.1. That information is based on the assumption that various new methods proposed to minimize the waste streams would be successfully implemented. The data in table I.4.1.2.8.1–3 represent an optimistic lower limit of waste generation. Comparison of these projections with the data in table I.4.1.2.8.1–2 indicates that pollution and waste could be reduced significantly, that is, by a factor of 2 to 10. Some key aspects of the minimization plan relative to NIF components and operations are outlined below.

The life span of a molecular sieve could be extended if, during flushing, the tritium was captured at a low atmospheric pressure, increasing the tritium concentration. One method to accomplish this would be to flush the chamber at subatmospheric pressures. A second method would be to pump the tritium (following a NIF experiment) through liquid helium cryopanels.

The amount of scrap hardware requiring removal from the chamber could be minimized by using low-activation materials, minimizing the mass and volume of structures, and discouraging the use of temporary setups.

Installation of an oil-less vacuum-roughing pump system could eliminate 200 L (53 gal) of liquid mixed waste each year. Such pumps have become available only recently, and their suitability for use at NIF would be evaluated; however, their cost and dependability remain uncertain.

Cleaning of the debris shields with carbon dioxide pellets could remove the anti-reflective coating and particulate matter. This procedure, if successful, could significantly reduce or even eliminate the production of radioactive sodium hydroxide, which is currently listed as liquid mixed waste.

A large fraction of the general chemical waste from the Optics Assembly Building would involve the anti-reflective coating solution. One method for reducing this waste would be to distill the ethanol from the waste solution and reuse it as a cleaner.

Capacitors in the Laser and Target Area Building would be the predominant source of hazardous waste. This source could be reduced by purchasing units with a longer service life. This decision, however, would depend on the development and cost of longer-lasting capacitors.

In addition to reducing or eliminating the liquid LLW from cleaning the debris shield, carbon dioxide cleaning might also reduce solid LLW. Far fewer wipes would be needed for general decontamination purposes if a "general decontamination carbon dioxide station" were developed and functional. Such a system might also reduce other liquid LLW streams, as well as solid-mixed and liquid-mixed streams, because carbon dioxide could remove activated particulates, as well as tritium contamination, and eliminate the need for solvents.

I.4.8 Unavoidable Adverse Effects

Construction and operation of NIF at LLNL, LANL, NTS, NLVF, or SNL could result in adverse environmental impacts. The impact assessment sections (I.4.1.2, I.4.2.2, I.4.3.2, I.4.4.2, and I.4.5.2) have identified these potential adverse impacts along with mitigative measures (see section I.4.7) that could be implemented to either avoid or minimize these impacts. The remaining unavoidable residual adverse effects following mitigation are discussed below.

Depending on the site selected, up to 18.2 ha (45 acres) of land could be disturbed to construct NIF and provide additional supporting infrastructure and access roads (table I.3.6.1–1). Land requirements would represent less than 11 percent of the uncommitted land at each candidate site except at NLVF, where 56 percent (3.2 ha [7.9 acres]) of the uncommitted land would be required. In the areas disturbed for construction, soil erosion from wind and stormwater runoff would be minor.

Construction and operation of NIF would generate air pollutants that have the potential to exceed Federal and state ambient air quality standards and guidelines. Concentrations of particulate matter and TSPs are expected to be close to or exceed the 24-hour ambient PM_{10} and TSP standards during peak construction periods under dry and windy conditions. Such exceedances are not uncommon for large construction projects. Air pollutant concentrations during operation are expected to remain within Federal and state ambient air quality standards, except for 1-hour ozone concentrations at LANL and SNL, 1-hour nitrogen dioxide concentrations at LLNL, 1-hour carbon monoxide levels at SNL, and 24-hour PM_{10} at NTS.

For each of the candidate sites, use of water is unavoidable, but would not represent an adverse impact.

Loss of wildlife habitat within the disturbed areas would be unavoidable. However, only one percent or less of uncommitted lands at candidate sites with high-quality habitat (LANL and NTS) would be potentially disturbed by NIF construction. Additionally, the potential NIF locations at these sites are not critical habitat for threatened or endangered species and do not consist of ecotypes rare to the area. Construction of NIF would have some unavoidable adverse effects on biota. Larger and more mobile animals could move out of the construction areas to similar habitats nearby, but smaller, less mobile animals could be destroyed during land-clearing activities. Rare, threatened, or endangered species could be affected directly or indirectly by construction of NIF. Where potential exists for impacts on listed species, mitigation measures would be developed in consultation the U.S. Fish and Wildlife Service or the state's Department of Natural Resources.

No unavoidable adverse impacts to cultural resources would be expected at any of the NIF candidate sites.

Few unavoidable adverse impacts related to socioeconomic issues would occur in any of the ROIs for the NIF candidate sites. Burdens on community infrastructure would increase, but subsequent effects on the public finances of local governments in the ROI would be positive for the most part. Localized increases in traffic would result from construction and operation of NIF. No adverse, disproportionate environmental justice concerns would be expected at any of the candidate sites, except for a minor potential to impact minority populations in the ROI for NLVF.

Over the 30-year operational life of NIF, the public would be exposed to a very small dose of radiation (table I.3.6.1–1). No cancer fatalities would be expected to occur from exposures associated with routine NIF operations under either the Conceptual Design or Enhanced options. A radiological accident at NIF would not cause any cancer fatalities to the public, except possibly at NLVF and SNL. At NLVF, one death could occur from a maximum-release accident scenario under the Conceptual Design Option or two cancer deaths could occur for the maximum-release accident under the Enhanced Option. At SNL, one cancer death is calculated as possible for a maximum-release scenario under the Enhanced Option. However, because the chance of such an accident actually occurring is so low, the risk of such deaths is extremely unlikely. The cancer fatality risk associated with radiological exposure from an accident involving transport of the NIF tritium targets would range from $8x10^{-10}$ to $1x10^{-8}$; the nonradiological fatality risks associated with vehicular emissions and accidents are in the $1x10^{-3}$ to $1x10^{-4}$ range (table I.3.6.1–1).

Although each candidate NIF site would implement waste minimization techniques, the generation of additional low-level, hazardous, and nonhazardous wastes would be unavoidable. However, all candidate sites have current or planned capacity to handle wastes associated with NIF (although this would entail offsite shipment for some of the wastes for all sites but LANL) (table I.3.6.8–1).

I.4.9 Irreversible and Irretrievable Commitments of Resources

Resources that would be committed irreversibly or irretrievably during construction and operation of NIF include materials that could not be recovered or recycled and materials or resources that would be consumed or reduced to irrecoverable forms. Use of concrete, steel, fuel, power, and other materials would constitute an irreversible and irretrievable commitments of those resources (see table I.4.9–1). The use and consumption of these resources are believed appropriate and justified in terms of the national importance of the missions and objectives of NIF.

TABLE I.4.9–1.—*Irreversible and Irretrievable Commitments of Resources*

Resources	No Action	LLNL	LANL	NTS	NLVF	SNL
Construction Materials						
Concrete (m^3)	None	$5.3x10^4$	$5.6x10^4$	$5.5x10^4$	$5.7x10^4$	$5.6x10^4$
Steel (t)	None	$7.0x10^3$	$8.5x10^3$	$8.0x10^3$	$9.0x10^3$	$8.5x10^3$
Water (L/yr)[a]	None	$1.5x10^6$	$2.0x10^6$	$1.8x10^6$	$2.3x10^6$	$2.0x10^6$
Fuel						
Diesel fuel (L)	None	$8.0x10^5$	$1.1x10^6$	$1.0x10^6$	$1.2x10^6$	$1.1x10^6$
Natural gas (m^3)	None	$4.8x10^3$	$6.5x10^3$	$6.0x10^3$	$7.3x10^3$	$6.5x10^3$
Electricity (kWh)	None	$1.3x10^4$	$1.7x10^4$	$1.6x10^4$	$2.0x10^4$	$1.7x10^4$
Operations (Annual)						
Water (L)	None	$1.1x10^7$	$2.1x10^7$	$2.0x10^7$	$2.2x10^7$	$2.1x10^7$
Diesel fuel (L)	None	$7.0x10^2$	$2.8x10^3$	$2.2x10^3$	$3.7x10^3$	$2.8x10^3$
Natural gas (m^3)	None	$6.1x10^5$	$8.1x10^5$	$7.5x10^5$	$9.0x10^5$	$8.1x10^5$
Electricity (kWh)	None	$3.0x10^7$	$4.2x10^7$	$3.8x10^7$	$4.9x10^7$	$4.2x10^7$

[a] Based on 250 construction days/yr.
Note: Based on new buildings required for each site.
Source: Foley 1996.

The land that would be occupied by NIF could ultimately be returned to open space if buildings, roads, and other structures were removed and the land revegetated. Alternately, the NIF buildings could be modified for use in other programs. Therefore, the commitments of land to the NIF project is not necessarily irreversible. However, land rendered unfit for other purposes, such as that set aside for radiological and hazardous chemical waste disposal facilities, represents an irreversible commitments of those resources because wastes in belowground disposal areas may not be completely removed at the end of the project. The land could not be restored to its original condition or to minimum cleanup standards, nor could the site feasibly be used for any other purposes following closure of the disposal facility. This land would be perpetually unusable because the substrata would not be available for other potential intrusive uses such as mining, utilities, or foundations for other buildings. However, the surface area appearance and biological habitat lost during construction and operation of the disposal facilities could, to a large extent, be restored.

The irreversible and irretrievable commitments of material resources for NIF would include construction materials that could not be recovered or recycled, materials that would be rendered radioactive but could not be decontaminated, and materials consumed or reduced to unrecoverable forms of waste. Where construction is necessary, the required materials would include wood, concrete, sand, gravel, plastics, steel, aluminum, and other metals. These construction resources, except for those that could be recovered and recycled with current technology, would be irretrievably lost. However, none of these identified construction resources are in short supply, and all are readily available in the vicinity of locations being considered for NIF. The commitment of materials to be manufactured into new equipment that could not be recycled at the end of the project's useful lifetime would be irretrievable.

Consumption of operating supplies, miscellaneous chemicals, and gases, while irretrievable, would not constitute a permanent drain on local resources or involve any material in critically short supply in the United States as a whole. Materials consumed or reduced to unrecoverable forms of waste, such as radioactive waste, are also irretrievable. However, strategic and critical materials, or resources having small natural reserves, are of such value that economics promotes recycling. Plans to recover and recycle as much of these valuable, depletable resources as is practical would depend on need, and each item would be considered individually at the time a recovery decision is required.

The irretrievable commitment of resources during construction and operation of NIF would include the consumption of fossil fuels used to generate heat and electricity. Energy would also be expended in the form of diesel fuel, gasoline, and oil for construction equipment and transportation vehicles. The estimated amount of energy required to construct and operate NIF is presented in table I.4.9–1 and would be irretrievable.

I.4.10 Relationships Between Short-Term Uses and Long-Term Productivity

Adequate land exists at each of the five candidate sites to support ongoing programs and other foreseeable short-term uses of undeveloped areas. Construction of NIF at LLNL would require about 8 ha (20 acres) of land, which represents about 11 percent of land currently available for development within site boundaries. An additional 2.0 ha (4.9 acres) at LLNL would be used for a staging area during the construction period. The NIF land requirements at LANL would be 4 ha (10 acres), or about 1 percent of the land available for development. Both NTS and SNL are relatively large sites and would not experience conflicts between NIF construction/operation and short-term uses of land suitable for development. NIF construction at NTS would require an area of 18.2 ha (45 acres) within Area 22. Area 22 would have about 200 additional acres for future development, a relatively small percentage of a site with an area of approximately 350,000 ha (867,000 acres). SNL would require about 11 ha (27 acres) for NIF construction. This area represents about 7 percent of the land currently available for development but a much smaller portion of available land throughout the DOE complex.

The NLVF site consists of only 32 ha (80 acres), most of which is already developed. The NIF project would require approximately 4 ha (10 acres), which represents 56 percent of the land at NLVF that could be used for future development.

The use of land on any of the five candidate sites being considered for NIF would enhance the long-term productivity on each site in two ways. First, NIF represents long-term R&D production functions compatible with historic nuclear weapons support and would require a technically competent, skilled, and stable workforce. Second, in light of current reductions in the nuclear weapons stockpile, the lack of new weapons development or production, the moratorium on nuclear testing, and concerns about safety and reliability in the aging stockpile, DOE plans to downsize or consolidate existing facilities and provide upgraded or new experimental and computational capabilities that would enhance the long-term productivity of the selected sites.

Each candidate site would require the use of additional land (either onsite or offsite) for disposal of radiological and hazardous materials. Such short-term usage would remove this land from other beneficial uses indefinitely because of the presence of long-lived hazards. Disposal of solid nonhazardous waste generated from NIF construction and operation would continuously require additional land at a sanitary landfill site. This land would be unavailable for other uses over the long term. LLW would require additional space for onsite storage and processing and would involve the commitment of associated land, transportation, processing facilities, and other disposal resources. Creation of land disposal facilities would allow the site to be productive for the long term by protecting the overall environment and complying with Federal and state environmental requirements.

Land clearing and construction activities for NIF would eliminate habitat and destroy or displace wildlife. Although some destruction would be inevitable during and after construction, these losses would be minimized by site selection and through environmental reviews at the site-specific level. In addition, short-term disturbances of previously undisturbed biological habitats from the construction of new facilities could cause long-term reductions in the biological productivity of an area. These long-term reductions could occur primarily at LANL and NTS, where forested and desert habitat would be cleared, respectively. These habitats recover slowly from disturbances.

I.4.11 Cumulative Impacts

Cumulative impacts refer to the effect on the environment resulting from the incremental effects of the proposed action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. Because NIF would be located at a large multipurpose DOE laboratory, this section examines the potential impacts (at each candidate site) of constructing and operating NIF relative to other similar impacts of DOE laboratory operations, as well as similar events occurring elsewhere in the region.

In addition to the regional economic impacts addressed for each of the candidate sites, construction and operation of the proposed NIF will create additional economic activity throughout the United States. At the national level, NIF would create 500 direct jobs during the peak construction and target/laser assembly phase. Indirect economic activity resulting from procurement for capital, materials, and services, and investment in research and development will create an additional 5,400 jobs throughout the U.S. economy. Direct economic impacts from NIF operations include support for at least 330 full-time positions. Continued investment in research and development and procurement associated with maintenance and operation will indirectly create more than 1,200 jobs throughout the U.S. economy, sustained for the duration operational campaign.

I.4.11.1 *Lawrence Livermore National Laboratory*

Siting NIF at LLNL would be consistent with land-use plans for both LLNL and for the town of Livermore. The proposed location for NIF is within an area of similar structural features and increasing land development; therefore, NIF would not contribute to cumulative changes in the visual landscape of the surrounding portions of Livermore.

In the LLNL region, the 24-hour average background concentration for particulates, as measured by PM_{10}, is currently above the state ambient air quality standards. Fugitive dust emissions from construction of NIF would be an incremental addition to the already existing regional environmental impact. The greatest potential fugitive dust emission would occur during the one-month site clearing phase of construction. Mitigation measures would be used to reduce fugitive dust emission during construction by up to 90 percent for construction traffic and up to 65 percent for excavation activities.

Construction and operation of NIF at LLNL would contribute to the cumulative water demand of continuing operation of LLNL and urban developments in the region, which is experiencing water supply shortages during years of low precipitation. Operation of NIF would add about 16 percent to LLNL's site water requirement. LLNL has been implementing water conservation measures since 1988 to help reduce the cumulative impact. Stormwater runoff from the NIF location would contribute to the cumulative adverse effect of all industrial, commercial, and municipal developments on storm water quality. However, the incremental effect of NIF would be minor because stormwater pollution prevention measures would be implemented during both construction and operation of the project. Similarly, the siting of NIF at LLNL would contribute to the reduction of groundwater recharge through addition of impervious areas. However, the incremental effect of NIF would be minor because the area around the proposed location is already built-up with a high percentage of impervious area.

Construction of NIF would replace grassy habitats with areas of pavement and buildings. This conversion would be similar to that occurring with industrial and housing development at the boundaries of LLNL. However, the LLNL area contains extensive areas of grassy habitats, so any loss of grassy habitats would be incrementally very small, and the habitats would not be fragmented. Construction and operation of NIF would not affect any threatened or endangered species.

Construction and operation of NIF at LLNL would not affect any cultural, historical, or paleontological sites. No cultural resources are known for LLNL.

The construction and operation of NIF would result in a small incremental increase in employment, housing demand, and expenditures in the large, diverse economy of Alameda County. The potential development of NIF would sustain employment at LLNL in non-NIF jobs in the physics of inertial confinement fusion, dense materials applications, and weapons physics. If NIF were not constructed at any site (No Action), then employment at LLNL would decline by about 100 workers. No environmental justice issues were identified for either regional or local area impacts.

NIF operations would involve both radioactive and hazardous materials. NIF would be classified as a low hazard radiological facility on the basis of predictions of very low exposures from potential accidents at the facility. The radiological dose to the general public from 30-year NIF operations would be 6 person-rem, which is about 25 percent of the 23 person-rem (based on constant 1994 level) resulting from all other LLNL operations for 30 years. The cumulative dose of 29 person-rem is less than one millionth of the dose to the population from normal background radiation, consumer products, and medical sources. No cancer fatalities are expected in the region from the operation of NIF and other facilities at LLNL. Risks to the public from a NIF accident at LLNL would also be extremely low. The risk of a NIF accident-related cancer fatality occurring in the population within an 80-km (50-mi) radius of LLNL over the 30-year lifetime of the facility is approximately 1 in 10 million. Risks of a radiation-related cancer fatality from accidents during transportation of tritium targets to LLNL are also very low (less than 1 in 1 million over 30 years) in comparison with the risk from fatal vehicular accidents during transportation (about 1 in 8 over 30 years) or the cancer risk associated with exhaust emissions from transportation vehicles (about 1 in 16 over 30 years).

LLNL has the plans and capacity to handle wastes from NIF operations without facility expansion and resultant cumulative effects on either site or regional waste management.

I.4.11.2 *Los Alamos National Laboratory*

Although the proposed location for NIF at LANL is in an undeveloped forested area, placing NIF in that area would be consistent with the area's designation as an experimental science land-use zone. New buildings at the NIF location would alter the local visual environment and contribute to the developed aspect of the central portion of LANL.

Emissions of air pollutants from NIF construction and operation would not contribute to the violation of any air quality standard or to any regional air quality problem.

Construction and operation of NIF at LANL would contribute to the cumulative water demand of continuing operation of LANL and continuing urban developments in the region. Operation of NIF would add about 8 percent to LANL's site water requirement. Water requirements for projected development, including NIF, would be adequately met with utility upgrades under a long-range utility development plan. Stormwater runoff from the NIF location would contribute to the cumulative adverse effect of all industrial, commercial, and municipal developments on stormwater quality. However, the incremental effect of NIF would be minor because stormwater pollution prevention measures would be implemented during both construction and operation of the project.

Construction of NIF at the proposed LANL location would convert natural ponderosa pine and pinyon juniper habitats to managed habitats, pavement, and buildings. This conversion would extend the influence of urbanized/industrial habitats and increase fragmentation of wooded habitat. However, natural wooded habitats are abundant at LANL. Minor habitat loss might be experienced by several listed species at LANL, should they be present at the NIF location. No critical habitats would be affected.

Construction and operation of LANL would not affect any known or suspected cultural, historical, or paleontological sites. No cultural resources are known for the NIF location.

The construction and operation of NIF would result in a small incremental increase in employment, housing demand, and expenditures in a community developed around the presence of a large Federal facility. Housing demand for 1,500 NIF-related workers would be 17 percent of the expected housing vacancies, and such a high demand for housing could stimulate housing starts and affect housing costs in the area. The potential development of NIF would sustain employment at LANL in non-NIF jobs in the physics of ICF, dense materials applications, and weapons physics. If NIF were not constructed at any site (No Action), then employment at LANL would decline from current levels by about 20 workers. No environmental justice issues were identified for either regional or local area impacts.

NIF operations would involve both radioactive and hazardous materials. NIF would be classified as a low hazard radiological facility on the basis of predictions of very low exposures from potential accidents at the facility. The radiological dose to the general public from 30-year NIF operations would be 2 person-rem, which is about 5 percent of the 42 person-rem (based on constant 1994 level) resulting from all other LANL operations for 30 years. The cumulative dose of 44 person-rem is less than 0.002 percent of the dose to the population from normal background radiation, consumer products, and medical sources. No cancer fatalities are expected in the region from the operation of NIF and other facilities at LANL. Risks to the public from a NIF accident at LANL would also be extremely low. The risk of a NIF accident-related cancer fatality occurring in the population within an 80-km (50-mi) radius of LANL over the 30-year lifetime of the facility is approximately 1 in 10 million. Risks of a radiation-related cancer fatality from accidents during transportation of tritium targets to LANL are also very low (less than 1 in 1 million over 30 years) compared with the risk from fatal vehicular accidents during transportation (about 1 in 8 over 30 years) or the cancer risk associated with exhaust emissions from transportation vehicles (about 1 in 16 over 30 years).

LANL has the plans and capacity to handle wastes from NIF operations without facility expansion and resultant cumulative effects on either site or regional waste management.

I.4.11.3 *Nevada Test Site*

The proposed location for NIF at NTS is in Area 22 at an undeveloped desert site. NTS has not designated land-use zones for the area. However, development of NIF in Area 22 would not be a change to the historical land-use for the general area because the Mercury Base Camp and Desert Rock Air Strip are nearby. New buildings at the NIF location would alter the local and area-wide visual environment. Buildings would be visible from U.S. Highway 95, about 6.5 km (4 mi) away.

At the NTS location, the 24-hour average background concentration for particulates, as measured by PM_{10}, is currently above both the national and state ambient air quality standards. Fugitive dust emissions during construction of NIF would be an incremental addition to this existing regional environmental impact. Greatest potential fugitive dust emission would occur during the 2.5-month site clearing phase of construction. Construction activities at NTS would require an operating permit for any surface area disturbance of more than 2 ha (5 acres). During construction, fugitive dust air pollutant emissions would be controlled by using the best practical methods.

Construction and operation of NIF at NTS would not be expected to contribute cumulatively to regional water supply problems. Operation of NIF would add about 21 percent to NTS's site water requirements, but the NTS water supply system has adequate production and storage capacity to meet the additional demand.

Construction of NIF at the proposed NTS location would convert natural creosote bush desert habitats to managed habitats, pavement, and buildings. Creosote bush desert habitats are widespread in the NIF location area and would not be fragmented. Minor loss of desert tortoise habitat would occur, and individual tortoises might be threatened by construction activities. The ferruginous hawk would be discouraged from hunting in areas of human disturbance, but loggerhead shrikes would use the surrounding fence for perching and hunting. No critical habitats would be affected.

Construction and operation of NIF at NTS would not affect any known or suspected cultural, historical, or paleontological sites. No cultural resources are known for the NIF location.

The construction and operation of NIF would have little influence on the socioeconomics of the diverse regional economy in the Las Vegas area. Because of the number of vacant housing units in the region, there would be little demand for new construction. The No Action alternative would not affect NTS because NIF-related studies in ICF, high-density materials, or weapons physics are not pursued at NTS. No environmental justice issues were identified for either regional or local area impacts.

NIF operations would involve both radioactive and hazardous materials. NIF would be classified as a low hazard radiological facility on the basis of predictions of very low exposures from potential accidents at the facility. The radiological dose to the general public from 30-year NIF operations would be 0.03 person-rem, which is about 8 percent of the 0.36 person-rem (based on constant 1994 level) resulting from all other NTS operations for 30 years. The cumulative dose of 0.4 person-rem is less than two millionths of the dose to the population from normal background radiation, consumer products, and medical sources. No cancer fatalities are expected in the region from the operation of NIF and other facilities at NTS. Risks to the public from a NIF accident at NTS would also be extremely low. The risk of a NIF accident-related cancer fatality occurring in the population within an 80-km (50-mi) radius of NTS over the 30-year lifetime of the facility is less than 1 in 10 million. Risks of a radiation-related cancer fatality from accidents during transportation of tritium targets to NTS are also very low (less than 1 in 1 million over 30 years) compared with the risk from fatal vehicular accidents during transportation (about 1 in 6 over 30 years) or from the cancer risk associated with exhaust emissions from transportation vehicles (about 1 in 16 over 30 years).

NTS has the plans and capacity to handle wastes from NIF operations without facility expansion and resultant cumulative effects on either site or regional waste management.

I.4.11.4 *North Las Vegas Facility*

Siting NIF at NLVF would not change land use because this area is zoned for general industrial use. New buildings at the NIF location would alter the local visual environment and be visible from nearby residential areas. However, the visual environment in this area is characterized by industrial-type structures, so NIF would not substantially change the visual character of the local area.

In the NLVF region, the 24-hour average background concentration for particulates, as measured by PM_{10}, is just slightly less than the national and state standards. Fugitive dust emissions from construction of NIF would raise PM_{10} above the standard at the site boundary, but use of calcium-based dust suppressant and a reduction in workload would result in a cumulative concentration that complies with the standard. Otherwise, standards would be exceeded for the period of one month during the site-preparation phase of construction. Abatement of visible fugitive dust emissions is required under the Clark County Air Pollution Control regulations.

Construction and operation of NIF at NLVF would contribute to the cumulative water demand of continuing operation of NLVF and urban developments in the region. Operation of NIF would add about 220 percent to NLVF site water requirements, but current water supply capacity would be adequate to meet the additional demand. Stormwater runoff from the NIF location would contribute to the cumulative adverse effect on stormwater quality from all industrial, commercial, and municipal developments in the region. However, the incremental effect of NIF would be minor because stormwater pollution prevention measures would be implemented during both construction and operation of the project. Similarly, the siting of NIF at NLVF would contribute to the reduction of groundwater recharge through addition of impervious areas. However, the incremental effect of NIF would be minor because the area around the proposed location is already built-up with a high percentage of impervious area.

Construction of NIF at the proposed NLVF location would not result in the conversion of any natural habitats; the disturbed soil and scattered grasses and forbs in this industrial area are of negligible value to wildlife. Landscaping around the NIF buildings could improve the wildlife value of the site and contribute to maintenance of urban wildlife in this industrial area. NLVF does not contain any habitat of value to listed species.

Construction and operation of NIF at NLVF would not affect any known or suspected cultural, historical, or paleontological sites. No cultural resources are known for the NIF location.

The construction and operation of NIF would have little influence on the socioeconomics of the diverse regional economy. Because of the number of vacant housing units in the region, there would be little demand for new housing construction. The No Action alternative would not affect the North Las Vegas area because NIF-related studies in ICF, high-density materials, and weapons physics are not pursued at NTS. Environmental justice issues were identified for the NLVF location. The proportion of minority populations is higher in the local area than in Nevada as a whole. Thus, beneficial socioeconomic impacts and adverse radiological effects could disproportionately affect minority populations. The adverse effects on minorities (as identified in tables I-S.5-1 and I.3.6.1-1) are low and are based on the unlikely accident scenario which could result in one or two cancer fatalities.

NIF operations would involve both radioactive and hazardous materials. NIF would be classified as a low hazard radiological facility on the basis of the very low exposures from potential accidents at the facility. The radiological dose to the general public from 30-year NIF operations would be 18 person-rem, which is about two-millionths of the dose to the population from normal background radiation, consumer products, and medical sources. No radiation doses are expected from other NLVF operations. There would be no cancer fatalities in the region from the operation of NIF and other facilities at NLVF. Risks to the public from a NIF accident at NLVF would also be low. Although the postulated NIF bounding accident, if it occurred, might result in one or two cancer fatalities occurring in the population within an 80-km (50-mi) radius of NIF, the risk of that actually happening over the 30-year lifetime of the facility is approximately 1 in 700,000. Risks of a radiation-related cancer fatality from accidents during transportation of tritium targets to NTS are very low (less than 1 in 1 million over 30 years) compared with the risk from fatal vehicular accidents during transportation (about 1 in 7 over 30 years) or from the cancer risk associated with exhaust emissions from transportation vehicles (about 1 in 16 over 30 years).

NTS has the plans and capacity to handle wastes from NIF operations at NLVF without facility expansion and resultant cumulative effects on either site or regional waste management.

I.4.11.5 *Sandia National Laboratories*

Siting NIF at SNL would be consistent with existing land uses of the area. The proposed location is within an area of similar structures and would be removed from public view.

In the SNL region, the 24-hour average background concentration for particulates, as measured by PM_{10}, is currently within applicable standards. With the use of conventional dust control techniques, fugitive dust emissions from construction of NIF would not result in any violation of standards for particulates.

Construction and operation of NIF at SNL would contribute to the cumulative water demand of continuing operation of SNL and continuing urban developments in the region. Operation of NIF would add about 11 percent to SNL site water requirements. Stormwater runoff from the NIF location would contribute to the cumulative adverse effect on stormwater quality from all industrial, commercial, and municipal developments in the region. However, the incremental effect of NIF would be minor because stormwater pollution prevention measures would be implemented during both construction and operation of the project. Similarly, the siting of NIF at SNL would contribute to the reduction of groundwater recharge through the addition of impervious areas.

Construction of NIF would replace disturbed grassy habitats with areas of pavement and buildings. However, extensive areas of grassy habitat occur close to NIF location, and habitats would not be fragmented. Construction and operation of NIF would not affect any threatened or endangered species.

No cultural, historical, or paleontological sites at SNL would be affected by construction or operation of NIF. No cultural resources are known for SNL.

The construction and operation of NIF would result in a small incremental increase in employment, housing demand, and expenditures in a large, diverse urban region. The potential development of NIF would sustain employment at SNL in non-NIF jobs in the physics of ICF, dense materials applications, and weapons physics. If NIF were not constructed at any site (No Action), then employment at SNL would decline by about 20 workers. No environmental justice issues were identified for either regional or local area impacts.

NIF operations would involve both radioactive and hazardous materials. It would be classified as a low hazard radiological facility on the basis of the very low exposures from potential accidents at the facility. The radiological dose to the general public from 30-year NIF operations would be 6 person-rem, which is an 8-fold increase from the 0.8 person-rem (based on constant 1994 level) resulting from all other SNL operations. However, the cumulative dose of 6.8 person-rem is extremely low; about one millionth of the dose to the population from normal background radiation, consumer products, and medical sources. No cancer fatalities are expected in the region from the operation of NIF and other facilities at SNL. Risks to the public from the postulated bounding NIF accident would also be low. Such an accident might result in one cancer death in the population within an 80-km (50-mi) radius, but the risk of that actually happening is less than 1 in 1 million. Risks of a radiation-related cancer fatality from accidents during transportation of tritium targets to SNL are also very low (less than 1 in 1 million over 30 years) compared with the risk from fatal vehicular accidents during transportation (about 1 in 8 over 30 years) or the cancer risk associated with exhaust emissions from transportation vehicles (about 1 in 8 over 30 years).

SNL has the plans or capacity to handle some of the wastes that would be generated by NIF operations without facility expansion and resultant cumulative effects on either site or regional waste management.

I.5 Environmental, Occupational Safety, and Health Permits and Compliance Requirements

I.5.1 Introduction

This chapter identifies the major laws, regulations, Executive Orders, and compliance instruments that apply to the National Ignition Facility (NIF) proposed action and alternatives. Various Federal environmental statutes impose environmental protection and compliance requirements upon the Department of Energy (DOE). Further, certain state and local environmental authorities are also applicable because they are delegated to the state for enforcement or implementation under Federal law. It is DOE policy to conduct its operations in an environmentally safe manner in compliance with all applicable statutes, regulations, and standards. Although this chapter does not address pending legislation or regulations that may become effective in the future, DOE recognizes that the regulatory environment is rapidly changing and that the construction and operation of NIF must be conducted in compliance with the applicable statutes, regulations, and standards in effect at the time.

Under the *National Environmental Policy Act* (NEPA) of 1969 (42 *United States Code* [U.S.C.] 4321 et seq.), Federal agencies are required to prepare an environmental impact statement (EIS) for proposed major Federal actions that might significantly affect the quality of the human environment. DOE has determined that the proposed siting, construction, and operation of NIF is such an action. Therefore, this project-specific analysis has been prepared as a part of the *Stockpile Stewardship and Management Programmatic Environmental Impact Statement* in accordance with the Council on Environmental Quality (CEQ) Regulations (40 *Code of Federal Regulations* [CFR] 1500-1508) implementing NEPA and DOE NEPA Implementing Procedures (10 CFR 1021).

Under the *California Environmental Quality Act* (California Statutes, Public Resources Code, Division 13 - Environmental Quality, Section 21000 et seq.), any California state public agency taking any action that may cause either a direct physical change in the environment or a reasonably foreseeable indirect physical change in the environment must consider qualitative factors, economic and technical factors, long-term benefits and costs, and alternatives to the proposed action. Public agency actions include the issuance of a state permit, license, certificate, or other entitlement. The public agency must determine whether it will prepare an environmental impact report to identify the significant effects of the proposed project on the environment. All applicants for permits, license, certificates, or other entitlements from a public agency in support of the NIF proposed action may be required to submit data and information necessary to enable the public agency to determine whether the proposed project may have a significant affect on the environment and whether to prepare an environmental impact report.

The *Atomic Energy Act* of 1954 (42 U.S.C. 2011 et seq.) authorized DOE to establish standards to protect health or minimize dangers to life or property for its facilities and operations. DOE has established an extensive system of standards and requirements through DOE orders to ensure safe operation of its facilities.

Executive Order No. 12088, Federal Compliance with Pollution Control Standards, requires Federal agencies—including DOE—to comply with applicable administrative and procedural pollution control standards established by, but not limited to, the *Clean Air Act* (section I.5.2.1), the *Noise Control Act* (section I.5.2.1.4), the *Clean Water Act* (section I.5.3.1), the *Safe Drinking Water Act* (section I.5.3.2), the *Toxic Substances Control Act* (section I.5.7.2), and the *Resource Conservation and Recovery Act* (section I.5.8.1).

I.5.2 Air Quality and Noise Requirements

I.5.2.1 *Clean Air Act*

Construction and operation of NIF would result in air emissions of criteria and noncriteria pollutants, including sulfur dioxide, nitrogen dioxide, volatile organic compounds (VOCs), carbon monoxide, and particulates (PM_{10}). These emissions would be subject to the *Clean Air Act* (CAA) (42 U.S.C. 7401 et seq.), as amended. NIF would also be a source of radionuclide emissions, also subject to the CAA. No other emissions of hazardous air pollutants would be anticipated during construction or operation of NIF.

CAA requires the U.S. Environmental Protection Agency (EPA) to establish national primary and secondary ambient air quality standards as necessary to protect public health with an adequate margin of safety from any known or anticipated adverse effects of a pollutant. CAA also requires promulgation of national standards of performance for new major stationary sources, setting emissions limitations for any new or modified building, structure, facility, or installation that emits or may emit an air pollutant (42 U.S.C. 7411) and standards for emission of hazardous air pollutants (42 U.S.C. 7412). CAA also requires that specific emission increases from major sources be evaluated so as to prevent a significant deterioration in air quality (42 U.S.C. 7470). In addition, CAA requires EPA to promulgate rules to ensure that Federal actions conform to the appropriate state implementation plans (42 U.S.C. 7506).

Pursuant to such direction, EPA promulgated the primary and secondary National Ambient Air Quality Standards, including standards for emissions of sulfur oxides (measured as sulfur dioxide), nitrogen dioxide, carbon monoxide, PM_{10}, ozone, and lead (40 CFR 50); the standards of performance for new stationary sources within specific source categories enumerated in 40 CFR 60.16, including electric steam generating units, industrial-commercial-institutional steam generating units, and stationary gas turbines (40 CFR 60); the National Emission Standards for Hazardous Air Pollutants, including radionuclides (40 CFR 61); and the Prevention of Significant Deterioration (PSD) of Air Quality review regulations (40 CFR 52.21).

On November 30, 1993, EPA published its final rule for Determining Conformity of General Federal Actions to State or Federal Implementation Plans (58 *Federal Register* [FR] 63214). This rule requires states to file revisions to their state implementation plans to include conformity requirements (40 CFR 51.850-860). Once the state plans are revised, Federal agencies are subject to those revised state implementation plans. Until such revisions are submitted and approved, however, the rule adopts conformity requirements applicable to all Federal agencies (40 CFR 93.150-160). Only New Mexico and the Albuquerque/Bernalillo County Air Quality Control Board have revised their regulations to require conformity determinations for Federal actions (*New Mexico Regulations*, Title 20, Part 98 [uncodified]; Board Regulation No. 43). The regulations apply to all nonattainment and maintenance areas for criteria pollutants for which the area is designated.

Under the new rules, a Federal agency must make a formal determination that a Federal action conforms to the applicable implementation plan before such action may be taken. For Federal actions, a conformity determination is required for each pollutant when the total of direct and indirect emissions in a nonattainment or maintenance area caused by a Federal action would equal or exceed certain limits (40 CFR 51.853 or 93.153) (table I.5.2.1–1).

The direct and indirect emissions from the construction and operation of NIF at any site would not exceed these limits (sections I.4.1.2.2, I.4.2.2.2, I.4.3.2.2, I.4.4.2.2, and I.4.5.2.2). In addition, the total of direct and indirect emissions of any pollutant from a Federal action must not equal or exceed 10 percent of a nonattainment or maintenance area's total emissions of that pollutant. If it does, it is defined as a regionally significant action and a conformity determination is required. It is not expected that emissions from NIF would equal or exceed this 10 percent limit.

CAA provides that each state must develop and submit for approval to EPA implementation plans for controlling air pollution and air quality in that state. Under EPA regulations, California, Nevada, and New Mexico all have approved state implementation plans; however, not all parts of the CAA requirements are met in such plans and, in some cases, dual Federal/state regulations must be implemented.

California and Nevada have not been delegated the authority to regulate the emission of radionuclides from DOE facilities, and, therefore, Federal regulations would apply to such emissions at the

TABLE I.5.2.1-1.—*Conformity Determination Exceedance Limits*

Pollutant	Limit (tons/yr)[a]
Nonattainment Areas	
Ozone (volatile organic compounds or nitrogen oxides)	
Serious Nonattainment Areas	50
Severe Nonattainment Areas	25
Extreme Nonattainment Areas	10
Other ozone nonattainment areas outside an ozone transport region	100
Marginal and moderate nonattainment areas inside an ozone transport region	
Volatile organic compounds	50
Nitrogen oxides	100
Carbon monoxide	100
Sulfur dioxide or nitrogen dioxide	100
Particulate matter 10 microns or smaller	
Moderate Nonattainment Areas	100
Serious Nonattainment Areas	70
Lead	25
Maintenance Areas	
Ozone (nitrogen oxides), sulfur dioxide or nitrogen dioxide	100
Ozone (volatile organic compounds)	
Maintenance areas inside an ozone transport region	50
Maintenance areas outside an ozone transport region	100
Carbon monoxide	100
Particulate matter 10 microns or smaller	100
Lead	25

[a] To determine metric tons/year (t/yr), multiply values by 0.90718.

Source: 40 CFR 51.853 and 93.153.

Lawrence Livermore National Laboratory (LLNL) and the Nevada Test Site (NTS). In Nevada, the District Board of Health of Clark County and the Albuquerque/Bernalillo County Air Quality Control Board have adopted the Federal regulations, which would then be applicable to radionuclide emissions from the North Las Vegas Facility (NLVF) and Sandia National Laboratories/New Mexico (SNL). New Mexico has adopted the Federal standards for the emission of hazardous air pollutants (40 CFR 61); however, it has excluded from adoption Subparts H (National Emission Standards for Emissions of Radionuclides other than Radon from Department of Energy Facilities) and Q (National Emission Standards for Radon Emissions from Department of Energy Facilities). Therefore, Federal regulations would apply in New Mexico for the Los Alamos National Laboratory (LANL).

The Federal regulations for emissions of radionuclides and radon-222 from DOE facilities are set in 40 CFR 61, Subparts H and Q. Pursuant to 40 CFR 61.07, an application for approval of construction must be filed before construction begins (with Region IX for LLNL and NTS, with Region VI for LANL, with the District Board of Health of Clark County for NLVF, and with the Albuquerque/Bernalillo County Air Quality Control Board for SNL). Further, DOE must provide written notification to EPA (or appropriate authority) no more than 60 nor less than 30 days before the anticipated date of initial start-up of operations (40 CFR 61.09). However, if it is estimated that radionuclide emissions from the new construction or modification would be less than 1 percent of the effective dose equivalent of 10 mrem/yr to any member of the public, no application for approval of construction or notification of start-up is necessary (40 CFR 61.96).

I.5.2.1.1 *Clean Air Act* Requirements for California

The LLNL site is within the Bay Area Air Quality Management District (BAAQMD), and the district's regulations would apply to air emissions from NIF. NIF is not expected to have sufficient emissions to meet the definition of a major facility under California air regulations. The definition of one facility, however, includes related sources on a single property or contiguous properties, even though under different ownership, and related sources on noncontiguous properties under the same ownership. For this review, facilities under the same ownership that are located within a distance of 4.8 kilometers (km) (3 miles [mi]), property line to property line, are considered one facility if the facilities have the same first two digits in the Standard Industrial Classification code. However, current calculations show that LLNL's existing sources do not meet the definition of a major facility under the California regulations. Therefore, there is no requirement for a PSD review or major facility review for the construction and operation of NIF at LLNL (Regulation 2, Rules 2 and 6). New Source Performance Standards (40 CFR 60, Subpart D, as adopted by BAAQMD Regulation 10) would have to be met for the operation of steam boilers constructed as or modified to be support facilities for NIF. Under such requirements, any fossil-fueled steam boilers exceeding 73 megawatts (MW) input rate (250 million British thermal units per hour [Btu/hr]) must meet the standards for PM_{10}, nitrogen oxides, sulfur dioxide, and opacity.

Under BAAQMD regulations, any person responsible for the emission of air contaminants must register with the district (Regulation 1, Rule 1-410). In addition, any person who builds, installs, modifies, alters, or replaces any article, machine, equipment, or other contrivance, the use of which might cause, reduce, or control the emission of air contaminants, must first apply for and obtain an authority to construct from the Air Pollution Control Officer (Regulation 2, Rule 1-301). Also, any person wishing to use or operate such article, machine, equipment, or other contrivance must obtain a permit to operate from the Air Pollution Control Officer (Regulation 2, Rule 1-302).

Any facility that must obtain an authority to construct must be reviewed as a new source. Under the new source review rules (Regulation 2, Rule 2), the aggregate sum of all increases in emissions from a new or modified source must be calculated. These calculations will provide mechanisms, including the identification of best available control technology (BACT) and emission offsets, by which the District will grant the new or modified source the authority to construct (Regulation 2, Rule 2-101). Fugitive emissions of PM_{10} from temporary construction activities are not included in the calculation of the total potential to emit for the facility (DeBoisblance 1995). BACT must be applied to any new or modified source that will result in emissions of precursor organic compounds, non-precursor organic compounds, nitrogen oxides, sulfur dioxide, PM_{10}, or carbon monoxide in excess of 4.5 kilograms (kg) (10 pounds [lb]) per highest day (Regulation 2, Rule 2-301). Estimated emissions from boiler operations may exceed 4.5 kg (10 lb) per day, and BACT may have to be applied as determined by the permit process.

If the facility will emit more than 45 metric tons (t) (50 tons) per year of precursor organic compounds or nitrogen oxides, federally enforceable emission offsets will be required before a permit will be granted (Regulation 2, Rule 2-302). If the facility will emit more than 13.6 t (15 tons) per year but less than 45 t (50 tons) per year of precursor organic compounds or nitrogen oxides, the district will provide the emission offsets from the Small Facility Banking Account (Regulation 2, Rule 2-302). Offsets for PM_{10} and sulfur dioxide are mandatory only for major facilities with emissions over 91 t (100 tons) per year. A facility that emits less than 91 t (100 tons) per year of PM_{10} or sulfur dioxide may voluntarily provide emission offsets for all or any portion of their cumulative increase.

I.5.2.1.2 *Clean Air Act* Requirements for Nevada

NTS is located in Nye County and air emissions for the construction and operation of NIF would be governed by the Nevada State Air Pollution Control Regulations (NAC 445B.001 through 445B.395). NIF at NTS is not expected to be a major facility under Nevada regulations. The District Board of Clark County Air Pollution Control Regulations (APCR) are approved as part of the Nevada state implementation plan, and these regulations would govern air emissions from the construction and operation of NIF at NLVF. NIF is not expected to be a major facility under Clark County regulations. New Source Performance Standards (40 CFR 60, Subpart D, as adopted by NAC 445B.308 and Clark County APCR, section 14) would have to be met for the operation of steam boilers constructed as, or modified to be, support facilities for NIF. Under such requirements, any fossil-fueled steam boilers exceeding 73 MW heat input rate (250 million Btu/hr) must meet the standards for PM_{10}, nitrogen oxides, sulfur dioxide, and opacity.

In Clark County, all new, reconstructed, or modified stationary sources of volatile organic compounds, lead, PM_{10}, particulate precursors, and carbon monoxide that are proposed to be located in the Las Vegas Valley must register with the District (APCR, section 15.14). Under Clark County Air Pollution Control regulations, any person who proposes to install or construct any new stationary source of air emissions must apply for an "Authority to Construct" certificate before construction is begun (APCR, section 12.1.1.1).

Certain requirements must be met for specific air contaminants before a permit will be issued. NIF project, as a nonmajor source of PM_{10} in Las Vegas Valley (with a potential to emit less than 64 t [70 tons] per year), must incorporate BACT (APCR, section 12.2.1.1). The applicant must also provide documentation of emission reduction credits against other emissions if the total potential to emit for the new source will exceed 23 kg (50 lb) per day of total suspended particulates (APCR, section 12.2.1.3). Qualified road paving projects approved by the local public works department are recognized by the Control Officer as emission reduction credits for PM_{10} (APCR, section 12.4.1). Such credits are good for seven years. A one-year emission reduction credit is available by payment to the closest local participating public works department (APCR, section 12.4.2).

As a nonmajor source of VOCs in Las Vegas Valley (VOC emissions under 45 t [50 tons] per year), NIF must incorporate emissions controls that are designed for BACT (APCR, section 12.2.4.1). The applicant must also provide documentation of emission reduction offsets to all anticipated annual emission increases (APCR, section 12.2.4). The applicant must also apply BACT for sulfur dioxide and lead emissions and demonstrate that the total potential to emit will not cause, or contribute to, ambient concentrations that exceed ambient air quality standards for sulfur dioxide or lead (APCR, sections 12.2.8 and 12.2.10).

An applicant must apply BACT for all emissions of nitrogen oxides and must demonstrate that the total potential to emit will not cause, or contribute to, ambient concentrations exceeding the ambient air quality standard for nitrogen oxides (APCR, section 12.2.10.1). Emission credits equivalent to twice the new source's potential to emit are required (APCR, section 12.2.10.4). As a nonmajor source of carbon monoxide in Las Vegas Valley (potential to emit less than 64 t [70 tons] per year), NIF must incorporate emission controls that are designed with the BACT (APCR, section 12.2.11.1), and emission reduction credits must be greater than twice the potential to emit for the new source (APCR, section 12.2.11.4).

In addition, an operating permit is required for the operation of any emission unit in a stationary source (APCR, section 16). Such an operating permit might contain conditions, including emission limits, production rates, control methods, or operation limitations, subject to annual review.

For construction activities at NIF within Clark County, a Permit for Construction Activities is required (APCR, section 17) to satisfy the Authority to Construct requirements of APCR, section 12.2.1. As a condition of such a permit, the applicant must present and agree to implement an acceptable method to prevent particulate matter from becoming airborne. In addition, any person engaged in the operation of machines and equipment, the grading of roads, and the operation and use of unpaved parking facilities must take all reasonable precautions to abate fugitive dust from becoming airborne. Reasonable precautions may include, but are not limited to, the conditions agreed upon in the permit for the project, sprinkling, compacting, enclosure, chemical and asphalt sealing, cleaning up, sweeping, or other such measures as the Control Officer may specify.

APCR, section 41, also requires control of fugitive emissions during construction activities. Fugitive emission prohibitions include the following:

- Visible plume of dust, resulting from construction activities beyond the nearest property line, whichever is less
- Visible dust emissions on an unpaved road at a construction site being used by haul trucks
- Visible dust emissions generated by vehicles traveling over mud and directly carried out to a paved road near or adjacent to a construction site
- Handling, transporting, or storing material in such a manner as to become airborne

The regulations further indicate that a visible plume of dust resulting from construction activities that extends more than 45.7 meters (m) (150 feet [ft]) from the point of origin, but less than 91.4 m (300 ft) and that has not crossed the nearest property line may be subject to a Notice of Violation, including an Order to take Corrective Action.

Under Nevada air regulations, NTS, as the owner or operator of a proposed new nonmajor stationary source or a proposed modification to an existing nonmajor stationary source, must file an application and obtain a Class II operating permit before construction is begun (NAC, section 445B.291). A separate operating permit is required for each new and existing stationary source (NAC, section 445B.287). Before an operating permit may be issued for a new stationary source, any source that has the potential to emit greater than 23 t (25 tons) of a regulated air pollutant per year must submit an environmental evaluation to enable the director to make an independent air quality impact assessment and determine that the source will not prevent the attainment and maintenance of the state or national ambient air quality standards, cause a violation of the applicable control strategy contained in the approved state implemented plan, or cause a violation of any applicable requirement (NAC, section 445B.310). Because NIF is not expected to emit in excess of 23 t (25 tons) of any regulated air pollutant per year, no assessment would be necessary.

Construction activities at NTS would require an operating permit for any surface area disturbance (such as clearing, excavating, and leveling the land) involving more than 2 hectares (ha) (5 acres) of land (NAC, section 445.365). No person may engage in construction or use of unpaved or untreated areas without first putting into effect an ongoing program using the best practical methods to prevent particulate matter from becoming airborne (NAC, section 445B.365).

I.5.2.1.3 *Clean Air Act* Requirements for New Mexico

New Mexico Air Quality regulations would apply to air emissions from NIF if it was located at LANL. However, the Albuquerque/Bernalillo County Air Quality Control Board regulations would apply to air emissions from NIF if located at SNL.

Under New Mexico Air Quality regulations (which would apply at LANL), a permit must be obtained before constructing a stationary source or modifying an existing source with a potential emission rate greater than 4.5 kg/hr or 23 t/yr (10 lb/hr or 25 tons/yr) of any regulated air contaminant for which there is a Federal or New Mexico ambient air quality standard (Environmental Improvement Board/Air Quality Control Regulations [EIB/AQCR] 702, Part 2). If the threshold is exceeded for any one regulated air contaminant, all regulated air contaminants emitted are subject to permit review. A permit is also required for any source or equipment that is subject to the New Source Performance Standards, for any toxic air pollutant emissions or any major source of hazardous air pollutants, any source meeting the applicability requirements of the PSD review, or for permits for nonattainment areas (EIB/AQCR 702). It is not anticipated that the construction or operation of NIF at LANL would emit toxic air pollutants, be a major source of hazardous air pollutants, or be located in a nonattainment area. Therefore, no permit application would be required under this section. One PSD Class I Area, the Bandelier National Monument Wilderness Area, borders LANL to the south; however, to date, LANL has not been subject to PSD requirements (see section I.4.2.1.2.2). New Source Performance Standards (40 CFR 60, Subpart D, as adopted by 20 NMAC 2.77) would have to be met for the operation of steam boilers constructed as or modified to be support facilities for NIF. Under such requirements, any fossil-fueled steam boilers exceeding 73 MW heat input rate (250 million Btu/hr) must meet the standards for PM_{10}, nitrogen oxides, sulfur dioxide, and opacity.

Under Albuquerque/Bernalillo County Air Quality Control Board regulations, SNL as the owner or operator of NIF, a commercial or industrial stationary source that emits more than 0.9 t (1 ton) of any air contaminant per year, must obtain a registration certificate for the source (Regulation No. 22). In addition, any person planning to construct a new stationary source or modify an existing stationary source of air contaminants over certain thresholds must obtain a permit from the Albuquerque/Bernalillo County Air Quality Control Board before construction. Permits are required for any stationary source that will emit more than 4.5 kg/hr or 23 t/yr (10 lb/hr or 25 tons/yr) of one or more regulated air contaminants for which there is a Federal, state, or local air quality control standard, or if an already permitted source is to be modified (Regulation 20). However, since NIF would not be a major source under the regulations, no PSD review (Regulation 29) or operating permit (Regulation 41) is necessary. New Source Performance Standards (40 CFR 60, Subpart D, as adopted by the Albuquerque/Bernalillo County Air Quality Control Board) would have to be met for the operation of steam boilers constructed as or modified to be support facilities for NIF. Under such requirements, any fossil-fueled steam boilers exceeding 73 MW heat input rate (250 million Btu/hr) must meet the standards for PM_{10}, nitrogen oxides, sulfur dioxide, and opacity.

For construction of NIF in Albuquerque/Bernalillo County, a permit would be necessary for the disturbance of more than 0.30-ha (.75-acre) surface area (Regulation 8.03). In addition, the permittee must employ means specified in the permit to prevent the escape from the site of airborne particulate matter, if the opacity of which exceeds the opacity of the surrounding airborne background particulate matter by 10 percent.

I.5.2.1.4 Noise Requirements

Section 4 of the *Noise Control Act* of 1972 (42 U.S.C. 4901 et seq.) directs all Federal agencies to carry out programs in a manner that furthers a national policy of promoting an environment free from noise that jeopardizes health or welfare. EPA has not published regulations concerning noise levels from construction operations. However, the agency has issued guidelines for outdoor noise levels that are consistent with the protection of human health and welfare against hearing loss, annoyance, and activity interference (EPA 1974). Such guidelines state that "undue interference with activity and annoyance will not occur if outdoor levels [of noise] are maintained at an energy equivalent of 55 decibel." These levels are not to be construed as standards, however.

I.5.3 Water Resources Requirements

Regardless of the site selected for the project, NIF would use water for sanitary and domestic purposes, low-conductivity cooling, manufacturing, and processing operations for target and optics maintenance, environmental control of the site and facilities, and emergency and safety systems. It is also anticipated that industrial and sanitary/domestic water would be discharged from the operation of NIF at all sites. For construction activities, stormwater discharges are regulated.

I.5.3.1 *Clean Water Act*

The Federal *Clean Water Act* (CWA) (33 U.S.C. 1251 et seq.) provides that it is illegal to discharge pollutants from a point source into navigable waters of the United States except in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. Through administrative and judicial interpretation, the navigable waters of the United States encompass any body of water for which the use, degradation, or destruction would affect or could affect interstate or foreign commerce, including but not limited to interstate and intrastate lakes, rivers, streams, wetlands, playa lakes, prairie potholes, mudflats, intermittent streams, and wet meadows. This program is administered by the Water Management Division of EPA pursuant to regulations in 40 CFR 122 et seq. Any state may administer its own permit program for discharges into navigable waters within its jurisdiction by submitting the state program to EPA for approval (33 U.S.C. 1342[b]).

Sections 401 and 405 of the *Water Quality Act* of 1987 added section 402(p) to the CWA, which requires EPA to establish regulations for issuing permits for stormwater discharges associated with industrial activity. The language of the *Water Quality Act* of 1987 requiring an NPDES permit for stormwater discharge was codified into EPA regulations at 40 CFR 122.26 (54 FR 246, effective January 4, 1989). Pursuant to revised 40 CFR 122.26(a)(1)(ii), any stormwater discharge associated with industrial activity requires an NPDES permit application. EPA has delegated NPDES permitting authority to the States of California and Nevada. New Mexico, however, has not received such delegation, and NPDES permits in New Mexico are issued by EPA, Region VI. The New Mexico Environment Department certifies that permits meet all state and Federal regulations.

Pursuant to Section 404 of the CWA (33 U.S.C. 1344), there may be no discharges of dredged or fill material into waters of the United States, including rivers, streams, wetlands, and playa lakes (33 CFR 328.8), done by or on behalf of any Federal agency, other than the Corps of Engineers, without a permit issued pursuant to Corps of Engineers rules and regulations (33 CFR 320 through 328). These regulations prescribe special policies, practices, and procedures to be followed by the Corps of Engineers in reviewing applications for such permits to authorize such discharges (33 CFR, Parts 320, 323, and 325). Pursuant to 33 CFR 320.4, the Corps in issuing such permits must consider the impact that such an activity would have on floodplains and wetlands in accordance with Executive Orders 11988 and 11990.

I.5.3.1.1 *Clean Water Act* Requirements in California

California has NPDES permitting authority, and any permits or permit modifications required by the construction or operation of NIF at LLNL would be issued by the State Water Resources Control Board, Division of Water Quality. Sanitary wastewater from NIF located at LLNL would be discharged to the city of Livermore Water Reclamation Plant. Therefore, no NPDES permit would be necessary for NIF operations. Under current calculations, wastewater treatment capacity at the Reclamation Plant is expected to be sufficient to meet the additional requirements of NIF. However, it might be necessary to report any change in amount or character of discharges to the Livermore Plant under LLNL/city of Livermore pretreatment agreements, since discharge of spent cooling water would be considered an industrial discharge (Steenhoven 1995).

Construction activity associated with NIF would require Notice of Intent to the State Water Resources Control Board to participate in the California General Construction Activity Stormwater Permit. Under the permit, a stormwater pollution prevention plan would have to be developed to mitigate potential water quality impacts from construction activities through the use of best available technology and best conventional pollutant control technology. Once construction was completed, NIF would have to be added to the Livermore Site Industrial Activity Stormwater Pollution Prevention Plan through notification to the State Water Resources Control Board.

I.5.3.1.2 *Clean Water Act* Requirements in Nevada

Nevada is an NPDES-delegated state with general permitting authority. Although NTS holds a sewage treatment permit (GNEV 93001) from the Department of Conservation and National Resources for its current treatment systems, a sanitary wastewater treatment lagoon would have to be constructed to accommodate NIF operations at NTS. The new lagoon would not discharge to any water of the state (Monroe 1995). Under the Nevada Water Pollution Control Law, it is unlawful to discharge pollutants into waters of the state (which includes all streams, lakes, ponds, impounding reservoirs, marshes, watercourses, waterways, wells, springs, irrigation and drainage systems, and all bodies or accumulations of water, surface and underground, natural and artificial) without a written permit for such discharge under such reasonable terms and conditions as required by the Department of Conservation and Natural Resources and Environmental Protection Division (NRS, Title 40, chapter 445.287).

Industrial wastewater and sanitary sewage from NLVF are discharged into the city of North Las Vegas Water Treatment Plant. The North Las Vegas plant holds a current NPDES permit issued by the Nevada Division of Environmental Protection. Under Nevada Water Pollution Control regulations, no permit is required for discharges of pollutants, other than toxic materials, into a publicly owned treatment works, if the owner of such publicly owned treatment works has a valid permit from the state (NAC, section 445.140). Therefore, no permit is necessary for the discharge of NIF wastewater into the North Las Vegas plant. However, under pretreatment agreements and permits with the publicly owned treatment works, NLVF might have to report to the publicly owned treatment works the change in amount and character of its discharge resulting from the construction and operation of NIF. (NAC, section 445.169).

Both NTS and NLVF have requested the Department of Conservation and Natural Resources to issue a determination that stormwater from the sites does not discharge to waters of the state, and, therefore, no stormwater permits, for construction or industrial activity are necessary.

I.5.3.1.3 *Clean Water Act* Requirements in New Mexico

New Mexico has not been delegated NPDES permitting authority; therefore, EPA, Region VI, would issue any new NPDES permits or modify existing permits as necessary. The New Mexico Environment Department reviews and certifies NPDES draft permits issued by EPA to ensure that they meet all state and Federal regulations and standards. Sanitary wastewater from NIF construction and operations would be discharged into LANL's existing sewer system, which has been permitted by the Federal EPA (NPDES Permit NM 0028355). All reporting requirements under the permit regarding changes in the quantity, quality, or character of the discharge resulting from NIF operations must be made to EPA, Region VI (40 CFR 122.41(l), 122.62, 122.63). This requirement would include significant changes in process and quantity or quality of effluent discharged into the existing system and any new discharges. DOE, LANL, and New Mexico Environment Department have entered into a Settlement Agreement to study the stream uses associated with LANL effluent discharges under its NPDES regulations.

In addition to Federal requirements, the New Mexico Water Quality Control Commission regulations require that any person intending to make a new water contaminant discharge, or to alter the character or location of an existing discharge, must file a notice with the Water Pollution Control Bureau of the Environmental Improvement Division (WQCC 821-1-201). If it were necessary to modify the sewer system in a manner that would substantially change the quantity or quality of the discharge from the system, LANL would also have to file plans and specifications of the construction or modification with the Bureau. Otherwise, modifications having a minor effect on the character of the discharge would only have to be reported as of January 1 and June 30 of each year (WQCC 821-1-202).

Sanitary and industrial wastewater from SNL are discharged to the Albuquerque Wastewater Treatment Plant, which holds a Federal NPDES permit. SNL has pretreatment agreements with the plant to meet certain pretreatment standards for SNL industrial wastewaters prior to discharge to the plant. Therefore, it would have to notify the plant of any changes in discharges associated with the operation of NIF (40 CFR 403.12).

Since New Mexico has not been delegated NPDES permitting authority, LANL has submitted a Notice of Intent to the Federal EPA, Region VI, to participate in the Federal General Permit for Stormwater Discharges Associated with Construction Activities. As a condition of the permit, each facility must have a Stormwater Pollution Prevention Plan. Any construction associated with NIF would have to conform to the conditions of this permit.

I.5.3.2 *Safe Drinking Water Act*

The primary objective of the *Safe Drinking Water Act* (42 U.S.C. 300(f) et seq.) is to protect the quality of public water supplies, water supply and distribution systems, and all sources of drinking water. Sections of the Act address public water systems, protection of underground sources of drinking water, emergency powers, general provisions, and additional requirements to regulate underground injection wells. The National Primary Drinking Water regulations (40 CFR 141 et seq.), administered by EPA, establish standards applicable to public water systems. The regulations include maximum contaminant levels, including those for radioactivity, for community and noncommunity water systems. No new public water supply system is anticipated to be constructed at any of the sites.

I.5.3.2.1 *Safe Drinking Water Act* Requirements in California

Water used at the LLNL site is purchased primarily from the city of San Francisco Hetch Hetchy Aqueduct and from the Alameda County Flood and Water Conservation District, Zone 7. Significant alterations to LLNL's drinking water supply requirements due to NIF construction and operation might require that the suppliers be notified of such modification to ensure the new service connection would not cause pressure reduction below state standards (22 *California Code of Regulations* [CCR] 64568).

I.5.3.2.2 *Safe Drinking Water Act* Requirements in Nevada

Nevada has adopted the National Drinking Water regulations (40 CFR 141) for its public water systems regulations (NAC 445.247). NTS will acquire domestic water from its permitted water supply system to serve NIF requirements. Notification of any modification to accommodate NIF operations would be made to the Department of Health Services, including submission of water system modification plans for approval (NAC 445A.657). NLVF would acquire domestic water for NIF from the city of North Las Vegas under an existing agreement. The city would have to be notified of any increase in NLVF water supply usage (Monroe 1995).

I.5.3.2.3 *Safe Drinking Water Act* Requirements in New Mexico

New Mexico has a comprehensive water supply program (NM Regulations [NMR] Title 20, Chapter 7 [uncodified]), under which every public water supply system must site, construct, and maintain its operation in compliance with the requirements of such program. Domestic water to be used at NIF would come from LANL's public water supply system. Under the New Mexico regulations, prior written approval from the New Mexico Environment Department must be obtained before starting any addition to, or modification of, an existing public water supply system that may affect the system reliability or the quantity or quality of the water supplied (NMR 20-7 502). Such approval is not required if the construction or modification is less than 305 m (1,000 ft) of distribution piping appurtenance during any 60-day calendar period, or if such construction or modification takes place at a facility where the water utility staff includes a professional engineer registered in New Mexico who will have responsibility for the project (NMR 20-7-502).

SNL does not own or operate a public water supply system but instead obtains its domestic water supply from the city of Albuquerque system or the Kirtland Air Force Base system. Official approval for any additional usage might have to be obtained from these water suppliers, although current water supply capacity is expected to be sufficient to meet the requirements of NIF (section I.4.5.2.3). Any new hookups would have to conform with any requirements of those suppliers.

I.5.3.3 *Executive Order 11988—Floodplain Management; Executive Order 11990—Protection of Wetlands*

Executive Order 11988 (May 21, 1977) requires Federal agencies to establish procedures to ensure that any actions undertaken in a floodplain consider the potential effects of flood hazards and floodplain management and that floodplain impacts be avoided to the extent practicable. Executive Order 11990 (May 24, 1977) requires all Federal agencies to consider protection of wetlands in decision making for a proposed action.

DOE has established procedures for compliance with these orders entitled "Compliance with Floodplain/Wetlands Environmental Review Requirements" (10 CFR 1022). These regulations require DOE to assess the effects of a proposed action on the survival, quality, and natural or beneficial values of wetlands and to avoid impacts to floodplains to the extent practicable. Pursuant to the regulations and concurrent with DOE's review of a proposed action, DOE shall prepare a floodplain/wetlands assessment that evaluates the positive and negative, direct and indirect, and long- and short-term effects of NIF construction on wetlands and floodplains and alternatives to the proposed action that might avoid adverse effects to floodplains or wetlands, and measures to mitigate the adverse effects of actions in a floodplain or wetlands area (10 CFR 1022.12). None of the sites selected for the construction are located in floodplains or wetlands (sections I.4.1.2.3, I.4.2.2.3, I.4.3.2.3, I.4.4.2.3, I.4.5.2.3, I.4.1.2.4.2, I.4.2.2.4.2, I.4.3.2.4.2, I.4.4.2.4.2, and I.4.5.2.4.2). However, the option I temporary construction staging area for LLNL would be built in the 500-year floodplain, and the bridge spanning Arroyo Las Positas would be within the 100-year floodplain. The bridge would be designed not to increase the risk of flooding. Also, no highly volatile, toxic, or water reactive materials would be stored in the staging area.

I.5.4 Ecological Resources Requirements

I.5.4.1 *Endangered Species Act*

The *Endangered Species Act* (16 U.S.C. 1531 et seq.) is intended to prevent the further decline of endangered and threatened species of animals and plants and to bring about the restoration of these species and their habitats. The Act is jointly administered by the U.S. Department of Commerce (marine species and their habitats under 5 CFR 222.23 and 227.4) and the U.S. Department of the Interior (all other plant and animal species and their habitats). Section 16 U.S.C. 1536 requires DOE to consult with the Department of the Interior, Fish and Wildlife Service, and/or Department of Commerce, National Marine Fisheries Service, to determine whether endangered and threatened species are known to have critical habitats on or in the vicinity of the sites for the proposed action. The identification of endangered and threatened species and their habitats is provided in 50 CFR 17 and 402. Each site has consulted with the Department of the Interior, Fish and Wildlife Service, concerning impacts on endangered and threatened species, migratory birds, and their critical habitats in the vicinity of the proposed locations for NIF.

I.5.4.2 *Migratory Bird Treaty Act*

The *Migratory Bird Treaty Act*, as amended (16 U.S.C. 703 et seq.), is intended to protect birds that have common migration patterns between the United States and Canada, Mexico, Japan, and the former Union of Soviet Socialist Republics. It regulates the harvest of migratory birds by specifying the mode of harvest, hunting seasons, and bag limits. The Act stipulates that it is unlawful at any time, by any means, or in any manner to "kill . . . any migratory bird." Although no permit is required under this Act, DOE would consult with the U.S. Fish and Wildlife Service, as appropriate, regarding impacts to migratory birds and to evaluate ways to avoid or minimize these impacts.

I.5.4.3 *Bald and Golden Eagle Protection Act*

The *Bald and Golden Eagle Protection Act* (16 U.S.C. 668-668d) makes it unlawful to take, pursue, molest, or disturb bald (American) and golden eagles, their nests, and their eggs anywhere in the United States. No permits or approval procedures are required unless a nest is found to interfere with resource development; in that case, a permit must be obtained from the Department of the Interior to relocate the nest. If a bald (American) or golden eagle nest was found in the vicinity of NIF activities during NIF development and construction, DOE would consult with the Department of the Interior regarding requirements under this Act.

I.5.5 Cultural and Paleontological Resources Requirements

Executive Order 11593, Protection and Enhancement of the Cultural Environment (May 15, 1971), requires Federal agencies to locate, inventory, and nominate qualifying properties under their jurisdiction or control to the National Register of Historic Places (NRHP). This process requires DOE to provide the opportunity for the Advisory Council on Historic Preservation to comment on the possible impacts of the proposed action on any potentially eligible or listed resources.

I.5.5.1 *National Historic Preservation Act*

The *National Historic Preservation Act* (16 U.S.C. 470 et seq.) provides that places with significant national historic value be placed on the NRHP. No permits or certifications are required under this Act. However, pursuant to regulations in 36 CFR 800 et seq., if a proposed action might impact a historic property resource, consultation with the State Historic Preservation Officer and the Advisory Council on Historic Preservation is required. Such consultation generally results in execution of a Memorandum of Agreement that includes stipulations that must be followed to minimize adverse impacts. No historic places were identified by the appropriate State Historic Preservation Officers at any of the sites.

I.5.5.2 *Archaeological and Historic Preservation Act*

The *Archaeological and Historic Preservation Act* (16 U.S.C. 469a et seq.) is directed at the preservation of historic and archaeological data that would otherwise be lost as a result of Federal construction.

It authorizes the Department of the Interior to undertake recovery, protection, and preservation of archaeological and historic data. If the Federal agency determines that a proposed action might cause irreparable damage to archaeological resources, that agency is required to notify the Department of the Interior in writing. The agency involved may then undertake recovery and preservation or may request that the Department of the Interior undertake preservation measures. No such sites were identified at the proposed NIF locations.

I.5.5.3 *American Indian Religious Freedom Act*

The purpose of the *American Indian Religious Freedom Act* (42 U.S.C. 1996) is to protect and preserve for Native Americans their inherent right of freedom to believe, express, and protect the traditional religions of Native Americans, including, but not limited to, access to religious or traditional sites, use and possession of sacred objects, and freedom to worship through ceremonial and traditional rites. DOE has consulted with all affected Native American groups, and no Native American cultural resources were identified at any proposed NIF location (sections I.4.1.1.5, I.4.2.1.5, I.4.3.1.5, I.4.4.1.5, and I.4.5.1.5).

I.5.6 Environmental Justice

On February 11, 1994, President Clinton issued Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations* (59 FR 7629). This Executive Order, with accompanying cover memorandum, calls on Federal agencies to incorporate environmental justice as part of their missions, including decisions made in compliance with NEPA. Specifically, the President's cover memorandum to the Environmental Justice Executive Order mentions NEPA in two contexts:

Each Federal agency shall analyze the environmental effects, including human health, economic and social effects, of Federal actions, including effects on minority communities and low-income communities, when such analysis is required by NEPA. Mitigation measures outlined or analyzed in an environmental assessment, environmental impact statement, or record of decision, whenever feasible, should address significant and adverse environmental effects of proposed Federal actions on minority communities and low-income communities.

Each Federal agency shall provide opportunities for community input in the NEPA process, including identifying potential effects and mitigation measures in consultation with affected communities and improving the accessibility of meetings, crucial documents, and notices.

No formal guidance has been issued by the Federal Working Group on Environmental Justice or DOE concerning this Executive Order. Therefore, the analysis of environmental justice issues presented in the Socioeconomics sections of chapter I.4 may somewhat vary from whatever final guidance may be issued.

I.5.7 Radiation and Hazardous Chemical Environment

I.5.7.1 *Atomic Energy Act* of 1954

The *Atomic Energy Act* of 1954 (42 U.S.C. 2011 et seq.) authorized DOE to establish standards to protect health or minimize dangers to life or property for its operations and facilities. In accordance with the *Energy Reorganization Act* of 1974, DOE-related operations are not subject to licensing by the U.S. Nuclear Regulatory Commission (10 CFR 50.11). The transportation, storage, and use of radioactive and hazardous materials is governed by DOE orders. The major DOE orders pertaining to radioactive and hazardous material management at NIF are listed in table I.5.7.1–1.

In addition, DOE has promulgated regulations for the protection of occupational workers from radiation exposure (10 CFR 835). These regulations set occupational exposure limits and require DOE facilities to develop and comply with a radiation program, including periodic audits.

I.5.7.2 *Toxic Substances Control Act*

EPA has promulgated regulations governing the use, marking, storage, and disposal of polychlorinated biphenyl (PCB)-contaminated transformers or hydraulic equipment (40 CFR 761) under the *Toxic*

TABLE I.5.7.1-1.—*U.S. Department of Energy Orders Applicable to the National Ignition Facility Project*

Order	Subject
O 151.1	Comprehensive Emergency Management System
O 232.1	Occurrence Reporting and Processing of Operations Information
O 430.1	Life Cycle Asset Management
O 440.1	Worker Protection Management for DOE Federal and Contractor Employees
O 460.1	Packaging and Transportation Safety
O 460.2	Departmental Materials Transportation and Packaging Management
O 470.1	Safeguards and Security Program
5400.1	General Environmental Protection Program
5400.5	Radiation Protection of the Public and the Environment
5480.4	Environmental Protection, Safety, and Health Protection Standards
5482.1B	Environment, Safety, and Health Appraisal Program
5484.1	Environmental Protection, Safety, and Health Protection Information Reporting Requirements
5630.12A	Safeguards and Security Inspection and Assessment Program
5700.6C	Quality Assurance

Substances Control Act (15 U.S.C. 2601-2671). If any such PCB articles are removed during the renovation of existing buildings, they must be stored and disposed of properly. PCB transformers and equipment would be disposed of at licensed incinerators or chemical waste landfills. Shipment offsite of transformers or equipment contaminated with waste PCBs would be manifested, and a proper Certificate of Destruction would be obtained.

I.5.7.3 *Emergency Planning and Community Right-to-Know Act* of 1986

Under the *Emergency Planning and Community Right-to-Know Act* of 1986 (EPCRA or SARA, Title III) (42 U.S.C. 1101 et seq.), industrial facilities are required to provide information, such as inventories of specific chemicals used or stored there, to the appropriate State Emergency Response Commission and Local Emergency Planning Committee (LEPC) to ensure that emergency plans are sufficient to respond to accidental releases of hazardous substances. This Act originally did not appear to apply to Federal agencies; however, on August 3, 1993, Executive Order 12856 was issued making each Federal agency and its jurisdictional facilities subject to the provisions of EPCRA and the *Pollution Prevention Act* of 1990. Under EPCRA, facilities with more than a threshold quality of an "extremely hazardous substance" (40 CFR 355, appendixes A and B) must provide a representative to the LEPC, promptly inform LEPC of any "relevant changes" at the facility, and upon request, promptly provide LEPC with "information . . . necessary for developing and implementing the emergency plan." Also, all covered facilities that exceed certain volume thresholds must provide an inventory of the types and quantities of hazardous materials stored or used onsite to LEPC (40 CFR 370). It is not anticipated that NIF operations would require storage of extremely hazardous substances; however, if the site already has submitted information to LEPC, any relevant changes resulting from NIF operations should be communicated to LEPC.

The transportation of radioactive or hazardous materials is governed by the *Hazardous Materials Transportation Act* (49 U.S.C. 1801 et seq.). The implementing regulations by the Department of Transportation (DOT) (49 CFR 171-179) establish requirements for shipments along public highways, including shipping papers, marking, labeling, placarding, training, emergency response information, and packaging. Therefore, any shipments of radioactive or hazardous materials to or from the NIF location would have to comply with DOT shipping requirements.

I.5.8 Waste Management

I.5.8.1 *Solid Waste Disposal Act,* as Amended by *the Resource Conservation and Recovery Act* and the *Hazardous Solid Waste Amendments* of 1984

The treatment, storage, or disposal of solid, both nonhazardous and hazardous, waste is regulated under the *Solid Waste Disposal Act*, as amended by the *Resource Conservation and Recovery Act* (RCRA) (42 U.S.C. 6901 et seq.) and the *Hazardous Solid Waste Amendments* of 1984 (HSWA). Under Section

3006 of the Act, any state that seeks to administer and enforce a hazardous waste program pursuant to RCRA may apply for EPA authorization of such program. Approved state programs are not static, and as new Federal regulations, limitations, and restrictions are promulgated by EPA, state programs must be revised in response to such changes. Prior to HSWA, changes to Federal requirements were not enforced in authorized states until the state's program was appropriately modified and approved by EPA. Now, EPA enforces Hazardous Solid Waste Amendments requirements in an authorized state until the state receives approval under section 3006(g).

California, Nevada, and New Mexico have all received authorization to enforce a hazardous waste program under Subpart C of RCRA. Nevada and New Mexico have adopted the Federal requirements for hazardous waste management. California has an authorized hazardous waste program; however, not all the Hazardous Solid Waste Amendments to RCRA have been incorporated, and California operates under a dual state-Federal regulatory system.

Under RCRA, "source, special nuclear, and by-product materials," as defined by the *Atomic Energy Act* of 1954, are excluded from the definition of solid waste and, therefore, cannot be considered hazardous waste. However, by definition, a mixture of hazardous and radioactive wastes (mixed waste) contains constituents that require regulation under RCRA. On July 3, 1986, EPA issued a clarification that the hazardous components of radioactive mixed waste are regulated under RCRA, and the radioactive components are governed by applicable *Atomic Energy Act* regulations. Because of the dual nature of this waste, it was not until 1988 that EPA issued another clarification that states could submit for authorization to regulate mixed waste storage, treatment, and disposal under state programs. When treatment standards for the land disposal restrictions were issued for mixed waste in 1990, problems arose with the long-term storage of mixed waste, since under land disposal restrictions, restricted wastes may not be stored for more than one year (40 CFR 268.50). The storage and treatment capacity problems for mixed wastes created an enforcement problem for those storing mixed wastes, including DOE.

Congress addressed the problems of DOE mixed waste storage in the *Federal Facility Compliance Act* (FFCA) of 1992 (Public Law 102-386, 106 Stat. 1505, October 6, 1992). Although FFCA made it clear that sovereign immunity is waived for the enforcement of state RCRA regulations, it granted DOE facilities a 3-year extension period before waiving sovereign immunity concerning the enforcement of land disposal restrictions regulations as applied to mixed waste (October 1995). Section 104 of the Act requires DOE to submit a draft report to EPA and to authorized states that lists national inventories of all mixed waste on a state-by-state basis and analyzes mixed waste treatment capacities and technologies. To extend the application of such sovereign immunity beyond the 3-year period, DOE must also comply with section 105 of the Act, which requires DOE to develop a comprehensive plan to treat mixed wastes for all DOE facilities. Such plans must include a comprehensive requirement for developing schedules for almost all phases of mixed waste disposal. The plans are submitted to EPA, which in turn submits them to the authorized state. DOE announced it would develop such a National Compliance Plan for its mixed waste (57 FR 57710).

Currently California, New Mexico, and Nevada have been authorized to regulate mixed waste under RCRA. Therefore, any necessary permitting of facilities for the treatment, storage, or disposal of mixed waste resulting from NIF operations in California, New Mexico, and Nevada would proceed through their normal RCRA permitting process.

I.5.8.1.1 *California Resource Conservation and Recovery Act* Requirements

LLNL operates treatment, storage, or disposal facilities under Part A interim status pursuant to filings to the California Environmental Protection Agency, Department of Toxic Substances Control (previously the Department of Health Service). Under California regulations, no facility operating under interim status may manage hazardous wastes that are not specified in Part A of the facility's permit application, employ processes not described in Part A of the permit application, or exceed the design capacities specified in Part A of the permit application (22 CCR § 66265.1[c]). LLNL's Part A Permit application does have limitations as to the waste streams that may be stored or treated in the facilities and capacity limitations. However, if all hazardous waste and mixed waste generated at NIF were accumulated onsite and shipped offsite for treatment and disposal within 90 days, such permit requirements would not apply (22 CCR § 66265.1[d]). If hazardous or mixed wastes were to be stored for more than 90 days in the permitted treatment, storage, or disposal facility, it might be necessary to amend the facility permit to include new waste streams or new capacity requirements resulting from NIF operations (22 CCR § 66270).

I.5.8.1.2 *Nevada Resource Conservation and Recovery Act* Requirements

NTS has a permitted treatment, storage, or disposal facility for storage of hazardous wastes near the Radioactive Waste Management Site in Area 5; however, it is anticipated that hazardous waste, except mixed waste, will be accumulated onsite and shipped offsite for treatment and disposal. Such accumulation does not require a permit if it meets all Federal RCRA generator requirements (40 CFR 262), as adopted by Nevada (NAC 444.8632). NTS has submitted a revised Part B Permit application, which includes a separate storage and disposal unit for solid mixed waste. Such application is pending action by the Nevada Division of Environmental Protection. NTS operates a mixed waste storage facility under Part A interim status. Under agreement between DOE and the State of Nevada, no offsite mixed waste is being accepted, pending the permit review (DOE, Permit No. NV 3890090001; Settlement Agreement for Transuranic Mixed Waste Storage Issues between the State of Nevada and DOE; Mutual Consent Agreement for the Storage of Low Level Land Disposed Restricted Mixed Waste between the State of Nevada and DOE). No mixed waste disposal is currently being conducted at the Part A interim status land disposal unit, pending land disposal restriction treatment determination. Mixed liquid waste may not be disposed of at NTS pursuant to the NTS Waste Acceptance Criteria, NVO-325. However, there are plans to develop this capability, and such a liquid mixed waste treatment facility would have to be permitted by the Nevada Division of Environmental Protection. Otherwise, mixed liquid waste can be stored at the NTS Part A interim status mixed waste storage facility for shipment to an offsite facility for treatment and disposal.

NLVF does not have a permitted treatment, storage, or disposal facility, and hazardous waste at NIF would be accumulated for transportation to offsite treatment, storage, or disposal facilities. Mixed waste would be accumulated for shipment to NTS, once the NTS Part B Permit is issued. Such accumulation would not require a permit if it met all Federal RCRA generator requirements (40 CFR 262), as adopted by Nevada (NAC 444.8632). If hazardous or mixed waste were to be stored for more than 90 days, a treatment, storage, or disposal facility would have to be sited, permitted, and operated under the regulations governing and operators of such facilities (40 CFR 264).

I.5.8.1.3 *New Mexico Resource Conservation and Recovery Act* Requirements

SNL has a permitted treatment, storage, or disposal facility for storage of hazardous waste. Hazardous waste generated at NIF would be stored in this facility until it is shipped offsite to an approved disposal facility. SNL is currently storing its liquid mixed waste at the site of generation (Wheeler 1995). Such accumulation does not require a permit if it meets all Federal RCRA generator requirements (40 CFR 262), as adopted by New Mexico (NM Regulations, Title 20, chapter 4). SNL is currently performing treatability studies at its Radioactive and Mixed Waste Management Facility to obtain a Part B Permit from the State of New Mexico. Once the facility is permitted, mixed waste will be treated there to remove the hazardous component. The residue will be disposed of as radioactive waste. When treatment of the hazardous component is not feasible, the mixed waste will be stored onsite until a disposal option becomes available. It may be necessary to amend the facility permit or the Part A application to include new waste streams or new capacity (40 CFR 270.42 and 270.72).

LANL has a permitted treatment, storage, or disposal facility; however, it is anticipated that all hazardous waste and mixed waste at NIF would be accumulated onsite and shipped offsite for treatment and disposal. Such accumulation would not require a permit if it met all Federal RCRA generator requirements (40

CFR 262), as adopted by New Mexico (NM Regulations, Title 20, chapter 4). LANL also has Part A interim status facilities. It might be necessary to amend the facility permit to include new waste streams or new capacity (40 CFR 270.42).

I.5.8.2 *Low-Level Radioactive Waste*

It is anticipated that low-level radioactive waste (LLW) will be generated as a result of the operation of NIF. As stated above, the *Atomic Energy Act* of 1954 authorized DOE to establish standards to protect health or minimize dangers to life or property. In accordance with the *Energy Reorganization Act* of 1974, DOE-related operations, including the treatment, storage, and disposal of LLW, are not subject to licensing by the U.S. Nuclear Regulatory Commission (10 CFR 50.11). Under the *Low-Level Radioactive Waste Policy Act* (42 U.S.C. 2021b et seq.), the Federal Government is responsible for the disposal of LLW owned or generated by DOE. The disposal of LLW at disposal facilities established or operated exclusively for the disposal of waste generated by the Federal Government is not subject to the other portions of the Act concerning the establishment of state-governed compacts for the disposal of LLW in those states. Therefore, the transportation, treatment, storage, and disposal of LLW generated by DOE is governed by DOE orders. The major DOE orders pertaining to LLW resulting from operation of NIF are listed in table I.5.8.2–1. DOE Order 5820.2A establishes policies and guidelines that are the framework for the LANL LLW management program.

TABLE I.5.8.2–1.—*U.S. Department of Energy Orders Concerning Low-Level Waste*

Order	Subject
O 232.1	Occurrence Reporting and Processing of Operations Information
5400.5	Radiation Protection of the Public and the Environment
5820.2A	Radioactive Waste Management

On March 25, 1993, DOE published a Notice of Proposed Rulemaking to establish standards for the protection of the public and the environment against radiation from DOE activities (Draft 10 CFR 834). The requirements would be applicable to the control of radiation exposures to the public and the environment from normal operations under the control of DOE and DOE contractor personnel. The regulations include the four basic elements of the radiation protection system:

- Establish dose limits for exposure of members of the public to radiation and implementation of DOE's as low as reasonably achievable policy.
- Manage radioactive materials in liquid waste discharges, in soil columns, and in selected solid-waste-containing radioactive materials, including groundwater protection programs for each DOE site.
- Establish requirements for decontamination, survey, and release of buildings, land, equipment, and personal material; and for the management, storage, and disposal of wastes generated by these activities.
- Establish an environmental radiation protection program and plan, including an effluent monitoring and environmental surveillance program, to set forth the programs, plans, and other processes to protect the public from exposure to radiation. On August 31, 1995, DOE issued a Notice of Limited Reopening of Comment Period for the draft regulation.

Once promulgated as a final rule, 10 CFR 834 would govern the management of radioactive materials and wastes at all the proposed NIF sites.

I.6 LIST OF PREPARERS

Name	Education/Expertise	Contribution
Timothy Allison	M.S. Mineral and Energy Resource Economics, M.A. Geography; 11 years experience in regional analysis and economic impact analysis	Socioeconomic Analysis
John Arnish	M.S. Nuclear Engineering, B.S. Physics; 2 years experience in transportation risk analysis	Radiological Transportation Risk Analysis
Susan Barisas	M.S. Water Resources; 7 years experience in environmental management; 10 years experience in environmental site assessment	Affected Environment
Bruce M. Biwer	Ph.D. Chemistry; 5 years experience in radiological pathway analysis, dose calculations, radiological transportation risk analysis	Radiological Transportation Risk Analysis
Christopher Burke	M.S. Technology Management, B.A. Geology; 20 years experience in environmental and energy impact assessment; 5 years experience in site and technology assessment	Purpose and Need, Site Descriptions
Young-Soo Chang	Ph.D. Chemical Engineering; 9 years experience in air quality impact analysis	Air Quality
John D. DePue	M.S. Biology; 20 years experience in technical editing of environmental assessment documents	Technical Editor
Lisa Durham	M.S. Geology; 7 years experience in hydrogeologic analysis; 8 years experience in environmental impact statements	Environmental Impacts Assessment
Rebecca Haffenden	J.D. Law; 15 years experience in legal research and analysis; 5 years experience in environmental impact statements	Environmental, Occupational Safety and Health Permits and Compliance Requirements
John F. Hoffecker	Ph.D. Anthropology; 20 years experience in archaeology; 12 years experience in environmental assessment and cultural resources management	Cultural and Paleontological Resources
Kou-John Hong	P.E., C.H.P., Ph.D. Nuclear Engineering; 16 years experience in radiological engineering and risk assessment	Radiological Impact Assessment
Sunita Kamboj	Ph.D. Health Physics, M.S. Physics; 5 years experience in health physics instrumentation, environmental monitoring; 1 year experience in radiological risk assessment	Proposed Action
Fred Kirchner	Ph.D. Radiation Biology, Diplomate, American Board of Toxicology; 16 years experience in toxicology	Affected Environment
David Kuhaneck	P.E., M.S. Environmental Engineering, B.S. Civil Engineering; 15 years experience in environmental analysis, permitting, and regulations	Air Quality, Acoustics

Name	Education/Expertise	Contribution
Michael A. Lazaro	P.E., M.S. Environmental/Atmospheric Sciences; M.S. Nuclear Engineering; 19 years experience in atmospheric and environmental science research and assessment; 12 years experience in project management; 6 years experience in hazard/consequence assessment	Project Manager
William Metz	Ph.D. Geography; M.I.S. Information Management; 20 years experience in socioeconomic assessment and mitigation; 10 years experience in public participation	Public Participation, Scoping
George H. Miley	Ph.D. Chemical Engineering/Nuclear Engineering; Professor of Nuclear Engineering and Electrical and Computer Engineering; Director of Fusion Studies Laboratory; 37 years experience; pioneer in the development of nuclear-pumped lasers; extensive experience in fission reactor safety, advanced ICF target design, laser-plasma interactions, and fusion technology	Waste Management Environment
Marshall Monarch	M.A. Administration; B.S. Chemical Engineering, P.E.; 25 years experience in technology and regulatory evaluation of industrial air pollution/control systems and energy analysis	Air Quality Impacts
Lee Northcutt	Program Assistance; 20 years of editorial and program management assistance; 5 years experience in environmental impact statement preparation	Glossary, List of Preparers, Abbreviations, Chemical Symbols and Units of Measure, Metric Conversion Chart
Edwin D. Pentecost	Ph.D. Zoology/Ecology; 25 years experience in environmental assessment, terrestrial ecosystem analysis, natural resources management and planning	Assistant Project Manager
John M. Pfingston	M.A. History, M.P.A. Environmental Administration; 4 years experience in energy and natural resource research; 5 years experience in environmental assessment and land-use analysis	Land Use
Anthony J. Policastro	Ph.D. Civil Engineering; 20 years experience in air quality analyses; 15 years experience in environmental assessment	Air Quality, Hazardous Chemical Impact Assessment, Acoustics
Markus Puder	Master Law; 3 years experience in environmental and energy legislation, regulation, and policy; 1 year of experience in environmental impact statements	Public Participation, Scoping
Elisabeth Ann Stull	Ph.D. Zoology; 25 years experience in environmental assessment and ecological sciences	Project Description, Purpose and Need
William Vinikour	M.S. Ecological Resources; 20 years experience in environmental research and assessment; 19 years experience in environmental impact statements	PSA Coordinator, Ecological Resources

Name	Education/Expertise	Contribution
David Walitschek	M.S. History; 8 years experience in archaeological research; 3 years experience in environmental assessment	References, Distribution List
Dee Wernette	Ph.D. Sociology/Demographics; 15 years experience in social impacts, demographics, and related social science analyses	Environmental Justice Analysis
Stephen Yin	M.S. Civil Engineering; 10 years experience in environmental impact studies; 15 years experience in hydrologic analysis and water resources planning and design	Water Resources

I.7 GLOSSARY

acoustic: Containing, producing, carrying, arising from, actuated by, related to, or associated with sound.

activation products: The radionuclides formed as a result of a material being activated. For example, cobalt-60 is an activation product resulting from neutron activation of cobalt-59.

acute exposure: The absorption of a relatively large quantity of radiation or intake of radioactive material over a short period of time.

Air Quality Control Region (AQCR): An interstate or intrastate area designated by the Environmental Protection Agency for the attainment and maintenance of National Ambient Air Quality Standards.

air quality maintenance area: An area which, due to current air quality or projected residential and industrial growth, has the potential for exceeding a national ambient air quality standard.

air quality: Measure of the health-related and visual characteristics of the air, often derived from quantitative measurements of the concentrations of specific injurious or contaminating substances. Air quality standards are the prescribed level of constituents in the outside air that cannot be exceeded during a specific time in a specified area.

ALARA (as low as reasonably achievable): A philosophy of protection that controls and maintains exposures to individuals and to the work force and general public as low as technically and economically feasible below the established limits.

alluvial fan: Cone-shaped deposits of alluvium made by a stream. Fans generally form where streams emerge from mountains onto the lowland.

alluvial/alluvium: Relating to material deposited by running water, such as clay, silt, sand, and gravel. Sedimentary material transported and deposited by the action of flowing water.

alpha particle: A positively charged particle consisting of two protons and two neutrons that is emitted during radioactive decay from the nucleus of certain nuclides. It is the least penetrating of the three common types of radiation (alpha, beta, and gamma). Symbol: α.

ambient air: The surrounding atmosphere as it exists around people, plants, and structures.

ambient noise levels: All encompassing background noise levels associated with a given environment, usually a composite of sounds from many sources, near and far.

ambient sound level (LDN): The 24-hour equivalent continuous sound level with a night-time penalty added, i.e., the time-averaged A-weighted sound level, in decibels, from midnight to midnight, obtained after the addition of 10 dB to sound levels from midnight to 7:00 a.m. and from 10:00 p.m. to midnight.

***American Indian Religious Freedom Act* of 1978:** This Act establishes national policy to protect and preserve for Native Americans their inherent right of freedom to believe, express, and exercise their traditional religions, including the rights of access to religious sites, use and possession of sacred objects, and the freedom to worship through traditional ceremonies and rites.

AP-42: see "emission factors".

aquifer: A saturated geologic unit through which significant quantities of groundwater can migrate under natural hydraulic gradients.

Argus: Laser system at Lawrence Livermore National Laboratory.

arithmetic mean: The average of a set of terms, computed by dividing their sum by the number of terms. See "geometric mean".

arroyo: A gully or channel cut by an intermittent stream.

atmospheric dispersion: The spreading downwind of airborne material due to wind speed and atmospheric turbulence; the greater the spread, the greater the dilution and the smaller the airborne material concentrations.

attainment area: An area considered to have air quality as good as or better than the national ambient air quality standards as defined in the *Clean Air Act*. An area may be an attainment area for one pollutant and a nonattainment area for others (see "nonattainment area").

background radiation: Ionizing radiation present in the environment from cosmic rays and natural sources in the Earth; background radiation varies considerably with location.

basement rocks: The undifferentiated complex of rocks that underlies the rocks of interest in an area. The crust of the earth below sedimentary deposits, extending downward to the Mohorovicic discontinuity. In many places the rocks of the complex are igneous and metamorphic and of Precambrian age.

beamlets: Independent laser beams.

Best Available Control Technology (BACT): A term used in the Federal *Clean Air Act* that means the most stringent level of air pollutant control considering economics for a specific type of source based on demonstrated technology.

Best Management Practices: Activities, procedures, or physical structures for reducing the amount of pollution entering the surface water and groundwater.

beta particle: An elementary particle emitted from a nucleus during radioactive decay; it is negatively or positively charged, identical in mass to an electron, and in most cases easily stopped, as by a thin sheet of metal. Symbol: β.

Biological Resources Evaluations Team (BRET): The team within the Environmental Protection Group of Los Alamos National Laboratory responsible for biological assessments.

biota: The plant and animal life of a region.

bounding: In the context of accident analysis, bounding is a condition, consequence, or risk that provides an upper bound that is not exceeded by other conditions, consequences, or risks. The term is also used to identify conservative assumptions that will likely overestimate actual risks or consequences.

British thermal unit (Btu): A unit of heat; the quantity of heat required to raise the temperature of one pound of water by one degree Fahrenheit. One British thermal unit equals 1,055 joules (or 252 calories).

cancer: A group of diseases characterized by uncontrolled cellular growth. Increased incidence of cancer can be caused by exposure to radiation or to certain chemicals at sufficient concentrations and exposure durations.

candidate sites: Candidate sites for the National Ignition Facility are Lawrence Livermore National Laboratory (LLNL) as the preferred site, and Los Alamos National Laboratory (LANL), Sandia National Laboratories (SNL), and the Nevada Test Site (NTS) (Area 22 main site location and North Las Vegas Facility [NLVF] location near NTS) as alternative sites.

carbon monoxide (CO): A colorless, odorless gas that is toxic if breathed in high concentration over a period of time.

change-out: A procedure by which components affected by induced radioactivity are periodically rotated between in-service and out-of-service status to allow the induced radioactivity to decay below predetermined limits and thus maintain a lower total level of radioactivity or a longer useful life. In some cases, decontamination cleaning may also be done during the out-of-service period.

chronic exposure: The absorption of radiation or intake of radioactive and/or chemical materials over a long period of time.

Class I area: Pristine areas in the United States whose air quality requires special protection from pollution from new sources.

Class II area: Areas in the United States with acceptable air quality levels where moderate increases in air pollutant concentrations from new sources are allowed.

Class III area: Areas in the United States with acceptable air quality levels where larger increases in air pollutant concentrations from new sources are allowed than in Class II areas.

***Clean Air Act Amendments* of 1990:** Expands the Environmental Protection Agency's enforcement powers and adds restrictions on air toxins, ozone-depleting chemicals, stationary and mobile emissions sources, and emissions implicated in acid rain and global warming.

***Clean Air Act*:** Federal Act that mandates the promulgation and enforcement of air pollution control standards for stationary sources and motor vehicles.

***Clean Water Act* of 1972, 1987:** Federal Act regulating the discharge of pollutants from a point source into navigable waters of the United States in compliance with a National Pollution Discharge Elimination System permit as well as regulating discharges to or dredging of wetlands.

climatology: The science that deals with climates and investigates their phenomena and causes.

***Code of Federal Regulations* (CFR):** All Federal regulations in force are published in codified form in the *Code of Federal Regulations*.

collective committed effective dose equivalent: The committed effective dose equivalent of radiation for a population.

colluvium: A general term applied to any loose, heterogeneous, and incoherent mass of soil material and/or rock fragments deposited by rainwash, sheetwash, or slow continuous downslope creep, usually collecting at the base of gentle slopes or hillsides. Deposition by a combination of gravity and water.

committed dose equivalent: The predicted total dose equivalent to a tissue or organ over a 50-year period after an intake of radionuclides into the body. It does not include external dose contributions. Committed dose equivalent is expressed in units of rem or Sievert. The committed effective dose equivalent is the sum of the committed dose equivalents to various tissues of the body, each multiplied by the appropriate weighting factor.

Composite Noise Rating: see "Modified Composite Noise Rating" (CNR).

Conceptual Design Option: This option would use an ICF approach called indirect drive. In indirect drive, laser beams would illuminate and heat the interior surfaces of a metal case (hohlraum) containing a deuterium-tritium-filled capsule. The beams would cause the case to emit x rays that would strike the fusion target capsule and drive the fusion reaction.

criteria pollutants: Six air pollutants for which national ambient air quality standards are established by the Environmental Protection Agency under Title I of the Federal *Clean Air Act*. The six pollutants are sulfur dioxide, nitrogen oxides, carbon monoxide, ozone, particulate matter smaller than 10 microns in diameter (PM_{10}), and lead.

critical habitat: Air, land, or water area and constituent elements, the loss of which would appreciably decrease the likelihood of survival and recovery of a listed species or a distinct segment of its population.

cryogenic target positioner: The system that is composed of a telescoping arm that is used to insert and withdraw the complete target cryogenic system and target, and allows aiming, alignment, and engagement by the NIF laser.

cultural resources: Archaeological sites, architectural features, traditional use areas, and Native American sacred sites or special use areas.

curie (Ci): A unit of radioactivity equal to 37 billion disintegrations per second; also, activity of that quantity of material in which 3.7×10^{10} atoms are transformed per second.

dBA (Decibel, A-weighted): A unit of weighted sound pressure level that correlates overall sound pressure levels with the frequency response of the human ear; measured by the use of a metering characteristic and the "A" weighting specified by the American National Standard Institute S1.4-1971(R176).

decommissioning: The process of removing a facility from operation, followed by decontamination, entombment, dismantlement, or conversion to another use.

decontamination: The actions taken to reduce or remove substances that pose a substantial present or potential hazard to human health or the environment—such as radioactive contamination from facilities, soil, or equipment—by washing, chemical action, mechanical cleaning, or other techniques.

deuterium: The hydrogen isotope that is twice the mass of ordinary hydrogen and that occurs in water; also called heavy hydrogen.

diatomaceous: Composed of or containing numerous diatoms or their siliceous remains.

DOE Orders: Requirements internal to the U.S. Department of Energy (DOE) that establish DOE policy and procedures, including those for compliance with applicable laws.

dose: The amount of energy deposited in body tissue due to radiation exposure. Various technical terms—such as dose equivalent, effective dose equivalent, and collective dose—are used to evaluate the amount of radiation an exposed individual or population receives.

driver: A device for supplying the primary source of energy to an inertial fusion energy target; drivers can be lasers, ion beams, or intense gamma ray sources.

effective dose equivalent (EDE): The sum of the products of the dose equivalent to the organ or tissue and the weighting factors applicable to each of the body organs or tissues that are irradiated. The EDE includes the dose from radiation sources internal and/or external to the body and is expressed in units of rem. The International Commission on Radiological Protection defines this as the effective dose.

emission factors: An average value that relates to the quantity of an air pollutant released to the atmosphere with the activity associated with the release of the pollutant and usually expressed as the weight of pollutant divided by a unit weight, volume, distance, or duration of the activity that emits the pollutant. Emission factors are widely used for estimating air pollutant emissions and are often acceptable by regulatory authorities as an appropriate estimation of air pollution emissions to determine compliance with regulations.

emission offsets: Areas that allow no net increase in air pollution emissions require that a new source offset emission increases by decreasing an equivalent amount of emissions from an existing source. In some cases emission offsets or credits can be obtained from a depository that collects emission credits from retired sources.

endangered species: Any species that is in danger of extinction throughout all or a significant portion of its geographic range.

Enhanced Option: The Enhanced Option would include the indirect drive operations of the Conceptual Design Option and a second approach called direct drive. The Enhanced Option would also include the capability to perform an increased number of yield experiments to accommodate greater user needs. No hohlraum would be used in the direct drive approach. Instead, a large number of laser beams would be employed to ensure good uniformity of the driving force (laser light) over the face of the target. The laser beams would impinge directly on the deuterium-tritium-filled capsule to drive the fusion reaction.

Environmental Assessment (EA): A concise public document that provides sufficient evidence and analysis for determining whether to prepare an environmental impact statement (EIS) or a finding of no significant impact for a proposed action. An EA includes brief discussions of the need for the proposed action, the features of alternatives, the environmental impacts of the proposed action and alternatives, and a listing of agencies and persons consulted.

Environmental Impact Statement (EIS): A document required of Federal agencies by the *National Environmental Policy Act* for major proposals or legislation significantly affecting the environment. A tool for decisionmaking, it describes the positive and negative effects of the undertaking and alternative actions.

environmental justice: The fair treatment of people of all races, cultures, incomes, and educational levels with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment implies that no population of people should be forced to shoulder a disproportionate share of the negative environmental impacts of pollution or environmental hazards due to a lack of political or economic strength.

ERPG-2 (Emergency Response Planning Guidelines-2): Concentration level for a 1-hour inhalation exposure that would allow a person to take protective action and avoid irreversible health effects.

exposure pathways: The course a chemical or physical agent takes from the source to the exposed organism. An exposure pathway describes a unique mechanism by which an individual or population is exposed to chemicals or physical agents at or originating from a release site. Each exposure pathway includes a source or release from a source, an exposure point, and an exposure route. If the exposure point differs from the source, a transport/exposure medium such as air is also included.

exposure: The condition of being made subject to the action of radiation. Sometimes also used as a generic term to refer to the dose of radiation absorbed by an individual or population.

fault: A fracture in the earth's crust accompanied by displacement of one side of the fracture with respect to the other and in a direction parallel to the fracture.

federally listed species: see "threatened, endangered, candidate, or rare species".

fission: The splitting of a heavy atomic nucleus into two nuclei of lighter elements, accompanied by the release of energy and generally one or more neutrons. Fission can occur spontaneously or be induced by neutron bombardment.

flood, 100-year: A flood event of such magnitude it occurs, on average, every 100 years (equates to a 1-percent probability of occurring in any given year).

flood, 500-year: A flood event of such magnitude it occurs, on average, every 500 years (equates to a 0.2-percent probability of occurring in any given year).

floodplain: The lowlands adjoining inland and coastal waters and relatively flat areas including, at a minimum, that area inundated by a 1-percent or greater chance flood in any given year. The base floodplain is defined as the 100-year (1.0 percent) floodplain. The critical action floodplain as defined as the 500-year (0.2 percent) floodplain.

footprint: The layout of a facility on the ground; also refers to an area affected by release of radioactive materials.

fugitive dust: The dust released from activities associated with an alternative such as construction, manufacturing, or transportation.

fugitive emissions: Uncontrolled emissions to the atmosphere from pumps, valves, flanges, seals, and other process points not vented through a stack. Also includes emissions from area sources such as ponds, lagoons, landfills, and piles of stored material.

fusion: Nuclear reaction in which light nuclei are fused together to form a heavier nucleus, accompanied by the release of immense amounts of energy and fast neutrons.

fusion fuel: Mixture of deuterium and tritium contained in a small capsule called the target.

fusion reaction: When two nuclei of lighter elements are brought into close enough proximity, they can undergo thermonuclear fusion forming a single nucleus and releasing energy at the slight expense in mass of the original constituents. Typically, a deuterium and tritium nucleus are fused in such a reaction to produce a helium nucleus plus one free neutron. The released energy of 17.6 MeV (million electron volts) is carried mostly as kinetic energy by the neutron (14 MeV).

gamma: High-energy, short-wavelength electromagnetic radiation (a packet of energy) emitted from the nucleus. Gamma radiation frequently accompanies alpha and beta emissions and always accompanies fission. Gamma rays are very penetrating and are best stopped or shielded against by dense materials such as lead or uranium. Gamma rays are similar to x rays, but are usually more energetic. Symbol: γ.

geometric mean: For a set of *n* terms, the *n*th root of their product. For a set of positive numbers, the geometric mean is always less than or equal to the arithmetic mean (see "arithmetic mean").

habitat: Area where a plant or animal lives.

hazardous chemical: Any chemical that is a physical hazard or a health hazard as defined by the Occupational Safety and Health Administration (29 CFR 1910.1201). For *Superfund Amendments and Reauthorization Act* (SARA) Title III, Section 311, the term is defined the same with certain named exceptions.

hazardous waste: Under the *Resource Conservation and Recovery Act*, a solid waste, or combination of solid wastes, which because of its quantity, concentration, or physical, chemical, or infectious characteristics may (a) cause or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness; or (b) pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, or disposed of, or otherwise managed. Source, special nuclear material, and byproduct material, as defined by the *Atomic Energy Act*, are specifically excluded from the definition of solid waste.

hohlraum: The metal case surrounding the target on indirect-drive inertial confinement fusion.

igneous: Refers to a rock or mineral that solidified from molten or partly molten material, i.e., from a magma; also, applied to processes leading to, related to, or resulting from the formation of such rocks. Igneous rocks constitute one of the three main classes into which rocks are divided, the others being metamorphic and sedimentary.

ignition: Ignition (fusion) is defined as the conditions leading to the self-heating of the fusion fuel by the fusion driver (such as laser beams). That condition occurs during the final part of the laser pulse when the fuel core is compressed to 20 times the density of lead (226 g/cm^3) and simultaneously heated to 100 million °C. The self heating of the fuel capsule is caused by alpha particle (fusion reaction byproduct) deposition. Ignition occurs when the reaction product deposition becomes faster than the heating caused by compression.

ignitron switch: A high current switch used to discharge energy storage capacitors, which are used to fire laser flashlamps.

inertial confinement fusion (ICF): An energetic driver beam (laser, x ray, or charged particle) initiated nuclear fusion using the inertial properties of the reactants as a confinement mechanism.

inertial fusion energy (IFE): The use of high-repetition-rate lasers or ion drivers (about 10 pulses per second) to accomplish laboratory and commercial thermonuclear fusion.

ingestion dose: An internal dose that results from the oral intake of food, water, soil, or other media contaminated with radioactive material.

input parameters: Values of variables needed to run a computer model.

interim (permit) status: Period during which treatment, storage, and disposal facilities coming under the *Resource Conservation and Recovery Act* of 1980 are temporarily permitted to operate while awaiting denial or issuance of a permanent permit.

isotope: An atom of a chemical element with a specific atomic number and atomic mass. Isotopes of the same element have the same number of protons but different numbers of neutrons and different atomic masses.

Joule: A metric unit of energy, work, or heat, equivalent to 1 watt-second, 0.737 foot-pound, or 0.239 calorie.

Key Decisions (KDs): The Department of Energy's procedure for approving large projects such as NIF is based on "Critical Decisions" (formerly known as Key Decisions) made by the Secretary of Energy. In January 1993, the Secretary approved "Key Decisions" 0, which affirmed the need for NIF and authorized a collaborative effort by the three DOE defense laboratories and the University of Rochester Laboratory for Laser Energetics to produce a conceptual design report. This report was completed in April 1994. "Key Decisions" 1 was signed by the Secretary in October 1994. This decision initiated preliminary design, safety analysis, cost and schedule validation and a two-year EIS, which will include public involvement. Critical Decision 3 (formerly known as Key Decision 3), scheduled for late 1997, will authorize construction and major procurements.

laser optics: Many large optical components are required for NIF and are located throughout the laser system. These include laser slabs housed within the amplifier columns, lenses used in the spatial filters for image relaying and on the target chamber for final focusing of the beams on the target, mirrors to reflect the beams within the laser cavity, and to direct the beam on the target chamber, polarizers and potassium dihydrogen phosphate crystal for switching and frequency conversion, and phase plates to smooth the beams and protect the final focus lenses from debris. Many other optical elements are used in laser diagnostics, in beam control systems, and for pulse injection into the main amplifiers.

laser pulse: The duration of time from the beginning of laser deposition on a surface to the end of the laser deposition.

laser: A device that produces a beam of monochromatic (single-color) "light" in which the waves of light are all in phase. This condition creates a beam that has relatively little scattering and has a high concentration of energy per unit area of the beam.

latent cancer fatality: Term used to indicate the estimated number of cancer fatalities which may result from exposure to a cancer-causing element. Latent cancer fatalities are similar to naturally occurring cancers and may occur at any time after the initial exposure.

LDN: see "ambient sound level".

leaching test: A test conducted to determine the leach rate of a waste form. The test results may be used for judging and comparing different types of waste forms, or may serve as input data for a long-term safety assessment of a repository.

level of concern: The concentration of an extremely hazardous substance (EHS) in the air above which there may be serious irreversible health effects or death as a result of a single exposure for a relatively short period of time.

level of service (LOS): The extent of community, health care and educational services provided by local jurisdictions in the vicinity of the proposed NIF sites. LOS is measured in terms of per capita expenditures on services in each of these categories. In traffic studies, LOS means the different operating conditions that occur in a lane or roadway when accommodating various traffic volumes. A qualitative measure of the effect of traffic flow factors such as special travel time, interruptions, freedom to maneuver, driver comfort, convenience, and (indirectly) safety and operating cost. Levels of service are described by a letter rating system of A through F, with LOS A indicating stable traffic flow with little or no delays and LOS F indicating excessive delays and jammed traffic conditions.

location: In this EIS, location refers to the proposed location of the National Ignition Facility within or near the larger DOE-controlled Federal site.

LOS: see "level of service."

low-income status: Based on Census data definitions of individuals below the poverty line. For the 1990 Census, for example, low-income status included individuals in 4-person families with 1989 incomes at or below $12,674. Other poverty thresholds are provided by the Census Bureau for larger and smaller family sizes.

low-level waste (LLW): Waste that contains radioactivity but is not classified as high-level waste, transuranic waste, spent nuclear fuel, or "11e(2) by-product material" as defined by DOE Order 5820.2A, *Radioactive Waste Management.* Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranic waste is less than 100 nanocuries per gram.

maintenance pollutants: Criteria air pollutants in an Air Quality Maintenance Area that may exceed the ambient air quality standard over time.

master-oscillator power-amplifier (MOPA) chain: Solid-state laser design that provides the required laser beam energy and power amplification using a single-pass MOPA chain. The MOPA chain starts with a small oscillator (the master oscillator) that produces a laser pulse, which enters a preamplifier before making a single pass through a chain of amplifiers of gradually increasing size.

Master Oscillator Room (MOR): A self-contained special-purpose room that would house the NIF Master Oscillators and their supporting equipment. The purpose of this facility is to supply the 192 individually shaped and timed low-level laser pulses to the Preamplifier Modules located beneath the Spatial Filters in the main laser hall.

maximally exposed individual (MEI): A hypothetical individual who could potentially receive the maximum possible dose of radiation (or hazardous chemical).

maximum contaminant levels: Maximum permissible concentration of a contaminant in water which is delivered to any user of a public water system.

maximum design yield: The NIF Target Area has been designed to safely confine and withstand the effects of the yield of its targets up to this yield on some routine basis (e.g., weekly).

maximum yield experiment: A fusion ignition experiment that generates maximally expected fusion energy.

meteorology: The science dealing with the atmosphere and its phenomena, especially as it relates to weather.

millirem (mrem): One-one-thousandth of a rem (see "rem").

minority populations: Includes individuals who report themselves as belonging to any of the following racial groups: Black (reported their race as "Black or Negro," or reported entries such as "African American, Afro-American, Black Puerto Rican, Jamaican, Nigerian, West Indian, or Haitian"); American Indian, Eskimo, or Aleut; Asian or Pacific Islander, or "Other Race." In addition, individuals identifying themselves as Hispanic origin are also included in the minority category. Hispanics can be of any race, however. To avoid double-counting minority Hispanic individuals, only white Hispanics were included in the number of racially based minorities in a tabulation, since nonwhite Hispanics had already been counted under their minority racial classification.

Miocene: A geologic epoch in the Cenozoic Era dating from 26 to 7 million years ago.

mixed waste: Radioactive waste that contains nonradioactive toxic or hazardous materials that could cause undesirable effects in the environment. Such waste has to be handled, processed and disposed of in such a manner that considers the chemical as well as its radioactive components.

model: A conceptual, mathematical, or physical system obeying certain specified conditions, whose behavior is used to understand the physical system to which it is analogous.

Modified Composite Noise Rating (CNR): Noise rating system that determines impacts from a fixed noise source using objective and subjective factors. Noise ranked A through D is generally considered to be acceptable with "A" representing essentially no impacts. Rankings above "D" are usually addressed with mitigative measures unless the source is temporary.

molecular sieve: A material with a rigid, uniform pore structure that completely excludes molecules larger than the structure pore openings and that can absorb certain classes of small molecules from a fluid in contact with the material.

MOR: see "Master Oscillator Room".

mrem: One one-thousandth of a rem (see "rem").

NAAQS: see "National Ambient Air Quality Standards".

National Ambient Air Quality Standards (NAAQS): Air quality standards established by the *Clean Air Act*, as amended. The primary National Ambient Air Quality Standards are intended to protect the public health with an adequate margin of safety, and the secondary National Ambient Air Quality Standards are intended to protect the public welfare from any known or anticipated adverse effects of a pollutant.

***National Environmental Policy Act* (NEPA) of 1969:** The Act that established the national policy to protect humans and the environment, requiring environmental reviews of Federal actions that have the potential for significant impact on the environment, and established the Council on Environmental Quality.

***National Historic Preservation Act* of 1966, as amended:** This Act provides that property resources with significant national historic value be placed on the National Register of Historic Places. It does not require any permits but, pursuant to Federal code, if a proposed action might impact an historic property resource, it mandates consultation with the proper agencies.

National Ignition Facility (NIF): The proposed international research center comprising the world's most powerful laser, NIF would achieve ignition of fusion fuel and energy gain for the first time in a laboratory.

National Pollutant Discharge Elimination System (NPDES): Federal permitting system required for hazardous effluents regulated through the *Clean Water Act*, as amended.

***National Register of Historic Places*:** A list maintained by the National Park Service of architectural, historic, archaeological, and cultural sites of local, state, or national significance.

neodymium: A rare-earth metal listed in the periodic table of elements with an atomic number of 60 and an atomic weight of 144.24. The metal has a bright silvery metallic luster. Neodymium is one of the more reactive rare-earth metals and quickly tarnishes in air, forming an oxide that spalls off and exposes the metal to oxidation. Besides its use in producing coherent light in glass lasers, this metal has been used in astronomical work to produce sharp bands by which spectral lines may be calibrated. Neodymium salts are also used as a colorant for enamels, and in its separated form it is used to color glass in delicate shades ranging from pure violet to wine-red and warm gray.

neodymium glass laser: A type of solid-state laser that uses neodymium-doped optical fibers, rods, or glass slabs, with small amounts neodymium added, in which laser generation and amplification equipment are made. This equipment includes a master oscillator, preamplifier, and a series of amplifiers needed to generate and propagate laser beamlines that are highly stable and with the desired peak power level and frequency.

NEPA: see *National Environmental Policy Act.*

neutron: An uncharged elementary particle with a mass slightly greater than that of the proton, found in the nucleus of every atom heavier than hydrogen-1; a free neutron is unstable and decays with a half-life of about 13 minutes into an electron and a proton.

nitrogen oxides (NO_x): Refers to the oxides of nitrogen, primarily NO (nitrogen oxide) and NO_2 (nitrogen dioxide). These are produced in the combustion of fossil fuels and can constitute an air pollution problem. When nitrogen dioxide combines with volatile organic compounds, in sunlight, ozone is produced.

No Action alternative: Under this alternative, DOE would not construct and operate NIF and its support facilities. In the absence of NIF, the Nova Facility at LLNL would continue to operate beyond the year 2000.

***Noise Control Act* of 1972:** This Act directs all Federal agencies to carry out programs in a manner that furthers a national policy of promoting an environment free from noise that jeopardizes health or welfare.

nonattainment area: An air quality control region (or portion thereof) in which the Environmental Protection Agency has determined that ambient air concentrations exceed national ambient air quality standards for one or more criteria pollutants.

nonhazardous wastes: Routinely generated, nonhazardous wastes include general facility refuse such as paper, cardboard, glass, wood, plastics, scrap, metal containers, dirt, and rubble. These wastes are segregated and recycled whenever possible.

normal operations: All normal conditions and those abnormal conditions that frequency estimation techniques indicate occur with a frequency of more than 0.1 event per year.

Nova: A 10-beam, neodymium glass fusion laser facility at Lawrence Livermore National Laboratory capable of operating at 50 terawatts at 1/3 micrometers that was completed in 1984 and used for inertial confinement fusion target irradiation experiments.

NPDES: see "National Pollutant Discharge Elimination System".

nuclear weapon: The general name given to any weapon in which the explosion results from the energy released by reactions involving atomic nuclei, either fission, fusion, or both.

Occupational Safety and Health Administration (OSHA): Oversees and regulates workplace health and safety, created by the *Occupational Safety and Health Act* of 1970.

opacity restrictions: Visible-emission regulations that are based on the light-scattering properties of suspended matter in the ambient atmosphere and apply to near-field emissions of fixed sources.

ozone (O_3): The triatomic form of oxygen. In the stratosphere, ozone protects the Earth from the sun's ultraviolet rays; in lower levels of the atmosphere, ozone is considered an air pollutant.

paleontology: The study of fossils.

particulate (airborne): Small particles that are emitted from fixed or mobile sources and dispersed in the atmosphere.

Pasquill stability categories: Classification scheme that describes the degree of atmospheric turbulence. Categories range from extremely unstable (A) to extremely stable (F). Unstable conditions promote the rapid dispersion of atmospheric contaminants and result in lower air concentrations as compared with stable conditions.

perennial stream: A watercourse that flows year-round.

Permissible Exposure Limit (PEL): Occupational exposure limits endorsed by OSHA. May be for short-term or 8-hour duration exposure.

person-rem: The unit of collective radiation dose commitment to a given population; the sum of the individual doses received by a population group.

pH (potential of hydrogen): A measure of the hydrogen ion concentration in aqueous solution. Pure water has a pH of 7, acidic solutions have a pH less than 7, and basic solutions have a pH greater than 7.

photochemical oxidant: A class of compounds typified by ozone that represents oxidizing compounds created in the atmosphere with sunlight as a catalyst under low wind conditions.

piedmont: An area, plain, slope glacier, or other feature at the base of a mountain.

playa: Level area at the bottom of a desert basin that at times is temporarily covered with water; a dry lake bed.

Pleistocene: The geologic epoch that began approximately 1.8 million to 10,000 years ago (is generally equated with the "Ice Age").

Pliocene: Geologic epoch between the Miocene and the Pleistocene epochs approximately 5.5 to 1.8 million years ago.

plume: The spatial distribution of a release of airborne or waterborne material as it disperses in the environment.

PM_{10}: Particulate matter of aerodynamic diameter less than 10 micrometers.

population dose (population exposure): Summation of individual radiation doses received by all those exposed to the source or event being considered. The collective radiation dose received by a population group, usually measured in units of person-rem.

Precambrian: Dating from before the Cambrian geologic period more than 570 million years ago.

precursor pollutants: Pollutants that must be present in the atmosphere before chemical reactions take place and form the pollutant of interest. For example, nitrogen oxides, volatile organic compounds, and carbon monoxide are precursor pollutants to the formation of ozone.

preferred alternative: The preferred alternative for NIF is the Enhanced Option (indirect and direct drive) constructed at LLNL, the preferred site.

Prevention of Significant Deterioration (PSD): Regulations established by the 1977 *Clean Air Act* Amendments to limit increases in criteria air pollutant concentrations above baseline.

Project-Specific Analysis (PSA): This document provides an environmental evaluation of the impacts of construction and operation of the NIF as a basis for DOE's decision on whether to construct and operate such a facility at any of five locations at four candidate sites.

Proposed Action alternative: To site, construct, and operate the National Ignition Facility, which would be capable of achieving fusion ignition by the inertial confinement fusion process.

PSD: see "Prevention of Significant Deterioration".

public: Anyone outside the boundary of a DOE site at the time of an accident or during normal operations.

Quaternary: The period of geologic time since the end of the Pliocene, comprising the Pleistocene and Holocene, from about 1.6 million years ago to the present.

radiation: The emitted particles or photons from the nuclei of radioactive atoms. Some elements are naturally radioactive; others are induced to become radioactive by bombardment in a reactor. Naturally occurring radiation is indistinguishable from induced radiation.

radioactive decay time: Associated with the spontaneous transformation of one nuclide into a different nuclide or into a different energy state of the same nuclide; the process results in a decrease, with time, in the number of original radioactive atoms in the sample. The half-life decay "time" is generally defined in terms of the time required for one-half of the original species to decay.

radioactive decay: The decrease in the quantity of a radioactive material with the passage of time.

radioactive waste: Materials from nuclear operations that are radioactive or are contaminated with radioactive materials and for which use, reuse, or recovery are impractical.

radioactivity: The spontaneous decay or disintegration of unstable atomic nuclei, accompanied by the emission of radiation.

radiological risk: The product of the accident consequence (dose) and the probability of the accident occurring; calculated by considering a wide range of accidents, from high-probability low-consequence events to low-probability high-consequence events.

radionuclide: An atom that exhibits radioactive properties. Standard practice for naming a radionuclide is to use the name or atomic symbol of an element followed by its atomic weight (e.g., cobalt-60 or Co-60, a radionuclide of cobalt).

rare species: Populations and/or individuals occurring in very low numbers relative to other similar taxa in the state, although common or regularly occurring throughout much of their range. They may be found in a restricted geographic region or occur sparsely over a wider area. Although rare, populations are apparently stable.

region of influence (ROI): The area surrounding each proposed NIF site in which at least 90 percent of the current DOE workforce lives, and counties in which at least 5 percent of the DOE workforce lives.

rem: The dosage of an ionizing radiation that will cause the same biological effect as one roentgen of x ray or gamma-ray exposure.

***Resource Conservation and Recovery Act* (RCRA), as amended:** The Act that provides a "cradle to grave" regulatory program for hazardous waste and that established, among other things, a system for managing hazardous waste from its generation until its ultimate disposal.

resuspended inhalation: Exposure route in which radioactive materials enter the body through inhalation of air contaminated with radioactive particulates that were previously deposited on the ground following an accidental release.

riparian: Of, on, or pertaining to the bank of a river, stream, or lake.

risk factor: Numerical estimate of the severity of harm associated with exposure to a particular risk agent.

roentgen: a unit of exposure to ionizing x- or gamma radiation equal to or producing 1 electrostatic unit per cubic centimeter of air. It is approximately equal to 1 rad.

***Safe Drinking Water Act*, as amended:** This Act protects the quality of public water supplies, water supply and distribution systems, and all sources of drinking water.

SARA: see *Superfund Amendments and Reauthorization Act.*

sedimentary rock: A rock resulting from the consolidation of loose sediment that has accumulated in layers, consisting of mechanically formed fragments of older rock transported from its source and deposited in water or from air or ice.

seismic zone: An area defined by the Uniform Building Code (1991), designating the amount of damage to be expected as the result of earthquakes. The United States is divided into six zones: (1) Zone 0 - no damage; (2) Zone 1 - minor damage; corresponds to intensities V and VI of the modified Mercalli intensity scale; (3) Zone 2A - moderate damage; corresponds to intensity VII of the modified Mercalli intensity scale (eastern United States); (4) Zone 2B - slightly more damage than 2A (western United States); (5) Zone 3 - major damage; corresponds to intensity VII and higher of the modified Mercalli intensity scale; (6) Zone 4 - areas within Zone 3 determined by proximity to certain major fault systems.

seismicity: The tendency for the occurrence of earthquakes.

severity: Function of the magnitudes of the mechanical forces (impact) and thermal forces (fire) to which a package may be subjected during an accident; any sequence of events that results in an accident in which a transport package is subjected to forces within a certain range of values is assigned to the accident severity category associated with that range.

shielding: Any material or obstruction (bulkheads, walls, or other constructions) that absorbs radiation in order to protect personnel or equipment.

shot: Refers to all (192) laser beams hitting the target simultaneously.

site: In this PSA, the term "site" refers to a DOE-controlled Federal site, such as Los Alamos National Laboratory or the Nevada Test Site.

socioeconomics (analyses): Analyses of those parts of the human environment in a particular location that are related to existing and potential future economic and social conditions. The welfare of human beings as related to the production, distribution, and consumption of goods and services.

Solid Waste Management Unit (SWMU): Any discernible unit at which solid wastes have been placed at any time regardless of whether the unit was intended for solid or hazardous waste management.

source: Any physical entity that may cause radiation exposure, for example by emitting ionizing radiation or releasing radioactive material.

stability class: see "Pasquill stability categories".

Stockpile Stewardship and Management Program: A single, highly integrated technical program for maintaining the safety and reliability of the U.S. nuclear stockpile in an era without nuclear testing and without new weapons development and production.

Stormwater Pollution Prevention Plan: A plan required by an NPDES permit for controlling stormwater pollution resulting from construction or industrial activities.

sulfur oxides (SO_x): A general term used to describe the oxides of sulfur; pungent, colorless gases formed primarily by the combustion of fossil fuels. Sulfur oxides, which are considered major air pollutants, may damage the respiratory tract as well as vegetation.

***Superfund Amendments and Reauthorization Act* (SARA):** Public Law 99-499 passed in 1986 which amends the *Comprehensive Environmental Response, Compensation and Liability Act* (CERCLA) of 1980. SARA more stringently defines hazardous waste cleanup standards and emphasizes remedies that permanently and significantly reduce the mobility, toxicity, or volume of wastes. Title III of SARA, the *Emergency Planning and Community Right-to-Know Act*, mandates establishment of community emergency planning programs, emergency notification, reporting of chemicals, and emission inventories.

targets: Refers to a microstructure containing a tiny fuel capsule at which the lasers are directed.

tectonic: Pertaining to the processes causing, and the rock structures resulting from, deformation of the earth's crusts.

terawatt (TW): The equivalent of one trillion watts (10^{12}).

terrestrial: Pertaining to plants or animals living on land rather than in water.

thermoluminescent dosimeter: A radiation detection device that accumulates a dose or exposure over a period of time.

threatened species: Any species that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

threshold limit value (TLV): The recommended concentration of a contaminant that a worker may be exposed to according to the American Council of Governmental Industrial Hygienists.

time-weighted average (TWA): Time-weighted average representing 8 hours per day for 40 weeks for 40 years of exposure.

total suspended particulates (TSP): Particulate matter present in the atmosphere.

***Toxic Substances Control Act* of 1976 (TSCA):** Act authorizing the Environmental Protection Agency to secure information on all new and existing chemical substances and to control any of these substances determined to cause an unreasonable risk to public health or the environment. This law requires that the health and environmental effects of all new chemicals be reviewed by the Environmental Protection Agency before they are manufactured for commercial purposes.

transuranic (TRU) waste: Waste contaminated with alpha-emitting radionuclides of atomic numbers greater than 92 with half-lives greater than 20 years and concentrations greater than 100 nanocuries/gram at time of assay. It is not a mixed waste.

tritium: A radioactive isotope of the element hydrogen with two neutrons and one proton. Common symbols for this isotope are H-3 and T.

tuff: A rock formed of compacted volcanic fragments, generally smaller than 4 millimeters in diameter.

Type A packaging: Packaging designed to retain the integrity of containment and shielding required by regulation under normal conditions of transport as demonstrated by the required test. Type A packaging (e.g., 55-gallon drums) is typically used to transport materials such as low-level radioactive waste.

volatile organic compounds (VOCs): A broad range of organic compounds (such as benzene, chloroform, and methyl alcohol), often halogenated, that vaporize at ambient or relatively low temperatures.

waste management: The planning, coordination, and direction of those functions related to generation, handling, treatment, storage, transport, and disposal of waste, as well as associated surveillance and maintenance activities.

waste minimization: Actions that economically avoid or reduce the generation of waste by source reduction, reducing the toxicity of hazardous waste, improving energy usage, or recycling. These actions will be consistent with the general goal of minimizing current and future threats to human health, safety, and the environment.

weapons effects: Deals with outputs of nuclear weapons and the associated effects on materials and the environment.

wetland: Land or area containing hydric soils, saturated or inundated soil during some portion of the plant growing season, and containing plant species tolerant of such conditions (includes swamps, marshes, and bogs).

wind rose: A depiction of wind speed and direction frequency for a given period of time.

x rays: Penetrating electromagnetic radiations with wavelengths shorter than those of visible light, usually produced by irradiating a metallic target with large numbers of high-energy electrons. In nuclear reactions, it is customary to refer to photons originating outside the nucleus as x rays and those originating in the nucleus as gamma rays, even though they are the same.

yield experiments: A measure of fusion energy/neutron production in experiments that use a mixture of deuterium and tritium isotopes as fuel.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

ACRONYMS, ABBREVIATIONS, CHEMICAL SYMBOLS, AND UNITS OF MEASURE

Acronyms and Abbreviations

AMCCOM	U.S. Army Armament, Munitions, and Chemical Command
CFF	Contained Firing Facility
D&D	decontamination and decommissioning
DOE	Department of Energy
EIR	Environmental Impact Report
EIS	Environmental Impact Statement
FR	*Federal Register*
FXR	Flash X-Ray
HEPA	high-efficiency particulate air
HTO	tritiated water
LLNL	Lawrence Livermore National Laboratory
LLW	low-level waste
MAP	Mitigation Action Plan
MMRP	Mitigation Monitoring and Reporting Program
NEPA	*National Environmental Policy Act*
NESHAP	National Emissions Standards for Hazardous Air Pollutants
ROD	Record of Decision
SJVUAPCD	San Joaquin Valley Unified Air Pollution Control District
TRU	transuranic
UC	University of California
VOCs	volatile organic compounds

Chemical Symbols

CO	carbon monoxide
HCl	hydrogen chloride
HCN	hydrogen cyanide
HF	hydrogen fluoride
NH_3	ammonia
NO_x	nitrogen oxides

Units of Measure

cm	centimeters
ft	feet
ft^2	square feet
ft^3	cubic feet
gal	gallons
ha	hectares
hr	hour
in	inches
kg	kilogram
km	kilometers

L	liters
lb	pounds
μg	micrograms
m	meters
m^2	square meters
m^3	cubic meters
mg	milligrams
$\mu g/m^3$	micrograms per cubic meter
mi	miles
rem	roentgen-equivalent-man (a measure of radiation dosage)
yd	yards
yd^3	cubic yards

Metric Conversion Chart and Metric Prefixes

APPENDIX J: CONTAINED FIRING FACILITY PROJECT-SPECIFIC ANALYSIS

J.1 Introduction

The Department of Energy (DOE) proposes to construct and operate a facility to provide containment of explosives test experiments at Lawrence Livermore National Laboratory (LLNL). These tests are currently conducted outdoors on a firing pad (also called a firing table) at the existing operational Building 801 (B801) facility, located at LLNL's Experimental Test Site (Site 300). Detonation experiments using explosives have been conducted outdoors at Site 300 since the early 1950s. The proposed Contained Firing Facility (CFF) would be a modification to the existing B801 Flash X-Ray (FXR) Facility and would consist of an enclosed Firing Chamber, a Support Facility, and a Diagnostic Equipment Facility. An Office Module, to be constructed approximately 46 meters (m) (150 feet [ft]) from the proposed Firing Chamber, is also proposed.

Two alternatives to the proposed action are addressed in this environmental assessment:

- No action (continue operation of the current B801 facility and its outdoor firing activities at planned levels).
- Build the CFF at an alternative Site 300 location (vicinity of B851).

The Record of Decision (ROD) issued January 27, 1993, for the August 1992 *Final Environmental Impact Statement and Environmental Impact Report for Continued Operation of Lawrence Livermore National Laboratory and Sandia National Laboratories*, Livermore, DOE/Environmental Impact Statement (EIS) 0157, (1992 EIS/Environmental Impact Report [EIR]) (DOE/University of California [UC] 1992), published the Secretary of Energy's decision to continue to operate LLNL, including near-term proposed projects (those within 5 to 10 years). The proposed B801 CFF is described as one of the projected, budgeted new facilities under the proposed action, (table 3–3) in the 1992 EIS/EIR, and is further discussed in section A.2.5.3 (Proposed Construction Projects, LLNL, Site 300) and table 4.15–2 (LLNL Site 300, Overview) of the 1992 EIS/EIR. The potential impacts of construction and operation of the proposed CFF are expected to be within the scope of the impacts of normal Site 300 operations and potential Site 300 accidents as outlined in the 1992 EIS/EIR. This environmental impact analysis is tiered from the 1992 EIS/EIR and provides additional detailed information on CFF operations and its potential impacts.

This environmental impact analysis was prepared in accordance with the *National Environmental Policy Act* (NEPA) of 1969, as amended, (42 *United States Code* section 4321 et seq.) and adheres to policies and procedures for DOE compliance with the NEPA as set forth in 10 *Code of Federal Regulations*, Part 1021 (57 *Federal Register* [FR] 15122, April 24, 1992).

J.2 Purpose and Need for Action

To meet its present and future strategic stockpile stewardship responsibilities DOE needs to insure its long-term ability to continue conducting hydrodynamic testing of certain explosive and metal containing materials at its existing FXR Facility (Building 801) at LLNL's Site 300. As the most up-to-date U.S. hydrodynamic test facility, the current Building 801 FXR Facility serves a key role in providing essential hydrodynamic test data needed by DOE to assess key elements of stockpile safety and reliability in the absence of nuclear testing by the United States.

In order to assure its continued future ability to provide this needed test data at its Site 300 facility and consistent with its policy of improving environmental, safety, and health posture of its operations, DOE proposes to further reduce the environmental, safety, and health impacts of its current Site 300 explosives tests by conducting certain experiments (such as those involving depleted uranium, tritium, and beryllium) in an enclosed Firing Chamber.

The purpose of the CFF enclosure would be to reduce gaseous and particulate air emissions from explosives testing, reduce the generation of solid low-level radioactive waste (LLW) (resulting from present Site 300 outdoor firing table activities), reduce testing noise, improve the safety of testing by controlling fragment dispersion, and improve the quality of diagnostics data derived from testing by better controlling experimental conditions.

Without the CFF's enclosed Firing Chamber and supporting project elements, hydrodynamic testing would have to continue to be done in the outdoor environment, thus reducing test scheduling flexibility, and continuing the currently projected outdoor firing, environmental, and safety postures.

Siting such a facility at LLNL's Experimental Test Site, Site 300, was included as a projected facility under the proposed action of DOE's 1992 EIS/EIR to continue operation of LLNL (section 3.1.2 and table 3–3, 1992 EIS/EIR); the Secretary of Energy issued the ROD on this EIS January 27, 1993 (58 FR 6268).

J.3 Description of the Proposed Action and Alternatives

J.3.1 Proposed Action

The proposed action is to design, construct, operate, and ultimately decontaminate and decommission (D&D) a CFF in the area of B801 at LLNL's Site 300 (figures J.3.1–1 and J.3.1–2) and to modify the existing FXR Facility in B801 so as to preclude damage to FXR equipment when detonations occur in the adjacent, proposed CFF Firing Chamber (figure J.3.1–3) (LLNL 1995).

J.3.1.1 *Design*

J.3.1.1.1 Current B801 Complex

The core elements of the current 1,628 square meters (m^2) (17,522 square feet [ft^2]) B801 complex are the bunker, housing the firing control room, and the linear induction accelerator/FXR Facility and other diagnostic equipment, as well as an outdoor gravel pad firing table. Detonations of explosives assemblies (which may contain depleted uranium, beryllium, and/or tritium-containing components) are done on the gravel firing table, and the dynamics of the detonation process are recorded by the FXR system and associated diagnostics equipment through ports in the B801 FXR Facility. Other infrastructure at the present B801 complex includes support buildings, loading docks, underground control and gas storage bunkers, an underground camera (optics) room, and utilities.

J.3.1.1.2 Proposed Contained Firing Facility Design Concept

The proposed CFF would augment and be collocated with (adjacent to) the current B801 (see figure J.3.1–3). The four main elements of CFF would be the Firing Chamber, Support Facility, Diagnostic Equipment Facility, and an Office Module, totaling approximately 2,685 m^2 (28,900 ft^2) of additional developed space within the present B801 complex area. The present B801 gravel firing table would be partially paved after it was ensured that any gravel and debris contaminated above regulatory limits were removed. The new proposed facility elements would be designed and placed to provide an efficient, safe, fully integrated test and diagnostics complex that would operate for a projected 30-year lifetime. The facility would be designed and operated in full compliance with applicable DOE orders as well as applicable Federal and state laws and regulations.

J.3.1.1.3 Firing Chamber

The Firing Chamber would be designed to contain the blast overpressure and fragment effects from detonations of explosives assemblies (figure J.3.1.1.3–1). It would retain solid debris, gases, and particulate and aerosol products generated from the detonation, allowing for their selective removal, or, in the case of certain gases, their controlled release to the atmosphere through use of scrubbers, absorbents, high-efficiency particulate air (HEPA) filters, and other similar equipment. The explosives quantities would vary with a maximum of 60 kilograms (kg) (132 pounds [lb]) of plastic-bonded explosive 9404, or an equivalent trinitrotoluene design weight of 94 kg (207 lb). The inside walls of the chamber would be protected from high-velocity detonation fragments by replaceable shielding.

The Firing Chamber would be a cast-in-place, steel-reinforced concrete structure with diagnostic and optical line-of-sight ports for data collection. Walls would be 1.2-m (4-ft) thick and would support a

FIGURE J.3.1–3.—*Building 801 Showing Addition of the Firing Chamber, Diagnostic Equipment Facility, Support Facility, and Office Module.*

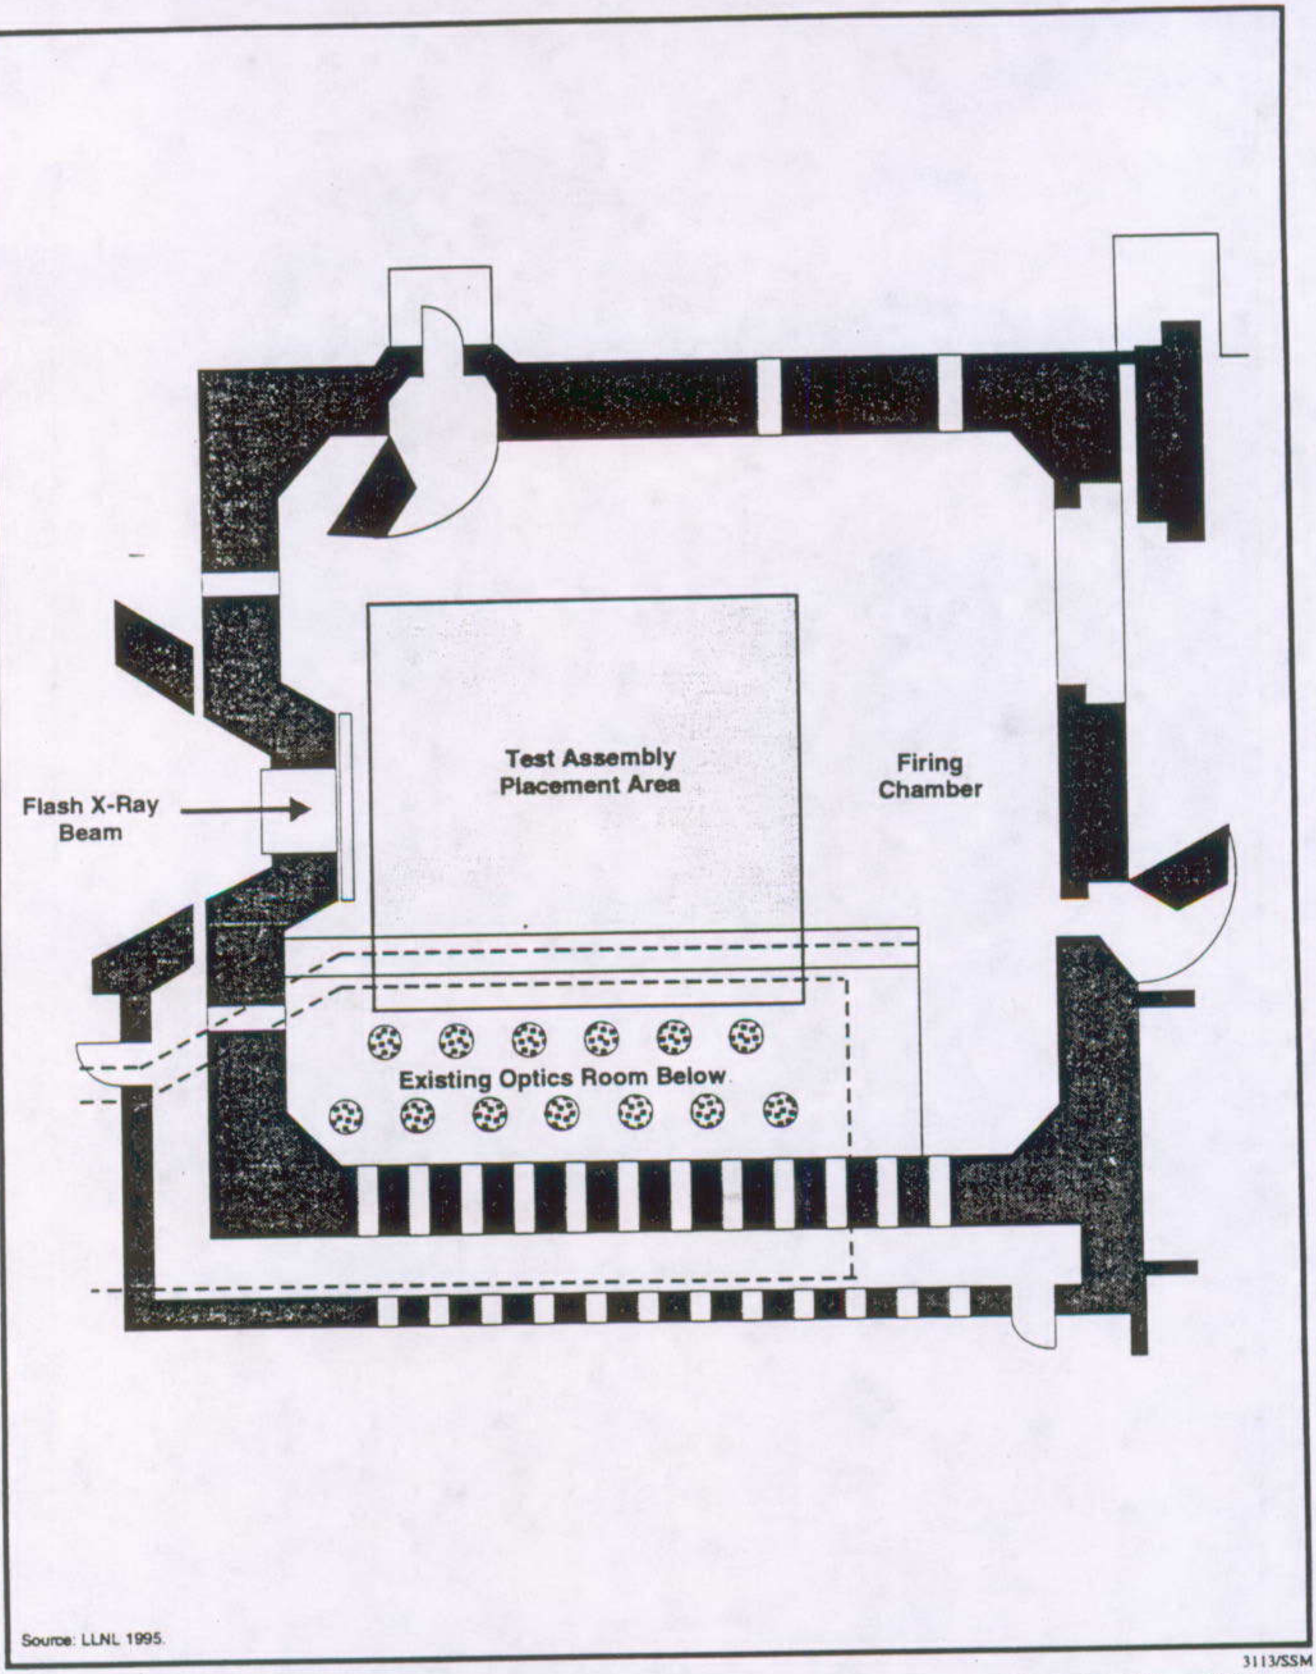

FIGURE J.3.1.1.3–1.—*Firing Chamber Portion of the Contained Firing Facility in Building 801.*

1.4-m- (4.5-ft)-thick ceiling slab and be supported on a 1.8-m- (6-ft)-thick floor slab. On the south side, an existing camera room would be integrated into and be used as part of the chamber. The 0.9-m (3-ft)-thick existing roof of the camera room would be covered by a 0.6-m- (2-ft)-thick concrete overlay to increase its structural capacity.

All interior surfaces of the chamber would be lined with 1.3 centimeters (cm) (0.5 inches [in]) steel plate. Replaceable 2.5 cm (1 in) thick steel tiles would be attached to the steel-lined walls and ceiling. Floors would also be covered with replaceable steel tiles whose thickness would vary with the experiment. Equipment would be brought into the Firing Chamber through a 3.7 m (12 ft) by 4.3 m (14 ft) blast door. Two personnel safety exit doors would be situated to provide egress during test setup. Blast doors would also be protected from detonation fragments. The chamber would have conditioned air, lighting, a water washdown system, a separate tritiated-gas stripping system, a drain leading to a holding tank, and water recycling and evaporation systems. The air supply and exhaust openings would also be protected from blast damage by shielding dampers and blast valves.

The air management system supporting the chamber would consist of a normal operation exhaust system with a post-firing air purge system, and a gas-stripping system for use after experiments involving tritium. During normal operation, the exhaust system (figure J.3.1.1.3–2) would maintain a negative pressure in the Firing Chamber relative to the Support Facility.

Following a test firing, an air purge system would exhaust air, suspended particulates, and gases from the chamber through filter and scrubber systems before the discharge of air and remaining gases to the atmosphere through a roof-mounted stack approximately 15.2 m (50 ft) above ground level. Air would be taken in through openings in the chamber wall. Ductwork would be protected from dynamic and static blast overpressure. The filtration system for use after detonations would consist of a centrifugal precipitator; a 95-percent efficient pulse-jet dust collector with fusible sprinkler head; 30-percent efficient prefilters; 99.97-percent efficient, nuclear-grade HEPA filters; a scrubber system to remove gases and vapors; and a fan. The filter housing would be a bag-out type, and would include ports for testing HEPA filter-bank efficiency and monitoring pressure drop across the filters. Any waste storage and treatment areas that may be required for processing liquid from the gas absorption wet scrubber would be designed and operated in conformance with applicable waste management procedures and DOE orders.

After tests involving tritium-containing materials, a tritium scrubber system would be activated. In addition to filtering particulate, this system would also remove at least 95 percent of any tritium. The tritium scrubbing system would consist of a standard hot catalyst/desiccant system designed to ensure oxidation and removal of airborne tritium as primarily tritiated water (HTO).

The chamber also would be designed with water washdown systems for post-test cleaning and fire protection (figure J.3.1.1.3–3). The washdown system installed in the ceiling of the chamber, consisting of an articulating nozzle, would direct water to all interior surfaces. The high-velocity spray nozzle could operate automatically or manually via remote controls with the use of video monitoring. When operated manually, personnel would use hoses from reels located outside the chamber. Residual water retained by pitted floor tiles would be removed by manual or mechanical methods. A floor drain (protected by a blast-resistant valve) would collect contaminated water and direct it to a holding tank for analysis followed by filtration and evaporation or transfer to an appropriate treatment facility.

J.3.1.1.4 Support Facility

The Support Facility would provide a staging area for preparation of the nonexplosive components of an experiment; storage of equipment and materials; and personnel locker rooms, rest rooms, and decontamination showers. A mezzanine above the personnel area would house mechanical equipment. A mechanical equipment area would be located adjacent to the staging area. The size of the Support Facility would be approximately 1,542 m^2 (16,600 ft^2).

The Support Facility would be separated into gray and clean areas. The gray areas would be areas in which contamination could occur. Egress from the gray areas would require passage through decontamination and change areas prior to entering the clean areas. The Support Facility rooms would have a negative air pressure relative to the clean areas to control the potential for migration of contamination to clean areas.

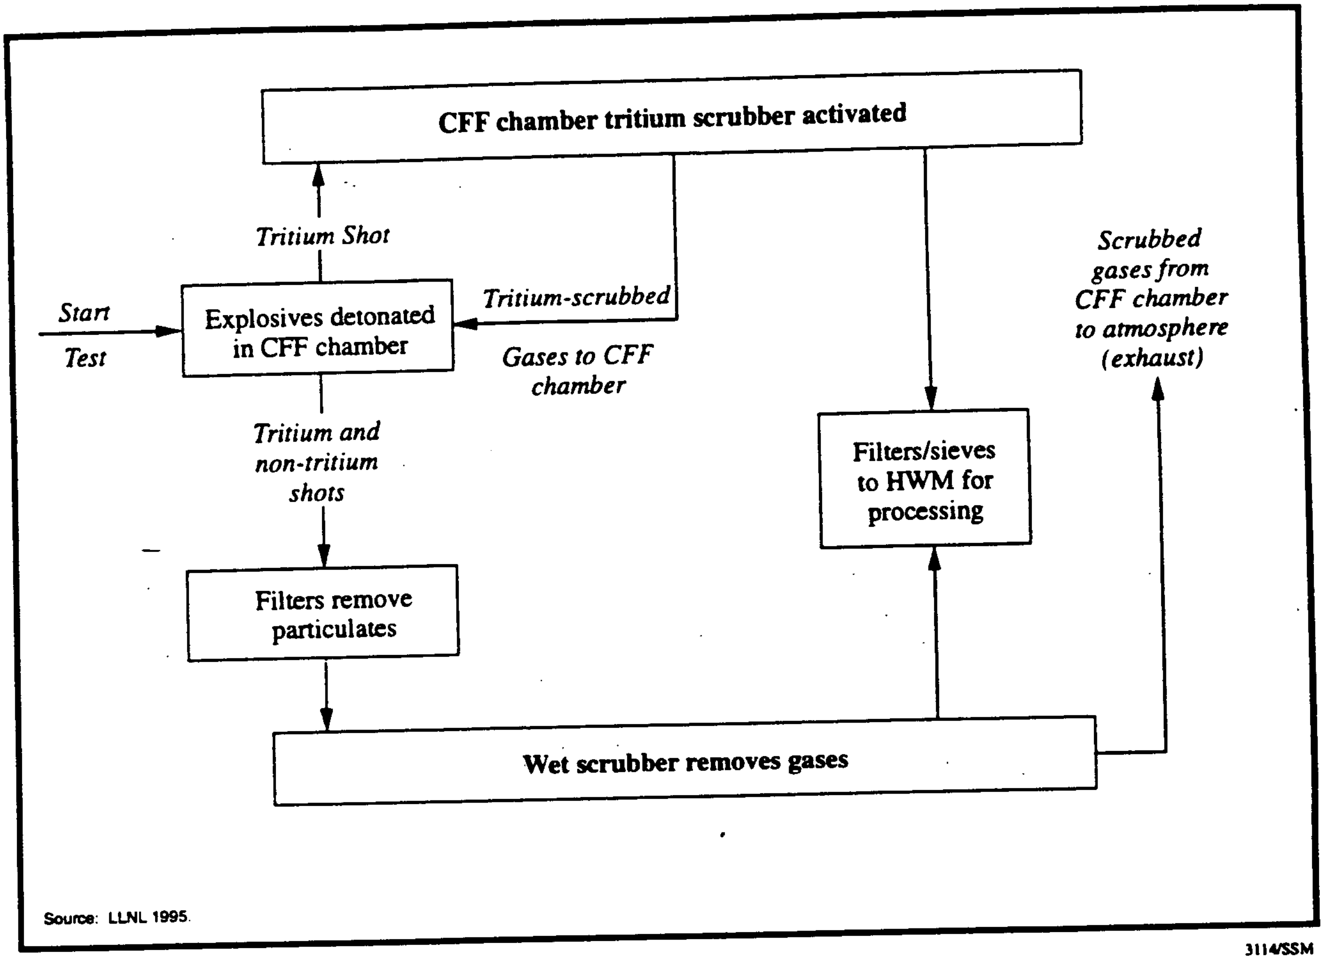

FIGURE J.3.1.1.3–2.—*Simplified Post-Test Contained Firing Facility Gas Scrubbing Schematic.*

J.3.1.1.5 Diagnostic Equipment Facility

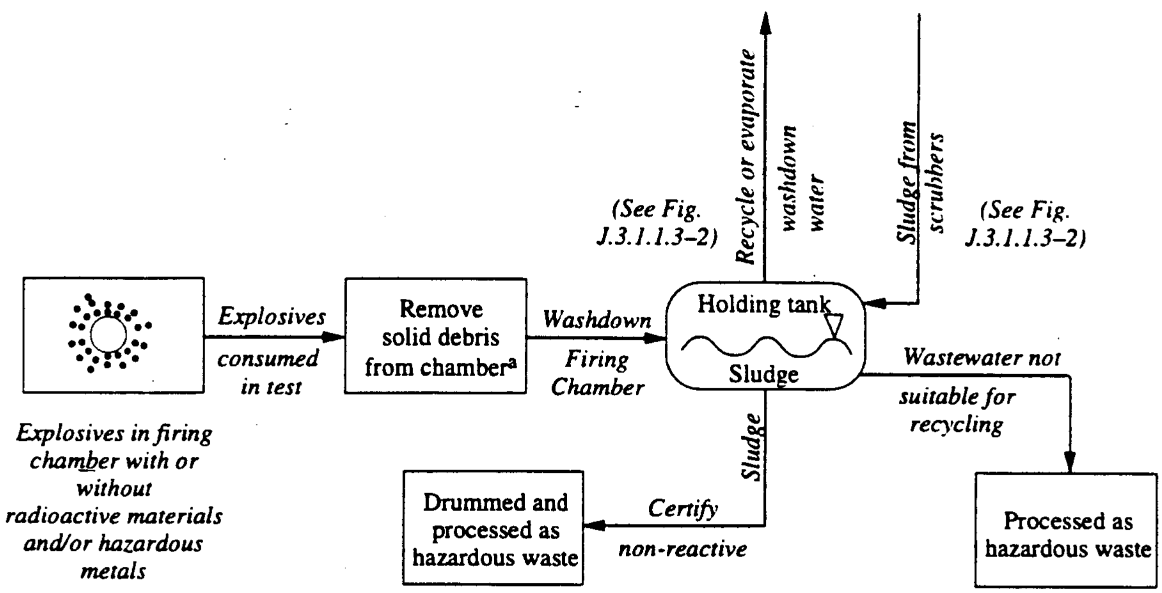
The Diagnostic Equipment Facility would house various diagnostic equipment used to evaluate the results of explosives tests. The Diagnostic Equipment Facility would be similar in construction to the Support Facility but would be designed to protect personnel who occupy this area during the tests. The facility would be approximately 576 m^2 (6,200 ft^2). The Diagnostic Equipment Facility would be controlled as, and be considered to be, a clean area. An additional 0.6 m (2 ft) thickness of reinforced concrete wall would be placed 1.2 m (4 ft) from the Firing Chamber wall to create a utility corridor for diagnostic devices, as well as to provide an additional safety buffer wall for personnel. Pressure-rated personnel doors would be installed at either end of the corridor for access. The Diagnostic Equipment Facility would be the main personnel entrance into the new CFF complex.

J.3.1.1.6 Office Module

A premanufactured Office Module of approximately 223 m^2 (2,400 ft^2) would be constructed adjacent to the north side of the existing B801D, approximately 46 m (150 ft) southwest of the proposed Firing Chamber. This facility would provide administrative space for the B801 complex staff.

J.3.1.2 *Construction*

Site preparation would require site excavation and demolition work. The CFF design concept would require excavation of about 41,300 cubic meters (m^3) (54,000 cubic yards [yd^3]) of existing soil from adjacent hillsides. This material would be sampled and analyzed to verify that it is uncontaminated. Any identified hazardous, LLW, or mixed wastes would be appropriately packaged and labeled in accordance with all applicable regulatory, DOE, and LLNL



[a] Solid debris characterized, sorted, and processed as low-level radioactive, mixed, or hazardous waste, as appropriate.
Source: LLNL 1995.

FIGURE J.3.1.1.3–3.—*Post-Test Water Washdown Schematic.*

requirements. Site preparation would also require removal of an underground utility bunker and the relocation of a 0.8 m (2.5 ft) storm drain line. Explosives tests would be diverted from the B801 complex to other firing facilities (principally to B851) during construction at B801. Site improvements would include excavation, grading, trenching, electrical service augmentation, underground utilities augmentation, curbs and gutters, and debris removal. Structures would be designed in accordance with the requirements of the most current edition of the Uniform Building Code.

J.3.1.3 *Operation*

When CFF is constructed and operational, it is estimated that approximately 100 explosives research and diagnostic experiments could be conducted annually. Quantities of explosives expended in most typical tests would be less than 25 kg (55 lb). Certain of these tests typically involve some components of beryllium and depleted uranium. General pre-test, test, and post-test activities at CFF are described below.

J.3.1.3.1 Pre-Test and Test Activities

Nonexplosive support fixtures and apparatus needed for the test assemblies would be assembled in the Support Facility, then transported to and set up in the Firing Chamber. This apparatus often includes heavy foundations or shot stands to support the explosive experiment, armored radiographic film cassettes, heavy steel momentum-transfer plates, mild steel and wooden shrapnel shields, glass optical turning mirrors and mounting hardware, expendable capacitor discharge units, high-pressure gas-filled devices, and other special diagnostic equipment. Much of this apparatus is expended in the test. Motor-driven cranes and forklifts may be used to move both the inert apparatus and the explosives, if needed. Strict administrative controls would be applied to restrict personnel movement and location while certain of these setup operations are conducted.

The explosive charge would usually be the last item to be placed at the Firing Chamber. When all other equipment has been readied, the explosives assembly would be brought by truck to the chamber from its assembly point at the Site 300 process area or from an explosives storage magazine and carefully set in position, with only essential personnel in attendance. System checks in the form of dry runs would be performed to show that all electrical and mechanical systems have been properly connected and to verify that proper time delays between individual events have been programmed.

When all dry run testing is complete, the chamber would be secured, personnel assembled and accounted for (mustered) within the protected control room (bunker), and the experiment conducted.

J.3.1.3.2 Post-Test Activities

Tests Not Involving Tritium. After an experiment that does not involve tritium, the Firing Chamber would be allowed to cool. Television cameras and infrared sensors would be used to survey the chamber interior for burning debris. Fires would be quenched by a short-duration water washdown or allowed to self-extinguish. The chamber purge system would draw air through scrubber, filtration, and exhaust systems (figure J.3.1.1.3–2). Gas sampling devices would monitor the chamber gas concentrations before and after purging.

After about 10 fresh-air makeup exchanges (and after observation of the television monitor indicates that entry is permissible), qualified explosives handlers (using breathing protection, if necessary) would reenter the chamber. Any smoldering materials or unreacted explosive would be rendered safe so that others could enter. Diagnostics data would be collected and the chamber cleaned in preparation for the next experiment.

The chamber washdown system, consisting of an articulating, ceiling-mounted nozzle would be used to periodically wash detonation test residue from the chamber walls (figure J.3.1.1.3–3). A manually operated hose would be used to complete the washdown once access is permitted. The washdown water would be supplied from Site 300's domestic water supply system, supplemented by recycled washdown water. This washdown water and spent scrubber liquid would be diverted to a holding tank, filtered, and reused, evaporated, or sent to LLNL's Hazardous Waste Management Division for processing. Floor drains, floor sinks, drainage trenches, wash basins, and emergency shower and eyewash drains from portions of the Support Facility would also be gravity-fed into a separate water collection system. This wash water would be monitored, filtered, and recycled for reuse as part of the Firing Chamber washdown system.

Evaporation would be used to substantially reduce the volume of wastewater. Waste residues from this process would be treated by methods that meet applicable criteria for handling industrial wastewater (e.g., treatment and/or stabilization). Sludge containing metals and other contaminants that would be typical residue from evaporating this form of wastewater would be routinely handled by LLNL's waste management facilities.

Tests Involving Tritium. Tests involving tritium-containing components are administratively limited to 20 milligrams (mg) (200 curies) tritium each, and it is estimated that a maximum of 10 such tests per year would be performed. After an experiment, the tritium scrubber system would be activated. The system would operate in a recirculating mode until monitoring and analysis indicated that most undesirable gases had been removed. Additional tritium removal would then be accomplished by adding a few liters of water as a mist to moisturize the air and chamber surfaces to help remove additional tritium (as tritiated water, HTO). (The chamber air would then be scrubbed again to remove additional tritium.) These moisturize/scrub cycles would be repeated until most readily exchanged tritium (as HTO) had been removed and monitored chamber tritium levels were deemed acceptable for reentry. Reentry scheduling would also be dependent on the levels of any other residual radiation, the intensity of which would also be monitored during and after an experiment. The tritium (as tritiated water vapor, HTO) would be absorbed and collected onto a solid medium, such as molecular sieves, during this air-scrubbing process.

As an adjunct to the air-scrubbing removal of tritium, a more aggressive water washdown of the chamber surfaces would be done with about 1,900 liters (L) (500 gallons [gal]) of water. The volume of this washdown water would be controlled to minimize generation of tritium-contaminated water. This would be achieved by regulating the flow into the articulating, ceiling-mounted nozzle, limiting washdown time, and/or manual washing of the chamber. Washdown water would separately be collected and may be reduced in volume, then be managed as low-level liquid (or solidified) radioactive waste. The estimated volume of the wastewater filtration sludge expected from this process would be approximately 85 L (22 gal).

It is estimated that up to 25 55-gallon (208 L) drums and 2 2.8 m^3 (100 ft^3) boxes of solid LLW would be generated for each tritium-containing test.

J.3.1.4 *Decontamination and Decommissioning (Closure)*

A useful lifetime of 30 years is assumed for CFF. Projections of the need for D&D versus conversion to different usages for CFF after that time cannot yet be made. Such proposals, when identified, would be subject to separate NEPA review, if necessary.

J.3.2 Alternatives to the Proposed Action

J.3.2.1 *No Action Alternative*

The No Action alternative would leave B801 in its current configuration and would continue the routine detonation of explosives experiments outdoors. No construction disturbance would occur with this alternative. The primary effect of adopting the No Action alternative would be an annual release of emissions from up to an estimated 100 test detonations of explosives and associated materials, equipment, and assemblies directly into the atmosphere and surrounding soils or gravel; the continued generation of solid LLW from test debris and the periodic removal and processing of firing table gravel; and the continued noise levels and blast overpressure to the surrounding area.

An indication of the explosion-related product amounts released to the environment under the No Action alternative (continued outdoor testing) can be derived from the database of materials used in past outdoor explosives experiments at Site 300. Table J.3.2.1–1 shows the estimates of annual hazardous, radioactive, and other material dispersals that could be expected each year under the No Action alternative, based on compositions of tests at B801 for calendar years 1990 to 1994. Most of this material dispersal would be in the form of solid debris that is recovered after the test or is deposited in firing table gravel. Because the experiments were conducted outdoors, the remainder has, for the most part, been dispersed to the environment (primarily as metal or oxides). The materials listed in table J.3.2.1–1 are, therefore, an indication of what would constitute the source terms for waste streams and/or emissions that would likely result from conducting approximately 100 tests per year outdoors at B801 under the No Action alternative.

As noted above, solid LLW in the form of contaminated firing pad gravels after a series of outdoor tests involving radioactive material at B801 would continue if CFF is not built and operated. (By comparison, no contaminated gravel from enclosed B801 CFF operations would be generated under the preferred alternative.) Additional solid LLW in the form of test debris (such as wood, plastic, metal, and burlap bags) is generated each year under the No Action alternative; the generation of these types of test debris would likely continue under the No Action alternative as well as under the proposed action.

The organic explosives (noted in table J.3.2.1–1) used at B801 can be expected to oxidize very efficiently upon detonation to produce gaseous carbon dioxide less than 97 percent, water, and trace amounts of nitrogen, carbon monoxide, carbon (soot), oxides of nitrogen, and assorted volatile organic compounds (VOCs) (U.S. Army Armament, Munitions, and Chemical Command [AMCCOM] 1992).

J.3.2.2 *Build the Contained Firing Facility at an Alternative Site 300 Location (B851)*

B851 is a 1,270 m^2 (13,681 ft^2) complex located in the northwest quadrant of Site 300. It features a gravel firing pad, an electron beam accelerator, and several laboratories, shop areas, and offices. B801 has a more powerful and modern accelerator (the FXR) than B851 and is therefore much more capable of performing a thorough data analysis of test results from certain tests than the facilities at B851.

Construction of CFF at the B851 site would have about the same construction-related impacts as construction at B801. Operational impacts would also be similar in terms of safety, potential accident impacts,

TABLE J.3.2.1–1.— *Estimated No Action Hazardous Materials Release to the Environment (Air, Solid Debris, and Particulate)*

Material	Estimated Dispersal per Year, kg[a,b]
Barium	0.002
Beryllium	15.3
Chromium[c]	6.9
Cobalt	0.01
Copper[d]	580
Fluoride salts	3.6
Lead	4.1
Molybdenum	1.3
Nickel[c]	8.6
Silver	1.6
Vanadium	3.6
Zinc	0.1
Lithium salts	22.6
Depleted uranium[e]	430
(Explosives)[f]	(1,662)
Tritium[g]	0.0002

[a] Projected future dispersals per year based on the estimated composition of 100 tests. The basis for these projections is the B801 shot materials database for the previous 5 years (1990 to 1994), during which the number of tests ranged from 21 to 97 per year and averaged 50 per year.

[b] Only a very small fraction of the weights of the metallic materials and salts listed in this table would be expected to be volatilized as gaseous or aerosol products.

[c] Source is primarily alloying materials on test hardware, such as nuts, bolts, etc. Most of this material is large enough to be retrieved by hand following an experiment, so that it can be disposed of in a managed waste stream, or recycled.

[d] Source is primarily electrical leads and wire. Most pieces of this material are large enough in size as to be retrieved by hand following an experiment, where it is disposed of in a managed waste stream or recycled.

[e] In rare instances, thorium may be used in place of depleted uranium.

[f] This weight of explosives would be converted to thermodynamically stable products of combustion (such as carbon dioxide and water) very efficiently upon detonation.

[g] Tritium has not been used in the most recent past few years. However, the 1992 DOE/UC EIS/EIR discusses an administrative limit of 20 milligrams (mg) of tritium, an environmental emission that can be expected under the No Action alternative. This projection is based on an estimated maximum of ten tests per year at 20 mg each.

Source: Model results.

and noise. Thus, although possibly a reasonable alternative, it offers no significant advantages and several significant disadvantages to the B801 site.

J.4 DESCRIPTION OF THE AFFECTED ENVIRONMENT

A brief description of the environment surrounding the location of the proposed facilities is presented in this section. A more detailed description can be found in the 1992 EIS/EIR (DOE/UC 1992), which is incorporated by reference.

J.4.1 Topography

Site 300 is located in the Altamont Hills and consists of southeasterly trending ridges and canyons of moderate-to-high relief. These ridges vary in elevation from slightly more than 153 m (500 ft) at the Corral Hollow Creek entrance to the site to over 518 m (1,700 ft) at the highest point. The onsite drainage pattern is well-developed and flows generally east and south toward Corral Hollow Creek.

CFF would be built as a modification to B801 and would, therefore, be nestled among hills ranging from 34 to 104 m (110 to 340 ft) above its floor elevation to the north, east, and south. The floor level would be at approximately 323 m (1,060 ft) above mean sea level.

J.4.2 Seismicity

Site 300 is located on the eastern edge of the seismically active San Francisco Bay area. A number of active faults are considered capable of causing strong ground motion at Site 300. The nearest of these faults to Site 300 is the Carnegie-Corral Hollow Fault, which crosses the southwest portion of the site (Carpenter et al., 1991). No significant recorded earthquakes have occurred on any of the local faults. The effect of seismic activity at Site 300 is likely to be confined to ground shaking with no surface displacement. Raber and Carpenter (1983) have identified the principal seismic hazard at Site 300 as being the potential for strong ground shaking caused by an earthquake on the Greenville Fault, located about 8 kilometers (km) (5 miles [mi]) west of Site 300.

J.4.3 Climate

Site 300 has a semi-arid, Mediterranean-type climate. Annual mean precipitation is approximately 28 cm (11 in), most of which falls between October and April during major winter storms. Strong, persistent winds are characteristic of the Site 300 area as marine air flows through the canyons of the Site into Corral Hollow and the San Joaquin Valley to the east. This flow results in strong afternoon and evening winds with gusts up to 70 km/hour (hr) (44 mi/hr).

J.4.4 Air Quality

J.4.4.1 *Criteria Air Pollutants*

The California Air Resources Board conducts criteria pollutant monitoring for the San Joaquin Valley Unified Air Pollution Control District (SJVUAPCD), which includes Site 300. Based on the California Air Resources Board's measurements, the district is classified as a nonattainment area for ozone and particulate matter smaller than 10 micrometers (or microns).

J.4.4.2 *Hazardous Air Pollutants*

Toxic air contaminants are subject to the National Emission Standards for Hazardous Air Pollutants (NESHAP). NESHAP standards pertaining to operations at Site 300 are those for beryllium and radionuclides. Beryllium concentrations from test activities at Site 300 are monitored by LLNL and average 0.42 percent of the SJVUAPCD NESHAP standard. Airborne radionuclide concentrations also are monitored at Site 300. In 1994, uranium-238 and uranium-235 concentrations were $5x10^{-5}$ $\mu g/m^3$ and $3x10^{-7}$ $\mu g/m^3$, respectively. In contrast, the derived concentration guide (a calculated concentration of radionuclides that could be continuously consumed or inhaled and not exceed the DOE primary radiation protection standard to the public of 100 millirem per year effective dose equivalent) for uranium-238 and uranium-235, respectively, were 0.3 $\mu g/m^3$ and 0.047 $\mu g/m^3$. The effective dose equivalent to the maximally exposed member of the public due to potential radionuclide releases from B801 testing in 1994 was 0.041 millirem (the NESHAP allowable standard is 10 millirem). Thus, the monitored concentrations for outdoor testing activities at Site 300 are already well below guideline levels, and operations also comply with the NESHAP limits.

J.4.5 Hydrology: Surface and Groundwater

Several ephemeral streams flow through Site 300 during the wet winter months and discharge into Corral Hollow Creek at the southern boundary of the site. Most flow is direct runoff with a very small contribution from both intermittent and perennial springs. Minor erosion results from both natural and induced conditions.

The groundwater of the Site 300 area is characterized by two regional aquifers or major waterbearing zones: (1) an upper water-table aquifer in the sandstones and conglomerates of the Neroly formation about 30 m (100 ft) below ground surface, and (2) a deeper, confined aquifer located in Neroly sandstones just above the Neroly/Cierbo contact, about 91 m (300 ft) below ground surface (Raber and Carpenter, 1983).

In addition to the two regional aquifers, several localized perched aquifers contain water at higher elevations above low-permeability layers (6 to 15 m [20 to 50 ft] belowground surface). Depth to groundwater beneath B801 is estimated as at least 30 m (100 ft). Neither the groundwater beneath firing tables at B801 nor B851 are known to be contaminated with tritium or uranium from past operations.

J.4.6 Vegetation

Five major vegetation types are found at Site 300. They are (1) introduced annual grassland, (2) native perennial grassland, (3) coastal sage scrub, (4) oak woodland, and (5) riparian (Taylor and Davilla, 1986). Most of the vegetation at Site 300 is grassland dominated by mixtures of introduced annual and native perennial grasses.

A detailed, systematic survey for populations of rare and endangered plants was conducted at Site 300 in the spring of 1986 (Taylor and Davilla, 1986); an additional survey was conducted in 1991 in support of the 1992 EIS/EIR (DOE/UC 1992). The only sensitive plant species known to exist at Site 300 is the large-flowered fiddleneck (*Amsinckia grandiflora*), listed as both federally-endangered and state-endangered. This species has been identified in two locations at Site 300. Neither are near the proposed B801 CFF site. Both *Amsinckia grandiflora* populations are closer to B851 than to B801.

J.4.7 Wildlife

The wildlife at Site 300 strongly reflects the dominance of grasslands. Twenty-six species of mammals, 70 species of birds, and 20 species of reptiles and amphibians were observed at Site 300 during threatened and endangered species surveys in 1986 and 1991. The 1991 survey was conducted for the 1992 EIS/EIR (DOE/UC 1992). Since the 1991 surveys, an additional 12 species have been identified: 1 mammal, 1 amphibian, 9 birds, and 1 nonsensitive fairy shrimp species. The only sensitive species that might be expected to exist in the vicinity of the proposed CFF are the burrowing owl (*Athene cunicularia*) and the American badger (*Taxidea taxus*), both state species of special concern. The 1992 EIS/EIR mitigation measures routinely implemented before conducting construction projects (such as the proposed CFF) include the field surveys for these latter two species. Burrowing owl dens are known to occur approximately 1.6 km (1 mi) north of the present B801 complex, in spite of the conduct of routine outdoor testing of explosives at that site. A burrowing owl den was identified in 1994 to be within 0.32 km (0.2 mi) (west) of B851 (figure J.4.7–1). Transient badgers also use ground squirrel dens in areas near B801 and B851.

Site 300 is located in the extreme northern portion of the range of the San Joaquin kit fox (*Vulpes macrotis mutica*) (Federal endangered species, state threatened species). Detailed surveys for the kit fox were conducted at Site 300 in 1980 (Rhoads et al., 1981), 1986 (Orloff 1986), and 1991 (DOE/UC 1992). Since that time, approximately 54 project-specific surveys for active kit fox dens have been made at Site 300; all have been negative. Neither the kit fox nor active dens were observed at Site 300 during any of these surveys. At present, the kit fox is not considered a resident species at Site 300, although the site may offer potential habitat. Field surveys for the presence of the kit fox are, however, still routinely performed before conduct of any ground-disturbing project (as they will be before construction of the proposed CFF) as part of the mitigation measure commitments implemented subsequent to issuance of the 1992 EIS/EIR ROD in January 1993.

J.4.8 Cultural Resources

Site 300 was surveyed for cultural resources in 1981, and 24 archaeological sites were identified (Busby, Garaventa, and Kobori, 1981). Of these 24 sites, 3 were prehistoric, 20 were historic, and 1 was a multi-component site consisting of both prehistoric and historic materials. Also, recent archival research and field surveys were performed in support of the 1992 EIS/EIR (DOE/UC 1992). An additional 4 prehistoric and 1 historic sites have been located since 1992. One identified site is within approximately 396 m (1,300 ft) of B851 and another is within approximately 396 m (1,300 ft) of B801.

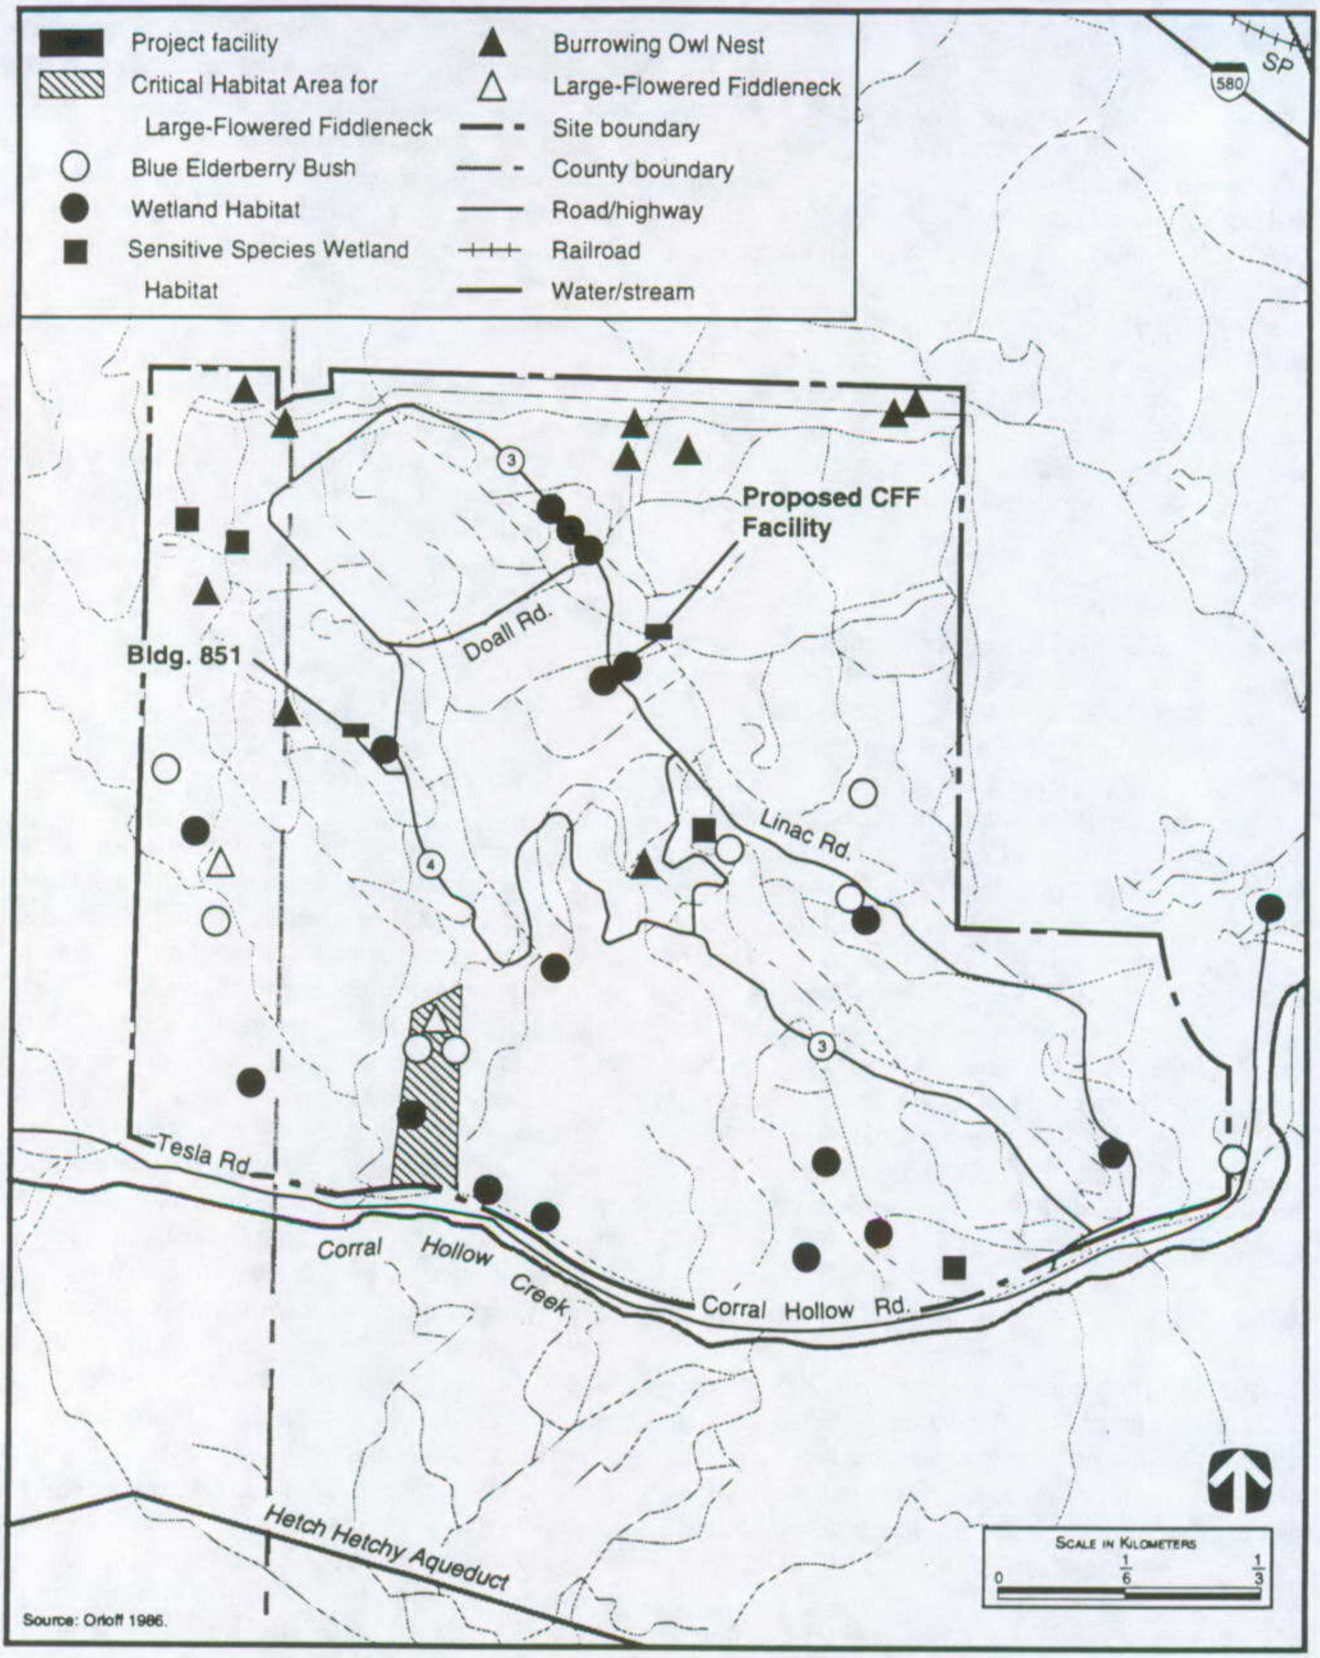
J.4.9 Land Use and Socioeconomic Factors

Most of Site 300 is located in San Joaquin County, with a small portion in Alameda County. The proposed action is located entirely within San Joaquin County. Site 300 is located approximately 13 km (8 mi) southwest of Tracy in a remote rural area in the Altamont Hills that has traditionally been used for cattle grazing and recreation. Much of the land adjacent to Site 300 is private ranch land and is used for grazing. Physics International, Inc. (adjacent to Site 300) and SRI International (south of Site 300) also have facilities that are used to routinely test explosives. The Carnegie State Vehicular Recreation Area off-road motorcycle park is located immediately south of Site 300 on Corral Hollow Road.

The San Joaquin County General Plan land-use designation for Site 300 is Public and Quasi-Public Other Governmental and Institutional (DOE/UC 1992). This designation allows the use of Site 300 for military installations and other major Government buildings. There is no prime agricultural land at Site 300, and grazing and other agricultural activities are excluded.

Since 1993, private developers have been pursuing a proposal to build residential units adjacent to Site 300's northern and eastern boundaries (Tracy Hills project) and commercial and industrial facilities further east of Site 300, astride Interstate 580 and west of the Tracy Municipal Airport. A project-specific EIR under provisions of the *California Environmental Quality Act* is being planned for preparation by the city of Tracy in 1995.

The 1993 population of Tracy has been estimated to be 34,000. Approximately 200 full-time LLNL employees and full-time support contractor staff work at Site 300; of this number, an average of approximately 20 employees work at the present B801/FXR complex.



3161/SSM

FIGURE J.4.7–1.—*Selected Sensitive, Natural Resources, Site 300.*

J.4.10 Soils

Site 300 soils have developed on marine shales and sandstones, uplifted river terraces, and fluvial deposits. They are classified as loamy Entisols (young soils with little or no horizon development). Clay-rich soils (Vertisols) are also present and have been mapped as the AloVaquero complex. Vertisols are mineral soils, characterized by a high clay content, that are subject to marked shrinking and swelling with changes in water content. The Entisols erode easily; the Vertisols exhibit low permeability and are subject to moderate erosion. Soils in the B801 area are generally classified in the AloVaquero complex.

J.4.11 Wetlands

Wetlands at Site 300 were mapped during 1991 using the unified Federal method (Federal Interagency Committee for Wetland Delineation, 1989), and a total of 2.7 hectares (ha) (6.76 acres) of wetlands were identified (DOE/UC 1992) (figure J.4.7–1). These wetlands are small and are in areas associated with natural springs or runoff from several building complexes onsite. The majority of the wetlands 1.9 ha (4.58 acres) exist at springs in the bottom of deep canyons in the southern half of the site. Other wetlands 0.76 ha (1.88 acres) were formed from building runoff, including a small *Typha latifolia* wetland formed by B801 cooling tower drainage that begins approximately 61 m (200 ft) south-southwest of B801. A small wetlands patch 0.032 ha (0.08 acre) exists approximately 213 m (700 ft) southeast of B851 and another 0.072 ha (0.18 acre) exists immediately adjacent to the B851 complex.

J.4.12 Noise

Existing chronic noise sources at Site 300 include vehicular traffic and heating, ventilating, and air conditioning equipment. Acute sources include construction activities; a small arms range; and explosives testing. Background noise levels are generally low, ranging from 56 to 66 decibels (DOE/UC 1992).

Meteorological conditions at Site 300 are monitored before each test, so that noise levels can be projected through use of a well-established computer program. Based on the results of this computer modeling, the quantities of the explosives that can be tested at the present B801 outdoor firing table without adverse noise generation as measured at six Tracy-area receptor site locations (stations) are projected. These stations monitor peak noise levels for a period of 90 seconds, starting at detonation. The results of these noise-monitoring activities demonstrate that noise levels from explosives testing at LLNL Site 300 have not exceeded 126 decibels at the city of Tracy station locations.

J.4.13 Water Use

Water consumption for domestic, infrastructure operation, and programmatic activities at Site 300 averaged approximately 120 million liters per year (31.8 million gallons per year) during the period from 1986 to 1990 (DOE/UC 1992).

J.5 Potential Effects of the Proposed Action and Alternatives

J.5.1 Impacts Related to Construction Activities

Containment of firing operations at B801 would result in minor construction-related impacts at Site 300 in the vicinity of the B801 complex. Construction noise and dust would be experienced throughout a 21-month excavation and construction period. Soils from the hill to the north of the firing pad, and the berm to the east of the firing pad would be excavated and removed to provide space for the new facility. Dust suppression and stormwater pollution prevention (runoff) mitigation technologies would be applied to reduce these impacts to insignificance. Biological surveys for special status, threatened, and endangered species would be conducted prior to any land-disturbing activities. If sensitive species are observed, appropriate mitigation measures to avoid any significant impact would be taken, as outlined in the 1992 EIS/EIR (DOE/UC 1992) and its associated Mitigation Action Plan (MAP) and Mitigation Monitoring and Reporting Program (MMRP). These measures have been routinely applied at Site 300 since 1992. The closest archaeological site is approximately 396 m (1,300 ft) away and is not expected to be affected by the proposed action. Experimental tests would be scheduled at other firing facilities (principally at B851) during construction in the B801 area, possibly increasing the workload and traffic to this area to a minor degree.

J.5.1.1 *Ground Disturbance Topography Change*

Construction of CFF would require excavation of about 41,300 m^3 (54,000 yd^3) of material surrounding the current facility. The proposed facility extends into hillsides to the northeast and southeast of the existing bullnose (the high-energy end of FXR, which is covered with protective armor) (figure J.3.1–3). Cut hillsides would be sloped and, where local geology allows, revegetated (using hydroseeding) to prevent erosion. The direction and volume of existing runoff would not be altered by the proposed site work because all earthwork would be accomplished within the same micro-drainage area below the division for adjacent watersheds. All construction and ground-disturbing activities would be done according to the requirements of the National Pollutant Discharge Elimination System California General Construction Activity Stormwater Permit.

All cut slopes, excavations, and/or fills would be designed and constructed in accordance with the Uniform Building Code Chapters 29 and 70 and any other applicable requirements. It is expected that the area of permanent ground disturbance immediately around the B801 complex would only be about 1.2 ha (3 acres) as a result of necessary slope contouring and construction of CFF.

J.5.1.2 *Soils*

In 1991, soils surrounding the existing firing pad were sampled and analyzed for 17 different metals and radioactivity (gamma radiation) using approved methods. LLNL has previously determined that surface soils contamination from beryllium cadmium, copper, and uranium-238 exists near the B801 firing pad (or table) (Webster–Scholten 1994). Samples will be taken and tested during construction to determine whether or not contamination exists. If isolated areas are determined to be contaminated, the soils would be handled in accordance with approved DOE procedures and all applicable Federal and state regulations.

Soils exposed by project construction, especially on the hillsides, are considered to be moderately vulnerable to erosion; their clay content provides slightly more resistance to erosion than does the high loam content of Entisols, which dominate Site 300 soil types. Erosion, if it occurs, would not be an important impact because of the brevity of the erosion event and the small quantity of soils expected to be lost. Erosion of the small hillsides surrounding the proposed project would not be expected beyond one growing season.

J.5.1.3 *Air Quality*

Construction could result in some short-term particulate matter emissions; dust suppression measures would be implemented to mitigate these emissions to levels that meet SJVUAPCD requirements. Site 300 air emissions from vehicle and equipment exhausts would be expected to increase approximately 15 to 20 percent temporarily (during the early months of the 21-month construction period). This incremental increase is expected to be an insignificant contributor to air basin emission levels, given the continued high rate of construction activity envisioned by the city of Tracy's growth projections noted in its 1993 Urban Management Plan/General Plan.

J.5.1.4 *Cultural Resources*

No impact is expected to one identified cultural resource site approximately 396 m (1,300 ft) from the proposed project at the existing B801 Facility. If culturally important artifacts are discovered during construction activities, work would stop until the discovery could be evaluated by a qualified archaeologist in accordance with the DOE MAP and the University of California MMRP, implemented in conjunction with the 1992 EIS/EIR (DOE/UC 1992).

J.5.1.5 *Sensitive Species*

No known Federal- or state-listed endangered plant or animal species are present within the zone of direct or indirect influence of project construction (1992 EIS/EIR DOE/UC 1992 and later surveys). However, a preconstruction survey monitoring for San Joaquin kit fox (*Vulpes macrotis mutica*) would be conducted not earlier than 60 days prior to the start of construction, as outlined by the mitigation measures discussed in the MAP, MMRP, and 1992 EIS/EIR (DOE/UC 1992). If kit fox is discovered within the project site, the steps prescribed in the MAP and MMRP would be followed prior to construction startup.

Dens of the American badger, a state species of special concern, have been identified within the vicinity of the proposed project in the past. Similarly, dens of the burrowing owl are known to occur within approximately 1.6 km (1 mi) (north) of the proposed site. The proposed project's impact on the badger is considered slight to none because of the relatively small portion of the badger's home range (less than 1 percent) occupied by the project, the large amount of unrestricted land at Site 300, and the widely recognized transient nature of badgers. Similarly, no impacts to burrowing owl dens are expected because they have actually become established during periods of road construction south of B801 and during long periods of outdoor explosives testing at the present B801 complex. A pre-construction survey for dens of American badger and burrowing owl would be conducted within 60 days of project start. If found, active dens of the badger or owl would be avoided by construction activity through the establishment of exclusion zones around the dens. If direct impact to an active den is considered unavoidable, the California Department of Fish and Game would be consulted for permission to reduce the size of the exclusion zone or for permission to relocate the animal to other lower-impact areas within Site 300, as outlined in the MMRP and the 1992 EIS/EIR.

J.5.1.6 *Wetlands*

Soil transport from stormwater runoff during construction would be controlled so as to ensure that there is no potential for adverse impact to the wetlands patch identified approximately 61 m (200 ft) south-southwest of the B801 complex.

J.5.1.7 *Socioeconomic Factors*

Construction of CFF will take place over a 21-month period during which CFF contractor construction crew and staff day-shift population may reach a maximum peak of 20 to 30 workers during a peak 6-month period, while being less during the remaining parts of the construction period. The addition of this incremental number of onsite, day-shift contractor crew is not expected to significantly affect Site 300 infrastructure and support services or facilities or city of Tracy support services for its 34,000 population.

J.5.1.8 *Water Usage*

A maximum of 3,800,000 L (1,000,000 gal) of water would be used for dust suppression and other related activities during construction.

J.5.2 Impacts Related to Facility Operations

J.5.2.1 *Air Quality*

It is expected that emissions (such as particulate metal oxides and soot, acid gases, and VOCs) from Firing Chamber operations would be below regulatory limits because of the extensive air scrubbing, filtration, and absorption systems that would be operated in conjunction with CFF. The bulk of the resulting emissions from the air control system should then be limited to those such as carbon dioxide, nitrogen, water, and, when tritium is used in the chamber, tritiated water as well as very minor amounts of activated air gas molecules.

It is expected that the projected scrubber removal rate for the gases ammonia (NH_3), hydrogen cyanide (HCN), hydrogen fluoride (HF), and hydrogen chloride (HCl) would be 90 percent, and would be 50 percent for oxides of nitrogen (NO_x) which may be produced. Although some removal of detonation-produced carbon monoxide (CO) by air scrubbing would occur, no reduction of CO is assumed, resulting in a conservative conclusion. Based on these factors, the following approximate levels of CFF-related emissions can be expected to reach the atmosphere annually from detonating explosives during 100 tests at CFF: NH_3 < 1.8 kg (4 lb), HCN ~0.9 kg (2 lb), HF ~0.9 kg (2 lb), HCl < 1.4 kg (3 lb), and NO_x < 12 kg (27 lb). Additionally, CO emissions would be expected to be less than 15 kg (33 lb) and all VOCs and semivolatile combustion products combined should be limited to approximately 0.2 kg (0.4 lb) (based on emission factors from trinitrotoluene detonation data contained in Volume 2 of the 1992 AMCCOM report). Particulate air emissions are expected to be negligible due to the extensive use of air scrubbing and filtration systems. These emission levels should have an insignificant (negligible) adverse impact on the air quality of the area air basin. The net impact of containing these 100 CFF tests per year by use of CFF (when compared to the No Action alternative) is beneficial.

The air emission of potentially greatest (bounding) impact is HTO. On approximately 10 tests per year, up to 200 curies (20 mg) of tritium may be used on each test. It is assumed that, as a worst case, all tritium would become converted to HTO. Of the 200 curies of tritium present in the chamber, 180 curies (90 percent) is expected to be vapor, and 20 curies (10 percent) would condense on the steel walls, floor, equipment, and debris. After completion of air scrubbing and chamber cleanup, it is expected that the 200 curies of tritium would be partitioned as follows: approximately 175 curies would reside in solidified waste from processing the various air scrubbing and filtration systems, 18 curies (from the 20 curies of HTO condensed on walls or solids) would also reside in a separate solidified waste from a water washdown of the chamber walls and surfaces, a maximum of 5 curies might escape to the atmosphere by leakage from the chamber, and 2 curies would remain adsorbed on interior surfaces and may, therefore, become transferred to waste water used after a non-tritium-containing test which would normally follow as the next test. This 2 curies of HTO would be evaporated to the atmosphere as part of the approximately 94,600 L (25,000 gal) of such wastewater. On balance, a possible maximum of 7 curies of the original 200 curies of tritium used in the test may escape as HTO to the atmosphere over a several-day to week-long period following each of the 10 tritium-containing tests; the remainder would be captured as LLW. By comparison, the amount of tritium contained in the typical theater exit sign is about 10 curies.

All appropriate and applicable air permits would be obtained for facility construction and operation. It is expected, based on a preliminary analysis of proposed normal facility operation, that Environmental Protection Agency Region IX approval and notification of startup for operations involving radionuclides will not be required. Provisions for sampling radionuclide air effluents would be incorporated into the design of CFF, and continuous monitoring, if required, would be performed according to NESHAP requirements.

J.5.2.2 *Waste*

A beneficial impact of the proposed action is that essentially all detonation products would be captured before release of remaining, mainly innocuous gases, to the environment. Two distinct waste streams would result from totally containing the tests at B801. The first waste stream consists of the shot debris, canisters, HEPA filters, scrubber fluids, and any other component of the pollution control system that becomes contaminated. The second stream is the washdown water itself and/or components of the washdown water system. The levels of the washdown water would be processed (filtered), stored, reused throughout an extended number of firings and eventually evaporated. Components of the processing system, such as used filters and washdown water system sludge, would be characterized and handled as hazardous, radioactive, or mixed waste.

The proposed facility, with its washdown and tritium removal system, would result in the generation of LLW and/or mixed waste because of the collection of sludge produced by the washdown operations. Conservative estimates are that 25 55-gal (208-L) drums of evaporator solids, tritium adsorption media, and stabilized washdown water, and 2 2.8 m^3 (100 ft^3) boxes of shot or test debris would be generated from each test with tritium. Generation of mixed waste is not expected, but to be conservative, a projection of 0.1 m^3 (3.7 ft^3) of mixed waste per shot is assumed. The balance would be conservatively considered LLW. For tests performed without tritium, only one 2.8 m^3 (100 ft^3) box of debris (LLW) would be generated. Because CFF would eliminate the use of firing table gravels, the total amount of solid waste that would be generated represents a significant reduction from the total amount of solid waste that is now generated annually during uncontained testing at B801.

The proposed CFF represents a decrease in waste generation from current and projected levels should the CFF not be constructed and operated. The types of waste generated at CFF would have some, but manageable, impact on waste handling activities at LLNL. Table J.5.2.2–1 shows the amounts of mixed, hazardous, and radioactive waste generated in activities conducted at LLNL and compares those values with the amounts of wastes, by type, expected to be generated at CFF annually. The CFF data in this table are based on the assumption that an average of 50 tests, and possibly up to 100 tests would be conducted annually, either at CFF or at the present B801 gravel firing pad (the No Action alternative). These projected annual test rates are based on recent (1991-94) testing data at the present B801 Facility. None of the waste types expected to be generated by the CFF/FXR would be unique to LLNL and each type would be processed and managed, stored, treated, disposed, or transported appropriately as is routinely done at LLNL for the same types of wastes from other current LLNL operations.

TABLE J.5.2.2–1.—*Comparison of Annual Lawrence Livermore National Laboratory and Contained Firing Facility Waste-Generation Rates (Weights Rounded)*

Columns	1	2	3	4	
Category	Waste Generation from All LLNL Activities (1992 EIS/EIR) (kg)	Waste Generation from Only S300 Activities (kg)	Waste Generation from B801 (50 Tests per year) (kg)[a]	Projected Waste Generation from CFF, (kg)	
				50 Tests/yr	100 Tests/yr
Hazardous[b]	1,413,000	173,000	6,100	6,100	12,000
Low-level radioactive[c]	295,000	152,000	53,000	23,000	45,000
Mixed[d]	43,000	~900	~0	(0 to 2,200)	(0 to 4,400)
Transuranic[e]	36,000	0	0	0	0
Total	1,789,000	325,000	59,000	31,000	62,000

[a] The selection of the 50-tests-per-year level analyzed here is based on an annual average of tests done at B801 from 1990 through 1994. The maximum annual testing level was approximately 100 tests a year. Waste projections were based on average annual data from 1991 to 1994. If 100 tests per year were conducted (the No Action alternative), waste projections shown in this column would be doubled.

[b] Columns (1), (2), and (3) reflect hazardous waste generation data found in tables B-15 and B-17 of the 1992 EIS/EIR. This waste consists primarily of waste oil, oil-contaminated rags and equipment as well as film processing solids and solutions used in support operations. The solid portion is approximately 4,000 kg (8,800 lb). Liquid volumes were converted into kg using 1,000 kg per m^3. Column (4) represents wastes projected from CFF operations at a level of 50 tests per year (average annual) and 100 tests per year (maximum annual).

[c] Columns (1), (2), and (3) reflect LLW values. Column (1) data was derived from tables B-10 and B-12 of the 1992 EIS/EIR for the Livermore Site, plus Site 300 data from Column 2. Column (2) was derived by averaging annual Site 300 shipping log information from 1989 to 1994. Column (3) was derived from annual average from 1991 to 1994. Column (4) data includes an estimated expected 25-percent reduction in the weight of waste debris below that of current operations and complete elimination of the generation of gravel waste since the CFF would not use a gravel firing table and would not use tent structures as are presently used at B801.

[d] Columns (1) and (2) reflect mixed waste values derived from Table B-13 and the discussion in Section B.4.3.3 of the 1992 EIS/EIR. Column (4) estimates were derived from conservative assumptions that operation of CFF could generate up to 0.1 m^3 (440 kg per m^3) of mixed waste from each test although none is expected. This waste would derive from evaporator sludge, from water washdown activities, and spent filter media. This further assumes that all CFF wastes would potentially be contaminated by low-level radioactivity after the first test that involves uranium, thorium, or tritium.

[e] Transuranic (TRU) wastes are not now generated from explosives testing at Site 300. Table B-11 of the 1992 EIS/EIR shows 6 months of generation at the LLNL Livermore Site in 1990 to be 36 m^3 (1,271 ft^3). Thus, a year's generation would be estimated to be 72 m^3 (2,543 ft^3). An average density of 500 kg per m^3 was used to convert volume to weight (Column [1]).

Source: DOE/UC 1992.

Waste generated by facility D&D is assumed to be all LLW and is conservatively estimated to be 110 percent of the volume of the Firing Chamber construction materials. This would be approximately 1,830 m^3 (64,610 ft^3). If built at B851, as an alternative, these waste generation impacts should not be different than those for CFF that would be sited at B801. The waste would be handled in the same manner as other solid LLW generated from LLNL operations at that time.

J.5.2.3 *Noise*

The proposed action would have beneficial effects on the environment and on employees by reducing noise levels onsite and offsite, respectively. The current practice at the Site 300 firing areas relies on a combination of administrative and operating controls to ensure that neither site workers nor the public are adversely affected by exposure to high-impulse noise generated by the explosives test activities. These controls include restricted entry into the firing area when tests are scheduled, required accounting for all test-site-area personnel inside the protective building prior to testing, and limiting the size of the test (or precluding testing altogether) during unfavorable meteorological conditions. Containing the detonations of explosives would greatly reduce noise levels under all conditions and would eliminate the possibility that a test would need to be canceled or rescheduled because of potential noise levels resulting from inappropriate atmospheric conditions.

Noise sources anticipated during and following explosives tests in a containment facility would include low-energy impulse from the test, the relief of containment vessel overpressure, and other noises associated with the operation of the air handling system used to purge the containment vessel. These noises are not expected to be perceptible to Tracy-area residents or area ranchers, and they would not exceed the occupational noise exposure limits adopted by DOE for the protection of employees.

J.5.2.4 *Ionizing Radiation*

Detonations in the Firing Chamber could involve radioactive materials such as tritium (up to 20 mg on each of 10 tests), depleted uranium, and on some tests, thorium. Additionally, certain test configurations may occasionally generate small quantities of neutrons, which may then yield neutron-activation products. Because of the modest neutron production potential, (10^{16} neutrons per test on certain tests), the very effective shielding provided by the Firing Chamber, and the low specific activity of depleted uranium, the potential radiation impacts are dominated by tritium and activation-product buildup. These potential impacts to involved workers, noninvolved workers, and members of the general public are summarized in table J.5.2.5–1. Because these results are based on very conservative assumptions used when calculating projected impacts (as described below), they are considered bounding for routine CFF operations.

Some of the assumptions used in deriving table J.5.2.5–1 estimates were:

- A maximum of 10 detonation tests per year involving a maximum of 20 mg (200 curies) of tritium each.
- A maximum level of diagnostic neutron production (10^{16}) per test, on a maximum of 10 tests per year.
- From each of 10 tests per year, up to 5 curies of released tritium as HTO from the Firing Chamber at ground level by leakage during chamber cooling and scrubbing, and an additional 2 curies of residual tritium released as HTO later during evaporation of washdown water through the facility stack that is also assumed released at ground level for purposes of dispersion modeling.
- Up to three involved CFF-area workers spend up to 2 days each within the Firing Chamber, entering the first day after detonation, and after air-scrubbing and chamber cleanup have reduced the tritium level in the chamber to approximately 5×10^{-6} curies/m^3; all three workers are assumed to spend full time within 2 m of the shot location, where activation product doses would be maximized.
- Primary washdown water and dry air-scrubbing would yield an estimated maximum of 193 curies per test as solid low-level radioactive waste.

If the maximally exposed individual in the general public stayed at the nearest fenceline to CFF over the entire expected 30-year lifetime of the facility, the estimated lifetime fatal cancer risk to that individual from potential whole-body effective dose equivalent exposure to 3.8×10^{-5} person-rem would be 5.7×10^{-7} (that is, about one fatal cancer in 2 million). This potential dose is about 1,000 times less than the DOE guideline dose limit (that which might produce 1 fatal cancer per 2,000). Additionally, each of the three CFF workers who would be expected to accrue the greatest exposure dose (from removing debris from and cleaning the Firing Chamber after each test) should each receive a dose of less than 0.25 rem per year. This is less than 5 percent of the DOE worker exposure limit guideline of 5 rem per year. By comparison, the average annual dose received by an aircraft flight attendant is about 0.5 rem, or twice the dose expected for these CFF Firing Chamber workers.

J.5.2.5 *Slope Stability*

Document review suggests that existing B801 site slopes are stable. Unconsolidated overburden is only a few feet thick in the area and bedrock dips at a shallow angle (about 5 degrees) northeast. However, a recently active landslide deposit has been observed within about 244 m (800 ft) east of the site. This landslide is reported having generated a mudflow which reached the vicinity of the B801 site during a 15-year period prior to 1983. This mudflow appears to have been mitigated by placement of an earthen fill between the flow and the B801 site. Appropriate slope

TABLE J.5.2.5–1.—***Maximum Potential Annual Radiation Exposure Impacts from Normal Contained Firing Facility Operations***

Individual or Group	Tritium	Activation	Total	Excess Cancer Fatalities (per year)[b]
Individual Potential Dose, Rem Per Year[a]				
Involved CFF-area worker	0.09	0.16	0.25	1.0×10^{-4}
Non-involved worker (50 m)[c]	5.2×10^{-3}	0	5.2×10^{-3}	2.1×10^{-6}
Total worker[d]	1.6	0.5	2.1	8.4×10^{-4}
Collective Potential Dose, Person-Rem Per Year				
Maximally exposed member of general public (site boundary, 1,340 m)	3.8×10^{-5}	0	3.8×10^{-5}	1.9×10^{-8}
Total general public[e]	0.32	0	0.32	1.6×10^{-4}

[a] See discussions, section J.5.2.4.
[b] Based on DOE dose-to-risk conversion factor of 4×10^{-4} (4 in 10,000) latent cancer fatalities per person-rem for workers and 5×10^{-4} (5 in 10,000) for the general public.
[c] Assumed to be all Site 300 noninvolved workers (approx. 260) standing 50 m from CFF resulting in an extremely conservative estimate.
[d] The total worker cumulative dose is the sum of doses to both the involved CFF workers and noninvolved workers within 50 m of the CFF.
[e] Using the EPA-approved computer code, CAP88-PC, version 1.00, the total general public cumulative dose estimate was calculated by considering the approximate population within 80 km (50 mi) of Site 300 and using annual site meteorological data.
Source: Model results.

stabilization measures would be taken in design and construction of graded slopes (see also section J.5.1.1).

J.5.2.6 *Water Use*

It is expected that washdown of the CFF Firing Chamber, after considering the contribution of planned water recycling activities, would involve the use of 950,000 L (250,000 gal) of water annually. This water consumption level, plus that for cooling towers (1,100,000 L [300,000 gal]), and domestic uses 190,000 L (50,000 gal), would add a total of approximately 2,300,000 L (600,000 gal) annually to the Site 300 water consumption rate of approximately 120 million L (31.8 million gal) over projected groundwater use (DOE/UC 1992), which is less than a 3-percent increase.

J.5.3 Accident Scenarios

The reasonably foreseeable accident scenarios that could produce the greatest potential impacts are the following:

- Case 1: Accidental detonation of a test of a 60-kg (132-lb) charge of explosives at the B801 firing table. (Applicable to No Action alternative.)
- Case 2: Accidental detonation of a 60-kg (132-lb) test that could contain up to 20 mg (200 curies) of tritium with dispersal through an unsecured blast door during final preparation. No neutron generation potential would exist, because blast doors would be closed before any accident scenario that would involve neutron generation (misfire). (Applicable to either B801 or B851 alternatives.)

One accident scenario that was considered but was not felt to be reasonably foreseeable included:

- Case 3: Same test configuration as in Case 2, but the planned detonation takes place yielding the potential for neutron generation; accidental rupture of the CFF Firing Chamber occurs (considered to be a beyond-design basis accident and therefore, not reasonably foreseeable). (Applicable to either B801 or B851 alternatives.)

In each case, the involved workers would probably be fatally injured from blast effects due to peak overpressure and debris, but there would be no injury offsite to members of the general public. No damage to current buildings offsite or in other areas of Site 300 would be expected, although window rattling might occur. Projected radiation effects from two scenarios are summarized in table J.5.4–1.

These projected radiation doses are still lower than DOE guideline limits for workers and for the general public; thus, the greatest effects would be fatalities or injuries to workers due to primary blast effects, as noted above.

J.5.4 Cumulative Impacts

The primary negative impacts resulting from the proposed action would occur as a result of construction-related activities. These activities would be short term and are not expected to result in significant increases in ambient amounts of airborne dust or noise. Approximately 45,000 kg (20,500 lb) of solid LLW from Firing Chamber air-scrubbing and washdown following contained firing operations could be generated each year. This volume of waste represents a reduction from the levels that would be projected if the same number of detonations were to take place at the current facility (No Action alternative). The proposed project is expected to greatly reduce the air emission of detonation combustion products and to reduce cumulative buildup of LLW by eliminating outdoor explosive testing on gravel firing tables (which must be handled as LLW because some of the explosive test devices would contain radioactive components). The proposed action would therefore greatly reduce the release of emittants to the air and ground.

J.5.5 Conformity

Site 300 is in an air basin area designated as non-attainment with respect to ozone. The design, construction, operation, and ultimate D&D of CFF would not result in levels of emissions of ozone precursors (oxides of nitrogen and precursor organic compounds) that would place Site 300 above conformity thresholds; and the facility would not cause or contribute to any violation of the National Ambient Air Quality Standards. The facility would be operated in conformance with all rules and regulations of the SJVUAPCD which are included as part of the state implementation plans.

J.5.6 Socioeconomic Factors and Environmental Justice

J.5.6.1 *Staffing*

The addition of another 5 to 6 full-time LLNL employees (for CFF operation) to augment the present B801/FXR operating staff (which averages 20 employees) will be an insignificant incremental impact over that of operating the current FXR Facility and its associated firing table.

J.5.6.2 *Environmental Justice*

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, requires that Federal agencies identify and address, as appropriate, dispro-

portionately high and adverse human health or environmental effects of their programs and activities on minority and low-income populations. DOE is developing official guidance on the implementation of the Executive Order. However, given the demographic makeup of Tracy and its surrounding agricultural areas, it is expected that there would be insignificant or no potential for differential or disproportionate impacts from the proposed action (or from its alternatives) to offsite populations that could be characterized as predominantly minority or low-income.

J.6 Persons and Agencies Contacted

No persons or agencies outside the LLNL and DOE have been contacted.

APPENDIX K: ATLAS FACILITY PROJECT-SPECIFIC ANALYSIS

K.1 PURPOSE AND NEED FOR AGENCY ACTION

K.1.1 Background

This project-specific analysis for the proposed Atlas Project is intended to provide specific information about the siting and construction of Atlas at the Los Alamos National Laboratory (LANL) in Los Alamos, NM. The purpose and need set forth in this document is focused on the additional capabilities that the Atlas Project would provide to LANL. Environmental impacts resulting from this proposed action are assessed for LANL only. Information relating the Atlas Project to the broader assessment of complex wide Stockpile Stewardship and Management environmental impacts is found in the *Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (PEIS).

Modeling of nuclear weapons to assess and ensure safety, reliability, and performance as weapons age or are modified or remanufactured, is part of the science-based stockpile stewardship mission. Without nuclear testing, mathematical calculations based on experimental data would be the only way to obtain needed information on weapons performance and reliability. However, the Department of Energy (DOE) has not yet determined how to predict this behavior with sufficient accuracy from calculations alone. Developing and verifying more accurate predictive modeling requires both empirical data on underlying physics and benchmarking of computational predictions against experimental observations. This is particularly necessary in the case of nuclear weapon stewardship, for which substantial simplifications of physics are necessary for practical computational models. To ensure that the physical approximations and models are adequate, and provide proper physical data and adequate benchmarking, experiments must be done in regimes of appropriate physical parameters.

It is the requirement as presented in the Stockpile Stewardship and Management PEIS for experimental data in the regimes of extreme physical parameters common to nuclear weapons that underlie the need for high-energy-density experimental facilities. Lasers and pulsed-(electrical)-power experimental facilities are complementary in providing these capabilities. High-energy lasers provide the highest temperatures and pressures in small experimental volumes for a few billionths of a second. High energy pulsed-power facilities make different aspects of this high-energy-density regime accessible because pulsed power can focus much higher total energy on a larger (e.g., centimeter [cm] scale) experimental target for a much longer time, albeit at somewhat lower temperature and pressures. Pulsed power will be of most value to the science-based stockpile stewardship program in addressing properties of materials, implosion hydrodynamics, and radiation flow physics. These are some of the areas identified by DOE as the most significant concern to weapons scientists.

LANL already has capability in pulsed power in the microsecond regime and applies it to stockpile stewardship. In particular, LANL uses the Pegasus II 4-megajoule (MJ[1]) capacitor bank, as well as high-explosive (HE)-driven pulsed power generators such as the Procyon generator, which are used in single-shot experiments at appropriate HE firing locations. Typically, the pulsed electrical currents produced by the capacitor bank or HE generator create strong magnetic fields that implode a cylindrical "liner," which would impact a centimeter-scale target to produce hydrodynamic pressure. Alternatively a liner accelerated to high velocity toward the axis of the cylinder could produce soft x rays when it impacts. The 4-MJ Pegasus II capacitor bank is already used for a variety of experiments associated with the physics of both primaries and secondaries. Heavy liners can provide highly symmetric and smooth implosion drive, with asymmetries of 0.5 percent or less, that can help weapons scientists isolate and study certain physical phenomena without complicating effects.

K.1.2 Purpose and Need

DOE must maintain the safety, security, and reliability of the U.S. nuclear weapons stockpile. As a result

[1] 1 megajoule is 0.28 kilowatt-hrs of electricity.

of the moratorium on underground nuclear testing and pursuit of a *Comprehensive Test Ban Treaty*, DOE is forming a science-based stockpile stewardship program. This program is being carried out by the weapons laboratories using a variety of technologies, including lasers and pulsed power to support the computer modeling of nuclear weapons' performance over time as the stockpile ages.

As a result of the stockpile stewardship mission, LANL is tasked with enhancing their pulsed-power capability, resulting in the ability to accurately benchmark calculations on weapon performance. An extensive amount of high-energy shots need to be performed for a variety of potential physical defects such as cracks, voids, corrosion, or other modifications to material that may be caused by aging or introduced from remanufacturing. The capability and energy of existing facilities is insufficient to reach the pressures, volumes, and energy densities needed to accurately benchmark weapon-related computational predictions as required to support the stockpile stewardship mission at LANL. In particular, existing facilities cannot support large-scale experiments in the ionized regime, an important capability for analyzing primary and secondary-physics issues, such as implosion hydrodynamics, materials properties, and interactions.

K.2 DESCRIPTION OF ALTERNATIVES

K.2.1 Proposed Action

K.2.1.1 *Description*

The need to perform experiments with macroscopic pulsed-power targets, as well as with lasers, exists not only because of the limits of measurement diagnostics or improved ease of measurement at larger scale, but also because some of the physical phenomena that must be investigated cannot be readily scaled down to smaller sizes without affecting some parameters of importance. For example, DOE must perform experiments to develop and benchmark calculations on weapon performance for a variety of potential physical defects such as cracks, voids, corrosion, or other local modifications to material that may be caused by aging or introduced from remanufacturing. Studying the hydrodynamic effects of such perturbations in a pulsed-power experiment and comparing the results to calculations is one of the means used. Figure K.2.1.1–1 illustrates this hydrodynamic process. If the perturbations being investigated were scaled down to the volumes accessible by laser experiments, in many cases the perturbations would be of a similar size to natural material grains or pores, which would complicate or even obscure the experimental results.

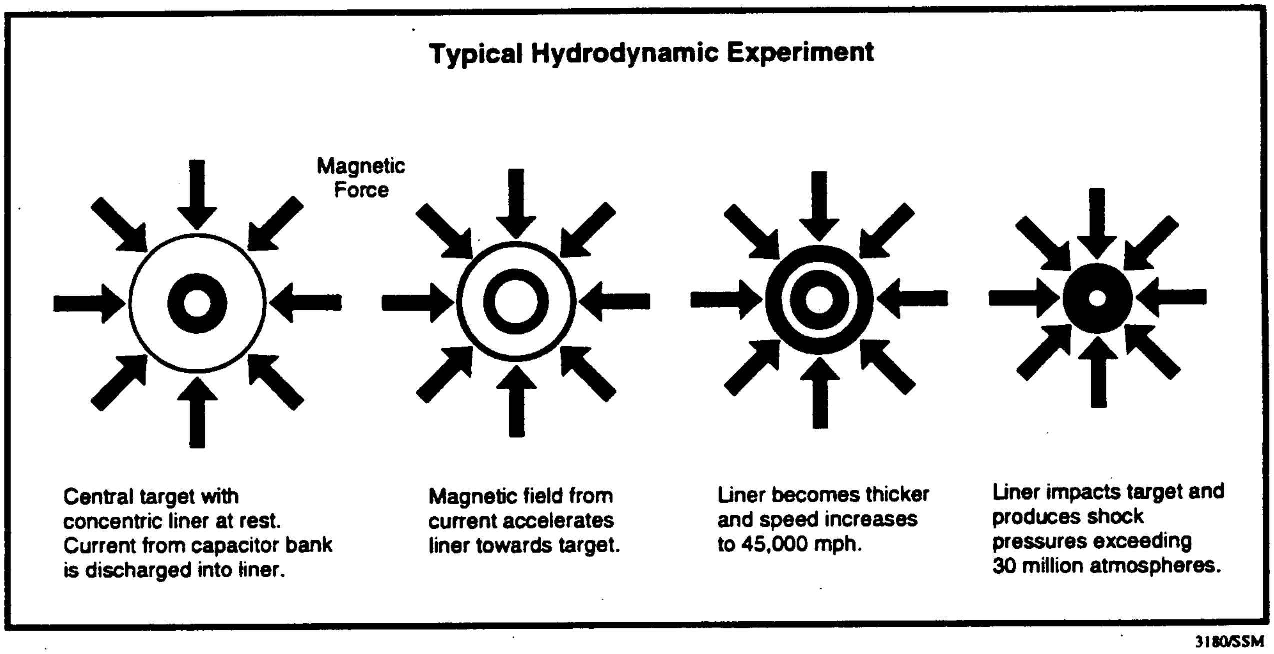

FIGURE K.2.1.1–1.—*Hydrodynamic Process of Pulsed Power Experiments at Atlas Facility, Los Alamos National Laboratory.*

However, the energy of Pegasus II is insufficient to reach the pressures and volumes needed to accurately benchmark weapon-related computational predictions. In particular, Pegasus is not adequate to drive dense hydrodynamic targets into the ionized regime, an important capability for analyzing some secondary-physics issues.

Atlas has been designed to provide enhanced pulsed-power capability specifically to address these areas. Atlas has been conceptually designed as a 36-MJ inductive energy store capacitor bank that would nominally deliver 25 to 30 megamperes (MA) (60 MA peak) to an imploding liner or plasma. For hydrodynamic experiments, Atlas would implode heavy precision liners to velocities of over 2 cm/microsecond with final kinetic energies of 2 to 5 MJ. Pressures of >5 to >30 megabars would be achieved (depending on design of the experiment). One dimensional calculations benchmarked to past HE pulsed-power results predict that Atlas will produce x-ray yields > 2 MJ with temperatures >100 electron volts (eV). In a switched mode of operation, Atlas x-ray output would approach 200 eV temperature.

For study of material properties and development of dynamic materials models, Atlas would produce pressures and strain rates in cubic centimeter (cc) scale samples at least 5 to 10 times greater than possible with the present Pegasus Facility.

Fidelity of scaled implosion hydrodynamics experiments is essential for them to be used to verify predictions of design codes. Even the simplest set of physical equations governing compressible hydrodynamics have four parameters that should be the same for fidelity. High-energy density hydrodynamic flow calculations must be validated by experiments with an energy density high enough to get materials into the appropriate state of matter, to ensure adequate fidelity of the important parameters.

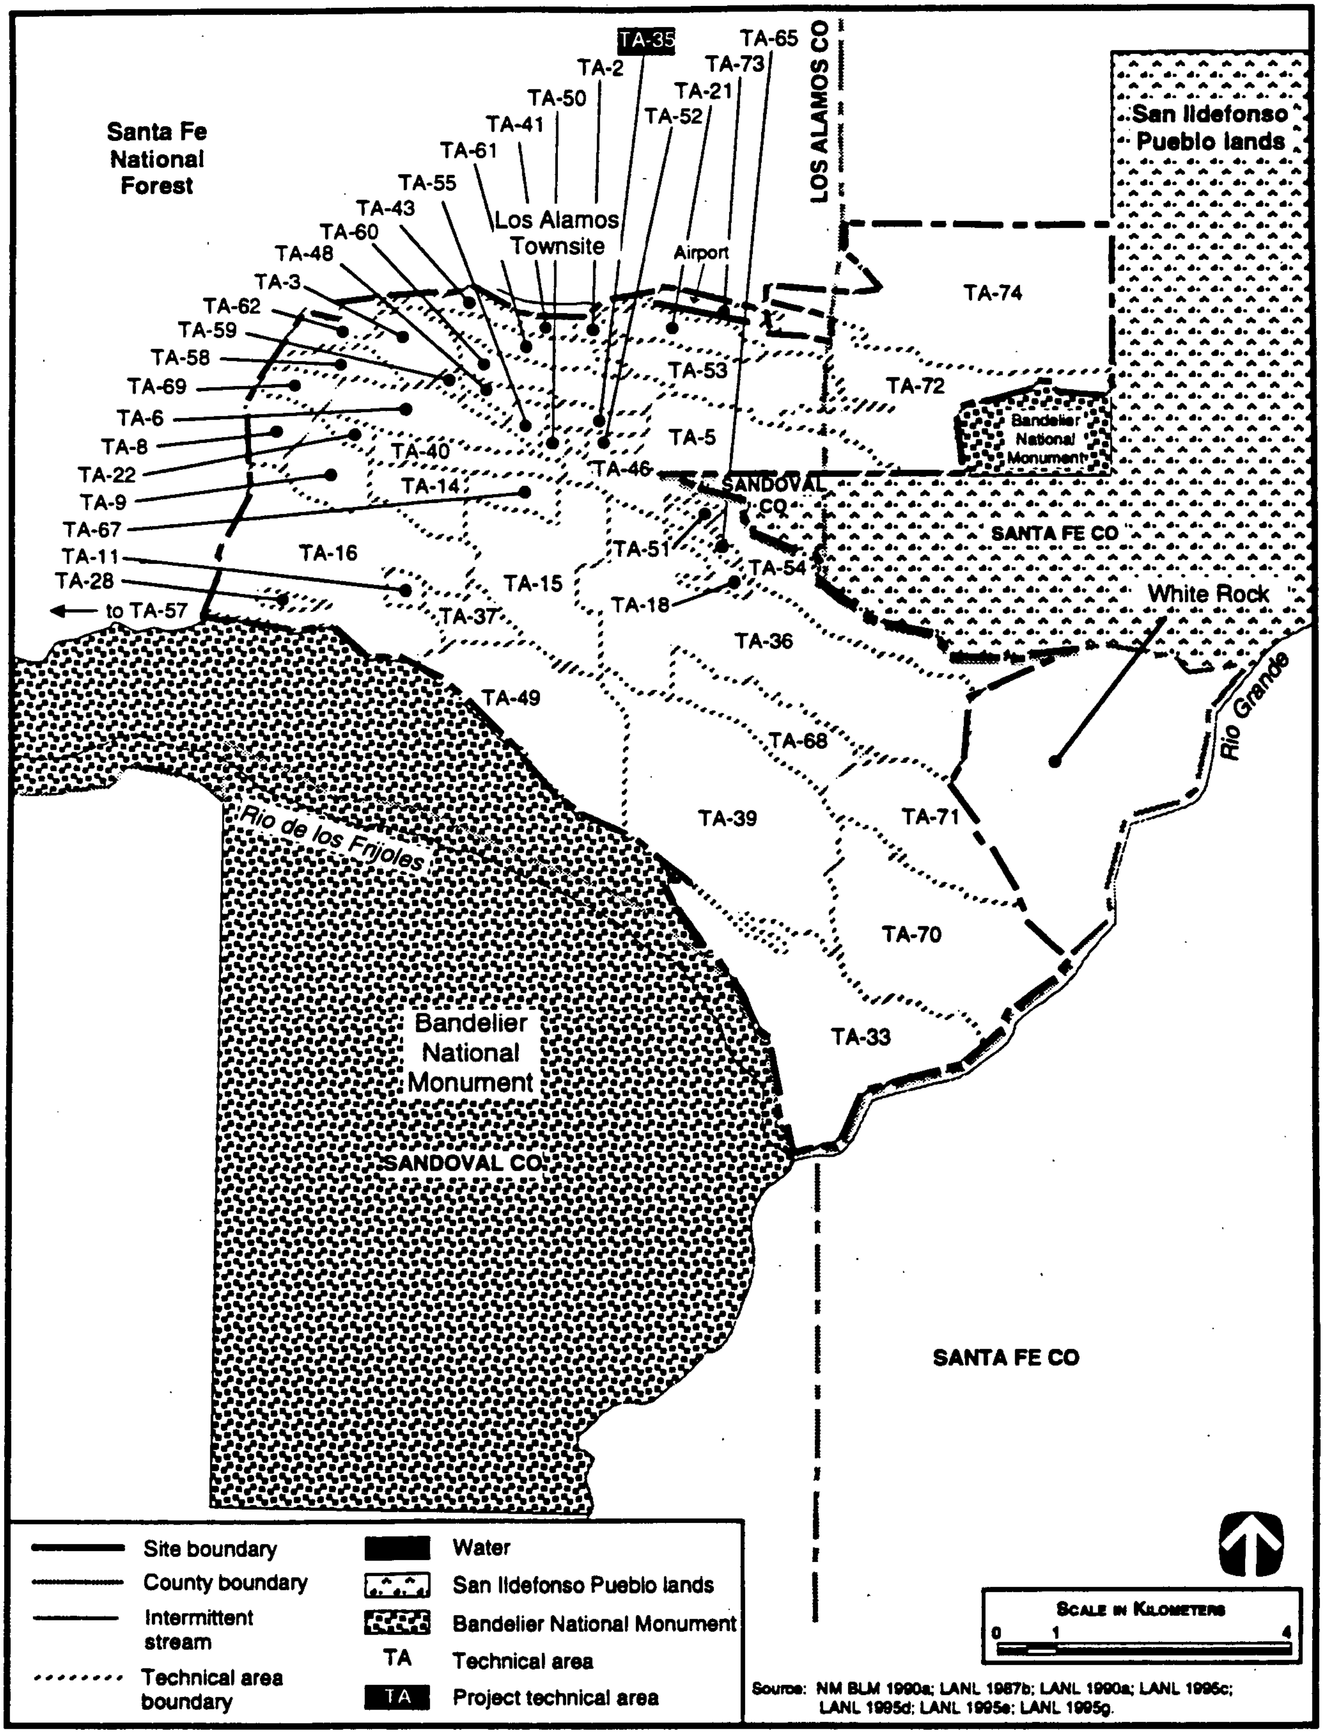
A key need satisfied by the Atlas Facility would be the capability of doing large-scale hydrodynamic experiments at high temperatures to ionize the material. This is important for understanding physics phenomena associated with late stages of primary as well as secondary implosion. Atlas will be the first pulsed-power facility that will have the capability for generating the state of matter — ionized, highly correlated materials — that governs two of the most important of these similarity parameters, compressibility and Reynolds number. For metals, this requires 500 kilojoules (kJ)/cc, and for plastics 200 kJ/cc. To access this energy density regime, a typical experiment large enough to have easily resolved features needs to be driven with 2 to 5 MJ of kinetic energy. Solid-liner kinetic energies in this range cannot be achieved on presently operating pulsed-power facilities.

Atlas would provide these conditions in large experimental volumes (cc) for benchmarking and verifying models used to evaluate effects of aging (e.g., high aspect ratio cracks), or changes due to remanufacturing, on weapon performance and reliability. Atlas would make available an order of magnitude increase in dynamic pressure over Pegasus, which would greatly enhance DOE's ability to study such important phenomena as melting and hydrodynamics in primaries, early and late time spall in converging geometries, distortion in implosion systems, and effects of gaps.

The expected lifetime of the Atlas Facility is 20 years. After that time, the facility would be cleaned up and decommissioned, which would generate an estimated quantity of nonhazardous waste totaling approximately 841 cubic meters (m^3) (30,000 cubic feet [ft^3]). This waste would be recycled or disposed of at a sanitary landfill. A separate *National Environmental Policy Act* (NEPA) analysis would be conducted at that time.

K.2.1.2 *Facility*

The Atlas Facility would be located at LANL's Technical Area (TA)-35 (see figure K.2.1.2–1). TA-35 is used primarily for research and development (R&D) activities in the fields of physics, chemistry, fusion, and materials science. Construction of the facility would involve renovating existing buildings for use in performing pulsed-power experiments. The construction phase would also involve the installation of high-power electrical Special Facilities Equipment (SFE). To accommodate the facility and its support requirements, five existing buildings within TA-35 would be modified, and external concrete pads, transportable office/diagnostic space, and storage tanks would be added. These relatively minor



3152/SSM

FIGURE K.2.1.2–1.—*Proposed Location of Atlas at Los Alamos National Laboratory.*

modifications have an estimated cost of $2.5 million and would be completed within 6 to 9 months of the facility construction start-date.

Atlas operations would require the following major SFE elements: 1,430 megawatt (MW) generator (existing); 80 MW alternating current to direct current (ac-to-dc) converter; 50 MJ inductive energy transfer system; 36 MJ capacitor bank; target chamber; and various control, diagnostic, and data acquisition equipment. The facilities and infrastructure requirements necessary to support this SFE include heavy lab construction with overhead material handling capability, vibration-free high-power generation, electromagnetically-shielded and security-hardened data acquisition areas, and dielectric fluid storage and transfer equipment. All SFE and supporting facilities/infrastructure meet or will be designed to meet the construction requirements for a "low hazard, non-nuclear" facility.

The Atlas Facility would use portions of Buildings 124, 125, 126, 294, and 301 at TA-35 (see figure K.2.1.2–2) in the following manner to meet these SFE facility and infrastructure requirements:

TA-35-124/125	Atlas Experimental Area, Control Room and Coordination Center
TA-35-126	Mechanical Services Building
TA-35-294	Power Supply Building
TA-35-301	Generator Building

Detailed building-use information, including building modifications, is included in the following paragraphs. Up to 35 construction workers would be involved in the building modifications and equipment installations at any given time; the workers would be a combination of relocated workers from other completed construction sites and a limited number of new hires as needed. Approximately 15.3 m^3 (20 yd^3) of noncontaminated construction waste would be generated during construction.

Buildings 35-124 and 35-125. The total space the Atlas Facility would use in these buildings is approximately 1,151 square meters (m^2) (11,770 square feet [ft^2]). Buildings 124 and 125 are proposed to house the primary Atlas Facility components because they could provide safe, secure, and convenient working and experimentation space; access to the Atlas capacitor bank could be controlled and limited; and diagnostic support platforms are available for conducting and analyzing proposed experiments. These buildings have the following special features:

- *Heavy-industrial, high-bay construction.* Atlas requires, at a minimum, 929 m^2 (10,000 ft^2) of high-bay building with a heavy-duty gantry crane to house the capacitor bank and user-support facilities. Building 124 and 125 were designed for large-scale experimental work and have high ceilings with heavy duty gantry cranes that can access the entire interior space. Buildings 124 and 125 satisfy all the Atlas space requirements.

- *Reinforced walls and ceiling.* Atlas requires reinforced walls and ceilings to protect workers and the public against shrapnel from possible high-energy electrical faults in the capacitor bank. Buildings 124 and 125 were designed to house the power amplifiers and target chamber of a laser-fusion facility. To protect the public from associated hazards, the buildings were constructed with concrete walls and roofs. This type of construction is ideal for a high-energy capacitor bank because shrapnel from possible faults will be contained within the building. The walls and ceiling will also contain any diagnostic x rays produced. Buildings 124 and 125 satisfy all the containment requirements of Atlas.

- *Collocation with the 1430-megavolt ampere (MVA) generator.* Atlas would utilize a multi-hundred MVA generator to charge the capacitor bank rapidly. The facility housing this generator (Building 301) includes a spring-mounted generator pad which isolates vibrations due to generator operations from surrounding experimental areas. This rapid charging technique is similar to other large physics facilities for which power from the existing electrical grid is insufficient to meet the facility technical requirements. In the case of Atlas, this

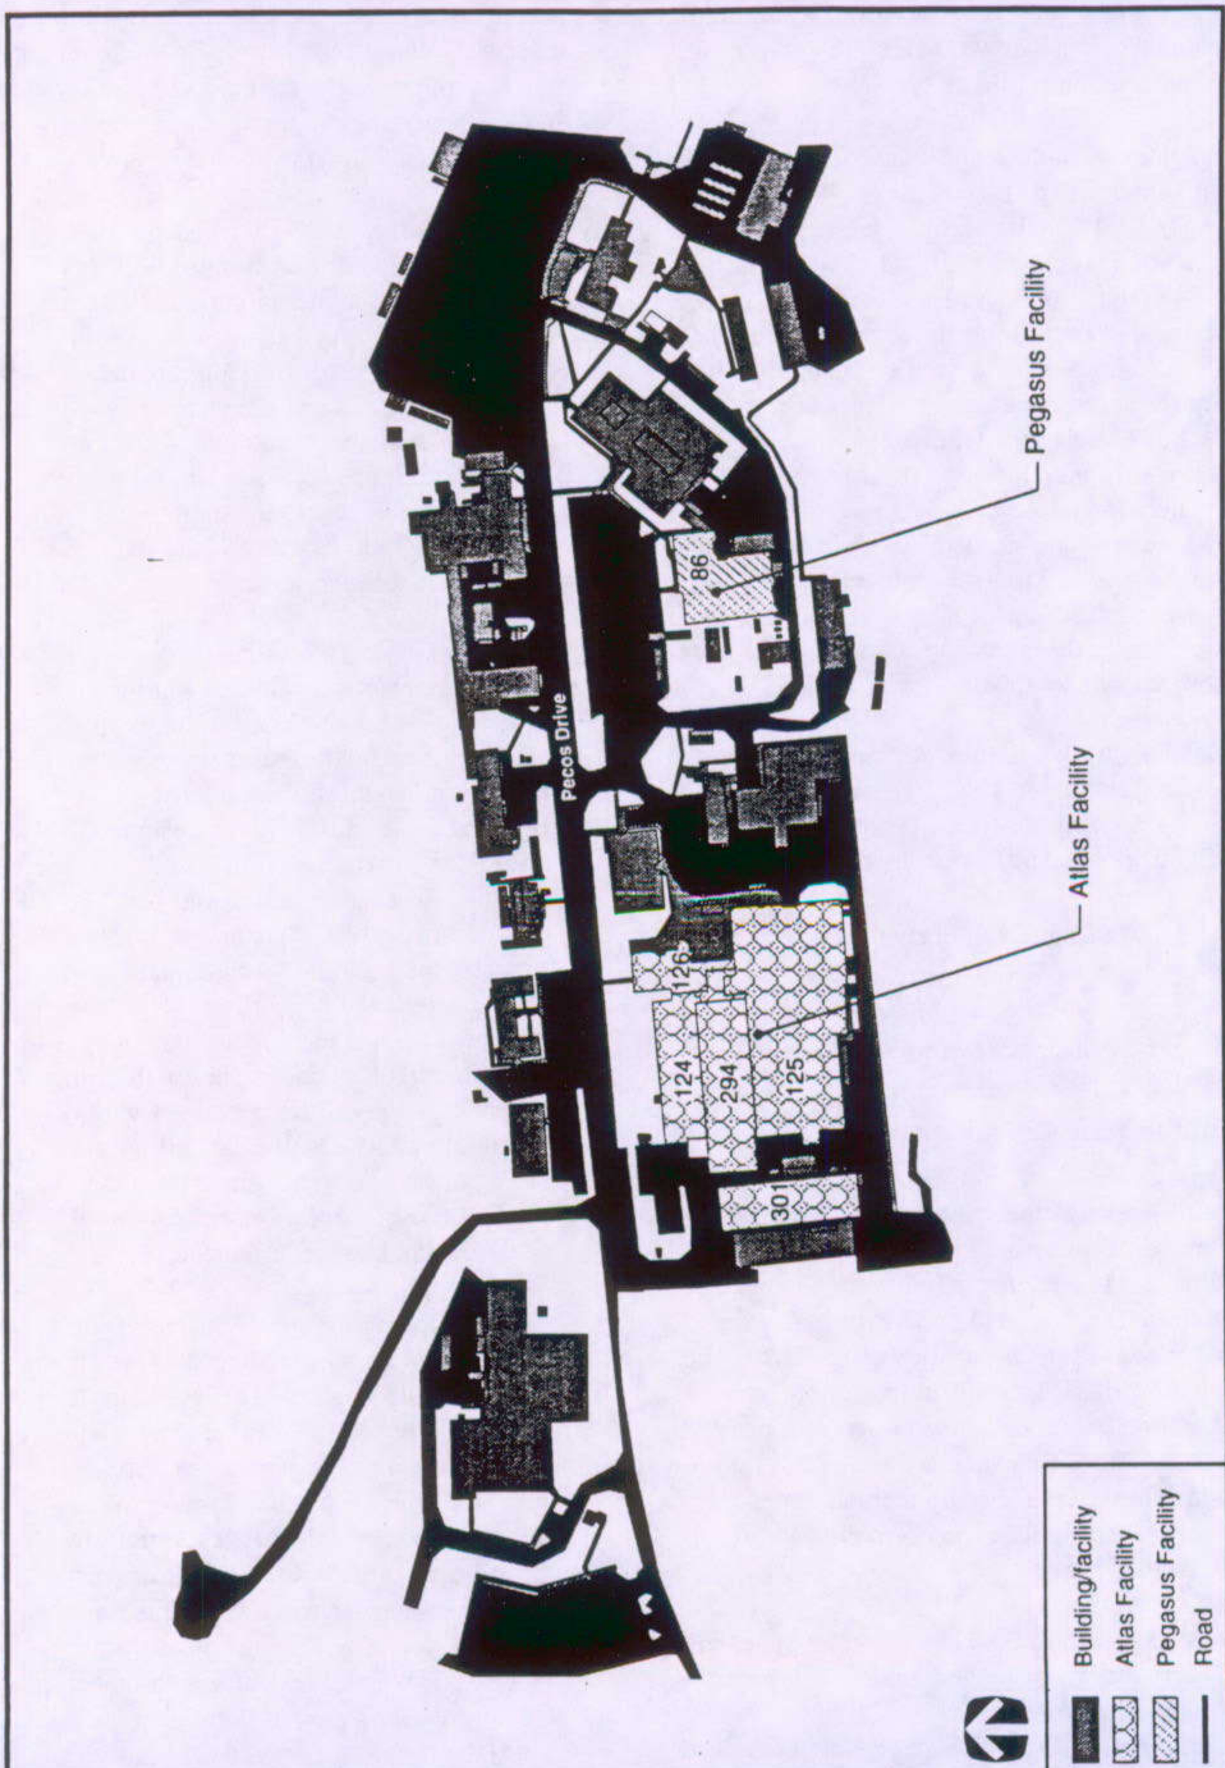


FIGURE K.2.1.2–2.—*Proposed Location of Atlas Facilities and Location of Pegasus II Facility.*

requirement stems from a common fault mode for large capacitor banks; premature electrical breakdown (prefire) of a capacitor switch. A prefire usually destroys the target and much of the rest of the experimental assembly, both of which are expensive and require days to replace. Since the probability of prefire is proportional to the time during which the switches must hold high voltage, the problem is greatly diminished by rapidly charging the capacitor bank and then quickly triggering the switches.

Due to the large number (300) of capacitor switches in Atlas and the programmatic and cost impacts of recovering from frequent prefires, Atlas will use rapid charging to satisfy its reliability requirements. Because of the extremely large energy storage required, even multi-megawatt power lines would still take 10 to 20 seconds to charge the Atlas capacitor bank. DOE has estimated that a faster charging rate will be required to provide sufficient confidence that Atlas will meet its reliability requirements. Buildings 124 and 125 are proposed to house Atlas because a 1430-MVA generator, located adjacent to these buildings in Building 301, is available and is capable of charging the capacitor bank in as little as 0.04 seconds. This configuration forms the basis of the Atlas conceptual design.

- *Electromagnetically shielded, data-acquisition room for classified data.* Atlas will require an electromagnetically shielded, data-acquisition room for classified data. The laser-fusion machine, for which Building 124 was originally designed, has many similarities to Atlas' operational requirements, including the capability to retrieve and store classified data. Inside the building is an electrically shielded data acquisition room that is also protected by a concrete wall. During classified tests, the entire building could be secured, and all classified data could be electronically routed to this room.

  This room satisfied the requirement for a secure site for classified data for the laser-fusion machine, and would also satisfy the Atlas requirement.

- *Electromagnetically shielded room for machine-control and unclassified data.* Atlas requires a machine-control room that is isolated from the machine and provides space for unclassified data acquisition. Just outside Building 124 in Building 125 is an 86 m^2 (925 ft^2) electrically shielded control and data acquisition room that was originally constructed to control the laser-fusion facility. This room already has conduit to Building 124 for machine-control and unclassified data acquisition lines. This room satisfies Atlas requirements for machine-control and unclassified data acquisition.

- *Oil storage.* Atlas will likely require storage capabilities for electrically insulating mineral oil. Just outside Building 125 are 3 underground oil storage tanks with a total capacity of 90,850 liters (L) (24,000 gallons [gal]). These tanks were installed to support the laser-fusion pulsed-power systems. Ownership of these tanks recently became available, and if Atlas uses oil for capacitor-bank insulation, these tanks would help satisfy Atlas oil-storage requirements.

Figure K.2.1.2–3 provides a perspective of the Atlas primary facility components, including the SFE, proposed for installation at TA-35. These consist of:

- Target chamber containing implosion target
- Imaging radiography darkrooms
- 36 MJ capacitor bank
- Target assembly clean room
- Laser diagnostic systems
- Satellite control room

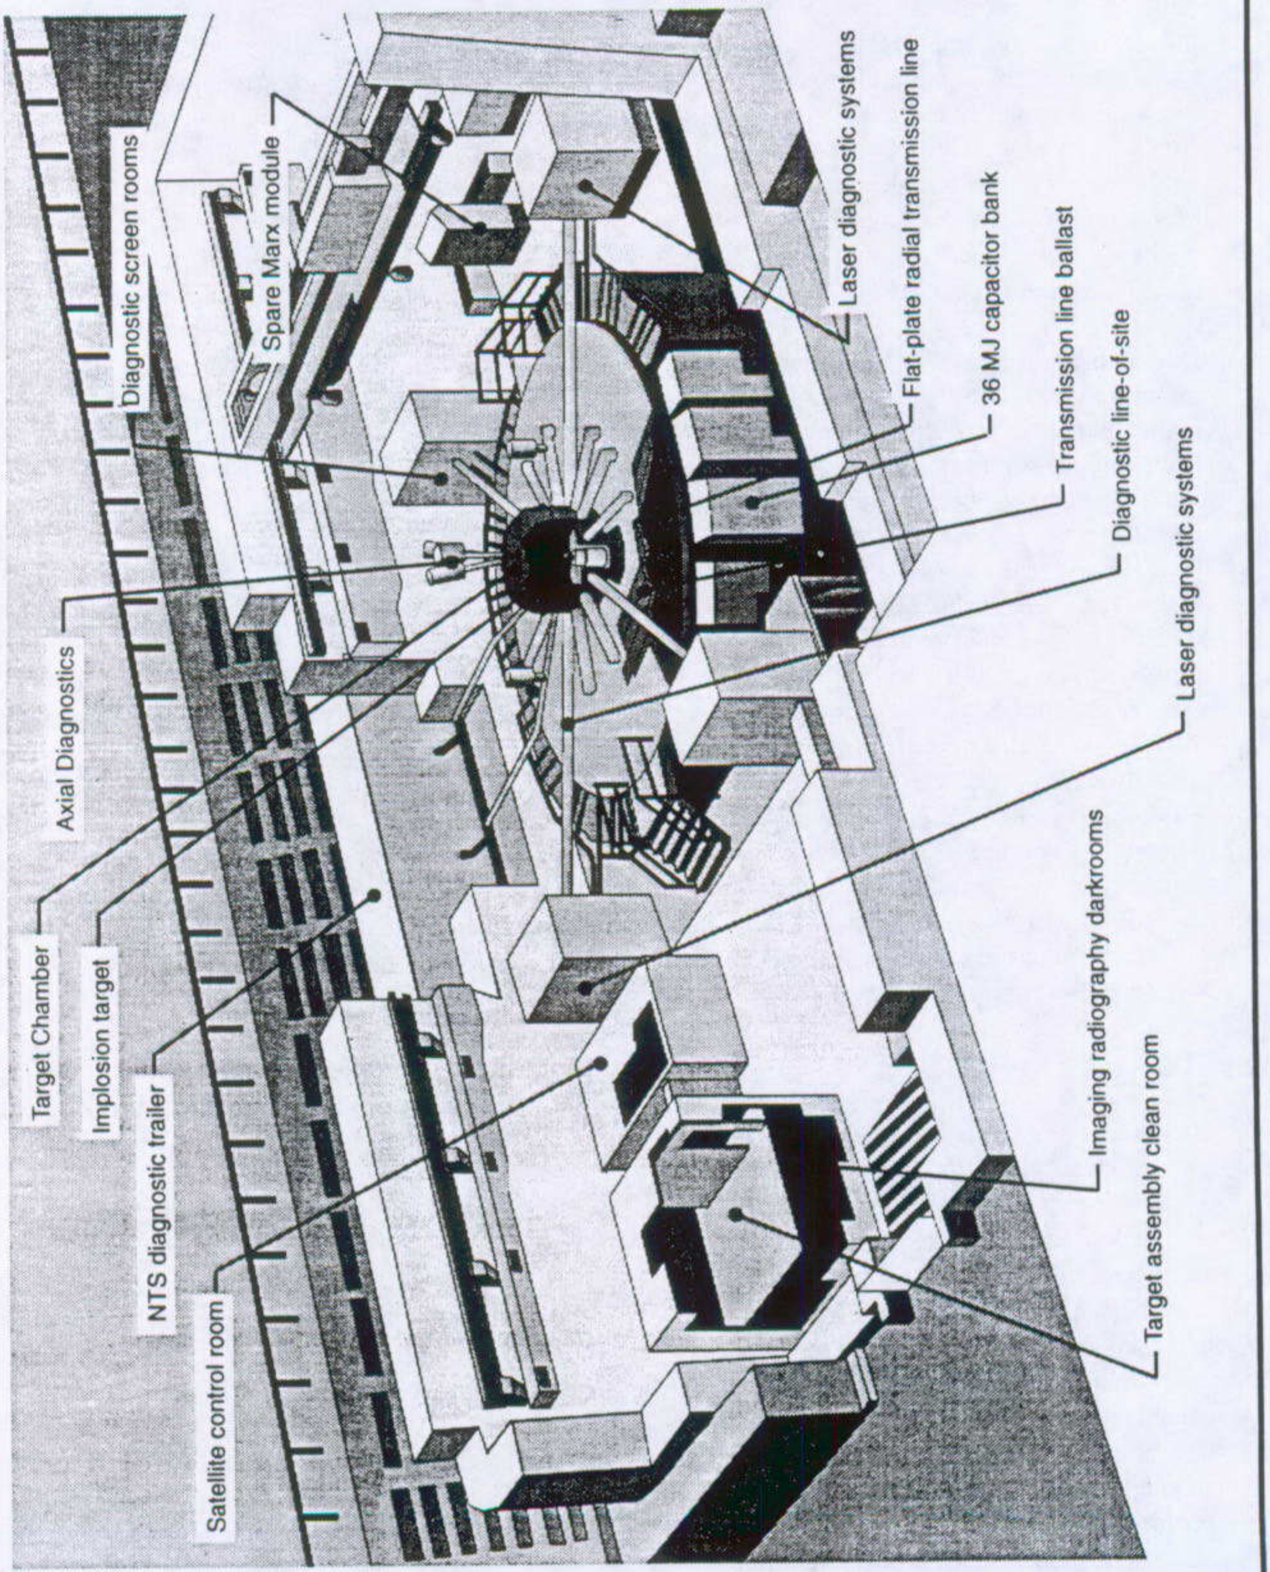

FIGURE K.2.1.2–3—*Atlas Facility Conceptual Perspective.*

- Diagnostic screen rooms
- Diagnostic trailer
- Axial diagnostics
- Spare Marx module
- Vacuum pumps
- Structural platforms and stairwells
- Flat-plate radial transmission line
- Oil storage and transfer system
- Transmission line ballast
- Chilled water, nitrogen, and compressed air systems

Structural modifications and improvements to Buildings 124 and 125 and surrounding areas required to accommodate the Atlas Facility components would include the following:

- The heating, ventilation, and air conditioning may be modified or relocated. Stairwells may require installation in the floor to permit access to and from the interior of the capacitor bank inner area. A 300 L (80 gal) liquid nitrogen storage tank and a supplemental 151,400 L (40,000 gal) non-polychlorinated biphenyl mineral oil storage tank would be stationed aboveground outside these buildings and piping connecting the tanks to the facility would be added. The oil storage tank would be bermed or similarly contained and would comply with all Spill Prevention Control and Countermeasures requirements.
- Support utilities such as compressed air, chilled water and electrical distribution systems would be added or improved to support the SFE equipment.
- A new 16.8-meter (m) by 24.4-m by 15-cm (55-feet [ft] by 80-ft by 6-inch [in])-thick concrete slab would be installed to accommodate two portable diagnostic trailers, a mobile air conditioning unit, and a power pedestal. The pad would slope slightly from north to south to provide positive drainage.
- A diagnostics data center, project management office, and a visitor center would be constructed and housed in Building 125.

All other facility requirements already exist in Buildings 124 and 125, and no other facility modifications would be required.

Building 35-126. Building 126 was constructed in 1980 of concrete block and cast-in-place concrete with exterior-applied insulation. The roof system is made of precast concrete tees with insulation and single-ply roofing. The 640 m^2 (6,900 ft^2) building houses the existing heating, ventilation, and air conditioning and major electrical equipment that serves Building 125 and 294. No modifications to this building would be required.

Building 35-294. Building 294 was constructed in 1990 of steel framing with synthetic stucco panels at the east and west ends. The building is approximately 75.6 by 20 by 11.6 m (248 by 66 by 38 ft) in size. The building fills the space between Building 124 to the north and Building 125 to the south and shares the exterior north and south walls of these buildings. The Atlas Facility components in this building would occupy about 163.5 m^2 (1,760 ft^2). Atlas component equipment to be installed in this building includes an ac-to-dc converter, communication circuits, and the switching system.

The only building modifications would be the addition of internal trenches and cable tray supports for the communication and electrical systems.

Building 35-301. Building 301 was constructed in 1990. The structure is a pre-engineered steel building set on a concrete pad. The 1087 m^2 (11,700 ft^2) building houses a 1430 MVA generator, unique in the DOE-Defense Program complex, which can rapidly charge the Atlas capacitor bank. This building has several significant features to isolate generator vibrations from surrounding buildings. The generator and associated controls and alarms currently serves the National High Magnetic Field Laboratory (NHMFL), located in Building TA-35-127. The NHMFL would continue to use the generator when it is not in use serving the Atlas Facility. Only one application would be run by the generator at any one time. No modifications are planned for this building.

K.2.1.3 *Operations*

The heart of the Atlas Facility would be a pulsed-power capacitor bank that would deliver a large amount of electrical and magnetic energy to a centimeter-scale target in a very short time ($\leq$10 microseconds [(μs]). Each experiment would require extensive preparation of the experimental assembly and diagnostic instrumentation. The Atlas Facility would be designed to handle up to 100 experiments per year, but not more than 3 experiments per week. Approximately 15 workers would be employed at TA-35 in support of the Atlas Facility once it is operational. The workers would be a combination of relocated workers from currently operating facilities and a limited number of new hires as needed.

Atlas would support many related types of experiments. For example, in a typical experiment, a hollow cylindrical piece of metal (such as aluminum, copper, or gold) fabricated with known cracks, voids, or other defects would be placed in the target chamber. Heavy (e.g., 30 gram (g) [1.1 ounce {oz}]) targets would be used in such experiments designed to validate computer simulations of the hydrodynamic effects of such defects, which in turn support evaluation of potential defects in aging weapons. Light (e.g., 50 milligram [0.00175 oz]) targets would be imploded to produce a hot plasma source of soft (<200 eV) x rays to study radiation physics pertinent to stockpile stewardship.

During an experiment, electromagnetic energy would go sequentially from the generator to the ac-to-dc converter, through the inductor (optional), to the capacitor, and would finally be delivered to the target.

The Atlas capacitor bank would be designed to be flexible enough so that it has the capability to transfer energy in various quantities and within a spectrum of time intervals. The following is a description of what would happen during an experiment requiring maximum possible currents and generating the maximum possible magnetic fields from the facility.

When such an experiment setup was completed, power from the LANL electrical grid would be used to spin the generator to 1,800 revolutions per minute (rpm) over a period of 15 to 20 minutes (the generator may already be spinning for NHMFL experiments). When full speed is reached, a switch would close to allow electricity to flow from the generator to an 80-MW ac-to-dc converter. This converter would transform the high-voltage ac output of the generator to a low-voltage dc charging current in the inductor. The converter would provide this charging current for 3 to 5 seconds. When the peak current of 28 kiloamperes is reached, a switch would disconnect the converter from the inductor. The inductor would produce peak magnetic fields of 40,000 gauss (G) at the coil surface during this few-second interval.

When the inductor reaches 50 MJ of stored energy, various switches would close and open, and energy would be transferred to the capacitor bank, which consists of an array of Marx modules. Within 40 milliseconds, each stage in the Marx modules would acquire a voltage of 60 kilovolts. When the capacitor bank reaches full charge, switches would connect all of the modules into a series configuration, producing many times the original voltage (nominally <1 MV) at the terminals of the transmission line. At this time, the 36 MJ of energy stored in the capacitor bank would be discharged as electric current through the transmission line into a load or liner in the target chamber. The discharge would take approximately 10 μs. If the experiment requires low energy x-ray production, then Atlas may utilize a "plasma flow switch" in the electrical transmission section near the target to decrease the implosion time from several μs down to half a μs or less.

This very large current would produce a large magnetic field in the localized area around the target, causing it to implode, and possibly vaporize or melt, depending on the thickness of the metal. A light liner used inside the target would collide with itself on axis, producing a plasma and low energy x rays. A heavy liner used within the target would compress sample materials to high pressures or, when driven into a central target, would produce extremely high shock pressures that can produce partial material ionization. Solid shrapnel and vaporized molecules would be generated but would be stopped by the walls of the target chamber. Vaporized molecules would deposit onto the walls of the target chamber.

The target chamber would be equipped with a number of ports to allow connection of diagnostic equipment and data acquisition equipment. Diagnostic equipment would include air monitoring devices, voltage probes, current probes, and magnetic field measuring instruments. Data acquisition equipment would consist of cameras, lasers, x-ray detectors, and other similar equipment. Experiments with heavy targets would yield laser holographic images and x-ray radiographs of the implosion which would be captured and recorded to determine the hydrodynamic behavior of the experiment. Experiments with light targets would measure the quantity and energy of radiation (x rays) generated during the implosion and investigate the interaction of this radiation with other parts of the experimental assembly.

After each experiment, LANL personnel would clean the target chamber of metallic debris and deformed metallic targets. Up to 150 L (42 gal) of ethanol would be used each year for cleaning. Discarded materials following each experiment would consist mostly of small amounts of aluminum, copper, very small quantities of gold, and oxides of these metals, or other similar nonradioactive heavy metals. Any metal pieces recovered would be salvaged for reuse. Personnel would also perform routine maintenance, such as replacement of worn dielectric insulation. All waste would be sampled and analyzed in accordance with LANL procedures to determine whether *Resource Conservation and Recovery Act* (RCRA)-regulated hazardous materials are present in regulated quantities. For purposes of this analysis it is assumed that a small amount (<1 m^3 annually) of liquid or solid hazardous waste would be generated by occasional experiments involving lead or other simulant materials. This waste would be staged in the onsite hazardous waste accumulation area and shipped to off-site commercial RCRA-permitted treatment, storage and disposal facilities. Uncontaminated waste (such as paper waste), expected to be about 0.15 m^3 (5 ft^3) per week, would be disposed of at the Los Alamos County Landfill.

K.2.2 Continued Operations Alternative (No Action)

K.2.2.1 *Description*

For the purpose of this analysis, Pegasus II would remain at its current energy level and current rate of experiments. The Pegasus II Facility is located at TA-35 and features a capacitor bank consisting of 8 Marx modules that store up to 4.3 MJ of electrical energy. The Pegasus II Facility is being used by personnel in the weapons physics community to perform experiments in hydrodynamics and radiation transport. It has served as a test bed and will continue to provide important data for experiments in a particular energy regime.

The No Action alternative analysis provides an environmental baseline from which to measure the potential impacts of the proposed action and other alternatives against. However, the No Action alternative does not meet DOE's purpose and need for action. Continued operation of only the Pegasus II Facility would mean that pressure and temperature regimes, critical to understanding weapon aging effects, will not be attained. For instance, in hydrodynamic experiments, Pegasus does not have sufficient power to drive shock pressures that can ionize dense materials. In radiation transport experiments, Pegasus does not have sufficient power to produce >1 MJ of x rays with temperatures >100 eV. Both of these capabilities are important to study relevant issues associated with thermonuclear secondary devices. For experiments relevant to primary physics, Pegasus has insufficient power to drive the larger-scale hydrodynamic targets required for high-fidelity diagnostic access. Operation of only Pegasus II would prevent DOE from providing adequate experimental validation of computer predictions of the effects of certain aging phenomena.

The expected lifetime of the Pegasus II Facility is 15 to 20 years; it became operational in 1987. Future decontamination and decommissioning activities associated with the Pegasus II Facility would require separate NEPA analyses.

The Pegasus II Facility is included as part of the No Action alternative for the Stockpile Stewardship and Management PEIS (DOE 1995a).

K.2.2.2 *Facility*

The Pegasus II Facility is located at TA-35, Building 86 (see figure K.2.1.2–1). The Pegasus II capacitor bank is situated in Room 100, and the control center, data collection room, and office areas are located in Rooms 101 and 205. The detonators used in firing the capacitor bank are stored in a non-propagating container in a steel safe in Room 101.

The Pegasus II Facility occupies 1,300 m^2 (14,000 ft^2) of combined laboratory and office space. The building is constructed of prefabricated metal building components (steel columns, sheet metal siding, and masonry brick) on a concrete pad. The lower level (Room 100) houses the experimental area.

No construction or remodeling of the Pegasus II Facility is anticipated under the No Action alternative.

K.2.2.3 *Operations*

The heart of the Pegasus II Facility is a 4.3 MJ capacitor bank used to deliver a pulse of electrical and magnetic energy to a target. The capacitor bank has eight modules and uses air as the dielectric between the individual capacitors. The Pegasus II Facility is used for up to 24 experiments per year. In a typical experiment, a metal cylinder is placed in the target chamber, diagnostic equipment is attached to the target chamber, and the air in the chamber is pumped out with a vacuum system to form a vacuum condition for the experiment. Operators in Room 100 prepare the power supply system, and personnel are evacuated from the room. Operators in Room 205 open and close switches to charge up the individual capacitors and allow the eight modules to be hooked up in the test configuration. HE detonator switches then fire to transfer energy from the capacitor bank. The 4.3 MJ of energy stored in the capacitor bank discharges as a 12 MA current through a transmission line to the target. The discharge rises in about 6 µs. For experiments which require production of low energy x rays, a special switch ("plasma flow switch") can be placed just before the target to decrease the discharge rise time to only a few tenths of a microsecond.

After each experiment, LANL personnel clean the target chamber of metallic debris and deformed metallic targets. About 5 L (1.3 gal) of ethanol are used per year to clean the target chamber and other parts. Discarded materials generated from each experiment consist mostly of aluminum and copper and oxides of these metals. Any metal parts are salvaged for reuse. About 0.06 m^3 (2 ft^3) of uncontaminated waste (such as paper waste) per month is disposed of at the Los Alamos County Landfill. No hazardous waste is generated.

The detonator switches use a total of 19.2 g (0.672 oz) of HE per experiment, for a total of about 461 g (16.2 oz) per year. All HE is destroyed during detonation. After the test shot is complete, switches are disposed of at the Los Alamos County Landfill.

K.2.3 Alternatives Considered but Eliminated from Further Consideration

The following alternatives were considered but eliminated from further analysis in this project-specific analysis because they fail to meet the purpose and need for DOE action. Failure to meet this purpose and need results from programmatic deficiencies identified in the Stockpile Stewardship and Management PEIS or from technical inadequacies which preclude these alternatives from being reasonable alternatives to the proposed action.

K.2.3.1 *Build Atlas at Another DOE Site*

DOE considered, but dismissed as unreasonable, the alternative of locating, constructing, and operating the Atlas Facility at a site other than LANL and other than at the Pegasus II Facility. As discussed in section 2.1.1, Atlas would expand the capabilities of the existing Pegasus II Facility through the addition of enhanced pulsed-power and other equipment sufficient to reach the temperatures necessary to ionize materials. Other sites at LANL, as well as other DOE sites which have a hydrodynamic testing infrastructure, do not have the existing special equipment provided by the Pegasus II Facility. Although it would be possible to duplicate this special equipment elsewhere, DOE considers this to be an unreasonably expensive option.

K.2.3.2 *Use An Alternate Building at LANL*

Under this alternative, DOE would construct and operate the Atlas Facility at a LANL location other than TA-35. The requirements for an alternate site at LANL are the same requirements as those described in section K.2.1.2. Siting and construction of a new building at LANL to house the Atlas Facility would require placement near the 1430-MVA generator building. Additional environmental disturbances from foundation and utility work would occur. Although other existing buildings could fulfill requirement 1, with extensive and costly modifications, none of these sites fulfill requirements 2 to 6. Therefore, this alternative has been eliminated from further consideration.

K.2.3.3 *Modify Pegasus II to Conduct Atlas Experiments*

Action under this alternative would involve modifying the existing Pegasus II Facility so that it could function at the Atlas Facility power level to meet DOE's purpose and need for action. Currently, the Pegasus II Facility supplies limited data regarding weapons physics, but the facility does not have sufficient energy capability to reach all the conditions required to adequately investigate primary and thermonuclear secondary issues. Modifying the Pegasus II Facility would require extensive expansion of the existing building housing the facility. During this expansion process, which would include construction, procurement, and verification testing, the current Pegasus II operations could not be conducted. The current Pegasus II operations are critical to DOE's existing nuclear weapons stockpile stewardship and management mission. Due to direct conflicts with the existing critical operations of Pegasus II, this alternative does not meet DOE's purpose and need for action.

K.2.3.4 *Explosive-Based Pulsed Power Technology*

As an alternative to the proposed action, DOE could rely solely on conducting tests using explosive-based pulsed power technology, such as that used by the Procyon generator at LANL. Procyon currently furnishes limited data regarding weapons physics. Although the explosive-based pulsed-power technology would apply to the type of experimental tests needed, this technology can only support a maximum of 12 to 15 experiments per year due to test preparation time constraints, scheduling of detonation, and subsequent site cleanup following detonation. The Agency need for action requires a capability of conducting up to 100 experiments per year. Because of this factor, this alternative has been eliminated from further consideration.

K.3 AFFECTED ENVIRONMENT

This section presents a summary of information regarding the general environmental setting of LANL and the immediate TA-35 site vicinity. More extensive information about the LANL environment is presented in the annual LANL Environmental Surveillance Report (LANL 1994b), as well as LANL's Site-Wide Environmental Impact Statement (DOE 1979).

K.3.1 General Site Setting

LANL and the associated residential and commercial areas of Los Alamos and White Rock are located in Los Alamos County in north-central New Mexico (figure K.3.1–1). LANL facilities cover approximately 560 hectares (1400 acres) of the Federal land managed by DOE in Los Alamos County. The LANL developed area is divided into 30 active TAs for administrative purposes (figure K.2.1.2–1). Unoccupied land area surrounds LANL buildings, providing security, safety buffer zones, and a reserve for future development.

TA-35 is located near the center of Pajarito Mesa, a southeast-trending mesa immediately north and east of Pajarito Canyon in Los Alamos County. Pajarito Road bounds the proposed Atlas Facility site less than 0.8 kilometer (km) (0.5 mile [mi]) to the south, and Pecos Drive bounds the site directly to the north. Although the general public is currently allowed free access to these roads, and Pajarito Road has heavy public traffic, access to all roads in the general site area are DOE-controlled. They can be closed for brief periods as needed. The proposed TA-35 site is surrounded by adjacent TAs -63, -50, -55, -48, -60, and -52. These TAs include facilities conducting a variety of ongoing R&D that may involve use of chemicals and radioactive materials. The site is generally considered highly developed.

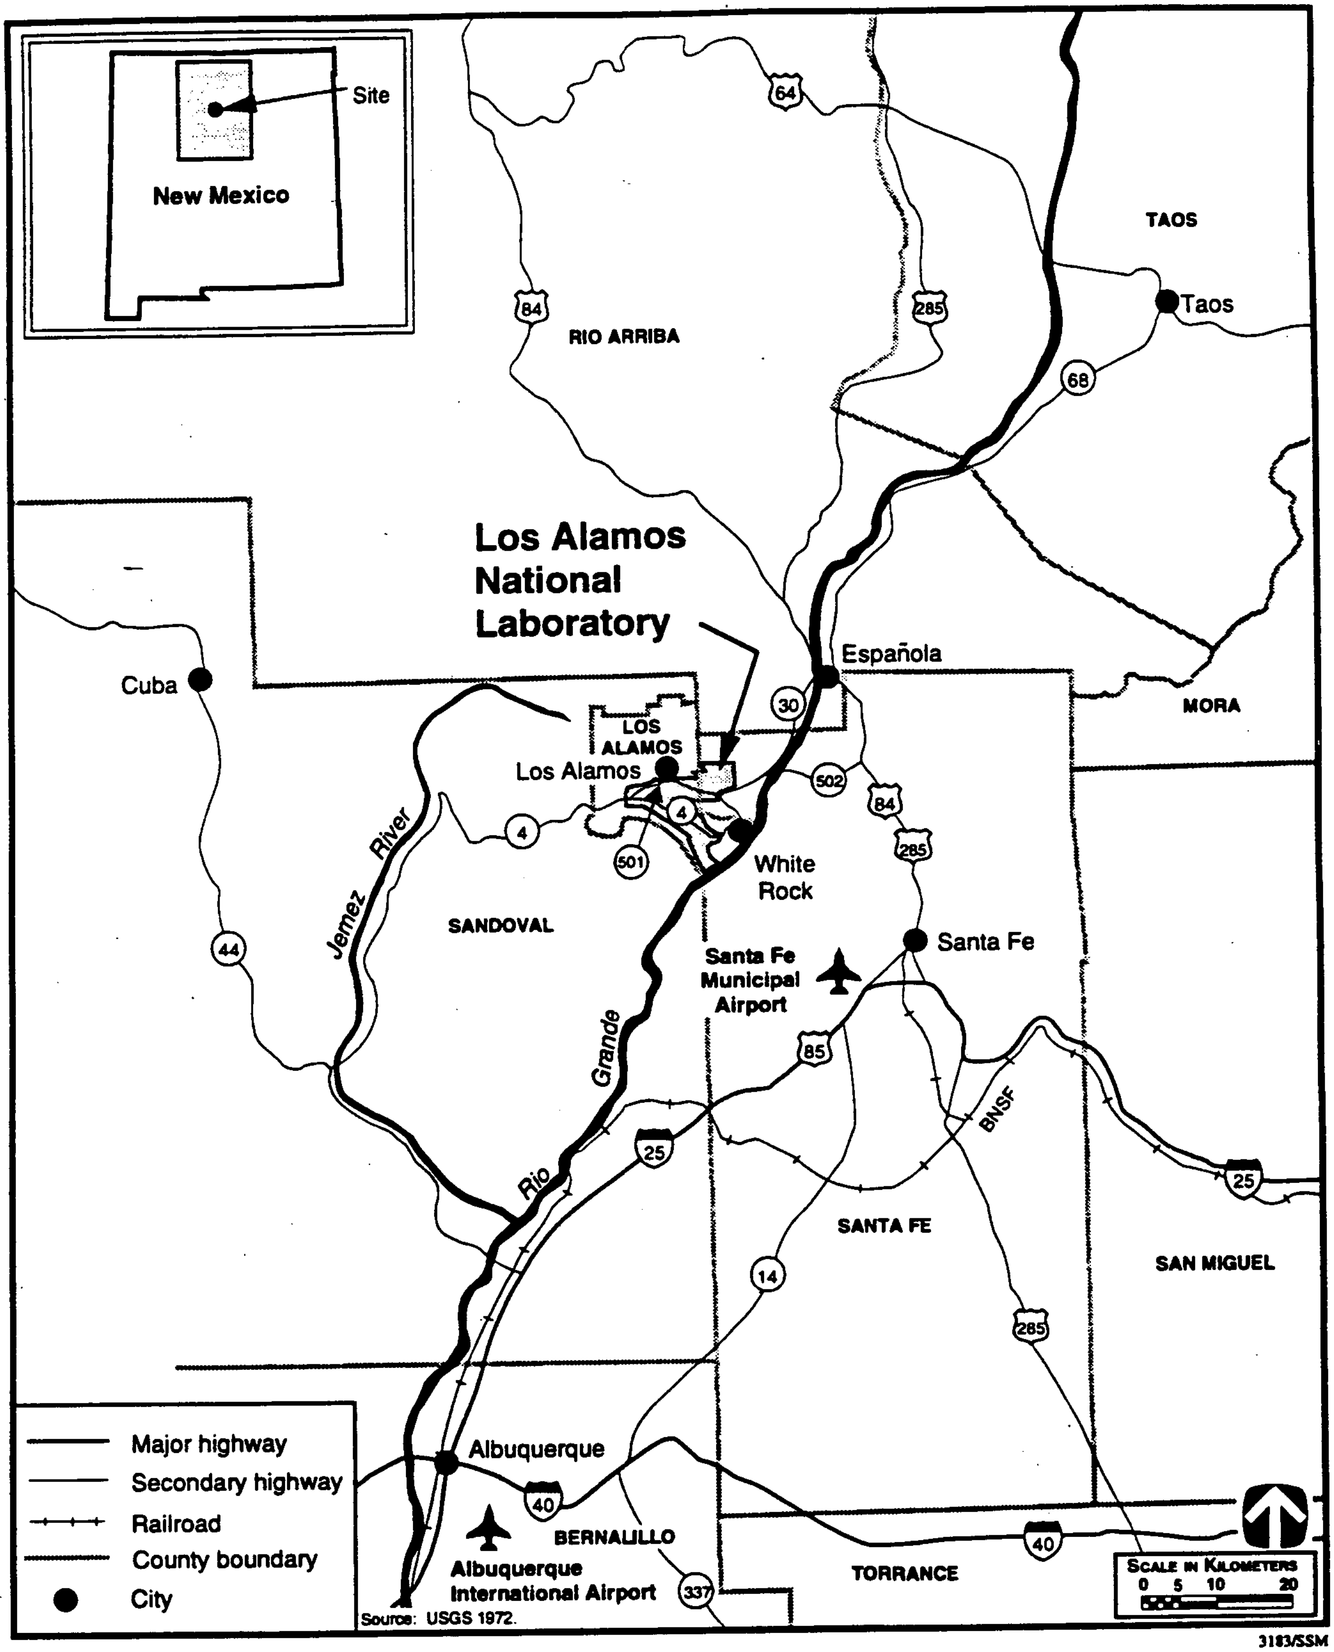

FIGURE K.3.1–1.—*Los Alamos National Laboratory, New Mexico, and Region.*

Los Alamos County has an estimated population of approximately 18,115 (U.S. Census 1994); the Los Alamos town site has an estimated population of 11,400, and White Rock has an estimated population of 6,800. There is a small, privately owned residential area, Royal Crest Trailer Park, surrounded by LANL property. Royal Crest Trailer Park is situated approximately 1.6 km (1 mi) northwest of the proposed project area with an estimated population of 500 (Morris 1994). The principal population centers are Santa Fe, Espanola, and the Pojoaque Valley located within an 80 km (50 mi) radius of LANL with an approximate population of 214,707 people. Fourteen pueblos are located within a 80 km (50 mi) radius of LANL. The populations of the four closest pueblos are as follows: the San Ildefonso Pueblo has a population of 1,499; the Santa Clara Pueblo has a population of about 3,000; the Cochiti Pueblo has a population of 1,342 people; and the Jemez Pueblo has a population of 1,750 people (Commerce 1991). LANL employs approximately 12,250 people (LANL 1994b) principally living within 80 km (50 mi) of LANL.

K.3.2 Environmental Issues Considered But Dismissed

The following environmental issues were not discussed as part of the affected environment because they either do not exist in the proposed action site vicinity (since the proposed action is in an existing building in a developed area) or neither the proposed action nor the No Action alternative would have any identified effect on these resources:

- Hydrology: surface and groundwater
- Vegetation
- Wildlife (Biotic Resources) — threatened, endangered and sensitive species, critical habitat, and migratory birds; wild horses and burros; wetlands and floodplains; wild and scenic rivers; coastal or tundra zones
- Cultural and Paleontological Resources
- Land Resources — mineral and timber resources; prime or unique farmlands
- Socioeconomics
- Water Quality — drinking water from surface or underground aquifers
- Soils and geology
- Parks, Monuments, Public Recreational Areas
- Site Infrastructure
- Visual Impacts
- Transportation

Under Executive Order 12898, Federal agencies are responsible for identifying and addressing the possibility of disproportionately high and adverse health and environmental impacts of programs and activities on minority (all people of color, exclusive of white non-Hispanics) and low-income (household incomes less than $15,000 per year) populations. Within a 16 km (10 mi) radius of the proposed Atlas site, about 14 percent of the population is of minority status. Within an 80 km (50 mi) radius, about 54 percent of the population is of a minority status. In terms of low-income populations, 8 percent of the households within a 16 km (10 mi) radius have annual incomes below $15,000. Within an 80 km (50 mi) radius of the site, 24 percent of the households have annual incomes below $15,000. Detailed environmental justice information is contained in the *Dual-Axis Radiographic Hydrodynamic Test* (DARHT) *Facility Final Environmental Impact Statement* (EIS) (DOE 1995b)[2].

TA-35 is situated on top of a mesa in a developed, disturbed area. Any impacts associated with building construction have already occurred and no new impact potential has been identified for the proposed action or the No Action alternative.

[2] The DARHT Final Environmental Impact Statement was issued on August 25, 1995. The Record of Decision for DARHT was issued on October 11, 1995.

K.3.3 Environmental Issues Considered

K.3.3.1 *Air Quality*

Prevailing winds at LANL are affected by several factors, including large-scale atmospheric wind patterns, regional weather disturbances (thunderstorms and cold fronts), complex surface terrain, and local cold-air drainage across the Pajarito Plateau. Winds in Los Alamos consist of light westerly surface winds that average 2.8 meters per second (m/s) (6.3 miles per hour [mph]). The strongest winds typically occur between March and June, when intense seasonal storms and cold fronts move through the region. During this season, sustained winds blow from the southwest to the northeast and can exceed 11 m/s (25 mph), with peak gusts exceeding 22 m/s (50 mph). Historically, no tornadoes have been reported to have touched down in Los Alamos County. Strong dust devils can produce winds up to 34.4 m/s (77 mph) at lower elevations in the area. The irregular terrain at Los Alamos affects wind motion and spreading. Localized wind gusts may not be in the same direction as average wind patterns. The wind behavior results in greater dilution of air contaminants that are released into the atmosphere.

Air quality in the LANL area is typical of arid-climate clean air. Median visibility ranges between 106 and 161 km (66 and 100 mi). The New Mexico Environment Department under the Environmental Protection Agency designated the LANL area as an air quality attainment area under the *Clean Air Act* or National Ambient Air Quality Standards in which all regulated ambient air quality standards are to be met. These standards apply to the following air emissions: total suspended particulates (TSP), particulate matter less than or equal to 10 microns in diameter (PM_{10}), sulfur dioxide, total reduced sulfur, hydrogen sulfide, carbon monoxide, and nitrogen oxides (New Mexico Environmental Improvement Board [NMEIB] 1981). Current emissions from operations around the proposed project site are within the required and existing permitted thresholds for LANL.

K.3.3.2 *Human Health*

As part of ongoing operations at LANL, several TAs, including TA-35 and those in close proximity to it, have facilities that conduct experiments involving electrical hazards and the generation of magnetic fields and x rays. Ongoing experiments and operations are conducted according to strict guidelines established by existing LANL standard operating procedures. Under these standard operating procedures, engineering and administrative controls are implemented to minimize worker and public exposure to electrical hazards, magnetic fields, and x rays. The magnitude of electrical hazards and x rays present from these experiments is regulated by Occupational Safety and Health Administration standards implemented under specific DOE orders. In addition, magnetic field threshold limit values have been developed as guidelines by the American Conference of Governmental Industrial Hygienists.

Generation and potential exposure to x rays is closely monitored under the implementation of existing health and safety requirements for maintaining worker exposure to as low as reasonably achievable standards, but not to exceed the current threshold of 5 rem per year. Magnetic fields are generated by the NHMFL at TA-35. These fields will not be additive to the fields produced during the charging of the Atlas capacitor bank because only one application can be conducted at a time. The public exposure to static magnetic fields in the TA-35 area is much less than the current pacemaker warning limit (10 G). Members of the public receive less than a 0.1 rem dose from x-ray sources generated in the TA-35 area or less than the admissible dose under DOE orders regulating public exposure to radiation.

K.3.3.3 *Waste Management Facilities*

RCRA-regulated hazardous chemical waste management is conducted at TA-54, Area L. TA-54, Area J, has a landfill dedicated to administratively controlled sanitary, non-hazardous wastes. All other sanitary waste is disposed in the Los Alamos County Landfill located near TA-3 along West Jemez Road.

K.4 Environmental Consequences

Neither the proposed action nor the No Action alternative would pose a disproportionate adverse health or environmental effect on minority or low-income populations within an 80 km (50 mi) radius of the proposed site.

K.4.1 Environmental Issues Considered

A summary of environmental issues is presented in table K.4.1–1. A discussion of the issues associated with the proposed action and the No Action alternative follows in the succeeding paragraphs.

K.4.2 Proposed Action

K.4.2.1 *Air Quality*

The air emissions expected due to operations at the Atlas Facility are presented in table K.4.2.1–1, along with the health-based New Mexico Air Quality Control Regulations (AQCR) 702-regulated levels. All expected emissions generated during normal operations would be below current regulatory levels. No permitting would be required under AQCR 702 or under the National Emission Standards for Hazardous Air Pollutants (NESHAP). No use of facility air filters or scrubbers would be required. Most of the metal targets used during experiments would vaporize and deposit onto the inside surface of the target chamber. Only minute quantities of metals would stay volatilized. Other nonradioactive heavy metals may also be used, but the metals listed in table K.4.2.1–1 are representative of any metals that would be used. The majority of the ethanol used for cleaning would evaporate. Small amounts of hazardous chemicals such as isopropyl alcohol, trichloroethylene and 1,1,2-trichloroethane may occasionally be used as cleaning solvents and would also evaporate. The quantity of air emissions as shown in table K.4.2.1–1 would not harm workers, collocated

TABLE K.4.2.1–1.—*Air Emissions from the Atlas Facility*

Constituent	Calculated Emissions[a]	AQCR 702 Limit
Aluminum	less than 1 g (0.0022 lb)	0.133 lb/hr
Copper	less than 1 g (0.0022 lb)	0.0133 lb/hr
Gold	less than 1 g (0.0022 lb)	0.42 lb/hr
Ethanol	less than $1.5x10^3$ g[b] (3.3 lb)	10 lb/hr
Isopropylalcohol	less than 30 g[c]	65.3 lb/hr
Trichloroethylene	less than 30 g[c]	18.01 lb/hr
1,1,2-Trichloroethane	less than 30 g[c]	3 lb/hr

[a] Amount calculated is per experiment using that specific type of metal or cleaning solvent. Any emissions would occur after the target chamber is repressurized to ambient pressure and temperature.

[b] Scientific notation (see glossary for explanation).

[c] Total for isopropyl alcohol, trichloroethylene, and 1,1,2-trichloroethane.

Source: Model results; NMEIB 1981.

TABLE K.4.1–1.— *Environmental Issues Considered for Normal Operations/Accidents*

Issue	Proposed Action Alternative	No Action Alternative
Air Quality	Potential impacts discussed in appendix section K.4.2.1. Per experiment: minor metals (copper, aluminum, gold [less than 1 g]); and solvent ($1.5x10^3$ g ethanol) air emissions. Occasional small (<30 g) quantities of isopropyl alcohol, trichloroethylene and 1,1,2-trichloroethane may also be used as solvents.	Potential impacts discussed in appendix section K.4.3.1. Per experiment: minor metals (same as proposed action for copper and aluminum, no gold used), solvent (18.1 g ethanol), and high explosive (12.7 g carbon monoxide, 34.0 g nitrogen oxides, 95.2 g PM_{10}, 0.91 g volatile organic compounds, all per year) air emissions.
Human Health	No radioactive materials; potential health effects of electricity, magnetic fields, x rays discussed in appendix sections K.4.2.2 (normal operations) and K.4.4 (accidents).	No radioactive materials; potential health effects of electricity, magnetic fields, x rays discussed in appendix sections K.4.3.2 (normal operations) and K.4.4 (accidents).
Waste	Disposal of uncontaminated construction waste (15.3 m^3), other uncontaminated, nonhazardous solid waste, such as paper, dielectric insulation, etc. (7 m^3 per year), and small amounts (<1 m^3 annually) of liquid or solid hazardous waste would be generated by occasional experiments involving lead or other simulant materials. Within normal scope of LANL waste management activities, appendix section K.4.2.3.	Disposal of uncontaminated, nonhazardous solid waste, such as paper and dielectric insulation, etc. (0.7 m^3 per year), within normal scope of LANL waste management activities, appendix section K.4.3.3.

workers (those at TA-35 but not involved with the Atlas project), or members of the public. Small amounts of dust would be generated due to outdoor excavation activities. Standard dust suppression techniques, such as watering, would be used as needed.

K.4.2.2 *Human Health*

This section presents potential health hazards to site workers, collocated workers, and the general public during normal operations of the Atlas Facility experiments. The identified hazards to human health are electrical hazards, magnetic field hazards, and radiological hazards.

Electrical. Normal operations at the Atlas Facility during conduct of experiments would include electrical hazards to researchers, technicians, and other Atlas Facility personnel because the capacitors associated with Atlas would be charged to a high-voltage. The Atlas capacitor bank could deliver an instantaneous lethal current if special operating precautions are not taken. To minimize electrical risks associated with Atlas experiments, all applicable electrical codes specified by DOE Order 6430.1A (such as adequate grounding and lightening protection) would be incorporated into the Atlas capacitor bank and facility and related electrical components. In conjunction with meeting local electrical codes and DOE Order requirements, the Atlas capacitor bank would be isolated in an interlocked room where access would be controlled. During the actual charging, discharging, and energy release of the system, personnel access to the room would be denied. To aid in assuring no admittance takes place, guards would also be posted at the entrance. Other engineering safety features would be built into the Atlas Facility, such as:

- All switches would be fail-safe; i.e., either a loss of compressed air or electrical power would disengage the switches.

- A direct cut-off to the Atlas Facility systems would be available to the control room operator should the master computer malfunction. The direct cut-off would automatically return systems to their normal fail-safe position.

- Switches could not be operated until all interlocks have been made.

- If an interlock is broken during a charge cycle, shutdown would occur.

These Atlas Facility engineering controls, as well as administrative controls such as personnel training and standard operating procedures, would significantly decrease the probability of an electrical accident occurring during normal operations.

Magnetic Fields. The generator located in Building 301 would be running for 15 to 20 minutes at the beginning of each experiment. The generator would generate magnetic fields during operations of either the Atlas Facility or the NHMFL, but only one operation would be conducted at any one time; therefore, no cumulative impacts to workers would be expected due to magnetic fields resulting from generator operations. The ultimate magnetic field generated would have a frequency dependent on the final rotation speed of the generator (1800 rpm); this frequency would be approximately 60 cycles per second. Workers and members of the public are shielded from the magnetic field by the building's walls, and the generator itself is designed with adequate shielding so that a magnetic field of less than 10 G would exist near the generator. The magnetic field due to the generator would be less than 1 G at Pecos Drive, the nearest public-access roadway, about 75 m (245 ft) from Building 301.

A second source of magnetic field would come from the energy transfer into the inductors' storage coils. During the 3 to 5 seconds that it would take to transfer energy into the inductor, a dc current would be present in the coils of the inductor located on the roof of Building 124. This dc current would have an associated magnetic field of 40,000 G near the coils. There would be a few-second duration magnetic field of less than 10 G at Pecos Drive, which is approximately 33 m (110 ft) from Building 124.

All Atlas Facility workers and nearby collocated workers would be informed of the magnetic hazards associated with individual proposed experiments and those with pacemakers, etc., would be moved to a safe location. Administrative and engineering controls would be in place during experiments to keep magnetic field exposure as low as reasonably achievable. Atlas Facility workers and nearby collocated workers would be exposed to the two magnetic fields during each experiment, for a total of up to 100 times per year. Atlas Facility workers and nearby collocated workers without pacemakers, etc., would not be exposed to more than an instantaneous magnetic field exceeding 500 G.

Magnetic fields of as much as 20,000 G are not considered harmful to individuals who do not have pacemakers or other metallic body inclusions (ACGIH 1993). A magnetic field (such as that produced by the generator) of 1 G can affect some types of cardiac pacemakers; larger fields can also exert a force on suture staples, aneurysm clips, prostheses, etc. Administrative controls, such as exclusion from Buildings 124, 125, and 294 during individual experiments, would be placed on employees with pacemakers or metallic inclusions so that exposure to excessive magnetic levels would be avoided for these individuals. If there is a potential for the public to be exposed to non-static magnetic fields of 1 G or more generated during experiments, warning signs and other administrative controls (such as road blocks) would be in place prior to operation of the Atlas Facility for conduct of those experiments. Magnetic fields would be monitored at various locations at and near the Atlas Facility during experiments to ensure that these levels are not exceeded.

Radiological. The Atlas Facility experiments would utilize a target chamber which would have walls of stainless steel 2.54 cm (1 in) thick, twice the thickness of the Pegasus II Facility's target chamber walls. An individual target implosion would produce an estimated one to four MJ of 100 to 200 eV x rays at the time of the experiment. These low-energy x rays are not expected to penetrate the stainless steel target chamber; the energy would be converted into heat and dissipated into the target chambers' walls.

Neither Atlas Facility workers, collocated workers, nor members of the public onsite or offsite would be exposed to these x rays because x rays would be contained within the target chamber and because personnel would be excluded from the area of the target chamber during an experiment. Standard LANL radiological protection procedures would be followed, including standard operating procedures developed for the Pegasus II Facility, and revised as needed.

Diagnostic apparatus used to take x rays of the events occurring during experiments within the target chamber would be located outside the chamber and would use high-energy x rays, similar to medical x rays. The diagnostic apparatus operation would be interlocked to the entrances to the target area such that the apparatus would not operate if an exterior door were opened. Existing standard operating procedures and facility shielding would be used to protect workers. In addition, personnel protection staff would conduct surveys in and around the target area to measure radiation produced by the diagnostic x-ray apparatus when they are operated. Additional shielding would be added if needed.

Collocated workers or members of the public, either onsite or offsite, would not be exposed to high-energy x rays. These x rays would be shielded and contained within the interlocking room housing the capacitor bank.

K.4.2.3 *Waste Management Facilities*

Uncontaminated waste (such as paper waste and dielectric insulation), expected to be about 7 m^3 (240 ft^3) per year, would be disposed of at the Los Alamos County Landfill. The landfill would not require expansion due to the waste generated by the Atlas Facility. For purposes of this analysis it is assumed that a small amount (<1 m^3 annually) of liquid or solid hazardous waste would be generated by occasional experiments involving lead or other simulant materials. This waste would be staged in the onsite hazardous waste accumulation area and shipped to offsite commercial RCRA-permitted treatment, storage, and disposal facilities. Construction waste (about 15.3 m^3 [20 yd^3]) would be disposed of at the Los Alamos County Landfill.

K.4.3 No Action Alternative

K.4.3.1 *Air Quality*

The air emissions due to the Pegasus II Facility are presented in table K.4.3.1–1, along with the health-based New Mexico AQCR 702-regulated levels and the AQCR 707 (Prevention of Significant Deterioration)-regulated levels. All emissions are below current regulatory levels. No permitting is required under AQCR 702, AQCR 707, or NESHAP. No special air filtration or scrubber is required for the

TABLE K.4.3.1–1.—*Air Emissions from the Pegasus II Facility*

Constituent	Calculated Emissions[a]	AQCR 702/707 Limits
Aluminum	less than 1 g (0.0022 lb)	0.133 lb/hr
Copper	less than 1 g (0.0022 lb)	0.0133 lb/hr
Ethanol	18.1 g (0.04 lb)	10 lb/hr
High Explosives[b]	12.7 g (0.028 lb) carbon monoxide	200,000 lb/yr
	34.0 g (0.075 lb) nitrogen oxides	40,000 lb/yr
	95.2 g (0.21 lb) particulate matter 10 microns or smaller	25,000 lb/yr
	0.91 g (0.002 lb) volatile organic compounds	40,000 lb/yr

[a] Amount calculated is per experiment using that specific type of metal. Any emissions would occur after the target chamber is repressurized to ambient pressure and temperature.

[b] Emissions due to high explosives are calculated for one year, not per experiment.

Source: Model results; NMEIB 1981; 40 CFR 52.21.

Pegasus II Facility. Most of the metals would vaporize and deposit onto the inside surface of the target chamber. Only minute quantities of metals would stay volatilized. The majority of the ethanol used for cleaning would evaporate. The quantity of air emissions would not harm workers, collocated workers (those at TA-35 but not involved with the Pegasus II project), or members of the public.

K.4.3.2 *Human Health*

Electrical. Normal operations during conduct of experiments at the Pegasus II Facility present electrical hazards to researchers, technicians, and other Pegasus II Facility personnel because the Pegasus II capacitor bank is charged to a high voltage. The Pegasus II capacitor bank could deliver an instantaneous lethal current if special precautions are not taken during experiments. Engineering controls and administrative controls the same as or similar to those described for the proposed Atlas Facility, such as interlocked rooms, fail-safe switches, standard operating procedures, and direct cut-offs, significantly decrease the probability of an electrical accident occurring during normal operations.

Magnetic Fields. Magnetic fields are not generated during the conduct of experiments under the No Action alternative; power for charging the Pegasus II capacitor bank is obtained from the existing LANL electrical power grid and does not require the use of a separate facility power generator.

Radiological. Experiments conducted at the Pegasus II Facility produce up to 0.2 MJ of low-energy x rays, 10 percent of the level expected during the same type of experiment from the proposed Atlas Facility (2.0 MJ). Operating experience has demonstrated that these low-energy x rays do not penetrate the target chamber. Neither Pegasus II Facility workers, collocated workers, nor members of the public either onsite or offsite would be exposed to x rays from continuing to operate the Pegasus II Facility experiments.

K.4.3.3 *Waste Management Facilities*

About 0.7 m^3 (24 ft^3) of uncontaminated waste (such as paper waste and dielectric insulation) per month is disposed of at the Los Alamos County Landfill. No RCRA-regulated hazardous waste is generated.

K.4.4 Impacts Associated With Accidents

This section considers bounding case accidents that could be associated with the operation of the Atlas Facility that could affect site workers, collocated workers, the public, and the environment. Accidents with the highest consequence to workers have the likelihood of occurring once in 100 years. Accidents with the highest consequence to collocated workers, the public, and the environment have the likelihood of occurring once in 10,000 years. This information is summarized in section K.7. Other accident scenarios are contained within the Preliminary Hazard Analysis for the proposed Atlas project (LANL 1995). Accidents analyzed in this project-specific analysis are summarized in table K.4.4–1.

TABLE K.4.4-1.—*Accidents Analyzed*

Accidents	Likelihood of Event	Worst Consequence
Worker Mechanical collapse of crane; High-energy power source electrocution	Less than 1 in 100 years	Serious worker injury or death
Collocated worker Fire resulting from capacitor bank failure and release of smoke and sprinkler system water	Less than 1 in 10,000 years	Irritation or discomfort but no permanent health effects
Public Fire resulting from capacitor bank failure and release of smoke and sprinkler system water	Less than 1 in 10,000 years	Irritation or discomfort but no permanent health effects
Environment Fire resulting from capacitor bank failure and release of smoke and sprinkler system water	Less than 1 in 10,000 years	Release of smoke and effluent discharge containing sprinkler system water and mineral oil

Source: LANL 1995.

K.4.4.1 *Site Worker*

The bounding case accident for a site worker involves electrocution from a high-energy power source or mechanical collapse of the overhead crane. Of these scenarios, both have an equal likelihood of occurrence. The impact to a site worker in these scenarios could be death; however, the likelihood of occurrence is less than once in 100 years of operation.

K.4.4.2 *Collocated Worker*

The most likely accident scenario that could result in an impact to collocated workers involves exposure to emissions and effluents from a capacitor bank fire. In this scenario, a collocated worker would receive minimal exposure to smoke and sprinkler system water containing mineral oil spilled from a Marx module. The impact to a collocated worker in this scenario would be temporary irritation and discomfort; however, the likelihood of occurrence is less than once in 10,000 years of operation. In the event of a fire, all site and collocated workers would be evacuated immediately.

K.4.4.3 *Public*

The most likely accident scenario that could result in an impact to the public involves exposure to emissions and effluents from a capacitor bank fire. In this scenario, a member of the public could receive minimal exposure to smoke. The impact to a member of the public in this scenario would be less than that experienced by a collocated worker. Exposure to smoke could result in very mild and temporary irritation and discomfort. The likelihood of this accident occurring is less than once in 10,000 years of operation. In the event of a fire, all members of the public would be evacuated from the site area immediately and road closures and exclusion zones would be implemented, as appropriate. Based on the accident scenario and impact analysis in section K.7, there are no probable accidents which would result in an adverse impact to the public.

K.4.4.4 *Environment*

The bounding case accident scenario that could result in an impact to the environment involves the release of emissions and effluents from a capacitor bank fire. In this scenario, smoke and sprinkler water containing spilled mineral oil could be released to the environment. The impact to the environment in this scenario would be temporary and minimal. Smoke from a fire in this scenario would disperse quickly and the sprinkler water containing mineral oil would be contained by site soils and controlled drainage systems. Water containing mineral oil does not present a serious environmental concern given the nonhazardous nature of mineral oil, and in the event of a fire, spill prevention control measures would be implemented immediately. The likelihood of such an accident occurring under normal operating conditions is once in 10,000 years.

K.5 Agencies and Persons Consulted

No external agencies or persons were consulted for the project-specific analysis of the proposed Atlas Facility.

K.6 Permit Requirements

No external regulatory or permit requirements have been identified for the Atlas Facility.

K.7 Supplementary Information: Accidents

Tables K.7–1 and K.7–2 provide a summary of the types of hazards and scenarios that could result in impacts to the public, environment, collocated worker or the facility worker. Listed in table K.7–2 are the risk ranks resulting from the likelihood and consequence of a given scenario and hazard.

Table K.7–1.— *Hazard Sources for Atlas Preliminary Hazard Assessment Chart*

Electricity	-High voltage current -Static electricity
Radiant energy	-Electromagnetic fields
Radiation	-X rays
Mechanical structures	-Failure and collapse of critical structural assemblies -Leaks from storage tanks
Chemicals	-Toxic materials -Flammable materials -Asphyxiant gas
Implosion/ explosion	-Target chamber malfunction
Fire	-Mechanical/electrical malfunction -Target chamber malfunction

Source: LANL 1995; Model results.

Table K.7–2 shows that the highest consequence of any Atlas hazard scenario would have the greatest impact on the facility worker (Column 5, Impact on Worker). This is indicated by three hazards (radiation, mechanical structures, and fire) showing a risk ranking factor of two. The other impact receptors (e.g., collocated worker or environment) all have maximum risk ranks of 3 which means that risks are acceptable with sufficient controls and safeguards in place. Information charts on the following pages of this project-specific analysis have been provided to present the methodologies used to determine risk categories, probabilities, consequences, and requirements for risk mitigation during the typical preliminary hazard assessment process. The final preliminary hazard assessment risk reduction recommendations would be incorporated into the project design or in the project standard operating procedures.

Further information may be found in the preliminary hazard assessment for Atlas (LANL 1995).

K.8 Glossary

Angstrom (Å): Unit of length equal to $1x10^{-10}$ meter.

Dielectric: A nonconductor of electric current.

Electrolyte recirculation system: A water circulation system with salt additives which is used for controlling resistance near the capacitors.

Electron volt (eV): The energy equivalent ($1.602x10^{-19}$ Joules) of an electron passing through a voltage differential of 1 volt.

Environmental impact statement: A document required by the *National Environmental Policy Act* (NEPA) of 1969, as amended, for proposed major Federal actions involving potentially significant environmental impacts.

Foil implosion: To burst inward; i.e., the effect of applying large doses of electrical current to a thin walled cylinder.

Gauss (G): Unit of magnetic induction in the electromagnetic and Gaussian systems of units. Equal to 1 maxwell (measure of magnetic flux through an area) per square centimeter.

High-energy pulsed-power: A technique used in compressing electrical energy and storing it at high levels and then releasing it to a target in a very short time period.

High-energy x ray: An x ray in the 0.03 to 1 Angstrom wavelength range (e.g., medical x rays).

TABLE K.7-2.—*Summary of Hazards and Impacts with Risk Ranks from the Atlas Preliminary Hazard Assessment* [Page 1 of 2]

Hazard	Scenario	Impact on Public (Risk Rank)	Impact on Collocated Worker (Risk Rank)	Impact on Worker (Risk Rank)	Impact on Environment (Risk Rank)	Highest Consequence (Risk Rank)
Electricity	Access Breach	No	No	Yes (3)	No	Potential fatality
Radiant energy (EMF)	Inadvertent access of personnel to roof during charging	No	No	Yes (3)	No	Potential exposure of personnel to EMF
Radiation (x rays)	Implosion of experiment	No	Yes (4)	Yes (2)	No	Potential exposure of facility/ collocated workers
Mechanical structures	Failure and collapse of critical structures	No	No	Yes (2)	No	Potential worker injury/fatality
Mechanical structures	Leaks from storage tanks	No	No	No	Yes (3)	Release of untreated fire suppression water
Chemicals	Marx tank oil leak	Yes (3)	Yes (3)	Yes (3)	Yes (3)	Mineral oil is leaked to the facility and possibly to the environment
Chemicals Asphyxiant	Sulfur hexafluoride resupply hose leaks	No	No	No	Yes (3)	Sulfur trifluoride vaporizes and escapes; Potential exposure of facility/co-located workers
Explosion	Capacitor explodes	No	No	Yes (3)	No	Debris and mineral oil released to facility, possible worker injury
Implosion	Target chamber malfunction	No	No	No	No	Loss of vacuum and operational capability
Fire	Generator fire during power generation	No	No	Yes (3)	No	Worker injury from inhalation of fire combustion products
Fire	Marx generator capacitor banks fail	Yes (3)	Yes (3)	Yes (2)	Yes (3)	Fire in capacitor banks, potential injury to facility worker

Consequence Likelihood Categories

I (1 to 0.1)	Normal Operations: Frequency as often as once in 10 operating years or at least once in 10 similar facilities operated for 1 year.
II (0.1 to 0.01)	Anticipated Events: Frequency between 1 in 10 years and 1 in 100 years or at least once in 100 similar operating facilities operated for 1 year.
III (10^{-2} to 10^{-4})	Unlikely: Frequency between 1 in 100 years and 1 in 10,000 years or at least once in 10,000 similar facilities operated for 1 year.
IV (10^{-4} to 10^{-6})	Very Unlikely: Frequency between 1 in 10,000 years and once in 1 million years or at least once in a million similar facilities operated for 1 year.
V	Improbable: Frequency of less than once in a million years.

Note: EMF - electromagnetic force.

Source: LANL 1995.

TABLE K.7–2.—*Summary of Hazards and Impacts with Risk Ranks from the Atlas Preliminary Hazard Assessment* [Page 2 of 2]

	Consequence Severity Categories, Maximum Possible Consequence			
Category	**Public**	**Collocated Worker**	**Worker**	**Environment**
A	Immediate health effects	Immediate health effects	Loss of life.	Substantial offsite contamination
B	Long-term health effects	Long-term health effects	Severe injury or disability.	Substantial contamination of originating facility/activity, minor onsite contamination; no offsite contamination.
C	Irritation or discomfort but no permanent health effects	Irritation or discomfort but no permanent health effects	Lost-time injury but no disability	Minor or no contamination of originating facility/activity; no offsite contamination
D	No substantial offsite release	No substantial offsite effect	Minor or no injury and no disability	Minor or no contamination of originating facility/activity; no offsite contamination

Note: Offsite: Public, private, or Indian lands that are not part of Laboratory property; Onsite: Laboratory property but not necessarily the originating technical area; Facility: Originating technical area of the Laboratory.

Risk Ranking Matrix

	Likelihood of Consequence				
Severity of Consequence	**I**	**II**	**III**	**IV**	**V**
A	1	1	2	3	3
B	1	2	2[a]	3	4
C	2	3	3	4	4
D	3	4	4	4	4

[a] Assign risk rank of 3 if severity category rank of B is based upon worker injuries and offsite consequence severity is less than B.

Risk Rank	Recommendation
1	Unacceptable: Should be mitigated to risk rank 3 or lower as soon as possible.
2	Unacceptable: Should be mitigated to risk rank 3 or lower within a reasonable time period.
3	Acceptable with Controls: Verify that procedures, controls, and safeguards are in place.
4	Acceptable as is: No action is necessary.

High explosives: Any chemical compound or mechanical mixture that, when subjected to heat, impact, friction, shock, or other suitable initiation stimulus, undergoes a very rapid chemical change with the evolution of large volumes of highly heated gases that exert pressures in the surrounding medium; the term applies to materials that detonate.

Joule: Unit of energy equivalent to one watt-second.

Low-energy x ray: An x ray in the 1 to 10 Angstrom wavelength range. Low-energy x rays do not have enough energy to penetrate a sheet of paper.

Marx modules: Assemblage of electric capacitors charged in parallel and discharged in a series are said to be of a "Marx Configuration."

Megajoule (MJ): One million joules which is a measure of energy or work in the meter-kilogram-second system of units, equal to 1 Newton.

Micron: A unit of length equal to one-millionth of a meter; one meter equals 3.2 feet.

National Emission Standards for Hazardous Air Pollutants: Hazardous air pollution standards established through the *Clean Air Act*, as amended.

Plasma flow switch: An electrical switch used to open a circuit through the use of ionized gas (plasma).

Prevention of Significant Deterioration: Refers to provisions in the *Clean Air Act*, as amended, and state air quality regulations, to ensure that an area in attainment with the National Ambient Air Quality Standards will stay in attainment.

Rem: Roentgen equivalent man; unit for measuring radiation dose equivalence. The rem takes into account the energy absorbed (dose) and the biological effect on the body (quality factor) due to the different types of radiation.

***Resource Conservation and Recovery Act* of 1976:** Establishes a comprehensive "cradle-to-grave" approach to the regulation of hazardous waste. Also establishes a framework for instituting corrective action for releases of hazardous wastes.

Reynolds Number: A dimensionless numerical value relating fluid density and viscosity to particle size and relative velocity.

Roentgen: A unit of exposure to ionizing x- or gamma radiation equal to or producing one electrostatic unit of charge per cubic centimeter of air.

Science-based stockpile stewardship: DOE program to develop a new approach, based on scientific understanding and expert judgment, to ensure continued confidence in safety, performance, and reliability of the nuclear weapons stockpile.

SOP: Standard operating procedures; written and authorized procedures for conducting an activity.

Special facilities equipment (SFE): An assemblage of high power electrical equipment and systems to support Atlas (i.e., target chamber, vacuum equipment, etc.).

Swale: A low-lying stretch of land where water could collect or puddle.

Threshold limit value: Refers to airborne concentrations of substances and represents conditions under which it is believed that nearly all workers may be repeatedly exposed day after day without adverse health effects.

Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management

Comment Response Document

Volume IV

United States Department of Energy

September 1996

ABSTRACT: In response to the end of the Cold War and changes in the world's political regimes, the United States is not producing new-design nuclear weapons. Instead, the emphasis of the U.S. nuclear weapons program is on reducing the size of the Nation's nuclear stockpile by dismantling existing nuclear weapons. The Department of Energy (DOE) has been directed by the President and Congress to maintain the safety and reliability of the reduced nuclear weapons stockpile in the absence of underground nuclear testing. In order to fulfill that responsibility, DOE has developed a Stockpile Stewardship and Management Program to provide a single highly integrated technical program for maintaining the continued safety and reliability of the nuclear stockpile. The Stockpile Stewardship and Management PEIS describes and analyzes alternative ways to implement the proposed actions for the Stockpile Stewardship and Management Program.

Stockpile stewardship refers to activities associated with research, design, development and testing of nuclear weapons and the assessment and certification of the safety and reliability. The stockpile stewardship portion of the PEIS evaluates the potential impacts of three proposed facilities: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. The stockpile stewardship alternatives involving these facilities could affect four sites: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and Nevada Test Site (NTS).

Stockpile management refers to activities associated with the production, maintenance, surveillance, refurbishment, and dismantlement of the nuclear weapons stockpile. The stockpile management portion of this PEIS evaluates the potential impacts of carrying out stockpile management alternatives at eight sites: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. The stockpile management alternatives are assessed for nuclear weapons assembly/disassembly and for fabricating pits, secondaries and cases, high explosives, and nonnuclear components.

The Stockpile Stewardship and Management PEIS also evaluates the No Action alternative of relying on existing facilities and continuing the missions at current sites to achieve both the stockpile stewardship and management missions. The No Action alternative assesses the environmental impacts of the on-going Stockpile Stewardship and Management Program and provides a baseline against which alternatives can be evaluated.

DOE has identified the following preferred alternative for the Stockpile Stewardship and Management Program:

Stockpile Stewardship:
- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:
- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL
- Assembly/Disassembly—downsize at Pantex
- High Explosives Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) highly enriched uranium strategic reserve storage at Y–12; and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS*. Decisions on strategic storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the *Stockpile Stewardship and Management Final PEIS* and the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

Evaluation of impacts on land resources, site infrastructure, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, socioeconomics, waste management, environmental justice, as well as radiological and hazardous chemical impacts during normal operation and accidents to workers and the public are included in the assessment. The PEIS presents unclassified information only. A classified appendix has also been prepared to support the PEIS.

or leave a message at (800) 472-2756

ABSTRACT: In response to the end of the Cold War and changes in the world's political regimes, the United States is not producing new-design nuclear weapons. Instead, the emphasis of the U.S. nuclear weapons program is on reducing the size of the Nation's nuclear stockpile by dismantling existing nuclear weapons. The Department of Energy (DOE) has been directed by the President and Congress to maintain the safety and reliability of the reduced nuclear weapons stockpile in the absence of underground nuclear testing. In order to fulfill that responsibility, DOE has developed a Stockpile Stewardship and Management Program to provide a single highly integrated technical program for maintaining the continued safety and reliability of the nuclear stockpile. The Stockpile Stewardship and Management PEIS describes and analyzes alternative ways to implement the proposed actions for the Stockpile Stewardship and Management Program.

Stockpile stewardship refers to activities associated with research, design, development and testing of nuclear weapons and the assessment and certification of the safety and reliability. The stockpile stewardship portion of the PEIS evaluates the potential impacts of three proposed facilities: the National Ignition Facility (NIF), the Contained Firing Facility (CFF), and the Atlas Facility. The stockpile stewardship alternatives involving these facilities could affect four sites: Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and Nevada Test Site (NTS).

Stockpile management refers to activities associated with the production, maintenance, surveillance, refurbishment, and dismantlement of the nuclear weapons stockpile. The stockpile management portion of this PEIS evaluates the potential impacts of carrying out stockpile management alternatives at eight sites: Oak Ridge Reservation (ORR), Savannah River Site (SRS), Kansas City Plant (KCP), Pantex Plant (Pantex), LANL, LLNL, SNL, and NTS. The stockpile management alternatives are assessed for nuclear weapons assembly/disassembly and for fabricating pits, secondaries and cases, high explosives, and nonnuclear components.

The Stockpile Stewardship and Management PEIS also evaluates the No Action alternative of relying on existing facilities and continuing the missions at current sites to achieve both the stockpile stewardship and management missions. The No Action alternative assesses the environmental impacts of the on-going Stockpile Stewardship and Management Program and provides a baseline against which alternatives can be evaluated.

DOE has identified the following preferred alternative for the Stockpile Stewardship and Management Program:

Stockpile Stewardship:

- Construct and operate NIF at LLNL
- Construct and operate CFF at LLNL
- Construct and operate the Atlas Facility at LANL

Stockpile Management:

- Secondary and Case Component Fabrication—downsize the Y-12 Plant at ORR
- Pit Component Fabrication—reestablish capability and appropriate capacity at LANL

- Assembly/Disassembly—downsize at Pantex
- High Explosives Fabrication—downsize at Pantex
- Nonnuclear Component Fabrication—downsize at KCP
- Based on the analyses performed to support this PEIS, the preferred alternatives for strategic reserve storage are as follows: (1) highly enriched uranium strategic reserve storage at Y–12; and (2) plutonium pit strategic reserve storage in Zone 12 at Pantex. The preferred alternatives for strategic reserve storage could change based upon decisions to be made in regard to the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS*. Decisions on strategic storage will not be made in the upcoming ROD for the Stockpile Stewardship and Management Program. Storage decisions are not expected to be made until both the *Stockpile Stewardship and Management Final PEIS* and the *Storage and Disposition of Weapons-Usable Fissile Materials Final PEIS* are completed.

The preferred alternative for plutonium-242 oxide at SRS is to transport the material to LANL for storage.

Evaluation of impacts on land resources, site infrastructure, air quality, water resources, geology and soils, biotic resources, cultural and paleontological resources, socioeconomics, waste management, environmental justice, as well as radiological and hazardous chemical impacts during normal operation and accidents to workers and the public are included in the assessment. The PEIS presents unclassified information only. A classified appendix has also been prepared to support the PEIS.

PUBLIC COMMENTS: The public comment period on the Draft PEIS was conducted from March 8, 1996 to May 7, 1996. During the comment period, public hearings were held in Los Alamos, NM; Albuquerque, NM; Las Vegas, NV; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. The Draft PEIS was made available through mailings, requests to DOE's Office of Reconfiguration, and at DOE Public Reading Rooms. In preparing the Final PEIS, DOE considered comments received by mail, fax, handed in at hearings, transcribed from messages recorded by telephone, and those transcribed via Internet. In addition, comments and concerns identified during discussions at public hearings were considered.

In response to comments submitted after issuance of the Draft PEIS and due to additional technical details not available at the time of issuance of the Draft, Volumes I, II, and III of the Final PEIS contain revisions and changes. The revisions and changes made since the issuance of the Draft document are indicated by a double underline for minor word changes or by a sidebar in the margin for paragraph or larger changes. In addition, Volume I and each appendix in Volume III provide a unique reference list to enable the reader to further review and research selected topics. Volume IV (Comment Response Document) of the PEIS contains the comments received during public review of the Draft PEIS and the DOE responses to those comments. DOE has public reading rooms near each affected site and in Washington, DC where these referenced documents may be reviewed or obtained for review.

PUBLIC COMMENT PROCESS

Public
omment Process

CHAPTER 1: PUBLIC COMMENT PROCESS

This chapter of the Comment Response Document describes the public comment process for the **Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management** *and the procedure used in responding to those comments. Section 1.1 describes the means through which comments were acquired, summarized, and numbered. Section 1.2 discusses the public hearing format that was used to solicit comments from the public. Section 1.3 describes the organization of this document as well as how the comments were categorized, addressed, and documented. Section 1.3 also provides guidance on the use of this document to assist the reader. The chapter concludes with a discussion of the major comments and changes to the* **Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management** *resulting from the public comment process.*

1.1 INTRODUCTION

In February 1996, the Department of Energy (DOE) published the *Draft Programmatic Environmental Impact Statement (PEIS) for Stockpile Stewardship and Management*, which described and analyzed alternative ways to implement the proposed actions for the Stockpile Stewardship and Management Program. DOE developed the Program to provide a single highly integrated technical program for maintaining the safety and reliability of the nuclear stockpile in the absence of underground nuclear testing. The 60-day public comment period for the Stockpile Stewardship and Management Draft PEIS began on March 8, 1996, and ended on May 7, 1996.

During the comment period, public hearings were held in Los Alamos, NM; Las Vegas, NV; Albuquerque, NM; Oak Ridge, TN; Kansas City, MO; Livermore, CA; Washington, DC; Amarillo, TX; Santa Fe, NM; and North Augusta, SC. Figure 1.1–1 shows the locations and dates of the hearings. Five of those public hearings were joint meetings to obtain comments on both the Stockpile Stewardship and Management Draft PEIS and the *Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement* (Storage and Disposition Draft PEIS) (DOE/EIS-0229-D, February 1996). Two of the joint meetings (Pantex Plant [Pantex] in Amarillo, TX and Savannah River Site [SRS] in North Augusta, SC) also included the *Draft Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (Pantex Site-Wide Draft EIS) (DOE/EIS-0225-D, March 1996). In addition, the public was encouraged to provide comments via mail, fax, electronic bulletin board (Internet), and telephone (toll-free 800-number).

Attendance at each hearing, together with the number of comment summaries recorded, is presented in table 1.1–1. Attendance numbers are based on the number of participants who completed and returned registration forms and may not include all of those present at the meetings. In addition to comments received at the public hearings, comments were also received during the public comment period through the other means described above.

All public hearing comment summaries were combined with comments received by other means during the public comment period. Comments received by mail, fax, Internet, or telephone were date stamped and assigned a sequential document number according to origin (e.g., fax or mail) of the document. Chapter 2 of this volume contains copies of the documents DOE received. Table 1.1–2 provides an overview of the number of documents and comments submitted by each method. The document number codes that were assigned to each document based on the method of submission are given in parentheses in table 1.1–2. For example, all documents that were handed in at public hearings have document numbers beginning with SSM-H.

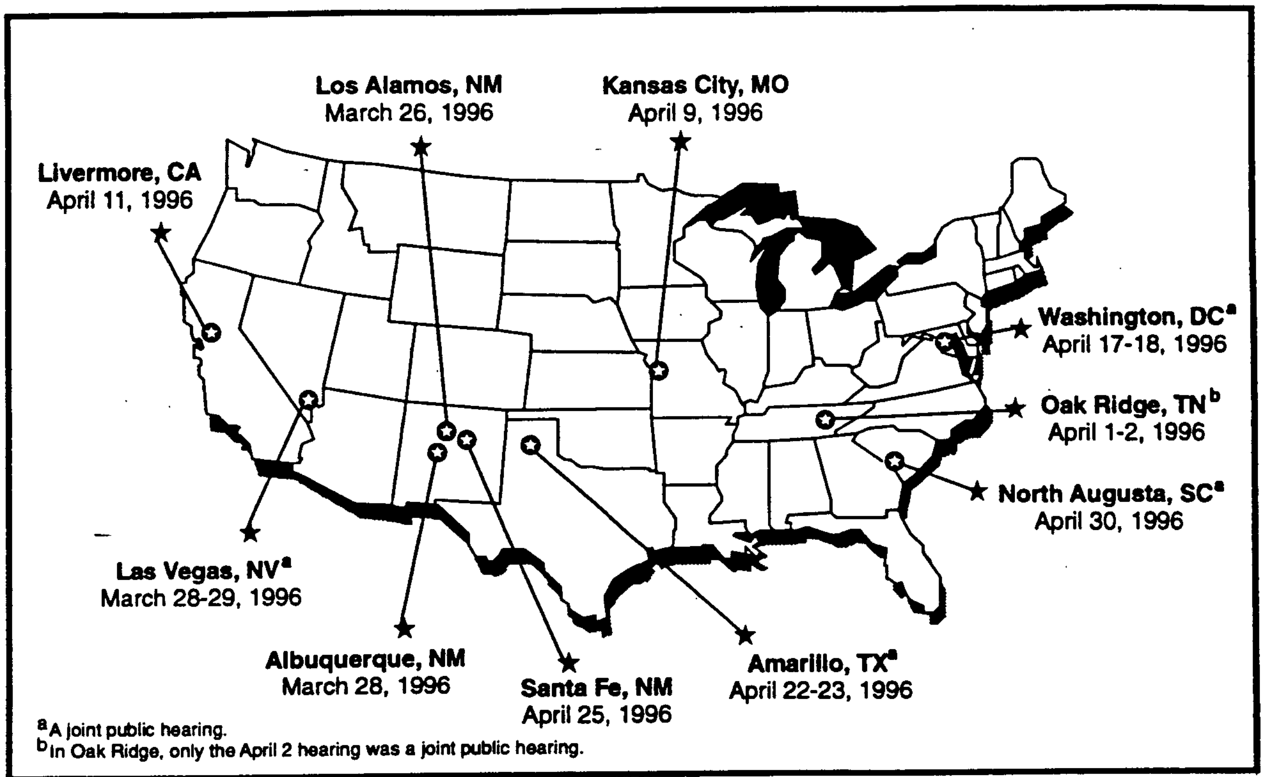

FIGURE 1.1–1.—*Public Hearing Locations and Dates, 1996.*

TABLE 1.1–1.—*Public Hearing Locations, Attendance, and Comment Summaries*

Hearing Location	Total Attendance	Comment Summaries
Los Alamos, NM	87	89

Letter/postcard campaigns (SSM-C)	6,675	7,038
Fax (SSM-F)	30	155
Phone (SSM-P)	9	10
Electronic bulletin board (SSM-B)	0	0
Transcripts (SSM-ET)	2	11

1.2 PUBLIC HEARING FORMAT

The public hearings used a modified traditional hearing format which allowed for two-way interaction between DOE and the public and encouraged informed public input and comments on the document. Neutral facilitators were present at the hearings to direct and clarify discussions and comments. Court reporters were also present to provide a verbatim transcript of the proceedings and record all formal comments that the public wished to present. The transcripts are available in DOE Public Reading Rooms near each site and in Washington, DC. These transcripts have been marked with sidebars to identify specific comments and how the comments were categorized into issue codes.

The format used for each hearing included a Program overview, interactive discussions, and a summary session. There was also an opportunity for formal comment provided for any attendee who wished to read a prepared statement of no more than 5 minutes. The Program overview session opened with a welcome from a site representative, followed by an overview of the Stockpile Stewardship and Management Program by a DOE representative. After clarifying questions, the facilitator opened the interactive general question and discussion period. A notetaker was present at each session to document and consolidate comments for the preparation of the Stockpile Stewardship and Management Final PEIS. Following the question and discussion period, a summary session was held to present the major comments and issues identified in each discussion group. An opportunity for additional comments or clarification was provided at this time. Modifications to the format were made at each public hearing location to best fulfill special needs or requests from the attendees. Following the public hearings, comment summaries were prepared by the notetakers (see chapter 2) with the verbatim transcripts being used as a reference.

1.3 ORGANIZATION OF THIS COMMENT RESPONSE DOCUMENT

This Comment Response Document has been organized into the following sections:

- Chapter 1 describes the public comment process and contains tables to assist readers.
- Chapter 2 contains notetaker-generated summaries of the comments received at the public hearings and scanned copies of comment documents received during the public comment period.
- Chapter 3 contains comment summaries and DOE responses by category.

Tables are provided at the end of this chapter to assist commentors and other readers in locating individual comments regarding the Stockpile Stewardship and Management Draft PEIS. Once comments were received, they were categorized by issue (e.g., land resources or water resources) and assigned a category code. Table 1.3–1 lists the issue categories and corresponding category codes. Similar comments within the same issue category were then summarized and assigned a summary code.

Table 1.3–2 identifies the individuals who attended public hearings and the pages where the notetaker-generated comment summaries from those hearings appear. Commentors interested in locating their comment document and reviewing how it was coded can use tables 1.3–3 and 1.3–4. Table 1.3–3 consists of a list of members of the general public who submitted comments. Commentors are listed by last name, with their assigned document numbers and the pages on which their comment documents appear. Table 1.3–4 consists of a list of state and local officials and agencies, companies, organizations, and special interest groups that submitted comments. The commentors in table 1.3–4 are listed by organization in alphabetical order with the names of the particular individuals who submitted those documents. For each commentor, the assigned document number and the pages on which their comment documents appear are listed.

In some instances multiple duplicate documents were received from a commentor. As a result of the multiple submissions, documents were deleted and gaps exist in the numerical sequence for tables 1.3–5 and 1.3–6. Some commentors submitted documents which were classified as letter writing or postcard campaigns. These campaigns were conducted by various organizations and special interest groups to express either support or opposition to aspects of the Stockpile Stewardship and Management Program. Although many postcards and duplicate documents were received, only one document scan of each type is included in chapter 2. The names of commentors who participated in most campaigns are included in tables 1.3–3 and 1.3–4. However, the names of commentors who participated in two very large campaigns, identified as campaign 4 (SSM-C-004) and campaign 5 (SSM-C-005), are not provided due to their volume. Lists of these commentors are available in DOE Public Reading Rooms near each site and in Washington, DC.

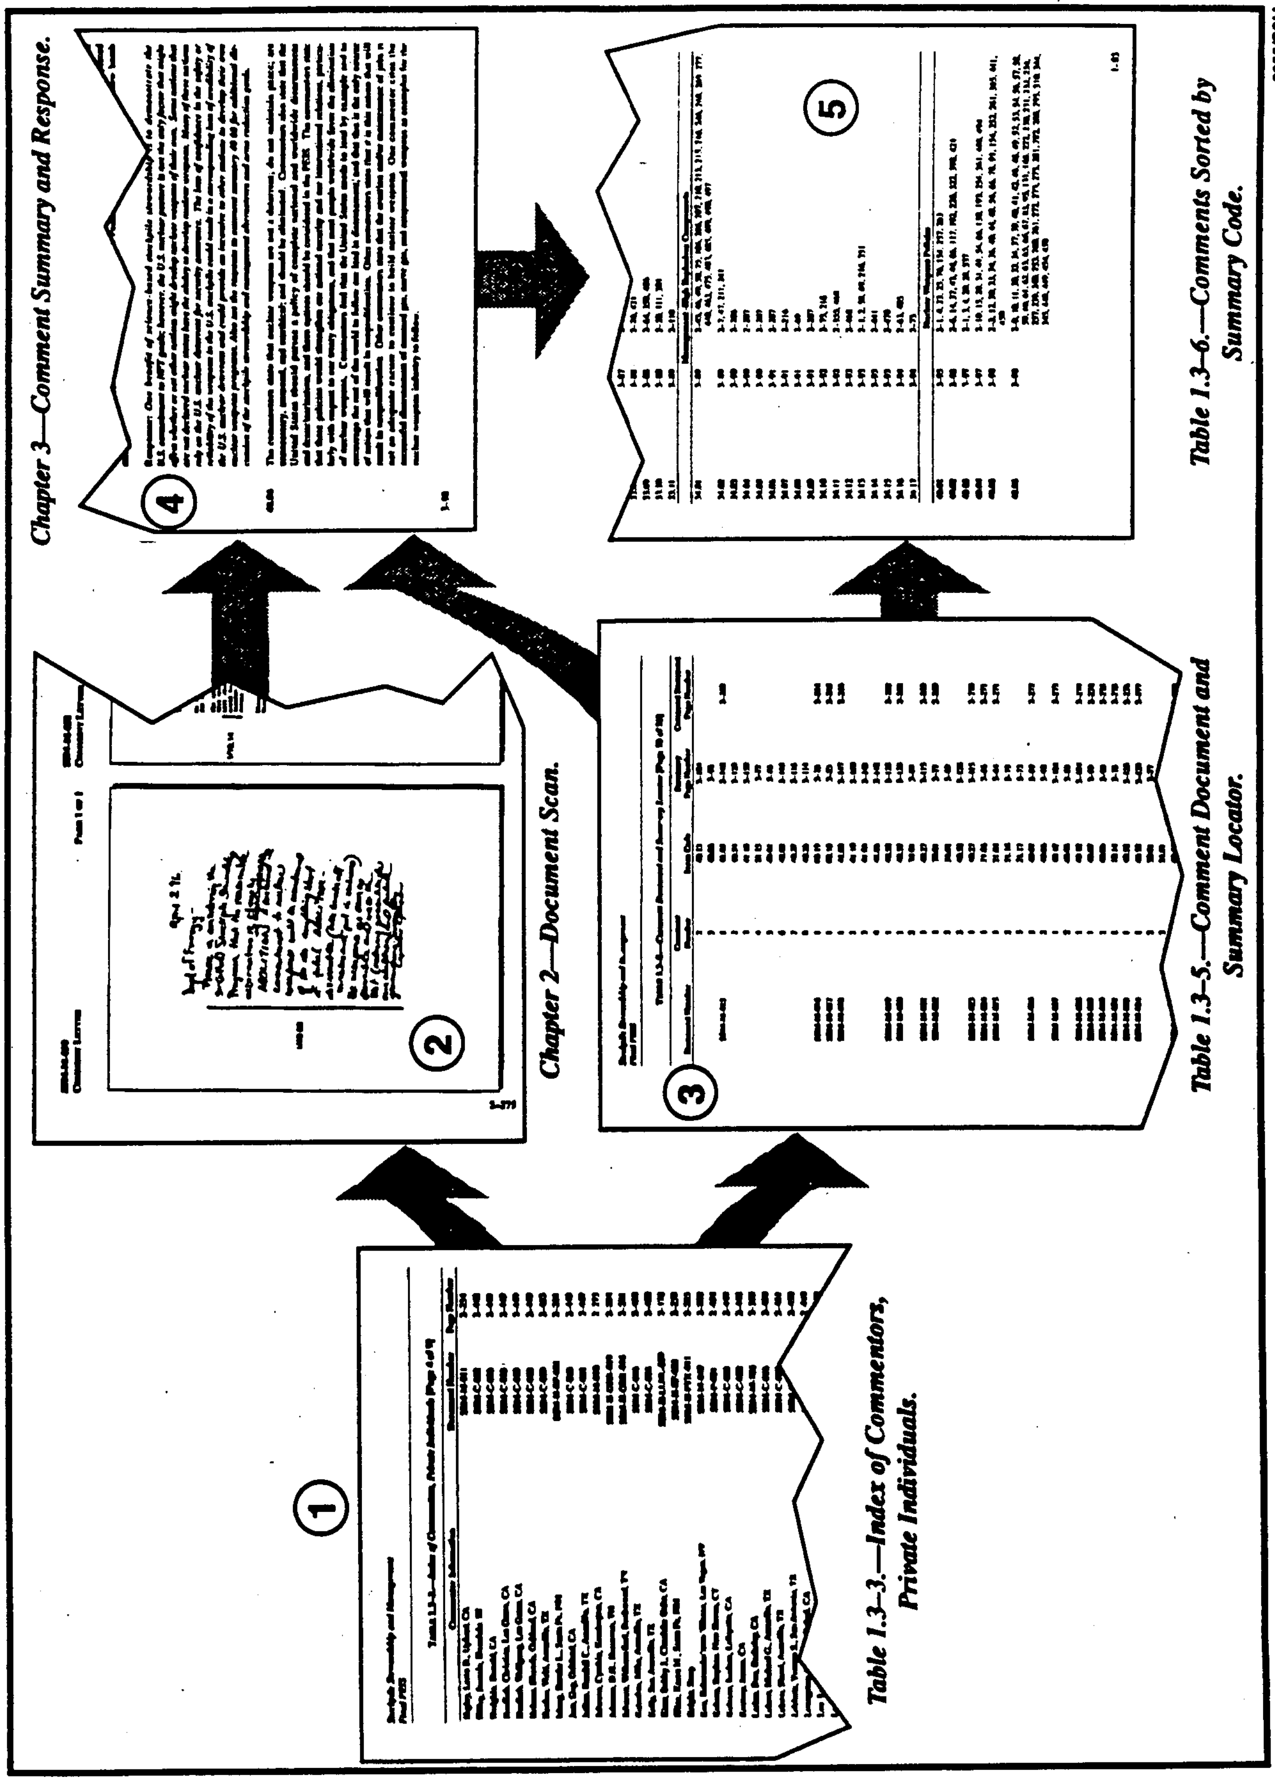
Table 1.3–6 is organized by summary code. Using the appropriate summary code, commentors can locate all of the comments that are reflected in each summary. The table also lists the page on which the comment summary and corresponding response appear and the pages on which the actual comment documents appear. Some comment documents presented in chapter 2 consist of multiple pages. The document page number given in tables 1.3–2 through 1.3–5 refers to the first page on which the comment document appears. The document page number given in table 1.3–6 refers to the page on which the individual comment begins within a document.

Scans of the documents received during the public comment period are shown in chapter 2. A document number code was assigned to each comment document based on the method of submission. Documents that were handed in at public hearings, mailed, or faxed have document numbers beginning with SSM-H, SSM-M, and SSM-F, respectively. Some documents were mailed in as part of letter writing or postcard campaigns and were given document numbers beginning with SSM-C. Comments that were received over the telephone were transcribed and given document numbers beginning with SSM-P. No comments were received through the electronic bulletin board. Comments from elected officials were given document numbers beginning with SSM-E. Documents from elected officials are not indicated separately in table 1.1–2, but are included in the total document counts based on the type of submission. Elected officials' comments that were transcribed at public hearings and were not submitted in another form were given document numbers beginning with SSM-ET.

1.4 How to Use this Comment Response Document

This section and figure 1.4–1 will assist the reader in tracking comment documents and determining how they were responded to. Begin by locating the appropriate name or organization in table 1.3–3 or 1.3–4. Table 1.3–3 consists of private individuals who submitted comments. Table 1.3–4 is a list of organizations and public officials who submitted comments. Both of these tables also list the document number that was assigned to each comment document and the page number on which that document appears in chapter 2. In order to see what issue codes were assigned to the comments identified within a document, locate the document number in table 1.3–5. Table 1.3–5 contains information on the number of comments identified in each document, the issue code assigned to each comment, and the page number for the corresponding summary and response that appears in chapter 3. In order to locate other comments in chapter 2 that address the same issues as a certain document, or to locate comments that address a certain issue code, use table 1.3–6. Table 1.3–6 lists the summary codes, the page on which the corresponding summary and response appears in chapter 3, and the page numbers on which each comment that was assigned that issue code appears in chapter 2.

For example, if Cynthia Johnson wanted to track her comments, she would go to table 1.3–3 to find her name, corresponding document number (SSM-M-030), and the corresponding page on which her document appears in chapter 2 (page 2–275). On page 2–275, Ms. Johnson would find that her scanned document has been side-barred and coded for summary number 40.06. After obtaining the comment document number SSM-M-030, she could use table 1.3–5 to locate the number of comments identified (one), the issue code that her comment was assigned (40.06), the summary page number on which the corresponding summary and response is found in chapter 3 (page 3–93), and the document page number (page 2–275). After obtaining the issue code from either the scanned document on page 2–275 or table 1.3–5, Ms. Johnson could use table 1.3–6 to see how her



3255/SSM

FIGURE 1.4-1.—*Use of this Comment Response Document.*

comment was categorized (nuclear weapons policies), and to locate the page numbers on which other comments that express similar concerns appear in chapter 2. Using table 1.3–6, Ms. Johnson would find that similar concerns were expressed in 80 notetaker-generated comment summaries and comment documents appearing in chapter 2 on pages 2–9, 10, 11, 30, 33, 34, 37, 39, 40, 41, 42, 46, 48, 49, 52, 53, 54, 56, 57, 58, 59, 60, 61, 62, 63, 65, 66, 67, 83, 95, 131, 165, 222, 230, 231, 232, 234, 237, 239, 240, 253, 260, 261, 272, 273, 275, 281, 282, 288, 295, 310, 344, 345, 448, 449, 454, and 458.

1.5 CHANGES FROM THE DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

In response to comments submitted after issuance of the Stockpile Stewardship and Management Draft PEIS, and due to additional technical details not available at the time of issuance of the Draft, Volumes I, II, and III of the Stockpile Stewardship and Management Final PEIS contain revisions and changes. The revisions and changes made since the issuance of the Draft PEIS are indicated by a double underline for minor word changes or by using a sidebar in the margin for paragraph or larger changes. In addition, Volume I and each appendix in Volume III provide a unique reference list to enable the reader to further review and research selected topics. These referenced documents and transcripts from the public hearings on the Draft PEIS may be reviewed or obtained for review in DOE Public Reading Rooms. A brief discussion of the more significant changes is provided in the following paragraphs.

Alternatives Considered but Eliminated from Detailed Study and Related Issues. In response to public comments expressing a concern DOE had not analyzed a reasonable range of alternatives, section 3.1.2 of Volume I was expanded. The changes were in response to specific questions concerning compliance with treaties, stockpile size, maintenance and remanufacturing options, and the stockpile stewardship alternatives, including No Action. The discussions in section 3.1.2 provide greater detail and more clarification on why alternatives were eliminated from detailed study in the PEIS. Together, chapter 2 and section 3.1.2 of Volume I explain the framework and the constraints of national security policy that have shaped the proposed actions and reasonable alternatives for the PEIS.

No Action Alternative. Several commentors did not think that the No Action alternative was clearly explained in the Draft PEIS. More specifically, they were not sure which existing facilities at Los Alamos National Laboratory (LANL), Lawrence Livermore National Laboratory (LLNL), Sandia National Laboratories (SNL), and the Nevada Test Site (NTS) were part of the ongoing stockpile stewardship program. As a result, the description of No Action was modified in Volume II, appendix A (Stockpile Stewardship and Management Facilities) to include a listing of major DOE Office for Defense Programs (DP) function facilities at LANL, LLNL, SNL, and NTS. Additionally, the discussion of impacts of No Action at LANL (Volume I, section 4.6.3) was revised as appropriate to include the effects of the Dual Axis Radiographic Hydrodynamic Test (DARHT) Facility.

Socioeconomics at Oak Ridge Reservation, Kansas City Plant, and Pantex Plant. Based on public comments and revised workforce size estimates, the socioeconomic impact sections for the downsizing alternatives at Oak Ridge Reservation (ORR) (Volume I, section 4.2.3.8), Kansas City Plant (KCP) (Volume I, section 4.4.3.8) and Pantex (Volume I, section 4.5.3.8), have been revised. The analyses were also expanded to cover the "base case single-shift" options in greater detail. At these three sites, downsizing of existing facilities is the preferred alternative. For such downsizing, the "base case single-shift" scenario represents the bounding analysis for the workforce. The change in worker estimates did not cause any of the major indicators in the socioeconomic analysis to change in any significant manner.

Accident Impacts at Pantex Plant. The analyses of impacts due to an aircraft impact and resulting release of plutonium by a fire or an explosion were modified to include more updated data on probability and source terms developed for the Pantex Site-Wide EIS. Volume I, section 4.5.3.9, and Volume II, appendix sections F.2.1.1 and F.2.1.2, were revised to incorporate the new analytical results. Based on the updated data, the potential impacts and risks to the public from the composite accident presented in the PEIS would be less than previously reported in the Draft PEIS. This change was not significant.

Normal Operation Radiological/Chemical Impacts. The discussion of the normal operation radiological affected environment for LANL, Volume I, section 4.6.2.9, has been updated to include data from *Environmental Surveillance at Los Alamos During 1993* (LA-12973-ENV, October 1995). The normal operation radiological impact sections 4.2.3.9, 4.3.3.9, and 4.6.3.9 in Volume I have also been revised to include the contribution of recent facilities at ORR, SRS, and the new environmental surveillance data for LANL. The chemical health effects sections in Volume I, 4.6.3.9 for LANL and 4.7.3.9 for LLNL, were revised based on new analyses using updated dispersion rates. Tables in Volume II, appendix section E.3.4, supporting these sections were also updated. The majority of these changes affected the No Action alternative analyses. None of the changes to these sections significantly changed the analysis of impacts for the "action" alternatives.

Cumulative Impacts. Volume I, section 4.13, Cumulative Impacts, has been modified to incorporate a discussion of normal operation radiological impacts and other changes based on more recent data from *National Environmental Policy Act* documents and Record(s) of Decision. The changes to this section did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

Los Alamos National Laboratory Water Resources. Changes were incorporated in Volume I, section 4.6.2.4, Water Resources, for LANL based on more recent water use and water quality data. The Draft PEIS had erroneously stated that the LANL water allotment would be fully used by about the year 2000. The Final PEIS correctly reports that this allotment would be fully used by about the year 2052. This change did not have a meaningful effect on the analysis/comparative evaluation of alternatives. Minor revisions reflecting the baseline changes were also made to the LANL water resources impact discussion in Volume I, section 4.6.3.4.

Health Effects Studies. Appendix section E.4 in Volume II outlining epidemiological studies at the alternative sites was rewritten to provide more detail and incorporate more recent and other applicable studies. Although these epidemiology sections do not affect the environmental analysis of future stockpile stewardship and management missions, they do provide relevant information regarding potential health effects from past actions. These changes did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

New Section. A new section has also been added to the Final PEIS (Volume II, appendix section F.4, Secondary Impacts of Accidents). This section evaluates the secondary impacts of accidents that affect elements of the environment other than humans (e.g., farmland). The section was added because of public comments. The results of this analysis show that secondary impacts from accidents would generally not extend beyond site boundaries, except at Pantex and LLNL, where it is possible that some surface contamination could occur. This new analysis did not have a meaningful effect on the analysis/comparative evaluation of alternatives.

TABLE 1.3–1.—*Issue Categories*

Yard, Charles R., Tennessee Department of Environment and Conservation, Oak Ridge, TN	
April 2, 1996—Oak Ridge, Tennessee	
Evening Session	2–28 to 2–29
This public hearing was held specifically to obtain comments on the Storage and Disposition Draft PEIS. For this reason, there is no list of hearing attendees for this session included in this document. Despite the fact that the focus of the hearing was the Storage and Disposition Draft PEIS, notetakers identified eight comments that pertained to the Stockpile Stewardship and Management Program. Those comments are included in Chapter 2.	
April 9, 1996—Kansas City, Missouri	
Afternoon Session	2–29
Black, Peter C., Allied Signal, Lenexa, KS	
Clegg, Karen K., Allied Signal, Kansas City, MO

COMMENT DOCUMENTS

Comment
Documents

CHAPTER 2: COMMENT DOCUMENTS

This chapter is a compilation of all the documents that the Department of Energy received during the public comment period on the **Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management.** *The documents are keyed by number to table 1.3–3, Index of Commentors. The documents are presented by type in the order in which they were received. On each document the first number represents the comment number within that document and the second number represents the issue summary code assigned to this comment. This number can be used to locate the summary and response relating to this comment. Section 1.3 further describes the organization of this Comment Response Document and discusses the tables provided in chapter 1 to assist readers.*

PUBLIC HEARING—LOS ALAMOS, NEW MEXICO

MARCH 26, 1996—AFTERNOON SESSION

1/40.03 The commentor asks what procedure would be followed if the director of Los Alamos National Laboratory (LANL) judged the stockpile unreliable.

2/43.15 The commentor believes that the history discussion in chapter 2 of the *Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (Draft PEIS) should go back further than the beginning of the Cold War in order to provide a better perspective on nuclear weapons issues.

3/40.03 The commentor asks if the Draft PEIS analyzed the pressures that would be put on the laboratory director while making the reliability decision.

4/40.21 The commentor believes that the safety record of the past 50 years is evidence of the competence of the people who create, manage, and control nuclear weapons.

5/40.11 The commentor believes that a thorough understanding of the weapons needs to be maintained at the laboratories, especially in light of the Comprehensive Test Ban Treaty (CTBT).

6/40.01 The commentor believes that the ban on underground nuclear testing is a mistake. The commentor advises the Nation to continue underground nuclear testing to ensure the reliability of nuclear weapons.

7/21.01 The commentor states that the National Ignition Facility (NIF) may be able to conduct interesting experiments, but the facility will provide very little information on the reliability of nuclear weapons.

8/34.13 The commentor asks when a decision will be made on the preferred alternative for high explosives (HE) fabrication.

9/32.01 The commentor wants to know the difference between pit remanufacturing and pit refurbishing (whether it is a one-to-one process). The commentor asks if the pit fabrication facility will have the capability to make smaller pits for different applications in addition to remanufacturing.

10/32.02 The commentor asks if the fissile materials will be melted and purified before being remanufactured.

11/11.07 The commentor states that the radiation sources are not carefully stated and asks if linear extrapolation was used to determine the doses to the workers at LANL and the Savannah River Site (SRS) in section 5.4.1. The commentor believes that these are overestimates of what would happen to the workers.

12/40.11 The commentor believes that the document should consider the possibility of non-ratification of the Strategic Arms Reduction Talks (START) II protocol and CTBT when considering the stockpile size.

13/40.35 The commentor asks how the President gets information regarding the Nuclear Weapons Complex (Complex).

14/11.07 The commentor asks how the radiation doses to workers calculated in the PEIS for pit fabrication at LANL compare to the doses that were observed at Rocky Flats when pit fabrication was performed there.

15/10.01 The commentor asks what kind of waste will be put into the expanded Area G and what safety measures will be used at the facility.

16/32.05 The commentor asks what economic impacts would be associated with pit production at LANL. The commentor also asks what is the annual budget for the pit fabrication facility.

MARCH 26, 1996—EVENING SESSION

1/41.05 The commentor believes that the format used in the scoping meetings was better because some people may hesitate to approach a microphone during the public comment meetings.

2/41.05 The commentor believes that the Department of Energy (DOE) is not telling the truth and that the public meetings are only for public relations purposes.

3/32.01 The commentor asks if there will be pit production at the Pantex Plant (Pantex) or at other facilities.

4/32.01 The commentor wants to know what the pit production level was at the height of the Cold War.

5/40.22 The commentor wants to know if the plutonium pits have had any problems over the past three years (since the moratorium) that required repair or replacement to get a sense of how the number of 50 pits was arrived at. The commentor also wants to know how many pits were destroyed.

6/32.12 The commentor wants to know if the pit production capacity at Technical Area (TA) -55 is still classified and the definition of inherent and full capacity. The commentor wants to know the pit production capacity at TA-55 (plutonium handler area) in LANL. The commentor also wants to know how easily the pit production capacity at TA-55 could be expanded and what would be the three-shift capacity.

7/32.06 The commentor wants to know if the pit production facility at SRS will be dismantled.

8/34.13 The commentor asks if DOE has decided to leave the HE fabrication mission at Pantex or move it to LANL.

9/11.08 The commentor asks what DOE considers an accident and if there is enough historical data to constitute a fair analysis of accidents. The commentor asks if the analysis examines risks more to the public than to the workers in the workplace. The commentor also asks if the accident modeling included real accidents at TA-55 reported to the Occurrence Reporting System.

10/11.07 The commentor asks if LANL ever had pit production capacity and if data on worker safety, accidents, and contamination was used in the PEIS.

11/09.05 The commentor questions the safety record of nuclear shipments in the LANL area. The commentor has heard conflicting reports concerning the number of accidents from Los Alamos to the thruway and requests clarification.

12/09.05 The commentor cites a safe secure trailer truck turnover in Colorado about five years ago as proof that there have been accidents with nuclear cargo.

13/40.36 The commentor asks DOE to justify the need for the Stockpile Stewardship and Management Program by citing specific examples of problems that have been found in the stockpile that could not be solved with existing technology.

14/40.22 The commentor wants to know how old the weapons in the stockpile are and how long they will be maintained in the stockpile.

15/40.03 The commentor asks if underground nuclear testing would resume based on the recommendations of the laboratory directors that adequate simulation or testing capacity is not available.

16/40.25 The commentor is of the opinion that stockpile management has been better analyzed than stockpile stewardship, which in the words of the commentor is still very weak. The commentor believes that the stewardship part of the Program has muddled science with politics in developing the preferred alternative in stockpile stewardship. The commentor believes that more stewardship alternatives should be analyzed including simpler and less grandiose alternatives.

17/40.35 The commentor questions the ability of the proposed program to get the job done.

18/21.01 The commentor believes the technical justification for NIF is poor and is not cogent.

19/40.14 The commentor questions the need for the Nevada Test Site (NTS) at such an enormous cost.

20/40.08 The commentor questions the peer review system of the stockpile stewardship plan. The commentor believes that the peer review system should be carefully considered because it is fraught with conflict of interest problems.

21/40.69 The commentor believes that DOE should address the historical record of lies and deceptions in the nuclear program.

22/40.05 The commentor states that the goals of the Stockpile Stewardship and Management Program are not clear. The commentor wants to know if the Program will maintain the capability to design new weapons.

23/40.07 The commentor believes that the nonproliferation aspects of the Program have not been properly addressed except in the case of NIF.

24/40.41 The commentor requests an open discussion on the role of plutonium-242 in the Program. The commentor points out that plutonium-242 has been linked to serious environmental problems at SRS.

25/41.18 The commentor wants to see a comprehensive discussion in a programmatic context of: hydrotesting, Dual Axis Radiographic Hydrodynamic Test (DARHT), the Contained Firing Facility (CFF) at the Pulsed High Energy Radiation Machine Emitting X-Rays (PHERMEX) Facility, the Big Explosives Experimental Facility (BEEF), and the Lyner facility.

26/10.03 The commentor notes that page 11 of the summary in the Waste Management Draft PEIS shows a large amount of waste generation related to stockpile stewardship and management.

27/11.15 The commentor believes that the accident analysis tends to trivialize accidents for stockpile stewardship. The commentor notes that very low probability events that have very catastrophic consequences are difficult for the decisionmaking process.

28/11.27 The commentor believes that even the risk of an accident carries certain costs. The commentor believes that the mere perception that an accident is possible could damage the tourist industry of New Mexico.

29/41.03 The commentor believes that there should be a national referendum to find out in which direction the Stockpile Stewardship and Management Program should go.

30/40.01 The commentor notes that the *National Defense Authorization Act* requires NTS to maintain a ready state to do underground nuclear testing if an emergency was declared.

31/40.03 The commentor points out that there is a range of options besides nuclear testing that would allow a director to recertify the reliability of the stockpile once it is declared unreliable.

32/40.22 The commentor asks if there are currently weapons in the stockpile that are beyond their design life. The commentor also notes that an ultra enhanced surveillance program may be needed in the future if we continue to have weapons in the stockpile.

33/32.10 The commentor notes that the environmental impacts per pit produced would be reduced by using advancements such as new welding techniques, dry machining, and the reduction of oils and organic solvent usage. The commentor also points out that the actual environmental impacts may be less than the impacts outlined in the document since conservative estimates were used in the analysis of the impacts.

34/40.08 The commentor believes that the focus should be on national security not politics. The commentor believes that the country is lucky to have LANL.

35/40.08 The commentor believes that the politicians making the decisions on the stockpile stewardship mission do not have a firm grasp on weapons issues and could be influenced by self-serving advisors in the weapons program.

36/40.35 The commentor questions the ability of the Program to catch problems in the stockpile. The commentor also asks what yardstick the President, Congress, and DOE used when judging the potential success of the alternatives in the PEIS.

37/40.35 The commentor believes that DOE is gambling by depending on the Program to replace underground testing.

38/40.08 The commentor believes that political leaders are not making decisions with good information and that the wrong decision has been made in this case, but the commentor believes the plan for stewardship is tolerable and that DOE should proceed.

39/32.02 The commentor asks if DOE currently has facilities in place to change the plutonium alloy mix if a problem developed in the future or would different plutonium handling methods be required from what currently exists at LANL. The commentor also asks if DOE would replace the pits with a different alloy or use the same alloy if a pit metal problem developed.

40/43.10 The commentor is concerned that the Federal Government is expanding nuclear programs in the State of New Mexico without investing any money in the state. The commentor asks how much money is being committed to New Mexico compared to how much is being committed for high energy physics programs. The commentor believes that DOE has no commitment to public health surveillance in the state despite a rapid large-scale expansion of nuclear programs.

41/40.08 The commentor is concerned about the conflict of interest that can result from having the directors of large bureaucratic institutions responsible for major national issues. The commentor believes that the politicians have no option but to accept these recommendations despite the conflict of interest.

42/40.21 The commentor points out the conflict of calling for increased environmental monitoring and more studies from a DOE that they do not trust.

43/40.21 The commentor believes that DOE has not fulfilled the requirements of the Tiger Team. The commentor states that people involved with tracking the Tiger Team findings were all laid off and cites the Martinez electrocution accident report as proof that the findings were never addressed. The commentor further states that citizens should be involved in deciding if the Tiger Team findings should be discarded or not. The commentor also wants to know what happened to the lessons learned program that resulted from the Tiger Team in 1991.

44/40.21 The commentor believes that there have been issues of classification that obscure safety problems at the laboratory.

45/40.21 The commentor believes that intimidation and fear of losing jobs has prevented people from raising safety concerns at LANL. The commentor believes that a separate reporting structure for safety concerns should be developed before nuclear materials handling is expanded at LANL.

46/41.07 The commentor points out that the Defense Facility Nuclear Safety Board was created by Congress to review and identify problems in DOE. The commentor notes that the board does an annual report and that they work extensively at the facilities.

47/40.07 The commentor believes that the PEIS fails to mention that the Stockpile Stewardship and Management Program will be used to maintain the expertise of weapons development, research, design, testing, prototyping, and certification. The commentor believes the PEIS should consider a future treaty that may require DOE to disclose whether or not the Program does weapon designing. The commentor believes that DOE should separate the advancement of the science of nuclear weapons from the maintenance work.

48/40.07 The commentor believes that if DOE continues to pursue the advancement of nuclear science, it will make it easier for someone to design a nuclear weapon in the future.

49/40.07 The commentor believes that the long- and short-term nonproliferation impacts have not been fully analyzed.

50/40.02 The commentor questions the timing, purpose, and need for the subcritical test planned for June 18, 1996 at NTS. The commentor wants the PEIS to address the issue and how it may affect the Russian elections and CTBT.

51/41.05 The commentor is glad that DOE is conducting the public comment meetings and hopes that DOE will continue to have public meetings.

52/40.51 The commentor is thankful for DOE and LANL and believes that LANL is capable of continuing its mission because it has the proper technology and scientific knowledge needed to protect our way of life.

53/41.07 The commentor points out that the Citizens Advisory Board is not accountable to the citizens of Los Alamos and does not speak for the citizens of Los Alamos, specifically with respect to safety concerns.

54/32.11 The commentor asks if the need for pit production outweighs the additional risks to the citizens of Los Alamos. The commentor asks what the citizens of Los Alamos will gain from bringing pit production to LANL.

55/08.06 The commentor believes that any additional work that would come to Los Alamos from pit production should be contracted out to a private taxpaying company instead of going to the University of California which does not pay taxes to the state or the community.

56/40.31 The commentor believes that information available to the public is increasingly being taken out of the public record. The commentor cites the Operating Experience Summary Report which was recently taken offline, presumably to hide the number of troublesome incidents at TA-55.

57/40.21 The commentor feels the workers at LANL are eminently competent to monitor their own safety and environmental concerns.

58/41.07 The commentor points out that there is an advisory committee that has recommended that the Environmental Protection Agency (EPA) and Occupational Safety and Health Administration (OSHA) be allowed to oversee DOE facilities.

59/42.02 The commentor would like to see additional nonweapons work at LANL and recommends that the *Los Alamos Site-Wide Environmental Impact Statement* (EIS) look at the enhancement of nonweapons work.

60/41.05 The commentor asks if the *National Environmental Policy Act* (NEPA) process allows DOE to lie in the PEIS. The commentor also asks if DOE is required to respond to comments from the public.

61/40.35 The commentor believes that the gamble that DOE is taking is inherent in all research and development (R&D) projects.

62/41.05 The commentor believes that the public meetings are a valuable forum for the public.

63/40.21 The commentor believes that safety has deteriorated at LANL because the responsibility for safety has been shifted from the workers to the bureaucrats.

64/40.08 The commentor does not believe that the laboratories are guilty of collusion with respect to peer review because, as far as the commentor has seen, the three laboratories do not work well together.

65/40.44 The commentor believes that the science-based stewardship program is very important because it will maintain the competence of the people and the tools needed to answer questions that arise.

66/40.30 The commentor believes that LANL laid off employees at the plutonium facility in TA-55 even though they knew that TA-55 was probably going to expand.

67/08.05 The commentor believes that the socioeconomic analysis does not consider the social and economic impact to the people who were laid off at the plutonium facility. The commentor believes that the socioeconomic analysis needs to look at the integrity of the people running the facility. The commentor also believes that the 22 people laid off at the plutonium facility should be interviewed for the socioeconomic analysis.

68/40.30 The commentor believes that a constant fear exists at the plutonium facility that if an employee is critical of how the facility is managed then that employee will be replaced immediately.

69/34.02 The commentor believes that the HE mission should be brought to LANL because a synergism can be created through the R&D mission and the production of HE.

70/40.38 The commentor points out that the disarmament community wants to maintain competence in the stockpile, but they are also concerned about how many people and what skills are needed, what work will be performed, and who will be trusted to establish the transparency that the Stockpile Stewardship and Management Program needs.

71/40.07 The commentor suggests international oversight of the stockpile stewardship part of the Program to help solve nonproliferation concerns.

72/40.30 The commentor points out that TA-55 may be vulnerable to sabotage if the constant threat of lay-offs exists.

73/40.21 The commentor believes that LANL could avoid more accidents in the future by making safety a part of the workers' culture.

PUBLIC HEARING—ALBUQUERQUE, NEW MEXICO

MARCH 28, 1996—EVENING SESSION

1/40.40 The commentors ask about the current nuclear weapon stockpile size, including pits and warheads, and the amount of damage one nuclear warhead can do.

2/08.08 The commentor asks for a definition of environmental justice.

3/40.37 The commentor believes that DOE has been inconsistent when talking about the timeframe covered in the PEIS. DOE has not been clear on whether the PEIS covers a 25-year timeframe or an indefinite timeframe.

4/41.18 The commentor asks why DARHT is not in the Draft PEIS even though it was discussed at the scoping meeting for stockpile stewardship and management.

5/12.01	The commentor believes that DOE has unfairly placed their nuclear facilities in low income areas. The commentor notes that New Mexico, "the home of the bomb," has a low per capita income and a high minority population.
6/12.01	The commentor believes that the minority population maps for LANL and Sandia National Laboratories (SNL) have errors in them.
7/08.08	The commentor asks about the difference between socioeconomics and environmental justice.
8/04.11	The commentor would like to know where hydrology is discussed in the PEIS.
9/40.22	The commentor asks why the 160 problems found in the nuclear packages, HE, and secondaries in the 1950s were included in the three-laboratory study of weapons aging, but were not included in the Sandia Stockpile Study. The commentor also asks if all of the 160 problems are in the enduring stockpile and for a breakdown of the number of problems found in the nuclear components versus HE.
10/40.13	The commentors ask what is the past, present, and future budget of the stockpile program and, in particular, the surveillance budget at SNL.
11/40.38	The commentor asks if a three-laboratory stockpile evaluation program has been organized and which DOE office has the responsibility for the program.
12/43.06	The commentor recommends that a section for the catastrophic environmental impacts of the past weapons program should be included in the summary of environmental impacts section. The commentor cites Rocky Flats as an example of how DOE activities have catastrophically affected the public and the environment.
13/11.04	The commentor believes that a 100-mile (mi) radius would be more appropriate for the analysis of radiation health affects to the public.
14/09.02	The commentor notes that there are no evacuation plans for the people of Santa Fe and Albuquerque in case of a transportation accident involving nuclear materials.
15/40.19	The commentor believes that DOE is using the reestablishment of pit manufacture at LANL as an opportunity to redesign nuclear weapons. In particular, the commentor is concerned that DOE will make "mini-nukes" out of the pits that are melted down at LANL.
16/08.08	The commentor states that environmental justice does not just deal with socioeconomics. The commentor suggests DOE is supposed to do an environmental justice analysis for each of the other possible impacts. For example, DOE should conduct an environmental justice analysis of the air pollution to see if the air pollutants are falling in neighborhoods of concentrations of minority and low income people. Then DOE should do the same thing for water and soils, and geology and socioeconomics. According to the commentor, environmental justice is really an umbrella under which you are supposed to evaluate all of the other impacts.
17/40.19	The commentors question why DOE needs to produce more plutonium pits when they have thousands of dismantled pits at Pantex.
18/40.31	The commentor cites the new bomb designs that were on the Internet as proof that DOE is still working on new bomb designs.

19/40.07 The commentors believe that the reconfiguration program is a ploy which DOE will use to design new weapons in violation of the treaties.

20/11.05 The commentor asks if the PEIS considers multigenerational problems in the analysis of cancer fatalities. The commentor also asks if the cancer statistics and studies from Chernobyl and Nagasaki are taken into consideration in the calculation of the cancer fatality numbers.

21/41.01 The commentor believes that DOE has been very candid and open when answering questions from the public.

22/40.13 The commentor asks how much money will be saved by rightsizing the weapons complex.

23/40.13 The commentor questions how much money is being spent on the enhanced experimental program.

24/10.05 The commentor wants to know what portion of the DOE budget is going towards site cleanup and solution of the nuclear waste problem. The commentor believes that new solutions need to be developed to handle the terrible problem of nuclear waste because the current practices are not working.

25/40.15 The commentor believes that we are fouling the earth by increasing the amount of nuclear waste throughout the years.

26/40.06 The commentors believe that the United States should not manufacture any more nuclear weapons and should move towards denuclearization.

27/41.07 The commentor believes that a civilian review board should be set up to oversee DOE.

28/40.69 The commentor believes a war crime tribunal should be established to review past mistakes of DOE in order to charge them with first-degree murder and hang them.

29/41.01 The commentors believe that the public was not given adequate notice for public comment meetings.

30/40.07 The commentor believes that the Program violates the Nonproliferation Treaty (NPT) by continuing the research and design of new nuclear weapons. The commentor cites pit production at LANL and NIF as specific examples of nonproliferation violations.

31/40.33 The commentor cites a physicist at the Lawrence Livermore National Laboratory (LLNL), Mr. Dewitt, who says that the stockpile can be maintained through direct remanufacture. Furthermore, the commentor believes that DOE will try to improve nuclear weapons every time a warhead is decommissioned.

32/40.12 The commentor believes that enormous amounts of taxpayer money is being wasted on militarily unusable weapons. The commentor believes that the money should be spent on more useful programs such as medical care and daycare. The commentor also believes that the Program is a pork-barrel project for the nuclear military industrial complex and the corporations that serve the Complex.

33/40.34 The commentor believes that DOE uses the word "reliability" incorrectly. The commentor believes that DOE is really talking about explosion radius and the number of people that would be killed when they talk about the reliability of a weapon.

34/40.06 The commentor states that nuclear weapons are no longer a deterrence in today's world.

35/10.03 One commentor notes that the Waste Management Draft PEIS predicts a 1,370,000 cubic meter (m^3) increase in waste over the next 20 years. The commentor believes DOE has not changed directions from the past practices of producing massive quantities of nuclear waste.

36/10.06 The commentors state that New Mexico is contaminated in many places and that DOE should not dump anymore nuclear waste in the State of New Mexico.

37/11.06 The commentor believes that DOE downplays the dangers of radiation. The commentor states that DOE should investigate the elevated levels of thyroid and breast cancer in Los Alamos, Bernalillo County, and surrounding towns.

38/11.06 The commentor believes that DOE should initiate a series of health studies to determine the extent of contamination in the State of New Mexico. The commentor believes that these studies have not been carried out because it would be bad.

39/40.15 The commentor states that the Chemistry and Metallurgy Research building should be cleaned up before any new projects are brought to LANL.

40/40.21 The commentor believes that the current system within DOE to shelter whistleblowers is not effective in protecting the whistleblowers.

41/11.27 The commentor states that one nuclear accident would destroy the tourist, manufacturing, and agrarian industries in the State of New Mexico.

42/10.01 The commentor states that DOE plans to continue the production of nuclear waste but does not talk about what they plan to do with the waste. The proposed expansion of Area G at LANL is unacceptable to the commentor.

43/09.02 The commentor states that the emergency response personnel along the transportation routes are not properly trained and equipped to handle an accident involving nuclear materials.

44/43.19 The commentor states we cannot undiscover plutonium.

45/11.06 The commentor believes that the cancer rates in Los Alamos are in line with the cancer rates expected from a town located at an elevation of 8,000 feet (ft). The commentor notes that dosimetry readings and air monitoring data on the Internet prove that the area is safe.

46/40.04 The commentor believes that the fact that the United States has nuclear weapons as a deterrent allows the nonproliferation process to work. The commentor believes that the country needs to keep nuclear weapons because countries like China will still have weapons even if we stopped making weapons.

47/40.21 The commentor believes that the people laid off at LANL were not laid off because they were whistleblowers.

48/30.03 The commentor points to Nevada and its thriving tourist industry as proof that a state can be both a nuclear-weapons state and a tourist state.

49/10.07 The commentor believes that nuclear waste should be centralized into a repository to provide better safety monitoring for the material. The commentor does not believe that there would be significant risk in transporting nuclear materials to a repository.

50/10.01 The commentor believes that the expansion of Area G would not have any adverse affects on the area.

51/10.07 The commentor believes that consolidating waste at one site would lead to increased risks due to the risks involved with transportation of the nuclear materials.

52/40.07 The commentor states that the rationale for designing new weapons to keep the scientists from getting rusty is not enough to warrant continued design of weapons. The commentor also states that we do not need to alter the designs to meet new challenges from countries like Iran and Iraq because the current weapons are already so powerful.

53/11.06 The commentor believes that her two-year old sister, who died of brain cancer, was exposed to radiation from bomb tests over the Pacific.

54/11.17 The commentors believe that New Mexico has received a disproportional amount of the nuclear weapons industry work, and do not want any new DOE work in the state.

55/40.07 The commentor states that DOE is working with the University of New Mexico on new weapons designs.

56/40.06 The commentor cites the successful disarmament of mustard gas, nerve gas, and antipersonnel weapons as examples for the nuclear weapons industry to follow.

57/40.08 The commentors believe that the Stockpile Stewardship and Management Program is driven by scientists and contractors who have personal interests in mind as opposed to larger human goals.

58/40.27 The commentor wants all DOE facilities in New Mexico converted for civilian use.

59/40.29 The commentor believes that right-sizing the Complex is a good idea, but the commentor does not see the reductions reflected in the document.

60/40.38 The commentor asks if a study was done to determine how many active DOE scientists would be needed to reactivate the weapons program (the enhanced experimental programs) if this was needed in the future.

61/07.01 The commentor asks what the cultural and paleontological analysis involved.

62/40.19 The commentor suggests using the same old weapon designs so that the pits at Pantex could be used as replacement pits.

63/32.04 The commentor asks how often a flaw in a pit applies to an entire weapon type.

64/40.06 The commentor believes the continued testing of nuclear weapons violates the spirit of the NPT.

65/41.18 The commentor believes that DARHT, BEEF, and the low-yield explosion facility should have all been a part of the Draft PEIS. The commentor believes these facilities are related to stewardship and should not have been allowed to go ahead without including them in the Draft PEIS.

66/40.12 The commentor is concerned that enormous amounts of taxpayer money have been spent on nuclear weapons in the name of national security when national security is really about having a well-educated, nonviolent, clean, and safe community.

67/41.03 The commentor feels shut-out of the decisionmaking process as it relates to defense spending.

68/40.15 The commentor believes that the country cannot afford to maintain anything other than a minimal stockpile when faced with the immense cost of cleaning up the environmental problems caused by the nuclear weapons industry.

69/40.07 The commentor believes the country is giving impetus to other countries to develop nuclear weapons.

70/09.04 The commentor believes that the PEIS should consider the risks of hijacking when looking at the intersite transport of nuclear materials.

71/41.01 The commentor appreciates the effort that was put into writing the document and holding the public comment meetings.

72/41.08 The commentors believe that the threat of using nuclear weapons and the environmental impacts that result from using the weapons are impacts that should be analyzed in the PEIS.

73/40.07 The commentor is concerned that the Program will increase the risk of the use of nuclear weapons in the future. The commentor believes that advancing the technology of nuclear weapons will make it easier for other countries and terrorists to design a nuclear weapon.

74/40.05 The commentors believe that DOE is assuming a nuclear war fighting posture instead of a deterrence posture. Two commentors believe that the safety of the weapons is not in question and that DOE is orienting the Stockpile Stewardship and Management Program toward examining the explosive yield of the weapons. One commentor states that the deterrence would be just as effective with a lower-yield weapon.

75/40.07 The commentor believes that the Program would make commitments that would indicate to the rest of the world that the country is moving forward with a robust nuclear weapons program.

76/40.08 The commentor believes that a conflict of interest exists within DOE because elected officials are advised by the people who would benefit from the Program the most. The commentor believes that since DOE scientists have exclusive possession of the classified scientific knowledge that is needed to steer the Program, a danger exists that the scientists might act in their own self interest.

77/40.22 The commentor asks why information from the Sandia Stockpile Study was left out of the PEIS. In particular, information stating that weapons defects decrease over time and the statement that nuclear weapons do age but do not wear out and are not allowed to degrade.

78/32.01 The commentor is concerned that establishing pit production at LANL may open the door for increased future production. The commentor wants to know the maximum number of pits that could be produced at the proposed facility.

79/40.36 The commentor believes that DOE should consider the problem-centered stockpile stewardship approach as an alternative. The commentor believes that new facilities should only be built to solve specific problems that are found in the stockpile.

80/41.09 The commentor asks how much money has been spent on the Stockpile Stewardship and Management PEIS.

81/41.08 One commentor is of the opinion that the PEIS should state that any of the stockpile sizes analyzed could obliterate the planet.

82/40.60 The commentor believes that the PEIS should analyze the environmental impacts for a very low stockpile size of 0 to 100 weapons. The commentor feels that the PEIS will be legally deficient until the 0 to 100 stockpile size is analyzed. The commentor notes that the NPT states that we should move towards total disarmament, therefore a 0 to 100 stockpile is a reasonably foreseeable situation.

83/21.05 The commentor believes that NIF is a shiny new bomb factory that should not be discussed in the PEIS. The commentor believes that a separate NEPA analysis is needed for NIF.

84/04.01 The commentor believes that the construction of NIF and other upgrades at Sandia would not comply with the city of Albuquerque water use and discharge policies. The commentor believes that water conservation issues in Albuquerque should be discussed in the document.

85/40.13 The commentor asks for a cost comparison between the proposed surveillance program and a program for replacing components on a periodic basis. The commentor questions the need to have a surveillance program on a very small stockpile.

86/40.60 The commentor believes that an independent agency should decide if the 0 to 100 stockpile is a reasonable alternative for the PEIS.

87/41.01 The commentor asked for at least a month of notice before the public hearings.

PUBLIC HEARING—LAS VEGAS, NEVADA

MARCH 28, 1996—EVENING PLENARY SESSION

1/43.15 The commentor asks DOE how they differentiate with certainty between the phraseology post-Cold War and neo-Cold War. The commentor states that we still have a cold war—it is just a question of who and when.

2/07.02 The commentor states that DOE is taking and has taken land from the Western Shoshones. The commentor claims that DOE has ignored the native peoples who own the land at NTS and Yucca Mountain through treaties.

3/12.02 The commentor states that DOE has polluted Western Shoshone land and that, as a result, cancer rates are high in the area. The commentor urges moving activities elsewhere.

4/21.04 The commentor asks why we must spend $4.4 billion on NIF if we are not developing new weapons.

5/40.10 The commentor would like DOE to consider site location (proximity to population centers) in the decisionmaking and siting process and urges DOE to perform their missions somewhere else.

6/40.56 The commentor asks if there is a No Action alternative for stockpile stewardship and management.

MARCH 28, 1996—EVENING SESSION

1/12.07 The commentor would like to know if social and environmental comments are going to be considered in the *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (Final PEIS), or just scientific and technical ones.

2/43.15 The commentor asks what the dominating, identifying characteristic of the Cold War was.

3/40.07 The commentor questions the fundamental assumptions behind the Program and states that nuclear deterrence should not be a cornerstone of our defense policy. The Program should be based on Article VI of the NPT and consistent with other international treaties such as the CTBT. The commentor states that the following are not consistent with international treaties: 1) NIF and the other new, proposed facilities; 2) the next generation facilities; 3) subcritical testing; 4) reestablishing pit fabrication capability; and 5) new designs for weapons.

4/42.01 – The commentor would like DOE to elaborate on the issue of the Pantex Site-Wide Draft EIS and how it relates to the Stockpile Stewardship and Management Draft PEIS and the Storage and Disposition Draft PEIS.

5/09.01 The commentor states that DOE must consult with local governments regarding the routing of shipments (nuclear waste or otherwise hazardous materials) and must notify interested parties.

6/09.02 The commentor states that the town of Pahrump and Nye County in Nevada have been ignored by DOE, even though transportation routes go through there. DOE needs to provide better oversight and notification regarding shipments through Pahrump and Nye County. Specifically, emergency preparedness must be improved through the addition of trained workers. According to the commentor, Pahrump does not have, demographically-speaking, the population to be trained.

7/09.01 The commentor states that DOE must consult with local governments and citizens along the transportation routes in order to educate them about hazardous shipments and the risks associated with such shipments.

8/21.13 The commentor asks how much NIF is going to cost, and states that whatever the estimate, the actual life-cycle cost will probably end up greater than the estimate.

9/20.01 The commentor asks how much CFF will cost.

10/21.04 The commentor questions the value of NIF in support of stockpile stewardship and states that it costs too much.

11/21.15 The commentor claims that the real purpose of NIF is nuclear weapons research, development, and testing (RD&T), not fusion research.

12/40.02 The commentor questions the rationale for subcritical tests. The commentor explicitly mentions the tests planned for June 18, 1996, at NTS. Specifically, the commentor wonders why the tests are necessary given that the stockpile has been certified to be safe and reliable as recently as November 1995.

13/21.13 The commentor asks if the PEIS calls for a total systems life-cycle cost process for NIF. The commentor states that a "total systems life-cycle cost" study should be performed, and updated every few years, for NIF. This would be similar to what is required of the Yucca Mountain project under the *Nuclear Waste Policy Act*.

14/41.03 The commentor notes that money has already been allocated for NIF in DOE's budget for fiscal year 1997. The commentor asks if it is usual to budget a facility before a NEPA decision. The commentor wonders what would happen if No Action is selected. The commentor states that this gives the perception that DOE has already decided to proceed with construction and operation of NIF, even though the NEPA analysis is not finished. This is not a good perception for the public to have, according to the commentor.

15/40.04 The commentor asks what our security would be if we unilaterally went away from our deterrence and placed our security in the hands of others. The commentor states that the United States should not drop its nuclear deterrence policy, seeing as we have based our security on it. The commentor asks if the impact statement ever relates to the reliability of our cold nuclear powers. The commentor asks if we have ever arrived at a position where we trust either identified opponents, or covert or overt opponents. The commentor asks what it would take to totally dissolve these kinds of efforts. The commentor states that his comments are in response to the concern over cost. Costs can be eliminated by strictly adopting a unilateral disarmament and saying we are going to put our security in the good will and good faith of our friends and enemies.

16/41.01 The commentor states that at the first meeting in Washington, DC for the PEIS, he was told the public education budget for the Stockpile Stewardship and Management Program was $49 million. The commentor states that DOE has not conducted an effective public education program regarding the Stockpile Stewardship and Management Program and other nuclear issues. The commentor urges more outreach and public involvement in the decisionmaking process. Specific recommendations include visiting schools and universities and better advertisement. The commentor claims that DOE has not even planned for a big meeting, as evidenced by the room size.

17/41.01 The commentor states that there was plenty of notice for the meeting and that the number present at the meeting is a reflection of the interest people have.

18/43.19 The commentor states that in the General Accounting Office reports, there were 55 million gallons of highly radioactive waste stored in 177 underground tanks at Hanford. The commentor asks what would happen if the plutonium and uranium were to go critical. The commentor states that this mess has been going on for 50 years and the Federal Government has been characterizing it for 10 years. The taxpayers, the commentor notes, might have to pay $36 billion to clean up this mess. The commentor states that the public has been lied to about Hanford and that the waste there could go critical. The commentor asks when DOE is going to remove the radioactive waste from NTS and ship it to Idaho and other places.

19/40.15 The commentor states that DOE has not cleaned up past contamination and yet feels free to propose another program. The public attitude, according to the commentor, is that there is no hope regarding nuclear waste and contamination. According to the commentor, the public has been beaten down by 50 years of being threatened with extinction. To change this indifferent attitude, DOE must redouble efforts to educate the public and provide necessary resources (trained emergency response workers) to the areas around the sites.

20/43.01 The commentor feels that science has been totally neglected. At the last DOE meeting of the Yucca Mountain board, the commentor asked about colloidal studies. The Federal national laboratory did colloidal studies, according to the commentor, and the commentor now wants to know why the studies were not commercialized upon.

21/04.07 The commentor is fearful that her water will be totally poisoned by all of DOE's activities. The commentor states that radionuclides have been found in the water in Las Vegas.

22/10.12 The commentor mentions the nuclear waste that DOE potentially is going to be bringing from the various laboratories to NTS. The commentor is talking about the temporary storage at NTS that Congress was just debating and that DOE would be in charge of. The commentor asks if costs will increase if this comes to Nevada. The commentor wonders why DOE would bring it to Nevada.

23/40.33 The commentor states that the remanufacturing alternative should not be dismissed and should be analyzed in greater detail.

MARCH 28, 1996—EVENING SUMMARY SESSION

1/43.12 The commentor sees the nuclear issue as an issue for the rest of human time. We are the last generation, according to the commentor, that will have the opportunity to address this issue in a responsible manner simply because we are responsible for it. The commentor also stresses the need to have the best scientists working in the nuclear arena.

MARCH 29, 1996—MORNING SESSION

1/41.03 The commentor notes that DOE states in its handouts that a more informed public leads to better decisions. This line is disingenuous and misleading, according to the commentor, since DOE gets its direction from Congress and the President only, and pays the public little heed. If DOE were to pursue this philosophy of Government decisions are best when they are in agreement with the public, Yucca Mountain would be shut down.

2/40.32 The commentor states that the security at NTS leaves a lot to be desired.

3/41.10 The commentor sees the combined meetings as a step forward. DOE is recognizing that there are some overlaps among programs.

4/13.01 The commentor is concerned about the cumulative impact of different programs on local communities. The commentor urges DOE to adopt a "local community" perspective and create a document which would detail the cumulative impacts (in transportation and waste management, for instance) of different programs. DOE would present this document to the public to increase their awareness of the overall impact of DOE activities.

5/11.03 The commentor believes that DOE uses different risk standards for different programs (specifically Yucca Mountain versus other programs) and that the public does not understand the risks associated with DOE activities. The commentor voices concern over the 300 million curies (Ci) at NTS. The commentor urges DOE to use one risk standard in its analyses and educate the public about the risk numbers and what they mean.

6/09.10 The commentor states that the transportation risk numbers are terrifying.

7/40.45 The commentor states that NTS has been part of any number of programs that could possibly come to NTS, but yet those programs end up going to LANL and LLNL and asks if there is any possibility that NIF may come to NTS.

8/40.13 The commentor states that the Stockpile Stewardship and Management Program should take into account life-cycle costs for waste management since the Program could continue indefinitely.

9/43.19 The commentor asks about the operation at Hanford and the building of another sludge facility at SRS.

10/09.03 Commentors state that there is local concern about the transportation of nuclear weapons parts and materials on the highways of Nevada in general and Clark County in particular. The commentors do not want these types of materials to go through Clark County and urge implementation of a rail system through low-population areas. The rail system could serve a multitude of purposes (e.g., mining) in addition to DOE transportation, and would eliminate the danger of highway transportation. The commentors urge a study of this alternative and state that the rail system would provide equity to the people of Nevada.

11/09.02 The commentor contends that DOE has not provided equal treatment to local communities in regards to transportation issues such as emergency response and preparedness. In particular, the commentor claims that DOE has funded counties in the past, but not tribes, for emergency preparation and response. The commentor urges DOE to reach out to all local communities and inform them of important transportation issues.

12/09.01 The commentor states that it is insufficient to provide only risk numbers to the public. DOE needs a translator for lay people, someone to provide structure and meaning to the analysis and numbers, to make it clear what it means to a person, group, or locality. The commentor would like to comment on the methodology used by DOE to choose transportation routes, parking areas, and the overall transportation plan. This openness would lead to better acceptance by the people who may be affected by transportation issues. The commentor states that people at the local level want to know about the immediate effects of transportation such as the effect of additional truck shipments on traffic patterns and the effect of shipments on property value along the routes. The commentor would like DOE to expand the region of influence beyond 50 mi since these people could be affected by transportation issues as well. The commentor states that DOE should have discussed these issues with the public during the scoping process.

13/09.01 The commentor states that DOE must coordinate with local communities now, before decisions are made, regarding each community's transportation needs (the need for additional roads, for example) and each community's role in the transportation system.

14/40.15 The commentor cites problems with the PEIS process. Specifically, the commentor believes that DOE has not addressed adequately the cleanup of the 300 million Ci at NTS or the fact that the NTS region is becoming a highly populated area. DOE should have addressed these issues earlier in the process, before the preparation of the Draft PEIS.

15/43.17 The commentor applauds DOE's efforts and the fact that we do have a Nation that is willing to put things together, and consolidate nuclear waste and/or enriched uranium and plutonium.

16/30.03 The commentor lists reasons why NTS should continue to receive DOE work: 928 devices were detonated at NTS and tourism did not fall off; Nevada is the seventh largest state; existing infrastructure; and a skilled workforce. The only problem that the commentor sees is transportation.

17/10.07 Commentors state that Yucca Mountain does affect the local communities, but DOE does not want to talk about it. The commentors also note that the NTS Site-Wide EIS omits discussion of Yucca Mountain and suggest that DOE is trying to segregate the issue.

18/42.01 The commentor urges better integration and timing of the NTS Site-Wide EIS, the Stockpile Stewardship and Management Draft PEIS, and the Storage and Disposition Draft PEIS. The commentor states that site-wide decisions will be made before programmatic decisions and that this will limit public involvement and full analysis of the alternatives. The commentor wonders why site-wide decisions will be made before programmatic decisions, especially since the programmatic decisions will have an impact at the site.

19/43.19 The commentor states that the NTS Site-Wide EIS says that there will be one tortoise alive.

20/40.40 The commentor asks what the nuclear arsenal is at now and what DOE is doing to reduce it.

21/43.19 The commentor would like to know, other than plutonium, if there are any other fissionable materials to be stored at NTS.

22/43.19 The commentor asks if plutonium storage would be at the Devise Assembly Facility.

23/30.03 The commentor states reasons to bring programs to NTS: established infrastructure, ideal location, trained workforce, and opportunity to utilize a great national resource.

24/42.06 The commentor asks what kind of capacity level Pantex is at right now and how close they are to reaching that capacity level.

PUBLIC HEARING—OAK RIDGE, TENNESSEE

APRIL 1, 1996—EVENING SESSION

1/40.24 The commentor states that the PEIS has cost millions of dollars, has little value, and lots of errors. The commentor believes that the wrong people came up with the data: the non-knowledgeable, non-production western laboratories, R&D folks. In addition, the commentor states that if DOE is going to talk about highly enriched uranium (HEU), they should start with the Y-12 Plant (Y-12), Oak Ridge Reservation (ORR). The commentor states that the workers at Y-12 ask for a level playing field with accurate data from knowledgeable folks that can and have done the work and can back it up with true facts.

2/40.35 The commentor is concerned with some of the actions to be taken from both an economic and national security standpoint, and feels they may jeopardize the defense posture of the country.

3/40.08 The commentor believes that the study represents a small segment of the nuclear weapons business, and does not represent the wide spectrum of activities and expertise available to do an accurate study. The commentor states that there are hundreds of retired experts, scientists, and craftsmen that are available to participate in such a study, and to focus it on the weapons design laboratories was a mistake.

4/40.23 The commentor states that there has never been a place for stewardship in the nuclear production business and the manufacturing business as there is in the design laboratories. The commentor also states that the quality, configuration management, and integrity of today's stockpile is a result of the production people.

5/40.24 The commentor would like the PEIS to address what DOE intends to do with respect to its explicit responsibility for assurance of continued competence in the Y-12 manufacturing technology.

6/33.02 The commentor would like the PEIS to provide specific examples of the HEU recycling purification or processing technology as well as lithium processing technology that exists to a comparable extent with either of the design agencies as well as Y-12.

7/40.40 The commentor would like to see an analysis of what the limiting factors are in each of the various areas, secondaries, pit production, and HE, and what is the true surge capability and has the Department of Defense (DOD) bought off on the capability.

8/40.33 The commentor questions the assumption in the PEIS that remanufacturing is unacceptable.

9/40.11 The commentor is concerned about our optimism of world peace in the future, and that we are not protecting the option that the world might revert to a more hostile place. The commentor would like the Draft PEIS to discuss the possibility that we may need levels higher than START I Treaty.

10/40.25 The commentor states that an enormous amount of time has been spent analyzing stockpile management and that, in order to have a balanced plan, stockpile stewardship should receive the same level of analysis.

11/40.23 The commentor states that there has been no independent review of the laboratory stewardship plan. According to the commentor, this is important because we are proposing a new way from the way we have done it for 50 years. The commentor believes that before we launch in a new direction, we better study it thoroughly.

12/40.91 The commentor states that the Stone and Webster document referenced in the PEIS should be made available to the public.

13/08.03 The commentor asks what the community is going to do with the used-up workers that have been at Oak Ridge National Laboratory (ORNL) for 20 to 25 years.

14/33.05 The commentor asks how many indirect jobs would be necessary to support the 870 direct jobs. The commentor states that the number of indirect jobs is not found in the summary. The commentor states that Los Alamos would be able to pick up the work of Y-12 workers with only 321 direct and no indirect jobs. In addition, the commentor states that LLNL says they can pick up the work with only 290 direct and 722 indirect jobs. The commentor suggests that these sites have underestimated the work needed. The commentor states that based on these inaccuracies, you have to question the abilities of the people at LANL and LLNL who made the estimates that they really do understand all of the various processes at Y-12 well enough that they can make estimates that are accurate.

15/08.07 The commentor states that there is no detailed breakdown of the job structure and how the waste job structures at Y-12 will be moved to Los Alamos and how many people for each function will be at all three of the sites. In addition, the commentor states there is no description on the function by function basis of how the fabrication process can be implemented at another site, and this oversight of a detailed functional breakdown allows wildly unrealistic estimates at the other sites.

16/10.04 The commentor questions the sites estimates of waste streams. The commentor states that other sites claim theirs is going to be a 102,000 m^3 of sanitary waste and that they will be able to handle these huge volumes of waste with no changes whatsoever.

17/40.08 One commentor states that the Preferred Alternatives Report dated February 1996, pages 5 and 6, detail DOE's decision to give "explicit responsibility for oversight of surveillance" and "for assurance of continued competence in weapons technology to the weapons laboratory." The commentor is concerned about the increased responsibility given to the design laboratories and believes that this would result in duplication of staffs and facilities.

18/33.10 The commentor asks what is the intention of DOE in downsizing of the process development function which is a vital part of the production team.

19/33.01 The commentor is concerned with the transfer of troubleshooting and problem solving from experienced workers at Y-12 to the inexperienced laboratories and believes this would be a duplication of staff and facilities. The commentors ask that DOE not throw away 50-plus years of expertise upon a trash heap in exchange for an unknown quantity and unknown quality.

20/40.24 The commentor contends that the laboratories cannot learn manufacturing anymore than Y-12 can learn the research business. The commentor states that there is insufficient recognition that simply beginning with core competencies is not enough. The commentor goes on to state that no effort finding the workload to continually do the necessary exercising of the production capability, regardless of where it is, is evident. The commentor questions whether this aspect is being examined seriously and states that we have got to have work to keep this competency no matter where it is.

21/40.24 The commentor suggests that DOE should get together with DOD to arrange some work at Y-12 on a routine basis that keeps production capacity exercised.

22/40.24 The commentor is particularly concerned about the laboratories potential role in the weapons component and subassembly testing and inspection.

23/40.07 The commentor believes that the PEIS presumes an enduring stockpile, and that the PEIS undermines our commitment to nonproliferation and destroys our credibility in the international community. In addition, the commentor states that we cannot plan to maintain a stockpile of thousands of nuclear weapons and expect to persuade other countries not to pursue their own capability.

24/33.01 The commentor states that dismantling weapons secondaries, and processing and storing HEU is Y-12's future mission and that Y-12 has the best people to do it. In addition, the commentor believes that part of Y-12's mission is cleaning up and that mission would provide good jobs for the next generation of workforce.

25/21.01 The commentor contends that NIF will only benefit an elite few who pay for it.

26/40.03 The commentor would like clarification on a statement made at the meeting that the United States may sometimes see fit to step out of the CTBT to test underground.

27/11.09 The commentor questions the exposure limits for non-involved and involved workers in table 4.2.3.9–2. The commentor is concerned that the exposure limits for non-involved workers is higher than for involved workers. The commentor wants to know where the decontamination and decommissioning (D&D) workers are in the table. In addition, the commentor is concerned with the quality of estimates to the general public.

28/43.13 The commentor states that in the last couple of years, LANL has rebuilt and installed a number of major capital facilities and hired extensively scientific personnel. The commentor finds it hard to believe that there is enough money in the system as a taxpayer to support extensive R&D work in manufacturing activities at both sites. The commentor believes that the preferred option in the PEIS is extensive and continuous R&D at the design laboratories. The commentor states that NIF and Atlas Facility could only be accomplished by massive capital and operational investments.

29/40.33 The commentor questions why we need to stewardship facilities when it is inherently cheaper and easier to remanufacture the weapons that we have in our present stockpile. This commentor also states that remanufacturing maintains the extensive ties and maintains the capability of the extensive craftsmen that have been in place for some time in the stockpile.

30/40.13 The commentor asks what is the annual cost of the proposed Program for the next decade and how does this cost compare to the cost of a conventional surveillance program, such as the one that has been used successfully for the last 50 years.

31/40.33 Regarding the inadequacy of using remanufacturing, the commentor claims the explanation is superficial and that the public deserves enough information about these things to be able to understand it.

32/40.36 The commentor states that meeting the challenge of stockpile stewardship will be neither inexpensive nor without risk. The commentor would like an explanation as to why the public should be expected to feel good about a plan that appears to be very, very costly and gives us less, not more nuclear deterrent.

33/40.36 The commentor asks why a non-science-based approach to maintain the stockpile was eliminated from the PEIS.

34/40.33 The commentor would like DOE to identify any example and components that Y-12 makes that cannot be remanufactured.

35/40.23 The commentor does not understand why DOE wants to tighten the relationship between the laboratories and the plants. The commentor believes that the laboratories and plants have worked well independently of each other.

36/40.33 This commentor suggests the United States should reconstitute the stockpile like the British by remanufacturing. The commentor states that the benefits of remanufacturing is that it will keep the stockpile young, never out of date, and always certified. In addition, this commentor would like a cost comparison of the approach of replenishing the stockpile by remanufacturing as opposed to science-based cost.

37/40.80 The commentor asks where fabrication of enriched uranium primaries will be assigned.

38/33.01 The commentor states that the loss of experienced staff at Y-12 cannot simply be replaced at the laboratories by increasing their staff with non-experienced personnel. The commentor believes that this does not make economic sense.

39/40.23 The commentor states that research and manufacturing are almost antagonistic in culture, and that combining these two functions runs counter to established methodology in both industry and government.

40/40.15 The commentor is concerned about the planning that is currently taking place that would move facilities and activities over to the DOE Office of the Assistant Secretary for Environmental Management (EM) and what funds are going to be available to take care of it.

41/40.09 The commentor referred to an article in the *New York Times* in February 1996 that stated that DOE was having trouble verifying that sources of weapons grade materials in Russia were actually coming from weapons of dismantlement. The commentor suggests that DOE not only look at downsizing, but what they are going to do in terms of verifying sources of weapons grade materials in Russia.

42/41.10 The commentors state that the public was bombarded with materials related to DOE activities and feel that the public was not given ample time to review these important decisions. Therefore, DOE has not met the challenge to involve local citizens as partners in this process.

43/41.04 The commentor states that the public cannot continue to make decisions in bits and pieces and that they need to be looking at the whole picture.

44/33.01 The commentor believes that the mission should remain at Y-12 because of the existing infrastructure and that if money is to be spent, it should be spent on upgrading the infrastructure at Y-12.

45/10.04 The commentor does not believe that other sites have adequate infrastructure to handle waste without having to build new facilities. The commentor states that ORR has available infrastructure in the private sector that are outstanding and a model for the world.

46/41.03 The commentor believes that the decisions to be made in the PEIS were predetermined.

47/08.16 The commentor states that the PEIS does not address the social impacts that go beyond the direct number of jobs, such as unnecessary infrastructure and empty schools.

48/32.02 The commentor states that Rocky Flats spent 10 years and tens of millions of dollars on the near-net shape casting without success due to the complex metallurgical phase structure of the plutonium system. The commentor asks why we think that better computer modeling will change the problem.

49/08.13 The commentor contends that there are inconsistencies between the PEIS (figure 4.2.3.8–1) and the Preferred Alternative Report (page 39) regarding manning levels. The commentor would like to know where the numbers on these pages came from. In addition, the commentor asks if the public is to judge DOE's viability on the basis of downsizing to 870 in 2003 and then holding steady, like it is put in the Preferred Alternatives Report, or are they supposed to believe that there is going to be a continual decline in the Y-12 level for the next 35 years.

50/08.03 The commentor is concerned about the database used for the socioeconomic study and the financial impact studies which show so little impact on the ORR region.

51/40.92 The commentor refers to table 3.7.1 and asks if anyone has placed these numbers into a common reference frame. According to the commentor, the LANL direct numbers, utility requirements, and some of the discharge numbers do not make sense.

52/02.01 The commentor referred to tables 3.4.4.2–2 and 3.4.4.3–2 and pointed out that there is an order of magnitude difference in the estimates for the power requirements for Y-12 and LANL to do the same job. The commentor does not understand why Y-12 would use 1.5 billion liters (L) of water and LANL only 55 million.

53/08.07 The commentor did not see addressed in the PEIS the number of indirect people needed to support secondary and case workers.

54/40.47 The commentor would like to know if the sites followed any standards when submitting numbers for the PEIS.

55/41.09 The commentor is concerned with the cost of the PEIS and would like DOE to spend taxpayer money more frugally.

56/08.01 The commentor states that numbers in table 3.7.1–5 imply that people required for D&D would provide an immediate amelioration of the socioeconomic impacts. The commentor is concerned about when the D&D work is budgeted for. The commentor states that the D&D on building 9201-4 has been scheduled for 15 years and does not seem to be a priority. The commentor is also concerned about who will be scheduled to do the D&D work (Lockheed-Martin people or contract workers), and how soon it would have to be scheduled in order for Lockheed-Martin workers to be kept on the payroll.

57/40.08 The commentor states that the PEIS attempts to justify the stewardship facilities which will primarily benefit the western laboratories.

58/40.01 The commentor states that this justification is presumptive in that it assumes that these facilities will work perfectly and will preclude the need for test devices at NTS. The commentor is skeptical about using new and unproven facilities and is concerned for the future safety and reliability of the Nation's stockpile.

59/40.11 The commentor believes that a deficiency in the PEIS is that it assumes that START treaties will be honored. In addition, the commentor believes that the PEIS should include plans to support a larger stockpile.

60/40.24 The commentor believes that DOE needs to bring in more nonnuclear work to Y-12 to keep the arms program strong.

61/40.13 The commentor states that costs shown at the meeting do not show a very good correlation between cumulative costs and annual costs. The annual costs were decreasing markedly for the Program, but the cumulative costs showed only a marginal decrease in the overall cost of the Program over a period of years which did not seem consistent.

62/40.08 The commentor would like know how DOE would equate the statement raised at the Armed Forces Subcommittee last month by DOE's spokesperson, Mr. Smith, where he says, "Today we do not have the capability to manufacture replacements for warheads that comprise our existing stockpile." The commentor would also like to know if DOE concurs with the proposed slashing of production capabilities in order to build up further the duplicated and larger weapons laboratories basic programs.

63/40.38 The commentor would like to know what DOE has done to downsize the laboratories consistent with the smaller stockpiles and with the loss of the new weapons design and testing missions.

64/04.02 The commentor states that section 4.6.2.4 shows that LANL water resources will be used up by the year 2000, and wonders how LANL can produce weapons such as Y-12 has done without a water supply.

65/11.10 The commentor questions the accident history given in section 4.2.2.9, Accident History, which states that the most noteworthy accident at Y-12 resulted in temporary radiation for a few ORR employees. The commentor would like to know whether the employees involved in this accident view its effects as temporary radiation sickness.

66/40.33 The commentor states that the way to assure that remanufacturing does not work is to let design engineers do it.

57/40.13 The commentor would like the PEIS to address the difference in worker experience between Y-12 and the laboratories and the cost of having to train a new work force.

68/33.01 The commentor states that the PEIS gives the impression that one reason for involving the laboratories much more in production work is because production facilities are old and use old processes. The commentor states that the manufacturing skills at Y-12 are state of the art and facilities have been regularly upgraded.

69/33.01 The commentor believes that the people at Y-12 are unique craftsman and that dismantling Y-12 would be doing away with a natural resource.

70/41.06 The commentor believes that the proceeding is procedurally defective. The commentor states that by putting the pen in the hands of one of the locations we have created an environment where there is a lack of credibility in the entire report process and the conclusions made, especially when there are perceived advantages which go to the locations where that authorship takes place. In addition, the commentor suggests that DOE obtain competent independent evaluations, not location centered, but more broadly centered, using the expertise of people attending the meeting and elsewhere in the Nation.

71/04.03 The commentor questions section 4.2.3.4 and would like to know what the increased operating requirements of existing secondary and case fabrication facilities are in the No Action alternative.

72/40.23 The commentor suggests that efforts should be directed towards understanding the processes that we are using and devote all of our efforts to a thorough understanding of what we are doing rather than driving our program by things that are no longer relevant.

73/21.01 The commentor would like to know if DOE can identify a single past safety or liability issue that NIF would provide the ability to evaluate.

74/40.23 The commentor believes that design experts have little appreciation for what is involved with producing weapons parts. The commentor states that certification of weapons parts requires a world of expertise. In addition, the commentor believes that DOE should move carefully when making a decision.

75/08.01 The commentor states that Summary section S.4.1 says impact of the Y-12 downsizing will be mitigated by the creation of approximately 1,308 new D&D jobs and 1,830 new indirect D&D jobs. The commentor would like to know specifically what jobs are going to be created and if Washington agrees that these new jobs are going to be funded. If they do intend on funding the new D&D jobs, how many years can the level of expenditure continue once it starts. In addition, the commentor would like to know if the cost estimates reflect the cost of putting the buildings at Y-12 into the D&D program.

76/40.23 The commentor believes that combining the laboratories and production plants is unwise. The commentor states that the mission of a laboratory is to seek improvement and change, and that of manufacturing is to produce a reliable and saleable product. The commentor does not recommend placing a manufacturing facility in either LANL or ORNL. The commentor believes that the missions are too different.

77/40.24 The commentor states that the PEIS has put an emphasis on the design side. The commentor believes that there must be a continued emphasis on manufacturing technology and that cutting back on manufacturing technology in order to add more to R&D efforts is asking for trouble in the long term.

78/43.13 The commentor states that Los Alamos has been billed as "the little Oak Ridge" for quite some time and it looks like a $600 million project. The commentor would like the PEIS to discuss whether Los Alamos has received $600 million for a capital project.

79/40.24 The commentor states that if money is going to be spent that DOE should spend money on upgrading buildings at Y-12 with better heating and air conditioning systems and the like.

APRIL 2, 1996—MORNING SESSION

1/41.10 The commentor would like to know when DOE will make a decision on whether more time and funding will be made available for independent review of the Draft PEIS.

2/41.10 The commentor does not believe that the combined meetings reduced the burden on the public. The commentor states that there was a meeting at the high school going on at the same time as the public meeting that many people would have liked to have attended.

3/40.36 The commentor would like more discussion about why there is a need for improvement in the current process for a Complex that is not going to be building new weapons.

4/40.01 The commentor states that every time changes have been made in the process, we have only been able to verify that change using underground testing. The commentor questions whether designers will be happy with anything less than underground testing to satisfy them to all the new processes that are being developed.

5/40.25 The commentor feels the analysis of the stewardship facilities is inadequate and that the schedule will not allow for more time to be spent on the stewardship side of the PEIS.

6/08.11 The commentor is confused about the difference between direct and indirect jobs.

7/40.28 The commentor would like to know what plan the PEIS is based on and whether it is still the Stockpile Stewardship and Management Program plan, dated May 1995, and whether this plan has undergone significant revisions.

8/41.03 The commentor referred to a document issued by the White House titled, *National Security Science and Technology Strategy*, which says, "The nuclear weapons laboratories will assume more responsibility for production and remanufacture capability in addition to their responsibility to scientific understanding." The commentor states that the PEIS refers to the White House as the source of DOE guidance and does that mean that DOE or the White House has already made decisions on how the Complex shall operate. The commentor believes that decisions on the Stockpile Stewardship and Management PEIS have already been made (predecisional) and that this is a violation of NEPA.

9/40.24 The commentor asks what assurance they have that the number of employees estimated for the downsized Y-12 mission represents enough capability for DOE to do its job.

10/41.10 The commentor is concerned that the PEIS process is driven by pressure and schedule.

11/08.17 The commentor questions the sentence in section 4.3.2.8, Socioeconomics; "Operation of the downsized facility at Y-12 in the case surge mode will require 870 direct jobs and 2,448 support jobs" and the figure 4.2.3.8–1. The commentor states that figure 4.2.3.8–1 shows 2,250 Y-12 and support jobs in the year 2003. The commentor asks if this number is supposed to be 870.

The commentor would like to know if the erroneous data in figure 4.2.3.8–1 was the basis for the financial and socioeconomic analysis.

12/08.01 The commentor would like DOE to provide a simple table in the PEIS that would summarize the socioeconomic impacts and would begin in the year 1996 and go to 2030. In addition, the commentor would like the table to show direct, indirect, and support jobs and any funding that would support these jobs. The commentor would like this table before the comment period ends.

13/08.11 The commentor would like definitions of direct, indirect, and support jobs in the glossary of the PEIS.

14/40.34 The commentor suggests that we need to look at DOD and DOE policy in regard to what we really mean by stockpile reliability at this point in time. The commentor believes our definition of reliability dates back to when we had thousands more weapons.

15/33.08 Regarding the proposal to pre-produce enough uranium components and lithium hydride components to last for 100 years, the commentor refers to the time when it was decided to pre-produce separated lithium and put facilities on standby. The commentor states that a few years later the technology was completely lost, and that this may be a consequence of pre-producing uranium and lithium components.

16/40.60 The commentor refers to a statement in the PEIS that there is no stockpile size at which the size of the stewardship facilities could be made smaller. The commentor states that this is an illogical statement because it implies that any nation that has any size of stockpile would require the same size facility as we have. The commentor states that if some time in the future the number of weapons is going down to thousands or hundreds, at some point that statement is no longer going to be true. The commentor states that the public can only accept the PEIS as representing the range of between 1,000 to 6,000 weapons, and that any other level would require a reexamination of policies.

17/40.13 The commentor is concerned with how DOE is allocating its resources. Specifically, the commentor refers to the LANL budget of up to $1 billion over several years that would go towards facilities that already exist. The commentor suggests that this duplication should be looked at by the General Accounting Office.

18/42.17 The commentor asks if DOE at this time assumes that as material is transferred on the books from strategic into surplus, that it is then covered by the current EIS on surplus HEU or will there be additional need for documentation to look at the additional material as it gets transferred over.

19/33.01 The commentor questions the dismantlement process and how much of it is going on at Y-12. The commentor would like to know how much real dismantlement we have going on, and how much material we have and in what forms that potentially pose different kinds of risks, such as proliferation risks, worker risks, or public health and safety risks.

20/42.16 The commentor states that the Storage and Disposition Draft PEIS and Stockpile Stewardship and Management Draft PEIS contradict each other in that the Storage and Disposition Draft PEIS indicates that ORR is considered for plutonium, but the Stockpile Stewardship and Management Draft PEIS states that plutonium would not be located anywhere it is not already located. Conversely, continues the commentor, one of the sites that was not mentioned at all was LANL. The commentor wants to know why LANL was not included in the Storage and Disposition Draft PEIS.

21/40.27 The commentor refers to the Notice of Intent for the Stockpile Stewardship and Management PEIS and states that descriptions of LANL and LLNL were identical. The commentor states that this suggests there is a duplication of effort and raises the question of whether the existence of two laboratories is necessary. The commentor would like to know how DOE can justify the continued operation of both LANL and LLNL.

22/21.20 The commentor is concerned that the decision to locate NIF at LLNL is a political decision. The commentor does not support NIF, a $1 billion plus facility, and does not support the existence of LANL and LLNL. The commentor feels these facilities are a waste of money.

23/40.23 The commentor states that the manufacturing expertise lies at the production plants. The commentor is concerned with transferring manufacturing to the laboratories where the expertise does not exist.

24/08.18 The commentor would like to know the composition or breakdown of the 870 direct jobs under the downsized Y-12 mission including: the breakdown of skills for the 131 crafts workers, how many of the 870 people will be involved with quality and certification, and how many people will be involved with process development.

25/33.01 The commentor would like Congressman Wamp's speech emphasized in the PEIS, particularly the comment that Secretary O'Leary made to him. When responding to Congressman Wamp's concern over the threat of relocating Y-12's production capabilities, Secretary O'Leary stated that it was a "no brainer," that we should leave the weapons production capabilities at Y-12 and downsize in place. The commentor also states that the PEIS is misleading and would like that corrected.

26/41.10 The commentor states that getting a copy of the Draft PEIS was difficult and that they did not have enough time to adequately review the document.

27/42.01 The commentor states that the PEIS is extremely difficult to interpret, and suggests that in the future documents are simplified so that there is not repetitive information from one section of the document to another which are sometimes contradictory to each other.

28/33.01 The commentor states that although the PEIS designates Y-12 as the preferred alternative for secondary and case fabrication, DOE reserves the right to change for the Record of Decision (ROD) and this creates doubt.

29/40.23 The commentor is concerned about the quality of the stockpile if the manufacturing capabilities are transferred to the laboratories.

30/40.23 The commentor states that the PEIS leads you to believe that laboratory people would be located at Y-12 and would direct development work. The commentor would like to go back to the old way of doing business, and does not want the laboratories telling them how to do their job. The commentor states that if you let them do that, it will screw things up.

31/08.07 The commentor would like to know how LANL and LLNL propose to pick up the people to take over the secondary and case fabrication mission. The commentor states that manufacturing these weapons is a very difficult job and that you cannot hire machinists off the street to do this type of work.

32/41.10 The commentor would like to know if DOE has ever considered using an independent panel of retired designers to get an unbiased look at the Program and issues of safety and reliability.

33/08.01 The commentor believes that the discussion about D&D jobs should be taken out of the PEIS because it may be 10 to 15 years before these jobs are available to the unemployed.

34/40.23 The commentor feels that Y-12 should be given work to maintain their capabilities.

35/40.04 The commentor believes that we should have the ability to upsize if our national security is threatened.

36/40.03 The commentor asks if he is to understand that there will be no weapons testing except under dire circumstances and that there would be no new weapons designs.

37/40.23 The commentor suggests that the problem we face is not to let the weapons become different than the weapons database. The commentor states that this requires that we thoroughly understand the manufacturing process in a way that is better than we have in the past when we could test so that we can maintain specifications without testing. The commentor suggests that there is a need in the manufacturing process for a new effort; namely to stabilize production so that those weapons perform as they were intended in spite of the inadvertent changes in manufacturing processes which occur along the way. The commentor states that we do not need to worry about the weapons database. The commentor states that DOE needs to be concerned about the stability of the production process.

38/41.05 The commentor stated that the axis of one of the charts that was handed out at the meeting was not labeled. The commentor states that this makes it difficult to compare numbers in reports.

39/08.13 The commentor is confused about the number of employees required for the downsized Y-12 under single shift and three shift, and at which level will funding be available.

40/08.01 The commentor refers to Admiral Gustavson's testimony to the Senate Armed Forces Subcommittee that one of the plans to mitigate downsizing is to move people from the K-25 site (K-25) at ORR. The commentor is concerned that people from K-25 are included in the D&D that is planned for Y-12. The commentor is concerned that we are moving people and money and then losing it somewhere else.

41/40.24 The commentor states that there are a number of components in the weapons of which the functional aspects are sometimes specified by the design agencies and for which Y-12 proposed the materials, developed the processes, and developed the certification processes even when some of the certification processes proposed by design agencies were not functional. The commentor doubts that there is expertise with these materials elsewhere.

April 2, 1996—Evening Session

1/40.13 Several commentors are concerned with the cost of the stockpile stewardship facilities, and wonder if current facilities could be used.

2/40.13 The commentor is concerned that with the current cutbacks in the Federal budget, spending money on new facilities is counterproductive.

3/40.07 The commentor states that the stewardship facilities are irreconcilable with the stated goals of the NPT of the United States. The commentor believes that the development of these experimental facilities creates a potential for a new breed of competition among the nuclear weapons states.

4/40.15 The commentor states that stockpile stewardship would add extra environmental burdens. The commentor states that both environmental burdens and health impacts of the Oak Ridge community from past activities have not been adequately addressed.

5/40.85 The commentor states that the scope of the PEIS is too narrow and that it did not consider the full range of facilities actually being proposed and built into the guides of the stockpile stewardship.

6/41.18 The commentor states that the explosive experimental facilities at NTS and DARHT at LANL were not addressed in the draft. The commentor also states that DOE should justify each new and existing facility in light of the end of the Cold War and the true national security needs that we are facing.

7/40.14 The commentor states that the PEIS did not address the need for underground testing at NTS. The commentor believes there is no technical justification to keep the underground part of NTS open. The commentor states that closing the test site will help prevent the spread of nuclear weapons by demonstrating U.S. resolve to end its weapons-development program. In addition, the commentor believes that it would be fiscally prudent.

8/40.07 The commentor questions whether DOE is proposing to enhance the plutonium pit manufacturing capability at LANL. According to the commentor this would go against NPT goals.

PUBLIC HEARING—KANSAS CITY, MISSOURI

APRIL 9, 1996—AFTERNOON SESSION

1/08.04 The commentor recognizes that downsizing the nonnuclear fabrication mission will result in a loss of jobs over time. The commentor points out that there is also the possibility of additional work coming in. The commentor wants to know if it is possible to maintain a higher rate of employment in the Kansas City area.

APRIL 9, 1996—EVENING SESSION

1/31.01 The commentor is concerned about the loss of expertise and skill base as a result of downsizing at the Kansas City Plant (KCP).

2/31.01 Commentors state that KCP should become a benchmark for other sites within the Complex on labor management.

3/31.01 The commentor wants to know what level of flexibility is built into decisions should things change in the future.

4/31.01 Commentors support the Secretary of Energy's decision to downsize the nonnuclear fabrication mission at KCP rather than transfer this mission to an alternative site.

5/40.16 The commentor recognizes the significance of downsizing and wants to know if the PEIS discusses a transition finding similar to that at the Mound Plant. For example, reuse of plants, refitting, revised missions, and the like that could possibly give futures to some displaced workers.

6/08.04 The commentor is aware that with downsizing at KCP there will be a possible loss of 300 to 900 jobs. The commentor wants to know what can be done, what resources can be utilized, and how the business community can help to lessen the number of jobs lost.

PUBLIC HEARING—LIVERMORE, CALIFORNIA

APRIL 11, 1996—AFTERNOON SESSION

1/40.41 The commentor wonders why a classified appendix supporting the need for plutonium-242, which the commentor suspects will be stabilized at SRS for future weapons R&D, was referenced.

2/41.05 The commentor states that DOE should have had a meeting in Oakland, in addition to Livermore, for similar reasons Santa Fe hosted a public meeting.

3/21.12 The commentor states that DOE's description of NIF as a nonnuclear facility may be misleading since there will be a deuterium-tritium reaction in this facility which is a nuclear reaction.

4/41.13 The commentor is interested in knowing DOE's definition of the term "minimal" with respect to environmental impacts.

5/40.06 The commentor states that NIF will cost approximately $40 to $50 billion. The commentor states that 90 percent of people polled favored worldwide cuts in nuclear weapons, 82 percent prefer the elimination of most or all nuclear weapons, and 82 percent would prefer to have no nuclear tests at all (including aboveground and oceanic testing).

6/10.03 The commentor feels the amount of nuclear waste generated from the nuclear weapons program is a much greater problem. The commentor states that the Waste Management Draft PEIS states that over 1,370,000 metric tons of low-level waste (LLW) and 144,000 metric tons of mixed LLW will be produced as a result of the Program. The commentor notes that the figures for these waste values are not consistent between the Stockpile Stewardship and Management Draft PEIS and Waste Management Draft PEIS.

7/40.12 The commentor feels the money that would be spent on the Program, specifically the $40 billion allocated for NIF, should be spent on schools, housing, infrastructure, conservation, renewable energy, environmental cleanup, and the like.

8/40.05 The commentor feels the United States should not act as a "national security state" which threatens the rest of the world by continuing nuclear weapons programs.

9/40.06 The commentor feels the United States should concentrate on dismantling all nuclear weapons.

10/40.07 The commentor states that experts have said the stockpile is safe and reliable and may exist as it exists today. The commentor feels the proposed facilities may encourage proliferation by providing new weapons designs and does not abide by the NPT.

11/11.11 The commentor states that workers at LLNL are 400 percent more likely to develop malignant melanoma, a skin cancer, than the general public. The commentor contends that the children of Livermore are six times more likely to develop skin cancer as a result of activities at LLNL. The commentor states that these figures were obtained from the Department of Health Services.

12/40.12 The commentor points to the former Soviet Union's experience in Chernobyl as an example of why the United States should discontinue nuclear weapons research. The commentor suggests the money should be spent to research renewable, nonpolluting energy sources.

13/21.06 The commentor feels NIF at LLNL will not result in adverse impacts. The commentor believes the expensive costs justify the need to eliminate underground nuclear testing and develop enhanced future fusion projects.

14/40.13 The commentor expresses confusion regarding the period of time during which the $40 billion expense would be incurred.

15/21.06 The commentor notes that the yearly cost of the NIF project is a reasonable expenditure.

16/40.04 The commentor states that for 25 to 30 years, critics denounced the research activities of LANL and LLNL fearing a nuclear "holocaust." The commentor states that the Soviet collapse occurred as a result of their inability to keep up with U.S. technological advances, especially the advances at LANL and LLNL. The commentor believes that nuclear weapons designers contributed 10 times more to peace than all of the nuclear critic groups put together.

17/41.03 The commentor expresses disappointment that DOE did not consider comments and suggestions from the scoping meeting.

18/40.36 The commentor believes there is no new need for weapons design and that a "passive" program may maintain the stockpile safely.

19/40.25 The commentor expresses disappointment that DOE has published an *Analysis of Stockpile Management Alternatives* report and a *Stockpile Management Preferred Alternatives Report* but has not completed a comparable analysis for stockpile stewardship. The commentor states that DOE should complete a parallel document regarding stockpile stewardship.

20/40.31 The commentor states that a document posted on DOE's World Wide Web Defense Programs (DP) Home Page from the Office of Research and Inertial Fusion on January 31, 1996 implied that the United States will continue to introduce emerging technologies into weapons application, develop new designs, and modernize existing weapons for "deterrence" purposes. The commentor states a specific example of current development, the B-61 Modification 11 "earth-penetrator" is currently under development, demonstrating the United States is actually developing new weapons.

21/43.16 The commentor feels that a weapons program is needed to ensure national security.

22/40.44 The commentor believes that the NPT and CTBT depend on the Stockpile Stewardship and Management Program, especially NIF.

23/21.07 The commentor feels NIF is justified for the potential of future fusion energy projects, considering there may a lack of natural resources in the near future.

24/21.06 The commentor states there is broad support for the PEIS, especially the NIF project.

25/40.34 The commentor states that there are 8,500 strategic weapons which need a condition of safety but reliability issues are only relevant if the United States actually plans on using these weapons.

26/40.13 The commentor feels that DOE could continue with past and present stockpile management procedures for cost efficiency purposes.

27/40.07 The commentor feels the Program is a dangerous and ambitious plan since it promotes new weapons design and, therefore, contradicts the CTBT. The commentor believes the United States is legally committed to disarmament since it has signed the NPT.

28/42.03 The commentor expresses concern that new programs such as bringing spent nuclear fuel rods from other countries and wastes produced from new programs will contribute to waste management problems since there is no place to dispose of this waste.

29/40.15 The commentor believes there are other more important issues such as the disposition of waste and spent nuclear fuel that the scientists should help resolve.

30/40.13 The commentor feels the United States should let the stockpile exist as it currently exists, spending several orders of magnitude less money.

31/41.18 The commentor believes DOE "arrogantly" decided which alternatives are reasonable and does not agree with the justification for the No Action (Summary, section S-4) alternative as an unreasonable alternative.

32/40.85 The commentor points out that DOE apparently considers an expansion of experimental facilities as the only reasonable alternative as evidenced from Summary table 3.6.1 which only presents the capabilities of the enhanced facilities.

33/42.04 The commentor also notes that the Lyner facility remains classified so that the "enemy" cannot determine the equation of state information yet there is no way to determine the environmental impacts of this project.

34/40.15 The commentor states that environmental cleanup expenditures are being delayed due to classification of projects which hinders the analysis of environmental impacts.

35/01.02 The commentor also notes that the maps of the NTS site presented in the document need to depict Area 51.

36/40.34 The commentor feels that the document presents several misused terms and euphemisms which are intended to deceive the public. The commentor feels the following terms should be changed or decoupled so that there would be less acceptance of the proposed program: 1) "safety and reliability"—the commentor feels this phrase translates into the expected blast of a nuclear weapon must be greater than 90-percent yield. The commentor feels reliable weapons are not required and that the stockpile may be maintained with existing technology. The commentor feels that greater unreliability may in fact discourage proliferation. 2) "flexibility"—the commentor feels this term translates into continued development of new nuclear weapons. 3) "modification"—the commentor feels this term applies to the construction of new nuclear weapons. 4) "national security"—the commentor believes this euphemism destructs "true" national security which is the environment. The commentor feels that the Nation is less secure because the money proposed for the Program may be used for poverty, education, and waste management.

37/10.08 The commentor wonders if the PEIS includes an analysis of the overall waste management plans at LLNL for the next 20 years.

38/10.09 The commentor notes that in addition to waste created from the Program, there is a proposal to construct an incinerator to handle mixed nuclear waste at Site 300.

39/40.12 The commentor feels millions of dollars are spent needlessly and that this money would be better spent on health care, education, renewable energy programs, and solar energy.

40/40.06 The commentor feels the document should have a broader view of evaluating environmental impacts and should assess these impacts to the country and the rest of the world.

41/40.06 The commentor believes that the United States should consider disarmament by the end of this century and the United States currently does not display the appropriate sense of urgency to the rest of the world.

42/40.15 The commentor would like the United States to use its best minds to focus on cleaning up existing nuclear waste.

43/43.19 The commentor suggests DOE remove the atomic symbol from the official seal.

44/40.50 The commentor disapproves of the Stockpile Stewardship and Management Program.

45/21.15 The commentor states NIF will continue weapons development and expresses opposition for that reason.

46/11.14 The commentor would like the PEIS to address the impacts which would result from a nuclear explosion, including the resulting deaths, the cancers created, and the spread of radioactivity.

47/10.03 The commentor is concerned about the nuclear waste that will be generated by this Program and the increased risk of waste production.

48/11.11 The commentor states that the breast cancer rate in Livermore is the highest in the nation.

49/40.13 The commentor believes the Program is driven by U.S. greed and fear that it may not be a leader and dominate economic markets. The commentor feels the United States should invest in peace, trust, and equality.

50/40.05 The commentor states the underlying planning for the Program is the Nuclear Posture Review (NPR) which is based on the first strike capability of U.S. nuclear weapons and that is why these weapons require "reliability."

51/40.50 The commentor urges DOE to consider the morality of the threat and use of nuclear bombs that kill.

52/40.06 The commentor feels that the United States could strengthen its national security by cooperating with Russia and discontinuing to rely on nuclear weapons and energy. The commentor feels U.S. reliance on nuclear weapons and energy is contradictory to the Nation's public health and economic concerns.

53/40.50 The commentor feels that the Program, including NIF, is dangerous and morally wrong. The commentor feels it is a waste to use "human genius" in this manner since that same genius could be used to solve the growing problem of inequality in the world. The commentor believes the

United States is misinforming people by saying the United States will not be producing and testing nuclear weapons.

54/40.12 The commentor points out that the Program is more costly than Star Wars while helpful social programs are being cut. The commentor states that from 1985 to 1995 there was an increase of chronically hungry children from 500 million to 800 million and that the money for the Program could be spent on these children.

55/40.06 The commentor states that a document just issued on political responsibility reports an active commitment by the United States to worldwide disarmament for moral reasons.

56/43.08 The commentor suggests that the United States take a leadership role in the elimination of anti-personnel mines but realizes U.S. economic motivation of the production of mines may make this difficult.

57/40.50 The commentor feels the Program should be discontinued.

58/41.12 The commentor feels DOE has prepared a "minimum" PEIS by rejecting many of the alternatives proposed by the public in the scoping process.

59/40.31 The commentor points out that the United States claims that it has halted new testing but a lot of public information defies this. The commentor points out that in addition to DOE's World Wide Web site, other documents, including *FY '97 Conceptual Design and Assessment: Exploration of Concepts and Technologies that Offer Potential Options for Meeting Future National Security Requirements and Missions*, detail U.S. plans to continue prototyping, experimentation, and conceptual designs.

60/40.37 The commentor feels today's weapons policies are not the only important factor to consider, especially since the Program extends approximately 30 to 40 years into the future.

61/40.37 The commentor feels since policy may change over the next 40 years the PEIS should analyze the capabilities of the proposed facilities and the possible effects this may have on international proliferation.

62/41.12 The commentor feels the NEPA process requires by law a range of reasonable alternatives so the public may evaluate an evenhanded analysis which includes many analyzed alternatives and their ramifications on the environment and international policy.

63/41.11 The commentor feels the PEIS represents a sequence of site-specific reviews which is not an adequate EIS.

64/40.05 The commentor believes the U.S. policy is a policy which relies on violence, evident by a large military expenditure and the continued development of nuclear weapons.

65/40.06 The commentor recommends worldwide disarmament.

66/40.06 The commentor believes the United States lacks the courage to work at a concrete time-frame with other nations to get rid of nuclear weapons.

67/40.60 The commentor wonders whether the PEIS evaluates a stockpile level which is less than the START II levels.

68/43.19 The commentor wonders whether the neutron source that is part of modern warhead design is the tritium boosting or yet another source of neutrons.

69/40.15 The commentor notes that approximately $320 billion is required for cleanup costs within the Complex and that the $40 billion required for the Program will subtract from funds allocated for cleanup.

70/40.60 The commentor suggests evaluating the following alternative which is more reflective of the minimum destructive power required for deterrence: approximately 100 strategic warheads multiplied 10 times to factor in overkill for a total of 1,000 weapons and completely eliminating theater and tactical warheads. The commentor proposes the stockpile would not require new facilities or weapons designs rather a record of detailed designs of the existing weapons would suffice. The commentor states that there would be no need for weapons effects testing and a less stringent reliability requirement. The commentor notes that continued assembly and disassembly (A/D), secondary case components, and nonnuclear components operations would be necessary because of potential aging effects. The commentor points out that there would be no intrusive pit reuse and minimal nonintrusive pit reuse and tritium recycling only.

71/40.31 The commentor states that advanced technology as a substitute for underground testing is not the solution to maintaining national security. The commentor notes that the document found on DOE's network confirms DOE has had plans for at least 15 years to develop substitutes for underground testing while continuing the arms race. The commentor feels that this is the wrong approach for security and humanity.

72/40.60 The commentor feels DOE should evaluate a zero-level stockpile.

73/40.07 The commentor notes that the United States has committed the nation to disarmament by agreeing to the NPT, yet current national nuclear weapons policy contradicts the goals and morals of the NPT.

74/21.20 The commentor feels troubled that elected officials lobby for NIF at LLNL on the basis of jobs and economics.

75/40.50 The commentor feels people should look at the global implications and morality of the Program.

76/40.12 The commentor feels the United States is spending an inordinate amount of money on the development of nuclear weapons and that the money could be devoted for "positive" uses.

77/40.07 The commentor notes that despite the disappearance of a Soviet threat, the United States continues to maintain a dangerous policy of maintaining adequate nuclear force.

78/21.10 The commentor feels NIF at LLNL will not result in prosperity, jobs, and increased national security like some members of the public believe.

79/40.07 The commentor notes that the original idea of the CTBT was to eliminate nuclear weapons and nuclear weapons research but the United States is instead undertaking a policy which continues the nuclear weapons testing.

80/21.06 The commentor supports NIF and describes the need for NIF as the result of an evolutionary process towards how the world will deal with nuclear weapons in this era. The commentor feels NIF represents a gradual realization of a slow process which will lead to the eventual cessation of nuclear weapons production.

81/21.17 The commentor states that discussions to determine the impacts of NIF on proliferation have occurred. The commentor also indicates support for NIF.

82/40.44 The commentor feels although this process is slowly moving towards peace, that the United States is moving in the right and responsible direction.

83/21.07 The commentor feels NIF affords many scientific benefits in addition to weapons research.

84/21.06 The commentor feels that since NIF does not contribute to proliferation, secondary benefits such as economics are just an added bonus.

85/40.50 The commentor feels nuclear weapons are the greatest public health hazard.

86/21.15 The commentor likens NIF to a "super-oven" and is opposed to locating the facility at LLNL.

87/40.12 The commentor feels a fraction of the funds allocated for NIF would be better spent on health care and education.

88/40.14 The commentor notes that on the eve of the CTBT, instead of closing NTS, DOE hired Bechtel to run and operate NTS for $1.5 billion over 5 years and Secretary O'Leary authorized 6 subcritical tests.

89/40.39 The commentor feels the zero-level stockpile is a reasonable alternative.

90/21.07 The commentor feels the purpose of NIF is to advance nuclear weapons science and that DOE would like the public to believe that it is a civilian program. The commentor notes that if NIF is to be used for civilian purposes like DOE claims, then let private companies compete for the funding of this civilian program.

91/40.07 The commentor points out that DOE cleverly decoupled the terms "design" and "development," and "nonproliferation" and "disarmament." The commentor feels the United States says there are no plans to produce and deploy new weapons but design activities are occurring to some extent.

92/40.07 The commentor feels DOE, at the very least, intends to make weapons modifications.

93/40.07 The commentor states that the United States is basically sending a message to the international community that implies the United States may maintain nuclear weapons forever while the rest of the world cannot. The commentor points out that Article VI of the NPT specifically mandates worldwide disarmament.

94/40.05 The commentor notes that DOE has coupled the terms "deterrence" and "first-use," diminishing the difference between nuclear deterrence and first-strike capability since this Program will maintain those types of weapons.

95/41.12 The commentor states displeasure with the comment process and would like DOE to respond to and evaluate all reasonable alternatives.

96/40.15 The commentor states stewardship implies the United States is caring for the world. The commentor feels the scientists at LLNL should resolve nuclear waste issues since the scientists created it.

97/40.15 The commentor notes that the United States is allocating more money for this Program but they should resolve waste issues.

98/40.12 The commentor states that the jobs created for the Program could be created for projects such as constructing schools and hospitals.

99/40.02 The commentor feels DOE is not honest while presenting programs such as subcritical tests to the public.

100/40.06 The commentor feels the abolition of nuclear weapons is a reasonable alternative.

101/21.04 The commentor feels the Program is not the policy direction the United States should undertake and that the public should inform public officials that NIF is not necessary.

102/21.17 The commentor feels the Program, especially NIF, will actually lead to a less secure nation.

103/41.03 The commentor states DOE will proceed with the Program despite public comments.

104/43.16 The commentor feels national security will result from people working towards peace and justice.

APRIL 11, 1996—EVENING SESSION

1/21.06 The commentor notes that the issue of nonproliferation was discussed among union members and they support NIF's impacts and purpose.

2/21.06 The commentor expresses support for the assessment that concluded NIF's role in promoting world peace. The commentor notes the unions support the finding that NIF will not destabilize world peace.

3/40.44 The commentor feels the Program is a responsible and necessary program for the U.S. stockpile of nuclear weapons.

4/21.06 The commentor feels NIF is part of a process of disarmament and supports this project.

5/41.05 The commentor notes that the discussion on impacts to peace have already occurred and feels the public meeting should focus on environmental impacts.

6/40.44 The commentor states that the unions welcome jobs and feel the jobs should not come at the expense of security to families and instability to world peace.

7/21.10 The commentor feels the construction workers are an important part of the infrastructure and that NIF is a responsible project which would not be trivial work and should not be minimized.

8/40.07 The commentor feels NIF will contribute to proliferation.

9/21.10 The commentor notes that the Alameda County Building and Construction Trades support NIF at LLNL.

10/40.02 The commentor feels nuclear testing should end and the scientists who designed them should ensure the remaining weapons are reliable and safe. The commentor notes that the scientists should be equipped with the "best tools available" to ensure the reliability and safety of the remaining stockpile.

11/21.06 The commentor notes that NIF is required to keep weapons scientists knowledgeable and ensure the security of the United States.

12/21.07 The commentor states NIF will help advance scientific research in areas such as new energy sources without damaging the environment.

13/21.12 The commentor expresses confidence that NIF is a safe facility which is not hazardous to the environment.

14/21.06 The commentor points out that despite the statements of critics, the construction and operation of NIF at LLNL will create 3,320 and 890 jobs, respectively. The commentor states that these figures do not include the potential economic benefits which may result from any resulting technological inventions.

15/40.12 The commentor states that money allocated for NIF should be used for socially beneficial construction jobs, such as "clean" cars and waste management, which improve lives and do not continue the nuclear weapons race.

16/40.41 The commentor wonders why there exists a reference to a classified appendix which may regard the use of reprocessed plutonium-242 for the Program.

17/10.03 The commentor notes that the waste volumes for LLW, mixed LLW, and transuranic (TRU) waste differ between the Stockpile Stewardship and Management Draft PEIS and the Waste Management Draft PEIS.

18/40.07 The commentor notes the Stockpile Stewardship and Management Draft PEIS states there will be no new weapons designs. The commentor disagrees since new materials will require new designs and NIF will help contribute to new designs. The commentor wonders what will be the difference between the era of the 1960-80s, when nuclear weapon designs occurred, and today.

19/21.02 The commentor notes that with respect to environmental impacts, the public should be skeptical of the statement, "... there will be no significant impacts." The commentor notes that LLNL's environmental report claims "no significant impact" yet over a million Ci of radiation has been released into the air. The commentor states that 120 cancers and 60 cancer deaths resulted from the top 10 accidents that occurred at LLNL. The commentor points out that tritium levels in rainwater and drinking water in Livermore has been measured to be over seven times the acceptable level. The commentor also points out that plutonium-contaminated soil was discovered at a local playground.

20/21.12 The commentor feels NIF will incrementally add to the amount of tritium and other toxic chemicals which will be released into the environment.

21/42.07 The commentor expresses concern regarding the Waste Management Draft PEIS proposed alternative for LLNL's Site 300, which is already on the EPA's Superfund List, as a regional facility for mixed LLW.

22/40.27 The commentor believes LLNL should be converted from a hazardous nuclear weapons R&D site to safe civilian missions site. The commentor states that an alternative study was prepared outlining methods for the conversion of LLNL's missions which demonstrates the "green" use of LLNL may create more jobs.

23/40.12 The commentor states that cleanup programs and their workers are losing funds as a result of NIF and other defense programs.

24/21.10 The commentor feels the conversions of LLNL into a civilian facility will create more jobs per dollar and would benefit the country and community. The commentor feels it is too costly to create laboratory-related jobs for NIF and that the capital and equipment costs are expensive.

25/40.06 The commentor would like a companion study for stockpile management which would evaluate the denuclearization, maintenance, and remanufacturing alternatives.

26/21.04 The commentor does not support the NIF facility.

27/21.11 The commentor feels the construction of NIF will be delayed because the decision regarding NIF will drag on for the next few years.

28/21.06 The commentor notes DOE has been candid about NIF's role as a nuclear weapons design and research facility and has not emphasized its potential for energy research.

29/21.05 The commentor states that an analysis of NIF within the PEIS will not be sufficient and a specific EIS will need to be completed.

30/40.60 The commentor feels the document is not adequate because it does not evaluate a stockpile size of less than 1,000 weapons and does not consider the NPT. The commentor feels approximately 1 to 100 weapons would suffice for deterrence purposes.

31/40.60 The commentor feels DOE employed irrational reasoning for not evaluating a stockpile of less than 1,000 weapons because DOE claims treaties take too long to reach smaller stockpile levels. The commentor states DOE cannot rely on the inability to set a precise time-line for not evaluating smaller stockpile levels and suggests DOE seek advice from the Control and Disarmament Agency. The commentor suggests DOE chooses a reasonable timeline for this evaluation which could vary between 25 to 50 years for the complete global elimination of nuclear weapons.

32/40.60 The commentor points out that a zero-level stockpile alternative must be analyzed in the document because this may result in a vastly differently complex which may not require the proposed experimental facilities.

33/41.18 The commentor notes that the No Action alternative should represent a scenario which would not involve any of the facilities. The commentor points out the No Action alternative for the Stockpile Stewardship and Management Draft PEIS represents a complex of current facilities already involved in weapons design and testing.

34/21.06 The commentor states that NIF is understood to function primarily as a fusion defense facility. The commentor also notes that NIF represents a facility required for the reduction of the arms race and may create many employment opportunities in the region as a result of new fusion technology.

35/40.07 The commentor feels the nuclear scientists are taking advantage of new ideas, similar to the supposedly "cleaner" breeder reactor, to promote nuclear technologies. The commentor states that NIF is connected to the cycle of nuclear weapons production, which is continuing the arms race. The commentor feels the United States and Russia need to reconsider continuing nuclear development.

36/40.11 The commentor states that while United States and Russia continue downsizing, France and China are not. The commentor also expresses support for NIF.

37/21.06 The commentor points out that there is an existing stockpile that needs to be maintained and NIF is necessary for this purpose.

38/40.14 The commentor compares the Program to Safeguard C, an atmospheric testing readiness capability measure in the early 1960s which cost $1.6 billion to maintain facilities on Johnson Atoll to permit the resumption of atmospheric testing. The commentor notes that Congress promptly discontinued funding when they learned of the Program. The commentor sees the Stockpile Stewardship and Management Program as a similar program contending that although DOE is proposing NIF, NTS will remain operational as a tacit option for resumed underground nuclear testing.

39/40.14 The commentor believes the environmental impacts of underground testing are unavoidable and contaminates land forever. The commentor believes land is sacred and that DOE should not receive funds to maintain NTS.

40/21.06 The commentor supports NIF and inertial confinement fusion at LLNL and feels mitigation measures are sufficient to minimize the impacts. The commentor believes these technological advancements afford more job opportunities, which is good for the community and the United States.

41/12.09 The commentor expresses concern regarding an analysis of people and their families in the environmental justice sections.

42/40.12 The commentor states the funds allocated for this Program could be better spent to rebuild a public health infrastructure.

43/40.06 The commentor feels the denuclearization alternative is reasonable and should not be dismissed from the evaluation.

44/40.05 The commentor feels replacing underground nuclear testing with an expanded laboratory infrastructure is an attempt to legitimatize nuclear weapons and demonstrates renewed U.S. commitment to the nuclear arms race. The commentor feels aggressive maintenance of nuclear weapons research and design may restart the nuclear arms race and hinder nonproliferation. The commentor notes that despite the public's suggestion to abolish nuclear weapons, DOE will maintain nuclear weapons capability. The commentor feels denuclearization is the only alternative consistent with the NPT and CTBT.

45/40.36 The commentor wonders why the U.S. nuclear weapons arsenal must remain reliable.

46/04.04 The commentor states a contaminated water plume is drifting offsite at LLNL yet budget cuts may not allow for the cleanup.

47/11.11 The commentor states that activities at LLNL have created plutonium pollution at nearby parks, tritium contamination of the water, and onsite contamination from leaking drums. The commentor states that facilities to store these wastes do not exist and taxpayers should not have to support new programs.

48/40.36 The commentor states that a stewardship program is unnecessary and a maintenance program would not require a facility such as NIF.

49/40.15 The commentor feels the degradation of the environment in the past should be an important factor in the decision.

50/40.06 The commentor feels a denuclearization alternative should be considered for two reasons: 1) a recent speech by Warren Christopher suggests environmental policy issues should be linked with foreign policy issues, therefore, waste impacts as a result of stockpile stewardship and management will impact other countries as well; and 2) the United States should meet the treaty obligations of the NPT.

51/21.19 The commentor feels LLNL is not accurately reporting tritium contamination in the yearly environmental report and the values presented are underestimated. The commentor feels the tritium released from NIF will probably not be reported accurately as well. The commentor states tritium in the valley is approaching 1 million Ci and is a major problem. The commentor points out that the problem exists because the values reported represent contaminated water only. The commentor notes that tritium organically bound in organic surroundings, such as grass, and tritiated water are not being measured and they represent a hazard which is approximately 25,000 to 2,500,000 times more toxic than tritium gas.

52/11.11 The commentor states that despite submitting written reports documenting health hazards at LLNL, such as inaccurate reporting of tritium levels, at the suggestion of DOE, these concerns were not adequately addressed.

53/40.07 The commentor feels it is hypocritical of the United States to build NIF and other stockpile stewardship and management projects while discouraging other countries in their nuclear pursuits. The commentor wonders why the United States would continue the arms race while there is no clear division of the world.

54/40.06 The commentor feels that unless the United States initiates dismantlement, weapons proliferation will continue. The commentor expresses displeasure with DOE's short-term vision to settle with rapid changes. The commentor feels DOE should have the "political will" to evaluate a Complex without weapons and experimental facilities.

55/40.12 The commentor notes that the local unions will not benefit from these projects and feels there are greater benefits to constructing hospitals and schools.

56/21.06 The commentor states NIF is required for peace.

57/41.13 The commentor feels statements such as "none," "minimal," "within regulatory statutes and guidelines," "manageable," and "amenable" are not credible when describing environmental impacts.

58/21.09 The commentor states there are several varying estimates regarding the number of jobs which will be created by NIF.

59/40.60 The commentor feels DOE should consider and evaluate a zero-level stockpile.

60/40.06 The commentor feels that a nuclear weapons program is not necessary.

61/40.04 The commentor states support for downsizing but abolishing the stockpile is not realistic because the United States cannot control other nations' policies. The commentor believes DOE can increase waste management efforts but adds the United States is initiating "positive" policy by discontinuing the manufacture of new weapons.

62/40.06 The commentor feels the United States may take a leadership role in the downsizing of nuclear weapons worldwide.

63/40.07 The commentor believes supporters of the Program, particularly NIF, feel this Program represents downsizing and maintaining weapon reliability and safety. The commentor states that the Program will actually allow DOE to accomplish further developments and advances in weapons research, resulting in an unsafe world. The commentor notes that in Summary section S.2.5, Nonproliferation, the PEIS states that the United States has "halted the development and production of new design nuclear weapons." The commentor also notes that the meaning for the term "new weapons designs" has changed over the years yet new weapons designs are ongoing. The commentor also feels that this is a policy matter which may or may not change in the future. The commentor feels that in the meantime facilities such as NIF and DARHT, combined with historical data and computer modeling, will enable DOE scientists to develop advanced nuclear weapon designs. The commentor states that NIF will isolate fusion experiments without the "noise" of an underground explosion while DAHRT will provide detailed three-dimensional "pictures" of a nuclear explosion. The commentor feels the scientists will advance weapons scientists with these tools which will further experiments, prototypes, and designs, which may used to develop a new weapon. The commentor believes that if a shift in policy to revert back to nuclear weapons production were to occur, the United States will justify this with the exorbitant amount of money and personnel that was spent on these projects that probably will have proved the United States is capable of building advanced nuclear weapons to replace outdated weapons. The commentor feels these facilities represent an advancement from previous research and will promote proliferation.

64/40.07 The commentor states that new weapons design is occurring, noting that the B-53 is slated to be replaced by the B-61 Modification 11, which has earth-penetrating capability. The commentor states that this is an example of new nuclear design but DOE will not announce this as a new nuclear design. The commentor notes that according to DOE "nuclear development" and "nuclear design" have different meanings yet it seems nuclear designs will occur as a result of nuclear developments. The commentor states NIF, as a nuclear development, will enable scientists to develop new designs. The commentor feels the certification of nuclear weapons without testing is a "big jump" but it has happened in the past and these facilities will lead to a "nuclear weapons science."

65/40.07 The commentor feels DOE plans concept studies and development of prototypes which, when combined with potential changes to future policies (i.e., such as disregarding the objectives of the CTBT) and a drive to certify these new weapons, create a tremendous proliferation risk.

66/40.07 The commentor believes the United States will not be able to protect the spread of information from the Program to other countries with an industrial capacity.

67/21.01 The commentor feels new facilities, like NIF, are not needed for maintenance of the stockpile.

68/40.07 The commentor states that other nations evaluate U.S. intent and capability of these programs and they are unable to assess the nuclear weapons program, therefore, other nations may feel the need to undertake similar programs. Therefore, the commentor believes a nonproliferation analysis of the Program, including the entire Inertial Confinement Fusion Program, should be included in the document.

69/41.05 The commentor feels the public meeting did not contain a discussion regarding the environmental impacts of the Program.

70/41.12 The commentor feels DOE did not evaluate all reasonable alternatives required by NEPA and did not provide an adequate basis of comparison.

71/21.12 The commentor states that DOE cannot state the radiological health threat of NIF is small with certainty from a threshold exposure basis.

72/40.60 The commentor states individuals advocating downsizing lobby on a global basis. The commentor feels global downsizing may occur if the United States reduces to at least 1,000 weapons as a first step and then negotiates an abolition treaty, which would eliminate all nuclear weapons and the bases which employ them. The commentor feels the proposed facilities are not necessary for maintenance and DOE should not eliminate alternatives which use existing facilities for remanufacturing and maintenance. The commentor notes that the U.S. Ambassador to the Geneva Test Ban Treaty negotiations recently confirmed a belief in worldwide disarmament and the need for the CTBT and discontinuing development. The commentor notes that there is a broader scope of discussion regarding the legality of the use of nuclear weapons on an international level which will most likely determine there is a need to meet NPT obligations and find nuclear weapons illegal. The commentor believes the zero-level alternative should be considered. The commentor feels the Program is a U.S. effort to maintain the capability to design and develop nuclear weapons.

73/21.15 The commentor states that NIF, being an experimental fusion facility, may or may not lead to fusion nuclear weapons but will lead to new nuclear weapon designs.

PUBLIC HEARING—WASHINGTON, DC

April 17, 1996—Afternoon Session

1/41.05 The commentor believes that there was a breakdown in communication between the military and production network groups and DOE regarding the April 17, 1996, Washington, DC, public meeting format. The commentor thought the session was to be an informal meeting with no opening presentations. Consequently, many of the group did not pre-sign.

2/40.36 The commentor believes that the capability to be maintained in the Stockpile Stewardship and Management alternatives and the Preferred Alternatives Report is still a bit overblown.

3/40.25 The commentor compliments DOE for the analysis of stockpile management alternatives in the PEIS. However, the commentor believes that the PEIS does not contain a parallel analysis of stockpile stewardship.

4/41.17 The commentor believes that by eliminating from detailed study the non-science-based alternatives for stockpile stewardship found in Summary section S.3.2 of the Stockpile Stewardship and Management Draft PEIS has not met the minimum requirements of NEPA.

5/40.07 The commentor suggests an overall proliferation analysis in the PEIS.

6/40.02 The commentor notes that inertial confinement fusion in NIF, the upcoming subcritical tests, and other testing technologies have come under fire internationally. The commentor believes that underground subcritical tests will be seen internationally as a nuclear test and wants DOE to cancel these tests.

7/21.01 The commentor believes that NIF is the least relevant alternative as far as safety and reliability, and believes that the stockpile can be maintained without it.

8/42.14 The commentor is shocked that the amount of waste to be produced over the next 20 years by the stockpile stewardship and related nuclear research programs as presented in the Waste Management Draft PEIS is much more than what is currently in storage.

9/42.14 The commentor states that the waste figures presented in the Waste Management Draft PEIS are not consistent with those in the Stockpile Stewardship and Management PEIS.

10/40.12 The commentor states that the Program will take $40 billion in tax dollars and in return will generate more radioactive and mixed waste. The commentor believes the money would be better spent on environmental restoration, for civilian programs, and for a sensible curatorship program to maintain the existing arsenal safely as it awaits dismantlement.

11/40.34 The commentor does not understand what "safety and reliability" means and asks for clarification.

12/40.31 The commentor saw a DOE document and now believes that DOE is designing new weapons as part of the Stockpile Stewardship and Management Program.

13/40.07 The commentor says that the Secretary of Energy stated at a recent arms control committee hearing that the PEIS is a proxy for underground nuclear testing. The commentor asks how this can be reconciled with CTBT.

14/40.07 The commentor believes that NIF might be perceived as skirting international treaties and commitments.

APRIL 18, 1996—MORNING SESSION

1/41.10 The commentor has significant concerns about the Stockpile Stewardship and Management PEIS and Storage and Disposition PEIS combined public hearings. The commentor believes that since the PEISs are long and contain complex issues, the integration of issues is more difficult. The commentor wonders if this new format is aiding the process and being more substantive or not.

2/40.31 The commentor believes that the United States is moving forward on new nuclear weapons designs and points to a Defense Programs document viewed on the Internet that DOE later took offline as evidence.

3/40.31 The commentor requests that the Internet document believed to address new weapons designs be made available to the public.

4/40.05 If it is true that the option to design new weapons must remain open, the commentor believes that the impacts of this should be addressed in the PEIS.

5/40.02 The commentor does not believe that the upcoming subcritical tests are included in the PEIS. The commentor asks if there is a plan to include next year's test in the Final PEIS. The commentor believes that the two tests scheduled this year at NTS should be postponed so they may be included in the PEIS.

6/40.02 The commentor asks if subcritical tests are included in the NTS Site-Wide EIS.

7/21.17 The commentor is concerned about proliferation impacts of sharing technology with foreign countries, such as with NIF, and asks if the PEIS addresses this. The commentor points to an April 17, 1996 *Washington Times* op-ed piece that questions this.

PUBLIC HEARING—AMARILLO, TEXAS

APRIL 22, 1996—EVENING OPENING SESSION

1/40.40 The commentor wants to know the size of the stewardship stockpile.

2/40.52 The commentor states that any new work at Pantex must be done in an environmentally safe manner.

3/08.15 The commentor states that there are not enough words to say how important Pantex is to the job situation in Amarillo. Using a multiplier index, the commentor states that the 3,500 jobs at Pantex create an additional 13,500 in the community.

APRIL 22, 1996—EVENING BREAKOUT SESSION

1/34.01 The commentor states that if the HE mission moves to the laboratories, HE production capability will be lost and our nuclear deterrent will be in jeopardy.

2/40.23 The commentor states that 1,300 HE units will be needed sometime around 2010. The commentor doubts that the laboratories will have adequate capacity for this quantity.

3/34.01 The commentor notes that the core capability for HE is largest at Pantex. The commentor questions the need to move HE to the laboratories in order to "maintain core capabilities."

4/34.01 The commentor offers other options for the HE mission. The commentor would like DOE to consider a sharing of the mission or the possibility of laboratory personnel performing HE work at Pantex.

5/40.52 The commentor makes the point that the HE costs at Pantex in the near-term, for which DOE can be most certain, are cheaper than the HE costs at the laboratories.

6/40.36 The commentor asks about extending the life of the weapons through an evaluation program. This is a program whereby the life of a weapons system is extended by upgrades to the weapon program, which are based on evaluation activities.

7/34.01 The commentor asks if the cost studies included the transportation of the HE to and from the laboratories.

8/40.35 The commentor asks how the decision criteria (that were given to the sites in developing the alternatives) were applied in formulating the preferred alternatives. Also, the commentor indicates that Pantex scored highest for most, if not all, of these decision criteria.

9/40.23 The commentor wants to know how the laboratories are maintaining their core competency in HE work today and how this relates to HE manufacturing in the future. The commentor states that there is a manufacturing risk at the laboratories.

10/40.40 The commentor refers to the lowest case stockpile size (1,000 weapons) and asks what influence this had on the choice of preferred alternatives.

11/40.52 The commentor notes that, despite uncertainty in the out years for HE costs, Pantex is consistently cheaper, year after year, than any other alternative.

12/40.52 The commentor states that cost is affected by the quality of the workforce and the work ethic. The commentor urges DOE to consider the quality (excellent in this case) of the Pantex workforce in its cost estimates.

13/40.13 The commentor asks if the A/D and HE costs include the cost of facilities operation in the out years. The commentor notes that older HE facilities at the laboratories may incur additional costs due to upgrades.

14/08.15 The commentor states that in the summary section for the PEIS, job losses number 3,500 for Pantex. The commentor doubts that this amounts to only a 1-percent effect.

15/08.14 The commentor states that the 1,100 employees that have been added to the Pantex workforce in the past few years are mostly environmental, safety, and health (ES&H) workers, not A/D workers.

16/08.25 The commentor wants to know why the Pantex Site-Wide Draft EIS and the Stockpile Stewardship and Management Draft PEIS use different economic multipliers.

17/40.08 The commentor suggests politics, and not a NEPA analysis, will have the greatest influence regarding decisions for such a program.

18/40.06 The commentor would like DOE to consider denuclearization. The NPT calls for denuclearization, according to the commentor.

19/34.01 The commentor states that the cost of moving HE to the laboratories is $40 to $50 million and that this is a fact worth considering in the decisionmaking process. The commentor also notes that Pantex scores 100 for all decision criteria, the highest score among all alternatives. The commentor urges DOE to move more HE work to Pantex to maintain this capability.

20/34.01 The commentor would like to know why DOE would consider the HE laboratory alternative when such a decision would result in higher costs to the taxpayer and less capacity (therefore less flexibility) for the Complex.

21/08.24 The commentor states that DOE should not consider 33 HE jobs insignificant. In both human and economic terms, these jobs are significant.

22/34.01 The commentor is concerned that political considerations will overshadow the decision criteria which position Pantex as the logical choice for HE work. The commentor wonders if these decision criteria even matter.

23/40.06 The commentor states that cost and environmental impact would be less if a smaller stockpile were maintained.

24/40.14 The commentor does not want NTS to maintain a test-readiness posture.

APRIL 22, 1996—EVENING FORMAL COMMENT PERIOD

1/41.05 The commentor states that it was never the intention of the citizens groups at Pantex that DOE would not be able to respond to comments in the formal comment room.

2/41.03 The commentor believes that DOE is putting on a show of gathering public comments and that they are withholding important information from the public.

3/11.26 The commentor notes that there are no results of long-term health exposure studies of the current mission at Pantex.

4/11.26 The commentor cites several fires and explosions that have occurred at Pantex and expresses concern that additional problems may arise because there is a lack of scientific study used in the document.

5/34.02 The commentor believes that moving all of the HE activities of the Complex to Pantex is not in the best interest of the community.

6/04.05 The commentor believes that there is not enough water in the Pantex area for the proposed DOE projects. The commentor notes that Pantex has pumped one and a half times their allotment for the past six years and that water use restrictions may be instituted this summer in Amarillo. The commentor also notes that the city has unsuccessfully attempted to find more water by developing new well fields and refurbishing old well fields.

7/04.05 The commentor calls on DOE to release reports on the contamination problems at Pantex to the public. The commentor believes that the damage reports will allow the public to make more informed comments by providing an accurate picture of the present situation at Pantex. The commentor specifically asks for the release of the Zone 12 Groundwater Assessment.

8/43.19 The commentor believes that the United States has failed to recognize the sacrifices made by unknowing men, women, and children during the Cold War. The commentor believes that it is unpatriotic to not recognize the casualties that resulted from the contamination of the Cold War.

9/05.02 The commentor notes that Pantex is located on a geologic fault that has been active enough in the last century to cause damage to farm buildings.

10/04.12 The commentor is concerned about the quality of the drinking water. The commentor notes that Pantex is monitored for 160 contaminants, the majority of which ended up being discharged to groundwater. The commentor wants a broader spectrum of contaminant analysis for the drinking water.

11/11.25 The commentor wants more information on the open air experiments performed at Pantex. Specifically, the commentor is concerned about releases of strontium-90 and deuterium.

12/41.05 The commentor appreciates the formal hearing format option in Amarillo. The commentor believes that the formal hearing room option allows more people to comment and is more comfortable than the workshops.

13/41.10 Commentors believe that combining three documents into a single opportunity for public input is unreasonable and does not do justice to the NEPA process. The commentors believe that more time is needed for public review of the documents.

14/41.05 The commentor believes that the workshop format public hearings do not meet the Government's responsibility to the public as envisioned by NEPA. The commentor also believes that DOE can control the output of the meetings using the workshop format.

15/13.03 The commentor believes that DOE should look at the cumulative impact of all three of these programs.

16/40.27 The commentor believes that stockpile stewardship and management is an attempt by the Government to justify the continued operation of all three of the weapons laboratories. The commentor believes that the redundant laboratory capacity is an obscene abuse of taxpayer money.

17/40.79 The commentor believes that the PEIS does not make a realistic distinction between strategic and surplus plutonium. The commentor believes that the effort to maintain two-thirds of the plutonium is evidence that the United States is not serious about disarmament and also gives rise to the suspicion that some effort is being made towards using plutonium for commerce.

18/40.73 The commentor does not want Pantex to become the next Rocky Flats where the only jobs are for nuclear waste handlers and regulators. The commentor believes that Pantex is the wrong place for plutonium storage.

19/41.09 The commentor believes that a lot of taxpayer money was spent to produce a PEIS that is flawed in many ways.

20/40.36 Commentors believe that the alternatives in the PEIS are too expensive and are not prudent in light of recent budget cuts and downsizing.

21/40.06 The commentors believe that DOE should not build new RD&T facilities at a time when the rest of the world is looking to the United States for leadership in extending the NPT and CTBT.

22/40.05 The commentor asks if DOE is trying to keep war and war games going in the pretense of building peace and achieving economic development in rural America.

23/10.13 The commentor is concerned that more waste will be produced when there are no licensed facilities to handle the waste.

24/08.02 The commentor wants to know where the impacts to the agricultural economy were analyzed in the PEIS.

25/04.05 Commentors express concern about the water in the Pantex area. One commentor believes that the PEIS failed to address the issue that Pantex is located above the Ogallala aquifer.

26/40.50 The commentor believes that the basic issue of morals has not been addressed. The commentor contends that underneath all of the complex issues, the questions are what kind of country do we want to be, what kind of security do we want to provide, and do we want to have the capability to destroy the planet.

27/40.40 The commentor wants to know the number of nuclear warheads in the stockpile.

28/40.07 The commentor believes that the purpose behind the PEIS proposals is to develop nuclear weapons.

29/41.03 The commentor believes that DOE has made a mockery of asking for citizen input.

30/41.01 The commentor notes that it was very difficult to make plane reservations to get to the meetings at Pantex because the meeting times kept changing. The commentor also was not aware of the meetings in the afternoon and would have changed flight plans to attend the meetings if possible.

31/40.12 According to the commentor, the costly expansion of the nuclear weapons program is alarming in light of proposed cuts that will affect children and the elderly.

32/40.06 The commentor believes that the United States should destroy nuclear weapons and rely on a nonviolent means of conflict resolution.

33/40.60 The commentor wants to know why DOE has decided that long-term storage in Zone 4 is unsafe.

34/40.73 The commentor does not want plutonium stored at Pantex and believes that plutonium is too dangerous to transport.

35/30.01 The commentor supports the selection of Pantex for weapons A/D functions.

36/34.01 The commentor favors the continuation of the HE mission at Pantex.

37/40.52 The commentor believes that Pantex should be selected for additional environmentally sound stewardship and management functions.

38/40.52 The commentor points out that the community has been overwhelmingly supportive of Pantex and is in favor of bringing new environmentally sound missions to Pantex.

39/40.52 The commentor believes that most people are supportive of most of the work that is done at Pantex.

40/40.52 The commentors believe that the outstanding work ethic and dedication of the employees at Pantex make it the best site for stewardship and management alternatives.

41/04.05 The commentor believes that opponents to Pantex have no factual basis to support their fears. The commentor believes that opponents fear all things nuclear and cites their fears of contaminating the Ogallala aquifer as an example.

42/40.52 The commentor supports the operations/mission at Pantex and further states that there has never been a time when any one of the generations of her family has feared for their safety because of activity at Pantex.

43/04.05 The commentor believes that concerns about the Ogallala aquifer are unfounded.

44/40.52 The commentor believes that DOE should remember that the workers of Pantex have an excellent place to live, Amarillo.

April 22, 1996—Evening Closing Session

1/41.10 The commentor states that the public has not had adequate time to review all three EISs.

2/41.05 The commentor would like to know how the public can comment on the cost studies for stockpile stewardship and management.

APRIL 23, 1996—MORNING SESSION

1/41.12 The commentor believes that the lack of preferred alternatives in the documents under discussion prevents full participation and thorough analysis by the public.

2/42.09 The commentor urges collocation of the strategic reserve and the surplus material. This would minimize transportation risks and costs, according to the commentor.

3/34.01 The commentor states that if HE moves to the laboratories, the manufacturing capability will be lost. The commentor would like to know if DOE considered moving HE design to Pantex. If not, the commentor would like to have an explanation.

4/40.27 The commentor would like to know why LANL and LLNL were not consolidated.

5/34.01 The commentor would like to know how the laboratories maintain their core competencies (especially in HE) in the absence of any new design work. Also, the commentor states that the laboratories come to Pantex for production experience since their capability in this area is minimal.

6/34.01 The commentor states that HE production will be necessary in the future in order to extend a weapon's life or to refurbish a weapon. The commentor states that DOE should maintain the core competency of HE production at Pantex in order to meet this requirement and fund R&D for HE either at the laboratories or Pantex. This way, according to the commentor, both a design and a manufacturing capability would be preserved.

7/40.21 The commentor states that the recent increase in employment at Pantex is due mostly to an enhanced safety culture. The commentor believes that the PEIS baseline does not consider the level of work necessary for an adequate safety culture.

8/40.67 The commentor states that, according to his information, the workload at Pantex will be increasing in 1997 and 1998. The commentor would like to know why, then, the budget for Pantex is decreasing, along with employment levels, for 1997 and 1998.

9/34.01 The commentor states that facility operating costs and overhead are lower in the Pantex region than in the Albuquerque and Livermore regions. Accordingly, the commentor does not understand why operating costs in the net present value graphs are assumed to be equal for these regions.

10/40.21 The commentor states that the facilities at LANL and LLNL do not meet DOE personnel explosive safety requirements.

11/30.08 Referencing page 7-17 of the *Stockpile Management Alternatives Report*, the commentor believes a stockpile of 1,000 weapons was analyzed in order to increase the chance that production work would be moved to the laboratories. The 1,000 level favors lower production capability at the laboratories and makes Pantex look extremely large in cost, according to the commentor.

12/40.13 The commentor states that there is a $50 million difference in operational costs per year between downsizing Pantex and transferring to the laboratories. The commentor would like DOE to comment on this fact.

13/40.11 The commentor, in response to the justification for a sub-START II stockpile analysis, states that there are others who argue in the opposite direction, for an even greater stockpile. The commentor urges analysis of such a stockpile level.

APRIL 23, 1996—AFTERNOON SESSION

1/40.11 The commentor states that, in light of French and Chinese testing, it is foolish to be thinking of reducing the stockpile.

2/43.09 The commentor states that no consideration is given to all the chemicals that are poisoning the human body by allowing the chemical companies to put all of their chemicals into food supplies which will harm all humanity in the United States. The commentor asks which is worse: the pollutants that go out by Pantex that affect the local population, or all the chemicals that go into our food supplies affecting the whole Nation.

3/08.15 The commentor states that it will hurt the economy of the city to have another payroll eliminated. The commentor is against cutting the payroll of the city any further.

4/40.67 The commentor states that the fiscal year 1997 budget as proposed will lead to a reduction in force at Pantex. The commentor notes that the Preferred Alternatives Report reveals that Pantex, but not Y-12 or KCP, will undergo this decrease in budget. The commentor would like to know why Pantex is suffering budget cuts if the workload is constant and the other production facilities are not suffering budget cuts.

5/12.09 The commentor states that in the environmental justice sections of the PEIS, human health is covered but no socioeconomic analysis is done.

6/40.67 The commentor would like DOE to reconcile a declining budget at Pantex with a constant workload.

7/40.67 The commentor refers to the Preferred Alternatives Report, pages 33, 36, and 39, regarding the projections of annual cost at KCP, Y-12, and Pantex. The commentor states that the annual cost is fixed at Y-12 and KCP for the succeeding four years. At Pantex, however, there is a decrease. The commentor states that this furthermore suggests that although the Pantex alternative in terms of definition of costs against the stockpile management was designed within the assumptions, and those assumptions were laid forth to provide common basis of comparison across sites, that those have now been translated into a budget planning document. The commentor states that this is not what NEPA is for.

8/40.68 The commentor states that the enduring stockpile was built from the late 1970s to the early 1990s, approximately a 12-year period. Assuming the stockpile has 8,400 weapons in it and that the life of a weapon is about 30 years, in 2008 we would have to replace the stockpile at a rate of 700 units per year. DOE is sizing the Complex to handle about 300 units per year. The commentor would like DOE to explain this disconnect and what DOE proposes to do about it.

APRIL 23, 1996—CLOSING SESSION

1/13.02 The commentor quotes from the cumulative impact section of the Council on Environmental Quality (CEQ) regulations and asks why past socioeconomic actions (that led to reductions in employment and that are still felt today) are not discussed in the cumulative impact section of the PEIS. Specifically, the commentor mentions the cancellation in 1988 of the DOE program of a mine geologic repository for spent nuclear fuel and high-level radioactive waste in Deaf Smith County and the more recent announcement of the Department of Interior's Bureau of Mines Helium Operation.

PUBLIC HEARING—SANTA FE, NEW MEXICO

APRIL 25, 1996—AFTERNOON SESSION

1/41.05 The commentor questions why the comments collected through these meetings do not go through an impartial agency rather than to the reading rooms.

2/40.06 Commentors support total nuclear disarmament. The commentors feel that nuclear weapons kill innocent citizens and the radiation from nuclear explosions harms many innocent people; therefore, the use of nuclear weapons is immoral and cannot be justified.

3/40.06 The commentor feels that U.S. possession of nuclear weapons encourages rather than discourages other nations to develop and use nuclear weapons, possibly on us, making us less secure rather than more secure.

4/41.08 Commentors state that the American people cannot trust that our nuclear weapons, if they exist, will not be used on civilians again. The commentors cite the dropping of the atomic bomb on Japanese cities, stating that it could have been demonstrated in a nonpopulated area to show U.S. capability.

5/40.06 Commentors state that even if the weapons are never used again, every stage of their production, from mining to waste disposal, is hazardous to the workers involved, to our environment, and to future American citizens. It is not logical to harm our own people in the name of defending ourselves. Even some LANL employees do not want to build nuclear weapons.

6/40.06 Commentors nationwide call for a permanent moratorium on the production of any nuclear weapons. In addition, the commentors do not want LANL or anyone else to maintain and manage the existing stockpile of nuclear weapons. Instead, they seek the dismantling of all nuclear weapons.

7/10.24 Commentors ask that waste be stored where it happens to be, not shipped from all around the country to further endanger American citizens.

8/40.50 Commentors urge that the Government use this Nation's great minds and resources to resolve our conflicts with other nations in ways that do not involve killing people.

9/40.12 Commentors suggest that the main thrust of our brain and brawn and money should be immediately directed to implementing and developing alternative ecological renewable technologies and energies, such as solar power, hydrogen, and electric engines. The commentors believe we must free ourselves from a petroleum-based world economy which is polluting our air, water, and soil.

10/40.06 The commentor states that nuclear energy is not a solution for the short- or long-term, and it is dastardly dangerous, basically stupid, and non-biofriendly.

11/40.15 The commentor advocates immediate downscaling of nuclear facilities except for the cleanup of numerous contamination sites.

12/40.72 The commentor believes that the track record of LANL's emission violations is immoral and criminal. Creating more nuclear radioactive waste materials is not acceptable.

13/11.27 The commentor states that Santa Fe is the capital of New Mexico with an increasing populace and the area surrounding LANL is in very near proximity. The commentor feels possible contamination of the water, groundwater, and the radioactive accident or sabotage, if they would occur, would make Santa Fe and the surrounding area uninhabitable.

14/40.27 The commentor states that there is no question LANL should be shut down immediately as a nuclear development facility and immediately turned into an "ecological alternative technology think tank" and implement new nonlethal systems. If this were done, the commentor believes Los Alamos would be a shining city of innovative light for mankind, not as its present title implies "Ciudad de la Muerte," city of death.

15/40.06 The commentor states that nuclear security is an illusion. In the commentors' opinion, the nuclear genie is loose and proliferation is rampant, so the immediate shutdown and dismantling of nuclear devices is warranted.

16/40.27 The commentor states that everyone he knows is against the nuclear establishment's plans for Northern New Mexico. In the commentor's estimation, with the end of the cold war it makes no sense to continue this huge militarization with just as much money going into the military now as ever before. The commentor states that the people of Santa Fe do not want LANL to be the "plutonium capital of the world." The commentor believes that Complex decisions are merely a debate over political power and not environmental issues, and that with 5 electoral votes, New Mexico is short on the political power end of the debate and high on the environmental impacts.

17/41.05 Commentors believe that DOE officials do not listen to the public and DOE does what it wants regardless of what the public expresses, since the public has no power.

18/41.05 The commentor states that she heard a DOE official confess that these hearings bore him silly since we lay people go on about our feelings. This commentor further notes that only people with Ph.D.s can tell DOE not to make LANL the pit fabrication facility.

19/42.15 The commentor expresses opposition to building the DAHRT and its so-called subcritical detonations of plutonium.

20/42.10 The commentor expresses opposition to building a tritium facility.

21/09.10 Commentors express opposition to the transportation of nuclear waste and other deadly toxins.

22/41.02 The commentor believes that NEPA just delays actions; it does not change them. The commentor noted that NEPA only requires EISs and public hearings; it does not mandate that anyone choose the least destructive course of action.

23/41.03 Commentors question whether the decision to implement the Stockpile Stewardship and Management Program has already been made, whether the Secretary of Energy is solely responsible for that decision, whether the Secretary of Energy gets records of all the comments made at the meetings, and whether the Secretary's decision is revocable.

24/40.04 The commentor states that regardless of what is being said at this small meeting, the majority of Americans do want the protection of nuclear weapons. The commentor adds that it is important to keep the stockpile safe and reliable and supports the need for stockpile stewardship and management and the ability to resume underground nuclear testing if in the Nation's best interest.

25/40.24 The commentor states that a critical requirement for the Stockpile Stewardship and Management is the availability of trained people to investigate weapons components and design solutions for problems if problems are found or suspected. The Program will flounder unless a way is implemented to replace retiring and expiring employees in DOE and its contractors.

26/40.14 Commentors state that they do not want pit fabrication in New Mexico or anywhere else.

27/40.21 The commentor states that she would not feel safe if there was expansion going on at LANL.

28/41.08 Commentors feel that there is no way to be aware of all the possible effects of nuclear weapons at this time. Commentors believe that there is technically too much that is unknown, and that the world needs to obtain a better understanding of the impacts of nuclear materials.

29/40.07 The commentor feels that the Complex's decisions are driven by socioeconomics. The commentor suggests that if the United States can pay farmers not to grow crops, then they can pay engineers not to build bombs. The commentor feels that having nuclear weapon production facilities in the area essentially devastates it economically.

30/40.07 The commentor questions the credibility of the United States who simultaneously signs nonproliferation treaties while creating more new nuclear weapons.

31/40.12 The commentor resents paying to support LANL considering the work being done there and feels that it sacrifices the beautiful State of New Mexico. In addition, the commentor states that DOE scientists could be putting their abilities into alternative energy, medicine, and other positive work.

32/41.13 The commentor states that there are measurable environmental impacts as a result of the activities at LANL including the following: the fish downriver have measurable amounts of nuclear transuranic stuff in them; the water up in Los Alamos has tested positive for tritium and probably a few other things that they have not told us about; a rather large cluster of brain cancer in Los Alamos; and the sacred canyons of the Anasazi Indians that are now off limits because of waste that has been buried there.

33/41.08 The commentor feels that DOE should consider in the PEIS the global consequences of an accident like Chernobyl would cause; its effects were greater than the 50-mi radius the PEIS models for.

34/40.04 The commentor states that there is a lot of paranoia about nuclear weapons. The commentor feels that people in the United States should feel safer than anyone in the world. Growing up in Israel, the commentor said bombs were dropping on her head and the commentor does not understand why people in America are fearful. The commentor states that people should recognize that it is not realistic to reduce the stockpile down to zero; the United States must always have a way to protect itself.

35/40.06 The commentor states that mining uranium and converting it to plutonium, the transporting of it, and its use in weapons and energy sources are the links in a chain of death; we know this and we know that we have taken from the earth more fossil fuel than she in all her generosity can spare. The commentor calls for the irrevocable ban on all nuclear weapons and energy, and production, the return to full employment at LANL to detoxify, cleanup, and properly store the existing toxic waste.

36/10.01 The commentor states that waste should be kept where it was created and stored above-ground where it can be monitored.

37/09.02 Commentors state that the local areas are not prepared to handle an emergency response such as the type involved with nuclear weapons; local fire departments and hospitals do not have the proper protective clothing and equipment. DOE should provide money, equipment, and expertise in decontamination and emergency response. One commentor also adds that her county does not have a hazardous materials team, and it would take the closest hazardous materials team approximately two hours to respond.

38/09.13 Commentors are concerned about the transportation and safety of LLW on commercial carriers and inquire about the security.

39/09.10 The commentor asks who handles a radioactive waste accident on pueblo lands.

40/09.09 The commentor asks if it would violate security to tell us how many shipments of radioactive material are going through Santa Fe at this time.

41/09.09 The commentor expresses the need for evacuation plans for all towns en route from Pantex to LANL.

42/09.09 The commentor notes that if a spill occurred in Santa Fe, it would take 4 years and millions of dollars to clean up.

43/40.08 The commentor states that nuclear war is outright insanity. The commentor also believes that LANL is just lining their pockets, while it is the welfare of the people that should count.

44/40.69 The commentors urge scientists to be more responsible for their actions/inventions; they have a moral obligation to inform the public of all consequences known. The secrecy at LANL and within DOE is disturbing; it is also the reason people do not trust DOE.

45/11.23 The commentor believes that the PEIS's risk analysis is one-dimensional and not accurate. It cannot take into account the future legacy of radioactivity, the future health and genetic consequences, or the environmental impacts, according to the commentor.

46/40.08 The commentor feels that New Mexico was chosen for the mission of producing pits, testing and retrofitting of the existing stockpile and design of the next generation of weapons like the earth penetrator because the powerful nuclear and military interests in Washington have realized that New Mexico is sparsely populated, it is rapidly impoverishing, and it is perceived to be depoliticized and a house divided.

47/40.50 The commentor expresses opposition to the proposal, saying that she is for peace and sanity instead.

48/40.60 Commentors question why we need 36,000 nuclear weapons.

49/11.06 The commentor wonders why there is such a high rate of cancer in northern New Mexico.

50/40.29	The commentor urges DOE to make the Complex smarter and smaller not bigger, greedier, and filthier.
51/41.05	The commentor believes that DOE does not listen to the public.
52/40.15	The commentor believes that DOE has spent vast amounts of money resulting in contaminated air, water, land, and people, causing deaths by accidents and proximate living, all of this producing nuclear waste to kill without solutions as to its poisonous presence.
53/10.25	The commentor feels that DOE should focus massive attention on the subject of transmutation; it is critical that we learn how to neutralize nuclear waste onsite.
54/40.05	The commentor feels that DOE should develop skills of mediation to be used nationally and universally, instead of threats of weapons and military might, where everyone loses and nobody wins. The commentor feels that we need to wage a war of peace and have a Department of Peace in this country.
55/40.36	The commentor believes that expensive new facilities are not needed.
56/40.15	The commentor states that the United States does not need more waste.
57/40.12	The commentor feels programs proposed at LANL are just one big huge "pork-barrel boondoggle." The commentor feels that money should not be wasted on laboratories and weapons but instead should go to education, clean water, health care, endangered species, and saving forests.
58/40.72	The commentor wants all nuclear facilities and production and storage at LANL to be reduced and phased-out and efforts turned to D&D.
59/07.02	The commentor states that DOE should keep its word and return these Indian lands cleaned up to their rightful owners.
60/40.08	The commentor believes that the Program is essentially a pay-off from Bill Clinton to the employees at LANL in exchange for passing the CTBT.
61/40.36	The commentor believes that the new test facilities are "dinosaurs." The commentor believes that these machines are obsolete by the time they are built because actual ground testing, now the major nuclear powers of the world have agreed, is totally obsolete.
62/43.10	The commentor feels that the people of New Mexico are the big losers with the mountain of radioactivity in their backyards. The commentor feels that they are politically impotent, impoverished, and they are paying for it as well.
63/40.06	The commentor feels that the right decision is the one the French president took, which is to abolish the testing laboratories and totally decommission all their nuclear weapons.
64/40.12	The commentor believes that the PEIS is economically elitist, financially grossly inflated, militarily unnecessary, politically corrupt, environmentally dangerous, socially unacceptable, and morally idiotic.
65/43.06	The commentor after viewing the "Front Line" program on Rocky Flats, wants to know if DOE has better ideas now to ensure that the contamination problems they had there will not happen at LANL.

66/43.06 The commentor asks what kind of help is available for people who have been poisoned at Rocky Flats or LANL.

67/41.03 The commentor states that pit fabrication at LANL was being planned in 1993.

68/40.07 Commentors question whether the Nation's stockpile needs repair and maintenance to the degree that the PEIS proposes. The commentor references two DOE documents, a 1993 SNL Report and the Stockpile Surveillance Report, which both conclude that the Complex anticipates having one to two defects requiring corrective activity in the foreseeable future. The commentor believes that stockpile stewardship and management is a fig leaf for continuing design and production capabilities.

69/43.05 The commentor does not support the new armory being proposed for Taos, NM.

70/10.26 The commentor urges DOE to figure out a way to dispose of plutonium onsite.

71/41.08 The commentor believes that LANL is a bomb designer's dream come true and that the United States will use these weapons if it wants to. The commentor believes this because of a quote from DOD attorney John McNeil stating "nuclear weapons can be targeted in ways that either increase or decrease resulting incidental civilian injury and collateral damage, and their use may be lawful or not depending upon the enemy's conduct." The commentor does not agree with these views, especially the idea of incidental civilian injuries considering the fact that there were 210,000 dead within months of the bombing of Hiroshima and Nagasaki and 300,000 survivors suffering slow deaths and painful lives over 50 years.

72/41.01 The commentor believes that there has been a virtual press blackout of the hearing because the United States wants these weapons to be declared legal so that it can use them if it wants to, and if new public opinion would be opposed to this, since the World Court judges all come from nuclear arms super powers, it is unlikely that they will make a decision opposing the legality of these weapons.

73/40.12 The commentor states that in 1994 alone, the United States delivered $6.7 billion worth of weapons to underdeveloped countries, 85 percent of which were nondemocratic nations. The Government spends $75 million each and every day to prepare to fight a nuclear war. In 1995, the United States spent $27 billion preparing for nuclear war; it seems to the commentor to be more cost- and life-effective to give most of that $27 billion a year to whomever the Government perceives as the enemy of the day with all kinds of humane action strings attached so it goes to upgrade the quality of life of the citizens of the so-called enemy country and save a few billion to give our scientists to get on with the job of cleaning up radioactive waste.

74/43.04 The commentor believes that with the recent anniversary of the Chernobyl accident and uncovering of much higher human deaths and illnesses caused by that accident should make us all question why our Government insists that it needs to create more radioactive material with the potential for disaster even if the weapons are never used.

75/10.27 The commentor feels that efforts should be concentrated towards D&D.

76/40.06 The commentor feels that the United States should help other countries simultaneously move towards goals of nonproliferation and D&D.

77/40.21 The commentor admits that she is scared that she and other kids might only live to be 17 or 18 years old and not have a grown-up future to make decisions they want to make.

78/40.06 The commentor opposes the production and use and deployment of nuclear weapons.

79/43.07 The commentor states that LANL needs competitive bidding for the management contract; the laboratory needs New Mexican oversight.

80/32.01 The commentor does not want plutonium pits transferred from Rocky Flats to LANL.

81/09.11 The commentor does not want high-level waste trucked to LANL or on New Mexico highways. The commentor states that Federal Emergency Management Agency does not even have a protocol for dealing with a collision spill.

82/04.06 The commentor states that the public does not want LANL wandering up Cerrillos Road, two blocks up beyond the old Ramada Inn, pumping radioactive waste into the Santa Fe water table.

83/43.14 The commentor states that the Government could save $18 million of the laboratory's $40 million travel budget if top brass drove from Albuquerque airport instead of chartering it.

84/41.03 The commentor feels that if this is a democracy and majority rules, then the public should be allowed to vote.

85/40.51 The commentor feels that the mission of LANL must be changed; there is no reason to shut it down. The commentor feels that there is wisdom in having the talented and highly trained scientists of LANL do whatever they want, whatever their interest. We could have some Nobel Prize winners up there if we turn these people loose.

86/40.06 The commentor believes the myth that nuclear bombs have kept peace for 50 years is contradicted by the fact that tens of thousands died in Korea and Vietnam and Desert Storm and more recently in Bosnia; none of these people were intimidated by the bomb.

87/32.01 The commentor states that LANL produces 50 pits per year, pits that cannot be used.

88/43.06 The commentor feels that LANL, over a longer time frame, will become as contaminated as the now-closed Rocky Flats.

89/40.06 The commentor feels that a disaster will occur if one of the bombs accidentally goes off. According to the commentor, one bomb is too many, no matter who owns it.

90/43.11 The commentor asks all the employees of all the laboratories, all the way up to Hazel O'Leary, if there is a solid foundation in nonweapons production, then wouldn't that be real job security when the balanced budget axecutters come after you. The commentor states that global competition for the U.S. businesses could be affected tremendously. The commentor believes that the scientists in Japan and Germany are helping their businesses design products to be sold around the world. The commentor states that we are doing great in weapons production, but in everything else, we seem to be falling apart.

APRIL 25, 1996—EVENING SESSION

1/34.13 The commentor points out that since DOE does not have a preferred alternative for HE fabrication it makes it difficult to comment on the possible location(s). The commentor wants to know if LANL is a candidate site for HE fabrication and what would be involved in HE fabrication at LANL.

2/09.12 The commentor is concerned about the number of pits that would be transferred between Santa Fe and Pantex, and asks if there would be trucks going through Santa Fe with Hiroshima-size nuclear potentials on them.

3/30.06 The commentor would like to know what DOE means by stating they would like to keep the stockpile as young as possible, and asks if there is going to be some A/D going on to keep the stockpile fresh. In addition, the commentor asks what happens to those pits that come out of the disassembled weapons.

4/32.15 The commentor wants to know if there will be waste management associated with the pit fabrication mission at LANL.

5/11.06 The commentor wants to know difference per year in fatalities if the Stockpile Stewardship and Management Program was initiated at LANL versus if the Program was not and if brain and breast cancers and leukemias would be included in that estimate.

6/40.06 Regarding weapons production, the commentor asks if DOE sees no acceptable alternative to remaining on a global suicide course.

7/41.03 The commentor states that if the public meetings are to inform the public and the Government proceed with the Program whether the public agrees with it or not, the public has as much freedom as the civilian population of Hiroshima and Nagasaki. In addition, the commentor asks if DOE has already made their decision or of they are waiting for the public's consent.

8/40.06 The commentor points out that it is unfortunate that nuclear weapons exist but we are getting rid of them and we must continue to do so.

9/09.01 The commentor wants to know what assurances DOE and the Department of Transportation (DOT) can provide to the citizens of Santa Fe that in transporting nuclear components every precaution will be taken to prevent the possibility of an accident and that the risks will be minimized.

10/40.06 The commentor states that we are part of the future and we do not want the world to be in major bombing and violence. The commentor states that it is bad enough the way it is, and the last thing we need are bombs.

11/40.06 The commentor does not care whether there are 2 or 100 nuclear weapons in the stockpile. The commentor wants an end to all nuclear weapons.

12/40.06 The commentor wants an end to all nuclear weapons. The commentor realizes that this may ruin jobs but will accept this consequence as long as it does not ruin us.

13/32.17 The commentor wants to know, for the pit production mission at LANL, if DOE will focus its attention on the greater hazards of processing and handling of plutonium and the eventual disposal of the waste or on simply the shipment of the finished product.

14/43.06 The commentor points out that part of the problem at Rocky Flats was not so much the technology as it was the unwillingness on the part of leadership to acknowledge when there were problems. The commentor wants to know if the corporate culture that led to the disaster at Rocky Flats has changed.

15/41.02 The commentor does not understand the recent decision on DAHRT, where the judge claims that it is only required that an environmental study be completed, not that it would be found to not have negative effects.

16/40.22 The commentor points out that DOE has determined that the risks involved with the proposal at LANL would be minimal. The commentor believes that this assessment is a lie.

17/40.06 The commentor is of the opinion that nuclear power is actually a breach of national defense and national security and should not be used as a rationale for jobs.

18/40.06 The commentor states that a favorite argument of DOE and the pro-nuclear faction is that the nuclear weapons industry creates jobs.

19/43.03 The commentor is of the opinion that denial is a major roadblock to making progress towards peace in the United States because the people working in armaments are deep in denial about how their work is affecting the society and the public's health.

20/40.07 The commentor states that LANL is simulating nuclear tests of plutonium at the very moment when negotiations are going on in Geneva to reach a CTBT. The commentor feels that these plutonium tests are undermining the negotiations and sending the message to the world that the United States does not mean what it says. The commentors believes that these tests should not take place.

21/43.06 The commentor wants to know what happened at Rocky Flats and why it had to be shutdown, how much of the area around Colorado was contaminated, and what is DOE's long-range plan for dealing with the waste at Rocky Flats.

22/43.06 The commentor asks why DOE is bringing waste from Rocky Flats to LANL.

23/09.12 The commentor asks if there are trucks right now on the highway that are transporting waste between Pantex and LANL.

24/40.50 The commentor believes that the United States must revise its objectives and should be focusing more on educating the youths of society and finding a cure for cancer. The commentor does not believe the numbers associated with downsizing.

25/40.50 The commentor points out that the public knows the truth from a lie, and the lie is the production and expansion of destructive weapons in the society.

26/41.03 The commentor points out that the public meeting is not about NEPA but that NEPA is simply the excuse that the public has once in awhile to be hosted by DOE. The commentor feels that the public meetings are the only means available to speak to DOE and suggests that other ways be found.

27/40.06 The commentor opposes nuclear weapons and will not allow the production of nuclear weapons to continue. The commentor vehemently opposes the pit production mission coming to LANL and plans to prevent there ever being a plutonium pit produced at LANL.

28/40.27 The commentor feels that the New Mexico is being forced to bear the brunt of most nuclear weapons manufacturing and testing and this is too much to ask of the people of New Mexico.

29/40.06 The commentor suggests that we honor our treaties by not producing any more nuclear weapons and continuing to downsize.

30/32.01 The commentor wants to know why outside nuclear dangers exist if DOE and the Government are looking after our self interests and acting in a beneficial and benevolent way. The commentor wants to know how is pit production in the public's interest or in any way safe after what happened at Rocky Flats.

31/40.27 The commentor is of the opinion that the nuclear power structure is not feasible. The commentor also believes that we could be using LANL to solve some of our problems such as alternative and cleaner sources of energy and to develop technologies to clean up the environment.

32/40.06 The commentor feels that there should be a disarmament alternative in the PEIS.

33/40.35 The commentor asks when the mission of DOE was last considered.

34/40.15 The commentor is of the opinion that there is no management of nuclear materials and there has been no ability to manage these materials since the inception of the nuclear industry, and yet, more weapons are continuing to be produced.

35/10.16 The commentor asserts that the reason DOE wants to move all the wastes to Waste Isolation Pilot Plant (WIPP) is so that they can continue plutonium production.

36/32.01 The commentor opposes continued production of plutonium pits and is of the opinion that the nuclear industry is the greatest threat to life on this planet.

37/40.12 The commentor thinks that we do not have the money to continue making nuclear weapons.

38/40.06 The commentor wants to understand the rationale for continued production of nuclear weapons.

39/40.36 The commentor wants to know the rationale for the new proposed facilities and the expenditures on these facilities.

40/41.18 The commentor wants to know what are the reasonable alternatives to the items on the list entitled "DOE stockpile stewardship costs" and for anything that DOE does.

41/40.22 The commentor points out that according to a 1993 laboratory study, DOE does not allow nuclear weapons to wear out or degrade. Based on that information, the commentor asks what defects in the nuclear stockpile justifies the need to spend billions of dollars on—about $30 billion in the next 10 to 20 years.

42/10.16 The commentor states that WIPP must not be opened without meeting environmental standards.

43/40.71 The commentor asks what are the environmental, social, cultural, and spiritual impacts of having stockpile stewardship including DARHT, on all the communities near LANL, the people, the air, the flora, the fauna, aquifers, livestock, agriculture, rivers, streams, businesses, and tourism of the states of New Mexico, Texas, Arizona, Colorado, and Utah, and in the Nation.

44/40.27 The commentor was of the opinion that LANL was a research facility not a bomb factory. The commentor urges LANL be converted to peaceful and beneficial purposes.

45/40.22 The commentor wants to know the true rationale for the Program because the experts agree safety is not an issue. The commentor states that if DOE insists that safety is the real concern then DOE should produce hard data supporting this position.

46/40.36 The commentor wants to know what is wrong with our current weapons and why we need to continue researching weapons design. The commentor asks what type of improvements DOE is seeking and what will be gained through continuing research.

47/40.07 The commentor asks what are the ramifications of the Program on the NPT and the proposed CTBT and does the Program undermine the goals of the CTBT which seeks to halt nuclear weapons development. The commentor is of the opinion that the United States reaffirmed the NPT in 1995. The commentor believes if the United States behaves as a hypocrite, its actions will cause other nations to either continue or begin to accumulate their own nuclear weapons.

48/10.32 The commentor wants to know where the nuclear waste from the pit fabrication mission at LANL will be stored, how much it will cost, and where will the money come from.

49/09.12 The commentor wants to know the extent of transportation (e.g., number of trucks, routes, safety precautions, accident mitigation) of all nuclear materials along New Mexico's roads and the extent to which this will increase once the pit fabrication mission is implemented at LANL.

50/40.12 The commentor questions why funding for many worthwhile projects (i.e., environmental cleanup and technology transfer) are being cut while at the same time billions of taxpayers dollars will be used for maintaining and potentially improving U.S. nuclear capacity. The commentor wants to know where the money for the Stockpile Stewardship and Management Program is coming from and why the Government is spending so much money on weapons projects when the wastes generated by previous defense programs has not been dealt with. The commentor states that this Program will only contribute to the waste problem; and programs which seem to infinitely more important and necessary for society are being cut and eliminated.

51/32.03 The commentor oppose the pit fabrication mission at LANL because the people of New Mexico would be living with illness and environmental degradation. The commentor is of the opinion that what DOE is doing is continuing to make war.

52/09.01 The commentor urges DOE, in transporting nuclear materials and in processing plutonium, to use every safeguard possible to insure that the public is not at risk.

53/40.06 The commentor believes that there should be a national commitment to reduce nuclear weapons and a global commitment to reduce the threat of nuclear weapons. The commentor suggests a mutual build-down of nuclear weapons by the nuclear states to assure security from a nuclear threat by other nations.

54/40.51 The commentor points out that stockpile stewardship is only a small part of what goes on at Los Alamos and only addresses the maintenance of safety and reliability of the stockpile with downsizing. According to the commentor, LANL has a major role in the Program.

55/40.51 According to the commentor, LANL is developing the technology for recycling, storage, and disposal of plutonium and enriched uranium; and the technologies to reclaim contaminated sites and safely dispose of waste. LANL is also said to have programs that transfer technology to the Soviet Union and monitor and analyze the storage of nuclear components. The commentor also points out that LANL has and is developing the technology to detect clandestine nuclear tests and is the only place where this technology exists. The commentor is of the opinion that given the state of affairs in the world today with respect to nuclear weapons, if LANL did not exist, it would have to be invented because this Nation and the world needs LANL and the technologies that it can provide.

56/40.06 The commentor opposes the enriching of more plutonium, the building of more nuclear weaponry, and the nuclear industry because the United States does not have the technology to keep it under control.

57/40.21 The commentor points out that DOE has stated that all safety measures will be taken with regard to the Program. In light of this, the commentor asks why funding for the satellite air monitoring system (NuNet) and the state environmental agency are threatened to be cut.

58/40.06 The commentor sees stockpile stewardship as one more event in the chain of extinguishing life on earth. According to the commentor, the dangers of the Program are obvious to those downwind and globally with continued productive capability. The commentor states that the Program is oversized in terms of money and what it plans to achieve. The commentor is of the opinion deterrence can be achieved without the dimensions of the Program. The commentor believes stockpile stewardship is closing the window of opportunity we have in the world today which is delegitimizing weapons.

59/32.01 The commentor is of the opinion that the problem is not the plutonium pit production technology but the people because the current technology is better than the technology used at Rocky Flats. According to the commentor, the corporate culture that exists at LANL is rooted in secrecy and denial.

60/40.72 The commentor expresses opposition to the Program because they do not want LANL to become another Rocky Flats; the commentor does not want an increase in the amount of nuclear material that is being transported through Santa Fe.

61/40.07 The commentor does not want tax dollars spent to contravene the nuclear proliferation ban by enabling development of deadlier weapons.

62/41.03 The commentor states that they have no faith in the NEPA process and believes that the hearing is insincere. The commentor contends that it was conceived that DARHT would exist and go forward long before now, and that the words of the public are sort of moot.

63/40.15 The commentor opposes the Program and wants DOE to turn the laboratories into institutions that engage in research to clean up the wastes that has been generated.

64/40.21 The commentor alleges that LANL is trying to get rid of the Tiger Team because the laboratory has never met its obligations concerning safety, health, and the environment. The commentor wants the Tiger Team dealt with in an open public process. The commentor states that LANL's past record does not give him much confidence in bringing the plutonium pit mission there.

65/34.16 The commentor points out that there is a disparity in the air emissions data being presented for sites conducting the same missions. According to the commentor, for the HE fabrication mission, Pantex, LLNL, and LANL propose to emit 413, 1,315, and 4,530 kilograms per year (kg/yr) of carbon monoxide; 122, 45, and 4,540 kg/yr of organics; 1,560, 349, and 22,700 kg/yr of nitrous oxides; and 0.02, 4.5, and 454 kg/yr of ammonia, respectively. In addition, the amount of HE powder required is different at each site. The commentor does not understand the reason for the disparity in both inputs and emissions for the same mission at different sites and wants to know where the numbers are coming from.

66/32.14 The commentor points out a disparity in the amount chemicals being used for fabricating pits at LANL and SRS. According to the commentor, SRS proposes to use 3,420 kg and LANL 32,886 kg—a difference of a factor of about 10.

67/33.09 The commentor points out the differences in the amounts of chemicals being used for the same mission at different sites. According to the commentor, for the secondary fabrication mission, Y-12, LLNL, and LANL propose to 1,000, 300, and 20,000 kg/yr of nitric acid and 0, 0, and 20,000 kg/yr of sulfuric acid, respectively. The commentor points out that the number 20,000 shows up on nitric/sulfuric acid for LANL.

68/33.09 The commentor is concerned about the disparity in the air releases and the amounts of chemicals being used for the same mission. The commentor is of the opinion that the chemicals used have no basis in reality and, therefore, the emissions has no basis in reality. The commentor thinks that the PEIS is a disgrace.

69/40.21 The commentor states that LANL is out of compliance with air quality and does not seem to feel any need to get into compliance. The commentor contends that DOE has not provided the funding required to achieve compliance and points out that with the DARHT facility Los Alamos will be emitting toxic materials such as beryllium and mercury into the air. The commentor is of the opinion that issues regarding ES&H are not a priority at LANL and will not be a priority if the stockpile stewardship and management alternatives for LANL are implemented.

70/40.21 The commentor points out that in the mid-1980s there were peaks in breast, ovarian, prostate, thyroid, leukemia, brain, and nervous system cancers, and non-Hodgkins sarcoma. The commentor states that it is obvious that something was occurring in the 1980s and does not want the Stockpile Stewardship and Management Program at LANL for fear it may cause these peaks to reoccur.

71/40.21 The commentor does not understand why DOE would bring more nuclear weapons work to Los Alamos when the laboratory has had a horrible health and safety record. The commentor wants the laboratory to improve its health and safety record; come into compliance with all of the environmental, air quality, and water quality regulations; and work toward zero release and then ask about increasing nuclear weapons work at LANL.

72/32.03 The commentor is of the opinion that pit fabrication mission at LANL is not a great opportunity for jobs but for further contamination of workers, children, and the surrounding population for more birth defects, more cancers, more sterility, and more fertility problems.

73/32.03 The commentor is of the opinion that the pit fabrication mission proposed for LANL is a done deal. The commentor suggests that the public focus less on talks of peace and love and instead insist that DOE do what is necessary and safe to get the public's vote of confidence on pit fabrication work. The commentor is of the opinion that this can be achieved by people who are professionals in the fields, not using people from groups who produced the bombs. The commentor states that if the laboratory does not conduct the pit fabrication mission correctly, LANL will become another Rocky Flats.

74/40.35 The commentor states that things change a lot in science and that today's estimates about safety may be accurate according to current knowledge but there is no guarantee that this is the actual condition and how things will be assessed in 10 years from now. The commentor is not confident in the information and the science and is not comfortable charging ahead with something so dangerous under these conditions. The commentor does not want a plutonium plant in his backyard.

75/40.44 The commentor states that given the requirement for a safe and reliable stockpile, the ban on underground testing and the shrinking size of the stockpile, downsizing the overall DOE Complex while building new facilities is reasonable. The commentor supports the new facilities proposed because they are necessary to provide missing data for computer modeling which cannot be supplied by underground nuclear testing and can validate fixes for defects discovered during surveillance and testing.

76/40.13 The commentor states that the alternative and related environmental impacts presented in the PEIS are reasonable with the following two exceptions: one, the incremental costs of new and relocated operations at each location and the offsetting savings at old locations are not presented and the PEIS is not clear on how DOE will maintain the core intellectual and technical competencies needed for stockpile stewardship and management. The commentor wants DOE to state the strategy to solve the intellectual and technical competency problem.

77/32.03 The commentor supports the preferred alternative of relocating pit fabrication at LANL. The commentor also supports the mission at LANL because it is closer to the assembly and pit storage at Pantex. The commentor is of the opinion that using an existing modern facility is more effective solution than building new facilities.

78/21.20 The commentor suggests that NIF should be located in LANL to create the basis for future nonweapons work at LANL.

79/40.22 The commentor strongly supports more funds for environmental studies and surveillance by an independent monitor. The commentor contends that DOE critics do not believe DOE and LANL statistics, and an independent monitor lends credibility to studies and measurements.

80/41.01 The commentor applauds DOE for a job well done on a complicated topic in this PEIS.

81/40.51 The commentor suggests that the most prudent approach for DOE is to consolidate a minuscule of weapons production capability at LANL.

82/40.06 The commentor contends that given a choice of having the weapons complex with 25 or 5 percent of the size of our historical capability that there would be no hesitation on choosing the latter because the commentor thinks it is important for our national security and for world peace to diminish the process of weapons production.

83/40.07 The commentor states that the Program is not minuscule but is in fact an increase over what we currently have and is more than twice what the United States was spending on nuclear weapons in 1975 in the middle of the Cold War when we were testing, designing, and producing weapons.

84/40.11 The commentor is of the opinion that START II is far from being a done deal. The commentor states that there is a lot of language written into law that the United States would certainly not take its arsenal down to the START II level, which means START II plus hedge unless Russia ratifies START II and carries out the dismantlements. The commentor contends that the actual equilibrium stockpile size of the United States is somewhere above 8,500 and probably close to 10,000.

85/40.07 The commentor believes that the Program is meant to substitute for nuclear testing. The commentor states that the United States does not have a test ban and in fact, the Program is a serious impediment and causing international problems for a comprehensive test ban. The commentor contends that the United States is adamantly opposed to any kind of commitment on vertical proliferation in the test ban because of LANL. The commentor is of the opinion that the United States will not get the strong nonproliferation that is needed in the world if we cannot follow the procedure that we are asking other nations to follow.

86/40.04 The commentor states that the United States said it would consider taking out the capability of another country, mainly Libya, to produce weapons of mass destruction. The commentor points out that the United States is making nuclear threats based on the capability of another country and intends to use a weapon not currently in the stockpile. The commentor is of the opinion that with the lack of an opposing superpower, the number, frequency, and intensity of nuclear threats from the United States will increase.

87/40.36 The commentor states that the safety questions that the Program aims to answer are nowhere near what one would think. The commentor believes that there have only been two safety problems in the weapons that are intended to remain in the stockpile, one having to do with the parachute system and the other, the tritium system. The commentor is of the opinion that there are no expected safety problems that would warrant DOE doing this country a disservice by throwing these phrases around for the purpose of selling stockpile stewardship.

88/40.05 The commentor contends that there have not been so many reliability problems as DOE has recently maintained in the tri-laboratory study. The commentor believes that the study is "cooked" and that production errors have been blended in with design and aging error to push the numbers up. The commentor states that reliability is a concern for those who wish to continue with a credible war threat and is not nearly a concern if you are interested only in providing a nuclear deterrent.

89/40.33 The commentor suggests that the Program lacks any coherent technical basis and should be dropped and replaced with a much simpler curatorship and if necessary, remanufacturing program. However, the commentor believes that there is no rush to remanufacture because the weapons are not that old.

90/40.12 The commentor is of the opinion that there is an unnecessary momentum being given to the Program because it is driven by budget cycles and bureaucratic inertia. The commentor suggests that we use the money for the Program to pay for Russian weapons dismantlement, to put the "E" back in DOE, and to implement programs the country really needs and which contribute to national security to a greater extent.

91/40.08 The commentor is concerned that the laboratories will use the Program together with Safeguard F, which gives the laboratory directors the power to certify a weapon as safe and reliable, to influence the Nation's sense of confidence in its nuclear deterrent and hence over the budget process.

92/40.23 The commentor contends that the two-laboratory DOE peer review process has never worked and it is dangerous to leave it in place.

93/40.02 The commentor states that modifying and changing nuclear weapons is not necessary. According to the commentor, the JASONs in chapter 10 of their 1994 study made the same recommendation to DOE. The commentor is fearful if DOE changes the weapons, changes will occur and will move away from the fount of confidence and may necessitate underground testing.

94/40.06 The commentor states that continued legitimization of nuclear weapons exerts a constant corrosive effect on our democratic institutions.

95/40.69 The commentor believes that we are engaged willy-nilly in a process of internationalizing stockpile stewardship. The commentor states that great dangers exist and do not think that LANL can address these dangers adequately by working in secrecy.

96/40.06 The commentor says no to nuclear weapons. According to the commentor, we should address the dangers of nuclear weapons now because it is acute.

97/11.27 The commentor states that the United States does not need more nuclear weapons and that residents of Santa Fe do not want nuclear weapons in their backyard. The commentor points out that Santa Fe is a city that thrives on tourism and contends that tourists will not come to a place that is polluted and where there is a possibility of getting cancer from breathing plutonium in the air.

98/04.06 The commentor suggests that the nuclear laundry in Santa Fe be closed and that the jobs should be transferred to LANL.

99/40.12 The commentor states that the new facilities will cost billions of dollars for computers, capital, and associated costs and feels that the money could be used on beneficial and productive things that are really needed and which could provide us with national security. The commentor points out that the projection are to maintain these facilities far into the future and try to reduce and dismantle the nuclear weapons stockpile. The commentor believes that there is an obvious contradiction in the Program and that DOE is headed in two directions which undermines U.S. commitment and trustworthiness.

100/40.07 The commentor states that the public is being sold a bill of goods about the necessity of maintaining and also the productivity and manufacturing and development of nuclear weapons under the guise of maintenance and surveillance of existing weapons what is really production of new weapons. The commentor opposes nuclear weapons because he believes we do not need and cannot afford them.

101/32.03 The commentor states that most of the resident of Santa Fe opposes the pit fabrication mission proposed at LANL. The commentor vows not to perpetuate the tyranny of nuclear weapons and the Program.

102/41.03 The commentor perceives DOE's position on national security policy as being a policy of so much complexity that it is well beyond the grasp of the public. In the commentor's opinion, there is no such thing as national security in a world where one state can reduce another to ashes.

103/41.03 The commentor is of the opinion that DOE has made the decision on placing the pit fabrication mission at LANL. The commentor wants to know who gets to make the final decision and whether the input of the public is being heard.

104/32.01 The commentor states that the majority of the residents of Santa Fe are against the plutonium proposals for LANL.

105/40.51 The commentor supports the need for the preferred alternative at LANL.

PUBLIC HEARING—NORTH AUGUSTA, SOUTH CAROLINA

APRIL 30, 1996—MORNING SESSION

1/41.14 The commentor asks if the comment period will be extended.

2/42.01 The commentor asks if there will be an attempt to produce a simplified document suitable for the general public to understand, showing the relationship between the three documents (i.e., Stockpile Stewardship and Management PEIS, Storage and Disposition PEIS, and Pantex Site-Wide EIS).

3/41.14 The commentor asks if there will be another public comment period after the Final PEIS.

4/41.15 The commentor believes that NEPA mandates an analysis of economic impacts on future generations. The commentor also believes that costs, timing, and consumption of non renewable resources should together drive the PEIS. The commentor wants a complete environmental impact assessment which includes the impact on future generations. The commentor points out that the words "future generations" are not stated in the document. The commentor questions why these items are missing.

5/40.76 From an economic development standpoint, commentor encourages DOE to consolidate processes at SRS and to use the existing intellectually capable work force and physical infrastructure.

6/12.03 The commentor wants to know exactly what was analyzed under environmental justice in the three documents.

7/40.76 The commentor believes that preservation of core intellectual and technical competencies in the SRS area (i.e., South Carolina and Georgia) is important. The commentor believes that in order to accomplish this, SRS needs continued missions.

8/01.01 The commentor is concerned that other DOE sites do not have a future use plan like SRS. The commentor also states that the SRS future use plan restricts future development to areas with prior development. The commentor wants this to become a DOE-wide policy.

9/40.76 The commentor would like to see the recommendations implemented at SRS, believing it would be in the best interest of the Nation and the local area. The commentor cites the following as support: SRS is an integral part of the community, is a good neighbor, and is well and contentiously run; existing SRS facilities and land area are available for utilization; core experiences and technologies would be maintained; and existing manpower and expertise would be utilized.

10/41.01 The commentor notes the lack of diversity in public hearing participants and wonders what weakness of DOE outreach strategy does not facilitate diversity.

11/01.01 The commentor proposed a land-use concept of multiple use for SRS. Primary uses would be located within the center and environmental uses would occur within the surrounding buffer area.

12/42.02 The commentor thinks it ironic that the PEIS proposes an upgrade of pit production at LANL while the Storage and Disposition PEIS is concerned about what to do with these pits.

13/34.13 The commentor asks what is the preferred alternative for HE.

14/34.08 In regard to HE fabrication, the commentor asks if the primary work is in the development program as opposed to fabrication.

15/40.27 The commentor asks if maintaining the two laboratories will be part of the Stockpile Stewardship and Management PEIS decision.

16/21.03 The commentor wants to know what the key factors were in the NIF preferred alternative decision and if the timetable for NIF is the same as the PEIS.

17/08.20 The commentor believes that the main issue at SRS is jobs.

18/40.29 The commentor wants to know if DOE avoids closing the plants.

19/40.88 Due to its focus away from consolidation, the commentor believes that the Program is very different from Complex 21.

20/33.04 The commentor wonders what will happen to the buildings and infrastructure if downsizing of Y-12 occurs and asks if there is a future uses study addressing this.

21/41.03 The commentor is fascinated that DOE is making its most significant policy decisions through EISs.

22/40.13 The commentor asks what is DOE's plan for releasing cost data on the alternatives.

23/32.06 The commentor believes SRS should get pit fabrication, not LANL. The commentor believes that locating pit fabrication at LANL will consume most of the capability at TA-55 and that existing operations would need to be relocated during construction. The commentor also wants to know if upgrade of the Chemistry and Metallurgy Research facility is part of the cost estimate.

24/11.23 The commentor wants to know the impact of radiation as a result of the Program on children, particularly with regard to causing birth defects.

25/11.17 The commentor views the reservations near LANL as a "dump" (i.e., nuclear waste and radiation) and believes the populations are affected.

26/12.04 The commentor asks if it is a Government policy to view certain demographic groups as less valuable or more expendable than institutions like SRS.

27/32.06 The commentor wants SRS to be a viable technical facility but at the same time, wants SRS to be good stewards and to conduct research to protect the environment. The commentor believes that to say that the issue at SRS is just jobs is not the whole story.

28/11.18 The commentor wants to know to what extent the analysis of cancer risk factors in different schools of thought. The commentor notes that Dr. Alice Stewart has a different view on exposure to radiation and its effects. The commentor wants a balanced view in the PEIS.

29/41.03 When the commentor asked elementary questions in the breakout sessions, the commentor felt disrespected by others with more technical knowledge or differing views.

30/11.19 The commentor asks if the PEIS projects what would be considered a safe dose of radiation in the future. The commentor notes that what we may have considered safe 25 years ago is much different based on today's knowledge.

31/40.07 The commentor is concerned about proliferation issues, specifically, the source of the decision to have weapons of destruction and what to do with the materials from weapons dismantlement.

32/41.03 The commentor believes that the public should have input from the beginning. The commentor feels that input at the public hearing is backtracking and that policy decisions will continue to be made behind the public's back.

33/41.03 The commentor is skeptical that public input counts, believing that the decisions are already made.

34/32.06 The commentor asks if DOE has a preferred site and is that site SRS. The commentor also asks what the preferred site is for pit fabrication.

35/32.09 The commentor wonders if there is an effective way for citizens to close down SRS and help DOE to focus on another DOE site.

36/12.05 The commentor believes that African-Americans and low-income populations are being affected by SRS activities.

37/06.01 The commentor is concerned that SRS is destroying the natural habitat along the Savannah River.

38/41.03 The commentor believes a brochure titled "DOE is Interested in Your Comments" is misleading and should be clarified because it appears that SRS is the preferred alternative for all program activities and facilities (Stockpile Stewardship and Management Draft PEIS, Storage and Disposition Draft PEIS, and Pantex Site-Wide Draft EIS).

39/41.03 If the Draft PEIS does not have DOE's preferred site and alternative decision, the commentor then wonders if another EIS would be prepared after the decision if made.

40/40.35 The commentor asks by what process does DOE weigh strategic concerns against potential negative impacts to local populations.

41/41.07 The commentor asks if DOE engages an independent peer review of the PEIS analysis.

42/41.10 The commentor believes that DOE should fund citizen groups so they may hire an independent reviewer of the PEIS. That way, citizen groups and DOE can equally sit at a round table.

43/41.03 The commentor points out that the preferred alternative is not always the final choice.

44/41.03 The commentor asks if there is a mechanism for citizens to get the ROD changed.

45/41.03 The commentor wants to know the procedure for challenging the ROD, not necessarily changing it.

46/41.05 The commentor notes that a PEIS viewgraph presented by DOE during the public hearing graphically makes it appear that the public has no direct input in decisionmaking.

47/41.05 The commentor believes that laypeople do not understand a lot of the statements made at the public hearing because the PEIS is so large and complicated.

48/32.06 The commentor asks if it is final that SRS is no longer under consideration for new mission, activities, and programs.

49/11.20 The commentor states that Savannah, GA is known to be a cancer site. The commentor asks if the PEIS contains statistics on the amount of radiation that flows through Savannah via SRS plus the existing high cancer rate.

50/11.21 The commentor wants to know how old the epidemiological studies are that were used in the PEIS.

51/11.22 The commentor is concerned that a direct link cannot be identified between SRS radiation releases and latent cancer. The commentor also states that at the same time, it cannot be proven scientifically that radiation from Federal facilities does not cause cancer.

52/09.07 The commentor asks how reliable the PEIS transportation computer modeling is.

53/41.01 The commentor believes that current DOE outreach methods are not enough and that DOE needs to make a special effort to involve minority, downstream, and rural communities into public involvement. Additionally, the commentor believes that DOE should promote a strategic initiative to train these communities so they may contribute substantial comments.

54/12.06 The commentor wants the impact analyses to include the combined exposure of not only SRS, but other non-DOE industrial uses on low-income and affected communities.

55/41.01 The commentor states that a substantial turnout of the black community should occur at SRS public hearings, otherwise, the requirements of NEPA would not be met.

56/41.01 The commentor states that NEPA mandates the involvement of local elected officials in the process. The commentor believes that DOE should try to involve Georgia government officials. The commentor notes that since SRS is in South Carolina, Georgia seems to ignore it. The commentor believes this does not make sense since waterways flow to Georgia and many SRS workers live in Georgia.

57/41.10 The commentor believes it is almost a disservice to regular people to ask them to wade through three large documents. The commentor believes that DOE must take into consideration that the SRS area has a third-grade reading level and therefore DOE must prepare laypeople to intelligently understand and comment on these documents.

58/41.10 The commentor wants DOE to also provide citizens with facts from reputable, independent scientists that may be trusted.

59/41.01 The commentor believes that people of color need more input in public hearings since they are the ones who must live with the decisions made.

60/41.01 The commentor believes that SRS employees are an under-represented group at the public hearing and that DOE needs to find a way to involve their own employees and contractors.

61/32.09 The commentor asks what kind of impact a large number of persons calling or writing DOE to oppose new facilities at SRS or to close SRS altogether would have on decisionmaking.

62/32.09 The commentor believes that SRS should close down and operations be transferred to another DOE site, preferably ORR or Pantex.

63/40.81 The commentor does not want decisions concerning the location of operations and activities to fall into the "not in my back yard" syndrome. The commentor believes that risk should be minimized to all workers, families, and communities; and to the environment.

APRIL 30, 1996—EVENING SESSION

1/32.06 The commentor believes that area chambers of commerce are united together in wanting future missions, especially defense missions, at SRS.

2/32.06 The commentor looks forward to future missions at SRS.

3/41.01 The commentor wants to know how to receive copies of the Stockpile Stewardship and Management PEIS.

4/40.59 The commentor asks if DOE has integrated the PEIS with DOD mission.

5/42.01 The commentor believes that DOE's track record in program integration is not good and is therefore concerned about the interrelationship between the Stockpile Stewardship and Management PEIS, Storage and Disposition PEIS, and Pantex Site-Wide EIS. The commentor believes there should be an integrated program to find the most cost-effective solution.

Subject: PEIS For Stockpile Stewardship and Management
:
Date: March 12, 1996
Pages: 1, including this cover sheet.

COMMENTS:

The following comment is submitted in response to the Draft PEIS for Stockpile Stewardship and Management (DOE/EIS-0236):

1/34.17 Concerning the HE Fabrication mission and associated options, what consideration has been given to the potential increase in risk of accidental explosions that might result should weapons assembly/disassembly work at Pantex no longer have the benefits of the safety expertise/culture generated by the HE Fab mission? The safety of the weapons A/D mission at Pantex has always relied on and benefited from the HE Fab mission at the Plant. The HE Fab mission is the on-site source of a cadre of explosives experts who can provide knowledge, assessment, and immediate assistance with potential safety concerns, plus the HE mission also provides a continuing source of highly trained production technicians with excellent hands on experience of handling/processing explosives. It is my understanding that the HE Fab mission at Pantex is the roots of the excellent safety record at Pantex, and separating the two missions will destroy these synergistic safety-significant benefits. Because of the extraordinary high level of safety required for the weapons mission, I urge you to keep these two missions together.

Respectfully,

Sharon J. Hemphill

CITIZENS FOR NATIONAL SECURITY

P.O. Box 4941
Oak Ridge, TN 37831-4941

March 11, 1996

The Honorable Hazel R. O'Leary
Secretary of Energy
1000 Independence Avenue, SW
Washington, DC 20585-1000

Dear Secretary O'Leary,

1/41.10 The Department of Energy is restricting the opportunity for public review and comment on the draft Stockpile Stewardship and Management Programmatic Environmental Impact Statement and the draft Storage and Disposition of Weapons - Usable Fissile Materials Programmatic Environmental Impact Statement.

Both of these voluminous draft documents cover significant federal actions directly affecting the future of the nation's nuclear weapons program and deserve careful and thorough review. By issuing both documents simultaneously and by requiring the comment periods to be concurrent, the Department of Energy is placing an unnecessary and unreasonable burden on the public. Rather than attempting to restrict public review, the Department of Energy should be soliciting the widest possible involvement consistent with the intent of the National Environmental Policy Act.

In announcing the release of these two draft environmental impact statements, you stated, "Today, we are preparing the nation for nuclear challenges of the 21st Century." The Department of Energy should also prepare for independent review and comment on nuclear plans by technical experts no longer associated with the government or its contractors.

The Citizens for National Security is committed to providing unbiased review, analysis, and comment on proposed actions by the Department of Energy that may impact the safety and reliability of the nuclear weapons stockpile. A substantial number of our members are retired nuclear weapons experts capable of providing an entirely different perspective from that of the Department of Energy's contractors. Other members of our organization are retired research scientists, engineers, and representatives of all craft skills whose professional lives were devoted to the nation.

H. O'Leary
March 11, 1996
Page 2

Our organization was formed following the July 25, 1995, Public Scoping Meeting in Oak Ridge, Tennessee, on the Stockpile Stewardship and Management Programmatic Environmental Impact Statement.

2/41.05 Currently, we are analyzing the draft Stockpile Stewardship and Management Programmatic Environmental Impact Statement for the public hearing dedicated to this voluminous document on April 1, 1996. The Department of Energy has allocated only four hours in one of the smallest meeting rooms in Oak Ridge. Nevertheless, we intend to attend and provide extensive technical comments. Unlike the Public Scoping meeting, we suggest that the Department of Energy transcribe all comments for written response in the final Stockpile Stewardship and Management Environmental Impact Statement. We are especially sensitive to the tendency of program officials to modify their verbal responses from site to site. Written responses are available for review by a larger audience and carry a commitment not present with verbal responses.

1/41.10 continued The Citizens for National Security cannot provide the same depth of review of the draft Storage and Disposition of Weapons - Usable Fissile Materials Programmatic Environmental Impact Statement as for the Stockpile Stewardship and Management document. The decision by the Department of Energy to place the burden of concurrent review of these two major federal actions on the public can only impact the ultimate implementation of the Storage and Disposition of Weapons - Usable Fissile Materials.

Sincerely,

Bill Bibb

Department of Energy
Stockpile Stewardship and Management Proposal

To Whom it May Concern:

1/40.12 I attended the Santa Fe public hearing on the environmental impact statement on Thursday, April 25, but had to leave after 2 hours. My feedback is (as a teacher of business) that I feel it is completely inappropriate to expand the work at Los Alamos Labs as you have planned - the country simply has far higher priorities than your proposal given our budget constraints. I feel the current warhead management program is more than effective. Any program (such as you have recommended) that will both phenomenally increase costs in a time of budget crisis and will also phenomenally increase nuclear waste generation when there is no acceptable disposal method on the table is unacceptable. Further,

2/11.27 any nuclear accident (however small) would destroy the fragile tourist economy of the State of New Mexico.

Thank you for considering my input.

Sincerely,

Lee Cartwright

RE: Comments and questions regarding the Stockpile Stewardship and Management (SSM) Programmatic Environmental Impact Statement (PEIS)

Dear Sir or Madam:

Thank you for the chance to comment on the SSM PEIS, a document that is of great importance to the Pantex Plant, and consequently to the economic vitality of Amarillo and the Texas panhandle.

1/30.01 In addition to my gratitude at the opportunity to comment on the PEIS, I appreciate DOE's commitment to operating in an environmentally sound fashion at Pantex. The continuation of environmentally sound operating and management principles at Pantex is essential to the continued operation of the plant and paramount to all further comments about current or contemplated missions being performed at Pantex.

2/34.01 I do agree with the conclusions drawn in the SSM PEIS that Pantex is the best site for the continued assembly/disassembly missions required by the DOE. I also urge DOE to abandon any plan to remove the High Explosive fabrication mission from Pantex. Pantex offers the best site for continuation of HE work from the perspective of cost and manufacturing expertise and experience. Additionally, should production demand increase in the future, the HE facilities at Pantex are already appropriately sized for greater production capability. It is in the best economic, safety and defense interests of the nation to retain the production capability in HE fabrication that exists by continuing that mission at Pantex.

After having studied the Draft SSM PEIS documents, I offer the following comments(•) and questions(o) to the DOE for inclusion in the comment summary document:

3/41.03
- To what extent was public support (or lack thereof) at the various candidate sites considered in the PEIS process?

4/08.24
- Please describe the statistical rationale for your statement in the SSMPEIS that direct and indirect jobs lost (from the transfer of the HE manufacturing mission to the Labs) would create no observable change to the Pantex regional economic area unemployment rate, housing/rental vacancies and public finance expenditures/revenues.

[illegible]

SSM-F-004
COMMENT LETTER PAGE 2 OF 2

2/34.01 continued
- In the draft SSMPEIS report you state that the criteria to be used for evaluating the alternatives and ultimately arriving at the most suitable Record of Decision (ROD) are environmental impact, cost and technical feasibility.
  - o Please explain how these criteria have been applied to the alternatives for HE manufacturing.

5/34.10
- o Please explain how DOE can justify the cost of 432 people at the weapons labs to manufacture explosive components when Pantex has identified about 50 to perform the operation.

6/08.25
- The socioeconomic analyses of the three EISs are not consistent. The SWEIS (p.5-17) assumes 1.66 indirect jobs in the region for every job at Pantex. The SSMPEIS (p.8-32) assumes 1.16 and the S&DPEIS (p.4-205) assumes 3.51.
  - o Please explain these differences.

7/08.26
- The Amarillo Economic Development Commission (AEDC) analysis, based on local knowledge of the area and a regional impact study performed by Dr. Ray Perryman of Southern Methodist University, gives a ratio of 2.87 additional jobs in the region to every one Pantex job (for a total job multiplier of 3.87).
  - o Why didn't the DOE consult with the AEDC and/or the City of Amarillo and use the expert analysis that local taxpayers had already paid for?

8/12.07
- Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, and President Clinton's February 11, 1994, Memorandum for the Heads of all Departments and Agencies requires an analysis of environmental effects on low-income and minority populations to include human health, social, and economic effects.
  - o Why do the draft Pantex SWEIS, SSMPEIS, and S&DPEIS analyze only human health effects of the proposed actions and not the social and economic effects, as required?

Thank you for your attention to these comments and questions.

Sincerely,

Bob Jabs
Pantex Retention and Expansion Coordinator

Comments:

1/40.01 I am deeply concerned about continued nuclear testing + development at Los Alamos.

2/43.18 The recent fire brought home the very real potential for a major disaster. Why don't you pursue other safe means of energy supply such as solar etc. etc.

Our planet can not absorb the toxins anymore - everything is so out of balance + the Lab is a major contributor to the death + destruction of our planet. Please stop before it is too late.

3/40.27 With all the brilliant minds employed at Los Alamos - why use them on nuclear development? Put them to use with developing safe + non-toxic ways to generate energy. I feel helpless

Please continue on the other side if you wish to use additional space. THANK YOU for your comments and your interest in us.

Date of Receipt: Receiver's Initials:

Comments (cont'd):

3/40.27 continued because nobody listens to the people - everyone I know is against nuclear power + waste. This is not a democracy in the real sense. The people in power are pursuing this path totally for money + greed. Please use the lab for disease research, safe + non-toxic energy + development of new technology.

REVIEW COMMENTS
STOCKPILE STEWARDSHIP AND MANAGEMENT
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT (EIS)
Texas Natural Resource Conservation Commission (TNRCC)
Office of Air Quality
April 30, 1996

This review is on the section on air quality impacts in Section 4.5.3.3. of Volume 1 and Appendix B, table B.1.3.5-1 of the above-referenced EIS.

1/03.09
- The emission rates reports in Appendix B and the estimated pollutant concentrations listed in table 4.5.3.3-1 are the same as discussed in the Storage and Disposition of Fissile Materials EIS. Therefore, comments regarding the discrepancy between estimated concentrations and TNRCC monitored concentrations of particulate matter holds true for this EIS.
- The conclusion that the No Action alternative and the Downsize Assembly/Disassembly and High Explosive Fabrication alternative will not produce air pollutant concentrations exceeding Federal and State regulations and guidelines is acceptable.

If you have any questions regarding the above comments, please contact Mr. Joe Panbach, Office of Air Quality, Ambient Monitoring Section, at (512) 239-1656.

Comments of the Institute for Energy and Environmental Research on the Department of Energy's Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management (DOE/EIS-0236)

Hisham Zerriffi and Arjun Makhijani

May 6, 1996

The Institute for Energy and Environmental Research (IEER) submits the following comments on the Department of Energy's (DOE's) draft Programmatic Environmental Impact Statement (DPEIS) for the Stockpile Stewardship and Management program (SSM). Generally, these comments are based upon IEER's review of the environmental, safety, reliability, and non-proliferation issues of the SSM.

Overview

The DPEIS is fundamentally deficient on several counts:

1/40.60
1. It does not consider a reasonable range of alternatives for the size of the stockpile. For instance, it excludes the views of many analysts who have concluded that deep reductions far below 1,000 warheads are desirable for U.S. and global security, even though analysts with extensive military-related experience are among the people who hold such views.

2/41.18
2. It excludes a cumulative environmental analysis of the entire SSM program, including existing facilities such as Lyner in Nevada, and facilities under construction such as DARHT at Los Alamos, and does not consider programmatic alternatives with different cumulative environmental impacts. For instance, it does not consider alternatives to uncontained underground subcritical tests, even though such tests are possible.

3/40.34
3. It does not separate out safety and reliability in its analysis of the need for the program, even though they have very different environmental implications. Safety issues involving the primaries of nuclear warheads could result in severe environmental damage in the event of an accidental detonation, but there is no risk of accidental

European office: Wilhelmstr. 3, 69120 Heidelberg, Germany, Tel: (011-49) 6221-47070, Fax: (011-49) 6221-470710

Printed on recycled paper

detonation (and therefore no possible environmental damage) from reliability problems.

4/40.07

4. It does not consider the instabilities in the non-proliferation regime that could be triggered by the program and the large security and environmental consequences of resuming the arms race in the event of such instabilities.

5/40.37

5. It has an internally contradictory definition of "reasonably foreseeable future." This is defined as 2003 for the purposes of reference stockpile size. At the same time, the DOE is confident that it requires new facilities which will not even begin full operation until after that date and projects that such needs will exist for several decades. This is used as a justification for building the new facilities. If the DOE can reasonably foresee the need for such facilities, it should also consider possible related events in a several-decade timeframe. Otherwise it ought to abandon new facilities that will not come into full operation until 2003 or after.

6/41.12

6. The technical decisions on SSM seem to be coming from policy decisions. This is the reverse of normal NEPA requirements in which technical alternatives that can fulfill larger social goals (whether in the realm of security or economics) but have differing environmental impacts, are compared. The DOE has not compared differing ways of achieving overall security goals, but rather simply defined away the problem by assuming it to be coterminous with existing policy. This has allowed DOE to dismiss all major programmatic alternatives to the course it has already chosen, even though these alternatives have widely differing environmental impacts.

These basic deficiencies mean that the DPEIS is seriously lacking in its consideration of the environmental impact of alternative means of achieving security goals and meeting existing treaty commitments, including commitments under the NPT.

7/40.33

The DPEIS does not fulfill the mandate of NEPA even at a minimally acceptable level because it does not provide a reasonable set of alternatives for the public to consider and comment upon. Our main recommendation is that DOE re-issue the Draft PEIS and, at a minimum, include the following options in addition to the ones considered:

- Remanufacturing weapons to original specifications.
- Maintenance of weapons through enhanced surveillance and then solving problems either through remanufacture or "fixes."
- Entirely phasing out nuclear weapons over the same period that the SBSS program facilities are projected to be operational(about three decades).
- Maintaining or constructing facilities needed to support a deterrence strategy based on keeping the following numbers of warheads in the U.S. nuclear arsenal for the long-term: 10 and 100.
- The SBSS program, carried out as presently envisioned, except with permanent closure of the Nevada Test Site, moving the planned underground subcritical tests to contained facilities at Los Alamos and/or Livermore.

1/40.60
continued

For each option the DOE should consider whether the SBSS program described would be required and what types of facilities would be used or eliminated.

8/40.05

In addition, the DOE should separate consideration of safety and reliability throughout the document. Specifically, it should take into account the differences between SBSS facilities required under a nuclear weapons strategy based only on retaliation to nuclear attack compared to those required for options that include (i) a possible first strike, especially a counterforce strike, against a nuclear armed adversary or (ii) use of nuclear weapons against a non-nuclear-armed adversary. Finally, DOE should amend the PEIS to take into account the other specific criticisms discussed below.

Safety and Reliability

The separation of safety and reliability issues is basic to consideration of the environmental impacts of the SSM program. This is because some safety defects, notably with primaries, can cause severe environmental impacts, while reliability defects relate only to the performance of the warhead when it is detonated.

The two paragraph discussion of the stockpile data summary (p 2-6) is wholly inadequate and misleading since there is no separate discussion of safety and reliability. These data form the technical basis for the DOE's purpose and need for the SSM program. We have analyzed this data and on this basis find the following specific problems in the DPEIS:

3/40.34
continued

1. When safety and reliability issues as separated, our analysis of the data on actionable defect types indicates that:
   a) Seventy-four percent of actionable defect types have affected the reliability, rather than the safety, of the warhead.
   b) Eighty-one percent of reliability problem types affect non-nuclear components, not the primaries and secondaries on which the stockpile stewardship program focuses.
   c) Secondaries exhibit very few problems. Only two safety and eight reliability problem types have been found with secondaries out of a total of 186 reliability problem types.
   d) The vast majority of safety problem types found with primaries were found with warheads that were produced around the time of the 1958-1961 moratorium. This time period of warhead development and production has been linked by Dr. Ray Kidder to rushed design and production work.

2. There is no discussion of the source of problems found with the stockpile. The majority of Actionable Findings are due to design, production or causes other than aging. Our analysis of the data revealed that:
   a) Aging accounts for only twelve percent of safety problem types (Figure 1) and twenty-four percent of reliability problem types (Figure 2).
   b) Primaries have exhibited no aging-related safety problems since the surveillance program began in 1958 (Figure 3). All problems have been the result of design of the warhead. As a result, eighty percent of safety problem types affecting primaries were found within the first four years of production.

3/40.34 continued

c) Only eight aging-related safety problem types have been found since 1958. Only two of these have been found with warheads scheduled to remain in the arsenal and these affected the parachute system and the gas transfer system.

3. The DPEIS does not discuss the effect of reliability problems on the potential wartime performance of the arsenal. If the DOE assumes wartime use of nuclear weapons, this is absolutely necessary in order to analyze the need for the SSM program. Data provided elsewhere by the DOE show that:
a) Sixty-eight percent of reliability problem types result in a reduction to the reliability of less than one percent. Only five percent reduce reliability by more than ten percent (Table 1).
b) Overall, only thirty-three percent of problem types require a retrofit or major design change. The rest can be solved without changes to the warhead.

Table 1: Reliability Reductions

Percent Reduction in Reliability	Number of Defect Types	Percentage of Defect Types
zero to one percent	112 defect types	68%
one percent to five percent	37 defect types	23%
five percent to ten percent	6 defect types	4%
over ten percent	9 defect types	5%

9/40.22

None of the preceding information was presented in the DPEIS despite its relevance to the purpose and need for the SSM program. The DOE has provided this information only in the Tri-laboratory report (reference SNL 1996a in the DPEIS), which is grossly inadequate for proper analysis of the data.

First, data which is vitally important for establishing the need for the program should be analyzed carefully in the DPEIS. Second, the SNL 1996a report is deficient in its analysis of the data, and is therefore an inadequate basis for conclusions in the DPEIS. The SNL report does not systematically separate safety and reliability and often uses total figures (with safety and reliability numbers added) in its charts. The report also fails to distinguish clearly between aging problems and other problems. The report does not show how aging affects important components such as the primary. Our review of the data indicates that these methods of presenting the data are inadequate and misleading. (See also further comments on reliability below.)

Further, the Analysis of Historical Stockpile Data places too large an emphasis on the role of nuclear testing. According to the DPEIS, the surveillance and non-nuclear testing of production and stockpiled weapons through the Stockpile Evaluation Program has "detected about 75 percent of all problems ultimately detected, and it has been the principal mechanism for discovering defects and initiating subsequent repairs and replacements." (DPEIS, p.2-5) The Stockpile Evaluation Program merits only one paragraph in the DPEIS while underground nuclear testing is discussed for five

9/40.22 continued

paragraphs. Underground testing has played a relatively small role in detecting problems and maintaining existing weapons.

Additionally, the DPEIS fails to consider the analysis of Dr. Kidder of Lawrence Livermore National Laboratory in 1987 which stated that nuclear testing after production was only necessary in solving problems with warheads in the sixties and eighties because these warheads were not properly designed and tested in the first place.[1]

5/40.37 continued

Non-proliferation and time frame issues
In discussing the Nuclear Nonproliferation Treaty (DPEIS, p. 2-2) the DPEIS states that "[F]or the Stockpile Stewardship and Management DPEIS, speculation on the terms and conditions of a 'zero level' U.S. stockpile with international verification, as some have suggested during the scoping meetings, goes beyond the bounds of a reasonably foreseeable future." In this context, the DOE indicates that the most useful definition of the term "reasonably foreseeable future" is 2003, the time frame for achieving all START II mandated reductions (p. 2-1). At the same time, the DOE is predicting that it will need new facilities because it is highly unlikely that the U.S. and other nuclear powers will arrive at a specific disarmament agreement

1/40.60 continued

The DOE cannot assume that arms reductions will stop at 1,000 (the low case considered in the DPEIS). A number of analysts, including the first director of Lawrence Livermore National Laboratory, Herbert York, have concluded that far smaller arsenals (100 warheads or even less), would suffice for deterrence. These views cannot be dismissed out of hand as DOE has done in the DPEIS, because the environmental and security impacts of maintaining large arsenals (roughly 1,000 to several thousand warheads) would be considerably different than those of a stockpile of 100 warheads or less.

4/40.07 continued

Finally, the U.S. has an explicit commitment under the NPT, which is the law of the United States, to negotiate in good faith towards nuclear disarmament. By ignoring the disarmament option for the foreseeable future, DOE is basing its DPEIS on the assumption that the U.S. will not give up nuclear weapons under any circumstances. If a general in the Strategic Air Command (General Horner) could see advantages in nuclear disarmament for the U.S., we fail to see why the DOE does not consider it even as one option among many. Instead of examining carefully the fulfillment of the solemn treaty commitments of the U.S. under the NPT, the DPEIS actually subverts the intent of the NPT and seems to confirm the critics' views of U.S. policy in the current CTBT negotiations. Specifically, the DPEIS claims that because there is no time frame for disarmament in the NPT, the U.S. should have a large SSM program. To use the lack of a timetable to create an infrastructure designed to perpetuate a large nuclear arsenal is, in our view, a violation of the spirit of the "good faith" requirement of Article VI of the NPT.

[1] R. E. Kidder. *Maintaining the U.S. Stockpile of Nuclear Weapons During a Low-Threshold or Comprehensive Test Ban*. UCRL-53820. Lawrence Livermore National Laboratory. October 1987. pp. 4-5

4/40.07 continued

The discussion of the non-proliferation impacts of the SSM program (pp. 2-11 to 2-12) is inadequate and based on flawed assumptions. Specifically:

- There is no analysis of the non-proliferation impacts of the SBSS program. A comprehensive review of the vertical and horizontal proliferation risks of the SBSS program should be conducted. In contrast, this section of the DPEIS does not even refer to potential proliferation risks. It simply states that "[O]ne benefit of science-based stockpile stewardship is to demonstrate the U.S. commitment to NPT goals." There is disagreement over this issue and it should be addressed in the DPEIS. While one view is that the SBSS program furthers non-proliferation goals by enabling the U.S. government to advocate a "zero yield" CTBT, other views regard the SBSS program as provocative and as an instrument that could undermine the NPT. The SBSS program could pose both a vertical proliferation risk by maintaining weapons designers and expanding design capabilities, and a horizontal proliferation risk by destabilizing the non-proliferation regime. For instance, it could create pressures for the U.S. to withdraw from the CTB in order to test weapons modifications. Or it could spur weapons research and design in other countries and hence cause the U.S. to escalate its own work in these areas. In view of the wide range of opinion on this subject, it is simply unacceptable for the DPEIS to state without analysis that the "[p]roliferation drivers for other states would remain unchanged" (p. 2-11) regardless of whether the U.S. implemented an SBSS program.

3/40.34 continued

- The argument on incentives for other countries with the capability to produce nuclear weapons mixes the technical and political aspects of nuclear weapon reliability. The DPEIS states that "The loss of confidence in the safety or reliability of the weapons in the U.S. stockpile could result in a corresponding loss of credibility of the U.S. nuclear deterrent and could provide an incentive to other nations to develop their own nuclear weapons programs." (2-11) If U.S. nuclear strategy is truly based on deterrence, then technical reliability issues are not significant. Only a small number of potential reliability problems have a significant impact on reliability (see Table 1 above). Moreover, the DOE defines reliability in a very restrictive way. Reliability is defined by the DOE as the probability that a warhead will detonate at the rated yield or higher. Any defect that decreases this probability is considered one that affects reliability. This is true even if the yield reduction is minimal. The effects of nuclear weapons are so severe that a small chance that it will not provide at least the rated yield should not have an effect on retaliatory deterrence. DOE should explicitly discuss the comparative need for the SBSS program if a strategy of retaliatory deterrence is adopted as distinct from a strategy that includes the possibility of a first use of nuclear weapons, especially counterforce strategies.

4/40.07 continued

- The assumptions made about proliferation drivers such as "international competition or the desire to deter conventional armed forces" (2-11) fail to address the potential proliferation effects of the U.S. maintaining a nuclear weapons design and production infrastructure.
- The DPEIS ignores the spirit, if not the letter, of Article VI of the NPT which calls for good faith negotiations on nuclear disarmament. In contrast the DPEIS states that the "treaty does not mandate stockpile reductions by nuclear states, and it does not

4/40.07 continued

address actions of nuclear states in maintaining their stockpiles." Good faith negotiating precludes *plans to indefinitely maintain* a nuclear weapons arsenal. Additionally, maintaining the ability to design new nuclear weapons does not show good faith. DOE should define an option for the DPEIS that includes a reduction of the U.S. nuclear arsenal over a several decade period comparable to the operating life of the SBSS facilities. The option should include a phase out of SBSS facilities as they become unnecessary for the remaining arsenal DOE should define the need for operating each facility explicitly in relation to safety criteria and reliability criteria, which should each be considered separately.

Other Issues Related to Program Alternatives:

The DOE has omitted alternatives without giving them due careful consideration.

7/40.33 continued

1. Remanufacturing: The DOE states that precise replication is not always possible and therefore remanufacturing is not a reasonable alternative. Additionally, the DPEIS states that the emphasis is on "nuclear components which can no longer be functionally evaluated by nuclear tests." The elimination of this option fails to take into account several key points:
   a) A number of experts, including former nuclear weapons designers, such as Ray Kidder, J. Carson Mark, and Richard Garwin, have stated that remanufacture is a reasonable method to maintain the nuclear arsenal after a Comprehensive Test Ban.[3]
   b) The failure to consider systematic ways to deal with safety and reliability issues arising from non-nuclear components is an egregious omission. Nuclear components exhibit fewer problem types than non-nuclear components. For instance, the primaries, which are nuclear components, have exhibited no aging-related safety problems, but non-nuclear components have had such defects.
   c) The DPEIS does not consider the implications of a recommendation that "fixes" to the primary should be avoided, even if meant as "improvements." Kidder, Mark, and Garwin, among others, have stated that changes to the "physics package" of warheads should be avoided since they can introduce unnecessary uncertainties.
2. Maintenance: This approach is the most similar to the proposed SBSS program. The major difference seems to be that new experimental facilities would not be constructed, while surveillance of weapons would be enhanced. Existing experimental facilities would continue to be used. Eliminating this option makes it clear that this DPEIS is biased towards one outcome. The maintenance option, like the remanufacturing option, is reasonable and should have been included. It would have allowed both the DOE and the public to compare the environmental impacts more clearly. Furthermore, the DPEIS states that current facilities would be inadequate to make the technical judgments necessary for remanufacturing or "fixes" where nuclear testing played a role. Only by including this alternative can the DOE truly judge whether existing facilities are inadequate. For the DOE to begin with the premise that proposed facilities are absolutely necessary is prejudicial. Further, by beginning with this premise and not

[3] Ibid. pp. 6-9, 27-29 and Richard L. Garwin, "Atoms do not age." *The Bulletin of the Atomic Scientists*, Vol. 49 No. 8 (October 1993), pp. 10-11.

7/40.33 continued

providing the public with the opportunity to make its own judgment on the issue, DOE violates the intent of NEPA.

1/40.60 continued

By eliminating reasonable alternatives, such as the ones mentioned above, the DOE has made it impossible to conduct a true comparative analysis of the SBSS program. It has biased the DPEIS towards the SBSS program. The DOE has also failed to provide adequate rationale for eliminating the above alternatives. In this respect DOE is not in compliance with the spirit of NEPA which requires all reasonable alternatives to be considered.

2/41.18 continued

The DOE's program alternatives are also incomplete because the entire program is not analyzed. The DOE has conducted a separate EIS for the DARHT facility. This facility is an integral part of the DOE's SBSS program. For this DPEIS to have been truly Programmatic, DARHT should have been analyzed as a component of the program. A facility-specific EIS for DARHT should have been conducted only after the SSM DPEIS was completed. As it stands, DARHT is considered part of the No Action alternative. This is unacceptable, especially since DARHT is under construction and both axes are not projected to be in operation for over five years.

Further, by subsuming DARHT's environmental impacts under the No Action alternative, the DPEIS does not present a clear assessment of the cumulative environmental impacts of the all the new facilities it proposes under the SSM program.

Issues related to the SBSS Facilities

In presenting arguments in favor of the three proposed SBSS facilities (NIF, CFF, and Atlas) the DPEIS simply compares their operating parameters to previous facilities and states that information from these facilities would be used to modify computer codes that model nuclear weapons. While it is clear that the new facilities operate at higher temperatures, volumes, etc. this does not necessarily provide justification for constructing them.

10/40.36

The DOE must justify any new facilities by making a clear case for their need in relation to specific safety or reliability issues. In such an analysis the DOE must be very precise and clear on whether these facilities will aid in maintaining safety or reliability, whether the problems being discussed are due to aging, and exactly how the facility would be of help. The DPEIS must also state what specific deficiencies existing facilities have and whether existing facilities can perform the task adequately. These analyses must take into account comments made above regarding the use of data from the Stockpile Evaluation Program.

The DOE must also explain how it will resolve the issue of scaling information from these facilities to the volumes, pressures, temperatures, and energies of nuclear explosions. The DOE has not adequately explained how it will deal with the fact that these facilities can only study isolated phenomena and not the complex interaction of phenomena occurring in nuclear weapons. An explanation of how these difficulties would be overcome must be

provided for the public and the DOE to determine if these facilities are relevant to maintaining either the safety or reliability of the existing arsenal. Of particular concern is the possibility that modifications to computer codes based on information from these facilities would reduce the relevance of the codes to *existing* warheads.

10/40.36 continued

The DOE has also failed to prioritize facilities according to need. The DPEIS states that since the facilities perform separate functions, "they are complementary in nature and not alternatives to one another." (DPEIS, p. 2-10) However, this fails to take into account that while these facilities do not perform the same function, they may not all be necessary. Are facilities that focus on secondary performance as necessary as facilities that focus on primary safety? Are any new facilities necessary to ensure safety of nuclear components? Primaries, secondaries, and non-nuclear components all present different problems and some are more likely than others to exhibit problems. Therefore, it is only reasonable to assume that facilities dedicated to studying certain components would differ in importance. If the DOE and the public are to make judgments concerning the need to construct facilities and the cost versus benefit of individual facilities as part of an overall program, it is necessary to have a clear idea in a PEIS of the relative importance and role of various facilities.

4/40.07 continued

The DOE has not discussed the possible weapons design use of these facilities. This is necessary if the public is to adequately assess the impacts of the program. Existing experimental facilities have been an integral part of the weapons design process in the past. As stated in the Environmental Impact Statement for DARHT, this facility was originally proposed in the eighties as part of the weapons design program. This programmatic impact statement should address the weapons design potential of each facility, as well as the change in weapons design capabilities of the laboratories as a whole if these facilities are constructed.

In the NIF Non-Proliferation Study, one of the arguments put forth by the DOE to prove NIF was not contributing to vertical proliferation was to state that the United States was no longer developing warheads of new design. This argument, also presented as fact in this DPEIS, has three fundamental flaws:

- What is at issue is weapon design *capabilities*. Even if the DOE is not developing new design weapons currently, this does not imply that new facilities would not aid in future weapons design work if the policy were to change.
- This does not actually prevent the laboratories from *designing* new warheads, even if they are not developed or produced. These designs could be rapidly developed if the United States so desired.
- Halting the development of "new" design weapons does not prevent the DOE from making militarily significant modifications of existing designs. The current example would be the modification of the B61 mod 7 into a B61 mod 11 in order to replace the aging B53. The modification is not being done for either safety or reliability. The modification is intended to change the military characteristics of the warhead. Recent

statements by Dr. Harold Smith, of the Pentagon, indicates that the U.S. plans to not just to develop the warhead, but actually to deploy it.[3]

Plutonium-242

11/40.41 The cover sheet to the DPEIS states that a classified appendix presents the "purpose of and need for the plutonium-242 to be stabilized at SRS for use in future weapons complex research and development activities." Unclassified portions of this appendix should be provided as part of the DPEIS. Further, the note on the appendix should have been prominently presented in the body of the DPEIS, rather than at the end of the cover sheet.

The non-proliferation implications of separating Pu-242 and its environmental impacts should be explicitly discussed in the context of this PEIS, even though these may be covered in facility-specific statements.

Disclosure of information

8/40.05 continued The DOE has not provided data sufficient to determine whether the programs described would be required under a nuclear weapons strategy based only on retaliation to nuclear attack compared to ones that include (i) an option of first strike against a nuclear armed adversary or (ii) an option of use against a non-nuclear-armed adversary. Such data should be published as part of the PEIS.

May 3, 1996

Hazel R. O'Leary
Secretary of Energy
1000 Independence S.W.
Washington D.C. 20585

Dear Secretary O'Leary:

On November 14, 1995, the Pantex Plant Citizens' Advisory Board commented on the proposed Stockpile Stewardship and Management PEIS

A reply, dated December 15, 1995, was received from Thomas P. Seitz. It provided background information and general statements, but there were no specific replies to the issues raised. The Department of Energy said it would respond to the concerns during the hearings.

However, the specific issues outlined in the December 14 letter were not addressed at the meetings in Amarillo on April 22 and 23; therefore, the PPCAB is reissuing the advice.

We would appreciate receiving specific responses to the issues raised.

Sincerely yours,

Louise Daniel

RE: Preferred Alternatives for the Weapons Complex
Stockpile Stewardship and Management EIS

Dear Secretary O'Leary

As you consider the reconfiguration alternatives of the weapons complex in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement, we want to emphasize the value which the Pantex Plant Citizens' Advisory Board places on a fair and equitable evaluation of existing facilities and sites necessary to fulfill the long-term needs of the future nuclear weapons complex. If long-term stockpile stewardship and management requirements call for a major assembly/disassembly/maintenance site as well as a major High Explosive (HE) manufacturing site, we believe Pantex has existing facilities and capabilities which must be given careful consideration. Advantages of Pantex as the Explosive Fabrication Facility are

1/30.01

1) Existing Facilities

We believe that DOE must fully evaluate the more maintenance free, cost-effective HE operations which Pantex could contribute. Since 1980, DOE has been upgrading Pantex facilities, which currently include modern HE fabrication facilities. Pantex now has a new Explosives Machining facility (12-121), an Explosive Analysis Laboratory (11-51), a Developmental Machining

facility (11-50) to which the HE formulation will be relocated, and an HE Synthesis Facility currently under construction (11-55). The PPCAB expects the DOE to conduct a detailed investigation for location of HE operations and to be held accountable for the resulting decision.

1/30.01 continued

2) Manufacturing Experience

A prime concern of this community is the safe processing of explosive materials. Pantex has been producing explosive materials and weapons for over 40 years. During this time, Pantex employees have gained valuable manufacturing experience and technical skills. This level of expertise is unique to the workforce at Pantex and is an important asset to the DOE. During the past five years, Pantex has been working to formalize its operation and train its workforce in the philosophy of Conduct of Operations. Added assets include the Voluntary Protection Program and the Metal Trades Council Safety Officer Program.

3) Benefits of Collocation and Maintenance of Core Competency

HE fabrication and assembly/disassembly operations currently share facilities and support operations at Pantex. The potential adverse impact of separating these two operations must be taken into consideration. unnecessary costs due to duplicating the infrastructure necessary to support HE fabrication at the new sites(s), transporting machined HE components between HE fabrication and assembly/disassembly operation sites; and increased numbers of component inspections prior- and post- transportation. Risks to the public, the workers, and the integrity of the HE components due to handling and transport, must be fully evaluated also.

Safer, more environmentally sound, and cost-effective operations are important reasons to consider maintaining the HE core competency in association with the nation's nuclear assembly/disassembly facility.

SSM-F-009
COMMENT LETTER **PAGE 4 OF 5**

4) Operating Costs

1/30.01 continued

Based on the information the PPCAB has sought, the estimated incremental operating costs for HE manufacturing at Pantex is just over three million dollars annually; this is approximately half that of the other site alternatives. There has been some misunderstanding in assessing the current HE fabrication operating costs at Pantex. It appears the DOE is comparing the incremental costs for HE fabrication at the two laboratories with the stand-alone costs of HE fabrication at Pantex which distorts the cost comparison. During these times of budget cutting, the DOE must not irrationally compromise the reliability, effectiveness, experience, and knowledge at Pantex. For the sake of clarity, all basic assumptions and methods of comparison and evaluation must be fully disclosed.

5) Environmental Issues

The new Pantex facilities designed for HE machining address many environmental concerns for the continuing HE operations. Should HE operations be relocated to another site, we feel strongly that operations should not compromise the environment at those sites, creating additional future restoration problems. Pantex is actively exploring alternatives to open air burning of HE, is seeking to eliminate effluents containing trace concentrations of HE to unlined ditches within the next year, and is committed to the goals set by Clean Texas 2000. Our support for retaining continuing HE operations is contingent upon a satisfactory completion of these initiatives, adequate sampling of Pantex site agricultural products to ensure product viability, and an assumption that there will be no increase in emissions resulting from HE disposal at the Burning Grounds. The continuation of HE work should also be contingent on the ability to meet RCRA/CERCLA standards for HE at inactive firing sites and an in-depth analysis of active firing sites to determine environmental risks.

In light of current openness initiatives within the bounds of national security, citizens should be provided with information on the anticipated range of volumes of HE needed to meet expected nuclear arsenal requirements.

2/04.05

The major water source for the High Plains of Texas is the Ogallala Aquifer underlying Pantex. This aquifer is the source for agriculture in this semi-arid

SSM-F-009
COMMENT LETTER **PAGE 5 OF 5**

2/04.05 continued

region and is an essential source for human consumption. Products grown in this area are shipped all over the world. Any possibility of contamination to area agricultural products could destroy that industry which has been the keystone to economic stability in this region. Continuation of current monitoring programs at Pantex, with upgrades as new technologies emerge, are vital to safeguarding this area.

We appreciate your commitment to community involvement and know our comments will be considered in the evaluation and recommendation for the future of High Explosive Fabrication.

Sincerely,

[signature]

Dear Mr. Rose:

The State has reviewed the Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management (DOE/EIS-0236), affecting Lawrence Livermore National Laboratory, Alameda and San Joaquin Counties, submitted through the Office of Planning and Research.

We coordinated review of this document with the Regional Water Quality Control Board; the Energy and State Lands Commissions; and the Departments of Fish and Game, Health Services, and Transportation. The Department of Transportation states "If there is any transportation of nuclear material, please contact the appropriate CALTRANS District office. For Alameda County contact Phillip Badal at (510) 286-5505 and for San Joaquin County contact Dana Cowell at (209) 948-7906." The California Energy Commission has indicated that they will reply directly to you.

Thank you for providing an opportunity to review this project.

Sincerely,

Maureen F. Gorsen
Assistant General Counsel

RE: COMMENTS ON THE DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT FOR STOCKPILE STEWARDSHIP AND MANAGEMENT

1/40.43 We are writing to express our concern regarding the lack of credible alternatives considered under the Stockpile Stewardship program.

2/40.36 After review of the SSM/DPEIS we have come to the conclusion that the document is fatally flawed in that it proposes new "enhanced experimental capabilities," at an enormous cost, to accomplish what is essentially the downsizing of the US nuclear weapons arsenal. The DPEIS also fails to establish the need for any of the new facilities proposed within it in the context of ongoing international arms reductions. We are of the opinion that after conducting well over 1000 nuclear tests, the fundamental understanding of nuclear weapons mechanics should be sufficient to maintain and downsize the existing arsenal in a safe reliable manner. Therefore, we recommend in the strongest terms, that the SSM/DPEIS be withdrawn, rewritten and reissued, to include sensible alternatives which will not cost the U.S. taxpayers billions of unnecessary dollars.

Thank you for an opportunity to comment. Please allow our comments to be reflected in the record.

Re: Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management

Dear Sir or Madam:

I write for the Pueblo of San Ildefonso (the Pueblo) to comment on the U.S. Department of Energy's (DOE) Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management (PEIS). The Pueblo appreciates the opportunity to comment on the draft PEIS, and looks forward to working with DOE on it.

Introduction

1/12.08 The Pueblo is concerned about the DOE stockpile stewardship and management program because of the impacts that Los Alamos National Laboratory (LANL), which is one of the facilities involved in the stockpile stewardship and management program, has had and will continue to have on the Pueblo. The Pueblo and LANL share a boundary, and LANL is built on land that originally belonged to the Pueblo. In addition, that land includes many sites that are sacred to members of the Pueblo, and LANL's use and disposal of radioactive and other materials during the past 50 years has caused serious contamination of the Pueblo's air, soil, and water. The DOE's continued operation of LANL threatens the Pueblo with further contamination and with the destruction of more sites sacred to Pueblo members. LANL also has had and threatens to continue to have disproportionate impacts on the Pueblo, impacts that raise issues of environmental justice.

2/41.03 The Pueblo has two specific concerns about the PEIS. First, the PEIS was developed without the involvement of the Pueblo, and the Pueblo is being asked to comment on a completed document. Second, although the Pueblo does not have the resources with which to analyze the PEIS in detail, there are certain technical matters of concern to the Pueblo that are not adequately addressed in the PEIS.

1. The DOE should have involved the Pueblo in preparation of the PEIS.

The Pueblo was not involved in the preparation of the

SSM-F-012
COMMENT LETTER

PAGE 2 OF 4

Office of Reconfiguration
May 7, 1996
Page 2

2/41.03 continued

PEIS. Rather, the Pueblo was given a copy of the three volume PEIS and was briefed on it only after it was completed. That does not provide the Pueblo with an opportunity for meaningful input into the PEIS. Moreover, the Pueblo does not now have an adequate staff with which to analyze those three volumes and to comment on them within the 60 day comment period. That is not appropriate.

The Pueblo is a federally recognized Indian Tribe, and President Clinton has directed the heads of federal agencies to operate on a government to government basis with all such Tribes, and to consult those Tribes and take into account their concerns prior to taking actions that affect them. In addition, DOE Secretary O'Leary has directed all elements of DOE to deal with Tribes on that government to government basis, and to follow the DOE American Indian Policy. It specifically provides that DOE shall treat Tribes as governments in accordance with their status and DOE's trust responsibility towards them, and that DOE shall consult and involve Tribes in decisions that affect them. Finally, DOE has entered into an Accord with the Pueblo and has witnessed a Cooperative Agreement between LANL and the Pueblo. Each of those documents also provides that the Pueblo will be given a role in decisions concerning LANL that affect the Pueblo.

The United States, DOE, and LANL therefore have each made a commitment to involve the Pueblo in decisions concerning LANL that affect the Pueblo, its members, and their environment. Despite that, the DOE prepared the PEIS without consulting the Pueblo, and has effectively precluded the Pueblo from having the role in development of the PEIS that is required by the directives of both President Clinton and Secretary O'Leary, and by the accord between DOE and the Pueblo. This problem is exacerbated by the importance of the activities discussed in the PEIS to the Pueblo, and by the failure of the PEIS to analyze adequately the environmental impacts of the stockpile stewardship and management program.

2. The PEIS does not adequately analyze issues that are of concern to the Pueblo.

3/04.06

The PEIS's characterization of the existing environment at LANL is not adequate. For example, the section on groundwater (page 4-242) is quite misleading. The subsection on groundwater quality implies that there are no groundwater problems. Table 4.6.2.4-2 shows data from 1992 and indicates that all levels of contaminants are below regulatory levels of concern. In fact, however, levels have fluctuated over the years, and there is evidence that contaminants are

SSM-F-012
COMMENT LETTER

PAGE 3 OF 4

Office of Reconfiguration
May 7, 1996
Page 3

3/04.06 continued

reaching the deeper aquifer from surface discharges and shallower more contaminated areas. Considerable mobility of contaminants in the subsurface at Mortendad canyon has been discovered, even though this is an area in which contaminants were initially predicted to be relatively immobile. Moreover, this is an area into which LANL currently discharges a significant portion of its liquid radioactive wastes.

This section on groundwater contamination therefore is misleading because it glosses over the shallow and deeper aquifer contamination problems that have only recently been

4/05.01

recognized. Similarly, contamination in soils is omitted almost entirely in the discussion of the current environment. (Page 4-234)

5/43.18

The PEIS does not address the effects of forest fires in the LANL area. As the residents of the Pueblo know, that is a major issue in northern New Mexico in this hot dry summer of 1996. A recent fire in the Los Alamos and Bandelier area came within two miles of LANL before it was brought under control, and any discussion of the current environment at LANL must include consideration of such fires.

6/09.02

The PEIS also does not adequately analyze the impacts of accidents at LANL on the Pueblo and its members. The impacts of accidents are assessed for populations within 80 km (see table 4.6.3.9-3, for example). More to the point, and more important from an environmental justice perspective, are the risks to the Native American populations living immediately adjacent to LANL.

The main road that leads into LANL passes through the Pueblo's lands, and the Pueblo has no resources with which to deal with any accident involving radioactive or hazardous materials that occurs on the reservation. The Pueblo has one policeman and a totally volunteer fire department, and its personnel are not adequately trained to deal with radioactive or hazardous materials. Moreover, there has been no determination by the Pueblo, the Department, and the State of New Mexico about which entity or entities would have jurisdiction or responsibility to deal with such an accident or how those entities would coordinate their responses. In addition, the Pueblo's population is so limited (less that 1,500 people) that any excess cancer deaths would have a much more severe impact on the Pueblo than on another, larger community. The PEIS therefore should analyze separately accidents on the reservation.

SSM-F-012
Comment Letter

Page 4 of 4

Office of Reconfiguration
May 7, 1996
Page 4

1/12.08 continued

Finally, the PEIS should take into account specific risks from accidents to Native American populations. The GENII code used to compute risks does not include pathways specific to the land use of the Native Americans who live near LANL, and the estimated risks therefore are not valid. Such Native American specific pathways include, for example, use of medicinal plants, smoking of herbs, and making of pottery with contaminated clays. Furthermore, it is not clear in the PEIS which assumptions and pathways were used for specific sites (such as LANL) when applying the GENII code. The PEIS states that not all pathways were available at each site (volume II, page B-9), but it is not clear which pathways were not used for the analysis involving LANL. As an example, the Pueblo's members consume downstream waters in the canyons in and around LANL, but DOE analyses have usually ignored this use.

The PEIS's analysis of accidents therefore is inadequate for protection of the Pueblo and its members. This raises questions of environmental justice, which also is not given adequate attention in the PEIS. This is exacerbated by the failure of DOE to involve the Pueblo in the preparation of the PEIS.

Conclusion

The Pueblo requests that these and other deficiencies in the PEIS be corrected before it or a final EIS is used as the basis for a decision on the stockpile stewardship and management program. The Pueblo also requests that DOE involve the Pueblo in the preparation of the final EIS in a manner appropriate to the Pueblo's status as a sovereign government and in accordance with the directives of President Clinton and Secretary O'Leary and the DOE/Pueblo accords.

Thank you for your attention to these issues.

Yours truly,

Douglas Meiklejohn

COMMENTS ON THE DRAFT PEIS FOR STOCKPILE STEWARDSHIP AND MANAGEMENT (DOE/EIS 0236)

The Nevada Alliance for Defense, Energy and Business is a trade group that represents those contractors that are currently performing work at the Nevada Test Site (NTS), as well as those industrial firms either serving as providers to the NTS or that might have an interest in the future of the NTS. The Alliance has reviewed the Draft PEIS for Stockpile Stewardship and Management and have the following comments

General Comment

1/30.03

Throughout the draft, references to the possible contribution of the NTS and its facilities to the Stockpile Stewardship requirements are summarily dismissed by very arbitrary statements. Examples of these statements are found in Section 11 of the Weapons Assembly/Disassembly Report. In the second paragraph of the section entitled "Effects of Workload on Alternatives," there is a statement that says, "It should be noted that in the high case workload there are an estimated 5.6 cells required to support operations, however, there are only five cells currently at the NTS." That statement is representative of the treatment of NTS throughout the entire report. Anyone familiar with either Pantex or the DAF facility at NTS knows that the difference between 5.6 or 5.0 is not measurable in the context of the disassembly requirements. To arbitrarily eliminate a $100M facility because it lacks four percent of the capability to support the "high case" is inventing a reason to eliminate the inclusion of the NTS. Similarly, throughout the

2/30.07

report, there is no recognition that the DAF is a backup to Pantex that could be critical to the successful implementation of treaty requirements, as well as a backup facility should Pantex be shut down as a result of a natural disaster, such as a tornado, or shut down as a result of a perceived safety violation, such as has just resulted in the shutdown of the Y-12 plant at Oak Ridge for over a year. It is clear that the PEIS process has analyzed two options: the first being to keep assembly and disassembly operations at Pantex; and the second to transfer those assembly and disassembly operations to NTS. Completely disregarded is the option to combine assembly and disassembly operations in a way that more completely protects the national options of the President

Specific Comments

3/40.86

Table 3.2.9-1, page 3-14, Volume 1 should be modified. Subcritical tests should be added for completeness, as well as references to High Explosive and dynamic experiments. Testing of nuclear weapons should be mentioned, as well as the testing of weapon effects.

4/40.45

Table 3.3-1, page 3-18, Volume 1 should acknowledge the expertise at the NTS in the experimental primaries and secondaries. The same table should also recognize the NTS as a potential site for the siting of large experimental facilities to do weapons simulation and effects tests

SSM-F-013
COMMENT LETTER **PAGE 2 OF 2**

U. S. Department of Energy
Office of Reconfiguration
Alexandria, VA 22302
COMMENTS ON THE DRAFT PEIS FOR STOCKPILE STEWARDSHIP AND MANAGEMENT
(DOE/EIS 0236)
Page 2

5/40.49 Section 3.3.6, page 3-28 of the Summary should list the NTS as an alternate site for all of the large experimental physics machines that are contemplated.

6/41.18 On page 3-20 is a description of the NTS that describes the current NTS mission as "maintaining the capability to test." Ongoing operation of experimental facilities such as Lyner and BEEF should be recognized.

NTS should be recognized as a technically viable location for the storage of plutonium in the form of oxides, metal, or fabricated pits. Both the DAF facility and the large tunnels already constructed provide cost effective solutions to the storage of strategic reserves of plutonium, as well as possible locations for back-up manufacturing and reuse facilities.

1/30.03 continued Finally, we believe the remoteness of the NTS, which affords a place to do hazardous operations with essentially zero risk to the general public, coupled with the existence of a viable infrastructure that consists of facilities and personnel, makes the NTS a viable candidate for primary and alternate use in almost any stockpile stewardship scenario. We request that the NTS be properly represented and described in the final draft of the proposed EIS.

The Nevada Alliance for Defense, Energy and Business stands ready to assist the Department of Energy in ensuring that long term national defense objectives are met in the most cost effective manner, which involves the NTS in almost every category. The Alliance requests consideration of our comments and looks forward to working with the Department of Energy in this most important matter.

Very truly yours,

COMMENT LETTER **PAGE 1 OF 7**

Los Alamos Study Group

May 7, 1996

Mr. Steve Sohinki, Director
U.S. DOE Office of Reconfiguration
P.O. Box 3417
Alexandria, VA 22302

Re: Comments on the draft Stockpile Stewardship and Management Programmatic Environmental Impact Statement (SS&M PEIS, or simply PEIS)

Dear Mr. Sohinki:

The following comments supplement those made orally in Los Alamos on March 26 and in Santa Fe on April 25.

1/40.85 Illness abridges these comments. They are confined to some of the programmatic issues. Their conclusion is simple: the draft PEIS is so fatally and fundamentally flawed that a more in-depth analysis by the DOE along the lines established in the draft PEIS is neither possible nor desirable. The flaws cannot be corrected simply by issuing a better final PEIS.

Instead, the Department of Energy (DOE), if it wishes to comply with its own regulations implementing the National Environmental Policy Act (NEPA), needs to withdraw the current draft PEIS and enter once again into the scoping process. The reasons for this follow. Page numbers without other document citations refer to the draft SS&M PEIS.

1. <u>The purpose and need for the SS program has not been established.</u>

2/40.05 The PEIS says that no new weapons production is occurring or will occur (1-1, paragraphs 3 and 4, and 2-11). This is a deceptive oversimplification at best. As revealed by Dr. Harold Smith in a Pentagon press briefing on April 23, the first B61 mod 11 will be deployed by the end of 1996, and production activities will continue in FY1997 (DOE Congressional Budget Request Vol. I [CBR], p. 209). This weapon is only the first in a category or series of earth-penetrating modifications of nuclear weapons (Kenneth Bacon, DOD Press Conference, 4/23/96). Vic Reis spoke of four near-term stockpile modifications underway or completed (W76, W88, B61-11, W87) (written testimony, 4/16/96, Senate Appropriations Subcommittee on Energy and Water Development). The FY1997 CBR mentions as well "upgrades" to the B83 (p. 213).

I go into this detail because this is nothing more than implementation of the Nuclear Posture Review (NPR), embraced by the DOE as a policy driver on p. 2-1, which "requires" DOE to indefinitely retain the capability to design, certify, and produce new nuclear weapons. It is in fact this new-design "requirement," rather than requirements to maintain safety and reliability of existing weapons, that drives the shape of the SS program.

I have written on the subjects of safety and reliability at length and will not repeat those facts

212 E. Marcy St., Santa Fe, NM 87501; tel. 505-982-7747 fax: 505 982 8502

2/40.05 continued

here. The recent release of historic stockpile surveillance data has only further confirmed those earlier conclusions that 1) safety is not a driving issue for nuclear physics package stewardship, and 2) reliability is a problem which can be economically solved with yesterday's technology. All this is only what Norris Bradbury, Carson Mark, Hans Bethe, Richard Garwin, Andre Sakharov, and others were already saying in the 1970s. The proposed stockpile stewardship program is not needed to maintain the safety and reliability of the present U.S. arsenal.

Perhaps this will bear a little more emphasis and elucidation.

U.S. nuclear explosives are based on very sophisticated analysis and thorough testing. But they are very robust, and not very complicated, devices. As noted above, just about 5% of the parts in the weapon are contained in the explosive device itself. While there have been several serious design errors--errors which destroy confidence in the two-lab peer review system that is a central goal of the DOE's proposed SS program--extensive stockpile surveillance data shows that nuclear weapons have been kept in a highly reliable condition with a very small effort from the two design labs.[1] Once a weapon was fully tested, nuclear testing played essentially no role in maintaining the stockpile, and hence no giant new program is needed to replace it.

Within the weapon as a whole, the nuclear explosives themselves have accounted for a very small fraction of the problems encountered in routine surveillance, and a small proportion of the number of these problems that required fixes. The upshot is that the modern weapons selected to remain in the U.S. stockpile into the next century are extremely safe[2] and reliable, and the explosive parts of those weapons are in fact the most reliable parts of them.

What has caused serious problems in the past, and can be expected to do so in the future, is the substitution of untested designs for the fully-tested ones now present in the stockpile. As an independent panel of nuclear scientists warned DOE in 1995:

> However greatest care in the form of self-discipline will be required to avoid system modifications, even if aimed at "improvements," which may compromise reliability.[3]

---

[1]Reliability in this context means the probability, after exposure to the stockpile-to-target sequence of conditions, that a nuclear weapon will explode within the certified yield range. For further information see Mello, 1995, "No Serious Problems, Reliability Issues and Stockpile Management," Tri-Valley CAREs, Livermore, CA.

[2]"Safe," in this context, means safe from accidental nuclear detonation. Nuclear weapons are in most but not all cases extremely resistant to accidental chemical detonation as well. The relevant literature and testimony is summarized in Mello, 1995, "Nuclear Weapons Safety: No Design Changes are Warranted," Tri-Valley CAREs, Livermore, CA.

[3]Drell, Sidney, et. al, 1995, "Nuclear Testing: Summary and Conclusions." Report of JASON panel to DOE Defense Programs.

2/40.05 continued

The most reliable weapons are thus the ones we have tested. No new nuclear designs are needed or wanted. The implication of this is that maintaining the nuclear arsenal requires skills and capabilities, but only a small fraction of the design personnel now employed at the weapons labs. The DOE is going in exactly the contrary direction: attempting to maximize funding, not reliability.

2. <u>The DOE's nonproliferation analysis is worthless.</u>

3/40.07

The DOE's nonproliferation analysis--just 4 paragraphs in length, on p. 2-11--is worthless. There is U.S. case law which says that agencies bringing forward a class of impacts in an EIS cannot defensibly do so in a way which omits the negative impacts in that class, as DOE has done here. DOE's analysis is specious and self-serving, if for no other reason than it omits the entire current controversy in Geneva over the intent and capabilities of the stockpile stewardship program and the scope of the proposed comprehensive test ban, as well as the commitments made in Article VI of the NPT.

3. <u>The DOE has unreasonably constrained the alternatives it analyzes.</u>

4/41.03

The Department of Energy (DOE) lists, on p. 2-1, a number of policy constraints for the SS and SM programs, including Presidential decision directives and memoranda, an act of Congress, three treaties, one proposed treaty, and one study. The most limiting of these constraints were developed with full DOE participation. In effect, the DOE has constrained itself, and now seeks to be excused from any analysis of other reasonable alternatives. In the case of the SS program, DOE's constraints have narrowed what is "reasonable" to the one alternative that is preferred. It is quite remarkable that only this program, not anything more, not anything less, and not anything different, is reasonable.

In fact, agencies must consider and analyze reasonable alternatives to proposed actions regardless of prejudicial actions they have already taken. It is precisely to avoid such prejudicial actions that NEPA analysis, and specifically programmatic NEPA analysis, is required. Programmatic decisions embodied or latent in Presidential decision directives, acts of Congress, and the Nuclear Weapons Stockpile Memorandum (NWSM) are not immune from NEPA alternatives analysis, where the actions which flow from them involve significant environmental impacts.

The fact that construction, or "line-item construction," has begun--the PEIS is ambiguous about which of these it means--likewise does not exempt any facility from analysis as part of a programmatic EIS. This is all the more true when construction was begun illegally, as in the case of DARHT.

Overall, DOE appears to misunderstand the nature of programmatic analysis. This is especially the case in the SS program. In the PEIS, DOE treats its programmatic SS decisions as already made, and then proceeds to construct a so-called "programmatic" EIS that is largely composed of a combination of project-specific analyses that implement that single preferred action, without recourse to any alternative. It would be far more cost-effective, and better NEPA analysis, to

4/41.03 continued

address a genuine range of programmatic alternatives and to do so openly, thoroughly, and with a broader brush, prior to attempting to understand the detailed impacts of each alternative. To pretend that no other alternative exists throughout much of its program, as the DOE does, is inexcusable, technically insupportable, and illegal.

5/41.18

4. **There is no programmatic analysis of alternatives in the SS program whatsoever, and under the mis-named "no action" alternative, DOE is already building most of the new facilities in the SS program.**

After dismissing some important proposed alternatives DOE received during the scoping process on pp. 3-5-7, DOE slides right past establishing any SS alternatives it does consider, either overall or in specific parts of its program.

First, no programmatic alternatives are being considered for maintaining testing readiness. DOE is in fact currently looking at alternative ways to fulfill Safeguard C of the President's August 11, 1996 announcement (oral communication, V. Reis) but these aren't mentioned in PEIS.

Second, there are essentially no alternatives mentioned for maintaining understanding of nuclear weapons primaries. The only alternatives mentioned are to build the Contained Firing Facility (CFF) or to not build it. DARHT is considered a fait accompli, and it is claimed that DARHT construction will not affect any subsequent DOE hydrotesting decision.

6/40.43

> For the purposes of this PEIS, DOE includes DARHT as an existing facility at LANL because DOE has reached an independent decision to construct and operate the facility. (3-17)

The decision to build DARHT is premature, as it has been done without analysis of reasonable alternatives. It is to avoid such a prejudicial "independent decision" that programmatic analysis is required. And such a "decision" is not an adequate basis to exclude DARHT from active analysis in the PEIS, either to reconsider the advisability of DARHT (taken as a whole or considering portions, such as the second axis, only) in light of other contemporaneous hydrotesting upgrades, or to reconsider the advisability of the other hydrotesting projects in light of DARHT.

Many alternatives are open to the DOE to maintain an adequate hydrodynamic testing capability. Instead of comparing these against each other, DOE is already proceeding in parallel with all of them, with the single exception of the environmental enclosure for LLNL's FXR facility (i.e. the CFF), and DOE has the gall to lump all of this ongoing work, amounting to more than $200 M in construction costs, under the "no action" alternative.

Under the mis-named "no action" alternative, DOE is:

- Maintaining PHERMEX
- Upgrading PHERMEX to double-pulse with a new detection system

6/40.43 continued

- Maintaining FXR, recently the subject of a major upgrade and renovation
- Establishing double-pulse capability at FXR
- Completing BEEF at NTS
- Completing DARHT with both axes and committing to phased containment
- Completing LYNER

Thus, under DOE's "no action" alternative, major new capabilities are now being installed at four different hydrotesting machines at three different sites, not counting LYNER. The single so-called "programmatic" alternative being provided is nothing more than an environmental mitigation measure at one of these facilities.

In addition, the so-called "next generation" Advanced Hydrotest Facility (AHF), considered by DOE to be too far in the future to analyze, has been funded by DOE since FY95. DOE is already investing funds (CBR pp. 25, 76ff) in a facility it claims it cannot programmatically analyze (p. 3-21) because its design is not yet fixed. In fact, conducting "detailed environmental impact analysis" is not the point of a PEIS. Those detailed analyses are conducted in EISs that follow a PEIS. Thus the "no action" alternative actually contains significant programmatic commitment to the next generation hydrodynamic testing facility.

7/40.36

There has likewise been no programmatic analysis of alternatives for retaining knowledge of secondary physics. DOE proposes to build NIF and Atlas, but does not mention why this is necessary, particularly given the remarks of Sakharov cited in Kidder's 1987 paper--that secondary function can be established simply by scaling. We know the computational resources he had available! The DOE's own surveillance data, together with the yield data compiled by Kidder in 1987, likewise suggest that secondary function is not an issue.

Once again, this bears spelling out a little, at the risk of repetition. The relative simplicity and high reliability of the physics package has already been discussed above. Within the nuclear explosive in turn, the secondary has been the most reliable part, having experienced only one or two trivial problems that were very easily fixed. These secondaries are sealed and have no high explosives in them. They have a long life, and are relatively inexpensive to remanufacture as needed. The U.S. now possesses an enormous manufacturing overcapacity in this area, which can be maintained in a standby condition at "minimal" cost.*

These facts are important because the contribution of NIF and Atlas to the stockpile stewardship program lie in their alleged role in studying nuclear weapons secondaries--components which have had essentially no problems and need little study. If there were problems in the future (which is not expected), NIF and Atlas could not really discover or solve them in any case. Those are tasks for routine surveillance and remanufacturing, which are necessary and sufficient, as well as far simpler and cheaper.

*See DOE, 1996, "Draft Stockpile Management Preferred Alternatives Report," p. 17.

7/40.36 continued

NIF's (and Atlas') link to stockpile maintenance is thus indirect, through its role in maintaining and training staff. The actual data it would provide is admitted to be far secondary, if relevant at all.

The DOE has omitted any mention, or programmatic/environmental analysis of, the OMEGA laser at U. of Rochester, (p. 174, CBR), or the Nike laser at NRL.

8/41.17

In the realm of weapons effects testing, DOE's "no action" SS alternative appears (I have been told) to include ongoing work on SNL's X-1 facility. I have not had time to investigate this, but we see in the CBR, p. 67, that modification of PBFA-II is to be completed, and "advanced pulsed power" will continue.

5/41.18 continued

DOE's "no action" alternative also apparently includes the fait accompli decision to modify LANL's LAMPF facility into LANSCE (transferred to DP in FY96; see p. 80, CBR). This is a $783 M project (LANL FY1996-2001 Institutional Plan, p. 83).

DOE's "no action" alternative likewise apparently includes its Nuclear Weapons RD&T Facilities Revitalization, Phase II, Various Locations project, (CBR, p. 165ff), including (highlights only):

- 01-Integrated Materials Research Laboratory, SNL/NM
- 02-Defense Engineering Laboratory, SNL/CA
- 03-Advanced Technology Laboratory, NTS
- 06-Nuclear Test Technology Complex, LLNL
- 07-Materials Science Laboratory, LANL
- 08-Explosive Components Facility, SNL/NM
- 11-Defense Programs Research Facility, LLNL

Thus the "no action" alternative effectively embraces most of the DOE's actual proposed SS program, even just looking a new construction. When operations are included—which are probably responsible for most of the environmental impacts in the SS program—the "no action" alternative looms even bigger.

5. <u>The Department has not considered, programmatically, the degree to which some of its existing programs may substitute for new construction.</u>

ASCI (FY96 $85M, FY97 $122M requested; CBR p.44) and the Enhanced Surveillance Program should be evaluated in this light.

6. <u>DOE is already building, prejudicially, stockpile management facilities.</u>

These include the CMR Upgrades at LANL (CBR p. 137ff); PETL at SNL (CBR p. 121ff). "Stockpile Management Restructuring Initiative—Pit Component Fabrication Capacity/LANL" (CBR p. 207; p. 213 says this program began in FY95 at the latest, is now [FY96] funded, and

5/41.18 continued

is requested to be funded in FY97); and, I believe, other facilities for which time is too limited to research

This must conclude my comments at this time. Obviously, they are incomplete. Were sickness not an issue, I would still be wondering if this EIS was worth any further investment of time, given its fundamentally flawed character. Please withdraw it and start again. If you give me a decent document I will give you more thorough comments.

Sincerely,

Greg Mello

Greg Mello, Director

SSM-F-015 COMMENT LETTER

REVIEW COMMENTS
STOCKPILE STEWARDSHIP AND MANAGEMENT
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT (EIS)
TEXAS NATURAL RESOURCE CONSERVATION COMMISSION (TNRCC)
OFFICE OF WASTE MANAGEMENT
April 30, 1996

1/11.35 The TNRCC believes that, contrary to the statement in Section E.3.1, page E-13, exposure to hazardous chemical releases to surface water, groundwater, and soils should be included when assessing the risk to the public and site workers. Although waste management performance has greatly improved at Pantex and is expected to continue, past experience indicates that hazardous constituents can be released to the environment. In addition, wastewater discharges to the ditches and playas can be expected to contain some contaminants, even if they are at permitted levels.

2/11.41 It is not readily apparent whether DOE's risk assessment includes those hazardous constituents that do not meet the narrow definition of hazardous waste under RCRA or toxic substances under TSCA. As an example, hazardous wastes destined for the wastewater treatment plant are pretreated before reaching the wastewater treatment plant. After pretreatment, DOE considers the constituents remaining in the wastewater stream to be non-hazardous and, as defined in Table H.1.1-1, page H-2, without a defined health risk. Although the definition of hazardous vs. non-hazardous may be technically correct from a RCRA waste management perspective, the constituents still pose a degree of risk that should be taken into account. In a broader sense, it would be appropriate for DOE to consider the risk posed to human health and the environment by what DOE defines as non-hazardous waste constituents.

3/40.61 The TNRCC also suggests that DOE provide a definition of hazardous chemicals in the glossary or possibly use the term "hazardous substances".

4/11.36 The TNRCC is concerned that the Hazard Indexes and Total Cancer Risk provided for the Phaseout Alternative at Pantex (Table E.3.4-12) are not properly evaluated. The risks for the phaseout of Pantex are lower than the risks cited for the other programmatic alternatives, with the exception of the Assembly/Disassembly and High Explosives Fabrication Alternative, which essentially equal the risks of the phase-out alternative. However, the amounts of hazardous and mixed low-level waste generated during phaseout of Pantex are anticipated to be a hundred to a thousand times greater than the other alternatives (Tables 4.5.3.10-2 and 4.5.3.10-3). The TNRCC suspects that the risk from hazardous substance exposure during the phaseout of Pantex would be greater than all the other alternatives. The discrepancy may be due to the fact that the wastes generated during the phaseout process will occur over a six year period, while the risks for the other alternatives are modeled over a 25 year period.

Page 4-220 of the EIS states that no hazardous chemical emissions are anticipated for the phaseout alternative at Pantex and that the hazard index and cancer risk for the public and onsite workers would be zero. The TNRCC believes that it is more reasonable to assume that some exposure will occur during a phaseout of Pantex when over 6 million cubic meters of waste is generated.

If you have any questions regarding these comments, please contact Mr. Geoffrey Meyer, Industrial and Hazardous Waste Division, Federal Facilities Team, at (512) 239-2577.

To Whom it May Concern
(1-800-820-5156)

May 6, 1996

From L.B. Thomas *LT*
3409 Pickard Ave, NE
Albuquerque, NM 87110

Subject: Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management Comments

I wish to present the following comments:

1/40.74 — 1) The Purpose and Need on page 2-7 should include the new mission of recertifying dispositioned HEU and Pu.

2/40.23 — 2) Like WIPP support functions of DOE management, SSM research and development should be moved to where assembly and storage occur. DOE is not following its own procedure and principles found in DOE Order 5480.19. Support functions like research and design are not line functions. Therefore the labs should be moved to the line. What part of DOE Order 5480.19 authorizes separating assembly and research facilities. Recommend relocating labs to Amarillo or change 5480.19.

1/40.74 continued — 3) Should the Industrial Base on page 2-8 include a mission for recertifying non-fissile materials placed into storage and disposition? Please also address comments sent to S & D PEIS.

3/40.32 — 4) Did DOE consider under the Nonproliferation mantle which facilities or sites pose the least security risk? Why isn't security capabilities addressed in infrastructure impact analysis. DOE should consider redoing infrastructure analysis to include security capabilities. If LANL has a bad record like the apparent security breach that helped the Russians develop their first weapon, why doesn't DOE consider an alternative site where security is taken seriously?

1/40.74 continued — 5) Stockpile management on page 3-23 should include recertification of Pu and HEU?

4/40.52 — 6) Why isn't Pit Reuse Facility at Pantex included as a reasonably foreseeable activity.

5/10.21 — 7) On page 3-84 second column, second paragraph-Based on the discussion of reduced scrap, waste, and residue, is Pu and HEU pits, scrap, materials, and residue placed into storage a solid waste?

6/10.28 — 8) Further on page 3-84, second column, third paragraph-Pu is a hazardous waste or at least a hazardous residue. Question-When does Pu and HEU meet the definition of a solid waste? This section clearly makes the argument that machining and processing residues are a solid waste. Question-is stored Pu and HEU in any form a solid waste as defined under RCRA? Please provide independent confirmation of this issue by EPA and the US Justice Dept.

7/10.17 — 9) Further on page 3-85, column one, paragraph two-HEU machining scrap is recycled. Is it not true that recycled materials are defined as a "solid waste?" What is DOE's legal interpretation of their statement and the definition of "recycled?" Does EPA and US Justice Dept concur? If I machined lead (Pb) are the residuals a hazardous waste?

10) Page 3-85, column one paragraph two-What is meant by the term "residue production?" Isn't it DOE's policy to prevent and minimize residue not produce it?

1

Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management Comments

SSM-F-017
COMMENT LETTER

PAGE 2 OF 4

1/40.74 continued

11) Section 3.5.4. Why are explosive materials disposed but Pu and HEU are dispositioned? If a pit and Pu/HEU residue is classified and thus dispositioned why would HE that is classified is disposed?

12) Further section 3.5.4. Why is classified HE potentially part of an "alternative disposal technologies"? Why not "alternative disposition technologies"?

13) Further-What is excess explosive materials? What is the difference between excess explosive materials and surplused Pu and HEU? What is the difference between surplused Pu and HEU and lead-acid batteries accumulated speculatively?

8/10.18

14) Page 3-88 column two, paragraph 2. "Both sites have adequate waste management facilities to treat, store, and/or dispose..." Is this true? I thought NTS mixed waste disposal was limited to ER activities from certain projects? Is there mixed waste disposal for operational wastestreams? At Pantex, is it not true that they are planning to treat mixed waste but currently have limited disposal? How many offsite disposal shipments have they done since 1984? 1976?

9/11.33

15) Page 3-88 column one, paragraph two-"Worker exposure to radiation is expected to be about equal." Question is it reasonable to believe NTS workers might receive higher doses for several years because of the lack of experience compared to Pantex workers? I realize that the workers at NTS receive training but nothing replaces actual experience. DOE should consider a learning curve at NTS.

10/30.04

16) Page 3-89 column one paragraph one. Should it read "in the unlikely event?"

3/40.32 continued

17) Page 4-2 section 4.1.2 Since nonproliferation is so important should not infrastructure evaluate the security capabilities of the sites with a key element being the quantity security breaches over the last ten years? Aren't there comparisions and assessments of each sites capabilities. The decision maker should know which sites are truly meeting the expectation of nonproliferation. Sites that are lacking should not be considered for more work.

11/11.34

18) Page 4-9 Hazardous Chemical Impacts. Why was CERCLA guidance used? Isn't CERCLA guidance based on NIOSH information? Do not believe the CERCLA guidance bounds the issue because the higher risk occupations would not be covered such as medical personnel, fire fighters, radiation workers, HE workers, roofers, machine operators, security personnel, etc.

12/10.19

19) Section 4.1.10 Is it prudent to include waste minimization in the analysis? The impact assessment is reduced and does not bound the impacts.

13/40.21

20) Page A-38 Env. Reg Setting According to this page DOE is in compliance with all requirements. "All" is unlikely. Reword.

14/43.02

21) Global comment. Why are all DOE's really bad Superfund sites called a National Environmental Research Park (NERP)? DOE should change it to National Environmental Research Disaster Site (NERDS). Is DOE upset that Love Canal, probably the most notorious Superfund site, has cornered the word love. I'll bet the public relation guys in DOE worked really hard on this one. I wonder which definition of park is being used-my vote is for a place of ground... for ornament and recreation.

1/40.74 continued

22) Page A-40, should considered adding a sixth mission surveillance and recertification of Pu and HEU reserves.

15/10.20

23) Page A-51 Is an unusable part a waste? Is sanitize and demilitarize a treatment process? Please describe what sanitize and demilitarize mean. What are these processes and their purpose? Is an unusable part in-herently waste like?

2

Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management Comments

SM-F-017
COMMENT LETTER

PAGE 3 OF 4

16/40.75

24) Page A-56 Based on the estimate of 200 weapon parts per weapon how many parts are backlogged waiting for sanitization and demilitarization. If a backlog exists, what are the impacts of downsizing, relocating, no action, etc on this backlog. Since nonproliferation is so important who is responsible for sanitization and demilitarization? Why isn't this discussed in infrastructure? Why aren't the impacts assessed? What is the through put capacity of sanitization and demilitarization for each of the 200 estimated parts? Are these processes readily available at other sites? Has DOE considered this nonproliferation capability in selecting alternatives?

15/10.20 continued

25) What is the expected timeframe for the sanitization and demilitarization of all qualified HE? What processes are used? Are these considered in selecting alternatives?

26) If NTS is selected to do A/D, would Pantex finish backlog of sanitization and demilitarization or NTS. Have the impacts been analyzed?

27) If LANL or LLNL is selected to do HE, would Pantex finish backlog of sanitization and demilitarization or LANL/LLNL. Have the impacts been analyzed?

17/30.05

28) Table A.3.1.1-1 Should include a Burning Ground?

29) Table A.3.1.1-1 Where are the sanitization and demilitarization facilities? Where are the waste management facilities?

16/40.75 continued

30) Figure A.3.1.1-5 The figure shows classified waste being sent to sanitization? I thought classified stuff are sent to sanitization before becoming a waste? Is sanitizing a RCRA treatment? So classified waste (parts) are a solid waste? In figure A.3.1.1-5 Bulk HE wastes go to explosives waste treatment and then classified parts go to sanitization and demilitarization. So classified parts are solid waste?

31) Figure A.3.1.1-5 Where are the exit arrows for sanitization and demilitarization? Recommend using arrows in both direction that way the classified waste is in a constant state of movement without revealing its true nature or secrets.

5/10.21 continued

32) Since nonproliferation is so important why aren't sanitization and demilitarization capabilities discussed?

33) On page A-93 Classified wastes enter a declassification step resulting in classified and unclassified waste. What does this mean? Is DOE stating that some materials will be classified no matter what physical or administrative action occurs? So when does stored Pu and HEU become a "solid waste."

34) Figure A.3.3-1 shows nonnuclear parts become waste without further processing. If classified nonnuclear parts become waste, why isn't Pu and HEU surplused a "solid waste"?

15/10.20 continued

35) Figure A.3.3.1-3 solid waste enters the flow diagram activities including classified shapes to which some solid waste enters the sanitizing process and solid waste exits. What is the difference between storage of Pu and HEU as classified material (especially surplused material) and solid waste in a classified shape?

36) Table A.3.5.1-2, where are sanitization and demilitarization facilities? Is the Burning Ground limited to explosive disposal? Does it complete sanitization and demilitarization through open burning? Doesn't RCRA define materials are solid waste if they are abandoned by being: burned or incinerated; or accumulated, stored, ... in lieu of being abandoned by being disposed of, burned, or incinerated?

37) Page A-131 (missing the number) second column paragraph one. According to the above mentioned figures explosive components are solid waste. Where does treatment and disposal fit into demilitarization, sanitization, and disposition?

Re: Draft PEIS for Stockpile Stewardship & Management (DOE/EIS-0236)

Dear Sir or Madam:

These comments are submitted on behalf of Plumbers and Steamfitters Local 342 of Concord, California.

1/21.06 Local 342 supports construction of the National Ignition Facility at Lawrence Livermore National Laboratory. This project will achieve significant national and international goals with respect to Stockpile stewardship that are essential to continued national security as well as safety of the Stockpile.

As a matter of allocating its resources, Local 342 has focused its review on the site specific analysis of construction and operation of the NIF at LLNL. Local 342 believes that this analysis of environmental impacts fairly and adequately presents information which, together with the comments on this draft and the responses thereto, can support a federal decision to proceed with the NIF at LLNL.

As presented in the Draft PEIS, the adverse impacts at this site are generally not significant. In fact, the LLNL site offers many advantages for the NIF.

2/21.18 Particular care, however, should be taken with respect to compliance with both state and federal air quality standards.

A1342.001

SSM-F-018
COMMENT LETTER **PAGE 3 OF 3**

U.S.DOE
May 7, 1996
Page 2

2/21.18 continued This facility may contribute to exceedances of state standards for PM_{10} and VOC emissions. As the Draft PEIS notes, the San Francisco Bay Area generally enjoys good air quality; and Local 342 believes that complying with air quality standards will help sustain economic growth and vitality in the region. Consequently, Local 342 recommends that the NIF obtain offsets to mitigate its emissions of PM_{10} and VOC from operation of the Facility. These offsets should be provided as a matter of comity even if they are not legally mandated.

Thank you for your consideration of these comments.

Very truly yours,

Thomas R. Adams

May 7, 1996

U.S. Department of Energy
Office of Reconfiguration—Attn. SSM PEIS
P.O. Box 3417
Alexandria, VA 22302
FAX 703-931-9222

Dear U. S. Department of Energy:

1/40.84 Thank you for providing the public with the opportunity to respond with comments concerning the DPEIS for the nuclear Stockpile Stewardship and Management Program. I would like to say, with due respect, that I found the Document unclear in presenting what the intended aims and plans are that are being proposed for our Panhandle area. For that reason, it has seemed difficult to comment with detail; however, some points stand out. I would hope that all options will be considered to insure the safety and well-being of persons and environment in this country and elsewhere. It appears that smaller stockpiles are needed now than have been needed in the past. This would indicate that the Government could concentrate on cleaning up nuclear waste generated from past operations, and the research that would show the best determinations for the nuclear waste. Problems go unsolved, as is universally recognized. Many people feel that the best determination for these untenable waste situations is to conduct serious research at the sites where the waste is now located. Rocky Flats is one of these major sites.

2/42.06 Amarillo citizens are aware, from newspaper articles and other public informations sources, that Coloradoans face a major environmental disaster from the storage of excess plutonium and other nuclear wastes at Rocky Flats, and from run-off from Martin-Marietta and from the Arsenal in different areas close to Denver. Amarillo citizens do not want plutonium problems.

3/40.07 There is also concern that proliferation of weapons sends the wrong message to other countries, when we are encouraging all to downsize their stockpiles. This has been much in the news lately. I personally feel that waste generation is a threat to all of us, beyond the weapons threat. United States citizens are so grateful to see a diminishing of the need for nuclear weapons stockpiles, and we would also like to see further effort at protecting our national resources such

4/04.05 as the Ogallala Aquifer, the largest freshwater aquifer in the U.S. Our agricultural land is also of the scope to be important in world economy. These things are of the scope to come in to consideration in a plan such as the DPEIS for Stockpile Stewardship and Management.

Many considerations may play into the final document for this Program. I hope that the exigencies of time do not unduly force the Department of Energy to overlook or ignore factors which are important to the well-being of U. S. citizens. Unwise use of funds should not threaten things which are important in the long run. A conservative approach to use of funds can be a key to conserving resources as well. Thank you for accepting our comments. Other countries have pledged not to develop nuclear weapons in response to a perceived conservative stockpile policy

2/42.06 continued on our part. I hope particularly, that we can intelligently find solutions to the excess plutonium and other hazardous materials problems that we have now, without moving the plutonium about and further complicating clean-up considerations.

Thank you,
Mary L. Shennum

Re: COMMENTS ON DOE'S DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT FOR STOCKPILE STEWARDSHIP AND MANAGEMENT (DOE/EIS 0236) (February 1996)

We have reviewed the US Department of Energy's (DOE) Draft Programmatic Environmental Impact Statement for Stockpile Stewardship and Management (DEIS). The California Energy Commission is one of the agencies (along with the Department of Health Services, the Highway Patrol, the Office of Emergency Services, and Department of Transportation) responsible for developing policy on the state's nuclear waste activities. As such, we have provided comments on earlier DOE nuclear waste transport proposals.

DOE has identified in this EIS the preferred alternatives of: constructing and operating the National Ignition Facility (NIF) and the Contained Firing Facility (CFF) at the Lawrence Livermore National Laboratory (LLNL) in California. The NIF project, which would allow the study of radiation physics in the laboratory under conditions approximating a thermonuclear detonation, would generate low-level, mixed, and hazardous waste during operation. In addition, as part of the Stockpile Stewardship and Management proposal, LLNL is being considered for Secondary and Case Fabrication, which currently is performed at Oak Ridge and involves uranium processing to provide finished uranium parts and products, High Explosives (HE) fabrication (Pantex currently manufactures HE components and may be downsized), and nonnuclear fabrication. LLNL is also a candidate site for a waste treatment and disposal facility as described in DOE's Waste Management Programmatic EIS (WM EIS). Under the latter proposal, LLNL would treat and dispose onsite its own low-level and low-level mixed waste, as well as wastes from offsite. DOE, as part of the DEIS on Stockpile Stewardship and Management, is also considering relocating the weapons assembly/disassembly function (retired weapons dismantled, nuclear components and nonnuclear components assembled into nuclear weapons, and weapons surveillance) to the Nevada Test Site, which, depending on routes, could impact California.

1/10.12 Clearly, these combined activities will have a significant impact on the numbers and quantities of nuclear and hazardous materials and wastes moved in and out of the LLNL site and to and from the Nevada Test Site. The large number of nuclear waste shipments anticipated in the WM EIS and the DEIS for Stockpile Stewardship and Management, combined with waste shipments from other DOE proposed activities at LLNL, including environmental restoration activities, would be unprecedented. The cumulative transport and waste management impacts of these combined proposed actions must be considered in any decisions regarding future activities at LLNL.

Mr. Rose
May 6, 1996
Page 2

2/09.08 It is essential that transport issues be addressed in a thorough and timely manner prior to shipment, that DOE work closely with corridor states impacted by these shipments to develop transport plans and emergency response preparedness, and that DOE's waste treatment and disposal facilities be sited in areas that minimize public risk.

Our comments on the Draft Programmatic EIS for Stockpile Stewardship and Management are enclosed.

Sincerely,

Barbara Byron
Nuclear Issues Coordinator

H. Daniel Nix
Deputy Director

Enclosure: 1

Comments on the

US DEPARTMENT OF ENERGY'S
DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT
FOR STOCKPILE STEWARDSHIP AND MANAGEMENT (DOE/EIS-0236)
FEBRUARY 1996

May 1996

The State of California has provided comments on nuclear waste transportation impacts considered in various DOE environmental assessment and impact statements. These include environmental impacts pertaining to the U.S. Foreign Research Reactor Spent Nuclear Fuel Program, the Lawrence Livermore National Laboratory, the Waste Isolation Pilot Plant, and DOE's Programmatic Environmental Impact Statement for Managing Treatment, Storage and Disposal of Radioactive and Hazardous Waste.

2/09.08 continued

Over the last decade, we have raised a number of concerns regarding transuranic waste shipments in California including: (1) transuranic shipment routes in California traverse densely populated areas, including the Los Angeles Basin, that are subject to long delays and congestion; (2) DOE has used outdated packaging for transuranic waste shipments in California that provide far less protection than the double-contained TRUPACT II planned for shipments to the Waste Isolation Pilot Plant in New Mexico; (3) emergency response capability to handle a potential accident involving transuranic materials needs improving; and (4) DOE needs to provide the State with accurate, reliable information on planned transuranic waste shipments and provide adequate lead time for emergency response preparation. Similar concerns regarding routing, packaging, emergency response preparedness, and need for shipment information also apply to the radioactive shipments described in DOE's Draft Programmatic EIS for Waste Management (DOE/EIS-0200-D) and the Draft Programmatic EIS for Stockpile Stewardship and Management (DOE/EIS-0236). State involvement in federal nuclear transportation planning is essential to provide the public with assurance that DOE's transportation programs are designed in a safe manner and that public safety concerns are addressed in connection with actions pertaining to DOE's programmatic goals.

Recommendation 1: DOE should: (a) directly involve corridor states and tribes in preparing for large quantity radioactive material shipments associated with DOE's Stockpile Stewardship and Management program and other DOE programs; this would include developing rail and truck transport plans, preferred routes, and procedures prior to shipment (similar to that developed by DOE and the Western Governors' Association for transuranic waste shipments to WIPP); (b) use only shipping containers that can be manufactured to meet current federal transport safety requirements; and, (c) provide accurate projected shipment information (quantities, schedules), as well as necessary assistance and lead time for state emergency response preparation.
Waste Management

Waste Management

DOE's proposal [under the Waste Management Programmatic EIS (WM EIS)] to site a low-level (LLW) and low-level mixed waste (LLMW) treatment and disposal facility at LLNL is included in the No-Action alternative in the cumulative waste management impact evaluation of this DEIS. In effect, this DEIS assumes that LLNL would become a LLW and LLMW permanent disposal site. However, there is absolutely no basis upon which to make this conclusion. By including the LLW and LLMW from the proposed treatment and disposal facility at LLNL in the No Action Alternative, the Draft EIS underestimates the cumulative impacts of the proposed alternatives. The waste management cumulative impacts for the Stockpile Stewardship and Management alternatives at the Livermore site, shown on p. 4-550, are, therefore, misleading since they show very little change over the No Action Alternative.

1/10.12 continued

Recommendation 2: The No Action Alternative in the DEIS' estimates of cumulative waste impacts should use current waste generation annual rates at LLNL, not waste generation rates from a non-existent waste treatment and disposal facility at LLNL.

The DEIS states that LLW is packaged in approved waste containers and transported for staging onsite, pending shipment to the Livermore site or shipment directly to the Nevada Test Site (NTS) for disposal (P. 4-345). Mixed wastes generated by Site 300 are currently stored and will be stored at LLNL until DOE-approved disposal options are available (p. 4-346). It is our understanding that the NTS is not available for LLW or LLMW disposal from LLNL. What are LLNL's options for waste disposal should NTS not become available for receiving these wastes and should the LLW and LLMW treatment and disposal facility at LLNL not be approved?

Recommendation 3: The DEIS should state what options are available for LLW and LLMW disposal in the event that NTS and the proposed LLW/LLMW Treatment and Disposal Facility at LLNL are not available.

The DEIS estimates the annual generated waste volumes for Stockpile Stewardship and Management Alternatives at LLNL as: Low Level Liquid Waste would increase from 181 cubic meters to 287 cubic meters (an increase of 106 cubic meters); low-level solid wastes would increase from 307 to 680 cubic meters (+373); mixed low-level liquid wastes would increase from 20 to 32 cubic meters (+12); hazardous liquid wastes would increase from 342 to 892 cubic meters (+550); and hazardous solid wastes would increase from 237 to 263 cubic meters (+26). These are significant increases in the total amount of nuclear and hazardous wastes generated at LLNL.

Nuclear waste has been accumulating onsite at LLNL, pending DOE securing a means of disposing of this waste. DOE's proposal to construct new facilities at LLNL that would nearly double the current annual waste generation rates at LLNL would appear to be ill-advised without adequate identified means of treating and disposing of these wastes. Siting a new low-level waste and low-level mixed waste treatment and disposal facility at LLNL, as envisioned in the WM PEIS, is not an acceptable means of mitigating potential waste storage capacity impacts at

LLNL from the Stockpile Stewardship and Management program. LLNL has the highest health risk population (6,324,234) and the highest seismic risk of the sites considered in the WM EIS. In light of the high seismic risk at the LLNL site, high surrounding population density, LLNL's proximity to major drinking water sources (the South Bay Aqueduct, a branch of the California Aqueduct, is just south of the Livermore site), and the fact that both LLNL and Site 300 have been listed on the National Priorities List because of environmental contamination, the potential impacts from project proposals at LLNL must be carefully evaluated. DOE's proposal to site additional waste generating facilities at LLNL (including a waste treatment and disposal facility) that would result in a significant increase in the generation, handling, and transport of radioactive and hazardous wastes to and from LLNL would only compound existing problems and cannot be viewed as a solution.

Siting a low-level and low-level mixed waste treatment and disposal facility at LLNL is not an acceptable means for solving waste management problems at LLNL that may arise from the proposed actions. DOE's selection of LLNL as a candidate site for a LLW/LLMW treatment and disposal facility, despite LLNL having the highest offsite population density and being located in one of the most seismically active regions of the US, demands a critical review of DOE's site selection criteria

1/10.12 continued

Recommendation 4: DOE should reconsider its selection of LLNL as a candidate site for expanded Stockpile Stewardship and Management Alternatives that would significantly increase waste generation rates at LLNL and risk to the surrounding population.

DOE has stated that "radioactive and mixed waste shipments will increase significantly under the transportation requirements of corrective activities and environmental restoration programs at LLNL". (Briefing on LLNL's Five-Year Plan for Fiscal Years 1992–1996, August 22, 1990, WGA Transport Advisory Group Meeting with DOE at LLNL.) (Environmental restoration activities include facility cleanup, decommissioning, stabilizing contaminated soils, and exhuming buried drums of wastes.)

Recommendation 5: The Draft EIS' evaluation of cumulative impacts resulting from waste management and transport to and from DOE facilities should include an evaluation of environmental restoration-generated wastes.

LLNL has been criticized for its inadequate waste characterization procedures and handling of radioactive and hazardous wastes. A 1990 Tiger Team Assessment of LLNL operations found the systems were not in place to properly characterize the waste, and waste drums may not have contained what the labels identified; process records for containers of stored waste were not considered adequate for proper classification and management. Mischaracterization of waste could result in higher or lower radionuclide inventories than those used in transport risk assessments.

Recommendation 6: The DEIS should explain how transport and facility risk assessments take into consideration uncertainties and inaccuracies in waste characterization data and

1/10.12 continued

procedures. The DEIS should explain how potential human errors during waste handling and packaging will be minimized.

Impact on LLNL's Regional Economy

3/08.27

If the Secondary and Case Fabrication, High Explosives Fabrication, Nonnuclear Fabrication, National Ignition Facility Missions and Contained Firing Facility were all located at LLNL, the resulting benefits to the regional economy (changes in total employment and per capita income) is estimated by DOE to still be less than 1 percent. Given the additional radioactive and hazardous materials and wastes to be shipped to and from LLNL and handled at the facility, the projected increases in radiological risk to the public (albeit small, as estimated by DOE), how would the regional/State costs from these proposed actions be offset by benefits?

Recommendation 7: The DEIS should explain how regional/State economic costs resulting from the proposed action will be offset by benefits to the regional economy. The potential impact on the local economy of the public perception of increased public risk caused by the proposed activities should be evaluated.

Groundwater Quality

4/04.08

Maximum groundwater concentrations of gross alpha, nitrate/nitrite, trichloroethylene, and tritium exceeded water quality criteria/standards in 1993 (p. 4-325). VOCs have been detected in the onsite groundwater and in the area around the Livermore site. VOC-contaminated water is present under 85% of the Livermore site (p. 4-325). The contaminated plumes have migrated off site and one plume of tetrachloroethylene is migrating northwest at about 68.9 ft. per year. Three municipal supply wells located about 2.4 miles from the plume are potentially impacted (p. 4-327). Given current groundwater quality issues at LLNL, what measures are proposed to mitigate further groundwater contamination at LLNL resulting from the proposed actions?

Recommendation 8: The DEIS should describe in detail what measures are planned to limit further groundwater contamination at LLNL from the proposed actions.

Radiation Doses and Potential Risk to the Public

The radionuclides released from LLNL in 1994 are shown on p. 4-342. Releases prior to and since 1994 should also be provided. One year of data is insufficient in showing whether these values are truly representative or whether it was an unusual year.

5/11.15

Health risks to the surrounding population should weigh heavily in potential decisions regarding future activities at LLNL. For example, the DEIS states that, in the event of an accident involving High Explosives fabrication at LLNL, due to the higher population surrounding LLNL, public impacts could be higher at LLNL, compared to Los Alamos and Pantex (p. 5-37).

5/11.15 continued

Recommendation 9: The DEIS should provide at least 5-10 years of radionuclide releases from LLNL, including past accidental releases to the environment and their potential health impacts. Health risks to the surrounding population should be a key screening criteria used for siting new facilities in the DOE Weapons Complex.

The Radiation and Hazardous Chemical Environment Section 4.73.9 needs rewriting to provide a clear, more easily understood explanation of potential health impacts from the proposed alternatives. The DEIS states that the "HI for the public (1.12) narrowly exceeds the cumulative HQ screening level of 1.0 (the HI) as a result of the total emissions of over 100 of 130 hazardous chemicals listed in appendix table E.3.4-22 under the No Action alternative. Individual OSHA standards for specific effects were not necessarily exceeded. However, if reanalyzed according to organ/tissue specific effects (i.e., after second stage analysis), it is very likely that the HIs would prove acceptable. The cancer risks for the onsite worker (.00000179) narrowly exceed the EPA default values as a result of the emissions of 1,1-dichloroethylene, 1,4-dioxane, arsenic, benzene, cadmium, carbon tetrachloride, chloroform, chromium VI, epichlorohydrin, folpet, methylene chloride, nickel and trichloroethylene." (p. 4-374) This explanation and analysis is far from being readily understandable.

The DEIS states that operations under the "low case scenario" for secondary and case, High Explosives, and nonnuclear fabrication would not adversely affect the health impacts and cancer risks to the public and the onsite worker (p. 4-377). However, the DEIS further states that operations under the "high-case scenario" for secondary and case fabrication could result in up to a 2 to 4-fold increase in the emission of hazardous chemicals at LLNL and a substantial increase in the health impacts to the public. Cancer risks for the onsite worker were reported to already exceed the "EPA default value" and operations under the high-case scenario would further contribute to the adverse cancer risk impacts. What are the low-case and high-case scenarios? Are either of these scenarios envisioned in the proposed facilities at LLNL? What is the "EPA default value?" What is the significance of exceeding this value?

Similarly, the DEIS states that operations under the high-case scenario for High Explosives fabrication may result in a two-fold increase in the emission of hazardous chemicals from LLNL (p. 4-377) and raise the HI for the onsite worker, which already exceeds the "EPA default value", above the HQ screening level of 1.0. This section again needs to be more clearly written and the significance of these values and findings explained.

The DEIS states that the combined program health impacts for the public narrowly exceed the acceptable health regulatory level; this discussion is not clear since below this statement it states that the onsite worker health impacts and cancer risk to the public are within the acceptable regulatory levels, but that cancer risks to the onsite worker would remain above the EPA default value (p. 4-379).

Recommendation 10: The Draft EIS' discussion of potential health impacts from the

program alternatives is unclear and needs a better explanation of its findings and conclusions.

Accident History

5/11.15 continued

The DEIS says that there were no accidents at LLNL prior to 1960 with offsite impacts and that, since 1960, there have been a number of accidents that have resulted in offsite exposures (p. 4-344).

Recommendation 11: The DEIS should identify the accidents and provide estimated exposures resulting from these accidents and their potential impact to onsite workers and the public.

Characterization of Radioactive Material Shipments

The DEIS compares the percentage of radioactive packages shipped by DOE annually (6,200 radioactive packages) to the number of shipments made nationwide by all shippers (2.8 million packages). A more meaningful comparison would be the quantities (in terms of curie levels and volumes) shipped by DOE compared to other shippers. The majority of commercial shipments of radioactive materials are small quantity radiopharmaceuticals, whereas, most of the large quantity radioactive shipments that are projected or have been made in the past are by the Department of Energy. The DEIS should provide pertinent statistics about the projected increase in the number of shipments likely from the proposed action.

2/09.08 continued

Recommendation 12: The DEIS should quantify the number, volume, transport mode, and characteristics of radioactive materials being transported under the proposed alternatives relative to baseline shipments.

Comments of

SOUTHWESTERN PUBLIC SERVICE COMPANY

Amarillo, Texas

to

UNITED STATES DEPARTMENT OF ENERGY

Re: Drafts

Programmatic Environmental Impact Statement

for Stockpile Stewardship and Management, February 1996

Environmental Impact Statement

for Continued Operation of the Pantex Plant

and Associated Storage of Nuclear Weapon Components, March 1996

and

Storage and Disposition

of Weapons-Usable Fissile Materials, February 1996

May 7, 1996

Southwestern Public Service Company is the investor-owned electric energy provider to the Pantex Plant, near Amarillo, Texas, and to approximately 367,500 other customers (about one million persons) in the Panhandle and South Plains of Texas, eastern and southeastern New Mexico, the Oklahoma Panhandle, and southwestern Kansas. SPS through the past several years has been an attentive and active participant in United States Department of Energy public information/participation activities related to DOE nuclear complex planning.

1. SPS actively supports the interests of Pantex and Pantex employees -- so long as those interests are coincident with protection and improvement of environmental conditions in the Pantex region of influence and with prudent and rational national defense policies and strategies.

1/40.11

2. At this juncture in the proposed and appropriate downsizing of the nuclear complex, we again strongly encourage the Department and Administration to predicate all actions related to the nuclear complex on the conservative assumption that at least rogue-state or terroristic nuclear aggression against the United States is probable.

U.S. vigilance and nuclear preparedness are key to coexistence with mad nations and persons.

2/30.01

In turn, the Pantex Plant is, uniquely, a key to economically efficient continuing nuclear preparedness.

SPS's further comments today on the three major draft environmental impact statements under review intentionally are brief. We forego repetition of comments filed with the Department in the past, and concentrate on issues of particular relevance to appropriate future missions for Pantex:

3/40.52

3. Fundamental to DOE's further consideration of the roles Pantex should play relative to the changing missions of the nuclear complex is the unequivocal recognition that even accumulatively, there would be NO significant adverse environmental impacts from retention and potential expansion of the variety of missions possible for Pantex.

The summaries of the relevant draft EISs do not report this fundamental conclusion explicitly; rather, in some instances, the summaries misrepresent that conclusion, reporting, instead, effectively minuscule environmental potentialities that are characterized as "adverse" only because they do not equate to measurable "benefits." We suggest the rote language of EISs should be expended to recognize effectively neutral outcomes (not merely "beneficial" or "adverse" consequences).

However, the underlying draft statements themselves are conclusive in regards to the actual insignificance of "adverse" potential impacts of expanded missions at Pantex. Moreover, DOE and consultant representatives in public meetings in Amarillo publicly and explicitly acknowledged that fundamental conclusion (see, especially, transcript of April 23, 1996, morning discussions).

Because the Department, through its representatives in Amarillo on April 23, committed to highlighting, in the subject Final Environmental Impact Statements, this fundamental and irrefutable conclusion about the actual insignificance of any adverse environmental impacts of increased missions at Pantex, Southwestern will not enumerate and rebut the litany of potential environmental concerns reflected in the EISs.

4/42.10

5. (However, we do request that the Department include in the record "dockets" for these EISs the comments by SPS relative to listed potential environmental concerns recited in the draft Tritium Production-related EIS of 1995.

In those comments, SPS rebutted the overly sensitive, generally not really site-specific but knee-jerk and ill-informed, and frequently inaccurate characterizations of environmental "concerns" about expanded missions at Pantex. Clearly, those earlier characterizations of possibly "adverse" impacts, especially those related to uses of ground water, now are rejected by DOE. Nonetheless, a replete record supportive of the Department's April 23, 1996, publicly articulated conclusion that NO significant adverse impacts would result, is appropriate.)

2/30.01 continued

6. Southwestern endorses the Department's "preferred alternative" for continuing assembly, disassembly, and pit reuse functions at Pantex. This "preferred alternative" is environmentally sound, and economically appropriate. Transferring these functions to the Nevada Test Site would be highly questionable in both regards.

5/34.01

7. We strongly encourage the Department to retain high explosives functions at Pantex (rather than relocating those functions to Los Alamos and Lawrence Livermore labs). There would be negative environmental impacts, of course, associated with transfer of those functions to the labs – impacts related to construction and expansion of the labs' facilities, for instance. Those impacts would not occur at Pantex, where facilities already are available and in use for these very purposes. Additionally, there would be economic waste associated with such transfers; simply put, it would be more expensive – by DOE's estimate, $50 million more expensive – to move the functions than to retain them where they presently are performed.

Too, high explosives functions should be retained at Pantex because under the assembly/disassembly preferred alternative, Pantex would be required to continue to have high explosives capabilities sufficient to handle disposition and disposal of current inventories and those anticipated from near-term dismantling --

again, retaining the high explosives functions at the present site would eliminate the necessity of duplicating them elsewhere.

Finally, high explosives functions should be retained at Pantex because, should future need arise for new weapons production, it will be critical to have the high explosives facilities at the weapons production/assembly site -- which site, demonstrably, should be the Pantex site.

5/34.01 continued

8. The environmental and related socio-economic impacts of new storage and disposition functions at Pantex (as outlined in the Fissile Material programmatic EIS) certainly suggests Pantex in fact is the prime candidate for those functions -- especially the storage functions (both those related to reserve weapons grade plutonium and "excess" materials, for which Pantex already has facilities and demonstrated expertise).

Clearly, the facilities and expertise for storage are existent at Pantex: the site provides storage for over 6,500 pits, and has FONSI (Finding of No Significant Impact) authority to house 12,000 pits. With slight modifications, the site likely could "FONSI-out," following an environmental assessment for 20,000 pits. Equally clearly, Pantex is well prepared to store some 21.3 metric tons of the 38.2 tons of the nation's "excess" plutonium – the 21.3 tons are in place at Pantex now. Apparently, only slight expansion would be necessary to securely store the remainder.

3/40.52 continued

Fundamental to this conclusion, too, are the obvious synergies of collocation of assembly/disassembly activities with necessarily attendant, on-site storage.

In fact, as a result of the (altogether appropriate) decision to continue assembly *and disassembly* at Pantex, all plutonium functions, including storage and

3/40.52 continued

disposition, logically flow to Pantex. Incurring extraneous and unnecessary, and high, costs for redundant activities at separate sites would be imprudent.

2/30.01 continued

9. Pantex is the nation's premier nuclear complex production facility; it is imperative that the "production core competencies" presently at the site not be lost or diluted by transfer of management (or production) functions to the labs.

The Department indicates that "stewardship core competencies" must be preserved, perhaps at the laboratories – and the Department seems to indicate that may mean sacrificing "core production competencies" existent at Pantex. It would make better sense to maintain the stewardship competencies by visits or residency at Pantex, than to lose the production competencies that have evolved there.

Transferring assembly and disassembly functions to any site inexperienced in weapons production and, likely, incapable of significant weapons production, could prove disastrous should the need for an augmented nuclear arsenal arise (or when such need arises). Please, do not eliminate or significantly diminish our nation's most effective weapons production facility's competencies.

Relative to disposition alternatives, Southwestern Public Service Company notes that electric power and energy that could be used in immobilization and vitrification, or in processing for oxide fuel, would be priced very competitively at Pantex. (We refer the Department again to our comments, relative to electric supply and costs, in the Tritium Production EIS Inquiry.) We are confident that Southwestern's position as a low-cost producer will encourage the Department to choose Pantex as the most cost-effective site for disposition activities.

3/40.52 continued

10. DOE always should seek the most cost-efficient alternatives for the nuclear complex's operations. Generally, the most cost-efficient alternatives, rather

3/40.52 continued

related to capital investments, transportation, training, security, energy utilities, etc., will be those available to the nation at Pantex.

We request – we are tempted to demand – that fair and open cost comparisons among the alternative sites for each function be used in analyzing sites, and that such accountings be shared with the publics that have demonstrated interest in the nuclear complex.

11. Southwestern must specifically reject the conclusion in the Storage and Disposition draft EIS, under Phaseout, page S-21 (emphasis supplied), as it would apply to the Pantex region of influence: "All of the regional economic areas surrounding the DOE sites would experience a loss in employment with phaseout. However, *compared to total employment in these areas, the loss of jobs would have no or negligible impacts* at all the DOE sites."

6/08.25

In fact, the impact of Pantex employment in the region of influence is highly significant to the region. Measured in terms of total payroll, Pantex is by far the area's largest employer. The reasonable job multiplier developed by Dr. Ray Perryman at Southern Methodist University, a multiplier of 3.87, applied to the some 3,500 employees at Pantex, suggests the site is responsible for a total of over 13,500 jobs. *Employment related to Pantex represents over 12% of the jobs in the Amarillo metropolitan area.*

Incidentally, the three subject EISs inconsistently analyze the indirect jobs created in the region by Pantex employment: The site EIS assumes 1.65 indirect jobs for each job at Pantex; the stewardship and management EIS assumes 1.16; the storage and disposition EIS, 3.51 (by far, the most consistent with Dr. Perryman's, which is the same, regional-experience-based multiplier employed by the Amarillo Economic Development Commission).

6/08.25 continued

Certainly, we consider a potential 10% to 12% reduction in metro-area employment a major loss, and by no means a "negligible" concern. We strongly urge the Department to correct the socio-economic impact portions of all three EIS documents to accurately reflect the impact of Pantex employment in its region of influence.

3/40.52 continued

12. Unlike other nuclear complex sites, for instance the notorious Rocky Flats, Hanford, and Savannah River sites, and yes, Los Alamos, Pantex has not had radioactive materials contamination problems. The nuclear complex-related operations at Pantex, in fact, apparently are the best-managed, relative to protection of the environment, in the nuclear complex. Partially to reward the superior, environmentally benign, history of the site, and certainly to capitalize on superior environmental performance, the Department should retain and expand the technically competent operations at Pantex.

Public support for retention and expansion of the Pantex operations has been nurtured by the facility's performance over many decades. Just as the public here has respected that performance, so should the Department.

Moreover, the Department must surely recognize in the resounding public support Pantex enjoys still further advantages to retention and expansion of the missions at Pantex.

In summary, the criteria for evaluating the alternatives and arriving at the most suitable Record of Decision -- the criteria of environmental impact, cost, and technical feasibility -- support retention and expansion of nuclear complex missions at the nation's premier production site, Pantex Plant.

Southwestern appreciates the opportunity to participate in this important decision making process, and welcomes questions and dialogue, directed to:

US Department of Energy
Office of Reconfiguration
PO Box 3417
Alexandria, VA 22302

To Whom It May Concern:

As the Governor's Lead Contact for National Environmental Policy Act (NEPA) state reviews, I am responding on behalf of the State of Tennessee to the *Draft Programmatic Environmental Impact Statement (DPEIS) for Stockpile Stewardship and Management; No. DOE/EIS-0236; February 1996.*

1/40.13 The State of Tennessee supports efforts to streamline functions and increase fiscal efficiency within the DOE Complex system due to changing national and international policy. We realize that these decisions will not be made easily. However, we urge you to consider costs and benefits of the proposed alternatives in a holistic manner.

Holistic consideration of costs associated with the management of existing facilities or transfer of operational authorities to more efficient locations should include: (1) costs of creating and operating new facilities on currently uncontaminated sites; (2) costs to dismantle existing facilities or manage existing facilities in "cold standby"; (3) costs to manage the balance of facilities remaining after operational functions are transferred to other facilities and (4) fair and realistic assessments of the Department of Energy's responsibility and ability to meet its obligations for environmental restoration at active, dismantled or "cold standby sites". We believe that the Department of Energy has not offered adequate information in the current PEIS for the state or the public to adequately assess the true costs and benefits of the proposed alternatives.

States like Tennessee with major DOE facilities whose functions may be transferred or terminated cannot make proper evaluations of these potential actions without adequate information. Enclosed are many questions that we feel should be addressed in your DPEIS. Your response to these concerns and questions will be expected. If given appropriate notice and time, our positions can be reevaluated.

2/33.01 Due to concerns stated in the adjoining comments, the State of Tennessee supports that the DOE Y-12 facility in Oak Ridge retain its secondary and case fabrication mission. We believe

Office of Reconfiguration
May 6, 1996
Page 2

2/33.01 continued that this is in the interest of the nation as well as Tennessee. The selection of any other alternatives will require much more justification than is currently provided in this PEIS. If DOE prefers to pursue other alternative actions we urge you to issue a second draft PEIS or DOE amendments to the current draft that provides additional justification and reflects public comments. This will require an additional draft comment period.

Please consider the enclosed comments as additional clarification of the positions taken by the State of Tennessee for this NEPA document. If you have any questions, please contact our NEPA staff coordinator at (615) 532-0545. Your consideration of our interests is greatly appreciated.

Sincerely,

Justin Wilson
Commissioner

COMMENT LETTER

PAGE 3 OF 6

STATE OF TENNESSEE
DEPARTMENT OF ENVIRONMENT AND CONSERVATION
DOE OVERSIGHT DIVISION
[illegible]
[illegible]

April 24, 1996

Mr. Justin Wilson, Commissioner
Tennessee Department of Environment and Conservation
c/o Tennessee Environmental Policy Office
14th Floor L&C Tower
401 Church Street
Nashville, Tennessee 37243 - 1553

Dear Commissioner Wilson

Document NEPA Review -- Draft Programmatic Environmental Impact Statement: Stockpile Stewardship and Management, DOE/EIS-0236, February 1996

The Tennessee Department of Environment and Conservation, DOE Oversight Division has reviewed the above document for your concurrence and transmittal to the following DOE office

U.S. Department of Energy
Office of Reconfiguration
PO Box 3417
Alexandria, VA 22302

The Division's review was conducted in accordance with the requirements of the National Environmental Policy Act (NEPA) and associative implementing regulations 40 CFR 1500 - 1508 and 10 CFR 1021.

2/33.01 continued | After review and research, the Division supports the Y-12 plant in retention of the secondary and case fabrication mission. The Y-12 plant has the existing infrastructure to continue the secondary and case mission without negative environmental impacts.

SSM-F-022
COMMENT LETTER

PAGE 4 OF 6

Justin Wilson, Commissioner
April 24, 1996
Page Two

3/10.33 | The Division is concerned that this document lacks adequate information from which to draw conclusions for future impacts should the shifting of Y-12 plant facilities to cold standby conditions occur if the proposed preferred alternative is selected. DOE must make it clear that continued readiness of environmental treatment systems (West End Treatment Facility, Y-12 steam plant, wastewater treatment, solid waste disposal, air pollution control) in cold standby will remain, should future increases in production occur.

4/33.11 | The Division recommends that DOE have the funding mechanisms for proposed downsized Y-12 facilities in place prior to the Record of Decision.
5/41.10 | Also, the Division is concerned with the overburden of numerous NEPA documents released to local stakeholders for simultaneous review. Within the review and comment window for this document the Division also reviewed five other NEPA documents.

We request that the attached comments on the above document be given full consideration in the preparation of the Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management.

If you have any questions, please contact Dale Rector at (423) 481-0995 or Steve Nisley at (423) 481-0163.

Sincerely

E.C.L.

Earl C. Leming, Director

Comments on Draft Programmatic Environmental Impact Statement, DOE/EIS-0236, February 1996, Stockpile Stewardship and Management

GENERAL COMMENTS

2/33.01 continued

If the secondary and case work is moved from Y-12 to the western laboratories, Y-12 may ultimately loose all defense funding. The loss of defense funding could leave Y-12 with inadequate funding for environmental cleanup, including decontamination and decommissioning (D&D) of abandoned facilities. In addition, if the secondary and case work is moved from Y-12, good usable facilities (which are already contaminated) would be abandoned at Oak Ridge and new facilities would be constructed on uncontaminated sites in the western United States. As a result, current brownfields would be abandoned and new brownfields would be created out of greenfields.

6/33.10

If the "Secondary and Case Component Fabrication - downsize the Y-12 Plant at Oak Ridge Reservation" alternative is chosen, necessary utilities, wastewater systems, and other operating systems at Y-12 will be tremendously oversized. Also, the downsizing will impact the decontamination and decommissioning program at Y-12. As a result of the proposed downsizing please explain the impacts to future continued operation of these facilities, operating systems, and programs.

4/33.11 continued

Explain how Y-12 can be assured of timely funding for environmental cleanup activities if Y-12 "Secondary and Case Component Fabrication" is downsized at. Also, explain what funding mechanism would be used to accomplish decontamination and decommissioning of excess facilities in the event the secondary and case work is downsized at Y-12.

2/33.01 continued

In projecting annual costs for the ORR in millions of dollars versus fiscal year and Core Stockpile Management costs over the next ten years of downsizing, explain why the costs shrink significantly. The costs of displaced labor will be an appreciable fraction of the labor costs because ORR workers in downsizing areas have been employed an average of fourteen years or more. Please provide information on the cost estimates of training required for transformation of an employee into a skilled craftsman or competent researcher.

If LLNL is chosen to manage "Secondaries and Cases," the costs associated with dismantling and cleanup of corresponding segments of the Y-12 facility and the cost of dismantling plus future costs of cleanup of the LLNL facilities at a future date should be included in the costs associated with the preferred site cost estimates.

Will Y-12 equipment and material require transfer to other DOE facilities? If so, please provide the costs associated with appropriate Y-12 equipment and material transfers in the cost evaluations of manufacturing "Secondaries and Cases" at LLNL and/or LANL.

7/40.47

The data from LLNL and LANL sites are not as complete as ORR in regard to many of the tabulations on resource requirements such as water. Please provide complete data. Without complete data, no inferences supporting the conclusions of the document can be made.

8/21.05

The scope of this draft PEIS appears to be limited. Clarify with regard to the choice of reasonable alternatives on why this programmatic document includes a Project-Specific Analyses. The Council on Environmental Quality NEPA Regulation 1506.1 states that an agency cannot take any action that would limit the choice or reasonable alternatives before a Record of Decision is issued. It appears inappropriate to include Project-Specific Analyses in this PEIS. The Contained Firing Facility, National Ignition Facility, and the Atlas Facility Project-Specific Analyses within this document appear to bias the decision-makers toward the potential location of those proposed facilities.

SPECIFIC COMMENTS

2/33.01 continued

1. Summary, Page S-17, Paragraph 4
"These components are designed by LANL and LLNL; therefore, each of those facilities would be reasonable alternative sites if this function is transferred to the weapons laboratories." Please explain how LANL and LLNL, which have no experience in actually building these weapons, could be reasonable alternatives for this proposed project.

9/04.13

2. Volume I, Section 4.2.3.4, Page 4-46, Paragraph 3
"The phaseout of the secondary and case fabrication mission at ORR would have no adverse impact on water quality in the East Fork Poplar Creek." Please address whether or not the proposed downsizing will result in decreased water flow in East Fork Poplar Creek. If so, provide the cumulative impacts on the phaseout of process water. Also, provide information on any potential impacts to the methylmercury from sediments in the water column, and impacts on biota.

10/08.01

3. Volume I, Section 4.2.3.8, Page 4-50, Paragraph 3
"These losses would be offset by an increase in the decontamination and decommissioning (D&D) effort which would require approximately 1,318 workers." Please provide information on the D&D jobs. Would these jobs move in immediately or are they to be phased in over several years. Are the 1,318 D&D jobs a steady number required for D&D?

11/40.93

4. Volume I, Pages 3-64, 3-68, 3-71, 3-76, 3-77, and 3-82
"Surge Operation Annual Requirements" is shown in the title of several tables on the referenced pages, but is not defined in the glossary in Chapter 9. Please provide a detailed explanation of "Surge Operations" in the glossary.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

MAY 7 1996

OFFICE OF ENFORCEMENT AND COMPLIANCE ASSURANCE

Mr. Jay Rose
Office of Reconfiguration
U. S. Department of Energy
1000 Independence Avenue, S.W.
Washington, DC 20585
Attention: SSM PEIS

Dear Mr. Rose:

The Environmental Protection Agency (EPA) has reviewed the Department of Energy's (DOE) Draft Programmatic Environmental Impact Statement (PEIS) for Stockpile Stewardship and Management. Our review is provided pursuant to the National Environmental Policy Act and Section 309 of the Clean Air Act.

1/11.15 The proposed action is to provide an integrated technical program for maintaining the continued safety and reliability of the nuclear weapons stockpile in the absence of underground nuclear testing and no new nuclear weapons production. The stockpile stewardship portion of the draft PEIS analyses the potential environmental effects of three proposed facilities on four potential sites, and a no action alternative. The stockpile management portion of the draft PEIS evaluates the potential environmental effects of five management activities at eight potential sites, and a no action alternative. EPA has rated the document EC-2, environmental concerns - insufficient information. We recommend that the DOE provide additional information and clarity concerning the accident risk analysis. In particular, more information on the assumption inputs to the MELCOR Accident Consequence Code System model could greatly enhance the public's understanding of the differences in safety risk between alternatives if an accident were to occur. Currently, the PEIS provides only limited review of the model but relies heavily on it to conclude that there is little danger to the public from accidents and little difference in accident risk among the alternatives considered. Further discussion could strengthen the credibility of these conclusions. An explanation of EPA's ratings is provided in Enclosure 1. Detailed comments are provided for your consideration in Enclosure 2.

Thank you for the opportunity to comment. If you have any questions, please contact Susan Offerdal at (202) 564-7158.

Sincerely,

Richard E. Sanderson
Director
Office of Federal Activities

Enclosures

Enclosure 1

SUMMARY OF THE EPA RATING SYSTEM
FOR DRAFT ENVIRONMENTAL IMPACT STATEMENTS:
DEFINITIONS AND FOLLOW-UP ACTION *

Environmental Impact of the Action

LO--Lack of Objections

The EPA review has not identified any potential environmental impacts requiring substantive changes to the proposal. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal.

EC--Environmental Concerns

The EPA review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce the environmental impact. EPA intends to work with the lead agency to reduce these impacts.

EO--Environmental Objections

The EPA review has identified significant environmental impacts that should be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no-action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

EU--Environmentally Unsatisfactory

The EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potential unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the CEQ.

Adequacy of the Impact Statement

Category 1--Adequate

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis of data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

Category 2--Insufficient Information

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses, or discussion should be included in the final EIS.

Category 3--Inadequate

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the NEPA and/or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

* From EPA Manual 1640 Policy and Procedures for the Review of Federal Actions Impacting the Environment

February, 1987

Enclosure 2

EPA COMMENTS ON THE DRAFT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT FOR STOCKPILE STEWARDSHIP AND MANAGEMENT

Radiation: In general, it appears that the conclusion drawn in the programmatic environmental impact statement (PEIS) to the effect that there are no major radiological consequences of any of the alternatives is reasonable. Both the doses modeled and the probability of these doses are small. This conclusion seems particularly warranted in the case of routine operations.

2/11.12 In the case of accidents, while the conclusion of little or no risk is still plausible, some questions do arise. The PEIS does not clearly differentiate the safety risks associated with each alternative if an accident were to occur. This is of some note because, as the PEIS notes, accidents are of major concern to the public and the decisionmaker.

3/11.24 The accident scenarios assume a worker a kilometer away from the accident site. Is this a reasonable assumption? What is the basis for this? At least in the case of Hanford, the effect of a facility accident on the maximally exposed individual in the general population is a hundredfold less than the worker already a kilometer away. What assumptions produce this result? Again, more discussion of how the MELCOR Accident Consequence Code System (MACCS) model is applied would add to the confidence one has in the results. It is clear that given the small dose the model predicts and the very low assumed probability of the more serious accidents (a severe earthquake has a one-in-ten million chance of occurring) the resulting risk is small and not of concern.

4/11.28 The PEIS needs to document more fully why these assumptions and others associated with the accident scenario are reasonable, and how these and other inputs are used by the MACCS model.

5/12.10 Environmental Justice: Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires special attention to be given to subsistence consumption of fish and wildlife. "Federal agencies, whenever practicable and appropriate, shall work in a coordinated manner to publish guidance reflecting the latest scientific information available concerning methods for evaluating the human health risk associated with the consumption of pollutant-bearing fish and wildlife. Agencies shall consider such guidance in developing their policies and rules." Consumption issues are important to address in this PEIS because of their uniqueness in minority and low-income populations and the detrimental range of impacts they may have.

SSM-F-024
COMMENT LETTER

PAGE 5 OF 5

6/43.06 — **Executive Summary**: The executive summary could benefit from summary tables of environmental effects and a section on cumulative impacts.

7/22.02 — **Proposed Atlas Facility (page S-27)**: The description of this facility is limited in both the executive summary and on page 319 of Volume 1. We recommend that the DOE expand the discussion of the uses of the facility since it is unclear, and therefore, difficult to review the potential environmental impacts.

8/41.12 — **Next Generation Stewardship Facilities (Page S-28)**: There is no discussion of the current proposed alternatives' relationship to the anticipated next generation stockpile stewardship facilities. There may be some utility in this discussion since some of the proposed alternatives may integrate better with the next generation facilities and when evaluated together may have less adverse environmental impacts (e.g., the anticipated timing of the current alternatives and the next generation facilities may be of interest).

Comments on
the Draft Programmatic Environmental Impact Statement
for Stockpile Stewardship and Management

The Oak Ridge Environmental Peace Alliance

May 7, 1996

Introduction

The Department of Energy has prepared a draft programmatic environmental impact statement which sketches the broad outlines of the nuclear weapon stockpile support complex of the future. Under the title "science-based stockpile stewardship and management," the Department proposes to build new facilities and upgrade current facilities in order to maintain a huge nuclear arsenal and to maintain the capability to research, design, produce and test new nuclear weapons.

1/40.07 These actions of the Department of Energy are in fundamental and essential conflict with the stated nonproliferation policies of the United States as well as with international treaty obligations. The Department has chosen to ignore these conflicts in preparing the draft programmatic environmental impact statement.

2/40.27 The current draft programmatic environmental impact statement fails to consider all reasonable alternatives; it is clear from the first page of the document that it has been prepared by the national laboratories responsible for weapons production whose naked self-interests are served throughout the document. In response to political pressure by those responsible for weapons production activities in Oak Ridge, the Department of Energy has publicly agreed to re-examine its preference for moving highly enriched uranium production activities from Oak Ridge. The Department also announces in its cover sheet that, as a result of its study, it has identified only one "preferred alternative," choosing in this election year to build a $4.5 billion facility in the state with the most electoral votes of any state. The blunt politicization of decisions related to nuclear weapons is despicable and sad. The implications for both our national policy, for domestic spending, and for international relations are profound and none of them are positive.

The Oak Ridge Environmental Peace Alliance calls on the Department of Energy to set aside all political consideration and address in a reasonable way the issues surrounding the maintenance of a declining nuclear weapons stockpile. Such analysis should have as its primary goal the support of US nonproliferation policy and the international treaty obligations of the United States.

1/40.07 continued

Concerns of the Oak Ridge Environmental Peace Alliance

Enduring stockpile or Declining stockpile?

The Stockpile Stewardship and Management draft programmatic environmental impact statement begins with the presumption of an enduring stockpile of nuclear weapons (p. S-1). This presumption reflects the commitments of the national weapons laboratories, but is in direct conflict with the commitment of the United States under Article VI of the nuclear Nonproliferation Treaty. Furthermore, the commitment to an enduring stockpile, when measured against the shift in geopolitical reality of the last ten years and the agreement entered into by the United States and Russia to reduce stockpiles, is less reasonable than a commitment to a declining stockpile. Clearly the Stockpile Stewardship and Management draft programmatic environmental impact statement should address the safest and most appropriate way to "build down" the US weapons stockpile. The draft programmatic environmental impact statement should support, rather than an "enduring" stockpile, *a declining nuclear stockpile until such time as the United States achieves its commitments under Article VI of the nuclear Nonproliferation Treaty."*

The Department's commitment to an enduring stockpile, at the same time that it presents itself as a champion of nonproliferation, is not credible. The plans outlined in the current draft programmatic environmental impact statement undermine all US efforts to reduce the nuclear danger at home and abroad. The US can not credibly achieve its nonproliferation goals while it moves forward toward "next generation facilities" (p.S-5). Clearly, the list on page S-5 attempts to leap forward in time over the current attempts to construct the true "next generation facilities" which are covered in this draft programmatic environmental impact statement—the National Ignition Facility, the Contained Firing Facility, and the Atlas Facility. There is no credible argument which can reconcile construction of these next generation facilities with our nonproliferation objectives. The only explanation which makes sense out of the Department's current course is that nonproliferation objectives have been subjugated to political goals of the

1/40.07 continued

current Administration and the directors of our national weapons laboratories.

Article VI—Reasonable or Not?

The current draft programmatic environmental impact statement contains an internal inconsistency in its discussion of Article VI of the nuclear nonproliferation treaty. On page S-7, the draft programmatic environmental impact statement lists "four principal national security policy overlays and four related treaties that define program conditions for the reasonably foreseeable future." This list includes the Nuclear Nonproliferation Treaty (sixth bullet).

Understanding the moral and legal authority of the nonproliferation treaty, and the central role Article VI will play in the success of the nonproliferation treaty (as was clearly demonstrated in last summer's negotiations over the renewal of the nonproliferation treaty), members of the public asserted in overwhelming numbers during DOE's earlier scoping hearings on stockpile stewardship and management, that DOE must consider as a reasonable alternative, a zero-stockpile option.

3/40.60 The Department has chosen to disregard this overwhelming public desire and instead to assert, on page S-10, in a paragraph describing the nonproliferation treaty, that it consideration of a zero-weapons stockpile "goes beyond the reasonably foreseeable future." This statement, coming only three pages after the draft programmatic environmental impact statement acknowledges the nonproliferation treaty defines the reasonably foreseeable future, is simply an assertion of the document preparers which describes their shortsightedness and their commitment to an enduring stockpile rather than the realistic future. The Department's commitment in examining reasonable alternatives must be to the realistic future. Efforts to bolster the dismissal of the public's scoping comments with a quote from a US Ambassador are inconclusive at best—if the Ambassador believes it is unwise to predict the future, and if the Department agrees with him, it stands to reason that the Department should consider all reasonable alternatives rather than excluding some. It is the Department, in denying the possibility of the United States keeping its commitment to the nonproliferation treaty, which is predicting the future and limiting options.

DOE attempts to further bolster its dismissal of the zero-weapons stockpile with an opposite comparison, saying, "For the same reason, DOE has not chosen to speculate on a return of the nuclear arms race requiring a stockpile larger than START-I size"—though it is *not at all for the same reason!* The reasons for considering a zero-weapon stockpile are three-fold:

- the nonproliferation treaty obligates the US to pursue complete nuclear disarmament;
- all recent accords between nuclear nations and the clear desire of the international community is toward continued reductions in arsenal size, not a return to an arms race; and
- in the scoping hearings, where the public identifies for the agency what issues it considers within the scope of the environmental analysis, the overwhelming sentiment was for consideration of a zero-weapons stockpile.

The reasons for considering a return to an arms race, which DOE tries to equate with zero-stockpile alternatives, would require the complete disregard of each of the above reasons. The two alternatives are in no way comparable.

1/40.07 continued

Finally, DOE makes a specious argument that the nonproliferation treaty is not applicable in this document because, "the NPT does not provide any time period for achieving this goal." This statement is the argument made by those resisting the moral and legal obligations of the treaty. It is comparable to the position of southern governors who resisted school desegregation in the wake of *Brown v. The Board of Education* for nearly ten years.

The lack of a specific time period for achievement of the goal of the nonproliferation treaty in no way relieves the US of its obligation to pursue in good faith the achievement of that goal. Quite the opposite, without a specific timeline, the nations of the world rely solely on the good faith of the United States and other weapons states to make good on their Article VI promise to pursue "at an early date" negotiations in pursuit of complete disarmament. Not only is our reputation and credibility on the line, but our efforts to achieve nonproliferation goals around the world are supported or undermined by our activities in pursuit of Article VI.

3/40.60 continued

In summary, the draft programmatic envirnmental impact statement provides not one persuasive or supportable argument for the failure to consider the zero-weapon stockpile as an alternative in the future. Arguments DOE attempts to marshall to support its position actually undermine its position. DOE must consider as a reasonable alternative for analysis the build-down-to-zero option.

Oak Ridge—a confusion of mission?

The Oak Ridge reservation's Y-12 Plant has a clearly defined mission for the future—the dismantlement of nuclear weapons secondaries and the processing and long-term storage of weapons-usable highly enriched uranium. This mission is currently confirmed by the Department's Environmental Assessment on the Interim Storage of Highly Enriched Uranium at Y-12 and the environmental impact statements currently in preparation regarding the disposition of surplus highly enriched uranium and the long-term storage of highly enriched uranium.

4/40.24

This mission, consistent with the nonproliferation goals of the United States, is not consistent with continued support activities for weapons research, developing, production and testing in Oak Ridge.

US dismantlement, disposition and storage activities must, in order to achieve US nonproliferation goals, be subject to international verification. Transparency at virtually every step in the process will be required. Currently, the International Atomic Energy Agency maintains administrative control of one storage vault in Oak Ridge.

Attempting to maintain a production mission at Y-12 will inevitably compromise efforts to achieve complete transparency. A production mission at Y-12 would also increase Y-12's attractiveness as a target of hostile forces and divide the community's support for Y-12's mission and activities.

5/40.36

The Department of Energy, except for an unsubstantiated assertion, has not demonstrated the need for a commitment of resources to weapons research, development, production and testing. The draft programmatic environmental impact statement should not include further production activities in its scope. There is no justification for consideration of alternatives which include "fabricating pit, secondary and case, HE, and other nonnuclear components. (S-5)"

Furthermore, it is inadvisable for the Department to co-locate production and dismantlement activities at the same facility for the reasons cited above. The Department should be clear with the community in Oak Ridge about its future mission and should make an enduring commitment with the community that it will continue to receive the support of the federal government for its important dismantlement/disposition/storage mission.

Conclusion

4/40.24 continued

The flaws noted above are not insignificant or trivial; they are fundamental and profound. The draft programmatic environmental impact statement on Stockpile Stewardship and Management can not proceed to a decision until these flaws are addressed. The Department of Energy, in carrying out its responsibilities under the National Environment Policy Act, must analyze "all reasonable alternatives" in the programmatic environmental impact statement. This includes a zero-weapons stockpile. The draft programmatic environmental impact statement for Stockpile Stewardship and Management should be withdrawn, redrafted, and re-issued for public comment when it provides the legally required analysis of all reasonable alternatives.

Re: SAI# 96300148: State of Nevada Comments on the U.S. Department of Energy's Draft Stockpile Stewardship and Management Programmatic Environmental Impact Statement

Dear Mr. Sohinki:

Thank you for providing us the opportunity to review the Draft Stockpile Stewardship and Management Programmatic Environmental Impact Statement (SSM-PEIS).

As you might recall, in August 1995, the State of Nevada submitted extensive scoping comments on the Notice of Intent for this PEIS. In those comments, we identified several issues of national and local concern. From a national perspective, we suggested that DOE should evaluate a weapons remanufacturing and limited non-nuclear/hydronuclear testing alternative. From the local perspective, we suggested that certain institutional constraints that directly affect the Nevada Test Site (NTS) should be analyzed if the NTS were to be considered for major projects such as the National Ignition Facility (NIF). Unfortunately, our review of this draft PEIS indicates that neither of these concerns has been addressed.

1/40.33 In reference to the first issue, we were not surprised that DOE chose to avoid a detailed assessment of the weapons remanufacturing and limited nuclear and hydronuclear[1] testing alternative in the PEIS. With the recent presidential decision to achieve a "zero" yield Comprehensive Test Ban Treaty, we realize that DOE had little incentive to assess a remanufacturing and limited nuclear/hydronuclear testing program. We still contend, however, that this alternative could easily provide a "short term" 20-year strategy to address safety, reliability, and performance of the nation's enduring nuclear stockpile. Additionally, the cost of implementing a remanufacturing program would be far less than the cost of the proposed National Ignition Facility.

2/40.07 In a related matter, we are concerned that the construction and operation of the NIF[2], along with other proposed "nuclear simulation machines," could undermine national policies designed to ensure safety and reliability in the nuclear stockpile (i.e., stockpile maintenance). It appears that these simulation machines could also be used to improve and advance new warhead designs. The Final EIS should clarify whether or not this is the policy of the United States. The Draft SSM-PEIS is not clear on this point. It is worth mentioning that the Nuclear Nonproliferation Treaty (Article VI), along with existing Presidential decisions, directives, and public laws[3], promotes the concept of maintaining reliability and safety of the stockpile as opposed to the development of new weapons design capabilities.

---

1 *Hydronuclear tests can produce nuclear yields of a few pounds to a few hundred pounds of TNT.*

2 *The Proposed Action sites the NIF at the Lawrence Livermore National Laboratory in California.*

3 *See SSM-PEIS Summary, page S-11.*

3/40.02 The PEIS also fails to make a clear distinction between the types of sub-critical tests[4] proposed at the NTS and how these tests relate to stockpile reliability and performance simulations that would be conducted using the NIF, the Contained Firing Facility, and the Atlas Facility. Hence, the Final PEIS should both explain and clarify how all of these testing activities fit together to foster safety, reliability, and performance of the nuclear stockpile.

4/40.45 The second issue we addressed during scoping concerned the assessment of the impacts of national siting decisions for specific projects like the NIF on the environment, infrastructure, and institutional constraints at the NTS. Since most of these concerns are now moot because the NTS[5] is not being considered a preferred alternative for major Stockpile Stewardship and Management activities, we have purposely forgone a detailed review of the environmental impacts presented in the PEIS. Nevertheless, there are other issues that DOE officials should be aware of that were not addressed in the PEIS. These issues could play an important role if the NTS were ever reconsidered for any of these new defense facilities. As we mentioned during scoping, there are unique legal and institutional issues that pertain exclusively to the NTS, and we contend that these issues cannot be ignored in the context of federal agency compliance with the National Environmental Policy Act.

5/01.06 Specifically, the current Public Land Orders[6] for the NTS limit the use of the site to weapons testing and related research and development facilities only. And,

---

4 *Lyner Complex and the Big Explosive Experimental Facility, See NTS Site-Wide EIS (DOE EIS 0243)*

5 *In this context, NTS also includes the North Las Vegas facility, which is also evaluated as a siting alternative for the NIF.*

6 *Public Land Orders (PLOs) 805, 1662, 2568 and 3579. Bureau of Land Management (BLM). 1984. Continuation of Withdrawals, Department of Energy, Nevada Test Site 4310-84. (This file is located at the BLM State Office in Reno, Nevada*

SSM-F-028
COMMENT LETTER

PAGE 4 OF 5

5/01.06 continued

when the Nevada Legislature ceded its jurisdiction to the public lands that now comprise the NTS, it did so on the basis of these stipulated uses. Although the Draft SSM PEIS indicates that the lands comprising the NTS are federal lands, they are in fact public lands that have been withdrawn for a specific national defense purpose, and that purpose does not include large scale weapons' assembly/disassembly and/or the siting of laser fusion technologies such as the NIF.

During the scoping process, we suggested that DOE should propose a path forward in the PEIS to address actions concerning the mission of the site and that this path forward should identify a process for seeking approval from the Nevada Legislature to use NTS for purposes other than nuclear testing (the Nevada Legislature approved the NTS withdrawal as a federally sanctioned activity). We note that CEQ regulations [1506.2(d)] require EIS statements to discuss any inconsistencies with approved plans or laws. Accordingly, if the NTS is chosen for one or more of these major testing facilities, an analysis must be contained in the Final PEIS that addresses the stipulated facility-use restrictions contained in the Public Lands Orders. A precedent for such an analysis has been acknowledged in DOE's recently published Storage and Disposition PEIS.[1] In that document, it is clearly stated that the potential for adverse impacts to land resources exists "due to nonconformance with existing land-use plans, policies, or controls" at the NTS. The referenced PEIS also mentioned that the expanded-use alternative presented in the NTS Draft Site-Wide EIS is inconsistent with the NTS land withdrawal.

6/42.09

Finally, in reference to the interim storage of plutonium pits and/or pits assembly/disassembly, Nevada's position on this issue continues to be that DOE must develop a final proposed action for the permanent disposition of plutonium pits before selecting an interim or long-term storage site for this long-lived material. Nevada

officials have said that DOE should link long-term fissile materials consolidation and management with options for final materials disposition before siting interim or long-term pit storage facilities, whether it is for surplus materials or strategic reserves. DOE should not fragment major federal decisions to support either short- or long-term plutonium storage and disposition, where such decisions could cause significant impacts to the people and environment in Nevada. Such actions would not conform to the spirit and intent of the National Environmental Policy Act.

Again, we appreciate the opportunity to provide comments on the Draft SSM-PEIS. If you have any questions about these comments, please contact me or Mr. John B. Walker, Nuclear Waste Project Office at 702-687-3744.

DOE Public Meeting on
Draft Environmental Impact Statements
April 30,1996

There are three draft environmental impact statements on which the DOE is soliciting public comments. These three documents cover plutonium storage and management:

* The Pantex EIS considers SRS as an alternative for storage of up to 20,000 plutonium pits, most of which are currently stored at Pantex.
* The Stockpile Stewardship and Management EIS evaluates SRS as an alternative for plutonium recovery and remanufacturing of plutonium pits to maintain the nuclear stockpile.
* The Disposition of Weapons Usable Fissile Materials EIS considers alternatives for consolidating plutonium storage and technologies for disposing of surplus plutonium.

SRS is under consideration for a major role in each of these programs. Following are some points that relate to these issues:

(1) A key part of any decision concerning these programs is the attitude of the neighboring communities.

1/32.06

SRS's neighbors in Georgia and South Carolina have supported SRS operations since the location was named 46 years ago as a weapons material production plant. Over these years, operators of SRS have been prudent, responsible, and world-class in technical ability. This community naturally welcomes additional missions of this type and jobs and money coming in, especially after so much has left the last few years. We also know and trust the people at SRS. Because of the support SRS enjoys, we urge DOE to choose SRS as the site for the future needs discussed in these EIS's.

(2) In many cases SRS has the facilities and capability already in place for certain of the EIS alternatives, and additions needed could be installed very cost-effectively by DOE.

Storage of nuclear materials, for example, is commonplace activity at SRS, and SRS officials report that they are already planning a modular storage facility, which could be easily modified for additional capacity. The storage unit is budgeted at $150 million, and additional storage capacity would roughly double that number.

(3) If it is determined that the national interest requires a large scale effort to reconstitute the plutonium pits now in the stockpile, a large percentage of which are decades old and potentially unreliable, SRS has the expertise and many of the facilities to perform that job

SSM-H-SRS-001
COMMENT LETTER
PAGE 2 OF 2

1/32.06 continued

cost-effectively.

The capital investment of that option is about $350 million, much of which would return to he community in the form of purchases and construction wages.

(4) Excess plutonium must be managed properly. Storage is an option, but there is also the possibility of obtaining energy benefit from plutonium by making mixed oxide fuels for use in nuclear reactors. SRS is a logical place for fuel manufacture because of the existing plutonium handling facilities and expertise onsite. This would represent construction and related expenditures of about $350,000.

At the same time, SRS is essentially the center of applied vitrification technology in this country, and would be the ideal location for vitrifying plutonium as an anti-proliferation action. Capital costs would be about $500 million.

(5) It must be remembered that SRS has the only active large-scale plutonium processing facility in the nation.

(6) SRS not only has the capability to perform each of these missions safely and effectively, but in fact, is the only site that which can perform all of the missions.

SRS has the technology, infrastructure support, and facilities to immediately implement the NEPA decisions. Only SRS retains large-scale functioning plutonium capability. Only SRS has experience at startup and operation of nuclear facilities with today's standards of operation. Only SRS can provide the Department the capability to merge all of its plutonium functions at a single site with billions of dollars of savings which will result from this approach.

VIA FAX

Dear Sirs:

Thank you for the opportunity to present my views on the Stockpile Stewardship and Management Draft EIS on April 30, 1996 in North Augusta, SC. As a follow up, I have additional points to be expressed. They are:

1. After years of study of the land use and environment of the Savannah River Site and the potential environmental impact this project may have; it is my conclusion that *SRS can accommodate a project of this magnitude without adversely affecting the environment.* Forty-five years of government control has actually enhanced the environment of SRS. This has been documented by the Savannah River Ecology Laboratory (University of Georgia) and the Savannah River Forest Station (USFS/USDA). However, there are indeed pockets of contamination that require attention. These can be controlled by institutional controls on future land uses.

1/40.76 2. *Many large-scale future missions can be accommodated by SRS.* Given the infrastructure, security, workforce competency, community support and land use, there is no reason why new missions such as this project cannot be located at SRS. This does not mean that development should be given carte blanche. Environmental controls, comprehensive planning and operational safeguards should be implemented. Having lived in Alaska during the construction of the Alyeska Pipeline, I saw first-hand how development and the environment could co-exist. However, this technological accomplishment did not come without a tremendous amount of work.

2/41.10 3. *This and the other projects discussed at the EIS meetings on April 30, should be considered in one planning document* (It does not have to be large). Besides being programmatically linked, future uses such as these should be judged in the aggregate. This would save time, resources and reduce confusion to the public and SRS employees.

3/01.01 4. Most importantly, *careful land use planning should be undertaken prior to this or any other large scale projects.* Section 101 of NEPA generally states that planning should be undertaken and coordinated by the federal government. However, Section 102 specifically states that planning is very important and should be utilized. This was reiterated by "The Father of NEPA," Dr. Lynton Keith Caldwell, when he visited SRS on April 2. Land use planning studies concerning large federal facilities in other agencies, other DOE sites and SRS have yielded significant results - Most notably in environmental protection, consolidation of resources and savings to the public.

4/10.07 5. Finally, *there should be a concerted effort to open Yucca Mountain.* It is difficult to view this project in fair terms if no end-state of nuclear materials is identified.

To provide a little background on myself, please see the attachment.

Thank you again for considering my comments.

Sincerely,

[signature]

"FUTURE ENVIRONMENTAL USES AT FEDERAL FACILITIES"

CHRISTOPHER NOAH, Ph. D.

Public Meeting
Draft Programmatic Environmental Impact Statements for Plutonium Storage and Management
North Augusta, South Carolina
April 30,1996

Situation

Environmental Uses At Federal Facilities Are:

Reactive To:

Myriad Of Federal Acts, For Example:

- NEPA
- CERCLA ("Residential Use")
- Community Environmental Response Facilitation Act (Land Transfer)
- RCRA
- Endangered Species
- Federal Land Policy And Management Act
- Federal Property And Administrative Services Act
- National Historic Preservation Act
- McKinney Act (Homeless)
- State Primacy And MOAs
- Etc.

C Noah

Situation (Continued)

Responsive To Outside Stimuli, Such As:

- **Community Re-Use Organizations (CROs)**
- **Environmental Groups**
- **State Governments**
- **Federal And State Legislators**

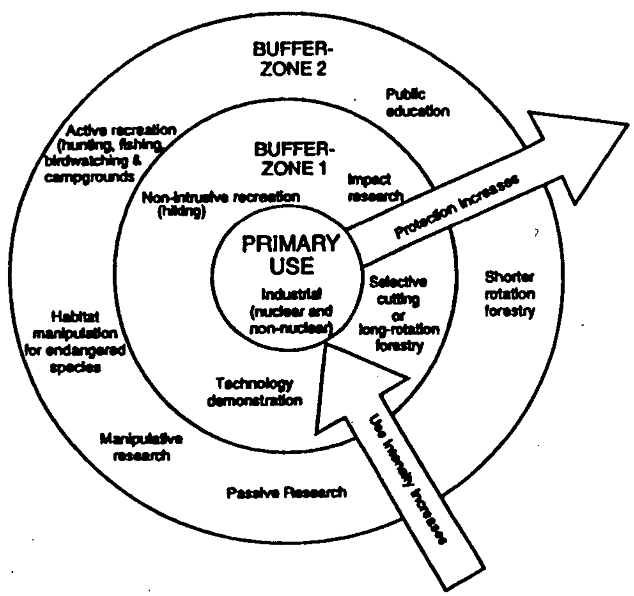
PROPOSED MULTIPLE LAND USE MODEL FOR SRS



Christopher Noah
Westinghouse Savannah River Company
April 1996

Examples Of Environmental Uses Which Could Be Expanded

Research

Technology Demonstration

Natural Resource Management

Recreation

Public Education

C. Noah

Recommendations for Future Uses of the Savannah River Site

SRS Boundaries Should Not Change And The Primary Mission Should Remain Industrial With Multiple, Concurrent Activities.

- **Reason One - The Number, Time Frame And Cost Of Studies Prior To Turnover**
- **Reason Two - Possible Future Need**
- **Reason Three - SRS' Uniqueness**

No Area Of The Site Should Be Designated "Residential"

Environmental Research And Technology Demonstration Activities Should Be Increased.

Natural Resource Management Activities Should Be Maintained And Possibly Increased.

Recreation Activities Should Be Significantly Increased.

Public Education Activities Should Be Significantly Increased.

C. Noah

Conclusion

Federal Facilities *Should* Be Viewed As Environmental Assets *Not* Environmental Liabilities

C. Noah

1/32.06 SRS SHOULD RECEIVE A MAJOR PORTION/ROLE IN EACH OF THE RESULTING DECIDED PROGRAMS AS DETERMINED IN THE RECORDS OF DECISION. SRS HAS THE PEOPLE, FACILITIES, INFRASTRUCTURE, AND EXPERIENCE THAT IS NEEDED FOR SAFE, SECURE, COST EFFECTIVE AND INSPECTABLE OPERATIONS, MANAGEMENT, AND SATISFACTORY DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS. IN GENERAL THE SUPPORT FROM ADJACENT COMMUNITIES IS VERY FAVORABLE AND THIS NEEDED SUPPORT WILL GREATLY ASSIST DOE IN ACCOMPLISHING THE DESIRED MISSIONS.

FOR BETTER REASONS, THE EXCESS WEAPONS GRADE PLUTONIUM SHOULD BE UTILIZED TO MAKE MOX FUEL. SMALL REASONS SHOULD BE ELIMINATED AND RESOLVED TO ALLOW SUCCESSFUL USE OF MOX FUEL.

Department of Energy
PEIS Hearing
Santa Fe, New Mexico

SUBJECT: STOCKPILE OVERSIGHT

1/40.51 The stewardship of the Nuclear Stockpile is a function that is best done at Los Alamos National Laboratory. This is a very critical component of our nation's security. My lawnmower will not start immediately after sitting all winter – it is ridiculous to assume that a sophisticated device consisting of over 5,000 parts, and some very exotic materials, would not require close and careful monitoring to ensure safety and reliability.

In addition, Japan and Germany are relying on the United States to maintain a credible stockpile, and if we don't they would probably proceed to develop a weapon of their own, possible within just months.

The Los Alamos Study Group's (consisting for the most part of people outside Los Alamos) vision for Los Alamos is a ghost town - a vision which if realized would destroy the economy of North Central New Mexico and threaten national security. They have forgotten the lessons of the 1990s.

Our vision for Los Alamos is to guarantee the integrity of our nation's stockpile, and thus the freedom of this Country. Also, the Laboratory has, and will continue to make substantial contributions to finding solutions to problems in diverse areas including medicine, energy, and transportation. As a County, we whole heartedly support Los Alamos National Laboratory in their efforts.

Sincerely,

Denise Smith

SSM-H-LLNL-001
COMMENT LETTER **PAGE 1 OF 2**

CITY OF LIVERMORE

April 11, 1996

Honorable Chairperson,

1/40.44 My name is Cathie Brown and I am the Mayor of the City of Livermore. On behalf of the 65,000 residents of the City, I would like to thank you for holding this public hearing in the City of Livermore and for giving me the opportunity to speak to you about the City's overwhelming support for the Department of Energy's (DOE's) Stockpile Stewardship and Management Program. Also, since the proposed National Ignition Facility (NIF) is the cornerstone of the Stockpile Stewardship Program, I am strongly encouraging the DOE to not only support construction of the NIF but to locate it in Livermore at the Lawrence Livermore National Laboratory (LLNL).

2/21.06 My review of the Environmental Impact Statement (EIS) leads me to conclude that the NIF does not undermine the objectives of our Nation's Comprehensive Test Ban Treaty. This conclusion is further supported by the report the DOE prepared last year at the request of Congressman Dellums. This report looked at the question of whether the NIF would hinder or aid United States nonproliferation efforts. This DOE study confirmed the conclusions of the 1994 JASON Committee Report which stated (1) The technical proliferation concerns of NIF are manageable and therefore can be made acceptable; and (2) NIF can contribute positively to United States arms control and nonproliferation goals.

Another reason I am encouraging you to adopt the Programmatic Environmental Statement is because our community is eagerly awaiting the positive economic impacts construction of the NIF will have on our local and regional economy. The $1.07 billion construction costs will create 3,320 high-paying construction jobs, as well as 890 permanent jobs.

Honorable Chairperson
April 11, 1996
Page Two

3/21.12

Lastly, the Laboratory has been a good neighbor to the City of Livermore. They have been very concerned with and open about public health and safety issues associated with past and present projects at the Laboratory. It is because of this past track record that the City has confidence in the Laboratory that they will accept and diligently implement any mitigation measures that are contained in the Final Environmental Impact Statement on the NIF.

1/40.44 continued

In summary, the City is pleased to offer its support to the Laboratory and to the Department of Energy for funding the National Ignition Facility, and is grateful to the Laboratory's leadership for their efforts in viewing the City as a coequal partner in ensuring the future viability of the Laboratory. We are confident this partnership will continue to prosper in the future and look forward to working with you toward this mutual goal.

Thank you,

Cathie Brown

The Regional Economics Of Constructing
The National Ignition Facility

1/21.09

1. Will the NIF create 1500 jobs?

The jobs created in the Livermore region by the NIF will vary during each year of construction. During year one, only 22 jobs will be created. By year five, approximately 600 jobs will be created. Construction jobs will then fall to 120 jobs by year seven. Only about 230 long-term operating jobs will stay at the NIF.

2/21.10

2. How much does it cost to create one job at the NIF?

LLNL data shows it costs almost $1 million to create each lab-related job. Construction jobs cost about $420,000 each, and electrical equipment-related jobs cost about $750,000 each to create.

3. How much does it cost to create construction and electrical jobs in the Bay area?

According to the Department of Commerce, it costs about $120,000 each to create either of these jobs anywhere else in the Bay area.

4. Will the NIF be a "magnet" for high tech industries and will this create local jobs?

Industries choose to relocate for many reasons, but regional economists recognize the following factors as being most important:

- Lifestyle: recreation, congestion, crime
- Low cost per square foot of building space
- Easy transportation access
- Low taxes and low fees.

The NIF will drive up the per-square foot cost of local construction due to the higher wages paid at the facility and competition for construction materials. Further, high tech industries that rely on tech transfer have been shown to be poor regional job producers.

5. Where will the money for the NIF come from?

The United States is operating at a deficit while trying to decrease our national debt. There is no money for new projects that does not come by shutting down old projects. NIF's initial funding was accompanied by cuts in nuclear weapon production waste cleanup, both nation wide and at LLNL. Further, there are

3/21.04

indications that additional funding for the NIF will come at the expense of other LLNL projects. These cuts will mean job losses that could offset any job gains realized from the NIF.

6. What is the outlook for the NIF project?

2/21.10 continued

The NIF is a "big science" project. The history of funding such projects in the US is not good, with the cancellation of the Superconducting Super Collider being only the most recent example. Because of its nuclear weapons connection and because of its high cost and because of its lack of credible justification, the NIF is unlikely to survive the annual budget process in Washington. If it is terminated after the the NOVA laser is dismantled, it will result in large job losses throughout the region. If it is built, cutbacks at other LLNL projects will probably be required. This will result, at best, in a neutral employment situation in the Livermore region.

William J. Weida – Economists Allied For Arms Reduction – March 8, 1995

Life Cycle Costs and Tradeoffs Associated With The
Proposed Stockpile Stewardship and Management (SS&M) Program

William J. Weida
Economists Allied For Arms Reduction
April 9, 1996

The Department of Energy (DOE) has proposed a Stockpile Stewardship and Management (SS&M) Program to "consolidate" the nuclear weapons complex and to preserve weapons research, development and manufacturing capabilities into the 21st century. This program is intended to maintain DOE's ability to design, fabricate and certify new warheads in the absence of underground nuclear testing.[1] It is being proposed in spite of the fact that the overwhelming majority of the American people want deep reductions in nuclear arsenals and a permanent end to nuclear testing. According to a national poll conducted at the beginning of 1995, 90% of Americans favored further stockpile cuts worldwide; 82% favored the elimination of most or all nuclear weapons, and 82% favored a global ban on all nuclear tests.[2]

The 1996 budget negotiations that led to the FY1997 SS&M budget request were based on a ten-year, $40 billion program. However, the amounts actually allocated to the program in that request were approximately:

$3.7 billion in FY1997
$3.8 billion in FY1998
$3.9 billion in FY1999 and thereafter.

There have been indications that annual SS&M allocations could rise to the promised levels of $4 billion per year after 2002.[3]

1/40.13 Given these budget projections, the total life cycle cost of SS&M can be calculated based on assumptions concerning the actual amount of funding provided, the length of the program, and the discount rate experienced over its life. The following calculations assume two probable life spans for the SS&M program--20 years and 40 years. The calculations also assume the discount rate is approximated by the current 7% rate the federal government pays to borrow money and that likely levels of SS&M funding are bracketed

[1] Statement by Dr. Harold P. Smith, Jr., Assistant to the Secretary of Defense (Atomic Energy) before the Senate Energy and Water Development Appropriations Subcommittee, March 1, 1995.
[2] Poll of 1,011 Americans by ICR Survey Research; results cited in the Congressional Record, January 17, 1995, p. E110-11.
[3] Hearing of the Subcommittee on Military Procurement, Committee on National Security, US House of Representatives, Washington DC, March 12, 1995.

1/40.13 continued

by the current level ($3.7 billion/year) and the promised level ($4 billion/year). With these assumptions, the present values of the life cycle costs of the SS&M program are shown in Table 1.

Program Specifications	Life Cycle Cost
$4 billion/year for 40 years	$53.34 billion
$4 billion/year for 20 years	$42.38 billion
$3.7 billion/year for 40 years	$49.33 billion
$3.7 billion/year for 20 years	$39.18 billion

Table 1
Alternative SS&M Life Cycle Costs

Thus, the likely present value cost of the proposed SS&M program lies somewhere between $40 and $55 billion (in FY1996 dollars). As a means of comparison, $1 billion can purchase:

- more than eighty new schools;
- eight electric power plants, each capable of serving 60,000 people;
- eight fully-equipped hospitals;
- about 120 miles of interstate highway.

As a further standard of comparison, the life cycle costs of the SS&M program could finance the following parts the 1995 US government budget:

1. all natural resources and environment programs for two years.
2. all transportation programs for a year and a half.
3. all education, training, employment, and social services programs for a year.
4. all Department of Justice programs for three years.
5. the operations of the entire US government for four years.[4]

Much of the expense for the SS&M program is directly related to pay for personnel. However, significant expenses are also related to the construction of new facilities. The DOE is planning $2.66 billion in construction or upgrades of SS&M Program facilities over the next decade. An advanced computing program--the Terraflop computer--will cost an additional $2.1 billion over 20 years. DOE's specific cost projections for the envisioned SS&M program facilities are displayed on the following page.

The $40-55 billion life cycle cost range substantially understates the actual costs of a SS&M program. This program will receive a considerable subsidy as site maintenance costs are transferred to DOE's environmental management program. Further, the SS&M proposal accounts for neither the

[4] Economic Report of the President, US Government Printing Office, 1995.

1/40.13 continued

PROJECTED STOCKPILE STEWARDSHIP FACILITIES COSTS

Facility	Location	Purpose	Cost
Advanced Hydrotest Facility	NTS or LANL	6 - 8 simultaneous views of imploding simulated primaries; will use DARHT technologies	$422 million
Atlas Facility	LANL	capacitor bank for simulated weapons environments; for study of secondaries.	$48.4 million
Chemical and Metallurgical Research (CMR) Building	LANL	3 phases of upgrades to LANL's largest building; analytical chemistry of plutonium and highly enriched uranium; first phase is under way.	$224 million
Contained Firing Facility	LLNL	contained hydrodynamic testing; study of nuclear weapon primaries.	$48.5 million
Dual Axis Radiographic Hydrotest Facility (DARHT)	LANL	open-air hydrodynamic testing; for study of nuclear weapons primaries; under construction, currently enjoined by court order.	$148 million
Explosives Components Facility	SNL	contained high explosives testing; under construction.	$27.8 million
Jupiter Facility	SNL	x-ray weapons effects facility; jointly funded by DOE and DNA.	$240 million
National Ignition Facility (NIF)	LLNL	192 beam laser system for fusion ignition and study of secondaries	$1.07 billion**
Phase II Facilities Revitalization	3 labs & NTS	9 subprojects for new or upgraded facilities	$248 million*
Phase III	SNL, NTS	infrastructure	$112 million
Phase V	SNL	infrastructure	$34.6 million
Phase VI	LANL	infrastructure	$34.7 million

*In DOE budget requests, DARHT is one of the nine subprojects in Phase II. In this table, DARHT costs are separated.
**The NIF has a $4.5 billion dollar life-cycle cost. (Does not include WM or D&D.)

Notes:
1. Total cost for proposed facilities construction and revitalization: $2,661,100,000
2. Accelerated Strategic Computing Initiative (ASCI): a massively enhanced computer network; cost extrapolated through 2010: $2,104,300,000
3. Combined costs (facilities + revitalization phases + ASCI) = $4,765,400,000
4. LANL=Los Alamos, LLNL=Lawrence Livermore, and SNL=Sandia National Laboratories; NTS=Nevada Test Site.

3

1/40.13 continued

decommissioning and dismantlement costs arising from its proposed activities nor for the environmental restoration activities the program will necessitate. In addition, as the US increases its technological advantage over other nuclear weapons states in areas ranging from hydrodynamic testing, inertial confinement fusion and pulsed power to computer simulation, it becomes more difficult for other nations to assess US capabilities. This raises the possibility of a "virtual arms race" in simulated test technologies, and it provides incentives for both nuclear weapons states and potential

2/40.07

proliferants to "break out" of a test ban regime. If such a breakout occurs it could restart the costly nuclear arms race that consumed so many US resources over the last forty years. The SS&M program would bear substantial responsibility for the resumption of these costs.

Conclusion:

3/40.33

One method to help combat the proliferation dangers posed by the SS&M program, and to help reduce the financial burden this program places on the citizens of the US could be to implement of a passive curatorship of the stockpile through the replication of weapons components as needed. At the curatorship level, it should be possible to maintain two teams at LANL & LLNL, each with 2 dozen scientists and engineers to monitor about a half-dozen weapon types. Including a support staff, 400 people could perform the task of Stockpile Stewardship (SS) at a cost of less than $100 million per year with redundant teams, contractors and oversight.

These annual SS costs equate to a present value cost of about $1.33 billion for a 40 year program, or $1.1 billion for a 20 year program--a savings of $38-53 billion over the proposed SS&M program. Additional stewardship funding would also be required for Sandia National Laboratory, but even in the unlikely event that this funding doubled the cost of the curatorship program, the results would still be a significant savings compared to the cost of the proposed SS&M program.

4/40.15

These savings gained by implementing a curatorship program would allow DOE to redirect funds to cleaning up the DOE weapon complex. Cleanup funds were cut by $400 million in 1996, and the Environmental Budget is scheduled to be cut by another $4.4 billion over the next 5 years. In fact, the President's Budget Request released on March 19, 1996, cuts DOE's defense and non-defense Environmental Management budget by $205 million while increasing the nuclear weapons budget by $244 million. These cuts are more troubling when one realizes that the DOE projects that the SS&M Program will generate 1,370,000 cubic meters of "low-level" waste and 144,000 cubic meters of "low-level" mixed waste over the next 20 years.[5]

4

THE REGIONAL ECONOMIC IMPLICATIONS OF THE CONSTRUCTION OF THE NATIONAL IGNITION FACILITY (NIF)

William J. Weida
Professor of Economics
The Colorado College
Economists Allied for Arms Reduction

March 7, 1994

Summary Of Findings

1/21.09

The regional economic impacts from building the NIF cited in the Conceptual Design Report are inflated and misleading.

Regional economic effects of the construction and pre-operation of the NIF will be relatively small over most of the 7 year construction period. A large influx of construction employees during years three, four and five of the construction period and a correspondingly large decrease in construction employees during years six and seven has the potential to create a boom and bust scenario in the Livermore region: The Livermore region would have about 1200 people move in and out during the last four years of the construction of NIF.

The NIF is would be constructed in a time in which DOE budgets are falling and there is no new money for projects of any size. Thus, a real cost of building the NIF is the tradeoff its construction will cause with other projects such as cleanup and continued use of the NOVA laser. Virtually any other use of the NIF construction funds would create more jobs in the Livermore region than the NIF will, and since it costs so much to create one job at the NIF, allocating one-fourth of the money budgeted for the NIF to other construction work or one seventh to electrical equipment manufacturing in the Bay area would create the same number of jobs created by building the NIF.

Construction of the NIF also entails a cost to the nation as a whole. For example; a $2 billion program is roughly equivalent to new schools in more than twenty cities; two electric power plants, each serving a town of 60,000 people; or five fully equipped hospitals. There is no indication that the NIF will provide social benefits comparable to any of these alternative uses.

Lastly, many of the jobs at the NIF will be filled by those who are currently employed at the NOVA laser. These jobs are regarded as a "gain" by LLNL, but they are actually only a transfer of employment from one facility to another. To be correctly regarded as an

1/21.09 continued

employment gain, these jobs would have to have been lost at the NOVA laser, but the NOVA has an ample backlog of business to keep it in operation for some time to come. Further, when the NOVA is shut down due to NIF construction, a loss of jobs to the region will result. It is unclear whether the NIF will replace all these jobs, and thus, it is also unclear if the NIF will result in a net gain or loss of jobs.

ANALYSIS

Employment Calculations

The regional economic impacts from building the NIF are misleading. Most jobs associated with the project will be located outside the Livermore region and the Bay area. One-fourth of NIF project costs are slated to go to foreign industry.[1]

LLNL claims the following employment impacts from NIF construction:[2]

Location	Budget	Employment	$ to Create 1 Job
LLNL	$218	230	$948,000
Other Labs	$86	90	$960,000
Const Indust	$169	400	$420,000
Mfgr Indust	$600	800	$750,000
Total	$1073	1520	

This figure of 1520 jobs, often cited by LLNL, is meaningless. NIF construction will be a 7 year project. Spending is very uneven over the entire period of the construction, and thus, the number of jobs created each year varies widely. As Figure 1 shows, the number of direct jobs varies from 22 to 612 jobs per year, depending on which of the 7 years of construction is chosen. Figure 1 uses LLNL estimates for spending on the NIF (LLNL Budget Estimates) and estimates derived from the author's research (Alternative Budget Forecast). The differences between these two forecasts are explained in the sections that follow.

In addition, the 1520 jobs cited by LLNL are located all over the United States, not in the Livermore region. In fact, the map on page 18 of

[1] "LLNL ICF Program and Stockpile Stewardship with NIF", UCRL-MI-118179, L-18362-1, Lawrence Livermore National Laboratory, August 30, 1994, Executive Summary.
[2] Ibid., p. 22.

the Conceptual Design Report (CDR) Executive Summary shows that NIF contracts will go to 43 of the 50 states.[3]

1/21.09
continued

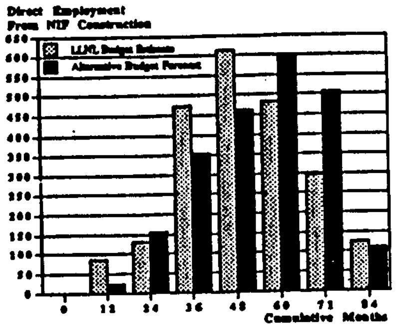

Figure 1
Direct Employment From NIF Construction
LLNL Budget Estimate and Alternative Budget Forecast

Annual Employment and Spending Impacts From NIF Construction

According to the LLNL Conceptual Design Report, spending associated with NIF construction occurs over seven years in the following manner:

	FY96	FY97	FY98	FY99	FY00	FY01	FY02
Budget Outlay($ Millions)	33	50	181	234	184	113	48

The total direct employment calculations on page 22 of the CDR Executive Summary ignore the differences in annual expenditures and hence, are incorrect. However, a basic expenditure curve can be used to calculate the annual employment associated with construction of the NIF. Figure 2 shows the expected cumulative expenditure curve for laser based projects.

[3]Ibid., p. 18.

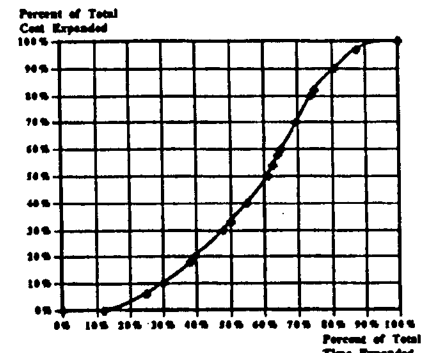

Figure 2
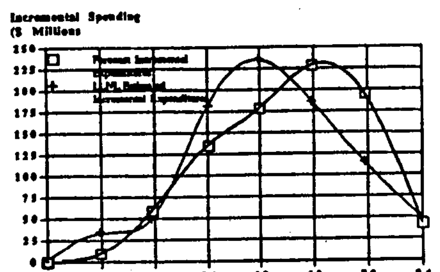
General Cost Curves For
Laser-Based Projects

This curve allows one to derive an independent forecast (called the "Alternative Forecast" in the sections which follow) to check the spending pattern chosen by LLNL. Figure 3 shows, on an incremental spending basis, the comparison between outlays for all past laser projects and those chosen for the NIF.



Source: National Ignition Facility Conceptual Design Report, NIF-LLNL-94-113, L-16873-1, Executive Summary, August, 1994, p.22.

Figure 3
Forecast And LLNL Estimated Incremental Spending For The NIF
Over Time During Facility Construction

2/21.08

While Figure 3 indicates a general agreement between the expenditure patterns called for by LLNL and those that have occurred in the past, the unevenness of LLNL's early expenditure estimates, coupled with the rapid growth of spending a year ahead of when it would be expected to occur based on past projects, leads one to conclude that the NIF may overspend early in the project cycle and may experience significant delays due to the attempt to "push" the project in the first four years.

Based on the incremental expenditures shown in Figure 3, one can derive the annual employment during construction of the NIF. Using these expenditures, annual construction employment for the NIF Facility under both the LLNL and the Alternative Forecast scenarios would be:

LLNL Estimate, NIF Facility Const., (MM of FY94$)							
Fiscal Year	FY96	FY97	FY98	FY99	FY00	FY01	FY02
Total Budget	33.4	49.5	181	234	184	113	47.5
Budget Obligation, NIF Facility Construction ($mm) In 1989 Dollars:	26.6	39.5	144	186	147	90.3	37.9
Regional Spending Impact (allocated at 40% of Annual Expenditures)	10.6	15.8	57.6	74.5	58.8	36.1	15.1
Annual Jobs (i.e., Total Regional Jobs) from New and Repair Construction (factor = 23.8 jobs per $1 million)	253	376	1371	1774	1399	860	360
Annual Direct Jobs from Construction (Total jobs divided by 2.9)	87.4	130	473	612	482	296	124
Alt. Forecast, NIF Facility Const., (MM of FY94$)							
Fiscal Year	FY96	FY97	FY98	FY99	FY00	FY01	FY02
Total Budget	8.43	59	135	177	228	194	42.2
Budget Obligation, NIF Facility Construction ($mm) In 1989 Dollars:	6.72	47	108	141	181	155	33.6
Regional Spending Impact (allocated at 40% of Annual Expenditures)	2.69	18.8	43	56.4	72.6	61.8	13.4
Annual Jobs (i.e., Total Regional Jobs) from New and Repair Construction (factor = 23.8 jobs per $1 million)	64	448	1024	1343	1727	1471	320
Annual Direct Jobs from Construction (Total jobs divided by 2.9)	22.1	154	353	463	595	507	110

Table 1
Annual Construction Employment
Both NIF Construction Scenarios

Additionally, a number of construction jobs will be taken by site staff. Out of a total construction/assembly/installation budget of $142,493,000, $17,735,000 or 12.4% of all work will be done by site staff. All annual employment effects will be substantially lower if it takes longer to build the facility, and it is likely that the CDR has underestimated the time required to build the initial parts of the project.

If the object is to create jobs, NIF is an extremely expensive way to go about it. For example, for the Bay area, the Department of Commerce's Rims II model predicts:

	Const	Elec Equip
Total Jobs per million$	23.6	22.4
Multiplier	2.93	2.57
Direct Jobs per million$	8.12	8.71
$ To Create 1 Job	$123,000	$115,000

These figures are about one-fourth of the amounts required to create a construction job on the NIF and one-seventh the amounts required to create electrical industry jobs for NIF products.

In sum, the regional economic effects of the construction and pre-operation of the NIF will be relatively small over most of the 7 year construction period. However, a large influx of employees during years four, five and six of the construction period and a correspondingly large decrease in employment during year seven both indicate that it is likely that the Livermore region will suffer a moderate boom-and-bust scenario.

Regional Impacts of Indirect Employment from the NIF

1/21.09 continued

The total number of jobs (both direct and indirect) created in the LLNL region is also exaggerated by the 1500 direct jobs figure used in recent LLNL briefings.[4] The total number of jobs created during the seven year construction phase are likely to be about:

	FY96	FY97	FY98	FY99	FY00	FY01	FY02
Total Jobs Created	64	448	1024	1343	1727	1471	320

Thus, each direct job discussed in the previous sections result in about 1.9 additional (indirect) jobs in whatever region the NIF is constructed. For this reason, the inflation of direct jobs that occurs in the CDR also results in an overstatement of indirect jobs by 190%. Further, since technology is completely portable there is little reason for any company to locate in the region where the NIF is located. The Stevenson-Wydler Technological Innovations Act of 1980 mandates the transfer of

[4]Ibid., p. 22.

technology from government to private hands, but it does not permit constraints on the location in the United States where that technology is used. In sum, the employment possibilities from the NIF appear to be significantly overstated.

Nuclear Weapons Safety: No Design Changes Are Warranted

A Review for Tri-Valley CAREs

by

Greg Mello

July 1, 1995

I am pleased to report the stockpile today is safe, secure, reliable, and meets current military requirements. We make that statement with confidence today and for the immediate future....Our stockpile is becoming safer and more reliable simply because we are retiring older weapons...Thus, we should enter the 21st century with a modern, safe, and reliable stockpile consistent with the demands of START I and with anticipated military requirements.

–Dr. Harold Smith, Assistant to the Secretary of Defense for Atomic Energy, to Congress on March 15, 1994

In addition to reducing the sheer size of the active nuclear inventory, a number of additional actions have been or are being taken to improve nuclear safety, security, and use control...I can confidently report today that the stockpile is safe, secure, and reliable. It also meets the requirements of DoD and the Services.

–Dr. Smith to Congress on March 1, 1995

Nuclear Weapons Safety: No Design Changes Are Warranted

An Issue Brief for Tri-Valley CAREs by Greg Mello, July 1, 1995

Summary

1/40.12
- The quest to make nuclear weapons "safe," in the fullest sense of the term, can never succeed and guarantees large appropriations without clear results.

2/40.70
- Weapons in the current U.S. arsenal are, technically speaking, safe and becoming more so as older weapon types are retired. Here, "safe" means that all the weapons in the START II stockpile are fully protected against accidental nuclear explosion.

3/40.77
- It is impossible to reduce the risk from nuclear weapons accidents to zero, however, and in particular there will always remain some risk that plutonium will be dispersed by fire or explosion. The simplest and best ways to further minimize this possibility are
  - o operational and deployment changes that reduce the chances of an accident and the risk to the public should there be one, and
  - o further retirements, leading to a smaller arsenal.

- The safety concerns raised at the beginning of this decade by the Drell panel have been mostly resolved by retirements and by changes in handling procedures. Dr. Drell now believes that changes in the design of the nuclear components of weapons to achieve greater safety are not warranted, given the reliability, arms control, and nonproliferation costs of such changes.

4/40.36
- While it would in theory be possible to replace some warheads in the arsenal to make them safer still, neither the Air Force nor the Navy, nor the Department of Defense (DOD), nor the Department of Energy (DOE) believes this action is merited. Therefore no warhead replacements for safety are currently planned.

- No safety problems are expected to occur in the aging process.

- The proliferation risks of upgrading the U.S. arsenal for any purpose, safety included, are potentially great.

5/40.07
- If the countervailing risks resulting from weapons testing, production, waste management, and eventual decommissioning and cleanup are included, it is highly likely that efforts to produce "safer" weapons will degrade overall nuclear safety.

- Attempts to upgrade safety will decrease reliability, because new designs cannot be tested.

1

4/40.36 continued

- None of the proposed new science-based stockpile stewardship (SBSS) facilities is needed to maintain the safety of existing nuclear weapons. Most proposed facilities, like the National Ignition Facility at Livermore, the Atlas facility at Los Alamos, and the Jupiter facility at Sandia, have no safety-related missions at all.

- The safety benefits per dollar spent on weapons safety upgrades are several orders of magnitude smaller than other federal safety investments, civilian or military.

6/11.31

- Morbidity and mortality in the cleanup crews at nuclear weapons accidents have not been studied, and long-term effects at these sites are unknown. With these possible exceptions, no one is known to have ever been injured from a nuclear weapon in an accident.

3/40.77 continued

- The risk of death from a nuclear weapons accident appears to be, very roughly, about a million times smaller than other causes of accidental death and about 100-1000 times smaller than the public health risks from exposure to environmental pollution at current health standards.

7/40.26

- The real purpose of the disproportionate and irrational drive to maximize safety in just one part of a complex and countervailing system of risks is to make nuclear weapons jobs and funding, and not the public, safe.

- For all these reasons, weapons safety concerns need not and should not drive the stockpile management program.

1. Introduction

"Safe" is hardly the first word anyone would choose to describe nuclear weapons. After all, nuclear weapons have been designed and amassed precisely because they are enormously destructive, i.e. because they are not "safe." From the outset, it is obvious that the oxymoronic quest to make nuclear weapons "safe" can never succeed. To adopt such a quest as a goal of public policy is a way of assuring that no amount of money, however large, will ever be adequate to complete the job. What might be called "existential safety" for nuclear weapons will never be achieved.

Yet, if the problem of nuclear weapons safety is defined in the narrow sense of preventing accidental detonation of the weapons or dispersal of their nuclear materials, there is a consensus among authorities that current nuclear weapons are safe--if not absolutely so then at or near the practical limit of safety. What might be called "practical safety" for nuclear weapons has already been achieved.

The contradiction between what has already been achieved and what can never be achieved has been harnessed by the Department of Energy (DOE) to produce enormous amounts of rhetoric. Where logic has faltered, the nuclear weapons orthodoxy demands faith, and to this end maintaining and improving the "safety, security, and reliability" of the nuclear arsenal has

become a constant litany that is ritually intoned to ensure support of the DOE's science-based stockpile stewardship (SBSS) program. This slogan is offered with little or no further explanation by the weapons laboratories and their sponsors whenever appropriations are questioned. Of the "safety, security, and reliability" trinity, it is the quest for endlessly "safer" nuclear weapons that has retained the most political cachet, pandering as it does to existential fears whose solution entirely transcends further technical adjustments in weapons design.

2/40.70 continued

The central theme of this paper is that nuclear weapons safety, as a technical problem for weapons designers, has been solved. Additional operational changes offer some further reductions in risk, but risks from nuclear weapon accidents are already orders of magnitude lower than in the recent past. Not only will further efforts to improve weapons safety be expensive and lead to greatly diminished returns in risk reduction, but when the safety issue is placed in its overall context, such "improvements" are shown to decrease overall nuclear safety.

At the same time, replacing selected weapons in the arsenal to "improve" safety will inevitably decrease reliability if the new weapons are not proof-tested. For these reasons, nuclear weapons safety is not an absolute good. The proper goal is an optimum level of nuclear weapons safety, not a maximum.

In some respects, the problem of "How safe is safe" is similar to the problem of "How clean is clean"—completely safe and clean are not the right answers. But there are differences: the nuclear weapons problem is relatively easy to solve politically, technically, and managerially; it has been a central goal since 1944; and it has been accomplished. None of these apply to the cleanup problem.

Often nuclear weapons safety and security are spoken of together, the two concerns being combined in the term "surety," which sometimes includes reliability concerns as well. With the planned addition of permissive-action links (PALs) to submarine-launched ballistic missiles, adequate use-control over the entire U.S. nuclear arsenal will in time be achieved.[1] Security will not be discussed in this paper.

2. The Drell panel

In December 1990, the Report of the Panel on Nuclear Weapons Safety, usually called the Drell Report after its chairman, Dr. Sidney Drell, published its strong recommendations for a greater emphasis on safety in nuclear weapons design and deployment and in the institutional arrangements governing weapons.[2] In brief, the Drell panel found that some weapons in the U.S. stockpile were not as safe from accidental detonation as had been thought (the particular weapons systems involved were kept vague). The panel also observed that most of the weapons in the stockpile were not equipped with state-of-the-art features to prevent plutonium contamination in the event of an explosion or fire.

To remedy these problems, Drell called for operational changes, some of which were quickly implemented, and the incorporation of the most modern safety features into all stockpiled

2/40.70
continued

weapons. To fully implement this latter recommendation for the large and diverse 1990 stockpile would have required dozens of underground nuclear tests and tens of billions of dollars in appropriations for weapons design and manufacturing. It would have required the construction of a new nuclear weapons manufacturing complex and the operation of that complex over an extended period of time, and it would have required the costly modification of some delivery platforms.

Thus, although the scope of the panel's investigation was ostensibly technical, its recommendations called for an enormous amount of new work (and new funding) for DOE's nuclear weapons program and its laboratories, just as the Cold War was winding down. Fortunately, Drell's most expensive and controversial recommendations were mooted by events which led to the retirement of some weapon systems and the stand-down of others.

The first of these events was the START I treaty, signed by the United States and the Soviet Union in July of 1991, followed by the "joint understanding" in June 1992 which led to START II in January of 1993. Major reductions in the deployment of tactical nuclear weapons were announced by the U.S. and Soviet Union in the fall of 1991, together with the removal of nuclear weapons from bombers on alert. In 1992, President Bush announced that there was no need for further U.S. nuclear weapons tests to develop new weapons, and in July of 1993, President Clinton joined the Russian-led moratorium on nuclear testing.

In addition to improving nuclear weapons safety, all these changes collapsed the central mission of the DOE weapons labs, which had been the design of new weapons. The result has been that, even though the nuclear arsenal has become markedly safer, the labs and DOE are all the more vociferously clamoring for "more" safety as a new mission. "Safety" has thus become more and more of an empty slogan as it expands into the vacuum of purpose that characterizes large portions of the laboratories.

3. All authorities agree: U.S. weapons are safe

Are U.S. nuclear weapons, in fact, "safe?" The unequivocal and unanimous conclusion of the nuclear weapons establishment is affirmative. In his testimony on March 15, 1994, Dr. Harold Smith, Assistant to the Secretary of Defense for Atomic Energy, told Congress.

> I am pleased to report the stockpile today is safe, secure, reliable, and meets current military requirements. We make that statement with confidence today and for the immediate future....Our stockpile is becoming safer and more reliable simply because we are retiring older weapons...Thus, we should enter the 21st century with a modern, safe, and reliable stockpile consistent with the demands of START I and with anticipated military requirements.[3]

This statement was made in the presence and with the approval of Dr. Victor Reis, Assistant Secretary of Energy for Defense Programs, who added.

4

2/40.70
continued

> Right now, as Dr. Smith said, that stockpile is safe and reliable.[4]

Dr. Reis and Dr. Smith are, respectively, a member (one of three) and the Executive Secretary and Staff Director of the Nuclear Weapons Council. There is no higher or more integrative authority on this subject. And what they said has been a consistent theme over the past few years. Smith's predecessor, Robert Barker, told the Senate in March of 1992,

> The Air Force and Navy, in cooperation with the Office of the Secretary of Defense and the Energy Department, evaluated the safety of all ballistic missiles that carry nuclear warheads. It was determined that there is not now sufficient evidence to warrant our changing either warheads or propellants.[5]

John Deutch, now Deputy Secretary of Defense, reiterated Barker's general conclusion for the specific case of the W88 warhead on may 3, 1993 when he told the House Panel on the Military Application of Nuclear Energy that incorporation of insensitive high explosive (IHE) into that warhead would not be worth its considerable cost (more than $3 billion).[6]

A few days later, Rear Admiral John T. Mitchell, Director, Strategic Systems Programs Office, U.S. Navy, was even more blunt. On May 11, 1993, he told a Senate committee that, for the W88 warhead, "We believe that there would be no gain in safety in changing to insensitive high explosive."[7] These comments by Deutch and Mitchell signalled that the safety questions that had been raised by the Drell Report regarding the W88 (see below) had been resolved, at least to the satisfaction of the DOD and the Navy.[8]

Deutch, a strong advocate of nuclear weapons design and testing, recently reiterated the government's consensus on the safety of U.S. nuclear weapons. On October 5, 1994, Chairman Hamilton of the House Foreign Affairs Committee suggested to Deutch, following the latter's presentation of the Nuclear Posture Review, that safety concerns might be a reason to resume nuclear testing. Deutch demurred, saying unequivocally, "It is my judgment that all the nuclear weapons that we have are adequately safe."

Dr. Smith unambiguously reiterated the continuing safety theme on March 1, 1995, in testimony before the Senate Appropriations Committee, Energy and Water Development Subcommittee.

> In addition to reducing the sheer size of the active nuclear inventory, a number of additional actions have been or are being taken to improve nuclear safety, security, and use control...I can confidently report today that the stockpile is safe, secure, and reliable. It also meets the requirements of DoD and the Services.

The repeated testimony cited here was offered by the highest responsible sources after careful review of those portions of the Drell Panel's recommendations that remain outstanding. This testimony states with abundant clarity that no safety problem currently exists in the nuclear weapons stockpile. Yet, since the weapons labs still hawk greater "safety" as a mission, many decisionmakers conclude that nuclear weapons safety is an unresolved issue.[9]

5

8/40.21

4. What is the nuclear weapons safety problem?

Those responsible for designing, building, and maintaining U.S. nuclear weapons do so with a keen appreciation of the dangers inherent in these weapons and in the materials they contain. It is their job to make the protection of public safety a paramount concern in every aspect of their work. Their real goal is to effectively protect the public, not simply to build safer weapons at any cost. These two goals are not the same, as can be seen from the following outline, which supplies a common-sense context for analyzing the safety problem and maximizing the safety benefits of federal spending.

The Nuclear Weapons Safety Problem in Context

The Overall Goal: Protect the public[10]

A. from dangers other than those from nuclear weapons

B. from nuclear weapons dangers (DOE: "reduce the nuclear danger"[11]), including

1. nuclear attack
   a. by an existing nuclear-weapons state
   b. by a proliferant nation or group
2. risks to workers from nuclear weapons testing, manufacture, waste management, deployment, decommissioning and decontamination, and cleanup
3. risks to public health from the nuclear weapons operations listed above
   a. risks to current populations
   b. risks to future generations
4. any environmental risks not included in 3, such as loss of tribal lands and sites, environmental damage that is not human health damage *per se*
5. other, indirect, nuclear dangers (e.g. threats to democracy from counterterrorism activities)
6. nuclear weapons accidents
   a. unintentional nuclear detonation
   b. dispersal of plutonium

8/40.21
continued

Based on this outline, there are three relevant hierarchical levels of safety goals. The most fundamental goal is maximizing overall public safety. This means to minimize morbidity and early mortality, from whatever cause. Since it is clear that there is a finite amount of money available to the federal government to do this, it is certain that seeking to maximize safety from one type of danger without regard to cost, e.g. nuclear weapons, would damage overall public safety, not to mention impede other important goals of government. Choices will have to be made, then, and an optimum, not a maximum, level of safety chosen for each particular program, nuclear weapons included.

A subset of public safety is safety from nuclear weapons. Optimizing this—which is called by DOE "reducing the nuclear danger"—means to minimize morbidity and mortality from nuclear weapons operations taken as a whole: the production, storage, processing, and manufacturing of weapons materials, and the design, production, maintenance, deployment, and disassembly of the weapons themselves. It includes the public health aspects of waste management, as well as environmental restoration or the lack of it. It includes safety from any intentional use of nuclear weapons, and from nuclear accidents.

But since only a very limited amount of money is available for this task, it is possible, even certain, that seeking to reduce any one aspect of the nuclear danger without regard to cost—either cost in dollars or in environmental or proliferation risks—could well increase, not decrease, the overall nuclear danger.

Finally, a subset of safety from the dangers of nuclear weapons is safety from nuclear weapons accidents, which is served by the incorporation of safety features into the design of nuclear weapons systems. It is also served by operational changes that decrease the likelihood of accidents or the public health exposures from accidents, should any occur.

Thus the technical or design aspect of weapons safety is an important goal, but it is a subservient one. A sense of proportion is required. An optimum, not a maximum, amount of nuclear weapons safety is the inevitable and proper goal.

At present, however, the DOE weapons labs are promoting the quest for greater nuclear weapons safety as if it were an absolute good—as if it had no conflict with the other goals of the agency or with the other goals of the government as a whole. The damage that this quest could do to those larger goals is discussed briefly below, following a summary of the technical aspects of nuclear weapons safety.

5. Design aspects of nuclear weapons safety

In a nutshell, the nuclear weapons safety problem as it affects the design laboratories consists of minimizing the probability of two general kinds of untoward events:

1) unintentional nuclear detonation of a weapon, either from

8/40.21 continued

a) accidental activation of the firing circuits (e.g. by lightning or other electromagnetic pulse) or from

b) accidental detonation of the high explosive (HE) in the primary from an impact, fire, or other non-electrical cause; and

2) dispersal of plutonium due to an accident of any kind.[12]

The following discussion reviews each of these safety concerns in turn, and concludes with an overview of problems related to aging of weapons.

A. Accidental activation of the firing circuits is a problem that has been solved

Electrical safety in U.S. weapons is addressed by means of a protection policy known as Enhanced Nuclear Detonation Safety (ENDS), which is achieved by a technology called Enhanced Electrical Isolation (EEI). The Drell Panel describes this system in detail.

> The ENDS is designed to prevent premature arming of nuclear weapons subjected to abnormal environments. The basic idea of ENDS is the isolation of electrical elements critical to detonation of the warhead into an exclusion region which is physically defined by structural cases and barriers that isolate the region from all sources of unintended energy. The only access point into the exclusion region for normal arming and firing electrical power is through special devices called strong links that cover small openings in the exclusion barrier...Detailed analyses and tests give confidence over a very broad range of abnormal environments that a single strong link can provide isolation for the warhead to better than one part in a thousand. Therefore, the stated safety requirement of a probability of less than one a million...requires two independent strong links in the arming set, and that is the way the ENDS system is designed...both strong links have to be closed electrically--one by specific operator-coded input and one by environmental input corresponding to an appropriate flight trajectory--for the weapon to arm.
>
> ENDS includes a weak link in addition to two independent strong links in order to maintain assured electrical isolation at extreme levels of certain accident environments, such as very high temperature and crush. Safety weak links are...designed to fail, or become irreversibly inoperable, in less stressing environments than those that might bypass and cause failure of the strong links.
>
> The ENDs system provides a technical solution to the problem of preventing premature arming of nuclear weapons subject to abnormal environments...ENDS was developed at the Sandia National Laboratory in 1972 and introduced into the stockpile starting in 1977.[13] (emphasis added)

While there are some older weapons in the U.S. arsenal that do not contain ENDS, these weapons are currently being retired.[14] With these retirements, the problem of electrical safety of U.S. nuclear weapons has been solved.

8

8/40.21 continued

Note that the one-in-a-million standard applies in the case of accidents, which are themselves infrequent, and not in routine operations. The applicable specification for the probability of an accidental explosion during normal operations, including all environments in the stockpile-to-target sequence, must be less than 10^{9} per warhead lifetime.[15] Since the probability of a highly abnormal enviroment, i.e. an accident, is now much lower than it was during the Cold War with its intensive airborne transport of nuclear weapons, projects to develop firing circuits with still greater isolation possess only very small benefits.

Such work is, in any case, unlikely to affect the nuclear components--the physics package--of the warhead. It is primarily Sandia which designs and maintains the arming and safing systems of warheads, not the two physics labs. Modifications to these electrical systems are relatively routine and need not trigger major stewardship expenses.

B. The possibility of an accidental nuclear explosion due to impact or fire has been the subject of intensive study and is extremely unlikely

The second aspect of preventing an accidental nuclear explosion consists in ensuring that impacts, fires, explosions, and any other causes not covered by the electrical safety system cannot set off any weapon's high explosive in such a way that any significant nuclear yield results. Recognition of this danger led to the adoption of the so-called "one-point-safety" standard in 1968. This quantitative standard requires all weapons in the stockpile to be "one-point safe," which is defined as achieved if the probability of a nuclear explosion with a yield of four pounds TNT-equivalent or greater from detonation of the HE at any single point is less than one in a million in an accident.[16] And this safety performance must be intrinsic to the design, i.e. it must obtain in the absence of any mechanical safing device.[17]

Using more detailed computational analysis than had previously been available, the Drell Panel found that "unintended nuclear detonations present a greater risk than previously estimated (and believed) for some of the warheads in the stockpile."[18] To solve these problems, the Drell Panel recommended a major competitive effort at the weapons laboratories to design new warheads. Yet other than an implicit recommendation to quickly retire the SRAM-A system[19] and make sure the entire stockpile has ENDS, the unclassified Drell Report contains no specific recommendations for improving the nuclear detonation safety of the U.S. arsenal.

However, the report did recommend a broad and in-depth review of the safety of the Trident II (D5) missile system, given the fact that the W88s used there do not contain IHE and are mounted in a ring around the third-stage rocket motor, which contains a detonatable propellant. Kidder concurred with this recommendation and suggested that the Trident I (C4) W76 system be closely examined as well.

The results of the examination, which set these worries to rest, were provided to Congress in the testimony quoted above. Meanwhile, operational changes in the way Trident missiles were loaded into submarines were immediately implemented. Trident missiles are no longer loaded

9

8/40.21
continued

into their launching tubes with their warheads in place, which means, according to Drell, that there is now "no worry" about a dockside warhead explosion.[20]

C. To prevent plutonium dispersal, operational changes are most effective

Plutonium—capable of causing cancer deaths from doses in the microgram range—can be dispersed into the environment in any accident in which the conventional explosive in a nuclear weapon burns or explodes. If the explosive involved is IHE, an explosion is highly unlikely, since IHE is remarkably difficult to detonate. In the case of a fire, the plutonium will burn along with the IHE. Warheads made with HE may also burn in a fire rather than explode, and in fact this happened six times at U.S. Air Force bases between 1958 and 1965 when nuclear warheads were involved in fires.

The only good news here is that, in the absence of an explosion, the mean particle size of the plutonium oxide produced is larger and less likely to be inhaled, and is dispersed over far less area, resulting in many fewer potential casualties.[21] The Air Force in fact claims that these six accidents resulted in only localized contamination, which was cleaned up in some fashion in each case.[22]

All in all, between 1950 and 1980 there were 32 serious nuclear weapons accidents ("Broken Arrows"). None have occurred since 1980. During that 30-year period there were two accidents that involved explosions with plutonium.[23] These were airplane crashes at Palomares, Spain in 1966 and at Thule, Greenland in 1968. Luckily, these occurred in relatively unpopulated areas, and no major public exposures resulted. It seems likely, however, that significant danger was experienced by the cleanup crews, which were probably not well trained or equipped, both in these cases as well as in the six accidents in which weapons burned.

Can the possibility of nuclear weapons accidents in which plutonium is dispersed be eliminated? The answer, of course, is no. Even with IHE, with fire-resistant pits (FRPs, which have a refractory shell[24] surrounding the plutonium), and with speculative "super-safe" designs in which the fissile material is somehow kept separate from the HE or IHE until the arming sequence—there will always be a finite chance of plutonium dispersal in the event of a fire or other accident. And this finite chance will continue to be much greater than the one-in-a-million standard adopted for electrical isolation and for one-point safety.

Still, the dangers from plutonium dispersal, while quite serious, are far less than those from a nuclear detonation. Claims by lab officials that a plutonium dispersal accident could be "worse than Chernobyl" are at least two orders of magnitude off base.[25]

In order to prevent plutonium dispersal, the Drell committee recommended that "all nuclear bombs loaded onto aircraft—both bombs and cruise missiles—[be built] with both IHE and FRPs." On its face, this had some appeal, since some 84 percent of serious nuclear weapons accidents have involved aircraft.

10

8/40.21
continued

Unfortunately, equipping all airborne U.S. weapons with IHE and FRPs would require redesigning and rebuilding thousands of nuclear weapons, entailing dozens of nuclear tests and the construction of new nuclear weapons factories, such as a replacement for Rocky Flats. Kidder's more practical recommendation was, instead, to implement cost-saving operational changes that would reduce the risk of accidents which could result in plutonium dispersal to near zero. These changes basically consist of not putting nuclear weapons on aircraft in peacetime, eliminating the possibility of any aircraft accident leading to plutonium dispersal. Carson Mark, Director of the Theoretical Division at Los Alamos for 26 years, had argued a month before Drell that operational limitations on warheads (e.g. no routine deployment for airborne weapons) would be far more cost-effective than redesigning them to, for example, incorporate IHE.[26]

Removing nuclear weapons from aircraft has now largely been effected. In September of 1991, not long after Kidder's study, President Bush decided to take all U.S. strategic bombers off alert, meaning that all U.S. airborne strategic nuclear weapons have now joined U.S. tactical nuclear weapons in secure storage bunkers, out of harm's way. President Bush's initiative essentially solved the safety issues for airborne nuclear weapons.[27]

Since, according to Drell, the consequences of a plutonium explosion are roughly one hundred times worse than a plutonium fire, the addition of IHE to a weapon removes about 99 percent of the plutonium dispersal danger. FRPs could remove part of the remaining 1 percent of the danger. FRPs add no degree of safety if the explosive in the warhead detonates, so there is little point in adding FRPs to a weapon that does not also have IHE. FRPs cannot reliably withstand a rocket propellant fire, which could be much hotter than a jet fuel fire (about 2000 degrees centigrade versus 1000 degrees), so there is little point in adding FRPs to ballistic missile warheads.

So are FRPs worth the expense? Even before President Bush took nuclear weapons off airplanes, Assistant Secretary of Energy for Defense Programs Richard Claytor told Congress that "for weapons such as the B-61 family and the W-80, which already have IHE, this [addition of FRPs] will be a very costly upgrade to accomplish a modest improvement in safety." He added that "for tactical systems, where weapons are normally stored in bunkers, the reduction in risk may be very small."[28]

The Air Force's official response to the Drell Panel also panned the marginal benefits of FRPs.

> Qualitative assessment indicates that [the] safety risk associated with incorporating FRP into bombs and cruise missile warheads which already have ENDS and IHE would exceed the safety gain realized by FRP, [and so such weapons] should not be modified to incorporate FRP.[29]

The Drell Panel called for an aggressive study of "super-safe" designs, such as designs in which the plutonium was physically separate from the IHE or HE. In response, Kidder pointed out that such designs had been under study for at least 15 years (by 1991) without practical result. Furthermore, any designs finally created would very likely be quite complex, which means that

11

8/40.21 continued

they might have serious reliability problems. In any case they would require numerous nuclear tests. This recommendation, like the one calling for all airborne warheads to have IHE and FRPs, was evidently not considered practical by the Nuclear Weapons Council, leading to the testimony cited previously.

Note that IHE was intentionally not incorporated into the W88 Trident D5 warhead, because IHE is less energetic and reduces the yield of the weapon, the range of the missile, and/or the number of warheads it can carry. A conscious decision was therefore made to not make these particular weapons as safe as possible, because they were, and still are, judged to be safe enough. In addition to the W88, IHE is also not present in the W62 and W78 Minuteman III warheads and the W76 Trident C4 warhead. The W62 and W78 warheads are being retired, which will leave the Navy's W76s and W88s as the only warheads in the START II arsenal lacking IHE.[30]

Interestingly, an FRP-equipped cruise missile warhead (the W84, one of only three such FRP-equipped weapons in the stockpile) has been taken out of the active stockpile, in favor of cruise missile warheads that lack FRPs (specifically, the W80-0 and W80-1).[31] Thus the Air Force, the Navy, and the Nuclear Weapons Council have, on at least three occasions if not also on others, concurred in decisions that chose warheads for the so-called "enduring" stockpile that lack some of the possible safety features that could have been incorporated. The decisions to forego FRP- and IHE-equipped weapons contrast sharply with the rhetoric coming from the labs calling for so-called "safer" weapons.

Finally, note that incorporation of an FRP and, especially, IHE into a weapon would require a substantial redesign and would, in effect, amount to a new weapon. Kidder suggests that roughly three nuclear tests per warhead or bomb would be necessary to proof-test the former and that six such tests would be required for the latter.[32] Thus these are not minor changes, and they would require perhaps two dozen nuclear tests to accomplish for the entire START II stockpile. It is certainly not accurate to call such changes "safety improvements to existing weapons," as is now commonly done.

Table 1 (attached) shows the planned U.S. stockpile and its safety features.

D. Dr. Drell believes that physics package safety improvements should not be undertaken

Since his 1990 work, Dr. Drell has clarified his position on the advisability of modifying nuclear weapons physics packages to increase safety.[33] Writing with Bob Peurifoy, Drell acknowledges that some weapons in the so-called "enduring" arsenal do not have every safety feature to prevent plutonium dispersal and that some questions involving multi-point safety remain for the Trident systems. But these deficiencies should not, in their view, lead to modification of the stockpile physics packages.

12

8/40.21 continued

Drell and Peurifoy point out that if multipoint safety was judged to be inadequate for the Tridents, and monies were actually to be budgeted to improve them, this could be done by means other than modifying the warhead: installation of blast shielding around the third-stage motor and decreasing the number of warheads to compensate for the weight, changing the third-stage propellant, costing about 4% in range, or omitting the third stage motor altogether and decreasing the number of warheads from eight to four to give the same range as at present.[34]

Should some "devices"--the term used by Drell and Peurifoy for the nuclear explosives themselves--be changed to make plutonium dispersal less likely? They say not.

> Most importantly, in the case of a test ban, one should not tamper with the device hardware once it has been certified...in the absence of follow-on stockpile testing, hardware modifications must be avoided...New, untested devices should not be considered.
>
> ...
>
> From a technical point of view, safety improvements could be achieved in a continued underground testing program focused on safety. From a political perspective, however, continued testing of nuclear weapons may hinder efforts to counter, if not prevent, the proliferation of nuclear weapons in the years ahead.
>
> ...
>
> In our view, the early achievement of a strengthened and durable worldwide nonproliferation regime will contribute more significantly to worldwide nuclear safety than will further improvements in the safety of part of the US nuclear force.[35]

Drell and Peurifoy then call for the U.S. to "take the initiative" and "lead a joint effort by the five declared nuclear powers to negotiate an end to all nuclear weapons testing" (emphasis added). They also call for "a diverse and coordinated scientific program at the national weapons laboratories so that they can maintain and certify confidence in the US nuclear deterrent over a long period without testing."[36] Maintaining safety is not mentioned as a challenge for that program, for reasons that will now be examined.

E. There are no safety problems related to aging of weapons

9/40.22

Although authorities agree that nuclear weapons are "safe" now, often vague reference is made to possible safety problems that could arise in the future. What these problems might be is never mentioned, however. After all this intensive review by the Drell Panel and subsequently by the labs--who were, it is fair to say, searching for every possible reason to continue nuclear testing and nuclear weapons design work in general--it is difficult to imagine that some heretofore overlooked safety problem of real significance would suddenly appear.

Likewise, no safety problems are expected to occur in the aging process. This was the first question posed to Dr. Kidder by the senators, and he makes it clear that aging does not create safety problems.

13

9/40.22
continued

Safety problems with nuclear warheads are generally inherent in the design of the warhead itself, not the result of aging or other causes. Such problems may not be identified until long after the warhead enters stockpile, but they were there to begin with.

Metals corrode, and organic materials such as plastics, adhesives, and HE that are present in a nuclear warhead will deteriorate with age. Such aging effects degrade a warhead's reliability rather than its safety. (The sensitivity to impact or fire of the HE used in nuclear warheads does not increase significantly with age.)

A severe case of aging was the deterioration of the HE in the W68 Poseidon warhead, which produced a harmful, chemically reactive effluent. This resulted in a potential loss of warhead reliability that necessitated a complete rebuild of all W68 warheads in stockpile. The reliability, but not the safety, of the warhead was affected.[37] (emphasis added)

Dr. John Immele, Director of Los Alamos National Laboratory's (LANL's) Nuclear Weapons Technologies Program, spoke to this same point on December 8, 1994 at a public hearing in New Mexico.

> Audience: I have one more question...in a deleterious way, they may age or crack. What do you mean, is there a risk to the public?
>
> Immele: No, there's not a safety risk. There's a performance problem...because insensitive high explosive is so insensitive that sometimes if it's cracked it won't light on the other side when it's supposed to, so it's basically a performance problem...We have not found aging problems that affect safety, that make the explosive more sensitive.[38] (emphasis added)

This testimony is very important, since the long-term behavior of IHE is not understood as well as that of HE, and it is sometimes mistakenly implied that this uncertainty extends to questions of safety, which it clearly does not.

The impression should not be left that once weapons are put into the stockpile they are forgotten. The stockpile surveillance program coordinated by the laboratories, especially by Sandia, routinely inspects weapons and their components and ensures, among other goals, that safety problems do not develop. Thus safety throughout the aging process is ensured by both the current weapons' inherent safety features and a coordinated surveillance program.

F. DOE's proposed new facilities have nothing to do with weapons safety

As part of its proposed SBSS program, DOE is planning to build a number of new experimental weapons science facilities with a total cost running into the billions of dollars.[39] The largest of these is the National Ignition Facility (NIF), a laser fusion machine with a currently-estimated capital cost of about $1.2 billion and a lifetime cost of about $4.5 billion.[40] The role of NIF

9/40.22
continued

in the SBSS program is to simulate the implosion process that occurs in the thermonuclear "secondaries" of nuclear weapons.

Throughout the 40-year history of the thermonuclear arsenal, no safety problems have ever been identified with secondaries, which contain neither plutonium nor high explosives. Nor are any expected. It is therefore patently obvious that NIF has nothing to do with nuclear weapons safety. Dr. Steven Younger, who was at the time Deputy Program Director of the LANL Nuclear Weapons Program, was among others who made statements to this effect at a DOE-sponsored workshop on NIF on September 8, 1994 in Washington.[41]

For the same reason, other facilities for simulating secondary implosion, like ATLAS (LANL's proposed new pulsed-power implosion facility) have nothing to do with nuclear weapons safety either. The only facilities with potential relevance for nuclear weapons safety are those being built or planned for the simulation of nuclear weapons primaries. These are the hydrodynamic testing facilities: the $124 million Dual-Axis Radiographic Hydrotest facility (DARHT), under construction at LANL but halted for environmental review, and the $422 million Advanced Hydrotest Facility (AHF), planned for the early years of the next century.

Hydrotest facilities cannot test either the high explosives or the plutonium pits of stockpiled weapons. The former cannot be separated intact from the pit they embrace, and the latter cannot be tested without a nuclear explosion. Therefore, these facilities test mock weapons assemblies. There is very little point in conducting hydrodynamic explorations of the safety of existing weapons. These weapons are already known to be one-point safe and their plutonium-dispersal properties are already clear--either they have IHE and FRPs or they do not.

The only purpose of these facilities, as far as safety is concerned, is that they can be used to design new primaries that have IHE and FRPs, either primaries for new weapons with new military characteristics or to retrofit into existing warheads and bombs. This can be done either directly, by testing mockups of these new primaries, or indirectly, by conducting precise hydrodynamic tests on existing designs for which nuclear testing data is available ("benchmarking"). Benchmarking allows the nuclear testing database to better inform the nuclear weapons codes, which can then be used to design new weapons.

Actually, DARHT may be inadequate either to design new weapons with IHE and FRPs or to benchmark some stockpiled systems, with or without these features.

> Recognizing the importance of continued research in radiography, the Laboratory [LANL] cites DARHT as its top construction priority...For a number of stockpile systems, particularly those that are designed with insensitive high explosives and fire-resistant pits, planned radiography upgrades [i.e. DARHT] do not provide resolution adequate to observe the gas cavity configuration of the primary stage late in the implosion process. For effective monitoring of stockpile weapons [sic] of this type, a next-generation hydrodynamic testing capability will need to be developed. Such an Advanced Hydrotest Facility (AHF) will include multiple

9/40.22 continued

beams that produce X-rays from four to six directions at various times to characterize the physical state of the pit more thoroughly.[42]

It is difficult to avoid the inference that DARHT is useful primarily to design new weapons which lack IHE and FRPs. This is not at all unlikely from a policy point of view, given that these features have already been intentionally omitted from significant portions of the arsenal.

Any use of these new hydrotesting facilities to examine safety problems relating to aging of weapons is moot, since logic, together with Drs. Kidder and Immele, all agree that there are no such issues.

6. Reducing the nuclear danger

The risk to the public from a nuclear weapons accident is only one among many interrelated risks associated with nuclear weapons. Attempts to increase safety from nuclear weapons accidents through redesigning warheads may easily create countervailing risks throughout this interconnected system. For example, the replacement of hundreds or thousands of warheads, and especially the plutonium pits of warheads, will create risks to workers and the general public during the manufacturing process and in the management of its wastes, not to mention during the eventual decontamination of buildings and equipment that will later be required. Any environmental contamination that occurs will require cleanup. These considerable risks tend to be minimized or forgotten entirely by the advocates of weapons redesign.

In fact, these manufacturing, waste management, decommissioning, and cleanup risks are likely to be much greater than the risk reduction that could be achieved by the addition of, for example, IHE to W88s and W76s, to pick one modification currently under consideration. The historical record suggests this. While there have been no known or putative deaths due to accidents from explosions or plutonium dispersal from completed weapons--even during the Cold War when thousands of weapons were shuttled all over the world--numerous deaths have occurred due to ordinary occupational causes in the nuclear weapons complex as well as to chemical toxins and radioactivity.[43] Meanwhile cleanup, which could be quite hazardous, has barely begun.[44]

Moreover, should the U.S. elect to upgrade its nuclear arsenal for the sake of "improved" safety or for any other reason, it can be expected that the other nuclear powers, particularly Russia and China but probably also Britain and France, may do likewise. In that case, the morbidity, mortality, and environmental damage in other countries, again notably Russia and China, can be expected to be equal or greater than here.

Thus, the quest for greater nuclear weapons "safety," if allowed to proceed within the compartmentalized thinking that characterizes the bureaucratic "stovepipes" of the federal nuclear establishment, will likely saddle current populations and future generations, here and abroad, with increased, not decreased, risk. And, as has been the case up to now, this risk will tend to

9/40.22 continued

fall most heavily on the vulnerable members of society and the populations that are weakest politically.

A. The proliferation impacts of safety "improvements" must be examined

Another component of the overall nuclear danger is nuclear proliferation. A public opinion poll conducted by Sandia National Laboratory for DOE suggests that the public considers the risk from nuclear proliferation to be the number two danger facing us today, right behind world hunger and ahead of AIDS, drug trafficking, and global warming.[45] Thirty-two percent of the public thought nuclear proliferation was an "extreme risk." This opinion is matched by a widespread concern among experts that the proliferation problem, far from being under control, is a very serious threat to the security of the United States. Assuming this is true, we can conclude that if safety improvements in nuclear weapons design incur even a small incremental risk to the world's nonproliferation regime, such "improvements" are likely to increase, not decrease, the nuclear danger. On its face, nuclear proliferation is simply a much more serious problem than nuclear weapons safety.

It is beyond the scope of this paper to discuss in any detail the proliferation dangers inherent in upgrading the U.S. arsenal to achieve "increased" safety. Suffice it to say that even a heuristic analysis of comparative risk must embrace the reality that such safety upgrades attempt to prevent events whose probabilities are already very low. The probability of proliferation under current policies, however, is not low at all, and the probability of nuclear attack or threat of attack by proliferant nations or groups approaches certainty in the long run if more effective leadership on this issue is not forthcoming.

Any analysis of the nonproliferation impacts of contemplated weapons upgrades must therefore consider every possible impact, even those which are slight. Just as every credible nuclear weapons accident should be examined and prevented, so should every credible potential proliferation impact also be prevented. The probability of an accidental nuclear detonation is kept at 10^{-6} per warhead lifetime, or roughly 10^{-3} for the current arsenal taken as whole over the next few decades; any decision to upgrade U.S. weapons should likewise be examined to see whether, through their impact on the nonproliferation regime, such upgrades could cause an increase in the probability of an intentional attack on the U.S. as small as 10^{-3} over the next few decades. Clearly, the expected mortality from an intentional attack is much larger than that for any credible accident, further emphasizing the relative importance of proliferation risks and the efforts needed to combat it.

This spring, the Nuclear Nonproliferation Treaty (NPT) was extended indefinitely. Despite some media claims to the contrary, this was not done by consensus but by an uncontested acknowledgement that a majority of states favored extension.[46] This extension was won only after what the Washington Post called a "global full-court press" by the U.S.;[47] as late as January of this year, roughly one hundred countries did not support indefinite extension.[48] The reason for the vocal and sometimes bitter debate that went on in New York was, above all else, deep international discontent with the failure of the nuclear weapon states to dismantle their

9/40.22 continued

nuclear arsenals pursuant to Article VI of the NPT. Because of this failure, substantive further strengthening of the world's nonproliferation regime now appears to be temporarily out of reach.

When even maintenance of arsenals can threaten to unravel the fragile fabric of the world's nonproliferation efforts, as it did this spring, how can upgrading that arsenal, whether for so-called "safety" improvements or any other purpose, not damage U.S. nonproliferation efforts? The conclusion of Drell and Peurifoy is sound: safety improvements to the nuclear components of weapons, which cannot be undertaken without underground testing, run counter to U.S. nonproliferation objectives.

Other nations may be concerned that "safety upgrades" can mask the development of entirely new weapons. There is considerable justification for that concern, as is discussed in detail by William Arkin, Greenpeace, and Tri-Valley CAREs.[49] Foreign "safety upgrades" may also be used to mask new weapon development, an outcome with negative security implications for the United States.

B. Fewer deployments and further retirements are virtually the only way greater overall nuclear weapons safety can be achieved

Given that upgrading and replacing nuclear weapons is likely to create serious countervailing risks--risks which, on their face, are considerably greater than those gained from any purported safety "improvements"--the search for greater nuclear safety must be directed elsewhere. Clearly, all other factors being equal, the probability of a serious weapons accident is proportional to the overall size of the arsenal. A minimum deterrent force--however one may define "minimum"--is also, therefore, an optimum safety arsenal. It is a minimum cost arsenal as well. A smaller arsenal would assist U.S. nonproliferation objectives, and would cause fewer dangers to the environment, to worker safety, and to public health. A smaller arsenal, to the extent that it corresponds to smaller arsenals abroad and especially in Russia, reduces the number of missiles which could be targeted at the United States.

Indeed, given comparable reductions in other nations' stockpiles, it can be persuasively argued that the optimum safety arsenal is one that is extremely, if not vanishingly, small. Many military and senior civilian defense leaders, past and present, have come to adopt this view.[50]

In addition to reducing the size of the arsenal, the movement of additional weapon systems away from active deployment and into safe bunkers would also reduce risk from accidents, as would the movement of nuclear weapons away from bases located in populous areas. Further restrictions on the airborne transport of nuclear weapons should also be considered.

C. Increasing safety will decrease reliability--and hence could generate calls for nuclear testing

As we have seen, the quest for "increased" safety has a very marked cost in terms of weapons reliability. That is, if weapons are changed to make them "safer," they will be less reliable--

18

9/40.22 continued

unless we are able to proof-test the new designs. Resuming nuclear testing, however, would conflict strongly with nonproliferation goals and our treaty commitments. Thus the quest for "safer" weapons, if accepted at face value, could keep the weapons labs in a booming business for a long time by eroding the reliability of the weapons.[51]

7. Public safety, not nuclear safety, is the goal

So far we have examined nuclear weapons safety issues from a narrow technical perspective and in the broader context of reducing the nuclear danger as a whole. From the still broader vantage point of public health and safety as a whole, further investments in safer designs for nuclear weapons have vanishingly small returns.

1/40.12 continued

A. Further investments in nuclear weapons safety have a very low benefit/cost ratio compared to other public safety investments

Would upgrading to IHE and FRPs be worth the expense? Analysis--not to mention common sense--shows that investments in other government programs (e.g. highway improvements, cancer screening) yield orders of magnitude greater safety benefits to the general public.

Steve Fetter and Frank von Hippel estimate that a worst-case accident involving explosion of the HE in ten W88 warheads at the Bangor Trident base directly upwind from Seattle would involve on the order of 1,000 plutonium-induced cancer fatalities in the long run.[52] They suggest, for the sake of argument, that the risk of this accident can be assumed to be on the order of 0.1% per year, in which case the expected fatality rate from this type of nuclear weapon accident is 1 death per year. The prevention of this accident by the spending of about $1 billion (Drell and Peurifoy's more recent article cites a cost of $1.6 to 1.8 billion) to equip some 3000 submarine missile warheads with IHE would represent a cost on the order of $100 million per fatality avoided.[53] This accident has, subsequent to their paper, been made very unlikely by loading the missiles and the warheads separately, lowering the expected fatality rate by probably at least one, if not two or more, orders of magnitude and correspondingly raising the cost per fatality avoided.

Fetter and von Hippel cite cost estimates in the range of $20,000 to $140,000 per life saved by cancer screening, $400,000 per life saved by kidney dialysis, and $30,000 to $300,000 per life saved for various highway safety improvements. Thus the IHE warhead upgrade program, even by their highly conservative calculations, would cost on the order of 250 to 3,000 times more than these other prevention programs per life saved--or, given the operational changes already put in place by the Navy, at least 10 to 100 times as much as this. This great disparity of benefit--at least 3 if not more than 5 orders of magnitude--signals that the overall sense of their conclusion is robust with respect to large changes in their assumed accident rate.

What is more, the government and private programs cited by Fetter and von Hippel are almost certainly not the most effective ones offered by government or private sources, either in terms of average cost or marginal cost per life saved. Programs targeted at populations at risk like

19

1/40.12 continued

the Women, Infants, and Children (WIC) program, for example, are arguably at least one order of magnitude more effective per dollar spent than highway improvements in preventing deaths. And, on average, WIC and other perinatal programs address a younger population--one young adult and one infant--than do the programs Fetter and von Hippel cite, giving more years of life saved per person in these cases.

It would be interesting to compare Fetter and von Hippel's numbers to the benefits of investments in strictly military health and safety. The military environment is a dangerous place, and large numbers of military accidents occur annually, sometimes with accompanying civilian deaths. It is highly likely that it would be more cost-effective to use a billion defense dollars to prevent unnecessary military mortality--through, for example, more complete training--than it would be to use this sum to upgrade Trident missiles and their warheads, for which purpose a billion dollars would probably not be adequate in any case.

This, of course, is a peacetime comparison. Since, realistically, nuclear weapons are useless in actual fighting, any investment in them deprives the soldier, sailor, or airman of just that much supporting materiel or training when he or she needs it most.

<u>B. The quest for nuclear weapons safety is inconsistent with other federal and DOE positions, past and present</u>

In the United States, 32.5 persons per 100,000, or approximately 81,250 people, died from "accidents and adverse effects" in 1990.[74] This is a very large fatality rate, much more even than a major conventional war. In the same year (as in every other year since the beginning of the nuclear age) not one person died from the accidental explosion of a nuclear weapon or, <u>as far as is known</u>, from exposure to nuclear materials from a nuclear weapons accident.[75] Actuarially speaking, nuclear weapons accidents don't even appear on the ledger.

But what about the future? A heuristic analysis, which can only be very crudely approximate, suggests that an estimate of risk of death due to a nuclear weapons accident is likely to be, on its face, two to three orders of magnitude below the risk factors typically used as a basis for federal environmental health standards, namely 10^{-4} per lifetime of exposure.[76] This comparison is made, for all its inevitable flaws, because the weapons laboratories from time to time engage in struggles to weaken these environmental standards, notably in regard to ground and surface water quality, saying that the safety risks involved are "negligible." Irony aside, this comparison is a *prima facie* indication that the public health cost of weapons safety "improvements" could easily exceed the risk reductions attainable through design changes--even if those "improvements" caused only those population exposures which were considered safe and no accidents did not occur in production, waste management, decommissioning, and cleanup associated with the design changes.

More ironic still is the fact that the same laboratories who are even now clamoring for money to develop "safer" nuclear weapons--this after the weight of evidence presented in the past four years and the military's lack of interest in the subject--are exactly the ones who were saying that

1/40.12 continued

above-ground nuclear testing was not dangerous just a few decades ago. Federal agencies, such as the Veterans Administration and the Department of Justice, as well as many individuals at the laboratories, still deny the legacy of this testing in specific cases and in general.

When it was convenient to do so, these institutions systematically lied to the public and to the servicemen who were intentionally exposed about the actual risks of nuclear testing. Even today they continue to withhold extensive information about measured fallout distributions.[77] Unlike nuclear weapons accidents, which, as far as we know, have been the cause of no casualties, the casualties of this intentional program were immense. A special team convened by the International Physicians for the Prevention of Nuclear War calculated the expected mortality from fallout worldwide to be 430,000 deaths by the turn of the century.[78] Frank von Hippel's update of Sakharov's 1958 estimates of mortality from above-ground testing suggest that the long-term death toll will be in the neighborhood of 5 million persons.[79] Against this background, the call for "safer" nuclear weapons rings very hollow indeed.

8. Conclusion

We have seen how fears about the "safety" of nuclear weapons have been rhetorically advanced by the weapons laboratories and the DOE with little regard to these simple facts:

- current U.S. nuclear weapons have the benefit of fifty years of technical improvements in safety, and further design improvements can bring only marginal and diminishing returns in actual risk reduction at a very large dollar cost;
- upgrading the arsenal for the sake of safety will create countervailing risks throughout the complex and the world;
- upgrading the arsenal could have enormous nonproliferation impacts; and
- much more cost-effective and elegant non-technical solutions to decreasing risk are available--such as retirements, further reductions in arsenal size, and changes in deployment and transportation.

It is as if the Department were simply pandering to images of doom in order to generate political capital for its science-based stewardship program, which actually has very little to do with safety. The Department as a whole is unreasonably tolerant of the stark contrast between its own very public promotional rhetoric and that of its contractors regarding the "safety" issue, on the one hand, and its joint testimony with the DOD to Congress, on the other, which essentially lays the issue to rest.

From a broader perspective, the nuclear weapons "safety" debate has lost its sense of proportion because it has focused on the safety of the <u>weapons</u>, rather than on the safety of <u>people</u>. In this all-too convenient process of linguistic contraction, weapons are made the primary reference reality, not the public. These distortions have occurred because the pitch from the labs and the DOE is actually not motivated by safety, but by a desire for a less-conflicted weapons ideology, especially for the younger scientists, and for perpetual funding. It is this <u>funding</u> that would be

1/40.12 continued

made safer. Nothing else can explain the irrationality of the open-ended quest for so-called "safer" nuclear weapons.

Endnotes

1. Testimony of Deputy Secretary of Defense John Deutch before the House Foreign Affairs Committee, October 5, 1994: "...advanced permissive action devices, so-called coded control devices, will be introduced into the B-52, the Minuteman IIIs, and eventually into the Trident force as well."
The draft "Stockpile Stewardship Program Plan for Fiscal Years 1995 through 1997," prepared for the Interagency Working Group on February 27, 1995, makes it clear that permissive action links are the subject of active research, development, and replacement in several, if not many or all, weapons in the stockpile.

6. Quoted in Frank von Hippel and Tom Zamora-Collina, "Testing, Testing, 1, 2, 3--Forever," Bulletin of the Atomic Scientists, July/August 1993, p. 28-32. Deutch went on to say, "...there are operational steps that one can take to...ameliorate the safety problems when you mate the warheads to the missiles that are being looked into, but I would not think this an immediate problem..."

7. Testimony before the Senate Subcommittee on Nuclear Deterrence, Arms Control, and Defense Intelligence, cited by von Hippel and Zamora-Collina.

8. Sidney Drell, John Foster, and Charles Townes, Report of the Panel on Nuclear Weapons Safety, House Armed Services Committee, December 1990.

9. The most authoritative and detailed review of these issues in the open literature is still that of senior Livermore weapons physicist Ray Kidder, who was requested to provide an independent analysis of the safety question by several members of the U.S. Senate. See Kidder, "Report to Congress: Assessment of the Safety of U.S. Nuclear Weapons and Related Nuclear Test Requirements," July 26, 1991, UCRL-107454, and also his "Post-Bush Initiative Update" of the same paper in December of 1991, UCRL-109503. His thorough investigation followed, and built upon, that of the Drell Panel and incorporates relevant portions of their work in summary fashion.

10. Public safety is only one of the goals of government, and so this hierarchy of goals is really just one component of a larger picture. While this outline is an oversimplification, the primary roles and risks of nuclear weapons are all included here. Some believe that nuclear weapons have a role in extended deterrence, i.e. in protecting against conventional attack against U.S. forces on foreign soil or against non-nuclear weapons of mass destruction. Others, such as the present writer, believe that nuclear deterrence in any form is counterproductive and illegal in the long run, if not also in the short run. These issues are beyond the scope of this paper.

11. This slogan has been in frequent use in the nuclear weapons community since at least 1993. It is the integrating principle of the draft DOE National Security Strategic Plan, dated November 3, 1993. Reducing the Nuclear Danger: The Road Away From the Brink is the title of a book by McGeorge Bundy, William Crowe, and Sidney Drell (Council on Foreign Relations, 1993).

12. These safety concerns are reflected in the military characteristics (MCs) required by the Pentagon during the weapon design process. Those requirements include, in order of priority, nuclear safety, size and weight, plutonium dispersal safety, operational reliability, yield, conservative use of nuclear materials, and operational simplicity. In the event of a conflict between design priorities, nuclear safety is the highest priority. See George H. Miller, Paul S. Brown, and Carol T. Alonso, "Report to Congress on Stockpile Reliability, Weapon Remanufacture, and the Role of Nuclear Testing," 1987, UCRL-53822.
Interestingly, this official paper, in its exhaustive review of all the reasons to continue nuclear testing, does not mention any unresolved safety issues with then-current warheads or bombs. It was only in the early 1990s that safety issues gained prominence, first during the nuclear testing debate, and now as a challenge for science-based stockpile stewardship.

13. Drell, Foster, and Townes, pp. 25-26.

14. These weapons are the 9-megaton B53-1 gravity bomb (which has only one electrical safety system rather than two independent ones) and the W62 Minuteman III warhead; see Christopher Paine, "CTB Negotiating Issues with Implications for Nuclear Nonproliferation," Natural Resources Defense Council, 1994, and Stan Norris and Bill Arkin, "Nuclear Notebook," Bulletin of Atomic Scientists January/February 1995, pp. 69-71.

15. Drell, Foster, and Townes, p. 13.

16. More recently, "multi-point" safety has also been made an objective. The discussion which follows includes both one- and multi-point safety concerns.

17. Mechanical safing, which has been available and in successful use for more than two decades, can virtually eliminate the possibility of an unintended nuclear explosion, even if many points of the HE or IHE are detonated at once. According to Frank von Hippel, mechanical safing can be added to a nuclear warhead without nuclear testing. See von Hippel, testimony to the Senate Foreign Relations Committee, July 23, 1992.

18. Drell, Foster, and Townes, p. 25. The only place these analyses could have been done, given the classification barriers, the specialized codes, and the data requirements, was the weapons labs. It is quite likely that at least preliminary analyses of this type had already been done when the Drell Panel began its work. Indeed, at least part of the impetus for the Drell Panel was testimony offered by the three weapons lab directors before the Senate Armed Services Committee in May, 1990, which all but said that the Short-Range Attack Missile-A (SRAM-A) was too dangerous to deploy in peacetime (see Drell, p. 40).

19. "It is not sufficient to pull such weapons off the alert ALFA force but retain them in the war reserve stockpile in view of the hazards they will present under conditions of great stress..." *Ibid.*, p. 32.

20. *Ibid.*, p. 29.

21. The Drell Panel estimates that a Pu fire or deflagration would contaminate about one square kilometer, while an explosion "could" contaminate an area of "roughly" one hundred square kilometers. *Ibid.*, p. 30.

The potential proliferation impacts of the DOE's "science-based stockpile stewardship" program, and DOE's design program for new nuclear weapons, will be analyzed in forthcoming papers from Tri-Valley CAREs.

50. General Horner, former head of the Air Force Space Command and leader of the air war against Iraq, is one ("U.S. Should Trash Nukes, Top Air Force General Says," Albuquerque Journal, July 16, 1994). General Andrew Goodpaster, former NATO commander, is another ("Tighter Limits on Nuclear Arms: Issues and Opportunities for a New Era," and "Further Reins on Nuclear Arms: Next Steps for the Major Nuclear Powers," The Atlantic Council of the United States, 1992 and 1993 respectively). The views of Les Aspin, recent Secretary of Defense, are likewise well-known.

Even some weapon designers are beginning to agree. Tom Thompson, dean of current designers at Livermore, admits, "I can't think of any target for anything in our stockpile" ("Science Comes in from the Cold," Los Angeles Times, 12/22/94).

51. Dr. Steven Younger, Deputy Program Director for Nuclear Weapons Technology at Los Alamos, admitted to the writer that these arguments were "defensible." He concluded, for these reasons as well as reliability concerns, that "we should not open up existing weapons [to changes] unless it is absolutely necessary" (personal communication after Los Alamos Study Group panel discussion in Los Alamos, July 18, 1994).

52. Steve Fetter and Frank von Hippel, The Hazard from Plutonium Dispersal by Nuclear-Warhead Accidents, Science & Global Security, Volume 2, 1990.

53. Norris and Arkin estimate that the total number of W76s which will remain after START II is 1328, and that of W88s 400, making 1728 submarine-launched warheads without IHE after START II, slightly more than half the number von Hippel and Fetter used in 1990.

54. Statistical Abstract of the United States, U.S. Governmental Printing Office. The accidental death rate has declined some 40 percent over the last two decades, reflecting the effectiveness of societal investments in safety like the highway improvements cited by Fetter and von Hippel. These investments, which compete for funding with nuclear weapons, have apparently prevented tens of thousands of deaths annually.

55. The unclassified record summarized by Chuck Hansen in his U.S. Nuclear Weapons: The Secret History shows what appear to be nine nuclear weapon accidents involving release of nuclear materials from weapons. The official summaries of each event do not mention which, or how much, nuclear materials were released. A tenth such accident, cited by Drell and Peurifoy in their Table 1, involved the detonation of a bomb at Kirtland AFB in 1957; that bomb did not have its plutonium pit installed when it was inadvertently dropped from the airplane. Declassification of nuclear weapons accidents is not complete, however, and it is possible that further accidents have occurred.

It is likely that cleanup crews were exposed to plutonium at some of these accident sites. The accidents at Palomares, Spain (January 17, 1966), and at Thule, Greenland (January 21, 1968), as well as possibly at Dyess AFB, Texas (November 4, 1958) involved detonations of HE with resultant nuclear contamination; these accidents appear to be the ones generating the most difficult cleanup problems and the greatest likelihood of long-term residual contamination. I am not aware of any study of morbidity or mortality of the workers who cleaned up after these or any other accidents. The cleanup crews, together with any undocumented population exposures (at the time of the accident or in the long run), represent the primary uncertainties in the claim that no one is known to have been injured from the specifically nuclear aspect of U.S. nuclear weapons accidents.

56. These order-of-magnitude estimates are included here, for all their uncertainty, because it has been observed that rational thought often breaks down when nuclear weapons safety is discussed. This occurs even, or perhaps especially, at the top-most levels of the DOE. With the image of the mushroom cloud foremost in our minds--particularly in the minds of those who are responsible for nuclear weapons--no amount of funding for safety improvements seems too much. That, of course, is because they have not been asked to choose between their own programs and other societal means of reducing morbidity and early mortality. It may also be because safety as a goal is psychologically compensatory for those who participate in threatening other nations with weapons of mass destruction, which is, after all, what nuclear deterrence is all about.

These estimates suffer not only from attempting to quantify what cannot be quantified, but also from the implicit error of assuming that the risks of low-probability, catastrophic events are comparable to high-probability, less-severe events. An accidental nuclear explosion, or even a plutonium accident, would arguably have a qualitatively much more severe long-term effect on a society than a comparable number of automobile fatalities.

From 1950-1980, the rate of "Broken Arrow" accidents was approximately one per year. Current safety standards require that a warhead or bomb be able to endure such accidents with a 10^{-4} or less chance of nuclear detonation. Applying the 1950-1980 rate of serious accidents to the deployed START II arsenal, the probability of roughly 4,000 total weapons experiencing one accidental detonation per year with some nuclear yield greater than 4 pounds of TNT-equivalent is less than 4 X 10^{-1}. The current accident rate is much smaller than the historical rate, however, since (a) there are to be fewer deployed weapons than the height of the Cold War, (b) these weapons are now flown around on airplanes much less frequently than in 1950-1980, (c) dangerous exercises like airborne refueling are surely no longer conducted with live nuclear weapons, and (d) these weapons are not kept on alert aircraft parked on runways. These four factors, taken together, probably reduce the rate of "Broken Arrow" accidents by a factor of about 100. Our order-of-magnitude estimate of the current accident rate might therefore be about 10^{-2} per year, and of accidental nuclear explosion about 4 X 10^{-3}.

Most nuclear weapons are stored and transported away from urban areas, so the probability of an accidental explosion in a city is quite small. The size of an accidental nuclear explosion could, by definition, be anywhere between 4 pounds TNT-equivalent and about 1.2 megatons (see Table 1). Perhaps 10^5 people is a reasonable upper bound for the number that would be likely to die from an accidental explosion; that is approximately the number of fatalities that occurred when the center of a city largely made of light buildings--Hiroshima--was bombed. In other words, we might expect, in very round numbers, a reasonable upper bound of 4 deaths per year from a nuclear weapon explosion, with an expected number of deaths per year perhaps two orders of magnitude below this, or 0.04 deaths per year.

This compares with the worst-case scenario drawn up by Fetter and von Hippel for a plutonium dispersal accident, for which the corresponding number was 1 death per year. The probability of the particular accident scenario which Fetter and von Hippel analyzed has been greatly reduced if not virtually eliminated, however, by the simple expedient of separating warheads from rocket motors during loading. The possibility of a plutonium-dispersing accident elsewhere than the Trident docks has not entirely vanished, of course, despite the fact that all

of these non-Trident weapons have IHE and some of them have FRPs as well (see Table 1). Assume, arguendo, that these changes have reduced the expected annual deaths by a factor of 10 to 100, i.e. to about 0.01 to 0.1.

It seems therefore plausible that the *a priori* expected number of annual deaths from a nuclear weapons accident is on the order of 0.1 or fewer persons/year, or roughly one million times less than the expected number of deaths from other accidents. The probability of dying in any accident is, in turn, about 50 times less than dying of a disease, which is about 0.98. Our rough estimate of the probability of any given person in the U.S. dying from a nuclear weapons accident in a given year is thus about 4 X 10^{-10} or less, or less than 3 X 10^{-8} in a 75-year lifetime. These numbers are very low, and errors in them of up to three orders of magnitude will not affect the conclusions which follow in the text.

No Serious Problems:
Reliability Issues and Stockpile Management

An Issue Brief for Tri-Valley CAREs by Greg Mello, February 6, 1995

Summary

1/40.70

- The U.S. nuclear arsenal has been extensively tested and is reliable.
- The arsenal is becoming more reliable each year as older weapon types are retired.
- The weapons which are to remain in the stockpile can be expected to last many more years if serviced. So far, age has tended to make nuclear weapons more, not less, reliable, and no weapon has ever been retired due primarily to aging problems.
- Although the nuclear arsenal is increasing in reliability, confidence in nuclear weapons is declining as nuclear weapons lose political importance. The two issues--reliability and confidence--should not be confused.
- U.S. nuclear weapons are adequately "robust" with respect to the minor variations in manufacture that have occurred throughout the prototyping and production processes.

2/40.33

- There is no serious technical impediment to remanufacturing existing kinds of weapons and weapon parts. For example, Los Alamos is now gearing up to remanufacture plutonium pits.

3/40.01

- Changing the design of nuclear weapons without nuclear proof-testing has been the source of serious reliability problems in the past and can be expected to cause more problems if it is done in the future.

2/40.33 continued

- The present, effective process for monitoring the reliability of nuclear weapons places only small demands on weapons research and development personnel.
- A high level of weapons reliability can be assured with modest levels of funding and with current diagnostic facilities. New facilities, especially the $2 billion National Ignition Facility, are not needed. Engineering and production skills, rather than scientific research, are most essential to maintaining and remanufacturing nuclear weapons.

4/40.05

- The only purpose of reliable nuclear weapons is to deter a nuclear attack. Efforts to continually refine nuclear weapons conflict with U.S. nonproliferation goals and could well degrade confidence in the overall efficacy of our deterrent.

1

Introduction

In the debate over a nuclear test ban in the late 1980's, advocates of continued testing, led by the two weapons physics laboratories, took the position that the reliability of U.S. nuclear weapons would decline unacceptably under any kind of testing ban. Specifically, weapons labs managers argued that changes in manufacturing techniques, materials, and personnel would seriously degrade confidence in the U.S. nuclear deterrent.

These concerns were not shared by everyone in the weapons design community, however, and the lab managers' view, when weighed against contrary technical evidence from senior independent and retired experts, failed in the end to convince even the Pentagon. All relevant agencies of the government--including the managers of the labs--now agree that it is feasible to maintain a nuclear deterrent without nuclear testing. While not everyone in government wants a test ban--John Deutch, Undersecretary of Defense does not, for one[1]--everyone now finally admits, either implicitly or explicitly, that the U.S. nuclear stockpile can be maintained under a comprehensive test ban treaty (CTBT).

Indeed, the current leadership at the Pentagon "requires" that the nation retain the capacity--even under a test ban--to design, fabricate, and certify new weapons, a much more difficult task than simply refabricating existing weapon types.[2]

With a CTBT now an official goal, reliability issues, like safety concerns, are again being raised, this time to promote the new facilities and large appropriations proposed for the Department of Energy's (DOE's) expansive "science-based stockpile stewardship" (SBSS) program. Are these concerns real? Is it necessary to keep research, development, and testing (RD&T) spending at Cold War levels to maintain reliable weapons? Are major new facilities needed? This paper, part of a series on these and related questions, suggests that reliability concerns can be addressed in a much simpler and relatively cost-effective manner through more effective management of the nuclear weapons complex.[3]

Congressional testimony shows that the U.S. arsenal has no significant current reliability problems.

1/40.70 continued

The best starting point for this discussion is the most authoritative testimony available. Speaking before Congress on March 15, 1994, Dr. Harold Smith, Assistant Secretary of Defense for Atomic Energy, said

> I am pleased to report the stockpile today is safe, secure, reliable, and meets current military requirements. We make that statement with confidence today and for the immediate future....Our stockpile is becoming safer and more reliable simply because we are retiring older weapons...Thus, we should enter the 21st century with a modern, safe, and reliable stockpile consistent with the demands of START I and with anticipated military requirements.[4]

2

1/40.70 continued

So not only are U.S. nuclear weapons reliable, but they are, at least for the "immediate future," becoming even more reliable as older weapons are retired. This statement was made in the presence of, and with the approval of, Dr. Victor Reis, Assistant Secretary of Energy for Defense Programs, who added,

> Right now, as Dr. Smith said, that stockpile is safe and reliable.[6]

Make no mistake: nuclear weapons in the stockpile are certified to explode at nominal yield <u>after</u> experiencing all the environments that a deployed weapon could reasonably be expected to weather in its life, and <u>after</u> the severe accelerations, cold, heat, shock and radiation (e.g. from the explosions of other warheads) that are expected to occur during the stockpile-to-target sequence. This performance is exhaustively analyzed and tested in a diverse array of demanding tests coordinated primarily by Sandia, whose mission is to weaponize the physics packages' developed at the other two laboratories. It appears that most, or perhaps even all, of the weapons in the current stockpile have been tested in underground nuclear tests using not only prototypes but also actual production weapons, with simulated end-of-life and stockpile-to-target conditions.[7]

So the reliability concerns that have been raised are concerns over the long term. What, in this context, is the "long term?" And just how serious are these concerns?

<u>No serious reliability problems are expected in the stockpile for many years, even without remanufacture.</u>

Dr. Dan Kerlinsky investigated in detail the subject of reliability in relation to stockpile stewardship throughout the summer and fall of 1994 for the Secretary of Energy's Panel on the Future of the DOE Labs (the Galvin Panel). In the process, he attended and initiated numerous classified discussions and interviews with senior scientists and managers at all three weapons laboratories.

Kerlinsky found that data on historical reliability and repair had been systematically collected by Sandia National Laboratory in a two-year study commissioned by Secretary Watkins, called the Stockpile Life Study, which was completed in 1994. This study was designed to answer two basic questions: (1) "How long do nuclear weapons last?" and (2), "What programs and activities are required to keep them in the stockpile?" To answer these questions, the detailed history of the entire stockpile was examined over the past thirty years.[8]

Sandia was in an excellent position to gather this data, as it is the laboratory that coordinates the stockpile surveillance program for the Department. But in order to be sure that the Sandia study did not leave out any problems that might be known to Los Alamos and Livermore but not to Sandia, Kerlinsky interviewed weapons program personnel at these two laboratories as well. He found that the Sandia data was indeed comprehensive.

The thirty years of experience summarized in this study revealed that there is not known to be any upper limit on weapon life, given appropriate maintenance and renewal of perishable

3

1/40.70 continued

materials and parts (e.g. tritium). No U.S. weapon has ever been retired due primarily to aging problems, even though some weapons have, in the past, been in the active stockpile for more than 30 years before being superseded by new designs. (The weapons in the present stockpile are, in contrast, believed to be all between about 6 and 15 years of age.) Aggregate data show that the rate of required modifications and repairs of stockpiled weapons <u>decreases</u> as the years go by, reflecting continually increased reliability as the "bugs" are gradually worked out of weapons systems.

Fully half of the 300-odd problems encountered in the stockpile over the years were judged to have no effect at all on the reliability of the weapon. At least another 40% of the problems investigated would have had only a slight impact on reliability. Only a small minority–less than 10%–of the problems found would have led to a decrease of 10% or more in the probability of achieving the certified yield. All of these problems have been fixed. Many of them were caused by rushing inadequately-tested weapons into the stockpile, as will be discussed below.

Overall, among the defects found, very few have been in the physics packages, which typically are the simplest part of the weapon, comprising less than 5% of the overall number of parts in the B83, to pick one example.[9]

What is most important to realize is that the weapons in the enduring stockpile have been designed and built using all this and more accumulated experience. Design and production mistakes that occurred with earlier weapons have not been repeated. The stockpile is more reliable than ever before, and is increasing in reliability as older systems are retired.

Before examining this subject in greater technical detail, it is important to step back and look at the difference between reliability of, and confidence in, the stockpile.

<u>Reliability is sought only for the purpose of creating a convincing deterrent.</u>

It is important to distinguish between the <u>reliability</u> of a warhead and <u>confidence</u> in a nuclear deterrent. Reliability is a technical problem. Confidence is based on reliability, but it is also based on psychological, social, and political realities and perceptions. Confidence is not at all the same to every observer. For most decision makers, confidence in a nuclear deterrent is the genuine objective of nuclear weapons expenditures, not simply reliability. They seek this confidence in an attempt to allay fears of a nuclear attack, and they attempt to project this same confidence to would-be aggressors and potential enemies in our foreign wars.

Confidence is eroded whenever the experts at the nuclear weapons labs, who have a strong financial and institutional interest in the matter, say there is a reliability problem of any kind, no matter how trivial or even false. So the scientists at the weapons labs, along with their sponsors at the DOE and DOD and the consultants who serve them, are precisely in a position of considerable influence over confidence in the U.S. stockpile, quite independent of actual weapon reliability.

4

1/40.70
continued

In a different and perhaps more fundamental sense, confidence in the stockpile is also eroded whenever the utility of warheads to accomplish national goals—including deterring non-nuclear aggression—is questioned. This is now occurring with greater and greater regularity. Many people believe that the 49-year *de facto* norm against the use of nuclear weapons, together with the repugnance with which the nations of the world would regard their use, make that use quite unrealistic and counterproductive for any purpose other than the narrowest one of deterrence of nuclear attack.[10] In a very real sense, nuclear weapons are becoming less reliable as instruments of policy and power. They are becoming politically unreliable—which makes everyone more secure.

In this context, senior bureaucrats, members of Congress, defense officials in the executive branch, and others who have focused years of their life on the production, maintenance, and deployment of nuclear weapons sympathize readily with the fretting about long-term reliability now being done by the laboratories and their sponsors. Confidence in the ability of U.S. nuclear weapons to explode is not in any serious doubt, but the funding, purpose, direction, and meaning of the U.S. nuclear weapons program is very much in doubt, and the two kinds of doubt are very easily confused.

In any case, perfect reliability is not essential to deterrence. The technical—as opposed to the political and psychological—requirements of deterrence consist only of providing any aggressor with enough confidence that U.S. weapons might explode to deter his attack.[11]

A more detailed technical analysis of the reliability
question does not reveal any serious problems.

The "reliability" question was authoritatively examined in a 1987 report to Congress by Dr. Ray Kidder, a senior Livermore weapons physicist, commissioned by former Congressman (and later, Secretary of Defense) Les Aspin. Kidder's overall conclusion was,

> It is found that a high degree of confidence in the reliability of the existing stockpile is justified, and that it is sufficiently robust to permit confidence in the reliability of remanufactured warheads in the absence of nuclear explosive proof-tests.[12]

Note that this confidence was warranted in 1987, without the new facilities that are proposed for the SBSS program.

In the course of his study, Kidder found that in the entire history of the U.S. stockpile, only one weapon (the W68) experienced reliability problems after being in the stockpile more than four years.[13] The Stockpile Life Study's conclusions, as we have seen, confirm this vote of confidence and bring it up to date.

In his paper, Kidder analyzed the fourteen often-cited cases of stockpiled weapons that required nuclear tests to evaluate problems. Nine of these occurred in the 1960's—Kidder calls these the

5

1/40.70
continued

"Sixties Nine"—as a direct result of the rush to build and stockpile weapons during the 1958-1961 test moratorium. That rush led "to a stockpile that was very poorly tested by today's standards," he notes. Kidder continues,

> Our understanding of how nuclear weapons work, our experience with nuclear tests, and our computational capabilities were all significantly inferior to that which exists today [i.e., in 1987]. There has been no rush to build the present stockpile, and it has benefited from a quarter-century of additional nuclear and nonnuclear tests since the hectic days of the Moratorium. For these reasons, it is concluded that experience with the Sixties Nine, long ago, has little or nothing to say about the reliability of the stockpile of nuclear weapons that exists today.[14]

Five other actual or potential reliability problems occurred in the 1980's, likewise as a result of inadequate testing. In two cases, the production weapons were different than the tested prototypes and had never actually been tested at all (one worked; one didn't). In two cases, weapons had never been tested after the rugged stockpile-to-target sequence of events (one worked; one didn't). And in one case, the high explosive in a weapon was changed; the explosive—unique to that failed weapon—had never been adequately tested in the first place and didn't work properly. All these problems, and the lack of testing that allowed them to go unnoticed prior to production, are irrelevant to the current stockpile.

Carson Mark, Director of the Los Alamos Theoretical Division for 26 years, summed up the situation in 1993 by saying that the reliability argument, as it was then being used against a test moratorium, was "utter rubbish."[15] Mark links reliability and stockpile confidence to preservation of the original warhead design, without change or "improvement."

> Most important, no changes or improvements in matters which could affect the behavior of the nuclear system in an existing, certified weapon design would be acceptable [during a test ban].[16]

Mark makes the further point that the real threat to confidence and reliability of the arsenal is the historical insistence that, to quote an old policy of the DOE, "the nuclear weapons stockpile must dynamically evolve to satisfy changing threats and deterrent requirements."[17]

2/40.33
continued

Reliable warhead remanufacture is feasible.

The concept of maintaining confidence by preservation of design is at the heart of "warhead remanufacture," to which we now turn. Kidder tabulated the results of U.S. nuclear tests, dividing them into four groups, and found that the agreement between predicted and actual yield was "remarkably" good. He concludes that

> this impressive record would not have been possible if U.S. nuclear weapons were not comfortably tolerant of the small variations in materials and manufacturing that accompany any practical production process...The test record

6

2/40.33
continued

> indicates that the nuclear weapons in the existing U.S. stockpile are sufficiently robust to allow for future replication...This conclusion is in agreement with earlier statements by nuclear weapons authorities Dr. Hans A. Bethe, Norris E. Bradbury, Richard L. Garwin, J. Carson Mark, and Andrei Sakharov affirming the possibility of reliable remanufacture without nuclear explosive proof-tests.[18]

This conclusion is reinforced by an experiment at Los Alamos in which an intentionally off-spec pit was made and successfully tested in Nevada.[19]

Kidder appends the convincing statements of these authorities to his paper. Needless to say, when he wrote these words in 1987 Kidder did not, nor could he have, made them contingent upon the existence of new science-based stewardship facilities.

Kidder added, however, that for later remanufacture to be feasible, original materials would have to be used. If changes were made, confidence would be undermined. When I spoke to him last year about this, he did not think that material substitution would be a problem in each and every case. Some changes could, in fact, be tolerated: parts which are supposed to be transparent to radiation, for example, could be replaced with parts which are at least as transparent, and parts which are supposed to be opaque, with parts at least as opaque. He noted that since his 1987 study, there have been further classified studies of this issue, including a "Stockpile Remanufacture Study" in FY91. At the present time, he is "not aware of any problems" with warhead remanufacture, provided adequate funding is available.[20]

Mark agrees. On the materials question, he says

> it is ridiculous to suppose that substitutes would ever be needed. Nuclear weapons production has never been dependent on commercial supplies or suppliers to meet its needs for obtaining and handling separated isotopes, polonium, plutonium, or explosives. The production system can certainly be set up, or arrange, to acquire safely any needed supplies of beryllium, plastics, asbestos, or whatever else may have served effectively in past production even if in the future it should be dropped from commercial use because of hazards or lack of demand.[21]

As for the level of expertise needed to implement such a remanufacture program, Mark points out that the only real need for experienced weapons designers would arise in the determination of "whether a particular problem found in the surveillance program did or did not require replacement of the stockpiled weapons with new ones built to the original, certified, and tested specification." . Mark, for one, has no doubt that if the problem were considered important enough, a body of experienced experts could be convened <u>regardless of the level of staffing at the weapons laboratories</u>. Mark goes on to say,

> Past experience casts doubt on our supposed utter dependence on maintaining a corps of scientific and engineering veterans of the Nevada test site. There were no such persons anywhere in 1943 when the effort to build an atomic bomb was

7

2/40.33
continued

> begun; and in 1950 when official hydrogen bomb efforts were announced, the corps of seasoned experts was very small and had very meager experience in testing - now said to be the *sine qua non* of capability. Yet in each case, the United States succeeded in developing and testing a weapon based on an entirely new physical principle within two to three years.[22]

Kidder points out that the institutional arrangements needed to maintain reliability are "nothing new." It would, in his opinion, take only relatively small teams, with focused responsibility for each weapon system, to resolve stockpile questions. At present, he said, it is rare for weapons designers to receive questions regarding changes in weapons specifications. Before this happens, several levels of expertise--the inspectors and production engineers at Pantex, then their supervisors, then the weapons engineering teams from the weapons labs which regularly travel to the production plants--must be exhausted first. He believes there is no reason to change this system, which works. The highest priorities for a strong remanufacture program would probably be product and production engineering, test equipment, and so on, rather than new science *per se*, although a scientific base must also be maintained, including hydrotesting facilities.[23]

In 1987 Kidder concluded, long before SBSS, with its proposed panoply of new design and diagnostic facilities, appeared, that

> The robust character of the nuclear weapons in the present stockpile, together with the ample time available to accomplish the task, suggests that it will eventually be possible to be confident of the reliability of remanufactured nuclear weapons without requiring the services of nuclear weapon design engineers and scientists that have themselves benefited from direct experience with nuclear explosive tests. (p. 9)

At the same time--1987--as Kidder conducted his study, managers at Lawrence Livermore National Laboratory (LLNL) were writing their own report.[24] This report--a *cri de coeur* for nuclear testing--is very useful as a compendium of problems that had been experienced in weapon design and manufacture. Based on the historical record, these managers believed three kinds of problems would occur in a future without nuclear testing: the loss of both scientific and production experience, unavailability of materials (and/or subtle variations in them) with no way to test how substitutions and changes affected performance, and inadequate documentation and specifications for many materials and processes, leading to inadvertent production changes.

Yet the official LLNL conclusions of 1987--that exact remanufacture is impossible and that nuclear testing is necessary to retain the reliability of the arsenal--have both now been widely rejected. In the end, data like that of Ray Kidder have been strongly persuasive over the attempt to extrapolate future problems from problems discovered--and corrected--in the past. For if minor variations in manufacture, materials, or specifications were indeed a serious problem, we just would not see what Kidder called the "impressive" testing record in Nevada, either for new primaries or stockpiled weapons. Especially given the near-perfect record for <u>new</u> primaries, why should it be so difficult to merely maintain existing designs?[25]

8

2/40.33
continued

The JASONs believe the best approach to reliability is exact remanufacture.

In their recent report on SBSS, the JASONs—an elite group of academic defense consultants convened by the MITRE corporation—endorse exact replication of weapons, especially plutonium pits, as the best way to ensure confidence in the arsenal.

> ...the primary—if not the sole—nuclear weapons manufacturing capacity that must be provided for in an era of no nuclear testing is the remanufacture of copies of existing (tested) stockpile weapons...the ultimate goal should be to retain the capability of remanufacturing SNM [special nuclear materials] components that are as identical as possible to those of the original manufacturing process and not to "improve" those components. This is especially important for pits..."[26]

The plutonium pit forms the core of the fission primary, and its function is critical to the reliability of the entire weapon. Pits are composed of various materials which must be alloyed, shaped, and joined with great precision. Even so, the JASONs point out that it is the finished pit that must be the same as the proof-tested model, and not every manufacturing detail or process along the way. To ensure this, they call for "a narrowly defined, sharply focused engineering and manufacturing curatorship program."[27] This is an excellent approach to stockpile management overall, but the point here is that they found no serious obstacles to their exact remanufacturing proposal. That is, the inevitable inexactness of "exact" remanufacture evidently appeared quite tolerable to the JASONs, contrary to what is often said by the laboratories.

Remanufacturing is not only practical—it is about to start.

In addition to alleged reliability problems caused by declining expertise, unavailable materials, and inadequate documentation, it has more recently been suggested that there will be reliability problems associated with the adoption of novel production methods. For example, plutonium metallurgy is complex, and the processes formerly used at Rocky Flats to make pits are different in some respects from those now being set up at Los Alamos to do the same job. But Los Alamos is remanufacturing pits.

> Associated with pit surveillance activities is the Pit Rebuild Program, which will demonstrate the capability at Los Alamos to fabricate pits of war reserve quality. Specific technology areas that must be developed or enhanced at Los Alamos include certification of the beryllium machining capability, certification of the tubulation capability, development of the capability to interface pit materials, and development and certification of joining processes. The capability for manufacturing a pit for a W88 weapon will be in place in FY 1996...
>
> Los Alamos is currently the only DOE site capable of fabricating a plutonium pit and, as such, may be the only practical near-term upgrade-in-place option for plutonium processing and fabrication. In conjunction with its plutonium research and development responsibilities, Los Alamos will maintain

9

> those technologies and capabilities required to build plutonium pits for development and demonstration purposes..."[28]

Thus the capability to produce W88 pits for the stockpile will be put in place long before any of the so-called "necessary" new diagnostic facilities, such as the Dual-Axis Radiographic Hydrotest (DARHT) facility, are available.[29] While both DOE and the laboratories are trumpeting exotic solutions to alleged reliability "problems," a fully-certified production line is being set up this year for the most critical and difficult-to-manufacture component in a weapon: the plutonium pit.

What is more, much of the slow start-up in the Pit Rebuild Program results not so much from the difficulty of being sure the pits produced will be good enough *per se*, but from the painstaking work of matching or modifying the specifications and procedures--the official cookbook--that LANL inherited from Rocky Flats. It is the quality assurance aspect that takes the most time. Asked how long it would take to produce a working pit for the stockpile in an emergency, independent of the formality of the certification process, LANL managers told Kerlinsky, "Three days."[30]

But this is not all–

> As part of the Stockpile Support Program, Los Alamos will maintain a capability to make the components for a complete nuclear physics package, thereby ensuring that the requisite technologies and expertise are retained in the DOE complex and that weapons RD&T requirements can be met in the future. Because upgrades in canned subassembly (CSA), assembly, and radiation-case capabilities will be required, Los Alamos and Livermore are preparing a study for DOE/AL to evaluate joint capabilities in both pit and CSA manufacturing."[31]

Thus LANL at least believes that it can manufacture not only pits but entire physics packages for RD&T purposes, if not also for the stockpile. And the two labs together not only have confidence in, but are actively seeking, manufacturing capability for complete physics packages for the stockpile.[32] Thus, what the labs said just a few years ago couldn't be done for all the reasons they trumpeted, they are now actively promoting—and at their own facilities, no less.

To the extent that nuclear weapons are to be retained, reliability and quality assurance issues will always require attention. But the inescapable conclusion from the labs' current programs and proposals is that they do not believe that reliability issues stand in the way of remanufacture of nuclear weapons.

There is no need to retain weapons in the stockpile long after their expected life.

It is often mistakenly asserted that, with an end to nuclear testing, weapons will have to remain in the stockpile for unprecedented periods of time. There is no reason why this need be the case. About six weapon types could remain in the "enduring stockpile" for a long time, should further disarmament measures fail, but individual weapons can be remanufactured if it is decided

10

to do so. Therefore there is no need to endlessly study how problems which develop only after decades in the stockpile might affect reliability—if reliable nuclear weapons are desired, new parts, or new weapons, of existing types can be made. This logic applies to the aging of insensitive high explosive (IHE), to metallurgical changes in plutonium pits, and in fact to essentially all potential long-term stockpile problems.

Stockpile problems are now detected by a variety of non-exotic means, such as physical inspection, static radiography, chemical analysis, and testing of subsystems. These problems can be simply remedied, if necessary, by replacement of the affected part from inventory or from remanufacture—or by retiring the weapon.

Conclusion

Retention of a nuclear deterrent is not a demanding technical requirement. Such a task is not a major scientific undertaking at all. It is rather an engineering and organizational problem with scientific components.

5/40.58 In particular, there is no need to construct advanced new diagnostic facilities. While these facilities could, in some cases, marginally advance the state of U.S. nuclear weapons science,
6/40.07 to the extent they do this they will inevitably undermine the global nonproliferation regime.[33] Thus, while contributing little or nothing to the reliability of U.S. nuclear weapons, these new facilities could well decrease confidence in the overall efficacy of our nuclear deterrent.

5/40.58 continued What is more, a DOE budget centered around SBSS, with funding included for large, unnecessary, and distractive gadgets like the proposed National Ignition Facility, could overshadow and weaken those programs most useful for actually maintaining the existing stockpile. This fact has not escaped the notice of many analysts, including the Congressional Budget Office and the Natural Resources Defense Council.[34]

Fundamentally, the scale and direction of the science-based stockpile stewardship program envisioned by the DOE and the weapons labs is not so much driven by concerns about the reliability of weapons as it is driven by concerns regarding the reliability of funding. Creating new "products"—i.e. new weapons designs—in that program, an outcome which is probably necessary to maintain internal interest in the program in the long run if not also in the short run, may be the best way to create reliability problems in an arsenal which now has none.[35]

Endnotes

1. The following exchange occurred between Chairman Hamilton and Dr. Deutch during the latter's presentation of the Nuclear Posture Review to the House Foreign Affairs Committee, October 5, 1994:

Rep. Hamilton: "Do we need more (nuclear) testing?"
Dr. Deutch: "In the near term? How long do you have in mind, sir?"
Rep. Hamilton: "You pick the time frame. It doesn't make any difference."
Dr. Deutch: "The position of the administration, I believe, is that we don't need more testing..."
After three more attempts by Rep. Hamilton to elicit candor from Deutch, the latter finally admitted:

"Mr. Chairman, you catch me personally here at a rather awkward position, and let me explain to you straight why, and that is that I have written widely on this subject before I entered government, and so what I'm trying to answer to you now is the position of the administration."

Although Hamilton questioned Deutch closely as to reasons to continue nuclear testing, Deutch provided none, even though he was personally in favor of testing. Hamilton even suggested that safety as a reason to continue testing, but Deutch demurred, saying "It is my judgment that all the nuclear weapons that we have are adequately safe." At no point did Deutch bring up any reliability issues—either past, present, or possible future.

2. See the viewgraphs used to present the Nuclear Posture Review in late September and early October, 1994, available from the Pentagon; the one quoted here is titled "DOD requirements to DOE." The "requirements" terminology is both problematic and revealing.

6. Physics package: the nuclear "core" of a weapon, typically and schematically comprised of the fission primary, the thermonuclear secondary if present, related initiating and boosting devices, and the case.

7. Ray Kidder, "Maintaining the U.S. Stockpile of Nuclear Weapons During a Low-Threshold or Comprehensive Test Ban," October 1987, UCRL-53820, LLNL, pp. 4-5. His exact word or adjectival phrase has been omitted by the classifiers but the import of his sentence is clear. Kidder discusses stockpile confidence tests (SCTs) more extensively on p. 3 and in Appendix B of his report, both of which have been substantially classified as well. I do not know how many SCTs were done in the years between 1987 and 1992, when testing ceased, or whether there remain, at this point, any weapons which have not been so tested, or whether any systems without SCTs are to be retained in the START II arsenal. It is quite doubtful that inadequately tested weapon systems would be chosen for retention in the so-called "enduring arsenal." Even if so, the "remarkably accurate" predictability of SCTs (Kidder, p. 15) supports a high level of confidence in the reliability of any weapon (if there is one) which has not had this final, post-production, test. The large number of nuclear tests that were available for such tests argues that if any SCTs were not done, it was because they were not considered very important. The Nuclear Testing Moratorium Act specifically allowed testing for reliability purposes, but none has been requested.

8. Classified and unclassified results of this study were made available to the Galvin Panel. The unclassified summary is currently being suppressed by Assistant Secretary Rais and Undersecretary Curtis.

9. This information is found in viewgraphs prepared by Sandia National Laboratory.

10. Seth Cropsey of the Heritage Foundation is one such person (see "The Only Credible Deterrent," Foreign Affairs, March/April 1994, pp. 14-20. General Horner, head of the Air Force Space Command, is another ("U.S. Should Trash Nukes, Top Air Force General Says," Albuquerque Journal, July 16, 1994). Tom Thompson, dean of current weapons designers at Livermore, is another. As he recently put it, "I can't think of any target for anything in our stockpile" ("Science Comes in from the Cold," Los Angeles Times, 12/22/94).

Many senior military commanders have held and/or hold the view that nuclear weapons are useful only to deter other nuclear weapons, and not for any military use; Robert McNamara listed some he has known to hold this view in the United States and Britain in a speech to the Economists Allied For Arms Reductions in New York on May 19, 1994. Still other civilian and military defense leaders cited by McNamara have stronger views—that nuclear weapons should never, under any circumstances, be used at all. McNamara says he conveyed this opinion, which he has held since the early 1960's, to Presidents Kennedy and Johnson.

11. One senior weapons manager at LANL put the whole reliability question in perspective with a pointed question. "Would an aggressor gamble that Israeli nuclear weapons [which are far less tested than U.S. weapons] won't explode?" To be understood, any aggressor must have confidence that the U.S. deterrent as a whole won't work, i.e. that all, or essentially all, of the weapons launched by the U.S. will be complete duds. It is this aggregate reliability that counts for deterrence, and the burden of proof is solidly on those who would doubt that aggregate reliability. As described in the previous note, many people—the present writer included—believe it would be a mistake to retaliate against an attack, even a nuclear attack, with nuclear weapons. As General Horner put it,

"I just don't think nuclear weapons are usable. I'm not saying that we unilaterally disarm. I'm saying that I have a nuclear weapon, and you're North Korea and you have a nuclear weapon. You can use yours. I can't use mine. What am I going to use it on? What are nuclear weapons good for? Burning cities. What President of the United States is going to take out Pyongyang?"

If, however, nuclear weapons are to be maintained and deployed as just another weapon of war, ready for first use against an enemy in times of crisis, a higher standard of reliability is required. Yet even this dangerous and counterproductive posture can be readily and reliably supported by maintenance and remanufacturing of existing weapon types.

There is yet another reason why confidence in deterrence is robust relative to reliability of a weapon. In a nuclear explosion, the maximum radius at which a given overpressure is experienced is proportional to the cube root of the explosive yield. A five-fold decrease in explosive power thus causes only a 1.7-fold decrease in destructive radius and a 2.9-fold decrease in destructive area. (See Samuel Glasstone, The Effects of Nuclear Weapons, U.S.A.E.C., 1964, p. 127.) Even significant declines in expected yield are unimportant outside a warfighting context.

12. Kidder, op. cit., p. 1.

13. This problem, arising from chemical instability in a type of HE that is no longer used, is not relevant to the current arsenal.

25. "During the past decade [1977-1986], new boosted primaries have been designed and developed by the weapons laboratories...performed satisfactorily the very first time they were tested, the observed yield in no case falling short of that expected by more than...The one new primary that failed was of a more complex, less predictable design than the others. This primary was subsequently redesigned, tested, and failed again. None of the primaries in the existing stockpile employ...

"This experience demonstrates that the ability of the weapons labs to predict the performance of newly designed, as yet untested, boosted primaries of the kind currently in stockpile is indeed impressive—there were no significant surprises. This could hardly have been the case had these primaries been sensitive to differences that inevitably exist between the weapon configuration calculated and the weapon tested." Kidder, op. cit., p. 25.

26. "Science Based Stockpile Stewardship," Sidney Drell et al, November 1994, MITRE, McLean, VA, p. 81. The chapter quoted proceeds from different assumptions than most of the rest of the report. That report is criticized in a paper related to the present study, available from Tri-Valley CAREs, "Ask Few Questions, Get Few Answers: A Critique of the JASONs' Stockpile Stewardship Study," Greg Mello, 1995.

28. Los Alamos National Laboratory, Institutional Plan, FY1995-2000, pp. 50-51.

29. DARHT, like the existing Flash X-Ray (FXR) and Phermex facilities at Livermore and Los Alamos, respectively, would evaluate mock pits during implosion. DARHT, if built, is expected to be available for experiments in approximately the year 2000.

30. Dr. Daniel Kerlinsky, personal communication.

31. Los Alamos National Laboratory, op. cit., p. 51.

32. The overall outlines of the labs' proposal can be found in a presentation by Larry Woodruff of LLNL to the National Security subgroup of the Galvin Panel on August 8-9, 1994. The responsibilities of Rocky Flats, Savannah River, and the Y-12 Plant would all be moved to LANL and LLNL under this plan, with Sandia taking over for Pinellas and the Kansas City Plant. The production capacity would be 150 weapons per year, with LANL specializing in fabricating parts made from fissile materials.

33. Detailed discussion of this point will soon be available from the present writer and Tri-Valley CAREs.

34. Congressional Budget Office, "The Bomb's Custodians," July 1994, p. x; Christopher Paine, personal communication.

35. See Defense Week, 8/15/94. Dr. John Deutch, Undersecretary of Defense, and Dr. Vic Reis, Assistant Secretary of Energy, were and may still be pressing for development of a new warhead. This notion differs from the military's preferred road map for maintaining reliable nuclear weapons, which does not involve reliance on an untested weapon.

Ask Few Questions, Get Few Answers:
The JASONs' "Science Based Stockpile Stewardship" Study

A Review for Tri-Valley CAREs

by

Greg Mello

February 14, 1995

Ask Few Questions, Get Few Answers:
The JASONs' "Science Based Stockpile Stewardship" Study

A Review for Tri-Valley CAREs by Greg Mello, February 1, 1995

Summary

1/40.17

- The Department of Energy (DOE) asked the JASONs, a respected group of academic defense advisors, to evaluate its science-based stockpile stewardship (SBSS) program. The JASONs were not asked, however, about the relative merit of specific projects in SBSS, or which of these projects—if any—were essential, or to evaluate projects by their benefit-to-cost ratio. As a result their report is not very helpful in evaluating the DOE program.
- The JASON group cannot be considered "independent," since many of the group, including the chairman Dr. Sidney Drell, are closely connected to the DOE.

2/40.07

- In the JASONs' view, "compensation" to the weapons labs for the loss of underground testing is the "basic principle" of the SBSS plan. They recognize, however, that if other nations view SBSS as compensation, this could conflict with U.S. nonproliferation goals.
- The JASONs' nowhere demonstrate the need for most aspects of SBSS to maintain a deterrent.
- The JASONs assume that new nuclear weapons must be developed and deployed and that SBSS is necessary to accomplish this. At the same time, the JASONs do not want the perception of this activity to be widely shared.
- The JASONs' analysis of the nonproliferation impacts of the SBSS is quite abridged. They essentially ignore the requirements of the Non-Proliferation Treaty.
- The JASONs propose declassifying many of the technical details of the SBSS program in order to defuse nonproliferation concerns. A senior DOE declassification officer strongly disagreed with this approach, citing direct proliferation risks. The JASONs' declassification proposal seems calculated to gain more scientific users of the new machines and therefore more political support for them.
- The JASONs endorse most of the proposed new facilities that will be the foci of the SBSS program, including all the hydrodynamic testing upgrades planned for this century and the National Ignition Facility (NIF). Yet they offer no reasons why these facilities, including NIF, are in any way necessary. They call for a public-relations campaign to sell NIF within the scientific community.
- The JASONs' prescription for plutonium capabilities calls for a narrowly-defined "curatorship" and for exact reproduction of existing designs, contradicting the rest of the report.

Introduction

In November of 1994, 17 members of the JASON group published their study of the Department of Energy's (DOE's) science-based stockpile stewardship (SBSS) program, which is in its first year of implementation. Even in its draft form, DOE was very pleased with the results of the study and was, in October of 1994, looking forward to reprinting it for wide distribution.[1] The JASON study is likely to be influential in the policy debates of 1995 and beyond and so deserves careful scrutiny.

The JASONs are an elite group of academic defense advisors periodically convened to study selected scientific issues for the military. Their origins lie in the secret studies sponsored by the Pentagon in the late 1940s and early 1950s, most often coordinated by the Massachusetts Institute of Technology (MIT). The first of these was Project Lexington in 1948, which started the ridiculous nuclear-powered bomber program. This was followed by Project Charles, which studied civil defense against nuclear war, and then by many others. By 1966, the JASONs had become a permanent institution, enthusiastically advising McNamara regarding the promise of the "electronic battlefield" in Vietnam, an effort later described by one JASON as "very naive--extraordinarily naive."[2]

It is not clear from whence the name of the group was taken; one long-time JASON recently joked that it comes from the legend of Jason and the golden fleece. The JASON office is at the MITRE corporation, reflecting its MIT roots.

The point of this brief history is that even bright and well-meaning groups like the JASONs are often wrong, sometimes very wrong. They are especially vulnerable if the questions posed to them are too narrow or if those questions imply a narrow range of answers, all of which are yes. Such is the case in the present study.

Quoting from the abstract,

> The DOE asked JASON to review its Science Based Stockpile Stewardship program with respect to three criteria: 1) contributions to important scientific and technical understanding and to national goals; 2) contributions to maintaining and renewing the technical skill base and overall level of scientific competence in the defense program and the weapons labs, and to the broader U.S. scientific and engineering strength; and 3) contributions to maintaining U.S. confidence in our nuclear stockpile without nuclear testing through improved understanding of weapons physics and diagnostics.

Pointedly, the DOE did not ask the JASONs their opinion about which elements of the proposed SBSS program were necessary, or even to rank them in importance. Where multiple projects were being advanced toward the same end (as, for example, in hydrotesting) DOE did not ask the JASONs which facility or facilities to fund. DOE did not ask the JASONs to evaluate any other approach to maintaining the arsenal other than SBSS, or whether big-ticket SBSS projects could take resources from stockpile surveillance and remanufacturing. DOE did not ask how

2

2/40.07
continued

many scientists and engineers were necessary to retain in the labs' nuclear weapons programs, with which skills, and DOE did not ask in detail about the nonproliferation impact of the SBSS program. Unbelievably, the JASONs were apparently not asked, nor did they volunteer, to evaluate the programs and projects proposed on the basis of cost.

In short, the DOE appears to have not asked any of the hard questions it should have asked to help set its programmatic priorities and overall funding level. Quite the contrary: it is difficult to see the above questions as anything but an invitation—indeed a requirement—to glorify SBSS, using the outline conveniently provided by DOE. The charge to the JASONs assured that their report would be positive and devoid of any detailed tradeoffs between policy options. And so it is.

While the narrow technical qualifications of the JASONs cannot be impugned, it is not obvious that the JASONs comprise a truly independent review. Many of the authors of this report have worked or still do work for institutions which receive substantial funding from the DOE.[3] Some are the recipient of awards from the DOE. Dr. Sidney Drell, chairman of this and other studies on related subjects for the DOE, works at the Stanford Linear Accelerator (SLAC), which receives some $180 million annually from the DOE. This is not to imply that Dr. Drell or any of the other authors of this report are dishonest. But it is difficult for any of us to provide an entirely dispassionate analysis when the funding, perhaps even the survival, of institutions to which we have devoted ourselves could be at risk.

Neither is it obvious that the JASONs have in every case carefully thought through, or sought expert advice on, some of their conclusions. An illustrative case concerns the nonproliferation impact of SBSS activities. When Dr. Drell was asked by Joe Cirincioni of the Campaign for the Non-Proliferation Treaty what scientific data he could provide to support his assertion that the National Ignition Facility (NIF) need not, in the eyes of other nations, compromise U.S. commitments under Article VI of that treaty, he replied that he had obtained no data—that he and the other JASONs had relied entirely on personal judgement and intuition for their conclusion in this area.[4]

Conversely, Jonathan Medalia of the Congressional Research Service reports that:

> Many nonnuclear nations...view a halt to all nuclear explosions of all types for all time as the *minimum* scope of a CTB [comprehensive test ban]. Some want to go further, restraining stewardship to cement shut the door to testing and encourage further denuclearization. For example, Indonesia would ban computer simulations of nuclear tests; Egypt, Germany, and Sweden would ban preparation for nuclear tests; and Iran, Nigeria, and Pakistan would close test sites. Nuclear states feel themselves to be on a treadmill of rising expectations...
>
> ...
>
> At the same time, a large stewardship program might jeopardize indefinite NPT [Nuclear Non-Proliferation Treaty] extension. Many nonnuclear states want the scope of a CTB drawn to eliminate the nuclear nations' *ability* to design, test, and

3

2/40.07
continued

> certify new nuclear weapons. These states may view a large stewardship program as preparing to pursue the nuclear arms race by other means, circumventing the spirit of a CTB.[3] (emphasis in original)

This information is widely available. We must assume that the JASONs simply weren't interested in it or didn't take the time to obtain it. Unfortunately, the JASON study is replete with unsupported judgements such as the ones Dr. Drell described to Mr. Cirincione.

Unlike the JASONs, we cannot hope to convince by mere prestige. Nor do we have their access to classified information—information which is always carefully selected as it is provided to them. Our comments therefore seek to point out inconsistencies and to draw the reader's attention to facts and testimony the JASONs may have overlooked. We urge the reader to look beyond the knowledge of physics that went into the JASONs' report and to face the policy choices to be made regarding the future of the nuclear weapons program.

<u>Overall Comments</u>

"Compensation" (note the pun) for the ending of underground nuclear testing is understood by the JASONs to be the "basic principle" of the SBSS plan, to be achieved by "improved diagnostics and computational resources that will strengthen the science-based understanding of the behavior of nuclear weapons" (p. 1). Yet when the subject of nonproliferation is broached a few pages later, the JASONs say that the SBSS program

> must avoid the appearance that, while the U.S. is giving up nuclear testing, it is as compensation introducing so many improvements in instruments and calculational ability that the net effect will be an <u>enhancement</u> of our advanced weapons design capabilities." (p. 17, emphasis in original)

It is not clear how the SBSS program can "compensate" on p. 1 and "avoid the appearance...[of] compensation" on p. 17. This contradiction is a fundamental theme underlying much of the JASON report and indeed much of the SBSS program. It reflects poorly on the thoughtfulness with which the JASONs approached their subject. This quote makes clear, as we will see again below, that the JASONs think any nuclear weapons research and development (R&D) effort—short of one giving the <u>appearance</u> of designing advanced new weapons—does not conflict with nonproliferation efforts.

While the JASONs do not want the SBSS program to "be <u>perceived</u> as an attempt by the U.S. to advance our own nuclear weapons with new designs for new missions" (p. 3, item 2, emphasis added), we find later in the report that

> Over time it may become desirable to introduce design changes in some components of the present stockpile...It will require considerable computational analyses of both primaries and secondaries in order to develop even a limited capability for redesign of warheads without proof-testing. (pp. 89-90)

4

2/40.07
continued

We have already seen elsewhere[4] how DOE, while publicly abjuring new weapons, is actually seeking to design and fabricate a new so-called "robust" warhead and has design teams working on several other concepts as well, some of which do indeed involve new designs and new missions.

So the "threefold" purpose of SBSS (p. 2) must really be expanded to "fourfold," with the additional purpose being to provide, to the greatest degree that is consistent with a CTB, the capability to certify new weapons. The Pentagon made this requirement crystal clear in its September 22, 1994 briefing on the Nuclear Posture Review, which included the following viewgraph language:

> DOD requirements to DOE:
> ...
> —Demonstrate capability to refabricate and certify weapon types in enduring stockpile
> —<u>Maintain capability to design, fabricate, and certify new warheads</u>
> ... (emphasis added)

This language is echoed by the JASONs on p. 12, where they assume that "The US nuclear infrastructure under the SBSS will retain a capability to design and build new weapons, which could be deployed should the need arise..."

Quite apart from this contradiction, it is not clear why it is necessary to "compensate" for the termination of underground testing, since: a) the reliability and especially b) the safety of existing nuclear weapons do not require such compensation, as is discussed elsewhere in depth.[5] Improved diagnostics and computational resources are certainly not necessary to maintain reliability or safety; maintenance of a small core of technical staff, with continuing investments in surveillance and a small remanufacturing capability would be effective for these ends. The purpose of a CTB is to end the testing of new weapons, not merely shift its location.

The JASONs regard a "strong" SBSS program as an "essential component for the U.S. to maintain confidence in the performance of a safe and reliable nuclear deterrent under a comprehensive test ban" (p. 3). Nowhere do they, however, specify just <u>how</u> "strong" the program should be, nor do they ever clearly state why particular SBSS elements are actually needed. The entire question of need is simply dismissed with a wave of the hand and an invocation of the mantra of safety and reliability.

The JASONs assume that the same aging warheads will need to remain in the stockpile for "at least several decades" (p. 1). It is not at all clear why this need be the case. Warheads can simply be rebuilt whenever their reliability falls below some desired level. Furthermore, the United States has rightly committed to eliminating all its nuclear warheads in Article VI of the Non-Proliferation Treaty (NPT). It is hard to understand why the JASONs see no conflict between keeping a nuclear stockpile for "at least several decades" and the clear language of the NPT. In this connection, note that their periphrasis of that Article on p. 18 bears shockingly little resemblance to the actual treaty language.[6]

5

2/40.07
continued

Finally, it is by no means clear that an "improved understanding of warheads" is necessary or desirable for U.S. or global security purposes. Knowledge is not free of costs, and investments in the U.S. nuclear weapons program will have a variety of serious costs: to the federal fisc, to the effectiveness of the world's nonproliferation regime, to the environment, and to every other kind of scientific pursuit. It is not knowledge, but wisdom, that is in short supply in the nuclear weapons business. The JASONs have not improved this situation.

<u>The JASONs' Chapter 2: Basic Assumptions</u>

Much has been made, in the JASON report and elsewhere, of President Clinton's July 3, 1993 statement that "we will <u>explore</u> other means of maintaining our confidence in the safety, the reliability and the performance of our own weapons" (emphasis added). Note that the President said "explore;" he did not say "we will establish, for the indefinite future, a Cold War level of funding for science-based stockpile stewardship"—which is how his statement is being taken by the JASONs and others in the nuclear weapons community. The next sentence in the President's speech has been ignored, by both DOE and the JASONs:

> We will also refocus much of the talent and resources of our nation's nuclear labs on new technologies to curb the spread of nuclear weapons and verify arms control treaties.

Unfortunately, there has been no such refocus. The attitude at the weapons labs is instead typified by a conversation recently overheard by a UNM professor between lab managers on an airplane flight in which the two gentlemen assured one another that they would "outlast" the Clinton administration's attempted refocusing.*

The JASONs assume that old, more "robust," stockpile designs could be introduced into the stockpile, apparently with modifications to allow more modern "engineering and manufacturing practices" (p. 12). It is far from clear that this would be acceptable to the military. The assumption that new or redesigned warheads should and will be introduced and built is one that pushes the cost of stockpile stewardship very high, both in dollars and probably also in reliability. It is entirely unnecessary.

Missing from this chapter and this report are any quantitative assumptions about the arsenal or any descriptions of the warheads it will contain. The JASONs say the arsenal will continue to decrease in number and variety—but how? Failure to specify their assumptions about the arsenal more closely makes the reader suspect that the SBSS program they review is independent of the stockpile and its real-world requirements and problems.

Since the criteria by which the JASONs evaluated the SBSS program (their Chapter 3) have been strongly criticized for their narrowness already, we turn now to nonproliferation concerns.

<u>The JASONs' Chapter 4: Nonproliferation</u>

The JASONs understand that

6

2/40.07
continued

> Ultimately, non-proliferation can only be successful if the NNWS [non-nuclear weapons states] are persuaded that their national security is better served without nuclear weapons than by possessing them (p. 19).

How can all these countries possibly be persuaded of this when the nuclear weapons states (NWSs) assert just the opposite for themselves—that nuclear weapons are <u>central</u> to their national security? These NWSs are of course not just armed with nuclear weapons, but also with qualitatively and quantitatively superior conventional weapons as well. Yet still they assert that nuclear weapons are indispensable. Nowhere do the JASONs face or even acknowledge the fundamental contradiction between their statement above and U.S. plans, not just to maintain its nuclear arsenal indefinitely, but to continually "improve" it, an effort the JASONs acknowledge, approve, and seek to facilitate.

The JASONs, in their rush to bless DOE's plans, have fundamentally misread the politics of nonproliferation. After squirming their way past the clear language of the NPT and failing to address the fundamental contradiction of U.S. nonproliferation policy, they limit their concerns about the proliferation impact of SBSS to basically just one:

> One worrisome aspect of the SBSS program is that it may be perceived by other nations as part of an attempt by the U.S. to continue the development of ever more sophisticated nuclear weapons. (p. 19)

But this is hardly the entirety, let alone the root, of the problem. They compound their error with arrogance in the next sentence:

> This perception is particularly likely to be held by countries that are not very advanced technologically since they are less able to appreciate the limits on advanced weapons design that a lack of testing enforces.

Yet on the same page, the JASONs confirm this "perception":

> <u>While the potential for future developments cannot be excluded</u>, the SBSS activities should not be <u>interpretable</u> as laying the basis for the development of newer generations of nuclear weapons...(emphasis added)

It appears that the only policy consistent with all these confused statements is a policy of deception, which is the height of folly. Such deception would have to be aimed at the American people as well as other nations, and cannot succeed even temporarily. Clandestine vertical proliferation would be implicitly or explicitly used as an excuse by some horizontal proliferant some day, and would, by its very nature, threaten the integrity of the nonproliferation regime, which requires clarity and transparency to work. Such a policy would be very costly to U.S. national security.

The impacts of the SBSS program on nonproliferation efforts are certainly not confined to problems caused by the "perception" or "interpretation" that the U.S is engaged in further

7

2/40.07 continued

weapons development. This was thoroughly discussed at the September 8 workshop mentioned above, with Dr. Drell in attendance. It is worth reviewing the whole issue briefly from first principles.

The basic goal of nonproliferation, as it is perceived officially in the United States, is one of preventing other countries from acquiring nuclear materials and, especially, nuclear weapons. Most countries, of course, have no interest in taking on the dangers, cost, and opprobrium of nuclear weapons. But it is not the Danish bomb that is of concern. To effectively prevent proliferation in every case, even the difficult ones, a variety of tools are required: international treaties, national laws, bi- and multi-lateral agreements, and unwritten norms—all of which must, to be effective, carry with them an implicit or explicit possibility of political, economic, criminal, or military sanctions, directed against countries, companies, or individuals as appropriate. Positive rewards for compliance with nonproliferation norms also can be and have been used.

These potential sanctions, in their variety and comprehensiveness, are the real deterrent to proliferation in the most important cases. They must be credible to work. They are not likely to be credible if they are not very broadly based among nations, especially among the nuclear powers. And surely it is difficult to get very broad-based cooperation in enforcing tough nonproliferation sanctions if we ourselves violate the norms we would enforce. We cannot get treaties implemented by others that we do not follow or intend to follow. Nor can we easily enforce, except at great and often prohibitive cost, provisions of treaties—like the NPT—that we ourselves do not honor.

Let's get real: we will not stop nuclear proliferation unless we have tough laws and effective sanctions, actively supported by nearly every nation involved. This requirement is incompatible with our ongoing violation of the NPT, and with the maintenance and "improvement" of our own large nuclear arsenal, especially as this arsenal is accompanied by a declaratory policy of possible first use and configured to make this threat real.

The conflict between U.S. nuclear policy, including SBSS, and U.S. interests in nonproliferation is therefore much more fundamental than the perception that we might develop more advanced nuclear weapons. This perception would, of course, simply make our nonproliferation and credibility problems even worse, while advanced weapons and weapons science would provide no deterrent against a proliferant threat.

The JASONs faulty and superficial analysis of the nonproliferation problem leads them to a questionable recommendation for relieving the well-deserved "suspicions" of the non-nuclear weapons states. The JASON approach: declassify most of the SBSS program.

This strategy attempts to remove the potential complaints of the non-nuclear weapons states--which could, after all, have negative ramifications for SBSS funding—by simply inviting them to the weapons technology table. Any problems concerning proliferation of technology out of the SBSS program would be solved, in effect, by a redefinition of proliferation. Proliferation done officially wouldn't count anymore.

8

2/40.07 continued

History provides a warning: in every case since 1950, programs to build fission bombs have been conceived, hidden, and matured within the womb of fission energy programs. If we follow the JASONs' advice, we may have fusion weapons being developed under the cover of fusion energy programs—using data, codes, and techniques developed and disseminated in and by the U.S.

Aside from the rationale the JASONs provide, another political motivation for the declassification they propose is that it will to create a broader user community—and hence a broader constituency—for the stewardship program and its funding. This is particularly the case for NIF.[10]

Of particular concern is the possible declassification of all but "critical" parts of the weapons codes (p. 21) in order to allay the "suspicions" of the non-nuclear weapons states. Even if these suspicions did comprehend the entire nonproliferation impact of the SBSS program, which they don't, why would the declassification of technical arcana allay anything? More to the point would be the declassification of policy and planning documents, such as the nuclear stockpile memorandum.

3/40.06

Looking at the problem of nonproliferation impacts of the U.S. nuclear weapons program as a whole, non-nuclear states' concerns—which are a matter of public record, not merely a possibility—could be better addressed by:

- a stronger and more successful effort toward a CTB;
- a change in U.S. declaratory policy on first use;
- the elimination of tactical weapons;
- bilateral reductions in strategic forces below START II;
- a ban on weapons-usable fissile material production;
- a limit on stockpile stewardship to the minimum that is actually needed; and
- opening U.S. weapons facilities to credible domestic and international inspectors, perhaps from Canada, Australia, or other appropriate non-nuclear-weapon states.

To succeed in its nonproliferation goals in the long run, the U.S. needs to accept the same level of transparency that it demands of other nations. Publishing major portions of U.S. nuclear weapons codes has not exactly been on the top of anybody's non-proliferation wish-list, however.

The JASONs assert that most new proliferators could derive no immediate benefit from these codes. Even if this is true, what about China, or Israel, or Japan—or India or Pakistan, for that matter? Wouldn't the knowledge that scientists from these countries get by using the NIF and its related computer codes train them to do secondary physics, just as U.S. scientists are trained? Or perhaps they could take the now-enclassified codes and modify them for weapons analysis, saving themselves person-years of work on the way to deliverable boosted fission or thermonuclear bombs. When the JASON declassification proposal was brought up in the context of NIF at DOE's September 8, 1994 NIF workshop, a senior DOE classification officer rose to vigorously contest the appropriateness of declassifying information from experiments at

9

3/40.06 continued

temperatures and pressures at or approaching those of a nuclear explosion, data which would definitely be useful in the design of weapons.[11]

International scientific cooperation is in general a very good thing. But scientists at the weapons labs of the various countries have more in common with each other than they do with their respective governments, as Dr. Hecker at Los Alamos National Laboratory (LANL) once remarked about Russia. The U.S. weapons labs have already been the source of a great deal of knowledge for foreign weapons programs.[12] Why open the door wider?

<u>The JASONs' Chapter 5: Stewardship Program Elements</u>

To provide a justification for enhanced SBSS capabilities, the JASONs refer on p. 24 to the "limited" number of cases where nuclear testing was needed to remedy or validate the remedies to stockpile problems of the past. These cases--fifteen in number--are extensively discussed by senior Livermore weapons scientist Ray Kidder in his 1987 study of weapon reliability under a test ban, and his conclusions--(1) that these resulted from rushing inadequately tested designs into the stockpile, and (2) that these problems are all lessons learned, i.e. of historical, but not predictive, importance--still stand.[13] As discussed elsewhere at length, there are no known safety or reliability problems in the U.S. arsenal.[14]

Certainly we need to retain, at least for now, some nuclear weapons scientists, as the JASONs point out on p. 24. It is not clear that we need to retain the <u>thousands</u> of scientists, engineers, and technicians now working in this program. If the intent is merely to retain our existing knowledge and expertise about nuclear weapons, there are cheaper and less provocative ways to do it than SBSS, namely by emphasizing retention of unique knowledge in archives and in a relatively few staff members. The emphasis should be on uniqueness, not quantity.

<u>The JASONs' Chapter 6: Hydrotesting</u>

The JASONs' treatment of hydrotesting and the proposed Dual-Axis Radiographic Hydrotest (DARHT) facility at LANL provides further examples of their lack of careful analysis. The JASONs believe that this facility will provide "capabilities of importance" (p. 4) to the SBSS program. In fact, they appear to offer unqualified support for <u>all</u> the hydrotest upgrades planned for this century, drawing the line at the Advanced Hydrotest Facility planned for the out years. But nowhere do they say <u>why</u> these capabilities are important.

In Kidder's 1987 paper we find the following.

> During the past decade [1977-1986], new boosted primaries have been designed and developed by the weapons laboratories...performed satisfactorily the very first time they were tested, the observed yield in no case falling short of that expected by more than...(See Tables H1 and H2 and Fig. H1) The one new primary that failed was of a more complex, less predictable design than the others. This primary was subsequently redesigned, tested, and failed again. None of the primaries in the existing stockpile employ...

10

3/40.06 continued

> This experience demonstrates that the ability of the weapons labs to predict the performance of newly designed, as yet untested, boosted primaries of the kind currently in stockpile is indeed impressive--there were no significant surprises. This could hardly have been the case had these primaries been sensitive to differences that inevitably exist between the weapon configuration calculated and the weapon tested.[15]

This "impressive" capability existed between seven and seventeen years ago, in the <u>design</u> of <u>new</u> primaries. It is not clear why it is not enough to simply <u>maintain</u> <u>existing</u> primaries today.

Kidder's last point, which speaks to the insensitivity of primary yield to minor variations in manufacture, was corroborated by a manager (name withheld) at Los Alamos, who told Dr. Kerlinsky of the Galvin Panel that deliberately "off-spec" pit(s) had been manufactured at Los Alamos and tested successfully at the Nevada Test Site.[16]

Then why are all these new facilities needed? The JASONs answer this question on p. 27.

> Such information [from hydrotests integrated with code development] will lead to greater confidence in our understanding of weapons and, perhaps ultimately, <u>to a willingness to make relatively simple changes in primary design without underground tests</u>. (emphasis added)

Once again, it is not simple maintenance of a deterrent through remanufacture of existing weapons that is driving the "acknowledged need" (p. 28) for increased radiography capability, but the desire to design and certify new weapons in the absence of nuclear tests. It is the "design community" (p. 29) that has this "need," not the stockpile surveillance program, and certainly not the nation. The surveillance program has never depended upon hydrotesting, let alone advanced hydrotesting, to do its job.

Overall, it is far from "clear" that "improved hydrotesting is crucial to continued confidence in the safety and reliability of nuclear primaries" (p. 32). As far as reliability is concerned, this statement is contradicted by the data collected and presented by Kidder. And in Kidder's paper, the JASON opinion is contradicted by that of Hans Bethe, Carson Mark, Norris Bradbury, Richard Garwin, and Andrei Sakharov, all of whom felt that simple remanufacturing--<u>without</u> advanced new hydrotesting facilities--was completely feasible.[17]

4/21.07

<u>The JASONs' Chapter 7: The National Ignition Facility</u>

The JASONs find the NIF "exciting" (p. 37). They are crazy about it. And crazy is hardly too strong a word, for they quickly gush: "Nuclear weapons operate under conditions...of great interest to astrophysics." Yes, no doubt this is true, but it is hardly the central point, and it is not reassuring to hear it put quite that way. <u>Avoiding</u> the "operation" of nuclear weapons is what this report is, or should be, about. In their passion for hotter hohlraums,[18] they neglect the human. It is not the JASONs' chilling objectivity which is distressing here, but their chilling <u>lack</u> of objectivity. Their enthusiasm is about physics, not nuclear weapons policy. And the

11

4/21.07 continued

fact that nuclear weapons "operate" only with unimaginable horror is not a noticeably important factor in the JASONs' thinking about NIF.

Their discussion of NIF's importance as a "proof-of-principle" experiment appears overblown. Ignition of deuterium-tritium pellets has already been achieved in experiments at the Nevada Test Site. The NIF would not so much demonstrate the principle as demonstrate--what? That inertial confinement fusion (ICF) is feasible? No, not this either. Perhaps this: that ICF can be funded, papers can be published in the subject, and careers can be pursued by real people with real ambitions. ICF is, by all accounts, a remote and unlikely source of energy, one that has already been superseded by proven renewable sources that do not share its enormous costs, its environmental and social externalities, its proliferation problems, or its uncertainties.

The attainment of ignition is not the major problem in developing fusion energy, in any case. It is the engineering and materials problems in any practical ICF system that are more likely to be insurmountable at anywhere near a realistic life-cycle cost per unit energy produced.

While the JASONs downplay the uncertainty of ignition, some scientists at both LLNL and LANL do not.[8] The margin of uncertainty in the minimum energy needed to overcome instability and other difficulties may be significantly larger than the 1.8 megajoules NIF will deliver. Therefore, the statement on p. 41 that "...the attainment of ignition in NIF <u>will</u> demonstrate..." seems too confident and a little premature. It betrays the lack of objectivity that concerns us throughout this report.

There is no question that NIF could provide interesting experiments in several fields of physics. But a closer look at the JASONs' zeal for creating a user community for NIF (pp. 43-47) goes far beyond science to reveal the JASONs as a special interest lobby, calling for an active sales effort for the NIF project. They wrap up this four-page discussion by saying that:

> ...the growth of this nascent enterprise [user communities] needs to be further encouraged by way of the vigorous dissemination of information about the capabilities and accomplishments of the ICF program and about the scope of activities to be undertaken at the NIF...if scientific goals are to be a significant component in the justification of the construction of the NIF (as we strongly believe they should be), then the ICF community bears a special responsibility in fostering an "out-reach" program...Succinctly stated, the NIF represents a credible and powerful opportunity to strengthen otherwise disjoint efforts in the weapons, the ICF, and the university communities. (p. 47)

Why are the JASONs so interested in promoting NIF? Why are they, here and elsewhere, so preoccupied with the "credibility" of cross-linking the nuclear weapons community with ICF and university science? Why is it necessary to encourage a "vigorous" program of disseminating information about NIF--can't scientists decide for themselves whether it can help them? Why is it so desirable to recruit the ICF "community" to support NIF? The simple truth to which these questions point is that, when it comes to NIF, the JASONs themselves view their role as promotional, not objective.

The weapons applications of NIF, which the JASONs leave to last, are not convincing. There is no need to quantify the "effects of low tritium concentration" (p. 49) and no need to study cracked radiation cases (p. 50). Replacing the latter is cheaper than studying whether or not to replace them, and retiring them is the safest and cheapest solution of all.

The defects of the JASON analysis of the nonproliferation impacts of NIF have been discussed above. It is important to make one addition here. Contrary to what the JASONs say, "balancing non-proliferation objectives of the United States with responsible stewardship under a[n] SBSS program" (p. 50) is <u>not</u> the problem. Given that weapon safety and reliability "problems" are not difficult to solve and the requirement for an effective deterrent rather easy to meet, responsible stewardship can only be defined as that form of stewardship which best supports nonproliferation goals. Stewardship should be a subset of nonproliferation efforts.

<u>The JASONs' Chapter 8: LANSCE, Stockpile Surveillance, and Materials Science</u>

The JASONs assume that weapons will remain in the stockpile far beyond their lifetime, and therefore will require intensive study of issues relating to aging. It is not clear why this need be the case.

5/40.36

This chapter, like most of the others, does not really begin with the needs of the stockpile surveillance program but with what a particular facility--the Los Alamos Neutron Science Center (LANSCE)--might be able to do for the program. Again, the approach is one of a major facility looking for missions to justify it, and several possibilities are suggested. The JASONs are lukewarm, however, about these possibilities and make any endorsement of LANSCE contingent upon several "ifs."

The claim that a 1 mm resolution in neutron radiography would "perhaps" be enough to see cracks, etc. in pits seems optimistic (p. 61). A 1-mm crack is very large. It would be better to begin with, or at least mention, the needs of the program rather than the capabilities of the projects already being promoted.

<u>The JASONs' Chapter 9: Pulsed Power</u>

There is no real need for any of these facilities for stewardship of the existing stockpile, and the JASONs have not provided any justification for them. Further weapons effects testing, beyond what is already known, is a relic of warfighting strategies and should be dropped from the stockpile stewardship program. Likewise, the (further) study of cracks in implosion need not be of particular interest. If one wants reliable weapons of mass destruction, replace the cracked ones. Better still, help meet our treaty obligations and retire them. And why not? The START II strategic arsenal of 3500 weapons is enough to create a 5-psi overpressure spike--a lethal amount--over most of the area of <u>all</u> the cities over 500,000 people in the world. To deter one or two countries requires a very tiny number of weapons.

5/40.36 continued

The JASONs' Chapter 10: Special Nuclear Materials (SNM) and Processing

This chapter does not share with the preceding and succeeding ones the assumption that new weapon designs are inevitable and desired; in fact, it assumes quite the contrary.

> ...the primary—if not the sole—nuclear weapons manufacturing capacity that must be provided for in an era of no nuclear testing is the remanufacture of copies of existing (tested) stockpile weapons...the ultimate goal should be to retain the capability of remanufacturing SNM components that are as identical as possible to those of the original manufacturing process and not to "improve" those components. This is especially important for pits...(p. 81)

If nuclear weapons must be manufactured at all, this is the best way to do it.

The JASONs point out that it is the finished pit that must be the same as the proof-tested model, not every manufacturing detail or process along the way. And they suggest that a production capacity of "ten or so" pits per year is adequate for the present time (p. 85).

This is a scale of activity consistent with practical maintenance of an arsenal. While it does not imply rapid drawdown of that arsenal, as we might wish, this approach is compatible with such drawdown. It is highly unlikely that a smaller scale of effort would meet current political realities. In any case, Los Alamos already has a nascent capacity to manufacture pits at least ten times this great.[3]

The JASONs do not take up the issue of how best to make tritium. They correctly point out that a number of options exist for procuring this material, and that any need for it may be postponed by further stockpile reductions. They appear to err, however, in saying that

> Dismantlement of U.S. nuclear weapons under START II and correspondingly large reductions in tactical nuclear weapons will result in a recovered amount of tritium adequate to supply the needs of the remaining operational stockpile until close to the end of the first decade of the twenty-first century. (p. 83)

The best information available to us strongly suggests that current supplies of tritium are adequate to maintain the larger START I, not just the START II, arsenal, until approximately 2014.[4]

The JASONs conclude this chapter by saying that

> Having an open research program on the physics and metallurgy of uranium and plutonium is highly undesirable from the perspective of nuclear proliferation. Consequently, we see the SNM manufacturing component of the stewardship program as a narrowly defined, sharply focused engineering and manufacturing curatorship program. (p. 85)

14

5/40.36 continued

There is absolutely no reason that this excellent, common-sense approach cannot be applied to the other elements of the stewardship program as well, thus eliminating the "need" for expensive new SBSS facilities with their attendant proliferation impacts.

In fact, if this approach is to stand at all, it logically must be applied to the stewardship program as a whole. For what is the point of designing improvements in weapons if it is decided in advance not to make them? And making them would be a bad idea, for the sound reasons the JASONs articulate in this chapter. So not just the assumptions, but the conclusions of this chapter—with which we find little fault--are quite inconsistent with the rest of the report.

The JASONs' Chapter 11: Advanced Computing for Stewardship

2/40.07 continued

Aside from the dangerous assumptions incorporated into this chapter on p. 89 (quoted on page 4 above) and what may be applied from our other comments to the question of the purpose and need for weapons computing advancements, we offer few additional comments.

Obviously, the proliferation dangers of weapons codes that have been brought up to date, documented properly, and translated to run on inexpensive and universally-available computers are increased in the event of any security breach. This is a specific case of a general rule: the more weapons activities that are going on, and the more open these activities are, the greater the likelihood that somebody will steal or be given something important.

Concluding Remarks

5/40.36 continued

The JASONs are clearly enamored with science, and they clearly want to see the weapons labs fully funded to do work they consider interesting. Their approach to the issues surrounding stockpile stewardship is too narrow and too vague, however, to be of much use in evaluating even the technical questions, let alone the policy and nonproliferation questions. It is hoped that the DOE will seek further clarification of these issues before continuing its marketing of science-based stockpile stewardship, based as it is upon specious assumptions and the questionable goals of keeping weapons scientists busy and producing new weapon designs. These activities are costly and dangerous to this country and others.

6. See "Redefining Stockpile Stewardship," Greg Mello for Tri-Valley CAREs, Livermore, CA.

7. Ibid.

8. The actual language of Article VI of the NPT is: "Each of the Parties to the Treaty undertakes to pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament, and on a Treaty on general and complete disarmament under strict and effective international control."

The JASONs paraphrase this as "The NWS [nuclear weapons states] will reduce their nuclear weapons stockpiles and will reduce, over time, the reliance of their national security policy on nuclear weapons, thereby decreasing the discriminatory nature of the non-proliferation regime" (p. 18). The legal commitment made by the U.S. and the other nuclear powers to nuclear disarmament is entirely discounted by the JASONs.

Aside from this, the JASONs' "interpretation" is illogical: if a NWS like the U.S. decreases its arsenal to only 1000 or even 100 nuclear weapons, as versus zero for a non-nuclear weapons state, this does virtually nothing to "decrease[e] the discriminatory nature of the non-proliferation regime."

9. Denise Fort, personal communication.

10. It is not just the JASONs that recognize the importance of expanding the political constituency of the nuclear weapons program. In 1993, Dr. Immele of LANL waxed glowingly about the new corporate "sponsors" of the LANL weapons program in his "State of the Nuclear Weapons Program" address in December, available in video from LANL. Numerous other examples could be provided.

11. Marylia Kelley, personal communication. In the case of the NIF, and the inertial confinement fusion (ICF) program in particular, the Arms Control and Disarmament Agency (ACDA) recognized these direct proliferation dangers as early as 1980 in their FY 1981 Arms Control Impact Statements (written for the committees on Foreign Affairs and Foreign Relations of both houses of Congress). As they put it then, "If an advanced non-nuclear weapon state with an ICF research program undertook a nuclear weapon program, it might subsequently be able to move more quickly to develop boosted fission and thermonuclear weapons than would otherwise be the case."

The subject of direct proliferation impacts is discussed more fully in Mello, op. cit.

12. For examples, see William E. Burrows and Robert Windrem, Critical Mass: The Dangerous Race for Superweapons in a Fragmenting World, Simon and Schuster, NY, 1994.

13. Ray Kidder, "Maintaining the U.S. Stockpile of Nuclear Weapons During a Low-Threshold or Comprehensive Test Ban," LLNL, 1987, UCRL-53820, p. 25.

14. Mello, op. cit.

15. Kidder, op. cit.

16. Dr. Dan Kerlinsky, personal communication.

17. These men all speak with great authority on this issue. Nobel Laureate Hans Bethe directed the Theoretical Division at Los Alamos during the war and has consulted at LANL up to the present day; Carson Mark was his successor and directed that Division for 26 years; Norris Bradbury was Oppenheimer's successor and directed Los Alamos for 25 years; Richard Garwin has been a consultant to Los Alamos since 1950 and is highly regarded for his analysis of a range of defense issues; and Andrei Sakharov, preeminent among Soviet weapons designers, was responsible for the independent development of the Soviet thermonuclear bomb.

18. *Hohlraum* is a German word which means to physicists what "black body" does in English: an idealized non-reflective cavity which radiates energy in accordance with its temperature. The interior of a nuclear weapon, and the hollow target cylinder at NIF, resemble and are called hohlraums.

19. It is best not to say who, because even so senior a scientist as Dr. Steven Younger at LANL has already been called on the carpet by Assistant Secretary Reis for his true statement that NIF has nothing to do with safety of nuclear weapons, made at the September 8, 1994 DOE NIF workshop.

20. The original design specifications of Building PF-4 of TA-55 at LANL were reported by John Fleck of the Albuquerque Journal on December 8, 1993. In 1978, PF-4 had a capacity of 100 kg Pu per month for casting and machining, or about 20 weapons/month. Since then, occupational radiation exposure limits have decreased from 5 rads/yr to 2 rads/yr, and PF-4 has been reconfigured, both of which decrease this capacity, according to LANL.

A presentation by Larry Woodruff of LLNL to the Galvin Panel on August 8, 1994 entitled "Downsizing the Capacity of the Nuclear Weapons Complex" shows a capacity for making 150 pits/yr in the downsized complex, i.e. at LANL. While LLNL now has the capacity make pits, the presentation to the Galvin Panel, along with interviews with LLNL personnel by Dr. Kerlinsky of that Panel, make it clear that LLNL anticipates transferring its pit manufacturing technology to LANL.

The LANL FY1995-2000 Institutional Plan says on p. 51 that LANL's Pit Rebuild Program will be capable of building pits for W88 warheads "by FY1996."

21. The statement of Dr. Harold Smith, Assistant Secretary of Defense for Atomic Energy, to the House Appropriations Subcommittee on Energy and Water Development, March 15, 1994 contains the following.

> The Nuclear Weapons Stockpile Plan, which outlines specific requirements for the nuclear weapons program...requires an active nuclear stockpile that supports the START I limits through 1999 and then transition to START II in subsequent years. ...[The Plan requires the U.S.] to retain the capability to reactivate weapons from the inactive stockpile if necessary, to maintain a policy that provides an assured supply of tritium...
>
> In the absence of a new source, in [deleted] the U.S. may not have sufficient tritium to support the nuclear weapons stockpile and required reserves consistent with START I commitments...The current goal is to make a decision on a new source for tritium in FY95 with initial funding for the development of that source beginning in FY96." (pp. 737 and 741, Vol. 6, Energy and Water Development Appropriations for 1995, emphasis added)

In his oral remarks that day, Dr. Smith emphasized that the U.S. must be able "to return to START I in the 21st century" (Ibid, p. 415). This cannot be done without a tritium supply consistent with a START I arsenal.

Dr. Victor Reis, Assistant Secretary of Energy for Defense Programs, shed additional light on the subject during that same hearing in response to a question:

> If one assumes...that a new [tritium] facility is to be built, then based on the current stockpile plan and the conservative view that a new tritium production source could take as long as 15 years to produce new tritium, a funding decision would be necessary in FY1996. That would allow the facility to be in production 3 years before strategic reserves of tritium are exhausted. (Ibid, p. 458)

Congressman Myers was hearing different dates from DOE and DOD regarding the acquisition of a new source of tritium, and asked for clarification. Reis gave an enigmatic reply, then Smith said, "There is plenty of discussion going on between the two Departments, between Dr. Reis and myself. The driver here is the assumption on whether or not we want to have the ability to maintain or return to levels consistent with START I." (Ibid, pp. 423-424, emphasis added)

It appears that there is adequate tritium to support a START I arsenal until 1996+15 years for construction+3 years, i.e. until 2014. The "START II arsenal" appears to include the capacity to bring enough reserve weapons back into the active arsenal to reconstitute a START I force level.

MEMORANDUM

From: Marylia Kelley, Tri-Valley CAREs
Subject: Arms Control Disarmament Agency analysis of Inertial Confinement Fusion

Last spring, Pierce Cordon of ACDA (and head of the "backstopping" committee on the CTB negotiations) suggested to me that I ask Livermore Lab for a copy of an analysis he did at ACDA on ICF. I have just received that analysis. I think this document will be of interest to you.

While the analysis was submitted to Congress in May 1980, much of it is surprisingly relevant today. Moreover, advances in ICF and world changes since 1980 have exacerbated many of ACDA's concerns (as well as adding new issues).

1/21.12

ACDA raises the concern that "others may be attracted by the peaceful 'cover' ICF provides for weapons-related research and development" (page 474). Further, on the same page, ACDA cites "...perceptions by non-nuclear weapons states of the potential value of ICF research to nuclear weapon states could affect our arms control policy objectives."

ACDA speaks directly to the usefulness of ICF research to nations with technological sophistication in speeding their ability to achieve boosted fission and/or thermonuclear capability. For example, ACDA says, " (an advanced state) might subsequently be able to move more quickly to develop boosted fission..." (page 471). This concern is raised in several places.

Long-range ACDA concerns include the proliferation promoting aspects of a fusion-fission hybrid reactor, which would breed, for example, plutonium 239 in a blanket of uranium 238 (page 472 and elsewhere). That tritium will be bred from a lithium blanket is taken as a given by ACDA, and is of some concern to the agency as well.

This document raises several of the same concerns as those voiced by Tri-Valley CAREs and others. I am not happy that in the approximately 18 hours of "round table" discussion we have had with LLNL on the proposed NIF, no one from LLNL has put this analysis on the table. It is only because I was at a conference with the report's principal author from ACDA that I even knew to ask for it. And, it is only through repeated requests that I got a copy.

INERTIAL CONFINEMENT FUSION

I. INTRODUCTION

This Arms Control Impact Statement addresses the Department of Energy (DOE) program in inertial confinement fusion (ICF) research.

The bulk of US ICF research and development (R&D) is carried out at Lawrence Livermore National Laboratory (LLNL), Los Alamos National Scientific Laboratory (LANSL), and Sandia National Laboratories Albuquerque (SNLA) which conduct nuclear weapon research as well as non-weapons energy research for the DOE. Supporting work in ICF is being conducted at Brookhaven, Argonne and Lawrence Berkeley Laboratories, at the Naval Research Laboratory, KMS Fusion, Inc., and the University of Rochester. The DOE ICF research is supported by Defense Program funding and has been justified as having application to some aspects of nuclear weapon technology, and potential longer-term application to civil energy production. A large share of the current program effort is directed toward development of high-energy, short-pulse lasers and particle beam sources. This effort is largely unclassified. Some of the target design and experimental work is classified because it utilizes still classified nuclear weapon-related information and technology. Supporting technologies, such as target fabrication, system studies and diagnostics, are

(460)

similarly classified [deleted].

[Deleted]. The open (visible) ICF program in the Soviet Union has suffered numerous setbacks in recent years [deleted]. Japan has a rapidly expanding and advancing laser fusion program; [deleted]. Other countries doing research in ICF include Argentina, Canada, China, France, FRG, Israel, Poland, Spain, and the UK.

At the time of the 1975 Non-Proliferation Treaty (NPT) Review Conference, the Swiss raised questions about ICF research. The US responded by declaring that in its view certain types of ICF energy sources* do not constitute nuclear explosive devices within the meaning of the NPT. [Deleted].

---

* Identified as "involving nuclear reactions initiated in millimeter-sized pellets of fissionable and/or fusionable material by lasers or by energetic beams of particles, in which the energy releases, while extremely rapid, are designed to be, and will be non-destructively contained within a suitable vessel." For full text, see page 12.

[Deleted].

II. PROGRAM DESCRIPTION

A. The Concept.

Inertial confinement is a concept for attaining the density and temperature conditions that will produce nuclear fusion by use of lasers or other high power sources to compress and heat small pellets containing fusionable fuel (deuterium and tritium, isotopes of hydrogen denoted by D and T). If a properly shaped pulse of sufficient energy can be delivered to the pellet, the density and temperature should become high enough for fusion or "burn" of a significant portion of the fuel to occur before it is dispersed. The energy thus released is in the form of fast neutrons, X-rays, charged particles, and debris, and can be used in much the same way as the energy output of any other fusion (or fission) process. Specifically, the energy could be captured and converted into heat energy to drive electric generators. Capture of neutrons by a lithium or lithium compound blanket would also produce tritium, which could be recovered from the blanket material and used as fusion fuel or for other applications.

Another scheme for energy production which could be used with either ICF or other neutron producing processes would use thorium-232 or uranium-238 isotopes in the blanket. Capture of neutrons would lead to creation of the fissile isotopes, uranium-233 or plutonium-239. These isotopes could be separated from the remainder of the blanket material and used as fuel for nuclear fission power reactors or for nuclear weapons. This concept of energy production is termed "hybrid" since it utilizes both nuclear fusion and fission processes. Other possible applications include hydrogen production by radiolysis and process heat.

[Deleted].

B. Program Status.

A short pulse of high energy is required to compress and heat the fuel for ICF. Sources for this energy which are now being investigated include lasers, electron beams, and beams of light or heavy ions. The facilities at LLNL, KMS Fusion, Naval Research Laboratory and Rochester use glass lasers; those at LANSL use CO_2 gas lasers; and Sandia uses pulse power generators for both electrons and light ions. Other groups at the Argonne, Brookhaven, and Lawrence Berkeley laboratories are investigating heavy ion beam concepts.

Most US and foreign experimental data to date have been obtained using laser beams. The LLNL and LANSL groups have constructed large facilities for amplifying, shaping, and focusing high-power laser pulses, and have succeeded in releasing small amounts of fusion energy. The energies produced have been much less than the energy consumed by the lasers, and both groups are still years away from the "scientific breakeven" point, at which the energy produced by fusion reactions equals the beam energy used to cause the reactions. Forecasts are that scientific breakeven may be reached within six to ten years. Significant civil energy production by ICF is estimated to be at least 40 years away if the concept proves practical for this purpose.

Until recently, experimental evaluation of pellet design concepts has been limited largely to energy absorption studies and very small pellet yields at very low power compared to practical fusion energy requirements. The lasers and particle beam generators now available are being used to initiate studies of energy absorption and transport and fuel compression to many times liquid density. Consideration of the physics involved, experimental results and use of calculational codes (i.e., computerized mathematical models) have identified a number of system concepts as promising.

Much of the evaluation in the US of fuel pellet design and performance has been done using LASNEX, (deleted). Some earlier, simpler programs developed in the weapon program have been declassified, are in the public domain, and therefore are available for use in ICF research or for any other purpose. Some examples include hydrodynamics programs and neutron transport programs.

Compared with laser system development and fuel pellet design, relatively little work has been done so far on the problem of containment and energy conversion. These problems will be important in any eventual practical applications of ICF. Some possible approaches are under investigation, but intensive work awaits convincing demonstration of the basic ICF concept.

Within the past two years the HELIOS carbon dioxide laser at LANSL and the PROTO II electron beam source at Sandia

have come into operation. Encouraging indications of ablative compression of targets have been obtained in experiments on SHIVA (LLNL) and HELIOS (LANSL). The 6-beam Nd:glass laser at the University of Rochester has become operational; when completed as a 24-beam system, it is to serve as a national users facility.

In the past, gas targets have been compressed over 1000-fold, and, during the past year, compressions to 50-100 times liquid density have been attained with laser beams. Light ion beam power densities of over 10 terawatts per square centimeter on target have been achieved. In FY 1981 and following, experiments will be conducted to achieve higher compressed densities and to develop the pellet physics scaling laws leading to breakeven. Ultra-violet and visible wavelength laser target experiments will also be done to provide greater understanding of the effects of laser wavelength on target compression and guidance for the development of scalable lasers for fusion. Electron and light ion beam sources will continue to be developed and used to confirm beam transport and focusing approaches for electrons and light ions.

In addition to the carbon dioxide and glass lasers and electron and light ion pulsed beam sources referred to above, visible-to-UV wavelength lasers and heavy ion beams are considered as candidates for fusion energy drivers. Short wavelength lasers will be selected for scaling up to about the one kilojoule level. Laser selection will be heavily influenced by visible and UV wavelength target experiments. Induction and radio frequency linear accelerators, used for accelerating heavy ions, will be developed for an Accelerator Demonstration Facility to be built in the FY 1982-84 period.

C. Possible Applications.

The lasers currently being used in ICF research are also being used to make measurements of the physical properties of materials in regions of high temperature and pressure. These measurements are applicable to the modeling of some aspects of nuclear weapon performance and of nuclear weapon design.

Study of the behavior of ICF pellets will have potential applications to the study of nuclear weapon physics, the modeling of some aspects of nuclear weapon performance, and the development and proof of some features of computer codes for nuclear weapons.

In the future, if sufficiently large nuclear energy releases can be obtained from pellet fuel burn, it should be possible to simulate some of the effects of nuclear weapons (now simulated using other techniques) for the study of the vulnerability of weapon system components to such effects. Such nuclear energy releases may also have limited applicability to the simulation of some of the phenomena resulting from atmospheric and high altitude nuclear explosions.

If ICF proves practical as a source of energy its principal civil value would be to provide electrical or thermal energy or to breed fissile fuel, thus reducing concern about energy shortages.

III. STATED MILITARY REQUIREMENTS

There are no stated military requirements.

IV. FUNDING ("then year" $ in millions)

	FY 79	FY 80	FY 81
Operating	104.0	107.8	158.2
Equipment	8.2	8.5	11.0
Construction	31.0	28.5	31.5
Personnel Resources	.9	1.1	1.3
TOTAL ICF	144.1	145.9	202.0

V. ANALYSIS

A. Consistency with Arms Control Policy.

The US has not considered certain types of ICF R&D to be inconsistent with US nonproliferation policy. However, classified ICF work in the US and other nuclear weapon states has drawn from the theory, experiments, and technology of their nuclear weapon programs. [Deleted]. Concerns exist within the French, UK, US, and USSR governments that an ICF R&D program could be a precursor to an advanced nuclear weapon program insofar as non-nuclear weapon states used ICF work to acquire the information, technology, trained people, and facilities applicable to nuclear weapon development.

There has been a non-programmatic event which may significantly alter the implications of ICF for non-proliferation. This event is the recent public disclosure (in spite of rigorous executive branch efforts) of certain information on the basic design principles of thermonuclear explosives which occurred with the publication of a letter by Charles Hansen in the Madison Press Connection and subsequent publication of an article by Howard Morland in The Progressive magazine. [Deleted].

[Deleted]. The full impact of this disclosure relative to the arms control implications of ICF is not yet clear. However, the disclosure of such information has not changed the Administration's non-proliferation goals, or the objective to restrict information that could be used for proliferation purposes.

[Deleted]
[deleted].

A long range concern (perhaps 40 years in the future) relates to the possible use of ICF for civil energy production, since materials useful for building nuclear warheads would be produced. Tritium [deleted] would be used in the fusion pellets and would be produced from neutron capture in a lithium blanket material as part of the normal operation of an ICF driven power facility. Diversion of

some of the tritium to weapon purposes could occur. In addition, fissile material such as plutonium-239 produced in an ICF driven hybrid reactor could be diverted to weapon uses.

However, any fusion reactor — when available — burning deuterium and tritium, whether inertial or magnetic, would involve the use of tritium and the potential for diversion to weapon purposes. Also, any fusion reactor would be a source of fast neutrons and could be designed to produce plutonium or U-233 (currently produced in fission reactors). The possibility of diversion of these materials is, therefore, not unique to ICF.

B. Relation to Arms Control Agreements.

As noted previously, the US currently regards certain types of ICF research as consistent with the NPT in terms of what is meant by a nuclear explosive device. This is evidenced in the US statement at the 1975 NPT Review Conference:

> "Certain questions have been raised by the delegation of Switzerland related to the development of a potential source of energy, and its relation to the NPT. As we understand it, the question related to research which has been reported, involving nuclear reactions initiated in millimeter-sized pellets of fissionable and/or fusionable material by lasers or by energetic beams of particles, in which the energy releases, while extremely rapid, are designed to be, and will be non-destructively contained within a suitable vessel. On the basis of our present understanding of this type of energy source, which is still at an early stage of research, we have concluded that it does not constitute a nuclear explosive device within the meaning of the NPT or undertakings in IAEA safeguards agreements against diversion to any nuclear explosive device."*

---

* Review Conference of the Parties to the Treaty on the Non-Proliferation of Nuclear Weapons, Final Document, Part III, NPT/ CONF/35/III, p.298. Geneva, 1975.

This statement was made in light of the then-current status of ICF research and perceptions of its applications. [Deleted]. Increasing international interest in ICF, as well as progress in US and other programs, has prompted the US government to keep under continuing review the relationship of ICF R&D by non-nuclear weapon states to US nonproliferation policies.

C. <u>Effect on Current and Prospective Negotiations.</u>

It is not anticipated that ICF research would be constrained under the prospective limited duration comprehensive test ban (CTB). [Deleted].

D. <u>Effect on Global and Regional Stability.</u>

ICF research might have some effect on regional or world-wide security. For example, if ICF work resulted in a major new source of civil energy, reducing worldwide dependence on oil, coal, natural gas, and uranium supplies, it could be stabilizing. To the extent that ICF facilitated acquisition of nuclear weapon technology or fissionable material that could be diverted to weapon use or that provided a useful "cover" for a weapons program, however, it could be destabilizing.

1. <u>Nuclear Weapon Technology.</u>

The development of a first generation fission device would be a demanding but relatively straightforward undertaking for a technically advanced country. The results of a sophisticated ICF research program would probably only be of indirect value to such an effort; [deleted].

ICF research could stimulate development of nuclear weapons technology in non-nuclear weapon states. [Deleted]

[deleted]. If an advanced non-nuclear weapon state with an ICF research program undertook a nuclear weapon program, it might subsequently be able to move more quickly to develop boosted fission and thermonuclear weapons than would otherwise be the case. This would almost certainly require full-scale and extensive nuclear testing, but ICF experience might serve to shorten the test program somewhat. Of course a non-nuclear weapon state capable of executing an ICF program would be capable of developing a nuclear weapon at a fairly brisk pace in any case.

For countries having already produced and tested nuclear weapons, weapon experts believe that ICF will be useful to some extent in improving the understanding of the physics of nuclear weapons and in effects simulation. The US, in fact, has stated that it expects these benefits to be significant. One relationship of ICF to weapon work is the similarity of computer codes used in the two activities. [Deleted]. Many of these codes, especially earlier, simpler codes, are unclassified and have been made available outside the weapon laboratories. Growing interest in ICF creates pressure for release of current, classified ICF and weapon codes. [Deleted].

2. Fissile Material.

As noted above, another concern is that an ICF program could facilitate the production of weapons-usable fissile material. This concern is very long range; such production might not occur until the 21st century. The concern is based on the possibility of using ICF for hybrid reactors — or fission/fusion pellets being used to transmute fertile material into fissile material (e.g., U-238 into Pu-239). The problem would be similar to that associated with operation of the world's fission reactors, which also create weapons-usable fissile material. This problem is not unique to ICF since a comparable situation would exist with any fusion reactor. One way of dealing with this problem might be to use safeguards via the IAEA as is done with many of the present civil nuclear reactors.

E. Technological Implications.

Even before demonstration of breakeven, ICF may contribute to nuclear weapon technology in states already possessing an advanced nuclear weapon capability, and, as noted above, to the possible acquisition of such technology by non-nuclear weapons states. [Deleted].

F. Potential Interaction with Other Programs.

While a long term justification for ICF programs is the possible civil energy applications, the near-term justification for the US is the anticipated usefulness to the nuclear weapon program. Some other potential nuclear energy sources would have fewer weapon technology concerns associated with them than would ICF. However, other nuclear energy sources could also be used to breed fissile material and could possibly be of some limited use in weapons effects studies.

G. Verification.

Currently, no agreement stipulates verification of ICF work, and, at present, there are no prospective arms control agreements which would place limitations thereon. [Deleted].

[Deleted].

VI. SUMMARY AND OVERALL ARMS CONTROL ASSESSMENT

ICF research is being pursued by a number of countries, including those possessing nuclear weapons; ICF research and development is partly justified by nuclear weapon states as contributing to their nuclear weapons technology. Information and technology developed in connection with nuclear weapons programs have been used in these ICF research programs [deleted].

[Deleted].

Although potential civil applications of ICF energy are very long term, a number of countries have already established their own ICF programs. The growing interest in ICF among countries not possessing nuclear weapons, together with the overlap between nuclear weapons technology and ICF technology, has raised concerns that ICF R&D might adversely affect US arms control policies. These concerns arise from the following points:

— Although it is unlikely that ICF research would be pursued by countries not already possessing nuclear weapons as the sole or even principal means of developing a simple fission weapon, [deleted].

— Countries already possessing a fission weapon capability (but not a thermonuclear weapon capability) might acquire the capability to develop thermonuclear weapons somewhat more rapidly in conjunction with ICF research than might otherwise be the case.

— Countries already possessing advanced thermonuclear weapons might derive some benefit for their weapon programs with regard to code development and physics measurements from ICF research.

In all cases, however, it is almost certain that full scale and extensive nuclear explosives testing would be required to develop or significantly modify any nuclear weapon more sophisticated than a simple fission device. ICF research will not provide a viable source of energy or fissile material for civil purposes in this century — indeed, it may never do so — but the possibility of such a long-term payoff is sufficient inducement to many countries to proceed with this research; others may be attracted by the peaceful "cover" ICF provides for weapons-related research and development.

The possible applications of ICF to nuclear weapon programs are primarily indirect. However, ICF programs in non-nuclear weapon states, and perceptions by non-nuclear weapon states of the potential value of ICF research to nuclear weapon states could affect our arms control policy objectives.

Testimony at Hearings on the Department of Energy "Stockpile Stewardship and Management" Plan

Shaping a peaceful world is a challenge, and it involves the hope of transforming society to one where justice is experienced by every person.

In light of the above, I find the DOE's "Stockpile Stewardship and Management" plan fails on a number of points:

Stewardship of the earth in our day requires the wisest choice for the investment of natural resources, human resources, and the national treasury, which is to be at the service of all, especially those most in need, and including future generations.

1/40.50

It is shortsighted, dangerous, and morally wrong to plan to fight a nuclear war. The NIF program is a program involving nuclear research and testing that has as its goal precise reliability of nuclear weapons for use in warfare.

The tremendous focusing of human genius, education, and talent in this direction is a error beyond calculating. This focus robs the country and the world of that same genius, education, and talent in solving the tremendous and most dangerous of all challenges, the growing inequality and stratifying of the world into rich and poor nations, and of nations into rich and poor people. From where do wars come? Is this not the question and the answer to which we should be dedicating ourselves?

The country is erroneously being lulled into belief that no more nuclear weapons are being made, and that we are moving toward signing the Comprehensive Nuclear Weapons Testing Ban which would outlaw nuclear testing, part of the machine of "better" nuclear weapons.

This fact will become known to signatories nations of the Nuclear Non Proliferation Treaty, which our administration favors extending

indefinitely into the future. In this way, the very purpose of the treaty, keeping other countries our of the exclusive "nuclear club", will be defeated.

2/40.12

The cost for the elaborate program over the next ten years has been given as $40 Billion, some of this including money for clean-up. This makes this program more costly to the US taxpayers than the Star Wars program. The shame is that this is happening simultaneously with the tremendous cuts and the dismantling of many necessary programs which have been proven to help our people.

3/21.04

The NIF program involves a deceitful manipulation of words in order to camouflage the reality that it is meant to keep power, world power in our own hands. It makes even more distant the world of justice, equality, and peace for which the Catholic Church stands.

The documents of the Catholic Church condemn the nuclear arms race, they demand that human resources be used for what benefits people.

Each of the above points could be elaborated at length.

Department of Energy
PO Box 3417
Alexandria, VA 22302

To Whom it May Concern:

I have been a resident of Livermore for 42 years, am a retired veterinarian, and a former Mayor, and over the years have taken an active interest in what goes on at Lawrence Livermore National Laboratory (LLNL).

I have followed the National Ignition Facility (NIF) proposal through the Key Decision One and Key Decision One-Prime, and am glad to see it has now undergone an extensive environmental impact study.

1/21.07 It is evident from the study that the NIF constructed at LLNL will not have an adverse environmental impact on our community.

I believe NIF is important to our nation to evaluate the reliability and usefulness of our nuclear weapons until such time they are no longer required in our inventory of weapons. While I feel the NIF costs are justified as part of a system of facilities that will make underground nuclear testing unnecessary for our security, I also strongly feel the costs are justified to determine what is required to sustain a confined thermonuclear reaction (ignition) in the hope that we might someday develop energy from fusion reactions. In my opinion, it is very important to learn if fusion energy is a possibility or not, and the NIF program will give us answers to that important question.

It is my hope our nation will continue to fund the construction of NIF to achieve the security and economic benefits of the project.

Very sincerely,

John Shirley

SSM-H-LLNL-013
Comment Letter

Livermore Make-Work
National Ignition Facility (Livermore Lab, CA) **$4.5 billion**

Proposal & savings:
Terminate program. Save more than $4.5 billion over the 30 year lifetime of the project.

Background: The National Ignition Facility (NIF) is a project proposed by the Department of Energy (DOE). The DOE's preferred site is at the Lawrence Livermore National Laboratory in northern California.

Funded as a defense program, the NIF would use Inertial Confinement Fusion technology to beam lasers onto a fuel pellet of radioactive tritium and deuterium, which, if it works, would ignite a tiny thermonuclear explosion. The NIF's principal stated mission is to increase understanding of nuclear weapons physics and to provide an above-ground simulation capacity for testing nuclear weapon effects. Project proponents also hope that the facility will help in the development of inertial fusion energy for application to civilian power production in the distant future.

Recent action: For FY96, DOE requested $61 million which included $37.4 million for construction and $23.6 million for preliminary planning, manufacturing, engineering and Environmental Impact Studies. House budget-cutters on the Appropriations Committee attempted to cut the $37.4 million in construction funds, expressing skepticism about the availability of future funding given the other needs of the weapons program. The funding was restored in conference to the full amount.

Taxpayer & economic argument:
First, the NIF is unreasonably expensive, and its price tag is sure to rise. According to DOE's optimistic estimates, the NIF would cost at least $4.5 billion, including at least $1.1 billion for construction and another $3.5 billion for operating costs over the thirty year lifespan of the facility. However, NIF technology is unproven, fraught with scientific uncertainties, and has not left the drawing board.

Second, at a time when DOE is proposing major cuts in its programs it should not make this major budget commitment. The NIF would be the largest single defense program ever built at Livermore. Considering its title as the most expensive element of DOE's Stockpile Stewardship program, the NIF's value to stewardship of the U.S. nuclear arsenal is dubious at best. Seymour Sack, a prominent nuclear weapons physicist at Livermore Lab and a member of the JASON panel (an elite group of academics periodically convened to study scientific issues for the military), called NIF "worse than worthless" for ensuring either the safety or reliability of the nation's nuclear arsenal. The NIF's primary purpose appears to be maintaining the nuclear weapons budget at Livermore.

1/21.09 Third, despite its high price, operation of the NIF would create fewer long-term jobs at the Lab than almost any conceivable civilian project of comparable cost. Documents peg those jobs at only 230.

2/21.07 Fourth, the highly speculative future of inertial confinement fusion as a commercial energy source makes this justification for the NIF extremely suspect. Even supporters admit that a commercially viable demonstration plant will not be possible for at least three to four decades.

Environmental argument:
3/21.12 First, NIF would create radioactive waste. The fuel for the NIF experiments will consist of a 50/50 mix of radioactive tritium and deuterium, and the experiments will create additional radioactive materials, called activation products, along with radioactive wastes.

Further, the NIF poses serious nuclear non-proliferation threats. The NIF and other aspects of the science-based stockpile stewardship program undermine U.S. efforts to conclude a Comprehensive Test Ban Treaty (CTBT). By providing a means for nuclear weapons designers to continue their research and development in the absence of underground testing, the NIF attempts an end run around the primary purpose of a CTBT to cut off nuclear weapons advancement. By sending a hypocritical message to other countries, the NIF undermines the U.S. goal of non-proliferation.

An Alternative Budget for Lawrence Livermore National Laboratory and How to Get There

March 28, 1994

The Present Situation: Lawrence Livermore at the Crossroads

In February, Secretary O'Leary submitted to Congress the Clinton Administration's second Department of Energy (DOE) budget request.[1] That request included a proposed cut of about 6% for DOE national security programs, including an 8% cut in nuclear weapons research, development, and testing (RD&T). Other DOE programs are, as of this writing, slated for support at current levels or higher, with the exception of the Superconducting Supercollider, now terminated.

The Administration's request would cut Lawrence Livermore National Laboratory's (LLNL's) DOE budget about 14% overall, from $743M to $638M. The proposed cuts at LLNL and the corresponding 6% cuts at Los Alamos National Laboratory (LANL) reflect not only changing national priorities, but probably also a recognition of the almost complete redundancy between the two labs' weapons programs.[2]

1/40.27 This downscaled budget request brings Lawrence Livermore to a crossroads. Can a nation with no real requirements for new nuclear weapons afford to support two complete nuclear weapons physics labs, each with tremendous overhead requirements?[3] We think not. Unfortunately, Lawrence Livermore's current leadership has no intention of relinquishing its nuclear weapons

---

1. Department of Energy FY1995 Congressional Budget Request, DOE Office of Chief Financial Officer.

2. Even the technology transfer initiatives sponsored by the two labs, while they differ in details, fall into the same general technology classes. LLNL had, in January of 1994, 107 cooperative research and development agreements (CRADAs) with industry. Because of repetition and double-counting, these referred to 91 projects, and two of these were strictly military in nature. Of the 89 civilian or dual-use projects, 33% were in materials and associated processing, 16% in metrology and manufacturing technologies, 15% were related to electronic components, 12% in computers and software, and the balance in propulsion systems, biotechnologies, environmental technologies, fossil fuel R&D, nanotechnologies, and microwave technologies. While the individual projects are different, Los Alamos' mix of CRADAs repeats, with some variation, these general emphases.

3. See "Cuts killing future for nuclear weapons work," Los Alamos Monitor, 3/23/94, which quotes LANL Deputy Director Jim Jackson as saying that 80% of weapons spending at LANL goes to such activities as environmental protection, safety and health, physical plant support, and facility management.

2

1/40.27 continued

identity. LLNL is now attempting to compensate for its budgetary losses by seeking very large new weapons-oriented projects like the National Ignition Facility (NIF), currently being promoted (misleadingly) as an energy research facility.[4] At the same time, LLNL is attempting to carve a niche for itself in the consolidated weapons manufacturing complex. To this end, LLNL has subsidized the development and demonstration of novel plutonium pit manufacturing capabilities and hopes to provide backup pit production capability for the complex, despite the absurdity of starting up "Rocky Flats II" in the California suburbs. LLNL also hopes to manufacture uranium bomb parts for the arsenal, and seeks to build a new high explosives manufacturing plant for stockpile maintenance purposes.

These efforts, even if successful, will confine Lawrence Livermore's future to an increasingly-sterile extension of its past. As the nuclear weapons budget continues to shrink, LLNL will shrink with it. Under such a scenario it will be increasingly difficult and expensive to attract or keep talent at the Lab. An unwanted result of the Laboratory's obsession with quantity over quality—on maintaining literally thousands of staff on the nuclear weapons payroll, in parallel to other thousands at Sandia and Los Alamos—will in all likelihood be, not competence, but institutional stagnation and mediocrity. Unfortunately, this is now the shape of the future at all three labs.

<u>Our Vision: Livermore as a "Green Lab"</u>

In contrast, what is described here is a laboratory devoted to urgent, genuine national needs along with fundamental scientific research, a laboratory which contributes directly to national security by helping rebuild the tattered American economy. Our vision for Lawrence Livermore is built around many of LLNL's existing competencies, which we would devote to research and development (R&D) in renewable energy technologies, in energy-saving transportation, in environmental research and new environmental technologies, and in a wide variety of cooperative projects for industry. These emphases, especially if undertaken in concert with supporting national policies, could create literally millions of new jobs while markedly increasing energy security, decreasing the trade deficit, enhancing the urban environment and saving the tens of thousands of lives now lost annually due to air pollution in our cities.

We present these alternatives in the table which follows these introductory remarks and in the notes which accompany it.

If LLNL invested the energy it now puts into promoting its nuclear weapons agenda into positioning itself to address urgent national needs, its future could be bright, and morale at the Laboratory would be buoyed by a renewed sense of purpose. But while LLNL dithers, competing laboratories—in government, academia, and industry—are positioning themselves to

---

4. It should be noted that there are also serious technical questions about this project within the nuclear weapons community.

1/40.27 continued

take advantage of new currents in the nation's technology policy debate.

Our alternative provides for maintenance of nuclear weapons expertise at Los Alamos and Sandia, where downscaled programs in maintenance of a rapidly declining nuclear stockpile, dismantlement, nonproliferation, treaty verification, along with others, would responsibly reduce the nuclear danger—the often-exaggerated claims of the weapons laboratories notwithstanding.[5]

Current LLNL management asserts that further development of our nuclear arsenal is essential to combating nuclear terrorism. Even if this were true, there is no need for LLNL to do this work. And it is certainly not true: new U.S. nuclear weapons designs will not deter nuclear threats to the United States from either terrorist groups or irrational national leaders. Neither are new weapons needed to deter a nuclear attack from any of the existing nuclear powers; our existing arsenals are more than adequate for this.

Rather, it is urgently in the United States' interest to delegitimize nuclear weapons worldwide, and to embrace effective prohibitions against all nuclear weapons testing (both explosive testing and hydronuclear testing), against weapons proliferation (both horizontal and vertical), against nuclear weapons deployment, and against any possible use of nuclear weapons. We should also both embrace and demand increasing transparency in stockpile maintenance.

In this country, there is broad public support for further nuclear disarmament beyond the requirements of the START II treaty, and it serves both U.S. interests, as well as U.S. treaty commitments, to continue the global disarmament process while the opportunity exists.[6] Protocols in all these areas of concern need to be embodied into binding treaties upon which multi-lateral enforcement can be based. A downscaled RD&T budget and capabilities are essential to signal U.S. intent in this regard.

Instead of supporting these activities, LLNL, together with Los Alamos and Sandia, comprises a strong regressive force working to maintain and expand the legitimacy of nuclear weapons as instruments of national policy, not just in their traditional nuclear deterrent role but in dangerous new domains as well. They anticipate not just designing new weapons, but building small lots

---

5. An egregious recent example of this was LLNL Director John Nuckolls March 22, 1994 testimony to the House Armed Services Committee, in which he warned that "the fabric of civilization" would "collapse" without at least $300 million more added to current nuclear weapons RD&T budgets, <u>plus</u> additional funds to counter nuclear proliferation ("Lab head urges $300 million more yearly to oversee nukes," <u>The Oakland Tribune</u>, 3/23/94).

6. Results of an ICR Survey Research Group poll of 1003 adults conducted on January 5-9, 1994 showed what Americans want: A global test ban treaty by 1995 (80%); further cuts in Russian and U.S. nuclear arsenals below START II levels of 3,500 each (84%); an official U.S. nuclear policy of "No first use" (64%); and a ban on plutonium production for weapons (63%).

1/40.27 continued

of weapons for "special" purposes.[7] They are apparently unaware that for most of the world, this is nuclear terrorism.

Not least, our alternative will directly save the nation billions of dollars each year, not only in reduced nuclear weapons RD&T requirements but also in relief from needless, technology-driven upgrades in both stockpiled warheads and their delivery systems.

Development of truly important new civilian technologies at LLNL, with tremendous value-added for the nation, is simply far less expensive than keeping excess nuclear weapons expertise exercised. And, while a few civilian technologies have come out of the LLNL weapons program, that program has not been and will never be a cornucopia of peacetime benefits.

Needless to say, the economic benefits of a civilian Laboratory will be greater, not just to the nation, but to the California economy as well, as discussed further below.

Our plan for Lawrence Livermore is based on completely phasing out all nuclear weapons RD&T and Department of Defense projects there. We present this case not as an extreme, but as the most reasonable option available. Ending these activities in Livermore would have several important benefits. First, the overhead costs associated with the nuclear weapons infrastructure at LLNL could be saved. Now, it has been argued that some of these facilities are unique to LLNL and therefore of irreplaceable importance to nuclear defense programs. Granted that some of these facilities are unique, it does not, however, follow that they are important, let alone necessary, to provide stewardship for the nuclear stockpile.

Second, the costs of the security apparatus—and the culture it spawns—would be virtually eliminated. These costs manifest as dollars spent on security and on background checks, as impaired communication with peers at other institutions, as difficulty in attracting talented scientists, and in the atmosphere of fear that circumscribes expression at LLNL. It is absolutely essential that the culture of secrecy be transformed, not just on the margin but in its entirety, if LLNL is to function effectively in an increasingly civilian role and to serve the needs of democratic society.

Third, the distortion of nuclear weapons policies which is occasioned by LLNL lobbying and self-promotion—which is well-funded, continuous, and highly-effective—would be brought to an end. It is no exaggeration to say that LLNL has confused the security of its own nuclear weapons programs with the security of the country as a whole, and its advice, which is considered very carefully in Washington, reflects this confusion. While lobbying by Los Alamos would continue, the effect of political pork on nuclear weapons policies would be greatly diminished.

---

7. John Immele, "State of the Nuclear Weapons Program," Director's Colloquim, LANL, December 1, 1993.

1/40.27 continued

In any case it is, we note, simply impractical to keep a small cadre of weapons experts at one lab, while another lab conducts the bulk of the maintenance for the arsenal—an arsenal which would continue to diminish rapidly in size under sound policies. Some 79% of the so-called "enduring" arsenal was designed in Los Alamos, and it is primarily to Los Alamos, supplemented by key LLNL personnel, that the nation should turn to diminish the nuclear threat and guide us to a nuclear weapon-free world.

Our proposal closely resembles, in many respects, that offered in 1992 by Representative George Brown, Chairman of the House Science, Space, and Technology Committee. Brown spoke of the redundancy embodied in the three DOE weapons laboratories and the need for new lab missions in a letter to then-Secretary James Watkins. His proposal reads, in part:

> 1) Consolidate all nuclear defense and nuclear non-proliferation work at Los Alamos. Through a gradual transfer lasting perhaps three to five years, all nuclear design, ballistic missile defense, and other classified defense activities currently at Lawrence Livermore would be terminated or transferred to Los Alamos...
>
> 2) Establish Lawrence Livermore as a civilian technology lab. Building on strengths at the lab in materials science, fusion, computational science, environmental remediation, and biotechnology, create a new, entirely civilian mission for Lawrence Livermore, with particular emphasis on building consortia with industry and academia in areas of critical technologies and environmental technologies...
>
> ...
>
> 4) Reduce the DOE nuclear weapons research, development, and testing budget by 20 percent per year over the next four years...(emphasis in original)[8]

This proposal made sense two years ago; it makes even greater sense today. There is no need for new kinds of nuclear weapons; nuclear testing has ceased and there is no reason to re-initiate testing regardless of the actions of other countries; and the nuclear arsenal is shrinking as fast as possible. And, as was pointed out above, nearly all the warheads and bombs that will remain were designed in Los Alamos.

The Brown proposal cuts nuclear weapons spending everywhere; under his scenario, even if LLNL's weapons program is cut to zero and Sandia's to half its current size, Los Alamos' program also shrinks substantially. Brown's 1992 plan does not so much move anything to Los Alamos as it preserves enough of what is now there to care for a declining arsenal. It adds new missions, in non-proliferation for example, as needed.

What is missing from Rep. Brown's brief outline is a detailed and consistent analysis of the

---

8. Letter from George Brown to James Watkins, February 8, 1992.

civilian work that is needed at Livermore and Sandia. Such an analysis would be the foundation for a unified new vision for LLNL, which is a necessary step in its transformation. For example, while Brown alludes to environmental work at LLNL, he also mentions research into fusion energy, which is intrinsically beset by environmental, economic, security, and other problems. As a potential energy supply, it is easily eclipsed by far more attractive and available technologies.

We suggest that the organizing principles around which LLNL's new work in the service of national needs constellate be "green" ones. These can be expressed as:

- ecological sustainability,
- social equity,
- grassroots democracy,
- personal and social responsibility,
- nonviolence,
- decentralization,
- community-based economics,
- respect for diversity,
- global responsibility and partnership, and
- responsibility toward future generations.

1/40.27 continued

Going further, we assert that technology development which does not in some way serve values such as these (or other similar ones) will not--even despite anticipated positive cash flows for some individuals--really contribute to either the nation or the world. Private benefit does not, as we should now know all too well, lead invariably to net benefits to the community or to the environment. There is considerable cogency to the conservative argument that R&D which leads only or primarily to private benefit, which is then redistributed by increasingly flawed and increasingly transnational market mechanisms, should be funded by private capital. In contrast, public funding should be applied to public, rather than private, purposes. These purposes include but must transcend economic growth. The articulation, and application in national policies, of values like those listed above can provide an effective basis for 21st century market growth and economic renewal, albeit in a new key and with new measures of success. It may be that such "green" principles actually provide the only fertile basis for a sustainable and just economic renewal.

However distant we may be from guidance by principles such as these--and nowhere more so than at the DOE weapons laboratories--University of California administrators have taken notice of LLNL Director John Nuckoll's slow pace in building LLNL's civilian programs. Because of this concern, as well as LLNL's intransigence on the nuclear testing issue, the University of California committee which oversees LLNL has reportedly called for his resignation.[9]

9. San Francisco Chronicle, March 16, 1994.

7

The University is correct in doing so. Setting aside the question of the Nuckolls team's performance in managing a nuclear weapons laboratory, it will be necessary, first and above all, to bring in a new management team for any change to occur at LLNL.

An Alternative FY1995-1998 Budget for Lawrence Livermore

For the past several years, citizens' groups in Livermore and in New Mexico have studied how the consolidation and transformation of the two weapons physics laboratories, Lawrence Livermore and Los Alamos, could be accomplished.[10] At the same time a number of studies of, and hearings on, this topic have proceeded in official venues in Washington, and a considerable literature on the subject has developed, too much to summarize in a short memorandum.

The accompanying table, which grows out of this previous work, shows one alternative budget for LLNL. It reflects genuine post-Cold War priorities in the general framework originally offered by Congressman Brown. It follows the same categories DOE used in its FY95 request to Congress for ease of reference.

1/40.27 continued

Under this consolidation and conversion plan, Lawrence Livermore would become an increasingly civilian and "green" lab. Some of the new and expanded programs it would host are discussed in the notes following the budget table.

In this scenario, Los Alamos would become the custodian of the nation's nuclear weapons expertise and the center, along with Sandia Albuquerque, for technical studies related to treaty verification, non- and counter-proliferation, increased transparency, training of inspectors, and for a variety of studies related to reducing the nuclear threat. It is interesting to note that Senator Domenici of New Mexico has also been arguing that a big part of LANL's future lies in these same programs. The New Mexico labs could also do much more civilian work.

Needless to say, no reorientation of this type should take place without intensive and substantive citizen involvement and discussion in both California and New Mexico. Such involvement is not merely a means to an end, it is a central value of any conversion process. It is, or rather would be, a renewal of democracy itself, now gravely imperiled by current political processes and, not least, by nuclear culture. To provide new forums of public involvement, which can make large bureaucracies increasingly responsive to local as well as executive and congressional priorities, and to institutionalize those forums, is a very high priority.

10. See, for example, The Conversion of Los Alamos National Laboratory to a Peacetime Mission: Barriers and Opportunities, November 1992, by Greg Mello and Lisa Oberteuffer, Concerned Citizens for Nuclear Safety, Santa Fe. Good earlier work at LLNL was done by Wendy Batson et. al. of the Nuclear Weapons Lab Conversion Project in "Shaping alternatives at Lawrence Livermore Laboratory: A Preliminary Analysis." 1979.

8

What is more, public discussion of the nuclear weapons issues underlying lab consolidation would irrevocably change, not just the political context in which U.S. nuclear policy decisions are made, but the decisions themselves. Current U.S. policies apparently rely largely on public inattention and secrecy for their maintenance, given the large discrepancy between what the public wants (see note 6, p. 4) and the policies we have.

Overall, the size of LLNL is somewhat less under this scenario than at present. For many reasons, the existing culture at either Lawrence Livermore or Los Alamos cannot be positively changed without downsizing them, and in any case these smaller laboratories are large enough to accomplish what the nation needs from them. What is more, the national security benefit--and even the economic benefit--from the national labs must be more and more closely compared with that resulting from other investments the nation could make, e.g. in health care and education. Of course, if LLNL fails to convert, it could well--and should--become considerably smaller than what is shown here.

1/40.27 continued

The size of the Laboratory is not, by itself, indicative of the regional economic importance of LLNL. The economic benefit of the Laboratory to the region would likely be quite a bit higher after conversion, due to increased industrial participation and an increased number of business spin-offs. Should local and state governments initiate markets for the technologies developing at LLNL--in this case, new greenish technologies--by means of feebates, regulations, taxes, or other incentives, large new industries could well be the result, both in California and elsewhere in the nation.

In any case, LLNL's existing budget should not be continued simply in order to preserve the jobs it provides, since LLNL constitutes a highly inefficient means to accomplish that end. Almost any other government investment would be more effective at creating direct employment than is high-technology R&D.[11] What is more, nuclear weapons R&D has never been and will never be a fertile field for new civilian technologies.

We suggest that a re-missioned LLNL be organized around the following missions:

- **Renewable energy and energy conservation R&D**
- **Advanced transportation technologies and underlying sciences**
- **Cooperative work for industry**
- **Environmental R&D**
- **Materials science**
- **Basic science, pure and applied, in LLNL's traditional specialties**

---

11. It is often hoped that helping American companies compete in the global marketplace will create new jobs for Americans. This may be partially true but is being greatly overstated by both companies and the laboratories, who can hardly be expected to be objective on the subject. Further remarks on the "competitiveness" mission will be included in the longer analysis which this memorandum summarizes.

- **Advanced computation (now driven by climate modelling instead of weapons R&D)**

LLNL has now, or has had in the past, programs in all these areas.

Note that the Laboratory envisioned here is an open campus, with no classified areas. This is preferable for many reasons: for economy, for identification with the scientific value of openness and thus providing increased appeal to talent, but most of all for promoting a culture that values the rapid and informal give-and-take of ideas that will maximize the value of public investments made in its missions.

The list of possible missions above, and the programs which follow, are the result of examining an initial larger list of many possible new missions for LLNL. There is no lack of R&D ideas, but filtering the various possibilities to see which are really green or greenish, which are compatible with LLNL's skills or reasonable extensions of them, and which can arguably be done well at LLNL limit the number of new missions we have found to the ones shown.

1/40.27 continued

<u>**How to Get There**</u>

1. **Make a clear decision** this year to remission LLNL, either at the DOE or in the Congress. Dragging out the inevitable transformation could ultimately waste billions of dollars and decrease the contribution of LLNL to the nation by failing to attract and retain skilled people at LLNL. The redundancy and waste embodied in the current LLNL/LANL competition is so widely appreciated that the DOE Secretary's Task Force on the Labs should, after an initial orientation, cut to the chase and issue an interim recommendation along these lines. If this cannot be done expeditiously in the Executive Branch, Congress--if for no other reason than economy--should step in and eliminate redundant programs.

2. **Halt new DOE Defense Programs (DP) and construction at LLNL** immediately. These projects are both redundant and unnecessary and have negative nonproliferation value. Detailed analysis supporting this assertion will be the subject of a separate memorandum. Funding for these new initiatives should be eliminated from the budget now before Congress.

3. **Halt new DOD and intelligence agency programs at LLNL** this year.

4. **Make the DOE Office of Energy Research the new landlord at LLNL** at the beginning of FY95.

5. **Support new legislation** this year which a) guides and b) funds an expanded industrial research program in the DOE laboratories. Rep. Brown's bill (HR 1432) should be modified to provide such guidance and funding.

6. At first in the White House and subsequently, in greater measure, in Congress, **fund major new initiatives in a) renewable energy and conservation R&D, and b) advanced**

transportation R&D, to be done at least in part at LLNL. Program start-ups can be financed in the interim by Laboratory-directed R&D (LDRD) funds. Funding for these initiatives, which serve national security directly in many ways, should come from cuts in DOE's nuclear weapons program.

1/40.27 continued

7. Replace current management during this fiscal year. The new management team would be selected by a panel co-chaired by the new DOE landlord agency and the University of California or its successor, but which would also contain local stakeholders. It is important that the community, as well as the prime contractor and the funding agency, have, in effect, veto power over the selection of LLNL management in order to restore the confidence that all parties need to advance the new missions of the Lab. In the long run, the size of LLNL will depend upon its degree of integration with the region around it.

8. Revise the LLNL management contract in a number of areas, such as contractor accountability, personnel practices, public information and participation,, and project review.

In Conclusion

We hope this summary will stimulate discussion, critique--and other proposals. In the final analysis, no facility can be converted without leadership from within. We do not know LLNL's strengths as well as the people who have those strengths. We hope you will come forward and make your voice heard.

AN ALTERNATIVE BUDGET FOR LLNL
(All amounts in millions)

DOE Budget Category	FY1994	DOE FY95 Request	TVC FY95	TVC FY98[12]
Energy Supply R&D	$99.8	$98.9	$110	$246
Uranium Enrichment	49.7	3.4	0	0
General Science	1.8	1.7	2	2
Weapons Activities	410.9	361.9	308	0
Environmental Restoration & Waste Management (ER&WM)	89.5	80.2	100	113
Materials Support & Other Defense Programs	74.1	73.9	56	0
DOE Administration	2.2	1.1	1	1
Fossil Energy R&D	0.9	0.4	4	11
Energy Conservation	0.4	0.5	24	158
Nuclear Waste Fund	13.8	16.1	16	18
Energy Information	0.5	0.5	1	1
Total DOE Funding	743.1	638.2	622	550
DOD Funding	122.0	77.8	58	45
Other Non-DOE Federal Work	77.2	74.8	30	34
Total LLNL Federal Funding	942.3	790.8	710	629
Industrial R&D Match	28?	40?	100	200
Total LLNL Funding	970	831	810	854

Notes to Table:

Energy Supply R&D: This includes biological and environmental research and magnetic fusion, along with several other programs. Ramp down magnetic fusion to zero over four years, and replace it with a large and diverse program in renewable energy technologies and related basic sciences. The DOE FY1995 Budget Request Highlights shows that many renewable energy technologies have or are about to greatly expand their market potential, becoming competitive with fossil fuels and nuclear power even with today's unrealistic pricing system. Further research, provided it meets certain basic criteria, should pay off handsomely with fertile

12. Reflects 4%/yr inflation.

industrial partnerships and significant public benefits.

Uranium Enrichment: This is the DOE portion of the uranium atomic vapor laser isotope separation facility (U-AVLIS) funding; we do not know if the U.S. Enrichment Corporation (USEC) is currently funding AVLIS, and the future of USEC funding is uncertain. There is no need for more enriched uranium. This technology presents a proliferation danger.

General Science: This modest program in high-energy and nuclear physics is unchanged in our scenario.

Weapons Activities: Ramp down to zero as duplicative, useless, and dangerous activities are ended and the remaining few essential stockpile activities transferred to Los Alamos and LLNL's facilities are cleaned up and out as quickly as is practical. The four-year pace of consolidation gives program staff and management time to make the necessary transitions, find important new work, and archive data to make room for new civilian missions.

In the current DOE request, the great bulk of the weapons funding is in the R&D and testing line items; these categories should be dropped altogether and the small fraction of genuinely important work subsumed under Stockpile Support, which embraces all or essentially all the justifications being offered for the RD&T lines.

Environmental Restoration (ER) and Waste Management (WM): Here give an initial boost to the ER program for equipment installation, on-going source investigations, and initiation of Site 300 clean-up; taper off WM as the waste load declines due to programmatic shifts while significantly expanding the program in environmental cleanup technologies, now slated for cancellation. The ER&WM program is given its own directorate in our scenario, rather than being stuck as an orphan in unrelated programs as at present.

Materials Support and Other Defense Programs: Despite the name, this also includes verification and control technology and related programs. Ramp these programs down to zero at LLNL, sending nonproliferation and related work to Los Alamos along with any essential materials support functions (which will be very small).

Fossil Energy R&D: This program is destined for large percentage growth in our scenario, though it remains a small program. It focuses on a variety of practical R&D problems of interest to the fossil fuel industry.

Energy Conservation: Begin two new programs here in FY95, one in broad-based energy conservation technologies and related policies, and the other (which would rapidly grow into a major focus of LLNL) developing advanced transportation technologies, especially an ultra-light clean car, along with underlying materials and related sciences.

The innovative transportation initiative would proceed on a very rapid basis, in order to leapfrog incremental automotive improvements and to jumpstart new manufacturing industries.

Nuclear Waste Fund: This is research on Yucca Mountain.

DOD Funding: (The first two columns are estimates from the LLNL FY1994-1999 Institutional Plan.) Our scenario envisions ending all strictly defense-related R&D at LLNL, with industrially-oriented dual-use R&D continuing.

Other Non-DOE Federal Work: (The first two columns are from the FY1994-1999 Institutional Plan; these include a hypothetical $45 million in FY94 and $40 million in FY95 from USEC for AVLIS.) This line also contains work for the intelligence agencies, which would ramp to zero in this scenario. We envision other intra-federal contract work as rising to partially compensate for this loss, including increased work for the Department of Commerce and the Environmental Protection Agency.

Industrial R&D Match: The first two entries on this lines are estimates; LLNL does not publish this information on an annualized basis. This line grows rapidly because of anticipated new legislation that makes CRADAs easier to consummate and fund, but even more so because industry can be anticipated to be quite interested in the technologies LLNL is developing under this alternative plan. Some industrial partners will be likely to set up shop in facilities freed by weapons program cuts.

1/21.05 I am a retired Engineer. I have worked for/with the Government for 35 years. I have seen the government do some good work and sometimes very poor work. I compliment on the logical approach you have taken on the evaluation of NIF and the EIS. The view graphs were very clear on what is being done including proposed time frame. The main thing missing was some specific data on the impact. Was Mary Lee Kelly's data correct. She had an impact on the audience. You could have countered that with some hard data. Although you run the risk of confusing some.

COMMENT LETTER — **PAGE 1 OF 2**

J. Michaels

From: J. Michaels
5516 Cory Place
Las Vegas, NV 89107

Date: March 28, 1996

Comment regarding Stockpile Stewardship and Management PEIS:

I consider your preferred alternative to downsize PANTEX (PX) in place rather than relocate operations to the Nevada Test Site (NTS) after stockpile reduction to START level is achieved to be absolutely wrong. For the following reasons:

1/40.13 1. You state this is less expensive. Your argument that it is less expensive to operate both the NTS and PX than to operate just NTS is absolutely wrong. Your assumption that it costs too much to shut down and cleanup PX therefore you will operate both facilities is flawed. The expense to clean up PX was bought into as soon as PX was assumed from the Army after WWII. This is a sunk expense that DOE must bear, delaying cleanup only increases its ultimate cost, the present value of these clean up costs is relatively constant, no matter how long you delay cleanup. Delaying cleanup does not save any money. Please provide detailed economic assumptions and calculations, performed by a credetialled economist, that properly explains this socioeconomic issue.

2/30.02 2. Even if it was true that shutting down PX was more expensive. Please address why this is environmentally superior to cleanup at PX. How can you justify passing up the opportunity to closeup and cleanup the PX site. For the sake of money you are willing to keep such a contaminated site open. How much do you think it saves in terms of dollars and pay back. Please address why this is more justified than cleaning up and getting out of one more site.

3/11.01 3. Please address worst case accident analysis for a "perking lot" nuclear weapons accident for PX and NTS. On a safety basis to the public how you can justify operations at PX instead of at NTS. I read that DOE is taking special mitigating actions at PX to keep site boundary dose under 100 REM per person in the event of an accident at PX. The same accident at the NTS Device Assembly Facility must be less than 1% of this. No one lives at the NTS site boundary. The actual dose based on nearest resident must be less than 10 millirem. Please explain how for the sake of saving money you justify this additional risk to the public. How far is it to the nearest residence at PX and what is the expected dose to the public for a 10E-7 accident involving maximum bay limits of Pu and HE at PX and the NTS. How many people total would receive a dose greater that 100 millirem in case of such an accident at PX and NTS.

SSM-H-NTS-001
COMMENT LETTER **PAGE 2 OF 2**

Page 2

3/11.01 continued	4. The NTS is in completely controlled airspace. The DOE has the ability to close all airspace for 5 miles around the DAF. The probability for an aircraft accident is at least 1000 times less than at PX. PX is in the flight path of an major city (Amarillo) airport. Please address how you can justify exposing the public to this added risk just to save money. What is the dose to the public if such an accident occurs. Please address why this is justified in order to save money.
2/30.02 continued	5. Please explain the difference in operating costs for security guards at the DAF versus PX. You do not have to address the number of guards or total payroll costs if that is classified. However, please report the ratio or the difference in these costs: DAF vs. PX.
1/40.13 continued	6 If ultimate disposition is to be at NTS or Yucca Mountain. There will be extra transportation costs to ship to PX for disassembly and then ship pits to NTS. What are these extra costs vs. shipping once to NTS for disassembling and disposing.

1. I have attended a great many of these public meetings in recent years & it is painfully obvious that —
   - a. Meetings are attended by & large by the same people grinding out their own agendas. Obviously not interested in facts
   - b. Too many participants suggesting they're representing the public — often this amounts to a public of 1 or 2
   - c. Meetings provide a forum for many negative anti-establishment & emotional vitriolic attacks on any good [illegible] efforts

2/40.04

2. In my opinion DOE officials need to do a better job addressing the fact that the nuclear deterrent is necessary & a fact of life for several more decades
   - a. We cannot unilaterally disarm & rely on the generosity of others in our national security
   - b. We must always be in the position to enforce peace, not beg for it.
3. We must do a better job of pointing out that our country is making a good faith effort in disarmament, dismantling, storage/disposal of material, etc. We have nothing to apologize for.
4. Perhaps, it's time to question the continuation of these meetings. Is the cost & effort really worth it?

1/40.89

- Nuclear Weapons Stockpile Stewardship surely includes storage security, safety, inspection, and maintenance so that the operability of any stored weapons are known and satisfactory.

- Presumably, weapons and weapons-material security have been studied exhaustively, so plans should be based on the thinking employed for some time. Those responsible should remain aware of technological advances in remote drilling control etc. that might make previously-secure storage locations less so.

- The need for inspection and maintenance is based on the possibility that materials in an assembled weapon might become functionally degraded over time through thermal or possibly radiation effects on material composition or physical properties. Since I do not know what materials are present and do not know the ambient conditions, I cannot suggest details.

2/40.36

I assume the weapons can periodically be disassembled, carefully inspected, and subjected to non-destructive examination (NDE). If so, small scale techniques are to be preferred to efforts to apply massive NDE techniques to fully assembled devices. The most-desired efforts probably do not require massive new machines as proposed for some of the stockpile stewardship work at the weapons laboratories. Technicians and mechanics have the main skills required, though those employed for these tasks must be very highly trained, experienced, and be <u>quite</u> careful and reliable!

- In the past I have not been concerned about continued safety in work with fissile materials, at Y-12 for example. However, I have read in the press that a transformation is underway from knowledge-based to procedure-based operations. This revelation was scary!

I believe in excellent procedures, and have composed some. However, one must combine procedures with thorough knowledge! I trust that the new paradigm does combine worker knowledge with well stated procedures.

3/08.07 • Assuming disasters are avoided, the main adverse impacts of a Stockpile Stewardship program would be associated with the construction of any new facilities and in the societal effects of shifting responsibilities among installations. If stewardship can be addressed as I propose, such effects could be minimal.

Stockpile Stewardship and Management Program

1/41.06 The PEIS costs millions of dollars with very little value, but lots of errors. The wrong people were used to come up with the data; the non-knowledgeable, non-production western laboratories research and development folks. If you are going to talk about highly enriched uranium production you would start with Y-12.

The bargaining unit, hourly production workers at Y-12, asks for a level playing field with accurate data from knowledgeable folks that can and have done the work, and can back it up with true facts.

For national security we will be glad to deal with the true facts and real data.

We would like for this document to become a part of the PEIS.

Sincerely,

Carl R. Scarbrough

COMMENT LETTER **PAGE 1 OF 2**

CITY OF
OAK RIDGE

OFFICE OF THE MAYOR

POST OFFICE BOX 1 • OAK RIDGE, TENNESSEE 37831-0001

March 29, 1996

The Honorable Hazel R. O'Leary
Secretary of Energy
U.S. Department of Energy
7A-257 Forrestal Building
1000 Independence Ave., SW
Washington, DC 20585

Dear Secretary O'Leary:

1/40.23 The enclosed Resolution No. 3-42-96 was unanimously adopted by the Oak Ridge City Council at its regular meeting on March 25, 1996, and will be read on April 1, 1996, at the public involvement meeting to be held by the Department of Energy on the Stockpile Stewardship and Management Draft Programmatic Environmental Impact Statement (PEIS). This resolution places the Council on record in opposition to the "science based stockpile stewardship" approach as proposed in the draft PEIS and in support of maintaining the Oak Ridge Y-12 Plant's capabilities and competencies as integral elements in the future configuration of our nation's nuclear weapons complex.

The Council's concerns regarding the Stockpile Stewardship and Management Draft PEIS are many, but principally:

2/40.24
- We are concerned that the current proposal will adversely impact national security due to the tremendous reduction of skilled machinists, welders, chemical workers, assembly persons, sheet metal workers, inspectors and other critical craftspeople as well as technical and engineering specialists, all of whom are required to safely monitor and maintain quality nuclear weapons components. The collective ability of these craft groups and technical experts can not be replaced by science.

3/08.03
- We are concerned that the socioeconomic impact to Oak Ridge and our surrounding neighbors has not been appropriately analyzed. No Oak Ridge City staff person was directly involved in this analysis; therefore, the study's results must be questioned.

4/41.10
- We are concerned that our community cannot adequately analyze the constant stream of PEIS documents, including this proposal, within the constraints of our limited resources or in the time frame DOE has provided. We feel that DOE support for the PEIS process leans heavily towards proposal preparation and away from proposal analysis.

SSM-H-ORR-005

COMMENT LETTER — **PAGE 1 OF 1**

RESOLUTION OF THE TOWN OF FARRAGUT BOARD OF MAYOR AND ALDERMEN FOR SUPPORT FOR DEPARTMENT OF ENERGY'S Y-12 NUCLEAR FACILITY

WHEREAS, citizens of Farragut and surrounding communities have strengthened the security of the United States and her allies since 1943 through their work at the Oak Ridge Y-12 Plant, and

WHEREAS, through the efforts of these skilled craftsmen, engineers, and scientists, and countless other men and women throughout the United States, the Cold War has now ended and the President and Congress have directed the Department of Energy (DOE) to maintain a strong nuclear deterrent with a smaller and more efficient nuclear weapons complex, and

WHEREAS, the DOE is considering transferring the responsibility for the Y-12 Plant's nuclear weapons production, surveillance, dismantlement, and process development mission to another location, and

WHEREAS, transferring this mission would result in increased cost through the duplication of production facilities and the replacement of trained, skilled craftsmen, scientists, and engineers, and

WHEREAS, the culture and expertise necessary to continue this unique nuclear weapons mission exists only at the Y-12 Plant and that culture and expertise does not exist elsewhere, including the nuclear weapons design laboratories, and

WHEREAS, if the responsibility for the Y-12 production mission is reassigned to another site, the future security of the United States will be adversely impacted and there will be greater cost to the taxpayer,

NOW, THEREFORE, BE IT RESOLVED by the Board of Mayor and Aldermen of the Town of Farragut, Tennessee:

1/40.23 That the Farragut Board of Mayor and Aldermen express grave concern over any consideration by the DOE of moving the Y-12 nuclear production responsibility to another site where the facilities and production skills do not now exist and the potential for reduced national security exists while the DOE duplicates the capability with added expense.

BE IT FURTHER RESOLVED that the Board fully supports the retention of the traditional responsibility for the unique Y-12 mission in Oak Ridge so that the citizens of Farragut and surrounding communities can continue to further the national security through their skills and knowledge, without compromising our nuclear weapons stockpile.

BE IT FURTHER RESOLVED that the Board asks the Department of Energy to listen intently and without bias to the citizenry of the area who are experts in the production technology and who can advise the DOE properly on the continuation of this important mission assignment.

Signed this 28th day of March, 1996.

NUMBER 3-42-96

RESOLUTION

WHEREAS, for over 50 years, the security of the United States and her allies has been strengthened through the efforts and the unique skills of the employees of the Oak Ridge Y-12 Plant, and

WHEREAS, due in part to the efforts of the employees of the Y-12 Plant, the world has witnessed the end of the Cold War, the halting of new nuclear weapons design, the end of underground testing by the United States, and the dismantlement of large numbers of nuclear weapons, and

WHEREAS, the President and Congress have directed the Department of Energy (DOE) to maintain the safety and reliability of the reduced nuclear weapon stockpile without any future underground nuclear testing, and

WHEREAS, to this end, the DOE has issued the Stockpile Stewardship and Management Draft Programmatic Environmental Impact Statement (PEIS) which provides various alternatives for stockpile maintenance, and

WHEREAS, this Draft PEIS employs as its foundation a completely new, unproven, risky, and expensive approach to maintaining our nation's nuclear stockpile. This approach, called "science based stockpile stewardship," shifts the major responsibility for oversight of process development, stockpile maintenance, surveillance, refurbishment, and dismantlement work from experienced production sites like Y-12 to weapons design laboratories, and

WHEREAS, this concept, if implemented, will require the reduction of nearly 2000 uniquely skilled defense program employees at the Oak Ridge Y-12 Plant as well as substantial reductions at the other nuclear weapons production and manufacturing facilities, while increasing the staff at the weapons laboratories even though their primary mission of design has been significantly diminished and the testing mission has been ended, and

WHEREAS, this concept, if implemented, will needlessly cost our nation's taxpayers billions of dollars for construction of new facilities, movement of mission expertise, and decommissioning of older, yet safe and functional facilities, and

WHEREAS, this concept, if implemented, will compromise the historic separation of the weapons laboratories' research, design and testing function from the manufacture, assembly, disassembly and surveillance function of the production complex that has successfully produced the highest quality nuclear weapons since 1945, and

WHEREAS, this concept, if implemented, will adversely impact the national security of the United States of America.

NOW, THEREFORE, BE IT RESOLVED BY THE MAYOR AND COUNCILMEN OF THE CITY OF OAK RIDGE, TENNESSEE:

1/33.01 That via this resolution, the Oak Ridge City Council transmits its grave concerns to the DOE over the impact to the national security of the United States if the Oak Ridge Y-12 Plant's core production, maintenance, surveillance, refurbishment, and dismantlement capabilities and competencies are not maintained as integral elements in the future configuration of the nation's nuclear weapons complex.

SSM-H-ORR-010
COMMENT LETTER

PAGE 2 OF 2

2/08.03 BE IT FURTHER RESOLVED that this Council challenges the DOE's analysis which concludes that there will be minimum socioeconomic impacts to the City of Oak Ridge and her surrounding neighbors associated with the reduction of nearly 2000 skilled, defense program positions at the Oak Ridge Y-12 Plant when no one from the City staff has been directly involved in assuring the data utilized in the analysis are accurate.

3/41.10 BE IT FURTHER RESOLVED that this Council urges the DOE to provide assistance to the City to allow for an independent evaluation of the cumulative socioeconomic and environmental impacts of this and other major DOE actions which when taken together have the potential to cause serious long-term impacts not evaluated in individual statements. It is no longer reasonable for the federal government to expect local communities to expend their limited resources to analyze Programmatic Environmental Impact Statements involving thousands of pages that government contractors have spent millions of dollars preparing.

This the 25th day of March 1996.

DRAFT

Anderson County Commission

The U. S. Department of Energy (DOE) has provided two draft environmental impact statements to the Anderson County Commission for review and comments.

One document ~~proposes~~ addresses **significant job loss at the Oak Ridge Y-12 Plant and since the plant is located in Anderson County, it could have a detrimental economic impact on the County. The second document proposes to built a facility to locate the Department of Energy's plutonium in Oak Ridge which could have detrimental environmental and economic impacts on Anderson County.**

1/41.10 **The Department of Energy has spent ~~millions~~** thousands of thousands **of dollars preparing the environmental impact statements. DOE should not expect local communities with limited resources to review the voluminous reports without providing financial assistance. With modest financial assistance, Anderson County could contract for independent technical review with the University of Tennessee or some equally qualified organization. DOE will make decisions based on information and analysis prepared by Department of Energy contractors. It is critical that local communities impacted by DOE decisions be allowed suitable time and resources to analyze these documents. It is time that the federal government recognizes its obligation to assist local governments in meeting their obligations to the impacted communities.**

We ~~challenge~~ respectfully request that **the Department of Energy to provide funding to the Anderson County Commission for our independent review and analysis consistent with the intent of the National Environmental Policy Act.**

LOCATION OF NUCLEAR WEAPONS MANUFACTURE AT A LABORATORY

I am Donald B. Trauger of Oak Ridge, Tennessee, retired with fifty years experience in the nuclear field. This was first at Columbia University on the Manhattan Project, then in the laboratory of the K-25 Gaseous Diffusion Plant and, for nearly forty years, with the Oak Ridge National Laboratory. As an Associate Director at ORNL, I visited Los Alamos on several occasions and once served, as a reviewer for LANL non-weapons programs. I hold both ORNL and LANL in high regard as excellent laboratories.

1/40.23 Based on the cited experience, I conclude that combining a manufacturing production with a laboratory function other than quality control is unwise. The mission of a laboratory is to seek improvement and change, that of manufacturing to produce a reliable and salable product. I could not recommend placing a manufacturing facility at either LANL or ORNL. In fact, when working in the laboratory at K-25, I petitioned the management to transfer research to ORNL as a better environment. A secondary purpose was freedom the constraint imposed by the manufacturing unit on major changes that had promise.

In the mission for restoring and maintaining weapons where the product can not be tested, it is critically important to keep the manufacture and, perhaps even thought processes, separate from research. Small revisions can be dangerous. Although external constraints are now present for weapons development, that may not always prevail. The present arrangement with Y-12 is proven; it should not be changed.

My question relates to the Draft Program Environmental Impact Statement for Stockpile Stewardship and Management

1/08.01 3 7.1-5 Table The numbers used here imply that people required for D&D would provide an immediate amelioration of the socioeconomic impact of change in staffing, but what fiscal year budget does the reduction come in and what fiscal year is the D&D work budgeted in? The D&D on building 9201-4 has been on the long range schedule on and off for fifteen years and still has not risen to a level which would rate priority and considering the priority problems associated with D&D of plutonium facilities, does it not seem probable that this work might be scheduled thirty years from now? Would this work be done by Lockheed-Martin people or by contract workers, and how soon would it have to be scheduled in order for L-M workers to be kept on the payroll to do it?

Please include the answer to this question in the final Stockpile Stewardship and Management Environmental Impact Statement

Lori Barber, Farragut, TN.

I am concerned about the increased responsibility that is being given to the design laboratories, ~~particularly LANL~~ for the production process development, quality surveillance and production oversight

1/40.24 for the secondaries manufactured by Y-12. I am particularly concerned about their potential role in ~~component assembly~~ weapons component and subassembly testing and inspection.

Why would we want to duplicate ~~facilities~~ ~~on~~ these testing and inspection ~~capabilities~~, personnel and ~~another site~~ ~~both trained people and possibly~~ facilities at another site?

SSM-H-ORR-017
COMMENT LETTER

PAGE 2 OF 2

Y-12 Physical Testing and Nondestructive Testing Capability

The Y-12 Plant has developed an extensive physical testing and nondestructive evaluation and inspection capability over its 50-year life which was put in place specifically for application to nuclear weapons components and subassemblies. These testing capabilities, which are not available in general industry, had to be developed because of their uniqueness to the nuclear weapons program needs. Extensive and unique facilities have been constructed throughout the Y-12 Plant to support the various testing needs for different materials, processes, and assembly operations.

Y-12 testing engineers played an important role for the nuclear weapons designers. They added the testing technology that the designers needed to fully understand and evaluate their designs. Designers would typically present conceptual designs to Y-12. These designs would not include important things such as joining details, fabrication tolerances, or material uniformity requirements. The Y-12 testing and inspection engineers would develop the details for the designer for his or her consideration or approval. Y-12 would then develop and engineer the tests for production application. Only with this important link between the weapons designer and the inspection or test engineer has the United States been able to deploy such a successful nuclear weapons stockpile.

Developing, designing, and engineering testing and inspection capability along with the production process has become a necessary way of doing business for the Y-12 Plant. This is because new technology with new materials and new requirements were being developed with each new weapon design. It became necessary as a part of the development process to test and evaluate the materials and components to verify that they met design requirements. This extensive testing guided the process development. Verification that expectations were being met is as important as making the product itself. Ways to measure or test material or component properties were continually being challenged. More knowledge was continually being sought about a product or process. The Y-12 testing community responded with new and innovative methods to prove and improve its product.

2/40.13 Y-12 testing facilities include extensive radiographic, ultrasonic, metallurgical, radiation gauging, and other testing facilities. Many facilities are engineered specifically for unique weapons materials or assemblies. The materials involved include some that are hazardous or radioactive, and therefore require special tooling or construction to protect the material or the worker. These materials range from radioactive uranium or thorium to hazardous beryllium, lithium or mercury. The government has invested millions of dollars for these capabilities, and they are still suitable for supporting weapons production and development. They should not be duplicated elsewhere.

COMMENT LETTER **PAGE 2 OF 4**

1/40.24

Whereas the current PEIS draft gives more recognition to "core intellectual and technical competences" required for manufacturing, the feeling of the authors of the document that manufacturing competences are somehow inferior to those required for research is still apparent. Highly educated and trained people have spent 40+ years honing their abilities just as persons at the design labs have done. The labs cannot learn manufacturing anymore

SSM-H-ORR-018
COMMENT LETTER **PAGE 3 OF 4**

1/40.24 continued

than Y-12 can learn the research business

As a second concern there is insufficient recognition that simply beginning with core competences is enough. No effort to find work load to continually do the necessary exercising of the production capability, regardless of where it is, is evident. The nice line drawn in about the year 2003 on the workload chart is no more than someones fondest wish.

SSM-H-ORR-018
COMMENT LETTER **PAGE 4 OF 4**

Is this aspect being examined seriously and if so by whom

SSM-H-ORR-019
COMMENT LETTER **PAGE 1 OF 1**

My name is D.H. Johnson and I live at 321 Peninsula Rd, Harriman, TN.

1/40.23

Comment: I take exception to Ms. Whiteman's comment that there is no intent to cut back on process development at Y-12. For example - examine the case of radiation case development. In the early 70's there was a conscious decision that this work would be done at Y-12. Over the years, the design labs cut back in staff and facilities and provided only oversight of the Y-12 development program. However, recently and in a timeframe which corresponds to the preparation of the PEIS document, LANL has built and refurbished a number of facilities to do the extensive development and manufacturing processing necessary to do this function. I find it hard to believe that monies are available to do work at both places.

2/40.33

Question: The draft PEIS is based on a preferred alternative of extensive, continuous nuclear R&D at the design labs. This is to be accomplished by large or massive capital and operational investment. What is the data which was used to make this decision compared to the inherently cheaper option of remanufacturing weapons which will help to/will maintain the strong process development and production ties which currently exist?

SSM-H-ORR-020
COMMENT LETTER

PAGE 1 OF 1

My name is James C. Franklin and I live at 141 Cumberland View Drive in Oak Ridge. I have both concerns and questions about the Draft PEIS the Stockpile Stewardship and Managment Plan (SSMP). Please answer the questions and concerns in the final PEIS.

The concerns:

1/40.33 A. The plan as I understand it, will use an untried and new program to assure that the weapons stockpile is both safe and reliable. The science based stewardship chosen as preferred alternative to remanufacturing has not been used and involves a large assumption that the "new" system will provide the required weapons stockpile assurance. It seems that DOE should provide a better description and justification of the rejection of the remanufacturing system of asssurance of the stockpile. The assertion that remanufacture to original specifications is not feasible requires justification. Can better justification of the science based stewardship option be provided?

2/40.29 B: The START I and START II require drastic reductions in stockpile and no production or design of new weapons, with very low rates of manufacture. I support the idea of reducing the size of the weapons complex, but it is difficult to understand how all the production plants are severly downsized to some small fraction of the 1980 levels with some plant closures, but the design agencies (LLNL SNL, LANL) are actually increased in capability, capacity, and staff with no design function required. Will DOE elaborate on the logic used to discard remanufacturing as a system to assure safety and reliability of the stockpile?

Questions:

3/40.24 A: The PEIS addresses urgently the need to attract and retain staff at the Design Laboratories, but does not mention the need to retain and attract staff to provide the technical skills to keep the production plants current. How is Y-12 expected to keep the core competencies in compliance with the National Defense Authorization Act, 1994 with a budget of $100 X 10^6 as shown for 2003 forward?

3 AREAS of Discussion

8 [illegible] 700 units per year

- The PEIS workload was ~~based upon~~ determined from projected stockpile sizes based upon treaties or agreements with other nations. Specifically the former Soviet union. ~~[illegible]~~ It does not appear that the ~~[illegible]~~ Russians are

1/40.11 eliminating their stockpiles at as great of pace as ~~[illegible]~~ we are. Do you not think that we are to ambitious toward dismantling not only our stockpile but our production capabilities as well?

~~What [illegible] are being built into the PEIS to upscale~~

2/40.68 - All the enduring stockpile was built from the late 1970 to Early 1990 (approximately 12 yr period) Assume the stockpile has 8400 weapons and the life of a weapon is 30 years then in about 2008 we would have to replace the stockpile at 700 units per year, yet we are sizing the complex to handle 300 units per year this appears to be a disconnect what is DOE Doing to address this?

SSM-H-PTX-001
COMMENT LETTER

PAGE 2 OF 2

1. So slow on disposal

1/40.11 continued
2. With our present President we donot know from one day to the next what he is going to do!
France is testing
China is testing etc.
It is foolish to be thinking of reducing the stockpile as it seem to be propose.

3/43.09
3 The environment damage that you may seem will affect this area. No consideration is given to all the chemicals that is poisoning the human body by allowing the chemical companies to put all their chemicals into our food supply which will harm all humanity in the U.S.
a. which is worse "the pollutants" put out by Pantex that affects the local Population. or
b. all the chemicals that go into our food which affects the whole nation

4/08.15
1. It will hurt the economy of this city to have another "pay roll" eliminated. The main 4 plans under plans to dispose of, and these already ... are - the air Base. Bell Helicopter.

Having read through The three volumes of Documents, The Draft Stockpile Mgmt. Preferred Alternatives Report, the Draft Analysis of Stockpile Management Alternatives, and the Activity Implementation Plan (AIP) for the Transfer of High Explosives Production and surveillance from Pantex to the Los Alamos, Lawrence Livermore, and Sandia National Laboratories, I have the following questions and comments:

1/40.52
1) National Laboratory's Facilities are old - Los Alamos, built in the early sixties, Livermore, built in early seventies - These facilities do not meet current DOE Personnel Safety Requirements. Where in contrast - Pantex has facilities which are state-of-the-art both in meeting personnel safety requirements & meeting environmental requirements.

2/34.03
2) The High Explosive Mission is to be assigned only to facilities with existing infrastructure.
According to the Draft Analysis of Stockpile Mgmt Activities LANL is currently establishing a production infrastructure for the manufacture of detonators - however as late as December '95 no detonators have been produced.
According to the AIP - LLNL will restructure Site 300 to meet manufacturing requirements.

3/34.01
3) Transfer of Equipment
In the PEIS and the Draft Stockpile Mgmt Preferred Alternatives Report "no capital investments associated with transition are required" - Existing facilities and equipment

TELEPHONE: (806) 1477-4496

3/34.01 continued
AT TA-16 could be utilized. However, in the LAB AIP 60 pages of Equipment and 27 pages of processes are listed for transfer.

2) In the PEIS, The National LaBs supposedly have established expertise - the public is told time and again the labs are engaged in same type activities - However in the LaB AIP a significant period of process development/ process prove in - is required.

4/34.04
5) In PEIS - Four HE Alternatives are proposed & discussed - however in the Draft Stockpile Mgmt Preferred Alternative Report Only two options are recognized - Downsizing of Pantex and the Two LaB Concept. According to the Ranking Criteria Process the two LaB Concept ranks significantly

5/34.09
lower than Pantex, which itself received a ranking of 100 in all catagories. It is interesting to note as the Ranking Criteria Process was applied to each catagory throughout the SSM PEIS, the facility which ranked highest received the mission - High Explosive Fabrication is the only catagory which seems to run contrary to that rule.

6/34.06
6) What is the operating cost for the High Explosive Fabrication mission in the LaB Implementation plan?

7/09.06
7) Have hearings been held to discuss main charge transportation through the appropriately affected States?

MY COMMENT(S) ON THE PANTEX PLANT DRAFT ENVIRONMENTAL IMPACT STATEMENT IS/ARE:

GIVEN THE PAST EXPERIENCE WITH DOWNSIZING THE DOE BY RELOCATING MISSION ASSIGNMENTS FROM MOUND, PINELLAS AND

1/34.01
ROCKY FLATS TO OTHER SITES, I'M CONCERNED ABOUT THE POTENTIAL REASSIGNMENT OF THE HIGH EXPLOSIVES MISSION TO THE LABS FROM PANTEX. PAST AND/OR RECENT

2/34.05
SITE TRANSFERS HAVE YET TO PRODUCE ONE WR QUALITY PART AT THE LABS. THIS "LESSONS LEARNED" DOESN'T APPEAR TO BE CARRYING APPROPRIATE WEIGHT IN

1/34.01 continued
THE DECISION TO SITE HE OPERATIONS. H.E. MANUFACTURING MUST REMAIN AT PANTEX TO MAINTAIN QUALITY PROCESSES FOR WR USE AND PROPERLY MAINTAIN PRODUCTION SITE CORE COMPETENCY.

(USE BACK OF PAGE IF NECESARY)

Comments can be faxed in the SWEIS Faxline (1-800-822-5499), telephoned in on the SWEIS Hotline (1-800-788-0306), mailed in to DOE care of: Ms. [illegible], US Department of Energy, Albuquerque Operations Office, PO Box 5400, Albuquerque, NM 87185-5400; or sent via the Internet to [illegible]. Deadline is July 12, 1996.

COMMENT LETTER **PAGE 1 OF 2**

April 22, 1996

My name is Addis Charless, Jr. I own, live on, and operate a ranch ten miles north of the Pantex facility.

Although I am somewhat comfortable with the current mission at Pantex, I have marked reservations about an expanded role at Pantex that would include permanent storage of plutonium pits, other plutonium scrap, uranium, etc., as well as processing/reprocessing of same, and the possiblity that a nuclear reactor of whatever type might be built there to accommodate any burning of mixed oxide fuel (MOX), or to produce tritium.

1/04.05 To expand Pantex's role to accommodate any or all of the above is to me grossly irresponsible in view of the fact that the plant lies above the largest fresh water aquifer in the U. S., and that said aquifer is the lifeblood of this area's agriculture industry. Why the Ogallala aquifer has not been classified as a Class I water source is a puzzlement to me

2/11.13 None of the draft PEIS's have adequately addressed what would happen to this area's farm and ranch economy if a significant accident releasing substantial quantities of radionuclides were to occur regardless of how well it were to be cleaned up. I think the public's perception of the contamination would be such that it would make our products unmerchantable not just for the immediately affected area, but for the entire Panhandle's products.

SSM-H-PTX-004
COMMENT LETTER **PAGE 2 OF 2**

1/04.05 continued

It is a further contention by Pantex boosters that no substantial water pollution has occurred except for the perched water above the Ogallala aquifer. On June 27, 1995, a water sample was taken from one of my windmill wells and submitted for analysis. The results yielded the following information:

For 16 high explosives tested for, results were BQL.
For gross alpha, gross beta, Pu 239/240, Ra 226/228, Sr-90, tritium, U 234/238--detected, but below Safe Drinking Water Act maximums.

How much will these levels rise if Pantex's role is expanded? Is it something we are willing to risk? Is it truly necessary for the viability of Amarillo's or the Panhandle's economy? Is short term economic prosperity worth eternal contamination?

Issues of vital interest & concern for our state, our country, our world

Introduction —

I wish to address what is for me, the basic issue underlying the Stockpile Stewardship and Management Proposal -

1/40.50 This basic issue - which is not being addressed in these sessions - is a moral one & that the possession & therefore the threat - to use nuclear weapons of massive human and planetary destruction.

The DOE - PEIS proposal for the stockpile makes a mockery of our national integrity

2/40.07 1) To the signers of the recent non-proliferation treaty - and

2) As leaders in the Geneva discussions for a comprehensive test ban.

3/40.12 The costly expansion of nuclear weapon stockpiling in the proposal without any security justification, is particularly alarming in light of proposed cuts that will affect the lives of children - including "my children I guess" - and the elderly of this country.

Thank you -

Anna Marie Harkey

Mr. Vance Reed
President, Amarillo Economic Development Corporation

Comments on the Stockpile Stewardship & Management PEIS, the Storage & Disposition of Fissile Materials PEIS, and the Pantex Site-Wide EIS

Thank you for this opportunity to provide input to the Department of Energy regarding the operation of the Pantex plant. I would like to address two primary issues tonight regarding Pantex's future: 1) the environment, and 2) jobs.

1/40.52 Starting with the environment, I would like to reiterate this community's adament position that all work performed at Pantex continue to be done in a fashion that protects the environment. While the public has heard a great deal about "contamination" at Pantex, there has been little media attention given to the nature of pollution problems at Pantex. Most contaminants at Pantex are related to solvents and hydrocarbons that are very similar to those that would be found at practically any large manufacturing facility. This community is very reassured by the fact that Pantex has not had contamination problems from radioactive materials, such as occurred at Rocky Flats and Hanford.

The Amarillo Economic Development Corporation views Pantex in much the same manner as we view other large manufacturers in terms of presenting risks to the environment. For instance, if we were recruiting a computer chip manufacturer, we would realize that these plants have hazardous waste streams including arsenic and other heavy metals. The A.E.D.C. would only recruit a company that is committed to full compliance with E.P.A. and state environmental regulations. High tech businesses have created whole new industries and thousands of jobs, while working with very hazardous substances. This shows that protection of the environment and job creation can go hand-in-hand.

Likewise, we believe that Pantex can be a site where good, high-paying jobs are created in a work environment that includes potentially dangerous materials. When

SSM-H-PTX-006 COMMENT LETTER

PAGE 2 OF 2

measured in terms of total payroll, Pantex is by far the area's largest employer. With 3,500 employees at the plant, a job multiplier of 3.87 shows that Pantex is responsible for a total of over 13,500 jobs in this region. This multiplier was established by Dr. Ray Perryman at Southern Methodist University. The multiplier reflects the fact that the money that Pantex brings into the local economy supports many retail, medical, educational, finance, insurance and real estate jobs. All told, employment related to Pantex represents over 12% of all jobs in the Amarillo metropolitan area. I urge the D.O.E. to correct the socio-economic impact portions of all three EIS documents to accurately reflect the impact of Pantex on our local economy. 2/08.15

Because of the importance of Pantex to our local economy, the A.E.D.C. is very pleased that Pantex has been chosen as the preferred site for continued assembly and disassembly functions. We also believe this decision is in the best economic interests of the nation, as it saves more than 1.5 Billion dollars to American taxpayers. 3/30.01

I also urge the D.O.E. to continue the high explosive fabrication mission that is currently performed at Pantex. Again, this not only protects jobs in our region, it saves American taxpayers 50 Million dollars compared with the cost of moving these operations to New Mexico. 4/34.01

For Pantex's future, the D.O.E. should locate storage and disposition missions at Pantex, as long as they can be done in an environmentally safe fashion. I urge the Department to make use of the expertise of the Amarillo National Resource Center for Plutonium. This resource center, which is operated by the University of Texas System, the Texas A&M University System, and the Texas Tech University System, can provide world-class evaluation of disposition options. I believe the Amarillo area will prove to be an outstanding operating environment for those storage and disposition functions that have been fully scientifically evaluated and safely implemented.

Once again, thank you for the opportunity to address you in this workshop tonight.

COMMENTS REGARDING PANTEX HEARINGS

AMARILLO, TEXAS; APRIL 22, 1996 by JERI OSBORNE

I am Jeri Osborne. My husband Jim and I live and farm across FM 293 on the northside, downwind and downstream from the Pantex site. We raised our family of three children, one nephew, and kept another nephew and neice a good part of their lives on the farm. Jim and his brother and sisters were also raised there. His father bought the place in 1927.

I have come to speak on health and safety issues as well as the feasibility of having plutonium, other nuclear materials, and other types of hazardous materials and chemicals in our front yard as well as over the areas major water supply and in this very productive and vital agricultural, and a major food source -- for the nation as well as the world just for Amarillo's "powers that be" to possibly create a few more jobs and wealth for themselves.

At this time, there are no known results of long term health exposures to the effects of whatever is the present mission of Pantex --let alone future missions that may result from DOE's new plan. The technology is just not available at this time to perform many of the proposed missions. DOE does not now know what to do with surplus and weapon grade plutonium and other nuclear materials. How can they be so sure of the consequences of future missions that may be brought to the site? 1/11.25

Pantex is probably cleaner than other DOE sites, but it is on the superfund list. It may be safer than other sites, but we can

2/11.26 prove that accidents -- at least I hope the incidents that have affected us personally were accidents --have happened that has endangered our property as well as our personal safety and others in the neighborhood of Pantex. There have been numerous major fires on the site, three or four within the past two years. We took cold drinks and ice to the firemen on various occasions. We have had cast steel shrapnel chunked at us. We have picked up some 300 to 400 pounds of a naval breech block -- one piece weighing 59 pounds. Some of this shrapnel was found some one and one-half to two miles from where it was exploded. We have had tractor tires ruined from it.

Through the years, we have had windows broken, pictures knocked off walls, etc. On October 4, 1995, a very large charge of explosive was set off to signal the start of an emergency management drill. This "test" (drill) broke our house, cracked the slab, rafters, walls, brick, shower, plumbing causing flooding of the basement, and other damages, resulting in some $30,000 in repairs and replacement of carpets and other floor coverings, rebuilding the shower, cracks, etc. We also must have the house leveled. This incident was not only very frightening and dangerous, but has caused us much anxiety and inconvience. Trying to put up family for my mother's death and funeral and having family in for Christmas with a flooded basement, large holes drilled through the living room floor and in other areas of the house causes a great deal of stress to say the least.

Too many questions are yet unanswered by the studies that have been conducted. Granted, it would be impossible to anticipate all potential problems that may arise, but there does seem to be a lack of scientific research used for the study. It would appear that a conclusion has been drawn and figures to support that conclusion were used without any real scientific information.

One must question the credibility of those responsible for the documents and the realibility of the studies when such glaring inaccurate information can be found within the documents. One example of this is found in Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement, Volume II, Pages 4-796 and 4-797 clearly show the town of Canyon outside the 80 kilometers radius and located within Deaf Smith County just north of Castro County. The population distribution map should show Canyon to be just south of Amarillo in Randall County, perhaps some 40 kilometers from Pantex. at the most.

We do not see the location of long term storage of nuclear materials, the possibility of processing /reprocessing, modification of pits, or the location of nuclear reactors at Pantex very good ideas. Nor do we

3/34.02 believe the moving of all the high explosive activities (to Pantex) in our best interests. The DOE has sites that are much larger and much farther away from population, agricultural areas, and major sources of water for its future missions than is Pantex.

Thank you.

Perhaps a site around the 2000 block of Harmony or the 2700 block of Tecks or in SW Amarillo would suffice. If the city fathers ~~would~~ wouldnot want the activity in their neighborhoods, why would they want it for those neighbors to the east of Amarillo where a great deal of those within the trade area live and work to put food on their tables?

HON. DIANNE BOSCH
CITY COMMISSIONER
CITY OF AMARILLO, TEXAS

COMMENTS ON THE STOCKPILE STEWARDSHIP AND MANAGEMENT PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT, STORAGE AND DISPOSITION OF FISSILE MATERIALS PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT AND PANTEX SITE-WIDE ENVIRONMENTAL IMPACT STATEMENT

THANK YOU FOR THE CHANCE TO ADDRESS THE DEPARTMENT OF ENERGY IN THIS INTERACTIVE WORKSHOP FORMAT. AS AN AMARILLO CITY COMMISSIONER SINCE 1989, I HAVE WITNESSED COUNTLESS D.O.E. HEARINGS ON PANTEX. THE GIVE-AND -TAKE BETWEEN THE AUDIENCE AND THE D.O.E. OFFICIALS IS VERY

1/41.05 INFORMATIVE TO EVERYONE IN ATTENDANCE. THE D.O.E. IS TO BE APPLAUDED FOR THE USE OF AN INTERACTIVE FORMAT, AND SHOULD CONTINUE TO USE IT IN FUTURE HEARINGS.

2/40.21 THE D.O.E. IS ALSO TO BE APPLAUDED FOR THE OPEN MANNER WITH WHICH IT HAS, AND CONTINUES TO, ADDRESS LOCAL ENVIRONMENTAL CONCERNS. WE ARE ALSO THANKFUL THAT GOOD MANAGEMENT AT PANTEX BY THE D.O.E.'S CONTRACTORS, MASON & HANGER AND BATTELLE, HAS PREVENTED PANTEX FROM HAVING ENVIRONMENTAL PROBLEMS OF THE TYPE AND MAGNITUDE FOUND AT OTHER D.O.E. SITES. AS IS EVIDENT BY THE LARGE TURNOUT TONIGHT, THIS COMMUNITY STRONGLY SUPPORTS PANTEX, AND THIS

SSM-H-PTX-009
COMMENT LETTER

PAGE 2 OF 4

SUPPORT COMES IN LARGE MEASURE FROM THE D.O.E.'S

2/40.21 continued COMMITMENT TO OUR LOCAL ENVIRONMENT. THAT CONTINUED COMMITMENT TO THE ENVIRONMENT IS CRITICAL FOR COMMUNITY SUPPORT OF ALL CONTINUED OR NEW MISSIONS AT PANTEX.

3/30.01 REGARDING THE STOCKPILE STEWARD SHIP AND MANAGEMENT PEIS, I STRONGLY SUPPORT THE CHOICE OF PANTEX AS THE PREFERRED ALTERNATIVE FOR THE ASSEMBLY AND DISASSEMBLY MISSION. THIS COMMUNITY IS EXTREMELY PROUD THAT PANTEX PLAYED AN IMPORTANT PART IN WINNING THE COLD WAR, AND WILL CONTINUE TO PLAY A CRITICAL ROLE IN REDUCING THE SIZE OF THE NATION'S NUCLEAR ARSENAL IN THE POST-COLD WAR PERIOD. KEEPING THIS MISSION AT PANTEX IS NOT ONLY THE RIGHT CHOICE FOR AMARILLO, IT ALSO MAKE SENSE FROM A NATIONAL PERSPECTIVE BECAUSE IT MAINTAINS A CONTINGENT PRODUCTION CAPABILITY, AND IT SAVES MORE THAT 1.5 BILLION DOLLARS WHEN COMPARED TO THE COST OF TRANSFERRING THE WORK TO THE NEVADA TEST SITE.

AS LONG AS WE ARE ON THE SUBJECT OF COST SAVINGS AND RETENTION OF PRODUCTION CAPABILITY, THE D.O.E. MUST NOT LET

4/34.01 THE HIGH EXPLOSIVE (H.E.) FABRICATION MISSION BE MOVED FROM PANTEX. PANTEX EMPLOYEES HAVE SUCCESSFULLY PERFORMED THIS MISSION FOR MORE THAN FORTY YEARS, AND THERE IS

4/34.01 continued

ABSOLUTELY NO REASON FOR THIS WORK TO BE MOVED. WHEN THE WEAPONS COMPLEX WAS ORGANIZED, IT MADE LOGICAL SENSE TO LOCATE HIGH EXPLOSIVE WORK WITH ASSEMBLY AND DISASSEMBLY. IT STILL MAKES SENSE. FURTHERMORE, THE D.O.E.'S OWN ANALYSIS INDICATES THAT THE COST OF TRANSFERRING H.E. WORK TO NEW MEXICO LABS WOULD BE FIFTY MILLION DOLLARS. IT IS INCONCEIVABLE. THAT THE D.O.E. MIGHT SEEK TO JUSTIFY SPENDING FIFTY MILLION DOLLARS ONLY TO END UP WITH LESS PRODUCTION CAPABILITY IN A LOCATION THAT HAS NEVER PERFORMED THIS MISSION.

IN TERMS OF STORAGE AND DISPOSITION ACTIVITIES, I WOULD FIRST LIKE TO NOTE MY PREVIOUS COMMENTS ABOUT THE NEED TO PROTECT THE ENVIRONMENT. I AM ENCOURAGED BY THE PREVIOUS COMMENTS ABOUT THE NEED TO PROTECT THE ENVIRONMENT. I AM ENCOURAGED BY THE OUTSTANDING ENVIRONMENTAL RECORD THAT PANTEX HAS REGARDING STORAGE OF PLUTONIUM OVER MANY YEARS. I HOPE THAT THE D.O.E. WILL MAKE THE RIGHT CHOICE AND CONTINUE THE SAFE STORAGE OF SURPLUS PLUTONIUM AT PANTEX. I ALSO HOPE THAT THE D.O.E. WILL KEEP IN MIND THAT PLUTONIUM FROM DISMANTLED WEAPONS REPRESENTS A TREMENDOUS INVESTMENT AND MAY PROVE TO BE A VALUABLE ASSET IN CIVILIAN

USE. I URGE THE D.O.E. TO CHOOSE PANTEX AS THE SITE FOR ENVIRONMENTALLY SOUND DISPOSITION ACTIVITIES.
