ABSTRACT:

This document assesses the potential environmental impacts over approximately 10 years of continued operation of Pantex Plant, including foreseeable projects and activities. For Pantex Plant, this document assesses the alternatives of No Action, Relocation of the storage of plutonium components (pits) resulting from nuclear weapon disassembly activities at Pantex Plant to another site, and the Proposed Action (Preferred Alternative) of continuing operations and increasing the quantity of pits in interim storage at Pantex Plant. For the Pit Storage Relocation Alternative, this document also assesses the potential environmental impacts to three DOE candidate sites and one Department of Defense candidate site that could be selected for the relocation of the nuclear component storage activities from Pantex Plant. Evaluations of site infrastructure, land resources, geology and soils, water resources, air quality, acoustics, biotic resources, cultural resources, socioeconomic resources, intrasite transportation, waste management, human health, aircraft accidents, and environmental justice for Pantex Plant and the candidate sites are included in the assessment. The intersite transportation of nuclear and hazardous materials is also assessed.

PUBLIC COMMENTS:

In preparing the Final EIS, DOE considered comments received by mail, fax, e-mail, handed in at hearings, or transcribed from telephone messages. In addition, interactive public hearings were held in April, May, and June 1996 at the following locations where comments and concerns identified during discussions were transcribed: Amarillo, Texas; North Las Vegas, Nevada; North Augusta, South Carolina; Albuquerque, New Mexico; and Richland, Washington.

CHAPTER 1

Introduction

CHAPTER 1 INTRODUCTION

This chapter provides background information to facilitate a general understanding of operations conducted at Pantex Plant, the circumstances that resulted in the preparation of this Environmental Impact Statement (EIS), and the types of analyses that are presented in subsequent chapters. Chapter 1 begins with an overview of Pantex Plant, including a brief history and description of its current mission. Following this overview is a discussion of the evolution of this EIS, the decision making process, significant issues addressed in the EIS, related environmental studies, interagency cooperation, and agency consultations for implementing the alternatives. The chapter concludes with a summary of the subjects covered in other chapters of this EIS.

1.1 INTRODUCTION

The Department of Energy (DOE) (the Department) is the Federal agency responsible for ensuring the safety, reliability, and effectiveness of the Nation's nuclear deterrent. The Department's Stockpile Stewardship and Management Program integrates the expertise and capabilities of three national laboratories, four plant sites, and a field testing site to accomplish this mission. Pantex Plant is an essential element in the program and its continued operation and associated storage of nuclear components are the subjects of this Environmental Impact Statement (EIS). A major aspect of this EIS is to assess the environmental impacts of increasing the number of plutonium components (called "pits") that are to be placed in interim storage as a result of ongoing weapons dismantlement operations.

This chapter provides the foundation for understanding the nature of Pantex Plant and its specific missions, the decisions that the Department faces, and the facts that bear upon these decisions. The chapter begins with a site description and a discussion of the history and mission of Pantex Plant. This is followed by a summary of the origin of this study and changes that have occurred as the EIS has evolved. Subsequent sections address the decision making process and decisions that are to be made, public involvement in identification of issues through the scoping process, the interagency cooperation in the development of this EIS, and agency consultations for implementing the alternatives.

1.2 PANTEX PLANT OVERVIEW

Pantex Plant is located in the Texas Panhandle, approximately 27 kilometers (17 miles) northeast of Amarillo, Texas (Figure 1.2–1). Pantex Plant is bounded on the north by Texas Farm-to-Market Road (FM) 293, on the east by FM 2373, and on the west by FM 683. To the south, DOE-owned property extends to within 1.6 kilometers (1 mile) of United States (U.S.) Highway 60 (Figure 1.2–2).

Pantex Plant Site consists of land owned and leased by DOE. DOE owns approximately 3,683 hectares (9,100 acres) at Pantex Plant proper and 436 hectares (1,077 acres) of detached property, called Pantex Lake, approximately 4 kilometers (2.5 miles) northeast of the main plant site. Pantex Plant operations near its southern boundary require DOE to lease approximately 2,347 hectares (5,800 acres) of land between the plant and U.S. Highway 60 from Texas Tech University (TTU), primarily for safety and security buffer areas. DOE also leases a small facility at the Amarillo International Airport for its own

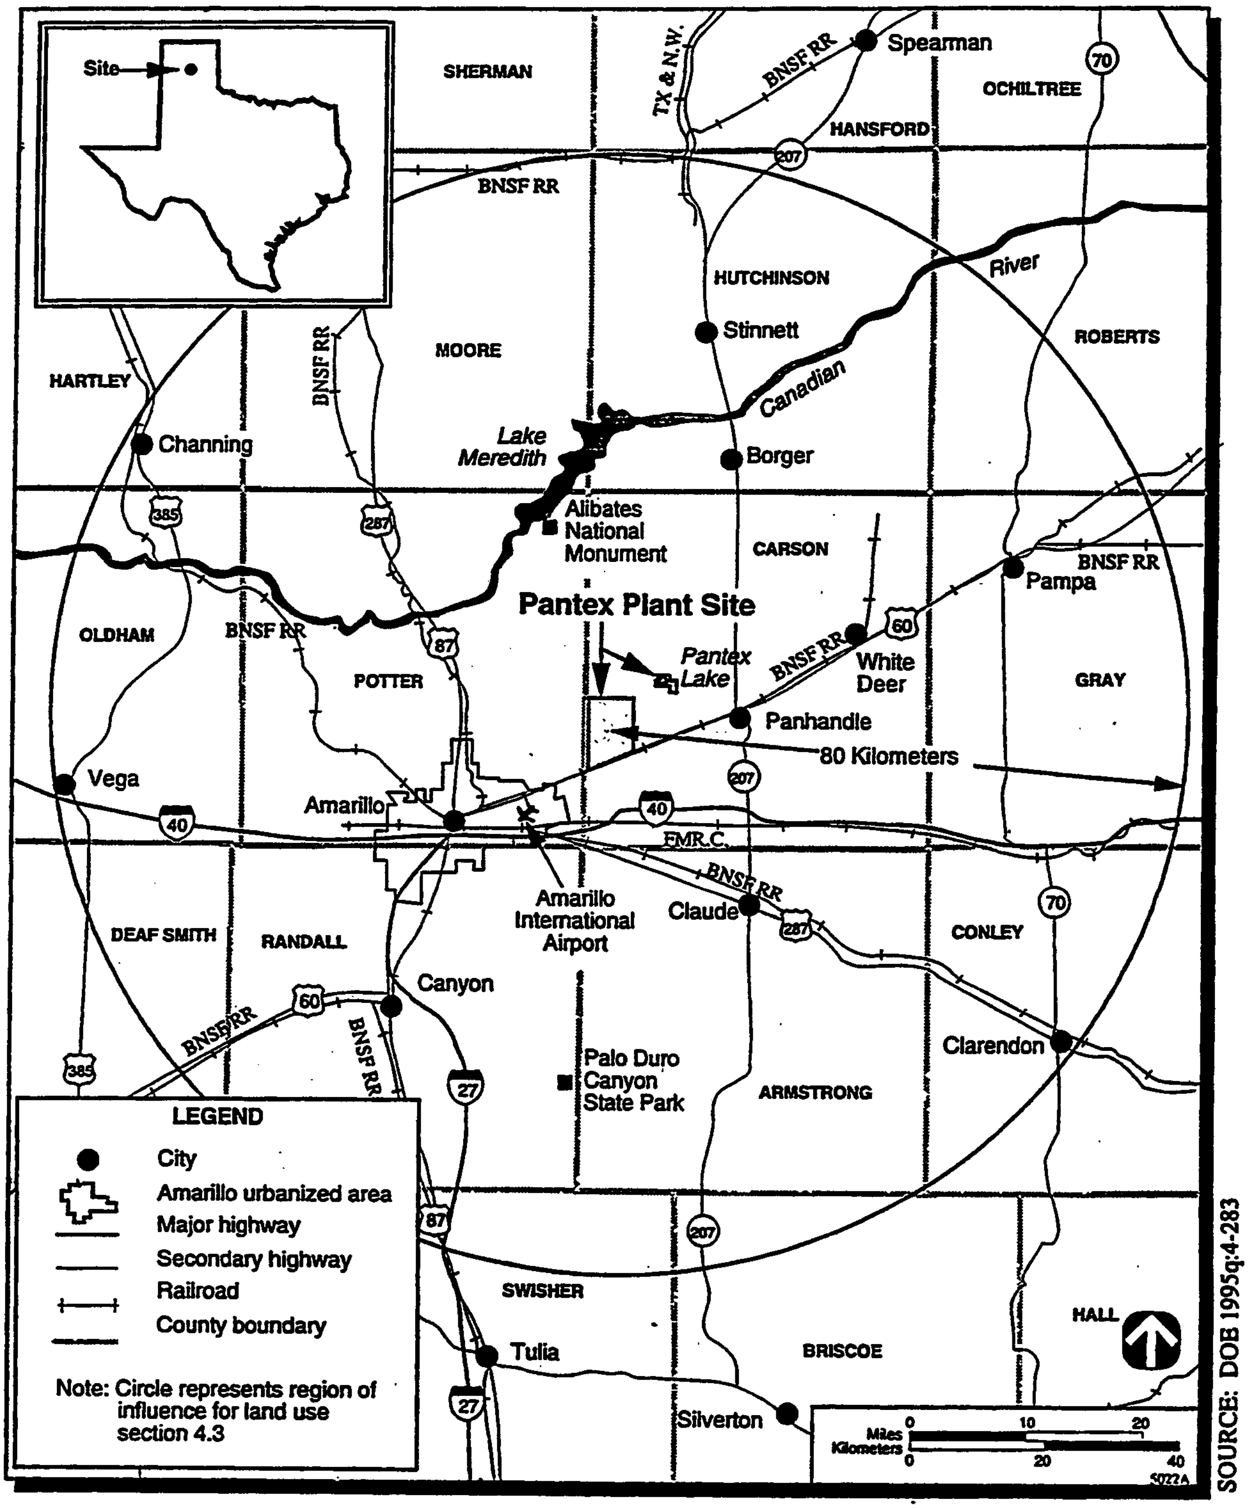

FIGURE 1.2–1.—*Location of Pantex Plant Site in the Texas Panhandle.*

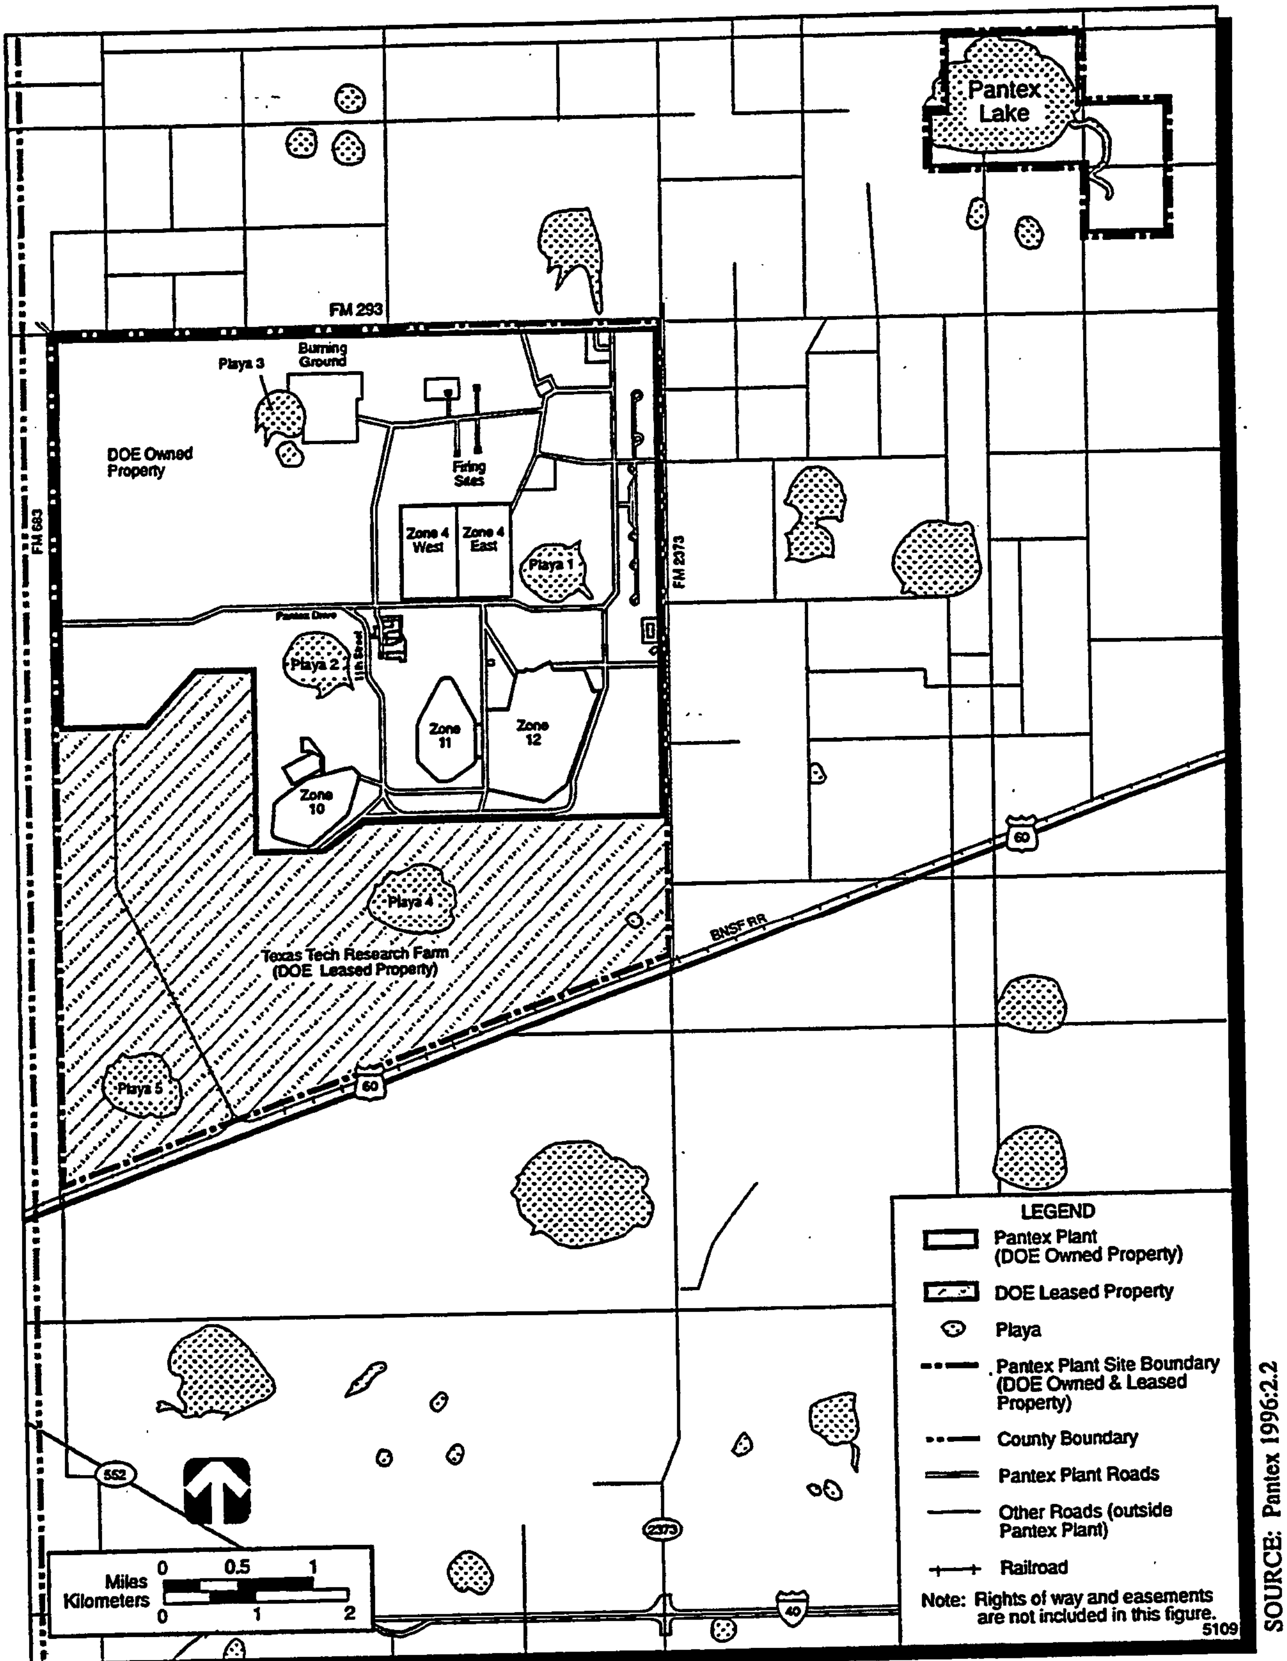

FIGURE 1.2–2.—*Location of Key Areas at Pantex Plant Site.*

transportation use. Approximately 809 hectares (2,000 acres) of Pantex Plant proper are used for industrial operations, the Burning Ground, and firing sites. Some land not actively used for plant operations is provided to TTU for agricultural purposes through a service agreement. The amount of land used for agricultural purposes is variable and subject to periodic change. Approximately 2,596 hectares (6,421 acres) of land were included in the service agreement as of April 1995.

Approximately 476 buildings containing 230,674 square meters (2,483,020 square feet) are located on DOE-owned property. An additional 144 structures, containing 39,928 square meters (429,780 square feet), support the principal operations. The operations that take place in these buildings and structures can generally be divided into four broad categories; production, storage, administration, and support. The production category includes assembly/disassembly and applied technology buildings, representing approximately 33 percent of the site's total building floor area. Storage buildings range from weapons and component staging magazines to portable waste storage dwellings, accounting for approximately 24 percent of the site's total building floor area. The administrative and support categories account for 30 and 13 percent of the total building floor area on the site, respectively.

Pantex Plant currently employs about 3,800 people. In fiscal year 1995, the operating budget was $268 million.

1.2.1 History of Pantex Plant

Pantex Plant was originally built for the U.S. Army during the early days of World War II with the mission of producing conventional munitions—bombs and artillery projectiles. After the war, the plant was deactivated and lay vacant until 1949, when Texas Technological College (now TTU) purchased the site for $1.00.

PANTEX PLANT PROGRAMMATIC MISSION STATEMENT

- *Fabricate chemical high explosive components for nuclear weapons.*
- *Assemble nuclear weapons for the Nation's stockpile.*
- *Maintain and evaluate nuclear weapons in the stockpile.*
- *Disassemble nuclear weapons being retired from the stockpile.*
- *Store plutonium pits from dismantled weapons on an interim basis.*

In 1951, the Atomic Energy Commission (predecessor of DOE) asked the Army to reclaim the main plant and surrounding land under the recapture clause of the sale agreement. Upon transfer to the Atomic Energy Commission, Pantex Plant was used to assemble nuclear weapons. Originally, there were four plants performing the weapons assembly and modification missions. However, between 1965 and 1975, the plants at Clarksville, Tennessee; Medina, Texas; and Burlington, Iowa were shut down. Since then, all nuclear weapons assembly and disassembly operations have occurred at Pantex Plant.

1.2.2 Current Mission of Pantex Plant

Pantex Plant is where DOE fulfills its responsibilities regarding the assembly and disassembly of nuclear weapons, certain maintenance and modification activities regarding the nuclear weapons stockpile, stockpile evaluation, quality assurance testing of weapon components, and research and production of high explosive(s) (HE) components for nuclear weapons. Related activities at Pantex Plant include certain quality assurance evaluations of weapons; research and development activities supporting nuclear weapons; demilitarization and sanitization of weapon parts, equipment, and related materials; waste management; environmental restoration; and onsite transportation, as required. While most of the work currently taking place at Pantex Plant relates to the disassembly of nuclear weapons, the plant must be capable of responding to any mix of assembly, disassembly, modification, or quality assurance operations that may be necessary to maintain the stockpile in the future.

Figure 1.2.2–1 describes the design elements of a typical nuclear weapon and how they interact to create a nuclear explosion. The nonnuclear components, weapon parts, equipment, and related materials resulting from weapons disassembly are demilitarized and sanitized. Activities at Pantex Plant include recycling, salvaging, and disposal, including through commercial firms. Examples of these nonnuclear components include HE, electronics, and structural parts.

The nuclear components resulting from weapons disassembly include pits, highly enriched uranium (HEU) assemblies, radioisotopic thermoelectric generators (RTGs) (encapsulated plutonium heat sources), and classified components made of or containing depleted uranium and tritium. The pit is composed of a plutonium metal core surrounded by a hermetically sealed, nonradioactive outer case. The pits are currently placed in interim storage at Pantex Plant in Modified Richmond and Steel Arch Construction (SAC) magazines.

1.2.2.1 . *Pantex Plant Operations*

A brief description of current operations and other related activities at Pantex Plant is provided in the following sections. More detailed explanations of operations, activities, and facilities may be found in the Pantex Plant *Programmatic Information Document* (Pantex 1996b).

Assembly of Nuclear Weapons

The assembly, modification, and repair of nuclear weapons have occurred at Pantex Plant since the early 1950's. These operations are performed in the bays and cells of Zone 12, and include HE components prepared in Zone 11. Locations of these zones are shown in Figure 1.2–2.

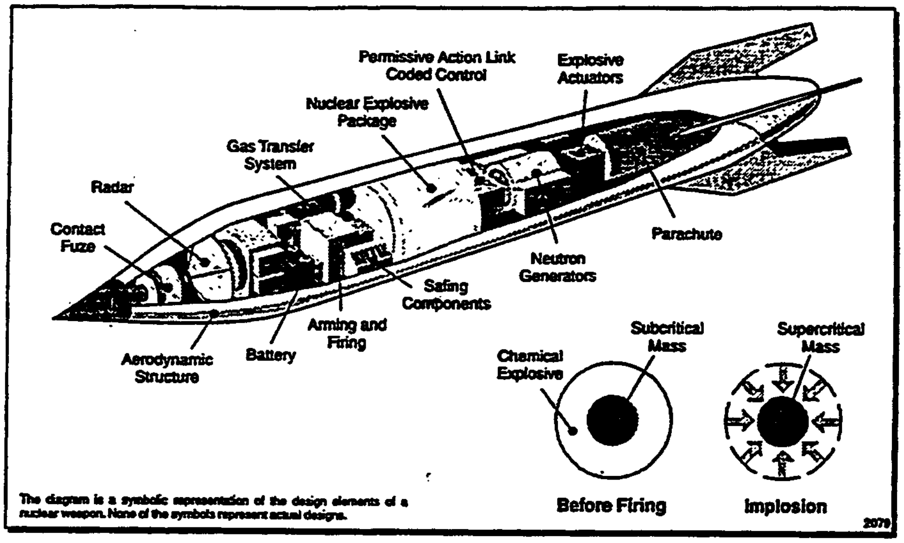
Weapons assembly requires written, prescribed steps to combine separate parts or subassemblies to form a new weapon. Complete weapons assembly is accomplished in the following stages:

- Physics Package assembly.
- Mechanical and Electronic Components assembly.
- Final Package or Ultimate User Package assembly.

The physics package is a subassembly combining HE components (produced at Pantex Plant) and nuclear components (manufactured at other sites) within a protective shell. Physics package assembly entails bonding or mating the main charge subassemblies to a nuclear pit and then inserting this subassembly into a case along with other components. Mechanical and electronic components assembly entails placing the physics package in a warhead case and then installing the components for the arming, fusing, and firing systems; the neutron generator; and the gas transfer system. The final package assembly involves installing additional components and packaging the weapon for shipment.

Currently, the only weapons assembly activities in progress at Pantex Plant are modifications (retrofits and rebuilds) for weapons remaining in the stockpile and the assembly of Joint Test Assemblies (JTAs). JTAs are assemblies of

Nuclear explosions are produced by initiating and sustaining nuclear chain reactions in highly compressed material that can undergo both fission and fusion reactions. Most modern nuclear weapons use a nuclear package with two assemblies: the primary assembly, which is used as the initial source of energy; and the secondary assembly, which provides additional explosive energy release. The primary assembly contains a central core, called the "pit", which is surrounded by a layer of high explosive. The "pit" is typically composed of plutonium-239 and other materials.



Primary Detonation

The primary nuclear explosion is initiated by detonating the layer of chemical high explosive that surrounds the pit which in turn drives the pit material into a compressed mass at the center of the primary assembly. This implosion process is illustrated in the inset of the diagram.

Boosting

In order to achieve higher explosive yields from primaries with relatively small quantities of pit material, a technique called "boosting" is used. Boosting is accomplished by injecting a mixture of tritium (T) and deuterium (D) gas into the pit. The deuterium and tritium are stored in high-pressure reservoirs until the gas transfer system is initiated. The implosion of the pit and the onset of the fissioning process heat the D–T mixture to the point that the D–T atoms undergo fusion. The fusion reaction produces large quantities of very high energy neutrons which flow through the compressed pit material and produce additional fission reactions.

Secondary Activation

The energy released by the primary explosion activates the secondary assembly. The secondary assembly is composed of lithium deuteride and other materials. As the secondary assembly implodes, lithium in the isotopic form lithium-6 is converted to tritium by neutron interactions. The tritium product in turn undergoes fusion with the deuterium to create the thermonuclear explosion.

Nonnuclear Components

Nonnuclear components include contact fuzes, radar components, aerodynamic structures, arming and firing systems, gas transfer systems, permissive action link coded controls, neutron generators, explosive actuators, safing components, batteries, and parachutes.

FIGURE 1.2.2–1.—*Nuclear Weapons Design.*

components in weapon-like configurations that are delivered to the Department of Defense (DOD) for flight testing under field conditions. In these JTAs, the physics package, consisting of the cased HE and nuclear materials components of the nuclear weapon, is replaced with electronic equipment that monitors the desired test functions and simulates the unit mass.

As previously mentioned, Pantex Plant would continue to maintain the capabilities necessary to assemble new nuclear weapons in the future.

Disassembly of Nuclear Weapons

Weapons returned to Pantex Plant for disassembly are received, inspected, and staged in magazines at Zone 4 West preparatory to beginning the actual disassembly process. The disassembly of nuclear weapons is performed within the bays and cells of Zone 12. Disassembly includes the following activities:

- Weapons staging in Zone 4, which includes inspection and verification after receipt from DOE.
- A variety of specialty operations (e.g., X-ray examinations, leak testing, coding, packaging, painting, verification, etc.) in special purpose bays.
- Mechanical disassembly operations in bays.
- Nuclear disassembly operations in cells.
- Demilitarization and sanitization of weapon components, which includes grinding, crushing, and open-air burning.
- Packaging and shipping HEU and tritium components to Oak Ridge Reservation (ORR) and Savannah River Site (SRS).
- Interim storage of pits at Pantex Plant.
- Segregation of waste products into non-hazardous, hazardous, low-level radioactive, and low-level mixed waste categories.

Final package dismantlement begins in an assembly/disassembly bay by performing a series of verification steps to ensure that the weapon is in a safe condition and internal components are intact. The steps include tritium monitoring, electrical system test, gamma spectrometry safeguards verification, and a radiographic verification of the weapon status system.

Next, warheads are removed from the final package container and the mechanical assembly is separated. The mechanical weapon disassembly entails removing the components for arming, fusing, and firing systems; the neutron generators; the gas transfer system; and the outer weapon case.

Finally, the physics package dismantlement is accomplished in an assembly/disassembly cell by opening the case, removing the HE/pit subassembly and other components, and separating the HE main charge from the nuclear pit. The physics package may require a radiographic inspection for an evaluation before disassembly. The balance of the weapon dismantlement function involves managing the various weapon parts such as mechanical, gas transfer, and electrical components. These parts may be recertified and staged for reuse, shipped to the originating vendor site for evaluation or disposition, or demilitarized and sanitized at Pantex Plant. A diagrammatic representation of the weapons dismantlement process is shown in Figure 1.2.2.1–1.

Many nuclear weapon components and items cannot be considered for discard or disposal until demilitarization and sanitization activities are performed. Demilitarization and sanitization are manufacturing activities used to remove classified and other nuclear proliferation-sensitive information. These activities include thermal shock, thermal treating, machining, granulation, melting, mechanical crushing, fluid jet machining, chemical dissolution, grinding, cutting, or chipping and actuation.

FIGURE 1.2.2.1–1.—*Weapons Dismantlement and Pit Storage at Pantex Plant.*

Modification and Maintenance of Nuclear Weapons

Weapons remaining in the stockpile that require maintenance or modification are returned to Pantex Plant. Modification and maintenance activities can range from replacement of limited life components to almost total rebuilds for the purpose of retrofitting or upgrading the weapons (e.g., for improved safety or enhanced security features).

Stockpile Evaluation

Stockpile evaluation involves the disassembly and evaluation of pre-selected weapons returned from DOD. The main purpose of stockpile evaluation is to determine the reliability of the weapon system based on the test results of a representative sample of each weapon system in the stockpile. The weapons returned for evaluation are divided into two categories, laboratory tests and flight tests. Following evaluation, some of the weapons are rebuilt and returned to the stockpile. As part of the laboratory tests, select weapon systems are exposed to variable temperatures for prolonged time periods to simulate environmental conditions that the weapons could be subject to during their lifetimes. This type of test is referred to as aging studies. Aging studies are conducted in environmental chambers located in Buildings 12–94 and 12–104A. Currently, these environmental chambers are not in use. Prior to use, these environmental chambers will be subject to review under NEPA and site safety management systems.

Quality Assurance Testing of Weapons Components

To maintain the reliability of the Nation's nuclear weapons stockpile, a certain number of preselected weapons from each type of weapon are returned to Pantex Plant each year for component surveillance testing and evaluation. Weapons are evaluated in a selective dismantlement process whereby certain components are physically removed from the weapon, assembled into specified test configurations, and subjected to electrical and/ or explosives testing.

Research and Production of High Explosives and Weapons Components

Pantex Plant researches the physical and chemical characteristics of the used parts in nuclear weapons. Highly specialized explosive main charges and initiation systems are required for a weapon to produce a nuclear explosion. Research at Pantex Plant includes the use of insensitive HE for increased safety as well as refinement of HE manufacturing methods and safety procedures. Pantex Plant performs HE synthesis, formulation, machining, extrusion, testing, process development, and analytical operations in performing its HE research and development and production missions. These operations are performed in Zone 11 or Zone 12 using HE materials stored in Zone 4 East.

The products of manufacturing operations are explosive main charges, small explosive components, and other highly specialized explosive materials. Main charge subassemblies are emplaced in the physics package of a nuclear explosive during the weapon assembly process. Various small explosive subassemblies and pellets are produced from explosives, metal or plastic components, electrical components, hardware, assembly materials, and small explosive components that are manufactured offsite. Punch and die pressing, laser welding, explosive extrusion loading, and mechanical assembly of HE are some of the functions carried out at Pantex Plant. Currently, most explosives components are made for modification, random testing, and maintenance of stockpile weapons.

In March 1994, a formal literature search was conducted to investigate treatment/processing methods for HE other than OB/OD. The review identified processes currently in use (e.g., OB/

OD and chemical treatment), as well as those in various stages of development. A Best Available Control Technology (BACT) analysis for air emissions from explosives treatment at Pantex Plant Burning Ground was conducted and documented in a DOE letter to the Texas Natural Resources Conservation Commission (TNRCC) dated October 15, 1993. The BACT review concluded that controlled open thermal treatment with existing administrative controls constituted BACT.

In a subsequent study, the alternatives were determined to be either technically infeasible for Pantex Plant explosives or economically infeasible on a cost-per-unit mass of air pollutants that could be controlled (Radian 1994:1). The alternative emerging explosive treatment technologies were identified as: advanced thermal treatment methods (i.e., molten salt destruction, supercritical water oxidation, and advanced plasma incineration), chemical/biological treatment methods (e.g., base hydrolysis, chemical/electrochemical oxidation, and biological oxidation), and explosives recovery/reuse technologies (e.g., critical fluid extraction, explosives as supplemental fuels, and solvent recovery).

Since 1994, the development of refined procedures for HE chemical treatment has warranted the further investigation of a base hydrolysis treatability study program to be housed in Building 11–36. Though the most commonly generated HEs resulting from dismantlement processes are HMX based, this treatability study can accommodate other types of HE (e.g., RDX, TNT, HNS, TATB, and some of their respective formulations).

Alternative methods to open burning-open detonation of HE are summarized in appendix G. Recycling and commercial use of Pantex Plant explosives are currently utilized to reduce Burning Ground activities.

Interim Storage of Pits

Once the pit is removed from the weapon, it is stored at Pantex Plant as an interim measure. The term "interim storage" does not refer to a specific timeframe, but rather to the interval of time which will occur until a Record of Decision (ROD) is made on long-term storage and the site and facilities selected in that ROD are ready to receive the pits. The decision on the site and facilities for long-term pit storage will be based on analyses in the *Long-Term Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement* (S&D PEIS) (DOE/EIS-0229).

As of August 1996, approximately 9,000 pits had accumulated at Pantex Plant as a result of dismantlement activities. Pantex Plant has the authority to provide interim storage for up to 12,000 pits. Decisions regarding interim pit storage beyond this level will be made as a result of this EIS. Pantex Plant has a sufficient number of magazines to safely accommodate 20,000 pits. Eighteen Modified Richmond and 42 SAC magazines have been identified for storage of pits. Each Modified Richmond magazine can accommodate up to 440 pits and each SAC magazine can hold up to 392 pits. The designation of 60 magazines provides for more than 20,000 storage spaces to allow for operational flexibility. Some of the excess magazine capacity may be used for staging of weapons or components. The *Environmental Assessment for Interim Storage of Plutonium Components at Pantex* (DOE/EA–0812) (DOE 1994w) provides a more complete discussion of the SAC and Modified Richmond magazines, as well as a general description of pit storage configurations (DOE 1994w).

The pits removed from weapons are currently packaged in AL–R8 storage containers. These containers were previously used for both transportation and storage. DOE discontinued using them for transportation in 1990, and they are currently used solely for interim storage of pits. A new, more robust storage and transport container, known as AT–400A, is being developed and tested for transportation and long-term storage. Scheduled for use beginning in 1997, the container design incorporates upcoming, more stringent regulatory requirements for transportation. The design of the AT-400A package will meet the latest Type B package certification testing requirements. The AL–R8 and AT–400A containers are further described in volume II, appendix F.

The pit storage containers would be stored in a multiple stacking configuration of containers placed horizontally on steel pallets. Pallets for this configuration have been designed to ensure structural integrity and stability in a maximum credible earthquake scenario. The pallets are placed in storage using a commercially available rotating turret forklift. The forklift has been modified to provide special shielding that reduces operator exposure to extremely low levels of radiation. This electric forklift would be used for storage, retrieval, and inventory operations.

Automated Guided Vehicles (AGVs) have also been developed to place pits in storage facilities and to assist in taking inventories using bar code readers. The use of AGVs virtually eliminates any need for humans to enter any pit storage facilities.

Operations in the storage facilities include periodic inventory and inspections. Inspections coincide with planned inventory activities (generally every 18 months) and consist of a visual inspection of facility conditions and container surfaces, as well as removal of selected containers for surveillance tests. Container integrity is further evaluated via inspection (using both destructive and nondestructive evaluation techniques) of the container surfaces (for corrosion), weld integrity, and integrity of insulation and plastic parts. Both the shielded forklift and the AGVs can carry a bar code reader, camera, and gamma spectrometer to allow inventory and inspection to be performed without operator exposure to radiation.

Transportation of Weapons and Components

Pantex Plant is involved in the transportation of many different types of hazardous materials. These include nuclear explosives, nuclear components, HE components and materials, tritium, industrial chemicals, and other hazardous materials. Typical vehicles and equipment used in transport operations include forklifts, hardened trailers, Safe Secure Tractor Trailers, flatbed trailers, vans, trucks, pallet jacks, and tow motors. Approximately 30,000 transfers of radiological and explosive materials occur each year at Pantex Plant. In addition, Pantex Plant ships and receives radiological components or materials to and from other sites. To ensure the safety of operations, drivers are carefully trained, certified, subjected to physical examinations, and routinely screened for drugs and alcohol. Further information on transportation is provided in sections 4.12 and 4.16 of this volume of the EIS.

Decontamination and Decommissioning

Pantex Plant is currently planning to streamline operations and reduce maintenance and operating costs by consolidating operations into fewer buildings. At this time, no plans have been made for the decommissioning of any facilities at Pantex Plant. The designation of facilities is pending decisions regarding the future of Pantex Plant being made in the *Stockpile Stewardship and Management Programmatic EIS* (SSM PEIS) (see section 1.7).

Facilities at the plant are potentially historic resources in terms of both their age and their role in the Cold War. In accordance with the Pantex Plant Cultural Resource Management Plan being developed, the plant will consult with the Texas State Historic Preservation Office prior to initiation of any decontamination and decommissioning activity to ensure that no historic facilities are inadvertently destroyed. Separate *National Environmental Policy Act* (NEPA) (42 U.S.C. 4341) documentation will be prepared when plans are developed for specific decontamination and decommissioning projects.

1.2.2.2 *Environmental Protection Activities*

The Environmental Protection Program is continuously improving Pantex Plant's ability to ensure that missions are performed in a safe and environmentally protective manner. Currently, the program consists of nine elements:

- Public communication, to inform and involve stakeholders on issues of concern.
- Oversight, to work closely with State agencies in verifying and addressing impacts of facility operations to the environment.
- Quality assurance, to ensure integration of quality assurance practices in environmental protection.
- Compliance, to integrate environmental protection into production line and planning activities.
- Pollution prevention and waste minimization, to encourage waste elimination, waste minimization, air emissions reduction, material substitution, recycling, alternative disposal method studies, energy conservation, and water conservation.
- Environmental monitoring, to document emissions and effluents.
- Cultural resources, to identify and manage archeological and historic resources at Pantex Plant.
- Natural resources, to improve management of lands, surface water and playa wetlands, groundwater, soils, air quality, and flora and fauna at Pantex Plant.

Each of these elements is discussed in detail in the *1994 Environmental Report for Pantex Plant* (DOE 1995b). The DOE Amarillo Area Office is initiating the development of a resource stewardship strategy to guide future planning and management of all environmental resources at Pantex Plant.

Because of the extent of current and planned site investigations and corrective actions, the environmental restoration program is described separately in the section that follows.

1.2.2.3 *Environmental Restoration*

Environmental restoration activities involve determining the nature and extent of contamination, and performing remediation as needed, in compliance with all appropriate regulatory requirements.

In 1989, the U.S. Environmental Protection Agency (EPA) conducted a *Resource Conservation and Recovery Act* (RCRA) (42 U.S.C. 6901, et seq.) facility assessment to identify solid waste management units from which hazardous constituents may migrate. A total of 144 solid waste management units were originally identified at Pantex Plant. These have been organized into 14 groups for corrective action. To evaluate compliance with provisions of the RCRA permit, DOE conducts assessments and audits, and TNRCC and EPA conduct independent inspections. The environmental restoration activities at Pantex Plant will continue until all remediation work is accomplished in accordance with regulatory requirements, regardless of decisions which may be made on other aspects of the plant's mission (see section 4.5 in this volume and appendix I in volume II for further details).

Pantex Plant was placed on the National Priorities List in 1994 under the *Comprehensive*

Environmental Response, Compensation, and Liability Act (CERCLA) (42 U.S.C. 9608). Pantex Plant is currently in the process of negotiating an agreement with EPA and TNRCC to integrate both RCRA and CERCLA requirements into a comprehensive site-wide strategy. The majority of environmental restoration activities are expected to be completed by the year 2000.

Although this EIS does not provide project-specific NEPA documentation for these CERCLA projects, overall effects of these projects are included in this EIS for complete assessment and full disclosure of the cumulative impacts of all operations at Pantex Plant.

1.2.2.4 *Waste Management Activities*

The types of wastestreams generated and managed by Pantex Plant include low-level radioactive waste (LLW), low-level mixed waste (LLMW), hazardous waste (HW), nonhazardous waste (NHW), and recyclable materials. See volume II, appendix G for a discussion of recyclable materials. Three drums of transuranic (TRU) waste were generated in 1993 as a result of an incident during weapons dismantlement. The waste is stored in an appropriately monitored facility awaiting shipment to an approved offsite management facility. No TRU waste is generated on the site as a result of normal operations.

LLW generated, processed, and stored at Pantex Plant is regularly transported to the Nevada Test Site (NTS) for disposal. Building 12–42 provides processing capabilities for LLW.

LLMW generated, processed, and treated is generally stored onsite until it can be shipped offsite for disposal. Building 11–9 and the Burning Ground provide onsite treatment capabilities for LLMW. In 1994, 32.6 cubic meters (42.6 cubic yards) of LLMW was transported to a commercial disposal facility in Utah. In 1996, 70 cubic meters (91 cubic yards) of LLMW were disposed at the same facility. Another shipment in September 1996 further reduced LLMW inventories by a total of 50 percent. Additionally, Pantex Plant is capable of treating and processing (such as compaction and repackaging) hazardous waste including LLMW in tanks and containers.

HW generated, processed, and stored at Pantex Plant is transported by commercial vendors for disposal. The Burning Ground burns HE and HE-contaminated wastes in accordance with regulatory permits.

NHW generated is managed through both onsite and offsite facilities. NHW, including oils and debris, are shipped offsite for disposal. Ordinary trash is either recycled (e.g., aluminum and paper) or shipped to the Amarillo Landfill through commercial vendors for disposal. Construction debris is disposed onsite in a landfill located in Zone 10.

Other types of waste, including asbestos, polychlorinated biphenyls, and medical wastes, are generated, processed, and stored prior to disposal through commercial vendors specifically licensed to manage each waste.

Sanitary and industrial wastewater is treated onsite in the Waste Water Treatment Facility. Industrial wastewater from production and manufacturing of HE components is filtered in Buildings 12–43 and 11–50. All wastewater discharges are disposed of onsite (section 4.6.1.1).

Pantex Plant has a continuing program of pollution prevention and waste avoidance initiatives. These include source reduction, process changes, material substitution, and administrative policies that not only reduce waste and pollution, but also result in cost savings for taxpayers. In 1996, the Pollution Prevention and Waste Minimization (PP/WM) program at Pantex Plant received the President's "Closing the Circle" Award for achievements in recycling and waste prevention. This program saved approximately $4.5 million of taxpayer money in 1995. Appendix G in volume II presents details of the program.

The *Environmental Information Document* provides a detailed description of waste streams and waste management practices and facilities (Pantex 1996). The *Federal Facility Compliance Act* Agreed Order and approved Site Treatment Plan-Compliance Plan contain detailed descriptions of waste treatability groups and waste management milestones.

Waste treatment, storage, and disposal operations are contingent on programmatic decisions resulting from the WM PEIS.

1.2.2.5 *Facility Construction and Upgrade*

Several operations essential to the assembly, disassembly, and maintenance of weapon systems are currently housed in outmoded facilities. To continue Pantex Plant's mission, it is necessary to shift these operations to other existing and newer facilities or to construct new facilities that would maximize worker safety and allow for greater efficiency in meeting all regulatory requirements. An average of one or two new construction projects are funded annually. In 1995, Pantex Plant received $26.4 million for construction and equipment. The *Programmatic Information Document* provides more detail on future construction/modification projects (Pantex 1996b). Those projects that are at a stage of development where sufficient detail is known to perform a NEPA analysis are discussed in this EIS (see volume II, appendix H). As plans for other projects become more detailed and ready for the decision making process, NEPA review will be conducted prior to authorization.

1.3 EVOLUTION OF THIS ENVIRONMENTAL IMPACT STATEMENT

The operations of Pantex Plant were assessed previously in a site-wide EIS (DOE/EIS–0098) published in 1983 (DOE 1983a). The scope of operations at Pantex Plant included the staging of pits prior to transfer to other DOE sites for processing. A new site-wide EIS was in the planning stage, but had not been scheduled, when pit transfer activities were suspended for operational reasons and, later, disarmament commitments. The *Environmental Assessment for Interim Storage of Plutonium Components at Pantex* (DOE/EA–0812) assessed the impacts of interim storage (DOE 1994w).

Prior to the release of this Environmental Assessment, the Secretary of Energy advanced the schedule for the planned Pantex Plant EIS and committed the Department to consider alternate sites for interim storage (Letter 1994). Additionally, the Secretary of Energy directed that the S&D PEIS be prepared to analyze the long-term storage of plutonium in all forms, including pits, and the ultimate disposition of the material. Additional details on the evolution of the S&D PEIS are provided in section 1.7.3.

Volume I, chapter 2 of the SSM PEIS discusses in detail the national security policies, responsibilities, strategies, and directives placed on DOE. For the reasonably foreseeable future, the START II protocol is most useful in helping define a specific time period to bound the reasonably foreseeable future.

The START I Treaty and the START II protocol only control the number of strategic nuclear weapons that can be loaded on treaty-specified and verified strategic missiles and bombers. These nuclear weapons are limited to 6,000 by the START I Treaty and 3,500 by the START II protocol. The treaties do not control the total stockpile or the composition of strategic and nonstrategic nuclear weapons. The U.S.

stockpile will be larger than 6,000 under START I and 3,500 under START II since the stockpile includes retaining weapons for nonstrategic nuclear forces, including DOD operational spares and spares to replace weapons attrited by DOE surveillance testing.

1.4 The Decision Making Process and Decisions to be Made

This Pantex Plant EIS provides both DOE and the public with information on the potential environmental impacts associated with the Proposed Action and Alternatives. This EIS covers all current and reasonably foreseeable facilities and activities at Pantex Plant, interim storage requirements for pits from weapons dismantlement, and the transportation of classified components shipped from Pantex Plant. This EIS was also scoped to address alternate locations for interim pit storage (i.e., until longer-term storage decisions are made and implemented). Accordingly, it also addresses potential environmental impacts at NTS, SRS, Hanford Site, and Kirtland Air Force Base (KAFB) should one of these installations be chosen as an alternative site for the interim storage of up to 20,000 pits.

There are two additional DOE NEPA documents that address the storage of pits. The SSM PEIS addresses the long-term storage of pits that will be needed for national security requirements (strategic reserve pits). The S&D PEIS addresses storage of all pits, including pits that have already been, or later may be, declared surplus to national security requirements, and the approach for dispositioning surplus pits.

The Proposed Action in this EIS was designed specifically to encompass the interim storage of pits from weapons dismantlement until such time as longer-term decisions regarding storage and disposition could be made and implemented. The Preferred Alternative for the interim storage of pits in this EIS is to continue to store them at Pantex Plant. The Preferred Alternative in the Draft SSM PEIS provides for the long-term storage of strategic reserve pits at whatever site is selected for the assembly/disassembly function in the future weapons complex; the Draft SSM PEIS identifies Pantex Plant as the preferred site for that function.

The Draft S&D PEIS analyzed a number of alternatives and suboptions for the storage of pits and other forms of surplus material pending disposition, but it did not identify a Preferred Alternative for the storage of pits. Several alternative sites, including Pantex Plant, were analyzed for the mission of storing surplus material pending disposition. The Draft S&D PEIS contemplated the possible transfer of surplus material to Pantex Plant for storage around the year 2004, after upgrades to existing storage facilities in Zone 12 had been completed. The Rocky Flats Environmental Technology Site (RFETS) was identified in the Draft S&D PEIS as one source of this surplus material.

The Final S&D PEIS will include an alternative that is a refinement of the Draft S&D PEIS alternatives described above. Under this alternative, pits could be transferred from RFETS to Pantex Plant as early as 1997 and stored temporarily in existing Zone 4 facilities until the upgraded facilities in Zone 12 are available. The environmental impacts associated with transferring surplus pits from RFETS to Pantex Plant, including the impacts of their storage at Pantex Plant, will be included in the Final S&D PEIS. The potential addition of RFETS pits at Pantex Plant would not exceed the storage limit of 20,000 pits proposed and analyzed in this EIS. Moreover, surplus RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant. (Refer to sections 1.7.2 and 1.7.3 for more information on the SSM PEIS and the S&D PEIS, respectively.) If this alternative were selected in the ROD for the S&D PEIS, surplus pits already at Pantex Plant would continue to be stored there pending disposition and, in addition, surplus pits from RFETS would be transferred to Pantex Plant in the near term for storage, also pending disposition.

At this time DOE projects that the Records of Decision (RODs) for both the SSM PEIS and the S&D PEIS will be issued in late 1996 or early 1997, at or about the same time as the ROD for this EIS, and that decisions on the longer-term storage of pits will be made in the RODs of the two PEISs. As described above, if DOE selects the Pantex Plant storage alternatives in the SSM PEIS and the S&D PEIS, strategic reserve pits would be stored at Pantex Plant indefinitely and surplus pits (including the pits currently at RFETS) would be stored at Pantex Plant until DOE implements decisions regarding their disposition. The ROD for this EIS will take into consideration the decision-making process for the PEISs when making a decision on the interim storage of pits.

However, if there is a significant delay in RODs for either PEIS, or if DOE does not make a decision on the long-term storage of pits in those RODs, then a decision will be needed on the location of interim storage of pits, uninformed by a decision on long-term storage. In any event, this EIS was completed with the analysis of interim storage alternatives, including addressing the issues and comments received from the public on this EIS, to support a decision relating to the storage of pits until a long-term storage decision has been made and implemented.

DOE encourages interested parties to comment, during the period between issuance of the Final PEISs and issuance of the RODs, on the Preferred Alternative for the SSM PEIS and the alternatives for the S&D PEIS as they affect the storage of pits at Pantex Plant.

The DOE decision-making process for the interim storage of pits will consider the analysis presented in this Final EIS along with mission requirements, costs, other technical factors, the national interest, and public input. The Secretary of Energy will then issue a ROD. The ROD may be issued no sooner than 30 days after the Final EIS. The ROD will explain all factors, including environmental impacts, that DOE considered in reaching its decision. The ROD will specify the alternative or alternatives that are considered to be environmentally preferable.

If the selected alternative is different from the environmentally preferred alternative, the ROD will present the rationale for the Department's selection. Specifically, the ROD will document the decision as to how operations at Pantex Plant would be conducted, at which site(s) interim pit storage should be performed and in what quantity, and what mitigative measures should be taken. As discussed in section 3.1, the ROD may combine aspects of various alternatives in the decision.

If mitigation measures are adopted as part of the agency's decision, these will be summarized in the ROD, as applicable, and included in a Mitigation Action Plan. The Mitigation Action Plan would explain how and when mitigation measures will be implemented. The Mitigation Action Plan must be in place prior to taking any action that is the subject of a mitigation commitment.

1.5 Comment Period, Public Hearings, and the Analysis of Comments

In March 1996, the Department published the *Draft Environmental Impact Statement for the Continued Operation of Pantex Plant and Associated Storage of Nuclear Weapon Components*. A Notice of Availability of the Draft EIS was published in the *Federal Register* (61 FR 15232) on April 5, 1996. The comment period for the Draft EIS began on April 5, 1996, and originally was to end on July 5, 1996. However, at the request of stakeholders in the Amarillo, Texas area, the ending date was extended to July 12, 1996, for a comment period of 98 days. Any comments received after that date were included to the extent practicable.

During the comment period, public hearings were held in Amarillo, Texas; North Las Vegas, Nevada; North Augusta, South Carolina; Albuquerque, New Mexico; and Richland, Washington. In addition, a separate Technical Exchange Meeting was held in Amarillo, Texas, with representatives of the State of Texas, City of Amarillo, Panhandle Water Conservation District No. 3, the University Consortium (Texas Tech University, Texas A&M University, University of Texas, and West Texas A&M University), Amarillo Economic Development Corporation, Pantex Plant Citizens Advisory Board, and members of the public.

All public meeting comments were combined with comments received by all other means (e.g., hand-ins, faxes, letters, e-mail, etc.) during the public comment period. All comments were categorized by subject area and were considered for potential changes or additions to the EIS. For further information, see volume III of this EIS.

1.6 CHANGES SINCE THE ISSUANCE OF THE DRAFT EIS

Since the March 1996 issuance of the *Draft Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components*, there have been several changes in information, regulatory status, and related EISs, as well as a revision of the Draft DOE Standard for Aircraft Crash Analysis. In addition, comments from agencies, organizations, and the public requested elaboration and additional assessment of numerous issues. These changes are reflected in this Final Pantex Plant EIS.

New and updated information has been included in the discussions for almost all environmental resources. The new information includes a different pit repackaging concept and a reduced scope for the proposed Hazardous Waste Treatment and Processing Facility (HWTPF). The new pit repackaging concept is still at a very early planning stage and is not detailed in this Final EIS. However, the foreseeable impacts have been bounded to the extent possible in the infrastructure, waste management, and human health sections. Appendix H includes discussion of both a large and a small version of the HWTPF. Since the Draft EIS, the smaller version has become the preferred alternative for this facility. The impacts of the larger version are still discussed in the appropriate sections of the EIS in order to bound the impacts. None of the new or updated information results in a significant difference in the impacts assessed.

The regulatory status of several permits has changed since the Draft EIS. The new permitted levels and resulting changes in operations have been taken into account in the assessment of impacts.

Updated information regarding related EISs has been added in the Summary, section 1.4, section 1.7, and in the discussions of cumulative impacts where appropriate. The information was updated in this EIS as a result of advances in the decision-making process in the related EISs.

The methodologies for assessing the risk of an aircraft crash and for assessing the cumulative impacts have changed to a degree since the Draft EIS. The aircraft crash methodology has been in development throughout the preparation of the Draft and Final EIS. The July 1996 Draft was used for this Final EIS. The assessment of cumulative impacts, which has been changed to more accurately reflect the potential impacts, is discussed in more detail in section 4.21 of volume I of the Final EIS.

The changes due to comments received during the comment period are detailed in volume III of the Final EIS and discussed briefly in the Summary.

1.7 RELATED NATIONAL ENVIRONMENTAL POLICY ACT STUDIES

There are several other ongoing NEPA documents for programs or activities that could also have impacts at Pantex Plant. These include the following:

- The *Waste Management PEIS for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (WM PEIS).
- The *Long-Term Stockpile. Stewardship and Management PEIS* (formerly part of the *Reconfiguration PEIS*).
- The *Storage and Disposition of Weapons-Usable Fissile Materials PEIS.*
- The *Site-Wide EIS for Continued Operation of the Los Alamos National Laboratory* (LANL).
- The *EIS for the Nevada Test Site and Off-Site Locations in the State of Nevada.*

Each of these documents is briefly described in subsections 1.7.1 through 1.7.5. The impacts of these programs on Pantex Plant are addressed in the "Cumulative Impacts" sections of this EIS to the extent that information relevant to Pantex Plant from the other documents is currently available.

1.7.1 *The Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste (DOE/EIS–0200)*

DOE is preparing the WM PEIS to evaluate the potential environmental impacts of alternative configurations of DOE's waste treatment, storage, and disposal facilities (DOE 1995t). On the basis of the evaluations in the WM PEIS and other information, DOE will decide whether to consolidate the management of some or all of its five types of waste and, if it does select consolidation, the Department would also select sites that will manage each type of waste. The WM PEIS evaluates consolidation over the next 20 years. In contrast, the Pantex Plant EIS evaluates site-specific impacts over a 10-year period.

Of the 54 sites for which DOE has waste management responsibility, 17 are considered "major" DOE sites in the WM PEIS and are candidates to receive wastes generated at other sites, to host disposal facilities, or manage HLW. Pantex Plant is a major site considered in the WM PEIS and is a potential site for management of its own LLMW, LLW, and HW. Currently, Pantex Plant has only three drums of TRU waste and no HLW. The TRU waste is awaiting shipment to an approved offsite management and disposal facility. After the TRU waste is shipped offsite, Pantex Plant is not expected to handle TRU waste or HLW in the future. This is contingent upon decisions contained in the WM PEIS, SSM PEIS, and S&D PEIS.

To assist DOE in making decisions about whether and where to consolidate waste management, the WM PEIS considers 36 alternatives organized into four major alternative categories (No Action, Decentralized, Regionalized, and Centralized). The following bullets describe the alternative categories and how each alternative could impact waste management at Pantex Plant:

- **No Action** alternatives involve the use of only existing or planned waste management facilities.
  - No Action—*status quo* would be pursued. Only existing or currently planned (i.e., funded) facilities would be operated or constructed at Pantex Plant. Waste currently shipped off-

site would continue to be shipped off-site.

- **Decentralized** alternatives locate waste management facilities where waste is currently located or where it will be generated, treated, or disposed of in the future.
  - — Decentralized—Under this alternative, Pantex Plant would treat and dispose of its LLMW and LLW onsite. All HW would continue to be shipped to commercial facilities.
- **Regionalized** alternatives locate waste management facilities at several sites throughout the Nation.
  - — Regionalized—Under a few alternatives, Pantex Plant would treat and/or dispose of all its LLMW and LLW onsite. However, under most alternatives, Pantex Plant would ship its LLMW and LLW to one or more of DOE's other sites for treatment and disposal. Under all alternatives, HW would continue to be sent to other DOE sites or commercial vendors.
- **Centralized** alternatives locate large waste management facilities at only one or two sites.
  - — Centralized—Under all alternatives, Pantex Plant would ship all its LLMW and LLW to a single DOE site for treatment and disposal. Centralized management of HW was not analyzed.

The Pantex Plant EIS discusses the cumulative impacts of these activities at Pantex Plant. Alternatives analyzed in the WM PEIS for Pantex Plant do not include receipt of wastes from other sites.

Differences in waste volume projections in the WM PEIS and this EIS are a result of different databases. The WM PEIS used waste load forecasts developed for the 1992 Integrated Database (IDB) for LLW; the 1994 Mixed Waste Inventory Report (MWIR) for LLMW; and both the 1992 IDB and the 1993 MWIR for TRU waste. Where more recent data could impact programmatic decision making, updated forecasts and analysis are presented in the Final WM PEIS. DOE plans to update the estimates of LLW at Pantex Plant in the Final WM PEIS. The Pantex Plant EIS uses the Pantex Plant *Environmental Information Document*, the Agreed Order, and approved Plans containing 1995 and 1996 waste stream inventories. Cumulative Impacts of alternatives in the WM PEIS and Pantex Plant EIS are presented in volume I, section 4.13.5.1. The Pantex Plant PP/WM program originally implemented in 1991, has significantly reduced waste volumes. Appendix G in volume II of this EIS discusses in detail the PP/WM program.

1.7.2 The *Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (DOE/EIS-0236)

Stockpile stewardship includes activities required to maintain a high level of confidence in the safety, reliability, and performance of nuclear weapons in the absence of underground testing, and to be prepared to test weapons if directed by the President. Stockpile management activities include maintenance, evaluation, repair, or replacement of weapons in the existing stockpile.

Pantex Plant currently performs missions that are examined in the SSM PEIS. The ROD for this PEIS is expected to determine which facilities at Pantex Plant should be upgraded, downsized, or replaced as part of the future SSM program.

The SSM PEIS evaluated three alternatives relative to Pantex Plant operations: the No Action Alternative, which would allow Pantex Plant to continue providing the weapons assembly and disassembly capabilities, storage of pits, and HE fabrication capability; the Downsize Existing Capability Alternative, which includes downsizing the assembly/disassembly and HE fabrication capability, providing the capability to perform nonintrusive modification for pit reuse, and evaluating the possible storage of strategic reserve materials (plutonium in the form of pits and uranium in the form of canned subassemblies); and the Relocate Capability Alternative, which includes transferring the weapons assembly/disassembly capability to NTS and HE fabrication to LANL and/or Lawrence Livermore National Laboratory; and a complete phase-out of facilities at Pantex Plant.

In the Draft SSM PEIS, DOE announced as its preferred alternative a portion of the Downsize Existing Capability Alternative. That is, assembly/disassembly operations would remain at Pantex Plant; however, no preferred alternative was identified for HE fabrication. Other alternatives in the Draft SSM PEIS, entitled No Action and Relocate Capability, respectively, would have maintained Pantex Plant at its present size, or would have relocated the Pantex Plant activities to another location, were not the Department's preferred alternative. The Final SSM PEIS was issued on November 8, 1996, with a preferred alternative which stated that both assembly/disassembly operations and HE fabrication would remain at Pantex Plant, but would be downsized. The analysis contained in the Final SSM PEIS with respect to Pantex Plant is not significantly different from that presented in the Draft SSM PEIS. The Record of Decision for the SSM PEIS can be issued no earlier than December 16, 1996.

The SSM PEIS evaluated the remaining stockpile in the year 2005 and beyond. The Pantex Plant EIS does not address the impacts of these alternatives. It does, however, incorporate by reference, the effects identified in the WM PEIS as part of the discussion of cumulative impacts at Pantex Plant.

1.7.3 The *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement* (DOE/EIS–0229)

The S&D PEIS is evaluating alternatives for the long-term storage of weapons-usable fissile materials and for the disposition of weapons-usable plutonium declared surplus to national defense needs by the President. The S&D PEIS generally evaluates storage beginning in the year 2005 with impact evaluation conducted through the year 2055. Storage of weapons-usable fissile materials includes both pit and non-pit forms.

The interim storage of HEU was addressed in the *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y-12 Plant, Oak Ridge, Tennessee* (DOE/EA–0929) (DOE 1994).

Disposition of surplus HEU is the subject of a separate EIS, *Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement* (DOE/EIS–0240). The Final EIS was issued on June 17, 1996, and the ROD was issued on July 29, 1996.

DOE decided to implement a program to make surplus HEU non-weapons-usable by blending it down to low-enriched uranium (LEU). DOE will gradually sell up to 85 percent of the resulting LEU over time for commercial use as fuel feed for nuclear power plants to generate electricity (including HEU and natural uranium that will be transferred to the United States Enrichment Corporation), and will dispose of the remaining LEU as LLW. This decision does not affect the Pantex Plant because no activity relating to HEU disposition would occur at Pantex Plant.

DOE sites currently storing weapons-usable fissile materials include Pantex Plant, Hanford

Site, Idaho National Engineering Laboratory, Rocky Flats Environmental Technology Site, SRS, LANL, and ORR. The S&D PEIS is considering four alternatives for the long-term storage of fissile material: No Action, Upgrade Storage Facilities, Consolidate Plutonium at one site, and Collocate Plutonium and HEU at one site. The S&D PEIS is currently examining for long-term storage the same four DOE interim storage sites considered in this EIS as well as ORR. The Pantex Plant EIS includes a discussion of the cumulative impacts of locating a potential storage facility at Pantex Plant, and incorporates and summarizes relevant information from the S&D PEIS.

The Draft S&D PEIS analyzed, as part of its storage alternatives, transfer of RFETS surplus material, including pits, to Pantex Plant. The Draft S&D PEIS considered, as an alternative, the storage of surplus material, including both surplus pits from disassembled weapons and material from RFETS, in existing buildings in Zone 12 at Pantex Plant. These buildings would require upgrades before they could be used for storage, however, and the S&D PEIS estimated that the upgrades could be completed by the year 2004. The environmental impacts of this action were discussed for cumulative purposes throughout Chapter 4 in the Draft Pantex EIS.

The Final S&D PEIS will include an alternative involving the transfer of pits from RFETS to Pantex Plant that is a refinement of the alternatives presented in the Draft S&D PEIS. Under this alternative, materials would be removed from RFETS as soon as practicable in order to assist in the cleanup of that site. Pits now at RFETS could be transferred to Pantex Plant as early as 1997 and stored in Zone 4, in the same facilities as pits from disassembled weapons, until the upgraded facilities in Zone 12 are ready. Other fissile materials at RFETS, in the form of metals and oxides, would be transferred to the Savannah River Site under this alternative.

If this alternative were selected in the ROD for the S&D PEIS, surplus pits already at Pantex Plant would continue to be stored there pending disposition and, in addition, surplus pits from the RFETS would be transferred to Pantex Plant in the near term for storage, also pending disposition. The total number of pits that could potentially be stored at Pantex Plant, including those brought from RFETS, would not exceed the storage limit of 20,000 pits proposed and analyzed in this EIS. Moreover, surplus RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant.

The Final S&D PEIS will contain environmental analyses of the various elements of this alternative including: intersite transportation of the pits from RFETS to Pantex Plant; packaging operations both at RFETS and Pantex Plant; storage of the pits, first in Zone 4, and then in Zone 12; and intrasite transportation from Zone 4 to Zone 12. The environmental impacts of this action have been added to the cumulative impact discussion in Chapter 4 of this Final EIS. These impacts would occur sooner, but would be smaller than the impacts of the Collocation Storage Alternative.

The Collocation Storage Alternative and the Evolutionary Light Water Reactor Disposition Alternative from the S&D PEIS are discussed in this Pantex Plant EIS, because those alternatives, if they occurred at Pantex Plant, could potentially have the greatest impacts to the Pantex Plant Site. It is important to note that these are conservative bounding impacts.

The Final S&D PEIS will designate a preferred alternative for the storage of fissile materials. Furthermore, for disposition, the PEIS will contemplate further site-specific tiered NEPA documentation, as appropriate, before any specific site is selected. If different alternatives or a site other than Pantex Plant were selected in the ROD (and tiered RODs) for the S&D PEIS, then impacts to Pantex Plant from storage and disposition would be reduced and might not occur.

1.7.4 The *Site-Wide Environmental Impact Statement for Continued Operation of the Los Alamos National Laboratory* (DOE/EIS–0238)

This site-wide EIS will address foreseeable laboratory operations and planned activities over an approximately 10-year period, paralleling the timeframe considered in the Pantex Plant EIS. The EIS will focus on operating practices and facility management, and provide an analysis of all activities at LANL and all DOE land management activities related to operations at LANL. The Pantex Plant EIS is related to the activities at LANL in that Pantex Plant ships RTGs and pits (for evaluation) to LANL. The Pantex EIS addresses transportation of these components to and from LANL.

1.7.5 The *Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada* (DOE/EIS–0243)

This site-wide EIS addresses projects and activities at the NTS, the Tonopah Test Range, portions of the Nellis Air Force Range Complex, the Central Nevada Test Area, and the Project Shoal Area. These programs include ongoing activities for the stewardship of the Nation's nuclear weapons stockpile, management of radioactive waste, and environmental restoration. This EIS also examines newer programs such as the proposed Solar Enterprise Zone sites at NTS, Dry Lake Valley, Eldorado Valley, and Coyote Spring Valley.

The EIS addresses potential environmental impacts including those resulting from transportation and disposal of wastes that are generated onsite and offsite of NTS. The Pantex Plant EIS is related to activities at NTS in that Pantex Plant currently ships LLW to NTS for disposal. Continuation of LLW shipments to NTS is also within the scope of the WM PEIS. Impacts of interim pit storage are within the scope of the Pantex Plant EIS only.

1.8 Interagency Cooperation

During the public scoping for the Pantex Plant EIS, DOE received comments recommending that DOD sites be considered as alternative storage sites.

DOE formally requested that the Nuclear Weapons Council Staff identify the viability of available DOD sites for pit storage. In all, 60 DOD sites were assessed for a possible pit storage mission. One of these sites, the Manzano Weapons Storage Area at KAFB, was subsequently selected for consideration as an alternative in the EIS. Upon DOE request, and Pursuant to 40 CFR 1501.6, the U.S. Air Force agreed to become a Cooperating Agency and participated in the preparation of this EIS.

1.9 Agency Consultations for Implementing the Alternatives

Coordination of NEPA documents with other environmental review requirements is required by CEQ regulations (40 CFR 1502.25) and DOE NEPA implementing regulations (10 CFR 1021). The objective is to ensure an integrated assessment and compliance with statutes including, but not limited to, the *Fish and Wildlife Coordination Act* (16 U.S.C. 661 et seq.), the *National Historic Preservation Act of 1966* (16 U.S.C. 470 et seq.), and the *Endangered Species Act of 1973* (16 U.S.C. 1531 et seq.), as well as applicable State laws and regulations.

This EIS examines impacts of the Proposed Action and Alternatives at Pantex Plant, NTS, SRS, Hanford Site, and KAFB. Since the natural environment and potential impacts at each site differ, DOE identified relevant Federal and State agencies that may require formal consultations regarding each site. As part of the consultation process, the March 1996 Draft EIS was provided to each of these agencies for review and comment. Additional details of regulatory requirements are provided in chapter 6 of this EIS.

1.10 ORGANIZATION OF THE ENVIRONMENTAL IMPACT STATEMENT

This Final EIS is comprised of the Summary and three volumes:

- Volume I, 11 chapters of the main report.
- Volume II, 10 appendixes.
- Volume III, the public comments, analyses, and responses.

In volume I, chapter 2 describes the purpose and need for action. Chapter 3 describes the Proposed Action and Alternatives and concludes with a comparison of the environmental impacts of each of the alternatives.

Chapters 4 through 6 provide the core of the environmental impact analysis and actions necessary to implement each alternative. Chapter 4 describes the affected environment and environmental consequences at Pantex Plant. This chapter examines potential environmental impacts within 14 environmental resource and issue areas at Pantex Plant for each of the alternatives. In a similar manner, chapter 5 describes the affected environment and environmental consequences at each of the alternative pit storage sites that were considered for the Pit Storage Relocation Alternative. Chapter 6 describes the environmental compliance requirements for implementing the alternatives.

Chapters 7 through 11 provide supplementary information about this EIS and references for the reader. Chapter 7 provides the list of references cited in the EIS. Chapter 8 contains the list of preparers, and chapter 9 presents the list of agencies, organizations, and persons to whom copies of this EIS were sent. Chapter 10 provides a glossary of terms used in this EIS and chapter 11 is the index.

In Volume II, 10 appendixes are provided for detailed supporting information. Appendix A describes the methodologies applied in the determination of environmental impacts. Appendixes B, C, D, E, F, and I contain additional discussion and data supporting the air quality, water resources, human health, aircraft accident, transportation, and soil quality analyses, respectively. Appendix G addresses the current and planned activities to further objectives for pollution prevention and waste minimization. Appendix H contains a detailed description of six proposed Pantex Plant projects and an assessment of the impacts associated with their construction and operation. Appendix J includes copies of correspondence with consulting agencies.

Volume III describes the public comment and public hearing processes. All public meeting comments were combined with comments received by all other means (e.g., hand-ins, faxes, letters, e-mail, etc.) during the public comment period. All comments were categorized by subject area and were considered for potential changes or additions to the EIS. In addition, volume III details the comments received, the analysis and categorization of the comments, the responses to the comments, and indicates what changes were made in the EIS in response to the comments. Volumes I and II have been marked with a line down the left side of the text columns to indicate where changes or additions have been made to the EIS text.

CHAPTER 2

Purpose and Need for Action

CHAPTER 2
PURPOSE AND NEED FOR ACTION

The main focus of chapter 2 is a description of the purpose and need for Department of Energy action at Pantex Plant. Following that discussion is a description of the scope of this EIS.

PURPOSE AND NEED FOR AGENCY ACTION

DOE needs to continue to fulfill its responsibilities as mandated by statute, Presidential direction, and Congressional authorization and appropriation. DOE's goal, or purpose, in meeting this need is to do so in a manner that enhances the protection of human health and the environment while preventing a break in DOE's ability to perform its responsibilities.

2.1 Purpose and Need for Action

The requirement for DOE to provide for nuclear weapons operations is provided in Section 91 of the *Atomic Energy Act* of 1954 as amended (42 U.S.C. 2121). That act authorized the Atomic Energy Commission (predecessor to DOE) "to engage in the production of atomic weapons... to the extent that the express consent of the President has been obtained, which consent and direction shall be obtained at least once each year." The consent and direction of the President are given each year in a Presidential Decision Directive. This directive is based on the annual Nuclear Weapons Stockpile Memorandum jointly prepared and agreed upon by the Department of Defense, National Security Council, and DOE. The Nuclear Weapons Stockpile Memorandum specifies the nuclear weapon stockpile levels for current and future years and is the driver for associated production and retirement of all nuclear weapons. DOE then issues the Production and Planning Directive to direct the Nuclear Weapons Complex, which includes Albuquerque Operations Office, to execute the directed workload. Annual appropriations to carry out the Presidential directives are then provided through the combined action of the House of Representatives, the Senate, and the President. It is DOE's responsibility to meet the stockpile management requirements.

The Department's nuclear weapons stockpile management requirements at Pantex Plant include the assembly, disassembly, modification, and maintenance of nuclear weapons; monitoring of the weapons stockpile; production of high explosive(s) (HE) components for nuclear weapons; quality assurance evaluation and testing of weapon components; and research and development activities supporting nuclear weapons.

Recent Presidential directives have sharply reduced the number of weapons required in the nuclear weapons stockpile. This has resulted in a large increase in the number of nuclear weapon components that must be disposed or stored. Pantex Plant is currently the only site at which weapon disassembly operations are performed and is the primary location for interim storage of pits removed from weapons. In accordance with the approved Finding of No Significant Impact (59 FR 3674, January 26, 1994) regarding interim storage levels, Pantex Plant is currently authorized to provide interim storage of up to 12,000 pits. Other nuclear weapon components are currently shipped to other sites, as depicted in Figure 2.1–1.

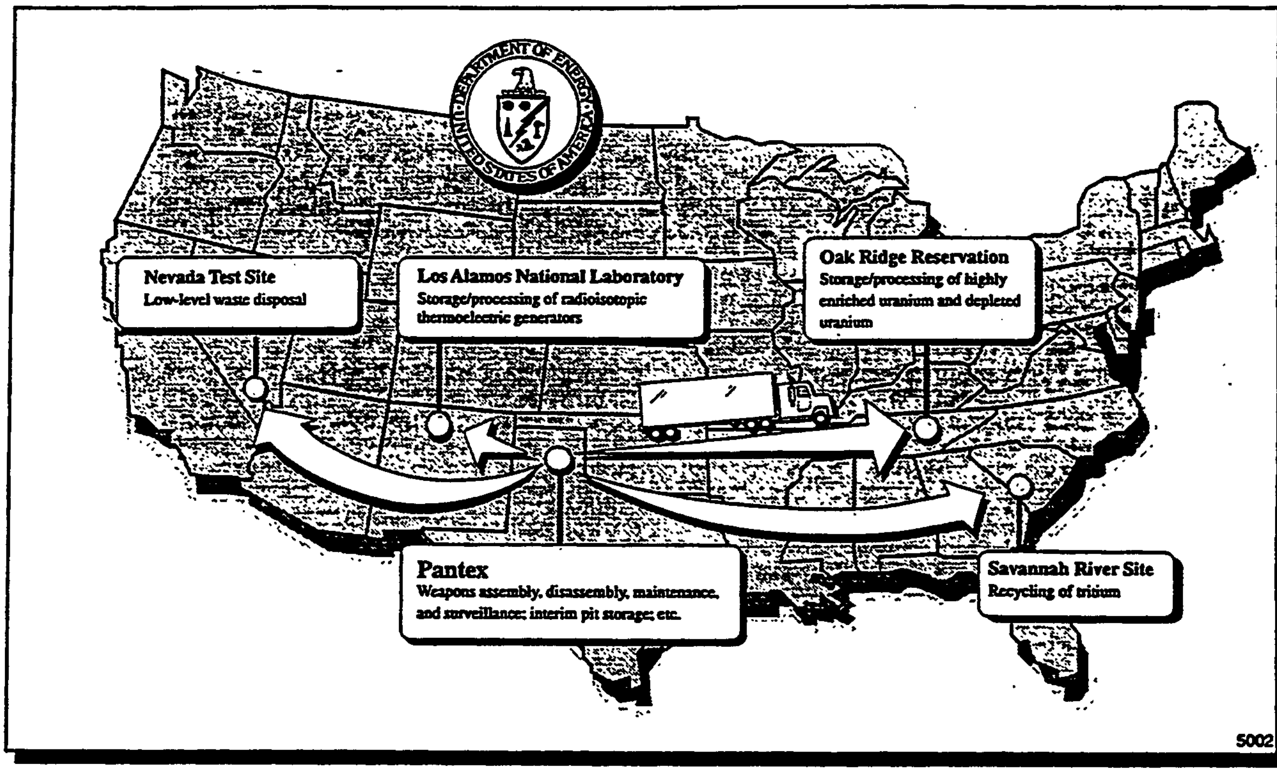

FIGURE 2.1–1.—*Sites That Receive Nuclear Components or Materials from Pantex Plant.*

DOE must fulfill assigned responsibilities for stockpile stewardship and management and must respond to Presidential direction on requirements for the nuclear weapons stockpile. DOE must respond to the military services returning weapons as a result of changes to the nuclear weapons stockpiles and provide storage for components as a result of dismantlement. There is a need at this time to update the Department's evaluation and understanding of environmental impacts associated with ongoing operations at Pantex Plant and evaluate any additional or changed impacts associated with an increase in dismantlement and near-term storage of nuclear components from the dismantlement process.

2.2 SCOPE OF THIS ENVIRONMENTAL IMPACT STATEMENT

The scope of this EIS includes the assessment of impacts relative to each area of the human and natural environment potentially affected by operations performed at Pantex Plant. A complete list of the resource areas investigated in this EIS is provided in volume I, chapter 4. The analysis concentrates on issues related to the proposal as identified through internal and public scoping. Activities that could potentially result in adverse impacts are associated with:

- Ongoing operations, including interim pit storage, at Pantex Plant.
- Transporting pits to and storing them on an interim basis at an alternate site.
- Transporting classified components between Pantex Plant and other sites.

The EIS analysis assumes that the combined activities of assembly, disassembly, and modifications would not exceed 2,000 weapons per year. For assessment of environmental impacts, the EIS examines impacts across a reasonable range of operations by assessing impacts of activity levels for 2,000, 1,000, and 500 weapons per year.

These numbers of weapons per year represent a reasonable, but conservative estimate of work that may be required at Pantex Plant based on current policy directives, and allow a set of defined tasks to be accurately analyzed. The operations on each of the weapons in these defined sets is assumed to be extensive (i.e., representative of full assembly or disassembly). Actual workload and range of tasks to be performed on each weapon processed at the plant may vary, but individual tasks are well understood, and impacts of actual operations are expected to be encompassed by this conservative analysis. Accordingly, over 2,000 weapons per year may be worked on at Pantex Plant without exceeding the environmental impacts identified in this conservative, bounding analysis. The operations on 2,000, 1,000, and 500 weapons per year should not be considered to be specific limits.

As shown in Figure 2.1–1, some nuclear components removed from weapons and nuclear materials are shipped to other sites. Therefore, this EIS considers the impacts of continuing to transport such components to those sites. Whenever appropriate, this EIS incorporates the information and analyses of other NEPA documents.

This EIS includes an assessment of activities over a period of approximately 10 years or until programmatic decisions regarding the nuclear weapons complex, including long-term storage and disposition of weapons components and materials, can be implemented. The scope of activities at Pantex Plant includes mission operations, routine maintenance, facility upgrades and modifications, planned new facilities, and transportation activities. Key areas of Pantex Plant that support these missions are:

- Zone 12, where assembly, disassembly, and surveillance operations are performed and nonnuclear components are staged.
- Zone 11, where HE research and production is performed and nonnuclear components are staged.
- Zone 4 West, where nuclear weapons and classified components are staged and pits are stored on an interim basis.
- Zone 4 East, where HE is stored and nonnuclear components are staged.
- The Burning Ground, where HE materials are burned.

These areas are shown on Figure 1.2–2. Other activities that are included in the EIS are environmental protection, pollution prevention, environmental restoration, waste management, and agricultural operations on the site.

The scope of activities at other sites is related only to interim storage of pits and transport of other weapons components from Pantex Plant to these sites.

There are several other ongoing DOE programs that could have impacts on Pantex Plant. Five of these programs for which NEPA documents have either been prepared recently or are in the process of preparation are identified in volume I, chapter 1. The potential impacts of these programs on Pantex Plant have been included in the cumulative impact sections of this EIS to the extent information was available. Impacts of possible relocation of operations from Pantex Plant are discussed in this EIS, as this is one of the options considered in the *Stockpile Stewardship and Management Programmatic EIS* (DOE/EIS-0236). Cumulative impacts also address the incremental effects of the action added to other past, present, and reasonably foreseeable future actions undertaken by Pantex Plant or other agencies in the specific Region of Influence identified for each environmental resource area.

(This Page Intentionally Left Blank)

CHAPTER 3

The Proposed Action and Alternatives

CHAPTER 3
THE PROPOSED ACTION AND ALTERNATIVES

Chapter 3 describes the Proposed Action, which is the Department's Preferred Alternative, and the alternatives to that Proposed Action. These alternatives include "no action" and the relocation of interim pit storage from Pantex Plant to one of four candidate sites. Following that discussion is a summary of the method whereby the Department identified candidate sites for receiving some or all of the plutonium pit storage function. Also addressed are alternatives that were considered but eliminated from detailed study in this EIS. Chapter 3 concludes with a summary comparison of the environmental impacts of the Proposed Action and Alternatives. Detailed discussions of these environmental impacts are presented in chapter 4 (for Pantex Plant) and chapter 5 (for the four candidate sites).

3.1 RANGE OF ALTERNATIVES

ALTERNATIVES

The Preferred Alternative involves all of the different weapons activities historically performed at Pantex Plant, storage of up to 20,000 pits at the plant, and the possible implementation of six new projects.

The No Action Alternative involves all of the different weapons activities historically performed at Pantex Plant, storage of up to 12,000 pits, and the implementation of only previously funded projects. With this alternative, dismantlement would cease once a storage level of 12,000 pits has been achieved.

The Relocation of Interim Pit Storage Alternative involves all of the different weapons activities historically performed at Pantex Plant, relocation of storage of 8,000 or 20,000 pits to another site, and the possible implementation of six new projects.

The alternatives considered in this EIS are the Proposed Action, the No Action Alternative, and the Relocation of Pit Storage Alternative (for interim pit storage only). These are described in sections 3.1.1 through 3.1.3. The Department's Preferred Alternative is the Proposed Action.

The Proposed Action involves continuing operations at Pantex Plant, increasing the pit storage limit from 12,000 pits up to 20,000 pits, and the construction of several new projects. These new projects, outlined in appendix H, are analyzed at a project-specific level of detail. For each of these projects, there is a range of reasonable alternatives that include, as a minimum, a Proposed Project (i.e., implementing the proposed change) and not implementing the proposed project.

The No Action Alternative involves continuing operations with the limitation of ceasing weapon dismantlement after a storage level of 12,000 pits is reached. No new projects are included with this alternative. DOE also understands that the No Action Alternative does not satisfy the purpose and need for action for weapon disassembly or goals for enhanced management of wastes.

In the March 1996 Pantex Plant Draft EIS, the proposed construction of the Hazardous Waste Treatment and Processing Facility (HWTPF) was considered necessary for improving waste operational efficiency and safety and meeting regulatory requirements established in the Agreed Order. With offsite disposal shipments of mixed waste in 1994 and two shipments in 1996, as described in section 4.13.2.3 of this volume, and changes contained in the August 1996 Federal Facility Compliance Act (FFCA) Compliance Plan Annual Update document, construction of the HWTPF is no longer considered a regulatory requirement. DOE's purpose and need for enhanced efficiency and safety of its current mixed waste, low-level radioactive waste, and hazardous waste operations remain and are discussed in greater detail in volume II, appendix H. Without the HWTPF, waste treatment and processing capabilities are greatly limited.

The Pit Storage Relocation Alternative involves continuing the operations at Pantex Plant, construction of several new projects, and relocating the storage of some or all of the pits to another site. The candidate sites for relocation of interim pit storage provide a range of geographical, operational, and environmental alternatives.

The types and numbers of weapons operations performed at Pantex Plant in any year are principally defined by the Stockpile Memorandum. The Memorandum is set by the President and authorized and funded by Congress. In order to fully encompass the operations of Pantex Plant, different levels of all of the types of operations that Pantex Plant can and has performed are assessed.

Because future stockpile requirements cannot be accurately predicted, this EIS examines the impacts of activity levels for operations on 2,000, 1,000, and 500 weapons per year (see section 2.2). Additional information about activities associated with stockpile management missions is in the Pantex Plant *Programmatic Information Document* (DOE 1996b).

Weapons disassembly operations and weapons assembly operations result in roughly equivalent impacts and are the dominant contributors to the impacts resulting from plant operations. Therefore, the mix of weapons operations that is assessed for each alternative is dominated by these operations. For the No Action Alternative, the operations mix is dominated by assembly operations, once the disassembly operations limitation of 12,000 pits in storage is reached.

The activity levels of operations on 2,000, 1,000, and 500 weapons per year are representative levels of Pantex Plant activity. The 2,000 weapons level represents recent and current levels of activity. The 1,000 weapons level represents the level that will most likely occur in the near future, if there are no changes in current directions in the Stockpile Memorandum. The 500 weapons level represents the minimum level of activity required at Pantex Plant to maintain all of its mission capabilities. An activity level ranging from 330 to 680 weapons per year is evaluated in the SSM PEIS. This is based on the remaining stockpile in the year 2005 and beyond, after the successful disassembly of up to 20,000 weapons.

In the Record of Decision that will follow completion of this EIS, the Secretary of Energy will consider the environmental impacts of each alternative along with mission requirements, technical factors, and the public interest. In balancing these considerations, the Secretary could decide to implement all or part of any alternative. Likewise, the Secretary may decide to include a particular aspect of an alternative in a decision to implement another alternative. For example, the Secretary could decide to implement the No Action Alternative, but include the construction of the HWTPF described in the Proposed Action.

3.1.1 Proposed Action

DOE proposes to continue nuclear weapons stockpile management operations and related activities at Pantex Plant; continue the interim storage of pits at Pantex Plant; continue transportation of nuclear components to the Savannah River Site (SRS), the Oak Ridge

Reservation (ORR), and Los Alamos National Laboratory (LANL); and implement projects and facility upgrades at Pantex Plant consistent with fulfilling these missions for approximately 10 years. Specifically, the Proposed Action includes:

- Continued operation of Pantex Plant, including activities associated with the following stockpile management missions:
  - — Assembly of nuclear weapons.
  - — Disassembly of nuclear weapons.
  - — Modification and maintenance of nuclear weapons.
  - — Quality assurance testing of weapons components (surveillance).
  - — Research and production of high explosives (HE) and weapons components.

Because future stockpile requirements cannot be accurately predicted, the Proposed Action will include impacts of activity levels for operations on 2,000, 1,000, and 500 weapons per year.

- Management of nuclear weapons components and materials as follows:
  - — Increasing the maximum quantity of pits in interim storage at Pantex Plant from 12,000 to 20,000.
  - — Continuing to transport highly enriched uranium (HEU) and depleted uranium components from Pantex Plant to ORR for storage or processing and staging those components pending shipment.
  - — Continuing to transport tritium from Pantex Plant to SRS for storage and recycling and staging these reservoirs pending shipment.
  - — Continuing to transport radioisotopic thermoelectric generators (RTGs) from Pantex Plant to LANL for heat source removal and storage. Some RTGs from disassembled weapons would be retained at Pantex Plant as spares for future use in weapons maintenance, modification, or replacement, as required.
  - — Continuing to transport a few selected pits per year from Pantex Plant to LANL for surveillance, inspection, and testing.
  - — Continuing demilitarization and sanitization of components (including demilitarization and sanitization of HE), equipment, and related materials, and burning of HE and HE-contaminated wastes at the Burning Ground in accordance with applicable Federal and State regulations.
  - — Continuing to dispose of other items resulting from mission operations in accordance with regulatory requirements.
- Performing environmental protection and environmental restoration activities. Environmental protection activities include the management and stewardship of resources as previously noted in section 1.2.2.2. Restoration activities include site characterization to define the nature and extent of contamination, evaluating potential corrective measures, coordinating with State and Federal regulatory agencies, and performing corrective measures.
- Continuing routine Pantex Plant activities such as waste management, infrastructure and building maintenance, operations and equipment relocation and consolidation, routine modifications to buildings, general landscaping, cooperative agreements with universities, technology transfer activities, transportation of materials, and similar support activities.
- Continuing the transportation of nuclear weapons, nuclear components, HE materials, wastes, and other materials to and/

or from Pantex Plant. Additional information describing onsite transportation activities is provided in section 4.12 of this volume of the EIS.

- Performing all required facility upgrades, modifications and replacement of facilities, and new proposed projects that are foreseeable at Pantex Plant, as described below:
  - — A new HWTPF that would accommodate management of low-level, hazardous, and mixed waste. The facility activities would include DOE developed technologies capable of mixed waste treatment.
  - — Modifications of existing facilities to provide a Pit Reuse Facility in Zone 12. This facility would allow non-intrusive modification of certain pits in order to enhance their safety and allow their future reuse.
  - — Construction of a new Gas Analysis Laboratory in Zone 11 to replace a structure of World War II vintage. The facility would provide new analytical laboratory space with the requisite environmental controls for sensitive gas analysis equipment.
  - — Construction of a new Materials Compatibility Assurance Facility in Zone 11 to replace a structure of World War II vintage. The facility would be used for the environmental aging and compatibility testing of nonnuclear weapon components.
  - — Construction of a new Nondestructive Evaluation Facility in Zone 12 to replace a structure of World War II vintage. The facility would house operations such as radiography, ultrasonic analysis, digital imaging, penetrant testing, laser sampling, radiometry, and computer tomography of nonnuclear weapon materials.
  - — Construction of a new Metrology and Health Physics Calibration and Acceptance Facility in Zone 12. The facility would provide the capability and capacity to perform health physics calibration and product acceptance control in support of the disassembly/assembly programs. The Health Physics Laboratory would provide necessary calibration and maintenance support for radiological instrumentation and monitors. The Product Acceptance Control Laboratory would provide the capability for calibration and support of product acceptance testing and equipment.
  - — Operations involving an AT-400A pit repackaging system using existing bays in Zone 12 are planned.

  These projects are further described in volume II, appendix H, except for the pit repackaging operation, which is described in sections 4.3, 4.13, and 4.14 of this volume.

Figure 3.1.1–1 shows the proposed location of these projects, and Table 3.1.1–1 presents relevant data for each project. This EIS provides the project-specific NEPA analysis sufficient for decisions on whether to implement each of these projects. There are two other projects underway which have already been through the NEPA process and have been determined to be in a class of actions that would have no significant environmental impacts (i.e., categorically excluded). Consequently, these projects, described below, are not analyzed in detail in this EIS:

- A Plutonium Resource Center that was approved by Congress and began operation in fiscal year 1995. The center is being developed to study environmental impacts of plutonium storage and future uses of plutonium. It occupies space in an existing commercial building in the City of Amarillo. No radioactive materials are handled or stored in the resource

Sources: DOE 1995j; Pantex 1996b

center. The NEPA review was approved in December 1994.

- The Burning Ground Upgrade project would consist of a covered, three-sided structure with a fan to exhaust emissions through an elevated stack. The wood currently used as an auxiliary heat source would be replaced by natural gas. The NEPA review for this project was approved in July 1994.

These projects have been taken into account in the evaluation of the impacts of each of the alternatives assessed in this EIS. It is foreseeable that within the next 10 years, actions (such as movement of pits within Zone 4 or modifications to security) may be required to implement third-party inspections of weapons facilities as a part of the National Nonproliferation Policy. These actions would be implemented to the extent feasible within existing capability. As the implementation of this policy has not yet been fully defined, these actions have not been through the NEPA process nor are they discussed in detail in this EIS.

3.1.2 No Action Alternative

The No Action Alternative includes the continuing and historical nuclear weapons assembly/disassembly operations and related activities of Pantex Plant; continuing the current nuclear components storage activities at Pantex Plant; continuing environmental protection and restoration programs; and continuing transportation of components to ORR, SRS, and LANL, as described in the Proposed Action.

This alternative differs from the Proposed Action in that:

- The six projects described in Table 3.1.1–1 would not be implemented.

- Weapons disassembly operations would cease when 12,000 pits have been placed in interim storage at Pantex Plant. Note, however, that all other stockpile management operations would continue. Because current mission requirements are dominated by dismantlement, a significant drop in the activity level would be expected to occur when dismantlement ceases. However, with the No Action Alternative, Pantex Plant still has the requirement to support the stockpile with other operations, including weapons production, modification, and surveillance activities. Because future stockpile requirements cannot be accurately predicted, the No Action Alternative includes impacts of operations on 2,000, 1,000, and 500 weapons per year.
- Only 12,000 pits from weapons disassembly would be placed in interim storage at Pantex Plant. No pits would be transferred to another site for storage.

It should be noted that the No Action Alternative would allow only partial fulfillment of the Pantex Plant mission, by limiting the amount of weapon disassembly, and would not fully satisfy the purpose and need for agency action discussed in chapter 2.

3.1.3 Relocation of Interim Pit Storage Alternative

With the Relocation of Interim Pit Storage Alternative, only the interim pit storage functions would be transferred to another site. The options detailed below describe how some or all of the pits currently or potentially stored at Pantex Plant would be stored at another site. With this alternative, all weapons operations (e.g., disassembly, assembly, etc.) would continue to be performed at the plant. The new projects (HWTPF, Pit Reuse Facility, Gas Analysis Laboratory, Materials Compatibility Assurance Facility, Nondestructive Evaluation Facility, and Metrology and Health Physics Calibration and Acceptance Facility) are needed to maintain the capability of the plant to perform weapons operations efficiently. Therefore, they are included in this alternative. Additionally, all other functions described in the Proposed Action, including the impacts of operations on 2,000, 1,000, and 500 weapons per year, were assessed for this alternative. This alternative examines the environmental impacts, at Pantex Plant and other sites, of relocating interim pit storage from Pantex Plant to other sites.

Specific features of interim pit storage relocation options are described below:

- Option 1—Relocating interim storage of up to 20,000 pits from Pantex Plant to one of the following candidate sites: Nevada Test Site (NTS), about 104 kilometers (65 miles) northwest of Las Vegas, Nevada; SRS, 19 kilometers (12 miles) south of Aiken, South Carolina; and Kirtland Air Force Base (KAFB), just southeast of Albuquerque, New Mexico.
- Option 2—Relocating interim storage of up to 8,000 pits to one of the following candidate sites: NTS; Hanford Site, just north of Richland, Washington; SRS; and KAFB.

With this alternative, the number of pits stored at Pantex Plant could conceivably be increased beyond 12,000 initially. Once the rate of pit shipments to an alternate site is sufficient to handle the number of pits generated by disassembly operations, the backlog of stored pits would begin to be transported and the number of pits stored on site would decrease. The maximum number of pits stored at Pantex Plant with this alternative would depend on the time needed to implement any required upgrades at the alternate site and the availability of a new container certified by the DOE under the requirements found in 10 CFR 71. Once the alternate site is operational and containers are available, shipments would begin.

For the relocation site alternatives, the EIS scope includes:

- Performing at Pantex Plant all operations, upgrades, and modifications of the Proposed Action.
- Performing at the alternative sites only those facility upgrades and modifications or replacement of facilities that would be needed to accommodate the interim pit storage mission. These sites and their respective storage facilities are described in chapter 5.

3.1.4 Selection of Site Alternatives for Interim Pit Storage

A DOE Site Screening Committee systematically evaluated the potential of DOE and Department of Defense (DOD) sites as alternative interim pit storage sites. The site screening process evaluated a large number of candidate sites to determine the range of reasonable alternative sites. This was accomplished by developing site suitability criteria, applying the criteria to candidate sites, and determining the best sites to represent the range of reasonable site alternatives.

Five exclusionary criteria were used to qualify sites for consideration as reasonable candidates. In order to be considered in the reasonable range, a site must be:

- Located within the boundaries of the 48 contiguous states of the U.S. and accessible during all seasons by all-weather highways.
- Currently owned by or transferable to the Federal Government.
- Available for use by DOE Defense Programs beginning in 1997.
- Under DOE control through at least 2007.
- Capable of storing a minimum of 8,000 pits.

Favorability criteria were then used to assess how well each remaining site was suited for the intended use. The favorability criteria were:

- Degree of construction required to adapt existing facilities for the pit storage mission.
- Degree of isolation from civilian populations.
- Indication of environmental hazards potentially impacting the intended mission.

After applying these favorability criteria to DOE sites and visiting finalist sites to look at the specific facilities that would be used for pit storage, DOE selected NTS, Hanford Site, and SRS as DOE site alternatives for interim pit storage.

In parallel to the committee's screening of DOE sites, the Nuclear Weapons Council Staff conducted a review of 60 DOD installations to determine which ones were feasible for the interim pit storage functions. Using the same site screening criteria, the Council Staff found that most of the examined installations either had military missions incompatible with pit storage or were too far into the base realignment and closure process to be made available to DOE. The Council Staff found that only two bases, KAFB (at Albuquerque, New Mexico) and the Seneca Army Depot (at Romulus, New York) appeared to be feasible for interim pit storage.

DOE then asked the Department of the Air Force and the Department of the Army to concur that these sites were available for DOE use and for each Department to become a Cooperating Agency for the preparation of this EIS. The Air Force agreed that sufficient storage area at the Manzano Weapons Storage Area (WSA) on KAFB could be made available and consented to be a Cooperating Agency. After a visit to the Manzano WSA to validate the suitability of the site under the site selection criteria, the

Manzano WSA was confirmed to be in the reasonable range of alternatives and the impacts associated with interim pit storage at this site are analyzed.

Subsequent to the actions of the Nuclear Weapons Council staff, the Seneca Army Depot was placed on the 1995 Base Realignment and Closure (BRAC) list. Because of this, the Army and DOD could not make a determination as to its availability until the BRAC list was approved. The list was approved September 29, 1995, and Seneca Army Depot was approved for closure in accordance with the procedures established by the *Defense Base Closure and Realignment Act of 1990* (Public Law 101–510). In accordance with these procedures and the Memorandum for Federal Agencies, dated September 29, 1995, Subject: Notice of Availability of Excess Real Property at Seneca Army Depot, Romulus, New York, it was determined that Seneca Army Depot would not serve as a viable alternative within the Pantex Plant EIS, because DOE cannot fulfill a key BRAC requirement in stating that none of its holdings and property can satisfy the purpose for which the base is sought. The requirement for storing nuclear weapons components can be accomplished with DOE's current holdings. Therefore, Seneca Army Depot was not considered further as an alternative pit storage location.

3.1.5 Alternatives Considered but Eliminated from Detailed Study

DOE considered three other action alternatives that were eliminated from detailed study in this EIS. These action alternatives were:

- Relocation of Pantex Plant operations.
- Shutdown of Pantex Plant.
- Relocation of storage for HEU, depleted uranium, tritium, and RTGs.

Each of these is discussed below in sections 3.1.5.1–3.1.5.3.

3.1.5.1 *Relocation of Pantex Plant Operations*

The original Notice of Intent (NOI) (59 FR 26635) for preparation of this EIS included the possibility of relocating some or all of Pantex Plant operations as part of the Relocation Alternative. Upon further review, it was determined that the relocation of operations from Pantex Plant within the time period of this EIS would not meet the purpose and need for DOE to maintain minimum disruption of weapons disassembly operations. As discussed in the Amended Notice of Intent (60 FR 32661), the SSM PEIS evaluated the relocation of Pantex Plant operations. This EIS incorporates by reference and summarizes impacts of relocating operations as identified in the SSM PEIS. These impacts are discussed in qualitative terms in the cumulative effects sections of this EIS.

3.1.5.2 *Shutdown of Pantex Plant*

The original NOI (59 FR 26635) also mentioned an alternative of shutting down Pantex Plant operations as a means of evaluating environmental baseline conditions. However, Pantex Plant is the only facility currently capable of carrying out the requirements to assemble, disassemble, and perform quality assurance tests on the nuclear weapons and weapon components. These activities are required to maintain the safety of the nuclear weapons stockpile. The near-term shutdown of Pantex Plant before any other facility could fulfill these responsibilities would result in the interruption of these safety requirements. Therefore, as announced in the Amended NOI (60 FR 32661), the shutdown of Pantex Plant operations within the near-term scope of this EIS is considered unreasonable.

3.1.5.3 *Relocation of Storage for Nuclear Components Other Than Pits*

The nuclear components (e.g., RTGs, HEU, and depleted uranium) resulting from the disassembly of weapons are either stored at Pantex Plant; stored or processed at LANL, in Los Alamos, New Mexico; or stored or processed at ORR, near Knoxville, Tennessee. Tritium pressure vessels are processed and the tritium is recycled at SRS, near Aiken, South Carolina.

The original NOI (59 FR 26635) suggested that DOE might consider relocation of current nuclear component storage activities to other DOE or Federal sites. However, after further review of the nature of the components being shipped to other sites and the operations that must be performed preparatory to storage, DOE determined that, for the time period of this EIS, there are no other sites with the capability and capacity to perform pre-storage operations and processes than the sites to which the components currently are sent. Thus, tritium must continue to go to SRS for recycling and storage pending reuse. HEU and depleted uranium components must continue to go to the Y–12 Plant at ORR for the specialized component separation, demilitarization, and declassification operations that can only be performed there. Likewise, RTGs must continue to be shipped to LANL, which is the only place where the capability and capacity exists to remove the plutonium pellets for storage or reuse.

Because of the uniqueness of these facilities within the Nuclear Weapons Complex, relocation of storage for nuclear components other than pits is not reasonable during the time period of this EIS. Instead, the detailed study of relocation of HEU, tritium, and RTGs is being assessed in detail in the S&D PEIS, the SSM PEIS, the *Tritium Supply and Recycling PEIS*, and the *Highly Enriched Uranium EIS*, as well as site-wide NEPA documentation for the impacted sites.

3.1.6 Preferred Alternative

The Council on Environmental Quality regulations require an agency to identify its preferred alternative(s) in the Final EIS (40 CFR 1502.14(e)). The preferred alternative is the alternative that the agency believes would best fulfill its statutory mission, giving consideration to environmental, economic, technical, and other factors.

Based on the analyses in the Final EIS and consideration of schedule and technical information, the Department's Preferred Alternative is to continue nuclear weapons operations at Pantex Plant; implement projects and facility upgrades consistent with fulfilling these operations; and increase interim storage levels for plutonium components (pits) from 12,000 to 20,000 pits.

3.2 Comparison of Environmental Impacts of Alternatives

Table 3.2–1 presents a comparative summary of the potential impacts to the environment at or near Pantex Plant that would be expected to result with implementation of the Proposed Action, No Action, and Pit Storage Relocation alternatives. The potential impacts that would be expected to result with implementation of the Pit Storage Relocation Alternative at Pantex Plant and the candidate sites are presented in Table 3.2–2.

For most of the environmental resources assessed in this EIS, there is no real difference among the impacts for the different alternatives. This is due to the nature of the activities described in each alternative. Each of the alternatives examines the activities at Pantex Plant in terms of three levels of activity for operations on 2,000, 1,000, and 500 weapons per year. The differences among the alternatives are in the number of pits that will be stored at Pantex Plant and the new projects that might be implemented.

Impacts to facilities and infrastructure, land resources, air quality, acoustics, cultural resources, socioeconomics, waste management, intrasite transportation, and environmental justice were determined to be similar for each of the alternatives. The main differences in impacts among the alternatives would involve the disturbance to soils and biotic resources due to construction of the new projects, radiation exposure to workers involved in the transfer of pits, and risks associated with aircraft accidents.

Table 3.2–2 presents a comparison of impacts among the candidate sites for the relocation of pit storage activities. Five facilities at four candidate sites were assessed for the storage of 8,000 or 20,000 pits.

For most of the environmental resources assessed in this EIS, there are no real differences in the impacts to the individual resources among the different candidate sites. This is due to the nature of the pit storage activities. The methods and procedures involved in the storage of pits have evolved and been refined at Pantex Plant to reduce the potential for impacts. This analysis assumes that the same methods and procedures would be used at each candidate site should it be chosen for pit storage. While the environments at each of the candidate sites are different, the storage methods minimize the impacts to those environments. The real differences among the candidate sites in regard to pit storage are the frequency and consequences associated with operational and external accidents.

Impacts that would result from pit storage operations at candidate sites on facilities and infrastructure, land resources, geology and soils, water resources, air quality, acoustics, biotic resources, cultural resources, socioeconomic resources, and waste management would be negligible, primarily because no new construction of facilities would be required at any of the candidate sites. Further, normal operations, including handling and storage of pits, do not require substantial amounts of utility or resource use. There would be unavoidable exposures to radiation from handling of the pits during transfer to storage. There would also be additional impacts to Pantex Plant workers from loading the pits for transfer to the storage site, if one is chosen. Likewise, there is a potential for accidents involving forklifts during unloading and storage of pits. Such accidents would affect the workers, but would not result in any health risk to the public.

The risks associated with accidents are discussed in terms of their frequency of occurrence. This EIS uses the following definitions for frequency of occurrence:

- *Anticipated*—frequency of occurrence is less than 10^{-0} and greater than or equal to 10^{-2} per year (less than 1 in 100 chance of occurring per year).
- *Unlikely*—frequency of occurrence is less than 10^{-2} and greater than or equal to 10^{-4} per year (in between 1 in 100 and 1 in a 10,000 chance of occurring per year).
- *Extremely unlikely*—frequency of occurrence is less than 10^{-4} and greater than or equal to 10^{-6} per year (in between 1 in 10,000 and 1 in a 1,000,000 chance of occurring per year).
- *Not reasonably foreseeable*—frequency of occurrence is less than 10^{-6} per year (less than 1 in 1,000,000 chance of occurring per year).

TABLE 3.2–1.—*Summary Comparison of Environmental Impacts at Pantex Plant*

PROPOSED ACTION ALTERNATIVES (Includes Storage of Up to 20,000 Pits)			NO ACTION ALTERNATIVE (Includes Storage of Up to 12,000 Pits)	PIT STORAGE RELOCATION ALTERNATIVE (Pantex Plant Impacts of Relocating 8,000 or 20,000 Pits [See Table 3.2–2 for Impacts to Other Sites])
2,000 WEAPONS LEVEL	1,000 WEAPONS LEVEL	500 WEAPONS LEVEL		
PLANT FACILITIES AND INFRASTRUCTURE (SEE SECTION 4.3 IN MAIN TEXT)				
The annual utility usage for this activity level and six new projects would be: Steam - 181M kg (398M lb) Electricity - 90,400 MWh Natural Gas - 16.2M m^3 (573M ft^3)	The annual utility usage for this activity level and six new projects would be: Steam - 145M kg (319M lb) Electricity - 68,200 MWh Natural Gas - 13.0M m^3 (458M ft^3)	The annual utility usage for this activity level and six new projects would be: Steam - 73M kg (160M lb) Electricity - 57,100 MWh Natural Gas - 6.5M m^3 (229M ft^3)	Lower than the Proposed Action because no new facilities are proposed.	Same as the Proposed Action.
LAND RESOURCES (SEE SECTION 4.4 IN MAIN TEXT)				
New facilities would require an area of 15,902 m^2 (171,160 ft^2), equal to 0.04 percent of the total DOE-owned area of Pantex Plant.			No impacts to land resources.	Same as the Proposed Action. New facilities would require an area of 15,902 m^2 (171,160 ft^2), equal to 0.04 percent of total area of Pantex Plant.
GEOLOGY AND SOILS (SEE SECTION 4.5 IN MAIN TEXT)				
Temporary disturbance of 31,800 m^2 (342,000 ft^2) of soils resulting from construction of new facilities.			No new facilities are proposed.	Temporary disturbance of 31,800 m^2 (342,000 ft^2) of soils resulting from construction of new facilities.

TABLE 3.2–1.—*Summary Comparison of Environmental Impacts at Pantex Plant*-Continued

PROPOSED ACTION ALTERNATIVES (Includes Storage of Up to 20,000 Pits)			NO ACTION ALTERNATIVE (Includes Storage of Up to 12,000 Pits)	PIT STORAGE RELOCATION ALTERNATIVE (Pantex Plant Impacts of Relocating 8,000 or 20,000 Pits [See Table 3.2–2 for Impacts to Other Sites])
2,000 WEAPONS LEVEL	1,000 WEAPONS LEVEL	500 WEAPONS LEVEL		
WATER RESOURCES (SEE SECTION 4.6 IN MAIN TEXT)				
The increase in Pantex Plant annual water usage (currently 0.7 percent of withdrawal from the Ogallala aquifer in Carson County) would not significantly affect the ongoing regional depletion of the aquifer. Wastewater - 647M liters (171M gal) Water - 1,011M liters (267M gal) The new facilities represent 3.9M liters (1.0M gal) of the total water usage.	The amount of annual water usage would decrease from 1994 levels, reducing Pantex Plant's contribution to ongoing regional depletion of the Ogallala aquifer. Wastewater - 522M liters (138M gal) Water - 791M liters (209M gal) The new facilities represent 3.9M liters (1.0M gal) of the total water usage.	The amount of annual water usage would decrease from 1994 levels, reducing Pantex Plant's contribution to ongoing regional depletion of the Ogallala aquifer. Wastewater - 439M liters (116M gal) Water - 689M liters (182M gal) The new facilities represent 3.9M liters (1.0M gal) of the total water usage.	Water and wastewater annual usage and impacts for 2,000, 1,000, and 500 weapons levels would be lower than for the Proposed Action because no new facilities are proposed.	Water and wastewater annual usage and impacts for 2,000, 1,000, and 500 weapons levels would be the same as for the Proposed Action. The new facilities represent 3.9M liters (1.0M gal) of the total water usage.
AIR QUALITY (SEE SECTION 4.7 IN MAIN TEXT)				
Offsite concentrations of air pollutants would be below the TNRCC Effects Screening Levels (ESLs) and no adverse impacts to human health are expected. Onsite air quality levels are below those that would pose health risks to workers. The impacts from temporary increases in emissions during construction of new facilities would be negligible.			Same as the Proposed Action except temporary increases in emissions during construction of new facilities would not occur.	Same as the Proposed Action. The impacts from temporary increases in emissions during construction of new facilities would be negligible. Pollutant emissions from increased SST activity from relocation of the pits would be a small fraction of the total emissions from Pantex Plant.

TABLE 3.2–1.—*Summary Comparison of Environmental Impacts at Pantex Plant*-Continued

PROPOSED ACTION ALTERNATIVES (Includes Storage of Up to 20,000 Pits)			NO ACTION ALTERNATIVE (Includes Storage of Up to 12,000 Pits)	PIT STORAGE RELOCATION ALTERNATIVE (Pantex Plant Impacts of Relocating 8,000 or 20,000 Pits [See Table 3.2–2 for Impacts to Other Sites])
2,000 WEAPONS LEVEL	1,000 WEAPONS LEVEL	500 WEAPONS LEVEL		
ACOUSTICS (SEE SECTION 4.8 IN MAIN TEXT)				
Except for airblast from high explosives detonation, noise levels from Pantex Plant activities would be below 65 dBA at the plant boundary. The detonations could be audible at a distance of 5 to 10 kilometers (3 to 6 miles). Due to the size of the site, noise from construction of the new facilities would not reach the public.			Same as the Proposed Action except no new facilities are proposed.	Same as the Proposed Action. Due to the size of the site, noise from construction of the new facilities would not reach the public.
BIOTIC RESOURCES (SEE SECTION 4.9 IN MAIN TEXT)				
The construction of the new facilities would result in loss of 15,900 m^2 (171,000 ft^2) of common plant and animal habitat.			No new facilities are proposed.	The construction of the new facilities would result in loss of 15,900 m^2 (171,000 ft^2) of common plant and animal habitat.
SOCIOECONOMIC RESOURCES (SEE SECTION 4.11 IN MAIN TEXT)				
For this weapons level, 3,800 direct jobs and 6,257 secondary jobs would continue. A total personal income of $564 million (in 1994 dollars) would continue to be added to the economy annually. Construction of the new facilities would temporarily generate 1,227 direct and indirect jobs. A total of $56 million of personal income would be added to the economy in the peak cor[illegible]tion year.	This weapons level would support 3,000 direct jobs and 4,925 secondary jobs. Personal income additions to the economy would be reduced to $445 million annually. Construction of the new facilities would temporarily generate 1,227 direct and indirect jobs. A total of $56 million of personal income would be added to the economy in the peak construction year.	This weapons level would support 2,400 direct jobs and 3,950 secondary jobs. Personal income additions to the economy would be reduced to $356 million annually. Construction of the new facilities would temporarily generate 1,227 direct and indirect jobs. INTRASITE TRANSPORTATION (SEE SECTION 4.12 IN MAIN TEXT)				
Approximately 50 workers would be involved in these activities. This weapons level would have an estimated worker exposure of 61 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.024.[1] No impact to the public would result from intrasite transportation.	Approximately 50 workers would be involved in these activities. This weapons level would have an estimated worker exposure of 48 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.019.[1] No impact to the public would result from intrasite transportation.	Approximately 50 workers would be involved in these activities. This weapons level would have an estimated worker exposure of 41 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.016.[1] No impact to the public would result from intrasite transportation.	Approximately 50 workers would be involved in these activities. The No Action Alternative would have the following impacts for the three weapons levels: 2,000 weapons - worker exposure of 44 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.018.[1] 1,000 weapons - worker exposure of 31 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.012.[1] 500 weapons - worker exposure of 25 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.010.[1] No impact to the public would result from intrasite transportation.	Approximately 50 workers would be involved in these activities. The Pit Storage Relocation Alternative would have the following impacts for the two relocation amounts. These exposures include the impacts for the rest of the activities (equivalent to Proposed Action 2,000 weapons level). 20,000 pits - worker exposure of 344 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.14.[1] 8,000 pits - worker exposure of 174 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.07.[1] No impact to the public would result from intrasite transportation.

TABLE 3.2–1.—*Summary Comparison of Environmental Impacts at Pantex Plant*-Continued

PROPOSED ACTION ALTERNATIVES (Includes Storage of Up to 20,000 Pits)			NO ACTION ALTERNATIVE (Includes Storage of Up to 12,000 Pits)	PIT STORAGE RELOCATION ALTERNATIVE (Pantex Plant Impacts of Relocating 8,000 or 20,000 Pits [See Table 3.2–2 for Impacts to Other Sites])
2,000 WEAPONS LEVEL	1,000 WEAPONS LEVEL	500 WEAPONS LEVEL		
WASTE MANAGEMENT (SEE SECTION 4.13 IN MAIN TEXT)				
This weapons level would result in the annual generation of the following amounts of waste: LLW - 249 m^3 (326 yd^3) LLMW - 183 m^3 (240 yd^3) HW - 192 m^3 (251 yd^3) NHW (Class 1) - 742 m^3 (970 yd^3) NHW (Class 2) - 574 m^3 (751 yd^3) Additional LLMW storage could be required in 2004, if no shipment of waste offsite occurs.	This weapons level would result in the annual generation of the following amounts of waste: LLW - 132 m^3 (172 yd^3) LLMW - 118 m^3 (155 yd^3) HW - 108 m^3 (141 yd^3) NHW (Class 1) - 525 m^3 (687 yd^3) NHW (Class 2) - 453 m^3 (593 yd^3) This activity level would not require additional LLMW storage space until after 2007.	This weapons level would result in the annual generation of the following amounts of waste: LLW - 72 m^3 (94 yd^3) LLMW - 81 m^3 (106 yd^3) HW - 64 m^3 (84 yd^3) NHW (Class 1) - 388 m^3 (508 yd^3) NHW (Class 2) - 363 m^3 (475 yd^3) This activity level would not require additional LLMW storage space until after 2007.	The waste management impacts for the 2,000, 1,000, and 500 weapons levels would be the same as the Proposed Action. However, if the new Hazardous Waste Treatment Processing Facility is not implemented, Pantex Plant waste treatment and processing capabilities are greatly limited.	The waste management impacts for the 2,000, 1,000, and 500 weapons levels would be the same as the Proposed Action.

HUMAN HEALTH (SEE SECTION 4.14 IN MAIN TEXT)				
Approximately 330 workers would be involved in weapons-related activities associated with exposure to radiation. This weapons level would have an estimated worker exposure of 330 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.13.	Approximately 330 workers would be involved in weapons-related activities associated with exposure to radiation. This weapons level would have an estimated annual worker exposure of 165 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.07.	Approximately 330 workers would be involved in weapons-related activities associated with exposure to radiation. This weapons level would have an estimated worker exposure of 82 person-rem, and a group excess cancer fatality risk for 10-year exposure of 0.03.	The human health impacts for the 2,000, 1,000, and 500 weapons levels would be the same as the Proposed Action.	The human health impacts for the 2,000, 1,000, and 500 weapons levels would be the same as the Proposed Action. See Table S–2 (or 3.2–2) for impacts at the other sites.
AIRCRAFT ACCIDENT (SEE SECTION 4.15 IN MAIN TEXT)				
An aircraft accident capable of causing a release from a pit storage or weapons storage magazine is extremely unlikely (frequency of occurrence less than 10^{-4} but greater than or equal to 10^{-6}). A person in the vicinity of the plant has an approximately 3.0×10^{-12} increase in fatal cancer risk from potential aircraft crash plutonium dispersal accidents from pit storage magazines only.	The risks of an aircraft accident at Pantex Plant are dependent on the number of weapons or pits present at any time at the plant, not on the weapons level. The impacts for this weapons level would be equal to or less than those described for the 2,000 weapons level.	The risks of an aircraft accident at Pantex Plant are dependent on the number of weapons or pits present at any time at the plant, not on the weapons level. The impacts for this weapons level would be equal to or less than those described for the 2,000 weapons level.	The No Action Alternative would involve the storage of only 12,000 pits, which would require all 18 Modified Richmond magazines and 18 of the 42 SAC magazines. With fewer magazines used, the likelihood of an aircraft crash into a magazine containing pits is reduced by 44 percent.	The risks of aircraft accidents in Zone 4 are partly dependent on the pit storage level. 20,000 Pit Storage Relocation - With no pits stored at Pantex Plant, the likelihood of an aircraft accident capable of causing a release from a pit storage magazine is reduced to zero. 8,000 Pit Storage Relocation - The likelihood of an aircraft accident capable of causing a release from a pit storage magazine is the same as discussed for the No Action Alternative.

TABLE 3.2–1.—*Summary Comparison of Environmental Impacts at Pantex Plant*-Continued

PROPOSED ACTION ALTERNATIVES (Includes Storage of Up to 20,000 Pits)			NO ACTION ALTERNATIVE (Includes Storage of Up to 12,000 Pits)	PIT STORAGE RELOCATION ALTERNATIVE (Pantex Plant Impacts of Relocating 8,000 or 20,000 Pits [See Table 3.2–2 for Impacts to Other Sites])
2,000 WEAPONS LEVEL	1,000 WEAPONS LEVEL	500 WEAPONS LEVEL		
INTERSITE TRANSPORTATION OF NUCLEAR AND HAZARDOUS MATERIALS (SEE SECTION 4.16 IN MAIN TEXT)				
For the current baseline 10-year weapon shipment schedule, the public would receive an exposure of 2.0 person-rem with a corresponding excess cancer fatality risk of 9.0×10^{-4}. SST crew members would receive 1.6 person-rem with an expected number of excess cancer fatalities of 6×10^{-4}. For a 100-percent increase from the current shipment schedule, the public exposure would be 4.0 person-rem and excess cancer fatality risk would be 1.8×10^{-3}. SST crew members would receive 3.2 person-rem with an expected number of excess cancer fatalities of 1.3×10^{-3}.			Impacts would be the same as for the Proposed Action.	In addition to the impacts described for the Proposed Action, the following impacts would result with this alternative: 20,000 Pit Storage Relocation - Public would receive an additional exposure of 3.0 person-rem (maximum) for a total of 7.0 person-rem with a corresponding increase in excess cancer fatalities of 1.5×10^{-3} for a total number of expected excess cancer fatalities of 3.3×10^{-3}. 8,000 Pit Storage Relocation - Public would receive an additional exposure of 1.2 person-rem (maximum) for a total of 5.2 person-rem with a corresponding increase in excess cancer fatalities of 6.0×10^{-4} for a total number of expected excess cancer fatalities of 2.4×10^{-3}.
ENVIRONMENTAL JUSTICE				
Minority and low-income populations in the Pantex Plant Region of Influence would not be disproportionately affected.				

[1] For the approximately 50 people involved with transportation and staging activities historical dosimetry records indicate a maximum individual dose of 300 mrem with an individual excess cancer fatality risk for 10-year exposure of 1.2×10^{-3}.

FY - fiscal year
HW - Hazardous waste
LLW - Low-level radioactive waste
LLMW - Low-level mixed waste
SST - Safe Secure Tractor Trailer
ER - Environmental restoration
M - Million
NHW - Nonhazardous waste
MWh - Megawatt-hour

TABLE 3.2–2.—*Summary Comparison of Environmental Impacts of Pit Storage Operations at Pantex Plant and Alternative Pit Storage Relocation Sites*

PANTEX PLANT (PIT STORAGE IMPACTS ONLY—20,000 PITS)	ALTERNATIVE PIT STORAGE RELOCATION SITES			
	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
	SITE FACILITIES			
No change in the site's security force. No change in the site's annual electrical demand. No major modifications needed.	A small increase in the site's security force. Annual electrical demand of 4,110 MWh/yr would be 2.3 percent of the site's remaining system capacity. DAF: No major modifications needed. P-Tunnel: Construction of access control at the mouth of the tunnel.	A small increase in the site's security force. Annual electrical demand of 4,110 MWh/yr would be 0.2 percent of the site's remaining system capacity. No major modifications needed.	A small increase in the site's security force. Annual electrical demand of 4,110 MWh/yr would be a 1.2 percent increase over the site's 1994 usage of 345,500 MWh. No major modifications needed.	A small increase in the site's security force. Annual electrical demand of 4,110 MWh/yr would be a 0.7 percent of the site's remaining system capacity. No major modifications needed.
	LAND RESOURCES			
Additional magazines in Zone 4 would be used for pit storage. No change in land use.	DAF: No land disturbance or change in land use. P-Tunnel: Construction of access control in previously disturbed portal area. No change in land use.	No land disturbance or change in land use.		
	GEOLOGY AND SOILS			
No soil disturbance.	DAF: No soil disturbance. P-Tunnel: Construction of access control at the mouth of P-Tunnel in a previously disturbed area.	No soil disturbance.		

TABLE 3.2–2.—*Summary Comparison of Environmental Impacts of Pit Storage Operations at Pantex Plant and Alternative Pit Storage Relocation Sites*-Continued

PANTEX PLANT (PIT STORAGE IMPACTS ONLY—20,000 PITS)	ALTERNATIVE PIT STORAGE RELOCATION SITES			
	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
	WATER RESOURCES			
Operations would not impact surface water or groundwater. The annual water demand would be negligible. The wastewater would not have a measurable effect on groundwater quality.				
	AIR QUALITY			
Impacts to air quality from normal pit storage operations would result entirely from vehicle emissions which would add negligible amounts to regional emissions.	Impacts to air quality from normal pit storage operations would result entirely from vehicle emissions.			Impacts to air quality from normal pit storage operations would result entirely from vehicle emissions. The emissions have been determined not to exceed the specified threshold levels for the Albuquerque-Rio Grande Intrastate Air Quality Control Region.
	ACOUSTICS			
Noise impacts from the pit transportation vehicles and the air conditioning and heating equipment associated with pit storage personnel would be minimal at any of the sites.				
	BIOTIC RESOURCES			
No impacts to sensitive species, their habitats, or wetlands are anticipated. No impacts to biotic resources would be expected.	No impacts to sensitive species, their habitats, or wetlands would be expected. DAF: Area of infrequent desert tortoise activity. No impacts would be expected. P-Tunnel: No desert tortoise activity. No impacts to biotic resources would be expected.	No sensitive species, habitats, or wetlands would be disturbed. No sensitive species reside at P-Reactor. No impacts to biotic resources would be expected.	No sensitive species, habitats, or wetlands would be disturbed. No sensitive species reside at FMEF. No impacts to biotic resources would be expected.	A sensitive plant species and four springs are present within the perimeter of Manzano WSA. However, pit storage activities would not disturb the plants or the springs. No impacts to biotic resources would be expected.

TABLE 3.2–2.—*Summary Comparison of Environmental Impacts of Pit Storage Operations at Pantex Plant and Alternative Pit Storage Relocation Sites*-Continued

PANTEX PLANT (PIT STORAGE IMPACTS ONLY—20,000 PITS)	ALTERNATIVE PIT STORAGE RELOCATION SITES			
	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
	CULTURAL RESOURCES			
Pit storage activities would not disturb any of the resource sites. Therefore, no impacts would be expected.	DAF: Nine cultural resource sites have been identified, but were not recommended for NRHP eligibility. P-Tunnel: No historic resources have been found. Pit storage activities would not result in any direct impacts to cultural resources.	No cultural resources have been found in the vicinity of P-Reactor. Pit storage activities would not result in any impacts to cultural resources.	No cultural resources have been found in the vicinity of the FMEF. Pit storage activities would not result in any impacts to cultural resources.	Historic and prehistoric resources have been found within the Manzano WSA. Pit storage activities in the magazines would not result in any impacts to cultural resources.
	SOCIOECONOMIC RESOURCES			
While pit storage activities at Pantex Plant require security personnel, these personnel are also required for the other storage activities in Zone 4. The security requirements would not change with or without pit storage.	Pit storage activities would require 150 personnel (30 facility, 120 security). Impacts of this employment on each region's economy would be negligible.			

TABLE 3.2–2.—*Summary Comparison of Environmental Impacts of Pit Storage Operations at Pantex Plant and Alternative Pit Storage Relocation Sites*-Continued

PANTEX PLANT (PIT STORAGE IMPACTS ONLY—20,000 PITS)	ALTERNATIVE PIT STORAGE RELOCATION SITES			
	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
	INTRASITE TRANSPORTATION			
Pit storage at Pantex Plant would not result in any impacts beyond those described for all intrasite transportation and staging operations in Table 3.1–1.	Worker exposure at NTS from normal pit unloading and transfer operations would be 283 person-rem for 20,000 pits and 113 person-rem for 8,000 pits, resulting in 0.11 and 0.04 excess fatal cancers, respectively. Pit loading operations at Pantex Plant would result in an additional 283 person-rem for 20,000 pits or an additional 113 person-rem for 8,000 pits.	Worker exposure at SRS from normal pit unloading and transfer operations would be 283 person-rem for 20,000 pits and 113 person-rem for 8,000 pits, resulting in 0.11 and 0.04 excess fatal cancers, respectively. Pit loading operations at Pantex Plant would result in an additional 283 person-rem for 20,000 pits or an additional 113 person-rem for 8,000 pits.	Worker exposure at Hanford from normal pit unloading and transfer operations would be 113 person-rem for 8,000 pits, resulting in 0.04 excess fatal cancers. Pit loading operations at Pantex Plant would result in an additional 113 person-rem for 8,000 pits.	Worker exposure at KAFB from normal pit unloading and transfer operations would be 283 person-rem for 20,000 pits and 113 person-rem for 8,000 pits, resulting in 0.04 excess fatal cancers, respectively. Pit loading operations at Pantex Plant would result in an additional 283 person-rem for 20,000 pits or an additional 113 person-rem for 8,000 pits.
	WASTE MANAGEMENT			
The pit storage operations would generate less than 1 cubic meter each of low-level mixed, low-level, and hazardous waste annually. This amount of waste does not impact current waste management at Pantex Plant.	The pit storage operations would generate less than 1 cubic meter each of low-level mixed, low-level, and hazardous waste each annually. This amount of waste would not impact current waste management at any of the sites.			

TABLE 3.2–2.—*Summary Comparison of Environmental Impacts of Pit Storage Operations at Pantex Plant and Alternative Pit Storage Relocation Sites*-Continued

PANTEX PLANT (PIT STORAGE IMPACTS ONLY—20,000 PITS)	ALTERNATIVE PIT STORAGE RELOCATION SITES			
	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
	HUMAN HEALTH			
The range of potential accidents is dominated by an aircraft accident capable of causing a release from a pit storage magazine. The likelihood of this incident is extremely unlikely (frequency of occurrence: less than 10^{-4} and equal to or greater than 10^{-6} per year). A person in the vicinity of the plant has an approximately 2.5×10^{-12} increase in fatal cancer risk from potential aircraft crash plutonium dispersal accidents from pit storage magazines only.	The range of potential accidents is dominated by the puncture of a pit at the DAF due to a forklift accident (frequency per single pit handling is extremely unlikely [10^{-4} to 10^{-6}]). The impacts of this accident would be 3.3×10^{-5} person-rem to the public in the vicinity of NTS, resulting in a risk of 1.1×10^{-15} excess fatal cancers/yr to an average member of the public.	The range of potential accidents is dominated by the puncture of a pit at the P-Reactor due to a forklift accident (frequency per single pit handling is extremely unlikely [10^{-4} to 10^{-6}]). The impacts of this accident would be 4.6×10^{-3} person-rem to the public in the vicinity of SRS, resulting in a risk of 3.0×10^{-15} excess fatal cancers/yr to an average member of the public.	The range of potential accidents is dominated by the puncture of a pit at the FMEF due to a forklift accident (frequency per single pit handling is extremely unlikely [10^{-4} to 10^{-6}]). The impacts of this accident would be 2.9×10^{-5} person-rem to the public in the vicinity of Hanford Site, resulting in a risk of 5.3×10^{-17} excess fatal cancers/yr to an average member of the public.	The range of potential accidents is dominated by the puncture of a pit at the Manzano WSA due to a forklift accident (frequency per single pit handling is extremely unlikely [10^{-4} to 10^{-6}]). The impacts of this accident would be 4.0×10^{-2} person-rem to the public in the vicinity of KAFB, resulting in a risk of 2.6×10^{-14} excess fatal cancers/yr to an average member of the public.
	AIRCRAFT ACCIDENTS			
An aircraft accident capable of causing a release from a pit storage magazine is extremely unlikely (frequency of occurrence: less than 10^{-4} and equal to or greater than 10^{-6} per year). A person in the vicinity of the plant has an approximately 2.5×10^{-12} increase in fatal cancer risk from potential aircraft crash plutonium dispersal accidents from pit storage magazines only.	The annual aircraft hit probability hazard frequency at the DAF at NTS is 1.5×10^{-6}. Due to the construction of the DAF, a breach of pit containers in storage from aircraft impact resulting in a release of Pu is not reasonably foreseeable (frequency of occurrence: less than 10^{-6} per year). The P-Tunnel would be immune from aircraft accidents.	The annual aircraft hit probability hazard frequency at the P-Reactor at SRS is 1.2×10^{-6}. Due to the construction of the P-Reactor, a breach of pit containers in storage from aircraft impact resulting in a release of Pu is not reasonably foreseeable (frequency of occurrence: less than 10^{-6} per year).	The annual aircraft hit probability hazard frequency at the FMEF at Hanford is 1.2×10^{-6}. Due to the construction of the FMEF, a breach of pit containers in storage from aircraft impact resulting in a release of Pu is not reasonably foreseeable (frequency of occurrence: less than 10^{-6} per year).	The annual aircraft hit frequency hazard frequency at Manzano is 8.8×10^{-5}. Due to construction of magazines designated for potential storage of pits, a breach of pit containers in storage from aircraft impact resulting in a release of Pu is not reasonably foreseeable (frequency of occurrence: less than 10^{-7} per year).

TABLE 3.2–2.—*Summary Comparison of Environmental Impacts of Pit Storage Operations at Pantex Plant and Alternative Pit Storage Relocation Sites*-Continued

PANTEX PLANT (PIT STORAGE IMPACTS ONLY—20,000 PITS)	ALTERNATIVE PIT STORAGE RELOCATION SITES			
	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
	INTERSITE TRANSPORTATION OF NUCLEAR AND HAZARDOUS MATERIALS (TRANSPORTATION OF PITS ONLY)			
Storage of all pits at Pantex Plant (i.e., the Proposed Action) would not require additional intersite transportation. Therefore, there would be no additional impacts to the public at Pantex Plant.	The transportation of a maximum of 20,000 pits to NTS for storage would result in a cumulative dose of 2.0 person-rem to the public. This would result in 1.0×10^{-3} excess cancer fatalities from incident-free operations.	The transportation of a maximum of 20,000 pits to SRS for storage would result in a cumulative dose of 3.0 person-rem to the public. This would result in 1.5×10^{-3} excess cancer fatalities from incident-free operations.	The transportation of a maximum of 8,000 pits to Hanford Site for storage would result in a cumulative dose of 1.2 person-rem to the public. This would result in 6.0×10^{-4} excess cancer fatalities from incident-free operations.	The transportation of a maximum of 20,000 pits to Manzano WSA for storage would result in a cumulative dose of 0.5 person-rem to the public. This would result in 2.5×10^{-4} excess cancer fatalities from incident-free operations.
	ENVIRONMENTAL JUSTICE			
Normal operations would not have any offsite impact. Abnormal events would not disproportionately impact minority or low-income populations.	Normal operations would not have any offsite impact at any of the sites. Abnormal events would not disproportionately impact minority or low-income populations.			

DAF - Device Assembly Facility
FMEF - Fuels and Materials Examination Facility
MWh - Megawatt-hours
Pu - Plutonium
SRS - Savannah River Site
SST - Safe Secure Tractor Trailer
WSA - Weapons Storage Area

CHAPTER 4

Affected Environment and Environmental Consequences at Pantex Plant

CHAPTER 4
AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES AT PANTEX PLANT

Chapter 4 provides information on the methods of analysis applied in this EIS and the results of analyses for Pantex Plant. The chapter begins with an introduction and a summary of the impact assessment methodologies that have been applied. The chapter continues with presentations of the affected environment at Pantex Plant and the impacts of the Proposed Action and Alternatives. These presentations are organized by type of resource (e.g., plant facilities and infrastructure, land resources, water resources, etc.) and other issue areas (e.g., intrasite transportation, waste management, intersite transportation, and environmental justice). Also addressed later in this chapter are irreversible and irretrievable commitments of resources, unavoidable adverse environmental impacts, relationships between short-term uses of the environment and long-term productivity, and cumulative impacts.

4.1 INTRODUCTION

The Council on Environmental Quality (CEQ) regulations for implementing NEPA direct Federal agencies to follow the standard format contained in 40 CFR Parts 1500–1508 for preparation of an EIS. However, the regulations allow Federal agencies to use different formats if "the agency determines that there is a compelling reason to do otherwise" (40 CFR 1502.10). Due to the complex, interwoven nature of the activities discussed in this EIS, the number of sites involved with these activities, and the inclusion of additional sites as possible alternatives for relocation of these activities, DOE has determined that a modified format would better serve the public interest and more efficiently satisfy the regulatory requirement for clear presentation of the Proposed Action, the Alternatives, and the associated environmental consequences.

In applying the standard format, agencies frequently use separate chapters for discussions of the affected environment and environmental consequences. This EIS, however, is formatted such that the affected environment for Pantex Plant and associated environmental consequences are contained in chapter 4, while the affected environment and environmental consequences associated with the other sites are contained in chapter 5. Furthermore, both chapters are internally formatted so that the discussion of each aspect of the affected environment at a site (e.g., water resources, air quality, transportation, etc.) is followed by discussions of the impacts to that aspect for the Proposed Action, No Action, and Pit Storage Relocation Alternatives, respectively. Subsequently, the cumulative impacts to that aspect of the environment and potential measures to mitigate adverse environmental impacts are discussed.

This chapter begins with a brief discussion of the methodologies used to characterize each aspect of the affected environment and assess potential impacts to that aspect. In accordance with the CEQ regulations, the affected environment is defined comprehensively to include the natural and physical environment and the relationship of people with that environment (40 CFR 1508.14). In the interest of presenting the reader with the relevant information in the most practical manner, the discussions in this chapter are limited to summaries of key information. Additional information and discussions of analyses are contained in the appendixes.

Affected Environment

The descriptions of the affected environment provide a baseline for understanding the direct, indirect, and cumulative effects of the Proposed Action and Alternatives. The scope of the discussions varies by resource areas to ensure that all relevant issues are included.

For land resources and geology and soils, discussions include Pantex Plant Site and its surroundings, generally an area within 80 kilometers (50 miles) of Pantex Plant Site and referred to as the Region of Influence (ROI) for each resource. This information provides a basis for understanding both direct effects and the overall resource base that could be affected by the changes in the activity levels at Pantex Plant.

Ambient conditions are described for air quality, acoustics (noise), and water resources. Discussions focus on air quality and noise conditions at the site boundaries and the surface water bodies and groundwater aquifers that could be affected. This information serves as a basis for analyzing key air and water quality parameters to obtain results that can then be compared to regulatory standards. Biotic and cultural resources conditions are described for the area within the boundaries of Pantex Plant Site and also at Pantex Lake.

Socioeconomic conditions are described for the counties and communities that could be affected by regional population changes associated with the changes in the activity levels at Pantex Plant. The socioeconomic ROI is large enough to account for growth related to direct project employment as well as secondary jobs that may be induced by the changes in the activity levels at Pantex Plant. The socioeconomic ROI for Pantex Plant includes four counties: Carson, Armstrong, Potter, and Randall.

In addition to those natural and human environmental resources discussed above, the affected environment sections include a number of issues related to ongoing DOE activities at Pantex Plant. These issues involve plant facilities and infrastructure, intrasite and intersite transportation, waste management, and radiological and hazardous chemical impacts on human health during normal operations and accidents, including risks from potential aircraft accidents.

Environmental Impacts

In accordance with CEQ regulations, the environmental consequences discussions provide the analytical detail for comparisons of environmental impacts associated with the changes in the activity levels at Pantex Plant. Discussions are provided for each environmental resource and relevant issues that could be affected.

For comparison purposes, environmental concentrations of emissions and other potential environmental effects are presented with appropriate regulatory standards or guidelines. However, compliance with regulatory standards is not necessarily an indication of the significance or severity of the environmental impact for NEPA purposes.

The purpose of the analysis of environmental consequences is to identify the potential for environmental impacts. The environmental assessment methods used and the factors considered in assessing environmental impacts are discussed in section 4.2, Impact Assessment Methodologies, and in the appropriate appendixes. The potential for impacts to a given resource or relevant issue is described in the introduction to each section that follows (sections 4.3 through 4.17).

4.2 IMPACT ASSESSMENT METHODOLOGIES

The following is a brief description of the impact assessment approaches used in this EIS for addressing potential impacts of Pantex Plant continued operations at different activity levels and at candidate pit storage sites.

Plant Facilities and Infrastructure

Changes to plant facilities and infrastructure are assessed by comparing the support requirements of the Proposed Action and the Alternatives to site infrastructure capacities. These assessments focus on transportation, infrastructure, and utility systems.

Land Resources

Land use impacts are assessed based on the extent and type of land that would be affected and potential direct impacts resulting from the conversion or from the incompatibility of land use changes with special status and protected lands.

Geology and Soils

The geologic setting, structural geology, and the soil and sediment quality are discussed. The geologic setting is composed of the geomorphology and the stratigraphy of the region. Structural geology includes regional geology, seismicity, and subsidence. Potential seismic impacts are assessed based on the locations of capable faults and the history of the seismicity in the region. The section on soil and sediment quality includes discussions on soil types and the current environmental restoration processes at Pantex Plant. Impacts to the soil include any activities which would result in erosion and taking soils out of production, which is discussed in the Land Use section. Impacts from the soil would be contaminated soil potentially impacting human health. Soil types at Pantex Plant Site are described and a qualitative analysis is performed to assess the effects of potential contaminants of concern in soils at Pantex Plant Site.

Water Resources

Surface water impacts are assessed based on wastewater discharges from Pantex Plant activities. The assessment of water quality impacts from wastewater (sanitary and process) and stormwater runoff qualitatively address potential impacts to surface water and groundwater resources at Pantex Plant.

Impacts to floodplains are assessed based on whether any Pantex Plant activities, including construction of new facilities, would be located within floodplains.

Groundwater resource impacts are assessed based on the effects on aquifers, groundwater usage, and groundwater quality within the Pantex Plant ROI. Total groundwater use at Pantex Plant and projections of future usage determine the short- and long-term impacts associated with changing activity levels at Pantex Plant. Impacts of groundwater withdrawals on existing contaminant plumes because of construction and facility operation are also assessed.

Air Quality

The assessment of potential impacts to air quality is based on the comparison of impacts from the Proposed Action and Alternatives with applicable State, local, or National Ambient Air Quality Standards or the potential exceedance of Prevention of Significant Deterioration increments. The more stringent standards serve as the comparison criteria. The comparison of project toxic pollutants includes guidelines or standards adopted by the State of Texas. Air quality modeling was performed in order to assess the conservative maximum concentrations of individual pollutants that the workers or members of the public might experience. Air quality monitoring data collected by the Texas Natural Resources Conservation Commission

(TNRCC) has been used to help benchmark the model. However, the data does not correlate to the modeling on a one-to-one basis, as the placement and operation of air quality monitoring stations do not allow for a comprehensive assessment of the impacts of air emissions to the workers and the public.

Acoustics

Acoustic impacts are assessed qualitatively on the basis of the potential degree of change in noise levels at sensitive receptors with respect to ambient conditions. Blast noise from high explosives detonation is calculated using an airblast prediction model called BLASTO.

Biotic Resources

Potential impacts are assessed based on the degree to which various habitats or species could be affected by Pantex Plant operations. Where possible, impacts are evaluated with respect to Federal and State protection regulations and standards.

Impacts to wildlife are evaluated in terms of disturbance, displacement, or loss of wildlife. Results of biouptake of radionuclides are identified from monitoring data. Impacts are assessed based on the proximity of wetlands to Pantex Plant operations. Impacts resulting from wastewater discharge into a wetland are evaluated, recognizing the effluents would be required to meet Federal and State standards. A list of species potentially present at Pantex Plant Site was obtained from the U.S. Fish and Wildlife Service and appropriate State agencies, and was used in the process of assessing whether Pantex Plant operations would impact any plant or animal under section 7 of the *Endangered Species Act.*

Cultural and Paleontological Resources

Impacts on prehistoric and historic resources are assessed by considering whether continued operations at Pantex Plant could substantially add to existing disturbance of resources in the area, adversely affect National Register of Historic Places-eligible resources, or cause loss of, or destruction to, important prehistoric resources. Impacts on Native American resources are assessed by considering whether Pantex Plant activities have the potential to affect sites that are historically important or have a position in a Native American system of belief. Impact assessments for paleontological resources are based on the numbers and kinds of resources that could be affected, as well as the quality of fossil preservation in a given deposit.

Socioeconomics

The assessment of impacts on local and regional socioeconomic conditions and factors includes changes in population, employment, and income in the ROI. The changes to these factors are projected on an annual basis because an exact schedule for changes in the activity levels are not currently known. The assessment includes bounding cases for activity levels.

Intrasite Transportation

The focus of this analysis is on the intrasite transfer and handling of hazardous materials, particularly the radiological effects from the transportation and handling of radioactive materials. Accidents involving the transportation and handling of hazardous materials have the potential of leading to human fatalities, excess cancer fatalities, and serious environmental contamination. Radiological exposures and excess cancer fatalities are calculated for workers handling the material. Impacts to the public outside the Pantex Plant boundaries are not expected from intrasite transfer and handling of radioactive materials.

Waste Management

The analysis addresses the waste types and waste volumes generated from Pantex Plant operations, including environmental restoration activities. Impacts are assessed in the context of site practices for treatment, storage, and disposal; associated capacities for the different waste types; and the applicable regulatory requirements.

Pantex Plant does not have existing onsite low-level waste disposal; the number of shipments required to transport low-level waste from Pantex Plant to the Nevada Test Site is thus part of the analysis. The risk associated with additional shipments is addressed in the Human Health section.

Human Health

The health effects are determined for Pantex Plant operations by identifying the types and quantities of material to which one is exposed, estimating exposures, and calculating the resultant health effects. The impacts on human health for workers and the public during normal operation and postulated accidents from various alternatives are assessed. Computer codes such as Melcor Accident Consequence Code System (MACCS) and Explosive Release Atmospheric Dispersion (ERAD) are used to simulate impacts. Atmospheric dispersion modeling using Industrial Source Complex Short-Term Model, Version 2 (ISCST2) was performed for the air quality analysis and the results are used in the evaluation of impacts to workers from hazardous chemicals. Data from continuous air monitoring stations are used to assess impacts from radiological emissions.

Public health impacts could result from exposure to radioactive or hazardous chemical materials released during operation. Experience from past and current operations that are similar to future operations is used to estimate the radiological health impacts to workers. Modeling is used to estimate the type and amount of material released and the associated radiological and chemical doses. These doses are converted to health effects using appropriate health risk estimators.

The relative consequences of postulated accidents in the evaluation of each alternative are assessed. The accident analysis involves less detail than a formal Probabilistic Risk Assessment by addressing bounding accidents (relatively low probability/high consequence) and a representative spectrum of possible operational accidents (relatively high probability of occurrence and low consequence). The technical approach for the selection of accidents is consistent with the DOE Office of NEPA Oversight *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statement* guidance, which recommends consideration of two major categories of accidents: within design basis accidents and beyond design basis accidents (DOE 1993).

Aircraft Accidents

One of the scenarios in the accident risk impact assessment is the potential for an aircraft-induced hazardous material dispersal accident. The likelihood and consequences of this accident scenario have been studied extensively since the start of nuclear explosive operations at Pantex Plant, and studies continue to this day. For purposes of this analysis, new data from a Radar Airspace Monitoring System has been used to determine the amount, type, and frequency of aircraft movements in proximity to Pantex Plant. A Draft DOE standard methodology (see appendix E) is used to estimate the likelihood of an aircraft impacting a critical facility at Pantex Plant. Human health risks from aircraft-induced radiological releases are assessed using the MACCS and ERAD computer codes. The resulting doses are converted to a predicted number of excess cancer fatalities.

Intersite Transportation

The intersite transportation assessment was based on the transport mode, weight of material, curies, proximity dose rates (transport index), type of package, number of shipments, and distance. Health impacts are presented for transportation of pits and other nuclear weapon components. Impacts were evaluated for both incident-free transportation and accident conditions using the Analysis of Dispersal Risk Occurring in Transportation (ADROIT) code developed by Sandia National Laboratories.

Environmental Justice

The potential for disproportionately high and adverse human health or environmental effects on minority and low income populations are evaluated in accordance with Executive Order 12898, *Federal Action to Address Environmental Justice in Minority Populations and Low Income Populations*. The environmental justice analysis addresses selected demographic characteristics of the Pantex Plant ROI, defined as an 80-kilometer (50-mile) circle centered on Pantex Plant. Similar analyses have also been performed within the ROI for each of the alternate sites considered for interim storage of pits.

The analysis of environmental justice presented in this EIS is based on the definitions of minority and low income populations as contained in the notice for the EPA Office of Environmental Justice (59 FR 192). These definitions call for identification of Census Tracts where 25 percent or more of the persons in 1990 were either minority group members or below poverty level based on their income in 1989. For comparison purposes, definitions of minority and low income populations as provided by the Council on Environmental Quality (CEQ) in August 1995, and also reported in *Guidance for Incorporating Environmental Justice Concerns* in EPA's NEPA Compliance Analysis (EPA 1996a), are also applied to the 1990 Census data and results of both analysis are reported in the EIS.

Cumulative Impacts

Cumulative impacts include the incremental impacts of the actions (usually the proposed or preferred action) when added to other past, present, and reasonably foreseeable future actions. Although several DOE programs described in section 1.7 of this EIS have the potential to impact the Pantex Plant ROI, sufficient information for incorporation in this document is currently available for only three programs: the Waste Management (WM), the Stockpile Stewardship and Management (SSM), and the Storage and Disposition of Weapons-Usable Fissile Materials (S&D) programs. Programmatic EISs (PEISs) are being prepared by DOE for each of these programs.

The cumulative impacts associated with the three DOE programs were, in some instances, overestimated in the Draft Pantex Plant EIS. This overestimation was due to conservative assumptions concerning the scope and time period associated with each program. After the Draft PEIS for each program was issued and further coordination among the programs clarified the details of certain alternatives, some assumptions concerning the assessment of the cumulative impacts were modified.

In the Draft Pantex Plant EIS, the cumulative impacts associated with both the waste management program and the storage and disposition program were calculated by adding the impacts from the Pantex Plant EIS Proposed Action (at a 2,000 weapons per year level) to those for the different alternatives discussed in each of the PEISs. However, the cumulative impacts associated with any new mission or facility at Pantex Plant should be placed in the context of the overall impacts at the Pantex Plant Site at the time those new facilities or missions would be implemented.

The Pantex Plant EIS and the SSM PEIS both discuss the operations of the entire Pantex Plant, but over different time frames. The level of operations, and associated impacts, discussed in the Pantex Plant EIS is for an approximately 10-year time frame beginning in the year 1997. The SSM PEIS discusses a lower level of the same kind of operations for the time frame of approximately the year 2005 and later, so that the operational levels discussed in the Pantex Plant EIS Proposed Action will evolve over the next 10 years into the level of operations discussed in the No Action Alternative of the SSM PEIS.

In recognition of this evolutionary process, the Final Pantex Plant EIS has been modified so that the cumulative impacts from potential WM PEIS missions and facilities, which would be implemented during the next five to seven years, are combined with the impacts from the level of operations discussed in the Pantex Plant EIS Proposed Action. However, the cumulative impacts from the potential missions and facilities discussed in the bounding storage and disposition alternatives of the S&D PEIS, which would be implemented during the next seven to 20 years, are combined with the impacts from the level of operations discussed in the SSM PEIS No Action Alternative.

There is one exception to this methodology for presenting cumulative impacts. As discussed in sections 1.4 and 1.7.3 of this volume, the Final S&D PEIS will include an alternative under which pits from the Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex for storage in Zone 4 as early as 1997. This alternative would result in impacts occurring at the Pantex Plant sooner than they would occur under the bounding storage and disposition alternative of the S&D PEIS (1997 vs. 2004); however, these impacts would be less than those for the bounding case because substantially less total fissile material would be transferred to Pantex.

Storage of pits from RFETS would have incremental impacts in addition to the storage of pits from disassembled weapons. However, this increase is generally accounted for within the level of activities assumed for the Proposed Action in this EIS. That is, the pits from RFETS would not cause the total number of pits stored in Zone 4 to exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Likewise, the intrasite transport of the RFETS pits would cause cumulative impacts, but these impacts are also accounted for within the transportation necessary to move 20,000 pits into storage. The receipt of RFETS pits would require an additional repackaging operation (from FL containers into AL-R8 containers) prior to intrasite transport into storage, as compared to the handling of pits from disassembled weapons, and this operation would contribute cumulative impacts that would not be accounted for by the Proposed Action, but that are addressed in the cumulative impacts analysis.

Another factor that resulted in the over-estimation of some cumulative impacts in the Draft Pantex Plant EIS was the double counting of operations that were assessed in all of the EISs. In the Draft Pantex Plant EIS the cumulative impacts associated with the Waste Management program and the Storage and Disposition program were calculated by adding the impacts from the Pantex Plant EIS Proposed Action (at a 2,000 weapons per year level) to those for the different alternatives discussed in each of the PEISs. Since the impacts detailed in both of these documents included all operations at the site (most of which will not change), this addition of impacts resulted in the impacts from many operations being counted twice.

An example of this double counting is the air emissions associated with the steam plant. When the air quality impacts in the Draft Pantex Plant EIS, which included the emissions from the steam plant, were added to those in the S&D PEIS, which also included the steam plant emissions, these emissions were counted twice. While this double counting of many impacts certainly bounded the cumulative impacts to be expected from these programs, it did not provide the best estimate of the cumulative impacts. In the Final Pantex Plant EIS, the cumulative impacts have been recalculated to more accurately reflect the impacts that could be expected if the decisions discussed in the documents were implemented.

In addition to the DOE programs, information on other Federal, State or local projects, including private developments, was sought through contacts with Federal and State regulatory agencies, the Amarillo Economic Development Corporation, the Panhandle Municipal Water Authority, and the City of Amarillo.

This effort yielded only one project (future closure of the Helium Plant) that would contribute to the cumulative impacts in the Pantex Plant ROI. The U.S. Bureau of Mines has been operating the Helium Plant in the Amarillo area since the early 1940s. On October 9, 1996, the President signed the *Helium Privatization Act of 1996*, directing helium operations to discontinue production and sale of refined helium no later than 18 months from the date of enactment (by April 1998). The impacts of this action are analyzed in section 4.11.5, because cumulative impacts of closing or downsizing this facility would be limited to socioeconomic impacts.

Context of Operations on 2,000, 1,000, and 500 Weapons

These workloads were used to determine a reasonably foreseeable impact of operating Pantex Plant. Because the dismantlement of a specific weapon system was not analyzed, a bounding impact per category of operation, i.e., dismantlement, assembly, surveillance (not by weapon type, nor by individual operations) was derived from historical data. Then the total impact was derived by scaling these data by number of weapons or, in some cases, by number of people. This is not a limitation to the number of personnel that can be hired. However, it does mean that the level and type of impacts to individual resource areas must remain within the envelopes as stated in the EIS.

This EIS is focused on determining impacts from full-scale dismantlement or disassembly and assembly of an entire weapon. This imparted a conservative, yet "reasonably foreseeable," estimation as to what the impacts would be from operating Pantex Plant. The use of activity levels for operations on 2,000, 1,000, and 500 weapons was a tool to generate estimates for total emission levels, waste generation, risk, etc. The analysis should therefore envelope the impacts from operating the plant without unnecessarily constraining specific process decisions (see section 2.2).

To restate this conclusion, once impact levels are determined, there may exist several permutations on the number of weapons and impact per weapon that fall within the derived impact levels. Specifically, this EIS does not state what processes are accomplished, or a given ratio of particular processes. If some process is needed whereby work on over 2,000 weapons is necessary, but the impacts remain within the impact envelopes, no supplemental EIS would be required. Ongoing assessments would continue to be necessary to ensure that the level of impacts to the environment have not drastically changed. The total number of weapons operations would be evaluated, because it is a key indicator as to whether or not additional NEPA documentation would be required. However, exceeding these numbers does not, by itself, mandate additional Environmental Assessments or EISs. Understanding whether or not there are additional impacts from specific processes is required, but a simple checklist or screening analysis is typically the only documentation necessary to confirm that no additional impacts would result from a process or set of processes. On the other hand, if the analysis confirmed that impact parameters were surpassed, additional NEPA documentation would be required.

4.3 PLANT FACILITIES AND INFRASTRUCTURE

4.3.1 Affected Environment

This section addresses the current status of Pantex Plant facilities and supporting infrastructure. Included are discussions of the plant's buildings, operations, services, roads, railroads, and utilities. These discussions help the reader understand the current status of operations at the plant to allow for better comparison of the effects of implementing the Proposed Action or the Alternatives.

4.3.1.1 *Facilities*

Pantex Plant Facilities/Buildings

Major operations performed at Pantex Plant include: assembly and disassembly of nuclear weapons, repair and modification of weapons, production of high explosive(s) (HE) components, evaluation and testing of weapon components, research and development, staging (temporary storage) of nuclear weapons, packaging and shipping of weapons and components, and interim storage of pits. These operations are housed in 476 buildings, containing 230,674 square meters (2,483,020 square feet) of work space. The principal building classifications are administrative, storage, production, service, and research and development. An additional 144 structures, containing 39,928 square meters (429,780 square feet), support the principal operations (DOE 1994j:3-3). These structures include temporary buildings, leased trailers and buildings used for additional office space, and temporary storage containers. Zone 4 magazines (95 buildings) are used for staging of nuclear weapons, storage of explosives, and interim storage of pits (Pantex 1991:3).

Table 4.3.1.1–1 provides a summary of the buildings and their gross areas, by selected construction periods. Approximately 48 percent of the buildings at Pantex Plant were constructed prior to 1966. These buildings are being considered for shutdown after consolidation of functions into newer buildings (DOE 1995j:3, 7). Table 4.3.1.1–2 provides the number of buildings occupied by principal missions at the plant.

TABLE 4.3.1.1–1.—*Buildings at Pantex Plant, by Construction Period*

YEAR BUILT	NUMBER OF BUILDINGS	SQUARE METERS	SQUARE FOOTAGE
Pre-1945	126	60,568	651,956
1946–1955	43	13,930	149,948
1956–1965	61	16,283	175,274
1966–1975	60	30,881	332,412
1976–1985	56	36,098	388,571
1986–1990	66	40,519	436,155
1991–1994	50	30,382	327,036
Not Reported	14	2,013	21,668
Total	476	230,674	2,483,020

Pantex Plant Operations/Services

The operating contractor for Pantex Plant is Mason & Hanger Corporation. Under the office of the General Manager, the plant is organized into 13 divisions including: Capital Projects; Information Management; Quality; Safeguards, Security, and Fire Protection; Human Resources; Administrative Services; Operations Support; Applied Technology; Facility Operations; Manufacturing; Engineering and Design; Environment Safety and Health; and Waste Management and Environmental Restoration (Pantex 1996:2.1). Extensive descriptions of key operations and services are provided in the *Pantex Plant Safety Information Document*. Additionally, appendix D of the *Pantex Plant Safety Information Document* provides brief descriptions of each current and planned facility and its operations and services (Pantex 1996a:App D; Pantex 1996b:App C).

TABLE 4.3.1.1–2.—*Mission Facilities Summary*[1]

MISSION	APPROX. # OF BLDGS.	EXAMPLE FACILITIES	APPROX. AREA m^2 (ft^2)	YEAR BUILT (average)	REMAINING LIFE (average years)
Assembly, Disassembly, QA Testing, & Maint. & Mod.	94	Assembly & Disassembly Bays, Assembly & Disassembly Cells, Production Support Laboratories, Tool & Component Warehousing, Weapon Staging Magazines	84,400 (908,000)	1966	31
HE Research and Development	124	HE Machining Bays, HE Pressing Bays, HE Formulation, HE Synthesis, Firing Sites, Production Support Laboratories, HE Storage Magazines	46,300 (498,000)	1955	15
Facility Operations	141	Maintenance and Craft Shops, Security, Medical, Fire Department, ES&H, Support Laboratories, Offices	76,600 (814,800)	1977	22
Pit Storage	22[2]	Magazines, Vaults, Staging Facilities	6,900 (74,200)	1949	34

[1]Table excludes tanks, chemical storage, ramps (concrete floor enclosed walkways between buildings), guard towers, utility structures (e.g., pump houses), and miscellaneous structures (e.g., bus stop hut).
ES&H - Environment, Safety, and Health

Pantex Plant has a mature maintenance upgrade program supported with appropriate NEPA related documentation. Since 1990, Pantex Plant has initiated 354 environmental checklists and other NEPA related documents; 206 of the 354 were identified as facility upgrades, repairs, improvements, and maintenance related activities (Pantex 1996b:App D).

4.3.1.2 *Infrastructure*

Two categories of infrastructure, transportation access and utilities, are described below for Pantex Plant Site. Transportation access includes roads, railroad, and airport operations. Utilities include steam, electricity, natural gas, water, and wastewater treatment.

Roads

Access to the site is provided by the Texas Farm to Market roads bounding the site on the north, east, and west and by U.S. Highway 60, 1.6 kilometers (1 mile) to the south. Interstate Highways 40 and 27 provide access to the interstate highway system. Additionally, 76 kilometers (47 miles) of roads exist within the plant boundaries (Figure 4.3.1.2–1) (Pantex 1996:2.2).

Onsite transportation involves movement of nuclear explosives, nuclear components, HE components and materials, tritium, chemicals, and other hazardous materials, including waste. Nuclear explosives and components are transported to and from Pantex Plant in Safe

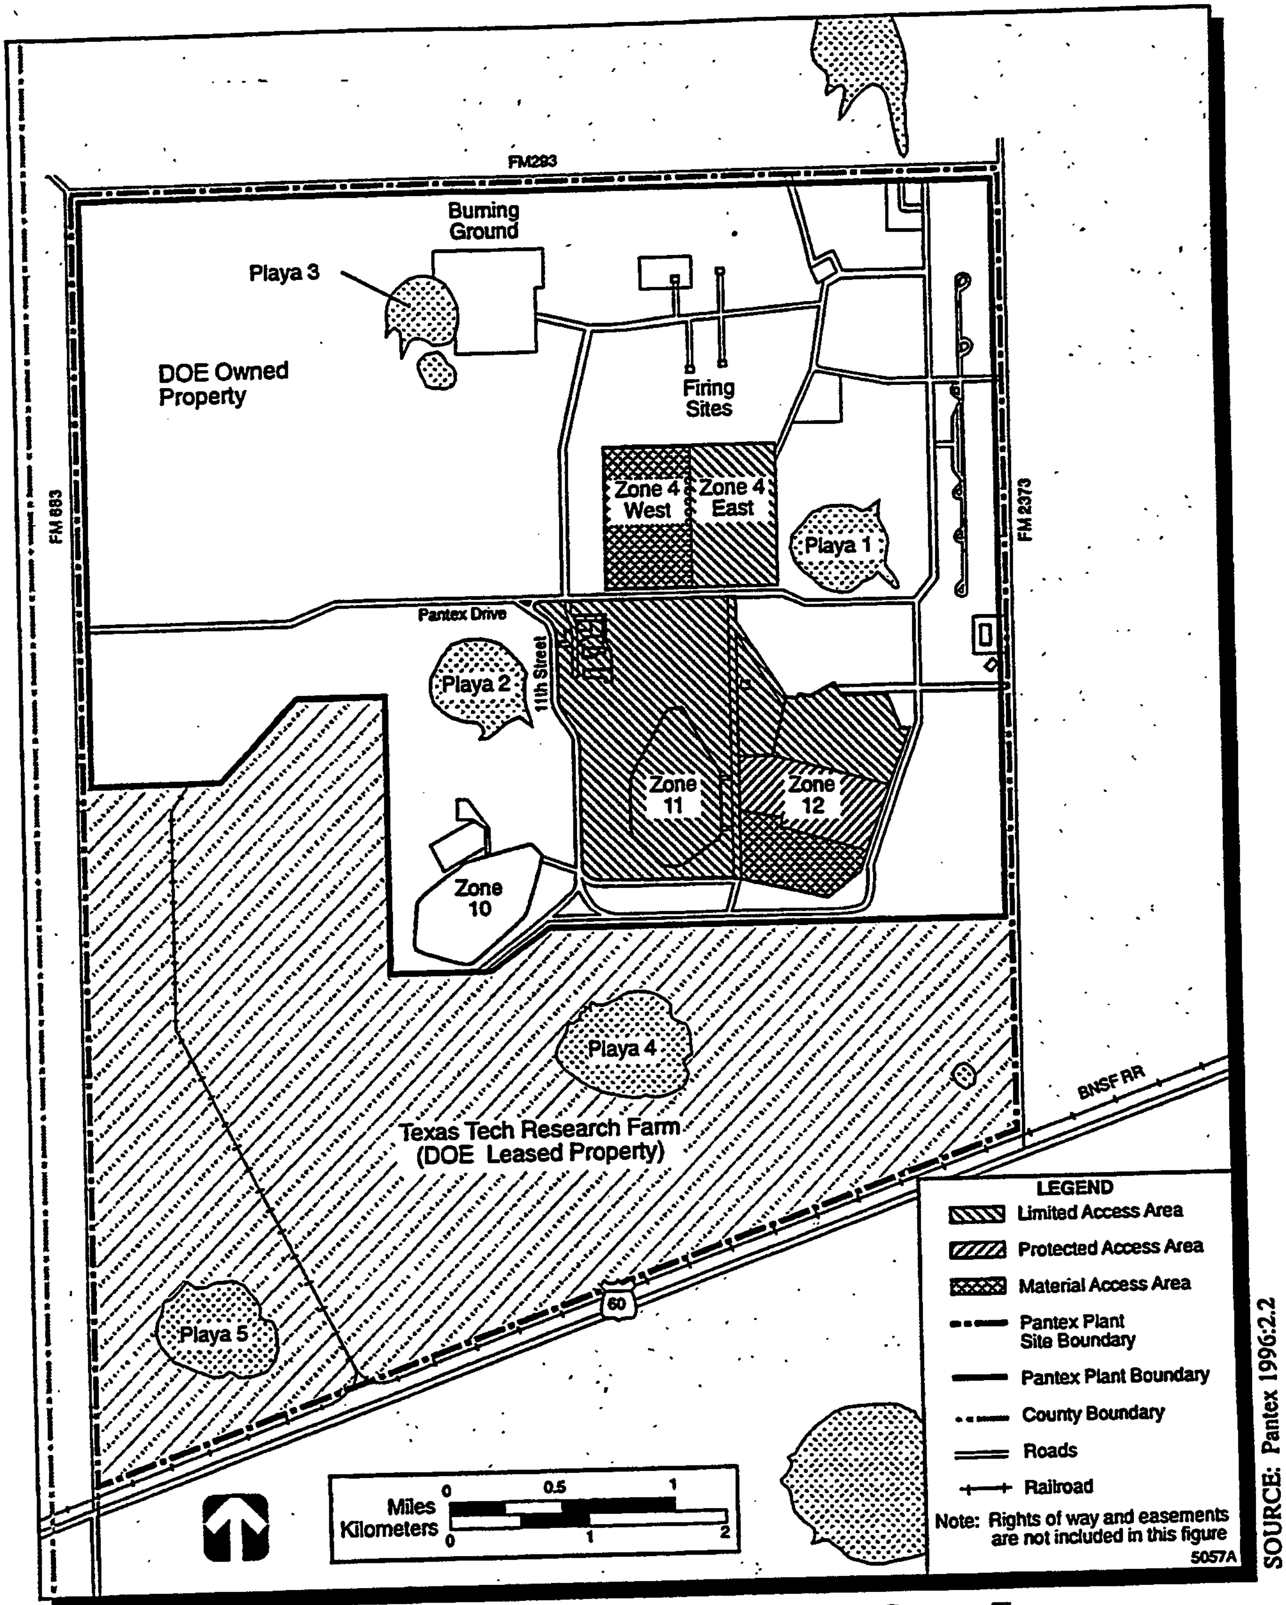

FIGURE 4.3.1.2–1.—*Pantex Plant Site in Carson County, Texas.*

Secure Tractor Trailers by the Transportation Safeguards Division. Onsite transportation is accomplished with hardened trailers and Safe Secure Tractor Trailers as well as other conventional vehicles, which include flatbeds, trailers, vans, trucks, pallet jacks, forklifts, and tow motors. Onsite transport of materials is on paved roadways or enclosed ramps between buildings (Pantex 1996b:3.9). Additional discussion on transportation is provided in section 4.12, Intrasite Transportation, and section 4.16, Intersite Transportation of Nuclear and Hazardous Materials. The Traffic Section of the Packaging and Shipping Department is responsible for the receipt of commercial materials from offsite and for handling materials to be transported out of the plant. Building 16–19, Central Shipping and Receiving, handles commercial materials moving into and out of the plant (Pantex 1996a:5.5).

Railroads

A major rail center for the Burlington Northern Santa Fe Railroad, formerly known as the Atchison, Topeka, and Santa Fe Railroad, is located in Amarillo, Texas. The railroad passes along the southernmost portion of the Texas Tech University (TTU) property at Pantex Plant Site (Pantex 1996:9.5). An operational spur of the railroad extends through the TTU property into Pantex Plant from the southwest (Figure 4.3.1.2–1). Except for occasional bulk concrete shipments, the site railroad track is currently unused (Pantex 1996:9.5).

Airport

The Amarillo International Airport is located approximately 12 kilometers (7.5 miles) southwest of Pantex Plant (Pantex 1996:9.5). The airport is primarily used for commercial aviation and is equipped for international commerce. Pantex Plant leases a small facility at the airport for its own transportation use (Pantex 1996b:2.2). Mason and Hanger Corp. Transportation Department provides the necessary ground transportation.

Utilities

Utilities include steam, electricity, natural gas for fuel, water, and wastewater treatment. Table 4.3.1.2–1 provides current utility usage rates, Pantex Plant system capacity, and offsite utility net capacity for fiscal year (FY) 1994.

Steam. Pantex Plant provides steam for operations and facility heating. Building 16–13,

TABLE 4.3.1.2–1.—*Utility Usage and Capacities at Pantex Plant*

UTILITY[1]	FY 94 USAGE	FY 94 PANTEX PLANT SYSTEM CAPACITY	FY 94 OFFSITE UTILITY EXCESS CAPACITY
Water	836M liters (221M gal)	1,893M liters (500M gal)	5,526M liters (1,460M gal)[2]
Wastewater Treatment	477M liters (126M gal)	829M liters (219M gal)	NA
Steam*	153M kg (337M lb)	596M kg (1,314M lb)	NA

Natural Gas	14.6M m^3 (515M ft^3)	289M m^3 (10,220M ft^3)	Not Reported

*At 150 psi
M = million
NA - Not Applicable
[1] Approximately 1.8 million liters (0.47 million gallons) of petroleum, oil, and lubricants were used at Pantex Plant in 1994. These supplies, obtained from commercial vendors, are readily available and are not discussed further in this EIS.
[2] City of Amarillo offer of treated wastewater (for industrial use) for potential new Pantex Plant missions.
Sources: DOE 1995j:10; DOE 1991b:16

the plant's boilerhouse, contains four boilers and operates on natural gas (Pantex 1996a:App D; DOE 1994f:7). Two of the boilers each have the capacity to produce 22,680 kilograms (50,000 pounds) of steam per hour and the other two have the capacity to produce 11,340 kilograms (25,000 pounds) of steam per hour each (DOE 1995j:9). Steam heat is used where open flames, flammable liquids, and flammable gases pose a potential safety risk.

Electricity. Pantex Plant receives electrical energy from Southwestern Public Service Company. In 1994, the company had a peak of 3,370 megawatts, a system net capability of 4,061 megawatts, and an excess capacity of 691 megawatts or approximately 6 million megawatthours. In 1994, Pantex Plant consumed approximately 84,420 megawatthours of electricity. In 1995, consumption decreased to 80,500 megawatt hours (Pantex 1996:9.1). Two 115-kilovoltampere electrical substations are located onsite with a capacity of 23 megawatts (DOE 1995j:9). There are several generators, both fixed and portable, that provide standby power in the event of an interruption of normal service to critical systems.

Natural Gas. The Texas Panhandle is one of the major oil and gas producing regions in the country with considerable reserves. Natural gas is supplied to Pantex Plant by Anthem Energy (Pantex 1996:9.1). The natural gas is delivered through a 25-centimeter (10-inch) main supply line, which is capable of supplying 289 million cubic meters (10,220 million cubic feet), sufficient capacity for all future plant requirements (DOE 1995j:10). Tank 12–076 holds a reserve of 2,384,550 liters (630,000 gallons) of fuel oil for use, should interruption of the natural gas supply occur (DOE 1994j:12–1). In 1995, consumption decreased by 1.3 million cubic meters (46 million cubic feet) (Pantex 1996:9.1).

Water. Water for Pantex Plant is pumped from the Ogallala aquifer by five production wells located in the northeast portion of the site. A well and two reservoirs were completed in 1994. The plant pumped 836 million liters (221 million gallons) in 1994. Approximately 25 percent of the water pumped at Pantex Plant was used by TTU for irrigation (DOE 1995j:9). Net plant use was 617 million liters (163 million gallons) in 1995 (Pantex 1996:9.3). Water storage reservoirs are integrated into the water distribution system. Total storage capacity exceeds 20 million liters (5.2 million gallons) (DOE 1994f:6). The City of Amarillo has pledged 5,526 million liters per year (1,460 million gallons per year) of treated wastewater as part of potential plant expansion (DOE 1991b).

The Ogallala formation is capable of yielding adequate water for all current and foreseeable uses by Pantex Plant (PC 1994a:1). Additional discussion on the adequacy of groundwater resources is provided in section 4.6.1.2, Groundwater.

Wastewater Treatment. Pantex Plant has two types of wastewater treatment. The primary wastewater treatment operation is located just south of Playa 1. This system consists of a lagoon that is divided into an aerated section and a facultative (settlement and biotreatment) section. The water is disinfected with chlorine and discharged to Playa 1. Other wastewater treatments are operation specific. Examples are presented in Table 4.3.1.2–2. The wastewater treatment system is permitted to allow a daily average discharge of up to 2.5 million liters (0.65 million gallons). In 1995, wastewater volume decreased to 421 million liters (111 million gallons) (Pantex 1996:9.2). The FY 1996 Sewage Treatment Quality Upgrade will improve the plant's sanitary sewage system to assure wastewater standards are maintained (DOE 1995j:8). The upgrade was covered as a categorical exclusion (NEPA LIN–96–003–C) (Pantex 1996b:App D).

TABLE 4.3.1.2–2.—*Examples of Facility Specific Wastewater Treatment Operations*

BUILDING NUMBER	BUILDING DESCRIPTION	PROCESS DESCRIPTION	CAPACITY	DISCHARGE MANAGEMENT
11–29	Photo Lab	Electroplating and evaporation closed loop system for reprocessing rinsewater.	Information not available	Drummed for offsite silver reclamation.
11–50	HE machining	HE-contaminated water, particle settling tank, and carbon filtration system.	57,000 liters (15,000 gallons) per month	Filtered water discharge to Playa 2.
12–43	HE wastewater filtration	HE-contaminated water is passed through a 1-micron particulate filter and a carbon filter.	15,000 liters (4,000 gallons) per month	Filtered water discharge to Playa 1.
12–121	HE machining facility	HE-contaminated water, particle settling tank, and carbon filtration system.	38,000 liters (10,000 gallons) per month	No discharge. Closed loop system. Scheduled operation date is FY 1996.
Waste Water Treatment Facility	Two part lagoon system with chlorinator and pH adjuster	Sanitary wastewater treatment and industrial wastewater treatment.	76 million liters (20 million gallons) per month	Discharge to Playa 1.

Sources: Pantex 1996a:3.3; DOE 1994f:7; PC 1995d:1; Pantex 1996:14.7

Rights of Way and Easements. In addition to property owned by TTU, Burlington Northern Santa Fe Railroad owns parcels located between Highway 60 and TTU property along the Pantex Plant Site boundary. Anthem Energy and Southwestern Public Service Company have utility easements associated with utility operations. Carson County Farm to Market roads exist along the east, west, and north site boundaries (Pantex 1996:2.2; TNRCC 1995a).

4.3.2 Impacts of Proposed Action

4.3.2.1 *Impacts of Continued Operations*

Weapons-Related Activities

This section discusses the impacts on plant facilities and infrastructure from continued operations at Pantex Plant. With regular maintenance and upgrades, all plant facilities and infrastructure would support the continuing activities and missions without any foreseeable capacity difficulties (DOE 1995j:1, 8, 10). A comparison of estimated utility resource needs for continued operations at three weapons levels is provided in Table 4.3.2.1–1 (see section 2.2). Projections indicate that sufficient capacities exist should demand exceed current expectations (DOE 1995j:1, 8, 10).

In 1994, Pantex Plant experienced a workload slowdown due to facility maintenance. Therefore, 1993 usage rates were chosen as the most recent representative year for the 2,000 weapons per year operational level. In addition, the 1993 consumption rates were higher for all utilities with the exception of electricity (DOE 1994f:7; DOE1995j:10). The 1,000 weapons level utility consumption rate is based on

TABLE 4.3.2.1–1.—*Projected Utility Consumption Rates and Capacities*[1]

WEAPONS LEVELS	STEAM Mkg/yr (Mlb/yr)	ELECTRICITY MWh/yr	NATURAL GAS Mm^3/yr (Mft^3/yr)	WATER Mliters/yr (Mgal/yr)	WASTEWATER TREATMENT Mliters/yr (Mgal/yr)
2,000[2]	181 (398)	90,400	16.2 (573)	1011 (267)	647 (171)
1,000[3]	145 (319)	68,200	13.0 (458)	791 (209)	522 (138)
500[4]	73 (160)	57,100	6.5 (229)	689 (182)	439 (116)
System Capacity[5]	596 (1,314)	201,480	289 (10,220)	1,893 (500)	829 (219)

M = million

[1]Table represents total consumption rates of all Pantex Plant operations.
[2]Based on 1993 consumption rates. Rates include a 10% margin to provide a conservative estimate.
[3]Based on 2005 projected consumption rates. Rates include a 10% margin.
[4]Prorated reduction of electricity, water, and wastewater based on straight-line reduction utilizing 2,000 and 1,000 weapons consumption rates. Reduction of steam and natural gas consumption rates for the 500 weapons level are based on the use of an existing, auxiliary, 25,000 lb rated boiler instead of the 50,000 lb rated boiler. Rates include a 10% margin.
[5]Capacity based on *FY1995 Pantex Plant Site Development Plan* (DOE 1995j).
Sources: DOE 1994f:7; DOE 1995j:10

currently planned needs for FY 2005 (plus 10 percent) (DOE 1995j:10; Pantex 1996b:App A). The 500 weapons level consumption rates were prorated using straight-line reductions based on 2,000 weapons and 1,000 weapons level scenarios.

Data in Table 4.3.2.1–1 show a proportional straight-line decrease in utility consumption rates as the level of activities decreases from the 2,000 weapons level to the 500 weapons level. For example, electricity consumption ranges from 90,400 to 57,200 megawatthours per year; inversely, the system capacity remaining would increase from 111,280 to 144,480 megawatthours per year.

Two exceptions to proportional decrease in utility consumption exist for the 500 weapons level. Steam and natural gas consumption during the 500 weapons level scenario are reduced by 50 percent instead of a 26 percent straight-line reduction in steam and 15 percent straight-line reduction in natural gas. This is because an existing smaller natural gas boiler would be utilized in the 500 weapons level scenario.

Pit Storage Activities

Currently, all existing Modified Richmond and SAC magazines have the necessary utility support and material access control, and are supported by existing plant facilities and infrastructure. SAC magazines are used to stage nuclear assemblies and nuclear components, and require similar levels of infrastructure support as the Modified Richmond magazines (Pantex 1996a:3.2). No new construction of plutonium storage magazines is required as a result of increasing interim storage to 20,000 pits. Therefore, current levels of infrastructure and utility support are expected to continue (DOE 1994w:6-1).

Pit Repackaging Operations

The repackaging of pits from AL-R8 containers into AT-400A containers is expected to begin in late 1996 or early 1997. This operation would be performed in existing bays within Zone 12 and as such will not require new construction nor extensive facility modifications. Utility usage for this operation would be minimal and well within the total usage described for the Proposed Action. The pit repackaging operations would not result in any impacts to land use, geology and soils, water resources, air resources, acoustics, biotics, cultural resources, socioeconomics, or environmental justice and, therefore, are not discussed in those sections. The intrasite transportation impacts have already taken the impacts for pit repackaging into account. The pit repackaging would involve waste management and would result in additional worker radiological exposures. These impacts are discussed in sections 4.13 and 4.14.

Environmental Restoration Activities

Environmental restoration activities are designed to maintain or improve the environment. Since 1989, environmental restoration activities have been assessing inactive sites through temporary field operations that, for the most part, require minimal usage of plant utilities and plant facilities (Pantex 1996:15.0). Heavy equipment such as drill rigs operate with self-sufficient power supplies while field sampling typically uses manual labor or portable power supplies. Portable toilets, fire protection, potable and nonpotable water, and temporary power and lighting are typically required and provided by the contractor (Pantex 1992:4-1, 9-1, Appendix B). By the year 2000, activities are expected to be reduced to monitoring and groundwater and soils management, such as bioremediation of soils and perched zone groundwater remediation. No new facilities would be needed for the environmental restoration activities.

Recycling restoration wastewater is currently under study. After 1999, 65,942 liters (17,420 gallons) could be reclaimed annually (Pantex 1996:14.5).

Waste Management Activities

Waste management activities utility consumption has been accounted for in the facility-wide totals presented in Table 4.3.2.1–1. Impacts of infrastructure support (closures, treatment, storage, and disposal) are discussed in section 4.13, Waste Management.

4.3.2.2 *Impacts of New Facility Construction and Upgrades*

A comparison of site infrastructure and facility resource needs for the proposed facility construction and upgrades is provided in Table 4.3.2.2–1. As noted in this table, sufficient utility capacity exists to handle the demand from these facilities. The Gas Analysis Laboratory, the Materials Compatibility Assurance Facility, the Nondestructive Evaluation Facility, and the Metrology and Health Physics Calibration and Acceptance Facility represent an operational consolidation effort that would not increase utility usage.

The Pit Reuse Facility represents a potential 0.18 percent increase in annual site utility consumption based on the addition of 7 new employees to a 3,800-employee baseline for all utilities except industrial water and steam. No industrial water or steam heat is needed to support the Pit Reuse Facility. The utility consumption increases would be minimal since the Pit Reuse Facility operations would occupy an existing facility (DOE 1995j:4, 5).

The Hazardous Waste Treatment and Processing Facility (HWTPF) project would modernize, consolidate, and expand existing waste operations capabilities (Battelle 1995:1). This project is expected to increase infrastructure requirements by 0.13 percent based on the addition of five new employees. Industrial water usage is estimated to increase by 3.4 million liters (0.9 million gallons) a year or 0.3 percent of 920 million liters (243 million gallons) used in 1993. Discharges of industrial

[1]These facilities are not anticipated to utilize natural gas.

M = Million

Assumptions:

- Number of employees are based on Conceptual Design Report (CDR) information.
- Domestic water use is based on current use per employee.
- Industrial water use is based on current use per employee for the HWTPF, Nondestructive Evaluation Facility, Materials Compatibility Assurance Facility, and Metrology and Health Physics Calibration and Acceptance Facility. No water is expected to be used by Pit Packaging, Pit Reuse, and Gas Analysis Lab.
- Domestic wastewater generated is assumed to equal domestic water use.
- Industrial wastewater generated is assumed to equal 85 percent industrial water use.
- Electricity use is based on current use per employee.
- Natural gas for heating is taken from CDRs.
- Steam requirements are taken from CDRs.
- 0.125 gallon of water is needed to produce one pound of steam.
- 0.96 ft^3 of natural gas is needed to produce one pound of steam.

Source: PC 1995g

water are expected to increase by 2.9 million liters (0.77 million gallons) per year.

4.3.2.3 *Summary of Impacts*

Pantex Plant facilities and infrastructure have adequate capacities for all scenarios covered in the Proposed Action (DOE 1995j:1, 8, 10). As shown in Table 4.3.2.1–1, the largest demand is expected from the 2,000 weapons level. Expected electricity demand, 90,400 megawatthours, represents only 45 percent of the plant's capacity, with an additional 111,080-megawatthour capability. Future water consumption is expected to utilize only 53 percent of capacity with 882 million liters (233 million gallons) per year net reserve. The wastewater treatment facility is predicted to operate at 78 percent capacity or 647 million liters (171 million gallons). The Boilerhouse (Building 16–13) steam supply system is anticipated to function at only 30 percent capacity or 181 million kilograms (398 million pounds) per year. The natural gas needs of the plant utilize only 6 percent of the natural gas main supply line design capacity.

4.3.3 Impacts of No Action Alternative

Weapons-Related Activities

The demands on infrastructure and utilities would remain the same under the No Action Alternative, until the interim storage of pits reached 12,000. At that point weapons disassembly operations would cease. Even after the disassembly operations cease, it is assumed for purposes of analysis that the weapons levels would remain at 2,000, 1,000, or 500, as described for the Proposed Action, because other weapons operations would continue. The infrastructure impacts due to the No Action Alternative would therefore be expected to remain similar to those described for the Proposed Action except that none of the proposed new projects would be built under the No Action Alternative.

Pit Storage Activities

No impacts on plant facilities or infrastructure directly supporting pit storage would occur. Pit storage support operations (e.g., security) are currently in place (DOE 1994w:6-1).

Environmental Restoration Activities

Environmental restoration activities are independent of the No Action Alternative since these activities would continue even if the plant activities are reduced. Therefore, the impacts would be the same as discussed for the Proposed Action.

Waste Management Activities

With the weapons levels remaining at the levels described for the Proposed Action, the waste management activities would not change substantially from those described for the Proposed Action. Further discussion of treatment, storage, and disposal impacts is provided in section 4.13, Waste Management.

4.3.4 Impacts of Pit Storage Relocation Alternative

4.3.4.1 *Impacts of Relocating 20,000 Pits*

Under the scenario of relocating 20,000 pits to other site(s), overall plant impacts would be similar to those identified for the Proposed Action. Only 18 magazines are currently used for pit storage. If all the pits are transferred elsewhere, these 18 magazines would become available for other uses. The 18 Modified Richmond magazines total less than 1,800 square meters (19,000 square feet) of nearly 0.23 million square meters (2.5 million square feet) or 0.8 percent of the total floor space at Pantex Plant. Zone 4 operations include weapon staging and special nuclear material staging. These storage operations, like pit storage, require access control, security, and electricity. Therefore, no reduction in infrastructure support or utility usage is anticipated as a result of relocating 20,000 pits.

4.3.4.2 *Impacts of Relocating 8,000 Pits*

Under the scenario of relocating 8,000 pits, overall infrastructure impacts would remain similar to those described for the Proposed Action. The storage of 12,000 pits would be satisfied from existing magazines at the plant site; no new building construction would be required, other than what is currently required. Increases in infrastructure requirements would not occur.

4.3.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.3.5.1 *Impacts of Alternatives in the Waste Management Draft Programmatic Environmental Impact Statement*

The WM PEIS Decentralized Alternative, which would generate the greatest impacts, would increase the electrical consumption by 3.33 megawatts. The existing total capacities of Pantex Plant and the local area utility system are adequate to handle this increase. Wastewater generation would increase by 43,660 liters (11,535 gallons) per day, The existing total capacity of Pantex Plant is adequate to handle this increase. Water usage would increase by 96,200 liters (25,416 gallons) per day. The existing capacity is adequate for this increase.

4.3.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur, and there would be no construction impacts. Due to the reduced workload expected, future infrastructure impacts are expected to be less than current impacts. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Facilities would be consolidated and impacts would be expected to be less than current impacts. Under the relocation alternative, the facilities would undergo decontamination and decommissioning (DOE 1996b).

4.3.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading existing plutonium storage facilities in Zone 12, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative since it would have the greatest impacts.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant.

For site infrastructure, small increases in available oil resources would be required. During operations, all site infrastructure resource requirements would be less than those already available at the site.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide (MOX) fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

For disposition only, construction and operation would require 24,333 and 1,154,000 megawatthours per year of electricity, respectively. Also, construction and operation would require 1,356,200 liters (354,100 gallons) per year and 844,750 liters (218,473 gallons) per year of oil, respectively. Operations would require 8,976,000 cubic meters (237 million cubic feet) per year of natural gas. Transmission lines would be constructed and upgraded for the increased and redistributed electrical load. Additional primary and secondary access roads as well as railroad right-of-way would be needed and are available. Fuel requirements would exceed current site availability, but can be accommodated through normal contractual means (DOE 1996a:chapter 4).

4.3.6 Potential Mitigation Measures

Since adequate capacities exist for infrastructure as described above at any level of the three weapons activity levels analyzed, no mitigations are currently required or justified under the Proposed Action, No Action, and Pit Storage Relocation Alternatives.

4.4 LAND RESOURCES

4.4.1 Affected Environment

This section discusses land use issues at Pantex Plant and in the surrounding 16-kilometer (10-mile) and 80-kilometer (50-mile) radius areas, hereafter called the Regions of Influence (ROIs). Particular attention is given to the 16-kilometer (10-mile) ROI in response to extensive public comments on agricultural issues in the areas nearest to Pantex Plant Site. The land use discussion includes agricultural, commercial, residential, industrial, institutional, and public lands. The following subsections characterize the existing land use within and adjacent to Pantex Plant, describe regional and site land use plans and policies, identify any access areas restricted to the public due to Pantex Plant operations, address prime and unique farmland, and identify areas of special interest, such as parks and recreational areas, within the ROIs. See Figure 1.2–1 for major features within the land resources ROIs.

4.4.1.1 *Pantex Plant Land Use*

Of the approximately 6,475-hectare (16,000-acre) site, DOE owns approximately 3,683 hectares (9,100 acres) at Pantex Plant and 436 hectares (1,077 acres) of a detached piece of property called Pantex Lake, approximately 4 kilometers (2.5 miles) northeast of the main plant site. Adjacent to the DOE-owned land, approximately 2,347 hectares (5,800 acres) are leased from Texas Tech University (TTU). Pantex Plant activities occur on approximately 809 hectares (2,000 acres) of the 6,475-hectare (16,000-acre) site; the remaining lands are used primarily for safety and security purposes (Figure 1.2–2). As of April 1995, approximately 2,596 hectares (6,421 acres) of the DOE-owned land were being used by TTU for agricultural purposes through a service agreement. The DOE-owned acreage used for agricultural purposes by TTU is variable and subject to periodic changes. Approximately 23 percent of Pantex Plant land, including that leased from TTU, has been developed for industrial use. There are 76 kilometers (47 miles) of roads located within the Pantex Plant boundaries, and a spur of the Burlington Northern Santa Fe (formerly Atchison, Topeka and Santa Fe) Railroad extends onto the site (Pantex 1996:2.2, DOE 1996e:81).

Historically, Pantex Plant Site was divided into functional areas referred to as "Zones". The only current functional areas that retain this designation are Zone 12, which contains fabrication, assembly/disassembly, technical areas, and administrative support areas; Zone 11, which contains the high explosives development area; Zone 10, which serves as an excess property storage site; and Zone 4, which includes the weapons/high explosives magazines and interim pit storage area (see Figure 4.3.1.2–1).

Currently, the following four Security Control Areas occur over both DOE-owned and leased land: Protected Property Area, Limited Area, Pantex Plant Protected Area, and Material Access Area. The Property Protection Area is the entire 3,683 hectares (9,100 acres) of DOE land and the 2,347 hectares (5,800 acres) of leased TTU land, exclusive of the Pantex Lake area, and is commonly referred to as the "Pantex Plant Site." The remaining three areas are shown in Figure 4.3.1.2–1 (Pantex 1996:2.2).

Pantex Plant contains several soil types that, according to the Natural Resources Conservation Service (NRCS [formerly, Soil Conservation Service]), have been classified as prime farmland. Prime farmland, unique farmland, and farmland of Statewide or local importance are identified by the NRCS. Prime farmland, as defined in 7 CFR 657, contains the best combination of physical and chemical characteristics for producing crops. This includes cropland, pastureland, rangeland, and forest land. Prime farmlands must have a dependable and adequate water supply from precipitation or irrigation; must be within a favorable climatic zone; have an adequate growing season; a fairly rockless location; and contain an acceptable acidity, alkalinity, and salt and sodium content. These lands usually are protected from flooding and are only moderately erodable with temporary water saturation (Pantex 1996:7.1). These soil types cover the majority of Pantex Plant. The soil types on Pantex Plant are discussed in section 4.5, Geology and Soils.

The *Farmland Protection Policy Act* (FPPA) (7 U.S.C. §§4201) and the regulations promulgated as a result of FPPA (7 CFR 658) require agencies to make FPPA evaluations part of the NEPA process. The purpose of FPPA is to reduce the conversion of farmland to nonagricultural uses by Federal projects and programs. The Act requires that Federal agencies comply to the fullest extent possible with State and local government policies to preserve farmland. Specifically, FPPA advises that evaluations and analyses of prospective farmland conversion impacts be made early in the planning process before a site or design is selected. Pantex Plant is exempt from FPPA under section 1540(c)(4) (7 U.S.C. §§4201) since the acquisition of Pantex Plant property occurred prior to FPPA's effective date of June 22, 1982.

Pantex lies in the Llano Estacado or Staked Plains portion of the Southern Great Plains. Pantex Plant has a relatively flat topography and is characterized by rolling grassy plains and numerous natural playa basins. This part of the Panhandle is characterized as a semi-arid farming and ranching area. Pantex Plant is surrounded by agricultural land, with several significant industrial facilities located nearby (DOE 1996e:82-83).

Pantex Plant Farmland

A large portion of Pantex Plant is used for grazing cattle and dryland crop production of wheat and sorghum. Cropland is planted under dryland conditions in a winter-wheat/grain-sorghum/fallow sequence that produces two crops every three years within the Pantex Plant boundaries. Grain sorghum and forage sorghum are grown under limited irrigation (on TTU land only) and/or dryland conditions because they are drought resistant. During periods of inadequate rainfall, the TTU property can be irrigated with water from the Ogallala aquifer. In 1994, the plant provided 133 million liters (35 million gallons) of water from the Ogallala well field at Pantex Plant for TTU's onsite use for irrigation and personal consumption (there are only two residences on TTU, so personal usage was limited). About half of the crops grown in the local area are strictly dryland because of the high cost of pumping water from the Ogallala aquifer.

Agricultural chemicals are applied to the Pantex Plant crops in accordance with Pantex Plant Standard 7030 and the Land-Applied Chemical Use Plan. As with other areas in the region, these chemicals have the potential of being transported to the playas through storm water runoff or drift. The chemicals used prior to February 1994 consist of herbicides and insecticides, and their application rates are listed in Table 4.4.1.1–1 (Pantex 1996:10.2). Pesticide use at Pantex Plant is reviewed annually. Table 4.4.1.1–2 shows the pesticides allowed for use during the 1996-1997 growing season. This list is updated annually based on current issues (MH 1996c; PC 1996o).

The TTU property leased to the plant also contains Conservation Reserve Program (CRP) lands which are considered a subset of cropland by the NRCS. CRP is a Federally funded program that allows land owners to place otherwise cultivated cropland in a dormant state for 10 years in return for an annual payment by the government. A grass cover must be planted in the fields to prevent erosion. This program is administered by the Agricultural Stabilization and Conservation Service (Pantex 1996:10.2).

Livestock Grazed on Pantex Plant

A large portion of the plant is used for grazing cattle. Stocker calves, which are calves that have been weaned and turned out to pasture, are the most typical livestock operation onsite. Cattle are moved to different areas according to the availability of forage. Grazing is allowed on the uplands and in Playa 4 and Pantex Lake.

Stocking rates at the plant are one animal unit per 2 to 4 hectares (5 to 10 acres) of rangeland, with calves being grazed from November to March on winter wheat (when the weather is conducive to forage production) (Pantex 1996:10.2).

Future Land Use at Pantex Plant

Future land and facility use at Pantex Plant will be managed by DOE through the Land and Facility Use Planning process (DOE P 430.1). This guidance for future site development and reuse is based on the shared long-term goals and objectives of Pantex Plant and stakeholders. The planning process allows for the holistic management of the Department's land and facilities through an integration of missions, ecology, economics, and regional cultural and social factors (DOE 1996h).

Future recommendations at the Plant combine agricultural, industrial/commercial, and open space uses. This includes resource management and livestock grazing. Land resources are expected to remain constant at the plant, with continued leasing of TTU land for security and safety reasons. Pantex Plant has a Site Development Plan that represents the plant upon completion of the projects outlined in the Technical Site Information Five Year Plan (Pantex 1996:10.5, DOE 1995j:8) (Figure 4.4.1.1–1).

Management plans for the playas and surrounding areas are being implemented as a best management plan to protect cultural and natural resources. This will ensure surface water quality and facilitate compliance with quality requirements for air, water, and natural resources. The plan will also protect archaeological sites and ecological resources (DOE 1996e:81; Pantex 1996:10.5).

Four playas (including Pantex Lake) located on the DOE-owned portion of the site have been designated as wetlands. These wetland areas are of particular concern and are subject to protection under various statutes, regulations, Executive orders and DOE orders. The Interim Guidance Document for Pantex Plant Playas and the Management Plan for Playa 2 Management Unit: Phase One provide additional oversight for the protection of playas. Management plans for Playas 1, 2, and 3 on DOE-owned land have been implemented. These plans will protect the playas by controlling intensive grazing and the plowing of sensitive areas. The following actions are proposed for the approximate 0.4 kilometer (0.25 mile) radius buffer zone surrounding each playa on DOE-owned land:

- Cattle are excluded from Playa Management Units 1, 2, and 3.
- The farmed area within the buffer zone will be planted in native grasses. The entire ecosystem of the playa, both the wetlands and the prairie, will be inventoried, assessed, and allowed to recover from agricultural disturbances (Pantex 1996:10.5).

4.4.1.2 *Land Use in the Region of Influence*

This section discusses land use within a 16-kilometer (10-mile) and an 80-kilometer (50-mile) radius of Pantex Plant. Urban land use in the Pantex Plant ROIs is dominated by the Amarillo Metropolitan Area, focusing on the City of Amarillo. Other towns in the ROIs are Borger, Claude, Canyon, Pampa, Panhandle, and White Deer, each with populations under 25,000. The ROIs are transected by Interstate

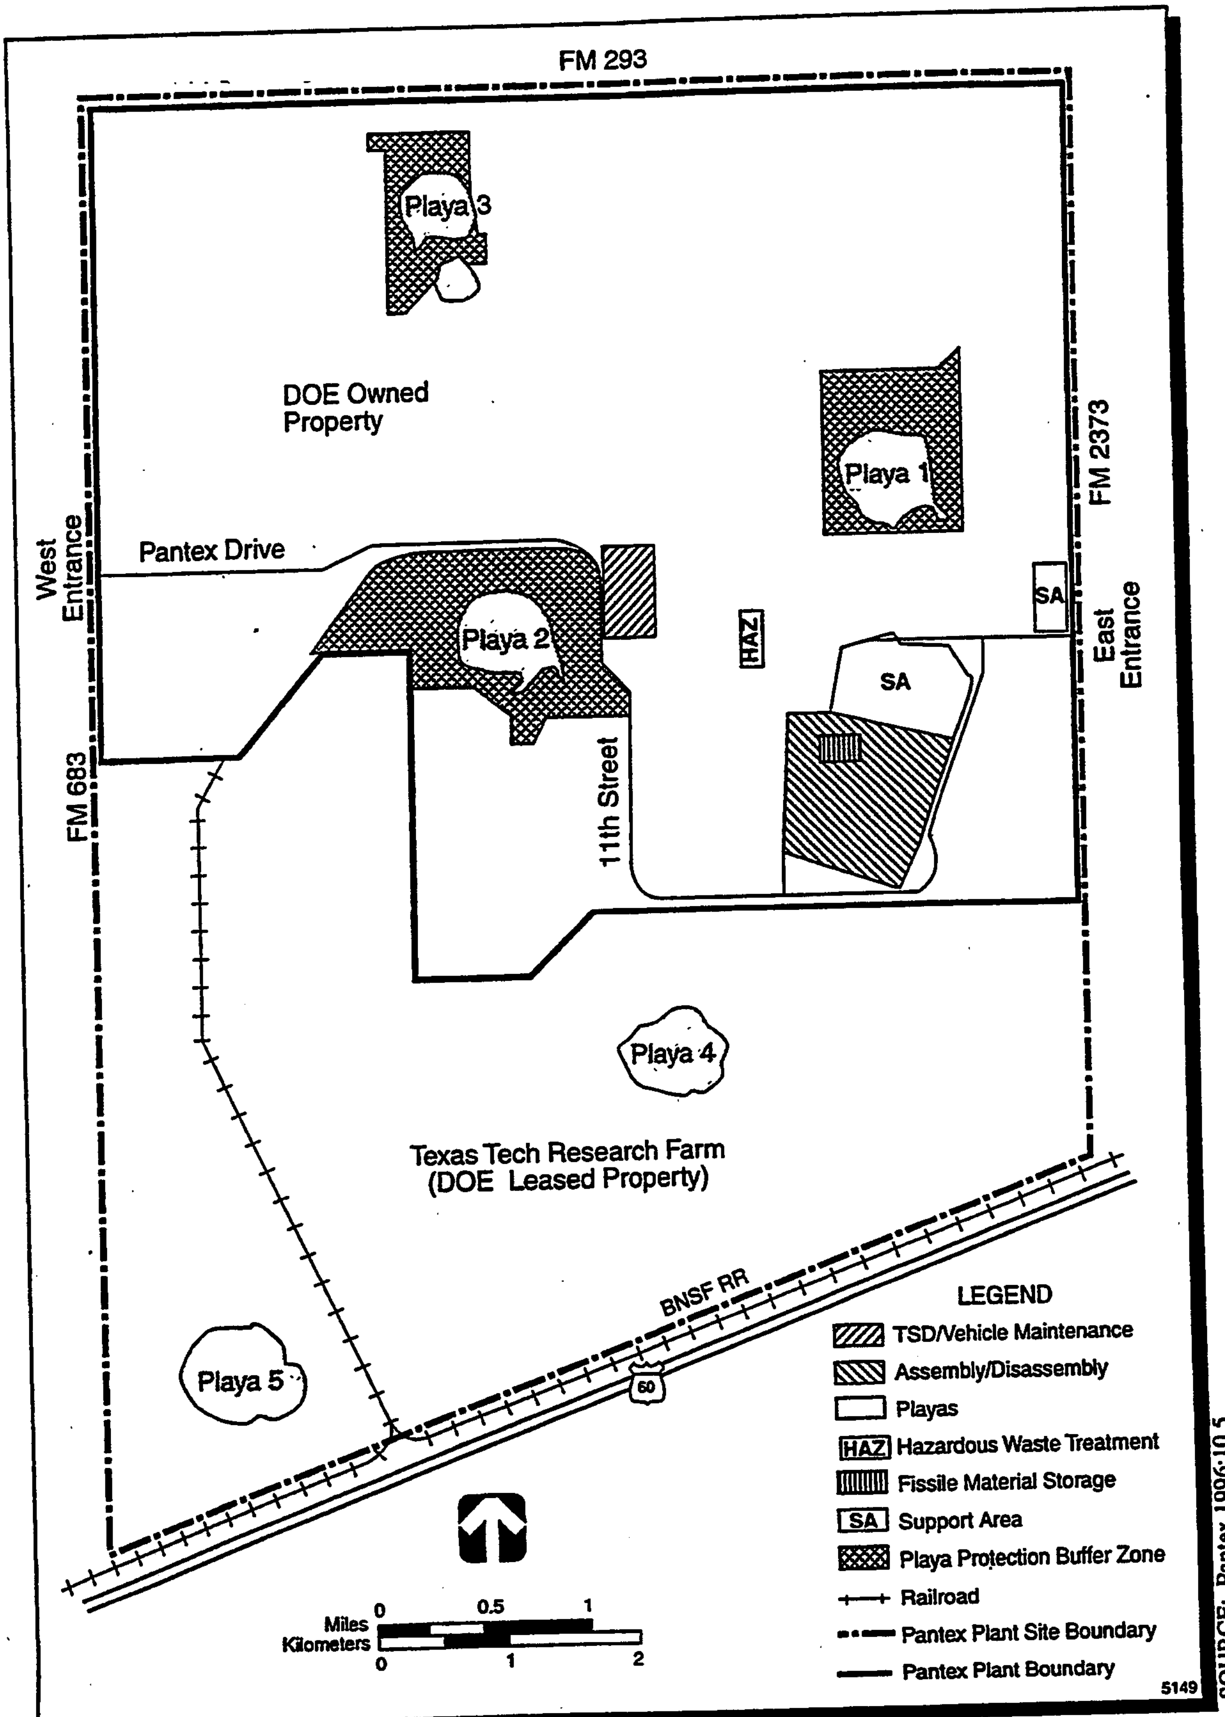

FIGURE 4.4.1.1–1.—*Future Land Usage Projection of Pantex Plant Site Development Plan.*

Highways 40 and 27; U.S. Highways 60, 87, and 287; State Highways 136, 207, and 217; and numerous Farm-to-Market roads.

Current Land Use Within a 16-Kilometer Radius of Pantex Plant

Residences are located throughout the 16-kilometer (10-mile) radius of the plant, with nearly half located to the east, in the town of Panhandle. Another major concentration of residences is located southwest of the plant, in Highland Park Village, which was once associated with the Amarillo Air Force Base. Washburn, located to the south of the Plant, has a somewhat smaller concentration of residences. Within this radius commercial land use is limited to the communities of Panhandle and Washburn, and the Amarillo International Airport. The Iowa Beef Processors Inc., Amarillo Plant, located 10.4 kilometers (6.4 miles) southwest of the center of Pantex Plant, and Fraser Industries, Inc., located 13.3 kilometers (8.3 miles) southwest of the center of the plant make up the area's industrial facilities. Two grain elevators are also located within this area, one to the northeast, the other to the east-southeast of the plant (Pantex 1996:10.3).

Farmland in the 16-Kilometer Region of Influence

Most of the land surrounding the plant is dryland or irrigated farmland, with farms averaging about 518 hectares (1,280 acres) in size. These farms primarily produce corn, wheat, and sorghum.

Data on 729 gardens within the 16-kilometer (10-mile) radius of the plant were obtained in 1995. These gardens usually contained tomatoes, pumpkins, green onions, peas, corn, okra, squash, cucumbers, leafy vegetables, root crops, and fruit trees. Whether these crops were sold at market was not determined. The largest garden in this area, 54.7 hectares (135 acres), belongs to the William P. Clements correctional facility and is maintained for produce for the inmates of that facility (Pantex 1996:10.2).

Livestock in the 16-Kilometer Region of Influence

The herd size of beef cattle (expressed as cow-calf pairs/beef cattle) in the 16-kilometer (10-mile) radius of the plant averages 500 animals or less. As of January 1, 1994 the livestock inventory for Potter and Carson counties was as follows:

- Potter—43,000/5,000.
- Carson—63,000/5,000.

In a 1995 household survey, only two residents in this area indicated that they had dairy cattle. One individual reported 2,000 cows that were under a year old and not yet producing milk. These cattle were being reared as replacement heifers for sale to other dairy farms. The other resident had six animals that were maintained for personal use (Pantex 1966:10.2). Tables 4.4.1.2–1 and 4.4.1.2–2 further discuss the livestock located within a 16-kilometer (10-mile) radius of Pantex Plant.

Land Resources Within an 80-Kilometer (50-Mile) Radius of Pantex Plant

Currently, land within the 80-kilometer (50-mile) radius area is predominately used for agriculture. The largest agricultural area is rangeland that is located along the Canadian River drainage to the north of Pantex and to the south along the tributary drainage of the Red River.

The second largest land use category is irrigated and dryland crops. Commercial, residential, industrial, institutional and public lands comprise a small part of the total land use within this. These areas are predominantly associated with the towns and cities of the region. The City of Amarillo, predominantly a residential area, is the largest urban area in the region. Other major industrial and commercial land areas are

associated with the towns of Canyon, Pampa, Borger and Dumas.

Industrial land use within the 80-kilometer (50-mile) ROI includes Pantex Plant and over 60 industrial facilities involved primarily with beef packing, chemical plants, and construction materials manufacturing. Amarillo and the area surrounding it support approximately 20 of these facilities, and the Pampa and Borger areas have 13 facilities. There are 29 grain elevators in the 80-kilometer (50-mile) area (see Table 4.4.1.2–3) (Pantex 1996:10.1, 10.3).

Crops and Rangeland

Agriculture is an important industry throughout the ROI. The settlement pattern associated with agriculture in the Texas Panhandle is characterized by a highly dispersed residential distribution. Farmsteads are usually located along major secondary roadways throughout the rural parts of this area. Information on the predominant crops in the 80-kilometer (50-mile) ROI surrounding Pantex Plant was determined using information from the Texas Natural Resource Information System and crop data from TNRCC. The major crops in the ROI include corn, wheat, sorghum, cotton, soybeans, peanuts, sunflowers, and sugar beets (Table 4.4.1.2–4).

Crop patterns vary by year and by season, utilizing both dryland or irrigation methods. When irrigated, the water is usually pumped

from the Ogallala aquifer or from the playas (Pantex 1996:10.1, 10.2).

Livestock

Table 4.4.1.2–5 shows the beef cattle feedlots, open range cattle, and dairy operations located within a 80-kilometer (50-mile) radius of the plant. The beef cattle industry in the Texas Panhandle has four distinct aspects that are affected by precipitation levels and the local and future market prices for beef. These are:

- Cow-calf operations on open range.
- Grazing of stockers on pasture.
- Feedlot operations.
- Slaughter and meat-packaging operations.

The number of calves grazed on wheat pastures during the winter and spring varies significantly based on how the weather affects wheat growth. The number of cow-calf pairs/beef cows recorded in the January 1, 1994 inventory of Texas Agricultural Statistics for the counties within the 80-kilometer (50-mile) area were as follows: Armstrong, 63,000/5,000; Briscoe, 17,000/9,000; Carson, 73,000/9,000; Castro, 283,000/11,000; Deaf Smith, 681,000/15,000; Gray, 114,000/9,000; Hansford, 251,000/8,000; Hartley, 213,000/6,000; Hutchinson, 40,000/7,000; Moore, 189,000/6,000; Oldham, 79,000/12,000; Potter, 51,000/6,000; Randall, 170,000/9,000; Roberts, 35,000/9,000; Sherman,

159,000/4,000; and Swisher, 212,000/9,000 (Pantex 1996:10.2).

Table 4.4.1.2–6 shows the 20 cattle feedlots located within the ROI by sector. Local market prices, feed yard capacity, transportation costs, available feed, and the condition of the cattle, govern the number of animals in a feedlot at any time. Four dairies are located in the area (see Table 4.4.1.2–7), and the Plains Creamery in Amarillo is the only creamery in the vicinity.

The slaughter and processing end of the livestock cycle is governed by market costs. This being the case, the carcasses of these Panhandle cattle may be shipped to another state for cutting and packaging. It is estimated that over 25 percent of the beef cattle processed in these large operations are consumed by out of state consumers, and that little of this beef returns to the Amarillo area. Conversely, approximately 95 percent of the cattle processed by the small meat processors in the area are consumed locally (Pantex 1996:10.2).

Future Land Use Within the 80-Kilometer (50-mile) Region of Influence

No future land use has been projected by the City of Amarillo or county planning agencies for the majority of land within the 80-kilometer (50-mile) ROI. Based on the City of Amarillo's Comprehensive Plan, the population is expected to grow to 195,000 by the year 2005. This will require approximately 2,429 hectares (6,000 acres) of new land, two-thirds of which will be located within the existing city limits (Pantex 1996:10.5; City 1989:6-20, 6-22).

Recreational Resources

A number of recreation areas and parks are present within the land resources ROI, including

Lake Meredith National Recreation Area, Palo Duro Canyon State Park, Buffalo Lake National Wildlife Refuge, Alibates Flint Quarries National Monument, Greenbelt Reservoir, Lake McClellan National Grasslands, and the city parks of Amarillo and Canyon. More information on these areas of special interest may be found in the Land Use chapter of the Pantex Plant *Environmental Information Document* (Pantex 1996:10.6).

Other Land Resources

All other land uses are classified as commercial, residential, industrial, institutional, and public lands and comprise only a small part of the total land uses within the ROI. The ROI has 134 primary and secondary schools as well as 6 institutions for higher learning. Amarillo is the medical center for the panhandle region, with 5 hospitals. Additional hospitals are located in the towns of Canyon, Borger, Pampa, and Dumas. The nine-county region also has a total of 27 nursing/convalescent homes that care for the needs of the elderly (Pantex 1996:10.4).

Pantex Plant maintains a full-time capability to respond to any medical, fire, or hazardous materials emergencies that may occur at the plant. Fire departments with full-time and/or volunteer staff are located in the City of Amarillo, and the towns of Borger, Canyon, Channing, Claude, Pampa, Panhandle, Stinnett, Vega, and White Deer.

Commercial areas in the Amarillo metropolitan area are located in the central business district, at major shopping centers and malls, and along major streets in the form of strip development.

4.4.2 Impacts of Proposed Action

4.4.2.1 *Impacts of Continued Operations*

Weapons-Related Activities

Impacts to land resources at Pantex Plant as a result of the weapons-related activities planned under the Proposed Action are expected to be limited. Operations under the Proposed Action would not appreciably change current land use at Pantex Plant; therefore land resources would not be adversely affected.

Pit Storage Activities

The storage of 20,000 pits planned under the Proposed Action would use existing storage space in Zone 4. Therefore, no land resources, including agriculture, floodplains, and wetlands, would be affected.

Environmental Restoration Activities

Environmental restoration activities will have a long-term impact on land resources. Some remediation activities (e.g., soil removal) may temporarily restrict the use of land resources but the cleaned-up lands would then be available for other uses.

Waste Management Activities

Waste management activities would not use any additional land under this alternative than is currently used. Impacts are therefore considered negligible.

4.4.2.2 *Impacts of New Facility Construction and Upgrades*

Under the Proposed Action, six facilities are to be constructed or modified in or adjacent to Zones 11 and 12, in areas that have been previously disturbed. The area required for these facilities is provided in Table 4.4.2.2–1. The total area required for these projects amounts to 15,902 square meters (171,160 square feet), which is 0.04 percent of the DOE-owned property on Pantex Plant Site. Impacts on land resources are therefore considered negligible.

4.4.2.3 *Summary of Impacts*

Continued operations at Pantex Plant would not disturb any new lands; land disturbed by the construction of the new facilities under the Proposed Action amounts to 0.04 percent of the DOE-owned property on Pantex Plant Site. Additional impacts to agriculture and industry in the ROI are not anticipated. Impacts on land resources are therefore considered negligible.

4.4.3 Impacts of the No Action Alternative

Impacts to land resources at Pantex Plant as a result of continued operations, environmental restoration, and waste management under the No Action Alternative are expected to be similar

TABLE 4.4.2.2–1.—*Proposed Facility Construction and Modification for the Proposed Action*

PROPOSED CONSTRUCTION/ MODIFICATION	LOCATION	REQUIRED AREA m^2 (ft^2)
Hazardous Waste Treatment and Processing Facility	Adjacent to Zones 11 and 12	2,648 (28,500)
Pit Reuse Facility	Zone 12	494 (5,314)
Gas Analysis Laboratory	Adjacent to Zone 11	2,537 (27,304)
Materials Compatibility Assurance Facility	Adjacent to Zone 11	2,015 (21,690)
Nondestructive Evaluation Facility	Zone 12	3,734 (40,196)
Metrology and Health Physics Calibration and Acceptance Facility	Zone 12	4,474 (48,156)

Source: PC 1995g

to or less than those identified for the Proposed Action. Under the No Action Alternative discussed in section 3.1.2, no new facilities would be constructed. Activities associated with the No Action Alternative would not create any significant impact to land resources.

4.4.4 Impacts of Pit Storage Relocation Alternative

As discussed in section 3.1.3, the Pit Storage Relocation Alternative would involve relocation of pits from storage at Pantex Plant to storage at one or more alternate sites. Activities at Pantex Plant Site would remain similar to those identified for the Proposed Action, including the construction of six new facilities. Impacts on land resources would, therefore, be similar to those identified for the Proposed Action.

4.4.4.1 *Impacts of Relocating 20,000 Pits*

The interim storage of up to 20,000 pits at other DOE or Department of Defense sites would make the current storage facilities in Zone 4 available for other uses. No land use change is anticipated.

4.4.4.2 *Impacts of Relocating 8,000 Pits*

The interim storage of up to 8,000 pits at other DOE or Department of Defense sites would make some of the current storage facilities in Zone 4 available for other uses. No land use change is anticipated.

4.4.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.4.5.1 *Impacts of the Alternatives in the Waste Management Programmatic Environmental Impact Statement*

In conjunction with the Proposed Action, the location of treatment and disposal facilities as described in the WM PEIS could increase land use by a maximum of 10.6 hectares (26.3 acres) at Pantex Plant Site. Cumulative impacts on land resources would not be considered significant. Moreover, this land is already DOE-owned. The new requirements would not be in conflict with DOE plans and policies or the plans and policies of the local governments in the Pantex Plant vicinity.

4.4.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur, and there would be no change in land use.

Under the downsizing alternative, facilities would be consolidated and impacts would be expected to be less than current impacts. Under the relocation alternative, the Pantex Plant facilities would be decommissioned and no longer active.

4.4.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. Potentially, pits could be stored in Zone 12 for long-term storage. The Collocation Alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. Although the new construction would convert undeveloped land, the proposal would conform with the Pantex Site Development Plan. Therefore, direct effects to land use would be negligible. Land disturbance would be 89.5 hectares (221 acres) during construction and 87 hectares (214 acres) during operations.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor (LWR) is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide (MOX) fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

Land disturbance during construction would be 14 hectares (35 acres) for the pit disassembly and conversion facility, 36 hectares (90 acres) for the plutonium conversion facility, 121 hectares (300 acres) for the MOX facility, and 284 hectares (700 acres) for the evolutionary LWR. Land required for operations would be 12 hectares (30 acres) for the pit disassembly and conversion, 28 hectares (70 acres) for the plutonium conversion facility, 81 hectares (200 acres) for the MOX facility, and 138 hectares (341 acres) for the evolutionary LWR. The evolutionary LWR would be located on land which is in agricultural use in the northwest portion of Pantex, west of the Burning Ground and Zone 5. Construction of the evolutionary LWR would change current agricultural land use (DOE 1996j:S-11, S-130, 131).

Because this proposed action is not part of the Site Development Plan, a potential adverse direct impact to land use could occur. It should be noted that preconstruction activities for disposition would require about 5 years to perform the tiered NEPA analyses and to obtain necessary permits and designs. About another 5 years would be required for construction, startup, preoperational testing, and operational readiness review. Construction of completely new reactors could take longer (DOE 1996a:chapter 4).

4.4.6 Potential Mitigation Measures

Since no long-term adverse impacts to land resources have been identified relative to the Proposed Action, No Action, or the Pit Storage Relocation Alternatives, no mitigation measures are needed.

4.5 Geology and Soils

4.5.1 Affected Environment

This section addresses the geology and soils in and around Pantex Plant. The geologic setting, including geomorphology, stratigraphy, and issues related to structural integrity, such as subsidence and seismology, is discussed. Also included are discussions of baseline soil and sediment quality on and in the vicinity of Pantex Plant.

4.5.1.1 *Geology*

Geomorphology

Pantex Plant is located in the Southern High Plains, a region of relatively flat topography containing many surficial depressions known as playa basins. Playa basins collect surface water runoff via natural and manmade drainage systems. Considerable attention has been given to the possible origin of playas. Researchers have proposed varied ideas concerning the origin of the typical, roughly circular, shallow playa basin. One idea is that the formation of these basins is the collective result of most of the cited origins (i.e., wind, erosion by streams, lake deposits, soil formation processes, dissolution of soil carbonate, salt dissolution and subsidence, and animal activities) all acting intermittently (Pantex 1996:3.4).

Playas have been identified as a source of recharge to the Ogallala aquifer (Scanlon 1994:94). Interplaya areas, such as unlined ditches, and natural drainage areas were also identified as significant additional groundwater recharge points (DOE 1995r:3-38). Investigations of the ditches and playas, related to the potential for contamination, are being performed through the Pantex Plant environmental restoration program (Pantex 1996:5.2).

Surface elevations at Pantex Plant (excluding the playa basins) range from approximately 1,076 meters (3,530 feet) in the southeast corner of Pantex Plant to 1,096 meters (3,596 feet) in the northwest corner of Pantex Plant (USGS, 1973). Erosion by water runoff is negligible at Pantex Plant in the inter-playa areas due to the relatively flat nature of the land surface and short drainage distance (less than 5 kilometers [3 miles]) into numerous local playas (see Figure 4.6.1.1–1 in section 4.6.1.1). The regional slope is about 1.5 to 1.9 meters per kilometer (8 to 10 feet per mile). Slopes within the playa basins reach up to 5 percent; thus, erosion could be more active within the playa basins. Pantex Plant lies within the "Dust Bowl" region of the 1930's. Wind erosion and deposition continue to be active processes. Current agricultural practices make the land surface more susceptible to wind erosion (Pantex 1996:3.4).

Stratigraphy

Figure 4.5.1.1–1 depicts a complete stratigraphic column of the Palo Duro Basin and Amarillo Uplift in the vicinity of Pantex Plant. The stratigraphy of the sediments and rocks beneath Pantex Plant is discussed in descending chronological order from more recent layers (surface deposits) to Permian-age layers (salt deposits). Pre-Permian rocks will not be discussed because they are not relevant to the affected environment.

The uppermost formation at Pantex Plant is the Blackwater Draw Formation. The Blackwater Draw Formation consists of a sheetlike body of windblown sand and silt having a number of buried soil horizons and ranges from 12 to 22 meters (40 to 75 feet) in thickness at Pantex Plant. Surface soils of the Blackwater Draw Formation consist of Pullman soils on the plains and Randall soils in the playas (Pantex 1996:3.3).

The Pullman soils are up to 1 meter (3 feet) thick and consist of unsaturated, silty clay loam,

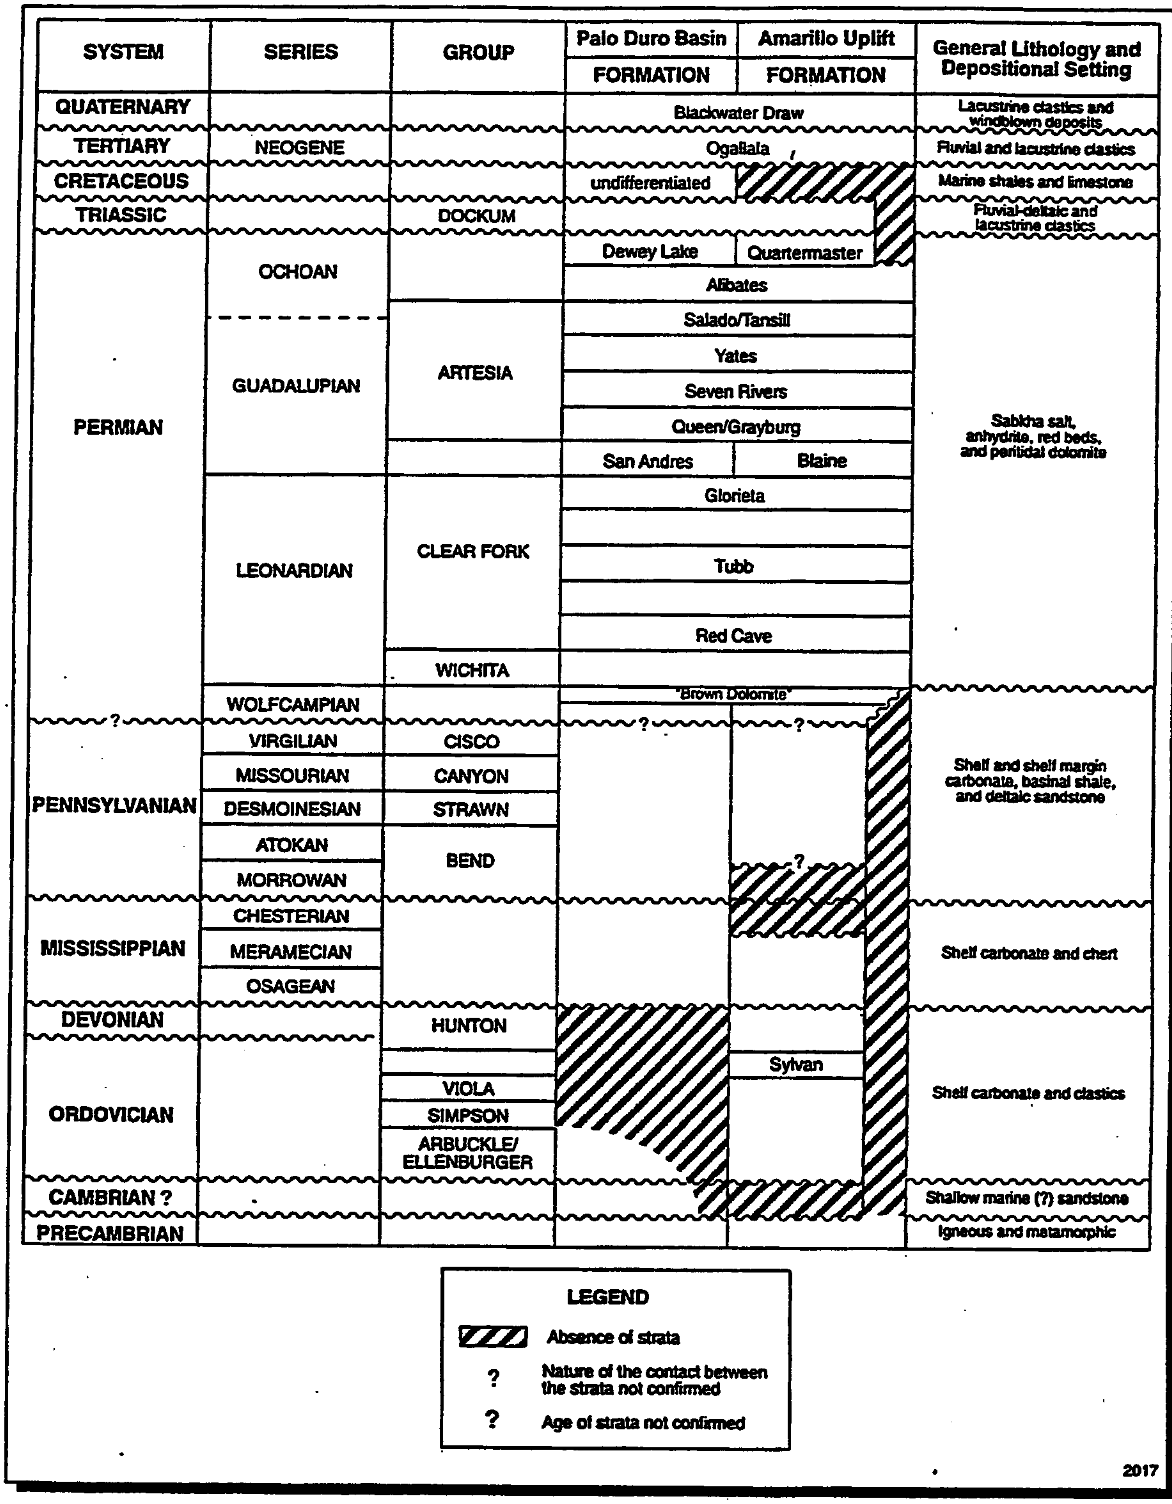

FIGURE 4.5.1.1–1.—*Stratigraphic Column of the Palo Duro Basin and Amarillo Uplift in the Vicinity of Pantex Plant.*

which is slightly permeable. These soils formed in fine-textured, calcareous sediments that probably originated from windblown material. Pullman soils have little or no relief except where they surround intermittent lakes or playas.

The Randall soils are up to 8 meters (25 feet) thick and consist of deep, very poorly drained, noncalcareous massive clay. These soils formed from sediment washed from the surface of surrounding soils within the individual playa watershed. During wet seasons, these soils may remain underwater for long periods of time (USDA 1962:14). Underlying these surface deposits (surface soils or playa basin deposits) is a 12- to 23-meter (40- to 75-foot) thick unit of unsaturated silty sand with caliche of the Blackwater Draw Formation (DOE 1994h:13).

Sediments of the Blackwater Draw Formation encountered in boreholes at the northeast corner and central south boundary of the plant show that these sediments contain numerous open tubules formerly occupied by plant roots. Buried soils within the Blackwater Draw Formation commonly contain fractures that bound soil aggregates. Both root tubules and fractures contain evidence (in the form of clay coatings, manganese stains, and calcium carbonate filaments) that these features have served as groundwater flow paths (Pantex 1996:3.3).

The Ogallala Formation underlies the Blackwater Draw Formation and is the primary water-bearing unit in the Southern High Plains. The Ogallala Formation consists of sediments derived from two distinctive depositional systems: the upper portion which consists of wind-blown deposits and the lower portion which consists of fluvial deposits. It is important to recognize that the Ogallala Formation is a sequence of related deposits rather than a single lithologic unit.

The Ogallala consists of mostly fine to coarse sand, gravel, and silt with some clay and is primarily unconsolidated. A caliche layer has formed in a 1- to 2-meter (3- to 6-foot) thick layer near the top of the formation. Ogallala thicknesses between 60 and 120 meters (200 and 4000 feet) are common in the Palo Duro Basin area with a maximum thickness of 250 meters (800 feet) occurring in the Panhandle Paleovalley northeast of Pantex Plant. There is little relief on the upper surface of the Ogallala, changes in thickness are related primarily to variations in the elevation of the pre-Ogallala surface. The pre-Ogallala surface was controlled not only by erosion but by salt dissolution as well.

The upper portion of the Ogallala Formation consists of 40 to 46 meters (130 to 150 feet) of fine-grained calcareous (calcium carbonate) wind-deposited sand. Many caliche concretions are present throughout this layer. All of these concretions are thin and discontinuous except at the top of the Ogallala Formation, where a relatively persistent caliche layer, called the Caprock caliche, is found (Pantex 1996:3.1).

The lower part of the Ogallala Formation is separated from the upper part by a relatively low permeability zone, 7 to 12 meters thick, referred to as the "fine-grained zone". Stratigraphic test wells drilled near the center and northeast corner of the site have revealed that the fine-grained zone consists of a series of coalescing and upward-fining sequences. It is important to note that the lateral extent of these sequences is unknown but varies from four sequences in the northeast corner of the plant to two sequences near the center of the plant (Pantex 1996:3.3).

Perched groundwater occurs in the discontinuous porous buried channel beneath Pantex Plant (refer to section 4.6.1.2). The position of the buried channel follows the geometry of the fine-grained zone, which was probably aligned along the regional subsurface collapse related to salt dissolution that produced topographic lows beneath and within the Ogallala sediments. Figure 4.6.1.2–3 in section 4.6.1 illustrates a geologic cross section of the inferred lithologies beneath and in the vicinity of Pantex Plant.

The fine-grained zone is composed of a pink, clayey fine-grained sand which is relatively impermeable to water. The irregular top of the fine-grained zone is probably due to a combination of erosion and subsidence. Within the area of Zone 12 and its vicinity, the relief of the top of the fine-grained zone is at least 18 meters (60 feet). The perched zone is bounded below by the fine-grained zone; therefore, the perched zone may not be present in areas where the fine-grained zone is topographically high or absent (DOE 1995f:3).

The lower part of the Ogallala Formation consists of fluvial (stream or river) channel deposits composed of sands and coarse gravels and associated overbank deposits composed of fine sands and clay. These fluvial deposits accumulated in the lowlands. At the same time, wind-blown deposits were accumulating in the highlands. The fluvial sediments are believed to have derived from erosion of the Southern Rocky Mountains. At Pantex Plant, driller's lithology logs for wells penetrating the Ogallala show much lateral variation in the Ogallala deposits; wells only one-half mile apart often are not particularly easy to correlate in detail. Typically, correlations are limited to the upper interval, the fine-grained zone, and the lower interval. The nature of the depositional environments proposed for the Ogallala is such that only the sheets of windblown sediments should exhibit much lateral extent. It is important to note that the complex heterogeneity of the Ogallala Formation plays an important role in groundwater movement (Pantex 1996:3.3). Hydrologic aspects of the Ogallala Formation are discussed in section 4.6.1.2.

The Dockum Group underlies the Ogallala Formation and consists of siltstones, sandstones, conglomerates, and claystone. Less than 30 meters (100 feet) of Dockum Group strata are present below Pantex Plant. Toward the northeast portion of Pantex Plant, the Triassic Dockum strata have been eroded, and the underlying Permian strata are in contact with the Tertiary-age Ogallala Formation (Figure 4.5.1.1–1) (Pantex 1996:3.3).

Underlying the Dockum Group are the Upper and Middle Permian layers, which are composed predominantly of thick and widespread deposits of salt. The Lower Permian consists predominantly of complex accumulations of shale, limestone and argillaceous limestone, and dolomite. The total thickness of salt deposits under Pantex Plant have been estimated to exceed 300 meters (1,000 feet) (Pantex 1996:3.3).

4.5.1.2 *Structural Integrity*

The structural integrity or stability of the geological formations underlying Pantex Plant is important to the geotechnical stability of buildings and other operational features (e.g., utility structures) onsite. Two main geological processes are relevant to the Pantex Plant vicinity: seismic activity and subsidence. Slope stability is not an issue at Pantex Plant due to the relatively flat surface topography.

Regional Geology

The underlying geology is made up of two major basins in the Texas Panhandle; these are the Anadarko and the Palo Duro basins. These basins are separated by a west-northwest trending uplifted area comprised of the Amarillo Uplift and the Oldham-Harmon Trend. The Anadarko Basin is asymmetrical with the deepest portions and steepest flank occurring adjacent to the Amarillo Uplift (Pantex 1996:3.2). The Amarillo Uplift is part of the Pennsylvanian-age Ancestral Rocky

Mountain building belt that extends from Utah to Oklahoma.

The Whittenburg Trough separates the Amarillo Uplift from the Bush and Bravo Domes which are the result of strike slip faulting associated with the formation of the Oldham-Harmon Trend. This narrow deep trough is approximately 15 kilometers (10 miles) wide and 55 kilometers (35 miles) long and extends from the northwestern Tascosa Basin to the southeastern Carson Basin (TBEG 1989a:19, 39). The Pantex Plant is located at the southeastern edge of the Whittenburg Trough in the Carson Basin (see Figure 4.5.1.2–1). The faults that could potentially contribute to the risks associated with earthquakes at the Pantex Plant are related to the structures described above.

Seismicity

Less than 100 years of seismic data are available for the region around Pantex Plant, only a few decades of which is recorded instrumentally. In addition, accurate and sensitive seismic coverage for Pantex Plant is not available; the regional seismicity record is not complete for all events that have occurred in the Texas Panhandle (Pantex 1996:3.5).

An assessment of natural hazards at Pantex Plant, which included a study of seismic events, concluded that intense seismic events could pose a threat to the structural integrity of buildings, including their foundations (Jacobs 1993:5-3). Approximately 25 earthquakes have been recorded in the Texas Panhandle, the largest with a maximum intensity of VI on the

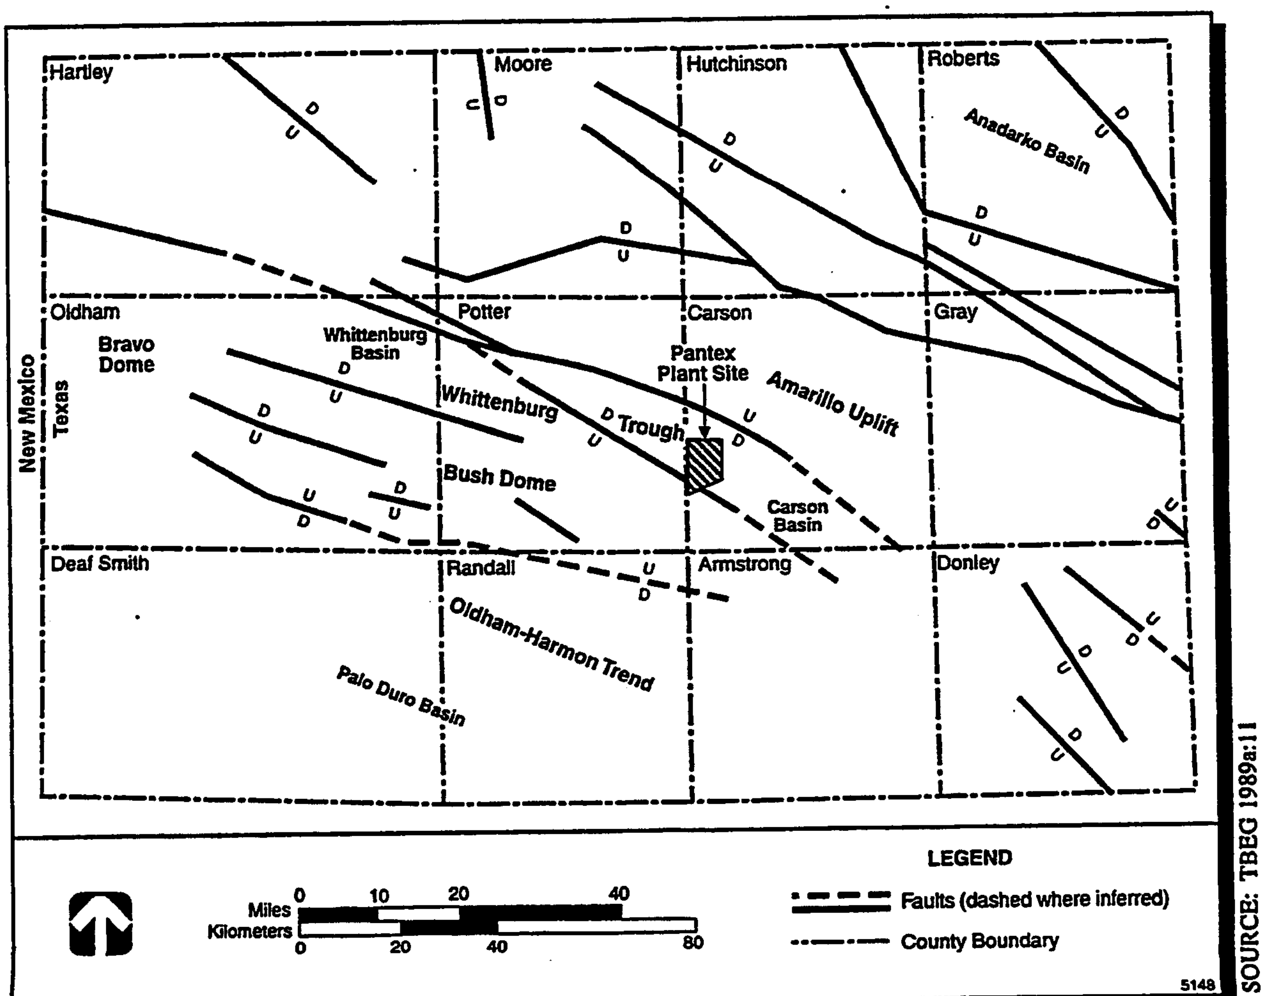

FIGURE 4.5.1.2–1.—*Pennsylvanian and Lower Permian Tectonic Structures.*

Modified Mercalli Scale, a scale based on observed damage that is used in the absence of instrument recording (Table 4.5.1.2–1). An earthquake of this intensity in the Texas Panhandle would not result in structural damage except for a few instances of fallen plaster or damaged chimneys (Pantex 1996:3.5). Figure 4.5.1.2–2 shows the locations and intensities of earthquakes in the Texas Panhandle and their relation to tectonic features.

In the Panhandle region, earthquakes with magnitudes of greater than or equal to 5.0 on the Richter scale are predicted to occur with a frequency on the order of four times in 100 years. The annual probability of a maximum credible earthquake (6.3 on the Richter scale) occurring within a distance of 16 kilometers (10 miles) of Pantex Plant, however, is very low—on the order of 10^{-3} to 10^{-4} (Pantex 1996:3.5).

Three major subsurface faults and one minor surficial fault exist in the area of the Pantex Plant, and these are located as follows: (1) approximately 250 kilometers (155 miles) long, about 40 kilometers (25 miles) north of the site, (2) approximately 69 kilometers (43 miles) long, about 8 kilometers (5 miles) south of the site, (3) approximately 64 kilometers (40 miles) long, about 11 kilometers (7 miles) north of the site, and (4) approximately 6 kilometers (4 miles) long, about 32 kilometers (20 miles) northwest of the site (surficial). However, there is no evidence of active faults at the Pantex Plant (DOE 1995i:11).

The procedure used for evaluating the risk from earthquakes to the Pantex Plant assumes that the largest earthquake to be expected in the region can happen anywhere in the region, which also includes at Pantex itself (DOE 1994aa). Within the southern plains seismic zone, the estimated recurrence interval for a 6.5 Richter magnitude earthquake is once in a thousand years (Blume 1976:41). Section 4.14, Human Health, presents the accident scenarios that could result in a release of radioactive or other hazardous material as a result of an earthquake at the Pantex Plant.

Subsidence

The presence of salt beds in Permian formations and the ongoing dissolution of some of those beds are addressed because of the potential for salt dissolution. Salt dissolution can cause subsidence, which may result in collapse depressions, sinkholes, fractures, or faults. Table 4.5.1.2–2 summarizes the Permian formations and estimated thicknesses of salt deposits beneath Pantex Plant.

The presence of saline springs around the margins of the Southern High Plains indicates active dissolution. Recent work using shallow seismic data has determined that the structures beneath the playas on Pantex Plant and adjacent areas show displacement of Ogallala strata. This displacement is attributed to the dissolution of underlying salt beds (TBEG 1994a:27, 29).

While salt dissolution is an active process in the region, it is a very slow process relative to human activities (Gustavson 1980). Most active salt dissolution in the region is concentrated near the Eastern Caprock and at the Canadian River Escarpments (Pantex 1996:3.7). Figure 4.5.1.2–3 shows zones of active salt dissolution and counties in which associated sinkholes and fractures have been identified. Sinkholes and fractures have not been identified in Carson County, where Pantex Plant is located. However, sinkholes and fractures have been identified in adjacent Armstrong County to the south and Hutchinson County to the north (Gustavson 1981:10).

4.5.1.3 *Soil and Sediment Quality*

Soil Types

The soil types at and in the vicinity of Pantex Plant, including the land leased from Texas Tech University, belong to the Pullman-Randall

TABLE 4.5.1.2–1.—*Modified Mercalli Intensity Scale of 1931 Abridged Version*[1]

INTENSITY	EFFECT
I	Felt by very few under specially favorable circumstances. (I)
II	Felt only by a few persons at rest, especially on upper floors of buildings. Delicately suspended objects may swing. (I to II)
III	Felt quite noticeably indoors, especially on upper floors of buildings, but many people do not recognize it as an earthquake. Standing motorcars may rock slightly. Vibration like passing of truck. (III)
IV	During the day, felt indoors by many, outdoors by few. At night, some awakened. Dishes, windows, doors disturbed; walls make creaking sound. Sensation like heavy truck striking building. Standing motorcars rocked noticeably. (IV to V)
V	Felt by nearly everyone, many awakened. Some dishes, windows, etc., broken; a few instances of cracked plaster; unstable objects overturned. Disturbances of trees, poles, and other tall objects sometimes noticed. Pendulum clocks may stop. (V to VI)
VI	Felt by all, many frightened and run outdoors. Some heavy furniture moves; a few instances of fallen plaster or damaged chimneys. Damage slight. (VI to VII)
VII	Everybody runs outdoors. Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable in poorly built or badly designed structures; some chimneys broken. Noticed by persons driving motorcars. (VIII-)
VIII	Damage slight in specially designed structures; considerable in ordinary, substantial buildings, with partial collapse; great in poorly built structures. Panel walls thrown out of frame structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned. Sand and mud ejected in small amounts. Changes in well water. Persons driving motorcars disturbed. (VIII+ to IX)
IX	Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb; great in substantial buildings, with partial collapse. Buildings shifted off foundations. Ground cracked conspicuously. Underground pipes broken. (IX+)
X	Some well-built wooden structures destroyed; most masonry and frame structures destroyed with their foundations; ground badly cracked. Rails bent. Landslides considerable from river banks and steep slopes. Shifted sand and mud. Water splashed (slopped) over banks. (X)
XI	Few, if any, masonry structures remain standing. Bridges destroyed. Broad fissures in ground. Underground pipelines completely out of service. Earth slumps and land slips in soft ground. Rails bent greatly.
XII	Damage total. Waves seen on ground surfaces. Lines of sight and level distorted. Objects thrown upward into air.

[1]Equivalent intensities on the Rossi-forel scale, used prior to 1931 in the United States, are given in parentheses.

Note: Many of the criteria in the intensity scale result from the integrated effects of the total sequence of ground motion from an earthquake as experienced at a particular point. Duration is an important factor. Intensities are critically dependent both on distance from the source of earthquake waves and on the local ground conditions. On the other hand, magnitude is a number intended to quantify the size of an earthquake at its source, independent of other considerations. The two scales are difficult to correlate without detailed study of the local geological structure, rock mechanics, and instrument recordings of local earthquakes over an extensive period of time. These studies have not been conducted for the Amarillo region.

TABLE 4.5.1.2–2.—*Salt Present Beneath Pantex Plant in the Permian Formation*

FORMATION	NET SALT PRESENT
Dewey Lake	No salt.
Alibates	No salt.
Salado-Tansill	No salt, possibly experienced dissolution in the past.
Yates	No salt.
Seven Rivers	No salt, possibly experienced dissolution in the past, major salt unit elsewhere in Palo Duro Basin.
Queen-Grayburg	No salt.
Upper San Andres	Near the distal end (no salt) of zone of active dissolution. Adjacent formation salt is about 60 meters (200 feet) thick.
Lower San Andres	Near the proximal end (110 meters [350 feet] of salt) of zone of active dissolution. Adjacent formation salt is about 110 meters (350 feet) thick.
Glorieta	About 30 meters (100 feet) of salt.
Upper Clear Fork	About 73 meters (240 feet) of salt.
Tubb	Only a few evaporite layers.
Lower Clear Fork	About 91 meters (300 feet) of salt.
Red Cave	Some evaporite strata.
Wichita	No salt.
Wolfcamp	Limestone, shale, and dolomite with sands.

soil association. The Pullman-Randall soil association consists of nearly level to gently sloping deep noncalcareous loamy soils. The Pullman soils occupy the interplaya areas at Pantex Plant and make up about four-fifths of the Pullman-Randall soil association. These soils consist of silty clay loam and are deep and well drained. The slopes range from 0 to 1 percent in the interplaya areas and 1 to 3 percent near the playas. Pullman soil has a high natural fertility, is slightly permeable, and has the ability to retain a moderate amount of water (Pantex 1996:7.1). This soil is classified as a Mollisol, which is noted by wide, deep cracks throughout the year (USDA 1981:ii). These cracks aid in groundwater recharge. The major land uses are grazing and dryland farming (Foth 1984:268).

The Randall clay soils are generally found in the bottom of the playas. They are somewhat poorly drained but have high natural fertility, very slight permeability, and high available water capacity except during droughts (Pantex 1996:7.1). This soil is classified as a Vertisol, which contains a large amount of clay and has cracks at some times of the year (USDA 1981:ii). Agriculturally, these soils have great potential (Foth 1984:280, 282).

Within the Pantex Plant region of influence (ROI), land use is predominantly agricultural. In the High Plans areas of both Carson and

Potter counties, Pullman soils are the most extensive arable soils in Texas (Pantex 1996:7.1, 10.1). According to the 1992 Census of Agriculture, farming and ranching contributed nearly $300 million to the economy of the ROI. Extensive description of cropland, rangeland, and associated soils are provided in the Pantex Plant *Environmental Information Document* (Pantex 1996).

General Environmental Restoration Process

An environmental restoration (ER) or cleanup process is typically governed by the *Resource Conservation and Recovery Act* (RCRA) or the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA) (in some cases, both) and their associated regulations. Both sets of regulations govern how environmental contamination is defined, characterized, and remediated. While there are regulatory differences, they generally follow a common process. This common process includes the following steps: initial assessment of suspected areas of contamination; a preliminary prioritizing of areas that should be characterized; planning and implementing a formal sampling and analysis program; drafting of recommendations based on the data as to how much remediation, if any, is needed for each area; review and approval of these recommendations by the regulator; feasibility studies for alternative methods of remediation; and implementation of remedial actions and post-remediation activities. The following is a description of the common process by which environmental contamination is characterized and remediated.

Initially, an assessment of a site or facility is performed. This assessment can be conducted by the facility's personnel or by personnel from the Environmental Protection Agency (EPA) and the State's regulatory agency. This assessment identifies places where hazardous materials (as defined by the appropriate regulations) are being, or could have been, released to the environment. This identification process starts with the review of the existing documentation, discussions with facility personnel, and onsite observations. Areas suspected of being contaminated are called solid waste management units (SWMUs) under RCRA and Operable Units (OUs) under CERCLA. These SWMUs or OUs can be single areas of suspected contamination or a grouping of such places.

After the identification of the SWMUs or OUs, priorities are set by the regulators concerning the timing of investigations and any immediate remediations that might be needed. A detailed and formal priority setting process can involve an investigation of the degree of threat to human health and the environment potentially posed by the suspected contamination. This investigation can include more detailed review of documentation, further discussions with current and past employees, and even some sampling of the SWMUs or OUs. The degree of threat posed by the SWMUs or OUs is determined by considering a conservative estimate of the level of contaminants suspected to be present and the potential pathways for exposure to the human environment. The SWMUs or OUs are then ranked according to the degree of perceived threat. Those SWMUs or OUs with a high ranking are usually designated for immediate remediation. The remainder can be slated for full investigation and sampling according to their perceived threat.

The investigative process involves the preparation and subsequent approval of work plans by the regulators and stakeholders. Sampling and analysis of the areas are then performed. At this point, the types and amounts of contamination present at the facility are fairly well characterized. This allows for reasonable projections as to the amount of cleanup activity that might ultimately be needed to accomplish the ER program goals. Based on the analysis of data, recommendations are made as to whether individual SWMUs or OUs need either immediate remediation, feasibility studies of different remediation methods, additional sampling and characterization, or no further action (NFA). These recommendations are based on evaluations of the types and amounts of contamination indicated by the sampling data and the associated health risk levels set by the regulators. A draft report is sent to the regulator reporting the data and analyses as well as the cleanup recommendations. After review by the regulator, subsequent revision of the report, and final approval by the regulator, the final report is made available to the public. The approval of the report includes approval of the recommendations.

After the approved report is issued, any additional work is performed on those SWMUs or OUs needing further sampling and characterization. Those SWMUs or OUs that do not need additional characterization or cleanup are then taken out of the ER investigation program. Monitoring and maintenance activities may continue at these sites. In accordance with the recommendations approved in the final report, cleanup of the SWMUs or OUs needing immediate remediation is initiated, and feasibility studies to evaluate alternative methods for cleaning up or immobilizing the contamination in the remaining SWMUs or OUs are started. These feasibility studies are submitted to the regulator for review and determination of the appropriate cleanup method. Subsequent to the regulator's determination, cleanup work begins on the remaining SWMUs or OUs.

Once it is demonstrated that a SWMU or an OU has been remediated to the satisfaction of the regulator, it is closed. A closed SWMU or OU can still have some continuing activities, such as ongoing remediation of groundwater. Some remedial actions can be initiated in advance of the formal process, but these remediations are still reviewed by the regulators. If an advance remedial action is not satisfactory to the regulators, further remediation of the SWMU or OU will be required.

Environmental Restoration Process at Pantex Plant

Pantex Plant's ER program is currently being conducted under RCRA in accordance with the Hazardous Waste Permit and EPA and State of Texas regulations. A timeline showing key dates for the Pantex Plant ER program is shown in Figure 4.5.1.3–1. The approval for RCRA methodologies is contained in the hazardous waste permit. All decisions and determinations associated with the ER program are made in negotiation with the regulators. Since CERCLA also applies to Pantex Plant, EPA placed the plant on the National Priorities List on May 31, 1994. Negotiations are currently underway with EPA and the State of Texas to integrate the two processes. The current plan is to complete the remediation process in such a way as to satisfy both RCRA and CERCLA requirements. In addition, Pantex Plant currently plans to perform advance remedial actions (i.e., interim and voluntary corrective actions) where feasible.

Under the RCRA regulations, 144 SWMUs (i.e., places of suspected contamination) have been identified at Pantex Plant. The 144 SWMUs were combined into 14 groups for investigation and are discussed in the Soil and Sediment Quality at Solid Waste Management Units subsection which follows. All prioritization of work activities associated with ER at Pantex Plant has been closely coordinated with EPA and TNRCC. The methodology for Pantex Plant prioritization has been to concentrate on areas of contamination which pose the greatest risk to the public health and other biological populations, and to clean up areas of contamination which are easily corrected. This methodology allows Pantex Plant to focus resources on priority sites while accelerating cleanup and reducing human health and ecological risks. Both EPA and TNRCC have approved this methodology through the issuance of the RCRA permit.

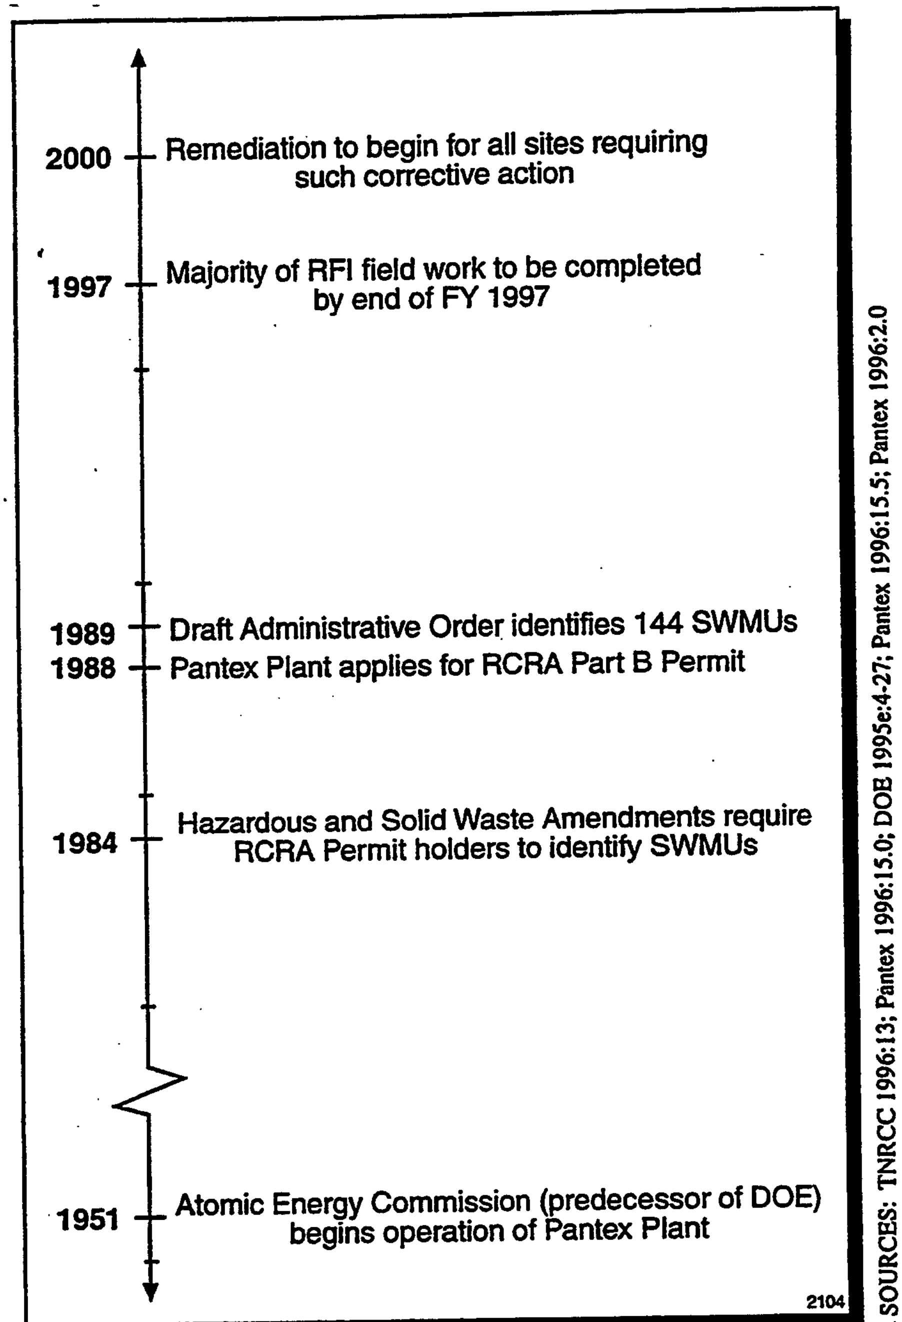

FIGURE 4.5.1.3–1.—*Timeline Showing Important Dates for Pantex Plant Environmental Restoration Program.*

Of the 14 RCRA Facility Investigations (RFIs) ongoing at the plant, 12 have proceeded to the draft report stage. The rest of the RFIs have proceeded only as far as the sampling and analysis stage. At this point, the types and amount of contamination present at Pantex Plant is fairly well characterized, allowing projections to be made as to the amount of cleanup activity that might ultimately be needed to accomplish the ER program goals. Based on the levels of contamination that have been reported in the 12 draft RFIs and the range of contaminant levels that are being seen in the other investigations, many of the 144 SWMUs are expected to be recommended for no further sampling or remediation (i.e., No Further Action (NFA)). While those recommendations are only in draft form and are subject to review and approval by the State of Texas, they indicate that the types and amounts of contamination at the plant are much less than initially estimated. Plans by the plant to initiate advance remedial actions are reflected in the current reduced estimates of impacts and waste projections that would result from the ER program.

Soil and Sediment Quality at Solid Waste Management Units

Past industrial operations at Pantex Plant have generated both solid and liquid wastes, including high explosive(s) (HE) materials, organic solvents, and metals.

In January 1989, EPA conducted a RCRA facility assessment to identify SWMUs, (defined as any unit from which hazardous constituents may migrate) that may require investigation and/or corrective action under the 1984 Hazardous and Solid Waste Amendments to RCRA. In September 1989, the draft Administrative Order of Consent, pursuant to Section 3008(h) of RCRA, was issued. The ER group identified 144 SWMUs, of which 113 SWMUs were organized into 14 groupings (see Figure 4.5.1.3–2, Figure 4.5.1.3–3, and Table 4.5.1.3–1).

A site may be initially designated as a SWMU during the RCRA facility assessment based on process knowledge, visual observations, or even the recollection of a single employee regarding past accidents, spills, or operations, before confirming the presence of contaminants by collecting and analyzing samples from the site. NFA may be recommended for many of the SWMUs after sampling and analysis of the site confirms either low levels or probable absence of contamination due to natural degradation of the contaminants over time. In addition, NFA may also be recommended if contaminant levels are below appropriate TNRCC Risk Reduction Standards (RRS), which are discussed in detail later in this section.

RFIs are conducted by the ER group at Pantex Plant to determine whether hazardous constituents have been released into the environment from the SWMUs or areas of concern. The 14 groupings are undergoing investigations on independent schedules. Thirty-one of the sites are either active non-RCRA sites or sites that could not be verified and located in subsequent field surveys. The 31 sites are being reviewed to verify that no hazardous materials are present; then they will undergo administrative closure.

TNRCC has established three closure/ remediation performance standards (RRSs 1, 2, and 3) that are applicable to remedial actions undertaken in response to a release or spill. These risk reduction rules attempt to clarify cleanup levels across the state while reducing time delays and accelerating both the investigation and remediation of contaminated sites. The ER group at Pantex Plant has compared analytical results from soil and sediment samples to TNRCC RRSs 1, 2, or 3.

RRS 1 requires removal and/or decontamination of all waste, waste residues, leachate, and contaminated media to background levels unaffected by waste management or industrial activities. 30 TAC 335.554 (d) states that "If the Practical Quantification Limit (PQL) is greater than background, then the PQL rather than the background shall be used as the cleanup level provided that the person satisfactorily demonstrates to the executive director that lower levels of quantification of a contaminant are not possible." The PQLs are generally defined as the lowest level (concentration) quantifiable among laboratories within specific limits during routine laboratory operations.

RRS 2 requires removal and/or decontamination of all waste, waste residues, leachate, and contaminated media to standards and criteria such that any substantial present or future threat

to the human health or environment is eliminated.

RRS 3 requires that removal, decontamination, and/or control of all waste, waste residues, leachate, and contaminated media occur to levels and in a manner such that any substantial present or future threat to human health or the environment is eliminated or reduced to maximum extent practicable. Because of greater concentrations of contaminants that may be left at the site with RRS 3, an evaluation of the effectiveness of the proposed remedy must be submitted to TNRCC and approved before implementation of the remedy.

RRSs 1 and 2 are the goals for determining cleanup levels and as decision criteria for additional sampling needs at a site. The "cleanup" levels represent the concentrations below which any additional site characterization or remedial action initiatives would be for the purpose of satisfying objectives other than minimizing human health risks. For example, observations of a specific chemical hazard in excess of background (RRS 1) but within acceptable risk-based criteria (RRS 2) may be acted upon differently by DOE under differing site-specific conditions. The cleanup for contamination located at 1.5 to 3.0 meters (5 to 10 feet) below ground surface is to background (RRS 1), thus avoiding deed recording requirements with RRS 2 (30 TAC 335.560) and future liability relative to a potential changing land use classification. Conversely, for the same contaminant at the same concentration located at a depth of 1.5 to 30 meters (5 to 100 feet) below ground level, DOE is likely to accept the criteria outlined in RRS 2 in which technical feasibility and cost limitations preclude cleanup to background.

By virtue of 30 TAC 335.557 (3), the future land use designated at Pantex Plant is nonresidential. However, in areas subject to excessation, the land use may revert to residential, thereby requiring increased scrutiny of the site to determine if risk-based criteria for a residential scenario have been satisfied. The DOE risk managers will need sufficient characterization data regarding these sites to quickly determine the most prudent closure strategy to assume; i.e., cleanup to background or to some risk-based level established for residential or nonresidential uses. The decision criteria is generally determined by processes such as the one described above.

The RRSs are continually being revised as new information becomes available. Preliminary Remediation Goals (PRGs) are, therefore, currently accepted cleanup levels and may be revised as RRSs are revised. Further explanation on the methodology for applying the RRSs to RFIs being conducted at Pantex Plant can be found in the *Draft Final Risk Reduction Rule Guidance for Pantex Plant RCRA Facility Investigations* (DOE 1994z).

All RFI work plans have been approved, and field investigations have been initiated at all sites. RFI reports have been completed for five AL–PX groupings: AL–PX–01, AL–PX–02, AL–PX–06, AL–PX–08, and AL–PX–12 (see Tables 4.5.1.3–1 and I.1.1–1). These documents are in draft form and are currently being reviewed by TNRCC. Adequate data have been collected on many of the SWMUs to recommend either NFA or interim corrective measures (ICMs). ER of the SWMUs at Pantex Plant is ongoing concurrently with the generation of this document. The information presented below is the latest published data available. Five of the draft RFIs are at a stage where the data may be referenced in this EIS and are discussed further below. Additional data will be provided in the Final EIS as new information becomes available.

The Burning Ground (AL–PX–01) grouping, located adjacent to the eastern side of Playa 3, consists of the former chemical burn/solvent evaporation pit, explosive burn pads, landfills, burn trays, burn racks and flashing pits, burn cages, and demonstration facilities (USCOE 1995:iii, v). The site is used for the burning of HE components and treatment of HE-contaminated waste and various HE-contaminated liquids and solvents.

Disposal of residues from burning of solvents at the site was discontinued in the early 1980's (Pantex 1994a:2-1). The highest concentrations of contaminants were found in the landfills; however, contaminants have not migrated past the landfill's boundaries (Pantex 1996:15.4). Primary contaminants are HE, solvents, and metals. Phase II of the RFI was completed in November 1995, and a revised Draft Final RFI report has been submitted to TNRCC. Although contamination is generally limited to the upper 6 meters (20 feet) of soil, some volatile organic compounds (VOCs) have been detected at deeper intervals (Pantex 1996:15.4). Hotspot removal ICMs may be required at selected sites. DOE may also recommend to TNRCC some in situ remediation such as soil vapor extraction and bioremediation based on final data review (PC 1996b:3).

The Draft RFI Report for the Burning Ground Assessment was completed in May 1995 and submitted to TNRCC in August 1995. The following is a summary of the contaminants of potential concern identified in the soil during this investigation that exceeded the decision criteria. The contaminants include HE, metals, pesticides, and semivolatile organic compounds (SVOCs). HE compounds that exceed the decision criteria for soil include RDX, 1,3,5-TNB, and 2,4,6-TNT, HMX (surface soil only) and 1,3-DNB (subsurface soil only). Also, a contaminant of potential concern, 4-amino 2,6-dinitrotoluene, has been identified in the soils.

RDX had a range of concentrations exceeding the decision criteria (2.6 milligrams/kilogram for surface and subsurface soil) in surface soils of 2.9 to 510 milligrams/kilogram and 2.6 to 64 milligrams/kilogram in subsurface soil.

Seven metal compounds were detected in soil samples at concentrations which exceed the decision criteria. Nickel and vanadium concentrations only exceeded the surface soil decision criteria (0 to 2 feet [0 to 0.6 meters] in depth). Arsenic only exceeded the decision criteria in one subsurface soil sample. Barium, copper, lead and mercury were detected in surface and subsurfaqe soil samples above decision criteria. Barium had a range of concentrations exceeding the decision criteria for surface soils (200 milligrams/kilogram) of 200 to 2,440 milligrams/kilogram. Lead exceeded the decision criteria for surface soils (15.7 milligrams/kilogram) ranging from 16 to 160 milligrams/kilogram. Mercury exceeded the decision criteria for surface soils (0.20 milligram/kilogram) ranging from 0.22 to 1.7 milligrams/kilogram.

Four pesticides (aldrin, alpha-BHC, dieldrin, and gamma-BHC) were identified in the soil that exceed the decision criteria. SVOCs exceeding the decision criteria for soil include benzyl alcohol and bis-(2-ethylhexyl) phthalate (USCOE 1995). Sampling of soil at the Burning Ground is also conducted on an annual basis. These sampling results are discussed in the soil and sediment sampling subsections that follow.

The High Priority Potential Release Sites group (AL–PX–02) consists of five SWMUs, one area of concern (AOC), and three firing sites. Phase I and II fieldwork has been completed. The nine sites were split into two separate RFI reports. The two Draft Final RFI reports were submitted to the TNRCC for review in September 1994 and March 1995, respectively (Pantex 1996:15.4).

Chemical constituents detected in the soil and sediment at SWMUs north of Pantex Drive include minor amounts of HEs, metals, VOCs and SVOCs. Elevated levels of lead were detected east of Playa 3 and north of Zone 4 at Firing Site 22. Low concentrations of metals and common anions were detected in soils of the inactive, lined, solar evaporation pond located in Zone 11. Elevated levels of lead and chromium were detected in soils on the northeast side of Building 12–68 (an electroplating facility on the east side of Zone 12). Low concentrations of metals were detected in soils near Building 12–59's subsurface leaching system. Lead, VOCs and SVOCs were detected in soils at the former solvent disposal pit located in the northeastern corner of Zone 12.

In 1995, ICMs were conducted on the Building FS–16 surface impoundment and sump, FS–22 container, and Building 12–68 concrete sump. Contaminants included chromium and HE. Confirmation sampling indicated cleanup action attained RRS 2 levels, and Pantex Plant has recommended this grouping to TNRCC for NFA. No additional cleanup is anticipated for this SWMU grouping (Pantex 1994a:3-1 through 3-4, PC 1996b:2).

The Former Cooling Tower (AL–PX–03) was used for the HE machining operations water cooling from 1950 to 1964. The unit was dismantled in the early 1970's, and now only a concrete slab remains. Results from the Phase I analysis revealed low levels of metals, VOCs, SVOCs, nitrogen series (as nitrate and nitrite), and HE in the near-surface and subsurface soils. Barium, lead, and hexavalent chromium were detected in concentrations exceeding background but were below RRS 1 levels. The RFI report prepared and submitted to TNRCC on October 15, 1993 recommended NFA. Subsequent to this investigation, ancillary piping, which may have led to the cooling tower, was discovered. Thus, additional characterization work has been initiated to characterize and evaluate the need for further action (Pantex 1996:15.4; Pantex 1994a:4-1, 4-2; PC 1996b:2). Treatability Study fieldwork started in May of 1996. Soils will be analyzed for total and hexavalent chromium. Treatability/remediation activities will continue into 1997 (Pantex 1996:15.4).

The Old Sewage Treatment Plant (OSTP) Sludge Beds (AL–PX–04) were operational from 1942 until 1987. The OSTP received wastewater from Amarillo Air Force Base, the Amarillo International Airport, Bell Helicopter Plant, and Pantex Plant. The Phase I field work was completed, and low levels of metals and VOCs were detected in the sludge beds and in the subsurface soils. Pantex Plant recommended NFA to TNRCC in September 1993, based on the remote location of the OSTP sludge beds, lack of a continuing source, depth to groundwater, low concentrations of contaminants detected (below RRS 2 levels) and the limited aerial extent of contamination (Pantex 1994a:5-1). Regulatory approval is pending (Pantex 1996:15.4).

The Fire Training Area Burn Pits (AL–PX–05) were used by the Pantex Plant Fire Department as a fire training area. Various solvents, chemicals, and fuels were ignited and extinguished in the training process. Concentrations of zinc, dioxins/furans, fluorine, naphthalene, phenanthrene and 2-methyl-naphthalene were detected in sediment and soil samples. Phase I fieldwork was completed in 1993. Contamination was found to be localized and confined to the upper 1.5 meters (5 feet) of soil (Pantex 1996:15.4, Pantex 1994a:6-1). The ICM was performed in July 1995, and the upper 0.6 meter (2 feet) of soil has been removed and backfilled with clean topsoil (Pantex 1996:15.4). A request for NFA was submitted to TNRCC based on confirmation sampling results that indicated Risk Reduction Level 2 was achieved in the remaining 0.9 meter (3 feet) of soil (Pantex 1996c:52, 53). The Draft Final ICM Closure Report was submitted to TNRCC in November 1995 (Pantex 1996:15.4).

Zone 12 Groundwater group (AL–PX–06) comprises all perched groundwater contamination below Pantex Plant. Details of characteristics and current remedial activities for Zone 12 Groundwater are discussed in section 4.6, Water Resources, and in appendix C. Primary contaminants are RDX, HMX, chromium, and solvents. A dual phase groundwater extraction/soil vapor extraction treatability system has been installed and implemented to determine the feasibility of several remediation options including pump and treat, soil vapor extraction of the vadose and dewatered zones, and oxygen augmentation of the vadose and dewatered zones. Treated groundwater analytical results are showing less than detection limits for HE. With approval of the TNRCC, the treated groundwater is being reinjected in an upgradient monitoring well to aid in the containment of the groundwater contaminant plume and increase the efficiency of the recovery system. Injection began in April 1996. Currently, initial results indicate that the system is injecting 158,987 liters per day (42,000 gallons per day) of treated water into the injection well (Pantex 1996:15.4, Pantex 1994a:7-1).

The Draft RFI for Zone 12 Groundwater was completed in November 1995 and submitted to TNRCC for approval. The purpose of the RFI report is to describe the nature and extent of releases of hazardous constituents to Zone 12 Groundwater at Pantex Plant and to gather sufficient data to support the Corrective Measures Study. Potential sources of contamination to Zone 12 Groundwater identified in the draft RFI include the Burning Ground, Landfill 3, Flow Systems 1 and 4, Leaking Underground Storage Tanks (USTs) at Buildings 12–35 and 16–1, and Miscellaneous HE/Radiation Sites (see appendix I) (Argonne 1995a).

Landfills group (AL–PX–07) has been used to dispose of sanitary and industrial wastes at the plant since 1942. Twenty-three landfills exist throughout Pantex Plant with a majority being located in Zones 11 and 12. Fifteen of these landfills are included in this group (Pantex

1996:15.4). Figure 4.5.1.3–4 illustrates landfills currently under RCRA Facility Investigation (RFI). VOCs were detected in soils above and adjacent to some of the landfills at various concentrations, up to levels where remediation must be considered. Asbestos and VOCs were detected in soil samples of Landfills 1 and 3 (Pantex 1994a:8-1 to 8-8). Characterization data indicate that NFA is recommended on all landfills except Landfill 3. However, maintenance caps will be placed as needed over selected landfills as a proactive measure to prevent potential water infiltration. Preliminary data packages for Phase I fieldwork were submitted to TNRCC for review in December 1994.

The landfills have been separated into three different groupings: Group I, Landfills 4 and 11; Group II, Landfills 5, 6, 7, 9, 10, 12, and 15; and Group III, Landfills 1, 2, 3, and 13, Original Abandoned Zone 10, and Sanitary Landfills. A recommendation for NFA for Group I Landfills was submitted to the TNRCC on June 28, 1995. A Draft Final RFI recommending NFA for all Group II Landfills was submitted to TNRCC on January 15, 1996. A Draft Final RFI for Group III Landfills is scheduled to be submitted to TNRCC by June 28, 1996. The Draft Final RFI for Group III Landfills will recommend NFA for many of the landfills; Landfill 3 may require additional corrective measures (Pantex 1996:15.4). In situ treatment is being evaluated as a potential option for remediation of residual HE contamination found at Landfill 3 (PC 1996b:1).

The Ditches and Playas group (AL–PX–08) consists of five playas (Playas 1, 2, 3, 4, and Pantex Lake) and their associated network of man-made ditches. The ditches receive treated wastewater effluent and stormwater runoff from buildings in Zone 11 and 12. Playa 3 receives stormwater runoff from the Burning Ground, and Playa 4 receives stormwater runoff from the south ends of Zones 11 and 12. In the past, Pantex Lake received wastewater effluent from the OSTP. Playa 4 is currently permitted to receive industrial discharges and stormwater runoff from Pantex Plant (Pantex 1996:15.4). Pantex Lake receives neither industrial discharges nor stormwater runoff from Pantex Plant.

This group has been divided into Flow Systems which are described in Table 4.5.1.3–2. Surface and subsurface soils were collected from various locations throughout the Flow Systems. Table 4.5.1.3–2 is a summary of the types of contaminants identified from analytical results which exceed the decision criteria (Pantex 1994a:9-1, 9-2). An expedited ICM to remove the hotspots within the ditch SWMUs began in June 1996 (Pantex 1996:15.4). Phase II fieldwork (completed in January 1995) involved collection of surface and subsurface soils from various locations throughout flow systems 1 through 5. Proposed ICMs would lower contaminant concentrations in the ditches. The ICMs scheduled for the summer of 1996 include site-specific removals, in situ remediation, and natural attenuation. A baseline risk assessment is being prepared to evaluate the applicability of Risk Reduction Level 3 closure for those sites that are not candidates for ICMs (Pantex 1996c:53).

Of these five flow systems, only flow systems 1 and 4 have been identified as areas suspected of affecting Zone 12 Groundwater (Argonne, 1995a:3-10). Flow System 1 is divided into four subareas: Flow Pathways 1A, 1B, 1C, and Playa 1 area. Contaminants which exceeded the PRGs in Flow Pathway 1A include an HE (HMX), some inorganics (antimony, lead and selenium), SVOCs, one pesticide (dieldrin), and PCBs. Contaminants exceeding the PRGs in Flow Pathway 1B include various inorganics due to historical discharges from Zones 11 and 12 (mercury exceeded the PRG by 28 to 810 percent at six sampling locations), VOC, SVOCs, and pesticides (including aldrin, 4-4'-DDT, and dieldrin). Contaminants which exceeded the PRGs in Flow Pathway 1C include HE (HMX and RDX), various inorganics, SVOCs, pesticides (4-4'-DDT and chlordane),

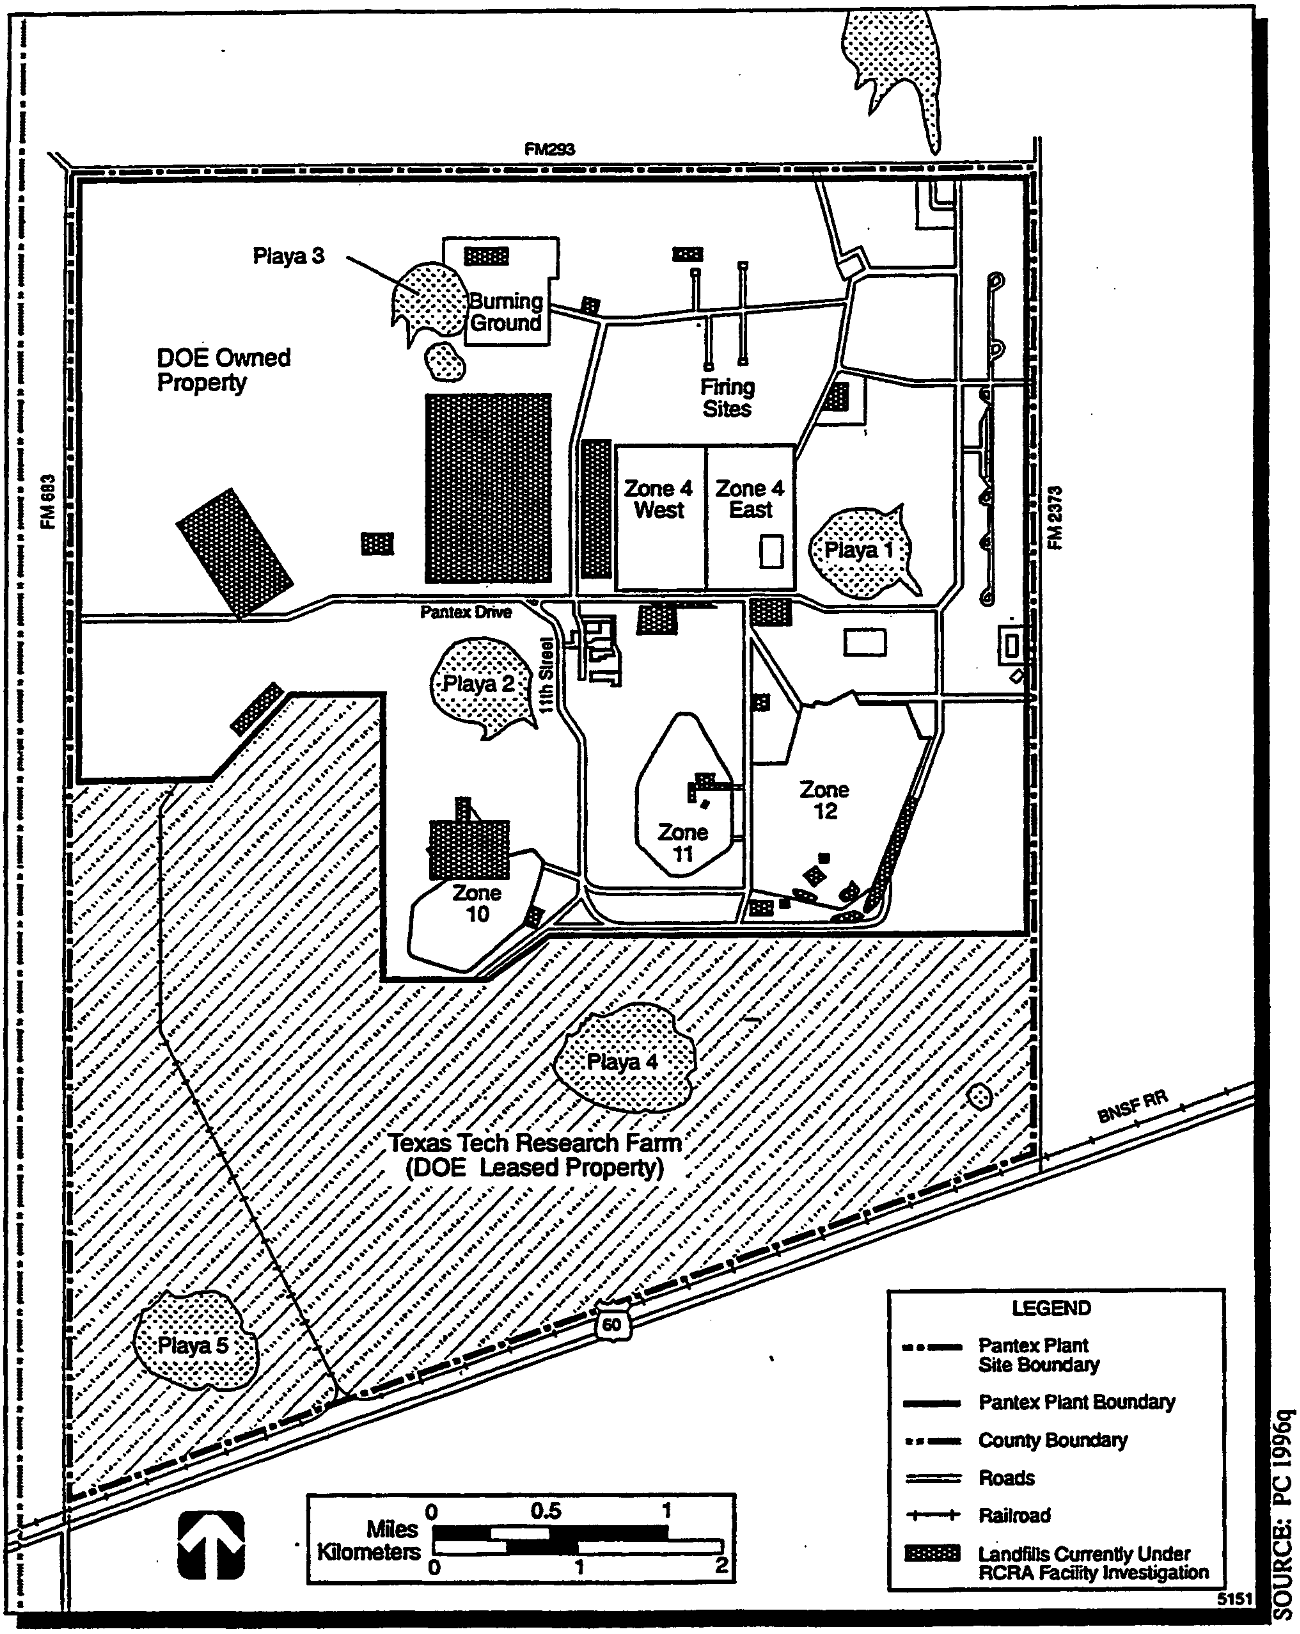

FIGURE 4.5.1.3–4.—*Landfills Currently Under RCRA Facility Investigation.*

TABLE 4.5.1.3–2.—*Summary of Flow Systems 1 Through 5 and Compounds Identified as Exceeding the Decision Criteria in Surface and Subsurface Soils*

FLOW SYSTEM 1	FLOW SYSTEM 2	FLOW SYSTEM 3	FLOW SYSTEM 4	FLOW SYSTEM 5
		DESCRIPTIONS		
Flow system 1 consists of Playa 1 and the unlined, man-made ditches that direct runoff and wastewater discharge away from Zones 11 and 12 to this playa.	Flow system 2 consists of several unlined, man-made ditches that direct runoff and wastewater discharge away from Building 11-50 to Playa 2.	Flow system 3 is composed only of Playa 3.	Flow system 4 consists of several unlined, man-made ditches that direct runoff and wastewater discharge away from Zone 11 and Zone 12 south.	Flow system 5 consists of Pantex Lake and two unlined, man-made ditches that direct runoff and wastewater discharge from the OSTP.

and PCBs. Contaminants exceeding the PRGs in Playa 1 include seven inorganics (the most common was chromium, which exceeded the PRG by up to 250 percent at 15 locations), and two pesticides (4-4'-DDT, and aldrin). Contaminants detected above the PRGs at Flow System 4 include metals, VOCs, pesticides, and HE. The Ditches and Playas RFI recommends additional sampling at many locations within this grouping to further define the horizontal and vertical extent of contamination (USCOE 1995f:Vol. 1 of 5).

The Firing Sites group (AL–PX–09) consists of seven firing sites, located in the north-central portion of Pantex Plant, that have been in operation since 1952. Five of the firing sites are active, and two are currently inactive. The sites have been used for testing of HE in connection with quality control and research and development activities. Some radioactive materials, primarily depleted uranium (DU), were involved in the testing program. Sampling of soil at Firing Sites 4, 5, and 10 is conducted on an annual basis and is discussed in the following section.

The Pantex ER program addresses only inactive sites. Active sites are closed under the RCRA permit process. A request has been submitted to TNRCC to remove the four active firing sites from the Pantex Plant ER program. An ICM is being conducted on FS–5 to remove surface DU contamination. Subsequent confirmation sampling and risk assessment will be conducted at FS–5. Confirmation sampling will be conducted to confirm that protective levels have been attained and NFA will be required. Additional hotspot removal will be conducted until the remediation goals have been achieved. FS–6 and FS–15 contaminant levels were below RRSs and have been proposed to TNRCC for NFA (Pantex 1996:15.3, 15.4; PC 1996b:1).

The Leaking USTs group (AL–PX–10) is comprised of two gasoline release sites near Buildings 12–35 and 16–1. The USTs were used to store gasoline, diesel, and used motor oil. Five USTs were removed in 1988 from Building 12–35, and two USTs were removed from Building 16–1 in 1989. The Draft Final Corrective Action Plan, submitted to TNRCC in October 1994, proposed NFA based on the fact that contaminant levels were below remediation goals. Benzene levels below the site in the perched aquifer exceed RRS and will be addressed in the Zone 12 Groundwater assessment (Pantex 1996:15.4; PC 1996b:2).

The Miscellaneous Explosive/Radiation Sites group (AL–PX–11) consists of 12 sites, including a temporary explosives burning site, radioactive residue storage, a subsurface leaching bed, trinitrotoluene settling pits, two buildings where explosives were filtered from wastewater, and the soil surrounding an explosive fabrication building. Analytical results from soil samples taken in 1985 near the temporary explosive burning site indicate the following: low concentrations of silver and pesticides at 0, 3, and 4 meters (0, 9, and 14 feet); total organic compounds of 22,600 parts per million at the surface. All radioactive waste staged below ground at Pantex Plant was retrieved and disposed of at an approved DOE burial ground. The decontamination of this site consisted of the removal of the buried radioactive waste, as well as any soil that may have been contaminated by the buried material.

Soil samples were taken before and after site cleanup. Tritium, uranium, and plutonium-239 were detected below the trench before cleanup. Soil analyses subsequent to the cleanup revealed low levels of the same radionuclides (Pantex 1994a:12-1 to 12-2; Pantex 1996:15.4). The vertical and lateral extent of contamination are currently being evaluated. Buildings 12–43 and 12–24 North are being evaluated for an in situ explosives treatability demonstration. Recent data indicate that explosive contaminants may be degrading naturally as a result of microbial action. Studies are being proposed to define the degradation mechanism and the potential to enhance the process (Pantex 1996c:54).

Twenty-four sites have been identified at Pantex Plant where spills or releases of chemicals have occurred and are referred to as AL–PX–12, Miscellaneous Chemical Spills and Release Sites. These sites are located within Zones 10, 11, and 12 and areas west of Zone 11. Table 4.5.1.3–3 summarizes the contaminants of concern (COCs) identified in the soil at AL–PX–12. No signs of contamination were found at the main electrical substation (AOC No. 2), and TNRCC granted an NFA on the site in September 1993. The primary COCs for the remaining sites include metals, solvents, pesticides/PCBs, and HE. Characterization data are currently under evaluation. Preliminary results indicate that contaminant levels are below RRS 2 and NFA will be required (PC 1996b:1; Pantex 1996c:54; Pantex 1996:15.4).

Supplemental Verification Sites (AL–PX–13) consists of eight inactive SWMUs, including five landfills, a barren area where herbicides were applied, parallel depressions, and the old pistol range. The pistol range is still in operation and was removed from the ER program. The Zone 10 abandoned landfill was also removed from this grouping and added to the AL–PX–7 Landfills investigations. Diesel fuel residuals, hydrocarbon compounds, and dioxins were all detected below RRSs in an area where herbicides were applied near Playa 1. Low levels of VOCs, SVOCs, and pesticides were detected in the depressions in Zone 11 below RRSs. Phase I fieldwork was completed in 1993. All sites within this grouping are being

TABLE 4.5.1.3–3.—*Summary of Contaminants of Concern Identified in the Soil at AL–PX–12 and Recommendations*

SWMUs/ AOCs	COCs FOR SURFACE SOILS	COCs FOR SUBSURFACE SOILS	RECOMMENDATIONS
Zone 10 SWMUs Scrap Salvage and Storage Yard (SWMU #84)	SVOC- Benzo(b)fluoranthene Pesticides/PCBs- Aldrin, Dieldrin, PCBs (total)	Pesticides/PCBs- Aldrin, Dieldrin, PCBs (total) Metals- Chromium (total), Chromium VI	Additional characterization of PCBs to further define the surface extent.
Former Waste Drum Storage Area (SWMU #143)	SVOCs- Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene Pesticides-Aldrin, Dieldrin Toxaphene PCBs (Total) Metals-Cadmium, Lead*	Pesticides/PCBs-Aldrin, Dieldrin PCBs (Total)	This area has not been characterized to background for several analytical groups, including pesticides, PCBs, and metals. Further sampling is recommended to define the extent of constituents identified as COCs.
Battery Storage Areas Former Battery Storage Area (SWMU #103)	Metals-Cadmium, Lead*	Metals-Selenium	Extent of contamination has been defined. No additional site characterization is recommended.
Battery Storage Area (AOC #14)	Metals-Lead*	None identified.	Extent of contamination has been defined. No additional site characterization is recommended.
Overflows From Building 11-36 Collection Sump (SWMU #113)	HEs-1,3,5-Trinitrobenzene, 2,4,6-Trinitrotoluene Metals-Arsenic, Lead*	SVOCs- Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene Di-benzo(a,h)anthracene Metals-Arsenic, Cadmium, Mercury, Lead*	Additional site characterization is recommended. However, it is recommended that further action be deferred until after operations cease, at which time further characterization will occur and efforts will not be duplicated.
Transformer Leak and PCB Spills Transformer Leak (AOC #1)	Pesticides/PCBs- Aldrin, Heptachlor epoxide, PCBs (Total)	Pesticides/PCBs-Aldrin, Dieldrin, PCBs (Total)	Additional surface soil samples to define the lateral extent of PCBs are recommended.
Main Electrical Substation (AOC #2)			NFA has been granted by the TNRCC and was not considered further in the RFI/Corrective Measures Studies process.
Electrical Equipment Boneyard (AOC #5)	Pesticides/PCBs- Aldrin, Chlordane, Dieldrin, PCBs (Total)	None identified.	Extent of contamination has been defined. No additional site characterization is recommended.

TABLE 4.5.1.3–3.—*Summary of Contaminants of Concern Identified in the Soil at AL–PX–12 and Recommendations*-Continued

SWMUs/ AOCs	COCs FOR SURFACE SOILS	COCs FOR SUBSURFACE SOILS	RECOMMENDATIONS
Capacitor Bank Rupture in Zone 12	PCBs (Total)	None identified.	Extent of contamination has been defined. No additional site characterization recommended.
Former Boiler House Areas (AOC #3) Boiler House in Zone 10	Metals-Lead*	None identified.	Extent of contamination has been defined. No additional site characterization recommended.
Boiler House in Zone 11	SVOCs- Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoranthene, Di-benzo(a,h)anthracene Metals-Mercury, Lead*	None identified.	Additional surface soil analysis using EPA Method 1312 for Synthetic Precipitation Leaching Procedure is recommended to define the lateral extent.
Sulfuric Acid Spills (AOC #7) Oleum Tank at Building 11-36	HE-RDX	None identified.	It is recommended that AOC #7 be considered for NFA, as there is no evidence of a significant release.
Sulfuric Acid Tank near Building 12-4	None identified.	None identified.	This site is recommended for NFA.
Sulfuric Acid Pit at Building 12-64	None identified.	SVOCs- Benzo(a)anthracene, Benzo(b)fluoranthene, Benzo(k)fluoranthene	It is recommended that this site be considered for NFA, as there is no evidence of a significant release.
Various Solvent Leaks (AOC #8) Drum Storage at Pad 11-12/ 11-13	HE-2,4,6-Trinitrotoluene Pesticides/PCBs- Aldrin, Dieldrin, PCBs (Total)	Pesticides/PCBs-Aldrin, Dieldrin, PCBs (Total)	It is recommended that this site be considered for NFA, as there is no evidence of a significant release.
Drum Storage near Building 11-17	Pesticides/PCBs-PCBs (Total), Chlordane, Dieldrin	Pesticides/PCBs-Aldrin, Dieldrin, PCBs (Total)	It is recommended that this site be considered for NFA, as there is no evidence of a significant release.
Drum Storage near Building 11-22	Pesticides/PCBs- Aldrin, Dieldrin, PCBs (Total)	Pesticides/PCBs-Aldrin, Dieldrin, PCBs (Total)	It is recommended that this site be considered for NFA, as there is no evidence of a significant release.
Drum Storage near Building 11-36	SVOC- Di-benzo(a,h)anthracene Pesticides/PCBs- Aldrin, Dieldrin, PCBs (Total)	Pesticides/PCBs-Aldrin, Dieldrin, PCBs (Total)	Extent of contamination has been defined. No additional site characterization recommended.

TABLE 4.5.1.3–3.—*Summary of Contaminants of Concern Identified in the Soil at AL–PX–12 and Recommendations*-Continued

SWMUs/ AOCs	COCs FOR SURFACE SOILS	COCs FOR SUBSURFACE SOILS	RECOMMENDATIONS
Pesticide Releases Pesticide Building 12-43A (AOC #10)	HEs-1,3,5-Trinitrobenzene, 2,4,6-Trinitrotoluene, RDX SVOC-Benzo(a)pyrene Pesticide/PCBs-Chlordane, PCBs (total)	SVOC-Chlordane Pesticides/PCBs-Dieldrin, PCBs (Total)	Extent of contamination has been defined. No additional sampling is recommended.
Pesticide Building 12-51 (AOC #10)	SVOCs-Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(k)fluoranthene Pesticide/PCBs-Chlordane, PCBs (total)	Pesticide/PCBs-Aldrin, Dieldrin, PCBs (total)	Additional site characterization is recommended to define the extent of pesticide contamination. Leachability studies of soils at this site, using EPA Method 1312 for Synthetic Precipitation Leaching Procedure may support NFA.
DDT Release at Building 12-35 (AOC #15)	SVOCs-Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(a)anthracene Pesticide/PCBs-Chlordane, Heptachlor epoxide, PCBs (total)	Pesticide/PCBs-Aldrin, Dieldrin, PCBs (Total)	Additional characterization is needed to define the extent of pesticide contamination, and lateral extent of PCB contamination.
Evaporation Pits/Leaching Beds Evaporation Pits near Building 11-20	Metals-Chromium (Total), Mercury, Lead*	HE-RDX Metal-Lead*	Extent of contamination has been defined. No further characterization is recommended at the Evaporation Pits Near Building 11-20.
Former Leaching Beds near Building 11-36	HE-RDX Metal-Mercury	None identified.	Extent of contamination has been defined. No additional characterization is recommended for this site.
Building 12-5 Sump	SVOCs-Benzo(a)pyrene, Benzo(b)fluoranthene, Benzo(a)anthracene Metals-Chromium (Total), Cadmium, Nickel, Lead*	None identified.	A recommendation has been made to collect additional data to verify that Building 12-5 Sump is the source of contamination and to determine the extent of contamination.

*Lead was eliminated during the toxicity evaluation of the Focused Risk Analysis because there are no published toxicity values in the hierarchy of information sources specified in the Texas Risk Reduction Regulations. However, lead has been treated as a COC at this site because measured concentrations of lead exceed the established background Upper Tolerance Limit values.

Source: USCOE 1995e

considered by the TNRCC for NFA based on the fact that contaminant levels were below remediation goals (Pantex 1996:15.4; Pantex 1996c:55).

AL-PX-14, the USTs at other RFI locations, consists of areas in Zone 12 where five USTs containing diesel fuel and waste oil were removed. Total petroleum hydrocarbons were detected above TNRCC cleanup level of 500 milligrams per kilogram in surface soils at UST-9. All other soil samples collected and analyzed in this unit were within acceptable concentration levels. Phase I fieldwork to remove contaminated soil has been completed and NFA has been recommended for all but UST No. 9. Additional fieldwork will be conducted on this UST, and an in situ treatability demonstration is being conducted (Pantex 1996c:55).

Annual Soil and Sediment Sampling

This section discusses the results of routine and nonroutine (special request) surface soil surveillance at Pantex Plant. The routine soil surveillance program plays an important role in assessing the potential environmental impacts of operations at Pantex Plant. Soil surveillance provides a direct measure of environmental contamination because soil accumulates contaminants that are deposited from the air over time. Thus, soil surveillance allows evaluation of long-term trends. This sampling program is conducted on an annual basis and is separate from the ER programs which deal specifically with SWMU sampling conducted under RCRA and CERCLA as discussed in the previous section.

The following is a summary of the 1994 annual sampling results along with an independent review of these results. The *1995 Environmental Report for Pantex Plant* (Pantex 1996) was released in June 1996. The results from the 1995 annual sampling were reviewed and compared to the 1994 results. A summary of the comparison of sampling results is also included in this section.

Soil quality sampling was conducted in 1994 at 17 offsite and 31 onsite soil surveillance locations at the Burning Ground; Firing Sites 4, 5, and 10; and Playas 1, 2, and 3 (refer to appendix I). One of the offsite sampling areas is at Bushland, approximately 55 kilometers (34 miles) west of Pantex Plant and is considered the control sample. These samples were generally collected from playa bottoms and inter-playa uplands. The soil samples were analyzed for radionuclides, metals, explosives, and VOCs; results are presented in appendix I and summarized below.

Soil samples for radionuclides were collected at Firing Sites 4, 5, and 10; the Burning Ground; Playas 1, 2, and 3; and offsite locations. The samples were analyzed for uranium-234, uranium-238, plutonium-239/240, and tritium.

The average 1994 concentrations of plutonium-239/240 were comparable to Bushland averages, indicating that no plutonium-239/240 contamination from Pantex Plant operations is detectable in area soils. Uranium-238 is the most prevalent radionuclide present in the soils at Pantex Plant. Soils at Firing Site 5 exhibited the highest radionuclide activity, which is attributed to HE test firings with DU components. Firing Sites 4, 5, and 10 have a low uranium-234 to uranium-238 ratio (0.43 or less), indicating DU contamination in these areas.

The Burning Ground, Playas 1 and 3, offsite, and Bushland locations have uranium-234 to uranium-238 ratios near 1.0, indicating that no DU contamination has occurred in these locations. Playa 2 had a uranium-234 to uranium-238 ratio of 0.59, which may indicate DU contamination. Historical averages of uranium-238 and uranium-234 measured at Bushland were 0.74 picocuries per gram and 0.58 picocuries per gram, respectively. The 1994 averages for radionuclide activity at all locations were generally below the historical averages.

Soil samples at the Burning Ground, Playa 3, and Bushland were analyzed for tritium. The average concentrations for tritium were low (0.27 or less) at all locations (Pantex 1996:16.1).

Soil samples for metals were collected at the Burning Ground, Playa 3, and offsite locations. The samples were analyzed for aluminum, boron, cadmium, chromium, cobalt, copper, magnesium, manganese, molybdenum, mercury, nickel, silver, and zinc. All metals were below TNRCC RRS (cleanup levels) and EPA Region III-Risk Based Concentrations (RBCs) with the exception of manganese, which was above RBCs for residential soil. However, manganese concentrations were within the upper limit of background for surface soil (600 milligram/kilogram), with the exception of P3-SS-01 which was slightly higher (640 milligram/kilogram) (DOE 1995b:12-17). All the metals listed above were below industrial standards. RBCs were used for comparison because cleanup levels for manganese do not exist. RBCs are not enforceable standards.

Soil samples for explosives were collected at the Burning Ground, Playa 3, and offsite locations. The samples were analyzed for HMX, RDX, pentaerythritoltetranitrate, and trinitrotoluene. The majority of samples did not have detectable amounts of explosives. Samples that were above detection limits were all below cleanup levels and RBCs (DOE 1995b:12-20, 12-21).

Soil samples collected at Playa 3 and offsite locations were analyzed for VOCs. VOCs were not found at levels above the minimum detection limits (DOE 1995b:12-6). The results of the soil sampling at Pantex Plant and offsite locations do not indicate that deposition of emissions from the Burning Ground activities have substantially impacted the soils.

Average 1995 tritium concentrations were statistically greater than 1994 averages, but were similar to that observed in the control locations. Both uranium 234 and uranium 238 at the Burning Ground were statistically less than the 1994 average concentrations for the same sites. Uranium-234 and uranium-238 at the playa locations were similar to the 1994 ranges of concentrations for the same sites. As in the past, uranium-238 concentrations at the firing sites were higher than concentrations of other radionuclides at Pantex Plant. These higher levels are attributed to the use of DU during test firings of explosives, which ceased in 1986.

The firing sites are scheduled to undergo investigation and remediation under the ER program, and remedial activities have already begun in the area of Firing Site 5. Monitoring data for 1995 are within historic ranges for uranium-238 and uranium-234 at the three firing site areas where samples were collected. Average 1995 concentrations of plutonium-239/240 at all onsite and offsite locations were equivalent to historical and control location averages, indicating no detectable plutonium contamination from Pantex Plant in area soils (Pantex 1996c:12.0).

Results in 1995 for metals at onsite locations were within the expected ranges of concentrations for their soil types, with the exceptions of boron at BG–SS–05, manganese at several Burning Ground locations (BG–SS–01, BG–SS–06, BG–SS–07, BG–SS–08, and BG–SS–09), and zinc at BG–SS-01 (Pantex 1996c:12.0).

Overall soil monitoring results for 1995 were within the observed ranges of concentrations for uncontaminated soil and comparable to historical results and those for the control locations. Boron, manganese, zinc, HMX, and total xylene concentrations in the area of the Burning Ground were higher than those at the control locations and the range of concentrations for native uncontaminated soil.

However, all observed concentrations were less than those considered to indicate environmental risk. Concentrations of these compounds will be carefully monitored to document any trends during 1996 (Pantex 1996c:170).

4.5.2 Impacts of Proposed Action

4.5.2.1 *Impacts of Continued Operations*

Weapons Related Activities

Pantex Plant is located on the northern portion of the Southern High Plains on relatively flat topography. Although erosion is an active process along the northern, eastern, and western margins of the Southern High Plains, it occurs at a rate of only 0.11 meters (0.36 feet) per year. This rate would result in a 1.1-meter (3.6-foot) retreat of the Southern High Plains over 10 years. Weapons-related activities which are mostly confined to Zone 12 and Zone 4 do not result in soil erosion. Some soil erosion occurs as a result of agricultural activities on Pantex Plant Site, but these impacts are considered minimal and similar to the rate experienced in the Southern High Plains in general.

Salt dissolution is another active process in the High Plains area. However, no surficial expression of sinkholes or fractures associated with salt dissolution have been identified in Carson County (Gustavson 1981:10). Potential impacts due to subsidence (resulting in sinkholes and/or surface rupture) are considered negligible, because salt dissolution is a slow process relative to human activities (Gustavson 1980).

There are no capable faults identified beneath Pantex Plant. Holocene faulting, however, has occurred on one portion of the Amarillo Wichita-Uplift structure (the Meers fault in Oklahoma) and may have occurred on another part of the same structure in Potter County. This fault is considered to be capable, as defined in 10 CFR 100 Part A. The Wichita-Ouachita Zone includes the Amarillo Uplift and a surrounding Residual Events Zone that includes Pantex Plant Site. Estimated magnitudes for the maximum earthquake for the Amarillo Uplift and the Residual Events Zone are Richter magnitudes of 6.3 and 5.3, respectively.

The maximum credible earthquake of 6.3 magnitude on the Richter scale occurring within a distance of 16 kilometers (10 miles) of Pantex Plant is considered to be an infrequent event having an annual probability of occurrence on the order of 10^{-3} to 10^{-4} (Pantex 1996:3.5). The damage due to an earthquake to facilities at Pantex Plant would be dependent on the distance from the facilities to the center of the earthquake, the soil structure beneath the facilities, and the construction of each facility. Damage to facilities may or may not cause a release of materials that could result in health impacts. The potential health impacts from accidental releases of contaminants associated with geological hazards and ability of storage facilities to withstand seismic events are discussed in section 4.14, Human Health.

Releases to the soil from continued operations would result from regulated wastewater discharges, deposition from the Burning Ground emissions, and construction activities. As discussed in section 4.5.1, soil sampling at the Burning Ground does not show any contamination above regulatory action cleanup levels. Significant impacts to the sediments and soils would not occur under normal conditions because the Wastewater Treatment Facility has the capacity to treat wastewater generated from weapons related activities (section 4.6) and air emissions have been calculated to be too small to result in a significant impact (section 4.7.2).

Pit Storage Activities

Impacts to pit storage activities due to potential erosion, subsidence, and seismic hazards are the same or less than those addressed for the weapons-related activities. Storage activities do not pose additional impacts to soil and sediment quality under normal conditions because the pits would not come in contact with the soil or sediment. Accident release scenarios are discussed in section 4.14, Human Health.

Environmental Restoration Activities

ER activities pertinent to geology and soils include activities such as soil and sediment sampling, characterization of vertical and horizontal extent of contamination in soils, remediation of soils, and possible removal of contaminated soils. Impacts to the soil as a result of ER activities are predicted to be minimal. Strategies to reduce the amount of waste generated during investigations as well as the amount of waste handled, treated, or disposed of during site cleanups have been implemented. Key points of these strategies include minimizing the amount of waste generated during the RFI by using sonic drilling, hydropunches, geophysical and soil gas survey techniques, and other types of surveys that generate data with minimal waste generation (DOE 1995e:3-7).

Corrective measures will give preference to techniques that do not generate waste or disturb the land's surface topography. Such measures include, for example, in situ bioremediation or capping. Some corrective measures may involve the removal of contaminated soils. In these cases, the waste will be disposed of as described in section 4.13, Waste Management, and excavated areas will be backfilled with clean soil to restore the natural topography. ER activities are expected to be completed by the year 2000. Impacts to soil and sediment at Pantex Plant are expected to be beneficial.

Waste Management Activities

Impacts to soils and sediments at Pantex Plant due to waste management activities are not expected to occur. Waste generated from waste management practices and which come in contact with the sediment and soil are typically nonhazardous. These wastes include treated wastewater from the Wastewater Treatment Facility and construction debris located onsite in a Class 3 landfill. Residuals from the Burning Ground are disposed of in accordance with specifications of the hazardous waste permit. Spills or releases of hazardous wastes and hazardous substances are managed per the Spill Prevention Control and Countermeasures Plan/ RCRA Contingency Plan (TWC 1991a). All of these facilities have the capacity to handle these wastes (sections 4.6, Water Resources, 4.7, Air Quality, and 4.13, Waste Management).

4.5.2.2 *Impacts of New Facility Construction and Upgrades*

Impacts to all new facility construction and upgrades due to potential erosion, subsidence, and seismic hazards would be the same as those addressed in section 4.5.2.1. Temporary soil disturbance for each of the new facilities is summarized in Table 4.5.2.2–1.

During the operations phase of these projects, impacts to the soil and sediment quality would be negligible. Moreover, existing and proposed treatment facilities will have the capacity to handle all discharges associated with the new facilities.

4.5.2.3 *Summary of Impacts*

There are no impacts to geology and soil due to the Proposed Action. Temporary disturbance of soil in Zones 11 and 12 would occur due to construction activities. Potential impacts to the Proposed Action due to erosion and subsidence (resulting in sinkholes or surface rupture) are negligible. The annual probability of the occurrence of a maximum credible earthquake of 6.3 Richter magnitude within a distance of 16 kilometers (10 miles) from Pantex Plant is on the order of 10^{-3} to 10^{-4} (Pantex, 1996:3.5). The potential for a seismic event of this magnitude to result in a release is discussed in section 4.14, Human Health.

4.5.3 Impacts of No Action Alternative

The impacts to geology and soil due to the No Action Alternative are the same or less than those described for the Proposed Action.

4.5.4 Impacts of Pit Storage Relocation Alternative

The Pit Storage Relocation Alternative includes continued operation and maintenance activities at Pantex Plant and transportation and interim storage of pits from Pantex Plant to other DOE and/or Department of Defense facilities. Relocating the pits would not impact the geology and soils at Pantex Plant. There would be no impacts to the soil while pits are stored at Pantex Plant prior to relocation because the pits would not come in contact with the soil under normal conditions. Impacts due to erosion, subsidence, and seismic hazards are the same as those described for the Proposed Action.

4.5.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.5.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

Soil disturbance due to the location of waste management facilities was not addressed in the WM PEIS. However, temporary disturbance of

TABLE 4.5.2.2–1.—*Area of Temporarily Disturbed Soil Due to the Construction of New Facilities*

NEW FACILITY TO BE CONSTRUCTED	LOCATION	AREA OF TEMPORARILY DISTURBED SOIL[1]
Hazardous Waste Treatment and Processing Facility	Adjacent to Zones 11 & 12	5,296 m^2 (57,000 ft^2)
Pit Reuse Facility	Zone 12	987 m^2 (10,628 ft^2)
Gas Analysis Lab	Adjacent to Zone 11	5,073m^2 (54,608 ft^2)
Materials Compatibility Assurance Facility	Adjacent to Zone 11	4,030 m^2 (43,380 ft^2)
Nondestructive Evaluation Facility	Zone 12	7,468 m^2 (80,392 ft^2)
Metrology and Health Physics Calibration and Acceptance Facility	Zone 12	8,948 m^2 (96,312 ft^2)

[1]Area of temporarily disturbed soil is estimated to be twice the floor area of facilities listed above.
Source: PC 1995g:7-10

as much as 21.2 hectares (52.6 acres) could occur during the construction phase. Contamination of the soil and sediments are not expected to occur as a result of construction activities.

The WM PEIS determined that there were no programmatic issues that would affect the selection of alternatives for any waste type at Pantex Plant. Future site-wide or project-specific NEPA reviews would be expected to assess such issues as soil erosion, soil characteristics, etc.

4.5.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur, and there would be no construction. Therefore, impacts to soils are expected to remain the same as those from current operations. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Consequently, no significant land disturbance would occur. Under the relocation alternative, decontamination and decommissioning of the facilities would not be expected to have impacts to the soil.

4.5.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. No apparent direct or indirect effects on the geologic resources are anticipated, because neither facility construction and operational activities nor site infrastructure improvements would restrict access to potential geologic resources. Soil impacts during operation are expected to be minimal.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on choosing the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, MOX fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

No apparent direct or indirect effects on the geologic resources are anticipated, because neither facility construction, operational activities, nor site infrastructure improvements would restrict access to potential geologic resources. The soil erosion potential from direct and indirect impacts associated with construction and operational activities is low for Pantex Plant.

4.5.6 Potential Mitigation Measures

Since there are no impacts to geology and soils, no mitigation measures are required. DOE may choose to implement one or more of the following measures to mitigate the temporary disturbance to soils during construction activities. These measures include erosion control measures such as application of commercial dust suppressants, wind fences for particulates greater than 10 micrometers, sediment traps, diversion of surface water runoff from areas of construction, dikes, silt fences, or covering the disturbed area with rip rap.

4.6 WATER RESOURCES

4.6.1 Affected Environment

This section describes the water resources at and in the vicinity of Pantex Plant. The discussions include identification of prominent surface water features, hydrologic characteristics, floodplains, baseline surface water quality, surface water usage, and surface water rights and permits. Also included are discussions of hydrogeologic characteristics of unsaturated materials and water-bearing units (aquifers); baseline groundwater quality of regional and local aquifers; onsite and offsite groundwater usage; and groundwater rights, agreements, and allocations.

The Region of Influence (ROI) for water resources includes Pantex Plant and the surrounding area that could be impacted by plant operations. The ROI for surface water is the onsite playas and ditch system, and the floodplains delineated by the U.S. Army Corps of Engineers (COE), as discussed in section 4.6.1.1. The ROI for the perched aquifer is based on the extent and migration of contaminants, and is discussed in detail in section 4.6.1.2. Although the ROI for the Ogallala aquifer has not been quantifiably defined, it includes the recharge area and is limited by the extent of drawdown in Pantex Plant wells. The ROI for the Ogallala aquifer is graphically depicted in Figure 4.6.1.2–1.

The discussion of water quality, while including naturally occurring compounds, is mainly concerned with the existence of, and potential for, contamination. Pantex Plant operations have been ongoing since 1951. Over the years, wastes generated from site-related production activities were released, or discharged, at the ground surface to soils, sediment, and surface water. Infiltrating rainwater, stormwater runoff, and other water discharged on the ground surface has moved the contaminants resulting from past discharges downward toward the groundwater. As a result, contaminants that were released at the ground surface over the past 40 years have moved downward and affected the water quality in the uppermost water-bearing zones, known as perched aquifers, where they exist beneath Pantex Plant. DOE is investigating the potential for contaminant migration to the Ogallala aquifer from Pantex Plant in homestead wells that are located southeast of the plant boundary.

Although the low levels of high-explosive(s) (HE) contamination have been detected in a domestic Ogallala well located on private property southeast of Pantex Plant proper, efforts to mitigate further contamination have been completed. The well in question has been properly plugged and sealed under the supervision of TNRCC and a replacement Ogallala well has been drilled and completed in order to prevent further potential cross-contamination of the Ogallala aquifer. Pantex Plant's Groundwater Protection Project addresses these and future steps to assure the integrity of offsite groundwater quality (section 4.6.1.2) (MH 1996a).

Since the late 1980's, wastestreams (liquid and solids) generated in the actual production activities at Pantex Plant have been reworked to greatly reduce the amount of contaminants in current discharges. As a result of enhanced industrial wastewater treatment practices, the potential for surface water contamination from wastewater discharges has been greatly reduced. Pantex Plant has worked very closely with Environmental Protection Agency (EPA) Region 6 and TNRCC to produce wastewater discharge permits (EPA National Pollutant Discharge Elimination System [NPDES] Permit No. TX-0107107 and TNRCC Wastewater Discharge Permit No. 02296) that provide stringent wastewater discharge requirements that are protective of human health and the environment. Pantex Plant's Environmental Protection Department conducts environmental monitoring on a routine basis. The results of environmental monitoring activities are summarized and presented in annual environmental reports that are available to the public.

The potential spread of the contamination in the groundwater from historical site-related activities is influenced by the physical and chemical characteristics of the soil and the underground materials, the presence and flow of groundwater, and the remediation efforts that are planned or underway. This section describes these factors and existing water contamination.

4.6.1.1 *Surface Water*

Hydrology

There are no streams or rivers at or in the vicinity of Pantex Plant; all site water needs are met by groundwater (DOE 1995k:4-292). Six playas are associated with the Pantex Plant Site. Playas 1 through 3 are located on Pantex Plant proper. Playas 4 and 5 are on the property DOE leases from Texas Tech University (TTU). Playa 1 contains water throughout the year. Playas 2 through 5 are dry most of the year. Pantex Lake (the sixth playa) is located approximately 4 kilometers (2.5 miles) northeast of the main site. Pantex Lake does not receive runoff from the plant and is dry most of the year. The only major stream in the area is the Canadian River, which is located approximately 40 kilometers (25 miles) north of Pantex Plant. Since surface runoff at the plant flows into local playa basins, the Canadian River is not affected by activities at Pantex Plant. Most of the surface drainage within the plant is directed to the playas via several major drainage ditches, as shown in Figure 4.6.1.1–1.

Playa 1 receives continuous discharges from the Pantex Plant Wastewater Treatment Facility (WWTF). Only in the ditch running from the WWTF to Playa 1 does flow occur throughout the year, at approximately 950,000 liters (250,000 gallons) per day (Pantex 1996:5.2.2, 5.2.3). All effluents from plant operations are treated and, along with some noncontact industrial discharges, are directed into ditches that drain into Playas 1, 2, and 4 (Pantex 1996c:111). Playa 3 receives stormwater runoff from the Burning Ground. Current Pantex Plant activities do not involve Playa 5 or Pantex Lake. However, wastewater from Pantex Plant was discharged to Pantex Lake from 1942 through 1987. Playa 5 has received wastewater from numerous sources other than Pantex Plant in the past (Pantex 1989:223).

Playas are a significant part of the surface and subsurface hydrologic systems at Pantex Plant. All playas at the site receive stormwater runoff from the Pantex Plant vicinity. The playas have also been identified as possible sources of focused recharge to the groundwater flow system at Pantex Plant. Unlined ditches have been used to convey wastewater and stormwater in the past. This practice continues today; however, the water quality and outfalls are subject to the conditions of surface water discharge permits and permit limits. Unlined ditches transmit treated waters or stormwater from discharge points at Pantex Plant to Playas 1, 2, and 4. These unlined ditches and areas away from the ditches are believed to be additional sources of groundwater recharge (Pantex 1996:4.5.1). Recharge to the area aquifers is not fully understood. Investigations of the ditches and playas, related to the potential for contamination, are being performed through the Pantex Plant environmental restoration (ER) program. Current corrective measures include preventing further migration of contamination by identifying and removing contaminated soils along the ditches to Texas Risk Reduction Standards (RSS) (Stroller 1996:1-1).

Floodplains

Floodplains at Pantex Plant were delineated by the Tulsa Office of COE in accordance with Executive Order 11988 (EO 11988:804; 44 FR 1022:B.7-2). This assessment also fulfills the environmental review requirements under *Compliance with Floodplain/Wetlands Environmental Review Requirements* (10 CFR 1022). Although not formally stated there, the Notice of Intent to prepare this EIS (59 FR 26635) was the Notice of Floodplain/Wetlands Involvement. Locally intense rainfall can cause stormwater runoff and ponding in the playa basins (LLNL 1988:3-1). The COE delineated floodplain boundaries for Playas 1 through 4, Pantex Lake, and Pratt Lake (located north of Pantex Plant), using criteria for 100-year, 500-year, and Standard Project Flood boundaries. Detailed floodplain delineations at Pantex Plant are shown in Figure 4.6.1.1–2. Flood frequencies and their corresponding peak flood elevations as calculated by COE are provided in Table 4.6.1.1–1.

Except for Playa 3, the floodplains are within the drainage boundary for each playa. The 500-year and Standard Project Flood runoff into Playa 3 will overflow out of the drainage basin creating shallow (less than 30 centimeters [1 foot]) flooding of the drainage basins for Playas 1 and 2 (DOE 1995c:2). The elevations of the Burning Ground structures were not included in these floodplain studies, but have been included in Table 4.6.1.1–1 for informational purposes. The only structures that currently exist above land surface at the Burning Ground are the explosive burn trays (USCOE 1995:2-6, 2-7). These structures have a height of 0.6 meters (2 feet) above ground surface and an approximate surface elevation of 1,089 meters (3,572 feet) above mean sea level. The explosive burn trays are outside of the 100- and 500-year delineated floodplains for Playa 3, and are therefore, in compliance with 40 CFR 264.18 (Location Standards for Floodplains).

Surface Water Quality

Surface water monitoring is conducted at Playas 1 through 4 and at Pantex Lake. In addition, offsite surface water quality control samples (used as background samples) were collected from Bushland Playa, located 54 kilometers (34 miles) west of the plant, for comparative purposes (Pantex 1996c:111). Surface water quality sampling was conducted at the locations shown in Figure 4.6.1.1–1 for a full suite of analytical parameters including radionuclides, metals, HE, polychlorinated biphenyls (PCBs), pesticides, herbicides, volatile organics, semivolatile organics, and other miscellaneous constituents and field parameters. Table 4.6.1.1–2 gives the current and historic sources of flow for each monitoring location. Analytical water quality sampling results are presented in volume II, appendix C.

Pantex Plant conducts effluent monitoring at designated sampling locations in accordance with the requirements of the NPDES Permit (EPA 1996) and TNRCC Wastewater Discharge Permit (TNRCC 1996b). Flow from the WWTF is small but continuous. The NPDES Permit specifies a daily average discharge limitation for Outfall 001 of 2.5 million liters (0.65 million gallons) per day. Environmental surveillance monitoring is conducted at the other sampling locations when surface water is present (usually after rainfall). Surface water samples are analyzed for both radiological and non-radiological constituents.

Sampling locations, water quality parameters measured, and sampling frequency may change from one year to the next. Detailed information on surface water quality monitoring is summarized in annual environmental reports prepared for Pantex Plant. Results from 1994

Sources: Pantex 1996:5.4; DOE 1996c:112

surface water sampling confirm that Pantex Plant was in compliance with all regulations regarding discharge water quality (DOE 1995b:11-1, 11-35). There were no exceedances of the Quality Levels for Inland Waters as established by 30 TAC 319.29 (Pantex 1996c:150). With the exception of a high water level in Playa 1 in May and June 1995 due to rainfall events, all the requirements of the TNRCC Permit No. 02296 were met (Pantex 1996c:150). The high water level does not present a problem to the environment or human health.

Surface water quality samples from 1994 and 1995 that were tested for radionuclides were less than the DOE derived concentration guides for ingested water established by DOE for radiation protection of the public and the environment (DOE Order 5400.5). DOE is self-regulating with respect to standards and requirements for radiation. The *Atomic Energy Act of 1954*, as amended, authorizes DOE to protect public health and safety and the environment in conducting programs, such as Pantex Plant operations. The DOE derived concentration guide values given in DOE Order 5400.5 are reference values for radiological protection programs at operational DOE facilities. Even though no derived concentration guides exist for gross alpha/beta, results indicate that 1995 radionuclide levels in surface water were similar to historical levels, levels at the control location, and levels in water from the Ogallala aquifer. Thus Pantex Plant operations do not affect the radiological content of discharged waters (Pantex 1996c:111).

As at any 50-year old industrial facility, a variety of constituents are occasionally detected at very low concentrations. The semivolatile organic, 3,3'-dichlorobenzadine, and the HEs PETN, RDX, and TNT were detected in surface water quality samples from Playa 1 in 1993, but were not detected in surface water samples collected at this location in 1994. No PCBs, pesticides, or herbicides were detected in 1995. In Outfall 002, the HE HMX (0.047 mg/L) was detected in September and the HE RDX was detected in June and July 1995 (0.28 mg/L and 0.13 mg/L, respectively). Water quality data from 1990 through 1994 are summarized in volume II, appendix C.

In addition to the routine surface water monitoring described above and presented in volume II, appendix C, additional surface water, surface soil, and subsurface soil samples were collected as part of the Ditches and Playas Flow System 1 *Resource Conservation and Recovery Act* (RCRA) Facility Investigation (RFI) (USCOE 1994a:ES-4). Surface water samples were collected from Playa 1 (Flow System No. 1). The following five suspected contaminants were identified in the COE Preliminary RFI Report: chromium, lead, phosphorous, 4,4'-DDT, and heptachlor. Of these, only two, lead and phosphorous, were determined to be statistically significant. Elevated lead levels may be associated with the historical routine use of leaded gasoline in plant vehicles. Studies are currently being conducted to establish an industrial background for lead. Elevated phosphorous levels are assumed to be associated with onsite agricultural fertilizer usage.

Surface Water Uses

Playas at TTU Research Farm are periodically used for grazing livestock, but not on DOE-owned property. This is discussed in section 4.4.1.1 (Pantex 1996:5.5). In addition to the grazing operations, some areas of Pantex Plant are cultivated. Water for irrigation is used only on the TTU Research Farm, and when used, it is potable water pumped from the Ogallala aquifer. Water for irrigation of TTU land is pumped from five Pantex Plant wells and is sold to TTU under an interagency agreement between TTU and DOE (PC 1996v). There is no irrigation of DOE property.

Surface Water Discharge Permits

Pantex Plant is required to conduct all operations in compliance with the water resource permits listed in Table 4.6.1.1–3. These permits include NPDES Permit No. TX-0107107, TNRCC Wastewater Discharge Permit No. 02296 as amended, NPDES General Stormwater Discharge Permit TXR00G138, and a *Clean Water Act* (33 U.S.C. 1251) Section 404 Dredge and Fill Permit (EPA 1996; TNRCC 1996b; EPA 1995; USCOE 1994). Each of these surface water permits are discussed below.

NPDES Permit No. TX-0107107. In 1990, Pantex Playas 1, 2, 3, 4, and Pantex Lake were determined to be jurisdictional wetlands by COE, and are therefore considered to be waters of the United States subject to protection by the NPDES. EPA Region 6 NPDES Permit No. TX-0107107 authorizes Pantex Plant to discharge to the waters of the United States, under specified effluent limitations and monitoring requirements (EPA 1996). Pantex Plant discharges treated domestic and industrial wastewater into ditches and Playas 1, 2, and 4 under the terms and conditions of this permit. The discharge from Pantex Plant is directed into four playa lakes adjacent to the watershed of McClellan Creek (about 8 kilometers [5 miles] to the east), which flows into the North Fork of the Red River (Waterbody Segment Code No. 0224 of the Red River Basin). There are no known surface water connections that could transport potential contaminants from Pantex Plant into the Canadian River. Due to the flat, level topography of Pantex Plant, streams are not well developed on the landscape and surface waters drain to the playa basins.

The NPDES permit has daily average and daily maximum effluent volume limitations of 2.5 and 3.1 million liters (0.65 and 0.82 million gallons) per day respectively for Final Outfall 001. Effluent is regulated in the NPDES Permit for the following parameters or chemical constituents at one or more outfalls:

- *Metals* - antimony, arsenic, beryllium, cadmium, chromium, cobalt, copper, cyanide (total and amenable), lead, manganese, mercury, molybdenum, nickel, selenium, silver, thallium, titanium, and zinc;
- *HEs* - HMX, RDX, PETN, and TNT; and
- ***Miscellaneous Water Quality Parameters*** - ammonia, biochemical oxygen demand, chemical oxygen demand, oil and grease, pH, total suspended solids, and total dissolved solids.

TABLE 4.6.1.1–3.—*Water Resource Permits Issued to Pantex Plant*

Sources: Pantex 1996c:15; EPA 1996; TNRCC 1996b; EPA 1995

Effluent permit limits vary per outfall. Specific NPDES permit requirements are tabulated in volume II, appendix C (Table C.1.2–2). The requirements and limitations specified in this NPDES permit formed the basis for amendments to TNRCC Permit 02296.

TNRCC Permit No. 02296. Historically, Pantex Plant discharged treated domestic and industrial wastewater into ditches and Playas 1 and 2 under the terms and conditions of TNRCC Wastewater No-Discharge Permit 02296, first issued on May 19, 1980 and renewed and modified on May 3, 1988. The term "No Discharge" referred to the playa lakes at Pantex Plant not being considered waters of the State of Texas by the State at the time of permit issuance. Recently TNRCC Permit 02296 was amended (effective June 14, 1996) and generally reflects the same effluent limitations and requirements as the EPA Region 6 NPDES Permit that became effective on June 1, 1996.

Pantex Plant has worked very closely with EPA Region VI and TNRCC to produce wastewater discharge permits (EPA NPDES Permit No. TX-0107107 and TNRCC Wastewater Discharge Permit No. 02296) that provide stringent wastewater discharge requirements that are protective of human health and the environment. The Pantex Plant wastewater discharge permit limits meet or exceed all current regulations that apply to surface water. Since the State of Texas applies regulations through the concentration limits specified in permits, the decision criteria for surface water compliance is based on the permit limits established in the NPDES Permit and Wastewater Discharge Permit for Pantex Plant. EPA and TNRCC determined which constituents would have reporting requirements and/or permit limits specified in the NPDES and Wastewater Discharge permits based on a review of the most recent surface water quality data available for the main outfalls and internal outfalls. The most recent analytical data at the time of regulatory review were from 1993. TNRCC calculated effluent limitations that were based on the Texas State Surface Water Quality Standards (Title 30 TAC 307). The actual effluent limitations, cited in the permits, are more stringent than those calculated by TNRCC and reported in its Fact Sheet (TNRCC 1995a). As stated in the NPDES Permit, EPA has accepted the statistical calculations provided by Pantex Plant and has established metal limitations on a case-by-case basis through best professional judgment under 402 (a) of the *Clean Water Act* for best available technology economically available.

The Pantex Plant Environmental Protection Department conducts environmental monitoring to assure that all regulated surface water outfall discharges are in compliance with the established permit limits. In addition to the constituents that are regulated in the permits, the Pantex Plant Environmental Protection Department also has conducted analyses for the following constituents that were not specified in the permit: nitrite, strontium, vanadium, 4-methylphenol, 3,3-dichlorobenzidine, acetone, benzoic acid, chloroform, ethylbenzene, methylene chloride, phenol, toluene, xylene, boron, and tin. By monitoring for these additional constituents, Pantex Plant is providing additional assurance that any changes in chemical constituents and their relative concentrations are protective of human health and the environment.

TNRCC Wastewater Discharge Permit No. 02296 (as amended) requires that within one year of the effective date of the permit (June 14, 1996), Pantex Plant must conduct a study (which is currently underway) that determines the feasibility of eliminating or minimizing discharges to playa lakes and open ditches or improving the quality of discharge. According to the permit, the study should, at a minimum, include the following proposals:

- Upgrading existing treatment facilities or constructing new treatment facilities to ensure no groundwater quality effects from discharges to playa lakes and ditches;
- Constructing synthetically-lined impoundments to confine treated effluent and a closed collection system from all process areas to the treatment facilities;
- Establishing an irrigation disposal site and accompanying disposal practices plan to eliminate discharges to the playa lakes;
- Establishing a reuse and conservation program for all process wastewaters, thereby eliminating any industrial effluent discharge to the playa lakes and ditches; and
- Developing a schedule for completion of proposals or any other proposals deemed feasible by the permittee.

NPDES General Stormwater Discharge Permit TXR00G138. EPA issued a Stormwater General Permit Coverage Notice on February 15, 1995. Additionally, Pantex Plant has filed Notices of Intent for Stormwater Discharge Associated with Construction Activities for individual construction projects that disturb 2 hectares (5 acres) or more.

***Clean Water Act* Section 404 Dredge and Fill Permit.** This permit, issued by COE, was required for previous field activities conducted for hydrogeologic site characterization. Since these site characterization efforts have concluded, the permit was allowed to expire without renewal.

4.6.1.2 *Groundwater*

Assessment of the affected environment for groundwater resources consists of the following factors. Hydrogeologic properties are characterized to determine the presence and flow characteristics of aquifers, or water-bearing units, beneath Pantex Plant. The physical and chemical properties of soils and subsurface sediments, coupled with the occurrence and flow characteristics of the aquifers, are controlling factors in determining how potential contaminants discharged at the ground surface can migrate into subsurface materials, the presence or probable absence of contamination in groundwater, and the potential for contaminant movement in or between aquifers.

Characterization of the existing (baseline) water quality is necessary to determine the current extent of contamination and to determine how the actions proposed in this EIS may impact the current water quality conditions. The potential impacts to the existing water quality from the Proposed Action are discussed in section 4.6.2. It is important to note and to distinguish between the existing water quality conditions that have been affected by over 40 years of Pantex Plant operations and the associated waste generation versus the water quality of treated wastewater discharges that are currently entering the system.

Past discharges contained what is regarded under today's standards as unallowable amounts of contamination. Since 1980, wastestreams generated from the production activities have been reworked to greatly reduce the potential for contaminants to be discharged. As discussed in section 4.6.1.1, surface water discharge permits have been in effect since 1980, and all future discharges that occur at Pantex Plant will need to be in compliance with the plant's TNRCC and EPA permits. Current groundwater uses and groundwater rights and permits are discussed to provide a general background of groundwater availability and will be used for assessment of impacts in section 4.6.2.

Hydrology

Groundwater provides the primary water supply for the High Plains area, a major agricultural region of the United States. The High Plains aquifer, commonly called the Ogallala aquifer, underlies the whole of the Texas Panhandle and the South Plains, as well as parts of New Mexico, Oklahoma, Colorado, Kansas, Nebraska, Wyoming, and South Dakota. The Ogallala aquifer is the principle aquifer and major source of water in the vicinity of Pantex Plant and the surrounding ROI. The locations of private and municipal supply wells in the vicinity of Pantex Plant are shown in Figure 4.6.1.2–1. A hydrogeologic feature that occurs locally at and in the vicinity of Pantex Plant are perched aquifers; these features form due to the presence of low-permeability materials that impede and may even prevent the downward migration of infiltrating water (Pantex 1996:4.1). Perched groundwater in Zone 12 is the uppermost water-bearing unit that has been affected by Pantex Plant activities.

Hydrogeologic site characterization activities to establish baseline conditions are underway as a component of the site's ongoing ER program. The Texas Bureau of Economic Geology (Texas A&M University) conducted extensive characterization studies at Pantex Plant from 1990 to 1995. Recent and ongoing hydrogeologic field investigations currently are being conducted by Battelle-Pantex and Argonne National Laboratory. These field investigations include the installation of several new wells and test borings, the collection of additional groundwater level measurements, aquifer testing, and groundwater quality sampling. The locations of existing Pantex Plant wells are shown in Figure 4.6.1.2–2. A north-south trending hydrogeologic cross-section is shown in Figure 4.6.1.2–3.

Pantex Plant is underlain by the following hydrogeologic units (from the ground surface downward), as shown in Figure 4.6.1.2–3:

- Unsaturated sands and clays of the Blackwater Draw Formation and upper Ogallala Formation.
- Discontinuous perched aquifers in the upper Ogallala Formation.
- The thick, extensive regional Ogallala aquifer in the lower Ogallala Formation.
- The Dockum Group.

Unsaturated Zone

The unsaturated zone consists of surface soils (generally consisting of Pullman soils on the plains and Randall soils in the playas); Blackwater Draw Formation soils, playa sediments, sands, silts, clays, and gravels; and the discontinuous upper Ogallala Formation Caprock caliche (cemented sediments) that is interbedded with sands, silts, clays, and gravels (Pantex 1996:4.2). Caliche layers, including the Caprock Caliche at the boundary between the Blackwater Draw and the Ogallala Formations, appear to vary locally in composition and thickness (DOE 1994nn:3-21). Shallow saturated or partially saturated zones occur to depths of 14 meters (45 feet) beneath Playa 2 and the major drainage ditches, and approximately 70 meters (230 feet) above the perched aquifer. The infiltration of surface water (e.g., rainfall, plant discharges) occurs within this unsaturated zone. It is possible that in the past this infiltration might have resulted in vertical migration of contaminants (DOE 1994n:5-2).

Perched Aquifer

The perched aquifers are the uppermost saturated subsurface units capable of producing water in the Pantex Plant area. An expedited site characterization was conducted in 1994 and 1995 to characterize the location, shape or geometry, and depth of the perched aquifer; nature of recharge; and direction of groundwater flow. An expedited site characterization for the Pantex Plant Zone 12 groundwater was conducted to develop a working model of the perched aquifer. Specific

objectives included characterizing the extent of the perched aquifer, nature of groundwater recharge, direction of groundwater flow, groundwater contamination, and identification of potential receptors.

The findings of the expedited site characterization are presented in the *Draft RCRA Facility Investigation Report for Groundwater in Zone 12 at the DOE Pantex Plant* (Argonne 1995a). Data collected during the expedited site characterization were used to predict contaminant movement and to evaluate cleanup options for perched groundwater; the results of this study are reported in *Two-dimensional Groundwater Flow Model and Design Tool for Evaluation of Remedial Options for Perched Groundwater at Pantex Plant* (Battelle 1996a). The primary area of concern in this modeling effort is the perched aquifer underlying Zones 11 and 12 and the area east and southeast of the plant boundary. Additional investigations have been conducted on private property south and southeast of Pantex Plant, under the Pantex Plant Groundwater Protection Project (MH 1996a).

The perched aquifer occurs as localized groundwater mounds that form beneath the playas from focused surface water recharge. Perched groundwater flow is unconfined (i.e., the water table forms the upper boundary of this aquifer). Perched groundwater accumulates in gravel and sand channel deposits at approximate depths of 64 to 88 meters (210 to 290 feet) below the ground surface. These water-bearing buried channel deposits are on top of a zone of fine-grained clays, clayey silts, and sands, as shown in Figure 4.6.1.2–3. The existence of the perched aquifer is dependent on the occurrence of the underlying fine-grained zone, which is of variable thickness, as shown in Figure 4.6.1.2–4. This fine-grained zone has a low vertical hydraulic conductivity that impedes the downward movement of infiltrating groundwater. Vertical hydraulic conductivity measurements for fine-grained sediments ranged from 4.62×10^{-6} to 6.92×10^{-9} centimeters per second (1.31×10^{-2} to 1.96×10^{-5} feet per day) (Texas A&M University 1995a:7).

The perched zone has an irregular surface, and generally occurs 90 meters (300 feet) below land surface (Battelle 1996a:4). Where the fine-grained zone is present, perched groundwater collects in overlying sand and gravel deposits that form subsurface channel features and have a greater permeability than the fine-grained zone deposits. As a result, the buried channel deposits form a conduit for groundwater flow, and groundwater movement follows the course of the buried channel deposits. Variations or heterogeneities in the specific types, grain size distributions, and configurations of subsurface sediments result in preferential subsurface flow.

The changes in the direction and gradient of groundwater flow indicate that the perched aquifer exhibits radial flow from Playa 1. The perched aquifer is thickest beneath Playa 1. The only Pantex Plant playa that contains water throughout the year, Playa 1 is considered to be a source of focused recharge to the perched aquifer. Groundwater in the perched aquifer is considered to flow radially away from Playa 1. As shown in Figure 4.6.1.2–5, the groundwater flow direction in the perched aquifer may be locally to the west, northwest, southwest, and southeast due to radial flow and lithologic changes within the perched aquifer.

The physical boundaries and groundwater flow conditions of the perched aquifer affect the extent and direction of suspected contaminant movement. The groundwater flow direction is primarily to the south and southeast under Zone 12, as shown in Figure 4.6.1.2–5. The perched aquifer is known to extend off the plant site to the east and southeast. Although data suggest that the perched aquifer may extend offsite to the north and to the west, hydraulic continuity is not completely understood due to lack of wells

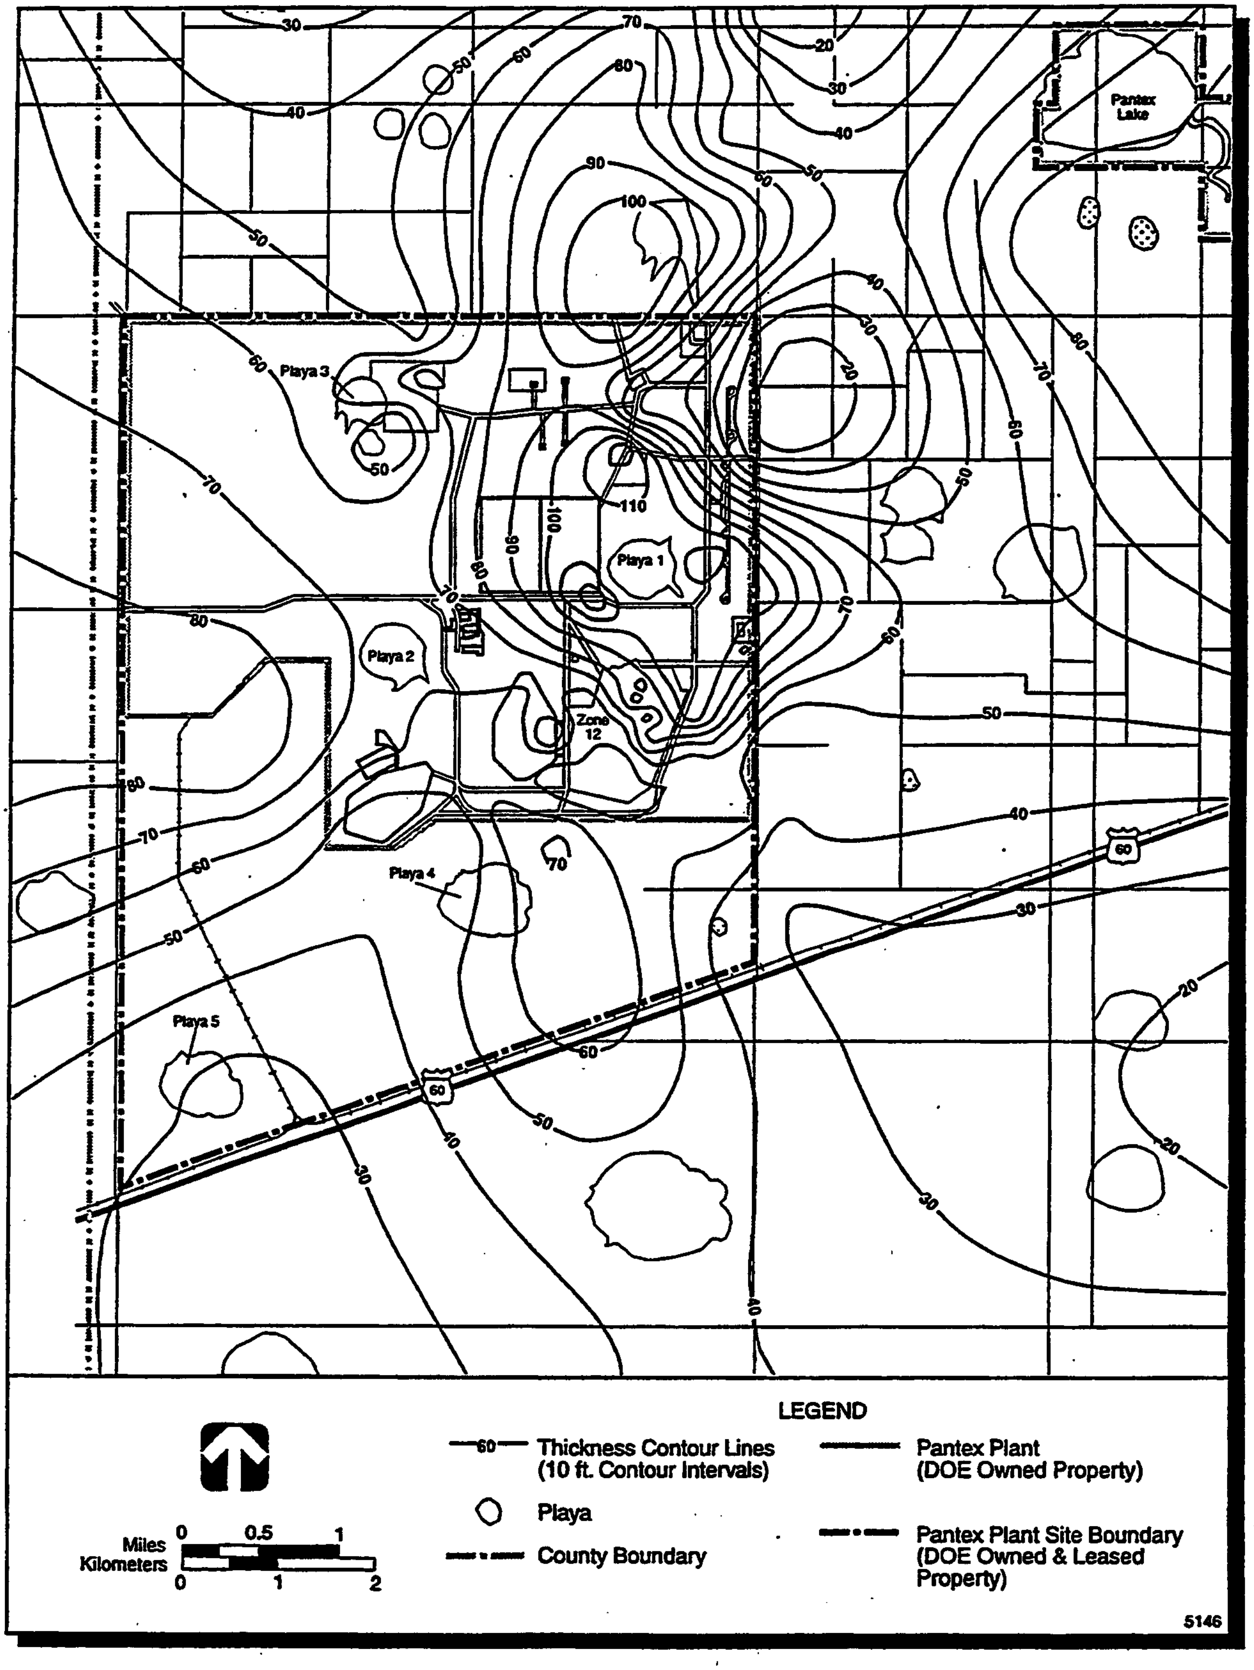

FIGURE 4.6.1.2–4.—*Thickness of the Fine-Grained Zone, Pantex Plant.*

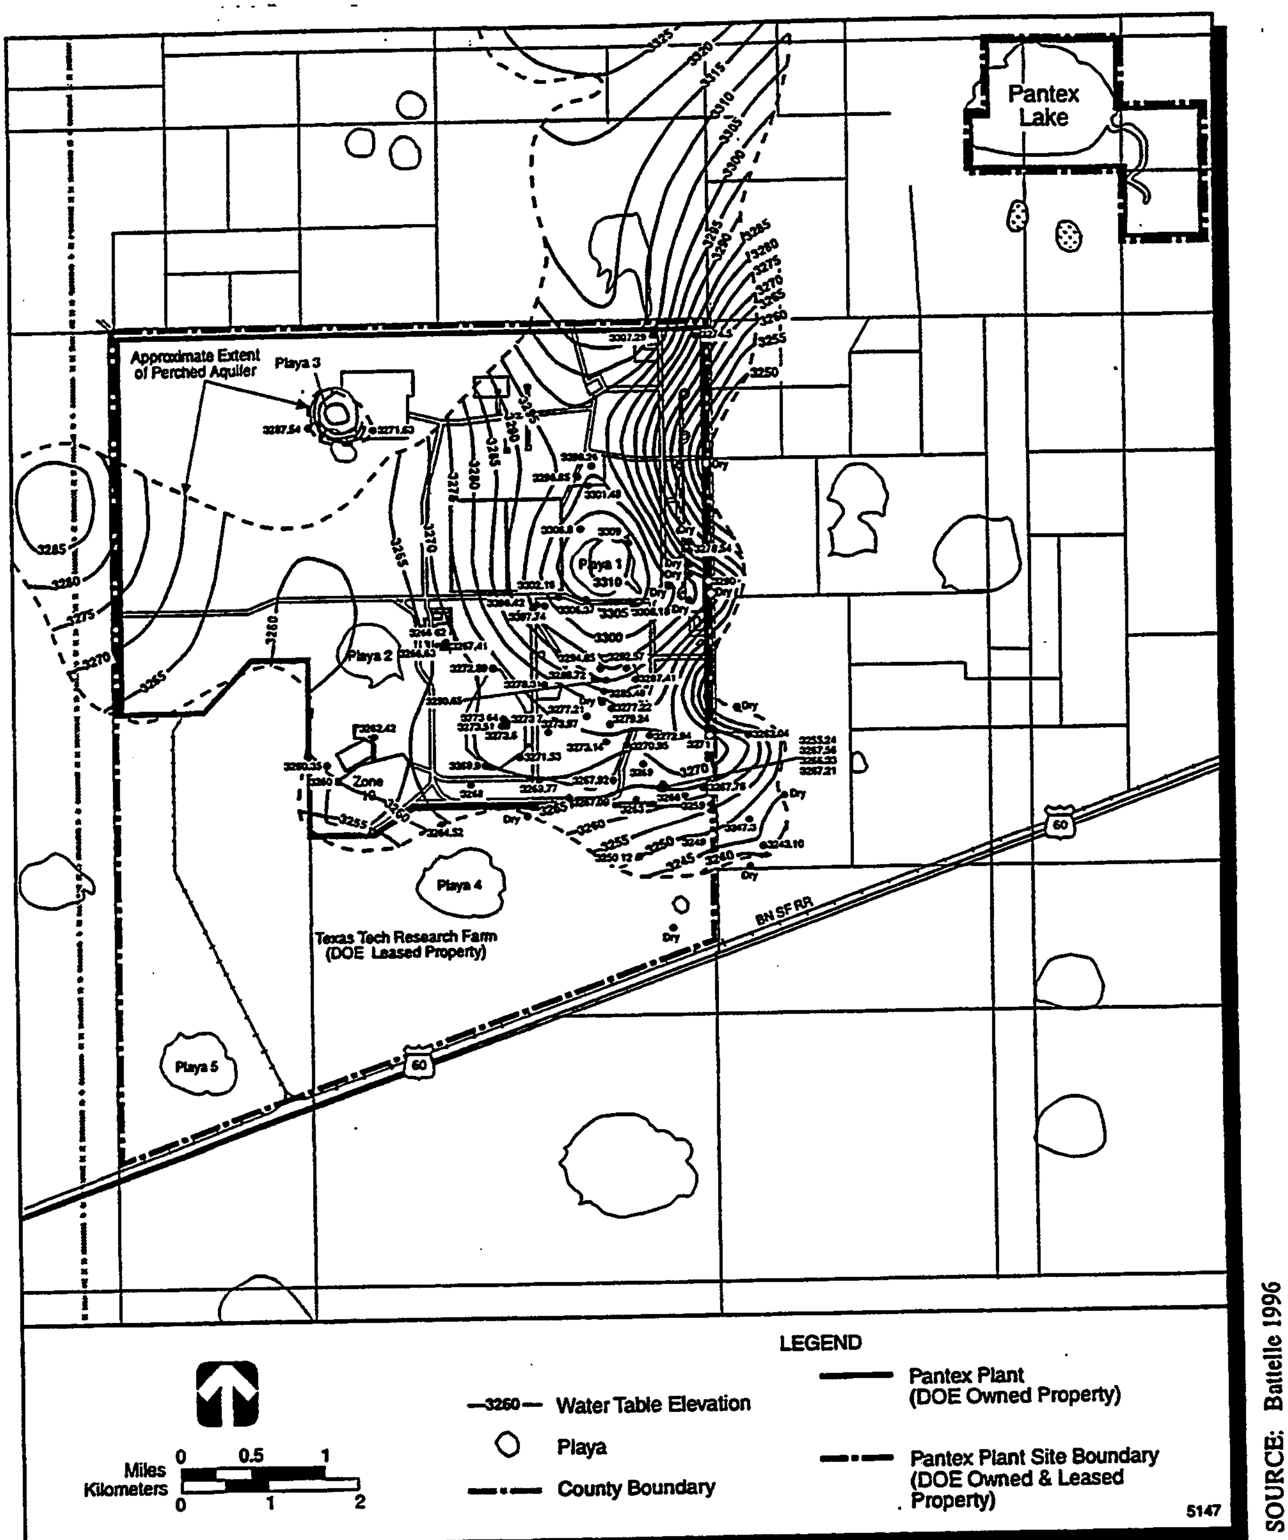

FIGURE 4.6.1.2–5.—*Water Table Contour Map of the Perched Aquifer, Pantex Plant.*

drilled in those areas. Recharge varies laterally between playa, interplaya, and drainage ditch environments.

Although the effectiveness of the fine-grained zone to act as a retardant to vertical groundwater movement is not fully understood, the presence of the fine-grained zone under the perched aquifer probably serves to significantly slow the downward migration of contamination to the Ogallala aquifer while allowing the horizontal spread of potential contamination to be limited to buried channel deposits in the perched aquifer. It is important to note that the perched aquifer is stratigraphically higher (closer to the surface) and not directly hydraulically connected with the underlying Ogallala aquifer. The depth to groundwater ranges from 64 to 88 meters (210 to 290 feet) below land surface in the perched aquifer and from 100 to 140 meters (340 to 460 feet) in the underlying Ogallala aquifer (Figure 4.6.1.2–3).

The rate of groundwater movement, otherwise known as the groundwater velocity, can be calculated from estimates of the following physical hydrogeologic properties: hydraulic conductivity, defined as the estimation of the relative ease of groundwater movement; hydraulic gradient, or slope of the groundwater level; and the effective porosity, or the amount of void space through which groundwater movement can occur. The hydraulic properties have been measured from field and laboratory tests. These properties are used to calculate the rates of groundwater withdrawal and the potential spread of contamination. Aquifer performance tests were used to estimate groundwater velocities.

The results of these aquifer tests are highly variable and are dependent on the testing location, relative heterogeneities in the subsurface sediments from one location to another, duration of the test, variations in testing procedures, and the method of analysis. These variations in aquifer performance testing lead to differences in groundwater velocity estimates. Travel time estimates for groundwater movement in the perched aquifer are provided in Table 4.6.1.2–1. Three estimates are given.

TABLE 4.6.1.2–1.—*Estimated Groundwater Velocities and Travel Times in the Perched Aquifer*

HYDRAULIC PARAMETER	CONSERVATIVE ESTIMATE	REALISTIC ESTIMATE	UPDATED CALCULATION
Hydraulic Conductivity meters/day (feet/day)	24.6 (80.7)	12.3 (40.4)	16.9 (55.6)[a]
Hydraulic Gradient	0.011	0.0071	0.008[b]
Effective Porosity	0.15	0.25	0.34[c]
Linear Velocity meter/day (feet/day)	1.8 (5.9)	0.34 (1.1)	0.06 (0.2) to 0.40 (1.3)
Travel Time (years)	2.1	11	9.5 to 62

[b]Average hydraulic gradient in Zone 12 and east area
[c]Specific yield value from Neuman analysis of PTX06-1017
Sources: Texas A&M University 1995:62; Argonne 1995a:4-19; PC 1996; Pantex 1995K:19, 27

The first two estimates are based on initial onsite aquifer tests conducted in Zones 11 and 12, that assume hypothetical porosity values and a range of hydraulic gradients (Texas A&M University 1995:62, 64, 65). The third estimate is a realistic calculation based on long-duration onsite aquifer testing and field data collected during the Zone 12 Treatability Study in September and October of 1995 (Pantex 1995k).

It should be noted that Texas A&M University's conservative estimate of 1.8 meter (5.9 feet) per day produces a higher velocity than is expected to be generally true. The Texas A&M University report states that a value of 0.34 meter (1.1 feet) per day is more realistic. However, these flow velocity calculations do not include the travel time required for the surface water to percolate through the unsaturated zone or any retarding effects that physical, chemical, or biological processes may have on contaminant transport.

Aquifer performance test data from monitoring wells PTX06–1014 and PTX06–1017, obtained from the Zone 12 Treatability Study, were used to calculate groundwater flow velocities. Perched groundwater in the Zone 12 Treatability Study area moves to the east-southeast, at velocities ranging from 0.07 to 0.49 meter (0.23 to 1.6 foot) per day. Eliminating the outliers yielded a groundwater flow velocity of 0.18 meter (0.6 foot) per day. Similarly, velocities from each Treatability Study well to the pumping well, PTX06–1014 were calculated using the same hydraulic conductivity and water level measurements used in the Treatability Study calculations. Values ranged from 0.009 to 0.07 meter (0.03 to 0.24 foot) per day; eliminating outliers yielded a velocity of approximately 0.06 meter (0.2 foot) per day. From the velocity results, local velocities in the Treatability Study area and the velocities to the Pantex site boundary vary by a magnitude of three. These velocity differences may stem from changes in hydraulic conductivities or, more likely, from lithologic controls and the undulating perched aquifer surface (PC 1996a). Velocities ranging from 0.10 to 0.3 meter (0.32 to 0.96 foot) per day may most accurately characterize perched groundwater movement towards the Pantex Plant boundary in Zone 12 (Argonne 1995a:4-19).

The conclusion drawn from this data is that actual movement of contaminated groundwater offsite, once the contaminants percolate down to the perched aquifer, would require about 10 to 20 years, and may take as long as 50 or more years, to move a contaminant plume offsite using the most current test data described above. Recent investigations have indicated that contaminated groundwater in the perched aquifer has migrated to the eastern plant boundary and has migrated offsite. Because contaminated groundwater does migrate offsite in the perched aquifer, DOE conducted a program, known as the Pantex Plant Groundwater Protection Project, to identify and evaluate abandoned homestead wells and prevent potential pathways of contamination to the Ogallala aquifer. The Groundwater Protection Project, completed in September 1996, involved sealing 5 onsite and 2 offsite homestead wells; drilling 2 offsite wells completed in the perched aquifer and 1 offsite well completed in the Ogallala aquifer; and upgrading existing onsite wells.

If perched groundwater that has exceedances of contaminants of concern (COCs) is used for domestic or agricultural purposes, a potential for human exposure could result (Argonne 1995a:5-37). A groundwater treatability study is currently underway to evaluate perched groundwater treatability and potential reuse of treated water as a Pantex Plant water supply.

Ogallala Aquifer

The Ogallala aquifer underlies the whole of the Texas Panhandle and the South Plains, as well as parts of New Mexico, Oklahoma, Colorado, Kansas, Nebraska, Wyoming, and South Dakota. It is the principal aquifer and the major source of water in the vicinity of Pantex Plant. Groundwater flow directions in the regional Ogallala aquifer in the vicinity of Pantex Plant trend from the southwest to northeast as shown in Figure 4.6.1.2–6. Groundwater movement is unconfined in the Ogallala aquifer. Depth to groundwater in the regional Ogallala aquifer ranges from 104 meters (340 feet) at the southern boundary of Pantex Plant to 140 meters (460 feet) at the northern boundary. The saturated thickness of the Ogallala Formation ranges from 15 meters (50 feet) to more than 120 meters (400 feet) and in some areas is capable of producing yields in excess of 4,000 liters (1,000 gallons) per minute (DOE 1991b:13). A summary of hydraulic parameters measured onsite is presented in volume II, appendix C.

Regional hydraulic conductivity in the Ogallala aquifer ranges from 0.9 to 79 meters (3 to 260 feet) per day. Estimates of annual recharge rates to the Ogallala aquifer vary from 0.02 to 4.1 centimeters (0.01 to 1.6 inches) per year, based on earlier studies that investigated slow regional infiltration of precipitation and recent studies that explored recharge of water through playa lakes and leakage from the Dockum Group aquifer into the Ogallala aquifer (Texas A&M University 1988:16, 25; TWD 1993:6). While these studies support the concept of Dockum recharge to the Ogallala in some areas of the Panhandle, the hydraulic characteristics of the Dockum Group aquifer have not been fully investigated in the vicinity of Pantex Plant. In 1990, the recoverable volume of water in storage and available for use in the Ogallala aquifer was estimated at approximately 5.15×10^{14} liters (1.36×10^{14} gallons) in the High Plains aquifer system (TWD 1993).

Dockum Group

The Dockum Group underlies the Ogallala aquifer and consists of shales, clayey siltstones, and sandstones. Beneath the Dockum Group are Permian salt beds and salt dissolution residues, as discussed in section 4.5, Geology and Soils. Aquifer properties of the Dockum Group near Pantex Plant are highly variable, but generally have low permeability, low average yields of 400 liters (105 gallons) per minute, and poor water quality (high total dissolved solids) relative to the overlying Ogallala aquifer. Near Pantex Plant, however, water quality in the Dockum Group aquifer is relatively good, possibly due to intermixing of waters from the overlying Ogallala aquifer (Pantex 1996:4.3). Several wells near Pantex Plant lie in what is considered the Dockum aquifer and are used for domestic and livestock purposes. However, since the overlying Ogallala aquifer is the primary source of groundwater for the area, pumping in the Ogallala is expected to cause upward groundwater movement from the Dockum Group. Furthermore, leakage from the Dockum Group upward into the Ogallala aquifer has been reported as a potential source of recharge to the Ogallala aquifer (TWD 1993:6).

Groundwater Quality

Assessment of the existing groundwater quality is necessary to establish a baseline, in order to assess the potential for the Proposed Action to impact groundwater resources. It is important to note that this section only describes a water quality "snapshot" of the existing conditions (baseline) of contaminants that were released in the past and have reached the water table. It does not describe the quality of surface water discharge that is currently being released at the ground surface (see section 4.6.1.1, and volume

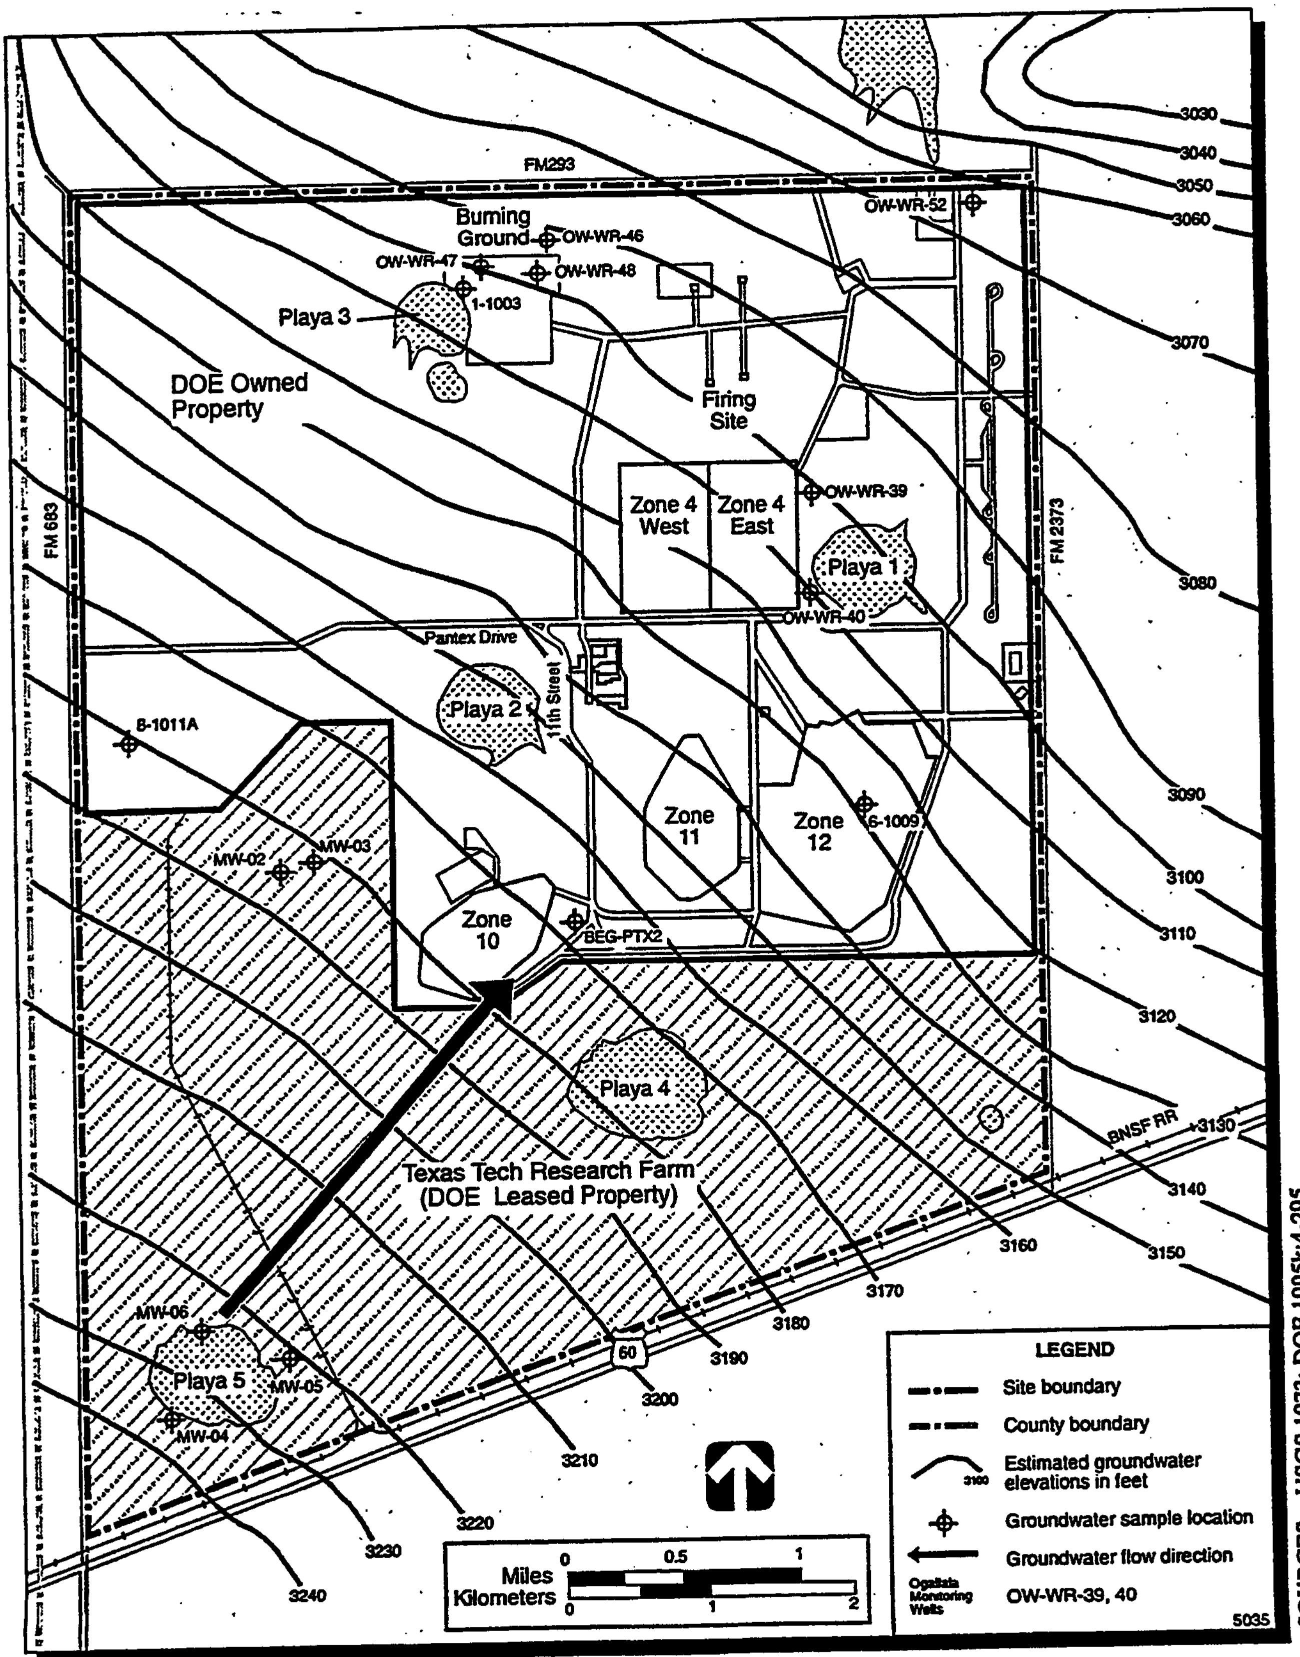

FIGURE 4.6.1.2–6.—*Contour Map of the Ogallala Aquifer, Pantex Plant.*

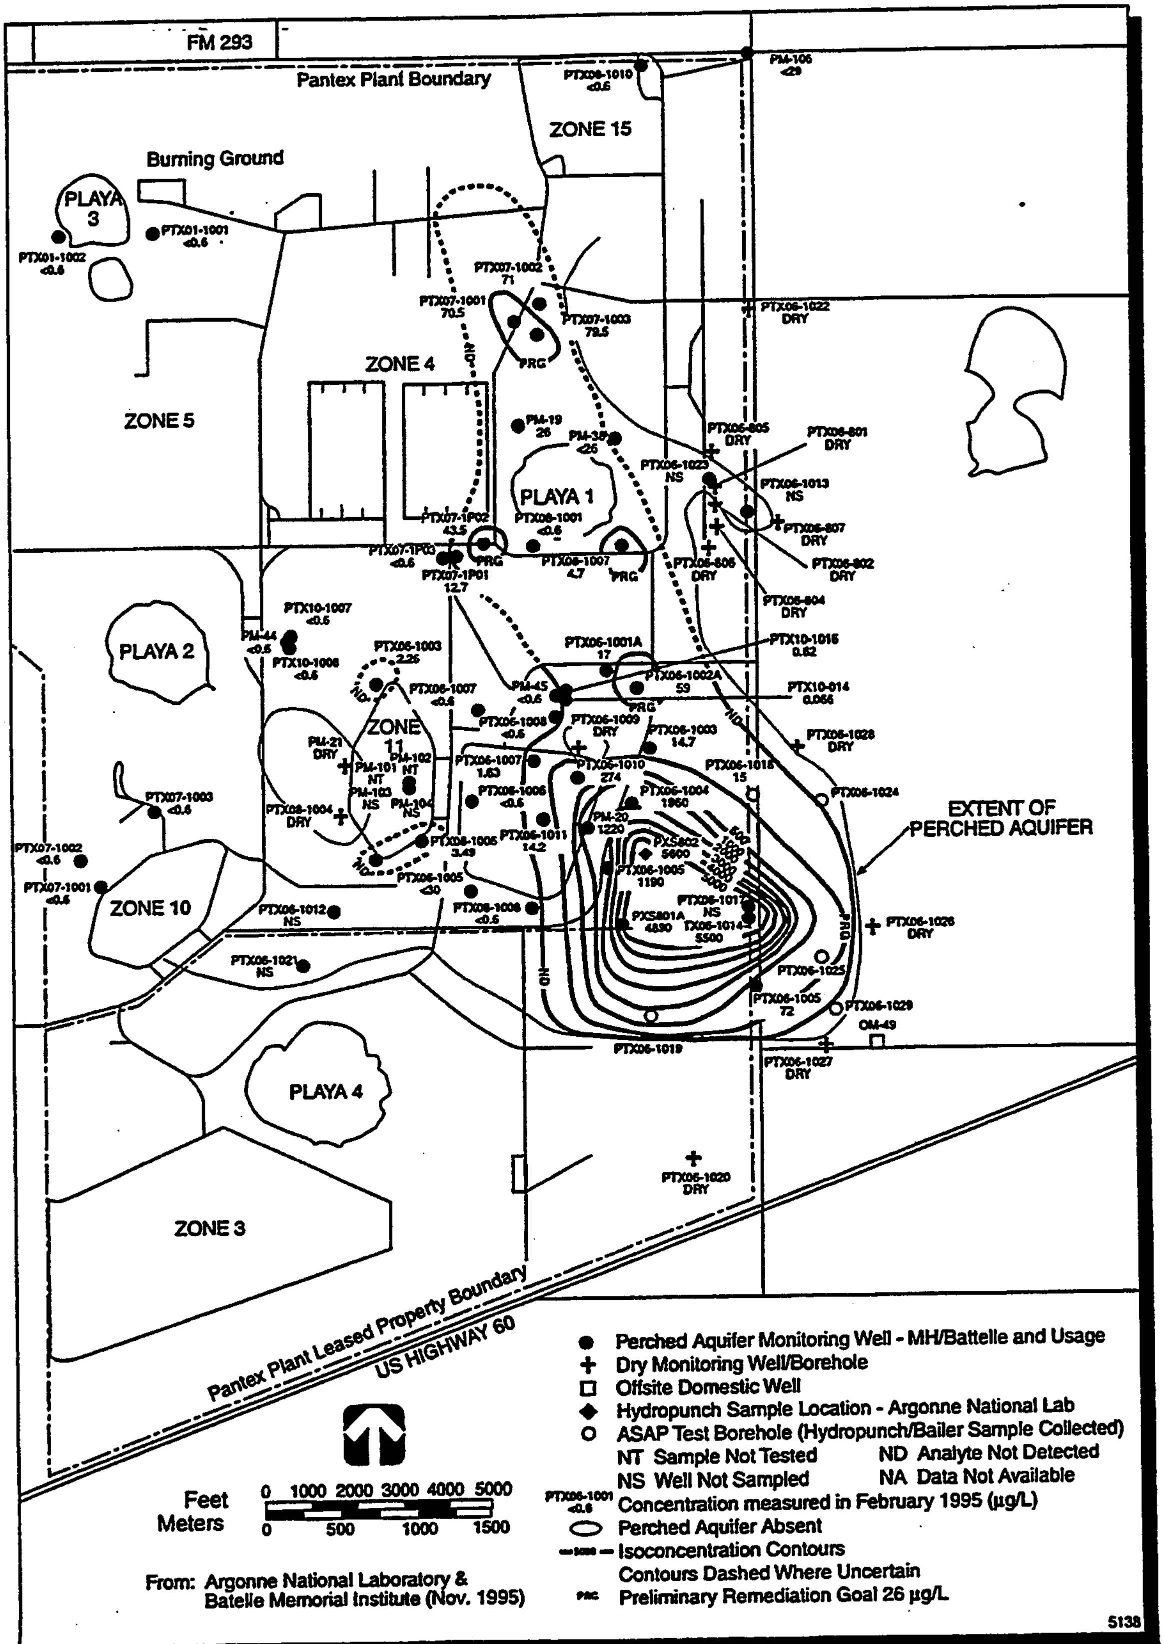
II, appendix C). Potential sources of historical contamination include the solid waste management units (SWMUs) that were identified during an RFI in January 1989. Discussion of these SWMUs is presented in section 4.5.1.3.

Under the existing DOE environmental monitoring program, groundwater monitoring of the perched and Ogallala aquifers has been conducted at Pantex Plant for the past 20 years. Before the initiation of the RFI activities, the scope of perched groundwater quality sampling was limited and consisted of sampling five wells on a monthly basis. However, due to the absence of appropriate quality control methods, analytical data obtained from these wells before 1990 are generally considered unreliable (USCOE 1995a:4). After instituting appropriate quality control procedures in 1990, monitoring wells in the perched and Ogallala aquifers continued to be sampled. After the RFI work began, groundwater monitoring wells installed by COE in conjunction with the RCRA site investigations were compiled into a network of wells that are used to routinely monitor perched groundwater quality for a wide range of constituents (volume II, appendix C). Available groundwater quality data that have been collected from 1990 to 1994 and reported in either the Annual Site Environmental Reports (published annually by DOE) or the COE investigation have been compiled in volume II, appendix C.

Pantex Plant perched and Ogallala monitoring wells are sampled and analyzed for radionuclides, metals, explosives, PCBs, pesticides, herbicides, volatile organics, and other selected parameters, as discussed in volume II, appendix C. Results of five years of groundwater quality data, presented in volume II, appendix C, indicate that the perched aquifer is contaminated with HE, volatile organics, and metals. Based on the number of exceedances and magnitude of contamination, the most significant contaminants are RDX, 1,3,5-trinitrobenzene, trichloroethylene, and chromium. Overall, results for 1995 were similar to those for 1994 (Pantex 1996c:82).

Suspected HE COCs include RDX, 1,3,5-trinitrobenzene, 2,4,6-trinitrotoluene, and HMX. An additional HE, DNT, was detected in 13 out of 211 samples in 1995 (Pantex 1996c:85). In terms of areal extent and magnitude, RDX and 1,3,5-trinitrobenzene are the most significant HE compounds. Problem wells, in terms of the highest concentrations of multiple HE compounds, are perched monitoring wells PTX06–1004 and PTX06–1005 (USCOE 1995a:51). The most extensive HE contaminant plumes (for all suspected HE COCs) have developed just east of Zone 12 beneath the approximate location of Landfill 3. Concentrations of RDX in perched monitoring wells PTX06–1004 and PTX06–1005 range from over 1,000 micrograms per liter to almost 5,000 micrograms per liter, which significantly exceed Pantex Plant RRS of 26 micrograms per liter. Contamination from RDX extends beyond the eastern boundary of Pantex Plant (Figure 4.6.1.2–7).

The migration of RDX is to the southeast from the east side of Zone 12 and appears to occur within the buried channel deposits of the perched aquifer (DOE 1995f:5-20). RDX contamination has been determined to extend offsite. Concentrations of 1,3,5-trinitrobenzene in these perched monitoring wells have ranged from over 300 micrograms per liter to over 2,200 micrograms per liter, which significantly exceed the standard of 5.11 micrograms per liter. Trinitrotoluene and trinitrobenzene were only found in groundwater at the base of the perched aquifer. In contrast, RDX and HMX generally decreased in concentration from the top to the bottom of the aquifer near the source and reversed this trend away from the source.



SOURCE: Argonne 1995a

FIGURE 4.6.1.2–7.—***RDX Concentrations in the Perched Aquifer, Pantex Plant.***

The absence of trinitrotoluene in the upper part of the perched aquifer may indicate a decline in historical usage and disposal of trinitrotoluene over time, and the subsequent release of trinitrotoluene from the unsaturated zone, since discharge of HE-contaminated water ceased in 1989 (DOE 1995f:5-20). Evidence of natural attenuation and degradation of HE compounds, such as trinitrotoluene, has been documented during treatability studies. In order to define the stratification of contaminants within the perched aquifer, due to different densities of the contaminants, it is necessary to sample at discrete intervals and depths.

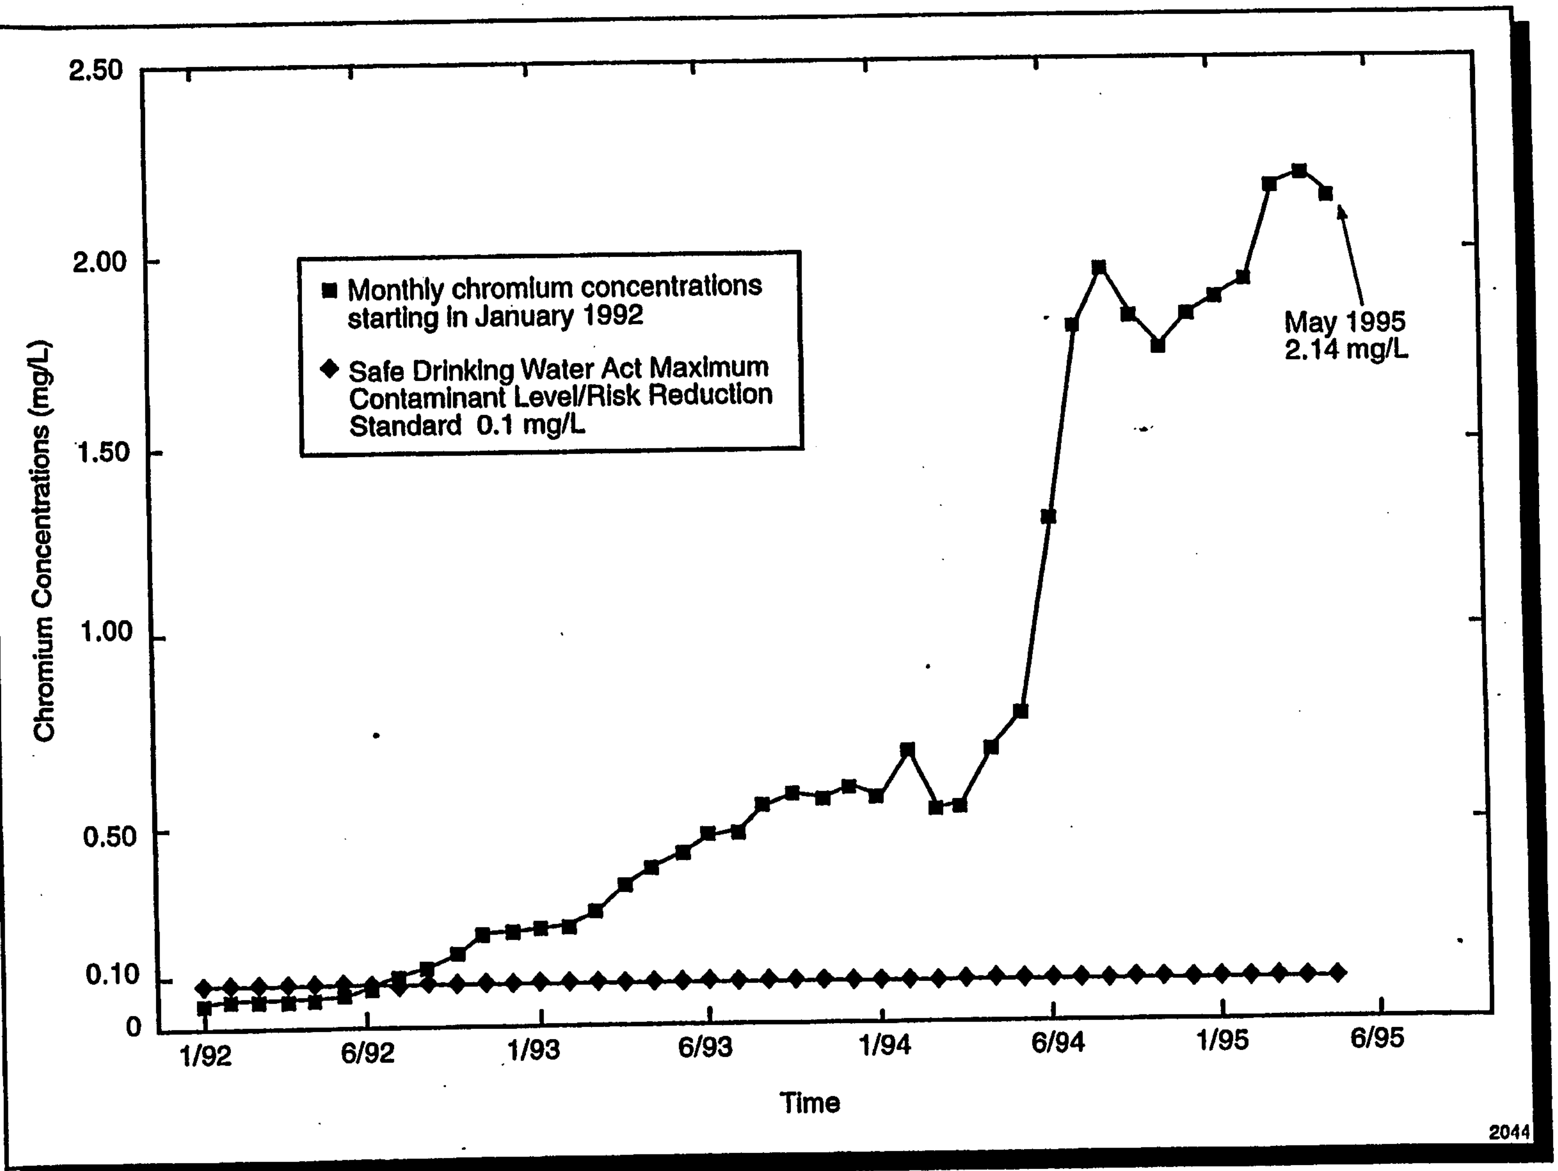
Volatile organic COCs include trichloroethylene, 1,2-dichloroethane, methylene chloride, tetrachloroethene, and benzene. Based on the number of exceedances and magnitude of contamination, trichloroethylene is the most significant volatile organic contaminant. However, much of the trichloroethylene contamination occurred at levels that often barely exceeded the RRS decision criteria of 5 micrograms per liter. Additional information is presented in volume II, appendix C.

Metal COCs include chromium, hexavalent chromium, copper, nickel, iron, lead, and manganese. Chromium and hexavalent chromium are the most widespread and have the highest concentrations of the metals detected in perched groundwater. In several perched aquifer wells, chromium concentrations exceeded the decision criteria standard of 100 micrograms per liter (TNRCC Primary Maximum Contaminant Levels for Drinking Water and Pantex Plant RRS). These exceedances ranged from barely over the standard to over 9,000 micrograms per liter in perched monitoring well PTX06–1010.

An example of how concentrations of chromium have changed over time is shown in a graphical plot of time versus chromium concentration for one well, OW–WR–20, in Figure 4.6.1.2–8. The areal extent of chromium concentrations in the perched aquifer is shown in Figure 4.6.1.2–9. Chromium concentrations for the perched aquifer are shown as isopleths (lines showing levels of equal concentration). One area of chromium contamination that requires further delineation occurs along the eastern plant boundary, in the vicinity of offsite borehole PTX06-1025, where filtered and unfiltered perched aquifer samples were collected and analyzed for chromium. The concentration of chromium measured in the filtered sample was less than the detection limit of 10 micrograms per liter, whereas the concentration of chromium measured in the unfiltered sample was 198 micrograms per liter (Figure 4.6.1.2–9) (MH 1995c:18).

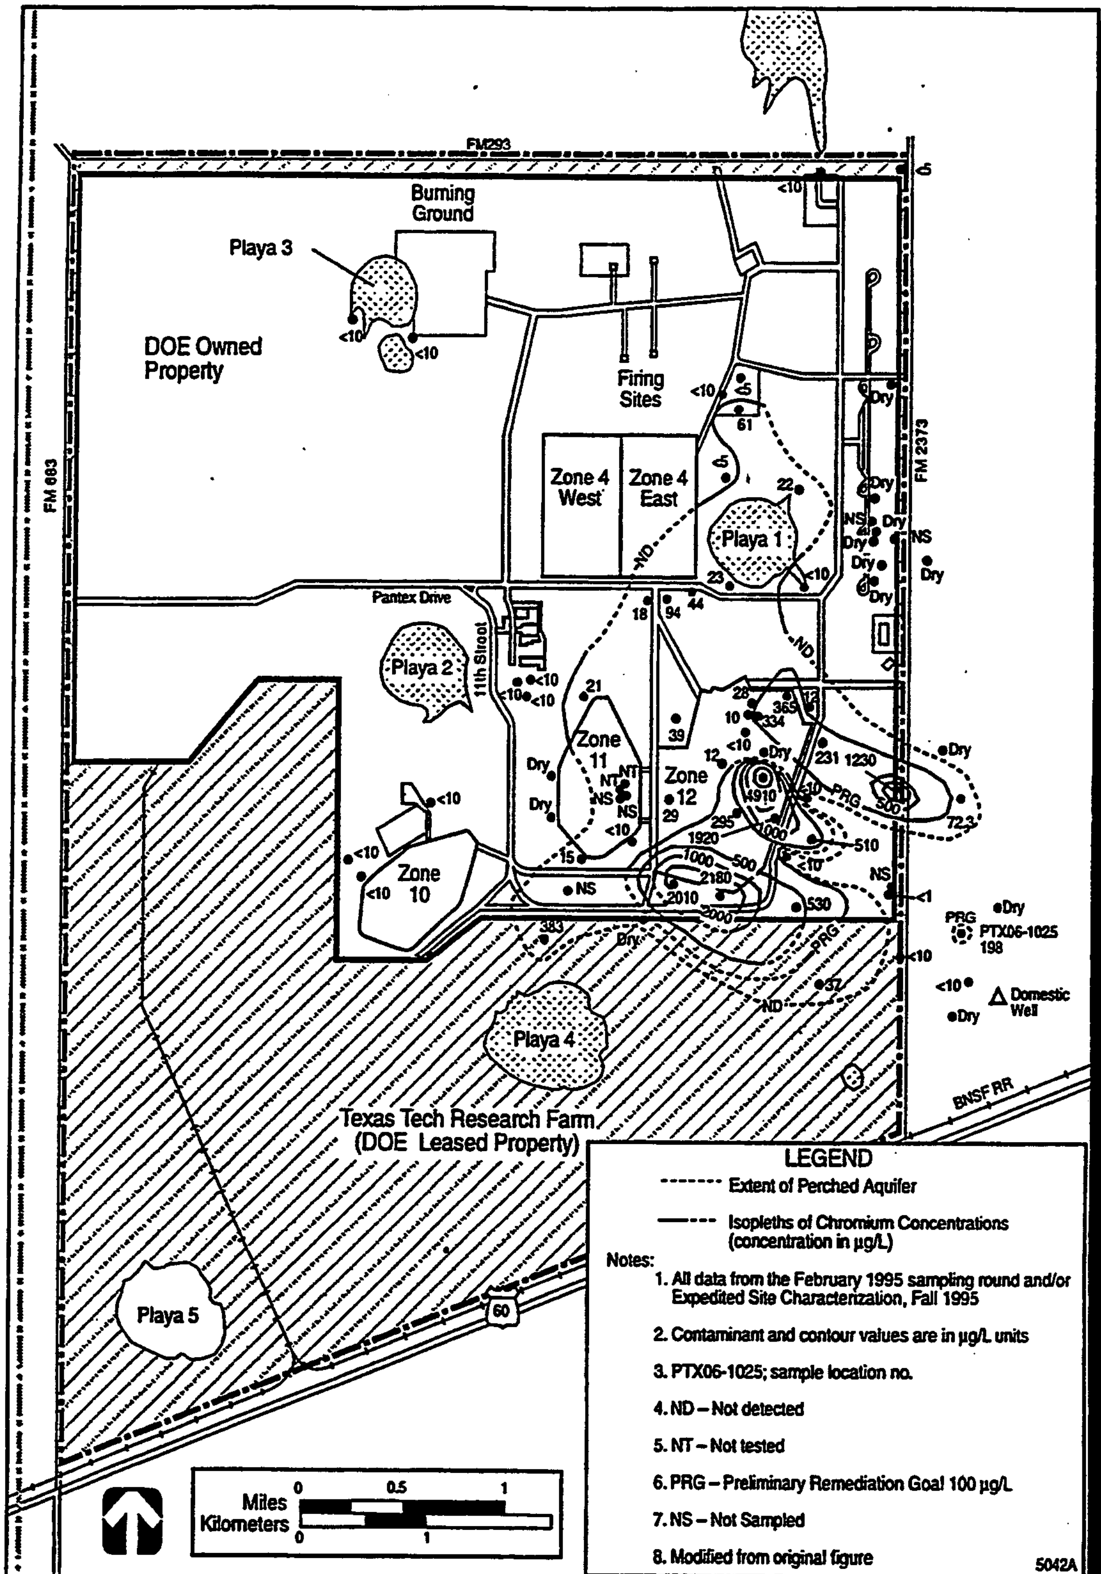
The historical sources of chromium processing were located in the vicinity of where the highest chromium concentrations occur. For example, chromium was processed in Zone 12 at an electroplating facility (tool and die shop) in the form of a chrome plating solution between 1976 and 1986. During this time, electroplating wastewater effluent would be discharged to a below-grade sump that would occasionally overflow. Other historical sources of chromium at Pantex Plant include chromate compounds used in the former cooling tower operations (from 1950 to 1964); residues of chromic acid in old sewage treatment plant sludge beds, the construction debris landfills, waste products at the Burning Ground, past effluent disposal at Playa 1, and in containers and materials dumped in Landfills 1, 5, and 13 (Argonne 1995:3-29 to 3-49). It is highly likely that these earlier releases contributed to the high concentrations of chromium that occur in the perched monitoring wells today.

Investigations regarding the sources, concentrations, and removal of chromium at Pantex Plant are ongoing. These chromium investigations include determining whether elevated chromium levels could have been



SOURCE: PC 1995i

FIGURE 4.6.1.2–8.—*Chromium Concentrations at OW–WR–20 from January 1992 through May 1995.*



SOURCE: Argonne 1995a

FIGURE 4.6.1.2–9.—*Chromium Concentrations in the Perched Aquifer, Pantex Plant.*

caused by the amount of chemicals used for conditioning cooling water during the tower's operational period (1950 to 1964), chromium anion exchange and column studies to determine whether ion exchange resins would be an effective treatment technology, and geochemical modeling to predict the fate and transport of chromium species in groundwater. Additional data for metals that exceed the decision criteria are provided in volume II, appendix C.

Radionuclides are also measured in groundwater quality samples; however, the levels (or activities) of radionuclides are less than the decision criteria specified in the DOE derived concentration guides for ingested water for radiation protection (DOE Order 5400.5). As a result, radionuclides are not considered to be suspected COCs in perched groundwater at Pantex Plant.

Groundwater quality in the perched aquifer has been affected by the activities that have occurred over the past 40 years at Pantex Plant. Since the perched aquifer is the shallowest water-bearing zone in the area, it is the first groundwater unit affected by migration of contaminants that were released from past industrial operations. These operations generated HE materials, organic solvents, and metals in liquid and solid wastes. The direction and rates of contaminant movement in the perched aquifer are controlled by the location of buried channel deposits and the underlying fine-grained zone, direction and rate of groundwater movement, and source areas of historical contamination. Contaminants originating in Zone 12 have reached the perched aquifer through historical vertical infiltration from ditches, landfills, and other past localized source areas in the interplaya area (DOE 1995f:5-16).

Available information on the historical sources of contamination and the waste disposal history has revealed that the inorganic wastes were discarded primarily in acid pits in the southern part of Zone 12. Explosive wastes were disposed of in the ditches in the eastern part of Zone 12 and at other locations cited in Table 4.6.1.2–2 (DOE 1994nn:3-33, 3-38). Argonne National Laboratory has noted that HE contaminant distributions suggest that a significant or dominant proportion of recharge to the perched aquifer in the Zone 12 area has occurred between the playas. This may be a result of vertical infiltration from unlined surface ditches used to carry liquid wastes onsite. HE was found at a depth of 14 meters (45 feet) in unsaturated zone samples collected from a ditch leading from Zone 12 to Playa 1. At this location RDX and HMX were found to a depth of 6 meters (20 feet), and 1,3,5-trinitrobenzene was found between 6 and 14 meters (20 and 45 feet). No trinitrotoluene was detected in the unsaturated zone. Because of its solubility and biodegradable characteristics, it is believed to have been leached or degraded since the practice of discharging effluent that may have contained HE was discontinued (DOE 1995f:5-20).

Downward migration of perched groundwater could potentially affect the groundwater quality of the underlying Ogallala aquifer. The low vertical permeability of the fine-grained zone could potentially be compromised by abandoned homestead wells that could provide contaminant pathways through the fine-grained zone to the Ogallala aquifer. Low levels of HE contamination have been detected by TNRCC at less than one part per billion of RDX in a domestic Ogallala well located on private property southeast of Pantex Plant. As a precautionary measure, DOE has identified and evaluated abandoned homestead wells in order to prevent potential pathways of contamination into the Ogallala aquifer. Efforts to mitigate further possible contamination have been completed. The well in question was properly

Source: DOE 1994nn:2-16 through 2-32

plugged and sealed under the supervision of TNRCC and a replacement Ogallala well was drilled and completed in order to prevent further potential cross-contamination of the Ogallala aquifer.

Pantex Plant's Groundwater Protection Project was conducted to ensure the integrity of offsite groundwater quality (MH 1996a). The scope of this project included performing three distinct tasks to protect groundwater beneath Pantex Plant from cross contamination between the perched aquifer and the Ogallala aquifer. The activities associated with these tasks were completed in September 1996 at 23 different well locations. These tasks included upgrading existing monitoring wells, sealing offsite homestead wells, and installing new wells offsite.

Monitoring well upgrade activities included installation of barrier posts, installation of protective metal casings, construction or repair of concrete pads, painting exposed steel structures, and resurveying well locations. Well sealing and plugging was necessary for existing vintage Ogallala production wells that could potentially result in cross-contamination between the perched and Ogallala aquifers. Under this task, five wells at Pantex Plant and two private production wells on land adjacent to the plant were sealed. The third task involved installing three monitoring wells, two new perched wells and one new Ogallala well, on private property adjacent to and east of the plant. The Ogallala well has also been designated for use as a domestic production well.

Available routine groundwater quality analytical results from 1990 through 1994 are summarized in volume II, appendix C for groundwater samples collected from the regional Ogallala aquifer. Levels of copper in one Pantex Plant well, iron in four wells, and lead in three wells measured in the Ogallala aquifer have either met or been higher than Pantex Plant RRS and drinking water maximum contaminant levels on several occasions, as shown in volume II, appendix C. However, no exceedances of HE, organic compounds, or radionuclides were measured in Ogallala wells onsite. There was no evidence of contaminated groundwater from the overlying perched zone reaching the Ogallala aquifer in samples collected from Ogallala aquifer monitoring wells (Pantex 1996c:87). Elevated concentrations of copper, lead, iron, and zinc may be related to other factors, such as well construction and piping, rather than the spread of contaminants in groundwater.

Additional Investigations

The rate of potential contaminant transport under and beyond Pantex Plant boundaries is dependent upon the rate of infiltrating surface water recharge; the concentrations of contaminants; the solubility of these contaminants; vertical and horizontal groundwater movement; the mixture of contaminants present; soil and sediment characteristics; and physical, chemical, and biological processes, such as adsorption and biodegradation. Investigations to characterize the potential for contaminant migration are ongoing.

The University Consortium (University of Texas Austin, Texas A&M University, and TTU Water Resources Information Center) is conducting several investigations to support, supplement, and enhance the activities of the Pantex Plant ER Program. A perched aquifer tracer test at the Pantex Plant Zone 12 treatability site is being conducted to evaluate the efficiency of groundwater recirculation for remediation, to determine potential retardation effects on HEs from the injection of treated wastewater, and to predict long-term performance of the remediation system. Soil vapor extraction modeling and a tracer test in unsaturated sediments above the perched aquifer is being conducted to predict the efficiency of soil vapor extraction. Several bioremediation investigations are being conducted, including an evaluation of the effectiveness of selected microorganisms for HE degradation.

Ecological risk assessments are being conducted to determine potential contaminant pathways for biota. Ongoing chromium investigations include determining whether elevated chromium levels could have resulted from chemicals used for conditioning cooling water during the tower's 14-year operational period, determining potential soil and groundwater geochemical reactions through chromium anion exchange and column studies, determining whether ion exchange resins would be an effective treatment technology, and geochemical modeling to predict the fate and transport of chromium species in groundwater, as previously discussed.

Groundwater Uses

The Ogallala aquifer is a primary source of groundwater in the High Plains and is used for irrigation, industrial process water, and the municipal potable water supply at and in the vicinity of Pantex Plant. This aquifer has not been classified by EPA. The City of Amarillo draws its raw water from the Ogallala aquifer and Lake Meredith. During the 1995 water year (from October 1994 through September 1995), approximately 23.6 billion liters (6.2 billion gallons) were pumped from the Carson County wellfield, located just north and northeast of Pantex Plant (Table 4.6.1.2–3). This wellfield consists of 37 wells and 2 standby wells completed in the Ogallala aquifer (Pantex 1996:4.8).

The withdrawal of water from regional pumping in the Ogallala aquifer continues to exceed recharge, causing groundwater levels in the Ogallala aquifer to decline in the Pantex Plant area at a rate of approximately 0.6 to 2 meters (2 to 5 feet) per year (DOE 1995k:4-293). Water levels have declined approximately 30 meters (100 feet) since the Carson County production wells went into use (DOE 1990b:16). From 1980 to 1990, the Carson County Wellfield experienced up to 20 meters (60 feet) of water level decline, which may have contributed to a depression in the groundwater surface northeast of Pantex Plant (TWD 1993:11).

TABLE 4.6.1.2–3.—*1995 Water Withdrawal by Pantex Plant, City of Amarillo, and Irrigation in Carson County*

SOURCE	WITHDRAWAL OR USE Mliters (Mgal)	PERCENT OF TOTAL WITHDRAWAL/USE
Pantex Plant Wells Approximately 25 percent was used by TTU	869 (230)	0.7
City of Amarillo's Carson County Well Fields	23,610 (6,210)	18.8

Total Withdrawal	125,264 (33,062)	100

Sources: Pantex 1996c:9,11; PC 1996c

Five Ogallala production wells (15–17, 15–6, 15–20, 15–16, and 15–26) in the northeast corner of Pantex Plant serve the plant's industrial and potable water needs. An additional water supply well (15–32) has been drilled to the east of 15–26 but has not been completed (Pantex 1996:4.8). In 1995, Pantex Plant reported a total production level of 869 million liters (230 million gallons) of water from onsite production wells; 618 million liters (163 million gallons) were used by Pantex Plant for industrial or domestic purposes, and 251 million liters (66 million gallons) were used by TTU for irrigation or domestic consumption (Table 4.6.1.2–3). The 1995 plant consumption was a reduction from the 1994 consumption, which was 707 million liters (186 million gallons) (Pantex 1996c:9, 11).

The Ogallala aquifer is a critical resource for the Texas Panhandle, and its capacity, while quite large, is being drawn down. Typically, Carson County agriculture relies heavily upon irrigation to achieve economic production rates. The current operations of Pantex Plant have not impacted the region's agriculture. Water use at Pantex Plant accounted for only 0.7 percent of the total estimated water use in Carson County for 1995 (Table 4.3.1.2–3). In 1995, Carson County irrigated 25,751 hectares (63,629 acres), using 101 billion liters (26.6 billion gallons) per year. Thus irrigation use accounted for 80.5 percent of the total water consumption in 1995 for Carson County. Production and use of groundwater in the vicinity of Pantex Plant are affected by the growing season, climatic conditions, and demand for irrigation water for crop production (Pantex 1996:4.8).

In addition to water use from the Ogallala aquifer, at least two private wells tap the perched aquifer(s) within 0.8 kilometers (0.5 miles) of Pantex Plant Site. These two private wells located north and west of Pantex Plant are believed to be cross gradient (i.e., groundwater moves in a different direction) from the contaminated groundwater in Zone 12, which flows to the southeast. The approximate locations of all private and municipal supply wells are shown in Figure 4.6.1.2–1. Investigations to determine the potential for contaminant migration are ongoing.

Groundwater Rights and Permits

Texas enacted a groundwater law in 1949 that authorized the formation of local districts having the power to make and enforce regulations governing groundwater withdrawal. By virtue of this law, Texas has given the power of regulation to local groups, thus placing the responsibility for regulation at the lowest possible governmental level capable of performing the desired functions (USGS 1976). The Texas Water Code Section 52.024 grants the Texas Water Commission the authority to designate Underground Water Management Areas in the State of Texas in the form of a rule to protect groundwater resources. Groundwater resources in the area governed by the Panhandle Groundwater Conservation District, including the Pantex Plant area, have not been designated as Class I or a critical area. Pantex Plant is located in Panhandle Groundwater Conservation District No. 3, which has the authority to require permits and limit the quantity of water pumped.

Historically, the Panhandle Groundwater Conservation District does not limit the quantity of water pumped (DOE 1995k:4-297). However, for new wells drilled after July 19, 1995 that produce annually more than 1.3 million liters (350,000 gallons) of water per acre owned, on a section by section basis, landowners will be required to obtain a High Production Permit from the Panhandle Groundwater Conservation District (PGCD 1995:25). TNRCC and the Texas Water Development Board are the two State agencies primarily involved with groundwater fact finding, data gathering, and analysis.

4.6.2 Impacts of Proposed Action

4.6.2.1 *Impacts of the Continued Operations*

Weapons-Related Activities

Surface Water. Operations at Pantex Plant have not substantially impacted delineated flood-prone areas in the past, and continued operations are not expected to cause impacts in the future. The proposed areas of activity are outside of 100-year, 500-year, and Standard Project Flood boundaries. Pantex Plant is in compliance with current wastewater and stormwater discharge permits. Wastewater discharge associated with operations on 2,000, 1,000, or 500 weapons per year is expected to continue. These discharges are not expected to impact surface water quality because, while the projected annual wastewater discharges represent a 36 percent increase over fiscal year (FY) 1994 usage for the 2,000 weapons level, the levels of contaminants in the wastewater are held by current regulations to levels that do not impact the environment. This increase is only 48 percent of the site's remaining wastewater treatment capacity. The 500 weapons level would represent an 8 percent decrease in wastewater production (Table 4.6.2.1–1).

Groundwater. Section 4.6.1.2 provided an assessment of the existing (baseline) hydrogeologic and water quality conditions that exist at Pantex Plant. The existing groundwater contamination that has been detected in the perched aquifer is the result of over 40 years of past activities and waste generation at Pantex Plant. Over this time period, contaminants that were previously released at the ground surface had to percolate through unsaturated soil and sediments to the perched aquifer. Groundwater contamination of the perched aquifer has been detected offsite to the east and southeast. As stated in section 4.6.1.2, if contaminated groundwater from the Zone 12 perched aquifer is used in the future for domestic or agricultural purposes, a potential exposure pathway (i.e., ingestion, bathing, or irrigation) could result (Argonne 1995a:5-37). Pantex Plant's Groundwater Protection Project was implemented to ensure the integrity of offsite water quality by sealing homestead wells, upgrading some monitoring wells, and drilling additional monitoring wells (MH 1996a).

Assessment of the impacts of the continued operations to groundwater resources at the plant involves the evaluation of the potential for additional groundwater contamination from wastewater discharge activities, and the

TABLE 4.6.2.1–1.—*Current and Projected Annual Water Usage and Capacities, Pantex Plant (million liters [million gallons])*[1]

	FY 1994 USAGE	FY 1994 CAPACITY	2,000 WEAPONS LEVEL	1,000 WEAPONS LEVEL	500 WEAPONS LEVEL
Wastewater	477 (126)	830 (219)	647 (171)	522 (138)	439 (116)
Water	836 (221)	1,890 (500)	1011 (267)	791 (209)	689 (182)

FY – fiscal year

Sources: DOE 1995j:10; DOE 1994f:7

evaluation impacts from future groundwater use projections; these areas of concern are considered in this section. The potential for additional impacts to groundwater quality from wastewater discharge activities is minimal due to the contaminant removal efficiency of the industrial and sanitary wastewater treatment process currently being used. Although the projected annual wastewater discharges represent a 36 percent increase over FY 1994 usage, the quantity of wastewater discharge is less than the total wastewater discharge capacity. The quality of the wastewater discharge is such that it will not degrade the quality of the groundwater in either the perched or Ogallala aquifers, because the wastewater discharge is regulated through the EPA Region 6 NPDES Permit and TNRCC Wastewater Discharge Permit. Pantex Plant has worked very closely with EPA Region 6 and the TNRCC to produce wastewater discharge permits (EPA NPDES Permit No. TX-0107107 and TNRCC Wastewater Discharge Permit No. 02296) that provide stringent wastewater discharge requirements that are protective of human health and the environment (section 4.6.1.1).

The hydrology and recharge of the perched aquifer is very complex and the effects upon the vadose zone from continual discharge of water into the existing playas and drainage ditches does not necessarily result in contaminated groundwater being driven into the Ogallala aquifer. ER investigations, conducted at or before the time of publication, have indicated that the extent of offsite contamination detected in the perched groundwater has been limited to within one-half mile southeast of the main Pantex Plant site boundary. The ER Program is currently conducting corrective actions to protect human health and the environment.

Groundwater contamination has occurred in the perched aquifer as a result of past site-related activities. For the past seven years, the Pantex Plant ER Program has assessed inactive sites, conducted investigations to determine the nature and extent of contamination, and implemented remediation strategies to eliminate any present or future threat to human health and the environment. These activities to investigate historical sources of contamination and correct the extent of problems created by past practices will continue in the future through the ER program. Wastewater discharge would be released to the playas and natural drainage channels in accordance with the EPA NPDES and TNRCC Wastewater Discharge Permit requirements. There are no direct discharges to groundwater (DOE 1995k:4-327).

No additional impacts to groundwater quality conditions from routine continued operations are anticipated since all wastewater discharge must comply with TNRCC and EPA wastewater discharge permit limits. Although groundwater in the perched aquifer is contaminated as a result of past site-related activities, the ER program is currently conducting field activities to characterize the nature and extent of contamination. Groundwater monitoring for the perched and Ogallala aquifers will continue, and groundwater treatability options are currently being explored. The impacts of discharging treated wastewater, within permit limits, to the playas and ultimately to the groundwater system are negligible when compared to baseline conditions and in consideration of the ongoing ER activities at Pantex Plant.

Groundwater used for continued operations would be withdrawn from the onsite Pantex Plant production wells, completed in the Ogallala aquifer, at the projected withdrawal rates listed in Table 4.6.2.1–1. The 2,000 weapons level would represent a 20 percent increase over FY 1994 withdrawals. This increase represents 16 percent of the remaining water supply capacity at the plant.

Pit Storage Activities

Under the Proposed Action, the maximum number of pits that could be stored at Pantex Plant would be increased from 12,000 to 20,000. Storage activities do not pose additional impacts to water quality or availability beyond those described for the continued operations above.

Environmental Restoration Activities

Under the Environmental Protection program, routine surface water and groundwater monitoring is conducted at Pantex Plant. Since a potential exists for the migration of contamination from the soils into groundwater resources, impacts to water resources would be expected to decrease as a result of ER activities.

Groundwater characterization efforts are ongoing at Pantex Plant. Current activities include determining the extent of groundwater contamination; determining the sources of contamination, contaminant mobility and transport properties; and technical support and information transfer for site characterization studies from the University Consortium of the University of Texas at Austin, Texas A&M University, and Water Resources Center at TTU (section 4.6.1.2).

DOE completed a Groundwater Protection Project to clean up the groundwater to residential drinking water standards beyond the facility boundary. The Groundwater Protection Project included efforts to identify, evaluate, and seal homestead wells which could provide contaminant pathways of contamination to the Ogallala aquifer, as previously discussed. Additional remediation activities that are currently underway at Pantex Plant include contaminated soil removal within the vicinity of onsite ditches and playas and a groundwater treatability study to determine the most effective method(s) to clean up perched groundwater (Stroller 1996:1-1).

The groundwater treatability system, located in Zone 12, combines a dual groundwater pump-and-treat system with a soil vapor extraction system to remediate and abate the migration of onsite HE, volatile organic compounds, and metal contaminants beneath Zone 12 and its immediate vicinity. This system is designed to treat contaminants in both the unsaturated soils and groundwater of the perched aquifer (MH 1995a:1). Granulated activated carbon adsorption would be expected to remove most of the COCs. A resin-based treatment to remove chromium is also included in the process. Groundwater treatment involves pumping contaminated groundwater out of the perched aquifer, treating the contaminated groundwater in a carbon-filtration system to remove HE contamination, and then draining it back into the perched aquifer. The only direct discharge is the draining of treated groundwater to the perched aquifer. This ER treatability study has been approved by the TNRCC.

When the treated groundwater is reintroduced into the perched aquifer, it flushes and displaces the existing contaminated groundwater, moving it toward the treatment system wells for cleanup. Groundwater moves through void spaces in between unconsolidated sand, silts, and gravels, and is treated at an approximate rate of 160,000 liters (42,000 gallons) per day. The treatability system began operating just eight months after the initial boundary contamination was discovered. The treated water now meets drinking water standards, as confirmed by co-sampling conducted by the TNRCC (Pantex 1996c:55). Evidence of natural attenuation and degradation of HE compounds including trinitrotoluene have been documented during the treatability studies (PC 1996n).

4.6.2.2 *Impacts of New Facility Construction and Upgrades*

Six new facilities have been proposed for Pantex Plant. The projected construction phase for these facilities spans from 1996–2001. All of these facilities would be located in Zones 11 and 12. Since no 100-year, 500-year, or Standard Project Flood boundaries have been delineated in Zones 11 and 12, there would be no impacts to floodplains. Surface water use is not an issue because all water required for construction or operation would be supplied from groundwater. The treated effluent from the process wastewater treatment would be discharged to the playas and monitored to comply with EPA NPDES Permit and TNRCC Wastewater Discharge Permit requirements. Environmental impacts to water resources from the proposed facility construction and upgrades for each of the six facilities are summarized in Table 4.6.2.2–1.

All water required for construction or operation would be supplied from groundwater withdrawn from Pantex Plant wells. Projected water usage is compared to current water usage on a site-wide and facility-specific basis. The upper bounding conditions (i.e., 2,000 weapons level) would result in a projected annual groundwater withdrawal of 1,011 million liters (267 million gallons), or an increase of 64 percent over FY 1995 industrial and domestic water use. Under the 2,000 weapons scenario, Pantex Plant groundwater withdrawals would only account for 0.8 percent of the total estimated annual groundwater withdrawals in Carson County.

Hazardous Waste Treatment Plant Facility

Domestic wastewater from the Wastewater Treatment Facility (HWTPF) would be collected in the Pantex Plant sanitary sewer system and treated in the WWTF prior to discharge into Playa 1. A treatment facility, such as the HWTPF, that is constructed and maintained properly would prevent further

TABLE 4.6.2.2–1.—*Current and Projected Annual Water Usage for Facility Upgrades, Pantex Plant (million liters [million gallons])*

USAGE	HWTPF	PIT REUSE	GAS ANALYSIS LABORATORY	MCAF	NDEF	METROLOGY HPCAF
WASTEWATER GENERATED

Sources: DOE 1995j:10; PC 1995g

injury to natural resources. Industrial wastewater generated by operations associated with waste treatment would be disposed of in accordance with applicable Federal, State, and local environmental laws and regulations.

Particular industrial disposal options are discussed in section 4.13.1. An additional 0.227 million liters (0.06 million gallons) of domestic wastewater and 2.9 million liters (0.77 million gallons) of industrial wastewater would be generated each year, based on the difference between current and projected generation for the HWTPF (Table 4.6.2.2–1). However, this additional output is less than a 0.7-percent increase of the 477 million liters (126 million gallons) total site-wide FY 1994 volume of treated wastewater, less than 0.5 percent of the 649 million liters (171 million gallons) projected wastewater volume for the 2,000 weapon level, and less than 1.8 percent of the total remaining wastewater system capacity of 181 million liters (48 million gallons). The increased usage of 3.6 million liters (0.96 million gallons) per year of water that would be required for the HWTPF would be less than 0.4 percent of the reported groundwater usage in FY 1994 (836 million liters [221 million gallons]) and just over 0.3 percent of the remaining total system capacity.

Pit Reuse Facility

Discharge of domestic water from the Pit Reuse Facility would be collected in the Pantex Plant sanitary sewer system and treated in the WWTF. The projected annual demands are anticipated to be 0.32 million liters (0.084 million gallons) per year for water and wastewater (Table 4.6.2.2–1). Pit reuse is not a current activity at Pantex Plant so there are no existing water consumption and wastewater generation figures. Treated wastewater generated from the Pit Reuse Facility would be less than a 0.07 percent increase over the plant's FY 1994 wastewater discharges. The additional water demands of the pit reuse facility represent less than a 0.04 percent increase over the total amount of water used in FY 1994 at Pantex Plant. Therefore no increase in impacts is expected.

Gas Analysis Laboratory

Water consumption and wastewater generation are expected to remain the same at 0.912 million liters (0.241 million gallons) per year (Table 4.6.2.2–1). Thus there would be no change in impacts to water resources from this facility.

Materials Compatibility Assurance Facility

Proposed water consumption and wastewater generation are expected to remain the same as current conditions of 8,640 million liters (2,280 million gallons) of water usage and 7.62 million liters (2.013 million gallons) of wastewater generated (Table 4.6.2.2–1). No change in impacts is anticipated.

Nondestructive Evaluation Facility

The total annual volume of water consumed and treated wastewater generated is not expected to change from the current conditions of 9.1 million liters (2.4 million gallons) per year of water usage and 8.02 million liters (2.1 million gallons) of wastewater generated (Table 4.6.2.2–1). As a result, no change in impacts to water resources would be expected.

Metrology and Health Physics Calibration and Acceptance Facility

Wastewater generated at this new facility is expected to remain at 9.30 million liters (2.45 million gallons) per year. No additional inputs for wastewater generation are expected as a result of construction. Water usage is expected to remain at 10.5 million liters (2.78 million gallons) per year.

4.6.2.3 *Summary of Impacts*

This is the Floodplain Statement of Findings as required by 10 CFR 1022. Continued operations and increasing pit storage would not affect the delineated floodplains.

An analysis of wastewater discharged to the playas indicates that the volume of the release would be within the TNRCC permitted limit of 2.5 million liters (0.65 million gallons) per day (PC 1995d). Impacts to groundwater quality from normal operations during the period covered by this EIS are expected to be negligible because only wastewater that complies with EPA and TNRCC permit limits would be released to ditches and playas.

Site-wide groundwater use at Pantex Plant is projected as approximately 1,011 million liters (267 million gallons) per year for the 2,000 weapons scenario. The plant pumped 618 million liters (163 million gallons) for industrial or domestic uses in 1995. The 2,000 weapons scenario would result in an increase of approximately 393 million liters (104 million gallons) per year above the 1995 plant water use. Therefore, under the 2,000 weapons scenario, total Plant water use would increase by approximately 64 percent. In 1995, Pantex Plant's actual water usage was approximately 33 percent of the plant's total groundwater production capacity. Under the 2,000 weapons scenario, the projected water usage is 53 percent of the plant's total capacity of 1,890 million liters (500 million gallons), representing an increase of 20 percent of the total production capacity for industrial and domestic water uses. Pantex Plant production wells withdraw a relatively small amount of groundwater from the Ogallala aquifer, currently only about 0.7 percent of the total amount of groundwater used in Carson County (section 4.6.1.2). Typically, Carson County agriculture relies heavily upon irrigation to achieve economic production rates. Irrigation use currently accounts for 80.5 percent of the total water consumption in 1995 for Carson County.

4.6.3 Impacts of No Action Alternative

Under the No Action Alternative, DOE would continue current and planned activities at Pantex Plant as discussed in section 3.1.2. The potential impacts that could result from continued operations, ER, and waste management are similar to or less than those identified for the Proposed Action. No additional impacts to water resources are anticipated beyond the effects of existing and planned activities.

4.6.4 Impacts of Pit Storage Relocation Alternative

The Pit Storage Relocation Alternative involves continued operation and maintenance activities at Pantex Plant and transportation and interim storage of pits from Pantex Plant to other DOE or Department of Defense sites. The impacts to water resources from activities other than storage that would continue at Pantex Plant are the same as those discussed for the Proposed Action. While the pits are stored at Pantex Plant, they are placed in secured buildings on concrete slabs that do not permit contact with soils, surface water, or groundwater. The transportation of pits that would be relocated (20,000 or 8,000) would not affect the water resources at Pantex Plant.

4.6.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No

Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.6.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

If the facilities described in the WM PEIS were located at Pantex Plant, no groundwater quality impacts are expected, i.e., there would be no exceedances of water quality standards or permitted levels. Section 4.3.5.1 discusses water use and wastewater generation impacts.

4.6.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, impacts to water resources from operations would be expected to be less than current impacts. Water requirements would be met without increased aquifer drawdowns. Under the downsizing alternative, the groundwater withdrawals would reduce by 16 percent compared to those under the No Action Alternative. Under the relocation alternative, all water use for assembly and disassembly operations and HE fabrication would cease.

4.6.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. Water requirements for construction and operation would require approximately 107 million liters (28 million gallons) per year and 130 million liters (34 million gallons) per year, respectively. For the Proposed Action, and if the Waste Management program is located at Pantex Plant, a total of 96,200 liters (25,416 gallons) per year.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, MOX fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

Construction for the Disposition Alternative would require 110.2 million liters (29.1 million gallons) per year of wastewater discharge and 130.2 million liters (34.4 million gallons) per year of groundwater use.

Operation for the Disposition Alternative would require 484.7 million liters (128 million gallons) per year of wastewater discharge and 572.9 million liters (151.8 million gallons) per year of groundwater use.

4.6.6 Potential Mitigation Measures

The Proposed Action is not expected to have a significant impact on water resources at Pantex Plant. However, new best management practices and institutional controls, coupled with the ongoing ER activities, could further mitigate the occurrence of any impacts to water resources. ER activities will continue and are an integral part of each alternative. In addition, DOE could choose any of the new measures being considered to reduce effects from stormwater runoff during construction, including silt fences, dikes, and sediment traps to divert runoff away from disturbed areas. Soils and materials such as rip rap or mulch could be used for stabilization in order to prevent direct exposure to soils and runoff. Surface recharge from wetted areas of ditches in playas is naturally mitigated, to some extent, by high evaporation rates (TTU 1994).

Groundwater conservation measures that could be considered include decreasing TTU Research Farm irrigation demands through dry land farming, limiting groundwater production hours, installing dripless faucets, and process water reuse. If there were a Pantex Plant mission that required large quantities of treated wastewater, the City of Amarillo would consider developing reclaimed wastewater from the City of Amarillo Hollywood Road Wastewater Treatment Plant. The use of reclaimed wastewater could curtail the annual withdrawal rate of the Ogallala aquifer (TIE 1996).

(This Page Intentionally Left Blank)

4.7 AIR QUALITY

4.7.1 Affected Environment

The following sections describe the affected environment at Pantex Plant and surrounding region for meteorology and climate, atmospheric dispersion, air quality, and atmospheric radiological environment.

4.7.1.1 *Meteorology and Climate*

Pantex Plant is located in the Texas Panhandle, approximately 27 kilometers (17 miles) northeast of Amarillo, at an elevation of approximately 1,085 meters (3,560 feet).

Regional Climate

The climate at Pantex Plant and the surrounding region is characteristically that of middle latitude steppe. It is typified by large variations in temperature and precipitation from year to year, with summers that are hot and dry and winters that are mild. A high percentage of sunshine and a rather low humidity prevail over the region. The region is subject to rapid and large temperature changes, especially during the winter when cold fronts from the northern Rocky Mountains and Plains move across the region at speeds up to 64 kilometers (40 miles) per hour. In the spring, moving low-pressure systems produce high winds, with March and April having the strongest. Severe local storms are infrequent, though a few thunderstorms, with damaging hail, lightning, and wind in very localized areas occur most years, usually in spring and summer. These storms are often accompanied by very heavy rain, which produces local flooding.

Local Climate

The nearest representative station with long-term climatological data (30 years) is 16.1 kilometers (10 miles) west of Pantex Plant at the Amarillo International Airport. Meteorological data have been recorded at the airport over a period of more than 60 years (1931 to present).

The annual average temperature in the area is 13.6 °C (56.4 °F); average daily temperatures vary from a minimum of -5.7 °C (21.8 °F) in January to maximum of 32.8 °C (91.1 °F) in July and August. The average annual precipitation is 49.7 centimeters (19.56 inches). Seventy-five percent of the total annual precipitation falls between April and September. The average annual snowfall is 42.9 centimeters (16.9 inches). The snow usually melts in a few days (Pantex 1996:6.2).

Pantex Plant is located in an area with a relatively high frequency of tornados. Fifty-three tornados were recorded in Carson County between 1950 and 1994 (Pantex 1996:6.3). The estimated probability of a tornado striking a point at Pantex Plant is 2.3×10^{-4} per year (DOE 1995q).

Average wind speeds at Amarillo are relatively high. For the period 1944 through 1993, the average speed was 22 kilometers (14 miles) per hour. Calms occur about 1 percent of the time. The wind blows predominantly from the south from May to September and from the southwest the remainder of the year (Pantex 1996:6.2). Figure 4.7.1.1–1 is a wind rose for the Amarillo International Airport (EPA 1995a).

4.7.1.2 *Atmospheric Dispersion*

Once pollutants are emitted into the atmosphere, the prevailing weather conditions determine their dispersion. Atmospheric stability controls the dispersion of pollutants in the vicinity of a source. This factor is especially important to the assessment of primary pollutant impacts. Stability is affected by thermal and mechanical turbulence of the atmosphere and wind velocity of the layer of air closest to the ground. When the atmosphere is unstable, usually during daytime, dispersion of airborne particulates increases. Data collected at the Amarillo

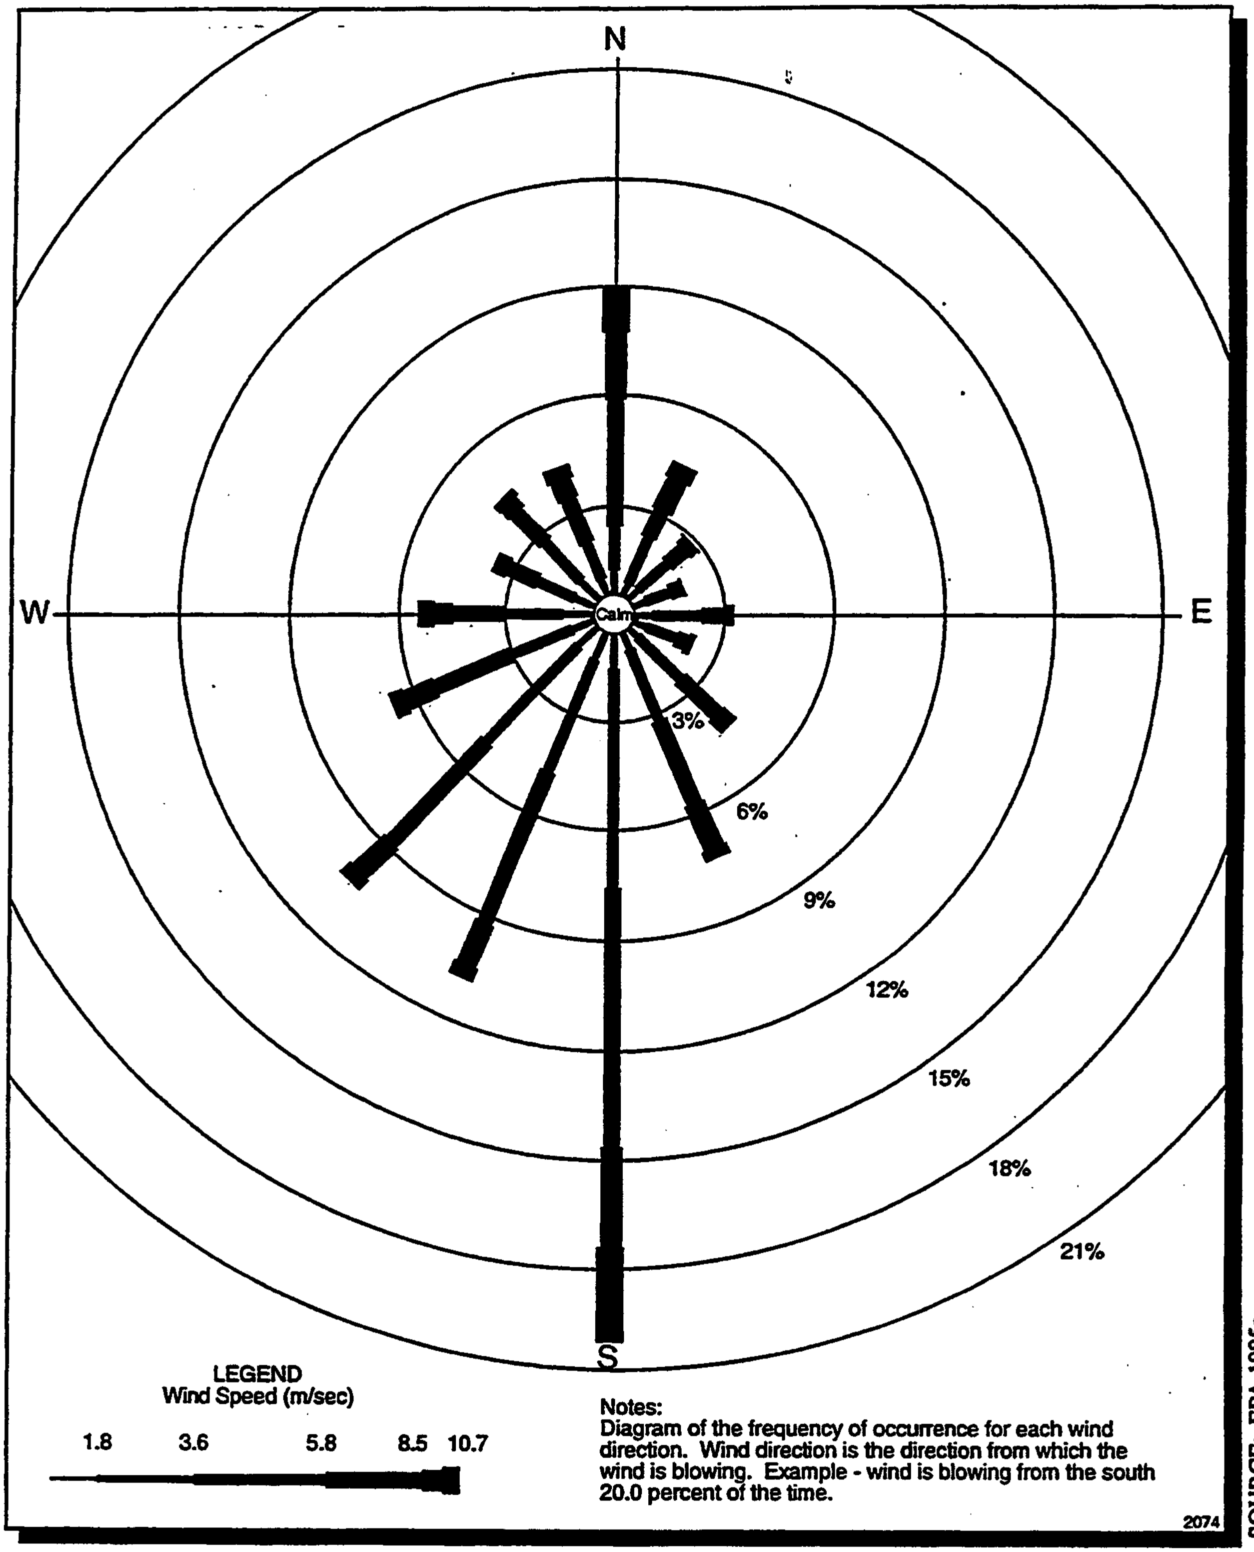

FIGURE 4.7.1.1–1.—*Distribution of Wind Speed and Direction at the Amarillo International Airport, Texas, 1988.*

National Weather Service station for 1988 indicated that unstable conditions occurred approximately 16 percent of the time, neutral conditions approximately 60 percent, and stable conditions approximately 24 percent, on an annual basis (DOE 1995q:B–17). Thus, relatively good vertical dispersion occurs about 76 percent of the time in the vicinity of Pantex Plant.

Another meteorological element that influences dispersion is the mixing height. The mixing height is the height above the ground through which relatively vigorous vertical mixing occurs. The mixed layer dilutes pollutants released in it. Annual average mixing heights over the Amarillo area range from about 328 meters (1,076 feet) in the morning to about 1,973 meters (6,473 feet) in the afternoon (Pantex 1996:6.4). Therefore, based on stability and mixing height considerations, atmospheric dispersion at Pantex Plant and vicinity is, in general, quite good.

4.7.1.3 *Ambient Air Quality*

Ambient air quality is determined by the emission of pollutants and their interaction with atmospheric conditions. Air quality is described in terms of concentrations of pollutants. If these concentrations in the ambient air are high enough to cause health concerns or effect visibility in visual resource areas then emissions are regulated to bring the concentrations down. Ambient air quality is assessed by the monitoring of pollutant levels in the air and modeling of emissions' interactions with atmospheric conditions. This subsection discusses the regulation and control of air pollutants, the air quality monitoring at Pantex Plant, and the modeling performed to evaluate potential impacts of the Proposed Action and the Alternatives.

Regulation of Air Quality

Concentrations. Air quality in a given location is described by the concentration of various pollutants in the atmosphere expressed in units of parts per million or in micrograms per cubic meter. The standards and limits set by regulations on air quality are listed in concentrations averaged over certain time limits (e.g., 30 minutes, 1 hour, 3 hours). The averaging times listed in the tables in this section correspond to the regulatory averaging times for the individual pollutants. Ambient air is defined as that portion of the atmosphere external to the buildings to which the general public has access. Ambient air quality standards specify upper limits of concentrations and durations of pollutants in the ambient air that are consistent with the goal of preventing harmful effects.

The impact of exposure to ambient contaminants is a function of the pollutant involved, the duration of the exposure, and the concentrations reached during the exposure. The significance of pollutant concentrations is determined by comparing the concentrations with appropriate Federal or State ambient air quality standards. These standards represent the allowable pollutant concentrations at which public health and welfare are protected and include a reasonable margin of safety.

Another determining factor in the significance of pollutant concentrations is whether the area is in attainment or nonattainment for that pollutant. An area is designated by the U.S. Environmental Protection Agency (EPA) as being in attainment for a pollutant if ambient concentrations of that pollutant are below the National Ambient Air Quality Standards (NAAQS) and nonattainment if exceedances of NAAQS occur. Areas where insufficient data are available to make an attainment status designation are listed as unclassified. Unclassified areas are treated as attainment areas for regulatory purposes.

The NAAQS were established by EPA. The State of Texas implements and enforces the NAAQS, plus TNRCC has placed regulations on additional pollutants. NAAQS have been established for ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), particulate matter (fine dust) of aerodynamic diameter less than 10 micrometers (PM_{10}), and lead (Pb). These NAAQS pollutants are sometimes referred as "criteria" pollutants. TNRCC has also set net ground level limitations for total suspended particulate matter, inorganic fluoride compounds calculated as hydrogen fluoride (HF), hydrogen sulfide, sulfuric acid, and beryllium. NAAQS and the Texas Air Quality Standards are presented in Table 4.7.1.3–1 (TNRCC 1993a).

The EPA has granted to TNRCC the authority to implement regulations to prevent the significant deterioration of air quality in areas that are designated as attainment or unclassifiable. The Prevention of Significant Deterioration (PSD) program is implemented in large part through the use of "increments" and area classifications that effectively define what "significant deterioration" is for individual pollutants. The *Clean Air Act's* area classification scheme for PSD establishes three classes of geographic areas (Class 1, 2, and 3) and applies increments of different stringency to each class. Air quality impacts, in combination with other PSD sources in the area, must not exceed the maximum allowable increments presented in Table 4.7.1.3–2 (TNRCC 1993a).

Visibility. Class 1 areas are those of special National concern where any appreciable deterioration in air quality is considered significant. Consequently, the most restrictive increments apply in Class 1 areas. Class 1 areas include all international and National parks, wilderness areas, and memorial parks that exceed certain sizes.

The *Clean Air Act* (CAA) (42 U.S.C. 7401) requires a visibility analysis for any new or modified major stationary sources, in an attainment or nonattainment area, whose emissions would affect the visibility in a Class 1 area. The nearest PSD Class 1 areas to Pantex Plant are the Salt Creek Wilderness, in New Mexico, approximately 274 kilometers (170 miles) to the southwest, and the Wichita Mountains Wilderness, in Oklahoma, approximately 290 kilometers (180 miles) to the east-southeast (40 CFR 81.421 and 81.424). Since these Class 1 areas are approximately 274 kilometers (170 miles) from Pantex Plant, pollutant emissions from Pantex Plant facilities would not have an adverse impact on the air quality in these areas and no additional analyses would be required. No public recreational areas are located within 16 kilometers (10 miles) of Pantex Plant.

Less restrictive increments apply in areas designated as Class 2 or Class 3. Class 2 areas are all PSD areas that are designated as attainment or unclassifiable with respect to the NAAQS and are not classified in CAA as Class 1 areas. Individual states have the authority to redesignate Class 2 areas to Class 3 areas to allow for higher levels of industrial development and emissions growth. There are as yet no designated Class 3 areas.

PSD requirements apply to major stationary sources. CAA specifies 26 categories of stationary sources which are considered major sources if they emit or have potential to emit 90.7 metric tons (100 tons) per year or more of any pollutant subject to CAA regulation (40 CFR Section 52.21). Any other stationary source which emits or has the potential to emit 226.8 metric tons (250 tons) per year or more of any air pollutant subject to regulation under CAA is considered a major source and is subject to PSD requirements.

Pantex Plant stationary sources do not fall within the 26 categories of stationary sources. Also, plant stationary sources emit less than 226.8 metric tons (250 tons) per year of any regulated pollutant (see Tables 4.7.1.3–3 and 4.7.1.3–6). Pollutant emissions from future

TABLE 4.7.1.3–1.—*National Ambient Air Quality Standards and Texas Limitations*

POLLUTANT	AVERAGING TIME	NATIONAL STANDARDS[1] PRIMARY CONCENTRATION	NATIONAL STANDARDS[1] SECONDARY CONCENTRATION	TEXAS STANDARDS
Ozone (O_3)	1-hour	0.12 ppm (235 μg/m³)	Same as primary standard	Same as NAAQS
Carbon Monoxide (CO)	8-hour	9 ppm (10,000 μg/m³)	—	Same as NAAQS
	1-hour	35 ppm (40,000 μg/m³)	—	Same as NAAQS
Nitrogen Dioxide (NO_2)	Annual	0.053 ppm (100 μg/m³)	Same as primary standard	Same as NAAQS
Sulfur Dioxide (SO_2)	Annual	0.03 ppm (80 μg/m³)	—	Same as NAAQS
	24-hour	0.14 ppm (365 μg/m³)	—	Same as NAAQS
	3-hour	—	0.5 ppm (1,300 μg/m³)	Same as NAAQS
	30-minute[5]	—	—	0.4 ppm[2] (1,021 μg/m³)
PM_{10}	Annual	50 μg/m³	Same as primary standard	Same as NAAQS
	24-hour	150 μg/m³		Same as NAAQS
Lead	Calendar Quarter	1.5 μg/m³	Same as primary standard	Same as NAAQS
Total Suspended Particulates	3-hour[5]	—	—	200 μg/m³
	1-hour[5]	—	—	400 μg/m³
Hydrogen Fluoride (HF)	30-day[5]	—	—	1.0 ppb (0.82 μg/m³)
	7-day[5]	—	—	2.0 ppb (1.63 μg/m³)
	24-hour[5]	—	—	3.5 ppb (2.86 μg/m³)
	12-hour[5]	—	—	4.5 ppb (3.68 μg/m³)
	3-hour[5]	—	—	6 ppb (4.9 μg/m³)
Hydrogen Sulfide	30-minute[5]	—	—	0.08 ppm[3] 0.12 ppm[4]
Sulfuric Acid	24-hour[5]	—	—	15 μg/m³
	1-hour[5]	—	—	50 μg/m³
Beryllium	24-hour[5]	—	—	0.01 μg/m³

[1]National standards for ozone and PM_{10} are determined by statistical methods. Both ozone and PM_{10} NAAQS are based on exceedances; i.e., non-sampling days must be accounted for when calculating attainment determination. NAAQS is attained when expected number of days per calendar year, averaged over a three-year period, with a maximum hourly average concentration for ozone and 24-hour average concentration for PM_{10} above the standard, is equal to or less than one. Sulfur dioxide annual, nitrogen dioxide annual, and lead quarterly NAAQS are not to be exceeded. Carbon monoxide 1-hour and 8-hour, and sulfur dioxide 3-hour and 24-hour standards cannot be exceeded more than once per year.

[2]Conversion from ppm to μg/m³ assuming temperatures of 90 °F, standard is 0.28 ppm for Galveston and Harris Counties and 0.32 ppm (no ground-level concentrations from all sources on property) for Jefferson and Orange Counties

[3]If it affects a residential area, business, or commercial property.

[4]If it affects only property used for other than residential, recreational, business, or commercial purposes.

[5]Texas net ground level limitations applicable at the property line. The maximum predicted concentration is compared with the appropriate standard for each averaging time. These are TNRCC's standards.

TABLE 4.7.1.3–2.—*Maximum Allowable Concentration Increases Under Prevention of Significant Deterioration Regulations*

POLLUTANT	AVERAGING TIME	MAXIMUM ALLOWABLE INCREMENT (µg/m³)		
		CLASS 1	CLASS 2	CLASS 3
PM_{10}	Annual	4	17	34
	24-hour	8	30	60
Sulfur Dioxide	Annual	2	20	40
	24-hour	5	91	182
	3-hour	25	512	700
Nitrogen Dioxide	Annual	2.5	25	50

Source: 40 CFR 52.21

Pantex Plant operations would also be less than 226.8 metric tons (250 tons) per year (see Tables 4.7.2.1–3 and 4.7.2.1–4). Therefore, Pantex Plant would not be subject to PSD requirements.

Assessment of Air Quality

Assessment Parameters. Existing ambient air quality in the region is defined by air quality data and emissions information. Air quality data were obtained from air quality monitoring stations maintained by TNRCC (TNRCC 1993c; TNRCC 1995d). Information on pollutant concentrations measured for short-term (24 hours or less) and long-term (annual) averaging periods were extracted from the monitoring station data to characterize the existing air quality background of the area. The emission inventory for the region was obtained from EPA and Pantex Plant. Inventory data are separated by pollutant and reported in pounds and tons per year to describe the baseline conditions of pollutant emissions in the area (EPA 1988). Since the TNRCC air quality monitoring stations do not operate continuously and are not placed at the borders of Pantex Plant, the monitoring data do not indicate the impacts to the public from plant air emissions.

Identifying the Region of Influence (ROI) for an air quality assessment requires knowledge of the pollutant types, source emission rates and release parameters, the proximity relationship of project emission sources to other emission sources, and local and regional meteorological conditions. For inert pollutants (all pollutants other than SO_2, O_3, and its precursors NO_2 and volatile organic compounds [VOCs]) the ROI is generally an area extending a few miles downwind from the source. The ROI for O_3 may extend much farther downwind than the ROI for inert pollutants. For the purpose of this air quality analysis, the ROI is defined as Carson County and its eight surrounding counties: Potter, Randall, Armstrong, Donley, Gray, Roberts, Hutchinson, and Moore.

The windrose in Figure 4.7.1.1–1 indicates that pollutants from Pantex Plant might be transported into any of these surrounding counties. As mentioned previously, the ROI for O_3 extends farther downwind than the ROI for inert pollutants. This greater distance occurs because in the presence of solar radiation, the maximum effect of precursor emissions on O_3 levels usually occurs several hours after they are emitted and therefore, many miles from the source.

The ROI and Pantex Plant are located in the Amarillo-Lubbock Intrastate Air Quality Control Region (AQCR) 211. AQCR 211 is designated by EPA as "better than national standards" for SO_2, "unclassifiable/attainment" for CO and O_3, "cannot be classified or better than National standards" for NO_2, "unclassifiable" for PM_{10}, and "not designated" for lead (40 CFR 81.344).

Air Monitoring Results. TNRCC operates six air quality monitoring stations in the ROI, one at Amarillo and five at Pantex Plant. The Amarillo station only monitors PM_{10}. The monitoring report issued by the TNRCC for the year 1992 indicated that concentrations of this pollutant in Amarillo were within the NAAQS (Pantex 1996:6.5).

TNRCC, through a grant from DOE, established five air quality monitoring stations at Pantex Plant in September 1992. Locations of these stations are shown in Figure 4.7.1.3–1. In August 1995, one of these monitoring stations (Site No. 3) was repositioned to a new location (Site No. 6). The first annual report on this program covered the period January 1 to December 31, 1993 (TNRCC 1995d). Twenty-four hour sampling is conducted once every six days. The TNRCC measures inorganic pollutants as PM_{10} and HF. Organic pollutants are measured as VOCs in parts per billion by volume (ppbv). A few samples have been analyzed for metals, but this is not done on a regular basis. At two sites, wind speed, wind direction, temperature, and relative humidity are measured.

A Fourier Transform Infrared (FTIR) continuous monitor has also been installed at the Masterson Pump station located two miles north of Pantex Plant. The data collected with this sampler is considered developmental data since the TNRCC is still developing procedures (including quality assurance procedures) for this method. Initial screening of the data, however, does not indicate levels that might be harmful to public health and/or welfare. The first annual report on this program covered the period from January 1, 1993 to December 31, 1993 (Pantex 1996).

During 1993, only one 24-hour PM_{10} measurement exceeded the NAAQS while, in 1994, the standard was exceeded on one day in January and one day in June. From July 6, 1993, through December 31, 1994, TNRCC air sampling coincided with Pantex Plant burn days on 57 occasions. Of those 57 days, all had valid PM_{10} samples at one or more sites; however, the exceedance of the standard on the January day was a non-burn day and TNRCC stated that windblown dust particles are strongly suggested as a major contributor to that exceedance (TNRCC 1995c; Pantex 1996:6.5).

Two compounds, methylene chloride and 1,2-dibromoethane, exceeded the TNRCC Effects Screening Levels (ESLs) once each during 1993. Methylene chloride was measured at 213.7 ppbv on July 6, 1993 (TNRCC 1993c). The concentration was approximately seven times the ESL (30 ppbv) established by TNRCC. In 1994, the maximum concentration of methylene chloride was measured at 11.75 ppbv, which is lower than the ESL (TNRCC 1995c).

The TNRCC ESLs are "tools" the Toxicology and Risk Assessment Staff of TNRCC use to evaluate the impacts of air pollutant emissions. They are not ambient air standards. If predicted or measured airborne levels of a certain chemical do not exceed its screening level, it would not be expected to have any adverse health or welfare effects. If ambient levels of air contaminants exceed the screening levels, it does not necessarily indicate a problem. It is just a trigger for a more in-depth review. Therefore, TNRCC sets the ESL at levels where TNRCC would not expect adverse effects. These levels are sometimes below the limit of detection for a pollutant.

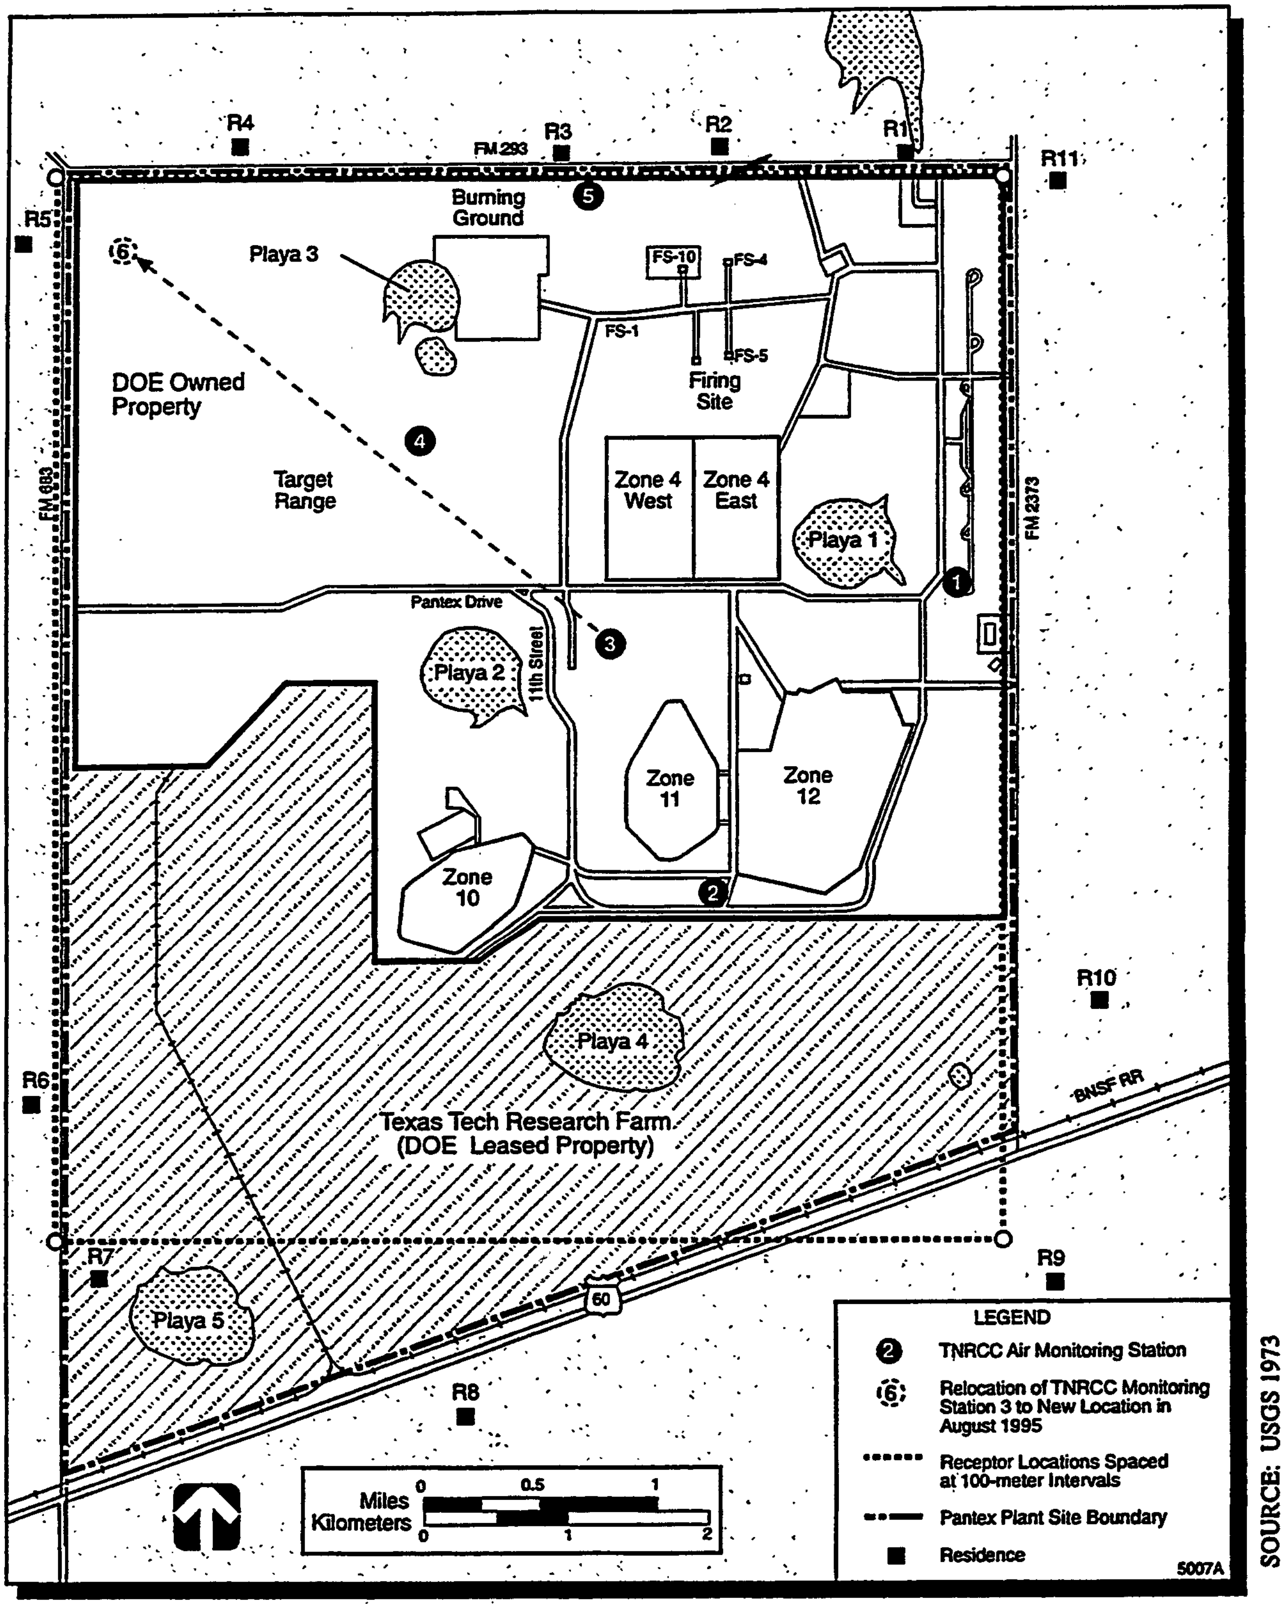

FIGURE 4.7.1.3–1.—*Air Quality Monitoring Stations at and Residences near Pantex Plant Site.*

In 1995, 1,2-dibromoethane was detected at 0.23 ppbv (TNRCC 1993b), which exceeded the ESL (0.2 ppbv). In 1994, the concentration of 1,2-dibromoethane (0.72 and 0.51 ppbv) exceeded the ESL on two occasions (TNRCC 1995c). In 1995, the concentration (0.29 ppbv) of 1,2-dibromoethane exceeded the ESL once (TNRCC 1996d).

The TNRCC concluded that in the 1993 and 1995 case of the 1,2-dibromoethane, it was not certain the compound was actually present at the reported concentration. In the case of the 1993 methylene chloride exceedance, the TNRCC Toxicology and Risk Assessment Section staff stated that the one exceedance was not expected to result in any long-term health effects. Monitoring in the last quarter of 1995 indicated that all organic compounds were measured below their respective ESLs, concentrations of HF were measured below the TNRCC Regulation III Standard, and measured concentrations of PM_{10} were below the NAAQS. The October-December 1995 TNRCC Ambient Air Monitoring Report for Pantex Plant is the last quarterly report the TNRCC will produce; however, quarterly data summaries will be accessible via the Internet, at the following address:

http://www.tnrcc.state.tx.us/air/monops

Annual reports will continue to be published (Pantex 1996).

Air Quality Modeling

Since the onsite air quality monitoring network cannot be used to evaluate the effect of Pantex Plant pollutant emissions on offsite ambient concentrations, air dispersion models were applied to assess the maximum pollutant concentrations that could occur on or near the Pantex Plant boundary. Modeling was performed with EPA preferred Industrial Source Complex Models (ISCST2 and ISCLT2). Hourly surface and upper air data from the Amarillo International Airport were used in the ISCST2 model. The meteorological data were for the year 1988. This year's data is the only data with mixing heights approved by TNRCC. For the ISCLT2 model, the joint frequency distribution of wind speed, wind direction, and stability contained in the stability array program output, based on 1985 through 1989 Amarillo International Airport data, were used.

Discrete receptors with a spacing of 100 meters were established along the northern, eastern, and western boundaries of the site. The southern line of receptors were located on an east-west line south of the Pantex Plant boundary, but generally north of the site boundary along U.S. Highway 60 (see Figure 4.7.1.3–1).

The emission rates used in the Industrial Source Complex models were provided by Pantex Plant personnel (PC 1994b). These emission rates are consistent with the submittal to TNRCC. Emissions from the Burning Ground, where high explosive(s) (HE) are burned, were confined to particular hours of the day. For all explosives that emitted HF, the burning hours were limited to the period 11:00 a.m. to 6:00 p.m., while all other explosives could be burned during the period 7:00 a.m. to 6:00 p.m.

Two scenarios were assumed for the Burning Ground. One scenario assumed that 363 kilograms (800 pounds) of explosives were burned while the second scenario assumed a 45.4-kilogram (100-pound) burn. The 360 kilograms (800 pounds) of HE was assumed to consist of a mixture of 90.7 kilograms (200 pounds) of LX–17 and 272.1 kilograms (600 pounds) of PBX–9404, while the 45.5 kilograms (100 pounds) of HE consisted of 11.4 kilograms (25 pounds) of LX–17 and 34.1 kilograms (75 pounds) of PBX–9404. The different kinds of HE are mixed to maximize the heat produced by the burning and keep the amount of HF emitted below the regulatory limits. In order to be conservative, the HE mixes modeled in this EIS were chosen for the lowest heat output and highest emission of HF allowed by regulation.

Modeling Results. Four criteria air pollutants, 36 air pollutants that are listed in CAA, and 50 air pollutants that are listed by the TNRCC have been identified that are emitted from existing Pantex Plant operations (Pantex 1996:6.6). All 90 air pollutants were modeled. The Pantex Plant chemical air emissions inventory is summarized in Table 4.7.1.3–3. The maximum estimated fence line concentrations of these pollutants are presented in Tables 4.7.1.3–4 and 4.7.1.3–5. Table 4.7.1.3–4 presents the results for the criteria pollutants CO, NO_2, PM_{10}, and Pb. The NAAQS for each pollutant is also presented in Table 4.7.1.3–4. As shown in the table, none of the pollutant concentrations exceeded standards at the Pantex Plant boundary.

The results for the rest of the chemical air pollutants emitted by Pantex Plant are presented as two groups. The first group includes those chemical air pollutants emitted by Pantex Plant that are listed in CAA, as amended, plus those pollutants with estimated concentrations above the appropriate ESL. Only alcohols, modeled as a group, were estimated to exceed an ESL. The second group includes those chemical air pollutants emitted by Pantex Plant that are listed in State of Texas regulations (except for alcohols as mentioned above). Both groups were originally modeled for the current status of the plant (i.e., Affected Environment) and the potential future impacts related to the alternatives.

The maximum estimated fence line concentrations for both groups are presented in Table 4.7.1.3–5 in comparison with the appropriate TNRCC ESLs. The first group, including alcohols, was also modeled for the maximum estimated concentrations at eleven of the residences near the boundaries of the Pantex Plant Site. These results are presented in Table B.4.1–1 in appendix B. All of the air pollutants except alcohols were estimated to be below their respective ESLs at the Pantex Plant boundary.

The group of alcohols consisted of those alcohols used by Pantex Plant for which there were no individual emission rates. TNRCC does not have an ESL for the family of alcohols, but rather chose in their modeling of Pantex Plant to use a conservative ESL equal to 100 $\mu g/m^3$ as the ESL for the group of alcohols. The group of alcohols exceeded the conservative 1-hour ESL at and near the Pantex Plant boundary. The maximum estimated fence line concentration for alcohols (195 $\mu g/m^3$) was almost twice the conservative ESL. As explained earlier, the exceedance of an ESL does not necessarily indicate a problem. It is just a trigger for a more in-depth review.

A subsequent review of the inventory of the amounts of the individual alcohols present at the Plant showed that the ESL used in the modeling was excessively conservative (PC 1996b). Since the emission rates for the individual alcohols in the group were not speciated in the original emissions inventory, a second inventory was obtained to determine quantities of individual alcohols maintained on-hand at the plant. An estimation of the maximum fence line concentration for each of the alcohols was then calculated based on the ratio of the amount of each alcohol to the total inventory of the group of alcohols present at Pantex Plant (see Table B.4.1–2 in appendix B). None of the individual alcohols were found to exceed their respective ESLs at or near the plant boundary.

HF is a pollutant regulated by TNRCC. The modeling results predicted a maximum 3-hour average concentration of 1.52 $\mu g/m^3$. This concentration is below the standard of 4.90 micrograms per cubic meter. This concentration resulted from a 45.4-kilogram (100-pound) burn of HE. For a 363-kilogram (800-pound) burn of HE, the 3-hour average maximum concentration was also below the standard (see Table 4.7.1.3–5).

[a]EPA Model ISCST2 was used to calculate maximum fence line concentrations.
[b]Hours of operations were taken into account for emissions from open burning and engine emissions for CAA listed air pollutants.
[c]The group of alcohols, while not listed in CAA, were estimated to exceed the conservative ESL used by TNRCC. Therefore, alcohols were included for more complete presentation of results.
[d]Hours of operation were not taken into account and emissions were modeled for an entire year of meteorological data for TNRCC listed air pollutants.
[e]The ISCST2 air quality model returns a value of 0.00 for any concentration equal to or less than 1.00×10^{-5} $\mu g/m^3$ (i.e., less than one ten millionth of a part per billion or less than ten parts per quadrillion).
[f]Solvents that are not listed under 40 CFR 261.33 (Hazardous Waste from Non-Specific Sources).
NA - An ESL has not been established by TNRCC.
Sources: TNRCC 1996a; CAA as amended

The maximum pollutant concentrations which were predicted to occur at 11 residences that are located near the plant boundaries are all below respective NAAQS. Appendix B presents tables of these concentrations for each of the 11 residences.

In summary, the modeling results presented in this document are the highest concentrations predicted by the model. The modeling results suggest that existing short-term air quality may be slightly degraded on or near the boundary of Pantex Plant by alcohol emissions. However, subsequent review of specific alcohol concentrations indicates that this degradation would not occur and that the regional and long-term air quality is good.

Emissions. The amount of pollutants entering the atmosphere (from all sources) in a given time period is used by EPA to determine the overall emissions in an area. This definition facilitates the identification of the sources that can be defined as the major sources whose control can lead to a considerable reduction in the pollutant levels for the area. There are various other sources that contribute to overall pollutant emissions, including mobile sources, point (stationary) sources, and area emissions.

Mobile sources include conventional motor vehicles (including Safe Secure Tractor Trailers) and others such as boats, trains, planes, and off-road motor vehicles. Point sources include most industrial and energy-producing facilities that have stacks, vents, or flues from which emissions discharge. Area sources are groups of similar emission sources that do not individually contribute significant amounts of air pollutants, but that do contribute collectively.

CAA, as amended in August 1977 and November 1990, dictates that project emission sources must comply with ambient air quality standards and regulations that have been established by Federal, State, and county regulatory agencies. These standards and regulations focus on the maximum allowable ambient pollutant concentrations resulting from project emissions, both separately and combined with other surrounding sources, and the maximum allowable emissions from the project.

The primary emission sources of criteria pollutants at Pantex Plant are steam plant boilers, the explosives burning operation, diesel and gasoline engines and motor vehicles. Potential emission sources of chemical air pollutants include the HE synthesis facility, the explosive burning operation, miscellaneous laboratories, and other small operations. Table 4.7.1.3–6 presents a summary of the 1993 criteria pollutant emission inventory for stationary and mobile sources at Pantex Plant (Pantex 1996: 6.6.1). The mobile source emissions were developed using emission factors from the EPA mobile sources emission factor model MOBILE 5a and estimates of the traffic volumes on Pantex Plant (EPA 1994; Pantex 1996: 9.5).

The 1990 CAA amendments established a new control standard for air toxics called Maximum Achievable Control Technology (MACT), which will have as its foundation the maximum level of control achieved in practice within industry. The MACT standard must be achieved by sources with the potential to emit 9.08 metric tons (10 tons) per year of any single hazardous air pollutant (HAP), or more than 22.7 metric tons (25 tons) per year of any combination of HAPs. Since, as shown in Table 4.7.1.3–3, none of the emissions of the individual HAPs at Pantex Plant exceed 9.1 metric tons (10 tons) per year and the combined emissions of all the HAPs are less than 22.7 metric tons (25 tons) per year, MACT standards are not applicable.

A summary of the criteria pollutant emissions for the nine counties in the ROI is shown in Table 4.7.1.3–7. These emissions include both stationary and mobile source emissions and were obtained from the EPA National Emissions Data System. Pantex Plant emissions are also shown in the table for comparison with ROI emissions.

Pantex Plant emissions contribute a small portion of pollutants to the overall pollutant burden in the ROI. Because of good atmospheric dispersion and relative low emissions over the region, the existing air quality in the ROI is generally very good.

4.7.1.4 *Atmospheric Radiological Environment*

The population of the Texas Panhandle is exposed to environmental radiation from both natural and manmade sources. This section

Source: EPA 1988; Pantex 1996

summarizes the sources and levels of radiation exposure in this geographical region, including sources of airborne radionuclide emissions from Pantex Plant. Estimates of radioactivity levels and radiological doses from current Pantex Plant operations are provided and discussed (DOE 1995b).

Sources of Radioactivity

The major source of radioactive exposure in the Texas Panhandle is natural background radiation. Sources of radioactivity related to Pantex Plant operations contribute a negligible amount of additional exposure.

Background radiation includes sources such as cosmic rays; radioactivity naturally present in soil, rocks, and the human body; and the airborne radionuclides of natural origin (such as radon). Radioactivity still remaining in the environment as a result of atmospheric testing of nuclear weapons also contributes to the background radioactivity level, although in very small amounts. The natural background dose for residents of the Texas Panhandle is about 95 millirem per year. For comparison, the average annual dose equivalent to any citizen of the U.S. is about 160 millirem, excluding exposure to radon (NCRP 1987).

Potential sources of radioactivity at Pantex Plant from weapons activities include radioactive materials that may be present in the components of weapons and in radiation-generating devices. The radioactive materials in weapons include tritium, various isotopes of plutonium and uranium, and thorium. Gamma radiation is produced by equipment that contains sealed gamma sources (e.g., cobalt-60 and cesium-137), Van de Graaf generators, and linear accelerators.

In normal operating situations, little potential exists for exposure to Pantex Plant personnel, the public, or the environment from release of radioactive materials. Small amounts of tritium escape as a gas or vapor during normal operations, and some tritium residual is present onsite as a result of an accidental release in 1989. Recent amounts of tritium released in 1993 and 1994 were 0.312 curie and 0.446 curie, respectively (DOE 1994b: 4-4; DOE 1995b:7-2). On May 17, 1989, an unplanned release of tritium occurred in Cell 1 in Zone 12 during a routine disassembly operation. The accidental release of tritium in 1989 was conservatively estimated as 40,000 curies (Pantex 1996:16.1).

Existing Radiological Conditions

Monitoring and assessment activities are conducted to characterize existing radiological conditions at Pantex Plant and the surrounding environment (DOE 1995b:8-6 to 8-7). Results of these activities show that exposures resulting from airborne radionuclide emissions are well within applicable standards and are a small fraction of the dose from background sources. These results are discussed separately below for onsite and offsite environments.

Onsite Doses. An indication of onsite radiological conditions is obtained by comparing measured onsite concentrations with those from Pantex Plant nearby locations and a distant location. Results from onsite and nearby locations include contributions from background conditions and Pantex Plant emissions, while the distant location represents background conditions beyond the influence of Pantex Plant emissions. Pantex Plant has 10 offsite, 7 onsite, and 17 perimeter air sampling locations for the air monitoring program for airborne radioactive emissions only. Nine of the 10 offsite units are located within an approximately 8-kilometer (5-mile) radius of the plant. A control site, used to collect background air data is located 48 kilometers (30 miles) west of Pantex Plant at the Bushland Agricultural Research Station (Pantex 1996:16.1).

The data show that 1994 average airborne radioactivity and radiation exposure levels within and around Pantex Plant were only slightly different than those at the control station. The average annual dose (as measured by thermoluminescent dosimeters during 1994) was 97 millirem onsite, 95 at the nearby offsite locations and 93 at the control station (DOE 1995b).

Offsite Doses. The offsite population may receive a very small radiation dose as a result of radiological conditions directly attributable to Pantex Plant operations. The dose associated with baseline radiological emissions is assessed for a maximally exposed individual. The maximally exposed individual is a hypothetical person whose habits and proximity to Pantex Plant are such that the person would receive the highest dose projected to result from site-wide radiological emissions.

The dose calculated for the maximally exposed individual for 1994 was 5.8×10^{-5} millirem per year. The offsite radiation doses from onsite sources were calculated using the CAP88/PC model and 1994 meteorological data in accordance with 40 CFR 61, Subpart H (Pantex 1996). This value was obtained for tritium, the only radionuclide that was released in 1994. The maximally exposed individual dose was well below the National Emissions Standards for HAPs dose limit (10 millirem per year) and the dose received from background sources (95 millirem per year).

The collective dose to the surrounding population as a result of Pantex Plant emissions, assessed using the total population residing within a circular area with an 80-kilometer (50-mile) radius extending from the plant, was 1.37×10^{-4} person-rem in 1994. This population dose was distributed over a population of about 267,000. This population dose is very small when compared with the dose received by the same population from background sources (over 26,000 person-rem).

Results of fence line monitoring for oxidized tritium, elemental tritium, uranium-234, uranium-238, plutonium-239, plutonium-240, and gross alpha and beta were compared to the Derived Concentration Guidelines (DCG) for inhalation listed in DOE Order 5400.5 "Radiation Protection of the Public and the

Environment." The measured concentrations of these radionuclides were found to be several orders of magnitude below the DCG levels (DOE 1995b).

Health risks associated with maximum potential exposure levels in the onsite and offsite environments are described in section 4.14, Human Health.

4.7.2 Impacts of Proposed Action

4.7.2.1 *Impacts of Continued Operations*

Weapons-Related Activities

Ambient Concentrations. The estimation of air quality impacts for continued operations was made using the following assumptions:

- Continued operations cover the 10-year period examined.
- Three weapons levels are representative of the range of likely levels:
  - — 2,000 weapons per year.
  - — 1,000 weapons per year.
  - — 500 weapons per year.

The term "weapons level" includes activities related to the assembly and disassembly of nuclear weapons, certain maintenance and monitoring activities regarding the nuclear weapons stockpile, modification of nuclear weapons, production of HE, and the open burning of HE.

Air quality modeling was performed for each level of continued operations using the ISCST2 and ISCLT2 models to estimate ambient concentrations. The modeling methodology was the same as outlined in section 4.7.1.3 (Ambient Air Quality) and more fully described in appendix B.

The emissions inventory used for the 2,000 weapons level was the same as that used for the Affected Environment (section 4.7.1.3 and appendix B), except that the Burning Ground Upgrade emissions were added and the HE explosive mixture that was burned included LX–04 and PBX–9404 rather than LX–17 and PBX–9404. Information from Pantex Plant personnel indicated that LX–17 would not be burned in the 1997 to 2007 period.

The Burning Ground Upgrade project would replace the current methods of removing HE contamination from equipment and parts. The upgrade would consist of a covered three-sided structure with a fan to exhaust emissions through an elevated stack. The wood currently used as an auxiliary heat source for the burns would be replaced by natural gas. The modeling results are presented in Tables 4.7.2.1–1 and 4.7.2.1–2.

Table 4.7.2.1–1 presents the maximum criteria pollutant concentrations that were obtained at or near the Pantex Plant boundary. The NAAQS for these pollutants are also shown for comparison. Table 4.7.2.1–2 presents the maximum chemical pollutant concentrations that were obtained at or near the Pantex Plant boundary. The applicable State of Texas ESL is also shown for comparison. Table 4.7.2.1–2 presents the concentrations calculated for the continued operations at the 2,000, 1,000, and 500 weapons levels for those pollutants that are listed in CAA (plus alcohols) and the 2,000 weapons level for those pollutants that are listed by TNRCC.

The tables show that, except for alcohols, all criteria pollutant and chemical air pollutant concentrations are below their respective ambient air quality standards or their respective ESLs for continued operations at all three levels. For those pollutants listed by TNRCC, the estimated concentrations are low enough for the 2,000 weapons level that the results for the reduced operations levels (i.e. 1,000 and 500 weapons levels) were not calculated.

TABLE 4.7.2.1–1.—*Estimated Maximum Fence Line Concentration of Criteria Pollutants for the 2,000, 1,000, and 500 Weapons Levels*

[a]EPA Model ISCST2 was used to calculate maximum fence line concentrations for all three operations levels.
[b]Hours of operations were taken into account for emissions from open burning and engine emissions for CAA listed air pollutants.
[c]The group of alcohols while not listed in CAA were estimated to exceed the conservative ESL used by TNRCC. Therefore, alcohols were included here for more complete presentation of results.
[d]Hours of operation were not taken into account and emissions were modeled for an entire year of meteorological data for TNRCC listed air pollutants.
[e]The ISCST2 air quality model returns a value of 0.00 for any concentration equal to or less than 1.00×10^{-5} $\mu g/m^3$ (i.e., less than one ten millionth of a part per billion or less than ten parts per quadrillion).
[f]Solvents that are not listed under 40 CFR 261.33.
BGU - Burning Ground Upgrade
NA - An ESL has not been established by TNRCC.
Sources: TNRCC 1996a; CAA as amended

The maximum concentrations of criteria pollutants and CAA listed air pollutants estimated to occur at the 11 residences located near the Pantex Plant boundary are below their respective ambient air standards or their respective ESLs. Appendix B presents tables of these concentrations for each of the 11 residences.

Alcohols exceeded the ESL at the boundary and at residence 10. These alcohols were modeled as a group and compared with the conservative ESL used by TNRCC. However, subsequent review of the inventories of the types of alcohols and quantities on hand at the plant showed that the use of the conservative ESL for the group of alcohols was excessively conservative. When the total concentrations of the individual alcohols were prorated, none of the individual alcohols exceeded their respective ESLs at or near the fence line. Table B.4.1–2 in appendix B shows the prorated concentrations of these alcohols.

Since ambient concentrations of all criteria pollutants and HAPs do not violate any of the ambient standards or ESLs beyond the Pantex Plant boundary, the air quality impacts from continued operations under the Proposed Action would be minor and would not be considered significant.

Criteria and VOC Pollutant Emissions

A summary of criteria and VOC pollutant emissions for the 2,000, 1,000 and 500 weapons levels are presented in Tables 4.7.2.1–3, 4.7.2.1–4, and 4.7.2.1–5, respectively. Emissions for the 2,000 weapons level would be about the same as those shown in Table 4.7.1.3–6 with the addition of emissions projected for the Burning Ground upgrade. In general, emissions for 1,000 and 500 levels are less than those for the 2,000 weapons. However, emission reductions are not directly proportional to weapons level reductions. This result occurs because some facility emissions would not be reduced when weapons levels are reduced (e.g., heating of buildings).

Source: Pantex 1996; PC 1994

Criteria pollutant emissions resulting from continued operations at Pantex Plant would contribute about 1 percent or less to the overall pollution burden in Carson and Potter Counties (see Table 4.7.1.3–7 for county emissions). Since this represents such a small impact on the two closest counties, emissions from Pantex Plant would be expected to have a negligible impact on the regional air quality.

Radiological Emissions

The radiological emissions that were discussed for the Affected Environment (section 4.7.1.4) were assumed for the 2,000 weapons level. The impacts from these emissions would also be the same as those discussed in the Affected Environment above. The impacts from these emissions are several orders of magnitude below the DCGs and National Emissions Standards for Hazardous Air Pollutants (NESHAP) dose limits. Therefore, the impacts would not be significant. The emissions levels associated with the 1,000 and 500 weapons levels would be less than those for the 2,000 weapons level. Therefore, the impacts for these levels are bounded by the impacts for the 2,000 weapons level and are also not significant.

Pit Storage Activities

Only indirect pollutant emissions would result from pit storage activities. Pollutant exhaust emissions from the Safe Secure Tractor Trailers hauling weapons or pits to Pantex Plant and from the vehicles used by personnel responsible for pit storage would be the principal sources. Onsite pit transfers are accomplished with electric forklifts which do not emit any pollutants.

Pollutant emissions from these indirect sources are a small fraction of the total emissions from Pantex Plant. Therefore, air quality impacts resulting from pit storage activities would be negligible.

Environmental Restoration Activities

In May 1994, Pantex Plant was placed on the National Priorities List by EPA. The primary motivations for cleanup of these sites are to protect the general environment and to protect the health and safety of persons in proximity to the site.

Environmental restoration (ER) activities at Pantex Plant are expected to generate 772.6 cubic meters (1,010 cubic yards) of hazardous solid waste between 1997 and 2000 (see section 4.13), most of which will be in the form of contaminated soil. The majority of ER activities are expected to be completed by 2000.

Remedial actions at Pantex Plant could involve handling of contaminated soil. This handling could result in fugitive dust emissions that can carry inorganic particles and organic constituents that are contained in or are adhering to the dust.

Soil handling can also lead to enhancement of volatile organic emissions due to exposure of the contaminated soil to the atmosphere. Specific activities with emission potential include excavation, transport, dumping, storage, and grading.

Pantex Plant procedures for minimizing fugitive dust emissions would keep the impacts to a minimum. Thus, air quality impacts from ER activities would be reduced to a minimum and would, therefore, be negligible.

Waste Management Activities

The principal sources of pollutant emissions related to waste management activities are as follows:

- Burning Ground.
- Drum sampling.
- Bulk transport.

The emissions from these sources were included in the site-wide dispersion modeling. As indicated previously, the results of the site-wide modeling indicated that the continued operation of Pantex Plant would produce only negligible impacts to the regional and local air quality (see section 4.7.2.1).

4.7.2.2 *Impacts of New Facility Construction Upgrades*

Construction Impacts

During the construction phase of the new facility upgrades, exhaust emissions from construction equipment would consist of CO, VOCs, NO_2, SO_2, and particulate matter. The calculation of emission rates of exhaust pollutants from construction equipment was based on emission factors provided in the EPA document AP–42, *Compilation of Air Pollutant Emission Factors* (EPA 1995b, volume 2, Table II-7.1). For highway vehicles (worker commuting vehicles and delivery vehicles) emission factors were obtained from the EPA Mobile Source Emission Factor Model (MOBILE 5a) (EPA 1994).

Construction equipment composition that was assumed for the peak construction year, 1999, is shown in Table 4.7.2.2–1. (See section 3.1.1 for description of facility upgrade projects.) Fugitive dust generated during the clearing, grading, and other earth-moving operations is dependent on a number of factors, which include silt and moisture content of the soil, wind speed, and area disturbed. A common procedure to estimate fugitive emissions from an entire construction site is to use the EPA emission factor of 1.2 tons per acre per month of construction activity (EPA 1995b, volume 1, Section 13.2.3.3). This emission factor represents particles less than 30 microns in diameter. A multiplication factor of 0.5 was used to correct the emission rate to one for PM_{10} (EPA 1995b, volume 1, Page 13.2.2-3). Also, it was assumed that water would be applied to disturbed areas. This would reduce emission rates by about 50 percent (EPA 1985). It was estimated that construction of the facilities would disturb a total of 3.2 hectares (7.9 acres) over the construction period. It was assumed that the disturbance would occur in the first 2 years, 1998 and 1999, of the construction period.

TABLE 4.7.2.2–1.—*Assumed Equipment Used for Construction of New Facility Upgrades for 1999, the Peak Construction Year*

TYPE OF EQUIPMENT	NUMBER USED DAILY
Bulldozer	3
Grader	1

Backhoe	2
Roller	2
Crane	1
Portable Generator	3
Off-Highway Truck	3

The estimated annual pollutant emissions resulting from construction activities for the years 1998 through 2004 are presented in Table 4.7.2.2–2. Construction emissions during the peak year, 1999, increase the Pantex Plant annual emissions (see Table 4.7.1.3–7) by about 8 to 13 percent. The emission increases for the other construction years (1998, 2000, and 2001) are less. These temporary increases are too small to result in violations of the NAAQS beyond the Pantex Plant boundary. Therefore, air quality impacts resulting from construction of the new facility upgrades would be negligible.

Operations Impacts

Emissions resulting from the operation of the new or upgraded facilities have been mostly accounted for in the site-wide air quality analysis for continued operations under the

Source: Calculated values

Proposed Action (section 4.7.2.1). Emissions from the Materials Compatibility and Assurance Facility, the Metrology and Health Physics Calibration and Acceptance Facility, the Nondestructive Evaluation Facility, and the Gas Analysis Laboratory currently occur at Pantex Plant. The only change in their emissions would be a change in their location.

The HWTPF and Pit Reuse Facility would be new facilities. The HWTPF and Pit Reuse Facility will use high efficiency particulate air (HEPA) filters to reduce particulate emissions. The HEPA filters have a collection efficiency of 99.97 percent. Activated charcoal canisters or equivalent equipment would be used to absorb organic gases at the HWTPF. These filter systems are capable of controlling both radioactive and nonradioactive pollutants. Since the emissions from this facility would be reduced to very low levels, air quality impacts would be negligible.

Overall, the emissions from these new or upgraded facilities would not produce ambient concentrations that would exceed the NAAQS or the Texas ESLs. In addition, no increases in radiological emissions are anticipated. Therefore, the air quality impacts would be negligible.

4.7.2.3 *Summary of Impacts*

An analysis of pollutant emissions and ambient concentrations resulting from Proposed Action activities found that air quality standards or guidelines would not be violated beyond the Pantex Plant boundary. Specifically, maximum ambient concentrations that would occur at the 11 residences near the boundary were found to be below the NAAQS and Texas ESLs. Therefore, air quality impacts resulting from the Proposed Action would be negligible.

4.7.3 Impacts of No Action Alternative

Weapon-Related Activities

The major difference between this alternative and the Proposed Action is that weapons disassembly operations would cease when 12,000 pits have been placed in interim storage at Pantex Plant. However, the requirement to support the weapons stockpile with other operations, including weapons assembly, modification, and surveillance activities will continue. Three weapon levels—2,000, 1,000, and 500—are assumed for analysis. In addition, no upgrade projects would be initiated under the No Action Alternative. Therefore, there would be no emissions from construction under this alternative.

Since the activities related to the assembly of weapons produce chemical and radiological pollutant emissions similar to those produced by disassembly, the ambient concentrations resulting from the three levels of weapons for this alternative would be approximately the same as those described in the Proposed Action (section 4.7.2.1). No operational emissions or air quality impacts above those described in the affected environment would occur because new facility upgrades would not be implemented under this alternative. Therefore, it may be concluded that the air quality impacts resulting from continued operation under the No Action Alternative would be similar to the Proposed Action; i.e., impacts would not be significant.

Pit Storage Activity (12,000 Pits Only)

The emissions resulting from pit storage activity would be the same as those for the Proposed Action (section 4.7.2.1). Indirect emissions from Safe Secure Tractor Trailers hauling weapons or pits to Pantex Plant would be only a small fraction of the total Pantex Plant emission inventory. Also, once the storage limit of 12,000 pits has been reached, the emissions related to this activity would cease. Thus air quality impacts resulting from the storage of 12,000 pits would be negligible.

Environmental Restoration Activities

ER activities under the alternative would proceed in the same manner as under the Proposed Action (section 4.7.2.1). Emissions related to soil disturbance activities would be minimized through the application of water. Particulate emissions would not cause PM_{10} standards to be violated offsite. Air quality impacts would be negligible.

Waste Management Activities

Waste management activities under this alternative would be the same as under the Proposed Action. The emissions from these activities were included in the site-wide dispersion modeling for the Proposed Action. Air quality impacts for waste management activities under this alternative would also be negligible.

4.7.4 Impacts of Pit Storage Relocation Alternative

4.7.4.1 *Impacts of Relocating 20,000 Pits*

The Pit Storage Relocation Alternative includes all operations, upgrades, and modifications of the Proposed Action. Emissions resulting from activities related to the relocation of 20,000 pits would be added to those of the Proposed Action (see section 4.7.2.1). Indirect emissions from exhausts of the vehicles required to haul the pits to the alternative sites would be the only chemical or radiological emissions associated with the Pit Storage Relocation Alternative. These additional pollutant emissions would constitute a small fractional increase in the site-wide emission inventory of the Proposed Action. This small emission increase would not produce any detectable change in the ambient concentrations described in the Proposed

Action. Therefore, as in the case of the Proposed Action, air-quality impacts would not be significant.

4.7.4.2 *Impacts of Relocating 8,000 Pits*

Emissions resulting from the relocation of 8,000 pits would be less than the emissions from the relocation of 20,000 pits. Therefore, as described in the previous section, the air quality impacts of relocating 8,000 pits would not be significant.

4.7.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.7.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

The WM PEIS evaluated alternatives for the construction and operation of LLMW and LLW waste facilities at Pantex Plant. None of the alternatives are expected to cause an exceedance of air quality standards. For a discussion of the atmospheric release effects on human health related to a chemical or radiological accident, see section 4.14.5.1 in this volume.

4.7.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, air quality impacts from operations are expected to be less than current impacts. Air quality would remain within regulatory limits. Under the downsizing alternative, the operations would be consolidated. Air quality impacts would be equivalent to those of the No Action Alternative. Under the Relocation Alternative, air quality impacts from assembly and disassembly operations and HE fabrication would cease.

4.7.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. Increased PM_{10} and total suspended particle concentrations may occur during the peak construction period, particularly during dry and windy conditions. Appropriate control measures would be followed to minimize pollutant concentrations during construction. Concentrations of all pollutants at the site boundary would remain within applicable Federal and State ambient air quality standards. During operation, concentrations of criteria and toxic or hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines (DOE 1996a:chapter 4).

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on choosing the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding Disposition Alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, MOX fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

4.7.6 Potential Mitigation Measures

Although the air emissions do not involve significant impacts, DOE used Best Available Control Technology as defined in TNRCC regulation and will continue to do so, to identify operational areas where improvements can be made in the management practices. An example is the ongoing substitution of newer, more environmentally benign cleaning solvents.

DOE may chose one or more of the following measures to alleviate the temporary dust emissions from construction activities. These measures could include covering, watering, or applying nontoxic solid binders to exposed piles of gravel, sand, dirt; and suspending all excavation and grading operations when wind speeds are exceedingly high.

(This Page Intentionally Left Blank)

4.8 ACOUSTICS (NOISE)

4.8.1 Affected Environment

This section addresses noise issues at Pantex Plant. The characteristics of sound include parameters such as amplitude, frequency, and duration. The decibel (dB), a logarithmic unit that accounts for large variations in amplitude, is the accepted standard unit measurement of sound. Different sounds have different frequency content.

When measuring sound to determine its effects on the human population, A-weighted sound levels (dBA) are typically used to account for the response of the human ear. A-weighted sound levels represent adjusted sound levels. The adjustments are made according to the frequency content of the sound. Examples of typical A-weighted sound levels are shown in Figure 4.8.1–1.

Another sound scale is the C-weighted scale (dBC). In contrast to the A-weighted scale, the C-weighted scale provides no adjustment to the noise signal over most of the audible frequency range. The C-weighted scale is generally used to measure impulsive noise such as airblasts from explosions, sonic booms, and gunfire.

Noise is usually defined as sound that is undesirable because it interferes with speech, communication, or hearing; is intense enough to damage hearing; or is otherwise annoying. Noise levels often change with time. To compare levels over different time periods, several descriptors were developed that take into account this time-varying nature. These descriptors are used to assess and correlate the various effects of noise on man, including land use compatibility, sleep and speech interference, annoyance, hearing loss, and startle effects.

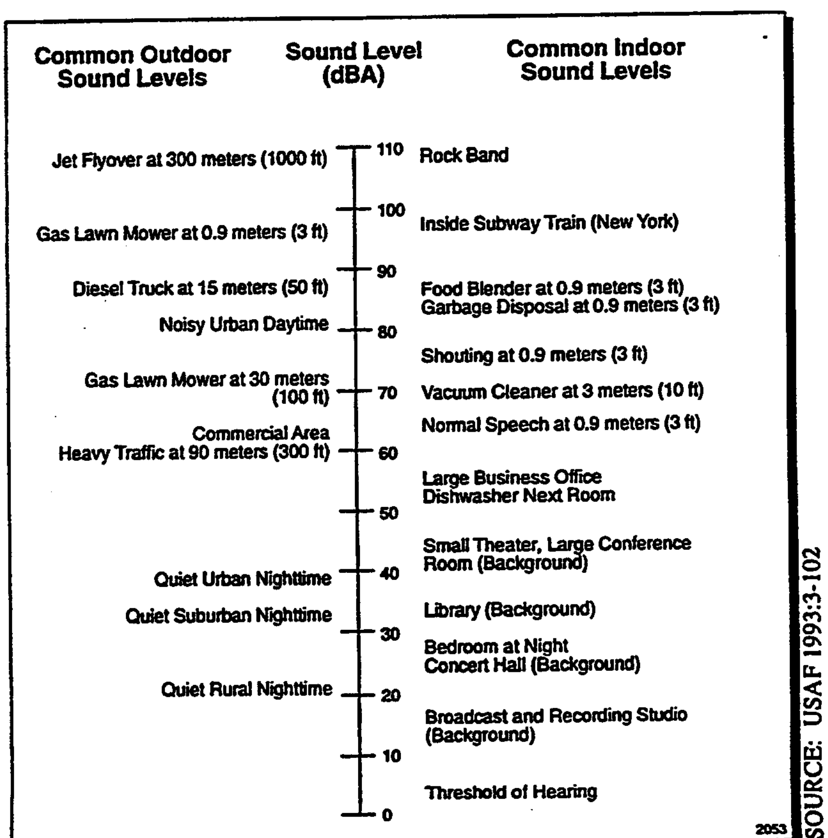

FIGURE 4.8.1–1.—*Comparative A-Weighted Sound Levels.*

The day-night average sound level (DNL) (also written as L_{dn} in equations) was developed to evaluate the total community noise environment. The DNL is the average A-weighted sound level during a 24-hour period with 10 dB added to nighttime levels (between 10:00 p.m. and 7:00 a.m.). This adjustment is added to account for the increased human sensitivity to nighttime noise events. The DNL was endorsed by the Environmental Protection Agency and is mandated by the U.S. Department of Housing and Urban Development, the Federal Aviation Administration, and the Department of Defense for land use assessments.

The DNL is sometimes supplemented with other metrics, primarily the equivalent sound level (L_{eq}). The L_{eq} is the equivalent, steady state level that would contain the same acoustical energy as the time-varying level during the same time interval.

Frequently, statistical values of noise levels are used to describe a time-varying noise measured in dBA. The noise variation is described in terms of the percentage of time a given noise level is exceeded. The L_{eq} values usually used are L_{10}, L_{50}, and L_{90}, the noise levels that are exceeded 10, 50, and 90 percent of the time, respectively. L_{10} gives an indication of the top end of the level range though it can still be substantially less than the occasional peak (L_{max}). L_{90} corresponds to the background noise level in the absence of nearby noise sources. L_{50} is the median noise level.

Table 4.8.1–1 shows how differences in sound magnitudes are perceived. Differences over long timespans, such as before and after a project requiring several years to complete, are more difficult to judge. Consequently, for changes that take place over a long period of time, sound level shifts of 5 dBA or more may be "barely perceptible."

Except for the prohibition of nuisance noise, neither the State of Texas nor its local governments have established specific numerical environmental noise standards applicable to Pantex Plant. However, community annoyance surveys have provided a basis for establishing guidelines for sound levels compatible with various land uses. Table 4.8.1–2 shows land uses that are defined by the Federal Aviation Administration and the Federal Interagency Committee on Urban Noise as normally compatible with various noise exposures. This table is used to ensure compatible planning around airports and is appropriate for evaluating exposures from other noise sources. The guidelines define

TABLE 4.8.1–1.—*Subjective Response to Changes in Sound Level*[1]

CHANGE IN SOUND LEVEL	PERCEIVED CHANGE IN LOUDNESS
±1 dB	Requires close attention to notice
±3 dB	Barely perceptible
±5 dB	Quite noticeable[2]
±10 dB	Dramatic; sounds nearly twice or half as loud
±20 dB	Striking; fourfold change in loudness

[1]Comparative judgments of sounds presented within a short timespan
[2]OSHA considers a 5 dB increase to represent a doubling of acoustic energy effects on hearing.

Golf courses, riding stables, and water recreation	Y	Y	25	30	N	N

[A]The designations contained in this table do not constitute a Federal determination that any use of land covered by the program is acceptable or unacceptable under Federal, State, or local laws. The responsibility for determining the acceptable and permissible land uses and the relationship between specific properties and specific noise contours rests with the local authorities. The Federal Aviation Administration determinations under Part 150 are not intended to substitute Federally determined land uses for those determined to be appropriate by local authorities in response to locally determined needs and values in achieving noise-compatible land uses.

Y (Yes) - Land use and related structures compatible without restrictions.
N (No) - Land use and related structures are not compatible and should be prohibited.
25, 30, or 35 - Land use and related structures generally compatible; measures to achieve Noise Level Reduction (NLR) of 25, 30, or 35 dB must be incorporated into design and construction of structure.

1 - Where the community determines that residential or school uses must be allowed, measures to achieve outdoor-to-indoor NLR of at least 25 dB and 30 dB should be incorporated into building codes and be considered in individual approvals. Normal residential construction can be expected to provide an NLR of 20 dB; thus, the reduction requirements are often stated as 5, 10, or 15 dB over standard construction and normally assume mechanical ventilation and closed windows year-round. However, the use of NLR criteria will not eliminate outdoor noise problems.

2 - Measures to achieve an NLR of 25 dB must be incorporated into the design and construction of portions of these buildings where the public is received, offices areas, noise-sensitive areas, or where the normal noise level is low.

3 - Measures to achieve an NLR of 30 dB must be incorporated into the design and construction of portions of these buildings where the public is received, offices areas, noise-sensitive areas, or where the normal noise level is low.

4 -Measures to achieve an NLR of 35 dB must be incorporated into the design and construction of portions of these buildings where the public is received, offices areas, noise-sensitive areas, or where the normal noise level is low.

5 - Residential buildings require an NLR of 25.

6 - Residential buildings require an NLR of 30.

7 - Residential buildings not permitted.

8 - Land use-compatible, provided special sound reinforcement systems are installed.

Source: 14 CFR 150

compatibility with noise exposure as a function of land use in terms of DNL. For all residential uses, compatibility is considered to exist with sound levels up to 65 dB without qualification and up to 75 dB for certain specific uses with suitable building features. For livestock farming and breeding, compatibility is considered to exist up to 75 dBA. These guidelines are advisory in nature and are not mandatory (14 CFR 150).

Also, the Environmental Protection Agency has determined that no significant effects on public health and welfare occur for the most sensitive portion of the population (within an adequate margin of safety) if the prevailing DNL is less that 55 dB (NAS 1977).

Major noise emission sources within Pantex Plant include various industrial facilities, equipment, and machines. Traffic is the primary source of noise at the site boundary and at residences near roads. Other sources of noise include aircraft, wind, insect activity, and agricultural activity.

4.8.1.1 *Ambient Noise Levels*

A survey of outdoor ambient sound levels at Pantex Plant, both onsite and offsite, was conducted September 8–16, 1994. During this time a total of 11 locations were selected as representative of onsite sound levels and the noise environment of offsite receptors. Figure 4.8.1.1–1 shows the measurement locations that are representative of those adjoining Pantex Plant and the location of points for which acoustic modeling was used to predict noise from blasts at firing sites. The figure also shows those onsite noise sources that have been identified as audible at offsite locations. These sources are the high explosive(s) (HE) firing sites and the target range used by Pantex Plant's Security and Courier sections. The summer-autumn sound survey was augmented with an autumn-winter survey conducted December 1–3, 1994. At this time, four locations (J, K, L, and M) were added, and measurements were made at these and one of the previously monitored locations, location F.

Traffic is the primary source of noise at the site boundary and at residence near roads. As shown in Table 4.8.1.1–1, L_{eq} levels ranged from 38 to 58 dBA. Onsite noise L_{eq} levels generally ranged from 40 to 60 dBA. However, measurements which were C-weighted indicated noise levels at a distance of 366 meters (1,200 feet) from the target ranges of 70 to 103 dBC (Pantex 1996:11.2.1, 11.2.3). A summary of the noise measurements is presented in Table 4.8.1.1–1.

4.8.1.2 *Occupational Noise*

Representative occupational noise levels are summarized in Table 4.8.1.2–1. The noise levels are representative of exposure-monitoring data obtained in the hearing conservation program. In addition to industrial noise exposure, the data include noise exposure of Security and DOE Courier section personnel while maintaining weapons proficiency.

4.8.1.3 *Noise from High Explosive Detonation*

Pantex Plant detonates explosive charges in open air. These charges generally vary in weight from 2 to 21 kilograms (5 to 47 pounds). During 1994, Pantex Plant detonated 60 charges of HE (Pantex 1996:11.2.2). The maximum HE charge exploded was 24.9 kilograms (55 pounds). In October 1995, during an emergency preparedness training exercise, a charge greater than 24.9 kilograms (55 pounds) of HE was detonated. Since the plant does not typically detonate charges larger than 25 kilograms (55 pounds) of HE equivalent, that size charge was modeled for various wind speeds. Should a larger charge be exploded in the future, the plant would perform appropriate NEPA review for that charge.

Airblast noise resulting from the detonation of HE is impulsive in nature and generally lasts less than a second in duration. Although the duration of individual blasts is short, the rapid onset of such sounds could be a source of discomfort to many persons. In addition, the vibration of buildings and other structures induced by the noise impulse could be a source of increased annoyance. This vibration and the rapid onset produce "startle" effects.

The noise produced by airblast results from the generation of shock waves. Figure 4.8.1.3–1 depicts a typical blast impulse, which consists of an abrupt compression (characterized by an extremely short rise time) followed by a gradual pressure reduction to below ambient pressure, and finally a recovery to ambient. The overpressure (and therefore the noise level) is a function of the source strength (charge weight), meteorological conditions, and distance to observer. For explosions aboveground, propagation of the airblast is influenced by wind and temperature gradients, which can create focusing effects.

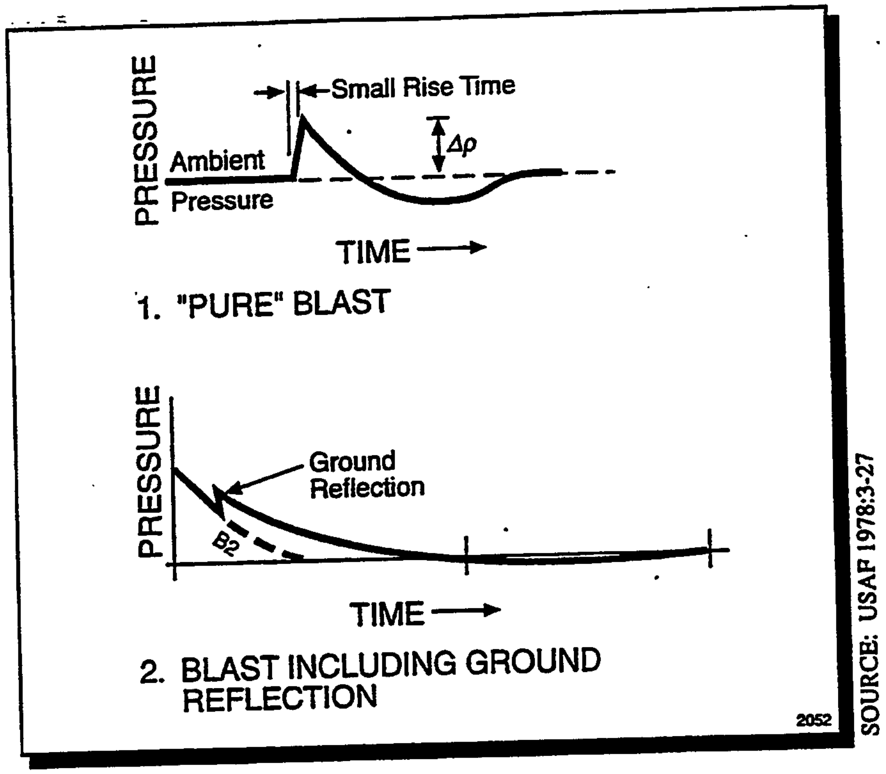

FIGURE 4.8.1.3–1.—*Typical Blast Impulses.*

There is no record of measurements of noise levels or overpressures made in connection with Pantex Plant detonations. Therefore, an airblast prediction model called BLASTO was used to estimate the overpressures resulting from Pantex Plant HE detonations (Reed 1995:1-17). A neutral lapse rate was assumed. Overpressures (dB) and their downwind distances from the source are presented for three wind speeds in Table 4.8.1.3–1. As shown in the table, the maximum size of Pantex Plant HE detonations could be audible out to distances of 5 to 10 kilometers (3 to 6 miles), depending on atmospheric conditions.

TABLE 4.8.1.3–1.—*Summary of Overpressures and Their Distances from the Source at Pantex Plant Predicted by the Airblast Model BLASTO*

WEIGHT OF EXPLOSIVE CHARGE (kg)		WIND SPEED (km/hr)		
24.9 (55 lb)	11.3 (25 lb)	4.28 (6.9 mph)	7.15 (11.5 mph)	11.42 (18.4 mph)
OVERPRESSURE (dB)		DISTANCE FROM SOURCE (meters)		
140	137.7	1,100 (3,608 ft)	1,490 (4,888 ft)	2,200 (7,218 ft)
133	131.7	2,200 (7,218 ft)	2,900 (9,514 ft)	5,200 (17,060 ft)
128	125.7	4,400 (14,436 ft)	6,200 (20,341 ft)	>10,000 (>32,808 ft)

Source: Reed 1995:1-17

4.8.2 Impacts of Proposed Action

4.8.2.1 *Impacts of Continued Operations*

Operations are assumed to continue at any of the three potential annual activity levels for the approximately 10-year period examined in this EIS. The three activity levels are for operations on 2,000, 1,000, and 500 weapons per year.

Noise levels onsite and near the Pantex Plant boundary for operations on 2,000 weapons per year would be about the same as those which currently exist (see section 4.8.1.1). Noise sources would consist of vehicular traffic, industrial facilities, aircraft overflights, and railroad trains. Traffic is the primary source of noise at the site boundary and at residences near the Farm-to-Market (FM) roads adjacent to Pantex Plant boundary. Noise levels (L_{eq}) range from 40 to 60 dBA. Target range noise at 366 meters (1,200 feet) ranged from 70 to 103 dBC. Aircraft overflights can produce maximum noise levels of 90 dBA (Pantex 1996:11.2.1 and 11.2.6).

A reduction to operations on 1,000 and 500 weapons per year would produce some decrease in noise levels because of reduced traffic, resulting from fewer employees commuting to and from work. Noise from HE detonations would continue for all three levels of weapon operations. On the other hand, the frequency of explosive tests would decrease as the level of weapons decreased.

Except for airblast noise, noise levels at the Pantex Plant boundary for all three levels of weapon operations would be below the 65 dBA guideline level (see section 4.8.1). Thus noise impacts from the usual noise sources at Pantex Plant would be negligible. Airblast noise resulting from detonation of HE would continue for the 2,000 weapons level at about the same frequency that is currently used at Pantex Plant.

The reduction of weapons levels to the 1,000 and 500 unit levels would likely result in fewer HE detonations. Since current levels of HE detonations have not generated significant noise impacts at any of the residences near the Pantex Plant boundary, continued operations would, therefore, not produce significant noise impacts at these sensitive receptors.

Pit Storage Activities

The principal noise source from pit storage activities would be the tractor-trailers used to haul the weapons or pits to Pantex Plant. The number of tractor-trailers would be a very small fraction of the total traffic generated by Pantex Plant (less then 0.2 percent). Overall noise level increases resulting from pit storage activities would not be detectable by the human ear (see Table 4.8.1–1). Therefore, noise impacts from pit storage activities would be negligible.

Environmental Restoration Activities

Environmental restoration activities will require various types of construction equipment to cleanup hazardous waste sites on Pantex Plant. Types of equipment would include bulldozers, backhoes, front-end loaders, drill rigs, and dump trucks. Noise levels in the immediate vicinity (15 meters [50 feet]) of the remediation site would range from 80 to 90 dBA.

These noise levels would be reduced to 45 to 55 dBA at 914 meters (3,000 feet) from the remediation area. This is the approximate distance from a remediation site to the nearest residence. These noise levels are about the same as the ambient noise levels existing at the residences near the Pantex Plant boundary. Thus, noise levels generated by restoration activities on Pantex Plant would not be noticeable at the sensitive receptors outside the plant boundary. Noise impacts from environmental restoration activities, therefore, would be negligible.

Waste Management Activities

Sources of noise from waste management activities are trucks which haul waste offsite, a garbage truck, a document incinerator, and two compactors. About one truck per week is used to haul waste offsite. Onsite sources are at sufficient distance from the Pantex Plant boundary that noise originating from these sources would not be detectable at the boundary or at any of the sensitive receptors outside the boundary. Therefore, noise impacts from waste management activities would be negligible.

4.8.2.2 *Impacts of New Facility Construction and Upgrades*

Noise sources during the new facility construction and upgrade would include heavy-construction and increased traffic. Small increases in traffic would occur onsite and along offsite transportation routes used to bring construction material and workers to the site. Small increases in noise levels would occur at the residences located along FM Roads 2373 and 683. Noise levels would be below the 65 dBA level specified as acceptable in the Federal Interagency Committee or Urban Noise guidelines (see section 4.8.1). Due to the size of the site, noise emissions from construction and operation activities of the facilities would not be expected to cause annoyance to the public. Therefore, noise impacts associated with construction and operation of the new facilities would be negligible.

4.8.2.3 *Summary of Impacts*

Noise levels associated with the Proposed Action may be increased slightly during construction activities. Operational noise levels from operations on 2,000 weapons per year would be approximately the same as the noise levels which currently exist onsite and offsite. Airblast noise levels from HE detonations would also continue at current levels. The reduction to the 1,000 and 500 weapons per year levels would reduce noise levels a few decibels. Therefore, noise impacts associated with the Proposed Action would be negligible.

4.8.3 Impacts of No Action Alternative

Noise sources for the No Action Alternative would be similar to those of the Proposed Action. Three levels of activity, operations on 2,000, 1,000, and 500 weapons per year, are assumed for the No Action Alternative. The major difference between this alternative and the Proposed Action is that weapons disassembly operations would cease when 12,000 pits have been placed in storage at Pantex Plant. Construction of new facilities would not take place under the No Action Alternative. Therefore, construction noise levels would be less than those described for the Proposed Action (see section 4.8.2). HE detonations would continue at about the same level as would occur under the Proposed Action.

Noise impacts for this alternative would therefore be approximately the same as the Proposed Action; i.e., they would be negligible.

Pit Storage Activity

Impacts of pit storage activities under this alternative would be the same as the Proposed Action until the 12,000 pits are stored. After this storage level is achieved, transportation of pits to other facilities would occur. Overall, the noise levels resulting from these activities would be about the same as the Proposed Action. Noise impacts for pit storage activities under this alternative would, therefore, be negligible.

Environmental Restoration Activities

Noise sources and resulting noise levels associated with environmental restoration under this alternative would be the same as those described under the Proposed Action. Noise impacts, therefore, would be negligible.

Waste Management Activities

Noise sources and resulting noise levels related to waste management activities would be the same as those under the Proposed Action. Noise impacts would be negligible.

4.8.4 Impacts of Pit Storage Relocation Alternative

4.8.4.1 *Impacts of Relocating 20,000 Pits*

The principal source of noise would be from the tractor-trailer units used to haul the pits to another facility. Over a 10-year period, this would involve no more than one or two shipments per week. The increase in noise levels over general plant activity noise levels would not be detectable. Thus, noise impacts under this alternative would be negligible.

4.8.4.2 *Impacts of Relocating 8,000 Pits*

Noise levels related to this activity would be less than those related to relocating 20,000 pits. Noise impacts, therefore, would be negligible.

4.8.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.8.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

Should the WM PEIS result in a decision to site waste management facilities at Pantex Plant, future NEPA documentation would be prepared for the specific project and specific location proposed in order to assess noise impacts on workers, offsite populations, and other sensitive receptors.

Noise sources during construction of the waste management facilities would include heavy construction equipment and increased traffic. Increased traffic would occur onsite and along major offsite transportation routes used to bring construction material and workers to the site. Most nontraffic noise sources associated with operation of any waste management facilities would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would continue to be small. Due to the size of Pantex Plant Site, noise levels from construction and operation activities would not be expected to cause annoyance to the public (DOE 1995k). Therefore, the cumulative noise impacts of the Proposed Action and the construction and operation of the waste management facilities would be minor and not significant.

4.8.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, noise impacts from operations are expected to be less than current impacts. Under the downsizing alternative, facilities would be consolidated. The noise impacts would be equivalent to the No Action Alternative. Under the relocation alternative, noise from assembly and disassembly operations and HE fabrication would cease.

4.8.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage.. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. Nontraffic operational noise sources associated with the consolidation of plutonium and collocation of plutonium and highly enriched uranium alternatives include additional equipment and machines. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide fuel fabrication facility, and a light water reactor. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

Nontraffic operational noise sources associated with the Disposition Alternative includes additional equipment and machines. These noise sources would be located at sufficient distance from offsite areas that the contribution to offsite noise levels would be small. Due to the size of the site, noise emissions from construction equipment and operations activities would not be expected to cause annoyance to the public (DOE 1996a:chapter 4). However, should Pantex Plant be selected as the site for such a facility, further NEPA review would be performed to assess the noise impacts on workers, offsite populations, and other sensitive receptors.

4.8.6 Potential Mitigation Measures

DOE currently uses standard silencing packages on construction equipment and provides workers in noisy environments with appropriate hearing protection devices meeting Occupational Health and Safety Administration standards. As required, noise levels are measured in worker areas, and a hearing protection program has been implemented. This program would continue in the future.

While the amount of offsite noise from explosives testing at the plant is not significant and no mitigation measures are required, DOE could chose to implement such measures as limiting the hours of such testing or setting prohibitions on testing during unfavorable atmospheric conditions to further reduce the noise levels.

4.9 BIOTIC RESOURCES

4.9.1 Affected Environment

The biotic resources considered in this section consist of the following components: terrestrial resources, aquatic resources, wetland resources, and protected and sensitive species. Scientific names of threatened and endangered species are presented in Table 4.9.1–1 while those for nonthreatened and nonendangered species are presented in Table 4.9.1–2.

4.9.1.1 *Terrestrial Resources*

Vegetation

Pantex Plant Site is located within the Southern High Plains whose vegetation is characterized as shortgrass prairie (DOE 1993b). The shortgrass prairie is dominated by two grass species: blue grama (*Bouteloua gracilis*) and buffalo grass (*Buchloe dactyloides*). Other typical, less abundant grass species include sideoats grama (*Bouteloua curtipendula*), western wheatgrass (*Agropyron smithii*), vine mesquite (*Panicum obtusum*), and silver bluestem (*Bothriochloa laguriodes*) (Pantex 1996:7.1). Much of the native shortgrass prairie has been converted and used for agricultural purposes, primarily crop cultivation and cattle grazing (Haukos 1994:85). The current state of the altered shortgrass prairie at Pantex Plant ranges from unvegetated, in the south-central region, to a variety of species elsewhere on the site.

The dominant vegetation on the uplands surrounding Playas 3, 5, and Pantex Lake is buffalograss, while the uplands surrounding Playa 1 support buffalograss, blue grama, and prickly pear (*Opuntia macrorhiza*). The area south of Playa 1 contains a small grove of crabapple (*Malus sylvestris*), Asiatic honeysuckle (*Lonicera tatarica*), and Russian olive (*Elaeagnus angustifolia*). Playa 2 uplands support buffalograss, blue grama, and silver bluestem; and Playa 4 uplands consist of buffalograss and blue grama. The Texas Tech University Farms headquarters area has grass lawns with planted mimosa tree (*Albizia julibrissin*), Siberian elm (*Ulmus pumilia*), and black locust (*Robinia pseudoacacia*). The previously cultivated southeastern portion of Pantex Plant is dominated primarily by silver bluestem and rare individuals of yankee weed (*Eupatorium compositifolium*). The west-central region of Pantex Plant has vegetative composition of predominantly kochia (*Kochia scoparia*) and pigweed (*Amaranthus sp.*), with lesser extents of buffalograss, planted Siberian elm, and cottonwood (*Populus deltoides*) (DOE 1993b:7-31, 7-44).

Pantex Plant has historically monitored radionuclide levels in both onsite and offsite vegetation. The 17 offsite and 5 onsite collecting locations are sampled for uranium and tritium isotope levels in primarily native and domestic grasses. The onsite stations and the offsite control station, at Bushland, Texas, are sampled monthly for comparison; the non-control offsite stations are sampled quarterly. No standards exist for uranium or tritium concentrations in vegetation; however, with few exceptions, concentrations at Pantex Plant in recent years have been comparable to the offsite vegetation monitored at Bushland (MH 1991:67, 75; Battelle 1992:4-38, 4-48; DOE 1994b:9-1, 9-2).

Radiological surveys of beef cattle raised on or near Pantex Plant Site have not been considered necessary based on the results of a study that showed routine operations do not pose a risk to the public from the consumption of these animals (LANL, 1982; 22-23; Pantex 1996:16.1). The study indicated that if beef consumption of 79 kg/yr is assumed, then the 50-yr dose commitment to an adult from ingestion of ground beef at 1.6 x 10^{-4} pCi/g weight would be 0.2 mrem to bone, 0.01 mrem to kidneys, and 0.01 mrem to liver. These values are 500 times below the radiation dose each year from natural background (LANL

thirteen-lined ground squirrel	*Spermophilus tridecemlineatus*	**FISH**	
desert cottontail	*Sylvilagus auduboni*	fathead minnows	*Pimephales promelus*
black-tailed prairie dog	*Cynomys ludovicianus*	black bullhead	*Ictalurus melas*
striped skunk	*Mephitis mephitis*		

1982:23). The largest source of uranium in the cattle feed was from commercial mineral supplements typically fed to cattle in the area (Pantex 1996:16.1). An ecological analysis of potential risks to various animals from either direct or indirect ingestion of radiological residues in vegetation in the immediate vicinity of Pantex Plant obtained similar conclusions (PC 1995s).

Agriculture within the Pantex Plant Region of Influence is considered an important asset. A detailed discussion of the ecological and land use resources of the regional agricultural industry is provided in the Pantex Plant *Environmental Information Document* (Pantex 1996).

Wildlife

The uplands of Pantex Plant support a variety of invertebrates, reptiles, amphibians, birds, and mammals. With individuals of the following taxa recorded at Pantex Plant, the insect class is well-represented: grasshoppers, beetles, true bugs, flies, bees, wasps, ants, moths, butterflies, and dragonflies (DOE 1994k:6). The most frequently occurring species of reptiles and amphibians include the following: the Great Plains toad (*Bufo cognatus*), Woodhouse's toad (*Bufo woodhousei*), Plains spadefoot toad (*Scaphiopus bombifrons*), Great Plains skink (*Eumeces obsoletus*), Western coachwhip snake (*Masticophis flagellum testaceus*), bullsnake (*Pituophis melanoleucus sayi*), checkered garter snake (*Thamnophis marcianus marcianus*) and prairie rattlesnake (*Crotalus viridis viridis*) (DOE 1994e:8; DOE 1994k).

Some of the more common species of birds that have been observed at Pantex Plant include the Western meadowlark (*Sturnella neglecta*), horned lark (*Eremophila alpestris*), mourning dove (*Zenaida macroura*), Bewick's wren (*Thryomanes bewickii*), mockingbird (*Mimus polyglottos*), house finch (*Carpodacus mexicanus*), common nighthawk (*Chordeiles minor*), greater roadrunner (*Geococcyx californianus*), killdeer (*Charadrius vociferus*), Swainson's hawk (*Buteo swainsoni*), red-tailed hawk (*Buteo jamaicensis*), and turkey vulture (*Cathartes aura*) (DOE 1994g:2-6; DOE 1993c:A.1, A.2; DOE 1994k:7-10).

Representative mammals that occur at Pantex Plant are the deer mouse (*Peromyscus maniculatus*), plains harvest mouse (*Reithrodontomys montanus*), white-footed mouse (*Peromyscus leucopus*), hispid cotton rat (*Sigmodon hispidus*), Southern Plains wood rat (*Neotoma micropus*), thirteen-lined ground squirrel (*Spermophilus tridecemlineatus*), desert cottontail (*Sylvilagus audoboni*), black-tailed prairie dog (*Cynomys ludovicianus*), striped skunk (*Mephitis mephitis*), and coyote (*Canis latrans*) (DOE 1993c:10, B-1; DOE 1994k:11).

4.9.1.2 *Aquatic Resources*

Aquatic resources at Pantex Plant are not extensive and are comprised of the perennial Playa 1 and several concrete ponds located in the northeast area of Pantex Plant. Since Playas 1 through 4 and Pantex Lake are considered wetlands, they are described in more detail in section 4.9.1.3. Playa 1 is permanently inundated with water, receiving discharge from the Pantex Plant wastewater treatment plant. The aquatic regions of Playa 1 support over six genera of plants. The dominant vegetation is cattail *(Typha anqustifolia)*, great bulrush *(Scirpus validus)*, and three species of smartweed *(Polygonum sp.)* (DOE 1993b:4, B-7). During surveys in 1992, 26 families of macroinvertebrates were collected from Pantex Plant playas. The notable orders of organisms found include the following: beetles, true bugs, flies, and crustaceans (DOE 1993c:12). Vertebrate species recorded at Playa 1 include the Plains leopard frog (*Rana blairi*), the Woodhouse's toad, and the upland chorus frog (*Pseudoacris triseriata feriarum*) (DOE 1994e:7).

The concrete ponds, representing another aquatic habitat at Pantex Plant, are inhabited by six different species of amphibians, including: the barred tiger salamander (*Ambystoma tigrinum mavoritum*), the upland chorus frog, and the Great Plains toad. In May 1996, Pantex Plant personnel resampled the earthen stock tank near Pantex Lake. No specimens of *Notropis* minnows were found, but a number of fathead minnows (*Pimephales promelus*) and one black bullhead (*Ictalurus melas*) were collected (PC 1996d).

4.9.1.3 *Wetlands*

This assessment fulfills the environmental review requirement of *Compliance with Floodplain/Wetlands Environmental Review Requirements* (10 CFR 1022). There are six playas on DOE-owned or leased land at the Pantex Plant Site: Playas 1, 2, and 3 are on the main Pantex Plant; Playas 4 and 5 are on land leased from Texas Tech University; and Pantex Lake is on a separate parcel of DOE-owned property (Pantex 1996:7.2). Playas 1 through 4 and Pantex Lake have been delineated as jurisdictional wetlands using the U.S. Army

Corps of Engineers' *Wetland Delineation Manual* (Pantex 1996:7.2; MH 1995). These delineations are being used for ecosystem management at the Pantex Plant Site wetlands noted above. Wetlands are very important to wildlife, especially in an area having little undisturbed native grassland. They provide stopovers for migrating waterfowl and habitat for countless other species of birds, reptiles, amphibians, and mammals (TTU 1988:5; Bolen 1979:24).

4.9.1.4 *Playa Vegetation*

Playa vegetation on the Southern High Plains varies from one playa to another and throughout the changing conditions of the seasons. When water is prevalent within the basins, playa vegetation is usually composed of emergent and submergent aquatic species; however, as available water subsides, the species shift to semiaquatic annuals. With little moisture present, playa vegetation is commonly made up of characteristic upland species (Haukos 1994:93). Because of the diversity among individual playas, a specific vegetative characterization is presented for each playa at Pantex Plant. Most botanical information about Pantex Plant playas was gathered during a comprehensive floristic survey conducted during May, July, and September of 1993 and updated in June, July, and September 1995.

Playa 1

This playa is continuously inundated with water received from the Pantex Plant Wastewater Treatment Facility. As such, it supports 19 obligate aquatic plant species, the highest number of any playa at Pantex Plant (Pantex 1996:7.2). Like most wet playas, the dominant plants are emergent and submergent species. Cattail and bulrush are present at Playa 1 (DOE 1993b:4). Other notable obligate aquatic species present within the playa were pondweed (*Potamogeton nodosus*), arrowhead (*Sagittaria montevidensis*), spikerush (*Eleocharis macrostachya*), and smartweed (Pantex 1996:7.2). The following facultative aquatic or semiaquatic species are found at Playa 1: several species of smartweed (*Polygonum sp.*), slim aster (*Aster subulatus*), and western black willow (*Salix goodingii*). The uplands surrounding Playa 1 are typical overgrazed High Plains grassland composed of buffalograss, blue grama, and prickly pear (DOE 1993b:5; Haukos 1995:5).

Playa 1 has received some attention relative to the uptake of various chemicals. Pezzolesi, in his Master's Thesis, analyzed nutrient and heavy metal cycling in vegetation (i.e., cattail and smartweed), surface water, and soil of this playa (TTU 1994a:26–30). However, a high degree of variability was noted in nutrient and heavy metal concentrations. Additional information on the Pantex Plant biomonitoring activities is provided in Chapter 16 (Radiation and Hazardous Chemical Environment) of the *Environmental Information Document* (Pantex 1996).

Playa 2

The basin of this playa is dominated by several species of smartweed, primarily *Polygonum pensylvanicum*, *P. amphibium*, and *P. coccineum*. Other significant species within the basin included mallow (*Malvella leprosa*), ragweed (*Ambrosia grayii*), and sunflower (*Helianthus annuus*). One small association of cattails was also noted within the playa. The edge of the playa basin contains tumbleweed and frog fruit, while, slightly above the basin, the major plant species are wheatgrass and snow-on-the-mountain (*Euphorbia marginata*). The plant composition of the uplands surrounding Playa 2 is very similar to that of Playa 1 (DOE 1993b:5).

Playa 3

This playa, adjacent to the Burning Ground, has a basin floral composition of primarily spikerush with little vervain (*Verbena* *bracteata*) and hairy water clover (*Marsilea vestita*). The edge of the basin is dominated by spikerush and cocklebur (*Xanthium strumarium*), and the uplands surrounding Playa 3 have a species composition similar to Playas 1 and 2 (DOE 1993b:6).

Playa 4

The low areas of this playa contain abundant spikerush and ragweed, with some hairy water clover and buffalograss. One of the lowest areas in the basin supports cattails and several species of smartweed. Extensive stands of wheatgrass are present on the slopes leading from the basin to the uplands. The shortgrass prairie immediately adjacent to Playa 4 has a composition similar to other areas at Pantex Plant, but with a greater coverage of buffalograss (DOE 1993b:7).

Playa 5

When mostly dry, this playa exhibits large areas of bare clay. The plant species found within the playa include *Suckleya suckleyana*, goose foot (*Chenopodium glaucum*), and cocklebur. In a small, wet area of the playa, cattails and great bulrush were found to be locally prevalent, and their coverage expands when the playa contains more water from seasonal rains. The lower slopes, which transition into the surrounding grassland, contain buffalograss and wheatgrass. The High Plains grassland surrounding Playa 5 is similar in composition to the remainder of the site, except that three-awn has a more significant presence (DOE 1993b:8).

Pantex Lake

Major plants within the basin of Pantex Lake are spikerush, wheatgrass, and cocklebur. The area at the edge of the basin is dominated by wheatgrass, but there is a transition into High Plains grassland dominated by buffalograss and, to a lesser degree, three-awn and blue grama (DOE 1993b:11). In the past, Pantex Lake received discharge from site activities, but does not now.

4.9.1.5 *Playa Wildlife*

The Southern High Plains of Texas contain relatively little native undisturbed grassland. Land in the Texas Panhandle which is used for agricultural purposes does not support extensive wildlife populations. The remaining, undisturbed playas are "islands" of wildlife habitat, allowing the continued existence of many species (Smith 1994:119, 120; Dierauf 1994:246; Haukos 1994:85). Wildlife surveys conducted at Pantex Plant have characterized wildlife presence and use of the entire site, rather than focusing on each playa specifically. However, organisms and groups of organisms known to be specific to the playas are presented below.

Insects, Protistans, and Other Invertebrates

Insects identified from Pantex Plant playas include the following: mayflies (one family), dragonflies and damselflies (three families), beetles (six families), true bugs (six families), and flies (three families). There were also four families of crustaceans, two families of mollusks, leeches, and water mites (DOE 1993c:E.1). Unicellular organisms (protistans) from the phyla Chlorophyta, Chrysophyta, Cyanophyta, and Ciliophora, as well as two types of nematode worms, have also been collected from Pantex Plant playas (DOE 1994k:3, 4).

Reptiles and Amphibians

Members of the classes Amphibia and Reptilia that have been identified at Pantex Plant playas include: the plains leopard frog, Woodhouse's toad, the upland chorus frog, the prairie rattlesnake, the Great Plains skink, the hognose snake (*Heteredon nascius*), the northen earless lizard (*Holbrookia maculata maculata*), and the bullsnake (DOE 1994e:7).

4.9.1.6 *Protected and Sensitive Species*

Table 4.9.1–1 lists observed and potentially occurring protected and candidate species at the site. The bald eagle (*Haliaeetus leucocephalus*) is the only Federally protected species known to inhabit Pantex Plant for extended periods of time. Currently it is listed as threatened by the U.S. Fish and Wildlife Service (FWS) (Pantex 1996:7.4). It winters in the high plains of Texas, usually from October through February or March (a 4- to 5-month period), and forages near bodies of water (playas), feeding on fish, waterfowl, and small mammals. The bald eagle is sighted yearly at Pantex Plant and is considered a winter resident and a spring and fall migrant.

Additional listed species that may occur on or around Pantex Plant include the following: the American (*Falco peregrinus anatum*) and Arctic peregrine falcon (*Falco peregrinus tundris*), a spring and fall migrant; the interior least tern (*Sterna antillarum athalassos*), a possible spring and fall migrant; and the whooping crane (*Grus americana*), a spring and fall migrant. The whooping crane has been sighted at Pantex Plant in recent years.

No critical habitat for Federally threatened or endangered species exists on or around Pantex Plant (Pantex 1996:7.4). On May 9, 1996, Pantex officials submitted a biological assessment (BA) addressing section 7 (i.e., interagency consultation) *Endangered Species Act* requirements to FWS (Letter 1996). On May 27, 1996, the FWS stated that "We commend Pantex for developing a comprehensive and complete BA, and concur that the proposed action is not likely to adversely affect any Federally listed threatened or endangered species (Letter 1996a)."

The Texas horned lizard (*Phrynosoma cornutum*) is a Pantex Plant resident and has State-threatened status. The State also lists the white-faced ibis (*Plegadis chihi*), a spring and fall migrant and summer resident at Pantex Plant, as threatened.

Species that are Federally proposed or candidates for listing as threatened or endangered species do not receive legal protection under the *Endangered Species Act.* However, FWS encourages the consideration of impacts to these species in project planning since their status can be changed to threatened or endangered in the foreseeable future. The FWS has recently changed the classification of species under review for listing as threatened or endangered (61 FR 7596). Proposed species include those plants and animals for which a proposed rule to list as threatened or endangered has been published. Candidate species include those plants and animals for which the FWS has on file sufficient information on biological vulnerability and threat to support issuance of a proposed rule for listing as threatened or endangered. Candidate species previously included Category 1 (species appropriate for listing as protected) and Category 2 (species possibly appropriate for listing as protected). Due to the recent rule change, candidate species (now) include only those which are appropriate for listing as protected species (i.e., species formerly (classified) as Category 1). The Category 2 designation has been omitted in Table 4.9.1–1. Species typically in Category 2 are now classified as species of concern, a term that describes a broad realm of plants and animals whose conservation status may be of concern to the FWS, but do not have official status. Some of the species previously identified as Federal candidate 2 in the Draft version of this EIS also have State status and continue to be evaluated for potential impacts.

The swift fox (*Vulpes velox*) is the only Federal candidate species known to occur at the Pantex Plant Site. An adult fox was observed south of Playa 2 on Texas Tech land in May 1996 and signs of scat and other signs of activity were observed at a number of sites on the facility in 1995 (WTU 1995; WTU 1996). This mammal has been observed at the Pantex Plant Site since 1971 (CSU 1976). The mountain plover (*Charadrius montanus*) is a Federal candidate species that has not been reported in bird surveys at the Pantex Plant Site, but may potentially occur there based on its presence elsewhere in the state of Texas (DOE 1994g; DOE 1996d).

The ferruginous hawk (*Buteo regalis*), black tern (*Childonias niger*), and loggerhead shrike (*Lanius ludovicianus*) are species of concern that formerly were given Federal candidate status, but not State listed. These species lost candidate status as part of the reclassification of notice of review species (61 FR 7596). To date, two adult ferruginous hawks have been radio-tagged and one remained at Pantex Plant for approximately one month (Pantex 1996:7.4). At Pantex Plant Site, the ferruginous hawk frequents the playas and large prairie dog town near Playa 2. In August 1993, a pair of black terns was identified foraging at Playa 2.

There are no protected plant species known to occur at Pantex Plant or within Carson County (Pantex 1996:7.4). However, two rare cacti have been identified adjacent to Playa 1: *Coryphantha vivipara* and *Echinocereus viridiflorus* var. *viridiflorus*. An additional rare cactus, *Coryphantha missouriensis*, was confirmed in June 1995 at Playa 2. The Playa 1 *Echinocereus viridiflorus* population may be the largest one existing in the world (DOE 1993b:5). A floristic survey was conducted in the summer of 1995 to determine if any additional plant species of concern exist at the Pantex Plant Site. Although no Federal or State protected species were identified during this survey, 35 additional plant species were identified in 1995 for the first time at the Pantex Plant Site (Johnston 1995).

4.9.2 Impacts of Proposed Action

4.9.2.1 *Impacts of Continued Operations*

Weapons-Related Activities

Impacts to biotic resources at Pantex Plant as a result of the weapons-related activities are expected to be minimal. No additional disturbance is required whether operations are conducted at the 2,000, 1,000, or 500 weapons level; therefore, direct impacts to biotic resources are not anticipated. Existing operations generate noise due to human activity and operation of equipment and vehicles, which could have a temporary impact on some terrestrial, aquatic, and threatened and endangered species. Animal and plant surveys conducted for this EIS have not shown any decline in the number of species present. The Ecology chapter of the *Environmental Information Document* describes the measures underway to ensure that continuing operations do not adversely affect wetlands and biotic resources at this Federal facility (Pantex 1996). As stated earlier, a biological assessment was prepared to address section 7 *Endangered Species Act* requirements, and obtained FWS concurrence that the proposed action is not likely to adversely affect any Federally listed threatened or endangered species at the Pantex Plant (DOE 1996d; Letter 1996a).

The trace level of radionuclides in vegetation due to Pantex Plant activities and biouptake of heavy metals in playa vegetation has not been found to cause adverse impacts in plants and animals on or around this Federal facility (Pantex 1996:16.1; TTU 1994a:26-30). In fact, wetland resources would benefit from continued operations since Pantex Plant officials are taking steps to further increase the beneficial use of Pantex Plant playas by various species (Pantex 1996:7.5). In summary, continued operations would not create any significantly adverse impact to biotic resources, and existing natural resource programs are attempting to manage the portions of the property for the benefit of native resident and migratory wildlife species.

Pit Storage Activities

Section 3.1.1 discusses increasing interim storage of pits at Pantex Plant from 12,000 to 20,000 as part of the Proposed Action. This storage would use existing facilities and would not pose adverse impacts to biotic resources.

Environmental Restoration Activities

The environmental restoration activities will have a long-term beneficial impact on plant and animal species at Pantex Plant as contamination from past activities is removed from soils and water at Pantex Plant Site. Some remediation activities (e.g., soil removal) may have a temporary impact on some species, through the loss of some vegetation and some of the less mobile animals such as reptiles and small mammals, but these impacts would not be considered significant.

Waste Management Activities

Waste management activities are not anticipated to have any significant adverse impacts to animal and plant species at Pantex Plant. The facility's compliance with the *Resource Conservation and Recovery Act* and implementing TNRCC regulations are intended to minimize, if not preclude, direct impacts to threatened or endangered species or wetlands.

4.9.2.2 *Impacts of New Facility Construction and Upgrades*

Under the Proposed Action, the following facilities would either be constructed or upgraded at Pantex Plant between 1996 and 2001: Hazardous Waste Treatment and Processing Facility; Pit Reuse Facility; Gas Analysis Laboratory; Materials Compatibility Assurance Facility; Nondestructive Evaluation Facility; and Metrology and Health Physics Calibration and Acceptance Facility. Facility construction would be in or adjacent to Zones 11 and 12 (as shown Figure 3.1.1–1) and could result in the loss of some vegetation and some of the less mobile animals, such as reptiles and small mammals. However, since the construction would occur in previously disturbed areas and the disturbance would involve less than 1 percent of the DOE-owned land at Pantex Plant Site, the potential for impacts to biotic resources is anticipated to be minimal.

Playas 1 through 4 have been declared as jurisdictional wetlands under section 404 of the *Clean Water Act* by the U.S. Army Corps of Engineers. Although the proposed facilities do not threaten these playas, the potential impact of soil runoff to wetlands can be minimized by applying the standard soil erosion and sedimentation control measures during the land disturbance phase of new projects.

The bald eagle, a Federally listed species, forages at the playas during winter. Since the playas are more than 1 kilometer (0.6 miles) from the nearest construction site, no impacts to bald eagles are expected. Impacts to black tern, white faced ibis, and swift fox would also be negligible because these species are not resident at the proposed construction sites. Prior to clearing operations, it may be necessary to conduct preactivity surveys to identify nests of migratory birds as well as the presence of Federal and State protected and/or sensitive species. This would allow measures to be taken to protect these species and avoid clearing operations during the breeding season of migratory birds. The impacts of new facility construction and upgrades to biotic resources are not anticipated to be significant.

4.9.2.3 *Summary of Impacts*

The continued operations at Pantex Plant at any of the weapons activity levels would be minimal. Land disturbed by new facility construction would be confined to Zones 11 and 12, which are already substantially altered. The impacts to biotic resources are, therefore, considered to be negligible. Environmental protection activities currently ongoing at the plant meet all regulatory requirements of FWS.

4.9.3 Impacts of No Action Alternative

Impacts to biotic resources at Pantex Plant as a result of the No Action Alternative are expected to be minimal. Since the weapons activity levels under the No Action Alternative would remain the same as described for the Proposed Action, the impacts on terrestrial, aquatic, and threatened and endangered species would remain negligible.

4.9.4 Impacts of Pit Storage Relocation Alternative

As discussed in section 3.1.3, the Pit Storage Relocation Alternative would involve the relocation of stored pits at Pantex Plant to one or more alternate sites. Two Pit Storage Relocation Alternative options are proposed; the first involves the storage of 20,000 pits at an alternative site, and the second involves the storage of 8,000 pits.

4.9.4.1 Impacts of Relocating 20,000 Pits

Under this Pit Storage Relocation Alternative option, up to 20,000 pits would be relocated from Pantex Plant to other DOE or Department of Defense sites. Impacts to biotic resources are not expected.

4.9.4.2 Impacts of Relocating 8,000 Pits

Under this Pit Storage Relocation Alternative option, up to 8,000 pits would be relocated from Pantex Plant to other DOE or Department of Defense sites. Impacts to biotic resources are not expected.

4.9.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.9.5.1 Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement

The location of waste management facilities at Pantex Plant would increase the impacts to biotic resources. However, no specific sites have been identified in the WM PEIS. Therefore, no cumulative impacts can be identified at this stage.

4.9.5.2 Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize

Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Impacts to biological resources from operations would be expected to remain the same as current impacts. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Consequently, no potential impacts to biota would occur. Under the relocation alternative, decontamination and decommissioning activities of the existing facilities would not impact biotic resources.

4.9.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. The collocated storage alternative would disturb 94 hectares (232 acres) of habitat. Construction would adversely affect some animal populations. Vegetation within the proposed site would be lost during land-clearing activities.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, MOX fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

Construction and operation of the evolutionary Light Water Reactor would adversely affect some animal populations and would result in the disturbance of terrestrial resources on about 7.9 percent of the site. Land on which the facility would be built is presently used for agricultural purposes. Two Federal candidate species may be affected by construction activities. The bald eagle is the only consistently occurring Federal-listed species at Pantex Plant that has the potential to be affected by construction (DOE 1996a:4.0).

4.9.6 Potential Mitigation Measures

Since no significant impacts on biotic resources are identified from the Proposed Action, No Action, or the Pit Storage Relocation Alternatives, no mitigation measures are needed.

4.10 CULTURAL RESOURCES

4.10.1 Affected Environment

This section addresses the cultural resources associated with Pantex Plant. Because of the sensitive locational nature of cultural resources, the Region of Influence for this resource is the area inside the Pantex Plant boundaries. Cultural resources identified at Pantex Plant include prehistoric sites, consisting primarily of lithic scatters; historic sites that are mostly farmsteads; World War II Era buildings and structures that were once part of Pantex Ordnance Plant (1942–1945); and structures and features representing Cold War Era (1951–1991) resources (USCOE 1994b:167-168; Pantex 1996:12.0, 12.1). In addition, Pantex Plant also houses valuable historic documents, records, and artifacts pertinent to interpretation of the prehistoric and historic human activities conducted on Pantex Plant Site.

In an ongoing effort to manage and protect these resources and comply with applicable cultural resource management (CRM) laws and regulations at Pantex Plant, DOE is currently developing a CRM Plan (CRMP) that is scheduled for completion by calendar year (CY) 1998 (Pantex 1996:12.0). DOE will complete an Impact Mitigation Plan as part of the CRMP.

The CRM laws and regulations pertinent to Pantex Plant are described in chapter 6.0, Environmental Compliance Requirements for Implementing the Proposed Action and the Alternatives. Until the CRMP is implemented in CY 1998, cultural resources at Pantex Plant will be managed according to sections 106 and 110 of the *National Historic Preservation Act* (NHPA) (36 CFR 800).

4.10.1.1 *Prehistoric and Historic Resources*

Prehistoric Resources

Included in the general chronology developed for the Texas Panhandle, covering the period from 10,000 B.C. to A.D. 1750, are prehistoric sites identified at Pantex Plant. Tests conducted on 23 prehistoric sites at Pantex Plant suggest that a majority of the sites were occupied during either the Late Archaic (1,000 B.C.–A.D. 0) or the Late Prehistoric (A.D. 0–A.D. 1541) periods. These prehistoric sites are generally associated with local playas and contain cultural materials consisting mainly of lithic scatters of stone tools and flakes with varying amounts of fire-cracked rock. One tested site produced several stone artifacts in stratigraphic association with bison bone. To date, 57 prehistoric sites have been identified on Pantex Plant land, including Texas Tech University (TTU) property leased to DOE (USCOE 1994b:14, 167-168; Pantex 1996:12.1; Battelle 1996b:1).

Historic Resources

Historic sites also follow the period chronology developed for the Texas Panhandle, covering the period from A.D. 1541 to A.D. 1942 (USCOE 1994b:14). Historic sites include foundations of demolished buildings such as homes and agricultural support structures (e.g., barns, windmills), and surface scatters of metal, ceramic, or glass artifacts. To date, 12 pre-1942 historic sites have been identified on Pantex Plant land, including TTU property leased to DOE (Pantex 1996:12.1; Battelle 1996b:1). Three of these sites (41CZ45, 41CZ46, and 41CZ47) have been identified on the main DOE-owned plant site. The remaining five sites (41CZ52, 41CZ68, PP–2, PP–3, and PP–8) are located on the TTU property leased to DOE.

Historical resources representing the World War II (1942–1945) and Cold War (1951–1991) Eras include standing structures, building foundations, and features reflecting these periods (Pantex 1996:12.1). Brief histories of Pantex Plant covering the period 1942–1992 have been prepared by B.H. Carr (Carr 1992), N.A. Stricker and R.M. Poet (Legacy 1994 and 1994a). Pantex Plant began as Pantex Ordnance Plant in 1942, with its primary mission being the production of military ordnance. Since 1951, Pantex Plant has had Cold War and post-Cold War missions, including the fabrication of high explosives for nuclear weapons, nuclear weapons assembly and disassembly, and repair and modification of existing nuclear weapons (Pantex 1996:12.2).

Surveys/Inventories

Surveys of archaeological resources have been conducted at Pantex Plant since the first professional archaeological study conducted by West Texas State University during the spring of 1981 (MH 1981). This initial effort was a non-systematic survey of areas surrounding the playas on the main Pantex Plant Site and Pantex Lake (Pantex 1996:12.1). Other field investigations included the following: a 1992 Ditches and Playas *Resource Conservation and Recovery Act* Facility Investigation study by Mariah Associates; Phase II test excavations of 23 archaeological sites on Pantex Plant from 1993 through 1994 by Geo-Marine, Inc.; and a 1994 cultural resources survey of 1,700 hectares (4,200 acres) of previously unsurveyed land at Pantex Plant conducted by Geo-Marine, Inc. (Battelle 1993; USCOE 1994; USCOE 1994b). The 1994 study involved land owned by TTU and leased to DOE. In addition, 971 hectares (2,400 acres) of DOE land were systematically resurveyed in 1994 by Geo-Marine, Inc. (MH 1995b:1, 25).

During the 1981 survey, remains of 42 prehistoric Native American campsites and three pre-World War II farmsteads were identified. Except for one historic site (farmstead), all sites were found near Pantex Lake and Playas 1, 2, and 3 on the main plant site. None of the sites appear to be potentially eligible for inclusion in the National Register of Historic Places (NRHP), but the researchers felt that 17 sites had "medium" to "high" significance and recommended preservation or additional investigation (MH 1981:65-66). The 1992 survey of ditches and playas identified 5 new sites and 39 isolated occurrences (IOs). Three of the sites and 14 IOs were located along the perimeter of Playa 2, and 2 sites and 25 IOs were located along the perimeter of Playa 4. The 1994 survey on TTU land identified 6 Native American sites, 2 historic sites, and 17 IOs. The 1994 resurvey of DOE land identified 4 new prehistoric Native American sites and 22 IOs (MH 1995b:79).

A comprehensive survey of the World War II historical resources at Pantex Plant was conducted from 1992 to 1994, when DOE authorized an inventory of buildings constructed between 1942 and 1945 (Pantex 1996:12.2; Legacy 1994 and 1994a). Initially, survey work focused on World War II standing structures, such as buildings used for magazine storage and bomb-loading lines, in the active zones of Pantex Plant. Through 1993 and 1994, survey efforts expanded to other World War II Era standing structures that had not been previously surveyed, and World War II Era foundations and ruins inside historical boundaries of Pantex Ordnance Plant. This effort inventoried an additional 29 World War II standing structures and documented 82 foundations and ruins (Pantex 1996:12.2). Historical resources still exist in the general area of Pantex Plant and include structures such as guard tower foundations, the Dunnage Mill Complex ruins, standing and in-use water towers, and a control lab foundation.

Cold War operations at Pantex Plant date from 1951 to 1991. Although historical resource surveys for this period of Pantex Plant operations have not yet been conducted, plans are currently being developed to begin such a survey. Completion of this work, combined with the surveys and evaluations of archaeological and World War II resources, will lead to the implementation of a comprehensive CRMP scheduled for completion by late 1998. The CRM staff at Pantex Plant considers resources from the Cold War period to be among the most important historical resources at Pantex Plant (Pantex 1996:12.2).

As part of the comprehensive CRMP, an Impact Mitigation Plan will be developed for preservation of cultural resources on Pantex Plant Site. Many of these resources have remained relatively undisturbed because of the security maintained by Pantex Plant during the past 50 years. Until a CRMP can be completed in CY 1998, cultural resources will be managed and protected by DOE. A programmatic agreement for the continued interim management of NRHP-eligible archaeological and historical resources at Pantex Plant will be implemented by DOE in 1996. The PA will be produced in consultation with the State Historic Preservation Office (SHPO) and the Advisory Council on Historic Preservation, and will contain procedures that DOE will follow to ensure that plant operations comply with Section 106 and Section 110 requirements.

Cultural Resources Eligible for National Register Listing

Eligibility criteria for listing cultural resources on the NRHP are contained in Code of Federal Regulations, Title 36, Part 60 (36 CFR 60.4). Cultural resource studies and eligibility determinations have been and are being coordinated with the Texas SHPO in accordance with Sections 106 and 110 of NHPA. Eligibility criteria are met if a cultural resource has integrity and exhibits any of the following characteristics:

- Association with events that have made a significant contribution to the broad patterns of our history.
- Association with the lives of persons significant in our past.
- Illustration of a type, period, or method of construction; for its aesthetic values or for its representation of the work of a master; or if it represents a significant and distinguishable entity whose components may lack individual distinction.
- It has yielded, or may be likely to yield, information important in prehistory or history.

Earlier survey work on prehistoric sites at Pantex Plant did not result in a consensus on prehistoric sites eligible for the NRHP (MH 1981; Mariah 1992). However, test excavations conducted from 1993 to 1994 on 23 prehistoric sites did result in a recommendation that 22 out of the 23 sites may be ineligible for listing. No determinations of NRHP eligibility for Native American archaeological sites at Pantex Plant have been made (USCOE 1994b; Pantex 1996:12.1).

To date, no historic sites at Pantex Plant have been recommended as potentially eligible for NRHP listing; however, numerous World War II historical resources at Pantex Plant are potentially eligible for listing under the criteria discussed above (USCOE 1994b:174; Mariah 1992:3; Pantex 1996:12.1, 12.2, 12.4).

4.10.1.2 *Native American Groups*

In 1994, 10 Native American tribes with possible traditional interests in the Pantex Plant area were notified by Pantex Plant regarding their potential interest in proposed activities to be addressed in the Pantex EIS; these included the following: the Comanche Tribe of Oklahoma; the Kiowa Tribe of Oklahoma; the Apache Tribe of Oklahoma; the Mescalero Apache Tribe; the Jicarilla Apache Tribe; the Cheyenne-Arapaho Tribe of Oklahoma; the Wichita and Affiliated Tribes; the Caddo Tribe of Oklahoma; the Delaware Tribe of Western Oklahoma; and the Fort Sill Apache Tribe. The Jicarilla and Mescalero Apache Tribes stated that they did not have concerns in the Central Texas Panhandle.

The eight remaining tribes were provided detailed information on EIS/NEPA and NHPA activities. Appendix J contains this documentation. These tribes expressed an interest in acquiring further information on future activities at Pantex Plant. In response, the Pantex Plant Cultural Resource Management staff visited each of the eight tribal offices during June, 1994. Each tribe was given a Pantex Plant EIS/NEPA information packet, an opportunity to view an informational video on the Pantex Plant EIS process, and CRMP/ NHPA information packets. Only the Kiowa and Apache Tribes of Oklahoma have been in contact with the plant since these 1994 visits.

The U.S. Indian Claims Commission has found that the Kiowa Tribe of Oklahoma, the Comanche Tribe of Oklahoma, and the Apache Tribe of Oklahoma have legally recognized traditional interests in the Texas Panhandle. These 3 tribes have been contacted and encouraged to participate in the EIS, NEPA, CRMP, and NHPA processes at Pantex Plant (Pantex 1996:12.4).

Inventory of Traditional Sites

Native American sites, traditional cultural properties (TCPs), or mortuary remains have not been discovered at Pantex Plant. If these are located during future activities they will be managed in compliance with relevant cultural and historical resource management regulations and statutes. DOE recognizes that its management of Pantex Plant may have cultural implications for concerned Native American tribes. To address these concerns, the DOE asked the tribes during their consultations in 1994 if any of Pantex Plant's mission plans impacted their traditional interests. No TCP's within the plant boundaries were identified by the tribes. The tribes are encouraged to notify the plant regarding potential future concerns of a cultural nature. This process will allow the DOE to address concerns on a government-to-government basis. No Native American mortuary remains have been located at Pantex Plant; however, if any such remains are uncovered, they will be managed in compliance with the *Native American Graves Protection and Repatriation Act* (25 U.S.C. 3001) (Pantex 1996:12.4).

Treaty Considerations

To ensure that the rights and interests of Native Americans are protected, DOE is performing a historic treaties search and a public outreach program to involve Native American stakeholders in decision making related to the use of plant land and the protection of cultural resources (Pantex 1996:12.4).

4.10.1.3 *Paleontological Resources*

The surficial geology of the Pantex Plant area consists of silts, clays, and sands of the Blackwater Draw Formation. In other areas of the High Plains, this formation contains Late Pleistocene vertebrate remains, including bison, camel, horse, mammoth, and mastodon, with occasional and important evidence of their use by early humans. A recent archaeological testing program at the plant recovered bison bones associated stratigraphically with stone artifacts along an active drainage that flows south into Pantex Lake (USCOE 1994b:140, 154; DOE1995k:4-300).

4.10.2 Impacts of the Proposed Action

4.10.2.1 *Impacts of Continued Operations*

Weapons-Related Activities

Impacts to cultural and paleontological resources at Pantex Plant as a result of the weapons-related activities under the Proposed

Action are expected to be negligible. No land disturbance is proposed for these activities. Impacts of construction of new facilities under the Proposed Action are discussed separately in section 4.10.2.2.

Pit Storage Activities

The storage of up to 20,000 pits would utilize existing facilities and would not pose adverse impacts to cultural resources.

Environmental Restoration Activities

Although no cultural resources have been identified in the contaminated areas identified for environmental restoration, a cultural resources monitor would be present to identify any subsurface cultural resources during the land disturbance phase. Land disturbance for environmental restoration activities is a small fraction (less than 1 percent) of the total DOE-owned land at Pantex Plant Site. Cultural resource impacts, if any, would not be significant.

Waste Management Activities

The waste management activities will not disturb any new lands; hence no cultural resource impacts are anticipated.

4.10.2.2 *Impacts of New Facility Construction and Upgrades*

The six new facilities constructed under the Proposed Action will be located in or adjacent to Zones 11 and 12 (as shown in Figure 3.1.1–1). Some soil disturbance would be associated with these construction and facility upgrade projects. Although no cultural resources have been identified on the surface, subsurface cultural resources may be discovered during construction, remodeling, or land altering activities. If that occurs, the work would be stopped until an evaluation can be conducted to determine the significance of the resource. Mitigation, documentation, and/or preservation measures would be conducted as necessary.

The Hazardous Waste Treatment and Processing Facility would be constructed in an area that has previously been surveyed for cultural resources. No sites were located in the area to be affected by the proposed construction of this facility.

Modifications and building upgrades are proposed to convert bays 2, 4, 6, and 8 at Building 12–104 into a Pit Reuse Facility. Building 12–104 is of recent construction, and its eligibility to the NRHP has not been determined. Further, no prehistoric or historic sites are known to exist in this area.

The activities proposed for the Gas Analysis Laboratory are currently being conducted in Building 12–21. This was originally the location of the third Cooling and Top-off Building at the Pantex Ordnance Plant. This structure was demolished and replaced with a new building in 1951. The building was included in Legacy's 1994 historic building survey. Based on that evaluation, Building 12–21 was not recommended by the Texas SHPO as potentially eligible to the NRHP (Legacy 1994:107, 109, 111, 125). No cultural resources are known to exist in the proposed construction area.

The proposed construction of the Materials Compatibility Assurance Facility is within an area that has been inventoried for historic structures (Legacy 1994:167-168). The foundations of Ramp 11–R–23 are located adjacent to and immediately south of the proposed Materials Compatibility Assurance Facility. The remains of another structure, Building 11–13, adjacent to the south end of Ramp 11–R–23, are not considered eligible to the NRHP, and would not require avoidance. The remains of Ramp 11–R–23 will need to be monitored for avoidance during construction, and/or mitigated prior to construction.

Construction of the Nondestructive Evaluation Facility and the Metrology and Health Physics Calibration and Acceptance Facility is planned within Zone 12. These areas have been extensively disturbed by the growth and building activities within Zone 12 and are not adjacent to any buildings thought to be eligible to the NRHP. Further, no prehistoric sites are known to exist in this area.

4.10.2.3 *Summary of Impacts*

No impacts to cultural resources are anticipated from the continued operations at Pantex Plant. No surface remains or historical structures potentially eligible for the NRHP have been identified at the six new project sites. If subsurface cultural features or artifacts are identified during land disturbance for construction, appropriate mitigation measures would be taken in consultation with the SHPO.

4.10.3 Impacts of No Action Alternative

Impacts to cultural resources at Pantex Plant as a result of the No Action Alternative are expected to be negligible. Plant operations will not impact known cultural resources at Pantex Plant Site. No new projects would be constructed under this alternative. Impacts, therefore, are considered negligible.

4.10.4 Impacts of Pit Storage Relocation Alternative

As discussed in section 3.1.3, the Pit Storage Relocation Alternative would involve relocation of pits from storage at Pantex Plant to storage at one or more alternate sites.

4.10.4.1 *Impacts of Relocating 20,000 Pits*

Even if 20,000 pits are relocated from Pantex Plant to any other site, Pantex Plant activities would remain as identified for the Proposed Action, including the construction of six new projects. The only exception would be the availability of current storage magazines for other uses when pits are relocated to another site. Impacts on cultural resources would, therefore, be similar to those identified for the Proposed Action.

4.10.4.2 *Impacts of Relocating 8,000 Pits*

The impacts of relocating 8,000 pits would be similar to those identified for the Proposed Action and relocation of 20,000 pits, except that fewer magazines would become available for other uses once the pits are transferred. The alternative uses of these magazines would not affect their historic structure status; thus no impacts are anticipated.

4.10.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.10.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

The actual location of waste management facilities would likely disturb additional DOE-owned land at Pantex Plant. However, no specific locations have been identified in the WM PEIS. Therefore, cumulative impacts to cultural resources cannot be identified at this stage. In general, given that specific projects would likely undergo their own NEPA review, it is unlikely that the eventual siting would impact cultural resources.

4.10.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Impacts to cultural resources from operations are expected to remain the same as current impacts. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Consequently, no potential impacts to cultural resources would occur.

4.10.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. No prehistoric or historic resources were identified in the project area. Impacts to prehistoric or historic resources are not anticipated.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, MOX fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

Some NRHP-eligible resources may be affected by the construction of the disposition facilities. Any resources would be identified during Section 106 of the NHPA compliance process. There would be no operational impacts to archaeological remains because no additional ground disturbance is involved. Construction and operation of these facilities may affect some Native American resources. Native American resources would be identified through project-specific consultation with potentially affected groups. Some paleontological resources may occur in the area to be affected by construction. These operations would not have an additional impact (DOE 1996a:4.0).

4.10.6 Potential Mitigation Measures

No long-term adverse impacts to cultural resources have been identified relative to the Proposed Action, No Action, or Pit Storage Relocation Alternative; hence, no mitigation measures are needed. A Programmatic Agreement (PA) for the continued interim management of the NRHP-eligible archaeological and historical resources at Pantex Plant is being developed for implementation in 1996. The PA will be superseded by the CRMP, which is scheduled for implementation in 1998 (Pantex 1996).

If subsurface remains are identified during project construction, mitigation measures would be taken in consultation with the SHPO. These may include: groundwork monitoring, stopping work upon discovery, and mitigation or avoidance of cultural resources to minimize the potential for adverse effects.

If Native American traditional use resources are identified, but cannot be avoided through project design or location, than acceptable mitigation measures to lessen the effect on the resources would be determined in consultation with the appropriate Tribal organizations or governments. Mitigation measures may include; reconfiguration of project plan designs, appropriate relocation of human remains and associated funerary items in compliance with the *Native American Graves Protection and Repatriation Act* (25 U.S.C. 3001), reducing visual intrusion, or transplanting/harvesting traditional or secular plant resources to minimize the potential of adverse effects.

4.11 SOCIOECONOMIC RESOURCES

4.11.1 Affected Environment

This section addresses the population, housing, labor force, income, and public finance characteristics in the Pantex Plant region.

Pantex Plant is located in Carson County in the central Panhandle of Texas, 27 kilometers (17 miles) northeast of Amarillo on U.S. Highway 60. The western boundary of the site nearly coincides with the border between Potter and Carson Counties. The Amarillo metropolitan area extends between Potter County and its neighbor to the south, Randall County. A few miles south of Pantex Plant is Armstrong County, which shares its western border with Randall County and its northern border with Carson County. More than 96 percent of the employees at Pantex Plant reside within the rectangle formed by these four counties, and this area is accordingly defined as the Region of Influence (ROI) for this socioeconomic analysis. The area is depicted in Figure 4.11.1–1.

4.11.1.1 *Regional Population*

According to the 1990 Census, there were 196,144 persons and 75,067 households in the ROI. More than 95 percent of the persons and households were found in the Amarillo metropolitan area. In 1990, almost four-fifths (79.7 percent) of the ROI's population was White, 13.1 percent was Hispanic, and 4.9 percent was Black. Virtually all of the non-White population in the ROI is concentrated in the Amarillo Metropolitan Statistical Area (MSA), as shown in Table 4.11.1.1–1. More detailed information on the racial/ethnic composition of Amarillo's population is presented in section 4.17, Environmental Justice.

Outside of the Amarillo urbanized area are several small towns scattered across the ROI. Canyon, with a 1990 population of 11,365, is located south of Amarillo in central Randall County. Panhandle, with a 1990 population of 2,353, is situated approximately 16 kilometers (10 miles) east of Pantex Plant in south-central Carson County. The community of White Deer, with 1,125 persons, is situated northeast of Pantex Plant and the town of Panhandle, in east-central Carson County.

In north-central Armstrong County, southeast of Pantex Plant, is the town of Claude, with a 1990 population count of 1,199. The remainder of the 1990 population in the ROI—22,487 persons, or 11.5 percent of the ROI's total population—lived in communities with populations under 1,000 and on farms and ranches found throughout the four-county area. Table 4.11.1.1–2 presents the racial/ethnic characteristics of the small town and rural populations in the ROI.

The estimated population in the four-county ROI on July 1, 1995 was 209,762, an increase of nearly 13,700 persons from the time of the 1990 Census enumeration in April 1990. Thus, the overall rate of population growth in the ROI during this period was 6.9 percent or 1.4 percent per year (Pantex 1996:8.1).

According to the Texas State Data Center, the projected population in the ROI in 2005 ranges between 214,353 and 246,464, depending on specific economic development scenarios (TSDC 1994). The low-end projection represents a 0.6 percent average annual rate of growth in the ROI during the 15 years following the 1990 census, while the high-end figure represents a 1.7 percent average annual rate of growth in the ROI during this period.

The Amarillo Metropolitan Statistical Area (MSA), which consists of Potter and Randall Counties, accounted for 96 percent of the ROI population in 1995. Table 4.11.1.1–3 presents the history of population growth in the ROI and in the MSA during the period 1960–1995. As shown in this table, the Amarillo MSA

Sources: City 1989; TX Cen 1961:6; TX Cen 1973:9; TX Cen 1982:14; TX Cen 1992a:1; TX Cen 1996; TX Cen 1996a

experienced a 3.4 percent decline in population between 1960 and 1970. This was largely attributable to the closing of the Amarillo Air Force Base in 1968. Amarillo MSA quickly recovered from this population loss by the mid 1970's. Between 1970 and 1980, it increased its population at an average annual rate of 2.0 percent. The growth rate slowed down to 0.8 percent per year in the 1980's but increased again to 1.4 percent per year during the 1990's (1990-1995).

4.11.1.2 *Regional Income and Poverty*

In 1989, the median household income in the ROI was $25,763, compared to the median of $27,016 for Texas as a whole. Per capita income in the ROI was $12,639 in 1989, compared to the State-wide per capita income of $12,904. A total of 30,253 persons in the ROI were below the poverty level based on their 1989 incomes, representing 15.4 percent of all persons in the ROI. Over 97 percent of these persons were residents of the Amarillo metropolitan area. Across Texas, 18.1 percent of all persons were below the poverty level based on their incomes in 1989. Table 4.11.1.2–1 summarizes the information on income and poverty levels in the ROI.

4.11.1.3 *Regional Housing*

Throughout the four-county area, a total of 84,506 housing units were counted in 1990. Slightly more than 11 percent, or 9,439 of these units were vacant, while just over 75,000 were occupied by an average of 2.56 persons per unit. Nearly 65 percent of the units were owner-occupied dwellings, while the remainder were occupied by renters. Less than 5 percent of the occupied units were overcrowded, with more than one person per room. Less than 1 percent of all housing units in the ROI lacked either complete plumbing or kitchen facilities. Table 4.11.1.3–1 presents the housing characteristics for the ROI as a whole and the four counties that comprise the ROI.

4.11.1.4 *Regional Labor Force*

In 1990, two-thirds of the ROI's population 16 years of age and older, or 97,713 persons, were in the civilian labor force. Of this total, 91,412 were employed, with 71,134 working at least 35 hours per week. Unemployed persons totaled 6,301, or 6.5 percent of the civilian labor force.

One-third of the persons in the ROI 16 years of age and older were not in the labor force, i.e., they were neither working nor seeking work. Characteristics of the ROI's labor force are summarized in Table 4.11.1.4–1.

Slightly more than two-thirds of employed persons in the ROI in 1990 were wage or salaried workers in private for-profit business enterprises. Exactly 15 percent of the employed, or 13,686 persons, were government workers at the local, State, or Federal levels. Slightly more than 9 percent, or 8,373 persons, were self-employed, with 1,091 persons in this group being self-employed in agriculture. Seven percent of employed persons were wage and salaried workers in private non-profit work environments. Table 4.11.1.4–2 presents information on the various classes of workers in the ROI.

Table 4.11.1.4–3 shows the distribution of the ROI's employed workforce across the major industrial sectors. One-third of the employed, or 30,623 persons, in the ROI in 1990 worked in the service industry. The next largest group, 23,602, or 25.8 percent of employed persons, worked in the retail or wholesale trade industry. Those employed in manufacturing, which includes the operations at Pantex Plant, numbered 10,441, or 11.4 percent of the employed workforce. The remaining industrial sectors each employed less than 10 percent of the ROI's working population, with agriculture providing work for 2.8 percent of working persons in the four-county area.

Nearly one-third of the ROI's employed persons worked in technical and administrative support occupations in 1990, while just less than one-fourth of the workforce had managerial and professional positions. Approximately 14,000 of the 91,412 employed persons, or 15 percent, had service jobs, while another 12,600, or 14 percent, worked as operators, fabricators or laborers. Precision production, craft and repair jobs were held by another 13 percent of the workforce, and 2,243 persons, or 2.4 percent of the employed, worked in farming occupations. It should be noted that the Bureau of the Census

utilizes the broad Farming, Fishing, and Forestry occupational category to classify persons with these types of jobs. However, in the Texas Panhandle, this category includes only farm workers, since there are no fishing or forestry business operations in the area (PC 1995o). As shown in Table 4.11.1.4–4, at least 96 percent of the employed persons in the ROI lived in the Amarillo MSA, with the exception of those in farming jobs, of whom 79 percent resided in the Amarillo metropolitan area.

Of the persons in the ROI with work experience but who were unemployed in 1990, more than one-fourth, or 1,624, had held technical and administrative support positions. Nearly 1,200, or one out of five experienced unemployed persons, had been operators, fabricators, or laborers. Slightly more than 1,000, or 17 percent, had been precision production, craft, or repair persons, and nearly 600, or 10 percent of the experienced unemployed, had held managerial or professional positions (Table 4.11.1.4–5).

According to the Texas Employment Commission, the labor force in 1994 in the Amarillo MSA, consisting of Potter and Randall Counties, averaged 107,545 persons. Of this total, 103,116 were employed and 4,429 were unemployed and seeking work. Thus, the average unemployment rate in 1994 for the Amarillo MSA stood at 4.1 percent (TEC 1995).

4.11.1.5 *Regional Economy*

According to the Census Bureau's report on 1992 business patterns, there were more than 5,300 business establishments in the four-county ROI. Services, retail, and wholesale businesses constituted 70 percent of the establishments in the ROI, employed two-thirds of the employed persons covered in the survey, and accounted for a total annual payroll in excess of $800 million. Construction firms represented 7.8 percent of the businesses in the ROI, but they employed less than 5 percent of the covered workforce, with an annual payroll

of $77 million. Nearly 10 percent of area businesses were finance, insurance, and real estate firms, which employed slightly more than 5 percent of the workforce, with a total annual payroll of $86 million.

There were 200 manufacturing establishments in the ROI that comprised less than 4 percent of area businesses yet employed 10,590 people, or 15.5 percent of the covered workforce, with an annual payroll of $281 million. Activities at Pantex Plant were included in the manufacturing category. The 3,800 employees at Pantex Plant constituted 36 percent of the ROI's workforce employed in manufacturing. Table 4.11.1.5-1 provides more detail about businesses in the ROI.

According to the 1992 Census of Agriculture, farming and ranching contributed nearly $300 million to the economy of the ROI. Nearly 1,300 farms and ranches operated in the four-county area, with an average of 1,560 acres, covering more than 86 percent of the total land area in the four counties (TX Cen 1994:1; TX Cen 1993d:4). Nearly two-thirds of these operations reported cattle and calves in their inventory, with a total of 281,551 cattle and calves counted in the ROI in 1992. The value of the cattle and calves sold by area ranches in 1992 was in excess of $254 million (TX Cen 1994:14). Livestock raised within the four-county ROI includes dairy operations and beef cattle in feedlots and open range. Dairy operations and milk production consist of approximately 3,000 cows that produce up to 64,000 pounds of milk per day.

The number of beef cattle is difficult to obtain because of inherent characteristics of the industry. The beef cattle industry in the Texas panhandle has the following four distinct aspects:

- Cow-calf operations on open range.
- Grazing of cattle on wheat and native pasture.
- Feedlot operations.
- Slaughter and meat packaging operations.

TABLE 4.11.1.5–1.—*1992 County Business Patterns in the Pantex Plant Region of Influence*

INDUSTRY	TOTAL # OF ESTABLISHMENTS	%	TOTAL # OF EMPLOYEES[1]	%	TOTAL ANNUAL PAYROLL[2] ($1000)
Agricultural Services, Forestry, Fishing	74	1.4	420	0.6	$7,656
Mining	102	1.9	610	0.9	$25,802

[1]Figures exclude self-employed persons, most government employees, railroad workers, agricultural production workers, domestic service workers, and employees of organizations totally exempt from FICA coverage. Total excludes 223 workers in Armstrong County who were not subdivided by industrial sector due to confidentiality considerations.
[2]Total payroll amount excludes $5.636 million in Armstrong County, which was not reported by industrial sector due to confidentiality considerations.
Source: TX Cen 1994a:Table 2

Each of these aspects is affected by precipitation levels and local and future agricultural meat prices for beef.

One step in beef cattle operations is slaughter and processing. The destination of beef cattle depends on market levels and transportation costs. Large meat processing operations often slaughter and ship carcasses to meat-cutting and meat-packaging operations, possibly in other states. Thus, the possibility that packaged beef is returned to the area of origin is very remote. It is likely that more than 95 percent of the beef cattle processed in large meat operations is distributed and consumed out of state. Conversely, more than 95 percent of the beef cattle processed by small-meat processors is distributed and consumed locally.

The number of cow-calf pairs and beef cows has been compiled by the Texas Agricultural Statistics Service for all Texas counties. As of the January 1, 1994 inventory, Armstrong County had 63,000 cow-calf pairs and 5,000 beef cows. Corresponding numbers for Carson County were 73,000 and 9,000. Potter had 51,000 and 6,000, and Randall had 170,000 and 9,000 (Pantex 1996:10.2).

Crops grown in the ROI during 1992 were sold for a total of $43.8 million (TX Cen 1994:1). Of the four counties, Carson County is an important agricultural county in the State of Texas. In 1993, Carson County was eighth among all Texas counties for production of wheat and grain sorghum, and was 28th for production of corn (Pantex 1996:10.1).

Since 1950, shortly before the nuclear weapons activities at Pantex Plant began, the value of crops grown and sold in the ROI has increased by 151 percent, relative to the 142 percent increase in the Producer Price Index for Crude Foodstuffs and Feedstuffs during this period. Cattle and calf sales in the ROI have increased by 2,007 percent since 1950, relative to a 153-percent increase in the Producer Price Index for Slaughter Livestock during this period. Details of the growth of the agriculture industry in the ROI are presented in Table 4.11.1.5–2.

Corn and sorghum grown for grain or seed and wheat grown for grain are the major cash crops of the four-county ROI. The number of bushels of each of the crops harvested in 1992 is depicted in Table 4.11.1.5–3. Corn production is significantly less than sorgham or wheat because extensive irrigation is needed for corn maturation. About half of the crops grown in the local area are strictly dryland because of the high cost of pumping water from the Ogallala aquifer (Pantex 1996:10.2).

In addition to agriculture, the economic activity in the ROI has historically depended on mining (oil and gas). Growth in manufacturing, distribution, food processing, and medical services has provided further diversification to the economy. In the 1960's, Amarillo Air Force Base, with a direct employment of approximately 4,000 military and civilian employees, was a dominant force in the Amarillo economy. With the closing of the Base in 1968, approximately 9,000 persons left the Amarillo area within a two-year period. The City of Amarillo, however, took immediate

TABLE 4.11.1.5–2.—*Characteristics of Farms in the Pantex Plant Region of Influence*

action to recover the airport portion of the airfield for civilian aviation and initiated plans for the development of the airport.

In February 1968, Bell Helicopter started operating a military helicopter modification and repair facility on part of the Air Force Base land. The non-airport land was acquired by the State of Texas for use as a technical vocational training site by the Texas State Technical Institute. The air carrier terminal building was completed in 1971 and the City was well on its way to recovery from the population loss resulting from the Air Force Base closure. In the 1970's, Amarillo maintained a healthy economy providing major medical, financial, professional, governmental, transportation, and retail services to the entire Texas Panhandle and beyond (City 1989; Cress 1980).

The 1980's saw two major events which had a substantial impact on Amarillo area economy. In 1986, the Department of Energy announced that a 60-acre site in Deaf Smith County, adjacent to the Amarillo MSA, would be tested as one of the three potential sites for the disposal of spent nuclear fuel and high-level radioactive waste in geologic repositories. Activities at the Deaf Smith site in 1987, employed approximately 300 engineers and scientists (AGT 1986). In December 1987, the Congress enacted the Nuclear Waste Policy Amendments Act of 1987, which directed the DOE to characterize only one site, the Yucca Mountain Site in Nevada, as a candidate for the first repository (DOE 1988a). This resulted in the closure of activities in Deaf Smith County with a loss of 300 direct jobs, mainly in the Amarillo metropolitan area. In 1989, Bell Helicopter announced it was closing the Amarillo facility. It eventually closed in March 1990 with a loss of 350 jobs. At its peak in early 1980's, Bell Helicopter employed between 800 and 1,000 workers (PC 1996t).

The U.S. Department of the Interior, Bureau of Mines, has been operating a Helium Plant in Amarillo area since the early 1940's. The facility presently employs approximately 175 workers. The U.S. Congress is currently considering downsizing or eventually closing the plant. The U.S. House of Representatives voted in May 1996 to downsize the plant. However, the U.S. Senate has not voted on it yet. If downsizing were to occur, the employment at the Helium Plant would be reduced to about 30 to 40 workers within 18 months of the decision (PC 1996s).

In spite of the employment and population loss represented by the activities described above, the decennial population growth presented in Table 4.11.1.1–3 clearly demonstrates that the Amarillo metropolitan area economy has remained vibrant. Because of the visionary approach of the local leaders in diversifying the economy of the metropolitan area, Amarillo has withstood adversities in the past and has remained the center of finance and business for the Texas Panhandle.

4.11.1.6 *Public Finance*

The local governments most likely to be affected by the Proposed Action are the City of Amarillo and the counties of Armstrong, Carson, Potter, and Randall. Tables 4.11.1.6–1 and 4.11.1.6–2 present the 1994 revenues and expenditures for these units of government, subdivided by major revenue and expenditure categories. Income from taxes constitutes the major single source of funding for each of the governmental units, ranging from 35 percent of Armstrong County's 1994 total revenue to 66 percent of Potter County's 1994 total revenue.

The City of Amarillo received 63 percent of its 1994 revenue from taxes. The City also obtained 15 percent of its 1994 income from licenses, fees, and charges for services such as solid waste collection and auditorium and coliseum rentals. Most of local government spending is for roads, bridges, and law enforcement. Expenditures for 1994 were below total revenues, except for Carson County, which had a deficit of less than $1,000.

The long-term outstanding debts of the various local governments at the end of their 1994 budget year are shown in Table 4.11.1.6–3. Each of the governments has a schedule for the elimination of its long-term debt. (County 1994d; County 1994a; County 1994b; County 1994c; City 1994).

4.11.1.7 *Pantex Plant Workforce*

As of January 1995, approximately 3,530 persons were employed at Pantex Plant. Of this total, 3,310 were Mason & Hanger-Silas Mason Company, Inc. and Battelle Memorial Institute employees, 75 were DOE Amarillo Area Office employees, 130 were DOE Transportation Safeguards Division employees, and 15 were Sandia and other National Laboratories employees. In addition to the 3,530 plant employees, approximately 250 employees associated with consultants, subcontractors, and oversight agencies worked at the plant site for a total of 3,780 employees onsite in early 1995. Including outside consultants, subcontractors, and oversight agencies, a total of 3,800 employees are expected onsite (DOE 1995j). This is equivalent to 3.7 percent of the total employment of 103,116 workers in the Pantex Plant ROI in 1994 (TEC 1995).

TABLE 4.11.1.6–1.—*Revenues of Governing Bodies Within the Pantex Plant Region of Influence*

SOURCE OF REVENUE	ARMSTRONG COUNTY	CARSON COUNTY	POTTER COUNTY	RANDALL COUNTY	CITY OF AMARILLO
Taxes	$258,807	$1,659,395	$14,267,472	$7,191,713	$45,228,109
Licenses, Fees, Charges for Services	$195,151	$437,354	$3,607,042	$3,077,463	$11,088,927
Intergovernmental	$126,991	$818,791	$1,994,799	$1,730,788	$7,179,176

4.11.2 Impacts of Proposed Action

4.11.2.1 *Impacts of Continued Operations*

Analysis of socioeconomic effects utilizes total output, employment, and earnings multipliers for the Pantex Plant ROI from the U.S. Bureau of Economic Analysis Regional Input-Output Modeling System. The current employment of 3,800 direct (onsite) workers is considered to be sufficient for the continuation of operations at the 2,000 weapons activity level per year. The results from the Input-Output Modeling System indicate that, as a result of this level of operations, a total of 6,257 secondary jobs would be created throughout the ROI from regional spending by direct workers as well as from procurement of equipment, materials, and supplies by Pantex Plant. Most of the secondary jobs in the local economy are in the retail trade and service sectors, resulting from the first-round spending by direct workers and secondary impacts induced from business activity dispersed throughout the ROI economy.

Aggregated annual earnings (salary and wages paid to employees) for direct employees total $222 million in 1994 dollars (PC 1995v). An additional $176 million (in 1994 dollars) of earnings is generated annually through secondary employment in the ROI. Thus, total annual earnings in the ROI as a result of this level of continued Pantex Plant operations is estimated at approximately $398 million. Total personal income (income received by persons from all sources including wages, interest, dividends, and other transfer payments) generated by Pantex Plant operations at the 2,000 weapons activity level adds approximately $564 million (in 1994 dollars) to the ROI economy each year.

If Pantex Plant operations are reduced to the 1,000 weapons activity level per year, direct employment would decrease to approximately 3,000 workers. This would result in a decrease of secondary jobs in the ROI to 4,925. The combined (direct and secondary) decrease of 2,132 workers from the 2,000 weapons activity level could increase the unemployment rate in the ROI from 4.1 percent to approximately 6.0 percent. Aggregated annual earnings would total $175 million for direct employees (in 1994 dollars) and $138 million for secondary workers in the ROI. The total annual earnings and personal income in the ROI would be reduced to approximately $314 million and $445 million, respectively, as a result of reduction in activity level to 1,000 weapons operations per year. This would amount to approximately 79 percent of the earnings and personal income generated by the 2,000 weapons activity level.

If Pantex Plant operations are reduced to the 500 weapons activity level per year, employment would decrease to about 2,400 direct workers, and secondary jobs throughout the ROI would decrease to about 3,950. The combined reduction of 3,715 direct and secondary jobs from the 2,000 weapons activity level would increase the unemployment rate in the ROI from 4.1 percent to approximately 6.2 percent. This could trigger some out-migration of workers from the ROI. Aggregated annual earnings would total $140 million (in 1994 dollars) for direct employees and $111 million for secondary workers in the ROI. The total annual earnings and personal income in the ROI would be reduced to $251 million and $356 million, respectively, as a result of reducing Pantex Plant operations to the 500 weapons activity level. This would amount to approximately 63 percent of the earnings and personal income generated by the 2,000 weapons activity level.

Dr. Perryman's analysis reported in Amarillo Economic Development Corporation release dated August 3, 1993 and an undated press release by Perryman Consultants "Analysis Shows Pantex Plant Adds a Billion in Revenues and Thousands of Jobs to Amarillo Economy," have provided different projections for changes in Pantex related jobs. Dr. Perryman, in one place, mentions that Pantex Plant employs

3,100 persons and estimates that the total employment resulting from Pantex Plant operations is 11,688, thus implying a total job multiplier of 3.77 and a ratio of 2.77 indirect jobs for each direct job.

In the same article, however, Dr. Perryman states that Pantex Plant expansion by 2,400 jobs would result in 5,312 total additional jobs. This implies a total job multiplier of 2.21 (Perryman 1993). Although DOE believes that a total job multiplier of 2.65 is more realistic, this alternative perspective has been provided in the interest of full disclosure of differing viewpoints.

Assuming that all 1,400 direct workers and 50 percent of the 2,315 indirect workers (1158 workers) and their families decide to leave the Pantex ROI in search of jobs elsewhere, the maximum decrease in population would amount to 5,756 persons (2,558 workers x 2.25 persons per household = 5,756 persons). This would represent a loss of 2.7 percent of the total ROI population of 209,762 in 1995. It should be noted that if this reduction takes place it would not occur instantaneously. Most people do not leave town soon after the loss of a job.

More importantly, the reduction of jobs at Pantex would not be abrupt or instantaneous. Work would be phased out over several years. Even when the weapons activity level is being reduced to 500 weapons per year, work relating to decontamination and decommissioning of facilities would employ many of the same people performing other activities at Pantex Plant. While there is reduction of employment in one activity at the plant, there would be a simultaneous increase in another activity. Therefore, the outmigration of unemployed workers is not likely to be as large as 2,558 as shown above.

The reduction of ROI population by 5,756 persons would impact the tax revenues of the local governments under whose jurisdiction Pantex-related employees (both direct and indirect employees) live. Property values would also be temporarily reduced. For making a quantitative assessment of the loss of tax revenues, the following assumptions are made to identify the maximum impacts:

- All 2,558 worker households live in the City of Amarillo (since City of Amarillo has the highest per capita tax rate in the ROI, tax revenues would be maximally impacted with this assumption).
- All workers and their families leave the city within one year (this would have the maximum impact on property value and property taxes).

Applying the 1994 per capita tax rate of $457 in Amarillo to the 5,756 persons leaving town, the reduction in tax revenue can be estimated at $2.8 million or 3.6 percent of the total tax revenues of $72.1 million in Amarillo. Since many of the Pantex employees live in other parts of the ROI where tax rates are generally lower than the City of Amarillo and because all workers would not leave town within a year, the annual losses in tax revenues in the ROI would be substantially smaller than presented above. Moreover, while it is acknowledged that the property values would decline, it is inconceivable that they would go down to zero, which is what the reduction of $2,630,492 in tax revenue represents.

In summary, the impacts of reduction in jobs with a reduction in weapons activity level to 500 weapons per year is not likely to have a significant impact on population, property values, or tax revenues of local governments. A temporary decline in population and tax revenues could possibly lead to reduced income for charitable organizations that rely on contributions of the employees at the plant and elsewhere in the community at a time when their services may be needed by more people who lose their jobs due to downsizing.

Impacts of Pit Storage Activities

Only 30 employees are directly involved in pit storage activity at Pantex Plant. Since they are part of the total employment of 3,800 workers at Pantex Plant, the socioeconomic effects are included in the foregoing discussion of continued operations.

Impacts of Environmental Restoration and Waste Management Activities

Personnel required for the environmental management and waste management activities are included in the workforce numbers presented in the foregoing discussion of continued operations. Thus, there are no significant additional socioeconomic impacts associated with the environmental management activities.

4.11.2.2 *Impacts of New Facility Construction and Upgrade*

Hazardous Waste Treatment and Processing Facility

During the peak year of its construction, the Hazardous Waste Treatment and Processing Facility would generate approximately 129 construction jobs. After construction is completed, 20 workers would be needed to operate the facility. Of these workers, 15 are already employed at the plant; only 5 new persons would be added when operations start. With the creation of 129 construction jobs in the peak year, an additional 211 secondary jobs would be created in the ROI, bringing the total jobs to 340. Additional earnings in the ROI, during the peak construction year of this facility, are estimated at $2.76 million. Additional personal income in the ROI is estimated at $3.91 million. After the construction is completed, operations at this facility would not add significantly to the socioeconomic effects described for the continued operations at Pantex Plant.

Pit Reuse Facility

During the peak year of its construction, the Pit Reuse Facility would generate about 50 construction jobs. After construction is completed, 7 workers would be needed annually for ongoing operations. During the peak construction year, 82 secondary jobs would be created in the ROI as a result of the construction of this project, bringing the total to 132 jobs in the peak year. Additional earnings in the ROI during the peak construction year are estimated at $4.54 million and additional personal income at $6.44 million. After the construction is completed, only 7 workers would be needed to operate the facility. This would not add significantly to the existing workforce of 3,800 employees at Pantex Plant. Socioeconomic impacts of this facility are, therefore, considered negligible, except for the short-term beneficial impacts during the construction phase.

Gas Analysis Laboratory

During the peak year of its construction, the Gas Analysis Laboratory would generate approximately 60 construction jobs. An additional 101 jobs would be created in the ROI as a result of the facility construction, bringing the total jobs to 161 in the peak construction year. Additional earnings in the ROI during the peak construction year are estimated at $5.14 million and additional personal income at $7.22 million. After construction is completed, 20 workers would be needed to operate the new facility. These workers would be transferred from the existing facilities at the plant and would not generate additional socioeconomic impacts.

Materials Compatibility Assurance Facility

During the peak year of its construction, the Materials Compatibility Assurance Facility would generate about 104 construction jobs (PC 1995g:Table 1). An additional 172 secondary jobs would be created in the ROI as a result of the facility construction, bringing the total jobs to 276. Additional earnings in the ROI during the peak year of construction are estimated at $3.20 million and additional personal income at $4.55 million. After the construction is completed, 40 workers would be needed to operate the new facility. These workers would be transferred from existing facilities at the plant and would not generate additional socioeconomic impacts.

Nondestructive Evaluation Facility

During the peak year of construction, the Nondestructive Evaluation Facility would generate about 224 construction jobs. An additional 370 secondary jobs would be created in the ROI as a result of the facility construction, bringing the total jobs to 594 in the peak construction year. Additional earnings in the ROI during the peak construction year are estimated at $18.83 million and additional personal income at $26.71 million. After construction is completed, 42 workers would be needed to operate this facility. These workers would be transferred from the existing facilities at the plant and would not generate additional socioeconomic impacts.

Metrology Health Physics Calibration and Acceptance Facility

During the peak year of its construction, the Metrology and Health Physics Calibration and Acceptance Facility would generate an estimated 60 construction jobs. An additional 99 secondary jobs would be created in the ROI as a result of the facility construction, bringing the total jobs to 159 in the peak construction year. Additional earnings in the ROI during the peak year of construction are estimated at $5.04 million and additional personal income at $7.15 million. After construction is completed, 48 workers would be needed to operate the new facility. These workers would be transferred from existing facilities at the plant and would not generate additional socioeconomic impacts.

4.11.2.3 *Summary of Impacts*

At the 2,000 weapons per year level, a total of 10,057 jobs would be generated in the ROI as a result of the activities at Pantex Plant Site. With weapons level reduced to 1,000 or 500 weapons per year, the employment at Pantex Plant would be reduced by 2,132 workers or 3,714 workers, respectively. Corresponding decreases in earnings and personal income would also occur as described in section 4.11.2.1. Construction and associated secondary jobs generated by the new projects in the peak construction year are estimated at 1,227 workers. This amounts to an increase of approximately 12 percent over the plant's permanent workforce.

However, this increase would provide only short-term benefits to the local economy. Because almost all construction workers can be locally hired, the benefits would generally accrue to the ROI population. Earnings in the ROI would temporarily increase to $437 million from $398 million generated by the continued operations at the 2,000 weapons activity level. Personal income would correspondingly increase from $564 million to $620 million. After the construction phase, the socioeconomic impacts would remain as described for the continued operations.

For the 1,000 and 500 weapons levels, the increase in employment, earnings, and personal income associated with new projects would be the same as described for the 2,000 weapons level scenario.

4.11.3 Impacts of the No Action Alternative

Under the No Action Alternative, the disassembly of weapons would cease when the pit storage at Pantex Plant reaches 12,000 pits. However, for purposes of analysis, it is assumed that the weapons levels would remain at 2,000, 1,000, and 500 as described under the Proposed Action. The activities associated with the disassembly would cease but would be substituted by an increase in activities associated with the assembly, modification, and surveillance of weapons to meet the stockpile requirements. With such a substitution, the workforce requirements at the plant and the expenditures that the plant would incur in Pantex Plant ROI would remain at the levels described under the Proposed Action. Therefore, socioeconomic impacts of the No Action Alternative would be similar to those described for the Proposed Action, with the exception that the impacts generated by the new projects planned under the Proposed Action would not occur.

4.11.4 Impacts of Pit Storage Relocation Alternative

4.11.4.1 *Impacts of Relocating 20,000 Pits*

Under this scenario, the activities at Pantex Plant would be similar to those described under the Proposed Action with 2,000 weapons per year activity level because the plant would continue to dismantle weapons until disassembly of 20,000 weapons is accomplished. The activities related to interim pit storage in Zone 4 of Pantex Plant would remain until pits are shipped to other site(s). As a result, the socioeconomic impacts of this Pit Relocation Alternative would be similar to those identified for the Proposed Action with 2,000 weapons per year activity level.

4.11.4.2 *Impacts of Relocating 8,000 Pits*

Even if only 8,000 pits are relocated to the other site(s), the assumption remains that Pantex Plant would continue to store 12,000 pits and weapons disassembly would continue until 20,000 weapons are disassembled. Socioeconomic impacts of this alternative scenario would, therefore, be similar to those identified for the Proposed Action with 2,000 weapons activity level per year.

4.11.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2. In addition, the cumulative impacts include impacts from the closure of the U.S. Department of Interior Helium Plant.

4.11.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

The location of waste management facilities at Pantex Plant could increase employment at Pantex Plant by an additional 654 workers as projected in the WM PEIS. It should, however, be noted that the WM PEIS is projecting employment for both treatment and disposal facilities. The Proposed Action in this EIS already includes the construction and operation of a hazardous waste treatment and processing facility. The remaining disposal facility, if developed at Pantex Plant, would not generate the entire workforce as projected in the WM PEIS, and the cumulative impacts would more likely be lower than described above.

4.11.5.2 Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, the most significant change at Pantex Plant would involve the number of workers associated with the assembly and disassembly mission, which would be expected to decrease from approximately 2,365 to approximately 915 for one-shift operations. The number of direct workers associated with HE fabrication would decrease from 365 to approximately 105.

Under the downsizing alternative, assembly and disassembly operations at Pantex Plant would proceed more efficiently and require approximately 800 workers for one-shift operations, 115 workers less than under the No Action Alternative. For three-shift operations, the bounding-case, approximately 1,266 workers would be required. All construction activities would be modifications to existing facilities. Consequently, socioeconomic impacts from the construction would be minimal.

Under the relocation alternative, approximately 1,644 direct and 1,905 indirect jobs would be lost in the regional economic area. The loss of approximately 3,549 total jobs would cause the regional economic area unemployment rate to increase from 4.8 to 6.2 percent. Housing and rental vacancies and public finance expenditures and revenue would change by less than 1 percent.

4.11.5.3 Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The Collocation Alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. Construction and operation of new storage facilities would require 1,524 and 676 workers, respectively.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on choosing the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

The Pantex EIS Proposed Action with 2,000 weapons activity level per year combined with the bounding disposition alternative at Pantex Plant could increase employment at Pantex Plant from its current 3,800 workers to 10,220 workers if the workforce increase of 1,298 workers and 5,122 workers (125 pit disassembly and conversion, 1,022 workers plutonium conversion facility, 475 workers mixed oxide facility, and 3,500 workers evolutionary Light Water Reactor) projected in the S&D PEIS, respectively, are fully realized.

It should be noted that preconstruction activities for disposition would require about 5 years to perform the tiered NEPA analyses and to obtain necessary permits and designs. About another 5 years would be required for construction, startup, preoperational testing, and operational readiness review. Construction of completely new reactors could take longer (DOE 1996a:4.0). By the time these facilities become operational, the workforce associated with the assembly/disassembly functions would be reduced to approximately 800 to 1,266 workers as shown in the SSM PEIS. Hence, the total workforce is not likely to reach the 10,220 worker level as shown above for the bounding case.

4.11.5.4 *Impacts from Other Potential Actions*

Information on other Federal, State, or local projects including private developments was sought through contacts with Federal and State regulatory agencies, the Amarillo Economic Development Corporation, the Panhandle Municipal Water Authority, and the City of Amarillo. This effort yielded only one project (downsizing or closure of the Helium Plant) that would contribute to the cumulative impacts in the Pantex Plant ROI.

The U.S. Department of the Interior, Bureau of Mines, has been operating a Helium Plant in the Amarillo area since the early 1940s. The facility presently employs approximately 175 workers. On October 9, 1996, the President signed the *Helium Privatization Act of 1996*, directing helium operations to discontinue production and sale of refined helium by no later than 18 months from the date of enactment (i.e., by April 1998).

The employment at the Helium Plant will be reduced to about 30 to 40 workers within 18 months. Reduction in employment and population at the Helium Plant will occur well before assembly and disassembly activities at Pantex Plant result in the downsizing of the Pantex Plant workforce. Nevertheless, the ROI will experience the cumulative effects of downsizing the Pantex Plant and Helium Plant operations.

4.11.6 Potential Mitigation Measures

Since the socioeconomic impacts of the continued operations of Pantex Plant are beneficial to the regional economy, no mitigation measures are needed.

(This Page Intentionally Left Blank)

4.12 INTRASITE TRANSPORTATION

4.12.1 Affected Environment

This section describes the intrasite transportation and handling of hazardous materials at Pantex Plant. Within Pantex Plant Site, approximately 30,000 transfers of nuclear and explosive materials take place each year, many of which are transported between zones, particularly Zones 4, 11, and 12, and between buildings in these zones. These materials include nuclear explosives, nuclear components, tritium, radioisotopic thermoelectric generators (RTGs), depleted uranium, high explosive(s) (HE) components and materials, chemicals, and other hazardous materials. The materials involved in these latter transfers do not involve an external radiation hazard as do weapons, pits, or to a lesser extent canned subassemblies (CSAs).

In addition, low-level waste, low-level mixed waste, and other hazardous wastes are transported onsite for storage, treatment, and disposal. Interzonal transfers between Zones 4, 11, and 12 are carried out on paved roads. Transportation between buildings in Zones 11 and 12 is frequently carried out via enclosed ramps. Typical vehicles and equipment used for transportation on roads include hardened trailers, Safe Secure Tractor Trailers (SSTs), flatbed trailers, vans, trucks, and tow motors. Transfer of materials via ramps is carried out by forklifts and pallet jacks.

The following subsections further describe the intrasite hazardous materials transportation activities at Pantex Plant. Worker doses resulting from transportation activities are also provided in these subsections to determine human health risks analyzed in section 4.14, Human Health.

4.12.1.1 *Onsite Transfers of Radioactive Material*

Onsite transfer of radioactive material is governed by DOE orders and Pantex-specific standards. The Transportation and Staging Department is responsible for transfers of nuclear explosives and nuclear explosive components between zones. The inventory control section of the Production Stores Department is responsible for transfers of nuclear explosives and nuclear explosive components between bays and cells within buildings in Zone 12. The Waste Operations Department is responsible for transportation of radioactive wastes onsite.

Nuclear Explosives

Within zones, nuclear explosives are transported on paved roads and covered walkways (ramps) using an electric forklift. During onsite transfers, nuclear explosives are retained in weapons-specific handling gear (H-gear) containers. Nuclear explosives within H-gear containers produce weapons system-specific external radiation hazards. Certain types of nuclear explosives are transported as a complete unit and are attached to their H-gear; this type of nuclear explosive has a bounding dose rate of 8 millirem per hour at 1 meter. Nuclear warheads, however, are contained within system-specific H-gear packages; this type of nuclear explosive has a bounding dose rate of 50 millirem per hour at the surface of the package. H-gear containers are towed between locations or lifted by the forklift and driven to locations. The speed limit for nuclear explosive transfers within ramps is 8 kilometers (5 miles) per hour.

Nuclear explosives are transported between zones within either hardened trailers or SSTs. SSTs are similar in appearance to commercial tractor trailers but are equipped with unique safety and safeguards features that prevent unauthorized cargo removal and minimize the likelihood of an accidental radioactive material release. Hardened trailers are similar in design to SSTs but have fewer security features than SSTs, which are designed for offsite transport. Table 4.12.1.1–1 shows the number of nuclear explosive and nuclear explosive component interzone transfers for 1993.

Pits

At the point of removal from a weapon, pits are swipe-tested to ensure that there is no surface radioactive contamination. Pits are then placed in AL–R8 containers and sealed with a tamper-indicating device. A pit within a container presents an external radiological hazard that is weapons system-specific. A typical dose rate is 3 millirem per hour at 1 meter for the AL–R8 container. Within Zone 12, pit transfers related to component testing, weapon assembly, or weapon modifications are accomplished with electric forklifts and special nuclear material (SNM) tie-down pallets.

All pits are expected to be staged using Stage Right techniques and equipment by December 1996. Stage Right techniques and equipment would enable the stacking of pit containers with the container's long axis oriented horizontally within a steel pallet. Figure 4.12.1.1–1 is an artist's rendition of a Stage Right magazine. These staging techniques and equipment have simplified pit transfers and reduced the need for entrance into magazines by personnel and their exposure to radiation. Pits being transferred to Zone 4 West for staging are placed at the disassembly point within a Stage Right pallet (either four or six containers per pallet) and, using an electric forklift, loaded into a pallet trailer, which can carry 24 pit containers. The pallet trailer is driven to Zone 4 West and parked at the storage magazine. In the past, hardened trailers and SSTs have been used to move pits between zones, and they could be used in the future.

Prior to the placement of pit pallets into a magazine, a temporary staging ramp with a pallet turner is installed. This ramp ensures that the Stage Right forklift is properly positioned to place the pit pallets within the storage magazine. Once the ramp installation is complete, a standard forklift removes the pallet from the pallet trailer and places it on the pallet turner with the pit containers in the vertical position (Figure 4.12.1.1–2). The pallet turner is then rotated 90 degrees so that the pit containers are in the horizontal position. A shielded Stage Right forklift (shown in Figure 4.12.1.1–1), or an automated guided vehicle, is then driven onto the staging ramp to the pit turner, where the forklift boom lifts the pallet off the turner. The forklift is then driven between the permanently installed guiderails inside the magazine to the desired location. Pits are retrieved from a storage magazine in a similar manner.

Canned Subassemblies

At the point of removal from a weapon, canned subassemblies (CSAs) which may contain

TABLE 4.12.1.1–1.—*1993 Interzone Transfers Of Nuclear Explosives and Nuclear Explosive Components*

	NUCLEAR EXPLOSIVES	PIT COMPONENTS	CSAs
Zone 4 to Zone 12	2,739	98	59

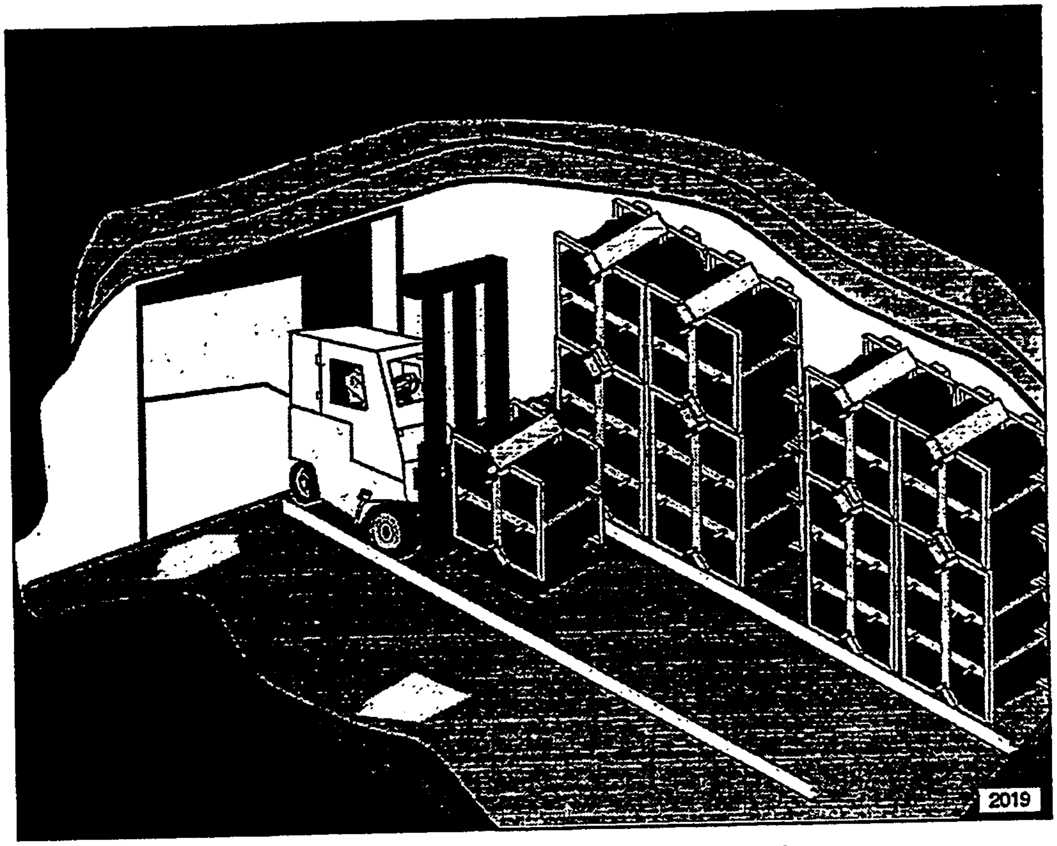

FIGURE 4.12.1.1–1.—*Stage Right Magazine.*

FIGURE 4.12.1.1–2.—*Placement of Stage Right Pallet on Pallet Turner.*

highly enriched uranium, are either packaged in sealed steel containers, fastened onto metal frames, or staged in plywood boxes. A packaged CSA produces a weapons system-specific external radiation hazard. A packaged CSA has a bounding dose rate of 0.2 millirem per hour at 1 meter. These components are loaded onto SNM tie-down pallets and transferred by electric forklift to an approved storage facility to await transfer to either the Y–12 Plant (at Oak Ridge Reservation) for final disassembly or Zone 4 for temporary staging. CSA transfers related to component testing, weapon assembly, or weapon modifications within Zone 12 are accomplished using either SNM tie-down pallets or special pallets and electric forklifts.

CSAs ready for transfer to Zone 4 are moved by electric forklift to a loading dock within Zone 12, where they are loaded into a hardened trailer or SST, tied down within the trailer, and driven to a storage magazine within Zone 4 West. Upon arrival at the magazine, CSAs are placed on a pallet and driven into the magazine using an electric forklift. CSAs are placed on the floor using the forklift, a manual hand truck, or a small hydraulic truck. CSAs are retrieved from a storage magazine in the same manner.

Radioisotopic Thermoelectric Generators

At the point of removal from a weapon, RTGs are placed in an approved container. The containers are then transported to an approved storage facility to await transfer to Los Alamos National Laboratory. RTGs within containers do not present a radiological hazard. RTG transfers related to component testing, weapon assembly, or weapon modifications within Zone 12 are accomplished with electric forklifts or carts using SNM tie-down pallets or wire baskets.

Tritium Reservoirs

At the point of removal from a weapon, tritium reservoirs are placed in either Kennedy Kits, metal suitcases, or H1616 containers. The reservoirs within the container do not present a radiological hazard. The container is transported to the Tritium Staging Facility to await transfer to the Savannah River Site. Some reservoirs are processed through a separate facility prior to delivery to the Tritium Staging Facility. Reservoir transfers occur in a wire basket secured to either a forklift or the bed of an electric cart. Tritium reservoir transfers related to component testing, weapon assembly, limited-life component replacements, or weapon modifications within Zone 12 are accomplished in a similar manner.

Low-Level and Mixed Radioactive Wastes

Both low-level and mixed radioactive wastes are transported from the generation point to the central collection area in Building 12–42. Upon approval for shipment to Building 12–42, the waste is loaded onto a flatbed or stakebed truck, secured with tie-downs, and relocated to the storage facility truck dock. At the truck dock, the waste package is checked for damage and proper paperwork and added to the facility inventory. From Building 12–42, radioactive wastes are transferred to an onsite storage facility using a flatbed or stakebed truck. These storage facilities include Building 11–9N, Building 11–7N Pad, Zone 4 East Magazines 50 and 56, and 25 Conex Boxes.

Transportation Management

Movements of nuclear explosives and nuclear components are coordinated with and tracked by the SNM control center via a secure telephone system. A custodian is assigned to oversee transfer operations. For Zone 12 transfers, a walker-spotter walks in front and directs all traffic, including foot traffic, to stop until the vehicle safely passes. Signs and corridor mirrors help alert drivers to any approaching hazards during transfers. The amount of combustible material allowed in ramps used for nuclear material transfers is strictly limited. The speed limit for vehicles carrying nuclear materials within and between buildings in Zone 12 is 8 kilometers (5 miles) per hour. The speed limit for SNM transfers between Zones 4 and 12 is 32 kilometers (20 miles) per hour. All personnel involved in these transfers are required to wear dosimeters. All Transportation and Staging Department personnel handling pit containers are required to wear lead aprons and lead-lined gloves.

4.12.1.2 *Zone 4 West Nuclear Material Staging Operations*

The Transportation and Staging Department is responsible for Zone 4 operations involving nuclear explosives and nuclear explosive components. The bulk of the activity associated with the Zone 4 West staging magazines involves material movements to and from the production areas in Zone 12, as discussed in section 4.12.1.1. Other activities that take place in Zone 4 West include:

- The performance of inventories and inspections of the SNM contents of the magazines.
- The documentation of the arrival or departure of each SNM item with the SNM control room.
- The unloading of weapons and nuclear components from arriving SSTs.
- The loading of weapons and nuclear components into departing SSTs.
- The loading of CSAs into departing SSTs.

Arriving weapons, Joint Test Assemblies, and Test Beds are driven to Zone 4 West, where they are unloaded in front of a storage magazine. Weapons contained in SSTs are unloaded as follows:

- A flatbed trailer with an electric forklift on the bed is backed up to the open SST trailer—the flatbed trailer is a 12-meter (40-foot) commercial trailer with the same bed height as the SST and side-boards to prevent objects on the bed from falling off.
- The tie-downs securing the nuclear explosive within the SST are removed.
- The forklift on the flatbed trailer drives into the SST, removes the H-gear containing the weapon, and places it on the flatbed trailer.
- An electric forklift on the ground removes the H-gear containing the weapon from the flatbed trailer and drives it into the magazine for storage.

The unloading of nuclear explosives using H-gear containers with rollers or casters is an exception to the above description. In this case, the H-gear containing the weapon is rolled to the edge of the SST, where it is placed on the ground by an electric forklift and rolled into the magazine. In addition, certain weapon systems are too heavy to be unloaded by either of the above methods. In such cases, a loading dock within Zone 4 is used.

DOE requires safeguards and security programs at facilities handling SNM. At Pantex Plant, this program requires the periodic inventory of magazines containing nuclear explosives and nuclear explosive components. The frequency of inventory for pit staging magazines is dictated by the staging class of the magazine. Pit staging magazines are divided into two classes, normal and exempt magazines. Normal staging magazines contain reserve components for existing weapon systems. For these magazines the maximum time between inventories would be 12 months and 1 week. Exempt magazines contain components that are not expected to be reused. For these magazines the maximum time between inventories would be 21 months and 1 week.

Inventories in the magazines when pit containers are placed in Stage Right configuration are performed with automatic bar code readers and video cameras attached to an inventory pallet. This pallet is moved inside the magazine by either the shielded Stage Right forklift or an automated guided vehicle. As the pallet is moved, the bar code reader and video camera verify the presence of each pit container within the magazine and the integrity of both the container and the tamper-indicating device. Only the driver using the shielded forklift is required to be in the magazine during the inventory. The use of an automated guided vehicle is currently being implemented. No personnel are required in the magazine with the automated guided vehicle. No pit movement is required for the inventory. All other inventories of magazines not in Stage Right configuration (weapons, weapons components, etc.) are inventoried by hand.

Random pit evaluations are required to meet component reliability requirements. Less than 30 pits (approximately) are selected each year for these evaluation activities. The pallets containing the pits chosen for evaluation are removed from the magazine either manually or using Stage Right techniques and equipment. These pits are transferred to Zone 12 for evaluation activities.

The shielded cab on the Stage Right forklift protects the driver from ionizing radiation while inside storage magazines. Stage Right forklifts are equipped with a special boom that prevents penetration of plutonium containers during handling operations. This boom is equipped with a limit switch that stops the forklift if the boom accidentally touches a pit container. Stage Right forklifts are operated within guide rails that prevent movement of the forklift outside a clearly defined path. Zone 4 personnel involved in pit movements are required to wear lead aprons.

4.12.1.3 *Radiological Exposures from Onsite Radioactive Material Shipments and Zone 4 West Nuclear Material Staging Activities*

Radiological exposures incurred by workers in the Transportation and Staging Department during the performance of both transportation and staging activities for the years 1993 through 1995 are provided in Table 4.12.1.3–1. Onsite transfers of SNM within buildings and between bays and cells are performed by the production technicians or Production Stores personnel. Exposures related to these activities are considered as part of production operations, not transportation. The doses incurred by workers in the Waste Operations Department are also provided in Table 4.12.1.3–1. These doses were incurred in the performance of all activities involving radioactive waste, not just transportation.

TABLE 4.12.1.3–1.—*Dosimetry Records for Transportation Staging and Waste Operations Department*

YEAR	CUMULATIVE DOSE (PERSON-REM)		NUMBER OF PERSONS MONITORED		MAXIMUM INDIVIDUAL DOSE (MREM)	
	Transportation and Staging Department	Waste Operations Department	Transportation and Staging Department	Waste Operations Department	Transportation and Staging Department	Waste Operations Department
1993	3.338	0.00	45	48	284	0.00
1994	2.150	1×10^{-2}	49	62	200	0.10
1995	3.642	2×10^{-2}	46	56	320	21.00

Source: PC 1995k:1

4.12.1.4 *Onsite Transfers of High Explosive Material*

Pantex Plant operations involve the onsite movement of HE. These explosives include Department of Transportation (DOT) Hazard Class/Division 1.1, DOT Hazard Class/Division 1.3, and DOT Hazard Class/Division 1.4. DOT Hazard Class/Division 1.1 explosives include, but are not limited to, RDX, HMX, and TNT.

These explosives are used as the primary HE component in nuclear explosives. DOT Hazard Class/Division 1.3 explosives include TATB. This explosive is also used as a primary HE component in nuclear explosives. TATB is considered an insensitive high explosive, because it is extremely stable and resistant to heat, shock, and impact. DOT Hazard Class/ Division 1.4 includes detonators, ignitors, timers, and switches.

HE is transferred at Pantex Plant Site to support assembly and disassembly operations. The HE is placed in an approved container prior to any transfer being performed. All transfers are conducted using Pantex Plant approved procedures. Routes for HE transport are restricted to paved roads. Vehicles used for the transport of HE must be equipped with a flashing amber light, which is operated at all times when explosives are being transported. The detonation of HE within an onsite trailer is considered an extremely unlikely event (10^{-4} to 10^{-6} per year) (Pantex 1994:3-71). In addition, the consequences of an HE detonation would not result in hazardous offsite consequences (Pantex 1993:3-15).

4.12.2 Impacts of Proposed Action

4.12.2.1 *Impacts of Continued Operations*

Under the Proposed Action, the following onsite transportation and staging activities will continue at Pantex Plant:

- Dismantlement activities with accompanying onsite hazardous material transfers (e.g., weapons, pits).
- Stockpile management activities with accompanying onsite hazardous material transfers (e.g., weapons, tritium reservoirs).
- Zone 4 staging of weapons, CSAs, and RTGs with accompanying inspection, inventory, and surveillance activities.
- Onsite transportation activities for other materials (e.g., wastes, chemicals).
- Storage of up to 20,000 pits with accompanying inspection, inventory, and surveillance activities at Zone 4, and pit transfers between Zone 12 and Zone 4.
- The transportation associated with the repackaging of pits from AL–R8 containers into other DOT-criteria containers (i.e., onsite pit transfers of up to 20,000 pits between Zone 4 and Zone 12).

Onsite Transfers of Radioactive Material

Nuclear explosives from both dismantlement and stockpile management activities would continue to be transported and handled within the Pantex Plant boundary. Transfers would be performed as described in sections 4.12.1 and 4.16.1 (Intersite Transportation of Nuclear and Hazardous Materials). No public exposure to radiation is expected from onsite, incident-free transport of nuclear explosives.

Pit components from both dismantlement and stockpile management activities would continue to be transported and handled within the Pantex Plant boundary. These transfers are described in sections 4.12.1 and 4.16.1. In addition to dismantlement and stockpile management activities, pit transfers would occur as part of the pit repackaging effort. The pit repackaging effort would require the transfer of pits in AL–R8 containers from Zone 4 West storage magazines to Zone 12, where they would be repackaged into DOT-criteria containers. The DOT-criteria containers would be returned to

Zone 4 West for interim storage. All container transfers would be performed using Stage Right techniques and equipment. Current schedules indicate an average repackage rate of approximately 1,000 pits per year starting in 1997. No public exposure to radiation is expected from onsite, incident-free transport of pits.

CSAs from both dismantlement and stockpile management activities would continue to be transported and handled within the Pantex Plant boundary. No public exposure to radiation is expected from onsite, incident-free movements of CSAs.

RTGs from both dismantlement and stockpile management activities would continue to be transported and handled within the Pantex Plant boundary. The twin pack currently used for onsite transport and handling of RTGs is being phased out in favor of a newer mode of the currently approved DOT–6M, Type B package for all onsite transfers. Onsite transfers of RTGs do not have the potential for significant environmental impacts because an RTG within a transfer container does not present an external radiological hazard and RTGs are constructed in such a way that an accidental release of plutonium is not reasonably foreseeable in the onsite transportation environment. RTGs are able to withstand an exposure of 1,000 °C (1,832 °F) for 1 hour or an impact of 571 kilometers (355 miles) per hour on a steel surface with no plutonium release (GE 1975).

Tritium reservoirs from both dismantlement and stockpile management activities would continue to be transported and handled within Pantex Plant boundary. No worker or public exposure to radiation occurs from onsite incident-free movements of tritium reservoirs.

Onsite transfers of depleted uranium (DU) would continue, but transfers of DU do not result in significant environmental impacts. DU does not present an external radiological hazard in the transportation environment. The radiological hazard of uranium depends upon its degree of enrichment. With increased enrichment, there is a corresponding increase in the radiological hazard from the uranium (DOE 1988).

DOE is using the safety analysis process as defined in DOE Order 5480.23 to identify and control threats to the safety of onsite shipments of radioactive material. Safety issues related to onsite transportation activities are currently evaluated in the Onsite Transportation Safety Risk Assessment (Pantex 1994). However, DOE is planning to issue a complete Safety Analysis Report for onsite transportation activities.

The bounding onsite transportation accident (low probability/high consequence), in terms of offsite consequences, would be an accident involving the detonation of HE contained within weapons during transit. An HE detonation within a weapon would lead to the dispersal of plutonium and other radioactive material into the environment. (Weapons are designed so that in the event of an accidental HE detonation, there would be no significant nuclear reactions.) An accidental HE detonation is only possible for those weapon systems containing conventional HE. The insensitive HE contained in some weapon systems does not have the potential to accidentally detonate. It has been determined that the following scenarios may lead to an accidental HE detonation within an in-transit weapon: a long-lasting fire supplied with fuel by a crashed aircraft; or a mechanical impact to a weapon from a tornado, a wind-generated missile, a direct hit by a crashing aircraft, or a bullet striking the HE.

Because of speed limits and protective handling gear, no onsite vehicle accident can create the impact conditions necessary for an HE detonation within a nuclear explosive. In addition, no onsite nuclear explosive movements are allowed in severe weather that may threaten the safety of the transport (e.g., tornado, severe wind). Nuclear explosives that are sensitive to bullet impacts (those containing conventional HE) are protected by a bullet resistant covering when not inside a hardened trailer or SST.

The likelihood of an aircraft crashing into a critical area at Pantex Plant is extremely remote. The probability of this event occurring is evaluated in section 4.15, Aircraft Accidents. The likelihood of an aircraft crashing into a critical area at Pantex Plant and affecting (by fire or direct hit) an intransit weapon is considered not reasonably foreseeable (frequency of occurrence is less than 10^{-6} per year) and at least several orders of magnitude less likely than an aircraft impact to a Pantex Plant facility (because of the limited target area of the trailer compared with facilities and the limited time that weapons are contained in a trailer).

In terms of risk (the product of probability and consequence), the potential environmental impacts from an airplane crash into a Zone 4 weapons magazine, as discussed in section 4.14 (Human Health), are much more significant than those associated with a crash into a hardened trailer. However, if this event were to occur, it would have the potential to cause environmental impacts. It is estimated that an HE detonation of numerous nuclear weapons within a hardened trailer would lead to a cumulative population dose of 4,820 person-rem with a corresponding public health risk of less than 2×10^{-7} excess cancer fatalities per year.

Other potential onsite transportation accidents are much more likely to occur but have less potential for environmental impacts. A characteristic high probability/low consequence accident involving radioactive material is a forklift puncture causing a release of plutonium from a pit container in the onsite transportation environment. This event is discussed in section 4.14, Human Health.

Zone 4 West Staging Activities

Under the Proposed Action, as many as 20,000 pits could be stored in Zone 4. Approximately 60 storage magazines would be required to store that number of pits. This total includes 18 Modified Richmond magazines and 42 Steel Arch Construction magazines. Pit magazine activities would include inspections, inventory, surveillance pit removals, and repackaging pit removals. All of these activities would be performed using the Stage Right equipment and techniques.

In addition to the surveillance pit removals, DOE plans to sample a number of sealed storage containers from Zone 4 magazines. The purpose of this evaluation is to verify the integrity of the storage containers. It is expected that 20 to 22 containers would be removed from the magazines annually and taken to Zone 12 for evaluation. The containers selected for evaluation will be removed from a storage magazine and transported to Zone 12 using Stage Right equipment and techniques.

Other magazine activities that may occur within the timeframe evaluated in this EIS include the restacking of pits in a limited number of magazines to comply with design laboratory pit temperature limits and pit movements and instrumentation placements in a limited number of magazines to facilitate third-party verifications. In addition, to allow for operational flexibility, DOE may choose to store a small number of pits in a non-Stage Right configuration. All storage magazine operations will be performed in a manner that minimizes worker radiological exposure.

Radiological Impacts From Onsite Transfers of Radioactive Material and Zone 4 West Staging Activities

Because future stockpile management requirements cannot be accurately predicted, this EIS examines impacts associated with operations on 2,000, 1,000, and 500 weapons per year (and associated interzone transfers) in

TABLE 4.12.2.1–1.—*Estimated Transportation and Staging Worker Exposures for the Proposed Action (Includes Transfers Associated with Pit Repackaging for 20,000 Pits)*

NUMBER OF WEAPONS LEVEL	10-YEAR WORKER EXPOSURE (PERSON-REM)	YEARLY AVERAGE EXPOSURE (PERSON-REM)	EXCESS CANCER FATALITIES FOR 10-YEAR EXPOSURE
2,000	61	6	0.024
1,000	48	5	0.019
500	41	4	0.016

addition to the pit movements described above. Table 4.12.2.1–1 presents the estimated exposures to the 50 people (based on current operation levels) who are directly involved with transportation and staging operations. Workers who are not directly involved are not allowed in the vicinity of material transfer operations. These exposures were estimated using historical dosimetry information from the Transportation and Staging Department. No public exposure to radiation is expected from non-incident onsite material transfers and Zone 4 staging operations (Pantex 1996c; Battelle 1994).

Excess cancer fatality risks were calculated using a dose-to-risk conversion factor of 4×10^{-4} excess cancer fatalities per person-rem (NAP 1990). Assuming an operations on 2,000 weapons activity level and assuming that the same 50 people remain involved in material handling for the 10 years under evaluation in this EIS, there would be an additional 0.024 excess cancer fatalities in this group due to this exposure. The probability of cancer fatalities from all causes in the general population is estimated at approximately 20 percent, which implies that 10 of 50 workers who are not exposed to radioactivity from Pantex Plant will develop a fatal cancer anyway.

Assuming that a maximum exposed worker receives less than 300 millirem per year (which is consistent with historical doses [see Table 4.12.1.3–1]) over the timeframe evaluated in this EIS, the incremental increase in lifetime fatal cancer probability from the projected exposure period of 10 years is approximately 1.2×10^{-3} (1 chance in 833). The estimated probability of an average member of the public developing a fatal cancer from causes not related to this radiation exposure is 0.2 (1 chance in 5).

4.12.3 Impacts of No Action Alternative

Under the No Action Alternative, DOE will perform the following onsite transportation and staging activities at Pantex Plant:

- Dismantlement activities with accompanying onsite hazardous material transfers until the 12,000 pit storage limit is reached (e.g., weapons, pits).
- Stockpile management activities with accompanying onsite hazardous material transfers (e.g., weapons, tritium reservoirs).
- The transportation associated with the repackaging of pits from AL–R8 containers into other DOT-criteria containers (i.e., onsite pit transfers of up to 12,000 pits between Zone 4 and Zone 12).
- Storage of 12,000 pits with accompanying inspection, inventory, and surveillance activities at Zone 4.
- Continuation of Zone 4 staging of weapons, CSAs, and RTGs with accompany-

TABLE 4.12.3–1.—*Estimated Transportation and Staging Worker Exposures for the No Action Alternative (Includes Transfers Associated with Pit Repackaging for 12,000 Pits)*

NUMBER OF WEAPONS LEVEL	10-YEAR WORKER EXPOSURE (PERSON-REM)	YEARLY AVERAGE EXPOSURE (PERSON-REM)	EXCESS CANCER FATALITIES FOR 10-YEAR EXPOSURE
2,000	44	4	0.018
1,000	31	3	0.012
500	25	2	0.01

ing inspection, inventory, and surveillance activities.

- Continuation of other onsite transportation activities (e.g., waste, chemicals).

Table 4.12.3–1 presents the estimated exposures to the 50 people who are in transportation and staging activities. No public exposure to radiation occurs from non-incident onsite material transfers. All other impacts would be similar to those described for the Proposed Action. The difference between the Proposed Action (Table 4.12.2.1–1) and the No Action Alternative (Table 4.12.3–1) is due to a reduction in the number of pits being repackaged and the number of weapons being dismantled.

4.12.4 Impacts of Pit Storage Relocation Alternative

4.12.4.1 *Impacts of Relocating 20,000 Pits*

Under this option, DOE would conduct the following onsite transportation and staging activities at Pantex Plant:

- Dismantlement activities with accompanying onsite hazardous material transfers (e.g., weapons, pits).
- Stockpile management activities with accompanying onsite hazardous material transfers (e.g., weapons, tritium reservoirs).
- Zone 4 staging of weapons, CSAs, and RTGs with accompanying inspection, inventory, and surveillance activities.
- Onsite pit transfers (of up to 20,000 pits) between Zone 4 and Zone 12 associated with repackaging of pits from AL–R8 containers into other DOT-criteria containers.
- Movement of pits to prepare for offsite shipment of up to 20,000 pits.
- Continuation of other onsite transportation activities (e.g., wastes, chemicals).

IMPACTS FROM PIT STORAGE RELOCATION ALTERNATIVES

- *Because of the addition of a large number of SST Loading Operations, Transportation and Staging worker doses will increase for the Pit Storage Relocation Alternatives.*
- *At a 2,000 weapons level, the Transportation and Staging Department worker dose is estimated to be 61 person-rem for 10 years of operation.*
- *At a 2,000 weapons level, and with the relocation of 20,000 pits, the Transportation and Staging Department worker dose is estimated to be 344 person-rem for 10 years of operation.*

Onsite movements of nuclear explosives, non-pit nuclear explosive components (excluding pits), and other hazardous material would be identical to those occurring under the Proposed Action including the repackaging of pits. Movements of pits would differ from the Proposed Action in that pits stored in Zone 4 would be shipped offsite. Impacts related to the offsite shipments of pits, including loading of pits into offsite shipment vehicles at Pantex Plant, are described below.

The loading and securing of pit containers within an SST will result in additional radiological exposures to onsite transportation workers. The over-the-road shipment of pits requires that the pit containers be restrained within the SST. Because of the complexity of the tiedown within a trailer, 10 to 15 minutes are required per container to perform the placement and tie-down operation. Transportation workers must be in proximity of the pit container during the placement and tie-down operation. Additionally, since an offsite pit shipment will contain more than one pit container, transportation workers will be in the proximity of numerous pit containers while operating within a trailer.

Because of the unavailability of historical dosimetry information specifically related to pit loading and unloading activities, conservative dose estimates have been made for this operation. Using estimates for time spent and position within a trailer during placement and tie-down operations and a dose rate of 1.5 millirem per hour at 1 meter from a pit package, the loading of pits into SSTs will result in an additional exposure of less than 27 person-rem per year (for 2,000 pits per year) or less than 270 person rem for 20,000 pits. Furthermore, the transfer of pits from magazines to SSTs would result in an additional 13 person-rem for the relocation of 20,000 pits. Further details of the assumptions used in these estimates are available in section F.7.

Onsite material movements for the 2,000 weapons level and the loading of 20,000 pits into SSTs is estimated to result in a 10-year cumulative dose of 344 person-rem (270 person-rem plus 13 person-rem for pit transfer loading activities plus 61 person-rem for normal operations) to transportation and staging workers. Using a dose-to-risk conversion factor of 4×10^{-4} excess cancer fatalities per person-rem and, assuming that the same 50 people remain involved in material handling and pit loading operations, there would be an additional 0.14 excess cancer fatalities in this group due to this exposure.

4.12.4.2 *Impacts of Relocating 8,000 Pits*

Under this option, DOE would relocate only 8,000 pits to other site(s). Pantex Plant would continue to store up to 12,000 pits onsite. All other activities would remain as described under the Proposed Action including the repackaging of pits.

Onsite material movements for the 2,000 weapons level and the loading of 8,000 pits into SSTs is estimated to result in a 10-year cumulative dose of 174 person-rem (113 person-rem for pit transfer and loading activities plus 61 person-rem for normal operations) to transportation and staging workers. Using a dose-to-risk conversion factor of 4×10^{-4} excess cancer fatalities per person-rem and assuming that the same 50 people remain involved in material handling and pit loading operations, there would be an additional 0.07 excess cancer fatalities in this group due to this exposure.

4.12.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant

EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

Cumulative impacts of radiological exposure of workers and the public in the Pantex Plant vicinity are described in section 4.14, Human Health.

4.12.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

Intrasite transportation is not addressed in detail in the WM PEIS, but is included in parts of the intersite transportation analysis. Future project-specific NEPA reviews would be expected to assess this issue, if one or more waste disposal facilities are to be constructed at Pantex Plant as a result of the WM PEIS.

4.12.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, impacts from intrasite transportation activities are expected to be less than current impacts. Under the downsizing alternative, the facilities would be consolidated. This could further reduce the amount of intrasite transportation impacts. Under the relocation alternative, intrasite transportation associated with assembly and disassembly operations and HE fabrication would cease.

4.12.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

As discussed in sections 1.4 and 1.7.3 of this volume, the final S&D PEIS will include an alternative under which plutonium pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. Impacts related to intrasite transportation and additional pit handling will be described in appendix Q of the S&D PEIS. Adding RFETS pits to pits from Pantex Plant dismantlement operations would not exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Furthermore, RFETS pits have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant.

Placing RFETS pits in Zone 4 storage would, however, require repackaging RFETS pits from FL-type containers into AL-R8 containers in Zone 12 prior to placement into Stage Right configuration. Additionally, once repackaged, the pits would be transferred from Zone 12 to Zone 4. The total exposure to workers from both the transfer of pit containers and the repackaging of pits arriving from RFETS would result in less than 10^{-2} additional latent cancer fatalities for involved workers, as reported in appendix Q of the S&D PEIS. No exposure to the public is expected from these operations.

4.12.6 Potential Mitigation Measures

Onsite shipments of radioactive material have been performed for many years at Pantex Plant without a significant accident involving radioactive material. Radiological exposures incurred from future onsite transportation activities would continue to be controlled and minimized by Pantex Plant procedures, administrative controls, and an active As Low As Reasonably Achievable program that promotes work practices that minimize worker exposures. The Pantex Plant *Radiological Control Manual*, and ultimately, the Federal regulations for occupational radiation protection dictate the magnitude of radiological exposure to workers and safe radiological work practices (Pantex 1995d; 10 CFR 835).

4.13 WASTE MANAGEMENT

4.13.1 Affected Environment

This section covers the ongoing waste management practices relating to generation, storage, treatment, and disposal of waste at Pantex Plant. It includes an overview of the regulatory framework and provides a summary of historic, current, and projected waste generation and waste management practices, including the quantities of wastes generated and managed under specified activities. Waste at Pantex Plant is primarily generated from ongoing assembly and dismantlement operations of nuclear weapons and high explosive(s) (HE) production. Waste is also generated from support operations at Pantex Plant, such as medical services, vehicle maintenance activities, general office work, construction activities, environmental monitoring, laboratory activities, and environmental restoration (ER) activities.

4.13.1.1 *Existing Waste Management Practices*

Regulatory Framework

The Pantex Plant waste management program operates under a number of Federal and State regulations and permits obtained under these regulations that are primarily under the authority of the Environmental Protection Agency (EPA) and TNRCC. Details on these laws and regulations are provided in chapter 6.0, Environmental Compliance Requirements for Implementing the Proposed Action and the Alternatives.

Regulatory agencies charged with enforcing regulations and statutes use the permit process as a primary tool. Table 4.13.1.1–1 lists Pantex Plant permits, the registration numbers, the issuing agency, the effective date, and the expiration date for each permit.

Pantex Plant is a large-quantity *Resource Conservation and Recovery Act* (RCRA) hazardous waste generator, an industrial solid waste generator, and a nonhazardous nonradioactive waste disposal facility. Pantex Plant operates under a RCRA Part B Permit as a hazardous waste treatment and storage facility (TNRCC 1996). Table 4.13.1.1–2 presents current waste management facilities.

The *Federal Facility Compliance Act of 1992* (FFCA) includes provisions for mixed waste compliance with RCRA and required DOE to have approved, site-specific low-level mixed waste treatment plans in place by October 1995. A draft Proposed Site Treatment Plan was submitted to TNRCC in March 1995 for its approval. The Final Site Treatment Plan–Compliance Plan was approved by TNRCC in September 1995 and an Agreed Order was issued October 2, 1995 (DOE 1995x).

The purposes of this Agreed Order and approved Site Treatment Plan-Compliance Plan include: fulfilling the requirements of FFCA; establishing regulatory milestones requiring DOE to develop treatment capacities and technologies and treat, ship to commercial treatment facilities, or otherwise meet RCRA land disposal restrictions (LDR) for all current inventory and projected inventories of all covered LDR mixed wastes; and allowing storage of current and projected LDR mixed wastes at Pantex Plant during the implementation and term of this Compliance Plan and Agreed Order (Pantex 1996f).

In the March 1996 version of the Pantex Plant EIS, the proposed construction of the Hazardous Waste Treatment and Processing Facility (HWTPF) was considered necessary for enhanced efficiency and safety and meeting regulatory requirements established in the Agreed Order. With offsite disposal shipments of mixed waste in 1994 and two shipments in 1996, as noted in section 4.13.2.3, and changes contained in the August 1996 FFCA

Compliance Plan Annual Update document, construction of the HWTPF is no longer considered a regulatory requirement. DOE's purpose and need for enhanced efficiency and safety of its current mixed waste, low-level radioactive waste and hazardous waste operations remain and are discussed in greater detail in appendix H. Without the HWTPF, waste treatment and processing capabilities are greatly reduced.

In terms of overall operational waste management, the RCRA Part B Permit is the most significant regulatory instrument. The State of Texas and EPA jointly issued Pantex Plant a Hazardous Waste Permit in April 1991 to address the processing and storage of hazardous waste. The permit was modified in January 1993 to allow treatment in tanks and containers in Building 11–9 and 11–15A. In July 1994, the permit was modified to increase permitted storage capacity for hazardous waste in Buildings 11–9N, 11–7A, and 11–7B by 780,700 liters (206,260 gallons) (TNRCC 1995a:9; PC 1995).

Pantex Plant requested a Class 3 modification to the Hazardous Waste Permit issued in April 1991 by TNRCC and EPA. The initial request for modification, made in November 1991 and revised in October 1992, asked for the addition of 17 RCRA units at the Burning Ground, which were excluded from the April 1991 permit but continued to operate under RCRA Interim Status, and 10 additional storage units. On February 16, 1996, the Class 3 permit modification was approved by TNRCC. As a result, permitted storage increased (5 Conexes and 3 magazines), 5 Burning Ground units (3 flash pits, 2 cages) were closed, and 15 Burning Ground units received permit status (DOE 1994b:2-6, 2-7; TNRCC 1996).

Air emissions from the ongoing Burning Ground activities are subject to general air quality conditions established in the Hazardous Waste Permit. The permit states that this facility shall be operated in accordance with and subject to the applicable provisions of the *Texas Solid Waste Disposal Act* and the *Texas Clean Air Act* as amended, Chapter 382 of the Texas Health and Safety Code, and all applicable rules, regulations, and orders of the TNRCC. The resulting ash shall be managed so as to not cause or contribute to a condition of "air pollution" as defined in subchapter 382.003 of the Texas Health and Safety Code (TNRCC 1996:20-22).

In 1984, RCRA was amended by the Hazardous and Solid Waste Amendments, which imposed waste minimization requirements on hazardous waste generators and treatment, storage, and disposal facilities. To comply with the waste minimization requirements, Pantex Plant established a Pollution Prevention and Waste Minimization program. Volume II, appendix G, Pollution Prevention and Waste Minimization, provides detailed information regarding pollution prevention and waste minimization at Pantex Plant. This program has been distinguished with the White House Closing the Circle Award and the Vice President's Hammer Award in 1996 (MH 1996b).

Pantex Plant is also active in the Clean Texas 2000 pollution prevention program. The organizations involved in this program commit to reduce chemical releases and hazardous waste generation by 50 percent by the year 2000, using the 1987 Toxic Release Inventory Report as a baseline. Current and planned studies examining alternative treatment methods to open burning-open detonation of high explosives are discussed in volume II, appendix G.

Waste Management Practices

The major categories of wastes generated at Pantex Plant are described below. The discussion covers waste characteristics, activities, locations, quantities, and general waste management practices. Activities at Pantex Plant generate wastes that are categorized as low-level radioactive waste (LLW), low-level mixed waste (LLMW), hazardous waste (HW), and nonhazardous nonradioactive waste (NHW). NHW has three categories—Class 1, 2, and 3 (see Table 4.13.1.1–3). Other wastes include sanitary and industrial wastewater, stormwater, polychlorinated biphenyls (PCBs), asbestos, and medical wastes.

Transuranic (TRU) and mixed TRU wastes are not normally generated, and no high-level radioactive wastes are currently generated at Pantex Plant. Three drums of TRU waste were generated in 1993 as a result of an incident during weapon dismantlement. The TRU waste is stored at Pantex Plant in an appropriately monitored facility awaiting approval of transfer to an offsite management facility (Pantex 1996:14.5). Pantex Plant uses trained personnel and approved program procedures to control waste from the point of generation through

TABLE 4.13.1.1–3.—*Nonhazardous (Nonradioactive) Waste Classification*

WASTE CLASS	REGULATION	CRITERIA	EXAMPLES	ONSITE S/T/D	ONSITE S/T/D
Class 1	30 TAC 335.505	Is not hazardous waste. Contains constituents in excess of levels specified in 30 TAC 335.506.	Empty containers, rags, wipes, protective clothing, wastewater, and soils.	S/T/D[1]	T/D
Class 2	30 TAC 335.506	Is not hazardous waste. Contains constituents in excess of levels specified in 30 TAC 335.506. Is not a Class 3 waste.	Paper, plastics, plant wastewater, and soils refuse.	S/T/D[1 2]	T/D
Class 3	30 TAC 335.507	Is not hazardous waste. Is inert, essentially insoluble, and poses no threat to human health and/or the environment.	Rock, brick, glass, dirt, and certain plastics and rubber.	D[2]	None

S/T/D - Storage/Treatment/Disposal
[1]Onsite treatment and disposal is limited to wastewater treatment and disposal.
[2]Onsite disposal is in a Construction Debris Landfill located in Zone 10.

storage, treatment, and disposal (TNRCC 1996).

4.13.1.2 *Waste Categories and Operations*

Table 4.13.1.2–1 shows the annual waste generation from 1992 through 1995 for LLW, LLMW, HW, and NHW. Table 4.13.1.2–2 shows ER program projected annual waste generation from 1997 to 2000 for LLW, LLMW, HW, and NHW. Table 4.13.1.2–3 shows projected waste generation from 1997 to 2007. As of September 1995, waste in storage included 474 m^3 (616 yd^3) of LLW, 147 m^3 (191 yd^3) of LLMW, 153 m^3 (199 yd^3) of HW, and 311 m^3 (404 yd^3) of NHW. Each of these waste types is discussed below. Additionally, Chapter 14 of the Pantex Plant Environmental Information Document provides detailed waste stream and waste management facility information.

Low-Level Radioactive Waste

LLW contains radioactivity not classified as high-level waste, TRU waste, spent nuclear fuel, or special by-product material as defined by DOE Order 5820.2A (DOE Order 5820.2A:Attachment 2, page 3). Pantex Plant's LLW wastestreams include materials contaminated during weapons assembly, disassembly, maintenance, or quality assurance testing. Other wastestreams include protective clothing, filters, wipes, plastic, foam, rubber, desiccant, and debris (PC 1995f).

LLW is stored onsite and shipped to the Nevada Test Site (NTS) for disposition. Pantex Plant must accumulate and store LLW in a manner that does not create a nuisance or endanger the public health or environment. Pantex Plant's LLW operating storage capacity is of at least 2,380 containers (Pantex 1996:14.8). To ensure that LLW does not pose a danger to the public or the environment, Pantex Plant manages LLW in accordance with the NTS Defense Waste

TABLE 4.13.1.2–1.—*Industrial Operation-Related Waste Volumes (in cubic meters [cubic yards]) 1992–1995*[1]

WASTE TYPE	1992	1993	1994	1995
LLW[3]	266 (346)	287 (373)	232 (302)	187 (241)
LLMW	51 (67)	38 (50)	25 (33)	29 (38)

TABLE 4.13.1.2–3.—*Annual Total Industry Related Waste Projections Excluding Environmental Restoration Waste at Pantex Plant, 1997–2007 (in cubic meters [cubic yards])*[1 2]

WASTE TYPE	WEAPONS LEVEL PER YEAR		
	2,000 WEAPONS/YEAR (3,800 EMPLOYEES)	1,000 WEAPONS/YEAR (3,000 EMPLOYEES)	500 WEAPONS/YEAR (2,400 EMPLOYEES)
LLW	249 (326)	131.5 (172)	71.6 (93.7)
LLMW	183.2 (239.6)	118.3 (154.7)	81.0 (105.9)
HW	191.6 (250.5)	107.9 (141)	63.8 (83.5)
NHW (Class1)	741.6 (970)	524.6 (686.2)	388.2 (507.8)
NHW (Class 2)	574 (751)	453 (593)	363 (475)
Total	1,939.4 (2239.1)	1,335.3 (1,746.9)	967.6 (1,265.9)

[1]Table excludes PCB, asbestos, and medical. Environmental restoration and wastewater discharge to playas and the wastewater treatment facility are covered in Table 4.13.1.2–2 and Table 4.3.2.1–1. NHW (Class 3) is not reported since the waste is inert, essentially insoluble, and poses no threat to human health or the environment (Pantex 1996:14.5). Transuranic wastes are not normally generated. No high-level radioactive wastes are currently generated at Pantex Plant.
[2]Table includes a 10 percent margin to provide conservative estimates.
Source: Pantex 1996:14.5

Acceptance Criteria Certification and Transfer Requirement Program (NVO–325). Under NVO–325, Pantex Plant is required to characterize wastes using process knowledge or sampling and analysis based on NTS-established analysis requirements and standardized reporting. In addition, each shipment of waste must be certified. Certification is the process of determining, verifying, and attesting in writing to compliance with the Waste Acceptance Criteria. Pantex Plant ensures compliance by conducting internal quality assurance and quality control audits. Furthermore, NTS conducts an annual program review and approval inspection of the plant's practices and quality controls (DOE 1992a:8, 17-20, 96-106).

Pantex Plant materials managed under NVO–325 for shipment to NTS for disposal include: demilitarized and sanitized weapon debris, desiccant, support materials, and packaging materials. Radioactively contaminated classified weapon components that cannot be demilitarized and sanitized are sent to the NTS classified repository. Pantex Plant is presently approved to ship nine LLW streams to NTS for disposal. Five more wastestreams have been through the NTS review process and have approval pending, waiting for sampling and verification. Pantex Plant has also identified 14 other potential streams for inclusion at a later date, and more may be added later. These wastes are currently stored onsite (Pantex 1996:14.5).

Low-Level Mixed Waste

LLMW contains both radioactive and hazardous constituents as defined by the *Atomic Energy Act* (42 U.S.C. 2011) and RCRA (DOE Order 5820.2A:Attachment 2, page 3). Pantex Plant's primary LLMW wastestreams are composed of debris from demilitarization and sanitization of weapons components contaminated during weapons assembly, disassembly, maintenance, and quality assurance testing. Other LLMW wastestreams include HE-contaminated support material, organic liquids, aqueous liquids, organic solids, inorganic solids, lab packs, liquid mercury, batteries, and compressed gas (PC 1995f).

Pantex Plant stores all of its LLMW onsite. LLMW is managed in accordance with the Agreed Order and Site Treatment Plan–Compliance Plan (Pantex 1996f), 30 TAC 335, the RCRA Part B Permit, and 40 CFR 260–280. The Permit's Waste Analysis Plan requires Pantex Plant to characterize wastes using process knowledge and test methods. The Waste Analysis Plan contains the methodologies and analyses used to properly characterize the LLMW (TNRCC 1996).

Pantex Plant treats LLMW and HW in three areas: the Burning Ground, Building 11–9, and Building 11-15A (Figure 4.13.1.2–1). The Burning Ground, an open air thermal treatment facility, operating under RCRA Permit Status, is located in the northern part of Pantex Plant. The Burning Ground is designed to handle waste HE and explosive-contaminated wastes from HE research and production activities. HE is treated in 15 thermal treatment units (nine trays, three pads, and three pans) (TNRCC 1996). Building 11–9, located in Zone 11, is permitted to allow treatment and processing of HW and LLMW in tanks and containers (TNRCC 1996).

While not part of the current operations, Pantex Plant plans to use the Hazardous Waste Treatment and Processing Facility (HWTPF) for LLMW, LLW, and HW treatment and processing. DOE is in the process of examining DOE developed technologies for enhancing HWTPF LLMW treatment and processing capabilities (Battelle 1995). Pantex Plant is also pursuing commercial LLMW treatment and disposal. A detailed discussion of the HWTPF can be found in appendix H. A detailed discussion of waste stream treatability groups can be found in the FFCA Agreed Order and the approved Site Treatment Plan-Compliance Plan.

Hazardous Waste

Under 40 CFR 261, HW is defined as a solid waste that meets any of these four conditions: is listed as a HW; exhibits a characteristic of a HW; is a mixture of a HW and a nonhazardous solid waste; or is derived from treatment, storage, or disposal of a HW. The term "solid" in this context does not specify physical form (i.e., HW may be solid, liquid, or gas) (40 CFR 261.3). The regulations exempt or exclude certain materials from its definition of hazardous wastes, and these exclusions and exemptions are not considered in this discussion. Pantex Plant generates HW during weapons assembly, disassembly, maintenance, and quality assurance testing; HE research and production; ER; and facility operations. Wastestreams include HE, solvents, protective clothing, filters, wipes, oils, soils, paint waste, desiccant, tools, wastewater, and debris (PC 1995f).

Pantex Plant stores HW onsite and treats it onsite and offsite. HW is disposed of offsite. Pantex Plant uses commercial facilities for offsite treatment and disposal. HW is managed in compliance with RCRA regulations from the point of generation to storage and disposal (Pantex 1996:14.5).

Nonhazardous Nonradioactive Waste

NHW is defined as a municipal solid waste or industrial solid waste that is not a listed or characteristic hazardous waste as defined in 40 CFR 261 and 30 TAC 335. Pantex Plant generates industrial solid NHW during weapons assembly, disassembly, maintenance, quality assurance testing; HE research and production; ER; and facility operations. Wastestreams include nonhazardous solvents, protective clothing, filters, wipes, nonhazardous oils, soils, nonhazardous paint waste, desiccant, tools, wastewater, and debris (PC 1995f).

Pantex Plant accumulates and stores NHW onsite, and the treatment of NHW occurs both

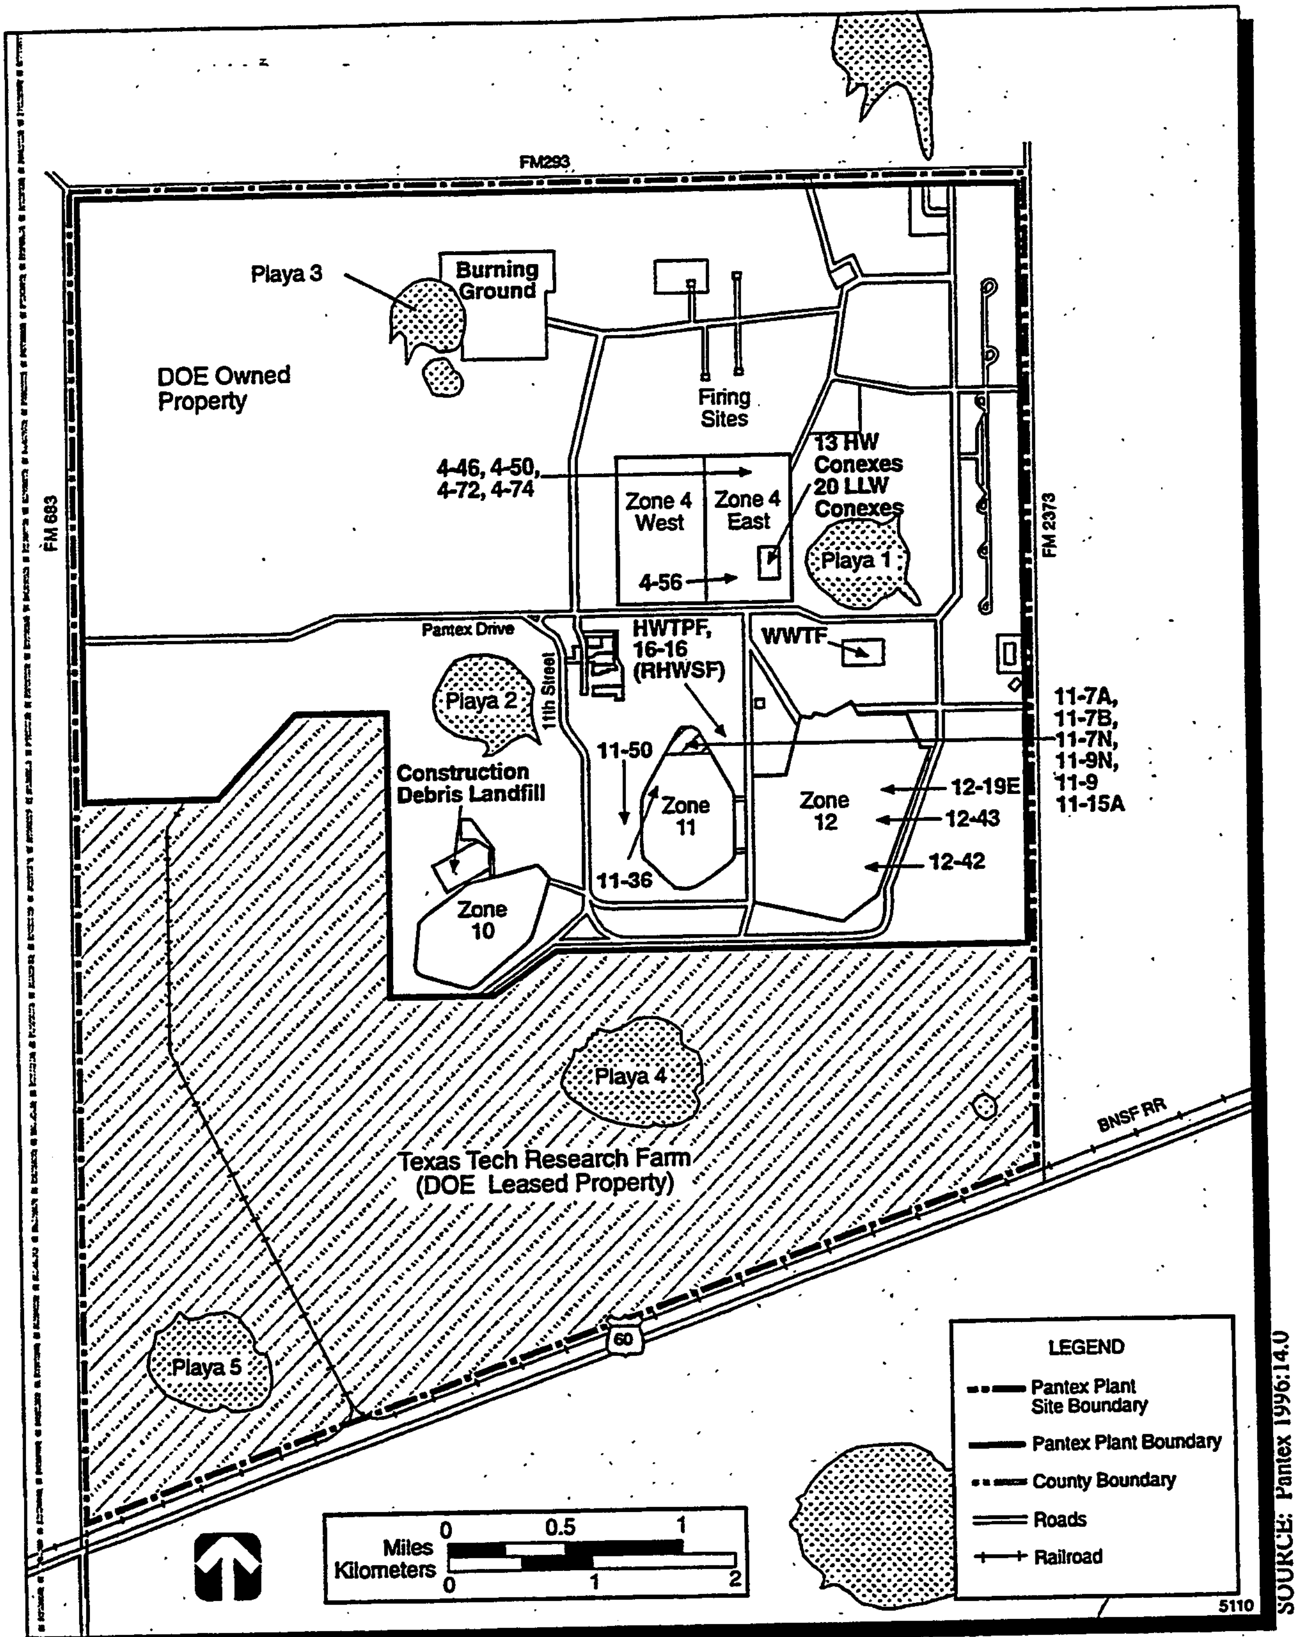

FIGURE 4.13.1.2–1.—*Waste Management Facility Locations at Pantex Plant.*

onsite and offsite. Onsite disposal of NHW includes construction debris in an onsite construction debris landfill. All other NHW wastestreams are disposed of offsite by commercial contractors. State regulation 30 TAC 335.4 allows Pantex Plant to accumulate and store NHW in any manner that does not create a nuisance or endanger public health or the environment. TNRCC requires Pantex Plant to characterize NHW as a Class 1, Class 2, or Class 3 waste. Table 4.13.1.1–3 lists the regulations where the waste class is defined; the criteria defining each waste class; examples of each type of waste; and the storage, treatment, and disposal that is conducted on each class both onsite and offsite (Pantex 1996:14.5). Pantex Plant expects to generate approximately 522 metric tons (576 tons) per year of Class 2 waste (trash). The trash is disposed of through commercial vendors and the Amarillo Landfill (Pantex 1996:14.5). The Amarillo Landfill has more than 25 years of capacity (Pantex 1996:9.4, 14.5). Class 3 (construction debris) waste volumes are not reported (Pantex 1996:14.5).

Other Waste Types

Sanitary and industrial wastewater is discharged into the Wastewater Treatment Facility. Stormwater drains to the playas onsite. Treated effluent from the Wastewater Treatment Facility is discharged into Playa 1.

The State of Texas defines medical waste as solid waste generated during the diagnosis, treatment, or immunization of human beings or animals during research, biological production, or biological testing. The Pantex Plant Medical Department generates medical waste during diagnosis, treatment, and immunization of plant personnel, and includes urine cups, medical gloves, cotton balls, blood samples, sharps containers, contaminated sharps, bandage material contaminated with body fluids, and scintillation vials with urine samples. The Pantex Plant Medical Department follows internal procedures for waste collection and management. Medical waste is disposed of offsite by a commercial contractor (Pantex 1996:14.5).

As of December 31, 1993, all PCB-contaminated parts and equipment used at Pantex Plant contained concentrations of less than 50 parts per million and are managed in accordance with the *Toxic Substances Control Act* (15 U.S.C. 2601) regulations (Pantex 1996:14.5). These PCB and asbestos wastes are transported to offsite permitted facilities for treatment and disposal (DOE 1995b:2-10). Transuranic wastes are not normally generated. No high-level radioactive wastes are currently generated at Pantex Plant.

Environmental Restoration Waste

EPA placed Pantex Plant on the National Priorities List as a Superfund cleanup site, effective June 30, 1994 (59 FR 27989). Superfund cleanup sites are regulated under the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA) (42 U.S.C. 9601), as amended by the *Superfund Amendments and Reauthorization Act* (42 U.S.C. 9608). Superfund sites are prioritized for cleanup of hazardous substance releases that pose threats to human health or the environment.

The ER program at Pantex Plant is now regulated both by the State of Texas and EPA under both the RCRA and CERCLA requirements. A tri-party Federal Facility Agreement is currently being negotiated to outline the reporting requirements, schedules, and funding. It is unknown at this time what impact any additional conditions and requirements specified in the Federal Facility Agreement will have on the Pantex Plant ER program (Pantex 1996:15.0).

Since CERCLA requirements are being negotiated, Pantex Plant is following the RCRA Part B Permit, which requires Pantex Plant to investigate and manage its 144 identified solid waste management units (SWMUs) as described in section 4.5, Geology and Soils. The permit also includes extensive investigation requirements and management criteria for SWMUs (TNRCC 1996:Attachments E–G).

While 144 SWMUs were identified as sites of potential concern and the early waste calculations were very high, subsequent investigations have determined that many of the sites are less contaminated and have smaller cleanup volumes (DOE 1995e:4-28). Table 4.13.1.2–2 provides the best available information on waste projections from ER activities. The ER program generates waste through investigation and remediation activities. Pantex Plant ER wastes are expected to include LLW, HW and NHW. The ER wastestreams include contaminated soils, HE-contaminated materials, protective clothing, wipes, tools, wastewater, and debris (PC 1995f). Starting in 1999, the ER wastes are expected to be primarily liquid wastes resulting from monitoring systems and restoration management of contaminated water from the perched aquifer (Pantex 1996:14.5, 15.5).

4.13.1.3 *Solid Waste Management Facilities*

Table 4.13.1.1–2 identifies the facilities where waste management activities are currently carried out. Wastes are collected from various generator sites in Zone 12 South at Pantex Plant and staged at Building 12–42 for sorting and segregating before they are transferred to various waste management facilities. Other generator sites throughout Pantex Plant move waste directly to the 11–7N storage pad or Building 11–9N (Pantex 1996:14.6, 14.7). Given below is a brief summary of the current and proposed management facilities for Pantex Plant waste. See Figure 4.13.1.2–1 for the location of these facilities.

Four facilities (11–7N Pad, 11–7A, 11–7B, and 11–9N) are used for storing waste in Zone 11. The 11–7N Pad is an above-grade permitted storage pad with two sheds. This facility is used to store LLMW, HW, LLW, and other wastes and materials. Units 11–7A and B are permitted storage pads adjacent to the 11–7N Pad and are used for storage of wastes on a single, above-grade concrete pad. Building 11–9 is used for the storage of HW, LLMW, LLW, and other wastes and materials. The north portion of this building is also used to repackage and stage waste for shipment (Pantex 1996:14.8).

In Zone 4, four HW magazines, one LLW magazine, thirteen HW Conex boxes, and 20 LLW Conex boxes are available for storage of wastes. The four HW magazines are used for storage of liquid and solid LLMW and HW. Containers of LLW are periodically moved from storage areas and transported to NTS for disposal. The Conex boxes are large steel containers with a capacity of about 72 cubic meters (94 cubic yards). The 13 HW Conex boxes have a permitted storage capacity of 4,467 drums and a total operating capacity of 946 containers. Twenty Conex boxes are used for storage of LLW until it is shipped offsite (Pantex 1996:14.8).

During 1996, three burn pits and two burn cages under went RCRA closure (TNRCC 1996). Closure plans for all RCRA permitted facilities are part of the existing permit; however, approved work plans are not in place. The plant has successfully completed several other RCRA closures and partial closures in recent years (TNRCC 1995a).

For wastewater treatment capabilities, also see sections 4.3, Plant Facilities and Infrastructure, and 4.6, Water Resources. Pantex Plant thermally treats HE and HE-contaminated wastes. Buildings 11–9 & 11–15A provide onsite LLMW treatment capabilities. Additionally, Pantex Plant is capable of treating and processing (such as compaction and repackaging) hazardous waste, including LLMW in tanks and containers.

4.13.2 Impacts of Proposed Action

This section discusses impacts of the Proposed Action on the regulatory status and waste management operations at Pantex Plant for an approximately 10-year period. This includes impacts on Pantex Plant's permit status, required RCRA closures, treatment methods, storage limits, disposal capacities, and the volume of waste transported offsite. Impacts are evaluated for continued operations, pit storage, ER, and new facility construction and upgrades. These activities would generate LLW, LLMW, HW, NHW, and other wastes. Since waste management impacts are dependent on total waste volume and waste category, impacts concentrate on LLW, LLMW, HW, and NHW (Class 1). Medical, PCB, and asbestos wastestreams are small at Pantex Plant and are not discussed further. Impacts from NHW (Class 2 and 3) are discussed to a lesser degree due to reduced risk to human health and the environment.

4.13.2.1 *Impacts of Continued Operations*

Weapons-Related Activities

Under the Proposed Action, three levels of operations on 2,000, 1,000, and 500 weapons per year are evaluated. Table 4.13.1.2–3 provides annual waste generation projections by waste type and activity level for the 10-year period for all site activities except ER.

If operations on 2,000 weapons are performed annually, approximately 249 cubic meters (326 cubic yards) of LLW would be generated per year. The volume of LLMW generated per year is expected to be 183.2 cubic meters (239.6 cubic yards), while the volume of HW and NHW (Class 1) generated per year would be 191.6 cubic meters (250.5 cubic yards) and 741.6 cubic meters (970 cubic yards), respectively.

If operations on 1,000 weapons are performed annually, annual LLW generation would decrease by approximately 47 percent compared to operations on 2,000 weapons; annual LLMW generation would decrease by approximately 35 percent. The volume of HW and NHW (Class 1) generated per year would decrease by approximately 44 and 29 percent, respectively.

If operations on 500 weapons are performed, annual generation of LLW would decrease by approximately 71 percent compared to operations on 2,000 weapons; annual LLMW generation would also decrease by 56 percent. The volume of HW and NHW (Class 1) generated per year would decrease by approximately 67 and 48 percent, respectively.

Pit Storage Activities

Pit storage activities generate LLW, LLMW, HW, and NHW. The amount of waste generated (less than 1 cubic meter [1.3 cubic yards] per year) for each waste category is small compared to the volume of waste routinely handled at the plant, and would not affect waste management activities (PC 1995j). The activities generating waste include Radiation Safety operations, (e.g., labels, security seals, and personnel protective equipment) and minor maintenance.

Pit Repackaging Operations

The repackaging of pits from AL-R8 containers into AT-400A containers is expected to begin in late 1996 or early 1997. At this point, empty AL-R8 containers resulting from the AT-400A repackaging effort will either be reused for other purposes at Pantex Plant or be turned over to the DOE's normal excess materials disposition program. Other wastes that would be generated would be routine and also well within the total waste generation described for the Proposed Action. The pit repackaging operations would result in additional worker radiological exposures. These impacts are discussed in section 4.14.

Environmental Restoration Activities

ER activities are expected to generate LLW, HW, and NHW, but the volume of waste generated from these activities would be independent of the number of weapon operations. When the majority of the remediation is completed, expected by the year 2000, a small amount of waste would continue to be generated (e.g., from monitoring and treatment). Table 4.13.1.2–2 provides estimates of waste generation from ER. Current waste volume projections are considered small when compared to pre-1994 conservative estimates.

Comparing ER waste projections in Table 4.13.1.2–2 and plant industrial waste projections from operations on 2,000 weapons per year shown in Table 4.13.1.2–3 shows that ER wastes would represent less than 3.8 percent of the industrial waste after 1999. In 1997 and 1998, the total volumes of ER projected waste and the projected wastes volumes for the 2,000 weapons level are 2,356 cubic meters (2,781 cubic yards) and 2,946 cubic meters (3,548 cubic yards), respectively. These volumes are below the historic high level managed in 1993. ER projected wastes are not considered to pose a major impact to waste management operations at Pantex Plant. Furthermore, no additional waste management facilities or modifications of existing waste management facilities are planned to support ER wastes. Current waste management facilities are planned to be used to support the ER activities. Current waste management facilities are expected to handle the projections in 4.13.1.2–2.

4.13.2.2 *Impacts of New Facility Construction and Upgrades*

Six new facilities would be constructed under the Proposed Action. Debris generated by construction or modification of the new facilities would be disposed of in the onsite landfill; trash would be disposed of in the Amarillo landfill. Generation of this waste would not affect Pantex Plant's waste management activities.

The Pit Reuse Facility is expected to generate 1.5 cubic meters (1.9 cubic yards) of LLW, 0.5 cubic meter (0.6 cubic yard) of LLMW, 0.6 cubic meter (0.8 cubic yard) of HW, and 6.0 cubic meters (7.8 cubic yards) of NHW (Class 1) annually. This relatively small increase in waste generated would not increase the impacts resulting from current waste management practices (PC 1995g:Table 3).

The Gas Analysis Laboratory, Material Compatibility Facility, Nondestructive Evaluation Facility, and the Metrology and Health Physics Calibration and Acceptance Facility are expected to generate the same types and quantities of waste as the existing facilities they would replace, and thus their operational impacts would not change from current waste management practices (PC 1995g:Table 3).

HWTPF is being designed to treat and process LLMW, LLW, and HW. Pantex Plant would need up to two years to obtain new permits or modify existing permits (Battelle 1995). DOE developed technologies are being considered for treatment of LLMW to meet RCRA land disposal restrictions in compliance with the FFCA Agreed Order and approved site treatment plan and waste acceptance criteria for potential disposal sites. The large volume treatment process (e.g., Macroencapsulation) may increase the volume of waste by a factor of 1.45, depending upon the process used. This increased waste volume is taken into account when determining the overall impacts on waste management operations (see section 4.13.2.3) (PC 1995g:Table 4). An expanded discussion regarding the HWTPF is presented in volume II, appendix H.

A discussion of energy conservation design criteria is provided in volume II, appendixes G and H for the new facilities and upgrades.

4.13.2.3 *Summary of Impacts*

As shown in Table 4.13.1.2–3, the volume of all waste types generated at Pantex Plant excluding ER wastes would decrease with the decrease in operations on weapons levels.

If the site continues to ship HW offsite on a monthly basis, no additional storage capacity would be required. Annual HW projections in Table 4.13.1.2–3 are equal to or below HW generated annually in 1992–1995 (DOE 1996f:18). The number of HW shipments is expected to be at or below historic levels. If HW is treated at the HWTPF, the number of shipments would begin to increase in the year 2002 because treatment is expected to increase waste volume.

The Pantex Plant permitted operating storage capacity is 7,044 containers of LLMW (TNRCC 1996). In July 1996, 482 containers of LLMW were stored (PC 1996f). If no offsite disposal is provided, for annual operations on 2,000 weapons, 879 containers containing 183.2 cubic meters (239.6 cubic yards) of LLMW would be placed into storage starting in 1997. As a result, additional waste storage capacity would be required in 2004, regardless of whether the waste is treated or not. Similarly, for annual operations on 1,000 and 500 weapons, 568 and 389 containers containing 118.3 cubic meters (154.7 cubic yards) and 81 cubic meters (105.9 cubic yards) of LLMW, respectively, would be placed in storage starting in 1997. As a result, additional waste storage capacity would not be needed for the 1,000 weapons level and the 500 weapons level. For operations on 2,000, 1,000, and 500 weapons, Pantex Plant would be annually required to provide storage for 1,275, 824, and 564 containers, respectively, for the treatment of LLMW. For operations on 2,000 and 1,000 weapons, Pantex Plant would need to provide additional waste storage for 6,405 and 1,895 containers, respectively, by 2007. For operations on 500 weapons, no additional waste storage facilities would be required by 2007.

In 1994, a shipment of LLMW totalling 33 cubic meters (43 cubic yards) was disposed at a commercial facility in Utah. A second shipment in June 1996 totalled 70 cubic meters (91 cubic yards) of LLMW. The June 1996 shipment reduced the LLMW inventory by 31.6 percent. A third shipment in September 1996 further reduced LLMW inventories by a total of 50 percent. Additional future offsite disposal would further reduce waste operation impacts including waste inventories (PC 1996e, PC 1995n).

To obtain additional storage for LLMW, Pantex Plant has two options. The first is to convert or expand an existing building. The second is to build a new facility. Both require permit changes, but the first option is more desirable. The first option was previously completed at Pantex Plant in July 1994 when Buildings 11–9N, 11–7A, and 11–7B were added. If additional storage is not approved, shutdown is possible with impacts to all Pantex Plant operations and employees.

If the site continues to ship LLW routinely throughout the year, no additional storage capacity would be required. From 1992–1994, the plant shipped 990.9 cubic meters (1,296.1 cubic yards) of LLW in 4,760 drums (PC 1995n). The plant has a storage capacity of at least 2,380 containers (495.82 cubic meters [648.53 cubic yards]). For operations on 2,000, 1,000, and 500 weapons, 1,195, 631, and 343 drums, respectively, would be generated annually. With an average of 1,587 drums shipped annually, the shipment capacity exceeds the generation projections for all weapons levels. If the shipments cease and the estimated storage capacity of 2,380 containers is exceeded, storage facilities would be added, as appropriate, to avoid impacting Pantex Plant principal operations.

Treatment and processing of LLMW, LLW and HW at the HWTPF is scheduled to begin in the year 2001. Depending on the treatment and processing techniques, the volume of waste could either increase or decrease, which would affect the number of offsite shipments. However, minimal impacts are expected since historical capacities are greater than the expected generation rates.

Minimal impacts to NHW management are expected. The amount of NHW projected would be below historic numbers generated during 1992–1995 (DOE 1996f:18). The Amarillo landfill has more than 25 years of capacity (Pantex 1996:9.4, 14.5). Onsite disposal of NHW Class 2 and NHW Class 3 wastes is currently allowed. Minimal impacts from ER wastes are expected as they represent less than 3.8 percent of waste generated from industrial operations after 1999.

Any additional storage, treatment, and disposal facilities required beyond existing and currently planned activities will be covered in future NEPA documentation.

4.13.3 Impacts of No Action Alternative

Under the No Action Alternative, the operations on 2,000, 1,000, and 500 weapons per year are the same as those evaluated under the Proposed Action except that disassembly of weapons would cease once pit storage reached the authorized level of 12,000.

Under the three levels of activity, LLMW, LLW, HW, and NHW operations would continue as described in the Proposed Action with minimal impacts. However, without the HWTPF, waste treatment and processing capabilities are greatly reduced. If Building 11–9, 11–7 Pad, or offsite capacities do not compensate for the lack of a HWTPF, the plant would pursue possible options to avoid adverse regulatory and operational impacts. One option is to expand Building 11–9 or 11–7 Pad, and a second is to continue to reduce waste generation through reduced workloads or a combination of the options. Additional information regarding the HWTPF is available in volume II, appendix H.

4.13.4 Impact of Pit Storage Relocation Alternative

This section discusses the impacts of the Pit Relocation Alternative on waste management operations and regulatory status at Pantex Plant that would result during the 10-year period. The operations at Pantex Plant would be the same as those discussed under the Proposed Action, section 4.13.2.1.

4.13.4.1 *Impacts of Relocating 20,000 Pits*

Pit storage activities generate minimal waste (less than 1 cubic meter [1.3 cubic yards] per year of LLW, LLMW, HW, and NHW); therefore, relocation of pit storage to another site would not affect waste management at Pantex Plant. Impacts to the relocation alternative sites are addressed in chapter 5.

4.13.4.2 *Impacts of Relocating 8,000 Pits*

Pit storage activities generate minimal waste (less than 1 cubic meter [1.3 cubic yards] per year of LLW, LLMW, HW, and NHW); therefore, relocation of pit storage to another site would not affect waste management at Pantex Plant. Impacts to the relocation alternative sites are addressed in chapter 5.

4.13.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No

Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

The final S&D PEIS will include an alternative that is a refinement of these storage alternatives. As discussed in sections 1.4 and 1.7.3 of this volume, the final S&D PEIS will include an alternative under which pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. The impacts of this alternative are fully accounted for in this EIS because the pits from RFETS could not cause the total number of pits stored in Zone 4 to exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Furthermore, RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant.

4.13.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

The WM PEIS examines the environmental impacts of alternative configurations for the management of radioactive and hazardous wastes at DOE sites throughout the U.S. Pantex Plant routinely manages three of the five waste types (LLMW, LLW, and HW) addressed in the WM PEIS. For the purpose of analyses, the WM PEIS considered a baseline inventory and a projected inventory after 20 years. Pantex LLMW represented only 0.3 percent of the entire DOE complex projected LLMW. Similarly, the analyses considered Pantex Plant LLW and HW projected waste inventory at 0.2 percent and 14 percent of the DOE Complex, respectively.

In most alternatives, LLMW and LLW wastes would be shipped offsite for treatment and disposal. Under all alternatives, HW would be shipped offsite for treatment and disposal.

Little or no cumulative waste management operational impacts from WM PEIS alternatives are expected. Current Pantex Plant waste management operational impacts are bounded by the Pantex Plant EIS. Additional and bounding impacts from HW operations are presented in the WM PEIS. Impacts of alternatives, including those noted above, are covered in the WM PEIS.

The WM PEIS provides environmental information to be used in deciding where to locate waste management activities on a national basis. Subsequent site- or project-level NEPA review would be conducted prior to implementing these decisions.

4.13.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, waste management impacts from operations are expected to be less than current impacts. Generated wastes would be adequately managed with existing waste management facilities. Under the downsizing alternative, Pantex Plant has adequate waste management facilities to treat, store, and dispose of its wastes—although waste treatment, storage, and disposal alternatives are contingent upon programmatic decisions of the WM PEIS. Under the relocation alternative, the amount of decontamination and decommissioning activities and wastes would eventually increase.

4.13.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. Construction and operation would have an impact on existing Pantex Plant waste management activities by increasing the generation of TRU, LLW, LLMW, HW, and NHW. Not including the Proposed Action or the Waste Management program, approximately 10 cubic meters (13 cubic yards) of TRU waste and 4 cubic meters (5 cubic yards) of mixed TRU waste would be processed and packaged to meet the offsite waste acceptance criteria. Approximately 1,300 cubic meters (1,700 cubic yards) of LLW contaminated with plutonium and uranium would require disposal. The 0.2 cubic meters (55 gallons) of liquid LLMW and 66 cubic meters (86 cubic yards) of solid LLMW would be treated and disposed of through the use of existing and planned facilities according to the *Pantex Site Treatment Plan* (Pantex 1996f). The 2 cubic meters (528 gallons) of liquid and 2 cubic meters (3 cubic yards) of solid HW would have a negligible impact on waste management activities at Pantex Plant. The 129,500 cubic meters (34,200,000 gallons) of liquid NHW may require construction of sanitary, utility, and process wastewater treatment systems. The 1,840 cubic meters (3,400 cubic yards) of solid NHW would require disposal at the offsite landfill.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

For disposition (not including the Proposed Action or the Waste Management program), approximately 52 metric tons (57 short tons) of spent fuel, 4 cubic meters (1,056 gallons) of liquid, and 651 cubic meters (846 cubic yards) of solid TRU, and approximately 204 cubic meters (265 cubic yards) of solid mixed TRU would be generated. Approximately 18,964 cubic meters (5.017 million gallons) of liquid and 2,498 cubic meters (3,247 cubic yards) of solid LLW and 1.24 cubic meters (177 gallons) of liquid and 235 cubic meters (308 cubic yards) of solid LLMW would also be generated. Liquid and solid HW generation would be 8 cubic meters (1,112 gallons) and 192 cubic meters (250 cubic yards), respectively. Liquid and solid NHW generation would be 485,300 cubic meters (128 million gallons) and 7,516 cubic meters (9,771 cubic yards), respectively (DOE 1996a:Summary).

Waste treatment, storage, and disposal alternatives are contingent upon programmatic decisions resulting from the WM PEIS.

4.13.6 Potential Mitigation Measures

Pantex Plant has an active waste minimization and pollution prevention awareness program. This program is an organized, comprehensive, continuing effort to prevent pollution and reduce waste generation at the plant. It includes specific waste reduction goals for major categories of waste. Program details are provided in volume II, appendix G.

4.14 HUMAN HEALTH

4.14.1 Affected Environment

This section addresses the sources of radioactivity and toxic chemicals at Pantex Plant and their effects on human health and the environment. The section also addresses the plant's vulnerability to accidents associated with these sources. Appendix D, Human Health Analysis, in volume II contains additional information.

The potential release of radioactivity and toxic chemicals to the environment from a DOE facility is an important issue for onsite workers and the public. Since the human environment contains many sources of radioactivity and toxic chemicals, it is essential to understand the sources of these substances and how effectively they are controlled.

Beyond radiation, chemical, and explosive hazards, workers involved with facility operations are exposed to common industrial workplace hazards (e.g., mechanical or electrical hazards). Adequate worker safety from these common industrial workplace hazards is furnished through compliance with the *Occupational Safety and Health Act of 1990* (5 U.S.C. 5108); and 29 CFR 1910, "Occupational Safety and Health Standards." As discussed in section 4.14.1.4, incidence rates at Pantex Plant are below national averages for general and manufacturing industries.

Exposure from inhalation is the overwhelmingly risk-significant pathway for public exposure. It bounds the risk in the assessment of chemical and radiological airborne hazards from normal operations. For accident scenarios involving the release of tritium, skin absorption of tritium oxide is accounted for since it represents about 50 percent of the dose of inhalation (DOE 1991). Inhalation remains the dominant pathway for all other releases.

In the case of a radioactive materials release, radiation doses to individuals result from immediate exposure to the passing radioactive material plume and from long-term exposure to radioactive material deposited in the environment during the plume passage. The dominant exposure pathway for cloud passage for plutonium accidents is inhalation. Plutonium does not readily absorb through the skin, and any ingestion of plutonium from the passing plume is minimal when compared with inhalation.

The long-term accumulation of doses to individuals affected by a radioactive material release could occur from (1) direct doses from groundshine and resuspension inhalation (inhalation dose from inhaling resuspended particles from the ground), (2) ingestion of food crops and milk produced from contaminated ground, and (3) ingestion of contaminated water. Independent of mitigative actions, both the magnitude of long-term doses and the relative importance between pathways is dependent on both the chemical and radiological behavior of the material released to the environment. The chemical nature of plutonium oxide decreases the importance of the ingestion pathways relative to inhalation. Plutonium oxide does not readily absorb into the body when ingested (PNL 1988). As such, the main health risk from plutonium oxide occurs when very small particles are inhaled and become lodged in the lungs.

Historical pathway analysis and dose reconstruction have clearly shown that inhalation is the dominant pathway for plutonium risk. The 1983 Pantex EIS (DOE 1983a) found that after a dispersal accident, over 95 percent of the total plutonium exposure is from inhalation, assuming no remediation or cleanup. With cleanup, over 99 percent of the estimated total plutonium exposure is from inhalation. The Rocky Flats dose reconstruction project analyzed the health impact of historical plutonium emissions from the Rocky Flats Plant and concluded that the only significant pathway, again without remediation or cleanup, for plutonium exposure is inhalation (ChemRisk 1994). Thus, the dominant risk pathway for plutonium dispersal accidents at Pantex Plant is the inhalation pathway.

The Federal government is required under the Federal Radiological Emergency Response Plan (61 FR 20944) to respond to a radiological emergency and provide resources to assist in the evaluation and mitigation of potential long-term exposure pathways to humans. Specifically, the agencies listed below will provide resources to perform specific functions following an accidental release. The Environmental Protection Agency (EPA) will assume responsibility from DOE for long-term monitoring and remediation following an accident. EPA will assist in the preparation of area restoration plans and will recommend cleanup criteria.

The Department of Agriculture (USDA) will inspect meat and meat products, poultry and poultry products, and egg products to assure that they are safe for human consumption. In addition, USDA, in conjunction with the Department of Health and Human Services (HHS), will assist in monitoring the production, processing, storage, and distribution of food through the wholesale level to eliminate contaminated product and in reducing the contamination in the product to a safe level. HHS will assist with the assessment, preservation, and protection of human health, and will assist State and local government officials in making evacuation and relocation decisions.

Figure 4.14.1–1 depicts the offsite population within an 80-kilometer (50-mile) radius of Pantex Plant, known as the Region of Influence (ROI) (UN 1995). The highest population density occurs southwest of Pantex Plant. Wind speeds and directions in the Pantex Plant vicinity are presented in Figure 4.7.1.1–1. The wind blows predominately from the south from May to September and from the southwest for the remainder of the year.

4.14.1.1 *Radiation Environment*

Table 4.14.1.1–1 summarizes the major sources of radiation exposure in the vicinity of Pantex Plant (NCRP 1987). Releases from Pantex Plant operations constitute a very small fraction of the total exposure to the public in the vicinity of the plant. Cancer statistics for the State of Texas indicate that annually, a person in the Pantex Plant vicinity has a 1.7 x 10^{-3} probability of contracting a fatal cancer. From examining nominal fatal cancer risk factors for the public and Table 4.14.1.1–1 data, it can be seen that fatal cancers attributable to environmental radioactivity released from Pantex Plant constitute an extremely small fraction (less than 0.01 percent) of the average yearly fatal cancer probability in the vicinity of Pantex Plant (DOE 1994l:4-20).

The majority of Pantex Plant workers receive no detectable radiation exposures (i.e., zero dose) during normal operations as a result of their work and are considered non-involved workers. Of those workers that received non-zero doses (involved workers total 329) over the last 5 years, the average annual dose was 111 millirem with a maximum individual dose of 0.905 rem (Pantex 1996a). These exposures were in addition to exposures received from background sources described in Table 4.14.1.1–1. DOE Order 5480.11 and 10 CFR 835 specify a limit of 5 rem per year for occupational workers. In addition, as of 1996, the Pantex Plant administrative control level is 500 millirem per year for most workers and 900 millirem per year for production (weapons operations) workers.

The plant plans to continue to reduce the control level for production workers to the 500 millirem per year level. Using fatal cancer risk factors for workers, the average annual probability of a Pantex Plant worker contracting a fatal cancer due to occupational radiation exposure is

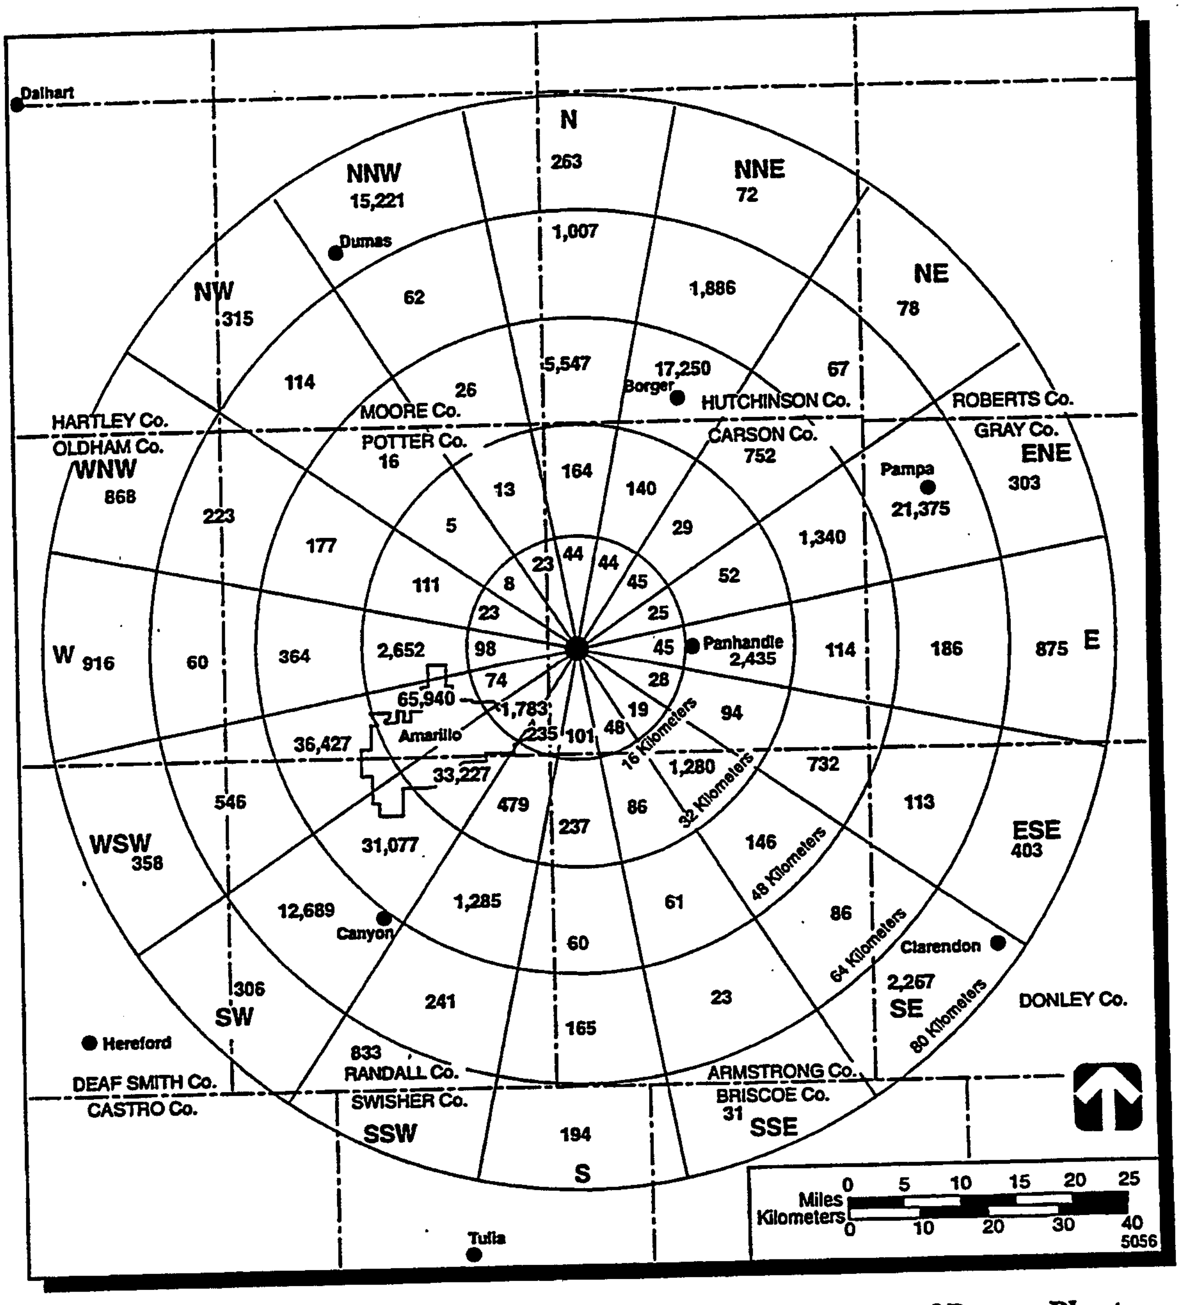

FIGURE 4.14.1–1.—*Population Within 80 kilometers (50 miles) of Pantex Plant.*

4.4×10^{-5}. For those Pantex Plant workers that receive radiation doses, this 4.4×10^{-5} value is essentially in addition to the average annual fatal cancer risk of 1.7×10^{-3} for the regional population.

The largest contributors to worker radiological doses at Pantex Plant are external exposures (i.e., those received from radiation-emitting sources). The largest potential for external doses occurs from weapon operations and pit repackaging. Worker population dose, from an external exposure viewpoint, has been significantly reduced at Pantex Plant due to improvements in work practices and changes in work scope. In 1980, Pantex Plant operations resulted in a cumulative worker dose of 148 person-rem over 719 personnel. In 1994, Pantex Plant operations resulted in a cumulative worker dose of 29 person-rem over 329 personnel (Pantex 1996a).

Internal exposures, received when radioactive materials are deposited through inhalation, ingestion, or absorption, are only minor contributors to worker doses. During normal operations, engineering controls (e.g., confinement and ventilation) are the primary methods of controlling airborne concentrations of radionuclides and minimizing internal exposure. Administrative controls (e.g., exposure limits and procedural requirements) and personnel protective equipment (e.g., respirators) are used as supplemental methods to control internal radiation exposure. The largest single source of internal exposures was from the contamination of Building 12–44 Cell 1 with tritium in 1989; the result was a total worker dose of approximately 1.5 person-rem, with a maximum individual dose of 1.3 rem.

The Pantex *Radiological Control Manual* (Pantex 1996d) establishes site-specific guidelines and procedures to minimize or eliminate radiological exposure and risk to workers while performing work involving radioactive materials and radiation–generating devices. The Pantex Plant manual is based on the requirements contained in the DOE *Radiological Control Manual* (DOE 1992); 10 CFR 835, *Occupational Radiation Protection*; and DOE Order 5480.11, *Radiation Protection for Occupational Workers.*

The "As Low As Reasonably Achievable" (ALARA) program at Pantex Plant is another control to help limit the number of personnel occupational exposures and public/ environmental exposures to radioactive material. This program applies to all plant facilities, equipment, processes, and operations involving a potential or actual exposure of personnel to ionizing radiation, and is based on the regulations discussed above.

4.14.1.2 *Chemical Environment*

Hazardous chemicals are used in the performance of certain Pantex Plant operations. A full listing of hazardous chemicals used at Pantex Plant is provided in the *Pantex Plant Safety Information Document* (Pantex 1996a). Pantex Plant operations that require the use of hazardous chemicals are performed in full compliance with Occupational Safety and Health Administration (OSHA) regulations and American Conference of Government Industrial Hygienists guidelines.

Under normal operations, various chemicals are released to the air that have the potential to impact the public. Table 4.14.1.2–1 lists the hazardous air pollutants released to the air and their calculated maximum potential concentrations at the plant fence line (see section 4.7, Air Quality). The concentrations were calculated with the EPA-approved ISCST2 and ISCLT2 codes (see volume II, appendix B) using existing Pantex Plant sources (PC 1994). Emission inventories used here also apply for the 2,000 weapons activity level. Effects screening levels (ESLs) from TNRCC are also listed in the table and used for comparison.

A useful measure of potential human health effects resulting from exposure to non-carcinogenic chemicals is the hazard index. In its most general form, a hazard index is a ratio of the actual exposure of a human receptor to an established exposure limit. If this ratio is appreciably less than unity, no adverse human health effects are expected. If the hazard index is close to unity, some adverse human health effects may occur; and if the hazard index is substantially greater than unity, severe health effects can results. Table 4.14.1.2–2 presents the individual hazard quotients, which summed together make up the hazard index. The hazard index for chemicals released from Pantex Plant is 0.0909. That is an order of magnitude less than 1.0, and no adverse health effects are expected.

Within the plant boundary, calculated concentrations are somewhat higher. They are, however, below exposure limits established by OSHA and considered safe from adverse noncancer effects. Table 4.14.1.2–3 shows a comparison between maximum onsite concentrations and allowable exposure limits.

Some toxic chemicals are also carcinogenic. Table 4.14.1.2–4 gives the available chemical risk factors for those pollutants that are carcinogens (except for lead, which does not have an available risk factor). When combined

Source: EPA 1995

with chemical concentrations and human exposures (e.g. the amount of time an individual is in contact with the chemical), it is possible to calculate a latent cancer probability. It was assumed that exposure to the public was entirely from inhalation, since airborne transport is the only viable pathway to the public. Using the calculated concentrations in Table 4.14.1.2–1, toxic chemical emissions would result in a probability of 1.2×10^{-5} that a hypothetical individual living at the plant boundary would contract a latent cancer.

4.14.1.3 *Health Effects Studies*

A June 1994 study by the Texas Cancer Registry, Texas Department of Health, showed significant increases in prostate cancer mortality among males in Potter and Randall Counties and leukemia mortality among Carson County males during the period 1981–1992. There were no statistically significant increases observed in site-specific cancer mortality among females during this period. For cancer incidence during the period 1986–1992, no statistically significant excesses in males were seen; however, cancer of the prostate was slightly elevated in males in Potter and Randall Counties. Analysis of the four major cell-specific types of leukemia showed a significant excess in the incidence of chronic lymphocytic leukemia among Potter and Randall Counties females. This cursory study was conducted in Carson, Potter, and Randall Counties, which are located near Pantex Plant. This study focused only on cancers of the breast, prostate, brain, thyroid, and leukemia, which were of specific concern to citizens in the area. Other radiation-associated cancers, such as bone and lung, were not included in this study. Although prostate cancer and chronic lymphocytic leukemia have not been linked to radiation exposure, further followup to this study was recommended.

An epidemiologic study of past and present Pantex Plant workers was done and published in the *Health Physics Journal* (Acquavella 1985). This study compared total and cause-specific mortality for Pantex Plant workers employed between 1951 and December 31, 1978, with expected cause-specific mortalities based on U.S. death rates. Significantly fewer deaths were observed in the workforce than would be expected from projections based on U.S. death rates for the following causes of death: all cancers, arteriosclerotic heart disease, and digestive diseases. Furthermore, no specific causes of death occurred significantly more frequently than expected. Slightly elevated mortality ratios were observed for brain cancer and leukemia; neither excess was statistically significant. The four deaths from brain cancer all occurred among those who had worked at the plant less than 5 years. The four deaths from leukemia occurred with equal frequency among those who had worked at the plant a short time and those who had worked over 15 years.

DOE Headquarters' Office of Epidemiological Studies initiated an epidemiologic surveillance program at Pantex Plant in 1993 in order to address the current health status of the workforce. This program tracks and analyzes the occurrence of illness and injury on a continuing basis. Monthly data collection began on January 1, 1994; data and reports will be issued on a semiannual basis. These reports provide an ongoing assessment of any health problems that may be associated with Pantex Plant operations. The Pantex 1994 annual report is available.

A followup of the 1985 mortality study of the Pantex Plant workforce is planned. The update will be conducted by the National Institute for Occupational Safety and Health as part of a research program funded by DOE under a Memorandum of Understanding with the Department of Health and Human Services. The followup study by the National Institute for Occupational Safety and Health is scheduled to commence either in late 1996 or early 1997. The study will provide additional years of data on the mortality experience of Pantex Plant workers.

4.14.1.4 *Accident Mitigation*

Yearly incidence rates provide an objective performance measure of Pantex Plant safety programs. The data in Table 4.14.1.4–1 can be used to compare the performance of Pantex Plant operations to that of the general, manufacturing, and chemical industries nationally; the table demonstrates that Pantex Plant safety programs tend to be more effective. For both total recordable cases and lost workday

TABLE 4.14.1.4–1.—*Comparison of Incidence Rates for Pantex Plant and Industry (National Averages)*[1]

OPERATION	INCIDENCE RATE (PER 100 FULL-TIME WORKERS PER YEAR)		
	TOTAL RECORDABLE CASES	LOST WORKDAY CASES	LOST WORKDAYS
Pantex Plant	5.1	2.2	74.3
General Industry	8.4	3.9	86.5
Manufacturing Industry	12.7	5.6	121.5
Chemical Industry	6.4	3.1	62.4

[1]Incidence rates refer to workplace injuries that may or may not result in lost work time.
Sources: DOE 19941; Pantex 1995e

cases, incidence rates at Pantex Plant are below industrial averages, with the exception of lost workdays, where Pantex Plant exceeds chemical industry incidence rates.

To minimize worker radiation and chemical exposures, a number of mitigation measures are in place at Pantex Plant. These measures reflect an overall defense-in-depth safety philosophy to prevent or minimize potential releases from internal or external initiating events. Essentially, this philosophy imposes multiple barriers between sources of radiation and the public. Typically at Pantex Plant, three separate types of barriers are imposed: cladding, packaging, and plant facilities. Cladding refers to the actual material covering radionuclides. Metallic pit cladding is used for the plutonium in pits. For tritium, the effective cladding is the reservoir. Though not completely passive, the only active component found on some tritium reservoirs is a small explosive squib that operates the valve mechanism used to release the tritium from the reservoir. Protective covers are installed over the squibs which include shorting plugs and/or shunts. These plugs and shunts provide protection against accidental firing of the squib.

The plutonium in radioisotopic thermoelectric generators has an exceptionally robust cladding designed to withstand high pressures and temperatures. Tests of radioisotopic thermoelectric generators have demonstrated their ability to withstand an exposure of 1,000 °C (1,832 °F) for 1 hour.

Packaging refers to the containers used for transporting and staging the clad radionuclides. The use of these qualified protective containers, when special operations are not being performed, is an important aspect of minimizing the frequency of operational accidents that could result in the release of radioactive materials.

In the unlikely event that cladding and packaging should be breached, the facilities themselves serve as the final barrier for the defense-in-depth philosophy. Regarding releases of radionuclides from the cells, where a large part of the operations take place, steel blast doors protect the equipment passageway and are expected to remain intact and closed. The blast valves in the intake and exhaust air supply ducts, as well as the contaminated waste isolation valve system, prevent radioactive particles from escaping through these pathways.

Within the bays, any accident involving a breach of cladding integrity will shut down the heating, ventilating, and air conditioning through the Radiation Alarm Monitoring System interlock upon detection of alpha radiation, thus limiting the potential contamination to the bay of occurrence. Building 12–64 is an exception because it does not have the interlock. The impact of this exception is accounted for in the evaluation of potential accident scenarios. Upon detection of tritium (beta radiation), an exhaust will ventilate the tritium to the atmosphere. The design features of buildings provide other barriers that prevent the dispersal of plutonium during accidents. The building features also reduce the probability of damage to the facility from natural phenomena and external events (e.g., earthquakes and tornadoes).

Structural analysis performed on buildings representative of Pantex Plant construction types shows that heavily reinforced structures are not vulnerable to damage from large scale tornadoes. Fire was identified as a possible release scenario. However, a fire limited to the interior of the facility by the fire suppression system or the fire fighters would only cause internal releases in the room of the fire. Where applicable, the high efficiency particulate air filters could prevent release to the exterior atmosphere.

Besides the systems and structures noted above, numerous other features serve to enhance facility safety. These features include:

- Rad-safe systems (radiation detection and alarm systems) and continuous air monitors to protect personnel from radiological exposure.
- Fire protection systems.
- Grounding and lightning protection systems.
- Electrical power stability, including an uninterruptible power supply and emergency lighting.
- An emergency communication system to notify personnel and provide quick response to accidents, adverse weather, or natural disaster.

The defense-in-depth philosophy summarized above emphasizes physical barriers. In addition to these physical barriers, Pantex Plant also employs numerous administrative controls that minimize the likelihood of operator errors.

Pantex Plant has numerous integrated programs that work together to establish and maintain "barriers" to protect the public, the workers, and the environment. Programs of this type include the SAR (Safety Analysis Report) Program that defines the safety envelope for each facility, establishes the required and allowable facility configurations, and formally authorizes facility operations. Similarly, the HAR (Hazards Assessment Report) Program serves to evaluate and authorize individual operations which are conducted within the aforementioned facilities.

Once facility configurations and operational procedures are established by the SARs and HARs, programs such as Configuration Management, Conduct of Operations, Maintenance Management, USQ (Unreviewed Safety Question) Program, and the Change Control Board serve to continually ensure that facilities are maintained and operations are conducted as authorized. In the event that any facility or operation is found to be out of compliance with the authorized safety basis, immediate steps are taken to correct the deficiency. A determination is made whether or not to continue operations. Facilities or procedures may be modified to allow continued operations while the deficiency is being corrected. Additional programs, which work together to establish and maintain safety at Pantex Plant, include the following:

- Nuclear Safety Management
- Operational Readiness Reviews
- Radiation Safety
- Nuclear Explosives Safety

Information on these programs is presented in the Program Information Document and the Safety Information Document.

4.14.1.5 *Compliance with Occupational Safety and Health Requirements*

The health and safety of all workers associated with Pantex Plant operations is a primary consideration in the decision resulting from this EIS. A comprehensive nuclear and occupational safety and health initiative was announced by the Secretary on May 5, 1993, entailing closer consultation with OSHA regarding regulation of worker safety and health at DOE contractor-operated facilities. Regulation of worker health and safety at DOE contractor-operated facilities will gradually shift from DOE to OSHA.

The *Occupational Safety and Health Act of 1970* (Public Law 91-596) establishes Federal requirements for assuring occupational safety and health protection for employees. DOE and OSHA have agreed to a temporary pilot project to facilitate the shift of worker protection to OSHA. Under this temporary pilot project, OSHA will regulate and oversee worker health and safety at the Argonne National Laboratory in DuPage, Illinois. During the pilot, OSHA will evaluate the current safety and health program at Argonne and respond to employee complaints.

Information obtained during the Argonne pilot project is expected to help the two agencies determine the resource needs of OSHA if it is to ultimately assume responsibility for worker safety and health at DOE facilities. While OSHA regulates and enforces worker health and safety at industrial and some government workplaces, current law exempts most DOE facilities from external regulation and enforcement. DOE internal regulations do, however, require all facilities to meet current OSHA standards.

DOE facilities also comply with the *Emergency Planning and Community Right-to-Know Act* (42 U.S.C. 11001), which requires facilities to report the release of extremely hazardous substances and other specified chemicals; provide material safety data sheets or lists thereof; and provide estimates of the amounts of hazardous chemicals onsite. The reporting and emergency preparedness requirements are designed to protect both individuals and communities.

Workplace Safety and Accidents

Operations at Pantex Plant expose workers to occupational hazards during the normal conduct of their work activities. Occupational safety and health training that includes specialized job safety and health training appropriate to the work performed is provided for all employees at Pantex Plant. This training also includes informing employees of their rights and responsibilities under the *Occupational Safety and Health Act of 1970*; Executive Order 12196, which established OSHA Federal Agency Standards; 29 CFR 1960—The OSHA Federal Agency Standards—which describes the safety and health programs that Federal agencies must establish and implement under Executive Order 12196; and DOE Order 440.1—Federal Employee Occupational Safety and Health Program. DOE provides implementation guidance in DOE Order 440.1, including the requirements and guidelines for the DOE Federal Employee Industrial Hygiene Program. DOE policy is to:

- Provide places and conditions of employment that are as free as possible from recognized hazards that cause or are likely to cause illness or physical harm.
- Assure that employees and employee representatives have the opportunity to participate in the Federal Employee Occupational Safety and Health Program.
- Establish programs in safety and health training for all levels of Federal employees.

- Consider the 29 CFR 1960 (OSHA Standards for Federal Agencies) requirements to be the minimum standards for DOE employees.

DOE contractor operations at Pantex Plant expose workers to hazardous constituents. DOE orders require that site operations have programs for protection of workers. DOE Orders 5480.11, Radiation Protection for Occupational Workers, and 440.1, Federal Employee Occupational Safety and Health Appraisal Program, establish procedures for protection of workers against radiological and hazardous materials, respectively. DOE Order 232.1, Occurrence Reporting and Processing of Operations Information, provides for reporting and guides appropriate corrective action(s) and follow-up should an exposure occur.

DOE Order 451.1, National Environmental Policy Act Compliance Program; DOE Order 5482.1B, Environment Safety and Health Appraisal Program for Department of Energy Operations; and DOE Order 5480.23, Nuclear Safety Analysis Reports provide the basis for review of all planned and existing construction and operation to determine the potential for accidents and the assessment of the associated human health and environmental consequences, should an accident occur. The results of these reviews are used as the basis for determining the need for controls or other mitigative actions to eliminate or greatly reduce the potential for and consequences of an accident. These reviews are required before authorization of construction or start of operation. These reviews also involve the identification of hazards and an analysis of normal, abnormal, and accident conditions. This analysis includes consideration of natural and man-made external events, including fires, floods, tornadoes, earthquakes, other severe weather events, human errors, and explosions.

In accordance with DOE Order 151.1, Emergency Management System, emergency response planning and training are provided to mitigate the consequences of potential accidents. Additionally, should an accident occur, the incident would be reported in accordance with DOE Orders 232.1, Occurrence Reporting and Processing of Operations Information. The reports would also include appropriate corrective action(s) and followup.

4.14.2 Impacts of Proposed Action

Under the Proposed Action, the following activities would occur at Pantex Plant:

- Assembly, disassembly, repair, retrofit, and evaluation of nuclear weapons in support of the national security policy.
- Development, fabrication, and testing of chemical high explosive(s) (HE) and HE components.
- Nuclear material staging as defined in section 3.1. Normal operational impacts associated with Zone 4 staging, and associated material movement are discussed in section 4.12, Intrasite Transportation.
- Construction and operation of new facilities. These are discussed in section 3.1.

This section describes the human health impacts from these activities.

4.14.2.1 *Impacts of Continued Operations*

The continuation of weapons-related operations at Pantex Plant would result in the continuation of radiological exposures to plant workers. Table 4.14.2.1–1 presents the expected radiological impact from future weapons operations based on historical exposures.

The combined involved worker dose from 10 years of operation at the 2,000 weapons activity level is estimated at 330 person-rem based on historical doses. Assuming that only 330 radiation workers (based on 1994 operations) are involved in weapon operations over a period

TABLE 4.14.2.1–1.—*Radiological Exposures to Workers from Normal Weapons Operations*

WEAPONS LEVEL	CUMULATIVE DOSE (10 YEARS OF OPERATIONS) (PERSON-REM)	EXPECTED EXCESS CANCER FATALITIES (10 YEARS OF OPERATIONS)
2,000	330	0.13
1,000	165	0.07
500	82	0.03

of 10 years (i.e., these people receive the entire plant dose), they would receive an average of 0.1 rem per person per year. The maximum dose an individual involved worker is allowed to receive annually is administratively limited to 900 mrem during normal operations. These involved workers include support personnel (e.g., auditors, inspectors) that participate in weapon operations.

Using a normal operations dose-to-risk conversion factor of 4×10^{-4} excess cancer fatalities per person-rem, there would be an additional 0.13 excess cancer fatalities experienced by this group in their lifetime. The probability of fatal cancer from all causes in the general population is estimated at 20 percent (NAP 1990:174), which implies that, on average, 66 of 330 people would develop a fatal cancer from all causes in their lifetime. As the weapon activity level decreases, so would the number of workers. The total person-rem and excess cancer fatalities would also decrease.

Non-involved personnel are not allowed in the vicinity of weapon operations and do not receive doses from weapons operations. The average dose to an individual member of the public or a non-involved worker results primarily from the small amounts of tritium offgassing from Cell 1, the small amounts from the Burning Ground, and the very small amounts that may escape during removal of tritium reservoirs. The total amount of tritium emissions are at the limit of detection. As a result, it is not possible to calculate doses and consequences to the non-involved workers and the public with high confidence levels. To the extent practicable, the dose to the public has been estimated to be less than 1.20×10^{-4} person-rem per year, resulting in 6.00×10^{-8} excess cancer fatalities. Practically speaking, the maximum dose to an individual non-involved worker or member of the public would be effectively zero.

The pit repackaging process is expected to begin operation in late 1996 or early 1997. It is planned that up to 20,000 pits will eventually be repackaged into AT–400A containers. This process will require the transfer of pits between Zone 4 and Zone 12. Impacts related to these transfers are described in section 4.12.

The pit repackaging will occur within existing facilities within Zone 12. Operations occurring as part of the pit repackaging process include:

1) Pit Leak Check—to verify the integrity of the pit encapsulation, pits will be leak checked prior to repackagement.
2) Pit Cleaning—pits with surface contamination that may initiate corrosion of the pit clad during storage will be cleaned prior to repackagement.
3) Placement of pits within inner containment vessel, inner containment vessel welding, inert gas introduction into inner containment vessel—pits will be placed within the inner containment vessel of

the AT–400A container. These vessels will be welded shut and filled with an inert gas mixture. The inner containment vessel will be leak checked to ensure the integrity of both the pit and the inner containment vessel.

4) Placement of inner containment vessel into outer containment vessel—once the integrity of the inner containment vessel is verified, the vessel will be placed in the AT–400A outer containment vessel. Further description of the AT–400A outer containment vessel is provided in volume II, appendix F.

All operations involving pits will be performed in a manner that minimizes radiological exposures to facility workers. However, the pit repackaging process will result in additional exposures at Pantex Plant. Because pit repackaging has not been done with this type container, there is no historical dosimetry information available. Therefore, conservative dose estimates have been made for this operation. For 2,000-pit repackage operations per year, it is estimated that an additional worker exposure of less than 30 person-rem will be incurred. Similarly, an additional worker exposure of less than 300 person-rem for the repackaging of 20,000 pits will be incurred. Using a normal operations dose-to-risk conversion factor of 4×10^{-4} excess cancer fatalities per rem, less than 0.12 excess cancer fatalities would be incurred in the workforce from this operation.

The dose estimates provided for the pit repackaging process are based on initial scoping studies performed prior to operation of the process. DOE expects that the actual worker doses will be less than the presented estimates. Additionally, as the pit repackaging effort proceeds, DOE will utilize the experience gained from initial operations to further reduce worker exposures.

Impacts of Potential Facility Accidents

For the purpose of this discussion an accident is defined as an unexpected or undesirable event that leads to a release of hazardous material within a facility or into the environment. Events that could result in an accidental release of hazardous material fall into three broad categories: external events, internal events, and natural phenomena events. External events (e.g., aircraft crashes and resulting explosions or fires) originate outside a facility. Internal events (e.g., equipment failures or human errors) originate within a facility. Natural phenomena events include weather-related occurrences (e.g., tornadoes and severe winds) and earthquakes. All of these events could lead to a release of hazardous material from a facility.

Identification of Risk Significant Accident Scenarios

Assessing the threat to public and worker health from potential accidents at Pantex Plant involved a screening process. The first step of this process was to identify a broad spectrum of potential accident scenarios that could occur during continued operations.

Facilities and operations at Pantex Plant have been analyzed to identify all hazards and potential accidents associated with the facilities and process systems, components, equipment, or structures and to establish design and operational means to mitigate these hazards to prevent potential accidents. The results of these analyses are contained in safety analysis reports and other safety basis documents including:

- *Basis for Interim Operations for the Pantex Plant*—Amarillo, Texas, Pantex Plant, June 1995 (Pantex 1995j).
- *Basis for Interim Operations for the Non-Nuclear Facilities*—Amarillo, Texas, Pantex Plant, September 1995 (Pantex 1995).

- *Chemical High Explosives Hazards Assessment for the Pantex Plant*, Jacobs Engineering, October 1993 (Jacobs 1993a).
- *Natural Phenomena Hazards Assessment for the Pantex Plant*—Amarillo, Texas, Jacobs Engineering, October 1993 (Jacobs 1993).
- *Recalculation of Potential Deposition Levels and Dose Exposure Levels for the Pantex Radiological Hazards Assessment*, Jacobs Engineering, October 1993 Jacobs 1993b).
- Pantex Plant, *Safety Information Document*, prepared for the U.S. Department of Energy, Albuquerque Operations Office, Albuquerque, NM, September 1996 (Pantex 1996a).

For each facility and operation at Pantex Plant, DOE has developed or is in the process of developing a safety analysis report. In addition, other facility-specific safety analyses have been performed and documented (e.g., process hazards reviews, hazards analysis documents, and justifications for continued operations). These documents were also utilized for the identification of potential accidents at Pantex Plant.

DOE Order 5480.23, Nuclear Safety Analysis Reports, provides the most recent guidance to determine the safety basis for facilities at Pantex Plant. However, safety analyses have been conducted at Pantex Plant for more than a decade using a gradually evolving chain of guidance documentation. Therefore, the safety documents used as a basis for the identification of potential accidents at Pantex Plant in this EIS represent a continuum of safety assessments. Appendix A in the *Safety Information Document* provides a list of DOE orders, statutory and regulatory requirements, codes, and other applicable standards relevant to the design and safe operation of Pantex Plant (Pantex 1996a).

The next step of the screening process involved the identification of representative accidents that contribute to the risk to public and worker health from continued Pantex Plant operations. Ideally, a complete evaluation of Pantex Plant Site risks would include all potential accident scenarios. However, this type of an approach is impractical. Therefore, the purpose of this step in the screening process was to identify a subset of accident scenarios that contribute a large fraction of the total risk from Pantex Plant operations. This step of the screening process involved the grouping of potential accidents based on both the magnitude of the frequency of occurrence and the magnitude of the expected consequence. Once the accidents were grouped, the accidents corresponding to the highest risk in each group were chosen for further analysis. (Further information on the accident scenario identification is available in volume II, appendix D, Human Health Analysis.)

Table 4.14.2.1–2 lists the scenarios that were identified as risk significant for Pantex Plant. This table includes both high-frequency low-consequence scenarios (such as those occurring during normal operations) and unlikely (low-frequency) scenarios that have potentially high consequences (i.e., scenarios initiated by natural phenomena or external hazards). Societal risk (listed in the column heading of that table) is the number of adverse events (in this case, excess cancer fatality risk) per year for a specified population. The frequency categories shown in Table 4.14.2.1–2 are explained below:

- *Anticipated* events have a frequency greater than or equal to 10^{-2} per year. Most anticipated events would be expected to occur at least once within a human lifetime (conservatively assumed to be 100 years).
- *Unlikely* events have a frequency between 10^{-2} per year and 10^{-4} per year. Unlikely events are not expected to occur within a human lifetime. The chances of

TABLE 4.14.2.1–2.—*Summary of Consequences to the Public from Risk Significant Accidents at Pantex Plant: Configuration 1*

SCENARIO	DESCRIPTION	FREQUENCY OF SCENARIO	POPULATION DOSE[1] (excess fatal cancer)	ANNUAL SOCIETAL RISK[2] (excess fatal cancers per year)
1	Explosive driven plutonium dispersal from internal event	Extremely Unlikely	1,200 Person-Rem (5.9×10^{-1} excess fatal cancers) Worker Fatalities	6.3×10^{-6}
2	Accidental high explosives detonation from internal event	Anticipated	No Public Impact, Worker Fatalities	NA
3	Explosive driven plutonium dispersal from external event/ natural phenomena	Not Reasonably Foreseeable	16,000 Person-Rem (8.0 excess fatal cancers), Worker Fatalities	7.2×10^{-6}
4	Accidental high explosives detonation from external event/ natural phenomena	Unlikely	Worker Fatalities, No Public Impact	NA
5	Tritium reservoir failure from internal event	Anticipated	0.080 Person-Rem (4.0×10^{-5} excess fatal cancers)	9.5×10^{-7}
6	Pit breach from internal event	Unlikely	0.00037 Person-Rem (1.9×10^{-7} excess fatal cancers)	1.5×10^{-9}
7	Multiple tritium reservoir failure from external event/natural phenomena	Not Reasonably Foreseeable	110 Person-Rem (0.055 excess fatal cancers)	2.2×10^{-8}
8	Fire driven plutonium release from external event/natural phenomena	Not Reasonably Foreseeable	1,100 Person-Rem (0.55 excess fatal cancers)	2.9×10^{-7}
9	Tritium or plutonium release caused by seismic event or aircraft accident	Unlikely	0.40 Person-Rem (2.0×10^{-4} excess fatal cancers)	6.8×10^{-8}
10	Chlorine release due to failure of system piping and valves or cylinder from natural phenomena	Unlikely	No adverse public impacts	NA
11	Chlorine release due to failure of system piping and valves or cylinder from internal event	Unlikely	No adverse public impacts	NA

[1]Appendix D presents details of the dose and excess fatal cancer consequence assessment methodology. No prompt fatalities in members of the general public from these scenarios are anticipated.
[2]Obtained by multiplying the scenario frequency by the excess cancer fatalities due to that scenario.

an unlikely event occurring within a human lifetime range from approximately 50 percent to less than 1 percent. Most unlikely events would not be expected to occur over a time span equal to the 200-year history of the U.S.

- *Extremely unlikely* events have a frequency between 10^{-4} per year and 10^{-6} per year. Extremely unlikely events are so rare that the chances of one occurring within a human lifetime range from less than 1 in 100 to less than 1 in 10,000. Extremely unlikely events would not be expected to occur over a timespan equal to the history of human civilization.
- *Not reasonably foreseeable* events have a frequency below 10^{-6} per year. The chances of such an event occurring within a human lifetime (100 years) are fewer than 1 in 10,000 (10^{-6} x 100 = 1 in 10,000). Examples of not reasonably foreseeable events are catastrophic natural phenomena. One such example is the impact of a meteorite in the U.S. severe enough to cause thousands of fatalities.

For all scenarios, the frequency and consequence assessments are performed on a site-wide, rather than a facility-specific basis.

For the accidents identified as risk significant, detailed consequence assessments were performed. The consequence assessment focused on exposures to involved and non-involved workers and the public. Radiological consequences to the public were evaluated using site-specific meteorological data, local demographic data, and either the Melcor Accident Consequence Computer Code System (MACCS) or the Explosive Release Atmospheric Dispersion (ERAD) computer code system. MACCS was principally used to model health impacts from scenarios that did not involve explosions, while the ERAD computer code system was used primarily to model the health impacts from releases initiated by explosions (see volume II, appendix D for additional information on MACCS and ERAD). Human health impacts were evaluated in terms of cumulative radiological exposure from an accident and the societal risks (subsequent number of expected excess LCFs). This process is summarized in Figure 4.14.2.1–1.

Expected Change in Societal Risks from Potential Pantex Accidents

During preparation of the Draft EIS, Pantex Plant personnel discovered that particular assembly/disassembly cells had larger gaps between the edges of personnel and/or equipment doors and their frames than had been analyzed in prior studies. The cumulative gaps around the personnel and equipment doors of individual cells varied, but the worst case resulted in a total gap area greater than the 42 square inches that had been analyzed in previous Safety Analysis Reports. Since the gap area affects the amount of radioactive material that can be forced out of a cell by the air pressure of an explosive accident, plant personnel immediately reported the variance and initiated an Unreviewed Safety Question.

To resolve the issue, the plant immediately implemented measures to reduce the amount of high explosives and plutonium allowed in the cell and then modified the doors to close the total gap area of each cell to less than 42 square inches. Additional modifications have been designed to further close the gap area of each cell to less than 5 square inches. These modifications have been approved and funded for implementation in Fiscal Year 1997. The Final EIS includes health risk analysis of cell accidents that portray a bounding gap area (42 square inches) and the future gap area (5 square inches).

In the interim period until modifications are completed, Pantex Plant is operating the cells under a Justification for Continued Operation (JCO) (MH 1996d). This JCO establishes administrative controls to minimize the consequences of a potential accident until the

How are Radiation Risks from Pantex Plant Operations Evaluated in the EIS? The discussion of risk in this EIS provides two relative comparisons:

- Between the risks from Pantex Plant operations and the risks from other causes.
- Between the alternatives under consideration in this EIS.

Baseline Cancer Incidence:

- Cancer incidence is defined as the probability of contracting a fatal cancer among individuals or groups of individuals. Approximately 20 percent of all deaths in the U.S. are from cancer (NAP 1990). Consequently an individual has, on average, a lifetime fatal cancer probability of approximately 0.2 (20 percent) from all causes. This probability varies from group to group and from individual to individual. Thus, this EIS uses the 20 percent figure solely to provide a relative comparison between baseline cancer incidence and the increase in fatal cancer probability from exposures related to Pantex Plant operations.
- Cancer incidence can also be described in terms of individual or societal risk. For the purpose of making comparisons between different contributors to risk, the risk associated with a specified event is defined as the "Consequence" of the event per unit of time. For example, there are approximately 25,090 deaths from cancer per year in the State of Texas. The total societal risk from cancer can therefore be defined as 25,090 deaths per year. Because the State of Texas contains approximately 17 million residents, the average individual risk is defined as:

$$\frac{\text{25,090 fatal cancers/year}}{\text{16,986,510 residents}} = 1.5 \times 10^{-3}\ \frac{\text{LCF for an individual}}{\text{year}}$$

Similarly, a person in the vicinity of Pantex Plant has an annual fatal cancer risk of 1.7×10^{-3} excess cancer fatalities/year. With 267,107 residents in the Pantex Plant Region of Influence, the societal risk from cancer can be calculated as:

$$\left[\frac{1.7 \times 10^{-3}\ \text{fatal cancers}}{\text{year individual}}\right][\text{267,107 residents}] = \text{454 fatal cancers per year}$$

The annual fatal cancer risk varies from group to group and from individual to individual. Thus, these calculations are used in the EIS solely to provide a relative comparison between baseline cancer risk and any increase in cancer risk from Pantex Plant operations.

Risk Factors for Radiological Exposures

- Exposure to ionizing radiation increases a person's likelihood of experiencing a latent cancer fatality. It is referred to as "latent" because the cancer may take many years to develop and for death to occur.
- Radiation exposure can cause other health effects, including non-fatal cancers and genetic effects. This EIS uses the risk of excess cancer fatality as the basis for comparison of impacts among alternatives. The International Commission on Radiological Protection conservatively estimates the total detriment (fatal cancers, non-fatal cancers, and genetic effects) by multiplying the estimates of excess cancer fatalities by 1.46.

FIGURE 4.14.2.1–1.—*Evaluation of Risk.*

Risk Factors for Radiological Exposures (Continued)

- DOE uses risk factors that are recommended by both National and International radiological protection organizations. The public and occupational health risk from radiological exposures analyzed in the EIS uses dose-to-risk conversion factors established in the National Research Council's Committee on the Biological Effects of Ionizing Radiation BEIR V Report, 1990 (NAP 1990). These risk factors have also been endorsed by the International Commission on Radiological Protection, U.S. Environmental Protection Agency, Nuclear Regulatory Commission, and National Council on Radiation Protection and Measurements. These risk factors are 0.0005 death per rem to the general public and 0.0004 deaths per rem for workers (the lower number for workers accounts for the absence of children in the workforce).

DOE's Position on Societal Risks from Accidents

- The number of cancer fatalities from accidents should be less than one-tenth of one percent of the number of cancer fatalities from all causes in the population at risk (Nuclear Safety Policy Notice, SEN-35-91, U.S. Department of Energy, Washington, DC, Secretary of Energy, September 9, 1991).
- This position implies a limit to the societal risk from accidents resulting from DOE activities at Pantex Plant to approximately 0.45 cancer fatalities per year in the Region of Influence (i.e., 0.001 x 454 cancer fatalities/year).

How is the Societal Risk from Potential Pantex Plant-related Accidents Evaluated for the Public Surrounding Pantex Plant?

- Risk is defined as Frequency x Consequences, or more specifically, the expected number of excess fatal cancers per year due to accidents at Pantex Plant. Where:

  Frequency = The number of expected occurrences per year of specific accident scenarios.

  Consequences = The expected number of excess fatal cancers given the occurrence of specific accident scenarios.

- For example, Accident Scenario 1-configuration 2 is expected to occur with a frequency of 1.1×10^{-5} per year. The consequences given the occurrence of this scenario would be 3.3×10^{-1} excess fatal cancers. Therefore, the societal risk from this potential accident is 3.5×10^{-6} excess fatal cancers per year. The average individual risk in the ROI from this potential accident is defined as:

$$\frac{3.5 \times 10^{-6}}{267{,}107} = 1.3 \times 10^{-11} \text{ excess fatal cancers/year}$$

- The societal risk from the risk-significant accidents for configuration 1 listed in Table 4.14.2.1–2 is approximately 1.5×10^{-5} excess fatal cancers per year. The average individual risk from the risk significant accidents is approximately 5.6×10^{-11}.

FIGURE 4.14.2.1–1.—*Evaluation of Risk*-Continued.

How are Cancer Risks Estimated for Exposures Received from Pantex Plant Normal Operations?

- The risk from exposures received from Pantex Plant operations is calculated as frequency x consequence.

  For exposures received during normal operations, frequency = 1.0.

  For a 10-year worker population exposure of 330 person-rem:

  $$\text{Risk} = (1) \times (330 \text{ person-rem}) \times \left(4 \times 10^{-4} \ \frac{\text{excess cancer fatalities}}{\text{rem}}\right) = 0.13 \text{ cancer fatalities}$$

  The value 0.13 cancer fatalities is the average number of excess cancer deaths that would result if a total dose of 330 person-rem were applied to many different groups of 330 people. The most likely outcome is zero excess cancer fatalities.

FIGURE 4.14.2.1–1.—*Evaluation of Risk*-Continued.

end objective of reducing the door gap area to 5 square inches is reached.

Currently, nuclear explosive cells (gravel gerties) have a bounding overall leak area of 42 square inches. Pantex Plant will reduce these leak areas such that the total leak area will be less than 5 square inches. For the purpose of analysis, Scenario 1, Configuration 1 assumes a 42-square inch leak area for the gravel gerties. The societal and individual risks from this configuration are presented in Table 4.14.2.1–2 and in the text in the following section.

Scenario 1, Configuration 2 is representative of the plant configuration when a leak area of less than 5 square inches is achieved. Table 4.14.2.1–3 presents the changing risks for Scenario 1 and for the overall societal risk. Individual exposure and risks for both the 5-square inch and 42-square inch configuration are discussed in the following section.

The societal risk in the Pantex Plant ROI from potential plant accidents is also dependent on the storage configuration of the Zone 4 West magazines. Two configurations are analyzed that describe the changes in storage configuration expected in the future. The changes in storage configuration expected in the next 10 years involves the increase in pit storage and corresponding decrease in weapon storage within Zone 4 West. Configuration 1 involves the storage of 12,000 pits within Zone 4 West in 36 total magazines. The remaining 24 magazines are in use for weapons storage. The societal and individual risks from this configuration are presented both in Table 4.14.2.1–2 (Scenarios 3 and 8) and in the following section. This configuration presents the highest risk for Pantex Plant operations.

Configuration 2 is representative of the plant configuration as fewer weapons and more pits are stored within Zone 4 West. Configuration 2 includes 60 magazines for pit storage and no weapons storage within Zone 4 West. The overall societal risks from potential accidents decrease as the storage configuration evolves. Table 4.14.2.1–3 presents the changing risks for those scenarios affected (Scenarios 3 and 8) by the storage configuration evolution as well as the change in overall societal risks.

Discussion of Risk Significant Accident Scenarios

The description of Scenario 1 includes explicit calculations for deriving the value discussed. These calculations are included to provide an example of how the values in the rest of the scenarios were derived. Unless otherwise noted, accident frequencies are based on the 2,000 weapons operational level.

Scenario 1: Explosive Driven Plutonium Dispersal from an Internal Event. Nuclear weapons may be made with either conventional or insensitive HE, depending upon weapon design. Scenario 1 represents the accidental detonation of conventional HE in the presence of plutonium due to an internally initiated event. HE is present with radioactive materials in facilities where nuclear explosives work occurs. Initiators for this scenario include accidental actuation of an electro-explosive device during disassembly and handling accidents. Insensitive HE is a negligible risk contributor because it is not susceptible to ignition under the conditions existing during assembly or disassembly operations. Insensitive HE is, thus, not a credible explosive source for this scenario.

Scenario 1 is comprised of three individual cases in which an accidental HE detonation is postulated to be initiated by an internal event. These cases differ in where the accidental detonation occurs; i.e., in a nuclear weapons assembly and disassembly cell, a bay, or a special purpose building. An HE detonation during assembly or disassembly would lead to the dispersal of radioactive material. Weapons are designed so that, in the event of an accidental detonation, there will be no significant nuclear reactions. Positive measures are engineered into nuclear explosives to preclude a nuclear yield from an accidental HE detonation.

For operation on 2,000 weapons annually, the frequency of Scenario 1 is 1.1×10^{-5} per year. It is, thus, *extremely unlikely* (frequency of occurrence is less than 10^{-4} per year but greater or equal to 10^{-6} per year). The derivation of this frequency involves summing of probabilities of different initiating events in different facilities (see appendix D, section D.4.1). Explosive driven plutonium dispersal from an internal event can result from operations conducted in bays, cells, or special purpose facilities. The probability per operation that an operational error could cause an explosive driven plutonium release was estimated for each facility using data from available safety analyses (see references mentioned in section 4.14.2.1 as well

TABLE 4.14.2.1–3.—*Societal Risk Evolution*

SCENARIO	CONFIGURATION 1	CONFIGURATION 2
Scenario 1 (Explosive Dispersal)	6.3×10^{-6} excess fatal cancers per year	3.5×10^{-6}excess fatal cancers per year
Scenario 3 (Explosive Dispersal)	7.2×10^{-6} excess fatal cancers per year	4.9×10^{-7}excess fatal cancers per year
Scenario 8 (Fire Dispersal)	2.9×10^{-7} excess fatal cancers per year	6.6×10^{-7} excess fatal cancers per year
Overall Risk	1.5×10^{-5} excess fatal cancers per year	5.7×10^{-6} excess fatal cancers per year

Configuration 1: Cell leak area = 42 square inches, Zone 4 storage configuration of 36 magazines with pits, 24 magazines with weapons.
Configuration 2: Cell leak area = 5 square inches, Zone 4 storage configuration of 60 magazines with pits.

as those cited in individual scenario descriptions). The frequency per year was then quantified by multiplying the probability per operation by the annual number of operations in each facility and summing the results.

Should this scenario occur, the public dose impact is estimated to be 1,200 person-rem for a cell leak area of 42 square inches and 660 person-rem for a cell leak area of 5 square inches. The consequence of Scenario 1 would be 5.9 x 10^{-1} excess fatal cancers in the population within 80 kilometers (50 miles) of Pantex Plant for a cell leak area of 42 square inches and 3.3 x 10^{-1} excess fatal cancers for a cell leak area of 5 square inches.

The derivation of this consequence involves calculating a weighted average of the consequence from the event occurring in bays, cells, and special purpose facilities. The consequences are calculated separately for the Scenario 1 accident occurring in a cell, bay, or special purpose facility. A weighted average is then obtained by multiplying the consequence related to each facility by the frequency of the event occurring in that facility and then summing the results. This result, which represents the overall risk, is divided by the frequency of Scenario 1 to obtain the frequency weighted consequence for the scenario. This process is illustrated in Figure 4.14.2.1–2.

λ_S = Frequency that Scenario 1 occurs in a Special Purpose Facility

C_S = Consequence if Scenario 1 occurs in a Special Purpose Facility

λ_B = Frequency that Scenario 1 occurs in a Bay

C_B = Consequence if Scenario 1 occurs in a Bay

λ_C = Frequency that Scenario 1 occurs in a Cell

C_C = Consequence if Scenario 1 occurs in a Cell

$$\text{Frequency of Scenario 1} = \lambda_S + \lambda_B + \lambda_C$$

$$\text{Risk from Scenario 1} = \lambda_S C_S + \lambda_B C_B + \lambda_C C_C$$

$$\text{Consequence if Scenario 1 occurs} = \frac{\lambda_S C_S + \lambda_B C_B + \lambda_C C_C}{\lambda_S + \lambda_B + \lambda_C}$$

2101

FIGURE 4.14.2.1–2.—*Consequence Calculation for Scenario 1.*

The bounding public dose impact to an individual is represented by a hypothetical person is located at the site boundary closest to the radiological release. The wind is assumed to blow the radiological release directly towards this individual. The bounding dose impact to a non-involved worker is represented by a hypothetical person located 100 meters (328 feet) downwind of release point. The exposures to the MEOI and to the non-involved worker for each of the cases is presented in Table 4.14.2.1–4.

The MEOI exposure is dominated by the case in which the accidental explosion occurs in a cell using a cell leak area of 42 square inches (i.e., for Configuration 1). The MEOI exposure is dominated by the case in which the accidental explosion occurs in either a bay or a special purpose facility using a cell leak area of 5 square inches (i.e., for Configuration 2). The doses for all accident scenarios are given as committed effective dose equivalents, which mean a 50-year committed dose, not an acute exposure.

The exposure to the maximally exposed non-involved worker is dominated by the case in which the accidental explosion occurs in a cell. The non-involved worker would be expected to receive an exposure of 2300 rem using a cell leak area of 42 square inches and exposure of 600 rem using a cell leak area of 5 square inches. This exposure to the non-involved worker is greater for the cell case because the plume of plutonium exits the cell at ground level and over a longer period of time through the very small gaps under the cell doors. Alternatively, the plume for the bay case or special purpose building case would exit very quickly through the roof. In addition, the cell case plume is less energetic, which would result in higher nearby concentrations. Public risk issues are discussed in detail later in this section as well as in Figure 4.14.1.1–1.

Note that the dose to the MEOI presented here is the bounding consequence for this accident scenario. As illustrated in Table 4.14.2.1–4, this scenario covers the consequences from three facilities, cell, bay, and special purpose buildings. Each facility has a slightly different consequence. Likewise, within each facility, operations on differing weapon systems occur. Each of these different weapon systems would have a different consequence at the site boundary. For example, in the Bay Safety Analysis Report (DOE 1996i), a dose range of 3 to 30 rem is estimated. This difference is dependent on the HE/Pu ratios from different weapon systems. However, the dose estimates in this document are point estimates that bound all weapons related operations at Pantex Plant.

The MEOI dose is a consequence measure, not a risk estimate. The reason for this is because the MEOI is an entirely hypothetical receptor. A reasonable estimate of the frequency that such a receptor is exposed to the scenario requires

TABLE 4.14.2.1–4.—*Representative Doses (REM CEDE) to Maximally Exposed Offsite Individuals and Non-Involved Workers for Individual Cases in Scenario 1*

SCENARIO 1 CASES	MEOI DOSE	NON-INVOLVED WORKER DOSE
Cell Case	49(11)[1]	2,300 (600)[1]
Bay Case	34	34
Special Purpose Building Case	34	34

[1]For 5-square inch cell leak area
Source: Calculations using MACCS model and ERAD model

multiplying the scenario frequency by the probability that a receptor is actually located at the nearest point on the site boundary when the accident occurs, and further multiplying by the probability that the wind is blowing toward the receptor. Although available data are too limited to permit quantifying the probability that a receptor is actually located at the nearest point on the site boundary, the probability that the wind is blowing towards that point is approximately 0.05 for Scenario 1.

No prompt fatalities would be expected among members of the public. However, workers within the cell at the time of an accidental explosion would not be expected to survive. With 267,107 people in the ROI, the average risk to a person in the ROI is on the order of 2.4×10^{-11} excess fatal cancers per year with a cell leak area of 42 square inches and 1.3×10^{-11} excess fatal cancers per year with a cell leak area of 5 square inches. The increased annual risk to a person is calculated by multiplying the frequency of the accident by the public consequences which have been averaged over the population in the ROI (i.e., 1.1×10^{-5} per year x 5.9×10^{-1} excess fatal cancers spread over 267,107 people). Cancer statistics indicate that the fatal cancer risk from all causes to a person in the vicinity of Pantex Plant is 1.7×10^{-3} fatal cancers per year.

The societal risk (annual expected number of excess cancer fatalities) is 6.3×10^{-6} excess fatal cancers per year (see Table 4.14.2.1–3) for a cell leak area of 42 square inches and 3.5×10^{-6} excess fatal cancers per year for a cell leak area of 5 square inches. This number is calculated by multiplying the excess fatal cancers resulting from the accident by the frequency of the accident (i.e., 5.9×10^{-1} excess fatal cancers x 1.1×10^{-5} per year).

Scenario 2: Accidental High Explosives Detonation from an Internal Event. This scenario represents the accidental detonation of HE, but without radioactive material present, due to an internally initiated event. This includes accidents associated with HE development, manufacturing, testing, evaluation, and treatment. Initiators that contribute to this scenario include handling accidents and mechanical failures resulting in HE detonation during HE machining (Pantex 1993).

The likelihood of this event is *anticipated* (frequency of occurrence greater than or equal to 10^{-2} per year). A fatal accident of this type has occurred once at Pantex Plant (in 1977) in over 40 years of operation. The specific circumstances that led to the prior occurrence no longer exist. The manually operated HE machining process was replaced by a robotic process.

This scenario poses a risk to worker safety. There is a possibility of a fatal injury resulting directly from the HE explosion, not from radionuclide exposure. Members of the public and non-involved workers are not at risk from this scenario.

Scenario 2 has a higher frequency than Scenario 1 because HE development, manufacturing, testing, evaluation, and treatment routinely expose bare HE to external stresses (e.g., stresses associated with HE machining) greater than the stresses associated with routine assembly/disassembly operations. If these stresses exceed allowable limits, an inadvertent HE detonation is possible. Although accidental HE detonations of the type included in Scenario 2 have occurred at Pantex Plant, none of the accidents included in Scenario 1 have been experienced.

Scenario 3: Explosive Driven Plutonium Dispersal from an External Event or Natural Phenomena. This scenario represents the accidental detonation of HE, in the presence of plutonium and tritium, due to an aircraft crash. HE is present with radioactive materials within nuclear explosives and in facilities where nuclear explosives work occurs. Initiators that contribute to this scenario include an aircraft impact initiated HE detonation in a Zone 12 facility containing nuclear material and an aircraft impact initiated HE detonation in a Zone 4 nuclear weapon storage magazine (DOE 1992f).

This scenario is dominated by an aircraft impact into a Zone 4 weapons magazine resulting in the HE detonation of numerous weapons with a small contribution from aircraft impacts into nuclear explosive bays. The overall likelihood of this scenario occurring is *not reasonably foreseeable* (frequency of occurrence is less than 10^{-6} per year). The public dose impact from this event is estimated to be 16,000 person-rem. No prompt fatalities would be expected in members of the public. The MEOI would be expected to receive an exposure of 60 rem. This corresponds to an incremental increase in lifetime fatal cancer probability of 3×10^{-2}. The 100-meter (328-foot) non-involved worker is not expected to survive the aircraft crash and explosion. If the individual did survive, the maximum expected dose would be 40 rem corresponding to an increase in lifetime fatal cancer probability of 1.6×10^{-2}. The non-involved worker is closer to the postulated release than the MEOI, yet receives a lower dose. This is due to the initial buoyancy of the released material as a result of the explosively driven dispersal event.

Considering the likelihood and consequence of this scenario, on the average, a member of the public will have an increased risk of developing a fatal cancer from this potential accident of 2.7×10^{-11} excess fatal cancers per year. The annual fatal cancer risk to a person in the vicinity of Pantex Plant from all causes is 1.7×10^{-3} fatal cancers per year.

Scenario 4: Accidental High Explosives Detonation from an External Event or Natural Phenomena. This scenario represents the accidental detonation of HE, with no radioactive material present, due to a seismic event or an aircraft crash. The scenario could occur in staging facilities and facilities involved with HE development, production, and disposal. The main initiator of this scenario is the seismic collapse of an HE development or manufacturing facility (Pantex 1993). These facilities tend to have lower structural strength than nuclear facilities.

The overall likelihood of this scenario occurring is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year). The blast resulting from the explosion could fatally injure a worker in the vicinity. Members of the public and non-involved workers are not at risk from this scenario.

Scenario 5: Tritium Reservoir Failure from an Internal Event. This scenario represents the release of tritium due to a reservoir failure during normal operations. Initiators for this scenario include an inadvertent squib valve actuation during weapon operations.

This type of event has occurred at Pantex Plant, and the frequency of this event is strongly dependent on the number of weapon operations being performed. For the 2,000 weapons activity level, this scenario is *anticipated* (frequency greater than or equal to 10^{-2} per year). For the 500 weapons activity level, this event is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year) (Pantex 1996a, DOE 1995g). This scenario is dominated by handling accidents during weapon operations. The public dose impact from this event is estimated at 8.0×10^{-2} person-rem. The MEOI would be expected to receive an exposure of 1.1×10^{-2} rem. This corresponds to an increase in lifetime fatal cancer probability of 5.5×10^{-6}.

Based upon the tritium exposure in 12–44 Cell 1, cited in section 4.14.1.1, a maximum worker exposure of between 1 and 2 rem is expected. This corresponds to an increase in fatal cancer probability of 8×10^{-4} or less, if the accident occurs. The non-involved worker (i.e., 100 meters [328 feet] downwind) would be expected to receive an exposure of 3×10^{-1} rem. This corresponds to an increase in lifetime fatal cancer probability of 1.1×10^{-4} (see appendix D, Table D.4.2.2–2).

Considering the likelihood and consequence of this scenario, a member of the public would have, on the average, an increase in the risk of developing a fatal cancer from this potential accident of 3.6×10^{-12} excess fatal cancers per year. The fatal cancer risk to a person in the vicinity of Pantex Plant from all causes is 1.7×10^{-3} fatal cancers per year.

Scenario 6: Pit Breach from an Internal Event. This scenario represents a pit breach, with resultant plutonium release, during normal operations. Initiators that contribute to this scenario include a pit drop due to a handling accident and a pit breach due to a forklift accident (Pantex 1996a, DOE 1994w).

This scenario is dominated by handling accidents in bays and special purpose facilities. The overall likelihood of this scenario occurring is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year). The public dose impact from this event is estimated to be 3.7×10^{-4} person-rem. The MEOI would be expected to receive an exposure of 1.0×10^{-4} rem. This corresponds to an increase in lifetime fatal cancer probability of 5.0×10^{-8}.

An individual worker would be expected to receive no more than a 7 rem exposure from Scenario 6 (DOE 1992f:7-40). This corresponds to an upper bound increase in fatal cancer probability of 2.8×10^{-3}, given that the release occurs. The non-involved worker would be expected to receive an exposure of 4×10^{-3} rem. This corresponds to an increase in lifetime fatal cancer probability of 1.6×10^{-6}.

Considering the likelihood and consequence of this scenario, a member of the public would have, on the average, an increase in the risk of developing a fatal cancer from this potential accident of 5.7×10^{-15} excess fatal cancers per year. The fatal cancer risk to a person in the vicinity of Pantex Plant from all causes is 1.7×10^{-3} fatal cancers per year.

Scenario 7: Multiple Tritium Reservoir Failure from an External Event or Natural Phenomena. This scenario represents the release of tritium from reservoir failures caused by a fire in the tritium storage vault. The fire could be initiated by a seismic event or aircraft crash.

The dominant event in this scenario is a seismic event initiated fire in the warehouse surrounding the tritium storage vault. For a release to occur, the protective vault fire door would have to be open and the fire protection system disabled by the seismic initiator. The overall likelihood of this scenario occurring is *not reasonably foreseeable* (frequency of occurrence is less than 10^{-6} per year) (Pantex 1994b, Pantex 1995i). The public dose impact from this event is estimated to be 110 person-rem. The MEOI would be expected to receive an exposure of 7.4×10^{-1} rem. This corresponds to an increase in fatal cancer probability of 3.7×10^{-4}.

A worker inside the vault when the fire started would normally evacuate the area. Should a worker be trapped inside the vault, the expected consequence is a fatality due to heat and smoke inhalation. The non-involved worker would be expected to receive an exposure of 50 rem. This corresponds to an increase in lifetime fatal cancer probability of 2.0×10^{-2}.

Considering the likelihood and consequence of this scenario, a member of the public would, on the average, have an increase in the risk of developing a fatal cancer from this potential accident of 8×10^{-14} excess fatal cancers per year. The fatal cancer risk to a person in the vicinity of Pantex Plant from all causes is 1.7×10^{-3} fatal cancers per year.

Scenario 8: Fire Driven Dispersal Involving Stored Pits from an External Event or Natural Phenomena. This scenario represents a pit breach, resulting in a plutonium release, initiated by a seismic event or aircraft accident. The main initiator for this scenario is an aircraft impact initiated fire in a Zone 4 pit storage magazine (DOE 1994w; DOE 1992f).

This scenario is dominated by a heavy aircraft impact into a Zone 4 pit storage magazine resulting in a fire driven dispersal from numerous pit containers. The overall likelihood of this scenario occurring is *extremely unlikely* (frequency of occurrence is less than 10^{-4} per year but greater or equal to 10^{-6} per year) with 20,000 pits in Zone 4 storage. It is not reasonably foreseeable with 12,000 pits in Zone 4 West. The public dose impact from this event is estimated to be 1,100 person-rem. No prompt fatalities would be expected in members of the public. The MEOI would be expected to receive an exposure of 34 rem. This corresponds to an incremental increase in lifetime fatal cancer probability of 1.7×10^{-2}.

Workers in the vicinity of the crash and explosion would not be expected to survive. The non-involved worker would be expected to receive an exposure of 3,000 rem. This corresponds to an increase in lifetime fatal cancer probability of 1.0. This is a 50-year committed dose equivalent, which means that the radiological exposure is not acute, but occurs over a 50-year time period. Consequently, no actute radiological fatalities are expected (LLNL 1995).

Considering the likelihood and consequence of this scenario, a member of the public would, on the average, have an increase in the risk of developing a fatal cancer from this potential accident of 2×10^{-12} excess fatal cancers per year (with 20,000 pits in Zone 4 West). The fatal cancer risk, from all causes, to a person in the vicinity of Pantex Plant is 1.7×10^{-3} fatal cancers per year.

Scenario 9: Plutonium Dispersal from an External Event or Natural Phenomena. This scenario represents a tritium or plutonium release, without an explosion, caused by a seismic event or aircraft crash. Initiators include an aircraft impact initiated fire in a Zone 12 nuclear explosive facility and a seismic collapse of a special purpose facility (Pantex 1993a).

This scenario is dominated by seismic events resulting in structural failure of special purpose buildings containing nuclear explosives. Many stockpile support activities (e.g., testing and maintenance) are performed in older facilities without the structural strength of the storage magazines. Thus, these facilities are more vulnerable to external events and natural phenomena. The overall likelihood of this scenario occurring is *unlikely* (frequency of occurrence is less than 10^{-2} per year but greater than or equal to 10^{-4} per year). The public dose impact from this event is estimated to be 0.40 person-rem. The MEOI would be expected to receive an exposure of 2.0 rem. This corresponds to an increase in lifetime fatal cancer probability of 1.0×10^{-3}.

A worker in the vicinity of the fire or facility collapse would not be expected to survive. The non-involved worker would be expected to receive an exposure of 3.7 rem. This corresponds to an increase in lifetime fatal cancer probability of 1.5×10^{-3}.

Considering the likelihood and consequence of this scenario, a member of the public would, on the average, have an increase in the risk of developing a fatal cancer from this potential accident of 2.5×10^{-13} excess fatal cancers per year. The fatal cancer risk to a person in the vicinity of Pantex Plant from all causes is 1.7×10^{-3} fatal cancers per year.

Scenarios 10 and 11: Chlorine Releases. All potential accidental chemical releases were evaluated using the risk screening methodology. Chlorine was the risk dominant chemical accident. Chlorine is the only chemical with the potential for significant adverse offsite consequences.

ERPG DEFINITIONS

ERPG–1 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing other than mild transient adverse health effects or perceiving a clearly defined objectionable odor.

ERPG–2 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing irreversible or other serious health effects or symptoms that could impair their abilities to take protective action.

ERPG–3 is the maximum airborne concentration below which nearly all individuals could be exposed for up to 1 hour without experiencing or developing life-threatening health effects.

Table 4.14.2.1–3 identifies chlorine as the hazardous chemical dominating the risk from nonradiological releases (predicated upon the screening methodology described in appendix D). Since chlorine is not carcinogenic, the consequences of exposure to chlorine (primarily acute effects) differ from the consequences of exposure to radionuclides (potential latent cancers). This difference precludes a direct comparison between the risk and consequences associated with hazardous chemical releases and radionuclide releases.

A useful measure of potential human health effects resulting from exposure to non-carcinogenic chemicals is the hazard index. In its most general form, a hazard index is a ratio of the actual exposure of a human receptor to an established exposure limit. If this ratio is appreciably less than unity, no adverse human health effects are expected. If the hazard index is close to unity, some adverse human health effects may occur; and if the hazard index is substantially greater than unity, severe health effects can result.

Numerous exposure limits are available to form a hazard index. Since exposure to an accidental chlorine release is an unlikely, short-duration event, chronic exposure limits are inapplicable. Instead, Emergency Response Planning Guidelines (ERPG) values will serve to develop hazard indices for chlorine exposure.

Scenarios 10 and 11 both involve chlorine releases. The impact of these scenarios represents a residual risk at Pantex Plant and is independent of the alternatives. The rooms in which chlorine gas is used are equipped with a chlorine sensor alarm system that consists of an alarm siren and flashing light located outside the building. The sensor system is set to activate this alarm at a chlorine concentration of 1.0 part per million in the air. The rooms are also ventilated with a floor-level exhaust fan and contain an elevated fresh air inlet.

Scenario 10 is a chlorine release due to failure of system piping and valves or cylinder caused by a seismic event. Scenario 11 is a similar accident initiated by an internal event, such as operator error. Chlorine is used in two facilities, 15–29 and 13–47. A release of chlorine to the environment due to an earthquake is an unlikely event.

Should an earthquake occur with sufficient magnitude to damage one of the facilities that uses chlorine, there is a reasonable chance that the second facility would also be damaged. In each of the two facilities, two chlorine cylinders are in use. Thus, an earthquake that damages both facilities could release the contents from the four chlorine cylinders in use. Other chlorine cylinders in the facilities are not ordinarily expected to contribute to a release initiated by an earthquake. However, in the unlikely event that a chlorine cylinder is stored without its valve cap in place or is substandard structurally when delivered, it is conservatively postulated that Scenario 10 could involve a release from up to six chlorine cylinders. The magnitude of this chlorine release could be as high as 408 kilograms (900 pounds) (Pantex

1996a). For Scenario 11, the expected release to the environment is no more than the contents of one chlorine cylinder, 68 kilograms (150 pounds), and the frequency classification for this release is also unlikely.

Prior assessments disclose that, if Scenario 11 were to occur, an ERPG–1 concentration of 1 part per million is exceeded out to approximately 10.5 kilometers (6.5 miles), an ERPG–2 concentration of 3 parts per million is exceeded out to 6.5 kilometers (4 miles), and an ERPG–3 concentration of 20 parts per million is exceeded out to almost 3.0 kilometers (2 miles) (Pantex 1996a). Using Pantex-specific demographic and meteorological data, it is estimated that less than 1 percent of the downwind population would be exposed to a concentration exceeding ERPG–1 levels, and that even fewer members of the public would be exposed to higher concentrations. Moreover, since ERPG–1 and higher concentrations are perceptible by humans, persons experiencing ERPG–1 or higher concentrations can move away from the chlorine plume, thus minimizing their exposure duration.

Releasing 408 kilograms (900 pounds) of chlorine to the environment would result in approximately 10 percent of the public downwind from the release being exposed to ERPG–1 or higher concentrations, but less than 1 percent would be exposed to concentrations exceeding ERPG–2. Because of the likelihood that people exposed to concentrations in excess of ERPG–1 would evacuate the area of the chlorine plume, no long-term adverse public health impacts are anticipated for Scenario 10.

No adverse health impacts are expected from Scenario 11 for persons capable of evacuating the area of the chlorine plume.

Workers in the vicinity of a chlorine release (either Scenario 10 or 11) could be exposed to chlorine concentrations in excess of EPRG–3 and threshold levels. No long-term adverse health effects are expected for workers who promptly evacuate the area. For any persons incapable of evacuating the area of the chlorine plume, no serious or irreversible health impacts are expected from EPRG–1 or EPRG–2 exposures since the exposure duration is less than 1 hour. Persons incapable of evacuating an area with EPRG–3 concentrations may experience adverse health impacts depending upon the actual chlorine concentrations encountered and the exposure duration. However, chronic lung disease, electrocardiographic changes, and death have occurred in humans exposed to high concentrations of chlorine as a consequence of industrial accidents (Calabrese 1991).

Ultimate Fate of Radionuclides from Accidental Releases

Potential consequences to the Ogallala aquifer from an accidental plutonium release were investigated in conjunction with a Safety Analysis Report and an Environmental Assessment by Los Alamos National Laboratory (LANL) (LANL 1992:1, 2, 10). The hypothetical accident leading to dispersal of plutonium to the environment around Pantex Plant was assumed to be a high-temperature fire caused by a jet plane impact into a Zone 4 storage magazine containing nuclear weapons components, and subsequent ignition of jet fuel.

LANL envisioned that the hypothetical jet fuel fire could disperse fine particulate plutonium downwind of Pantex Plant for a maximum distance of 80 kilometers (50 miles). Prompt decontamination efforts could reduce radiation levels to 0.2 microcuries per square meter, but surface runoff and wind transport could concentrate contamination at playa lakes, where surface soil radiation levels could be as high as 2.0 microcuries per square meter. Surface water infiltrating through this contaminated soil could carry plutonium and decay products down toward the Ogallala aquifer. The model assumed an average recharge rate of 3 centimeters (1 inch) per year (10 times the High Plains average), and that recharge water would reach the Ogallala aquifer at a depth of 20 to 100 meters (50 to 400 feet).

With these conservative assumptions in place, LANL performed two analyses. The first, an ultra-conservative non-dispersive piston-flow model, assumed that a contaminated layer of 3 centimeters (1 inch) of water moves downward through a 1-dimensional column in the unsaturated zone to the water table completely intact (i.e., without interacting with any other water or soils). The results of the non-dispersive piston-flow model indicated that plutonium levels would exceed calculated Environmental Protection Agency drinking water limits (1.3 picocuries per liter) in a 20-meter (50-foot) deep aquifer after approximately 76,000 years at an approximate maximum level of 7,700 picocuries per liter.

The second, more realistic analysis accounted for the processes of dispersion (i.e., mixing processes) that effectively change the composition of water as it would move downward through the soil column. The results showed that when the processes of dispersion were taken into account, peak plutonium levels in the 20-meter (50-foot) aquifer would never exceed the most restrictive drinking water dose limits. Additional factors were also qualitatively analyzed. These included colloidal plutonium transport, preferential flow, the effects of perched aquifers, opportunities for "short-circuit" flow through abandoned wells or other conduits, and fate of daughter products.

Of these factors, the one that would appear to produce the greatest effect would be short-circuit recharge paths to the Ogallala aquifer via unintentional flow through improperly constructed or abandoned water wells or intentional flow to the Ogallala aquifer as part of an artificial recharge project. The risk of short-circuiting along improperly constructed or abandoned wells could be mitigated by identification and sealing of these wells. In the event of a plutonium dispersal accident, active groundwater recharge projects should be monitored and, if necessary, shut down (LANL 1992:1, 11-15, 17-18, 31-32).

The final conclusion of these analyses is that the hypothetical plutonium dispersal accident does not pose a significant threat to the Ogallala aquifer. The assumptions of the analyses are extremely conservative because the scenarios were based on a depth to the water table of 20 meters (50 feet) whereas, at Pantex Plant, the typical depth to the top of perched groundwater is approximately 82 meters (270 feet), and the depth to the main Ogallala aquifer ranges from 104 to 140 meters (340 to 460 feet).

For water table depths of 60 and 100 meters (200 and 400 feet), LANL calculated plutonium travel times of 305,000 and 610,000 years, respectively. Interactions with both surficial materials and the unsaturated portion of the Ogallala Formation would be expected to retard the movement of plutonium relative to the infiltrating water (i.e., plutonium would move at a rate slower than the infiltrating water). During the transport time, radioactive decay would be expected to further reduce plutonium concentrations (LANL 1992:10,12). Where the perched aquifer is present, the downward movement of plutonium would be further reduced, because the low-permeability fine-grained zone would impede downward flow and potential contamination would be more likely to move horizontally and follow the course of buried channel sands and gravels, as discussed in section 4.6.1.2.

Conservatisms

The sequence of analyses performed to generate the radiological impact estimates from normal operation and facility accidents include: (1) selection of normal operational modes and accident sequences, (2) estimation of source terms, (3) estimation of environmental transport and uptake of radionuclides, (4) calculation of radiation doses to exposed individuals, and (5) estimation of health effects. There are uncertainties associated with each of these steps. Uncertainties exist in the way the physical systems being analyzed are represented by computational models and in the data required to exercise the models (due to measurement errors, sampling errors, or natural variability).

In principle, one can estimate the uncertainty associated with each source and predict the remaining uncertainty in the results of each set of calculations. Thus, one can propagate the uncertainties from one set of calculations to the next and estimate the uncertainties in the final results. However, conducting such a full-scale quantitative uncertainty analysis is neither practical nor a standard practice for a study of this type. Instead, the analysis is designed to ensure—through judicious selection of release scenarios, models, and parameters—that the results bound the potential risks. This is accomplished by making conservative assumptions in the calculations at each step.

The models, parameters, and release scenarios used in calculations are selected in such a way that most intermediate results and consequently, the final estimates of impacts are greater than what would be expected. As a result, even though the range of uncertainty in a quantity might be large, the value calculated for the quantity is close to one of the extremes in the range of possible values, so that the chance of the actual quantity being greater than the calculated value is low (or the chance of the quantity being less that the calculated value if the criteria are such that the quantity has to be maximized). This has been the goal of the radiological assessment for normal operation and facility accidents in this study (i.e., to produce results that are conservative).

4.14.2.2 *Impacts of New Facility Construction and Upgrades*

Radiological exposure related to activities associated with new projects and facilities, as described in section 3.1.1, will be small. Additional radiological exposures related to the new projects and facilities are bounded by the Table 4.14.2.1–1 estimates.

The construction of three planned facilities—the Gas Analysis Laboratory, the Materials Compatibility Assurance Facility, and the Nondestructive Evaluation Facility—would reduce risks from operations in current facilities. These facilities would have a reduced risk because they would replace existing facilities used for HE that are susceptible to seismic events.

The Pit Reuse Facility's contribution to risk is expected to be small. As discussed in appendix H, it will introduce a process that breaches the pit tube as part of normal operations, which is not currently undertaken at Pantex Plant. Due to the limited number and nature of pit reuse operations planned, preliminary assessments indicate that incremental risk impacts from the Pit Reuse Facility would be barely perceptible. Further safety assessment would be conducted prior to the pit reuse facility becoming operational.

The human health impacts from the Hazardous Waste Treatment and Processing Facility and the Metrology and Health Physics Calibration and Acceptance Facility are not expected to be significant.

4.14.2.3 *Impacts of Environmental Restoration and Waste Management Activities*

The scope and mission of the Environmental Restoration (ER) program is to assess all inactive solid waste management units, determine the nature and extent of contamination, and perform remediation to eliminate any substantial present or future threat to human health and the environment (Pantex 1995a:15-1 to 15-11). The program is conducted in compliance with all regulatory requirements. All *Resource Conservation and*

Recovery Act Facility Investigation workplans have been approved, and field investigations have been initiated at all sites. Adequate data have been collected on many of the solid waste management units to recommend either no further action or interim corrective action.

The scope and mission of the ER program would not change under any of the alternatives to the Proposed Action. As currently active waste management sites become inactive, they will undergo environmental remediation as required by the *Resource Conservation and Recovery Act* permit (issued jointly by the Environmental Protection Agency and TNRCC) authorizing Pantex Plant to store and process hazardous wastes. Since the purpose of the ER program is to eliminate any substantial present or future threat to human health and the environment, its net impact on human health is to reduce risk.

4.14.3 Impacts from No Action Alternative

Under the No Action Alternative, weapons operations would continue at Pantex Plant to meet the stockpile management requirements. Dismantlement activities would, however, cease when the 12,000 pit storage limit is reached.

The total number of weapons operations under both the Proposed Action and the No Action Alternative are assumed to be similar. Consequently, the frequencies of potential accident scenarios caused by internally initiated events are the same for the Proposed Action and No Action Alternatives. In addition, the impacts from normal operations would be similar.

The main difference between the Proposed Action and No Action Alternatives in terms of potential human health impacts is the number of pits stored in Zone 4 and the effect of this change on the likelihood of an aircraft impact into a storage magazine. The likelihood of an aircraft impact into a pit storage magazine depends on the number of storage magazines in use. The storage of the 12,000 pits associated with the No Action Alternative would require the use of fewer storage magazines than would be required for the 20,000 pit storage level associated with the Proposed Action. The actual number of storage magazines required for 12,000 pits would be dependent on the storage configuration used by the plant. The use of fewer magazines for pit storage reduces the likelihood that an aircraft impact would breach a storage magazine that had pits inside.

An important difference in the impacts of the No Action Alternative is that the following facilities will not be replaced: the Gas Analysis Laboratory, the Materials Compatibility Assurance Facility, and the Nondestructive Evaluation Facility. Without replacing these facilities with upgraded facilities, the existing facilities would remain more susceptible to seismic events.

4.14.4 Impacts of Pit Storage Relocation Alternative

4.14.4.1 *Impacts of Relocating 20,000 Pits*

Relocating 20,000 pits from Pantex Plant would eliminate the risk posed by aircraft crash into pit storage magazines at the plant. Impacts relating to offsite pit shipments are discussed in section 4.12, Intrasite Transportation, and section 4.16, Intersite Transportation of Nuclear and Hazardous Materials.

With the storage of no pits in Zone 4, the societal risk from risk significant accidents is dependent on the level of weapons storage within the 24 SAC magazines: the societal risk from risk dominant accidents is 1.5×10^{-5} excess fatal cancers per year. With no weapon storage within Zone 4, the plant risk is dominated by Zone 12: the societal risk from risk dominant accidents is 7.8×10^{-6} excess fatal cancers per year. Both societal risk estimates presuppose a 42-square-inch release area for cell explosions.

4.14.4.2 *Impacts of Relocating 8,000 Pits*

The significance of relocating 8,000 pits in terms of impacts from potential accidents is similar to the No Action Alternative described above.

With the storage of 12,000 pits, the societal risk is dependent on the level of weapons storage within Zone 4. With the storage of weapons within 24 SAC magazines, the societal risk from risk dominant accidents is 1.5×10^{-5} excess fatal cancers per year. With no weapon storage within Zone 4, the plant risk is dominated by Zone 12, the societal risk from risk dominant accidents is 8.1×10^{-6} excess fatal cancers per year. Societal risk estimates include 42 sq in release areas for cells.

4.14.4.3 *Summary of Human Health Impacts*

Table 4.14.4.3–1 presents a summary of Pantex Plant-related human health impacts from normal operations. Table 4.14.4.3–2 summarizes the impacts of radiological accidents at Pantex Plant.

4.14.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are generally combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

4.14.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

Pantex Plant is a potential site for location of the waste management facilities as described in the WM PEIS. If these facilities are located at Pantex Plant, they could result in additional impacts to workers and the public surrounding the plant. However, the WM PEIS has estimated human health impacts from waste management activities to be low; potential fatalities to the offsite population and to workers are essentially zero for treatment and disposal of low-level waste and low-level mixed waste under every alternative (DOE 1996).

The chemical environment for the Maximally Exposed Individual (due to an atmospheric release) is expected to result in chemical-related fatal cancer incidences ranging from 3×10^{-14} to 2.9×10^{-13}. This is essentially zero risk of fatal cancers from exposure to chemicals.

4.14.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability.

TABLE 4.14.4.3–1.—*Comparison of Human Health Impacts from Pantex Plant Activities for 10 Years of Incident Free Operation at 2,000 Weapons Activity Level*

ACTIVITY	AFFECTED POPULATION	PROPOSED ACTION	NO ACTION	20,000 PIT STORAGE RELOCATION	8,000 PIT STORAGE RELOCATION
Intrasite Transportation and Zone 4 Staging Operations	Public Dose (person-rem)	(3)	(3)	(3)	(3)
	Public Risk from Incident Free Operations (Number of Excess Cancer Fatalities)	NA	NA	NA	NA
	Worker[1] Dose (person-rem)	61	44	344	174
	Worker[1] Risk from Incident Free Operations (Number of Excess Cancer Fatalities)	2.4×10^{-2}	1.8×10^{-2}	1.3×10^{-1}	6.6×10^{-2}
Pit Repackaging	Public Dose	(3)	(3)	(3)	(3)
	Public Risk from Incident Free Operations (number of excess cancer fatalities)	NA	NA	NA	NA
	Worker Dose (person-rem)	300[(4)]	180[(5)]	300	300
	Worker Risk from Incident Free Operations (number of excess cancer fatalities)	1.2×10^{-1}	7.2×10^{-2}	1.2×10^{-1}	1.2×10^{-1}
Weapons Operations	Public Dose (person-rem)	1.37×10^{-3}	1.37×10^{-3}	1.37×10^{-3}	1.37×10^{-3}
	Public Risk from Incident Free Operations (Number of Excess Cancer Fatalities)	6.85×10^{-7}	6.85×10^{-7}	6.85×10^{-7}	6.85×10^{-7}
	Worker[1] Dose (person-rem)	330	330	330	330
	Worker[1] Risk from Incident Free Operations (Number of Excess Cancer Fatalities)	1.3×10^{-1}	1.3×10^{-1}	1.3×10^{-1}	1.3×10^{-1}
Intersite Transportation[2]	Public Dose (person-rem)	4.0	4.0	7.0	5.2
	Public Risk from Incident Free Operations (Number of Excess Cancer Fatalities)	1.8×10^{-3}	1.8×10^{-3}	3.3×10^{-3}	2.4×10^{-3}
	Worker[1] Dose (person-rem)	3.2	3.2	16.5	8.2
	Worker[1] Risk from Incident Free Operations (Number of Excess Cancer Fatalities)	1.2×10^{-3}	1.2×10^{-3}	6.6×10^{-3}	3.3×10^{-3}

[1]Worker—Involved workers who receive radiation exposures as a result of their work. Non-involved workers have the same risks as the public.
[2]To provide a bounding case, calculations assumed a 100 percent increase in current shipment schedule.
[3]No impacts to the public are expected from these operations.
[4]Includes the repackaging of 20,000 pits.
[5]Includes the repackaging of 12,000 pits.
NA - Not applicable.

TABLE 4.14.4.3–2—*Representative Impacts from Pantex Plant Radiological Accidents*

SCENARIO	DESCRIPTION	INVOLVED WORKER (rem—50-year CEDE)	MAXIMALLY EXPOSED OFFSITE INDIVIDUAL (rem—50 year CEDE)	NON-INVOLVED WORKER (rem—50 year CEDE)	PUBLIC DOSE (person-rem)	ANNUAL SOCIETAL RISK (excess cancer fatalities per year)
1	Explosive driven plutonium dispersal from internal event	Fatalities	Cell: 49 (11)[a] Bay: 34	Cell: 2300 (600)[a] Bay: 34	1,200 (660)[a]	6.3×10^{-6}) (3.5×10^{-6})[a]
3	Explosive driven plutonium dispersal from external event/natural phenomena	Possible fatalities*	60	40	16,000	7.2×10^{-6}
5	Tritium reservoir failure from internal event	2 rem	1.1×10^{-2}	0.30	0.030	9.5×10^{-7}
6	Pit breach from internal even	7 rem	1×10^{-4}	4×10^{-3}	0.00037	1.5×10^{-9}

8	Fire driven release from external event/natural phenomena	Possible fatalities*	34	3,000	1,100	2.9×10^{-7}
9	Tritium or plutonium release caused by seismic event or aircraft accident	Possible fatalities*	2.0	3.7	0.40	6.8×10^{-8}

[a]For cell leak area of 5 square inches.

*Fatalities are possible if personnel are present in the vicinity of the facility.

Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, human health impacts from operations are expected to be less than current impacts. The average radiological dose to workers would not be expected to change. The total worker dose, however, would change due to the reduced number of workers associated with a reduction in workload. Potential impacts from accidents, which are essentially independent of the level of operation, would not be expected to change.

Under the downsizing alternative, the average worker dose at Pantex Plant would be approximately 10 mrem per year. This would result in a total worker dose of 3.0 person-rem year, statistically equating to approximately 1 fatal cancer every 833 years. The incremental dose to the population within 80 kilometers (50 miles) would be 4.0×10^{-4} person-rem per year. The probability of a member of the public dying from cancer would be 2.0×10^{-7} year. Potential impacts from accidents were determined using computer modeling. For the composite accident, less than one fatal cancer would be expected for the population within 80 kilometers (50 miles).

4.14.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. The annual dose to the public from the collocated facility would be 5.3×10^{-5} person-rem. This would cause an estimated 1.3×10^{-6} fatal cancers during 50 years of operation. The alternative of storing surplus pits from RFETS at Pantex Plant in the near-term could cause less than 10^{-2} fatal cancers for affected workers due to repackaging operations. There would be no effect to the public.

The final S&D PEIS will include an alternative that is a refinement of these storage alternatives. As discussed in sections 1.4 and 1.7.3 of this volume, the final S&D PEIS will include an alternative under which pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. The impacts of this alternative are fully accounted for in this EIS because the pits from RFETS could not cause the total number of pits stored in Zone 4 to exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Furthermore, RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide (MOX) fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

During normal reactor operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. All doses would be within radiological limits and well below levels of natural background radiation (DOE 1996a:4.0).

4.14.6 Potential Mitigation Measures

DOE will continue to strive to reduce radiological exposures to plant workers. Radiological exposures incurred from future weapons operations will be controlled and minimized by Pantex Plant procedures, administrative controls, and an active ALARA program that promotes work practices that minimize worker exposures. The magnitude of radiological exposures to workers and safe radiological worker practices are dictated by the Pantex Radiological Control Manual, and ultimately, by 10 CFR 835.

Section 4.14.1.4 contains detailed information about accident mitigation.

(This Page Intentionally Left Blank)

4.15 AIRCRAFT ACCIDENTS

4.15.1 Affected Environment

Aircraft accidents are a concern at Pantex Plant because of the volume of local air traffic, the proximity of Pantex Plant to flight paths into and from the Amarillo International Airport, and overflights. Even though the likelihood of an aircraft crash at Pantex Plant is small, a crash has the potential of releasing radioactive material from Pantex Plant facilities.

The number of annual air operations in the immediate vicinity of Pantex Plant is influenced by several factors. There is a regional air navigational aid, known as a Very High Frequency Omni-Directional Radio Range with Tactical Air Navigation (VORTAC), located within 8 kilometers (5 miles) of Pantex Plant. Because the air traffic in low-altitude and high-altitude air corridors is serviced by the VORTAC, it contributes to the air traffic in the vicinity of Pantex Plant. A significant number of military (primarily Air Force) aircraft conduct instrument approach and landing practice at the Amarillo International Airport. Furthermore, aerial application activities, such as crop dusting for several farm plots near Pantex Plant Site, add to the air traffic volume in the immediate vicinity of Pantex Plant.

4.15.1.1 *Principal Features of Pantex Plant*

The principal features of Pantex Plant are illustrated in Figure 4.3.1.2–1. With respect to aircraft accidents, the primary concern is with the 42 Steel Arch Construction (SAC) magazines and the 18 Modified Richmond magazines in Zone 4 West, and certain buildings in Zone 12. Figure 4.15.1.1–1 shows the layout of the 60 magazines in Zone 4 West (Pantex 1996a:3.1). Typically, no more than four persons work in a Zone 4 magazine. The Zone 4 Safety Analysis Report limits operations to seven personnel inside the magazine. Moreover, no more than five magazines (counting the A and B sides of the Modified Richmond magazines as separate magazines) can be open at any one time (DOE 1992b:8-21). The buildings of concern in Zone 12 are facilities containing nuclear weapons and nuclear weapon components. These include the bays and cells that represent nuclear explosive facilities, the special purpose buildings, and the Zone 12 staging facilities. A layout of Zone 12 South is shown in Figure 4.15.1.1–2.

4.15.1.2 *Current Aircraft Approaches to the Amarillo Airport*

The current VORTAC location relative to Pantex Plant is illustrated on Figure 4.15.1.2–1 (DOE 1995h:16). Because this location is nearly centered on a line between Pantex Plant and Runway 22, aircraft using the VORTAC intercept the final approach course from the beacon in the vicinity of Pantex Plant and pass over it in a straight line toward the runway. Aircraft using the airport's Instrument Landing System (ILS) utilize the signals from the Back Course Localizer (BCL). This system guides the aircraft such that they fly over the northern portion of Zone 4. The BCL approach to Runway 22 is illustrated in Figure 4.15.1.2–2 (DOE 1995h:15).

4.15.1.3 *Comparison with Previous Aircraft Crash Analyses*

There have been several previous assessments of the risk posed to Pantex Plant due to an aircraft crash. These analyses date back to a 1976 study conducted by Sandia National Laboratories. It should be noted that with the exception of the current analysis, all of the past studies conducted for Pantex Plant aircraft crash risk analyses have used the Solomon model with different data sets. A Safety Analysis Report (SAR) for Zone 4 was completed in 1993. The aircraft crash analysis from the Zone 4 SAR was incorporated into the Environmental Assessment for Zone 4, which was released in

FIGURE 4.15.1.2–2.—***Current and Proposed Back Course Approaches.***

January 1994. This document resulted in a Finding of No Significant Impact (FONSI) for the interim storage of up to 12,000 pits in Zone 4.

At that time, the frequency of an aircraft crash into the storage bunkers, which could result in plutonium release, was reported to be 6.6×10^{-7}, and thus termed "incredible". However, an Unreviewed Safety Question Determination (USQD) for the analysis contained in the Zone 4 SAR was issued in the spring of 1995. This determination questioned the validity of the aircraft overflight data used in the analysis. Additionally, the USQD found that the study used an incorrect application of the Solomon model. As part of the USQD, a corrected analysis was presented which gave a new probability of hitting a Zone 4 facility of approximately 2×10^{-5}.

To obtain up-to-date aircraft overflight data for the study presented herein, DOE, with cooperation from the Federal Aviation Administration (FAA), installed a Radar Airspace Monitoring System (RAMS) at the Amarillo International Airport. This system collects data on the number and type of aircraft operations in the vicinity of Pantex Plant. These new data were used in this EIS to help evaluate the likelihood of an aircraft impact into Pantex Plant nuclear facilities. The new data are also being used to close out the USQD. The results of the past and current aircraft crash studies are presented in Table 4.15.1.3–1. As can be seen from these results, the trend for aircraft crash hit probability is in the low to mid 10^{-5} range.

From a risk perspective, the hit and release probabilities (Table 4.15.1.3–1, Hit and Release Probability column) are the values of interest rather than the hit probabilities alone. Analyses of this type tend to be conservative in nature due to the inherent uncertainties. It is difficult to quantify these conservatisms and as a result, the hit and release probabilities for the Final EIS should be considered a conservative point estimate. The issue of conservatism is discussed in section 4.15.7.

4.15.1.4 *DOE Initiatives to Reduce and Monitor Pantex Overflights*

Due to public concern regarding the risk of aircraft crash at Pantex Plant, the Secretary of Energy committed DOE officials to meet with the City of Amarillo, FAA, the U.S. Air Force, and other stakeholders to discuss alternative civilian and military flight patterns. An Overflight Working Group was formed to address ways to reduce the number of aircraft flying over Pantex Plant. Their recommendations are listed below (DOE 1995h:12, 13, 18).

TABLE 4.15.1.3–1.—*Results of Past Pantex Plant Aircraft Crash Analyses*

STUDY	HIT PROBABILITY	HIT AND RELEASE PROBABILITY
SAND 76-0120 (entire site)	4.7×10^{-5}	—
Zone 4 SAR (DOE 1992f) (an incorrect value)	1.85×10^{-6}	6.63×10^{-7}
Zone 4 USQD (Pantex 1995a) (corrected analysis)	1.95×10^{-5}	—
Pantex Plant Pre-Draft EIS (Zone 4, Solomon)	4.0×10^{-5}	—
Pantex Plant Draft EIS (Zone 4, DOE Draft Standard, July 1995 version)	2.4×10^{-5}	9.0×10^{-6}
Pantex Plant Final EIS (Zone 4, DOE Draft Standard, July 1996 version)	1.3×10^{-5}	1.2×10^{-6}

Sources: Studies as listed in table.

- Develop a Memorandum of Understanding (MOU) between DOE's Amarillo Area Office and the local FAA facility. The MOU would permit:
  - — Establishment of a telephone "hot line" between the Approach Control Facility and DOE's Amarillo Area Office Emergency Operations Center. Improved communication would permit the FAA to warn DOE of aircraft nearby with in-flight emergencies. This would allow the plant to modify activities vulnerable to aircraft crashes (completed).
  - — Modified vectoring of approaching aircraft. When aircraft safety will not be affected, air controllers will avoid extended vectoring of aircraft over the plant boundaries (completed).
  - — Use of discretionary holding patterns. When feasible, air controllers would offer a practice holding pattern away from plant boundaries when pilots request such practice (completed).
- Develop and implement a new Global Positioning System (GPS) non-precision approach that tracks around the plant's boundaries. This new navigation system was recently approved by FAA for use in all aircraft. As increasing numbers of aircraft become equipped with GPS, pilots will more frequently request this approach, which routes the aircraft away from plant boundaries (completed). A depiction of this approach is provided in Figure 4.15.1.3–1.
- Build an offset localizer approach with vertical guidance and distance measuring equipment, called an "Localizer Displaced Approach Glide Slope Approach." Because the Runway 22 BCL cannot be angled to the runway, this alternative is suggested. By adding a new antenna array at the end of Runway 22, aircraft equipped with instrument landing systems will be able to arrive along a path angled to the runway. This alternative will move aircraft tracks away from the nuclear materials stored in Zone 4. This new approach is illustrated in Figure 4.15.1.2–2.
- Install a GPS Ground Differential Station that would permit use of GPS precision minimums. FAA indicated that by building a GPS Ground Differential Station near the airfield, navigation accuracy of aircraft will be increased and glide-slope information can be added to the GPS approach mentioned above.
- Install a new enroute-approach navigation aid farther away from the plant (a new VORTAC). After installing this new VORTAC, the older VORTAC located midway between the airfield and the plant would be decommissioned. The new VORTAC station near the airport would permit the moving of existing FAA airways away from the plant. Existing VORTAC approaches that pass over the plant would be eliminated, and if warranted, FAA may elect to develop new approaches to the airport that are angled away from the plant.
- DOE has agreed to study new methods to fortify the areas where nuclear materials are handled or stored. Structures such as "Jersey Walls", fortified bunker entrances, and berms may be considered.

4.15.2 Impacts of Proposed Action

The Proposed Action would include the continued operation of Pantex Plant and the storage of up to 20,000 pits onsite. A quantitative assessment of the frequency (per year) that an aircraft crash could initiate an accidental release of plutonium at Pantex Plant was performed. Three terms were considered in the assessment:

- The frequency of an aircraft impacting the facility (hit probability).

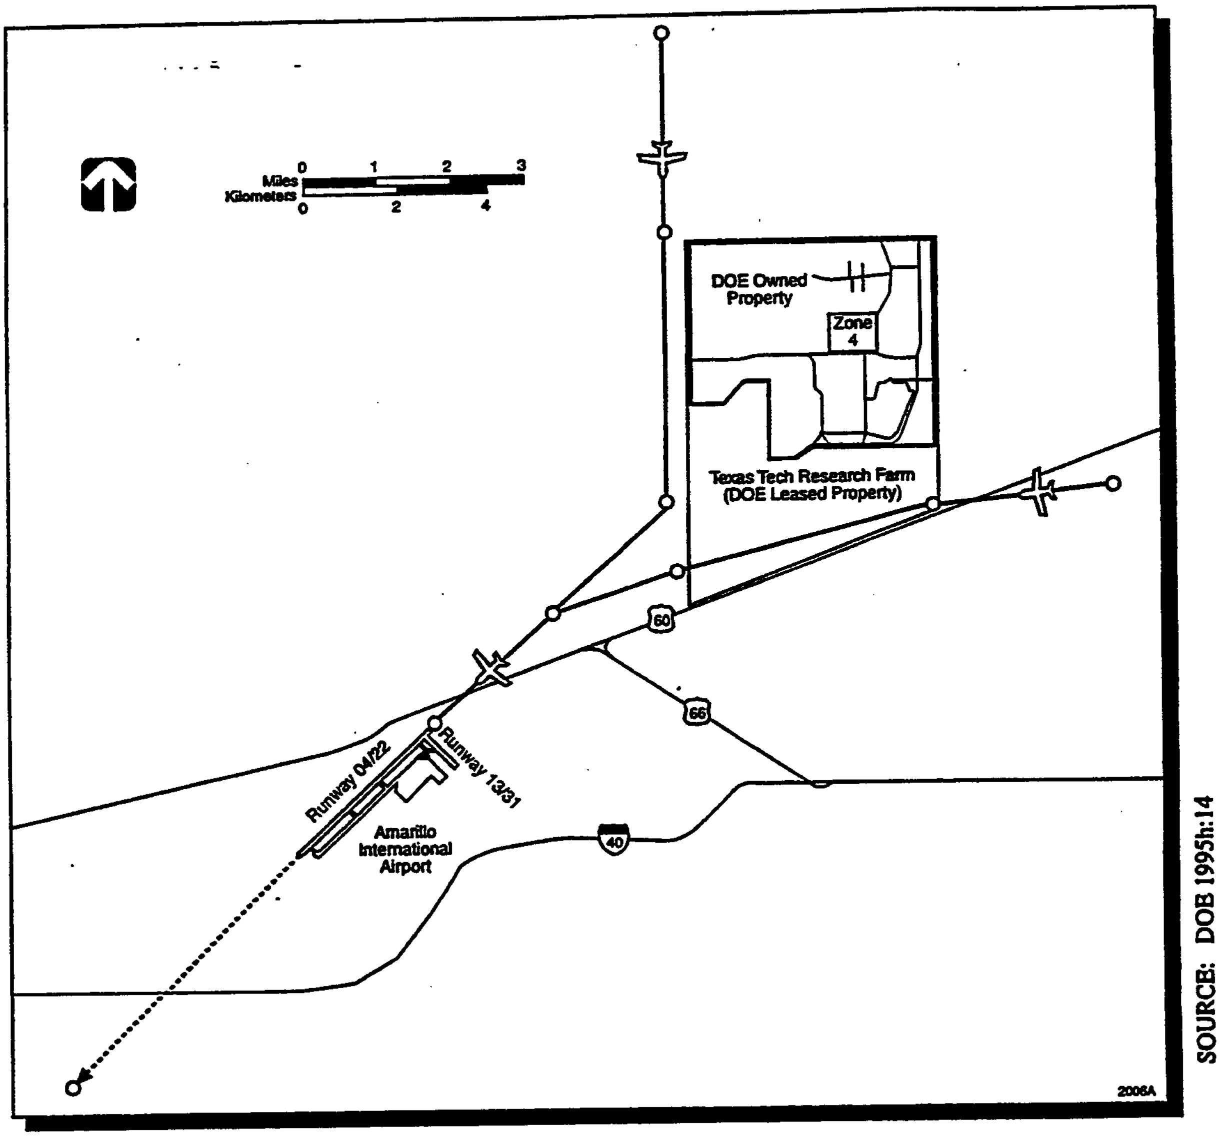

FIGURE 4.15.1.3–1.—*Global Positioning System Approach.*

- The potential of significantly damaging the building by scabbing or perforation, given the impact.
- The potential of a radioactive release, given significant building damage (release probability).

Facility Impact

Figure 4.15.2–1 is a graphical representation of the three events that must occur to have a radioactive material release from a Pantex Plant facility due to an aircraft crash. The frequency of an aircraft impacting a facility was calculated using the *Draft DOE Standard, Accident Analysis for Aircraft Crash into Hazardous Facilities* (Draft DOE Standard) (DOE 1996g). It should be noted that this analysis is applicable to accidents only, not intentional acts of sabotage or terrorism.

Air traffic data (for 6.5 years of runway operations) for the Amarillo International Airport were obtained from the FAA and used in conjunction with approximately 12 months of RAMS data collected at the Amarillo International Airport Tower (PC 1996h). Air traffic data in the vicinity of the airport on an annual basis are summarized in Table 4.15.2–1. Projected building areas and aircraft crash frequency data were combined with the air traffic data to calculate the aircraft impact

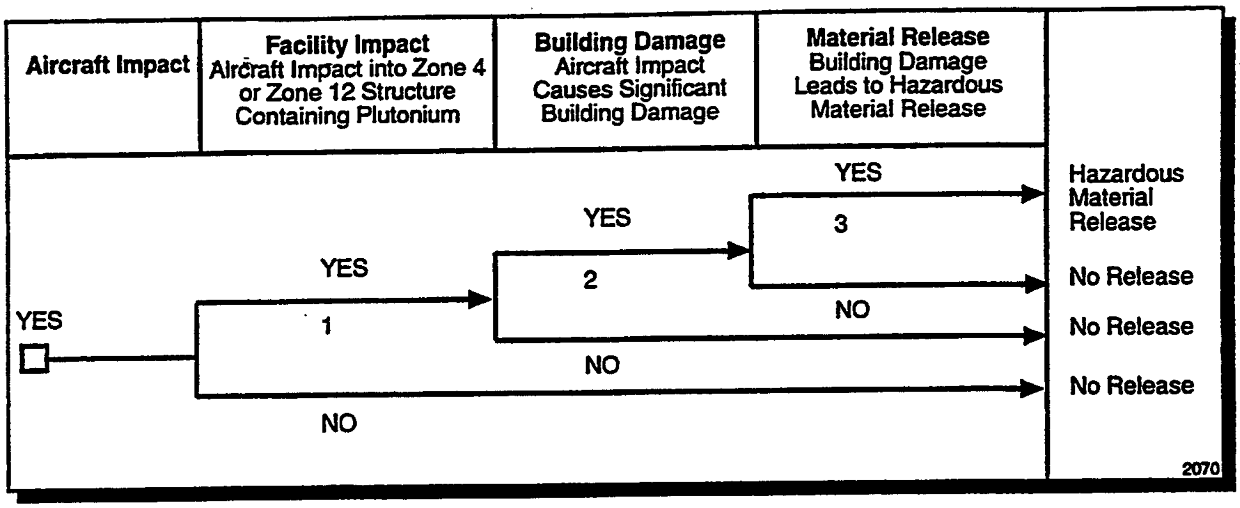

FIGURE 4.15.2–1—*Aircraft Impact Event Tree.*

TABLE 4.15.2–1.—*Maximum Yearly Flight Operations at the Amarillo International Airport*

AIRCRAFT CATEGORY	ANNUAL AIRCRAFT OPERATIONS
Commercial: Air Carrier	13,174
Commercial: Air Taxi	9,938
Military (large and small)	40,640
General (single-engine piston, multi-engine piston, turboprops, turbojets)	29,134
Helicopters	233
Total	93,119

Source: PC 1996h

frequency for Zone 4 and Zone 12 buildings. The likelihood of any aircraft impacting a building in either Zone 4 West or Zone 12 is extremely unlikely (3.2×10^{-5} per year). The likelihood that any aircraft impacts a Zone 12 building is slightly greater than that of impacting a Zone 4 West magazine, primarily due to the fact that the total Zone 12 target area is slightly larger than that of Zone 4 West.

Building Damage

The potential of significant building damage given an aircraft impact is then determined. If an impact occurs, the potential of significant building damage is predicated upon structural analyses that consider the weight and speed of the impacting aircraft compared with the resiliency of the facility. The potential for significant building damage from crashes involving various classes of aircraft was evaluated using the structural evaluation approach presented in the Draft DOE Standard (DOE 1996g). Table 4.15.2–2 presents the building damage matrix for each aircraft class for specific facilities in Zone 4 West and Zone 12. Significant building damage is defined as either *perforation*—when a missile (flying object) generated by an aircraft crash penetrates into a facility—or *scabbing*—when an impact of an aircraft missile on a facility generates a secondary missile inside the facility.

Based on calculations using structural penetration equations provided in the Draft DOE Standard, and given the nature of the heavily reinforced, earth covered structures at Pantex Plant, only about 9 percent of the potential aircraft impacts in Zone 4 West result in significant building damage. Similarly, for Zone 12, approximately 17 percent of the potential aircraft impacts in Zone 12 result in significant building damage.

Material Release

An aircraft impact into a Zone 12 building that causes significant damage may not necessarily lead to a release of radioactive material. Release of radioactive material is *not reasonably foreseeable* for nuclear explosive bays, cells, and special purpose facilities (frequency of occurrence is less than 10^{-6} per year). In addition, the radioactive materials inventory is much less than what would be found in Zone 4 West magazines.

Consequently, the probability of a release in Zone 12 is approximately equal to that for Zone 4 West facilities.

A high explosive (HE) detonation in Zone 4 West is possible only in weapon magazines. However, if an aircraft crashes into a magazine and causes significant damage, it is unlikely that the magazine will contain weapons, since most of the storage magazines will be used for pit storage. For the 12,000-pit case, approximately 70 percent of the magazines will contain pits only, whereas for the 20,000-pit case, up to 100 percent of the Zone 4 West magazines could be occupied by pits only.

An aircraft crash that causes significant damage to a weapons magazine would not necessarily lead to an explosive plutonium release. The likelihood of an explosive release is dependent on numerous factors, including the type of explosive contained within weapons stored in the magazine (conventional or insensitive high explosives) and the nature of the crash and damage to the magazine (e.g., if there is a fire inside the magazine or a missile from the crash impacts a weapon).

For this analysis, it was conservatively assumed that significant building damage to a magazine containing HE (in weapons form) would lead to an explosive plutonium release involving the contents of the magazine. The likelihood of an HE detonation in a weapon magazine due to an aircraft impact is *not reasonably foreseeable* (frequency of occurrence is less than 10^{-6} per year). The aircraft crash analysis in this section and in appendix E focuses on release probability only. This probability is combined with other conditional probabilities and consequences to evaluate the risk due to aircraft crash at Pantex Plant. The consequences and risk associated with this event are discussed in section 4.14.2, Human Health.

An aircraft impact into a Zone 4 pit magazine may damage a large fraction of the pit containers, and an ensuing fire could result in a release of plutonium. An aircraft crash that causes significant damage to a pit storage magazine would not necessarily lead to a plutonium release. Pits are currently stored in AL–R8 containers, which provide significant thermal and impact resistance. In the future, pits will be stored in a new container, the AT–400A, that will provide additional thermal and impact protection. Appendix F provides a description of current and potential future pit containers.

Whether perforation of a pit magazine would result in damage to pit containers is uncertain. In this analysis, it is assumed that 25 percent of the pit containers in a magazine contribute to a release (DOE 1994w:App I). Spilled aircraft fuel is likely to cause a fire in a crash that results in perforation of a storage magazine, and for this analysis it is conservatively assumed that a fire occurs 100 percent of the time. Whether or not this fire involves the contents of the magazine is also uncertain. In this analysis, it is assumed that it does. The likelihood of impact depends on the number of pit magazines in use. For the Proposed Action, the maximum number of pits stored will be 20,000. The likelihood of an aircraft impact causing a release is *extremely unlikely* (frequency of occurrence is less than or equal to 10^{-4} per year, but greater than or equal to 10^{-6} per year).

The risk and consequences of aircraft impacts at Pantex Plant are discussed in section 4.14.2.1, Impacts of Continued Operations. The risk to the public from aircraft impact dispersal accidents is low relative to other risks. A person in the vicinity of Pantex Plant has an approximately 4.3×10^{-12} increase in fatal cancer risk from potential aircraft crash plutonium dispersal accidents compared with a baseline annual fatal cancer risk of 1.7×10^{-3}.

4.15.3 Impacts of No Action Alternative

The likelihood of an aircraft impacting either a weapon magazine or a Zone 12 building is the same as discussed under the Proposed Action.

The likelihood of an aircraft impacting a Zone 4 pit magazine depends on the number of pit magazines in use. For the No Action Alternative, the maximum number of pits stored at Pantex Plant will be 12,000, which would require all 18 Modified Richmond and 18 SAC magazines. This reduces the likelihood of an aircraft impacting a pit magazine and causing a release by 44 percent from the Proposed Action, such that it is *not reasonably foreseeable*. The reason for this disproportional reduction is the preferential storage of pits in Modified Richmond magazines, which are less vulnerable to aircraft impacts than SAC magazines. For the 12,000-pit case it is assumed that the remaining 24 SAC magazines contain weapons. The release frequency for weapons magazines is also *not reasonably foreseeable* (6.8×10^{-7}).

4.15.4 Impacts of Pit Storage Relocation Alternative

The likelihood of an aircraft impacting either a weapon magazine or a Zone 12 building is the same as discussed under the Proposed Action.

As previously stated, the likelihood of an aircraft impacting a Zone 4 pit magazine depends on the number of pit magazines in use. The maximum number of pits stored at Pantex Plant under the Pit Storage Relocation Alternative would be 12,000. As discussed under the No Action Alternative, the relocation of 8,000 pits reduces the likelihood of an aircraft impacting a pit magazine and causing a release by 44 percent from the Proposed Action, such that it is *not reasonably foreseeable*. Relocating 20,000 pits to another site will ultimately reduce the Pantex Plant pit inventory to zero. This would reduce the likelihood of a release from an aircraft impacting a pit magazine at Pantex Plant to zero.

4.15.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

Since the DOE programs have not identified exact locations of buildings where plutonium would be resident, it is not possible to quantitatively determine the impacts from these three programs. Therefore, a qualitative assessment was done comparing the three programs to the existing facilities in use.

4.15.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

The WM PEIS is only concerned with plutonium as transuranic (TRU) waste. Under normal operations Pantex Plant does not produce TRU waste. Actions in the WM PEIS would not affect the locations of plutonium (both in pits and weapons) in Zone 4 or 12. Therefore, there would be no change in the aircraft accident probability from WM PEIS actions.

4.15.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Although the No Action Alternative does not account for the time plutonium is at risk, there would be a reduction in the risk from an aircraft crash because of the reduction in operations. Under the downsizing alternative, there would be a consolidation of facilities and a commensurate reduction in the risk from an aircraft crash due to the fewer number of target facilities. Under the relocation alternative, the risk from an aircraft crash into assembly, disassembly, and HE fabrication facilities would be reduced to zero.

4.15.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons Usable Fissile Materials Programmatic Environmental Impact Statement*

If any of the three storage alternatives (Upgrade Facilities at Multiple Sites, Consolidate Plutonium in One Facility, or Collocate Plutonium and Highly Enriched Uranium in Two Facilities) were implemented, there would be a change in the aircraft crash probability. Since the result of any of these alternatives would be to remove all pits (plutonium not in weapons) from Zone 4, this would reduce the aircraft crash induced release probability. If the Upgrade Alternative is selected, all plutonium pits would be moved to existing buildings 12–66 and 12–82. This would reduce the aircraft accident probability almost proportionally to the number of Modified Richmond and SAC magazines no longer used in Zone 4. The aircraft crash probability in Zone 4 would be only for those magazines where nuclear weapons are staged. The impact of additional plutonium in Zone 12 would be minimal because buildings 12–66 and 12–82 are adjacent to buildings 12–41 and 12–42.

The Consolidation Alternative has two options at Pantex Plant: (1) to build a new facility and modify existing facilities in Zone 12 South or (2) build a new facility in Zone 12 South. Under the first option, there would be a reduction in the aircraft accident probability due to a reduction in the plutonium inventory in Zone 4 and a minimal increase in Zone 12 South as discussed in the Upgrade Alternative. The new facility in Zone 12 South would have a smaller total area (true, shadow, and skid) compared to the pit storage magazines no longer used in Zone 4. There would be an increase in the hit probability for Zone 12 because of the addition of a new facility, but overall, the aircraft accident probability would be reduced. The impacts from the second option, building a new facility, or from the Collocation Alternative, would be similar to the Upgrade Alternative since material would be moved from Zone 4 to Zone 12 South.

The final S&D PEIS will include an alternative that is a refinement of these storage alternatives. As discussed in sections 1.4 and 1.7.3 of this volume, the final S&D PEIS will include an alternative under which pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. The impacts of this alternative are fully accounted for in this EIS because the pits from RFETS could not cause the total number of pits stored in Zone 4 to exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Furthermore, RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant. However, the receipt of pits from RFETS would require additional repackaging activities prior to storing them in Zone 4 (see section 4.12.5.3). Appendix Q of the S&D PEIS indicates that these repackaging and intrasite transportation activities could result in less than 10^{-2} additional latent cancer fatalities. Impacts from the disposition alternatives are not assessed since the S&D PEIS will select a technology and strategy, not a site for disposition.

4.15.6 *Potential Mitigation Measures*

Potential mitigation measures either reduce the frequency of an aircraft impact or reduce the probability that the aircraft impact causes a release due to significant building damage, fire, and/or HE detonation. Results from this study indicate that a large fraction of the risk associated with aircraft crash in Zone 12 comes from older facilities that are not heavily reinforced or earth covered. Recommendations of the Overflight Working Group are presented in section 4.15.1.4. DOE has committed to implement the risk reduction measures proposed by the overflight working group. It is estimated that implementation of the MOU, the offset localizer, relocation of the VORTAC, and 65 percent use of the GPS would result in an 82 percent cumulative risk reduction (DOE 1995h:22). This 82 percent reduction was estimated using the Solomon Model. Fortification of areas and structures in which nuclear materials are handled and stored could further reduce the impact of aircraft accidents.

4.15.7 *Conservatisms*

There are many conservatisms included in the Pantex Plant aircraft accident analysis that, if reduced or removed, have the potential to lower the probabilities of an aircraft crash incident substantially. This section presents some of these conservatisms and explains their effect on the aircraft crash risk to the Pantex Plant.

The Draft DOE Standard was created as a tool to be applied to all DOE sites where hazardous materials exist (DOE 1996g). As a result, it was written in a generic form without much site-specific detail. The Pantex Plant is unique in that it is situated close to an international airport. Because of this proximity, and the weapons operations conducted at Pantex Plant, the public has expressed concern regarding aircraft overflying the plant and crashing into nuclear facilities. DOE, in cooperation with the FAA, has responded to these concerns by attempting to reduce Pantex Plant overflights with the mitigation measures discussed in sections 4.15.1.4 and 4.15.6. When fully completed, these measures will reduce the number of aircraft overflying the Pantex Plant and the risk of an aircraft crash.

However, the Draft DOE Standard, as written, does not allow for consideration of these measures in the risk calculation. For the purposes of this analysis, it is assumed that all aircraft are on approach to the airport on the BCL, which intersects Zone 4 West. Even with the mitigation measures in place to move aircraft away from the current BCL, RAMS data indicate that aircraft do not typically fly this route. RAMS data also indicate high-altitude aircraft flying on defined airways, which is not recognized in the DOE Standard's non-airport methodology.

In the event of an aircraft crash, the assumption used in the aircraft accident methodology is that a skidding aircraft will hit a facility with the same velocity that it had when it began the skid. This results in a highly conservative impact velocity since no credit is taken for drag, friction, or other factors that would reasonably be expected to contribute to a reduction in velocity. Additionally, the impact angles given are conservative when applied to facility roof impacts, because at these angles, it is quite possible that the potential penetrating missiles from the aircraft would simply ricochet off the facility. Pantex Plant has some structures in Zone 12 that are considered structurally "super stout." No credit is taken for these "super stout" facilities in the analysis.

Other conservatisms in the analysis include the assumption that the entire aircraft engine is the penetrating missile of concern. This is conservative since most of the fan shroud would be expected to tear away after striking a facility, leaving the engine shaft as the secondary penetrator. For the purposes of this analysis, it is also assumed that any facility authorized to contain nuclear explosives is occupied by nuclear explosives 24-hours a day, seven days a week (conservative because none of the authorized facilities contain nuclear explosives on a continual basis), and that the probability of an explosion after an accident resulting in a plutonium release is 1. This assumption is conservative because all impacts would not be expected to cause scabbing or perforation sufficient to cause an explosion and there is no consideration given as to whether high explosives are sensitive or insensitive.

Release assumptions are also considered to be highly conservative for several reasons. Potential impacts that could cause a wall or roof to fail, or a collapse of the whole facility, take no credit for the fact that the overburden would likely suppress any fire and prevent dispersal of materials. Further, no credit was taken for the filtration effects provided by earth covers on bays, cells, and Zone 4 West magazines.

A release of plutonium (from a magazine, for example) due to a fire would require sufficient fuel inside the facility to create a fire that would consume (completely surround) the plutonium container for at least 30 minutes. A sustained fire is unlikely since the assumed penetrators (engines) do not carry sufficient quantities of fuel to produce a sustained fire (fuel is typically contained in the wings of the aircraft). Further, there is a high probability that a skidding aircraft, which represents the majority of the risk, would dispense its fuel contents prior to facility impact.

The analysis takes no credit for the protection provided by the pit container (AL-R8) or the ability of the pits to withstand a fire. Pits, by themselves, have some degree of resiliency to fire, and the AL-R8 containers currently being used were previously certified as type B containers (i.e., were designed to withstand an all-consuming 30-minute fire and various drop and puncture tests). The analysis also assumes that 25 percent of the containers in a magazine would be torn open and their contents released as a result of the fire. Given the size of the penetrator (engine), it is unlikely that 25 percent of pit containers would be involved in an aircraft crash or that a sustained fire could occur.

Considering these many conservative assumptions, which could not be quantified, the actual risk associated with aircraft crash is probably much less than the point estimates presented in this document. Similarly, the actual radiological doses resulting from the aircraft accident scenarios are expected to be much less than those presented in section 4.14, Human Health.

(This Page Intentionally Left Blank)

4.16 Intersite Transportation of Nuclear and Hazardous Materials

4.16.1 Affected Environment

Under the Proposed Action or any of the Alternatives the transfer of hazardous material between DOE and Department of Defense (DOD) sites, including nuclear explosives, nuclear components, high explosive(s) (HE), and radioactive wastes would be required. This section discusses the current intersite hazardous material transportation activities related to Pantex Plant. Radiological impacts are emphasized. Nonradiological impacts (i.e., Safe Secure Tractor Trailer [SST] vehicle exhaust) will not be considered; SST traffic will contribute less then one-tenth of 1 percent of the baseline vehicle traffic in the vicinity of Pantex Plant. Appendix F, Transportation Risk Analysis, provides detailed background information on transportation activities.

4.16.1.1 *Radioactive Material Shipments*

Intersite transportation of radioactive materials is governed by the requirements of DOE orders and Nuclear Regulatory Commission and Department of Transportation (DOT) regulations (Code of Federal Regulations [CFR] Titles 10 and 49). The Transportation and Staging Operations Department is responsible for transfers of tritium reservoirs to the Amarillo International Airport. The Transportation Safeguards Division (TSD) is responsible for coordinating offsite transfers of nuclear explosives and nuclear explosive components. The Waste Operations Department is responsible for offsite transfers of radioactive wastes and the Traffic Section of the Packaging and Shipping Department is responsible for coordinating offsite shipments of hazardous material by commercial carriers.

Intersite highway transportation of weapons, nuclear explosive-like assemblies, and weapons components is conducted by the DOE TSD using SSTs. Nuclear explosive-like assemblies not containing plutonium may be transported by air. SSTs are similar in appearance to commercial tractor-trailers but are equipped with unique safety and safeguard features that prevent unauthorized cargo removal and minimize the likelihood of an accidental radioactive material release. SSTs are also equipped with a robust tiedown and restraining system to prevent cargo movement during shipment.

Intersite shipment of tritium reservoirs is conducted by air, or infrequently, by SST. Hardened trailers are used to transport tritium reservoirs between Pantex Plant and the Amarillo Airport. Hardened trailers are similar in design to SSTs. Under contract with DOE and utilizing DOE aircraft, a contractor provides air transportation and related management services in support of the U.S. nuclear weapons program. One of the contractor's main functions is to transport tritium reservoirs to various locations throughout the continental U.S.

Offsite transfers of radioactive wastes and depleted uranium (DU) are performed by commercial trucks. These transfers are conducted in full compliance with Titles 10 and 49 of the CFR, which contain packaging requirements for intersite radioactive material transfers. These requirements are categorized based on the potential hazard of the material being shipped, which, in turn, is based on the type, quantity, and form of the radionuclide(s) being shipped.

Packaging refers to a container and all accompanying components or materials necessary to maintain confinement of radioactive material. For low potential hazard radioactive material, a DOT Type A packaging, designed to retain its contents under normal transportation conditions, is required. For higher potential hazard materials, such as weapons components, a DOT Type B packaging is required. Type B packages must meet all of the requirements for Type A packages as well as the requirement to prevent the release of radioactive material under all credible accident conditions. These conditions include the following:

- A 9-meter (30-foot) drop onto an unyielding surface.
- A dynamic crush test consisting of a drop of a 500-kilogram (1,100 pound) mass from 9 meters (30 feet) onto the container.
- A puncture test consisting of a free drop (greater than 102 centimeters [40 inches]) onto a 15-centimeter (6-inch) diameter steel pin.
- A 30-minute thermal exposure at 800 degrees Celsius (1,475 degrees Fahrenheit).
- Immersion in water for 8 hours (for fissile materials packaging only).

Appendix F provides a discussion of pit containers currently in use or planned for use at Pantex Plant.

Nuclear Explosives

Intersite nuclear explosive transfers are required for the following reasons:

- Weapons currently stored at classified DOD facilities are returned to Pantex Plant for dismantlement.
- Weapons are returned to Pantex Plant from DOD facilities for testing, modifications, component replacement, or repairs.
- Weapons are returned to DOD facilities from Pantex Plant after completion of testing, modifications, component replacement, or repairs.
- Weapons are shipped between Pantex Plant and DOD sites for field testing of subsystems.

SSTs and weapon-specific handling gear (H-gear) containers are used for intersite transportation of nuclear explosives. For a bounding case weapons shipment, an external dose rate of 3 millirem per hour at the outside surface of the trailer has been measured. Typical weapon shipments produce a much lower dose rate. No measurable radiation exposure occurs within the tractor cab (PC 1995q). Certain types of nuclear explosives are transported as complete units and are attached to their H-gear containers. Nuclear warheads, however, are contained in system-specific H-gear packages. All H-gear is designed to allow secure tiedown within SSTs.

Fully assembled nuclear explosives arrive at and depart from Pantex Plant at Zone 4 West. Loading and unloading activities are discussed in section 4.12, Intrasite Transportation.

Plutonium Pits

As part of stockpile management activities at Pantex Plant, a limited number of pits are shipped to Los Alamos National Laboratory (LANL) for testing. Pits are transported intersite by SSTs in FL containers or other approved Type B packages. FL containers are double-containment stainless steel drums categorized as Type B shipping packages. The FL container has an outer steel containment drum (51 centimeters [22.5 inches] in diameter, 127 centimeters [50 inches] in height) and a stainless steel inner containment drum (35 centimeters [13.8 inches] in diameter, 97 centimeters [38 inches] in height).

When a shipment of pits to LANL is required, the pits are repacked into FL containers, within Zone 12, and sealed with a tamper-indicating device. The containers are loaded onto a pallet and driven by electric forklift to a loading dock within Zone 12. The containers are loaded and secured into an SST and driven to LANL. Figure 4.16.1.1–1 shows the LANL delivery location with nearby access roads. Further operations involving pits at LANL will be discussed in the *Los Alamos Site-Wide Environmental Impact Statement.* The actual number of surveillance pit shipments from Pantex Plant is classified.

Canned Subassemblies

Canned subassemblies (CSAs) that may contain highly enriched uranium (HEU) and DU removed from dismantled weapons are shipped to the Y–12 Plant at the Oak Ridge Reservation (ORR) for prestorage processing and interim storage of nuclear material. CSAs are transported intersite by SSTs in DOT-criteria Type B packages including DT–23, DT–18, and DT–20. The number of CSAs shipped from Pantex Plant is classified. DOE has assessed the impacts of transporting CSAs to Y–12 in the *Environmental Assessment for the Interim Storage of Enriched Uranium at the Y–12 Plant* (DOE/EA–0919). A Finding of No Significant Impact was issued for this Environmental Assessment (EA) on September 14, 1995 (60 FR 54069).

When a shipment of CSAs is made from Pantex Plant, the containers, staged in an approved storage facility, are loaded onto a pallet and driven by electric forklift to a loading dock within Zone 12. These containers are loaded and secured into an SST that is then driven to the Y–12 Plant. CSAs staged in Zone 4 are loaded into SSTs at the storage magazine. The Y–12 Plant, which receives the uranium components from Pantex Plant, is located within the boundaries of ORR, near Knoxville, Tennessee. Figure 4.16.1.1–2 shows the location of ORR. Vehicular access to the Y–12 Plant is via Bear Creek Valley Road, a two-lane, paved State highway. Following this road, Interstate 40 is approximately 6 kilometers (4 miles) from the ORR site boundary and approximately 18 kilometers (11 miles) from the Y–12 Plant. Figure 4.16.1.1–3 shows the access roads to the Y–12 Plant. Arriving containers are unloaded and brought into a facility where a transfer check is performed. The transfer check confirms the identity and quantity of the shipment and verifies the integrity of the tamper-indicating devices on the containers.

Depleted Uranium

DU components removed from dismantled weapons are shipped to the Y–12 Plant at ORR for prestorage processing and interim storage. These shipments are made by commercial truck carriers using DOT Type A packaging and are made in full compliance with Titles 10 and 49 of the CFR. Table 4.16.1.1–1 presents the DU shipments for the years 1992–1994.

Tritium Reservoirs

Tritium reservoirs are shipped intersite for the following reasons:

- Depleted reservoirs removed from weapons are returned to the Savannah River Site (SRS) for reuse and recycling.

TABLE 4.16.1.1–1.—*Depleted Uranium Shipments from Pantex Plant*

YEAR	ROUTE	NUMBER OF SHIPMENTS	NUMBER OF COMPONENTS
1992	Pantex to ORR	20	2,119
1993	Pantex to ORR	13	794
1994	Pantex to ORR	4	857

SOURCE: DOE 1995k:4-177

FIGURE 4.16.1.1–3.—*Access Roads to the Y–12 Plant at Oak Ridge Reservation.*

- Filled reservoirs are shipped from SRS to Pantex Plant for installation in weapon systems.

Tritium reservoirs are transported intersite by air or by highway, in SSTs. Tritium reservoirs are shipped in H1616 containers, which are DOT-approved Type B packages. The H1616 container has an outer drum of stainless steel that is 41.65 centimeters (16.4 inches) in diameter and an inner containment vessel made of stainless steel that is 31 centimeters (12.11 inches) in diameter and 36 centimeters (14.3 inches) in height. Tritium reservoirs within these containers do not pose an external radiation hazard.

When a shipment of depleted reservoirs is made from Pantex Plant by air, the H1616 container is loaded and sealed with a tamper-indicating device at the Tritium Staging Facility. The H1616 container is taken to a loading dock within Zone 12 and loaded and secured within a hardened trailer. The vehicle is driven from Pantex Plant to a "secure" terminal at the Amarillo International Airport where the container is removed from the vehicle, loaded aboard the aircraft, and secured; loading operations are performed under controlled conditions in secured areas at the Amarillo airport. The aircraft is flown to Bush Field in Augusta, Georgia where the H1616 containers are removed from the aircraft and loaded and secured within an SST or similar vehicle. This vehicle is driven to the H-area at SRS, where the package is unloaded. Table 4.16.1.1–2 summarizes air shipments of tritium reservoirs. Further operations with tritium reservoirs at SRS are discussed in the *Environmental Assessment, Tritium Loading Facility* (DOE 1986). Newly filled tritium reservoir transfers from SRS follow a reverse procedure.

The H-area is located approximately 16 kilometers (10 miles) within the northwestern site boundary of SRS. Bush Field is located outside of Augusta, Georgia and is approximately 32 kilometers (20 miles) northwest of the SRS boundary. Vehicular access to SRS from Bush Field is via either South Carolina Highway 125 or U.S. Highway 278. The closest Interstate highway access to SRS is Interstate 20, approximately 32 kilometers (20 miles) northwest of the site boundary.

Radioisotopic Thermoelectric Generator

Radioisotopic thermoelectric generators (RTGs) removed from dismantled weapons are shipped to LANL for prestorage processing and interim storage of nuclear material. RTGs are transported intersite by SSTs in DOT Type 6M containers. The Type 6M container is a DOT-criteria Type B package. The Type 6M container is a standard 37.85-liter (10-gallon), DOT-specification metal package. This package is constructed of 20-gauge carbon steel

TABLE 4.16.1.1–2.—*Pantex Tritium Reservoir Air Shipments, 1992–1994*

YEAR	ROUTE	NUMBER OF FLIGHTS	TOTAL RESERVOIRS PER YEAR
1992	SRS to Pantex	5	52
	Pantex to SRS	12	1,215
1993	SRS to Pantex	6	82
	Pantex to SRS	27	1,055
1994	SRS to Pantex	6	37
	Pantex to SRS	22	2,254

Source: PC 1994b:1

and measures about 33 centimeters (13 inches) in diameter and 61 centimeters (24 inches) in height.

When a shipment of RTGs is made from Pantex Plant to LANL, the Type 6M packages are loaded onto a pallet and transported by electric forklift to a loading dock within Zone 12 where the containers are loaded and secured within an SST. The SST is driven to LANL where it is brought into the TA–55 area. Further operations with RTGs at LANL will be discussed in the *Los Alamos Site-Wide Environmental Impact Statement.*

Low-Level and Low-Level Mixed Radioactive Wastes

Pantex Plant currently ships low-level radioactive materials and wastes by commercial carriers to the Nevada Test Site (NTS) in southern Nevada for ultimate disposition. These transfers are made in Type A packages in full compliance with all applicable DOT regulations. In the years 1992–1994, no shipments of radioactive waste from Pantex Plant have produced measurable radiation levels outside the shipment trailer. Table 4.16.1.1–3 presents the low-level waste shipments for the years 1992–1994.

Pantex Plant currently ships low-level mixed waste by commercial carriers for ultimate disposal at the Envirocare Disposal Facility approximately 129 kilometers (80 miles) west of Salt Lake City, Utah. These shipments are made in full compliance with all applicable DOT regulations. Table 4.16.1.1–3 presents the low-level mixed waste shipments for the years 1992–1994.

Transportation impacts associated with intersite transfers of radioactive wastes and alternatives to the current shipping practices are evaluated in the *Draft Waste Management Programmatic Environmental Impact Statement* (DOE 1995)and the Environmental Impact Statement for the Nevada Test Site and Offsite locations in the State of Nevada (DOE/RIS-0243).

4.16.1.2 *Offsite Radioactive Material Shipments*

Nuclear explosives and nuclear explosive components are shipped by SST to and from Pantex Plant. Transportation is conducted by the DOE TSD. Since its establishment in 1975, TSD has accumulated more than 119 million kilometers (74 million miles) of over-the-road experience in transporting DOE-owned cargo without any accidents that resulted in a release of radioactive material. The Pantex Plant *Safety Information Document* provides a listing of all accidents involving SSTs that involved fatalities or resulted in damage to the vehicle (Pantex 1996a). TSD has a liaison program through which it communicates with law enforcement and public safety agencies throughout the Nation, making them aware of TSD operations. The liaison program provides law enforcement officers information to assist them in recognizing TSD vehicles should they be involved in an accident, and deciding what

TABLE 4.16.1.1–3.—*Pantex Radioactive Waste Shipments*

YEAR	WASTE TYPE	NUMBER OF SHIPMENTS	VOLUME m^3 (ft^3)	DESTINATION
1992	LLW	5	119.70 (4,227)	NTS
1993	LLW	11	261.43 (9,232)	NTS
1994	LLW LLMW	28 1	609.81 (21,535) 32.6 (1,150)	NTS Envirocare

Source: PC 1995n

actions to take in conjunction with the actions of the couriers in the rig and escort vehicles.

TSD personnel are briefed on construction, congestion, and severe weather prior to travel. TSD will make every effort to alter a route or change the travel time to avoid potential traffic hazards.

TSD directs and manages an emergency management drill and exercise program that involves facility personnel, resources, and offsite elements. To stay proficient in all aspects of TSD convoy operations, TSD annually plans, implements, monitors, and performs follow-up analysis for couriers, known as in-service training (IST). For each iteration of IST, TSD invites participation from a State police agency. These police agencies train with TSD in all aspects of the program, but TSD's primary interest is in their participation in convoy tactical training with emphasis on law enforcement link-up in the case of an emergency. Both Arkansas and Missouri State Police are participating in the present (fiscal year [FY] 1996) IST program; Oklahoma and Arizona State Police participated in FY 1995, and the Texas Department of Public Safety participated in FY 1994.

TSD's emergency response plans involve a tiered organizational response to radiological incidents. In Tier 0, local law enforcement and TSD couriers assess the severity of the accident and determine the need for radiological assistance. Tier I involves the deployment of Radiological Assistance Teams, a Regional Response Coordinator, and Public Affairs Office personnel. These personnel have appropriate monitoring and communications equipment to assess the radiological status of the incident. At Tier II additional technical expertise is provided to the response group. At Tier III the accident response group will assist in recovery, repackaging, and decontamination operations. These four tiers correspond, respectively, to the following levels:

- 0—no structural damage and no potential for public controversy.
- I—status of unknown or limited damage.
- II—excessive damage of SST or shipment.
- III—radiological release cleanup/ repackaging required.

Additional national emergency response resources from around the Nation are available if the severity of an SST convoy incident warrants such a call. Further details on other Federal agency responsibilities in the event of a radiological emergency can be found in the Federal Radiological Emergency Response Plan (61 FR 20944).

SSTs used for intersite transportation are specially designed semi-trailers that use penetration resistance and delay mechanisms to prevent unauthorized cargo removal. SSTs provide thermal protection for cargo within the trailer. A robust tie-down and restraining system is provided to secure cargo within the trailer.

SSTs are accompanied by escort vehicles equipped with armed couriers, communication and electronics systems, radiological monitoring equipment, and other equipment to enhance safety and security. Redundant communication systems assure that intra-convoy communications and communications between each vehicle and the Security Communications System in Albuquerque, New Mexico, are maintained.

SSTs follow strict procedures during transport and are not allowed to travel when hazardous road conditions exist. When hazardous road conditions are anticipated enroute, the SST stops at a safe haven, usually a predetermined military installation. In addition, SSTs are limited to a maximum 89 kilometer-per-hour (55 mile-per-hour) speed limit, even if the posted limit is greater.

TSD operations are in compliance with the requirements of 49 CFR 177 for selecting, notifying drivers of, and adhering to preferred routes. The majority of TSD travel (90 percent) is over interstate highway; the remaining 10 percent is over routes that meet the conditions for deviating from the preferred route. Regulations permit deviation from the preferred route when safety or security requirements dictate such deviation.

Regulations permit TSD deviation from the requirements regarding notification of the routes used. Routes used are classified, compartmented information that may not be disseminated except to persons with appropriate security clearance and a need to know.

All SST crew members wear radiation dosimeters. Because of the nature of the material and the design of the containers, the transport of both nuclear explosives and plutonium/uranium weapons components has led to ionizing radiation doses to SST crew members. SST crew members are required to inspect the cargo within the trailer prior to shipment. This action is the primary contributor to dose for the crew. Table 4.16.1.2–1 provides the doses received from transport operations for the years 1992–1994.

4.16.1.3 *Intersite Shipments of High Explosive Material*

Intersite transportation of HE material is governed by the requirements of DOE orders and DOT regulations. HE material is packaged and shipped in compliance with applicable regulations by DOE courier, commercial carrier, or by a DOE-contracted air carrier. Highway shipments are performed using the most direct route on interstate and state highways. Air shipments are performed through the Amarillo International Airport. Air transport of Class 1.1 explosives is allowed under DOT exemption number DOT–E–1088J. However, Class 1.1 shipments are generally sent by truck.

Most intersite shipments of HE material since 1992 have been bulk shipments involving unprocessed raw material that is no longer needed for weapons production. This material is being sold to commercial end users. Only a very limited amount of raw HE is expected to be shipped to Pantex Plant during the years under evaluation in this EIS.

All other hazardous material shipments are transported via commercial carriers in full compliance with applicable DOT regulations. Pantex Plant type operations do not consume or produce large quantities of hazardous materials. Consequently, the risks associated with Pantex Plant related hazardous material shipments are no greater than those associated with other industrial facilities. Further information on the types and quantities of hazardous material shipments associated with Pantex Plant operations is available in the *Safety Information Document* (Pantex 1996a).

TABLE 4.16.1.2–1.—*DOE Transportation Safeguards Division Dosimeter History*

YEAR	CUMULATIVE DOSE (PERSON-REM)	NUMBER OF PERSONS MONITORED	MAXIMUM INDIVIDUAL DOSE (REM)
1992	0.059	314	0.018
1993	0.067	306	0.021
1994	0.158	297	0.088

Source: PC 1995m

Transferring the HE fabrication mission from Pantex to LANL or LLNL would require an estimated 150 rebuilds to be shipped per year from the HE fabrication site to Pantex. The public accident risk from transporting this material would be no greater than the risk encountered from industry's transport of similar explosives. Transferring all or part of the HE fabrication mission from Pantex to LANL or LLNL would require an estimated 12 round trips per year to transport HE materials, including the return of scrap HE to the laboratories.

4.16.1.4 *Alternative Pit Storage Locations*

If a Pit Storage Relocation Alternative is chosen, pits in DOT-criteria shipping containers will be shipped to other sites by SSTs. Since NTS, SRS, the Hanford Site, and the Manzano Weapons Storage Area (WSA) at Kirtland Air Force Base (KAFB) are being considered as alternative pit storage locations, these sites must have roads that allow for all-weather highway access by the SSTs. This section provides a brief description of the roadways leading to alternative pit storage sites. (SRS is described in section 4.16.1.1).

Nevada Test Site

NTS is located in southern Nevada, approximately 105 kilometers (65 miles) northwest of Las Vegas. Interstate 15 is the major regional access road for NTS. Interstate 15 connects San Diego, California to Salt Lake City, Utah, passing through the Las Vegas metropolitan area. Vehicular access to NTS is provided by U.S. Route 95. The Mercury Highway is the primary route into NTS from U.S. Highway 95. Figure 4.16.1.4–1 shows the roadways in the vicinity of NTS.

Hanford Site

The Hanford Site is located in southeastern Washington State, northwest of the tri-cities of Richland, Kennewick, and Pasco. The tri-cities are linked to other regions of the country by interstate highways. Both Route 395 and Route 240, which crosses through the Hanford Site, connect with Interstate 90 to the north. The tri-city area is linked to other parts of the country via Interstate 82 and Route 12. Access to the Hanford Site is provided by Routes 240 and 24, which traverse the site. Figure 4.16.1.4–2 shows the roadways in the vicinity of the Hanford Site.

Manzano Weapons Storage Area

The Manzano WSA is located on KAFB, near Albuquerque, New Mexico. Interstate 40 and Interstate 25 provide access to the Albuquerque metropolitan area. KAFB can be accessed from Eubank or Wyoming Boulevard (from Interstate 40) or Gibson Boulevard (from Interstate 25). Figure 4.16.1.4–3 shows the roadways in the vicinity of KAFB.

4.16.2 Impacts of Proposed Action

Under the Proposed Action, DOE would continue to perform the following intersite transportation activities related to Pantex Plant:

- Nuclear weapon shipments between the Pantex Plant and DOD sites.
- Pit and RTG shipments between Pantex Plant and LANL.
- HEU component shipments between Pantex Plant and the Y–12 plant.
- DU shipments between Pantex Plant and the Y–12 Plant.
- Tritium reservoir shipments between Pantex Plant and SRS.

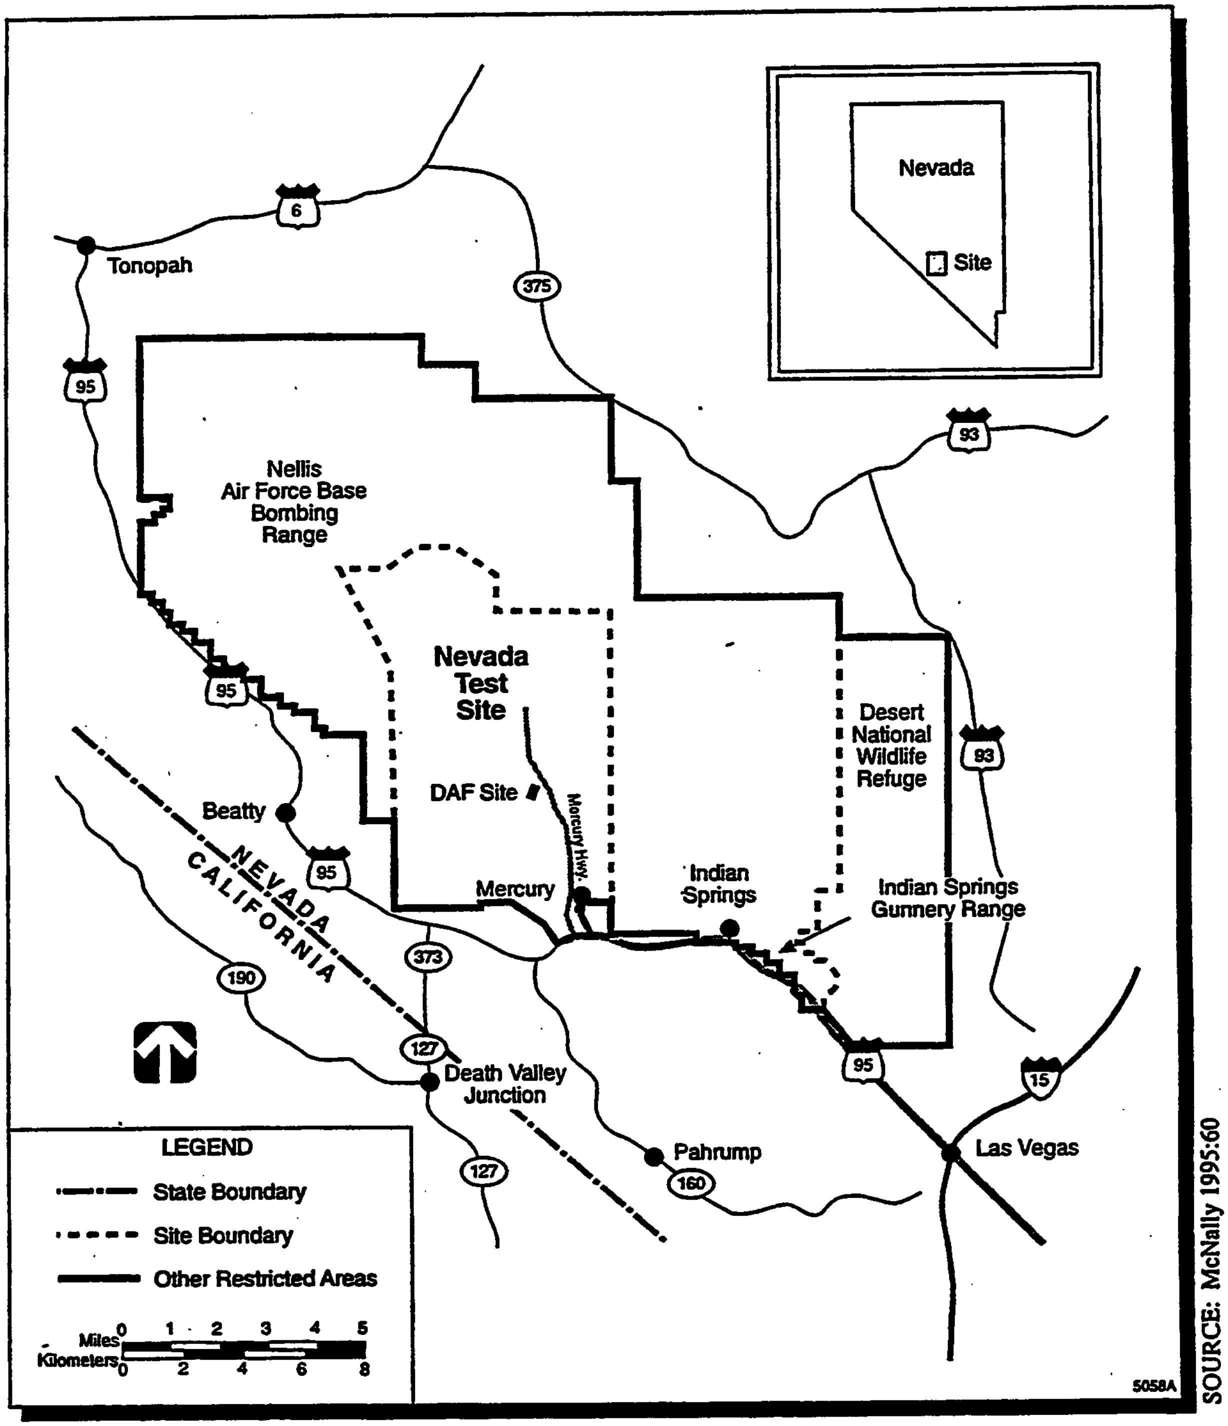

FIGURE 4.16.1.4–1.—*Roadways in the Vicinity of the Nevada Test Site.*

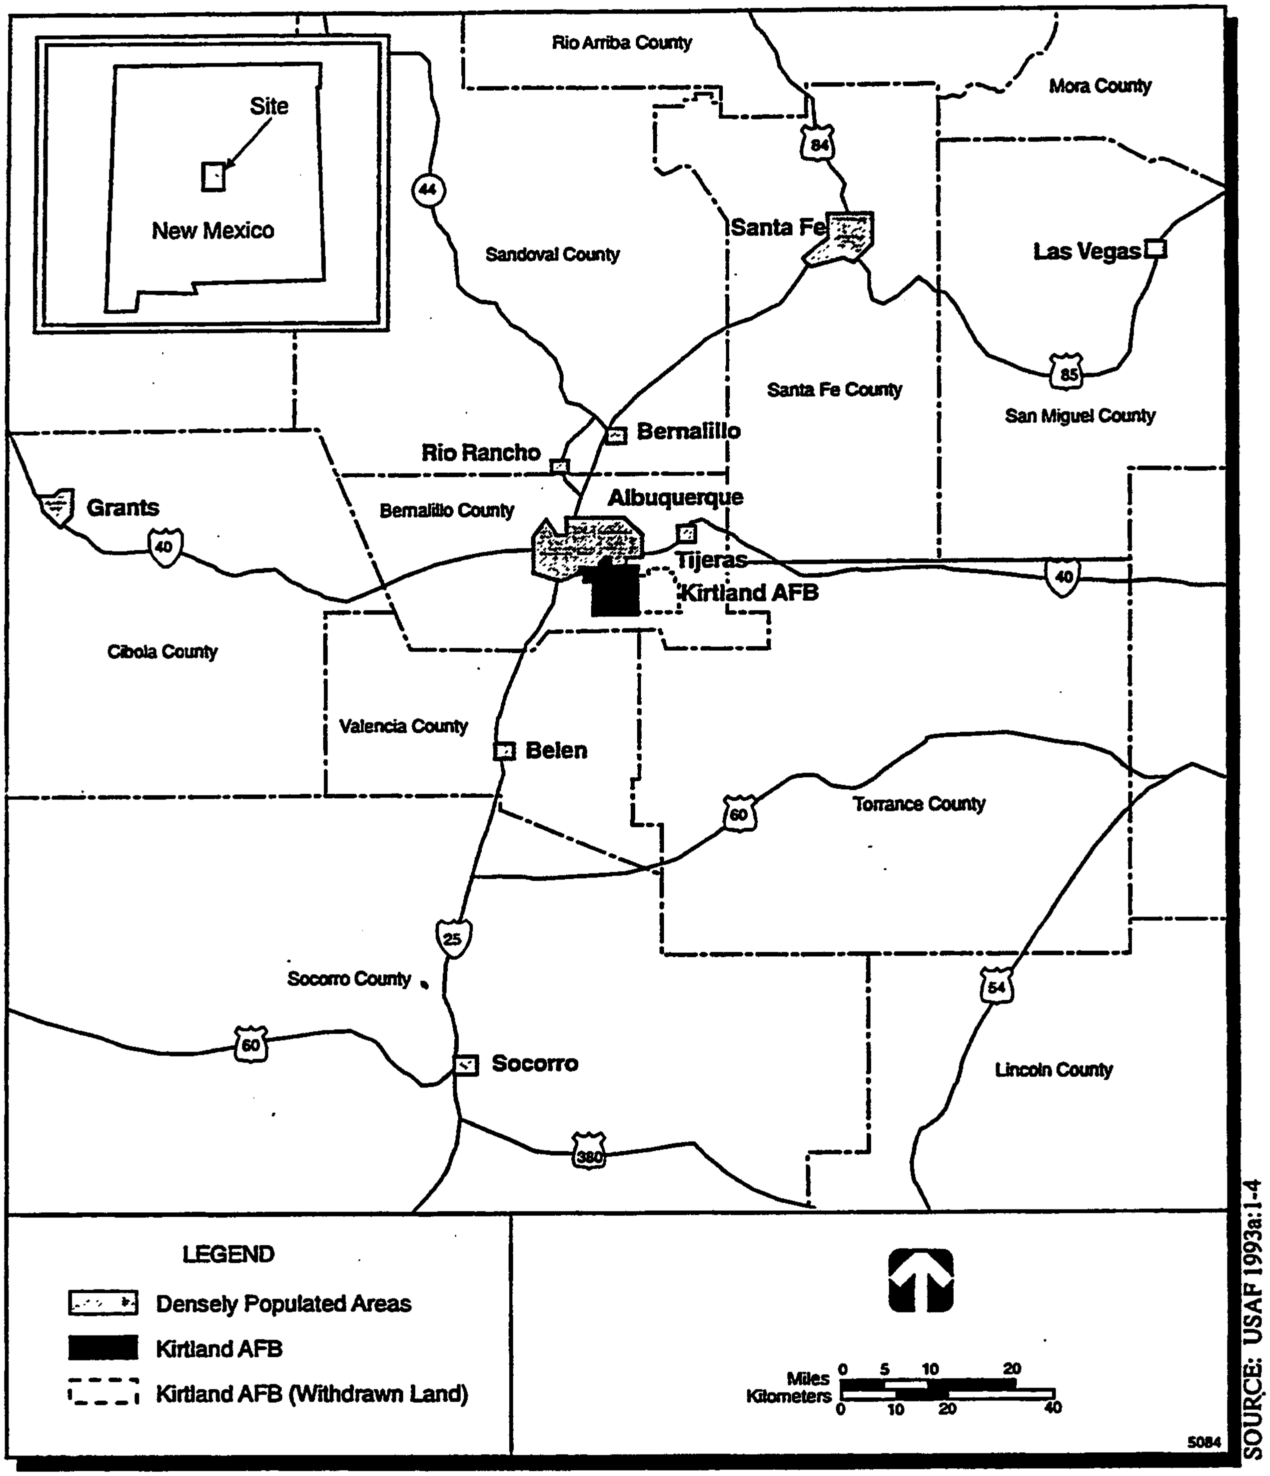

FIGURE 4.16.1.4–3.—*Roadways in the Vicinity of Kirtland Air Force Base.*

4.16.2.1 *Nuclear Weapon Shipments*

Human health impacts associated with weapon shipments include the radiological exposure of transport personnel and members of the general public as well as the potential release of radioactive material during an accident. The health risks associated with these shipments are evaluated in terms of the expected excess latent cancers (i.e., the number of cancers above those expected without any impacts from weapon shipments).

An analysis was performed using the Analysis of Risk Occurring in Transportation (ADROIT) code to determine the incident-free radiological impact to the public from intersite weapon shipments (a description of the ADROIT code is provided in appendix F). The ADROIT code utilizes the RADTRAN IV methodology to estimate incident-free exposures. This methodology is used to calculate the off-link exposure to persons adjacent to the transport route (e.g., residents); on-link exposure to persons sharing the transport route (e.g., passengers within passing vehicles); exposure to persons at stops (e.g., residents or truck crews not directly involved with the shipment); and maximally exposed members of the public. The exposures calculated for the first three groups are added together to estimate general population exposures for the 10-year period under evaluation in the EIS. The estimated radiation exposure to the public is provided in Table 4.16.2.1–1. Since the number of shipments between Pantex Plant and DOD sites is subject to change from the current schedule, Table 4.16.2.1–1 shows the impacts associated with possible changes from the base shipment schedule.

Approximately 20 percent of the general population is expected to develop a lethal cancer from all sources (NAP 1990). The incident-free impact from intersite weapons shipments is conservatively estimated to cause a maximum of 1.8×10^{-3} excess latent cancer fatalities (LCFs) in the exposed population on and along the roadways (for a 100 percent increase shipment scenario).

Intersite weapon shipments also pose a public health risk from potential severe accidents that could result in the dispersal of radionuclides from SSTs. The risk is the expected number of excess latent cancers caused by dispersal accidents. The ADROIT code calculates the public health risk from potential accidents involving SSTs carrying nuclear explosives and weapons components. The risk assessment implemented in the ADROIT code considers both the frequency and consequences of accidents resulting in severe impact, puncture, crush, and thermal environments. Probability of releases is developed based on event tree analysis. Consequences are evaluated through an assessment which integrates dispersal calculations, route characterization, population data, and dose-health effects models to provide an estimate of excess LCFs.

The accidental dispersal latent cancer risk is obtained by summing the risk (frequency times consequence) from potential accidents at different locations along individual weapon shipment routes. The dominant risk environments are highway accidents involving severe collisions and fires, particularly accidents involving very long duration fires. There is not a single, dominant scenario associated with risk significant events; instead, there is a collection of scenarios that constitutes the dispersal risk. These scenarios have the following characteristics:

- Accidents that involve either a severe collision and fire (such as a collision with a heavy truck or fixed object that also involves a fuel fire) or a very long duration fuel fire (such as an accident with a fuel tanker or train that involves a fuel fire).
- Accidents that result in a violent reaction of HE contained within a weapon.

TABLE 4.16.2.1–1.—*10-Year Impacts from Proposed Weapon Shipments*

SHIPMENT SCENARIO	PUBLIC EXPOSURE (PERSON-REM)[1]	MAXIMUM EXPOSED INDIVIDUAL (REM)	PUBLIC INCIDENT FREE RISK (EXPECTED NUMBER OF EXCESS LCFs)	PUBLIC ACCIDENT DISPERSAL RISK (EXPECTED NUMBER OF EXCESS LCFs FROM DISPERSAL ACCIDENTS)	CREW EXPOSURE (PERSON-REM)[2]	CREW INCIDENT FREE RISK (EXCESS CANCER FATALITIES)	EXPECTED NUMBER OF TRAFFIC FATALITIES
+100%	4.0	0.01	1.8×10^{-3}	1.6×10^{-6}	3.2	1.3×10^{-3}	1.2×10^{-2}
+ 50%	3.0	7.5×10^{-3}	1.4×10^{-3}	1.2×10^{-6}	2.4	1.0×10^{-3}	9.0×10^{-3}
+ 30%	2.6	6.5×10^{-3}	1.2×10^{-3}	1.0×10^{-6}	2.1	8.0×10^{-4}	7.8×10^{-4}
+ 10%	2.2	5.5×10^{-3}	1.0×10^{-3}	8.8×10^{-7}	1.7	6.6×10^{-4}	6.6×10^{-4}
Base Shipment Schedule	2.0	5.0×10^{-3}	9.0×10^{-4}	8.0×10^{-7}	1.6	6.0×10^{-4}	6.0×10^{-3}

[1]Exposure calculations performed using a conservative external SST dose rate of 3.0 mrem/hr.
[2]Crew exposures based on past DOE TSD Dosimetry.

Given a very severe transportation accident, radioactive materials could be dispersed into the atmosphere and subsequently expose the general public in the vicinity of the accident to ionizing radiation. Table 4.16.2.1–1 presents radiological risks from dispersion accidents occurring during intersite weapon shipments. The accidental dispersal of radionuclides from these shipments is estimated to cause 1.6×10^{-6} excess LCF in the population along weapon shipment routes with a maximum annual individual excess LCF risk of 1×10^{-9}. The annual LCF risk from all causes for an individual in the U.S. is 2.2×10^{-3} (DOE 1995v:4-110). Table 4.16.2.1–1 also summarizes the expected number of traffic fatalities resulting from weapon shipments. Appendix F provides additional information on traffic fatality estimates.

4.16.2.2 *Plutonium Pits*

Human health impacts associated with plutonium pit shipments to LANL include the radiological exposure of transport personnel and members of the general public as well as the potential release of radioactive material during an accident. The ADROIT code calculates the impacts from both incident-free transport and potential accidents resulting from pit shipments between Pantex Plant and LANL. The incident-free transport of pits during the 10-year period under evaluation in the EIS will result in 2×10^{-5} excess LCFs in the exposed population on and along the roadways. Approximately 20 percent of the general population is expected to develop a lethal cancer from all sources.

The expected number of excess LCFs associated with potential accidents has been estimated as 2×10^{-9} with a maximum annual individual excess LCF risk of 5×10^{-13}. The annual LCF risk from all causes for an individual in the U.S. is 2.2×10^{-3}.

4.16.2.3 *Canned Subassemblies*

DOE has prepared an *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y–12 Plant, Oak Ridge, Tennessee*, DOE/EA-0929 (DOE 1994). The Environmental Assessment evaluates the environmental effects of transportation, prestorage processing, and interim storage of bounding quantities of enriched uranium at the Y–12 Plant over a 10-year period. Included in the sources for HEU is the continued shipment of retired weapons components, known as secondaries or CSAs, which are removed from nuclear weapons dismantled at Pantex Plant.

The Environmental Assessment analyzes the effects of shipping the maximum bounding quantities of HEU to the Y–12 Plant from numerous sources, including Pantex Plant. The 10-year collective dose to all transport workers under incident-free conditions was estimated to be 246 person-rem for all shipments of HEU, including those from Pantex Plant. The 10-year collective dose to the public from incident-free transportation was estimated to be 486 person-rem for all shipments of HEU, including those from Pantex Plant. DOE has determined that these impacts are not significant (DOE 1995v).

4.16.2.4 *Radioisotopic Thermoelectric Generators*

RTG Shipments from Pantex Plant to LANL will continue. These shipments do not significantly contribute to potential environmental impacts from intersite transportation because:

- An RTG within a transfer container does not present an external radiological hazard.
- RTGs are constructed in such a way that an accidental release of plutonium is not a reasonably foreseeable event in the transportation environment. RTGs are

able to withstand an exposure of 1000 °C (1,832 °F) for 1 hour or an impact of 571 kilometers (355 miles) per hour on a steel surface with no plutonium release.

- RTGs are transported intersite in Type B packages, which further decrease the risk associated with their transport.

4.16.2.5 *Depleted Uranium*

Shipments of DU from Pantex Plant to the Y–12 Plant do not significantly contribute to potential environmental impacts from intersite transportation because DU does not produce an external radiological hazard. Moreover, the inhalation hazard of DU in the event of an accident is significantly less than that posed by other radionuclides shipped intersite (DOE 1988).

4.16.2.6 *Tritium Reservoirs*

Human health impacts associated with tritium reservoir shipments involve the potential for accidental dispersion of tritium due to reservoir failures during transfer. The ADROIT code calculates the public health risk from potential accidents involving aircraft carrying tritium reservoirs. The dominant risk environment is accidents at or near an airport that involve severe crashes and/or fires. The expected number of excess LCFs associated with potential accidents is estimated to be 4×10^{-8} (8×10^{-8} for a 100-percent increase shipment scenario) with a maximum individual annual cancer risk from tritium reservoir shipments of 9×10^{-11}. The annual LCF risk from all causes for an individual in the U.S. is 2.2×10^{-3}.

4.16.3 Impacts of No Action Alternative

Because of the uncertainty in predicting the number of future weapon shipments related to stockpile management, the potential environmental impacts from the No Action Alternative are bound within those presented for the Proposed Action. Even though dismantlement shipments would cease under No Action, other shipments related to stockpile management may increase.

INTERSITE TRANSPORTATION IMPACTS

- *The additional intersite shipment of 20,000 pits will increase the radiological impact to the public from 4.0 person-rem to a maximum of 7.0 person-rem over the period covered by the Proposed Action.*
- *The additional intersite shipment of 20,000 pits will increase the dispersal risk (i.e., the risk to public health from accidental releases of radioactive material) from 1.7×10^{-6} LCFs to 2.2×10^{-6} LCFs, a 29 percent increase over the Proposed Action.*
- *All intersite transportation alternatives meet the DOE Safety Policy of a cancer risk from radiological accidents of less than one-tenth of 1 percent above background cancer rates.*

4.16.4 Impacts of Pit Storage Relocation Alternative

4.16.4.1 *Impacts of Relocating 20,000 Pits*

Under this option, up to 20,000 pits would be relocated from Pantex Plant to one of three candidate storage sites: NTS, Manzano WSA at KAFB, or SRS.

Human health impacts associated with plutonium pit shipments to alternative storage sites include the radiological exposure of transport personnel and members of the general public as well as the potential release of radioactive material during an accident. The ADROIT code calculates the impacts from both incident-free transport and potential accidents resulting from pit shipments between Pantex Plant and the alternative pit storage sites. Table 4.16.4.1–1 summarizes the impacts associated with shipments of 20,000 pits.

The incident-free transport of pits would result in a maximum of 1.5×10^{-3} excess LCFs in the exposed population on and along the roadways. The baseline cancer fatality incidence in the general public is 20 percent.

The public risk from dispersal accidents is the expected number of latent cancers caused by accidents involving the dispersal of radionuclides from SSTs. Given a very severe transportation accident, radioactive materials could be dispersed into the atmosphere and subsequently expose the general public in the vicinity of the accident to ionizing radiation. Table 4.16.4.1–1 presents radiological risks from dispersion accidents occurring during intersite weapon shipments. The accidental dispersal of radionuclides from these shipments is estimated to cause 5×10^{-7} excess LCFs in the population along the pit shipment routes with a maximum annual individual excess LCF risk of 1×10^{-10} for the SRS alternative. The annual LCF risk from all causes for an individual in the U.S. is 2.2×10^{-3}.

4.16.4.2 *Impacts of Relocating 8,000 Pits*

Under this option, 8,000 pits would be relocated from Pantex Plant to one or more of four candidate storage sites: NTS, SRS, Hanford Site, and Manzano WSA at KAFB.

Table 4.16.4.2–1 summarizes the impacts associated with 8,000 pit shipments. Impacts related to loading or unloading pits into SSTs are discussed in Section 4.12, Intrasite Transportation.

The incident-free transport of pits would result in a maximum of 6×10^{-4} excess LCFs in the exposed population on and along the roadways.

TABLE 4.16.4.1–1.—*Radiological Exposure and Health Risk from 20,000 Pit Shipments from Pantex Plant to Other Potential Sites*

GENERAL PUBLIC	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WSA
Cumulative Dose (Person-Rem)[1]	2.0	3.0	NA	0.5
Maximally Exposed Individual (rem)	4×10^{-3}	4×10^{-3}	NA	4×10^{-3}
Expected Excess LCFs from Incident Free Impacts	1×10^{-3}	1.5×10^{-3}	NA	2.5×10^{-4}
Expected Excess LCFs from Plutonium Dispersal Accidents	4×10^{-7}	5×10^{-7}	NA	4×10^{-8}

TABLE 4.16.4.2–1.—*Radiological Exposure and Health Risk from 8,000 Pit Shipments from Pantex Plant to Other Potential Sites*

GENERAL PUBLIC	NEVADA TEST SITE	SAVANNAH RIVER SITE	HANFORD SITE	MANZANO WEAPONS STORAGE AREA
Cumulative Dose (Person-Rem)	0.80	1.2	1.2	0.20
Maximally Exposed Individual (rem)	1.6×10^{-3}	1.6×10^{-3}	1.6×10^{-3}	1.6×10^{-3}
Expected excess LCFs from Incident Free Impacts	4.0×10^{-4}	6.0×10^{-4}	6.0×10^{-4}	1.0×10^{-4}
Expected excess LCFs from Plutonium Dispersal Accidents	1.6×10^{-7}	2.0×10^{-7}	3.2×10^{-7}	1.6×10^{-8}
Maximum Annual Individual LCF Risk from Dispersal Accidents	4.0×10^{-11}	1.0×10^{-10}	1.0×10^{-10}	1.0×10^{-11}

The public risk from dispersal accidents is the expected number of latent cancers caused by accidents involving the dispersal of radionuclides from SSTs. The accident scenarios analyzed here have the following characteristics:

- Accidents that involve either a severe collision and fire (such as a collision with a heavy truck or fixed object that also involves a fuel fire) or a very long duration fuel fire (such as an accident with a fuel tanker or train that involves a fuel fire).
- Accidents that result in a fire-driven dispersal.

Given a very severe transportation accident, radioactive materials could be dispersed into the atmosphere and subsequently expose the general public in the vicinity of the accident to ionizing radiation. Table 4.16.4.2–1 presents radiological risks from dispersion accidents occurring during intersite weapon shipments. The accidental dispersal of radionuclides from these shipments is estimated to cause a maximum of 3.2×10^{-7} excess LCFs in the population along pit shipment routes with a maximum annual individual excess LCF risk of 1×10^{-10} for the Hanford Site and SRS alternatives. The annual LCF risk from all causes for an individual in the U.S. is 2.2×10^{-3}.

4.16.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

Pantex Plant-related transportation impacts result in a small increase in cumulative exposures from nationwide radioactive material shipments. Under the Proposed Action, Pantex Plant-related intersite transportation activities will result in a maximum annual collective dose to SST crews of 0.32 person-rem (3.2 person-rem for 10 years of operations) and a maximum annual collective general population dose of 0.40 person-rem (4.0 person-rem for ten years of operation).

The U.S. Nuclear Regulatory Commission evaluated radiological impacts for transportation of radioactive material categories unrelated to Pantex Plant activities. These categories include: limited quantity shipments, medical, industrial, fuel cycle, and waste. The transportation of these materials results in an annual collective worker dose of 5,600 person-rem. The annual collective general population dose for these shipments was estimated to be 4,200 person-rem.

Other studies of radioactive material transportation in the U.S. have been performed. Weiner et al. (1991) evaluated eight categories of radioactive material shipments by truck, including, industrial, radiography, medical, fuel cycle, research and development, unknown, waste, and other. Based on a median external exposure rate, an annual collective worker dose of 1,400 person-rem and an annual collective general population dose of 1,400 person-rem were estimated.

Weiner et al. (1991) also evaluated six categories of radioactive material shipments by plane: industrial, radiography, medical, research and development, unknown, and waste. Based on a median external exposure rate, an annual collective worker dose of 290 person-rem and an annual collective general population dose of 450 person-rem were estimated.

Pantex Plant-related transportation impacts result in a small increase in cumulative exposures from other reasonably foreseeable DOE transportation activities. Proposed projects that involve extensive transportation of radioactive materials include shipments of high-level radioactive waste to a geologic repository, shipments of transuranic waste to the Waste Isolation Pilot Plant, and DOE spent nuclear fuel regionalization by fuel type.

For the assumed geologic repository at Yucca Mountain, Nevada, the transportation impacts include a worker collective dose for truck shipments of 8,600 person-rem and a general population collective dose from truck shipments of 48,000 person-rem (DOE 1986).

For the Waste Isolation Pilot Plant, the transportation impacts include a worker collective dose from truck shipments of 1,900 person-rem and a general population collective dose from truck shipments of 1,500 person-rem (DOE 1990).

For the regionalization of DOE spent nuclear fuel by fuel type, the transportation impacts include a worker collective dose of 417 person-rem for the 40-year shipment campaign and a general population collective dose of 910 person-rem for the 40-year shipment campaign.

The determination of past transportation impacts is difficult because of the lack of historical shipping information. However, based on the projected impacts of Pantex Plant activities, along with the similarity of future activities with those of the past (excluding pit shipments between Pantex Plant and the Rocky Flats Plant, it is estimated that the impact from past Pantex Plant-related shipments were no more than 10 person-rem per year. Assuming 46 years of operation, past activities resulted in less than 0.23 excess LCFs.

4.16.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

The WM PEIS analyzes a range of alternatives, including waste shipments by rail and truck. These shipments included a range of 0 to 470 truck shipments and 0 to 200 rail shipments of

LLMW/LLW. Impacts to the offsite Maximally Exposed Individual are provided in section 4.14.5.1 (Human Health).

4.16.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability; and Relocate Capability. Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, impacts from intersite transportation activities are expected to be less than current impacts. Under the downsizing alternative, the facilities would be consolidated; however, this would not result in a reduction of intersite transportation impacts from those of the No Action Alternative. Under the Relocation Alternative, intersite transportation associated with assembly and disassembly operations and HE fabrication at Pantex Plant would cease.

4.16.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. If Pantex Plant is chosen as the collocation site, weapons-usable fissile materials would be transported from existing storage sites to Pantex Plant. The transportation health effects were calculated, and the potential fatalities would be 0.461.

For the Disposition Alternatives, because the emphasis at this stage in the decision process is on choosing the technology rather than the actual site, the cumulative impacts discussion is qualitative and necessarily imprecise, particularly for the generic sites. The evolutionary Light Water Reactor was chosen as the bounding alternative for disposition. Implementation of this Disposition Alternative would require construction and operation of the pit disassembly/conversion facility, the plutonium conversion facility, and the mixed oxide fuel fabrication facility. The bounding alternative also assumes that all facilities previously mentioned would be collocated at the same site. The potential fatalities from transporting materials for disposition would be 5.64 (DOE 1996a:chapter 4).

4.17 ENVIRONMENTAL JUSTICE

4.17.1 Affected Environment

Executive Order 12898, *Federal Action to Address Environmental Justice in Minority Populations and Low-Income Populations,* directs Federal agencies to address the environmental justice impacts of their actions on minority and low-income populations. Each Federal agency must analyze environmental effects, including human health, economic, and social effects, of Federal actions, including effects on minority communities and low-income communities, when such analysis is required by NEPA.

The Region of Influence (ROI) around Pantex Plant in which the target populations covered by the Executive Order were examined is an 80-kilometer (50-mile) radius circle centered in the southwest corner of Zone 4 of Pantex Plant. As noted in sections 4.11.1.1 and 4.11.1.2, which address socioeconomic resources, nearly all minority and low-income persons in the four-county socioeconomic ROI around Pantex Plant were found to reside in the Amarillo urbanized area in 1990. The ROI utilized for the environmental justice analysis extends beyond the four-county socioeconomic ROI, but in this larger area also, most minority and/or low-income persons were found in 1990 to be residing in the Amarillo urbanized area.

According to the 1990 Census, there were 267,107 persons within the Pantex Plant ROI. White persons comprised nearly 81 percent of the population, Hispanics were the second largest group with 13 percent, and Blacks accounted for just over 4 percent of the total population. American Indians, Asians, Pacific Islanders and other racial groups totaled slightly more than 2 percent of the population within the ROI (UN 1995).

Most of the population in the ROI resides in various cities and towns (Figure 4.17.1–1). Amarillo is the most populous city with 157,615 persons in 1990; overall, 23 percent of Amarillo's population were minority persons and 17 percent of all persons were below the poverty level. The town of Pampa, about 56 kilometers (35 miles) northeast of Pantex Plant, is the second largest community in the area, with a 1990 population of 19,959, nearly 15 percent of which was minority and 14 percent of which was below the poverty level. Forty kilometers (25 miles) north of the plant is the town of Borger, with 15,675 persons in 1990; over 18 percent of Borger's residents in 1990 were minority and 15 percent were below the poverty level.

Dumas is about 68 kilometers (42 miles) northwest of Pantex Plant and its 1990 census count was 12,871 persons; more than 30 percent of this town's population was minority and 12 percent was below the poverty level. Canyon, approximately 48 kilometers (30 miles) southwest of Pantex Plant, had 11,365 persons in 1990; nearly 14 percent of this population was minority persons and 17 percent was below the poverty level. The towns of Clarendon, Claude, Panhandle, and White Deer had 1990 populations ranging between 1,125 and 2,353, with none having more than 10 percent minority population. The remainder of the 1990 population within the ROI, approximately 43,000 persons, lived on farms and ranches and in communities with fewer than 1,000 persons (TX Cen 1992a:Table 6; TX Cen 1993:Table 178).

The analysis of environmental justice presented in this section is based on the definitions of minority and low-income populations as contained in the notice of the Environmental Protection Agency's (EPA's) Office of Environmental Justice (59 FR 192). These definitions call for identification of Census tracts where 25 percent or more of the persons in 1990 were either minority group members or below poverty level based on their income in 1989. For comparison purposes, definitions of minority and low-income populations as

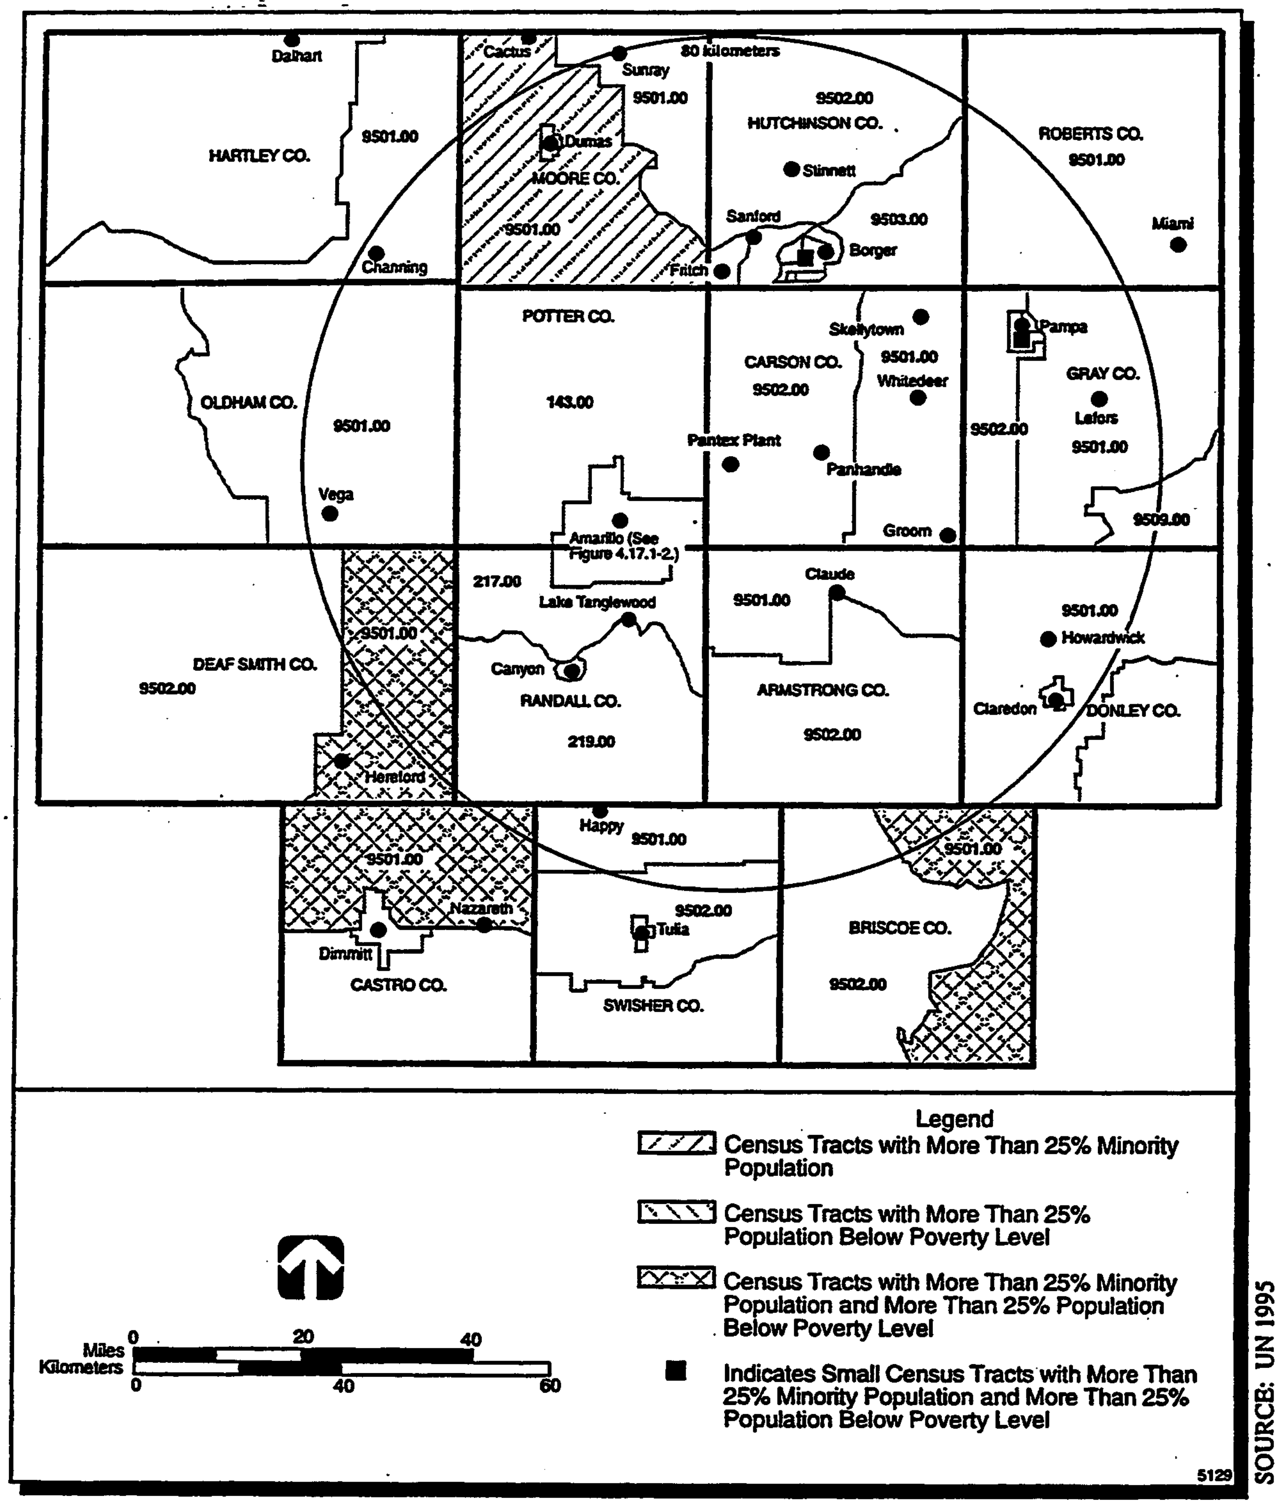

FIGURE 4.17.1–1.—*Minority and Low-Income Populations in the Pantex Plant Region of Influence, 1990.*

provided by the Council on Environmental Quality (CEQ) in April 1996 (CEQ 1996), and also reported in EPA's Guidance for Incorporating Environmental Justice Concerns in EPA's NEPA Compliance Analysis (EPA 1996a), were also applied to the 1990 Census data. Earlier EPA guidelines (59 FR 192), used in the following discussion, identified more Census tracts with minority and low-income populations than the CEQ or later EPA guidelines (EPA 1996a). Therefore, the impacts identified in the subsequent analysis in this document are more conservative (greater) than would have been the case if CEQ guidelines were applied.

The CEQ guidelines define minority populations as an area where either the minority population of the affected area (in this case, the Census tract or Block Numbering Area [BNA]) exceeds 50 percent or the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis (in this case, the ROI). Using the 50 percent criterion, only 10 Census tracts (all in the Potter County portion of the Amarillo Metropolitan Area) fall in the minority category. The second criterion of minority population being meaningfully greater than the regional average was defined as the average minority population plus one standard deviation that resulted in a minority population greater than 28.5 percent. Application of this criterion resulted in the identification of 19 Census tracts with meaningfully greater than average minority populations. In both cases, fewer than 23 tracts were identified with the application of EPA definition. If the CEQ guidelines are applied, the impacts on minority populations would be lower than those identified in this document.

The CEQ guidelines were also applied to the low-income populations. With the application of the first criterion using the U.S. Department of Health and Human Services definition, the affected Census tracts were reduced from 27 to 14 (12 in Potter County portion of the Amarillo Metropolitan Area and one each in the towns of Borger and Pampa). The number of Census tracts with low-income populations remained at 14 when the U.S. Department of Housing and Urban Development definition was applied. Once again, the definition applied in the present analysis on subsequent pages is more conservative (resulting in 27 Census tracts with low-income populations), and the impacts on low-income populations would be substantially lower if CEQ guidelines were applied.

Table 4.17.1–1 presents the 1990 Census counts of minority and low-income populations found in the rural BNAs wholly or partially within the ROI. Figure 4.17.1–1 identifies the BNAs where 25 percent or more of the persons, in 1990, were either minority group members or below the poverty level based on their incomes in 1989.

Figure 4.17.1–1 shows that 10 of the rural BNAs within the Pantex Plant ROI exceed the 25 percent thresholds for concentrations of minority and low-income persons. Most of the 10 areas are located in the outer reaches of the ROI, or more than 48 kilometers (30 miles) from Pantex Plant. Only small portions of the BNAs with minority and low-income populations in Briscoe and Castro Counties fall within the ROI. The community of Dumas in Moore County, northwest of the plant, and the rural area in the immediate vicinity of Dumas have resident populations that are more than 25 percent minority. BNA 9508, in the town of Borger in Hutchinson County due north of the plant, also has a more than 25 percent minority population. The remaining six BNAs, represent areas in which both minority and low-income populations have higher than 25 percent concentration.

Figure 4.17.1–2 presents the concentration of minority and low-income populations in the Amarillo metropolitan area, which extends across the Potter/Randall County line. Table 4.17.1–2 presents the 1990 Census counts of

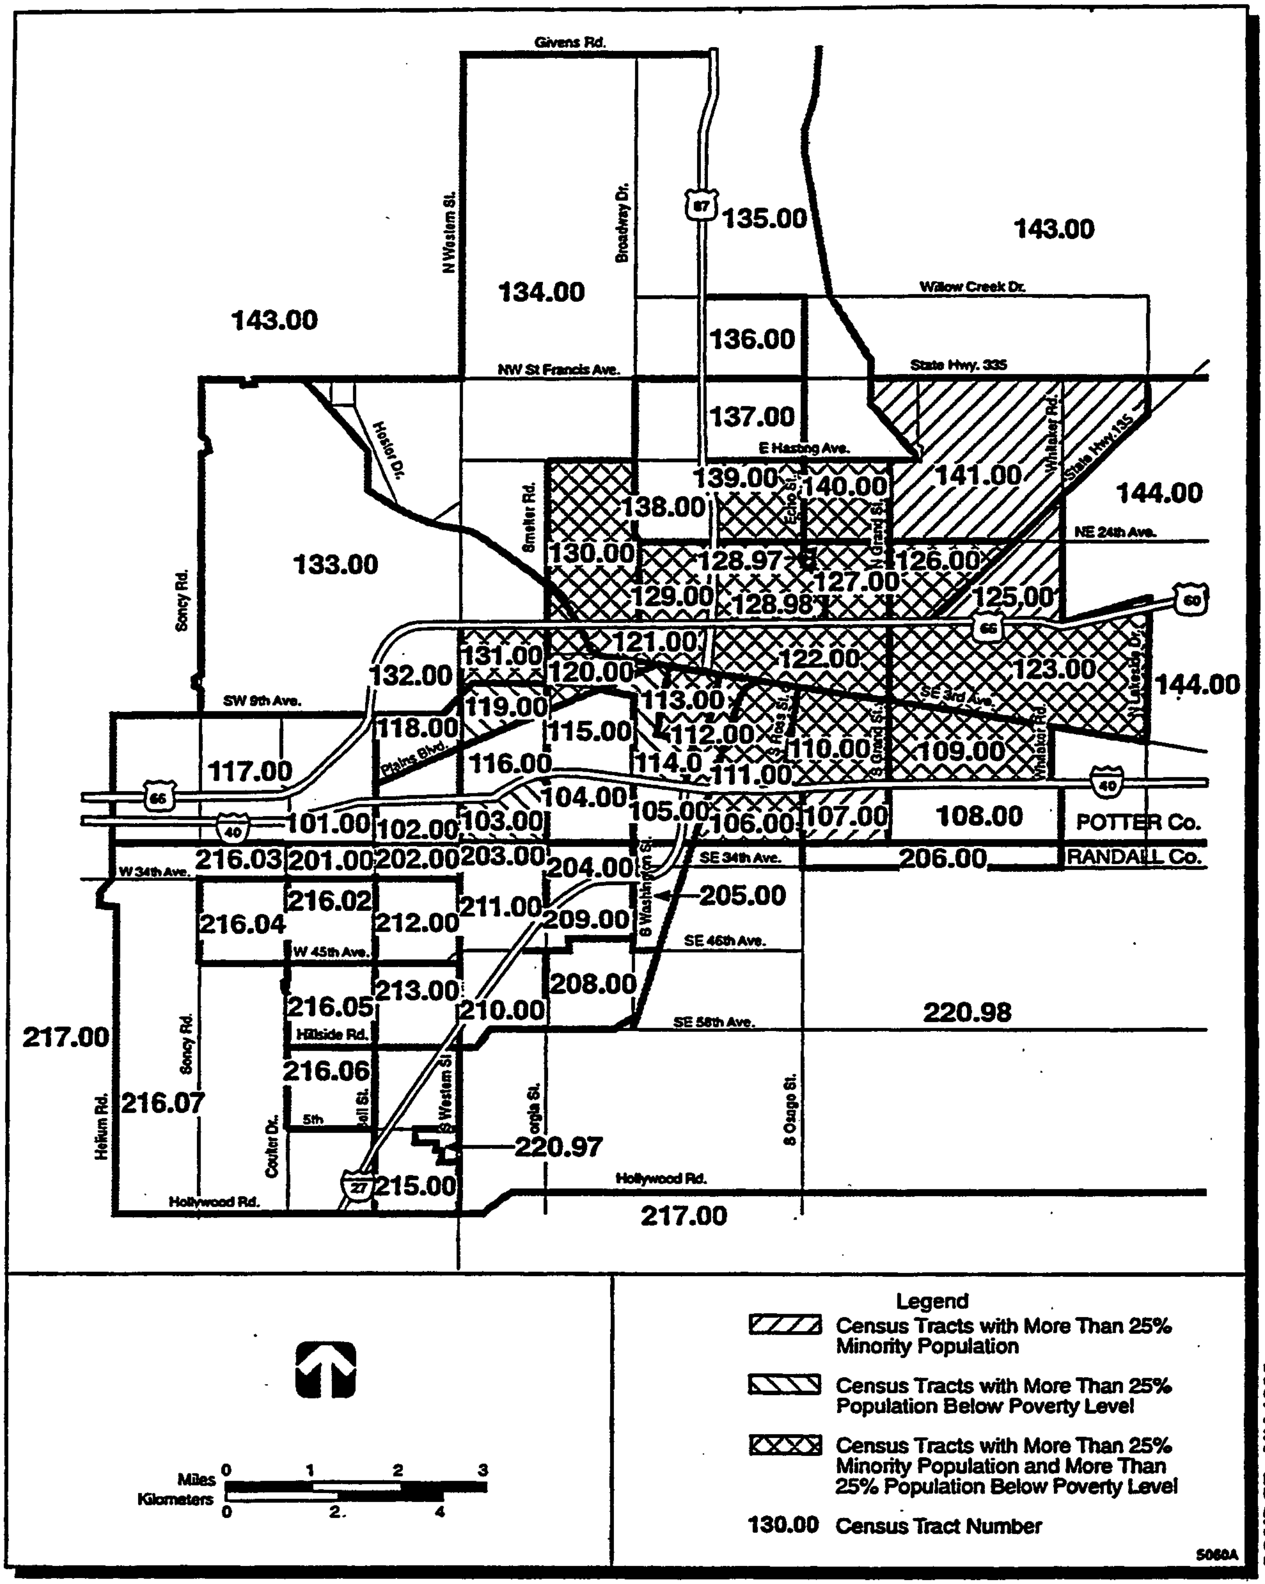

FIGURE 4.17.1–2.—*Minority and Low-Income Populations in the Amarillo Metropolitan Area, 1990.*

minority and low-income populations in Potter and Randall Counties.

There are no tracts in Randall County, within or outside of the Amarillo urban area, that had concentrations of 25 percent or more of minority or low-income persons. In Potter County, on the other hand, most tracts in the Amarillo urban area were characterized by one or both of these threshold conditions. These tracts are found primarily in the northeast quadrant of the city, in the general direction of Pantex Plant.

Tracts 125 and 141, the two tracts closest to Pantex Plant, were characterized by minority populations in excess of 25 percent, as were Tracts 107 and 128.97 in the east central and north central part of Amarillo. Tracts 103, 114, and 119, near the center of town, had more than one-fourth of their populations with incomes below the poverty level in 1989. Eighteen tracts, largely situated between the areas with one threshold condition or the other, are characterized by both threshold conditions; that is, more than 25 percent of their populations in 1990 were minority persons, and more than 25 percent of their populations were below the poverty level in 1989.

Thus, the minority and low-income populations specified by Executive Order 12898 are found in sufficient concentrations in 25 tracts in the northeast quadrant of the Amarillo urban area and in 10 rural BNAs within Pantex Plant ROI to warrant an analysis of the possible disproportionately high and adverse health and environmental impacts of the Proposed Action and the Alternatives considered in this EIS. Both Figures 4.17.1–1 and 4.17.1–2 clearly indicate that Pantex Plant is surrounded by rural tracts of white majority populations, and minority and low-income populations are located either in the Amarillo Urban area, approximately 27 kilometers (17 miles) away from Pantex Plant, or in the outer fringes of the ROI.

4.17.2 Impacts of Proposed Action

The Proposed Action includes the continuation of Pantex Plant operations at different levels of activity. Since the future stockpile requirements cannot be accurately predicted, three activities are analyzed to cover the possible range of activities at Pantex Plant: high level of activity which assumes handling of 2,000 weapons operations per year including assembly, disassembly, modifications, and surveillance activities; a moderate activity level to handle 1,000 weapons operations per year; and a low activity level to handle 500 weapons operations per year. To handle 2,000 weapons operations per year, the employment levels at Pantex Plant would remain at its 1995 operations. With no change in employment, the environmental impacts on the general population as well as on the minority and low-income populations would be similar to those currently experienced.

Approximately 60 percent of the total population in the Pantex Plant ROI is located in the City of Amarillo, and 96 percent are located in the Amarillo metropolitan area consisting of Potter and Randall Counties. Since Pantex Plant is located approximately 27 kilometers (17 miles) northeast of Amarillo, none of the biophysical impacts (such as impacts to air quality and water resources) and human health risks are experienced by the total population including the minority and low-income populations living in the metropolitan area. Even outside the Amarillo metropolitan area, most of the minority and low-income population is located in BNAs at the outer reaches of the ROI, more than 48 kilometers (30 miles) from Pantex Plant (Figure 4.17.1–1). The minority and low-income populations are, therefore, not expected to experience any disproportionately high or adverse human health, social, economic, or environmental effects from Pantex Plant operations.

Beneficial economic impacts of Pantex Plant are concentrated in the Amarillo metropolitan

Source: TX Cen 1993c:Tables 8 and 19

area where almost all of the employees working at the plant reside and where most of the local procurement expenditures for Pantex Plant occur. Almost 20 percent of the employees at Pantex Plant belong to the minority populations. This ratio is comparable to the minority population in the Amarillo metropolitan area where 20.9 percent of the total population belongs to minority. Employment at Pantex Plant, therefore, benefits both the majority (White) and minority populations proportionately.

Construction and/or modification of buildings for the six projects identified under the Proposed Action would not affect the minority and low-income populations disproportionately because these facilities do not require additional employees. The Gas Analysis Laboratory, Materials Compatibility Assurance Facility, Nondestructive Evaluation Facility, and Metrology and Health Physics Calibration and Acceptance Facility do not require additional workers; employees performing these functions in the existing facilities would be transferred to new facilities. The Hazardous Waste Treatment and Processing Facility and the Pit Reuse Facility would add 5 and 7 new employees, respectively. The impacts of these additions are considered negligible. In addition, all these facilities, except the Pit Reuse Facility, are intended to replace the existing facilities and to improve the health and safety conditions at the plant.

Overall, the minority and low-income populations in the Pantex Plant ROI are not disproportionately affected by the Proposed Action.

4.17.3 Impacts of No Action

Although the diassembly of weapons would cease at Pantex Plant once the number of pits stored at the site reaches 12,000, the weapons activity levels are assumed to stay at 2,000, 1,000, or 500. As a result, the employment levels and the biophysical impacts of the operations at Pantex Plant would be similar to those identified for the Proposed Action. No disproportionate effects on the minority and low-income populations are anticipated in the Pantex Plant ROI.

4.17.4 Impacts of Pit Storage Relocation Alternative

Even when the pits are relocated to other candidate site(s), the activity levels at Pantex Plant would remain the same as under the Proposed Action; only the activities related to pit storage would be eliminated. This would reduce Pantex Plant employment by approximately 30 workers and would not result in any substantial impacts. However, the pit handling activity at Pantex Plant would increase as pits are transferred to other sites. The impacts of this activity are discussed in sections 4.14, Human Health; 4.15, Aircraft Accidents; and 4.16, Intersite Transportation of Nuclear and Hazardous Materials. After the pits have been transferred to other site(s), human health and aircraft accident risks associated with the pit storage would be substantially reduced at Pantex Plant Site. These impacts are considered to be beneficial to the general population as well as to the minority and low-income populations in the Pantex Plant ROI.

4.17.5 Cumulative Impacts

The cumulative impacts presented here include impacts of the continued operations at Pantex Plant combined with impacts associated with activities described in the WM PEIS, SSM PEIS, and S&D PEIS. Since the Pantex Plant EIS Proposed Action and the SSM PEIS No Action Alternative represent a continuum of operations, the impacts associated with any new mission or facility that could be implemented at Pantex Plant are discussed in the context of that continuum. The impacts from the WM PEIS program are combined with those of the Pantex

Plant EIS Proposed Action. The impacts from the S&D PEIS are combined with those of the SSM PEIS No Action Alternative. A detailed discussion of this methodology is presented in section 4.2.

The final S&D PEIS will include an alternative that is a refinement of these storage alternatives. As discussed in sections 1.4 and 1.7.3 of this volume, the final S&D PEIS will include an alternative under which pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. The impacts of this alternative are fully accounted for in this EIS because the pits from RFETS could not cause the total number of pits stored in Zone 4 to exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Furthermore, RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant.

4.17.5.1 *Impacts of Alternatives in the Waste Management Programmatic Environmental Impact Statement*

Neither the Proposed Action nor the WM PEIS has identified any disproportionate effects on minority or low-income population in the Pantex Plant ROI. Hence, no cumulative impacts are anticipated.

4.17.5.2 *Impacts of Alternatives in the Stockpile Stewardship and Management Programmatic Environmental Impact Statement*

The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. None of the alternatives would result in impacts that would disproportionately affect minority or low-income populations in the Pantex Plant area.

4.17.5.3 *Impacts of Alternatives in the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement*

The S&D PEIS is considering Pantex Plant for long-term storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU), storage of inventories of surplus weapons-usable plutonium and HEU pending disposition, and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. The storage alternatives include upgrading the existing plutonium storage facilities, consolidation of plutonium from other sites, and collocation of plutonium and HEU storage. The collocation alternative is used for analysis purposes in this EIS as the bounding storage alternative.

Under the S&D PEIS Collocation Alternative, construction of new storage facilities would be required in order to store plutonium and HEU at Pantex Plant. The analysis of the demographic data indicates that even if there were any health impacts to the communities around the candidate sites, these impacts would not appear to disproportionately affect minority or low-income populations. Wind direction frequencies at all the DOE sites show that any emissions from the sites would not be disproportionately directed at minority or low-income communities.

For the disposition alternatives in the S&D PEIS, the emphasis at this stage in the NEPA decision process is on the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor is used for analysis purposes in this EIS as the bounding disposition alternative. Implementation of this disposition alternative would require the construction and operation of a pit disassembly and conversion facility, plutonium conversion facility, mixed oxide fuel fabrication facility, and one or more light water reactors. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

The analysis of the demographic data indicates that even if there were any health impacts to the communities around the candidate sites, these impacts would not appear to disproportionately affect minority or low-income populations. Wind direction frequencies at all the DOE sites show that any emissions from the sites would not be disproportionately directed at minority or low-income communities (DOE 1996a:4.0).

4.18 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

This section describes the major irreversible and irretrievable commitments of resources that can be identified at a site-specific level of analysis. A commitment of resources is irreversible when its primary or secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of a resource that is neither renewable nor recoverable for use by future generations.

This section discusses three major resource categories that are committed irreversibly or irretrievably under the Proposed Action: water, materials, and energy.

4.18.1 Water

There are no streams or rivers at or near Pantex Plant; all site water needs are met by groundwater. Regional demand on the Ogallala aquifer continues to exceed recharge. As such, a large portion of the water resources that support the plant represents expenditure of a nonrenewable resource. Taking the difference between the projected water usage and wastewater volumes for the 2,000 weapons scenario and those for FY 1995, this expenditure is estimated to be at least 300 million liters (80 million gallons).

4.18.2 Materials

The irreversible and irretrievable commitment of material resources during the entire life cycle and operation of Pantex Plant in support of assembly and disassembly facilities, high explosive manufacturing and processing facilities, plutonium storage, and operational support facilities includes construction materials (e.g., roofing materials), maintenance materials (e.g., paint), and operational support materials (e.g., chemicals). Consumption of these irretrievable materials is not expected to result in critical shortages.

4.18.3 Energy

The irretrievable commitment of resources during construction and operation of the facilities would include nonrenewable fuels to generate heat and power. Energy would be expended in the form of electricity and natural gas. The maximum consumption of electricity at Pantex Plant from continued operations at the 2,000 weapons level is estimated at 90,400 megawatt-hours per year. Corresponding natural gas consumption is estimated at 16.2 million cubic meters (573 million cubic feet) per year.

(This Page Intentionally Left Blank)

4.19 UNAVOIDABLE ADVERSE ENVIRONMENTAL IMPACTS

Continued operation, construction of new facilities, and an increase in plutonium storage capabilities at Pantex Plant would result in some adverse environmental impacts. The impact assessment conducted in this EIS has identified adverse impacts that cannot be fully mitigated. Residual impacts following mitigation are unavoidable.

Some unavoidable adverse environmental impacts would occur during construction of the new facilities. Natural resources would be impacted during construction as land is cleared for new facilities. However, the extent of the impact has been mitigated by selecting sites that were previously disturbed or are part of existing industrial areas.

During normal operations at Pantex Plant, a minimal amount of radioactive material is released to the environment. However, any radiation dose received by a member of the public from emissions from Pantex Plant is too small to be distinguished from naturally occurring background radiation. During normal operations at Pantex Plant, even with a strong As Low as Reasonably Achievable program and engineering and administrative controls, some radiological exposures to workers are expected.

During the timeframe of this EIS, the cumulative radiological exposure to the Pantex Plant workforce is expected to be essentially the same as for the Proposed Action (330 person-rem). This exposure will result in 0.13 excess cancer fatalities in the group. Maximum individual radiological exposures will be maintained below the DOE administrative goal of 900 millirem per year. Assuming that a single individual is exposed to 900 millirem per year for 10 years, this individual's risk of contracting a fatal cancer will increase by 3.6×10^{-3}.

Since hazardous and toxic chemicals are associated with the construction and operation of Pantex Plant facilities, worker exposure to these chemicals is unavoidable. However, no onsite chemical concentrations exceed the Occupational Safety and Health Administration threshold limit values. No fence line chemical concentrations exceed the TNRCC Effects Screening Levels (ESLs), and thus do not pose a threat to the public

Remote, automated, and robotic production methods (e.g., high explosive machining) are currently in place. Additional development through technology transfer is an ongoing effort. Continued success in the Pollution Prevention and Waste Minimization program (see appendix G) would further reduce the hazard index and could possibly eliminate the cancer risk.

Solid wastes (which include liquids and gases by definition) would be generated as an unavoidable result of Pantex Plant operations. Although Pantex Plant utilizes a Pollution Prevention and Waste Minimization program, generation of low-level, low-level mixed, hazardous, and nonhazardous wastes is unavoidable. No new waste types are expected as a result of the Proposed Action, No Action, or Pit Storage Relocation Alternative scenarios at Pantex Plant.

(This Page Intentionally Left Blank)

4.20 Relationship between Local Short-Term Uses of the Environment and the Maintenance and Enhancement of Long-Term Productivity

The implementation of the Proposed Action or one of the Alternatives would cause some adverse impacts to the environment and permanently commit some resources to specific plant activities. This section describes the relationship between short-term effects of the continued operations at Pantex Plant and the associated long-term effects on productivity.

The Proposed Action and Alternatives for Pantex Plant would require the short-term use of resources (e.g., fuel, electricity, water, construction materials, land, and labor) to achieve the long-term goal of maintaining a safe nuclear weapons stockpile. Under Presidential direction, the stockpile has been reduced. A large number of weapons are no longer designated for the stockpile. In assembled form these weapons require a great deal of security and monitoring. Disassembled, these weapons are safer, less likely to impact the environment, and less expensive to maintain and secure. Thus the short-term expenditure of resources to disassemble the weapons results in long-term benefits in terms of lowered risk and greater cost efficiency.

The use of land being considered for the continued operations and increasing plutonium storage at Pantex Plant would enhance the long-term productivity in two ways. First, assembly and disassembly of nuclear weapons, high explosive manufacturing and processing, and plutonium storage missions represent a long-term production function compatible with historic nuclear weapons support and require a skilled and stable workforce. Second, since existing facilities suitable to assemble and disassemble nuclear weapons, manufacture and process high explosives, and store plutonium do exist, DOE is able to minimize short-term impacts and selectively construct new, modern support facilities that will enhance the existing productivity and ensure long-term productivity at Pantex Plant.

The only requirements for additional land use are for the construction of six new projects. The continued operations, including existing plutonium storage, do not require additional land at this time. The Pit Reuse Facility would be placed in an existing building, and would enhance the safety and reliability of the plutonium stockpile without a production reactor. The Gas Analysis Laboratory, the Nondestructive Evaluation Facility, the Metrology and Health Physics Calibration and Acceptance Facility, and the Material Compatibility Assurance Facility projects, while requiring additional land for the consolidation and modernization of existing facilities and operations, are expected to enhance long-term productivity.

The Hazardous Waste Treatment and Processing Facility (HWTPF) represents an enhancement and modernization of existing capabilities in Building 11–9S. The HWTPF is part of a major commitment by Pantex Plant for the protection of the environment through the treatment of wastes in agreement with TNRCC and the Environmental Protection Agency (EPA). Through the *Federal Facility Compliance Act* Site Treatment Plan, the plant expects to treat waste to meet the EPA's Land Disposal Restrictions standards.

Losses of terrestrial habitats to accommodate the new facilities and temporary disturbances during construction of these facilities are expected. However, these impacts have been minimized by selecting sites in areas where industrial operations currently exist. Short-term disturbances and impacts on previously disturbed land are expected to be minimal.

Pantex Plant is developing and implementing plans for ecosystem management in specific areas of Pantex Plant (e.g., playa areas) and studying the use of existing surplus facilities for other purposes. The Pantex Plant environmental restoration program and Texas' Clean 2000 program are currently managing cleanup and restoration of 144 solid waste management units. Environmental restoration activities, while causing some short-term impacts, provide for long-term improvement.

4.21 Summary of Cumulative Impacts

Cumulative impacts include the incremental impacts of the actions (usually Proposed or Preferred Action) when added to other past, present, and reasonably foreseeable future actions. The impacts of past actions have been described in the Affected Environment sections of this EIS and are reflected in the Proposed Action impacts at the 2,000 weapons activity level (current operations at Pantex Plant). Additional DOE programs planned or underway at Pantex Plant include the Stockpile Stewardship and Management (SSM), Waste Management (WM), and Storage and Disposition (S&D) programs which are the subject of three separate Programmatic EISs described in section 1.7 of this volume.

In addition to the DOE programs, information on other Federal, State, or local projects, including private developments, was sought through contacts with Federal and State regulatory agencies, the Amarillo Economic Development Corporation, the Panhandle Municipal Water Authority, and the City of Amarillo. This effort yielded only one project (future closure of the Helium Plant) that would contribute to the cumulative impacts in the Pantex Plant Region of Influence. A discussion of its cumulative impacts has been added in section 4.11.5 because cumulative impacts are limited to socioeconomic impacts.

The Pantex Plant EIS and the SSM PEIS both discuss the operations of the entire Pantex Plant but over different time frames. The level of operations, and associated impacts, discussed in the Pantex Plant EIS is for an approximately 10-year time frame beginning in the year 1997. The SSM PEIS discusses a lower level of the same kind of operations for the time frame of approximately the year 2005 and later. The operational levels discussed in the Pantex Plant EIS Proposed Action will evolve over the next 10 years into the level of operations discussed in the No Action Alternative of the SSM PEIS. The cumulative impacts associated with any new mission or facility at Pantex Plant should be placed in the time frame of the overall impacts of Pantex Plant Site at the time those facilities or missions would be implemented.

In chapter 4, the new missions and facilities associated with the WM PEIS are assumed to take place in the same time frame as the Pantex Plant EIS Proposed Action. The new missions and facilities associated with the S&D PEIS are assumed to take place in the same time frame as the SSM PEIS No Action. While these assumptions are well founded, the elements of the different programs could be delayed or moved ahead. In this section, the impacts of the different programs are presented by themselves without being combined with the impacts of either the Pantex Plant EIS Proposed Action or the SSM PEIS No Action. This is done in order that the reader can see in detail the impacts associated with each of the different missions, facilities, and time frames, and can add the impacts in any combination.

The Preferred Alternative for stockpile management is a downsized (rightsized) plant to provide an effective and efficient manufacturing capability for a smaller stockpile. With a smaller stockpile and no new-design weapons production, industrial capacity can be reduced to meet anticipated manufacturing requirements for stockpile repair and replacement activities. If the SSM PEIS decision, as announced in the Record of Decision, is to downsize Pantex Plant, such action would commence in the year 1998 and be completed by approximately the year 2005. Because downsizing would involve internal modifications to existing facilities, no land would be disturbed, and there would be no significant change to any environmental resources during the completion of modifications. Consequently, there would no significant cumulative impacts associated with the downsizing of Pantex Plant facilities.

The SSM column in Table 4.21–1 shows the impacts of downsizing-in-place the assembly/

disassembly and high explosive (HE) fabrication facilities at Pantex Plant. These impacts are not in addition (cumulative) to the impacts identified for the continued operations at the 2,000 weapons activity level. Instead, environmental impacts resulting from SSM activities at Pantex Plant represent a reduced level of impacts after the plant completes its disassembly activities and evolves into a long-term stockpile management facility.

The WM PEIS examines the environmental impacts of alternative configurations for the management of radioactive and hazardous wastes at DOE sites throughout the U.S. Pantex Plant is considered one of 17 "major" sites managing DOE wastes. For Pantex Plant, the PEIS analyzes management of low-level mixed waste (LLMW), low-level waste (LLW), and hazardous waste (HW) in four configuration alternatives: No Action, Decentralized, Regionalized, and Centralized.

The most adverse impacts of activities at Pantex Plant would occur as a result of the Decentralized Alternative. Therefore, only the impacts of this alternative are provided in Table 4.21–1. With this alternative, treatment and disposal facilities would be constructed for LLMW and LLW at Pantex Plant. The treatment facilities needed for LLMW and LLW have already been evaluated in chapter 4 of this volume. The WM PEIS does not provide NEPA analysis for the construction of new disposal facilities, such as a landfill, which would be needed if the Decentralized Alternative is selected as the Preferred Alternative for LLMW and LLW disposal.

For the S&D PEIS, two bounding alternatives (alternatives with the most adverse environmental impacts), one for storage and the other for disposition activities, are considered in this cumulative impact analysis. For the storage alternatives, collocation of plutonium and highly enriched uranium (HEU) facilities generates the most adverse impacts as it would require construction of new storage facilities at Pantex Plant. For the disposition alternatives, the most adverse impacts would occur if the pit disassembly/conversion facility, the plutonium conversion (non-pit) facility, the mixed oxide (MOX) fuel fabrication facility, and the evolutionary light water reactor were all located at Pantex Plant.

As discussed in sections 1.4 and 1.7.3 of this volume, the final S&D PEIS will include an alternative under which plutonium pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. Impacts related to the intersite transportation of these pits are described in section 4.4 of the S&D PEIS. The total potential fatalities from the intersite transportation of the RFETS pits to Pantex Plant is estimated as 6.4×10^{-3} from both radiological and nonradiological impacts to the public and workers for both routine and accident conditions.

The impacts from the Storage Collocation Alternative and the MOX Fuel/Light Water Reactor Alternative would probably occur during the next seven to 20 years and, therefore, would be cumulative to the impacts discussed in the SSM PEIS No Action Alternative. However, the construction and operation of the S&D facilities could take place within the next five to seven years, and thus could be cumulative to the impacts discussed in the Pantex Plant EIS Proposed Action. So the impacts of the Storage Collocation Alternative, the construction of the MOX Fuel/Light Water Reactor Alternative, and the operation of the MOX Fuel/Light Water Reactor Alternative are presented separately in Table 4.21–1 without being combined with the impacts of either the Pantex Plant EIS Proposed Action or the SSM PEIS No Action.

Table 4.21–1 summarizes the impacts for Proposed Actions at the 2,000 weapons activity level and the most adverse impacts from the SSM, WM, and S&D programs at Pantex Plant.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
PLANT FACILITIES AND INFRASTRUCTURE					
The annual utility usage for the plant and six new projects would be: Steam - 181M kg (398M lb) Electricity - 90,400 MWh Natural Gas - 16.2M m^3 (573M ft^3) Utility demand would be substantially less than utility capacity; therefore, no significant impacts to infrastructure are expected.	Under the No Action Alternative, no downsizing or modification of facilities would occur, and there would be no construction impacts. Due to reduced workload expected in the future, infrastructure impacts from current operations would be expected to be less than current impacts. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Facilities would be consolidated and impacts would be expected to be less than current impacts. Under the relocation alternative, the facilities would undergo decontamination and decommissioning.	The utility usage would conservatively be: Steam - 180M kg (392M lb) Electricity - 33,350 MWh Natural Gas - 0.8M m^3 (27M ft^3) Utility demand would be within system capacity; therefore, there are no significant impacts to infrastructure expected	Site infrastructure resources required would be less than resources available onsite. No increases in electricity and gas usage would occur. Oil requirements would increase slightly during construction.	Site infrastructure requirements would be: Electricity - 24,333 MWh Oil - 1,356,233 liters Gas - 0 m^3	Site infrastructure requirements would be: Electricity - 1,154,000 MWh Oil - 844,750 liters Gas - 8,976,000 m^3

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
LAND RESOURCES					
The impacts to land resources are expected to be limited. New land use for new facilities would involve an area of 1.6 hectares (4 acres), equal to 0.04 percent of total area at Pantex Plant.	Under the No Action Alternative, no downsizing or modification of facilities would occur, and there would be no change in land use. Under the downsizing alternative, facilities would be consolidated and impacts would be expected to be less than current impacts. Under the relocation alternative, the Pantex Plant facilities would be decommissioned and no longer active.	Total land used for the new facilities would involve an area of 10.6 hectares (26.3 acres).	New plutonium (Pu) and HEU storage facility would require 89.5 hectares (221 acres) of land. No new land disturbance would occur.	Land disturbance would conservatively be 639 hectares (1,580 acres).	Land disturbance would conservatively be 403 hectares (995 acres).
GEOLOGY AND SOILS					
The impacts to geology or soils would be limited to the temporary disturbance of 31,800 m^2 (342,000 ft^2) resulting from construction of new facilities.	Under the No Action Alternative, no downsizing or modification of facilities would occur, and there would be no construction. Therefore, impacts to soils would be expected to be the same as those from current operations. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Consequently, no significant land disturbance would occur. Under the relocation alternative, decontamination and decommissioning of the facilities would not be expected to have impacts to the soil.	No impacts on soils identified in the PEIS. However, temporary disturbance of up to 21.2 hectares (56.2 acres) could occur during construction.	No apparent direct or indirect effects on geologic resources would be anticipated. Soil impacts during construction would be minimal.	No apparent direct or indirect effects on geologic resources would be anticipated. Soil impacts during construction would be minimal.	No apparent direct or indirect effects on geologic resources and soils are anticipated.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
WATER RESOURCES					
Annual wastewater generation and water demand for the plant and six new projects would be: Wastewater - 647M liters (172M gal) Water - 1,011M liters (267M gal) Compliance with current discharge standards would keep levels of contaminants the same. The increase in Pantex Plant annual water usage (currently 0.6 percent of regional withdrawal from the Ogallala aquifer) would not significantly affect the ongoing regional depletion of the aquifer.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, impacts to water resources from operations would be expected to be approximately 249M liters (66M gallons) per year. Water requirements would be met without increased aquifer drawdowns. Under the downsizing alternative, the groundwater withdrawals would be approximately 209M liters (55M gallons) per year, a reduction of 16 percent compared to those under the No Action Alternative. Under the relocation alternative, all water use for assembly and disassembly operations and HE fabrication would cease.	Annual wastewater generation and water demands would be: Wastewater - 43,660 liters (11,535 gal) Water - 96,200 liters (25,416 gal) The Pantex Plant water usage (currently 0.6 percent of regional withdrawal from the Ogallala aquifer) would not significantly affect the ongoing regional depletion of the aquifer.	Annual wastewater generation and water usage would be: Wastewater - 13M liters (3.4M gal) Water - 130M liters (34M gal)	Annual wastewater generation and water usage would be: Wastewater - 110.2M liters (29M gal) Water - 130.2M liters (34.4M gal)	Annual wastewater generation and water usage would be: Wastewater - 484.7M liters (128M gal) Water - 572.9M liters (151.3M gal)

TABLE 4.21-1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
AIR QUALITY					
Offsite concentrations of air pollutants were modeled and compared to screening levels which showed no adverse impacts to human health are expected. The onsite air quality levels are below those that would pose health risks to workers. The impacts from temporary increases in emissions from construction of new facilities would be negligible.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, air quality impacts from operations would be expected to be less than current impacts. Air quality would remain within regulatory limits. Under the downsizing alternative, the operations would be consolidated. Air quality impacts would be equivalent to those of the No Action Alternative. Under the relocation alternative, air quality impacts from assembly and disassembly operations and HE fabrication would cease.	Impacts would remain below the National and State air quality standards.	The new Pu and HEU facility would have minimal air quality impacts. Concentrations of criteria, toxic, and hazardous air pollutants are predicted to be in compliance with Federal, State, and local air quality regulations or guidelines.	Construction of facilities would result in emissions of some pollutants. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.	Operations of facilities would result in emissions of some pollutants. Emissions would typically not exceed Federal, State, or local air quality regulations or guidelines.
ACOUSTICS					
Except for airblast from HE detonations, noise levels from Pantex Plant activities would be below 65 dBA at the plant boundary. The detonations could be audible at a distance of 5 to 10 kilometers (3 to 6 miles). Due to the size of the site, noise from construction of the new facilities would not reach the public.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, noise impacts from operations would be expected to be less than current impacts. Under the downsizing alternative, facilities would be consolidated. The noise impacts would be equivalent to the No Action Alternative. Under the relocation alternative, noise from assembly and disassembly operations and HE fabrication would cease.	Associated construction activities include heavy construction equipment and increased traffic. Non-traffic noise associated with the operation would be located at sufficient distance that contribution to offsite noise levels would continue to be small.	Noise from construction equipment or operations activities would not be expected to cause annoyance to the public due to size of the site.	Noise from construction equipment would not be expected to cause annoyance to the public.	Noise from operations activities would not be expected to cause annoyance to the public.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
BIOTIC RESOURCES					
There would be no impacts to threatened or endangered species, wetlands, or terrestrial or aquatic resources from Pantex Plant operations. The construction of new facilities would result in loss of 15,900 m^2 (171,000 ft^2) of common plant and animal habitat, but would not impact sensitive species or habitats.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Impacts to biological resources from operations would be expected to remain the same as current impacts. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Consequently, no potential impacts to biota would occur. Under the relocation alternative, decontamination and decommissioning activities of the existing facilities would not impact biotic resources.	Since specific sites for disposal facilities have not yet been identified, no specific impacts can be discussed at this stage.	Construction and operations of new Pu and HEU facility would have minimal impact on biological resources due to use of disturbed area of the site.	Facility construction would adversely affect 429 hectares (1,150 acres) of vegetation from land clearing activities. Animal populations would also be affected.	Facility operations would not result in any additional impacts other than those shown for construction of facilities.

TABLE 4.21-1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
CULTURAL RESOURCES					
No impacts to cultural, Native American, or paleontological resources are anticipated from the Proposed Action or the construction of new facilities.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Impacts to cultural resources from operations would be expected to remain the same as current impacts. Under the downsizing alternative, all construction activities would be modifications to existing facilities. Consequently, no potential impacts to cultural resources would occur. Under the relocation alternative, decontamination and decommissioning of existing facilities would not impact cultural resources.	Since specific sites for disposal facilities have not yet been identified, no specific impacts can be discussed at this stage. In general, given that future siting priorities would include minimum or no impact to specific cultural resources, significant impacts from these activities are unlikely.	Impacts to prehistoric and historic resources are not anticipated within the previously disturbed construction area of the new facility. Operations would not result in additional impacts.	Facility construction could adversely affect some cultural resources on as much as 429 hectares (1,150 acres) of previously undisturbed lands.	Facility operations would not result in additional impacts other than those shown for construction of facilities.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
SOCIOECONOMIC RESOURCES					
3,800 direct jobs and 6,257 secondary jobs would continue. Total personal income of $564 million would be added to the economy annually. Construction of new facilities would temporarily generate 1,227 direct and indirect jobs. A total of $56 million of personal income would be added to the economy in the peak construction year.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, the most significant change at Pantex Plant would involve the number of workers associated with the assembly and disassembly mission, which would be expected to decrease from approximately 2,365 to approximately 915 for one-shift operations. The number of direct workers associated with HE fabrication would decrease from approximately 365 to 105. Under the downsizing alternative, assembly and disassembly operations at Pantex Plant would proceed more efficiently and require approximately 800 workers for one-shift operations, 115 workers less than under the No Action Alternative. For three-shift operations, the bounding-case, approximately 1,266 workers would be required. All construction activities would be modifications to existing facilities. Consequently, socioeconomic impacts from the construction would be minimal.	654 direct workers would be required during the operations period. This figure is conservative because the employment due to new treatment facilities is already taken into account in the figures for the Proposed Action.	Construction and operation of the new facility would require 1,524 and 676 workers, respectively.	Construction of facilities would require an average of 1,850 construction workers per year over a 6-year period.	Facility operations would require 5,122 new workers at the plant site.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
SOCIOECONOMIC RESOURCES (CONTINUED)					
	Under the relocation alternative, approximately 1,644 direct and 1,905 indirect jobs would be lost in the regional economic area. The loss of approximately 3,549 total jobs would cause the regional economic area unemployment rate to increase from 4.8 to 6.2 percent. Housing and rental vacancies and public finance expenditures and revenue would change by less than 1 percent.				
INTRASITE TRANSPORTATION					
The Proposed Action would have an estimated worker exposure of 61 person-rem, and a group latent cancer fatality risk for 10-year exposure of 0.024.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, impacts from intrasite transportation activities would be expected to be less than current impacts. Under the downsizing alternative, the facilities would be consolidated; this could further reduce the amount of intrasite transportation impacts. Under the relocation alternative, intrasite transportation associated with assembly and disassembly operations and HE fabrication would cease.	Potential fatalities to the offsite population and to workers from waste management activities are essentially zero for every alternative.			

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
		WASTE MANAGEMENT			
The Proposed Action would result in the annual generation of the following amounts of waste: LLW - 249 m^3 (326 yd^3) LLMW - 183 m^3 (240 yd^3) HW - 192 m^3 (251 yd^3) NHW (Class 1) - 742 m^3 (970 yd^3) NHW (Class 2) - 574 m^3 (751 yd^3)	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, waste management impacts from operations would be expected to be less than current impacts. Generated wastes would be adequately managed with existing waste management facilities. Under the downsizing alternative, Pantex Plant would have adequate waste management facilities to treat, store, and dispose of its wastes, although LLW at Pantex Plant would continue to be shipped offsite to Nevada Test Site. Under the relocation alternative, the amount of eventual decontamination and decommissioning activities and wastes would increase.	The Pantex Plant Proposed Action includes the construction and operation of the treatment facilities. The construction of the disposal facilities would not generate any waste, only fill dirt. The operation of the disposal facilities would not generate any wastes. Therefore, the amount of waste to be managed would remain as shown under the Pantex Plant Proposed Action.	The collocated facility would result in annual generation of the following amounts of liquid/solid waste: TRU Waste - 0.02/10 m^3 Mixed TRU - 0/4 m^3 LLW - 2.1/1,300 m^3 LLMW - 0.2/66 m^3 HW - 2/2 m^3 NHW - 129,500/ 1,840 m^3	Construction of facilities would result in the generation of minimal amounts of hazardous and non-hazardous wastes. These wastes would be managed onsite.	Facility operations would result in the annual generation of the following amounts of liquid/solid waste: TRU Waste - 3.2/651 m^3 Mixed TRU - 0/204 m^3 LLW - 18,964/2,498 m^3 LLMW - 1.24/235.7 m^3 HW - 8/191.7 m^3 NHW - 485,300/ 7,516 m^3 Spent fuel - 52 metric tons

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
HUMAN HEALTH					
The Proposed Action would have an estimated worker exposure of 330 person-rem, and a group latent cancer risk for 10-year exposure of 0.13.	Under the No Action Alternative, no downsizing or modification of facilities would occur. Due to the reduced workload expected in the future, human health impacts from operations would be expected to be less than current impacts. The average radiological dose to workers would not be expected to change, although the total worker dose would change due to the reduced number of workers associated with a reduction in workload. Potential impacts from accidents, which are essentially independent of a given operating tempo, would not be expected to change.	Potential fatalities to the offsite population and to workers from waste management activities are essentially zero for every alternative.	The annual dose to the public from the collocated facility would be 5.3×10^{-5} person-rem. This would cause an estimated 1.3×10^{-6} fatal cancers during 50 years of operation. The alternative of storing surplus pits from RFETS at Pantex Plant in the near-term could cause less than 10^{-2} fatal cancers for affected workers due to repackaging operations. There would be no effect to the public.	Facility construction is expected to have negligible human health impacts.	The annual doses resulting from facility operations would be within radiological limits and well below levels of natural background radiation.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
AIRCRAFT ACCIDENT					
An aircraft accident capable of causing a release from a pit storage or weapons storage magazine is extremely unlikely (frequency of occurrence less than 10^{-4} but greater than or equal to 10^{-6}). A person in the vicinity of the plant has an approximately 3.0×10^{-12} increase in fatal cancer risk from potential aircraft crash plutonium dispersal accidents for the bounding Zone 4 storage configuration.	The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. Although the No Action Alternative, does not account for the time plutonium is at risk, there would be a reduction in the risk from an aircraft crash because of the reduction in operations. Under the downsizing alternative, there would be a consolidation of facilities and a commensurate reduction in the risk from an aircraft crash due to the fewer number of facilities. Under the relocation alternative, the risk from an aircraft crash into assembly and disassembly and HE fabrication facilities would be reduced to zero.	The impacts resulting from an aircraft accident to waste management facilities were not calculated in the WM PEIS.	The collocated storage facility would result in a reduction in the probability of an aircraft crash into a building or magazine containing plutonium. This reduction is due to the reduced number of buildings and magazines that would be utilized.	Facility construction was not analyzed for aircraft accidents. No plutonium release would occur in the event of an aircraft crash.	No aircraft accident analysis was conducted in the S&D PEIS.

TABLE 4.21–1.—*Environmental Impacts of Pantex Plant Operations and Other Reasonably Foreseeable Projects*-Continued

IMPACTS OF PANTEX PLANT OPERATIONS AT PROPOSED ACTION LEVEL (2,000 WEAPONS LEVEL INCLUDING 20,000 PITS IN STORAGE)	IMPACTS OF PANTEX PLANT OPERATIONS AT STOCKPILE STEWARDSHIP AND MANAGEMENT PEIS LEVEL (SSM PEIS)	IMPACTS OF WASTE MANAGEMENT PROGRAM (WM PEIS)	IMPACTS OF COLLOCATION OF PU AND HEU STORAGE FACILITY (S&D PEIS)	IMPACTS OF CONSTRUCTION OF DISPOSITION FACILITIES (S&D PEIS)	IMPACTS OF OPERATIONS OF DISPOSITION FACILITIES (S&D PEIS)
ENVIRONMENTAL JUSTICE					
Minority and low-income populations would not be disproportionately affected.	The SSM PEIS includes three alternatives that apply to Pantex Plant: No Action, Downsize Existing Capability, and Relocate Capability. None of the alternatives would result in impacts that would disproportionately affect minority or low-income populations in the Pantex Plant area.	No disproportionate effects on minority or low income populations were identified in the WM PEIS.	Minority and low-income populations would not be disproportionately affected.	Minority and low-income populations would not be disproportionately affected.	Minority and low-income populations would not be disproportionately affected.

M - Million
LLW - Low-level waste
HW - Hazardous waste
dBA - Decibel A-weighted scale
MWh - Megawatt hours
LLMW - Low-level mixed waste
NHW - Nonhazardous nonradioactive waste

CHAPTER 5

Affected Environment and Environmental Consequences at Alternative Pit Storage Sites

CHAPTER 5
AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES AT ALTERNATIVE PIT STORAGE SITES

Chapter 5 focuses on the affected environment and impacts of relocating pit interim storage to the candidate sites. The candidate sites, in order of presentation, are Nevada Test Site, Savannah River Site, Hanford Site, and Kirtland Air Force Base. For each of these sites, the affected environment and impacts of relocating storage (for either 20,000 or 8,000 pits) are addressed by type of affected resource or other issue area—just as is done in chapter 4 for Pantex Plant.

5.1 INTRODUCTION

This chapter discusses the affected environment and the potential environmental impacts at the four sites being considered for the interim storage of pits under the Pit Storage Relocation Alternative. The discussion of the general information associated with relocation of pit storage operations is followed by discussions of each site, which focus on the facilities being considered for interim pit storage. Subsequently, the site's affected environment and the environmental impacts due to interim pit storage are presented.

General Information on Relocation of Pit Storage Operations

The AL–R8 pit packaging that is currently used for storing pits at Pantex Plant is no longer used for intersite transportation of pits. A new storage and transport container, known as AT–400A, is being developed by Sandia National Laboratories and could be used for relocation of pits to an alternative interim storage site. This container or any other containers certified by the Department of Transportation for shipment of pits to the alternative site would be transported from Pantex Plant to an alternative site by the DOE Transportation Safeguards Division's Safe Secure Tractor Trailers. The impacts of transporting pits to the candidate facilities are discussed in section 4.16, Intersite Transportation of Nuclear and Hazardous Material.

In the candidate facilities at any of the relocation sites, the pit transportation and storage containers would be stored in a manner similar to the Stage Right pit storage system currently used at Pantex Plant (i.e., a multiple stacking configuration of containers placed horizontally on pallets) (see section 4.12.1.1). The pallets for this configuration have been designed to ensure structural integrity and stability in a maximum credible earthquake scenario. The pallets are lifted into place using a commercially available turret forklift that has been modified to provide radiation shielding that reduces operator exposure to extremely low levels (essentially background level). This electric forklift would be used for storage, retrieval, and inventory operations.

Efforts are currently underway to develop Automated Guided Vehicles (AGVs) that could be used both to place pits in the interim storage facilities and to assist in taking inventories using bar code readers. The use of AGVs could virtually eliminate any need for humans to enter the interim pit storage area. The AGVs would be utilized at the candidate sites as soon as the system becomes available.

Operations in the candidate interim storage facilities would include periodic inventory and inspections. Inspections would coincide with planned inventory activities and would consist of a visual inspection of facility conditions and container surfaces as well as removal of selected containers for surveillance tests. Except at Hanford Site, the surveillance tests would be conducted at another facility where both visual and nondestructive evaluation techniques would be used for evaluation (for corrosion), weld integrity, and integrity of insulation and plastic parts. At Hanford Site, the facility that would be used for storage is also large enough to house surveillance testing. The shielded forklift or AGV would carry a bar code reader, camera, and gamma spectrometer to allow inventory and inspection to be performed without operator exposure to radiation.

For each of the sites being evaluated in this chapter, the candidate facilities would require at least minor modification and upgrades before interim pit storage could be implemented. These modifications and upgrades would mostly involve sealing wall penetrations, rerouting utilities, and installing new doors, security equipment, and equipment to store and monitor the pits (e.g., Stage Right). Approximately 30 persons would be needed to perform materials handling activities; materials control and accountability; surveillance testing; environment, safety, and health activities; and other support. In addition, approximately 120 security personnel would be needed to provide continuous security at the site. Equipment at a site would include but not be limited to two shielded forklifts or AGVs, gamma spectrometer, radiation inspection, monitoring, and calibration equipment. Any special modifications needed for a facility are discussed in the introduction to each candidate site. Approximately 2,000 pits per year are assumed to be transported to the site for storage.

In planning the transition of facilities to accept a pit storage mission, the following guidelines would be followed:

- Laws, regulations, formal agreements, and DOE orders will form the basis for transition planning and execution.
- Transition planning will be coordinated with the appropriate regulatory agencies, host state, and other affected stakeholders.
- DOE will ensure that all vital safety and utility systems within the affected facility will be fully functional prior to pit storage.
- DOE will develop a current safety analysis report and other technical safety requirements that address the change in facility mission and condition of the facility prior to pit storage.
- DOE will establish an appropriate Environment, Safety, and Health organization to support pit storage activities prior to pit storage.

The S&D PEIS is evaluating some of the sites being considered in this EIS for interim storage, for the long-term storage of weapons-usable fissile materials. The impacts of transporting fissile materials from interim storage site(s) to the long-term storage site are too speculative for meaningful assessment at this time and are, therefore, not discussed in this EIS.

THE NEVADA TEST SITE

5.2 NEVADA TEST SITE

Under the Pit Storage Relocation Alternative (see section 3.1.3), pit storage operations at Pantex Plant would be transferred to another site. The Nevada Test Site (NTS) is one of the candidate sites for the storage of pits (Figure 5.2–1). The Device Assembly Facility (DAF), located in Area 6, and the P-Tunnel complex, located in Area 12, are the specific facilities being considered for interim pit storage at NTS. This section discusses each facility, the affected environment at NTS, and the potential impacts that would be associated with pit storage.

Each aspect of the affected environment at NTS has been assessed and the potential environmental impacts to each have been evaluated. Each environmental resource is discussed commensurate with the degree to which the resource could be impacted by or have an effect on interim pit storage at the candidate facilities.

Nevada Test Site. NTS is a government-owned, contractor-operated facility, currently managed by Bechtel Nevada. NTS encompasses approximately 3,500 square kilometers (1,350 square miles) of land area reserved to the jurisdiction of DOE. This land has been withdrawn from all forms of appropriation under public land laws. The four existing land withdrawals that comprise NTS are still being used for the purpose for which they were withdrawn. NTS is located in Nye County, Nevada, approximately 105 kilometers (65 miles) northwest of Las Vegas (Figure 5.2–1) (DOE 1996c:4-9). Due to its large size, the perimeter of NTS is not fenced; however, security patrols are used to control the site. Security and hazardous areas are fenced and some are protected with armed guards and electronic security measures (DOE 1995q:A-7).

Major activities at the site include maintaining the capability to conduct underground nuclear weapon tests, performing environmental restoration actions, supporting the Yucca Mountain high-level waste repository project and the DOE nuclear emergency response team activities, operating a DOE low-level waste disposal facility, and offsite monitoring of nuclear treaty compliance (DOE 1995q:A-8). Both DAF and P-Tunnel complex were designed and built to support the site's historical nuclear weapons mission.

Device Assembly Facility. DAF, located approximately 24 kilometers (15 miles) north of Mercury, is designed specifically to accommodate operations involving nuclear materials (PC 1995a). DAF is a 9,000-square meter (100,000-square foot) facility with state-of-the-art safeguards and security systems (Figure 5.2–2). Approximately 1,170 square meters (12,600 square feet) of this space is available for storing up to 8,000 pits. The facility structures are designed to withstand effects of site-specific natural phenomena, and a Perimeter Intrusion Detection and Alarm System already exists around the building. No construction involving new land disturbance would be required at this site.

As shown in Figure 5.2–2, DAF consists of a number of separate facilities (assembly cells, assembly bays and high bays, testing laboratories, and staging areas) and corridors under an earth cover. Since the original mission of DAF was nuclear explosive operations, the design of bays and cells in DAF is based on existing designs for bays and cells at Pantex Plant.

DAF has two shipping and receiving buildings for loading and unloading of pit containers. These buildings provide truck loading and unloading equipment, including a truckbed-height dock with a built-in leveler ramp and a staging area that is forklift, cart, and crane accessible.

Should DOE choose to store pits at DAF, a pit placement, retrieval, and inventory system would be implemented. It is expected that a Stage Right-like automated or shielded pit

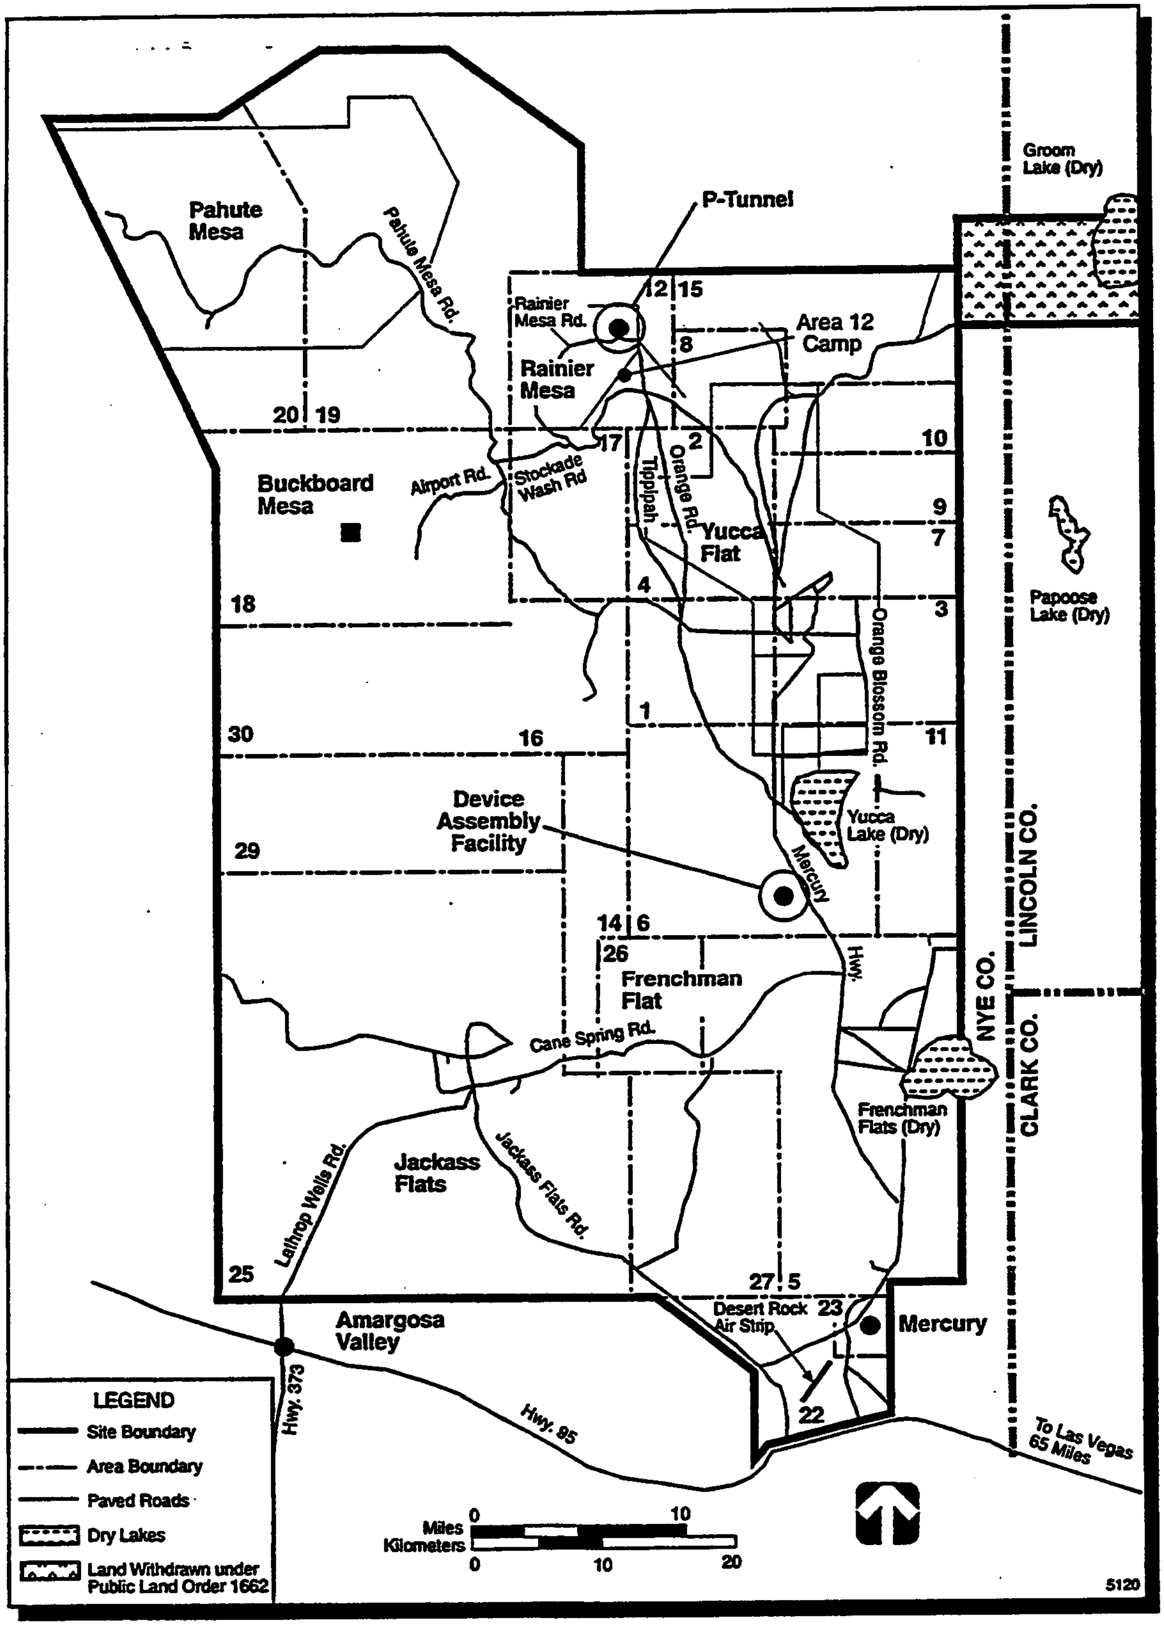

FIGURE 5.2–1.—*Location of Device Assembly Facility and P-Tunnel at the Nevada Test Site.*

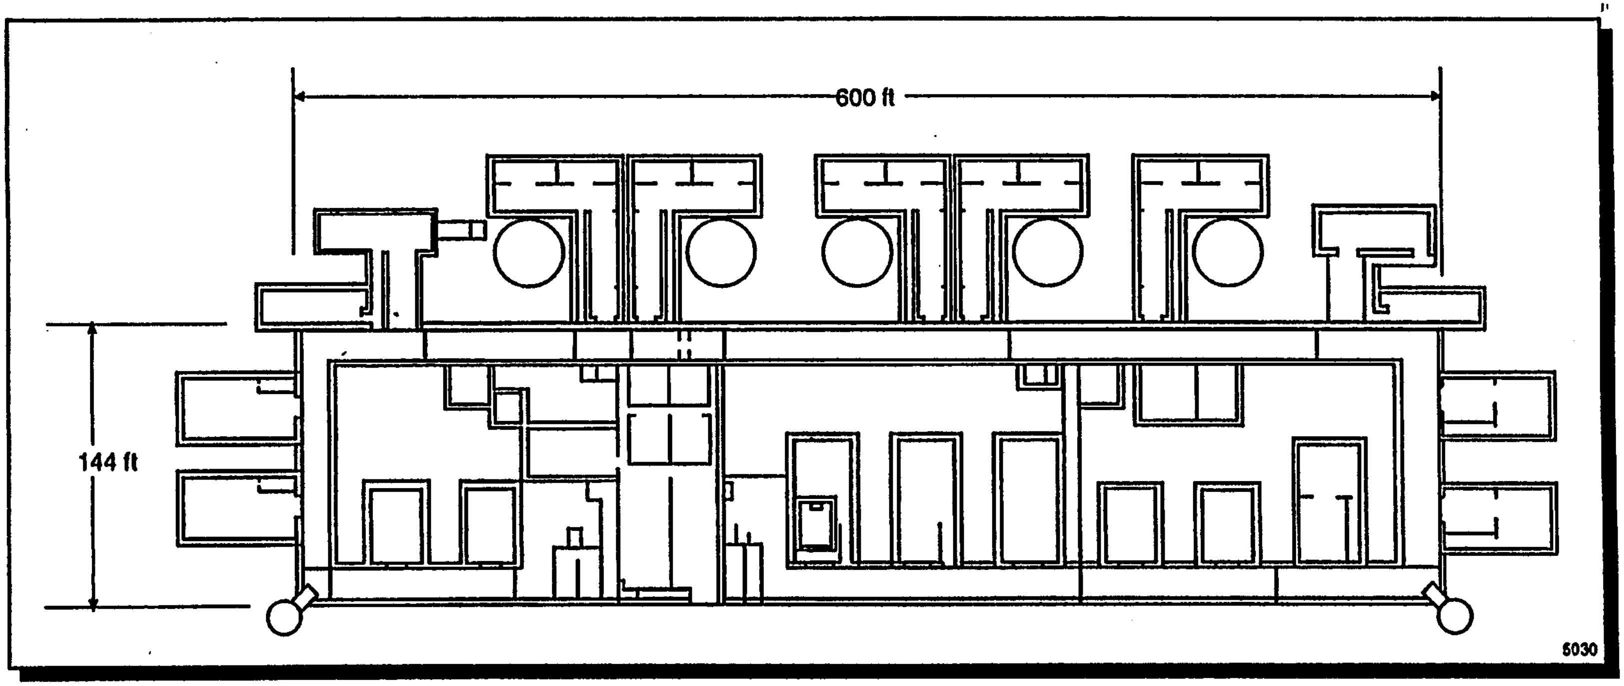


SOURCE: SNL 1994:13

FIGURE 5.2–2.—*Simplified Layout of Device Assembly Facility at the Nevada Test Site.*

handling and inventory system would be developed.

P-Tunnel. P-Tunnel is one of several tunnels at Rainier Mesa (Area 12 of NTS) previously used by the Defense Nuclear Agency for conducting underground nuclear experiments (Figure 5.2–3). This tunnel has approximately 5 kilometers (3 miles) of usable tunnel length and approximately 240 meters (800 feet) of protective overburden. The tunnel is large enough to accommodate more than 20,000 pits. The tunnel portal area currently has several support structures, but there is no security fence to protect the tunnel area. A security system to protect the tunnel portal can be developed within the already disturbed area without disturbing new lands.

P-Tunnel would require minimal facility upgrades (primarily the installation of guide rails for a Stage Right forklift). No new pit placement, retrieval, and inventory system development effort would be required to accept a pit storage mission. The P-Tunnel alternative is well suited for the Stage Right equipment and techniques successfully implemented at Pantex Plant.

P-Tunnel is also being proposed for the long-term storage of weapons-usable fissile materials. The *Storage and Disposition of Weapons-Usable Fissile Materials Programmatic EIS* (DOE/EIS–0229) will address the long-term storage options including the P-Tunnel.

5.2.1 Environmental Resources Not Discussed in Detail

Each of the following environmental resources at NTS has been assessed. The analyses show that the impacts to these resources from the potential storage of pits at either DAF or P-Tunnel are small enough to warrant a limited discussion. Therefore, these resources are discussed briefly below and will not be addressed further in this section.

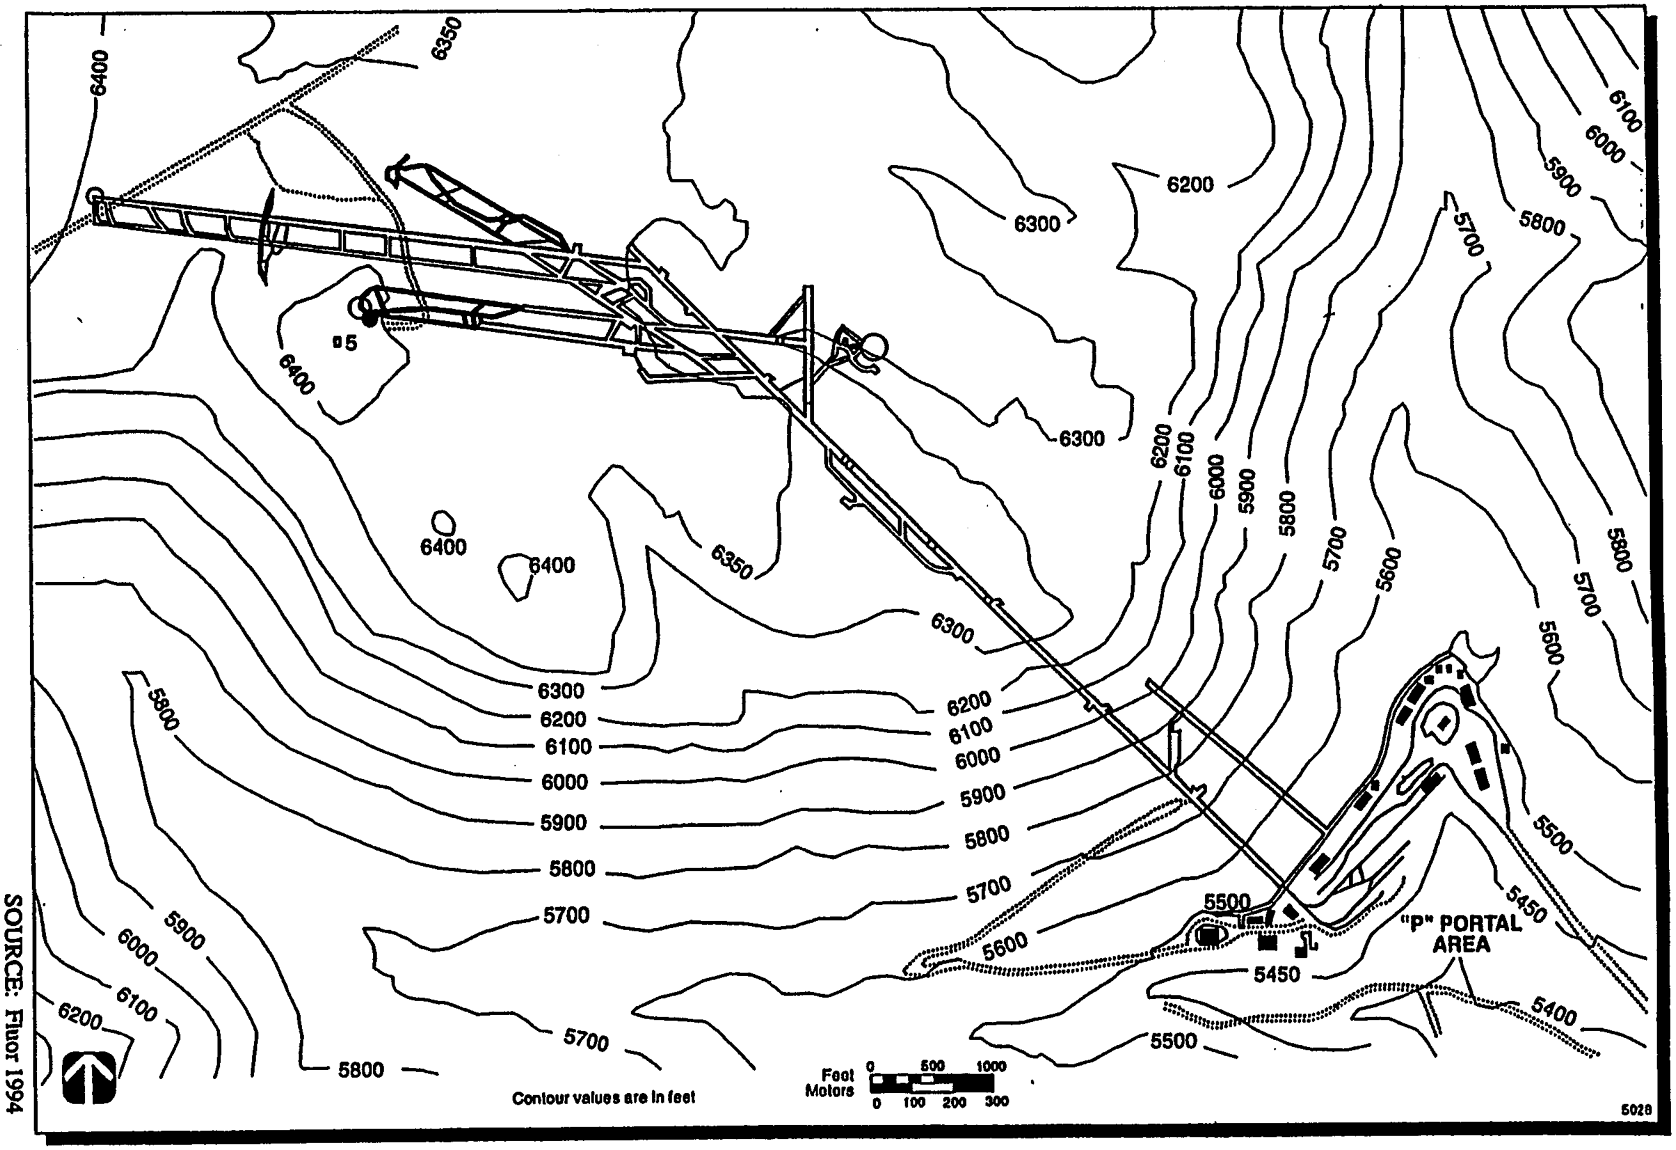
5.2.1.1 *Facilities and Infrastructure*

The infrastructure operations at NTS that could be impacted by or be expected to directly support pit storage operations include security, vehicle and building maintenance, utilities, administration, safety and health protection, and general support (e.g., cafeteria, general stores, etc.). Waste management and transportation support are discussed below and in sections 5.2.1.10 and 5.2.1.11, respectively.

Direct impacts from the implementation of pit storage include a small increase in the NTS security force. Electrical usage due to interim pit storage (estimated to be 4,110 megawatthours per year) represents a 2.4 percent increase over the site's fiscal year 1993 usage of 168,000 megawatthours and 1.2 percent of the site's fiscal year 1993 system capacity of 350,000 megawatthours (DOE 1995k:A-8). Maintenance support and the indirect impacts resulting from pit storage worker requirements (e.g., water, wastewater treatment, and fuel), would increase minimally in comparison to the current and historical onsite infrastructure support levels and system capacities. Neither facility is currently being utilized at historical or design levels. P-Tunnel modifications would involve construction of a secure access control system at the tunnel portal. There would only be a insubstantial temporary impact to infrastructure services during this construction.

5.2.1.2 *Land Resources*

No land disturbance is projected for DAF under the Pit Storage Relocation Alternative, and only limited soil disturbance in an already disturbed area is being considered for P-Tunnel (installation of a security system at the portal to P-Tunnel). The Pit Storage Relocation Alternative does not include any new land uses



SOURCE: Fluor 1994

FIGURE 5.2–3.—*Layout of P-Tunnel at the Nevada Test Site.*

at NTS. Impacts to land use would not be expected.

5.2.1.3 *Geology and Soils*

The only aspects of geology and soils that could be affected by or have an effect on the implementation of interim pit storage at NTS are soil disturbances and the risks associated with earthquakes. The risks due to earthquakes were assessed and found to be bounded by other accidents, as discussed in section 5.2.2.1. The only impact to soils would be from the construction of a secure access control system at the P-Tunnel portal. This area has already been repeatedly disturbed by the original mining of the tunnel and the subsequent activities associated with nuclear testing. Upgrades to DAF that would involve land disturbance are not anticipated; therefore, impacts to soils are not anticipated.

5.2.1.4 *Water Resources*

Because of the nature of pit storage activities, operations at DAF or P-Tunnel would not impact surface water or groundwater. The construction of a secure access control system at the P-Tunnel portal is expected to minimally impact surface water and groundwater because of the currently disturbed state of the ground surface. No surface waters are withdrawn for use at NTS. Wastewater is discharged to sewage lagoons, ponds, or septic tank/leach field systems and not to natural surface waters. Wastewater would not have a measurable effect on groundwater quality because of the combined effects of a deep water table (152 to 732 meters [500 to 2,400 feet] below land surface), low discharge volumes, high evaporation rates, and a composition consistent with treated and sanitary wastewater regulations. The water demands of pit storage operations are attributed to personnel usage and are considered negligible in comparison to the 2,400 million liters (633 million gallons) used annually at NTS (DOE 1995k:4-116, 4-147).

5.2.1.5 *Air Quality*

NTS air quality is well within all applicable local, State, and Federal ambient air quality standards except for particulate matter of aerodynamic diameter less than 10 micrometers (PM_{10}). The 24-hour PM_{10} standard is exceeded due to moderate background concentrations of dust and contributions from operations at NTS. The impacts to air quality from normal pit storage operations would be due entirely to vehicle emissions (approximately 150 vehicles per day) and are considered negligible relative to the overall vehicular emissions at NTS.

5.2.1.6 *Acoustics*

The major sources of noise at NTS include equipment, machines, blasting and explosives testing, and military aircraft operations. At the NTS boundary, away from most facilities, noise from most sources is barely distinguishable above background sources. The only sources of noise that would be associated with pit storage operations would be from transportation vehicles and air conditioning and heating equipment for the occupied areas of the facility. These impacts would be minimal and are not expected to be discernible offsite.

5.2.1.7 *Biotic Resources*

The threatened desert tortoise (*Gopherus agassizii*) is the only Federally listed threatened or endangered species that permanently resides on NTS, although the bald eagle (*Haliaeetus leucocephalus*) and American peregrine falcon (*Falco peregrinus anatum*) may occur on an incidental basis (DOE 1995p). DAF is in an area of infrequent desert tortoise activity, and P-Tunnel is outside the range of the desert tortoise at NTS. Though the existing U.S. Fish and Wildlife Service Biological Opinion for NTS requires a preactivity survey for any project that would result in soil disturbance, no soil disturbance is projected for interim storage of pits at DAF, where desert tortoise activity is infrequent (DOE 1995n:10). The existing U.S. Fish and Wildlife Service Biological Opinion requires all personnel at NTS to complete the DOE Nevada Area Office Desert Tortoise Education Program to minimize the risk to desert tortoises from construction, maintenance, and transportation activities (Letter 1992:7-8). No wetlands beyond those associated with isolated springs have been identified at NTS (DOE 1993g:4-12, 4-27). As a result, impacts to biotic resources would not be expected.

5.2.1.8 *Cultural Resources*

No historic or prehistoric sites have been found at P-Tunnel (DOE 1992d:1-4, 8). Nine sites, seven of which were single, isolated artifacts, were located at DAF. These sites were not recommended for eligibility to the National Register of Historic Places (DRI nd:1-3; DOE 1994s). The Pit Storage Relocation Alternative does not include any action that would disturb these sites. Therefore, no direct impacts to cultural or paleontological resources would be expected.

DOE has ongoing consultation with 13 Native American tribes and one pan-tribal organization (the Owens Valley Board of Trustees) that have cultural ties to NTS. Native American groups including the American Indian Writers Subgroup of the Consolidated Group of Tribes and Organizations at NTS have expressed concern regarding areas containing Traditional Cultural Properties (DOE 1995k:4-123). The Pit Storage Relocation Alternative is not expected to adversely affect these areas of concern. However, the Consolidated Group of Tribes and Organizations would be consulted prior to initiation of any activities.

5.2.1.9 *Socioeconomic Resources*

Approximately 150 additional personnel (including 120 security personnel) would be required for interim storage of pits at NTS. This number represents less than a 3 percent increase in the total NTS workforce. Most of these workers can be locally hired; therefore, no significant site or regional population and workforce increases are anticipated. According to the 1990 Census, 150 workers represent 0.03 percent of the employed workforce in the socioeconomic Region of Influence, which includes the Las Vegas metropolitan area (NV Cen 1993:Table 145). No socioeconomic impacts would be anticipated.

5.2.1.10 *Waste Management*

NTS currently manages mixed waste, low-level waste, hazardous waste, and nonhazardous waste in accordance with a number of Federal and State regulations, permits obtained under these regulations, and DOE orders. These requirements are primarily under the authority of the Environmental Protection Agency, DOE, and the State of Nevada Department of Environmental Protection's Bureau of Waste Management (DOE 1995k:Chapter 5). NTS anticipates disposal of 14,100 cubic meters (18,500 cubic yards) of mixed waste and 28,300 cubic meters (37,000 cubic yards) of low-level waste annually (DOE 1993h:63). Pit storage operations would generate less than 1 cubic meter (1.3 cubic yards) each of mixed, low-level, and hazardous waste, which would not impact the current waste management at NTS.

5.2.1.11 *Intrasite Transportation*

Mercury Highway is the primary route into NTS from U.S. Highway 95 (Figure 5.2–1). Vehicular access to the DAF is via the Mercury Highway, which is a 7.8-meter (26-foot) wide paved road. DAF is approximately 1.5 kilometers (4,900 feet) west of the Mercury Highway and is served by a paved access road. The Mercury Highway is a controlled access road within the NTS boundaries and is not open to the public.

P-Tunnel is located in Area 12 of NTS, north of the Area 12 camp. Vehicular access to P–Tunnel is via the Mercury Highway, Tippipah Highway, Rainier Mesa Road, and Road 12–01, as shown in Figure 5.2–1. The traffic on these roads is controlled by NTS personnel; no public traffic is allowed on these roads. Because a release of plutonium from an intersite pit shipment would require a severe accident (e.g., an accident with a fuel tanker or train [see section 4.16.4.2]), the controlled transportation environment within NTS does not pose a significant threat to pit shipments. Consequently, the contribution to overall transportation risk from onsite transportation is negligible.

Radiological impacts of unloading pits at the two facilities are described in section 5.2.2.1, Human Health.

5.2.1.12 *Aircraft Accidents*

The airspace above NTS, designated as R4808, is a special-use airspace identified by Federal Aviation Administration regulations. This designation applies to all aircraft and is unlimited in height. Clearance to enter the restricted airspace above NTS must be obtained from DOE. Aircraft pilots desiring to fly through NTS airspace are required to contact the DOE Operations Coordination Center at NTS; information regarding the type of aircraft and nature of flight into the restricted airspace must be provided. DOE does authorize flights into the restricted airspace.

There are four airports and five landing strips in the vicinity of DAF and P-Tunnel. Las Vegas McCarran International Airport is the major commercial airfield in the State of Nevada. This airport, located approximately 122 kilometers (76 miles) southeast of NTS, is used by commercial (air carrier and air taxi), military, and general aviation aircraft. In 1994, McCarran International Airport had 488,347 aircraft operations (take-offs and landings). North Las Vegas Airport is located just north of McCarran International Airport and is used by commercial air taxi, military, and general aviation aircraft. In 1994, North Las Vegas Airport had 188,707 aircraft operations (take-offs and landings). Table 5.2.1.12–1 summarizes the total number of airfield operations at the McCarran International and North Las Vegas Airports (PC 1996j). Nellis Air Force Base, located 107 kilometers (67 miles) from NTS, is also north of McCarran International Airport and is only used by military aircraft.

The closest airfield to NTS, Indian Springs Auxiliary Field, approximately 48 kilometers (30 miles) southeast of DAF, has two runways used only by military aircraft. Beatty Airfield,

TABLE 5.2.1.12–1.—*Las Vegas McCarran International and North Las Vegas Airport Operations for 1994*

AIRCRAFT CATEGORY	NUMBER OF OPERATIONS	
	MCCARRAN	N. LAS VEGAS
Air Carrier	229,497	0
Air Taxi	104,395	9,928
Military	17,280	1,164
General Aviation	137,175	177,615
Total Airfield Operations	488,347	188,707

Source: PC 1996j

approximately 67 kilometers (42 miles) west of DAF, has one runway used only by general aviation aircraft. There are five landing strips located on or near NTS; the most frequently used is the Desert Rock Airstrip, located in Area 22 southwest of Mercury. Desert Rock Airstrip has a single runway and is 30 kilometers (19 miles) south of DAF. Two single runway airstrips are located on NTS; one 6 kilometers (4 miles) north at Yucca Lake in Area 6, and the other 27 kilometers (17 miles) south in Area 22. Two single-runway airstrips are located west of NTS; one 62 kilometers (39 miles) west-northwest and the other 78 kilometers (49 miles) north-northwest.

Four of the landing strips and the four airfields are outside the probability density function boundary for the types of aircraft that use each of the facilities. The operations at the landing strip near Yucca Lake are infrequent and restricted to use by the public, and were therefore not included in the analysis. Only non-airport (in-flight) aircraft were therefore included in the analysis as required by the Draft DOE Standard (DOE 1996g). Further details on these nine facilities are contained in volume II, appendix E.

Penetration calculations for Manzano Weapons Storage Area (WSA) indicate aircraft cannot penetrate 9 meters (30 feet) of soil and rock. Since the proposed pit storage location inside of P-Tunnel is approximately 240 meters (800 feet) below the mesa, pits stored in P-Tunnel are immune from aircraft accidents (PC 1995b).

DAF was modeled conservatively as a single facility with a length of 201 meters (659 feet), a width of 76 meters (250 feet), and a height of 9 meters (30 feet) (PC 1994c). Using the Draft DOE Standard for determining the frequency of aircraft crashes, the frequency of hitting DAF was calculated as 1.5×10^{-6} for all types of aircraft (DOE 1996g). It should be noted that the frequency calculation represents a conservative upper bound. Since this frequency is greater than 10^{-7}, in accordance with the Draft DOE Standard, further analysis was necessary. A local response structural analysis for the facility was performed according to the Draft DOE Standard with a wall thickness of 46 centimeters (18 inches) (DOE 1986b). This wall thickness was selected since it is the minimum thickness for the bays and cells where plutonium would be stored. An overburden of 1.5 meters (5 feet) was included for three sides of the facility.

The analysis was performed for the maximum penetrator missile for each of the aircraft categories mentioned in section 4.15.2, except for helicopters. The commercial air carrier, large military, and small military aircraft categories were the only three aircraft missiles capable of penetrating the facility from the side with no overburden; the frequency of releasing material from DAF was 8.1×10^{-8}. Since this frequency is less than 10^{-7}, in accordance with the Draft DOE Standard, no further analysis was required. Further details of the frequency of hitting DAF and the frequency of releasing material are contained in volume II, appendix E.

5.2.2 Resources Discussed in Detail

5.2.2.1 *Human Health*

The basic approach used in assessing human health concerns is to first identify the affected environments and establish a baseline that represents the risk from current operations. Changes in this baseline risk resulting from the Pit Storage Relocation Alternative are then examined. Impacts from both normal operations and potential accidents are estimated.

Assessing the human health risk impact from potential accidents resulting from the relocation of pits to NTS and storing them in either DAF or P-Tunnel involves a risk screening process. The first step in this process is to identify a broad spectrum of potential accident scenarios. The second step in the process uses screening techniques to identify the specific scenarios that dominate risk (i.e., scenarios that contribute an appreciable fraction of the total risk), where risk is the product of frequency and consequence. Rigorous consequence evaluations are only performed for the identified risk-dominant scenarios.

Two types of accident consequences are examined:

- Worker and public exposure.
- The probability of the accident causing fatal cancer in a worker or the public.

If DOE chooses to relocate pits to NTS, two aspects of this relocation contribute to a potential for environmental impacts. They are the impacts associated with:

- Transferring pits from the transporter to their storage location inside the facility.
- Storage itself (i.e., potential impacts resulting from having the pits reside inside the facility).

Each time pits are transferred from the transporter to their storage location inside the facility, there is a small probability that an accidental release could occur due to a handling accident. In addition, the transfer of pits from the transporter to their storage location would result in radiological exposures to involved workers.

Affected Environment

The release of radioactivity and toxic chemicals to the environment from a DOE facility is an important issue for onsite workers and the public. Since the human environment contains many sources of radioactivity and toxic chemicals, it is essential to understand the sources of these substances and how effectively they are controlled.

Table 5.2.2.1–1 summarizes the major sources of radiation exposure in the vicinity of NTS. The average annual probability of developing a fatal cancer for a resident of Nevada is 1.4×10^{-3}. Using a nominal fatal cancer risk factor of 5×10^{-4} cancer fatalities per person rem and the environmental radioactivity data for NTS in Table 5.2.2.1–1, it is calculated that fatal cancers attributable to environmental radioactivity released from NTS constitute a negligible fraction of the average yearly fatal cancer probability in the vicinity of NTS (DOE 1994t:4-20).

Figures 5.2.2.1–1 and 5.2.2.1–2 depict the offsite population within an 80-kilometer (50-mile) radius of DAF and P-Tunnel, respectively. Wind speeds and directions in the NTS vicinity are presented in Figure 5.2.2.1–3. Winds are predominately from the southwest during the summer and from the northeast during the winter.

Impacts of Facility Upgrades

There is no significant impact on human health associated with NTS facility upgrades. The only upgrade required is to modify P-Tunnel and DAF to accept Stage Right transfer and storage equipment. The facility impact involves modifying floor space to accept Stage Right guide rails and fastening Stage Right attachment fixtures to storage facility walls. These are standard industrial operations that do not expose workers to any special hazards (e.g., radionuclides, toxic chemicals, or high explosives).

Impacts of Storing 20,000 Pits

Human health impacts from pit storage activities could potentially result from normal operations and potential accident scenarios. Normal operations would impact only onsite workers. Normal operational impacts result from the unloading of pits from Safe Secure Tractor Trailers (SSTs) at the P-Tunnel access area. Unloading operations would result in radiological exposure to cargo handlers. Based on conservative calculations made for the

Sources: NCRP 1987:15, 53; DOE 1994t:1-6; DOE 1994v:2.4-42

handling of pits at Pantex Plant, worker doses from unloading 2,000 pits per year are estimated to be 27 person-rem per year or 270 person-rem for unloading 20,000 pits (the maximum number of pits which may be stored at P-Tunnel). Once removed from the SSTs, pits would be transferred into P-Tunnel for storage. Pit transfers within P-Tunnel would result in radiological exposures to onsite workers handling the pits; doses of less than 2 person-rem per year for handling 2,000 pits and about 13 person-rem for the placement of 20,000 pits.

The combined worker dose from unloading and storage of 20,000 pits at P-Tunnel would be 283 person-rem distributed over the 30 people directly involved in material handling. Assuming that the same 30 people continue to handle 20,000 pits over a period of 10 years and using a dose-to-risk conversion factor of 4×10^{-4} latent cancer fatality (LCF) per person-rem, there would be an additional 0.11 LCF experienced by this group due to radiological exposure from pit handling.

The probability of LCFs from all causes in the general population is estimated at 20 percent, which implies that 6 of 30 workers would develop a fatal cancer from all other causes. With an additional 0.11 LCF from pit handling, the total risk of latent cancers among workers at P-Tunnel would increase by 1.8 percent.

Some operational accidents could result in impacts to both onsite workers and the offsite general population. Radiological exposures and the resultant risk of LCFs have been calculated.

The probability of an onsite worker contracting a fatal cancer from radiological exposures from

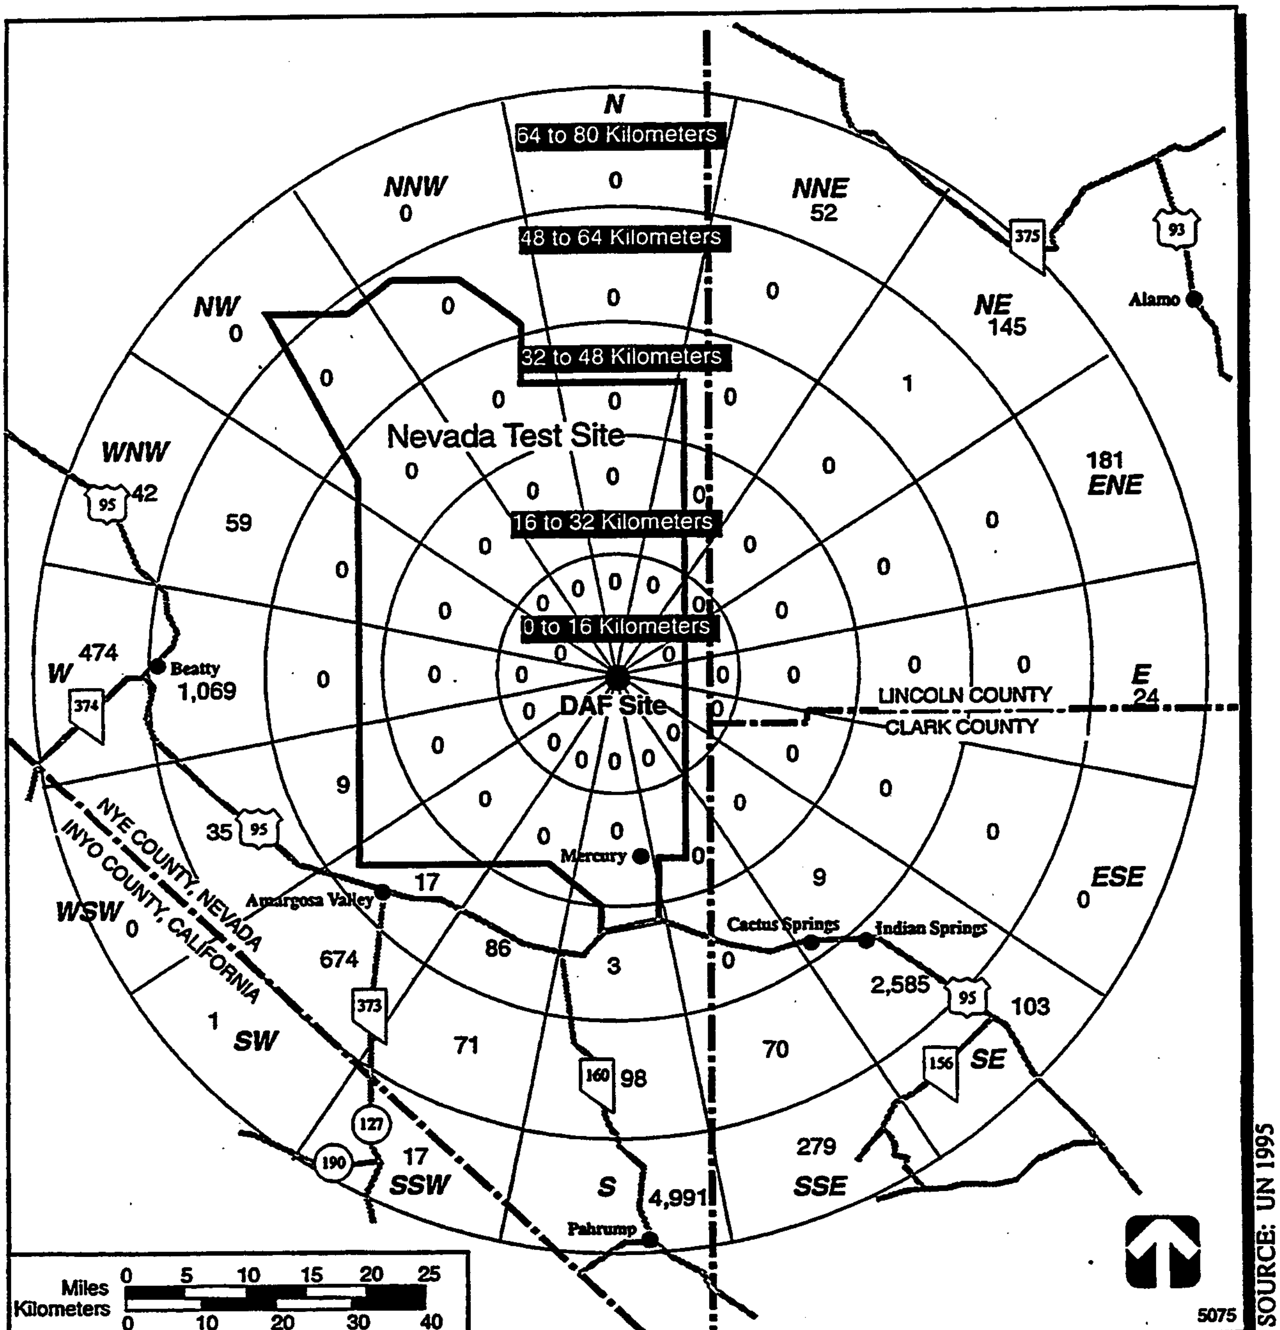

FIGURE 5.2.2.1–1.—*Population Within 80 kilometers (50 miles) of Device Assembly Facility.*

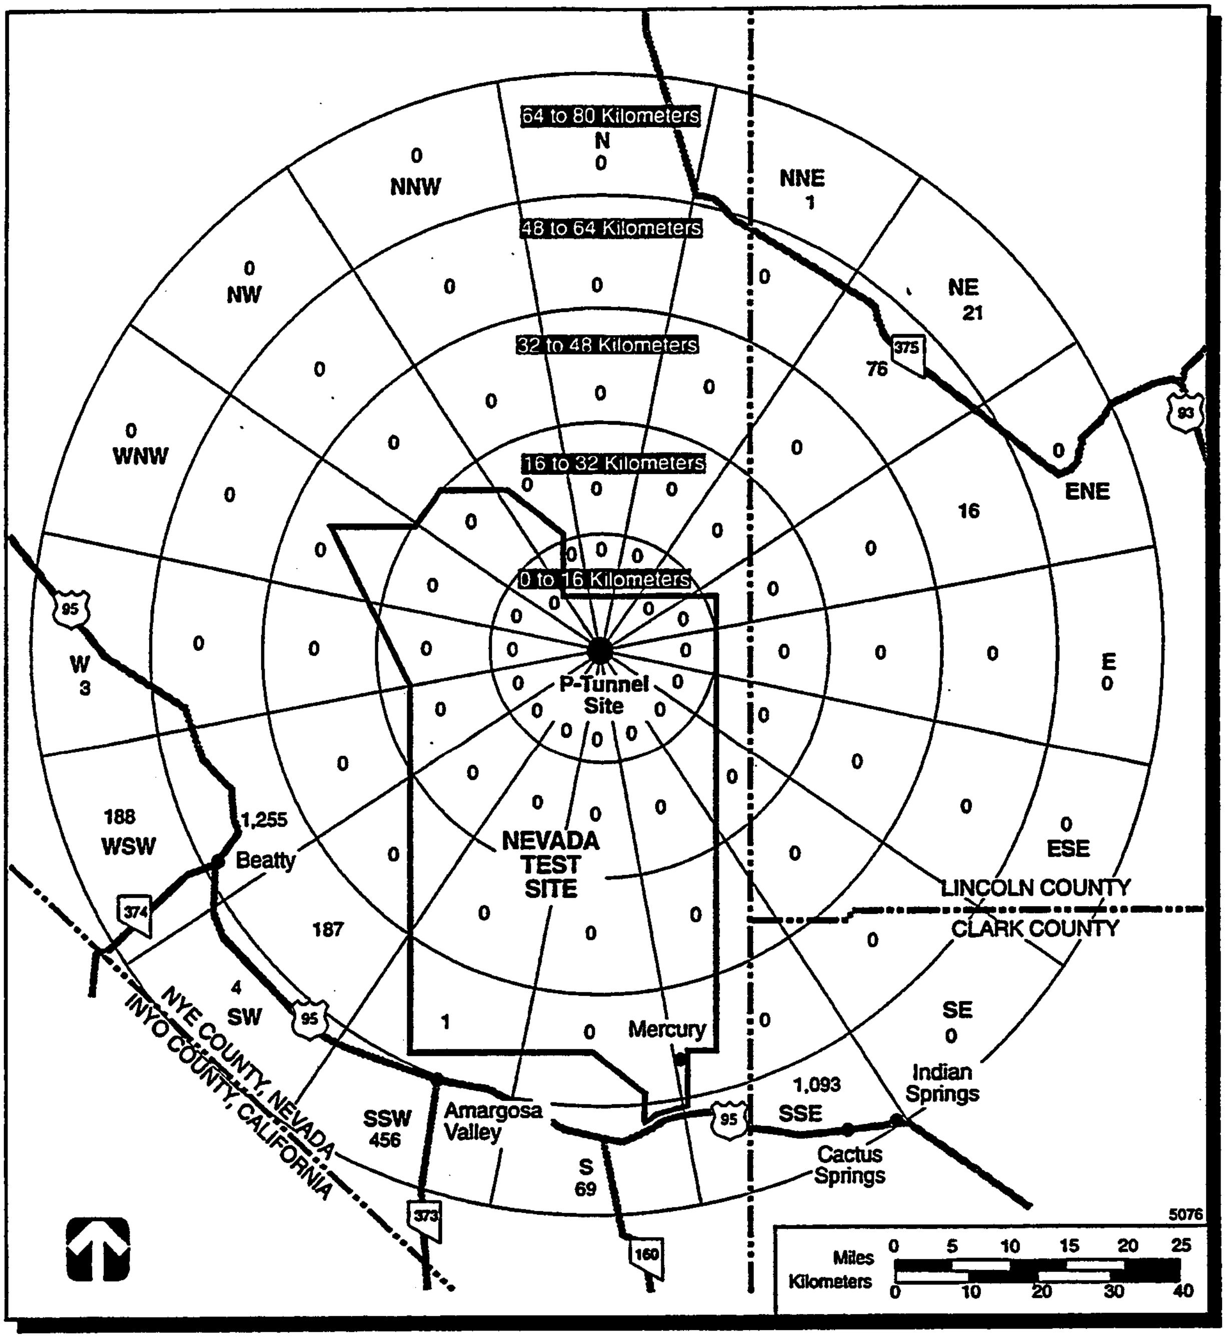

FIGURE 5.2.2.1–2.—*Population Within 80 kilometers (50 miles) of P-Tunnel.*

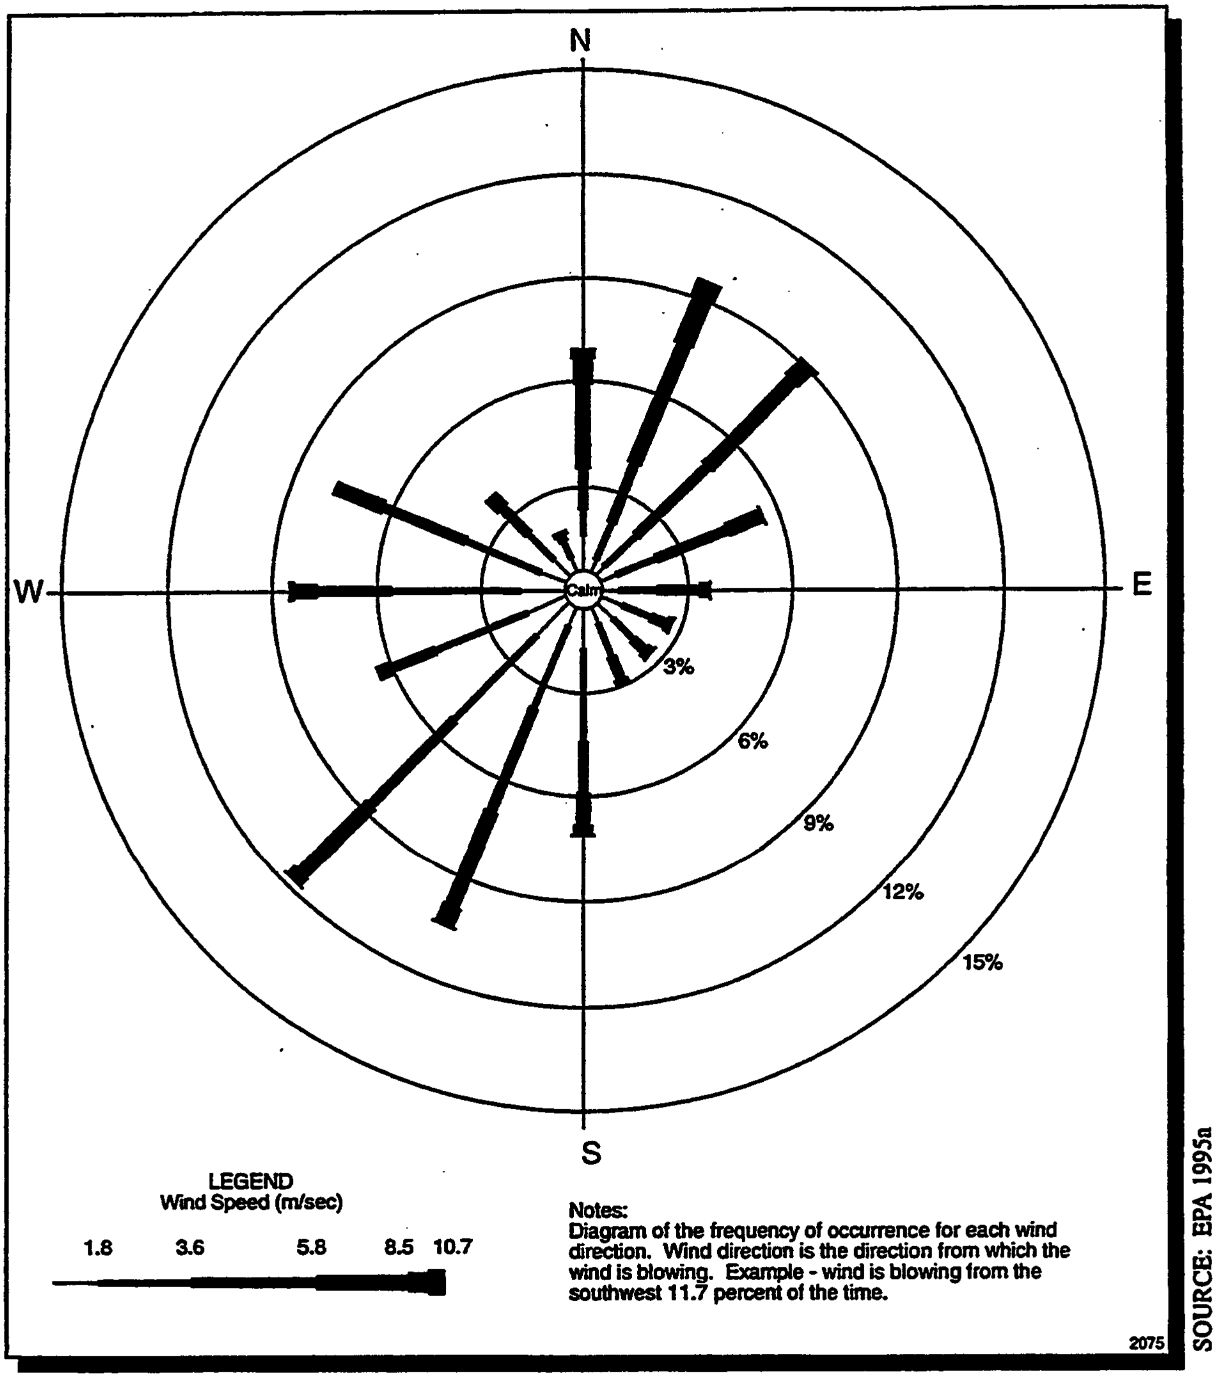

FIGURE 5.2.2.1–3.—*Wind Speed and Direction at the Nevada Test Site.*

pit storage activities was calculated using a fatal cancer risk factor of 4×10^{-4} LCF per person-rem, and the cumulative worker dose was estimated from previous historical doses resulting from similar operations (ICRP 1991).

The risk screening methodology indicates that the radiological health risk from accidents associated with the storage of 20,000 pits in P-Tunnel is dominated by handling accidents that could occur when the pits are being transferred from the transporter. A standard tine forklift is likely to be used to remove pit containers from an SST. Using DOE's methodology, the probability of a standard tine forklift causing a puncture during a single handling operation is in the extremely unlikely range (i.e., 10^{-4} to 10^{-6}) (DOE 1992h). For handling 2,000 pits annually, the accident frequency is approximately 10^{-3} per year. This relatively low accident frequency results from the robust construction of AT–400A shipping containers.

Pit container inventories at NTS are expected to be performed using either shielded or automated techniques and equipment. Consequently, these normal operations are not expected to result in any significant radiological exposure to workers.

Other storage activities that may occur within the timeframe evaluated in this EIS include:

- Restacking a limited number of pits to comply with design laboratory temperature goals.
- A limited number of pit movements and/ or instrumentation placements to facilitate third-party inspections.

Impacts of these routine activities are also considered to be negligible.

Earthquakes offer the greatest threat from natural phenomena (see appendix D). Available seismology studies show that active faults such as the Mine Mountain Fault, the Carpetbag Fault, Yucca Flat Fault, and the Cane Spring Fault in the NTS vicinity are capable of generating earthquakes of up to 0.85 *g* (Raytheon 1995:2-36). NTS has a natural background seismicity (Raytheon 1995:2-33). The Cane Springs fault, located 5 to 8 kilometers (3 to 5 miles) south-southeast of DAF, has been identified as the most significant feature from the standpoint of seismic risk. However, a large proportion of seismic events occurring near NTS may have been aftershocks from past nuclear explosions.

The proposed pit storage area in P-Tunnel is only a few hundred feet away from the site of some past nuclear explosions. Since the tunnel has survived these explosions without noticeable degradation, it is not reasonably foreseeable that the proposed pit storage area would be damaged by an earthquake. However, if the tunnel collapses, the impact forces could breach some certified shipping containers. The collapse would also seal the containers inside the tunnel, resulting in no significant short-term radionuclide releases to the exterior environment. Thus, the consequences to the public and workers are considered negligible. Some mitigation of a tunnel collapse would be needed after a major seismic event. A separate assessment of the risk associated with the mitigation would be necessary in order to address the specific magnitude of the collapse and the applicable mitigation technology.

Impacts of Storing 8,000 Pits

Storage of 8,000 pits could be accomplished at either P-Tunnel or DAF. The risks associated with storing 8,000 pits in P-Tunnel are similar to but less than those of the 20,000-pit storage alternative. The total worker doses from unloading and pit transfer operations would be below 113 person-rem over 4 years. This exposure would result in an additional 0.04 LCF in this group. With an additional 0.04 LCF from pit handling, the total risk of LCFs among workers at NTS would increase by 0.7 percent.

Risk screening methodology also indicates that the risk from storage of 8,000 pits in DAF is dominated by forklift handling accidents. Note that the risk screening methodology evaluated all potential threats to pit container integrity, such as fire, aircraft crash, earthquake, flood, and other internal and external events.

Although DAF is more vulnerable to external events and natural phenomena than P-Tunnel, the contribution from these events to overall risk remains negligible as discussed in appendix D. Compared to the risk from a forklift accident during pit handling, the risk from aircraft accidents and earthquakes at DAF is low. To a significant extent, the low seismic risk at DAF is attributable to the robust construction of the facility (Raytheon 1995:5-7). Aircraft accidents are negligible risk contributors because of the extremely low probability of an impact.

It is estimated that a forklift puncture of a pit container would release 9.2×10^{-5} curies of plutonium. This is a conservative estimate of the respirable, airborne release caused by a puncture of one shipping container (DOE 1992f:7-39).

Given such a release, an involved worker (the forklift driver) would receive a dose of 6.6 rem, corresponding to an incremental increase in lifetime fatal cancer probability of 2.6×10^{-3}. In addition, a non-involved worker 100 meters (328 feet) downwind along the center line of the plutonium dispersion plume would received a 6.3×10^{-2} rem exposure, corresponding to an incremental increase in lifetime fatal cancer probability of 2.5×10^{-5}. The maximally exposed member of the public would receive a 3.9×10^{-5} rem exposure, corresponding to an incremental increase in lifetime fatal cancer probability of 2×10^{-8}. The lifetime fatal cancer probability for an average individual from all other causes is approximately 0.2 (20 percent).

This event would result in an exposure to the public of 3.3×10^{-5} person-rem. Considering the likelihood and consequence of this event, on the average, a member of the public will have an increased annual risk of developing a fatal cancer from this potential accident of 1.1×10^{-15} fatal cancers per year. The annual fatal cancer risk to a person in Nevada from all other causes is 1.4×10^{-3} fatal cancers per year.

5.2.2.2 *Environmental Justice*

Affected Environment

In order to identify the target populations covered by Executive Order 12898, 80-kilometer (50-mile) radius circles centered on DAF and P-Tunnel were overlaid on 1990 Census tract maps (UN 1995). The communities that lie within these 80-kilometer (50-mile) circles, hereafter called the DAF and P-Tunnel Regions of Influence (ROIs), are shown in Figure 5.2.2.2–1.

Population. According to the 1990 Census, there were 11,741 persons within the DAF ROI. White persons comprised nearly 84 percent of the population, Hispanics were the second largest group with slightly more than 7 percent, and Blacks accounted for slightly less than 7 percent of the total population in the ROIs. American Indians, Asians, Pacific Islanders, and other racial groups totaled less than 3 percent of the total population within 80 kilometers (50 miles) of the DAF ROI in 1990 (UN 1995).

In 1990, nearly 96 percent of the population in the DAF ROI lived in the communities of Beatty, Pahrump, Mercury, and Indian Springs; the remaining population lived in the Amargosa Valley area (NV Cen 1992:Table 1; UN 1995). Thus, the entire population within the DAF ROI lived west, south, and southeast of the DAF site.

According to the 1990 Census, there were 4,386 persons within the P-Tunnel ROI. White persons comprised 84 percent of the population, Hispanics were the second largest group with 8 percent, and Blacks accounted for 5 percent of

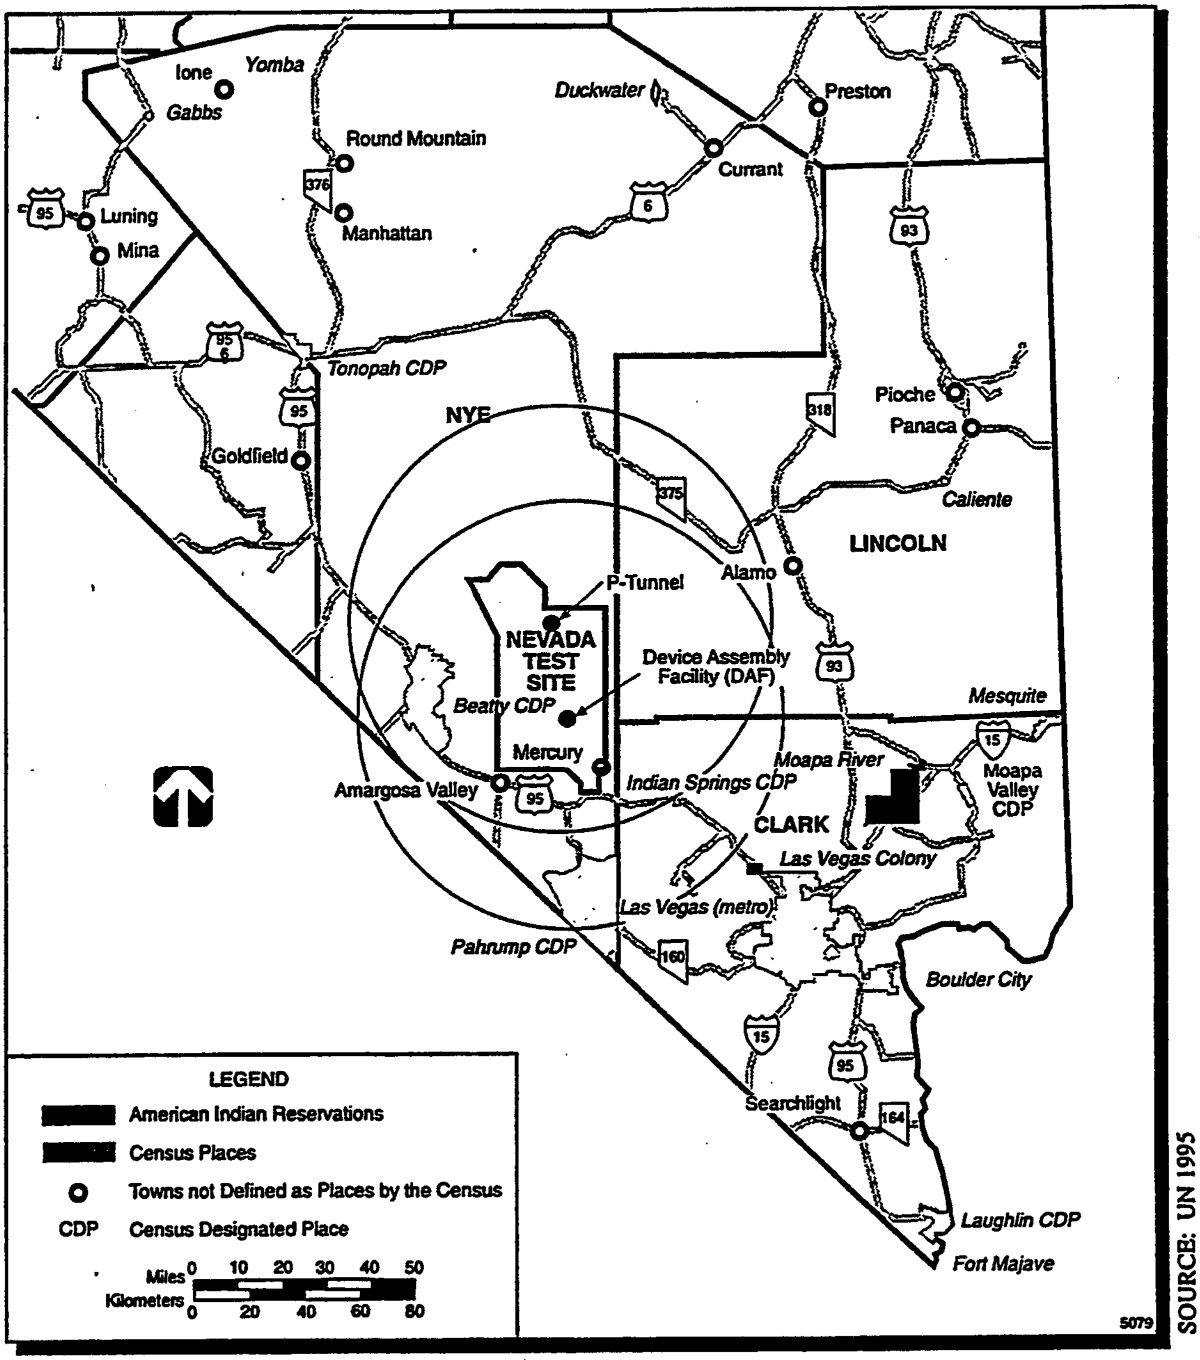

FIGURE 5.2.2.2–1.—*The Device Assembly Facility and P-Tunnel Regions of Influence in Nevada.*

the total population in the circle. American Indians, Asians, Pacific Islanders, and other racial groups totaled less than 3 percent of the total population within the P-Tunnel ROI in 1990 (UN 1995).

In 1990, nearly 87 percent of the population in the P-Tunnel ROI lived in the communities of Beatty, Mercury and Indian Springs; the remaining population lived in the Amargosa Valley area (NV Cen 1992:Table 1; UN 1995). Thus, the entire population within the P-Tunnel ROI lived south, southwest, and southeast of P-Tunnel.

Minority Population. Figure 5.2.2.2–2 shows the 1990 Census block groups within the DAF ROI. The block groups are shaded if 25 percent or more of their populations were minority persons in 1990 and/or if 25 percent or more of their populations were below the poverty level based on their incomes in 1989. The 25 percent threshold levels for minority or low-income persons are based on the working definitions contained in the notice of the EPA's Office of Environmental Justice (59 FR 192). Three block groups within the DAF ROI have populations which were at least 25 percent minority or non-White in 1990. These concentrations of minority persons are found primarily in the communities of Indian Springs, Cactus Springs, and Mercury. In the P-Tunnel ROI, the distribution of minority population is similar to that of the DAF ROI (Figure 5.2.2.2–3).

Low-Income Population. Three block groups within the DAF ROI have populations in which at least 25 percent of persons were below the poverty level based on their incomes in 1989. These concentrations of low-income persons are found primarily at the eastern edge of Pahrump, in the western portion of Amargosa Valley, and in the Death Valley Junction area in California. In the P-Tunnel ROI, only one block group (the western portion of the Amargosa Valley area) has a population in which at least 25 percent of persons were below the poverty level.

Impacts of Storing 20,000 Pits

Because the interim storage of pits at the P-Tunnel would not require any major construction and because all facility modifications would take place inside existing facilities, impacts to the natural environment would be minimal. Under normal operating conditions, there would be minor increases in air pollutants associated with vehicles used during pit storage activities. Also, a minor increase in PM_{10} concentrations would be expected. These increases are associated with the operation of forklifts which are used to move the pits from the unloading area to the storage area.

These impacts are not likely to affect the surrounding population. Radiological releases from normal pit storage operations would have no measurable effect on an individual occupying a position near the NTS boundary for an entire year. Levels at the site boundary would be indistinguishable from natural background radiation. No adverse health effects would be expected among the general public, including minority and low-income populations, as a result of normal storage operations.

An abnormal event, such as accidental puncture of a pit storage container by a forklift, has the potential of exposing the general public to radiation. The analysis in the section 5.2.2.1, Human Health, indicates that the risk to the public from such an accident would be negligible. With no measurable impacts on the general population, the minority and low-income populations would not be disproportionately impacted.

Impacts of Storing 8,000 Pits

The human health impact of storing 8,000 pits in P-Tunnel would be lower than those identified for the storage of 20,000 pits. No significant adverse impacts are expected, and minority and

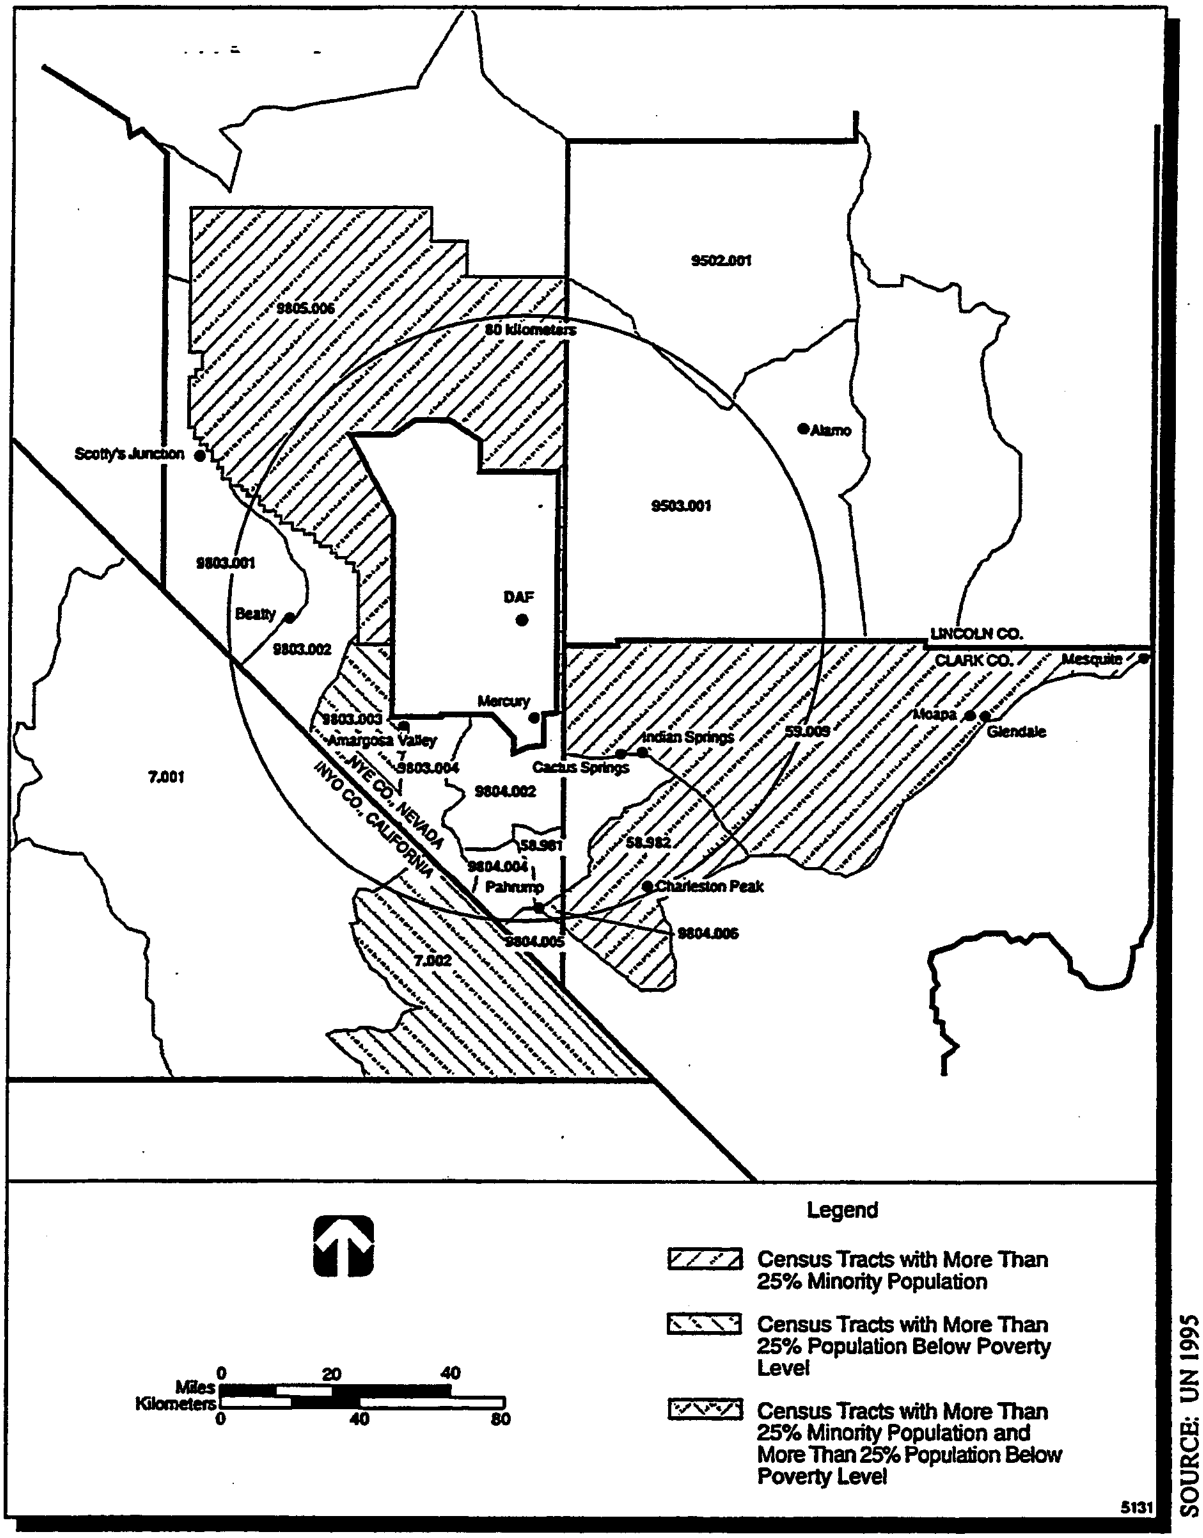

FIGURE 5.2.2.2–2.—*Distribution of Minority and Low-Income Populations in the Device Assembly Facility Region of Influence.*

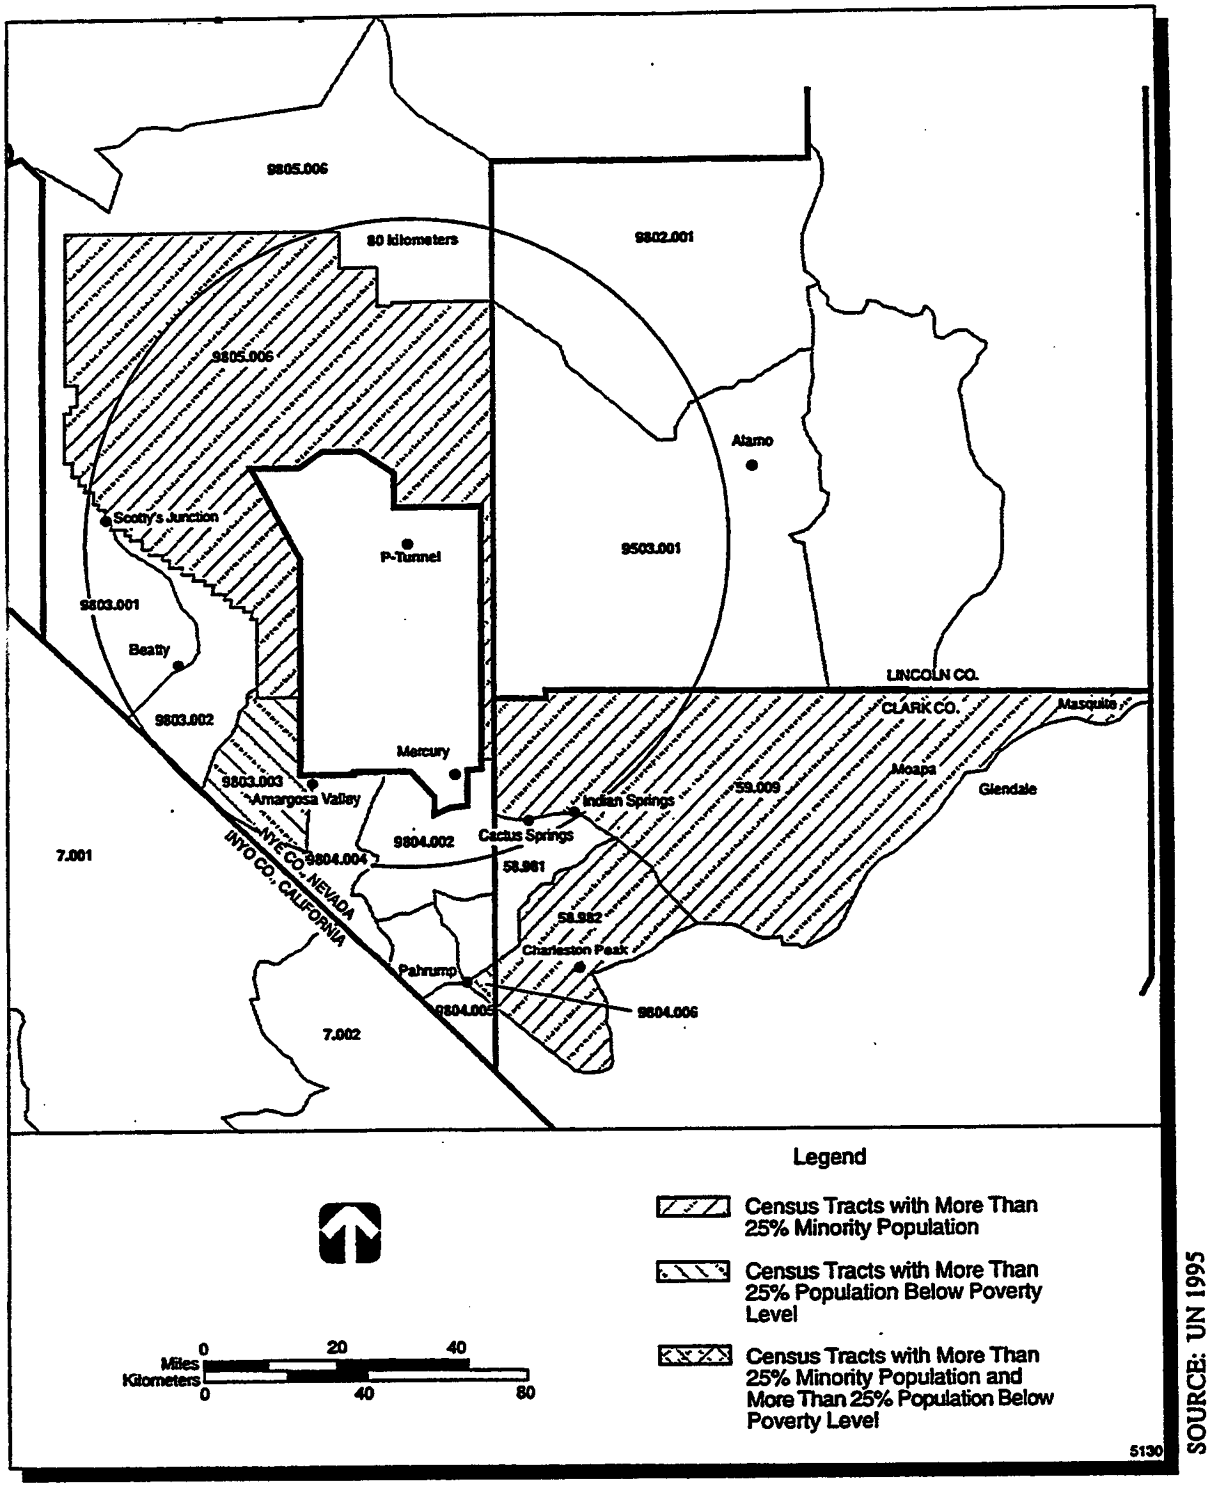

FIGURE 5.2.2.2–3.—*Distribution of Minority and Low-Income Populations in the P-Tunnel Region of Influence.*

low-income populations would not be disproportionately impacted.

The human health impacts of storing 8,000 pits in DAF would be negligible to the general public in the DAF ROI. Since impacts to the general public are expected to be negligible, minority and low-income populations would not be disproportionately impacted.

(This Page Intentionally Left Blank)

THE SAVANNAH RIVER SITE

5.3 SAVANNAH RIVER SITE

Under the Pit Storage Relocation Alternative (see section 3.1.3), the pit storage function currently carried out at Pantex Plant would be transferred to another site. The Savannah River Site (SRS) is one of the candidate sites for the storage of pits (Figure 5.3–1). The P-Reactor building is the specific facility being considered for the interim pit storage at SRS. This section discusses the P-Reactor facility, the affected environment at SRS, and the potential impacts that would be associated with pit storage.

Each aspect of the affected environment at SRS has been assessed and the potential environmental impacts to each have been evaluated. Each environmental resource is discussed commensurate with the degree to which the resource could be impacted by or have an effect on interim pit storage at the candidate facility.

Savannah River Site. SRS is a government-owned and contractor-operated facility, managed by Westinghouse Savannah River Company (DOE 1993d:3-42). DOE owns approximately 780 square kilometers (300 square miles) in Aiken and Barnwell Counties, South Carolina, approximately 26 kilometers (16 miles) southeast of Augusta, Georgia and 19 kilometers (12 miles) south of Aiken, South Carolina (DOE 1993f:1). Less than 5 percent of the site is developed; the remaining area (approximately 73,300 hectares [181,000 acres]) is primarily forest land (DOE 1995q:A-25).

The primary mission at SRS from the 1950's until the recent end of the Cold War was the production and processing of nuclear materials to support defense programs. Major categories of activities at the site include tritium recycling, the processing of plutonium-238 for space missions, processing of irradiated targets and spent nuclear fuel, the interim storage of plutonium, environmental restoration actions, waste management, and research and development. P-Reactor is one of five reactors (C, K, L, P, and R) at SRS (DOE 1995q:A-25).

P-Reactor. P-Reactor is the candidate pit storage facility at SRS; it is located within a controlled area about 4 kilometers (2.6 miles) east-southeast of the geographical center of the site and about 6.5 kilometers (4 miles) west of the closest site boundary (Figure 5.3–1). P-Reactor was built in 1954 and was shut down in August 1988 for maintenance. In February 1991, it was placed in cold standby so that it could be used to provide spare parts for L-Reactor and K-Reactor. P-Reactor is now permanently shut down. The reactor building is a reinforced concrete building that houses four major process areas; the reactor area, the assembly area, the disassembly area, and the purification area (Figure 5.3–2).

The assembly area within the P-Reactor building is the proposed facility for pit storage. The assembly area was originally built for receiving, handling, and preparing fresh fuel and target assemblies for P-Reactor. Separated from the reactor building by a reinforced concrete wall and steel doors, the assembly area is a large warehouse-type facility that is divided into three large rooms; the receiving bay, process zone, and final storage area. Up to 20,000 pits could be stored in this building if appropriate modifications are made. A Perimeter Intrusion Detection and Alarm System already exists around the building. No construction involving new land disturbance would be required at the site.

If DOE chooses to store pits at the P-Reactor facility at SRS, a pit placement, retrieval, and inventory system would be developed. It is expected that an automated or shielded pit movement and inventory system would be developed for this site.

The P-Reactor facility would require some internal facility modifications to enable a pit storage mission. Pit storage would require the installation of seismically qualified racks, and

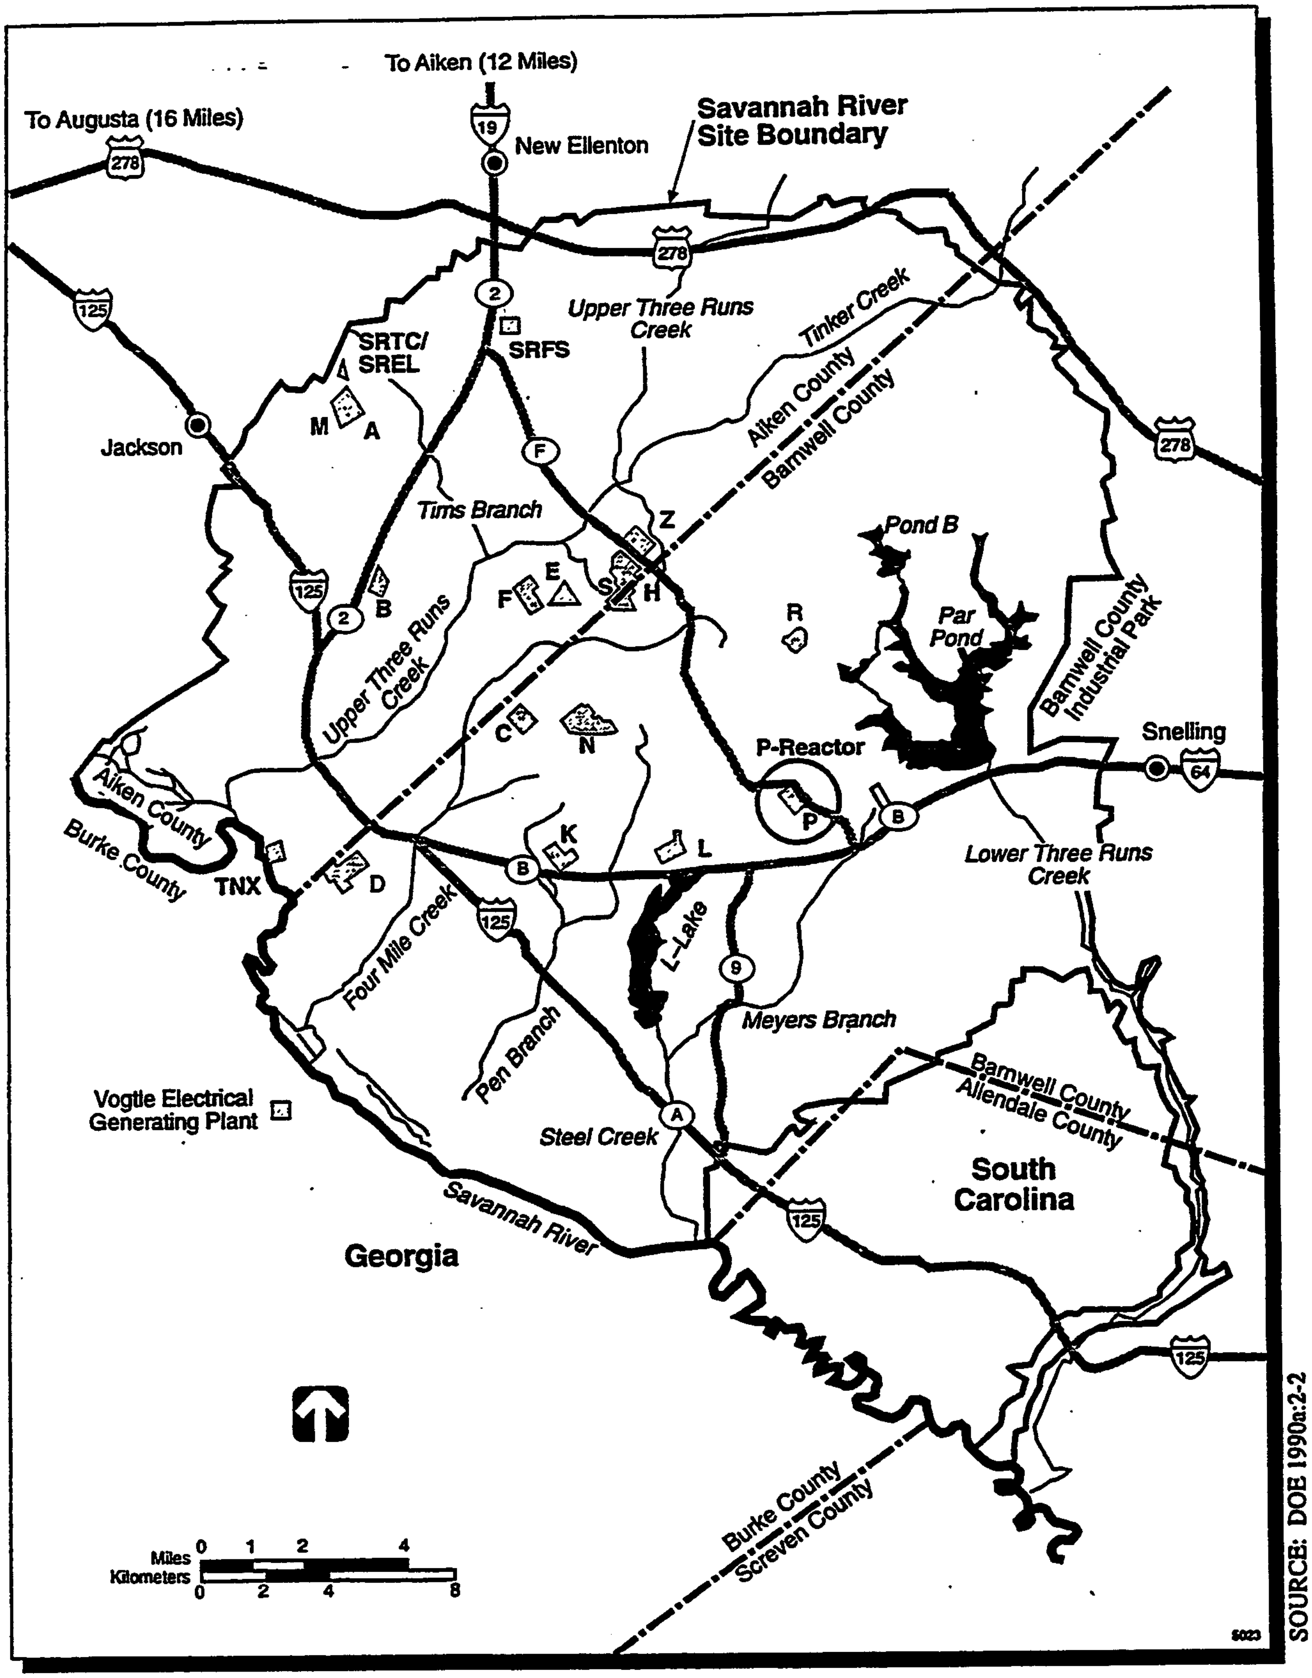

FIGURE 5.3–1.—*Location of P-Reactor at the Savannah River Site.*

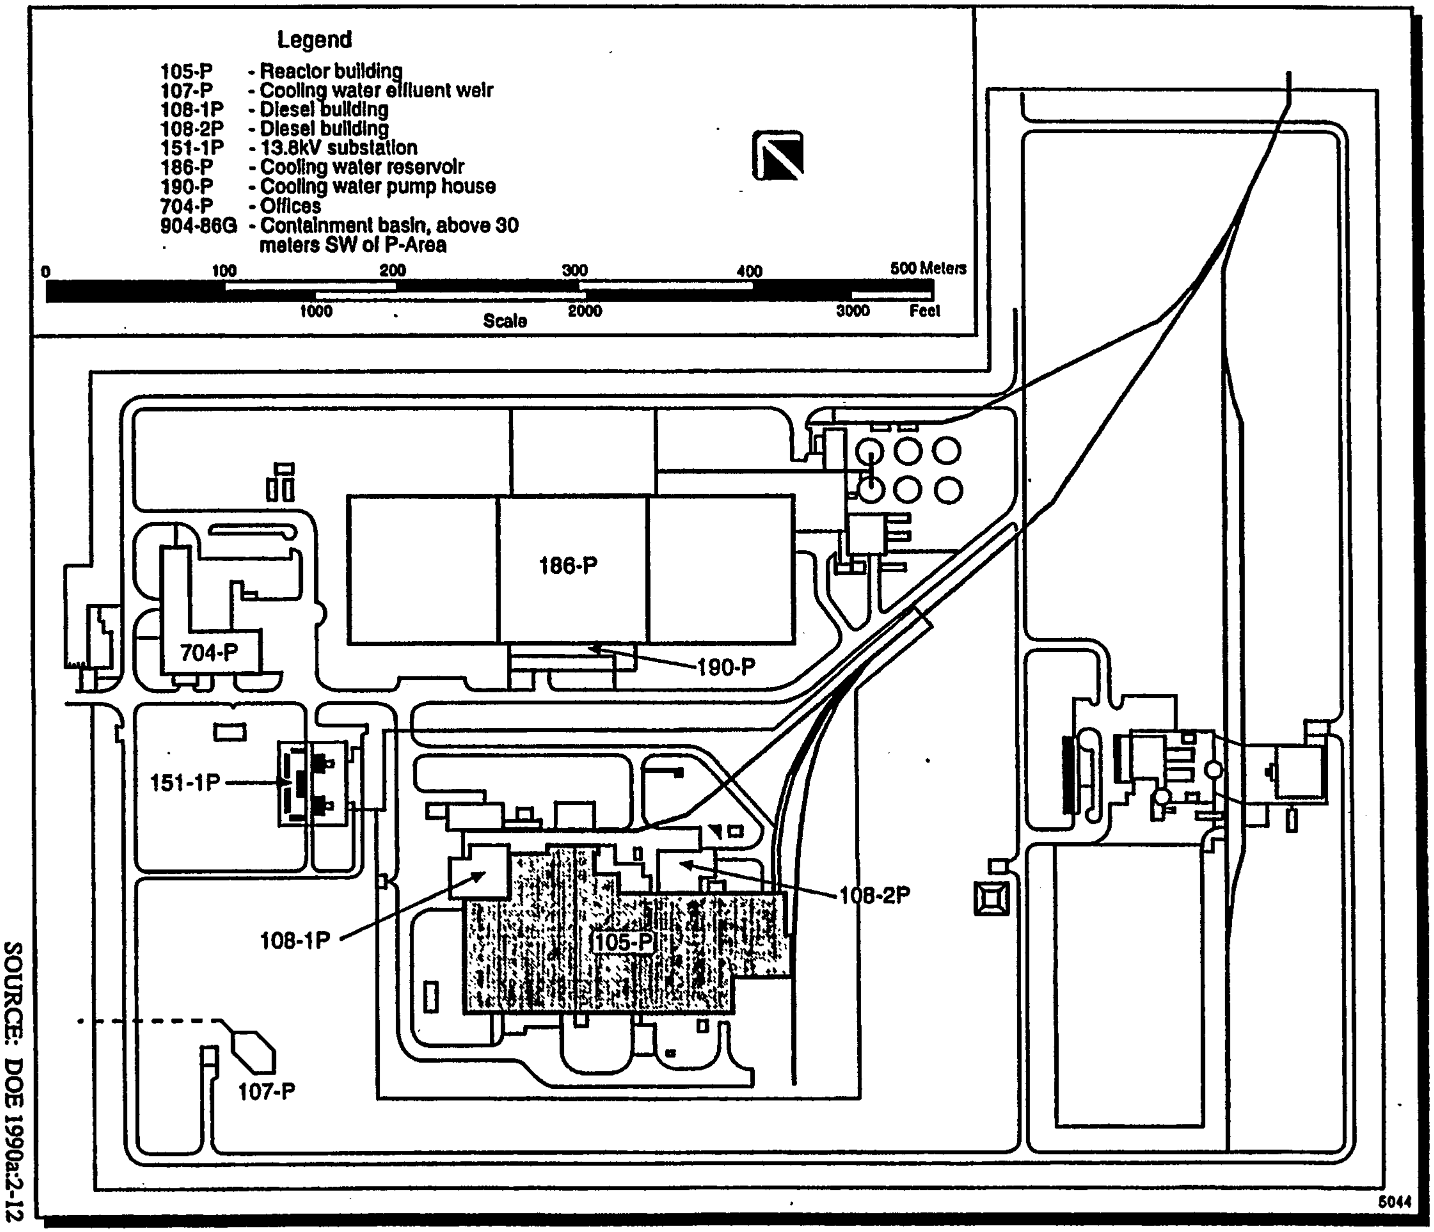

SOURCE: DOE 1990a:2-12

FIGURE 5.3–2.—*Layout of P-Reactor at the Savannah River Site.*

the development of an automated or shielded pit placement and retrieval system utilizing a bridge crane or high-lift forklift.

5.3.1 Environmental Resources Not Discussed in Detail

The environmental resources discussed below have been assessed at SRS. The analyses have shown that the impacts to these resources from potential pits storage activities at the P-Reactor facility would be small enough to warrant limited discussion. Therefore, these resources are discussed briefly below and will not be addressed further in this section.

5.3.1.1 *Facilities and Infrastructure*

The infrastructure operations at SRS that could be impacted by or be expected to directly support pit storage operations include security, vehicle and building maintenance, utilities, administration, safety and health protection, and general support (e.g., cafeteria, general stores). Waste management and transportation support are discussed below and in sections 5.3.1.10 and 5.3.1.11, respectively.

The direct impacts from the implementation of pit storage would include a small increase in the site's security force. Electrical usage due to interim pit storage (estimated to be 4,110 megawatthours per year) represents a 0.6 percent increase over the site's 1993 usage of 659,000 megawatthours and just under 0.2 percent of the site's remaining fiscal year 1993 system capacity of 2,980,000 megawatthours (DOE 1995p:C.4-66). Maintenance support and the indirect impacts resulting from pit storage worker requirements (e.g., water, wastewater treatment, and fuel) would increase minimally in comparison to the current and historical onsite infrastructure support levels and system capacities. The P-Reactor facility is not currently being utilized at historical or design levels; therefore, the utility systems generally have excess capacity available to support pit storage activity.

5.3.1.2 *Land Resources*

No land disturbance is projected under the Pit Storage Relocation Alternative for SRS. The Pit Storage Relocation Alternative does not include any new land uses at SRS. Impacts to land use would not be expected.

5.3.1.3 *Geology and Soils*

The only aspects of the geology and soils resource area that could be affected by or have an effect on the implementation of interim pit storage at SRS are the risks associated with earthquakes. P-Reactor is not anticipated to require upgrades that would involve land disturbance; therefore, impacts to soils are not anticipated. The risk due to earthquakes was assessed and found to be bounded by other accidents, as discussed in section 5.3.2.1.

5.3.1.4 *Water Resources*

Because of the nature of the pit storage activities, operations at the P-Reactor would not impact surface water, groundwater, or floodplains. The pit storage activities would not use surface waters at SRS and the nearest 100-year floodplain is 2.4 kilometers (1.5 miles) to the south and would not be impacted by pit storage activities. The increase in discharge of sanitary sewer waste due to a larger number of workers than presently utilized at the P-Reactor would be negligible in comparison to the site's annual wastewater treatment of 708 million liters (187 million gallons) and capacity of 2,043 million liters (540 million gallons). Since the site-wide compliance for SRS in 1993 was 99.9 percent, and because all sanitary discharges are regulated by National Pollutant Discharge Elimination System permits, no impacts to surface water quality are expected (WSRC 1994:16). No wastewater is discharged directly to groundwater; therefore groundwater quality would not be affected (DOE 1995k:4-411). The water demands of pit storage operations are solely due to use by storage personnel. In comparison to historical usage at the P-Reactor and the over 14 billion liters (3.7 billion gallons) used at SRS in 1993, water demands from pit storage are negligible (DOE 1995p:4-46).

5.3.1.5 *Air Quality*

Based on data collected at stations in Aiken and Barnwell counties, SRS and the surrounding area are well within all applicable local, State, and Federal ambient air quality standards (DHEC 1992; DHEC 1993; DHEC 1994). The impacts to air quality from normal pit storage operations would be due entirely to vehicle emissions (approximately 150 vehicles per day). The air impacts caused by vehicle emissions from pit storage activity would be negligible relative to the overall vehicular emissions at SRS.

5.3.1.6 *Acoustics*

The major sources of noise at SRS are located in developed or active areas and include industrial facilities, equipment, and machines. Because of the distance of P-Reactor from the site boundary and residential receptors, noise emitted from the site is not distinguishable above background noise levels at the SRS boundary (DOE 1995k:4-351). The only sources of noise that would be associated with pit storage operations would be from transportation vehicles and air conditioning and heating equipment for the occupied areas of the facility. These impacts would be minimal.

5.3.1.7 *Biotic Resources*

No Federally listed threatened or endangered plant and animal species are known to occur at P-Reactor (DOE 1995k:4-386). The smooth coneflower (*Echinacea laevigata*) is the only threatened or endangered plant that occurs on SRS. The bald eagle (*Haliaeetus leucocephalus*) and red-cockaded woodpecker (*Picoides borealis*) nest at SRS, and the wood stork (*Mycteria americana*) forages in the Savannah River Swamp and several of its tributaries on SRS. The peregrine falcon (*Falco peregrinus*) and Kirtland's warbler (*Dendroica kirtlandii*) may occur on an incidental basis. The shortnose sturgeon (*Acipenser brevirostrum*) occurs in the Savannah River near SRS (DOE 1995m:3-42 through 3-44). The interim storage of pits at the P-Reactor would not disturb the above mentioned species at SRS. Further, no wetlands at SRS would be disturbed by the Pit Storage Relocation Alternative (DOE 1995k:4-423). As a result, impacts to biotic resources would not be expected.

5.3.1.8 *Cultural Resources*

No historic, prehistoric, or paleontological sites have been found in the immediate vicinity of P-Reactor at SRS. Further, no National Register of Historic Places-eligible buildings are located at the P-Reactor. The Pit Storage Relocation Alternative would not adversely impact cultural and paleontological resources at SRS.

Native American groups with traditional ties to the area include the Westo, Shawnee, Yuchi, Apalachee, Chickasaw, Creek, and Cherokee (DOE 1993d). Consultations regarding traditional Cultural Properties and concerns have been conducted by DOE. As a result, Pee Dee, Creek, and Yuchi townsites are considered sensitive, and the Yuchi and Muskogee Creek groups have expressed a general concern regarding traditional use areas (DOE 1995m:55, 56; DOE 1993d:4-56, 57). These areas are not located at P-Reactor and, as a result, no impacts are expected from the Pit Storage Relocation Alternative.

5.3.1.9 *Socioeconomic Resources*

Approximately 150 additional personnel (including 120 security personnel) would be required for interim storage of pits at SRS. This number represents less than a 1.0 percent increase in the total SRS workforce. Most of these workers can be hired locally; therefore, no significant site or regional population and workforce increases are anticipated. According to the 1990 Census, 150 workers represent 0.07 percent of the workforce employed within the SRS Region of Influence (SC Cen 1993:Table 145; GA Cen 1993:Table 145). No socioeconomic impacts would be anticipated.

5.3.1.10 *Waste Management*

Currently, SRS manages high-level waste, mixed transuranic waste, transuranic waste, mixed waste, low-level waste, hazardous waste, and nonhazardous wastes in accordance with the requirements of a number of Federal and State regulations, permits obtained under these regulations, and DOE orders. These requirements are primarily under the authority of the Environmental Protection Agency, DOE, and the South Carolina Department of Health and Environmental Control. SRS anticipates generating 18,000 cubic meters (23,500 cubic yards) of low-level waste, approximately 2,000 cubic meters (2,600 cubic yards) of mixed waste, and 1,400 cubic meters (1,800 cubic yards) of hazardous waste in 1996 (DOE 1995m:A-1). The pit storage operations would generate less than 1 cubic meter (1.3 cubic yards) of mixed, low-level, and hazardous waste. This amount of waste would not impact current waste management at SRS.

5.3.1.11 *Intrasite Transportation*

The P-Reactor facility is located approximately 4 kilometers (2.6 miles) east-southeast of the geographical center of SRS and approximately 6.5 kilometers (4 miles) west of the closest site boundary (Figure 5.3–1). State Highway 125 provides access to the P-Reactor facility from the Augusta region; State Highway 64 provides access from Snelling. The P-Reactor facility is located on SRS primary Road F. All roads within SRS are suitable for passage in all weather conditions. Although some roads within the SRS boundaries are public access roads, the DOE would control access during passage of Safe Secure Tractor Trailer (SST) convoys. Because a release of plutonium from an intersite pit shipment would require a severe accident (e.g., an accident with a fuel tanker or train [see section 4.16.4.2]), the controlled transportation environment within SRS does not pose a significant threat to pit shipments. Consequently, the contribution of overall intersite transportation risk from onsite transportation is negligible.

5.3.1.12 *Aircraft Accidents*

There are four airports in the vicinity of P-Reactor. Bush Field, the major commercial airfield in the area, has two runways and is approximately 38 kilometers (24 miles) west-northwest of P-Reactor. The airport is used by commercial (air carrier and air taxi), military, and general aviation aircraft. In 1994, Bush Field had 39,461 aircraft operations (take-offs and landings). Table 5.3.1.12–1 summarizes the total number of airfield operations at Bush Field (PC 1996j). The closest airport, the

TABLE 5.3.1.12–1.—*Bush Field Operations for 1994*

AIRCRAFT CATEGORY	NUMBER OF OPERATIONS
Air Carrier	6,473
Air Taxi	5,961
Military	5,677
General Aviation	21,350
Total Airfield Operations	39,461

Source: (PC 1996j)

county airport near Barnwell, has three runways and is located approximately 18 kilometers (11 miles) east of P-Reactor. This airport is used by general aviation aircraft. Similarly, Aiken Airport, approximately 46 kilometers (29 miles) north-northwest, has three runways, used only by general aviation aircraft.

The North Army Base, approximately 61 kilometers (38 miles) northeast, has one runway used by military aircraft only. All four airports are outside the probability density function boundary for all categories of aircraft, and were therefore not included in the aircraft crash analysis. Only non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g). Further details on these four facilities are contained in volume II, appendix E.

P-Reactor was modeled conservatively as a facility with a length of 69 meters (225 feet), a width of 57 meters (187 feet), and a height of 9 meters (30 feet). Using the Draft DOE Standard for determining the probability of aircraft crashes and 1994 data from the FAA, the frequency of hitting P-Reactor was calculated as 1.2×10^{-6} for all types of aircraft (DOE 1996g). It should be noted that the frequency calculation represents a conservative upper bound. Since this frequency is greater than 10^{-7}, in accordance with the Draft DOE Standard, further analysis was required. A local response structural analysis was performed according to the Draft DOE Standard, for the facility with a wall thickness of 76 centimeters (30 inches).

The analysis was performed for the maximum penetrator missile for each of the aircraft categories mentioned in section 4.15.2, except for helicopters. The commercial air carrier and large military aircraft categories were the only two aircraft missiles capable of penetrating the facility; the frequency of releasing material from P-Reactor was $\leq 9.2 \times 10^{-9}$. Since this frequency is less than 10^{-7}, in accordance with the Draft DOE Standard, no further analysis was required. Further details of the frequency of hitting P-Reactor and the frequency of releasing material are contained in volume II, appendix E.

5.3.2 Resources Discussed in Detail

5.3.2.1 *Human Health*

The basic approach used in assessing human health concerns is to first identify the affected environments and establish a baseline that represents the risk from current operations. Changes in this baseline risk resulting from the Pit Storage Relocation Alternative are then examined. Impacts from both normal operations and potential accidents are estimated.

Assessing the human health risk impact from potential accidents resulting from the relocation of pits to SRS and storing them in the P-Reactor facility involves a risk screening process. The first step in this process is to identify a broad spectrum of potential accident scenarios. The second step in the process uses screening techniques to identify the specific scenarios that dominate risk (i.e., scenarios that contribute an appreciable fraction of the total risk). Finally, risk is the product of frequency and consequence. Rigorous consequence evaluations are only performed for the identified risk dominant scenarios.

Two types of accident consequences are examined:

- Worker and public exposure.
- The probability of the accident causing fatal cancer in a worker or the public.

If DOE chooses to relocate pits to SRS, two aspects of this relocation would contribute to a potential for environmental impacts. These impacts are associated with:

- Transferring pits from the transporter to their storage location inside the facility.

- Storage itself (i.e., potential impacts resulting from having the pits reside inside the facility).

Each time pits are transferred from the transporter to their storage location inside the facility, there is a small probability that an accidental release could occur due to a handling accident. In addition, the transfer of pits from the transporter to their storage location would result in radiological exposures to involved workers.

Affected Environment

The release of radioactivity and toxic chemicals to the environment from a DOE facility is an important issue for onsite workers and the public. Since the human environment contains many sources of radioactivity and toxic chemicals, it is essential to understand the sources of these substances and how effectively they are controlled.

Table 5.3.2.1–1 summarizes the major sources of radiation exposure in the vicinity of SRS. Cancer statistics for the States of Georgia and South Carolina indicate that annually, an average person in those states has a 1.7×10^{-3} probability of contracting a fatal cancer (DOE 1990a:4-36). Using nominal fatal cancer risk factor of 5×10^{-4} cancer fatalities per person rem and the environmental radioactivity data for SRS in Table 5.3.2.1–1, it is calculated that fatal cancers within 80 kilometers (50 miles) of SRS attributable to environmental radioactivity released from SRS constitute 0.005 percent of

TABLE 5.3.2.1–1.—*Major Sources of Radiation Exposure in the Vicinity of the Savannah River Site*

Sources: NCRP 1987:15, 53; DOE 1990a:3-52 the average yearly fatal cancer probability in Georgia and South Carolina (DOE 1994o:4-20).

Figure 5.3.2.1–1 depicts the offsite population within an 80-kilometer (50-mile) radius of SRS. Meteorological data for the P-Area are presented in Figure 5.3.2.1–2 (DOE 1994v:4-25; DOE 1993a:12). Winds from the northeast sector occurred most often, with southwest and northeast quadrants more frequent than northwest and southeast quadrants.

Impacts of Facilities Upgrades

There is no significant impact on human health associated with SRS facility upgrades. The principal upgrade required is to modify P-Reactor to accept Stage Right transfer and storage equipment. The facility impact involves modifying floor space to accept Stage Right guide rails and fastening Stage Right attachment fixtures to storage facility walls. These are standard industrial operations that do not expose workers to any special hazards (e.g., radionuclides, toxic chemicals, or high explosives).

Impacts of Storing 20,000 Pits

Human health impacts from pit storage activities could potentially result from normal operations and accident scenarios. Impacts from normal operations would be confined to onsite workers. Normal operational impacts result from unloading of pits from SSTs at the P-Reactor facility. Unloading operations would result in radiological exposure to cargo handlers. Based on conservative calculations made for handling of pits at Pantex Plant, the worker doses from unloading of 2,000 pits per year are estimated to be 27 person-rem per year or 270 person-rem for the unloading of 20,000 pits (the maximum number of pits which may be stored at the P-Reactor facility).

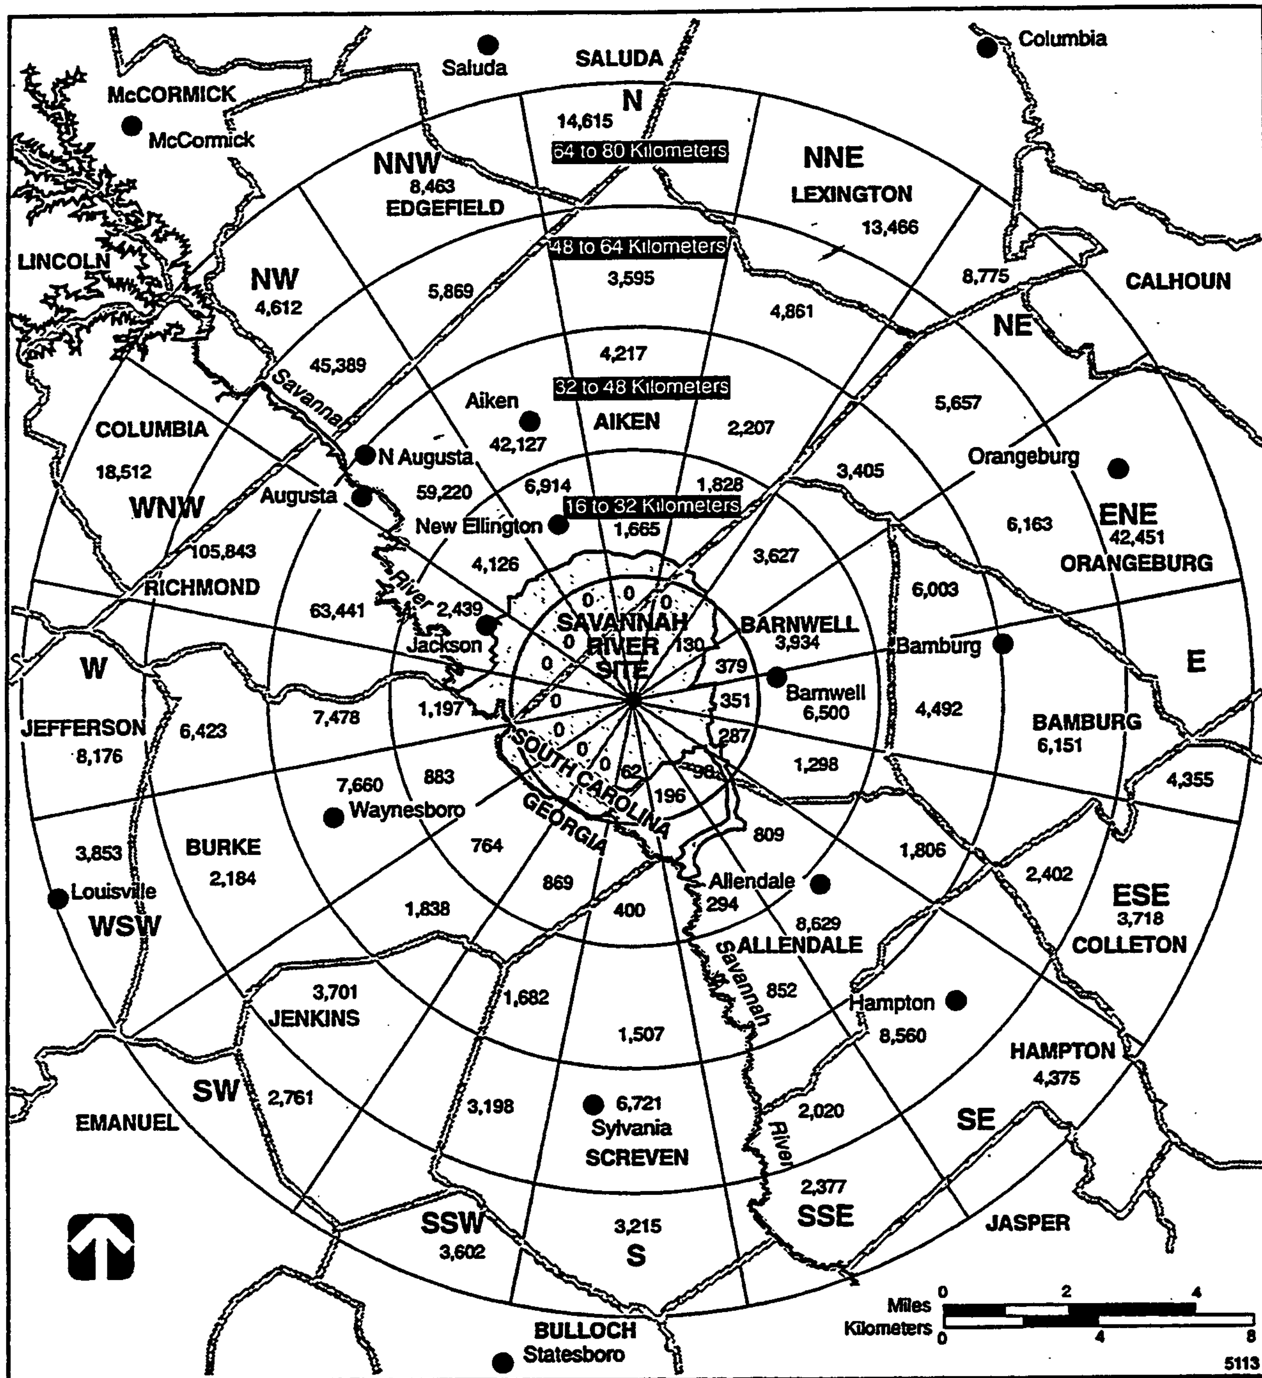
Once removed from SSTs, pits would be transferred into the P-Reactor facility for storage. Pit transfers within the P-Reactor facility would result in radiological exposures to onsite workers handling the pits. The transfer of pits would result in worker doses of less than 2 person-rem per year for handling 2,000 pits and about 13 person-rem for the placement of 20,000 pits. The combined worker dose from unloading and storage of 20,000 pits at the P-Reactor facility would be 283 person-rem distributed over the 30 people directly involved in material handling. Assuming that the same 30 people continue to handle 20,000 pits over a period of 10 years and using a dose-to-risk conversion factor of 4 x 10^{-4} latent cancer fatality (LCF) per person-rem, there would be an additional 0.11 LCF experienced by this group due to radiological exposure from pit handling.

The probability of LCFs from all causes in the general population is estimated at 20 percent which implies that 6 of 30 workers would develop cancer from all other causes. With an additional 0.11 LCF from pit handling, the total risk of latent cancer among workers at the P-Reactor site would increase by 1.8 percent.

Some operational accidents could result in impacts to both onsite workers and the offsite general population. Radiological exposures and the resultant risk of latent cancers have been evaluated and described in paragraphs that follow.

The risk screening methodology indicates that the radiological health risk from accidents associated with the storage of 20,000 pits in P-Reactor is dominated by handling accidents that could occur when the pits are being transferred from the transporter. A standard tine forklift is likely to be used to remove pit containers from an SST. The probability of a standard tine forklift causing a puncture during a single handling operation is in the extremely unlikely range (i.e., 10^{-4} to 10^{-6}).

It is estimated that a forklift puncture of a pit container would release 9.2 x 10^{-5} curies of plutonium. This is a conservative estimate of



SOURCE: UN 1995

FIGURE 5.3.2.1–1.—*Offsite Population in the Vicinity of the Savannah River Site.*

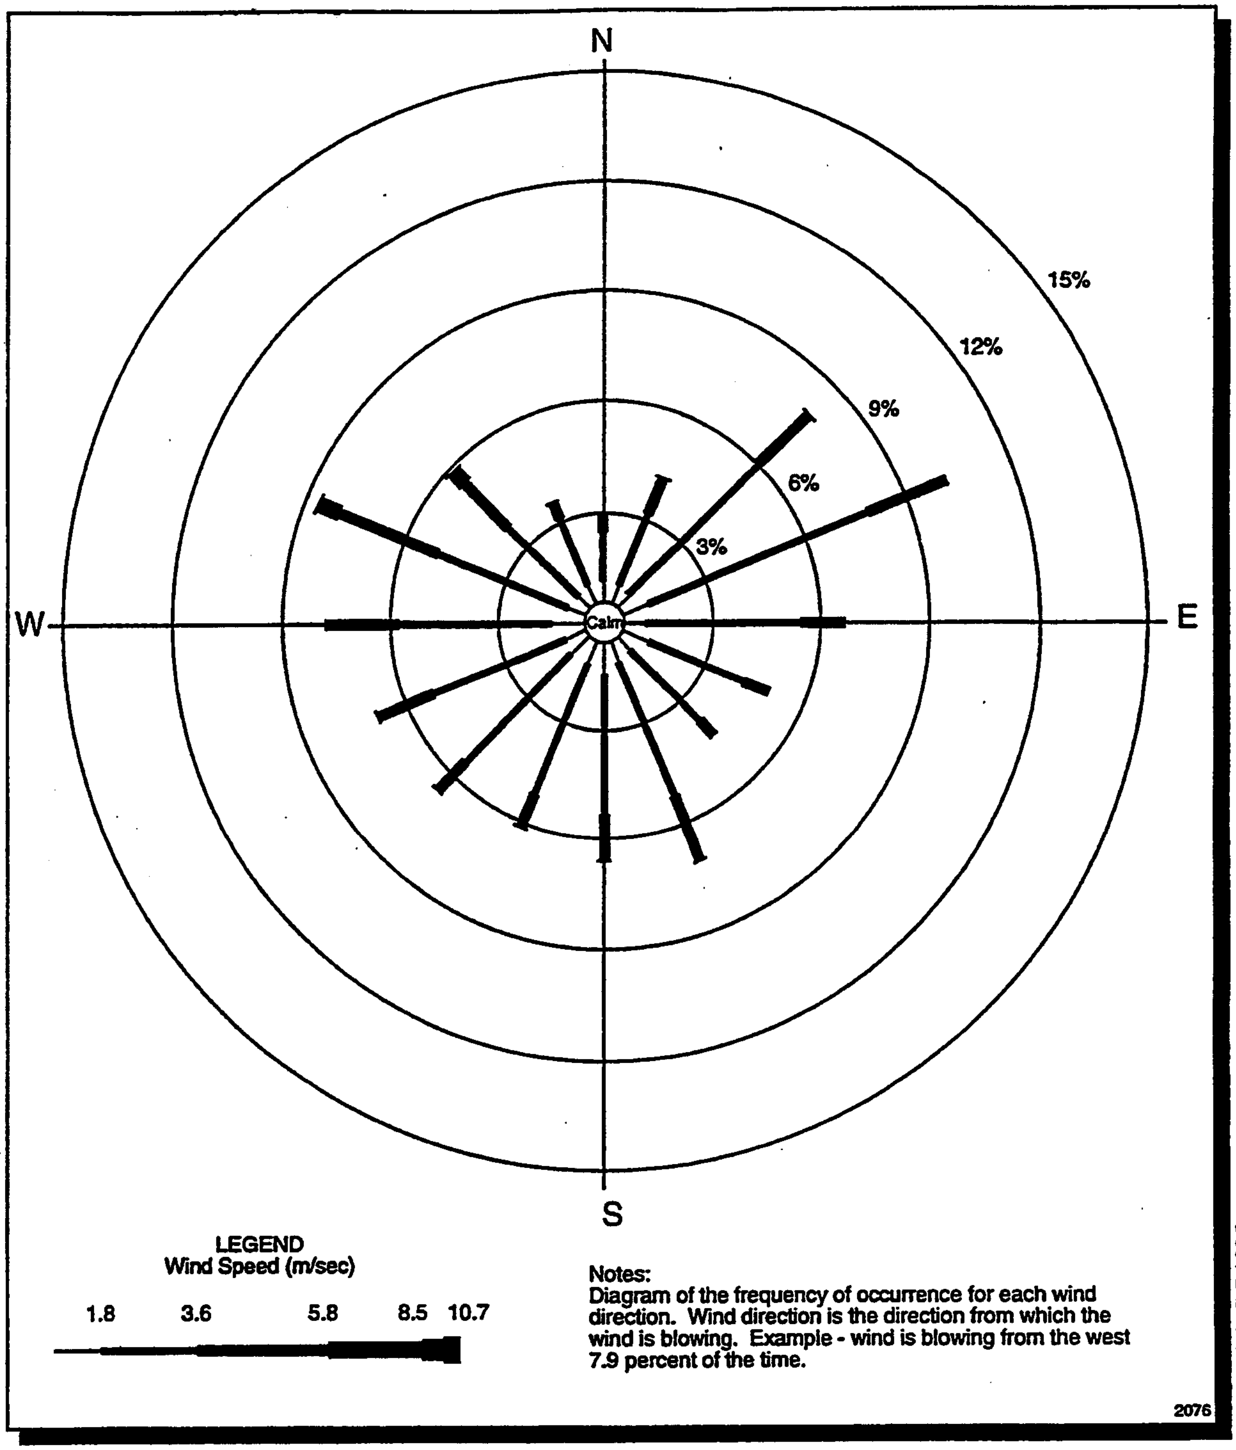


FIGURE 5.3.2.1–2.—*Wind Direction and Speed at the Savannah River Site, South Carolina, 1986.*

the respirable, airborne release caused by a puncture of one shipping container (DOE 1992f:7-39).

Given such a release, an involved worker (the forklift driver) would receive a dose of 6.6 rem, corresponding to an incremental increase in lifetime cancer probability of 2.6×10^{-3}. In addition, a non-involved worker 100 meters (328 feet) downwind along the center line of the plutonium dispersion plume would received a 5.2×10^{-2} rem exposure, corresponding to an incremental increase in lifetime fatal cancer probability of 2.1×10^{-5}. The maximally exposed member of the public would receive a 1.1×10^{-5} rem exposure, corresponding to an incremental increase in lifetime fatal cancer probability of 5.5×10^{-9}. The lifetime fatal cancer probability for an average individual from all other causes is approximately 0.2 (20 percent).

This event would result in an exposure to the public of 4.6×10^{-3} person-rem. Considering the likelihood and consequence of this event, on the average, a member of the public will have an increased annual risk of developing a fatal cancer from this potential accident of 3×10^{-15} fatal cancers per year. The annual fatal cancer risk to a person in the States of South Carolina and Georgia from all other causes is 1.7×10^{-3} fatal cancers per year.

Pit container inventories at P-Reactor are expected to be performed using either shielded or automated techniques and equipment. Consequently, these normal operations are not expected to result in any significant radiological exposure to workers.

Other storage activities that may occur within the time frame evaluated in this EIS include:

- Restacking a limited number of pits to comply with design laboratory temperature requirements.
- A limited number of pit movements and/ or instrumentation placements to facilitate third-party inspections.

Impacts of these routine activities are also considered to be negligible.

The greatest threat to pit containers from natural phenomena is from natural earthquakes. Analysis of available seismology studies and estimates of the reactor building's seismic capacity indicate that the relative risk from earthquakes is over two orders of magnitude below the risk from a forklift accident, (3.0×10^{-15} LCF per year to an average member of the public) (DOE 1994v:4-24; DOE 1994u:C-25; NRC 1985:C-45).

Impacts of Storing 8,000 Pits

The risks associated with storing 8,000 pits in P-Reactor are similar to but less than those of the 20,000-pit storage alternative. If DOE chooses to store only 8,000 pits at SRS, the worker doses from unloading and pit transfer operations would be below 113 person-rem over 4 years. This exposure would result in an additional 0.04 LCF in this group. With 0.04 LCF from pit handling, the total risk of LCFs among workers at SRS would increase by 0.7 percent.

Risk screening methodology also indicates that the risk from storage of 8,000 pits in P-Reactor is dominated by forklift handling accidents. These impacts would be similar to those described for the storage of 20,000 pits (i.e., a LCF risk of 3.0×10^{-15} latent fatal cancers per year to an average member of the public).

5.3.2.2 *Environmental Justice*

Affected Environment

P-Reactor is located at SRS in west-central South Carolina along the Savannah River which forms the border between South Carolina and its western neighbor, Georgia. A 1990–1991 survey of the SRS workforce found that 90.5 percent of onsite workers reside in four South Carolina counties and two Georgia counties (DOE 1992g). In order to identify the target resident populations covered by Executive Order 12898, an 80-kilometer (50-mile) radius circle centered on the P-Reactor facility at SRS was overlaid on 1990 Census maps. The communities which lie within the 80-kilometer (50-mile) circle, hereafter called the P-Reactor Region of Influence (ROI), are shown in Figure 5.3.2.2–1.

Population. According to the 1990 Census, 621,677 persons reside within the P-Reactor ROI. The population is 61 percent White and 37 percent Black (UN 1995). Twenty-seven counties are wholly or partially included within the ROI. Blacks are a majority of the population in ten of these counties; 7 of 14 counties in South Carolina and 3 of 13 counties in Georgia. The largest population concentration within the ROI is northwest of SRS in Aiken, Columbia, and Richmond Counties (GA Cen 1992:Tables 1 and 8; SC Cen 1992:Tables 1 and 8).

Communities with 1990 populations greater than 10,000 persons within the ROI are: Augusta, Georgia (44,639), the South Augusta Census Designated Place (CDP) (55,998), the West Augusta CDP (27,637), Aiken, South Carolina (19,872), North Augusta, South Carolina (15,351), and Orangeburg, South Carolina (13,739). There are also eight towns and CDPs within the ROI whose 1990 population counts are between 1,000 and 10,000 persons. The combined 1990 population for all communities within the ROI that are greater than 1,000 persons is 213,968, or 34.4 percent. Thus, nearly two-thirds of the 1990 population within the ROI lived in rural areas and in towns with populations less than 1,000 persons (GA Cen 1992:Table 6; SC Cen 1992:Table 6).

Minority Population. Figure 5.3.2.2–2 shows 1990 Census tracts within the ROI. The tracts are shaded if 25 percent or more of their populations were minority persons in 1990 or if 25 percent or more of their populations were below the poverty level based on their incomes in 1989. The 25 percent threshold levels for minority or low income persons are based on the working definitions contained in the notice of the Environmental Protection Agency's Office of Environmental Justice (59 FR 192).

With the exception of five tracts northeast of the P-Reactor facility and a number of ROI tracts to the northwest, in Augusta and Aiken Counties, virtually every tract within the ROI has at least a 25 percent minority population. All of the tracts in the largely rural counties west, south and east of the P-Reactor facility—namely, Burke, Emanuel, Jefferson, Jenkins and Screven in Georgia; and Allendale, Bamberg, Barnwell, Colleton and Hampton in South Carolina—have populations that are 25 percent or more minority or non-White. In the Augusta urban area, including the City and its unincorporated neighbors, West and South Augusta, most tracts contain 25 percent minority populations; Blacks comprise 45 percent of the total population (GA Cen 1992:Tables 5 and 6; SC Cen 1992:Tables 5 and 6).

Low-Income Population. The greatest concentration of low-income population within the ROI is found in the largely rural counties west, south and east of SRS. With the exception of seven tracts, all of Burke, Emanuel, Jefferson, Jenkins and Screven counties in Georgia have populations in which at least one in four persons live below the poverty level based on their incomes in 1989. In South Carolina, threshold levels of low-income persons are not as widespread. Portions of Allendale, Hampton, Bamberg and Barnwell counties in South Carolina are the areas closest to the P-Reactor facility where 25 percent or more persons lived below the poverty level in 1989.

Several cities and towns within the ROI have poverty rates which are characteristic of their neighboring areas. In Georgia, Augusta had a

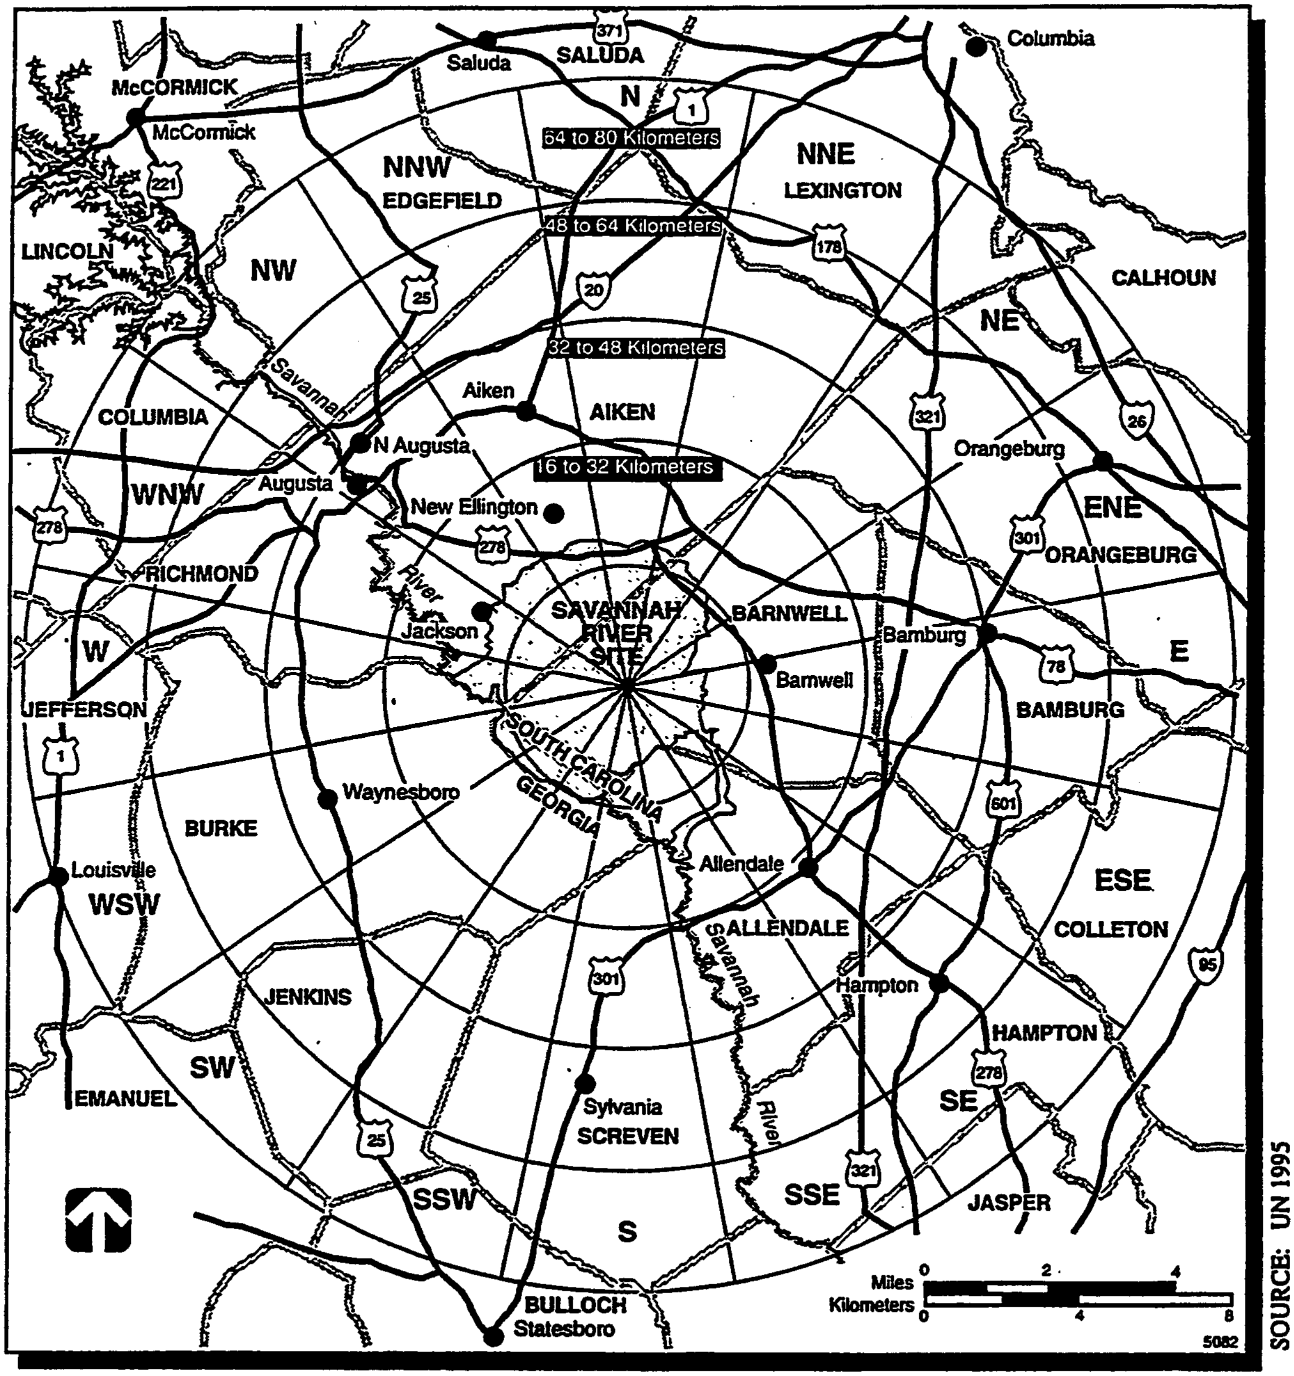

FIGURE 5.3.2.2–1.—*P-Reactor Region of Influence.*

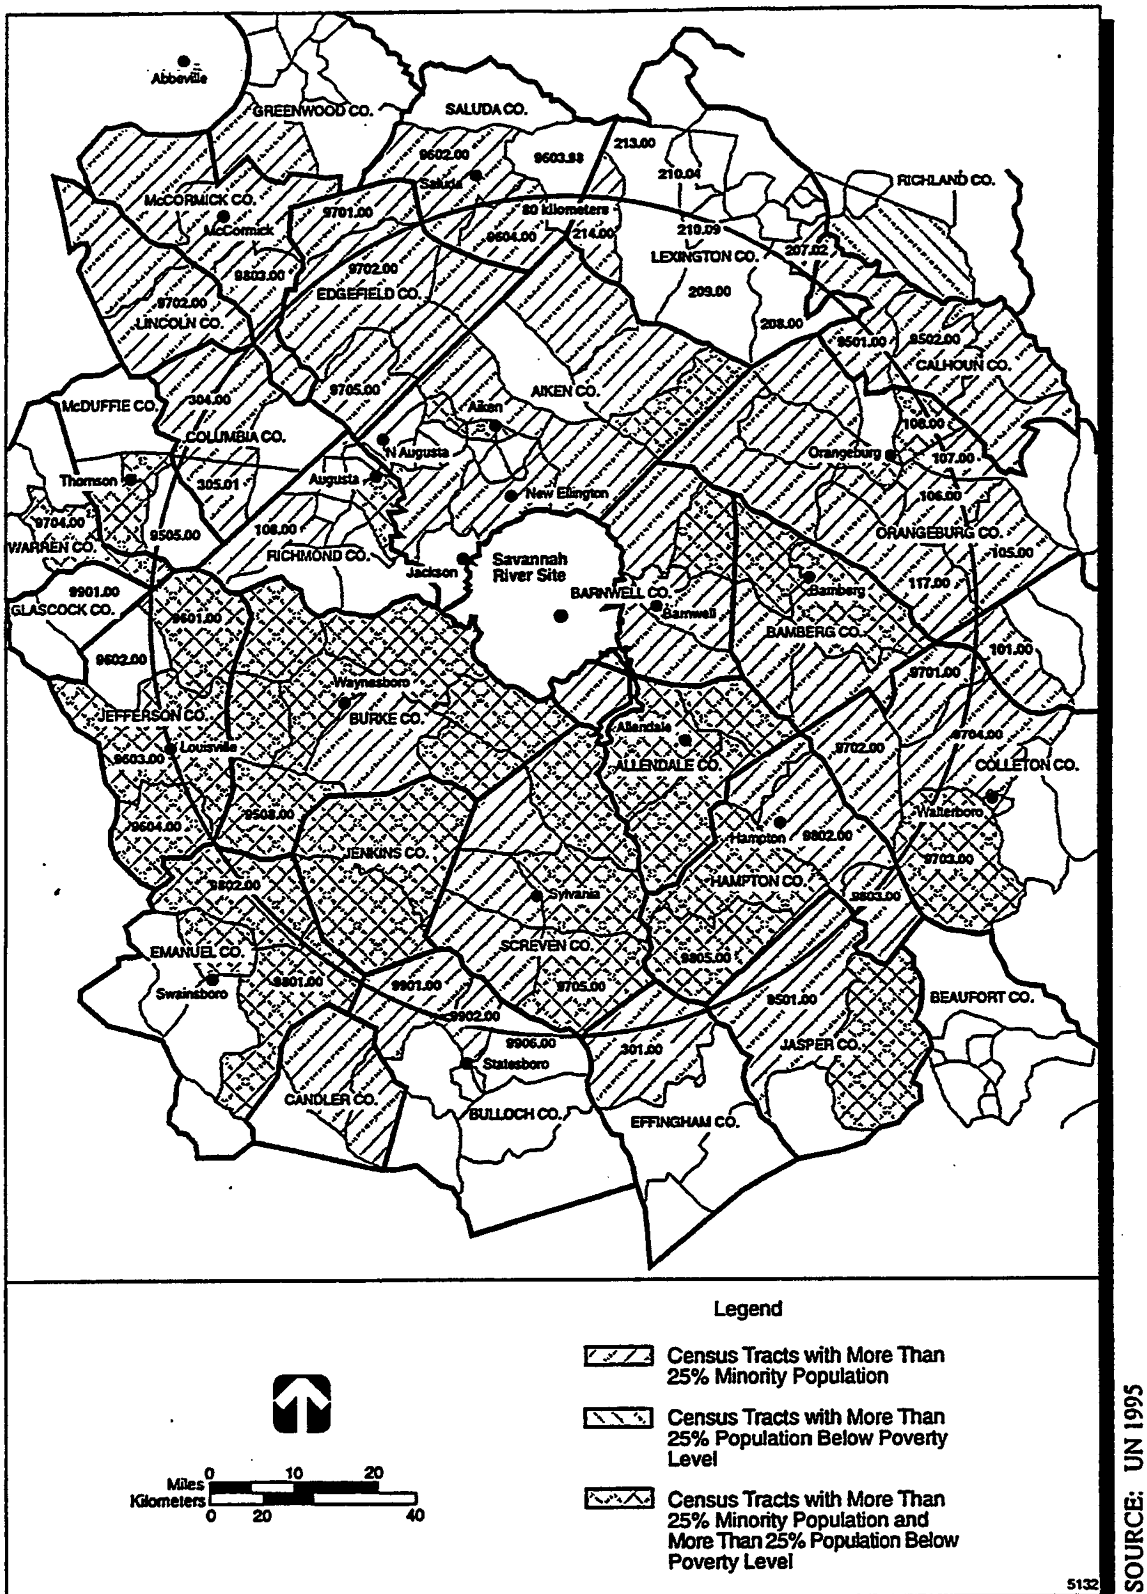

FIGURE 5.3.2.2–2.—*Minority and Low-Income Populations in the P-Reactor Region of Influence.*

33 percent rate, while Sylvania and Waynesboro had 26 and 34 percent rates, respectively. In South Carolina, Allendale had a 44 percent poverty rate, while Bamberg, Barnwell and Orangeburg had poverty rates of 34, 26, and 25 percent, respectively (GA Cen 1993:Tables 178 and 203; SC Cen 1993:Tables 178 and 203).

Impacts of Storing 20,000 Pits

Because the interim storage of 20,000 pits at the P-Reactor facility would not require any construction activities and because all facility modifications would take place inside existing facilities, impacts to the natural environment would be minimal. Under normal operating conditions, there would be minor increases in air pollutants associated with vehicles used during pit storage activities. Also, a minor increase in particulate matter of aerodynamic diameter less than 10 micrometers concentrations would be expected. These increases are associated with the operation of forklifts which are used to move the pits from the unloading area to the storage area. These impacts are not likely to affect the surrounding population.

Radiological releases from normal pit storage operations would have no measurable effect on an individual occupying a position near the SRS boundary for an entire year. Levels at the site boundary would be indistinguishable from natural background radiation. No adverse health effects would be expected among the general public, including minority and low-income populations, as a result of normal storage operations.

An abnormal event, such as accidental puncture of the transport container from a forklift, has the potential of exposing the general public to radiation. The analysis in the section 5.3.2.1, Human Health, indicates that the risk to the public from such an accident would be negligible. With no measurable impacts on the general population, the minority and low-income populations would not be disproportionately impacted.

Impacts of Storing 8,000 Pits

The human health impact of storing 8,000 pits at the P-Reactor facility would be lower than those identified for the storage of 20,000 pits. No significant adverse impacts are expected, and minority and low-income populations would not be disproportionately impacted.

THE HANFORD SITE

5.4 HANFORD SITE

Under the Pit Storage Relocation Alternative (see section 3.1.3), the pit storage function currently carried out at Pantex Plant would be transferred to another site. The Hanford Site is one of the candidate sites for the storage of pits (Figure 5.4–1). The Fuels and Materials Examination Facility (FMEF) is the candidate pit storage facility at the Hanford Site. FMEF is currently capable of storing approximately 8,000 pits with relatively minor modification. With more extensive modifications it may be possible to store up to 20,000 pits in the facility. However, due to the time constraints within which the facility would need to be available, this study only considers the alternative of storing 8,000 pits in FMEF.

This section discusses FMEF, the affected environment at and near the Hanford Site, and the potential impacts that would be associated with pit storage. The Plutonium Finishing Plant is not considered a viable option for interim pit storage of the minimum 8,000 pits. Readily available storage space is limited, and the cost of facility modification to accommodate the pits would be excessive. Additionally, the potential for pit storage operations to interfere with important stabilization activities makes the storage option at Plutonium Finishing Plant impractical.

Each aspect of the affected environment at the Hanford Site has been assessed and the potential environmental impacts to each have been evaluated. Each environmental resource is discussed commensurate with the degree the resource could be impacted by or have an effect on interim pit storage at the candidate facility.

Hanford Site. The Hanford Site is a government-owned and contractor-operated facility, managed by Fluor Daniel Hanford, Inc.; Lockheed Martin Hanford Corporation; Rust Federal Services of Hanford, Inc.; Duke Engineering & Services Hanford, Inc.; Babcock & Wilcox Hanford Company; Numatec Hanford Corporation; and Bechtel Hanford Inc. The approximately 145,000-hectare (358,000-acre) Site is located just north of Richland, Washington (DOE 1994s:O-1; DOE 1994r:4.3). The general Site location map, Figure 5.4–1, shows that most of the land is vacant. Due to its large size, the perimeter of the Hanford Site is not fenced; however, the Site is patrolled by car and boat. The primary missions at the Hanford Site are the management of stored defense wastes and wastes from current operations, environmental restoration (ER) of approximately 1,100 inactive waste sites and 100 surplus facilities, and research and development in a broad range of disciplines including ER and waste management technologies (DOE 1994p:3).

Fuels and Materials Examination Facility. FMEF is located in a controlled area (400 Area) in the southeastern part of the Hanford Site, approximately 11 kilometers (7 miles) from the City of Richland (Figure 5.4–2). Completed in 1984, FMEF was intended to support the Liquid Metal Fast Breeder Reactor Program. However, the building was never used for that purpose. About 8,000 pits could be stored in the main process cell of FMEF if appropriate modifications are made. Facility modifications would include plugging cell penetrations, moving doors, and installing vault doors and electronic equipment.

The FMEF building is divided into numerous compartments and areas, including shipping/receiving, maintenance and decontamination, entry tunnel, equipment rooms, and process cells. There are two areas within FMEF proposed for pit storage. These are the maintenance and decontamination cell (decon cell) and the main process cell (originally called the nondestructive evaluation cell and upper nondestructive evaluation cell). The main process cell is one large room with a 15-meter (50-foot) high ceiling and approximately 465 square meters (5,000 square feet) of floor space. A Perimeter Intrusion Detection and Alarm System already exists around the building. No

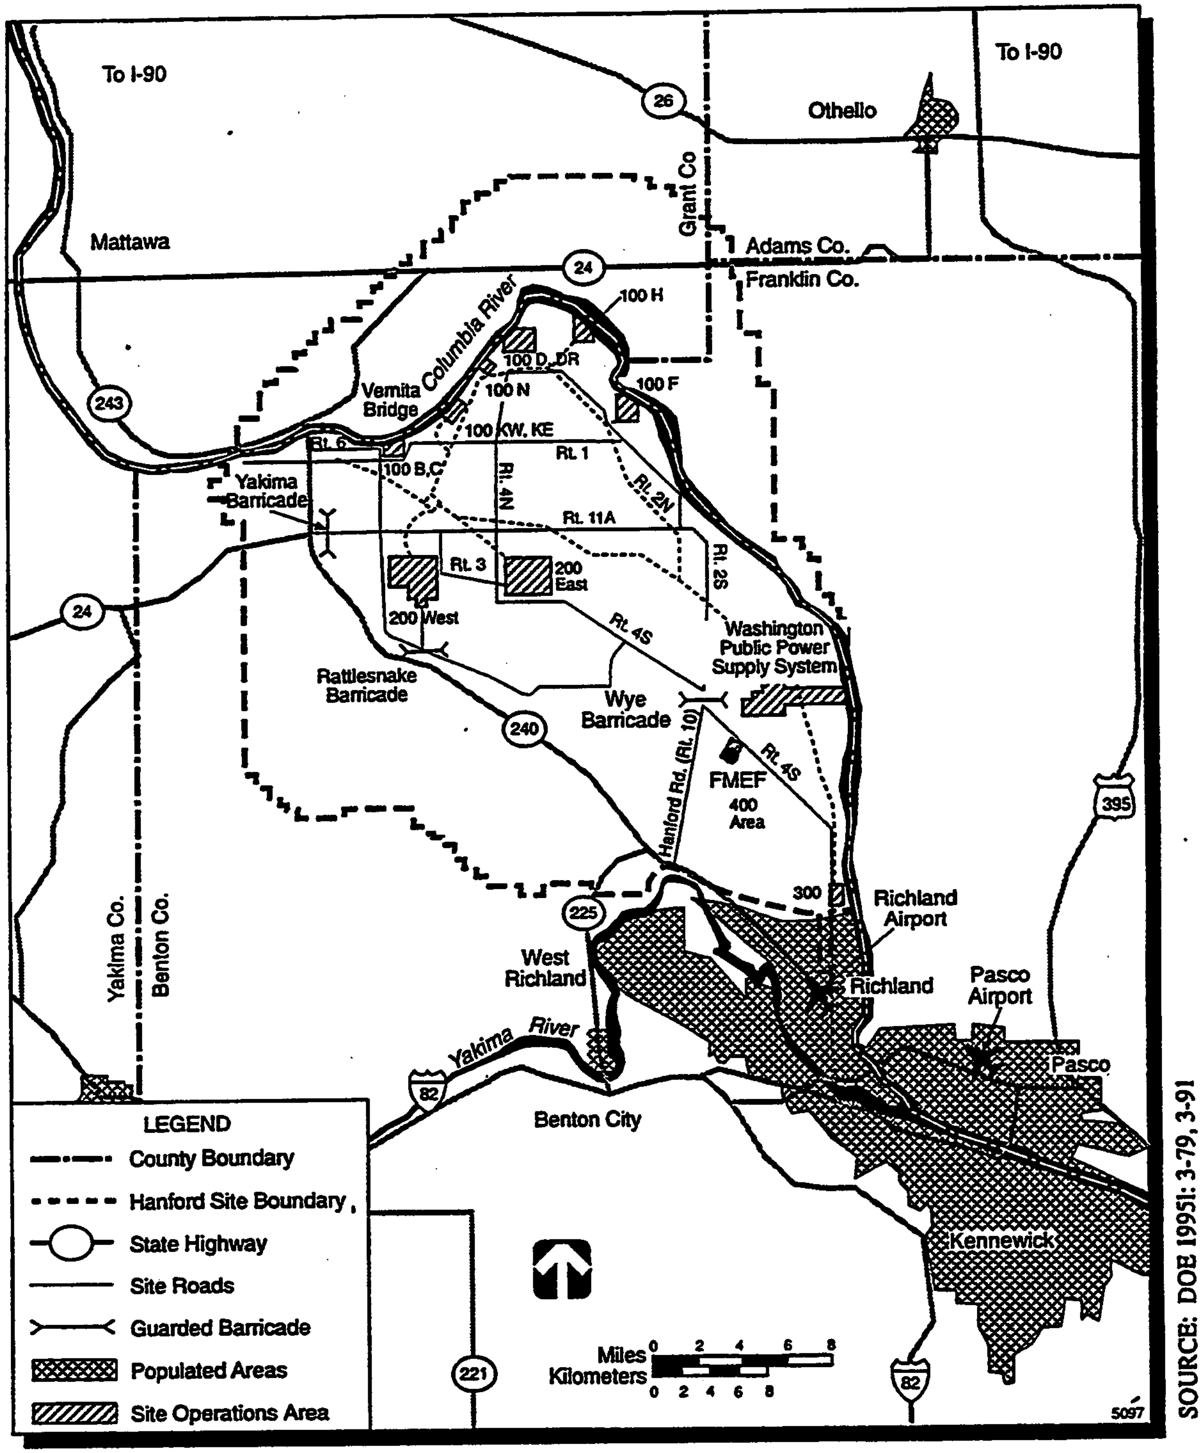

FIGURE 5.4–1.—*Location of the Fuels and Materials Examination Facility at the Hanford Site.*

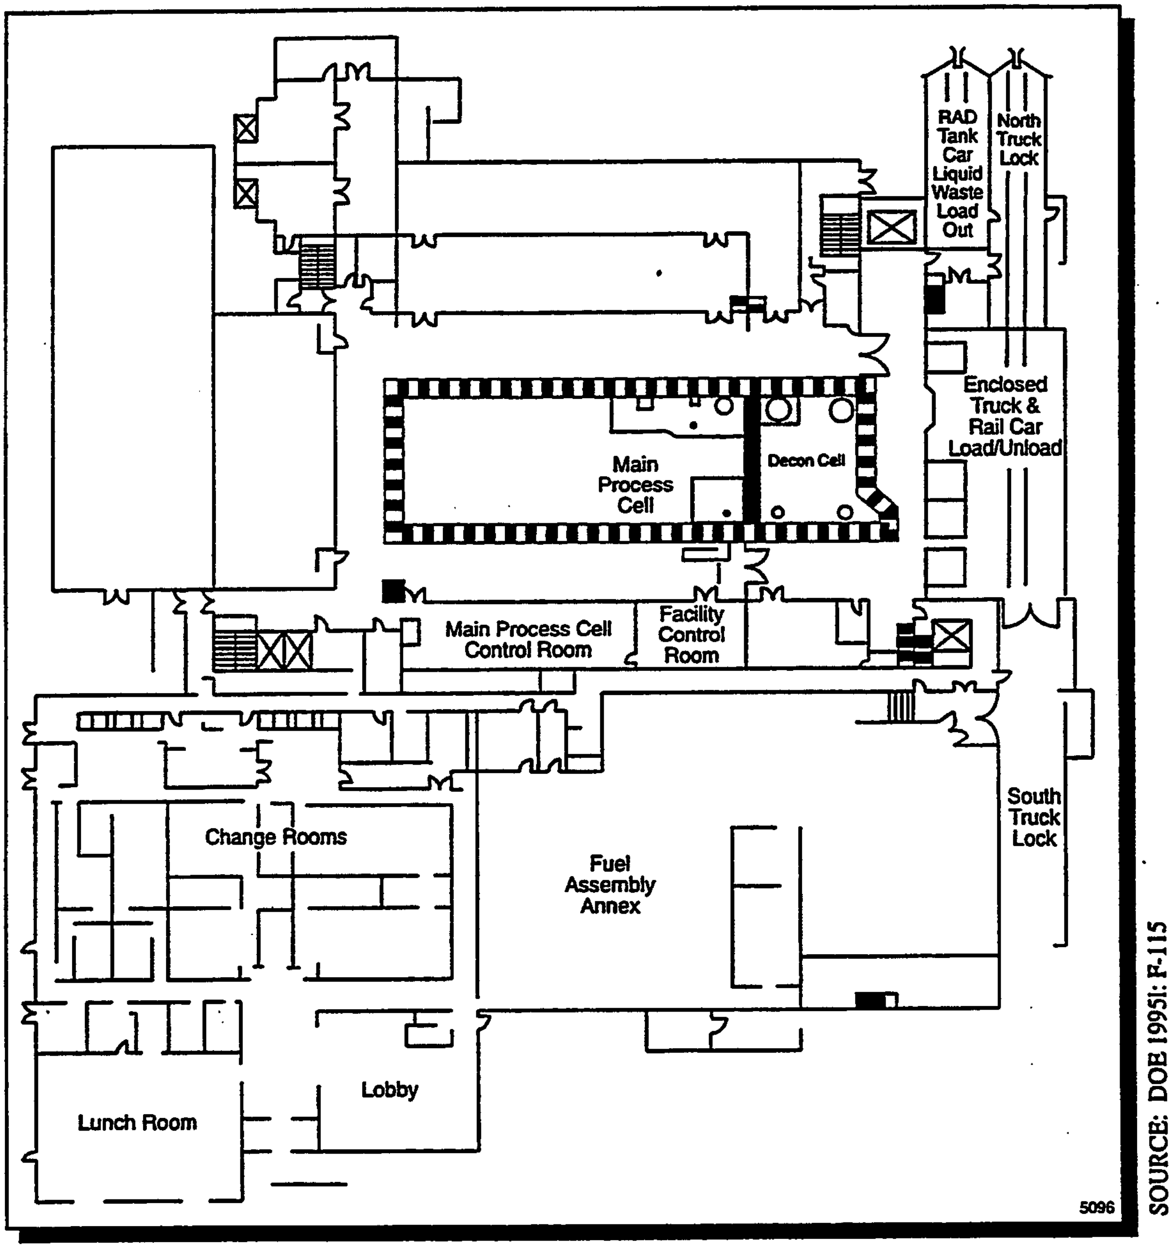

FIGURE 5.4–2.—*Layout of the Fuels and Materials Examination Facility.*

construction involving new land disturbance would be required at this Site. If DOE chooses to store pits at FMEF, a pit placement, retrieval, and inventory system would be implemented. It is expected that an automated or shielded pit movement and inventory system would be developed.

5.4.1 Environmental Resources Not Discussed in Detail

The following environmental resources at the Hanford Site have been assessed. The analyses have shown that the impacts to these resources from the potential storage of pits at the FMEF facility are small enough to warrant only limited discussion. Therefore, these resources are discussed briefly below and will not be addressed further in this section.

5.4.1.1 *Facilities and Infrastructure*

The infrastructure operations at the Hanford Site that could be impacted by or be expected to directly support pit storage operations include security, vehicle and building maintenance, utilities, administration, safety and health protection, and general support (e.g., road maintenance, general stores). Waste management and transportation support are discussed below in sections 5.4.1.10 and 5.4.1.11, respectively.

The direct impacts from the implementation of pit storage would include an increase in the Site's security force. Electrical usage due to interim pit storage (estimated to be 4,110 megawatthours per year) represents a 1.2 percent increase over the Site's 1994 usage of 345,500 megawatthours (DOE 1995s:Table B). Maintenance support and the indirect impacts resulting from pit storage worker requirements (e.g., water, wastewater treatment, and fuel) would increase minimally in comparison to current and historical onsite infrastructure support levels and system capacities. FMEF is not currently being utilized at design levels; therefore, the utility systems generally have excess capacity available to support pit storage activity.

5.4.1.2 *Land Resources*

No land disturbance is projected under the Pit Storage Relocation Alternative for FMEF. The Pit Storage Relocation Alternative does not include any new land uses near the FMEF. Impacts to land use would not be expected.

5.4.1.3 *Geology and Soils*

FMEF is not anticipated to require modifications that would involve land disturbance; therefore, impacts to soils are not anticipated. The risks due to earthquakes were assessed and found to be bounded by other accidents, as discussed in section 5.4.2.1.

5.4.1.4 *Water Resources*

Because of the nature of the pit storage activities, operations at FMEF would not impact surface water or groundwater. The pit storage activities would not use surface waters at the Hanford Site. The sanitary sewer waste from FMEF would be discharged first to an existing septic tank, then to the 400 Area sanitary leaching pond; therefore, no impacts to water quality are expected (DOE 1987:3-111). The wastewater generated by pit storage activity would not have a measurable effect on groundwater quality because of the combined effects of a deep water table (approximately 43 meters [140 feet]), low discharge volumes (less than 50 liters [14 gallons] per minute), and composition and concentrations consistent with existing treated and sanitary wastewater (DOE 1977:2.2-113, 3.2-4).

The water demands of pit storage operations are solely due to use by storage personnel. In comparison with the designed usage at FMEF of

142 million liters (37.5 million gallons) of groundwater from two vicinity wells, and the total quantity of surface water and groundwater used at the Hanford Site annually, the water demands for pit storage are negligible (DOE 1995p:4-65). Flooding at FMEF is not expected because it is located outside of the Probable Maximum Flood and dam failure floodplains.

5.4.1.5 *Air Quality*

The Hanford Site is well within all applicable local, State, and Federal ambient air quality standards (DOE 1994p). The impacts to air quality from normal pit storage operations would be due entirely to vehicle emissions (approximately 150 vehicles per day). The air impacts caused by vehicles involved in pit storage would be negligible relative to the overall vehicular emissions at the Hanford Site.

5.4.1.6 *Acoustics*

At the Hanford Site boundary, away from most facilities, noise from most sources is barely distinguishable above background sources. The only sources of noise that would be associated with pit storage operations would be from transportation vehicles and air conditioning and heating equipment for the occupied areas of the facility. These impacts would be minimal.

5.4.1.7 *Biotic Resources*

The bald eagle (*Haliaeetus leucocephalus*) is the only Federally listed threatened or endangered species that resides on the Hanford Site, although the Aleutian Canada goose (*Branta canadensis leucopareia*) and the peregrine falcon (*Falco peregrinus*) may occur on an incidental basis (DOE 1994r). The use of FMEF for interim storage of pits, would not disturb bald eagle roosting sites on the Hanford Site (DOE 1994p:28). Further, no wetlands at the Hanford Site would be disturbed by the Pit Storage Relocation Alternative (WHC 1986:3.4-8). As a result, impacts to biotic resources are not expected.

5.4.1.8 *Cultural Resources*

No historic, prehistoric, or paleontological sites have been found at or in the immediate vicinity of FMEF at the Hanford Site. Further, no National Register of Historic Places-eligible buildings are located at FMEF (DOE 1994q:4-89). The Pit Storage Relocation Alternative does not involve new land disturbance and would not adversely affect cultural or paleontological resources at the Hanford Site. Therefore, impacts to cultural and paleontological resources would not be expected.

Native American groups have retained traditional secular and religious ties to the region. Members of the Yakama, Umatilla, Warm Springs, and Nez Perce still adhere to the Washane religion, which has its origins on the Hanford Site. The secular and non-secular ties to this portion of the Columbia River Basin could make the entire area potentially eligible for the National Register of Historic Places based on its traditional cultural significance to Native Americans (DOE 1994q:4-80). However, the area containing FMEF has been completely disturbed by previous facility construction, and no impact to Traditional Cultural Properties is anticipated from the Pit Storage Relocation Alternative.

5.4.1.9 *Socioeconomic Resources*

Approximately 150 additional personnel (including 120 security personnel) would be required for the interim storage of pits at the Hanford Site. This number represents less than 1.0 percent increase in the total Hanford Site workforce. Most of the workers can be hired locally; therefore no significant Site or regional population and workforce increases are anticipated. According to the 1990 Census, 150 workers represent 0.1 percent of the employed workforce within the Hanford Site Region of Influence (WA Cen 1993:Table 145). No socioeconomic impacts would be anticipated.

5.4.1.10 *Waste Management*

Currently, the Hanford Site manages high-level waste, spent nuclear fuel, plutonium materials, mixed transuranic waste, transuranic waste, mixed waste, low-level waste, hazardous waste, and nonhazardous waste in accordance with the requirements of a number of Federal and State regulations, permits obtained under these regulations, and DOE orders. These requirements are primarily under the authority of the Environmental Protection Agency, DOE, and the Washington State Department of Ecology.

The Hanford Site generated approximately 2,300 cubic meters (3,000 cubic yards) of low-level waste, approximately 2,000 cubic meters (2,600 cubic yards) of mixed waste, and approximately 700 cubic meters (900 cubic yards) of hazardous waste in 1992 (DOE 1994d:248). The pit storage operations would generate less than 1 cubic meter (1.3 cubic yards) of mixed, low-level, and hazardous waste. This amount of waste would not impact the current waste management at the Hanford Site.

5.4.1.11 *Intrasite Transportation*

The Hanford Site onsite road system consists of a number of rural highway routes (see Figure 5.4–1). The majority of onsite travel, however, occurs on Route 4 and Route 11A, which are barricaded at the Yakima and Wye barricades, respectively, to control public access. Public Highways 240 and 24 provide access to the Site from the north and west up to the security control points at the Yakima and Rattlesnake Barricades. Although some roads within the Hanford Site are public access roads, the DOE would control access during passage of Safe Secure Tractor-Trailer (SST) convoys. Because a release of plutonium from an intersite pit shipment would require a severe accident (e.g., an accident with a fuel tanker or a train [see section 4.16.4.2]), the controlled transportation environment within the Hanford Site does not pose a significant threat to pit shipments. Consequently, the contribution to overall intersite transportation accident risk from onsite transport is negligible.

5.4.1.12 *Aircraft Accidents*

The Federal Aviation Administration (FAA) maintains a Very High Frequency Omni-Directional Radio (VOR) navigation aid at the Tri-Cities Airport. This VOR is used for en route navigation along airways as well as for instrument approaches to the airport. Several Federal airways pass in the proximity of FMEF. However, the FAA reports that these routes have low usage (WHC 1991). There are no military installations or training routes that would place military aircraft in the vicinity of FMEF.

There are five airports and one landing strip in the vicinity of FMEF. The Tri-Cities Airport, the major commercial airfield in the area is approximately 27 kilometers (17 miles) southeast of FMEF. The airport's two runways are used by commercial (air carrier and air taxi), military, and general aviation aircraft. In 1994, the Tri-Cites Airport had 81,867 aircraft operations (take-offs and landings). Table 5.4.1.12–1 summarizes the total number of airfield operations at the Tri-Cities Airport (PC 1996j).

The closest airport, Richland Airport, approximately 13 kilometers (8 miles) southeast of FMEF, has three runways used only by general aviation aircraft. Similarly, Vista Field in Kennewick, approximately 26 kilometers (16 miles) south-southeast, has two runways, also used by general aviation aircraft. Beardsley Field, near Prosser, approximately

TABLE 5.4.1.12–1.—*Tri-Cities Airport Operations for 1994*

AIRCRAFT TYPE	NUMBER OF OPERATIONS
Air Carrier	2,645
Air Taxi	21,807
Military	2,597
General Aviation	54,818
Total Airfield Operations	81,867

Source: (PC 1996j)

42 kilometers (26 miles) southwest, has one runway used only by general aviation aircraft. Sunnyside Airport is located 48 kilometers (30 miles) west-southwest and has one runway used by general aviation aircraft only. There is an unnamed landing strip near Horse Heaven Hills, approximately 32 kilometers (20 miles) south-southwest, which has one runway used only by general aviation aircraft.

All four general aviation airports and the landing strip are outside the probability density function boundary for general aviation aircraft and were therefore not included in the aircraft crash analysis. Only small military aircraft in the landing mode at the Tri-Cities Airport and non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g). Further details on these six facilities are contained in volume II, appendix E.

FMEF was modeled conservatively as a facility with a length of 98 meters (320 feet), a width of 47 meters (155 feet), and a height of 21 meters (70 feet). (DOE 1994bb). Using the Draft DOE Standard for determining the probability of aircraft crashes and 1994 data from the FAA, the frequency of hitting FMEF was calculated as 1.2×10^{-6} for all types of aircraft (DOE 1996g). It should be noted that the frequency calculation represents a conservative upper bound. Since this frequency is greater than 10^{-7}, in accordance with the Draft DOE Standard, further analysis was required. A local response structural analysis was performed according to the Draft DOE Standard for the facility with a wall thickness of 122 centimeters (48 inches).

The analysis was performed for the maximum penetrator missile for each of the aircraft categories mentioned in section 4.15.2, except for helicopters. None of the eight aircraft missiles was capable of penetrating the facility. Therefore, since this frequency is 0, in accordance with the Draft DOE Standard, no further analysis was required. Further details of the frequency of hitting FMEF and the frequency of releasing material are contained in volume II, appendix E.

5.4.2 Resources Discussed in Detail

5.4.2.1 *Human Health*

The basic approach used in assessing human health impacts is first to identify the affected environment and establish a baseline representing the risk from current operations. Changes in this baseline risk resulting from potential pit storage activities are then examined. Impacts from both normal operations and potential accidents are estimated.

Assessing the human health risk impact from potential accidents resulting from the storage of pits in FMEF at the Hanford Site involves a risk screening process. The first step in this process is to identify a broad spectrum of potential accident scenarios. The second step in the process uses screening techniques to identify the specific scenarios that dominate risk (i.e., scenarios that contribute an appreciable fraction of the total risk), where risk is calculated as the product of frequency and consequence. Rigorous consequence evaluations are only performed for the identified risk-dominant scenarios.

Two types of accident consequences are examined:

- Worker and public exposure.
- The probability of an accident causing fatal cancer in a worker or the public.

If DOE chooses to relocate pits to the Hanford Site, two aspects of relocation would contribute to potential environmental impacts. These impacts are associated with:

- Transferring pits within FMEF from the transporter to their storage location inside the facility.
- Storage itself (i.e., potential impacts resulting from having the pits reside inside the facility).

Each time pits are transferred within the facility from the transporter to their storage location, there is a small probability that an accidental release could occur due to a handling accident. In addition, the transfer of pits from the transporter to their storage location would result in radiological exposures to involved workers.

Affected Environment

The release of radioactivity and toxic chemicals to the environment from a DOE facility is an important issue for onsite workers and the public. Since the human environment contains many sources of radioactivity and toxic chemicals, it is essential to understand the sources of these substances and how effectively they are controlled.

Table 5.4.2.1–1 summarizes the major sources of radiation exposure in the vicinity of the Hanford Site. A person in the State of Washington has an average annual cancer probability of 1.4×10^{-3} (DOE 1994i:4-110). Using nominal fatal cancer risk factors and the data in Table 5.4.2.1–1, it is calculated that fatal cancers attributable to environmental radioactivity released from the Hanford Site constitute less than one ten-thousandth of one percent of the average yearly fatal cancer probability in the State of Washington (DOE 1994l:4-20).

Figure 5.4.2.1–1 depicts the offsite population within an 80-kilometer (50-mile) radius of FMEF at the Hanford Site. Wind speeds and directions in the Hanford Site vicinity are presented in Figure 5.4.2.1–2. The prevailing wind direction is from the south and southwest in the summer months and from the northwest in the winter months.

Impacts of Facility Upgrades

Numerous facility modifications are necessary before FMEF is suitable for pit storage. They include plugging cell penetrations, moving doors, and installing vault doors and electronic equipment. An additional upgrade required is to modify FMEF to accept Stage Right transfer and storage equipment. However, these are standard industrial operations that do not expose workers to any special hazards (e.g., radionuclides, toxic chemicals, or high explosives). No significant impacts from facility upgrades are anticipated.

Impacts of Storing 20,000 Pits

Hanford Site is not being considered for the storage of 20,000 pits; hence, there are no impacts for this option.

Impacts of Storing 8,000 Pits

Unloading operations would result in radiological exposure to cargo handlers. Based on conservative calculations made for handling of pits at Pantex Plant, the worker doses from unloading of 2,000 pits per year are estimated to be less than 11 person-rem per year or 108 person-rem for the unloading of 8,000 pits (the maximum number of pits which may be stored at FMEF). Once removed from the SSTs, pits would be transferred within FMEF for storage. Pit transfers within FMEF would result in radiological exposures to onsite workers

TABLE 5.4.2.1–1.—*Major Sources of Radiation Exposure in the Vicinity of the Hanford Site*

SOURCE OF EXPOSURE	DOSE TO AVERAGE INDIVIDUAL (mrem/yr)[1]	PERCENTAGE OF TOTAL EXPOSURE
NATURAL BACKGROUND RADIATION

handling the pits. The transfer of pits would result in worker doses of less than 2 person-rem per year for handling 2,000 pits and about 5 person-rem for the placement of 8,000 pits.

The combined worker dose from unloading and storage of 8,000 pits at FMEF would be 113 person-rem distributed over the 30 people directly involved in material handling. Assuming that the same 30 people continue to handle 8,000 pits over a period of 4 years and using a dose-to-risk conversion factor of 4×10^{-4} latent cancer fatality (LCF) per person-rem, there would be an additional 0.04 LCF in this group due to radiological exposure from pit handling.

The probability of LCFs from all causes in the general population is estimated at 20 percent, which implies that 6 of 30 workers would develop a fatal cancer from all other causes. With an additional 0.04 LCF from pit handling, the total risk of latent cancers among workers at the FMEF site would increase by 0.7 percent.

Storage of 8,000 pits could be accomplished at FMEF. Pit container inventories at the Hanford Site are expected to be performed using either shielded or automated techniques and equipment. Consequently, these normal operations are not expected to result in any significant radiological exposure to workers.

Other storage activities that may occur within the time frame evaluated in this EIS include:

- Restacking a limited number of pits to comply with design laboratory temperature requirements.

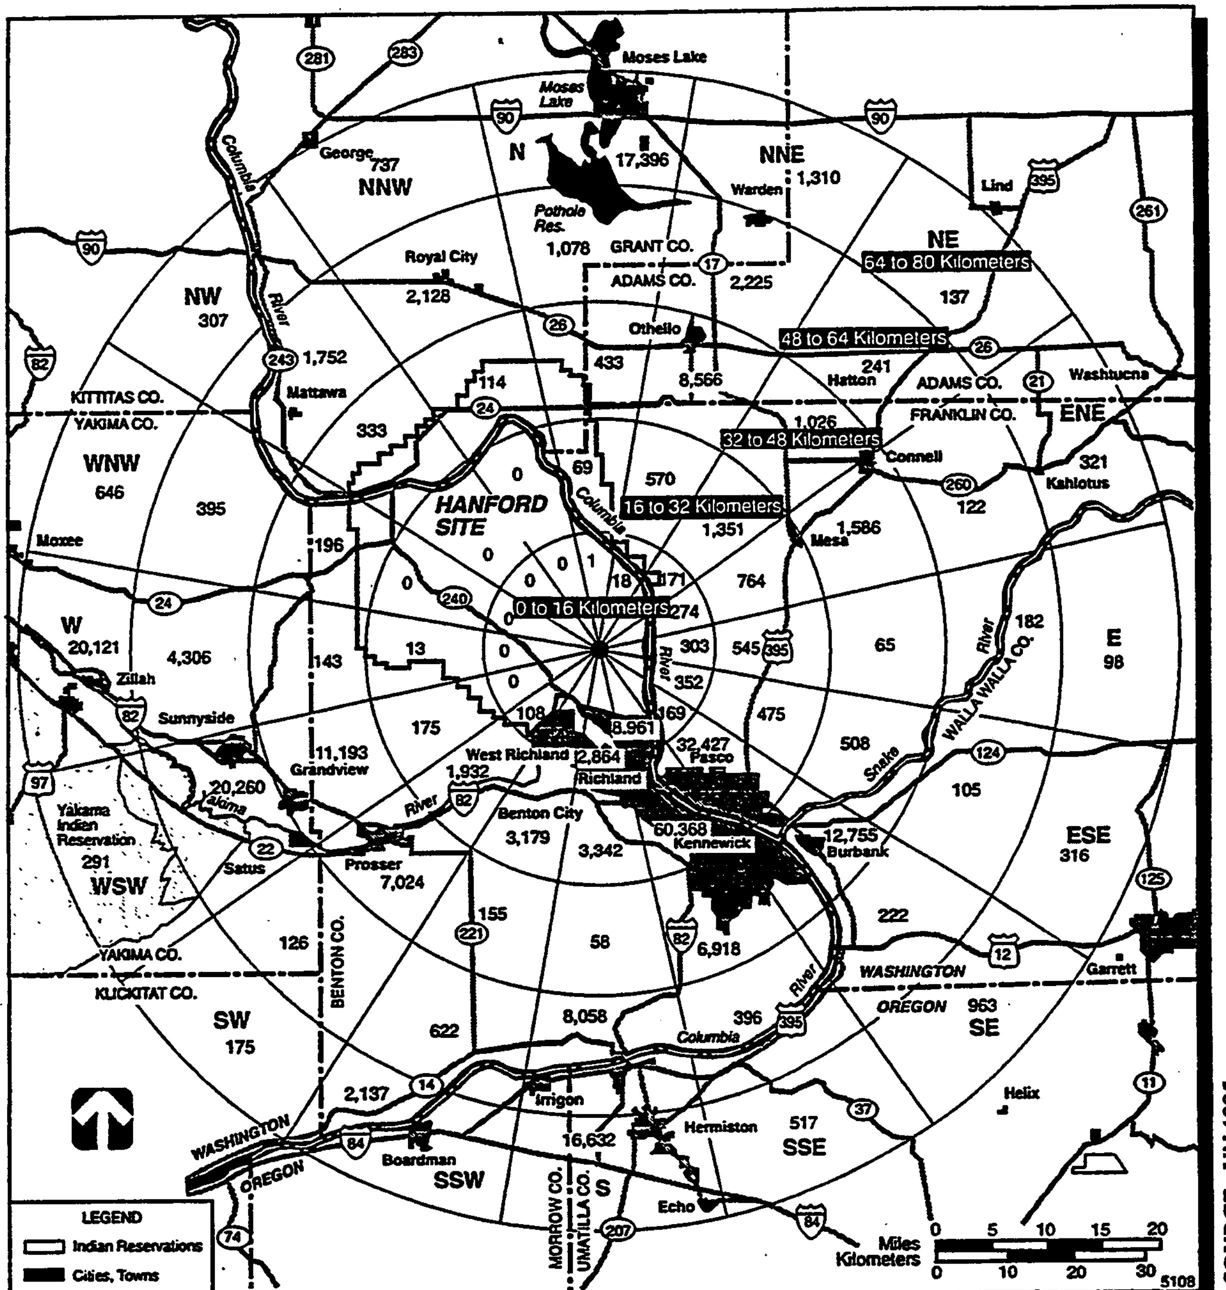

FIGURE 5.4.2.1–1.—*Offsite Population in the Vicinity of the Hanford Site (Distances Measured from the Fuels and Materials Examination Facility).*

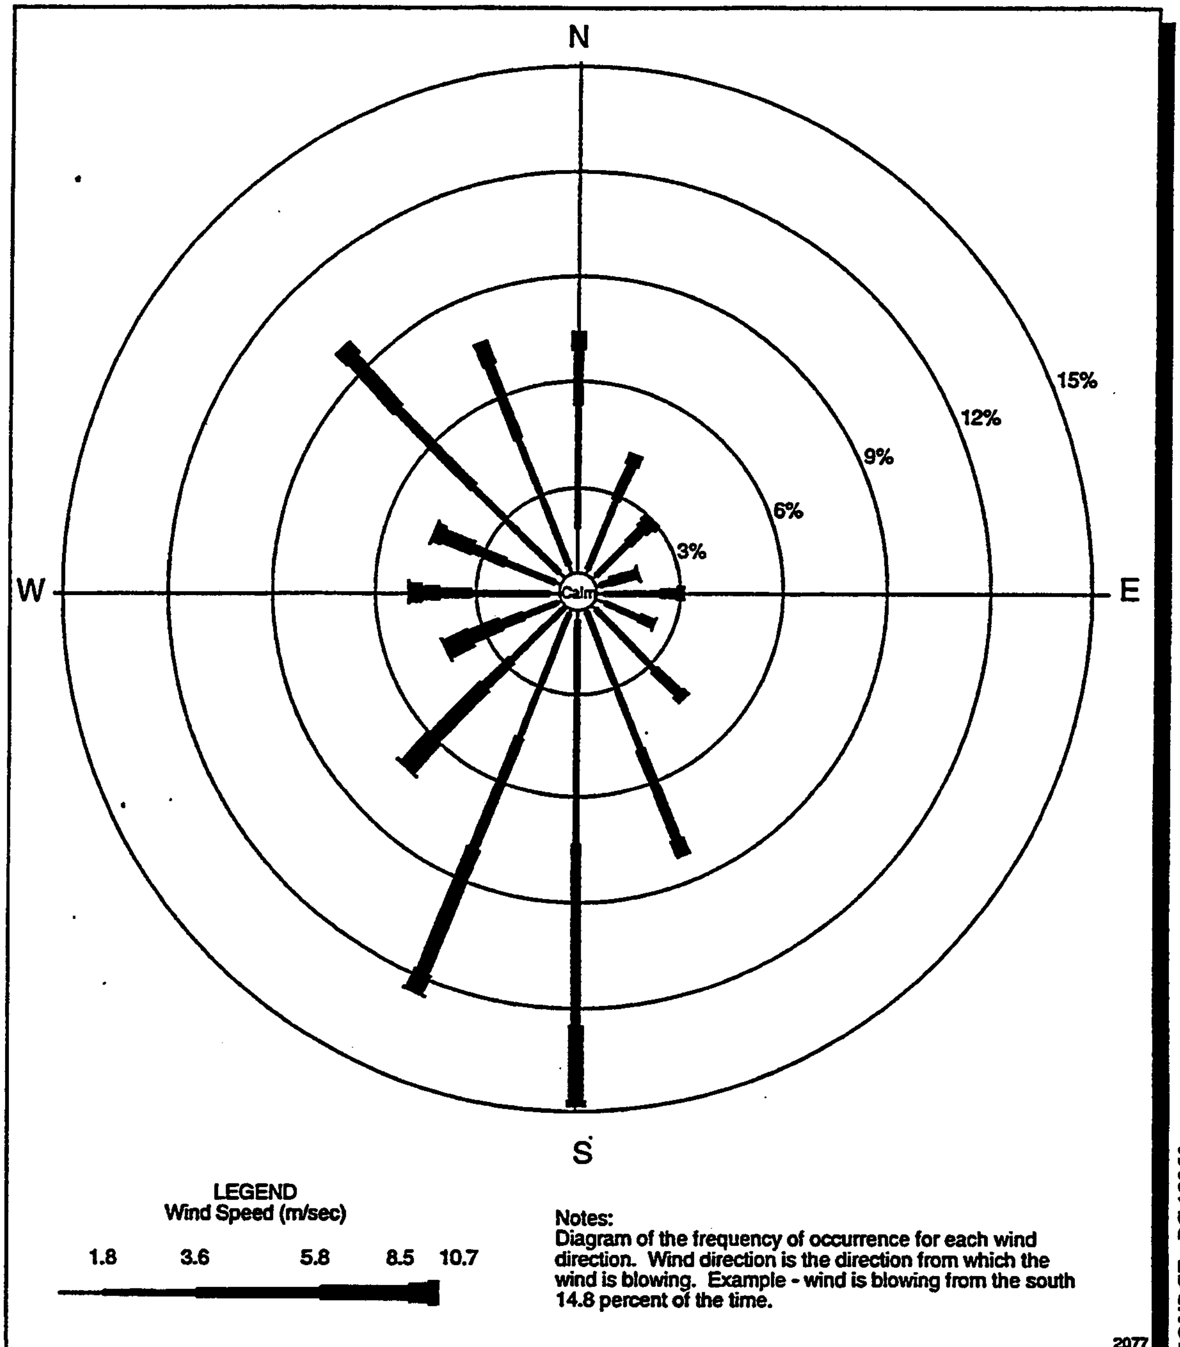

FIGURE 5.4.2.1–2.—*Wind Direction and Speed at the Hanford Site, Washington, 1994.*

- A limited number of pit movements and/ or instrumentation placements to facilitate third-party inspections.

Impacts of these routine activities are also considered to be negligible.

The risk screening methodology (appendix D) indicates that the radiological health risk from accidents associated with the storage of 8,000 pits in FMEF is dominated by handling accidents that could occur when the pits are being transferred from the transporter. A standard tine forklift is assumed to be used to remove pit containers from an SST. The probability of a standard tine forklift causing a puncture during a single handling operation is in the extremely unlikely range (i.e., 10^{-4} to 10^{-6}).

It is estimated that a forklift puncture of a pit container would release 9.2×10^{-5} curies of plutonium. This is a conservative estimate of the respirable, airborne release caused by a puncture of one shipping container (DOE 1992f:7-34).

Given such a release, an involved worker (the forklift driver) would receive a dose of 6.6 rem, corresponding to an incremental increase in lifetime fatal cancer probability of 2.6×10^{-3}. In addition, a non-involved worker 100 meters (328 feet) downwind along the center line of the plutonium dispersion plume would receive a 6.3×10^{-5} rem exposure, corresponding to an incremental increase in lifetime fatal cancer probability of 2.5×10^{-8}. The maximally exposed member of the public would be expected to receive an exposure of 5.5×10^{-8} rem, corresponding to an incremental increase in lifetime fatal cancer probability of 2.8×10^{-11}. The lifetime fatal cancer probability for an average individual from all other causes is approximately 0.2 (20 percent).

This event would result in an exposure to the public of 2.9×10^{-5} person-rem. Considering the likelihood and consequence of this event, on the average, a member of the public will have an increased annual risk of developing a fatal cancer from this potential accident of 5.3×10^{-17} fatal cancers per year. The annual fatal cancer risk to a person in the State of Washington from all other causes is 1.4×10^{-3} fatal cancers per year.

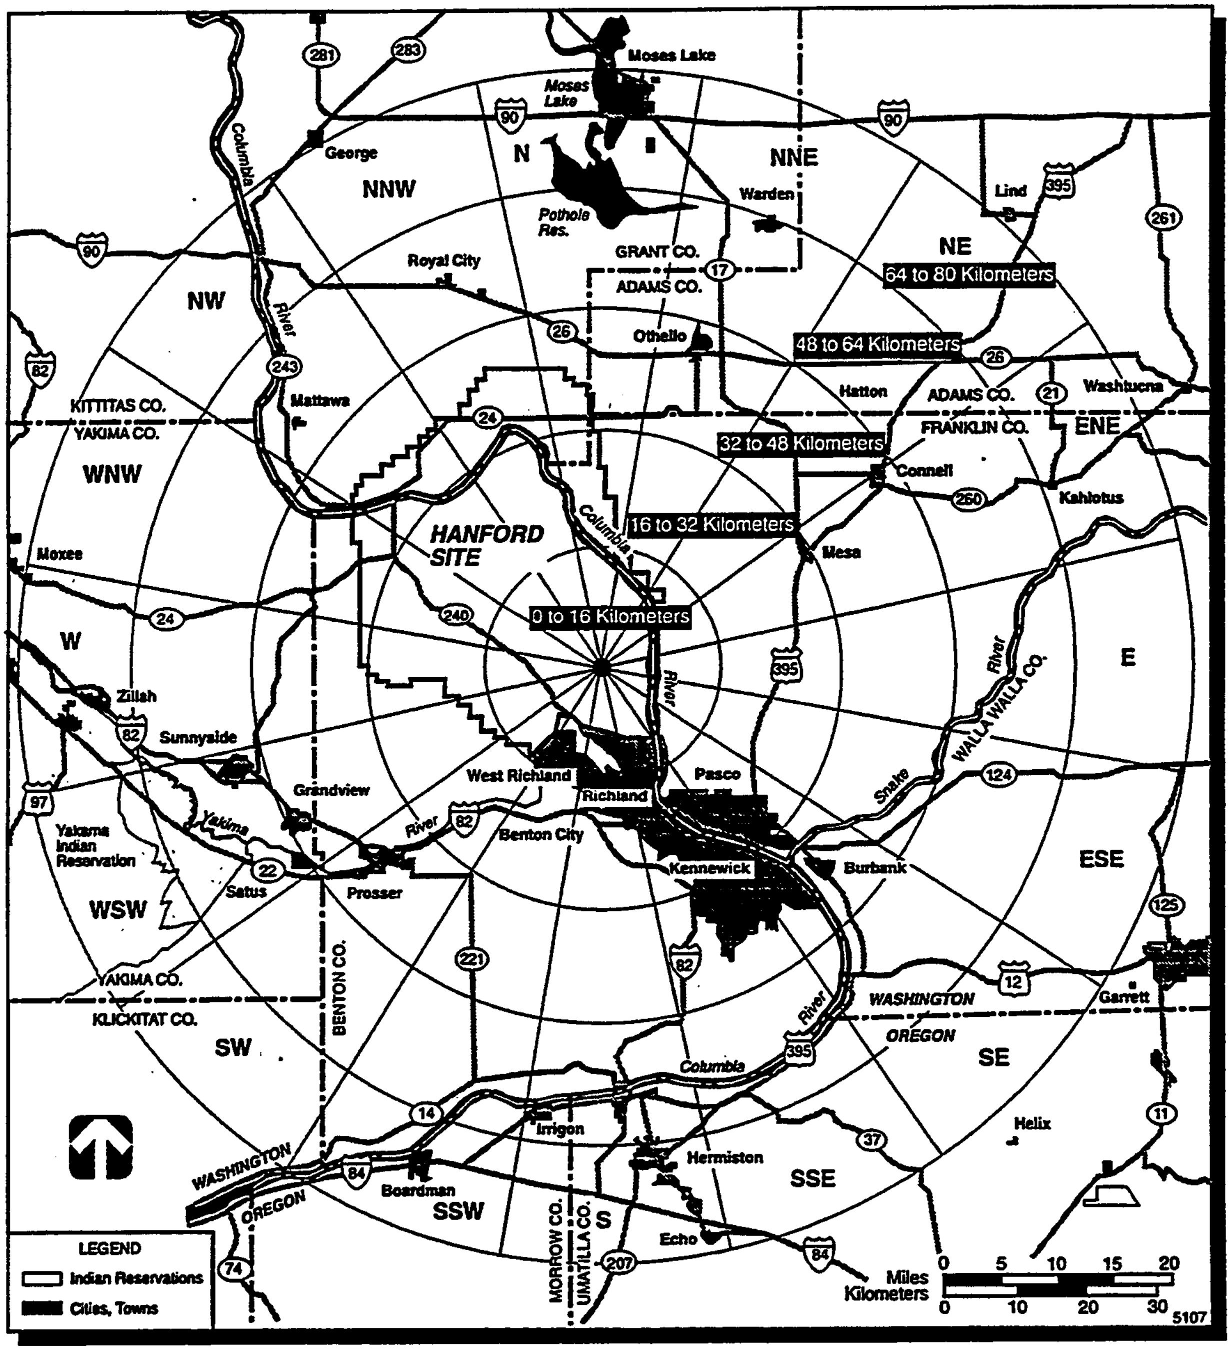
Seismic events are not important risk contributors at FMEF. The design basis for FMEF is a 0.25 *g* earthquake, which was considered to be the largest credible earthquake that could occur given the regional geology (WHC 1986:3.6-2, 4.2-6, 9.2-34). It is also larger than the 0.17 *g* standard for Performance Category 3 facilities per DOE–STD–1020–94 (DOE 1994u:C-25). As described in appendix D, there is no risk from external events or natural phenomena (including earthquakes) that are within the design basis. Even for earthquakes beyond the design basis (which have a very low probability), the onset of facility damage is typically insufficient to cause the AT–400A shipping containers to fail. Consequently, the relative risk from earthquakes is negligible because of the low frequency that the release can occur.

5.4.2.2 *Environmental Justice*

Affected Environment

FMEF is located at the Hanford Site, which is adjacent to the Tri-Cities (Richland-Kennewick-Pasco) urban area in the south-central part of Washington State. In order to identify the target populations covered by Executive Order 12898, an 80-kilometer (50-mile) radius circle centered on FMEF was overlaid on 1990 Census tract maps. The communities that lie within the 80-kilometer (50-mile) circle, hereafter called the FMEF Region of Influence (ROI) are shown in Figure 5.4.2.2–1.

Population. According to the 1990 Census, there were 274,391 persons within the FMEF ROI. White persons comprised 75 percent of



SOURCE: UN 1995

FIGURE 5.4.2.2–1.—*The Fuels and Materials Examination Facility Region of Influence.*

the population; Hispanics were the second largest group with 22 percent; and Asians, Pacific Islanders, American Indians, and Blacks accounted for the remaining 3 percent (UN 1995).

The largest concentration of the population in the FMEF ROI is in the Tri-Cities, which accounts for 94,807 or 34.6 percent of the total ROI population in 1990. Outside this urban concentration, two communities had populations of 10,000 or more. These were: Sunnyside (11,238 persons), located approximately 50 kilometers (32 miles) west of FMEF; and Moses Lake (11,235 persons), located approximately 72 kilometers (45 miles) north of FMEF. About 20 communities account for an additional 58,800 persons and the remaining 43,484 persons live in rural areas of the FMEF ROI. A portion of the Yakama Indian Reservation is located in the southwestern part of the ROI. Of the 26,961 persons counted on this Reservation in 1990, 6,110 were American Indians (WA Cen 1992:Tables 6 and 17; OR Cen 1992 Table 6).

Minority Population. Figure 5.4.2.2–2 shows 1990 Census tracts within the FMEF ROI. The tracts are shaded if minority populations comprised 25 percent or more of the total population in 1990 or if 25 percent or more of the persons in a tract were below the poverty level based on their incomes in 1989. The 25 percent threshold levels for minority or low-income persons are based on the working definitions contained in the notice of the Environmental Protection Agency's Office of Environmental Justice (59 FR 192).

The census tracts with 25 percent or more minority population are located north and southwest of the Site at a minimum distance of 16 kilometers (10 miles) from FMEF. Four tracts in Pasco and one in Kennewick also have minority populations greater than 25 percent. A number of tracts with primarily white populations are located closer to FMEF than the tracts with minority populations (UN 1995).

Low-Income Population. Low-income population tracts in the FMEF ROI are not as widely distributed as the tracts with minority populations. Concentration of low-income population is to the northwest and southwest of FMEF at a distance of more than 32 kilometers (20 miles). All four tracts in Pasco and one in Kennewick also have greater than 25 percent population below poverty level. Forty-six percent of American Indians in the Yakama Reservation had incomes below the poverty level (UN 1995; WA Cen 1992).

Impacts of Storing 20,000 Pits

FMEF is not being considered for storing 20,000 pits; therefore, there would be no impacts for this option.

Impacts of Storing 8,000 Pits

Because the interim storage of pits at FMEF would not require any construction activities and because all facility modifications would take place inside existing facilities, impacts to the natural environment would be minimal. Under normal operating conditions, there would be minor increases in air pollutants associated with vehicles used during pit storage activities. Also, a very minor increase in particulate matter of aerodynamic diameter less than 10 micrometers concentrations would be expected. These increases are associated with the operation of forklifts within FMEF that are used to move the pits from the unloading area to the storage area.

These impacts are not likely to effect the surrounding population. Radiological releases from normal pit storage operations would have no measurable effect on an individual occupying a position near the Hanford Site boundary for an entire year. Levels at the Site boundary would be indistinguishable from natural background radiation. No adverse health effects would be expected among the general public, including minority and low-

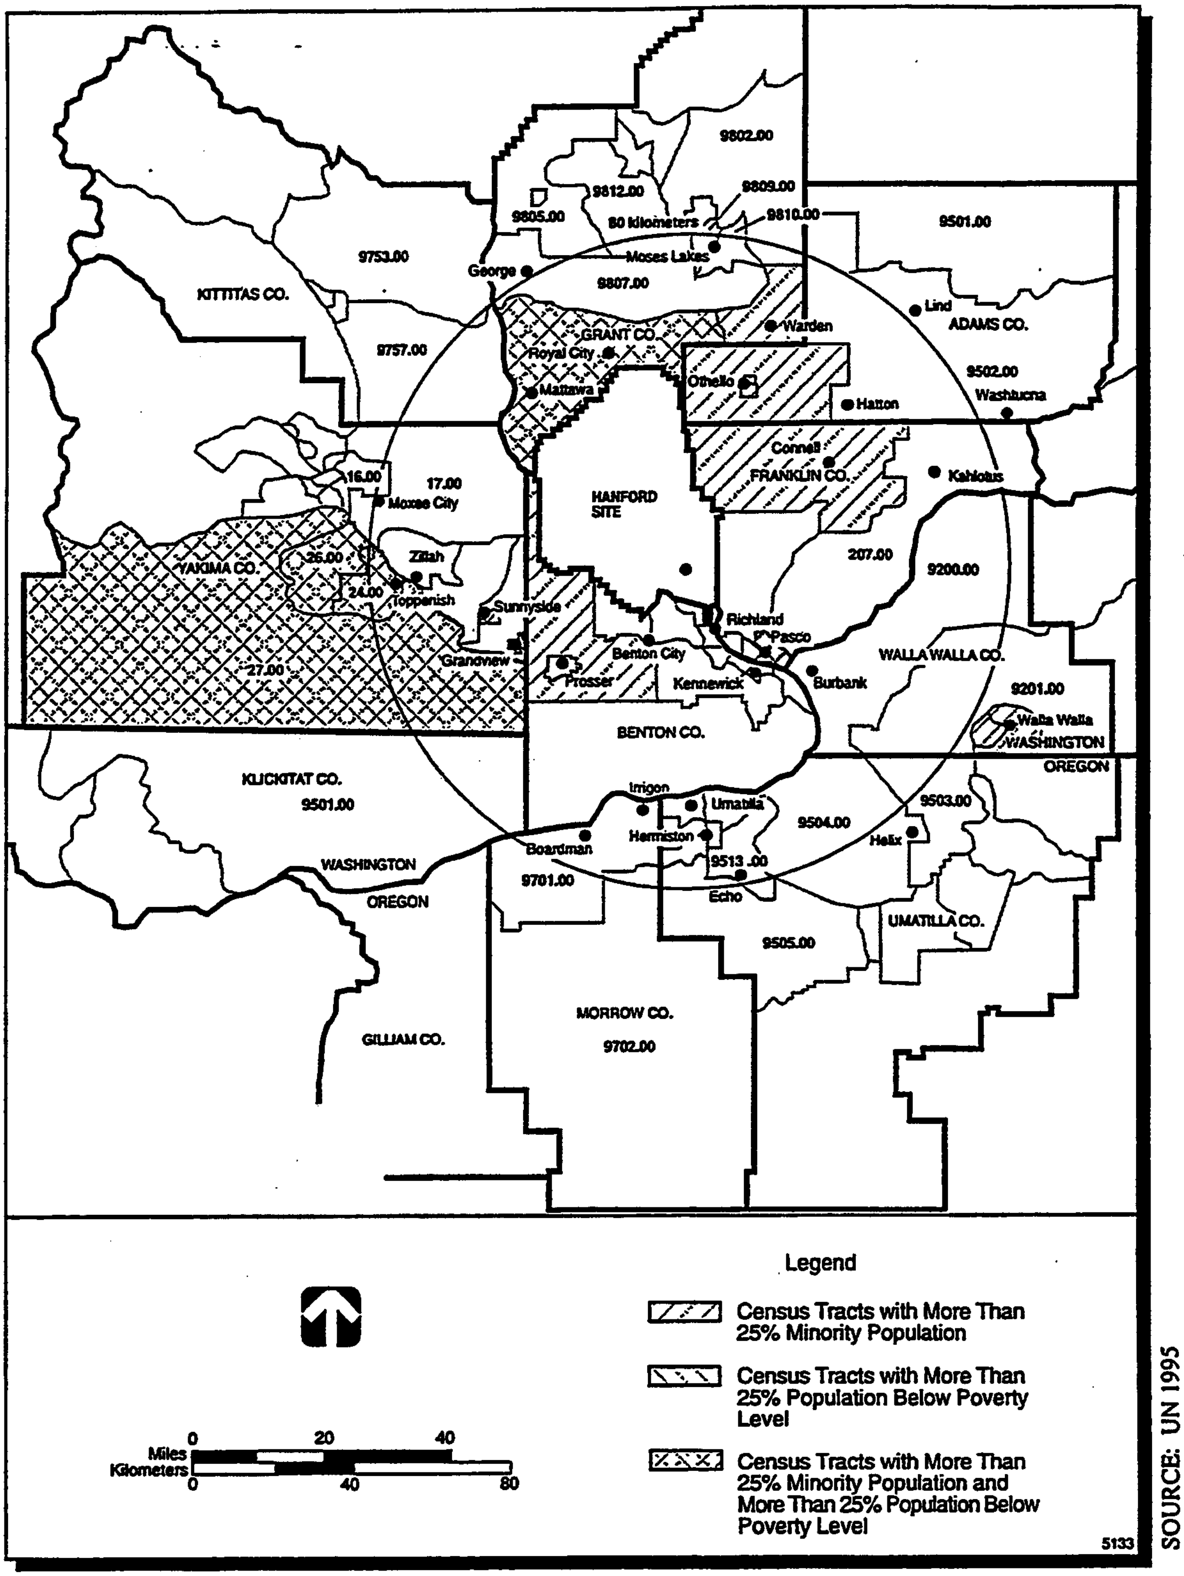


FIGURE 5.4.2.2–2.—*Low-Income and Minority Populations in the Fuels and Materials Examination Facility Region of Influence.*

income populations, as a result of normal storage operations.

An abnormal event, such as accidental puncture of a pit storage container by a forklift or seismic event, has the potential of exposing the general public to radiation. The analysis in section 5.4.2.1, Human Health indicates that the risk to the public from such accidents would be negligible. With no measurable impacts on the general population, the minority and low-income populations would not be disproportionately impacted.

KIRTLAND AIR FORCE BASE

5.5 KIRTLAND AIR FORCE BASE

Under the Pit Storage Relocation Alternative (see section 3.1.3) the pit storage function currently carried out at Pantex Plant would be transferred to another site. Kirtland Air Force Base (KAFB) is one of the candidate sites for the storage of pits (Figure 5.5–1). The Manzano WSA is the candidate pit storage facility at KAFB. This section discusses the Manzano WSA, the affected environment at KAFB, and the potential impacts that would be associated with pit storage.

Each aspect of the affected environment at KAFB has been assessed and the potential environmental impacts to each have been evaluated. Each environmental resource is discussed in detail commensurate with the degree to which the resource could be impacted by or have an effect on interim pit storage at the candidate facility.

Kirtland Air Force Base. KAFB is an Air Force Materiel Command base sharing base facilities and infrastructure with a number of major tenants, including DOE, Sandia National Laboratories (SNL), the Defense Nuclear Agency, and Phillips Laboratory. The base covers an area of 21,320 hectares (52,600 acres) on the southeast boundary of Albuquerque, New Mexico. Approximately 8,300 hectares (20,500 acres) of this area is withdrawn public lands (USAF 1993a:1-3).

Major Air Force units at KAFB include the 377th Air Base Wing, 58th Special Operations Wing (which performs helicopter crew training and pararescue training) and Phillips Laboratory (which performs research and development for space systems, ballistic missiles, geophysics, and directed energy systems). SNL conducts research and development for space systems, testing, stockpile surveillance, and the transportation of nuclear materials (USAF 1993a:3-2).

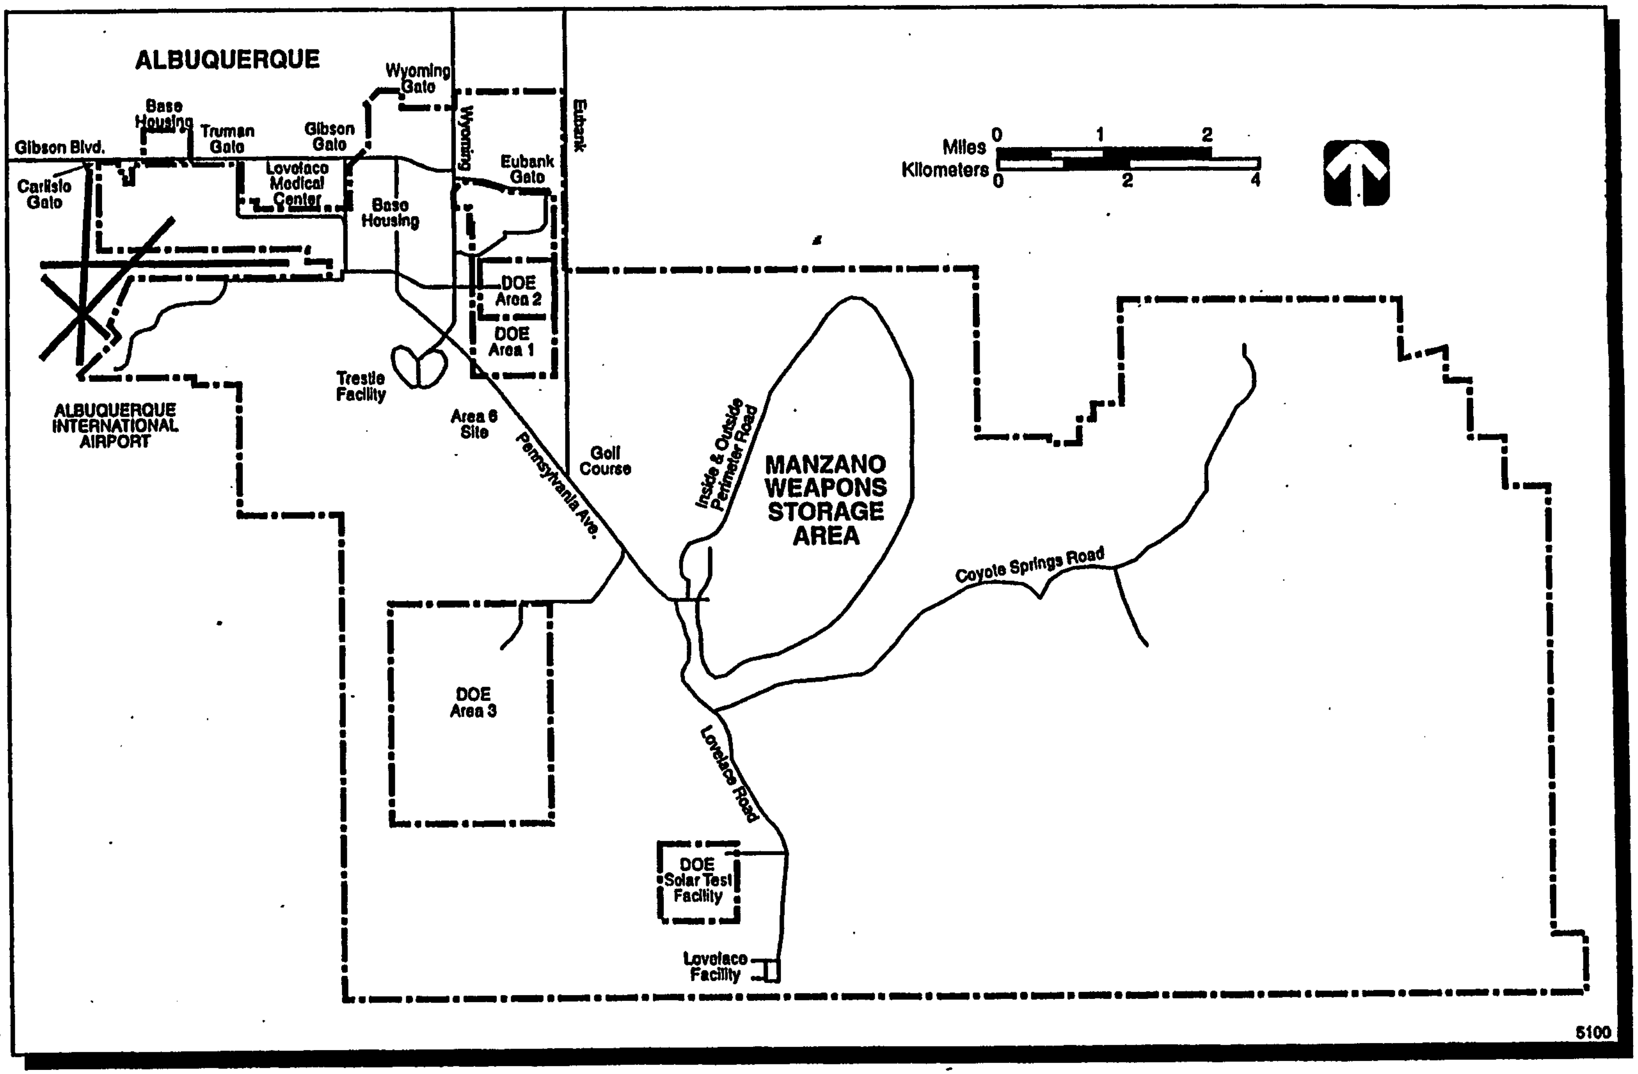
Manzano Weapons Storage Area. The Manzano WSA at KAFB consists of 4 plants inside Manzano Mountain (used primarily for research activities) and 122 magazines, of which 81 are earth covered and 41 are tunneled into the mountainside (KAFB 1993:13) (Figure 5.5–2). Construction began in June 1947, and the facility became operational in April 1950. In June 1992, the Manzano WSA was deactivated and Phillips Laboratory assumed responsibility for its maintenance. SNL continues to provide minimum security, although the Perimeter Intrusion Detection and Alarm System was deactivated with the termination of the main mission in 1992.

The Manzano WSA has enough magazine space to store more than 20,000 pits. The proposed location for the storage of pits is the set of 41 magazines that are tunneled into the mountainside. As many as 35 magazines have overburden greater than 9 meters (30 feet) of earth and granite. Depending on the storage capacity of individual magazines, it is estimated that not more than 25 of them would be required for storing 20,000 pits, leaving the rest of the magazines for other uses.

The existing fence would be reactivated to the extent necessary and no new fence or security systems would be required. If DOE chooses to store pits in the Manzano WSA at KAFB, a pit placement, retrieval, and inventory system will be implemented. The storage areas at the Manzano WSA are well suited for the Stage Right equipment and techniques successfully implemented at Pantex Plant. Consequently, the development of a pit placement, retrieval, and inventory system would not be necessary.

5.5.1 Environmental Resources Not Discussed in Detail

The environmental resources discussed below have been assessed for KAFB. Analyses have shown that the impacts to these resources from the potential storage of pits at the Manzano



SOURCE: KAFB 1993:16

FIGURE 5.5–1.—*Albuquerque International Airport and the Manzano Weapons Storage Area at Kirtland Air Force Base, New Mexico.*

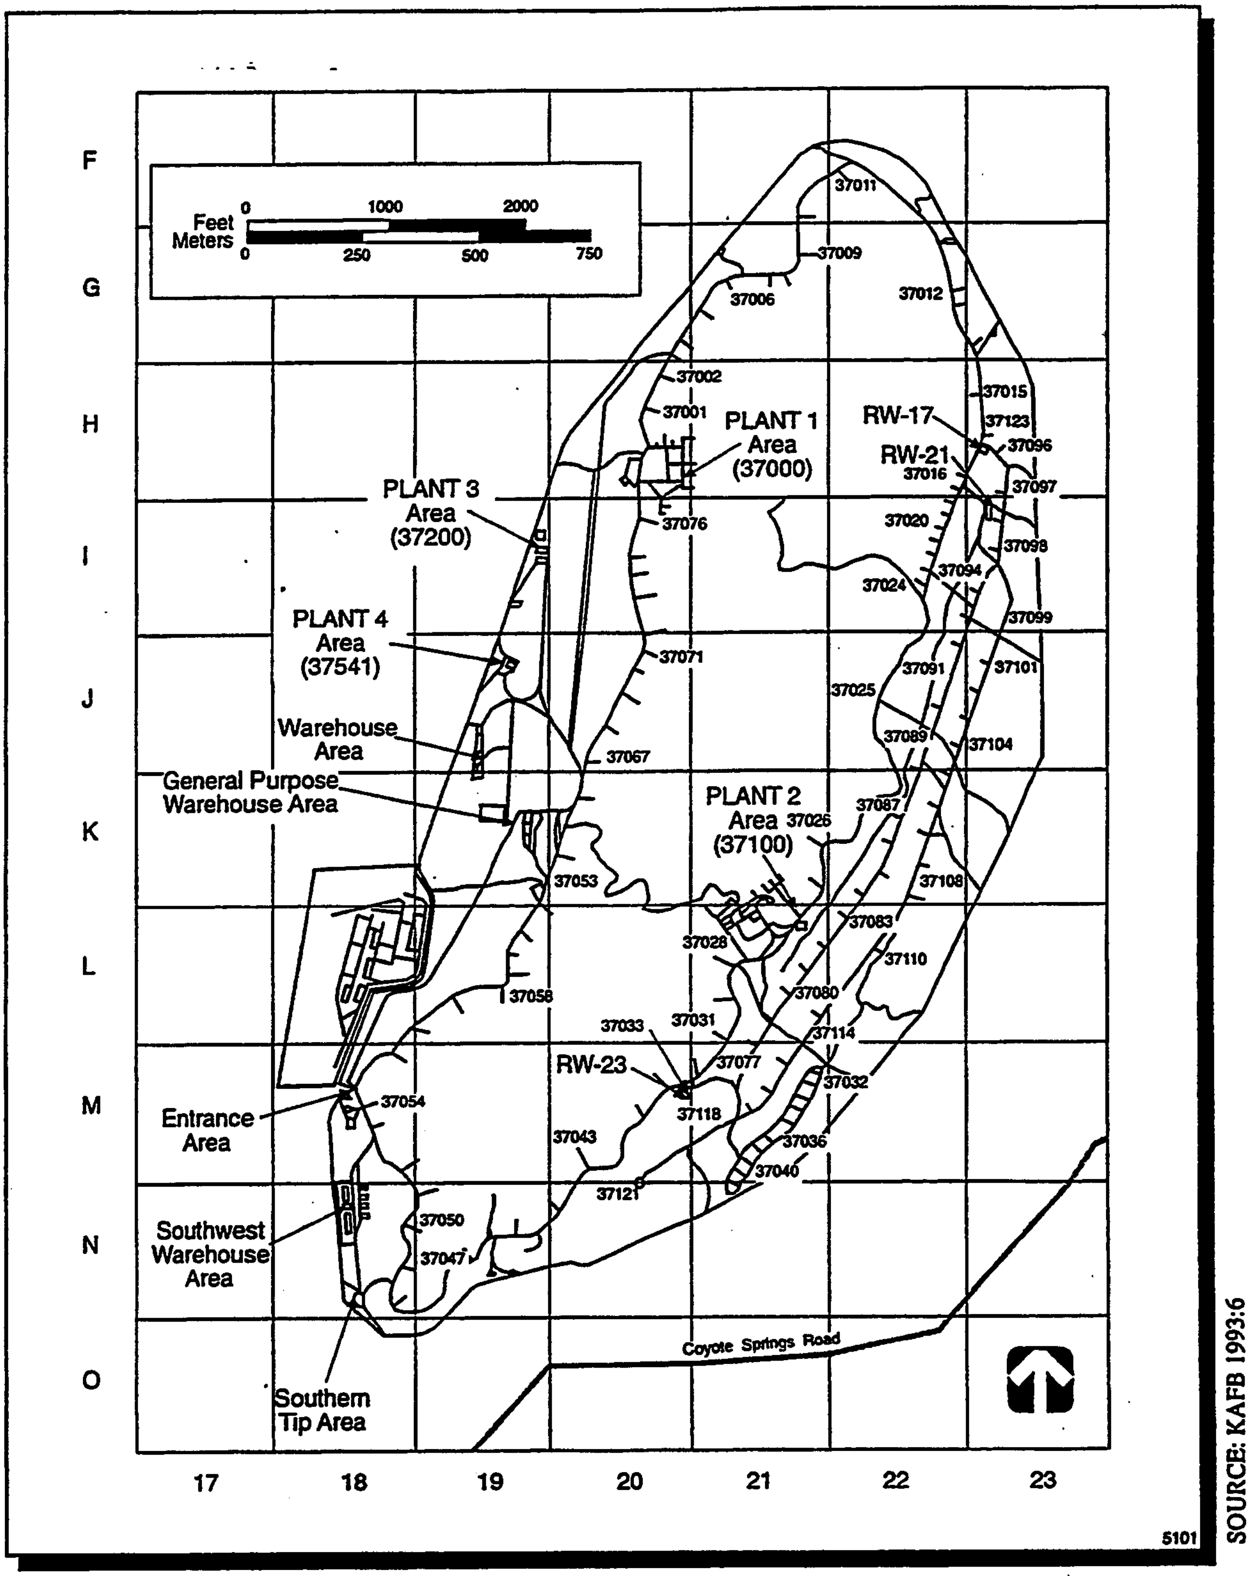


FIGURE 5.5–2.— *Layout of the Manzano Weapons Storage Area at Kirtland Air Force Base.*

WSA are small enough to warrant only limited discussion. Therefore, these resources are discussed briefly below and are not addressed further in this section.

5.5.1.1 *Facilities and Infrastructure*

The KAFB infrastructure is managed by the 377th Air Base Wing and includes support to all tenants. As the Manzano WSA is not a DOE site, the exact breakdown of infrastructure support activities that would be performed by KAFB and DOE personnel has yet to be worked out in detail. Should this site be selected for interim pit storage, a Memorandum of Understanding between the Department of the Air Force and DOE would be developed detailing these duties. The infrastructure operations at KAFB that could be impacted by or be expected to directly support pit storage operations include security, vehicle and building maintenance, safety and health protection, utilities, administration, and general support (e.g., cafeteria, general stores). Waste management and transportation support are discussed below and in sections 5.5.1.10 and 5.5.1.11, respectively.

The direct impacts from the implementation of pit storage would include a small increase in the site's security force. Electrical usage due to interim pit storage (estimated to be 4,110 megawatthours per year) represents a 0.8-percent increase over the site's fiscal year 1993 usage of 490,000 megawatthours and 0.4 percent of the fiscal year 1993 system capacity of 1,095,000 megawatthours (USAF 1993a:3-17). Maintenance support and indirect impacts resulting from pit storage worker requirements (e.g., water, wastewater treatment, and fuel) would increase minimally in comparison to the current and historical onsite infrastructure support levels and system capacities. The Manzano WSA is not currently being utilized at historical or design levels; therefore, the utility systems supporting this facility generally have excess capacity available to support pit storage activity.

5.5.1.2 *Land Resources*

The Manzano WSA is currently being used in part for storage of a variety of items such as furniture and document boxes. These items can easily be removed and space made available for storage of pits if such a decision were made. The use of some storage magazines for the interim storage of 8,000 to 20,000 pits would not change the array of potential storage materials for which these weapon storage magazines are designed. Additionally, no land disturbance is projected under the Pit Storage Relocation Alternative as it pertains to the Manzano WSA. Impacts to land use would not be expected.

5.5.1.3 *Geology and Soils*

The only aspects of geology and soils that could be affected by or have an effect on the implementation of interim pit storage at the Manzano WSA are the risks associated with earthquakes. The earthquake risk was assessed and found to be bounded by other accidents, as discussed in section 5.5.2.1. The Manzano WSA is not anticipated to require upgrades that would involve land disturbance; therefore, impacts to soils are not anticipated.

5.5.1.4 *Water Resources*

Because of the nature of the pit storage activities, operations at the Manzano WSA would not impact surface water or groundwater. The pit storage activities would not use surface waters at the Manzano WSA. The Manzano WSA has several springs and seeps. Four springs are located on the mountains that make up the Manzano WSA (USCOE 1995c:22, 23, 27). Some magazines show evidence of water intrusion (KAFB 1993:48). These magazines were designated as unsuitable for interim pit storage and would not be used. The sanitary sewer waste from the Manzano WSA would be discharged to approved septic systems. The wastewater would not have a measurable affect on groundwater quality because of the combined effects of a deep water table (15 to 30 meters [50 to 100 feet]), low additional discharge volumes, high evaporation rates, and a composition and concentration consistent with treated and sanitary wastewater.

The water demands of pit storage operations are solely due to use by storage personnel. The water demands would be less than historical usage at the Manzano WSA and negligible in comparison to the 6.4 billion liters (1.7 billion gallons) used annually at KAFB (USAF 1994:3-20). The Manzano WSA is located outside of the 100-year and 500-year floodplains (USAF 1979).

5.5.1.5 *Air Quality*

Manzano WSA is in an attainment area for carbon monoxide (CO). A more detailed air quality analysis for this site is provided in section 5.5.2.3.

5.5.1.6 *Acoustics*

The major sources of noise within KAFB include blasting and explosives testing, aircraft operations, and equipment and machine operations. The only additional sources of noise that would be associated with pit storage operations would be from transportation vehicles. These impacts would be minimal.

5.5.1.7 *Biotic Resources*

No Federally listed threatened or endangered plant and animal species have been reported from the Manzano WSA, although the peregrine falcon (*Falco peregrinus*) and the bald eagle (*Haliaeetus leucocephalus*) may be occasional KAFB migrants (USAF 1994:3-8, 3-9). The western burrowing owl (*Athene cunicularia hypergea*), a species of concern, has been reported 1.6 kilometers (1 mile) west of the Manzano WSA perimeter fence, but not within that facility's boundary. Additionally, a State endangered plant, the Wright's fishhook cactus (*Mammillaria wrightii*), was found on gravelly or rocky slopes at nine sites within the Manzano WSA (NHP 1995:15, C-176, C-177, plant map). Further, four springs were identified within the perimeter of the Manzano WSA (USCOE 1995c:ES 15–27). However, the Pit Storage Relocation Alternative does not include any action that would disturb the animal or plant species noted above or any of the four springs. Therefore, no impacts to biotic resources would be expected.

5.5.1.8 *Cultural Resources*

Twenty-seven historic and prehistoric archaeological sites have been found in the Manzano WSA. Of these sites, 8 have been recommended for inclusion in the National Register of Historic Places and 14 others are considered to be potentially eligible for inclusion (Argonne 1995:1-1, 1-2, 8-2 through 8-6). The Pit Storage Relocation Alternative does not include any action that would disturb these resources. No storage facilities identified in the Pit Storage Relocation Alternative have been nominated to the National Register of Historic Places. Therefore, no impacts to cultural and paleontological resources would be expected.

To identify areas of potential concern and locations of Traditional Cultural Properties, DOE has, in the past, sought consultations with Native American groups with traditional ties to the area. Two of these groups, the Sandia and Isleta Pueblos, expressed a general concern about the Manzano WSA. Isleta Pueblo considers the Four Hills area that comprises the Manzano WSA to be within their traditional area of cultural activities. They have requested that KAFB inform them of any archaeological finds at the Manzano WSA, specifically in regards to human remains and ritual paraphernalia (Argonne 1995:1-1, 1-2). The Pit Storage Relocation Alternative is not expected to adversely affect these concerns.

5.5.1.9 *Socioeconomic Resources*

Approximately 150 additional personnel (including 120 security personnel) would be required to operate the storage magazines at the Manzano WSA if pit storage activities are moved to this facility. This number represents less than a 0.8 percent increase in the total Federal workforce at KAFB. Most of these workers can be hired locally; therefore the increase to the KAFB workforce or the regional population would not be significant. According to the 1990 Census, 150 workers represent 0.06 percent of the of the workforce employed within the KAFB Region of Influence (NM Cen, 1993:Table 145). No socioeconomic impacts would be anticipated.

5.5.1.10 *Waste Management*

For the purpose of this assessment, it is assumed that DOE would manage the wastes from pit storage at the Manzano WSA. Waste management figures from SNL are used for comparison. SNL manages mixed transuranic waste, transuranic waste, mixed waste, low-level waste, hazardous waste, and nonhazardous wastes in accordance with the requirements of a number of Federal and State regulations, permits obtained under these regulations (e.g., New Mexico unilateral FFCA order), and DOE orders. These requirements are primarily under the authority of the Environmental Protection Agency, DOE, and the New Mexico Environment Department.

SNL generated an estimated 90 cubic meters (110 cubic yards) of low-level waste and an estimated 1.7 cubic meters (2.2 cubic yards) of mixed waste in 1994. In addition, SNL currently stores approximately 70 cubic meters (91 cubic yards) of mixed waste onsite (DOE 1995:6-4; DOE 1993d:3-71). The new Radioactive Mixed Waste Management Facility for handling these wastes is due to become operational in the near future. SNL generated 751 cubic meters (198,450 gallons) of liquid and 127 cubic meters (166 cubic yards) of solid hazardous waste in 1991 (DOE 1993d:3-71). The pit storage operations would generate less than 1 cubic meter (1.3 cubic yard) of mixed, low-level, and hazardous wastes. Compared to the amounts of waste generated and stored at SNL, the wastes generated by the pit storage activities would be minimal and would not impact the current waste management at SNL.

5.5.1.11 *Intrasite Transportation*

Interstate 40 and Interstate 25 provide access to the Albuquerque metropolitan area. Access to KAFB from Interstate 40 is provided from either the Wyoming or Eubank gate entrances (Figure 5.5–1). Access to KAFB from Interstate 25 is via Gibson Boulevard.

The onsite road system at KAFB consists of paved streets and access roads. The Manzano WSA is located on the east side of KAFB. Access to the Manzano WSA is via Pennsylvania Avenue. The Manzano WSA is surrounded by fencing. Access to facilities within the area is provided via a ring road which encircles the mountain (Figure 5.5–1). Traffic within the KAFB boundaries is strictly controlled and the roads are not open to public traffic. Base personnel traffic would be controlled as Safe Secure Tractor Trailer (SST) convoys pass through the base roads. Because a release of plutonium from an intersite pit shipment would require a severe accident (e.g., an accident with a fuel tanker or a train [see section 4.16.4.2]), the controlled transportation environment at KAFB does not pose a significant threat to pit shipments. Consequently, the contribution to overall intersite transportation accident risk from onsite transport is negligible.

Two high-speed transportation corridors (Gibson and Tijeras Arroyo corridors) that would traverse KAFB have been proposed. Of these, the Tijeras Arroyo Corridor would come in closest proximity to the Manzano WSA. Both transportation routes have been discussed for a number of years. . However, NEPA documentation has not been completed on either project.

5.5.1.12 *Aircraft Accidents*

The Manzano WSA is located in the foothills of the Manzano Mountains, approximately 6.5 kilometers (4 miles) southeast of the main (east-west) runway of the Albuquerque International Airport. Figure 5.5–1 shows the locations of the Manzano WSA relative to the two runways of interest for the Albuquerque International Airport, one of three airports in the vicinity of the Manzano WSA.

The Albuquerque International Airport is the major commercial airfield in the State of New Mexico; it is the only airport with regular commercial jet service. In addition to its role as a commercial airfield, the Albuquerque International Airport is used by military aircraft at KAFB. In 1994, the Albuquerque International Airport had 220,914 aircraft operations (take-offs and landings) (PC 1996j). Table 5.5.1.12–1 summarizes the total number of airfield operations at the Albuquerque International Airport.

TABLE 5.5.1.12–1.—*Albuquerque International Airport Operations for 1994*

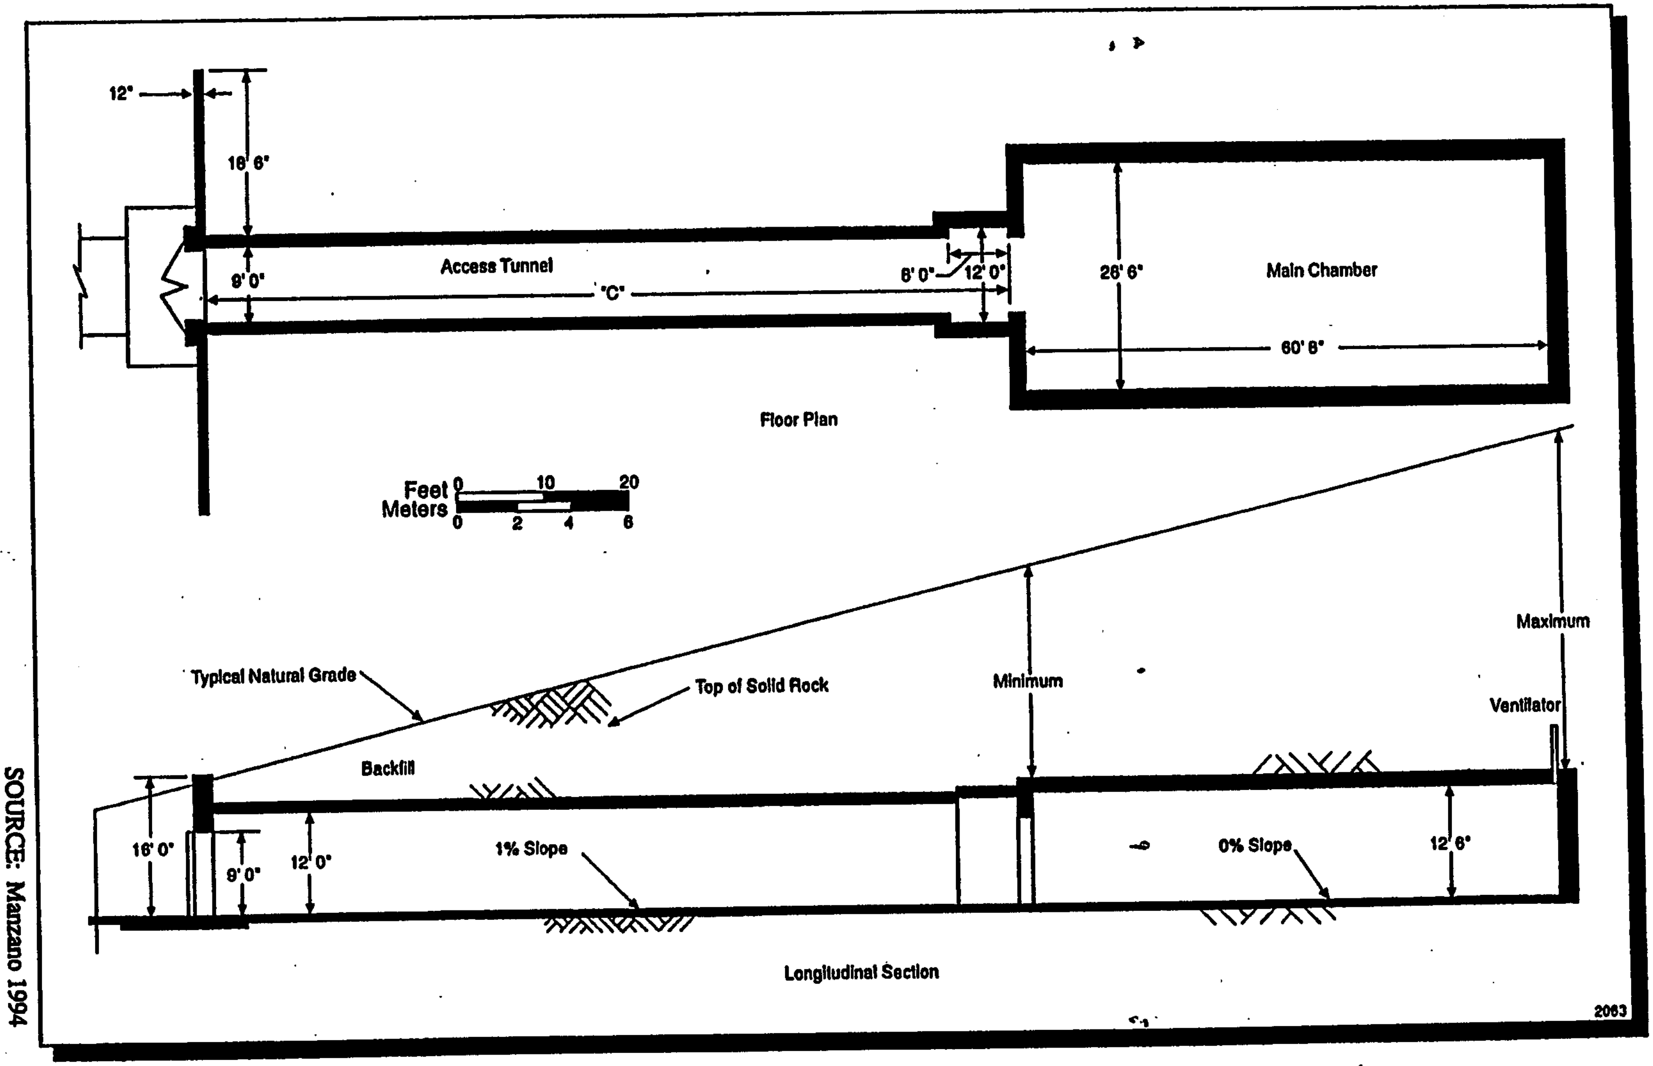
AIRCRAFT TYPE	NUMBER OF OPERATIONS
Air Carrier	77,978
Air Taxi	41,349
Military	29,929
General Aviation	71,658
Total Airfield Operations	220,914

Source: (PC 1996j)

In addition to the Albuquerque International Airport, there are two other airports in the Albuquerque area. Coronado Airport, approximately 19 kilometers (12 miles) to the north-northwest, has two runways, used only by general aviation aircraft. Similarly, Alameda Airport, approximately 24 kilometers (15 miles) to the northwest, has two runways also used by general aviation aircraft. Both of these airports are outside the probability density function boundary for general aviation aircraft and, therefore, were not included in the aircraft crash analysis. Further details on these two airports are contained in volume II, appendix E. Only the Albuquerque International Airport and non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g).

In the history of the Manzano WSA, there have been three aircraft crashes. One crash involved an F-100C; the crash site was located east of the Manzano WSA administration area. Another crash involved a B-29 in the northern portion of the site. This aircraft departed from KAFB and crashed after approximately three minutes in flight, killing the crew. The third crash also occurred in the northern portion of the site and involved an EC-135 (KAFB 1993:69, 73, 74). None of these crashes affected the storage facilities.

If DOE chooses to relocate pits to the Manzano WSA, the pits would be stored in Type D magazines. Type D magazines (as shown in Figure 5.5.1.12–1) have access tunnels that vary in length from 20 meters to over 30 meters (65 feet to over 100 feet). The main chambers are approximately 19 meters (61 feet) long and have the capacity to store up to 800 pit containers each in a Stage Right configuration. In addition, the main chambers are protected by two vault-like steel doors at both ends of the access tunnel.



SOURCE: Manzano 1994

FIGURE 5.5.1.12–1.—*Type D Storage Facility at the Manzano Weapons Storage Area.*

Type D facilities are tunneled into the mountainside, which provides significant earth overburden protection from penetrating aircraft. As many as 35 magazines have overburden greater than 9 meters (30 feet) and are potentially available for pit storage.

For the 20,000-pit storage option, approximately 25 Type D magazines would be utilized. For the 8,000-pit storage option, approximately 10 Type D magazines would be utilized. The frequency of an aircraft impact at the Manzano WSA is relatively high compared with other potential storage sites. However, the earth overburden of Type D magazine provides complete protection against potential damage from aircraft impacts.

At Manzano WSA, the potential exists for airplanes overflying the area to be carrying conventional bombs. An analysis was performed to determine whether expected bomb loads (one to four 909-kilogram [2,000-pound] bombs) could damage the Manzano WSA storage magazines in the event of an airplane crash. With the minimum overburden cover of 9 meters (30 feet) of granite and earth, the magazines can not be damaged by any foreseeable aircraft events (PC 1995e).

Using the Draft DOE Standard for determining the probability of aircraft crashes and 1994 data from the FAA, the frequency of hitting one of the 25 Type D magazines was calculated as 8.8×10^{-5} for all types of aircraft (DOE 1996g). It should be noted that the frequency calculation represents a conservative upper bound. Since this frequency is greater than 10^{-7}, in accordance with the Draft DOE Standard, further analysis was required. A local response structural analysis was performed according to the Draft DOE Standard for the facility with a 9-meter (30-foot) overburden. The analysis was performed for the maximum penetrator missile for each of the aircraft categories mentioned in section 4.15.2, except for helicopters. None of the aircraft missiles was capable of penetrating the facility. Since this frequency is 0, in accordance with the Draft DOE Standard, no further analysis was required. Further details of the frequency of hitting a magazine and the frequency of releasing material are contained in volume II, appendix E.

5.5.2 Resources Discussed in Detail

5.5.2.1 *Human Health*

The basic approach used in assessing human health concerns is to first identify the affected environments and establish a baseline that represents the risk from current operations. Changes in this baseline risk resulting from the Pit Storage Relocation Alternative are then examined. Impacts from both normal operations and potential accidents are estimated.

Assessing the human health risk impact from potential accidents that result from the relocation of pits to KAFB and storing them in the Manzano WSA involves a risk screening process. The first step in this process is to identify a broad spectrum of potential accident scenarios. The second step in the process uses screening techniques to identify the specific scenarios that dominate risk (i.e., scenarios that contribute an appreciable fraction of the total risk). Finally, risk is calculated as the product of frequency and consequence. Rigorous consequence evaluations are only performed for the identified risk-dominant scenarios.

Two types of accident consequences are examined:

- Worker and public exposure.
- The probability of the accident causing fatal cancer in a worker or the public.

If DOE chooses to relocate pits to KAFB, two aspects of this relocation contribute to a potential for environmental impacts. They are the impacts associated with:

- Transferring pits from the transporter to their storage location inside the facility.
- Storage itself (i.e., potential impacts resulting from having the pits reside inside the facility).

Each time pits are transferred from the transporter to their storage location inside the facility, there is a small probability that an accidental release could occur due to a handling accident. In addition, the transfer of pits from the transporter to their storage location would result in radiological exposures to involved workers.

Affected Environment

The release of radioactivity and toxic chemicals to the environment from a DOE facility is an important issue for onsite workers and the public. Since the human environment contains many sources of radioactivity and toxic chemicals, it is essential to understand the sources of these substances and how effectively they are controlled.

Table 5.5.2.1–1 summarizes the major sources of radiation exposure in the vicinity of the Manzano WSA. The average annual probability of contracting a fatal cancer in the State of New Mexico is 1.4×10^{-3}. Using a nominal fatal cancer risk factor of 5×10^{-4} cancer fatalities per person rem and the environmental

radioactivity data for Manzano/Sandia in Table 5.5.2.1–1, it is calculated that fatal cancers attributable to environmental radioactivity released in the vicinity of the Manzano WSA and SNL constitute an extremely small fraction (<<0.01 percent) of the average yearly fatal cancer probability in the State of New Mexico (Letter 1995).

Figure 5.5.2.1–1 depicts the offsite population within an 80-kilometer (50-mile) radius of the Manzano WSA. Wind speeds and directions in the Manzano WSA vicinity are presented in Figure 5.5.2.1-2. Winds are predominantly southerly during the summer and northerly during the winter.

Impacts of Facility Upgrades

There is no significant impact on human health associated with Manzano facility upgrades. The only upgrade required is to modify storage magazines to accept Stage Right transfer and storage equipment. The facility impact involves modifying floor space to accept Stage Right guide rails and fastening Stage Right attachment fixtures to storage facility walls. These are standard industrial operations that do not expose workers to any special hazards (e.g., radionuclides, toxic chemicals, or high explosives).

Impacts of Storing 20,000 Pits

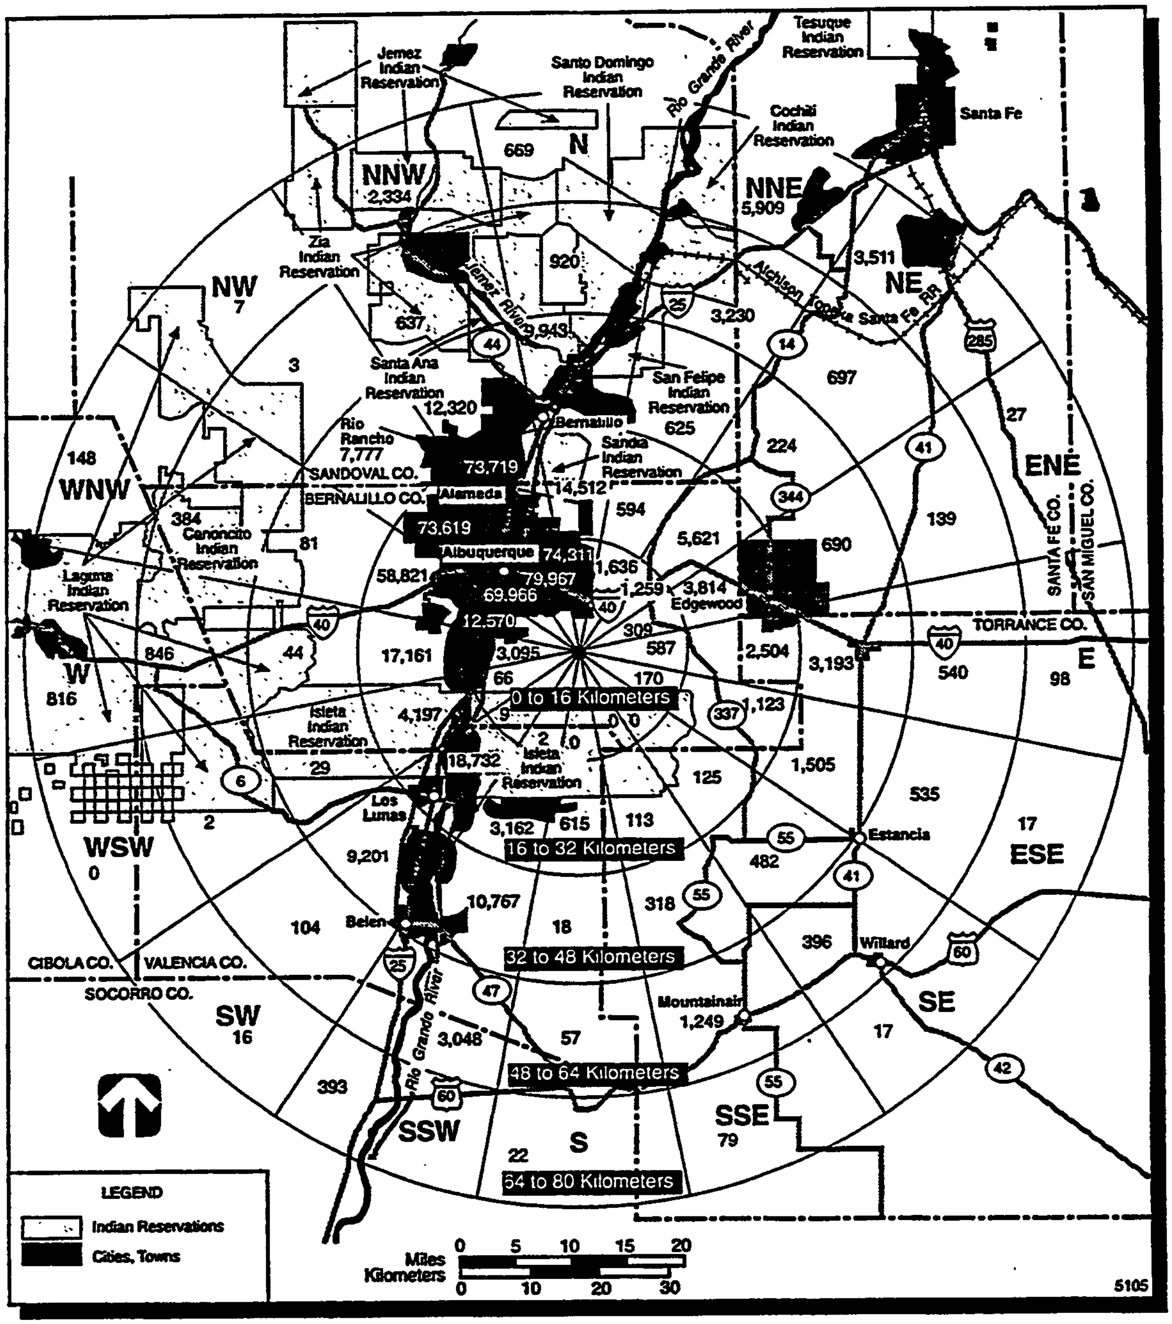
Human health impacts from pit storage activities could potentially result from normal operations and accident scenarios. Impacts from normal operations would be confined to onsite workers. Normal operational impacts result from the unloading of pits from SSTs at the Manzano WSA. Unloading operations would result in radiological exposure to cargo handlers. Based on conservative calculations made for handling of pits at Pantex Plant, the worker doses from unloading of 2,000 pits per year are estimated to be 27 person-rem per year or 270 person-rem for the unloading of 20,000 pits (the maximum number of pits which may be stored at the Manzano WSA).

Once removed from the SSTs, pits would be transferred into the Manzano WSA for storage. Pit transfers within the Manzano WSA would result in radiological exposures to onsite workers handling the pits. The transfer of pits would result in worker doses of less than 2 person-rem per year for handling 2,000 pits and about 13 person-rem for the placement of 20,000 pits. The combined worker dose from unloading and storage of 20,000 pits at the Manzano WSA would be 283 person-rem distributed over the 30 people directly involved in material movement. Assuming that the same 30 people continue to handle 20,000 pits over a period of 10 years and using a dose-to-risk conversion factor of 4×10^{-4} latent cancer fatality (LCF) per person-rem, there would be an additional 0.11 LCF experienced by this group due to radiological exposure from pit handling.

The probability of LCFs from all causes in the general population is estimated at 20 percent, which implies that 6 of 30 workers would develop cancer from all other causes. With an additional risk of 0.11 LCF from pit handling, the total risk of LCFs among workers at the Manzano WSA would increase by 1.8 percent.

Some operational accidents could result in impacts to both onsite workers and the offsite general population. Radiological exposures and the resultant risk of latent cancers have been evaluated.

The Manzano WSA is the candidate facility at KAFB for storing 20,000 pits. The risk screening methodology indicates that the radiological health risk from accidents associated with the storage of 20,000 pits is dominated by handling accidents that could occur when the pits are being transferred from the transporter. A standard tine forklift is likely to be used to remove pit containers from an SST. The probability of a standard tine forklift



SOURCE: UN 1995

FIGURE 5.5.2.1–1.—*Offsite Population in the Vicinity of the Manzano Weapons Storage Area.*

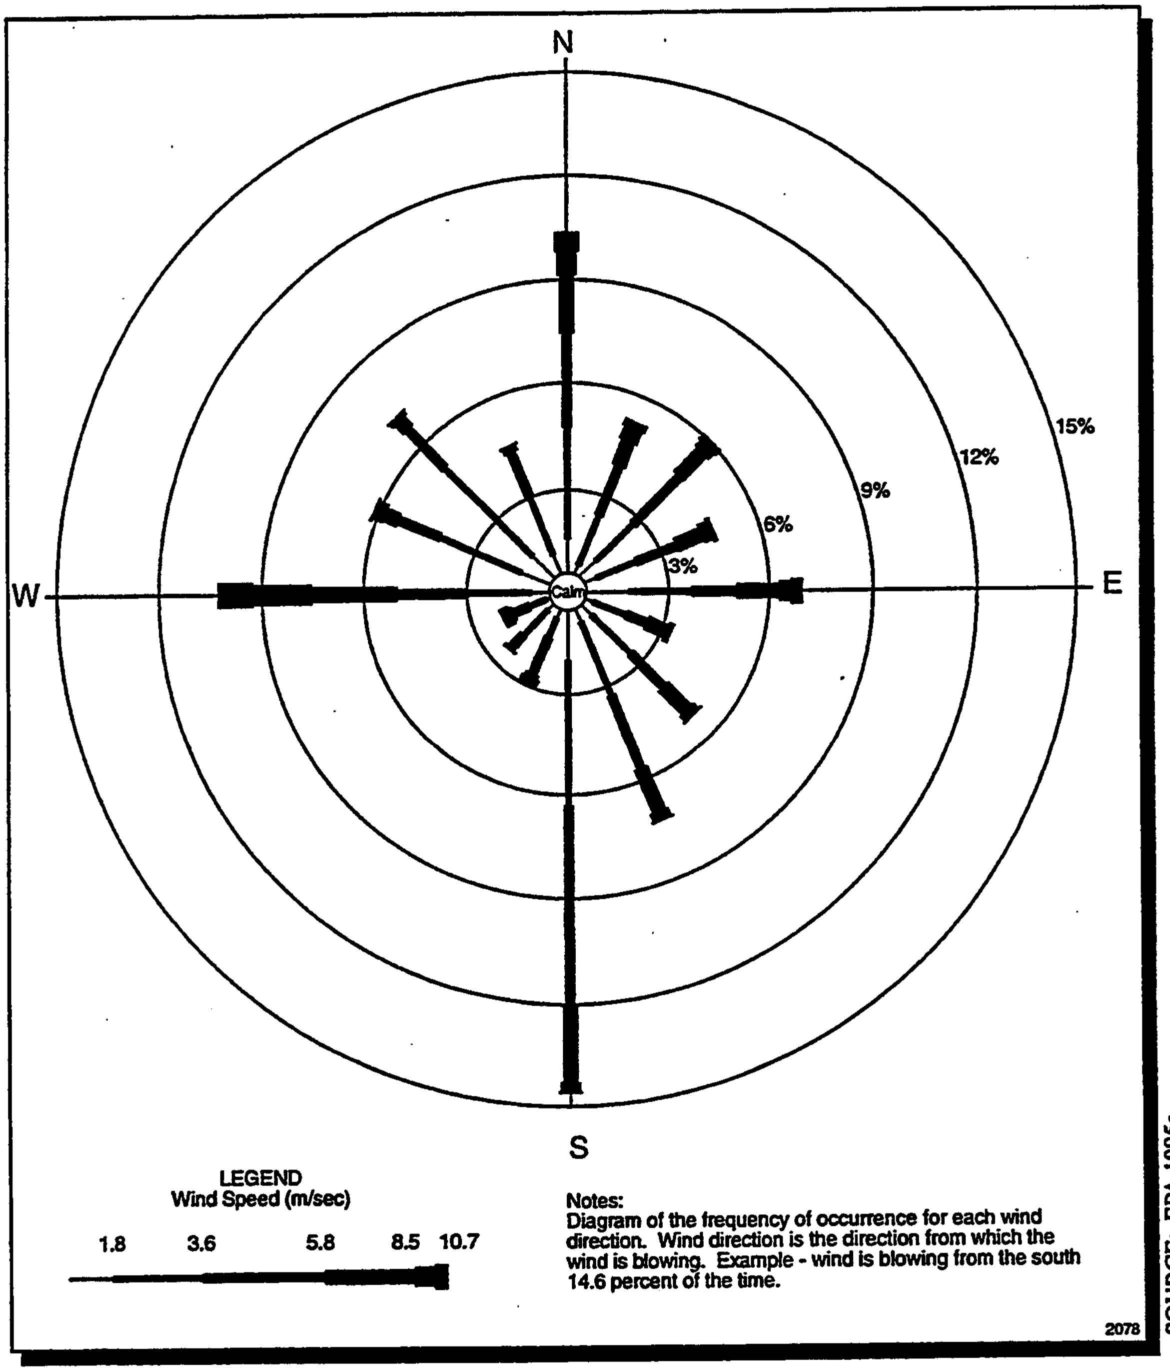


FIGURE 5.5.2.1–2.—*Wind Direction and Speed at Albuquerque International Airport.*

causing a puncture during a single handling operation is in the extremely unlikely range (i.e., 10^{-4} to 10^{-6}).

It is estimated that a forklift puncture of a pit container would release 9.2×10^{-5} curies of plutonium. This is a conservative estimate of the respirable, airborne release caused by a puncture of one shipping container (DOE 1992f:7-39).

Given such a release, an involved worker (the forklift driver) would receive a dose of 6.6 rem, corresponding to an incremental increase in lifetime fatal cancer probability of 2.6×10^{-3}. In addition, a non-involved worker 100 meters (328 feet) downwind along the center line of the plutonium dispersion plume would receive a 5.2×10^{-2} rem exposure, corresponding to an incremental increase in lifetime fatal cancer probability of 2.1×10^{-5}. The maximally exposed member of the public would be expected to receive an exposure of 1.7×10^{-3} rem, corresponding to an incremental increase in lifetime fatal cancer probability of 8.5×10^{-7}. The lifetime fatal cancer probability for an average individual from all other causes is approximately 0.2 (20 percent).

This event would result in an exposure to the public of 4.0×10^{-2} person-rem. Considering the likelihood and consequence of this event, on the average, a member of the public will have an increased annual risk of developing a fatal cancer from this potential accident of 2.6×10^{-14} fatal cancers per year. The annual fatal cancer risk to a person in the State of New Mexico from all other causes is 1.4×10^{-3} fatal cancers per year.

Pit container inventories at the Manzano WSA are expected to be performed using either shielded or automated techniques and equipment. Consequently, these normal operations are not expected to result in any significant radiological exposure to workers.

Other storage activities that may occur within the timeframe evaluated in this EIS include:

- Restacking a limited number of pits to comply with design laboratory temperature requirements.
- A limited number of pit movements and/or instrumentation placements to facilitate third party inspections.

Impacts of these routine activities are also considered to be negligible.

Impacts of Storing of 8,000 Pits

The risks associated with storing 8,000 pits are similar to those of the 20,000-pit storage alternative. If DOE chooses to store 8,000 pits at the Manzano WSA, the total worker doses from unloading operations would be below 113 person-rem over 4 years. This exposure would result in an additional 0.04 LCF from pit handling. With an additional risk of 0.04 latent cancers from pit handling, the total risk of latent cancers among workers at the Manzano WSA would increase by 0.6 percent.

Risk screening methodology also indicates that the risk from storing 8,000 pits in the Manzano WSA is dominated by forklift handling accidents. Note that the risk screening methodology evaluated all potential threats to pit container integrity, such as fire, aircraft crash, earthquakes, flood, and other internal and external events.

The relative risk contribution from earthquakes at the Manzano WSA could not be assessed due to insufficient storage facility fragility data. Since the Type D storage facilities are buried inside solid rock, a breach of a storage and shipping container would not result in a radionuclide release outside the facility as long as the rock overburden remains intact and the doors leading to the storage facility remain closed. Moreover, due to the robust design of the storage and shipping containers, a plutonium release caused by a seismic event is considered not reasonably foreseeable unless part of the rock overburden collapses and impacts a shipping container. Hence, the frequency of a plutonium release from a Manzano Type D storage facility is dependent upon the seismic capacity of the rock overburden.

The impacts of a forklift puncture at Manzano WSA would be the same whether 20,000 or 8,000 pits are stored at the site.

5.5.2.2 *Environmental Justice*

Affected Environment

The Manzano WSA is located on KAFB, which is adjacent to the southeastern city limits of Albuquerque, in central New Mexico. Besides the Air Force and other Department of Defense facilities, KAFB is also the location of various DOE operations, including SNL. Nearly 20,000 military and civilian personnel work on the base (KAFB 1995). In order to identify the target populations covered by Executive Order 12898, an 80-kilometer (50-mile) radius circle centered on the Manzano WSA was overlaid on 1990 Census tract maps. The communities that lie within the 80-kilometer (50-mile) circle, hereafter called the Manzano Region of Influence (ROI), are shown in Figure 5.5.2.2–1.

Population. According to the 1990 Census, there were 606,446 persons within the Manzano ROI. White persons comprised 55 percent of the population, Hispanics were the second largest group with 37 percent, and American Indians accounted for just over 4 percent of the total population. Indian Reservations and trust lands belonging to 10 Native American tribes are located within the Manzano ROI, and approximately half of the American Indians counted in the area in 1990 resided on Indian land. Blacks, Asians, Pacific Islanders and other racial groups totaled less than 4 percent of the total population in 1990 (UN 1995).

Most of the population in the Manzano ROI resides in various cities, towns and Census Designated Places. Albuquerque is the most populous community with 384,736 persons or 63 percent of the total population within the Manzano ROI in 1990. An unincorporated area known as the South Valley, located immediately southwest of Albuquerque and due west of KAFB, is the second largest community in the area with a 1990 population of 35,701. More than 70 percent of residents in the South Valley were Hispanics. Rio Rancho, northwest of Albuquerque in southcentral Sandoval County, is third largest with 32,505 persons in 1990.

North and south of Albuquerque, along the Rio Grande River, are a number of towns and villages, most with primarily Hispanic populations: Belen (5,960 persons in 1990, 67 percent Hispanic), Bernalillo (5,960 persons, 75 percent Hispanic), Bosque Farms (3,791 persons, 25 percent Hispanic), Corrales (5,453 persons, 27 percent Hispanic), Los Chaves (3,872 persons, 49 percent Hispanic), Los Lunas (6,013 persons, 58 percent Hispanic), Tome-Adelino (1,695 persons, 65 percent Hispanic) and Valencia (3,917 persons, 47 percent Hispanic) (NM Cen 1992:Table 6). Most of these communities are also characterized by fairly large low-income populations. For example, Belen had 28 percent of its population below the poverty level, Bernalillo had 24 percent below the poverty level, Los Chaves had 19 percent below the poverty level, Los Lunas had 25 percent below the poverty level, and Valencia had 15 percent below the poverty level (NM Cen 1993:Table 203).

There are also nine primarily American Indian communities in the Manzano ROI. A major portion of the northern boundary of the Isleta Indian Reservation borders the southern boundary of KAFB, but the Isleta people (2,699 in 1990) primarily live near the Rio Grande River, several miles from the KAFB boundary. In the Sandoval County portion of the Manzano ROI are seven additional Indian Reservations with persons residing in dense settlements

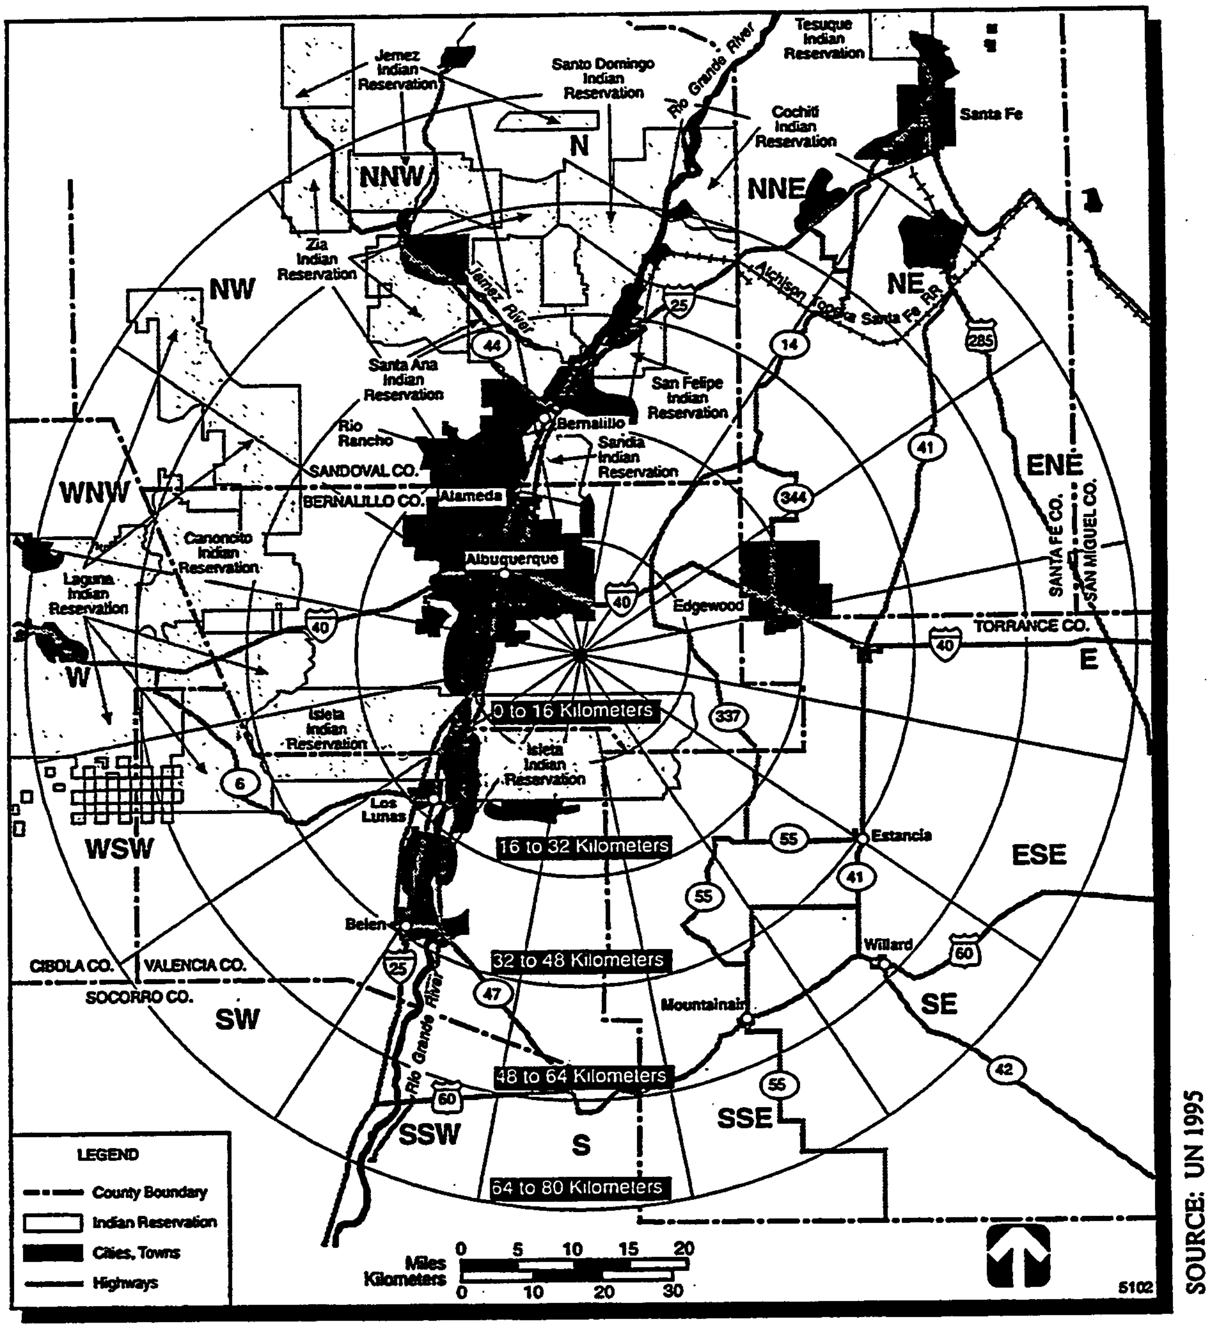

FIGURE 5.5.2.2–1.—*The Manzano WSA Region of Influence.*

known as Pueblos: Sandia Pueblo with 358 Indian residents in 1990; Santa Ana Pueblo with 481 Indian residents; San Felipe Pueblo with 1,859 Indian residents; Santo Domingo Pueblo with 2,947 Indian residents; Cochiti Pueblo with 666 Indian residents; Zia Pueblo with 637 Indian residents; and Jemez Pueblo with 1,738 Indian residents. In the northwest corner of Bernalillo County is the Canoncito Navajo Reservation, a satellite of the main Navajo Reservation, with 1,060 Indian residents counted in 1990 (NM Cen 1991:Table 17).

The most notable socioeconomic characteristic of these communities is their large numbers of low-income persons. The percentage of persons below the poverty level based on 1989 incomes found on these reservations were: Isleta, 27; Sandia, 19; Santa Ana, 13; San Felipe, 42; Santo Domingo, 34; Cochiti, 25; Zia, 33; Jemez, 37; and Canoncito, 60 (NM Cen 1993:Table 229).

Minority Population. Figure 5.5.2.2–2 shows 1990 Census tracts within the Manzano ROI. The tracts are shaded if minority populations comprised 25 percent or more of the populations in 1990 or if 25 percent or more of the persons in a tract were below the poverty level based on their incomes in 1989. The 25 percent threshold levels for minority or low-income persons are based on the working definitions contained in the notice of the Environmental Protection Agency's Office of Environmental Justice (59 FR 192).

Virtually every tract in the Manzano ROI had a population in 1990 in which at least 25 percent of persons were minority or non-Whites. The major exceptions were the southern-most tract in Santa Fe County, four tracts in Rio Rancho in southcentral Sandoval County, and 25 tracts located primarily in the northeastern quadrant of Albuquerque, including the Four-Hills Tract located just north of the Manzano WSA.

Low-Income Population. Low-income persons were not nearly as prevalent in the Manzano ROI in 1990 as were minority persons. High levels of poverty found in American Indian communities account for the shaded tracts in rural Sandoval County, eastern Cibola County, and western and southern Bernalillo County. The tracts shaded for low-income persons in rural Socorro, Valencia, Torrance and San Miguel Counties are also areas with largely Hispanic populations. In the Albuquerque area, high poverty levels were found primarily in the southern half of the city, with the greatest concentration of low-income persons situated in the southwest quadrant, in the unincorporated area known as the South Valley, with its 73 percent Hispanic population (NM Cen 1992:Table 6).

Impacts of Storing 20,000 Pits

Because the interim storage of pits at KAFB would not require any construction activities and because all facility modifications would take place inside existing facilities, impacts to the natural environment would be minimal. Under normal operating conditions, there would be minor increases in air pollutants associated with vehicles used during pit storage activities. Also, a minor increase in particulate matter of aerodynamic diameter less than 10 micrometers concentrations would be expected. These increases are associated with the operation of forklifts which are used to move the pits from the unloading area to the storage area.

These impacts are not likely to affect the surrounding population. Radiological releases from normal pit storage operations would have no measurable effect on an individual occupying a position near the KAFB boundary for an entire year. Levels at the site boundary would be indistinguishable from natural background radiation. No adverse health effects would be expected among the general public, including minority and low-income populations, as a result of normal storage operations.

An abnormal event, such as accidental puncture of a storage container by a forklift, has the

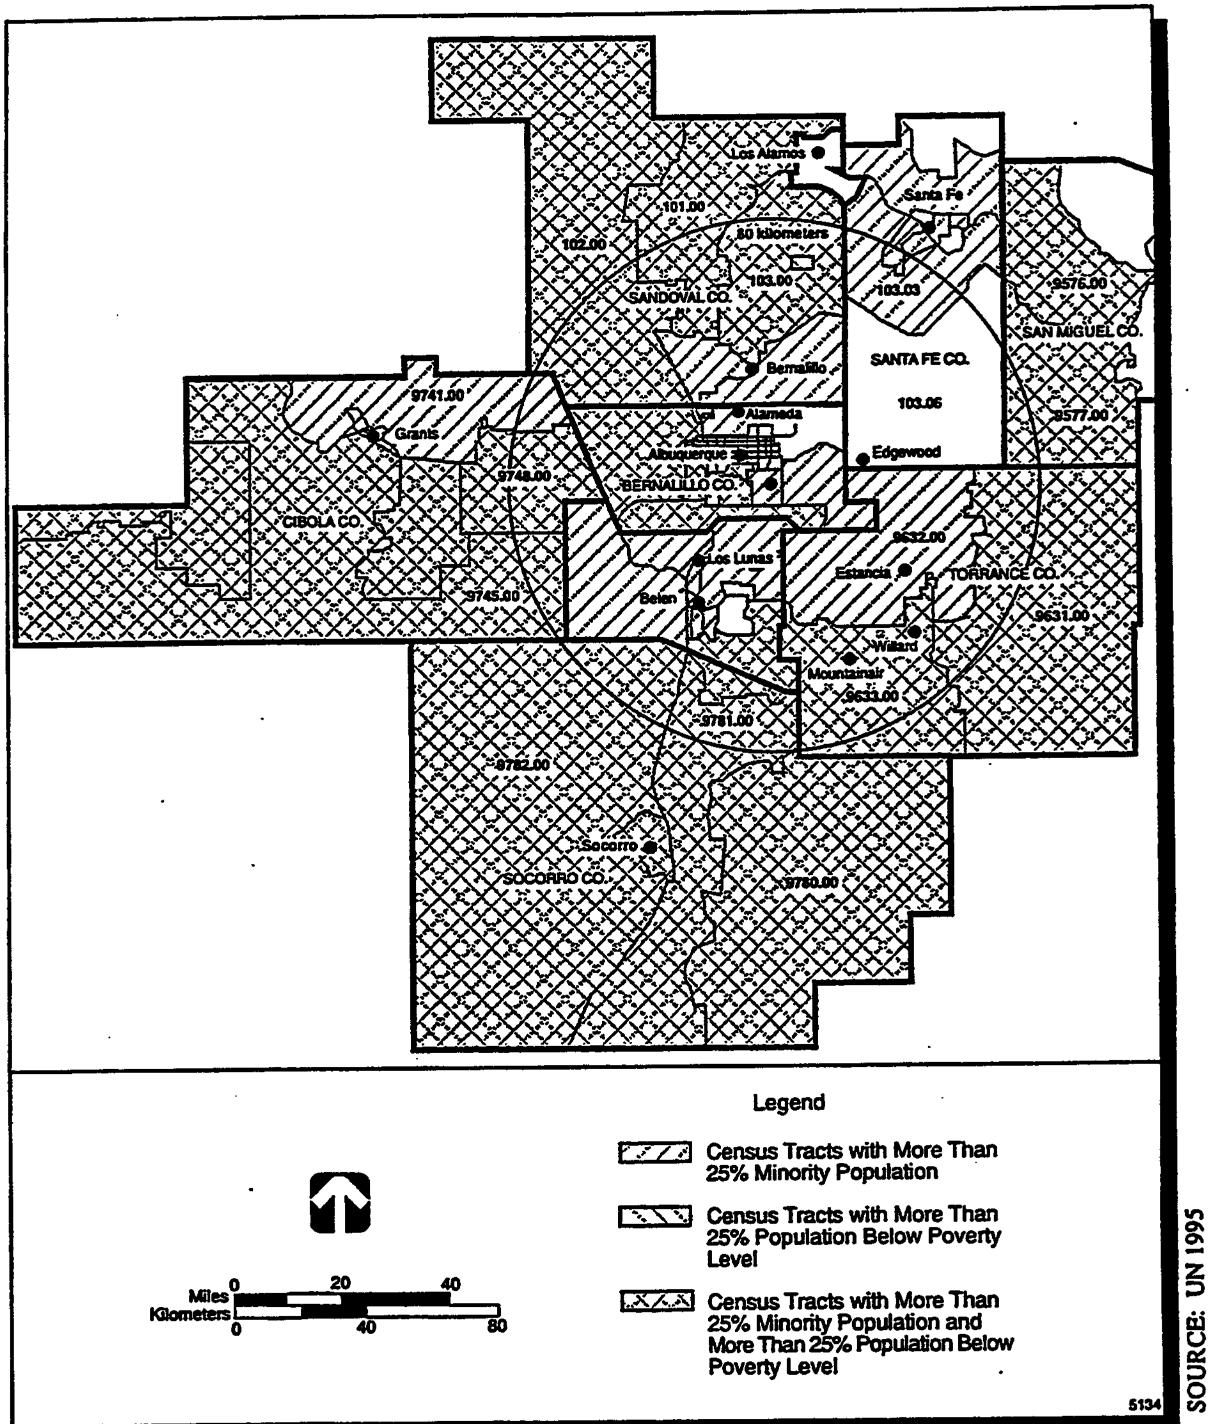

FIGURE 5.5.2.2–2.—*Minority and Low-Income Populations in the Manzano WSA Region of Influence.*

potential of exposing the general public to radiation. The analysis in section 5.5.2.1, Human Health, indicates that the risk to the public from such an accident would be negligible. With no measurable impacts on the general population, the minority and low-income populations would not be disproportionately impacted.

Impacts of Storing 8,000 Pits

The human health impact of storing 8,000 pits at the Manzano WSA would be lower than those identified for the storage of 20,000 pits. No significant adverse impacts are expected, and minority and low-income populations would not be disproportionately impacted.

5.5.2.3 *Air Quality*

Affected Environment

The Manzano WSA at KAFB is located in Bernalillo County, which is situated in the Albuquerque-Mid Rio Grande Intrastate Air Quality Control Region 152. The Manzano WSA lies outside the City of Albuquerque and is classified as "better than national standards" for sulfur dioxide (SO_2), "unclassifiable/ attainment" for ozone (O_3), "unclassifiable" for particulate matter, "cannot be classified or better than national standards" for nitrogen dioxide (NO_2), "attainment for CO, and "not designated" for lead. For CO, Bernalillo County has not had a violation during the past 3 years. As of July 15 1996, the Environmental Protection Agency redesignated Bernallilo County from nonattainment to attainment for CO. The nearest Prevention of Significant Deterioration Class I area to the Manzano WSA is the Bandelier Wilderness, approximately 80 kilometers (50 miles) to the north. The Manzano WSA has no emission sources subject to Prevention of Significant Deterioration requirements.

Impacts of Facility Upgrades

Project-related air quality impacts can be divided into two distinct categories. The first category is short-term construction-related impacts. The second category of impacts is characterized as long-term operations impacts. Long-term impacts would occur once construction is completed and the facility is in operation.

Facility upgrades would not be required at the Manzano WSA. Therefore, there would be no air quality impacts related to construction activities.

Impacts of Storing 20,000 Pits

There are no direct criteria pollutant emissions from the pits during storage. Indirect pollutant emissions would be produced from the exhausts of the vehicles used by employees used to commute to and from work. Also, exhaust emissions from the SSTs used to transport the pits from Pantex Plant to the Manzano WSA would contribute a small amount of pollution to the overall pollutant burden in Bernalillo County, New Mexico.

The calculation of emission rates of exhaust pollutants from employee and pit delivery vehicles was made based on emission factors obtained from the EPA Mobile Source Emission Factor Model (MOBILE 5a). The following assumptions were used in calculating the exhaust pollutant emissions:

- 120 vehicles would be used by security employees (365 days per year).
- 30 vehicles would be used by operations staff employees (255 days per year).
- Average round-trip commute distance: 48 kilometers (30 miles).
- Pit delivery truck round-trip distance in Bernalillo County: 80 kilometers (50 miles).

Table 5.5.2.3–1 presents the estimated annual pollutant emissions from employee and pit delivery vehicles. A comparison of these emissions with those in Bernalillo County is also provided in the table.

Table 5.5.2.3–1 shows that the resulting increase in the CO emission due to storage of pits at the Manzano WSA would be 0.08 percent. Also, these emissions from mobile sources would be distributed over a relatively large area. The increases in the ambient concentrations would, therefore, probably not be detectable. Bernalillo County was in a maintenance for attainment area for CO, and has recently been designated an attainment area for CO. Nor would these negligible increases cause any violations of the National Ambient Air Quality Standards for the other criteria pollutants. The air quality impacts resulting from the long-term storage of pits at the Manzano WSA would therefore be negligible.

Impacts of Storing 8,000 Pits

Pollutant emission resulting from the storage of 8,000 pits would be less than those resulting from the storage of 20,000 pits. Since the air quality impacts from the storage of 20,000 pits were found to be negligible, the air quality impacts resulting from the storage of 8,000 pits would also be negligible.

General Conformity Determination

The EPA published the General Conformity Rule 40 CFR parts 6, 51, and 93 on November 30, 1993 to implement section 176(c) of the *Clean Air Act* as amended in 1990. This section requires that Federal action conform to the appropriate State Implementation Plan. Conformity, as defined in the *Clean Air Act*, is conformity to the State Implementation Plan's purpose of eliminating or reducing the severity and number of violations of the National Ambient Air Quality Standards and achieving expeditious attainment of such standards.

A formal conformity determination is required for federal actions occurring in nonattainment areas when the total direct and indirect emissions of nonattainment pollutants (or their precursors) exceed specified annual de minimis (threshold) values. Because O_3 is a secondary pollutant, the conformity determination for O_3 uses the precursor emissions of volatile organic compounds (VOCs) and NO_2 as surrogate pollutants. The de minimis thresholds are presented in Table 5.5.2.3–2.

TABLE 5.5.2.3–1.—*Pollutant Emission Rates Related to Storage of Pits at the Manzano Weapons Storage Area (metric tons [tons] per year)*

SOURCE	POLLUTANT EMISSION RATE		
	CO	NO_2	VOC
Employee Vehicles	19.94 (21.98)	3.62 (3.99)	2.08 (2.80)
Pit Delivery Vehicle	0.04 (0.04)	0.05 (0.06)	0.01 (0.01)
Total	19.98 (22.02)	3.67 (4.05)	2.09 (2.31)
Bernalillo County (1993)	26303 (29458)		
% of County Emission	0.08		

NA - Emission factors not available.

TABLE 5.5.2.3–2.—*De Minimis Thresholds*

CRITERIA POLLUTANT	DEGREE OF NONATTAINMENT	METRIC TONS (tons/year)
Ozone (VOCs and NO_2)	Serious Severe Extreme Other ozone nonattainment areas (outside of ozone transport region)	45.4 (50) 22.7 (25) 9.1 (10) 90.7 (100)
VOCs	Marginal/moderate nonattainment (within ozone transport region)	45.4 (50)
NO_2	Marginal/moderate nonattainment (within ozone transport region)	90.7 (100)
Carbon monoxide (CO)	All	90.7 (100)
Particulate matter (PM_{10})	Moderate Serious	90.7 (100) 63.5 (70)
Sulfur/nitrogen dioxide (SO_2/NO_2)	All	90.7 (100)
Lead (Pb)	All	22.7 (25)

Since the Manzano WSA was in a maintenance for attainment area for CO, the de minimis value for CO was 90.7 metric tons (100 tons) per year. As shown in Table 5.5.2.3–1, the emission rate for CO is well below the de minimis value. Therefore, a general conformity analysis is not required for the Manzano WSA. Further, the County has recently been designated attainment area for CO.

CHAPTER 6

Environmental Compliance Requirements for Implementing the Proposed Action and the Alternatives

CHAPTER 6
ENVIRONMENTAL COMPLIANCE REQUIREMENTS FOR IMPLEMENTING THE PROPOSED ACTION AND THE ALTERNATIVES

Chapter 6 describes the environmental compliance requirements for implementing the Proposed Action and Alternatives. These include mention of applicable Federal and State laws as well as identification of agencies with regulatory purview over actions that would result from the Department's Record of Decision that will follow the completion of this EIS.

6.1 INTRODUCTION AND PURPOSE

This chapter provides information concerning the environmental standards and statutory requirements that relate to continuing operations at Pantex Plant. It presents some of the more important regulatory requirements associated with the Proposed Action by identifying the applicable environmental statutes, regulations, and approval requirements. The requirements are found in Federal and State statutes, regulations, permits, approvals, and consultations, as well as in the Executive and DOE orders, Consent orders, Federal Facility Agreements, Federal Facility Compliance Agreements, and Agreements-in-Principle. The status of consultations required by some statutes is documented, and potential new permits required by the Proposed Action are listed. In addition, this chapter provides historical background on environmental protection at Pantex Plant and alternative sites, identifies potential new permits that may be required, and explains the concept of shared Federal and State enforcement.

6.2 BACKGROUND

Since Pantex Plant was constructed during the 1940's and 1950's, before the advent of current environmental and worker health requirements, operational safety and national security requirements were the dominant factors in the design and operation of its facilities. With the emergence of environmental and health-related issues and the enactment of environmental and worker health programs, DOE shifted many of its resources into programs designed to achieve compliance with all applicable Federal, State, and local requirements. Today, many government agencies at the Federal, State, and local levels have regulatory authority over Pantex Plant operations due to compliance agreements between DOE and regulators.

6.3 ENVIRONMENTAL REQUIREMENTS

Section 6.3.1 discusses the major Federal and State statutes, regulations, and orders associated with this EIS. Section 6.3.2 summarizes consultations that have taken place. Finally, section 6.3.3 identifies existing permits obtained for Pantex Plant operations and highlights potential permits in support of certain projects at Pantex Plant during the EIS timeframe.

6.3.1 Environmental Statutes, Orders, and Agreements

The *Atomic Energy Act of 1954* (42 U.S.C. 2011) authorized the Atomic Energy Commission to establish standards to protect health and minimize dangers to life or property.

As a successor agency to the AEC, DOE has inherited these responsibilities. Other Federal environmental statutes and regulations have been established to protect the environment and to control the generation, handling, treatment, storage, and disposal of hazardous materials and waste substances. Table 6.3.1–1 (all tables are presented at the end of this chapter) lists the Federal environmental statutes, regulations, and Executive orders applicable to Pantex Plant. It also identifies the associated permit, approval, and consultation requirements generally required to site, construct, or operate the facilities discussed in this EIS. DOE is committed to fully complying with all applicable environmental statutes, regulatory requirements, and Executive and internal orders; many of these requirements and standards are established through DOE orders. Table 6.3.1–2 lists selected DOE orders that apply to all sites; however, they may affect each site differently.

DOE has entered into agreements with some regulatory agencies on behalf of Pantex Plant facilities. These agreements normally establish a schedule for achieving full compliance with regulations at Pantex Plant. Table 6.3.1–3 lists Texas State environmental statutes, regulations, and orders.

6.3.2 Environmental Consultations

The *National Environmental Policy Act* (NEPA) requires the proponent to involve a number of Federal, State, and local agencies with jurisdiction over various aspects of the Proposed Action and Alternatives to be consulted. The *Endangered Species Act* (16 U.S.C. 1531) and *National Historic Preservation Act* (16 U.S.C. 470) require consultation in regard to endangered species, critical habitat, and prehistoric and historic resources. Chapter 9 lists Federal and State agencies that have been offered an opportunity to comment on the Draft EIS. Appendix J contains letters pertaining to *Endangered Species Act* and *National Historic Preservation Act* consultations, together with others providing comments on the Draft EIS.

6.3.3 Environmental Permits

Pantex Plant has applied for various air, solid waste, and water permits in accordance with the Federal and State regulatory requirements outlined in Tables 6.3.1–1 and 6.3.1–3. Section 6.4 summarizes the status of permits and other important regulatory issues at Pantex Plant Site. The status of regulatory issues at alternative interim pit storage sites is briefly summarized in section 6.5.

6.4 Environmental Regulatory Setting at Pantex Plant

In 1989, the Secretary of Energy invited the host State of each DOE facility to independently determine and verify any impacts of plant operations to the environment. In response to this initiative, DOE entered into an Agreement-in-Principle with the State of Texas to focus on waste management, emergency response, and environmental monitoring. DOE provides required information to the State of Texas, and the State conducts sampling and research activities. DOE also issued a Grant-in-Aid for the hydrogeologic characterization studies at Pantex Plant. The plant provides office space for TNRCC officials who are assigned to this site.

Generally, Pantex Plant operations are currently in full compliance with applicable Federal and State regulations. However, since this facility existed prior to the promulgation of many current environmental laws and regulations, both the Environmental Protection Agency (EPA) and the State of Texas have allowed DOE to continue operations while taking actions to achieve full compliance with all applicable environmental regulatory requirements.

On May 31, 1994, EPA announced in the *Federal Register* that, effective June 30, 1994, Pantex Plant would be listed on the National Priorities List as a Superfund site pursuant to the provision of the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA) (59 FR 27989). This determination was based on the presence of contamination due to past practices. Pantex Plant officials, TNRCC, and EPA Region 6 are in the process of developing a Federal Facility Compliance Agreement to address Pantex Plant Superfund issues (Pantex 1995a:15-4).

Section 107 of CERCLA provides for the designation of Federal and State trustees who are responsible for assessing damages for injury to, destruction of, and loss of natural resources. As Pantex Plant's primary Federal Natural Resource Trustee, DOE has participated with various Federal and State Trustees including the U.S. Fish and Wildlife Service, the U.S. Geological Survey, TNRCC, and the Texas General Land Office (DOE 1996f:12). As completion of the Federal Facility Agreement for the Pantex Plant approaches, consultation will increase.

6.4.1 Air

The Burning Ground is the term used to describe 17 thermal treatment units. These units are used to treat, demilitarize, and sanitize explosives, explosive components, and explosive materials. The Burning Ground is operated under *Resource Conservation and Recovery Act* (RCRA) (42 U.S.C. 6901) interim status and a written grant of authority from TNRCC.

6.4.2 Water

Since 1980, pursuant to the Texas Water Code, TNRCC has permitted the plant to discharge its wastewater under a Wastewater No Discharge Permit (Permit Number 02296), which allows wastewater discharges not going to "Waters of the State." In 1980, the State did not consider playas to be "Waters of the State," and, on December 26, 1990, DOE filed a permit application to modify its permit. The permit application was resubmitted in May 1992, at the request of TNRCC, to change the permit from a No Discharge to a Discharge Permit. EPA Region 6 National Pollutant Discharge Elimination System (NPDES) Permit No. TX-0107107 and TNRCC Permit 02296, as amended, authorize the plant to discharge to the waters of the United States and Texas, under specified effluent limitations and monitoring requirements.

6.4.3 Land

Pantex Plant currently operates RCRA units under its Hazardous Waste Permit and under Interim Status. On April 25, 1991, TNRCC and EPA issued a permit to Pantex Plant to store containers and tanks and to treat hazardous waste in tanks and containers. The permit specifically excluded 17 RCRA units at the Burning Ground, but continued Interim Status of those units. Explosive waste and explosive-contaminated waste are thermally treated at the Burning Ground, which operates as a RCRA Interim Status unit and under a written Grant of Authority from TNRCC. In November 1991, DOE formally submitted a request to TNRCC for a Class 3 Modification to add the units at the Burning Ground to the permit. Pursuant to the public notice published on October 31, 1991, interested parties requested a hearing before a hearing examiner on the permit. On May 31, 1992, the TNRCC Office of Air Quality recommended draft hazardous waste permit provisions for the Burning Ground. TNRCC, DOE, and parties to the hearing process are continuing discussions on terms of the proposed permit modification.

EPA issued DOE a draft RCRA Administrative Order of Consent in September 1989 requiring Pantex Plant to conduct a RCRA Facility Investigation (RFI) to identify, assess, and correct actual and potential threats to human health or the environment resulting from the release of hazardous wastes or constituents at 144 solid waste management units (SWMUs) (Pantex 1996:15). In 1991, the RFI was incorporated into the hazardous waste permits (TWC 1991:Attachments C-G). The RFI has completed the initial investigation for 70 percent of the SWMUs (PC 1995r; DOE 1994x). Based on RFI results and recommendations, corrective measures will be evaluated and conducted at certain SWMU sites following the necessary approval. A Pantex Plant citizens advisory board has been created to provide stakeholders with information on environmental restoration activities, and also to serve as a forum to address their environmental concerns.

On October 3, 1995, TNRCC approved the Pantex Plant Site Treatment Plan-Compliance Plan and Agreed Order pursuant to the *Federal Facility Compliance Act of 1992* (42 U.S.C. 6961) (FFCA) (DOE 1995x). The Agreed Order and Site Treatment Plan-Compliance Plan establish schedules for development of treatment technologies for low-level mixed waste subject to Land Disposal Restrictions.

6.5 Pit Storage Sites

Tables 6.5–1 through 6.5–4 identify selected environmental statutes, regulations, and orders for states in which the four candidate sites for pit storage are located. Most of the candidate sites' operations are currently in compliance with applicable Federal and State regulations. Since many of the sites' facilities existed prior to the promulgation of many current environmental laws and regulations, EPA and the respective states have allowed DOE to continue most operations while taking actions to achieve full compliance with all applicable environmental regulatory requirements.

Kirtland Air Force Base (KAFB) is the only alternative storage site candidate that has RCRA Part B Permits issued to non-DOE agencies. The New Mexico Environment Department and EPA Region 6 have issued RCRA Part B Permits to the 377th Air Base Wing (the host Air Force element), in addition to those issued to DOE's Kirtland Area Office and Sandia National Laboratories. If DOE selects KAFB's Manzano Weapons Storage Area as a pit storage site, a decision would have to be made on whether to use KAFB, Sandia National Laboratories, or another DOE organization to handle hazardous, mixed, or radioactive wastes associated with the Pit Storage Relocation Alternative. New permits, or permit modifications, could be required. A Memorandum of Understanding (in consultation with regulators) would presumably be developed to address interagency environmental and other issues.

The final decision to issue a new permit or modify existing permits rests primarily with the New Mexico Environment Department. DOE expects at a minimum, language changes modifying existing RCRA Part B permits and identification of responsible parties in areas of site ownership, on-going solid waste management unit investigations and clean-ups, and waste management operations. Since no additional RCRA storage, treatment, or disposal facilities would be required to manage less than 1 cubic meter (1.3 cubic yards) per year of mixed waste and hazardous waste, the modifications are expected to be considered Class 1 as defined by 40 CFR 270 criteria.

Since the Hanford Site, Savannah River Site, Nevada Test Site, and Sandia National Laboratories each manage low-level mixed waste and hazardous waste, no impacts to the current waste management operations are expected from the small volumes routinely generated during pit storage activities (DOE 1995). Low-level mixed wastes would be managed in accordance with site-specific FFCA Site Treatment Plan–Compliance Plan and Site Agreed Order.

TABLE 6.3.1–1.—***Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant***

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Air Resources	*Clean Air Act* (CAA), as amended	42 U.S.C. §§7401 et seq.	EPA	Requires sources to meet standards and obtain permits to satisfy: National Ambient Air Quality Standards (NAAQS), Standards of Performance for New Stationary Sources, National Emission Standards for Hazardous Air Pollutants (NESHAP), and Prevention of Significant Deterioration (PSD).
	National Ambient Air Quality Standards/State Implementation Plans	42 U.S.C. §§7409 et seq.	EPA	Requires compliance with primary and secondary ambient air quality standards governing SO_2, NO_x, CO, O_3, Pb, and PM_{10} and emission limits/reduction measures designated in each State.
	Standards of Performance for New Stationary Sources	42 U.S.C. §7411	EPA	Establishes control/emission standards and record keeping requirements for new or modified sources specifically addressed by a standard.
	National Emission Standards for Hazardous Air Pollutants	42 U.S.C. §7412	EPA	Requires sources to comply with emission levels of hazardous air pollutants; may require a preconstruction approval, depending on the process being considered and the level of emissions that will result from the new or modified source.
	Prevention of Significant Deterioration	42 U.S.C. §§7470 et seq.	EPA	Requires comprehensive preconstruction review and the application of Best Available Control Technology to major stationary sources (emissions of 100 tons/year) and major modifications; requires a preconstruction review of air quality impacts and the issuance of a construction permit from the responsible State agency setting forth emission limitations to protect the Prevention of Significant Deterioration increment.
Acoustics	Noise Control Act of 1972	42 U.S.C. §§4901 et seq.	EPA	Requires facilities to maintain noise levels that do not jeopardize the health and safety of the public.
Water Resources	*Clean Water Act* (CWA)	33 U.S.C. §§1251 et seq.	EPA	Requires EPA or State-issued permits and compliance with provisions of permits regarding discharge of effluents to surface waters.

TABLE 6.3.1–1.—*Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant*-Continued

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Water Resources (cont'd)	NPDES Permit No. TX0107107	33 U.S.C. §1342	EPA Region 6	Authorizes Pantex Plant to discharge to the waters of the United States, under specified effluent limitations and monitoring requirements.
	Dredged or Fill Material-(section 404 of CWA)/ *Rivers and Harbors Appropriations Act of 1899*	33 U.S.C. §1344/33 U.S.C. §§401 et seq.	U.S. Army Corps of Engineers	Requires permits to authorize the discharge of dredged or fill material into navigable waters or wetlands and to authorize certain structures or work in or affecting navigable waters.
	Safe Drinking Water Act (SDWA)	42 U.S.C. §§300f et seq.	EPA	Requires permits for construction/operation of underground injection wells and subsequent discharging of effluents to ground aquifers.
	Executive Order 11988: Floodplain Management	3 CFR, 1977 Comp., p. 117	Water Resources Council, Federal Emergency Management Agency, Council on Environmental Quality (CEQ)	Requires consultation if project impacts a floodplain.
	Executive Order 11990: Protection of Wetlands	3 CFR, 1977 Comp., p. 121	U.S. Army Corps of Engineers/U.S. Fish and Wildlife (FWS)	Requires Federal agencies to avoid the long and short term adverse impacts associated with destruction or modification of wetlands.
	Compliance with Floodplain/ Wetlands Environmental Review Requirements	10 CFR 1022	DOE	Requires DOE to comply with all applicable floodplain/wetlands environmental review requirements.

TABLE 6.3.1–1.—*Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant*-Continued

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Soil Resources	RCRA/ Hazardous and Solid Waste Amendments of 1984	42 U.S.C. §§6901 et seq./PL 98-616	EPA	Requires proper management and, in some cases, permits for current operations involving hazardous waste and remediation of contamination from past activities (not addressed by CERCLA); changes to site hazardous waste operations could require amendments to RCRA hazardous waste permits involving public hearings.
	CERCLA/ *Superfund Amendments and Reauthorization Act of 1986* (SARA)	42 U.S.C. §§9601 et seq./PL 99-499	EPA	Requires cleanup and notification if there is a release or threatened release of a hazardous substance; requires DOE to pursue Interagency Agreements with EPA and State to control the cleanup of each DOE site on the National Priorities List (NPL).
	Community Environmental Response Facilitation Act	PL 102-426	EPA	Amends CERCLA (40 CFR 300) to establish a process for identifying, prior to the termination of Federal activities, property that does not contain contamination. Requires prompt identification of parcels that will not require remediation to facilitate the transfer of such property for economic redevelopment purposes.
	Farmland Protection Policy Act of 1981	7 U.S.C. §§4201 et seq.	Natural Resource Conservation Service	DOE shall avoid any adverse effects to prime and unique farmlands.
	Federal Facility Compliance Act of 1992	42 U.S.C. §6961	States	Eliminates RCRA waiver of sovereign immunity for Federal facilities and requires DOE to develop plans and enter into agreements with States as to specific management actions for specific mixed waste streams (e.g., New Mexico Unilateral FFC Order).
Biotic Resources	*Fish and Wildlife Coordination Act*	16 U.S.C. §§661 et seq.	FWS	Requires consultation on the possible effects on wildlife if there is construction, modification, or control of bodies of water in excess of 10 acres in surface area.
	Bald and Golden Eagle Protection Act	16 U.S.C. §§668 et seq.	FWS	Consultations should be conducted to determine if any protected birds are found to inhabit the area. If so, DOE must obtain a permit prior to moving any nests due to mission requirements.
	Migratory Bird Treaty Act	16 U.S.C. §§703 et seq.	FWS	Requires consultation to determine if there are any impacts on migratory bird populations due to mission requirements. If so, DOE will develop mitigation measures to avoid adverse effects.

TABLE 6.3.1–1.—*Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant*-Continued

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Biotic Resources (cont'd)	*Endangered Species Act of 1973*	16 U.S.C. §§1531 et seq.	USFWS/National Marine Fisheries Service	Requires consultation to identify endangered or threatened species and their habitats, assess DOE impacts thereon, obtain necessary biological opinions and, if necessary, develop mitigation measures to reduce or eliminate adverse effects of construction or operation.
Cultural Resources	*National Historic Preservation Act of 1966*, as amended	16 U.S.C. §§470 et seq.	Advisory Council on Historic Preservation	DOE shall consult with the State Historic Preservation Office (SHPO) prior to construction to ensure that no historic properties will be affected.
	Archeological and Historical Preservation Act of 1974	16 U.S.C. §§469 et seq.	DOI	DOE shall obtain authorization for any disturbance of archeological resources.
	Archeological Resources Protection Act of 1979	16 U.S.C. §§470aa et seq.	DOI	DOE shall obtain authorization for any excavation or removal of archeological resources.
	American Indian Religious Freedom Act of 1978	42 U.S.C. §1996	DOI	DOE shall consult with local Native American Indian tribes prior to construction to ensure that their religious customs, traditions, and freedoms are preserved.
	Native American Graves Protection and Repatriation Act of 1990	25 U.S.C. §3001	DOI	DOE shall consult with local Native American Indian tribes prior to, and during as necessary, construction to guarantee that Native American human remains are not disturbed.
	Executive Order 11593: Protection and Enhancement of the Cultural Environment	3 CFR 154, 1971-1975 Comp., p. 559	DOI	DOE shall aid in the preservation of historic and archeological data that may be lost during construction activities.
Worker Safety and Health	*Occupational Safety and Health Act* (OSHA)	5 U.S.C. §5108	OSHA	Agencies shall comply with all applicable worker safety and health legislation (including guidelines of 29 U.S.C. §660) and prepare, or have available, Material Safety Data Sheets.
	Hazard Communication Standard	29 CFR 1910.1200	OSHA	DOE shall ensure that its workers are informed of, and trained to handle, all chemical hazards in the workplace.

TABLE 6.3.1–1.—*Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant*-Continued

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Other	*Atomic Energy Act of 1954*	42 U.S.C. §2011	DOE	DOE shall follow its own standards and procedures to ensure the safe operation of its facilities.
	NEPA	42 U.S.C. §§4321 et seq.	CEQ	DOE shall comply with NEPA implementing procedures in accordance with 10 CFR 1021.
	Toxic Substances Control Act (TSCA)	15 U.S.C. §§2601 et seq.	EPA	DOE shall comply with inventory reporting requirements and chemical control provisions of TSCA to protect the public from the risks of exposure to chemicals; TSCA imposes strict limitations on use and disposal of PCB-contaminated equipment.
	Hazardous Materials Transport Action Act	49 U.S.C. §§1801 et seq.	DOT	DOE shall comply with the requirements governing hazardous materials and waste transportation.
	Hazardous Materials Transportation Uniform Safety Act of 1990	49 U.S.C. §1801	DOT	Restricts shippers of highway route-controlled quantities of radioactive materials to use only permitted carriers.
	Emergency Planning and Community Right-To-Know Act of 1986	42 U.S.C. §§11001 et seq.	EPA	Requires the development of emergency response plans and reporting requirements for chemical spills and other emergency release, and imposes right-to-know reporting requirements covering storage and use of chemicals which are reported in toxic chemical release forms.
	Pollution Prevention Act of 1990	42 U.S.C. 11001-11050	EPA	Establishes a national policy that pollution should be reduced at the source and requires a toxic chemical source reduction and recycling report for an owner or operator of a facility required to file an annual toxic chemical release form under section 313 of SARA.

TABLE 6.3.1–1.—*Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant*-Continued

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Other (cont'd)	Executive Order 12843: Procurement Requirements and Policies for Federal Agencies for Ozone-Depleting Substances	April 21, 1993	EPA	Requires Federal agencies to minimize procurement of ozone depleting substances and conform their practices to comply with Title VI of CAA Amendments reference stratospheric ozone protection and to recognize the increasingly limited availability of Class I substances until final phaseout.
	Executive Order 12856: Federal Compliance with Right-To-Know Laws and Pollution Prevention Requirements	August 3, 1993	EPA	Requires Federal agencies to achieve 50% reduction of agency's total releases of toxic chemicals to the environment and offsite transfers, to prepare a written facility pollution prevention plan not later than 1995, and to publicly report toxic chemicals entering any waste stream from Federal facilities, including any releases to the environment, and to improve local emergency planning, responses and accident notification.
	Executive Order 12873: Federal Acquisition, Recycling, and Waste Prevention	October 20, 1993	EPA	Requires Federal agencies to develop affirmative procurement policies and establishes a shared responsibility between the system program manager and the recycling community to effect use of recycled items for procurement.
	Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations	February 11, 1994	EPA	Requires Federal agencies to identify and address as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.
	Executive Order 12088: Federal Compliance with Pollution Control Standards	3 CFR, 1978 Comp., p. 243	Office of Management and Budget (OMB)	Requires Federal Agency landlords to submit to OMB an annual plan for the control of environmental pollution and to consult with EPA and State agencies regarding the best techniques and methods.

TABLE 6.3.1–1.—*Federal Environmental Statutes, Regulations, and Orders Applicable to Pantex Plant*-Continued

RESOURCE CATEGORY	STATUTE/ REGULATION/ ORDER	CITATION	RESPONSIBLE AGENCY	EIS-LEVEL POTENTIAL APPLICABILITY: PERMITS, APPROVALS, CONSULTATIONS, AND NOTIFICATIONS
Other (cont'd)	Executive Order 11514: Protection and Enhancement of Environmental Quality	3 CFR, 1966-1970 Comp., p. 902	CEQ	Requires Federal Agencies to demonstrate leadership in achieving the environmental quality goals of NEPA; provides for DOE consultation with appropriate Federal, State, and local agencies in carrying out their activities as they affect the environment.
	Nuclear Waste Policy Act of 1982	42 U.S.C. §§10101 et seq.	EPA	DOE shall dispose of radioactive waste per standards of 40 CFR 191.
	Low-Level Radioactive Waste Policy Act	42 U.S.C. §§2021b-2021d	Nuclear Regulatory Commission	DOE shall dispose of LLW per compacts of the states in which it operates.

Air Resources	Texas Air Pollution Control Regulations	TX Admin. Code, Title 30, Chapter 101-125, 305	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of an air contaminant source.
Water Resources	Texas Water Quality Standards	TX Admin. Code, Title 30, Chapter 305, 308-325	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of a water discharge source.
	Texas Consolidated Permit Rules	TX Admin. Code, Title 30	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of a water discharge source.
	Texas Water Quality Acts	TX Admin. Code, Title 30, Chapter 290	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of a water discharge source affecting a public water supply.
Soil Resources	Texas Underground Storage Tanks Rules	TX Admin. Code, Title 30, Chapter334	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of an underground storage tank.
	Texas Solid Waste Management Regulations	TX Admin. Code, Title 30, Chapter 305, 335	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of a solid waste disposal facility.
	Texas Solid Waste Disposal Act	TX Statutes, Article 4477-7	TNRCC (effective 9/1/93)	Permit required prior to construction or modification of a solid waste disposal facility.
Biotic Resources	Texas Parks and Wildlife Regulations	TX Parks and Wildlife Code, Chapters 67, 68, & 88	TX Parks and Wildlife Department	Permit required by anyone who possesses, takes, or transports endangered, threatened, or protected plants or animals.
Cultural Resources	Antiquities Code of Texas	TX Statutes, Volume 17, Article 6145	TX Historical Commission	Permit required for the examination or excavation of sites and the collection or removal of objects of antiquity.
Worker Safety and Health	No State-level legislation identified			

TABLE 6.5–1.—*Nevada State Environmental Statutes, Regulations, and Orders Applicable to the Nevada Test Site*

RESOURCE CATEGORY	LEGISLATION	CITATION	RESPONSIBLE AGENCY	POTENTIAL APPLICABILITY/ PERMITS
Air Resources	Nevada Air Pollution Control Law	NV Statutes, Title 40	NV State Environmental Commission	Permit required prior to construction or modification of an air contaminant source.
	Nevada Air Quality Regulations	NV Admin. Code, Chapter 445	NV State Environmental Commission	Permit required prior to the construction or modification of an air contaminant source.
Water Resources	Nevada Water Pollution Control Law	NV Statutes, Title 40, Chapter 445	NV Department of Environmental Protection	Permit required prior to construction or modification of a water discharge source.
	Nevada Water Pollution Control Regulations	NV Admin. Code, Chapter 445	NV Department of Environmental Protection	Permit required prior to construction or modification of a water discharge source.
Soil Resources	Nevada Underground Storage Tank Rules	NV Admin. Code, Chapter 459	NV Department of Environmental Protection	Permit required prior to construction or modification of an underground storage tank.
	Nevada Solid Waste Disposal Law	NV Statutes, Title 40, Chapter 444	NV Department of Environmental Protection	Permit required prior to construction or modification of a solid waste disposal facility.
	Nevada Solid Waste Disposal Regulations	NV Admin. Code, Chapter 44	NV Department of Environmental Protection	Permit required prior to construction or modification of a solid waste disposal facility; permit for septage hauling may be required.
	Nevada Hazardous Waste Disposal Law	NV Statutes, Title 40, Chapter 459	NV Department of Environmental Protection	Permit required prior to construction or modification of a hazardous waste disposal facility.
	Nevada Hazardous Waste Facility Regulations	NV Admin. Code, Chapter 444	NV Department of Environmental Protection	Permit required prior to construction or modification of a hazardous waste disposal facility.
Biotic Resources	*Nevada Non-Game Species Act*	NV Admin. Code, Title 45, Chapter 503	NV Department of Wildlife	Consult with NV Department of Wildlife and minimize impact.
Cultural Resources	Historic Preservation and Archaeology Regulations	NV Statutes, Title 26, Chapter 381-383	NV Advisory Board for Historic Preservation and Archaeology	Permit required prior to the investigation, exploration, or excavation of an historic or prehistoric site.

TABLE 6.5–2.—*South Carolina State Environmental Statutes, Regulations, and Orders Applicable to the Savannah River Site*

RESOURCE CATEGORY	LEGISLATION	CITATION	RESPONSIBLE AGENCY	POTENTIAL APPLICABILITY/ PERMITS
Air Resources	*South Carolina Pollution Control Act*/ South Carolina Air Pollution Control Regulations and Standards	SC Code, Title 48, Chapter 1	SC Department of Health and Environmental Control (SCDHEC)	Permit required prior to construction or modification of an air contaminant source.
	South Carolina Atomic Energy & Radiation Control Act	SC Code, Title 13, Chapter 7	SCDHEC	Establishes standards for radioactive air emissions.
Water Resources	*South Carolina Pollution Control Act*	SC Code, Title 48, Chapter 1	SCDHEC	Permit required prior to construction or modification of a water discharge source.
	South Carolina Water Quality Standards	SC Code, Title 61, Chapter 68	SCDHEC	Permit required prior to construction or modification of a water discharge source.
	South Carolina Safe Drinking Water Act	SC Code, Title 44, Chapter 55	SCDHEC	Establishes drinking water standards.
Soil Resources	*South Carolina Underground Storage Tanks Act*	SC Code, Title 44, Chapter 2	SCDHEC	Permit required prior to construction or modification of an underground storage tank.
	South Carolina Solid Waste Regulations	SC Code, Title 61, Chapter 60	SCDHEC	Permit required to store, collect, dispose, or transport solid wastes.
	South Carolina Industrial Solid Waste Disposal Site Regulations	SC Code, Title 61, Chapter 66	SC Pollution Control Authority	Permit required for industrial solid waste disposal systems.
	South Carolina Hazardous Waste Management Act	SC Code, Title 44, Chapter 56	SCDHEC	Permit required to operate, construct, or modify a hazardous waste treatment, storage, or disposal facility.
	South Carolina Solid Waste Management Act	SC Code, Title 44, Chapter 96	SCDHEC	Establishes standards to treat, store, or dispose of solid waste.

TABLE 6.5–2.—*South Carolina State Environmental Statutes, Regulations, and Orders Applicable to the Savannah River Site*-Continued

RESOURCE CATEGORY	LEGISLATION	CITATION	RESPONSIBLE AGENCY	POTENTIAL APPLICABILITY/ PERMITS
Biotic Resources	*South Carolina Nongame and Endangered Species Conservation Act*	SC Code, Title 50, Chapter 15	SC Wildlife and Marine Resources Department	Consult with SC Wildlife and Marine Resources Department and minimize impact.
Cultural Resources	South Carolina Institute of Archaeology and Anthropology	SC Code, Title 60, Chapter 13-210	SC State Historic Preservation Office	Consult with SC Historic Preservation Office and minimize impact.
Worker Safety and Health	No State-level legislation identified			

TABLE 6.5–3.—*Washington State Environmental Statutes, Regulations, and Orders Applicable to the Hanford Site*

RESOURCE CATEGORY	LEGISLATION	CITATION	RESPONSIBLE AGENCY	POTENTIAL APPLICABILITY/ PERMITS
Air Resources	*Washington State Clean Air Act*	WA State regulations (WAC 246-247)	WA State Department of Health, Division of Radiation Protection	Permit required to construction or modification of stacks emitting radiation.
	Nuclear Energy and Radiation Act	WA State regulations (WAC 402-80)	WA State Department of Health, Division of Radiation Protection	Monitoring and enforcement of air quality and emission standards for radionuclides.
Water Resources	*Washington Water Pollution Control Act*	WA State regulations (WAC 173-201, 173-216, 173-218, 173-220)	WA State Department of Health	Establishes water quality standards, a State waste discharge program, an underground injection control program, and a NPDES permit program.
	Washington Water Well Construction Act	WA State regulations (WAC 173-160)	WA State Department of Ecology	Minimum standards for construction and maintenance of water wells.
Soil Resources	*Washington Solid Waste Management, Recovery and Recycling Act*	WA State regulations (WAC 173-304)	WA State Department of Health	Minimum functional standards for solid waste handling; management of PCB waste.
	Washington Hazardous Waste Management Act	WA State regulations (WAC 173-303)	WA State Department of Health	Dangerous waste regulations.
	Nuclear Energy and Radiation Act	WA State regulations (WAC 402-61)	WA State Department of Health	Licensing requirements for land disposal of radioactive waste.
Biotic Resources	*Washington State Endangered Species Act*	WAC 232-12-014	WA State Department of Fish and Wildlife	Consult with WA State Department of Wildlife to minimize impact.
Worker Safety and Health	*Nuclear Energy and Radiation Act*	WA State regulations (WAC 402-24)	WA State Department of Health	Standards for protection against radiation.

TABLE 6.5–4.—*New Mexico State Environmental Statutes, Regulations, and Orders Applicable to the Manzano Weapons Storage Area at Kirtland Air Force Base*

RESOURCE CATEGORY	LEGISLATION	CITATION	RESPONSIBLE AGENCY	POTENTIAL APPLICABILITY/ PERMITS
Air Resources	*New Mexico Air Quality Control Act*	NM Stat., Title 74, Article 2	NM Environmental Department	Required prior to the construction of modification of an air contaminant source
	New Mexico Air Quality Standards and Regulations	NM Air Quality Control Regs., §100	NM Environmental Department	Required prior to the construction of modification of an air contaminant source
Water Resources*	*New Mexico Water Quality Act*	NM Stat., Title 74, Article 6	NM Water Quality Control Com.	Required prior to the construction or modification of a water discharge source
	New Mexico Water Quality Regulations	NM Water Regulations	NM Water Quality Control Com.	Required prior to the construction or modification of a water discharge source
Biotic Resources	*New Mexico Wildlife Conservation Act*	NM Fish and Game Regulations	NM Department of Fish and Game	Consult with NM Department of Fish and Game and minimize impact
Waste Management	*New Mexico Solid Waste Act*	NM Stat., Chap. 74, Article 8	NM Environmental Department	Required prior to the construction or modification of a solid waste disposal facility
	New Mexico Sold Waste Management Regulations	NM Solid Waste Management Regs.	NM Environmental Department	Required prior to the construction or modification of a solid waste disposal facility
	New Mexico Hazardous Waste Management Regulations	NM Solid Waste Management Regs.	NM Environmental Department	Required prior to the construction or modification of a solid waste disposal facility
Chemical and Material Storage	New Mexico Underground Storage Tank Regulations	NM Underground Storage Tank Regulations	NM Environmental Department	Required to comply with tank requirements prior to the construction or modification of an underground storage tank

*In addition to these statues and regulations, the Isleta Pueblo, which is located along the Rio Grande River downstream of KAFB, has received EPA approval to establish water quality standards under the treatment of State designation.

CHAPTER 7

References

CHAPTER 7
REFERENCES

Chapter 7 provides a list of all references cited in volumes I and III of this EIS. The list is organized in alphanumeric order. References that begin with a number (e.g., "10 CFR 20", "40 CFR 50") are listed first, followed in alphabetic order by references beginning with a letter (e.g., DOE 1990a, EPA 1992g).

10 CFR 71 — DOE, Nuclear Regulatory Commission, Packaging and Transporting of Radioactive Material, *Code of Federal Regulations*, Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC, January 1, 1992.

10 CFR 100 Part A — DOE, Nuclear Reactor Commission, Reactor Site Criteria, *Code of Federal Regulations,* Office of the Federal Register National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.

10 CFR 1021 — DOE, National Environmental Policy Act Implementing Procedures, *Code of Federal Regulations,* Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.

10 CFR 1022 — DOE, Compliance with Floodplain/Wetlands Environmental Review Requirements, *Code of Federal Regulations,* Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.

10 CFR 835 — DOE, Occupational Radiation Protection, *Code of Federal Regulations,* Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.

14 CFR 150 — FAA, DOT, Airport Noise Compatibility Planning, *Code of Federal Regulations*, Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.

15 U.S.C. 2601 — *Toxic Substances Control Act*, 15 United States Code, Section 2601.

16 U.S.C. 1531 — *Endangered Species Act of 1973*, 16 United States Code, Section 1531.

16 U.S.C. 470 — *National Historic Preservation Act of 1966*, 16 United States Code, Section 470.

16 U.S.C. 661 — *Fish and Wildlife Coordination Act*, 16 United States Code, Section 661.

29 CFR 1904 — DOL, Recording and Reporting Occupational Injuries and Illnesses, *Code of Federal Regulations,* Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.

29 CFR 1910	DOL, Occupational Safety and Health Standards, *Code of Federal Regulations,* Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington, DC.
29 CFR 1960	DOL, Basic Program Elements for Federal Employee Occupational Safety and Health Programs and Related Matters, *Code of Federal Regulations*, Office of the Federal Register, National Archives and Records Administration, U.S. Government Printing Office, Washington DC.

CSU 1976	*International Biome Project, Pantex Plant 1970-1976*, prepared by Natural Resource Geology Laboratory, Colorado State University, Ft. Collins, CO, 1976.
Davis 1989	Davis, S.D., W.D. Pennington, and S.M. Carlson, *A Compendium of Earthquake Activity in Texas*, Texas Bureau of Economic Geology, University of Texas, Austin, TX, 1989.
DHEC 1992	DHEC, *1991 Air Pollution Measurements of the South Carolina Air Quality Surveillance Network*, prepared by the South Carolina Department of Health and Environmental Control, Columbia, SC, 1992.
DHEC 1993	DHEC, *1992 South Carolina Air Quality Annual Report*, Volume XII, prepared by the South Carolina Department of Health and Environmental Control, Columbia SC, 1993.
DHEC 1994	DHEC, *1993 Air Pollution Measurements of the South Carolina Air Quality Surveillance Network*, prepared by the South Carolina Department of Health and Environmental Control, Columbia, SC, 1994.
Dierauf 1994	Dierauf, L.A., "Wildlife in the Playas: Environmental Challenges and Solutions," paper presented at the *Proceedings of the Playa Basin Symposium*, May 1994.
DOE 1977	DOE, *Final Environmental Impact Statement High Performance Fuel Laboratory, Hanford Reservation, Richland, WA*, prepared by Energy Research and Development Administration, for the U.S. Department of Energy, 1977.
DOE 1983	DOE, *Area Geological Characterization Report for the Palo Duro and Dalhart Basins, TX*, prepared under Contract DOE/C4/101-40-1, by Stone and Webster Engineering Corporation, for the U.S. Department of Energy, Office of Civilian Radioactive Waste Management, 1983.
DOE 1983a	DOE, *Final Environmental Impact Statement, Pantex Plant Site, Amarillo, Texas*, DOE/EIS-0098, U.S. Department of Energy, Washington, DC, October 1983.

DOE 1986 — DOE, *Environmental Assessment Tritium Loading Facility*, DOE/EA-0297, Unique Document No. SAC 200071840000, U.S. Department of Energy, Assistant Secretary for Defense Programs, March 1986.

DOE 1986a — DOE, *Environmental Assessment, Yucca Mountain Site*, prepared under Contract DOE/RW-0073, by Nevada Research and Development Area, for the U.S. Department of Energy, Washington, DC, 1986.

DOE 1986b — DOE, *Preliminary Safety Analysis Report, Device Assembly Facility, Nevada Test Site*, U.S. Department of Energy, January 1986.

DOE 1987 — DOE, *Environmental Survey Preliminary Report, Hanford Site, Richland, WA*, prepared under Contract DOE/EH/OEV-05-P, by Environment Safety and Health, Office of Environmental Audit, U.S. Department of Energy, Washington, DC, August 1987.

DOE 1988 — DOE, *Health Physics Manual of Good Practices for Uranium Facilities*, prepared under Contract DE-AC07-76IDO1570 by Idaho National Engineering Laboratory for the U.S. Department of Energy, June 1988.

DOE 1988a — DOE, *Site Characterization Plan Overview Yucca Mountain Site, Nevada Research and Development Area, Nevada*, DOE/FW 0198, U.S. Department of Energy, Office of Civilian Radioactive Waste Management, Washington, DC, December 1988.

DOE 1990 — DOE, *Waste Isolation Pilot Plant: Final Supplement Environmental Impact Statement*, prepared under Contract DOE/EIS-0026-FS, for the U.S. Department of Energy, Washington, DC, 1990.

DOE 1990a — DOE, *Final Environmental Impact Statement Continued Operation of K-, L-, and P-Reactors, Savannah River Site, Aiken, SC*, DOE/EIS-0147, U.S. Department of Energy, Washington, DC, December 1990.

DOE 1990b — DOE, *Groundwater Protection Management Program Plan*, prepared by Mason & Hanger-Silas Mason Co., Inc., Environmental Protection Department, Environment, Safety & Health Division, for the U.S. Department of Energy, Pantex Plant, Amarillo, TX, May 8, 1990.

DOE 1991 — DOE, *Health Physics Manual of Good Practices for Tritium Facilities*, prepared by EG&G Mound Applied Technologies, Miamisburg, OH, for the U.S. Department of Energy, Assistant Secretary for Environment, Safety and Health, December 1991.

DOE 1991a — DOE, *Nuclear Weapons Complex Reconfiguration Study*, DOE/DP-0083, U.S. Department of Energy, Washington, DC, January 1991.

DOE 1991b — Pantex Plant and Panhandle 2000 Task Force, *Panhandle 2000: Pantex Nuclear Weapons Complex Reconfiguration Proposal, Volume 4:* Environment, Safety and Health, U.S. Department of Energy, Amarillo, TX, May 1991.

DOE 1992	DOE, *U.S. Department of Energy Radiological Control Manual*, U.S Department of Energy, Assistant Secretary for Environment, Safety, and Health, Washington, DC, June 1992.
DOE 1992a	DOE, *Nevada Test Site Defense Waste Acceptance Criteria, Certification, and Transfer Requirements,* Revision 1, NVO-325, prepared by U.S. Department of Energy, Nevada Field Office and Reynolds Electrical & Engineering Co., Inc., Waste Management Department, June 1992.
DOE 1992b	DOE, *Safety Evaluation Report DP SER 92-1, Interim Storage and Staging Activities, Pantex Plant Zone 4 West,* prepared by the Technical Safety Review Panel, U.S. Department of Energy, December 1992.
DOE 1992d	Holz, Barbara A., *Desert Research Institute, Cultural Resources Reconnaissance, Short Report SR052692-1*, NTS Project 924912, prepared under Contract DE-AC08-90NV10845 for the U.S. Department of Energy, Nevada Field Office, Las Vegas, NV, July 1992.
DOE 1992e	DOE, *Hanford Site Environmental Report 1991*, U.S. Department of Energy, Richland, WA, June 1992.
DOE 1992f	DOE, *Final Safety Analysis Report Pantex Plant Zone 4 Magazines Staging and Interim Storage for Nuclear Weapons and Components*, prepared by Mason and Hanger-Silas Mason Co., Inc., for the U.S. Department of Energy, Amarillo, TX, December 1992.
DOE 1992g	DOE, *Socioeconomic Characteristics of Selected Counties and Communities Adjacent to the Savannah River Site*, prepared by the U.S. Department of Energy, Savannah River Field Office, Aiken, SC, July 1992.
DOE 1992h	Everline, C.J., *Plutonium Storage Requirements Alternatives Identification Risk Goals and Methodology*, SCIE–DOE–505–92, for the U.S. Department of Energy, November 9, 1992.
DOE 1993	DOE, *Recommendations for the Preparation of Environmental Assessments and Environmental Impact Statements,* Office of NEPA Oversight, U.S. Department of Energy, May 1993.
DOE 1993a	Huang, J.C., and P. Hang, *Impact of the New (1987-1991) SRS Meteorological Database on AXAIR89Q Dose Calculations (U),* prepared under Contract WSRC-RP-93-551 by Westinghouse Savannah River Company, Savannah River Technology Center, Aiken, SC, for the U.S. Department of Energy, September 1993.
DOE 1993b	Johnston, M.C., and J.K. Williams, *Floristic Survey Pantex Plant Site, Carson County, Texas 1993*, prepared under Contract FFP009901 by Environmental Consulting, Austin, TX, for the U.S. Department of Energy, Amarillo, TX, December 1993.

DOE 1993c	Cushing, C.E., R.R. Mazaika, and R.C. Phillips. *Ecological Investigations at the Pantex Plant Site, 1992,* prepared under Contract DE-AC06-76RLO 1830, by Pacific Northwest Laboratory, Richland, WA, PNL-8810 UC-702, for the U.S. Department of Energy, September 1993.
DOE 1993d	DOE, *Nonnuclear Consolidation Environmental Assessment,* Volume I, prepared under Contract DOE/EA-0792 by the U.S. Department of Defense, Office of Defense Programs, Deputy Assistant Secretary for Weapons Complex Reconfiguration, Washington, DC, June 1993.
DOE 1993f	DOE, *Environmental Assessment Natural Resource Management Activities at the Savannah River Site,* DOE/EA-0826, prepared by the Savannah River Operations Office, Environmental and Laboratory Programs Division, for the U.S. Department of Energy, July 1993.
DOE 1993g	DOE, *Technical Information Package, Proposal for Reconfiguration of Nuclear Weapons Complex at the Nevada Test Site,* Volume 4, submitted by the U.S. Department of Energy, Nevada Operations Office, to the U.S. Department of Energy, Deputy Assistant Secretary, Office of Weapons Complex Reconfiguration, Washington, DC, September 15, 1993.
DOE 1993h	DOE, *Environmental Restoration and Waste Management Site Specific Plan Fiscal Years 1994-1998,* prepared under Contract DOE/NV-336 by the U.S. Department of Energy, Nevada Field Office, January 1993.
DOE 1994	DOE, *Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y-12 Plant,* DOE/EA-0929, U.S. Department of Energy, Oak Ridge, TN, September 1994.
DOE 1994a	DOE, *Interim Guidance Document for Pantex Plant Playas,* prepared by D.F. Triebel, D.J. Ferguson, V. Loucks, G.W. Gabert, and L.D. Tilton of the Amarillo Area Office Playa Vicinity Land Management Team for the U.S. Department of Energy, December 1994.
DOE 1994aa	DOE, *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities,* prepared under Contract DOE-STD-1020-94, for the U.S. Department of Energy, Washington, DC, April 1994.
DOE 1994b	Mason & Hanger-Silas Mason Co., Inc., *1993 Environmental Report for Pantex Plant,* DOE/AL/65030-9413 UC-702, prepared under Contract DE-AC09-91AL65030 by Battelle Pantex and Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX, for U.S. Department of Energy, Albuquerque Operations Office, Amarillo Area Office, Amarillo, TX, June 1994.
DOE 1994bb	DOE, *FMEF Feasibility Assessment for Plutonium Storage,* prepared for the U.S. Department of Energy, February 23, 1994.

DOE 1994c — DOE, *Pantex Plant Draft Site Treatment Plan*, prepared by Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX, for the U.S. Department of Energy, August 1994.

DOE 1994cc — DOE, *Department of Energy Plutonium ES&H Vulnerability Assessment*, Pantex Site Assessment Team Report, Pantex Plant, Amarillo, TX, July 29, 1994.

DOE 1994d — DOE, *Annual Report on Waste Generation and Waste Minimization Progress 1991-1992*, DOE/S-0105, U.S. Department of Energy, February 1994.

DOE 1994e — Mazeroll, A.I., L.S. Boatman, and L.H. Boomershine, *Herpetofaunal Survey Pantex Plant Site, Carson County, Texas 1994*, prepared under Contract FFP019934 by EnviroCon, Canyon, TX, for the U.S. Department of Energy, August 1994.

DOE 1994f — DOE, *Pantex Plant FY 1994 Site Development Plan*, prepared under Contract DE-AC04-91AL-65030 by Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX, for the U.S. Department of Energy, March 1994.

DOE 1994g — Seyffert, K.D., *Checklist of Birds, Pantex Plant Site, Carson County, Texas 1994*, Report, prepared under Contract FFP016902, for the U.S. Department of Energy, Pantex Plant, Amarillo, TX, June 1994.

DOE 1994h — DOE, *Groundwater Protection Management Program Plan*, prepared under Contract DE-AC04-91AL65030 by Mason & Hanger-Silas Mason Co., Inc., Environmental Protection Department, Environment, Safety and Health Division, for the U.S. Department of Energy, Pantex Plant, Amarillo, TX, March 1994.

DOE 1994i — DOE, *Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Draft Environmental Impact Statement*, Volume I, Appendix A, prepared under Contract DOE/EIS-0203-D, by the Hanford Site Spent Nuclear Fuel Management Program, for the U.S. Department of Energy, Office of Environmental Management, Idaho Operations Office, June 1994.

DOE 1994j — DOE, *Pantex Plant FY 1996 CAMP Report Capital Asset Management Process* prepared under Contract DE-AC04-91AL-65030 by Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX for the U.S. Department of Energy, April 1994.

DOE 1994k — Rylander, M.K., *Resident and Migratory Animals Survey Pantex Plant Site, Carson County, Texas 1994*, prepared under Contract FFP011684 by Department of Biological Sciences, Texas Tech University, Lubbock, TX, for the U.S. Department of Energy, August 1994.

DOE 1994l — DOE, *Final Supplemental Environmental Impact Statement, Defense Waste Processing Facility*, prepared under Contract DOE/EIS-0082-S, for the U.S. Department of Energy, Savannah River Site, Aiken, SC, November 1994.

DOE 1994m — DOE, *National Pollutant Discharge Elimination System Permit Application*, prepared by Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX, for the U.S. Department of Energy, Pantex Plant, Amarillo, TX, August 1994.

DOE 1994n — DOE, *Draft Phase I Report and Phase II Work Plan: Expedited Site Characterization for the DOE Pantex Zone 12 Groundwater Investigations*, Version 00, prepared under Contract W-31-109-Eng-38, by Environmental Research Division, Argonne National Lab, Argonne, IL, for the U.S. Department of Energy, Assistant Secretary for Environmental Management, Washington, DC, September 1994.

DOE 1994nn — DOE, *Draft Work Plan Phase I and Phase II Expedited Site Characterization for the DOE Pantex Zone 12 Groundwater Investigation*, prepared under Contract W-31-109-Eng-38, by Environmental Research Design, Argonne National Lab, Argonne, Ill., for the U.S. Department of Energy, Assistant Secretary for Environmental Management, Washington, DC, April 1994.

DOE 1994o — DOE, *Draft Programmatic Environmental Impact Statement for Tritium Supply and Recycling*, Volume I, prepared under Contract DOE/EIS-0161 by Tetra Tech, Inc., Alexandria, VA, for the U.S. Department of Energy, December 5, 1994.

DOE 1994p — PNL, *Hanford Site Environmental Report for Calendar Year 1993*, prepared under Contract DE-AC06-76RLO-1830 by Pacific Northwest Laboratory, Richland, WA, managed by Battelle Memorial Institute for the U.S. Department of Energy, June 1994.

DOE 1994q — DOE, *Hanford Remedial Action, Draft Environmental Impact Statement*, Volume 1 of 2, prepared under Contract DOE/DEIS-0222 by the U.S. Department of Energy, September 26, 1994.

DOE 1994r — PNL, *Hanford Site National Environmental Policy Act (NEPA) Characterization*, Revision 6, prepared under Contract DE-AC06-76RLO 1830 by Pacific Northwest Laboratory, Richland, WA, managed by Battelle Memorial Institute for the U.S. Department of Energy, August 1994.

DOE 1994s — DOE, *Environmental Assessment for Device Assembly Facility Operations, Nevada Test Site, Nye County, NV*, Pre-Approval Draft, prepared by Raytheon Services, NV, Lockheed Environmental Systems and Technologies Company, for the U.S. Department of Energy, March 1994.

DOE 1994t — DOE, *Nevada Operations Office - Annual Site Environmental Report 1993*, DOE/ NV/11432-123, prepared by Reynolds Electrical and Engineering Co., Inc., Las Vegas, NV, for the U.S. Department of Energy, Nevada Operations Office, September 1994.

DOE 1994u — DOE, *DOE Standard, Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities*, prepared under Contract Number DOE-STD-1020-94 by the U.S. Department of Energy, April 1994.

DOE 1994v — DOE, *Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Draft Environmental Impact Statement*, Volume I, Appendix C and F, prepared under Contract DOE/EIS-0203-D, by the Nevada Test Site and Oak Ridge Reservation Spent Nuclear Fuel Management Programs, for the U.S. Department of Energy, Office of Environmental Management, Idaho Operations Office, June 1994.

DOE 1994w — DOE, *Environmental Assessment for Interim Storage of Plutonium Components at Pantex and Department of Energy Response to Comments on the Pre-Approval Environmental Assessment and the Revised Pre-Approval Environmental Assessment and Public Meeting*, Volume I, DOE/EA-0812, prepared by the U.S. Department of Energy, Albuquerque Operations Office, Amarillo Area Office and Pantex Plant, January 1994.

DOE 1994x — DOE, *Amended Charter: Environmental Management Site Specific Advisory Board*, U.S. Department of Energy, June 10, 1994.

DOE 1994y — DOE, *Implementation Plan for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components, Environmental Impact Study*, Revision 0, prepared under Contract DOE/EIS-0225-IP, for the U.S. Department of Energy, Washington, DC, December 1994.

DOE 1994z — DOE, *Risk Reduction Rule Guidance for Pantex Plant RCRA Facility Investigations, Draft Final*, prepared by U.S. Army Corps of Engineers, Tulsa District and Mason & Hanger-Silas Mason Co., Inc./Battelle Pantex for the U.S. Department of Energy, Amarillo Area Office, Environmental Restoration Program, April 1994.

DOE 1995 — DOE, *Draft Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste*, Volume I of IV, prepared under Contract DOE/EIS-0200-D for the U.S. Department of Energy, Office of Environmental Management, August 1995.

DOE 1995a — DOE, *Revised Land Use Census Pantex Plant*, prepared under Contract FFP 021977, by Burns & McDonnell, Kansas City, MO, managed by Mason & Hanger-Silas Mason Co., Inc., for the U.S. Department of Energy, June 1995.

DOE 1995b — Battelle Pantex and Mason & Hanger-Silas Mason Co., Inc., *1994 Environmental Report for the Pantex Plant*, DOE/AL/65030-9506, prepared under Contract DE-AC04-91AL65030, by Environmental Protection Department, Environment, Safety, and Health Division, for U.S. Department of Energy, Albuquerque Operations Office, Amarillo Area Office, Amarillo, TX, June 1995.

DOE 1995c — DOE, *Floodplain Delineation Report for Pantex Plant*, prepared by the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, for the U.S. Department of Energy, January 1995.

DOE 1995d — DOE, *Natural Resource Management Plan for Pantex Plant, Amarillo, TX*, prepared for the U.S. Department of Energy, January 5, 1995.

DOE 1995e — DOE, *Facility Action Plan*, prepared by Mason & Hager-Silas Mason Co., Inc., Battelle Pantex, U.S. Army Corps of Engineers and the U.S. Department of Energy, Amarillo Area Office for the U.S. Department of Energy, Albuquerque Operations Office, January 1995.

DOE 1995f — DOE, *Draft Final Report: Phase II Expedited Site Characterization for the DOE Pantex Zone 12 Groundwater Investigation*, prepared under Contract W-31-109-Eng-38, by Environmental Research Division Argonne National Lab, Argonne, IL, for the U.S. Department of Energy, Assistant Secretary for Environmental Management, Washington, DC, July 1995.

DOE 1995g — DOE, *Nuclear Explosives Facilities Final Safety Analysis Report Nuclear Explosives Bays Module (Buildings 12-64, 12-84, 12-99, 12-104)*, Revision 1, Draft 2, U.S. Department of Energy, Albuquerque Operations Office, December 1994.

DOE 1995h — DOE, *Summary Report of the Overflight Working Group on Recommended Measures to Reduce Overflights of the Pantex Plant*, prepared by the Office of the Deputy Assistant Secretary for Military Application and Stockpile Support, U.S. Department of Energy, February 1995.

DOE 1995i — DOE, *Fault Identification Study for the Pantex Plant*, DOE/AL/65030-9512, prepared under Contract DE-AC04-91AL-65030 by Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX, for the U.S. Department of Energy, April 1995.

DOE 1995j — DOE, *FY 1995 Pantex Plant Site Development Plan*, prepared under Contract DE-AC04-91AL-65030, by Mason & Hanger-Silas Mason Co., Inc., Amarillo, TX, for the U.S. Department of Energy, 1995.

DOE 1995k — DOE, *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling*, Volume I, prepared under Contract DOE/EIS-0161, by Tetra Tech, Inc., Alexandria, VA, for the U.S. Department of Energy, October 1995.

DOE 1995l — DOE, *Draft Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel*, Contact DOE/EIS-0218D, U.S. Department of Energy, March 1995.

DOE 1995m	DOE, *Savannah River Site Waste Management Draft Environmental Impact Statement*, Volume I and II, prepared under Contract DOE/EIS-0217D by the U.S. Department of Energy, Savannah River Operations Office, Aiken, SC, January 1995.
DOE 1995n	Woodward, B.D., R.B. Hunter, P.D. Greger and M.B. Saethre, *1994 Baseline Biological Studies for the Device Assembly Facility at the Nevada Test Site*, prepared under Contract DE-AC08-94-NV11432 by Reynolds Electrical & Engineering, Co., Inc., for the U.S. Department of Energy, February 1995.
DOE 1995p	DOE, *Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement*, Volume I, Appendix A and F, prepared under Contract DOE/EIS-0203-F, by the Hanford Site Spent Nuclear Fuel Management Program, for the U.S. Department of Energy, Office of Environmental Management, Idaho Operations Office, April 1995.
DOE 1995q	DOE, *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling,* Volume II, prepared under Contract DOE/EIS-0161, by Tetra Tech, Inc., Alexandria, VA, for the U.S. Department of Energy, October 1995.
DOE 1995r	DOE, *Draft Final Report: Phase II Expedited Site Characterization for the DOE Pantex Zone 12 Groundwater Investigation*, prepared under Contract W-31-109-Eng-38, by Environmental Research Division Argonne National Lab, Argonne, IL, for the U.S. Department of Energy, Assistant Secretary for Environmental Management, Washington, DC, April 1995.
DOE 1995s	DOE, *Storage and Disposition of Weapons-Usable Fissile Materials PEIS No Action Data Call, Hanford Site*, prepared by Tetra Tech, Inc., Alexandria, VA, for the U.S. Department of Energy, Office of Fissile Materials Disposition, January 1995.
DOE 1995u	DOE, *Interim Guidance Document for Pantex Plant Playas,* prepared by U.S. Department of Energy, Amarillo Area Office, Playa Vicinity Land Management Team, 1995.
DOE 1995v	DOE, *Finding of No Significant Impact Interim Storage of Enriched Uranium Above The Maximum Historical Level at the Y-12 Plant, Oak Ridge, TN,* prepared for the U.S. Department of Energy, September 14, 1995.
DOE 1995w	DOE, Programmatic Environmental Impact Statement, "The Waste Management PEIS and the Pantex Plant," Information Brochure, 1995.
DOE 1995x	*Pantex Plant Federal Facility Compliance Act Compliance Plan,* September 1995 (approved on October 3, 1993).

DOE 1995y	DOE, *Basis for Interim Operation Evaluation Report, DOE Order 5480.22, Technical Safety Requirements, DOE Order 5480.23, Nuclear Safety Requirements, Pantex,* prepared by the Pantex Plant, Risk Management Department, Amarillo, TX, for the U.S. Department of Energy, Albuquerque Operations Office, Albuquerque, NM, November 1995.
DOE 1995z	DOE, *Draft DOE Standard, Accident Analysis for Aircraft Crash into Hazardous Facilities,* SAFT-0030, prepared under Contract DOE-STD-3014-96, for the U.S. Department of Energy, Washington, DC, July, 1995.
DOE 1996	DOE, *Preliminary Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste,* Volume II of IV, prepared under Contract DOE/EIS-0200-D for the U.S. Department of Energy, Office of Environmental Management, September 1996.
DOE 1996a	DOE, *Concurrence Draft, Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement,* Volumes I–III, prepared under Contract DOE/EIS-0229-D for the Office of Fissile Materials Disposition, U.S. Department of Energy, September 1996.
DOE 1996b	DOE, *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management,* Vol. I, prepared under Contract DOE/EIS-0236 for the U.S. Department of Energy, August 1996.
DOE 1996c	DOE, *Draft Environmental Impact Statement for the Nevada Test Site and Off-Site Locations in the State of Nevada,* Vol. I, Chapters 1-9, Part A, prepared under Contract DOE/EIS-0243 for the U.S. Department of Energy, January, 1996.
DOE 1996d	DOE, *Biological Assessment of the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components,* prepared under Contract DE:96:53580\DE:96:53579 by the Environmental Protection Department, Environment, Safety and Health Division, Battelle Pantex, Mason and Hanger-Silas Mason Co., Inc., for the U.S. Department of Energy, Albuquerque Operations Office, Amarillo Area Office, Amarillo, TX, April 26, 1996.
DOE 1996e	DOE, *Charting the Course The Future Use Report,* Office of Environmental Management, Office of Field Management, U.S. Department of Energy, Washington, DC, April 1996.
DOE 1996f	Battelle Pantex and Mason & Hanger-Silas Mason Co., Inc., *1995 Environmental Report for the Pantex Plant,* DOE-AL-65030-9602, prepared under Contract DE-AC04-91AL65030, by the Environmental Protection Department, Environment, Safety and Health Division, for the U.S. Department of Energy, Albuquerque Operations Office, Amarillo Area Office, Amarillo, TX, May 1996.

DOE 1996g	DOE, *Draft DOE Standard, Accident Analysis for Aircraft Crash Into Hazardous Facilities*, SAFT-0030 prepared under Contract DOE-STD-3014-96 for the U.S. Department of Energy, Washington, DC, July 1996.
DOE 1996h	DOE, *Land Facility Use Planning,* DOE P 430.1, U.S. Department of Energy, Office of Field Management, Washington, DC, July 9, 1996.
DOE 1996i	DOE, *Safety Evaluation Report for the Pantex Nuclear Explosives Bays Safety Analysis Report*, U.S. Department of Energy, Washington, DC, September 1996.
DOE 1996j	DOE, *Concurrence Draft, Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement,* Summary, prepared under contract DOE/EIS-0229, for the Office of Fissile Materials Disposition, U.S. Department of Energy, September, 1996.
DOE Order 151.1	DOE, Comprehensive Emergency Management System, Washington DC, September 25, 1995.
DOE Order 231.1	DOE, Occupational Safety and Health Program for DOE Contractor Employees at Government-Owned Contractor-Operated Facilities, Washington, DC, June 22, 1983.
DOE Order 232.1	DOE, Occurrence Reporting and Processing of Operations Information, Washington, DC, September 25, 1995.
DOE Order 440.1	DOE, Worker Protection Management for DOE Federal and Contractor Employees, Washington, DC, September 30, 1995.
DOE Order 451.1	DOE, National Environmental Policy Act Compliance Program, Washington, DC.
DOE Order 5400.4	DOE, Comprehensive Environmental Response, Compensation and Liability Act Requirements, Washington, DC, October 6, 1989.
DOE Order 5400.5	DOE, Radiation Protection of the Public and the Environment, Washington, DC, January 7, 1993.
DOE Order 5480.1B	DOE, Environment Safety and Health Program for Department of Energy, Operations, Washington, DC, September 23, 1986.
DOE Order 5480.11	DOE, Radiation Protection for Occupational Workers, Washington, DC, June 17, 1992.
DOE Order 5480.23	DOE, Nuclear Safety Analysis Reports, Washington, DC, Effective Date, March 10, 1994.
DOE Order 5700.6C	DOE, Quality Assurance, Washington, DC, August 21, 1991.

DOE Order 5820.2A	DOE, Radioactive Waste Management, Washington, DC, September 26, 1988.
DOE Order 6430.1A	DOE, General Design Criteria, Washington, DC, April 6, 1989.
DOE Order N441.1	DOE, Radiological Protection for DOE Activities, Washington, DC, September 30, 1995.
DOL nd	Department of Labor, *No. 764 Producer Price Indexes, by Stage of Processing: 1950 to 1992*, Producer Price Indexes, Monthly and Annually, U.S. Bureau of Labor Statistics, Washington, DC.
DOT 1985	Department of Transportation, *National Air Traffic Training Program, Cooperative Education Student Reference Manual, Module B Course 55322, Aircraft Identification,* Appendix 1, MB-SRM-2, Federal Aviation Administration, April 1985.

PC 1996h — FAA-Amarillo ATCT, Instrument Operations, EIS request for information supplied by FAA-Amarillo ATCT to Jeff Petraglia, Tetra Tech Inc., Washington, DC, June 1996.

PC 1996i — Glover, J., Input for Pantex Plant EIS Document, Internal memorandum from Jeff Glover, Pantex, Risk Management, to Steve Young, Pantex Risk Management, Amarillo, TX, August 6, 1996.

PC 1996j — Trembley, N., FAA Traffic Control Tower Information, Fax from Nancy Trembley, Office of Aviation Policy Plans, and Management Analysis APO-110, to Davin Greenly, Tetra Tech, Inc., Amarillo, TX, May 14, 1996.

PC 1996k — Matthews, R.S., Building Blueprint, Fax from R.S. Matthews, Savannah River Site, NMP Planning, to Jeff Petraglia, Tetra Tech, Inc., August 1, 1996.

PC 1996l — Bowman, A., Identification of Alcohols, Pantex EIS request for information supplied by Alan Bowman, to Raji Sinha, Tetra Tech, Inc., Albuquerque, NM, July 12, 1996.

PC 1996m — Sims, B., TNRCC Fact Sheet, Fax from Barry Sims, Scientech, Inc., Amarillo, TX, to Kathy Monks, Tetra Tech, Inc., Albuquerque, NM, July 18, 1996.

PC 1996n — Ferguson, D., Environmental Impact Statement Response to TNRCC Comments, Fax from Dan Ferguson, Department of Energy, Amarillo Area Office, to Kathy Monks, Tetra Tech, Inc., Albuquerque, NM, July 18, 1996.

PC 1996o — Booker, J.D., List of Approved Agricultural Chemicals for the 1996–97 Growing Season, Fax from J. D. Booker, Battelle Pantex, Amarillo, TX, of a letter from Jerry Johnson, U.S. Department of Energy, Amarillo Area Office, to Jeffery Johnson, Texas Tech University, Lubbock, TX, dated May 24, 1996.

PC 1996p — McBride, D., Color Maps for the Various Flow Systems at Pantex Plant, Support request from Dave McBride, Battelle Pantex, TX, to Jason Moore, Tetra Tech, Inc., Albuquerque, NM, August 20, 1996.

PC 1996q — Erb, W.W., "Draft" Portrayal of the Landfills at Pantex Plant, Support request from W.W. Erb, Pantex Plant, to Dave McBride, Battelle Pantex, Amarillo, TX, September 3, 1996.

PC 1996s — Spisak, T., U.S. Department of Interior's Bureau of Mines Helium Operations, Telephone conversation from Tim Spisak, Chief of Planning, U.S. Department of the Interior/Bureau of Land Management, to Ev Avara, Tetra Tech, Inc., Amarillo, TX, September 1996.

PC 1996t — Taylor, A., Bell Helicopter Plant - Amarillo Operations, Telephone Conversation from Alan Taylor, Assistant City Manager of Amarillo, to Ev Avara, Tetra Tech, Inc., Amarillo, TX, September 1996.

PC 1996v — McBride, D., Irrigation Water Used by Texas Tech University, EIS request for information supplied by Dave McBride, Battelle Pantex, Amarillo, TX, September 19, 1996.

PC 1996w — Weems, J., Excerpts from the Firing Sites RCRA Facility Investigation Report complied by Morrison Knudsen in December 1995, Fax from Johnny Weems, Battelle Pantex, Amarillo, TX, to Raji Sinha, Tetra Tech, Inc., Albuquerque, NM, July 1, 1996.

PC 1996x — Guelker, J., Monitoring Wells in the Area of Playa 4, Personal communication with Johnny Guelker, Pantex Plant Environmental Restoration Team Lead, through Jerry Johnson, Department of Energy, Amarillo Area Office, Amarillo, TX, July 26, 1996.

PC 1996y — Peterson, J.B., Impact of H.R. 4168 *Helium Privatization Act of 1996* on Bureau on Land Management, Helium Operations, Fax from Joseph B. Peterson, Helium Field Operations, Amarillo, TX, to Lisa Johns, Tetra Tech, Inc., Albuquerque, NM, October 22, 1996.

Perryman 1993	Perryman Consultants, Inc., "Analysis Shows Pantex Plant Adds a Billion in Revenue and Thousands of Jobs to Amarillo Economy," Press Release, 1993.
PGCD 1995	*Rules of Panhandle Groundwater Conservation District No. 3,* Panhandle Groundwater Conservation District No. 3, White Deer, TX, July 19, 1995.
PL 91-596	Occupational Safety and Health Act of 1970, Public Law 91-596.
PL 102-484	National Defense Authorization Act of 1993, Public Law 102-484.
PL 101-510	Defense Base Closure and Realignment Act of 1990, Public Law 101-510, November 5, 1990.
PNL 1988	PNL, *Health Physics Manual of Good Practices for Plutonium Facilities,* PNL-6534, Pacific Northwest Laboratory, Richland, WA, May 1988.
Raytheon 1995	Raytheon Services, *Safety Analysis Report for the Device Assembly Facility at the Nevada Test Site,* DAF SAR-001-193-5394C, March 1995.
Reed 1995	Reed, J.W., *Airblast Predictions for Pantex Explosion Operations (Draft)* JWR Inc., Albuquerque, NM, June 30, 1995.
Ross 1994	*Transportation Evaluation Report for Ross Aviation, Inc.,* prepared for the U.S. Department of Energy Albuquerque Operations Office, by Ross Aviation, Inc., Albuquerque, NM, February 1, 1994.
Scanlon 1994	Scanlon, B.R., et al., Evidence for Focused Recharge Beneath Playas in the Southern High Plains, Texas, paper presented at the *Proceedings of the Playa Basin Symposium,* May 1994.
SC Cen 1992	Bureau of the Census, *1990 Census of Population General Population Characteristics-South Carolina,* Tables 1, 6, 7 and 8, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, 1992.
SC Cen 1993	Bureau of the Census, *1990 Census of Social and Economic Characteristics-South Carolina,* Table 145, 178, 203, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, 1993.
SEN 35-91	"Nuclear Safety Policy Notice" Sen-35-91, Secretary of Energy, U.S. Department of Energy, Washington, DC, September 9, 1991.
Smith 1994	Smith, L.M, The Role of Playas in Wildlife Management, paper presented at the *Proceedings of the Playa Basin Symposium,* May 1994.
SNL 1989	Sandia National Laboratories, *Site Development Plan,* Albuquerque, NM, April 1989.

SNL 1993 — *Sandia National Laboratories, New Mexico, Environmental Baseline Update*, SAND92-7339, prepared under Contract DE-AC04-76DP00789, by IT Corporation, Albuquerque, NM and Consensus Planning, Inc./Zephyr Design, Albuquerque, NM, managed by Sandia National Laboratories, Albuquerque, NM and Livermore, CA for the U.S. Department of Energy, January 1993.

SNL 1994 — Sandia National Laboratories, *Warhead Interim Storage Alternative Considerations for Using the Device Assembly Facility (DAF) at the Nevada Test Site for Interim Storage*, Albuquerque, NM, August 19, 1994.

SNL 1994a — Phillips, J.S., et al., *Determination of the Influence Factors and Accident Rates for the Armored Tractor/Safe Secure Trailer*, SAND93-0111, Sandia National Laboratories, April 1994.

SNL 1994b — Clauss, D.B., et al., *A Statistical Description of the Types of Severities of Accidents Involving Tractor Semi-Trailers*, SAND93-2580, Sandia National Laboratories, June 1994.

Stoller 1996 — *Draft Final Work Plan Pantex Plant Ditches Interim Corrective Measures Hot Spot Removal*, prepared for Mason & Hanger-Silas Mason Co., Inc., prepared by the S.M. Stoller Corporation, Boulder, CO, May 15, 1996.

TBEG 1982 — Texas Bureau of Economic Geology, *Geology and Geohydrology of the Palo Duro Basin, Texas Panhandle, A Report on the Progress of Nuclear Waste Isolation Feasibility Studies (1981)*, Geological Circular 82-7, prepared for the U.S. Department of Energy, Office of Nuclear Waste Isolation, by the Texas Bureau of Economic Geology, University of Texas, Austin, TX, 1982.

TBEG 1988 — Nativ, R., *Hydrogeology and Hydrochemistry of the Ogalalla Aquifer, Southern High Plains, Texas Panhandle and Eastern New Mexico*, Report of Investigation No. 177, prepared by the Texas Bureau of Economic Geology, University of Texas, Austin, TX, 1988.

TBEG 1989a — Budnik, Roy T., *Tectonic Structures of the Palo Duro Basin, Texas Panhandle,* prepared by the Texas Bureau of Economic Geology, University of Texas, Austin, TX, 1989.

TBEG 1994 — Mullican, W.F., III, A.E. Fryer and N.D. Johns, *Vertical Transport of Contaminants through Perched Aquifers to the Ogalalla Aquifer, Pantex Plant Area, Southern Plains, Texas,* prepared by the Texas Bureau of Economic Geology, University of Texas, Austin, TX, 1994.

TBEG 1994a — Paine, J., *Shallow Seismic Data Acquisition, Processing, and Interpretation at Pantex Lake, Carson County, Texas*, Texas Bureau of Economic Geology, Milestone Report Activity 2, Supplement to Scope of Work, 1992-93, University of Texas, Austin, TX, 1994.

TBEG 1995 Texas Bureau of Economic Geology, *Summary Hydrogeologic Assessment DOE Pantex Plant, Carson County, TX*, University of Texas, Austin, TX, May 1995.

TBEG 1995a Texas Bureau of Economic Geology, *Milestone Report on Potentiometric Surfaces and Vertical Hydraulic Conductivity Measurements for Perched Aquifers at the Pantex Plant, Carson County, Texas*, (Activity No. 4 of Appendix C. Supplement Scope of Work, 1993-1994), University of Texas, Austin TX, January 1995.

TDH 1994 Texas Department of Health, *Study of Cancer in Selected Counties Near the Pantex Nuclear Weapons Plant*, Cancer Registry Division, Austin, TX, June 24, 1994.

TEC 1995 Texas Employment Commission, *1994 Labor Force Estimates for the Amarillo Metropolitan Statistical Area*, prepared by Economic Research and Analysis Department in cooperation with the U.S. Department of Labor, Austin, TX, 1995.

TIE 1996 *Technical Information Exchange on Draft Environmental Impact Statement for the Continued Operations of the Pantex Plant and Associated Storage of Nuclear Weapon Components*, Transcript from afternoon session, page 81, Amarillo, TX, June 25, 1996.

TNRCC 1993 Texas Natural Resource Conservation Commission, *Permit to Dispose of Wastes Under Provisions of Chapter 26 of the Texas Water Code, Permit No. 02296*, Corresponds to NPDES Permit No. TX0107107, September 1993.

TNRCC 1993a Texas Natural Resource Conservation Commission, *Air Quality Modeling Guidelines,* Modeling Division, Austin, TX, December, 1993.

TNRCC 1993b Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Quarterly Report April-June 1993*, Austin, TX, October 1993.

TNRCC 1993c Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Quarterly Report July-September 1993*, December 1993.

TNRCC 1994 Texas Natural Resource Conservation Commission, *1993 Annual Waste Summary Report,* Austin, TX, 1994.

TNRCC 1994b Texas Natural Resource Conservation Commission, *Monitoring Operations Division, Smarter Air Monitoring for Texas*, Austin, TX, November 1994.

TNRCC 1994c Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Quarterly Report January-March 1994*, June 1994.

TNRCC 1995a — Texas Natural Resource Conservation Commission, *Fact Sheet for Permit to Dispose of Wastes Under Provisions of Chapter 26 of the Texas Water Code*, Permit No. 02296 (Renewal), July 26, 1995.

TNRCC 1995b — Texas Natural Resource Conservation Commission, *Modeling Analysis of the Pantex Plant Amarillo, Texas*, Austin, TX, June 1995.

TNRCC 1995c — Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Annual 1994 Report*, Monitoring Operations Division, September 1995.

TNRCC 1994d — Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Annual Report*, Austin, TX, September, 1995.

TNRCC 1996 — Texas Natural Resource Conservation Commission, *(Draft Revision) Permit for Industrial Solid Waste Management Site*, Permit No. HW-50284, Austin, TX, February 1996.

TNRCC 1996a — Texas Natural Resource Conservation Commission, *Effective Screening Levels (ESLs)*, Modeling Division, Austin, TX, April 15, 1996.

TNRCC 1996b — Texas Natural Resource Conservation Commission, *Permit to Dispose of Wastes Under Provisions of Chapter 26 of the Texas Water Code, Permit No. 02296*, Corresponds to NPDES Permit No. TX0107107, effective June 14, 1996.

TNRCC 1996c — Texas Natural Resource Conservation Commission, *Class 3 MOD; Permit HW50284, Wastewater Treatment Facility issued pursuant to Chapter 26 of the Texas Water Code*, Texas Natural Resource Conservation Commission, Austin, TX, February 27, 1996.

TNRCC 1996d — Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Quarterly Report, July-September 1995*, March 1996.

TNRCC 1996e — Texas Natural Resource Conservation Commission, *Pantex Nuclear Weapons Facility Ambient Air Monitoring Quarterly Report*, October-December 1995, June 1996.

TPW 1992 — Texas Parks and Wildlife Department, *Texas Threatened and Endangered Species*, Endangered Resources, Austin, TX, January 1992.

TPW 1993 — Texas Parks and Wildlife Department, *Special Plant List*, Texas Natural Heritage Program, Austin, TX, October 1993.

TSDC 1994 — Texas State Data Center, *Estimates of the Total Populations of Counties and Places in Texas*, Table 1, prepared by the Department of Rural Sociology, Texas Agricultural Experiment Station, Texas A&M University, College Station, TX, November 1994.

TT 1995 — *Quality Assurance Program Plan*, TTAL, QA-95-001, prepared by Tetra Tech, Inc., Albuquerque, NM, for the U.S. Department of Energy, Albuquerque Operations Office, Albuquerque, NM, March 1995.

TTU 1988 — Bolen, E.G., and D.L. Flores, *Prairie Wetlands of West Texas: The History and Ecology of Playa Lakes*, Texas Tech University, Lubbock, TX, 1988.

TTU 1994 — Greer, James Dupree, *Comparison of Infiltration and Evaporation Volumes for the Five Pantex Playa Lakes,* a master report prepared by Texas Tech University, Lubbock, TX, July 25, 1994.

TTU 1994a — Pezzolesi, T.P., *Nutrient and Heavy Metal Cycling in a Playa Lake Wetland Receiving Wastewater,* Texas Tech University, Lubbock, TX, 1994.

TWC 1991 — Texas Water Commission, *Permanent Rule Change Chapter 307 Texas Surface Water Quality Standards 307.2-307.10,* Effective July 1991.

TWC 1991a — Texas Water Commission, *Permit for Industrial Solid Waste Management Site*, Permit No. HW-50284, Austin, TX, April 1991.

TWD 1991 — Texas Water Development Board, *Surveys of Irrigation in Texas 1958, 1964, 1969, 1974, 1979, 1984, and 1989*, Report 329, prepared by the Soil Conservation Service, U.S. Department of Agriculture, Texas State Soil & Water Conservation Board, and Texas Water Development Board, Austin, TX, January 1991.

TWD 1993 — Peckham, D.S., and J.B. Ashworth, *The High Plains Aquifer System of Texas, 1980 to 1990 Overview and Projections,* Draft, prepared by Texas Water Development Board, Austin, TX, September 1993.

TX Cen 1952 — Bureau of the Census, *1950 Census of Agriculture, Counties and State Economic Areas–Texas,* Volume 1, Part 26, Tables 1,4,5, and 6, U.S. Department of Commerce, Washington, DC, 1952.

TX Cen 1961 — Bureau of the Census, *1960 Census of Population, Characteristics of the Population–Texas*, Volume 1, Part 45, Table 6, U.S. Department of Commerce, Bureau of the Census, Washington, DC, 1961.

TX Cen 1967 — Bureau of the Census, *1964 Census of Agriculture, Statistics for the State and Counties–Texas,* Volume 1, Part 37, Tables 1,5 and 11, U.S. Department of Commerce, Washington, DC, 1964.

TX Cen 1972 — Bureau of the Census, *1969 Census of Agriculture, Texas,* Volume 1, Part 37, Tables 1, 3, 13, U.S. Department of Commerce, Washington, DC, 1972.

TX Cen 1973 — Bureau of the Census, *1970 Census of Population, Characteristics of the Population–Texas*, Volume 1, Part 45, Table 9, U.S. Department of Commerce, Social and Economic Statistics Administration, Bureau of the Census, Washington, DC, 1973.

TX Cen 1981 — Bureau of the Census, *1978 Census of Agriculture, State and County Data–Texas,* Tables 1, 3, 11; U.S. Department of Commerce, Washington, DC, 1981.

TX Cen 1982 — Bureau of the Census, *1980 Census of Population, General Population Characteristics–Texas,* Table 14, U.S. Department of Commerce, Bureau of the Census, Washington, DC, 1982.

TX Cen 1989 — Bureau of the Census, *1987 Census of Agriculture, State and County Data–Texas,* Volume 1, Part 43, Tables 1, 16, U.S. Department of Commerce, Washington, DC, 1989.

TX Cen 1992 — Bureau of the Census, *1990 Census of Housing, General Housing Characteristics–Texas,* 1990 CH-1-45, Tables 49, 50, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, October 1992.

TX Cen 1992a — Bureau of the Census, *1990 Census of Population General Population Characteristics–Texas,* 1990 CP-1-45, Tables 1, 2, 5, and 6, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, June, 1992.

TX Cen 1993 — Bureau of the Census, *1990 Census of Population, Social and Economic Characteristics–Texas,* 1990 CP-2-45, Tables 3, 144, 145, 146, 147, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, September 1993.

TX Cen 1993a — Bureau of the Census, *1990 Census of Population and Housing, Population and Housing Characteristics for Census Tracts and Block Numbering Areas, Outside Metropolitan Areas–Texas,* Tables 8, 19, CPH-3-45, U.S. Department of Commerce, Washington, DC, 1993.

TX Cen 1993b — Bureau of the Census, *Detailed Housing Characteristics–Texas,* 1990 Census, Table 66, U.S. Department of Commerce, Washington, DC, 1993.

TX Cen 1993c — Bureau of the Census, *1990 Census of Population and Housing, Population and Housing Characteristics for Census Tracts and Block Numbering Areas, Amarillo, Texas Metropolitan Statistical Area,* Tables 8 and 19, CPH-3-66, U.S. Department of Commerce, Washington, DC, 1993.

TX Cen 1993d — Bureau of the Census, *1990 Census of Population and Housing, Population and Housing Unit Counts–Texas,* 1990 CPH-2-45, Table 4, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, March 1993.

TX Cen 1994 — Bureau of the Census, *1992 Census of Agriculture-Texas, State and County Data,* Tables 1, 14, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, 1994.

TX Cen 1994a — Bureau of the Census, *1992 County Business Patterns-Texas*, CBP-92-45, U.S. Department of Commerce, Economics and Statistics Administration Bureau of the Census, Washington, DC, October 1994.

TX Cen 1996 — Bureau of the Census, *1990 and 1995 State and County Population–Texas*, http:\\www.census.gov, downloaded off the Internet, September 18, 1996.

TX Cen 1996a — Bureau of the Census, *Population Estimates for Metropolitan Areas (MAs) Outside of New England, July 1, 1990 to July 1, 1995, Texas*, http:\\www.census.gov, downloaded off the Internet, September 19, 1996.

UN 1995 — Nevada Small Business Development Center, Bureau of Business and Economic Research, College of Business Administration, University of Nevada, Reno, NV, 1995.

USAF 1978 — U.S. Department of the Air Force, the Army, and the Navy, *Environmental Protection, Planning the Noise Environment*, AFM 19-10, TM 5-803-2 NAVFAC P-970, Washington, DC, 1978.

USAF 1979 — U.S. Department of the Air Force, *Flooded Areas Arroyo del Coyote, Kirtland Air Force Base* (topographic map), 1979.

USAF 1993 — U.S. Department of the Air Force, *Draft Environmental Impact Statement, Disposal and Reuse of Bergstrom Air Force Base, Texas*, Bergstrom Air Force Base, TX, January 1993.

USAF 1993a — U.S. Department of the Air Force, *Consolidation of Phillips Laboratory Split Directories KAFB, New Mexico, Environmental Assessment*, Albuquerque, NM, July 1993.

USAF 1994 — Earth Tech, Inc., *Environmental Assessment, Transportation and Storage of Rocket Systems, Launch Program Solid Rocket Motors, Kirtland AFB, NM*, prepared for the U.S. Department of the Air Force, July 1994.

USCOE 1987 — *Corps of Engineers Wetlands Delineation Manual*, Wetlands Research Program Technical Report, Y-87-1, AD/A176 734, U.S. Army Corps of Engineers, Waterways Experiment Station, Environmental Laboratory, Vicksburg, MS, 1987.

USCOE 1994 — Largent, F.B., Jr., and F. Winchell, et al., *A Cultural Resources Survey of 4,200 Acres at the U.S. Department of Energy Pantex Plant Facility, Carson County, Texas*, prepared under Contract DACW56-92-D-0010, by Geo-Marine, Inc., Plano, TX, for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, July 1994.

USCOE 1994a — Radian Corporation, *Preliminary Recommendations Memorandum for Flow System No. 1, Pantex RCRA Facility Investigation Ditches and Playas, ADS 1216*, Volume 1 of 3, prepared under Contract RCN269-045-19-01 for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, March 1994.

USCOE 1994b — Winchell, F., and F.B. Largent, Jr., et al., *Test Excavations of 23 Archaeological Sites at the U.S. Department of Energy Pantex Plant Facility, Carson County, TX, Draft*, Report No. 73, prepared by Geo-Marine, Inc., Plano, TX for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, May 1994.

USCOE 1994c — Radian Corporation, *Preliminary Recommendations Memorandum for Flow System No. 5, Pantex RCRA Facility Investigation Ditches and Playas*, ADS 1216, prepared under Contract RCN-269-045-19-01 for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, January 1994.

USCOE 1995 — IT Corporation, *Draft Final RCRA Facility Investigation Report for the Burning Grounds Assessment ADS 1232 (AL-PX-01) U.S. Department of Energy Pantex Plant, Amarillo, Texas,* Project No. 448109, prepared by IT Corporation, Austin, Texas, for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, May 1995.

USCOE 1995a — U.S. Army Corps of Engineers, *Groundwater Assessment, Monitoring Quarterly Report, November 1994 Sampling Round, Preliminary Data Package,* prepared for the U.S. Department of Energy, Pantex Plant, Amarillo, TX, May 1995.

USCOE 1995b — U.S. Army Corps of Engineers, Tulsa District, *Pantex Plant Well Location Map*, prepared by J. Martell and D. Wilkins, Tulsa, OK, February 2, 1995.

USCOE 1995c — U.S. Army Corps of Engineers, *Wetland Inventory Survey, Kirtland Air Force Base,* Albuquerque, NM, 1995.

USCOE 1995e — IT Corporation, *RCRA Facility Investigation Report for the Miscellaneous Chemical Spills/Releases ADS 1198 (AL-PX-12) U.S. Department of Energy Pantex Plant, Amarillo Texas,* prepared by IT Corporation, Austin, Texas, for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, August 1995.

USCOE 1995f — Radian Corporation, *Draft RFI Report Pantex RCRA Facility Investigation AL-PX-8 Ditches and Playas, ADS 1216,* Volume 1 of 5, prepared by Radian Corporation, Austin, Texas, for the U.S. Army Corps of Engineers, Tulsa District, Tulsa, OK, September 11, 1995.

USDA 1962 — Jacquot, L.L., *Soil Survey, Carson County, Texas,* U.S. Department of Agriculture, Soil Conservation Service in cooperation with the Texas Agriculture Experiment Station, Washington, DC, July 1962.

USDA 1981 — *Pullman Soils: Distribution, Importance, Variability, and Management,* Texas Agricultural Station, College Station, TX, in cooperation with the U.S. Department of Agriculture, Agricultural Research Service and Soil Conservation Service, 1981.

USGS 1973	U.S. Geological Survey, *Sevenmile Basin Quadrangle Texas 7.5 Minute Series Topographic Map,* U.S. Department of Interior, Denver, CO, 1953, Photorevised 1967 and 1973.
USGS 1976	Bedinger, M.S., and R.T. Sniegocki, *Summary Appraisals of the Nations Ground-Water Resources, Arkansas-White-Red Region,* USGS Professional Paper 813-H, U.S. Geological Survey, U.S. Department of Interior, Washington, DC, 1976.
WA Cen 1991	Bureau of the Census, *1990 Census of Population and Housing, Summary Population and Housing Characteristics,* Washington, Table 17, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, 1991.
WA Cen 1992	Bureau of the Census, *1990 Census of Population General Population Characteristics-Washington,* Table 6, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, 1992.
WA Cen 1993	Bureau of the Census, *1990 Census Social and Economic Characteristics-Washington,* Table 145, 229, U.S. Department of Commerce, Economics and Statistics Administration, Bureau of the Census, Washington, DC, 1993.
Weiner 1991	Weiner, R. F., P.A. LaPlante, J.P. Hageman, "An Approach to Assessing the Impacts of Incident-Free Transportation of Radioactive Materials: II Highway Transportation," *Risk Analysis*, Vol. II, No. 4, pp. 661-666, 1991.
WHC 1986	Westinghouse Hanford Company, *Fuel Cycle Plant-Final Safety Analysis Report,* prepared under Contract DE-AC06-76FF02170.39, for the U.S. Department of Energy, 1986.
WHC 1991	Westinghouse Hanford Company, *Aircraft Hazards to the Fast Flux Test Facility*, Richland, WA, November 1991.
WSRC 1994	Westinghouse Savannah River Company, *Savannah River Site Environmental Report for 1993*, WSRC-TR-94-075, prepared under Contract DE-AC09-89SR18035, for the U.S. Department of Energy, Savannah River Site, Aiken, SC, 1994.
WTU 1995	Blair, Kathleen B., *Swift Fox Survey at Pantex Plant Site, Carson County Texas*, Contract No. DE-AC04-94AL98863, Subcontract No. 030651, prepared by Kathleen B. Blair, West Texas A&M University, Canyon, Texas, for the U.S. Department of Energy, September 1995.
WTU 1996	Blair, Kathleen B., *Swift Fox (Vuipes Veiox) Live Trapping at Pantex Plant Site,* Carson County Texas, Contract No. DE-AC04-94AL98863, Subcontract No. 030651, prepared by Kathleen B. Blair, West Texas A&M University, Canyon, TX, for the U.S. Department of Energy, July 15, 1996.

List of Preparers

CHAPTER 8
LIST OF PREPARERS

Chapter 8 provides information about the people who participated in the preparation of this EIS. The names of these individuals, their role in the preparation of the document, organizational affiliation, education, and years of experience are listed.

Avara, Everett W., Community Relations Specialist, Tetra Tech, Inc.
B.A., Broadcast Journalism (Major) and Government (Minor), 1987, New Mexico State University, Las Cruces, New Mexico
Years of Experience: 9

Bailey, Edward R., Quality Assurance/Quality Control, Tetra Tech, Inc.
M.A., Environmental Administration, 1983, University of California, Riverside
B.S., Environmental Science, 1980, University of California, Riverside
Years of Experience: 14

Bartosch, James P., Waste Management, Pollution Prevention, and Facilities and Infrastructure Technical Lead, Tetra Tech, Inc.
B.S., Chemical Engineering, 1985, Syracuse University, Syracuse, New York
Years of Experience: 11

Bender, Gary L., Waste Management and Pollution Prevention Author, Advanced Sciences, Inc.
B.S., Business Management, 1981, University of Idaho, Moscow, Idaho
Years of Experience: 15

Bibiano, Angela, Word Processor, Tetra Tech, Inc.
Years of Experience: 17

Black, E. Cecil, Program Manager, Tetra Tech, Inc.
M.P.A., Public Administration, 1977, University of Oklahoma, Norman, Oklahoma
M.M.A.S., Military Arts and Sciences, 1976, United States Army Command and General Staff College, Fort Leavenworth, Kansas
B.S., Management, 1965, Mississippi State University, Mississippi State, Mississippi
Years of Experience: 31

Blair, Kathleen, Swift Fox Survey, West Texas A&M University
Ph.D., Mammalogy, 1989, Oklahoma State University, Stillwater, Oklahoma
M.S., Zoology, 1978, Oklahoma State University, Stillwater, Oklahoma
B.S., Wildlife Fisheries Conservation, 1975, Kansas State University, Manhattan, Kansas
Years of Experience: 21

Bolin, John M., Frequency Assessment Analyst, Scientech, Inc.
B.S., Nuclear Engineering, 1982, University of Cincinnati, Cincinnati, Ohio
Years of Experience: 14

Brasier, Robert I., Senior Technical Advisor, Tetra Tech, Inc.
M.B.A., Business Administration, 1980, University of New Mexico, Albuquerque, New Mexico
Sc.D., Engineering (Mechanical and Nuclear), 1965, University of New Mexico, Albuquerque, New Mexico
M.S., Mechanical Engineering, 1958, University of New Mexico, Albuquerque, New Mexico
B.S., Mechanical Engineering, 1949, University of Missouri, Columbia, Missouri
Years of Experience: 47

Brownlie, William R., P.E., Quality Assurance Manager, Tetra Tech, Inc.
Ph.D., Civil Engineering, Hydraulics, 1981, California Institute of Technology, Pasadena, California
M.S., Civil Engineering, Hydraulics/Water Resources, 1976, State University of New York, Buffalo, New York
B.S., Civil Engineering, 1975, State University of New York, Buffalo, New York
Years of Experience: 21

Butler, Rebecca, Document Production Supervisor, Tetra Tech, Inc.
B.A., Advertising, 1991, Marquette University, Milwaukee, Wisconsin
Years of Experience: 5

Cantrell, Robert T., Frequency Assessment Analyst, Scientech, Inc.
M.S., Nuclear Engineering, 1974, University of California, Berkeley, California
B.S., Physics, 1972, University of California, Berkeley, California
Years of Experience: 22

Carrara, Pier L., Human Health Risk Assessment Author, Scientech, Inc.
B.S., Mathematics and Statistics, 1974, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 22

Chung, Donald T., Consequence Assessment Task Leader, Scientech, Inc.
Ph.D., Nuclear Engineering, 1988, University of Maryland, College Park, Maryland
B.S., Materials Science and Nuclear Engineering, 1979, University of Maryland, College Park, Maryland
Years of Experience: 17

Clauss, David B., Transportation Risk Modeling, Sandia National Laboratories
M.S., Mechanical Engineering, 1980, University of Michigan, Ann Arbor, Michigan
B.S., Mechanical Engineering, 1979, University of Michigan, Ann Arbor, Michigan
Years of Experience: 17

Copus, Ervin R., Transportation Risk Modeling, Sandia National Laboratories
M.S., Nuclear Engineering, 1975, Texas A&M University, College Station, Texas
B.S., Nuclear Engineering, 1974, Texas A&M University, College Station, Texas
Years of Experience: 22

Dallman, R. Jack, P.E., Human Health Risk Assessment Technical Lead, Scientech, Inc.
M.S., Mechanical Engineering, 1978, University of Nebraska, Lincoln, Nebraska
B.S., Mechanical Engineering, 1977, University of Nebraska, Lincoln, Nebraska
Years of Experience: 18

Donahoe, Sean B., Biotic Uptake Analysis, Tetra Tech, Inc.
M.S., Biology, 1987, West Virginia University, Morgantown, West Virginia
B.S., Biology, 1985, Fairmont State College, Fairmont, West Virginia
B.S., Mathematics, 1985, Fairmont State College, Fairmont, West Virginia
Years of Experience: 11

Everline, Chester J., Risk Assessment Project Manager, Scientech, Inc.
B.S., Nuclear Science and Engineering, 1972, Rensselaer Polytechnic Institute, Troy, New York
Years of Experience: 24

Faich, Ronald G., Socioeconomics and Environmental Justice Technical Lead, Tetra Tech, Inc.
Ph.D., Sociology and Quantitative Research Methods, 1969, University of Wisconsin, Madison, Wisconsin
M.S., Sociology and Quantitative Research Methods, 1964, University of Wisconsin, Madison, Wisconsin
B.S., Mathematics (Major) and Physics (Minor), 1961, University of Wisconsin, Madison, Wisconsin
Years of Experience: 35

Farley, Kimberly D., Land Resources Technical Lead, Cultural Resources and Pollution Prevention Author, Advanced Sciences, Inc.
Ph.D., American Government, Public Administration, Environmental and Energy Policy, 1990, Texas Tech University, Lubbock, Texas
M.P.A., Public Administration, 1982, Texas Tech University, Lubbock, Texas
B.S., Political Science, 1980, University of Wyoming, Laramie, Wyoming
Years of Experience: 16

Founds, Nanette D., Project Manager, U.S. Department of Energy, Albuquerque Operations Office
B.S., Aeronautical Engineering, 1983, U.S. Air Force Institute of Technology, Wright-Patterson Air Force Base, Ohio
B.S., Chemistry, 1980, Nebraska University, Lincoln, Nebraska
Years of Experience: 16

Gomez, Anthony E., Word Processor, Tetra Tech, Inc.
B.S., Psychology (Major) and Computer Science (Minor), 1991, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 8

Greenly, Davin G., Aircraft Crash, Transportation, and Biota Analyses, Tetra Tech, Inc.
B.S., Environmental Engineering, 1994, California Polytechnic State University, San Luis Obispo, California
Years of Experience: 2

Greenspan, Jay, Technical Editor/Computer Network Administrator, Tetra Tech, Inc.
B.A., English, 1990, State University of New York at Albany, Albany, New York
Years of Experience: 6

Griffith, Richard O., Project Manager/SMTS, Modeling and Analysis Department, Sandia National Laboratories
Ph.D., Nuclear Engineering, 1990, Texas A&M University, College Station, Texas
M.S., Nuclear Engineering, 1986, Texas A&M University, College Station, Texas
B.S., Nuclear Engineering, 1984, Arizona State University, Tempe, Arizona
Years of Experience: 12

Hare, Gustin L., Air Quality Modeling, Water Quality, Soils, and Waste Management Analyses, and Comment Management, Tetra Tech, Inc.
B.S., Environmental Science, 1994, West Texas A&M University, Canyon, Texas
Years of Experience: 2

Hauquitz, George A., Quality Assurance Officer, Tetra Tech, Inc.
Years of Experience: 43

Jarman, Clifford J., Document Manager, Physical Sciences Group Manager, Tetra Tech, Inc.
M.S., Geophysics, 1989, New Mexico Institute of Mining and Technology, Socorro, New Mexico
B.S., Geology, 1985, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 11

Jensen, Kari J., Word Processor, Tetra Tech, Inc.
Years of Experience: 2

Jessen, James P., Transportation Risk Assessment Technical Lead, Human Health and Aircraft Crash Analyses, Tetra Tech, Inc.
Ph.D. Candidate, Environmental Engineering, University of Washington, Seattle, Washington
M.S., Nuclear Engineering and Radiological Health (Health Physics Emphasis), 1989, University of Washington, Seattle, Washington
B.S., Chemical and Nuclear Engineering, 1988, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 8

Johns, Lisa A., Socioeconomics, Environmental Justice, Water Resources Research Analyst, and Document Integrator, Tetra Tech, Inc.
B.A., Sociology, 1982, University of Pittsburgh, Pittsburgh, Pennsylvania
Years of Experience: 14

Johns, William H., Manager of Environmental Sciences, Tetra Tech, Inc.
B.S., Geography, 1988, Texas A&M University, College Station, Texas
Years of Experience: 14

Johnston, Marshall C., Floristic Survey, Consultant
Ph.D., Botany, 1955, University of Texas, Austin, Texas
M.S., Botany, 1952, University of Texas, Austin, Texas
B.S., Geology, 1951, University of Texas, Austin, Texas
Years of Experience: 26

Jones, Rebecca L., Public Information Center Librarian and Technical Assistant, Tetra Tech, Inc.
B.A., Radio, Television, and Film, 1987, West Texas State University, Canyon, Texas
Years of Experience: 9

Kirk, Dee A., Geology and Soils Technical Lead, Tetra Tech, Inc.
M.S., Geology, 1991, New Mexico State University, Las Cruces, New Mexico
B.S., Geology, 1987, Lake Superior State University, Sault Ste. Marie, Michigan
Years of Experience: 9

Kirk, Tim L., P.E., Water Resources and Infrastructure Author, Tetra Tech, Inc.
M.S., Civil Engineering (Environmental), 1993, New Mexico State University, Las Cruces, New Mexico
B.S., Mechanical Engineering, 1989, Texas Tech University, Lubbock, Texas
Years of Experience: 7

Knight, Terry L., Cultural Resources Technical Lead, Land Resources Technical Lead, and Document Integrator, Tetra Tech, Inc.
B.A., Anthropology, 1979, New Mexico State University, Las Cruces, New Mexico
Years of Experience: 20

Lilga, Mary C., Land Resources Author, Advanced Sciences, Inc.
M.S., Geology, 1984, University of New York—Fredonia, Fredonia, New York
B.S., Geology, 1976, Edinboro University of Pennsylvania, Edinboro, Pennsylvania
Years of Experience: 9

Lin, Tom, Radar Aircraft Monitoring System Data Collection and Processing, Sandia National Laboratories
Ph.D., Electrical Engineering, 1974, Ohio State University, Columbus Ohio
M.S., Electrical Engineering, 1966, Virginia Polytechnic Institute and State University, Blacksburg, Virginia
Years of Experience: 30

Luna, Robert E., Aerosol Deposition, Source Term Definition, and Weapon Accident Phenomenology, Sandia National Laboratories
MMgmt, 1985, Anderson Schools of Management, University of New Mexico, Albuquerque, New Mexico
Ph.D., Aerospace and Mechanical Sciences, 1965, Princeton University, Princeton, New Jersey
M.S.E., Mechanical Engineering, 1963, Princeton University, Princeton, New Jersey
B.S., Mechanical Engineering, 1960, Rutgers University, Rutgers, New Jersey
Years of Experience: 32

Mathur, Raj B., Deputy Program Manager, Tetra Tech, Inc.
Ph.D., Economic Geography, 1972, University of Minnesota, Minneapolis, Minnesota
M.A., Economics, 1960, Punjab University, Chandigarh, India
B.A., Geography, 1957, Punjab University, Chandigarh, India
Years of Experience: 38

Moieni, Parviz, Frequency Assessment Analyst, Scientech, Inc.
Ph.D., Nuclear Engineering 1983, University of California, Los Angeles, California
M.S., Nuclear Engineering, 1980, University of California, Los Angeles, California
B.S., Mechanical Engineering, 1977, Shiraz University, Shiraz, Iran
Years of Experience: 13

Monks, Katherine S., C.G.P., R.P.G., Water Resources Technical Lead, Tetra Tech, Inc.
M.S., Geology and Hydrogeology, 1987, Wright State University, Dayton, Ohio
B.S., Geology, 1983, Ohio University, Athens, Ohio
Years of Experience: 11

Moore, Jason B., Comment Management, Water Resources, Pollution Prevention, Tetra Tech, Inc.
B.A., Earth and Planetary Sciences (Major) and Biology (Minor), 1994, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 2

Moreland, William B., C.C.M., Air Quality and Acoustics Technical Lead, Tetra Tech, Inc.
M.A., Meteorology, 1953, University of California at Los Angeles, Los Angeles, California
B.A., Meteorology, 1948, University of California at Los Angeles, Los Angeles, California
Years of Experience: 48

Navarrete, Donna L., Technical Editor, Tetra Tech, Inc.
B.A. Candidate, English, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 13

O'Leary, Jim, Computer Network Administrator and Illustrator, Tetra Tech, Inc.
Years of Experience: 4

Petraglia, Jeffrey P., Aircraft Crash Analysis Technical Lead, Tetra Tech, Inc.
M.Eng., Nuclear Engineering, Pennsylvania State University, University Park, Pennsylvania
B.S., Nuclear Engineering, Pennsylvania State University, University Park, Pennsylvania
Years of Experience: 14

Pitts, Rachel E., Librarian and Security Specialist, Tetra Tech, Inc.
B.S., Sociology, 1974, Arizona State University, Tempe, Arizona
A.S., Fine Arts Education, 1988, Northern Virginia Community College, Fairfax, Virginia
Years of Experience: 22

Pratt, George K., Life Sciences Group Manager, Tetra Tech, Inc.
Ph.D., Entomology, 1981, University of Georgia, Athens, Georgia
M.S., Entomology, 1973, University of Georgia, Athens, Georgia
B.S., Biology (Major), Chemistry (Minor), 1971, Emory University, Atlanta, Georgia
Years of Experience: 25

Reed, Jack W., C.C.M., Acoustic Modeling, JWR, Inc.
B.S., Mathematics, 1948, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 48

Rosson, David E., Jr., Senior Program Manager, U.S. Department of Energy, Albuquerque Operations Office
B.S., Metallurgical Engineering, 1963, University of Tennessee, Knoxville, Tennessee
Years of Experience: 33

Sagartz, Mathias J., Transportation Risk Modeling, Sandia National Laboratories
Ph.D., Applied Mechanics, 1967, Northwestern University, Evanston, Illinois
M.S., Civil Engineering, 1965, Northwestern University, Evanston, Illinois
B.S., Civil Engineering, 1963, University of Notre Dame, South Bend, Indiana
Years of Experience: 33

Years of Experience: 10

Simpkins, Bret E., Risk Assessment Manager, Tetra Tech, Inc.
M.S., Nuclear Engineering, 1988, University of New Mexico, Albuquerque, New Mexico
B.S., Nuclear Engineering, 1983, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 13

Sinha, Raji, Air Quality and Acoustics Modeling Technical Lead, Tetra Tech, Inc.
Ph.D., Nuclear Engineering, 1990, University of New Mexico, Albuquerque, New Mexico
M.S., Physics, 1976, Polytechnic Institute of Brooklyn, Brooklyn, New York
M.S., Bioengineering, 1976, Polytechnic Institute of Brooklyn, Brooklyn, New York
M.S., Physics (Electronics), 1964, Patna University, Patna, India
B.S., Physics (with Honors), 1962, Patna University, Patna, India
Years of Experience: 34

Schwendenman, Kathryn D., Waste Management Author, Advanced Sciences, Inc.
B.S., Mechanical Engineering, 1984, Virginia Polytechnic Institute and State University, Blacksburg, Virginia
Years of Experience: 12

Tadios, Eden L., Thermal-Hydraulics Analyst, Sandia National Laboratories
M.S., Mechanical Engineering, 1987, University of Michigan, Ann Arbor, Michigan
B.S., Mechanical Engineering, 1985, California State University, Fresno, California
Years of Experience: 10

Torres, Gilbert V., Waste Management Author, Advanced Sciences, Inc.
B.S., Mechanical Engineering, 1980, University of New Mexico, Albuquerque, New Mexico
Years of Experience: 7

Turonek, Marianne V., Illustrator, Tetra Tech, Inc.
Years of Experience: 20

Uedoi, Tammy M., Program Management Support, Tetra Tech, Inc.
M.B.A., Business Administration, 1994, University of San Francisco, San Francisco, California
B.S., Mechanical Engineering, 1989, University of Hawaii at Manoa, Honolulu, Hawaii
Years of Experience: 7

CHAPTER 9

List of Agencies, Organizations, and Individuals to Whom Copies of this EIS are Sent

CHAPTER 9
LIST OF AGENCIES, ORGANIZATIONS, AND INDIVIDUALS TO WHOM COPIES OF THIS EIS ARE SENT

Chapter 9 provides the list of agencies, organizations, and individuals to whom copies of this Draft EIS were distributed. This distribution was made prior to the publication of the Notice of Availability of the Draft EIS. Additional copies of the document are available while supplies last, by written request to the address listed on the cover page of this document.

CHAPTER 10

Glossary

CHAPTER 10
GLOSSARY

This glossary lists terms of art or scientific expression that may not be familiar to some readers of this document. Should a reader need a definition for a term that is not in this list, please contact the Department of Energy, Albuquerque Operations Office, at the address shown on the cover page of this document.

Accident sequence: An initiating event followed by system failures or operator errors that can result in significant core damage, confinement system failure, and/or radionuclide releases.

Acute exposure: The exposure incurred during and shortly after a radiological release. Generally, the period of acute exposure ends when long-term interdiction is established, as necessary. For convenience, the period of acute exposure is normally assumed to end 1 week after the inception of a radiological accident.

Advisory Council on Historic Preservation: A 19-member body appointed to advise the President and Congress in the coordination of actions by Federal agencies on matters relating to historic preservation.

Air Quality Control Region: An interstate area designated by the Environmental Protection Agency for the attainment and maintenance of National Ambient Air Quality Standards.

Air quality standards: The level of pollutants in the air prescribed by regulations that may not be exceeded during a specified time in a defined area.

AL–R8 Pit Packaging: Currently the primary container used at Pantex Plant for pit staging. All AL–R8 containers are constructed of 18-gauge carbon steel. Each AL–R8 container contains Celotex (high-density cane-fiber pressboard) insulation. These containers do not possess an inner containment vessel.

Alluvial deposits: Deposits of earth, sand, gravel, and other materials carried by moving surface water deposited at points of weak water flow.

Ambient air: Ambient air is that portion of the atmosphere, external to the buildings, to which the general public has access.

Ambient sound: At a specified time, the all-encompassing sound associated with a given environment, being usually a composite of sound from many sources at many directions, near and far, including the specified sound source(s) of interest.

Aquatic biota: The sum total of living organisms within any designated aquatic area.

Aquifer: Rock or sediment in a formation, group of formations, or part of a formation that is saturated and sufficiently permeable to transmit economic quantities of water to wells and springs.

Aquitard: A less-permeable geologic unit in a stratigraphic sequence. The unit is not permeable enough to transmit significant quantities of water. Aquitards separate aquifers.

Archaeological sites (resources): Any location where humans have altered the terrain or discarded artifacts during either prehistoric or historic times.

Artifact: An object produced or shaped by human workmanship of archaeological or historical interest.

As low as reasonably achievable: A concept applied to the quantity of radioactivity released in routine operation of a nuclear system or facility, including "anticipated operational occurrences." It takes into account the state of technology, economics of improvements in relation to benefits to public health and safety, and other societal and economic considerations in relation to the use of nuclear energy in the public interest.

Assembly: The process of putting together a nuclear weapon or nuclear weapon component. This process takes place at Pantex Plant.

Atmospheric dispersion: The process of air pollutants being dispersed into the atmosphere. This occurs by the wind that carries the pollutants away from their source and by turbulent air motion that results from solar heating of the Earth's surface and air movement over rough terrain and surfaces.

Attainment area: An area considered to have air quality as good as or better than the National Ambient Air Quality Standards as defined in the *Clean Air Act.* An area may be an attainment area for one pollutant and a non-attainment area for others.

Background Noise: The total acoustical and electrical noise from all sources in a measurement system that may interfere with the production, transmission, time averaging, measurement, or recording of an acoustical signal.

Background radiation: Ionizing radiation present in the environment from cosmic rays and natural sources in the Earth; background radiation varies considerably with location.

Biological dose: The radiation dose absorbed in biological material measured in rem or millirem (one-thousandth of a rem).

Biomass: Literally, "living weight", refers to mass having its origin as living organisms (i.e., plants or animals).

Biota: Living organisms including plants and animals.

Blackwater Draw Formation: Quaternary formation consisting primarily of pedogenically modified eolian sands and silts interbedded with numerous caliche layers. The Blackwater Draw Formation overlies the Tertiary Ogallala Formation at Pantex Plant.

Burning Ground: The place at Pantex Plant where high explosive(s) (HE) are burned in trays. They are defined as Trays Hemisphere, Trays wet HE, and Trays HE.

Burning Ground upgrade: A facility that will be used to decontaminate the high explosive-contaminated components.

Caliche: Gravel, sand, or desert debris cemented by porous calcium carbonate; also the calcium carbonate itself. Found in Mexico and Southwest U.S., calcium carbonate precipitated as surface or near-surface crusts by the evaporation of moisture in the pore spaces of soils.

Cancer: The name given to a group of diseases characterized by uncontrolled cellular growth with cells having invasive characteristics such that the disease can transfer from one organ to another.

Canned Subassemblies: A component in certain nuclear explosives that may contain natural, depleted, or highly enriched uranium.

Capable fault: A fault that has exhibited one or more of the following characteristics (10 CFR 100, Appendix A): 1) Movement at or near the ground surface at least once within the past 35,000 years or movement of a recurring nature within the past 500,000 years, 2) macro-seismicity instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault, or 3) a structural relationship to a capable fault according to characteristics (1) or (2) of this paragraph such that movement on one could be reasonably expected to be accompanied by movement on the other.

Carbon adsorption: A unit physiochemical process in which organic and certain inorganic compounds in a liquid stream are absorbed on a bed of activated carbon; used in water or waste purification and chemical processing.

Chronic exposure: Low-level radiation exposure incurred over a long time period due to residual contamination. Exposure concentration for the chronic standard is less than that of the acute standard.

Cladding: A metal coating bonded onto another metal.

Climatology: The science that deals with climates and investigates their phenomena and causes.

Code of Federal Regulations: All Federal regulations in force are published in codified form in the Code of Federal Regulations.

Community (biotic): All plants and animals occupying a specific area under relatively similar conditions.

Conceptual design: Efforts to develop a project scope that will satisfy program needs; ensure project feasibility and attainable performance levels of the project for Congressional consideration; develop project criteria and design parameters for all engineering disciplines; and identify applicable codes and standards, quality assurance requirements, environmental studies, construction materials, space allowances, energy conservation features, health and safety, safeguards, security requirements, and any other features or requirements necessary to describe the project.

Confined aquifer: A permeable geological unit with an upper boundary that is at a pressure higher than atmospheric pressure.

Conglomerate: A rock that contains rounded rock fragments or pebbles cemented together by another mineral substance.

Conservation Reserve Program: A Federal program which requires land owners to plant croplands with grass and leave uncropped for 10 years. Agricultural Stabilization and Conservation Service administers the program.

Consumptive water use: The difference in the volume of water withdrawn from a body of water and the amount released back into the body of water.

Conex box: A large metal container constructed of carbon steel used for storing waste in the interim period before shipment offsite. Each measures 2.5 x 2.5 x 12 meters (8 x 8 x 40 feet) with a capacity of 72 cubic meters (94 cubic yards).

Cretaceous: The geologic period making up the end of the Mesozoic Era, dating from approximately 144 million to 66 million years ago.

Criteria pollutant: Six air pollutants for which National Ambient Air Quality Standards are established by the Environmental Protection Agency: sulfur dioxide, nitric oxides, carbon monoxide, ozone, particulate matter-10 (smaller than 10 microns in diameter), and lead.

Critical habitat: Defined in the *Endangered Species Act of 1973* as "specific areas within the geographical area occupied by [an endangered or threatened] species..., essential to the conservation of the species and which may require special management considerations or protection; and specific areas outside the geographical area occupied by the species... that are essential for the conservation of the species."

Cultural Resources: Districts, sites, structures, and objects and evidence of some importance to a culture, a subculture, or a community for scientific, traditional, religious, and other reasons. These resources and relevant environmental data are important for describing and reconstructing past lifeways, for interpreting human behavior, and for predicting future courses of cultural development.

Curie: A unit of radioactivity equal to 37 billion disintegrations per second; also a quantity of any nuclide or mixture of nuclides having 1 curie of radioactivity.

Day-night average sound (total): The sound exposure for a 24-hour calendar day calculated by adding the sound exposure obtained during the daytime (0700–2200 hours) to 10 times the sound exposure obtained during the nighttime (000–0700 and 2200–2400 hours).

Day-night sound exposure level (total): Ten times the common logarithm of the ratio of the (total) day-night sound exposure to the reference sound exposure (E0) of 400 micropascals-squared seconds ($400mPa^2s$). Measured in decibel (dB).

Decay (radioactive): The decrease in the amount of any radioactive material with the passage of time, due to the spontaneous transformation of an unstable nuclide into a different nuclide or into a different energy state of the same nuclide; the emission of nuclear radiation (alpha, beta, or gamma radiation) is part of the process.

Decibel: A unit of sound measurement. In general, a sound doubles in loudness for every increase of 10 decibels.

Decibel, A-weighted: A unit of weighted sound pressure level measured by the use of a metering characteristic and the "A" weighting specified by the American National Standard Institute (S1.4-1971[R176]).

Decontamination: The removal of radioactive or chemical contamination from facilities, equipment, or soils by washing, heating, chemical or electrochemical action, mechanical cleaning, or other techniques.

Demilitarization: An irreversible modification or destruction of a weapons component or part of a component to the extent required to prevent use in its original weapon purpose.

Depleted uranium: Uranium whose content of the isotope uranium-235 is less than 0.7 percent, which is the uranium-235 content of naturally occurring uranium.

Deposition: In geology, the laying down of potential rock-forming materials; sedimentation. In atmospheric transport, the settling out on ground and building surfaces of atmospheric aerosols and particles ("dry deposition") or their removal from the air to the ground by precipitation ("wet deposition" or "rainout").

Dismantlement: The process of taking apart a nuclear weapon or nuclear weapon component. This process takes place at Pantex Plant.

Dockum Group: Triassic sedimentary rocks that underlie the Ogallala Formation at Pantex Plant. The Dockum Group rocks consist of shale, clayey siltstone, and sandstone.

Dose: The energy imparted to matter by ionizing radiation. The unit of absorbed dose is the rad.

Dose equivalent: The product of absorbed dose in rad (or gray) and the effect of this type of radiation in tissue and a quality factor. Dose equivalent is expressed in units of rem or Sievert, where 1 rem equals 0.01 Sievert. The dose equivalent to an organ, tissue, or the whole body will be that received from the direct exposure plus the 50-year committed dose equivalent received from the radionuclides taken into the body during the year.

Dosimeter: A small device (instrument) carried by a radiation worker that measures cumulative radiation dose (e.g., film badge or ionization chamber).

Drainage basin: An aboveground area that supplies the water to a particular stream.

Drawdown: The height difference between the natural water level in a formation and the reduced water level in the formation caused by the withdrawal of groundwater.

Drinking-water standards: The prescribed level of constituents or characteristics in a drinking water supply that cannot be exceeded legally.

Ecosystem: Living organisms and their nonliving (abiotic) environment functioning together as a community.

Effluent: A gas or fluid discharged into the environment.

Emission standards: Legally enforceable limits on the quantities and/or kinds of air contaminants that can be emitted into the atmosphere.

Environmental Restoration (ER) program: Program at Pantex Plant responsible for investigation and remediation of Solid Waste Management Units (SWMUs).

Eolian: Pertaining to the wind; especially said of such deposits as loess and dune sand, of sedimentary structures such as wind-formed ripple marks, or of erosion and deposition accomplished by the wind.

Ephemeral stream: A stream that flows only after a period of heavy precipitation.

Epicenter: The point on the Earth's surface directly above the focus of an earthquake.

Epidemiology: The science concerned with the study of events that determine and influence the frequency and distribution of disease, injury, and other health-related events and their causes in defined human population.

Equivalent sound (pressure) level (L_{eq}): The equivalent steady sound level that, if continuous during a specified time period, would contain the same total energy as the actual time-varying sound. For example, L_{eq} (1-h) and L_{eq} (24-h) are the 1-hour and 24-hour equivalent sound level, respectively.

Exceedance level: Sometimes used instead of the term "percentile level".

Exposure limit: The level of exposure to a hazardous chemical (set by law or a standard) at which or below which adverse human health effects are not expected to occur: 1) reference dose is the chronic exposure dose (mg/kg/day) for a given hazardous chemical at which or below which adverse human non-cancer health effects are not expected to occur. 2) Reference concentration is the chronic exposure concentration (mg/m^3) for a given hazardous chemical at which or below which adverse human non-cancer health effects are not expected to occur.

Facultative species: Plant species that are more or less equally likely to occur in wetlands or uplands (i.e., a species that is classified as facultative would be found in wetlands from 33 percent and 66 percent of the time). (Symbol used for these plants is FAC).

Fault: A fracture or a zone of fractures within a rock formation along which vertical, horizontal, or transverse slippage has occurred. A normal fault occurs when the hanging wall has been depressed in relation to the footwall. A reverse fault occurs when the hanging wall has been raised in relation to the footwall.

Fissile material: Plutonium-239, uranium-233, uranium-235, or any material containing any of the foregoing.

Floodplain: The lowlands adjoining inland and coastal waters and relatively flat areas, including at a minimum that area inundated by a 1-percent or greater chance flood in any given year. The base floodplain is defined as the 100-year (1.0 percent) floodplain. The critical action floodplain is defined as the 500-year (0.2 percent) floodplain.

H-gear: Short for "Handling Gear". A container-like structure constructed at a metal frame, possibly containing casters. All have provisions for forklift tines or towing. There are many different sizes for different weapons systems. Some H-gear is for fully assembled weapons. This H-gear cradles the weapon around its mid-section

Hazardous material: A material, including a hazardous substance, as defined by 49 CFR 171.8 which poses a risk to health, safety, and property when transported or handled.

Hazardous waste: Defined by 40 CFR Part 261, as any material that (a) is a solid waste and (b) is a listed hazardous waste (Subpart D), or (c) exhibits any of the characteristics of ignitibility, corrosivity, reactivity, or toxicity (Subpart C).

High explosive: Any chemical compound or mechanical mixture which, when subjected to heat, impact, friction, shock, or other suitable initiation stimulus undergoes a very rapid chemical change with the evolution of large volumes of highly heated gases that exert pressure in the surrounding medium. Defined by 40 CFR Part 261.23 as any material that exhibits the characteristic of reactivity.

Highly enriched uranium: Uranium in which the abundance of the isotope uranium-235 is increased well above normal (naturally occurring) levels.

Hydraulic conductivity: A coefficient describing the rate at which water can move through a permeable medium.

Hydrostratigraphic unit: A formation, part of a formation, or a group of formations in which there are similar hydrologic characteristics that allow for a grouping into aquifers and associated confining layers.

Infrastructure: The basic services, facilities and equipment needed for the functioning and growth of an area.

Injection wells: A well that takes water from the surface into the ground, either through gravity of by mechanical means.

Insolation: A word contracted from the phrase incoming solar radiation that refers, in general, to solar radiation received at the earth's surface. Insolation on a horizontal surface is measure in langleys (1 langley = 1 gram calorie per square centimeter).

Interfluvial: Falling in the area between two streams.

Intersite: Transportation activities involving offsite activities.

Invertebrate: Animals characterized by not having a backbone or spinal column, including a wide variety of organisms such as insects, spiders, worms, clams, crayfish, etc.

Intrasite: Transportation activities occurring solely within the boundaries of a facility.

Isolated Occurrence: A grouping of less than ten artifacts or a single undatable feature. These often consists of redeposited material of questionable locational context that are not related to nearby archaeological sites.

Isotope: Nuclei of the same element with different numbers of neutrons are isotopes of the element. For example, oxygen has 3 stable isotopes containing 8, 9, and 10 neutrons.

Kennedy Kit: Container primarily used for onsite transport at tritium reservoirs. It is a light sheet metal briefcase style container measuring 12" x 10" x 8" with a methane foam liner.

Lacustrine: Found or formed in lakes; also, a type of wetland situated on or near a lake.

Lithic: A stone artifact that has been modified or altered by human hands.

Low-Income population: A population that is classified by the U.S. Bureau of the Census as having an aggregated mean income level for a family of four that correlates to $13,359, adjusted through the poverty index using a standard of living percentage change where applicable, and whose composition is at least 25 percent of the total population of a defined area or jurisdiction.

Llano Estacado: Spanish for "staked plain", used to refer to the Southern High Plains in Texas and New Mexico.

Loam: A rich, permeable soil composed of a mixture of clay, silt, sand, and organic matter.

Low-level mixed waste: Waste containing both radionuclides as defined by the *Atomic Energy Act*, and hazardous constituents as defined by 42 U.S.C. 6901 et seq. and 40 CFR 261.

Low-level waste: Waste that contains radioactivity but is not classified as high-level waste, transuranic waste, spent nuclear fuel, or "11e(2) by-product material" as defined by DOE Order 5820.2A, Radioactive Waste Management. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranic waste is less than 100 nanocuries per gram. Some low-level waste is considered classified because of the nature of the generating process and/or constituents, because the waste would tell too much about the process.

Magazine: A warehouse where explosives and ammunition are stored.

Mammal: Animals in the class Mammalia that are distinguished by having self regulating body temperature, hair, and in females, milk-producing mammary glands to feed their young.

Maximum contaminant level: The maximum permissible level of a contaminant in water delivered to any user of a public water system. Maximum contaminant levels are enforceable standards.

Megawatt: A unit of power equal to 1 million watts. Megawatt thermal is commonly used to define heat produced, while megawatt electric defines electricity produced.

Minority Population: A population that is classified by the U.S. Bureau of the Census as African American, Hispanic American, Asian and Pacific American, American Indian, Eskimo, Aleut, and other non-White persons, whose composition is at least 25 percent of the total population of a defined area or jurisdiction.

Meteorology: The science dealing with the atmosphere and its phenomena, especially as relating to weather.

Migration: The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

Mitigation: The alleviation of adverse impacts on cultural resources by avoidance through project redesign or project relocation, by protection, or by adequate scientific study.

National Ambient Air Quality Standards: Air quality standards established by the *Clean Air Act*, as amended. The primary National Ambient Air Quality Standards are intended to protect the public health with an adequate margin of safety, and the secondary National Ambient Air Quality. Standards are intended to protect the public welfare from any known or anticipated adverse effects of a pollutant.

National Emission Standards for Hazardous Air Pollutants: A set of National emission standards for listed hazardous pollutants emitted from specific classes or categories of new and existing sources. These standards were implemented in the *Clean Air Act Amendments of 1977.*

National Pollutant Discharge Elimination System (NPDES) Permit: Federal regulation (40 CFR Parts 122 and 125) that requires permits for the discharge of pollutants from any point source into the waters of the U.S. regulated through the *Clean Water Act*, as amended.

National Register of Historic Places: A list maintained by the Secretary of the Interior of districts, sites, buildings, structures, and objects of prehistoric or historic local, state, or National significance. The list is expanded as authorized by Section 2(b) of the *Historic Sites Act of 1935* (16 U.S.C. 462) and Section 101(a)(1)(A) of the *National Historic Preservation Act of 1966*, as amended.

Native American: A tribe, people, or culture that is indigenous to the U.S.

Noise: Unwanted or undesirable sound, usually characterized as being so loud as to interfere with, or be inappropriate to, normal activities such as communication, sleep, study or recreation. (See background noise.)

Non-criteria pollutant: A pollutant with an effects screening level guideline. Some non-criteria pollutant have a state standard as well.

Nonattainment area: An air quality control region (or portion thereof) in which the Environmental Protection Agency has determined that ambient air concentrations exceed National Ambient Air Quality Standards for one or more criteria pollutants.

Nuclear weapon: Device with a nuclear component that can produce damage to material and injury or death to personnel upon detonation or ignition.

Obligate species: Plant species that almost always occur in wetlands (i.e., greater than 99 percent of the time).

Occupational Safety and Health Administration: Oversees and regulates workplace health and safety, created by the *Occupational Safety and Health Act of 1970.*

Ogallala Formation: Tertiary formation consisting of gravel, sand, silt, and clay. The principal geologic unit in the High Plains aquifer, comprises the Ogallala aquifer in the Texas Panhandle, the primary source of groundwater in the region. The top of the Ogallala Formation in large areas of Texas and New Mexico consists of a resistant caliche layer. The Ogallala Formation at Pantex overlies the Triassic Dockum Group strata and underlies the Quaternary Blackwater Draw Formation.

Offsite: Outside the Pantex Plant Site boundary.

Onsite: Within the Pantex Plant Site boundary.

Ozone: The triatomic form of oxygen; in the stratosphere, ozone protects the Earth from the sun's ultraviolet rays, but in lower levels of the atmosphere ozone is considered an air pollutant.

Paleontology: The study of fossils.

Pattern (Aircraft operations): The path followed by an aircraft in the course of one landing and take-off combination. An open pattern is one in which an aircraft arrives in the airport traffic, lands, takes off and leaves the airport traffic. A closed pattern is one in which an aircraft performs touch-and-go landing and take-off one or more times, as in training flights.

Perched aquifer: Groundwater separated from the underlying main body of groundwater, or aquifer, by unsaturated rock.

Peripheral zone: The zone surrounding the playas which is just higher in elevation than the playa floor.

Permeability: The ability of rock or soil to transmit a fluid.

Permian: The last period of the Paleozoic era (after the Pennsylvanian) thought to have covered the span of time between 280 and 225 million years ago; also, the corresponding system of rocks. It is named after the province of Perm, Russia, where rocks of this age were first studied.

Person-rem: The unit of collective radiation dose commitment to a given population; the sum of the individual doses received by a population segment.

Pit: An assembly at the center of a nuclear device containing a sub-critical mass of fissionable material.

Playa: A term used in the southwestern U.S. for a dry, barren area in the lowest part of an undrained desert basin, underlain by clay, silt, or sand, and commonly by soluble salts. It may be marked by an ephemeral lake.

Plume: The elongated pattern of contaminated air or water originating at a point source, such as a smokestack or a hazardous waste disposal site.

Plutonium: A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially in a reactor by bombardment of uranium which neutrons and is used in the production of nuclear weapons.

Pollution prevention: Involves recycling or reduction of any hazardous substance, pollutant, or contaminate before generation.

Potable: Suitable for drinking.

Potentiometric surface: An imaginary surface defined by the level that water will rise to in a tightly-cased well.

Prehistoric: Of, relating to, or existing in times antedating written history. Prehistoric cultural resources are those that antedate written records of the human cultures that produced them.

Programmatic Agreement: A proposed document outlining specific plans for the interim management of cultural resources at Pantex Plant until a comprehensive, long-term Cultural Resource Management Plan is implemented. The parties to the agreement will be the U.S. Department of Energy, the President's Advisory Council on Historic Preservation, and the Texas State Historic Preservation Office.

Pullman soil series: Silty clay loams; soils found in the interplaya areas at Pantex Plant.

Quaternary: The second period of the Cenozoic era, following the Tertiary; also, the corresponding system of rocks. It began two to three Ma and extends to the present. It consists of two epochs, the Pleistocene and the Holocene.

Radiation: The emitted particles or photons from the nuclei of radioactive atoms. Some elements are naturally radioactive; others are induced to become radioactive by bombardment in a reactor. Naturally occurring radiation is indistinguishable from induced radiation.

Radioactive: The state of emitting radiation energy in forms of waves (rays) or particles.

Radioactive waste: Materials from nuclear operations that are radioactive or are contaminated with radioactive materials, and for which use, reuse, or recovery are impractical.

Radioactivity: The spontaneous decay or disintegration of unstable atomic nuclei, accompanied by the emission of radiation.

Radioisotopic Thermoelectric Generators: A small, self-contained, sealed source of thermally produced electricity that is used in the assembly and dissambly of nuclear weapon system.

Radon: A heavy gaseous, radioactive element with a half life of about 4 days.

Randall soil series: Clay soils present in the playa bottoms at Pantex Plant.

Raptor: Birds of prey including various types of hawks, falcons, eagles, vultures, and owls.

Rem: The quantity of absorbed ionizing radiation that has the same biological effect as 1 roentgen of high voltage x-ray radiation.

Remediation: The process, or a phase in the process, of rendering radioactive, hazardous, or low-level mixed waste environmentally safe, whether through processing, entombment, or other methods.

Residual sound: At a specified time, the all-encompassing sound, being usually a composite of sound from many sources at many directions, near and far, remaining at a given position in a given situation when all uniquely identifiable discrete sound sources are eliminated, rendered insignificant, or otherwise not included. Residual sound may be approximated by the percentile sound level exceeded during 90–95 percent of the measurement period.

Risk: A quantitative or qualitative expression of possible loss that considers both the probability that a hazard will cause harm and the consequences of that event.

Risk assessment (chemical or radiological): The qualitative and quantitative evaluation performed in an effort to define the risk posed to human health and/or the environment by the presence or potential presence and/or use of specific chemical or radiological pollutants.

Safety Analysis Report: A safety document providing a concise but complete description and safety evaluation of a site, design, normal and emergency operation, potential accidents, predicted consequences of such accidents, and the means proposed to prevent such accidents or mitigate their consequences. A safety analysis report is designated as final when it is based on final design information. Otherwise, it is designated as preliminary.

Safe Secure Tractor Trailer (SST): A specially designed trailer for transporting nuclear weapons or nuclear weapon components.

Sanitization: A process of destroying or removing classified or other controlled matter, as defined by the *Atomic Energy Act*.

Saturated zone: The zone in which the voids in the rock or soil are filled with water at a pressure greater than atmospheric pressure. The water table is the top of the saturated zone in an unconfined aquifer.

Sedimentation: The process of deposition of sediment, especially by mechanical means from a state of suspension in water.

Seismic: Pertaining to any earth vibration, especially an earthquake.

Seismic zone: An area defined by the Uniform Building Code (1991), designating the amount of damage to be expected as the result of earthquakes. The U.S. is divided into six zones: (1) Zone 0—no damage; (2) Zone 1—minor damage; corresponds to intensities V and VI of the modified Mercalli intensity scale; (3) Zone 2A—moderate damage; corresponds to intensity VII of the modified Mercalli intensity scale (Eastern U.S.); (4) Zone 2B—slightly more damage than 2A (Western U.S.); (5) Zone 3—major damage; corresponds to intensity VII and higher of the modified Mercalli intensity scale; and (6) Zone 4—areas within Zone 3 determined by proximity to certain major fault systems.

Seismicity: The tendency for the occurrence of earthquakes.

Socioeconomics: The social and economic condition in the study area.

Solid Waste Management Unit: Any unit from which hazardous constituents may migrate, as defined by the *Resource Conservation and Recovery Act.* A designated area that is or is suspected to be the source of a release of hazardous material into the environment that will require investigation and/or corrective action.

Sound level: Ten times the common logarithm of the square of the ratio of the frequency-weighted (and time-averaged) sound pressure to the reference sound pressure of 20 micropascals. Measured in decibel (dB). (See sound pressure.)

Sound pressure: Root mean square of the instantaneous sound pressures in a stated frequency band and during a specified time interval, unless another time-averaging process is indicated. Measured in Pascals (Pa). Instantaneous sound pressure is the total instantaneous pressure in a stated frequency band at a point in the presence of a sound wave minus the atmospheric static pressure at that point.

Sound receptor: A location, activity, person, or animal that is exposed, or potentially exposed, to acoustic energy.

Staging: Holding or storing an item temporarily between process steps.

Stratigraphic: Of, relating to, or determined by stratigraphy; the superposition of layers (soil, rock, and other materials) often observed at archaeological sites.

Stratigraphy: Division of geology dealing with the definition and description of rocks and soils, especially sedimentary rocks.

Threatened or Endangered species: Animals, birds, fish, plants, or other living organisms threatened with extinction by man-made or natural changes in their environment. Requirements for declaring species endangered are contained in the *Endangered Species Act of 1973*.

Threshold limit values: The recommended concentrations of contaminants workers may be exposed to according to the American Council of Governmental Industrial Hygienists.

Transmissivity: A measure of a water-bearing unit's capacity to transmit fluid: the product of the thickness and the average hydraulic conductivity of a unit. Also, the rate at which water is transmitted through a strip of an aquifer of a unit width under a unit hydraulic gradient at a prevailing temperature and pressure.

Transuranic (TRU) waste: Waste, without regard to source or form, that is contaminated with alpha-emitting radionuclides of atomic number greater than 92 (uranium) and with half-lives greater than 20 years in concentrations greater than 100m nanocuries per gram.

Treatment, storage, and disposal facility: Any facility that has been permitted by Federal and state regulations to treat, store, or dispose of hazardous waste.

Traditional Cultural Property/Use Area: Areas of significance to the beliefs, customs, and practices of a community of people that have been passed down through generations.

Tritium: A radioactive isotope of the element hydrogen with two neutrons and one proton. Common symbols for the isotope are H–3 and T.

Vertebrate: Animals that are members of the subphylum Vertebrata, including the fishes, amphibians, reptiles, birds, and mammals, all of which are characterized by having a segmented bony or cartilaginous spinal column.

Waste acceptance criteria: Requirements established by treatment, storage, and disposal facilities for the acceptance of waste into the facility.

Waste generator: Any individual or group of individuals that generate radioactive, mixed, hazardous, or other types of wastes at Pantex Plant.

Waste Minimization: Refers to a practice that reduces the environmental or health hazards associated with hazardous wastes, pollutants, or contaminants after generation.

Water Table: Water under the surface of the ground occurs in two zones, an upper unsaturated zone and the deeper saturated zone. The boundary between the two zones is the water table.

Weapon Component: An item in a nuclear weapon that can be either an assembly or individual subset of an assembly. Component can be used interchangeably with "part" or "assembly".

Wetland: Land or areas exhibiting hydric soil concentrations, saturated or inundated soil during some portion of the year, and plant species tolerant of such conditions.

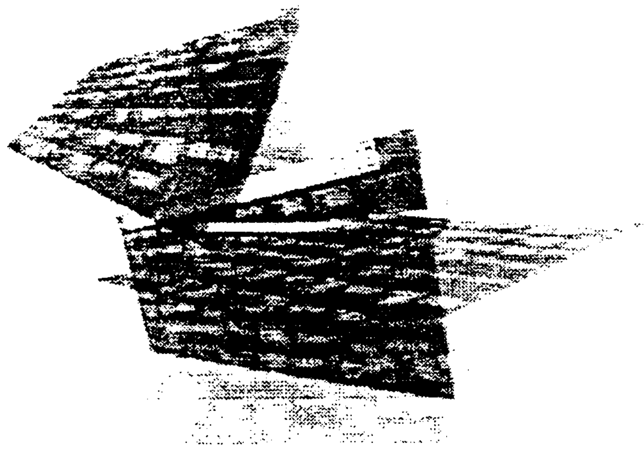
Tailored to Your Needs!



Selected Research In Microfiche

SRIM® is a tailored information service that delivers complete microfiche copies of government publications based on your needs, automatically, within a few weeks of announcement by NTIS.

SRIM® Saves You Time, Money, and Space!

Automatically, every two weeks, your SRIM® profile is run against all *new* publications received by NTIS and the publications microfiched for your order. Instead of paying approximately $15-30 for each publication, you pay only $2.50 for the microfiche version. Corporate and special libraries love the space-saving convenience of microfiche.

NTIS offers two options for SRIM® selection criteria:

Standard SRIM®–Choose from among 350 pre-chosen subject topics.

Custom SRIM®–For a one-time additional fee, an NTIS analyst can help you develop a keyword strategy to design your Custom SRIM® requirements. Custom SRIM® allows your SRIM® selection to be based upon *specific subject keywords*, not just broad subject topics. Call an NTIS subject specialist at (703) 605-6655 to help you create a profile that will retrieve only those technical reports of interest to you.

SRIM® requires an NTIS Deposit Account. The NTIS employee you speak to will help you set up this account if you don't already have one.

For additional information, call the NTIS Subscriptions Department at 1-800-363-2068 or (703) 605-6060. Or visit the NTIS Web site at *http://www.ntis.gov* and select SRIM® from the pull-down menu.

ACRONYMS AND ABBREVIATIONS

ADROIT	Analysis of Dispersal Risk Occurring in Transportation
AGV	Automated Guided Vehicle
AL	Albuquerque Operations Office
ALARA	As Low as Reasonably Achievable
AOC	Area of Concern
AQCR	Air Quality Control Region
ASER	Annual Site Environmental Report
AT&SF RR	Atchison, Topeka and Santa Fe Railroad
BG	Burning Ground
BGU	Burning Ground Upgrade
BNA	Block Numbering Area
BN&SF RR	Burlington Northern and Santa Fe Railroad
BOD	Biological Oxygen Demand
BRAC	Base Realignment and Closure
CAA	Clean Air Act
CAMS	Continuous Air Monitoring Systems
CDP	Census Designated Place
CDR	Conceptual Design Report
CEQ	Council on Environmental Quality
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CFR	Code of Federal Regulations
COC	Contaminant(s) of Concern
COD	Chemical Oxygen Demand
COE	U.S. Army Corps of Engineers
COPC	Contaminant(s) of Potential Concern
CRM	Cultural Resource Management
CRMP	Cultural Resource Management Plan
CSA	Canned Subassembly
CWA	Clean Water Act
CY	Calendar Year
DAF	Device Assembly Facility
DCG	Derived Concentration Guidelines
D&D	Decontamination and Decommissioning
DNL	Day-Night Average Sound Level
DOC	Department of Commerce

DOD	Department of Defense
DOE	Department of Energy
DOI	Department of Interior
DOT	Department of Transportation
DPTRA	Defense Programs Transportation Risk Analysis
EIS	Environmental Impact Statement
EO	Executive Order

µmhos/cm	microhms per centimeter

APPENDIX A

Methodology

APPENDIX A
METHODOLOGY

Introduction

The environmental impact assessment methodologies discussed in this section address the full range of natural and human resources and issue areas pertinent to the continued operations at Pantex Plant. These methodologies are also applicable to the analysis of candidate sites considered for the potential interim storage of pits, as described in chapter 5 of this EIS.

Plant Facilities and Infrastructure

Changes to plant facilities and infrastructure are assessed by comparing the support requirements resulting from the changes in the activity levels at Pantex Plant to projected site infrastructure capacities. These assessments focus on transportation and infrastructure and utilities (including water, wastewater treatment, electricity, and natural gas). Projections of site development plans are used to project site infrastructure conditions. Tables are presented that depict the changes in infrastructure. Where needed, requirements generated by the Proposed Action and Alternatives and mitigation considerations are identified that could reduce impacts due to changes in infrastructure on a site-by-site basis.

Land Resources

Land use changes associated with the changes in the activity levels at Pantex Plant could occur on both the plant site and the surrounding region, and could affect both developed and undeveloped land. The analysis of land use also considers impacts that could result from the activities related to the environmental restoration program and modification of existing facilities or the construction of new facilities on Pantex Plant Site.

The degree to which the alternatives affect future use or development of land at Pantex Plant Site are considered. Land use impacts are assessed based on the extent and type of land that would be affected. The land use analysis also considers potential direct impacts resulting from the incompatibility of land use changes with special-status lands, such as prime and unique farmlands.

Geology and Soils

Geology. Impacts to the geological environment could occur from destruction of or damage to unique geological features and subsidence caused by groundwater withdrawal. The local geology that could affect Pantex Plant operations, including geomorphology, stratigraphy, structural attitude of rocks, and faults and seismicity, are described. The locations of capable faults are identified and an overview of the seismicity of Pantex Plant Site, including the history and significance of earthquakes, along with their intensity and ground acceleration, is presented.

Soils. Soil types at Pantex Plant Site are described. Analysis is provided qualitatively to summarize the potential contaminants of concern in soils at Pantex Plant Site. The analysis describes the potential for contaminating soils and sediments from changing activity levels at Pantex Plant and activities related to the environmental restoration.

Water Resources

The quality and quantity of surface water and groundwater resources are described using available data. Potential effects on surface water and groundwater availability and quality are assessed.

Surface Water. Local surface water resources in the Pantex Plant region and their flow characteristics and relationships are used to describe current conditions. Data used for surface water impact assessments include rates of wastewater discharge from Pantex Plant operations.

The water quality of potentially affected surface water and groundwater is determined by reviewing current monitoring data. Focus is given to parameters that exceed applicable water quality criteria. Surface water quality data and effluent discharge data are compared to U.S. Environmental Protection Agency (EPA) National Pollutant Discharge Elimination System (NPDES) permit and TNRCC Wastewater Discharge Permit limits and requirements for Pantex Plant. The performance of Pantex Plant in complying with the permit requirements is presented. The assessment of water quality impacts from wastewater (sanitary and process) and stormwater runoff qualitatively addresses potential impacts to the receiving waters' minimum or average flow, as available and appropriate.

Floodplains are identified to determine whether any of the continuing or proposed operations or facilities are located within a floodplain.

Groundwater. Groundwater resources are analyzed for effects on aquifers, groundwater usage, and groundwater quality within the Pantex Plant Region of Influence (ROI). The affected environment discussion includes a description of the potentially affected hydrogeologic units. The local aquifers are described in terms of the extent, thicknesses, geologic formations, hydraulic properties, and quality of the groundwater. Groundwater recharge areas are also noted. Total baseline groundwater use at the facility is compiled using the best available data.

Available data on existing groundwater quality conditions are compared to Federal and State groundwater quality standards and DOE-derived concentration guidelines for radionuclides and risk reduction standards. Impacts of groundwater withdrawals from activity levels at Pantex Plant are assessed. Impacts are assessed by the degree to which groundwater quality, drawdown of groundwater levels, and groundwater availability to other users would be affected. Impacts on groundwater quality are based on current and anticipated wastewater discharge rates and applicable permit requirements.

Air Quality

Potential effects on the environment associated with air pollutant emissions from normal operations are evaluated for the current activity levels at Pantex Plant. This is assumed to be equivalent to handling 2,000 weapons per year and includes Burning Ground Upgrade operations. The assessment of air quality impacts includes identification of applicable criteria for assessing impacts, the development of emission inventories, and the estimation of air pollutant concentrations.

The assessment of potential impacts to air quality is based on comparison of effects of the Proposed Action and Alternatives with applicable local, State, or National Ambient Air Quality Standards or the potential exceedance of Prevention of Significant Deterioration increments for PM_{10} (particulate matter of aerodynamic diameter less than 10 micrometers), sulfur dioxide, or nitrogen dioxide.

Assessment criteria for pollutants include the EPA primary and secondary ambient air quality standards for criteria pollutants and those established by the State of Texas. The more stringent of either the EPA or State standards serve as the assessment criteria. The assessment criteria for toxic pollutants include guidelines or standards adopted or proposed by the State of Texas.

Ambient air monitoring data are used to determine maximum background concentrations of pollutants for Pantex Plant Site. Baseline concentrations of pollutants are calculated by modeling site emissions during the baseline year. The baseline concentrations are a conservative estimate of pollutant concentrations at Pantex Plant Site during a period considered representative of recent site activity.

Changes in concentrations of pollutants from the changing activity levels at Pantex Plant are calculated by modeling projected site emissions on an annual basis. Those concentrations are then compared to applicable Federal and State standards for air pollutants to provide an estimate of the potential effects on air quality.

.Modeling of site-specific emissions (using the EPA-recommended Industrial Source Complex Short–Term [ISCST2] Model and Long–Term [ISCLT2] Model) was performed in accordance with EPA's *Guideline on Air Quality Models* (EPA–450/2–78–027R).

Major source criteria and hazardous air pollutant emissions were modeled using actual source locations and stack parameters to determine environmental baseline and criteria pollutant concentrations. Onsite and/or representative National Weather Service meteorological data are used to define the dispersion characteristics of the site.

Acoustics

Acoustic impacts are assessed on the basis of potential degree of change in noise levels at sensitive receptors near the Pantex Plant Site boundary with respect to ambient conditions. The analysis uses available information on the potential types of noise sources and the location of Pantex Plant facilities relative to the site boundary and noise-sensitive locations. The potential for exposure of workers to noise and the measures taken to protect worker hearing are included. Quantitative analysis of blast noise from high explosives detonations is provided using an airblast prediction model called BLASTO.

Biotic Resources

Potential impacts to biotic resources are addressed for the following categories: terrestrial resources, wetlands, aquatic resources, and threatened and endangered species. Changing activity levels at Pantex Plant may affect biotic resources as a result of changes in land use and human disturbance and noise. In general, the potential impacts are assessed based on the degree to which various habitats or species could be affected by the changing activity levels at Pantex Plant. Where appropriate, impacts are evaluated with respect to Federal and State protection regulations and standards.

Terrestrial Resources. Potential impacts to terrestrial resources include loss and disturbance of plant and wildlife habitats. The loss of important or sensitive habitats is considered more important than the loss of a regionally abundant type. Impacts to wildlife are based to a large extent on plant community loss, which is closely associated with animal habitat. The disturbance, displacement, or loss of wildlife was also evaluated in accordance with wildlife protection laws such as the *Migratory Bird Treaty Act* and *Bald and Golden Eagle Protection Act.*

Very small concentrations of radionuclides are released to the atmosphere during operations at Pantex Plant. Results of biouptake of radionuclide levels have been identified from monitoring data.

Wetlands. Most impacts from continued operations at Pantex Plant are related to discharge of contaminants to the playas. Other impacts could potentially occur from construction activities conducted outside of wetland areas. No direct loss of wetlands resulting from construction and operation is expected at Pantex Plant Site. Impacts resulting from changing levels of flows are evaluated based on a comparison of expected discharge rates with present stream flow rates.

Aquatic Resources. Aquatic resources could be impacted as a result of sedimentation, increased flows, effluent discharge, and the introduction of thermal or chemical effluents and radionuclides.

Threatened and Endangered Species. Impacts to threatened and endangered species of wildlife and plants, including critical habitat, State-listed species, and species proposed for listing, are determined. A list of species potentially present on Pantex Plant Site is developed using information obtained from the U.S. Fish and Wildlife Service and appropriate State agencies. Impacts are determined in a manner similar to that described for terrestrial and aquatic resources because the sources of potential impacts are similar.

Cultural and Paleontological Resources

Cultural and paleontological resources include prehistoric, historic, World War II, Cold War, Native American, and paleontological resources.

Prehistoric Resources. The affected environment section for prehistoric resources includes a brief overview of the number and types of prehistoric sites at Pantex Plant Site and their status on both the National Register of Historic Places (NRHP) and appropriate State registers. The overview consists of a summary of existing information about prehistoric resources within the site boundary and a discussion of types of sites that are likely to occur.

Impact assessments for prehistoric resources focus mainly on those properties likely to be eligible for the NRHP. Impacts are assessed by considering whether the Proposed Action and Alternatives could substantially add to existing disturbance of resources in the project areas, adversely affect NRHP-eligible resources, or cause loss of or destruction to important prehistoric resources.

Historic, World War II, and Cold War Resources. The affected environment section for historic resources includes a brief overview, the number and types of historic sites at Pantex Plant Site and their status on both the NRHP and appropriate State registers. Impact assessments for historic resources focus mainly on those properties likely to be eligible for the NRHP.

Native American Resources. Native American concerns have been identified through direct consultation with tribal representatives. Impacts to Native American resources are assessed by considering whether the continued operations at Pantex Plant have the potential to affect sites important for their position in the Native American physical universe or belief system.

Paleontological Resources. The affected environment section for paleontological resources includes a description of known paleontological localities and geological formations at Pantex Plant Site that may be fossil bearing. Impact assessments for paleontological resources are based on the numbers and kinds of resources that could be affected as well as the quality of fossil preservation in a given deposit, particularly in deposits with high research potential.

Socioeconomics

This section describes and assesses impacts on local and regional socioeconomic conditions and factors, including population, employment, and income. This EIS assesses the socioeconomic impacts of both changing levels of activity and potential loss of mission at Pantex Plant. Geographically, the potential for socioeconomic effects is greatest in those local jurisdictions that are the residential locations of the majority of Pantex Plant employees. An

ROI, comprised of those local jurisdictions likely to experience the greatest socioeconomic impacts, is defined for Pantex Plant. The evaluation of impacts is based on the degree to which changes in employment and population affect the local economy on an annual basis. The following sections discuss each of the socioeconomic conditions and factors considered.

Employment. The changing level of activities at Pantex Plant would affect employment at the plant. Changes in plant employment would, in turn, directly affect local and regional populations and income. Current employment at Pantex Plant is described as well as projected employment associated with changing levels of activity at the plant. Emphasis is placed on evaluating total direct and indirect employment changes and impacts associated with potential mission relocations.

Income. The regional economy surrounding Pantex Plant is characterized. Emphasis is placed on the measurement of the relative contribution and importance of Pantex Plant's employment payroll and purchases to the economy. Changes to local economic conditions are evaluated based on the changing activity levels at Pantex Plant.

Population. The demographic changes in the region surrounding Pantex Plant are described and assessed. Demographic characteristics are presented for the ROI to support the assessment of socioeconomic impacts. Cumulative population impacts include the population impacts of other DOE actions under consideration.

Intrasite Transportation

The focus of this analysis is on the intrasite transfer and handling of hazardous materials at Pantex Plant. The impact analysis emphasizes the radiological effects from the transportation of radioactive materials. This focus is consistent with *National Environmental Policy Act* guidance and requirements as follows:

- The performance of Pantex Plant-type operations does not require or produce risk-significant quantities in regards to transportation of nonradioactive hazardous materials; therefore, transportation activities involving hazardous materials are small-scale operations that do not have the potential of causing significant damage to the human environment.
- The radiological hazard, not chemical toxicity, is the dominant risk from Pantex Plant-related transportation activities.

The affected environment includes the discussion of frequency and type of movement of materials within the plant boundaries and handling and packaging of materials onsite.

Accidents involving the transportation and handling of radioactive and hazardous material have the potential to lead to human fatalities, excess cancer fatalities, and serious environmental contamination. Normal transport may expose personnel to ionizing radiation. Impact analysis is conducted using Pantex Plant historical records and Safety Analysis Reports. Radiological exposures and excess cancer fatalities are calculated for the workers handling the materials. Impacts to the public outside the Pantex Plant boundaries are not expected from intrasite transfer and handling of radioactive materials.

Waste Management

Wastes generated during the operation of Pantex Plant facilities consist of four primary types: low-level radioactive waste (LLW), low-level mixed waste (LLMW), hazardous waste (HW), and nonhazardous waste.

Pantex Plant provides for the short-term management and onsite storage of wastes, including the means to minimize waste generation, until DOE either disposes of the wastes or places them in long-term storage. To provide a framework for addressing the impacts of waste management for continued operations at Pantex Plant, descriptive information is presented on waste management activities. The volumes of each waste type generated are estimated. These estimates, obtained from the plant, include consideration of concepts for waste minimization. The impact assessment addresses the waste types and waste volumes projected to be generated from the changing activity levels at Pantex Plant. Impacts are assessed in the context of site practices for treatment, storage, and disposal plus the applicable regulatory requirements.

Human Health

Pantex Plant uses a broad variety of processes involving both radioactive and chemical materials that can be hazardous to people who are exposed to them. The degree of hazard is directly related to the types and quantity of the particular radioactive or chemical material to which the person may be exposed. The health effects are determined for the operations at Pantex Plant by identifying the types and quantities of material to which one is exposed, estimating exposures, and calculating the resultant health effects.

The impacts on human health for workers and the public during normal operations and postulated accidents for the various alternatives are assessed. Computer codes are used to simulate the impacts on the health of workers and the public due to normal operations and postulated accidents. These computer codes include: the Melcor Accident Consequence Code System (MACCS) for airborne and liquid radioactive releases where no explosives were involved; and the Explosive Release Atmospheric Dispersion (ERAD) computer code where explosives were involved. Atmospheric dispersion modeling using the ISCST2 Model performed for the air quality analysis is also used in the evaluation of impacts to workers from radiological and hazardous chemicals.

Health Impacts on Plant Workers During Normal Operation. Because radiation workers are individually monitored, experience from past and current operations that are similar to future operations are used to estimate the radiological health impacts to workers. Health impacts from chemicals are discussed qualitatively. Chemical concentrations onsite are compared to published threshold limit values for chemical substances to determine potential human health impacts.

General Health Impacts on the Public During Normal Operation. Public health impacts could result from exposure to radioactive or hazardous chemical materials released during plant operations. The effect is the sum of internal exposure resulting from breathing air, eating food, drinking water, and of external exposure from standing on contaminated ground and being exposed to the air.

Modeling is used to estimate the type and amount of material released and the associated radiological and chemical doses. These doses are converted to health effects using appropriate health risk estimators.

Accident Analysis for Postulated Accident Scenarios. The relative consequences of postulated accidents in the evaluation of each alternative are considered. For the purpose of this assessment, risk is defined as the mathematical product of the probability and consequences of an accident. The specific accidents consider the types and location of facilities. Examples of accidents include those resulting from operator errors, spills, criticality, fire, explosions, common-cause failures, collocated facilities, severe weather, and earthquakes. Transportation and aircraft crash risks are described separately in this EIS.

A risk screening methodology was used to determine the accident scenarios that resulted in the highest combination of frequency and consequence. In all cases, public risk is dominated by the release and dispersion of radionuclides. In those scenarios that involved an explosion, the ERAD computer code was used to model the dispersion and resulting exposure to workers and the public. For nonexplosive scenarios, the MACCS code was used. Results from the computer modeling are radiological doses to the worker and the public. Worker risk is dominated by explosions without an accompanying release of radionuclides (i.e., the greatest risk to the worker is due to high explosive development, manufacture, and testing activities).

In summary, the radiological and hazardous chemical impact estimates presented in this document were obtained by:

- Using the best available data.
- Using state-of-the-art computational tools.
- Considering the processes, events, and accidents that are reasonably foreseeable for Pantex Plant operations.
- Making conservative assumptions when there is doubt about the exact nature of the processes and events taking place.

Aircraft Accidents

A unique and controversial scenario in the accident risk impact assessment is the potential for an aircraft-induced hazardous material dispersal accident. The likelihood and consequence of this accident scenario have been studied extensively since the start of nuclear explosive operations at Pantex Plant, and these studies continue to this day.

At Pantex Plant, data from a Radar Airspace Monitoring System (RAMS) have been utilized to determine the amount, type, and frequency of aircraft movement in proximity to Pantex Plant. The latest DOE Standard methodology (DOE 1996g) is utilized to estimate the likelihood of an aircraft impacting a Pantex Plant facility containing nuclear materials and causing a release (see appendix E). The estimated change in risk, both from the increased storage of components in Zone 4 and from any predicted changes in aircraft operations in proximity to Pantex Plant identified by the Overflight Working Group and committed to by DOE and the Federal Aviation Administration, is discussed.

Human health risks from aircraft-induced radiological releases are assessed using MACCS. The consequence assessment uses such site-dependent factors as meteorology, population distributions, and onsite facility location. The resulting doses are converted to a predicted number of excess cancer fatalities. Air dispersion of radionuclides following an accidental release not explosively initiated is modeled using MACCS, and air dispersion of radionuclides following an accidental release explosively initiated is modeled using the ERAD computer code package.

Intersite Transportation

The intersite transportation assessment focuses primarily on the transport of radioactive material. A transportation baseline, using historical and projected shipment information, is established for evaluating potential environmental impacts. The packaging required for the shipment of pits is described. Risks are calculated for transporting pits and other nuclear weapon components.

The potential environmental impacts of transporting pits and other nuclear weapon components are determined using existing health and accident risk data. For evaluating risk, the following elements are considered: transport mode, weight of material, curies, proximity dose rates (transport index), type of package, number of shipments, and distance.

The Analysis of Dispersal Risk Occurring in Transportation (ADROIT) code is used to evaluate the accident risk posed by the expected transfers of weapons, plutonium, weapons components, and tritium reservoirs. Developed by Sandia National Laboratories for the Defense Programs Transportation Risk Analysis study, the ADROIT code has unique abilities to evaluate the transportation risk from defense program material. This includes the ability to place ERAD data sets within the code for modeling explosively driven events.

Environmental Justice

The potential for disproportionately high and adverse human health or environmental effects on minority and low income populations are evaluated in accordance with Executive Order 12898, *Federal Action to Address Environmental Justice in Minority Populations and Low Income Populations*. The environmental justice analysis addresses selected demographic characteristics of the Pantex Plant ROI, defined as an 80-kilometer (50-mile) circle centered on Pantex Plant. Similar analyses have also been performed within the ROI for each of the alternate sites considered for interim storage of pits.

The analysis of environmental justice presented in this EIS is based on the definitions of minority and low income populations as contained in the notice for the EPA Office of Environmental Justice (59 FR 192). These definitions call for identification of Census Tracts where 25 percent or more of the persons in 1990 were either minority group members or below poverty level based on their income in 1989. For comparison purposes, definitions of minority and low income populations as provided by the Council on Environmental Quality (CEQ) in August 1995, and also reported in *Guidance for Incorporating Environmental Justice Concerns* in EPA's NEPA Compliance Analysis (EPA 1996a), are also applied to the 1990 Census data and results of both analysis are reported in the EIS.

Cumulative Impacts

Cumulative impacts include the impacts of continued operations at Pantex Plant combined with impacts associated with other reasonably foreseeable projects that could impact the environment at the plant or in the resource-specific ROIs. Although several DOE programs described in section 1.7 of this EIS have the potential to impact the Pantex Plant ROI, sufficient information for incorporation in this document is currently available for only three programs, the Waste Management (WM), Stockpile Stewardship and Management (SSM), and Storage and Disposition of Weapons-Usable Fissile Materials (S&D) programs. Programmatic EISs (PEISs) have been or are being prepared by DOE for each of these programs.

The WM PEIS examines the environmental impacts of managing radioactive and hazardous wastes at DOE Sites throughout the U.S. Pantex Plant was considered one of 17 "major" sites managing DOE wastes. For Pantex Plant, three types of waste were analyzed: LLMW, LLW, and HW. The WM PEIS analyzes the impacts associated with four management alternatives: No Action, Decentralized, Regionalized, and Centralized. The cumulative impacts of the WM program and the alternatives being considered for Pantex Plant operations in this EIS are discussed in each resource section to the extent information is available from the WM PEIS.

The SSM PEIS considered an alternative in which current Pantex Plant operations could be transferred to another site. This Pantex Plant EIS incorporates by reference and summarizes impacts of relocating operations as identified in the SSM PEIS. It is recognized that relocation of operations would involve a transition period during which relocation would occur in a systematic manner, and activities, such as decontamination and decommissioning and environmental restoration, would be accomplished to prepare the Pantex Plant property for disposal. Because a definite schedule for these transition activities is not yet available, it can only be assumed that employment and consumption of utilities at the plant would decline over several years and no sudden impacts would occur.

The S&D PEIS considers activities that would result in storage of inventories of nonsurplus weapons-usable plutonium and highly enriched uranium (HEU); storage of inventories of surplus weapons-usable plutonium and HEU pending disposition; and disposition of surplus weapons-usable plutonium. For storage, the strategy for long-term storage of weapons-usable plutonium and HEU, as well as the storage site(s), would be decided. For disposition, the strategy and technologies for disposition of surplus weapons-usable plutonium would be decided.

The S&D PEIS is considering Pantex Plant for both storage and disposition alternatives. With the S&D PEIS collocation alternative, construction of new storage facilities would be required to store plutonium and HEU at Pantex Plant. For the disposition alternatives, the emphasis at this stage in the NEPA decision process is on choosing the strategy and technology mix rather than the actual site. The evolutionary Light Water Reactor was chosen for the purpose of analysis as the bounding alternative for disposition. Implementation of this disposition alternative may require the construction and operation of one or more light water reactors, a pit disassembly and conversion facility, a plutonium conversion facility, and a mixed oxide fuel fabrication facility. The bounding alternative also assumes that all of the facilities previously mentioned would be collocated at the same site (potentially Pantex Plant).

The collocation storage alternative and the evolutionary Light Water Reactor disposition alternative from the S&D PEIS are discussed in this Pantex Plant EIS, because those alternatives if they occurred at Pantex Plant, could potentially have the greatest impacts to the Pantex Plant Site. It is important to note that these are conservative bounding impacts. The final S&D PEIS will include an alternative that is a refinement of these storage alternatives. As discussed in sections 1.4 and 1.7.3 of volume I of this EIS, the final S&D PEIS will include an alternative under which pits from Rocky Flats Environmental Technology Site (RFETS) could be transferred to Pantex Plant for storage in Zone 4 as early as 1997. The impacts of this alternative are fully accounted for in this EIS because the pits from RFETS could not cause the total number of pits stored in Zone 4 to exceed the storage limit of 20,000 pits analyzed under the Proposed Action. Furthermore, RFETS pits that could come to Pantex Plant would have the same characteristics, as analyzed in the S&D PEIS, as pits currently or previously stored at Pantex Plant. For disposition, further site-specific tiered NEPA documentation may be required, as appropriate, before any specific site is selected. If different alternatives or a site other than Pantex Plant were selected in the Record of Decision (ROD) (and tiered RODs) for the S&D PEIS, then impacts to Pantex Plant from storage and disposition would be reduced and might not occur.

In addition to the DOE programs, information on other Federal, State, or local projects, including private developments, was sought through contacts with Federal and State regulatory agencies, the Amarillo Economic Development Corporation, the Panhandle Municipal Water Authority, and the City of Amarillo.

This effort yielded only one project (future closure of the Helium Plant) that would contribute to the cumulative impacts in the Pantex Plant ROI. The U.S. Bureau of Mines has been operating the Helium Plant in the Amarillo area since the early 1940s. The

Helium Privatization Act of 1996 directs Helium Operations to discontinue production and sale of refined helium by April 1998. The impacts of this action are analyzed in volume I, section 4.11.5, because cumulative impacts of closing or downsizing this facility would be limited to socioeconomic impacts.

APPENDIX B

Air Quality Analysis

APPENDIX B
AIR QUALITY ANALYSIS

B.1 INTRODUCTION

This appendix presents more detailed information on the assessment of the air quality at and in the vicinity of Pantex Plant and the potential impacts associated with the alternatives being evaluated in this EIS.

B.2 OBJECTIVES

The overall objective of the air quality impact analysis is to determine the impact of air pollutant emissions resulting from construction and operation activities under the Proposed Action and Alternatives at Pantex Plant. Local and regional receptors include human beings, vegetation, and materials.

The impact and significance of ambient pollutant concentrations resulting from Pantex Plant emissions were determined by comparing the predicted concentrations with the appropriate Federal or State ambient air quality standards or guidelines. Ambient air quality standards represent the allowable pollutant concentrations at which public health and welfare are protected with a reasonable margin of safety.

Specific objectives include the following:

- Selection of an appropriate air quality dispersion model.
- Use of the model to evaluate maximum pollutant concentrations at the Pantex Plant boundary and residences near the plant boundary resulting from existing emissions and from emissions related to the Proposed Action and Alternatives.
- Estimation of air quality impacts at the plant boundary and at nearby residences.

B.3 METHODOLOGY

B.3.1 Model Selection

Model selection required consideration of the characteristics of Pantex Plant emission sources, terrain in the vicinity of the plant, and land use classification. Because of the large number of sources (over 100) and 90 pollutants, it was determined that a screening model could not be used for this air quality analysis. Screening models are most appropriate for assessing the air quality impacts of a single source with continuous, constant emission rates. Therefore, it was determined that a refined dispersion model would be required. The following attributes are required in the model:

- Accommodate multiple point, area, or volume, and fugitive sources.
- Allow for a sophisticated treatment of building downwash for point sources.
- Predict concentrations for flat and rolling terrain.
- Predict impacts on urban and rural land use classifications.
- Allow input of time-varying emissions rates (e.g., emission rates may vary by season, month, or hour-of-day).

A review of Environmental Protection Agency (EPA)-preferred air quality models listed in the *Guidelines on Air Quality Models (Revised)* (40 CFR, Part 51, Appendix W) indicated that the only model that would meet the above requirements was the Industrial Source Complex Model (ISC2). The model operates in both short-term (ISCST2) and long-term (ISCLT2) modes. ISCST2 can produce short-term concentrations averaged over periods of 1, 2, 3, 4, 6, 8, 12, or 24 hours. ISCLT2 can produce long-term concentrations averaged over a month, season, quarter, or year. ISCST2 can also produce annual concentrations and is often used in air analyses when both short-term and annual average concentrations are required.

B.3.2 Model Description and Application

B.3.2.1 *Model Description*

The ISC2 model is a steady-state Gaussian plume model that can be used to assess pollutant concentrations from a wide variety of sources associated with an industrial source complex. This model can account for the following:

- Settling and dry deposition of particles.
- Downwash.
- Point, area, line, and volume sources.
- Plume rise as a function of downwind distance.
- Multiple point sources.
- Limited terrain adjustment.

The ISC2 model is appropriate for the following regulatory uses:

- Industrial source complexes.
- Rural or urban areas.
- Flat or rolling terrain.
- Transport distance less than 50 kilometers (31 miles).
- One-hour to annual average times.
- Continuous toxic air emissions.

Input data requirements for the ISC2 model are as follows:

- Source data: location, emission rate, physical stack height, stack inside diameter, and stack gas temperature. Optional inputs include source elevation, building dimensions, particle size distribution with corresponding settling velocities, and surface reflection coefficients.
- Meteorological data: ISCST2 requires hourly surface weather data from the preprocessor program RAMMET, which provides hourly stability class, wind direction, wind speed, temperature, and mixing height. For ISCLT2, input includes stability wind rose (stability array [STAR] disk), average afternoon mixing height, average morning mixing height, and average air temperature.
- Receptor data: coordinates and operational ground elevation for each receptor.

For more detailed information concerning the ISC2 model refer to the EPA *Guidelines on Air Quality Models (Revised)* (40 CFR, Part 51, Appendix W).

B.3.2.2 *Model Application*

The air quality dispersion modeling was performed in accordance with the guidance provided in the EPA document *Guidelines on Air Quality Models (Revised)* and the Texas Natural Resources Conservation Commission (TNRCC) document *Air Quality Modeling Guidelines* (40 CFR, Part 51, Appendix W; TNRCC 1993).

The Industrial Source Complex (ISC) dispersion model (Version 93109) was used to estimate all pollutant concentrations.

B.3.3 Land Use Analysis

In this analysis rural dispersion coefficients were used. The selection of rural coefficients was based on the Auer land-use method (Auer 1978). This procedure involves classifying the land use within a 3,000-meter (9,843-foot) radius around the emission source. If urban land use types account for 50 percent or more of the total area, urban dispersion coefficients should be used; otherwise, rural dispersion coefficients should be used. In an earlier land-use analysis performed by the Radian Corporation for Pantex Plant, it was determined that the percentage of urban land-use within 3,000 meters (9,843 feet) was less than 5 percent (Radian 1993:3-1, 5-1). Since the percent of urban land use is less than 50 percent, rural dispersion coefficients were selected.

B.3.4 Meteorological Data

Meteorological data for the ISCST2 model consisted of hourly surface observations and mixing heights obtained from meteorological data recorded at the Amarillo International Airport for calendar year 1988. Meteorological data for the ISCLT2 model consisted of a joint frequency distribution of wind speed, wind direction, and stability class (STAR data). The STAR data were based on 1985 through 1989 surface observations recorded at the Amarillo International Airport. The meteorological data were obtained from TNRCC's bulletin board.

This set of meteorological data was selected because it was specified by TNRCC and was used by the Radian Corporation in modeling emissions from the Pantex Plant Burning Ground. Also, the use of these data would make the site-wide modeling performed for this EIS comparable with the Radian analysis from a meteorological standpoint (Radian 1994).

B.3.5 Emission Source Characteristics

Emission sources are located in several functional areas (some of these are referred to as numbered zones). These areas include a weapons assembly/disassembly zone (Zone 12), a weapons staging area (Zone 4), and an area for experimental explosives development (Zone 11), a drinking water treatment plant, a sanitary wastewater treatment facility, and a vehicle maintenance and administration area (see Figure B.3.5–1).

Other emission sources included an explosive test-firing facility, an open burning ground to burn high explosive(s) (HE) materials, and a Burning Ground Upgrade (BGU) facility for processing explosive-contaminated materials or components. Emission sources also included welding and cutting operations, standby diesel and gasoline engines, and the container storage area where drum sampling and bulk handling of chemicals are performed.

Most of the emissions from Pantex Plant are fugitive emissions, except emissions from Building 16–13. This building was a point source (stack) with the following parameters:

- Height of stack: 19.81 meters (65.0 feet).
- Diameter of the stack: 0.91 meters (3.0 feet).
- Exit Speed: 5.03 meters per second (16.5 feet per second).
- Exit Temperature: 418.76 °K (294.1 °F).

Building 16–13 was the only source at Pantex Plant that required the application of building downwash effects.

As indicated in Tables B.3.6–1 through B.3.6–9, facilities from which fugitive emissions were emitted were treated as volume sources (all tables are presented at the end of this appendix). The emission rates were expressed in grams per second. The release height of the emissions was assumed to be located at one half the building height. Groups of point sources with small emission rates were treated as an area source.

The Burning Ground is an onsite facility used to demilitarize and sanitize explosives components and treat materials contaminated with explosives. The Burning Ground covers approximately 23.5 hectares (58 acres) in the north-central portion of Pantex Plant (see Figure B.3.5–1), and currently includes the firing sites, nine burn trays, three burn pans, two burn cages, and three burn pits. There are no structures at the Burning Ground that could affect the normal dispersion of air pollutants during burning operations (Radian 1993:6-1).

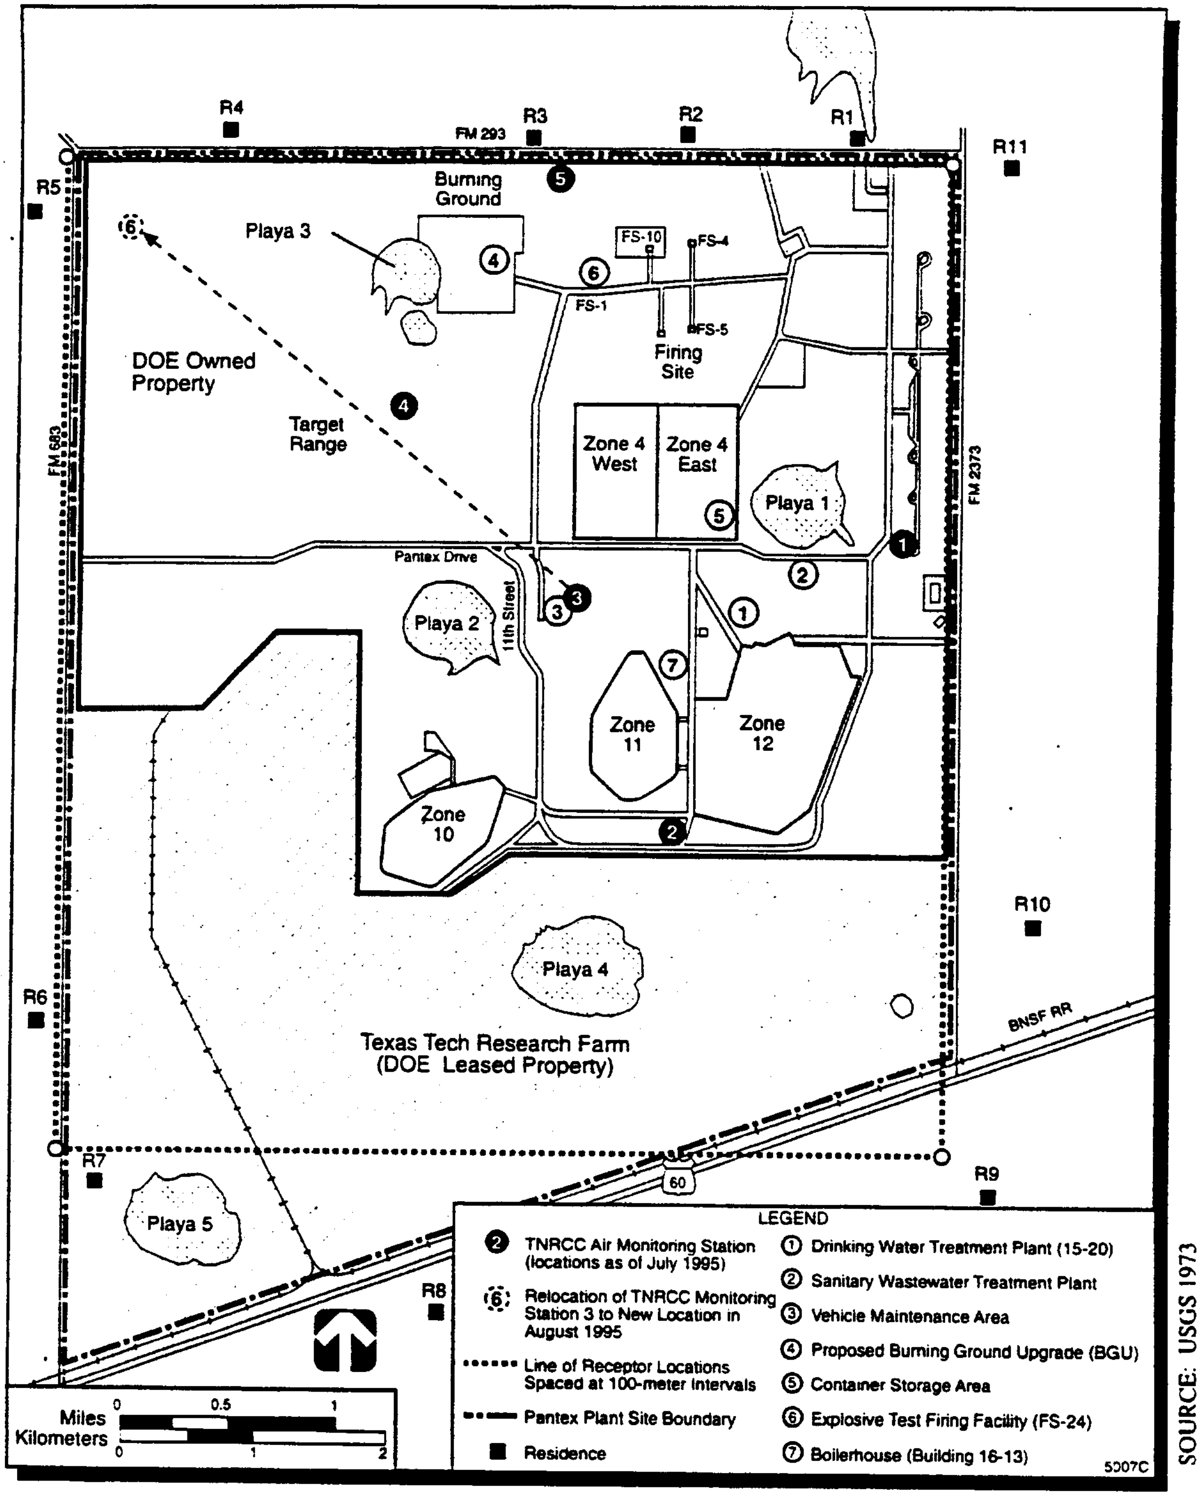

FIGURE B.3.5–1.—*Air Quality Monitoring Stations, Emission Sources, and Receptor Sites at Pantex Plant.*

The emissions from the open burning of HE in the trays were modeled using a "flare" methodology developed by the Radian Corporation and approved by TNRCC (Radian 1993). The input parameters used for the methodology were as follows:

- Flare release height above the ground: 2 meters (6.6 feet).
- Flame temperature: 1900 °K (2961 °F).
- Exit speed: 1.0 meter per second (3.3 feet per second).
- Effective Diameter of flare:
  - 45.4 kilograms (100 pounds) HE: 1.92 meters (6.3 feet).
  - 363 kilograms (800 pounds) HE: 8.66 meters (28.4 feet).

It was assumed that the burning of HE that did not contain fluorides would occur between the hours of 7:00 a.m. and 6:00 p.m. Explosives that contained fluoride would only be burned twice a day, at 11:00 a.m. and 3:00 p.m. It should be noted that not more than three burns can be conducted in a day. Also, there is at least a 3-hour waiting period between any two burns for explosives emitting hydrogen fluoride (HF). Two HE scenarios were modeled: one assumed that 45.4 kilograms (100 pounds) of HE were burned, while the other assumed a burn of 363 kilograms (800 pounds) of HE.

Pantex Plant has a commitment to construct a project called the Burning Ground Upgrade (BGU) to replace the current pit burn operation. This project should be completed in the timeframe analyzed in this EIS. This upgrade will consist of a covered three-sided structure with a fan to exhaust emissions through an elevated stack. The wood currently used as an auxiliary heat source for the pit burn will be replaced by natural gas in the BGU. These changes will improve the dispersion characteristics of emissions from this operation and eliminate the toxic emissions common to wood burning.

The BGU operation was assumed to be a point source (stack) with the following stack parameters:

- Stack height: 12.2 meters (40.0 feet).
- Stack diameter: 0.61 meters (2.0 feet).
- Exit speed: 16.2 meters per second (53.2 feet per second).
- Exit temperature: 388.8 °K (240.0 °F).

Building downwash for the BGU was not required for emissions released through the BGU stack (Radian 1994:6-1). Downwash from the BGU structure was also not a consideration with regard to tray burns (Radian 1994:6-1).

B.3.6 Emission Inventory Scenarios

The basic emission inventory used to derive emission rates for Pantex Plant air quality analysis was developed by the Radian Corporation. This emission inventory included emissions from furnaces, boilers, water heaters, diesel generators and engines, the BGU, tray burns (hemispheres, HE, and wet HE), and the solvent area (sampling and bulk handling). The emission sources used for this site-wide analysis are presented in Tables B.3.6–1 through B.3.6–5.

Tables B.3.6–1 and B.3.6–4 present the estimated emission rates for the criteria pollutants. The estimated emission rates in Table B.3.6–1 were used in modeling the current emissions (Affected Environment), which were assumed to be related to the 2,000 weapons level at Pantex Plant. In addition, emission rates for two other weapons levels (1,000 and 500) were developed. Table B.3.6–4 shows the estimated criteria pollutant emission rates for the BGU.

Pantex Plant personnel provided information regarding facilities whose emissions would change or would remain the same if weapons operations were reduced. The facilities whose emissions would change are indicated with a "W" in the Status column while those remaining the same are indicated with an "S". For those facilities whose emissions would be reduced, it was assumed that the reduction would be in proportion to the weapons operation reduction.

Table B.3.6–2 presents the estimated emission rates for 33 hazardous air pollutants (HAPs), as listed in the *Clean Air Act*, as amended, November 1990 (42 U.S.C. 7401). The emission sources and pollutant emission rates are presented in the same manner as described for Table B.3.6–1.

Table B.3.6–3 presents estimated emission rates for HAPs that are emitted from tray burns of hemispheres, HE, and wet HE. These emission rates are presented in the same manner as described for Table B.3.6–1.

Tables B.3.6–4 and B.3.6–5 present the estimated emission rates for criteria pollutants and HAPs from the BGU. These emissions were not used in modeling the current emission rates (Affected Environment) because the BGU project has not been started but should be completed in the next few years. Therefore, these emissions were included in modeling the emissions for the three weapons levels (2,000, 1,000, and 500) for future operations.

Two scenarios were assumed for modeling the emissions from the trays. One scenario assumed 45.4 kilograms (100 pounds) of HE were burned while the other assumed a burn of 363 kilograms (800 pounds) of HE. For modeling the affected environment, it was assumed that an HE mixture of PBX–9404 and LX–17 was burned. For modeling the emissions from 2,000, 1,000, and 500 weapons levels, it was assumed that a mixture of PBX–9404 and LX–04 was burned. The LX–17 and LX–04 HE were selected because they both emit HF. Although LX–17 is currently burned, it will not be burned during the 10-year period (1997–2007) covered by the EIS. LX–04, however, may continue to be burned during this period.

The emission factors that were used to calculate the emission rates for carbon monoxide (CO), nitrogen dioxide (NO_2), hydrogen chloride (HCl), and HF for these HE mixtures are presented in Table B.3.6–6. The different kinds of HE are mixed to maximize the heat produced by the burning and keep the amount of HF emitted below the regulatory limits. In order to be conservative, the HE mixes modeled in this EIS were chosen for the lowest heat output and highest emission of HF allowed under the regulatory limits. The emission rates for these HE mixtures are presented in Tables B.3.6–7 and B.3.6–8.

A summary of the estimated emission rates for CO, NO_2, PM_{10}, HCl, and HF for the affected environment and the three levels of future operations (2,000, 1,000, and 500 weapons per year) is presented in Table B.3.6–9.

B.3.7 Receptor Locations

A set of discrete receptors was placed at 100-meter (328-foot) intervals at the Pantex Plant boundary. Another set of 11 discrete receptors was established at the locations of the 11 residences which are situated near the Pantex Plant boundary. A grid of offsite receptors was not used since most of the emissions from Pantex Plant sources were released at relatively low heights above the surface. Surface concentrations from low-level releases will be highest near the source and decrease with increasing distance from the source. This concentration decrease with distance is the result of the pollutant cloud being continuously dispersed with increasing distance by atmospheric turbulence.

B.4 Modeling Results

This section presents the results of a conservative modeling of the current environment at Pantex Plant and the impacts associated with activity levels of 2,000, 1,000, and 500 weapons per year.

The model calculates the concentrations at each receptor resulting from the weather conditions for each hour within the year's worth of data (i.e., 8,760 hourly values for each receptor). The model uses meteorological data values that were recorded hourly at the Amarillo airport for an entire year (data was validated by TNRCC). The model returns the single maximum concentration seen by each receptor.

For example, for hourly results this maximum concentration value is associated with a certain hour's weather conditions (e.g., 9:00 a.m. December 3). A different receptor (especially one in a different direction from the source) would have a maximum concentration value returned that might be associated with a different set of meteorological conditions (e.g., 7:00 p.m. July 8). Per the example, the maximum concentration value for residence R5 occurs when a gentle wind blows from the source towards R5, and the maximum concentration value for residence R3 occurs when a gentle wind blows towards R3 (see Figure B.3.5–1). Therefore, it is difficult to discuss the relation between the values for different receptors solely in terms of distance from the source. For calculation of health effects, the maximum concentration hourly value is assumed (for conservatism) to exist at all receptors 24 hours a day 365 days a year.

B.4.1 Affected Environment

The maximum concentration found on the site boundary for each modeled criteria pollutant and each HAP is presented in volume I, Tables 4.7.1.3–4 and 4.7.1.3–5, respectively. The appropriate National Ambient Air Quality Standards (NAAQS) or Effects Screening Levels (ESLs) are also shown in the tables for comparison with the calculated concentration.

As shown in Table 4.7.1.3–4, none of the criteria pollutants are expected to exceed their ambient air quality standards. The emission inventory specified an emission rate for a group of pollutants called alcohols. The alcohol species included in the group were not speciated in the inventory. TNRCC in a modeling analysis of Pantex Plant developed a 1-hour ESL for the group of alcohols (TNRCC 1995b). The calculated maximum 1-hour average concentration at the Pantex Plant boundary for this group of alcohols is the only pollutant concentration that exceeded the guideline ESL (see Table 4.7.1.3–5 in volume I).

The maximum concentrations that were calculated for the 11 residences located near the plant boundary are presented in Table B.4.1–1 (see Figure B.3.5–1 for residence location). Alcohols, modeled as a group, were the only pollutants which exceeded the ESL at a residence. A subsequent review of the inventory of the amounts of the individual alcohols present at the Plant showed that the ESL used in the modeling was excessively conservative. Since the emission rates for the individual alcohols in the group were unknown, an estimation of the maximum fence line concentration for each of the alcohols was calculated based on the ratio of the amount of each alcohol to the total inventory of the group of alcohols present at Pantex Plant (see Table B.4.1–2). None of the individual alcohols were calculated to exceed their respective ESLs at or near the Plant boundary.

It should be noted that the maximum concentration at the residences shown in Table B.4.1–1 may not occur at the same time (day and hour). Since meteorological conditions also vary with time, the concentration values shown in this table cannot be used to determine the spatial variability of the concentrations. In order to determine the spatial variability the concentration would have to be determined simultaneously at all locations.

The modeling results for the current estimated pollutant emissions from Pantex Plant facilities indicate that the air quality at the plant boundary and beyond is not adversely impacted by Pantex Plant operations. The results also support the attainment designations for all criteria pollutants in the Pantex Plant area. The onsite air quality is well within the Threshold Limit Values for the pollutants. The impacts of the onsite air quality to workers are discussed in section 4.14.1.2 of volume I.

B.4.2 Air Quality Impacts

Air quality impacts were developed for three different levels of weapons which were assumed to occur during the analysis period of this EIS. The estimated maximum pollutant concentrations that would occur for each of the three levels of weapons are presented for criteria pollutants and HAPs in volume I, Tables 4.7.2.1–1 and 4.7.2.1–2, respectively. As shown in Table 4.7.2.1–1, concentrations of all the criteria pollutants are expected to be below their respective NAAQS.

As described in the Affected Environment (section B.4.1), only alcohols as a group exceeded the TNRCC ESL (see Table 4.7.2.1–2) for all three weapons levels.

Table B.4.2–1 presents the estimated maximum pollutant concentration on the Pantex Plant boundary for the 2,000 weapons level as a percentage of the NAAQS. The percentages for the 1,000 and 500 weapons levels would be the same or less than those shown in the table. The greatest percentages of the NAAQS were for the 24-hour and annual PM_{10}. The emission resulting from the burning of 45.4 kilograms (100 pounds) of HE resulted in maximum boundary concentrations that represented about 59 percent of the 24-hour average standard and 18 percent of the annual standard. Maximum concentrations from other criteria pollutants represented less than 7 percent of their respective standards.

Although the amount of pollutants released from the 363-kilogram (800-pound) HE burn is greater than the amount released from the 45.4-kilogram (100-pound) HE burn, the concentration of pollutants at the surface produced from the emissions of a 45.5-kilogram (100-pound) HE burn was greater than those produced by a 363-kilogram (800-pound) HE burn. The lower surface concentrations for the 363-kilogram (800-pound) burn are the result of a greater plume rise than occurs for the smaller burn. The higher plume rise is the result of a larger amount of the hot air than the smaller burn. The larger amount of hot air results in increased buoyancy or vertical lift. The dispersion of the pollutants from the larger burn is therefore greater due to this increased buoyancy. The greater dispersion for the larger burn results in lower surface concentrations than the smaller burn.

Table B.4.2–2 contains information for HAPs similar to what was contained in Table B.4.2–1 for criteria pollutants. As shown in Table B.4.2–2, alcohols were estimated to be 95 percent over the 30-minute average ESL. All other HAPs are expected to be below their ESLs. The next highest concentration was produced by emission of HF resulting from the burning of 45.4 kilograms (100 pounds) of HE. It represented about 85 percent of the 3-hour average HF standard. Other HAPs which were more than 50 percent of the respective ESLs were nickel, HCl, methylene chloride, carbon disulfide, and silver.

Table B.4.2–3 presents the estimated maximum pollutant concentrations that could occur at the 11 residences near the Pantex Plant boundary. Maximum pollutant concentrations for each of the three weapons levels (2,000, 1,000, and 500) are shown. Alcohols, modeled as a group, exceeded the 30-minute average ESL at the Pantex Plant boundary, and at residence R10 for all three levels of operations. All of the other pollutant concentrations at the 11 residences were estimated to be below their respective ESLs. Since the maximum concentrations for air pollutants listed in the TNRCC's list (volume I, Tables 4.7.2.1-1 and 4.7.2.1-2) are all below their respective ESLs at the fence line for the 2,000 weapons level, they will not have any impact at the fence line or residences for the 1,000 and 500 weapons levels.

Since violations of the NAAQS or the TNRCC ESLs would not occur at any of the 11 residences (sensitive receptors) near the plant boundary for any of the proposed levels of weapons operations, local air quality impacts would be negligible. In addition, since the emissions from Pantex Plant would contribute only a very small amount to the overall pollution burden in Carson County and the surrounding counties, regional air quality impacts would also be expected to be negligible.

[a] Letter designates change in emissions. S for static emissions or no change with time and W for change associated with change in weapons program.
[b] Letter designates source modeling category. V = volume source, A = area source, P = point source.
[c] Emissions inventory listed for 2,000 Weapons Scenario (PC 1994). For ISCST2 and ISCLT2 modeling, the emission rates (lb/hr and lb/yr, respectively) were converted to g/sec.
[d] Emissions inventory listed for 1,000 and 500 Weapons Scenarios have been assumed to be a linear regression (PC 1994).
NA - Emission rate was not quantified for modeling.
Source: PC 1994; calculated values.

[a] Letter designates change in emissions. S for static emissions or no change with time and W for change associated with change in weapons program.
[b] Letter designates source modeling category. V = volume source, A = area source, P = point source.
[c] Emissions inventory listed for 2,000 Weapons Scenario (PC 1994). For ISCST2 and ISCLT2 modeling, the emissions rates (lb/hr and lb/yr, respectively) were converted to g/sec.
[d] Emissions inventory listed for 1,000 and 500 Weapons Scenarios have been assumed to be a linear regression (PC 1994).
[1] As listed in the *Clean Air Act*, as amended, Nov 1990 (42 U.S.C. 7401).
CAS No. - Chemical Abstract Service Registry Number.
NA - emission rate was not quantified for modeling.
Note: Pollutants related to burning of explosives are presented in Tables B.3.6–3, B.3.6–4, and B.3.6–5.
Source: PC 1994; calculated values.

[a] Letter designates change in emissions. S for static emissions or no change with time in weapons program.
[b] Letter designates source modeling category. V = volume source, A = area source, P = point source.
[c] Emissions inventory listed for Affected Environment, 2,000, 1,000, and 500 Weapons Scenarios were calculated from Carter Emission Factors (Carter 1978).
[1] As listed in the Clean *Air Act*, as amended, Nov 1990 (42 U.S.C. 7401).
Note: Values summarized in this table were obtained from Tables B.3.6–7 and B.3.6–8.

[a]Alcohols - Alcohols is the only pollutant which exceeded the ESL at the fence line. Therefore, modeling results were also reported for all the residences for alcohols.
[b]Indicates a NAAQS. Other values are ESLs.
[1]As listed in the *Clean Air Act*, as amended, Nov 1990 (42 U.S.C. 7401).
NA - An ESL has not been established by TNRCC.
Note: Table shows the results (maximum concentrations at residences) from models ISCST2 and ISCLT2.
Sources: TNRCC 1993a; TNRCC 1996a

[a]The ISCST2 air quality model returns a value of 0.00 for any concentration equal to or less than 1.00 x 10^{-5} $\mu g/m^3$ (i.e., less than one ten millionth of a part per billion or less than ten parts per quadrillion).

[b]Percent of ESL is shown as zero, as it is below 0.05.

[c]Those solvents not listed under 40 CFR 261.33 (Hazardous Waste from Non-specific Sources).

Note: Table shows the modeling results (maximum concentrations at boundary) from models ISCST2 and ISCLT2. The above chemicals were modeled with appropriate time periods for Open Burning, Burning Ground Upgrade, and Engine Emission Area.

Source: TNRCC 1996a

APPENDIX C

Water Resources Analysis

APPENDIX C
WATER RESOURCES ANALYSIS

This appendix supplements the information on the characterization of surface water, groundwater, and water quality presented in section 4.6, Water Resources.

C.1 SURFACE WATER

Surface water studies and data were reviewed during a literature search performed for this EIS. Surface water availability and use were not primary issues of concern, because groundwater is the source of all water supplied to Pantex Plant.

C.1.1 Hydrologic Characterization

Playas are the primary surface water feature at Pantex Plant and the surrounding vicinity. The assessment and characterization of playas was important for determining the potential for flooding onsite, the significance of playas as a source of recharge to groundwater, and evaluation of playas as receptors of wastewater disposal. Numerous investigations have attempted to characterize the significance of playas at and in the vicinity of Pantex Plant. The characterization of surface water resources in the EIS took these and other investigations into account.

C.1.2 Surface Water Quality

Evaluation of baseline surface water quality is based on a review of data tabulated in Pantex Plant annual environmental reports for a 5-year period, from 1990 through 1994. Information regarding surface water monitoring stations and sources of flow are summarized in volume I, Table 4.6.1.1–2. Surface water quality samples were collected and analyzed for a full suite of analytical laboratory parameters, including radionuclides, metals, high explosive(s) (HE), polychlorinated biphenyls (PCBs), pesticides, herbicides, volatile organics, semivolatile organics and other miscellaneous constituents and field parameters. Samples were collected from 29 onsite sampling locations from 1990 to 1993; surface water samples were collected from only 17 of these sampling locations in 1994. The surface water quality data collected over the past 5 years do not include every sampling location each year, because some locations only have sufficient water to sample during storm events. One offsite location, Bushland Playa at the U.S. Department of Agriculture's Agricultural Experimental Station 54 kilometers (34 miles) west of Pantex Plant, was used as a control sample to give some insight on background surface water quality. Suspected contaminants of concern (COCs) were determined by comparing tabulated annual average values to the following defined surface water quality decision criteria:

- Texas State Water Quality Criteria, Aquatic Life Protection (§307.2–307.10) for fresh water acute aquatic life protection (TWC 1991).
- Texas State Water Quality Criteria, Human Health Protection (§307.2–307.10) for water and fish (TWC 1991).
- Environmental Protection Agency (EPA) Region 6 National Pollutant Discharge Elimination System (NPDES) Permit (No. TX-0107107) (EPA 1996).
- TNRCC permit to dispose of wastes (Permit No. 02296) (TNRCC 1996).
- DOE Derived Concentration Guides (DOE Order 5400.5) for radionuclide health standards.

The summary of surface water quality decision criteria defined for Pantex Plant is presented in Table C.1.2–1 (all tables are presented at the end of this appendix). The Texas State Water Quality Criteria do not apply directly to the

Pantex Plant playas; these decision criteria were selected for comparative purposes only. The State of Texas applies regulations through the concentration limits specified in permits; therefore, decision criteria for surface water compliance are based on permit limits established in the EPA NPDES Permit and TNRCC Wastewater Discharge Permit for Pantex Plant. Pantex Plant has worked very closely with EPA Region VI and TNRCC to produce wastewater discharge permits (EPA NPDES Permit No. TX-0107107 and TNRCC Wastewater Discharge Permit No. 02296) that dictate stringent wastewater discharge requirements protective of human health and the environment. Permit limits specified in the Pantex Plant NPDES Permit for various outfalls are provided in Table C.1.2–2.

Pantex Plant wastewater discharge permit limits meet or exceed all current regulations that apply to surface water. DOE Derived Concentration Guides (DOE Order 5400.5) are used as decision criteria for radionuclides. The *Atomic Energy Act of 1954* (42 U.S.C. 2011), as amended, authorizes DOE to protect public health and safety and the environment in conducting programs, such as Pantex Plant operations. As a result, DOE is self-regulating with respect to standards and requirements for radiation.

The following assumptions were made for this analysis:

- Some of the Texas State Water Quality Criteria standards (e.g., copper, nickel, zinc, cadmium, and lead) are defined as a function of hardness. The average water hardness at Pantex Plant was assumed to be 128 milligrams per liter. Therefore, the following criteria were determined:
  - — Copper = 0.024 milligrams per liter.
  - — Nickel = 1.75 milligrams per liter.
  - — Zinc = 0.144 milligrams per liter.
  - — Cadmium = 0.045 milligrams per liter.
  - — Lead = 0.112 milligrams per liter.
- Tabulated water quality data are assumed to be representative of the sampling locations. State-approved standard operating procedures have been used in sample collection and analysis, and the results are assumed to be validated using EPA-approved methodology.

The emphasis of the surface water quality analysis results is placed on Playa 1, since it is the only onsite perennial wetland and receives discharge from the Wastewater Treatment Facility. The suspected COCs in samples from Playa 1 are presented in Table C.1.2–3. With the exception of Playa 1, all Pantex Plant surface water sampling locations are usually dry except during storm events. Because of frequent dry periods, soil sampling is likely to be more representative of the extent of contamination, if any, at these sampling locations. Soil sampling is discussed in section 4.5 and appendix I. Surface water quality results for sampling locations other than Playa 1 are presented in Table C.1.2–4.

C.2 GROUNDWATER

Evaluation of Pantex Plant groundwater resources involved three primary components:

- Hydrogeologic site characterization of the perched and Ogallala aquifers.
- Evaluation of groundwater quality data.
- Determination of groundwater availability and use.

C.2.1 Hydrogeologic Properties

Hydrogeologic parameters (e.g., hydraulic conductivity, transmissivity, recharge, groundwater velocity) at Pantex Plant have been estimated during investigations by Battelle Pantex, the University Consortium (including Texas Tech University and Texas A&M University), the U.S. Army Corps of Engineers (COE), Argonne National Laboratories, Engineering-Science, Inc., and Radian Corporation.

Existing available well information for the Pantex Plant Site area has been identified, compiled, and tabulated (Table C.2.1–1). This table was compiled based on data provided by Pantex Plant, Texas A&M University, and COE. Wells reported with an unknown status are those for which data were unavailable. Well locations are shown in volume I, Figure 4.6.1.2–2. Well construction information and hydraulic parameter data were compiled and tabulated to determine which wells would provide enough information to assess the groundwater hydraulic parameters (Table C.2.1–2).

Available Pantex Plant area well logs and specific capacity estimates from wells within an 8-kilometer (5-mile) radius from Pantex Plant Site were obtained from COE except where noted. Vertical saturated hydraulic conductivities were determined for the Texas Department of Criminal Justice Playa, located approximately 11 kilometers (7 miles) northeast of Pantex Plant. The results of this playa investigation are summarized in Table C.2.1–3.

The following assumptions were made in the evaluation of the existing hydrogeologic data:

- The Theis curve method was assumed to be the most representative method to evaluate the drawdown data used to calculate transmissivities from perched monitoring wells OW–WR–19, –20, –38, –44, and –45.
- For wells BEG–PTX2, BEG–PTX3, PTX08–1008, and PTX06–1004, the ambient vertical hydraulic conductivity (K_V) value was reported.
- When actual Quality Assurance/Quality Control forms, data validation forms, or chain of custody information was unavailable it was assumed that the data presented in each report were valid and that approved methodologies for sample collecting and testing were implemented.

C.2.2 Groundwater Quality

Baseline groundwater quality was assessed using data tabulated in Pantex Plant annual environmental reports for a 5-year period, from 1990 through 1994. Additional perched groundwater quality data, collected in conjunction with the *Resource Conservation and Recovery Act* (RCRA) site investigations, were also examined. Groundwater quality monitoring data were collected from wells completed in the perched and Ogallala aquifers. Groundwater quality data used for the analysis were collected from reported onsite sampling locations from January 1990 to December 1994. The drinking water from an Ogallala water supply well at Bushland, located 54 kilometers (34 miles) west of Pantex Plant was also sampled to provide regional background groundwater quality data. The control well at Bushland is completed in the Ogallala aquifer upgradient from Pantex Plant and is, therefore, unaffected by plant operations (Pantex 1996a:82).

Groundwater samples collected from perched and Ogallala wells were analyzed for a full suite of analytical laboratory parameters, including radionuclides, metals, HEs, PCBs, pesticides, herbicides, volatile organics, semivolatile organics and other miscellaneous constituents and field parameters. It should be noted that the groundwater data collected over the 5 years does not include every sampling location or parameter each year. The following decision criteria for groundwater quality were used in the evaluation:

- TNRCC Primary and Secondary Drinking Water Standards Governing Drinking Water Quality and Reporting Requirements (§290.101–290.119).
- EPA, Drinking Water Regulations and Health Advisories, Maximum Contaminant Levels, and Secondary Maximum Contaminant Levels.
- DOE Derived Concentration Guides (DOE Order 5400.5) for radionuclide health standards.

In addition, groundwater quality data were compared to Pantex Plant Risk Reduction Standards (RRSs), or proposed groundwater cleanup levels for anticipated potential contaminants at Pantex Plant. These derived RRS values were established for the RCRA Facility Investigations (RFIs) (DOE 1994). The summary of groundwater quality decision criteria and RRS values is presented in Table C.2.2–1.

The following assumptions were made in the groundwater quality evaluation for the EIS:

- Gross alpha (dissolved) (GAd) and gross beta (dissolved) (GBd) values reported in the annual environmental reports were the actual measured values.
- Tabulated water quality data are assumed to be representative of the sampling locations. Agency-approved standard operating procedures have been used in sample collection and analysis, and the results are assumed to be validated using EPA-approved methodology.

In addition to the routine sampling documented in the annual environmental reports, available COE quarterly groundwater monitoring reports were reviewed. Quarterly groundwater monitoring was conducted to characterize the groundwater quality and extent of contamination in the perched aquifer, in association with the Ditches and Playas RFI for Flow System 6, groundwater in the perched aquifer. Flow System No. 6 includes groundwater data from perched monitoring wells constructed in Solid Waste Management Unit (SWMU) 5 Areas 10, 11, 12, and SWMU 6. Groundwater samples were collected from perched aquifer monitoring wells to determine the nature and presence or probable absence of contamination. Figure C.2.2–1 outlines the decision tree used to evaluate the groundwater data.

All groundwater samples were analyzed for total metals, cyanide, volatile organics, semivolatile organics, HEs, radionuclides, pesticides, and PCBs. Analytical data collected during the RFI were screened using a risk-based approach. This approach is based on the toxicological properties and the maximum reported concentrations of detected RFI target analytes. Throughout this screening process, the constituents that pose no significant risk to human health and the environment were eliminated from further consideration. After this process was complete, a list of suspected constituents of potential concern was compiled.

In general, analytical data were evaluated against decision criteria, including Texas RRS 1 (background upper tolerance limits and practical quantitation limits) and RRS 2 (risk based action levels), to determine the nature and extent of contamination and to assess the need for additional sampling (USCOE 1994:ES-1, ES-2, 1-1, 1-3). It should be noted that the water quality constituents that were analyzed for the COE investigation are not always the same constituents that were analyzed for the annual environmental reports. The results of both the annual environmental reports and COE investigations are presented in Table C.2.2–2 for the perched aquifer and Table C.2.2–3 for the Ogallala aquifer. Site characterization investigations are ongoing.

[1]TWC 1991:Table 1
[2]TWC 1991:Table 3
[3]TNRCC Permit No. 02296 (daily average/daily maximum) (TNRCC 1996).
[4]DOE Derived Concentration Guidelines (DCGs) (DOE Order 5400.5).
[5]Specific numerical criteria exists, however it is a function of water hardness which was not measured (assume a hardness of 128 mg/L as $CaCO_3$ to estimate each).
[6]Used Human Health Protection because Aquatic Life Protection had silver as free ion (0.00092 mg/L), which was not measured.
* NPDES Permit No. TX-0107107. Permit limits vary per sampling location. See Table C.1.2–2.
HMX - High melt explosive
NA - Not Applicable; NM - Not Measured; STD - Standard
PTEN - Pentaerythritoltetranitrate
RDX - Research development explosive
TNT - Trinitrotoluene

Note: The Wastewater Treatment Facility (Outfall 001) includes the following specific effluent sampling locations: Influent into the Wastewater Treatment facility (INCOMING), treatment lagoon, composite sampler at chlorinator (DACAUTO), and effluent. It should be noted that wastewater influent collected at the inlet weir (INCOMING) to the Wastewater Treatment Facility and the treatment lagoon have not undergone wastewater treatment and, therefore, would not be expected to meet the effluent discharge limitations.

Constituent abbreviations:

- BOD - Biological oxygen demand
- PETN- pentaerythritohetranitrate
- RDX - Research development explosive

NA - Not Applicable

Walco #5	Well 22 70–5	Unknown	Unknown	Abandoned

[1]Well Locations are displayed on Figure 4.6.1.2 –2.
[2]Neutron probe holes in the unsaturated zone with total depths ranging from 8.5 to 11 meters (28 to 37 feet) below land surface.
Note: Some data inconsistencies may exist from one source to another.

[1]Based on constant head tests of surface and shallow subsurface soils at the TDCJ playa. Individual test runs on the same sample consisted of using different constant heads, which resulted in different flow rates. Each value represents a separate test. For additional information, refer to TBEG 1992.
[2]Subsurface sample from 0.12 to 0.2 m (0.4 to 0.6 ft).
[3]Subsurface sample from 0.15 to 0.21 m (0.5 to 0.7 ft).
Texas Department of Criminal Justice (TDCJ1) Interplaya
TDCJ2 Next to current water level (Fringe) east
TDCJ4 Next to current water level (Fringe) west
TDCJ5 Fringe, halfway between TDCJ1 and TDCJ3
NM - Not measured

APPENDIX D

Human Health Analysis

APPENDIX D HUMAN HEALTH ANALYSIS

D.1 INTRODUCTION

The basic approach used in assessing human health impacts was to first identify the affected environments and establish a baseline representing the risk from current operations. This baseline was primarily established from empirical data (e.g., annual environmental reports, occupational incident rates, and worker exposure records). Next, changes in this baseline risk resulting from the Proposed Action, No Action, and Pit Storage Relocation Alternatives were examined to ascertain the human health impacts of the alternatives.

Radiological impacts on human health are an important consideration in establishing the baseline risk and estimating changes to it. The impact of radiation on human health is the topic of section D.2.

Assessing the human health impacts of the alternatives involved a four-step process. The first step was to identify a broad spectrum of potential accident scenarios. These scenarios were obtained from available, site-specific safety and environmental documents.

The second step in the process used screening techniques to identify the specific scenarios that dominate risk (i.e., scenarios that contribute an appreciable fraction of the total risk). This is described in section D.3.

Due to the large number of potential accident scenarios that could impact human health, it is impractical to evaluate all of them in detail. This is a common problem encountered in risk assessments. The standard approach is to apply scoping calculations during the screening step. Rigorous evaluations (the third step in the process) were only performed for the risk-dominant scenarios identified in step two. Section D.4 addresses the methodology used to evaluate the risk dominant scenarios.

The fourth and final step in assessing the human health impact of the alternatives was to evaluate the risk from normal operations (i.e., the risk if no accidents occur). This is the topic of section D.5. Consequence uncertainties in the assessment are the topic of section D.6.

D.2 RADIOLOGICAL IMPACTS ON HUMAN HEALTH

This section addresses the human health impacts resulting from exposure to radiation. The nature of radiation, its effects on human health, and the sources of radiation pertinent to this EIS are examined.

D.2.1 Nature of Radiation and Its Effects on Humans

For a uniform irradiation of the body, the incidence of cancer varies among organs and tissues; the thyroid and skin demonstrate a greater sensitivity than other organs. However, such cancers also produce relatively low mortality rates because they are relatively amenable to medical treatment. Because of the readily available data for cancer mortality rates and the relative scarcity of prospective epidemiologic studies, somatic effects leading to cancer incidence are presented in this EIS. The number of cancer fatalities can be used to compare the risks among the various alternatives.

The National Research Council's Committee on the Biological Effects of Ionizing Radiations has prepared a series of reports to advise the U.S. Government on the health consequences of radiation exposures. The latest of these reports, *Health Effects of Exposure to Low Levels of Ionizing Radiation BEIR V*, published in 1990, provides the most current estimates for excess mortality from leukemia and cancers other than leukemia expected to result from exposure to ionizing radiation (NAP 1990). The BEIR V report updates the models and risk estimates provided in the earlier report of the BEIR III Committee published in 1980. BEIR V models were developed for application to the U.S. population.

D.2.1.1 *Risk Estimates for Doses Received During Normal Operation*

For low doses and dose rates, a linear-quadratic model was found to provide a significantly better fit to the data for leukemia than a linear one, and leukemia risks were based on a linear-quadratic function. This reduces the effects by a factor of two over estimates that are obtained from the linear model. For other cancers, linear models were found to provide an adequate fit to the data, and were used for extrapolation to low doses. However, the BEIR V Committee recommended reducing these linear estimates by a factor between 2 and 10 for doses received at low dose rates. For this EIS, a risk reduction factor of two was adopted for conservatism.

Based on the above discussion, the resulting risk estimator would be equal to half the value observed for accident situations or approximately 500 excess fatal cancers per million person-rem (0.0005 excess fatal cancers per person-rem). This is the risk value used in this EIS to calculate fatal cancers to the general public during normal operations. For workers, a value of 400 excess fatal cancers per million person-rem (0.0004 excess fatal cancers per person-rem) is used. This lower value reflects the absence of children in the workforce.

The risk estimates may be applied to calculate the effects of exposing a population to radiation. For example, in a population of 100,000 people exposed only to natural background radiation (0.3 rem per year), 15 latent cancer fatalities per year would be inferred to be caused by the radiation (100,000 persons x 0.3 rem per year x 0.0005 latent cancer fatalities per person-rem = 15 latent cancer fatalities per year).

How should one interpret a nonintegral number of latent cancer fatalities, such as 0.05? The answer is to interpret the result as a statistical estimate. That is, 0.05 is the average number of deaths that would result if a total dose of 0.001 rem were applied to many different groups of 100,000 people. In most groups, no person (0 people) would incur a latent cancer fatality from the 0.001 rem dose each member would have received. In a small fraction of the groups, one latent fatal cancer would result; in exceptionally few groups, two or more latent fatal cancers would occur. The average number of deaths over all the groups would be 0.05 latent fatal cancers (just as the average of 0, 0, 0, and 1 is 1/4, or 0.25). The most likely outcome is zero latent cancer fatalities.

These same concepts apply to estimating the effects of radiation exposure on a single individual. Consider the effects, for example, of exposure to background radiation over a lifetime. The "number of latent cancer fatalities" corresponding to a single individual's exposure over a (presumed) 72-year lifetime to 0.3 rem per year is the following:

1 person x 0.3 rem/year x 72 years x

0.0005 latent cancer fatalities/person-rem

= 0.011 latent cancer fatalities.

Again, this should be interpreted in a statistical sense; that is, the estimated effect of background radiation exposure on the exposed individual would produce a 1.1 percent chance that the individual might incur a fatal cancer caused by the exposure. Presented another way, this method estimates that approximately 1.1

percent of the population might die of cancers induced by background radiation.

Although health risk factors are statistical factors, and therefore not strictly applicable to individuals, they have been used in the past to estimate the incremental risk to an individual from exposure to radiation. Therefore, the factor of 0.0005 and 0.0004 per rem of individual committed effective dose equivalent for a member of the public and for a worker, respectively, have also been used in this EIS to calculate the individual's incremental fatal cancer risk from exposure to radiation.

For the public, the health effects expressed in this EIS are the number of fatal cancers to the population within 80 kilometers (50 miles) from exposure to radioactivity released from the site. For workers, the health effects expressed are the risk to the average worker at a site and the number of fatal cancers to all workers at that site.

D.2.2 Sources of Radiation

The sources of radiation pertinent to this EIS can be classified as background (i.e., the radiation to which workers and the public are exposed exclusive of all radiation sources at Pantex Plant and the alternative sites) or site-specific in origin. With respect to background radiation, on the average, Americans receive a total of about 350 millirem per year from all sources of radiation, both natural and man-made. The sources of radiation can be divided into six different categories: cosmic radiation, external terrestrial radiation, internal radiation, consumer products, medical diagnosis and therapy, and other sources. Each category is discussed below.

Cosmic radiation is ionizing radiation resulting from energetic charged particles from space continuously hitting the earth's atmosphere. These particles and the secondary particles and photons they create are cosmic radiation. Because the atmosphere provides some shielding against cosmic radiation, the intensity of this radiation increases with altitude above sea level.

External terrestrial radiation is the radiation emitted from the radioactive materials in the earth's rocks and soils. The average annual dose from cosmic and external terrestrial radiation is about 55 millirem. The cosmic and external terrestrial radiation for the sites in this EIS ranges from about 70 to 120 millirem per year.

Internal radiation arises from the human body metabolizing natural radioactive material which has entered the body by inhalation or ingestion. Natural radionuclides in the body include isotopes of uranium, thorium, radium, radon, polonium, bismuth, potassium, rubidium, and carbon. The major contributor to the annual dose equivalent for internal radioactivity are the short-lived decay products of radon which contribute about 200 millirem per year. The average dose from other internal radionuclides is about 39 millirem per year.

Consumer products also contain sources of ionizing radiation. In some products, like smoke detectors and airport x-ray machines, the radiation source is essential to the products' operation. In other products, such as television and tobacco, the radiation occurs incidentally to the product function. The average annual dose from all consumer products is about 10 millirem.

Radiation is an important diagnostic medical tool and cancer treatment. Diagnostic x-rays result in an average annual exposure of 39 millirem. Nuclear medical procedures result in an average annual exposure of 14 millirem.

There are a few additional sources of radiation that contribute minor doses to individuals in the U.S. The dose from nuclear fuel cycle facilities such as uranium mines, mills and fuel processing plants, nuclear power plants and transportation routes has been estimated to be less than 1 millirem per year. Radioactive fallout from atmospheric atomic bomb tests, emissions of radioactive material from DOE facilities, emissions from certain mineral extraction facilities, and transportation of radioactive materials contribute less than 1 millirem per year to the average dose to an individual. Air travel contributes approximately 1 millirem per year to the average dose.

The collective (or population) dose to an exposed population is calculated by summing the estimated doses received by each member of the exposed population. This total dose received by the exposed population is measured in person-rem. For example, if 1,000 people each received a dose of 1 millirem (0.001 rem), the collective dose is 1,000 persons x 0.001 rem = 1.0 person-rem. Alternatively, the same collective dose (1.0 person-rem) results from 500 people each of whom received a dose of 2 millirem (500 persons x 2 millirem = 1 person-rem).

Site-specific sources of radiation are industrial sources and sources associated with nuclear weapons. The industrial sources are used to generate x-rays and gamma rays for non-destructive examinations of weapon components. Exposure to these sources of radiation only poses a potential risk to workers. However, since nondestructive examination using x-rays and gamma rays is a well established industrial practice, this contribution to worker risk is negligible.

The sources of radiation associated with nuclear weapons include tritium, uranium, and plutonium. Tritium is a radioactive form of hydrogen. By itself, its effects on human health are relatively modest. However, tritium can combine with hydrogen and oxygen to form a radioactive molecule that chemically mimics ordinary water. In this form tritium is readily assimilated by living tissue, which is subsequently irradiated as the tritium decays. This represents the most toxic form of tritium, and is especially a concern if the release involves a fire (which converts most of the tritium into the radioactive form of water).

Uranium is present at Pantex Plant both in the enriched and depleted forms. Enriched uranium contains a high percentage (up to 93 percent) of the 235 isotope, while depleted uranium is mostly the 238 isotope. Although uranium is toxic, its toxicity is so low relative to plutonium that its relative risk to workers and the public is negligibly small.

Plutonium is present in pits and radioisotopic thermoelectric generators (RTGs). The predominant plutonium isotope in pits is 239, while the 238 isotope is used as the RTG power source. Due to their highly robust design and construction, RTGs pose only a negligible risk to workers and the public.

Plutonium poses two principal human health risks: direct exposure to workers involved in disassembly and transportation activities; and a potential inhalation hazard to workers and the public if it is accidentally released and disperses as respirable particles. To be respirable, plutonium particles must be smaller than 10 microns. Particles larger than 10 microns are too large to disperse deeply into the lungs. As a result, they have a relatively short residence time and essentially cause no adverse health effects.

Inhaled plutonium particles smaller than 10 microns are not cleared from the lungs by normal bodily processes. This results in a potentially significant alpha dose to the lungs. Moreover, the plutonium will eventually cross the capillaries into the bloodstream. Once in the bloodstream, the plutonium eventually accumulates at the interface between hard bone and the marrow. Hence, the two most vulnerable organs to plutonium inhalation are the lungs and bone marrow. Both workers and the public are vulnerable to plutonium inhalation if an accident occurs that disperses it as respirable particles (e.g., a fire or explosion).

Plutonium inhalation is not a concern during normal operations because the plutonium is always contained.

D.3 SCENARIO SCREENING

Ideally, a complete risk assessment would express the total human health risk as the sum of all potential accident scenarios. Since it is impractical to rigorously quantify all of the terms in the ideal summation, the purpose of a screening methodology is to identify a subset of the terms such that the summation over this subset constitutes a large fraction (e.g., >95 percent) of the total risk.

The basic facility risk screening methodology used for the Pantex EIS is explained in section D.3.1. This basic methodology identifies the risk dominant potential accident scenarios that require a rigorous analysis in the EIS. A description of the methodology application is presented in section D.3.2.

D.3.1 Screening Methodology

Ideally, a complete risk assessment would express the total facility risk for a particular endpoint, R_T, as the summation:

$$R_T = \sum_{n=1}^{N} R_n \qquad \text{(Eq. D–1)}$$

where there are a total of N scenarios contributing to the risk. Rather than rigorously quantify all N terms in Equation D–1, the purpose of the screening methodology was to identify a subset of the N terms such that the summation over this subset, N', satisfies the relation:

$$\sum_{n \in N'} R_n \geq F \sum_{n=1}^{N} R_n \qquad \text{(Eq. D–2)}$$

where F is some large fraction (e.g., >0.95).

Three endpoints for which the screening methods were applied are:

- Potential direct exposure of workers or the public to radiation and hazardous chemicals as a result of continued operations or change in mission.
- Risk from an accidental release of radionuclides or hazardous chemicals as a result of continued operations or change in mission.
- Potential latent cancer fatalities as a result of continued operations or change in mission.

The first endpoint required addressing the quantities of radiation and hazardous chemicals to which workers or the public are exposed, regardless of the health effects associated with the exposure. The risk from accidental releases stated in the second endpoint definition is interpreted as the risk of fatalities. Quantifying the second and third endpoints necessitated examining both the amount of exposure and the health effects (in terms of the likelihood of a resultant fatality) associated with the exposure.

Risks associated with potential accident scenarios were quantified using probabilistic risk assessment (PRA) techniques. These techniques expressed risk as the product of two parameters:

λ_n	the frequency (per year) that scenario "n" is expected to occur.
C_n	the consequence (e.g., fatal cancers) associated with the occurrence of scenario "n".

The screening methodology used to identify risk dominant potential accident scenarios was predicated upon DOE 1994, DOD 1977, Jones 1988, and DH 1993. Essentially, it involved developing a risk matrix that divided the frequency and consequence ranges into a finite number of categories. The selected frequency categories were from criteria tabulated in DOE 1994:

- Anticipated ($\lambda_n \geq 10^{-2}$ per year).
- Unlikely (10^{-2} per year $> \lambda_n \geq 10^{-4}$ per year).
- Extremely unlikely (10^{-4} per year $> \lambda_n \geq 10^{-6}$ per year).
- Not reasonably foreseeable (10^{-6} per year $> \lambda_n$).

DOE 1994 does not address consequence categories. However, the consequence categories cited in DOD 1977, Jones 1988, and DH 1993 are:

- Catastrophic (consequences cause deaths).
- Critical (consequences cause severe injuries or occupational illnesses).
- Marginal (consequences cause minor injuries or occupational illnesses).
- Negligible (consequences corresponding to no injuries nor occupational illnesses).

The definitions in DOD 1977, Jones 1988, and DH 1993 include environmental consequences and facility damage. Although these additional consequences exceed the endpoint definitions, any potential accident scenario that can appreciably impact the environment or damage a facility is capable of contributing to the risk of a human receptor and was included in the screening process.

Figure D.3.1–1 depicts the risk matrix developed from these frequency and consequence categories. Since:

$$R_n = \lambda_n \times C_n \qquad \text{(Eq. D–3)}$$

it is evident from Figure D.3.1–1 that for a given frequency category, the dominant risk scenarios are those assigned to the highest consequence category. This resulted in the following risk screening process:

- Identification of anticipated scenarios. Those facility-specific, hazard-specific scenarios assigned to the highest consequence category were selected as risk dominant. This consequence was designated category C' (e.g., the marginal category).
- Examination of the unlikely scenarios. If none of these scenarios belonged to a consequence category higher than C', there are no risk dominant scenarios with unlikely frequencies. If some unlikely scenarios belonged to a consequence category higher than C', these facility-specific, hazard-specific scenarios were also risk dominant. If some unlikely scenarios belonged to a consequence category higher than C', then C' designated this higher consequence category (e.g., the critical category).
- Examination of the extremely unlikely scenarios. If none of these scenarios belonged to a consequence category higher than C', there were no risk dominant scenarios with extremely unlikely frequencies. If some extremely unlikely scenarios belonged to a consequence category higher than C', these facility-specific, hazard-specific scenarios were also risk dominant. If some extremely unlikely scenarios belonged to a consequence category higher than C', than C' designated this higher consequence category.
- Examination of the not reasonably foreseeable scenarios. If none of these scenarios belonged to a consequence category higher than C', there were no

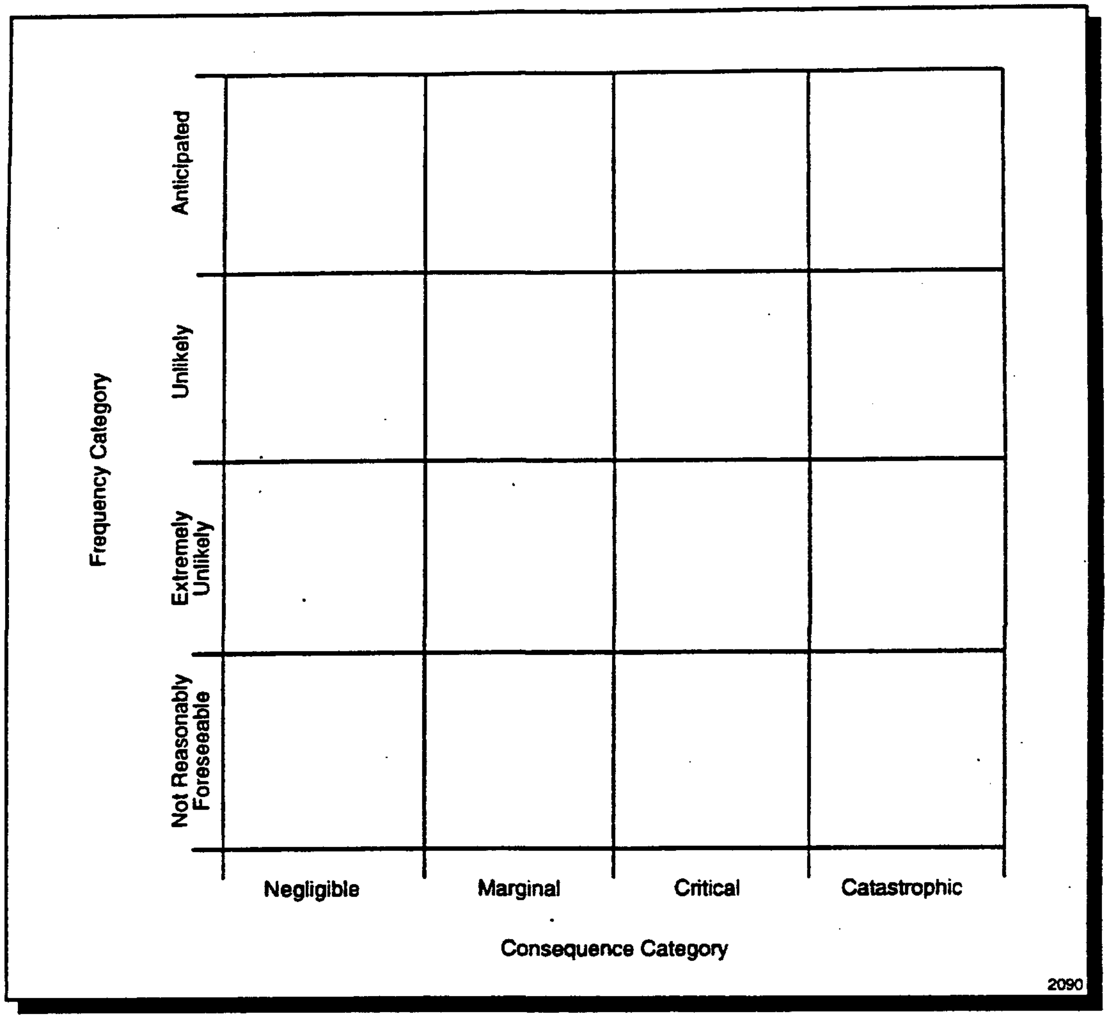

FIGURE D.3.1-1.—***Risk Matrix for Potential Accident Scenario.***

risk dominant scenarios with not reasonably foreseeable frequencies. If some not reasonably foreseeable scenarios belonged to a consequence category higher than C', these facility-specific, hazard-specific scenarios were also risk dominant.

These four steps constitute the process developed for screening risks associated with potential accident scenarios. To the extent practical, frequency categories and consequence categories were assigned using results from applicable risk studies. When applicable PRA results were unavailable, scoping calculations were used to assign scenarios to appropriate frequency and consequence categories.

Figures D.3.1-2 and D.3.1-3 further illustrate the risk screening process. A large X in Figure D.3.1-2 symbolizes that some scenarios have been assigned to a particular risk matrix category. Specifically, Figure D.3.1-2 indicates that:

- All anticipated scenarios have negligible consequences.
- Unlikely scenarios have negligible, marginal, or critical consequences.
- The extremely unlikely scenarios have marginal, critical, or catastrophic consequences.
- All not reasonably foreseeable scenarios belong to either the critical or catastrophic consequence categories.

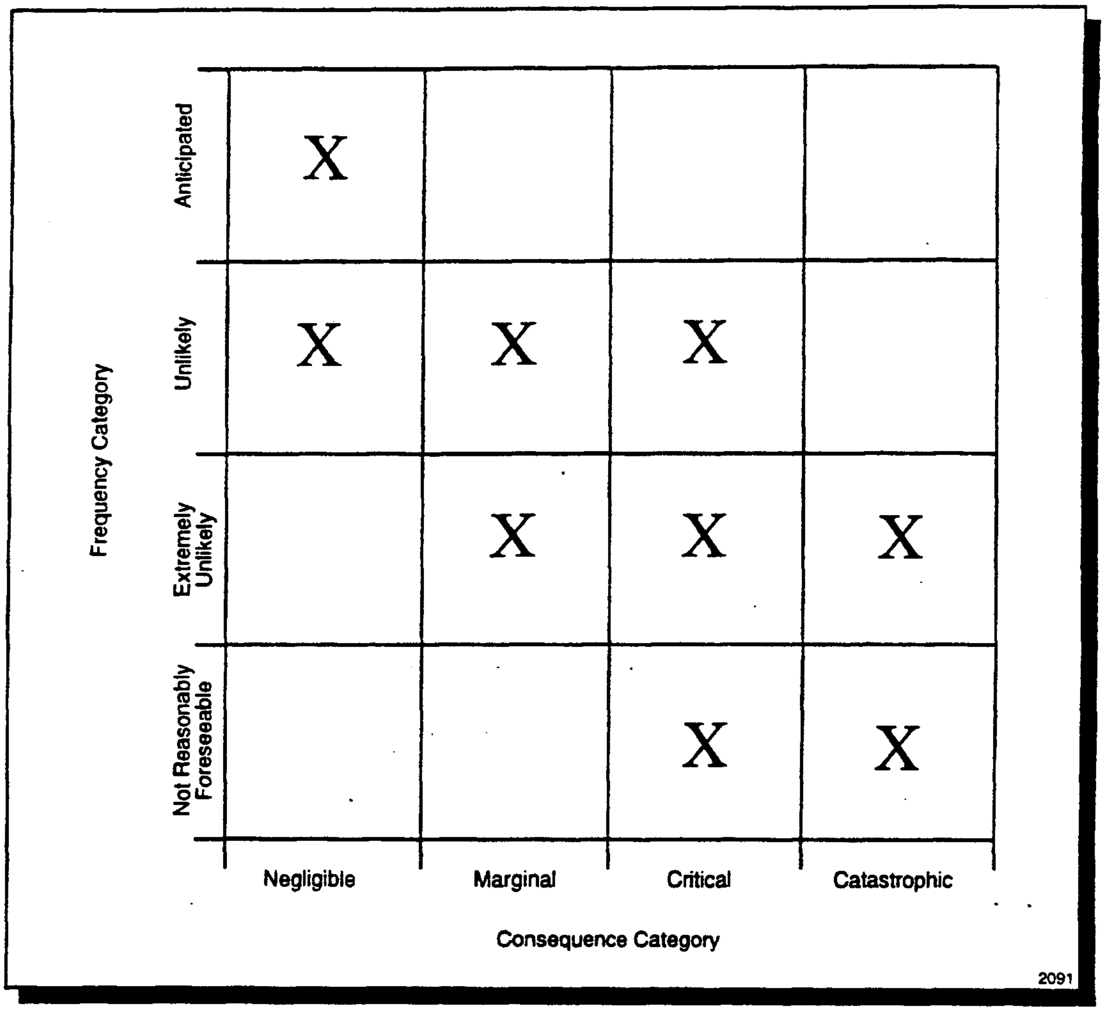

FIGURE D.3.1–2.—*Risk Matrix with Scenarios Assigned to Frequency and Consequence Categories.*

Beginning with the anticipated scenarios, all of them are selected as risk dominant (since they all belong to the same consequence category) using the risk screening process. This selection is depicted by the large circle surrounding the X representing this set of scenarios in Figure D.3.1–3.

Examining the unlikely scenarios disclosed that those assigned to the marginal and critical consequence categories are risk dominant because, even though they are far less likely than the anticipated scenarios, their consequences are greater. However, the unlikely scenarios with negligible consequences are not significant risk contributors. Since each frequency category spans at least two orders of magnitude, the frequency of an unlikely scenario will typically be an order of magnitude or more less than an anticipated scenario. Thus, given an anticipated scenario and an unlikely scenario assigned to the same consequence category, the anticipated scenario risk is typically an order of magnitude or more greater than the risk from the unlikely scenario.

Applying this same reasoning to the extremely unlikely scenarios showed that only those with catastrophic consequences are risk dominant. None of the scenarios assigned to the not reasonably foreseeable frequency category are risk dominant in Figure D.3.1–3.

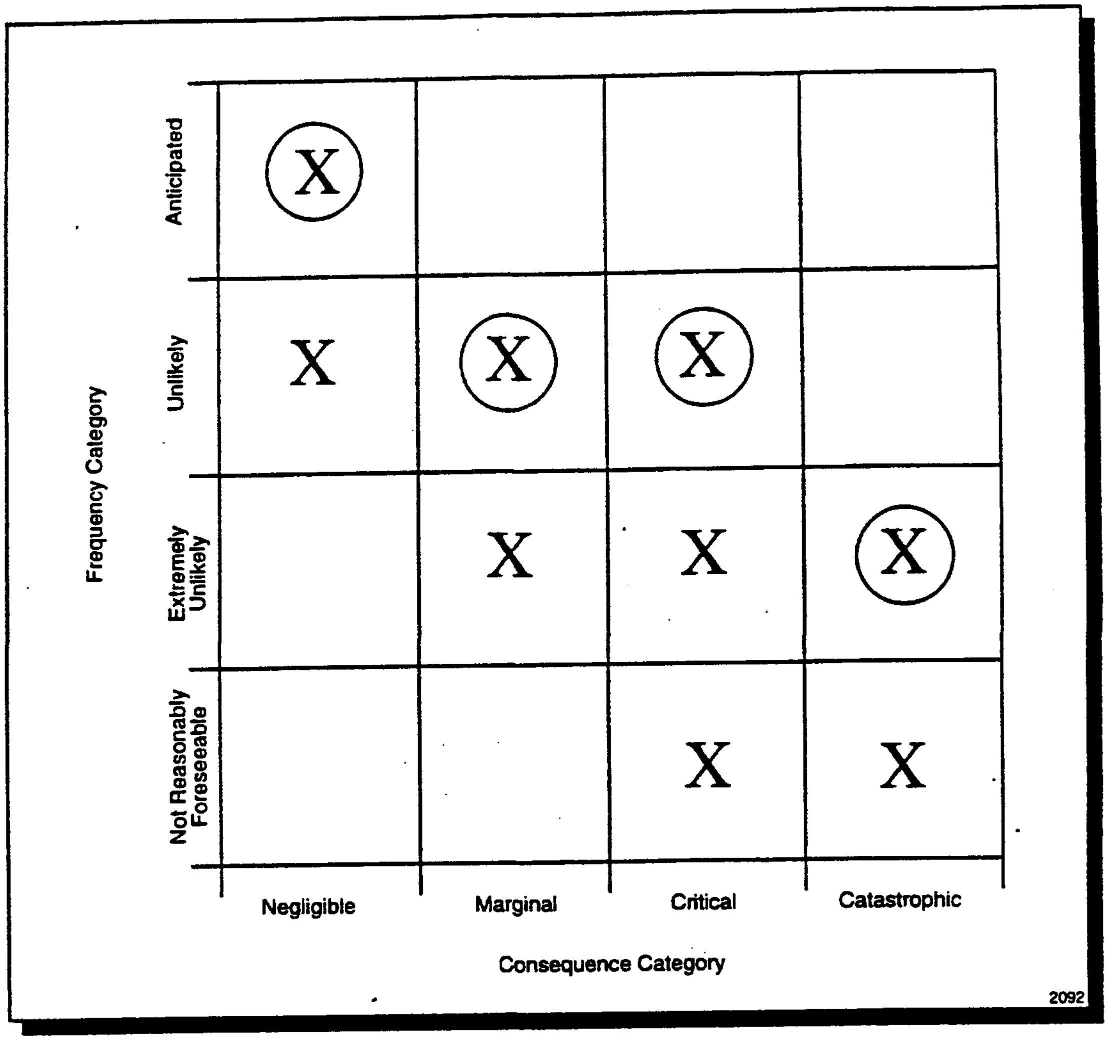

FIGURE D.3.1–3.—*Risk Matrix with Scenarios Identified for Detailed Evaluation.*

The result of this risk screening process is a set of risk dominant scenarios that required detailed analysis. In the context of Equations D–1, D–2, and D–3, the screening process exhibited in Figures D.3.1–1 through D.3.1–3 is an inferential approach for satisfying Equation D–2.

The basic screening methodology embodied in Equation D–2 is a relative risk approach. That is, it identified potential accident scenarios that contribute significantly to the overall facility risk without regard to scenario likelihood or consequence. Thus, it spans the spectrum from high probability-low consequence scenarios to those with extremely low occurrence probabilities, but large consequences. This approach differs from some conventional methods that screened low frequency scenarios without regard to their potential consequences (e.g., DOE 1992a). The typical justification for screening low frequency scenarios without regard to their potential consequences was that such scenarios are not reasonably foreseeable.

An important consideration in applying Equation D–3 is the contribution of the uncertainties inherent in frequency assessments involving numerous conditional probabilities. This consideration is important to provide confidence in the risk estimates (i.e., the product of the scenario frequency and consequence) and to ensure that no potentially risk dominant scenarios are excluded from consideration due to large uncertainties in their assessed frequency. A practical solution to this concern is to use a statistic for the frequency assessment that is relatively easy to calculate, but that also provides confidence that the frequency is not underestimated. The mean frequency is such a statistic. Although the actual impact of inherent uncertainties requires application-specific analyses, the importance of this concern can be illustrated by considering a single scenario with frequency, λ_n. In general:

$$\lambda_n = \lambda_{i,n} \prod_{k=1}^{K} P_k \qquad \text{(Eq. D–4)}$$

Here:

- $\lambda_{i,n}$ is the initiating event frequency for scenario "n".
- P_k is the conditional probability of the kth event that must occur in scenario "n".
- There are a total of K conditional probabilities needed to quantify the scenario frequency.

Uncertainty distributions for the parameters usually encountered in PRAs are lognormal with uncertainty factors (defined as the ratio of the 95th percentile to the median) in the range 2 to 10. Figures D.3.1–4 through D.3.1–6 depict the degree of confidence one can have on the value of λ_n, depending on the number of conditional probabilities in Equation D–4, the statistical values used for each parameter, and the uncertainty factors. A nominal frequency of 10^{-7} per year is used in Figures D.3.1–4 through D.3.1–6, since this represents a not reasonably foreseeable scenario (i.e., a scenario which will typically have large uncertainty). In Figures D.3.1–4 and D.3.1–5 the nominal value corresponds to the mean frequency.

Figure D.3.1–4 shows the mean and 95th percentile (i.e., values where there is 95 percent confidence that they exceed the actual frequency) as a function of the number of conditional probabilities in Equation D–4. If there are no conditional probabilities in the scenario:

$$\lambda_n = \lambda_{i,n} \qquad \text{(Eq. D–5)}$$

and there is 95 percent confidence that the actual frequency is less than 2.4×10^{-7} per year. Although the 95th percentile first increases, then decreases with K, Figure D.3.1–4 demonstrates that if all of the variables in Equation D–4 have uncertainty factors of 3, there is at least 95 percent confidence that the actual frequency exceeds the mean by no more than a factor of 4.

Uncertainty factors of 10 are used in Figure D.3.1–5. Here, the 95th percentile is actually less than the mean when K exceeds 4. This represents a fundamental property of the lognormal distribution—as the overall uncertainty increases the chances of exceeding the mean diminish. Also, Figure D.3.1–5 discloses that there is at least 95-percent confidence that the actual frequency exceeds the mean by no more than a factor of 4.

Figure D.3.1–6 compares the median (instead of the mean) to the 95th percentile. As in Figure D.3.1–4, an uncertainty factor of 3 is assigned to the variables in Equation D–4. Notice that as the number of conditional probabilities increases, the ratio of the 95th percentile to the median continually increases to over one and one half orders of magnitude.

The crucial difference between Figures D.3.1–4 and D.3.1–6 is that different statistical representations of the nominal frequency are used—the mean in Figure D.3.1–4 and the median in Figure D.3.1–6. This suggests that while there is reasonable confidence that the actual scenario frequency will not exceed the mean value, there can be an appreciable chance that the actual scenario frequency exceeds the median value.

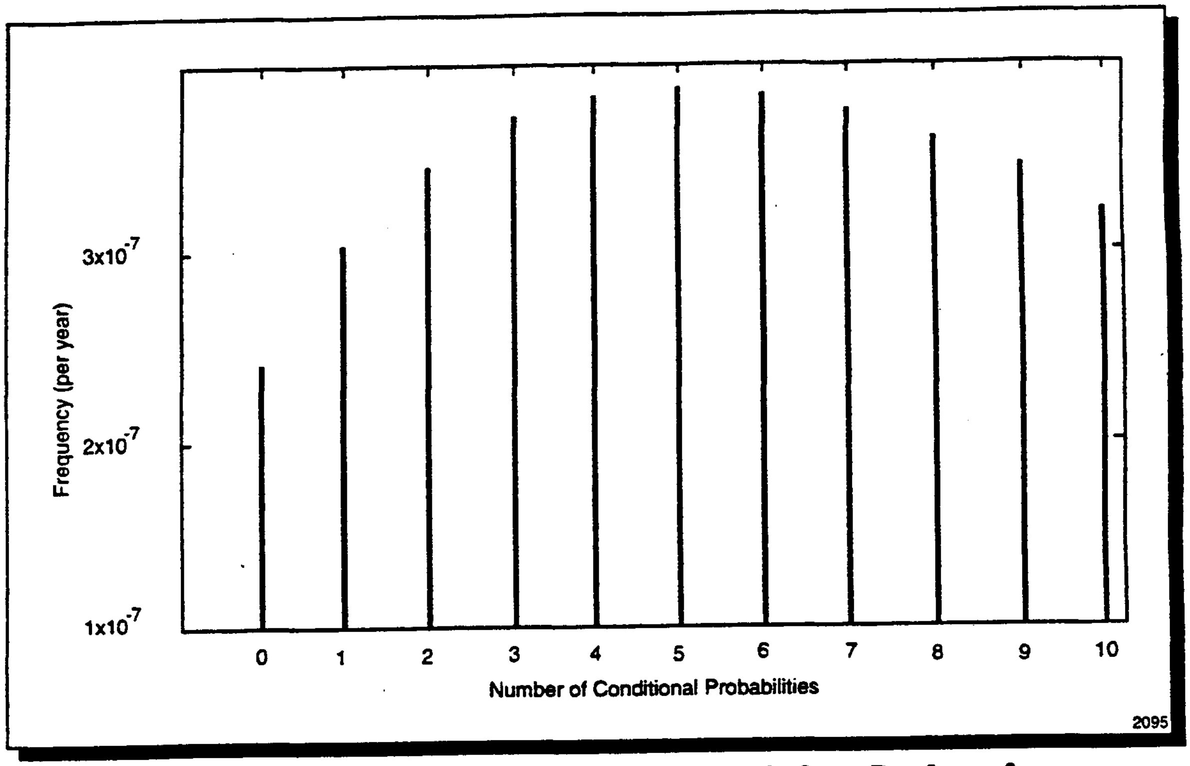

FIGURE D.3.1-4.—***Mean and 95th Percentile for a Product of Probabilities with Uncertainty Factors of 3.***

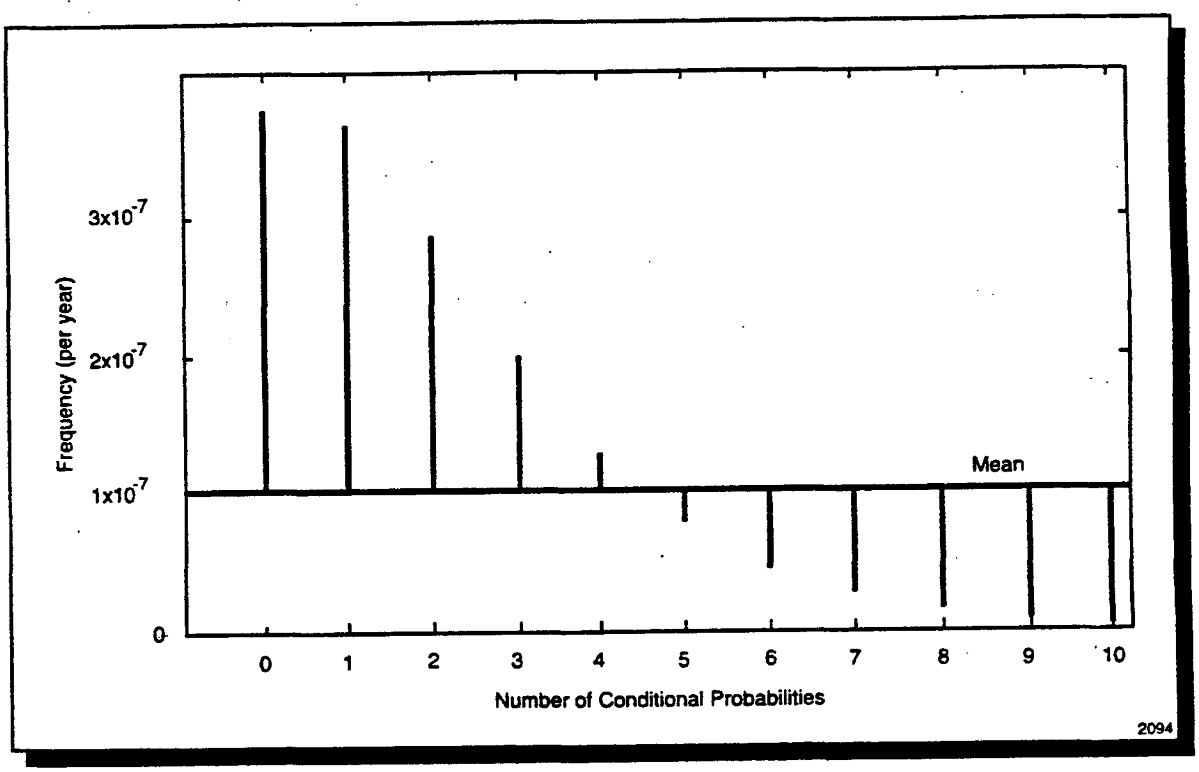

FIGURE D.3.1-5.—***Mean and 95th Percentile for a Product of Probabilities with Uncertainty Factors of 10.***

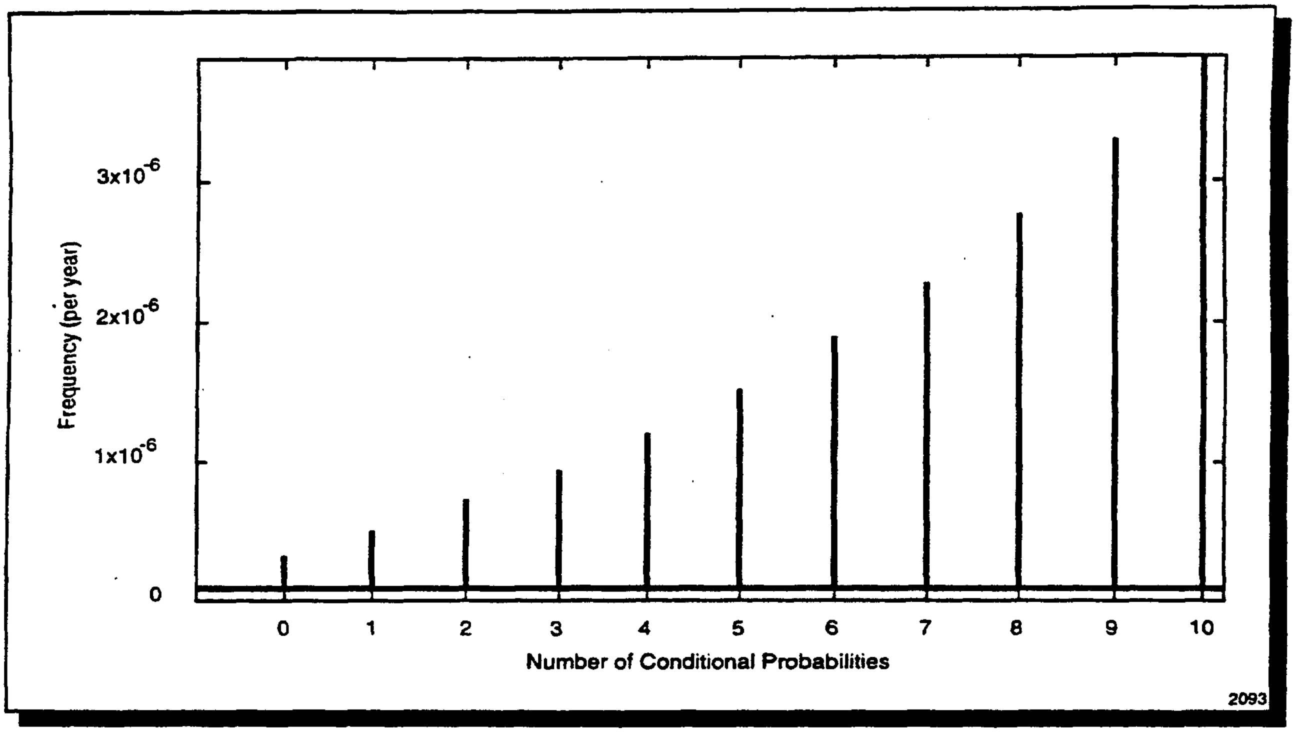

FIGURE D.3.1–6.—*Median and 95th Percentile for a Product of Probabilities with Uncertainty Factors of 3.*

Conclusions obtained from Figures D.3.1–4 through D.3.1–6 are only strictly applicable to situations involving the products of lognormally distributed parameters. Fortunately, such situations are commonly encountered in PRAs. However, caution must be exercised when estimating confidence levels for calculations differing from Equation D–4.

D.3.2 Screening Methodology Application

Table D.3.2–1 contains the risk dominant scenarios for Pantex Plant. These are the scenarios that remained after the section D.3.1 methodology was applied to the candidate scenarios in Table D.3.2–2. Using frequency and consequence estimates from available plant safety and environmental documents, the Table D.3.2–2 scenarios were grouped into the appropriate risk matrix categories. Since it is somewhat difficult to directly compare the consequences of all scenarios together, candidate scenarios involving radionuclide hazards, chemical hazards, and high explosive (HE) hazards were considered separately. The risk dominant scenarios for each of these three hazards appear in Table D.3.2–1 for Pantex Plant.

This same process was applied to the alternative sites. Since only relocation of pit storage is being considered at these alternative sites, many of the candidate scenarios in Table D.3.2–1 are inapplicable. For example, candidate scenario C40 in Table D.3.2–2 is applicable to pit storage at an alternative site (although the facility designations in Table D.3.2–2 would have to be modified to the appropriate facility at the alternative site—e.g., P-Reactor at the Savannah River Site). However, candidate scenario C2 in Table D.3.2–2 is inapplicable to the alternative sites since there will be no relocation of tritium. Similarly, candidate scenarios involving HE fires and explosions or

TABLE D.3.2–1.—*Risk-Dominant Scenarios for Pantex Plant*

SCENARIO	DESCRIPTION
1	HE explosion initiated during normal operation releases tritium and plutonium due to reservoir and pit failure.
2	HE explosion initiated during normal operation without accompanying radionuclide releases.
3	HE explosion initiated by seismic event or aircraft accident releases tritium and plutonium due to reservoir and pit failure.
4	HE explosion initiated by seismic event or aircraft accident without accompanying radionuclide releases.
5	Tritium release resulting from reservoir failure initiated during normal operation.
6	Pit breach with plutonium release initiated during normal operation.
7	Tritium release resulting from reservoir failures caused by a Building 12-42 South Vault fire initiated by a seismic event or aircraft accident.
8	Pit breach with plutonium release caused by seismic event or aircraft accident.
9	Tritium or plutonium release caused by seismic event or aircraft accident.
10	Chlorine release due to failure of system piping and valves, or cylinder caused by seismic event.
11	Chlorine release due to failure of system piping and valves, or cylinder initiated during normal operation.

TABLE D.3.2–2.—*Candidate Accident Scenarios for Pantex Plant*

CANDIDATE SCENARIO	DESCRIPTION[(1)]
C1	Pit breach with Plutonium release due to operational accidents in 12-64, 12-84, 12-99, and 12-104.
C2	Tritium release due to operational accidents in 12-64, 12-84, 12-99, and 12-104.
C3	Criticality accidents due to operational accidents in 12-64, 12-84, 12-99, and 12-104.
C4	HE explosions due to operational accidents in 12-64, 12-84, 12-99, and 12-104.
C5	HE fires due to operational accidents in 12-64, 12-84, 12-99, and 12-104.
C6	Aircraft initiated accidents involving 12-64, 12-84, 12-99, and 12-104.
C7	Earthquake initiated accidents involving 12-64, 12-84, 12-99, and 12-104.
C8	Tornado and high wind initiated accidents involving 12-64, 12-84, 12-99, and 12-104.
C9	Internal flood initiated accidents involving 12-64, 12-84, 12-99, and 12-104.
C10	Lightning initiated accidents involving 12-64, 12-84, 12-99, and 12-104.
C11	Pit breach with plutonium release due to operational accidents in 12-44, 12-85, 12-96, and 12-98.
C12	Tritium release due to operational accidents in 12-44, 12-85, 12-96, and 12-98.
C13	Criticality accidents due to operational accidents in 12-44, 12-85, 12-96, and 12-98.
C14	HE explosions due to operational accidents in 12-44, 12-85, 12-96, and 12-98.
C15	HE fires due to operational accidents in 12-44, 12-85, 12-96, and 12-98.
C16	Aircraft initiated accidents involving 12-44, 12-85, 12-96, and 12-98.
C17	Earthquake initiated accidents involving 12-44, 12-85, 12-96, and 12-98.

BG - Burning Ground.
[1]Numbers in this column refer to specific buildings.
[2]These scenarios are particularly applicable to the storage pits at the alternative sites.

hazardous chemicals are inapplicable to the alternative sites. Candidate scenarios particularly applicable to pit storage at the alternative sites are footnoted in Table D.3.2-2.

Relative to the hazards considered for Pantex Plant, the only hazardous material applicable to alternative sites is pits. Moreover, the only significant risk to these pits during normal operations is the risk from a forklift accident during transfer operations when the pits are being placed into storage.

All of the external events and natural phenomena considered for Pantex Plant are included in the candidate scenarios for alternative sites. In addition, some site-specific natural phenomena were added. When the relative risks from a forklift accident and candidate scenarios initiated by external events or natural phenomena are compared, the forklift accident is risk dominant at all alternative sites (with the possible exception of earthquakes at Manzano Weapons Storage Area [WSA]).

There are two reasons why forklift accidents are risk dominant at the alternative sites. First, fewer facilities are at risk at the alternative sites than at Pantex. For example, the Zone 4 storage magazines, as well as the Zone 12 bays, cells, and support facilities, are included in the aircraft accident analysis at Pantex Plant. Except for Manzano WSA, the number of facilities at risk, plus the intensity of aircraft traffic (especially aircraft capable of causing facility damage) is significantly higher at Pantex Plant than at the alternative sites.

At Manzano WSA, the rock overburden reduces the likelihood that an aircraft impact could cause a release from the candidate storage facilities to a negligible level (see section E.3.2.2). Therefore, the frequency of a radionuclide release caused by an aircraft impact is significantly lower at the alternative sites. Although the consequences resulting from a radionuclide release initiated by an aircraft impact are potentially greater than the consequences resulting from a forklift accident, the risk (expressed as the product of frequency and consequence) from aircraft impacts at the alternative sites is a small fraction of a percent relative to the risk associated with a forklift accident (with the possible exception of earthquakes at Manzano WSA).

The risk from natural phenomena at Pantex Plant is dominated by earthquakes. This is not a result of potential earthquake damage to storage magazines, but rather is due to the possibility of seismic damage to certain support facilities that were erected in the late 1940's and 1950's (and which could be replaced by proposed facility construction and upgrades at Pantex Plant as described in appendix H). In terms of relative risk, the contribution to the risk at Pantex Plant from external events that threaten the Zone 4 storage magazines is negligible. With respect to pit storage, this low relative risk is due to the robust construction of the magazines and the integrity of the AT-400A shipping containers. A similar situation exists at the alternative storage sites, and is the second reason why forklift accidents are risk dominant at the alternative sites (with the possible exception of earthquakes at Manzano WSA). Figure D.3.2-7 illustrates this concept.

Occurrence of an external event or natural phenomenon is the initiating event in Figure D.3.2-7. Given that the initiating event occurs, a release from the stored pits is only possible if facility damage results from the initiating event. None of the facilities being considered at the alternative sites are vulnerable to external events or natural phenomenon that are within their design basis. Moreover, even for external events or natural phenomenon that exceed the design basis (a low probability event), the onset of facility damage is typically insufficient to breach the AT-400A shipping containers. Of the natural phenomena capable of causing significant facility damage (if the design basis is sufficiently exceeded), earthquakes are the most likely to cause a significant release (relative to other natural phenomena). For this reason, earthquakes are the risk dominant natural phenomena at the alternative sites.

Preliminary test results demonstrate that an AT–400A shipping container can survive the impact of a half ton mass dropped from a height of 110 feet without any loss of containment capability (PC 1995). Thus, even if the external event or natural phenomenon induced facility damage is severe, there is a high probability that the containers will remain intact. In the context of Figure D.3.2–7, the frequency of a plutonium release is well into the not reasonably foreseeable range defined in section D.3.1. Although the consequences of a plutonium release initiated by an external event or natural phenomenon are potentially high, the relative risk from such scenarios is negligible because of the low frequency that the release can occur.

D.4 Evaluation of Risk-Dominant Scenarios

Both high frequency, low consequence scenarios (such as those occurring during normal operations), and low frequency scenarios having potentially high consequences (i.e., scenarios initiated by natural phenomena or external hazards), are included in Table D.3.2–1. These scenarios were left when the methodology discussed in section D.3 was applied to the Pantex Plant scenarios of Table D.3.2–2. For all scenarios, the frequency and consequence assessments were performed on a site-wide, rather than a facility-specific, basis. This means, for example, that the frequency of a hazardous material release involving a specific handling operation was estimated by first quantifying the probability, per handling operation, that the accident occurs and then multiplying that probability by the total number of handling operations performed annually on site. If the particular handling operation (e.g., involving weapon disassembly) is performed in several separate facilities, then the release frequency incorporates the contribution from all of the individual handling facilities. However, since handling operations typically involve only a single hazardous material unit at a time (e.g., just one pit or one tritium reservoir), the consequences were generally quantified using the release from a single, standard unit in an intact facility (unless the scenario involved an HE explosion).

Aircraft accidents (the risk dominant external hazard for all sites) were modeled somewhat differently. Due to the proximity of Zones 4 and Zone12 to established flight paths and their high inventory of radionuclides, the site-wide risk from aircraft accidents at Pantex Plant is

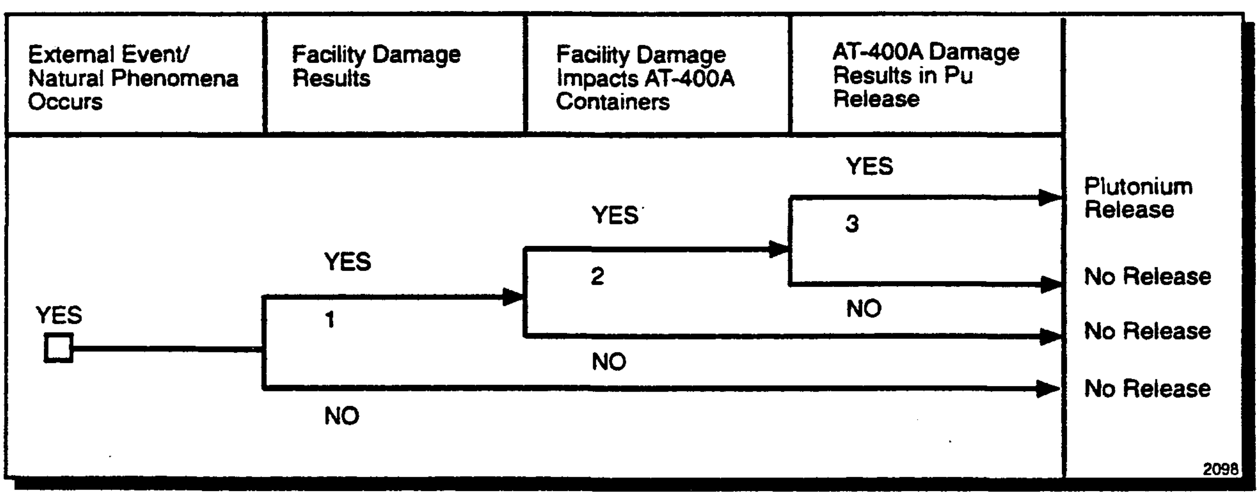

FIGURE D.3.2–7.—*External Event/Natural Phenomena Event Tree for Pits Stored in AT–400A Shipping Containers.*

governed by these zones. The material at risk from an aircraft accident is the inventory of the facility damaged by the impact. This differs from the consequences of most handling accidents (without an HE detonation) in that, in an aircraft accident, multiple units are involved and the facility can be extensively damaged. For alternative storage sites, the material at risk from an aircraft accident includes the inventory of the alternative pit storage facility.

Earthquakes are the risk dominant natural phenomena for all sites. All of the facilities that contain potentially risk significant quantities of hazardous materials were examined in the Pantex Plant seismic assessment. A unique aspect of this seismic assessment is that all site facilities would be simultaneously subjected to seismic stresses, given that an earthquake occurs. Hence, unlike handling and aircraft accidents, seismic events are truly site-wide and can result in releases from multiple facilities. For alternative storage sites, the material at risk from an earthquake is the inventory of the alternative pit storage facility.

D.4.1 Frequency Assessment

Quantifying the frequencies of risk-dominant scenarios required three distinct types of assessments addressing:

- Internal initiators.
- Aircraft accidents.
- Earthquakes.

The frequency assessment of internal initiators relied almost exclusively on published site-specific, accident-specific safety analyses (see references cited in volume I, section 4.14.2.1 and individual scenario descriptions). The basic methodology equated the scenario frequency to the frequency that an operation is performed (e.g., 2,000 disassemblies per year), multiplied by the probability that an operational error would result in a hazardous material release (e.g., the probability, per disassembly, that an operational error would cause a tritium or plutonium release).

For example, the explosive-driven plutonium dispersal from an internal event (Scenario 1) could result from operations conducted in bays, cells, and special purpose facilities. The probability (per operation) that an operational error would cause an explosive-driven plutonium release was estimated for each facility using data from available safety analyses. The frequency (per year) was quantified by multiplying the probability (per operation) by the annual number of operations in each facility, and then summing the results.

Appendix E describes the methodology used for assessing the frequency of aircraft accidents.

The frequency of hazardous material releases initiated by earthquakes is predicated upon a methodology developed in the DOE Standard for *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities* (DOE 1994:C-8, C-9, C-25). Conceptually, the earthquake assessment methodology considers two parameters:

- Frequency, per year, that earthquakes of different intensities occur.
- Probability of facility failure (e.g., building collapse) given an earthquake with a particular intensity.

For a given earthquake intensity, the product of the earthquake frequency and facility failure probability is the frequency, per year, that earthquakes with the specified intensity would cause the facility to fail. By summing these products over the entire range of earthquake intensities, an overall frequency for earthquake induced facility failure is obtained. This basic methodology was directly applicable to earthquakes at the alternative storage sites.

Multiple facilities are at risk from earthquakes at Pantex Plant. For the Pantex Plant assessment, it was necessary to multiply the earthquake frequency by the probability that just one, two, or a specified number of facilities fail in order to determine the frequency, per year, that earthquakes with the specified intensity would cause various combinations of facilities to fail. For a given combination of facility failures, summing these products over the entire range of earthquake intensities gave the overall frequency for earthquake induced facility failures. Considering the overall frequency of multiple facility failures was necessary to quantify the total risk from earthquakes, which threaten all of the facilities onsite.

Facility failure would not necessarily result in a hazardous material release (e.g., it is extremely difficult for a facility failure to breach a shipping container). Using a methodology similar to the one applied for internal initiators, the scenario frequency was determined by multiplying the facility failure frequency (due to an earthquake) by the probability the failure would result in a hazardous material release. For Scenario 7 in Table D.3.2–1, the scenario frequency was determined by multiplying the facility failure frequency (due to an earthquake) by the probability that the failure would result in a fire that would damage the 12–42 South Vault tritium reservoirs.

D.4.2 Radiological Consequence Assessment

Two computer codes were used to assess the consequences of a radionuclide release:

- Melcor Accident Consequence Code System (MACCS) (NRC 1990a, NRC 1990b, NRC 1990).
- Explosive Release Atmospheric Dispersion (ERAD) (DOE 1992).

ERAD was used to quantify the consequences from scenarios in which the radionuclides are dispersed into the atmosphere explosively (i.e., by an HE detonation). All other scenarios involving a radionuclide release were quantified with MACCS. Descriptions of both codes follow.

D.4.2.1 *Application of the Melcor Accident Consequence Code System*

The MACCS computer code models the offsite consequences of an accident that releases a plume of radioactive materials to the atmosphere (NRC 1990a; NRC 1990b; NRC 1990). Should such an accidental release occur, the radioactive gases and aerosols in the plume would be transported by the prevailing wind while dispersing in the atmosphere. The environment would be contaminated by radioactive materials deposited from the plume and the population would be exposed to radiation. The MACCS calculation estimates the range and probability of the health effects induced by radiation exposures (that are not avoided by protective actions). There are two fundamental aspects of the organization of MACCS which are basic to its understanding: the time scale after the accident is divided into various "phases" and the region surrounding the site is divided into a polar-coordinate grid.

The time scale after the accident is divided into three phases: emergency phase, intermediate phase, and long-term phase. The emergency phase begins immediately after the accident and could last up to 7 days following the accident. In this period, the exposure of population to both radioactive clouds and contaminated ground is modeled. Various protective measures can be specified for this phase, including evacuation, sheltering, and dose-dependent relocation.

The intermediate phase is used to represent a period in which evaluations are performed and decisions are made regarding the type of protective actions that need to be taken. In this period, the radioactive clouds are assumed to be gone and the only exposure pathways are those from the contaminated ground. The protective measure which can be taken during this period is temporary relocation.

The long-term phase represents all time subsequent to the intermediate phase. The only exposure pathways considered here are those resulting from the contaminated ground. A variety of protective measures can be taken in the long-term phase in order to reduce doses to acceptable levels: decontamination, interdiction, and condemnation of property.

The spatial grid used to represent the region is centered on the facility itself. The user specifies the number of radial divisions as well as their endpoint distances. Up to 35 of these divisions may be defined, extending out to a maximum distance of 9,999 kilometers (6,200 miles). The angular divisions used to define the spatial grid correspond to the 16 directions of the compass.

The emergency phase calculations use dose-response models for early fatality and early injury and are performed on a finer grid than the calculations of the intermediate and long-term phases. For this phase, the 16 compass sectors are divided into 3, 5, or 7 user-specified subdivisions in the calculations.

For the analysis of high consequence accidents at the different facilities, the MACCS calculations used the source term data and modeled the dispersion and deposition of radionuclides released from facilities to the atmosphere with a straight-line Gaussian plume. Plume rise and dry and wet deposition were taken into consideration. One year of hourly onsite meteorological data and a weather bin sampling technique were used to represent the dispersion process according to each site's characteristic weather. Downwind concentrations of radionuclides up to a distance of 80 kilometers (50 miles) were calculated for each of 16 directional sectors around the facility.

Radiation doses to an offsite population were calculated in the dosimetry models using the concentrations of radionuclides obtained from the dispersion models. Exposure pathways considered in MACCS for calculating doses received during the period following an accident were direct radiation from the passing plume and from radioactive material deposited on the ground, inhalation from the plume, deposition on skin, and inhalation of resuspended ground contamination. Long-term exposure pathways and liquid exposure pathways were not considered. No credit was taken for short-term actions such as evacuation, sheltering, and relocation.

Resuspension of particulate matter that has settled out of the plume is explicitly modeled in MACCS. The inhalation dose of the emergency phase from the resuspended radionuclides after passage of a plume segment is calculated for each of the fine spatial elements using the following equation:

$$DR_k = \left[\sum_i GC_i \cdot DFI_{ik}\right] \cdot BR \cdot J \cdot RF \cdot SFI \quad \text{(Eq. D–6)}$$

where:

DR_k = Resuspension inhalation dose (Sv) to organ "k" after passage of a plume segment over a fine spatial element.

GCi = ground concentration (Bq/m^2) of radionuclide "i" under the plume center line at the time that plume leaves the fine spatial element, calculated by the ATMOS module.

DFI_{ik} = inhalation dose conversion factor (Sv/Bq inhaled) to organ "k" for radionuclide "i", MACCS Dose Conversion Factors File.

BR = breathing rate (m^3/s), user-specified.

J = off-center line correction factor (dimensionless), of the fine spatial element.

RF = time-integrated resuspension factor (s/m) defined below.

SFI = inhalation shielding factor (dimensionless), specified by user.

The resuspension factor, RF, is calculated using the following equation:

$$RF = RC \cdot \int_{t_1}^{t_2} e^{-\lambda t} dt = RC \cdot \left(e^{-\lambda t_1} \cdot e^{-\lambda t_2}\right) / \lambda$$

(Eq. D–7)

where:

RC = the resuspension coefficient that relates ground concentration to air concentration (m^{-1}); user-specified.

λ = the natural log of 2 divided by the resuspension half-life (s^{-1}); user-specified.

t_1 = the time from plume departure to the entrance of the individual into the spatial element (s).

t_2 = the time from plume departure to the departure of the individual from the spatial element (s).

In addition, the chronic exposure model calculates doses from inhalation of resuspended radionuclides. These doses are calculated for all inhabitants living in areas that are not permanently interdicted.

The resuspension inhalation dose of the intermediate or long-term phase for a given time period is calculated for each of the coarse spatial elements using the following equation:

$$DR_k = \sum_i GC_i \cdot DFR_{ik} \cdot SFI \qquad \text{(Eq. D–8)}$$

where:

DR_k = resuspension inhalation dose (Sv) to organ "k" in a spatial element for a given time period.

GC_i = Initial ground concentration (Bq/m^2) of radionuclide "i" in a spatial element.

DFR_{ik} = resuspension inhalation dose factor ($Sv\text{-}m^2/Eq$) to organ "k" for radionuclide "i" for a given time period, defined below.

SFI = inhalation shielding factor (dimensionless).

For the intermediate and long-term phases, the inhalation shielding factor for normal activity (user-specified) is used in the resuspension inhalation dose calculation.

The computation of the resuspension dose factor, DFR_{ik}, for a specific time period t_1 to t_2 requires the evaluation of the following function:

$$DFR_{ik} = BR \cdot DFI_{ik} \cdot \int_{t_1}^{t_2} (e^{-\lambda t} \cdot Rw(t)\, dt)$$

(Eq. D–9)

where:

DFI_{ik} = inhalation dose conversion factor (Sv/Bq inhaled) of either acute or lifetime dose to organ "k" for radionuclide "i", MACCS Dose Conversion Factors File.

BR = breathing rate (m^3/s).

λ_i = decay constant (s^{-1}) of radionuclide i.

Rw(t) = resuspension weathering function, defined below.

If a radionuclide decays to a radioactive daughter, the resuspension inhalation dose resulting from the daughter is added to the resuspension inhalation dose of the parent radionuclide.

The resuspension weathering equation is a multi-term exponential decay function:

$$Rw(t) = \sum_{m=1}^{3} \left(RC_m \cdot e^{-\lambda_m t} \right) \quad \text{(Eq. D–10)}$$

where:

RC_m = resuspension weathering coefficient (m^{-1}) for the m-th term

λ_m = resuspension weathering decay constant (s^{-1}) for the m-th term

D.4.2.2 *Application of the Explosive Release Atmospheric Dispersion Computer Code*

The ERAD code was developed by Sandia National Laboratories (DOE 1992). ERAD provides a three-dimensional numerical simulation for the dispersal of gaseous and particulate airborne source materials in which initial cloud dynamics, turbulent diffusion, and buoyancy effects coupled with elevation-dependent physical and thermodynamic properties of the plume are considered. ERAD's meteorological component implements state-of-the-art scaling derived from Monin-Obukhov similarity theory to model turbulent velocity profiles in the planetary boundary layer. Particle dispersion and depletion are modeled as stochastic processes and simulated using a discrete-time Lagrangian Monte Carlo algorithm. Several thousand individual particle trajectories are traced to determine respirable dosage and deposition contours over the affected area. Particulate resuspension is not modeled in ERAD.

ERAD was developed to give real-time predictions, using field-portable computers, of the radiological hazards resulting from accidents arising in the storage and transportation of nuclear materials and possible acts of terrorism. Actual meteorological data are input to ERAD to model surface friction, thermal turbulence, and mixing height of the planetary boundary layer. These parameters include:

- Effective surface roughness length.
- Relative humidity and atmospheric pressure.
- Vertical profiles of atmospheric temperature, wind direction, and speed.

The menu-driven code has an extensive health physics library that allows the user to select specific radionuclides. Downwind consequences of different types of atmospheric releases of radioactive materials may be analyzed by three programs:

- Non-buoyant—continuous or puff releases.
- Detonation—releases resulting from the detonation of chemical high explosive.
- Fire Plume—continuous releases resulting from fuel fires.

The fire plume model for the ERAD code is currently undergoing verification and was not used for calculations in this EIS.

The complete ERAD code with UNIX-based graphical user interface was developed for Sun workstations. Depending on the speed of the machine, a 10,000-particle Monte Carlo simulation may take as long as 5 to 10 minutes to execute (5,000-particle simulations are usually adequate in most cases).

Health effects consequences for an accident under these circumstances are obtained by multiplying the predicted dosages or time-integrated concentrations by the proper scaling factors. Health risk to the exposed population may be determined by summing the individual health effects over the number of people residing in the affected area.

Perhaps the most notable feature of the ERAD result is the asymmetrical distribution of the dosage contours about the mean surface wind direction. The effect is caused by the variation of wind direction with altitude, relative to surface winds. ERAD also accounts for terrain effects through a term for effective roughness length. Mechanical turbulence increases with the roughness length due to increased surface friction. This decreases the area enclosed by a given dosage isopleth because of enhanced mixing of airborne materials with entrained air.

Two consequence assessments, representative and upper bound, are performed for each scenario that releases radionuclides. The representative consequence represents what is most likely to occur if the release is initiated, while the upper bound indicates sensitivity to uncertainties in the release source term, facility response, and meteorology. For MACCS calculations, the representative consequences cited in Tables D.4.2.2–1 and D.4.2.2–2 are estimated by Monte Carlo simulation. This is achieved because MACCS calculates the consequences for numerous meteorological

TABLE D.4.2.2–2.—*Representative and Upper Bound Radiological Consequences to the Non-Involved Worker from Risk-Dominant Scenarios*[1]

SCENARIO	EXPOSURE (PERSON-REM)		FATAL CANCERS	
	REPRESENT-ATIVE	UPPER BOUND	REPRESENT-ATIVE	UPPER BOUND
Pantex 1	2×10^3 (6×10^2)[2]	5×10^3 (1×10^3)[2]	9×10^{-1} (2×10^{-1})[2]	1 (6×10^{-1})[2]
Pantex 3	40 (30)[2]	50 (50)[2]	2×10^{-2} (1×10^{-2})[2]	2×10^{-2} (2×10^{-2})[2]
Pantex 5	3×10^{-1}	5×10^{-1}	1×10^{-4}	2×10^{-4}
Pantex 6	4×10^{-3}	9×10^{-3}	1×10^{-6}	4×10^{-6}
Pantex 7	50	4×10^2	2×10^{-2}	2×10^{-1}
Pantex 8	3×10^3	6×10^3	1	1
Pantex 9	4	9	1×10^{-3}	4×10^{-3}
Nevada Test Site (Handling Accident)	6×10^{-2}	2×10^{-1}	3×10^{-5}	8×10^{-5}
Savannah River Site (Handling Accident)	5×10^{-2}	1×10^{-1}	2×10^{-5}	6×10^{-5}
Manzano WSA (Handling Accident)	5×10^{-2}	1×10^{-1}	2×10^{-5}	6×10^{-5}
Hanford Site (Handling Accident)	6×10^{-5}	2×10^{-4}	3×10^{-8}	6×10^{-8}

[1]The risk to close-in workers from Scenarios 1 and 3 is dominated by HE blast effects. The risk to more distant workers (i.e., beyond the range where human health effects are dominated by the blast) contain large uncertainties associated with evacuation and/or sheltering. The consequences cited in Table D.4.2.2–2 are conservative in that they ignore both evacuation and sheltering.
[2]Values in parentheses are for Configuration 2, as described in section 4.14.2.1 of Volume I.

conditions and then identifies the mean and upper bound consequences.

ERAD lacks the Monte Carlo capabilities of MACCS. For ERAD calculations, the typical consequences cited in Tables D.4.2.2–1 and D.4.2.2–2 use mean meteorological parameters obtained from upper air soundings recorded at the Amarillo International Airport. Upper bound consequences obtained from ERAD are for upper bound meteorological conditions being used in developing Pantex Plant safety documents.

For example, the consequence of Scenario 1 is the arithmetic mean for the consequences associated with explosive driven plutonium releases from internal events in bays, cells, and special purpose facilities. This involved three sets of calculations. First, consequences were calculated for the case in which Scenario 1 occurs in a bay. Next, consequences were calculated for the case in which Scenario 1 occurs in a cell. Finally, consequences (both the exposure and excess fatal cancers) were calculated for the case in which Scenario 1 occurs in a special purpose facility.

The arithmetic mean of these consequences is the probability that Scenario 1 occurs in a bay, multiplied by the consequences of the case in which Scenario 1 occurs in a bay; plus the probability that Scenario 1 occurs in a cell, multiplied by the consequences for the case in which Scenario 1 occurs in a cell; plus the probability that Scenario 1 occurs in a special purpose facility, multiplied by the consequences for the case in which Scenario 1 occurs in a special purpose facility. The probability used for each facility was the ratio of the frequency (i.e., the probability per operation that an error causes a release from the facility, multiplied by the annual number of operations in the facility) that Scenario 1 occurs in the facility, divided by the frequency of Scenario 1 (i.e., 1.1 x 10^{-5} per year.)

Tables D.4.2.2–1 and D.4.2.2–2 give the representative and upper bound consequences for each risk dominant scenario that involves a radionuclide release. Table D.4.2.2–3 gives the source terms (i.e., curies of respirable plutonium and tritium released to the atmosphere as a result of a potential accident) used to quantify the representative public and non-involved worker consequences in Tables D.4.2.2–1 and D.4.2.2–2. The source term used for a handling accident at an alternative site is 9.2 x 10^{-5} curies of plutouium.

Table D.4.2.2–4 gives the representative upper bound consequences to the maximally exposed offsite individual for each risk dominant scenario that involves a radionuclide release. This hypothetical individual is located at the site boundary closest to the radiological release. The wind is assumed to blow the radiological release directly towards this individual. For scenarios such as Scenario 1 in which more than one facility has been modeled, results for the facility giving the highest consequence at the site boundary are presented in Table D.4.2.2–4.

The fatal cancer consequences presented in Table D.4.2.2–1 are the excess fatal cancers expected to occur over a 50-year period following the accident in the population in the Region of Influence (ROI). For Pantex Plant, the population in the ROI is 267,107 people. As stated previously, 20 percent of this population is expected to succumb to fatal cancer from all other causes (0.2 x 267,107 = 5.3 x 10^4 fatal cancers). For the fatal cancer consequences presented in Table D.4.2.2–2, the non-involved worker is defined as a receptor 100 meters (328 feet) downwind from the release point, along the plume center line.

Table D.3.2–1 identifies Scenarios 1 and 3 as involving radionuclide releases associated with HE explosions. In Scenario 1, the HE explosion is initiated during normal operations. A seismic event or aircraft accident initiates the HE explosion considered in Scenario 3.

Sensitivity studies using ERAD disclose that the consequences of scenarios involving HE explosions vary with the ratio of plutonium to HE. In assessing the consequences presented in Tables D.4.2.2–1 and D.4.2.2–2, the ratio of plutonium to HE was varied to determine the maximum consequences to the public.

TABLE D.4.2.2–3.—*Representative Source Terms*

SCENARIO	Pu RELEASE (Ci)	TRITIUM RELEASE (Ci)
Pantex 1	300 (270)[1]	3.0 x 10^5 (3.0 x 10^5)[1]
Pantex 3	9.4 x 10^3 (4.0 x 10^3)[1]	2.5 x 10^5 (2.5 x 10^5)[1]
Pantex 5	0	1.8 x 10^5
Pantex 6	1.8 x 10^{-5}	0
Pantex 7	0	4.0 x 10^7
Pantex 8	50	0
Pantex 9	1.2 x 10^{-2}	3.0 x 10^5

[1] Values in parentheses are for Configuration 2, as described in section 4.14.2.1 of Volume I.

Nevada Test Site (Handling Accident)	4×10^{-5}	1×10^{-4}	2×10^{-8}	5×10^{-8}
Savannah River Site (Handling Accident)	1×10^{-5}	3×10^{-5}	5×10^{-9}	1×10^{-8}
Manzano WSA (Handling Accident)	2×10^{-3}	5×10^{-3}	8×10^{-7}	3×10^{-6}
Hanford Site (Handling Accident)	5×10^{-8}	1×10^{-7}	3×10^{-11}	6×10^{-11}

[1]Values in parentheses are for Configuration 2, as described in section 4.14.2.1 of Volume I.

The impacts of accidents presented are meant to bound the consequences that would occur in the unlikely event of a serious accident at Pantex Plant. For example, the upper bound dose to the maximally exposed offsite individual (MEOI) from the bay explosion event within Scenario 1 varies significantly based on the high explosive charge to plutonium mass ratio of specific weapon systems that could be present in bays. When the upper bound MEOI dose is calculated for differing charge to mass ratios, the MEOI dose varies from 6 rem to approximately 100 rem (DOE 1996i). The upper bound dose numbers for the MEOI presented in Table D.4.2.2–4 are based on the worst case weapon system for MEOI exposures and as such bound the consequence from an accident involving the majority of weapons systems that could be present within the bays.

The representative consequences cited in Tables D.4.2.2–1 and D.4.2.2–2 were used for scenario screening and estimating risk. These typical values are utilized because they correspond to a greater level of human health risk than the upper bound values (which are included to indicate uncertainty levels). Except for Scenario 3, the representative and upper bound consequence assessments in Tables D.4.2.2–1 and D.4.2.2–2 rely on the MACCS software described in section D.2.1.2. Based on the Monte Carlo sampling used in MACCS, the probability of a potential accident scenario actually producing consequences equal to or exceeding the upper bound value is less than 0.05 (i.e., one chance in twenty). Thus, the frequency of an accident corresponding to the upper bound consequences is about a factor of 20 below the expected accident frequency.

Consider the first Pantex Plant scenario in Table D.4.2.2–1. If λ_1 denotes its expected frequency and $R_{T,1}$ represents its representative risk, then:

$$R_{T,1} = 1 \times 10^3 \lambda_1 \left(\frac{\text{person-rem}}{\text{year}}\right)$$

(Eq. D–11)

However, the risk associated with the upper bound value, $R_{U,1}$, is:

$$R_{U,1} = \frac{9 \times 10^3 \lambda_1}{20} \left(\frac{\text{person-rem}}{\text{year}}\right) = 0.45 R_{T,1}$$

(Eq. D–12)

This same conclusion applies to the other scenarios whose consequence assessments rely on MACCS.

The consequence assessment for Scenario 3 at Pantex uses ERAD calculations exclusively. A conservative estimate is that there is less than a 5 percent chance that Scenario 3 would produce consequences that exceed the upper bound values. If λ_3 denotes the expected frequency of Scenario 3 and $R_{T,3}$ represents its typical risk, then:

$$R_{T,3} = 2 \times 10^4 \lambda_3 \left(\frac{\text{person-rem}}{\text{year}}\right)$$

(Eq. D–13)

However, the risk associated with the upper bound value, $R_{U,3}$, is

$$R_{U3} < 3 \times 10^5 \times 0.05 \times \lambda_3 \left(\frac{\text{person-rem}}{\text{year}}\right) < R_{T,3}$$

(Eq. D–14)

Here again, the upper bound risk is less than the representative risk impact on human health. The single exception in Table D.4.2.2-1 is for Scenario 3 Configuration 2 at Pantex. Using the actual exposure estimates (4.4 x 10^3person-rem [representative] and 8.9 x 10^4 person-rem [upper bound]), the upper bound risk may exceed the typical risk by approximately 1 percent.

Direct comparisons between the scenarios assessed for the alternative sites and Pantex Plant can be misleading. Although Scenario 6 at Pantex Plant includes a pit breach initiated by a forklift accident, the risk from this scenario is dominated by handling accidents in bays and special purpose facilities. Thus, a number of different events contribute to the risk and consequences from Scenario 6 at Pantex Plant, as opposed to the single event (i.e., forklift accident) that dominates the risk at the alternative sites.

D.5 EVALUATION OF THE RISK FROM NORMAL OPERATIONS

Human health impacts from hazardous chemicals are only a concern at Pantex Plant, since relocating pit storage does not alter the human health impacts from hazardous chemicals at the receiving sites. Air quality analyses using the Industrial Source Complex Short-Term (ISCST2) Model quantified the air concentrations of chemical releases during normal operations (EPA 1987a; EPA 1987). These concentrations were evaluated for all chemicals considered to be carcinogenic and having associated risk factors. Using the chemical concentration results and the risk factors, an estimate of the cancer risk to workers and a qualitative evaluation of public risk was determined.

Toxic, noncarcinogenic chemicals were evaluated for offsite effects using a hazard index, as shown in volume I, chapter 4, Table 4.14.1.2–2. Chemical concentrations onsite were compared to published threshold limit values for chemical substances to determine the extent of potential human health impacts. None of the threshold limit values are exceeded onsite.

Radiation exposure during normal operations is dominated by external exposure to radiation workers. To quantify changes in worker exposure for different disassembly and assembly rates, As Low As Reasonably Achievable goals were used to estimate an average exposure per operation (PC 1994). This average exposure was then multiplied by the number of operations per year.

Radiation exposure to the public is predominantly from air emissions. The majority of these radiological air emissions are the result of off gassing from Cell 1 and not from normal operations. However, environmental monitoring data establish that these radiological air emissions contribute approximately a factor of one in a billion to the annual radiation dose to an average individual in the vicinity of Pantex Plant.

D.6 UNCERTAINTIES

The sequence of analyses performed to generate the radiological impact estimates from normal operation and facility accidents include: (1) selection of normal operational modes and accident sequences, (2) estimation of source terms, (3) estimation of environmental transport and uptake of radionuclides, (4) calculation of radiation doses to exposed individuals, and (5) estimation of health effects. There are uncertainties associated with each of these steps. Uncertainties exist in the way the physical systems being analyzed are represented by computational models and in the data required to exercise the models (due to measurement errors, sampling errors, or natural variability).

In principle, one can estimate the uncertainty associated with each source and predict the remaining uncertainty in the results of each set of calculations. Thus, one can propagate the uncertainties from one set of calculations to the next and estimate the uncertainties in the final results. However, conducting such a full-scale quantitative uncertainty analysis is neither practical nor a standard practice for a study of this type. Instead, the analysis is designed to ensure—through judicious selection of release scenarios, models, and parameters—that the results represent the potential risks.

This is accomplished by making assumptions in the calculations at each step. The models, parameters, and release scenarios used in calculations are selected in such a way that most intermediate results and consequently, the final estimates of impacts are greater than what would be expected. As a result, even though the range of uncertainty in a quantity might be large, the value calculated for the quantity is close to one of the extremes in the range of possible values, so that the chance of the actual quantity being greater than the calculated value is low (or the chance of the quantity being less than the calculated value if the criteria are such that the quantity has to be maximized). This has been the goal of the radiological assessment for normal operation and facility accidents in this study (i.e., to produce results that are conservative).

The degree of conservatism in the calculated results is closely related to the range of possible values the quantity can have. This range is determined by what can be expected to realistically occur. Thus, the only processes, events, and accidents considered are those credible for the conditions under which the physical system being modeled operates. This consideration has also been employed for both normal operation and facility accident analyses.

APPENDIX E

Aircraft Accident Analysis

APPENDIX E
AIRCRAFT ACCIDENT ANALYSIS

E.1 INTRODUCTION

This appendix presents an analysis of the likelihood of an aircraft crash into structures located within Zones 4 and 12 at Pantex Plant and storage facilities located at the alternative sites covered in this EIS. Sandia National Laboratories performed an assessment of the probability of aircraft impact into Pantex Plant structures in the mid-1970s (SNL 1976). That study used the K. Solomon Model and included a characterization of air traffic in the area, including the classes of aircraft (e.g., commercial, military), the nature of the operations, the number of operations per year, and other information that could affect the probability of an aircraft crash at Pantex Plant Site (ANPP 1975).

DOE has recently issued a *Draft Standard for Accident Analysis for Aircraft Crash Into Hazardous Facilities* that presents a standardized approach and the steps used to apply the approach (DOE 1996g). The DOE Standard methodology was applied in this EIS to estimate the probability of an aircraft crash into the structures of interest. An initial screening of the release frequency, as described in the Draft DOE Standard and based on past experience, indicated that the impact frequency would require detailed analysis. Current data describing air traffic are used in the analyses for both Pantex Plant and the alternative sites. Because the Draft DOE Standard uses English units for crash rates and probability density functions, all figures and tables in this appendix are in English units to avoid confusion when comparing the results with the Draft DOE Standard.

E.2 METHODOLOGY

The determination of the probability for causing sufficient damage to a facility consists of a series of calculations as shown in Figure E.2–1. The first step in the process is to determine the representative type of aircraft for each category. Representative wingspans, engine weights, and engine diameters are calculated by either using a known set of data, i.e., the number of each type of aircraft for operations near a site (e.g., Radar Airspace Monitoring System [RAMS] data identifying the number of 737s, DC10s, MD80s, etc. for commercial air carrier landing and take-off operations near Pantex Plant), or the maximum parameters for the category if the number of each type of aircraft is unknown.

The representative or maximum wingspans are used to calculate the true, shadow, and skid area of a facility taking into account shielding by nearby facilities, as described in section E.2.2. Using the calculated area of a facility, the number of operations near a facility, crash rates, and the probability density function, the probability of hitting the facility for each aircraft category is calculated as described in section E.2.1. The total probability for hitting a facility is the sum of all the aircraft category probabilities. If the probability of hitting a facility is greater than 10^{-7}, further analysis is required.

A structural calculation is performed to determine if an aircraft that hits a facility will cause sufficient damage to warrant further analysis. Aircraft missiles (i.e., flying objects from the crash) for the structural calculations are selected by using representative engine weights and diameters. The velocity of the aircraft is the impact velocity for each aircraft category. The structural analysis is performed by calculating the scabbing and perforation

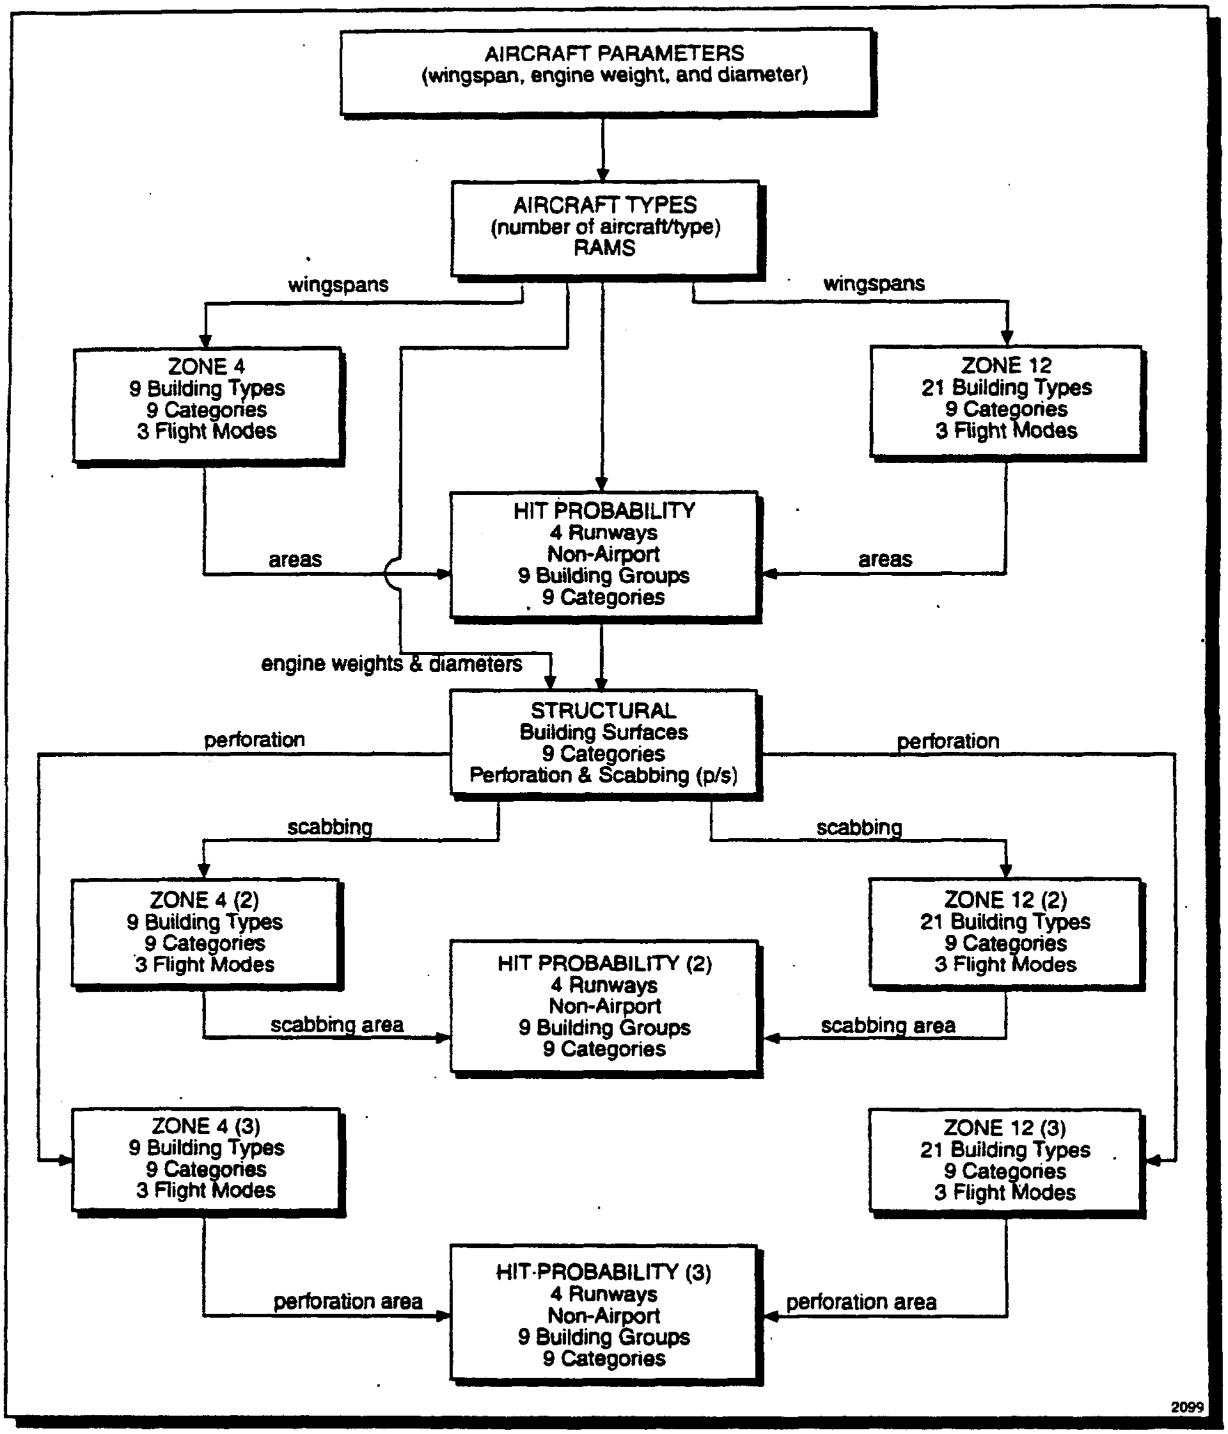

FIGURE E.2–1.—*Calculations Used to Determine Probability for Causing Sufficient Damage to a Facility at Pantex Plant.*

thickness for each aircraft category into the facility using an empirical model.

If an earth overburden exists, the velocity reduction through the earth overburden is calculated prior to the aircraft penetrating the facility. The roofs, walls, and doors of each facility were modeled independently when overburden or structure thickness varied. If scabbing or perforation is not possible, even though the facility can be hit, the material inside cannot be damaged and no further analysis is needed. If scabbing or perforation is possible, additional analysis is needed.

The area calculation is then performed again, eliminating the structural members whose aircraft categories cannot cause scabbing or perforation in a facility. After the area of a facility vulnerable to scabbing or perforation is determined, the probability of hitting a facility and causing either scabbing or perforation is calculated with the reduced area by using the same equation as described in section E.2.1. (This represents a conservative upper bound for causing an explosion in a facility since either a scabbed piece of concrete or a missile that has perforated a facility can cause an explosion.)

The area calculation is redone a third time, eliminating the structural members whose aircraft categories can only cause perforation, but not scabbing in a facility. After the area of a facility vulnerable only to perforation is determined, the probability of hitting a facility and causing perforation is calculated for the reduced area by using the same equation as described in section E.2.1. This represents a conservative upper bound for causing a fire in a facility since only a perforation can allow for sufficient amount of combustible materials to enter a facility. If the probability of hitting a facility and causing either scabbing or perforation is greater than 10^{-7}, a consequence analysis is performed.

E.2.1 Calculation of Aircraft Crash Probability

The Near Airport Model is used to estimate the probability of an aircraft crash for aircraft in the take-off and landing modes; in-flight aircraft crash probabilities are determined using the Non-Airport Model (DOE 1996g:41). The Near-Airport Model uses an aircraft mode and category-specific probability density distribution to estimate the possibility of an aircraft crashing into a particular location surrounding the airport. The Non-Airport Model uses DOE site-specific information to estimate the possibility of an aircraft crashing into a particular location surrounding the airport. In both models, the calculated probability includes all types of postulated impacts, whether slight or severe in consequence (i.e., to be conservative a touch is considered a hit).

A set of indices is used in the analysis to differentiate flight modes, aircraft categories, and flight sources. These indices are designated (i), (j), and (k), respectively. The index (i) differentiates the mode of operations (e.g., landing, in-flight, take-off) and can be equal to the following values:

$i = 1$ Landing

$i = 2$ In-Flight

$i = 3$ Take-off

The index (j) divides the aircraft types into categories. These categories included the following values (DOE 1996g:39):

$j = 1$ Commercial: Air Carrier

$j = 2$ Commercial: Air Taxi

$j = 3$ Military: Large (Bomber, Cargo, and Tanker aircraft)

$j = 4$ Military: Small (Attack, Fighter, and Trainer aircraft)

j = 5	Military: Rotary-wing (Helicopter)
j = 6	General: Fixed-wing, reciprocating, single-engine
j = 7	General: Fixed-wing, reciprocating, multi-engine
j = 8	General: Fixed-wing, turboprop
j = 9	General: Fixed-wing, turbojet
j = 10	Rotary-wing, reciprocating engine (Helicopter)
j = 11	Rotary-wing, turbine engine (Helicopter)

The index (k) describes the flight source and can take on the following characteristics:

k = 1...n	Runways
k = n+1	Non-Airport operations (high-altitude overflights, and local helicopter flights)

An approximation of the total probability per year (F) that any aircraft in any flight path, category, or mode of operation will impact structures is given by the four-factor formula:

$$F = \sum_{i,j,k} N_{ijk} \cdot P_{ijk} \cdot f_{ijk}(x,y) \cdot A_{ij}$$

where:

F	is the estimated total annual aircraft crash impact frequency for the facility of interest (number per year)
N_{ijk}	is the number of annual operations in flight mode (i), aircraft category (j), and flight source (k) (number per year, site dependent)
A_{ij}	is the effective Plant area for an aircraft of mode (i) and flight category (j) (site and aircraft dependent)
$f_{ijk}(x,y)$	is the generic aircraft crash location probability function evaluated at the facility location for each applicable summation parameter (per square mile for Near-Airport and Non-Airport operations)
P_{ijk}	is the generic aircraft crash probability (per take-off or landing for Near-Airport and Non-Airport operations) for each applicable aircraft category, flight mode, and flight source.

Table E.2.1–1 (tables are presented following the text) presents a listing of the values for aircraft crash rates, P_{ijk}.

The four-factor formula is implemented in two different ways depending of the flight phase:

- For Near-Airport operations, take-offs (i = 1) and landings (i = 3), the four-factor equation is implemented through the use of site-specific information and data contained in the Draft DOE Standard (DOE 1996g).
- For Non-Airport operations, (i = 2), DOE site-specific values for the expected number of crashes per square mile per year in the vicinity of selected DOE sites have been established. The value of the product NPf(x,y) is provided in the Draft DOE Standard for each aircraft category. The four-factor formula is implemented by multiplying this value by the facility effective area to assess hit probability.

The analysis of the impact frequency of Non-Airport operations for all categories of aircraft uses the same four-factor equation as for Near-Airport operations. The frequency, F_j, for the jth class of aircraft is

$$F_j = N_j \cdot P_j \cdot f_j(x,y) \cdot A_j$$

where the product of NP equals the expected number of in-flight crashes per year; f(x,y) is the probability, given the crash, that the crash occurs in a 1-square mile area surrounding the given facility; and A is the effective area of the facility. Combined, the product of NPf(x,y) is equivalent to the expected number of crashes per square mile per year in the vicinity of the given site. Table E.2.1–2 gives NPf(x,y) values for selected DOE sites. Also included in this table are minimum, average, and maximum values for facilities at other locations within the continental U.S. (CONUS). The values presented in this table are based on an analysis of the locations of crashes that have occurred in the past in the CONUS. Over 1,000 general aviation crashes were recorded, but available data for air carrier and large military aircraft is limited (DOE 1996g:42).

The calculation of impact frequency is slightly different for helicopters. The four-factor equation becomes

$$F_H = N_H \cdot P_H \cdot (2 \div L_H) \cdot A_H$$

where L is the average length, in miles, of the flights corresponding to the site-specific overflights.

E.2.2 Calculation of the Impact Area

The total effective area (A_{eff}) required for the probability model is the sum of the true area, the shadow area, and the skid area (DOE 1996g:B-27). It is believed that if an aircraft impact occurs within this total effective area, the structure will be hit either before ground impact or as a result of aircraft skid after impact. In estimating each area, allowance is made for aircraft dimension (i.e., wingspan).

The true area (A_t) is the base area of the building adjusted for aircraft dimension and is defined as:

$$A_t = (2 \cdot L \cdot W \cdot WS) \div R + (L \cdot W)$$
$$R = (L^2 + W^2)^{0.5}$$

where L is the facility length, W is the facility width, R is the facility hypotenuse, and WS is the aircraft wingspan. In this aircraft accident analysis, DOE Standard wingspans were used for unknown aircraft. Representative wingspans for Near-Airport operations were determined by examining RAMS data and selecting aircraft for each category that represented at least 50 percent of the aircraft category. Both DOE Standard and representative weighted wingspans are presented in Table E.2.2–1.

The shadow area (A_{sh}) is determined from the structure height, the hypotenuse, and the angle of the postulated aircraft impact and is defined as:

$$A_{sh} = (WS + R) \cdot H \cot\phi$$

where H is the facility height, WS is the aircraft wingspan, and ϕ is the angle the aircraft path makes with the horizon at impact (Figure E.2.2–1). Values for cot ϕ for the various aircraft categories are presented in Table E.2.2–2.

There is a possibility that an aircraft could impact the ground at some distance from a facility and still strike the structure as a result of skidding into it. The skid area (A_{skid}) is defined as:

$$A_{skid} = (WS + R) \cdot S$$

where WS and R are as defined above and S is the skid length. Values for the mean skid distance for each aircraft category are provided in the Draft DOE Standard (DOE 1996g:B-29). The skid distance can be reduced by calculating the critical velocities required to cause damage

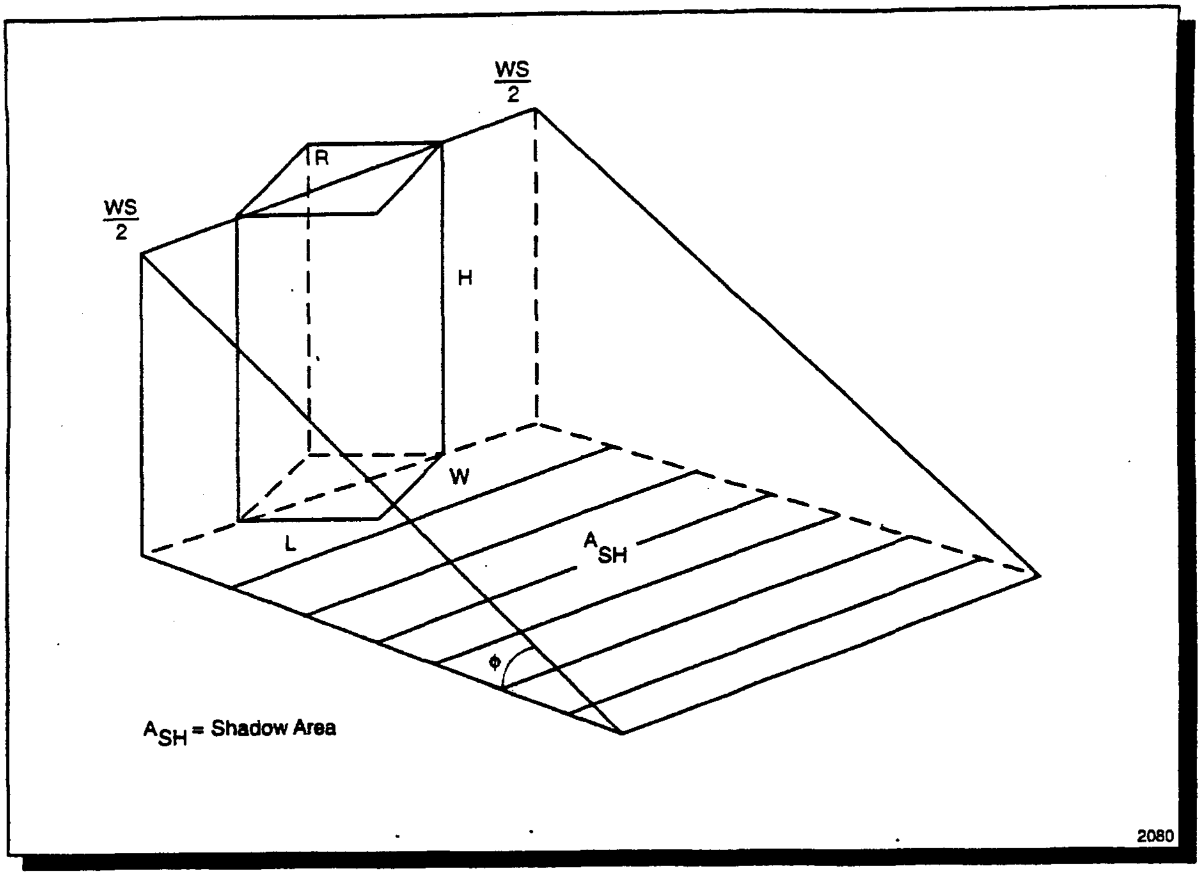

FIGURE E.2.2–1.—*Shadow Area.*

to a facility. Using the model contained in the Drake Report (Drake 1994), aircraft skid distances can be calculated and subsequently reduced from the mean distances given in the DOE Standard. However, this was not done in this analysis because of two cases encountered:

- Walls covered by enough overburden to stop an incoming missile did not require velocity reduction.
- Walls which are very thin, leading to imminent perforation, were still perforated even after velocity reduction.

E.2.3 Calculation of the Structural Response

The Draft DOE Standard (DOE 1996g) contains a methodology for analyzing a facility's local and global structural response to aircraft crash impact forces. The evaluation of structural response in this EIS is based solely on the local impact forces generated by non-rigid missiles on reinforced concrete and steel constructed facilities. These calculations were used to eliminate certain aircraft from their potential contributions to the overall release frequencies.

Although the global response analysis was not performed, it is not expected to result in significant increases in the estimated frequencies. Release frequencies will always be bounded by impact frequencies. In all cases, consequence calculations assume bounding amounts of material at risk, and as such, consequence calculations remain unaffected by the results of structural response calculations.

Formulas are provided for the impact analysis of both rigid and non-rigid missiles for both reinforced concrete and steel constructed facilities.

E.2.3.1 *Reinforced Concrete Targets*

Local impacts to facilities include penetration, perforation, and scabbing. Penetration occurs when the missile striking a facility intrudes into the outer surface of the structure. Perforation occurs when the missile punctures a hole all the way through the concrete or steel surface. Scabbing occurs when the missile does not perforate, but does cause concrete to be ejected from the inside face of the target into the facility.

The local response equations used for this calculation are referred to as the Chang equations for rigid missile penetration of reinforced concrete targets (DOE 1996g:60).

Scabbing

$$t_s = [1.84 \cdot (U \div V)^{0.13}] \cdot \{(MV^2)^{0.4} \div [D^{0.2} \cdot (f'_c)^{0.4}]\}$$

where:

$U =$	reference velocity = 200 ft/sec
$V =$	missile impact velocity (ft/sec)
$M =$	mass of missile = W/g where W = missile weight (lb) and $g = 32.2$ ft/sec^2
$D =$	effective missile diameter (ft)
$f'_c =$	ultimate compressive strength of concrete (lb/ft^2)
$t_s =$	scabbing thickness (ft)

To prevent scabbing, the minimum thickness of the concrete should be $\geq 1.1t_s$ (DOE 1996g:62). Because the missiles considered in this analysis are aircraft engines, they are considered non-rigid. As a result, and in accordance with the Draft DOE Standard, the value obtained for rigid missiles can be reduced to 60 percent (DOE 1996g:64).

Perforation

$$t_p = (U \div V)^{0.25} \cdot (MV^2 \div Df'_c)^{0.5}$$

To prevent perforation, the minimum thickness of the concrete should be $\geq 1.2t_p$ (DOE 1996g:62). Similarly, because the missiles in this analysis are aircraft engines which are considered non-rigid, the value obtained for rigid missiles can be reduced to 70 percent (DOE 1996g:64).

E.2.3.2 *Steel Targets*

The equation used for this calculation is the Ballistic Research Laboratory (BRL) formula for rigid missile penetration of steel targets (DOE 1996g:65).

Perforation

$$T^{1.5} = 0.5MV^2 \div 17{,}400K_sD^{1.5}$$

where:

$T =$	perforation depth (in)
$M =$	W/g missile mass (lbs-sec^2/ft)
$V =$	missile impact velocity (ft/sec)
$K_s =$	constant depending on the grade of steel (usually ≈ 1)
$D =$	missile diameter (in)

To prevent perforation of steel targets, the minimum thickness t_d should be > 1.25T (DOE 1996g:65).

E.2.3.3 *Overburden*

In addition to the above equations, an equation exists to allow calculation of a reduced missile velocity as the result of contact with earth overburden. This reduced velocity was calculated as follows (PC 1995d):

$$V_i = V_o \times \exp\{(-\rho A C_s t) \div W\}$$

where:

V_i = reduced missile velocity as a result of earth overburden (ft/s)

V_o = velocity of missile before contact with earth overburden (ft/s)

A = effective area of missile (ft^2)

W = maximum weight of missile (engine shaft) for the category of aircraft (lbs)

C_s = speed of sound in soil (ft/s)

$= \{(E_s \cdot g) \div \rho\}^{0.5}$

t = time (s) $= 4 \cdot (d \div V_o^{1.25})$

d = depth of soil overburden (ft)

ρ = density of soil = 130 lbs/ft^3

E_s = soil modulus of elasticity = 470,000 lb/ft^2

g = acceleration due to gravity = 32.2 ft/sec^2

For reinforced concrete, a determination is made as to whether the missile perforates or scabs the facility. The steel target equations allow determination of perforation only.

E.3 SITE ANALYSIS

Sites to be analyzed include those that have been selected as possible alternative sites for plutonium pit storage: Pantex Plant, the Manzano Weapons Storage Area (WSA) at Kirtland Air Force Base (KAFB), the Nevada Test Site (NTS), the Savannah River Site (SRS), and the Hanford Site.

E.3.1 Pantex Plant

Pantex Plant is located about 27 kilometers (17 miles) northeast of Amarillo, Texas, approximately 13.6 kilometers (8.5 miles) from the northeast-southwest runway at the Amarillo International Airport. There is a prohibited airspace extending to 1,460 meters (4,800 feet) above mean sea level (MSL) directly above Pantex Plant, which corresponds to 366 meters (1,200 feet) above ground level (AGL).

The principal instrument approaches to the Amarillo International Airport are provided by two methods: an Instrument Landing System (ILS) and a Very High Frequency Omni Directional Radio Range with Tactical Air Navigation (VORTAC), a regional air navigational aid. The main approach uses the azimuth portion of the runway's ILS signals, called the Back Course Localizer (BCL) (Figure E.3.1–1). Any aircraft using full instrument approach to the main runway (Runway 4/22) follows a path that takes it over the Plant's boundaries at an altitude of approximately 1,460 meters (4,800 feet).

The VORTAC is 8 kilometers (5 miles) west of Pantex Plant. An approaching aircraft using the VORTAC also follows a path that also takes it over the Plant's boundaries (Figure E.3.1–2). Thus, air traffic in each of the nine low-altitude and eight high-altitude air corridors serviced by the VORTAC contributes to air traffic in the vicinity of Pantex Plant (Figures E.3.1–3 and E.3.1–4). There is an additional VORTAC

FIGURE E.3.1-4.—*VORTAC and High-Altitude Federal Airways.*

north of the Plant near Borger. Aircraft flying in this high-altitude air corridor were included in data collected for Pantex Plant.

DOE and the Federal Aviation Administration (FAA) have signed a Memorandum of Understanding (MOU) to take several actions to reduce the number of flights directly over Pantex Plant. Some of these steps include establishing a Global Positioning System (GPS) route around Pantex Plant, moving the holding pattern for commercial aircraft away from the Plant, and moving the high-altitude VORTAC closer to the airport. The estimated reduction in risk for these changes is discussed in section E.3.1.7.

An estimate of an aircraft crash into any of the Zone 4 magazines and Zone 12 buildings at Pantex Plant was generated using the probability equations defined in section E.2.1, the effective areas defined in section E.2.2, and the structural response in section E.2.3.

E.3.1.1 *Radar Airspace Monitoring System Project*

The RAMS project is based at the Amarillo International Airport and consists of a computer system that records radar data from various aircraft overflights in the area. This radar data is then translated into data points that represent aircraft positions in relation to the airport and Pantex Plant. RAMS data include individual aircraft types that were divided into the aircraft categories defined in section E.2.1 to ratio the number of aircraft operations at the airport. The RAMS data was used to categorize the aircraft in more detail than the four categories i.e., Air Carrier, Air Taxi, Military, and General Aviation) supplied by FAA.

E.3.1.2 *Operations Near Pantex Plant*

An adjustment to the Near-Airport Model consisted of manipulation of the aircraft modes (i), aircraft categories (j), and flight sources (k) to model Pantex Plant conditions. The aircraft mode, i, was summed over three phases:

i = 1	Take-off
i = 2	In-Flight
i = 3	Landing

The aircraft categories are very similar to those presented in section E.2.1.

j = 1	Commercial: Air Carrier
j = 2	Commercial: Air Taxi
j = 3	Military: Large (Bomber, Cargo, and Tanker aircraft)
j = 4	Military: Small (Attack, Fighter, and Trainer aircraft)
j = 5	General: Fixed-wing, reciprocating, single-engine
j = 6	General: Fixed-wing, reciprocating, multi-engine
j = 7	General: Fixed-wing, turboprop
j = 8	General: Fixed-wing, turbojet
j = 9	Helicopters

The flight source, k, was set equal to five flight sources.

k = 1	Runway 22
k = 2	Runway 04
k = 3	Runway 31

k = 4 Runway 13

k = 5 Non-Airport Aircraft

It was determined that the following commercial aircraft are used at the Amarillo International Airport:

- American Airlines
  - — F100 (Fokker 100; 90+ passenger capacity)
  - — SF340 (Saab; approximately 35-passenger capacity)
  - — AT72 (ATR72; approximately 66-passenger capacity)
- Delta Air Lines
  - — AT72 (ATR72; approximately 66-passenger capacity)
  - — E120 (Brasilia; approximately 30-passenger capacity)
- United Airlines
  - — E120 (Brasilia; approximately 30-passenger capacity)
- Southwest Airlines
  - — 737 (Boeing; 100+ passenger capacity)

In this analysis, 1995 data obtained from the FAA indicate that there are approximately 74,911 operations per year at the Amarillo International Airport. The FAA supplied data for air carrier, air taxi, military, and general aviation aircraft, with 11,122; 7,134; 30,386; and 26,269 operations, respectively (PC 1995). Based on RAMS data, there were 233 helicopter operations in 1995.

Since the number of annual aircraft operations has been as high as 88,489 in 1992, the maximum number of operations from 1990 to 1996 were used in the analysis for each FAA aircraft category. Maximum values for air carrier, air taxi, military, general aviation, and helicopter operations are 13,174 (1990); 9,938 (1993); 40,638 (1993); 29,134 (1992); and 233 (1995), respectively.

FAA commercial and general aviation operations numbers do not include the number of times a commercial or general aviation may circle during a holding pattern, but holding patterns have been included in the crash rates for commercial and general aviation. The FAA number for military operations includes touch-and-go operations (PC 1995c). RAMS data were used to divide military and general aviation FAA data into aircraft categories (i.e., large or small military, and single-engine, multi-engine, turboprop, or turbojet general aviation).

Approximately 12 months of RAMS data were used to identify and categorize aircraft by type (DOT 1994; DOT 1985; LLNL 1995). The percentage of operations, using the RAMS data, was derived from the four sets of FAA data (i.e., air carrier, air taxi, military, and general aviation). The total number of operations was obtained by multiplying the percentage of RAMS operations for each aircraft category by the FAA data for each category.

The total number of operations that could occur on Runway 31 is the same as the total number of operations for each category except for air carrier and large military, which include aircraft that are too heavy to use Runway 31. The percentage of operations that occur on Runway 31 (6.8 percent) was obtained by evaluating a statistical sample of RAMS data and counting the number of operations on each runway (PC 1995a). The percentage of operations that land on Runway 22 (64.1 percent) versus take-off on Runway 04 (35.9 percent) was determined based on prevailing winds (Figure 4.7.1.1–1 in volume I). Table E.3.1.2–1 presents the number of operations for each aircraft category for Runways 04, 22, and 31.

In addition to FAA operations data, in the Near-Airport Model, in-flight aircraft at high altitudes were considered as Non-Airport operations in the Draft DOE Standard (DOE 1996g) methodology. The evolution of high-altitude aircraft is based on the DOE Standard NPf(x,y) values for Pantex Plant. All high-altitude overflights are assumed to be in-flight. The calculation of this impact frequency is performed using the equation discussed in section E.2.1.

E.3.1.3 *Crash Density Function Near Pantex Plant*

Because Zones 4 and 12 are within the aircraft category dependent exclusion distance from the Amarillo International Airport, the air operations of interest for this analysis are take-off, landing, and in-flight modes (i.e., i = 1, 2, 3). Therefore, the probability equation becomes:

$$F = \sum_{i=1,3}\sum_{j=1,9}\sum_{k=1,5} N_{ijk} \cdot A_{ij} \cdot f_{ijk}(x,y) \cdot P_{ijk}$$

The length of Runway 04/22 at the Amarillo International Airport is 4.12 kilometers (2.56 miles). It was assumed from the direction of the prevailing winds that Runway 22 is used 64.1 percent of the time (Figure 4.7.1.1–1 in volume I). Due to the aircraft category dependent exclusion distance, all aircraft considered as an airport operation on Runway 04/22 were either in the take-off or landing mode. For all runways, the pattern side for military operations was conservatively assumed to be the value for the side with the larger probability density function (pdf), since there is no dominant pattern at the Amarillo International Airport. For all runways, 50 percent of operations are take-off and 50 percent are landing.

The length of Runway 13/31 is 2.41 kilometers (1.50 miles). Approximately 6.8 percent of daily operations occur on Runway 13/31. Because Runway 13 has only about one operation per day, all operations on the runway were assumed to occur on Runway 31. Due to weight restrictions, air carrier and large military aircraft cannot use Runway 31. For this runway, all aircraft considered as an airport operation were either in the take-off or landing mode.

The center-line and perpendicular distances from the geometric center of the runway to specific points of concern in Zones 4 and 12 were determined as shown in Figure E.3.1.3–1 (USGS 1953; USGS 1953a; USGS 1973; USGS 1956). Because Pantex Plant resides within the aircraft category dependent exclusion distances, a Near-Airport Analysis was required and probability density function values were used in this analysis.

Figure E.3.1.3–1 (not to scale) represents the location of Pantex Plant facilities in relation to Runways 22/04 and 31/13 at the Amarillo International Airport. There are two key areas on this figure that are considered in assessing the aircraft impact probability:

- A 1-mile by 1-mile grid area encompassing most of Zone 4 West located southeast of the runway center-line.
- A 1-mile by 1-mile grid area adjacent to the first and encompassing all of Zone 12.

The aircraft impact probability assessment focuses on accidents in the vicinity of these areas; in particular the nearest facility for each of these zone areas. The assessment was performed by separating the displacement vector from the geometric center of the runway to specific points in the zone grids into two orthogonal components:

- Vector coincident with a direct projection of the center-line of the runway.
- Vector perpendicular to the first that extends from the first vector to the nearest impact point in the area. For Pantex Plant, this point represents the plutonium centroid of Zones 4 and 12 (refer to Figure E.3.1.3–1).

The lengths of these two vector components were used to implement the Near-Airport Model methodology. It was assumed for simplicity that all of the Zone 4 West magazines reside in the grid under consideration.

The NPf(x,y) values provided in the Draft DOE Standard (DOE 1996g) for the various aircraft categories reflect the crashes per square mile, per year, centered at a given site for non-airport operations. In this analysis, the following NPf(x,y) values for Pantex Plant were used (DOE 1996g:B-24, B-25):

NPf(x,y) General Aviation =	7×10^{-5}
NPf(x,y) Air Carrier =	6×10^{-8}
NPf(x,y) Air Taxi =	4×10^{-7}
NPf(x,y) Large Military =	1×10^{-7}
NPf(x,y) Small Military =	5×10^{-6}

The NPf(x,y) value for general aviation was split between the four general aviation categories for Pantex Plant based on the RAMS data. The value was divided up based on the following percentages:

Single-engine piston =	$43.8\% \Rightarrow 3.1 \times 10^{-5}$
Multi-engine piston =	$19.8\% \Rightarrow 1.4 \times 10^{-5}$
Turboprop =	$17.0\% \Rightarrow 1.2 \times 10^{-5}$
Turbojet =	$19.4\% \Rightarrow 1.4 \times 10^{-5}$

According to the Draft DOE Standard, it has been shown, based on helicopter crash data, that the contribution to impact frequency from non-local helicopter overflights is insignificant and need not be considered in the impact frequency calculations (DOE 1996g:45). However, it is necessary to consider local helicopter flights that consist of planned overflights dealing with facility operations, or flights dealing with area operations (e.g., Southwestern Public Service

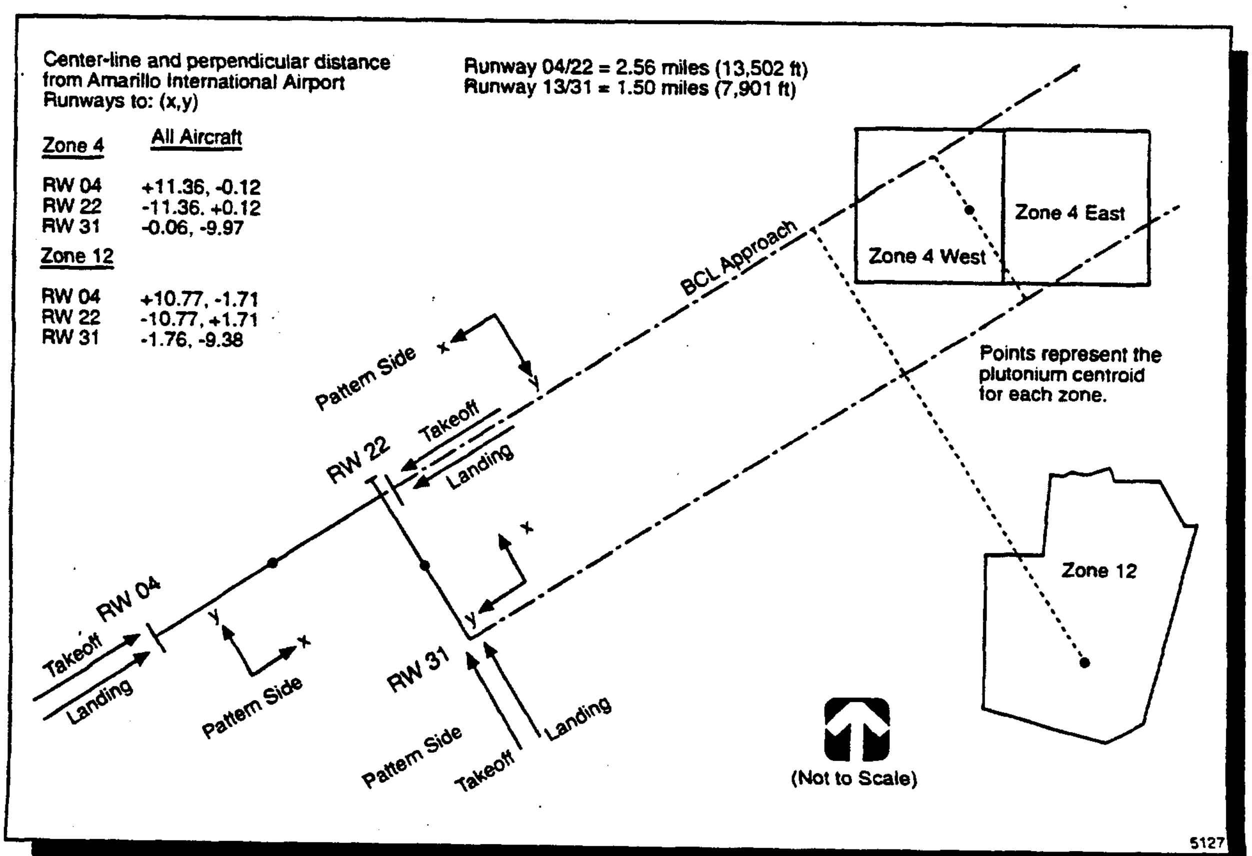

FIGURE E.3.1.3–1.—*Pantex Plant and the Amarillo International Airport.*

powerline maintenance flights), using the equation discussed in section E.2.1.

E.3.1.4 *Zone 4*

In this analysis, only facilities that contain plutonium and large amounts of tritium were considered, as determined in previous hazard assessments, since these materials have possible offsite consequences (Jacobs 1993; Jacobs 1993a; Jacobs 1992).

Area Calculation

To estimate the overall probability of aircraft impact into any magazine in Zone 4, the probability of striking an individual magazine or group of magazines is summed appropriately over the individual magazines or groups of magazines analyzed (i.e., 18 Modified Richmond (MR) magazines, 9 groups of 3 Steel Arch Construction (SAC) magazines, and 3 groups of 5 SAC magazines). The total effective area is the sum of the true areas (the magazine base area adjusted for aircraft dimension), the shadow areas (defined by the magazine height and the angle of postulated impact), and the skid areas (the area covered by a skidding aircraft after impact with the ground) posed by all 60 magazines in Zone 4.

The MR magazines were considered as single structures (18 total), while the SAC magazines were analyzed as 9 groups of 3 (27 total) and 3 groups of 5 (15 total). The distance between the SAC magazines in the groups was included in the value used for the length of the group because this length gave a better representation of the possible area of impact.

The following section illustrates the calculation of the individual areas and the effective area for the groups of three SAC magazines. In this calculation, the magazines were assumed to be in a position (e.g., east row on Figure 4.15.1.1–1 in volume I) that allows the longest skid distance prior to impact with a magazine.

An aircraft that impacts the ground prior to reaching a line of magazines, (i.e., in a skid mode) can impact one line of magazines, but is precluded from reaching the second. The effective areas for one line of magazines (and the five isolated MR magazines) were estimated using the mean skid distances presented in the Draft DOE Standard (DOE 1996g:B-29). However, the skid distances for magazines in the second line were reduced to no more than the distance between the two rows of magazines (125 meters [410 feet]) (Figure 4.15.1.1–1 in volume I). This reduced distance affects commercial and military aircraft only. In addition, the shadow area of the first row was eliminated since it is part of the skid area of the second row. The angle of impact was chosen based on the values presented in the Draft DOE Standard (DOE 1996g:B-29).

A total effective area for the Zone 4 magazines was then computed by combining the effective areas in the following manner. The effective area for magazines in the east row is the sum of the effective areas for three groups of three SAC magazines, three groups of five SAC magazines, and six MR magazines. The effective area for magazines in the west row is the sum of the effective areas for six groups of three SAC magazines and seven MR magazines. All of these effective areas were computed using the 125-meter (410-foot) inter-row separation as the skid distance for air carrier and military aircraft. The total effective area for Zone 4 is the sum of the effective areas for the east and west rows plus the effective areas of the five MR magazines on the west side of Zone 4. Table E.3.1.4–1 presents the Zone 4 building dimensions.

Table E.3.1.4–2 presents the aircraft operational data used for the Zone 4 analysis. In this table, both the Draft DOE Standard and representative wingspans for aircraft in the vicinity of Pantex Plant are given. Representative wingspans were determined by examining RAMS data and selecting aircraft for each category that represented the average of the aircraft (for the commercial and military aircraft categories, over 96 percent of the aircraft were included). Weighted average wingspans were then used in the calculations (Jane's 1961-1996). The skid length used corresponds to the skid distances presented in the Draft DOE Standard (DOE 1996g:B-29).

Hit Probability Calculation

Using the coordinate convention, the center-line (x distance) and perpendicular distances (y distance) to the plutonium centroid for Zone 4 are:

Zone 4	All Aircraft
Runway 04	11.36 mi, -0.12 mi
Runway 22	-11.36 mi, 0.12 mi
Runway 31	-0.06 mi, -9.97 mi

Based on these distances, all aircraft using the Amarillo International Airport were analyzed using the Near-Airport Model. The crash location probabilities for Runway 22 are presented in Table E.3.1.4–3 (DOE 1996g:B-12–B-23). The air carrier and air taxi crash location probabilities are identical because their crash density location probabilities are grouped into a commercial category. The crash location probabilities are zero for Runway 22 take-offs because in this analysis all take-offs are in a direction away from Pantex Plant, and thus are not a threat to the plant facilities.

The crash location probabilities for Runway 04 are provided in Table E.3.1.4–4 (DOE 1996g:B-12–B-23). Both the air carrier and air taxi crash location probabilities are identical because their crash location probabilities are grouped into a single commercial category.

The crash location probabilities for Runway 31 are presented in Table E.3.1.4–5 (DOE 1996g:B-12–B-23). Likewise, the air carrier and air taxi crash location probabilities are also identical because their crash location probabilities are grouped into a single commercial category.

The impact probability was obtained for the entire Zone 4 storage area by multiplying the number of flights, the impact area, the crash rate, and the crash density function for each category. With substitution of the above data into the probability equation for the specific aircraft type, the impact probabilities for Zone 4 were calculated. Table E.3.1.4–6 contains the crash probabilities for Runway 22 landings, Runway 04 take-offs, and the non-airport aircraft. Runway 31 crash probabilities are omitted because they are all zero.

Structural Calculation

For this analysis, 70th percentile velocities of aircraft were used (LLNL 1995:2-24, 3-81, 4-25, 4-26). The velocities chosen were in either take-off or landing operations, whichever was the largest. For facilities with earth overburden, these velocities were reduced according to the earth overburden velocity reduction equation previously defined.

The local response equations for rigid missiles impacting reinforced concrete structures were applied to the MR magazines, and the local response steel equations for rigid missiles were applied to the SAC magazines. A reduction in penetration depth was taken because the missiles were non-rigid. In this analysis, the aircraft engine was investigated as the missile of concern. These engines were treated in the equations as non-rigid missiles. Table E.3.1.4–7 presents representative engine weights and diameters for aircraft landing and taking off at the Amarillo International Airport. Representative engine weights and diameters were determined by examining RAMS data and selecting aircraft for each category that represented the average of the aircraft. Weighted average engine weights and diameters were then used in the structural calculations.

Local response structural calculations were performed for five different sets of overburdens and building thicknesses. These include the MR magazine roof and walls, the SAC magazine roof and walls, and the front doors of both magazine types. Since only the magazine entry barrier was modeled, doors for the SAC and MR magazines are the same. The roof and walls for both types of facilities were modeled separately since there is substantially greater overburden on the walls compared to the roof. The front face was modeled assuming the large security barrier was in place. Table E.3.1.4–8 presents the results for either perforation or scabbing for each of the five different sets. Similarly, Table E.3.1.4–9 presents the results for perforation.

Perforation and Scabbing Probability Calculations

For facilities with high explosives (HE) (weapons), the bounding accident is a perforation or scab leading to an explosion. For facilities without HE, the bounding accident is a perforation leading to a fire. Scabbing leading to an explosion is not possible in Zone 4 since material with HE is stored in SACs which cannot scab. The areas for the facilities were reduced using the structural analysis results. The reduced areas were then used to recalculate perforation and scabbing probabilities. These areas are shown in Table E.3.1.4–10, and used to calculate the perforation leading to a fire probabilities shown in Table E.3.1.4–11 and the perforation leading to an explosion probabilities shown in Table E.3.1.4–12.

The combined perforation and scabbing probabilities were used to calculate an explosion probability, since either perforation or scabbing could cause an explosion. For the case where no HE is present, the model was used to calculate the probability of a perforation leading to a fire. The true, shadow, and skid areas for the Zone 4 facilities were reduced for perforation or scabbing based on the following (see Tables E.3.1.4–8 and E.3.1.4–9):

- If the MR magazine roof is "ND" (no damage), then the true and shadow areas are reduced to 0.0.
- If the MR magazine walls are "ND", then the shadow and skid areas are reduced to the width of the building times the skid distance (damage can only occur through the front wall).
- Similarly, if the SAC magazine roof is "ND", then the true and shadow areas are reduced to 0.0.
- Similarly, if the SAC magazine walls are "ND", then the shadow and skid areas are reduced to the width of the building times the skid distance (damage can only occur through the front wall).
- If the MR or SAC magazine front door is "ND", then the skid area is 0.0.

E.3.1.5 *Zone 12*

The analysis performed for Zone 12 of Pantex Plant was virtually identical to that for Zone 4. The number of airport operations on Runways 22, 04, and 31 discussed in section E.3.1.4 and aircraft wingspans and crash rates used in the Zone 4 analysis were used in the Zone 12 analysis. Zone 12 facilities of concern to aircraft crash are those containing plutonium and large amounts of tritium as determined in previous hazard assessments, since these materials have possible offsite consequences (Jacobs 1993; Jacobs 1993a; Jacobs 1992).

Area Calculation

The following section illustrates the calculation of the individual areas and the effective area for the Zone 12 buildings. In this calculation, the buildings were assumed to be in a position that allows the longest skid distance prior to impact with a building (see Figure 4.15.1.1–2 in volume I). As an exception to using the skid distances provided in the Draft DOE Standard (DOE 1996g), for Zone 12, the skid distance was reduced to the maximum distance to nearby buildings when nearby buildings shield the particular facility. The skid distances are presented in Table E.3.1.5–1, as well as the reduced skid distances to account for shielding.

A total effective area for the Zone 12 buildings was then computed by combining the effective areas. The angle of impact was assumed to be that given in the Draft DOE Standard for the various aircraft types. Table E.3.1.5–2 presents the Zone 12 building dimensions.

Table E.3.1.5–3 presents the aircraft operational data used for the Zone 12 analysis. In this table, both the Draft DOE Standard and representative wingspans for aircraft in the vicinity of Pantex Plant are provided. Representative wingspans were determined by examining RAMS data and selecting aircraft for each category that represented the average of the aircraft (for the commercial and military aircraft categories, over 96 percent of the aircraft were represented). Weighted average wingspans were then used in the calculations. The skid length used corresponds to the mean skid distances presented in the Draft DOE Standard (DOE 1996g:B-29).

Hit Probability Calculation

Using the coordinate convention, the center-line (x distance) and perpendicular (y distance) distances to the plutonium centroid for Zone 12 are:

Zone 12	All Aircraft
Runway 04	10.77 mi, -1.71 mi
Runway 22	-10.77 mi, 1.71 mi
Runway 31	-1.65 mi, -9.38 mi

Based on the above distances, all aircraft using the Amarillo International Airport were analyzed with the Near-Airport Model. The crash location probabilities for Runway 22 are presented in Table E.3.1.5–4 (DOE 1996g:B-12–B-23). Air carrier and air taxi crash location probabilities are identical because their crash density location probabilities are grouped into a commercial category. The crash location probabilities are zero for Runway 22 take-offs because in this analysis all take-offs are in a direction away from Pantex Plant, and thus are not a threat to Plant facilities.

The crash location probabilities for Runway 04 are presented in Table E.3.1.5–5 (DOE 1996g:B-12–B-23). The air carrier and air taxi crash density location probabilities are identical because their crash location probabilities are grouped into a commercial category.

The crash location probabilities for Runway 31 are presented in Table E.3.1.5–6 (DOE 1996g:B-12–B-23). Similarly, both the air carrier and air taxi crash density location probabilities are identical because their crash location probabilities are also grouped into a single commercial category.

The impact probability was obtained for the entire Zone 12 operations area by multiplying the number of flights, the impact area, the crash rate, and the crash density function for each category. With substitution of the above data into the probability equation for the specific aircraft type, the impact probabilities for Zone 12 were calculated. Table E.3.1.5–7 contains the crash probabilities for Runway 22 landings, Runway 04 take-offs, Runway 04 landings and the non-airport aircraft. Runway 31 crash probabilities are omitted because they are all zero.

Structural Calculation

The same local response equations for concrete and steel structures used in the Zone 4 analysis were used in this analysis. Building 12–60 is a steel arch construction building and was treated as such. Building 12–41 is constructed with clay tile walls and perforation was assumed to occur for all aircraft types.

Local response structural calculations were performed for 15 different sets (roofs and walls modeled separately) of overburdens and building thicknesses. These include 12-64, 12-84 West (grouped with 12-99 and 12-104), 12-84 East, 12-44 (grouped with 12-85, 12-96, and 12-98), 12-41, 12-50, 12-60, 12-94, 12-104A, 12-26 Pit Vault, 12-42 North Vault, 12-42 South Vault, 12-44 Cell 8, 12-58, and 12-116. Table E.3.1.5–8 presents the results for either perforation or scabbing and Table E.3.1.5–9 provides the results for perforation.

Perforation and Scabbing Probability Calculations

For facilities with HE (weapons), the bounding accident is a perforation or scab leading to an explosion. For facilities without HE, the bounding accident is a perforation leading to a fire. The areas for the facilities were reduced using the structural analysis results. The reduced areas were then used to recalculate perforation and scabbing probabilities. These areas are shown in Table E.3.1.5–10, and used to calculate the scabbing leading to an explosion probabilities shown in Table E.3.1.5–11, the perforation leading to an explosion probabilities shown in Table E.3.1.5–12, and the perforation leading to a fire probabilities shown in Table E.3.1.5–13.

The combined perforation and scabbing probabilities are used to calculate an explosion probability, since either perforation or scabbing could cause an explosion. For the case where no HE is present, the model was used to calculate the probability of a perforation leading to a fire. The true, shadow, and skid areas for the Zone 12 facilities were reduced for perforation or scabbing based on the following ("ND" denotes no damage. See Tables E.3.1.5–8 and E.3.1.5–9):

- If the 12–64, 12–84 W, 12–99, 12–104 roofs are "ND", then the true and shadow areas are reduced to 0.0.
- If the 12–64 walls are "ND", then the skid area is reduced to the width of the building times the skid distance (damage can only occur through the front).
- If the 12–84 E roof and walls are "ND", then the true and shadow areas are reduced to 0.0 and the skid area is reduced to the width of the building times the skid distance (damage can only occur through the front).
- If the 12–44, 12–85, 12–96, 12–98 roofs and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.
- If the 12–50 roof is "ND", then the true and shadow areas are reduced to 0.0.
- If the 12–50 walls is "ND", then the skid area is reduced to 0.0 (there are no doors exposed to the skid direction).
- If the 12–60 roof is "ND", then the true and shadow areas are reduced to 0.0.
- If the 12–60 walls is "ND", then the skid area is reduced to 0.0 (there are no doors exposed to the skid direction).
- If the 12–41 roof and walls are "ND", then the true, shadow and skid areas are reduced to 0.0 (since this was a clay tile structure the facility was modeled as having no depth to assure that perforation occurs).
- If the 12–94 roof and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.
- If the Cell 8 roof and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.
- If the 12–26 Pit Vault, 12–42 North Vault, and 12–42 South Vault roofs and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.
- If the 12-116 roofs and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.
- If the 12-58 roofs and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.

- If the 12-104A roofs and walls are "ND", then the true, shadow and skid areas are reduced to 0.0.

E.3.1.6 *Consequence Analysis*

The probability of an aircraft hitting a facility in Zone 4 and Zone 12 is 1.3×10^{-5} and 1.8×10^{-5}, respectively, for a total of 3.1×10^{-5}. The probability of damaging a facility by scabbing leading to an explosion in Zone 4 is 0.0 because scabbing is only possible in MR magazines. These magazines are preferentially occupied by pits (no HE present), whereas the SAC magazines are incapable of scabbing because there is no concrete in the roof and walls. In Zone 12, the probability of scabbing is 1.5×10^{-7}, however, a study conducted by Jeff Glover of Mason & Hanger indicates that scabbed material from the missiles of concern do not possess the energy to cause a detonation within Zone 12 (PC 1996).

The probability of damaging a facility by perforation leading to an explosion in Zone 4 and Zone 12 is 6.8×10^{-7} and 2.3×10^{-6}, respectively, for a total of 3.0×10^{-6}. The probability of damaging a facility by perforation leading to fire for Zone 4 and Zone 12 is 5.2×10^{-7} and 4.7×10^{-7}, respectively, for a total of 9.9×10^{-7}. This represents a conservative upper bound for the probability of causing a fire or explosion resulting in plutonium dispersal. This conservative upper bound includes the probability that plutonium or tritium is in the facility, that all of the containers fail, that a fire occurs, and that the contents are exposed to the fire. All four of these probabilities are known to be less than 1 but have been conservatively assumed to be 1 for this calculation.

Consistent with the Draft DOE Standard (DOE 1996g), a consequence analysis has been performed for this accident. The consequence analysis is similar to the consequence analysis for other accidents and is provided for Scenarios 3 and 8 in Table 4.14.2.1–3, volume I.

E.3.1.7 *Risk Reduction Due to Overflight Working Group Initiatives*

Recommendations of the Overflight Working Group are presented in volume I, section 4.15.1.3. DOE has committed to implement the risk reduction measures proposed by this group. Based on the discussion in volume I, section 4.15.7, it is not possible to fully characterize the risk reduction that would result with implementation of the Overflight Working Group initiatives using the current methodology. However, it is estimated that implementation of the MOU, the offset localizer, relocation of the VORTAC, and 65 percent use of GPS non-precision approach tracks would result in an 82 percent cumulative risk reduction (DOE 1995:22). This 82 percent reduction was estimated using the Solomon model. Fortification of areas and structures in which nuclear materials are handled and stored could further reduce the impact of aircraft accidents.

E.3.2 Manzano Weapons Storage Area

The Manzano WSA is located near the Albuquerque International Airport, a major airport whose routine flight operations include many heavy aircraft. The methodology used to assess the aircraft impact probability is very similar to the analysis performed for the Pantex Plant, but in much less detail because there is only one building type to be analyzed.

The Manzano WSA is located in the foothills of the Manzano Mountains, approximately 6.5 kilometers (4 miles) southeast of the main (east-west) runway of the Albuquerque International Airport, one of three airports in the vicinity the Manzano WSA. The Albuquerque International

Airport is the major commercial airfield in the State of New Mexico; it is the only airport with regular commercial jet service. In addition to its role as a commercial airfield, the Albuquerque International Airport is used by military aircraft at KAFB. In 1994, the Albuquerque International Airport had 220,914 aircraft operations (take-offs and landings) (PC 1996a).

In addition to the Albuquerque International Airport, there are two other airports in the Albuquerque area. Coronado Airport, approximately 19 kilometers (12 miles) to the north-northwest, has two runways used only by general aviation aircraft. Similarly, Alameda Airport, approximately 24 kilometers (15 miles) to the northwest, has two runways used only by general aviation aircraft.

A description of the x and y coordinate system, the category of aircraft operations that occur, and a screening of the probability density function values for the three airports is presented in Table E.3.2–1. An initial screening of the probability density function values for the type of aircraft operations eliminated the Coronado and Alameda Airports. Both of these airports are outside the probability density function boundary for general aviation aircraft and, therefore, were not included in the aircraft crash analysis. Only the Albuquerque International Airport and non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g).

In the history of the Manzano WSA facility, there have been three aircraft crashes. One of the crashes involved an F-100C. The crash occurred east of the Manzano WSA administration area. Another crash involved a B-29 in the northern portion of the site. The aircraft departed from KAFB and crashed after approximately three minutes in flight, killing the crew. The third crash also occurred in the northern portion of the site and involved an EC-135 (KAFB 1993:69,73,74).

A major advantage offered by the Manzano WSA storage facilities is the amount of rock overburden that would shield the stored pits from damage due to aircraft accidents. This overburden is needed because the candidate storage facilities lack an automatic fire suppression system and cannot rely on prompt response from local fire fighters (due to remote facility location and lack of automatic fire detection capability).

If DOE chooses to relocate pits to the Manzano WSA, the pits would be stored in Type D magazines. Type D magazines (as shown in Figure 5.5.1.12–1 in volume I) have access tunnels that vary in length from 20 meters to over 30 meters (65 feet to over 100 feet). The main chambers are approximately 19 meters (61 feet) long and have the capacity to store up to 800 pit containers each in a Stage Right configuration. The main chamber is protected by two vault-like steel doors at both ends of the access tunnel.

Type D facilities are tunneled into the mountainside and thus, provide significant earth overburden protection from penetrating aircraft. As many as 35 magazines have overburden greater than 9 meters (30 feet) and are potentially available for pit storage.

For the 20,000 pit storage option, approximately 25 Type D magazines would be utilized. For the 8,000 pit storage option, approximately 10 Type D magazines would be utilized. The frequency of an aircraft impact at the Manzano WSA is relatively high compared with other potential storage sites. However, the earth overburden of Type D magazine provides significant protection against potential damage from aircraft impacts.

E.3.2.1 *Aircraft Crash Affected Environment*

An adjustment to the Near-Airport and Non-Airport Models consisted of manipulation of the flight modes (i), aircraft categories (j), and aircraft sources (k) to fit the Manzano WSA site. The flight mode, i, was set equal to three flight modes.

i = 1	Take-off
i = 2	In-flight
i = 3	Landing

The aircraft categories are very similar to Pantex Plant, except helicopters have been omitted because they are not shown to be penetrating missiles.

j = 1	Commercial: Air Carrier
j = 2	Commercial: Air Taxi
j = 3	Military: Large (Bomber, Cargo, and Tanker aircraft)
j = 4	Military: Small (Attack, Fighter, and Trainer aircraft)
j = 5	General: Fixed-wing, reciprocating, single-engine
j = 6	General: Fixed-wing, reciprocating, multi-engine
j = 7	General: Fixed-wing, turboprop
j = 8	General: Fixed-wing, turbojet

Here the aircraft sources, k, was summed over three phases

k = 1	Albuquerque International Airport Runway 1
k = 2	Albuquerque International Airport Runway 2
k = 3	Non-Airport Aircraft

Figure E.3.2.1–1 (not to scale, adapted from JDRC nd) represents the location of the Manzano WSA storage facilities in relation to east-west runway at the Albuquerque International Airport. There are three key points on Figure E.3.2.1–1 that were considered in assessing the aircraft impact probability:

1. Point 1, located at the geometric center of the east-west runway;
2. Point 2, located at the northern-most end of the candidate storage area;
3. Point 3, located at the south western end of the candidate storage area.

The aircraft impact probability assessment focuses on accidents in between points 2 and 3. The assessment was performed by separating the displacement vector from point 1 to both points 2 and 3 into two orthogonal components, a:

1. Vector coincident with a direct projection of the center-line of the runway; and
2. Vector, perpendicular to the first that extends from the first vector to the impact point (i.e., point 2 or point 3).

The lengths of these two vector components were used to determine the crash probability density. The length of the east-west runway at the Albuquerque International Airport is 4.2 kilometers (2.6 miles) (Smith 1995:9). Using this information, it was determined that the center-line and perpendicular distances from point 1 (the midpoint of the runway) to (JDRC nd):

	Runway 1 (east-west)	Runway 2 (north-south)
Point 2	5.88 miles, -0.22 miles	-0.22 miles, -5.88 miles
Point 3	4.71 miles, -2.78 miles	-2.78 miles, -4.71 miles

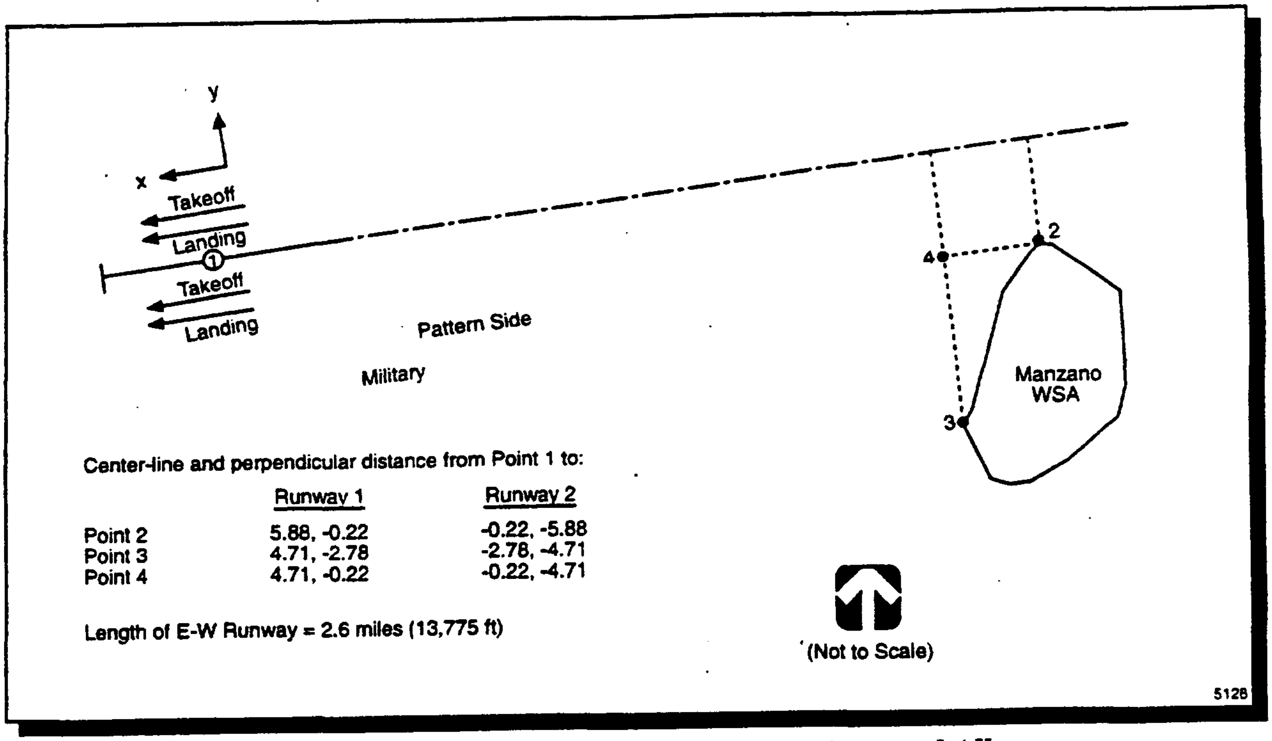

FIGURE E.3.2.1–1.—*Manzano Weapons Storage Area and Albuquerque International Airport.*

Because none of the Manzano WSA storage facilities have a center-line distance closer than 4.71 miles, nor a perpendicular distance less than 0.22 miles, Point 4 was conservatively adopted for the aircraft frequency assessment.

An estimate of an aircraft crash into the Manzano WSA storage facilities was generated using the probability equation defined in Section E.2.1. The south, east, and west are the preferred directions for take-offs and landings at the Albuquerque International Airport (Smith 1995:3). Table E.3.2.1–1 summarizes the 1994 Albuquerque International Airport traffic activity (PC 1996a).

Approximately one-third of the flights at the airport pass in proximity to the Manzano WSA. It was conservatively assumed for this analysis that all of the flights passed in proximity to the Manzano WSA. Since the number of operations included only air carrier, air taxi, military, and general aviation aircraft, the number of military and general aviation operations was divided by the same ratio that was determined for Pantex Plant. While this assumption may not necessarily be accurate, it does not affect the final results for this analysis.

The crash rates values described in section E.2.1 were used in this analysis. The distance to the runway and number of annual flight operations were modeled conservatively in this aircraft impact probability assessment.

Using this information, the probability equation becomes:

$$F = \sum_{i=1,3}\sum_{j=1,8}\sum_{k=1,3} N_{ijk} \cdot A_{ij} \cdot f_{ijk}(x,y) \cdot P_{ijk}$$

Data in Table E.3.2.1–1 does not differentiate between take-offs and landings. Hence, it was assumed that half of the tabulated operations are take-offs and half are landings. Crash rates are provided in Table E.3.2.1–2.

The aircraft crash location probability for each aircraft category and flight mode is presented in Table E.3.2.1–3 (DOE 1996g:B-12 to B-23). Using the coordinate convention in the Near

Airport Model, the center-line and perpendicular distances to Point 4, the hypothetical storage facility, are:

	Runway 1 (east-west)	Runway 2 (north-south)
Point 4	4.71 miles, -0.22 miles	-0.22 miles, -4.71 miles

The crash location probabilities in Table E.3.2.1–3 are identical for the air carrier and air taxi categories, and the four general aviation categories, because their crash location probabilities are grouped into a single category each.

The crash location probabilities for general aviation are asymmetrical in the Draft DOE Standard (DOE 1996g). Therefore, in preparing Table E.3.2.1–3, more conservative crash probabilities were used. This conservative convention was also applied to military crash location probabilities.

The model for aircraft in-flight was changed from a Solomon Model basis in the July 1995 version of the Draft DOE Standard (DOE 1995z) to the curve-fitted empirical Non-Airport Model in the Draft DOE Standard (DOE 1996g) based on crashes that have occurred throughout the country. The July 1996 Draft DOE Standard includes NPf(x,y) values for each DOE site. Only the area of the facility is calculated. For this analysis, the crash rate probabilities per square mile for Sandia National Laboratories, located north of the east-west runway, were used (Table E.3.2.1–4).

E.3.2.2 *Area Calculation*

The last parameter in the above probability equation requiring quantification is A_{ij}. The length, width, and height of a Manzano WSA Type D storage facility are: 18.5 meters (60.7 feet), 8.1 meters (26.5 feet), and 3.8 meters (12.5 feet) (Figure 5.5.1.12–1 in volume I). Using the methodology developed above for Pantex Plant for a rectangular facility (which is conservative since the Type D facilities have a stronger, concrete arch design):

$$A_t = (2 \cdot L \cdot W \cdot WS) \div R + (L \cdot W)$$

$$A_{sh} = (WS+R) \cdot H\cot\phi$$

$$R = (L^2 + W^2)^{0.5}$$

An impact angle, ϕ, dependent on the aircraft category and the flight mode, was used here as was done in the Pantex Plant analysis. The representative maximum wingspan dimensions, WS, for each aircraft category used are also the same.

The total area for the structures does not include the contribution from the skid area because it was assumed that any aircraft skidding along the mountain will skid across the top of storage facilities without damaging them (i.e., no significant forces normal to the rock face will be exerted). Hence, only an impact directly into the storage facility could cause a radionuclide release. The total area for the Manzano WSA storage facilities was obtained by multiplying the individual areas for each aircraft type by 25, the total number of facilities. Table E.3.2.2–1 presents aircraft operational data for take-off, in-flight, and landings used for this analysis.

E.3.2.3 *Impact Probability Calculation*

With substitution of the above data into the probability equation, the impact probabilities listed in Table E.3.2.3–1 were obtained. The impact probability was obtained for the entire Manzano WSA by multiplying the individual facility probability by the total number of facilities present. Since the frequency of hitting one of 25 Type D magazines, 8.8×10^{-5}, was greater than 10^{-7}, in accordance with the Draft DOE Standard (DOE 1996g), further analysis was required.

E.3.2.4 *Structural Calculation*

Given that an aircraft impacts into a Manzano WSA storage facility, there is only a risk to human health if the storage facility is penetrated and the storage containers are damaged sufficiently to release plutonium into the environment. Since the pits will be stored in AT-400A, a certified Type B shipping container, minor damage to the storage facility is not anticipated to cause container failure. However, significant damage to the storage facility is likely to damage containers sufficiently enough to cause a plutonium release.

A survey of Manzano WSA contour maps reveals that the minimum overburden for a facility is approximately 9 meters (30 feet). Therefore, the approach proposed for estimating the penetration probability is to determine if the velocity of the aircraft in take-off and landing modes is sufficient to penetrate 9 meters (30 feet) of rock, and then quantify the probability that the impact is sufficient to cause penetration.

A local response structural analysis was performed according to the Draft DOE Standard (DOE 1996g) for a facility with a 9 meter (30 feet) overburden. The analysis was performed for the maximum penetrator missile for each of the eight aircraft categories. The aircraft penetrators modeled, and if they penetrate the facility, are shown in Table E.3.2.4–1. None of the eight aircraft missiles were capable of penetrating the facility; therefore, the frequency of releasing material from one of the 25 Type D magazines was 0. Since the frequency of releasing material is less than 10^{-7}, in accordance with the Draft DOE Standard, no further analysis was required.

E.3.2.5 *Consequence Calculation*

The probability of an aircraft hitting a facility at Manzano WSA is 8.8×10^{-5}. The probability of damaging a facility by perforation is 0. Consistent with the Draft DOE Standard (DOE 1996g), a consequence analysis was not necessary.

E.3.3 Nevada Test Site

The airspace above NTS, designated as R4808, is a Special-Use Airspace identified by FAA regulations. This designation applies to all aircraft and is unlimited in height. Clearance to penetrate the restricted airspace above NTS must be obtained from DOE. Aircraft desiring to fly over NTS airspace are required to contact the DOE Operations Coordination Center at NTS. Requesters must provide information regarding the type of aircraft and nature of flight into the restricted airspace. DOE has approval authority for flights into the restricted airspace.

Based on penetration calculations performed for Manzano WSA and 9 meters (30 meters) of soil and rock, the proposed pit storage location inside of P-Tunnel at NTS is immune from aircraft accidents, since its location is approximately 240 meters (800 feet) below the mesa. Therefore, pits stored in P-Tunnel could not be affected by an aircraft crash (PC 1995b).

There are four airports and five landing strips in the vicinity of the Device Assembly Facility (DAF) and P-Tunnel. Las Vegas McCarran International Airport is the major commercial airfield in the State of Nevada. The airport, located approximately 122 kilometers (76 miles) southeast of NTS, is used by commercial, military, and general aviation aircraft. In 1994, McCarran International Airport had 488,347 aircraft operations (take-offs and landings).

Another airport located just north of McCarran International is the North Las Vegas Airport. This airport is used by commercial air taxi, military, and general aviation aircraft. In 1994, North Las Vegas Airport had 188,707 air taxi, military, and general aviation aircraft operations (PC 1996a). Nellis Air Force Base, located approximately 107 kilometers (67 miles) southeast of NTS, is also north of McCarran International Airport and is used by only military aircraft. The closest airfield to NTS is Indian Springs Auxiliary Field. This airfield, approximately 48 kilometers (30 miles) southeast of the DAF, has two runways used only by military aircraft. Beatty Airfield, approximately 67 kilometers (42 miles) west of the DAF, has one runway and is used by general aviation aircraft.

There are five landing strips located on or near NTS. The most frequently used is the Desert Rock Airstrip, located in Area 22 southwest of Mercury. Desert Rock Airstrip has a single runway and is 30 kilometers (19 miles) south of the DAF. Two unnamed, single runway airstrips are located on NTS; one 6 kilometers (4 miles) north at Yucca Lake in Area 6, and the other 27 kilometers (17 miles) south in Area 22. Similarly, two unnamed, single-runway airstrips are located west of NTS; one 62 kilometers (39 miles) west-northwest and the other 78 kilometers (49 miles) north-northwest.

A description of the x and y coordinate system, the category of aircraft operations that occur, and a screening of the probability density function values for the four airports and five landing strips is presented in Table E.3.3–1. All nine airports are either outside the probability density function boundary for all categories of aircraft or the activity at the facility was sufficiently low so it was bounded by the in-flight activity. These airports, therefore, were not included in aircraft crash analysis. Only non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g).

E.3.3.1 *Aircraft Crash Affected Environment*

An adjustment to the Near-Airport and Non-Airport Models consisted of manipulation of the flight modes (i), aircraft categories (j), and aircraft sources (k) to fit the NTS. The flight mode, i, was set equal to one flight mode.

$i = 1$ In-flight

The aircraft categories are very similar to Pantex Plant except helicopters have been omitted because they are not shown to be penetrating missiles.

$j = 1$ Commercial: Air Carrier

$j = 2$ Commercial: Air Taxi

$j = 3$ Military: Large (Bomber, Cargo, and Tanker aircraft)

$j = 4$ Military: Small (Attack, Fighter, and Trainer aircraft)

$j = 5$ General: Fixed-wing, reciprocating, single-engine

$j = 6$ General: Fixed-wing, reciprocating, multi-engine

$j = 7$ General: Fixed-wing, turboprop

$j = 8$ General: Fixed-wing, turbojet

Here the aircraft source, k, was summed over one phase

$k = 1$ Non-Airport Aircraft

An estimate of an aircraft crash into the DAF was generated using the probability equation defined in Section E.2.1. Using this information, the probability equation becomes:

$$F = \Sigma_{i=1}\Sigma_{j=1,8}\Sigma_{k=1} N_{ijk} \cdot A_{ij} \cdot f_{ijk}(x,y) \cdot P_{ijk}$$

The model for the aircraft in-flight was changed from a Solomon Model basis in the July 1995 version of the Draft DOE Standard (DOE

1995z) to the curve-fitted empirical Non-Airport Model in the July 1996 version of the Draft DOE Standard (DOE 1996g) based on crashes that have occurred throughout the country. The July 1996 Draft DOE Standard includes NPf(x,y) values for each DOE site. Only the area of the facility is calculated. The crash rate probabilities per square mile for NTS are provided in Table E.3.3.1–1.

E.3.3.2 *Area Calculation*

The DAF was modeled conservatively as a single facility with a length of 201 meters (659 feet), a width of 76 meters (250 feet), and a height of 9 meters (30 feet). (PC 1994). Using the methodology developed above for Pantex Plant for a rectangular facility:

$$A_t = (2 \cdot L \cdot W \cdot WS) \div R + (L \cdot W)$$

$$A_{sh} = (WS+R) \cdot H\cot\phi$$

$$R = (L^2 + W^2)^{0.5}$$

$$A_{sk} = (WS + R) \cdot S$$

An impact angle, ϕ, dependent on the aircraft category and the flight mode was used here as was done in the Pantex Plant analysis. Also, the representative maximum wingspan dimensions, WS, for each aircraft category used are also the same.

The total area for the structures includes the contribution from the skid area with the skid distances from the Draft DOE Standard (DOE 1996g). For large military aircraft, the take-off skid distance was used for in-flight aircraft since it was conservative. Table E.3.3.2–1 presents aircraft operational data for in-flight aircraft.

E.3.3.3 *Impact Probability Calculation*

With substitution of the above data into the probability equation, the impact probabilities listed in Table E.3.3.3–1 were obtained. Since the frequency of hitting the DAF, 1.5×10^{-6}, was greater than 10^{-7}, in accordance with the Draft DOE Standard (DOE 1996g) further analysis was required.

E.3.3.4 *Structural Calculation*

Given that an aircraft impacts into the DAF, there is only a risk to human health if the storage facility is penetrated and the storage containers are damaged sufficiently to release plutonium into the environment. Since the pits will be stored in AT–400A, a certified Type B shipping container, minor damage to the storage facility is not anticipated to cause container failure. However, significant damage to the storage facility may damage containers sufficiently enough to cause a plutonium release.

A local response structural analysis for the facility was performed according to the Draft DOE Standard, using a wall thickness of 46 centimeters (18 inches) (DOE 1986). This wall thickness was selected since it is the minimum thickness for the bays and cells where plutonium would be stored. An overburden of 1.5 meters (5 feet) was included for three sides and the roof of the facility. On the fourth side of the facility only the wall was modeled. The analysis was performed for the maximum penetrator missile for each of the eight aircraft categories. Commercial air carrier, large military, and small military aircraft were the only three aircraft that could produce missiles capable of penetrating the side of the facility without an overburden. The aircraft penetrators modeled, and if they penetrate the facility, are presented in Table E.3.3.4–1.

E.3.3.5 *Release Probability Calculation*

The impact probability calculation was repeated for the commercial air carrier, large military, and small military aircraft categories to determine the release probability. Only the side of the facility without an overburden was included. With substitution of the above data into the probability equation, the release probabilities were 1.3×10^{-8}, 3.7×10^{-9}, and 6.3×10^{-8}, respectively.

E.3.3.6 *Consequence Calculation*

The probability of an aircraft hitting the DAF at NTS is 1.5×10^{-6}. The probability of damaging the DAF due to perforation is 8.1×10^{-8}. The P-Tunnel was not analyzed since pits stored there would be immune from aircraft accidents. Consistent with the Draft DOE Standard (DOE 1996g), a consequence analysis has not been performed for this site.

E.3.4 Savannah River Site

There are four airports in the vicinity of the P-Reactor at SRS. Bush Field, the major commercial airfield in the area, has two runways and is approximately 38 kilometers (24 miles) west-northwest of the P-Reactor. The airport is used by commercial, military, and general aviation aircraft. In 1994, Bush Field had 39,461 aircraft operations (take-offs and landings) (PC 1996a). The closest airport, the county airport near Barnwell, has three runways used by general aviation aircraft, and is approximately 18 kilometers (11 miles) east of P-Reactor. Similarly, Aiken Airport, near Aiken, is approximately 46 kilometers (29 miles) north-northwest and has three runways used by general aviation aircraft. The North Army Base is approximately 61 kilometers (38 miles) northeast and has one runway used by military aircraft.

A description of the x and y coordinate system, the category of aircraft operations that occur, and a screening of the probability density function values for the four airports is presented in Table E.3.4–1. All four airports are outside the probability density function boundary for all categories of aircraft and therefore were not included in the aircraft crash analysis. Only non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g).

E.3.4.1 *Aircraft Crash Affected Environment*

An adjustment to the Near-Airport and Non-Airport Models consisted of manipulation of the flight modes (i), aircraft categories (j), and aircraft sources (k) to fit the SRS. The flight modes, i, was set equal to one flight mode.

$i = 1$ In-flight

The aircraft categories are very similar to Pantex Plant, except helicopters have been omitted because they are not shown to produce penetrating missiles.

$j = 1$ Commercial: Air Carrier

$j = 2$ Commercial: Air Taxi

$j = 3$ Military: Large (Bomber, Cargo, and Tanker aircraft)

$j = 4$ Military: Small (Attack, Fighter, and Trainer aircraft)

$j = 5$ General: Fixed-wing, reciprocating, single-engine

$j = 6$ General: Fixed-wing, reciprocating, multi-engine

$j = 7$ General: Fixed-wing, turboprop

$j = 8$ General: Fixed-wing, turbojet

Here the aircraft source, k, was summed over one phase

$k = 1$ Non-Airport Aircraft

An estimate of an aircraft crash into the P-Reactor was generated using the probability equation defined in Section E.2.1. Using this information, the probability equation becomes:

$$F = \Sigma_{i=1}\Sigma_{j=1,8}\Sigma_{k=1} N_{ijk} \cdot A_{ij} \cdot f_{ijk}(x,y) \cdot P_{ijk}$$

The model for the aircraft in-flight was changed from a Solomon Model basis in the July 1995 version of the Draft DOE Standard (DOE 1995z) to the curve-fitted empirical Non-Airport Model in the July 1996 version of the Draft DOE Standard (DOE 1996g) based on crashes that have occurred throughout the country. The July 1996 Draft DOE Standard includes NPf(x,y) values for each DOE site. Only the area of the facility is calculated. The crash rate probability per square mile for SRS is provided in Table E.3.4.1–1.

E.3.4.2 *Area Calculation*

The P-Reactor was modeled conservatively as a facility with a length of 69 meters (225 feet), a width of 57 meters (187 feet), and a height of 9 meters (30 feet). (PC 1996b). Using the methodology developed above for Pantex Plant for a rectangular facility:

$$A_t = (2 \cdot L \cdot W \cdot WS) \div R + (L \cdot W)$$

$$A_{sh} = (WS+R) \cdot H\cot\phi$$

$$R = (L^2 + W^2)^{0.5}$$

$$A_{sk} = (WS + R) \cdot S$$

An impact angle, ϕ, dependent on the aircraft category and the flight mode was used here, as was done in the Pantex Plant analysis. The representative maximum wingspan dimensions, WS, for each aircraft category used are also the same.

The total area for the structures includes the contribution from the skid area with the skid distances from the Draft DOE Standard (DOE 1996g). For large military aircraft, the take-off skid distance was used for in-flight aircraft since it was conservative. Table E.3.4.2–1 presents aircraft operational data for in-flight aircraft.

E.3.4.3 *Impact Probability Calculation*

With substitution of the above data into the probability equation, the impact probabilities listed in Table E.3.4.3–1 were obtained. Since the frequency of hitting the P-Reactor, 1.2×10^{-6}, is greater than 10^{-7}, in accordance with the Draft DOE Standard (DOE 1996g), further analysis was required.

E.3.4.4 *Structural Calculation*

Given that an aircraft crashes into the P-Reactor, there is only a risk to human health if the storage facility is penetrated and the storage containers are damaged sufficiently to release plutonium into the environment. Since the pits will be stored in AT-400A, a certified Type B shipping container, minor damage to the storage facility is not anticipated to cause container failure. However, significant damage to the storage facility may damage containers sufficiently enough to cause a plutonium release.

A local response structural analysis for the facility was performed according to the Draft DOE Standard (DOE 1996g) using a wall thickness of 76 centimeters (30 inches). The analysis was performed for the maximum penetrator missile for each of the eight aircraft categories. Commercial air carrier and large military aircraft were the only two aircraft capable of producing missiles capable of penetrating the facility. The aircraft penetrators modeled, and if they penetrate the facility, are presented in Table E.3.3.4–1.

E.3.4.5 *Release Probability Calculation*

The impact probability calculation was repeated for the commercial air carrier and large military aircraft categories to determine the release probability. With substitution of the above data into the probability equation, the release probabilities were 7.1×10^{-9} and 2.2×10^{-9}, respectively.

E.3.4.6 *Consequence Calculation*

The probability of an aircraft hitting the P-Reactor at SRS is 1.2×10^{-6}. The probability of damaging the P-Reactor by perforation is 9.2×10^{-9}. Consistent with the Draft DOE Standard (DOE 1996g), a consequence analysis has not been performed for this site.

E.3.5 Hanford Site

The FAA maintains a Very High Frequency Omni-Directional Radio Range navigation aid at the Tri-Cities Airport. Several Federal airways pass in proximity of the Fuels and Materials Examination Facility (FMEF). However, the FAA reports that these routes have low usage (WHC 1991). There are no military installations or training routes that would place military aircraft in the vicinity of FMEF.

There are five airports and one landing strip in the vicinity of the FMEF. The Tri-Cities Airport, the major commercial airfield in the area, is approximately 27 kilometers (17 miles) southeast of the FMEF. The airport's two runways are used by commercial, military, and general aviation aircraft. In 1994, the Tri-Cities Airport had 81,867 aircraft operations (take-offs and landings) (PC 1996a). The closest airport, the Richland Airport, is approximately 13 kilometers (8 miles) southeast of FMEF, and has three runways used only by general aviation aircraft. Vista Field in Kennewick, approximately 26 kilometers (16 miles) south-southeast, has two runways used only by general aviation aircraft. Beardsley Field near Prosser, approximately 42 kilometers (26 miles) southwest, has one runway used only by general aviation aircraft. Sunnyside Airport, 48 kilometers (30 miles) west-southwest, has one runway used by general aviation aircraft. There is an unnamed landing strip near Horse Heaven Hills, approximately 32 kilometers (20 miles) south-southwest, which has one runway, and is used only by general aviation aircraft.

A description of the x and y coordinate system, the category of aircraft operations that occur, and a screening of the probability density function values for the five airports and one landing strip is presented in Table E.3.5-1. All four general aviation airports and the landing strip are outside the probability density function boundary for general aviation aircraft and, therefore, were not included in the aircraft crash analysis. For the Tri-Cities Airport, only small military aircraft in the landing mode had a nonzero probability density function value. Therefore, only these aircraft in the landing mode at the Tri-Cities Airport and non-airport (in-flight) aircraft were included in the analysis as required by the Draft DOE Standard (DOE 1996g).

E.3.5.1 *Aircraft Crash Affected Environment*

An adjustment to the Near-Airport and Non-Airport Models consisted of manipulation of the flight modes (i), aircraft categories (j), and aircraft sources (k) to fit the Hanford Site. The flight mode, i, was set equal to two flight modes.

$i = 1$ In-flight

$i = 2$ Landing

The aircraft categories are very similar to Pantex Plant, except helicopters have been omitted because they are not shown to produce penetrating missiles.

j = 1 Commercial: Air Carrier

j = 2 Commercial: Air Taxi

j = 3 Military: Large (Bomber, Cargo, and Tanker aircraft)

j = 4 Military: Small (Attack, Fighter, and Trainer aircraft)

j = 5 General: Fixed-wing, reciprocating, single-engine

j = 6 General: Fixed-wing, reciprocating, multi-engine

j = 7 General: Fixed-wing, turboprop

j = 8 General: Fixed-wing, turbojet

Here the aircraft source, k, was summed over two phases:

k = 1 Tri-Cities Airport Runway 1

k = 2 Non-Airport Aircraft

An estimate of an aircraft crash into the FMEF was generated using the probability equation defined in Section E.2.1. Runway 1 is the preferred runway for take-offs and landings at the Tri-Cities Airport; it was assumed that all operations would occur on this runway. Table E.3.5.1–1 summarizes the 1994 Tri-Cities airport traffic activity (PC 1996a). It was conservatively assumed for this analysis that all of the flights passed in proximity to FMEF. Since the number of operations included only air carrier, air taxi, military, and general aviation aircraft, the number of military and general aviation operations was divided by the same ratio that was determined for Pantex Plant. While this assumption may not necessarily be the most precise, it does not affect the final results for this analysis.

The crash rates values described in Section E.2.1 were used in this analysis. The distance to the runway and number of annual flight operations were modeled conservatively in this aircraft impact probability assessment.

Using this information, the probability equation becomes:

$$F = \Sigma_{i=1}\Sigma_{j=1,8}\Sigma_{k=1}\, N_{ijk} \cdot A_{ij} \cdot f_{ijk}(x,y) \cdot P_{ijk}$$

Data in Table E.3.5.1–1 does not differentiate between take-offs and landings. Hence, it was assumed that half of the tabulated operations are take-offs, and half are landings. Crash rates are provided in Table E.3.5.1–2.

The aircraft crash location probability for each aircraft category and flight mode is presented in Table E.3.5.1–3 (DOE 1996g:B-12 to B-23). Using the coordinate convention in the Near-Airport Model, the center-line and perpendicular distances to the FMEF, are:

Runway 1 16.5 miles, 0.5 miles

Both the air carrier and air taxi crash location probabilities, and the four general aviation categories crash location probabilities, in Table E.3.5.1–3 are identical because their crash location probabilities are grouped into a single category.

The crash location probabilities for general aviation are asymmetrical in the Draft DOE Standard (DOE 1996g). Therefore, in preparing Table E.3.5.1–3, more conservative crash probabilities were used. This conservative convention was also applied to military crash location probabilities.

The model for the aircraft in-flight was changed from a Solomon Model basis in the July 1995 version of the Draft DOE Standard (DOE

1995z) to the curve-fitted empirical Non-Airport Model in the July 1996 version of the Draft DOE Standard (DOE 1996g) based on crashes that have occurred throughout the country. The July 1996 Draft DOE Standard includes NPf(x,y) values for each DOE site. Only the area of the facility is calculated. The crash rate probability per square mile for Hanford are provided in Table E.3.5.1–4.

E.3.5.2 *Area Calculation*

The FMEF was modeled conservatively as a facility with a length of 98 meters (320 feet), a width of 47 meters (155 feet), and a height of 21 meters (70 feet). (DOE 1994). Using the methodology developed above for Pantex Plant for a rectangular facility:

$$A_t = (2 \cdot L \cdot W \cdot WS) \div R + (L \cdot W)$$

$$A_{sh} = (WS+R) \cdot H \cot\phi$$

$$R = (L^2 + W^2)^{0.5}$$

$$A_{sk} = (WS + R) \cdot S$$

An impact angle, ϕ, dependent on the aircraft category and the flight mode was used here as was done in the Pantex Plant analysis. The representative maximum wingspan dimensions, WS, for each aircraft category used are also the same.

The total area for the structures includes the contribution from the skid area with the skid distances from the Draft DOE Standard (DOE 1996g). For large military aircraft, the take-off skid distance was used for in-flight aircraft since it was conservative. Table E.3.5.2–1 presents aircraft operational data for in-flight aircraft and landings.

E.3.5.3 *Impact Probability Calculation*

With substitution of the above data into the probability equation, the impact probabilities listed in Table E.3.5.3–1 were obtained. Since the frequency of hitting the FMEF, 1.2×10^{-6}, was greater than 10^{-7}, in accordance with the Draft DOE Standard (DOE 1996g), further analysis was required.

E.3.5.4 *Structural Calculation*

Given that an aircraft impacts into the FMEF, there is only a risk to human health if the storage facility is penetrated and the storage containers are damaged sufficiently to release plutonium into the environment. Since the pits will be stored in AT–400A, a certified Type B shipping container, minor damage to the storage facility is not anticipated to cause container failure. However, significant damage to the storage facility may damage containers sufficiently enough to cause a plutonium release.

A local response structural analysis for the facility was performed according to the Draft DOE Standard (DOE 1996g), using a wall thickness of 122 centimeters (48 inches). The analysis was performed for the maximum penetrator missile for each of the eight aircraft categories. None of the eight aircraft missiles were capable of penetrating the facility; therefore, the frequency of releasing material from the FMEF was 0. The aircraft penetrators modeled, and if they penetrate the facility are presented in Table E.3.5.4–1.

E.3.5.5 *Consequence Calculation*

The probability of an aircraft hitting the FMEF at Hanford is 1.2×10^{-6}. The probability of damaging the FMEF by perforation is 0. Consistent with the Draft DOE Standard (DOE 1996g), a consequence analysis is not necessary for this site.

(This Page Intentionally Left Blank)

APPENDIX F

Transportation Risk Analysis

(This Page Intentionally Left Blank)

APPENDIX F
TRANSPORTATION RISK ANALYSIS

F.1 INTRODUCTION

This appendix contains additional material for support of the impact analyses in the transportation sections of the EIS. Further information regarding Pantex Plant related transportation activities, including nonradiological hazardous wastes and materials, is provided in the Pantex Plant *Safety Information Document* and the *Ross Aviation Transportation Analysis Report* (Pantex 1996a; Ross 1994).

F.2 PACKAGING

Pantex Plant utilizes many different containers for packaging of nuclear explosives, explosives and explosive components, and radioactive materials. These containers provide protection against accidental release of hazardous material. Each container is designed for a specific application, and some have firm guidelines for their construction. Specifications for containers used during offsite transportation of radioactive materials are contained in 10 CFR 71. The following are examples of packaging guidelines for intersite shipment of radioactive material.

F.2.1 Limited Quantity/ Instruments and Articles

These materials are packaged in strong, tight packages that will not leak the radioactive contents during normal transportation.

F.2.2 Type A Packaging

Type A packages must be designed according to the requirements of 49 CFR Sections 173.24, 173.411, and 173.412. This package type must be adequate to prevent any loss of radioactive material or shielding while subjected to normal (i.e., incident-free) transport conditions. This packaging will be in appropriate inner containers to prevent leakage of the contents with the inner containers overpacked in one of the following containers:

- Strong fiberboard box.
- Tightly sealed can or drum.
- Strong wooden box.
- Approved Department of Transportation (DOT)–7A equivalent packaging.
- Original containers received from manufacturer, if in good condition.

Materials shall be cushioned to prevent movement, and containers shall be securely closed.

F.2.3 Type B Packaging

Type B packages must meet all of the requirements for Type A packaging as well as withstand test conditions that simulate serious accident damage. The test results must show that only a limited loss of shielding and essentially no loss of material occurs. The test conditions are determined by the Nuclear Regulatory Commission (NRC) in regulation 10 CFR 71.73 and include the following:

- A 9-meter (30-foot) free drop onto an unyielding surface.
- A dynamic crush test consisting of dropping a 500-kilogram (1,100-pound) mass from a height of 9 meters (30 feet) onto the container.
- A puncture test consisting of a free drop greater than 1 meter (3.3 feet) onto a 15-centimeter (6-inch) diameter steel pin.

- A 30-minute thermal exposure at 800 °C (1,475 °F).
- Immersion in water for 8 hours (for fissile materials packaging only).

In addition to requirements for accident survivability, the DOT places limits on the external radiological hazards posed by radioactive materials shipments. For both Type A and Type B radioactive materials packaging, the dose rate at any point on the outer surface of the package may not exceed:

- 200 millirem per hour on the surface of the package.
- 10 millirem per hour at 1 meter (3.3 feet).

If the packages are transported in an "exclusive use" closed transport vehicle, with the exception of aircraft, then the following maximum dose rates are allowed:

- 1,000 millirem per hour on the accessible package surface.
- 200 millirem per hour at the external surface of the transport vehicle.
- 10 millirem per hour at 2 meters (6.6 feet) from the external surface of the transport vehicle.
- 2 millirem per hour in any area of the vehicle that a person occupies.

The Pantex Plant *Safety Information Document* provides a comprehensive listing of containers used at Pantex Plant (Pantex 1996a).

F.3 PIT CONTAINERS

Pit containers are used as a protective barrier for interim pit storage at Pantex Plant and as Type B packages for offsite shipments. The following is a discussion of the pit containers currently in use or planned for future use at Pantex Plant.

F.3.1 AL–R8 Container

These containers were developed by DOW Chemical in the late 1960's and are shown in Figure F.3.1–1. The AL–R8 container was certified as a Type B package in 1974, and was used mainly for movement of pits between Rocky Flats and Pantex Plant. In 1988, a Revised Safety Analysis Report for Packaging was issued stating that the AL–R8 container did not meet all the Federal transportation regulations. In 1991, the use of the AL–R8 for intersite shipments was discontinued. The AL–R8 is now the primary container used for pit staging at Pantex Plant. The containers have a uniform, nominal outside diameter of 51 centimeters (20 inches). All AL–R8 containers are constructed of 18-gauge carbon steel. Within an AL–R8 container, a pit is secured on a metal frame and is surrounded by Celotex (a high-density cane-fiber pressboard) insulation. The AL–R8 does not have an inner containment vessel.

F.3.2 FL-Type Container

The FL-Type container is currently the only certified container used for pit transport and shown in Figure F.3.2–1. This Type B package has a 16-gauge stainless steel outer containment drum surrounding a 12-gauge stainless steel inner containment drum. Celotex insulation is present between the inner and outer containment drums. The inner containment drum measures 35.1 centimeters (13.8 inches) in diameter and 97 centimeters (38 inches) in height. The outer containment drum measures 57.2 centimeters (22.5 inches) in diameter and 127 centimeters (50 inches) in height. Both the internal and external containment drums are constructed of stainless steel. The inner containment vessel is sealed with dual concentric silicone O-rings. DOE has only 300 of these containers. They are currently used for transporting pits from Pantex Plant to Los Alamos National Laboratory (LANL).

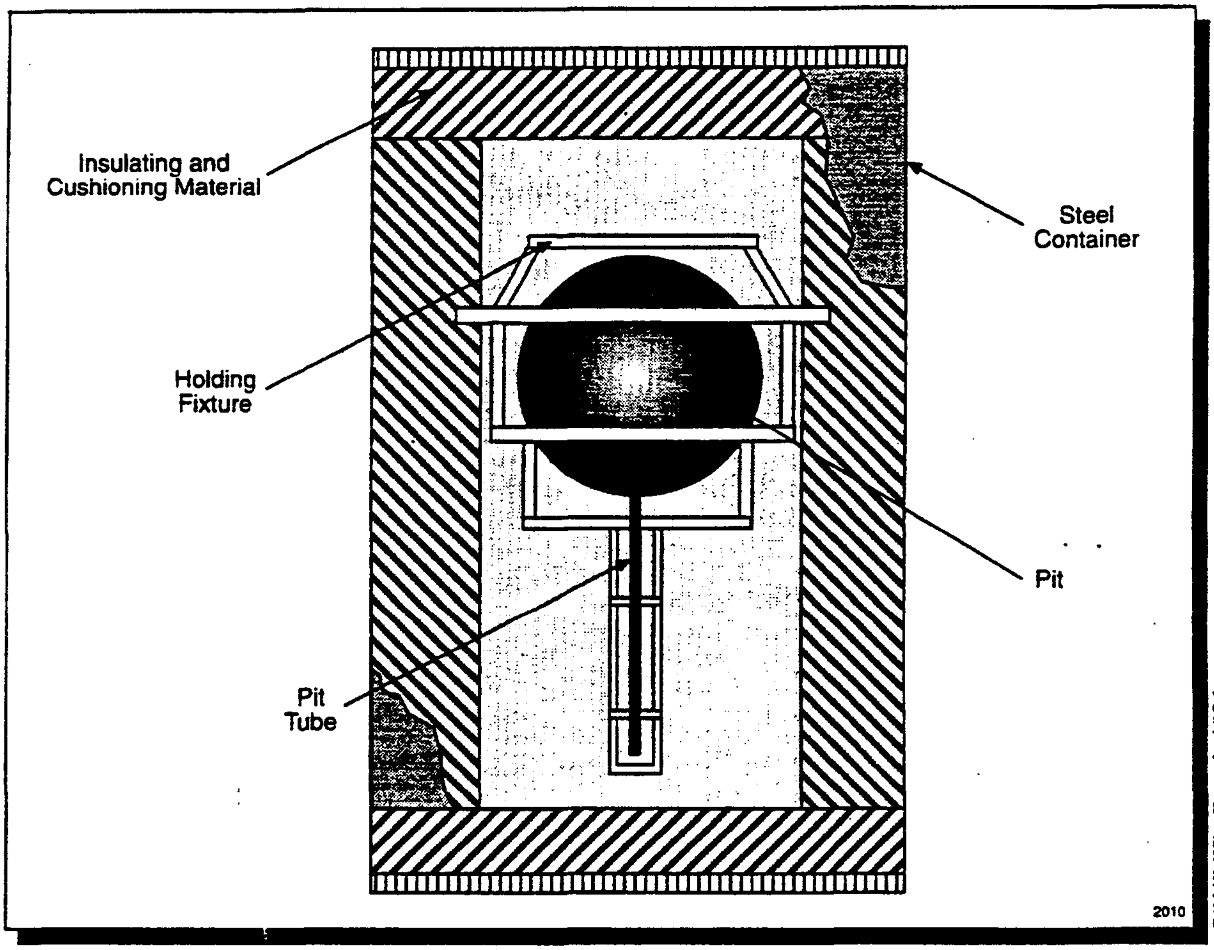

FIGURE F.3.1–1.—*Cross-Sectional View of an AL–R8 Container.*

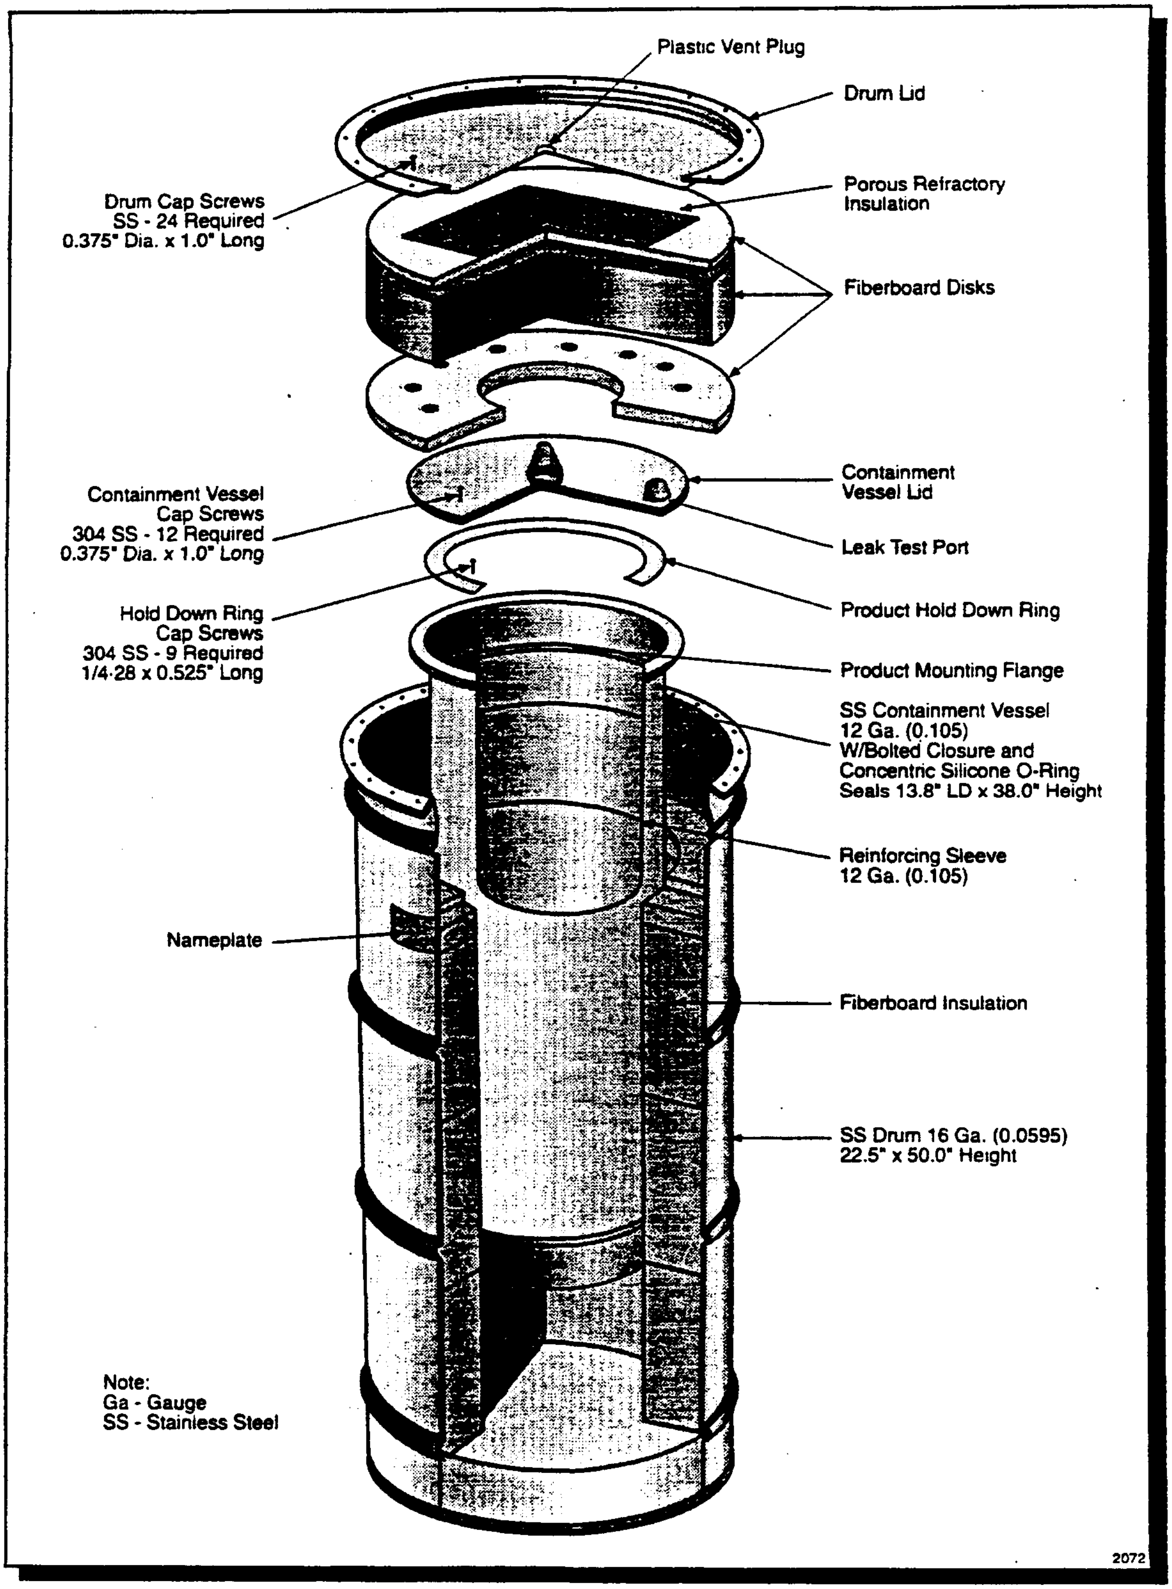

FIGURE F.3.2–1.—*Cross-Sectional View of an FL-Type Container.*

F.3.3 AT–400A Container

DOE commissioned Sandia National Laboratories, Lawrence Livermore National Laboratory, and LANL to design and build the AT–400A container. This container is expected to replace the AL–R8 for pit staging at Pantex Plant, and be the primary container for offsite shipments. The AT–400A is constructed from 304L stainless steel with a high density insulator foam liner and a welded inner containment vessel (see Figure F.3.3–1). This pit storage container is a container within a container. The pit is contained within an inner containment vessel that slightly resembles a small propane tank used for camping. The wall of the inner containment vessel is 0.635 centimeters (0.250 inches) thick, with a 34.29- centimeter (13.5-inch) inner diameter. A sampling tube exists at the top that is used to periodically sample the gas inside. The environment within the inner containment vessel is controlled and guaranteed via an inert gas backfill. The inner containment vessel sits between two foam filled inserts inside the outer container. The outer container dimensions are approximately 51 centimeters (20 inches) in diameter by 71 centimeters (28 inches) high. This containment vessel is totally fabricated from 304L stainless steel. The AT–400A is scheduled for use at Pantex Plant in late 1996. Sandia National Laboratories has tested prototypes of the AT-400A and a DOT Type B certification is pending. Initial performance testing of the AT–400A package indicates that the container can withstand a considerably more severe accident environment than the FL-type container. The inner

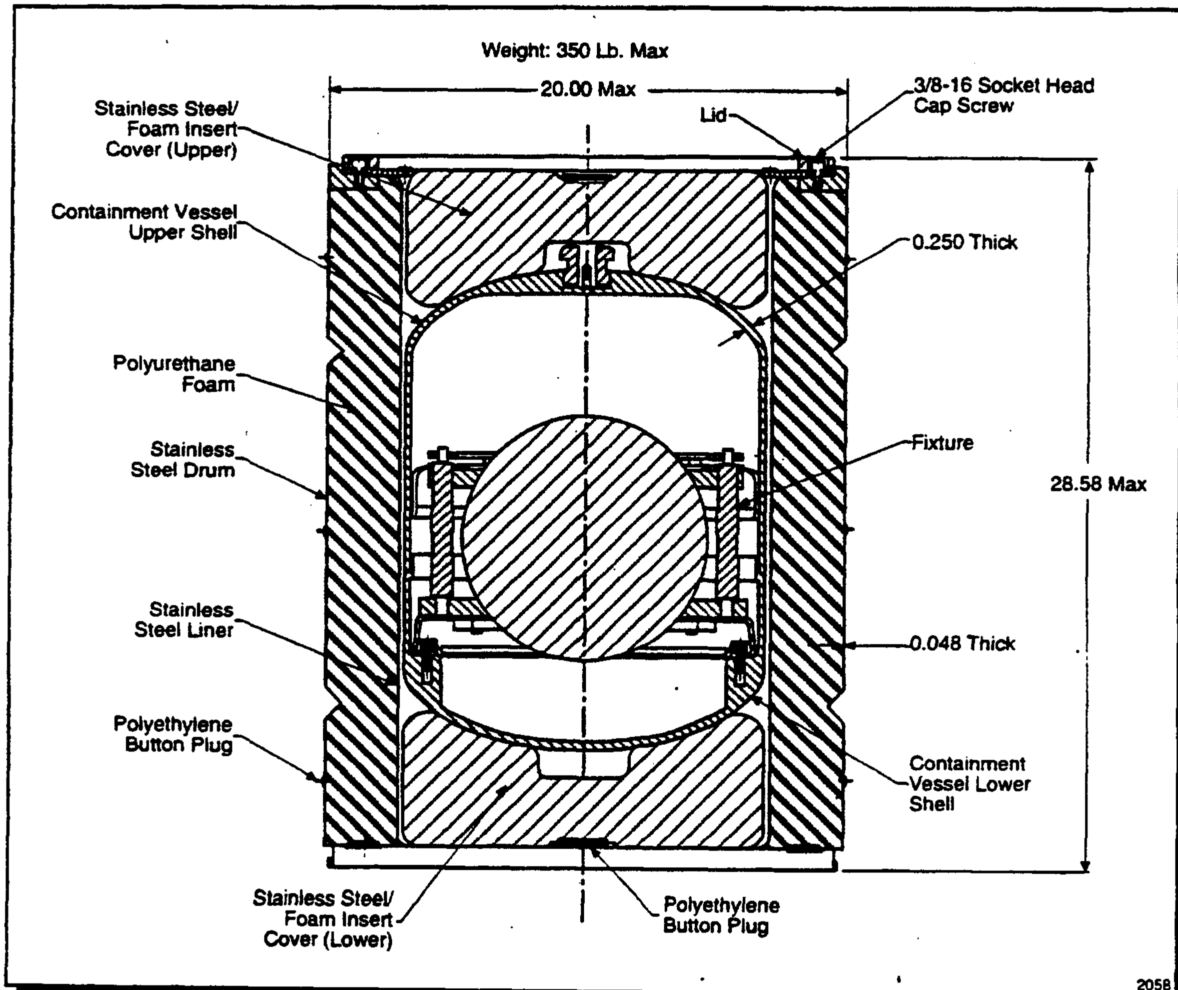

FIGURE F.3.3–1.—*Cross-Section of an AT–400A Container.*

containment vessel of the AT–400A is completely welded, which provides superior behavior in fire environments. The AT–400A container also performs significantly better than the FL container in impact, puncture, and crush environments.

F.4 TRANSPORTATION VEHICLES AND SAFETY AND SUPPORT EQUIPMENT

Vehicles used for onsite transportation include hardened trailers, flatbed trailers, Safe Secure Tractor Trailers (SSTs), forklifts, tow motors, Stage Right trailers, tractors, electric carts, and transportation carts. This section discusses the Stage Right equipment that is in use at Pantex Plant. Further information on transportation vehicles and equipment is provided in the *Safety Information Document* and the *Transportation Evaluation Report for Ross Aviation, Inc.* (Pantex 1996a; Ross 1994).

F.4.1 Stage Right Forklift

The Stage Right forklift is a technologically advanced electric forklift, specifically designed for the Stage Right project for pit storage. This forklift is larger than the other electric forklifts at Pantex Plant and is fully enclosed. The Stage Right forklift rides on a special rail system that keeps it in a straight line throughout its operation. This rail system contains a sensor system that detects the position of the forklift on the rails throughout its operation. The Stage Right forklift can perform its loading operations only when it is correctly positioned between these light sensors. The operator has a display in front of him to notify him when the forklift is in position.

The Stage Right forklift has one boom arm for lifting the Stage Right pallets. This boom arm has a unique safety feature to prevent an inadvertent puncture of a pit container. On the extreme end of the boom there exists a compression sensor that, when compressed, completely stops the action of the Stage Right forklift. The pressure of a person's outstretched arm is enough to compress the sensor and shut down the forklift. The boom has to be in exactly the correct position to fit into the Stage Right pallet boom slot. Once positioned, the Stage Right forklift can continue with its operation. The Stage Right forklift will be replaced by an automated guided vehicle when development at Pantex Plant is completed.

F.4.2 Stage Right Trailer

Pits are transferred between Zone 12 South and Zone 4 in either a double-axle, non-hardened pallet trailer or a hardened trailer. These pallet trailers are able to withstand a 2,722-kilogram (6,000-pound) load or more, and are towed by stakebed trucks. The trailer box is approximately 127 centimeters (50 inches) wide, 203 centimeters (80 inches) high, and 356 centimeters (140 inches) long. The frame of the trailer is the load-bearing structure so that the outer skin and rivets are not subject to any load other than their own weight. An emergency electric braking system is in place to stop the trailer in the event that the connection with the tow vehicle is broken. These Stage Right trailers are specifically built to hold Stage Right pallets (see Figure F.4.2–1).

F.4.3 Stage Right Pallet

Two types of these pallets exist. The first can accommodate four AL–R8 containers, and the second can hold six AL–R8 containers. In this pallet's design, the containers sit both in it and on it depending on the pallet's positioning (see Figure F.4.3–1).

A new Stage Right pallet that will be able to accommodate both the AL–R8 and AT–400A containers is in the design phase at Pantex Plant. This new pallet will be constructed of stainless steel. The Stage Right pallet that can accommodate four containers is approximately

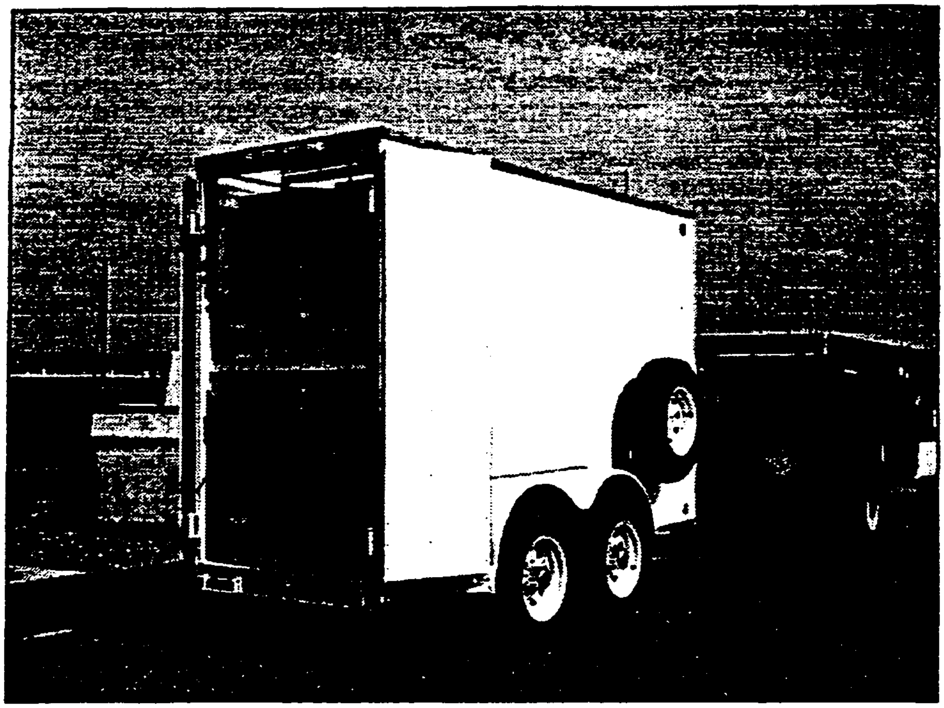

FIGURE F.4.2–1.—*Stage Right Trailer.*

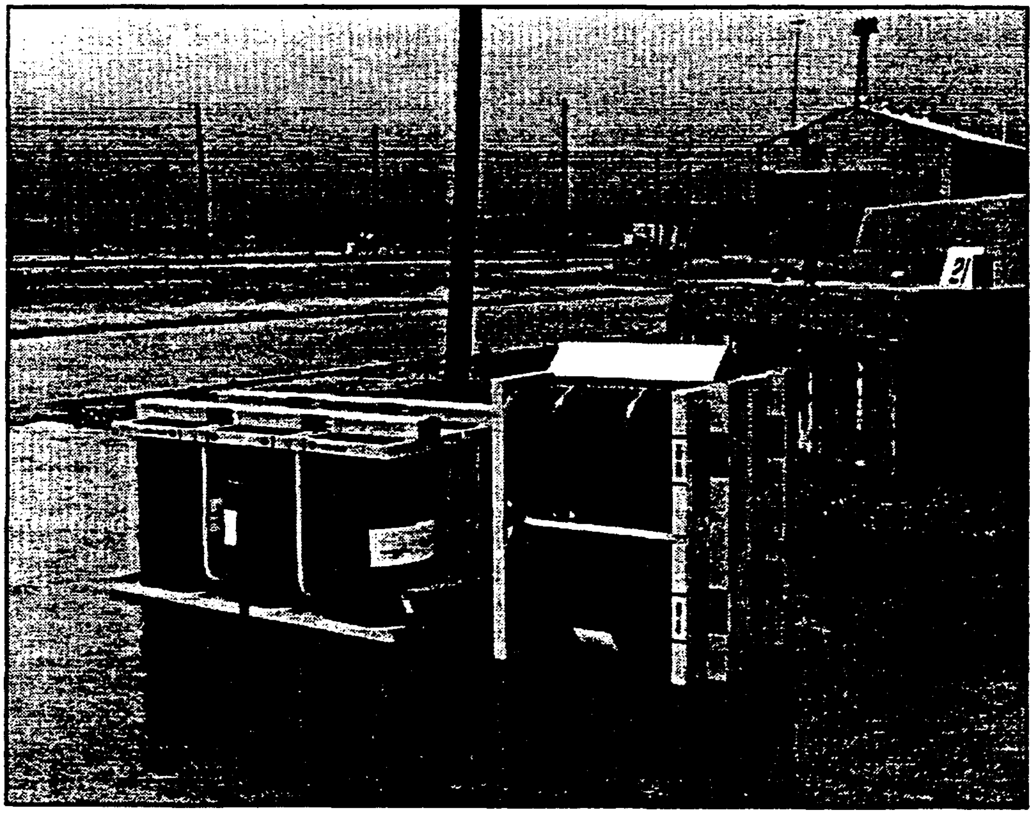

FIGURE F.4.3–1.—*Stage Right Pallet.*

104 centimeters by 99 centimeters by 74 centimeters (41 inches by 39 inches by 29 inches), and the Stage Right pallet that can accommodate six containers is approximately 155 centimeters by 99 centimeters by 74 centimeters (61 inches by 39 inches by 29 inches).

F.5 INTERSITE TRANSPORTATION IMPACT ASSESSMENTS

The Analysis of Dispersal Risk Occurring in Transportation (ADROIT) code was developed specifically for the Defense Programs Transportation Risk Analysis program and is currently being used in the development of safety analysis for DOE transportation activities. The code was designed specifically to evaluate event trees and conduct consequence assessments for SST shipments and air transport of tritium reservoirs. The code can also be used to evaluate the effect on the assessed risk of modifications to equipment or procedures (positive measures), changes in shipment campaigns, improvements in understanding of cargo, etc.
