Abstract: The statement describes two methods for permanent disposal of decommissioned, defueled reactor plants: land disposal by burial at existing Federal sites and deep sea disposal. The 'no action' alternative of long-term protective storage prior to permanent disposal at some time in the future is also discussed. Based upon the research work performed in support of this effort, and review of the public comments received, the Navy considers that permanent disposal can be conducted in an environmentally safe manner. Largely as a result of the highly uncertain regulatory status of sea disposal, the Navy considers land burial at existing Federal sites to be the preferred alternative. The 'no action' alternative would only delay the decision for permanent disposal and would result in increased costs without significantly changing the environmental impact.

FINAL ENVIRONMENTAL IMPACT STATEMENT
ON THE
DISPOSAL OF DECOMMISSIONED, DEFUELED NAVAL SUBMARINE REACTOR PLANTS

by the

United States
Department of the Navy (Lead Agency)
and
Department of Energy (Cooperating Agency)

Location of Department of Energy sites if land disposal were to be implemented:
Savannah River Plant, Aiken County and
Barnwell County, South Carolina
Hanford Site, Benton County, Franklin County,
and Grant County, Washington

The Department of Energy (DOE) is participating as a cooperating agency with regard to the land disposal option at DOE burial sites.

Abstract This statement describes two methods for permanent disposal of decommissioned, defueled reactor plants: land disposal by burial at existing Federal sites and deep sea disposal. The "no action" alternative of long-term protective storage prior to permanent disposal at some time in the future is also discussed. Based upon the research work performed in support of this effort, and review of the public comments received, the Navy considers that permanent disposal can be conducted in an environmentally safe manner. Largely as a result of the highly uncertain regulatory status of sea disposal, the Navy considers land burial at existing Federal sites to be the preferred alternative. The "no action" alternative would only delay the decision for permanent disposal and would result in increased costs without significantly changing the environmental impact.

FOREWORD

This Final Environmental Impact Statement (EIS) is issued by the U.S. Department of the Navy, Environmental Protection, Occupational Safety and Health Division (OP-45) in accordance with the Navy Manual, OPNAV Instruction 6240.3E, which implements the requirements of the National Environmental Policy Act of 1969 (NEPA). The format used in this statement is that recommended by the Council on Environmental Quality (CEQ), as published in the Code of Federal Regulations, 40CFR1502.10.

Prior to a major federal action that might significantly affect the quality of the human environment, the National Environmental Policy Act requires the preparation of a detailed statement on:

(i) the environmental impact of the proposed action,

(ii) any adverse environmental effects which cannot be avoided should the proposal be implemented,

(iii) alternatives to the proposed action,

(iv) the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity, and

(v) any irreversible and irretrievable commitments of resources which would be involved in the proposed action should it be implemented.

Pursuant to OPNAV Instruction 6240.3E, it was determined that a detailed statement on the foregoing considerations with respect to the disposal of decommissioned, defueled reactor plants should be prepared. A Notice of Intent to prepare an EIS was published in the Federal Register on January 14, 1982 (47FR2151). Input on the scope of the EIS was solicited from the public, interested organizations, States, and Federal agencies.

The Draft Environmental Impact Statement was published on December 22, 1982 and widely circulated. Over 1500 copies of the statement were distributed to individuals, environmental organizations, State and local officials, and other Federal agencies. Over six months were allowed for interested parties to comment on the Draft EIS. Over 500 letters were received providing comments.

The Navy held four public hearings in different parts of the country at which over 150 persons testified.

All substantive comments received by the Navy were analyzed and are addressed in the final statement. Volume 1 of the final statement is similar to the draft statement. Where changes have been made to the draft statement, the outer margins of Volume 1 are marked by vertical lines. Typographical changes and minor clarifications of the text are not marked.

Given the comprehensive technical work which has gone into preparing the statement, and the extensive public input which has been received, the Navy considers that there is an adequate basis upon which to make a decision as to how to proceed.

The U.S. Department of Energy (DOE) is a cooperating agency in the preparation of this statement in accordance with the CEQ regulations (40CFR1501). By participating as a cooperating agency, DOE obligations under NEPA will be fulfilled and no separate DOE EIS will be required with regard to the land disposal option at DOE burial sites.

SUMMARY

INTRODUCTION

This Final Environmental Impact Statement describes the alternate ways the Department of the Navy and the Department of Energy (DOE) have considered for disposing of nuclear-powered submarines after they are no longer useful. The practical choices are: (1) bury the submarine reactor compartment at an existing DOE land disposal site at the Hanford Site in the state of Washington, or at the Savannah River Plant in South Carolina, and dispose of the non-radioactive remainder of the submarine either by sinking at sea or by cutting up for sale as scrap metal, (2) place the entire submarine on the bottom of the ocean in deep water (deeper than 2.5 miles), far from the United States coast, or (3) keep the submarine in protective storage at a Navy inactive ship facility after decommissioning for disposal on land or at sea at a later time.

In all of these choices there would be no radioactive nuclear fuel left in the submarine. All the radioactive nuclear fuel would be removed before disposal. Nevertheless, there would be some low level radioactive materials left within the submarine. Therefore, this Final Environmental Impact Statement concerns disposal of the rest of the submarine after all the radioactive nuclear fuel has been removed.

On December 22, 1982, the Navy published its Draft Environmental Impact Statement on the disposal of decommissioned, defueled Naval submarine reactor plants. The Navy's intent since the outset of this Environmental Impact Statement process has been to identify and fully evaluate the reasonable alternatives so that an informed decision could be made on which approach to pursue. The Navy's Draft Environmental Impact Statement was widely circulated and a large number of public comments were received. Over 1500 copies of the statement were distributed to individuals, environmental organizations, State and local officials, and other Federal Agencies. Over six months were allowed for interested parties to comment on the Navy Draft Environmental Impact Statement. Over 500 letters were received providing comments. The Navy held four public hearings in different parts of the country at which over 150 people testified. All substantive comments received by the Navy were analyzed and are addressed in the final statement. Given the comprehensive technical work which has gone into preparing the statement, and the extensive public input which has been received, the Navy considers that there is an adequate basis upon which to make a decision as to how to proceed.

BACKGROUND

The Navy has about 120 nuclear-powered submarines now in operation. Approximately 100 of these submarines may be taken out of service in the next 20 to 30 years. Seven submarines have already been taken out of service and placed into protective storage.

A submarine is constructed with the nuclear power plant inside a single section of the ship called the reactor compartment. Figure 1 shows a typical submarine with the location of the reactor compartment identified. Figure 2 is a simplified picture of the nuclear power plant inside the reactor compartment. The components of the nuclear power plant include a high-strength steel container called the reactor pressure vessel, a heat exchanger (steam generator), and associated piping, pumps, and valves.

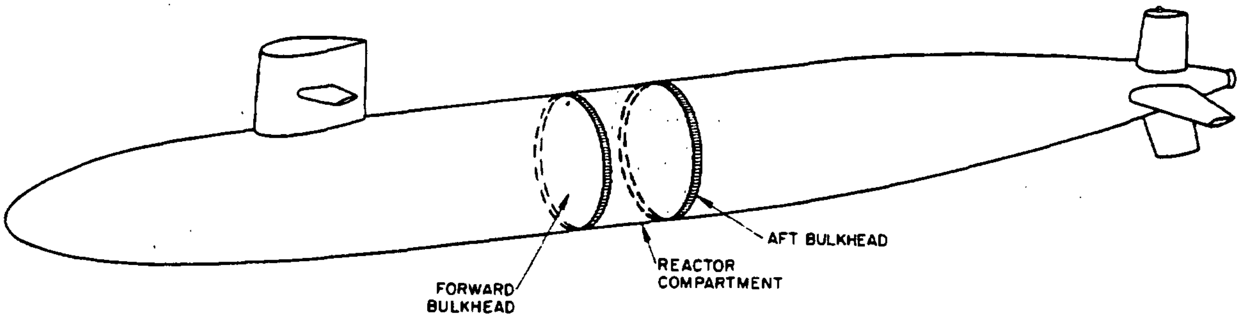

Figure 1. Typical Submarine with Reactor Compartment Identified

SCHEMATIC OF NUCLEAR PROPULSION PLANT

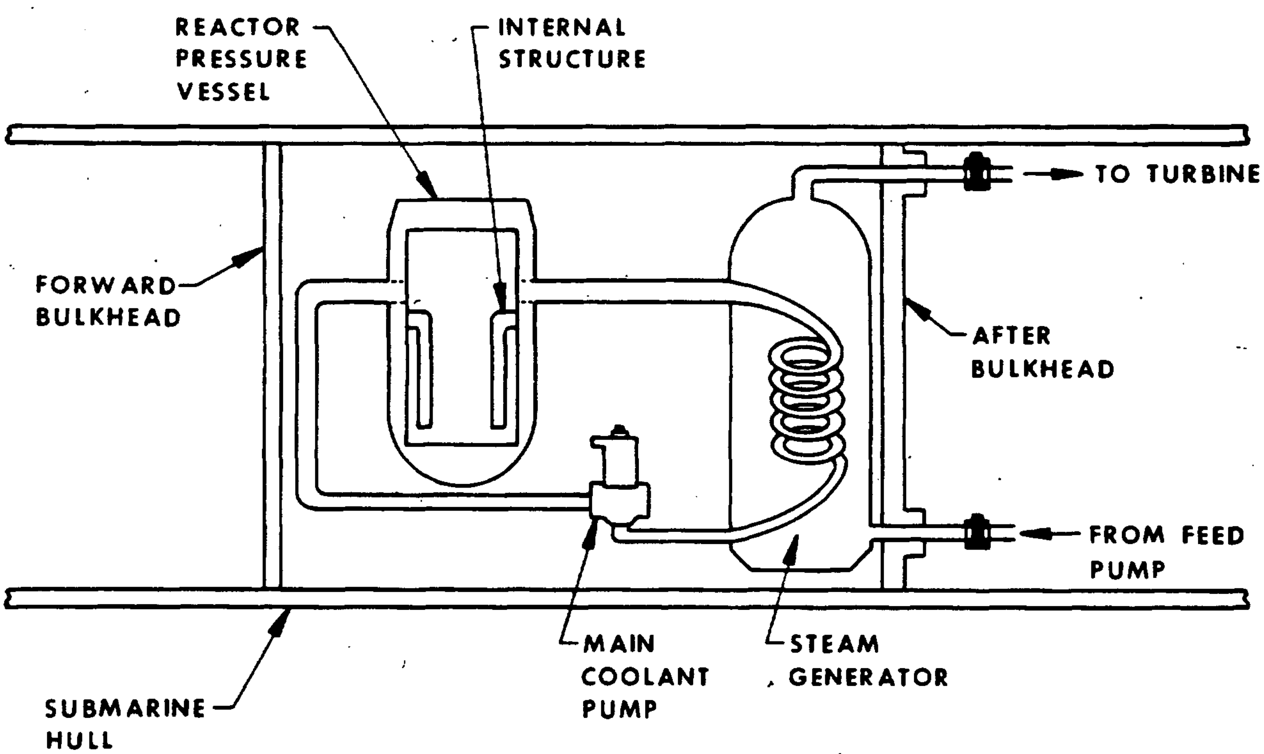

Figure 2. Nuclear Power Plant

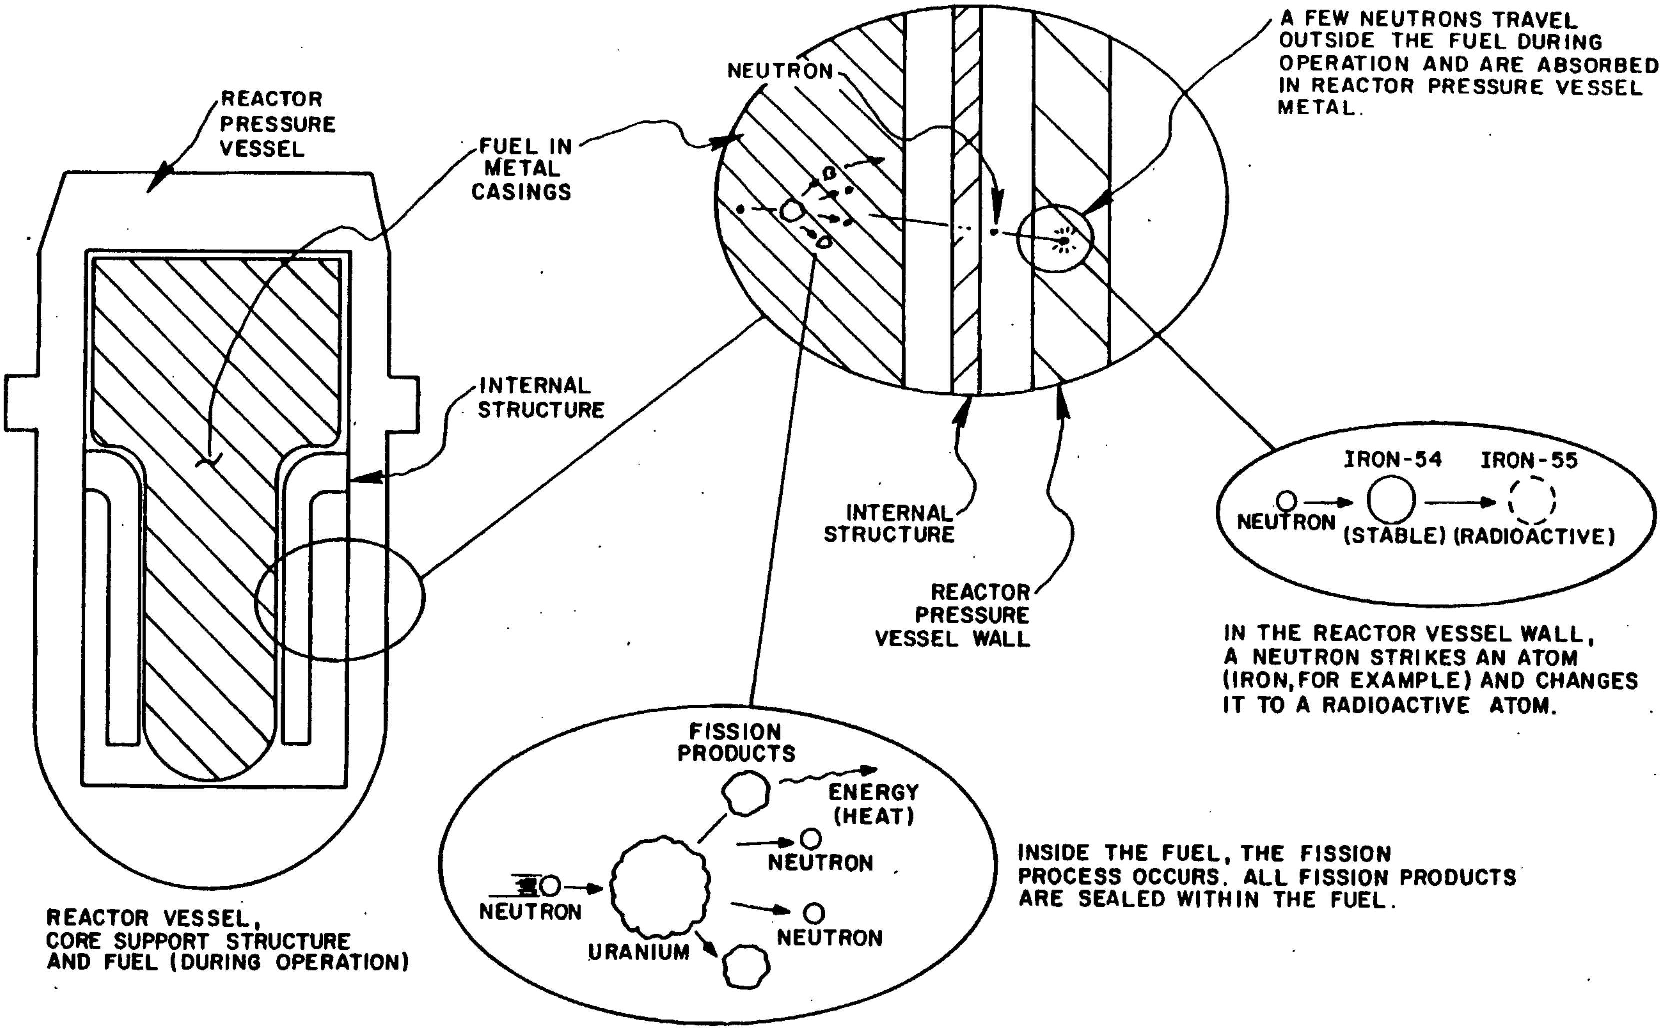
A brief description of the way energy is produced in a submarine's nuclear reactor will help to understand how the radioactivity in a submarine is generated. The fuel in a submarine reactor contains uranium atoms sealed within a metal casing. Uranium is one of the few materials capable of producing heat in a self-sustaining chain reaction. When a neutron causes fission in uranium, the nucleus splits into two parts called fission products (Figure 3). When formed, the fission products initially move apart at very high speeds, but they do not travel very far, only a few thousandths of an inch, before they are stopped within the fuel casing. Most of the heat produced in the fission process comes from stopping these fission products within the fuel and converting their kinetic energy into heat.

Nuclear fission creates highly radioactive fission products. Most of the radioactivity produced by nuclear fuel is in the fission products, which do not get outside the fuel casings. The uranium fuel is sealed within metal casings to prevent release of the fission products.

Fissioning of uranium also produces neutrons, as shown in Figure 3, while the nuclear power plant is operating. Most of the neutrons produced are absorbed by the atoms within the fuel casings and continue the chain reaction. However, some of the neutrons travel away from the fuel, go outside the fuel casings, and are captured in the metal structure or in the walls of the pressure vessel itself. The metal structure supports the fuel inside the reactor pressure vessel (Figure 3). These neutrons, when absorbed in the nucleus of a nonradioactive atom like iron, can produce a radioactive atom. For example, Iron-54 contains a total of 54 particles (neutrons and protons). Adding an additional neutron produces an atom containing 55 particles, called "Iron-55." This atom is radioactive. At some later time, it changes into a nonradioactive Manganese-55 atom by releasing energy in the form of radiation (Figure 4). This process is called radioactive decay.

Before a ship is taken out of service, the fuel is removed from the reactor pressure vessel of the submarine in a process called defueling (Figure 5). This defueling removes all of the uranium and all of the fission products. The removed fuel is shipped by the Department of Energy from the refueling shipyard to its facilities in Idaho. The shipment is performed under requirements of the Department of Transportation, the Nuclear Regulatory Commission, and the Department of Energy. The fuel is processed in the same manner as other expended nuclear fuel. It is not discussed in this statement because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

However, even after defueling, the radioactive atoms which were formed in the metal structure and the reactor pressure vessel will remain in the submarine. These atoms are an inseparable part of the metal and they are chemically just like the rest of the iron, nickel, or other metal atoms in the reactor plant. These radioactive atoms can only be released from the metal as a result of the slow process of corrosion, such as the rusting of common iron or steel (Figure 6). For each radioactive atom that would be released in this process, at least 1000 stable atoms of the same element would be released. This natural dilution effect can be important in limiting the intake of radioactive atoms by animals and man, because biological systems cannot discriminate between radioactive and stable atoms that have the same chemical form.



ACTIVATION

Figure 3. Neutrons and Fission Products from Uranium Fission

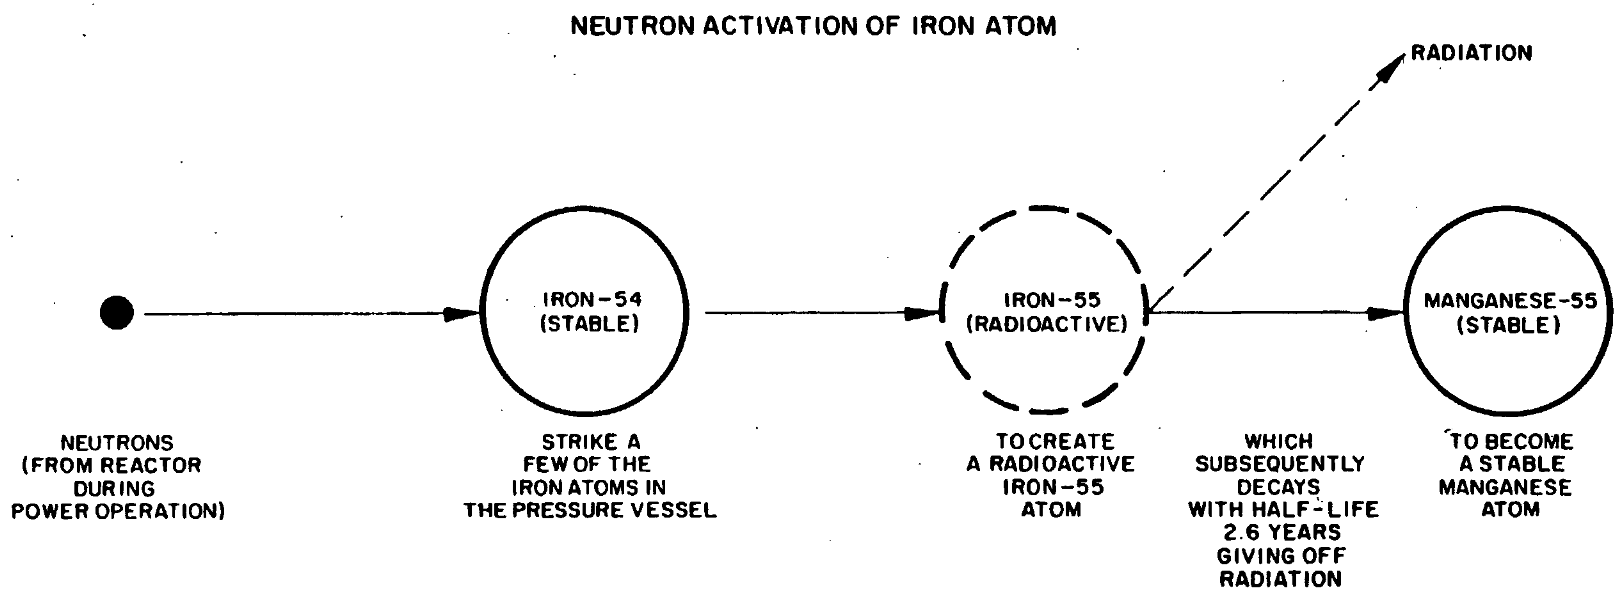


Figure 4. Capture of Neutrons in Iron of Pressure Vessel Wall

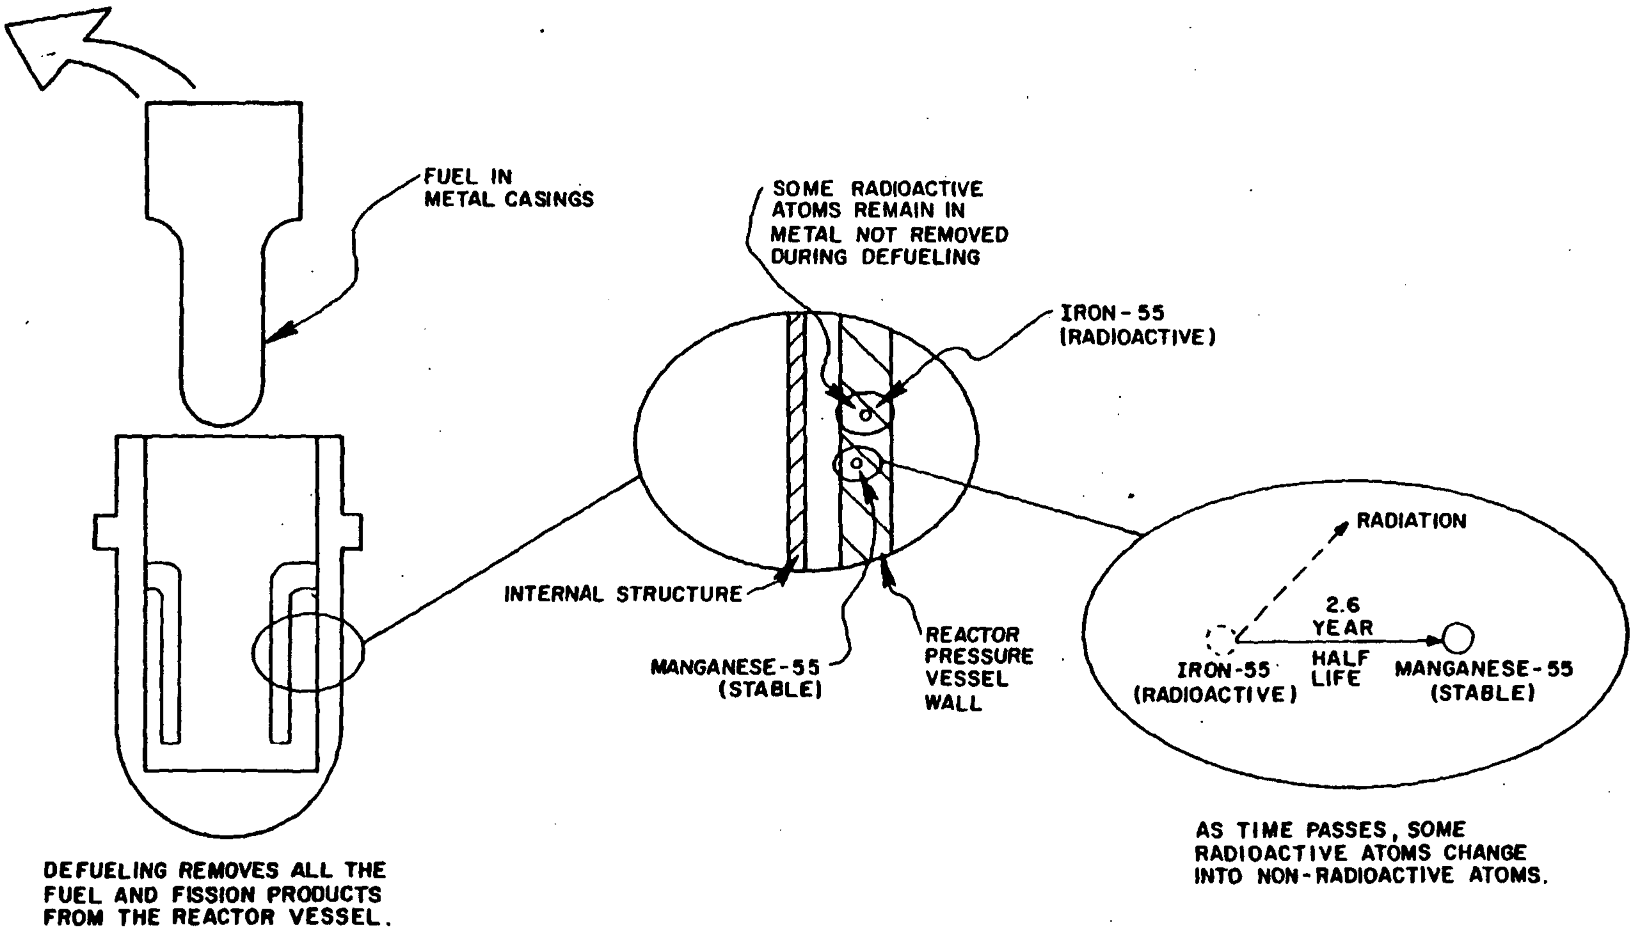

Figure 5. Activity in Pre re Vessel Wall After Defueling

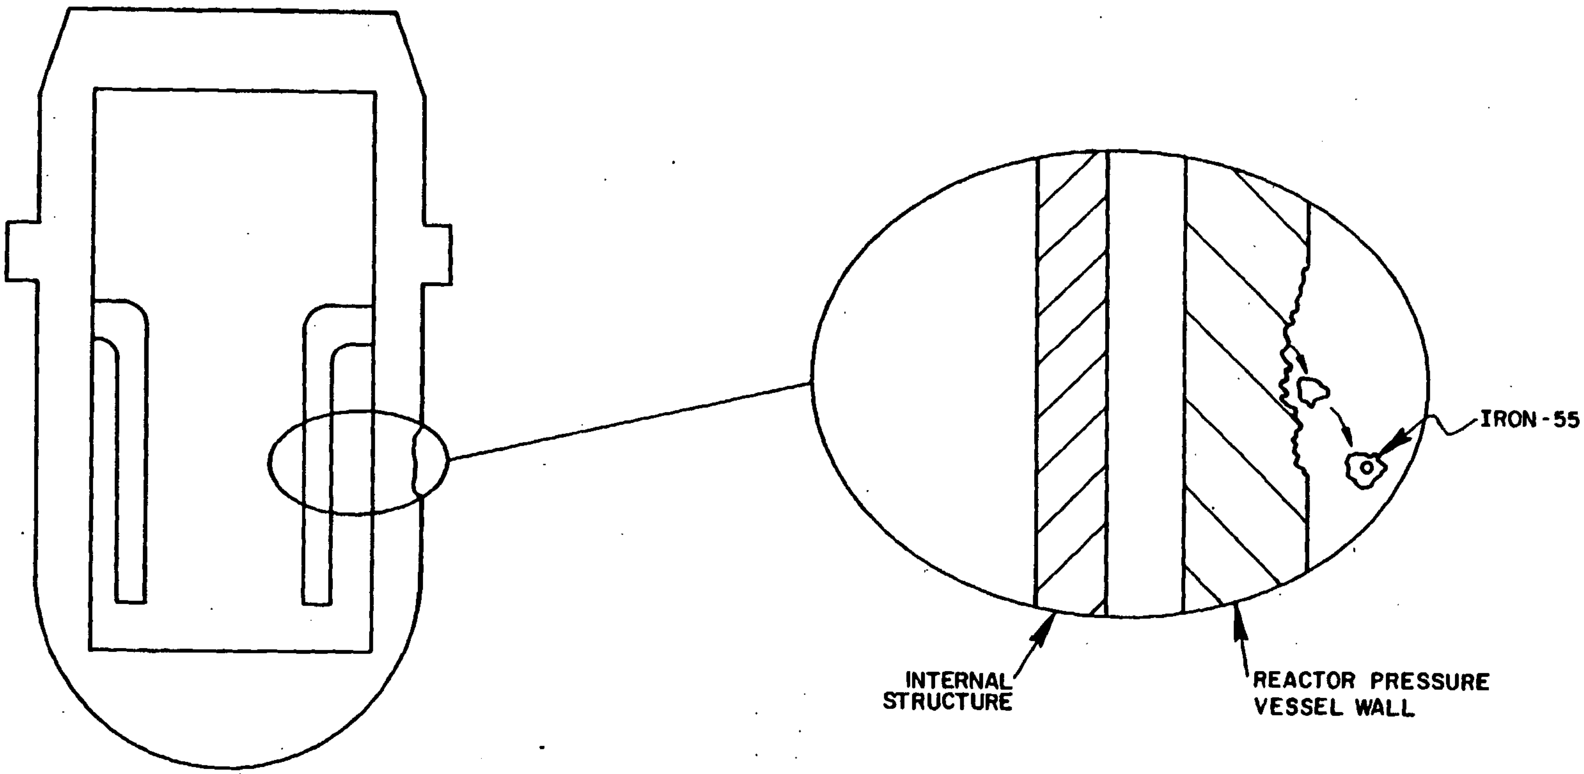

AFTER DISPOSAL, THE VESSEL WALLS BEGIN TO CORRODE OR RUST

.... AND SOME RADIOACTIVE ATOMS THAT HAVE NOT YET CHANGED TO NON-RADIOACTIVE ATOMS ENTER THE ENVIRONMENT AS PART OF RUST FLAKES.

Figure 6. Rusting of Steel in Pressure Vessel Wall

Prior to disposal, both the reactor pressure vessel and the reactor compartment would be sealed. Thus, they would act as a container for the radioactive atoms and delay the time any of the radioactive atoms inside would be released to the environment as the metal corrodes or rusts. This is important because radioactivity "decays" away with time—which means that as time goes on, radioactive atoms change into nonradioactive atoms. Since radioactivity decays away with time, the effect of a delay is that fewer radioactive atoms would be released to the environment.

ALTERNATIVES

A submarine would not be assigned for disposal by the Navy unless and until an evaluation had shown that no future Naval use could exist for it. After a decision has been made that a submarine no longer has sufficient military value to justify maintaining it, it can be placed in protective storage for an extended period followed by permanent disposal or it can be permanently disposed of right away with a minimum of delay.

Nuclear submarines can be placed into storage for a long time without risk to the environment. About every 20 years, each ship would have to be taken out of the water for an inspection and repainting to assure continued storage. However, this protective storage does not provide a permanent solution. Eventually, permanent disposal would be required.

The alternative to long-term protective storage is to permanently dispose of the defueled, decommissioned submarine. Permanent disposal can be accomplished by burying the sealed reactor compartment in the ground at an existing land disposal site owned by the federal government, or by sinking the entire submarine in the deep ocean in accordance with international procedures. In each case, the best way to permanently dispose of the parts of the submarine that are still radioactive (after the nuclear fuel has been removed) would be to leave them installed in the reactor compartment. This is because the work needed to remove these parts would result in unnecessary radiation exposure to shipyard personnel. Also, the sealed reactor compartment provides a good container for permanent disposal.

LAND DISPOSAL

In the land disposal option, the reactor compartments would be buried at a Federal government (DOE) owned disposal site located either at the Hanford Site in the state of Washington or the Savannah River Plant located in South Carolina. These sites are already being used for disposal of low level radioactive waste. The disposal of the reactor compartments would be consistent with current practice at these sites. The size of the package to be buried would be larger than current practice. Total space requirements for the burial of 100 reactor compartments would be approximately 10 acres.

Other government owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration. The others were either not close enough to navigable waterways or the groundwater at these locations was too near the soil surface. Therefore, if the land disposal option were to be selected, the only practical sites in which to bury the compartments would be at Hanford in the state of Washington or the Savannah River Plant in the state of South Carolina.

The preparation of the reactor compartment for transportation to the disposal site and land burial would utilize techniques already proven and equipment already available. With the ship in dry dock, the reactor compartment would be cut free from the remainder of the submarine. Then the openings into the reactor compartment would be welded shut. The reactor compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. A transporter (Figure 7) would then haul the reactor compartment overland to the burial location. It would be buried in accordance with existing requirements for burial of low level radioactive wastes. Non-radioactive portions of the submarine could be disposed of either by sinking at sea or cutting up for sale as scrap metal.

The Hanford Site is a large federal government site, operated by the U.S. Department of Energy, occupying 570 square miles (365,000 acres) in eastern Washington. The burial ground has over 1000 acres designated for low level waste disposal in the middle of the site on a plateau, about 7 miles from the Columbia River. A Final Environmental Impact Statement on Waste Management Operations at Hanford has been issued. The National Research Council study in 1976 concluded that no measurable harm to human health has resulted from past and present waste disposal practices.

The Savannah River Plant is located in South Carolina, approximately 25 miles southeast of Augusta, Georgia. The plant is a large site, occupying 300 square miles (192,000 acres). The burial ground comprises approximately 195 acres near the center of the site which is located about 7 miles from the Savannah River. A Final Environmental Impact Statement has also been issued for the waste management operations on this site. The National Research Council study in 1976 concluded that no measurable harm to human health has resulted from past and present practices.

There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial, or after burial. This is because radiation outside the reactor compartment would be well below federal limits and the reactor compartment would have been welded shut at the shipyard to prevent entry. Even if the reactor compartment were somehow unearthed after burial, there would be little or no risk. The thickness of the submarine hull and reactor compartment bulkheads would prevent inadvertent entry. As time passes, the radioactivity "decays" away as the radioactive atoms change into nonradioactive atoms. After about 100 years, this radioactive decay would essentially eliminate external exposure to radiation even if someone were to enter the compartment.

In addition to the possibility of external exposure to radioactive material, there can also be a risk to people if the material enters the body through inhalation or ingestion. Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the body. In considering this potential risk, it is important to note that at least 200 years would pass before the reactor compartment bulkhead would be penetrated by corrosion (rust). Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for an additional long period, probably exceeding several thousand years. Corrosion or rusting of the metal inside the reactor vessel could then slowly release the remaining radioactive atoms.

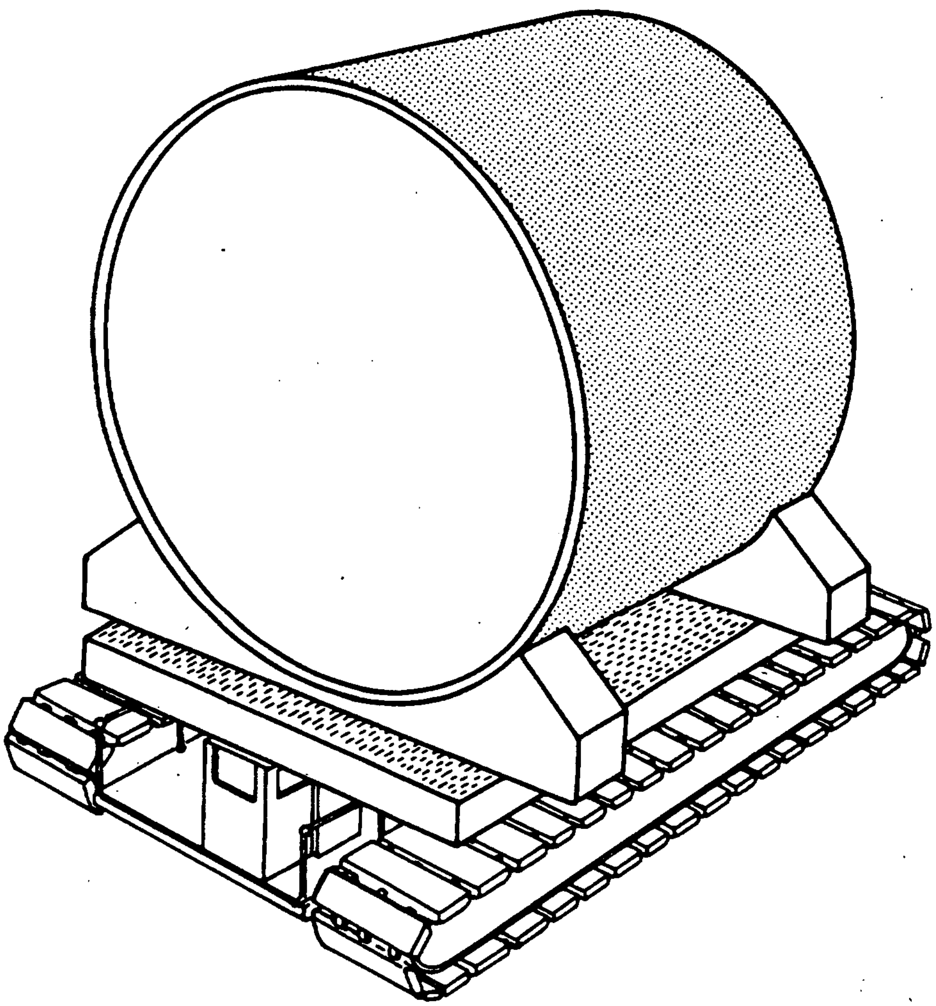

Figure 7. Concept for Land Transporter Movement of Reactor Compartment

An estimate of the amount of radioactive material which might enter the ground at the burial location has been developed. To make this estimate, it was assumed that the ground area would be continuously wet to provide conditions which would promote the most rapid corrosion. It was also assumed that a path was available to carry any radioactive atoms which corroded off the metal into a source of drinking and irrigation water. This is a conservative method to estimate the impact of the radioactivity released at the land disposal site. The result of this calculation showed that even if all 100 reactor compartments were buried at the same disposal site, an average individual living downstream of the burial ground would receive only 0.006 millirem per year of exposure. This is less than one ten-thousandth of the radiation exposure one normally receives from natural background radiation.

Natural background radiation is what all people receive every day from the sun or from cosmic radiation, and from the natural radioactive materials that are present in our surroundings, including the rocks or soil we walk on. The amount of radiation exposure a typical person in the United States receives each year from natural background radiation is 100 millirems. The amount of radiation that a person near the site would receive from land disposal of 100 submarines (0.006 millirem) would therefore be much less than he would receive from natural background radiation. An estimate has also been made for a "worst case" situation using the assumption that in the distant future a person might live and farm right at the disposal site. Even in this extreme case, this person would receive a whole body exposure not more than about 13 millirems per year of exposure.

A perspective on radiation exposure can be obtained by comparing the exposure a person would receive from natural cosmic background radiation if he lived in Denver, Colorado, instead of in New York City (near sea level). The exposure of the person in Denver would be approximately 20 millirems more every year than that of the person in New York. Because Denver is at a higher elevation than New York City, there is more cosmic radiation in the natural background in Denver.

OCEAN DISPOSAL

Locations for possible ocean disposal have not been selected. Locations are described in this statement but these are only study areas chosen to measure currents, biological activity, and other characteristics which are required in estimating the potential effects of ocean disposal. Study areas have been identified in the Atlantic and Pacific Oceans. These areas are typical of any that might be chosen under existing international rules for ocean disposal.

These study areas were selected based on criteria developed by oceanographic experts. The general approach was (1) to avoid areas which produce large amounts of seafood or which are the sources of food for seafood; (2) to avoid areas which are currently used by man for any purpose; and (3) to avoid areas which have potential for future use, such as oil or ocean mining locations. It was also desired to stay within 200 nautical miles of the coast of the United States, since this is the zone of economic control as established in concept under the United Nations Law of the Sea Convention. These criteria led to the examination of areas where very deep water exists and which are beyond the continental shelves. These areas are cold, dark, and tranquil with a sparse population of organisms.

The two Atlantic study areas are situated east of Cape Hatteras, North Carolina, about 200 nautical miles from the closest land point. The depth of the water in each area is between 13,000 and 16,000 feet (2.5 to 3 miles). The Pacific study area is centered approximately 160 nautical miles west of Cape Mendocino, California. The water in this area is between 14,000 and 15,000 feet deep (about 2.7 miles).

The animal life on or near the sea floor in these study areas is very sparse. None of the animals are used by man or form part of a food chain known to lead to man. No commercially exploited minerals are present on the sea floor. There are no plants because sunlight does not reach these depths. Bottom water current measurements indicate that the water movement is slow.

Preparations for ocean disposal would be made at one of the shipyards normally servicing nuclear-powered naval vessels. The reactor vessel would be sealed following defueling, and the reactor compartment would be sealed.

The submarine would be towed to the disposal location and sunk in a controlled flooding operation. When the submarine comes to rest on the ocean bottom, it would be intact. The additional containment of radioactive material provided by the intact reactor compartment is not crucial to the safety of the sea disposal option. This is because almost all of the radioactive material is also contained within the thick pressure vessel and is an integral part of the metal components.

Over a period of time, radioactive material would be released as the submarine slowly rusts away. Since the radioactive atoms inside the sealed reactor vessel are in turn inside the sealed reactor compartment, many years would elapse before these atoms are released to the water. Because of this delay, most of the radioactive atoms within the metal would have changed to nonradioactive atoms before corrosion could free them from the metal.

The nonradiological effects of disposal of these submarines would be similar to those associated with the sinking of surplus ships that are not nuclear powered. The disposal sites for nuclear submarines would be even deeper and more remote from land than sites used for surplus ships.

To evaluate the radiological effects, it was assumed that 100 submarines were sunk at a single location at a rate of three ships per year. These ships were then assumed to corrode and release radioactive materials to the ocean. The transport of radioactive material through the oceans included the effects of ocean currents, eddies, and water temperature and density variations, mixing in the water layers nearest the bottom, settling out of particles through the water column, etc.

The possible radiation exposure to members of the general public was calculated using realistic assumptions. The calculation was then repeated using very conservative assumptions; for example, that all the rusted particles were carried off by the water and none of them settled to the bottom.

The calculation using realistic assumptions gave a result of 0.000000000006 millirem per year of exposure to the typical affected person. For example, this person is assumed to eat all of his seafood from ocean fish caught at the fishing ground nearest the disposal site. This radiation exposure is approximately 0.06 trillionth of the average annual exposure to background radiation. The calculation using the very conservative assumptions gave a result of 0.0002 millirem per year of exposure, or approximately 2 millionths of normal exposure to background radiation.

To provide a "worst case" calculation, it was assumed that at some time in the future a person might eat a very large amount of seafood (145 pounds a year) all of which had somehow been caught right at the deep ocean disposal site. Even with this hypothetical shortcut of the food chain, this person would receive a whole body exposure of only 2 millirems per year of exposure. This is not considered to be an actual consequence of sea disposal but has been included to show that even a hypothetical short cut in the food chain would not result in significant exposure to any individual.

Exposure to individuals of other nations would be less than the exposures for persons living in the United States because the shortest distances to the location of people or fishing areas have been used in the calculations and the important exposure pathways have been included.

Although there is no technical basis for expecting that retrieval or further containment of an ocean-disposed submarine would ever become necessary, methods for doing so have been examined and found to be technically feasible. They are described in Appendix M.

PROTECTIVE STORAGE FOLLOWED BY LAND OR SEA DISPOSAL

If the submarine were kept in protective storage for years, this would delay the time at which a decision needs to be made between land burial or ocean disposal. However, protective storage is not a permanent solution. The submarine would eventually deteriorate at the floating storage site.

The potential radiation exposure to members of the public would not be significantly changed by protective storage—even if disposal were delayed for several decades. Ultimately the submarine must be disposed of by land burial or by sinking in the deep ocean. Whether the submarine is placed in protective storage or disposed of immediately, the containment provided by the hull and reactor compartment bulkheads would prevent the release of radioactivity until most of the radionuclides have decayed to stable atoms. Thus there would be no significant difference in the radiological exposure to the public.

COMPARISON OF DISPOSAL METHODS

The potential impacts on the environment from the permanent disposal of nuclear-powered submarines have been examined for each option. These impacts include the use of resources such as land or materials, the impact on animals or the ecology, the radiological effects on the general public or on shipyard workers, and the relative costs.

Permanent disposal by land burial requires considerably less space than ocean disposal. About 0.02 square mile (10 acres) would be required for land burial of 100 reactor compartments while ocean disposal of 100 submarines would require as much as 100 square miles. The larger area for ocean disposal assures that no submarine would fall on another already placed on the bottom. Additional area would be required for protective storage at a naval facility if permanent disposal were delayed, but this resource commitment would not be permanent.

One other resource commitment would be the loss of the metal in the submarine or part of it which is disposed. In ocean disposal as much as approximately 4000 tons of metal would be placed into the ocean for each submarine. In land disposal, one option would be to bury the approximately 1000 tons of the reactor compartment metal and salvage the rest of the metal. However, as seen later, it costs more to salvage the remaining 3000 tons of metal than the metal is worth as scrap. Thus, in the other option for land disposal, the remaining 3000 tons would be disposed of by sinking in the ocean while the reactor compartment would be buried on land.

The impacts on animals or the ecology would be small for either land or sea disposal. In land disposal, it is not likely there would be any effect on animals. In ocean disposal, it might be expected that the distribution of life in the localized area would be altered by sea life seeking shelter near the hull.

Preparations for either land or sea disposal would cause some amounts of noise and smoke or fumes from cutting or welding operations at the shipyards. However, this would be indistinguishable from other work at the shipyards.

The radiological exposures were reviewed above and are summarized in Table 1. These are listed for the year in which the largest impact on man would occur. This time would not occur until after 100 submarines had been disposed of and significant corrosion (rusting) had taken place. Even for this situation, however, it is seen that the radiological exposure is small and would have little impact on individuals or the population.

TABLE 1. RADIATION EXPOSURE OF A PERSON DURING YEAR OF LARGEST IMPACT

Option	Exposure
Land Disposal — 100 Reactor Compartments	0.006 millirem (conservative estimate)
Sea Disposal — 100 Submarines	0.0002 millirem (conservative estimate)
For Comparison	
One round trip airline flight Los Angeles to New York	1.9 millirem

An additional perspective on these very small exposures is obtained by comparing them to the radiation exposure received by an individual during a single round trip flight from Los Angeles to New York. During such a flight, a person receives more radiation from cosmic sources since he is at higher elevations where the atmosphere is less dense. Regardless of the option chosen, the potential exposure from the disposal of 100 reactor compartments at one location would be significantly less than one round trip flight.

Another viewpoint on the radiological impact can be made by comparing possible health effects due to the low level radiation from land or sea disposal with the possible health effects due to radiation received while watching television at home. Using an average exposure rate of 0.5 mrem per year to the gonads due to television viewing (NCRP Report #56, 1977) and a health effect correlation of one additional cancer case per 2200 man rem of exposure (Reference 4.15 of Chapter 4), an average of 0.023 additional cancer incidents can be expected each year, per one hundred thousand people who view television. Table 2 shows the comparison between the health effects of television viewing vs. land or sea disposal. As seen in Table 2, the potential health effects from either land or sea disposal of 100 submarines would be much less than the health effects caused by viewing television. Certainly the health effects from viewing television are not significant when compared to the approximately 300 cases of cancer per one hundred thousand people caused each year by other effects.

TABLE 2. COMPARISON OF HEALTH EFFECTS— YEAR OF LARGEST IMPACT

100 Submarine Reactor Compartments	Health Effects Per One Hundred Thousand People
Land Disposal	0.0003 (conservative estimate)
Sea Disposal	0.000009 (conservative estimate)
For Comparison	
Average television viewing for a year	0.023
Cancer cases normally experienced in a year	300

Based on these comparisons, either land or sea disposal of nuclear submarine reactor plants would have no significant radiological effect on man. Although small radiation exposures to the public have been conservatively estimated for both of the disposal options, the actual exposure to the public from either option would probably be zero.

Another impact which was considered is the occupational radiation exposure that would be received primarily by shipyard and Navy personnel. Individual exposure or total group exposure would be larger than the exposure of the general public but would be well within occupational limits for such work. Without protective storage, either land or sea disposal would result in a total occupational exposure of less than 18 man-rem per disposal. With protective storage, an additional total occupational exposure of approximately 3 man-rem would be received by these workers. In all cases, the occupational exposure for any individual worker would be consistent with other shipyard work.

Cost estimates have been prepared for the various cases and are listed in Table 3. Comparing the two land disposal options, it is seen that it would cost about $6 million more per submarine to salvage the remainder of the submarine after burying the reactor compartment than to sink the remainder. This is because it would cost much more to prepare the ship for salvage than would be recovered in salvage value (about $0.3 million) after the reactor compartment was removed.

TABLE 3. ESTIMATED COST TO DISPOSE OF ONE SUBMARINE (1981 Dollars)

	Bury Reactor Compartment and Salvage Remainder of Submarine	Bury Reactor Compartment and Sink Remainder of Submarine at Sea	Sea Disposal of Entire Submarine
20 Years of Protective Storage Before Disposal	16.2 million	10.2 million	8.4 million
Immediate Disposal	13.3 million	7.2 million	5.2 million

Extended protective storage before permanent disposal would increase the cost of disposal by approximately $3.0 million per submarine. Even this additional $3.0 million, however, would not cover the costs that might occur if new facilities for floating storage were required or extensive maintenance were needed during the storage period.

If the Navy decided to pursue ocean disposal, it could not lead to immediate implementation of this option, since additional administrative actions would be required. In accordance with the Marine Protection, Research and Sanctuaries Act, a permit from the U.S. Environmental Protection Agency would be needed. This means that the Environmental Protection Agency would have to proceed through their public decision-making process for evaluating and designating an appropriate sea disposal site.

In December, 1982, shortly after the Navy issued the Draft Environmental Impact Statement, an amendment to the Marine Protection, Research and Sanctuaries Act was included in legislation passed by the Congress. This amendment limited EPA's authority to issue permits for ocean disposal of radioactive wastes for two years except for research purposes. After this period expires, the amendment establishes a requirement for preparation of a Radioactive Material Disposal Impact Assessment of any permit requests submitted to the EPA and submission of such an assessment to the Congress. A joint resolution of Congress acting within 90 days of an EPA recommendation is required before the EPA may issue a permit. Further, EPA has stated it may need to revise its ocean disposal regulations.

COMMENTS RECEIVED ON THE DRAFT EIS

The Navy's Draft Environmental Impact Statement was widely circulated and a large number of public comments were received. Over 1500 copies of the statement were distributed to individuals, environmental organizations, State and local officials, and other Federal agencies. Over six months were allowed for interested parties to comment on the Navy Draft Environmental Impact Statement. Over 500 letters were received providing comments. The Navy held four public hearings in different parts of the country at which over 150 people testified.

The great majority of the comments dealt with the ocean disposal alternative. Many respondents were concerned about the possibility that radioactivity would enter the food chain and reach man in harmful quantities. Many people expressed an opinion that not enough was known about the deep ocean ecosystems to be able to adequately predict the environmental consequences of ocean disposal. The Navy's response to these comments was that the worst case analyses in the Draft EIS used many conservative assumptions which resulted in these analyses overestimating the actual environmental impact. The conservative nature of these analyses is corroborated by the demonstrated lack of any significant adverse environmental impact at the sites of the sunken nuclear powered submarines USS THRESHER and USS SCORPION.

A number of respondents expressed concern that the ocean disposal option was irreversible and did not allow for additional containment or retrieval if the submarines were determined to be causing an unacceptable environmental problem. Although the Navy's analysis demonstrated that there was no credible scenario that would require additional containment or retrieval, an appendix has been added which discusses methods which could be used to retrieve a submarine from the ocean bottom or to encase it in concrete on the bottom.

The Navy's ability to adequately monitor submarines disposed of in the deep ocean was questioned by some respondents. This capability exists and has been demonstrated; for example, by monitoring conducted at the THRESHER and SCORPION sites. Sections of the EIS covering monitoring for the ocean disposal alternative have been expanded to describe extensive monitoring of the THRESHER site which was conducted in 1983. Monitoring programs already exist at the land burial sites under consideration.

A number of respondents criticized the Draft EIS for not explicitly evaluating storage of the submarine reactor compartments above ground at an arid site. The Draft EIS did discuss floating storage of the submarine. Both floating storage and above-ground storage methods would only defer the need to make a decision about how to properly dispose of the reactor compartments. Above-ground storage at an arid site would incur essentially the same costs as land burial and provides less protection. Since no significant adverse impacts were identified for either disposal alternative, there is no reason to select above-ground storage over either permanent disposal alternative. Above ground storage is addressed in the Final EIS in Chapter 2.

All of these letters and the transcripts of the public hearings have been reprinted in Volume 2 of this EIS. The Navy's responses to the substantive issues raised in the letters and testimony are provided in detail in Volume 3.

PREFERRED ALTERNATIVE

Based on the research work performed in support of this effort, and review of the comments received as documented in the EIS, the Navy considers that permanent disposal can be performed in an environmentally safe manner. The highly conservative estimates used in conducting the analyses have amply compensated for any uncertainties that may exist in man's knowledge of the impacts of permanent disposal.

The Navy also examined the alternative of continued long-term floating protective storage of the submarine at a Navy facility. This is the "no-action" alternative because it represents the minimum action the Navy must take to ensure that decommissioned submarines are maintained without hazard to people or the environment. Although there would be no adverse environmental impact during storage, this alternative is not a permanent solution since it would require continued action to assure safety. Certain precautions are required for protective storage that are not needed for permanent disposal. These include the need for security measures because of the proximity of the submarines to human activity, the need to protect persons assigned to monitor the vessels, and the necessity to ensure continued acceptable storage conditions. Therefore, storage must be considered a temporary measure which ultimately would have to be followed by some method of permanent disposal to assure that the remaining radioactive material is isolated from human activities.

Since the Navy began its evaluation of disposal options, several developments associated with possible ocean disposal of low-level radioactive waste have occurred. These include Congressional action in December 1982 restricting the issuance of ocean disposal permits and requiring Congressional approval before any such permit may be issued by the EPA. In addition, the EPA has indicated additional regulations may be required before EPA could evaluate a permit request. In view of these and other related uncertainties associated with national acceptance of the ocean disposal option, the Navy considers that allocation of additional funds to pursue this option further is not warranted. Even though the analysis shows less cost for ocean disposal than for land disposal, the funds required to qualify and gain acceptance of an ocean disposal site and the costs of continuing to maintain excessed submarines in storage until ocean disposal was allowed by the Congress and the EPA would serve to narrow the cost differential between the two options.

Based on a consideration of all current factors bearing on a disposal action of the kind contemplated, the Navy's preferred alternative at this time is to dispose of the reactor compartments by land burial. Land burial is the method currently used in the United States for disposal of low-level radioactive waste and this disposal action would comply with existing requirements for use of the Government burial grounds. This approach will allow permanent disposal of this form of low-level radioactive material to proceed with no unacceptable environmental impacts. With most of the submarines to be decommissioned on the West Coast of the United States, it is expected that the Government burial ground to be used in the near future will be the low-level radioactive waste disposal site at Hanford in Washington State.

CHAPTER 1

PURPOSE AND NEED FOR ACTION

This final environmental impact statement (FEIS) describes the options for the permanent disposal of a defueled, decommissioned nuclear-powered submarine. The options examined are disposal of the reactor compartment at an existing land burial site, with the non-radioactive remainder of the submarine disposed of either by sinking at sea or by cutting up for sale as scrap metal, and disposal by sinking the entire submarine in the deep ocean. The alternative of long-term protective storage followed by land or sea disposal is also examined. Although the U.S. Department of the Navy has not decided to dispose of any submarines at this time, the nuclear submarines commissioned in the 1950's and early 1960's are approaching their design life and this statement has been prepared to allow enough time to decide on the best disposal method. This FEIS provides the information necessary to assess the impact of each available course of action and will serve as the basis for making a decision on the method to be used.

I. REACTOR PLANTS TO BE DISPOSED OF

A. NUMBER OF REACTOR PLANTS AND TYPE OF RADIOACTIVITY INVOLVED

The U.S. Navy currently operates approximately 120 nuclear submarines. As a submarine reaches the end of its service life, it becomes more difficult to maintain and operate. At some point, the cost of continued operation is not justified by the ship's military capability. The general subject of this Environmental Impact Statement is the disposal of the reactor plants from these ships and others added in future years, after they are eventually retired from service, decommissioned, and declared excess. The most immediate concern, and the action to which this statement is directed, is the disposal of the reactor plants from the approximately 100 nuclear submarines that may be decommissioned during the remainder of this century. The expected growth in number of decommissioned submarines over this time is shown on Figure 1-1. The Navy has made no decision to dispose of any submarine at this time, but this statement is being prepared so that disposal

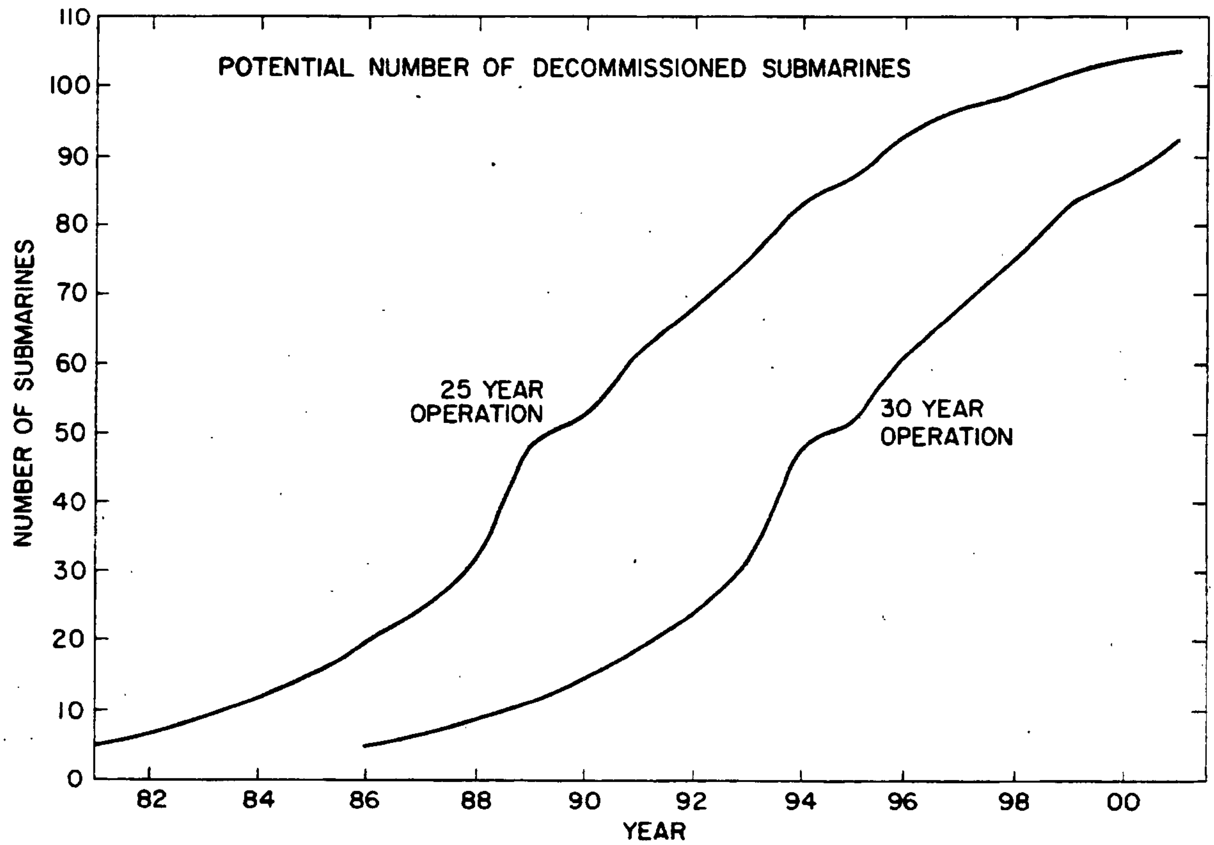

Figure 1-1. Number of Decommissioned Submarines vs. Time, To End of Century (Based on Either 25 or 30 Years of Operation)

methods can be identified and evaluated well in advance of any need. A submarine would not be assigned for disposal by the Navy unless and until an evaluation had shown that no future Naval use could exist for it.

Before a ship is decommissioned, all of the nuclear fuel (uranium) is removed. This defueling also removes the radioactive fission products from the reactor plant since they are contained within the fuel. The fuel is shipped by the Department of Energy from the refueling shipyard to its facilities in Idaho. The shipment is performed under requirements of the Department of Transportation, the Nuclear Regulatory Commission, and the Department of Energy. The fuel is processed in the same manner as other expended nuclear fuel. However, after defueling there remain portions of the reactor plant that are still radioactive; these must be disposed of in a way that will have a negligible impact on the environment.

There are several different design classes of nuclear submarines and a number of different reactor plant designs have been employed in the submarines. Each reactor plant has been or will be operated over different lifetimes and at somewhat different average power levels. To simplify the presentation of the radioactivity information while maintaining an accurate description of the amounts involved, one particular reactor plant has been selected to be typical of all. The plant selected is used in a large majority of the submarines, and its operating lifetime and average power level have been chosen to give a maximum radioactivity inventory for the type of reactor installed. It is therefore the most typical representative of all the reactor plants to be disposed of, and has a radioactivity inventory greater than the average of all reactor plants and one that is not significantly different from the absolute maximum of all the plants. The initial amounts of radioactive material remaining in a submarine after all fuel has been removed are provided in Table 1-1. The inventory is shown for both the earliest practicable disposal time, which is six months after final shutdown of the reactor, and after 100 years of radioactive decay.

Of the radioactive material that remains in the submarine, 99.9 percent is an integral part of the structural alloys forming the plant components (See Appendix G, Table G-1). The radioactivity was created by neutron irradiation of the iron and alloying elements in the metal components during operation of the ship. The predominant radioactive nuclide present is Cobalt-60, which decays by a factor of two every 5.3 years. As shown in Table 1-1, there are a total of 16 different radioactive nuclides, and the initial amount of radioactive material is approximately 62,000 curies. The only mechanism for release of this radioactivity to the environment would be through corrosion of the metal components of the reactor plant. Most of the radioactive nuclides would have decayed to stable atoms before they could possibly be released to the environment by the slow corrosion process. Figure 1-2 shows the relation between the total amount of radioactivity remaining in the submarine and the time after final reactor operation.

The remaining 0.1 percent of the radioactive material that remains in the decommissioned submarine is corrosion product activity (referred to as "crud") that was deposited as an adherent film on interior surfaces of the reactor pressure vessel, primary piping, pumps, and steam generator during reactor operation. Most of this tightly-adherent deposited activity (about 60 percent) is on surfaces within the reactor pressure vessel, which contains all but a few tenths of one percent of the radioactivity that is within metal components. Therefore, 99.7 percent of the total radioactivity would be contained within the reactor pressure vessel, which is a steel container several inches thick and capable of being completely sealed. As will be described in detail in Chapter 2, "Alternatives", the entire nuclear reactor is further contained in a separate submarine compartment enclosed by the ship's pressure hull and the compartment's two bulkheads.

Radioactive nuclides other than those shown in Table 1-1 are not present in quantities of one millicurie (10^{-3} curie) or more. However, since it is not possible to be certain that traces of nuclides such as Strontium-90, Cesium-137, and Plutonium-239 are absent from the corrosion deposits on the interior walls of reactor components, estimates have been made of the maximum effect of one millicurie of each of these nuclides. The maximum effects are not large enough to influence any of the total estimated radiation exposures that are based solely on the 16 nuclides of Table 1-1. Therefore it is judged that trace quantities of nuclides not included in Table 1-1 have been adequately accounted for in this statement and are not considered further.

The measurement of radioactivity in disintegrations per second or curies (as in Table 1-1 and Figure 1-2), does not adequately convey the potential radiation hazard of a mixture of nuclides because of the varying forms and amounts of energy associated with each disintegration. For example, Cobalt-60 (which is not only the principal gamma emitter but also a relatively rapidly-decaying nuclide) emits highly penetrating energetic gamma radiation, Chromium-51 emits relatively low energy gamma radiation, while Nickel-63 emits no gamma radiation, only beta particles, which would be essentially harmless to humans unless the nuclides

TABLE 1-1 (Cont'd)

NOTES: (1) Radioactivity values are the maximum predicted values (worst case) for the most representative reactor plant.

(2) X-rays — emitted when nucleus captures an orbital electron
gamma — emitted from nucleus accompanying most beta emissions
$beta^-$ — electron emitted from nucleus
beta+ — positron emitted from nucleus

(3) Based on Appendix I, Table I-6, Surface Dose Rate Conversion Factors (Total Body).

(4) Based on Appendix I, Table I-4, Adult Ingestion 70 Year Dose Commitment Conversion Factors (Total Body).

(5) One curie of activity produces 3.7×10^{10} disintegrations per second.

(6) The initial radioactivity is defined to be the amount present six months after final reactor shutdown, which is the shortest time in which the disposal could be accomplished. All radionuclides with an initial activity $\geq 1 \times 10^{-3}$ curie are included.

(7) With the exception of Figure 1-2, the half-life values used in radioactive decay calculations in this statement are the same as in the Draft EIS. In the Draft EIS, the half-life values for the following radionuclides were slightly different than those above: Co-60, 5.26 years; Ni-63, 92 years; Fe-55, 2.60 years; Co-58, 0.20 years; Mn-54, 0.83 years; Ni-59, 80,000 years; Nb-94, 20,000 years; and Tc-99, 212,000 years. Those not listed were the same in the Draft EIS as in this statement. Changes to the calculated radioactive decay were not necessary because they would have no significant effect on the results.

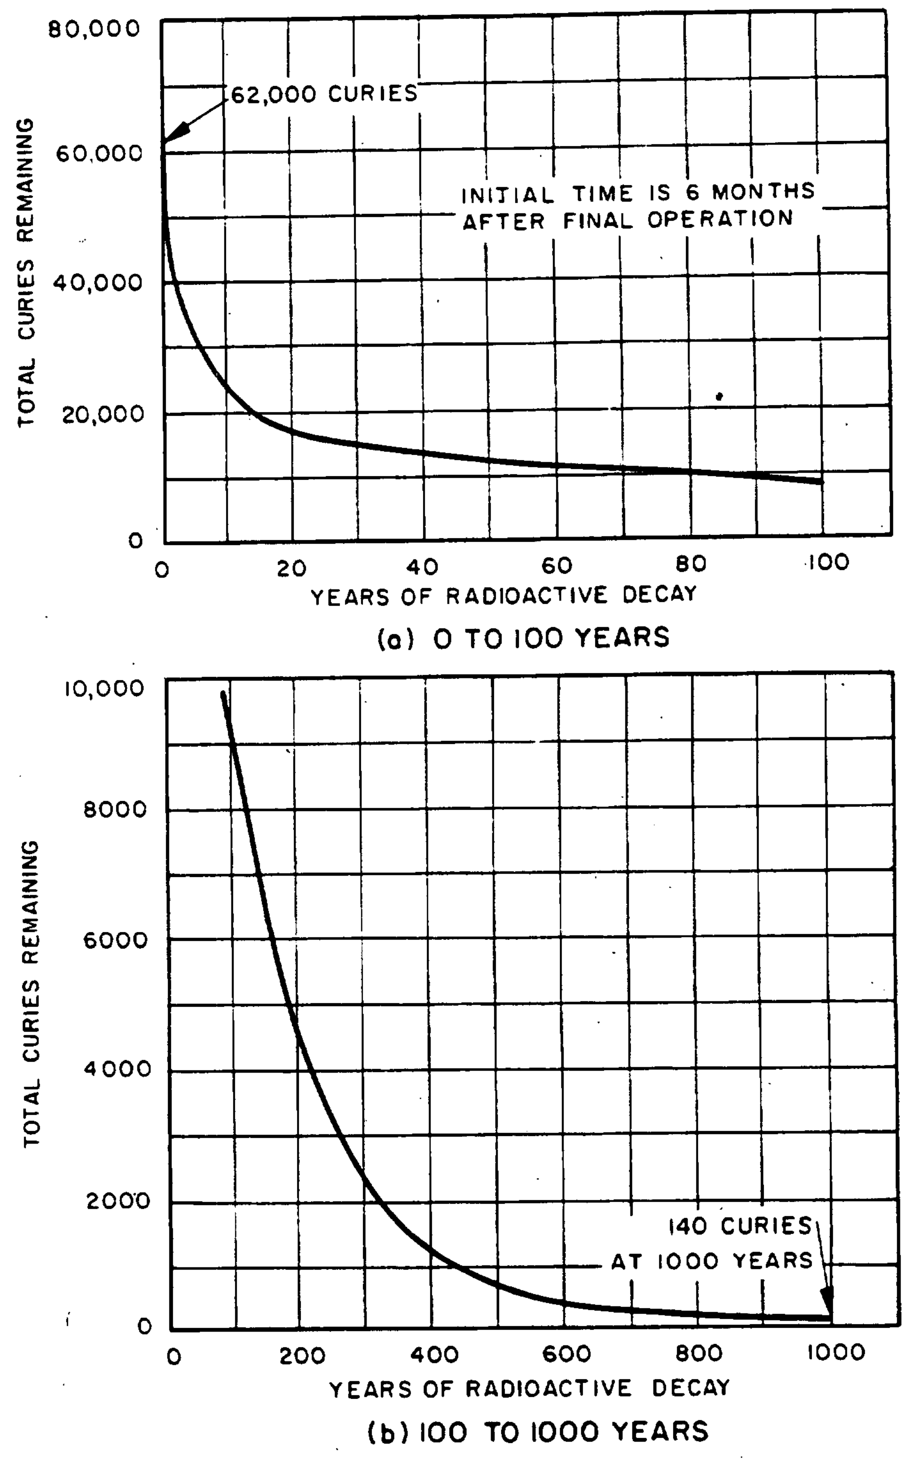

Figure 1-2. Total Radioactivity Present in One Decommissioned Reactor Plant vs. Time After Final Operation

were ingested or inhaled. To show the relative importance of each curie of activity in Table 1-1, entries are included for each nuclide, showing how each compares with Cobalt-60, the predominant nuclide. Both external hazard and internal hazard are shown. Section II of this chapter describes these two general categories of radioactivity hazard.

B. HEAT GENERATION

The radiation from the activated structural components produces a total thermal power of less than 800 watts at six months following final reactor operation. This is approximately the amount of heat given off by a small hair dryer, with the heat distributed over many tons of metal. This heat generation rate is primarily caused by Cobalt-60. Therefore it will decrease with approximately the same time dependence as Cobalt-60; for example, it falls to a rate of less than 400 watts after a period of about 5.3 years, and to less than 200 watts after about 10.6 years. A heat generation rate of this magnitude is not sufficient to cause any significant effects as far as long-term radioactive material release is concerned. The effect of such heat generation is considered, however, in the use of the reactor compartment as a shipping container (Appendix B).

C. NEED FOR SPECIAL PROCEDURES

Special procedures must be used during the disposal of the reactor plant of a nuclear-powered ship to prevent uncontrolled radiation exposure to the general public and to workers participating in disposal operations. The potential for inadvertent exposure remains until the radioactive components are finally placed in a permanent disposal site.

Even after permanent disposal, there would remain a small potential for future radiation exposure to individuals from long-lived radioactivity that eventually may be released to the environment. This statement provides estimates of the potential radiation exposure associated with each of the available disposal options.

II. RADIATION EXPOSURE

A. EXTERNAL GAMMA EXPOSURE

There are two general categories of radiation exposure associated with the decommissioned reactor plants. External exposure to gamma radiation is limited to the immediate vicinity of the reactor plant. The principal source of gamma radiation is the Cobalt-60 activity which is relatively short-lived, decreasing by a factor of two every 5.3 years. Hence, in 53 years the initial rate of gamma exposure is reduced by a factor of 2^{10} or about 1000. The exposure rates within accessible areas of the reactor compartment, which would be sealed to prevent entry after disposal, will decrease to about 0.1 mrem per hour after 53 years.

The initially large total number of curies of other nuclides (Table 1-1) has no significant effect on external gamma exposure in comparison to Cobalt-60. For example, the nuclides ranking second and third to Cobalt-60 in initial activity are Nickel-63, which emits a short-range beta particle when decaying to stable Copper-63, and Iron-55, which emits a low energy X-ray when decaying to stable Manganese-55. Other nuclides which emit gamma radiation, such as Cobalt-58 and Manganese-54, are initially present in much smaller quantities of activity than Cobalt-60, and also have shorter half-lives than Cobalt-60. Thus the external gamma radiation decreases with time according to the 5.3 year half-life of Cobalt-60. After about 100 years, the external gamma radiation would be reduced by a factor of more than 100,000 from its initial rate and would thereafter be essentially constant due to the presence of Niobium-94 (20,000 year half-life).

B. EXPOSURE DUE TO INGESTION OR INHALATION OF RADIOACTIVITY

The second general category of radiation exposure is the exposure to radiation from sources that have been taken into the body by ingestion or inhalation. The exposure would occur over the entire period in which the radioactivity remains in the body. For this reason, the term "dose commitment" is used to discuss internal exposure, since the individual would be committed to receiving a dose when the material is ingested or inhaled. The dose would be received until all of the radioactivity has decayed to stable form or left the body. The time period in which the dose would be received would depend on the nuclide's radioactive half-life and on the element's biological half-life.

Because the radioactive material present in the defueled reactor plant is present as a part of the structural metal itself (99.9 percent) or as adherent deposits (crud) on the structures (0.1 percent), it would not be readily available for release to the environment with the subsequent potential for ingestion or inhalation, even in the unlikely event that the material were not securely contained. The radioactive material would be released from the metal matrix only by the slow process of corrosion, a small fraction being released each year. Because of this delay effect, most of the radioactive atoms within the metal matrix would decay to stable atoms before corrosion release could occur. Radioactive nuclides with long half-lives are an exception. In the extreme case of Nickel-59 (80,000 year half-life), relatively little radioactive decay would occur prior to corrosion release. For this reason, Nickel-59 and the shorter-lived Nickel-63 (92 year half-life) represent the principal source of radioactivity with the potential for being released into the environment.

The maximum dose commitment due to intake of radionuclides is estimated by determining the maximum radioactivity (microcuries) that could be ingested or inhaled. This quantity is then multiplied by a "dose commitment factor" (mrem per microcurie) to calculate the lifetime dose commitment (mrems) resulting from that number of microcuries taken into the body. Dose commitment factors and complete information on the dose commitment estimates are provided in Appendix C, "Dose Commitment Estimates, Land Disposal" and Appendix J, "Dose Commitment Estimates, Sea Disposal".

III. MATERIALS OTHER THAN RADIOACTIVE MATERIALS

The following non-radioactive solid materials would be present in the decommissioned submarine's reactor compartment and other compartments: chromium and nickel metal as constituents of structural alloys; cadmium as plating material on certain fasteners; lead as ballast and radiation shielding installed on bulkheads and components; asbestos as thermal insulation on piping and components. These materials would be hazardous or toxic if they were available in a chemical or physical form that could be ingested or inhaled. However, the solid form of these wastes when disposed of would minimize the opportunities for their return to the environment as hazardous material. These materials would also be present in obsolete U.S. Navy ships that are not nuclear powered and such ships may currently be sunk at sea according to regulations of the U.S. Environmental Protection Agency (Reference 1.2). Burial of these materials at land disposal sites would be consistent with normal practice and would be performed in such a way that the end result would be at least as good as other available means for disposing of this material.

No liquids would remain in the reactor compartment or other compartments. The waste would not include materials considered to be ignitable, corrosive, or reactive. Other than the materials described above, the waste would not include materials considered to have the potential to become hazardous or toxic. The combination of any of the materials with water would not produce any consequences other than the slow process of corrosion.

IV. CURRENT STATUS OF DISPOSAL PROGRAM

The Navy's program for disposal of defueled and decommissioned reactor plants is at the stage where the earliest nuclear submarines, commissioned in the late 1950's and early 1960's, are now being taken out of active service. The actual disposal of an inactive ship would not occur until after it had been declared excess. No inactive nuclear submarine has as yet been declared excess and there are no disposals currently planned or scheduled.

Seven submarines, six of which are included in the action described by this environmental statement, have been decommissioned and are in protective storage at naval shipyards: TRITON, decommissioned in 1967; HALIBUT, decommissioned in 1976; ABRAHAM LINCOLN and THEODORE ROOSEVELT, decommissioned in 1981; ETHAN ALLEN and THOMAS A. EDISON, decommissioned in 1983. NAUTILUS, the first nuclear-powered submarine, was decommissioned in 1980 and will be designated an historic ship. The measures used to prepare these ships for inactive status ensure that no radiological concern exists either for Navy personnel, shipyard employes, or the general public. These ships can remain in protective storage for an indefinite time without hazard to the environment.

Additional submarines are expected to be placed in protective storage in 1984. During the remainder of the decade 1980-1989, it may be expected that an average of three additional nuclear submarines will be decommissioned each year. Thereafter an average of at least five decommissionings per year are expected based on the number of ships reaching retirement age (25 or 30 years) as shown on Figure 1-1.

Although, as noted above, a decommissioned submarine can be placed in protective storage for some period prior to ultimate disposal of the reactor plant, it is more efficient in terms of shipyard work and dry-dock time (and resulting costs) to perform all of the pre-disposal work during the period that the ship is in dry dock for the defueling and decommissioning work and then accomplish the disposal, because a number of inactivation tasks can therefore be eliminated (e.g., ensuring that the ballast tanks cannot accidentally flood during the protective storage period), as well as the routine work required during storage.

A decision on ultimate disposal of the reactor plants is needed in the near future to avoid costs that may be unnecessary and to avoid a large backlog of ships that must be processed for disposal at a later time. Storage space at inactive ship facilities is limited, and by 1990 action would be required to dredge additional piers and repair other piers. This would add appreciably to the cost of protective storage. To avoid the buildup of a large backlog of ships, the possibility of employing some combination of the two permanent disposal options has been considered and would appear to be acceptable if needed. For example, if the sea disposal option were preferred but was unavailable for some period of time, land disposal could be employed for a selected group of ships to be permanently disposed of.

Overall costs for delayed disposals will not decrease even though radioactive decay will reduce the radiation levels and the quantities of radioactive material present in each plant. The costs of protective storage followed by ultimate disposal are estimated to be about $3.0 million per ship more than immediate ultimate disposal. Details of estimated costs are provided in Appendix A, "Cost Analysis".

The options for ultimate disposal are discussed in the next chapter.

CHAPTER 2

ALTERNATIVES

Contents

List of Tables

List of Figures

CHAPTER 2

ALTERNATIVES

After a defueled and decommissioned nuclear submarine has been placed in the excess category, two general alternatives are available. These alternatives are: (1) disposal with a minimum of delay or (2) disposal after an extended period of protective storage. Even after an extended period of protective storage, the quantity of radioactive material remaining in the reactor plant would require permanent disposal. The alternative of disposal with minimum delay would accomplish the objective of safe, permanent, and environmentally acceptable removal of the radioactive material from human activities, without additional storage costs and without placing the responsibility for disposal on a future generation. The radiological impact on the environment would be comparable for either alternative, since no significant exposure to the public would occur in either case.

Two practical options exist for the safe and permanent disposal of radioactive nuclear reactor plants. One disposal option is to bury the ship's reactor compartment as low level radioactive waste at an existing Federal land disposal site, with the non-radioactive remainder of the submarine disposed of either by sinking at sea or by cutting up for sale as scrap metal. The second disposal option is to place the entire ship on the deep ocean bottom (greater than 13,000 feet) at a site considered acceptable for such disposal. Either of these options would be carried out in a manner that would provide containment of the radioactive material in the reactor plant and isolation from human activities.

Figure 2-1 shows a typical submarine with the reactor compartment identified. It is this part of the ship that would be removed and buried in the land disposal option. Figure 2-2 shows a view of the reactor compartment itself, simplified for the purpose of indicating both the location of the radioactive material (99 percent is within the reactor vessel), and the containment provided by the ship's hull and the forward and aft bulkheads of the compartment. Figure 2-3 shows a simplified view of the reactor vessel, empty of fuel but permanently containing the support structure that is the principal source of the radioactivity that remains after the fuel has been removed.

I. THE LAND DISPOSAL OPTION

If the land disposal option were selected, it would be implemented at Department of Energy waste disposal sites within either the Hanford Site in the southeastern corner of the state of Washington, or the Savannah River Plant located on the southern boundary of South Carolina. Such disposal would be identical to current practice, and the magnitude of the radioactivity inventories would be similar to those already being disposed of by land burial. However, the size of the reactor compartment disposals would be significantly larger than current disposal packages. Descriptions of these sites are provided in Chapter 3 with additional details in Appendix B. Other Department of Energy waste disposal sites that were considered for this project are also described in Appendix B.

Final preparation for land disposal of each reactor compartment would be made at a shipyard currently involved in radiological work. These shipyards include U.S. Navy shipyards at Portsmouth, New Hampshire; Norfolk, Virginia; Charleston, South Carolina; Pearl Harbor, Hawaii; the Mare Island Naval Shipyard at Vallejo, California; the Puget Sound Naval Shipyard at Bremerton, Washington; and commercial shipyards at Groton, Connecticut and Newport News, Virginia. The approximate distances from these shipyards to the burial sites, utilizing over-water routes, range from 250 to 6000 miles and may be at sea or through the Intercoastal Waterway on the U.S. East Coast. The disposal action could be carried out at the Department of Energy site on the same coast as the shipyard performing the preparatory work, or the barge loaded with a removed reactor compartment could be towed at an additional cost from one coast to the other.

A. METHOD OF DISPOSAL

Each submarine would have been defueled and decommissioned, with salvageable equipment removed.

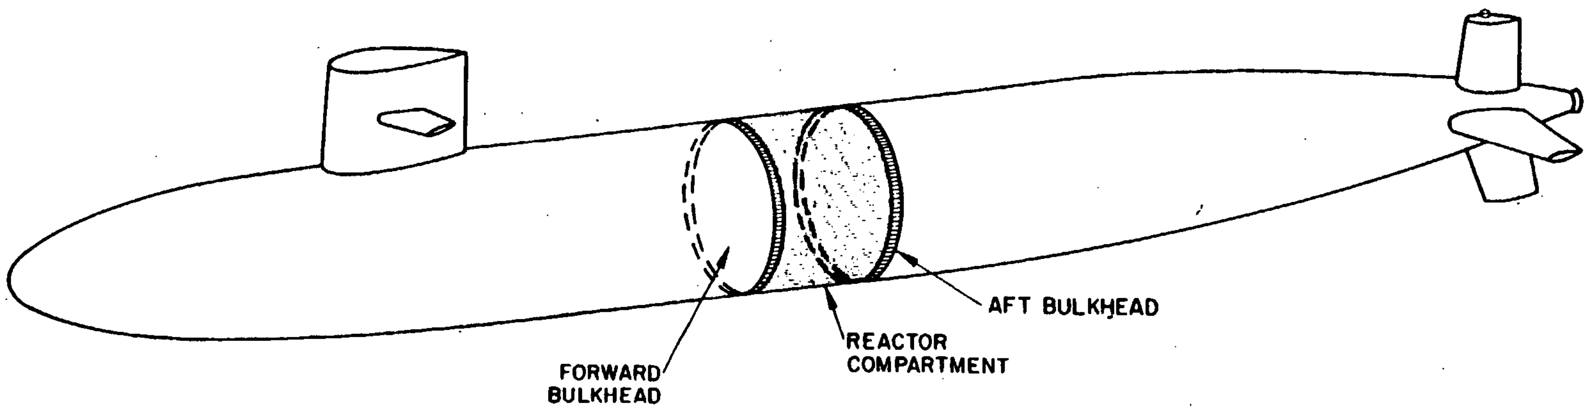

Figure 2-1. Typical Submarine with Reactor Compartment Identified

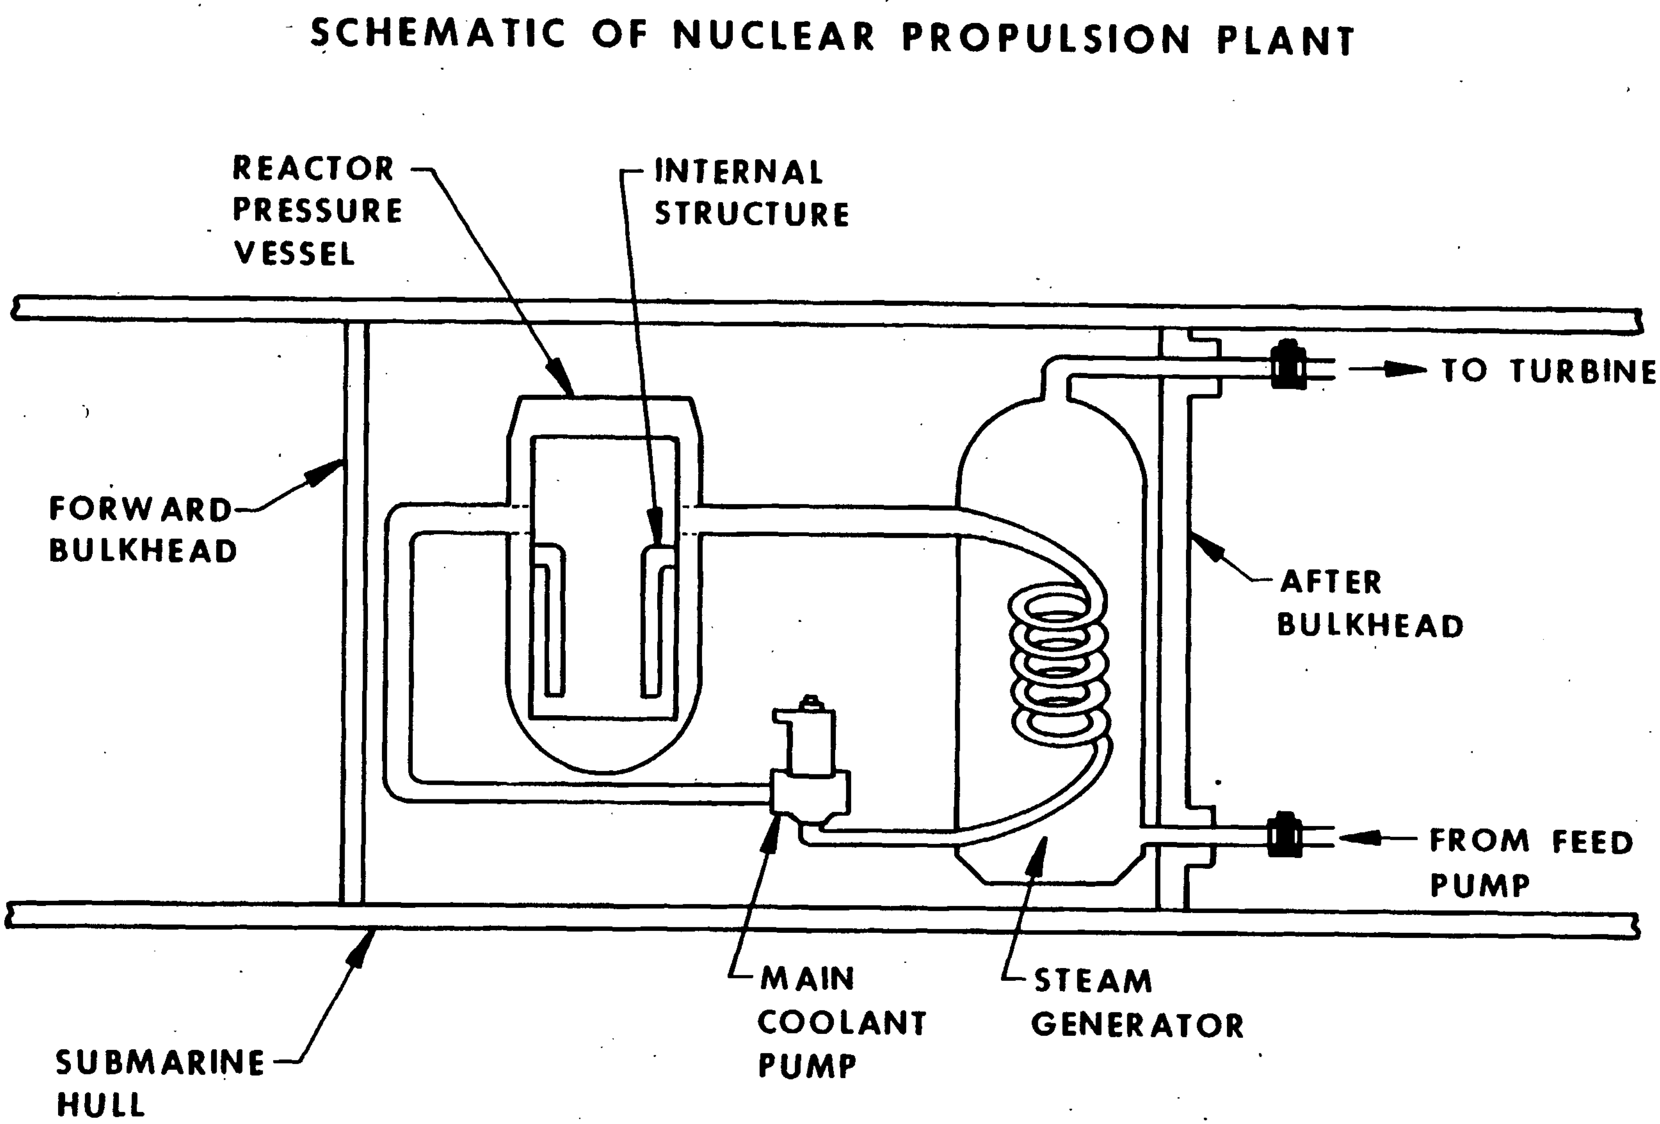

Figure 2-2. Reactor Compartment

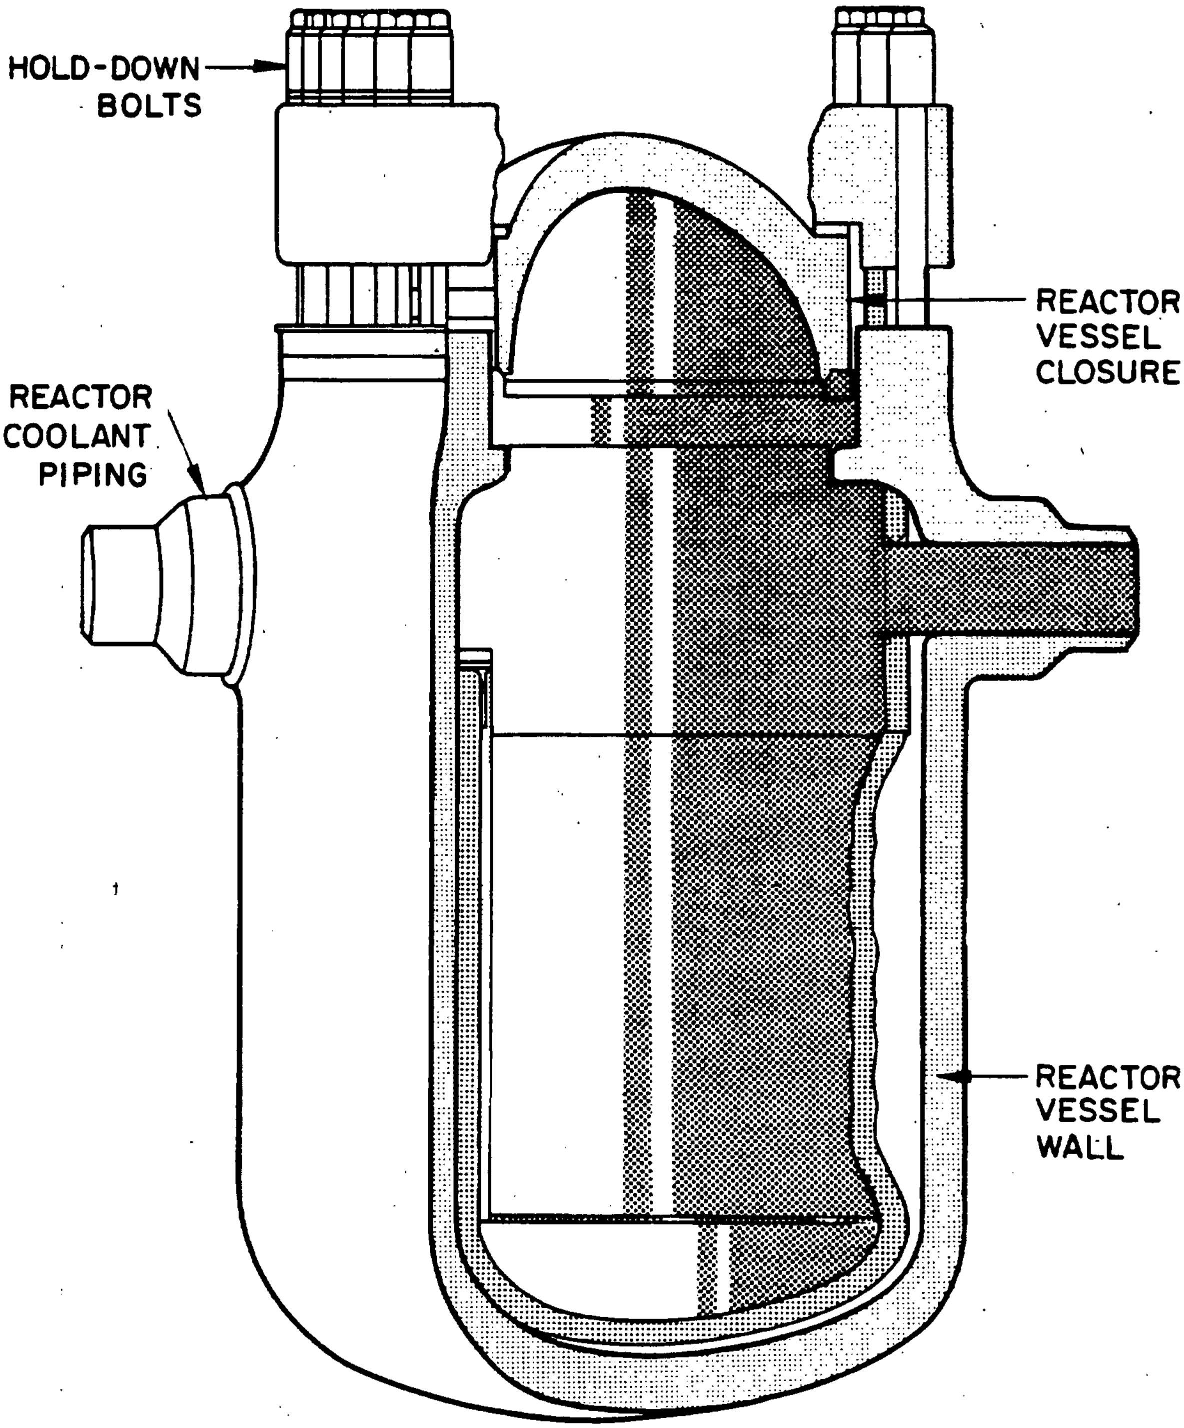

Figure 2-3. Reactor Vessel

With the ship in dry dock, the reactor compartment would be cut free from the remainder of the ship with cutting torches and all hull and bulkhead penetrations sealed by welding (see Figure 2-4). The weight of the reactor compartment in this condition would be approximately 1000 tons or less. Movement of the compartment onto a special purpose barge would be achieved by jacking up and supporting the compartment, placing rollers underneath and pulling the compartment horizontally onto the barge. The load would be welded securely to the steel barge deck for maximum security of the barge load during the trip to the disposal site.

The first part of the trip to the disposal site would be accomplished by towing the barge to the mouth of the Savannah River (South Carolina) or the Columbia River (Washington) using an ocean-going tug. A shallow-draft tug would then be employed to move the barge up the river to a landing site within a few miles of the final disposal site. At the river landing site, the barge would be grounded and the load would be freed from the deck of the barge. The compartment would then be jacked up to permit a crawler transporter to move under the compartment to assume the load and drive off the barge, as shown in Figure 2-5. The transporter would move the compartment overland to the burial ground for unloading in the disposal trench where the transporter would be driven into the trench and the load lowered onto previously prepared supports. After the reactor compartment had been removed from the transporter and the latter driven out of the trench, the trench would be backfilled to cover the reactor compartment with a minimum of four feet of earth at Savannah River and eight feet of earth at Hanford. The radiation level at the surface of the earth cover would be substantially less than the maximum allowable one mrem per hour. Since each two foot thickness of earth cover reduces the exposure rate by a factor of at least 10, the radiation level at the surface would be less than 0.1 mrem per hour.

Total space requirements for the burial of all 100 reactor compartments is approximately 10 acres. Details of the land disposal method are described fully in Appendix B.

B. COSTS

Detailed cost estimates for the land disposal option are provided in Appendix A. For a submarine just removed from active service, the total cost following decommissioning to completion of the burial operation would be approximately $7.2 million, assuming no period of protective storage. For an inactive ship, after 20 years of protective storage and periods of time in dry dock at the beginning and end of the time interval, the total cost would be approximately $10.2 million. Costs associated with missile compartment removal, where required, are not included. The costs cited here are based on the assumption that the remainder of the ship would be sunk at sea. If the hull were to be cut up and scrapped, the total cost per reactor compartment would increase by an estimated $6.0 million as described in Appendix A. Costs are in 1981 dollars.

Land disposal could result in a total occupational radiation exposure estimated to be approximately 17 man-rems for a ship that is disposed of promptly upon being retired from service, and approximately 20 man-rems for a ship which is prepared for interim storage and is disposed of later. For comparison, the occupational exposure limit for a shipyard work force of 200 persons is 1000 man-rems per year and 600 man-rems per quarter-year, with individual exposure limits of 5 rem per year and 3 rem per quarter-year.

C. SUMMARY OF ADVERSE ENVIRONMENTAL EFFECTS

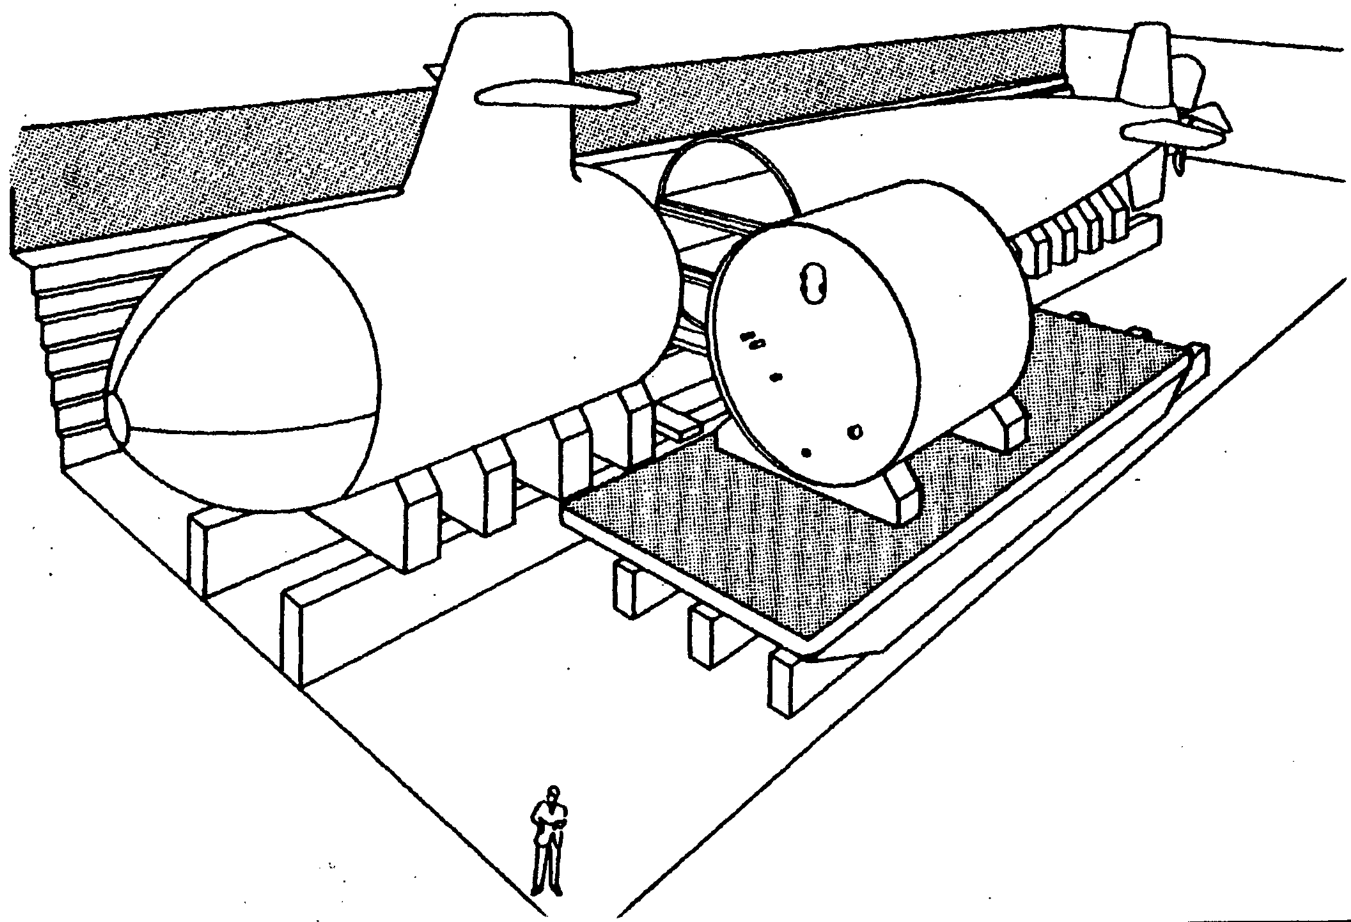
If the land disposal option were selected, the unavoidable adverse environmental effects would be:

1. Usage restrictions for approximately ten acres of DOE disposal site land for 100 reactor compartments.

2. Temporary removal from use of less than two acres of Savannah River site land for the construction of a landing slip at the site.

3. Temporary and minor environmental impacts associated with the construction of the Savannah River landing slip.

4. Temporary changes in river water levels if required to facilitate the passage of the loaded barge.



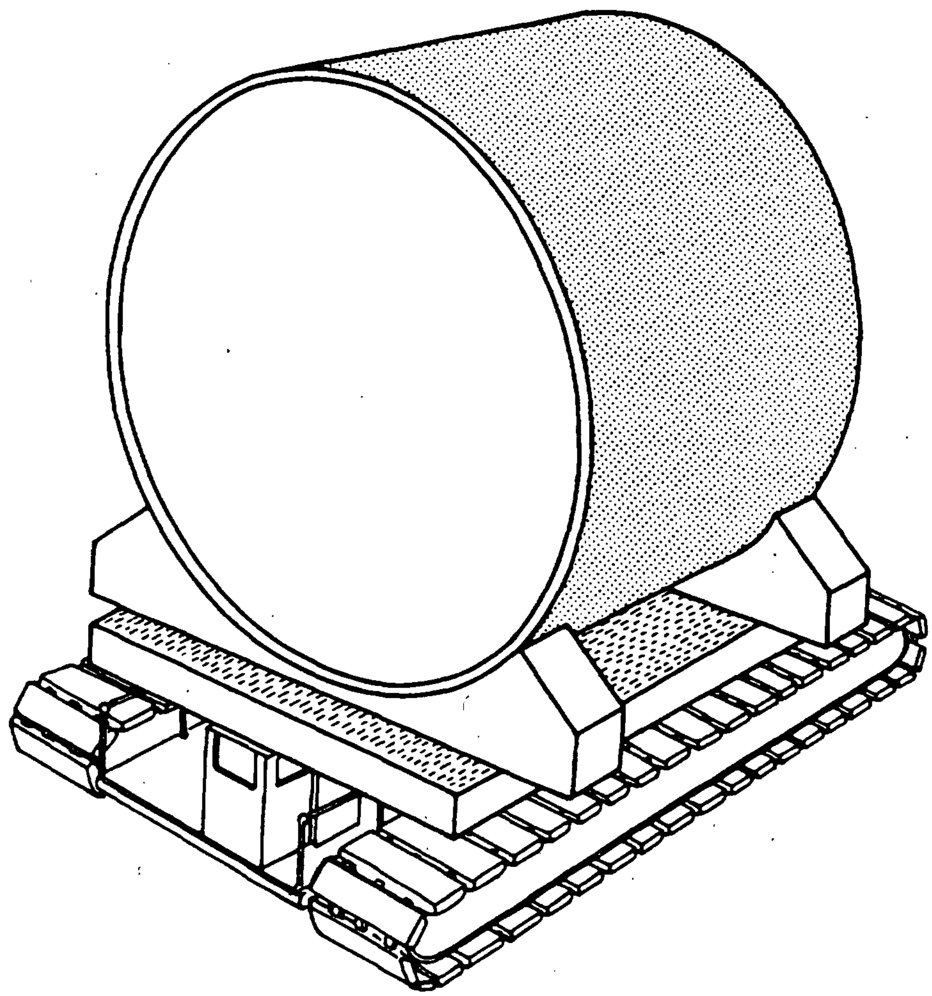


Figure 2-5. Concept for Land Transporter Movement of Reactor Compartment

5. Eventual addition (in several thousand years) to the soil underlying the disposal ground of as much as 120 curies of long-lived radioactivity (principally Nickel-59, with a half-life of 80,000 years) from each reactor compartment.

The population exposure to radiation which might occur has been estimated (Chapter 4 and Appendix C) and would be very small. This is based on a conservative estimate of the release of long-lived radioactive material from all 100 reactor compartments to water supplies after a period of several thousand years, when the reactor vessel containment is assumed to have been eliminated by corrosion. Exposure estimates, described in detail in Appendix C, are as follows:

The total body exposure to an average individual is estimated to be approximately 6×10^{-3} mrem per year from all 100 disposals at the same site.

The maximum total body exposure to a hypothetical "agricultural intruder" at some time in the distant future has been estimated to be less than 13 mrem per year, considering all 100 reactor compartments are buried at the same site.

The population exposure has been estimated to be less than 2.1 man-rems per year from all 100 reactor compartments buried at the same site. This estimate is based on a future population of 350,000 persons in the Savannah River area served by the potentially affected water supply. This population exposure estimate is conservative (high) for the Hanford area.

The potential adverse effects of land disposal are very limited and considered to be negligible. The potential radiation exposure to an average individual, even if all 100 reactor compartments were buried at the same site, would be less than 0.00006 of the normal background radiation.

Appendix L, "Floodplain/Wetlands Assessment," discusses the effects of possible disposal at the Savannah River Plant on floodplain management and protection of wetlands. Significant adverse environmental effects are not expected.

D. MEASURES TO MITIGATE ADVERSE EFFECTS

Even though the potential for adverse environmental effects would be very limited, the following steps would be taken to minimize the radiation exposure potential and land usage effect of the land disposal option. The reactor vessel would be closed and sealed after defueling. The reactor compartment would be welded shut prior to being transported to the disposal site. Department of Energy disposal sites currently used for the disposal of radioactive wastes would be used for the burials to minimize the removal of new land area from unrestricted usage. The reactor compartments would be buried in trenches with at least 10 feet of undisturbed earth between the bottom of the trench and the water table, to minimize corrosion of the containment exterior, and covered with at least four feet of earth. An additional mitigating effect would be provided by the sorptive properties of the soil, which would retard the rate of radioactivity movement from the burial site.

E. RETRIEVABILITY AND INSPECTABILITY

Any or all of the buried reactor compartments could be retrieved if necessary, following removal of the surrounding earth, using methods similar to those used to emplace the compartments. Furthermore, it is reasonable to expect that the compartments would be in condition to be moved for more than 200 years after initial burial. The gamma radiation level of the contents would have decayed to less than 0.1 percent of the initial gamma level by 53 years.

Inspection of the burial sites would be accomplished as a part of the normal monitoring of the existing disposal sites.

Routine inspection of the buried compartments themselves would not be possible, although if desired at some time in the future, it would be possible to inspect a compartment interior by removing the earth cover and cutting open the welded-shut door in either the forward or aft bulkhead. No routine maintenance of the earth cover would be required.

F. ENVIRONMENTAL MONITORING

The environmental monitoring associated with land disposal of nuclear submarine reactor compartments would be the same as the normal program already being conducted by the Department of Energy radioactive waste management operation at the Savannah River Plant (Reference 2.2) or the Hanford Site (Reference 2.3). Monitoring considerations for the disposal of submarine reactor plants are discussed in Appendix K. Extensive monitoring for radioactive material release is already performed at these DOE sites, as described in the respective Environmental Impact Statements (References 2.2 and 2.3) and subsequent review of this effort by the National Research Council (Reference 2.4). These monitoring and review actions have demonstrated that the operations of the low-level waste burial sites had no adverse environmental effects.

G. PERMITS

The land disposal of reactor compartments would be consistent with current practice in which irradiated components in shipping containers are shipped to the Hanford Site and Savannah River Plant for disposal. No new rule making by any agency would be required for transportation or disposal. Department of Transportation certification of compliance with shipping regulations would be obtained for shipment of the compartments and DOE authorization would be obtained for the use of the burial facilities. U.S. Coast Guard authorization would be required for the inland water transportation portion of the disposal action, and U.S. Army Corps of Engineers cooperation would be required in the event that dredging is required. No dredging of the channels is currently foreseen.

H. COMPARISON WITH NRC WASTE CONCENTRATION LIMITS FOR LAND BURIAL (10CFR61)

Table 2-1 shows how the reactor compartment radioactivity concentrations compare with limits established by the Nuclear Regulatory Commission for land burial of low level waste at licensed disposal sites (Reference 2.1). The activity concentrations in the defueled nuclear submarine reactor compartment were calculated by dividing the total activity for each isotope, as shown in Table 1-1 of Chapter 1, by a minimum volume of 400 cubic meters. This nominal volume is somewhat smaller than the actual reactor compartment, and is based simply on a right circular cylinder having a diameter of 30 feet and a length of 20 feet.

The concentrations of all isotopes in the submarine reactor compartments would be less than the least restrictive limits of the proposed regulation except for Nickel-63, which exceeds the "Class A waste" limit by 30 percent. Thus, the disposal package would be in the category of "Class B Waste" and would be required to provide structural stability of the waste in addition to certain minimum requirements of Reference 2.1 on the waste form and its characteristics. The thick steel hull and the very thick steel reactor vessel would provide a very strong burial container which would meet NRC stability requirements.

I. ADVANTAGES AND DISADVANTAGES OF THE LAND DISPOSAL OPTION

The land disposal option's advantages and disadvantages may be summarized as follows:

1. Advantages

a. Complete control exists over the disposal package for an indefinite time. Any or all of the buried reactor compartments could be retrieved, if necessary. The compartments would be in condition to be moved for at least 200 years after initial burial.

b. No new regulations by any agency would be required for transportation or disposal.

TABLE 2-1. NUCLIDE CONCENTRATIONS vs CONCENTRATION LIMITS FOR LAND BURIAL OF LOW LEVEL WASTE (10CFR61)

Nuclide (or Isotope)	Concentration in Reactor Compartment (Curies per cubic meter)	Concentration Limits (Curies per cubic meter)		
		Class A Waste	Class B Waste	Class C Waste
Cobalt-60	55	700	no limit	no limit
Nickel-63 in activated metal	45*	35	700	7000
Carbon-14 in activated metal	2.5×10^{-3}	8	8	80
Nickel-59 in activated metal	0.3	22	22	220
Niobium-94 in activated metal	2.1×10^{-4}	0.02	0.02	0.2
Technetium-99	9×10^{-6}	0.3	0.3	3
Any with half-life less than 5 years	<55	700	no limit	no limit

*The Nickel-63 concentration would decrease to 35 curies per cubic meter at 34 years.

---

c. The land disposal sites are currently used by the Navy and the Department of Energy for other wastes.

d. Land disposal would be a continuation of current low level radioactive waste disposal.

e. The method of overland transportation involves a proven vehicle (crawler transporter) and technique for the size and weight involved.

f. Land use would be small since about 12 reactor compartments could be buried per acre and only 10 acres would be required for 100 separate disposals.

2. **Disadvantages**

a. Land disposal would be more expensive than other options,

(1) approximately $2.0 million per ship more than sea disposal, provided that the remainder of the ship is disposed of at sea and

(2) approximately $8.0 million per ship more than sea disposal, if the remainder of the ship is salvaged.

b. Land disposal would be more complex than other options, since more shipyard production work would be required through completion of the disposal operation.

c. Use of ten acres of DOE disposal site land would be restricted in the future.

II. THE SEA DISPOSAL OPTION

If the sea disposal option were selected, it would be accomplished at ocean sites considered acceptable for such disposal and designated by the U.S. Environmental Protection Agency (EPA). Typical sites which might satisfy the criteria established by the International Atomic Energy Agency (IAEA) in Reference 2.5 exist in both the Atlantic Ocean and the Pacific Ocean. For the purposes of developing analysis models of possible environmental effects and estimating the magnitude of such effects, study areas in the Atlantic Ocean approximately 200 nautical miles southeast of Cape Hatteras, and in the Pacific Ocean approximately 200 nautical miles west of Cape Mendocino, California were selected, with the Pacific Ocean study area used for the principal analysis of environmental impacts. The nature of such study areas and the basis for the criteria used to identify them are described in Chapter 3 and in Appendix E. The study areas described in this statement are not sites that have been selected or proposed for sea disposal, but rather they have been chosen for data collection and study since they are representative of sites which would meet IAEA criteria. These study areas and the values of the key parameters measured at their locations have been used in the evaluation of possible environmental effects since it was judged that they would be as close to human activities as any sites which might be selected under the IAEA criteria.

Disposal at sea would also comply with requirements established by the U.S. Environmental Protection Agency in consideration of U.S. and international laws and treaties. International standards for disposal of radioactive material at sea are established by the IAEA, Reference 2.5, in compliance with all articles of the 1972 London Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter. These standards are implemented in the United States by the Marine Protection, Research and Sanctuaries Act of 1972 and are enforced by the EPA, which is authorized to issue ocean dumping permits.

Disposal at sea would not directly or indirectly affect land or water use in the coastal zone of any state, which is the zone extending seaward for three nautical miles. Nor would activities conducted in or on the water in the coastal zone, and in or on the shorelands within the zone, be affected.

A. METHOD OF DISPOSAL

Final preparation for disposal at sea would be carried out at a shipyard normally servicing nuclear-powered naval vessels. These shipyards are listed in Section I of this chapter. Each ship would have been defueled and decommissioned, with salvageable equipment removed. The ship's battery would be drained and removed and the contents of tanks (including oil tanks) would be replaced with water. The reactor vessel integrity would have been restored to normal following the defueling operation and the entire reactor plant would be filled with water. The reactor compartment would be sealed and filled with water. A check valve or one-way valve in the reactor compartment bulkhead would ensure that the reactor compartment pressure would be equal to the pressure in adjacent compartments during the sinking.

The submarine would be towed to the disposal site and prepared for final submergence. Here, covers would be removed from holes previously cut in the top of the hull to ensure rapid flooding. Ballast tanks would be flooded from the deck area and personnel would leave the submarine as it began to settle in the water and the tow line was disconnected. When the submarine submerged to the point where the hull openings were covered, rapid flooding would occur. It is estimated that complete flooding would occur less than one minute after the sinking is initiated, and that the submarine would free-fall at a constant vertical velocity of 45 feet per second (27 knots) or less.

When the submarine reached the bottom, well within 1500 feet of the release point (horizontally), the magnitude of the resulting shock would be less than 2g*, and would depend on the type of sediment and its thickness. For this reason, areas without thick deposits of sediment would be avoided as disposal sites. Based on the results of similar sinking operations and extensive related experiments and analysis, when the submarine settles on the ocean bottom, the reactor compartment containment integrity would be maintained and the reactor vessel and the remainder of the reactor plant would be intact.

*Deceleration from 45 feet per second to zero feet per second in 0.7 seconds is equivalent to 64 feet per second per second, or approximately 2g. The deceleration time interval is determined by the material that is struck.

The release of radioactive material to the ocean would occur only after at least 100 years, due to the slow process of corrosion of the hull and bulkheads and the reactor vessel walls. In the meantime, radioactive decay would convert much of the radioactive material to stable forms which are harmless and are identical, in most cases, to the metallic elements already present in the oceans.

B. COSTS

Detailed cost estimates for the sea disposal option are provided in Appendix A. (This includes cost estimates for, and a brief discussion of, sea disposal of the reactor compartment alone.) For an active ship, the total cost following decommissioning to completion of the disposal is estimated to be $5.2 million,* assuming no period of protective storage. For an inactive ship, after 20 years of protective storage and periods of shipyard time at the beginning and end of the time interval, the total cost is estimated to be $8.4 million. An allowance for monitoring costs is included, but costs associated with missile compartment removal for compliance with strategic arms limitation agreements, where required, are not included.

Sea disposal would require a total occupational radiation exposure estimated to be approximately 17 man-rems for an active ship, and approximately 20 man-rems for an inactive ship. For comparison, the occupational exposure limit for a shipyard work force of 200 persons is 1000 man-rems per year and 600 man-rems per quarter-year, with individual exposure limits of 5 rem per year and 3 rem per quarter-year.

C. SUMMARY OF ADVERSE ENVIRONMENTAL EFFECTS

If the sea disposal option were selected, the unavoidable adverse environmental effects would be as follows:

1. Some restrictions on the use of one or more remote areas of the ocean floor. Use of overlying waters would not be restricted. A circular area having a diameter of approximately 11 statute miles would be involved if all 100 submarines were placed in the same general area. (See Appendix D.) The total affected area would be less than 100 square miles and would represent approximately 1.3×10^{-4} percent of the sea floor that lies under 4000 or more meters of water. This area would be less than 3 percent of the maximum sea disposal site area (10,000 square kilometers) specified by the International Atomic Energy Agency.

2. Loss of approximately 3000 tons of recyclable material, mostly steel, per ship. None of the material is in short supply nor are the resources of these materials expected to be exhausted in the near future. Although the material is recyclable, the cost to the government to recover it would be far greater than the scrap value, as described in Appendix A.

3. Eventual addition to the ocean environment (primarily the sediment) of approximately 4000 tons of corrosion products per submarine. This would include a small quantity of intermediate and long-lived radioactive material, of which about 120 curies of Nickel-59 (80,000 year half-life) per submarine would be expected eventually to be released to the environment. Seawater already contains these stable elements in solution, as well as a quantity of natural radioactivity (primarily Potassium-40) amounting to approximately 1800 curies per cubic mile (derived from Reference 2.6), or 120 curies of natural radioactivity in a 700 meter cube.

As described in detail in Chapter 4, the following adverse effects might occur, based on a conservative estimate of the radiological exposure due to a fraction of the released radioactive material entering one or more pathways to humans.

1. Annual radiation exposures to the average individual and to the most-exposed individual, due to the disposal of all 100 submarines, would be less than 2×10^{-4} mrem per year and 3×10^{-3} mrem per year, respectively, based on a very conservative estimate. The corresponding population exposure has been estimated to be less than 6 man-rems per year, based on all 100 disposals at the same site and an

*Cost estimates in 1981 dollars.

affected population of 30 million persons. In the event of an extreme occurrence following which the reactor compartment and reactor vessel are assumed to provide no containment barrier to release, the maximum annual exposure could be 6×10^{-2} mrem per year, based on a very conservative estimate.

2. Minimal effects on sea life in the neighborhood of the disposal site would be expected because of the very low external radiation levels (0.001 mrem per hour or less outside the hull), and because of the limited potential for internal exposure, primarily by ingestion of sediment. In the unlikely event that a disposal site became of commercial or other interest in the future, it is likely that the ability to exploit the site would not be affected outside of the small area that would actually be occupied by the disposed submarines. Even in the close proximity of the hulls, the radiation levels would be very low.

D. MEASURES TO MITIGATE ADVERSE EFFECTS

Several measures in the implementation of the sea disposal option would mitigate any adverse effects associated with the option.

The disposals would be made only at a site considered acceptable on the basis of remoteness, low biological activity, depth, sedimentation, tranquility, and predictability of geologic properties, and where no human activity is expected for the foreseeable future.

Multiple barriers of containment would minimize radioactivity release. These barriers include the reactor compartment exterior walls, the reactor vessel walls, the containment provided by the radioactive metal itself, most of which is corrosion-resistant alloy (stainless steel), and the ocean sediment which can retain by adsorption some of the radioactive material which comes in contact with it (though no credit was taken for this latter barrier in the calculations). The reactor compartment would be sealed; pressure equalization devices would be provided to ensure that containment integrity would be maintained; and the method of emplacement on the sea floor would preserve the integrity of containment.

These measures provide effective isolation and containment of the radioactive waste.

In the unlikely event that further measures to mitigate adverse effects were to be required after disposal had occurred, containment of the residual radioactive material in concrete could be accomplished at any time, as described in Appendix M. Freshly mixed concrete could be delivered from the ocean surface by means of a long pipe to envelop the entire submarine in concrete. This is feasible using current technology and would require no advance preparation of the submarine.

E. RETRIEVABILITY AND INSPECTABILITY

Retrievability and inspectability would be feasible with current technology or with reasonable extensions of proven technology. Retrieval of the entire submarine should be possible for at least 50 years after disposal because of the strength and thickness of the structures, as described in Appendix M.

Inspection would be possible with deep submergence vehicles to determine the condition of the hull at the location of the reactor compartment. Photographic or television techniques could be used with either a submersible vehicle or a remotely-operated device deployed from a surface ship.

F. ENVIRONMENTAL MONITORING

Environmental monitoring would be performed before, during, and after the period of disposal in accordance with EPA regulations. The purpose of such monitoring would be to determine the possible extent of radioactive material dispersal in the nearby sediment and water column, and the concentrations of such material present in bottom-dwelling forms of life as well as those inhabiting the water column at various depths. Monitoring requirements are discussed in Appendix K.

G. PERMITS

Authorization would be required from the U.S. Environmental Protection Agency. The EPA would be responsible, under the Marine Protection, Research and Sanctuaries Act of 1972, to issue a disposal permit. Other nations would be informed in accordance with international requirements.

H. COMPARISON WITH IAEA LIMITS FOR OCEAN DISPOSAL OF RADIOACTIVE WASTE

International limits on ocean disposal of radioactive waste have been developed by the International Atomic Energy Agency (IAEA) for the London Convention (Reference 2.5). The activity concentration limit that would be applicable to submarine disposal at sea is 100 curies per metric ton for beta/gamma emitters (excluding tritium, H-3) with half-lives of at least 0.5 year. A metric ton equals 1000 kilograms or approximately 2200 pounds. The activity concentrations are to be averaged over a gross mass not exceeding 1000 metric tons, and the total tonnage of radioactive waste that can be disposed of each year at a single site is 100,000 metric tons.

As shown in Table 1-1, Chapter 1, the radioactivity contained in the reactor compartment of a defueled submarine six months after final operation would be approximately 62,000 curies, all of which would be beta/gamma emitters. The activity of beta/gamma emitters with half-lives exceeding 0.5 year is approximately 58,000 curies. Since the gross mass of each submarine reactor compartment is about 1000 metric tons, the activity concentration is approximately 58 curies per metric ton. Therefore, the limit of 100 curies per metric ton would be satisfied.

The single site limit of 100,000 metric tons per year would not be approached if sea disposal were implemented since the mass of a submarine reactor compartment is about 1000 metric tons. If up to five submarines per year were disposed of at a single site, the total would be less than 5000 metric tons or 5 percent of the limit.

Controls on disposal at sea would include those recommended by the IAEA and administered by the EPA. These controls include standards for selection of a disposal site, packaging of wastes, approval of the delivery ship and its equipment, supervision of disposal operations, and recordkeeping.

I. ADVANTAGES AND DISADVANTAGES OF THE SEA DISPOSAL OPTION

The sea disposal option's advantages and disadvantages may be summarized as follows:

1. Advantages

a. The cost of sea disposal would be significantly lower than either of the land disposal options, approximately $1.9 million per ship less than land disposal with sea disposal of the remainder of the ship and approximately $8.0 million per ship less than land disposal with the remainder of the ship scrapped.

b. Sea disposal would be simpler than land disposal, requiring less shipyard production work to prepare and sink the ship compared with the work required for land disposal.

c. The radioactive waste would be far from human activities and unlikely to be inadvertently disturbed.

2. Disadvantages

a. The environmental aspects of sea disposal are more controversial than those of land disposal. However, disposal at sea of low level radioactive waste is not prohibited by laws of the United States. Controversy has recently been focused on ocean dumping activities of the United States from 1946 to 1970, resulting in a review of the issues by the General Accounting Office (GAO) (Reference 2.7). This review determined that the "overwhelming body of scientific research and opinion shows that concerns over the potential public health and environmental consequences posed by past ocean dumping activity are unwarranted and overemphasized". The conclusions of Reference 2.7 were subsequently reviewed by the GAO at the request of the Chairman of the House of Representatives' Subcommittee on Oceanography, Committee on Merchant Marine and Fisheries. In Reference 2.8, the GAO stated that Reference 2.7 was accurate and, after careful reexamination, considered to be valid.

b. The sea disposal option would take longer to put into use than the land disposal option because sea disposal sites would have to be designated by the U.S. Environmental Protection Agency, and a permit from that agency would be required.

c. An amendment to the Marine Protection, Research, and Sanctuaries Act (Public Law 97-424, January 6, 1983) limits EPA's authority to issue permits for ocean disposal of radioactive wastes for two years except for research purposes. After this period expires, the amendment establishes a requirement for preparation of a Radioactive Material Impact Assessment and submission of such an assessment to the Congress.

III. THE "NO ACTION" ALTERNATIVE

The general alternative of taking no immediate permanent disposal action can be selected and successfully applied as a short term option, as shown by the protective storage status of seven decommissioned submarines (TRITON, since 1967; HALIBUT, since 1976; NAUTILUS, since 1980; THEODORE ROOSEVELT and ABRAHAM LINCOLN, since 1981; and ETHAN ALLEN and THOMAS A. EDISON, in 1983). The measures used to prepare these ships for protective storage and maintain them in such storage ensure that no radiological concern now exists or will exist for many years as long as periodic maintenance is performed.

This protective storage option is considered satisfactory as an interim measure, but does not provide permanent disposal. Continued maintenance in storage will be an increasing problem for the Navy as the ships age and the number of inactivated ships increases. For this reason protective storage is not a permanent solution to the disposal problem.

The option can continue to be used while other options are being developed. Other alternatives may be developed over the next 20 to 30 years. This is the major attraction of the "no action" alternative. However, it is unlikely that other options as yet unidentified could be significantly more advantageous in terms of environmental impact than immediate land or sea disposal, or in terms of cost or occupational exposure.

The delay period allows a major part of the radioactive material to decay under controlled conditions without release to the environment. The radioactive inventory of the reactor compartment would be decreased over a 20 year wait period to about 25 percent of its initial value (Chapter 1, Figure 1-2). While this would appear to be significant, it would not have a significant effect on environmental impact because the radioactive material would be contained within the reactor compartment for at least 100 years for sea disposal or 200 years for land disposal even with no delay period. The delay period could have an effect only on the eventual release of Nickel-63 which has a 92 year half-life. A 20 year delay period would decrease the Nickel-63 inventory at the disposal time by 14 percent, so that the eventual release of Nickel-63 would be 14 percent less than what it would be in the absence of delay. However, because of the long period of containment provided by the package and the metal itself, the eventual releases of Nickel-63 would be very limited even without protective storage. Since only about one-third of the total amount of radioactivity expected to be released in sea disposal is Nickel-63 and the remainder is Nickel-59, which would not decay significantly during storage, the total reduction in release due to a storage period of 20 years would be less than 5 percent. For land disposal almost no Nickel-63 would be expected to be released, so there would be no reduction in release due to a storage period of 20 or more years. Therefore, for sea disposal, the reduction in environmental effects attributable to protective storage would be minor and for land disposal it would be essentially zero.

The option is initially less costly than the other options. Initial costs would be: $1.2 million less than sea disposal, $3.2 million less than land disposal with sea disposal of the remainder of the ship, and $9.3 million less than land disposal with scrapping of the remainder of the ship. However, the extra costs involved in the two step process of placing the ship in protective storage and later disposing of it would be approximately $1.4 million per ship, not counting the annual cost of protective storage. See Appendix A for detailed cost estimates.

A. ADVANTAGES

1. The submarines would be easily retrievable.

B. DISADVANTAGES

1. The option only postpones the decision for permanent disposal, requiring the decision to be made at a future time.

2. Additional yearly costs of approximately $90,000 per year per ship would be involved for storage and retention at the inactive ship facility.

3. After approximately 20 years of waterborne storage, the ship would have to be placed in dry dock for inspection of the hull and necessary maintenance. Such re-docking would involve additional costs.

4. Additional occupational exposure to radiation would be required primarily to conduct radiation surveys during the storage period.

5. Security measures would be required to ensure that unauthorized persons do not have access to the ships.

6. Storage space at inactive ship facilities is limited. Based on projected decommissionings, pier space with sufficient water depth would become limiting by about 1990 without actions to dredge additional piers and repair piers. This would add appreciably to the cost of waterborne storage and the disposal of the dredged material would in itself be an environmental impact possibly requiring separate evaluation.

7. While initial cost is less, overall costs for future disposal will not decrease due to radioactive decay, since even after 100 years the reactor compartment would contain significant radioactivity (primarily Nickel-63 and Nickel-59) that would require permanent disposal.

IV. OTHER ALTERNATIVES THAT WERE ELIMINATED FROM CONSIDERATION

Land disposal and sea disposal, along with the "no action" alternative, are considered to cover all practical alternatives at the present time. Other approaches that may be feasible for certain radioactive waste disposal applications but are not considered practical in the present case are the following:

A. LAND DISPOSAL AT OTHER SITES

1. **Commercial Sites.** Land disposal of submarine reactor compartments at commercial radioactive waste burial sites would be unacceptable due to the classified nature of the waste package.

2. **Other Government Sites.** Burial of the reactor compartments at other Government-owned sites would not have any significant environmental benefit when compared to the two sites considered in detail since the environmental impacts are so small at those two sites. Other existing Government-owned burial sites have the significant disadvantage of lack of access by water transportation. Selecting and qualifying a new Government-owned site would involve unnecessary costs and duplication of effort.

B. LAND DISPOSAL OF SUBDIVIDED PORTIONS OF THE REACTOR PLANT

As described in Appendix B, "Land Disposal," three types of land disposal concepts were considered. As alternatives to land burial of the entire reactor compartment, the plant could be dismantled and the components could be either packaged in specially-built containers with concrete, or cut into pieces that could be packaged in steel drums with concrete. Of these three concepts, burial of the entire reactor compartment is preferred because no specialized facility would be required, costs would be less, and there would be less occupational exposure.

C. ABOVE-GROUND STORAGE OR DISPOSAL

Placement of the reactor compartments above ground in specially designed buildings or in an arid atmosphere was evaluated as an interim storage measure, and as a permanent disposal method.

As an interim measure, such storage would incur all of the impacts and costs associated with land disposal with no added benefit, since when buried, the thick submarine hull and bulkheads would remain intact for hundreds of years. This is much longer than typical storage buildings last.

As a permanent measure, long-term dry storage, whether above ground in an arid atmosphere or in a special building, has no real advantage over burial. Even assuming that the buried hull and reactor would corrode as rapidly as if they were in seawater, Table C-1 shows that only those nuclides with half-lives in the thousands of years are released to the ground in any appreciable fraction and only 80,000 year half-life Nickel-59 has more than 1 curie released over all time. Therefore, Nickel-59 is the only significant contributor to radiation exposure to people, as shown in Appendix C, Sections III and IV. Because of its long half-life, the radioactivity from Nickel-59 would be expected to be present long after any above-ground structures have deteriorated and vanished and after the hull and the reactor vessel and its contents have all turned to rust. Therefore, above-ground storage would still need to contend with exposure from Nickel-59 just as land burial would. These options would not constitute permanent disposal in compliance with current regulations since they do not permanently isolate the radioactivity from inadvertent contact with people, but they would incur all the environmental impacts associated with land burial, including those associated with worker exposure, transportation, and eventual deposition of radioactive material in the soil. In fact, placement above ground would increase the possible exposure because the radioactive material would end up on the surface where humans and foodstuff could be most directly affected.

In addition, the conservatively calculated estimated radiation exposure from land burial of 100 submarines, 0.006 mrem per year to an average individual, is so small in relation to the normal variation in background radiation levels that its effect on people is insignificant.

D. DISPOSAL BY TRANSMUTATION OR BY PUTTING WASTES TO BENEFICIAL USE

This "disposal by conversion" alternative is a future possibility for separated and concentrated solid forms of radioactive waste. Transmutation would generally involve extremely long-lived actinides, which would be subjected to neutrons (as in a reactor environment) and converted ("transmuted") to other radionuclides having shorter half-lives. As discussed in Chapter 1, Section I.A, no significant amounts of actinides are present in decommissioned and defueled nuclear propulsion plants. It should also be noted that the neutron environment required with this method would also activate some of the stable isotopes, thus defeating the purpose of the method.

The beneficial uses of radioactivity (such as Cobalt-60 used as a gamma-ray source in medical applications or food processing) would not apply to all isotopes and more economical sources of Cobalt-60 are available.

E. EXTRATERRESTRIAL DISPOSAL

This option may become attractive in the future for small volumes of highly concentrated waste. Decommissioned nuclear propulsion plant components are too massive for this to be practical. Also, an aborted launch might cause radioactive material to fall into an undesirable location.

F. LAND DISPOSAL OF THE ENTIRE SUBMARINE

Because of the excellent containment properties of the thick submarine hull, there could be incentive to dispose of the entire submarine on land, thus making available the otherwise unused volume of the ship for the disposal of other radioactive waste.

The movement of the entire submarine to the Hanford site is feasible. The submarine could be floated in the relatively shallow water of the Columbia River, landed at the terminal point of the river tow and transported overland to the disposal site. However, this would require a barge or flotation attached to the submarine hull capable of floating the entire ship in water of about 14 feet minimum depth; a dry dock for use in transferring the submarine to land transporters, and large, high-capacity transporters to move the submarine out of the dry dock and to the land disposal site. All of the necessary operations would be similar to the option of reactor compartment land burial, but on a much larger scale.

The environmental impacts from the burial of the whole decommissioned, defueled submarines would be similar to those for burial of only the reactor compartment. However, additional environmental impacts would occur as the result of construction of the large dry dock required and by the increased and inefficient use of land. Less than half the volume inside the submarine hulls could be used for other wastes because of difficult access to tanks and other spaces and interferences with piping, cables and machinery, meaning that at least twice as much burial ground space would be needed for this approach as for burial of the other waste in purpose-designed containers. This would represent extremely inefficient land use.

Therefore, while this would apparently represent an acceptable disposal method, it has not been pursued further in this statement.

V. PREFERRED ALTERNATIVE

Based on the research work performed in support of this effort, and review of the comments received as documented in the EIS, the Navy considers that permanent disposal can be performed in an environmentally safe manner. The highly conservative estimates used in the analyses of impacts have amply compensated for any uncertainties that may exist in man's knowledge relative to the impacts of permanent disposal.

Since the Navy began its evaluation of disposal options, several developments associated with possible ocean disposal of low-level radioactive waste have occurred. These include Congressional action in December 1982 restricting the issuance of ocean disposal permits and requiring Congressional approval before any such permit may be issued by the EPA. In addition, the EPA has indicated additional regulations may be required before EPA could evaluate a permit request. In view of these and other related uncertainties associated with national acceptance of the ocean disposal option, the Navy considers that allocation of additional funds to pursue this option further is not warranted. Even though the analysis shows less cost for ocean disposal than for land disposal, the funds required to qualify and gain acceptance of an ocean disposal site and the costs of continuing to maintain excessed submarines in storage until ocean disposal was allowed by the Congress and the EPA would serve to narrow the cost differential between the two options.

Based on a consideration of all current factors bearing on a disposal action of the kind contemplated, the Navy's preferred alternative at this time is to dispose of the reactor compartments by land burial. Land burial is the method currently used in the United States for disposal of low-level radioactive waste and this disposal action would comply with existing requirements for use of the Government burial grounds. This approach will allow permanent disposal of this form of low-level radioactive material to proceed with no unacceptable environmental impacts. With most of the submarines to be decommissioned on the West Coast of the United States, it is expected that the Government burial ground to be used in the near future will be the low-level radioactive waste disposal site at Hanford in Washington State.

CHAPTER 3

AFFECTED ENVIRONMENT

The affected environments for each of the two permanent disposal options are described in this chapter. For land disposal, two sites are under consideration: the Hanford Site in the state of Washington, and the Savannah River Plant in the state of South Carolina. For sea disposal, the sites can only be approximately characterized because (1) specific sites would have to be designated by the EPA and (2) applications for sea disposal permits to use the sites would also have to be approved by the EPA.

I. LAND DISPOSAL SITES

A. HANFORD SITE

The Hanford Site is located in the southeastern corner of the state of Washington, about 30 miles east of Yakima and 3 miles north of Richland. (See Figure 3-1.)

Hanford is a federal government site, operated by the U.S. Department of Energy, occupying 570 square miles (365,000 acres). The area designated as suitable for solid radioactive waste burial (Areas 200-W and 200-E in Figure 3-1) occupies over 1000 acres in the middle of the site in an isolated area on a plateau, about 7 miles from the Columbia River. A detailed description of the site, its geology and hydrology, and the associated plant and animal life is presented in the site's Final Environmental Statement on Waste Management Operations, Reference 3.1; therefore, only a brief summary is presented here. These burial grounds are currently being used, without adverse effect on the environment, for the disposal of solid radioactive wastes similar in isotopic content to those considered in this statement. A National Research Council study in 1976 on shallow land burial (Reference 3.2) included in its principal findings the conclusion that "no measurable harm to human health has resulted from the past and present practices in the land burial of solid low-level radioactive waste at the sites managed by the U.S. Atomic Energy Commission" (now the U.S. Department of Energy). A more recent (1978) study by the National Research Council, Reference 3.3, concludes, "that there has not been in the past, and is not at present, any significant radiation hazard to public health and safety from waste-management operations at Hanford." This includes the solid radioactive waste disposal operations.

The site is in the Pasco Basin, a semi-arid region in the rain shadow of the Cascade Range. Average annual precipitation is 6.25 inches, about 45 percent of which occurs during the months of December through February in the form of snow. Under the burial area, the groundwater table is 150 to 300 feet below the surface. Precipitation does not percolate to the water table, hence radioactive contamination remains immobilized in soil between the ground surface and the water table since there is no means for transporting the material out of the dry sand-gravel soil.

The eastern part of Washington, including the Hanford Site, is classified by the U.S. Coast and Geodetic Survey as being in Seismic Zone 2. This implies a potential for moderate damage from earthquakes, but underlying sands and gravels provide excellent protection from damage.

Tornadoes are relatively rare in this region and tend to be small with little damage when they do occur. Data analyzed to determine the probability of a tornado hitting a particular facility on this site yielded the estimate that the probability during a year is six chances in one million.

The Columbia River flows through the northern edge of the Hanford Site and forms part of the eastern boundary of the reservation. Farms near the site generally depend on water from the Columbia or Yakima River for irrigation. The long-term annual average flow of the Columbia River at Hanford is about 120,000 cubic feet per second (cfs) while the minimum flow is 36,000 cfs. The estimated population within 50 miles of the waste management area was approximately 246,000 persons based on 1970 census data (Reference 3.1). Based on current regional increase rates of about 2 percent per year (Reference 3.13), the population within 50 miles would be approximately 310,000 in 1982. Population downstream served by the Columbia River as a water source is estimated to be several hundred thousand persons. In the public radiation exposure estimates of Appendix C, it is conservatively assumed that any radioactive material released from the burial site would be transported via groundwater and streams to the Columbia River without delay, and that the water available to the downstream users would be an exposure pathway, along with fish taken from the river and food grown on irrigated land. This assumption is extremely conservative for the Hanford Site since: 1) there has been shown to be no water moving through the solid waste burial ground to groundwater because of the minimal rainfall and the distance to the groundwater; 2) due to the lack of water, no movement of radionuclides from the solid waste burial ground has been observed; and 3) migration via groundwater to the Columbia River would be substantially delayed due to chemical interaction between the radionuclides and the soil. Maximum-exposed individuals are assumed to obtain all water from local wells or streams and all food from locations close to the disposal Site. When these assumptions are applied, as shown in Appendix C, the diluting flow is assumed to be that of the Savannah River (7500 cfs) rather than that of the Columbia River (36,000 cfs). Hence, individual exposures that are estimated for the land disposal option have an additional large factor of conservatism when applied to burials at the Hanford Site.

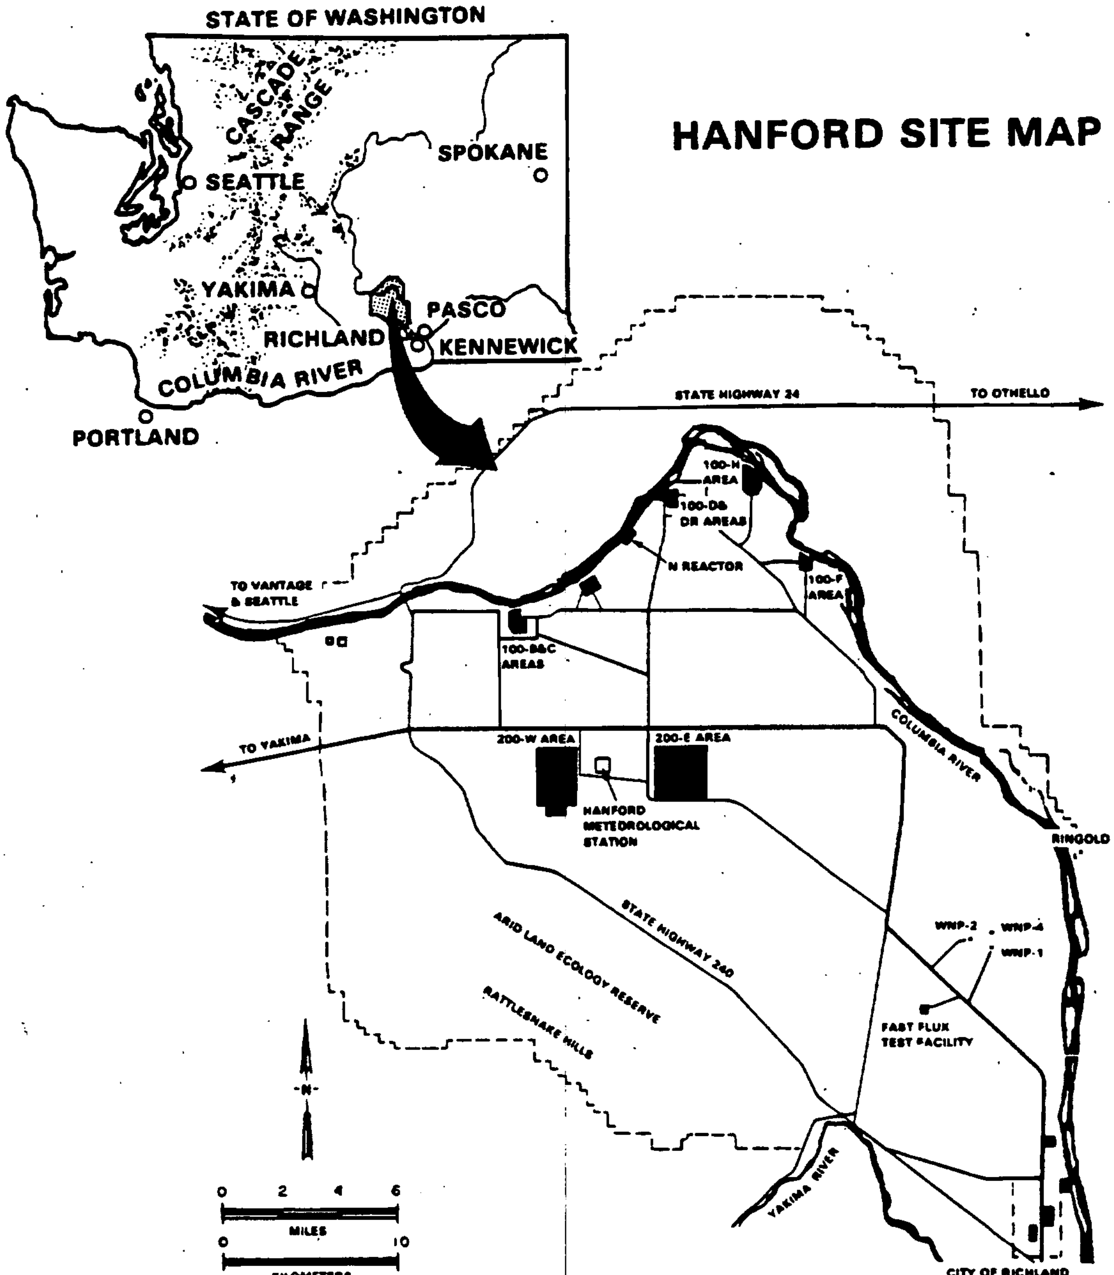

Figure 3-1. Hanford Site Map

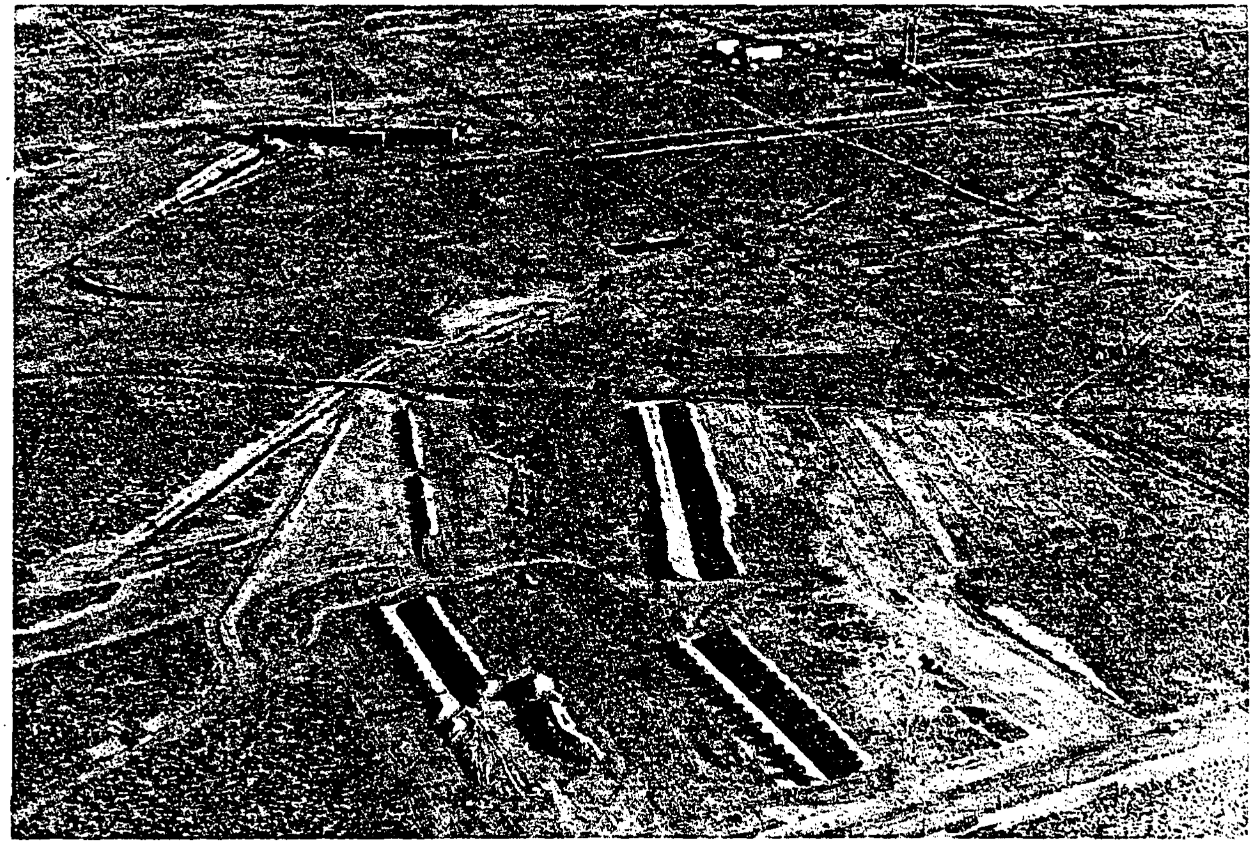

Figure 3-2. Aerial Photograph of Hanford Burial Ground (200-W Area)

The burial site is currently used for the disposal of low-level radioactive waste such as contaminated clothing, rags, and tools contained in 55 gallon drums, as well as activated metal reactor components buried within their shipping containers. No changes to the current use or procedures would be needed. The site maintains an active monitoring program that provides the basis for current population dose estimates. These estimated doses are only a small fraction of natural background.

Additional data on the physical characteristics and environmental monitoring program at the Hanford Site are included in Appendix B, "Land Disposal". Extensive information on the Site is available in Reference 3.1.

B. SAVANNAH RIVER PLANT

The Savannah River Plant is located on the Savannah River in South Carolina, approximately 25 miles southeast of Augusta, Georgia. (See Figure 3-3.) The plant is a Department of Energy site, occupying 300 square miles (192,000 acres). Approximately 195 acres (near the center of the site, about 7 miles from the Savannah River) are used for the burial of solid radioactive waste. (See Figure 3-4.) A detailed description of the site, its geology and hydrology, and the associated plant and animal life is presented in the site's Final Environmental Impact Statement on Waste Management Operations, Reference 3.4; therefore, only a brief summary is presented here. Solid radioactive wastes similar to isotopic content to those considered in this statement are currently being disposed of at the Savannah River burial ground. As noted in the description of the Hanford Site, the National Research Council has concluded that no measurable harm has resulted from past and present practices in these disposal operations.

The site is near the inner western edge of the Atlantic Coast Plain at about 500 feet above mean sea level, in an area protected by the Blue Ridge Mountains from the more vigorous winters prevailing in the Tennessee Valley. Average annual precipitation is 47 inches; snowfall and freezing rain are infrequent.

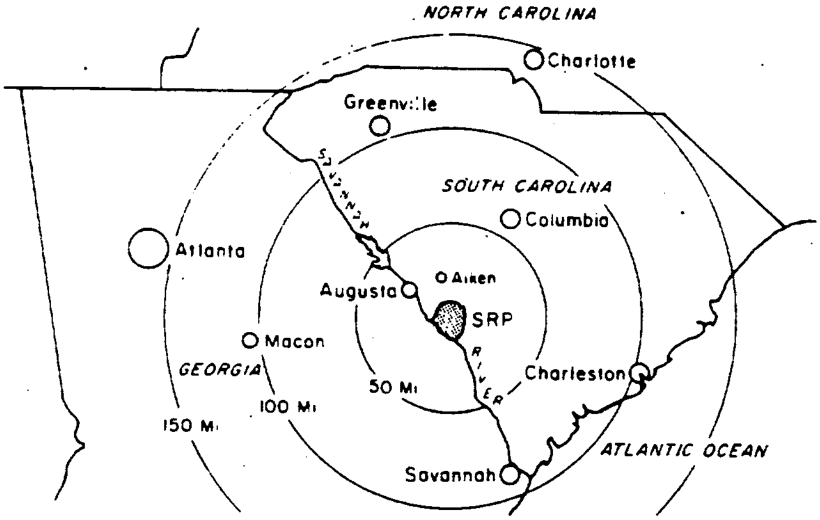

Figure 3-3. Location of Savannah River Plant (SRP) in South Carolina

Under the burial area, the groundwater table is 40 to 45 feet below the surface. No flowing streams cross the burial area. Surface runoff is through drainage ditches. Underlying sediments consist of sandy clay and clay beds with a predominance of sandy clays. Almost all of the plant site, including the burial site, is eventually drained by tributaries of the Savannah River. Each of the tributaries is fed by small streams, and no location on the site is very far from continuously flowing streams. The yearly average flow of the Savannah River in the vicinity of the plant is 10,420 cfs with a minimum yearly flow of 7500 cfs. The 7-day, 10 year low flow is calculated to be 5600 cfs.

The Savannah River Plant is located in Seismic Zone 2, where moderate damage might occur from earthquakes, according to the U.S. Coast and Geodetic Survey.

The plant is in an area where occasional tornadoes are to be expected. During the history of the plant, there has been no tornado damage to any production or support facility; however, there have been several unconfirmed sightings of tornadoes in unpopulated areas.

The estimated population within 50 miles of the center of the plant was approximately 460,000 people, based on 1970 census data (Reference 3.4). Based on current regional increase rates of 1.5 percent per year, (Reference 3.13), the population within 50 miles would be approximately 550,000 in 1982. Population downstream currently served by the Savannah River as a water source was estimated (Reference 3.4) to be 70,000 persons, although as described in Appendix C, a user population in the far-distant future of 350,000 persons was assumed for the purpose of estimating a general land disposal site population exposure. It is conservatively assumed in the exposure estimates of Appendix C that any radioactive material released from the burial site would be transported via groundwater and streams to the Savannah River without delay, and that the water available to the downstream users would be an exposure pathway, along with fish taken from the river and food grown on irrigated land. Maximum-exposed individuals are assumed to obtain all water from local wells or streams and all food from locations close to the disposal site.

The burial site is currently used in a way similar to that described above for the Hanford Site and no changes to present usage or procedures would be necessary. However, as described in Chapter 4, Section I.A.1, "Effect on Land Use," the 195 acre burial area is projected to be filled in the year 1994, and additional area would have to be designated if reactor compartment disposals are to be carried out at the Savannah River site beyond 1994. The Savannah River Plant also has an extensive environmental monitoring program with monitoring results reported on an annual basis.

Additional data on the physical characteristics and environmental monitoring program at the Savannah River Plant are included in Appendix B, "Land Disposal". Extensive information on the site is available in Reference 3.4.

C. OTHER SITES THAT WERE CONSIDERED FOR LAND DISPOSAL

As described in Appendix B, "Land Disposal", all Department of Energy land disposal sites have been considered for reactor compartment burial. However, all except the Hanford and Savannah River sites were eliminated from consideration after an initial assessment.

The potential site at Oak Ridge Reservation, Tennessee is considered impractical because of its shallow water table (14 feet from the surface) and because of the great distance required for transport from the ocean. The potential sites at the Idaho National Engineering Laboratories and the Los Alamos Scientific Laboratory in New Mexico are considered impractical because of the lack of suitable rivers for barge transportation.

II. OCEAN STUDY AREAS

Sea disposal sites have not been selected because a decision to pursue the sea disposal option has not as yet been made. The areas described in this section are only representative of the kinds of locations and the associated characteristics which would meet IAEA criteria. Such area descriptions have been included to provide the basis for determining the likely consequences of sea disposal if that option were to be selected.

At the present time three general areas have been identified for study purposes. These areas have been used in this statement for the purpose of estimating any possible adverse environmental effects associated with sea disposal since they appear to be as limiting as any that might be chosen in light of existing international rules for such sites.

The Atlantic areas are identified on Figure 3-5. The center of one study area, the Lower Continental Rise Area, is approximately 220 nautical miles east of Cape Hatteras, North Carolina. The center of a second Atlantic study area is approximately 280 nautical miles southeast of Cape Hatteras, in the Hatteras Abyssal Plain. The Pacific area is identified on Figure 3-6. Its center is approximately 160 nautical miles west of Cape Mendocino, California. All three of these study areas are much larger than would be required for a site for sea disposal of nuclear submarines.

Each of the three general areas is described in the background material supplied as Appendix E, "Description of Ocean Study Areas". The characteristics of each area are consistent with the particular "area identification criteria" that are explained below.

A. STUDY AREA IDENTIFICATION CRITERIA

In identifying the marine areas to be utilized for studying the possible effects in the event that sea disposal were implemented, consideration is given to the safety of man and his environment, national security, and economic matters. Study area identification criteria have been developed based primarily on the requirements of the International Atomic Energy Agency (Reference 3.5), as reproduced below:

"C.2. Requirements for Selection of a Dumping Site

C.2.1. In addition to the factors specified in Annex III to the Convention*, the following requirements shall be met by the appropriate national authorities in the selection of a site for the dumping of packaged waste:

(1) The chance of recovering the waste by processes such as trawling shall be minimized;

(2) Dumping shall be restricted to those areas of the oceans between latitudes 50°N and 50°S. The area shall have an average water depth greater than 4000 metres. Recognizing that variations in sea-bed topography do exist, this restriction should not be interpreted to exclude these sites within which there are localized areas with water depths of 3600 metres;

(3) Sites should be located clear of continental-margins and open sea islands, and not in marginal or inland seas. Nor should they be situated in known areas of natural phenomena, for example volcanic activity, that would make the site unsuitable for dumping;

(4) The area must be free from known undersea cables currently in use;

(5) Areas shall be avoided that have potential sea-bed resources which may be exploited either directly by mining or by the harvest of marine products, or indirectly (e.g., spawning) as feeding grounds for marine organisms important to man;

*See page 3-9.

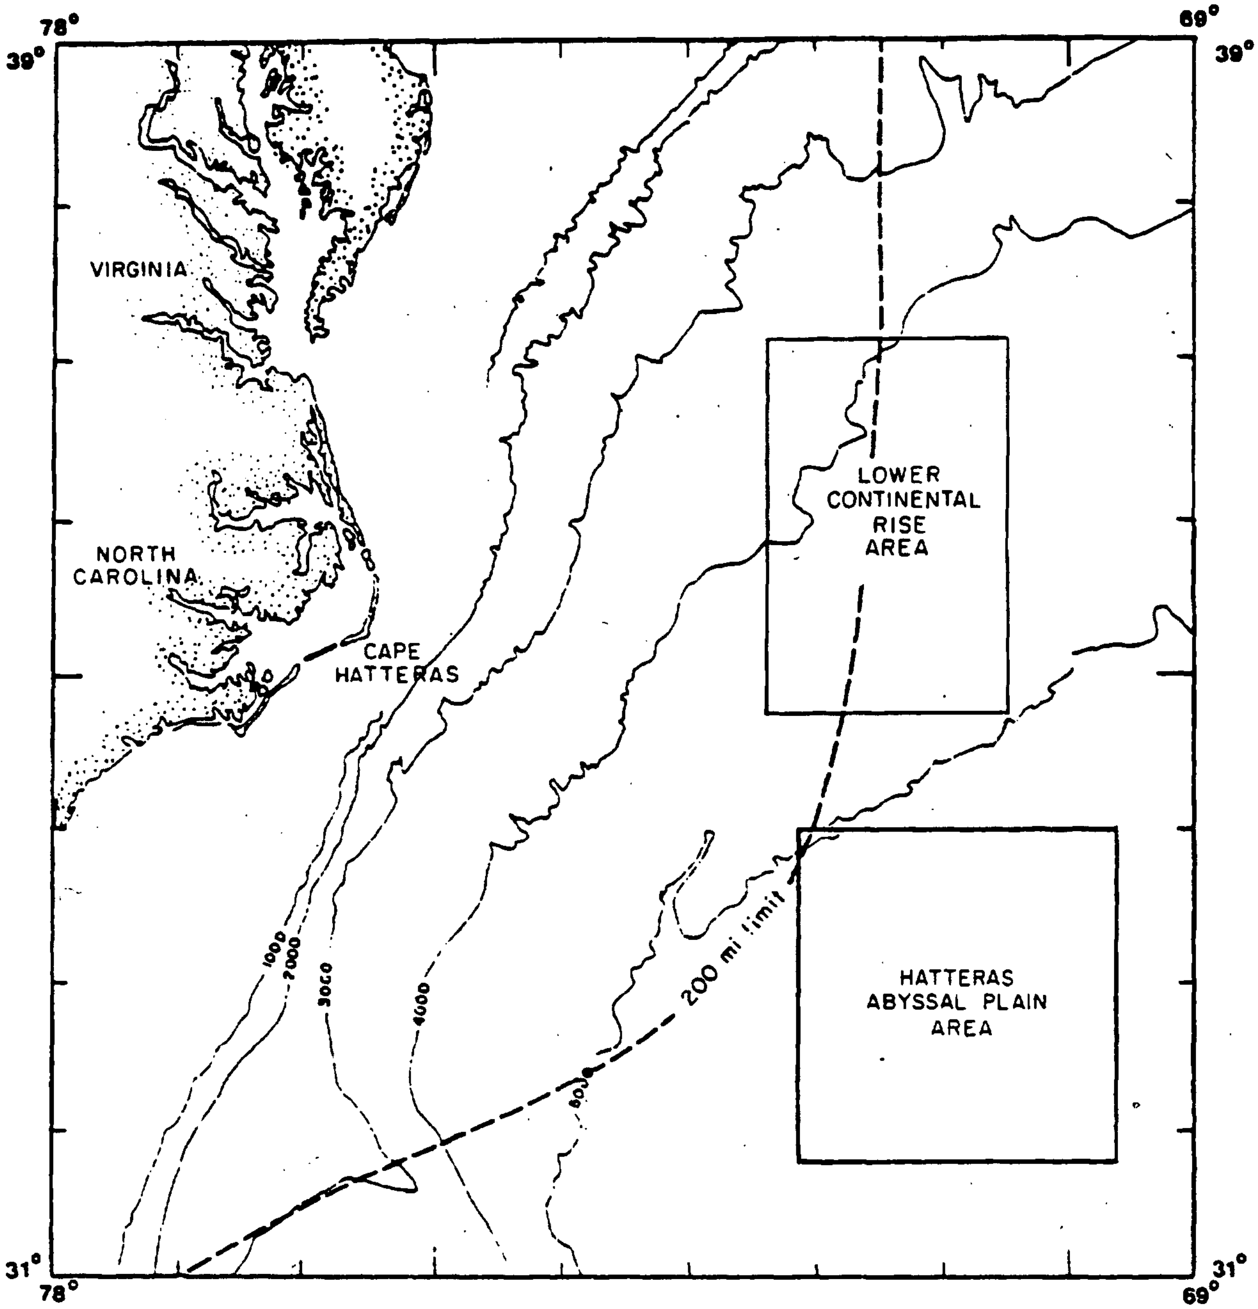

Figure 3-5. Atlantic Study Areas (Depth contours in meters)

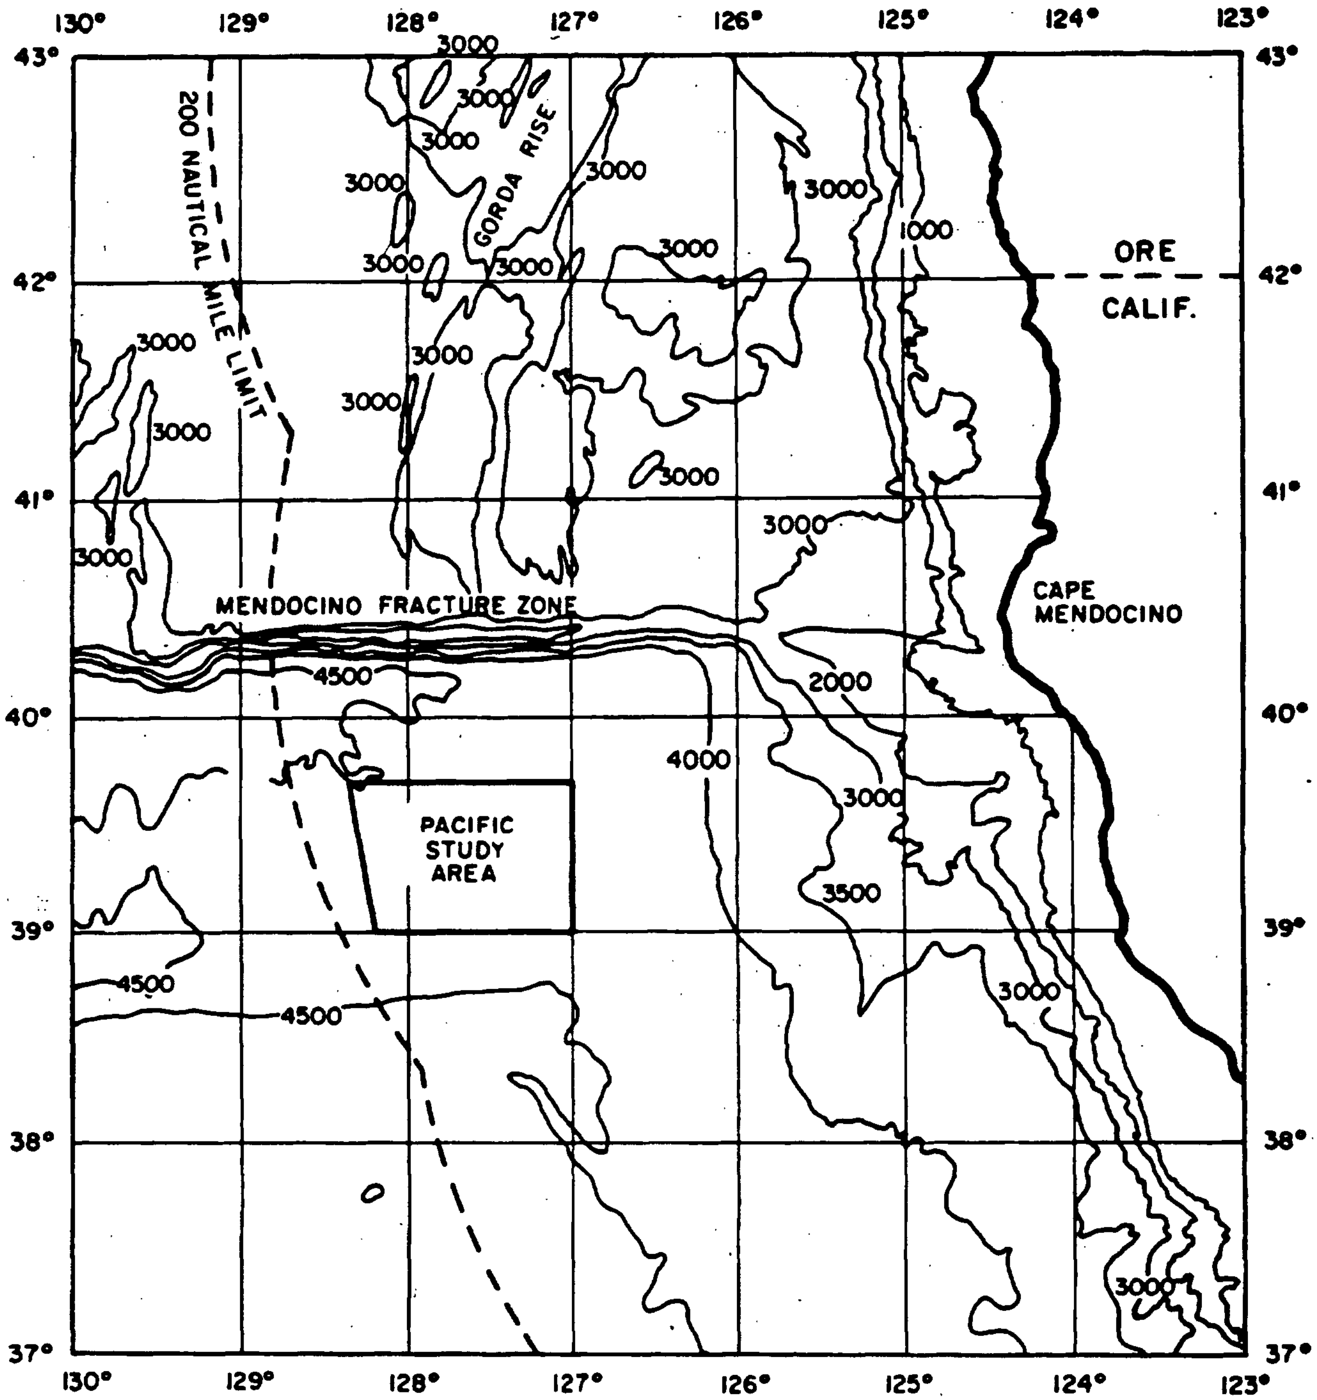

Figure 3-6. Pacific Study Area (Depth contours in meters)

(6) The number of dumping sites shall be strictly limited; and

(7) The area must be suitable for the convenient conduct of the dumping operation and so far as possible shall be chosen to avoid the risk of collision with other traffic during manoeuvring and undue navigational difficulties. The area chosen should preferably be one covered by electronic navigational aids.

C.2.2. The dumping site shall be defined by precise co-ordinates. In order to ensure a reasonable operational flexibility, it should have an area as small as practicable, but no larger than 10^4 square kilometres."

Annex III of the 1972 London Convention also lists general provisions to be considered in establishing the criteria to govern the issuance of sea disposal permits. Those provisions pertinent to site selection are as follows:

1. Depth and distance from the coast.

2. Location in relation to other areas, e.g., amenity areas, spawning, nursery and fishing areas, and exploitable resources.

3. Effects of currents, tides, and wind.

4. Water characteristics, e.g., temperature, pH, salinity, stratification, and chemical properties.

5. Bottom characteristics, including biological productivity.

6. Effects of other dumpings which may have been made in the area.

7. Possible effects of disposal on amenities, e.g., appearance of the water and its odor.

8. Possible effects on marine life, its culture, and harvesting.

9. Possible effects on other uses of the sea.

These IAEA requirements are self-explanatory in most cases. The 50° north and south latitude requirement is designed to avoid the sources of bottom water and the high biological productivity of the polar regions, and to avoid areas where debris may be deposited by ice-rafting, while the 4000 meter depth requirement is derived from the fact that biological, chemical, physical, and topographical changes generally diminish below 4000 meters and bottom water circulation is slower. Such depths are well below those penetrated by commercial fishing activity and are beyond the effects of major surface currents. Continental margins are excluded to avoid regions of high biological productivity, increased likelihood of resource exploitation, and the greater unpredictability and instability associated with the continental slope, rise, and associated alluvial fans.

The IAEA requirements were expanded in developing study area selection criteria by consultants from the Woods Hole Oceanographic Institution and the Oregon State University School of Oceanography (Reference 3.7). The added criteria are as follows:

1. Sites should be away from areas, such as submarine canyons, which have a high rate of exchange of the deep waters with surface layers of any adjacent continental shelf. This criterion is intended to avoid shortening of pathways to man, and is cited in Reference 3.5 as a factor to be considered, although it is not an IAEA requirement.

2. Bottom current shear stress should not exceed critical erosional shear stress. This is desired to prevent high rates of resuspension of sediments at the site, therefore preventing rapid movement of material.

3. Sites should be away from areas of intense mesoscale eddy activity. This is intended to avoid areas of enhanced eddy diffusivity which could shorten pathways to man.

A final factor that has been considered in identifying study areas is that they be within the 200 nautical mile Economic Control Zone boundary of the United States. Since such areas might be more desirable than areas that are well beyond the Economic Control Zone, it was felt that the study areas should represent the feasible locations closest to coastal regions. This would be expected to yield larger estimates of impacts on man than sites more distant from shore. Sites beyond 200 miles should not necessarily be excluded when determining an appropriate site for sea disposal. For example, the current Northeast Atlantic disposal site used by several European nations is well beyond 200 miles of any coast.

B. ATLANTIC STUDY AREAS (See Figure 3-5)

The first Atlantic study area (designated as the Lower Continental Rise Area) is situated east of Cape Hatteras, North Carolina, centered near 36° north, 71.5° west, approximately 220 nautical miles (410 kilometers) from the closest land point.

The second Atlantic study area (designated as the Hatteras Abyssal Plain Area) is situated southeast of Cape Hatteras, centered near 33° north, 71° west, approximately 280 nautical miles (520 kilometers) from the closest land point.

The depth in the study areas is approximately 4000 meters or 13,100 feet at the center of the Lower Continental Rise Area, and approximately 5000 meters or 16,400 feet at the center of the Hatteras Abyssal Plain Area. The ocean bottom is flat, having a slope of about 3 feet per 1000 feet at the Lower Continental Rise Area, and 1 foot per 1000 feet at the Hatteras Abyssal Plain Area. Sub-bottom profiles and precision echograms are available for enough of the general area to indicate that either of the study areas would probably satisfy disposal site selection criteria. However, additional field work and evaluation would be required to verify that a suitable location within the general area would meet all selection criteria.

Sediment deposition in the region of the two study areas occurs largely as a result of the seaward movement of material washed away from the land and deposited on the abyssal plain. Average depositional rates are approximately 8.5 centimeters per 1000 years. The sediment is composed of clay, silt, and sand deposits and sediment thickness is about 3.0 kilometers in the Lower Continental Rise Area, and about 1.5 kilometers in the Hatteras Abyssal Plain Area (Reference 3.6).

No recorded or known earthquakes were centered within the region of the two study areas, and the likelihood of future earthquakes is small. The closest active volcanoes are located in the Lesser Antilles Islands, about 900 miles to the southeast. It is highly improbable that the area would be affected directly or indirectly by a volcano.

The Gulf Stream moves roughly from southwest to northeast in this area. The Western Boundary Under-Current flows southward in this general area with the major portion of the current in depths greater than about 3500 meters but does not extend to the areas that would be typical of potential disposal sites. Bottom waters in the area tend to move slowly toward the northeast. An accurate measurement of bottom currents is underway, and preliminary results show that bottom water movement in the Hatteras Abyssal Plain area is moderate (approximately 8 centimeters per second mean net current velocity) with a direction to the northeast. The Hatteras Abyssal Plain study area does not appear to have been swept by strong bottom currents, although the possibility of intermittent turbidity currents is being studied. (Turbidity currents are a phenomenon natural to abyssal plains, where landslides from the continental slope and upper continental rise cause occasional seaward silt-laden currents of up to 50 knots or 93 kilometers per hour.) Portions of the Lower Continental Rise study area may have strong bottom currents, although a tranquil location may exist within this area and also within the 200 mile economic zone.

Some animal life is present on the sea floor in the study areas with low population density. None of the life forms are known to be used by man or are known to be a part of the food chain leading to man. No commercially exploited minerals are present on the sea floor in the Hatteras Abyssal Plain study area. However, the Lower Continental Rise study area lies adjacent to a recently mapped region that shows potential hydrocarbon resources (Reference 3.14). The waters in this general area are not exploited commercially and one of the bases for its selection was the likelihood that it will never attract commercial or other interest.

No undersea cables are known to pass through the Hatteras Abyssal Plain study area. One working telephone cable crosses the northeastern corner of the Lower Continental Rise Area but does not cross the subregion identified for further study (Appendix E, Section IV.B.1). None of these study areas is crossed by any major shipping lanes.

See Appendix E for a more detailed description of the Atlantic study areas.

C. PACIFIC STUDY AREA (See Figure 3-6)

The center of the Pacific study area is approximately 160 nautical miles (300 kilometers) west of Cape Mendocino, California, at 39° 20' north, 127° 40' west. The site characteristics, condensed from References 3.8 through 3.12, and from Appendix E, are as follows.

The area is beyond the continental margin, with depths varying from 4100 to 4500 meters (13,500 to 14,800 feet). The terrain is gently rolling with broad irregularities; the average slope in the center of the area is about 1 foot per 300 feet. Details of the sea floor characteristics have been obtained with sufficient detail to indicate that the area would probably satisfy the established selection criteria. As noted above for the Atlantic study areas, however, additional field work and evaluation would be required to verify that a suitable site within the general area would meet all selection criteria.

Sediment deposits in the area are in the form of silty clay with an average thickness of about 300 meters. The deposits probably result from particle settling from the water column rather than from bottom currents. Core samples indicate that the area has been stable for millions of years.

No recorded earthquakes were centered within the area, and the likelihood of future earthquakes is small. The general area is at least 40 miles south of the seismically active Mendocino Fracture Zone. On-site seismometer data may be of value to assess accelerations of the sea floor due to distant earthquakes. No seamounts or evidence of volcanic activity within the past million years are known to exist in the area.

Bottom water current measurements indicate that the water movement is slow with similar movement throughout at least the bottom 1250 meters, with a general overall direction toward the south-southeast or south-southwest and an average speed of about 1.0 kilometer per day. Surface velocities average less than 1/2 knot (approximately 1 kilometer per hour) and the direction of the current tends from the east (southeast to northeast).

The biology of the deep waters and the sea floor, which are not exploited commercially, has been studied to a limited extent, primarily by capturing specimens of fish and bottom-dwelling animals through bottom trawling and secondarily by analysis of the results of bottom photography. Both techniques indicate that the population density is low, relative to near-shore areas, with none of the sea life known to be used by man or known to be part of the food chain leading to man. The surface effects of burrowing animals have been visible in the examinations of core samples taken from the area. Commercial fishing has been carried out in surface waters in this area, which is on the outer fringe of the general fishing area. The estimated average annual fish catch (albacore) in this fringe area is low, being only 0.5 percent of the estimated average annual catch in the peak productivity area west of Cape Mendocino (see Appendix E, Figure E-20). No commercially exploited minerals are present on the sea floor (Reference 3.14).

There are no known undersea cables that pass through the area, and the area is well clear of major U.S. shipping routes.

See Appendix E for a more detailed description of the Pacific study area.

D. CHARACTERISTICS OF THE STUDY AREAS RELATED TO MODELING ENVIRONMENTAL EFFECTS

All of the existing data on the Atlantic and Pacific study areas described above indicate that it is likely that acceptable sites can be identified which meet IAEA criteria.

The information from the study areas has been used to model environmental effects of the sea disposal option. For example, dissolved oxygen concentrations, temperature data, and chemical properties of the sediment have been considered in selecting appropriately conservative corrosion rates for the metal components that would be placed on the sea floor. Sediment depth and physical properties (shear strength) have been considered in determining upper limits on the likely bottom impact resulting from free fall of the submarine. Bottom current speed and direction have been taken into account in modeling potential transport of radioactive material away from the disposal site by advection and diffusive processes.

The general locations of the study areas have been taken into consideration in selecting exposure pathways, seafood consumption rates, and the size of potentially exposed populations since it is expected that sites meeting the IAEA criteria would be no closer to man's activities. Available knowledge of the bottom-dwelling life in the study areas has been employed with the result that no exposure pathway to man has been identified, that is, beginning with bottom-dwelling animals and proceeding along a chain of predators to an end point resulting in human consumption of fish containing radioactive contamination. However, such pathways have been included in radiation exposure calculations, even if they are only hypothetical, to assure that no unforeseen pathway could cause an underestimate of environmental impacts.

The approach used in modeling the environmental impact of sea disposal has been two-fold. A best estimate of the radiation exposure is based on realistic values of the physical parameters at each step, and a conservative estimate of the radiation exposure is based on values of the physical parameters that are selected to provide an estimate that is conservatively high under actual conditions.

CHAPTER 4

ENVIRONMENTAL CONSEQUENCES

This chapter describes the potential environmental consequences resulting from the permanent disposal of approximately 100 defueled and decommissioned submarine reactor plants. The two practical permanent disposal options are (1) land disposal by burial of the submarine's reactor compartment at existing Department of Energy waste disposal sites and (2) sea disposal of the submarine at a site approved by the Environmental Protection Agency. Each option is discussed in a separate section. The effects of the "No Action Alternative" (an indefinite period of protective storage prior to either of the permanent options) are discussed in a third section. A final section provides a summary and conclusions.

I. LAND DISPOSAL OPTION

A. ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED SHOULD THE LAND DISPOSAL OPTION BE IMPLEMENTED

1. Effect on Land Use

Land disposal of the reactor compartments from all of the approximately 100 submarines considered in this statement would require an area of less than ten acres that would be indefinitely removed from unrestricted use. A ten acre area is 435,600 square feet, or about 3 1/2 times the total reactor compartment cross-section area of approximately 125,000 square feet that would actually be occupied by the buried compartments. It represents a small fraction of the land area of the Hanford Site (365,000 acres) or the Savannah River Plant (192,000 acres). The land that would be used is already part of low level waste disposal sites, which occupy over 1000 acres at the Hanford Site and about 195 acres at the Savannah River Plant.

The usable designated area available for low level waste burial at the Hanford Site appears to be adequate for all foreseeable operations. The usable designated area at the Savannah River Plant is currently approximately 55 to 60 acres. Department of Energy Nuclear Waste Management Program estimates (Reference 4.24) show that the Savannah River Plant capacity will be filled in 1994, based on an average use rate of about 4.5 to 5 acres per year. The effect of adding three reactor compartments per year (0.3 acre per year) to the total disposal rate would result in the existing burial area being filled approximately half a year earlier than the current estimate. At that time, another burial site would have to be designated either at Savannah River or elsewhere for both the remaining reactor compartments and the routine Savannah River radioactive solid waste.

For the construction of a river landing slip and barge unloading facilities at the Savannah River Plant, an additional area of approximately two acres would be temporarily withdrawn from use. No additional land would be required at the Hanford Site because such facilities are already available.

From the foregoing discussion, it is concluded that the land use impact of the land disposal option would be negligible.

2. Radiological Effects

(a) **Direct Radiation.** Direct radiation effects would be almost entirely occupational exposures (see Sections I.A.2.(c)(1) and (c)(2) below). The possible sources of direct radiation exposure to members of the general public would be the minimal exposure associated with normal transportation of the disposal package (less than 10^{-3} man-rem population exposure as described in Section I.A.2.(c)(3)), and the remote possibility of exposure resulting from an extreme transportation accident (see Section B.1.(a) below). Direct radiation levels at the disposal site would be less than 0.1 mrem per hour because of the low radiation levels that would normally exist on the compartment exterior, and the shielding effect of the earth cover.

(b) **Radioactive Material Release Due to Corrosion of Metals.** Although the number of curies of radioactivity in the decommissioned reactor plant could be substantial at the time of burial (Chapter 1,

Table 1-1), the actual release into the disposal site ground would be small because of the multiple containment of the radioactive material and the short radioactive decay half-lives of the nuclides making up the majority of the material. The thickness and durability of the containment barriers, combined with the fact that the radioactive material is almost entirely an integral part of the metal components, lead to the conclusion that all but the longest lived radionuclides (principally Nickel-59 with a half-life of 80,000 years) will have decayed to stable form before any release can occur.

A conservative estimate of the possible release of radioactive material has been developed in Appendix C, based on the conservative assumptions that the ground area in the vicinity of the buried compartment would be continuously wet and that sufficient water flow would be available to carry any corrosion products away from the burial site to a river which is a major source of water. The exterior containment would remain intact for at least 200 years, an estimate based on the minimum bulkhead thickness (one-half inch walls) and an average annual corrosion rate of 0.0025 inch for low alloy steel. Following an eventual penetration of the exterior containment, which would thereafter allow water into the reactor compartment, the reactor vessel would remain intact for an additional period of several thousand years. The structures within the reactor vessel would then be subject to corrosion release, with Nickel-59 being the only radioactive nuclide remaining in significant curie quantity.

The subsequent annual release rate of the Nickel-59 is estimated to be no greater than 0.057 curie for each reactor compartment, based on an average annual corrosion rate of 0.0003 inch per exposed surface for corrosion-resistant alloy (both surfaces of components within the reactor vessel are assumed to be exposed). Total Nickel-59 release to the burial site over all time would eventually be about 120 curies per reactor compartment. The maximum annual releases of all nuclides, and the corresponding releases over all time, are shown in Table 4-1 below. This approach is conservative for the estimate of radioactivity release at the Savannah River burial site, and even more conservative for the Hanford burial site where it is likely that the reactor compartments would remain dry for an indefinitely long period of time because of the low annual precipitation (6.25 inches per year) and the fact that the groundwater table is at least 150 feet below the surface. The effects would be further mitigated by the sorptive property of the soil which slows down the migration of the released radioactive material.

The release of radioactive material into the burial ground that could eventually occur compares favorably with what is expected using current practices. The principal difference with the buried reactor compartments would be the considerably longer-lasting containment relative to most low-level burial packages.

(c) **Radiation Exposure**

(1) **Exposure to Shipyard Personnel.** The total radiation dose to shipyard workers during preparations for the disposal action would be approximately 17 man-rem for each submarine reactor compartment processed for disposal under this option. This exposure would be to individual workers who are trained for radiation-related work. Each worker's exposure would not exceed established limits (3 rem per quarter and 5 rem per year to the total body). The exposure would be a consequence of the necessary tasks carried out in the gamma radiation field of the reactor compartment, such as removing salvageable components and draining reactor plant systems. The total occupational exposure associated with protective storage for 20 years followed by land disposal is estimated to be approximately 20 man-rem, as discussed in Section III.A.1. Additional information on occupational exposure is provided in Appendix A, Section III.D.1.

(2) **Exposure to Personnel Involved in Movement to Disposal Sites and Burial Operations.** The total radiation exposure to personnel involved in moving the reactor compartment from the shipyard to the burial site is estimated to be less than 1.0 man-rem, involving external exposure only. The estimate is based on approximately 600 man-hours of work actually in close proximity to the compartment, during which the average exposure rate would be approximately 1.5 mrem per hour. This exposure would not be to members of the general population but to workers whose exposure is monitored and controlled.

(3) **Exposure to the Public from Transportation of Reactor Compartments.** The radiation exposure to the public that might result from transportation of a reactor compartment from the shipyard to land

TABLE 4-1. RADIOACTIVE MATERIAL RELEASED TO THE DISPOSAL SITE RESULTING FROM LAND DISPOSAL OF ONE REACTOR COMPARTMENT

Nuclide	Maximum Release In Any Year (Curies per Year)	Approximate Time at Which Maximum Occurs (Years After Disposal)	Total Release Over All Time (Curies)
Ni-59	0.057	2800	120
C-14	0.0004	2800	0.6
Ni-63	0.0026	200	0.25
Nb-94	3.9×10^{-5}	2800	0.07
Mo-93	5.1×10^{-6}	200	0.0083
Tc-99	1.6×10^{-6}	200	0.0036
Fe-55	1.4×10^{-4}	1*	6.3×10^{-4}
Co-60	2.2×10^{-5}	1*	1.7×10^{-4}
Mn-54	3.2×10^{-6}	1*	5.7×10^{-6}
Co-58	1.8×10^{-7}	1*	1.8×10^{-7}
Fe-59	7.9×10^{-8}	1*	7.9×10^{-8}
Cr-51	2.8×10^{-8}	1*	2.8×10^{-8}
S-35	5.8×10^{-10}	1*	5.8×10^{-10}
Sc-46	6.4×10^{-11}	1*	6.4×10^{-11}

Corrosion rates: Low-alloy steel: 0.0025 inch per year per exposed surface
Corrosion resistant alloy: 0.0003 inch per year per exposed surface

*These early releases result from the radioactive material contained in the metal of the exterior boundary (hull and bulkheads), and the assumption that the activity is uniformly distributed in the metal.

disposal sites is estimated to be less than 10^{-3} man-rem (see Section IX of Appendix C). This estimate was developed by applying the estimating techniques contained in Reference 4.1, supplemented by Reference 4.2. The latter document describes the shipment by barge of a commercial nuclear plant steam generator that was similar to the shipment by barge of a submarine reactor compartment. The low radiation exposure expected from transportation of reactor compartments is consistent with the judgment expressed in Reference 4.1 that the population exposure associated with transport by barge is expected to be negligible. (See Section B.1 for a discussion of the consequences of a hypothetical accident during the transportation of a reactor compartment.)

(4) **Exposure to the Public from Release of Radioactive Material.** Exposures to the public resulting from the radiological waste disposal programs at the Hanford and Savannah River sites have been shown to be small fractions of natural background exposures. The maximum potential dose to an individual from effluents released at Hanford in 1972 was estimated to be 0.6 mrem/yr (Reference 4.3, page I-3). For effluents from the Savannah River Plant in 1975, the calculated whole-body dose to a hypothetical individual who resided at the plant boundary and consumed river water and 0.5 lb. of river fish per week was

1.2 mrem (Reference 4.4, page I-1). Doses to average individuals were much smaller than these maximum estimates. Depending to some extent on the population over which the average is determined, the average dose rate varied from 0.01 mrem per year in 1972 within 50 miles of the Hanford Site (Reference 4.3, page I-3), to 0.22 mrem per year in 1975 to the water-consuming population downstream of the Savannah River Plant (Reference 4.4, page I-1).

Exposures at Hanford or Savannah River as a result of the burial of defueled, decommissioned submarine reactor plants would similarly be very small. The reactor compartment would provide excellent containment, exceeding current requirements for such material, and the reactor plant would provide an additional level of containment of similar quality.

As described in Section I.A.2.(b) above and with additional details in Appendix C, radioactive material release from the buried reactor compartments would be small and most releases would be delayed for centuries. Assuming that all 100 reactor compartments were at the same disposal site, the average annual whole body exposure* to an individual would be approximately 0.006 mrem per year of exposure, or approximately 0.006 percent of natural background. This exposure would occur several thousand years after burial. The corresponding population dose commitment would be 2.1 man-rem to the total body per year of exposure, based on an assumed population at the time of exposure of 350,000 persons. The maximum number of health effects (cancers) predicted for this year of highest exposure would be about 0.001, calculated using the conservative linear relationship of 0.00045 additional cases of cancer in a population for each man-rem (Reference 4.15).

A maximum individual whole body exposure of 1.5 mrem per year has also been estimated for the period beginning several thousand years after burial, an exposure rate equal to about 1.5 percent of normal background. This maximum exposure is estimated with the assumption that a few individuals might live on or near the disposal site in the far-distant future (2000 to 3000 years from the present), and be exposed to radioactive material (Nickel-59, with an 80,000 year half-life) released to the local streams or wells (see Section V of Appendix C).

(d) **Engineered Improvements to Minimize Radioactivity Release.** When compared with the usual low level radioactive waste disposal packages placed in land disposal sites, the reactor compartment "package" has the following important advantages which may be regarded as engineered improvements.

(1) The reactor compartment hull and bulkheads provide an extremely thick, strong exterior steel container. The hull itself is high-strength steel designed to be suitable for deep submergence during submarine operations. The steel end walls (bulkheads) of the reactor compartment containment have a minimum thickness of 1/2 inch. All penetrations in the hull and bulkheads would be sealed shut by welding.

(2) The reactor vessel provides a secondary or inner containment that is even thicker and stronger than the exterior containment. Even when the exterior containment is penetrated by corrosion, over 99 percent of the radioactivity will still be held within the second sealed containment. The reactor vessel would remain isolated from the environment for at least 200 years and thereafter would be subject to corrosion from the exterior but not the interior.

3. Non-Radiological Effects

(a) **Irreversible or Irretrievable Commitment of Resources.** For each disposal, approximately 1000 tons of material that is primarily steel would be buried. Approximately 3000 additional tons would be discarded if the remainder of the ship were disposed of at sea. The materials are not in short supply and would represent a very small fraction of such materials produced annually in the United States. The 1000 tons of reactor compartment material is not considered salvageable in its present state because of the presence of low level radioactivity. Scrap value of the salvageable portion of the ship would be approximately $0.3 million per ship.

For the total of approximately 100 disposals, ten acres of land would be indefinitely removed from unrestricted use.

*All exposure estimates due to ingestion or inhalation are dose commitments over the entire lifetime of an individual (70 years).

(b) **Effects of Work in the Shipyard.** Shipyard preparations for land disposal would be accompanied by smoke and fumes from cutting and welding torches, noise, and the generation of quantities of scrap metal. These effects are expected to be no different from similar normal shipyard activities. They would affect only a small area in the immediate vicinity of the shipyard and would be in accordance with existing regulations and practices.

(c) **Burial of Non-Radioactive Solid Waste.** The solid material that would be buried is primarily steel, but also includes quantities of plastic, asbestos, and metal such as lead, nickel, chromium, cobalt, and cadmium. The disposal of all non-radioactive solid waste would be consistent with normal practice at the land burial sites and would be performed in such a way that the end result would be at least as good as other available means for disposing of this material. The waste to be disposed of would not contain liquids.

Lead shielding built into the reactor compartment would eventually be exposed to corrosion through moisture in the soil and could subsequently release lead corrosion products into the ground and groundwater systems; but the maximum concentrations of lead in the water at potential biota access locations, such as a downstream well or surface stream would be less than the water quality criteria published by the EPA for protection of human health and aquatic life. Corrosion data for lead exposed to land burial conditions are provided in Appendix F. Calculational methods for estimating the maximum concentrations of lead in groundwater are described in Reference 4.26. The EPA water quality criteria were obtained from Reference 4.27.

(d) **Other Pollutants.** Barge transportation of the reactor compartments from shipyard to burial site would result in some air and water pollution due to the burning of fuels and operating the tug and barge over the coastal waterways and rivers. Such added pollution would be within existing limits and its environmental consequences would be minor.

(e) **Secondary or Indirect Effects.** Implementation of the land disposal option would require the construction of a river landing slip and barge unloading facilities at the Savannah River Plant. This would require the removal of a volume of earth from the river bank of approximately 7800 cubic yards (Appendix L). The work would be carried out in accordance with applicable environmental and other regulations, and removed material would be disposed of in accordance with existing regulations and practices. Appendix L, "Floodplain/Wetlands Assessment," discusses the effects of possible disposal at the Savannah River Plant on floodplain management and protection of wetlands. Significant adverse environmental effects are not expected.

The permanent raising of overhead utilities along the overland route at both sites would be required. Underground pipe crossings along either of the land routes from the unloading site to the burial site may require strengthening to bear the weight of a loaded transporter but would entail only minor localized trenching and similar work. The environmental consequences of these activities would be minor.

The occurrence of endangered and threatened species at the Hanford Site and Savannah River Plant burial grounds is discussed in Reference 4.25, where it is concluded that disposal activities would not be expected to affect those species that are found in the two general areas. At Hanford, the bald eagle is found on the reservation, but not on the burial site, so its habitat would not be impacted. At Savannah River, the red-cockaded woodpecker, the American alligator, the wood stork and the short-nose sturgeon are known to occur, but suitable habitat for these species is not present at the burial ground or the barge slip that would be required at Savannah River.

Concerning archaeological sites of interest, no occurrence of such sites has been revealed at either the Savannah River Plant or Hanford Site burial grounds, even though extensive burial operations have been conducted at both sites for over 30 years. Therefore no impact on archaeological sites would be expected.

Socioeconomic impacts at the disposal sites would be minimal since the work would be similar to burial operations which are currently conducted at these sites. There would be no significant increase in the size of the workforce at the disposal sites.

B. ADVERSE ENVIRONMENTAL EFFECTS OF POSSIBLE ACCIDENTS INCIDENT TO THE LAND DISPOSAL OPTION

1. Accidents Involving Radioactive Material

(a) **Immediate Effects.** The most severe conceivable accident involving radioactive material during land disposal operations would be one that might cause both penetration of the containment normally provided by the reactor compartment hull and bulkheads and the fracture of the primary coolant system outside the isolated reactor vessel. This accident is considered highly unlikely (see Section I.B.2(c) below) and could occur only as the result of a worst-case sequence of events with the most severe consequences. An accident that would cause penetration of the isolated reactor vessel, which contains 99 percent of the initial radioactivity, is not considered credible because of the strength of the materials which make up the reactor vessel.

This hypothetical worst-case accident, which could release a small fraction of the contained radioactive material to the environment, has been analyzed in accordance with the standards for packaging radioactive material for transport, specified in Appendix B of Part 71 of Title 10, Code of Federal Regulations (10CFR71), Reference 4.5. Specific details concerning the analysis are presented in Appendix B, Section III.F.2. The analysis shows that less than 3.5 curies of surface-deposited radioactive material (crud) could be released from the reactor compartment due to hypothetical shipping accidents.

The consequences of an accidental release of 3.5 curies of radioactive crud have been estimated. All of the radioactivity was assumed to be Cobalt-60 since this nuclide would cause the highest exposure. If 0.1 percent of the release were to the atmosphere, a maximum individual dose commitment of 0.3 mrem (total body) and 49 mrem (lung) could result assuming that the exposed maximum individual were to remain 100 meters directly downwind for a 2-hour period (see Section X.A of Appendix C). This exposure includes the exposure resulting from inhalation, immersion in the contaminated cloud, and direct radiation from the accident-damaged reactor compartment. If the airborne release were deposited and uniformly distributed in a small body of water 100 meters in diameter and 3 meters deep, the dose commitment to a maximum individual could be 1.4×10^{-3} mrem (total body) and 2.3×10^{-2} mrem (GI tract) (see Section X.B of Appendix C). This assumes that the exposed individual would drink one full day's normal intake of water from this body of water before it was known to be contaminated.

For comparison purposes, the U. S. Nuclear Regulatory Commission (Reference 4.6) uses a 25 rem total body dose to evaluate proposed reactor sites with respect to such low-probability accidents. Therefore, the maximum organ dose commitment due to a worst-case accident involving the reactor compartment (49 mrem) would be less than 0.2 percent of this reference accident exposure.

The sequence of events required to cause these hypothetical accident dose commitments would be extremely unlikely to occur. It is expected that an actual accident of this type would result in much lower release values.

(b) **Delayed Effects.** In the unlikely event that a reactor compartment were accidentally sunk during transit to the burial site and not recoverable following breaching of the exterior containment (hull or bulkhead), there could be a delayed release of radioactive material due to the slow effects of corrosion. For the reactor compartment to be non-recoverable, the accident would have to occur in off-shore waters of at least 500 feet depth, since at shallower depths recovery could be accomplished within a short time relative to the time required for corrosion release. The magnitude of the release is assumed to be the same as the upper limit release estimated for an unrecoverable loss during transit for sea disposal (see Table 4-5) with the location of release as close to land as 25 kilometers (16 miles).

Assuming that the delayed release from a lost reactor compartment were to occur 25 kilometers from land, at highly productive fishing grounds, a conservative dose commitment has been calculated (Appendix J, Section III.E.3). The total body dose commitment would be approximately 3 mrem per year of exposure to the most-exposed individual. This conservative estimate further assumes that despite the close proximity of the sinking location to human activities, no interruption would occur in normal activities at the affected area.

The accident postulated here is very unlikely in view of the precautions that would be taken to prevent sinking of the barge or loss of the reactor compartment from the barge. The barge would be compartmented so that accidental flooding could occur without sinking. The compartment would be welded to the barge. A backup tug would be available during the sea portion of the trip.

Because of the very pessimistic assumptions made in the analysis of this accident, any other radiological accident associated with land disposal or sea disposal is considered to have even less significant immediate or delayed effects.

2. Non-Radiological Accidents

The following accidents and their consequences have been considered.

(a) **Fire or Explosion in the Shipyard.** No abnormal potential for fires or explosions would exist with this option. The hazards encountered during a normal submarine overhaul or refueling are not unusual and are of very low probability. Prevention of and recovery from fires and explosions are adequately covered by existing shipyard instructions. Flamecutting of large steel plates is a normal shipyard operation.

The proposed transport barges for this project are of all-steel construction including a steel deck and contain no fuel or volatile substances. Barge damage by fire or explosion is not considered to be probable, either in the shipyard or during transit.

(b) **Stability of the Removed Reactor Compartment.** The methods and structures that would be employed to remove the cylindrical reactor compartment from the submarine make it unlikely that the removed compartment would be unstable or have a tendency to roll out of control. Structures would be welded to the compartment exterior for support in its original attitude and for handling during transit which would make it difficult for the reactor compartment to roll or topple. The structural attachments would be required to meet paragraph 71.31(d)(1) of Title 10, Code of Federal Regulations (Reference 4.5).

Jacking and moving operations on the reactor compartment, in preparation for securing it to the barge, would be relatively less routine than other shipyard operations for early disposals, although the shipyards have extensive related experience. Adequate safety equipment and procedures exist for these operations.

(c) **Barge Transportation Accidents.** Barge transportation accidents include collisions such as with another vessel or with bridge supports, conceivably resulting in the sinking of the barge with its reactor compartment cargo. This accident is considered in Section B.1.(b) above.

An expected number of barge accidents can be estimated for the entire program. The calculated number of accidents, including minor collisions, is 0.3 based on an assumed 100 barge trips averaging 500 miles each for a total of 50,000 miles (80,600 kilometers), and an estimated domestic accident rate of 3.6 per million kilometers of cargo barge traffic (based on Reference 4.1). The calculated number of expected accidents in the "severe" or "extra-severe" categories of Reference 4.1 is 0.00009, since only about 0.03% of cargo barge accidents are in these categories. This implies that there would be only a very small probability of a serious barge accident throughout the entire land disposal program.

Nonradiological effects of accidents involving the barge shipment of reactor compartments would not be expected to be significantly different from those involving other barge shipments of large items of equipment.

(d) **Land Transportation Accidents.** An accident which might be hypothesized to occur during movement of the reactor compartment from the river dock to the burial site is that the load could fall off the crawler transporter and roll down hill. Such an accident is considered very unlikely for the following reasons:

(1) The crawler transporter is very stable due to the large area of its track pads (300 square feet). It is capable of operating on grades up to 12 percent with full load, and would not be required to operate at a grade greater than 6 percent for the burial sites considered. Load testing to 150 percent of the rated capacity would be performed.

(2) The structural supports and attachments to the package for securing the reactor compartment to the crawler transporter would be designed to ensure that the transporter and its load would remain fastened together.

(3) If the cylinder were to drop from the transporter to the ground, it would probably, because of its great weight, implant itself in the ground instead of rolling. The loading on the ground would be several tons per square foot. If the cylinder did begin to roll, it would stop before moving more than two-thirds of one revolution because the structural support pads that are welded to the package would dig into the ground. Figure B-1 of Appendix B shows a view of the support pads on the reactor compartment.

Collisions between the loaded crawler transporter and other vehicles would be extremely unlikely due to the limited speed of the transporter (approximately 1 mile per hour) and the use of escorts over roadways which would either be unused or temporarily blocked off from all other traffic.

C. CUMULATIVE EFFECTS OF REACTOR COMPARTMENT LAND DISPOSAL

The incremental environmental impact of disposal of all one hundred submarine reactor compartments at one land disposal site would be so small that there would be no significant cumulative impact resulting from this action. For example, based on very conservative calculations, the effect of land disposal might produce at most an incremental exposure of 0.006 millirem/year to a typical member of the population most directly affected. This potential exposure is very small in comparison to fluctuations in exposure resulting from variations in individual activities and geographic location. There is no potential for reactor compartment land disposal to contribute to a significant cumulative impact.

Considering the total of all land disposal activities, at the same Federal burial site as well as at other locations, the additional environmental impact of reactor compartment disposal would not cause a significant increase in the total environmental impact.

A synergistic effect between radiation and other physical, chemical, or biological agents is not likely. Such an effect would be one in which the combined effect of two or more agents would exceed the sum of the effects of the individual agents. As stated in Reference 4.31, "Except for the case of tobacco smoke, which may act synergistically with radiation in producing lung cancers under some working conditions, this study has been unable to document in man any clear case of interaction, at least of the kind which may result in substantial modifications of the estimates of risk for significant sections of the population."

II. SEA DISPOSAL OPTION

A. ADVERSE ENVIRONMENTAL EFFECTS WHICH CANNOT BE AVOIDED SHOULD THE SEA DISPOSAL OPTION BE IMPLEMENTED

1. Effect on Future Use of the Sea

If sea disposal were selected, it would be required that the disposal sites be designated by the U.S. Environmental Protection Agency and that site-specific environmental assessments be prepared. As described in Chapter 3, Section II.A, potential sites would be excluded from consideration if they were near (a) major shipping lanes, (b) communication cable routes, (c) defense areas or strategic routes, or (d) areas of potential seabed resources. This last item would eliminate sites in the vicinity of potentially valuable deposits of manganese nodules, gas or oil deposits, or significant feeding grounds for marine organisms important to man, or grounds where such organisms are harvested. Areas which have a high probability of such uses in the future would also be excluded.

In the unlikely event that a remote disposal site designated by the EPA were to become of interest for other purposes at some time after the site had been used, it would be highly improbable that the presence of defueled nuclear submarines would have any significant effect on usage of the water column. The submarines would be at a depth of at least 4000 meters and would produce no detectable radiation field. Even usage of the sea floor would likely be unaffected because of the small areas actually involved since each submarine would cover less than 10,000 square feet. The radiological effects of disposal would be very limited even at the immediate disposal site. For these reasons and because the total area of a disposal site, including space allowed between submarines for emplacement, would probably be less than 100 square miles, or less than 1.3×10^{-6} of the ocean floor deeper than 4000 meters, it is concluded that the impact of this option on uses of the sea would be negligible.

2. Effect on National Environmental Policy

Sea disposal has not been practiced by the United States since 1971, and many individuals and groups are opposed to the consideration of its resumption, as illustrated by the responses of some members of the public to the draft version of this document (see Volume 2). After the draft of this document was issued in December 1982, a two-year moratorium on sea disposal of low-level radioactive waste was included in legislation that became federal law in January 1983 as an amendment to the Marine Protection, Research and Sanctuaries Act of 1972 (Reference 4.8).

The two-year moratorium does not directly affect the Navy's possible use of the sea disposal option since no disposals would have been considered in the time period in which the moratorium is in effect. However, other provisions of the amendment place restrictions on the EPA's granting of a sea disposal license. These restrictions go beyond the National Environmental Policy Act and make the sea disposal option uncertain. Such is the case even though the sea disposal option is permitted under existing international treaties to which the United States is party, and under which other nations have conducted disposal of low level radioactive wastes into the ocean.

All actions taken in carrying out the sea disposal option would be consistent with the recommendations of the International Atomic Energy Agency, which acts as advisor to the International Maritime Organization (IMO). The latter organization administers the 1972 London Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter (Reference 4.7) to which the United States is signatory. The necessary regulations to enforce the convention requirements in this country are provided by the Marine Protection, Research, and Sanctuaries Act of 1972, as amended, and administered by the U.S. Environmental Protection Agency. Implementing regulations for the Act are contained in Reference 4.17, Subchapter H—Ocean Dumping. Therefore, sea disposal of defueled, decommissioned submarines would not violate existing law and would require no new laws, although as noted above it is uncertain when a sea disposal permit could be granted to the Navy by the EPA. The EPA is authorized to issue permits for radioactive waste disposal in the ocean according to Sections 220 through 229 of Part 40 of the Code of Federal Regulations, Reference 4.17. However, the 1983 Amendment referred to above requires approval of such EPA permit granting by both the U.S. Senate and House of Representatives. The EPA would be responsible for providing reports of all such disposal activity to the International Organization for Economic Cooperation and Development (OECD).

3. Radiological Effects

(a) **Radiation Effects on Bottom-Dwelling Sea-Life.** Direct radiation levels at the disposal site, even within the reactor compartment itself, would be negligible even in the earliest years following disposal, because of the shielding effect of water, which reduces the exposure rate caused by gamma radiation by a factor of approximately 10 for every 2 feet of additional distance from the source. The radiation levels inside the reactor compartment would be less than 100 mrem per hour before the compartment is filled with water during disposal preparations. With the compartment filled with water, the radiation level would be less than 10 mrem per hour at any position 2 feet away from the reactor vessel, less than 1 mrem per hour 4 feet away, and so forth. Outside the filled reactor compartment, the exposure rate would be approximately 0.001 mrem per hour or less. Since the reactor compartment would be inaccessible, no animals could be exposed to radiation exceeding their natural background radiation by any significant amount. After 100 years, when the reactor compartment containment is assumed to be penetrated, the radiation would be less than 0.001 mrem per hour throughout the entire compartment because the Cobalt-60, which is the principal source of gamma radiation, and most other radioactive sources would have decayed to stable nuclides.

In the unlikely event that bottom-dwelling sea life did inhabit the reactor compartment continuously, and received an exposure of 1 millirad per hour (corresponding to 1 mrem per hour) 4 feet from the reactor vessel, the resulting exposure would be less than 9 rad per year. Scientific studies have shown that "it requires, as the lower limit, an acute dose of about 100 rad to produce some mortality in a number of organisms but not in all," and "when experimental and field dose rates are less than 1 rad per day it becomes very difficult to observe effects which can be used as indicators of damage." (Reference 4.9, page 89). Therefore the effect of the hypothetical exposure would not be expected to result in any damage to deep ocean populations. This hypothetical exposure would be limited to the small number of animals assumed to inhabit the reactor compartment continuously, and the exposure rate would decrease by a factor of 2 every 5.26 years (the Cobalt-60 half-life).

Internal radiation exposure to sea life in the immediate vicinity of the disposal site would occur, with the expected maximum effect taking place after many centuries of gradual release of radioactive material had occurred. The means of exposure would be ingestion of the sediment or water containing the radionuclides released from the submarine. The maximum rate of internal exposure is estimated to be approximately 0.3 rad per year, assuming that Nickel-59 is the only radionuclide actually released to the environment in any significant curie amount (see Section II.A.3.(b) below).

All of the originally available long-lived Nickel-59 (120 curies) is assumed to be dispersed within a volume of sediment 560 meters by 140 meters, 15 cm thick. The surface area is the area associated with one day's tidal currents (Reference 4.23) and is the area in which all of the dispersed material is assumed to be distributed. Since sediment density is approximately 1.4 grams per cm^3, the average radioactive Nickel-59 concentration in the sediment, ψ, would be:

$$\psi = \frac{120 \text{ curies } (10^{12} \text{ picocuries/curie})}{(560 \text{ m})(140 \text{ m})(0.15 \text{ m})(1.4 \text{ g/cm}^3)\left(\frac{10^6 \text{ cm}^3}{\text{m}^3}\right)}$$

$$\psi = 7300 \text{ picocuries per gram.}$$

The maximum rate of exposure to animals on the sea floor is estimated by assuming that a large fraction of the animal would contain 7300 picocuries of Nickel-59 per gram. This fraction is assumed to be 25 percent to represent the fraction of the animal's weight equivalent to its gut. The calculation is made as follows:

$$D = f k \epsilon \psi$$

where

D = dose to animals dwelling in the sediment at the disposal site, rads per year

f = grams of sediment per gram of affected animal (0.25)

k = conversion constant (1.9×10^{10} disintegrations per year per curie multiplied by grams-rad per MeV)

ϵ = effective energy per disintegration (7.7×10^{-3} MeV per disintegration, for Nickel-59, based on Table B-5 of Reference 4.22)

ψ = 7300 picocuries per gram of sediment

D = 0.3 rad per year.

This estimate is comparable to that obtained by using the method outlined in Appendix D of Chapter 1 of Reference 4.9. An exposure rate of 0.3 rad per year is small compared to the annual internal exposure to the naturally-occurring radionuclide Polonium-210 that may be received by some mid-water-dwelling species (600 to 1500 meter depth). Reference 4.29 estimates that the natural doses to the most-affected organ (hepatopancreas) of certain species of shrimp (Gennadus valens) may be greater than 195 rem per year.

(b) **Release of Radioactive Material to the Marine Environment.** Since virtually all (99.9 percent) of the radioactive material associated with the proposed disposal was formed within structural metals as the result of neutron activation, it is integrally contained and could be released to the environment only through corrosion of the metals themselves. The slow rate of metal corrosion would therefore control the rate of release of radioactive material from the metal to the seawater, providing one of several forms of containment which are among the numerous barriers to movement from the disposal site to the human environment at some distant location. This containment provided by the solid metal in which the radioactive material is formed cannot be compromised by any event during emplacement.

The radioactive material that is not an integral part of the structural metal (about 0.1 percent of the total) consists of corrosion product activity deposited on and adhering to the interior surfaces of components. This material is fully contained within the reactor plant and would remain within the containment until it was penetrated.

Corrosion of metals in seawater at great depths is slower than corrosion near the surface because of the low temperature (1° to 2°C) and the absence of disturbing influences that might tend to damage corrosion films or disrupt the slow process of low temperature corrosion. The annual rates of corrosion employed in release-rate estimates for this statement have been conservatively estimated based on available research results (References 4.10 and 4.11). The background and basis for the corrosion rates chosen are provided in detail in Appendix F, "Corrosion of Structural Alloys."

The corrosion rates employed in release rate estimates are 0.0025 inch per year per exposed surface for low-alloy steels, and 0.0003 inch per year per exposed surface for corrosion-resistant alloys, such as stainless steel. Corrosion rates actually measured in deep ocean experiments have been lower than the assumed rates, as discussed in Appendix F. Since corrosion-resistant alloys such as stainless steel are subject to relatively rapid pitting, the analysis of radioactive material release due to corrosion takes into account the degradation of complete containment by pits that penetrate portions of the reactor vessel closures. The rate of pitting attack is assumed to be 0.0138 inch per year, a factor of 46 greater than the average surface rate of 0.0003 inch per year, based on information obtained from existing literature, as described in Appendix F.

To estimate the rate of release of corrosion products and the total amount of radioactivity released to the environment from disposal of defueled submarines, two different cases of radioactivity containment were selected for analysis. Details of each are provided in Appendix G. One case postulates only the minimum containment that is provided as a result of the fact that most of the radioactive material is an integral part of the metal. This case is intended to define an upper-bound estimate on any possible effects, including an accident, at a very high level of certainty. The second case is the expected result of a normal disposal, with the reactor compartment and reactor vessel containment intact. Other particular cases of interest would be expected to yield release rates and total releases that are less than the minimum containment estimate. It is important to note that the expected result of a sea disposal action would be the placement of the submarine in intact condition on the sea floor, a condition which would be consistent with the lower radioactivity release estimate. The basis for this expectation is provided in Appendix D, "Description of the Sea Disposal Method."

To estimate annual rates of radioactive material release and the total amount of radioactive material which might be released to the environment from all of the disposed submarines, the calculated releases from a total of 100 ships have been combined on the basis of three disposals per year for 33 years. This estimated release of radioactive material from submarine disposal is based on the following assumptions. (Also see Table 4-2.)

(1) Containment of the radioactivity is provided not only by the metal matrix, but also by the reactor vessel and the reactor compartment boundary. The latter containment is provided by the ship's pressure hull and the forward and aft reactor compartment bulkheads.

(2) Corrosion rates are conservative estimates compared to the rates that are actually expected. Surface-deposited radioactivity (i.e., the small fraction of the activity that is not an integral part of the metal) is added to the first year's corrosion release.

(3) All of the radioactive corrosion products are available to the surrounding water column or sediment immediately after release from containment. The material may then either settle to the sea floor in the immediate vicinity or be transported by the water movements. It is expected that most of the corrosion products would be deposited into the sediment within the immediate vicinity of the release point.

In contrast to the above, the extremely conservative minimum containment estimate of radioactivity release from submarine sea disposal is based on the following assumptions. (Also see Table 4-3.)

(1) The only containment for the radioactive material is its existence as an integral part of the metal itself.

(2) All of the radioactive corrosion products are immediately available to the surrounding water column as they are liberated from the metal components by corrosion. The released material may then either settle to the sea floor in the immediate vicinity or be transported by the water movements. To maximize the radioactivity concentration in the water, all of the corrosion products are assumed to enter the water in transportable form.

(3) As described above, surface-deposited radioactivity is added to the first year's corrosion release. This treatment is very conservative as indicated by monitoring data obtained in the vicinity of the THRESHER and SCORPION sites (Annex to Appendix D). Surveys conducted in the vicinity of these lost submarines have shown no significant release of radioactivity.

The estimated releases obtained with the minimum containment assumptions have been applied not only to the analysis of a postulated unforeseen event during disposal operations (which might cause the ship's hull at the reactor compartment location or the reactor compartment bulkheads to be damaged during emplacement), but also to that of an accidental sinking at a near-shore location. Even though it is incredible that the reactor vessel would be broken open in view of its strong construction, it has been assumed for this analysis that the reactor vessel containment is also penetrated. If the sea disposal option were used with the result that damage was likely to have occurred in the reactor compartment containment, the emplacement method would be reexamined and, if necessary, changed to prevent a second occurrence.

Based on the two different approaches outlined above, the most important events following disposal are the releases to the environment of radioactive materials as described in Tables 4-2 through 4-6. All of the release estimates by individual nuclide are summarized in Tables 4-4 and 4-5. The estimated maximum annual radioactive material release to the environment from a postulated unforeseen event during disposal is higher than the annual release from a normal disposal by a factor of approximately 150 as shown in Tables 4-4 and 4-5. The total release over all time is higher by a factor of approximately 8. Table 4-6 shows the estimate of the total and maximum annual releases by nuclide for all 100 ships when normal disposals are carried out at a rate of three per year for 33 years.

The limited significance of the expected radioactive material releases in Table 4-6 can be seen by comparing them with the approximately 54 curies of naturally-occurring radioactive thorium and uranium discharged to the oceans each year by the major rivers of the United States. This radioactive material is deposited near the ocean shore and in shallow water, in contrast to the releases estimated in Table 4-6, which would occur remote from shore in the deep ocean. As shown in Table 4-7, the relative radiation exposure effect of the natural radioactivity deposition would be about 25 times that of the material released from the 100 disposed submarines, if the releases from the submarines occurred at the same near-shore locations as the river discharges.

The basis for the estimate of 54 curies of thorium and uranium is as follows. The total annual flow into the oceans from the 12 largest U.S. rivers is 1.5×10^{12} cubic meters (Reference 4.12) which, when combined with the element concentrations in stream waters (Reference 4.14) and the fractional abundance of the radioactive nuclides (Reference 4.13), yields the annual discharge of 54 curies, U^{234} and U^{238} being assumed to be present in equal curie amounts. This estimate is limited to thorium and uranium and therefore does not include approximately 2800 additional curies of naturally-occurring radioactivity in the form of Potassium-40 deposited each year in the oceans by U.S. rivers.

(c) **Corrosion Release of Stable Elements.** For each atom of a radioactive nuclide that is released to the environment by corrosion, there would be a corresponding release of a large number of atoms of the same element in stable form. Calculations similar to those that produce Tables 4-4 through 4-6 show that when an atom of radioactive Cobalt-60 is released, at least 25,000 atoms of stable Cobalt-59 are also released, and when an atom of radioactive Nickel-63 is released, at least 700,000 atoms of stable Nickel-58, Nickel-60, Nickel-61, Nickel-62, or Nickel-64 are also released, with these ratios increasing over time as radioactive nuclides decay to stable nuclides. Values of these ratios for each nuclide are provided in Table 4-8 to illustrate this effect. This factor can be important because of its role in limiting the assimilation of a particular radioactive species. For example, if the maximum possible absorption of the element cobalt by a human or an animal were 1 milligram, the corresponding absorption of Cobalt-60 could be no more than 1/25000th of 1 milligram, since a biological system could not selectively take in one particular isotope of these elements. Biological systems do not discriminate between radioactive and stable isotopes of these elements in the same chemical form because all isotopes of each of these elements behave the same in the chemistry of the biological system. This effective dilution of radioactive isotopes by the stable isotopes, combined with the body's capacity for only limited amounts of certain elements, can serve to limit radiation dose commitments. It should be noted that the dilution of radioisotopes by stable isotopes has been used in only one of the radiation exposure estimates of this environmental statement, namely the hypothetical direct biological path via sediment at the deep ocean disposal site, described in Section II.A.3.(d)(4), "Individual Exposure Via a Hypothetical Pathway," and in Appendix J, III.D.2.

(d) **Radiation Exposure to Man**

(1) **Exposure to Shipyard Personnel.** The total radiation exposure to shipyard workers involved in the preparations for sea disposal would be approximately 17 man-rem for each submarine. This exposure would be to individual workers who are trained for radiation-related work. Each worker's exposure would not exceed established limits (3 rem per quarter and 5 rem per year to the total body). The exposure would be a consequence of working in the gamma radiation field in the reactor compartment, performing tasks such as removal of salvageable components and draining of reactor plant systems, filling the reactor plant with water to prevent crushing during the descent to the ocean bottom, and installing or positioning valves or other equipment as required for disposal. The total occupational exposure associated with protective storage for 20 years followed by sea disposal is estimated to be approximately 20 man-rem, as discussed in Section III.B.1. Additional information on occupational exposure is provided in Appendix A, Section III.D.1.

(2) **Exposure to Personnel Involved in Movement to the Disposal Site.** The total radiation exposure to personnel who would be involved in moving the submarine from the shipyard to the disposal site and in completing the necessary steps prior to the actual sinking of the ship is estimated to be less than 0.1 man-rem, involving external exposure only. The estimate is based on approximately 100 man-hours of work actually in the immediate vicinity of the submarine outside the reactor compartment during which the average exposure rate would be less than 1 mrem per hour. Such work would primarily be associated with preparations to sink the ship at the selected disposal site. There would be no need to enter the submarine after departure from the shipyard.

TABLE 4-2. SEQUENCE OF EVENTS FOR EXPECTED RADIOACTIVITY RELEASE ESTIMATE—SEA DISPOSAL

t = 0	Submarine would be placed intact on the sea floor. Corrosion would begin on all surfaces. Release to the environment would be limited to minute traces of activity contained in the reactor compartment exterior walls (hull and bulkheads).
t = approximately 75 years	Reactor vessel containment is assumed to be partially penetrated by initial pitting through the corrosion-resistant alloy that makes up part of the containment barrier. Release is assumed to begin from the reactor vessel interior into the reactor compartment by slow diffusion through pitting holes. Reactor compartment containment would still be intact.
t = approximately 100 years	Reactor compartment containment barrier is assumed to be penetrated by general surface corrosion of the compartment's bulkheads. Sea bottom currents are assumed to begin flowing through the reactor compartment. Immediate release to the environment occurs for all water-transportable corrosion products that have accumulated within the reactor compartment outside the reactor vessel. Release to the reactor compartment and the environment continues for all water-transportable corrosion products that have accumulated within the reactor vessel. Immediate release to the environment continues for all subsequent corrosion products formed outside the reactor vessel and released from the reactor vessel.
t = approximately 400 years*	Sea bottom currents are assumed to begin flowing through the reactor vessel.
t = approximately 4300 years	Radioactivity release to the environment would be 99 percent complete.

Corrosion rates for above sequence of events (average rates from Table F-1 and Section III.D.1 of Appendix F):

0.0025 inch per year per exposed surface (low alloy steel)
0.0003 inch per year per exposed surface (corrosion-resistant alloy)
0.0138 inch per year for pitting (corrosion-resistant alloy).

*In the conservative release estimate, this was changed to 100 years.

TABLE 4-3. SEQUENCE OF EVENTS FOR MINIMUM CONTAINMENT (ACCIDENT) RADIOACTIVITY RELEASE ESTIMATE—SEA DISPOSAL

t = 0	Submarine would be placed on the sea floor. All containment is assumed to be completely open to the sea, including the reactor vessel. Release to the environment is assumed to occur as soon as corrosion takes place. All surface-deposited activity is assumed to be released in the first year.
t = approximately 1800 years	Radioactivity release to the environment would be 99 percent complete.

Corrosion rates for above sequence of events (average rates* from Table F-1 of Appendix F):

0.0025 inch per year per exposed surface (low alloy steel)
0.0003 inch per year per exposed surface (corrosion-resistant alloy)

Pitting of corrosion-resistant alloy is not considered in this sequence since no containment is assumed to exist.

*In the conservative release estimate, the maximum corrosion rates from Table F-1 of Appendix F were used: 0.0050 inch per year per exposed surface for low-alloy steel and 0.0005 inch per year per exposed surface for corrosion-resistant alloy.

TABLE 4-4. RADIOACTIVE MATERIAL RELEASED TO THE DISPOSAL SITE RESULTING FROM SEA DISPOSAL OF ONE SUBMARINE

Nuclide	Maximum Release In Any Year (Curies per Year)	Approximate Time at Which Maximum Occurs (Years After Disposal)	Total Released Over All Time (Curies)
Ni-63	0.65	100	63.2
Ni-59	0.07	1300	119.9
Mo-93	7.2×10^{-4}	100	0.01
C-14	5.7×10^{-4}	1300	0.78
Fe-55	2.9×10^{-4}	1*	1.3×10^{-3}
Tc-99	2.2×10^{-4}	100	3.1×10^{-3}
Co-60	1.1×10^{-4}	100	4.7×10^{-4}
Nb-94	5.2×10^{-5}	1300	7.8×10^{-2}
Mn-54	6.5×10^{-6}	1*	1.2×10^{-5}
Co-58	3.7×10^{-7}	1*	3.7×10^{-7}
Fe-59	1.6×10^{-7}	1*	1.6×10^{-7}
Cr-51	5.6×10^{-8}	1*	5.6×10^{-8}
S-35	1.2×10^{-9}	1*	1.2×10^{-9}
Sc-46	1.3×10^{-10}	1*	1.3×10^{-10}
Total	0.65	100	183.9

Corrosion rates: Low-alloy steel: 0.0025 inch per year per exposed surface.
Corrosion-resistant alloy: 0.0003 inch per year per exposed surface.
Pitting rate: Corrosion-resistant alloy: 0.0138 inch per year.

*These early releases result from the radioactive material contained in the metal of the exterior boundary (hull and bulkheads), and the assumption that the activity is uniformly distributed in the metal.

(3) **Exposure to the Public from Movement to the Disposal Site.** Radiation exposure to the public from movement of the submarine to a sea disposal site would be negligible because the reactor compartment would be filled with water that would absorb virtually all radiation from the reactor compartment interior and reduce the exposure rate on the surface of the hull to less than 1 mrem per hour. Over half of the exterior of the floating submarine hull would be under water and every two feet of this water would cause the exposure rate to be reduced by a factor of approximately 10. For that portion of the submarine above water, the geometry of the ship and the location of the reactor plant (relatively low in the reactor

TABLE 4-5. MINIMUM CONTAINMENT RADIOACTIVITY RELEASE FROM ONE SHIP ACCIDENT CONDITION RELEASE ESTIMATE

Nuclide	Maximum Release in Any Year (Curies per Year)	Year in Which Maximum Occurs	Total Released Over All Time Curies
Ni-63	9.9	1	1170.4
Ni-59	0.06	1	120.4
Mo-93	1.0×10^{-5}	1	0.01
C-14	5.1×10^{-4}	1	0.83
Fe-55	48.0	1	77.0
Tc-99	2.8×10^{-6}	1	3.6×10^{-3}
Co-60	31.4	1	105.3
Nb-94	4.4×10^{-5}	1	7.9×10^{-2}
Mn-54	1.8	1	1.9
Co-58	2.4	1	2.9
Fe-59	0.37	1	0.37
Zr-95	0.33	1	0.33
Cr-51	0.13	1	0.13
Hf-181	0.12	1	0.12
S-35	7.6×10^{-5}	1	8.1×10^{-5}
Sc-46	6.0×10^{-5}	1	6.3×10^{-5}
Total	94.6	1	1480

Corrosion rates: Low-alloy steel: 0.0025 inch per year per exposed surface.
Corrosion-resistant alloy: 0.0003 inch per year per exposed surface.

TABLE 4-6. EXPECTED RADIOACTIVITY RELEASE FROM 100 SHIPS—SEA DISPOSAL

Nuclide	Maximum Release in Any Year (Curies per Year)	Approximate Time at Which Maximum Occurs (Years After First Disposal)	Total Released Over All Time Curies
Ni-63	39.0	420	6320
Ni-59	7.0	1300	12,000
Mo-93	2.8×10^{-3}	130	1
C-14	0.053	1300	78
Fe-55	4.1×10^{-3}	30	0.1
Tc-99	8.3×10^{-4}	130	0.4
Co-60	1.1×10^{-3}	30	5×10^{-2}
Nb-94	5.2×10^{-3}	1300	7.8
Mn-54	4.0×10^{-5}	30	1×10^{-3}
Co-58	2.4×10^{-6}	30	4×10^{-5}
Fe-59	1.6×10^{-6}	30	2×10^{-5}
Cr-51	9.2×10^{-7}	30	6×10^{-6}
S-35	6.5×10^{-9}	30	1×10^{-7}

Total	45.0	420	18,400

TABLE 4-7. COMPARISON OF EXPECTED RADIOACTIVE MATERIAL RELEASES FROM 100 SHIPS WITH NATURAL THORIUM AND URANIUM RADIOACTIVITY DEPOSITED EACH YEAR IN OCEANS BY MAJOR RIVERS OF THE UNITED STATES

	Nuclide	Annual Deposition or Release (Curies per Year)	Relative Ingestion Exposure per Curie*	Relative Annual Exposure Effect (Product of Two Previous Columns)
Natural Radioactivity from Rivers	Thorium-232	16**	1.000	16.00
	Uranium-234	19**	0.0035	0.07
	Uranium-238	19**	0.0030	0.06
	TOTAL	54 (each year)		16.13
Radionuclides from 100 Submarine Disposals	Nickel-63	39	0.0145	0.57
	Nickel-59	7	0.0055	0.04
	Carbon-14	0.05	0.2000	0.01
	TOTAL	46.05 (based on maximum year for each nuclide)		0.62

Relative radiation exposure effect if deposited at comparable sea locations = 16.13/0.62 = 25 (approximately)

*Thorium-232 is assigned the value 1.000; all other nuclides are assigned values based on the product of fish concentration factor (Reference 4.21) and total body ingestion dose conversion factor (Reference 4.22), relative to Thorium-232.
**Based on References 4.12, 4.13, and 4.14.

compartment) would combine to preclude any significant exposure on the water surface or on land even within a few feet of the submarine. Passage under bridges, if required, would not result in significant radiation exposure to persons on the bridge surface because of the combined effects of the shielding water within the reactor compartment, the minimum distance between the submarine hull and the bridge surface, and the brief time interval of passage.

With the exception of passage under bridges, as discussed in the preceding paragraph, members of the public would be separated from the submarine by the distance from the waterway channel to the nearest land (on the order of several hundred feet) during towing to sea. Once at sea, the general public would be far removed from the submarine. Therefore, the radiation exposure to the population during transportation from the disposal shipyard to any disposal location at sea would be negligible and would have no effect.

(4) **Exposure to the Public from Release of Radioactive Material**

Individual Exposures. Radiation exposure to the public from the release of radioactive material resulting from submarine disposal at sea would be minimal. This is based on the likelihood that the radioactive material would remain at or close to the deep and remote disposal site, isolated from man and his activities. Activities at such distances and depths are not practical because of the costs and physical obstacles involved. However, it is not possible to be totally certain that no exposure would occur since corrosion would eventually release some radioactivity which might be transported to areas of human activity. Therefore, even though it is unlikely that any exposure would occur, potential exposures have been estimated using conservative methods so that an upper limit on exposure to the public can be established.

TABLE 4-8. MINIMUM RATIO OF STABLE ELEMENT MASS RELEASE TO RADIOACTIVE MASS RELEASE (GRAMS PER GRAM)
(This Ratio Represents a Natural Dilution Factor of the Radioactive Atoms of Each Element)

Nuclide	Normal Disposals	Unforeseen Event
Ni-63	1×10^6	7×10^5
Ni-59	1×10^3	1×10^3
C-14	3×10^5	1×10^5
Mo-93	2×10^7	2×10^7
Co-60	1×10^{10}	2×10^4
Fe-55	4×10^{13}	6×10^8
Mn-54	3×10^{13}	3×10^8
Co-58	1×10^{13}	7×10^6
Fe-59	5×10^{17}	1×10^{12}
Cr-51	2×10^{16}	3×10^{10}
S-35	1×10^{16}	2×10^{11}

For minor nuclides not listed, dilution by the stable element was not estimated.

Twelve pathways by which individuals might be subjected to radiation exposure from radionuclides in seawater were analyzed. Seven of these pathways were direct ingestion paths: consumption of fish, crustacea, molluscs, seaweed, plankton, and salt; and the use of desalinated seawater for drinking water, cooking, and other uses. Four of these pathways were external: immersion in seawater, exposure to shore sediments, exposure to equipment such as fishing lines or nets, and immersion in air. Air inhalation was also included as an exposure pathway.

The analytical model used to estimate ocean transport has incorporated scientific thought concerning the movement of ocean waters, including the existence of eddies, a benthic boundary layer, upwelling, and long term horizontal currents. The existence of these phenomena has been recognized in the definition of the probability that concentrations in a particular region may be in a given range. The analysis also recognizes that any usage of ocean products or water by man would result in exposure to concentrations which would vary over the range of concentrations possible in the locality and would therefore have the effect of causing the net consumption to approximate the probable average.

Radiation exposure to the public has been estimated on the basis of the release of radioactive material summarized in Table 4-6* for 100 normal disposals and the releases summarized in Table 4-5** for an unforeseen event. Since, as assumed here, the unforeseen event would result in a reduction of containment effectiveness, the extreme condition of minimum containment was assumed for the calculations on which Table 4-5 is based. This accident situation has been assumed to occur either at the disposal site, to represent an unforeseen event during the emplacement operation, or at a location 25 kilometers from shore to represent an accident in which the submarine is sunk during transit in such a way that recovery is not possible (described in Section II.B.1).

With the radioactive material releases specified (either Table 4-6 for 100 normal disposals or the sum of releases from Tables 4-5 and 4-6 for one accident among approximately 100 disposals), the best estimate radiation exposure for an individual with average consumption and occupancy rates was determined. This best estimate was calculated using the most realistic value for each parameter. Next a conservative estimate (unrealistically high) was calculated assuming that no benefit would be derived from several processes which are known to exist but are difficult to evaluate, such as the removal of material from the water column by detritus. The beneficial effects of other processes were treated in a manner which would yield exposure estimates higher than expected. Finally, the radioactivity release rates were increased, as indicated in the notes of Tables 4-2 and 4-3, and as shown in Appendix G (Tables G-9 through G-15 and G-23 through G-29), to provide additional conservatism. The conservative estimate shows that even if unrealistic assumptions are used, similar to those used by the IAEA in development of the criteria for ocean disposal of low level radioactive waste (Reference 4.21), the exposures still would not present any hazard.

In all cases, the exposure for the average individual was calculated using the maximum concentration at any time at the assumed pathway entry locations, even though the entire coastal population would not be subject to the maximum concentration. This was used for simplicity in the mathematical treatment; even though it overestimates the total exposure of the population, the discrepancy is so small that the additional complication of calculating an average concentration would not be merited.

After the radiation exposure was estimated for a hypothetical average individual, a similar estimate was calculated for hypothetical individuals assumed to have the maximum seafood consumption rates of Reference 4.21 and who reside or work in the shore areas with the highest concentrations for greater-than-average fractions of the time. These maximum individual exposures were calculated by best estimate and conservative estimate methods, as described above, the only differences being the consumption rates and occupancy times.

In addition, a direct biological path to humans has been assumed in another calculation even though no such path has ever been found, to assure that this could present no hazard. The shortcut path is based on a hypothetical case in which seafood might be obtained from the ocean floor in the immediate vicinity of the postulated deep ocean disposal site and consumed at the maximum rates of Reference 4.21 by a limited number of individuals. The number of affected individuals in this hypothetical case would be small because the population of sea life in the vicinity of the disposal site would be small and would not support a large number of individuals.

The total body exposure estimates have been calculated for residents of the United States West Coast. Exposure to residents of the East Coast would be expected to be comparably small for disposal locations in the Atlantic. As a result of the greater ocean stirring and dilution effects and the greater distance offshore to areas which might satisfy site selection criteria, exposure estimates for East Coast residents would probably be even lower.

*See Appendix G, Tables G-3 through G-8, for time-dependent release rates of major nuclides (best estimate, expected containment).

**See Appendix G, Tables G-17 through G-22, for time-dependent release rates of major nuclides (best estimate, minimum containment).

The average individual exposure estimates are summarized in Table 4-9. For 100 normal disposals, the best estimate of total body exposure to an average individual is 6×10^{-12} mrem per year. If one of these disposals resulted in the minimum containment accident case, the corresponding best estimate would be 1×10^{-9} mrem per year. The conservative estimates of these average individual exposures are 0.0002 mrem per year and 0.003 mrem per year, respectively. These unrealistically high estimates are still very small.

Details of the methods used to develop these estimates and detailed results of the calculations for all pathways and nuclides are provided in Appendix H, which explains the method used to estimate the dispersion of released radioactivity in the ocean waters; Appendix I, which describes the exposure pathways and the methods used to estimate the radiation exposure to individuals and to the general population, based on the concentration of radioactivity in the seawater; and Appendix J, which summarizes the estimated annual dose commitments associated with sea disposal.

Exposure of the hypothetical "maximum-exposed individuals" would be as shown in Table 4-10. In each case the maximum individual exposures are higher than those for the average individual by a factor of at least 15 to 1, due to the much higher consumption rates and occupancy factors. Nevertheless, the highest exposure value for maximum-exposed individuals is only 0.06 mrem per year, the conservative estimate associated with one minimum containment accident case included among 100 disposals.

Exposure to individuals of other nations would be similar to, or less than, the limited exposures tabulated in Table 4-9, for persons living in the United States. The distances from the release point to the locations of human activities have already been minimized in the analysis, all exposure pathways of importance have been considered, and representative consumption rates have been employed. Where larger average individual consumption rates of some foods might be appropriate for certain other nations, the consumption increases would tend to offset the lower radionuclide concentrations that would be appropriate when the distance from the release point to the fishing area is greater.

Individual Exposure Via a Hypothetical Pathway. The exposure estimates in Tables 4-9 and 4-10 are based on the most likely path from the disposal site to man being the transport of radioactive material through the water to distant fishing grounds or to the shore.

TABLE 4-9. EXPOSURE TO RADIATION FROM SEA DISPOSAL — AVERAGE INDIVIDUAL

Scenario	Total Body Radiation Dose Commitment from One Year's Exposure (Highest Year)
a) 100 Submarines, 3 Disposals per Year for 33 Years, normal disposal	6×10^{-12} mrem per year (best estimate) 0.0002 mrem per year (conservative estimate)
b) 100 Submarines, 3 Disposals per Year for 33 Years, one disposal* results in a minimum containment accident	1×10^{-9} mrem per year (best estimate) 0.003* mrem per year (conservative estimate)

*Note that if *all 100* disposals resulted in a minimum containment accident, the corresponding conservative estimate of dose would not exceed 0.3 mrem per year.

TABLE 4-10. EXPOSURE TO RADIATION FROM SEA DISPOSAL—MAXIMUM EXPOSED INDIVIDUAL

Scenario	Total Body Radiation Dose Commitment from One Year's Exposure (Highest Year)
a) 100 Submarines, 3 Disposals per Year for 33 Years, normal disposal	1×10^{-10} mrem per year (best estimate) 0.003 mrem per year (conservative estimate)
b) 100 Submarines, 3 Disposals per Year for 33 Years, one disposal results in a minimum containment accident	2×10^{-8} mrem per year (best estimate) 0.06 mrem per year (conservative estimate)

The hypothetical direct biological path would involve exposure to radioactivity at or near the immediate disposal site, where the effects of dispersion and diffusion would be minimal. Although no biological pathway from the deep ocean directly to man has been identified, an estimate of exposure to man has been developed based on the assumption that fish or other sea life are continuously exposed to the maximum radioactivity concentrations either in the water or in the sediment at the deep ocean disposal site, and that one or more humans consume such seafood at the unusually high annual rates of Reference 4.21. The resulting total body exposure estimates are 0.2 mrem per year for the maximum radioactivity concentrations in the water and 3 mrem per year for the maximum radioactivity concentrations in the sediment at or near the disposal site. These conservative approaches for estimating exposures via a hypothetical pathway are described in Appendix J. These exposures are not considered to be a consequence of sea disposal of defueled submarines, but were included to show that this hypothetical pathway would not result in large exposures to the few individuals who might be affected.

Population Exposures. The maximum possible radiation exposure estimates for the year of highest concentration in coastal waters for the entire population of the United States West Coast, resulting from disposal of 100 submarines at sea, is estimated to be less than 6 man-rem. This estimate was obtained by multiplying the conservatively estimated (unrealistically high) exposure to individuals with average consumption and occupancy rates, shown in Table 4-9, by 30 million to represent the approximate 1980 population of all three West Coast states. The actual maximum year population exposure would be less than this because the entire population would not be exposed to the highest water concentrations.

The estimated maximum year exposure of 6 man-rem to the assumed population of 30 million would be less than 0.0002 percent of the annual exposure (3,000,000 man-rem) of the same population due to naturally-occurring background radiation, based on an average rate of 100 mrem per year (Section I of Appendix J). The maximum number of health effects (cancers) predicted for this year of highest exposure would be about 0.003 for the entire assumed coastal states' population, calculated using the conservative linear relationship of 0.00045 additional cases of cancer in a population for each man-rem (Reference 4.15). Even if the sensitivity to low level radiation were 10 to 20 times greater than this, as argued by some scientists (Reference 4.18, for example), only 0.03 to 0.06 additional cancers would be predicted. As mentioned earlier, the actual annual effects would be expected to be even less than 0.003 additional cases of cancer because part of the population would be expected to be exposed to lower concentrations of radioactive material in the pathways. Also note that if the best estimate exposure to average individuals were used, from Table 4-9, the population exposure would be 2×10^{-7} man-rem with a corresponding decrease in health effects.

The predicted effects are extremely small when it is recognized that in a country such as the United States, a population of 30 million would be expected to experience about 54,000 fatal cancers each year from all causes (Reference 4.19). The additional fractional case of cancer predicted to result from 100 submarine disposals at sea, for the conservative estimate of the year of maximum effect, would be less than 0.000006 percent of the total cases (i.e., 0.003 ÷ 54,000). This would be substantially less than the statistical fluctuation.

In the above discussion, health effects were estimated on the basis of total body exposure of the population. If the maximum organ exposure were used instead of total body exposure, the estimated health effects would be approximately the same or smaller.

(e) **Engineered Improvements to Minimize Radioactivity Release.** Disposal of decommissioned nuclear submarines could be accomplished merely by restoring the full containment integrity of the reactor vessel following defueling, and then towing the ship to the disposal area where the hull could be perforated to sink the ship. In this case, the radioactivity would be effectively contained since over 99 percent of the radioactivity is an integral part of the structural metal components contained within the reactor vessel, which would be expected to remain intact and closed even under the most severe conditions.

An additional consideration is that the containment that results solely from the inherent property of the activated metal places this material in the category defined by the Department of Transportation (Reference 4.16) as "special form radioactive material" which presents little hazard due to radiotoxicity and little possibility of contamination. Even though the disposal package would not present a significant hazard if predisposal preparations were minimal, a number of engineered improvements over the minimum have been developed in order to reduce the probability of release of even small amounts of radioactivity.

Of these improvements, several would be incorporated if the sea disposal option were selected. In addition, several other engineered improvements have been evaluated with the conclusion that they should not be given further consideration for the disposal action because of their low effectiveness relative to the worker's exposure and costs involved.

Those improvements that are considered to be of value and which would be implemented if sea disposal were selected, include the following:

(1) Restoration of the full integrity of the reactor compartment after defueling to provide maximum containment.

(2) Isolation of the reactor compartment from adjoining ship's compartments. A one-way valve would allow inward flow to the reactor compartment.

(3) Completely controlled filling of the reactor vessel, the remainder of the reactor plant, and the reactor compartment prior to sinking. This step would ensure that the reactor compartment is completely filled with water to avoid subsequent crushing by high pressures at great depth.

(4) Modifications of the hull outside the reactor compartment to ensure that the entire submarine would be flooded uniformly and early in the sinking operation, thereby avoiding crushing of any compartment. This precaution would also contribute to the objective of maintaining the ship at a normal angle during sinking.

These improvements would be intended to provide multiple containments for the radioactive material and preserve the integrity of those containments. This approach would provide a defense in depth against premature release of radioactive material to the environment.

Other engineered improvements that were evaluated but were not selected for further consideration because of expected high costs and essentially no gain in containment effectiveness include the following:

(1) The use of a special-purpose surface vessel such as the GLOMAR EXPLORER to lower the submarine to the sea bottom, thus providing exact placement of the hull and avoiding impact with the ocean floor.

(2) The use of drogues or parachutes to limit the impact when the submarine reaches the ocean floor.

(3) The addition of solid filler material (such as concrete) to the reactor vessel as a method of further retarding the release of radioactive material to the environment.

Since Navy experiments and calculations show that the hulls would not be damaged by impact with the clay sediment bottom typical of potential disposal sites at the maximum velocities expected, the first two measures would only increase the cost without benefit. For the third measure, in addition to cost considerations, the additional radiation exposure to shipyard workers involved in adding the solid filler material (approximately 10 man-rem per ship) would be greater than any reduction in exposure due to this engineered improvement.

(f) **Removal or Containment.** Although there is no technical basis for expecting that retrieval or containment of the radioactive waste would ever become necessary, methods for doing so have been examined and found to be technically feasible, as described in Appendix M. A practical and effective way to provide containment would be to envelop the entire submarine with freshly mixed concrete delivered from a ship on the ocean surface through a long pipe. This would draw on established technology and equipment. Alternatively, the submarine could be recovered from the ocean floor by a special, heavy-lift ship. Such a ship would have to be constructed or an existing vessel would have to be extensively modified, but this approach would also use existing technology as demonstrated by the Glomar Explorer. Costs of either approach would not be impractical.

4. Non-Radiological Effects

(a) **Irreversible or Irretrievable Commitment of Resources.** A total of approximately 4000 tons of potentially salvageable material per ship would be discarded. The material would be primarily low-alloy steel, with lesser quantities of stainless steel, copper, bronze, lead shielding, and other metals and plastics. During shipyard preparations prior to disposal, readily removable equipment of value and items in short supply or with long procurement times would be salvaged for reuse. Some material such as the batteries or ballast lead would be removed for salvage.

The amount of non-salvaged material, while substantial in total quantities, would not approach a significant fraction of the United States production during the disposal period. None of the materials is in short supply nor are the resources of these metals expected to be exhausted in the near future. The lost scrap value of the salvageable metal would be approximately $0.3 million per ship.

One or more limited and remote areas of the seabed would be irreversibly committed to use as a disposal site. An area probably less than 100 square miles required for a single disposal site accommodating the entire group of 100 ships would be identified, representing 1.3×10^{-4} percent of the ocean floor deeper than 4000 meters. For most practical purposes, the presence of sunken submarines on the ocean floor in areas such as those studied would have no adverse effect on usage of the sea, the seabed, or the sub-seabed. In general, a disposal area would in fact be selected for its lack of attraction for human activities, assuring that its use as a disposal site would have little effect.

(b) **Secondary or Indirect Effects**

(1) **Non-Radioactive Material Added to Ocean Waters.** The principal non-radiological effect associated with sea disposal would be the addition of quantities of dissolved and insoluble substances, primarily iron oxides and other metallic oxides, and smaller amounts of plastics and asbestos, to the water column and the sediment. These substances would not be added in unusual or significant amounts in comparison to the quantities of such materials added to the oceans by intentional dumping of construction

and demolition rubble, dredge spoils, and miscellaneous materials by maritime accidents, and by natural runoff of water from the land. On the basis of 100 submarines each contributing 4000 tons of iron to an ocean basin such as the nominal North Atlantic with a volume of 10^{17} cubic meters, it may be estimated that the total potential addition to the iron concentration in seawater would be on the order of 10^{-5} μg per liter, which is a small fraction of the normal seawater concentration of 3 μg per liter (Table 2 of Reference 4.14). However, most of the corroding iron would be expected to mix with the sediment instead of going into solution.

The addition of the heavy metal lead to the ocean environment would not cause any unacceptable environmental impact. For submarine disposal at sea, the non-salvageable lead would be in solid slabs of at least 95 percent purity, and very resistant to corrosion. The lead would not be in the form of soluble salt compounds or in the form of tetraethyl lead which are of greater environmental concern. The form of the lead therefore would prevent its becoming a significant source of toxicity (Reference 4.20).

The maximum concentrations of lead in the seawater at locations downstream from the disposal site would be less than the water quality criteria published by the EPA for protection of seawater aquatic life, Reference 4.27. Corrosion data for lead exposed to seawater are provided in Appendix F. Calculational methods for estimating the maximum concentrations of lead in seawater are described in Reference 4.28.

Small quantities of inert materials such as asbestos, shielding polyethylene, electrical insulation, and other plastics would be included along with the larger quantities of metal. Prior to disposal, all of the submarine's tanks containing liquids other than water would be drained and all other liquids and gases would be removed with only small residual quantities of fuel and oil remaining. For instance, as noted above, the ship's batteries would be drained and removed. Little or no mercury would be contained in the submarine, and the quantities of heavy metals such as lead, cadmium, and chromium would be reduced as far as practicable with no significant effects expected. These metals would be present as inert, insoluble, solid material. The small quantity of cadmium would not be in the "prohibited material" category of Reference 4.17, Section 227.6.

These non-radiological effects are the same as those associated with the sinking of surplus ships that are not nuclear powered. Such disposal by the Navy is already permitted by U.S. Environmental Protection Agency regulations (Part 229.2 of Reference 4.17). The disposal sites for these surplus ships must be at least 50 nautical miles from land with water depth of at least 6000 feet (1800 meters).

(2) **Effects on the Ocean and Seabed Ecology.** The presence of one or more submarine hulls on the ocean floor would provide an attraction to the small population of sea life in the area local to the disposal. For example, it could be expected that some part of the area population would seek shelter on or near the hulls. This phenomenon has been observed in shallow coastal waters where automobiles and other objects have been placed on the ocean floor. Observations made of the nuclear submarine SCORPION hull in 1979, eleven years after the submarine was lost off the Azores in over 10,000 feet of water, included the fact that some colonization had occurred, but the number of animals residing on or near the hull appeared to be approximately as small as that in the surrounding area. Grassy-looking small animals were observed to be present over much of the hull surface, but few higher animals were seen.

Visual and photographic observations of marine life were made in August 1983 at the THRESHER debris site. These observations indicate that the debris has not produced a significant reef effect during the approximately 20 years that it has rested on the bottom. There were no discernible differences in biomass concentrations between the debris site and the surrounding area. (See "Recent Results" in Appendix D, Annex.)

Radioactivity measurements were conducted on 63 individual fish (primarily rattails) obtained in August 1983 from the immediate vicinity of the THRESHER site, and on 15 samples containing hundreds of assorted marine macrofauna and benthos. No radioactivity above natural background or fallout levels was observed. This information is also provided in the "Recent Results" section of Appendix D, Annex.

For bottom-dwelling sea life that might inhabit the immediate area of a disposal site, the maximum radiation effect was estimated (Section II.A.3.(a) above) to be 0.3 rads per year. This rate would not be expected to have any significant effect, since it would be small in comparison to the natural radiation exposure received by some mid-water dwelling species, and in comparison to the dose rates that would be expected to produce any detectable change or significant deleterious genetic effects. (See Section II.A.3.(a)).

The non-radiological effects of submarine disposal on the local ecology would be expected to be less than or comparable to the local effects associated with any of the hundreds of large merchant vessels sunk each year throughout the world (Reference 4.19) as a result of storms, collisions, fires, or other mishaps. The planned sinkings of obsolete, conventionally-powered U.S. Navy ships are permitted by the U.S. Environmental Protection Agency (Reference 4.30) at depths of at least 6,000 feet, and at locations at least 50 miles from land. Sea disposal of decommissioned, defueled nuclear submarines would therefore occur only at deeper, more remote sites than currently approved for conventionally powered excess naval vessels.

(3) **Effect on the Economy of Coastal Areas.** Any acceptable sea disposal site would be remote from land and, as discussed in the preceding sections, submarine disposal at such a site would not impact coastal areas. Therefore the economy of coastal areas would not be subjected to any limitations on the use of land, water, fisheries, or other resources.

However, since the economies of many coastal regions depend on recreation, tourism, and fisheries, an effective environmental monitoring program would be essential to assure the public that no adverse impact had occurred.

(4) **Effects of Work in the Shipyard.** As with land disposal, as discussed in Section I.A.3.(b) but to a lesser extent, shipyard preparations for sea disposal would be accompanied by smoke and fumes from cutting and welding torches, noise, and the generation of scrap metal. These effects are expected to be similar to those from normal shipyard activities. They would affect only a small area in the near vicinity of the shipyard.

The overall effects of this action on the local environment and ecology are expected to be negligible.

B. ADVERSE ENVIRONMENTAL EFFECTS OF POSSIBLE ACCIDENTS INCIDENT TO THE SEA DISPOSAL OPTION

1. Accidents Involving Radioactive Material

There is one category of radioactivity-related accident involving a defueled and decommissioned nuclear submarine that stands out as having the potential to raise concern for the environment. This accident, which has been analyzed on a worst-case basis and found to have a very limited impact, would be the premature sinking of the submarine in waters close to areas that attract human activities with the submarine lost in such a way that recovery would not be possible. Although a non-recoverable premature sinking accident is unlikely, it is not impossible. However, it would require a collision that would open the submarine to rapid flooding, and the probability of such a collision would be minimized by a combination of precautions including traffic restrictions, weather requirements, and accompanying vessels.

The environmental consequences of this remote accident would be similar to those described for the land disposal transportation accident involving irrecoverable loss of the reactor compartment in the sea within approximately 25 kilometers (16 miles) from land (Section I.B.1.(b)). For the latter accident involving a barge shipment of the reactor compartment, the expected number of serious accidents during the entire land disposal program would be approximately 0.00009, as discussed in Section I.B.2.(c). The expected number of sinkings of a submarine being towed to a sea disposal site would similarly be much less than one, although statistics comparable to those for barge towing are not available.

A location 25 kilometers from shore was selected for the accident impact analysis because it would represent a region on the continental shelf, with water depth great enough that recovery might be difficult, and about as near to land as highly productive fishing grounds might be located. For that case, a conservative dose commitment of approximately 3 mrem per year was estimated for the most exposed individual, while the best estimate of this exposure is 0.9 mrem per year. For details of these exposure estimates, see Appendix J, Sections III.C and III.E.

If recovery were practical, it would be accomplished in a short time (estimated to be less than one year) so that any release of radioactive material would be less than that considered above for the irrecoverable loss accident, regardless of the effects of the accident on the reactor compartment containment or the reactor vessel containment.

2. Non-Radiological Accidents

The following accidents and their consequences have been considered.

(a) **Fire or Explosion in the Shipyard.** No abnormal potential for fires or explosions are foreseen with this option. This area of possible concern is discussed in Section I.B.2.(a).

(b) **Towing Accidents.** Towing accidents include collisions with another vessel or loss of the tow, with the most severe being the premature sinking of the submarine. The primary concerns would involve personnel safety. The environmental concerns associated with possible penetration of the hull and sinking the submarine closer to land than the normal disposal site have been discussed in Sections II.B.(1) and II.A.4.(b)(1). The personnel safety aspects of the towing operation would be adequately covered by operating instructions dealing with the prevention of accidents and response to emergencies. It is not expected that personnel would be aboard the submarine while it is being towed to the disposal site.

C. CUMULATIVE EFFECT OF SUBMARINE DISPOSAL AT SEA

The incremental environmental impact of disposal of all one hundred submarine reactor plants at one ocean disposal site would be so small that there would be no significant cumulative impact resulting from this action. For example, based on very conservative calculations, the effects of ocean disposal might produce at most an incremental exposure of 0.0002 millirem/year to a typical member of the population most directly affected. This potential exposure is very small in comparison to fluctuations in exposure resulting from variations in individual activities and geographic location. There is no potential for submarine disposal at sea to contribute to a significant cumulative impact.

Considering the total of all past and present sea disposal activities, the additional environmental impact of submarine disposal at sea would not cause a significant increase in the total environmental impact.

As described in Section I.C.a, synergistic effect between radiation and other physical, chemical, or biological agents is not likely.

III. NO ACTION ALTERNATIVE (PROTECTIVE STORAGE PRIOR TO PERMANENT DISPOSAL)

It would be possible to safely store nuclear powered submarines after defueling and decommissioning at one of the existing sites for protective storage of inactive naval vessels. In fact, such storage can be classified as the "No Action" alternative for this environmental statement. However, this storage is not a satisfactory permanent solution of the need for safe disposal because it only postpones the disposal. At the end of the storage period the submarine reactor plants would have to be disposed of as radioactive waste on land or at sea since these remain the only available options.

The containment for the radioactive material that is provided for both the land and sea disposal options would prevent the release of radioactive material to the environment for a period as long as or longer than it would be feasible to maintain the submarines in protective storage. Therefore, the net release to the environment following disposal from storage would be approximately the same as for immediate disposal by the same means. During the protective storage period, regular maintenance and inspection would be needed, resulting in costs and radiation exposure in addition to those associated with disposal. It would also be necessary every 20 years to move each ship into drydock for hull maintenance. Consequently, protective storage of the submarines should be considered only as a way of preserving the ships for future use, in accordance with national policy, and not as a disposal option.

This section summarizes the environmental impacts associated with protective storage in combination with both of the ultimate disposal options. An indefinite period of protective storage may be viewed as the "No Action" alternative within the context of the National Environmental Protection Act. The impacts associated with this would be as presented in the following sections.

A. LAND DISPOSAL OPTION COMBINED WITH PROTECTIVE STORAGE

The environmental consequences of the land disposal option, if carried out after an extended period of protective storage, would be the same as described in Section I, with the following exceptions.

1. Occupational radiation exposure would be increased from approximately 17 man-rem per submarine to approximately 20 man-rem if disposal preparations were conducted after a protective storage period of 20 years. This increase results from some duplication of effort plus necessary maintenance and surveys during the protective storage period which would add approximately 2 man-rem to the total exposure.

2. Direct radiation exposure to members of the public would be reduced by a small amount because of the radioactive decay of the principal source of external radiation (Cobalt-60). However, this exposure is insignificant in any case (10^{-3} man-rem population exposure if land disposal occurs immediately).

3. The radiation effects of hypothetical accidents would be essentially eliminated because of the decay of Cobalt-60, which is the principal radionuclide that might cause the hypothetical accident-related exposure. However, this exposure is small in any case (hypothetical maximum individual exposure would be less than 0.3 mrem to the total body and 49 mrem to the lungs if land disposal occurs immediately), and the probability of the extreme accident is very small.

4. The quantity of radioactive material that would be placed in the burial site would be decreased through radioactive decay by a factor of at least 4 (as shown in Figure 1-2 of Chapter 1). However, this would have no effect on the environmental aspects of land disposal because the only radioactive nuclides that would be released to the environment (principally Nickel-59, with a half-life of 80,000 years) would not be affected by any practical delay period. Those radioactive nuclides that would decay to stable form during the protective storage period would not be released to the environment even if land disposal were carried out immediately.

B. SEA DISPOSAL OPTION COMBINED WITH PROTECTIVE STORAGE

The environmental consequences of the sea disposal option, if carried out after an extended period of protective storage, would be the same as described in Section II, with the following exceptions.

1. Occupational radiation exposure would be increased from approximately 17 man-rem per submarine to approximately 20 man-rem if preparations for disposal were carried out after a protective storage period of 20 years. This increase results from some duplication of effort plus necessary maintenance and surveys during the protective storage period which would add approximately 2 man-rem to the total exposure.

2. Direct radiation exposure to members of the public would be reduced by a small amount because of the radioactive decay of the principal source of external radiation (Cobalt-60). However, this exposure is insignificant in any case (less than 10^{-3} man-rem population exposure if sea disposal occurs immediately).

3. The radiation effects of hypothetical accidents would be essentially eliminated because of the decay of Cobalt-60, which is the principal radionuclide that might cause the hypothetical accident-related exposure. However, this exposure is small in any case (hypothetical maximum individual exposure would be 4 mrem per year if sea disposal occurs immediately), and the probability of the extreme accident is very small.

4. The quantity of radioactive material that would be placed in the sea disposal site would be decreased by a factor of about 4 (as shown in Figure 1-2 of Chapter 1). However, the only environmental effect of this decrease would be a reduction in the release of Nickel-63, which has a half-life of 92 years. For a 20-year protective storage period the reduction would be 14 percent and for a 40-year protective storage period the reduction would be 26 percent. Since the environmental effects of the release of Nickel-63 would be very small even if sea disposal were to occur immediately (0.0002 mrem per year is the conservative, unrealistically high estimate of exposure to the average member of the population), these reductions are not significant. For radionuclides other than Nickel-63, the shorter-lived nuclides such as Cobalt-60 and Iron-55 would not normally be released to the environment even if sea disposal were carried out immediately, and for the longer lived nuclides (principally Nickel-59, with a half-life of 80,000 years) their eventual release to the environment would not be affected by any practical delay period.

IV. SUMMARY AND CONCLUSIONS

The expected environmental impacts of submarine disposal have been described in this chapter. The best estimate radiation exposures associated with sea disposal are of negligible magnitude, and even the unrealistically high estimates are extremely small. Table 4-11 shows a summary of all these conservative estimates of radiation exposure for both permanent disposal options. Normal exposures as well as accident-caused exposures are included in the table. These exposures are all of very limited magnitude; for example, the conservatively high estimate of population dose commitment for all 100 disposals is estimated to be 2.1 man-rem per year for land disposal and 6 man-rem per year for sea disposal. These estimates show no significant difference between the two disposal options, and no significant impact of either option. Comparisons of the other exposure estimates lead to the same observation.

Because of these very low radiation-related impacts, it is concluded that either option would be acceptable, and that the choice of options should not be based on radiological considerations.

The non-radiological impacts of the two disposal options are summarized in Table 4-12. Of these impacts, the only significant difference between the land and sea disposal options appears to be in the dollar costs, which are $1.8 to $2.0 million per ship greater for the land disposal option, assuming that with the latter option the rejoined hull would be sunk at sea. The difference between the two options increases to $7.8 to $8.1 million per ship if the hull is to be scrapped in the land disposal option.

It may be concluded that either option would have negligible environmental impact.

TABLE 4-11. TOTAL BODY EXPOSURE—SUMMARY OF ESTIMATES ASSOCIATED WITH LAND DISPOSAL AND SEA DISPOSAL OF DEFUELED, DECOMMISSIONED SUBMARINE REACTOR PLANTS

(Dose Commitments are from one year's exposure, highest year)

(Conservative estimates rather than "best estimates" have been used in this table.)

	Number of Disposals	Exposure to Average Individuals		Population Exposure		Exposure to Maximum-Exposed Individuals	
		Land Disposal	Sea Disposal	Land Disposal	Sea Disposal	Land Disposal	Sea Disposal
A Occupational Exposure							
1 At shipyard	1	≤3 rem/qtr*	≤3 rem/qtr*	17 man rem	17 man-rem	≤3 rem/qtr*	≤3 rem/qtr.*
2 During movement to and at disposal site	1	<1 0 rem	<0 1 rem	<1 0 man-rem	0 1 man-rem	<1 0 rem	<0 1 rem
B Public Exposure							
1 During transportation to disposal site	1	0.00006 mrem	<0 00006 mrem**	<0 001 man-rem	<0.001 man-rem**	0.0007 mrem	0.0007 mrem**
2. As a result of normal expected disposal	100	0 006 mrem/yr	0 0002 mrem/yr	2 1 man-rem/yr	6 man-rem/yr	1.5 mrem/yr	0.003 mrem/yr
3 As a result of sea disposal where only minimum containment results	99 normal plus one minimum containment	Not applicable	0 003 mrem/yr	Not applicable	90 man-rem/yr	Not applicable	0 06 mrem/yr
4. As a result of accident-related release							
a Immediate exposure	1	0.0014 mrem	Not applicable	0.0014 man-rem	Not applicable	0.3 mrem	Not applicable
b Delayed exposure	1	0 1 mrem/yr	0 1 mrem/yr	3 man rem/yr	3 man-rem/yr	3 mrem/yr	3 mrem/yr

*Exposures shown are occupational limits, which would not normally be approached, for shipyard workers trained for radiation-related work.

**Transportation exposures to the public associated with sea disposals are expected to be negligible. The tabulated values indicate that such exposures would be less than for land disposal.

TABLE 4-12. SUMMARY OF NON-RADIOLOGICAL IMPACTS OF THE TWO PERMANENT DISPOSAL OPTIONS

Environmental Aspect	Adverse Impact of Land Disposal: Hull Scrapped	Adverse Impact of Land Disposal: Hull Sunk at Sea	Adverse Impact of Sea Disposal
1. Commitment of Resources			
a. Costs* active ship	$13.3 million	$ 7.2 million	$5.2 million
inactive ship	$16.2 million	$10.2 million	$8.4 million
b. Material lost to possible future use (primarily steel)	1000 tons per ship	4000 tons per ship	4000 tons per ship
c. Area of radioactive waste disposal site removed from general use	Up to ten acres total plus temporary use of less than two acres additional area at Savannah River Plant for river landing slip and barge unloading facilities		Less than 100 square miles total (less than one million square feet actually covered by 100 hulls)
2. Material added to the radioactive waste disposal site	1000 tons per ship		4000 tons per ship
3. Preparation of landing slip and barge unloading facilities (land disposal only)	Removal of approximately 7800 cubic yards of earth at Savannah River Plant, requiring disposal in accordance with applicable regulations		Not applicable
4. Pollution Effects			
a. At and near shipyard	Localized noise pollution; smoke and fumes from cutting and welding torches; generation of scrap metal		Localized noise pollution; smoke and fumes from cutting and welding torches
b. From shipyard to disposal site	Limited air and water pollution due to burning of fuels and operating the tug and barge over the coastal waterway and rivers		Limited air and water pollution due to burning of fuels and operating ocean-going tug
c. At disposal site	Addition to site of asbestos, plastics, lead, and other metals, primarily steel		Addition to site of asbestos, plastics, lead and other metals, primarily steel
	No effect on local plant and animal life at land disposal site. If hull sunk at sea, the non-radiological impacts at the sea disposal site would be expected to be similar to those described for sea disposal of the entire submarine.		Disposed hulls might be expected to alter the distribution of life in the localized area. Effects should be the same as the small localized effects caused by other vessels sunk in deep water.

*Costs in 1981 dollars.

APPENDIX A

COST ANALYSIS

I. INTRODUCTION

This appendix provides information on the estimated costs associated with the options for disposal (by land or by sea) or for protective storage prior to disposal. Economic costs and radiation doses are both considered. Additional information is provided on the costs associated with certain activities within these options where significant alternatives were identified. These factors are important to deciding which alternatives should be considered further and which option should be considered most appropriate for disposal in a safe and environmentally acceptable manner.

Following the completion of normal service, a submarine would pass through a process that consists of six principal steps, in sequence:

1. Defuel the reactor and decommission the submarine.

2. Inactivate the submarine.

3. If applicable, prepare the submarine for protective storage and maintain it during protective storage.

4. Prepare the submarine for disposal by land or by sea.

5. Transport it to the disposal site.

6. Complete the disposal.

The first two steps are common to both land and sea disposal and to any storage plan, and have no significant alternative. The last four steps have significant alternatives that depend upon whether protective storage or land or sea disposal would be selected and upon which of the several alternatives would be chosen.

Defueling is a standardized operation for nuclear submarines, and would not differ significantly whether it would be followed by refueling for further service or by inactivation. Defueling and, where appropriate, removal of the missile compartment are not considered to be part of the disposal process, and the costs associated with defueling and missile compartment removal are excluded from consideration in this appendix.

In order to minimize radiation exposures to the workers and to minimize the costs of disposal, the plant would be prepared for disposal with little or no effort expended on maintaining the internal cleanliness of the reactor coolant systems or the functions of the various components that would be retained for disposal. Significant effort would be devoted to assure that radioactive material within the reactor plant would not be released to the environment during the preparations that would be made in the shipyard. Reasonable care and effort would be required to preserve intact the pressure boundaries of the reactor vessel and of the reactor compartment to provide long-term containment for residual radioactive material that would be involved in the disposal action.

Protective storage would be an alternative to immediate disposal, but eventually would be followed by disposal. Maintenance of proper storage conditions during the period of protective storage would incur significant costs. Storage would be in a naval inactive ship maintenance facility. Preparations for storage would include those actions necessary to assure storage in a safe and environmentally acceptable manner for at least 20 years, and periodic actions required during storage would include monitoring the decaying radiation levels and maintenance of essential storage conditions.

The alternatives within the land disposal option are few; they involve the choice of whether the rest of the ship's hull would be disposed of by towing it to sea and sinking it or by cutting it up for scrap. In either event, significant effort would be required to ensure that the rest of the ship's hull would be free of radioactive contamination before disposal. All of the other steps would not have significant alternatives because the actions involved in transport to the burial site by barge and by overland transporter were found to be essentially unique for each of the two potential burial sites: the Hanford Site, Richland, Washington and the Savannah River Plant, Aiken, South Carolina.

Among the numerous alternatives considered for the sea disposal option, one was found to be best in terms of technical feasibility, operational feasibility, and estimated cost: controlled sinking in the flooded free-fall condition. The alternatives considered involve methods for transferring the reactor compartment from the surface of the ocean to the bottom, ranging from free-fall sinking to controlled lowering. Depending upon whether the reactor compartment would be disposed of alone or with other sizeable portions of the submarine, there would also be corresponding alternatives in the necessary preparation and transport techniques.

The costs of the alternatives that appeared to be technically and operationally feasible with respect to safety and environmental considerations were evaluated.

II. SUMMARY

Disposal of submarine nuclear reactor compartments by sinking the entire ship at sea would be safe and environmentally acceptable, and it would be the least costly method of disposal. The estimated cost of disposal by this method is $5.2 million per ship. Other disposal methods considered in detail are estimated to cost as much as $16.2 million per ship.

For burial on land, the least costly method for disposal of reactor compartments is estimated to cost $7.2 million per ship, approximately $2.0 million more per ship than the least costly method of sea disposal. This method of land disposal would involve sea disposal of the rest of the ship's hull.

Alternative land disposal by burial of the reactor compartment and cutting up the rest of the ship's hull for scrap is estimated to cost $13.3 million per ship. Alternative disposal methods that would involve interim storage of the defueled and inactivated ship (including the reactor compartment) for a prolonged period of time, such as 20 years, would cost approximately $3.0 million more per ship, for preparation for storage, storage, and removal from storage before final preparations for disposal.

Interim storage without disposal for an extended period such as 20 years would cost approximately $5.8 million per ship, including inactivation of the ship, preparation for storage, and storage for 20 years. Since interim storage would only defer disposal and would not represent a permanent solution to the need for safe and environmentally acceptable disposal, additional costs would be required for disposal at the end of the storage period. With interim storage for 20 years, the total costs of disposal were estimated to be $8.4 million per ship for sea disposal, $10.2 million per ship for land disposal of the reactor compartment and sea disposal of the remainder of the ship, or $16.2 million per ship for land disposal of the reactor compartment and scrapping of the remainder of the ship. The estimated costs of disposal are summarized in Table A-1.

The estimated costs of monitoring the environment to determine periodically the concentrations of radioactive material associated with sea disposal are identified as a part of the costs of disposal. Monitoring of land disposal is part of existing programs at the land disposal sites and would not involve additional costs. Total costs for the effort required to qualify a sea disposal site are estimated to be approximately $6 million. Total costs for the effort required to monitor the environment in the regions that may be affected by a sea disposal site are estimated to have a present-value cost of nearly $9 million.

Radiation doses would be incurred as a result of any of these methods of disposal, and precautions would be necessary to ensure that the doses would be as low as is reasonably achievable. Radiation doses to the general population and to the hypothetical maximum individual associated with sea disposal are discussed in Appendix J and those for land disposal are discussed in Appendix C. Radiation doses to workers associated with disposal actions are discussed in this appendix; estimated doses amount to approximately 20 man-rem per ship, due mostly to exposures incurred by the shipyard workers during inactivation and preparations of the reactor compartment for either storage or direct disposal.

All of these methods of disposal are considered to be technically and operationally feasible, safe, and environmentally acceptable. Alternatives were identified and evaluated for technical and operational feasibility and for estimated costs before the selected options were chosen and evaluated in detail. The estimated costs and worker radiation doses for the selected options are summarized in Table A-1.

Land disposal of the reactor compartment would be accomplished by burial at either of the two Department of Energy sites, depending upon whether burial was scheduled to occur at Hanford or at Savannah River. These two sites are approved for the burial of low level radioactive wastes. The reactor compartment would be moved onto a barge by jacking and with rollers, transported by water route to the disposal site, and moved overland by a crawler transporter to the burial site.

Sea disposal would consist of sinking the ship with the reactor compartment in place, using the flooded free-fall method. After the reactor was defueled and the ship was inactivated and otherwise prepared for disposal, the control surfaces of the hull would be modified so that the ship would follow a nearly vertical path during descent and would land in a predictable location with rather small uncertainty. An intact landing would be expected to occur, based on model testing and on data obtained from study sites in the Atlantic and Pacific Oceans that were chosen to meet preliminary site selection criteria.

All of the disposal methods that are considered to be technically and operationally feasible are also considered to be safe and environmentally acceptable. None of the disposal methods involve any dose commitment that would approach an unacceptable level. Sea disposal of the entire ship, including the reactor compartment, would have the lowest estimated cost: $5.2 million per ship. Table A-1 summarizes the alternatives.

TABLE A-1. ESTIMATED COSTS OF DISPOSAL

	Estimated Cost per Ship(1)	
Disposal Alternative	Active Ship(2)(4)	Inactive Ship(3)(4)
Sea—Reactor Compartment and Hull Together	$ 5.2 M	$ 8.4 M
Land—Reactor Compartment and Sea-Ship's Hull	7.2	10.2
Land—Reactor Compartment and Scrap Ship's Hull	13.3	16.2

NOTES: (1) Excludes defueling and missile compartment removal.
(2) Estimated worker doses total 17 man-rem per ship.
(3) Includes preparation for and removal from storage as well as estimated costs for 20 years of storage. Estimated worker doses total 20 man-rem per ship, including doses due to preparation (17 man-rem), final actions (1 man-rem), and radiation surveys during storage (2 man-rem).
(4) An Active Ship is one that would be disposed of following completion of active service without protective storage. An Inactive Ship is one that would be disposed of after inactivation and protective storage.

III. DISCUSSION

This section discusses the details summarized above. Requirements are cited for analyzing costs and benefits, the plan of the analysis is described, and the results from the analysis of the alternatives are discussed in detail. Protective storage and the land and sea disposal options and alternatives within these options are discussed.

A. REQUIREMENTS

The primary need for careful disposal is to ensure that the radioactive material associated with the reactor plant is disposed of in a safe and environmentally acceptable manner. Careful disposal will isolate the radioactive material from man's environment until it has decayed to innocuous levels. Among the candidates for disposal methods that are technically and operationally feasible, the preferred ones would be those with the lowest economic costs and the lowest health effects.

The body of this environmental impact statement presents the environmental impacts of the reasonable alternatives in comparative form to sharply define the issues and provide a clear basis for choice among options. Among the alternatives, those that were eliminated from detailed study are identified and the reasons for their having been eliminated are briefly discussed. Substantial treatment is provided to each alternative considered in detail. The alternatives of no action and of appropriate mitigation measures are included. The details of the affected environments and the environmental consequences are described in the body of this document and in other appendices.

B. PLAN

The main considerations would be the choices between protective storage and prompt disposal, and between land and sea disposal, since extraterrestrial disposal is not considered to be a viable alternative. Either land or sea disposal or protective storage for approximately 20 years would be environmentally acceptable because detailed evaluations of both options have shown that no adverse environmental effect would approach an unacceptable level.

All of the alternatives that have been considered for disposal are identified schematically on Figure A-1. It starts at the point where the submarine to be disposed of has been defueled and decommissioned. It proceeds through the alternatives of disposal location and when it would be accomplished. Extraterrestrial disposal is cited, but is not considered to be feasible because of the great size and weight of the material and the large costs that would be involved. Interim and long-term storage are alternatives to prompt disposal which would lead ultimately back to the same considerations; although the amount of short-lived radioactivity would be decreased markedly and the costs would be increased markedly.

The focus of the evaluation is on prompt disposal because it is less costly, but storage is also considered. Long-term storage is considered to be a less desirable alternative because it avoids the responsibility for the disposal decision by assuming that a future technology might be superior to that of the present, and that the actual cost of long-term storage would be offset by potential benefits to be realized at the future time. This is considered to be unlikely. On this basis, long-term storage was not evaluated in detail, but the cost of storage for 20 years has been estimated. The remaining six alternatives have been evaluated in detail:

1. Sea disposal of the entire ship immediately
2. Sea disposal of the entire ship after interim storage
3. Land disposal of reactor compartment, rest of ship disposed of by sea; immediately
4. Land disposal of reactor compartment, rest of ship disposed of by sea; after interim storage
5. Land disposal of reactor compartment, rest of ship disposed of by scrapping; immediately
6. Land disposal of reactor compartment, rest of ship disposed of by scrapping; after interim storage.

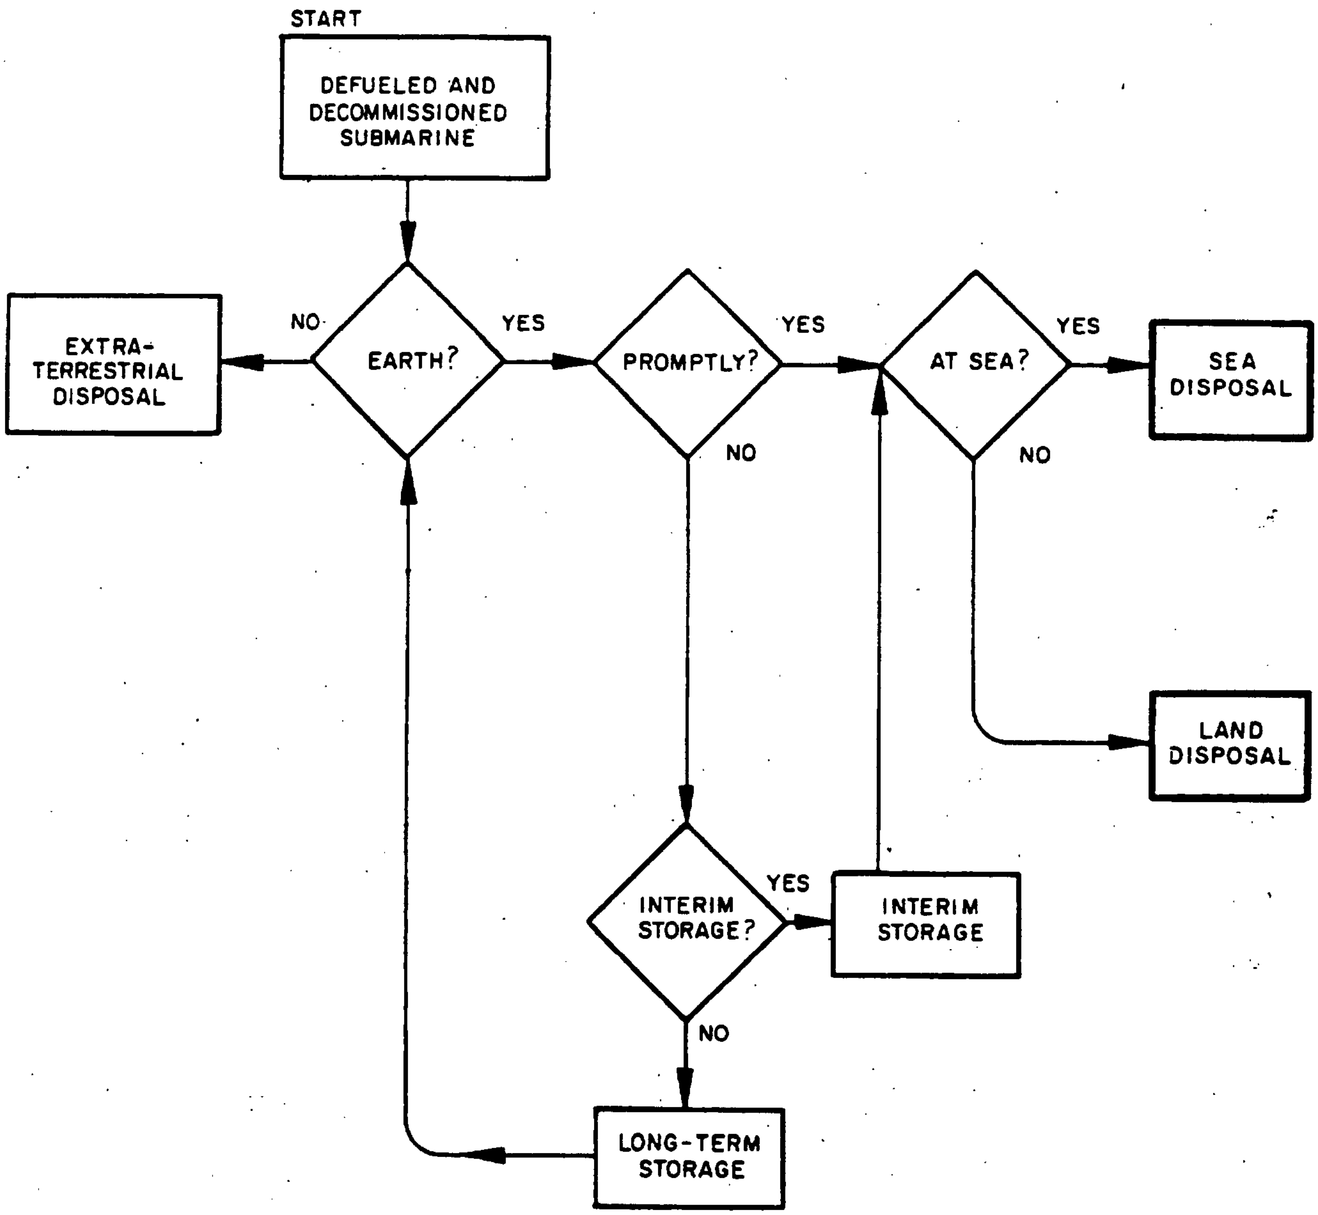

Figure A-1. Disposal Alternatives

Other factors were considered and the corresponding alternatives were evaluated. Some of these alternatives would have small environmental consequences; others would affect only the technical or operational feasibility of the disposal plan or its cost. The results are discussed below.

C. RESULTS

This section describes the alternatives that were considered within the land and sea disposal options.

1. Land Disposal

Land disposal would include removing desired equipment, inactivation of the ship and the reactor plant, and cutting the reactor compartment free from the rest of the ship. Remaining radioactive material would be removed from the rest of the ship and sealed within the reactor compartment. The rest of the ship would be surveyed to identify radioactive materials to be removed before disposal. The reactor compartment would then be moved by barge and overland transporter to an approved Department of Energy site for burial. The only two available sites are in South Carolina (Savannah River Plant) and Washington (Hanford Site). Radiation levels associated with the entire operation would meet all requirements of the Department of Transportation and the Department of Energy for radioactive waste and its disposal. The remaining bow and stern sections of the ship, after inactivation and removal of desired equipment, would be disposed of by either cutting them up for scrap or welding them together for sinking at sea.

There are few viable alternative methods for land disposal. After defueling and inactivation of the submarine, the reactor compartment would be prepared, removed, and transferred to a barge for shipment to the disposal site. Alternative methods for movement of the reactor compartment to the barge were identified and evaluated for technical and operational feasibility and comparative costs were estimated, as described in Appendix B (Section III.B.5). Of the six methods considered, the use of jacks and rollers was found to be optimum and would be preferred for disposals at either Savannah River or Hanford. There would be no significant difference in environmental consequences among the alternative methods for moving the reactor compartment.

Shipment by barge to the disposal site does not have a feasible alternative. The reactor compartment would be too large for either rail or truck transport to be suitable. The route to the site would be uniquely determined by the locations of the shipyard and the corresponding burial site.

At the disposal site, the reactor compartment would be removed from the barge and transported to the burial site by a commercially-available crawler transporter that would be capable of supporting the load and traveling over available routes. Tentative routes at Hanford and at Savannah River were chosen to minimize the cost and the interference with local traffic. Details are provided in Appendix B.

The dominant cost element for land disposal would be the shipyard effort for inactivation and preparation for disposal. Capital equipment and other one-time items would be needed to support land disposal operations. Jacks and rollers would be needed to move the reactor compartment to the barge, a barge would need to be built or modified, and the land route to the disposal site would need to be modified and upgraded. Recurring items for land disposal operations would include towing the barge, leasing a barge or amortizing the cost of building it, and leasing the crawler transporter. The estimated costs are discussed in detail below.

2. Sea Disposal

Sea disposal would include removing desired equipment, inactivation of the ship and the reactor plant, preparations for towing and controlled sinking, and placing the entire submarine on the ocean bottom at a specified deep ocean location. It is anticipated that the sites would be within the U.S. economic zone and located approximately 200 miles from the east or west coasts of the contiguous states.

Sites would be selected on the basis of geological stability, remoteness from human activity and food supplies, and low expectation of future human activity. Selected sites would be unlikely to be disturbed by seismic or volcanic action, or by ocean movement. At the selected sites, the ocean currents near the bottom would be very low, and the sea floor itself would be stable, with a thick layer of sediment over the underlying rock formation.

Controlled sinking of the entire submarine, including the reactor compartment and reactor plant, would be the preferred method of sea disposal. Other methods are described below. The reactor plant and reactor compartment would be filled with water to resist the crushing pressure of the deep sea, and the rest of the ship would be provided with sufficient holes to ensure rapid flooding of all spaces during sinking before the crush depth would be reached. The ship's control surfaces would be modified to control placement on the bottom. Both the reactor compartment and the reactor plant within the compartment would be intact on the ocean bottom. Corrosion of the metal of the hull and reactor plant would be the only way that undecayed radioactivity would be released because the reactor compartment, the reactor plant, and the reactor vessel would all be welded shut before disposal, and almost all of the radioactive nuclides present at disposal would decay to stable forms before any significant release to the ocean environment could occur.

There are a number of practical ways to dispose of the reactor compartment at sea. As with land disposal, preparation for disposal would be preceded by defueling and inactivation of the submarine. Preparation and transport methods would depend upon which alternative would be selected for transferring the reactor compartment from the surface to the bottom of the ocean. These methods are described below and estimated costs are tabulated for the more practical ones.

Methods for transferring the reactor compartment from the surface of the ocean to the bottom were considered from among three possibilities, depending upon the balance of applied forces:

a. It could be lowered to the bottom. Existing line and winch technology, with and without buoyancy assistance, and a ship such as the Glomar Explorer, with special features for raising and lowering heavy loads at great depths in the ocean, were considered.

b. It could be drawn down to the bottom. With buoyancy assistance to nearly balance the forces, a retrievable anchor could be used as a base to pull the unit to the bottom, using existing line and winch technology. After the unit was on the bottom, the buoyant transporter would be remotely detached and the anchor winched up for recovery and re-use.

c. It could be allowed to fall freely to the bottom. Flooded free-fall sinking was considered extensively because of the apparent simplicity. Additional consideration was given to modifications that would improve the accuracy of placement on the bottom and that would reduce the impact loads upon landing on the bottom. This is the lowest-cost method for emplacement, and has been evaluated in detail.

The dominant cost element for sea disposal would be the shipyard effort for inactivation and preparation for disposal. Capital equipment would be required to instrument the ship to measure ship attitudes and accelerations during the disposal process. The instrumentation would be recoverable for use in the ensuing disposals. One-time costs would be needed to support the effort that would be required to qualify potential sites for sea disposal, to ensure that they meet the criteria identified in Appendix E. Recurring items for sea disposal operation would be limited to towing the fully prepared ship to the selected site for sinking and to monitoring the sites, as described in Appendix K, to determine the extent of radioactive material in the environment due to the disposals. The estimated costs are discussed in detail below.

3. The No-Action Alternative

The closest reasonable approach to the "no-action" alternative would involve some minimal actions that would be considered prudent to provide minimal protection of the public safety and to prevent unacceptable environmental consequences. This alternative would include the minimum work which must be accomplished to inactivate the ship and the reactor plant and to prepare them for waterborne storage in a safe and environmentally acceptable manner. No specific action would be taken to enhance the ability to reactivate the ship. The work would include removing hazardous materials and fluids, removing strategic equipment, blanking sea connections, ensuring the preservation of containment barriers such as the hull, and installing fire and flooding alarms. This alternative would not include dehumidification of equipment or tank preservation beyond that needed for ship integrity for 20 years of waterborne storage. Extensive salvage of useful equipment and materials would be performed. Up to 20 years of waterborne storage is considered feasible before docking would be required. For convenience in citing estimated costs, up to one 20-year period of protective storage is considered interim storage, and more than one such period is considered long-term storage.

4. Summary of Other Sea Disposal Methods

Accurate placement on the bottom would minimize the area of the disposal site needed for multiple disposals. On this basis, the Glomar Explorer and buoyancy-assisted lowering were identified as alternatives. Standard line and winch technology would be inadequate for this application because of excessive line size requirements and problems associated with the dynamic loads that would be involved. The Glomar Explorer could handle three reactor compartments in one trip, or one reactor compartment attached to other parts of the submarine, but it would not be feasible to handle an entire submarine because of the need for costly modification that would be required. The Glomar Explorer is currently "mothballed" in the U.S. Maritime Administration's West Coast Reserve Fleet.

If the Glomar Explorer were not available because of other commitments such as the Ocean Margin Drilling Program, accurate placement of a reactor compartment could be achieved with buoyancy-assisted lowering. This method would be too costly to use with configurations larger than just the reactor compartment alone.

Since accurate placement is not necessary because adequate disposal area would be available, any of various flooded-free-fall methods would be suitable. The lowest-cost method was found to be the flooded free fall of an entire submarine. With only the stern planes removed to reduce gliding, the landing site would be between 2000 and 5000 feet from the launch point. The horizontal excursion may be reduced to approximately 1500 feet, thereby minimizing the area needed for disposal, by removing the sail planes and the stern planes and by shifting the center of gravity to obtain a nearly-vertical descent.

Because of the lack of sufficient self-buoyancy, flooded free fall of either a reactor compartment alone or a reactor compartment attached to the aft portion of the submarine would require a barge to move the unit to the disposal site. The barge would need to be designed so that the unit could be suitably launched from it at the disposal site. For the reactor compartment alone, the launch-barge method would allow placement within approximately 55 feet of the launch point, but the estimated cost of this method is undesirably high, as discussed below.

A method of very accurate placement of an entire submarine was not found unless extensive development and technological risk were assumed. Buoyancy-assisted lowering, Glomar Explorer, and a buoyant transporter were considered, but were not found to be suitable because of the high cost.

The relative costs for these sea disposal alternatives are summarized in Table A-2. The table lists the alternatives in approximate order of increasing unit disposal costs, and the corresponding capital costs and recurring costs are included. The unit cost is based on ten disposals at approximately three disposals per year. The costs in Table A-2 are partial costs based on preliminary evaluations and are used only to establish the rank of the relative costs among these alternatives; they include pre-disposal preparations, but not the costs of inactivation or work in the reactor compartment because these would be essentially constant.

The lowest-cost sea disposal method would use flooded free fall of an entire submarine. The next lowest-cost method, buoyancy-assisted lowering of an entire submarine, would not be suitable because of the high development costs and the associated technical risk.

obtain bottom water samples for dissolved oxygen measurements. At both the THRESHER and SCORPION sites, samples of water were transferred to Winkler bottles within 15 minutes after the submersible surfaced for measurement of dissolved oxygen.

Dissolved oxygen was measured using the method of Reference D.A9. Values obtained for the THRESHER and SCORPION debris sites were 7.8 ± 0.1 mg/l and 6.6 ± 0.3 mg/l, respectively. Five samples of water from the THRESHER site and a single sample of water from the SCORPION site were transferred to 500 ml Marinelli sample containers and analyzed at a shoreside laboratory. A sensitive, 150 cc solid state, lithium-drifted germanium detector and gamma spectrum analysis system was used to count and analyze the samples. The Marinelli counting container is a molded, plastic beaker having an inverted concentric well in the center. The depth and diameter of the well allows the detector to fit inside the well when the sample container is in the counting position, thus allowing greater sensitivity than would be possible by simply placing the same amount of sample material in an ordinary container directly upon the detector. The spectral data obtained as a result of the counting of the samples are analyzed by computer techniques to identify the radionuclides present in the samples. Results of the analyses are contained in Table D-A1.

TABLE D-A1. GAMMA SPECTRUM ANALYSIS RESULTS FOR WATER SAMPLES OBTAINED AT THE THRESHER AND SCORPION DEBRIS SITES, JULY 1977
(From Germanium (Lithium) Crystal Detector)

Debris Site	Radioactivity Concentration and 90 Percent Confidence Limits, pCi Per Liter		
	Potassium-40	Cesium-137	Cobalt-60
THRESHER(1)	328 ± 90(2)	ND	ND
SCORPION	236 ± 96(2)	ND	ND

ND = Not Detected. The minimum detectable activity ranged from 3 to 10 pCi per liter.
(1) Results are average values for five samples.
(2) Ninety-percent confidence interval.

B. SEDIMENTS

In-Situ Sediment Gamma Ray Spectrometry, Sediment Sampling, and Analysis

The first type of measurement at each of the two sites consisted of direct measurement of the gamma-emitting radionuclides in the sediments and on debris by employing an underwater gamma detector mounted on the outside of the submersible. The gamma detector used at the THRESHER site consisted of a 10-centimeter diameter by 10-centimeter high cylindrical crystal of cesium iodide. The crystal, its photomultiplier tube, and the associated electronics were contained in a pressure housing made of aluminum with a 2.5-centimeter thick hemispherical front end, cylindrical walls, and a 5-centimeter thick back end plate. The signals from the detector were wired into the diving sphere of the deep submergence vehicle TRIESTE, where a multichannel gamma spectrometer was used to monitor the signals. The multichannel analyzer displayed the gamma ray spectra and was connected to a printer such that each of the spectra could be recorded.

For the survey at the SCORPION site, a sodium iodide detector was used in addition to the cesium iodide detector. The sodium iodide detector consisted of two extruded NaI(Th) polycrystalline "scintillators," each 5 centimeters in diameter and 40 centimeters long. These scintillators, along with their photomultiplier tubes and associated electronics, were each contained in a separate pressure housing. The pressure housings were cylinders 7.5 centimeters in diameter and 100 centimeters long with hemispherical ends. The walls and ends were made of 0.63 centimeter thick alumina ceramic. The open ends were capped with 3.8 centimeter thick plates of monel. The two cylindrical vessels are held parallel, about 5 centimeters apart, by a supporting frame.

The detectors were deployed from the bow winch of the TRIESTE. This arrangement allowed the detectors to be lowered one to two inches into the bottom sediment at the various sampling stations.

A total of 13 sampling stations were selected to be monitored in the immediate vicinity of the THRESHER debris in 1977. At two of the stations direct probe measurements were made within a meter or two of the debris. The area surveyed was approximately 100 meters by 300 meters or roughly 30,000 square meters. For the SCORPION survey, a total of 17 sampling stations were monitored in the vicinity of the debris in 1979. The area surveyed was approximately 150 by 220 meters or roughly 33,000 square meters. Figure D-A4 shows the distribution of sample stations at the THRESHER site, and Figure D-A5 shows the distribution of sample stations at the SCORPION site. Cobalt-60 was the only radionuclide present in sufficient amounts to be detected with the gamma detectors. Tables D-A2 and D-A3 present the estimated Cobalt-60 concentrations in the sediment at the two sites as inferred from the direct gamma measurements.

In addition to in-situ measurement of gamma ray radioactivity on the surface of the sediments with the underwater detectors, samples of sediment from most of the same locations were taken by inserting 5-centimeter or 7-centimeter diameter core tubes into the sediment with the submersible's mechanical arm. At the surface, the water was removed from the top of the core and the sediment samples were kept under refrigeration until analyzed at a shoreside laboratory. Pore water was analyzed with the sediment. At the laboratory the core tubes were sectioned into 1 centimeter to 5 centimeter segments and analyzed for gamma-emitting radionuclides by placing the sediment samples into suitable counting containers ranging from 15 to 150 cubic centimeters. Samples from the SCORPION site were freeze-dried prior to counting to reduce sample size and to increase sample counting efficiency. Nickel-63 analyses were conducted only on those sediment samples that contained detectable concentrations of Cobalt-60 and on the marine life samples. The technique utilized included a radiochemical separation followed by beta spectrometry using liquid scintillation counting.

TABLE D-A2. ESTIMATED COBALT-60 CONCENTRATIONS IN SEDIMENT AT THRESHER SITE AS DETERMINED BY IN-SITU CESIUM IODIDE GAMMA RAY MEASUREMENTS, JULY 1977

Station No.*	Cobalt-60 Radioactivity (pCi/cm^2)	Station No.	Cobalt-60 Radioactivity (pCi/cm^2)
1	1.4	8	1.4
2	1.4	9	ND
3	1.3	10	1.1
4	1.9	13	ND
5	1.7	14	4.0
6	1.1	15	10.1
7	2.1		

ND = Not Detected. The minimum detectable activity was 0.3 pCi/cm^2.

*See Figure D-A4.

11	ND	ND
12	ND	ND

ND = Not Detected. The minimum detectable activity was 0.3 pCi/cm^2 for the Cesium Iodide (Cs-I) detector and 0.1 pCi/cm^2 for the Sodium Iodide (Na-I) detector.

*See Figure D-A5.

Results of the gamma spectrum and Nickel-63 analyses of the ocean bottom sediments from the THRESHER and SCORPION sites are shown in Tables D-A4 and D-A6, respectively. Activity concentration data for the upper 5 centimeter layer of bottom sediment cores are summarized in the tables. The tables also show the total Cobalt-60 radioactivity measured in the ocean bottom cores expressed in units of pCi/cm^2 in order to facilitate comparisons with activity concentrations that were estimated based on direct scintillation probe measurements obtained approximately 5 meters away from the individual sediment sampling locations (see Tables D-A2 and D-A3).

The results obtained with the underwater detector(s) and by gamma spectrometry analyses of sediment core samples are in general agreement for the THRESHER site but in poor agreement for the SCORPION site. At the SCORPION site, the sediments collected in the core tubes were so fine that a portion of the sediment leaked through the bottom closure of the core tube; the fine texture and floculent nature of the sediment also resulted in loss of some of the sample material from the top of the core tube as well as some mixing of material within the tube.

As shown in Table D-A4, all cores obtained at the THRESHER site indicated the presence of naturally-occurring uranium and thorium series radionuclides as well as the predominant natural radionuclide Potassium-40. With one exception, the sampled THRESHER site stations indicated the presence of low level Cobalt-60 in the top layers of sediment, i.e., in the top 5 centimeters of sediment. The only other radioactivity detected in any of the THRESHER site sediment core sections was due to Cesium-137. This radionuclide was detected in the surface layer of sediment at less than half of the stations, at extremely low values typical of that attributable to fallout from nuclear weapons testing as shown in Table D-A5 for deep Atlantic ocean sediments. Fallout Cesium-137 in the vicinity of the THRESHER debris ranged from 0.029 pCi per gram to 0.104 pCi per gram (dry weight) in the upper five centimeters of sediment as shown by the data for the Northwestern Atlantic Slope, Reference D.A10. The maximum value of 0.02 pCi per gram (wet weight) obtained at the THRESHER debris site is well within the fallout range when converted to equivalent dry weight radioactivity.

Table D-A6 indicates a generally similar pattern of activity for SCORPION site sediment. However, at the SCORPION site, Cobalt-60 was detected in less than half of the core samples. The infrequent occurrence of detectable Cobalt-60 from below the top 5 centimeters of sediment indicates minimal bioturbation below this depth and shows the relative impermeability of the sediments to the migration of the metallic corrosion products (Tables D-A7 and D-A8).

In order to estimate the total amount of Cobalt-60 activity present in the upper layer of ocean bottom sediment at the THRESHER site, the approximately 30,000 square meter sampling area was divided into several smaller areas based on the Cobalt-60 activity concentrations actually measured in the ocean bottom core sediment samples. The total Cobalt-60 sediment activity estimated in this way for the THRESHER site is 0.3 millicurie. Alternatively, based on in-situ measurements (Table D-A2), the total Cobalt-60 inventory is estimated to be 0.7 millicurie. These two estimates are considered to be in good agreement. However, the same approach applied to SCORPION site data does not yield consistent estimates of the Cobalt-60 activity in the site sediment. As indicated previously, the results of gamma spectrometry analyses of SCORPION site sediment core samples are in poor agreement with the results obtained with the independent in-situ measurements made using sodium iodide and cesium iodide detector systems. The lower results were obtained from the analyses of core sediment samples at the SCORPION site and may be attributable either to partial loss and mixing of core samples or to the fact that the in situ detector locations differed by approximately 3 meters from the sediment core sample locations. As evident from Table D-A3, the non-uniformity of the radionuclide distribution is demonstrated even at the distances separating the Cesium Iodide and Sodium Iodide in situ detectors. The higher estimates of the total amount of Cobalt-60 in the sediment at the SCORPION site, as based on cesium iodide and sodium iodide detector measurements, are 0.2 and 0.4 millicurie, respectively. Thus, it may be estimated that about 0.3 millicurie of Cobalt-60 were (in 1979) spread over an area of approximately 13,000 square meters of the SCORPION site (or about 40 percent of the total area of 33,000 square meters that were surveyed).

1. Source of the Released Cobalt-60

Samples of sediment from the THRESHER and SCORPION sites were also analyzed in an attempt to assess the magnetic properties of the contained Cobalt-60. Sediment was mixed with water and the resultant slurry

TABLE D-A4. SUMMARY OF RADIOACTIVITY CONCENTRATIONS IN SEDIMENT CORE SAMPLES OBTAINED FROM THE THRESHER SITE, JULY 1977

Station No.*	Measured Radioactivity Concentration in Upper 5 Centimeter Sediment Core Samples, Picocuries Per Gram						Total Core Cobalt-60 Activity Concentration pCi/cm²
	Uranium	Thorium	Potassium-40	Cesium-137	Nickel-63	Cobalt-60

14	0.4	0.6	11.7	0.02	<0.25	0.27	2.80
15	0.4	0.8	13.7	<0.01	<0.23	0.07	0.58
15	0.4	0.6	12.5	<0.01	<0.22	0.03	0.28

NOTE: The uranium, thorium, and Potassium-40 are naturally-occurring radioactive materials. The concentrations of Cesium-137 are consistent with levels due to fallout. Only the Cobalt-60 concentrations are attributable to the presence of the THRESHER debris. (NM = Not Measured).

*See Figure D-A4.

---

stirred in the presence of a strong permanent magnet that was housed in a glass tube suspended in the slurry. Material attached to the glass tube was periodically removed and the separation process continued. Although this separation method is considered to be only semi-quantitative, the results of applying the method are an important indicator of the source of the Cobalt-60, since most, if not all, of the Cobalt-60 was determined to be magnetic in nature. Cobalt-60 in magnetic form is associated with the magnetic corrosion products formed during previous operation of the THRESHER and SCORPION reactor plants and, as previously discussed, is distinguishable from the neutron-activated cobalt contained within the nuclear reactor pressure vessel internal structure. Therefore, the source of almost all of the Cobalt-60 in the sediment is the reactor coolant and the activity deposited by the coolant on the inside surfaces of piping and components. Corrosion that occurred after the sinkings does not represent a significant source of the Cobalt-60 found in the sediment. Although Nickel-63 was not detectable in individual samples of sediment and marine life, it was possible to detect Nickel-63 by performing a magnetic separation and concentration of corrosion products by combining those sediment samples from each site that contained the highest levels of Cobalt-60 contamination. The relative Cobalt-60 and Nickel-63 concentrations obtained from the SCORPION and THRESHER debris sites were then compared with expected relative concentrations for corrosion products in the reactor coolant and confirmed the origin of the radioactivity.

11	1.3	0.2	1.9	0.05	<0.19	0.03	0.13

NOTE: The uranium, thorium, and Potassium-40 are naturally-occurring radioactive materials. The concentrations of Cesium-137 are consistent with levels due to fallout. Only the Cobalt-60 concentrations are attributable to the presence of the SCORPION debris. (NM = Not Measured).

*See Figure D-A5.

The total Cobalt-60 estimated for the sediment at the THRESHER and SCORPION sites is in each case equal to approximately 0.3 millicurie, a small fraction of the total activity of this type (i.e., about 10 curies as described in Section III). As shown in Tables D-A4 and D-A5, the measured levels of Cobalt-60 are significantly lower than the naturally-existing radioactivity levels of potassium, uranium, and thorium present in the sediment at the debris sites. The only other non-natural radioactivity detected in sediments at the two sites, Cesium-137, is present at extremely low levels typical of levels associated with fallout from nuclear weapons testing.

ND = Not Detectable. The minimum detectable activity ranged from 0.014 to 0.068 pCi per gram dry weight.

C. DEBRIS

Debris from the THRESHER and SCORPION sites removed from the ocean bottom were monitored as a precaution aboard the support ship utilizing a sensitive survey meter equipped with a 5 centimeter by 5 centimeter sodium-iodide gamma ray scintillation detector. The detector system was set up to respond to a wide spectrum of gamma ray energies as well as to provide specific information for an energy interval covering the energies of the gamma rays emitted by Cobalt-60. This radioactivity monitoring of the recovered debris items did not disclose any activity above instrument background (50 counts per minute in the Cobalt-60 energy interval).

D. MARINE LIFE

Marine life, consisting of a holothurian (sea cucumber) and an echinoid (sea urchin) were collected adjacent to the THRESHER debris. Two macrourid fish (Coryphaenoides armatus), rat tails, were caught at the edges of the SCORPION debris field. As indicated by the results shown in Table D-A9, no corrosion product radioactivity or fission product activity attributable to the THRESHER or SCORPION was detected in the marine life samples. Laboratory experiments designed to investigate the biological accumulation of Cobalt-60 from irradiated stainless steel and its corrosion products have been conducted by Young (Reference D.A13), and the fact that these corrosion products are refractory (insoluble) in nature has been demonstrated (Reference D.A14). Results have indicated that Cobalt-60 is accumulated only to a very limited extent if at all by marine organisms, due primarily to the predominantly insoluble nature of these corrosion products (Reference D.A13). Other studies have also shown that this type of radioactivity is not readily assimilated in the tissues or skeletal material of marine organisms even after ingestion (Reference D.A15). Reference D.A1 and similar U.S. Navy reports issued over the past twenty years show no detected buildup of Cobalt-60 in marine life samples obtained from harbors frequented by U.S. naval nuclear-powered ships.

TABLE D-A9. RADIOACTIVITY ANALYSIS RESULTS FOR MARINE LIFE SAMPLES OBTAINED AT THE THRESHER AND SCORPION DEBRIS SITES

Month and Year	Debris Site	Sample Description	Radioactivity Concentration, Picocuries per Gram			
			Potassium-40	Cesium-137	Cobalt-60	Nickel-63
July 1977	THRESHER	Sea Urchin(1)	2.9	0.02*	<0.01	(5)

E. RECENT RESULTS

A comprehensive deep-ocean radiological environmental monitoring operation was conducted at the THRESHER site in August 1983 utilizing both surface ship deployed and submersible operated monitoring equipment as described in Appendix K. High resolution gamma spectrometry was conducted on sixty-three (63) individual fish, primarily rattails, obtained from the immediate vicinity of the THRESHER debris (Table D-A10). In addition, fifteen samples containing hundreds of assorted marine macrofauna and benthos including amphipods, sea urchins, snails, worms, cumaceans, and brittle stars were collected and analyzed for gamma-emitting radionuclides (Table D-A11). No radioactivity above background levels due to naturally-occurring radioisotopes or fallout was observed in any of the marine life samples analyzed. Figure D-A6 shows the stations at which the biological and seawater samples were obtained.

Sixteen sediment core tubes were collected by DSV ALVIN from twelve stations located in the area immediately adjacent to and surrounding the THRESHER debris (Figure D-A7). Cobalt-60 was detectable in eight of the sixteen core tubes to a maximum concentration of 0.266 picocurie per gram wet weight (Table D-A12). Cobalt-60 was not detectable in any of the samples of interfacial seawater obtained from the sediment-seawater interface by the core tubes. Nickel-63 analyses were performed only on those sediment samples that contained detectable concentrations of Cobalt-60 and on representative fish and marine life specimens. Nickel-63 was not detectable in individual samples of sediment, fish tissues and marine life. However, by performing a magnetic separation and concentration of corrosion products from the sediment sample that contained the highest level of Cobalt-60 contamination, it was possible to detect Nickel-63 in the sediment at a level slightly above the minimum detectable. The source of most of the Cobalt-60 and Nickel-63 in the sediment was again determined to be the reactor coolant and activity deposited by the coolant on inside surfaces of piping and components during prior operations of the submarine. This was confirmed by the magnetic properties of the corrosion products and their relative concentrations of Cobalt-60 and Nickel-63. Cesium-137 concentrations in excess of those attributable to fallout were not detected in any of the sediment samples indicating that the integrity of the reactor fuel inside the core has been maintained (Table D-A13).

Sediment core and interfacial seawater samples were also collected by the deployment of a box corer and tripod sphincter corer from the surface ship ORV CAPE FLORIDA. It was possible to obtain accurately positioned samples in the immediate vicinity of the THRESHER debris by the use of an acoustic transponder navigation network with verification of relative positions by DSV ALVIN. Cobalt-60 originating from the THRESHER reactor coolant was detectable in two of seven surface subsamples obtained from the box core and the upper two-inch segment from the tripod sphincter core at concentrations of 0.02 picocurie per gram wet weight in each. Cesium-137 concentrations in excess of fallout levels were not measured in any of the samples analyzed.

Seven in-situ gamma spectrometry measurements of the sediment were obtained by DSV ALVIN in the THRESHER debris area using the submersible mounted detector and multi-channel analyzer. None of the measurements obtained indicated any detectable concentrations of radioactivity above natural background levels.

Four large volume seawater samples of 441 liters, 392 liters, 587 liters, and 503 liters, respectively, were obtained by a submersible mounted and ship deployed pumping system including prefilters and chemisorptive cartridges for collection of radioactivity. In addition, two five-liter Niskin bottle samples were obtained in the THRESHER debris area. No radioactivity attributable to the THRESHER debris was found in any of the seawater samples analyzed (Table D-A14). Extremely low concentrations of Cesium-137 were detectable in samples obtained by the highly sensitive pumping systems. The Cesium-137 concentrations are typical of levels attributable to fallout from nuclear weapons testing.

Visual and photographic observations of the sessile marine life on submarine surfaces indicate little, if any, change in the extent of biological colonization since the 1977 observations. The THRESHER debris had not produced a significant "reef effect" during the approximately 20 years that it has rested on the bottom. There were no discernible differences in biomass concentrations between the THRESHER debris site and the surrounding area.

The currents in the THRESHER debris area were generally much lower in velocity than in 1977 and exhibited a tidal influence on speed and direction as shown in Figure D-A8. Maximum velocities of approximately 5 cm/sec were recorded.

(1) The "less-than" symbol (<) indicates that radioactivity was not detectable, and the concentration value listed is the smallest amount which could be detected if any radioactivity were present.
(2) NM = not measured.
(3) Assumes 10% collection efficiency.

The radioactivity concentrations measured in the 1983 sediment samples agree with expected results when compared with decay-corrected values for the 1977 samples including spatial variations in radioactivity levels. When compared with 1977 results, a smaller percentage of the core samples exhibited detectable concentrations of Cobalt-60 in the surface (0 to 5 cm) sediment segment. Similarly, a larger percentage of the cores exhibited detectable concentrations of Cobalt-60 in the deeper, 5 to 10 cm, segment and one core had detectable Cobalt-60 in the 10 to 15 cm segment. This indicates a dilution of radioactivity in the surface sediments that cannot be accounted for by radioactive decay alone. This dilution may be due to sedimentation and bioturbation resulting in the movement of radioactivity to greater depths. The main source of the radioactivity was still the corrosion products released from the reactor coolant at the time of the accident. Subsequent corrosion of activated structural material has not resulted in a significant increase in the radioactivity present in the sediment.

V. SUMMARY

In 1977 and 1979, direct radiation measurements were made of the gamma-emitting radionuclides contained in the upper layers of sediment at the THRESHER and SCORPION debris sites, respectively. In addition, samples of water, sediment, marine life, and debris were collected from the immediate debris areas and analyzed for radioactivity. Similar radiological environmental monitoring operations were repeated at the THRESHER debris site in 1983. None of these samples showed any evidence of release of radioactivity from the reactor fuel elements in either the THRESHER or SCORPION. Cobalt-60 that had been released from both the THRESHER and SCORPION coolant systems, or internal surfaces of piping or components, was detectable at low levels in sediment samples from localized areas that had not previously been sampled. Nickel-63 was detectable at low concentrations in corrosion products magnetically separated from composite sediment samples at each debris site. The Cobalt-60 and Nickel-63 radioactivity present in the sediments is small compared to naturally-occurring radioactivity. Although it would not be possible, if a single person were to consume all the sediment at either site containing detectable radioactivity above background, the resulting total body radiation exposure would be less than that allowed for a worker in one year by the U.S. Nuclear Regulatory Commission. Cobalt-60 and Nickel-63 were not detected in samples of water, marine life, or debris. Thus, neither the THRESHER nor SCORPION have had a significant effect on the radioactivity in the environment.

List of Figures

APPENDIX E

DESCRIPTION OF OCEAN STUDY AREAS

I. INTRODUCTION

This appendix describes the current state of oceanographic knowledge for three areas in the deep ocean, two in the Atlantic and one in the Pacific, which are thought to be representative of potential disposal sites. In order to develop an analytical model of the effects of any possible disposal, it was necessary to select a typical site so that specific values could be selected for the various physical parameters, such as current speed and direction, horizontal and vertical diffusion terms, and thickness of the bottom mixed layer. These study areas were selected as the result of preliminary screening of a number of possible sites near the 200 nautical mile United States economic zone boundary. The screening (References E.1 and E.2) was performed by oceanographers familiar with the available historical data, primarily relating to an area's water depth, remoteness from human activities, sediment thickness, regularity of the sea floor, absence of geologically significant activity, and the expected general circulation pattern of bottom waters. The criteria used in this screening were derived from those specified by the technical authority for the international convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter (Reference E.3), and on additional specifications which the oceanographers felt would increase assurance that the sites would be stable and predictable.

Based on the results to date of follow-up studies which have been conducted in the selected areas, as described below, study areas which satisfy all technical criteria have been identified in the Atlantic and Pacific Oceans within a reasonable distance from the United States coastline. The Pacific Ocean study area is within the United States 200 nautical mile economic zone boundary, and a sizable part of one of the Atlantic Ocean study areas is also within 200 nautical miles of the U.S. coast. It is possible that within the latter area a location that satisfies all technical criteria will be found. The study areas identified are expected to be as close to the United States coastline as any site which might eventually be selected, and for this reason they would be likely to produce maximum representative environmental impacts when used in the impact analysis. These areas are not "disposal sites" since approval of a site for actual disposal operations may require qualifying research beyond that performed in support of this statement. However, it was considered an essential part of the environmental evaluation that specific locations be identified to permit a realistic analysis. In this way, specific sea floor corrosion measurements could be made and representative ocean bottom currents and other ocean transport properties could be employed in estimates of the potential downstream transport of radioactive corrosion products. This approach also made it possible to base exposure estimates on an actual population, with realistic data describing the pathways by which individuals might be exposed to radioactive releases. Given the objective that specific locations be identified for realistic analysis, the ocean areas described in this appendix are considered to be typical of areas which are most likely to be acceptable. However, in the event that the sea disposal option is used, actual disposal sites could be selected from many other possible areas.

The two Atlantic Ocean locations (Figure E-1) are approximately 170 to 260 nautical miles east and 200 to 360 nautical miles southeast of Cape Hatteras, North Carolina on the Lower Continental Rise and on the Hatteras Abyssal Plain, respectively. Supporting studies of these areas are being conducted by the University of Rhode Island, Graduate School of Oceanography. The Pacific Ocean location selected for further examination (Figure E-2) is approximately 140 to 200 nautical miles southwest of Cape Mendocino, California. Supporting studies of this area are being conducted by the School of Oceanography, Oregon State University. Each of the specific areas has been subjected to a questioning approach, seeking characteristics that would rule it out as an acceptable disposal site. It is considered essential that any proposed site be approached in a similar questioning way.

Figure E-2. Pacific Ocean Study Location (Depths Shown in Meters)

II. OCEANOGRAPHIC DATA—BACKGROUND

The total area of the world ocean floor is approximately 139 million square miles, of which more than 80 million square miles have a water depth of at least 4000 meters (Reference E.4). In general, because of this large area and great depth, most remote areas that may be of interest for possible sea disposal would initially be known only in terms of their approximate depth and whether the topography is mountainous or hilly, or resembles a canyon or a plain. Similarly, the very lack of geological and biological activity which might make them suitable disposal sites causes the oceanographic community to have little interest in their study. If a specific area were to become of interest because it satisfied all of the more readily demonstrated selection criteria, it would be possible to concentrate on that area, probing to determine if any of its less obvious characteristics failed to meet requirements. In this way, using a variety of methods that have been developed by the oceanographic community, a more detailed picture can slowly be obtained of the water column, the forms of life on and near the bottom, the sea floor topography, and the underlying sediment. This section describes in general terms some of the methods employed to obtain a more detailed picture of a limited size area of interest. Reference E.4 provides details on the wide variety of underwater equipment and oceanographic instrumentation currently available.

A special-purpose vessel equipped with echo-sounder/recorder and precision navigation equipment repeatedly traverses the area of interest, gradually developing a topographic map of the bottom and searching for indications of irregular topography such as sea mounts, pinnacles, or trenches. The most effective way of performing detailed topographical studies for potential ocean disposal sites involves the use of an array-type survey capability which covers a wide band on either side of the oceanographic survey ship. Towed seismic systems provide an indication of the distance between the sea floor and the basement rock, thus giving a measurement of the sediment thickness along with the bottom profile.

Water temperature, density, oxygen content, and salinity as a function of water depth can be measured and recorded by instruments lowered by the ship from the surface to the ocean floor. Current speed and direction at several different depths are measured and recorded over an extended time period (up to one year) by instruments moored on the ocean floor and kept at fixed depths by flotation devices. Recovery of these current meters and their attached floats is achieved by a sonic signal from a recovery ship that actuates a mechanism which releases the string of floats and instruments from their anchor on the ocean floor, after which they rise to the surface for recovery.

Samples of the sediment, water, and sea life at selected locations within the study area can be obtained for analysis. Long cylindrical corers and relatively shallow box corers are used to remove a vertical tube of sediment, then retain it firmly while returning it to the surface in as undisturbed a condition as possible. The long coring device (3 meters or more in length) is lowered from the ship to the sea floor and its cutting edge is forced into the sediment by a heavy weight at the top of the cylindrical tube. It is then lifted to the surface by a winch. Coring can also be accomplished by free-fall of a weighted tube which penetrates the sediment, collects the sample, and then detaches itself from the weight for return to the surface aided by a hollow float.

Samples of sea life may be obtained by the use of nets and traps similar to commercial fishing gear. For work on the sea floor at very great depths, where the population of animals is likely to be low in abundance, baited traps can be lowered to the bottom to capture specimens. When specimens are brought to the surface, they are not likely to survive the reduced pressure and increased temperature conditions; however, specimens can be collected at pressure and maintained in a high-pressure environment on the recovery ship.

Water sampling at various depths employs specially designed "bottles" which are lowered to the desired depth and then closed to trap a sample for later analysis. Recovery of the water sample must be achieved without contamination being introduced by the sampling equipment or sampling technique.

Confirmation that the physical appearance of the sea floor has been correctly inferred from indirect data can be obtained by deep-sea photography at selected locations, usually black and white 35 millimeters, with the camera operated fixed-focus and the shutter controlled in conjunction with high-intensity strobe lights. Up to several hundred photographs may be taken during one underwater mission, with the pictures taken either at timed intervals or each time a trip weight on the camera-carrying rig contacts the sea floor at a new site. The camera, lights, battery power supply, and associated controls are mounted on a frame that is lowered to the sea floor from the oceanographic vessel.

The techniques described above provide the necessary material for laboratory analyses of sediment lithology and geochemistry, evaluation of sediment physical properties, and for development of estimates of the density of life on the sea floor and in the water column.

The data on current direction and speed for a particular location provide some of the input required for computer-modeling of the transport of dissolved or suspended material from the deep ocean disposal site to the nearest location of human activity. The following sections include descriptions of what has been learned about the Atlantic and Pacific study locations as a result of the concentrated effort to date on these areas of interest. Data derived from historical studies of larger areas are also included, where appropriate, to help provide as complete a description as possible.

III. STUDY AREA IDENTIFICATION

It would be impossible to determine the characteristics and evaluate the environmental effects for all portions of the deep ocean floor; therefore, specific areas had to be identified for study. This made it possible to collect measurements and observations for use in this evaluation where needed information was not already available. It also permitted the calculations of environmental effects to be based on realistic values.

The criteria established under the international convention (Reference E.3), described in Chapter 3, were translated by Dr. C. D. Hollister and Dr. G. R. Heath into guidelines for identifying areas that have a high probability of satisfying all site requirements. These guidelines were intended to assure that the study areas would be representative of the kinds of areas which would reasonably be expected to be selected as disposal sites. However, it is not intended to designate these study locations as ultimate disposal sites or to imply that other locations are not acceptable.

The guidelines, as interpreted and extended by Hollister and Heath, and explained in Reference E.1, are as follows.

1. Sites should be between 50° north and 50° south latitude.

   This criterion is designed to avoid the sources of bottom water and the high biological productivity of the polar regions. Ice rafting of large boulders is also a concern in the polar areas.

2. Depth at the site should be 4000 meters or more.

   This criterion is derived from the facts that the topographical, chemical, and biological gradients tend to flatten below 4000 meters, bottom water circulation may be slower, and organic carbon in the sediment generally is low. This criterion is also motivated by the desire to be clear of continental margins.

3. Sites should be remote from continental margins.

   This criterion is based on avoiding the regions of high biological productivity, increased likelihood of resource exploration and exploitation, and greater unpredictability and instability associated with the continental slope, rise, and associated submarine alluvial fans.

4. Sites should be away from areas of potential seabed resources.

   This criterion is designed to minimize the likelihood of future disturbances which might shorten pathways to man and to avoid possible conflicts in "land" uses.

5. Sites should be away from cables in use.

   This criterion is intended to avoid disturbances and conflicts in use.

6. Sites should be away from areas containing active geologic phenomena such as volcanoes, which would be unsuitable.

   This criterion is designed to reduce the likelihood of unpredicted disturbances which might shorten pathways to man.

7. The area of a site should be defined by precise coordinates, with an area as small as practicable, but no larger than 10^4 km^2.

   This criterion limits the affected area.

8. Sites should preferably be in areas covered by navigational aids.

   This criterion is intended to assist in location of the sites for monitoring and future observation or research.

9. Sites should be away from areas, such as submarine canyons, which have a high rate of exchange of the deep waters with surface layers of any adjacent continental shelf.

   This criterion is intended to avoid shortening pathways to man.

10. Sites should be chosen for convenient conduct of operations and to avoid, as far as possible, the risk of collision with other traffic and undue navigational difficulties.

    This criterion is specified to minimize hazards to navigation and safe operations at the site.

11. Bottom current shear stress should not exceed critical erosional shear stress.

    This criterion is desired to prevent high rates of resuspension of sediments at the site and to prevent rapid movement of material.

12. Sites should be away from areas of intense mesoscale eddy activity.

    This criterion is intended to avoid areas of enhanced eddy diffusivity which could shorten pathways to man.

IV. SITE-SPECIFIC INFORMATION

A. ATLANTIC OCEAN STUDY LOCATION—HATTERAS ABYSSAL PLAIN AREA

1. General Description

This rectangular area (Figure E-1) is centered near 33° north, 71° west and covers approximately 60,000 square kilometers. The area is on the Hatteras Abyssal Plain, centered at approximately 280 nautical miles (520 kilometers) from the closest land point at Cape Hatteras, North Carolina. The sea floor in this study area is almost flat, with water depths of approximately 5300 meters (17,400 feet), and appears not to be swept by strong bottom currents. The only technical reservation about the site was noted in Reference E.5, namely that the area may be intermittently swept by turbidity currents, a phenomenon natural to abyssal plains in which sediment-entrained currents of up to 50 knots are caused by landslides from the continental slope and upper continental rise. However, analysis of core samples taken from this study location suggests that no more than four rather weak turbidity currents have entered the location in the past 11,000 years. Analyses are being performed to estimate the range of velocities and consequent energies associated with these particular events. Reference to the current literature suggests that velocities should not exceed 15 cm per second.

The most recent studies of this area continue to show that the area satisfies all technical guidelines with the possible exception that resuspension of sediments may occasionally be caused by high velocity currents. The significance of this factor is discussed in the summary of this study area (p. E-16).

2. Topography

Figure E-3 (from Reference E.5) shows the topography of the Hatteras Abyssal Plain area, which is identified in the reference as E-N3. Contour lines are shown in meters. The slope of the sea floor in the center of the area is less than 1 foot per 1000 feet, essentially flat.

3. Photographs

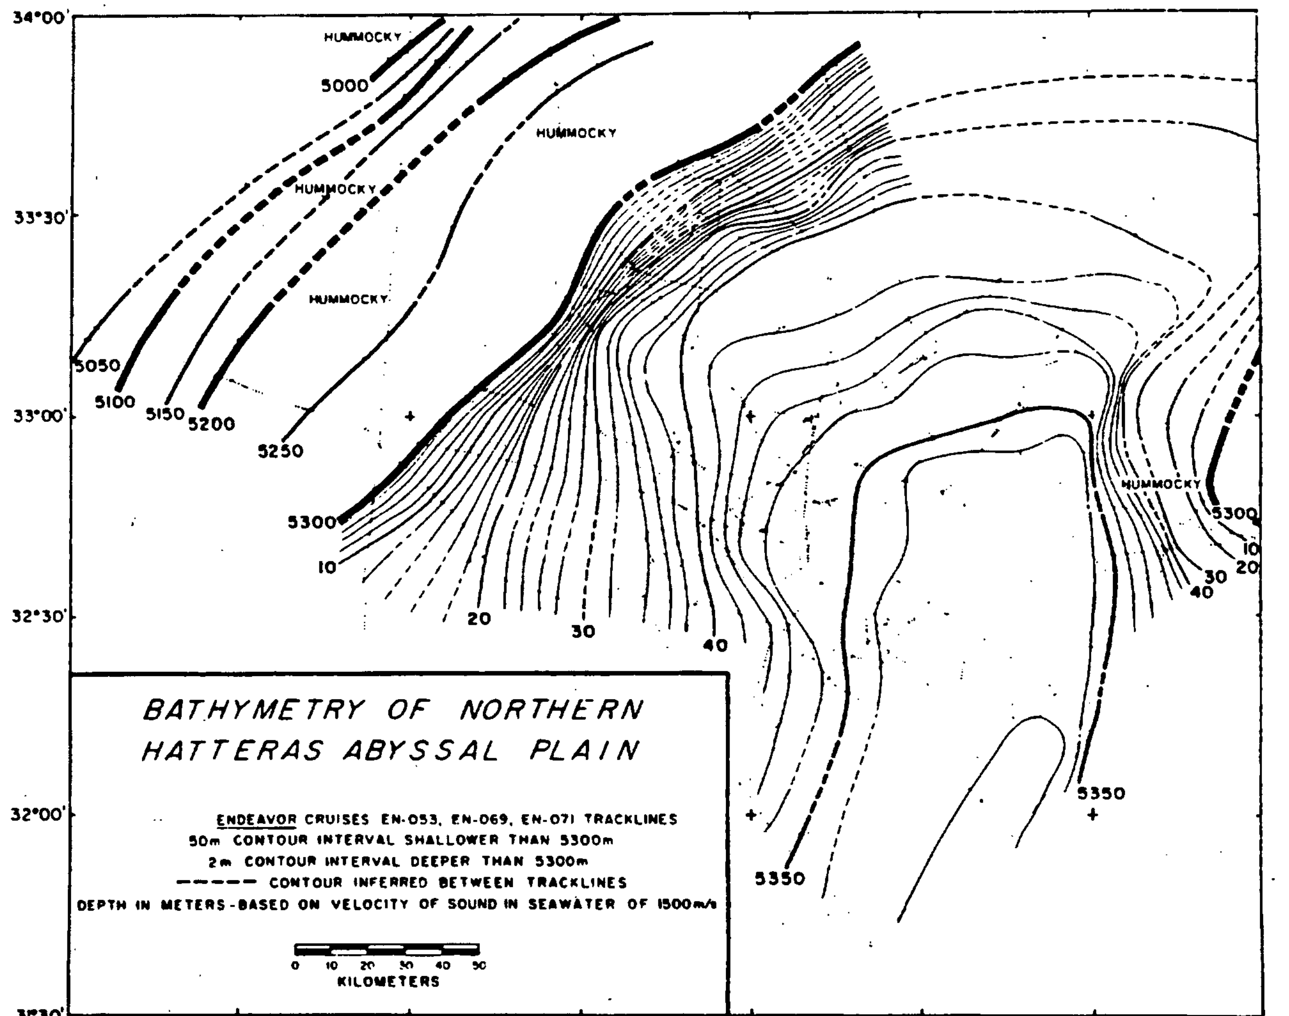
Two representative photographs of the sea floor in the Hatteras Abyssal Plain study area are shown in Figures E-4 and E-5. The former (located 70.5° west, 33° north) shows several scattered small cones and craters and a food can surrounded by sargassum weed. The can gives some indication of the approximate dimensions of the cones and craters. Figure E-5 (located at 70.8° west, 32.8° north), which is on the same scale as the previous photograph, shows numerous small craters and cones. A fairly large mound appears at the right center with an animal and sargassum weed. These and other photographs of the sea floor in this vicinity indicate that some life dwells on the bottom, but it is relatively sparse and its biology is not well known. The animals that have been identified from the photographs as inhabitants of the sea floor in the study area and its near vicinity are limited to starfish, holothurians, crinoids (sea lilies), and sea pens. Various types of crabs and worms are also likely to be inhabitants, based on observed tracks, trails, and mounds as well as information gathered at similar deep ocean sites. A general description of the types of features observed in these photographs is contained in Reference E.6.

The bottom photographs were summarized in Reference E.5 as showing "a relatively tranquil sea floor with the tracks and mounds of benthic organisms well preserved". There is no evidence of erosion by bottom currents and the scarcity of bottom life on the sediment surface is indicated by the photographs.

4. Currents

Bottom currents and their effects on the seabed have been studied with bottom photographs, moored current meters, and sediment cores. Bottom photographs taken in July and August of 1980 show a relatively tranquil seabed with no evidence of significant erosion by bottom currents in the recent past. Current meter measurements at five separate depths have been made near the center of the location at 32°38.61'N, 70°50.75'W, Reference E.14, page 46. The water depth at the mooring is about 5410 meters, and measurements were made about 50 meters, 500 meters, 1350 meters, 2160 meters, and 4340 meters above the bottom. This single mooring recovered in July of 1981 represents 290 days of current measurements and yielded the following results:

Mean Net Current Velocity (Centimeters per second; kilometers per day)	Distance above Bottom (Meters)
3.6; 3.1	50
3.2; 2.8	500
3.3; 2.9	1350
2.7; 2.4	2160
0.8; 0.7	4340



(Contour lines in meters)

Figure E-3. Atlantic Study Location—Topography of Hatteras Abyssal Plain Area

Figure E-4. Photograph of Ocean Floor—Hatteras Abyssal Plain Study Area
(Food can shown left center. Approximate dimensions: 8 inches high, 5 inches in diameter)

Figure E-5. Photograph of Ocean Floor—Hatteras Abyssal Plain Study Area

The current measurements indicate that water movement is moderate and relatively constant throughout the water column with a direction of movement to the northeast. The general northeastward flow is interrupted by a large number of low frequency events, either eddies or meanders in the general flow regime. One noteworthy feature of the current data was the lack of direction values about 220° true. This is the general direction toward the Blake—Outer Ridge, the nearest major submarine feature.

5. Physical Data vs. Depth

The following variables as a function of depth are plotted in Figures E-6 through E-8 respectively: temperature (°C), salinity (parts per thousand) and dissolved oxygen (milliliters per liter). These measurements from Reference E.5 were taken at approximately the center of the Hatteras Abyssal Plain site (70°37′ west, 32°42′ north).

6. Coring Results

The sediment in this area is deposited on the bottom largely as a result of the seaward movement of material washed away from land and deposited on the abyssal plain. Samples of the sediment were obtained by coring techniques which resulted in a total of seven core samples being recovered from the study area to date, five from the floor of the Hatteras Abyssal Plain (center of the area) and one each from the lower continental rise steps (northwest portion of the area) and the Bermuda Rise Hills (southeast portion). All five cores from the abyssal plain have been found to be almost entirely clay and very similar lithologically.

The following description is of the longest core (LGC-11-I, as identified in Reference E.5), which was recovered from a point close to the center of the study area. See Figure E-9 for the oceanographers' "visual core description".

Core LGC-11-I is 116 centimeters in length, with its bottom 22 centimeters composed of silt and its upper 94 centimeters composed of clay. The characteristics of this core suggest that the Holocene/Pleistocene boundary (which occurred approximately 11,000 years ago) lies 94 centimeters below the sea floor. This suggests a Holocene (recent epoch of geological time) sedimentation rate of about 8.5 centimeters per 1000 years. As noted in Section IV.A.1, four rather weak turbidity currents have entered the area during the past 11,000 years.

7. Bottom-Dwelling Life

As shown by numerous photographs of the bottom in Reference E.5, two of which are reproduced as Figures E-4 and E-5, some animal life is present and is believed to be typical of the forms and population density to be found in the deep areas of the Atlantic Ocean (Reference E.1). The most recent studies of this area show that the most common megafauna are "wormlike" organisms. This is based on photographic analysis; marine life specimens have not been collected. The benthic community is not fished because of the depth of the water and the sparse population; one of the bases for its selection was the likelihood that it will never attract commercial or other interest.

8. Characteristics Determined from Surveys of Available Data

The previously-described information on the Hatteras Abyssal Plain area was developed primarily as a result of the concentrated oceanographic work in the area. The following information is based on data that are of general interest and important to a site selection although not originally generated specifically for this study area.

a. **Seismicity.** There are no recorded earthquakes that were centered within the area. The likelihood of future earthquakes is small (Reference E.1).

b. **Volcanic Activity.** The closest active volcanoes are located in the Lesser Antilles Island arc, 900 miles to the southeast. It is highly improbable that the area would be affected directly or indirectly by a volcano (Reference E.1).

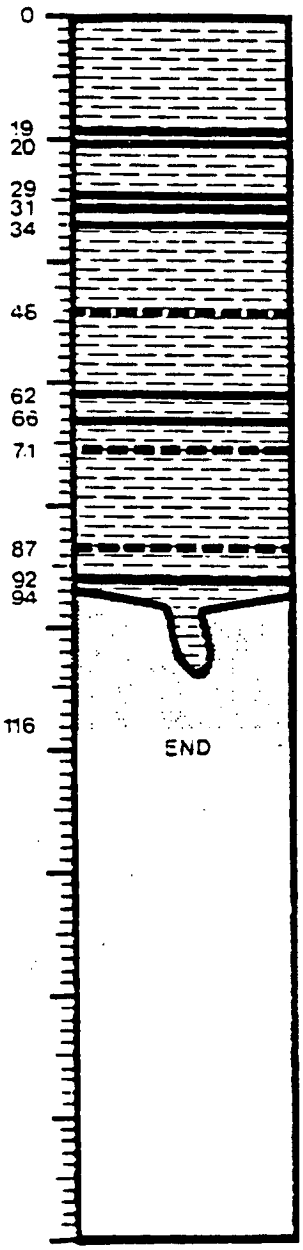
PHYSIOGRAPHY & LOCATION Abyssal Plain, Western North Atlantic

cm LITHOLOGY



DESCRIPTION

0-19 cm: Clay 10 yr 5/3 brown, very soft, extensively mottled w/10 yr 4/2 dark grayish brown, - mottle 1 cm dia at 6 cm, black fragments of organic matter.
Contact: gradational(?), horizontal

19-20 cm: Void

20-29 cm: Clay 10 yr 5/3 brown, soft, moderately mottled, several 1 mm laminae of alternating 10 yr 5/3 brown, and 10 yr 3/3 dark brown, mottles disrupt laminae.
Contact: sharp, horizontal

29-31 cm: Clay 2.5 y 5/4 light olive brown, soft.
Contact: sharp, horizontal

31-34 cm: Clay 5 y 5/2 olive gray, soft.
Contact: sharp, horizontal

34-48 cm: Clay 2.5 y 4/2 dark grayish brown, soft, extensively mottled w/2.5 y 5/2 grayish brown, at top of unit a 5 mm band of clay 5 y 5/2 olive gray w/sharp irregular bottom contact.
Contact: gradational, horizontal

48-62 cm: Clay 10 yr 5/3 brown, soft.
Contact: sharp, horizontal, irregular.

62-66 cm: Clay 2.5 y 5/2 grayish brown, soft.
Contact: sharp, horizontal

66-71 cm: Clay, 2.5 y 5/2 grayish brown, soft, extensively mottled w/2.5 y 4/2 dark grayish brown.
Contact: gradational, horizontal

71-87 cm: Clay 2.5 y 5/2 grayish brown, soft, extensively mottled w/2.5 y 6/2 light grayish brown - mottle elliptical 2 cm dia.
Contact: gradational, horizontal

87-92*cm: Clay 2.5 y 5/2 grayish brown, soft.
Contact: sharp, concave; *88-90 cm: Fe-rich layer

92-94 cm: Clay 2.5 y 4/2 dark grayish brown, soft.
Contact: sharp, concave

94-116 cm: Silt 2.5 y 3/2 very dark grayish brown, micaceous, w/foram fragments, soft.

SYMBOLS

clay | silty clay | clayey silt | silt | sharp contact | gradational contact

Figure E-9. Visual Core Description of a 116 cm Long Core Recovered from the Center of the Hatteras Abyssal Plain Area (LGC-11-I)

c. **Sediment Thickness.** Sediments in the general area of the Atlantic study areas are expected to be at least 1300 meters thick (Reference E.5).

d. **Cable Routes.** No undersea cables are known to exist in the study area.

e. **Shipping Lanes.** The study area is outside of normal shipping lanes.

9. Summary of Hatteras Abyssal Plain Area

This area is extremely smooth and featureless with no indication of erosive currents. All of the tentatively identified site identification guidelines (Section III) appear to be met. As noted previously, one technical reservation has been identified to date by the oceanographic experts in their search for possible negative aspects of the site. This reservation is based on the observation that abyssal plains are constructed by occasional swift currents (turbidity currents) which sweep the sea floor in the seaward direction as a result of continental slope or continental rise landslides from the landward direction. Although turbidity currents at a disposal site could confound the job of post disposal monitoring, such currents would not result in an unfavorable environmental impact due to sea disposal, and in fact would tend to bury the deposited material and thus reduce disposal effects. Present analyses indicate that no more than four turbidity currents have entered the Hatteras Abyssal Plain study location in the past 11,000 years. Analyses are being designed to determine the speed of these currents and their net effect on the study location.

In general, the Hatteras Abyssal Plain study area would likely prove acceptable as an ocean disposal site, based on the site selection criteria described in Section III of this appendix.

B. ATLANTIC OCEAN STUDY LOCATION—LOWER CONTINENTAL RISE AREA

1. General Description

This rectangular area (Figure E-1) is centered near 36° north, 71°30′ west and covers approximately 45,000 square kilometers. The area is located approximately 180 to 240 nautical miles east of Cape Hatteras. The sea floor is almost flat in the center of the area, with water depths of approximately 4000 to 4200 meters (13,100 to 13,800 feet).

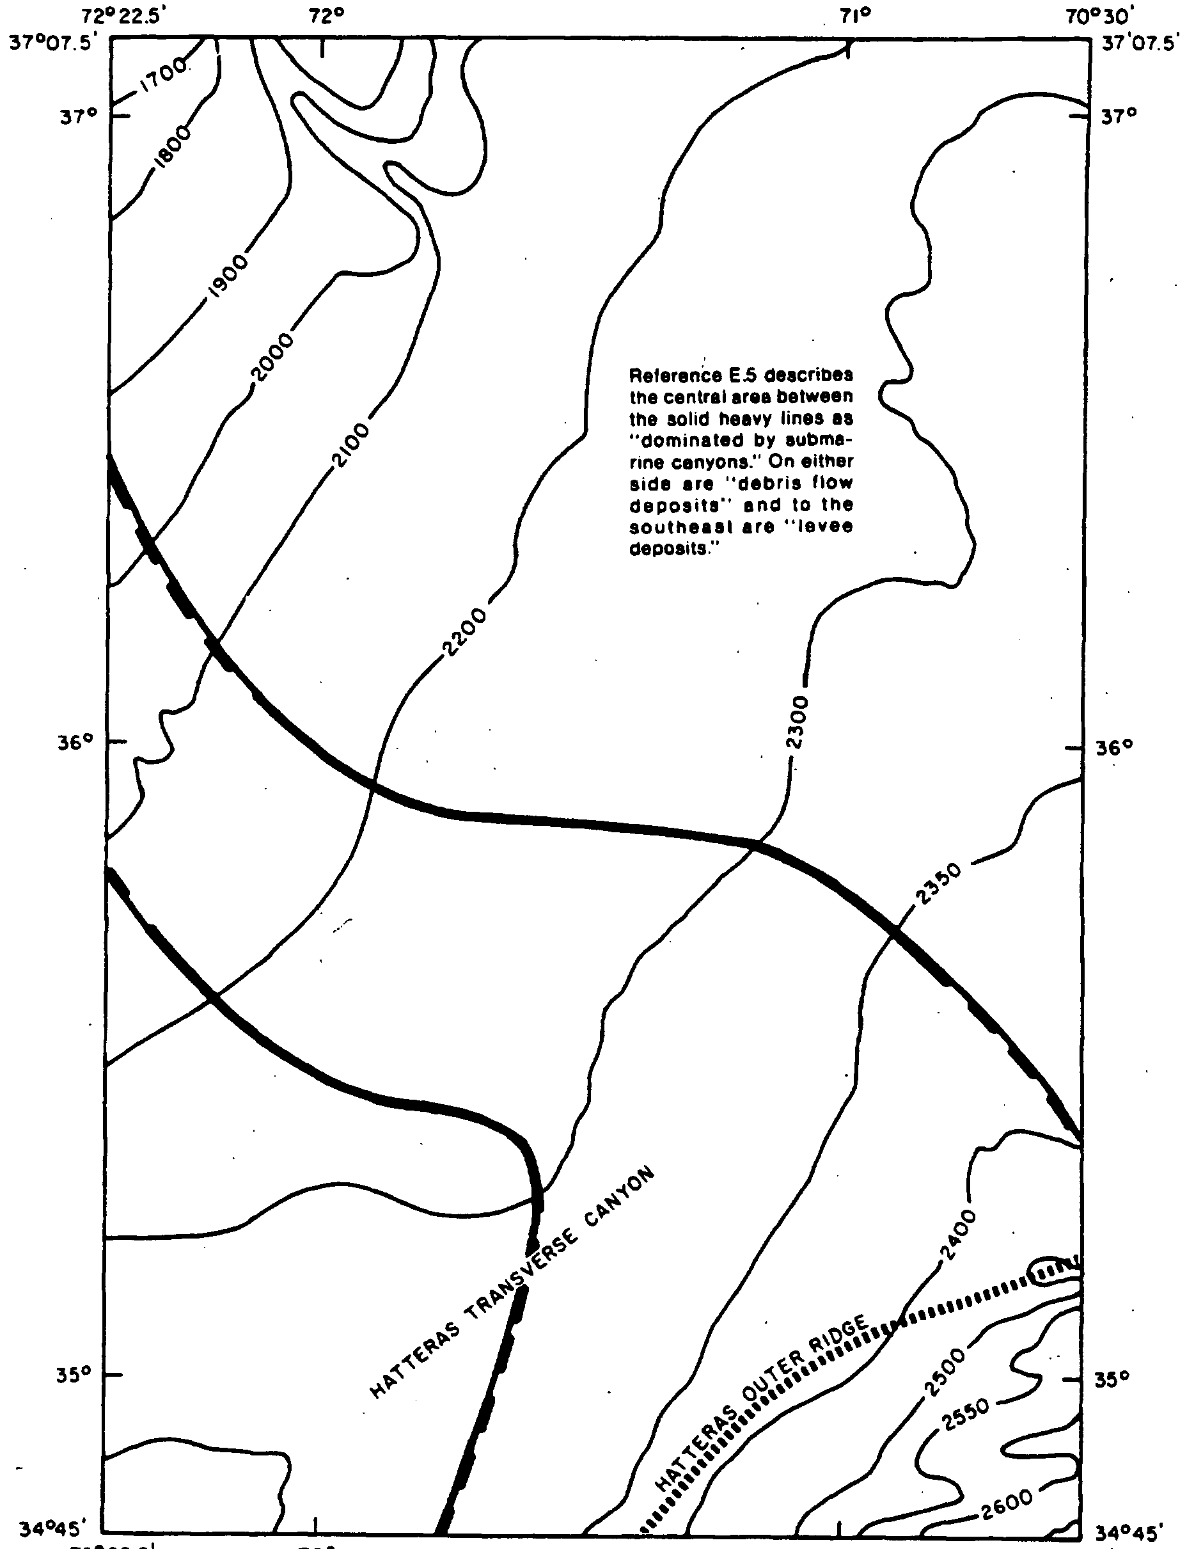
Several locations within this general area and within the 200 nautical mile economic zone boundary have been identified, Reference E.1, but were not initially selected for concentrated study because of the extreme simplicity, both environmentally and topographically, of the Hatteras Abyssal Plain area (Section IV.A) and because of the possibility of stronger bottom currents being encountered closer to the continental slope. Detailed study of a location within this area and within the 200 nautical mile economic zone boundary began in 1982. These studies indicate that only a small area of approximately 1500 km^2 and centered roughly at 36° 30′ north, 71° 30′ west, appears to be suitable for further study. In much of the study area, levee and debris deposits have questionable slope stability; the potential exists for exploitable hydrocarbons; and evidence of sediment resuspension has been observed.

2. Topography

Figure E-10 (from Reference E.5) shows the topography of the Lower Continental Rise study area, which is identified in the reference as E-N2. Contour lines are shown in fathoms, so the 2300 line corresponds to 13,800 feet or about 4200 meters. The slope of the sea floor in the center of the area is about 3 feet per 1000 feet, essentially flat.

3. Photographs

Photographs taken of the sea floor at the center of the Lower Continental Rise study area are very similar to those from the Hatteras Abyssal Plain area (Figures E-4 and E-5). A representative photograph of the former



(Contour lines in fathoms)

Figure E-10. Atlantic Study Location—Topography of Lower Continental Rise Area

Figure E-11. Photograph of Ocean Floor—Lower Continental Rise Study Area

area (taken at 71.6° west, 36.5° north) is shown as Figure E-11. Numerous small cones and craters are visible in the picture, along with a starfish (top center) and scattered tracks and trails. The seabed and the immediately adjacent water column appear relatively tranquil in all photographs, and there is no evidence of erosive currents. Preliminary indications are that the general study area contains locations that are similar to the Hatteras Abyssal Plain study area, and that would meet study area identification guidelines.

4. Currents

Bottom currents and near-bottom currents have been measured at several locations within the general study area.

5. Physical Data vs. Depth

The physical data plotted in Figures E-6 through E-8 for the Hatteras Abyssal Plain study area are also representative of the data measured at the Lower Continental Rise study area.

6. Coring

Many sediment core samples have been taken in the study area.

7. Bottom-Dwelling Life

Marine life specimens have not been taken in this area. As with the Hatteras Abyssal Plain Study Area, the benthic community is not fished because of the depth of the water and the sparse population.

8. Characteristics Determined from Surveys of Available Data

Based on the proximity of the two Atlantic study areas, the general characteristics described in Section IV.A.8 are equally applicable to the Lower Continental Rise study area, except that there is a working telephone cable that crosses the northeastern corner of the Lower Continental Rise area but which does not cross the subregion identified as suitable for further study.

9. Summary of Lower Continental Rise Area

Of the two Atlantic study areas, the Lower Continental Rise area has received relatively less scrutiny to date because of the very favorable conditions at the Hatteras Abyssal Plain location. However, several promising locations within the former area are within the 200 nautical mile economic zone boundary and have been identified as meriting concentrated study. Information gathered to date on the Lower Continental Rise study area indicates that it may be possible to select a relatively small area in the Atlantic on the lower continental rise, within 200 nautical miles of land, and meeting all study area identification guidelines.

C. PACIFIC OCEAN STUDY LOCATION

1. General Description

This nearly-rectangular area (Figure E-2) is centered at 39°20′ north, 127°40′ west and covers approximately 10,000 square kilometers. The area's western boundary is approximately the 200 nautical mile economic zone boundary. The area is seaward of the slope reversal that marks the outer edge of the continental rise in this region. It is west of the northern Delgada Fan, and is a region of rolling topography at the boundary between the abyssal Pacific deposits (pelagic clays) and the distal fan deposits (hemipelagic clays). The closest land point is approximately at Cape Mendocino, California. The area is west of the major west coast fisheries, and a benthic fishery in the area is precluded on the basis of energy requirements. That is, the low population density on and near the bottom, combined with the time and fuel costs for lowering and raising extremely long lengths of cable to 14,000 feet, would make it an extremely inefficient benthic fishing area. No potentially exploitable hard mineral or petroleum resources exist in the area. A second possible area in the eastern North Pacific, centered approximately 200 nautical miles west of San Diego at 32° 30′ north, 123° 30′ west, was also identified (References E.2 and E.11). This second area would probably be acceptable but has not been the subject of concentrated study.

2. Topography

The sea floor in the selected study area is under approximately 4200 to 4450 meters of water (13,800 to 14,600 feet). The topography is gently rolling, with broad irregularities as indicated in the bathymetric map shown in Figure E-12, from Reference E.7. The average slope in the sea floor in the center of the area is about 1 foot per 300 feet, while the maximum slope in several locations appears to be about 1 foot per 10 feet. The entire site is underlain by about 300 meters of silty clay.

3. Photographs

Two photographs of the sea floor in the Pacific study area are shown in Figures E-13 and E-14. As was seen in photographs of the Atlantic sites (Figures E-4, E-5, and E-11), the sea bottom sediment surface population is sparse, with brittle stars, echinoids, and holothurians representing the most abundant visible species. One of the Pacific site photographs (Figure E-13) shows a bathysaurus fish that appears to be approximately 2 to 3 feet long. This photograph is one of only three out of a total of 180 that shows a fish residing near the bottom. Analysis of the photographs by benthic biologists is in progress.

4. Currents

Extensive current measurements at three separate depths have been made near the center of the site, at 39° 27.6′ north, 127° 41.5′ west, Reference E.9. The water depth at the current meter mooring location is about 4250 meters, and the measurements were made about 40 meters, 450 meters, and 1250 meters off the bottom. The three moorings recovered through 1981 represent a recording period of 748 days, and yielded the following results:

Mean Net Current Velocity from Reference E.13, Table 2 (Centimeters per second; kilometers per day)	Distance above Bottom (Meters)
1.13; 0.98	40
1.20; 1.04	450
1.18; 1.02	1250

The current measurements indicate that water movement is slow and relatively constant in at least the bottom 1250 meters, with a direction of movement toward the south-southeast at 29 and 438 meters above bottom, and south-southwest at 1200 meters, with an average speed of about 1.2 centimeters per second, or 1.0 kilometers per day. As shown in Reference E.13, the general southward flow is interrupted at one to two month intervals by mesoscale eddies (oceanic "anticyclones") that produce loops of 10 to 60 kilometers diameter in the progressive current vectors, and that persist for a week to as long as a year. The progressive current vector diagram is drawn by connecting in "tail-to-head" sequence each current measurement, each having a length proportional to the current speed, and a direction corresponding to that actually measured. Surface velocities (long term monthly averages) are in the range 0.04 to 0.5 knot, and trend generally to the south (Reference E.11).

5. Physical Data vs. Depth

Measurements of temperature and salinity as a function of depth at 39°32.2′N, 127°39.6′W are shown in Figures E-15 and E-16. Figure E-17 shows a northeast Pacific profile of dissolved oxygen, with bottom values from the Pacific study area.

6. Coring

Initial data of importance in establishing the composition of the sediment in the study area were obtained from the Deep Sea Drilling Project, Reference E.10. As part of the project, two holes, one 295 meters deep, the second 384 meters deep, were drilled in the sea floor in an area that became the northeast quadrant of the

DSDP SITE 33

Summary of Lithology

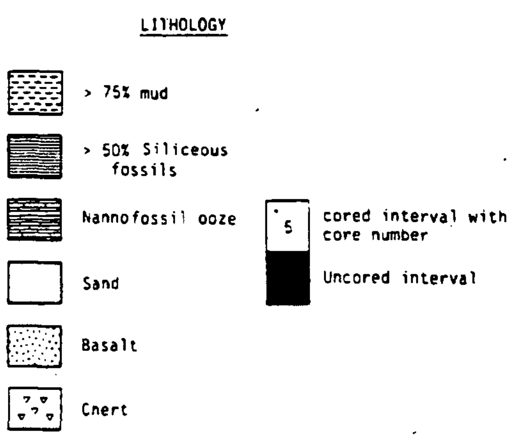
0-∿170 meters, cores 1-5, Pleistocene to Lower Pliocene in age. Dark green-gray dominantly clayey mud. Some siliceous fossil mud occurs in cores 3 and 5. Minor amounts of siliceous fossils and nannofossils occur throughout the interval. Silty mud layer from 7-9 meters. Fresh glass volcanic ash layer at 8.5 meters. Manganese clay pellet (?) at 17 meters. Pyrite spheres scattered throughout core 2. Black mottling in core 4. Cores 3, 4, and 5 have traces of zeolite, pyrite spherules, and silt-size fresh feldspar.

∿170-256 meters, cores 6-9, Upper Miocene-Middle Miocene in age. Dark greenish-gray beds. Mostly siliceous fossil ooze with thin nannofossil-siliceous ooze at bottom of cores 6 and 9. Some pyritized diatoms at base of core 6. Mottled in the lower part of core 8 and volcanic glass content increases down core 8.

256-270 meters, core 10 and top of core 11, Middle Miocene in age. Thin beds of greenish-gray nannofossil ooze. Round dark green cherty mudstone concretion with minor slightly pyritized and recrystalized fossil remains at 257 meters. Mottling at base of core 10. Approximately 262 meters represents the first reflection (.375 seconds) in the seismic profile. This closely corresponds to the top of the chert bearing sediments.

270-293 meters, bottom of core 11 to core 14, Middle Miocene in age. Dominantly siliceous fossil mud with significant quantities of dark green cherty fragments. Decrease in coring rate along with increased chert fragments between cores 11 and 12 suggest top of main cherty formation at 275 meters. Cherty layers alternating with softer sediments to the base of this section. Glassy ash layer at 284 meters and ash fragments in core catcher at 293 meters.

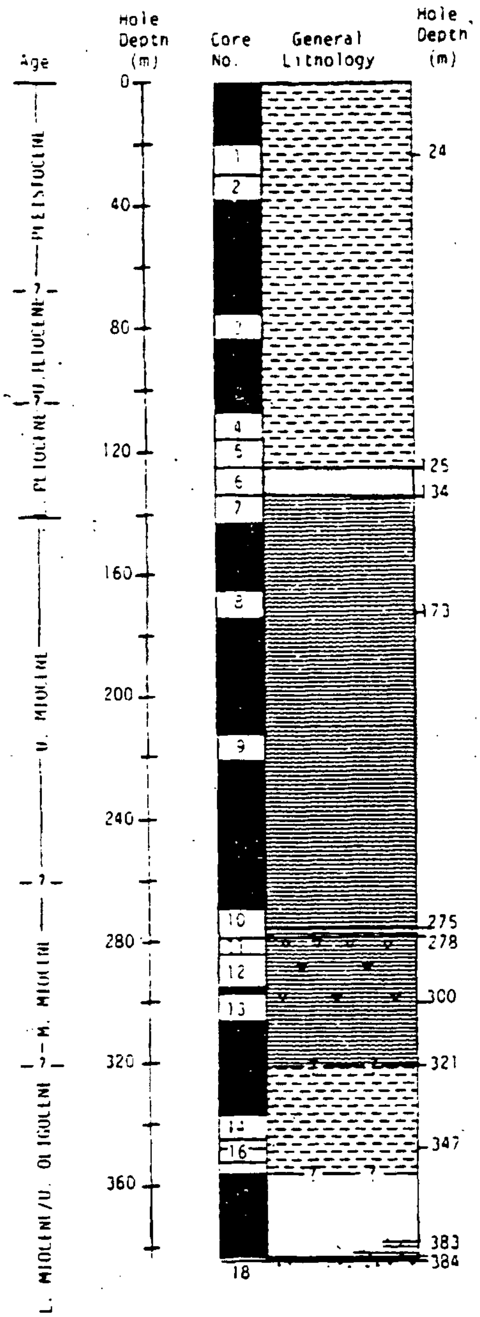
293-295 meters, core 15, Middle Miocene in age. Dark green to light green-gray nanno-siliceous fossil ooze interbedded with mud siliceous fossil ooze. Some chert chips. Hole terminated by hard horizon, lithology unknown. Basement not reached. Estimated that .475 second seismic reflection representing 350 meter depth is basement contact.



Lithologic summary of DSDP Drill Site 33. (latitude 39° 28.48'N, longitude 127° 29.81'W). Water depth of 4284 meters and hole depth of 295 meters. The basement was not reached at this site.

Figure E-18. Lithology of Deep Sea Drilling Project Site 33

DSDP SITE 34



Summary of Lithology

0-125 meters, cores 1-5, Pleistocene to Lower Pliocene in age. Greenish-gray mud with some siliceous fossils. Prominant nannofossils mud and muddy nannofossils ooze interbedded with gray mud in core 3 and top of core 4. Ashy bed at 24 meters. Rare sand pods and pyrite replacement of siliceous fossils in core 2. Slight to moderate mottling in core 3. Volcanic ash pods with some pyrite nodules and worm tubes in core 5. Increasing amounts of siliceous fossils in lower portion of core 5.

125-134 meters, core 6, Lower Pliocene in age. Mostly alternating greenish-gray and green-black silty siliceous fossil ooze. 5 to 25 centimeter beds of well sorted, fine-medium silty sand. Sandy beds are graded and have sharp upper and lower boundaries. The 0.18 second seismic reflection may correspond to this sand section.

134-275 meters, core 7 to top of core 10. Lower Pliocene to Middle Miocene in age. Greenish-gray siliceous fossil mud and non-fossiliferous clay. Thin bed of nannofossil mud near base of core 7. Graded 7 centimeter ash bed at 173 meters. First appearance of siliceous mudstone pebbles in core 9 and scattered olive black silicified mudstone pebbles in upper part of core 10.

275-278 meters, bottom of core 10. Middle Miocene in age. Thin greenish-gray and bluish-gray nannofossils siliceous clayey ooze.

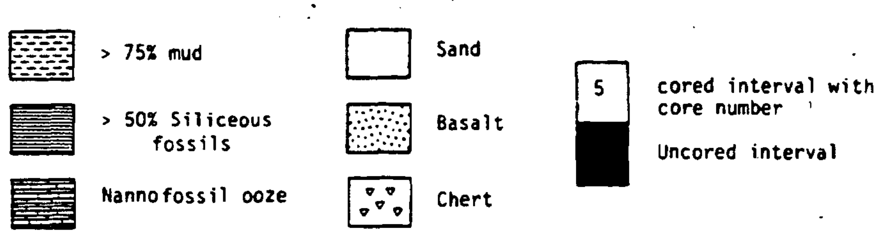
278-321 meters, cores 11-13, Middle Miocene in age. Greenish-gray and bluish-gray siliceous-fossil ooze and siliceous fossil mud. The main cherty sequence starting at the top of core 11 may correspond to the 0.39 second seismic reflection at 278 meters. Significant chert found in cores 11, 12, and 13 with slow penetration and poor recovery. Mottling in cores 12 and 13 with pyritic replacement of siliceous fossils in core 13. Two volcanic ash horizons near 300 meters.

321-356 meters, cores 14-17, Lower Miocene to Oligocene in age. Dark greenish-gray to greenish-gray mud and zeolitic mud with nannofossils ooze near base of interval. Local dolomite rhombs and rare burrow mottling in core 14. Scattered whitish zeolite pods throughout interval, especially concentrated at 347 meters. Thin beds with slump structures and mottling in core 16. Semi-lithified rock fragments in core 17 show extensive mottling.

383 meters, top of core 18, the age of core 18 is questionable. Contact between the sediments and basement not well preserved because of coring. Sediments are dark gray, yellow, orange and green; fine grained and contain calcite with some chlorite. No fossils noted.

384 meters, bottom of core 18, basement rock. Dark gray altered glassy basalt containing microamygdules of chlorite and fractures filled with carbonate and chlorite minerals.

LITHOLOGY



Lithologic summary of DSDP Drill Site 34. (latitude 39° 28.21'N, longitude 127° 16.59'W). Water depth of 4322 meters and hole depth of 384 meters to top of basaltic basement.

Figure E-19. Lithology of Deep Sea Drilling Project Site 34

study area. The latter hole reached the basement basaltic rock. Figures E-18 and E-19 provide summary descriptions of the lithology of these two sites. As stated in Reference E.11, the absence of significant lithologic breaks or coarse grained sediments in samples from the upper 200 meters of these holes suggests that depositional conditions have been very stable for millions of years.

Nine gravity cores of up to 3 meters in length, along with seven box cores between 19 and 34 centimeters in length were taken from the sea floor throughout the study area during August 1979. The following is a summary of the observations made in Reference E.12 regarding the lithologic properties of the area as shown by visual and microscopic examination of these cores.

The descriptions fall into three main groups:

a. Sediments from the eastern one-third of the study area (five core samples) are somewhat coarser than the more westerly sites, and contain thin beds of fine sand (1 to 11 centimeters thick) that were laid down at the seaward end of the Delgada Fan which is marked by the valley running southwest from 39°45' north, 127° west to 39° north, 127°25' west. All the cores are strongly mottled due to burrowers in the upper 10-30 centimeters. Based on the colors of the core materials, manganese is reduced at 4 to 25 centimeters below the sea floor. Thus, pore waters below this depth range do not contain dissolved oxygen. Conditions become strongly reducing at 2 to 3 meters, as indicated by the presence of fine sulphides in the deepest core.

b. Sediments from the low rise in the western two-thirds of the area (five core samples) are finer and firmer than those in the eastern one-third. (The two "3-meter gravity cores" penetrated only 79 and 81 centimeters.) Manganese reduction is indicated at 5 to 20 centimeters beneath the sediment surface, but no sulphides were evident. As in the core samples from the eastern one-third of the area, burrowing is indicated by mottling of the depositional structures in one of the core samples.

c. Sediments from the depressions to the north and south of the "4250 meter high" (six cores) are fine-grained and softer than the sediments sampled elsewhere in the area. (Three of the "3-meter gravity cores" over-penetrated to depths in excess of 350 centimeters.) All of the cores are strongly burrow-mottled. Manganese reduction is indicated at 5 to 35 centimeters and fine sulphides are visible in two of the longer cores, indicative of sulphate reduction (strong reducing conditions).

In summarizing the results of the Pacific site core sample examinations, Reference E.12 states that the "cores confirm that (the site) is a transitional pelagic-hemipelagic area dominated by the deposition of fine-grained terrestrial clays." The gradual downcore increase in shear strength is "typical of pelagic rather than turbidite deposits, suggesting that abrupt vertical or horizontal variations in properties are unlikely." Based on the appearance of the core material, Reference E.12 concludes that the "supply of organic debris from the sea surface is sufficient to consume the dissolved porewater oxygen" and, at greater depths, to reduce "first solid manganese oxyhydroxides, then porewater sulphate." Thus, the undersurface of any large object on the sea floor would be subject to anoxic chemical conditions, whereas the portions exposed to seawater would be subject to oxic reactions.

Three successful doppler penetrometer deployments have been made in the Pacific study area, one drop near the center and two in the northwestern portion, Reference E.8. The sediment shear strength, as determined from the penetrometer data, is higher than the shear strength deduced from recovered core samples by a factor of two. This difference is not considered to be exceptional when in-situ shear strength measurements are compared with those from recovered samples that are analyzed either onboard ship or in the shore laboratory. Therefore the shear strength of sediments at other locations can be deduced from recovered core samples without the need for penetrometer measurements, so long as adequate allowances for uncertainty are made.

The absence of thick sediments and reservoir beds guarantees that commercial hydrocarbon deposits are absent, and the absence of ferromanganese nodules ensures that the region will not be of interest to deep-sea miners.

7. Bottom-Dwelling Life

Research currently in progress includes biological sampling carried out to characterize the benthic invertebrate community and to identify the foodweb connections of this seafloor ecosystem. Benthic samples were collected using large "otter trawls" and box corers at 8 locations and 9 locations, respectively. Additional information on population numbers per unit area was obtained using bottom photographs at 10 locations. Although the characterization work is still in progress, the developing benthic picture appears to be similar to other deep sea benthic communities. The epibenthic megafauna is dominated by echinoderms both with respect to the number of species and organisms. The dominant benthic species are benthic rat tails (coryphaenoides armatus and coryphaenoides yaquinae).

Fish abundances at midwater depths are low, based on relatively shallow trawling at 2090-2525 meter depths, amounting to about one fish per 100,000 m^3, and 2 grams per 1000 m^3. The dominant pelagic species is another rat tail (coryphaenoides filifer). It was not found close to the bottom.

The sea floor in this area is not exploited by commercial fisheries, and one of the bases for its selection was the likelihood that it will never attract such fisheries.

8. Commercial Fishing

Commercial fishing in the surface waters of the Pacific Study Area occurs with low productivity (Reference E.11). The annual albacore catch by the U.S. fishing fleet off the west coast is sampled by the National Marine Fisheries Service (NMFS), a branch of the National Oceanographic and Atmospheric Administration, in La Jolla, California. Annual average albacore catch by the sampled portion of the U.S. fishing fleet (approximately 15 percent of the total) is as shown in Figure E-20, based on NMFS unpublished data for the entire 22-year period of available data (1961-1982). For the general location of the Pacific Study Area (a one degree by one degree rectangle), the annual average albacore catch is about 0.02 percent of the total. The values in Figure E-20 can be made representative of the entire U.S. fishing fleet by multiplying each entry by 1/0.15 or about 7. Whether or not this scale-up is performed, it is apparent that the average annual catch in the general location of the Pacific Study Area is a small fraction (0.5 percent) of the average annual catch in the most productive area of the same size. If the NMFS data were selected to cover shorter time intervals than the entire 22-year available period, the relative catches in the Pacific Study Area location would be 0.2 percent (1961-1970), 1.1 percent (1971-1980), and 0.5 percent (1981-1982) of those in the most productive area of the same size.

9. Characteristics Determined from Surveys of Available Data

The previously-described information on the Pacific Ocean site was developed primarily as a result of the concentrated oceanographic work in the area, exceptions being the Deep Sea Drilling Project results and the commercial fish catch data. The following information is based on data that ara of general interest and important to a site selection although not originally generated specifically for the study area.

a. **Seismicity.** Earthquake records (since 1853) indicate that no earthquakes of magnitude 3.5 or greater were centered within the area (Reference E.11).

Recent research shows the oceanic basement beneath the sediments to be the result of a simple sea floor spreading along a straight north-south section of rise crests between what were the Mendocino and Pioneer transform faults. This indicates that the (Pacific Study) area has not been tectonically disturbed by either the Mendocino or Pioneer fracture zones or the Delgado Fan.

b. **Volcanic Activity.** There is no known recent volcanic activity in the study area. The nearest active tectonic feature is the Mendocino Fracture zone, some 40 to 80 nautical miles (70-150 kilometers) to the north. This fracture zone, which forms the boundary between the Gorda-Juan de Fuca and Pacific lithospheric plates, is well defined seismically and topographically. Its associated seismicity does not extend into the study area.

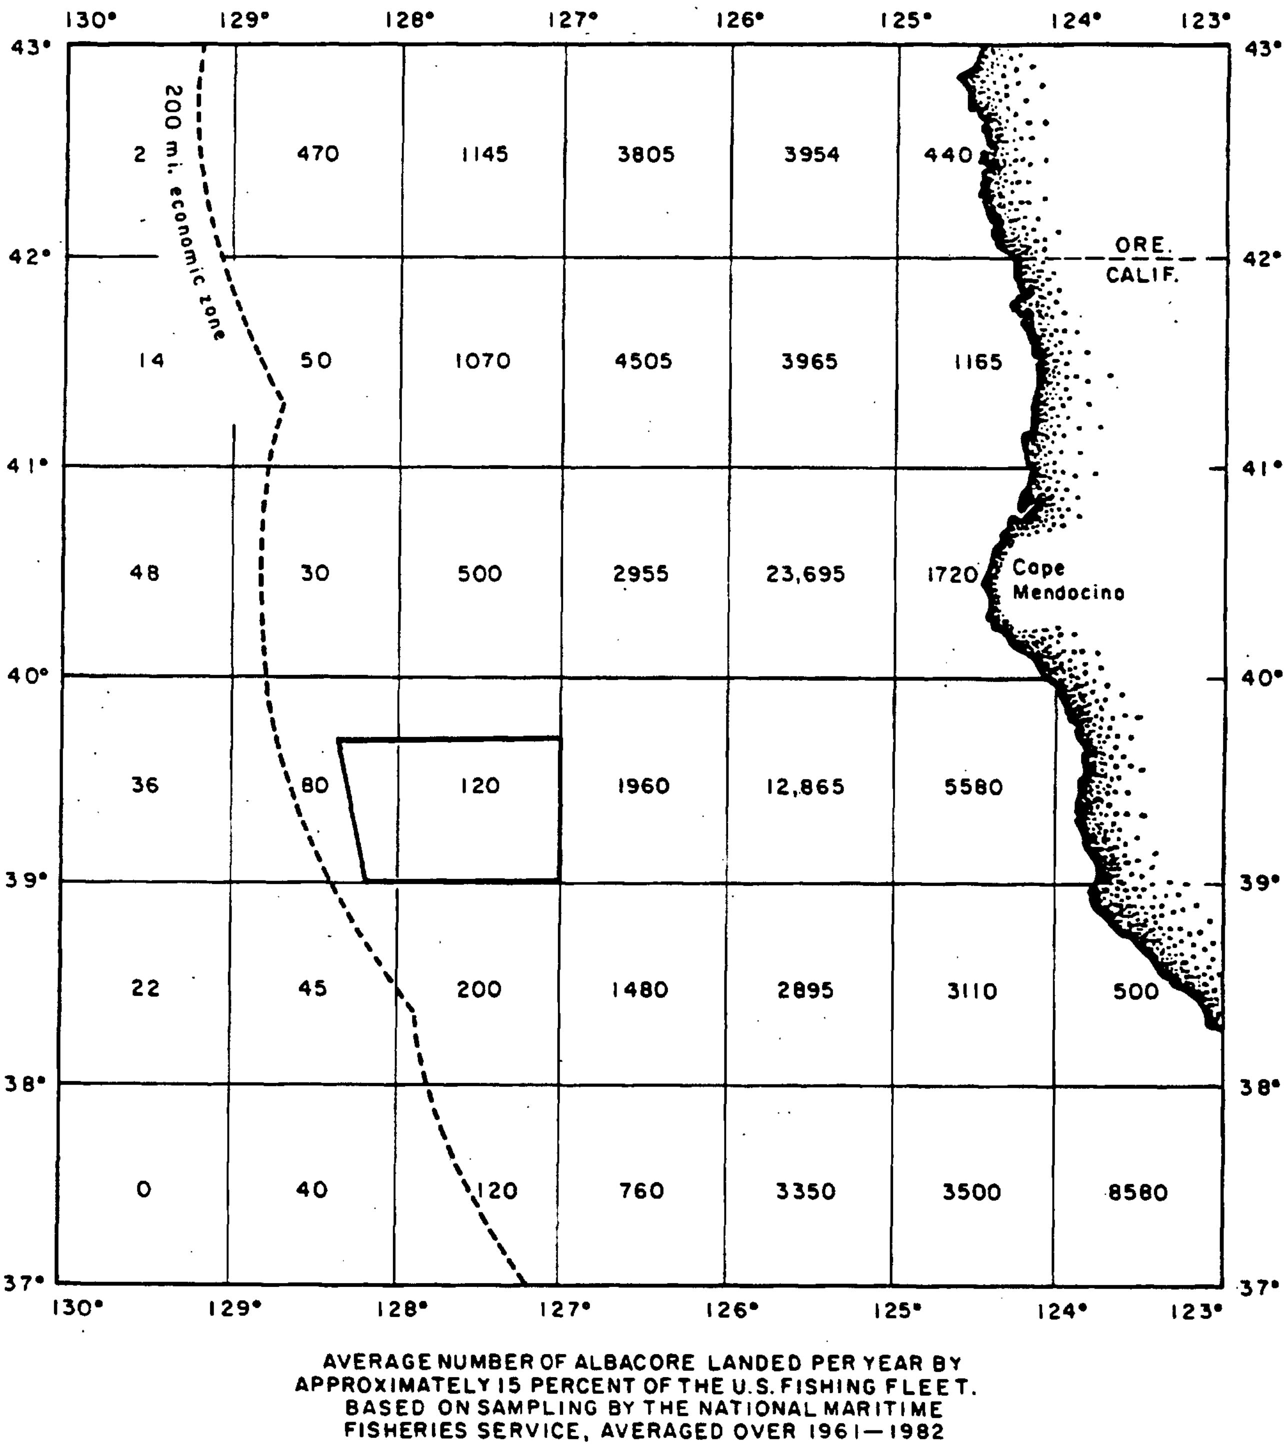


Figure E-20. Average Annual Albacore Landings by Approximately 15 Percent of U.S. Fishing Fleet (1961-1982)

c. **Sediment Thickness.** Historical data show a fairly uniform sediment thickness of about 300 meters, in agreement with Deep Sea Drilling Project results (Reference E.7). This relatively thin sediment column precludes the accumulation of and future exploration for oil or gas.

d. **Cable Routes.** There are no known cable routes in the area.

e. **Shipping Lanes.** The area is well clear of major U. S. shipping routes, although it does lie on the northern route from Vladivostok to Panama (Reference E.11).

10. Upwelling

Recent research on the subject of upwelling has employed infrared images of the coastal and off-shore ocean along Oregon and California. These images, obtained from satellite photographs, show near-shore upwelling events that take place within 25 kilometers of shore. Cold water "filaments," rich in nutrients, are frequently caught between near-shore eddies and appear to trail out on the surface from the coast to 400 kilometers or more as they are stirred. This phenomenon does not represent a "shortcut" between the sea floor at the study area and the waters at or near the surface. The upwelled water originates from relatively shallow depths on the continental shelf and has not circulated from the bottom waters of the study area, where there is very little vertical mixing of waters and where the direction of bottom water circulation is to the south.

11. Summary of Pacific Ocean Location

All information compiled to date on the Pacific site shows it to be an isolated, tranquil, and predictable area compatible with the tentative study site identification guidelines of Section III of this appendix. The area would be likely to prove acceptable as an ocean disposal site, based on the site selection criteria used to identify study areas.

CORROSION OF STRUCTURAL ALLOYS

Contents

List of Tables

List of Figures

APPENDIX F

CORROSION OF STRUCTURAL ALLOYS

I. INTRODUCTION

Corrosion is the natural process which eats away the exposed surfaces of metals and alloys, and changes strong structural alloys from solid objects into unrecognizable forms of flakes and powder and soluble substances. This appendix describes the need for quantitative corrosion information, the actions that were taken to acquire it, and the results that were obtained for use in this environmental assessment. Background information on some closely-related topics is included.

Practically all of the radioactivity involved in this environmental assessment is "induced" activity wherein the originally-inactive structural alloys in the new reactor plant were exposed to neutrons during normal operation of the reactor plant. These neutrons penetrated these alloys and reacted with the various nonradioactive atoms in them to form some radioactive atoms. These radioactive atoms exist throughout the mass of the alloys, not just on the surfaces. Since the radioactivity has been induced throughout the structures, it will continue to decay in place until it is exposed by corrosion. The longer the alloy can resist the corrosive action of its local environment, the more time there would be for harmless decay to occur. The rate at which the remaining undecayed radioactivity would be released to the environment depends on the corrosion rate of the alloy in its surroundings.

II. SUMMARY

Natural corrosion processes would eventually penetrate the containment barriers and degrade the structure of the radioactive alloys until the remains would be dispersed into the environment by diffusion and other natural processes. During the time that would be required for corrosion to reduce these massive structures to dispersible forms, radioactive decay would be decreasing the amount of radioactivity remaining to be dispersed. Those alloys that are more corrosion resistant would survive longer, and their radioactivity would decay further before being released to the environment.

The structural alloys used in the submarine and in the reactor plants have been assessed for their corrosion rates in seawater and in soil based on data from the literature and from supporting ocean and laboratory seawater corrosion tests. The long-term results indicate that the alloys have either of two characteristic rates:

1. The larger rate (up to 5 mils per year) is characteristic of low alloy steels. Exposed surfaces tend to corrode uniformly with some irregularity, but no significant pitting. For convenience, carbon steels are included with the low alloy steels.

2. The smaller rate (up to 0.5 mil per year) is characteristic of corrosion resistant alloys that exhibit most of their weight loss by pitting. Observed weight changes are expressed for convenience as the amount of thickness that would have been lost by the exposed surface if the loss were uniform, by dividing the weight change by the corresponding density and surface area. Such thicknesses are expressed here in mils (0.001 of an inch); one mil is also equal to 25.4 micrometers (μm).

The rates in seawater were determined from the maximum and average values for long-term corrosion testing based on published data for these materials in the ocean, as illustrated in Figure F-1. The values from the enveloping lines are listed in Table F-1. The one-year values account for the faster corrosion rates that occur during the first few years of exposure. Published values for corrosion of these materials in soil tend to be somewhat lower.

Supporting tests were planned and executed, to confirm the adequacy of the limiting values from the literature and to examine the effects of additional variables. Ocean-bottom experiments, laboratory tests, and their results are all described in detail.

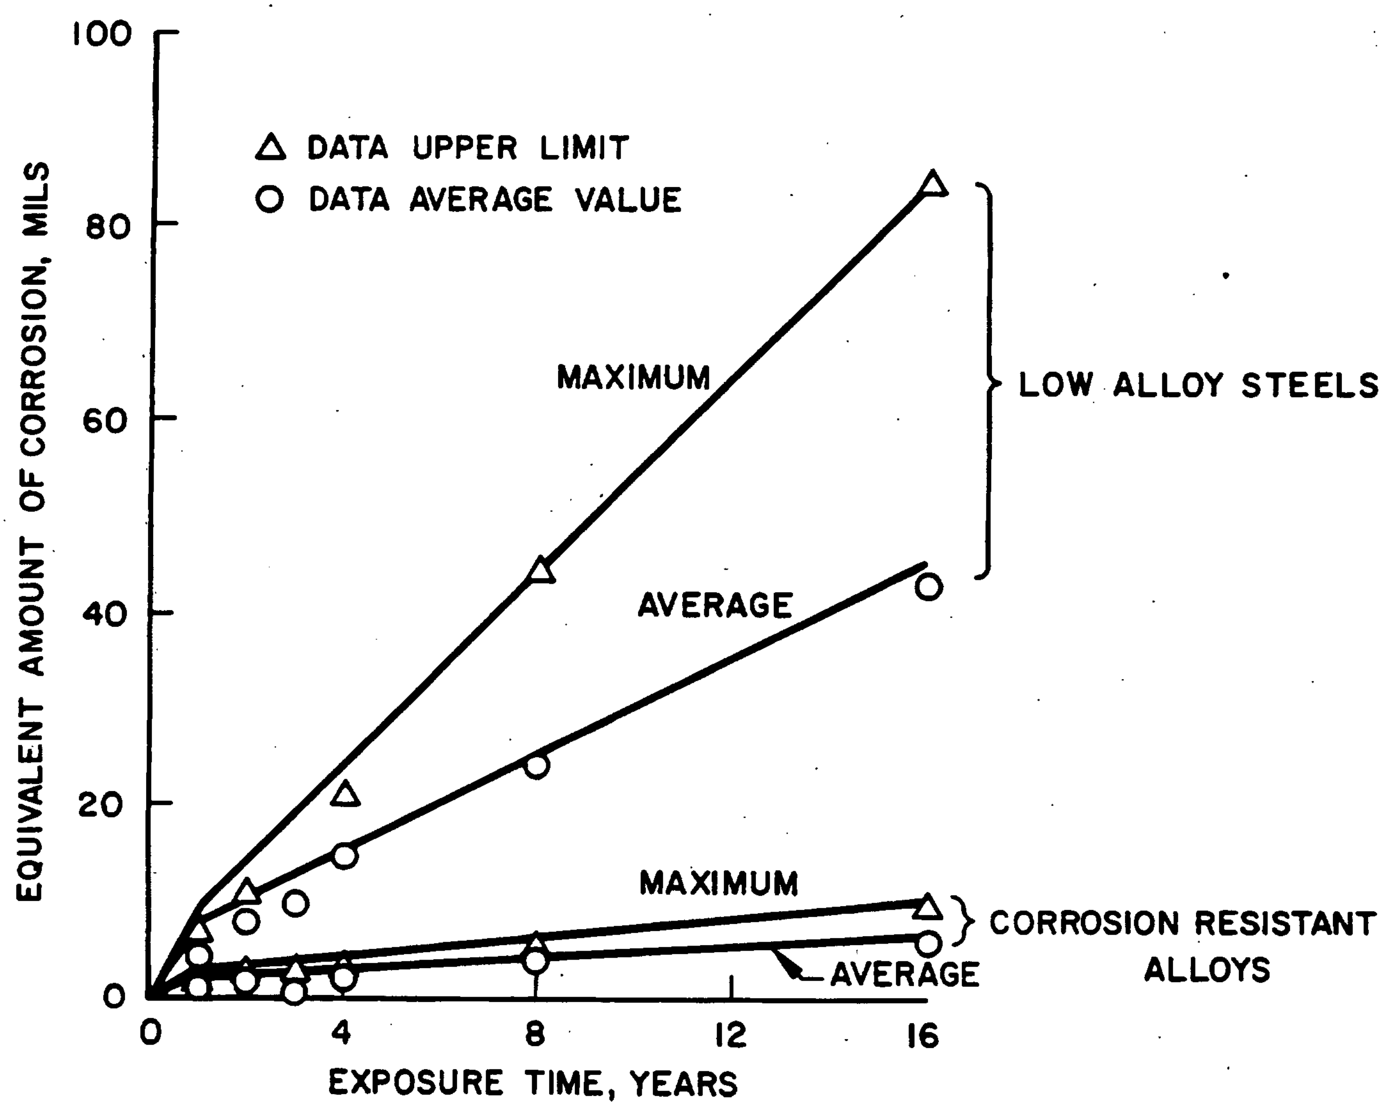

Figure F-1. Amount of Corrosion in Seawater for Low Alloy Steels and Corrosion Resistant Alloys

III. DISCUSSION

Conservative values for the corrosion release rates were determined from published values for applicable tests and were confirmed by specific ocean and laboratory seawater corrosion tests. This effort is described in detail below.

A. REQUIREMENTS FOR CORROSION INFORMATION

Corrosion rates for the structural alloys determine the rates at which they would be penetrated as containment barriers and the rates at which their induced radioactivity would be released to the surrounding environment. These rates depend upon two different characteristics of corrosion: pitting and average corrosion. The average corrosion rate is the rate at which the mass of the alloy is changed from the metallic form to the various corrosion products. The release of induced radioactivity would be proportional to the amount of corroded alloy, and the average corrosion rate would be the appropriate measure of this effect.

TABLE F-1. CORROSION RATES FOR LOW ALLOY STEELS AND CORROSION RESISTANT ALLOYS IN SEAWATER

	Material	
Long-Term Rates	**Low Alloy Steels**	**Corrosion Resistant Alloys**
Maximum(1)	5 mils/year	0.5 mil/year
Average(2)	2.5 mils/year	0.3 mil/year
One-Year Values		
Maximum	9 mils	3 mils
Average	8 mils	2.2 mils

NOTES: (1) Maximum values from envelope of highest values in published data discussed in text.
(2) Average values from envelope of highest averages in published data discussed in text.

The pitting rate is the rate at which the thickness of the alloy is penetrated by corrosion in localized regions of an exposed surface. The pitting rate always exceeds the average rate. The time it would take to penetrate a containment barrier would depend on its thickness and its pitting rate. Pitting rates are conveniently expressed as a factor applied to the average corrosion rate to express the ratio by which the pitting rate exceeds the average rate.

Corrosion of lead in the disposal environment would occur eventually when lead shielding in the reactor compartment would be exposed by corrosion and begin to corrode due to exposure to soil moisture or to seawater. Subsequent release of lead corrosion products into the surrounding environment would allow some lead to be transported away from the disposal site by groundwater flow or by seawater flow. As described in Chapter 4, the maximum concentrations of lead in the groundwater and seawater at locations downstream from the disposal site would be less than the EPA criteria. Corrosion data were required to estimate the dispersibility of the lead corrosion products in groundwater, and to estimate the corrosion release rate in seawater.

There is a characteristic difference between the amount of corrosion that occurs in a structural alloy and the amount of alloy material that is released to its environment because some of the alloy material is retained as corrosion products that adhere to the corroding surface in the form of a film or scale, as shown in Figure F-2. This difference is significant early in the corrosion process when the scale or film is being established, but while the thickness of the corrosion scale increases to achieve its steady-state value, the corrosion release rate increases to become equal to the corrosion rate. For estimating the effects of the corrosion release processes, it would be conservative to use the long-term corrosion rate as the corrosion release rate.

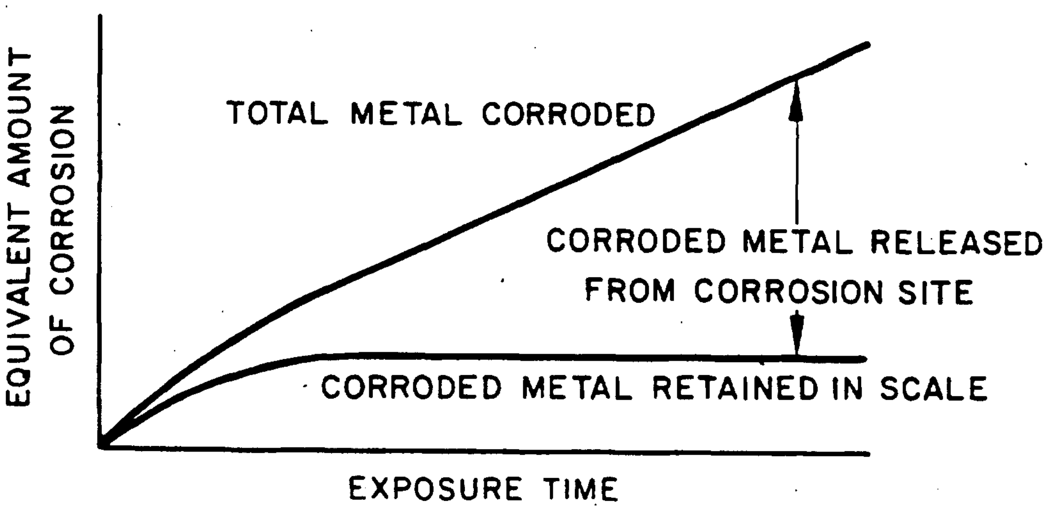

Figure F-2. Difference Between Corrosion and Corrosion Release

Not all of the released corrosion products are equally dispersible in the environment. A very small fraction of the corrosion products is soluble and would be dispersed readily in seawater or in groundwater, but the corrosion products from typical structural alloys are not very soluble in either seawater or freshwater. So, the bulk of the released corrosion products would be insoluble and would tend to precipitate in the immediate vicinity of the corroding structure. Some of these corrosion products would be sizeable flakes that would settle rather rapidly and others would be in a small enough size range that they could disperse for some distance before they would be expected to be deposited on a solid surface. Ultimately, all of the corrosion products would be dispersed to a degree that would depend on the time scale considered. However, during the time when the large flakes or piles of powder would be retained nearby, their radioactivity would be continuing to decay and to become progressively lower.

Maximum and average values of the corrosion release rates for the structural alloys were estimated as follows:

1. The highest measured long-term corrosion rates were used to estimate the maximum corrosion release rates.

2. The average values of measured long-term corrosion rates were used to estimate the average corrosion release rates.

All of these needs were satisfied by information acquired from published data. Maximum and average limits for long-term corrosion rates, short-term corrosion allowances, and pitting ratios have been determined. In addition, laboratory and ocean-bottom seawater corrosion tests were conducted to clarify some specific corrosion effects, as described below.

B. PLAN OF ACQUISITION

Corrosion information is acquired experimentally. As planned, the bulk of the needed information was obtained from published results of appropriate tests. Additional experiments were conducted to confirm the adequacy of using the published data and to clarify the effects of certain variables such as stress, temperature, and oxygen concentration.

C. ACTIONS TAKEN

A literature search for applicable corrosion data was conducted, and corrosion experiments were performed in the oceans and in the laboratory.

The literature search was conducted in three parts. A computer-aided search of abstracts by key words was conducted using the remote-access retrieval system operated by the Department of Energy (DOE) Technical Information Center at Oak Ridge, Tennessee. Over 10,000 abstracts on corrosion and related topics were searched for pertinent information. In addition, available secondary sources were searched for applicable data and for references to primary sources of such data. References F.1 and F.2 were found to be useful. Finally, personal communications provided useful leads to primary sources of such data. The results are discussed below.

In-situ ocean corrosion experiments were conducted in both the Atlantic and Pacific Oceans. Corrosion experiments were conducted at two locations at the bottom of the Atlantic Ocean (at depths of 3200 meters and 3700 meters) to obtain data from specimens of structural materials exposed to the Western Boundary Undercurrent on the western North Atlantic continental rise. Data was obtained for exposures ranging from nine months to three years. The alloys tested are listed in Table F-2, and the results of this testing are discussed below.

A one-year experiment was conducted at the bottom of the Pacific Ocean (at a depth of 5860 meters) to obtain preliminary data from exposure of structural alloys and to test experimental methods. The alloys are

TABLE F-2. ALLOYS TESTED IN OCEAN CORROSION EXPERIMENTS

Low Alloy Steels	Typical Applications
AISI 4340[a] ASTM A302 Grade B ASTM A516[b] Carbon Steel[b] HY-80	Submarine and reactor plant structures
Corrosion Resistant Alloys	
Nickel-Chromium-Iron (NiCrFe) Alloy 600 Stainless Steel, CRES 304 Stainless Steel, CRES 304L[b] Stainless Steel, CRES 308[b] Stainless Steel, CRES 347[b]	Reactor plant structures

Note: (a) Tested in Pacific Ocean only.
(b) Tested in Atlantic Ocean only.

listed in Table F-2. This was followed by a three-year experiment to obtain longer-term data from structural alloys at the bottom of the Pacific Ocean at another site (at a depth of 4245 meters). The results of this testing are discussed below.

A one-year laboratory corrosion tests of 24 specimens were conducted as discussed below to determine the effects of three different temperatures and two oxygen concentrations on the corrosion and release of corrosion products from corrosion resistant alloys (CRES 304 and NiCrFe Alloy 600) in seawater.

D. RESULTS

Results are provided from the literature survey, the ocean corrosion experiments, and laboratory seawater corrosion testing.

1. Literature Survey

Of the many references examined for applicable corrosion data, reports published by the U.S. Naval Civil Engineering Laboratory (NCEL) and by the Naval Research Laboratory (NRL) were found to be most useful for seawater corrosion. The most applicable ones are listed in Table F-3. The summaries reported by K. H. Logan of the National Bureau of Standards in Reference F.7 provided the soil corrosion values listed in Table F-3. Most of the other sources examined were found to be not applicable either because they reported unique experiments of limited applicability or they did not address the topics of concern. The quantity and quality of the data from these Naval Laboratories were found to be adequate to define the corrosion characteristics of the structural alloys for environmental assessment.

The Naval Civil Engineering Laboratory has conducted extensive corrosion tests in the Pacific Ocean at two deep ocean sites that are approximately 80 miles from Port Hueneme, California. Test Site I has a nominal depth of 1800 meters; Test Site II is approximately 700 meters. Their tests consist of many test specimens attached to submersible test units that are lowered to the ocean floor for periods of exposure that ranged from nine months to three years, then retrieved.

The Naval Research Laboratory has conducted extensive immersion corrosion tests in the Pacific Ocean at a shallow water site at Naos Island in Panama, as a part of a larger program that involved exposure of many specimens to five different environments in Panama for periods of time up to 16 years. All specimens were exposed simultaneously. Each set of specimens consisted of 10 replicates so that duplicate specimens could be removed after exposures of 1, 2, 4, 8, and 16 years. Further details are available in Reference F.8.

TABLE F-3. CORROSION DATA FROM THE LITERATURE

a. Seawater Exposure

Material	Exposure Time	Equivalent Amount of Corrosion(1): Range of Values (mils)	Average (mils)	Adjusted Average(2) (mils)	Source
Low Alloy Steels	0.34 year	0.5-1.9	1.0	1.7	NCEL, Ref F.3
	0.54	0.5-1.0	0.8	2.6	NCEL, Ref F.3
	1	0.3-6.9	5.5	4.4	NRL, Ref F.4
	2	8.5-11	10.0	7.9	NRL, Ref F.4
	2.91	0.7-7.4	2.8	9.8	NCEL, Ref F.3
	4	15-21	19.0	14.8	NRL, Ref F.4
	8	25-44	32.4	24.0	NRL, Ref F.4
	16	45-84	60.2	43.3	NRL, Ref F.4
Corrosion Resistant Alloys	0.34	<0.03-0.3	0.08		NCEL, Ref F.5
	0.54	<0.05-0.3	0.07		NCEL, Ref F.5
	1	0.6-1.5	1.1		NRL, Ref F.6
	1.10	<0.1-1.8	0.3		NCEL, Ref F.5
	2	0.3-2.2	1.4		NRL, Ref F.6
	2.06	<0.2-3.5	1.1		NCEL, Ref F.5
	2.91	<0.3-2.9	0.6		NCEL, Ref F.5
	4	0.3-3.5	2.4		NRL, Ref F.6
	8	2.1-5.5	4.2		NRL, Ref F.6
	16	0.8-9.5	5.9		NRL, Ref F.6

b. Soil Exposure

Material	Exposure Time	Penetration Rates(3): Range	Average	Source
Low Alloy Steels	4-12 years	6-25 mils/yr	14 mils/yr	Ref F.7
Corrosion Resistant Alloys	5-14	0.4-4.3	1.3	Ref F.7

NOTES: (1) Equivalent to observed weight loss during corresponding exposure time.

(2) Averages for low alloy steels only were adjusted for differences between the seawater temperatures and oxygen concentrations at the testing site versus those at the Pacific study area, in accordance with the formula developed by NCEL and published in Reference F.9.

(3) Equivalent rates for weight loss are considerably less: 1.1 mils/yr with a penetration rate of 25 mils/yr for black iron in four years; and 0.00017 mil/yr for stainless steel in nine years after which the surface was visually "unaffected".

The applicable data from these tests is summarized in Table F-3. It includes data from specimens exposed to seawater alone and to the sediments at the bottom of the ocean. Tabulated values are averages of results from duplicate specimens. The amounts of corrosion for the low alloy steels are characteristically greater than those of the corrosion resistant alloys. The averages for the low alloy steels were adjusted to account for the effects of different temperatures and different oxygen concentrations between the testing sites and the Pacific study area. The adjustment was calculated from a formula developed by NCEL and reported in Reference F.9. The magnitude of the adjustment of the averages depended mostly upon the differences in the oxygen concentration which accounted for between 65 and nearly 100 percent of the adjustment in each case. No adjustment was available for the average amounts of corrosion on corrosion resistant alloys in seawater, but the unadjusted values are considered to define suitable values for use in the environmental assessment.

Adjusted values for the NRL average data for low alloy steels and the corresponding NCEL data are in good agreement over the range of common periods of exposure. The data on corrosion resistant alloys shows that the NRL data from Panama are consistently greater than the NCEL data, most likely due to the higher temperature at the Panama test site. Oxygen in the range of 1 to 10 parts per million by weight (ppm) was found in laboratory corrosion tests to not have a large effect on corrosion of corrosion resistant alloys. Since no formula has been established to correct the possible effects on corrosion resistant alloys due to the differences in temperature and oxygen concentration between the test sites and the study area, no adjustment was made. The maximum values and the average values for the corrosion resistant alloys selected for assessing environmental effects are considered to be conservatively high due to the effect of these differences in oxygen and temperature values.

The results of the naval experiments listed in Table F-3 are plotted on the graphs in Figure F-3 for comparison with the limiting lines developed from these data. The lines were devised to provide conservative representations of these data for use in the environmental assessment. The corrosion rates listed in Table F-1 were obtained from the slopes of these lines.

Conservative representations of the corrosion data were used in the environmental assessment so that the assessment would be suitable even if new corrosion data were to include some results that might exceed the reference lines by small amounts. It is expected that new corrosion data would agree in general with the range and trend of these data, but the natural variability of corrosion data might result in some small exceptions in new corrosion data.

An historic example of long-term corrosion behavior of metals on the ocean bottom was obtained from the USS MONITOR which was lost at sea in a storm off North Carolina in 1862. In 1977, a section of wrought iron hull plate was recovered from the wreck and examined for mechanical properties and metallurgical characteristics. The tests showed that sound metal approximately 1/4 inch thick remained from an original thickness thought to have been approximately 3/8 inch, indicating that the plate had corroded at an average rate of approximately 0.5 mil per year from each side during the 115 years that it was exposed on the ocean floor under 200 feet of seawater. Further details are available in References F.10 and F.11.

Pitting data for corrosion resistant alloys in seawater are reported in References F.5 and F.8. Reference F.5 reports the maximum pit depth in each specimen, and Reference F.8 reports both the maximum pit depth and a 20-pit average. The 20-pit average was determined from the five deepest pits on each of the two major surfaces (9 × 9 inches each) of each of the two duplicate specimens. For assessing the environmental effects, the 20-pit average was used for the average case and instant penetration was used for the maximum case, to ensure adequate conservatism.

For corrosion resistant alloys in Reference F.8, the average value for the 20-pit average over a 16-year period is 46 times the average penetration based on weight loss. The factor of 46 indicates that the average of the 20 deepest pits in 2.25 square feet of surface is 46 times deeper than the thickness calculated by dividing the corrosion weight loss by the product of the density and the surface area. The pitting ratio is used in this assessment to estimate when a containment barrier would be penetrated by corrosion processes, and it reflects the fact that penetration occurs at a faster rate than weight loss alone would account for. The penetration time is estimated by dividing the material thickness by the product of pitting ratio and the average rate of corrosion loss.

Data on the corrosion of lead in land burial were obtained from Reference F.12 in which the National Bureau of Standards reported the results of field tests in 38 different types of soil with exposures that ranged

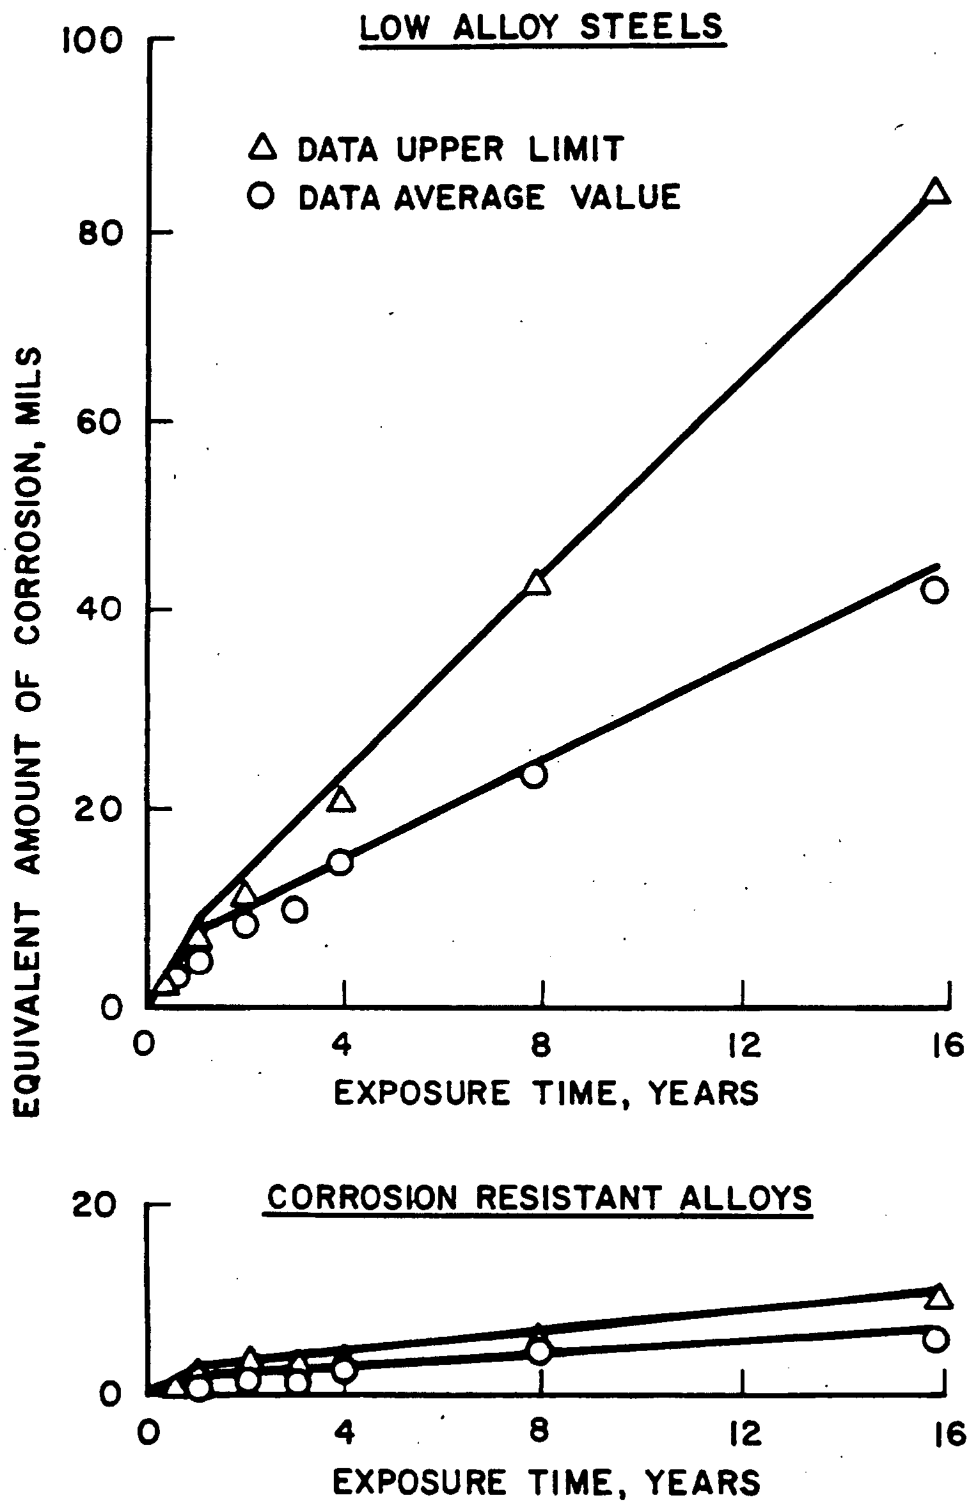

Figure F-3. Time-Corrosion Plots for Published Data up to 17 years. From tests in Cecil clay loam, which is similar to the soil in the Savannah River burial ground, the amount of corrosion did not exceed 0.8 mil (weight-loss basis) in 10 years of exposure, an average corrosion rate of not more than 0.08 mil per year. Lower corrosion rates would be expected at Hanford because the rainfall is less and the ground at the burial site is drier.

In seawater, data from the naval experiments reported in References F.8 and F.9 indicated that the amount of corrosion did not exceed 4.9 mils in 16 years of exposure, an average corrosion rate of approximately 0.3 mil per year. One-year exposures resulted in amounts of corrosion in the range of 0.3 to 0.6 mil.

Due to its corrosion resistance, lead pipes installed and used in ancient Rome have endured in place and were dug up in modern times from the ruins of Pompeii and Rome. Many of these lead pipes were in an almost perfect state of preservation after 1900 years of exposure.

2. Ocean Corrosion Experiments

The first Pacific Ocean experiment has been completed and the second one is in progress. The Atlantic Ocean experiments are also continuing.

The data from these experiments indicate that actual corrosion at these sites is typically less than that inferred from the literature survey. The amounts of corrosion suffered by the corrosion resistant alloys are characteristically lower than those of the low alloy steels. The results of these experiments are plotted on the graphs in Figure F-4. For comparison, the limiting lines developed from the literature survey are also shown. The data include results from specimens exposed to seawater alone and to the sediments at the bottom of the ocean, and represent averages of results from duplicate specimens. The data from the ocean corrosion experiments are within the limits of the literature values, and the average values tend to be somewhat lower than the literature values. This appears to be characteristic of corrosion in the deep ocean, where corrosion rates tend to be low because of the low temperature and relatively quiescent conditions. Details of the Atlantic Ocean corrosion experiments and results of evaluations of the data that has been acquired are reported in Reference F.13. Details of the first Pacific Ocean corrosion experiment and evaluation of the acquired data are reported in Reference F 14.

3. Laboratory Seawater Corrosion Testing

Laboratory corrosion tests were conducted to examine the effects of temperature and oxygen concentration on corrosion and release of corrosion products. Twenty-four specimens representing two corrosion resistant alloys were exposed for one year of cumulative-exposure.

The data from the tests show the effects of three different seawater temperatures and two different oxygen concentrations on the amount of corrosion suffered by two different corrosion resistant alloys during the first three months of exposure and after one year of cumulative exposure. The amounts of corrosion increase with temperature, but are relatively insensitive to different oxygen concentrations in the range of 1 to 10 ppm and to the two different alloys: CRES 304 and NiCrFe.

The amount of corrosion products released from the specimens during 12 months of exposure to seawater at 2°C increased from 0.3 percent of the amount of corrosion to 2.2 percent. At 36°C, the maximum was 2.4 percent, and at 80°C, the maximum was 4.0 percent. The unreleased corrosion products formed the corrosion-resistant film on the metal surfaces. On the basis of these tests, it would be reasonable to expect that the release rate for corrosion resistant alloys in the cold seawater of the deep ocean during the first year would not exceed five percent of the amount of corrosion. Details of this experiment and evaluation of the data are reported in Reference F.15.

Corrosion theory predicts that the corrosion release rate will approach but not exceed the long-term corrosion rate, as described in Section IV.A (Corrosion Theory, Corrosion Model), below. The long-term corrosion rate for corrosion resistant alloys is 14 percent of the one-year value, using the average values from Table F-1. Since this value exceeds the values obtained from laboratory testing, it would be conservative to use the long-term corrosion rate as the corrosion release rate for the short-term exposures as well as for the long-term ones.

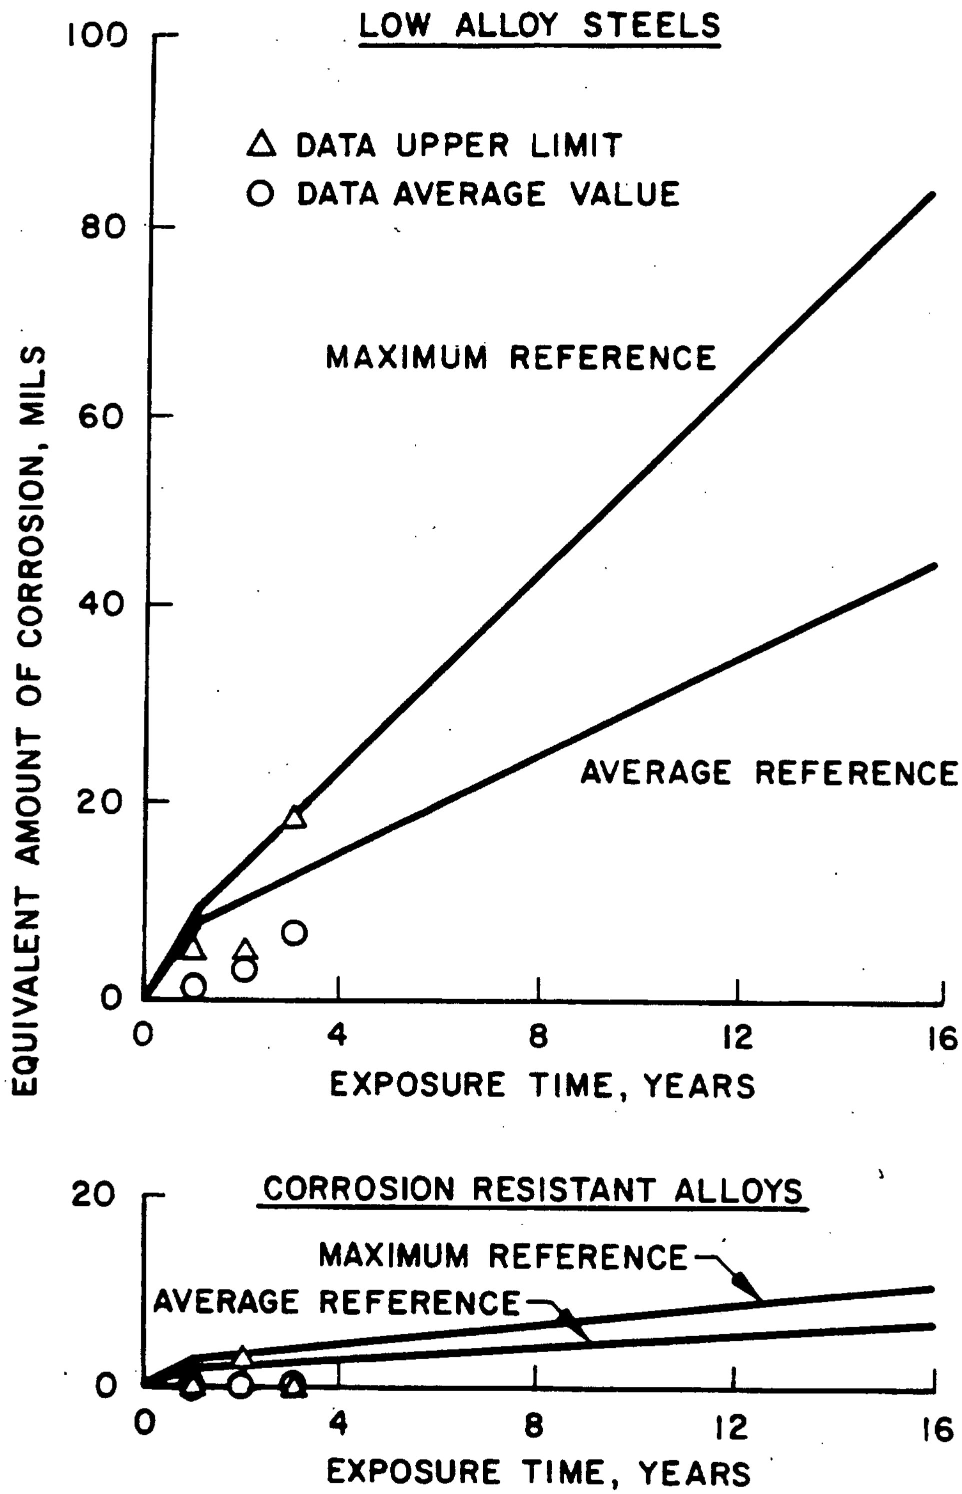

Figure F-4. Time-Corrosion Plots for Ocean Corrosion Experiments

IV. BACKGROUND

This section summarizes some corrosion-related details that may not be readily available.

A. CORROSION THEORY

The main features of corrosion theory are summarized in this section. For simplicity and brevity, many of the fine points that are very significant to the science and technology of corrosion are omitted. The emphasis is on the fundamental concepts that relate to the specific topics discussed here.

Structural alloys immersed in seawater corrode because the atoms of the metallic elements at the surface of these alloys have a natural tendency to escape from the surface of the alloy and pass into the seawater as ions. When these ions escape from the metal, the electrons that they leave behind also escape to a nearby surface where they react with other ions or molecules in the seawater. These reactions are the main processes in general corrosion, as illustrated in Figure F-5, where iron (Fe) is used as an example. While the iron is escaping as ferrous ions (Fe^{++}), the electrons are reacting with hydrogen ions (H^+), with dissolved oxygen molecules (O_2), or with both, depending upon their availability in the local region. These reactions are written as electro-chemical reactions, as follows:

$$Fe \rightarrow Fe^{++} + 2e^-$$

$$2e^- + 2H^+ \rightarrow H_2$$

$$\text{or, } 2e^- + \frac{1}{2}O_2 + H_2O \rightarrow 2(OH)^-$$

Since ocean waters normally contain both hydrogen ions and dissolved oxygen, these reactions can proceed without difficulty, producing the relatively rapid corrosion rates experienced by structural alloys with clean, uncorroded surfaces.

As the corrosion reactions continue, there is a natural accumulation of ferrous ions and hydroxyl (OH^-) ions in proximity to the corroding surface. This creates an alkaline condition at the surface, and tends to reduce the corrosion rate by reducing the local concentration of hydrogen ions and by increasing the local concentration of ferrous ions.

As the local concentration of oxygen tends to be consumed by the corrosion reaction, additional oxygen diffuses into the local region from the surrounding seawater and supports the corrosion process. The rate of corrosion is limited by the rate at which oxygen diffuses through the local region. While diffusing through this region, some of the oxygen is consumed in a reaction with the ferrous ions, converting them to ferric ions and making more hydroxyl ions:

$$2Fe^{++} + \frac{1}{2}O_2 + H_2O \rightarrow 2Fe^{+3} + 2(OH)^-$$

Since ferric hydroxide is much less soluble than ferrous hydroxide, some of the iron in solution precipitates as ferric hydroxide either locally or at some downstream location—creating at first the familiar rusty stain. During this process, the ferric hydroxide ages and partially dehydrates to form a hydrous ferric oxide:

$$Fe(OH)_3 \rightarrow FeO(OH) + H_2O$$

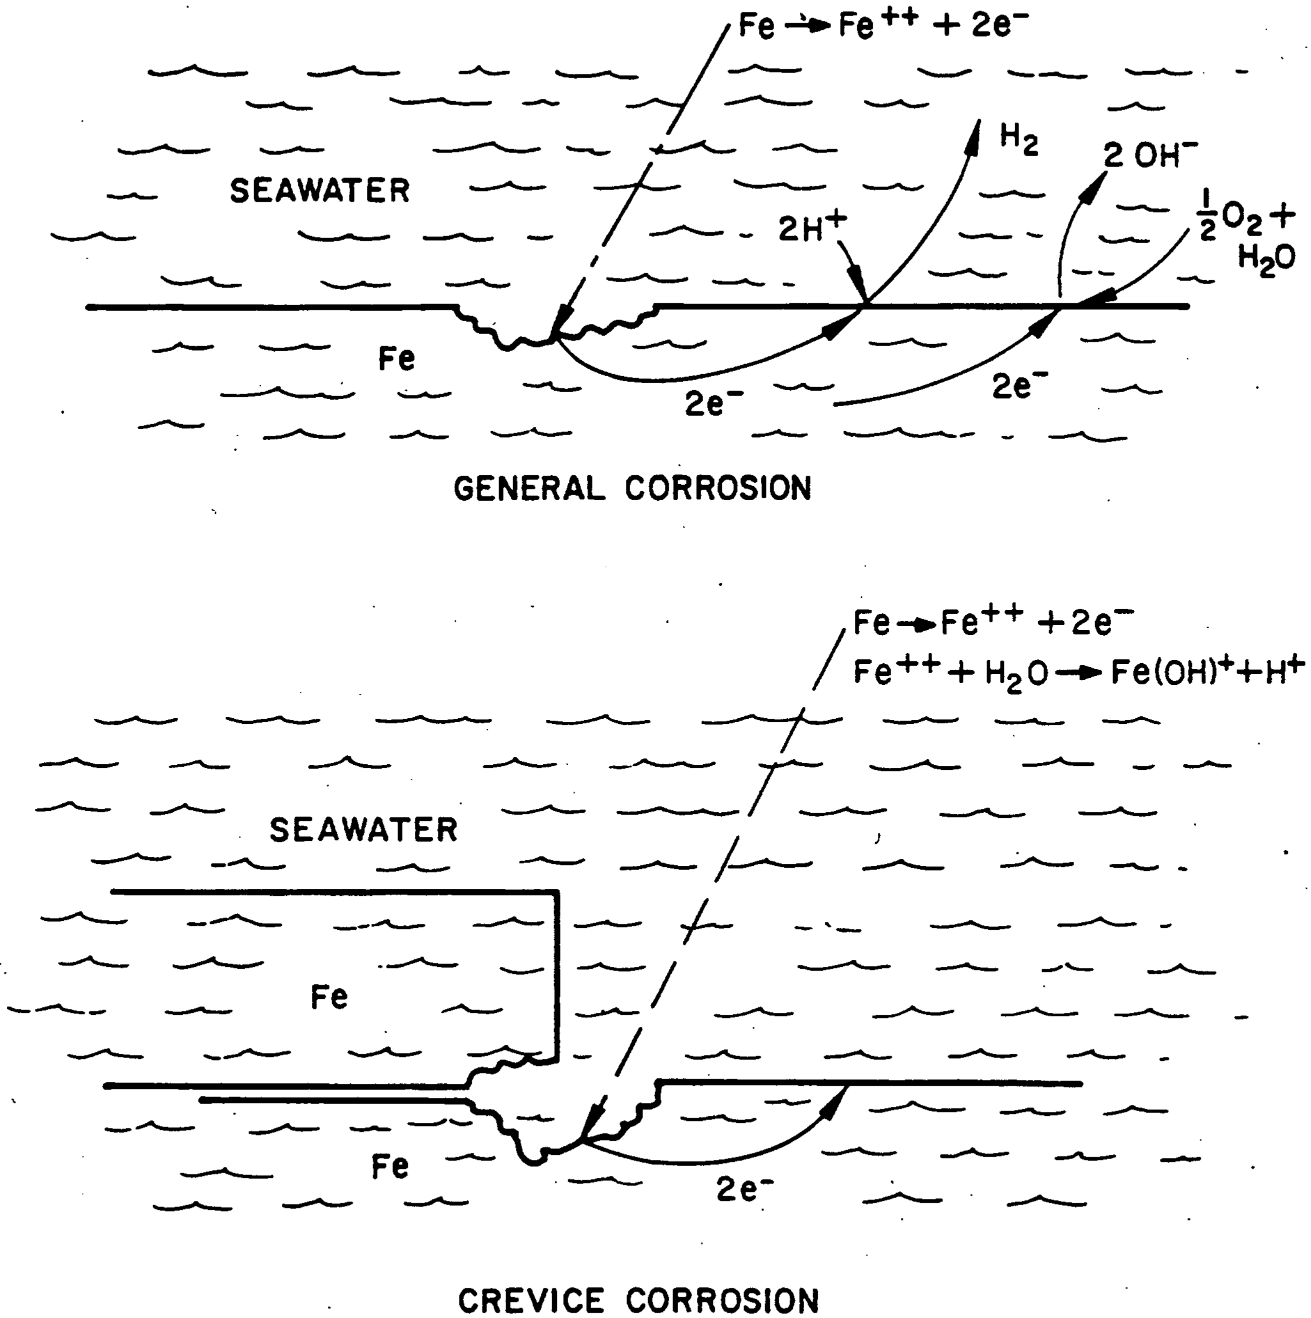

Figure F-5. Corrosion Processes

Ordinary rust is the result of further aging and dehydration, to produce ferric oxide:

$$2\,FeO(OH) \rightarrow Fe_2O_3 + H_2O$$

As the corrosion process continues, the corrosion products (iron hydroxides and oxides) accumulate and tend to interfere with the diffusion of hydrogen away from the local corrosion site and of oxygen to the local corrosion site. The result is that the part of the local corrosion site closest to the surface of the corroding metal acts as a protective barrier and tends to slow the corrosion process. Also, the lack of sufficient oxygen prevents the ready oxidation of the ferrous ions. In this environment of limited oxygen, a mixture of ferrous ions and ferric ions exists and tends to react with the local concentration of hydroxyl ions to form the black corrosion product, magnetite:

$$Fe^{++} + 2\,Fe^{+3} + 8(OH)^- \rightarrow Fe_3O_4 + 4\,H_2O$$

On low alloy steels exposed to seawater, the usual rusty-colored corrosion product was found to have such a layer of black material under it.

By the actions of these processes, the corrosion processes proceed, with relative rapidity on bare metals at first, but slowing down as the accumulation of corrosion products on the surface of the metal slows the diffusion of reactants to the local corrosion region and the diffusion of the soluble portion of the reaction products from the local corrosion region. The soluble portions that are able to diffuse away are a small fraction of the total, but they are "released" to the environment in this way. In addition, some of the insoluble portions of the corrosion products are also released if they are not bound tightly to the surface.

In this regard, there is a large difference between low alloy steels and corrosion resistant alloys. The corrosion products of corrosion resistant alloys are naturally bound to the alloy surface very strongly—thus providing the necessary diffusion barrier to make the alloy corrosion resistant. On low alloy steels, the corrosion products are less strongly bound and are less protective. Hence, the low alloy steels corrode faster than the corrosion resistant alloys and tend to release more of their solid corrosion products because they are not strongly bound together. Ultimately, either type of alloy achieves a dynamic steady state where corrosion products are being released at the same rate that new ones are being formed at the metal surface. After this point, the amount of retained corrosion products tends to remain constant, providing a constant resistance to further corrosion, and limiting the corrosion rate of the metal to its lowest and constant long-term rate.

Corrosion products are released in two ways by these processes. A small fraction is released directly as a result of the corrosion process. This fraction consists of the soluble portion of the corrosion products that diffuses through the existing layer of corrosion and escapes to the surrounding seawater. Some small particles (diameter less than approximately 0.45 μm, for example) escape at the same time and are considered to be released directly. The results of laboratory seawater corrosion testing showed that not more than five percent of the corrosion products formed from corrosion resistant alloys during the first year were released directly and could be considered to be readily transportable.

The larger fraction is released later on, after residing with the adherent corrosion products for a while, when the old corrosion products are displaced by new ones and the old ones are lost by mechanical processes associated with the development of stresses built up in the corrosion products as they get thicker. These corrosion products are released as large particles or flakes that tend to fall to the surface below. In the ocean, this would typically be to the sediment at the ocean bottom. Eventually, even this material would be slowly dissolved and would diffuse away and be released to water in the environment, but it would take thousands of years.

The external processes whereby corrosion products are released to the environment are illustrated in Figure F-6. Overall, the mass of metal (M) is reduced by its corrosion rate (C) to produce corrosion products that form an adherent scale (S) or film, and subsequently form a local residue (R) of undistributed corrosion products. A fraction (r) of the corrosion products formed is released directly into the environment (E). The scale formed is released gradually (αS) to form the local residue, and the local residue is transported gradually (βR) by various mechanisms into the surrounding environment (E). The corrosion model is discussed further in sections below.

In addition to general corrosion, where the metal surface and its corrosion products are freely exposed to the seawater, there are seven other corrosion processes that are significant:

1. Crevice Corrosion

When two surfaces of the same kind of structural alloy are in close proximity, as in a bolted joint, for example, the narrow gap between them creates a unique corrosion situation. Dissolved oxygen can diffuse to the exposed region outside the crevice, where it reacts to form hydroxyl ions (OH^-). Inside the crevice, iron corrodes and goes into solution as ferrous ions (Fe^{++}). Since diffusion of ferrous ions out of the crevice and hydroxyl ions into the crevice is slow, acidic conditions can be created by hydrolysis according to the equation:

$$Fe^{++} + H_2O \rightarrow H^+ + Fe(OH)^+$$

These conditions are illustrated in Figure F-5. In addition, chloride ions (Cl^-) can migrate into the crevice to balance the charge of the positively charged ions (Fe^{++}, $Fe(OH)^+$ and H^+). Higher chloride concentrations can also contribute to corrosive conditions. This effect was quite evident in the specimens from the ocean corrosion experiment, where the low alloy steel couples exhibited the grooving effect of crevice corrosion around the boundary of the crevice region associated with the strip bolted to the plate. A similar effect was found in specimens of low alloy steel that were bolted to the nylon support; there was a groove around the boundary. The crevice formed between the steel specimen and the essentially-inert nylon. Specimens of corrosion resistant alloys also exhibited crevice corrosion effects, which were typically deeper than those in the low alloy steel couples.

2. Galvanic Corrosion

When two different metals are in contact with each other and immersed in seawater, a galvanic cell is formed. By their nature, one of the metals will be more "noble" than the other one and it will corrode <u>less</u> than it would by itself, possibly not at all. The more "active" metal in the cell will corrode <u>more</u> than it would by itself. This was demonstrated in an ocean corrosion experiment, where plates of A302B low alloy steel were coupled with smaller strips of CRES 304. The average amount of corrosion of the more noble CRES 304 was reduced by a factor of 47 (range: 5 to 1200). The average amount of corrosion of the more active A302B was not increased significantly (range: 0.11 to 1.5) because its surface area was greater by a factor of approximately four. The larger area reduces the electrical current density (amperes per square meter) and reduces the intensity of the corrosion damage to the larger surface. Conversely, if a <u>smaller</u> piece of low alloy steel were coupled to a large piece of corrosion resistant alloy, the low alloy steel would be corroded at a large rate for two reasons:

a. Low alloy steel is more active than corrosion resistant alloys by approximately one-half volt. This is almost as great as the potential difference between zinc and low alloy steels, and zinc is used as a sacrificial anode to protect steels against excessive corrosion.

b. The smaller area would increase the current density and would increase the intensity of the corrosion damage.

Because of this effect, fasteners exposed to a corrosive environment are usually made of a material that is more noble than the materials being fastened.

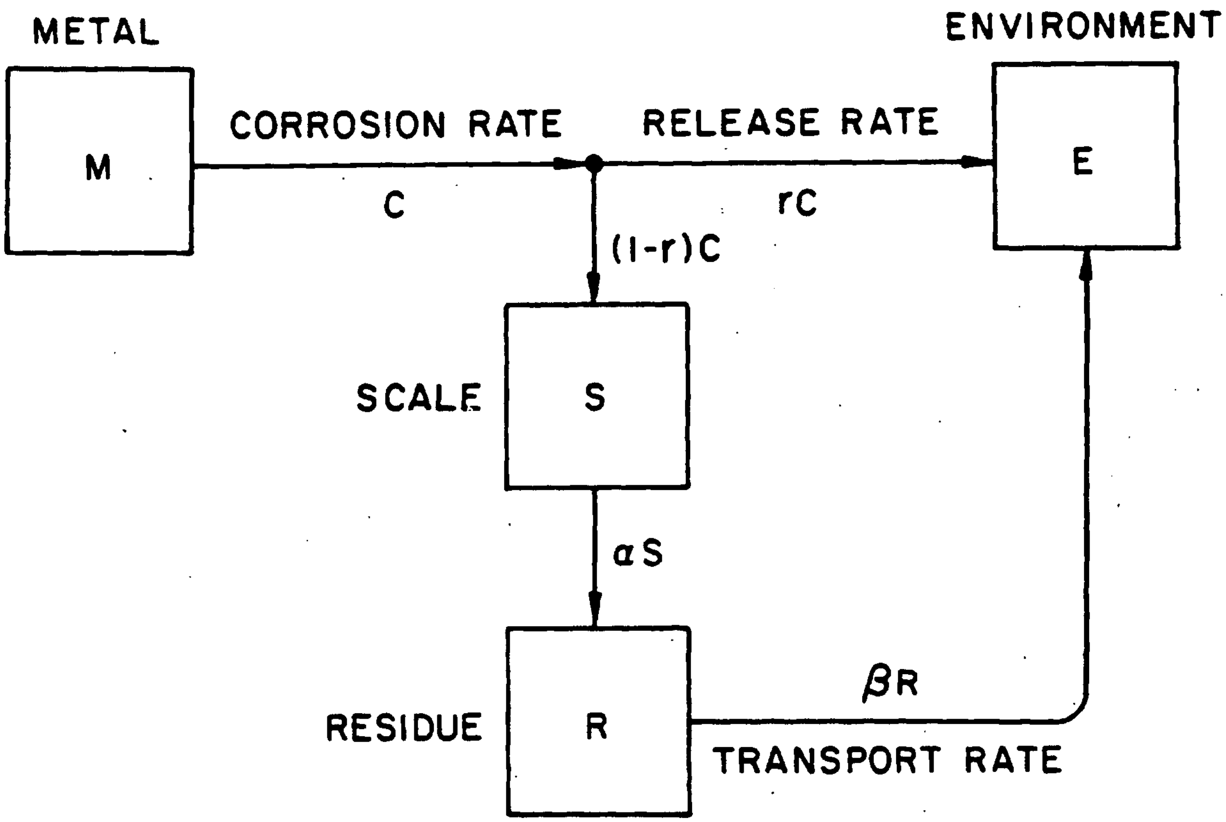

Figure F-6. Corrosion Release Model

Where two materials of the same size and thickness but of galvanically different metals have been welded together and exposed to seawater, the exposed areas of the two metals are essentially the same, but galvanic corrosion would occur. Normally, the more-active metal would be expected to corrode through at an earlier time, but when the more-noble metal is a corrosion resistant alloy, pitting usually occurs and may cause earlier penetration because the pitting corrosion effect is aggressive and localized. The term "pitting" is used here in the broad sense of localized penetration, as discussed below in Section IV.A.3.

If low alloy steel and corrosion resistant alloy were welded and exposed to seawater, galvanic effects would cause the low alloy steel in the vicinity of the bimetallic weld to corrode at an accelerated rate. Correspondingly, the corrosion resistant alloy in the vicinity of the bimetallic weld would corrode at a diminished rate. Away from the weld, the two metals would corrode locally at nearly their normal (non-galvanic) rates, as though they were not connected. This difference in nearby corrosion rates is caused by the different resistance to the flow of the galvanic current at different distances from the weld. The bulk of the current and the bulk of the corresponding corrosion effects are localized near the weld. At remote distances, the galvanic current and the corresponding galvanic effects are reduced, and the normal corrosion phenomena prevail.

For the environmental assessment, it was estimated that the containment represented by such a region would be penetrated earliest by the pitting action of seawater on the corrosion resistant alloy remote from the weld rather than by galvanic corrosion of the low alloy steel near the bimetallic weld. The basis for this is that the pitting rate in the corrosion resistant alloy away from the weld was calculated from corrosion data to be faster than the galvanically-enhanced corrosion rate in the low alloy steel near the weld. The calculations given below indicate that exposure of at least one hundred years would be required for either of these penetrations to occur.

The penetration rates for the low alloy steel that is remote from the weld and for the corrosion resistant alloy that is near the weld would be less than either of the two rates cited above. The low rate for the remote low alloy steel is due to it being relatively distant from the site of the galvanic acceleration, and the low rate for the corrosion resistant alloy near the weld is due to it being galvanically protected.

For the environmental assessment, the depth of pitting in corrosion resistant alloys after the first year was expressed as

$$D = 46\,(2.2 + 0.3\,(t - 1))$$

where D is the depth in mils and t is the time in years. The factor of 46 is the average pitting factor from the literature study (Section III.D.1). A typical value for the maximum pitting factor in corrosion resistant alloys is approximately 200, more than a factor of four larger than the average pitting factor of 46. The other values are the averages based on weight-change data obtained from the literature (Table F-1).

The depth of galvanic corrosion in low alloy steel was expressed as

$$D_1 = 2.4\,(8 + 2.5\,(t - 1))$$

where D_1 is the depth in mils. The factor of 2.4 is the average galvanic corrosion factor for low alloy steel from data in Reference F.8. A typical value for the maximum galvanic corrosion factor for low alloy steel is approximately 10, more than a factor of four larger than the average galvanic corrosion factor of 2.4. The other values are from Table F-1.

Comparing the two equations, the depth of pitting in the corrosion resistant alloy (D) is always greater than the depth of galvanic corrosion in low alloy steel (D_1) by a factor of at least 2.3; pitting would penetrate faster than galvanic corrosion by at least this factor. For example, a one-inch thickness of corrosion resistant alloy would be penetrated by pitting in seawater in approximately 66 years, but an equal thickness of low alloy steel would require approximately 160 years to be penetrated by galvanic corrosion.

To predict that the low alloy steel would be penetrated by galvanic corrosion sooner than pitting would penetrate an equal thickness of an equal area of corrosion resistant alloy, the amount of corrosion in the low alloy steel near the bimetallic weld would have to be predicted to exceed the amount of pitting corrosion in corrosion resistant alloy given by the expression above for the depth (D) as a function of time. Thus, at one year the predicted amount of such corrosion in low alloy steel would have to exceed 101 mils; two years, 115 mils; three years, 129 mils; etc., increasing by almost 14 mils each year. Observed penetrations have not been as large as these values.

These values were obtained from the average values used in the environmental assessment to calculate the best estimates of the effects of such corrosion. For assessments of worst-case conditions, it was assumed that all containment barriers failed instantly at the time of disposal. Since this assumption is more conservative in terms of earlier penetration of containment than any realistic estimates of maximum pitting and galvanic corrosion rates, the actual maximum rates from the literature were not used for environmental assessment.

3. Pitting Corrosion

Corrosion resistant alloys corrode in seawater and in soils and lose weight primarily by concentration-cell corrosion and by under-deposit corrosion. For simplicity in discussion and in estimating penetration rates in corrosion resistant alloys, data from these types of corrosion and simple pitting corrosion were combined under the common term of pitting. Pitting in the combined sense is used to refer to corrosion which is localized in one or more spots over the affected surface. In some cases, the local corrosion will be aggravated by an electrochemical cell caused by a difference in concentration of a reactant in the corrosion process: concentration-cell corrosion. In other cases, a deposit of some material (living or not) on the surface will enable crevice corrosion to occur where the structure itself has no crevice: under-deposit corrosion. In simple pitting, the natural surface of the material is such that it tends to corrode in local spots distributed over the affected surface rather than corrode uniformly. Since all of these represent corrosion situations where the rate of penetration significantly exceeds the average rate based on weight change alone, the common term of pitting is applied to them all even though corrosion specialists distinguish among them.

Although there is some general corrosion, it is typically quite low, for the film of corrosion products is quite adherent and quite resistant to corrosion attack. Pits begin by a failure of the film at a defect in the film. At the pit, the exposed metal surface is more active than the surrounding protected surfaces, so an electrolytic cell is established (similar to the galvanic cell described above) with a smaller area for the active surface. As in the galvanic cell, a small-area active surface is attacked rapidly. In corrosion resistant alloys, the cell potential is approximately one-half volt.

Pitting in seawater is aggravated by the chemical nature of the corrosion products. With the available chloride ions from the seawater, the confining geometry of a pit allows ferrous and ferric chloride to accumulate and aggravate the local corrosion process and cause more rapid penetration. These solutions may become quite acidic (pH of approximately 1.0) and are effective in attacking the corrosion resistant film and causing additional pitting or an elongated pit where the higher-density solution is exuded by the pit onto an adjacent surface where attack continues in the downward direction.

There are two main aspects of pitting that are modeled for computational purposes. Both are simple, conservative estimates of complicated situations. First, the time is estimated when pitting would penetrate the barrier wall; then, the time is estimated when pitting would progress so far that the barrier is no longer significant to retard outward diffusion or hydraulic transport of radioactivity in comparison with other restrictions that are connected with it in series. The latter would occur, for example, when a pipewall would be penetrated by pitting corrosion to such an extent that the total open area due to pitting exceeded the cross-sectional area of the pipe.

In this assessment, the average penetration time is estimated as described below; the maximum case is based on instant penetration rather than maximum pitting rates because pitting is not the maximum means for penetration, compared to mechanical failure, for example. At the time of penetration, consistent with the 20-pit average, the wall thickness (Θ) is equal to the product of the pitting ratio (P) and the amount of corrosion (A) equivalent to the weight loss per unit surface and,

$$\Theta = P \cdot A$$

After the first few years,

$$A = a + bt_l$$

where t_1 is the average time when penetration would occur. From these,

$$t_1 = \frac{(\Theta/P) - a}{b}$$

For example, if

$\Theta = 1.125$ inches

$P = 46$

$a = 0.0019$ inch

$b = 0.0003$ inch/year

then, $t_1 = 75$ years.

After penetration would occur, pitting would continue and the barrier would become more and more penetrated by increasing pitting. If all of the pitting attack were effective in penetrating the wall, although some of it is not, the volume of corroded metal (V) would be equal to the product of the open flow area (F) and the wall thickness (Θ),

$$V = F \cdot \Theta$$

The volume of corroded metal (V) is also equal to the product of the surface area (S) and the amount of corrosion (A) equivalent to the weight loss per unit surface area,

$$V = S \cdot A$$

From these two,

$$\frac{F}{S} = \frac{A}{\Theta} = \frac{a + bt}{\Theta}$$

where t is the time since exposure to seawater began. This indicates that the relative amount of open area (F/S) would increase linearly with time. If the open flow area (F) has a restricted flow area (F') in series with it, the flow rate would be limited by F' even after F became larger than F'. The time when the amount of open area would equal the value (F') would be

$$t_2 = \frac{\Theta(F'/S) - a}{b}$$

For example if

$\Theta = 1.125$ inches

$F' = 5$ square feet

$S = 54$ square feet

$a = 0.0019$ inch

$b = 0.0003$ inch/year

then $t_2 = 340$ years.

Extrapolation to values of (F/S) approaching unity may not provide realistic estimates of the time because of the simplifying assumptions used to construct the model in contrast to the complicated situation that would exist with extremely extensive pitting, but the results are considered to be conservative because the calculated times would be less than the actual times when the actual amount of remaining metal is grossly less than the initial amount.

4. Sediment Corrosion

Although the preliminary ocean corrosion experiments disclosed no significant difference between specimens exposed to water only and specimens exposed to the sediment on the bottom, other experiments reported in the literature indicate that aggravated corrosion can occur in metals exposed to ocean-bottom sediments. In some cases the aggravated-corrosion effect is due to a differential-oxygen cell, where part of the metal is immersed in the sediment and part of it is exposed to the water above. In other cases the aggravated-corrosion effect is related to hydrogen sulfide produced by microorganisms that can thrive in anaerobic conditions and produce hydrogen sulfide by reducing naturally-occurring sulfate ions. If the sediment were aerated by adequate diffusion from the water above or by bioturbation, anaerobic conditions would be precluded and hydrogen sulfide could not be produced. Furthermore, if the oxygen concentration in the pore water was nearly zero and the metal was uniformly exposed to it, corrosion would be retarded by the low oxygen concentration.

A differential-oxygen cell could exist if the oxygen concentration in the pore water of the sediment were different from (typically, less than) that in the water above. Such a difference might occur if oxygen dissolved in the pore water was being consumed by corrosion or biological processes in the sediment. Metal exposed to such different oxygen concentrations would suffer aggravated corrosion in the region of lower oxygen concentration, especially in that part of the region closer to the sediment-water interface; the more remote parts of the region would be somewhat less corroded because they would be exposed to somewhat more uniform conditions. In many respects, this type of corrosion is similar to crevice corrosion, as described above, where the greatest damage is done in the vicinity of the interface between the free-water region and the confines of the crevice region, and much of the damage is attributable to the electrochemical cell created by the two different concentrations of dissolved oxygen acting on the same metal.

This is important to this environmental impact statement in the case of the estimate of how long the external containment (the reactor compartment) could resist penetration by corrosion. Since the containment boundary consists of different thicknesses of low alloy steel exposed to environments with possibly different corrosion rates (water or sediment), the penetration time for each one was estimated to identify the one which would be penetrated soonest. The bulkhead would be expected to be penetrated by seawater corrosion before the hull would be penetrated by aggravated sediment corrosion because the hull is so much thicker than the bulkhead that it could resist aggravated sediment corrosion for a longer time than the bulkhead could resist seawater corrosion.

The most important organisms affecting corrosion in seawater are the sulfate-reducing bacteria. Where anaerobic conditions can exist, such as under thick corrosion products on low alloy steels or in sediments that contain decomposing organic material, the presence of such organisms may be sufficient to support a corrosion rate of 4 mils per year. In "Marine Corrosion" (Reference F.16), LaQue states, "The steel specimens on which a high population of sulfate reducing bacteria were present were found to be corroding at what must be considered to be a normal rate of corrosion of steel in quiet seawater — about 25 mg/(dm^2)(day) or 0.004 in./year." In such a case, the organisms appear to act in lieu of the oxygen to support the cathode reaction and may even consume hydrogen formed at the cathodes to permit the corrosion processes to occur at near-normal rates. These organisms participate in the cathodic reaction by enabling the reduction of normally-occurring sulfate ions to the sulfide form to accommodate the electrons provided by the anodic reaction, where metallic iron becomes ferrous ions.

Sulfide ions (more frequently, H_2S or HS^- ions) are produced by the sulfate-reducing bacteria, and, in the presence of sufficient ferrous ions, iron disulfide forms and precipitates, according to the reaction

$$Fe^{++} + 2H_2S \rightarrow FeS_2 + 4H^+ + 2e^-$$

This reaction produces the characteristic sulfide forms of the various corrosion products that develop in the presence of the sulfate-reducing bacteria.

If the sulfide environment were somehow removed, the precipitated iron disulfide would subsequently dissolve, but the concentration of soluble iron ions would be limited by the precipitation of ferrous hydroxide, and if sufficient oxygen were to become available the ferrous iron would be oxidized and would be precipitated, as described at the beginning of this section. The precipitation of iron (and other corrosion products) as the sulfide or hydroxide or oxide acts to retard the free release of such corrosion products and cause them to remain longer at or near the corrosion site rather than disperse freely in the environment.

5. Soil Corrosion

Corrosion of structural alloys in soil follows the same general principles as in seawater provided there is sufficient moisture present to allow ionization to occur. Test data published in the literature for exposures of 4 to 14 years are summarized in Reference F.7. Low alloy steels exhibit some pitting-type penetration rates of up to 25 mils per year (average: 14 mpy) and weight losses equivalent to as much as 1.1 mils per year. Corrosion resistant alloys are much less affected: pitting-type penetration rates range from "unaffected" in nine years to 4.3 mils per year (average: 1.3 mpy) and a weight loss in one case equivalent to 0.00017 mil per year. These values are approximately equivalent to the corresponding values for seawater exposure, and are tabulated above in Table F-3. On this basis, the values for seawater corrosion, listed in Table F-3, were also applied to assessments of corrosion and corrosion release in the land burial scenarios.

6. Stress Corrosion Cracking

Susceptible alloys that have a surface in tension that is exposed to certain corrosive agents can fail prematurely due to the formation and growth of characteristic cracks. Many corrosion resistant alloys such as stainless steel are susceptible to stress corrosion cracking (SCC) when exposed to seawater, tensile stress, and elevated temperatures. Austenitic stainless steels seldom exhibit SCC in seawater below approximately 50°C, as reported in Reference F.17. Low alloy steels stress-relieved above approximately 1100°F are not susceptible to SCC in seawater. It is expected that SCC would not be a failure mode for the containment boundary because the low alloy steel forming the reactor compartment is not a susceptible alloy.

7. Corrosion Release

To establish characteristic rates for environment assessments, a corrosion model correlating corrosion data with time was used. The amount of corrosion was plotted as a function of time and characteristic growth patterns were observed. Typically, there is a general increase in the amount of corrosion as time progresses, as shown on Figure F-7. During the first few years, the typical corrosion curve is steeper and the corrosion rate is larger than it is later on, due to incomplete development of the corrosion film (or scale) which acts to

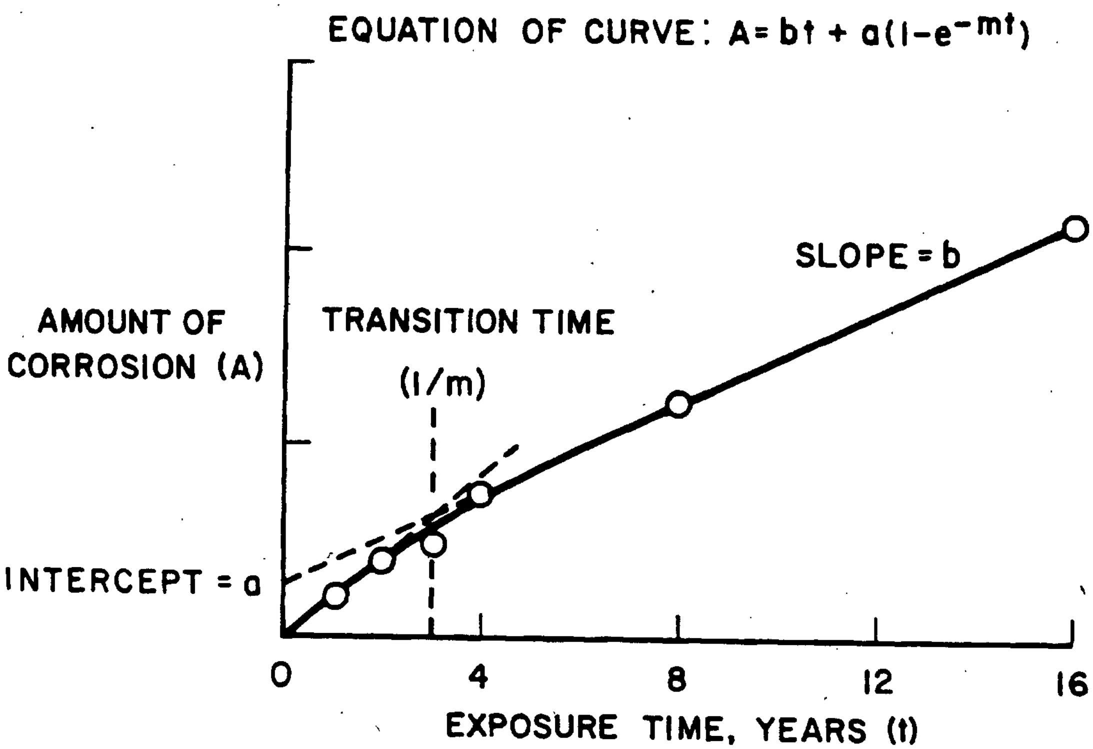

Figure F-7. Typical Time-Corrosion Curve

retard faster corrosion. After the film or scale achieves its steady state thickness, corrosion continues at the minimum rate and the corrosion curve continues upward with a constant slope. After the characteristic slopes were established from the data in the literature, the long-term rate (slope = b) was calculated from the slope. The time at which the two straight lines intersect is the mean lifetime for the development of the long-term slope, and leads to the equation,

$$A = bt + a(1 - e^{-mt})$$

where

A = the amount of corrosion at time, t

b = long-term rate of corrosion

a = intercept for line through the long-term data

m = reciprocal of time at intersection of two lines.

This equation is consistent with the kinetic model which assumes that the corrosion rate decreases with time at a rate that is directly proportional to the difference between the corrosion rate and its long-term constant value.

This model of the corrosion process was applied to the corrosion release model illustrated in Figure F-6 to explore the implications for the total release rate represented by the sum

$$\frac{dE}{dt} = rC + \alpha S$$

where

E = the amount of corrosion products released to the environment

C = corrosion rate

r = fraction of corrosion products released to the environment

S = the amount of corrosion products retained as scale

α = fractional rate at which corrosion products in the scale are released from the scale.

This sum represents the total release to the environment when the delay-effect of the residue is eliminated from consideration by setting βR equal to αS, as though the residue did not exist. This was assumed for simplicity and to conservatively maximize the calculated release rate.

The differential equation for the amount of scale,

$$\frac{dS}{dt} + \alpha S = (1 - r)\, C .$$

where the corrosion rate, $C = b + ame^{-mt}$. Integration provided

$$S = (1 - r)\left[\frac{b}{\alpha}(1 - e^{-\alpha t}) + \frac{am}{m - \alpha}\,(e^{-\alpha t} - e^{-mt})\right]$$

for the case where $\alpha \neq m$ and the initial value of S = 0. From this, the total release rate,

$$\frac{dE}{dt} = r\,(b + ame^{-mt}) + \alpha(1 - r)\left[\frac{b}{\alpha}(1 - e^{-\alpha t}) + \frac{am}{m - \alpha}\,(e^{-\alpha t} - e^{-mt})\right]$$

The data from the laboratory corrosion release testing were used to estimate values for the parameters r and α for corrosion resistant alloys. The results indicated that direct release (r) amounts to approximately 0.2 percent of the amount of corrosion and that the release rate from the scale (α) amounts to approximately one percent per year of the amount of scale present. At steady-state, the total release rate calculated by this equation would be equal to the parameter, b, the long-term corrosion rate. At earlier times, the total release rate would be calculated to be less than b. On this basis, it would be conservative to assume that the release rate is equal to the long-term corrosion rate. This is consistent with the results of the laboratory corrosion release testing described above and in Reference F.15.

The corrosion release model, illustrated in Figure F-6, includes provision for a residue that would exist where the corrosion scale would flake off and deposit particles on the surface below. This would be expected for low alloy steels, which rust more freely than corrosion resistant alloys do, but for the latter the residue would be expected to consist of very small particles of scale and precipitated corrosion products that might be small enough to be carried readily by the stream and might be transported a considerable distance before they would be deposited on the bottom sediment. An estimate of this effect indicated that particles with a diameter of 0.1 micron (typical of particles of fine clay, tobacco smoke, or atmospheric dust) could be transported for a distance of 200 miles in a stream moving at one centimeter per second before gravity would cause them to settle from an initial height of 10 meters. Similarly, particles as large as 10 microns would be transported a distance of approximately one mile. Since these estimates suggest that corrosion products might also be transported for a considerable distance from the corrosion site, the conservative assumption would be that all corrosion products are readily transported by ocean currents even though some of them would not travel such great distances, but would be found within the sediments in the local vicinity of the source.

B. CORROSION-RELATED ASPECTS OF THE OCEAN-BOTTOM ENVIRONMENT

Corrosion theory and experience indicate that the temperature and the oxygen concentration of the seawater are the prime variables that determine the corrosion rate of a particular structural alloy. Values for these two parameters are listed in Table F-4 for the sites where significant data were obtained. In general, the oxygen concentration is a few ppm and the temperature is a few degrees Celsius.

Data from the ocean corrosion experiments indicate that the corrosion of specimens exposed to the sediment on the bottom is approximately the same and typically less than it is for those exposed to water only. This indicates that the surface layer of the bottom sediment is well oxygenated, probably in equilibrium with the oxygenated water at the bottom. Oceanographic data indicate that anoxic conditions are found deeper into the sediment, beginning at approximately one meter or so.

Limited evidence indicates that there is little or no biofouling effect on corrosion in the ocean at depths below 1200-2100 meters. The corrosion and corrosion release rates used in this assessment make no explicit allowance for such effects, but the data from the ocean corrosion experiments and that selected from the literature would naturally reflect any effect of biofouling to the extent that it exists.

TABLE F-4. CHARACTERISTICS OF OCEAN-BOTTOM ENVIRONMENTS

Location	Oxygen Concentration	Temperature	Depth
Pacific Ocean Corrosion Experiment Site No. 1 (MPG-1)	5.3 ppm	1.6°C	5860 m
Pacific Ocean Corrosion Experiment Site No. 2 (W-N)	4.7	1.5	4245
Atlantic Ocean Corrosion Experiment Site No. 1 (Test Stand)	10.0	2.8	3000

NCEL Exposure Site No. V	8.2	12-19	1.5
NRL Test Site (Fort Amador)	6.2	16-32	4.3

Accelerated corrosion may occur with biofouling, and this has been allowed for in the assessment. A dead-water pocket may exist between certain organisms and the metallic surface, and the local metal surface may become anodic and corrode if anaerobic bacteria are prevalent because they may lower the pH of the water and cause pitting corrosion. Since the data from the literature and from the supplemental ocean corrosion testing include the effects of natural conditions such as biofouling, and since pitting corrosion rates are uniformly applied to the corrosion resistant alloys, which tend to pit, no further allowance needed to be made for the effects of biofouling on either low alloy steels or on corrosion resistant alloys. In addition, the data from the literature were interpreted conservatively in selecting maximum values and conservative average values for the corrosion rates of low alloy steels and corrosion resistant alloys, as listed in Table F-1.

On the basis of all of the available information, the corrosion and corrosion release rates used in these assessments are considered to be suitable for estimating the times when containment barriers would be penetrated and the rates at which radioactive material would be released to the environment.

APPENDIX G

ESTIMATED RADIOACTIVE RELEASES FOLLOWING DISPOSAL AT SEA

I. INTRODUCTION

This appendix describes the methods used to estimate the rates at which radioactive material might be released from defueled and decommissioned nuclear submarines should the ocean disposal alternative be selected.

During the operation of a nuclear submarine, radioactive nuclides are created within the metal matrix of components exposed to neutrons from the reactor core. These components include the structural supports for the core (inside the reactor pressure vessel), the reactor pressure vessel and, to a much smaller extent, the metal structures outside the reactor pressure vessel (see Figure G-1). If a decommissioned submarine were placed on the ocean floor, the radionuclides would become available for release to the environment only as the metal components corrode and their containment is penetrated.

Two conditions of containment are evaluated in this appendix. The first case considers three levels of containment which are the metal matrix, the reactor vessel, and the reactor compartment. In this case the radioactive corrosion products in the reactor vessel could not be released to the environment until both the reactor vessel containment and the reactor compartment were penetrated by corrosion. This condition corresponds to the expected condition of the submarines after emplacement and is referred to as expected containment. The second case examines the release rates where the metal matrix represents the only containment. In this case all metal surfaces are assumed to be exposed directly to the ocean waters immediately upon disposal and the radioactive corrosion products are available for transport by the ocean as the corrosion occurs. This case is called minimum containment and conservatively models the results of accidents in transit to the disposal site or a mishap during disposal at the disposal location.

In the expected containment condition two sets of assumptions were considered. The first set of assumptions is the "best estimate" and was established to provide a conservative yet reasonably realistic release rate to the environment. The second set of assumptions is very conservative and was designed to provide a significant overestimate of the release rate to the environment. The very conservative release rates are used to evaluate the effects on the environment with release rates significantly larger than realistically expected.

The corrosion rates used in estimating the release rates are taken from Appendix F and the initial inventories of radioactive nuclides are those given in Table 1-1 (Chapter 1). The calculations assumed that the submarines would be placed on the ocean bottom six months after their final reactor operations, which is a shorter time than expected to be required for completion of shipyard preparations. The shorter time tends to maximize the release since it minimizes radioactive decay before disposal.

The release rates calculated by the equations described in this appendix are used as the source of radioactivity in the transport calculations (Appendix H) that examine physical ocean transport and biological transport.

Section II below describes the approach used to evaluate the release rates, Section III summarizes the results of the evaluation, and Section IV provides the equations used to perform the calculations.

II. DESCRIPTION OF THE RELEASE MECHANISMS

A. EXPECTED CONTAINMENT

1. General

Tests have demonstrated (Appendix D) that decommissioned nuclear submarines would remain intact when emplaced on the deep ocean bottom. With the submarine intact, three levels of containment would exist for most of the radioactive material. The containment barriers are the metal matrix, the reactor pressure vessel and associated piping, and the reactor compartment (shown schematically in Figure G-1). The effectiveness of each barrier is illustrated by examining where the radioactive material is located relative to the barriers. A summary of the distribution of the radioactive material (six months after final reactor shutdown) is given in Table G-1. From this table it can be seen that approximately 97.8 percent of the total activity would be located within the structural components inside the reactor pressure vessel and another 0.1 percent would be inside the reactor vessel and plant piping in the form of an adherent corrosion product film containing some radioactive particles called "crud*." Another 1.8 percent of the radioactivity would be in the metal structure of the very thick reactor pressure vessel wall. Essentially 0.3 percent of the activity is part of the metal which makes up the structural components outside the pressure vessel but inside the reactor compartment volume defined by the compartment bulkheads and hull. A minute fraction of the radioactive inventory (0.00006 percent) is contained within the metals of the compartment bulkheads and hull. This radioactive material is treated as being uniformly distributed in the metals of the submarine hull and reactor compartment bulkheads and is assumed to be released to the environment as these metals corrode. Hence, the initial release of an extremely small amount of radioactivity to the environment is calculated to begin when the corrosion of the hull begins.

TABLE G-1. DISTRIBUTION OF RADIOACTIVE MATERIAL SIX MONTHS AFTER LAST REACTOR OPERATIONS

	Percent of Total Curies
Structural Components (corrosion resistant alloys) inside the reactor vessel.	97.8
Crud—corrosion products from reactor operation. Present as a film on surfaces inside reactor vessel and piping of the plant.	0.1
Reactor Pressure Vessel Wall	1.8
Structural Components outside the reactor vessel and inside the reactor compartment.	0.3
Compartment Bulkheads and Hull	0.00006

The basic factors that affect the release rates of radioactive material from the containment are the corrosion rates, the radioactive decay, and the corrosion product transport and settling. The discussion below describes how each of these factors is handled for the "best estimate" and the "conservative estimate" (unrealistically high) conditions.

2. Expected Containment—Best Estimate

a. Corrosion Rates

The corrosion rates are the average rates taken from Table F-1 of Appendix F. The corrosion rates are highest in the first year and thereafter they are constant with time. The appropriate corrosion rates are applied to individual components and each component is assigned its thickness. Corrosion is assumed to continue on each individual component until that component is completely consumed.

*Crud is used here to denote the corrosion product film on the internal reactor vessel and piping surfaces left from reactor operations and the activation products trapped within this film. The adherent corrosion film is indistinguishable from any other corrosion on these materials and behaves in the same manner.

SCHEMATIC OF NUCLEAR PROPULSION PLANT

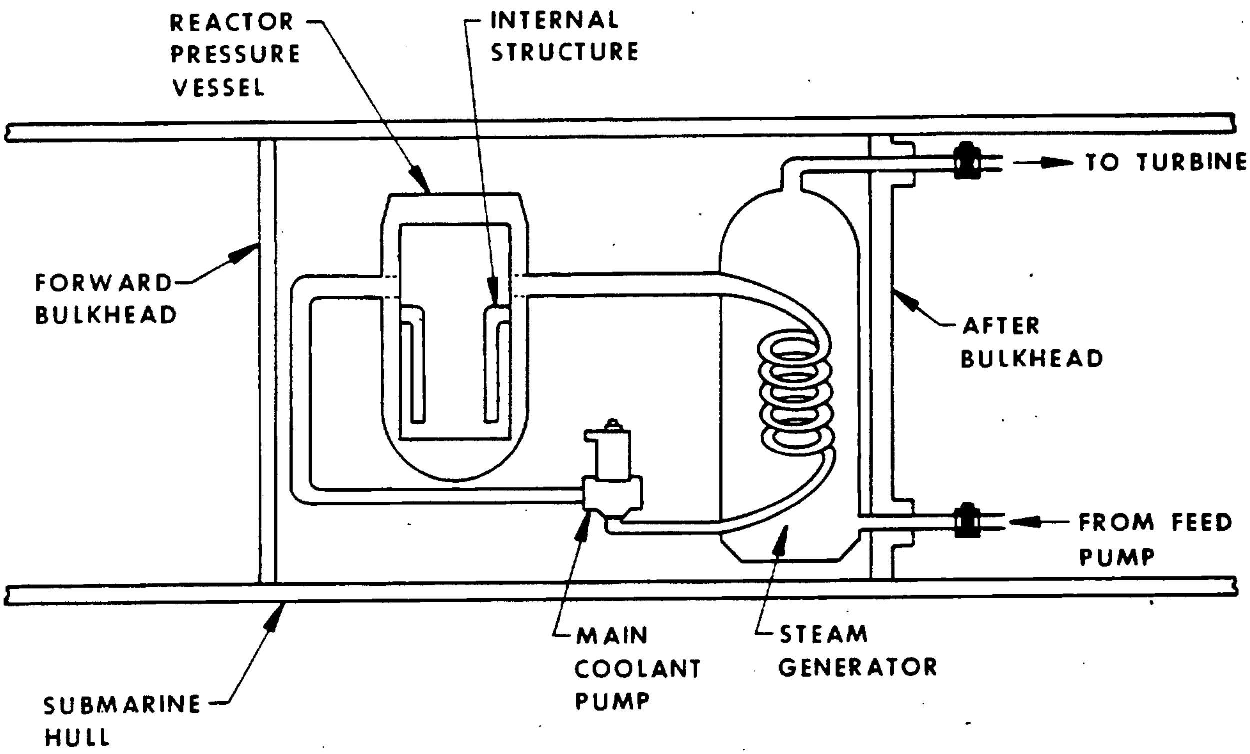

Figure G-1. Submarine Reactor Compartment

The corrosion rates of individual components are also used to establish the times when penetration of the containment barriers could occur. Examples of the individual components that are analyzed in this manner are the reactor compartment bulkheads, the reactor vessel, reactor plant piping, and the various core support structures in the reactor vessel (see Figure G-1).

The low alloy components are assumed to corrode uniformly over their surface. However, the components made of corrosion resistant alloys, such as stainless steel, corrode at localized points in a manner that causes pitting. Therefore, a pitting acceleration factor was applied to the corrosion rates of these alloys to account for localized holes through those components. These holes are then assumed to be a pathway through which radioactive corrosion products might move well before general surface corrosion would penetrate the containment.

Based on the corrosion rates of individual components, it was determined that on the average the inlet and outlet piping to the reactor vessel would pit through in approximately 75 years and the reactor compartment bulkhead would be penetrated in approximately 100 years. General surface penetration of the reactor vessel would not occur until approximately 1300 years; however, it was assumed that a flow through the reactor vessel would be established approximately 400 years after disposal, as discussed in Section II.A.2.b below.

b. **Transport and Settling of Corrosion Products**

As the metal corrodes, some of the corrosion products will be soluble, some will be very small particles that are easily transportable, some will be large particles that will settle to the bottom of the reactor vessel or reactor compartment, and some material will form a solid oxide film attached to the metal. However in the release rate calculations, it was assumed that all corrosion products were released from the metal in a soluble form or as very small particles that are transportable. Based on the expected corrosion particle size distribution, the settling time half-life is 40 days. This settling is assumed to continue until a flow is established in the reactor vessel by the effects of the ocean current passing through openings corroded in the reactor piping. At that time, resuspension in the reactor vessel would become dominant and settling is assumed to be discontinued. In the release calculations outside the reactor vessel, all corrosion products are considered to be transportable and no credit is taken for settling.

In approximately the year 100 the reactor compartment bulkheads could be penetrated, and it is assumed that all transportable material in the reactor compartment would be released to the environment during the first year following penetration. In the following years all transportable corrosion products in the reactor compartment are considered to be released to the environment as they become available.

Between the time pitting holes first occur in the piping leading to the reactor vessel (year 75) and the time a current is established through the reactor vessel (about 400 years), the transport of material out of the reactor vessel into the reactor compartment is accounted for by a diffusion-type process. Because of the small size of the pitting penetrations and the large size of the vessel, a current through the vessel is not possible through the pits. In fact, a substantial current through the reactor vessel would not be expected until general surface penetration of the reactor vessel occurs about 1300 years following disposal. However, to be conservative, a substantial current through the reactor vessel was assumed to begin in approximately 400 years. When the current is initiated through the reactor vessel, all transportable material in the reactor vessel is assumed to be released to the environment. In the following years, the newly-formed transportable material in the reactor vessel is assumed to be released to the environment as it becomes available.

c. Decay

As discussed in Section II.A.2.a, the corrosion process is evaluated for individual components. Hence by knowing the concentration of the radionuclide in individual components, it is possible to calculate the release rate for each isotope. This tracking of isotopes makes it possible to accurately account for radioactive decay prior to release. The decay constants used in the calculation correspond to the half-lives presented in Chapter 1 (Table 1-1).

3. Expected Containment—Conservative Estimate

The release rates calculated with this scenario were used for the conservative dose estimates (unrealistically high). In this treatment the corrosion and decay are identical to that used in the best estimate of the expected containment. However the transport and settling of the corrosion products are significantly different. The treatment of these factors is discussed below.

As with the best estimate calculation, the conservative release rates assumed that all corrosion products would be released from the metal in a transportable form. However, in the very conservative approach, the settling time for the corrosion products was increased by a factor of approximately 30 which has the effect of significantly increasing the concentration of radioactive material suspended in the reactor vessel. Then the leakage coefficient between the reactor vessel and the reactor compartment (between years 75 and 100) was increased by a factor of 45. Both of these changes have the effect of significantly increasing the concentration of radioactive material in the reactor compartment at the time the reactor compartment is penetrated (approximately year 100).

At the time the reactor compartment would be penetrated (approximately year 100), a flow was assumed to occur through the reactor compartment and the reactor vessel. This flow rate has the effect of sweeping out the suspended radioactive material. The assumption of a flow rate through the reactor vessel in approximately the 100th year is particularly conservative since at that time the only penetration into the reactor vessel volume is the small pitting holes in the corrosion resistant alloy piping.

The effect of these very conservative assumptions is to maximize the amount of radioactive material suspended in the reactor compartment and the reactor vessel at the time the reactor compartment is penetrated. This amount of radioactive material is then released to the environment over a short period of time immediately after the bulkhead penetration has occurred. Since the dose to man is based on the maximum ocean water concentration (see Appendix H), this treatment maximizes the calculated dose.

B. MINIMUM CONTAINMENT—BEST ESTIMATE AND CONSERVATIVE ESTIMATE

The minimum containment condition assumes that the surfaces of all radioactive components will be exposed directly to the free ocean water as soon as the submarine reaches the ocean floor. In this case, the metal matrix would provide the only containment and the radioactive corrosion products would be available to the environment as the corrosion occurs. Because the containment provided by the reactor vessel and reactor compartment are not considered, transport and settling within the submarine are not considered and all corrosion products are released directly to the environment.

The basic factors in evaluating the radioactive material release rates are the corrosion rates and radioactive decay. In the minimum containment case, the only difference between the best estimate and the conservative estimate is the corrosion rates. The best estimate-minimum containment calculations used the highest average corrosion rates presented in Appendix F, Table F-1. The conservative estimate-minimum containment calculations used the maximum values presented in Appendix F, Table F-1. The corrosion rates are applied to individual components and each component is assigned its individual thickness. Corrosion of each component is assumed to continue until it would be completely consumed. By knowing the radionuclide content of each component, it is possible to calculate the independent release rate for each isotope. This tracking process also allows the radioactive nuclide concentration to be adjusted for radioactive decay.

All radioactivity is assumed to be released in a transportable form directly to the environment. The crud is assumed to be uniformly released to the environment during the first year after disposal and corrosion products are assumed to be released to the environment as the corrosion occurs. The transport and settling characteristics of the corrosion products once in the ocean waters are discussed in Appendix H.

III. SUMMARY OF RESULTS

A. EXPECTED CONTAINMENT

1. Best Estimate

The best estimate of the release rates to the environment are summarized in Figure G-2 for the disposal of 100 submarines with expected containment. It is assumed that the 100 submarines would be disposed of at a rate of three per year. Most of the radioactivity released is Nickel-63 and Nickel-59 because the other nuclides originally present in larger quantities would have decayed to small quantities before the containment would be penetrated. An appreciation for the relative release rates of the 16 radioactive nuclides is found in Table G-2 which lists by nuclide the maximum annual release to the environment from all 100 submarines. For information, the year of the maximum release of each nuclide is identified. From this table it is seen that with the exception of Nickel-63 and Nickel-59, the maximum annual release rates of all other nuclides combined is less than 0.1 curie per year.

It is informative to compare the release to the environment shown in Figure G-2 to the ocean disposal release of 10^7 curies/year for mixed beta and gamma emitters permitted by the IAEA (INFCIRC/205/Add.1/Rev. 1, August 1978). The maximum annual release from the disposal of 100 submarines would be only 0.0004 percent of the release permitted by the IAEA. It should be pointed out that the IAEA assumed in the analysis supporting the development of the limit that all material dumped is immediately released to the ocean, and that the dumping would continue at that rate for approximately 40,000 years. Even if one assumed that all of the radioactivity in the submarine were released immediately upon disposal, the disposal of three submarines per year would still be less than 2 percent of that rate permitted by the IAEA. These comparisons are not used in evaluating the environmental impact on the dose to man; however, they do provide a perspective on the magnitude of the releases.

For information, the release rates as a function of time are displayed for Nickel-63, Nickel-59, Carbon-14, Iron-55, Cobalt-60, and Niobium-94 in Tables G-3 through G-8.

2. Conservative Estimate (Unrealistically High)

The release rates to the environment obtained using the conservative assumptions are summarized in Figure G-3 for the disposal of 100 submarines. It is assumed that the 100 submarines would be disposed of at a rate of three per year. Most of the radioactivity released is Nickel-63 and Nickel-59 because the other nuclides originally present in large quantities would have decayed to small quantities before the containment would be penetrated. The relative release rates of the various nuclides are found in Table G-9 that presents the maximum annual release for each nuclide.

Comparing the maximum annual release rates from Table G-9 to the IAEA limits shows that even with the unrealistically high estimate of the release, it is only 0.008 percent of the release rate allowed by the IAEA.

For information, the annual release rates as a function of time are displayed for Nickel-63, Nickel-59, Carbon-14, Iron-55, Cobalt-60, and Niobium-94 in Tables G-10 through G-15.

B. MINIMUM CONTAINMENT

1. Best Estimate

The best estimate release rates for the case of minimum containment are summarized in Figure G-4 for the one submarine accident condition. As seen in the figure, the highest release rate occurs in the first year. Most of the activity release in that year is due to Iron-55 and Cobalt-60. This can be seen in Table G-16 which displays the maximum annual release rate for each nuclide. The maximum annual release rate in the minimum containment case occurs in the first year primarily because all of the "crud" is assumed to be released to the environment during that year. This treatment is very conservative since it releases short-lived radioactive material directly and quickly to the environment. The extent of the conservatism can be seen by examining the monitoring data obtained in the vicinity of the THRESHER and the SCORPION which were lost at sea. Surveys conducted in the vicinity of these submarines (Annex to Appendix D) have shown no significant release of activity.

Comparing this maximum release rate to the IAEA limit shows that even the maximum accident would result in a release rate that is only 0.001 percent of the general limit established by the IAEA. For information, the release rates over time are displayed for Iron-55, Cobalt-60, Nickel-63, Cobalt-58, Manganese-54, and Zirconium-95 in Tables G-17 through G-22.

2. Conservative Estimate (Unrealistically High)

The release rates for the one submarine accident with minimum containment and conservative corrosion rates are summarized in Figure G-5 and Table G-23, which lists the maximum annual release for each nuclide. The behavior of these releases is essentially the same as the minimum containment best estimate presented above. The increased magnitude in the conservative case comes from the higher corrosion rates used, leading to higher releases by corrosion. Once again, the "crud" release of the first year dominates the early times after disposal. The nuclide specific release functions are provided for the individual nuclides Iron-55, Cobalt-60, Nickel-63, Cobalt-58, Manganese-54, and Zirconium-95 in Tables G-24 through G-29.

TABLE A-2. ESTIMATED COSTS FOR SEA DISPOSAL ALTERNATIVES

Condition	Configuration (2)	Disposal Costs (1) Capital	Recurring	Unit Disposal (3)
Flooded Free Fall (4)	A	$0.7 M	$1.0 M	$1.1 M
Buoyancy-Assisted Lowering	A	30.9	1.7	4.8
Glomar Explorer	B	3.0	4.2	4.5
	3C	3.0	4.7	5.0
	A	37.5	2.5	6.3
Launch Barge	C	4.2	5.1	5.5
Buoyancy-Assisted Lowering	2B	30.9	3.4	6.5
	C	19.0	4.3	6.2
	3C	30.9	4.3	7.4
Buoyant Transporter	C	35.6	4.4	8.0
	B	119.2	3.5	15.4
	A	203.1	1.8	22.1

NOTES: (1) Disposal costs include only those costs associated with the pre-disposal preparations; the relatively constant costs of inactivation and reactor compartment work are excluded.

(2) A = Entire submarine
B = Reactor compartment attached to the spaces aft
C = Reactor compartment only
2B or 3C = Multiple units transported to site

(3) Unit disposal costs are based on ten disposals at approximately three disposals per year.
Unit Disposal Cost = (Capital Cost)/10 + (Recurring Cost)
Costs expressed in millions of dollars.

(4) Controlled sinking by modification of ship's control surfaces.

The Glomar Explorer would be the lowest-cost method of very accurate placement without large development costs and associated risk. It would be applicable to either the reactor compartment alone (up to three in one trip) or attached to the spaces aft. There are three considerations of major concern for this application:

a. To be cost effective, the Glomar Explorer must be time-shared with other projects. Recent estimates of operating cost ($44,500 per day) are based on full utilization of the ship. If the ship were to be used only 15 percent of the time, as it would be for disposal alone, the cost per day would be much greater to account for the loss of revenue during the idle time.

b. Modifications to the Glomar Explorer must be compatible with the needs of other users. The Glomar Explorer may be used in the Ocean Margin Drilling Program when the Glomar Challenger is retired. If this plan were implemented, the heavy lift system might be removed and the well made smaller. Either of these actions would render Glomar Explorer unusable for the disposal actions considered here.

c. The Glomar Explorer is essentially a one-ocean vessel for repetitive tasks. Its beam is 115 feet 8 inches and the locks in the Panama Canal are only 110 feet in width. Additional cost would be involved to travel around Cape Horn.

Overall evaluation of the alternatives within the sea disposal option considered technical feasibility, operational feasibility, and estimated cost with equal emphasis. Recommendations for further consideration or conclusions against further consideration were based on these factors. Environmental effects would be involved in two ways:

a. The accuracy of placement would affect the amount of area required for disposal of multiple numbers of reactor compartments, as discussed above.

b. The type of placement may affect the integrity of the containment if an excessively fast descent were to occur onto a rocky bottom, but this would not be expected to occur. Evaluation of expected landing conditions has shown that the reactor compartment would be intact after landing at the expected velocity on a bottom having the expected condition because the design is compatible with predicted impacts. Three methods have been identified that could be developed to reduce the impact loads further, if this were necessary:

(1) A deformable structure could be attached to the unit to absorb on impact part of the energy of the falling unit.

(2) Appendages could be attached to the unit to increase the drag forces and limit the terminal velocity to a smaller value.

(3) Buoyancy could be added to the unit to offset part of the gravitational force.

These methods would require further development to mitigate the landing impact associated with a free-fall disposal, but none of these methods is considered to be necessary for intact emplacement on the sea floor.

D. COSTS OF DISPOSAL

The costs of disposal consist of three main categories:

1. Radiation doses that would be received by the general population and by the shipyard workers.

2. Economic costs that would be required to accomplish the disposals.

3. Other environmental impacts that would be anticipated to occur.

As discussed in Appendices C and J, the estimated radiation doses that would be received by the general population and the hypothetical maximum exposed individual would be quite small compared to natural background radiation. For comparable situations between land and sea disposal, such as normal disposals or credible accidents, the numerical results for estimated doses differ by small amounts since the estimated doses are small, even though their ratios may be quite large in some instances. Large ratios are considered to be due mostly to the uncertainties involved in the calculations rather than real differences in expected doses. Since the calculated differences are so small, the indicated differences are not considered to be significant; rather, the real difference is overwhelmed by the magnitudes of the uncertainties in the calculations. Under these conditions, the estimated doses are not considered to be an efficient basis for choosing between the land and sea methods of disposal. The estimated doses indicate that either of the options is safe and environmentally acceptable regarding its radiological consequences.

In contrast, the estimated economic costs have been found to be quite large, ranging from $5.2 million to $16.2 million per ship for the six cases given detailed evaluation. These estimates are considered to be reliable within ±15 percent of the estimated cost. Since the costs were all estimated on a consistent basis and the totals were arrived at by summing estimated costs for each main element of cost, differences of much less than 15 percent of the estimated total cost are considered to be realistic. On this basis, the estimated costs are considered to be an efficient basis for comparing the desirability of disposal methods.

1. Radiation Doses

The small radiation doses that would be committed by these disposals would be justified by the lack of a suitable alternative that would involve no dose commitment at all. There does not appear to be a practical alternative that would commit a smaller dose, even at much greater economic cost, as discussed below.

The estimated radiation doses that would be received by the shipyard workers during disposal activities are essentially independent of the disposal method because their work is essentially the same for each of the practical alternatives. The estimated values for these doses are listed in Table A-3. These values are based on measurements made during deactivation of the nuclear submarine HALIBUT in 1976. The doses would be incurred during the deactivation of reactor plant systems and preparations that would be required for disposal or storage in a safe and environmentally acceptable manner. Shipyard experience in doing work on radioactive reactor plant systems has evolved methods and procedures that would be applied to minimize the actual doses.

Similarly, the radiation doses that would be eventually received by the general population would differ slightly between land and sea disposal, but would be essentially independent of the alternatives within these options because the sources and release rates would be essentially the same for each of the alternatives within the land and sea disposal options. Details are provided in Appendices C and J.

If disposal were to be deferred and the ship and reactor compartment were to be stored instead of being disposed of promptly, the radiation doses that would be received by the shipyard workers would be essentially the same. Although much of the short-lived radioactivity would decay while the ship was in storage, and final preparations for disposal would be performed in much lower radiation fields than would prevail during prompt disposal, the amount of reduction of the workers' doses would be a small fraction of the total because the bulk of the exposure would occur during the initial deactivation of the systems: 17 man-rem in a total of 20 man-rem, as shown in Table A-3. In addition, there would be some unavoidable duplication of effort and radiological surveys would be required during storage. As a result, the total worker dose for deferred disposal would be approximately 20 man-rem per ship.

Population dose commitments are estimated for the maximum year to be not more than 2.1 man-rem per year for land disposal and not more than 6 man-rem per year for sea disposal, for a total of 100 ships. Estimates of the actual doses as well as conservative estimates of maximum population doses are given in Chapter 4 and are detailed in Appendices C and J. Since these estimates were obtained by conservative procedures, the actual doses would be expected to be considerably smaller than these conservative estimates indicate. This has two effects:

a. The actual doses and their difference for land and sea disposal are expected to be quite small in comparison with unacceptable doses since they would be a small fraction of the dose from natural background.

b. The actual doses and their difference would be expected to be quite small in comparison with the ranges of uncertainty in the estimates.

TABLE A-3. ESTIMATED WORKER DOSES FOR SELECTED DISPOSAL OPTIONS

Activity(1)	Estimated Dose(2)
Installation of temporary shielding	3 man-rem per ship
Installation and removal of radiological containments	1
Radiological control personnel	1.5
Engineering personnel	1
Nuclear inspection personnel	1
Other operations	9.5
WORKER DOSE, Active Disposal(3)	17 man-rem per ship
Radiological surveys(4)	2
Preparations for disposal(5)	1
WORKER DOSE, Inactive Disposal(6)	20 man-rem per ship

NOTES:
(1) Certain activities have been excluded from the disposal category, such as: establishing the proper plant conditions for defueling; and the defueling activities up to and including welding the closure penetrations; they are included in the defueling category.
(2) Based on measured values obtained from deactivation of HALIBUT in 1976.
(3) For disposal of ships decommissioned from active service without interim storage.
(4) Based on 20 years of interim storage.
(5) Based on 20 years of decay during interim storage.
(6) For disposal of ships after 20 years of interim storage.

The results of these two effects are that the doses can be judged to be safe and environmentally acceptable, but their difference cannot be used efficiently to choose between land and sea disposal.

In addition, since the estimated population dose is exceeded by the estimated worker dose, it is not considered to be beneficial to incur more worker dose to further mitigate the population dose unless some relatively greater benefit could be obtained for some very small increase in worker dose. The current plan for each alternative appears to provide as much benefit, in terms of providing long-term containment, as can be obtained with reasonable accrual of worker doses: to ensure that the reactor vessel is securely closed and sealed using minimum worker exposure, and to ensure that the reactor compartment is securely closed and sealed using minimum worker exposure. The worker exposures are considered to be as low as is reasonably achievable consistent with providing this level of containment for the protection of the public because the shipyard work practices are based on their experience in minimizing worker doses associated with normal maintenance and repair of nuclear submarines prior to disposal.

2. Economic Costs

The estimated costs for selected disposal options are listed in Table A-4. Six disposal options are summarized in this table: sea, land with sea disposal of the rest of the ship, and land with the rest of the ship disposed of as scrap, for active ships and inactive ships. The lowest estimated cost is for sea disposal of active ships, and the highest estimated cost is for land/scrap disposal of inactive ships. These six options are the ones

TABLE A-4. ESTIMATED COSTS FOR SELECTED DISPOSAL OPTIONS

Activity	Estimated Total Costs(1) Sea(2) Active(10)	Sea(2) Inactive(10)	Land/Sea(3) Active(10)	Land/Sea(3) Inactive(10)	Land/Scrap(4) Active(10)	Land/Scrap(4) Inactive(10)
Inactivation(5)(6)	$2.2 M	$4.0 M	$2.6 M	$ 4.0 M	$ 2.1 M	$ 4.0 M
Storage(7)	0	1.8	0	1.8	0	1.8
Preparation(6)	2.8	2.4	3.7	3.5	10.4	9.6
Operations(8)	0.1	0.1	0.9	0.9	0.8	0.8
Monitoring(9)	0.1	0.1	0	0	0	0
TOTAL COST	$5.2 M	$8.4 M	$7.2 M	$10.2 M	$13.3 M	$16.2 M

NOTES: (1) Millions of dollars per ship, 1981 dollars.
(2) Reactor compartment and ship's hull together would be sunk at sea.
(3) Reactor compartment would be buried on land and ship's hull would be sunk at sea.
(4) Reactor compartment would be buried on land and ship's hull would be cut up for scrap.
(5) Excludes defueling ($3.9 M) and removal of missile compartment if applicable ($0.4 M).
(6) Inactivation and preparation for disposal differ and include the following items that tend to make land disposal more costly than sea disposal: removal of reactor compartment and its transport to the burial site, and rejoining the hull for sea disposal or demilitarizing it and cutting it up for scrap.
(7) Includes estimated costs of materials and services required for minimal maintenance and periodic radiological surveys for 20 years. Possible additional costs for construction of additional storage facilities have not been included.
(8) Includes, as appropriate, $0.8 million per ship for land disposal of the reactor compartment (including amortization of capitalized costs for jacks and rollers and certain barge equipment) and $0.1 million per ship for towing the ship to sea for disposal. The recurring operational costs for land disposal include: barge, tugboat and transporter usage, jacking operations, overland transport, prorated burial pit preparation, engineering, and minor equipment rental.
(9) Includes estimated costs for qualifying a sea disposal site and for monitoring it. If two sea disposal sites would be used, the estimated cost would be nearly $0.3 million per ship. Refer to Appendix K.
(10) Active refers to a ship that would be disposed of following completion of active service without protective storage. Inactive refers to a ship that would be disposed of after inactivation and protective storage.

---

selected for detailed considerations; others not listed that were considered here have higher unit costs for the disposal operations, as shown in Table A-2. The main differences among these costs are in the shipyard activities required for preparation of disposal, as detailed in Note (6) of Table A-4.

In each option, the major costs would be for inactivation and preparations, and the costs of the actual disposal operations would be the smaller part. Disposal of active ships without storage would be less costly by approximately $3.0 million per ship because of the costs associated with preparation for storage, storage, and removal from storage. Land disposal of both the reactor compartment and the hull would be the most expensive option because of the large costs associated with demilitarization, removing major equipment from the hull, and cutting the hull for scrap. Preliminary estimates indicated that the scrap value of the hull material would be essentially offset by the cost to "demilitarize" the material and protect strategic information.

Land disposal at the Savannah River Plant would require construction of a barge slip to off-load the reactor compartment from the transport barge to the crawler-transporter for the overland trip to the burial site. The existing barge slip at the Port of Benton, near the Hanford Site, would be adequate for off-loading the reactor compartment. The proposed barge slip at Savannah River would cost approximately $1.3 million. This would include pre-construction surveys and environmental assessments, materials and labor for construction, and overhead and administrative costs.

The costs associated with preparation for and removal from a naval inactive ship maintenance facility are based on the minimum work required to store the ship and reactor plant in such a way that it would be safe and environmentally acceptable. Utilities and necessary maintenance services are included, but there is no allowance for periodic docking for hull inspection and repair. The future availability of sites for mooring inactive ships has not been addressed.

The differences among these costs and their principal elements of cost are illustrated in Figure A-2. The main differences are apparent in the costs of non-nuclear preparation for disposal; these are the costs associated with effort applied outside the reactor compartment.

The main elements of the costs of disposal are illustrated in a logic-flow diagram in Figure A-3. This figure shows what the costs are which are associated with the various components of the disposal process. At each decision point, the associated costs are separately identified in the boxes.

The preliminary steps which are common to all of these disposal options are defueling, decommissioning, and missile compartment removal (if applicable).

Before shipyard work can start to inactivate the ship and prepare it for disposal, three decisions would need to be made:

1. **Whether to store or not store the ship before disposal.** In Figure A-3, the minimum costs associated with these alternatives are shown as $4.9 million (active disposal) and $8.2 million (storage for inactive disposal) per ship, as a part of subsequent preparations for disposal.

2. **Whether to dispose of the ship by land or by sea.** The decision for sea disposal or for land disposal determines whether the reactor compartment would be left in the ship for sea disposal or would be removed ($0.4 million per ship) for land disposal.

3. **Whether the rest of the ship would be welded together and prepared for sea disposal or cut apart for scrap.** These additional costs to inactivate and prepare for disposal would differ slightly between active and inactive disposals but are mainly dependent upon the chosen disposal option.

Disposal operations are shown in Figure A-3 for moving either the ship or the separated hull and reactor compartment from the shipyard to the disposal site. A credit is shown for the scrap value of the hull in the land/scrap option. The total estimated costs are shown at the bottom of the tabulation.

In addition to the direct costs of disposal, i.e., processing the ship and disposing of its parts, an indirect cost is associated with qualifying the disposal site and monitoring the radioactivity in the environment in the vicinity of the disposal sites to provide assurance that unacceptable amounts of radioactivity have not accumulated. Details on monitoring are provided in Appendix K. In Figure A-3, these costs are included in the costs of preparation.

The estimated cost of monitoring a sea disposal site would include the initial cost to qualify the site. It is estimated that the qualification of a site would require an expenditure of approximately $6 million during the period of two to three years prior to the first sea disposal. After disposal started, there would be an ongoing program to verify satisfactory emplacement and to monitor the environment. It is estimated that the ongoing monitoring program for a sea disposal site would have a present-value cost of nearly $9 million. The total cost for qualifying and monitoring a site would amount to approximately $0.1 million per ship.

The land disposal sites being considered at Hanford and Savannah River are currently active and are being monitored on a continuing basis. These monitoring programs would continue and would be adequate to provide suitable monitoring for disposal of reactor compartments. No additional cost would be required.

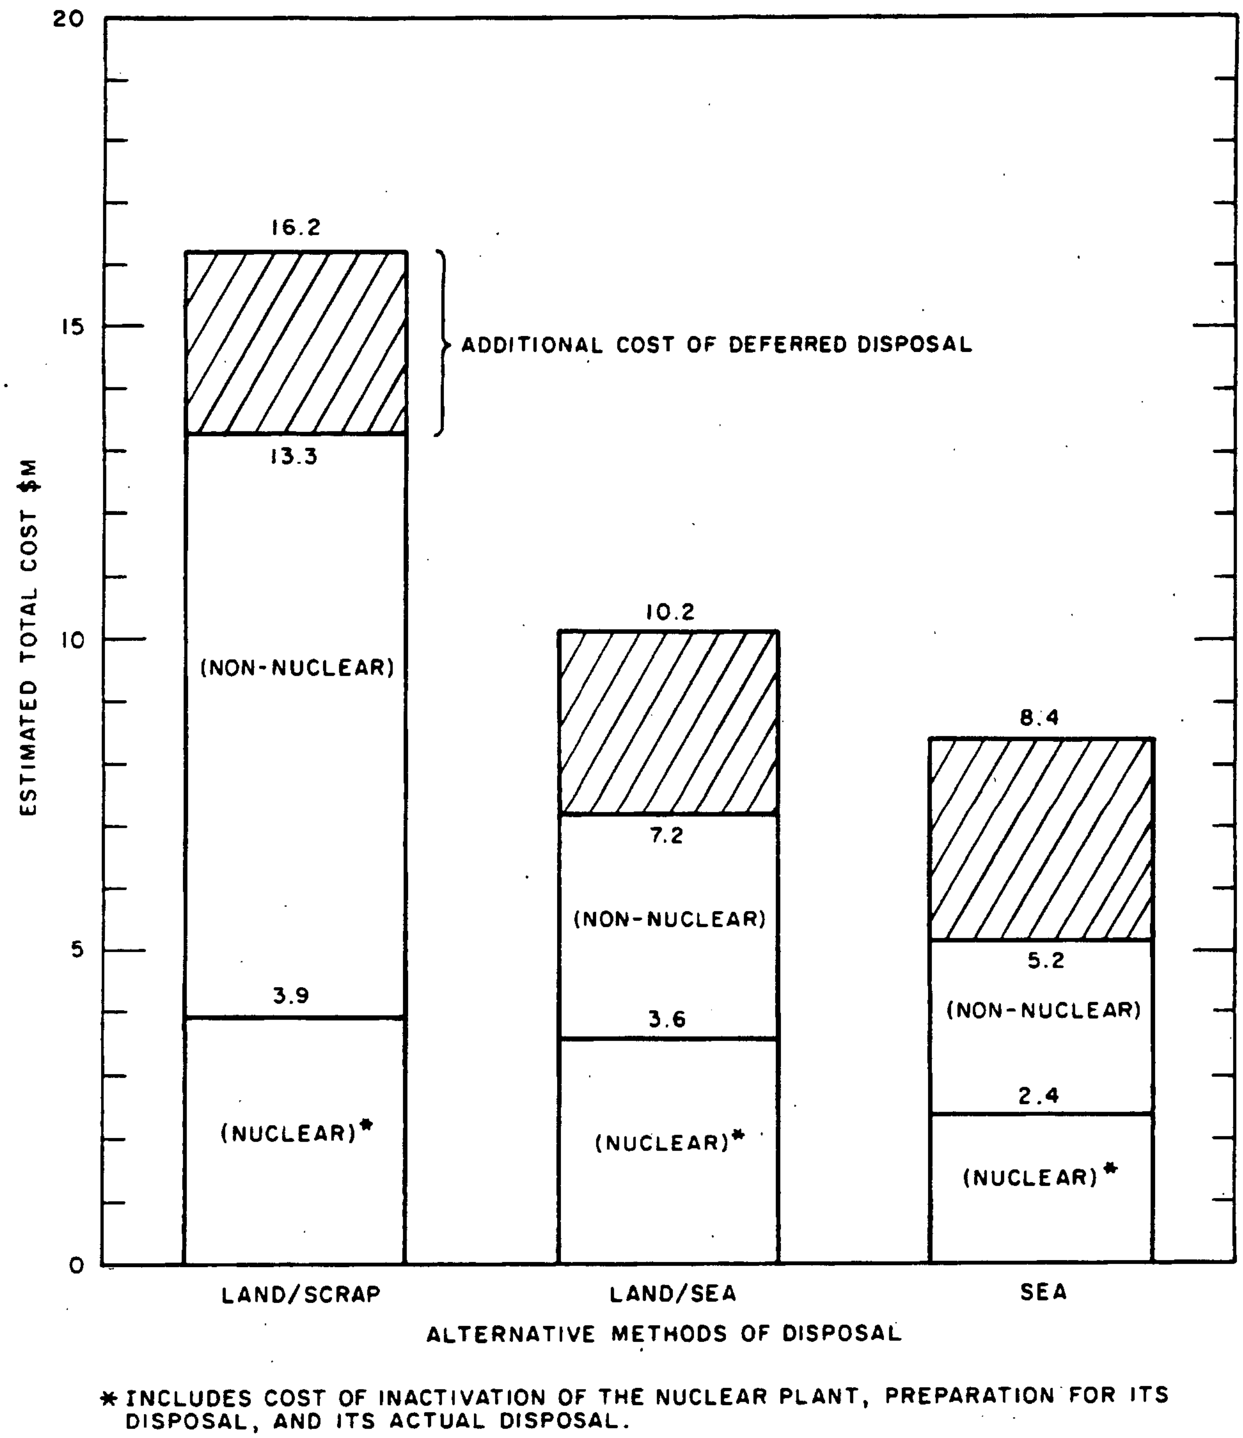

Figure A-2. Estimated Total Costs of Disposal

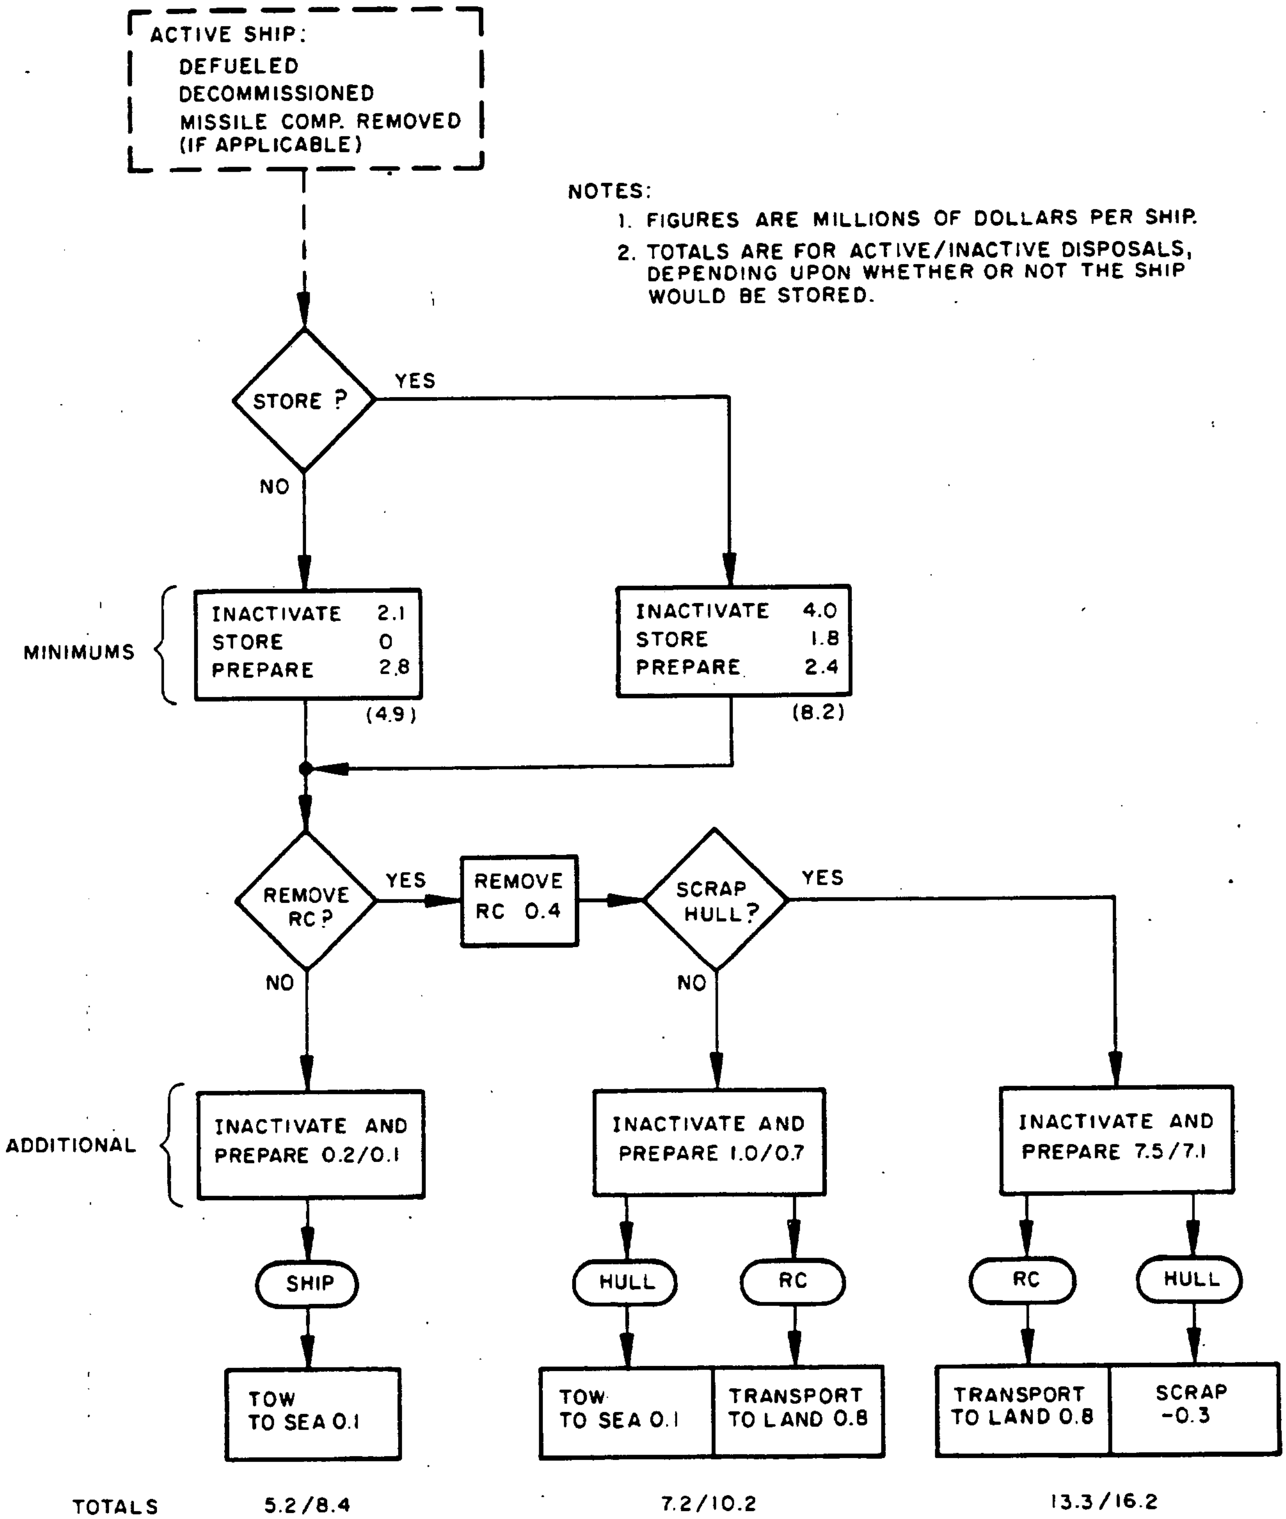

Figure A-3. Estimated Total Costs of Disposal

3. Other Environmental Impacts

Other environmental impacts were identified and examined for cost impacts.

Four other environmental impacts have been identified and have not been found to be unacceptable:

a. Normal transport and potential accidents during transport of the disposal unit would create additional risk of exposure to the workers and the general population. The extent of this risk was found to be small and would not have any significant impact on the choice of disposal method. Details are provided in Chapter 4.

b. Loss of land use (including the ocean bottom area if sea disposal would be used) is inherent in the contemplated disposal actions. At both land disposal sites, the land has already been withdrawn from other use for storage and disposal purposes. A total of approximately 10 acres of land would be required for the burial sites for 100 reactor compartments, and this land would not be expected to be returned to public use in the foreseeable future. This area is a small fraction of the areas of the Hanford Site and the Savannah River Plant which together occupy over 500,000 acres. For sea disposal, a larger area would be required. To allow for the uncertainties of placement locations on the bottom, a total of less than 100 square miles of ocean bottom would be required for the sea disposal sites. At potential sea disposal sites, the tentative site-selection criteria exclude sites that may have economic potential, such as resources or other unique utility. It does not appear that loss of land use would be a significant impact. Refer to Chapter 4 for details.

c. Change in the natural environment due to disposal actions may affect the local flora and fauna; however, this effect is considered to be a small one having highly localized significance. For land disposal, the disposal units would be covered with local earth and the disturbance would be expected to be a temporary one with no significant long-term or wide-spread effect that would place any species at risk. For sea disposal, experience in similar circumstances suggests that the presence of the disposal unit on the ocean bottom would change the local environment such that small species would be attracted to it for shelter from predators and large species would be attracted to it because of the increased concentrations of prey, but this effect would be highly localized to the area within a kilometer or so of the units. No change in species or overall abundance of species would be expected. In no event is it considered likely that any species would be exposed to a significant risk. See Chapter 4.

d. Methods for removal or containment of the radioactive material after disposal at sea, and their estimated costs have been assessed and are described in Appendix M. Since there is no technical basis for expecting that either removal or containment would ever become necessary, there is no expected economic cost and the costs identified in Appendix M have been excluded from the estimated costs for the sea and the land/sea disposal options.

On the basis of these results, no further cost impact is evident, and the assessment of the disposal options has been concentrated on estimating the potential radiation dose commitments and comparing the costs of the six options, as described above.

APPENDIX B

LAND DISPOSAL

I. INTRODUCTION

This appendix provides information on the details of the land disposal option for the disposal of reactor plants upon deactivation of naval nuclear submarines. It is based on engineering studies that were performed to identify and evaluate the tasks that would be required to accomplish land disposal in a safe and environmentally acceptable way. These studies indicated that land disposal would be technically feasible and within the capabilities of present-day equipment. It would involve removing the entire reactor compartment from a submarine and transporting it by water and land routes to a suitable burial site. The sequence of anticipated events and the expected operations are described.

II. SUMMARY

After the reactor has been defueled, land disposal of the reactor compartment would involve only low-level radioactive waste, and would be accomplished by the following sequence of principal events:

1. The reactor plant systems and mechanical equipment would be prepared for disposal. This would include removal of reactor coolant and ion exchange resin.

2. The reactor compartment would be cut from the submarine.

3. The reactor compartment would be closed and sealed.

4. The reactor compartment would be transported by barge and by crawler transporter to the burial site.

5. The reactor compartment would be buried at the disposal site.

6. The site would be monitored for radioactivity, and the results of this monitoring would be used to determine if regulatory requirements were being met.

The details of each of these steps are discussed in the sections which follow, with particular references to the approved U.S. Department of Energy land burial sites: Hanford Site, located on the Columbia River near Richland, Washington, and the Savannah River Plant, located on the Savannah River near Aiken, South Carolina.

III. DISCUSSION

A. CONCEPTS OF LAND DISPOSAL

Several different concepts of land disposal were considered before burial of the entire reactor compartment was selected to be the preferred concept for land disposal.

The general concept of land disposal is based on four main steps:

1. **Preparation of the items to be buried.** These preparations are intended to make as low as is practicable the following items: the rate at which the radioactivity would be released from the items to the environment, the amount of radiation exposure that would be received by those who prepare the reactor compartment and by the general public, and the economic costs that would be involved in these actions.

2. **Burial of the items.** Burial involves choosing a site and associated burial techniques that would minimize the rate at which radioactivity would be released to the environment and subsequently the possible dose to persons who may be exposed to such releases, and which would minimize the impact due to using the chosen site for this purpose.

3. **Monitoring the environment.** Monitoring involves measurement of the radioactivity in the environment around the burial site to determine the extent and magnitude of actual releases, if any, and whether the releases are within acceptable limits.

4. **Disposal of the remainder of the ship.** Two alternatives were evaluated for disposing of the greater, non-radioactive portion of the submarine:

   a. Sea disposal, by welding together the sections that would have been forward and aft of the reactor compartment and towing them to a suitable sea-disposal site.

   b. Scrapping, by cutting the remaining sections into suitably-sized pieces and selling them for scrap.

Three general concepts of land disposal were considered, varying mainly in the degree of preparation that would be required:

1. Dismantle the reactor plant and cut the radioactive components into pieces that could be packaged in steel drums with concrete. Burial of such packages would be consistent with current practice, but the extensive preparations would require specialized facilities and much manpower. A great deal of manpower would be required to dismantle the plant, and this would involve substantial exposure of radiation to workers during dismantling, even if temporary shielding were used. Specialized facilities would be required to cut and package the components and to limit the spread of radioactivity. Additional manpower would be required to operate the facility.

2. Dismantle the reactor plant and package whole components in specially-built containers. Burial of such packages would be a limited extension of current practice because it would be based on existing technology; however, less manpower and less radiation exposure would be expected, and less-specialized facilities would be required than in the above type because the components would not be cut into pieces.

3. Remove the entire reactor compartment from the submarine and bury it intact after sealing all openings, using the surrounding hull and bulkheads as a package. The reactor vessel itself would be sealed to contain the radioactivity within the reactor vessel and internal structures. The transport of such a package over the anticipated sea and land routes is feasible with currently available equipment. Less manpower and less radiation exposure to the workers would be expected in this case because less work would be done in the radiation area. No specialized facility would be required for dismantling or packaging. This is the preferred method for land disposal.

Among these concepts, the preferred method would be burying the entire reactor compartment because there would be less radiation exposure to the workers and no specialized facility would be required. Costs would also be less for this concept than for the others. On this basis, engineering studies were conducted on this concept to identify the necessary tasks and the potential problems. The results indicated that it would be feasible, as discussed below.

B. SITES CONSIDERED

Existing burial sites were considered and two were found to be suitable for burying entire reactor compartments: Hanford Site in Washington and Savannah River Plant in South Carolina. Others were dropped from further consideration because either they were remote from the shipyards or they were not government-owned. Access by waterway would be necessary to accommodate a barge carrying the reactor compartment and to minimize the need to transport the compartment overland by crawler transporter to the burial site. On this basis, the potential burial site at the Idaho National Engineering Laboratory in Idaho was eliminated, and the Oak Ridge National Laboratory site in Tennessee was considered to be too remote since the inland waterway is approximately 1600 miles long.

1. Hanford Site

The Hanford Site occupies approximately 570 square miles of semiarid land in the southeastern part of Washington. Waste management and reactor fuel processing facilities are located in what are known as the 200 Areas, on a plateau approximately seven miles from the Columbia River. Reactor facilities are located along the river in the 100 Areas, and reactor fuel manufacturing and the research and development laboratories are located downstream just north of Richland in the 300 Area. The Hanford Site begins at approximately 345 river miles from the mouth of the Columbia River.

The potential burial site lies along the west boundary of the 200W Separations Area. The specific area of consideration is currently in use as a burial ground, although, depending on long term needs, it may have to be expanded. The contemplated disposal of activated metal components is within the scope of existing disposals at Hanford, as described in the Final Environmental Statement for Waste Management Operations, Reference B.1.

The burial area (as well as the entire reservation) is underlain by a vast field of flood lavas of the Columbia River Basalt group. The basalt formations are estimated to be 10,000 to 12,000 feet thick and are overlain by approximately 500 feet of coarse to fine grained sediments deposited by glacial flooding. These sediments formed the soils now found on site.

The burial area lies at an elevation of approximately 700 feet above sea level. The topography is basically level with slopes of less than 2 percent. The primary soil type is classified as "Rupert Sand", which is a coarse grained sand overlain by fine-grained windblown sand. The relief characteristics consist of hummocky terraces and dune-like ridges. The natural vegetation of the site consists of sagebrush with cheat grass and sandberg bluegrass.

The water table under the burial site is constrained on the bottom by the basalt basement rock at an elevation of approximately 100 feet above sea level. Saturated soils exist to an elevation of approximately 450-475 feet above sea level. Thus, there is approximately 250 feet of unsaturated sandy-gravelly soils beneath the proposed burial site. Tests have shown that these soils are very dry in nature since the rainfall which is received (average 6.25 inches per year) does not penetrate to the groundwater table, but rather penetrates only to a shallow depth and is subsequently given off from the ground surface by evaporation.

The site is in a region of low to moderate seismicity. On the basis of the damage that has been experienced since 1840, the U. S. Coast and Geodetic Survey designated the area a Zone 2 seismic probability, implying the potential for moderate damage from earthquakes. The underlying sands and gravels at the site provide excellent protection against damage. Earthquake intensities greater than four on the Modified Mercalli Scale (MM-IV) have not occurred in the immediate Hanford area.

The National Research Council's Panel on Land Burial found that no measurable harm to human health has resulted from the past practices in the land burial of solid low-level radioactive waste at Hanford. This was reported in the results of a long study by the Panel of the problems associated with shallow land burial of solid low-level radioactive waste, Reference B.2.

Further details are available in References B.1 and B.2.

2. Savannah River Plant

The Savannah River Plant occupies approximately 300 square miles of mostly-forested land on the South Carolina side of the Savannah River, approximately 150 river miles from the river's mouth at Savannah, Georgia. The burial ground for solid waste storage and two tank farms for high-level liquid waste storage are located in what is known as the 200 Areas on the Aiken Plateau, approximately nine miles from the Savannah River. Reactor facilities are located centrally in the 100 Areas, reactor fuel and target fabrication (300 Area) and the Savannah River Laboratory and Administration (700 Area) are located in the northwestern part, and the Heavy Water Production and Recovery (400 Area) are located in the southwestern part of the plant site.

The potential burial site lies between two tank farms, just north of the central part of the plant site. The specific area of consideration is currently in use for solid waste storage, although, depending on long-term needs, it may have to be expanded. The contemplated disposal of activated metal components is within the scope of existing disposals at Savannah River, as described in the Final Environmental Statement for Waste Management Operations, Reference B.3.

The burial area and the entire plant site is underlain by bedrock over which are approximately 1000 feet of unconsolidated and semiconsolidated sediments. Five formations are identified, and these are interspersed with horizontal layers of clay. Immediately over the bedrock is the Tuscaloosa Formation, 500 to 600 feet of sand and clay which contains several prolific water-bearing beds. Water pressure measurements in the Tuscaloosa Formation indicate that the water in this major aquifer flows from off-site locations in the Aiken plateau, flows under the plant site, and discharges off-site in the Savannah River valley upstream from the Savannah River Plant.

Overlying the Tuscaloosa Formation are several formations: Ellenton, Congaree, McBean, and Barnwell, totalling approximately 350 feet, consisting predominantly of compact clayey sand and sandy clay. Any contamination from the burial area above them entering the groundwater in these formations would be transported both downward and laterally, principally laterally at each of several clay barriers. Because the water heads in the underlying Tuscaloosa and Ellenton Formations are higher than in the Congaree Formation approximately 200 feet below the surface, such contamination would be discharged into a surface stream (Upper Three Runs) before it could enter the Tuscaloosa aquifer. Further details on the hydrology of the region are available in Reference B.3.

The burial area lies at an elevation of approximately 300 feet above sea level. The topography is basically level with slopes of less than one percent. The natural vegetation of the dry sandy areas of the site consists of a scrub oak community dominated by various oaks and longleaf pine, with ground cover of three awn grass and huckleberry.

The site is in a region of moderate seismicity. On the basis of the damage that has been experienced since 1754, the U.S. Coast and Geodetic Survey designated the area a Zone 2 seismic probability, implying the potential for moderate damage from earthquakes. During the past 100 years, the area within 100 miles of the plant has experienced 16 shocks greater than IV (Modified Mercalli Scale): 1 shock of intensity X, 1 of intensity VIII, 2 of intensity VII, and 12 of intensity V. Seismic monitors, installed in the plant's reactor buildings between 1952 and 1955 have never indicated a shock in excess of 0.002 g (intensity II). The design basis earthquake acceleration for the plant is 0.2 g.

The National Research Council's Panel on Land Burial found that no measurable harm to human health has resulted from the past practices in the land burial of solid low-level radioactive waste at Savannah River. Although contaminants are slowly moving from the waste in the subsurface, the data indicate that the contaminants are well adsorbed in the soils or are adequately diluted by natural processes. These results were reported in Reference B.2.

Further details on the character of the plant site and its environmental impacts are available in References B.2 and B.3.

3. Other Potential Sites

Oak Ridge Reservation occupies approximately 58 square miles in east central Tennessee, approximately 25 miles west of Knoxville, Tennessee. It is approximately 1600 miles from the Gulf of Mexico, by the Mississippi, Ohio, Tennessee, and Clinch Rivers. It has a potential burial site at the Oak Ridge National Laboratory (X-10 area), located approximately eight miles from the K-25 area dock on the Clinch River. The water table at X-10 is relatively shallow and can be as little as 14 feet below the surface, so that a reactor compartment would have to be buried in soil that is partly saturated with groundwater. This limitation and the great distance required for transport from the ocean would put this site at a disadvantage relative to Hanford and Savannah River.

Further information is available in References B.2 and B.4.

Idaho National Engineering Laboratory occupies approximately 894 square miles of a desert plain in southeastern Idaho. The water table lies 200 to 900 feet below the surface, and radioactive solid wastes are currently stored and buried there. However, the lack of a suitable river for barge transportation of the reactor compartment makes this site less desirable.

Further information is available in References B.2 and B.5.

Los Alamos Scientific Laboratory Site occupies approximately 43 square miles in north central New Mexico, approximately 35 miles northwest of Santa Fe. It is situated on the Pajarito Plateau between the Jemez Mountains to the west and the Rio Grande Valley to the east. The Laboratory land area includes building sites, test area, waste disposal locations, and large buffer zones for safety and security. Since there is no suitable river for barge transportation, this potential site was not considered further.

Further information is available in References B.2 and B.6.

C. PREPARATION FOR TRANSPORT

After completion of defueling operations, the reactor vessel closure head would be sealed by welding, preparations for transport would start and would include the following sequence of primary steps:

1. Prerequisite operations and salvage.
2. Cutting and sealing piping systems.
3. Cutting the reactor compartment from the rest of the ship.
4. Closing and securing the reactor compartment.
5. Moving the reactor compartment to the barge and welding it to the barge.

These steps are discussed in the following sections.

1. Prerequisite Operations

The technical operations are discussed in these sections. Background information on regulations relating to shipper and carrier requirements are provided below in Sections IV.C.3 and IV.C.4.

a. **Primary Systems.** Radioactive liquids, toxic liquids, and ion exchange resin in the purification system would be removed from the reactor plant systems to the maximum extent practical prior to transport for burial. The operating manuals for the reactor plant contains procedures for blowing down and draining primary systems. These operations are a part of normal shipyard operations associated with the maintenance and repair of such systems. The environmental effects of these operations are within the scope of current practices at the shipyards.

b. **Reactor Vessel Pumpdown.** Water can be drained from the reactor vessel only to the bottom of the reactor vessel nozzles. To remove water from the reactor vessel, a pumpdown system would be used.

c. **Primary Shield Water Tank.** The shield tank would be pumped down to remove chromate-treated water. The water pumped from the tank would be processed by evaporation in the shipyard's radioactive liquid waste processing system, and the sludge from the evaporator would be solidified and disposed of as solid radioactive waste.

d. **Special Nuclear Material.** Some components in the reactor compartment contain special nuclear material and require special handling. This special nuclear material would be removed from the reactor compartment and disposed of separately.

e. **Salvage of Reactor Plant Components.** It is not considered to be cost effective to attempt to salvage any radioactively-contaminated component from the reactor compartment unless the component is of high value or in critically short supply. Items that would be considered for removal because of known shortages or high value include some instruments, pumps, and copper bus bars.

2. Cutting and Sealing Contaminated Piping

Contaminated piping and components external to the reactor compartment would be removed, capped securely, and stowed in the reactor compartment for disposal. Cut piping and small components located adjacent to the outside of the reactor compartment bulkheads would be left in place and would be capped where necessary. The lower portion of the aft bulkhead would be covered with a new watertight bulkhead because this would be more cost effective and would involve less radiation exposure than removing the numerous items located there. These operations are similar to normal shipyard operations associated with the maintenance and repair of such systems. The environmental effects of these operations are consistent with current practices at the shipyards.

3. Cutting the Reactor Compartment from the Rest of the Ship

After the reactor compartment has been prepared and contaminated systems external to the reactor compartment have been removed or covered, the entire reactor compartment and its components would be removed from the remainder of the submarine.

a. Hull cuts for removing the reactor compartment would consist of cutting and removing two 18-inch long hull sections forward and aft of the respective fore and aft reactor compartment bulkheads. The hull-cutting operations are a part of normal shipyard operations associated with the construction and overhaul of such ships. The environmental effects of the cutting are within the scope of current practices at the shipyards. The removed hull sections would provide clearances during removal and transfer to the barge. The location of the hull cut sections would provide for the following:

(1) The cutting work would be outside existing compartment shielding, therefore minimizing radiation exposure to personnel performing the cut-out and removal operations.

(2) The cuts would maintain the forward and aft reactor compartment bulkhead horizontal stiffener integrity. They also would keep the outermost frame members to maintain hull strength of the end sections for subsequent transfer to the barge and transit to the disposal site.

(3) A significant portion of contaminated piping outside the aft reactor compartment bulkhead would remain and would be removed intact with the reactor compartment.

b. In preparation for the hull cuts, the following would have to be accomplished:

(1) Piping and electrical cables passing through the reactor compartment bulkheads to the remaining fore and aft sections would be cut and capped.

(2) All piping, components, cables, and structure in the hull cut sections would be removed to provide clearance.

(3) Between the hull cut sections and their respective bulkheads, all piping and components except for those contaminated items that would remain intact for disposal with the reactor-compartment and structure not contributing to the strength of the bulkhead or hull would be removed.

(4) The outer shell or superstructure in way of the hull cut would generally be cut and removed from the pressure hull.

After the hull cuts were made, a new watertight bulkhead would be added at the aft cut to seal the lower half of the area outside the reactor compartment. The new bulkhead would provide a secondary boundary for contaminated piping that would remain intact on the aft bulkhead. The new bulkhead would meet the design strength of the reactor compartment bulkheads.

4. Closing and Securing the Reactor Compartment

a. **Reactor Compartment Integrity Requirements.** The existing strength of the reactor compartment envelope is considered adequate for transporting the reactor compartment by barge. The weakest portions of the reactor compartment envelope are the forward and aft compartment bulkheads. The strength requirements for closure of all reactor compartment cuts and penetrations would, as a minimum, meet the design strength of the reactor compartment bulkheads.

b. **Bulkhead Penetration Closures.** The environmental assessment for transporting the reactor compartment to a burial site was based in part on the fact that radioactive contamination in the reactor plant would be contained by at least two metal boundaries, the first being the all welded primary piping systems or components and the second being the pressure hull and the reactor compartment bulkheads. More than 99.8 percent of the radioactivity in the package would be present in the form of activity induced in the structural metals and therefore is further contained. To be consistent with these levels of containment, the piping, electrical and ventilation penetrations through the reactor compartment bulkheads and pressure hull would be sealed.

c. **Hull Penetration Closures.** There are two discharge valves that would be plugged and seal welded to provide a primary boundary. The secondary boundary would be a plate covering the plugged penetration and welded to the hull. The hull and backup valves would also be shut to provide additional isolation from system internals.

d. **Security.** It has been determined that the Department of Energy burial sites would have no requirement for entrance into the reactor compartments before or after burial. No requirement has been identified for personnel entrance into the reactor compartment during transportation from the shipyard to the burial site. Therefore, prior to leaving the shipyard, personnel accesses to the reactor compartment envelope would be welded shut or covered with a weldment to prevent entrance during transportation and at the burial site. This would assure that the reactor compartment would be completely sealed before leaving the shipyard, with no access possible other than by use of hull cutting equipment. Special security precautions are not required at the burial site because the existing burial site security for buried radioactive material is considered to be adequate.

e. **Reactor Compartment Tests.** Prior to shipping the reactor compartment to the burial site, a test would be conducted to verify the integrity of the reactor compartment envelope. The testing would be accomplished after all penetrations and openings into the reactor compartment envelope including the shielded tunnel, with the exception of the personnel access doors and test entry points, have been permanently closed and sealed.

5. Transferring and Securing the Reactor Compartment to the Barge

Several alternative methods were considered for movement of the reactor compartment to the barge after being cut free from the submarine. This section discusses the most practical one.

During the transfer, the load would be supported by at least eight chain-type rollers. Hardened steel rollers reduce the friction forces to the double-rolling-action of the chain and eliminate the need for a conventional axle. High capacity rollers such as Hillman Equipment Model 5XTDW (200-ton capacity) or 6X (300-ton capacity) are routinely used in multiples to move loads in the over-1000-ton range. The rollers require only 35 to 50 pounds of force to move one ton of load. They are conservatively designed to withstand twice their rated load without damage. The type "R" configuration has guide rollers and would be well adapted to transferring the reactor compartment along the load beams which would be used to transfer the compartment to the barge.

The reactor compartment would be transferred from its hull location to the deck of the barge by first raising it with jacks and blocks, not more than an inch at a time, to the level of the deck of the barge. With the roller assemblies in place, the reactor compartment would then be pulled along the load beams with chain falls to the deck of the barge. Finally, the reactor compartment would be lowered onto the deck of the barge with jacks and blocks, and would be welded securely to the barge.

a. **Preparations.** The submarine and a barge would be docked side-by-side in the drydock. The ship would be docked normally with the exception that four prefabricated support fixtures (described below) would be in place beneath the reactor compartment. The barge would be docked as low in the dock as possible and aligned such that the final stowage location on the barge deck would be directly opposite the compartment. After docking, the support fixtures would be raised, fitted, and welded to the ship's hull. These fixtures would then provide support for the compartment during all subsequent jacking, rolling, stowage, and transportation. Blocks would be installed under the fixtures and partially loaded so that as the hull cutting operation proceeds, the compartment's weight would be fully supported.

At a convenient time, four structural pads would be welded to the bottom of the compartment for use at the unloading site, to allow securing to the crawler which would transport the compartment from the barge slip at the unloading site to the burial site.

Prior to transferring the compartment to the barge, load distribution beams would be installed on the barge, if necessary, to distribute the weight of the compartment over sufficient area to meet the deck load rating of the barge. The beams would have a wear plate attached to their top surface which would bear the pressure of the rollers during the transfer operation to prevent scuffing and gouging. The rollers would have outrigger guide rollers which would bear on the load beam flanges. Attachment of the rollers to the support fixtures would include a rubber pad which would allow small vertical roller movements while maintaining uniform roller loading.

b. **Jacking.** Jacking and blocking would be used to raise the compartment. Four, 600-ton hydraulic jacks with 12- or 24-inch strokes would be operated from a control console. The console would allow operation of individual jacks from a common hydraulic power supply and would provide an indication of the load on each jack. The jacks would be tested in accordance with lifting standard requirements prior to use.

The compartment would be jacked so that the bottom of the support fixtures would be at an elevation approximately 12 to 18 inches above the elevation of the load beams on the barge deck. The compartment would then be securely blocked. Blocking for additional load beam sections would then be installed under the reactor compartment, and load beams would be placed on the blocking. Rollers would be attached to the bottom of the support fixtures and the reactor compartment lowered to allow the rollers to support the weight of the compartment on the load beams. At this time, the jacks would be removed to allow installation of the remaining blocking and load beam sections to allow transfer of the compartment to the barge.

c. **Moving the Reactor Compartment onto the Barge.** Rigging would be installed between the compartment and fixed points to provide the estimated 40 tons (maximum) horizontal pull required to move the compartment onto the barge. Suitable restraints would be provided to ensure positive control of the load at all times.

After the compartment would be moved onto the barge, the jacks would be repositioned under the support fixtures, the compartment jacked to allow removal of the rollers, and then lowered to allow the support fixtures to support the weight of the reactor compartment on the load beams. The support fixtures would be welded to the load beams and the load beam extensions removed to complete the transfer.

The primary advantage of this method is that one-time investment costs would be minimized. The investment cost of plant equipment for this method would be approximately $320,000. This would provide the load beam system, the rollers, and the keel blocks for use as beam supports and jack supports.

d. **Securing the Reactor Compartment to the Barge.** Prior to transferring the reactor compartment to the barge, load distribution beams would be installed on the barge deck, if necessary. These load distribution beams would be designed to distribute the weight of the reactor compartment over sufficient deck area to meet the deck-load rating.

Movement of the reactor compartment to the barge would require that four support fixtures be fitted and welded to the compartment's hull. These fixtures would then provide for support and attachment to the deck plates or the load distribution beams installed on the barge. The fixtures would be welded to the deck plates or the load distribution beams. The attachment to the compartment hull would be designed to withstand the maximum forces associated with the wind loading, list, trim, pitch, roll, yaw specified in MIL-STD-1399, Section 301, and any postulated credible accidents. Overall height of a typical reactor compartment above the barge deck following loading would be approximately 35 feet as shown in Figure B-1.

e. **Estimated Cost of Disposal Operations.** Unit costs for the land disposal operations alone are estimated to be approximately $0.8 million per reactor compartment. This amount is due mostly to recurring costs that would be required to move the reactor compartment from the ship to the burial site, and it includes the associated expendable materials, labor costs, and equipment rental costs. Unit costs were computed by averaging the estimated capital costs for reusable structures and materials over 10 ships and adding the ratio to the recurring costs. Estimated costs are listed in Table B-1. Further details on the costs of disposal are provided in Appendix A.

D. TRANSPORT TO THE DISPOSAL SITE

The Hanford Site would be the closest disposal site for submarine reactor compartments that would be deactivated in Honolulu or West Coast shipyards, such as the Puget Sound Naval Shipyard. Similarly, the Savannah River Plant would be the closest disposal site for submarine reactor compartments that would be deactivated in East Coast shipyards, such as the Charleston Naval Shipyard. At an additional cost, the reactor compartments could be transported from the shipyards to a disposal site on the opposite coast. The sections below describe the routes to these sites and the anticipated problems that were identified in developing plans for transporting the reactor compartments to these sites.

1. Transit Routes

The normal commercial shipping lanes would be used to transport the reactor compartments from the shipyards to the two potential disposal sites. Where appropriate, this would include the use of inland waterways. The shipyards that might be involved are listed in Table B-2.

The shortest routes are from Puget Sound to Hanford on the West Coast and from Charleston to Savannah River on the East Coast. The longest routes would involve those through the Panama Canal to the disposal site on the opposite coast, and from Pearl Harbor to Hanford or Savannah River. On the West Coast, the longest route to Hanford is from Mare Island. On the East Coast, the longest route to Savannah River is from Portsmouth Naval Shipyard.

a. **Route from Puget Sound Naval Shipyard to Hanford Site.** The normal commercial shipping lanes from Puget Sound Naval Shipyard would be used, via Rich Passage, past Restoration Point, northerly through Puget Sound, westerly through the Straits of Juan de Fuca, past Cape Flattery, and southerly down the Washington Coast to the mouth of the Columbia River.

After reaching the Columbia River, the remainder of the trip to the Port of Benton near the Hanford Site would be approximately 342 miles. Because of the number of dams on the Columbia River, the navigation will be through essentially slack waters until just prior to reaching the unloading site. Additional information on river limitations is given in Section III.D.2.a.

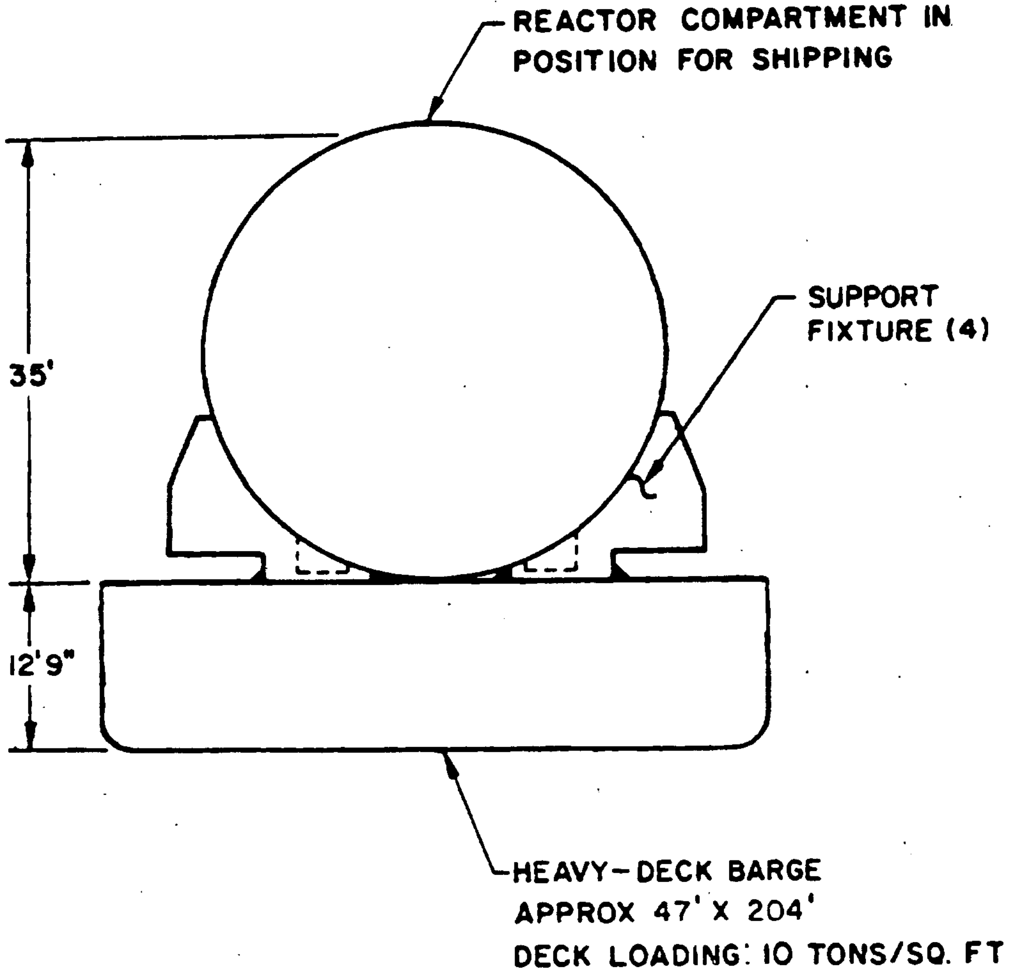

Figure B-1. Reactor Compartment on Barge

---

b. **Route to Savannah River Plant.** The normal commercial shipping lanes to the Savannah River Plant would be used from whichever shipyards would prepare reactor compartments for disposal. Navigation up the Savannah River to the Savannah River Plant would be more difficult than navigation up the Columbia River because of the water depth and limiting vertical clearances. Additional information on the Savannah River is given in Section III.D.2.b. Preliminary discussions with an experienced operator of barges and tugs indicate that a reactor compartment could be barged up the Savannah River without insurmountable problems. This operator has frequently moved barges up this river.

c. **Route from Hawaii.** The routes from Hawaii to either of the potential disposal sites would include considerable distances over waters that are very much deeper than the design depth of the reactor compartment bulkhead. If the barge were to sink in those waters, the bulkheads would be crushed by the pressure of the deep water until there was sufficient failure to allow leakage flow to equalize the pressure on the hull structures. The reactor plant would then be subjected to the increased pressure and would subsequently be crushed and the pressure boundaries would be expected to fail. Crushing would be expected to occur because there would be no water to support the structures against deep-sea pressure, as there would be in sea disposals.

TABLE B-1. ESTIMATED COSTS OF DISPOSAL OPERATIONS

Initial Costs		
Plant Equipment	$	320,000
Transportation Route[(1)]		830,000
Transport Barge[(2)]		5,700,000
Total Initial Cost	$	6,850,000
Recurring Costs (per ship)		
Barge Operations	$	60,000
Jacking		160,000
Land Operations[(3)]		210,000
Total Recurring Cost	$	430,000
Prorata Initial Cost[(4)]		400,000
Total Cost of Disposal Operations[(5)]	$	830,000 per ship.

Notes: (1) Includes utilities relocation and engineering.
(2) Sized to transport two reactor compartments per trip.
(3) Includes crawler rental and transport, prorata burial pit preparation, and engineering.
(4) Basis: 10 disposals except 20 for specially-built barge (two disposals per trip).
(5) The estimated total cost of disposal operations for the alternative of using a leased barge modified to meet technical requirements is $820,000 per ship.

TABLE B-2. SHIPYARD LOCATIONS

California	Mare Island Naval Shipyard, Vallejo
Connecticut	Electric Boat Company, Groton
Hawaii	Pearl Harbor Naval Shipyard, Honolulu
Maine	Portsmouth Naval Shipyard, Kittery*
New Hampshire	Portsmouth Naval Shipyard, Portsmouth*
South Carolina	Charleston Naval Shipyard, Charleston
Virginia	Newport News Shipbuilding and Drydock Company, Newport News Norfolk Naval Shipyard, Portsmouth
Washington	Puget Sound Naval Shipyard, Bremerton

***Portsmouth Naval Shipyard is located in two adjoining states: Maine and New Hampshire.**

The consequences of such an accident would be less severe than those of the sea-disposal accident in which it was assumed that all containment would fail. This accident has been evaluated in Appendix J (Dose Commitment Estimates, Sea Disposal), and the results of the analysis are discussed in Chapter 4. The results indicate that the consequences of such an accident are not sufficient to preclude using Pearl Harbor to process decommissioned submarines for land disposal at Hanford or Savannah River.

2. River Limitations

a. **Columbia River.** The off-loading site on the Columbia River at Port of Benton is located at River Mile 342.8. A navigation channel is maintained up the Columbia River by the Corps of Engineers to River Mile 335 which ends approximately at the mouth of the Yakima River. The minimum dimensions of this channel are 14 feet deep by 250 feet wide at the channel bottom. Soundings of the remaining 8 miles to the Port of Benton indicate that adequate channel depth (14 feet) exists. However, since this stretch of the river is not maintained by the Corps of Engineers, the channel depth would need to be verified prior to use.

Starting at the mouth of the Columbia River, the Port of Benton is reached through a series of four locks at the Bonneville, Dalles, John Day and McNary Dams. Lock sizes are as follows:

Bonneville—76 feet wide, 500 feet long, 24.2 feet deep

Dalles—86 feet wide, 675 feet long, 18.0 feet deep

John Day—86 feet wide, 675 feet long, 15.0 feet deep

McNary—86 feet wide, 675 feet long, 22.0 feet deep

The limiting horizontal clearance is the lock system at Bonneville Dam. The limiting vertical clearance is a highway bridge at River Mile 328.4, (Pasco-Kennewick Highway Bridge) that is 52.3 feet above the 340 foot normal pool elevation of the McNary Dam impound. These limits are not expected to be restrictive.

b. **Savannah River.** The proposed off-loading site on the Savannah River is presently an abandoned small-boat basin near an abandoned barge wharf both at River Mile 157. The authorized project depth of the river channel to this point is 9 feet deep and 90 feet wide at the channel bottom. This project depth, however, is not routinely maintained. The normal depth is a minimum of 7.5 feet at low water. The limiting horizontal clearance for the river is the 90 foot width of the project channel. The limiting vertical clearances on the river are two fixed bridges, one at River Mile 61.5 (vertical clearance of 38 feet at low water) and the second at River Mile 119 (vertical clearance of 40 feet at low water). The water depth under both these bridges is 13 feet at low water (based on National Oceanic and Atmospheric Administration Nautical Charts 11514 and 11515). The Corps of Engineers can control water level by regulating flow from a dam upstream of the Savannah River Plant. There is no dam downstream of the Savannah River Plant and therefore river level cannot be controlled by water impoundment. The low water levels of the river occur during the months of May through October.

A 33-foot diameter reactor compartment could be barged up the Savannah River under the two fixed bridges by adjusting barge ballast to provide one to two feet of free board when passing under the bridges with an overall barge depth not to exceed 13 feet. Low profile reactor compartment support fixtures would allow the bottom of the reactor compartment to remain within two feet of the barge deck. The river level could be controlled at the low level and the shipments could be scheduled to occur during the months of May through October. (During the months of November through April, the river depth at River Mile 157 fluctuates 13 feet between flood high (EL 96 feet) and low water (EL 83 feet).)

Following the above precautions, a clearance of about 1 1/2 feet could be maintained between the lowest bridge and load and between the barge and river bottom. The low water river depth would need to be verified under the bridges at River Miles 61.5 and 119 prior to shipment.

3. Barge Operations

There would be some environmental impact due to barge operations because of the size of the reactor compartment and the number of compartments (approximately 100) to be transported. Both of these factors are a matter of degree since barge traffic is a current practice on both the Columbia River and the Savannah River, but land disposal would add to the total traffic approximately three trips per year for approximately 35 years. Background information on transport barges is provided below in Sections IV.A. and IV.C.4.c.

a. **Tug Boat Criteria.** There is no known requirement or regulation on the size or number of tugs required when making a tow of such material. For safety and reliability considerations, the use of a twin screw twin engine tug would be desirable.

Traffic that is classified as hazardous may be given special consideration by the U.S.C.G. Captain of the Port. The Captain of the Port may require special handling procedures which could define the number of tugs, time of tow, control of traffic, and any other factors that he would consider necessary to assure a safe shipment.

Whatever size or number of tugs would be used, they would have appropriate navigational and communication devices that would assure adequate control of the tow. For instance, a depth finder would be considered mandatory since the tow will transit close to the shoreline and the depth should be monitored continuously during that phase of the transit. For transit through closely controlled waters, the tow would be required to have a continuous radio watch and channel guard with the U.S.C.G. Vessel Traffic Control System. Also, transit in ocean waters would probably require communication with the respective Captain of the Port.

b. **Barge Ballasting.** During the off-loading sequence at either the Hanford Site or the Savannah River Plant, the barge would be ballasted with water to sink the barge onto the grounding pad. Also, transit to the Savannah River site would require the barge tank system to be partially filled to reduce the freeboard to clear two of the fixed bridges on the river. Once these bridges have been passed, the barge tank system would again be emptied to regain maximum stability and to reduce draft for the remaining transit to the off-loading site.

A portable ballast system consisting of individual submersible pumps and plastic piping would be adequate instead of a built-in system, since only selected tanks would have to be ballasted and deballasted. Since the stability of the barge is reduced by the free-surface effect of a partially-filled tank, no more than one tank at a time would be ballasted or deballasted. The centerline tanks would be used to reduce the freeboard when the load would pass under the Savannah River bridges. These tanks, because of their central location, would have less effect on stability than the set of cross-connected port and starboard tanks.

c. **Permits and Regulations.** A reactor plant prepared for disposal would meet Department of Transportation (DOT) regulations regarding marking, labeling, and packaging prior to shipment. For shipping purposes, the reactor compartment enclosing the reactor plant would be considered a single package composed of its radioactive contents and packaging. The ship's hull and the forward and after bulkheads would provide the packaging. The shipper would provide shipping papers and a certification to the carrier that the package is in accordance with the regulatory requirements regarding marking, labeling, and packaging. The package would meet the safety standards set forth in 10CFR71 (Subpart C), "Packaging of Radioactive Material for Transport and Transportation of Radioactive Material Under Certain Conditions," Reference B.7, for normal conditions of transport and for hypothetical accident conditions. The package integrity and operational controls would be adequate to assure the safety of the shipment. Background information on applicable regulations is provided below in Section IV.C.

The major portion of the shipping route would be by water with the final portion being overland. Commercial carriers would have to comply with certain DOT regulations for transport of radioactive materials. These include not accepting a package for transport unless a shipper's certification is received that the package is in accordance with regulatory requirements, possession of shipping papers, preparation of a dangerous cargo manifest, reporting of incidents, and in the case of the overland portion of the route, application of placards to the vehicle. If a public vessel (Navy tug) were to be used, the DOT regulations would not apply to the water portion of the route.

The proposed water route to the Hanford Site, for example, falls under the jurisdiction of the Thirteenth Coast Guard District, and the Corps of Engineers has jurisdiction over the navigation locks that would be encountered. No regulation was found that would preclude the shipment of the subject package through the waterways, drawbridges, and navigation locks encountered in the proposed route. However, the various Captains of the Port would have to be notified 24 hours prior to arrival of the subject shipment in their respective areas.

Washington and Oregon, by virtue of a formal agreement with the NRC, have adopted regulations pertaining to intrastate shipment of radioactive material consistent with requirements of the DOT. Therefore, a shipment of radioactive material that would meet DOT requirements would also comply with regulations of Washington and Oregon.

No requirement for special licenses or permits was found for the proposed route and method of transport by virtue of the shipment being radioactive. This does not preclude licenses or permits required by the carriers to engage in commerce. It is concluded that the subject shipment could be made over the route and via the mode of transport proposed within the framework of existing federal and state regulations governing the transport of radioactive materials.

4. Off-Loading Sites

a. **Hanford Site—Port of Benton.** The optimum unloading place on the Columbia River for transporting a reactor compartment to the Hanford Site would be an existing barge slip in the Port of Benton Industrial Park located on the northern edge of Richland, Washington. Commercial nuclear power plant components weighing as much as 1,000 tons have been unloaded at this barge slip. In discussions with the contractor who unloaded the components, Neil F. Lampson Inc., Kennewick, Washington, it was determined that the barge slip is adequate for this type of operation.

The existing barge slip was constructed in 1972 for use by Westinghouse at the Port of Benton Industrial Park located on the northern edge of Richland. The industrial park consists of a 12 acre tract and a 280 acre tract. This land was deeded to the Port of Benton by the Government on a Quit Claim Deed in 1969. The deed stipulates that the 12 acre tract adjacent to the Hanford Site may be used for construction of public port facilities only and the 280 acre tract is restricted to industrial use only. The barge slip was constructed on the 12 acre tract under terms of a 1972 contract between Westinghouse Hanford Company and the Port of Benton.

The barge slip is approximately 1/4 mile south of the Hanford Site at River Mile 342.8. The slip has cellular sheet pile bulkheads on the upstream and landward sides and a riprapped bulkhead on the downstream side. (See Figure B-2.) The slip has a 60 × 150 foot gravel grounding pad at an elevation of 330 feet (based on Corps of Engineers Sea Level Datum 1947) which provides 8 to 10 feet of water at normal water conditions of 338 to 340 feet elevation. Gravel is added to or removed from the grounding pad as required to place the deck of the specific barge being used level with the top of the bulkheads. The 1972 Westinghouse contract with the Port of Benton requires that the user is responsible for preparation of the slip bottom to accommodate particular barges and must leave the slip bottom height between 10 to 14 feet below the height of the dock after each use. The landward bulkhead is capped by an 8-inch thick reinforced concrete slab, 8 feet in width. The remaining bulkhead areas have gravel surfacing. Existing mooring hardware is minimal and consists of 3 cleats. The maximum size barge which can be fully grounded at the existing facility is 60 × 150 feet; however, by using special grounding techniques a longer barge could be accommodated. The existing slip could also be modified to accommodate a wider barge with a mimimum of effort and expense (not more than approximately $50,000). However, present studies indicate that a barge wider than 60 feet would not be required for transporting a submarine reactor compartment.

There would be some relatively small environmental impacts associated with the use of the barge slip because the barge would need to be grounded each time, to unload the reactor compartment, and this would probably require that gravel in the grounding pad be adjusted. This would involve some relatively small cost and would disturb any accumulated sediment and marine life in the grounding pad. Additional cost and environmental disturbance would be involved if the slip needed to be modified, but this is not expected to be necessary.

b. **Savannah River Plant.** At the present time, no facility exists on the Savannah River that would be suitable for off-loading a reactor compartment to be buried at the Department of Energy's Savannah River Plant in South Carolina. An abandoned sheet pile barge landing wharf, an abandoned small boat basin, and a surfaced boat ramp are located at River Mile 157 at the Savannah River Plant. The small boat basin is adjacent to the wharf on the upstream side. The boat ramp, located approximately 50 feet upstream of the small boat basin, has a 21-foot wide black topped surface and exits the water at about 7 percent grade. Farther upstream, about 1/4 mile, is a dredged inlet canal used as a cooling water supply for the site. The canal is 500 yards long and approximately 50 yards wide. Upstream of the canal approximately 200 yards is the mouth of Upper Three Runs Creek. Downstream, the remaining shore bordering the river at the Savannah River Plant is extensive swamp land.

The concept for unloading facilities for the Savannah River Plant consists of a barge slip and grounding pad constructed in the small boat basin, as shown in Figure B-3. The alternative would be to use a crane at the abandoned wharf. Of these two options, the construction of the barge slip and grounding pad would be more feasible for the following reasons:

(1) A suitable access road exists to the area of the wharf, the small basin, and the boat ramp.

(2) The existing abandoned wharf would require the use of a crane for off-loading the reactor compartment due to the height difference between the nominal land level and the river surface. It is possible to install a stiff leg derrick or other crane at this site. An installed stiff leg derrick would cost approximately $3 million. The sheet pile bulkhead of the wharf appeared to be in satisfactory condition, however, the condition of the buried tie rods and piling anchors has not been verified. The timber fender piles would possibly require upgrading or replacement.

(3) The existing boat ramp site could possibly be used as a barge slip site but would have to be modified extensively by widening and contouring to facilitate off-loading. The ramp itself would have to be removed to make room for a barge grounding pad and a sheet pile slip constructed for unloading with a crawler. The barge would also extend farther into the river during unloading than if a barge slip were constructed in the small boat basin.

(4) The cooling water intake canal is considered unsuitable for use as an unloading site. The canal contains several subsurface pipes used to relieve pressure from subterranean water sources. It is possible to off-load just upstream of the entrance to the canal, however, river flow and soggy land would present major problems in construction of a barge slip and access road.

(5) The use of Upper Three Runs Creek for an unloading site would be undesirable because of its use for environmental studies, heavy timber along the shore, and extensive marsh lands adjacent to the creek.

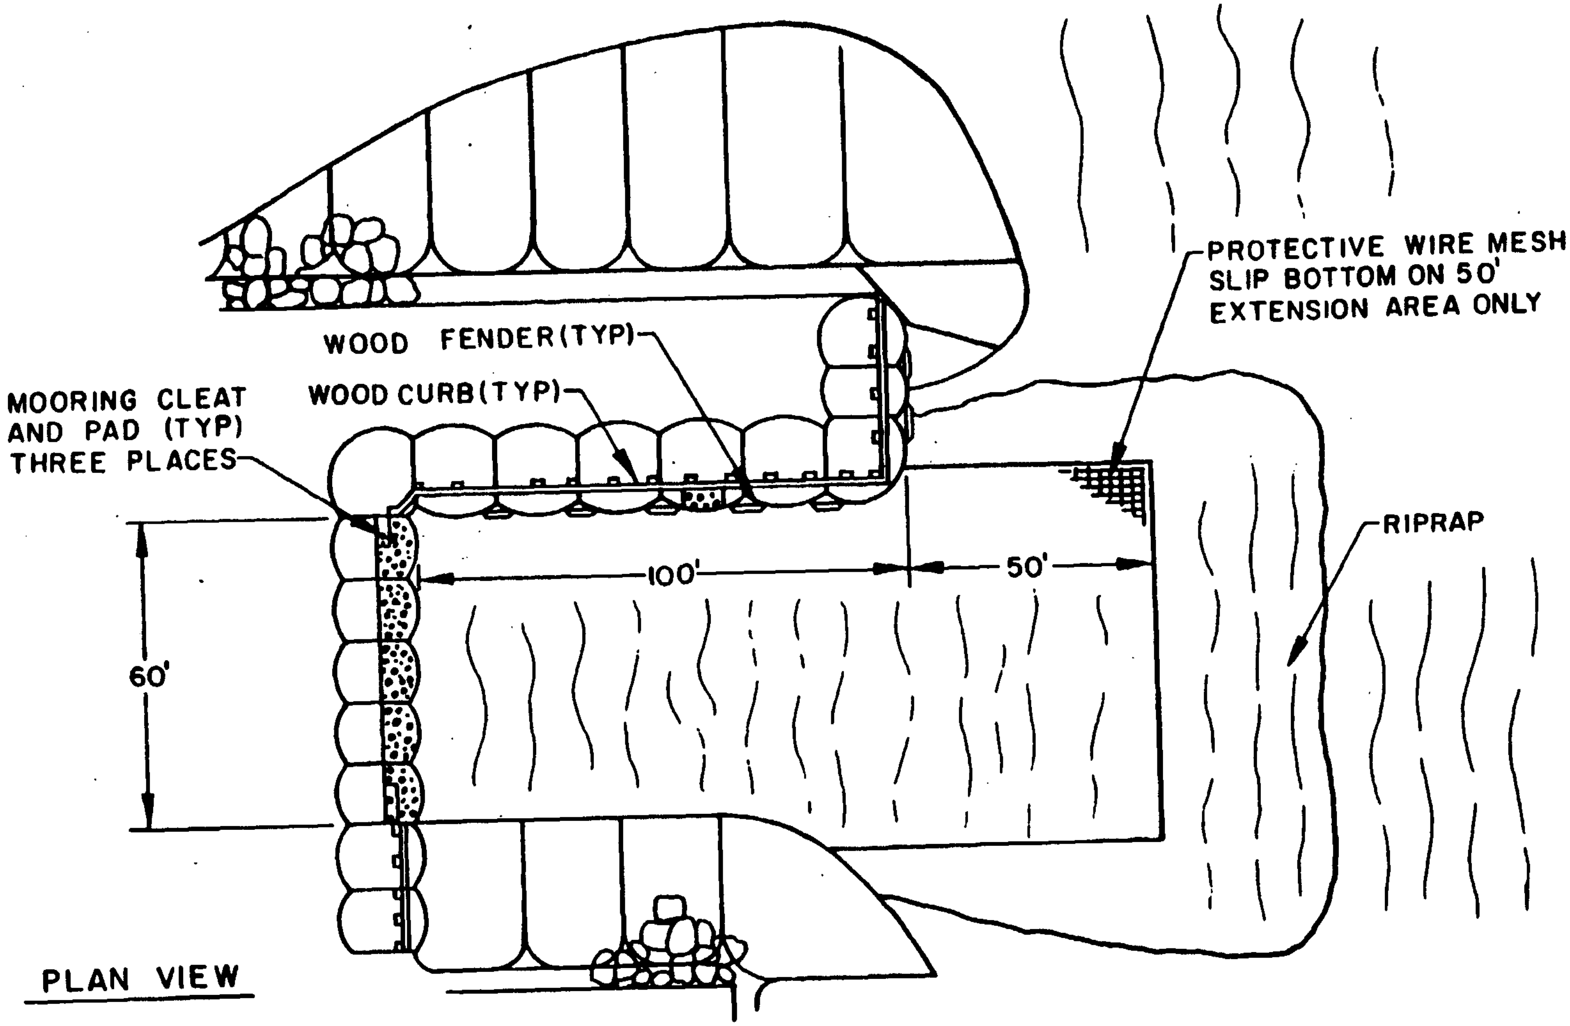

Figure B-2. Barge Slip at Port of Benton near Hanford Site

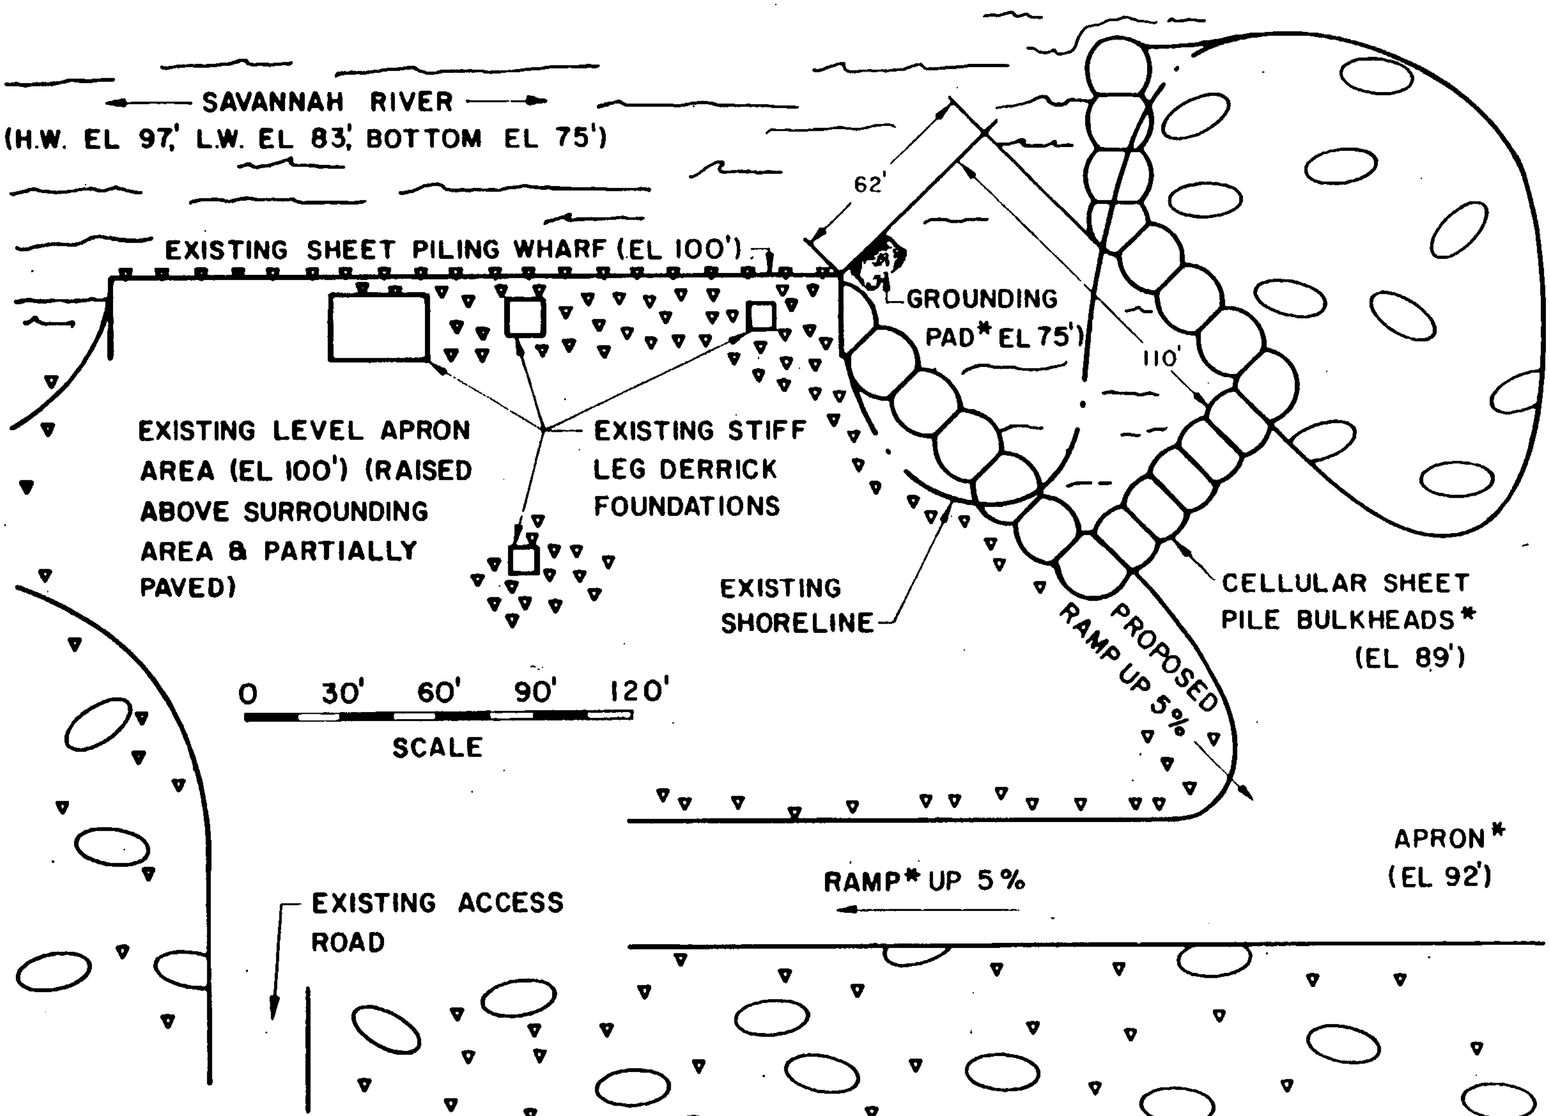

* ITEMS MARKED ARE PART OF THE CONCEPTUAL DESIGN AND DO NOT EXIST AT THIS TIME.

Figure B-3. Conceptual Design of the Potential Barge Slip at Savannah River Plant

(6) The remaining shore bordering the river at the Savannah River Plant is extensive swamp land.

(7) The use of a barge slip and grounding pad on the Savannah River would be limited to those months of the year with low water flow (May through October). During the months of November through April, the river fluctuates and may be too high to allow transporting the reactor compartment under fixed bridges that cross the river.

The estimated cost for construction of a barge slip such as that illustrated in Figure B-3 is approximately $1,300,000. This would include: pre-construction surveys, design, and assessment of environmental impacts; materials and labor for construction; and associated overhead and administrative costs.

There would be some environmental impacts associated with the construction and use of the barge slip due to disturbing the river bank and the local habitat and to the costs of construction and subsequent use. Additional impacts associated with silting and habitat disturbance would be involved due to the dredging of the river to open the channel to obtain sufficient clearance near the unloading site. These impacts are similar to other impacts that are a part of existing barge usage along the Savannah River. Details on the assessment of impacts on the floodplain and wetlands associated with the selection of the unloading site are provided in Appendix L.

5. Barge Unloading

The Port of Benton barge slip near the Hanford Site or the one proposed for the Savannah River Plant (see Figures B-3 and B-4) would be utilized to off-load the reactor compartment from the barge. In order to accomplish this, the elevation of the grounding pad at the slip would have to be adjusted prior to barge arrival so that upon grounding the barge, the deck would be approximately level with the top of the quay wall (within 4 or 5 inches). After the barge was grounded, timber mats would be used to construct a transition between the barge deck and the haul road, with gravel used to build up the road as required. If the barge were to extend past the end of the grounding pad at the slip, special grounding techniques are available which could be used to ensure that the barge would remain stable and level.

The unloading procedure would be applicable to either the Port of Benton or Savannah River unloading sites. Jacking is required to raise the compartment above the barge deck to allow loading onto the crawler. This would be accomplished as follows: A timber mat would be installed on the barge deck level with the top of the load beams and a road transition constructed dockside to match the timber mat. Jacks and cribbing would be installed at the jacking points. The welds securing the support fixtures would be cut and the reactor compartment jacked and cribbed to allow a crawler to be positioned under the support fixtures. The unit would then be lowered with the jacks until the previously attached pads on the reactor compartment would rest on the crawler. The compartment would be secured to the crawler and the unit would then be ready for the overland trip to the burial site. Background information on the use of the crawler is provided below in Section IV.B. In order to support jacking operations, temporary services would be required to support weight handling operations. Submersible pumps and piping, and a power supply for the pumps would be required to ballast and deballast the barge.

6. Overland Route from Unloading Site to Burial Site

a. **Hanford Site.** There are currently existing road facilities from the barge slip to the proposed burial site. The total overland distance is approximately 31 miles. At a transporter speed of 1 mph, the overland haul would take approximately one and one-half days.

There would be some relatively small environmental impacts resulting from using the anticipated route. Costs would be involved in raising or moving overhead utility lines (electric power and telephone, for example), in providing load-distribution or reinforcing structures, in having an architect engineer evaluate the load-carrying capacity of existing unloading docks and roadways, and, if necessary, modifying them. Traffic along the public part of the route would be affected temporarily, but this impact could be minimized by scheduling the moves to avoid the periods of peak traffic. These impacts are similar to the corresponding impacts that occurred when large components for the Hanford reactors were moved by barge and roadway to their present locations at the Hanford Site.

The first one-quarter mile is off the Hanford Site. The slip access road is a 28-foot-wide gravel road which includes a 6 percent grade. (See Figure B-4.) The remaining distance to the reservation is one block along "C" Avenue, a little-used two-lane road. Both of these roads lie within the industrial park operated by the Port of Benton. A map of the Hanford Site is located in Chapter 3, Figure 3-2.

The Hanford Site is encountered upon crossing Horn Rapids Road. A one-mile-long unimproved transporter route has already been cut diagonally across country to connect with Hanford Route 4 South, a four-lane road leading toward the burial areas. Approximately the first nine miles of this route have been used to transport loads in excess of 1,000 tons with no apparent problem. Previous experience indicates that the use of one lane in addition to the shoulder or median strip provides an adequate haul surface for a crawler when using the four-lane roads while still allowing near-normal traffic flows. After approximately nine miles, Route 4 branches to the left of the Wye barricade and becomes a two-lane highway. The original four-lane road continues straight ahead as Hanford Route 2 South. Both roads connect to Hanford Route 11A which leads directly to the 200W area burial site. Either of these routes would be sufficiently wide and are properly sloped and graded to accommodate a crawler transporter. Although Hanford Route 2 may be preferred because it is wider and less traveled, the final selection would probably be Hanford Route 4 based on the cost of raising Route 2 overhead electric power lines, as discussed below. If Hanford Route 4 were to be selected, scheduling of the move would be arranged to avoid blocking the two-lane roadway during morning and evening peak traffic, as this is the main route for workers from N Reactor and the 200E and 200W areas.

A third route was also investigated. The unimproved telephone right-of-way, leading from the 300 area near the Port of Benton, connects with the Army Loop Road which leads directly to the burial area via Route 3. It appears that the telephone right-of-way could be extended to the burial ground, but there is an extensive radiologically controlled area between the loop road and the 200W area which cannot be traversed. Although there are few overhead utilities on this route, the 13 mile unimproved road would have to be extensively widened, cut and filled, and the 14 mile paved Army Loop Road is only 20 feet wide which would not accommodate a 28 foot transporter. Therefore, this route was not considered further.

Several overhead utilities would need to be relocated to clear the approximately 42 foot height of the loaded crawler.

The Bonneville Power Administration, in a letter to D.O.E., Richland on 27 June 1978, indicated that the minimum safe clearance to an energized line is 6 feet for a 115 KV line, 7 feet for a 230 KV line, and 13 feet for a 500 KV line.

Travel to the burial site via Hanford Route 4 would require raising one 115 KV and seven 13.8 KV or smaller power lines at an estimated total cost of $158,000. If Hanford Route 2 were selected, it would be necessary to raise four 115 KV and eight 13.8 KV or smaller power lines at an estimated total cost of $225,000.

In addition, approximately five telephone lines, approximately five guy wires, and at least one set of traffic signals would have to be raised or removed for either route.

Route 4 crosses a set of underground radioactive waste transfer lines and an export water line. Route 2 crosses two export water lines. These crossings may require load distributing timber or other strengthening to bear the weight of a loaded crawler. An architect engineer would have to evaluate the need and specify requirements.

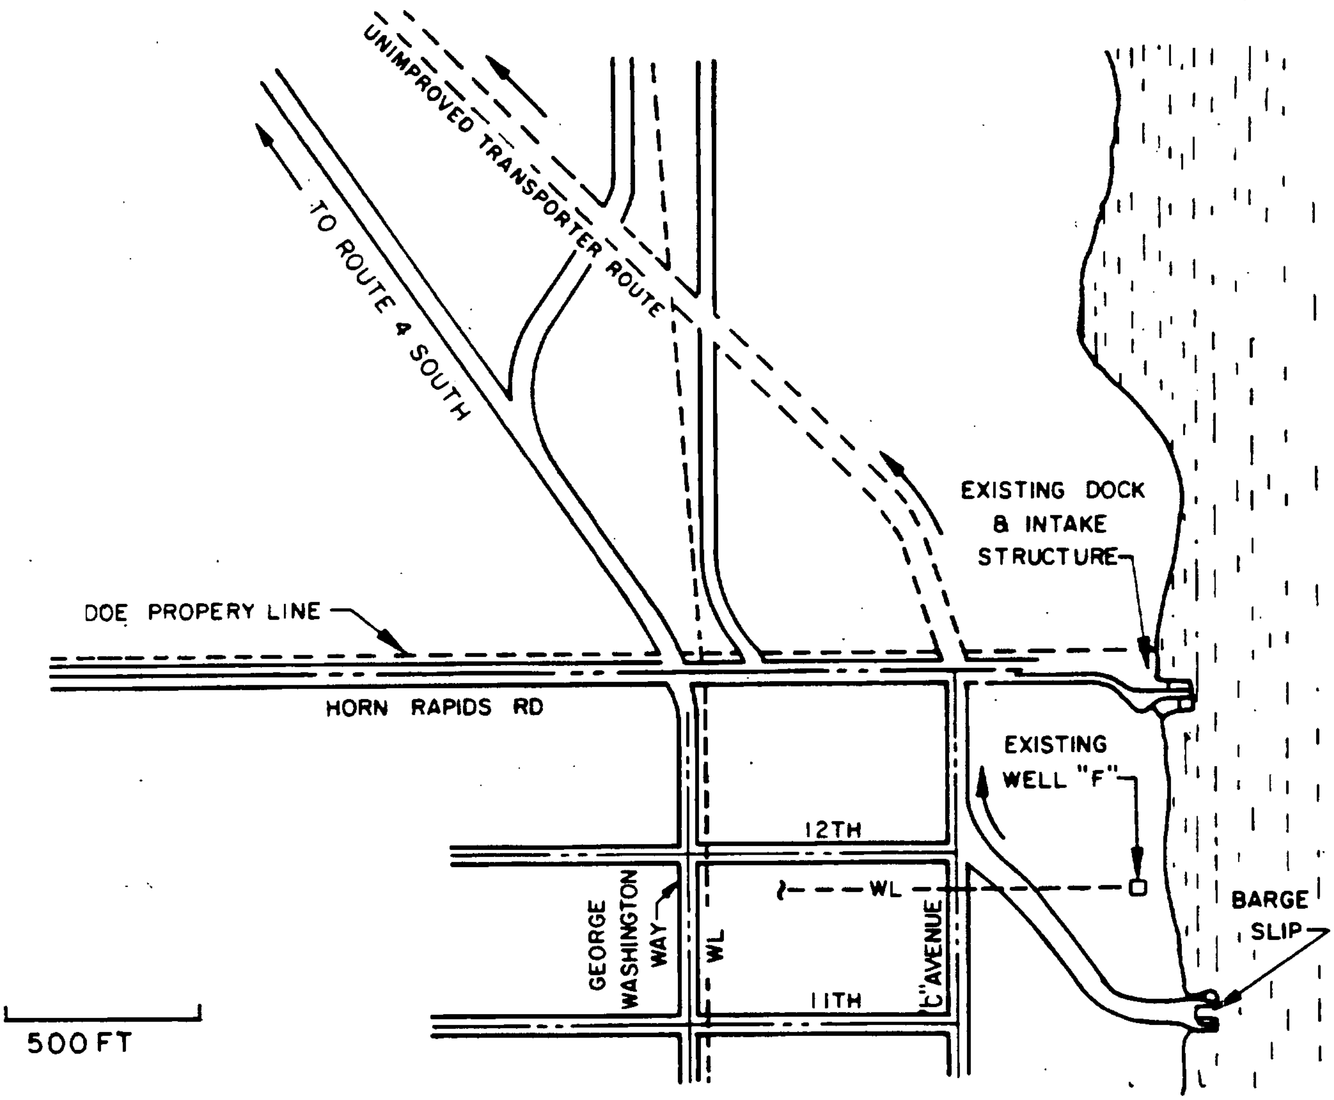

Figure B-4. Debarkation Area at Port of Benton

Several railroad tracks would be crossed on either route. These would pose no problem except three of the crossings have signals on arms cantilevered over the roadway. It appears that the crawler could be maneuvered around these obstructions, although it may be more appropriate to arrange to loosen four clamp bolts and swing the arms out of the way.

The load carrying capacity of the unloading dock and all roadways would need to be evaluated prior to accomplishing the haul to the burial site. A preliminary road investigation has been conducted by the Department of Energy, Hanford. However, a final evaluation would need to be made by an architect engineer, similar to the Road Evaluation Study made in 1973 for transferring Fast Flux Text Facility components from the Port of Benton to the site.

Based on the cost of revising overhead utilities and provided the load bearing capacity of the road is adequate, the two lane Route 4 would be more appropriate for the crawler route to the burial site.

b. **Savannah River Plant.** The route from the proposed off-loading site, near the abandoned barge landing wharf area on the river, to the burial ground is approximately 9.3 miles long. (See Figure B-5.) The criteria used in selecting the route were to make maximum use of existing roads or right-of-ways and to keep the distance as short as practical.

There would be some environmental impacts resulting from using the anticipated route. Costs would be involved in raising or moving overhead utility lines, in improving some of the road surfaces, and in providing load distribution or reinforcing structures where the route crosses over underground piping. The land route would be entirely within the site which is a closed government site except for controlled through-traffic on South Carolina Highway 125 and the Seaboard Coastline Railroad, both of which would be crossed. The crossings would be scheduled to avoid periods of peak traffic and would be controlled to assure the safety of the parties involved. These impacts are similar to previous ones which occurred when large components for the Savannah River reactors were moved by barge and roadway to their present locations at the site. Details on the assessment of impacts on the floodplain and wetlands associated with the selection of the overland route are provided in Appendix L.

Starting at the proposed off-loading site on the river, the route would be as follows:

(1) Northeast along the dock access road for 0.3 mile to River Road. This road has a 21-foot wide pavement and is 33 feet wide shoulder-to-shoulder.

(2) Southeast on River Road for 0.6 mile to Road 3. River Road has a 21-foot wide pavement and is 33 feet wide shoulder-to-shoulder.

(3) Northeast on Road 3 for 2.3 miles to a 115 KV power line right-of-way. The width is adequate for the crawler.

(4) North on the 115 KV power line right-of-way for 0.4 mile to the start of Burma Road. There would not be a problem with interference of the power line along the right-of-way. The right-of-way would need to be bladed and widened at some points for the crawler.

(5) Northeast on Burma Road for 4.5 miles to four-lane Highway "C". The first 0.3 mile of Burma Road is paved. The next 1.1 miles is an abandoned dirt road that would need blading to permit crawler passage. The last 3.1 miles on the Burma Road is a recently improved dirt road and would be satisfactory. Large trucks have used this last portion of the road with no difficulty. The width is adequate for the crawler.

(6) Southeast on Highway "C" for 0.4 mile to a two-lane paved road, Highway "E". The width is adequate for the crawler.

(7) East on Highway "E" for 0.8 mile to the burial ground entrance. Highway "E" is a good paved two-lane road with a 21-foot wide pavement and is 33 feet wide shoulder-to-shoulder.

The personnel at the Savannah River Plant have stated that there would be no difficulty with blockage of two-lane paved roads for the time required for passage of the crawler.

To obtain the estimated 42-foot vertical clearance required for the loaded crawler, three 115 KV power lines may have to be raised, one on Road 3 and two on the Burma Road. Some guy wires for power poles along the 115 KV power line right-of-way would also have to be relocated or temporarily disconnected.

The tentative haul route crosses two cooling water supply lines, a 72-inch diameter line on River Road, and a cooling water lateral along the 115 KV power line right-of-way. A liquid transfer line in the burial ground would also be crossed. Additional investigation would be needed to determine the amount and method of bridging or strengthening that these underground lines would require.

Two sets of railroad tracks, one on Road 3 and the second in the burial ground, would need to be crossed.

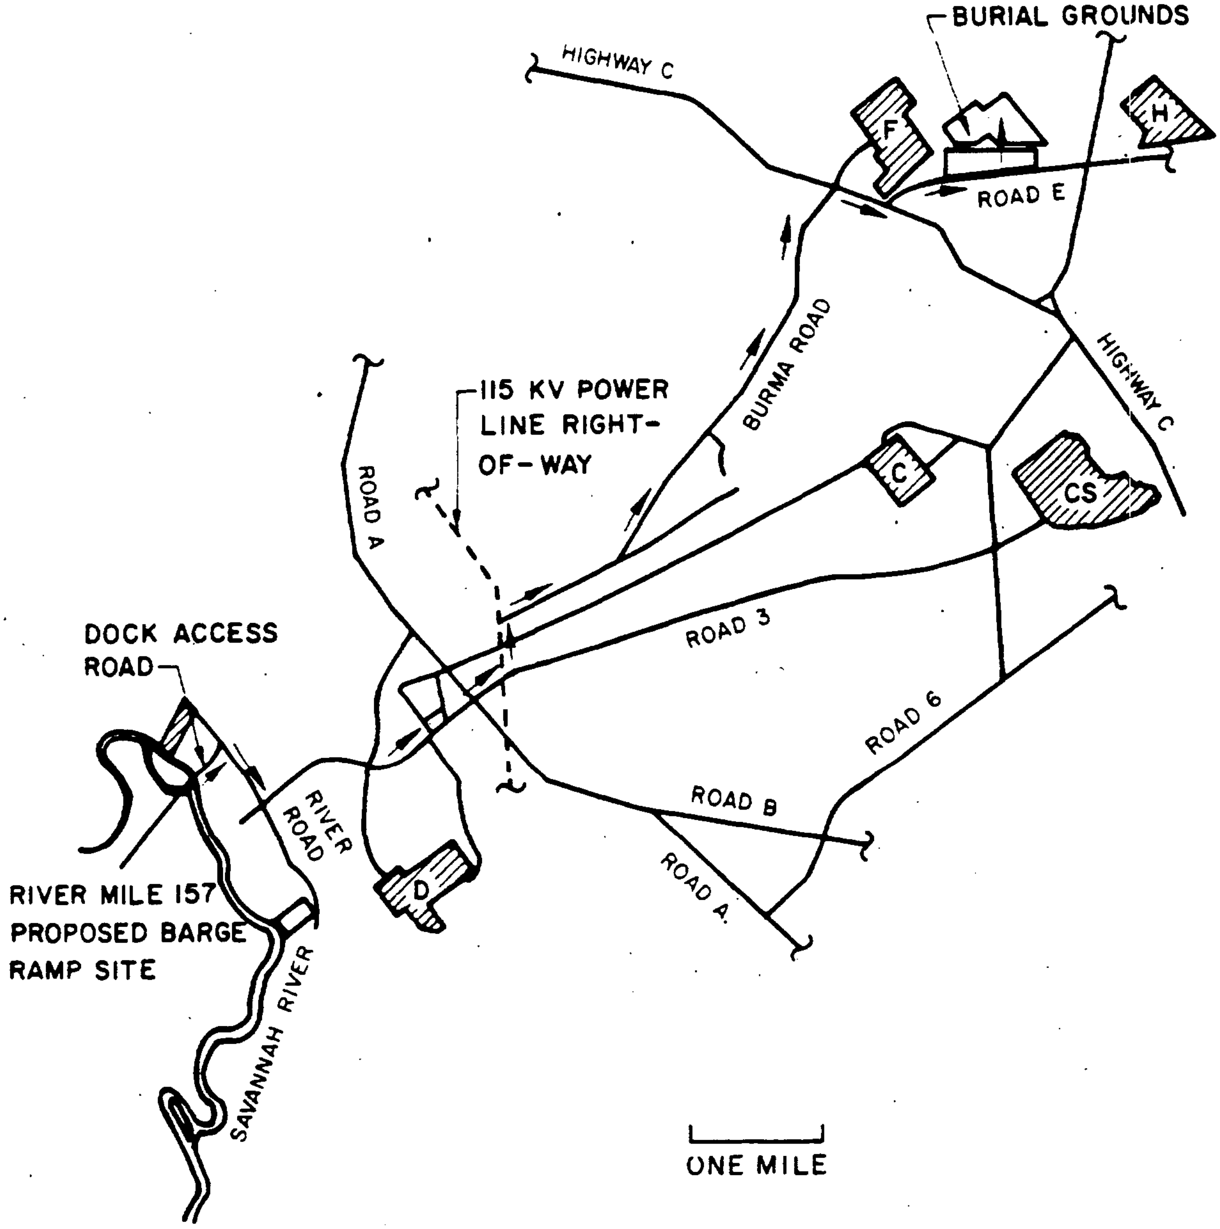

Figure B-5. Crawler Route at Savannah River Plant

E. BURIAL SITE OPERATIONS

1. Burial Site Soils

The proposed burial location for the Hanford Site lies along the west boundary of the 200W Separations Area. The site soil is sandy—gravelly having a water table level 250 feet below grade. This soil is very dry since the average rainfall (6.25 inches per year) does not penetrate to the groundwater table, but rather penetrates only to a shallow depth, and is subsequently given off from the ground surface by evaporation. The reactor compartment would be buried with a minimum cover of eight feet of soil to meet technical standards at the Hanford Site.

At the Savannah River Plant, technical standards require that all solid radioactive waste be stored with a cover of at least four feet of soil and with at least ten feet of undisturbed soil between the permanent groundwater table and the stored waste. An annual rainfall of 47 inches results in some perched water tables in the burial area. Excess surface water is controlled at the Savannah River Plant burial ground by the use of trenches dug around the burial areas.

2. Size of Pit

To allow maximum utilization of the burial ground, it is planned that a long trench would be dug to allow placement of a number of reactor compartments in a row. The bottom of the trench would be flat and approximately 42 feet wide. Entry to the trench would be via a ramp with a 5 to 6 percent grade. For the most economical use of the burial ground, additional rows of reactor compartments would be buried adjacent to the first row. If this scheme were used, the first row would only be partially backfilled initially to allow access to the adjacent second row. It is estimated that approximately 12 reactor compartments could be buried adequately in one acre of ground, and that eight to ten acres would be sufficient to bury 100 compartments.

At Hanford, concrete blocks would be placed to support the reactor compartment when the load is transferred from the crawler by jacking. Due to the nature of the soil, the trench sides would slope outward at 45° Excavation would be accomplished using the Hanford Site's dragline equipment.

At the Savannah River Plant, the reactor compartments would be jacked down to pier supports at the bottom of the trench after the load was transferred from the crawler to temporary blocks and the crawler was removed. The sides of the trench could be almost vertical because of soil conditions in the area. Other considerations of the trench would be similar to those for the Hanford Site. The trench would be prepared using local grading equipment.

3. Unloading Compartment from Crawler

Burial would be accomplished by driving the crawler, with attached reactor compartment, down a dug ramp and into the trench between preplaced pier supports. When in position, jacks would be used with blocking and cribbing to raise the compartment to allow removal of the crawler from the trench. The compartment would then be lowered and secured to the pier supports.

The trench would be backfilled to bury the reactor compartment with the required amount of soil coverage using equipment available at the site.

F. SAFETY OF TRANSPORT

Detailed engineering studies have been performed to assess the safety of shipping a deactivated submarine reactor compartment to a land burial site. The packaging and transportation would be governed by the requirements specified by Title 10, Code of Federal Regulations, Part 71 (10CFR71), Reference B.7. The results of the engineering studies indicate that the shipment would comply with all specified requirements. If the land disposal option is employed, the Navy would satisfy all requirements of the Nuclear Regulatory Commission Transportation Certification Branch to obtain approval for the use of the reactor compartment package for shipment of radioactive material. Specific information from the engineering studies is summarized below.

The reactor compartment was analyzed for use as its own shipping and disposal package. The cylindrical pressure hull together with the forward and aft bulkheads would be the containment boundaries for the reactor compartment. Requirements for the containment of radioactive material being transported under normal and accident conditions are specified by 10CFR71. Both normal and accident transport conditions are discussed below.

1. Normal Transport

The shipment would comply with the requirements for normal transport conditions as specified by 10CFR71. The requirements involve evaluating the reactor compartment under free drop, puncture, heat, cold, pressure, water spray, and vibration conditions and then comparing the results with specific requirements for normal transport.

If the reactor compartment were to fall 1 foot, the hull would be deformed locally approximately 2 3/8 inches, and the contents of the reactor compartment would experience an impact deceleration of 11 g. There would be no significant damage because the local deformation would not affect the integrity of the containment, and the calculated deceleration would be much lower than the design shock load for submarines. Additionally, it would be expected that the reactor compartment would not be able to drop a distance of 1 foot. During disposal operations which involve raising or lowering the reactor compartment, jacking and blocking would be such that no more than a 1-inch free drop could occur.

Reactor compartment integrity was also assessed by evaluating the effect of various impact conditions which might cause the reactor compartment to be punctured. One hypothetical impact condition involved striking the exposed bulkhead with a 150-pound bar, 6 inches in diameter, having the energy equivalent to a 15-foot free drop. The results indicated that the energy of the bar would be approximately 30 percent of the minimum energy required to puncture the bulkhead and no puncture would occur. A second impact condition involved striking the area which would be most vulnerable to penetration with a 13-pound steel cylinder, 1 1/4 inches in diameter, dropping from a height of 40 inches. The area most vulnerable to penetration is the bulkhead, and the results indicate that the energy of the steel cylinder would be approximately three percent of the minimum energy required to puncture the bulkhead and no puncture would occur.

If the reactor compartment were subjected to an ambient temperature of 130°F in direct sunlight, the structures in the reactor compartment would achieve a temperature of less than 187°F. Structures inside the reactor vessel would be heated further by the energy released by the normal processes of radioactive decay. The heat produced would be mostly due to the decay of Cobalt-60 and would produce a temperature of less than 530°F in the hottest part of these structures. These temperatures are less than normal service temperatures and would cause no damage to the reactor compartment. The associated pressure increase would be less than 27 psia, would be well within the design capability of the reactor compartment, and no damage would occur.

If the reactor compartment were subjected to an ambient temperature of −40°F, differential thermal contraction may cause local yielding, but it is not expected to affect the integrity of the reactor compartment. Additionally, the steels which make up the hull and bulkheads have good material properties at temperatures lower than −40°F; therefore, no brittle fracture failures would occur.

If pressure equal to 0.5 standard atmospheric pressure (7.4 psi), were applied either on the outside or on the inside of the reactor compartment, there would be no damage to the reactor compartment.

If the reactor compartment were subjected to water spray sufficiently heavy to keep the entire exposed surface continuously wet for 30 minutes, no water would be able to enter the reactor compartment because it would have been closed and sealed at the shipyard. Additionally, the reactor compartment would be tested for leaks prior to shipment.

During normal transport, the reactor compartment would be subjected to vibrations over a broad spectrum of frequencies. Conservative calculations were made to determine what frequencies would occur during shipment for disposal, and those frequencies were compared to the design limits for the reactor compartment. The results showed that the vibrations incurred in transporting the reactor compartment would occur at frequencies that would be less than one-fourth of the design frequencies of the reactor compartment and reactor compartment components. Therefore, there would be no resonance and no damage to the reactor compartment would occur due to vibration.

Radiation levels outside the reactor compartment during normal transport conditions would not exceed the criteria specified in Title 49, Code of Federal Regulations Part 173 (49CFR173), Reference B.8, which require that the radiation levels not exceed 10 mrem per hour at 6 feet from the hull or 200 mrem per hour on contact with the package surface. Conservative shielding calculations demonstrated that these requirements would be satisfied. Additionally, a detailed radiation survey at the shipyard would be performed before transport to confirm that the radiation levels would be within the requirements.

2. Accidents

The engineering studies also showed that the shipment would comply with the requirements for hypothetical accidents specified in Appendix B of 10CFR71, Reference B.7. The requirements involve evaluating the reactor compartment under free drop, puncture, and thermal accident conditions and then comparing the results with specific requirements.

If the reactor compartment were to fall 30 feet onto an unyielding surface, the maximum dynamic impact force would occur on the aft bulkhead in an end drop orientation. This would do the most damage to the internal components and some of the components might break free of their foundations. These internal components would not break through the pressure hull or the bulkheads due to the bluntness of the components and the strengths of the hull and bulkhead materials. The reactor vessel would not be damaged and would remain in its normal position. As a result, the reactor compartment containment would not be ruptured.

If the reactor compartment were to fall 40 inches onto a 6-inch diameter mild steel bar mounted vertically on an unyielding horizontal surface, the hull would probably be punctured. The bar would not penetrate the reactor vessel but it might puncture the shell of the steam generator and some of the heat-exchanger tubes might be ruptured, depending on the orientation of the drop.

Since the reactor compartment containment could be penetrated by the accident conditions identified above, a conservative estimate of the radioactivity which might be released under these accident conditions was made. The results of this analysis were then compared to the allowable limits specified in 10CFR71 and are presented below.

More than 99.8 percent of the radioactive material in the reactor compartment is due to neutron activation of the structural materials within the reactor compartment. This radioactive material cannot become loose and be released from the reactor compartment under accident conditions. Only the surface-deposited activated corrosion products could potentially become available for release.

The activated corrosion products amount to a total of approximately 66 curies of radioactive material. This material consists of normal corrosion and wear products, originally carried by the reactor coolant, which had adhered to all wetted surfaces inside the reactor vessel, pipe walls, and steam generators. Most of this material is tightly adherent and only a small fraction would be released if a severe shock to the reactor compartment were to occur. In developing an estimate of the activity to be released, it has been conservatively assumed that 33 percent of the deposited activity is "loose" and would be available for potential release under accident conditions. The amount of loose activity assumed represents an upper limit based on shock tests, and the actual amount of loose material present would be expected to be less than 33 percent.

Because of the complex geometry of the primary coolant system, only a small fraction of the loose material could be released under accident conditions. It was conservatively assumed that 100 percent of the loose activity in the steam generators, and 20 percent of the loose activity in the reactor vessel, purification system, and main coolant piping could enter the reactor compartment.

Only a small fraction of the radioactivity that could enter the reactor compartment could be released to the environment because the release paths would be blocked by shut valves, welded closures, and similar barriers. Since the majority of the time in transport would be over water, it was conservatively assumed that the reactor compartment would be immersed in water during this accident. This could allow approximately 50 percent of the radioactivity loose in the reactor compartment to be released to the environment.

Based on the conservative assumptions presented above, a maximum total of approximately 3.5 curies could be released to the environment due to these hypothetical accidents. This amount would be less than 10 percent of the limit specified by 10CFR71. Additionally, the requirements in 10CFR71 specify that of the total number of curies released, only certain amounts of specifically grouped radionuclides can be released. The total was broken down into the radionuclide groups specified and the results showed that the amount of grouped radionuclides released would be less than 25 percent of the limits specified by 10CFR71.

If the reactor compartment were subjected to a 1475°F fire during an accident, there could be some melting of the lead shielding in the reactor compartment. The remainder of the reactor compartment would not be materially altered by the fire. Since some of the lead shielding could be melted and the containment of the reactor compartment could be penetrated as a result of the other hypothetical accidents identified above, a shielding evaluation was performed to determine external radiation levels.

The requirements in 10CFR71 specify that, under hypothetical accident conditions, the maximum radiation level at 3 feet from the hull must not exceed 1000 mrem per hour. It was conservatively assumed in the shielding calculations that no lead shielding would remain in place in the reactor compartment. The analysis showed that a maximum radiation level of 988 mrem per hour at 3 feet from the hull could occur; therefore, the requirements of 10CFR71 would be met. The actual presence of some of the lead shielding would lower the actual radiation levels compared to the calculated levels.

The potential structural damage to the reactor compartment and its contents is concluded to cause no condition which would exceed specified limits for normal transportation and hypothetical accident conditions. All analyses were done conservatively to ensure that the conclusions based on them would be safe ones.

G. MONITORING

Both Hanford Site and Savannah River Plant monitor their areas for potential releases of radioactivity to the environment, and they periodically report the results of their environmental monitoring in several series of reports:

1. Hanford Site

a. Groundwater data and evaluations are reported in the series, "Radiological Status of the Groundwater Beneath Hanford Project for . . . (the specified period)."

b. Data from locations within the plant boundaries are presented in the annual "Environmental Status of the Hanford Reservation for . . . (the specified period)."

c. Data from offsite locations are presented in the annual "Environmental Surveillance at Hanford for . . . (the specified period)."

d. Summary information is available in Reference B.1.

2. Savannah River Plant

a. Offsite data and evaluations are reported in the annual "Environmental Monitoring in the Vicinity of the Savannah River Plant. Annual Report for (the specified year)."

b. Summary information is available in Reference B.3.

The results of these evaluations are summarized in Table B-3 which lists the population doses for the areas surrounding the two sites due to their total operations. References B.1 and B.3 should be consulted for details regarding the calculation of these results. Further information on monitoring the disposal sites is provided in Appendix K (Monitoring Program).

TABLE B-3. SUMMARY OF POPULATION DOSES AT HANFORD AND AT SAVANNAH RIVER

Site:	Hanford	Savannah River
Natural Background, man-rem/yr	27,000	86,000
Maximum Due to Operations:		
Whole Body, man-rem/yr	2.5	131
Thyroid, man-rem/yr	12	73
Lung, man-rem/yr	2.5	0.004

IV. BACKGROUND

This section provides background information that would be useful to most readers, but might not be readily available.

A. TRANSPORT BARGE

A flat deck ocean barge would be used to transport the reactor compartments to the burial site. This barge would be required to have a deck load rating of approximately 20,000 pounds per square foot, and to be capable of remaining stable after sustaining damage that would flood two of its watertight compartments if it were in an accident. The maximum sized barge which could be fully grounded at the existing barge slip at the Port of Benton and the proposed Savannah River unloading sites is 60 feet by 150 feet. However, by using special grounding techniques, a longer barge could be accommodated. The maximum barge height which could be used for Savannah River transports would be limited to 13 feet because of the minimum bridge clearance of 38 feet at low water at River Mile 61.5. A similar barge height restriction does not exist for barge transport on the Columbia River.

Demurrage rates for a 204 foot × 47 foot × 12.75 foot barge, for example, would be about $700 a day based on a 60-day use. Transportation of such a barge from the East Coast to Bremerton, Washington would take approximately 25 days and cost about $210,000 (this includes barge demurrage for the 25 days). If the barge were needed at Puget Sound for 60 days to load the reactor compartment, transport the reactor compartment to Hanford and unload, the cost would be approximately $250,000 for the 60-day period.

Over a period of 20 years, assuming that 1 1/2 ships per year would have the reactor compartment removed and disposed of, and that the barge would be available locally after the first usage, the total cost of renting the barge is estimated to have a present value of $6.3 million.

The cost of constructing a barge for the purpose of transporting reactor compartments has also been investigated. The barge would be designed for a 20,000 pounds per square foot deck loading and would be constructed with two longitudinal watertight bulkheads and transverse watertight bulkheads every 30 feet of barge length. The outboard compartments would be cross-connected with 6-inch diameter piping to prevent listing in the event of rupture of an outboard compartment. The proposed barge would have the basic dimensions of 150 feet × 48 feet × 12.75 feet and would displace 360 tons. The barge with a 1000-ton load would have a draft of about 7 feet-6 inches, leaving a freeboard of 5 feet-3 inches. The barge materials would be mild steel.

The cost for constructing the 150 foot × 48 foot × 12.75 foot barge was estimated to be $2.9 million in 1981 dollars. Maintenance was estimated at $8,800 per year. Over a 20-year period, the total cost of building and maintaining a barge would have a present value of approximately $3.0 million. The cost of constructing a larger barge, one that would be capable of carrying two reactor compartments, would be approximately $5.7 million, and would be advantageous in reducing the associated costs of towing and transporting each reactor compartment.

B. USE OF CRAWLER FOR MOVEMENT OF HEAVY LOADS

Wheeled vehicles were initially used to transport heavy loads such as reactor vessels. These vehicles were very complex, required extensive road preparation, and reached a practical load limit at about 600 tons.

The introduction of crawlers in the early 1970's has allowed the overland transportation of loads in excess of 1000 tons. The crawlers used to transport 1000-plus-ton loads are fairly compact and simple. Figure B-6 shows the basic configuration and dimensions of a 1000-ton crawler. After an evaluation of the crawlers design specifications, reviewing the history of previous loads moved by crawlers, and observing crawlers at work moving 1000-plus-ton prefab modules onto barges for shipment to Prudhoe Bay, Alaska, the crawler method was selected for compartment transportation. The Lampson 1200-ton transporter from Neil F. Lampson Inc., Kennewick, Washington, was selected as the reference compartment transport vehicle (other firms' equipment would be considered if and when it becomes available). The 1000-ton crawler is illustrated in Figure B-6.

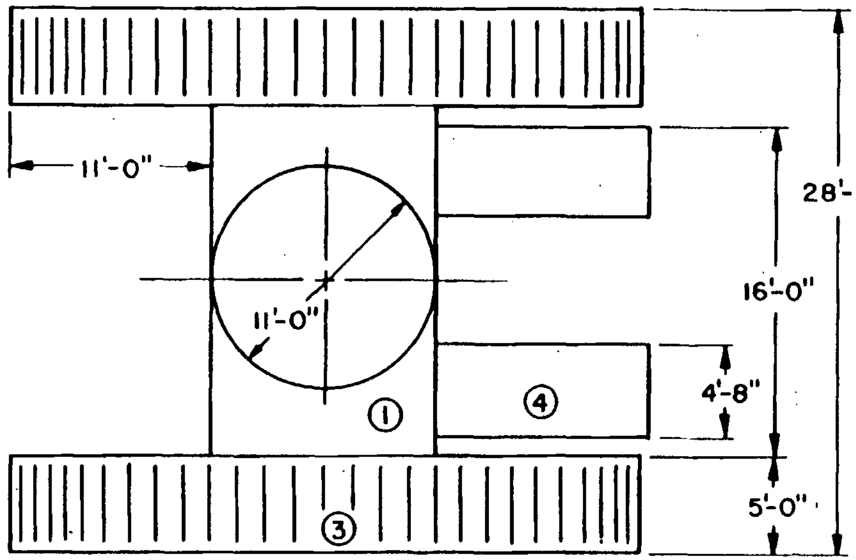
Features of these vehicles are as follows:

Each track is individually powered allowing positive steering by counter rotation of tracks. Due to the transmission used, steering through turns is continuous, smooth and gradual using torque and throttle without brake application.

The final drives produce over a million pound-feet of torque—the crawlers are not limited by power, only by traction, on very steep inclines.

The crawlers are very stable, due to their large track area, and are capable of operating on grades up to 12 percent with full load, although 5 or 6 percent grades would be the maximum recommended when transporting the compartment.

Track loading of the road surface would be approximately 60 pounds per square inch; this is comparable to that of commercial trucks and is compatible with most road surfaces. Some scuffing of the road surface would be experienced due to the steel treads, however, protective measures, such as placement of strips of rubber conveyor belting under the treads, would be employed where scuffing is unacceptable. Steel plate turning mats would be employed where scuffing damage must be avoided when steering the crawlers through tight turns.



SUBASSEMBLIES

		WT, LB	QTY
(1)	CAR BODY	62,000	1
(2)	SIDEFRAME	65,000	2
(3)	TRACK	35,000	2
(4)	POWER UNIT	18,000	2

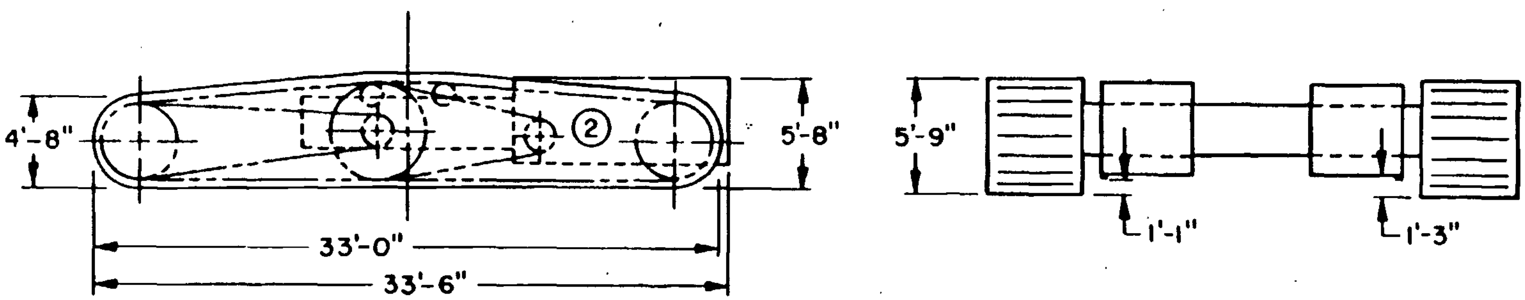


Figure B-6. Crawler Transporter (1000-Ton Capacity)

The 1000-ton crawler weighs about 150 tons and is composed of five pin-connected sections and the two steel tracks. The heaviest section is the side frame which weighs 33 tons each. The sections are shipped by truck (four truck loads) and can be assembled in about eight hours.

The 1200-ton crawler has a tested capacity of 1320 short tons and would meet the nuclear requirement that the maximum loading not exceed 80 percent of tested capacity. The expected weight of the reactor compartment is 964 short tons; 80 percent of the tested capacity of the crawler is 1056 short tons, a margin of 10 percent above the nuclear requirement.

The cost of renting a 1200-ton transporter would be approximately $30,000 per month and the purchase price would be approximately $800,000.

C. REGULATIONS APPLICABLE TO SHIPMENT OF REACTOR PLANTS FOR DISPOSAL

1. Introduction

This section reviews the applicable Federal and State regulations which would have to be met in transporting a decommissioned reactor plant to the disposal site, using a shipment from Puget Sound Naval Shipyard to the Hanford Site as an example. For the purposes of this review, it was assumed that a reactor compartment, when mounted on a barge, would be moved via tugs from the shipyard through Puget Sound, the Straits of Juan de Fuca, down along the Washington Coast and up the Columbia River to the Port of Benton dock just north of Richland, Washington. The reactor compartment would then be transported via a crawler type transporter from the Port of Benton to the burial site at Hanford.

2. Applicable Regulations

The U. S. Department of Transportation has regulatory responsibility for safety in the transportation of hazardous materials (except postal shipments) by all modes of transport in interstate or foreign commerce (rail, road, air, water) and by all means (truck, auto, ocean vessel, airplane, river barge, rail car, etc.). These regulations are promulgated by Reference B.8.

Part 172 of Reference B.8 designates radioactive material as a hazardous material for the purposes of transportation in commerce. Regulations of this part also cover the preparation of shipping papers, marking, labeling, and placarding requirements. Part 173 of Reference B.8 specifies packaging requirements that must be met by the shipper when preparing hazardous material for shipment. In the case of the subject shipment, the U. S. Navy, Naval Sea Systems Command would have responsibility as the shipper. The shipyard would transfer legal custody for a radioactive waste shipment to the organization responsible for disposal prior to departure of the shipment from the shipyard. It is also indicated in Part 173 of Reference B.8 that shipments of hazardous materials by the Department of Defense (DOD) must be packaged in accordance with these regulations or in containers of equal or greater strength and efficiency as required by DOD regulations. Additionally, the Navy requires that radioactive material shipped from shipyards be in accordance with Reference B.8.

Parts 176 and 177 of Reference B.8 prescribe requirements that must be observed by commercial carriers with respect to the transportation of hazardous material by vessel or motor vehicle, respectively. It is noted that Part 176 does not apply to public vessels (e.g., U.S. Navy vessels) not engaged in commercial service. The applicability of Part 176 will depend on whether the subject shipment is made using Navy vessels or is contracted to a commercial tug company.

The U.S. Nuclear Regulatory Commission (NRC) has responsibility for safety in the possession and use, including transport, of by-product, source, and special nuclear materials. In Reference B.7, the NRC has established requirements which must be met for its licensees to transport or deliver to a carrier quantities of licensed materials in excess of Type A quantities. One of these requirements is that the licensee shall not transport or deliver any licensed materials to a carrier except as authorized in a general or specific license issued by the NRC. Although the U.S. Navy is not a licensee of the NRC by virtue of the Atomic Energy Act of 1954 as amended, in certain instances Reference B.8 requires the use of packaging which meets the pertinent requirements of Reference B.7.

The states of Oregon and Washington have entered into formal agreements with the NRC by virtue of the Atomic Energy Act of 1954 as amended, whereby the regulatory authority over by-product, source, and less than critical quantities of special nuclear material has been transferred to the states from the NRC. These "Agreement States" have adopted uniform regulations pertaining to intrastate transportation of radioactive materials which require the shipper to conform to the packaging, labeling, and marking requirements of the DOT (i.e., Reference B.8) to the same extent as if the transportation were subject to the rules and regulations of that agency. The only exception is that any notification of incidents referred to in Reference B.8 are also to be filed with the cognizant state agency. In the state of Washington, these regulations are contained in the Washington Administrative Code ("Radiation Control Agency"). In Oregon the regulations are published by the Oregon State Health Division.

The U.S. Coast Guard has responsibility for enforcement of the regulations governing the water shipment of hazardous materials in accordance with Part 176 of Reference B.8. The shipping route of the cited example would fall under the jurisdiction of the Thirteenth Coast Guard District for shipments that would originate at Puget Sound Naval Shipyard, for example, as indicated in Reference B.11. The portion of the cited shipping route from Puget Sound Naval Shipyard to the 47°32'N latitude off the Washington Coast is within the Seattle Marine Inspection Zone and the Seattle Captain of the Port Area. The remainder of the route falls within the Portland Marine Inspection Zone and the Portland Captain of the Port Area.

The U.S. Coast Guard also has the authority to issue rules and regulations pertaining to the operation of drawbridges. The rules governing the operation of drawbridges on the Columbia River are provided in Part 117 of Reference B.11. These rules specify call signals, the requirements for advance notification, and the hours of drawbridge operation.

The Corps of Engineers has jurisdiction over the navigation locks on the Columbia River. In Part 207 of Reference B.12, rules are provided for navigating each of the locks on the Columbia River.

3. Shipper Requirements

Part 173 of Reference B.8 prescribes certain requirements to be observed by shippers in preparing radioactive materials for shipment. The steps involved include identifying the type of radionuclides that are to be shipped, the quantity of radionuclides, and whether the material is "special form" or "normal form." From this information a determination would be made as to the packaging requirements.

a. **Radionuclides.** The radionuclide content of a typical submarine reactor plant at six months after final operation is presented in Table 1-1 of Chapter 1.

b. **The Form of the Radioactive Material.** The radioactive material in a deactivated reactor plant would be classed as "normal form" since it is not considered that it would qualify as "special form" as defined in paragraph 173.389(g) of Reference B.8. Normal form radioactive materials are classified into seven "transport groups" according to their radiotoxicity and their relative hazard in transportation. As indicated by paragraph 173.390 of Reference B.8, the radionuclides in a deactivated reactor plant fall into transport group IV, with the exception of Cobalt-60 which because of its higher radiotoxicity falls into transport group III. Package quantity limits are a function of the transport group for normal form radioactive material (i.e., the lower the transport group the lower the limit).

c. **Packaging Requirements.** For shipping purposes, the complete deactivated reactor compartment is considered to be a single package composed of its radioactive contents and packaging. The radioactive contents would include the entire reactor plant system which is radioactive as the result of neutron activation. The ship's hull and the forward and after reactor compartment bulkheads when suitably sealed would provide the packaging. Since the quantity of radioactivity (i.e., transport groups III and IV) exceeds 200 curies, the package contents would be classed as a "large quantity of radioactive material in normal form." Such material must be packaged in accordance with the requirements of paragraphs 173.393, 173.395, and 173.398 of Reference B.8. These include general packaging and shipping requirements, special packaging test requirements, and the requirement that the packaging meet the pertinent requirements of Reference B.7. These include general packaging standards, structural standards, and evaluation of the package against standards for normal conditions of transport and hypothetical accident conditions.

d. **Compliance with Packaging Requirements.** The previous section defined the applicable package requirements for the type, quantity, and form of radioactive material to be shipped when disposing of a decommissioned reactor plant. In normal situations, packaging designers would design the packaging around these requirements. However, in the case of a decommissioned reactor plant where the hull and reactor compartment bulkheads would be utilized as the packaging, an assessment was made to determine that this approach would meet the applicable packaging requirements, as described above in Section III.F. The reactor compartment package would meet the established burial ground packaging requirements.

e. **Labeling and Marking Requirements.** As required by paragraph 172.300 of Reference B.8, the subject package must be plainly and durably marked on the outside of the package to indicate the following information:

(1) The proper shipping name (i.e., Radioactive Material, n.o.s.).

(2) The name and address of the consignee or consignor.

(3) The gross weight of the package.

As required by paragraph 172.400 of Reference B.8, the subject package would require a "Radioactive Yellow—III" label affixed to opposite sides of the package near the marked proper shipping name. The following information is to be entered on the label: (1) the names of the radionuclides, (2) the number of curies, and (3) the transportation index.

f. **Shipping Papers and Shipper's Certification.** As required by paragraph 172.200 of Reference B.8, each person who offers radioactive material for transportation shall describe the material on the shipping papers. For shipment by water, the shipping papers are to include the following information:

(1) The proper shipping name (i.e., Radioactive Material, n.o.s.).

(2) The total quantity (by weight, volume, or as otherwise appropriate) of the hazardous material.

(3) The name of each radionuclide in the radioactive material (e.g., see Table 1-1 of Chapter 1).

(4) A description of the physical and chemical form of the material (e.g., activated reactor components and metal corrosion and wear products).

(5) The activity content of the package.

(6) The category of label applied to the package (i.e., "Radioactive Yellow—III").

(7) The transport index assigned to the package.

(8) A notation of the package identification marking as prescribed in the applicable NRC approval.

(9) The type and gross weight of the package.

(10) The shipper's signed certification that the material is properly classified, described, packaged, marked, and labeled and is in proper condition for transportation.

(11) The name of the shipper.

g. **Notifications.** Page 124 of Reference B.11 requires that a vessel carrying radioactive material on board notify the applicable Coast Guard Captain of the Port at least 24 hours in advance of arrival in the area. This notification is to include the amount and stowage of the material. It would be expected that this notification would be made to the appropriate Captains of the Port Areas prior to the subject shipment leaving the shipyard.

4. Carrier Requirements

a. **Methods of Transport.** The disposal of a decommissioned reactor plant would involve two methods of transport. For example, during a transport from Puget Sound Naval Shipyard to Hanford, the major portion of the trip would be via barge from the shipyard to the Port of Benton and the remainder of the trip would be overland via crawler from the Port of Benton to the burial site. The requirements applicable to commercial carriers for the transport of radioactive material by vessel are contained in Part 176 of Reference B.8. The overland portion of the trip would start just outside the boundaries of the Hanford Site and the requirements for carriage of radioactive materials on the public highways contained in Part 177 of Reference B.8 would be applicable.

b. **Acceptance Requirements.** The carrier may not transport a hazardous material unless the material is properly described on the shipping papers and the shipper's certification has been provided that the material is properly classified, described, packaged, marked, and labeled. The shipper would provide this information to the carrier at the shipyard assuming the services of a commercial tug company were utilized. If Navy tugs were used, this information would be provided to the company providing the crawler service when the package was off-loaded at the destination site.

c. **Barge Requirements.** Subpart F of Part 176 of Reference B.8 specifies classes of barges which are authorized for the transportation of hazardous materials and prescribes certain applicable conditions. The barge proposed for transport of a decommissioned reactor plant would be classified as Class "A" with "AA" hull. This type of barge is authorized for transport of radioactive materials with the condition that outside containers vulnerable to damage by water may not be used. Since the outside of the subject package is of all metal construction with all closures seal welded, this condition would be satisfied.

d. **Inspection Requirements.** Part 176 of Reference B.8 requires that an inspection of the cargo on an unmanned vessel must be made after stowage has been completed to ensure this stowage has been accomplished properly and that there is no visible sign of damage to the packages or evidence of heating, leaking, or sifting. This is to be made by the individual who is responsible to the carrier and who is in charge of loading the cargo. Although for this particular situation the carrier would not be in charge of the loading (i.e., assuming the Navy does not take on the role of the carrier), it is expected that the carrier would inspect the load prior to departure from the shipyard.

e. **Placarding.** In accordance with subpart F of Part 172 of Reference B.8, the barge would not require placarding. The crawler would have to be placarded on each side and each end with "Radioactive" placards. The shipper would have to provide the necessary placards.

f. **Dangerous Cargo Manifest.** Part 176 of Reference B.8 requires that the master of a vessel transporting radioactive material prepare a dangerous cargo manifest. The carrier must keep the manifest on the vessel during transport and retain a copy of it for inspection one year thereafter. The information required on the manifest is in general similar to that provided on the shipping papers.

g. **Emergencies, Accidents, and the Reporting of Incidents.** Part 176 of Reference B.8 indicates that when an accident occurs on board a vessel involving hazardous material, the master is to adopt such procedures as will, in his judgment, provide maximum safety for the vessel and its crew. Also, hazardous material may be jettisoned only if the master believes this action to be necessary to prevent or substantially reduce a hazard to human life or reduce a substantial hazard to property. When a hazardous condition exists on a vessel transporting hazardous material, the master is to notify the nearest Captain of the Port as soon as possible and shall comply with his instructions.

For highway shipments, the carrier must notify the shipper at the earliest practicable moment following any incident in which there has been breakage, spillage, or suspected radioactive contamination involving radioactive material shipments. If radiological advice or assistance is needed, the Department of Energy Regional Office for Radiological Assistance is to be notified.

The carrier is to notify the DOT as soon as possible after each incident that occurs during the course of transportation in which, as a direct result of hazardous materials, (1) a person is killed or hospitalized, (2) property damage exceeds $50,000, and (3) fire, breakage, spillage, or suspected contamination occurs involving radioactive material. Each carrier is to submit a detailed hazardous materials incident report to the DOT within 15 days of such an incident. State authorities may also need to be notified.

APPENDIX C

DOSE COMMITMENT ESTIMATES, LAND DISPOSAL

I. INTRODUCTION

This appendix describes the estimation of possible long-term dose commitments that might occur as a result of land disposal of the reactor compartments of defueled and decommissioned nuclear submarines. The appendix also describes the transportation-related public exposure and the method used to estimate possible immediate effects of surface-deposited radioactive material (crud) that might be released to the environment as a result of a postulated extreme accident during land disposal operations.

For the radionuclides contained within the buried reactor compartment to reach man, the following events would have to occur. First, the reactor compartment outer boundary (pressure hull and bulkheads) would have to be penetrated by corrosion. This outer barrier is estimated to remain intact for at least 200 years, based on a thickness loss rate of 0.0025 inch per year, as described in Appendix F. Normal expectation is for the buried compartment to remain unpenetrated for an indefinite time, probably many centuries.

Second, water would have to flow through the corroded outer boundary and then corrode the components within the compartment. Small quantities of radioactive material might then be released, but over 98 percent of the initial radioactivity would be untouched for more than 2000 years after the outer barrier is penetrated because it is contained within the several-inch-thick reactor vessel. The result of this long delay before significant exposure of radioactive components to groundwater would be that almost all of the radioactive material, except the long-lived Nickel-59 and small amounts of Carbon-14, Nickel-63, and Niobium-94 would have decayed to stable form prior to release. (See Table C-1.)

Third, the groundwater would have to carry the radioactive corrosion products, most of which would be insoluble, away from the immediate disposal site to water supplies available to man. In estimating the effect on average individuals, it has been assumed that all of the radioactive material released by the corrosion process would reach a nearby river (Savannah River or Columbia River, depending on the disposal site) which would then be the major pathway to the general population. An alternate pathway is also assumed in order to determine the dose commitment to maximum-exposed individuals. This alternate pathway has been assumed to be either a well or a local stream passing through the burial site and entraining all of the radioactive material released from as many as ten of the buried reactor compartments. (See Section V.)

It has been assumed that all of the radioactive corrosion products would be dissolved or suspended uniformly in the groundwater and that this water would flow into the river, local stream, or well where it might become available for consumption and use by individual users. No credit is taken for retardation and diminution of the radionuclides by such mechanisms as absorption by soil particles, deposition in stream or river beds, and removal of radioactive material by water treatment systems that may be employed by downstream users. The resulting estimates of radiation exposure are shown to be conservative when compared (see Section VIII) with similar exposure estimates based on methods provided in the U.S. Nuclear Regulatory Commission generalized Environmental Impact Statement on Land Disposal (Reference C.1).

The exposure estimates are conservative (i.e., high) due to simplifications that do not take into account various factors that would actually lead to reduced exposure.

II. RADIOACTIVE MATERIAL RELEASE ASSOCIATED WITH NORMAL LAND DISPOSAL OPERATIONS

Table C-1 lists both the maximum annual radioactive material release estimates by individual nuclide, and the total release estimated to occur over all time. The tabulated values were calculated with the corrosion release model employed for sea disposal release estimates (Appendix G) with the following differences. The

TABLE C-1. RADIOACTIVE MATERIAL RELEASE ATTRIBUTABLE TO LAND DISPOSAL (ONE REACTOR COMPARTMENT BURIAL)

Nuclide	Maximum Annual Release (Curies Per Year)	Total Release Over All Time (Curies)
Ni-59	0.57×10^{-1}, year 2800	1.2×10^{2}
C-14	0.36×10^{-3}, year 2800	0.60
Ni-63	0.26×10^{-2}, year 200	0.25
Nb-94	0.39×10^{-4}, year 2800	0.70×10^{-1}
Mo-93	0.51×10^{-5}, year 200	0.83×10^{-2}
Tc-99	0.16×10^{-5}, year 200	0.36×10^{-2}
Fe-55	0.14×10^{-3}, year 1*	0.63×10^{-3}
Co-60	0.22×10^{-4}, year 1*	0.17×10^{-3}
Mn-54	0.32×10^{-5}, year 1*	0.57×10^{-5}
Co-58	0.18×10^{-6}, year 1*	0.18×10^{-6}
Fe-59	0.79×10^{-7}, year 1*	0.79×10^{-7}
Cr-51	0.28×10^{-7}, year 1*	0.28×10^{-7}
S-35	0.58×10^{-9}, year 1*	0.58×10^{-9}
Sc-46	0.64×10^{-10}, year 1*	0.64×10^{-10}

Corrosion rates: Low-alloy steel: 0.0025 inch per year per exposed surface
Corrosion resistant alloy: 0.0003 inch per year per exposed surface

*These early releases are based on the radioactive material contained in the metal of the exterior boundary (hull and bulkheads), and the assumption that this activity would be uniformly distributed in the metal.

corrosion of the outer containment barrier (bulkhead) was assumed to occur only from the outside, and during the period of 200 years in which the outer containment remains unpenetrated, none of the interior components would be significantly affected by corrosion because water would not have entered the compartment. After outer barrier penetration, components within the reactor compartment but outside the reactor vessel were assumed to corrode on both inner and outer exposed surfaces, while the sealed reactor vessel was assumed to experience only exterior surface corrosion. At this time, radionuclides present in the reactor vessel wall or in plant components outside the reactor vessel could begin to be released. After the reactor vessel is penetrated, components within the vessel were assumed to corrode on both inner and outer surfaces. Only the longest-lived radionuclides would remain after the reactor vessel is penetrated. Corrosion of the corrosion-resistant alloys was represented by general surface corrosion only because the addition of further releases by way of escape through pitting penetrations was considered to be an unnecessarily conservative assumption in the analysis of land disposal effects. This analysis is already conservative in view of the assumption of a continuously flowing supply of water to keep all of the affected surfaces wet and to carry away radioactive corrosion products.

As may be seen from Table C-1, all of the long-lived Nickel-59 (120 curies) has been assumed to be released over all time, along with a major part of the Carbon-14 (0.6 curie of the initial inventory of 1 curie). Release over all time of all other nuclides is estimated to be small, with Nickel-63 (0.25 curie) the only other nuclide which would amount to more than 0.1 curie. The maximum annual release would occur approximately 2800 years after disposal when penetration of the reactor vessel would initiate the release to the disposal site of the long-lived nuclides, primarily Nickel-59, which would amount to an estimated 0.057 curie per year.

The release of a small quantity of radioactive material is shown for early years, beginning as soon as disposal occurs. These releases are based on the minute quantities of radioactive material contained in the metal of the exterior boundary (hull and bulkheads), and the conservative assumption that this activity is uniformly distributed throughout that metal so that initial corrosion of the exterior boundary would begin the release of some radioactive material.

The maximum annual release rates of all radionuclides have been considered in estimating the highest possible annual exposure rate to the public, even though the maximum releases would not occur in the same period in some cases. In effect, however, as shown by the relative magnitudes of the annual releases shown in Table C-1, only the Nickel-59 release would have any significant effect on the exposure estimates. This not only simplifies the internal exposure calculations of Section IV, but also makes it practical to show the step-by-step dose calculations. For these calculations, the Nickel-59 maximum annual release has been increased to 0.07 curie per year, per reactor compartment, so that this activity release can conservatively represent all of the radionuclides.*

III. EXPOSURE PATHWAYS

A. AVERAGE INDIVIDUAL EXPOSURE PATHWAY

The approach used in this appendix to estimate the long-term consequences of reactor compartment burial was obtained using established methods and site-specific information for the Savannah River Laboratory (for the water consumption pathway), and was supplemented by the multiple exposure pathways analysis of Reference C.2. With this combination, the exposure is estimated for drinking water, fish, crops, milk, and meat consumption.

As described in the introduction to this appendix, the primary exposure pathway would most likely be through the groundwater to a nearby river that supplies water to major populations downstream, as well as supplying water for animals and irrigation and supporting food fish. For this analysis a major river such as the Savannah River was assumed to receive all released radioactive material.

The individual exposure analysis is also conservatively applicable to reactor compartment burial at the Hanford Site, where long-term releases might be received by the Columbia River. The minimum flow rate of the Columbia River is approximately five times as great as the minimum annual average Savannah River flow rate. The larger flow rate would reduce the estimated radioactivity concentration in the river water, and

***When external exposure hazard is also considered, as in the alternate approach shown in Section VIII.A, Table C-2, Niobium-94 is treated explicitly along with Nickel-59 and Carbon-14.**

would cause lower individual dose commitment estimates for users of Columbia River water, based on any given radioactive material release from the buried reactor compartments. The lower annual precipitation rate and greater depth of the water table at Hanford also imply that the analysis is conservatively applicable to both burial locations.

B. MAXIMUM INDIVIDUAL EXPOSURE PATHWAY

To allow for the possibility in the distant future that some individuals would receive radiation exposure as a result of living near the disposal site, a maximum exposure estimate has been calculated (see Section V) by assuming that all water consumed and used by such maximum-exposed individuals could come from a small local stream that passes through the site and picks up all of the released radioactivity from as many as ten of the reactor compartments. This approach would also represent water consumption and usage from a well hypothetically contaminated by all of the released radioactive material from ten reactor compartments. This number of reactor compartments would be in the path of a stream moving across a roughly square disposal pattern.

C. INHALATION AND DIRECT RADIATION PATHWAYS*

Transport of radionuclides to the population by the inhalation pathway is considered to be small in comparison to transport by surface streams or wells, since transfer of any corrosion product to the atmosphere would be hindered by the presence of the soil cover during at least the initial period after disposal, and since later, when corrosion release of radioactive material is occurring, the size of the corrosion particles would generally prevent transport through the air.

The effects of the direct radiation or intrusion pathway during the first 100 years after disposal would also be small because of the small number of people that would be involved, the low rate of external irradiation from the hull section (less than 0.1 mrem per hour), and the massive size and difficulty in penetrating the sealed reactor compartment. After the first 100 years, the direct radiation levels at any location within or near the disposal package would be virtually zero because of the radioactive decay of the nuclides (principally Cobalt-60) that produce the direct radiation.

IV. ESTIMATED 70 YEAR DOSE COMMITMENT TO AVERAGE INDIVIDUALS

Analyses of the effects of exposure to radiation or radioactive materials are based on the estimated dose commitments. A dose commitment is the total dose received by an individual during the entire remainder of his life following some specified period of exposure to radiation or radioactive materials. (This concept is described more fully in Appendix J, pages J-1 and J-2.) In this statement, the dose commitments are computed over the 70 years following a one year exposure, unless otherwise stated.

The estimates developed in this section are conservatively applicable to either possible disposal site for an average individual whose exposure is assumed to be due to the presence of Nickel-59 in water. The maximum annual release rate of Nickel-59 would be much larger than those of all other radionuclides, as shown in Table C-1, and has been rounded up to 0.07 curie per year per reactor compartment, so that the analysis is applicable not only for Nickel-59 but also for the sum of all available nuclides.

The various water-related pathways and associated maximum consumption rates for any age group are as follows.

1. water consumption (730 liters per year, Table J-2, Appendix J);

2. freshwater fish consumption (6.9 Kg per year, Table E-4, Reference C.2);

***The inhalation and direct radiation pathways are included in an alternate calculation method. See Section VIII.A (Agricultural Intruder).**

3. consumption of crops grown on irrigated soil (24 Kg per year. Thus, 10 percent of the total 240 Kg per year maximum of Table E-4, Reference C.2, is assumed to be taken from an area affected by contamination);

4. consumption of milk from cows that hypothetically consume contaminated water and crops (20 liters per year. Thus, 10 percent of the total 200 liters per year maximum of Table E-4, Reference C.2, is assumed to be from an area affected by contamination); and

5. consumption of meat from animals that hypothetically consume contaminated water and crops (9.5 Kg per year. Thus, 10 percent of the total 95 Kg per year maximum of Table E-4, Reference C.2, is assumed to be from an area affected by contamination).

The concentration of Nickel-59 in water was estimated to be 1×10^{-9} μCi/ml, based on the maximum estimated annual release (0.07 curie/yr per reactor compartment, as explained on page C-3), diluted by the minimum annual average flow of the Savannah River (7500 cubic feet per second). That is,

$$1 \times 10^{-9} \frac{\mu Ci}{ml} = \frac{(0.07\ Ci/yr)(100)(10^6 \mu Ci/Ci)}{(7500\ ft^3/second)(3.15 \times 10^7\ sec/yr)(28.32\ liters/ft^3)(1000\ ml\ per\ liter)}$$

This concentration is lower than the Reference C.3 unrestricted area limit for Nickel-59 (2×10^{-4} μCi/ml) by a factor of 200,000. On this basis, it might be expected that individual total body exposures would not exceed about 2.5×10^{-3} mrem per year, since the limits of Reference C.3 prevent annual total body exposures from exceeding approximately 500 mrem (i.e., 500 mrem/year ÷ 200,000 = 2.5×10^{-3} mrem/yr). However, each exposure pathway is evaluated separately in the following discussion and the sum of all such pathways yields the conservative estimate of 6.0×10^{-3} mrem per year for the total body exposure of an average individual. The following discussion also calculates the exposure to bone (bone is the organ that would receive the maximum exposure) for an average individual. If the actual annual average flow of 10,420 cubic feet per second were used, the calculated exposures would be approximately 28% lower.

A. WATER CONSUMPTION PATHWAY

i—Annual hypothetical intake of Nickel-59

$$= (730\ liters/yr)\left(\frac{1000\ ml}{liter}\right)\left(1 \times 10^{-9} \frac{\mu Ci}{ml}\right)$$

$$= 7.3 \times 10^{-4}\ \mu Ci/yr$$

ii—Annual exposure, total body

$$= (7.3 \times 10^{-4}\ \mu Ci/yr)(1.63 \times 10^{-3}\ rem/\mu Ci^*)(10^3\ mrem/rem)$$

$$= 1.2 \times 10^{-3}\ mrem/yr$$

iii—Annual exposure, bone

$$= (7.3 \times 10^{-4}\ \mu Ci/yr)(9.76 \times 10^{-3}\ rem/\mu Ci^*)(10^3\ mrem/rem)$$

$$= 7.1 \times 10^{-3}\ mrem/yr$$

*These dose commitment factors are from Table I-4, Appendix I, expressed in rem per μCi. The same factors are used throughout this section.

B. FRESHWATER FISH CONSUMPTION PATHWAY

i—Average hypothetical concentration of Nickel-59 in freshwater fish

$$= \left(1 \times 10^{-9} \frac{\mu Ci}{ml}\right)\left(100 \frac{Ci/g}{Ci/ml}\right)^{*} \left(\frac{1000\ g}{Kg}\right)$$

$$= 1 \times 10^{-4}\ \mu Ci/Kg$$

ii—Annual intake of Nickel-59

$$= \left(6.9 \frac{Kg}{yr}\ \text{fish}\right)\left(1 \times 10^{-4} \frac{\mu Ci}{Kg}\right)$$

$$= 6.9 \times 10^{-4}\ \mu Ci/yr$$

iii—Annual exposure, total body

$$= \left(6.9 \times 10^{-4} \frac{\mu Ci}{yr}\right)(1.63 \times 10^{-3}\ rem/\mu Ci)(10^{3}\ mrem/rem)$$

$$= 1.1 \times 10^{-3}\ mrem/yr$$

iv—Annual exposure, bone

$$= (6.9 \times 10^{-4}\ \mu Ci/yr)(9.76 \times 10^{-3}\ rem/\mu Ci)(10^{3}\ mrem/rem)$$

$$= 6.7 \times 10^{-3}\ mrem/yr$$

C. PATHWAY DUE TO CONSUMPTION OF CROPS GROWN ON IRRIGATED SOIL

The method of calculation follows that of Equation (4), page 1.109-3 of Reference C.2.

i—Irrigation rate

= 50 inches per year, inferred from Page II 3-7, Reference C.4

= 8.3 inches per month for a six month irrigation period

= 0.29 liter/m^2 per hour, during six months of irrigation

ii—Assumed period of long-term buildup of soil contamination

= 15 years, Table E-15, Reference C.2

iii—Hypothetical concentration in soil after 15 years, based on a surface density of 240 Kg per square meter of soil (Table E-15, Reference C.2)

$$= \frac{(0.29\ liter/m^2\ hr)(4380\ hrs/yr)(15\ yrs)(1 \times 10^{-9}\ \mu Ci/ml)\ (1000\ ml/liter)}{240\ Kg/m^2}$$

$$= 7.9 \times 10^{-5}\ \mu Ci/Kg$$

*Concentration factor of 100 for nickel in freshwater fish, from Table A-1 of Reference C.2.

iv—Hypothetical concentration in crops grown in this soil; considering uptake via roots, and a concentration factor of 0.019 for nickel (Table E-1, Reference C.2)

$$= (7.9 \times 10^{-5}\ \mu\text{Ci/Kg})(0.019)$$

$$= 1.5 \times 10^{-6}\ \mu\text{Ci/Kg}$$

v—Hypothetical activity of Nickel-59 on plant surfaces, based on 25 percent of the deposited activity being retained on the crops, and a rate constant of 0.0021 per hour (14 day half-life) for removal of activity on plant or leaf surfaces by weathering (Table E-15, Reference C.2)

$$= \left(1 \times 10^{-9}\ \frac{\mu\text{Ci}}{\text{ml}}\right)\left(\frac{0.29\ \text{liter}}{\text{m}^2\text{-hr}}\right)\left(\frac{1000\ \text{ml}}{\text{liter}}\right)(0.25)\left(\frac{1}{0.0021/\text{hr}}\right)$$

$$= 3.5 \times 10^{-5}\ \mu\text{Ci/m}^2$$

vi—Hypothetical activity of Nickel-59 per Kg of crops, based on an agricultural productivity of 2 Kg/m^2 (Table E-15, Reference C.2) (not including uptake via roots)

$$= (3.5 \times 10^{-5}\ \mu\text{Ci/m}^2) \div (2\ \text{Kg/m}^2)$$

$$= 1.8 \times 10^{-5}\ \mu\text{Ci/Kg}$$

vii—Total hypothetical activity of Nickel-59 per Kg of crops (= iv + vi)

$$= (1.5 \times 10^{-6} + 1.8 \times 10^{-5})\ \mu\text{Ci/Kg}$$

$$= 2.0 \times 10^{-5}\ \mu\text{Ci/Kg}$$

viii—Annual hypothetical uptake of Nickel-59

$$= (24\ \text{Kg/yr})(2.0 \times 10^{-5}\ \mu\text{Ci/Kg})$$

$$= 4.8 \times 10^{-4}\ \mu\text{Ci/yr}$$

ix—Annual hypothetical exposure, total body

$$= (4.8 \times 10^{-4}\ \mu\text{Ci/yr})(1.63 \times 10^{-3}\ \text{rem}/\mu\text{Ci})(10^3\ \text{mrem/rem})$$

$$= 7.8 \times 10^{-4}\ \text{mrem/yr}$$

x—Annual exposure, bone

$$= (4.8 \times 10^{-4}\ \mu\text{Ci/yr})(9.76 \times 10^{-3}\ \text{rem}/\mu\text{Ci})(10^3\ \text{mrem/rem})$$

$$= 4.7 \times 10^{-3}\ \text{mrem/yr}$$

D. MILK CONSUMPTION PATHWAY

i—cow's daily intake of crop (Table E-3, Reference C.2)

= 50 Kg/day

ii—cow's daily intake of water (Table E-3, Reference C.2)

= 60 liters/day

iii — cow's daily hypothetical intake of Nickel-59

$$= (50\ \text{Kg/day})(2.0 \times 10^{-5}\ \mu\text{Ci/Kg})(2.9^{*}) + (60\ \text{liters/day})\left(1 \times 10^{-9}\ \frac{\mu\text{Ci}}{\text{ml}} \times \frac{1000\ \text{ml}}{\text{liter}}\right)$$

$$= 2.9 \times 10^{-3}\ \mu\text{Ci/day}$$

iv — Nickel activity transfer coefficient to milk, per Table E-1, Reference C.2

$$= 0.0067\ \mu\text{Ci/liter per}\ \mu\text{Ci/day}$$

v — Hypothetical Nickel-59 activity in milk

$$= \left(\frac{0.0067\ \mu\text{Ci/liter}}{\mu\text{Ci/day}}\right)(2.9 \times 10^{-3}\ \mu\text{Ci/day})$$

$$= 1.9 \times 10^{-5}\ \mu\text{Ci/liter}$$

vi — Individual's hypothetical annual uptake of Nickel-59 via milk consumption

$$= (20\ \text{liters/yr})(1.9 \times 10^{-5}\ \mu\text{Ci/liter}) = 3.8 \times 10^{-4}\ \mu\text{Ci/yr}$$

vii — Annual hypothetical exposure, total body

$$= (3.8 \times 10^{-4}\ \mu\text{Ci/yr})(1.63 \times 10^{-3}\ \text{rem}/\mu\text{Ci})(10^{3}\ \text{mrem/rem})$$

$$= 6.2 \times 10^{-4}\ \text{mrem/yr}$$

viii — Annual hypothetical exposure, bone

$$= (3.8 \times 10^{-4}\ \mu\text{Ci/yr})(9.76 \times 10^{-3}\ \text{rem}/\mu\text{Ci})(10^{3}\ \text{mrem/rem})$$

$$= 3.7 \times 10^{-3}\ \text{mrem/yr}$$

E. MEAT CONSUMPTION PATHWAY

The Nickel-59 activity in all meat consumed is assumed to be equal to that of beef cattle.

i — Animal's daily intake of crop (Table E-3, Reference C.2)

$$= 50\ \text{Kg/day}$$

ii — Animal's daily intake of water (Table E-3, Reference C.2)

$$= 50\ \text{liters/day}$$

iii — Animal's hypothetical daily intake of Nickel-59 (same as calculated for milk in previous section)

$$= 2.9 \times 10^{-3}\ \mu\text{Ci/day}$$

iv — Nickel activity transfer coefficient to meat (Table E-1, Reference C.2)

$$= 0.053\ \mu\text{Ci/Kg per}\ \mu\text{Ci/day}$$

---

*The factor of 2.9 accounts for the lower agricultural productivity of crops per unit area when the grass-cow-milk-man pathway is considered (0.7 Kg/m^2 vs. 2.0 Kg/m^2, per Table E-15, Reference C.2).

v—Hypothetical Nickel-59 activity in meat

$$= \left(\frac{0.053\ \mu Ci/Kg}{\mu Ci/day} \right) \left(2.9 \times 10^{-3}\ \frac{\mu Ci}{day} \right)$$

$$= 1.5 \times 10^{-4}\ \mu Ci/Kg$$

vi—Annual hypothetical uptake of Nickel-59 via consumption of meat

$$= (1.5 \times 10^{-4}\ \mu Ci/Kg)(9.5\ Kg/yr)$$

$$= 1.4 \times 10^{-3}\ \mu Ci/yr$$

vii—Hypothetical annual exposure, total body

$$= (1.4 \times 10^{-3}\ \mu Ci/yr)(1.63 \times 10^{-3}\ rem/\mu Ci)(10^3\ mrem/rem)$$

$$= 2.3 \times 10^{-3}\ mrem/yr$$

viii—Hypothetical annual exposure, bone

$$= (1.4 \times 10^{-3}\ \mu Ci/yr)(9.76 \times 10^{-3}\ rem/\mu Ci)(10^3\ mrem/rem)$$

$$= 1.4 \times 10^{-2}\ mrem/yr$$

F. SUM OF EXPOSURES VIA ALL PATHWAYS

i—Sum of hypothetical exposures, total body

$$= 1.2 \times 10^{-3}\ mrem/yr\ (water) + 1.1 \times 10^{-3}\ mrem/yr\ (fish)$$

$$+ 7.8 \times 10^{-4}\ mrem/yr\ (crops) + 6.2 \times 10^{-4}\ mrem/yr\ (milk)$$

$$+ 2.3 \times 10^{-3}\ mrem/yr\ (meat)$$

$$= 6.0 \times 10^{-3}\ mrem/yr$$

ii—Sum of hypothetical exposures, bone

$$= 7.1 \times 10^{-3}\ mrem/yr\ (water) + 6.7 \times 10^{-3}\ mrem/yr\ (fish)$$

$$+ 4.7 \times 10^{-3}\ mrem/yr\ (crops) + 3.7 \times 10^{-3}\ mrem/yr\ (milk)$$

$$+ 1.4 \times 10^{-2}\ mrem/yr\ (meat)$$

$$= 3.6 \times 10^{-2}\ mrem/yr$$

These hypothetical total exposures are considered to be very conservative because all of the released radioactive material is assumed to be carried in the river water. Based on the observation discussed earlier in this section that the conservatively estimated Nickel-59 water concentration would be lower than the Reference C.3 limit by a factor of 200,000 to 1, the annual average individual total body exposure estimate of 6.0×10^{-3} mrem/yr is seen to be reasonable (i.e.,

$$\frac{500\ mrem/yr}{200{,}000} = 2.5 \times 10^{-3}\ mrem/yr\ ,$$

as compared with 6.0×10^{-3} mrem/yr).

V. ESTIMATED 70 YEAR DOSE COMMITMENT TO MAXIMUM-EXPOSED INDIVIDUALS

The maximum-exposed individuals are assumed to be exposed as a result of living near the disposal site in the distant future (several thousand years from the present) when the release of radioactive material at the maximum rate might occur, and when the site's identity as a radioactive waste disposal area is no longer recognized. The 70 year dose commitments are estimated in the same way as those for average-exposed individuals (see Section IV) except that the water flow rate is assumed to be much reduced, accounting for much higher concentrations in the water that is ingested, and all food consumed is assumed to be affected by the contamination, in contrast to the previous assumption that 10 percent of crops, milk, and meat consumed by average-exposed individuals is affected.

The source of hypothetical contamination for the limited number of maximum-exposed individuals is assumed to be a local stream flowing at 20 cubic feet per second* instead of the value used in the previous section (7500 cubic feet per second). This flow could represent a 15 foot wide stream one foot deep, moving at approximately one mile per hour. It has been assumed that all of the annually released material from up to ten of the compartments, which would be the approximate number of compartments in the path of a stream moving across a roughly square disposal pattern, could be taken up by this water. This approach increases the hypothetical Nickel-59 concentration in water from 1×10^{-9} μCi/ml, as used in the previous section, to 3.8×10^{-8} μCi/ml. Thus the maximum-exposed individuals are assumed to be exposed to water that has a hypothetical concentration of Nickel-59 about 38 times as high as the calculated average river concentration. This difference, and the added assumption that all food consumed would be affected by the Nickel-59 release, results in increased exposures in direct proportion to the higher concentration and consumption fraction.

Total body exposure is obtained by summing the individual contributions from Section IV.F. The contributions from crops, milk, and meat must be multiplied by a factor of 10 to adjust for the greater usage.

This total is:

$$38\,(1.2 \times 10^{-3}\ \text{mrem/yr}),\ \text{water} + 38\,(1.1 \times 10^{-3}\ \text{mrem/yr}),\ \text{fish}$$

$$+ (38)(10)(7.8 \times 10^{-4}\ \text{mrem/yr}),\ \text{crops} + (38)(10)(6.2 \times 10^{-4}\ \text{mrem/yr}),\ \text{milk}$$

$$+ (38)(10)(2.3 \times 10^{-3}\ \text{mrem/yr}),\ \text{meat}$$

$$= 1.5\ \text{mrem/yr, all pathways}$$

A similar approach yields a maximum organ (bone) exposure of 8.9 mrem/yr.

VI. MAXIMUM ANNUAL POPULATION DOSE COMMITMENT

The hypothetical population dose commitment estimate is obtained by multiplying the average individual total body dose commitment from one year of exposure (6.0×10^{-3} mrem per year, from Section IV) by the appropriate affected population. As noted previously, the exposure would not occur for several thousand years, so the estimate must be regarded as only a rough approximation, but one that is biased to be conservative.

*See page C-13 for an estimate of dose based on a minimum diluting flow rate of 3.84 gallons per minute (representing a well) combined with an annual radioactive material source that is estimated according to the method of NUREG-0782 (Reference C.1).

Downstream of the Savannah River Plant, the present population of water users is approximately 70,000 persons (Reference C.5). Based on internal studies by the Savannah River Laboratory, this population is assumed to increase over the next century and a half, reaching a level five times the present population, or 350,000, after which it remains constant. This value can be assumed to be appropriate for the Savannah River Plant, so the corresponding population total body dose commitment would be

$$(6.0 \times 10^{-3} \text{ mrem/yr})(350{,}000 \text{ persons})(10^{-3} \text{ rem/mrem}) = 2.1 \text{ man-rem/yr.}$$

The population downstream of the Hanford Site along the Columbia River is approximately four times as large as the downstream population along the Savannah River, based on information in Reference C.6, which includes 1979 census data for cities above 25,000 and 1970 census data for other cities and towns. It would be reasonable, therefore, to base the population dose commitment on a future population of 1.4 million rather than 350,000. If this approach were taken, the population dose commitment would be about 8.4 man-rem/year. The latter figure is **not** used, however, because it would be unnecessarily conservative inasmuch as the individual dose commitment estimate is based on a water concentration associated with the minimum flow of the Savannah River. When the five-fold larger flow of the Columbia River is used, the population dose commitment would be 1.7 man-rem per year. Therefore, the larger value, 2.1 man-rem per year total body, is considered appropriate. The corresponding population exposure to bone would be 12.6 man-rem per year.

If specific assumptions for the Hanford Site were used, including dietary assumptions, the population dose commitments for the Hanford area would be reduced, probably to a level near 0.2 man-rem/year, total body, and 1.3 man-rem/year, to bone.

VII. EXPECTED HEALTH EFFECTS OF LAND DISPOSAL

The maximum total body population dose commitment of 2.1 man-rem per year, combined with a conservatively estimated relationship between low-level dose and population health effects (0.45×10^{-3} additional cancer cases per man-rem, cited in Appendix D of Reference C.7), implies a total expected number of additional health effects of 0.001 per year, several thousand years in the future. That is,

$$\left(\frac{2.1 \text{ man-rem}}{\text{year}}\right)\left(0.45 \times 10^{-3} \frac{\text{additional cancer cases}}{\text{man-rem}}\right) = 0.001 \text{ per year}$$

The interpretation of this result is that it would be very unlikely that even one person would be affected in any year in the distant future as a result of radiation exposure attributable to the land disposal of the reactor compartments from defueled and decommissioned submarines. Consideration of the effects of various conservative assumptions used in this analysis suggest that the estimate of 0.001 health effects per year is conservative by several factors of 10, since most of the radioactive corrosion products eventually released to the disposal site would actually be expected to remain at the site, and most of the corrosion products that would be transported away from the immediate area would be expected to be either absorbed within a short distance by soil particles, deposited in stream or river beds, or removed by water treatment systems.

VIII. COMPARISON OF INDIVIDUAL DOSE COMMITMENT ESTIMATES WITH RELATED ESTIMATES

A. ALTERNATE ESTIMATES BASED ON NUREG-0782 (NRC LAND DISPOSAL ENVIRONMENTAL IMPACT STATEMENT)

General procedures for estimating the radiation exposure attributable to land disposal are presented in Reference C.1 (NUREG-0782) for a variety of different forms of low-level radioactive waste. As a check on the exposure estimates of Section IV, alternate estimates based on Reference C.1 for well users and surface water users are shown below.

Reference C.1 does not treat disposals that have the unique form of the sealed, high-integrity ship's compartment. However, its methods have been applied as directly as possible, as detailed below, to estimate exposure via drinking water and crop irrigation to the users of a well located on or near the disposal site, or a surface stream.* The results indicate that the average individual exposure calculated in Section IV of this appendix is conservative.

The separate components of the type of analysis described in Appendix G of Reference C.1, as applied to reactor compartment burial, are as follows for the predominant nuclide, Nickel-59.

1. Concentration of Nickel-59 in the waste form (C_w), where a reactor compartment has a volume of 400 cubic meters.

$$C_w = \frac{120 \text{ curies}}{400 \text{ m}^3} = 0.3 \text{ Ci/m}^3$$

2. T = source duration factor, representing the number of years during which the total curie content could be released at the maximum annual rate, i.e.

$$T = \frac{120 \text{ curies}}{\sim 0.06 \text{ curie/yr}} = 2000 \text{ years}$$

3. V_w = annual volume of water that percolates through the disposal ground

V_w = (180 mm/yr, from Reference C.1) × (Disposal Site Surface Area)

$V_w = (0.18 \text{ m/yr})(10 \text{ acres}) = 7.3 \times 10^3 \text{ m}^3/\text{yr}$

4. f_c = fraction of the radionuclides that could be transferred from the waste to the leachate, i.e., to the water volume V_w

$f_c = M_o \times t_c \times$ accessibility factor

where

a. M_o = ratio of the leachate concentration to the waste concentration

$M_o = 1.48 \times 10^{-2}$, from Reference C.1, for Nickel-59

b. t_c = fraction of the year in which the percolating water is in contact with the waste

$t_c = 6.47 \times 10^{-3}$, from Reference C.1

c. accessibility factor = 0.1 for metallic waste, with some activated corrosion products, from Reference C.1

$\therefore f_c = 1.48 \times 10^{-2} \times 6.47 \times 10^{-3} \times 0.1 = 9.6 \times 10^{-6}$

5. Combining the four factors from above yields the annual source of radioactive material from the 10 acre disposal site

$$S = \frac{C_w}{T} \times V_w \times f_c$$

$$S = \frac{0.3 \text{ Ci/m}^3}{2000} \times (7.3 \times 10^3 \text{ m}^3/\text{yr}) \times (9.6 \times 10^{-6})$$

$$S = 1.1 \times 10^{-5} \text{ Ci/yr}$$

*For the "agricultural intruder" of Reference C.1, see page C-14.

6. Q = minimum flow of water that dilutes the released radioactive material

   a. well

      $Q = 7.7 \times 10^3$ m^3/yr, from Reference C.1, equivalent to 3.84 gallons per minute, well pumping rate

   b. surface stream

      $Q = 4.5 \times 10^6$ m^3/yr, from Reference C.1, equivalent to five cubic feet per second, the minimum flow rate of a stream usable for human consumption

7. C_a = water concentration at the access location, i.e., at the well or at the surface stream

   $C_a = S/Q$

   a. well

$$C_a = \frac{1.1 \times 10^{-5}\ \text{Ci/yr}}{7.7 \times 10^{3}\ \text{m}^3/\text{yr}} = 1.4 \times 10^{-9}\ \text{Ci/m}^3$$

   b. surface stream

$$C_a = \frac{1.1 \times 10^{-5}\ \text{Ci/yr}}{4.5 \times 10^{6}\ \text{m}^3/\text{yr}} = 2.4 \times 10^{-12}\ \text{Ci/m}^3$$

8. PDCF = pathway dose conversion factor for the well water or the surface stream

   a. well

      PDCF = 8.54×10^6 mrem per year per Ci/m^3 (total body), from Table G-8, Reference C.1, for Nickel-59

   b. surface stream

      PDCF = 9.82×10^6 mrem per year per Ci/m^3 (total body), from Table G-9, Reference C.1, for Nickel-59

9. Total Body Exposure = (PDCF) × (C_a)

   a. well

      Total Body Exposure = (8.54×10^6 mrem/yr per Ci/m^3) (1.4×10^{-9} Ci/m^3)

      = 1.2×10^{-2} mrem/yr

   b. surface stream

      Total Body Exposure = (9.82×10^6 mrem/yr per Ci/m^3) (2.4×10^{-12} Ci/m^3)

      = 2.4×10^{-5} mrem/yr

For comparison, the total body exposure calculated in Section IV of this appendix, for the average exposed individual, would be 6.0×10^{-3} mrem per year, a value that is within the range of the above exposures for well users and surface water users. Considering that the exposure to surface stream users roughly approximates that to the average individual, it may be concluded that the exposure calculated in Section IV (6.0×10^{-3} mrem per year) is conservative.

The exposure to well users could be considered applicable to the maximum-exposed individual. However, Reference C.1 also postulates an "agricultural intruder" who takes up residence on the disposal site and consumes food grown there, without knowing the previous use of the site. An exposure estimate for this case has been made using the methods of Reference C.1, with the inadvertent intrusion assumed to begin several thousand years after disposal since that approximate length of time would be required to make the magnitude of the "agricultural intruder" scenario credible.

The calculation is as follows, employing the notation of Reference C.1.

$$H = \sum_{n} (f_o f_d f_w f_s)_{air} C_w \, PDCF\text{-}3 + \sum_{n} (f_o f_d f_w f_s)_{food} C_w \, PDCF\text{-}4$$

$$+ \sum_{n} (f_o f_d f_w f_s)_{direct} C_w \, PDCF\text{-}5$$

where:

H = annual dose in mrem per year, during the 50th year of exposure

PDCF-3, PDCF-4, PDCF-5 } radionuclide-specific dose conversion factors tabulated in Section 2.4 of Reference C.1 for air, food, and direct exposure pathways, respectively

C_w = radionuclide concentration in the waste

f_o = time delay factor

f_d = site design and operation factor

f_w = waste form and package factor

f_s = site selection factor.

The values of each of these components of the dose equation are listed in Table C-2.

If a maximum of 500 years of radioactive decay were assumed, as suggested in Section 3.3 of Reference C.1, a maximum exposure of 40 mrem per year to the bone would be estimated, primarily due to Nickel-63, which has a 92 year half-life. This exposure rate would be only 8% of the maximum exposure rate (500 mrem per year) on which the concentration limits of Reference C.1 are based. However, in view of the very long containment time provided by the thick reactor vessel (greater than 2000 years) it is not considered appropriate to include any exposure due to Nickel-63, which would be eliminated by radioactive decay well before the reactor vessel could be penetrated or any significant corrosion of metal containing radioactive nickel could occur. Therefore, the values listed in Table C-2 include the long-lived radionuclides Nickel-59, Carbon-14, and Niobium-94.

The annual intruder dose value (H), summed over all radionuclides, is 12.7 mrem per year to the total body, 13.4 mrem per year to the bone, and 12.6 mrem per year to the G.I. Tract—large lower intestine. Adding the well-user exposure to the "agricultural intruder" exposure provides a maximum estimate of 12.7 mrem per year, total body, and 13.5 mrem per year, bone. These extreme estimates are reasonably comparable to the maximum individual exposure estimates of Section V (i.e., 1.5 mrem per year, total body, and 8.9 mrem per year, bone).

B. ESTIMATED EXPOSURE ATTRIBUTABLE TO LAND DISPOSAL OF RESIDENTIAL SMOKE DETECTORS THAT CONTAIN AMERICIUM-241

As a further check on the hypothetical average individual exposure estimates discussed in previous sections, a comparison has been made with the estimated average individual exposures that might result

TABLE C-2. VALUES USED TO CALCULATE "AGRICULTURAL INTRUDER" DOSE

		Units	Ni-59	C-14	Nb-94	Basis for value used

from the disposal each year throughout the United States of 10 million ionization chamber smoke detectors that contain radioactive Americium-241 (Reference C.8). Each of these smoke detectors contains approximately 3×10^{-6} curies (3μCi) of Americium-241, and the total activity of 30 curies per year is expected to be discarded along with other domestic solid waste with no special restrictions.

The principal radiation exposure pathway involving Americium-241 is estimated in Reference C.8 to be the consumption of water that is slightly contaminated by the addition of 0.025 percent of the annual activity to 90 billion gallons of groundwater, i.e.,

$$\frac{(30 \text{ curies})(0.025 \text{ percent})}{90 \times 10^{9} \text{ gallons}} = \frac{0.0075 \text{ curie}}{340 \times 10^{9} \text{ liters}} = 2.2 \times 10^{-14} \text{ Ci/liter}$$

The annual average total body dose commitment reported in Reference C.8, attributable to Am-241 from smoke detectors in drinking water, is approximated below. It should be noted that this calculation uses the rate of water consumption specified in Reference C.8 (370 liters per year) rather than the rate used in this statement (730 liters per year) resulting in a lower dose commitment relative to the dose commitments of this statement.

$$(2.2 \times 10^{-14} \text{ Ci/liter})(370 \text{ liters/yr})(1.6 \times 10^{6} \text{ rem/Ci}) = 1.3 \times 10^{-5} \text{ rem/yr}$$

$$= 1.3 \times 10^{-2} \text{ mrem/yr.}$$

The average annual total body dose commitment attributable to other ingestion exposure pathways (irrigated crops, general crops, and crops grown on landfill) is estimated in Reference C.8 to be less than 1/2 of 1 percent of the water consumption pathway exposure, so that the water consumption pathway is the only significant ingestion path.

The annual average Americium-241 total body exposure, estimated to be 1.3×10^{-2} mrem per year, is higher than the corresponding water consumption exposure estimate attributable to reactor compartment land disposal (1.2×10^{-3} mrem per year, page C-5) by a factor of about 10. This relative difference is consistent with the different water concentrations, consumption rates, and dose conversion factors used to develop each estimate.

It is concluded that the average annual water consumption exposure calculation in this appendix is not only reasonably consistent with a related calculation, but also that the exposure estimate is even smaller than the very low value associated with the unrestricted disposal of smoke detectors.

IX. EXPOSURE TO THE PUBLIC FROM REACTOR COMPARTMENT TRANSPORTATION

Consistent with the approach of References C.13 and C.14, the maximum anticipated individual exposures to the public would be expected to occur if the barge carrying the reactor compartment passes under a bridge with 80 stationary cars (160 persons) waiting for a traffic jam to clear. The population dose calculation for this situation assumes the roadway to be a minimum expected distance of 30 feet above the upper surface of the reactor compartment with the barge moving at 6.5 mph (half normal speed to produce a conservatively high exposure time). With the conservative assumption that the radiation exposure rate would be the maximum allowable (49CFR173.393) 10 mrem per hour six feet above the reactor compartment upper surface, a conversion factor (K value) of 360 mrem-ft^2/hour is used with Figure D-1 of Reference C.13 extrapolated to a 30 foot perpendicular distance. This would yield an individual exposure of approximately 7×10^{-4} mrem and a population exposure for the occupants of the 80 cars of 1.1×10^{-4} man-rem.

At all times during the barge transport, the public along the edges of the oceans, harbors, or rivers would be far enough away from the low level radiation source to avoid any significant population dose, even with a large number of persons along the transportation route. The following estimate, also based on Figure D-1 of Reference C.13, assumes the exposed individuals to be 200 feet away from the barge, which is moving at 13 mph, with one person every tenth of a mile on each side of the river over the entire length of a 350 mile river transit. Therefore, 7000 persons would be assumed to be exposed, with the individual exposure equal to 6×10^{-5} mrem and the population exposure equal to 4.2×10^{-4} man-rem. The assumed population of one per tenth of a mile is based on a uniform density of 100 persons per square mile, which compares with a representative average of 58 per square mile inferred from Appendix E of Reference C.13. Persons located inshore beyond the first tenth of a mile from the water's edge would receive less than one percent of the dose received by those at the water's edge.

X. ESTIMATED IMMEDIATE RADIATION EXPOSURE FOLLOWING A LAND DISPOSAL ACCIDENT

This section of the appendix describes the method used to estimate the **immediate** effects of surface-deposited radioactive material possibly released to the environment as a result of a postulated accident during land disposal operations. The **delayed** effects of such an accident are the same as those described in Appendix J, Section V, for a sea disposal-related accident in which the submarine is lost at a point close to shore without the possibility of recovery.

As described in Chapter 4, Section I.B.1(a), the most severe radioactivity-related accident that can be postulated for land disposal operations is the accidental breaching of the reactor compartment outer containment, and a consequent release of 3.5 curies of surface-deposited activity (crud) from components such as piping outside the reactor vessel. The immediate consequences of this release are postulated to occur in the following way.

A. RELEASE TO THE ATMOSPHERE

The 3.5 curies of released activity are assumed to be Cobalt-60 to maximize the estimated consequences of this accident. Although this kind of release would most likely occur only in the event of submergence of the reactor compartment, a fraction of this material is assumed to become airborne and, based on the use of 0.1 percent airborne release from a similar accident study involving radioactive surface deposits (Reference C.14, page 23), the airborne release is assumed to be 0.0035 curie of Cobalt-60. That is

$$(3.5 \text{ curies})(0.1 \text{ percent}) = 0.0035 \text{ curie}$$

This material is assumed to be released over a two hour period, with a maximum-exposed individual located 100 meters directly downwind during the entire two hours.

With moderately stable atmospheric conditions that would tend to limit the dispersion of airborne contamination ("PASQUILL F" atmospheric stability conditions, wind speed one meter per second), the downwind concentration of radioactivity in the postulated cloud of contamination, without fallout, would be estimated to be

$$\chi = \frac{Q}{\mu \pi M \sigma_y \sigma_z} \text{ (per Reference C.11)}$$

where:

$$Q = \text{release rate} = \frac{0.0035 \text{ curie}}{(2 \text{ hrs})(3600 \text{ sec/hr})} = 4.9 \times 10^{-7} \text{ curies/sec}$$

μ = wind speed = 1 meter per second

π = 3.1416

$M\sigma_y$ = 19 meters, per Reference C.11 (includes meander factor M = 4)

σ_z = 2.3 meters, per Reference C.12

Therefore:

$$\chi = 3.6 \times 10^{-9} \text{ curies/m}^3 \text{ or } 3.6 \times 10^{-9}\ \mu\text{Ci/cc}.$$

If in two hours an individual breathes in one-eighth of a normal day's intake (i.e., 1/8 × 20 m^3 or 150 percent of the normal rate), his intake would be 9.3×10^{-9} curies or 9.3×10^{-3} μCi (Cobalt-60). The 70 year inhalation dose commitment factors for Cobalt-60 are 8.21×10^3 rem per curie (total body) and 5.29×10^6 rem per curie (lung), as shown in Appendix I, Table I-5. These dose commitment factors, combined with the inhalation intake of 9.3×10^{-3} μCi, imply 70 year dose commitments of 0.07 mrem to the total body and 49 mrem to the lung.

Additional accident-related exposure would be received by the individual postulated to remain 100 meters downwind from the accident location. The external exposure caused by immersion in the airborne radioactive material would be 0.016 mrem, based on a total body dose commitment for immersion equal to 2.16×10^3 rem per hour per Ci/m^3 (Appendix I, Table I-8). That is,

$$\left(3.6 \times 10^{-9} \frac{\text{curies}}{\text{m}^3}\right)\left(2.16 \times 10^3 \frac{\text{rem}}{\text{hour}} \text{ per } \frac{\text{curie}}{\text{m}^3}\right)(2 \text{ hours}) = 1.6 \times 10^{-5} \text{ rem} = 0.016 \text{ mrem}$$

Finally, the maximum-exposed individual during the accident could be subjected to direct radiation that could be as great as 0.1 mrem per hour at 100 meters. (See Appendix B, Section III.F.2 for a discussion of the shielding evaluation.) This abnormal exposure rate is attributed to the rearrangement of components within the reactor compartment, and the breach of reactor compartment containment, both of which are postulated to occur as a result of the extreme accident. Hence, the possible direct exposure during the two hour duration of the accidental exposure could be 0.2 mrem. The sum of the three hypothetical accident exposures described above is 0.3 mrem (total body), while the sum for exposure to the lung is 49 mrem.

B. RELEASE TO A SMALL BODY OF WATER

The airborne release of 0.0035 curie of Cobalt-60, from above, could next be hypothesized to be deposited in a small body of water from which a number of individuals (less than 1000) take one day's consumption (2 liters) of water before the water is discovered to be contaminated. The body of water is assumed to be 100 meters in diameter and 3 meters deep, so that its volume is 2.4×10^4 m^3. With 0.0035 curie distributed in a volume of 2.4×10^4 m^3, the Cobalt-60 concentration in the water would be 1.5×10^{-7} μCi/ml. A daily intake of 2 liters (2000 ml) implies a Cobalt-60 intake of 2.9×10^{-4} μCi, which is then combined with the Cobalt-60 ingestion dose conversion factors from Appendix I, Table I-4. These factors are 4.72×10^3 rem per curie (total body) and 8.02×10^4 rem per curie (G.I. Tract). The resulting 70 year dose commitments would be 1.4×10^{-3} mrem to the total body and 2.3×10^{-2} mrem to the G.I. Tract. These hypothetical dose commitments could be received in the one day period following the accident before users might be informed of the contamination of the water supply.

Hypothetical population dose commitments associated with these accident exposures would be 1.4×10^{-3} man-rem to the total body and 2.3×10^{-2} man-rem to the G.I. Tract.

XI. SUMMARY

This appendix describes the radiation exposure estimates associated with land disposal of submarine reactor compartments and the basis for their calculation. The estimates are as follows.

A. LONG-TERM EXPOSURES RESULTING FROM 100 NORMAL LAND DISPOSALS

The maximum long-term releases might cause radiation exposures in the far distant future (several thousand years from the present) not exceeding 6.0×10^{-3} mrem per year, total body, and 3.6×10^{-2} mrem per year, bone, for the average individual. This would mean that the population exposures would be less than approximately 2.1 man-rem per year, total body, and 12.6 man-rem per year, bone, assuming an exposed population of 350,000 persons. The hypothetical maximum individual exposures would be less than approximately 1.5 mrem per year, total body, and 8.9 mrem per year, bone, and would be applicable to only a very limited number of individuals.

The hypothetical population exposures would produce fewer than 0.001 additional health effects per year. This means that additional health effects would be improbable.

All of the above estimates assume that all 100 reactor compartments are buried in the same general disposal area. The exposure could not occur until more than 2000 years after burial, so the estimates are conservative approximations based on possible future populations and continuation of current consumption habits and practices. However, the estimates are biased toward high values and can be considered to be unrealistically high.

Natural background radiation, which is a minimum of 80 mrem per year and averages approximately 100 mrem per year, would be 13,000 to 17,000 times larger than the hypothetical exposure attributable to radioactivity released to the environment from buried reactor compartments.

B. IMMEDIATE EFFECTS RESULTING FROM AN EXTREME ACCIDENT

The maximum immediate effects of a postulated extreme accident involving land disposal operations could cause estimated exposures not exceeding 1.4×10^{-3} mrem to the total body and 2.3×10^{-2} mrem to the G.I. Tract of an average individual. This would yield a total body population exposure less than 1.4×10^{-3} man-rem, based on a population of 1000 individuals. The hypothetical maximum individual exposure would be less than 0.3 mrem to the total body and 49 mrem to the lungs.

The sequence of events required to cause these hypothetical dose commitments is considered to be extremely unlikely. Because of the high-strength reactor compartment, an actual accident of this type would most probably result in much lower values.

The exposure estimates for both normal operations and accident-related releases are intentionally estimated in a way to produce the largest values. Even with this approach, the results show negligible exposures resulting from normal disposal operations and very low accident-related exposures.

List of Figures

APPENDIX D

DESCRIPTION OF THE SEA DISPOSAL METHOD

I. INTRODUCTION

Sea disposal of defueled and decommissioned naval reactor plants would be consistent with the policy of isolation and containment of radioactive waste required by U.S. Environmental Protective Agency regulations. The locations of any sites that would be considered satisfactory for sea disposal would be remote from man and his activities, including food production. Almost all of the radioactive material would be packaged within two containment barriers, and a third containment barrier for 99.9 percent of the material is additionally provided by the fact that the radioactivity is an integral part of the structural metal of the reactor plant. Essentially all of the radioactive material would be within at least one containment barrier, primarily as an integral part of the structural metal. Only trace amounts of radioactivity (less than 0.0001 percent) would be part of the reactor compartment hull and bulkheads which constitute the first containment barrier.

The approach that would be taken in sea disposal is to maintain the integrity not only of the reactor compartment, which is formed by the outer hull and the forward and aft bulkheads, but also of the entire reactor primary coolant system. The latter includes the reactor vessel, which would be isolated from the remainder of the primary coolant system. To meet these containment objectives, a number of steps would be taken. (Also, see Appendix G, Section II.A for a discussion of the expected containment.)

The reactor compartment would be sealed at the shipyard and completely filled with water to assure that the compartment would not be damaged by submergence pressure after the submarine is sunk. The forward reactor compartment bulkhead would be fitted with a one-way valve (check valve) to permit inward flow for pressure compensation as the submarine travels in free fall from the surface to the desired depth of more than 4000 meters.

The submarine would be towed to the disposal area and intentionally flooded with water to begin the sinking operation. Complete flooding of the ship with water would occur soon after the sinking operation is begun, so that none of the compartments would be crushed by submergence pressure. The maximum terminal velocity has been estimated to be 45 feet per second (27 knots) and this velocity would be reached less than one minute after the sinking is initiated, so that the submarine would reach the bottom in approximately five minutes. It has also been estimated that the submarine would impact the relatively soft clay or mud bottom with a maximum deceleration of approximately 2 g, within 1500 feet of the release point (measured horizontally). The estimated attitude of the ship would be similar to normal ship's attitude, with a bow-up angle between 0 and 5 degrees.

Minor hull damage may be expected to occur upon impact. Breaching of the reactor compartment containment would not be expected, based on calculations, experiments in tanks with submarine models, tests at sea with large cylinders and a submarine model, and on previous submarine sinkings which were somewhat similar to the anticipated disposals, but which were not controlled as the disposals would be. The maximum shock load of deceleration on the reactor plant (that is the reactor vessel piping and components) would be less than the submarine's shock capability known from actual submarine shock tests.

This appendix describes the sequence of steps that would carry out the sea disposal option and the basis for predicting the intact condition of the submarine when it impacts the sea bottom. Total disposal site area is conservatively estimated.

II. SHIPYARD PREPARATIONS

A. REACTOR COMPARTMENT

Radioactive liquids, toxic liquids and resin beads would be removed from the reactor plant systems and disposed of in accordance with existing procedures and regulations. The reactor vessel would be isolated from the remainder of the primary plant and filled with water.

The remainder of the reactor plant would also be filled with water. The reactor compartment would be isolated from the two adjacent compartments and a pressure-equalizing one-way valve or check valve would be fitted on the forward bulkhead to permit flow only in the inward direction. The reactor compartment would be completely filled with water, just prior to towing to the disposal site. This would ensure that the reactor compartment would not contain any significant void spaces and therefore would not be subjected to significant pressure differences which would tend to crush the compartment during the period of submergence. After the submarine is on the bottom, with the pressure inside the reactor compartment approximately equal to or less than the pressure in the adjacent compartment, there would be no driving force for leakage from the reactor compartment. The only leakage through the valve would be into the reactor compartment if pressure in the adjacent compartment were greater.

Compatible materials would be used for the valve, which would be designed to handle the same pressure differentials as the bulkhead. Accelerated corrosion of the valve installed on the bulkhead would not be expected. The size and design of the valve would be such that dirt or small objects would not cause it to stick open and there would be no loose debris remaining in the ships' compartments large enough to interfere with proper functioning of the valve.

B. OTHER SUBMARINE COMPARTMENTS

All other compartments of the submarine would be altered prior to disposal at sea by cutting holes in the top of the hull to ensure that rapid flooding would occur early during the descent to the ocean floor. These holes would be spaced at approximately 12-foot intervals in compartments outside the reactor compartment, and would be approximately 2 feet in diameter. The holes would be fitted with cylindrical raised extension trunks, sealed before the sinking operation with removable covers. The purpose of the extension trunks would be to ensure that the compartments would not ship water while in transit and flood prematurely, because of the low freeboard of submarines. The covers would be removable for the actual sinking operation. To ensure that each compartment would flood with minimum void formation, holes would also be cut in the internal decking.

All other potentially compressible or crushable volumes of significance within the submarine, such as air flasks, sanitary tanks, torpedo tubes, etc., would either be flooded prior to towing operations or be opened and vented to allow rapid and complete flooding.

Some of the submarine's normal ballast material would be removed, along with salvageable equipment, and additional material (gravel) would be placed in an aft compartment to relocate the center of gravity approximately 2.5 feet aft of its normal location. As explained in Section VI.D, this would be the optimum location of the center of gravity for limiting the horizontal movement of the submarine during its descent to the sea floor.

C. SUBMARINE EXTERIOR

Horizontal control surfaces would be removed from the submarine, for the purpose of minimizing the horizontal distance that the submarine would travel during its descent to the ocean floor. A catwalk would be installed on the submarine exterior, fore and aft, to provide access for at-sea removal of the extension trunk covers. An operating station to allow flooding of the main ballast tanks by remote control would be located on the exterior of the hull on the catwalk adjacent to the submarine's "sail."

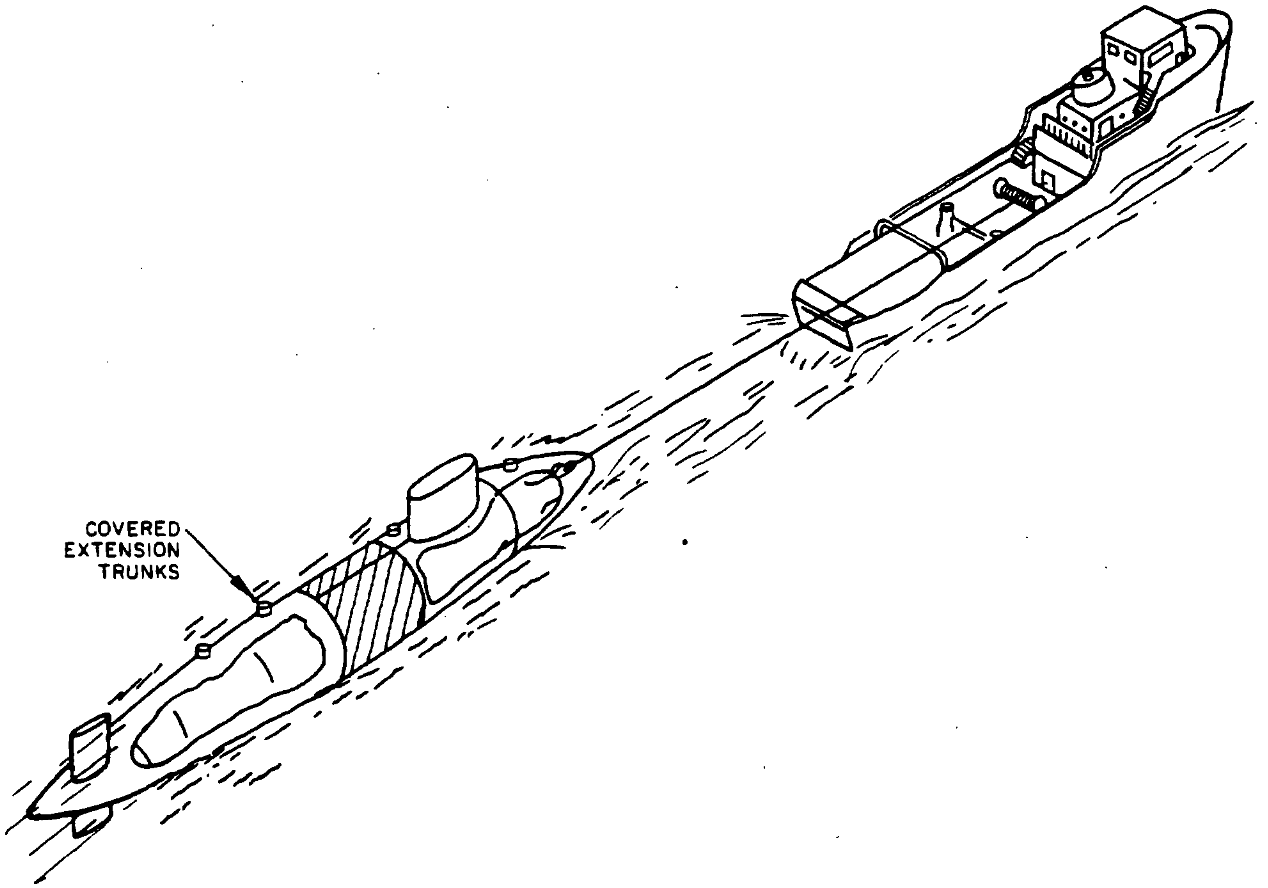

Figure D-1. Tow of Submarine to Disposal Site

III. TRANSPORTATION TO THE DISPOSAL SITE

A. TOWING FROM SHIPYARD TO SITE

The submarine would be towed bow forward from the shipyard to the disposal site by an ocean-going tug (Figure D-1), at a speed of less than 9.5 knots, the maximum stable towing speed in this configuration. The vessels would be accompanied by a Navy escort ship to assure that all other vessels would stay well clear of the tug and the towed submarine. Requirements on weather conditions for the entire time needed for the disposal operation would be imposed to minimize weather hazards. Further assurance that the submarine would be safely delivered to the disposal site for placement on the sea floor at the intended location is provided by consideration of its design and construction in separate watertight compartments. Each of the compartments would be isolated from adjacent compartments. In the unlikely event of an accident in which one or more of the isolated compartments were to develop a serious leak, the submarine would remain afloat even after taking on large volumes of water since its ballast tank vents would be valved shut until intentionally opened just prior to final submergence. The submarine's rugged construction as a warship, its successful operation for many years both in the normal submerged condition and on the surface under all weather conditions, and its restoration to seaworthiness after decommissioning, provide confidence that its final movement to the intended disposal site can be carried out with minimal likelihood of accidental sinking.

Submarines have in the past been towed long distances by the Navy. The towing stability of submarines as described above has been tested using models in towing tanks. All necessary steps would be taken to ensure that the tow would be safely conducted using procedures that have been proved safe by long experience by the Navy in similar tasks.

B. CONSIDERATIONS IN ESTABLISHING THE RELEASE POINT

The release point would be specified in advance of each disposal so that the probability of collision with a previously sunk submarine would be negligibly small. The determination of the release point would take into account the maximum navigational uncertainty, the maximum horizontal excursion or glide, the submarine's length, and the results of all previous disposals. Selection of the release point would have the objective of minimizing the eventual total disposal area consistent with avoiding collision with any previously emplaced submarines. The release point would be uncertain by no more than 0.1 mile, the assumed maximum navigation error. The total required area, as described in Section IX of this appendix, would depend on the maximum navigation error, the average glide distance, the ship length, and the total number of disposals.

IV. SINKING OPERATIONS

A. ACTIONS PRIOR TO SINKING

1. Instrumentation

Two instrumentation packages would be used. An array of sonobuoys would be deployed on the surface to determine the actual glide trajectory and the final bottom position. Other instruments, on the submarine hull, would record external and internal hull pressures, pitch-and-roll motion, and acceleration/deceleration during the sinking operation. These instruments would remain on the submarine until after impact; then they would automatically detach and float to the surface for retrieval and analysis and for re-use in later disposals. Data from both instrumentation packages would be of value in assessing the fate of the ship, particularly during the first disposals when detailed knowledge of hull behavior would be most limited.

An alternate instrumentation system that would be considered for use in monitoring the sinking operation is an array of transponders placed on the sea bottom, with several transponders placed on the hull itself. This fixed grid system could be "surveyed in" prior to sinking, replenished on a yearly basis or in case of failure, and could be used for post-sinking monitoring. These systems are available and considered to be very reliable.

2. Ship Preparations

At the disposal site (Figure D-2) a salvage crew would board the ship. The covers would be removed from the hull holes, the hull-mounted instrumentation would be activated; and the tow line would be released by the tug. Finally the ballast tank vent valves would be opened and the salvage crew would leave the ship. The submarine would settle in the water until the hull holes are submerged, after which rapid flooding would occur (Figure D-3).

B. MONITORING DURING THE SINKING OPERATION

1. Trajectory and Final Location

The array of sonobuoys laid down around the submarine at the release point would monitor the signals emitted from battery-powered precision "pingers" mounted on the bow and stern of the submarine. A reference time for the periodic output of each "pinger" would be established before sinking, and the output of each "pinger" would be relayed by the sonobuoys to the escort vessel or to an aircraft overhead. Sets of three sonobuoys would be selected and their outputs would be used in a triangulation computation to yield the position of one or the other of the "pingers" while the hull is sinking. A number of such sets would be used for the calculation and a best-estimate value of position would be obtained. In this way, not only would the hull's location be determined, but also its attitude. The position of the sonobuoy array on the earth's surface would be located by satellite or LORAN position fixes, so that the absolute position of the sunken hull (± the maximum navigation error) would be accurately determined.

2. Pressure, Acceleration/Deceleration, Roll and Pitch Angles

Recorders connected to sensors at various points on the submarine hull, would be carried down with the vessel as it sinks. Pressures, accelerations, and angles of roll and pitch would be recorded during the sinking.

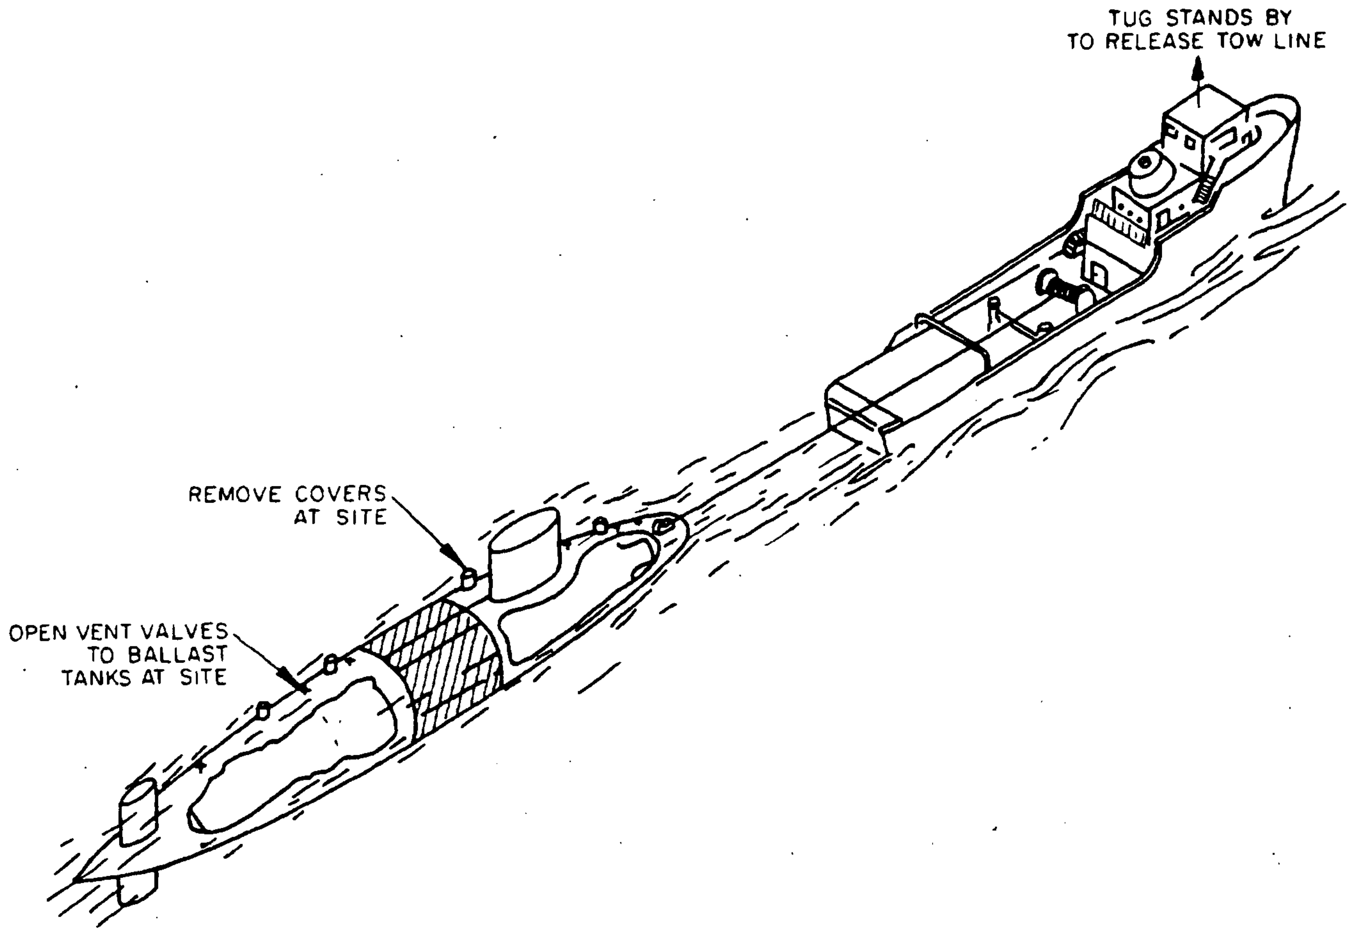

Figure D-2. Prepare to Flood and Free Fall

Each recorder, contained in a pressure cannister, would be released by a time-controlled explosive cutter after the submarine comes to rest. The cannisters would float to the surface and be picked up for analysis and reuse.

V. RESULTS OF SUBMARINE SINKINGS IN THE PAST

A. PLANNED SINKINGS

The expected condition of disposed submarines after they come to rest on the ocean bottom can be predicted from the results of comparable sinkings in the past. The most applicable data come from planned sinkings that were carried out during Project Thurber, a 1973 experiment off the coast of California, in which obsolete diesel-powered submarines were allowed to sink in a controlled way to a depth greater than 4000 meters. The second of the Project Thurber sinkings is the source of the following information. This sinking was selected primarily because of the better instrumentation used in that instance.

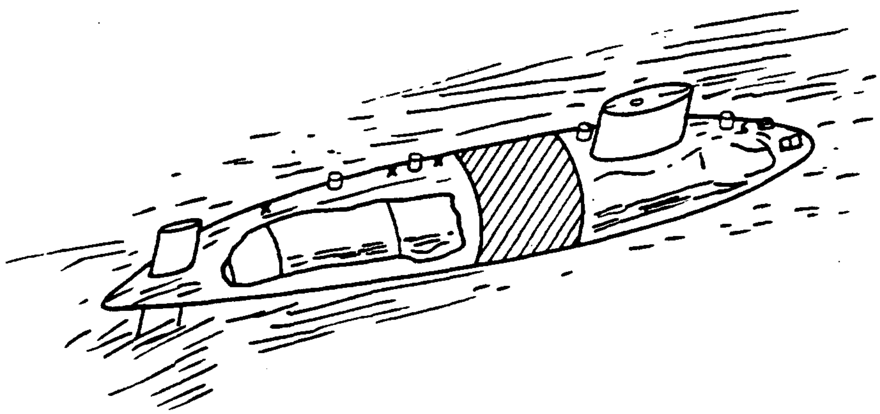

Figure D-3. Submarine Submerged With Compartments Flooding

Numerous instruments both on the submarine (ex-BLACKFIN, SS 322) and on the surface provided information on the hull's underwater velocity and final impact deceleration, as well as the structural events that took place as the initially air-filled hull partially flooded as it sank and collapsed due to hydrostatic pressure when the hull's collapse depth was reached. Hull collapse occurred in this case because the submarine was not provided with holes in its hull to ensure prompt and complete flooding, as would be provided in the event of nuclear submarine disposals at sea. As a result, the ship broke into two roughly equal sections, the stern portion of which filled with water and continued to sink, at a constant velocity of 20.5 feet per second (12 knots). Just before reaching the bottom, the attitude of the hull was slightly stern down. When it struck bottom, it stopped with a maximum deceleration of 1.7 g and penetrated into the bottom 6.5 feet. Similar information from the bow section was not obtained because the "pinger" mounted near the bow broke loose during hull collapse. The general conclusions of Project Thurber were that a satisfactory sinking procedure had been developed and that the several instrumentation schemes used in the experiment produced acceptable data.

B. ACCIDENTAL SINKINGS

An estimate of the most severe condition of the reactor plant containment of disposed submarines can be obtained from the actual results of two accidental sinkings of U.S. Navy nuclear submarines (USS THRESHER, SSN 593, and USS SCORPION, SSN 589). The sea bottom locations where the two submarines were lost have been surveyed on several occasions using submersibles with no evidence of leakage from the reactor vessel, which for these two operational submarines contained uranium fuel and fission product radionuclides, as well as the relatively small quantities of activated components that remain in defueled and decommissioned ships. In particular, the water, sediment, marine life, and debris have been monitored in the neighborhood of these sinking sites, and it has been concluded that no release of radioactivity has occurred from the reactor vessel. Only trace amounts of radioactivity originally contained in the reactor cooling water or on piping and component inner surfaces have been found. An evaluation of the most recent of these sea floor monitoring operations is provided as an annex to this appendix.

VI. RESULTS OF TESTING TO VALIDATE SINKING AND IMPACT EFFECTS

A. SUBMARINE MODEL TESTS IN A TANK

Sinking experiments were carried out in the U.S. Navy Undersea Weapons Tank at the Naval Surface Weapons Center at White Oak, Maryland. A 10-foot long scale model of a large nuclear-powered submarine (SSBN 616 class) was employed. The linear scale was 42.5 to 1. The tank was equipped with still and motion picture and television cameras in viewing ports at eight uniformly spaced depths from the surface to the bottom. The experimental program consisted of various free falls of the flooded model to a number of different depths up to 75 feet, with various configurations including removal of stern planes, fairwater planes, and rudders (Figure D-4). Initial conditions were also modified by varying the initial ballast conditions and initial pitch angles. Videotape, still photographs, and movies of each experimental run were taken. The results of the experimental program were used to verify the accuracy of a generalized computer simulation, or mathematical model, of sinking operations (next section), including ship attitude and terminal velocity.

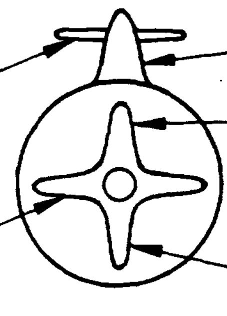

Figure D-4. View From Aft

B. COMPUTER SIMULATION

The motion trajectories for at-sea disposal of a large submarine were predicted utilizing the U.S. Navy Undersea Weapons Tank computer simulation. Such simulations were shown to provide predictions which matched the results of a wide variety of scale model experiments in the Undersea Weapons Tank.

As a result of the combined program of model testing in the tank and computer simulations, it was concluded that the most desirable configuration of the submarine for sea disposal would be as follows.

Stern planes should be removed to reduce both the maximum terminal velocity and the maximum horizontal glide. Fairwater planes should be removed to reduce the tendency toward rolling oscillations and to provide a regular spiral descent path, thereby causing reduced horizontal movement from the release point. The ship's propeller would be removed. To further reduce the maximum horizontal glide distance, ballast would be added to move the longitudinal center of gravity in the aft direction. Based on the successful combination of tank testing and computer simulation, further confirmatory tests at sea were carried out. Part C of this section describes tests at sea involving impact measurements of large cylinders. The submarine model tests are discussed in Part D.

C. IMPACT TESTS ON THE SEA FLOOR

Experiments at sea were carried out in April 1981 and January 1982 to determine the impact forces resulting from the free fall of large cylinders. Two locations were chosen for the impact tests to provide a range of soil properties. A sandy sea floor site was selected at a location 4 miles west of Port Hueneme, California, in 80 feet of water, to represent a relatively hard bottom. A clay sea floor site was selected at a location 30 miles west of Port Hueneme, in 1200 feet of water to represent a relatively soft bottom similar in strength to deep ocean clays. The deeper test location's geotechnical properties are documented in References D.1 and D.2. The objects dropped onto the sea floor were 1/4-inch thick steel-walled tanks 27 feet long and 8 feet in diameter, ballasted with concrete and water-filled, designed to achieve a terminal velocity of about 20 feet per second, and equipped with instruments to measure deceleration and internal pressure changes upon impact. Penetration distances were determined by post impact photographs of the tanks, which had been painted on each end with a grid for that purpose. The tanks used in the second round of testing in January 1982 had hemispherical ends to reduce water resistance effects and therefore increase the terminal velocity. Fully ballasted tanks weighed a minimum of 52,000 pounds in air, and about 31,000 pounds in water.

For each of the four free fall drop tests, a prediction of the maximum deceleration on impact and the penetration distance was obtained using a theoretical impact prediction model based on References D.3 and D.4. The series of tests therefore provided a measure of the accuracy obtainable with the prediction model for large cylinders, and an indication of the uncertainty associated with impact predictions for actual submarine disposals.

Comparison of the actual test data to impact prediction model results showed that the penetration predictions adequately estimated the actual penetration, with greater accuracy for clay floor drops than sandy floor drops. Actual cylinder penetration in clay was 4.5 feet while the predicted penetration was 3.6 feet. The comparison also showed the deceleration predictions adequately estimated the actual cylinder decelerations, with the measured decelerations being about 60 percent of the predicted values. In clay, the predicted deceleration was approximately 1.6 g while the actual value was 1.0 g.

On the basis of the predictions and test results with 27-foot long cylinders, it was concluded that the impact prediction model, when applied to actual submarine impacts, will yield penetration and deceleration estimates that are within ±50 percent of field results. This is considered to be a reasonable accuracy for a dynamics problem in geotechnical engineering.

D. SUBMARINE MODEL TESTS IN THE SEA

Experiments at sea were also carried out using an instrument-equipped 20-foot long scale model of a large nuclear powered submarine (SSBN 598 class). These hydrodynamic tests were performed to determine actual model trajectories during the free fall; the tests not only provided basic information but also served as a basis for comparison with computer simulations of the model's trajectories. This comparison was used to provide an indication of the uncertainty associated with the predicted motion of the actual submarine during its descent to the sea floor at the disposal site. The computer predictions employed an improved version of the predictive model used in the analysis of submarine model tank tests (Section VI.B).

The hydrodynamic experiments in the sea were performed offshore near San Diego, California in May 1981 and off San Clemente Island, California in May and November 1981. The experiments employed the 20-foot model, with a 400-foot recovery line. Various model configurations were tested: with and without stern planes, with and without fairwater planes, and with the center of gravity altered. For the configuration that would represent the submarine under actual disposal conditions, i.e., without stern planes and without fairwater planes, and with the center of gravity moved several feet in the aft direction, the effect of various initial angles was examined by releasing the model in a horizontal attitude, then with the bow 45° above horizontal, and finally with the bow 30° below horizontal.

From previous model experiments, analyses, and computer simulations on the free-fall characteristics of modern submarines, it was anticipated that the normal configuration (that is, with stern planes and fairwater planes attached and with normal center of gravity) would exhibit a pronounced tendency toward forward glide and large horizontal excursions during free fall. This was verified during early model runs.

All of the model configurations without the stern planes installed indicated little forward glide, with vertical descent in a nearly zero pitch attitude. In general, all of the configurations without stern planes and without fairwater planes (refer to Figure D-4) descended with less pitch and roll motion than configurations with only the stern planes removed. This result clearly showed the preferred configuration for actual disposal.

Vertical terminal velocity of the model tests without stern planes was in the range 39 to 45 feet per second, with a steady-state pitch angle from 1 to 5 degrees, bow up. Predicted velocity was 40 feet per second, indicating good agreement between actual test results and prediction.

The model configurations without stern planes installed usually moved in a counter-clockwise direction, such that when extrapolated to a 15,000-foot depth, the submarine would be expected to make up to two full turns (720° or less). Horizontal displacement from the point of sinking at the surface was limited to 100 feet per 1000 feet of descent, or up to 1500 feet in a 15,000-foot descent, when the center of gravity is moved 2.5 feet aft of its normal location. This movement of the center of gravity also results in a terminal velocity of 43 feet per second, with a steady-state pitch angle of 3.9 degrees, bow up.

In experiments with unusually high initial pitch angles (45° bow up and 30° bow down), the model recovered rapidly (less than 50 seconds when translated for the full scale object) with the steady state condition being about the same as for a zero initial pitch angle.

Computer simulation of the model motion was generally quite adequate for the needs of this program. It was observed, however, that much of the horizontal translation of the submarine model was actually lateral to the hull, that is "sidewise" motion not represented by the computer simulation. This indicates that the computer simulation would be of only limited accuracy in predicting precise horizontal translation when longitudinal glide is not a major factor. For this reason, a conservative 10 percent allowance (1500 feet) is made for horizontal displacement from the surface sinking point (termed g_{max} in Section IX of this appendix).

VII. EFFECT OF SEA BOTTOM CONDITIONS

In the event that sea disposal is selected, the sea floor at acceptable sites would be covered by thick layers of sediment, composed of at least 300 meters of clay, silt, sand or mixtures of these materials. The sediment properties would have been measured by core sampling and Doppler penetrometer surveys prior to site selection. The penetrometer surveys would show the degree of uniformity of the entire site area.

With the expected sea bottom conditions, and maximum predicted terminal velocity, the impact shock of the submarine hull on the sea floor would be less than design shock limits, thereby ensuring that the reactor compartment hull and bulkhead containment barriers would not be breached.

VIII. EXPECTED FINAL CONDITION OF THE SUBMARINE

If disposal at sea is selected it would be carried out with all precautions necessary to ensure that the reactor compartment containment remains intact. It is expected that the entire reactor plant would remain intact within the boundaries of the reactor compartment because the forces that would be encountered during sinking would be insufficient to damage the compartment. Of greatest importance to the containment of radioactive material is the integrity of the reactor vessel, and there is no reason to doubt that this extremely strong container would remain intact and completely closed when the submarine has come to rest on the ocean floor. If and when sea disposal of the first decommissioned submarine is performed, monitoring during and immediately after the sinking operation either will confirm that reactor compartment containment has remained intact, or it will reveal that some problem was not anticipated and reactor compartment containment integrity was lost or diminished. In the latter case, the sea disposal of the second decommissioned submarine would not be carried out until the procedure had been altered as appropriate. Since the maintenance of reactor compartment containment integrity is not a 100 percent certainty, the environmental effects of sea disposal have been conservatively estimated with the assumption that a sea disposal action could produce a "worst case" type of radioactivity release associated with complete loss of containment, that is, rupture of the reactor compartment and the reactor vessel. This assumption is very conservative because even if complete containment were not achieved, it is extremely unlikely that the reactor vessel containment would be penetrated even under the most severe landing conditions of the submarine.

IX. TOTAL DISPOSAL AREA REQUIRED

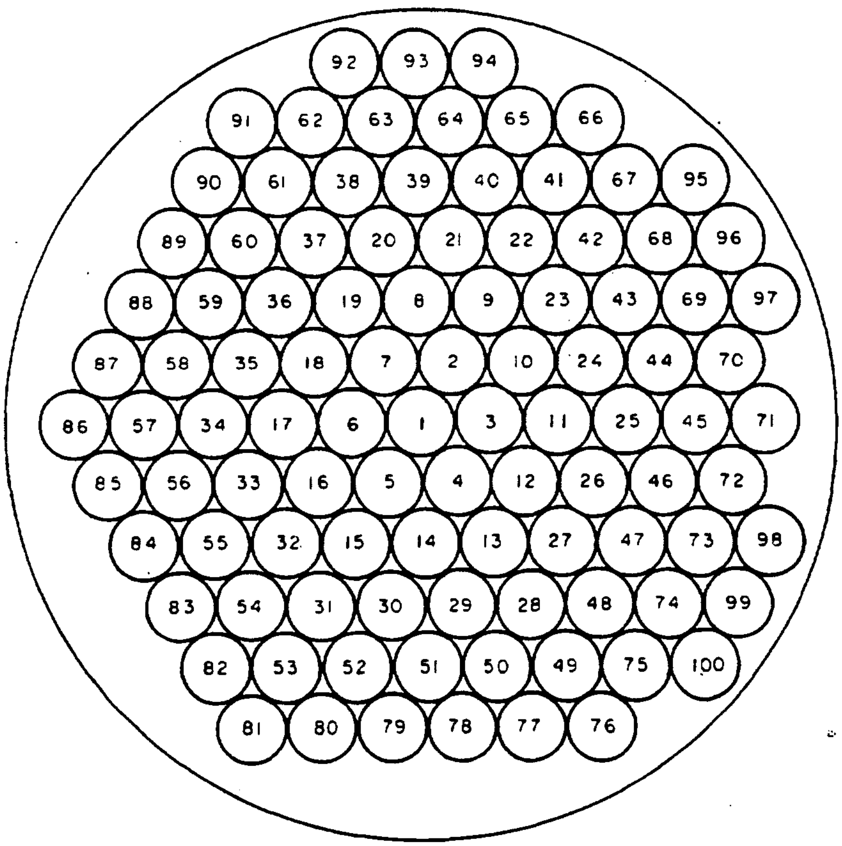
For a conservative estimate of the maximum required sea disposal area, the maximum diameter of a circular area would depend on the maximum navigational error (E_{max}) associated with establishing the surface release point, the maximum horizontal glide (g_{max}) of the submarine during the sinking, the ship length ($\mathcal{L}$), and the total number of disposals (N). As indicated in Figure D-5, when N equals 100 ships the maximum diameter of the circular disposal area would be approximately 12 times the diameter of a uniform size circle of uncertainty associated with each submarine. The latter diameter (or small circle diameter) is

$$d_{max} = 2(E_{max} + g_{max} + \mathcal{L})$$

and

$$D_{max} = 12\, d_{max}$$

The area defined in this way is conservatively large because it is based on the assumption that the final location of the submarine on the sea floor is known only within the possible glide distance. The monitoring that would be performed during sinking, however, would accurately establish the final location which in practice would reduce the actual required area.



Each small circle represents a maximum area of uncertainty associated with one disposal. Its radius equals (E_{max} + g_{max} + $\mathcal{L}$), i.e., the maximum navigational error plus the maximum horizontal glide distance plus the ship length. When 100 disposals are considered, the total area has a diameter somewhat less than 12 times the diameter of the small circle.

Figure D-5. Possible Scheme for Utilization of a Sea Disposal Area

Further conservative assumptions have been made as follows to determine a maximum disposal site area. The maximum navigational area (E_{max}) is taken to be 0.1 mile, g_{max} is assumed to be not more than 1500 feet and ℓ is taken to be a maximum length of 400 feet. The diameter of the circle of uncertainty around each submarine would then be 0.92 statute mile, and the diameter of the entire disposal area would be 11.0 statute miles. The circular area is therefore 96 square miles or 250 square kilometers. The area of a square in which this circle could be inscribed would be 320 square kilometers. These estimates show that the maximum required total area would be about 3 percent of the area limit of 10^4 km^2 proposed by the International Atomic Energy Agency included in the disposal site requirements of Chapter 3, Section II.A. Even if the maximum navigational error were taken to be 1 mile instead of 0.1 mile, the required total area would still be less than 28 percent of the area limit of 10^4 km^2.

Since as noted above the actual glide direction and distance would be known after each disposal action, the actual required area would be expected to be smaller than the estimates arrived at above.

ANNEX TO APPENDIX D

RADIOLOGICAL ENVIRONMENTAL MONITORING AT SITES OF NUCLEAR-POWERED SUBMARINE THRESHER AND SCORPION SINKINGS

I. INTRODUCTION

There have been two unfortunate occurrences involving the sinking of U.S. Navy nuclear-powered submarines. Reference D.A1 provides the Navy assessment of the radiological aspects of these sinkings as follows:

Loss of USS THRESHER and USS SCORPION

"Two U.S. Navy nuclear-powered submarines have been lost at sea in the Atlantic Ocean. The submarine THRESHER sank 10 April 1963, 100 miles from land in water 8,500 feet deep at latitude 41°45'N and longitude 65°00'W. The submarine SCORPION sank between 21 and 27 May 1968, 400 miles southwest of the Azores in more than 10,000 feet of water. The reactors used in all U.S. naval submarines and surface ships are designed to minimize potential hazards to the environment even under the most severe casualty conditions such as actual sinking of the ship. First, the reactor core is so designed that it is physically impossible for it to explode like a bomb. Second, the reactor fuel elements are made of materials that are extremely corrosion resistant, even in seawater. The reactor core could remain submerged in seawater for decades without releases of fission products while the radioactivity decays, since the protective cladding on the fuel elements corrodes only a few millionths of an inch per year. Thus, in the event of a serious accident where the reactor is completely submerged in seawater, the fuel elements will remain intact for an indefinite period of time, and the radioactive material contained in these fuel elements should not be released. The maximum rate of release and dispersal of the radioactivity in the ocean, even if the protective cladding on the fuel were destroyed, would be so low as to be insignificant.

"Radioactive material could be released from this type of reactor only if the fuel elements were actually to melt and, in addition, the high-strength, all-welded reactor system boundary were to rupture. The reactor's many protective devices and inherent self-regulating features are designed to prevent any melting of the fuel elements. Flooding of a reactor with seawater furnishes additional cooling for the fuel elements and so provides added protection against the release of radioactive fission products.

"Radiation measurements, water samples, bottom sediment samples, and debris collected from the area where THRESHER sank were analyzed for radioactivity shortly after the sinking and again in 1965 by various laboratories with highly sensitive equipment. Similarly, seawater and bottom sediment samples taken near SCORPION's hull were analyzed for radioactivity. None of these samples showed radioactivity above naturally-occurring background levels, and none showed evidence of radioactivity released from either THRESHER or SCORPION.

"In 1977, followup samples of water, sediment, marine life, and debris were collected from the immediate THRESHER debris areas. In 1979, followup samples of water, sediment, marine life, and debris were collected from the immediate SCORPION debris areas. None of these samples showed any evidence of release of radioactivity from the reactor fuel elements in either THRESHER or SCORPION. However, Cobalt-60 released from both THRESHER and SCORPION coolant systems was detectable at low levels in sediment samples in the debris areas. The amount of Cobalt-60 radioactivity in these samples was small compared to the naturally-occurring radioactivity in the sediments. Based on the samples, less than 0.001 curie of Cobalt-60 was estimated to be present in the sediment at either site. Cobalt-60 was not detectable in samples of water, marine life, or debris. Thus, the THRESHER and SCORPION have not had a significant effect on the radioactivity in the environment."

As indicated above, the initial radiological monitoring that was conducted shortly after the sinkings, using state-of-the-art techniques, did not detect radioactivity from either THRESHER or SCORPION. Subsequent returns to these two sites in 1977, 1979, and 1983 were made to reassess the situation after a period of time. The opportunity was also used to obtain some beneficial data from these unfortunate occurrences. It is the purpose of this annex to report the additional information determined in the 1977, 1979, and 1983 surveys upon which the above summary from Reference D.A1 was based. The radiological surveys at both sites consisted of in-situ gamma spectrum measurements of the sediment, obtained by descents to the sites in the submersible TRIESTE, as well as collections of bottom water, sediment cores, and bottom-dwelling marine life samples for later analysis in laboratory facilities.

II. SITE DESCRIPTION

A. THRESHER SITE

The THRESHER debris lies on the upper continental rise east of George's Bank and Brown's Bank in 2590 meters of water. The area where the debris lies is relatively flat and featureless. A slight slope exists which descends gradually to the southeast and the Sohm Abyssal Plain. The sediments in the area of the debris are estimated to be almost 100 meters thick with the first meter consisting of a silty, clayey sand at the surface (0 to 5 centimeters) with silty clay underneath. The sediments are well oxygenated by the overlying water with positive reduction-oxidation potentials occurring throughout the first 0.6 meter of the sediments. Chemical and mineralogical data for the sediments taken in 1977 from the debris site are given in Reference D.A2. A geological description of the sediments in the general area (40°43'N, 65°50'W to 40°16'N, 64°57'W) is given in Reference D.A16.

The THRESHER debris lies in an area along the Western Boundary Undercurrent flow. This current is a rapidly moving mass of cold (~3°C), well-oxygenated water that originates in the Arctic and sweeps down along the continental rise off Canada and the United States, as shown in Figure D-A1. The current velocity at the ocean bottom in the vicinity of the THRESHER debris was observed with the submersible to be roughly one half knot (about 26 cm/sec), flowing in a generally southwesterly direction. This agrees with the velocities of 9.5 to 26.5 cm/sec reported in Reference D.A3 for the Western Boundary Undercurrent. The average dissolved oxygen level in the water at the site was found to be 7.8 mg/liter based on measurements of water samples obtained by the submersible. The undercurrent, as it flows along the ocean bottom, is approximately 500 kilometers wide and varies in thickness (height off the bottom) from about 100 to 500 meters. The top of the undercurrent as it flows along the continental rise is always deeper than 1800 meters below the ocean surface. There is apparently little or no mixing of the Western Boundary Undercurrent with continental shelf water along the entire North American coast (Reference D.A4).

Based on observations from the submersible and examinations of preserved sediments, marine life in the vicinity of the THRESHER debris is relatively abundant and quite varied. Marine animals including nematode and polychaete worms, as well as tunicates, molluscs, foraminifera and brachipods are present in the sediments. Sponges, hydroids, gorgonians, echinoids, holothurians, isopods, amphipods, spider crabs, lobsters, and shrimp are found on the sediments or on the debris. Animal life in the water above the bottom sediments was observed to be much sparser than that found in or on the sediments.

The marine life observed in the water column included small octopus, squid, shrimp, and various fish. The most common fish noted in the debris area are the Macrourid species or rat tails. Rarer fish include Bathypteroids (tripod fish), Synaphobranchids (deep-sea eels), Halosaurids, Synodonts, Brotulids, and Chimaerids. None of these are fished commercially, and the THRESHER depth is over 2000 meters deeper than any known commercially fished areas. The closest commercial fishing is approximately 50 kilometers to the west at a depth less than 1000 meters.

B. SCORPION SITE

The SCORPION debris lies 400 miles southwest of the Azores in over 10,000 feet of water in a basin at the eastern edge of the Mid-Atlantic ridge (Figure D-A2). The area is relatively flat and featureless with very fine carbonate sediment (30-46 percent $CaCO_3$), and very low current. The sediment deposition rate in the region has been estimated at 1.8 centimeters per 1000 years, one of the lowest depositional rates in the Atlantic Basin (Reference D.A5).

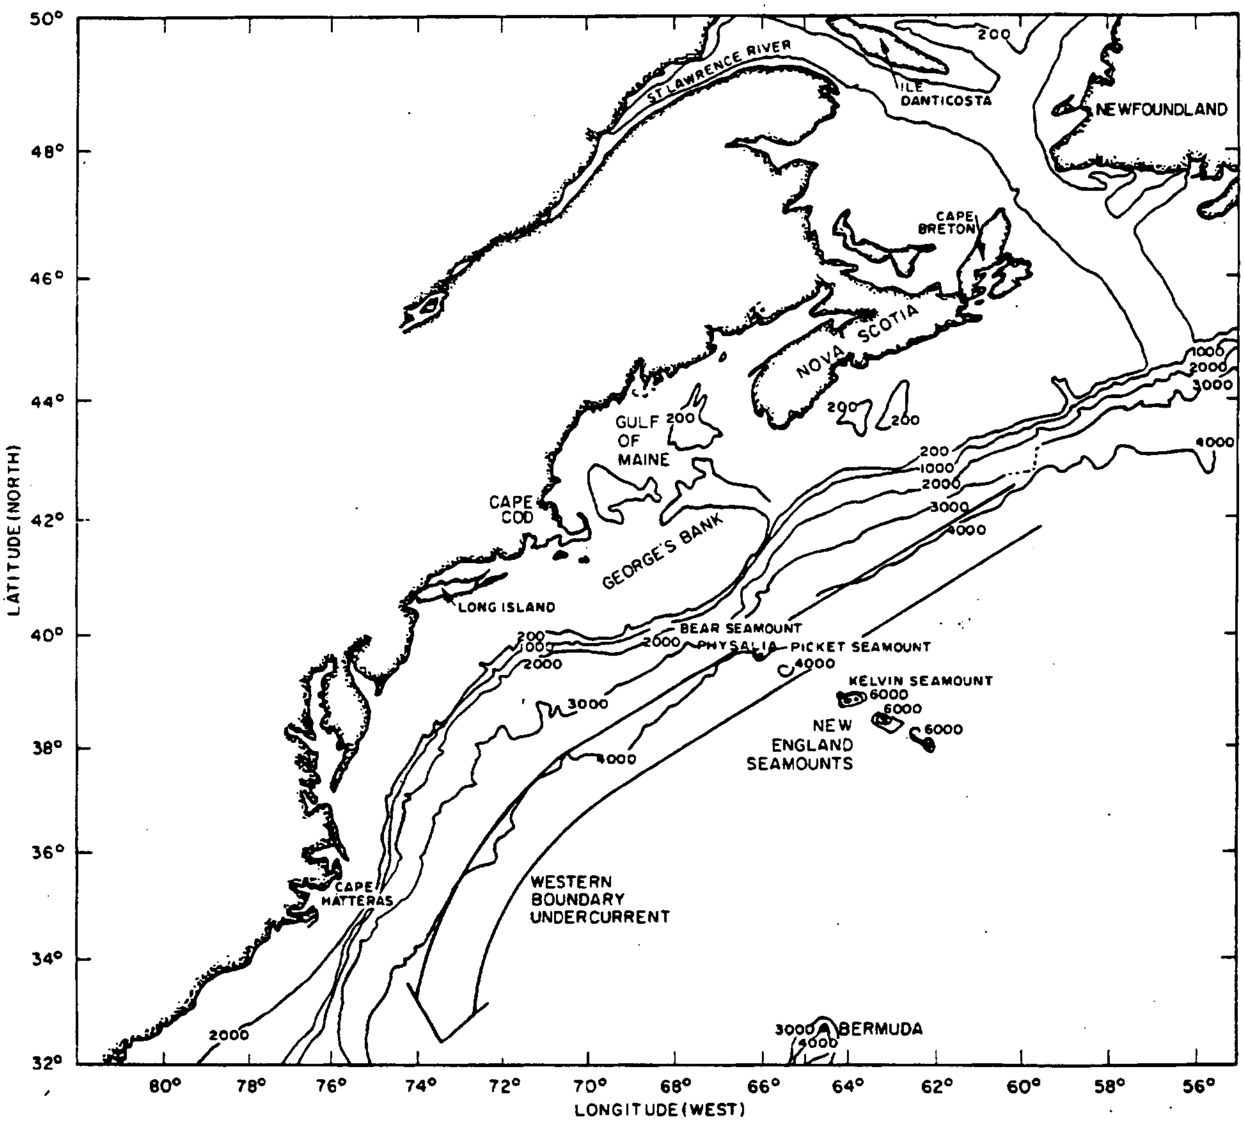

Figure D-A1. Western Boundary Undercurrent and North American Coastline (Depths are Shown in Meters)

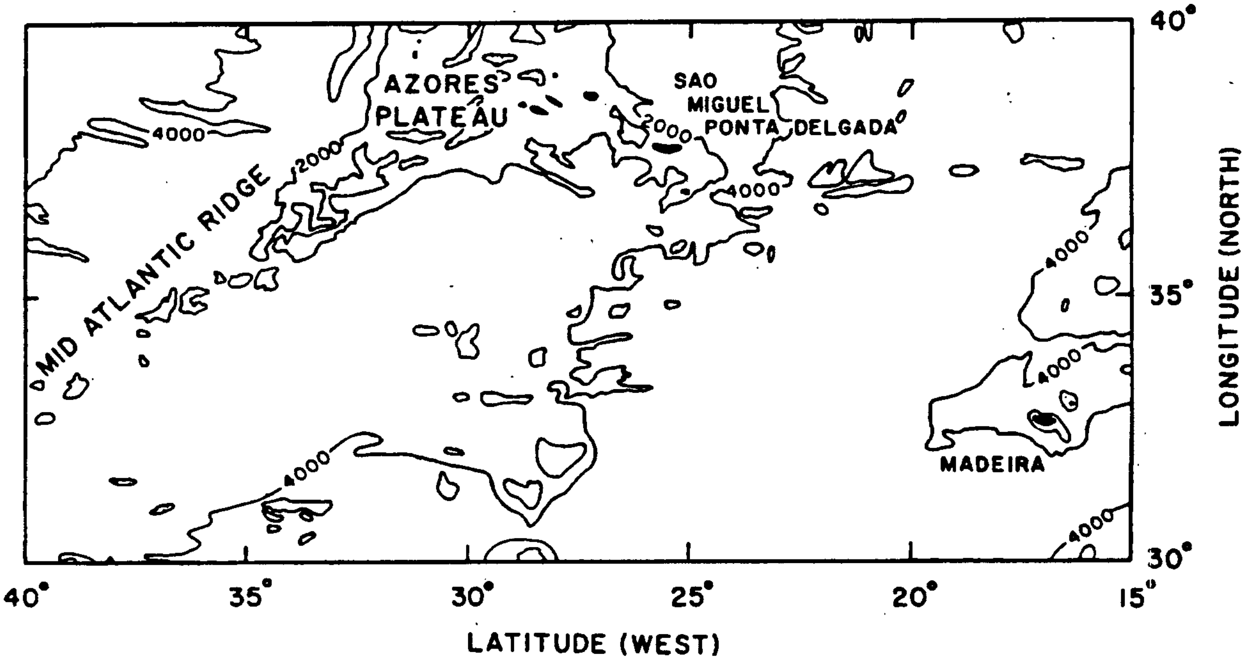

Figure D-A2. Eastern Atlantic Ocean in the Vicinity of the Azores (Depths are Shown in Meters)

Based on measurements of samples collected by the submersible, the sediments at the SCORPION site are well oxygenated by the overlying water with positive reduction-oxidation potentials occurring throughout the first 0.5 meter of the sediments. A detailed geological description of the sediments in the general area is given by Reference D.A5.

The water mass in this vicinity is described in Reference D.A6 as being made up in part of North Atlantic deep water and Mediterranean water. The well-oxygenated North Atlantic deep water originates in the Arctic and flows south, whereas the Mediterranean water, which is higher in salinity, flows down the continental slope out of the Straits of Gibraltar and spreads westward across the Atlantic toward the Mid-Atlantic ridge.

The temperature, salinity, dissolved oxygen, and current data obtained by the submersible at the SCORPION site are consistent with this hypothesis. The average dissolved oxygen measured in the water is 6.6 mg/liter, and the temperature is less than 6°C. The net current velocity measured over a one day period, as shown in Figure D-A3, is extremely low with a varying direction indicative of tidal basin slosh. The net current for the 25-hour period was 0.9 centimeter per second in the direction of 200 degrees magnetic.

Observations from the submersible revealed very little marine life on the surface of the sediments in the vicinity of the SCORPION. The sediment in the area is very fine textured and it is possible that animal tracks would not endure for long periods because of the shifting of the sediment. Debris are colonized by corals, sponges, crinoids, and primitive chordates (ascidians). Several fish consisting mainly of macrourids (rat tails), crustaceans (large and small shrimp), and Munidopsis (squat lobsters), were observed in the vicinity of the debris. Two macrourids approximately 40 centimeters long were caught at the debris site using a surface-deployed modified lobster trap. Bottom photographs of a rocky region in the general area of the

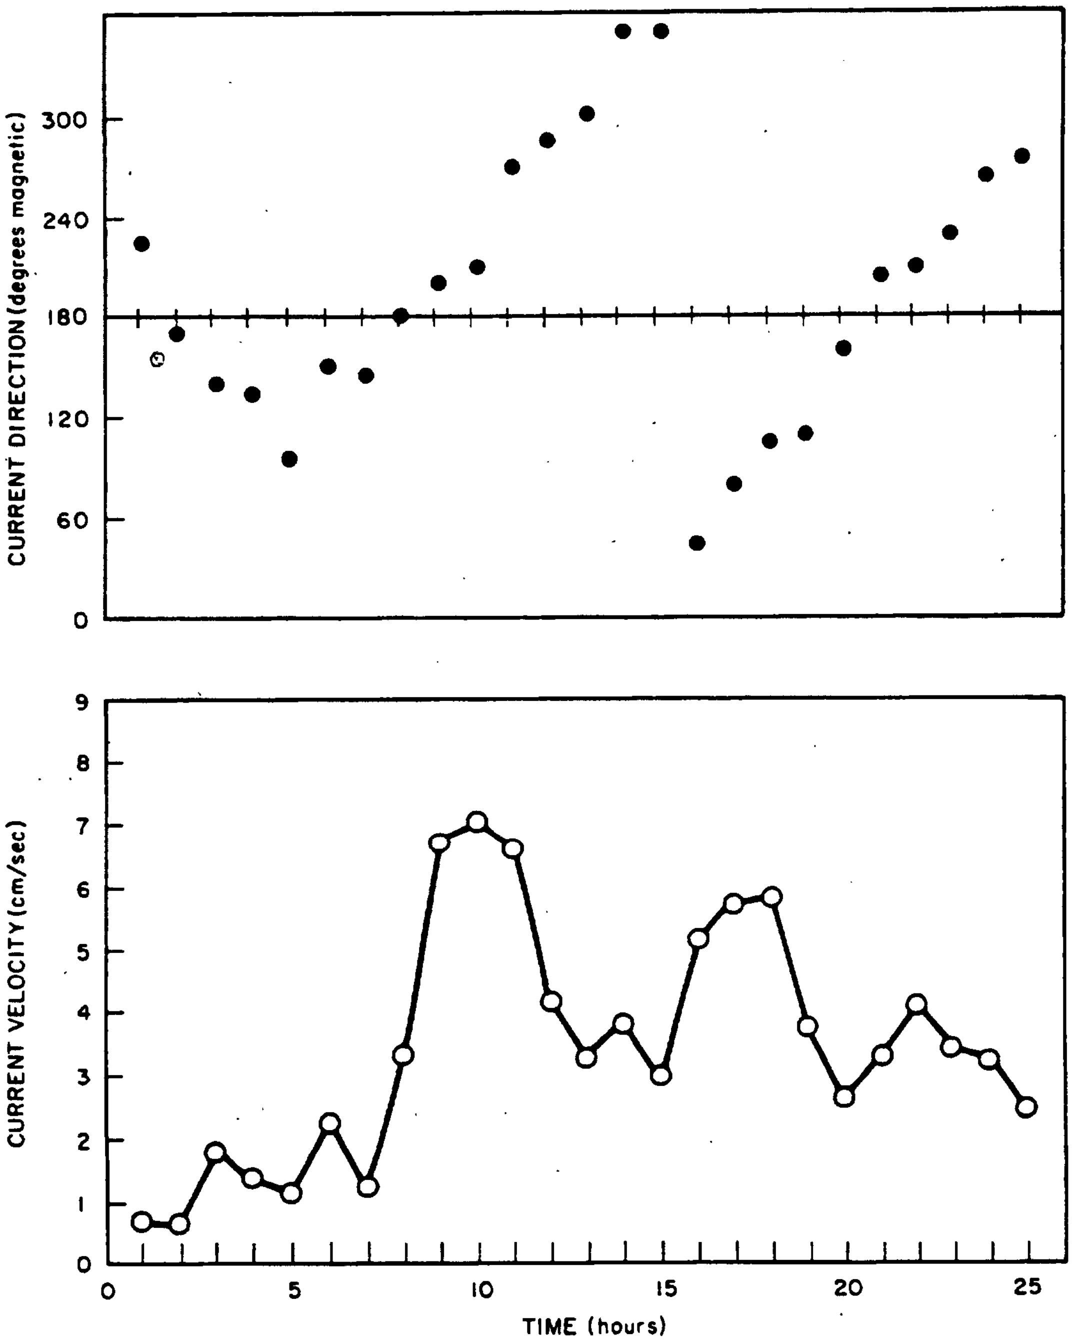

Figure D-A3. Bottom Current Data for 25-Hour Period Taken at the SCORPION Debris Site Area in September 1979

debris site (Reference D.A7) indicate a benthic faunal density of about 100 individuals or colonies per 4000 square meters, or about 0.025 per square meter. This would be equivalent to a biomass of 0.84 g/m^2 to 1.65 g/m^2 which compares with the value of 1.0 g/m^2 suggested in Reference D.A6 as the average biomass of the benthos in deep central Atlantic areas. These values are also similar to the epifaunal biomass at 4067 meters in the Pacific, Reference D.A8, but may be high by a factor of two or three for the actual biomass at the SCORPION site excluding the colonization of debris.

III. RADIOACTIVITY IN THRESHER AND SCORPION REACTOR PLANTS

There are three principal categories of radioactivity within the THRESHER and SCORPION debris. The first is the small amount of waterborne radioactive corrosion products which are formed during the operation of the reactor plant and adhere to the inside surfaces of the piping and components that contact the water coolant that is circulated through the nuclear reactor. These corrosion products are mainly in the form of small magnetic oxide particles that are very insoluble in both water and dilute acids. Less than 10 curies of radioactivity, predominantly Cobalt-60 and Nickel-63, is estimated to be currently present in these corrosion products at either site, with the majority of this radioactivity contained within the reactor vessel.

The second category of radioactivity is the neutron activated, corrosion-resistant metal making up the nuclear reactor pressure vessel and its internal structure. Again, most of the radioactivity is in the form of Cobalt-60 and Nickel-63 in the steel alloys completely within the massive steel reactor pressure vessel. The corrosion products generated by the slow process of corrosion in seawater are generally non-magnetic, and therefore would be distinguishable from the magnetic corrosion products formed during reactor operation. Less than 1000 curies and 5000 curies of radioactivity are estimated to be currently present as an integral part of the activated metals of the reactor plant in the THRESHER and the SCORPION, respectively.

The third category of radioactivity is the nuclear fuel which is protected from exposure to seawater by an alloy that is extremely resistant to seawater corrosion. The total fission product and actinide series radioactivity in the nuclear fuel in either the THRESHER or SCORPION reactor is presently less than 30,000 curies. This radioactivity is retained in the fuel, which is inside the reactor vessel, which in turn is inside the ship's hull.

IV. RADIOLOGICAL MONITORING, SAMPLE ANALYSIS PROGRAM, AND RESULTS

The radiological monitoring of the THRESHER and SCORPION sites in 1977 and 1979 was conducted by the Navy using the deep submersible TRIESTE. The 1983 monitoring of the THRESHER site utilized the deep submergence research vehicle ALVIN and its support ship LULU, and the oceanographic research vessel CAPE FLORIDA. The radiological monitoring program was based on analyzing for Cobalt-60, Cesium-137, and Nickel-63. Cobalt-60 is the predominant gamma-emitting radionuclide and Nickel-63 is the predominant beta emitter present in the small amount of corrosion products present inside the reactor coolant systems and contained in the activated metal structures inside the reactor vessel. Cesium-137 is the predominant long-lived gamma-emitting fission product radionuclide present in the reactor fuel. Potassium-40 is a naturally-occurring radionuclide. The methods of monitoring and analysis for the 1977 and 1979 samples are described below along with the results obtained. This is followed by a discussion of the more recent results obtained during the 1983 expedition to the THRESHER site.

A. BOTTOM WATER

Bottom water samples were taken in the immediate vicinity of the THRESHER and SCORPION debris for measurement of gamma-emitting radionuclides and dissolved oxygen. Water samples were obtained at the THRESHER site with one liter Niskin sterile bag samplers, with the inlet tubing facing forward, mounted to the TRIESTE superstructure. When the desired sampling locations were reached with the submersible, a mechanical arm was utilized to activate the samplers. At the SCORPION site, a similar arrangement using Teflon bag samplers was used to obtain water samples for radioactivity measurement while an electrically-operated General Oceanics Rosette sampler mounted on the submersible's superstructure was utilized to

IV. THE RELEASE MODEL

This section describes the mathematical model used to estimate the total rate at which radioactive nuclides would be released from the activated metals of the submarine into the nearby ocean environment. This model was constructed to account for the following processes:

(1) The corrosion of the activated components of the submarine plant.

(2) The penetration of various containment barriers within the submarine by corrosion.

(3) The accumulation of activity in the form of corrosion products within the contained volumes of the submarine prior to general penetration of barriers.

(4) The decay of radioactive isotopes during the time period when the materials are contained.

(5) The release of corrosion products into the open ocean environment.

The equations used in this model mathematically represent these processes in a general way, allowing for a wide variety of applications. The specific applications of this model are described in Section II. These applications used conservative values of the various parameters employed in the equations. A discussion of those values is presented in Section IV.D.

A. THE CORROSION OF ACTIVATED COMPONENTS OF THE SUBMARINE

After the submarine has settled on the ocean floor, the metal surfaces of the submarine will be subjected to the process of corrosion. This corrosion process will slowly liberate both stable and activated corrosion product particles which subsequently enter the surrounding water volumes. Details of the various corrosion processes which exist in the deep ocean are presented in Appendix F. The results of that appendix indicate that a simple mathematical model may be used to conservatively estimate the rates at which the metals will be corroded and subsequently released into nearby volumes.

1. Description of the Modeled Components

The metal components which make up the submarine reactor plant are mostly large, complicated structures. In order to estimate the rate at which corrosion products are liberated from a component, a simplified geometry was used for each component. All of the activated components of the reactor plant have a large surface area to volume ratio, thus the thickness of the metal comprising the component will be the limiting dimension in terms of corrosive penetration. Therefore, the components are modeled in a one-dimensional manner, i.e., the fraction of the entire component which is considered to be corroded away is the fraction of its initial thickness which has been consumed by corrosion processes.

2. Corrosion Release From a Single Component

Each component which contains activated metal was assumed in the previous section to be representable as a one-dimensional thickness. Assuming that the activity in the component is uniformly distributed throughout the initial thickness of the component leads to an activity density per unit thickness ($\rho(t)$) given by

$$\rho(t) = \frac{A_o e^{-\lambda t}}{\tau_o}$$

where:

A_o = the initial activity for a particular nuclide in the component at the time of disposal (Ci)

λ = the radioactive decay constant for a particular nuclide (yr^{-1})

t = the time since disposal (yr)

τ_o = the initial thickness of the component (cm).

The factor $e^{-\lambda t}$ accounts for the radioactive decay of the radionuclide while contained within the metal matrix. Multiplying the density of the activity per unit thickness times the rate at which the thickness is released by corrosion gives the rate at which the given component liberates activity, $\omega(t)$, into a nearby volume.

$$\omega(t) = \rho(t) r(t)$$

where:

$r(t)$ = the corrosion release rate, i.e., the total rate at which the thickness of the component enters the surrounding volumes.

Based on Section IV.7 of Appendix F, the corrosion release rate is conservatively given by the long term corrosion rate. As a result, the equation for $\omega(t)$ becomes:

$$\omega(t) = \rho(t)\,(2r_L)\,\xi(t) \qquad (G.1)$$

where:

r_L = the long term corrosion rate for the component. (The factor of two accounts for two sides corroding.)

$\xi(t)$ = a factor which takes into account whether or not the component is corroding at time t

$$= \begin{cases} 0 \text{ if the component has previously corroded away or if corrosion has not started} \\ 1 \text{ if the component is actively corroding at time t.} \end{cases}$$

3. Grouping the Components According to Containment

In Section II.A.1, three levels of containment were discussed with respect to the major portion of the activity. The first level, which includes virtually all of the initial activity, is the containment provided by the structural metals of the submarine reactor plant, since the activated atoms are an integral part of those metals. The second level of containment, which includes most of the initial activity, is that provided by the sealed reactor vessel which encloses the most active components. The third and final level of containment is that provided by the submarine reactor compartment bulkheads and external hull which enclose virtually all of the activated components. These last two levels of containment are made up of metal barriers which would be closed and sealed prior to disposal.

In the "expected containment" scenario, each of these barriers is assumed to be intact once the submarine reaches the ocean floor. As a result, the majority of the activated components are within the reactor vessel containment, a few components are within the reactor compartment but outside the reactor vessel, and one slightly active component (the outer surface of the hull and bulkheads which contain less than 40 mCi) is exposed directly to the environment. With this division in mind, three functions, Ω_{RV}, Ω_{RC}, and Ω_{out} are used to represent the total rate of introduction of corrosion products into the three volumes which receive the corrosion products: the reactor vessel, the reactor compartment volume outside the reactor vessel, and the open ocean, respectively. These functions are defined by the equations:

$$\Omega_{RV}(t) = \sum_{k=1}^{n} C_{(RV)_k}(t)\,\omega_k(t) = e^{-\lambda t} \sum_{k=1}^{n} C_{(RV)_k}(t) \left(\frac{A_{o_k}}{\tau_{o_k}} \,(2r_{L_k})\,\xi_k(t) \right) ; \qquad (G.2i)$$

$$\Omega_{RC}(t) = \sum_{k=1}^{n} C_{(RC)_k}(t)\,\omega_k(t) = e^{-\lambda t} \sum_{k=1}^{n} C_{(RC)_k}(t) \left(\frac{A_{o_k}}{\tau_{o_k}} (2r_{L_k})\, \xi_k(t)\right) \; ; \qquad \text{(G.2ii)}$$

$$\Omega_{out}(t) = \sum_{k=1}^{n} C_{(out)_k}(t)\,\omega_k(t) = e^{-\lambda t} \sum_{k=1}^{n} C_{(out)_k}(t) \left(\frac{A_{o_k}}{\tau_{o_k}} (2r_{L_k})\, \xi_k(t)\right) . \qquad \text{(G.2iii)}$$

where:

$\omega_k(t)$ = activity release rate for a particular component (Equation (G.1))

k = an index specifying a particular component

n = the total number of modeled components

$C_{(RV)_k}(t)$ = the reactor vessel containment coefficients, i.e., the fraction of the kth component which corrodes into the reactor vessel volume.

$$= \begin{cases} 1 & \text{if the particular component is entirely contained within the reactor vessel} \\ 1/2 & \text{if only one side of the component is enclosed by the vessel} \\ 0 & \text{if the component lies entirely outside the vessel.} \end{cases}$$

$C_{(RC)_k}(t)$ = the reactor compartment containment coefficient, i.e., the fraction of the kth component which corrodes into the reactor compartment volume outside the reactor vessel.

$$= \begin{cases} 1 & \text{if the particular component is fully contained in the compartment exclusively} \\ 1/2 & \text{if only one side of the component is enclosed} \\ 0 & \text{if the component lies entirely outside.} \end{cases}$$

$C_{(out)_k}(t)$ = the external containment coefficient, i.e., the fraction of the kth component which is directly exposed to external ocean waters, including those components which were previously unexposed to the external waters at times prior to barrier penetrations.

$$= \begin{cases} 1 & \text{if the particular component is fully exposed to the ocean waters at time t} \\ 1/2 & \text{if only one side of the component is exposed to the ocean waters at time t} \\ 0 & \text{if the component is not exposed to the ocean waters at time t.} \end{cases}$$

NOTE: The values of 1/2 are used only for those components which make up containment boundaries and as such, release material equally into two volumes.

The time dependence of these coefficients has been explicitly included to account for a shift in the containment levels of the components as the containment barriers are penetrated. For example, when the bulkheads which contain the reactor compartment volume are penetrated by corrosion, those components (or fractions of components) which were contained by the compartment are then considered to be exposed to the external ocean waters. Mathematically, this is accomplished by changing the values of the relevant containment coefficients at the appropriate times. Thus the value of the external containment coefficients for each component will gain the value of the corresponding compartment coefficient at the time of bulkhead penetration (t_{BLKD}). The values of the compartment coefficients will then drop to zero for all components indicating that for times **greater than** t_{BLKD}, no containment is afforded by the compartment volume. Similarly, the external containment coefficient for each component will increase by the value of the corresponding reactor vessel containment coefficient at the time when the vessel walls are penetrated by general surface corrosion (t_{RV}). The values of the vessel coefficients will then drop to zero for all components indicating that for times **greater than** t_{RV}, no containment is afforded by the reactor vessel volume.

Thus the containment coefficients are constrained so that

$$C_{(RV)_k}(t) + C_{(RC)_k}(t) + C_{(out)_k}(t) \equiv 1$$

for all times and components. This ensures that each component is fully accounted for at all times.

In summary, the function $\Omega_{RV}(t)$ represents the rate at which the components inside the reactor pressure vessel release activity as corrosion products into the vessel volume. Similarly, $\Omega_{RC}(t)$ represents the rate at which activity is released into the reactor compartment volume. Lastly, $\Omega_{out}(t)$ represents the rate at which the activity is released to the nearby ocean waters from corrosion of components which are directly exposed to those waters.

4. Corrosion Start and Stop Times

The functions $\xi_k(t)$ used in Equations (G.1) and (G.2) indicate whether or not a given component (the kth) is actively corroding at time t after disposal. Critical to the evaluation of $\xi_k(t)$ are the times when the kth component first begins to corrode and when it has fully corroded away. Since all components are exposed to water (either seawater or the water used as a pressure compensating medium), the starting time for all corrosion is t = 0, the time of disposal. The time when the component stops corroding, t_{s_k}, depends on its initial thickness and the applicable corrosion rates as defined by the equation:

$$t_{s_k} = \frac{\tau_{o_k} - (2(r_{s_k} - r_{L_k})(t_B))}{2r_{L_k}} \quad \text{(G.3)}$$

where:

τ_{o_k} = the initial thickness of the kth component (inches)

r_{s_k} = the first year corrosion rate (inches/yr)

r_{L_k} = the long term corrosion rate (inches/yr)

t_B = the time when the corrosion rate changes (= 1 year).

The factor of two in Equation (G.3) accounts for the corrosion of the component from two sides.

Thus the function $\xi_k(t)$ is explicitly defined by

$$\xi_k(t) = \begin{cases} 1 & 0 \leq t \leq t_{s_k} \\ 0 & t_{s_k} < t \end{cases}$$

The set of corrosion stop times defines a sequence of time values between which the functions Ω_{RV}, Ω_{RC}, and Ω_{out} are continuous; as such they are significant in the definition and solution of the various differential equations which follow (Sections IV.B and C). This set of values will be identified by the set notation $\{t_i\}$, where $t_i = t_{s_k}$ for some kth component.

B. THE ACCUMULATION OF CORROSION PRODUCTS

The previous section dealt with the corrosion of activated components and the rates at which activity is introduced by corrosion into various volumes of water. In the "expected containment" scenario, the reactor vessel and reactor compartment volumes are initially self-contained since there is no path for activity to leave these volumes at the time of disposal. As a result, the activity liberated by corrosion from the components within those volumes will accumulate within the two volumes, at least until the components which make up the barriers to movement are penetrated by corrosion. This section presents the functions and equations used in this model to represent the accumulation of activity inside these volumes.

1. Division of Corrosion Products into Transportable and Non-Transportable Fractions

Upon formation, corrosion products can be categorized within this model as either transportable or non-transportable. The transportable fraction of the corrosion products includes all of the material which could easily be transported by ocean waters if it were not contained. In particular, this fraction includes those corrosion products which are soluble or made of extremely small ($<0.45\ \mu m$ diameter) particles which could be carried long distances by ocean currents before settling onto the sediments. The non-transportable fraction of the liberated corrosion products includes the released material which would not be easily transported by ocean currents even if it were exposed to those currents. This fraction specifically accounts for the large corrosion flakes and particles which would settle quickly to the floor of the containing volume or onto the ocean sediments. In addition, a model of the exchange between the transportable and non-transportable fractions has been included to account for interaction processes between the two fractions which occur after formation. These processes include the coagulation and deposition of small transportable particles and the erosion and resuspension of non-transportable material.

2. Equations

a. The Accumulation of Activity Inside the Reactor Vessel

(1) Due to Corrosion of Internal Components

Prior to the penetration of the thick reactor vessel walls (at $t = t_{RV}$), the activity in the corrosion products released from the components inside the reactor vessel will accumulate within the vessel volume. The total amount of this activity, $N(t)$, can be divided into transportable $N_T(t)$, and non-transportable $N_N(t)$ fractions such that:

$$N(t) = N_T(t) + N_N(t)$$

Using a mass balance approach, simple differential equations can be constructed to model the behavior of these functions. Expressing the rate of change of $N(t)$ as the sum of various source and loss effects yields the equation:

$$\frac{dN}{dt} = \overbrace{\underbrace{\Omega_{RV}(t)}_{\substack{\text{corrosion of}\\ \text{internal}\\ \text{components}}}}^{\text{source terms}} - \overbrace{\Big(\underbrace{\Lambda\,(N_T, t)}_{\substack{\text{leakage loss}\\ \text{through}\\ \text{pitting holes}}} + \underbrace{\lambda N}_{\text{decay}}\Big)}^{\text{loss terms}} \qquad \text{(G.4)}$$

Applying the appropriate terms to each fraction yields the following equations for the transportable and non-tranportable functions:

$$\frac{dN_T}{dt} = \underbrace{f\,\Omega_{RV}(t)}_{\text{corrosion}} - \underbrace{\Lambda(N_T,t)}_{\text{leakage}} - \underbrace{\lambda N_T}_{\text{decay}} + \underbrace{\beta_1 N_N - \beta_2 N_T}_{\text{interaction terms}} \qquad (G.5)$$

$$\frac{dN_N}{dt} = \overbrace{(1-f)\,\Omega_{RV}(t)} - \overbrace{\lambda N_N} - \overbrace{\beta_1 N_N + \beta_2 N_T} \qquad (G.6)$$

Initial conditions: $N_T(0) = N_N(0) = 0$;

where:

$\Omega_{RV}(t)$ = the rate of release of corrosion products into the reactor vessel volume (Equation (G.2))

f = the fraction of newly formed corrosion products that are considered transportable*

$\Lambda(N_T,t)$ = the function which describes the rate of loss of transportable material due to leakage through small pitting penetrations (Section IV.B.2.b)

β_1 = the resuspension coefficient for non-transportable material within containment (yr^{-1})

β_2 = the coagulation-deposition coefficient for transportable material within the vessel (yr^{-1}).

The interaction term $\beta_1 N_N$ represents a simple linear model of the erosion and subsequent resuspension of non-transportable material into the transportable fraction. Similarly, the term $\beta_2 N_T$ represents the coagulation and subsequent deposition of transportable material into the non-transportable segment.

(2) **Accumulation of Activity Inside the Reactor Vessel Due to Crud**

For the crud activity inside the reactor vessel volume, the behavior of the transportable and non-transportable fractions $C_T(t)$ and $C_N(t)$, respectively, will be similar to the activity due to fresh corrosion products (N_T and N_N).

The basis of the equations used to describe these functions is essentially the same as that in the previous section; with the exception that the exchange mechanisms have not been included because the total amount of crud activity is relatively small, and that there is no corrosion source term for the crud. This basis leads to the equations:

$$\frac{dC_T}{dt} = -\Lambda(C_T,t) - \lambda C_T \qquad (G.7)$$

$$\frac{dC_N}{dt} = -\lambda C_N \qquad (G.8)$$

Initial conditions:

$$C_T(0) = f_c C_o \ ,$$

$$C_N(0) = (1 - f_c) C_o \ .$$

***In each of the calculated scenarios used in this analysis, the fraction f was assigned the value 1, which conservatively treats all newly formed corrosion products as being transportable. As a result, the terms representing the introduction of non-transportable material directly by corrosion were zero in the applications of this model.**

where:

f_c = the fraction of the initial crud activity which is assumed to be transportable*

C_o = the amount of crud activity present in the vessel at the time of disposal

$\Lambda(C_T,t)$ = the function which describes the rate of loss from the transportable material due to leakage through pitting penetrations (Section IV.B.2.b).

b. **Leakage Out of the Reactor Vessel Through Pitting Penetrations**

A few sections of metal which make up a small part of the reactor vessel containment barrier are made of corrosion resistant alloys which are subject to the pitting processes discussed in Appendix F (Section IV.A.3). As a result, these portions of the barrier would be penetrated by numerous small pits well before general surface corrosion penetrates the remaining bulk of the reactor vessel walls. The area opened by these pits would provide a path through which some of the transportable fraction of the activity in the vessel volume could move into the surrounding compartment. Since little or no pressure differential will exist between the reactor vessel and the reactor compartment, any transport of material through the pits would be due to a diffusion process. The terms used to model the loss of activity from the reactor vessel due to leakage, $\Lambda(N_T,t)$ and $\Lambda(C_T,t)$, are simple diffusion expressions. These expressions are given as the product of a diffusion coefficient, a cross sectional flow area, and the concentration gradient (assuming a zero concentration outside the vessel maximizes the gradient). Mathematically, Λ is given by the equations:

$$\Lambda(N_T,t) = \sum_{\substack{i \\ \text{pitting} \\ \text{components}}} \delta(t) \frac{\alpha_i(t)}{\theta_i} \frac{N_T(t)}{V_{RV}} \qquad \text{(G.9i)}$$

$$\Lambda(C_T,t) = \sum_i \delta(t) \frac{\alpha_i(t)}{\theta_i} \frac{C_T(t)}{V_{RV}} \qquad \text{(G.9ii)}$$

where:

$\delta(t)$ = the diffusion coefficient in seawater for the transportable materials (based upon the particle size) (cm^2/sec)

i = index used to indicate a particular pitting region

$\alpha_i(t)$ = the total area through which diffusion can occur in the particular pitting region (see below) (cm^2)

θ_i = the limiting path length through which the diffusing particles must travel (cm)

V_{RV} = the volume of water in the reactor vessel (cm^3).

The function $\alpha_i(t)$ represents the total area through which diffusion can occur. Initially, $\alpha_i(t)$ would equal the total area of the first pits which penetrate the component. Then, $\alpha_i(t)$ is assumed to increase linearly

*Actual calculations treated all crud as transportable by setting $f_c = 1$.

with time until such time when the area of the pits exceeds any area which occurs in series along the path of the diffusing particles (as in Appendix F, Section IV.A.3). Mathematically, $\alpha_i(t)$ is defined as:

$$\alpha_i(t) = \begin{cases} 0 \ , & t \leq t_{ip} \ , \\ \alpha_{io} + \dfrac{(\alpha_{im} - \alpha_{io})}{(t_{im} - t_{ip})}(t - t_{ip}) \ , & t_{ip} < t < t_{im} \ , \\ \alpha_{im} \ , & t \geq t_{im} \ ; \end{cases}$$

where:

α_{io} = the total area of the pits at the time of initial penetration. This area is defined as the total volume of corroded material divided by the pitted component thickness

$= S_i\,[(r_s - r_L)\,(t_B) + (t_{ip}\,r_L)]/\tau_{pi}$

α_{im} = the limiting diffusion area in series with the pitting area (e.g., the inner cross sectional area of a pipe when the pitted component is the pipe wall)

t_{ip} = the time when the pitted component is initially penetrated

$= [(\tau_{pi}/P) - (r_s - r_L)(t_B)]/r_L$

t_{im} = the time when the total area of the pits becomes equal to the limiting diffusion area

$= [\tau_{pi}\,(\alpha_{im}/S_i) - (r_s - r_L)(t_B)]/r_L$

S_i = the total surface area of the component subjected to pitting corrosion

r_s, r_L = the short and long term corrosion rates for the corrosion resistant alloys (Appendix F, Table F-1)

P = corrosion pitting factor (Appendix F, Section III.D.1)

τ_{pi} = initial thickness of the particular pitting region

t_B = the time when the corrosion rate changes (= 1 year).

The Equations (G.9i) and (G.9ii) complete the definitions of the differential Equations (G.5) and (G.7) respectively, in terms of defined variables or functions.

c. **Accumulation of Activity Outside the Reactor Vessel and Inside the Reactor Compartment**

Prior to general penetration of the enclosing bulkheads, the reactor compartment volume will accumulate corrosion products. During this period, the total activity contained within the reactor compartment outside the reactor vessel W(t), can be divided into transportable $W_T(t)$ and non-transportable $W_N(t)$ portions.

The differential equations for these functions are based on a mass balance as in the previous sections.

$$\frac{dW_T}{dt} = \underbrace{f\,\Omega_{RC}(t)}_{\text{corrosion source}} - \underbrace{\lambda W_T}_{\text{decay loss}} + \underbrace{\Lambda(N_T,t) + \Lambda(C_T,t)}_{\text{leakage gain from vessel}} \qquad (G.10)$$

$$\frac{dW_N}{dt} = \overbrace{(1-f)\,\Omega_{RC}(t)} - \overbrace{\lambda W_N} \qquad (G.11)$$

Initial conditions: $W_T(0) = 0$, $W_N(0) = 0$,

where:

f = the fraction of newly formed corrosion products that is considered transportable

$\Omega_{RC}(t)$ = the rate of release of corrosion products directly into the reactor compartment (Equation (G.2))

$\Lambda(N_T,t) + \Lambda(C_T,t)$ = the rate of transfer of activity from the reactor vessel into the compartment through pitting penetrations (Equations (G.9i) and (G.9ii))

λ = the radioactive decay constant (yr^{-1}).

The interaction terms included for the accumulation functions inside the vessel (N_T and N_N) have not been included here in order to model these functions (inside the reactor compartment volume) conservatively.

d. **Accumulation of Non-Transportable Activity Outside Contained Volumes**

During the entire time period that the corrosion of the submarine components progresses, non-transportable activity can be generated according to the non-transportable fraction $(1 - f)$ of the newly formed activity. In addition, non-transportable activity can be generated inside the reactor vessel volume by the coagulation and deposition of transportable material. The model allows some of the resulting non-transportable material to eventually lie outside containment barriers, either because it was formed by corrosion of components outside those barriers or because it became uncovered as the barriers were penetrated. The total amount of this non-transportable activity outside containment will be designated by the function $O_N(t)$. This function can be divided into four separate parts according to the origin of the activity.

$$O_N(t) = O_{NC}(t) + O_{NRV}(t) + O_{NK}(t) + O_{NRC}(t) \qquad (G.12)$$

where:

$O_{NC}(t)$ = the non-transportable activity outside containment due to the corrosion of components outside contained volumes

$O_{NRV}(t)$ = the remaining non-transportable activity outside containment which was contained by the reactor vessel at the time of vessel penetration (t_{RV})

$O_{NK}(t)$ = the remaining non-transportable activity outside containment due to the crud activity

$O_{NRC}(t)$ = the remaining non-transportable activity outside containment which was contained by the reactor compartment volume at the time of bulkhead penetration (t_{BLKD}).

Because it is assumed that all of the transportable activity available to the ocean is released to the environment and transported by the processes presented in Appendix H, the total amount of transportable activity outside containment is not considered in this section. However, part of the transportable activity released to the ocean waters is composed of material resuspended directly from the non-transportable material outside containment. The rate of release to the ocean waters of transportable material from the resuspension of uncontained non-transportable material S(t), (Section IV.C), is expressed as:

$$S(t) = \beta O_N(t) \tag{G.13}$$

where:

β = the rate coefficient for the resuspension of corrosion products into the ocean waters.

This term acts as a loss term for each of the functions contributing to the total non-transportable activity which leads to the following differential equations for those functions:

$$\frac{dO_{NC}}{dt} = (1 - f)\,\Omega_{out}(t) - \beta O_{NC} - \lambda O_{NC} \tag{G.14}$$

$$\frac{dO_{NRV}}{dt} = -\beta O_{NRV} - \lambda O_{NRV} \tag{G.15}$$

$$\frac{dO_{NK}}{dt} = -\beta O_{NK} - \lambda O_{NK} \tag{G.16}$$

$$\frac{dO_{NRC}}{dt} = -\beta O_{NRC} - \lambda O_{NRC} \tag{G.17}$$

subject to the initial conditions:

$$O_{NC}(O) = O$$

$$O_{NRV}(t_{RV}) = N_N(t_{RV})$$

$$O_{NK}(t_{RV}) = C_N(t_{RV})$$

$$O_{NRC}(t_{BLKD}) = W_N(t_{BLKD})$$

These initial conditions are such that these functions explicitly account for all of the non-transportable activity from the contained volumes after the barriers are penetrated.

3. Solutions of the Accumulation Equations

In order to evaluate the accumulation functions N_T, N_N, C_T, C_N, W_N, W_T, and O_N presented in the previous sections, the solutions of the differential equations defined for each function have been generated.

a. Solutions of the Reactor Vessel Accumulation Equations

(1) Establishment of Currents Inside the Reactor Vessel

After the reactor vessel containment boundary has been penetrated by pitting, the possibility of an ocean bottom current entering the vessel before general penetration of the vessel wall is extremely small. To conservatively account for this possibility, such a current can be assumed to start at a time (t_{ic}) after the pitting penetration time and before the overall vessel wall penetration (t_{RV}). The inception of this current within the reactor vessel volume is modeled within the existing equations by a discontinuous change in the value of the diffusion coefficient ($\delta(t)$) used in Equations (G.9i) and (G.9ii).

(2) Solutions of the Reactor Vessel Accumulation Equations Prior to Current Flow

Prior to the time (t_{ic}) when currents are assumed to flow through the reactor vessel, Equations (G.5), (G.6), (G.7), and (G.8) describe the behavior of the functions N_T, N_N, C_T, and C_N, respectively. During this period, the environment within the sealed reactor vessel would be extremely stable, with little or no water movement. As a result, the coagulation and deposition of transportable material would far outweigh the resuspension of non-transportable material (i.e., $\beta_2 N_T \gg \beta_1 N_N$). Therefore, assuming that the resuspension term is zero during this period simplifies Equations (G.5) and (G.6) while not substantially changing the results. Thus for $t < t_{ic}$, the applicable equations for these functions become:

$$\frac{dN_T}{dt} = f\Omega_{RV}(t) - \Lambda(N_T,t) - \lambda N_T - \beta_2 N_T \tag{G.18}$$

$$\frac{dN_N}{dt} = (1-f)\,\Omega_{RV}(t) - \lambda N_N + \beta_2 N_T \tag{G.19}$$

$$\frac{dC_T}{dt} = -\Lambda(C_T,t) - \lambda C_T \tag{G.7}$$

$$\frac{dC_N}{dt} = -\lambda C_N \tag{G.8}$$

Initial conditions:

$$N_T(0) = 0$$

$$N_N(0) = 0$$

$$C_T(0) = f_c C_o$$

$$C_N(0) = (1 - f_c)C_o$$

The solution of Equation (G.8) is straightforward and is given by the equation:

$$C_N(t) = (1 - f_c)C_o e^{-\lambda t} \tag{G.20}$$

The solutions of Equations (G.18), (G.19), and (G.7) can be approximated by dividing the time intervals defined by the set $\{t_i\}$ (see Section IV.A.4) over which the functions Ω_{RV} and Λ are continuous into small enough increments so that these functions can be represented in a simplified way. In other words, given the ith time interval $t_i \leq t \leq t_{i+1} \leq t_{ic}$, a set of intermediate and closely spaced time values $\{s_m\}_i$ can be constructed such that if $s_m \leq t \leq s_{m+1}$, then the equations:

$$\Omega_{RV}(t) \approx (Z_v)_m e^{-\lambda t} = e^{-\lambda t} \sum_k C_{(RV)_k}(s_m)\left(\frac{A_{o_k}}{t_{o_k}}(2r_{L_k})\,\xi_k(s_m)\right)$$

$$\Lambda(N_T,t) \approx N_T H_m = N_T \sum_i \delta(s_m)\frac{\alpha_i(s_m)}{\theta_i V_{RV}} \tag{G.21}$$

$$\Lambda(C_T,t) \approx C_T H_m$$

are reasonable approximations over the subinterval (s_m, s_{m+1})

where:

$(Z_v)_m$ = a constant defined by the summation for the $\Omega_{RV}(t)$ function defined by Equation (G.2i)

H_m = a constant defined by the summation for the $\Lambda(N_T,t)$ function defined by Equation (G.9i)

s_m = an entry in the set $\{s_m\}_i$ dividing the time interval between t_i and t_{i+1}.

These approximations simplify Equations (G.18), (G.19), and (G.7) so they can be rewritten as:

$$\frac{dN_T}{dt} = f Z_{vm} e^{-\lambda t} - N_T H_m - \lambda N_T - \beta_2 N_T$$

$$\frac{dN_N}{dt} = (1 - f) Z_{vm} e^{-\lambda t} - \lambda N_N + \beta_2 N_T$$

$$\frac{dC_T}{dt} = -C_T H_m - \lambda C_T$$

when t is such that $s_m \leq t \leq s_{m+1}$ is true.

The solutions of these equations are:

$$N_T(t) = N_T(s_m)e^{-(\lambda+\beta_2+H_m)(t-s_m)} + \left(\frac{f Z_{vm} e^{-\lambda t}}{(\beta_2 + H_m)}\right)(1 - e^{-(\beta_2+H_m)(t-s_m)}) \quad (G.22)$$

$$N_N(t) = N_N(s_m)e^{-\lambda(t-s_m)} + (1 - f)e^{-\lambda t} Z_{vm} (t - s_m)$$
$$+ N_T(s_m)e^{-\lambda(t-s_m)} \left(\frac{\beta_2}{\beta_2 + H_m}\right)(1 - e^{-(\beta_2+H_m)(t-s_m)}) \quad (G.23)$$
$$+ f e^{-\lambda t} Z_{vm} \left(\frac{\beta_2}{\beta_2 + H_m}\right) \left[(t - s_m) - \frac{(1 - e^{-(\beta_2+H_m)(t-s_m)})}{(\beta_2 + H_m)}\right]$$

$$C_T(t) = C_T(s_m)\, e^{-(\lambda+H_m)(t-s_m)} \quad (G.24)$$

These approximate solutions to Equations (G.18), (G.19), (G.7), and (G.8) provide a simple way to evaluate these functions at times $t < t_{ic}$, which was used in a computer program for this analysis. In addition, the approximations presented by Equations (G.21) do not introduce large errors in the evaluations of these functions because the specific terms or factors which are represented by the constants H_m and Z_{vm} either vary slowly or are indeed constant over the small time interval specified.

(3) Solutions of the Reactor Vessel Accumulation Equations After the Inception of Currents

After the time when currents are assumed to enter the reactor vessel (t_{ic}) and before general penetration of the vessel side wall (t_{RV}), Equations (G.5), (G.6), (G.7), and (G.8) apply to the functions N_T, N_N, C_T, and C_N, respectively. However, during this period these currents are assumed to cause the resuspension of non-transportable material to dominate the coagulation and deposition of transportable materials. Thus the term $\beta_1 N_N$ is assumed to be much greater than $\beta_2 N_T$ (i.e., $\beta_1 N_N \gg \beta_2 N_T$), which implies that the applicable equations during this time period can be rewritten as:

$$\frac{dN_T}{dt} = f\Omega_{RV}(t) - \Lambda(N_T,t) - \lambda N_T + \beta_1 N_N \quad (G.25)$$

$$\frac{dN_N}{dt} = (1 - f)\,\Omega_{RV}(t) - \lambda N_N - \beta_1 N_N \tag{G.26}$$

$$\frac{dC_T}{dt} = -\Lambda(C_T, t) - \lambda C_T \tag{G.7}$$

$$\frac{dC_N}{dt} = -\lambda C_N \tag{G.8}$$

for times such that $t_{ic} \leq t \leq t_{RV}$.

Since Equation (G.8) is the same in this time interval as in the intervals prior to the currents inception, the solution (G.20) still applies.

The solutions of Equations (G.25), (G.26), and (G.7) are generated in the same manner as before by dividing each time interval (t_i, t_{i+1}) into small subintervals defined by a set of intermediate time values $\{s_m\}_i$. Further, the division between each s_m and s_{m+1} is made small enough so that the approximations used before (Equations (G.21)) are reasonable when t satisfies the condition,

$$t_{ic} \leq t_i \leq s_m \leq t < s_{m+1} \leq t_{i+1} \leq t_{RV} \tag{G.27}$$

These simplifications reduce the above differential equations into the following forms:

$$\frac{dN_T}{dt} = f Z_{vm} e^{-\lambda t} - N_T H_m - \lambda N_T + \beta_1 N_N$$

$$\frac{dN_N}{dt} = (1 - f) Z_{vm} e^{-\lambda t} - \lambda N_N - \beta_1 N_N$$

$$\frac{dC_T}{dt} = -C_T H_m - \lambda C_T$$

whose solutions in terms of the values at the beginning of the subintervals are:

$$N_T(t) = N_T(s_m)e^{-(\lambda + H_m)(t - s_m)} + \frac{Z_{vm} e^{-\lambda t}}{H_m}(1 - e^{-H_m(t - s_m)})$$

$$- (1 - f)Z_{vm} e^{-\lambda t} e^{-\beta_1 (t - s_m)} (1 - e^{-(H_m - \beta_1)(t - s_m)}) \tag{G.28}$$

$$+ \frac{\beta_1 N_N(s_m) e^{-(\lambda + \beta_1)(t - s_m)}}{(H_m - \beta_1)} (1 - e^{-(H_m - \beta_1)(t - s_m)})$$

$$N_N(t) = N_N(s_m)e^{-(\lambda + \beta_1)(t - s_m)} + \frac{(1 - f)Z_{vm} e^{-\lambda t}}{\beta_1}(1 - e^{-\beta_1 (t - s_m)}) \tag{G.29}$$

$$C_T(t) = C_T(s_m)\, e^{-(H_m + \lambda)(t - s_m)} \tag{G.30}$$

for t values between s_m and s_{m+1}.

b **Solutions of the Reactor Compartment Accumulation Equations**

Before the time when the containing bulkheads are penetrated (t_{BLKD}), the reactor compartment volume will accumulate corrosion particles. During this period, the equations which describe the behavior of the transportable (W_T) and non-transportable (W_N) parts for times such that $0 \leq t \leq t_{BLKD} \leq t_{ic}$ are:

$$\frac{dW_T}{dt} = f\Omega_{RC}(t) + \Lambda(N_T,t) + \Lambda(C_T,t) - \lambda W_T \qquad \text{(G.10)}$$

$$\frac{dW_N}{dt} = (1 - f)\,\Omega_{RC}(t) - \lambda W_N \qquad \text{(G.11)}$$

Subject to the initial conditions:

$$W_T(0) = W_N(0) = 0$$

Dividing the intervals defined by the set $\{t_i\}$, once again, into smaller subintervals defined by the sets $\{s_m\}$, so that

$$t_i \leq s_m \leq t < s_{m+1} \leq t_{i+1} \leq t_{BLKD} \qquad \text{(G.31)}$$

is true, leads to the simplifying approximations:

$$\Omega_{RC}(t) = Z_{cm}\, e^{-\lambda t}$$

$$\Omega_{RV}(t) = Z_{vm}\, e^{-\lambda t}$$

$$\Lambda(N_T,t) + \Lambda(C_T,t) \approx (N_T + C_T)H_m$$

Where Z_{cm} and Z_{vm} are defined by the summations in Equations (G.2i) and (G.2ii), respectively, and H_m is defined by Equations (G.9i) and (G.9ii).

These approximations simplify the differential equations above, which become:

$$\frac{dW_T}{dt} = f Z_{cm}\, e^{-\lambda t} + H_m(N_T + C_T) - \lambda W_T$$

$$\frac{dW_N}{dt} = (1 - f)\, Z_{cm}\, e^{-\lambda t} - \lambda W_N$$

Subject to the conditions that W_T and W_N are continuous at time $t = s_m$ and for values of t is such that $s_m \leq t \leq s_{m+1}$ is true.

The solutions of these equations in terms of the values at the beginning of the subinterval are:

$$\begin{aligned} W_T(t) = {} & W_T(s_m)\, e^{-\lambda(t-s_m)} + f Z_{cm}\, e^{-\lambda t}(t - s_m) \\ & + N_T(s_m)\, e^{-\lambda(t-s_m)} \left(\frac{H_m}{H_m + \beta_2}\right) \left(1 - e^{-(\beta_2 + H_m)(t-s_m)}\right) \\ & + f Z_{vm}\, e^{-\lambda t} \left(\frac{H_m}{H_m + \beta_2}\right) \left[(t - s_m) - \left(\frac{1}{H_m + \beta_2}\right)\left(1 - e^{-(\beta_2 + H_m)(t-s_m)}\right)\right] \\ & + C_T(s_m)\, e^{-\lambda(t-s_m)} \left(1 - e^{-H_m(t-s_m)}\right) \end{aligned} \qquad \text{(G.32)}$$

$$W_N(t) = W_N(s_m)\, e^{-\lambda(t-s_m)} + (1-f) Z_{cm}\, e^{-\lambda t}(t - s_m) \qquad (G.33)$$

These equations provide a simple procedure for determining the values of $W_T(t)$ and $W_N(t)$ for any time $t \leq t_{BLKD}$.

c. Solutions of the Accumulation Equations for Uncontained Non-Transportable Activity

The differential equations for the individual parts of the total non-transportable activity outside the containment barriers are:

$$\frac{dO_{NC}}{dt} = (1-f)\,\Omega_{out}(t) - \beta\, O_{NC} - \lambda\, O_{NC} \qquad (G.14)$$

$$\frac{dO_{NRV}}{dt} = -\beta\, O_{NRV} - \lambda\, O_{NRV} \qquad (G.15)$$

$$\frac{dO_{NK}}{dt} = -\beta\, O_{NK} - \lambda\, O_{NK} \qquad (G.16)$$

$$\frac{dO_{NRC}}{dt} = -\beta\, O_{NRC} - \lambda\, O_{NRC} \qquad (G.17)$$

Subject to the initial conditions:

$$O_{NC}(0) = 0$$

$$O_{NRV}(t_{RV}) = N_N(t_{RV})$$

$$O_{NK}(t_{RV}) = C_N(t_{RV})$$

$$O_{NRC}(t_{BLKD}) = W_N(t_{BLKD})$$

Between each of the time intervals defined by the set $\{t_i\}$, the function $\Omega_{out}(t)$ is equal to the product of a constant Z_{oi}, and the decay factor $e^{-\lambda t}$, because all of the terms in the summation of Equation (G.2iii) are in fact constant within each time interval. Expressing $\Omega_{out}(t)$ in this form simplifies Equation (G.14) which becomes:

$$\frac{dO_{NC}}{dt} (1-f) Z_{oi}\, e^{-\lambda t} - (\beta + \lambda) O_{NC}$$

This solution of this equation is

$$O_{NC}(t) = O_{NC}(t_i)\, e^{-(\beta+\lambda)(t-t_i)} + (1-f) Z_{oi}\, e^{-\lambda t}\,(1 - e^{-\beta(t-t_i)}) \qquad (G.34)$$

for $t_{i+1} \geq t \geq t_i$. This formula provides a simple method for evaluating $O_{NC}(t)$ for all times $t \geq 0$.

The solutions of Equations (G.15), (G.16), and (G.17) are relatively straightforward. Assuming that each function is zero prior to its initial time values leads to:

$$O_{NRV}(t) = \begin{cases} 0, & t < t_{RV} \\ N_N(t_{RV})\, e^{-(\lambda+\beta)(t-t_{RV})}, & t \geq t_{RV} \end{cases} \qquad (G.35)$$

$$O_{NK}(t) = \begin{cases} 0\ , & t < t_{RV} \\ C_N(t_{RV})e^{-(\lambda+\beta)(t-t_{RV})}\ , & t \geq t_{RV} \end{cases} \qquad (G.36)$$

$$O_{NRC}(t) = \begin{cases} 0\ , & t < t_{BLKD} \\ W_N(t_{BLKD})e^{-(\lambda+\beta)(t-t_{BLKD})}\ , & t \geq t_{BLKD} \end{cases} \qquad (G.37)$$

Thus the total non-transportable activity outside containment $O_N(t)$ can be evaluated by summing each of the functions above.

C. RELEASES TO THE OCEAN ENVIRONMENT

With the mathematical functions modeling the corrosion release, leakage, and accumulation of corrosion products defined, the overall model giving the release rate of transportable activity to the ocean environment can now be constructed. The total release rate of transportable activity to the ocean is divided into five distinct parts based upon the general means or nature of release. Thus the total release rate function ($R(t)$) is defined by the equation:

$$R(t) = U(t) + K(t) + L(t) + B(t) + S(t)$$

where:

$U(t)$ = the release rate to the environment from the corrosion of structural components directly exposed to free ocean waters

$K(t)$* = the release rate to the environment from initially uncontained "crud" present at the time of disposal

$L(t)$ = the release rate to the environment due to the leakage of corrosion products through pitting penetrations in the otherwise intact reactor vessel

$B(t)$ = the rate of release to the environment of transportable material suspended within a contained volume, immediately after the containing walls are penetrated by surface corrosion

$S(t)$ = the release rate to the ocean waters due to the resuspension of non-transportable material outside contained volumes.

1. Release Rate Due to the Corrosion of Components Directly Exposed to Ocean Waters

For each nuclide the release rate to the environment due to the corrosion of components which are directly exposed to ocean waters, $U(t)$, is simply:

$$U(t) = f\ \Omega_{(out)}(t)$$

where:

f = the fraction of newly formed corrosion products that are considered transportable

$\Omega_{(out)}(t)$ = the rate at which the components exposed directly to ocean waters release activity in corrosion products (Equation (G.2iii), Section IV.A.3).

***In the expected containment scenarios, all of the crud activity is initially contained within the reactor vessel volume at the time of disposal, therefore, the $K(t) \equiv 0$ for these scenarios.**

2. Release Rate Due to Initial Surface-Deposited Activity (Crud)

Since the crud is expected to be initially contained within an intact reactor vessel, then the release of this small amount of activity will be included in the terms L(t), B(t), and S(t). Therefore, in the expected containment scenarios the function K(t) = 0 for all times. However, in the minimum containment case where the crud is assumed to be directly exposed to the ocean waters, the function K(t) is given by:

$$K(t) = \begin{cases} \dfrac{f_c C_o e^{-\lambda t_c}}{\epsilon}, & t_c \leq t \leq t_c + \epsilon \\ 0 , & \text{otherwise} . \end{cases}$$

where:

f_c = the fraction of the crud activity which is readily transportable

C_o = the initial crud activity (Ci)

t_c = the time of crud release (usually $t_c = 0$ in the minimum containment case)

ϵ = the assumed duration of the uniform crud release (yr).

NOTE: The effect of radioactive decay during the period of release was omitted to provide a simple but conservative estimate of the release.

3. Release Rate Due to Leakage of Corrosion Products From Within Containment

Between the time when the reactor compartment bulkheads are penetrated (t_{BLKD}) and the reactor vessel walls are penetrated by surface corrosion (t_{RV}), the total leakage out of the reactor vessel is released directly to the ocean waters. The function L(t) describes this release:

$$L(t) = \begin{cases} 0 , & t \leq t_{BLKD} \\ \Lambda(N_T,t) + \Lambda(C_T,t) , & t_{BLKD} < t \leq t_{RV} \\ 0 , & t > t_{RV} \end{cases}$$

where the leakage functions $\Lambda(N_T,t)$ and $\Lambda(C_T,t)$ are defined in Section IV.B.2.b, Equations (G.9i) and (G.9ii).

4. Release Rate of Transportable Material Immediately After Containment Penetrations

Immediately after a containment barrier is penetrated, the transportable corrosion products which are present with the contained volume are assumed to be released to the environment at a uniform rate over a time period (ϵ). The term B(t) specifically accounts for this release.

$$B(t) = a_1(t) \left[\frac{W_T(t_{BLKD})}{\epsilon}\right] + a_2(t) \left[\frac{N_T(t_{RV}) + C_T(t_{RV})}{\epsilon}\right]$$

where:

ϵ = the time period of the assumed uniform release (yr)

$$a_1(t) = \begin{cases} 0 & t < t_{BLKD} \text{ or } t > t_{BLKD} + \epsilon \\ 1 & t_{BLKD} \leq t \leq t_{BLKD} + \epsilon \end{cases}$$

$$a_2(t) = \begin{cases} 0 & t < t_{RV} \text{ or } t > t_{RV} + \epsilon \\ 1 & t_{RV} \leq t \leq t_{RV} + \epsilon \end{cases}$$

$W_T(t_{BLKD})$ = the amount of transportable activity in the reactor compartment volume at the time of bulkhead penetration (Sections IV.B.2.c and IV.B.3.b)

$N_T(t_{RV})$ = the amount of transportable activity in the reactor vessel volume at the time of vessel wall penetration (Sections IV.B.2.a(1), IV.B.3.a(2), and IV.B.3.a(3))

$C_T(t_{RV})$ = the amount of transportable crud activity in the reactor vessel volume at the time of vessel wall penetration (Sections IV.B.2.a(2), IV.B.3.a(2), and IV.B.3.a(3)).

NOTE: The effect of radioactive decay during the periods of release was omitted to provide a simple but conservative estimate of this release.

5. Release Rate Due to Resuspension of Non-Transportable Corrosion Products Outside the Containment Barriers

The total amount of non-transportable activity outside the containment is given by the function $O_N(t)$ defined in Sections IV.B.2.d and IV.B.3.c. This function was defined so that a fraction (β) of the total activity would be resuspended and removed by the ocean waters per unit time. Thus the release rate to the ocean from the uncontained non-transportable activity is

$$S(t) = \beta\, O_N(t) \qquad (G.13)$$

where:

β = the resuspension coefficient defining the rate at which corrosion products are shifted from non-transportable forms into transportable forms (yr^{-1})

$O_N(t)$ = the total amount of non-transportable activity outside containment barriers at time t (Sections IV.B.2.d and IV.B.3.c).

D. VALUES USED FOR PARAMETERS IN CALCULATIONS

1. Corrosion Release Rates (r_k)

The corrosion constants that were used are developed in Appendix F and presented in Table F-1. The multiplier P to convert average surface corrosion rate to pitting rate of corrosion resistant alloys was also developed in Appendix F. The value of P was assumed to be 46 and was used to establish penetration of corrosion resistant alloys.

2. Transportable Fractions (f and f_c)

All corrosion products and the crud were treated as being transportable at the time of release from the metal matrix. Therefore, both f and f_c were assigned a value of 1.0 for these calculations.

3. Period of Uniform Release (ϵ)

Material released to the environment in the terms dB/dt and dC/dt, was assumed to be released uniformly during a one-year period. Therefore ϵ is assigned a value of 1.0.

4. Decay Constants (λ)

The decay constants (λ) are based on the half-lives presented in Table 1-2 of Chapter 1. The relationship between a half-life and the decay constant is

$$\lambda = \frac{0.693}{T_{1/2}}$$

5. Leakage Coefficient (δ (t))

a. Best Estimate

The leakage coefficient is used to establish the transport rate of material through the water in the reactor vessel and then through the pits in the corrosion resistant alloys to the environment. The larger the particle size is, the slower the transport rate will be. For example, the transport of a particle at the limit of operational solubility (i.e., 0.45 micron) will be slower than that of a molecule. To calculate the transport rate, the leakage coefficient was selected to be the logarithmic mean between that for a molecule and that for particle with the maximum size for operational solubility. The leakage coefficient ($\delta(t)$) is 3.25×10^{-7} cm²/sec, corresponding to an average particle size of 0.015 micron. This size would be considerably smaller than the average corrosion particle size of 1 micron, so the leakage rate should assure that this effect is not underestimated.

This leakage coefficient (3.25×10^{-7} cm²/sec) controls the release from the reactor vessel until a water current is assumed to be established through the reactor vessel. Because of the small size of the pitting penetrations and the large size of the vessel, a current through the vessel would not be possible through the pits. In fact, a current through the reactor vessel would not be expected until general surface penetration of the reactor vessel occurred in the year 1300. However, to be conservative, a current through the reactor vessel was assumed to begin at an intermediate time between the initial pitting penetration of the reactor vessel and the time at which general surface penetration of the vessel is calculated to occur. This current is initiated (t_{ic}) approximately 400 years after disposal. At this time the leakage coefficient ($\delta(t)$) is set equal to an essentially infinite value (10^{99} cm²/sec) and provides for the release to the environment of all transportable material from within the reactor vessel.

b. Conservative Estimate

For this treatment the corrosion particles were assumed to behave as if they were the size of a water molecule. The leakage coefficient for this case is 1.5×10^{-5} cm²/sec. This maximizes the leakage rate from the reactor vessel to the reactor compartment until a flow is assumed to be established in the reactor vessel. The flow in the vessel is assumed to be initiated immediately when the reactor compartment is penetrated 100 years after disposal. At that time the leakage coefficient ($\delta(t)$) is set equal to an essentially infinite value (10^{99} cm²/sec) and provides for the continuing release to the environment of all transportable material from within the reactor vessel.

6. Resuspension Coefficient Outside Containment (β)

a. Best Estimate

The resuspension coefficient was estimated from a simplified model which assumed that settled corrosion products would become transportable by diffusing from a region of high concentration to a region of essentially zero concentration. The rate of resuspension is dependent on the sediment particle size and the flow rate of the water. To obtain a conservative estimate of the resuspension coefficient, the particles were considered to diffuse at the rate that molecular size particles would diffuse. The flow rate of the water was slightly greater than that measured on the ocean bottom. The resulting resuspension constant outside the containment is 5.9×10^{-4} year^{-1}.

b. **Conservative Estimate**

For this estimate an artifically high value of 0.01 was used to conservatively overestimate the resuspension effects. This value would correspond in the model above to a flow rate of 50 cm/sec, which exceeds measured average currents by a factor of 40.

7. Resuspension Coefficient Inside the Reactor Vessel (β_1)

a. **Best Estimate**

Using the same resuspension model discussed above, a value of 1.0×10^{-5} (year^{-1}) was calculated for the resuspension coefficient inside the reactor vessel.

b. **Conservative Estimate**

In the conservative estimate the artifically high value of 0.01 (years^{-1}) used outside containment was also used to conservatively model the resuspension effects inside the reactor vessel.

8. Coagulation—Deposition Coefficient (β_2)

a. **Best Estimate**

The value of the settling coefficient was estimated from the mean corrosion particle size (1 micron), its Stokes law settling velocity, and the average distance over which settling of corrosion products would occur. The settling coefficient $\beta_2 = 6.4$ years^{-1}.

b. **Conservative Estimate**

The value of the settling coefficient was estimated by assuming the corrosion particle size was approximately a factor of 4 smaller than the expected average particle size. The resulting settling coefficient was 0.2 year^{-1}.

APPENDIX H

DESCRIPTION OF THE OCEAN DISPERSION MODEL

I. INTRODUCTION

This appendix describes the methods used to estimate the possible transport and dispersion of radioactive nuclides through the ocean waters from defueled submarines disposed on the ocean floor to potential entry points into the pathways which might lead to man. The overall process through which this radioactive material might reach man includes (1) corrosion of the radioactive structural materials, (2) corrosion of the reactor plant and reactor compartment containments, (3) the eventual release of the radionuclides into the water or bottom sediment, (4) transport of the nuclides in the water column to locations where they might enter the pathways to man, and finally (5) the movement of these radionuclides along the pathways to man. Items (1) and (2) are described in Appendix F and Items (3) and (5) are described in Appendices G and I, respectively. This appendix concerns Item (4) transport in the water column and will describe the various mechanisms which might act on the released nuclides. This appendix presents the equation used to compute concentrations at the potential pathway entry points; the parameters used in the computations; and the assumptions used in developing and performing the calculations.

II. SUMMARY AND CONCLUSIONS

A mathematical model for estimating the radionuclide concentrations in ocean waters as a function of time and distance from the disposed submarine is presented. This model was developed after investigating a number of models available in the literature, including those formulated by Webb and Morley (Reference H.1) and by J. G. Shepherd (Reference H.2) as well as the plume calculation proposed by the International Atomic Energy Agency (IAEA) in the development of criteria for disposing of radioactive waste in the ocean presented at the London Convention (Reference H.13). Results of calculations performed using measured current speeds and directions as well as coefficients derived from oceanographic observations to describe stirring effects are presented. These calculations were made assuming that the postulated disposal site was approximately 300 kilometers from the shoreline and located in an area where high concentrations might be found because of low dilution by slow currents (advection). The values of the parameters (current speed, diffusion constants, detritus (sedimentation) removal coefficients, etc.) used in the calculations were either determined at one of the oceanographic study sites, taken from values presented in the literature, or inferred from available data. The appropriate study site data were selected for use to provide realistic maximum values for the nuclide concentrations.

The results of the best estimates* based on this model compare well with the observed behavior of Rn-222 near the deep ocean bottom and with the results obtained using conservative estimate* calculations as well as a previously developed model. For example, the action of the boundary layer formed along the ocean floor which would retain particles of corrosion product within the layer and prevent dilution by dispersion into the water above the layer is explicitly represented in this model.

The estimated maximum radionuclide release rates of 1.1×10^{-3}, 7.0, and 39.0 curies per year of Cobalt-60, Nickel-59, and Nickel-63, respectively, from 100 submarines disposed of on the ocean floor (see Table G-2, Appendix G) lead to the best estimates of 9.8×10^{-24}, 7.6×10^{-20}, and 4.2×10^{-19} curies per cubic meter, respectively, for the same nuclides as the maximum concentration at the entry to the pathways which might lead to man (see Table H-4). Since the present model explicitly represents bottom boundary layer effects and stratification of the ocean water column, the concentrations calculated are higher than those predicted by some earlier models.

---

*See Glossary.

In addition to the concentrations calculated for the best estimate parameters used for the specified disposal site, Table H-1, calculations were made to evaluate two "transit accident" cases described in Appendix J, e.g., (1) calculations are for the condition where a submarine is assumed to break open after settling to the bottom at the disposal site and lose the reactor compartment and reactor pressure vessel containment and (2) calculations are for the condition where the same minimum containment is reached during transport, but at a location slightly less than one-tenth of the distance from the shore to the postulated disposal site where the water is only about 800 meters deep. These results are presented in Tables H-5 and H-9.

III. GENERAL DISCUSSION

The major source of radiation in an operating nuclear submarine is the reactor fuel. After the ship is defueled, this source is removed and the largest source remaining would be the internal structure within the thick walled steel reactor pressure vessel which previously housed the reactor fuel core. Nearly 100 percent of the radioactivity in a defueled submarine would be in the form of radioactive metal atoms produced by neutron activation of the metal structures inside the reactor pressure vessel and in the inside walls of the pressure vessel itself during reactor operation. Approximately 0.1 percent would be in the corrosion products which were generated during plant operations and adhered to the inside of the pipes, valves, steam generator, and other components of the reactor coolant system.

Since all of this equipment is fully enclosed within an isolated compartment in the submarine, there are several barriers to the release of the contained radioactivity. Another significant barrier is provided by the fact that the radioactive atoms are an integral part of the thick metal structures contained within the sealed reactor pressure vessel. These barriers are described in Appendix G.

If the sea disposal option were selected, a defueled submarine would be allowed to settle to the bottom of the ocean at a depth of more than 4000 meters (about 13,000 feet). The reactor pressure vessel and the reactor compartment would have been filled with water and sealed prior to sinking in order to delay the release of any significant amount of radioactivity for many years. Natural radioactive decay processes would reduce the total radioactivity by more than 85 percent if the activity were contained in the submarine for about 100 years as illustrated in Figure 1-2 of Chapter 1.

When the sealed submarine compartment would eventually be penetrated by corrosion through the thinnest portion of the internal walls of the compartment containing the reactor plant components, (bulkheads), any corrosion product particles released from the reactor pressure vessel or reactor coolant piping would be free to move into adjacent compartments. Since these compartments contain openings to the ocean waters, the movements of small amounts of radionuclides to the external environment could begin at this time. The thick submarine hull would be expected to prevent direct dispersion of the nuclides to the open ocean for several hundred years, except through the openings in the compartments adjacent to the reactor compartment originally provided to ensure rapid and uniform flooding. The residual longer lived radionuclides would gradually be freed to move from the source (submarine reactor compartment) to the ocean environment where they might be transported to the entry points of the pathways to man.

The description of the method used to estimate the transport and diffusion of radionuclides through the ocean waters is based on the concepts described in References H.2, H.3, H.4, H.5, and H.6 and represents in many ways an extension of the model originally proposed by J. G. Shepherd (Reference H.2) to include an explicit representation of ocean stratification and removal of radioactivity by settling particulate matter.

IV. TRANSPORT MODEL DESCRIPTION

For the radioactivity in the submarine on the ocean floor to affect man it must first be converted from solid metal into some transportable form. Then it must be carried from the original site to man by one or more of the following modes of transportation: (1) movement in the sediment, (2) movement through biological processes such as transport by fish or other biota, or (3) by direct movement in the water. It is anticipated that a large fraction, perhaps as high as 95 percent of the corrosion product particles carrying radionuclides would settle to the ocean floor either through direct deposition or by removal by the detritus particles. This newly deposited sediment would be subjected to the usual biological, physical, and chemical processes, such as bioturbation, within the sediment layer. However, this sediment is expected to remain in the vicinity of the disposal area because the disposal location would be chosen to avoid currents which would be energetic enough to resuspend the sediment. Therefore, this material would not be expected to be a significant source of radiation exposure to humans because of its remoteness from human activity and because no known food chain having its beginnings in deep ocean sediment has ever been identified (see References H.3 and H.7).

Physical movement of the corrosion product particles from the sediment or the water in the vicinity of the disposal location by biological processes would be possible. However, an estimate of the relative importance of biological and physical processes in the transport of radionuclides from the ocean bottom to the surface reveals that the biological transport is about one-thousandth of the physical transport (Reference H.3). In addition, the absence of any known path which could directly link the biota in abyssal bottom waters with food consumed by man makes it unlikely that transport in a food chain would provide any important contribution (see Appendix I). Thus it was concluded that the most important pathway for radionuclide transport and concentration calculations would be movement by the ocean waters (see References H.2, H.5, and H.6). However, to allow the possibility that a food chain from the ocean floor to man may be identified in the future, calculations have been made assuming that fish exposed to the maximum concentrations of radioactivity were caught and eaten by man. This hypothetical maximum exposure case is discussed in detail and the results presented in Appendix J.

A. MODEL DEVELOPMENT

This section provides a brief description of the pertinent oceanographic phenomena involved in the transport calculations along with the assumptions and the values of the parameters used in the calculations. In some cases, it has been necessary to use the measured characteristics of specific locations to specify the values of certain parameters. In order to develop a set of measured values which would produce calculated concentrations unlikely to be exceeded for any probable disposal locations, study areas were identified in the Atlantic and Pacific Oceans using existing technical criteria (Appendix E). Examination of these study areas showed that one located in the north-eastern Pacific Ocean was about as close to the United States coast as could be possible to meet the IAEA requirements for a 4000 meter minimum disposal depth. This study area, called the Pacific W-N site, also met all the other criteria for site selection. It was assumed that the characteristics of this region would produce the least dilution and dispersion among the study areas (which also meet the established criteria) and points of interaction with man, thereby yielding maximum estimates of the doses to man.

Therefore, the study area in the Pacific Ocean about 300 kilometers west of the coast of California was identified as the source of data for the calculations. The parameters needed were either obtained from available data, measured at the study area (see Reference H.7), or inferred from the available measurements. The data are intended to represent the minimum dispersion, dilution, and distance to man from the large range of locations which might be chosen for submarine disposal. Use of these measurements does not mean that this study area has been chosen as a disposal location. The results are also intended to be interpreted as upper limits on concentrations which might be calculated for other Pacific or Atlantic Ocean locations.

1. Equation Development

In attempts to account for the distribution of finely divided particulate matter or for properties associated with elements soluble in the ocean such as salinity, oxygen content, and silica, mathematical models have been developed which make use of the knowledge of the general ocean currents (advection) and of the mixing caused by the observed tidal effects, turbulence, or eddies which have results similar to true diffusion.

In modeling these processes, an appropriate solution to an instantaneous unit pulse diffusion problem which estimates a concentration distribution is used to define the effects of these processes. Once established, this solution is then integrated in time to yield results for a continuous or chronic release of material.

The model used in this analysis is essentially an extension of earlier models, where modifications have been made to explicitly represent the well-mixed benthic boundary layer existing in the deep ocean, the removal of activity by detritus particles, and the stratification of the middle depths of the water column. The resulting equations used in this analysis are presented below.

2. Concentration Equation

The concentration of any particular radionuclide, at a given location within the ocean, at any time (t) after the submarine has settled on the ocean floor, is calculated by summing up (integrating) the contributions from a sequence of simple unit releases from the submarine. Each unit release is weighted by the amount of activity released at time (τ) multiplied by the appropriate loss factor accounting for decay and other loss processes.

$$\chi_i(x,y,z,t) = \int_0^t R_i(\tau) e^{-(\lambda + \lambda d)(t-\tau)} G_z(z,t-\tau)\, G_x(x,t-\tau)\, G_y(y,t-\tau) d\tau \qquad (1)$$

where:

χ_i = the concentration of the particular radionuclide at a given time and location in the ocean waters (Ci/m^3)

i = an index specifying the given radionuclide

R_i = the time dependent release rate of a particular radionuclide (Ci/hr)

λ_i = the radioactive decay constant for the particular radionuclide (hr^{-1})

λ_d = a constant defining the removal effects of detritus particles in the water column (hr^{-1})

t = the time since the disposal of the submarine (hr)

τ = the time that a specific unit release occurs (hr)

$(t - \tau)$ = the age of the unit release (hr)

x = the horizontal distance from the disposal point along the east-west direction (positive to the east) (m)

y = the horizontal distance from the disposal point along the north-south direction (positive to the north) (m)

z = the vertical distance above the ocean floor (m)

G_z = the vertical distribution of a unit release of activity as a function of the age of the release (m^{-1})

G_x = the east-west distribution of a unit release of activity as a function of the age of the release (m^{-1})

G_y = the north-south distribution of a unit release of activity as a function of the age of the release (m^{-1}).

3. Horizontal Distribution Equation

The product of the three distribution functions G_x, G_y, and G_z provides an estimate of the three-dimensional distribution of a unit release of activity as a function of the age of the release. These functions are defined in this and the following section and are based upon the diffusion-advection equation.

The functions G_x and G_y are similar in that they are written as gauss normal distributions which have been reflected by the boundaries of the ocean to conserve the amount of activity. These function are given by

$$G_x(x, \theta) = \frac{1}{\sqrt{2\pi}\sqrt{2K_x\theta}} \sum_{j=0}^{\infty} \exp\left[-\frac{1}{2}\left(\frac{x - u_x\theta - x_j}{\sqrt{2K_x\theta}}\right)^2\right] \tag{2}$$

$$G_y(y, \theta) = \frac{1}{\sqrt{2\pi}\sqrt{2K_y\theta}} \sum_{k=0}^{\infty} \exp\left[-\frac{1}{2}\left(\frac{y - u_y\theta - y_k}{\sqrt{2K_y\theta}}\right)^2\right] \tag{3}$$

where:

θ = the age of the release (hr) = $(t - \tau)$

K_x = the coefficient of eddy diffusivity in the east-west direction (m^2/hr)

K_y = the coefficient of eddy diffusivity in the north-south direction (m^2/hr)

exp(x) = the exponential function e^x

u_x = the long term averge east-west velocity (m/hr)

u_y = the long term average north-south velocity (m/hr)

x_j = the east-west position that appropriately models a reflected image source

y_k = the north-south position that appropriately models a reflected image source.

4. Vertical Distribution Equation

The vertical distribution function G_z (z, θ) is defined to account for variations in the eddy diffusivity and vertical velocity as a function of the vertical distance above the bottom. G_z (z, θ) is defined to be the solution of the one-dimensional diffusion advection equation,

$$\frac{\partial G_z}{\partial \theta} = \frac{\partial}{\partial z}\left(K_z(z)\,\frac{\partial G_z}{\partial z}\right) - \frac{\partial}{\partial z}\left(\nu_z(z)G_z\right) \tag{4}$$

θ = the age of the release (hr) = $(t - \tau)$

$\frac{\partial}{\partial \theta}$ = the partial derivative with respect to age of the release

$\frac{\partial}{\partial z}$ = the partial derivative with respect to the height above bottom

$K_z(z)$ = the vertical eddy diffusivity as a function of height (m^2/hr)

$\nu_z(z)$ = the vertical velocity as a function of height (m/hr).

This equation was solved numerically using the methods presented in Reference H.17.

5. Detritus Removal Coefficient

A detritus removal term (λ_d) is included in the formulation of ocean distribution equation used in the prediction of the dispersion of radioactivity in deep ocean waters. It was assumed, in developing this coefficient, that the detritus particles removed all activity from their path as they settled toward the ocean bottom. This coefficient is defined by the equation:

$$\lambda_d = \frac{C \cdot M}{\rho \cdot d} \tag{5}$$

where:

M = the mass flux of the particulate material settling in the deep ocean waters ($g/m^2/yr$)

ρ = particle density (g/m^3)

d = particle diameter (m)

C = constant relating the particle thickness with the major particle dimensions.

Use of the values for mass flux, particle density, and mean sediment particle diameter reported in Reference H.7 lead to a value of $\lambda_d = 5.6\ yr^{-1}$. This result was obtained for a value of C = 6 which represents particles with a major length and/or width dimension six times the thickness of the particle.

B. DESCRIPTION OF THE OCEANOGRAPHIC MECHANISMS

In the deep ocean regions studied and of interest in this appendix, the ocean bottom waters can be described in terms of three general vertical regions. A turbulent well-mixed region called the benthic or bottom boundary layer is found just above the ocean floor, and extends from a few meters to a few hundred meters above the ocean floor (References H.4 and H.7). This boundary layer is usually a well-established and relatively stable region which tends to prevent most water within it from escaping to the layers above it in the water column. This tendency reduces dilution by keeping tracers released in the bottom boundary layer from being vertically displaced.

The mid-depth region extends from the top of the bottom boundary layer up to the bottom of the permanent thermocline which may be as deep as 1000 meters below the ocean surface. The 1000 meter depth was used in the calculations since it would yield the most pessimistic result. This is a weakly stratified zone with slow vertical velocities ranging from about 0 to 3 meters per year (see Reference H.5).

The surface waters of the oceans are well-mixed to a depth of about 100 meters below the surface as a result of the action of solar heating, winds, and surface flow. These waters move generally under the influence of the prevailing surface currents which flow in the southerly direction for the study area from which measurements were obtained for these calculations (Reference H.7). The vertical and horizontal stirring in this region cause the mixing and stirring (diffusion) processes to operate at a higher rate than in the weakly stratified region above the bottom boundary layer. In the calculational model the well-mixed surface region is assumed to be 800 meters deep to add conservatism to the estimates of nuclide concentration and dispersion.

The movement of water has been assumed in these calculations to be controlled by coefficients representing horizontal and vertical velocities and by horizontal and vertical stirring rates, termed eddy diffusivities to differentiate from true diffusion rates. The eddy diffusivities are used to describe the total stirring effect resulting from such phenomena as tidal cycles, flow induced turbulence, eddy passage, and similar variations. The horizontal velocities are assumed to be constant in speed and direction in these calculations, but the vertical velocity is varied to represent the vertical regions. Similarly, the horizontal eddy diffusivity coefficients are assumed to be invariant, but the vertical diffusivity is assumed to vary with depth.

The relative magnitude of these parameters may be seen by using as an example the Eastern Pacific Ocean bottom waters where the measured long term average horizontal current is about one centimeter per second in a southerly direction and the east-west current is near zero (References H.4 and H.7). The horizontal eddy diffusivity, developed from information presented in References H.2, H.4, and H.5, is about 1×10^7 cm^2/sec in all horizontal directions. The vertical velocities and eddy diffusivities are assumed to be as depicted in Figure H-1 where the maximum vertical velocity is about 3 meters/year and the diffusivity is about 0.6 cm^2/sec (Reference H.5) in the middle zone, changing rapidly to about 24 cm^2/sec (Reference H.4) in the top and bottom boundary regions.

These mechanisms are used to calculate the potential for the movement of radionuclides to the entry points to the possible pathways to man. The specific pathways to man are described in Section III of Appendix I.

C. PARAMETER VALUES USED IN CONCENTRATION CALCULATIONS

The potential concentrations in the ocean waters for use in pathways analyses in this statement were calculated using the advection-diffusion method and the most realistic values for each variable in the equation. In as many instances as possible, direct measurements of the parameter obtained from a representative ocean location were used. In other cases values are derived from the literature and in some cases, the needed parameter values had to be inferred from observed ocean behavior. Each of the parameter values used is discussed in this section, including the source of the best estimate and conservative estimate values presented in Table H-1.

The concentrations calculated by using the values of the parameters which have been judged to be the most realistic have been defined as the best estimate results. Concentrations calculated by using highly conservative values for the parameters, that is, those values which lead to high concentrations of radionuclides have been defined as conservative estimates. The best estimate is believed to represent a somewhat conservative estimate of what would actually be expected whereas the conservative estimate is believed to represent the concentrations which would not be reasonably expected to be exceeded.

The vertical current velocity and eddy diffusivity values were developed using the assumption that the ocean water column can be visualized as three general vertically displaced horizontal layers or flow regions: the bottom boundary layer, the stratified mid-waters, and the well-mixed surface layer above the thermocline. The actual values used in the calculation are shown in Table H-1. The shape of the plot of the vertical diffusion coefficients as a function of depth was developed from the observed layering of ocean waters as described in References H.7, H.8, and H.9. The magnitudes of the vertical eddy diffusion coefficient for the bottom boundary layer was based on the information presented in Kupferman and Moore (Reference H.4) and the vertical diffusivity in the surface, well-mixed layer was assumed to be the same as in the bottom boundary layer. The mid-area of the vertical diffusivity was based on the work of Fiadeiro and Craig (Reference H.5). The vertical current speed variation was developed from the water movements reported in Reference H.5 modified by assuming the speed is a maximum at the bottom of the thermocline and decreases to zero at the air-water and sediment-water interfaces.

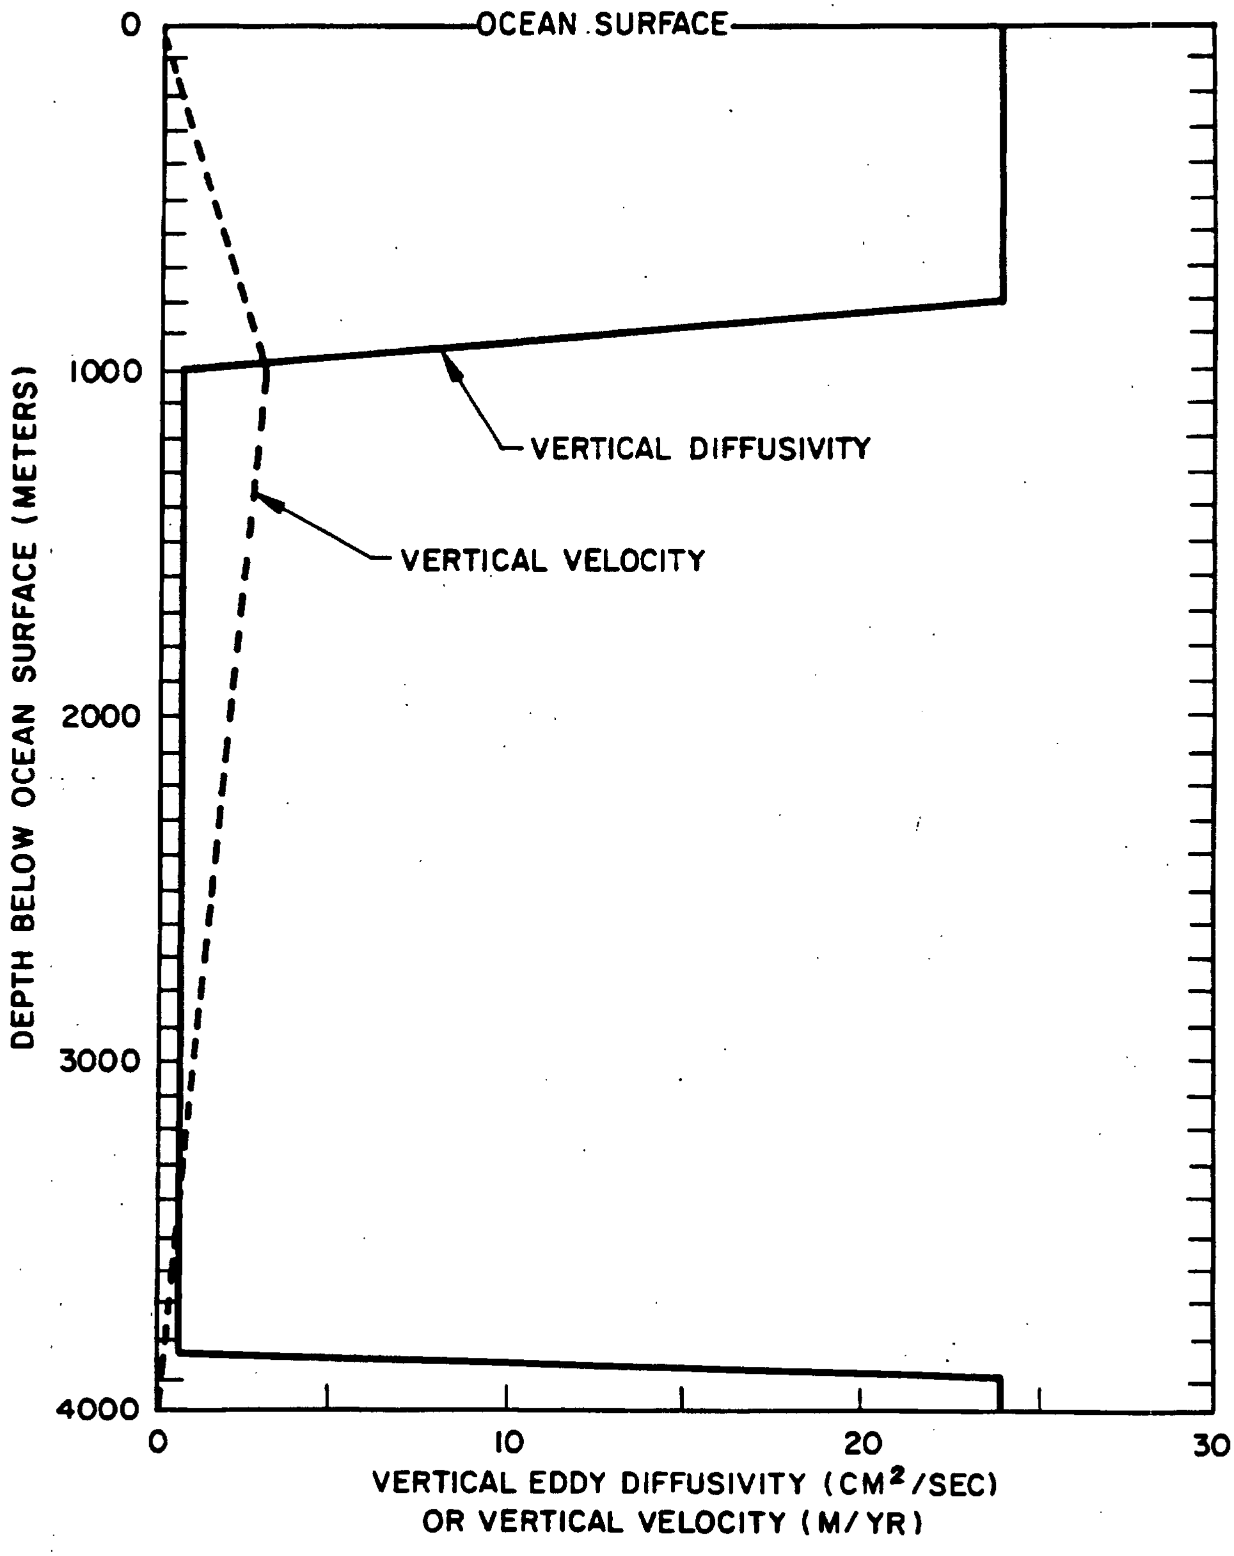

Figure H-1. Vertical Velocity and Eddy Diffusivity in the Pacific Ocean

TABLE H-1. PARAMETERS USED IN THE CALCULATION OF RADIONUCLIDE CONCENTRATION ESTIMATES

Parameter	Best Estimate	Conservative Estimate
1. East-West horizontal diffusivity (cm^2/sec)	1×10^7	1×10^7
2. North-South horizontal diffusivity (cm^2/sec)	1×10^7	1×10^7
3. Long term average east-west current velocity (cm/sec)	0.19 (to east)	0.0
4. Long term average north-south current velocity (cm/sec)	−1.12 (to south)	−1.0
5. Bottom boundary layer thickness (m)	170	200
6. Maximum vertical velocity (m/yr) (at the bottom of the thermocline)	3.0	3.0
7. Maximum vertical diffusivity in the bottom boundary layer and above the thermocline (cm^2/sec)	24.0	15.0
8. Vertical diffusivity in the stratified (mid-depth) region of the ocean (cm^2/sec)	0.6	0.6
9. Coefficient for removal of radionuclides by detritus (yr^{-1})	5.6	0.0
10. Vertical extent of the maximum vertical diffusivity in the bottom boundary layer (m)	92.4	30.0
11. Average corrosion particle settling velocity in the ocean (m/yr)	2×10^{-3}	0.0
12. Vertical distance from the ocean floor to the possible entry point to the pathway to man (m)	385	0.0

The eddy diffusivity in the horizontal plane was assumed to be the same at all points, as mentioned in the preceding section. The value used in the calculations for the eddy diffusivity in all horizontal directions is 1×10^7 cm^2/sec, based on data from References H.2, H.4, and H.5 and was used because application of this value in the preliminary calculations resulted in a spatial domain of occupation of the affected region that agreed with the region suggested by Kupferman and Moore (Reference H.4). In addition, 1×10^7 cm^2/sec fell into the range of values suggested by Shepherd (Reference H.2) and was close to the value used by Fiadeiro and Craig (Reference H.5). The direction and speed at a representative study location (Reference H.7) revealed that the current was 1.12 cm/sec to the south and 0.19 cm/sec to the east. It was assumed that the coast ran in the north-south direction.

The assumed thickness of the benthic or bottom boundary layer used in the calculations was 170 meters based on measurements at the representative study site (Reference H.7). The height above the bottom over which the maximum value of the vertical eddy diffusivity was applied was assumed to be 92.4 meters. This value was obtained by adding the height attained by the released material in the bottom boundary layer in a 12.4 hour tidal period to one half the distance from the top of this layer to the top of the benthic boundary layer.

The detritus removal coefficient of 5.6 per year was selected to reflect the removal of radioactive nuclides from the ocean waters by means of detritus particles. The detritus flux and sediment particle size data reported in Reference H.7 were used to estimate the value of 5.6. The adsorption of nuclides on silicate detritus is supported by the chemical characterization of sediment (Reference H.7) which is formed from the detritus and its similarity to Fuller's earth (Reference H.10) which is a well known purification filter material.

The settling velocity of the activity released to the environment, 2×10^{-3} m/yr, was calculated to correspond to the particles which have transfer coefficients defined in the release model described in Appendix G. A value of 385 meters above the ocean floor was used for the vertical location of the potential entry points of radionuclides to the pathways to man. This value was obtained by first estimating the time required for nuclides to climb from the ocean bottom in the boundary layer along the continental slope to the maximum deep fishing depth. This time period was then used to estimate the vertical movement which could occur in the weakly stratified region of the ocean above the well-mixed bottom boundary layer. This distance was then increased by the vertical extent of the bottom boundary layer, (92.4 m) over which the diffusivity is assumed to be constant, to obtain the vertical location used for the entry points of the radionuclides to the pathways which lead to man.

The range of possible values for each parameter, based on differing measurements, experimental techniques and uncertainties, and other sources of possible variability was evaluated in selecting each value, and in many cases this range can be quite large. Calculations of the concentrations at the potential pathway entry points were performed using a distribution of values for each parameter to determine the relative sensitivity of the calculated results to the variability of each parameter and to establish variations in the final result. These calculations demonstrated that the hypothetical disposal of submarines would not produce significant environmental effects even in the vicinity of the disposal. For example, radionuclide concentrations would not exceed the U.S. Environmental Protection Agency (EPA) drinking water limits (References H.11 and H.12) on the bottom at the submarine resting place.

V. TYPICAL RADIONUCLIDE CONCENTRATIONS AND COMPARISONS WITH OTHER TRANSPORT DISPERSION MODELS

In order to provide an example of the results of this calculation, nuclide concentration estimates have been made for a study site where the defueled nuclear submarines were postulated to be located on the ocean bottom about 4000 meters below the surface at a point 300 kilometers from the shore. This point is located 1600 kilometers south and 300 kilometers west of the northern and eastern boundaries, respectively, of the closed and finite ocean volume assumed in the calculational model and depicted in Figure H-2, where the north-eastern corner of the model is located at approximately 55°N and 127°W. The calculations show that the distribution of radioactive materials, as shown in Figure H-3, is highly concentrated in the immediate vicinity of the source with slight skewing in the southerly direction under the influence of the current. The distribution of radioactive material also shows that the concentrations are primarily restricted to the bottom boundary layer. Calculations have been made with best estimate values for the parameters in the mathematical model and also with conservative estimates for the parameters. The best estimate values represent the values best supported by available oceanographic and other scientific data while the conservative values represent the case where pessimistic assumptions were made to assure that the estimated dose to man was very unlikely to be exceeded.

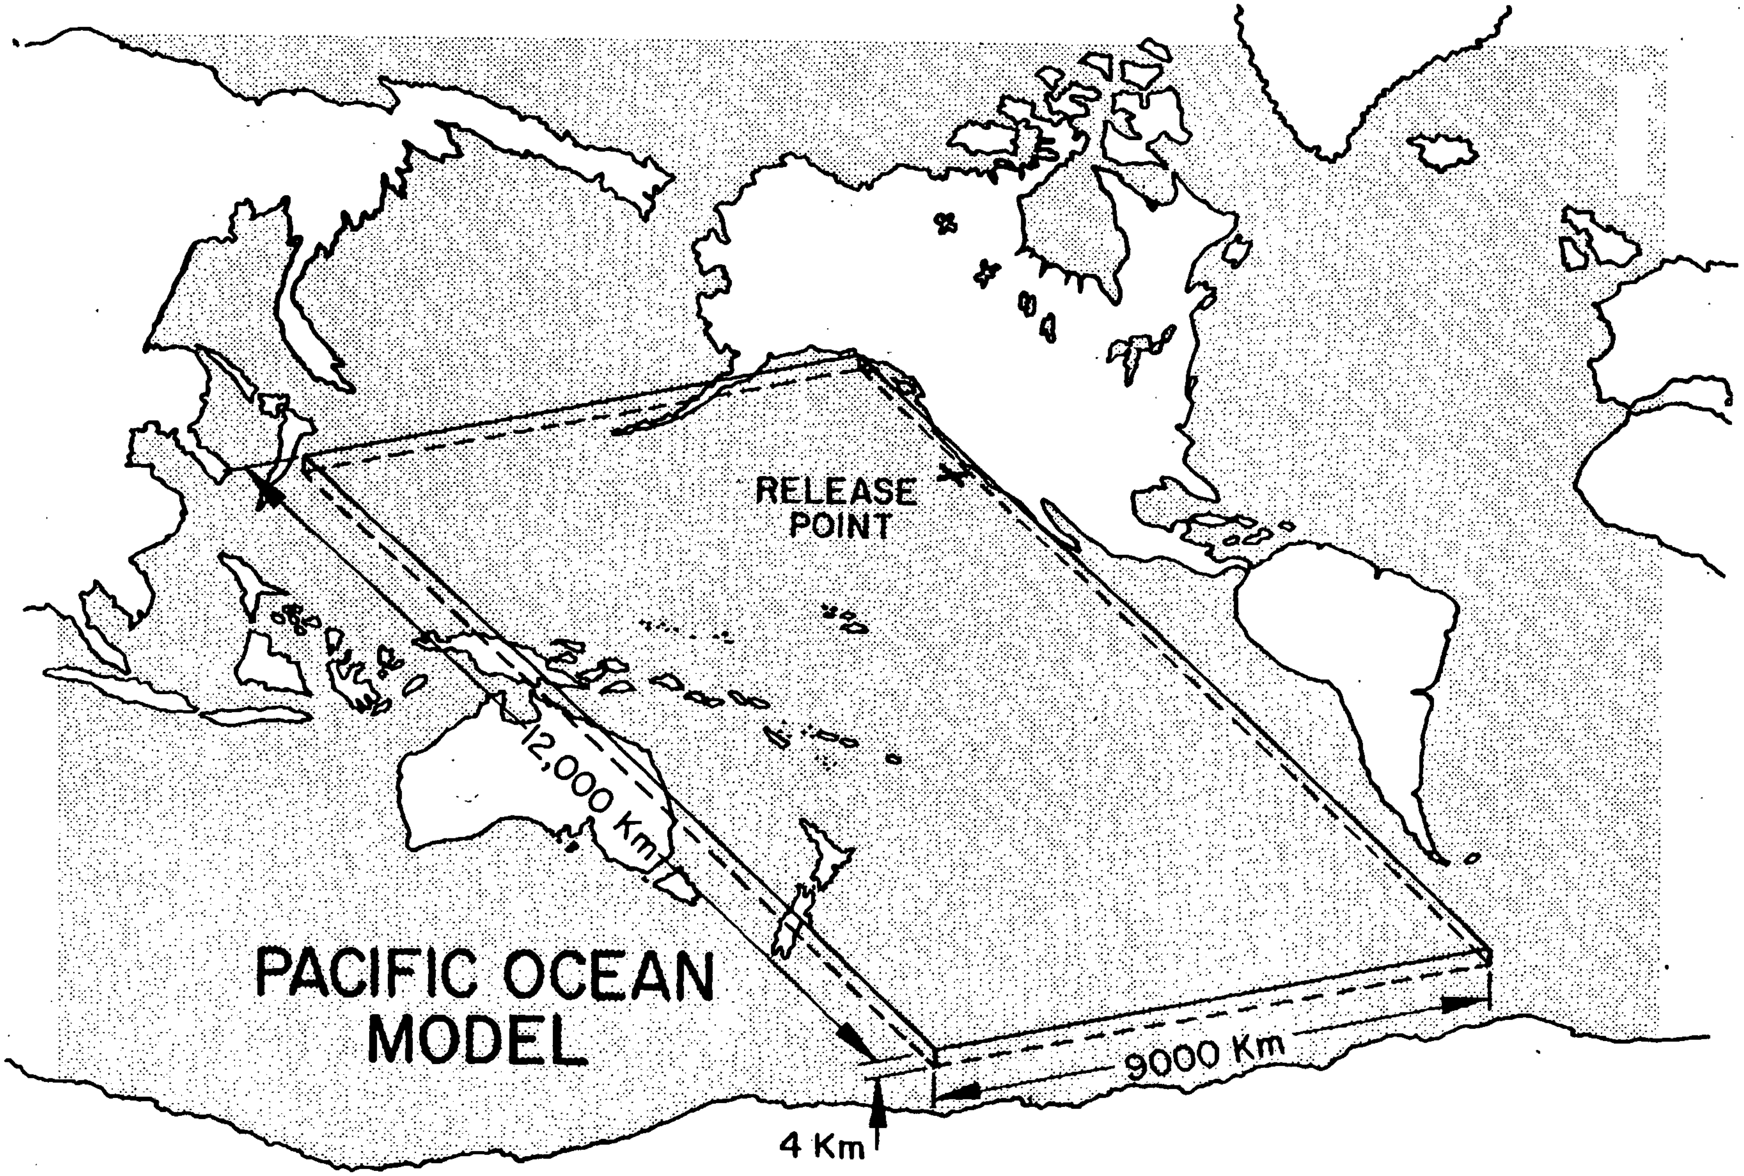

Figure H-2. Calculational Model for a Pacific Ocean Site

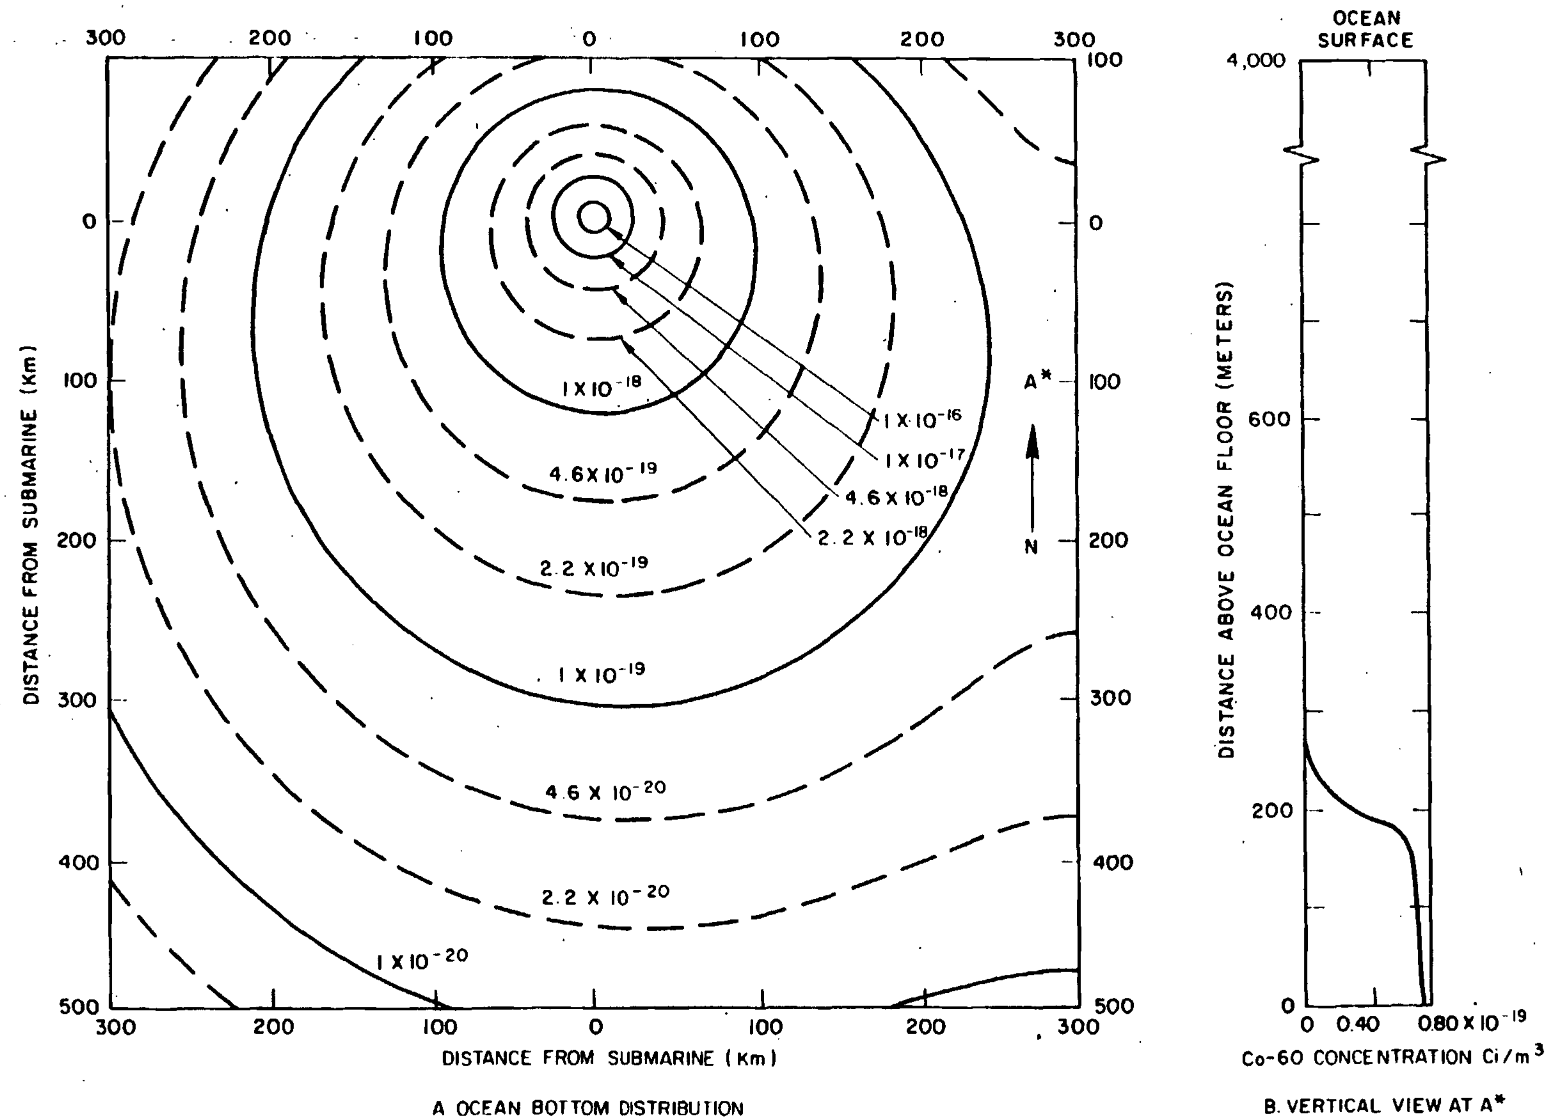

Figure H-3. Best Estimate Co-60 Concentrations Calculated for 100 Years After Disposal (Ci/m^3) – 1 Submarine

A. TYPICAL RESULTS

Based on the best estimate activity release rates developed in Appendix G, only very small amounts of radioactive material would be released from a typical submarine in the initial 100 years after settling to the bottom. The containment barriers might be penetrated by corrosion after 100 years and the initial release of radionuclides could occur. The maximum concentrations at the disposal site are tabulated in Table H-2. The calculations reveal that concentrations of 1.9×10^{-13}, 1.3×10^{-10}, and 1.1×10^{-9} Ci/m^3 could be found for Cobalt-60, Nickel-59, and Nickel-60, respectively (see Table H-2). These concentrations are much less than the NRC limits for unrestricted discharge into the ocean (Reference H.14) as well as the EPA drinking water limits calculated by the methods and element concentrations listed in References H.11 and H.12. Trace amounts of other nuclides would be released during the first year after containment penetration when the maximum concentration of radioactivity is attained. The amount of potential release dies off quickly in the following years as the inventory of corrosion products accumulated prior to containment penetration would be depleted. The new amount of radioactive material which could become available during the fifth year would be less than one-tenth of the quantity released during the first year after containment penetration.

Observations of tracers in the deep oceans and the calculations show that the maximum nuclide concentration would be restricted to the bottom boundary layer on the ocean floor as in Figure H-3. The radionuclide concentrations are predicted, by the calculations, to decrease to less than one percent of the bottom value at about 385 meters above the ocean floor. Predicted vertical distributions of radionuclides are similar to observations of excess Rn-222 tracer behavior in the deep ocean (Reference H.4).

While this tendency of the bottom boundary layer to prevent upward spread of the corrosion particles to higher waters would minimize dilution of the calculated releases, it also greatly retards the movement of radioactive material towards the shallower waters where it might affect human activities or the food chains to man. When combined with the extremely small releases possible from the submarines, the net effect would be to effectively prevent exposure to the general public, even with the restricted dilution permitted by the bottom boundary layer.

The maximum best estimate concentration of radioactivity for 100 submarines at the coastal location nearest the source would be less than approximately 9.8×10^{-24}, 7.6×10^{-20}, and 4.2×10^{-19} Ci/m^3 of Cobalt-60, Nickel-59, and Nickel-63, respectively. These values are, of course, judged to be higher than would actually occur because the calculations use release rates which are greater than expected. (See discussion in Appendix G.)

B. COMPARISON WITH SHEPHERD'S MODEL

The results of the calculations using the model presented in this appendix have been compared to the results of Shepherd's ocean dispersion model calculations for the same location. The comparisons were made using the maximum concentrations calculated for any location at the pathway entry points at any time after the initial release of radioactivity by applying "conservative" parameters to the models being considered.

The model of this appendix differs from Shepherd's model primarily by incorporating explicitly varying values of the vertical advection speed and vertical eddy diffusion coefficient instead of the single constant eddy diffusivity term used by Shepherd to account for both diffusion and advection. It further accounts for the effect of detritus removal which is not considered in the Shepherd model. In addition, Shepherd used a constant activity release rate while this model includes a variable release rate, representing the effects of corrosion on containment and release. Using the maximum vertical eddy diffusivity of 10 cm^2/sec defined by Shepherd, and not including any removal effects associated with detritus, comparisons of the results of the current model with those calculated with Shepherd's model indicate that the Shepherd's model concentrations do not reproduce the well-mixed region of the bottom boundary layer and that the Shepherd's model calculations overestimate the upward transport of the radionuclides. Further, these comparisons indicate that

TABLE H-2. BEST ESTIMATE MAXIMUM RADIONUCLIDE CONCENTRATIONS USED AT THE DISPOSAL SITE EXPECTED CONTAINMENT CONDITION FOR 1 OR 100 SUBMARINES*

Nuclide	Concentration (Ci/m³)
C-14	9.9×10^{-13}
S-35	3.5×10^{-18}
Sc-46	4.1×10^{-19}
Cr-51	5.3×10^{-16}
Mn-54	1.1×10^{-14}
Fe-55	5.0×10^{-13}
Co-58	1.4×10^{-15}
Fe-59	9.5×10^{-16}
Ni-59	1.3×10^{-10}
Co-60	1.9×10^{-13}
Ni-63	1.1×10^{-9}
Mo-93	1.3×10^{-12}
Nb-94	9.1×10^{-14}
Zr-95	0.0
Tc-99	3.8×10^{-13}
Hf-181	0.0

*The local radionuclide concentration in the vicinity of one submarine surrounded by other submarines is not significantly increased (less than 0.01 percent) above the value for one submarine alone because of the spacing between submarines.

the concentrations and therefore the eventual potential doses to man predicted by Shepherd's model are lower than those estimated along the ocean floor by the model developed in this appendix. The use of a vertical eddy diffusivity of 1.0 cm^2/sec will reduce the upward transport of radionuclides predicted by Shepherd's model but will still provide vertical transport estimates which are greater than estimated by the model described in this report.

Overall, this comparison shows that the model presented here better describes observed bottom water movement than Shepherd's model, explicitly representing the restrictions on dispersion. This prevents dilution, maximizing concentrations which might enter the food chain.

C. DETAILED RESULTS

To provide a deeper insight into the calculations made, some of the results have been tabulated and presented to show the concentrations which would result from the disposal of 1 to 100 submarines at the disposal location (Table H-2) and at the potential entry points to the possible pathways to man (Tables H-3 through H-9). The maximum best estimate concentrations for disposal of 100 ships at a rate of three ships per year over a period of approximately 33 years would be from 10 percent greater than for one ship up to approximately 100 times greater than for a single ship, depending on the half-life of the specific radionuclides and the amount of material remaining in each ship when the reactor compartment and reactor vessel containments would eventually be penetrated. All of the concentrations are very low, in most cases far less than the concentrations of the same nuclides already existing in the ocean (References H.7 and H.15).

In addition, the entry point concentrations resulting from an unexpected penetration of the reactor compartment and the reactor pressure vessel containment barriers for a ship during emplacement at the disposal site are presented in Tables H-5 and H-8. Tables H-6 and H-9 present the concentrations calculated for an accident during transit to the planned disposal location. In this case it was assumed that a submarine was irretrievably lost on the ocean floor about 25 kilometers from the coastal region and the reactor compartment and reactor vessel containments were penetrated as the submarine settles on the ocean floor (see Appendix G).

Table H-7 has been included to illustrate the magnitude of the increased nuclide concentration using the conservative values for the parameters used in Table H-1 in conjunction with the calculational model presented on page H-4. These maximum values listed in Table H-7 are still within the NRC and EPA limits.

TABLE H-3. MAXIMUM RADIONUCLIDE CONCENTRATIONS AT PATHWAY ENTRY POINTS (Ci/m^3) EXPECTED CONTAINMENT—BEST ESTIMATE 1 SUBMARINE

Nuclides	Disposal Site	Fish Pathway Entry Point (250 km)	Shoreline (300 km)	
			Air Concentrations at Pathway Entry Point	All Remaining Pathway Entry Points
C-14	9.9×10^{-13}	5.9×10^{-24}	5.9×10^{-35}	5.9×10^{-24}
S-35	3.5×10^{-18}	5.9×10^{-31}	5.9×10^{-42}	5.9×10^{-31}
Sc-46	4.1×10^{-19}	5.9×10^{-32}	5.9×10^{-41}	5.9×10^{-32}
Cr-51	5.3×10^{-16}	2.2×10^{-31}	2.2×10^{-40}	2.2×10^{-31}
Mn-54	1.1×10^{-14}	2.5×10^{-26}	2.5×10^{-35}	2.5×10^{-26}
Fe-55	5.0×10^{-13}	2.2×10^{-24}	2.2×10^{-33}	2.2×10^{-24}
Co-58	1.4×10^{-15}	1.0×10^{-28}	1.0×10^{-37}	1.0×10^{-28}
Fe-59	9.5×10^{-16}	8.2×10^{-30}	8.2×10^{-39}	8.2×10^{-30}

APPENDIX I

DOSE COMMITMENT CALCULATION METHODS, SEA DISPOSAL

I. INTRODUCTION

This appendix describes the exposure pathways and the equations and parameters used to estimate potential radiation dose commitments to man if defueled nuclear submarines were disposed of on the ocean floor. In this statement, a dose commitment is the total radiation dose (measured in rems) to an individual which occurs over a period of time due to the exposure of the individual to radioactive materials released into the environment.

The overall process by which radioactive material from a submarine could enter the environment and then reach man includes: the corrosion of the structural materials containing the radionuclides, the release of these corrosion products into the ocean environment, the transport of the corrosion product particles from the disposal site to locations where they could enter the paths which lead to man, and the movement of these corrosion product particles along these paths to man. The corrosion, release, and transport processes are described in Appendices F, G, and H respectively, and the pathways by which the radionuclides might reach man are described in this appendix.

The information presented in this appendix is divided into three sections. The first section describes the pathways by which radionuclides could reach man. The second section describes the equations used to calculate radiation dose commitments to man. The last section describes the parameters used for evaluating the dose commitment equations.

II. SUMMARY

Exposure pathways are presented which describe how radioactivity might be transferred from the seawater to man. Equations are presented which provide a means to estimate the dose commitments to man as a result of being exposed to the radioactivity via the exposure pathways. Values of the parameters in these equations are presented to provide the information required to evaluate the dose commitment equations. The pathways, equations, and parameters presented in this appendix are based on established information found in the literature (see references listed in Section VI).

The exposure pathways presented in this appendix fall into three general categories: ingestion, inhalation, and external exposure pathways. The assumed ingestion pathways include the consumption of fish, crustacea, molluscs, seaweed, plankton, desalinated seawater, and salt from seawater. The inhalation pathway is assumed to include breathing radionuclides released from the seawater and from shore sediments which had picked up radionuclides from the seawater. The assumed external pathways include immersion in seawater, exposure to equipment which had been immersed in the seawater, exposure to shore sediments, and immersion in air which is being breathed. The selection of these pathways is based on the information presented in Reference I.1 and represent the critical pathways by which the maximum amount of radioactivity could be transferred to man. The critical pathways approach used in this statement is within the guidelines provided by the International Commission on Radiation Protection for determining how radionuclides could be transferred to man (Reference I.3).

The equations presented in this appendix are simplified versions of the equations which were developed based on the information presented in References I.1, I.4, and I.5. The equations are based on the concentration factor approach for calculating doses which was used by a group of international scientists in establishing criteria for the IAEA for ocean disposal of radioactive wastes (Reference I.1). The equations are intended to estimate the dose commitment to man which might occur if radionuclides from defueled nuclear submarines emplaced in a deep remote ocean location could reach man through the exposure pathways identified in this appendix. Therefore, equations are presented for each of the ingestion, inhalation, and external exposure pathways.

The values of the parameters used in solving the dose commitment equations are presented. The values of these parameters are based on standard values found in the literature. Information is presented for individual consumption rates and occupancy factors (References I.1, I.9, I.10, I.11, and I.12), concentration factors (References I.1 and I.13), and dose commitment and dose rate conversion factors (References I.5, I.7, I.14, and I.15). The radionuclide concentrations at exposure pathways entry points for all radionuclides which might be present in a defueled nuclear submarine are presented in Section V of Appendix H.

The information in this appendix has been used to calculate the radiation dose commitment estimates to man which could occur as a result of defueled nuclear submarines being disposed of in the deep ocean. For the ingestion and inhalation pathways, the information presented in this appendix was used to estimate the dose commitments that an individual could receive during 70 years after being exposed to the maximum concentrations of the radionuclides. For the external exposure pathways, the information presented in this appendix was used to estimate the dose rate that an individual could receive after being exposed to the maximum concentrations of the radionuclides. In all dose commitment calculations, the maximum radionuclide concentrations which were calculated at any time after disposal operations were initiated were used in solving the dose commitment equations. Therefore, the dose commitment estimates calculated by using the information presented in this appendix represent upper limits of the dose commitments that could be received and are unlikely to be exceeded. The results of these calculations are presented in Appendix J.

III. EXPOSURE PATHWAYS

Radioactive material in ocean water might reach man along the pathways identified in Figure I-1. The pathways identified on this figure are based on the information presented by an international group of scientists who reviewed the radiological and oceanographic basis of the International Atomic Energy Agency (IAEA) recommendations concerning ocean disposal of radioactive wastes (References I.1 and I.2). The pathways identified in Figure I-1 are known as "critical pathways" because, in general, they represent the maximum rates at which radioactivity could be transferred to man by various mechanisms. The critical pathways approach used in this statement is within the guidelines provided by the International Commission on Radiation Protection for determining how radionuclides could be transferred to man (Reference I.3).

The pathways identified in Figure I-1 were used to estimate the amount of radioactivity that could be transported to man if defueled nuclear submarines were disposed of on the ocean floor. The method used in this statement for determining the amount of radioactivity that could reach man is the concentration factor method. The concentration of a radionuclide available in an organism or other physical item in a given pathway may be greater or less than the concentration in the surrounding seawater. If an equilibrium situation or a situation in which concentrations change slowly compared to the turnover rates in the items in the exposure pathways is expected, the use of the concentration factor method is considered applicable for determining the amount of radioactivity that could be transported to man through the exposure pathways (Reference I.1). In this statement, an equilibrium or near equilibrium situation is expected; therefore, the concentration factor method has been used. The concentration factor method directly relates the radionuclide concentration in an item in an exposure pathway to the radionuclide concentration in the seawater from which the item could be picking up the radioactivity.

The pathways presented in Figure I-1 provide a simplified approach for representing how radionuclides could be transferred from the ocean to man. As shown on this figure, organisms in the ocean could pick up radionuclides through their food webs and then transfer the radionuclides to man if he should use these organisms as food. Also, the radionuclides could accumulate in salt produced from seawater and in drinking water produced by desalinating seawater. Both of these pathways could result in radionuclides being ingested by man.

The radionuclides could also be transported to surface waters and then transferred to sediments along the shore. This could result in man being directly exposed to the radionuclides in the water and shore sediments. Additionally, the radionuclides in the surface waters and shore sediments could become airborne and enter the atmosphere. Radionuclides in the atmosphere could then be inhaled by man or result in man being externally exposed to the radionuclides since he would also be immersed in the air that he was breathing.

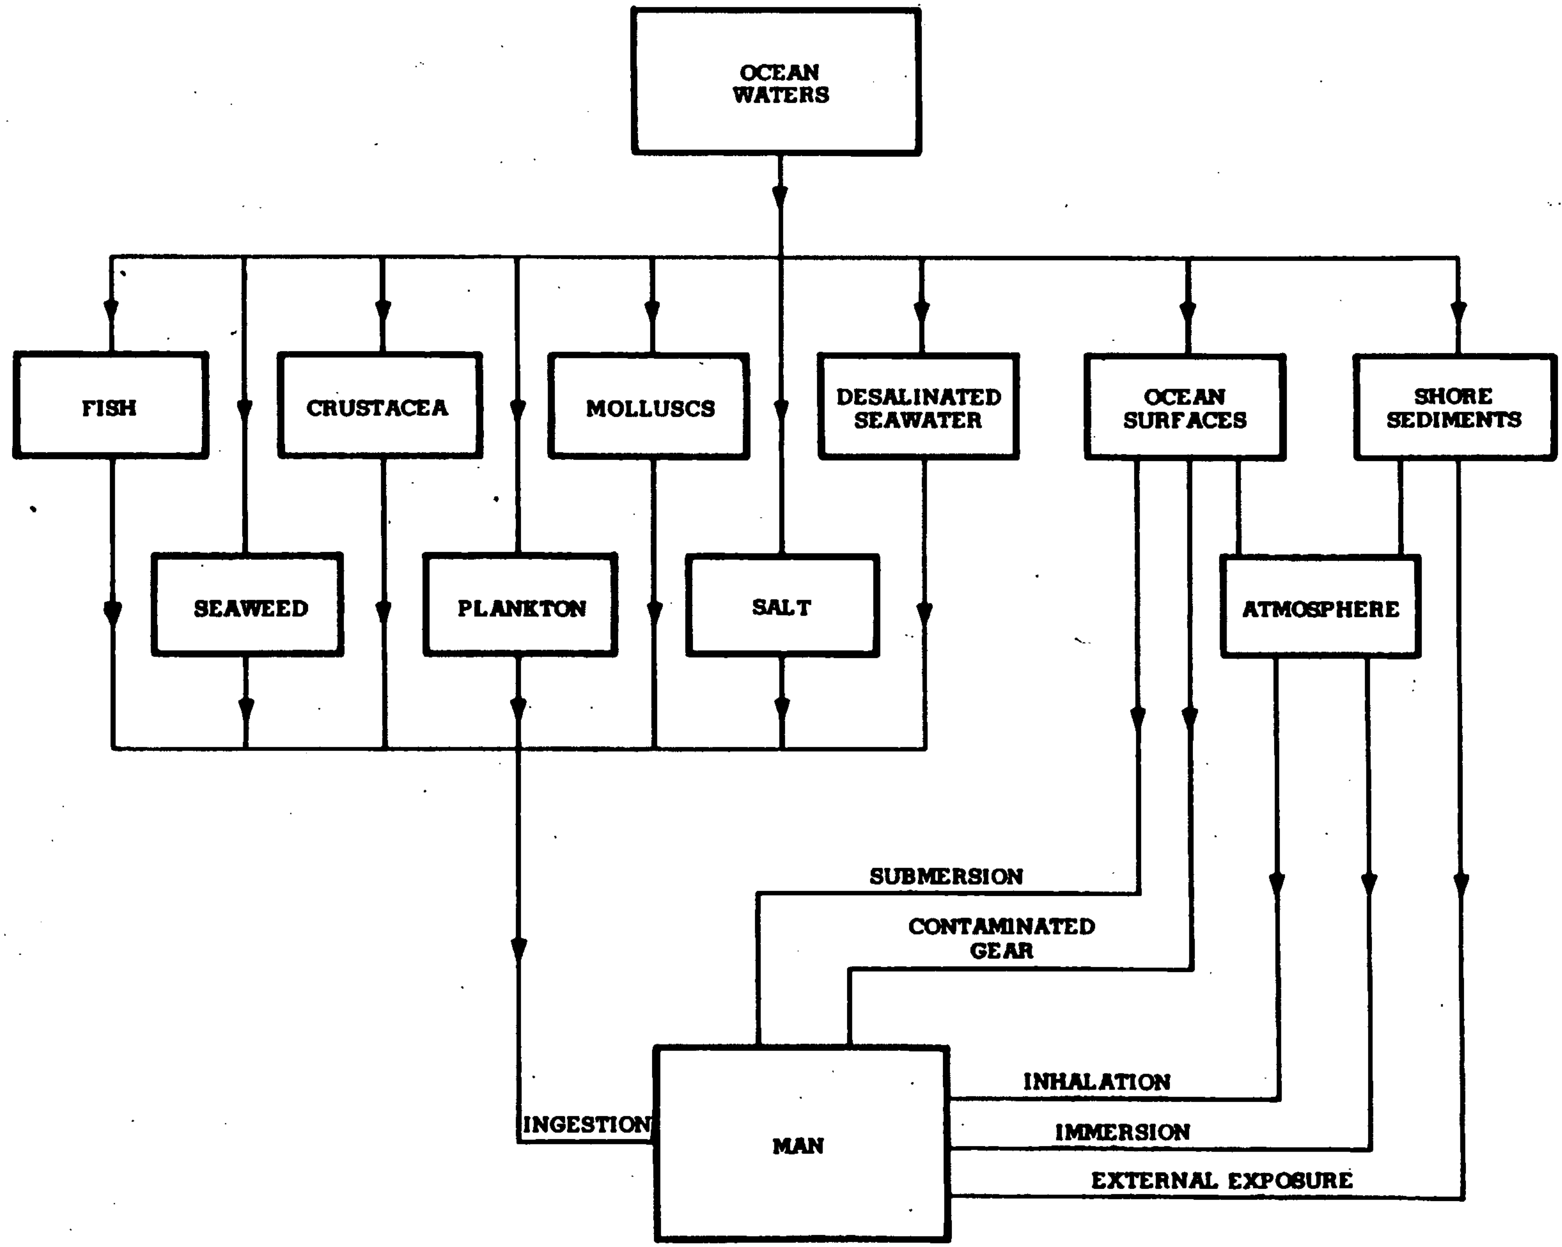

Figure I-1. Pathways to Man

The various pathways identified here can be grouped into the three general categories of ingestion, inhalation, and external radiation exposure. The following sections describe each of these categories of pathways.

A. INGESTION PATHWAYS

Ingestion pathways are those in which radionuclides could be introduced into the body through the gastrointestinal (GI) tract. Ingestion pathways may be divided into direct and indirect pathways. Direct ingestion pathways are those in which the ingested food items could obtain radioactive material directly from the seawater or from their predecessors in the food web. It has been assumed in this approach that the dose commitments to man associated with direct ingestion pathways will be proportional to the concentration of the radionuclides in the seawater in the region of the ocean from which the food item is withdrawn. This is consistent with the normal practice for using concentration factors, but it makes the inherent assumption that the food item is in equilibrium with the seawater. This may not be true in nature if the food item is highly mobile.

The direct ingestion pathways which have been used to provide estimates of the dose commitments to man are:

1. Consumption of fish.
2. Consumption of crustacea.
3. Consumption of molluscs.
4. Consumption of seaweed.
5. Consumption of plankton.
6. Consumption of desalinated seawater.
7. Consumption of sea salt.

The first five of these direct ingestion pathways represent processes through which there could be a biological transfer of radionuclides from the seawater to organisms. This transfer might be accomplished by either the direct assimilation of the radionuclides from the seawater or from the sediment which could pick up radionuclides from the seawater into the organism's tissues, or by the ingestion of predecessors in the food chain which have picked up radionuclides from the seawater or sediment, or by some combination of both. The last two direct ingestion pathways are directly dependent upon the radionuclide concentration in the seawater.

Indirect ingestion pathways are those in which the ingested food items might pick up radioactivity from a secondary medium such as the atmosphere or the soil rather than directly from the seawater. In general, the dose commitments to man associated with indirect ingestion pathways would be proportional to the concentration of the radionuclides in the secondary medium.

The amount of radionuclides available to enter the indirect ingestion pathways would be less than the amount available to enter the direct ingestion pathways because the radionuclides available for the indirect ingestion pathways would be subjected to considerably greater dispersion processes. As a result, the dose commitments associated with indirect ingestion pathways would be significantly less than the dose commitments from the direct ingestion pathways. Since the seawater concentrations which could affect these pathways are small (see Section V, Appendix H), and the resulting doses from the direct pathways are small (see Appendix J), the dose commitments from indirect ingestion pathways have not been calculated since they would not significantly affect the resulting doses, and only the dose commitments associated with the direct ingestion pathways were determined.

B. INHALATION PATHWAY

The inhalation pathway is one in which radionuclides could be introduced into the body through the lungs during the normal breathing process. The dose commitment to man from the inhalation pathway would be dependent on the concentration of the radionuclides in the air. In order for man to inhale the radionuclides, they would need to be transferred to the atmosphere from the seawater and a direct transfer of the radionuclides in the seawater to the atmosphere could occur as a result of wave spray or evaporation. An indirect transfer of the radionuclides in the seawater to the atmosphere could occur as a result of wind causing shore sediments, which had picked up radionuclides from the seawater, to become airborne. Both of these inhalation pathways were used to calculate the dose commitment to man resulting from inhaling the radionuclides.

C. EXTERNAL PATHWAYS

External pathways are those in which man is directly exposed to the radiation emitted by radionuclides outside the body. The external pathways which were used to provide estimates of the dose commitments to man are:

1. Immersion in seawater.

2. Exposure to equipment such as fishing lines, nets, and other items which have been immersed in seawater.

3. Exposure to shore sediments.

4. Immersion in air.

The dose commitments associated with the first two external pathways would be directly dependent on the radionuclide concentration in the seawater. The dose commitment from exposure to shore sediments would also be dependent on the radionuclide concentration in the seawater since the radionuclides in the shore sediments would originate from the seawater. The last external pathway is an extension of the inhalation pathway since an individual would also be immersed in the air that he was breathing.

Other external pathways can be postulated such as exposure to ground deposits of radioactivity formed by radionuclides falling out of the atmosphere, or exposure from using desalinated seawater for bathing, washing clothes, or other purposes. However, these external pathways were not used to estimate dose commitments to man. The amount of radioactive material available to enter these pathways would be considerably less than the amount of radionuclides available to the four previous external pathways since the radionuclides available for these external pathways would be subjected to considerably greater dispersion or dilution processes. As a result, the dose commitments associated with such pathways would be significantly less than those associated with the four previous external pathways. Therefore, only the first four external pathways identified were used to estimate the dose commitments to man resulting from external exposure pathways.

IV. DOSE COMMITMENT EQUATIONS

The equations described in this section were used to determine the radiation dose to man as a result of radioactivity assumed to be released to the environment from defueled nuclear submarines disposed of on the ocean floor. The equations presented are simplified versions of the dose commitment equations which were developed based on the information presented in References I.1, I.4, and I.5. Equations are presented for ingestion, inhalation, and external exposure pathways.

For the ingestion and inhalation pathways, the equations presented in this appendix were used to estimate the dose commitments that an individual could receive during 70 years after being exposed to the maximum concentrations of the radionuclides for a specified time period. For the external exposure pathways, the equations presented in this appendix were used to estimate the dose rate that an individual could receive after being exposed to the maximum concentrations of the radionuclides.

In all dose commitment calculations using the equations presented in this section, the maximum radionuclide concentrations which were calculated at any time after disposal operations were initiated were used in solving these dose commitment equations. Additionally, no removal terms, which would actually be present, were included in any of the equations. For example, no radioactive decay terms were included in any of the equations. Also, for the ingestion pathway, it was conservatively assumed that all of the radioactive material was in the edible portions of foods and would not be removed by gutting, washing, or any other cleaning operations. Therefore, the dose commitment estimates calculated by using the equations presented in this section represent upper limits of the dose commitments that could be received and are unlikely to be exceeded.

Equations are presented for the ingestion, inhalation, and external exposure pathways described in Section III of this appendix. The sources of the parameters identified in the equations presented in this section and the values used are described in Section V of this appendix. The dose commitment estimates obtained using the equations presented in this section are presented in Appendix J.

A. INGESTION PATHWAYS

The equation used for determining the possible dose commitment to man from ingesting radionuclides that could be released from defueled nuclear submarines disposed of on the ocean floor is:

$$D_I = KPqUX_w\Delta T$$

where

D_I is the dose commitment from ingestion of the radionuclide (in man-rem).

K is the dose commitment conversion factor for ingestion for each radionuclide (in rem per curie). This factor converts the amount of radioactivity (in curies) in the ingested material to the dose to the human body (in rem) and includes a consideration of the time the radioactive material may stay in the body.

P is the number of people for which the dose commitment estimate is being made.

q is the rate at which individuals may ingest the particular food considered (in grams per day) or drink desalinated seawater (in liters per day). The liters per day term requires conversion to units of grams per day when solving this equation.

U is the concentration factor which relates the radionuclide concentration in a unit mass of the item ingested to the radionuclide concentration in a unit volume of seawater from which the ingested item was obtained (in curies per kilogram of food per curies per liter of seawater). This term requires conversion to units of curies per gram per curies per cubic meter when solving this equation.

X_w is the concentration of the radionuclide considered in seawater (in curies per cubic meter).

ΔT is the time period over which an individual could be ingesting the food item (in days).

B. INHALATION PATHWAY

The equation used for determining the possible dose commitment to man from inhaling radionuclides that could be released from defueled nuclear submarines disposed of on the ocean floor is:

$$D_B = KPBX_a\Delta T$$

where

D_B is the dose commitment from inhalation of the radionuclide (in man-rem).

K is the dose commitment conversion factor for inhalation for each radionuclide (in rem per curie). This factor converts the amount of radioactivity (in curies) inhaled to the dose to the human body (in rem) and includes a consideration of the time the radioactive material may stay in the body.

P is the number of people for which the dose commitment estimate is being made.

B is the breathing rate for an individual (in cubic meters of air per day).

X_a is the concentration of the radionuclide considered in the air (in curies per cubic meter of air).

ΔT is the time period over which an individual could breathe the affected air (in days).

C. EXTERNAL PATHWAYS

This section presents the equations used for determining the possible dose commitment to man from external exposure to the radionuclides that might be released from the disposal of defueled nuclear submarines on the ocean floor. Hypothetically, humans could be externally exposed to the radionuclides by several routes such as immersion in the seawater, contact with equipment that had been immersed in the seawater, contact with shore sediments, or immersion in air being breathed.

1. Immersion in Seawater

The equation used for determining the possible dose commitment to man due to immersion in the seawater is:

$$D_S = KP\tau_s X_w \Delta T$$

where

D_S is the dose commitment due to immersion in the seawater (in man-rem).

K is the dose rate conversion factor for external exposure for each radionuclide (in rem per hour per curie per cubic meter). This factor converts the amount of radioactivity (in curies per cubic meter of seawater) in the seawater to the dose rate to the human body (in rem per hour).

P is the number of people for which the dose commitment estimate is being made.

τ_s is the amount of time that an individual could be immersed in the seawater (in hours per year).

X_w is the concentration of the radionuclide considered in the seawater which immersion occurs (in curies per cubic meter of seawater).

ΔT is the time period over which an individual could be immersed in the seawater (in years).

2. Exposure to Equipment

The equation used for determining the possible dose commitment to man due to exposure to equipment that had been immersed in the seawater is:

$$D_E = D_S F_e$$

where

D_E is the dose commitment due to exposure to equipment that had been immersed in the seawater (in man-rem).

D_S is the dose commitment due to immersion in the seawater (in man-rem).

F_e is a modifying factor which relates the dose commitment associated with exposure to equipment to the dose commitment associated with immersion in the seawater.

The procedure for using a modifying factor to relate the dose commitment associated with exposure to equipment to the dose commitment associated with immersion in the seawater was based on the treatment presented in Reference I.1. A typical value for the factor, F_e, is 0.1 (as reported in Reference I.1). This number is typical for handling fishing gear, such as nets and lines, and will be used in this statement to estimate the dose commitment due to exposure to equipment that had been immersed in the seawater.

3. Exposure to Shore Sediments

The equation used for determining the possible dose commitment to man due to exposure to shore sediments is:

$$D_V = KP\tau_v UX_w \rho \theta \Delta T$$

where

D_V is the dose commitment due to exposure to shore sediments (in man-rem).

K is the dose rate conversion factor for external exposure for each radionuclide (in rem per hour per curie per square meter). This factor converts the amount of radioactivity (in curies per square meter of sediment surface) in the sediments to the dose rate to the human body (in rem per hour).

P is the number of people for which the dose commitment estimate is being made.

τ_v is the amount of time that an individual could be exposed to the shore sediments (in hours per year).

U is the concentration factor relating the radionuclide concentration in a unit mass of shore sediments to the radionuclide concentration in a unit volume of seawater from which the shore sediments might accumulate the radionuclide considered (in curies per kilogram of sediments per curies per liter of seawater). This term requires conversion to units of curies per gram per curies per cubic meter when solving this equation.

X_w is the concentration of the radionuclide considered in the seawater adjacent to the shore sediments (in curies per cubic meter of seawater).

ρ is the density of the shore sediments (in grams per cubic meter of sediment).

θ is the thickness of the shore sediments which could contribute to the dose commitment (in meters).

ΔT is the time period over which an individual could be exposed to the shore sediments (in years).

The value of the density term, ρ, was chosen to be 2.65×10^6 grams per cubic meter (Reference I.6), based on the very conservative assumption that the density of shore sediments would be similar to pure SiO_2. The value of the thickness term, θ, was chosen to be 0.15 meter. This value was based on the thickness of sediments required to effectively shield the gamma radiation from Cobalt-60 since this radionuclide is the most critical for determining dose commitment estimates for the shore sediments pathway. Both of these values were chosen to be larger than actually expected so that the dose commitment estimates to man due to exposure to shore sediments would be unlikely to be underestimated.

4. Immersion in Air

The equation used for determining the possible dose commitment to man due to immersion in air is:

$$D_A = KP\tau_a X_a \Delta T$$

where

D_A is the dose commitment due to immersion in air (in man-rem).

K is the dose rate conversion factor for external exposure for each radionuclide (in rem per hour per curie per cubic meter). This factor converts the amount of radioactivity (in curies per cubic meter of air) in the air to the dose rate to the human body (in rem per hour).

P is the number of people for which the dose commitment estimate is being made.

τ_a is the amount of time that an individual could be immersed in the air (in hours per year).

X_a is the concentration of the radionuclide considered in the air which immersion occurs (in curies per cubic meter of air).

ΔT is the time period over which an individual could be immersed in the air (in years).

V. PARAMETERS FOR THE DOSE COMMITMENT EQUATIONS

The values of the parameters used to solve the dose commitment equations are described in this section. Information is presented for individual consumption rates and occupancy factors, concentration factors, and dose commitment and dose rate conversion factors. Each of these parameters is discussed in the following sections. The radionuclides which might be released from defueled nuclear submarines and associated radioactive decay data are also tabulated. The radionuclide concentrations at exposure pathway entry points for all radionuclides which might be present in a defueled nuclear submarine are presented in Section V of Appendix H.

A. RADIONUCLIDES AVAILABLE FOR RELEASE

The radionuclides remaining in a defueled nuclear submarine are listed in Table I-1 along with their half-lives and decay constants. The values presented in Table I-1 are based on the information contained in References I.7 and I.8. The radionuclides remaining in a defueled nuclear submarine would be contained either in the structural components of the reactor compartment or in corrosion products which form an adherent film on the inside of the components and piping of the primary coolant system. Nearly 100 percent of the radioactivity would be embedded in the structural components of the reactor compartment and reactor vessel. This radioactivity was formed by exposure of the structural components to neutrons during normal operation of the submarine. These radionuclides could not be released to the environment until the containment afforded by the reactor compartment and reactor vessel would be penetrated and then the rate of release would be limited by the rate of corrosion of the internal structures.

Approximately 0.1 percent of the total radioactivity remaining in a defueled nuclear submarine would be present in the form of an adherent corrosion film on the inside surfaces of the reactor coolant system. These corrosion products were generated during normal operation of the submarine and were incorporated in the corrosion film inside the primary coolant system. They are not removable by system flushing. These radionuclides could not be released to the environment until the containment afforded by the reactor compartment and the primary coolant system would be penetrated.

TABLE I-1. DECAY CONSTANTS AND HALF-LIVES OF RADIONUCLIDES USED IN ENVIRONMENTAL IMPACT CALCULATIONS

Nuclide	Half-Life(1)*	Decay Constant (hr^{-1})
C-14	5734 years	1.379×10^{-8}
S-35	88 days	3.282×10^{-4}
Sc-46	83.9 days	3.446×10^{-4}
Cr-51	27.8 days	1.042×10^{-3}
Mn-54	303 days	9.24×10^{-5}
Fe-55	2.6 years	2.929×10^{-5}
Co-58	71.3 days	4.05×10^{-4}
Fe-59	45 days	6.475×10^{-4}
Ni-59	80,000 years	9.88×10^{-10}
Co-60	5.26 years	1.503×10^{-5}
Ni-63	92 years	8.594×10^{-7}
Mo-93(2)	3500 years(2)	2.259×10^{-8}
Nb-94(2)	20,000 years(2)	3.953×10^{-9}
Zr-95	65 days	4.409×10^{-4}
Tc-99	212,000 years	3.73×10^{-10}
Hf-181	42.5 days	6.79×10^{-4}

(1) All half-life and decay constant data based on decay constants obtained from Reference I.7 unless otherwise noted.

(2) Half-life taken from Reference I.8.

*As described in Chapter 1 (Table 1-1, Note 7), the half-life values used in this final environmental impact statement are the same as those used in the draft statement. The calculations were not revised to reflect the most recent half-life values, shown in Table 1-1, because there would be no significant effect on the results or conclusions but confusion between the DEIS and FEIS would result.

B. CONSUMPTION RATES AND OCCUPANCY FACTORS

The rates at which individuals may consume various items, breathe, and occupy certain areas are listed in Table I-2 for each of the exposure pathways identified in Section III of this appendix. The rates presented in Table I-2 are for an adult individual and are based on the information presented in References I.1, I.9, I.10, I.11, and I.12 or have been estimated using similar procedures. Data are given for both an "average" individual and a "maximum" individual, with the difference being the values of the various consumption rates or occupancy factors.

TABLE I-2. CONSUMPTION RATES AND OCCUPANCY FACTORS

Pathway	Consumption Rates (g/day)(1)		Occupancy Factor (hrs/yr)(1)	
	Maximum Individual	Average Individual	Maximum Individual	Average Individual
Fish	179(2)	15.47(4)		
Crustacea	66.9(3)	2.54(4)		
Molluscs	53.9(3)	1.85(4)		
Seaweed	300	0.12(5)		
Plankton	62.9	0.12(5)		
Drinking Desalinated Seawater	2 liters/day	2 liters/day		
Salt	3	0.03(5)		
Inhalation	20 m^3/day	20 m^3/day		
Seawater Immersion			300	12(5)
Equipment			300	12(5)
Air Immersion			8766	8766
Shore Sediments			1000	50(5)

(1) All values from Reference I.1 unless otherwise noted.
(2) From Reference I.9.
(3) From data presented in References I.1, I.9, and I.10.
(4) From data presented in References I.11 and I.12.
(5) Estimated by authors.

The data presented for an average individual represent the consumption rates and occupancy factors for a typical member of the population along the west coast, Gulf coast, or east coast of the United States and are based on the averages reported in the references. In the dose commitment calculations, the individual with average usage factors, like the individual with maximum usage factors, will be assumed to be exposed to the pathways at the point of highest concentration for each pathway. This means that the dose commitments calculated for the average and maximum individual represent upper limits of the average and maximum dose commitments.

The data for a maximum individual represent the highest consumption rates and occupancy factors for a member of the same population who has unusually high usage of the individual pathways. For a given pathway, the data for a maximum individual represent the highest consumption rate or occupancy factor which is expected to be attained by any individual exposed to that particular pathway. Therefore, it would not be possible for any one individual to be exposed to all the maximum consumption rates or occupancy factors. For example, while one individual might consume a maximum amount of fish, only a separate individual could consume the maximum amount of crustacea, and the other maximum usages are similarly exclusive.

C. CONCENTRATION FACTORS

Concentration factors for each radionuclide present in a defueled nuclear submarine and for each exposure pathway are listed in Table I-3, except for the seawater immersion and equipment exposure pathways. These two pathways were not listed because concentration factors are not applicable for determining dose commitments from the direct exposure to the water assumed for these pathways. The information presented in Table I-3 is based on the information developed by the IAEA (Reference I.1) and the National Academy of Sciences (Reference I.13).

The data tabulated in Table I-3 represent estimates of the concentration of a particular radionuclide in organisms, desalinated seawater, salt, sediments, and air relative to the concentration of the radionuclide in the seawater from which the consumed product originated. For example, if a fish weighing 1 kilogram were to live in seawater which contained 1 picocurie per liter of Cobalt-60, the food web supporting that fish might accumulate the Cobalt-60 so that the fish could end up containing 100 picocuries of Cobalt-60.

D. DOSE COMMITMENT AND DOSE RATE CONVERSION FACTORS

Dose commitment and dose rate conversion factors convert the exposure to a given amount of radioactivity or radiation level to the dose that an individual could receive if he were exposed to that amount of radioactivity or radiation level. Particular organs of the body concentrate particular radionuclides differently; therefore, dose commitment and dose rate conversion factors vary for a particular radionuclide and organ of the body. Additionally, dose commitment conversion factors take into account the exposure resulting from the radioactive material that may stay in the body for a period of time, which is dependent on the material's biological half-life. Dose commitment conversion factors also vary depending on the age of the individual exposed and the time period over which the dose commitment estimate is being made. An adult individual was chosen and the time period chosen for determining the dose commitment was 70 years (see Section I of Appendix J).

Dose commitment or dose rate conversion factors for each radionuclide, pathway, and organ are presented in this section. The radionuclides considered are those that would be present in a defueled nuclear submarine. The pathways include ingestion, inhalation, and three external exposure pathways. The three external pathways represent exposure to shore sediments, water immersion, and air immersion exposure. The "organs" considered are the total body, bone, liver, kidney, gonads, lung, gastrointestinal (GI) tract, thyroid, and skin. These organs are normally used for determining dose commitment estimates (for example, see Reference I.7).

The dose commitment conversion factors for ingestion of radionuclides are presented in Table I-4. The information presented in this table is based on the information presented in References I.5, I.7, and I.14 or has been estimated. The data presented in Table I-4 represent the dose commitment to a particular organ over 70 years if the individual ingested 1 curie of a particular radionuclide.

The dose commitment conversion factors for inhalation of radionuclides are presented in Table I-5. The information presented in this table is based on the information presented in References I.5, I.7, I.14, and I.15. The data presented in Table I-5 represent the dose commitment to a particular organ over 70 years if the individual inhaled 1 curie of a particular radionuclide.

The surface dose rate conversion factors for exposure to shore sediments are presented in Table I-6 and are based on the information presented in References I.7 and I.15. The data presented in Table I-6 represent the dose rate in rem per hour to a particular organ if the individual were exposed to a surface deposit of 1 curie of a particular radionuclide per square meter of sediments.

The dose rate conversion factors for immersion in seawater are presented in Table I-7 and are based on the information presented in Reference I.15. The data presented in Table I-7 represent the dose rate in rem per hour to a particular organ if the individual were immersed in seawater containing 1 curie of a particular radionuclide per cubic meter of seawater.

TABLE I-3. CONCENTRATION FACTORS[1]
Ci/kg per Ci/liter

Nuclide	Fish	Crustacea	Molluscs	Seaweed	Plankton	Desalinated Seawater	Salt	Sediments	Air
C-14	5×10^4	4×10^4	5×10^4	4×10^3	3×10^3	1×10^{-4}	3×10^1	1×10^2	1×10^{-5}
S-35	1	1	1	1	1	1×10^{-4}	3×10^1	1×10^2	1×10^{-5}
Sc-46[2]	7.5×10^3	3×10^3	7.5×10^3	2×10^4	2×10^4	1×10^{-4}	3×10^1	5×10^4	1×10^{-2}
Cr-51	1×10^2	5×10^2	5×10^2	3×10^4	3×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Mn-54	5×10^2	1×10^4	1×10^4	1×10^4	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Fe-55	1×10^3	1×10^3	1×10^3	1×10^4	1×10^4	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Co-58	1×10^2	1×10^3	1×10^3	1×10^3	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Fe-59	1×10^3	1×10^3	1×10^3	1×10^4	1×10^4	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Ni-59	5×10^2	1×10^2	1×10^2	5×10^2	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Co-60	1×10^2	1×10^3	1×10^3	1×10^3	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Ni-63	5×10^2	1×10^2	1×10^2	5×10^2	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Mo-93	1×10^1	1×10^1	6×10^2	2.6×10^2	2.6×10^2	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Nb-94	1	1×10^2	1×10^3	5×10^2	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Zr-95	1	1×10^2	1×10^3	5×10^2	1×10^4	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Tc-99	1×10^1	1×10^3	1×10^3	1×10^5	1×10^3	1×10^{-4}	3×10^1	1×10^4	1×10^{-2}
Hf-181[3]	5×10^4	4×10^4	5×10^4	3×10^4	1×10^4	1×10^{-4}	3×10^1	5×10^4	1×10^{-2}

(1) Based on values in Reference I.1.
(2) Fish, crustacea, and plankton values taken from Reference I.13, mollusc and seaweed assumed equal to fish and plankton respectively, remaining values are assumed to be the highest value found in specific pathway for the referenced nuclides.
(3) Values assumed to be the highest value found in specific pathway for the referenced nuclides.

TABLE I-4. ADULT INGESTION 70 YEAR DOSE COMMITMENT CONVERSION FACTORS[1]
Rem/Ci

Nuclide	Total Body	Bone	Liver	Kidney	Gonads	Lung	GI Tract	Thyroid	Skin
C-14	5.68×10^2	2.84×10^3	5.68×10^2	5.68×10^2	5.68×10^2	5.68×10^2	5.68×10^2	5.68×10^2	5.68×10^2
S-35	2.6×10^3	6.69×10^3	2.6×10^3	2.6×10^3	1.02×10^4	2.6×10^3	6.47×10^3	2.6×10^3	0.0

The dose rate conversion factors for immersion in air are presented in Table I-8. These factors are based on the information presented in References I.7 and I.15. The data presented in Table I-8 represent the dose rate in rem per hour to a particular organ if the individual were immersed in air containing 1 curie of a particular radionuclide per cubic meter of air.

APPENDIX J

DOSE COMMITMENT ESTIMATES, SEA DISPOSAL

I. INTRODUCTION

This appendix presents estimates of potential radiation dose commitments to man if defueled nuclear submarines were disposed of on the ocean floor. These estimates have been calculated using the techniques described in Appendices F, G, H, and I, and the values of the parameters presented in those appendices. The dose commitments presented in this appendix represent conservative estimates of the dose commitments that could occur, and it is expected that actual human exposures would be less than those presented.

As explained in Appendix G, the radionuclides remaining in defueled nuclear submarines that might result in dose commitments to man would be contained either in the structural components of the reactor compartment or in corrosion products which form an adherent film on the inside of the components and piping of the primary coolant system. Nearly 100 percent of the radioactivity would be embedded in the structural components of the reactor compartment and reactor vessel. This radioactivity was formed by neutron activation of the metal atoms in the structural components during normal submarine operations. Approximately 0.1 percent of the total radioactivity would be present in the form of an adherent corrosion film formed during normal submarine operations on the inside surfaces of the reactor coolant system.

Radioactive material from defueled nuclear submarines could enter the environment and reach man only after several independent events occur. First, corrosion of the structural materials containing the radionuclides would have to occur which would release the corrosion product particles to the inside of the reactor vessel. Corrosion would then have to penetrate the reactor vessel to allow the corrosion products to enter the reactor compartment volume. After corrosion penetrated the reactor compartment, the corrosion products inside could then be released to the ocean environment. These corrosion product particles could then be transported from the disposal site to locations where they could enter the paths which lead to man. At every point through these steps, radioactive decay, settling, and other processes would reduce the amount of radioactive material in the ocean, thereby reducing the amount available to man. The corrosion, release, transport, and movement to man processes are described in detail in Appendices F, G, H, and I respectively.

Dose commitment estimates are presented in this appendix for the three general categories of exposure pathways described in Section III of Appendix I. These pathways are ingestion, inhalation, and external exposure. The assumed ingestion pathways include consumption of fish, crustacea, molluscs, seaweed, plankton, desalinated seawater, and salt from seawater. The inhalation pathway has been assumed to include breathing radionuclides released from the seawater and from shore sediments which might pick up radionuclides from the seawater. The assumed external pathways include immersion in the seawater, exposure to equipment which had been immersed in the seawater, exposure to shore sediments, and immersion in air which is being breathed.

The radionuclide concentrations available for entering the exposure pathways will vary depending on when the submarines' containment boundaries are penetrated and how corrosion processes release the radionuclides. The maximum calculated radionuclide concentrations for any time after disposal were chosen for determining the dose commitments that critical (maximum exposed) groups of people could receive via the exposure pathways. As a result, the dose commitment estimates presented in this appendix are conservative since the maximum concentrations of particular radionuclides were used in solving the dose commitment equations, and these maximum concentrations were assumed to occur along the entire shoreline, even though the concentrations of particular radionuclides would reach their maximum values at different times, and these maximum concentrations could not occur along the entire shoreline.

In this statement, a dose commitment is the total radiation dose (measured in rems) to an individual which occurs over a period of time as a result of exposure to radioactive material present in the environment for a specified period of time. As stated in Appendix I, the dose commitment estimates for the external exposure pathways represent the dose rate in millirem (mrem) per year that an individual could receive after being exposed to the maximum concentrations of the radionuclides. The dose commitment estimates for the ingestion and inhalation pathways represent the dose in mrem that an individual could receive in 70 years after being exposed to the maximum concentrations of the radionuclides for one year. If it can be assumed that the radionuclide concentrations would remain at their maximum levels over the 70 year period, the individual would maintain the same consumption rates and occupancy factors, and the effect and retention of the radionuclides would not change for the individual over the 70 year period, then the dose commitments for the ingestion and inhalation pathways could also represent the dose that an individual could receive during the 70th year after being exposed to the maximum concentrations of the radionuclides for 70 years. As a result, the dose commitment estimates presented in this appendix are in terms of an annual exposure rate which allows for comparisons to be made with radiation exposure standards and natural background radiation since these exposures are usually cited on the basis of an annual exposure rate. Dose commitment estimates were determined for particular organs of the body which were assumed to include the total body, bone, liver, kidney, gonads, lung, gastrointestinal (GI) tract, thyroid, and skin and for each exposure pathway and each radionuclide that could be released from a defueled nuclear submarine.

A dose commitment to an individual is dependent on the age of an individual when the exposure occurs. In this statement, the dose commitment estimates presented are for an adult individual. Total body dose commitment estimates were determined for adults, teens, children, and infants and the results indicated that the dose commitment estimates were all within a factor of two. On this basis, the dose commitment estimates for adults were judged to be representative of the population and were chosen to be reported in this appendix.

Dose commitment estimates are presented for an individual with average consumption rates or occupancy factors and for an individual assumed to be exposed at higher than average consumption rates or occupancy factors. In this statement, an average individual has been assumed to be an individual who could consume certain foods or occupy certain areas at rates which would be typical for a member of the population living on the west coast of the United States. Dose commitment estimates were determined for an individual living on the west coast because this yields a larger estimate of the dose commitments since a disposal site which might satisfy site selection criteria would be closer to the shoreline for a disposal site in the Pacific Ocean, and less stirring and dilution would be expected for a disposal site in the Pacific Ocean than would be expected for the Atlantic Ocean. A discussion concerning site selection criteria and a description of the ocean study areas is presented in Appendix E. A maximum individual has been assumed to be an individual who could consume certain foods or occupy certain areas at unusually high rates for a member of the population living on the west coast of the United States. The consumption rates and occupancy factors used for determining the dose commitment estimates for an average individual and a maximum exposed individual are presented in Section V.B of Appendix I. For both an average individual and a maximum individual, the maximum radionuclide concentrations which were calculated for any time after disposal operations were initiated were used in calculating the dose commitment estimates.

In order to put the dose commitment estimates presented in this appendix into perspective, they will be compared to exposure estimates from natural background radiation. An average adult individual in the United States receives between approximately 30 and 150 mrem of total body exposure annually from natural sources of radioactivity (Reference J.1). This average exposure does not include the exposure that could result from medical diagnostic procedures, primarily x-rays, which on the average, could add approximately 100 mrem to this exposure. In this statement, an average annual exposure of 100 mrem from natural background radiation will be used for comparison purposes.

The total body dose commitment estimate for ingesting fish which are exposed to naturally-occurring Radium-226 in seawater was also calculated for comparison purposes. This dose commitment estimate was calculated using the same calculational procedures used to obtain the dose commitment estimates presented in this appendix. The concentration of naturally-occurring Radium-226 in seawater is approximately 9×10^{-11} curies per cubic meter (Reference J.2). The concentration factor used for Radium-226 was 1×10^{2} curies per kilogram per curies per liter (Reference J.3) and the total body dose commitment conversion factor used was 3.1×10^7 rem per curie (Reference J.4). The resulting total body dose commitment estimate for an average adult individual is approximately 2 mrem for Radium-226. For a maximum adult individual who could consume fish at a higher rate, the total body dose commitment estimate is approximately 20 mrem.

The dose commitment estimates presented in this appendix are divided into five sections.

1. The dose commitment estimates for the disposal of 100 submarines under expected disposal conditions in which containment is maintained for all 100 submarines.

2. The dose commitment estimates for a postulated accident in which one submarine has its containment penetrated at a disposal site location.

3. The dose commitment estimates for a postulated accident during transit in which one submarine sinks with its containment penetrated at a distance from shore where commercial fishing operations could occur.

4. The dose commitment estimates for the consumption of fish which were postulated to live at the disposal site. Since no biological pathway which links organisms in the deep ocean directly to man is known, these dose commitment estimates were included in case such a pathway is identified in the future.

5. The dose commitment estimates for expected disposal conditions in which containment is maintained for 100 submarines; for a postulated accident in which one submarine has its containment penetrated at the disposal site; and for a postulated accident in which one submarine sinks during transit to the disposal site at a location where commercial fishing operations could occur and also has its containment penetrated. The estimates in this section are based on the same disposal scenarios presented in the first three sections except that the values of the parameters used in calculating the release and transport of radionuclides to man were chosen to be extremely conservative whereas the estimates in the first three sections were calculated using expected values for these parameters. For a detailed discussion on the parameters used and their expected and conservative values, see Sections II and III of Appendix G for the release parameters and Section IV.C of Appendix H for the transport parameters.

Additionally, an example of the calculations performed to obtain the dose commitment estimates presented in this appendix has been included.

The dose commitment estimates presented in this appendix were calculated using the equations presented in Section IV of Appendix I. The maximum radionuclide concentrations calculated for any time after disposal operations begin were used in solving these equations and are tabulated in Section V of Appendix H. The exposure pathways for which the dose commitment estimates were made are described in Section III of Appendix I, and the parameters used in solving the dose commitment equations are listed in Section V of Appendix I.

II. SUMMARY

Estimates of the dose commitments that might occur as a result of defueled nuclear submarines being disposed of on the ocean floor are presented in this appendix. Dose commitment estimates have been calculated using the maximum radionuclide concentrations which were calculated at any time after disposal operations were initiated. Dose commitment estimates have been calculated for average and maximum individuals in the critical (maximum exposed) population group and are presented for the following disposal scenarios: expected disposal conditions in which containment is maintained for 100 submarines, a postulated accident in which one submarine has its containment penetrated at the disposal site, and a postulated accident in which one submarine sinks during transit to the disposal site at a location where commercial fishing operations could occur and also has its containment penetrated. Dose commitment estimates are also presented for a postulated condition in which a hypothetical maximum individual ingests fish which were assumed to be living at the disposal site in close proximity to a submarine disposed under expected conditions. Additionally, dose commitment estimates for average and maximum individuals are presented for the disposal of 100 submarines under expected disposal conditions, for a postulated accident in which one submarine has its containment penetrated at the disposal site, and for a postulated accident in which one submarine sinks during transit to the disposal site at a location where commercial fishing operations could occur and also has its containment penetrated; for this series of estimates, the parameters used in calculating the release and transport of radionuclides to man were chosen to be extremely conservative.

Estimates of the total body and maximum exposed organ dose commitments that might occur as a result of the disposal scenarios identified are listed in Table J-1. The data included in this table represent both the best estimate of the dose commitments for expected and postulated accident disposal conditions, and the dose commitments for expected and postulated accident disposal conditions in which the parameters used in calculating the release and transport of radionuclides to man were chosen to be extremely conservative.

All of the total body dose commitment estimates for each of the disposal scenarios are significantly less than the average annual 100 mrem exposure from natural background radiation. Also, the total body exposures are less than the estimated 2 mrem for an average individual or 20 mrem for a maximum individual total body exposures from ingesting fish containing naturally-occurring Radium-226. All of the total body dose commitment estimates are also significantly less than the U.S. Nuclear Regulatory Commission (NRC) requirement that prevents an individual from receiving a total body exposure of more than 500 mrem per year (Reference J.5). Additionally, the dose commitment estimates are less than the U.S. Environmental Protection Agency (EPA) drinking water requirement that prevents an individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6).

Maximum dose commitment estimates were also calculated for a hypothetical biological pathway in which a maximum individual ingests fish which were assumed to be living at the disposal site in close proximity to a submarine disposed under expected disposal conditions. Two methods were postulated for the radionuclides released to become available for the fish. The first method assumed that the released radionuclides were present in the ocean water close to the disposed submarine with no deposition of the radionuclides in the sediment. The resulting total body dose commitment is approximately 0.2 mrem per year, and the maximum organ dose commitment is approximately 5 mrem per year to the bone. The second method assumed that the radionuclides were released to the ocean waters but then settled to the ocean floor and deposited in the sediment close to the disposed submarines. The resulting total body dose commitment is approximately 2 mrem per year, and the maximum organ dose commitment is approximately 17 mrem per year to the bone. Very conservative assumptions were used, and these dose commitment estimates were calculated only to determine the upper limit of the dose commitments associated with biological transport of radionuclides and are not considered to be a likely result of sea disposal of defueled nuclear submarines.

The dose commitment estimates presented in this appendix were calculated using the maximum radionuclide concentrations which were calculated at any time after disposal operations were initiated. As a result, the dose commitment estimates presented are conservative since these maximum concentrations were used in the calculations and these maximum concentrations were assumed to occur along the entire shoreline, even though the concentrations of particular radionuclides would reach their maximum values at different times, and these maximum concentrations could not occur along the entire shoreline. It is expected that actual human exposures would be less than those presented.

III. DOSE COMMITMENT ESTIMATES

Dose commitment estimates for average and maximum individuals in the critical (maximum exposed) population group are presented in this section for the following disposal scenarios: expected disposal conditions in which containment is maintained for 100 submarines, a postulated accident in which one submarine has its containment penetrated at the disposal site, and a postulated accident in which one submarine sinks with its containment penetrated during transit to the disposal site at a location where commercial fishing operations could occur. Dose commitment estimates are also presented for a postulated condition in which a hypothetical maximum individual ingests fish which were assumed to be living at the disposal site in close proximity to a submarine emplaced under expected disposal conditions. Additionally, dose commitment estimates are presented for expected disposal conditions in which containment is maintained for 100 submarines, a postulated accident in which a submarine has its containment penetrated at the disposal site, and a postulated accident in which one submarine sinks with its containment penetrated during

TABLE J-1. TOTAL BODY AND MAXIMUM ORGAN DOSE COMMITMENTS FOR VARIOUS DISPOSAL SCENARIOS

mrem

Disposal Scenario	Total Body		Maximum Organ	
	Best[(1)] Estimate	Conservative[(2)] Estimate	Best[(1)] Estimate	Conservative[(2)] Estimate
Expected Conditions, Average Adult, 100 Submarines	6×10^{-12}	2×10^{-4}	2×10^{-10} (Bone)	6×10^{-3} (Bone)
Expected Conditions, Maximum Adult, 100 Submarines	1×10^{-10}	3×10^{-3}	3×10^{-9} (Bone)	1×10^{-1} (Bone)
Postulated Site Accident, Average Adult, 1 Submarine	1×10^{-9}	3×10^{-3}	1×10^{-9} (Skin)	3×10^{-3} (Skin)
Postulated Site Accident, Maximum Adult, 1 Submarine	2×10^{-8}	6×10^{-2}	3×10^{-8} (Skin)	7×10^{-2} (Skin)
Postulated Transport Accident, Average Adult, 1 Submarine	5×10^{-2}	1×10^{-1}	5×10^{-2} (Skin)	2×10^{-1} (Skin)
Postulated Transport Accident, Maximum Adult, 1 Submarine	9×10^{-1}	3	1 (Skin)	3 (Skin)

(1) Best estimate dose commitments were calculated using conservative assumptions (for discussion, see Section IV of Appendix I).

(2) Conservative dose commitments were calculated the same as best estimate dose commitments, except the parameters used in calculating the release and transport of radionuclides to man were chosen to be extremely conservative (for discussion, see Sections II and III of Appendix G and Section IV.C of Appendix H).

transit to a disposal site at a location where commercial fishing operations could occur; for this series of estimates, the parameters used in calculating the release and transport of radionuclides to man were chosen to be extremely conservative.

The dose commitment estimates presented in this section have been separated into total body dose commitments and maximum organ dose commitments. The total body dose commitments represent estimates of the dose commitments to the total body that might occur for an individual exposed at each radionuclide-pathway combination. The maximum organ dose commitments represent estimates of the maximum dose commitments that might occur for a particular organ, including the total body as an organ, for an individual exposed at each radionuclide-pathway combination.

Unless otherwise noted, the total body and maximum organ dose commitment estimates presented in this section include all radionuclide-pathway combinations which resulted in a dose commitment within approximately 0.01 percent of the largest total body or maximum organ dose commitment estimate for a particular disposal scenario. Dose commitments below this level would not affect the sum of the dose commitment estimates and were not included.

A. EXPECTED DISPOSAL CONDITIONS

It is expected that the submarines would settle to the bottom of the ocean at a disposal site such that the containment afforded by the submarine hull, bulkheads, and reactor vessel would remain intact. Once the submarines were on the ocean floor, they would be subjected to corrosion processes, and the thinnest port of the reactor compartment bulkheads would not be penetrated before approximately 100 years after disp al. It has been assumed that the radionuclides which might be released by corrosion of the struct components in the reactor compartment and the radionuclides present in the corrosion products in primary coolant system would be immediately available for release as soon as corrosion first penetrates reactor compartment.

The locations at which the radionuclides could enter the exposure pathways, except the fish ingestion pathway, have been assumed to be on the shoreline parallel to the north-south ocean current at a minimum distance of 300 kilometers to the east of a hypothetical disposal site in the Pacific Ocean. The Pacific Ocean was selected for use in this analysis not because it is any more likely to be selected for a disposal location, but because it represents a location closer to shore and with slower currents, and therefore with less dilution than the Atlantic Ocean; therefore, this yields a larger estimate of the dose commitments. The location at which the radionuclides could enter the fish ingestion pathway has been assumed to be 50 kilometers off the coast at a depth of 2000 meters since this is approximately the location and maximum depth where commercial fishing operations could occur. The 2000 meter depth is used in the dose commitment calculations because even though the amount of fish that could be caught in the deep water would be expected to be much less, the radionuclide concentrations would be higher in the deeper water; therefore, this yields a larger estimate of the dose commitments.

1. Average Individual

Estimates of the total body and maximum organ dose commitments that might be received by a member of the population with average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with the disposal of 100 submarines under expected disposal conditions are presented in Tables J-2 and J-3, respectively. The dose commitment estimates for all radionuclide-pathway combinations have been presented in each of these two tables. As shown in Table J-2, the sum of the total body dose commitments would be approximately 6×10^{-12} mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-3, the largest sum of the maximum organ dose commitments for a particular organ would be approximately 2×10^{-10} mrem per year to the bone for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the total body and maximum organ dose commitment estimates would result from Nickel-63 through the fish ingestion pathway. The 6×10^{-12} mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the 2 mrem exposures estimated using the same calculational techniques for an average individual ingesting fish containing naturally-occurring Radium-226. The 6×10^{-12} mrem total body and 2×10^{-10} mrem to the bone maximum organ dose commitment estimates are less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6). The 6×10^{-12} mrem total body exposure to the most exposed average individual would yield a possible population exposure of less than 2×10^{-7} man-rem to the entire population of the three west coast states of the United States, assumed to be 30 million people. This population dose commitment would be less than the background radiation exposure received by one of the 30 million people living in the west coast states.

2. Maximum Individual

As stated in Section V.B of Appendix I, a maximum individual cannot be exposed at all of the maximum consumption rates or occupancy factors associated with all of the exposure pathways. No one individual could be expected to consume all of the items at the maximum ingestion rates, spend all of his time on the beach, or perform all of the functions required by the maximum individual for each pathway. As a result, the total body dose commitment estimates or the maximum organ dose commitment estimates for a particular organ should not be summed over all of the pathways if a realistic dose commitment estimate is desired. Therefore, in this statement, the largest dose commitment estimate for a single pathway will be used to define the dose commitment estimate for a maximum individual. This procedure has been used in this statement for all dose commitment estimates associated with a maximum individual.

Estimates of the total body and maximum organ dose commitments that might be received by a member of the population with higher than average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with the disposal of 100 submarines under expected disposal conditions are presented in Tables J-4 and J-5, respectively. As shown in Table J-4, the largest sum of the total body dose commitments for a particular pathway would be approximately 1×10^{-10} mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-5, the largest sum of the maximum organ dose commitments for a particular pathway and organ would be approximately 3×10^{-9} mrem per year to the bone for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the largest total body and maximum organ dose commitment estimates for a particular pathway would result from Nickel-63 through the seaweed ingestion pathway. The 1×10^{-10} mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the 20 mrem exposures estimated for a maximum individual ingesting fish containing naturally-occurring Radium-226. The 1×10^{-10} mrem total body and 3×10^{-9} mrem to the bone maximum organ dose commitment estimates are less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6).

B. ACCIDENT AT DISPOSAL SITE

Estimates of the total body and maximum organ dose commitments for individuals having average and maximum consumption rates and occupancy factors are presented in this section for a postulated accident which might result in one submarine coming to rest on the ocean floor at a selected disposal site with containment penetrated. This condition is assumed to be the result of a mishap during disposal operations at a designated disposal location. Therefore, the radionuclides present in the corrosion products which would normally be contained in the primary coolant system are assumed to be immediately available for release and the metal containing the radionuclides embedded in the structural components in the reactor compartment are assumed to be immediately subjected to corrosion processes in open water. Only one submarine has been considered because a full loss of containment is not a credible accident, and if containment were penetrated during a disposal operation, disposal operations would not continue until appropriate measures were taken to ensure that such an event could not occur again.

As for the case with expected disposal conditions, the locations at which the radionuclides could enter the exposure pathways, except the fish ingestion pathway, have been assumed to be on the shoreline parallel to the north-south ocean current at a minimum distance of 300 kilometers to the east of a hypothetical disposal site in the Pacific Ocean. The location at which the radionuclides could enter the fish ingestion pathway has been assumed to be 50 kilometers off the coast at a maximum depth of 2000 meters since this is approximately the location and depth of where commercial fishing operations could occur.

1. Average Individual

Estimates of the total body and maximum organ dose commitments that might be received by a member of the population with average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with a postulated condition in which one submarine has its containment penetrated during disposal operations are presented in Tables J-6 and J-7, respectively. As shown in Table J-6, the sum of the total body dose commitments would be approximately 1×10^{-9} mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-7, the largest sum of the maximum organ dose commitments for a particular organ would be approximately 1×10^{-9} mrem per year to the skin for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the total body and maximum organ dose commitment estimates would result from Cobalt-60 through the shore sediments pathway. The 1×10^{-9} mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the estimated 2 mrem exposures for an average individual ingesting fish containing naturally-occurring Radium-226. The 1×10^{-9} mrem total body and 1×10^{-9} mrem to the skin maximum organ dose commitment estimates are significantly less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5)

*Blanks in table indicate values which were less than approximately 0.01 percent of the largest maximum organ dose commitment estimate.

and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6). The 1×10^{-9} mrem total body exposure to the most exposed average individual would yield a possible population exposure of less than 3×10^{-5} man-rem to the entire population of the three west coast states of the United States, assumed to be 30 million people. This population dose commitment would be less than the background radiation exposure received by one of the 30 million people living in the west coast states.

2. Maximum Individual

Estimates of the total body and maximum organ dose commitments that might be received by a member of the population with higher than average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with a postulated condition in which one submarine has its containment penetrated during disposal operations are presented in Tables J-8 and J-9, respectively. As shown in Table J-8, the largest sum of the total body dose commitments for a particular pathway would be approximately 2×10^{-8} mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-9, the largest sum of the maximum organ dose commitments for a particular pathway and organ would be approximately 3×10^{-8} mrem per year to the skin for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the largest total body and maximum organ dose commitment estimates for a particular pathway would result from Cobalt-60 through the shore sediments pathway. The 2×10^{-8} mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the estimated 20 mrem exposures for a maximum individual ingesting fish containing naturally-occurring Radium-226. The 2×10^{-8} mrem total body and 3×10^{-8} mrem to the skin maximum organ dose commitment estimates are less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6).

C. ACCIDENT DURING TRANSIT TO DISPOSAL SITE

Estimates of the total body and maximum organ dose commitments for individuals having average and maximum consumption rates and occupancy factors are presented in this section for a postulated accident during transit which might result in a submarine sinking with its containment completely penetrated at a location where commercial fishing operations could occur. The radionuclides present in the corrosion products contained in the primary coolant system are assumed to be immediately available for release, and the radionuclides embedded in the structural components in the reactor compartment are assumed to be immediately subjected to corrosion processes in open water. Only one submarine has been considered because a full loss of containment is not a credible accident, and if an accidental sinking occurred, disposal operations would not continue until appropriate measures were taken to ensure that such an accident could not occur again. Also, based on the information presented in Reference J.7, only 3.6 accidents per million kilometers of barge traffic would be expected to occur; therefore, an accidental sinking would be highly improbable.

It was postulated that the submarine might accidentally sink at an area 25 kilometers away from the shoreline where commercial fishing operations could occur. This location was chosen because it represents a location closest to the shoreline at a sufficient depth where recovery of the submarine might not be feasible. Therefore, this location yields a maximum radionuclide concentration. As a result, the locations at which the radionuclides could enter the exposure pathways, except the fish ingestion pathway, have been assumed to be on the shoreline parallel to the north-south ocean current at a distance of 25 kilometers to the east of the postulated accident in the Pacific Ocean. The radionuclides have been assumed to be able to enter the fish ingestion pathway at the site of the postulated sinking.

1. Average Individual

Estimates of the total body and maximum organ dose commitments that might be received by a member of the population with average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with a postulated condition in which one submarine sinks during transit with its containment penetrated at a location where commercial fishing operations could occur are presented in Tables J-10 and J-11, respectively. As shown in Table J-10, the sum of the total body dose commitments would be approximately 0.05 mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-11, the largest sum of the maximum organ dose commitments for a particular organ would be approximately 0.05 mrem per year to the skin for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the total body and maximum organ dose commitment estimates would result from Cobalt-60 through the shore sediments pathway. The 0.05 mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the estimated 2 mrem exposures for an average individual ingesting fish containing naturally-occurring Radium-226. The 0.05 mrem total body and 0.05 mrem to the skin maximum organ dose commitment estimates are significantly less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6). The 0.05 mrem total body exposure to the most exposed average individual would yield a possible population dose of less than 2 man-rem to the affected population of the three west coast states of the United States, assumed to be 30 thousand people. The potentially affected population was assumed to be 30 thousand people rather than the entire population of the three west coast states because this hypothetical event was postulated to occur only 25 kilometers from the shoreline. This nearness to the shoreline would mean that only a limited area and the corresponding limited number of people might be affected.

2. Maximum Individual

Estimates of the total body and maximum organ dose commitments that might be received by a member of the population with higher than average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with a postulated condition in which one submarine sinks during transit with its containment penetrated at a location where commercial fishing operations could occur are presented in Tables J-12 and J-13, respectively. As shown in Table J-12, the largest sum of the total body dose commitments for a particular pathway would be approximately 0.9 mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-13, the largest sum of the maximum organ dose commitments for a particular pathway and organ would be approximately 1 mrem per year to the skin for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the largest total body and maximum organ dose commitment estimates for a particular pathway would result from Cobalt-60 through the shore sediments pathway. The 0.9 mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the estimated 20 mrem exposures for a maximum individual ingesting fish containing naturally-occurring Radium-226. The 0.9 mrem total body and 1 mrem to the skin, maximum organ dose commitment estimates are less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6).

D. HYPOTHETICAL MAXIMUM DOSE COMMITMENTS FOR BIOLOGICAL TRANSPORT

All of the dose commitment estimates presented previously in this appendix have been based on physical transport mechanisms which might move radionuclides from either a disposal site or accident location to pathway entry points and therefore affect the critical population group. This approach is based on the information presented in Appendix A of Reference J.8 which shows that the rate at which physical processes could transport radioactivity from the bottom waters of the deep ocean to the surface is much more important than that for biological processes. The application of the method presented in Reference J.8 indicates that the effect of physical transport in carrying radioactivity from the bottom waters to the surface is at least two orders of magnitude greater than the effects of biological transport.

*Blanks in table indicate values which were less than approximately 0.01 percent of the largest maximum organ dose commitment estimate.

No biological pathway is known which could link organisms in the deep ocean directly to man; however, it is always possible that such a pathway might be identified in the future. Therefore, dose commitment estimates have been calculated for a hypothetical biological pathway in which radionuclides are postulated to be transported directly to man from the disposal site by biological processes. These hypothetical dose commitment estimates have been calculated only to determine the upper limit of the dose commitments associated with biological transport and are not considered to be a likely result of sea disposal of defueled nuclear submarines. These dose commitment estimates have been calculated using very conservative assumptions, and any other dose commitment estimates associated with biological transport would be expected to be significantly less than the estimates provided here.

The dose commitment estimates for biological transport have been calculated using the very large consumption rates for a maximum individual. The biological process postulated for transporting the radionuclides directly to man from the disposal site has been assumed to be represented by the fish ingestion pathway. Two methods have been postulated for the radionuclides released from a defueled nuclear submarine to become available for the fish. For the first method, it has been assumed that the released radionuclides are present in the ocean water in close proximity to the disposed submarines with no deposition of the radionuclides in the sediment. For the second method, it has been assumed that the radionuclides are released to the ocean waters but then settle to the ocean floor and are deposited in the sediment in close proximity to the disposed submarines. For both of these methods, the radionuclides were assumed to remain close to the submarines so that dilution effects would be minimized and the maximum concentrations of the radionuclides would be available for the fish. Using these assumptions, total body and maximum organ dose commitment estimates have been calculated for a hypothetical fish-eating maximum individual for each of the two methods postulated for released radionuclides to become available for the fish.

1. Radionuclides in Ocean Waters

For this hypothetical biological pathway, it has been assumed that the released radionuclides are present in the ocean water in close proximity to the disposed submarines with no deposition of the radionuclides in the sediment. The maximum radionuclide concentrations which were calculated for any time after the start of disposal operations were assumed to be present in the ocean water. These maximum concentrations are presented in Table H-2 of Appendix H. Also, the fish were assumed to be living near the ocean bottom where these maximum concentrations are postulated to occur. This yields the highest possible radioactivity content in the fish which are ingested by a hypothetical maximum individual.

Table J-14 lists the total body and maximum organ dose commitment estimates for the postulated situation in which an individual eats fish, assumed to be from a proposed disposal site, at a maximum annual consumption rate. Results are tabulated for this individual for all radionuclides which might be released from one submarine under expected disposal conditions. As shown in this table, the sum of the total body dose commitment estimates for this postulated fish ingestion pathway would be approximately 0.2 mrem per year of exposure. The sum of the largest maximum organ dose commitment estimates for a particular organ would be approximately 5 mrem per year to the bone. The largest percentage of the sum of the total body and largest maximum organ dose commitment estimates for a particular organ would be associated with the Nickel-63 radionuclide.

2. Radionuclides in Ocean Sediments

For this hypothetical biological pathway, it has been assumed that the radionuclides are released from defueled nuclear submarines to the ocean waters but then settle to the ocean floor and deposit in the sediment. The radionuclides released were assumed to settle onto the sediment in the immediate vicinity of the disposed submarines within the distance that tidal action during one day might move the particles. This corresponds to an area approximately 560 meters by 140 meters. After taking into account radioactive decay processes, the maximum amount of each radionuclide deposited at any time after disposal operations began were assumed to be present in this small area of sediment. If the maximum amount of a particular radionuclide occurred before 100 years after disposal, the radionuclide was assumed to be uniformly distributed in the sediment to a depth of 1 centimeter. If the maximum amount of a particular radionuclide occurred after 100 years after disposal, the radionuclide was assumed to be uniformly distributed in the sediment to a depth of 10 centimeters.

*The biological pathway was assumed to be associated with the fish ingestion pathway.

All of the radionuclides released from the disposed submarine were assumed to behave in this manner with the exception of Carbon-14. Carbon-14 is expected to be released from the disposed submarines in a soluble form; therefore, it would not be deposited in the sediment. However, it was conservatively assumed that 10 percent of the Carbon-14 would be deposited in the sediment. Table J-15 lists the maximum radionuclide concentrations in the sediment and the year in which this maximum is expected to occur.

Along with the radionuclides deposited in the sediments, stable nuclides of some of the same elements would already be present in the sediments. It was assumed that the radionuclides and stable nuclides in the sediment would have equal availability for uptake by the fish because chemical and biological processes which cause compounds already in the sediment to become biologically available could cause submarine corrosion products to develop similar biological availability. To estimate the radionuclide content of the fish

TABLE J-15. MAXIMUM RADIONUCLIDE CONCENTRATIONS IN OCEAN SEDIMENTS

Hf-181	0.0	0.0

which were assumed to live close to the disposed submarines, it was assumed that such fish would take up both the radionuclides and stable nuclides in the sediment and replace the same elements present in their bodies with those from the sediments. The concentrations of stable elements in the sediments were based on the information presented in Reference J.9. The elemental composition of fish used in the calculations was based on the information presented in Reference J.10. More recent measurements of the trace metal concentrations in fish (Reference J.11) indicate that the values provided in Reference J.10 may be high by a factor of ten. However for conservatism, the values provided in Reference J.10 were used in the calculations. Additionally, a sediment density of 2.73 grams per cubic centimeter (Reference J.9) was used in the calculations.

Table J-16 lists the total body and maximum organ dose commitment estimates for the postulated situation in which an individual eats fish, assumed to be obtained directly from a postulated disposal site, at a maximum annual consumption rate. Results are tabulated for this individual for all radionuclides which might be released to the ocean waters and then settle to the ocean floor and deposit in the sediments. As shown in this table, the sum of the total body dose commitment estimates for this postulated fish ingestion pathway would be approximately 3 mrem per year. The sum of the largest maximum organ dose commitments for a particular organ would be approximately 17 mrem per year to the bone. The largest percentage of the sum of the total body and largest maximum organ dose commitment estimates for a particular organ would be associated with the Carbon-14 radionuclide.

These hypothetical dose commitment estimates have been calculated only to demonstrate that in the most extreme cases the dose commitments associated with biological transport would not be large. Extremely conservative assumptions were made for each of the two methods postulated for the radionuclides released from disposed submarines to become available for the fish. Any other dose commitment estimates associated with biological transport would be expected to be significantly less than these upper limit estimates. It should be noted that no individual actually catches fish which live at such great depths for a source of food and if these fish were caught, only a small number could live off the energy available in this limited area. For example, for the Tufts Abyssal Plain, which is âbout 3358 to 3655 meters deep, estimates of the mass of benthic fishes present range from 0.197 ± 0.178 grams per square meter to 0.376 ± 0.184 grams per square meter (Reference J.9). If the mass of benthic fishes was taken to be 0.56 grams per square meter, then 44 kilograms of fish would be available in the area assumed in the calculations (560 meters by 140 meters). This is less than the amount of fish assumed to be eaten by the maximum individual (65 kilograms of fish per year) which indicates the conservatism associated with these calculations. However, even under these extreme assumptions, the 0.2 mrem per year total body dose commitment estimate for the radionuclides

assumed to be in the ocean water, and the 3 mrem per year total body dose commitment estimate for the radionuclides assumed to be in the sediment are significantly less than the annual 100 mrem total body exposure from natural background radiation. Additionally, these two total body dose commitment estimates are less than the estimated 20 mrem total body exposure for a maximum individual eating fish containing naturally-occurring Radium-226. These two total body dose commitment estimates are also significantly less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5).

E. CONSERVATIVE DOSE COMMITMENT ESTIMATES

The dose commitment estimates presented in Sections III.A through III.C have been based on physical transport mechanisms which were chosen to best represent the transport of radionuclides from a postulated disposal site or accident location to pathway entry points for affecting the critical population group. In this section, dose commitment estimates are presented for various disposal scenarios in which the parameters used in calculating the release and transport of radionuclides to man were chosen to be extremely conservative. For a detailed discussion on the parameters used and their expected and conservative values, see Sections II and III of Appendix G for the release parameters and Section IV.C of Appendix H for the transport parameters.

Total body and maximum organ dose commitment estimates for an average and a maximum individual are presented in this section for expected disposal conditions in which containment is maintained for 100 submarines, a postulated accident in which one submarine has its containment completely penetrated at the disposal site, and a postulated accident in which a submarine sinks during transit to a disposal site where commercial fishing operations could occur and also has its containment completely penetrated. All conditions associated with these disposal scenarios are the same as those discussed in Sections III.A through III.C except that extremely conservative values were used for estimating the release and transport of radionuclides to man.

1. Expected Disposal Conditions—Average Individual

Conservative estimates of the total body and maximum organ dose commitments that might be received by an individual with average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with the disposal of 100 submarines under expected disposal conditions are presented in Tables J-17 and J-18, respectively. As shown in Table J-17, the sum of the total body dose commitments would be approximately 2×10^{-4} mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-18, the largest sum of the maximum organ dose commitments for a particular organ would be approximately 6×10^{-3} mrem per year to the bone for exposure to the maximum concentrations of the radionuclides.

The largest percentage of these conservative total body and maximum organ dose commitment estimates would result from Nickel-63 through the fish ingestion pathway. The 2×10^{-4} mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the estimated 2 mrem exposure for an average individual ingesting fish containing naturally-occurring Radium-226. The 2×10^{-4} mrem total body and 6×10^{-3} mrem to the bone maximum organ dose commitment estimates are less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6). The 2×10^{-4} mrem conservative total body exposure to the most exposed average individual would yield a possible population exposure of 6 man-rem to the entire population of the three west coast states of the United States, assumed to be 30 million people.

2. Expected Disposal Conditions—Maximum Individual

Conservative estimates of the total body and maximum organ dose commitments that might be received by an individual with higher than average consumption rates and occupancy factors exposed to the maximum radionuclide concentrations associated with the disposal of 100 submarines under expected disposal conditions are presented in Tables J-19 and J-20, respectively. As shown in Table J-19, the largest sum of the total body dose commitments for a particular pathway would be approximately 0.003 mrem per year for exposure to the maximum concentrations of the radionuclides. For the data in Table J-20, the sum of the largest maximum organ dose commitments for a particular pathway and organ would be approximately 0.1 mrem per year to the bone for exposure to the maximum concentrations of the radionuclides.

The largest percentage of the largest conservative total body and maximum organ dose commitment estimates for a particular pathway would result from Nickel-63 through the seaweed ingestion pathway. The 0.003 mrem total body dose commitment estimate is significantly less than the annual 100 mrem total body exposure from natural background radiation and the 20 mrem exposures estimated for a maximum individual ingesting fish containing naturally-occurring Radium-226. The 0.003 mrem total body and 0.1 mrem to the bone maximum organ dose commitment estimates are less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and the EPA drinking water requirement that prevents a total body or any organ exposure of more than 4 mrem per year (Reference J.6).

3. Site Accident and Transportation Accident—Average and Maximum Individuals

Conservative estimates of the total body and maximum organ dose commitments for an average and a maximum individual for a postulated site accident and a postulated transportation accident are presented in Table J-21. Individual nuclide-pathway combinations were not included in this table but the sum total is

TABLE J-21. CONSERVATIVE DOSE COMMITMENTS FOR SITE ACCIDENT AND TRANSPORTATION ACCIDENT—ADULT AVERAGE AND MAXIMUM INDIVIDUALS—ONE SUBMARINE

Disposal Scenario	Total Body		Maximum Organ	
	Dose Commitment (mrem)	Critical Pathway and Nuclide	Dose Commitment (mrem)	Critical Pathway and Nuclide
Postulated Site Accident, Average Adult	2.7×10^{-3}	Shore Sediments Co-60	3.3×10^{-3} (Skin)	Shore Sediments Co-60
Postulated Site Accident, Maximum Adult	5.6×10^{-2}	Shore Sediments Co-60	6.6×10^{-2} (Skin)	Shore Sediments Co-60
Postulated Transport Accident, Average Adult	1.4×10^{-1}	Shore Sediments Co-60	1.7×10^{-1} (Skin)	Shore Sediments Co-60
Postulated Transport Accident, Maximum Adult	2.7	Shore Sediments Co-60	3.3 (Skin)	Shore Sediments Co-60

presented along with the critical pathway by which the largest percentage of the dose commitment might be received. As shown in Table J-21, the sum of the total body dose commitments would be approximately 0.003 mrem per year for an average individual and 0.06 mrem per year for a maximum individual for a postulated site accident. The largest sum of the maximum organ dose commitments would be approximately 0.003 mrem per year to the skin for an average individual and 0.07 mrem per year to the skin for a maximum individual for the postulated site accident. The sum of the total body dose commitments would be approximately 0.1 mrem per year for an average individual and 3 mrem per year for a maximum individual for a postulated transportation accident. The largest sum of the maximum organ dose commitments would be approximately 0.2 mrem per year to the skin for an average individual and 3 mrem per year to the skin for a maximum individual for a postulated transportation accident.

The largest percentage of these conservative total body and maximum organ dose commitment estimates for a postulated site accident and a postulated transportation accident would result from Cobalt-60 through the shore sediments pathway. The total body dose commitments for both postulated accidents and for both an average and maximum individual are significantly less than the annual 100 mrem total body exposure from natural background radiation and the estimated 2 mrem exposures for an average individual or 20 mrem exposures for a maximum individual ingesting fish containing naturally-occurring Radium-226. The total body and maximum organ dose commitments for both postulated accidents and for both an average and a maximum individual are significantly less than the NRC requirement that prevents any individual from receiving a total body exposure of more than 500 mrem per year in an uncontrolled area (Reference J.5) and less than the EPA drinking water requirement that prevents any individual from receiving a total body or any organ exposure of more than 4 mrem per year (Reference J.6). The 0.003 mrem per year total body exposure to the most exposed average individual for a postulated site accident 300 kilometers from the shoreline would yield a possible population dose of 90 man-rem to the entire population of the three west coast states of the United States, assumed to be 30 million people. The 0.1 mrem per year total body exposure to the most exposed average individual for a postulated transportation accident 25 kilometers from the shoreline would yield a possible population dose of 3 man-rem to the affected population of the three west coast states of the United States, assumed to be 30 thousand people.

IV. SAMPLE DOSE COMMITMENT CALCULATION

An example of the calculations performed to obtain the dose commitment estimates presented in this appendix is provided in this section. The calculation for determining the total body dose commitment for an average adult individual due to ingestion of fish containing the maximum concentration of Nickel-63 is presented. The fish pathway entry point has been assumed to be 50 kilometers offshore at a depth of 2000 meters. The Nickel-63 concentration is the maximum that could occur for the disposal of 100 submarines under expected disposal conditions at a postulated disposal site 300 kilometers offshore at a depth of 4000 meters.

The equation for calculating this dose commitment estimate is presented in Section IV.A of Appendix I and is as follows:

$$D_I = KPqUX_w\Delta T$$

where

D_I is the dose commitment from ingestion of the radionuclide (in rem).

K is the dose commitment conversion factor for ingestion for each radionuclide (in rem per curie).

P is the number of people for which the dose commitment estimate is being made.

q is the rate at which individuals may ingest the particular food considered (in grams per day).

U is the concentration factor which relates the radionuclide concentration in a unit mass of the item ingested to the radionuclide concentration in a unit volume of seawater from which the food item was obtained (in curies per kilogram of food per curies per liter of seawater). This term requires conversion to units of curies per gram per curies per cubic meter when solving this equation.

X_w is the concentration of the radionuclide considered in seawater (in curies per cubic meter).

ΔT is the time period over which an individual could be ingesting the food item (in days).

The data necessary to calculate the total body dose-commitment estimate to an average adult due to a year's ingestion of fish containing Nickel-63 which could originate from 100 defueled nuclear submarines disposed of on the ocean floor at a proposed disposal location 300 kilometers offshore under expected disposal conditions are:

$K = 4.36 \times 10^3$ rem/Ci (Appendix I, Table I-4, Nickel-63, Total Body)

$P = 1$ (Average Adult)

$q = 15.47$ g/day (Appendix I, Table I-2, Fish, Average Adult)

$U = 5 \times 10^2$ Ci/kg per Ci/ℓ $= 5 \times 10^2/1 \times 10^6$ Ci/g per Ci/m^3 (Appendix I, Table I-3, Nickel-63, Fish)

$X_w = 4.2 \times 10^{-19}$ Ci/m^3 (Appendix H, Table H-4, Nickel-63, 100 Submarines, Fish Ingestion Pathway)

$\Delta T = 1$ yr $= 365$ days

Substituting the data into the equation yields:

$$D_I = \left(4.36 \times 10^3 \ \frac{\text{rem}}{\text{Ci}}\right)(1)\left(15.47 \ \frac{\text{g}}{\text{day}}\right)\left(\frac{5 \times 10^2}{1 \times 10^6} \ \frac{\text{Ci}}{\text{g}} \ \frac{\text{m}^3}{\text{Ci}}\right)\left(4.2 \times 10^{-19} \ \frac{\text{Ci}}{\text{m}^3}\right)(365 \text{ days})$$

$D_I = 5.2 \times 10^{-15}$ rem $= 5.2 \times 10^{-12}$ mrem

This value is reported in Table J-2 for Nickel-63 for the fish ingestion pathway.

APPENDIX K

MONITORING PROGRAM

Contents

APPENDIX K

MONITORING PROGRAM

I. INTRODUCTION

For either land disposal or sea disposal, a monitoring program would be needed to determine the radiological condition of the disposal site environment. Such a monitoring program would sample the pathways to man for the presence of radioactive material from the disposals. The results of these analyses and their evaluations would be published periodically for public information and review.

II. SUMMARY

Land disposal would use the existing monitoring programs that are already in operation at Hanford and at Savannah River. These programs are described in the respective final environmental impact statements for waste management operations at Hanford and at Savannah River, References K.1 and K.2. The National Research Council reported that no measurable harm has resulted from these operations, Reference K.3.

Environmental monitoring reports for these sites are published annually. For sea disposal, a new monitoring program would be required for each site. Such a monitoring program could be performed using existing, proven technology.

III. LAND DISPOSAL MONITORING

In the event of land disposal, the primary pathways to man are expected to be by way of groundwater and surface water. Existing monitoring programs at Hanford and at Savannah River have demonstrated that disposals of activated structural materials have not produced significant releases. Details are available in References K.1, K.2, and K.3. Measured releases are very low in concentration and travel through the surrounding environment very slowly. The result is that direct measurements along the pathways to man have not provided significant measures of the doses to man. Only at locations close to the sources are the measurements adequate to estimate the amount of related nuclides present. Estimates of the doses to man are obtained from these local measurements in conjunction with calculations based on conservative assessments of the pathways to man.

This situation is also expected to be the case for the contemplated disposals. Measurements farther along the pathways to man would probably not be sufficiently distinguishable from the background values to provide a direct measure of the effects of disposal, and the doses to man would have to be estimated from local measurements and conservative calculations. Even so, samples would be taken at other locations to verify that disposal nuclides actually were so low or to detect them if they were unexpectedly high.

At Hanford, for example, routine samples are currently taken of river water, sanitary water, waste water, and groundwater. Air is sampled for particles by measuring the radioactivity in filters and charcoal cartridges. In addition, direct radiation is measured at the waste site and along the river shore. Road surfaces are surveyed by vehicle-mounted detectors, aerial surveys are conducted, and food and other related items are sampled and measured. Many of the measurements at Hanford are associated with monitoring nuclides other than those related to the disposal of activated structural materials, such as Iodine-131 and tritium, but among the routine measurements there are typically 44 air samplers (all analyzed for gross beta activity and 15 are analyzed for total alpha activity), direct radiation at 64 fixed locations (Thermoluminescent dosimetry-TLD), portable-instrument measurements along the river shore, and various immersion measurements (TLD).

Soil and vegetation are currently sampled at 36 locations at Hanford to analyze for selected nuclear-fuel-related nuclides. River sediments at two locations are measured in layers by gamma scans. Surface waters are sampled for radiochemical analysis of water from several locations including the river, waste ponds, and ditches. Drinking water samples from Richland and two on-site locations are checked for total alpha, total beta, and gamma activities. Groundwater is sampled from numerous wells and analyzed for tritium and gross beta activities.

Deer and ducks are periodically sampled from Hanford site locations and whitefish are sampled from the river. Organs from these animals are measured for specific nuclides. Food-stuffs produced by local farms and commercial sources are also sampled and measured, including green goods, eggs, chicken, and beef. Milk is sampled from two groceries and four farms. Typical forage for farm animals is sampled and analyzed for nuclides of interest.

The scope of routine monitoring by Hanford is supplemented by programs conducted by the adjacent states of Oregon and Washington which include investigations of river shellfish, milk, groundwater, and direct radiation measurements in Richland.

Monitoring programs at Savannah River are of similar scope and are designed to measure any contribution from Savannah River Plant operations to off-site exposure by direct radiation, inhalation, ingestion, and deposition. Savannah River operates 12 atmospheric monitoring stations near the site perimeter, 12 more at distances of approximately 25 miles from the site, and four more at distant locations (approximately 60-120 miles away). The Savannah River is monitored above and below the site. Drinking water is sampled at 14 public locations. Vegetation such as grass is sampled at seven perimeter locations, at seven locations at approximately 25 miles distant, and at four locations at approximately 100 miles distant.

Milk is sampled within a 25-mile zone, and farm produce is sampled at 14 localities around the site to obtain 60 samples of four food categories. Deer and wild hogs taken on-site are sampled during hunting season. Fish are sampled from upstream, downstream, and site locations.

All potential effluent paths from the Savannah River Plant are monitored, including stacks, pipes, and basins. The specified frequency depends upon an assessment of the magnitude and the potential for human dose, and the samples range from continuous to periodic samples. At the burial grounds, as well as at other locations, surveillance wells provide data to assess leaching conditions and to monitor horizontal movement of groundwater in the saturated zone. Burial trenches are monitored by samples from trench wells that are screened at the trench-bottom level.

From these samples, Savannah River personnel monitor total activities and the activities of significant nuclides in the local and remote environment and in the potential effluent paths. These data enable dose calculations to be made for the contribution of plant operations to the doses to the surrounding communities. The contributions from the burial operations are a part of the totals.

The cost of monitoring these land disposal sites is provided for in current funding of the U.S. Department of Energy for operating these sites; no additional cost is anticipated.

IV. SEA DISPOSAL MONITORING

A monitoring program for sea disposal would consist of three phases: pre-disposal monitoring, monitoring during the period of submarine disposals, and monitoring after the active disposal period. These phases are discussed below. Additional discussion and background information on the inauguration of new sites for disposal of low-level radioactive waste are provided in Reference K.4.

A. PRE-DISPOSAL MONITORING

As part of site selection, pre-disposal investigations would be performed to provide background baseline data on the undisturbed condition of the site for comparison with results obtained during and after the period of active disposal.

The monitoring program, which would be initiated before the first disposal, would include such typical actions as:

a. Sea floor photography to provide a visual record of the sea floor conditions including animal activity.

b. Bottom water currents (speed and direction); electrical conductivity, temperature, and water density (CTD data); and dissolved oxygen concentration.

c. Sampling and analysis of bottom water for gamma-emitting radionuclides and x-ray and beta-emitting nickel nuclides (Nickel-59 and Nickel-63) dissolved in the water and present in the suspended particles.

d. Sampling and analysis of sea floor sediments for gamma-emitting radionuclides and for Nickel-59 and Nickel-63 adsorbed on the sediment particles and present in the interstitial water surrounding the sediment particles.

e. Collection and analysis of fish and benthic invertebrates for gamma-emitting radionuclides and for Nickel-59 and Nickel-63. The fish and invertebrates would be collected from the sediment surface and the overlying water by trapping.

The samples could be collected by either a manned submersible with mechanical arms or by unmanned apparatus deployed from a surface ship. Both of these techniques have been applied successfully in oceanographic research activities. All the major components of the monitoring program listed above have been successfully utilized by the Navy and the oceanographic scientific community for a number of years and no significant difficulty is anticipated in implementing such a monitoring program at a disposal site.

These measurements would provide reference data for the environmental characteristics of a site before disposal started, and could be acquired during several oceanographic research cruises. The cost of such a cruise is approximately $1.0 million (1978), as reported in Reference K.4. The cost would include a literature search to select an appropriate cruise area and the preparation of a cruise prospectus to define the work to be done. Total costs for the effort required to qualify a sea disposal site are estimated to be approximately $6 million during the required period of two to three years.

B. MONITORING DURING ACTIVE DISPOSAL

After the commencement of submarine disposals, the second phase of the monitoring program would begin. The sunken ships would be inspected photographically. Samples would be taken of the sediment, water, and biota in the vicinity of these ships to investigate whether radionuclides had been released and to observe how the disposals may have changed the local environment. In addition, similar samples and measurements would be made downstream from the sunken ships.

Based upon the analysis and experiments discussed earlier in this statement, the submarines would be expected to land on the ocean bottom with the containment provided by the reactor compartment and primary system remaining intact. Significant concentrations of radionuclides in the environment near the submarines would not be expected. If the initial monitoring surveys performed after commencement of disposal operations confirmed this expectation, the submarine disposals could proceed and the frequency of the monitoring surveys could be reduced.

The cost for a survey to monitor the environment in the vicinity of a disposal site would be approximately $0.8 million.

C. MONITORING AFTER THE PERIOD OF ACTIVE DISPOSAL

Monitoring surveys after the period of active disposal would be similar in scope and cost to those performed during the disposal period. The frequency of these surveys would be determined by the results of earlier surveys. If the analysis presented in this statement were to be corroborated by surveys performed during the period of active disposal, post-disposal surveys would be needed very infrequently.

It is estimated that the ongoing monitoring program for a sea disposal site (during and after the period of active disposal) would have a present-value cost of nearly $9 million. In combination with the effort required to qualify a sea disposal site, the present value of the total monitoring effort would be nearly $15 million, equivalent to approximately $0.1 million per ship for each sea disposal site.

D. DEMONSTRATED CAPABILITIES

As a part of the Navy's on-going program for monitoring the radiological condition of the environment where the nuclear-powered submarine THRESHER lies, comprehensive environmental measurements and sampling in the deep ocean were performed by the Navy during August 1983. This environmental monitoring provided results that are summarized in the Annex to Appendix D (Section IV.E) and also provided a demonstration of capabilities that are currently available for monitoring a deep-ocean site. The location where THRESHER sank in the Northwestern Atlantic Ocean has characteristics that are similar to those which might be anticipated if decommissioned submarines were to be disposed of in the ocean.

The monitoring program conducted at the THRESHER site included the following elements:

- high resolution photography of the submarine debris and adjacent sediment
- measurement of currents and temperature in the bottom water adjacent to the submarine debris
- collection of bottom water and sediment samples for radionuclide analysis
- collection of bottom-dwelling fish and marine life for radionuclide analysis
- operation of an acoustic transponder navigation network to ensure proper placement of oceanographic sampling and monitoring devices.

Some of the operations were conducted by deploying unmanned apparatus from a surface ship and some were conducted by a manned submersible.

Submersible operations were conducted by the Deep Submergence Research Vehicle (DSRV) ALVIN and its support ship R/V LULU. Surface ship operations were conducted by the Oceanographic Research Vessel (ORV) CAPE FLORIDA.

An acoustic transponder navigation network was established by deploying three acoustic transponders surrounding the THRESHER debris site. Each transponder was moored 200 meters off the bottom to minimize bottom interference. The actual locations of the acoustic transponders were determined by satellite navigation and LORAN C. The positions of the ships in relation to the acoustic transponders were tracked by computer, using frequent interrogation of the transponders. This provided precise positioning to navigate ALVIN and surface-deployed monitoring devices to within close proximity to the THRESHER.

Samplers on the end of a long cable attached to CAPE FLORIDA were navigated to within 3 to 40 meters of the desired location. A baited fish trap and a sampling pump were positioned and released at the bottom by CAPE FLORIDA for subsequent recovery as free vehicles after spending the required time on the bottom to complete the sampling objectives. The fish trap provided an excellent sampling of the benthic fish in the immediate vicinity of THRESHER by obtaining 56 fish in a four-day period. The surface-ship-deployed water pumping system included cartridges for collection of radioactivity. It obtained a large sample of seawater constituents by pumping 503 liters through the system. The pump was released from the bottom remotely and was recovered by CAPE FLORIDA. Tetrahedral marine-life traps, launched and recovered as free vehicles, were able to obtain samples of fish and amphipods as close as 50 meters to the target area. Box corers, modified for the collection of undisturbed surface sediment and interfacial seawater, proved to be an excellent means of collecting samples of surface sediment (upper 1/2 meter), interfacial seawater, and epifauna. This sampler was transponder navigated to the desired location and then retrieved by the trawl winch after its sample was obtained and the location recorded.

The submersible-deployed oceanographic sampling and monitoring devices were utilized in the immediate vicinity of the THRESHER. These operations included the collection of sediment core tubes, water samples, marine life samples, in situ gamma ray measurements, and photography at the desired locations. Water samples were collected by the use of Niskin bottles and by a modified version of the pumping system deployed by CAPE FLORIDA. The pumping system mounted on ALVIN pumped separate seawater samples of 440 liters, 392 liters, and 587 liters through its series of cartridges. The marine life samples were obtained using funnel traps and by special suction-type sampling systems for removing sessile organisms from hull surfaces. In addition, samples of marine organisms including polychaete worms were removed from a rock sample obtained at the THRESHER site.

The radiological environmental monitoring conducted from CAPE FLORIDA and ALVIN yielded very useful information on the suitability of various types of equipment for this type of operation. In general, surface-deployed devices, such as the box corer, which are heavier and more streamlined, are easier to deploy at a given target than those devices, such as the fish trap, which are more apt to drift on their way to the bottom. With careful maneuvering of the surface ship, it was possible to place monitoring devices close to the THRESHER debris. During this expedition, the positions of the reference transponders varied by as much as 40 meters due to the effect of the tidal bottom currents on the transponders moored 200 meters off the bottom. In spite of these conditions, it was still possible to navigate the transponder-guided samplers to within 3 to 40 meters of the target. Actual locations of the surface-deployed samplers as observed from ALVIN were at 10 to 20 meters from THRESHER. This is extremely close when compared to the size of the THRESHER. The differences between observed positions and computer-calculated positions are considered to be slight and were attributed to the current-induced drift of the reference transponders.

This demonstration of surface-ship- and submersible-operated radiological environmental monitoring involved two semi-independent means of accomplishing the required objectives. The application of this type of monitoring operation to disposal of decommissioned nuclear submarines could be accomplished by periodically using a surface ship with periodic verification by a submersible.

The estimated cost of conducting this type of environmental monitoring using surface-deployed equipment is $0.2 million, including approximately 10 days of ship time and approximately $0.1 million for equipment, services, and personnel. Similarly, the estimated cost of this kind of monitoring using a manned submersible is $0.3 million, including roughly 10 days of ship time and $0.1 million for equipment, services, and personnel. These costs are included in Section IV.C.

The radiological environmental monitoring conducted with CAPE FLORIDA and ALVIN at the site of the THRESHER sinking demonstrated the capability to conduct deep-ocean monitoring operations with existing means. CAPE FLORIDA was able to place surface-deployed samplers and monitoring devices in the immediate vicinity of THRESHER debris by the use of an acoustic transponder navigation network. The relative positions of these instruments were determined by computer and confirmed by ALVIN to be satisfactory.

This expedition demonstrated that a comprehensive radiological environmental monitoring program could be carried out using existing oceanographic technology at reasonable cost.

FLOODPLAIN/WETLANDS ASSESSMENT

Contents

List of Figures

APPENDIX L

FLOODPLAIN/WETLANDS ASSESSMENT

I. SUMMARY

This floodplain/wetlands assessment addresses the construction and operation of a barge slip on the Savannah River Plant, South Carolina. The potential site at Ellenton Landing (River Mile 156.8) plus other alternative sites on the Savannah River were examined and evaluated. Because the barge slip, by design, must be adjacent to the Savannah River, location of the structure outside the base floodplain would not be possible.

The construction and operation of a barge slip on the Savannah River at the Savannah River Plant would avoid to the maximum extent possible adverse impacts associated with the use and modification of the floodplain for the following reasons:

- There would be no modification of water levels or flow regimes, thus the natural and beneficial values of the floodplain would be maintained.
- If flooded, the barge slip would not create additional consequences to any potential emergency conditions.
- Access to the Savannah River Plant is strictly controlled; no inhabitants, dwellings, hospitals, schools, nursing homes, or other structures are located within the floodplain, thus no individuals or property would be affected.
- No essential and irreplaceable records, utilities, and/or emergency services would be affected or lost in the event of flooding.
- There would be no impact to cultural, agricultural, aquacultural, or forest resources.

The environmental impacts to wetlands resulting from the construction and operation of a barge slip on the Savannah River at the Savannah River Plant would be negligible for the following reasons:

- There would be no modification of the existing hydrological regime, thus wetlands vegetation would be unaffected.
- Although construction of the slip would eliminate a small amount of wetland vegetation, the area that would be eliminated is less than two acres in size and is of minimal value as wildlife habitat.
- If the dredge spoil were to be discarded in nearby upland areas, wetlands in the immediate vicinity or elsewhere would not be adversely affected.
- The potential site of the barge slip does not contain nor provide critical habitat for endangered or threatened species.

The Ellenton Landing Site is superior to the alternative sites along the river at the Savannah River Plant because (1) it contains an existing wharf, and the immediate area has been developed previously, (2) it would not require the construction of new access roads, (3) modification of the existing boat slip would minimize construction costs, (4) its location at the "bend" of the river would facilitate navigability and maneuvering of the transport barges, (5) there would be a very minimal loss (less than two acres) of wetland vegetation, and (6) there would be no impact to endangered or threatened species or their habitat. The alternative sites were less preferred because (1) new access roads would be required, (2) construction of the barge slip would require significantly greater removal of bottomland hardwood and/or swamp forests, (3) the amount of excavated material and dredge spoil would be greater, and (4) the potential of impacting endangered or threatened species would be higher.

It is concluded, therefore, that if land disposal at the Savannah River Plant is proposed, then construction and operation of a barge slip at Ellenton Landing would be the most practicable option available. Furthermore, its implementation would have no irreversible, adverse impacts to the floodplain or its wetlands.

II. INTRODUCTION

The Savannah River Plant (SRP) is being considered as an alternate disposal site for nuclear reactor plants from decommissioned submarines. If this option is chosen, the construction and operation of a barge slip along the Savannah River would be required as part of the transport process as discussed in Appendix B. Because the barge slip would be located on the floodplain and affect wetlands, a Floodplain/Wetlands Assessment is required in accordance with Executive Orders 11988 (Floodplain Management) and 11990 (Protection of Wetlands), and also by the U.S. Department of Energy regulation "Compliance with Floodplain/Wetlands Environmental Review Requirements" (10CFR1022).

Principal components of this assessment include a characterization of the affected environment, an environmental analysis of the potential action, and a discussion of alternative barge sites. No such assessment is required for the Hanford Site because an existing barge slip would be used if land disposal were selected.

III. AFFECTED ENVIRONMENT

A. THE SAVANNAH RIVER PLANT SITE

The Savannah River Plant was selected in 1950 by the United States Government as a nuclear products facility (Reference L.1). It occupies a 777-square kilometer (300-square mile) site along the Savannah River on the Upper Coastal Plain of South Carolina (Figure L-1). The SRP facilities include five nuclear production reactors (three currently operating), two chemical separations areas, a fuel and target fabrication facility, a heavy-water production facility (on standby), and various supporting facilities. These facilities are used in the production of defense nuclear materials, and occupy less than 5 percent of the total SRP area. Reservoirs and ponds occupy approximately 3000 acres. The remainder of the Savannah River Plant is comprised of pine plantations, wetlands, and other natural vegetation which are managed by the U.S. Forest Service under a cooperative agreement with the U.S. Department of Energy.

The elevation of the Savannah River Plant ranges from 27 to 122 meters (90-400 feet) above mean sea level (Reference L.2). The climate in the SRP area is temperate with mild winters and long summers. The average rainfall at the Savannah River Plant from 1952 through 1978 was approximately 120 centimeters (47 inches). Precipitation is the greatest in March, and the least in November (Reference L.1).

The potential barge slip at the Savannah River Plant location would be at Ellenton Landing near River Mile 157 on the Savannah River (Figures L-1 and L-2). The site currently contains an abandoned wharf, a small boat basin, and a small boat ramp (Figure L-3). The small boat basin lies adjacent to the wharf on the upriver side. The boat ramp, which is located approximately 15 meters (50 feet) upriver from the small boat basin, has a 6.4-meter (21-foot) wide asphalt surface with a 7-percent grade. Approximately 400 meters (1320 feet) upriver are the intake canal and pumphouse which provide the Savannah River Plant with a portion of its cooling water for reactor operations. The wharf, small boat basin, and boat ramp may be reached from River Road by a gravel access road.

A conceptual design for the barge slip at the Savannah River Plant is presented in Figure L-4. This design would require enlarging the existing boat slip and modifying the adjacent landing area to accommodate a grounding pad and sheet pile slip. A maximum of approximately 5950 cubic meters (7780 cubic yards) of soil and associated substrate would have to be excavated to accommodate the barge slip. The size and design of the barge slip shown in Figure L-4 would be similar regardless of the location selected for the unloading process.

B. HYDROLOGY

The Savannah River basin is one of the major watersheds in the southeastern United States (Reference L.2). The flow of the Savannah River is almost completely controlled by multipurpose storage reservoirs (Reference L.3). Clarks Hill Reservoir, which was completed in March 1953, is located 65 miles upriver from the Savannah River Plant and has a storage capacity of about 3.1×10^9 cubic meters (1.1×10^{11} cubic feet). Hartwell Reservoir, which was completed in June 1961, is located 132 miles upriver from the Savannah River Plant and also has a storage capacity of about 3.1×10^9 cubic meters (1.1×10^{11} cubic feet). These large impoundments provide power, flood control, and recreation to the Central Savannah River Area. These reservoirs and the New Savannah Bluff Lock and Dam, which is located 12 miles south of Augusta, Georgia, have stabilized the river flow near the Savannah River Plant to a yearly average of about 295 cubic meters (10,420 cubic feet) per second.

Russell Reservoir, which began filling in December 1983, will furnish about 1.2×10^9 cubic meters (4.2×10^{10} cubic feet) of storage to further stabilize Savannah River flows. Since 1963, it has been the intent of the U.S. Army Corps of Engineers to maintain a minimum flow of 178 cubic meters (6300 cubic feet) per second 80 percent of the time below the Savannah Bluff Lock and Dam at Butler Creek. During extremely dry periods, releases from Clarks Hill Reservoir may be reduced to the extent necessary to maintain a flow of only 164 cubic meters (5800 cubic feet) per second below the New Savannah Bluff Lock and Dam (Reference L.4). The 7-day, 10-year low flow at the Ellenton Landing Site is calculated to be 159 cubic meters per second (5600 cubic feet per second).

Figure L-5 shows the maximum, minimum, and mean monthly flow rates for the Savannah River measured near Augusta from 1964 to 1981. Mean flow rates were generally higher in the winter and spring, and the lowest in the summer and fall.

As noted above, Clarks Hill Reservoir provides flood protection for floodplains below the dam. The maximum discharge that can occur through the outlet works without appreciable downstream flooding is approximately 850 cubic meters (30,000 cubic feet) per second. The flood control storage of the lake (390,000-acre-feet) can be expected to be utilized once every 5 years (Reference L.4). The maximum recorded flood (1929) at Augusta had a discharge of 9911 cubic meters (350,000 cubic feet) per second. Since completion of Clarks Hill Dam in 1953 the maximum flow at Augusta was about 2393 cubic meters (84,500 cubic feet) per second, with a corresponding river stage at the Savannah River Plant (Ellenton Landing) of 31 meters (101.8 feet) from April 12-15, 1964.

In the vicinity of the Savannah River Plant, the Savannah River overflows its banks (or its 3-meter high levee bordering the swamp) when river elevations rise higher than 28 meters (91 feet) mean sea level. This river stage initiates flooding of the SRP Boat Dock (Ellenton Landing), and corresponds to a flow of 439 cubic meters (15,490 cubic feet) per second. Records taken at the SRP Boat Dock indicate that the SRP wetlands bordering the Savannah River have been flooded approximately 23 percent of the time (Reference L.2). Although floods may occur in any season, they are most likely to occur during February through March, and in connection with tropical storms and hurricanes during August through October (Reference L.4). Other facts concerning the flooding of the Savannah River during the 12-year period 1958 through 1969 are presented below (Reference L.1):

- Average number of flooding events (river stage $\geq$ 28 meters or 91 feet) is 6.4 per year.
- Number of consecutive days per flooding event

—Maximum	82 days per event (Feb 5-Apr 26, 1964)
—Mean	11 days per event
—Standard Deviation	14 days per event
—Minimum	1 day per event

The base flood or flood-prone area prior to the construction of Clarks Hill and Hartwell Reservoirs is shown in Figure L-2. Because of the flood controls currently associated with these reservoirs, the base flood area should be smaller than shown. The proposed and alternate barge slip sites at the Savannah River Plant, however, remain within the base flood area (Figure L-2).

C. ECOLOGY

The Savannah River Plant is located near the line that divides the oak-hickory-pine forest and the southern mixed forest. Consequently, it contains species representative of each forest association. In addition, the vegetation of the Savannah River Plant has been influenced strongly by farming, fire, topography, and the physical and chemical nature of the soil and water. Except for the production areas and their support facilities, many previously disturbed areas have been reclaimed by natural plant succession or planted with pine by the U.S. Forest Service. Currently, the Savannah River Plant contains a mosaic of structurally complex habitats ranging from dry upland hardwoods and conifers to Carolina bays and other wetlands. In turn, these habitats support an abundant and diverse vertebrate fauna.

The Savannah River Plant contains approximately 31,400 acres of diverse wetland types that include Carolina bays, emergent wetlands, aquatic beds, and forested wetlands. One of the largest wetlands on the Savannah River Plant is the forested wetland that borders the Savannah River (Figure L-1). Classified as part of the palustrine wetlands system of the U.S. Fish and Wildlife Service (Reference L.5), this mature swamp forest is approximately 16 kilometers long and 2.5 kilometers wide, and covers 7460 acres. The swamp was lumbered in the late 1800s and the present forest consists of a second growth of bald cypress, tupelo gum, and numerous hardwood species (Reference L.6). The undisturbed areas are also dominated by bald cypress and tupelo gum in the low areas, and along the stream channels by red maple, water ash, water elm, and other bottomland hardwoods in the higher areas (Reference L.7).

The swamp is bordered on the river side by a natural levee which is breached by three major stream outlets (Reference L.2). The swamp experiences seasonal water level fluctuations which are 3 to 4 meters higher in the winter. This seasonal flooding and ebbing cycle provides a renewal input of nutrients that increases the productivity of the swamp, and is critical to its existence (Reference L.7).

Floodplain/Wetlands Vegetation

Reference L.8 examined 58 forest stands along Upper Three Runs Creek and the swamp forest bordering the Savannah River. Two stands that were sampled in the immediate vicinity of the existing boat dock were categorized as *Quercus laurifolia - Ilex decidua* and *Nyssa aquatica - Fraxinus pennsylvanica*. Both stands had similar flooding levels ranging from 1.0 to 1.7 meters.

The forest along the Savannah River between the intake canals appears to be an admixture of both bottomland hardwood and swamp forests. Large mature trees such as water hickory, bald cypress, tupelo gum, sycamore, and red maple are common. In some areas, dense crowns of willow overhang the bank.

The wetland vegetation in the vicinity of the existing boat dock is shown in Figure L-3. The existing boat slip currently supports a predominantly woody community of young saplings dominated primarily by sycamore and water hickory. Adjacent to the water is a small area of duck potato and grasses. This area is less than two acres in size, and does not provide quality wildlife habitat.

Fauna

The Savannah River Plant contains an abundant and diverse wildlife fauna. Because of its temperate climate and interspersion of aquatic habitat, over 90 species of herpetofauna have zoogeographic ranges that include the Savannah River Plant. Reference L.9 provides an overview of the herpetofauna on the Savannah River Plant, including estimates of relative abundance.

The swamp forest along the Savannah River also provides habitat for numerous species of birds including passerines, waterfowl, and herons. Reference L.10 documented a total of 1062 birds representing 59 species during summer surveys in the vicinity of Steel Creek. Additionally, the swamp forest provides excellent habitat for wintering waterfowl (Reference L.11). Forty-one species of mammals have geographic ranges that include the Savannah River Plant (Reference L.19), 25 of which have been documented in the swamp forest.

Common species in the bottomland and swamp forests include small mammals (mice and shrews), gray squirrel, fox squirrel, flying squirrel, opossum, and raccoon. Large mammals inhabiting the swamp include the feral pig and white-tailed deer.

Shallow areas and quiet backwaters and marshes of the Savannah River near the SRP site support diverse aquatic invertebrate assemblages; however, the bottom substrate of most open portions of the river consists of shifting sand that does not provide the best habitat for bottom-dwelling organisms. A sharp decrease in the total number of invertebrate species that occurred in the river during the 1950s has been attributed primarily to the effects of dredging (Reference L.12). The stabilization of the river discharge and the elimination of habitat caused by the reduction in the flooding of backwater areas might also have contributed to the decline. Some recovery occurred during the early 1960s, but complete recovery has not taken place. The groups most affected are those sensitive to the effects of siltation and substrate instability. Results of insect faunal studies conducted during 1972 (Reference L.13) indicated substantial organic loading to the river upstream from the Savannah River Plant.

Like other typical southeastern coastal plain rivers, the Savannah River and its associated swamp and tributaries have a diverse fish fauna. Reference L.14 listed 102 freshwater species from the Savannah River drainage. Seventy-six of these species plus 15 additional species have been reported from water bodies on and near the Savannah River Plant (References L.10 and L.15).

Endangered and Threatened Species

The Endangered Species Act of 1973 (P.L. 93-205) affords protection to some 300 species of native American plants and animals. In addition to the federal list, the State of South Carolina also recognizes and affords protection to fauna in accordance with the South Carolina Nongame and Endangered Species Conservation Act of 1974. The State of South Carolina, however, does not afford protection to flora other than federally-protected species.

The following section addresses those species that (1) are protected by state and federal law, (2) have been documented to occur on the Savannah River Plant, and (3) could be affected by the construction and operation of a barge slip at the proposed Ellenton Landing Site on the Savannah River. Reference L.16 contains listings of unprotected taxa such as those of "special concern" or "peripheral."

Listed as "endangered" by Reference L.17 and "threatened" by the State, the American alligator (*Alligator mississippiensis*) is locally common on the Savannah River Plant and breeds in Par Pond and the Savannah River swamp system (Reference L.9). The population ecology of this species has been intensively examined on the Savannah River Plant. This species does not inhabit the Ellenton Landing area that would be affected by the construction of a barge slip.

The wood stork (*Mycteria americana*) is designated by South Carolina as "endangered," and has been designated as an endangered species by the U.S. Fish and Wildlife Service (49FR7332). As many as 478 observations of the wood stork were recorded in the Savannah River swamp in 1983. This species does not inhabit the Ellenton Landing area that would be affected by the construction of a barge slip.

Red-cockaded woodpeckers (*Picoides borealis*) occur in upland pine forests at the Savannah River Plant. Habitat suitable for colonies of the red-cockaded woodpecker are not located in areas impacted by the construction associated with the potential barge slip at the Savannah River Plant or the disposal of spoils material on the Savannah River Plant Site (Reference L.10). It is concluded that important wildlife habitats would not be affected by the construction and operation of a barge slip at the Ellenton Landing Site.

The short nose sturgeon is listed as endangered by the National Marine Fisheries Service. Since 1982, nine short nose sturgeon larvae have been collected from the Savannah River; of these, seven larvae were collected in the vicinity of the Savannah River Plant. Depending upon the season in which construction of the barge slip might take place and upon the extent and duration of any dredging activity associated with construction of the barge slip and deepening of the river channel, larval sturgeon could be affected. Consequently, consultation with the National Marine Fisheries Service would be initiated and completed prior to any decision to construct a barge slip at the Ellenton Landing Site.

IV. ENVIRONMENTAL ANALYSIS

The possible construction and operation of a barge slip on the Savannah River near River Mile 157 could have direct, indirect, long-term, and short-term impacts to the floodplain and wetlands.

A. DIRECT AND INDIRECT IMPACTS

Direct impacts would be those resulting solely from the construction of the barge slip, and would typically be associated with the following activities:

- on-site activities prior to construction
- non-radiological materials storage
- clearing of the site
- earth excavation and fill
- foundation preparation and construction of barge slip
- disposal of excavated materials
- dredging and placement of dredge spoil.

Because the site on the Savannah River at the Savannah River Plant (Figure L-3) has been previously developed and is near access roads and materials storage areas, the principal direct impacts would be those associated with the excavation of the slip, dredging, and the placement of the dredge spoils.

Excavation of the slip and dredging of the river bottom in order to maintain depth continuity would necessitate the disposal of approximately 5950 cubic meters (7780 cubic yards) of material. Except for the dredge spoil, this material would have no impact on the floodplain or wetlands if it were placed in an upland area, and if no runoff from this mass were permitted to reach the river. Dredge spoil would be discharged into the water if hydraulic dredges were employed, or into land disposal areas if bucket dredges were used. Neither action would cause any irreversible, adverse impact to the floodplain or wetlands, but would temporarily increase turbidity and sedimentation in the river.

Indirect effects of the barge slip would include those associated with its operation. Accidents and the possible release of radioactivity are discussed in Chapter 4. Other indirect effects could result from (1) maintaining the continued navigability of the Savannah River by dredging, (2) periodic cleaning of the barge slip to remove sediments, and (3) discharge or spillage of ballast, oil, or other materials from the transport barges. The U.S. Army Corps of Engineers has historically dredged the Savannah River in order to maintain shipping as far inland as Augusta, Georgia. Sediment build-up in the barge slip should not exceed 1 to 2 feet, and could be removed with a portable dredge. This would cause only minor sedimentation. Spillage of oil or other materials from the transport barges is considered infrequent, and its occurrence would be of minimal magnitude. Direct and indirect effects on the floodplain or wetlands are therefore not considered to be irreversibly detrimental to the environment.

B. SHORT-TERM AND LONG-TERM IMPACTS

Short-term impacts are temporary changes occurring during and immediately following the construction of a barge slip on the Savannah River at the Savannah River Plant, and persist for only a short period of time. Short-term impacts include the temporary disturbance of the site area, and sedimentation resulting from dredging and slip excavation; these would be insignificant.

Long-term impacts typically result from the cumulative effects of certain actions, such as the continued dredging of the river and sustained barge traffic and docking. The impact of dredging, which has been assessed by the U.S. Army Corps of Engineers, has been sedimentation at localized "high spots" along the river, but these were temporary and not detrimental to fish or benthic organisms. The frequency of barge traffic and docking is not considered to be great enough to pose harm to the environment.

C. IMPACTS TO INDIVIDUALS AND PROPERTY

Because there are no dwellings or inhabitants continuously living in proximity to the barge slip, there would be no impacts to individuals or property. Flooding of the barge slip might temporarily halt barge dockings, but would not constitute an extreme hazard to the structure itself.

D. IMPACTS TO NATURAL AND BENEFICIAL FLOODPLAIN VALUES

The construction and operation of the barge slip at the Ellenton Landing Site would result in a modification of less than two acres. Because this type of construction would not affect (1) the water quality maintenance and groundwater, (2) important wildlife habitat (endangered or threatened species), (3) cultural resource values (open space, archeological sites, scientific study areas, or recreational areas), and (4) cultivated resource values (agriculture, aquaculture, and forestry), the natural and beneficial value of the floodplain and wetlands would not be significantly altered.

V. ALTERNATIVES

Because the barge slip, by design, must be contiguous with a navigable waterway, there is no practicable alternative at Savannah River Plant to locating this structure anywhere other than within the base floodplain. Furthermore, the construction and operation of the barge slip at Savannah River Plant, if flooded, would not:

- create additional consequences to any potential emergency conditions;
- affect the occupants of buildings such as hospitals, schools, or nursing homes;
- affect essential and irreplaceable records, utilities, or emergency services.

Therefore, alternative sites at Savannah River Plant for a barge slip outside the base floodplain were not examined. Based on examination of alternative sites within the base floodplain, the most feasible location for a barge slip would be between River Mile 157 and 155 on the Savannah River. Because the environmental impact of constructing a barge slip at the Ellenton Landing Site appears to be less than the impact for any other practical site, it was concluded that the Ellenton Landing Site was the most practicable option for a Savannah River Plant location. The rationale for this conclusion follows.

In order to evaluate alternative sites for a barge slip at the Savannah River Plant, discriminant criteria were selected that would identify the most feasible and practicable options. These included the following:

- the site must be located on the Savannah River Plant and be contiguous with the Savannah River;
- construction and operation of the barge slip must be feasible from an environmental and engineering standpoint;
- the site must be located as near as possible to an existing access road;
- construction and operation of the barge slip at the Savannah River Plant must avoid to the extent possible any adverse impacts to wetlands and floodplains.

The Savannah River Plant adjoins the Savannah River at two locations (Figure L-1). In Allendale County the lower "arm" of the Savannah River Plant extends from River Mile 128 to 130, an approximate distance of slightly less than 2 miles. Because this portion of the Savannah River Plant consists primarily of wetlands, and is significantly remote from an access road and the burial ground, it was not considered further.

The second and principal parcel of SRP property that adjoins the Savannah River is located in Barnwell and Aiken Counties; this segment extends from approximately River Mile 141 to River Mile 157, a distance of about 16 miles (26 kilometers). This portion of the river is bordered by an extensive (7460 acres) swamp wetland, and below River Mile 155 is unacceptably remote from an access road. Additionally, the location of the barge slip along this segment of the river would adversely impact wetlands and significantly increase construction costs. Therefore, areas downriver from River Mile 155 were excluded from consideration (Figure L-2).

Because of the proximity of Upper Three Runs Creek and one of the cooling water pump houses, only that section of the Savannah River from River Mile 155 to the small boat ramp is considered to contain practicable alternative sites to the proposed barge slip.

APPENDIX M

METHODS FOR REMOVAL OR CONTAINMENT

I. INTRODUCTION

This appendix describes the feasibility of methods by which low level radioactive nuclides associated with the reactor plants of decommissioned, defueled nuclear submarines disposed of in the ocean could be removed or further contained at some future time.

Essentially all of the radioactive material remaining in the submarine is contained within the metal matrix as an integral part of the corrosion resistant alloys forming the internal components of the reactor vessel. The only mechanism for release of this radioactivity would be through corrosion of the metal components. Details of the sea disposal method are described in Appendix D.

Based on the worst case analysis of this statement, there is no technical basis for expecting that removal or containment would ever become necessary.

Nevertheless, methods for handling this contingency which are feasible using current technology and equipment are described in this appendix. Because of the remoteness of the possibility of actually implementing the methods, the estimated costs have not been included in the overall cost estimates in Appendix A.

The configuration of the nuclear submarines addressed in this appendix is that associated with the free-fall sinking of the complete submarine (see Appendix D).

II. SUMMARY

The least costly course of action would be to envelop the entire submarine with freshly mixed concrete delivered from the ocean surface by means of a drill pipe. The other method would be removal by means of a significantly modified Glomar Explorer or a new, larger Glomar Explorer-type heavy lift ship. Actual use of either method is considered to be a remote possibility.

A. CONTAINMENT

The containment method is feasible using current state of the art technology. It would require no advance preparation of the disposed submarine, could be implemented at any time after disposal, and would completely contain the submarine.

B. REMOVAL

The removal methods are considered technically feasible based on the fact that large objects have been recovered from similar depths using such systems. However, the significantly greater lifting forces required to remove an entire nuclear submarine from the deep ocean floor significantly increase the technical problems and costs associated with these methods. These methods would be practical only while the submarine still retained its structural integrity. In addition, the significantly higher costs associated with these options make them considerably less attractive than containment.

C. SCHEDULE

It is feasible to implement the plan to contain a submarine in freshly mixed concrete placed on the ocean floor in approximately 26 months. To remove the entire submarine would require approximately 60 months from initiation of planning to actual retrieval.

D. COST

The cost to contain one submarine is estimated to be $6.4 million (FY 83). This cost estimate is based on the availability of a large drill ship with dynamic positioning capability such as the Glomar Atlantic, Pacific, or Challenger. The drill ships must have the drill pipe capacity and a dynamic positioning system with the capability of positioning the ship to the accuracy required to control the pipe string position in water depths of 14,000 feet. A program to remove an entire submarine using a new heavy lift ship would cost approximately $508 million (FY 83).

III. DISCUSSION

A. METHODS OF REMOVAL OR CONTAINMENT

The U.S. Navy and commercial deep sea exploration companies have developed and utilized deep ocean large object recovery systems. These systems utilize a large commercial deep ocean drill ship especially configured to handle a heavy pipe string as the lifting strength member.

Methods for containment of an object the size of a nuclear submarine located on the ocean floor have not been used in the past. The use of concrete to form such a containment would be appropriate because of the proven strength and longevity of concrete in a water environment. Concrete has been used as a structural material for underwater construction for nearly 100 years and a large amount of data is available on this technology. Structural concrete has been placed under water in shallow depths in continuous pours on the order of 25,000 cubic yards in the construction of bridge piers. This volume of concrete is greater than the volume that would be required to contain a complete nuclear submarine on the ocean floor. The U.S. Navy has performed initial investigations into techniques for placing large quantities of freshly mixed concrete on the ocean floor in water depths up to 20,000 feet. The investigations were directed primarily toward on-site construction of deep ocean mooring anchors and foundations and secondarily toward large object containment.

B. MOST FEASIBLE METHODS

The use of the large heavy lift ship removal method is considered to be a near-term post-disposal option which would be successful as long as the submarine's pressure hull strength remains adequate. As the pressure hull strength is degraded by corrosion, the complexity of attaching a lifting device to the submarine would increase significantly.

The placement of freshly mixed concrete on the ocean floor to contain the submarine or reactor compartment is a less sophisticated approach and has a greater tolerance for error. It is equally applicable for both near-term and far-term requirements and could even be used on a submarine that had corroded into pieces. Concrete has the characteristic of retaining or increasing in strength in a water environment. Additionally, data exist on the durability of concrete submerged in seawater for more than 60 years (Reference M.1).

C. DESCRIPTION OF REMOVAL OR CONTAINMENT METHODS

1. Containment

a. Description

(1) **Basic concept.** The concept is to contain a defueled nuclear submarine lying on the ocean floor by completely enveloping the submarine in freshly mixed concrete. The concrete would be delivered to the bottom through a 3.5-inch to 5-inch drill pipe which could be precisely positioned relative to the submarine. The concrete flow through the pipe is forced by gravity and pumping, with the velocity of the concrete limited by pipe-wall friction.

The concrete would be built up around and over the submarine to form an elongated solid mound with a minimum covering thickness of approximately 4 feet. The concrete would initially settle into the bottom sediment and as additional weight of concrete was built up the sea floor, soil would be displaced until the bearing pressure could be supported. The concrete loads would average approximately 1.5 psi. With pelagic clay as the primary sea floor soil constituent, it is estimated that the concrete would eventually settle into the bottom sediment a distance of 3 to 5 feet, forming a seal between the concrete and the soil substrate.

The concrete would be mixed in a continuously operated batch process concrete plant located on the drill ship and delivered by concrete pumps to the pipe string swivel head. Concrete, sand, aggregate, and fresh water (if used) would be delivered to the drill ship by barge. A sketch of the concept is shown in Figure M-1. Figure M-2 shows a cross section view of the submarine contained in concrete.

The method for placing concrete on the deep ocean floor was developed at the Naval Civil Engineering Laboratory, Port Hueneme, California for the purpose of in-place construction of very heavy deep ocean (up to 20,000 feet) mooring anchors and foundations. Reference M.2 is the technical report on this proposal and is the basis for the development of the concrete containment method.

(2) **Containment characteristics.** Concrete containment is described in detail for the situation where the complete submarine has been placed on the deep ocean floor using the free fall disposal option, on a pelagic clay bottom at a depth of approximately 14,000 feet (approximately 4000 meters). It is expected that the submarine would be substantially on an even keel and would have penetrated somewhat into the soft bottom sediment. If the submarine were not on an even keel, a small correction might be necessary in calculating the volume of concrete required to contain the hull. For a complete submarine hull with a length of 277 feet to 332 feet, the volume of concrete required would be approximately 18,000 cubic yards to 20,000 cubic yards. The actual amount required would depend on the specific class of the submarine and the depth to which the hull would have penetrated into the bottom sediment. Concrete volumes of this magnitude and greater have been placed underwater, in shallow depths, by continuous pumping methods in the construction of bridge piers.

The delivery of the concrete to the submarine hull would be initiated adjacent to the hull and, after the buildup of sufficient concrete, the dispersal head of the drill pipe would be immersed into the concrete, expanding the volume of concrete from the inside. This technique minimizes the area of concrete exposed to seawater and limits dilution effects to the outer skin. The pipe string would be moved by means of the drill ship and pipe string positioning systems so as to progressively surround the hull with concrete, eventually completing the elongated mound of concrete over the top of the hull.

To maximize homogeneity in the structure, the sequence of placing the concrete would be such as to allow each layer to be placed within 4 to 6 hours of the previous layer. This time interval could be increased to some degree by using retarders. Layers placed at an interval greater than approximately 6 hours would result in a cold joint, which would be a discontinuity but which should still provide a tight seal. Additionally, the random location of cold joints as the concrete structure forms would guard against contiguous discontinuities. Likewise, some local cracking of the concrete is possible but would be random and not likely to result in a breach in the containment due to the great thickness of the concrete.

The resulting structure would cure to full strength (approximately 4000 psi compressive yield, Reference M.3) over a period of about four weeks. The total structure would require 16 to 18 days of continuous mixing and delivery of concrete down the drill pipe.

(3) **Concrete mixing.** The concrete batching and mixing operation would be performed utilizing a portable central mix concrete plant set up on the deck of the drill ship. The plant operation should be automatic to allow continuous operation for a period of 16 to 18 days with provisions for analyzing and adjusting the concrete mix design on a continuous basis. Mixing materials would be cement, sand, and

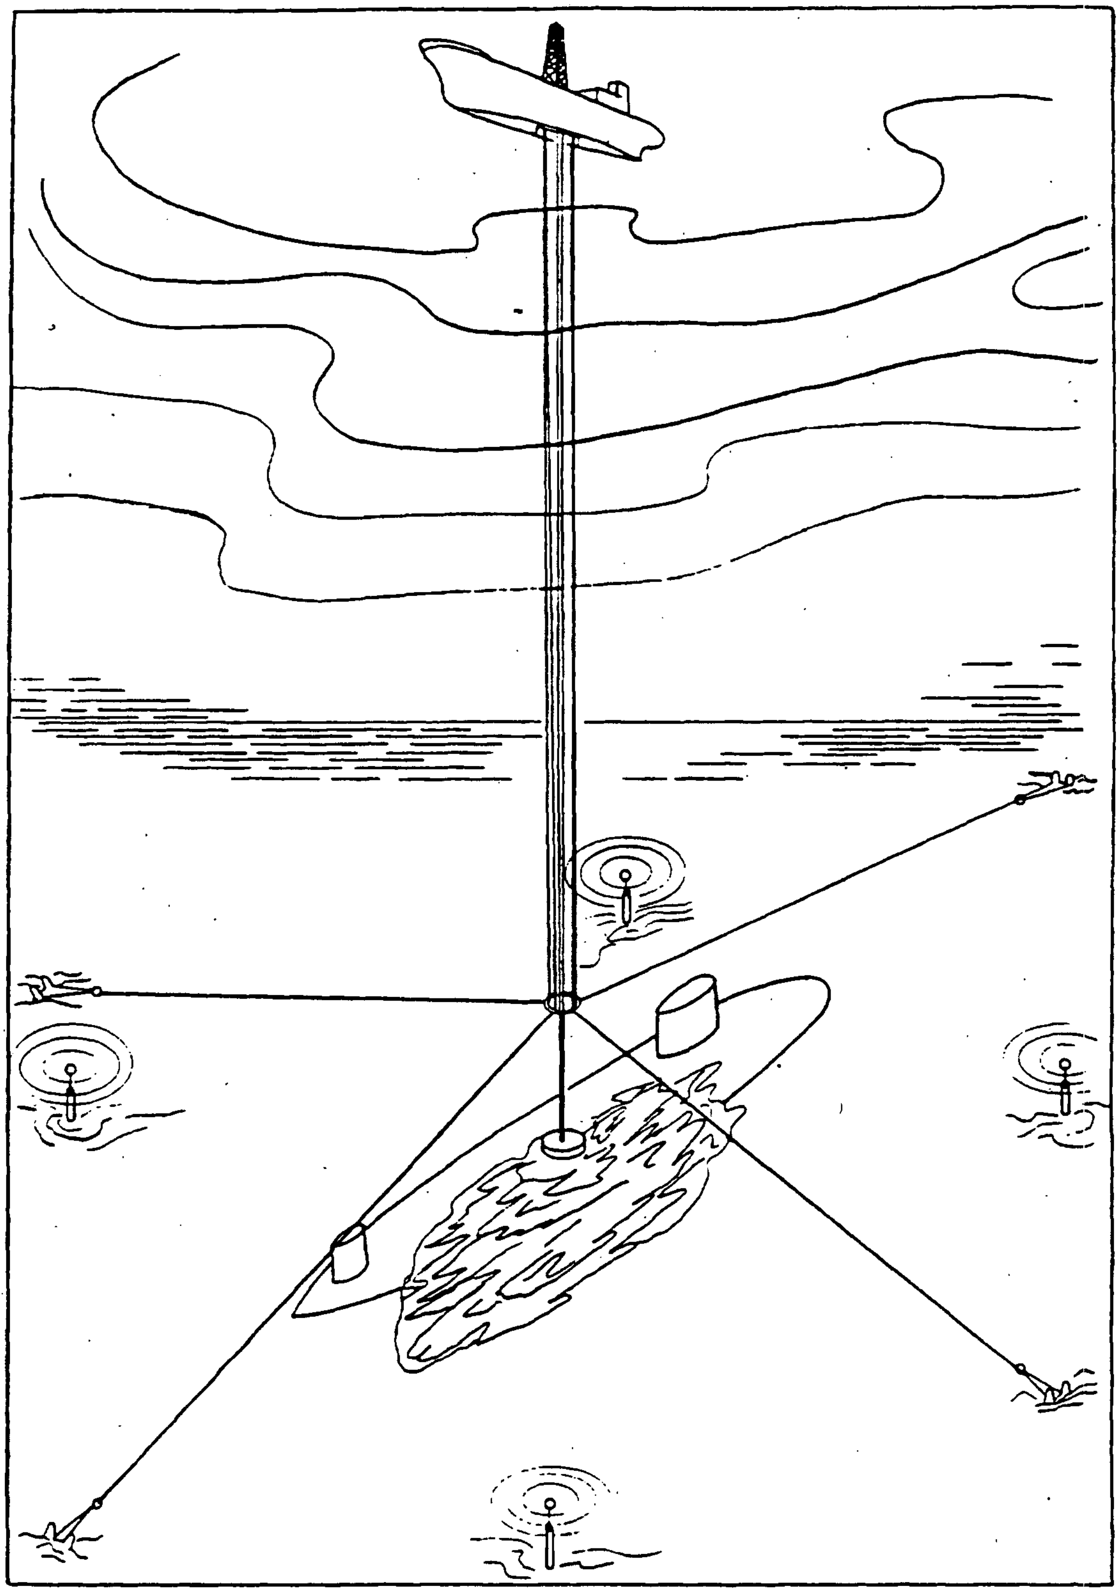

Figure M-1. Drill Ship Placing Concrete Over a Submarine

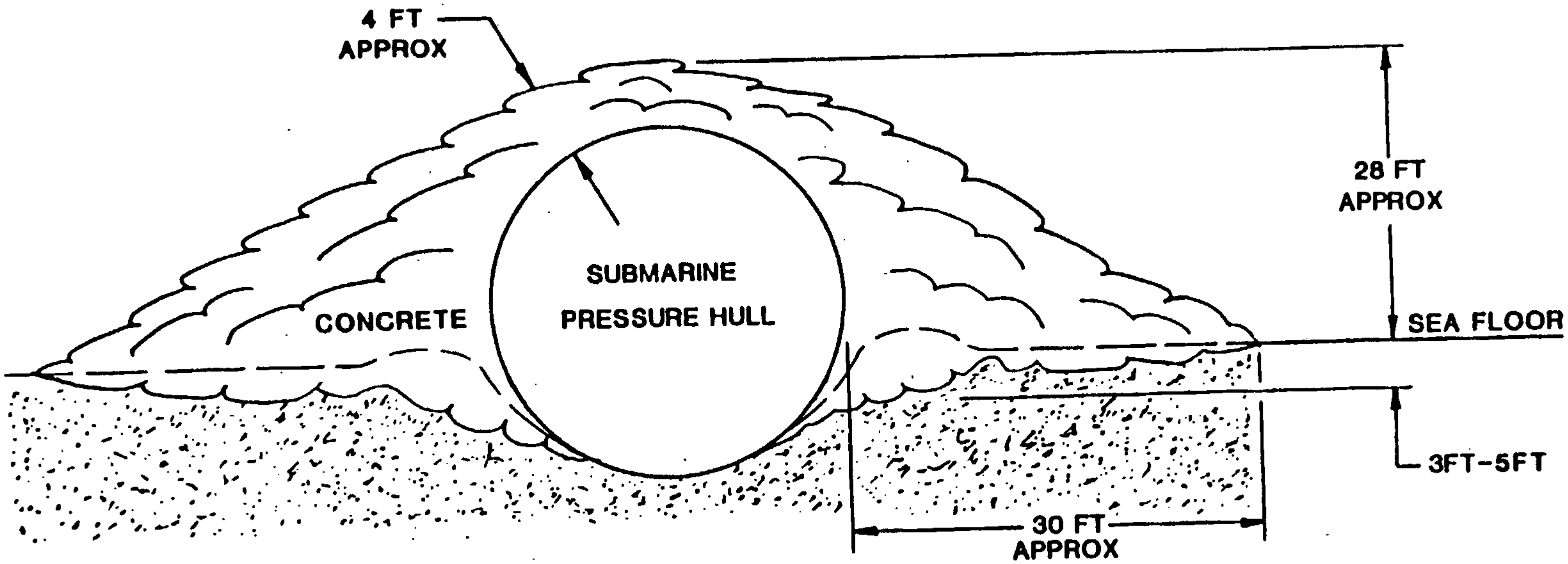

Figure M-2. Cross Section of Concrete Containment

gravel aggregates, water, and admixtures. Bulk materials storage and handling units are commercially available that are suitable for portable shipboard use. Ready materials would be stored on the drill ship with the main material supply located on a barge moored alongside. Resupply would be by barge on a shuttle schedule.

After batching and mixing, the concrete would be conveyed to the hopper of the concrete pumps which in turn would supply the concrete under pressure to the drill pipe concreting head. Rates of supply on the order of 50 cubic yards per hour would be sufficient to place the required volume of concrete with high reliability through the 3.5-inch to 5-inch internal diameter drill pipe. Equipment in the size ranges required is commercially available and is currently used in the heavy construction and offshore oil industries.

b. **Equipment Requirements**

(1) **Drill ship.** The key element of the concrete containment plan is the availability of a drill ship with a dynamic positioning system that will enable it to lower a drill pipe to the ocean floor in water depths of 14,000 feet. Various vessels are known to currently have this capability, such as the Glomar Challenger and the Glomar Explorer, for example. Each of these ships has the capability to carry and extend the pipe string, carry a deck-mounted central-mix concrete plant, and provide storage for sufficient cement, sand, aggregate, and water to sustain a continuous concrete production effort with replenishment materials supplied by barge.

(2) **Pipe string.** The drill pipe size to achieve the desired concrete flow velocity is in a size range (3.5-inch to 5-inch internal diameter) that is readily available. Some modifications to the pipe sections may be required to ensure smooth inside wall transition at the pipe joints. External attachments to the drill pipe string would be required for pipe positioning and concrete exit control.

(3) **Positioning system.** Technology currently exists to position a drill string in water depths up to 20,000 feet with sufficient accuracy to reenter a drill hole using only the drill ship positioning system (Reference M.4). This technology utilizes a sonar transducer which is dropped through the drill string to the tip, sonar reflectors placed on the drill hole reentry cone fixture, and a short baseline transponder drill ship positioning system. Systems which utilize active positioning devices located at the tip of the pipe string have been developed but it has not been necessary to use them in the deep ocean drilling work performed to date. These systems use either active jet propulsors or anchors with cables led through blocks at the pipe string tip and then to winches located on the drill ship (Figure M-3). These systems can be directed by a sonar or TV positioning system utilized in combination with the drill ship positioning system to control the pipe string tip location. It is anticipated that the drag on the pipe string tip resulting from the requirement to immerse the tip into the concrete will necessitate an active positioning system to accurately place the concrete.

(4) **Central mix concrete plant.** Central mix concrete plants of the required capacity (100 cubic yards per hour) are readily available in the heavy construction industry and are suitable for shipboard mounting. A typical off the shelf plant is shown in Figure M-4 along with the necessary ancillary equipment. Total plant weight is approximately 60,000 pounds and foot print area is approximately 610 square feet. In order to maintain continuous production of concrete it would be necessary to store sufficient cement, sand, aggregate, and fresh water on board the drill ship and install loading conveyors to continuously feed the concrete plant. Drill ships of the size required for this project already have sufficient cement storage in pressurized tanks as well as fresh water storage. Concrete can be transferred with compressed air to the central mix plant. Required ready service supplies of sand and aggregate in covered containers can be accommodated on the drill ship deck and storage holds. Table M-1 provides an estimate of required ready service materials to support continuous production of concrete with resupply accomplished by daily barge shuttle.

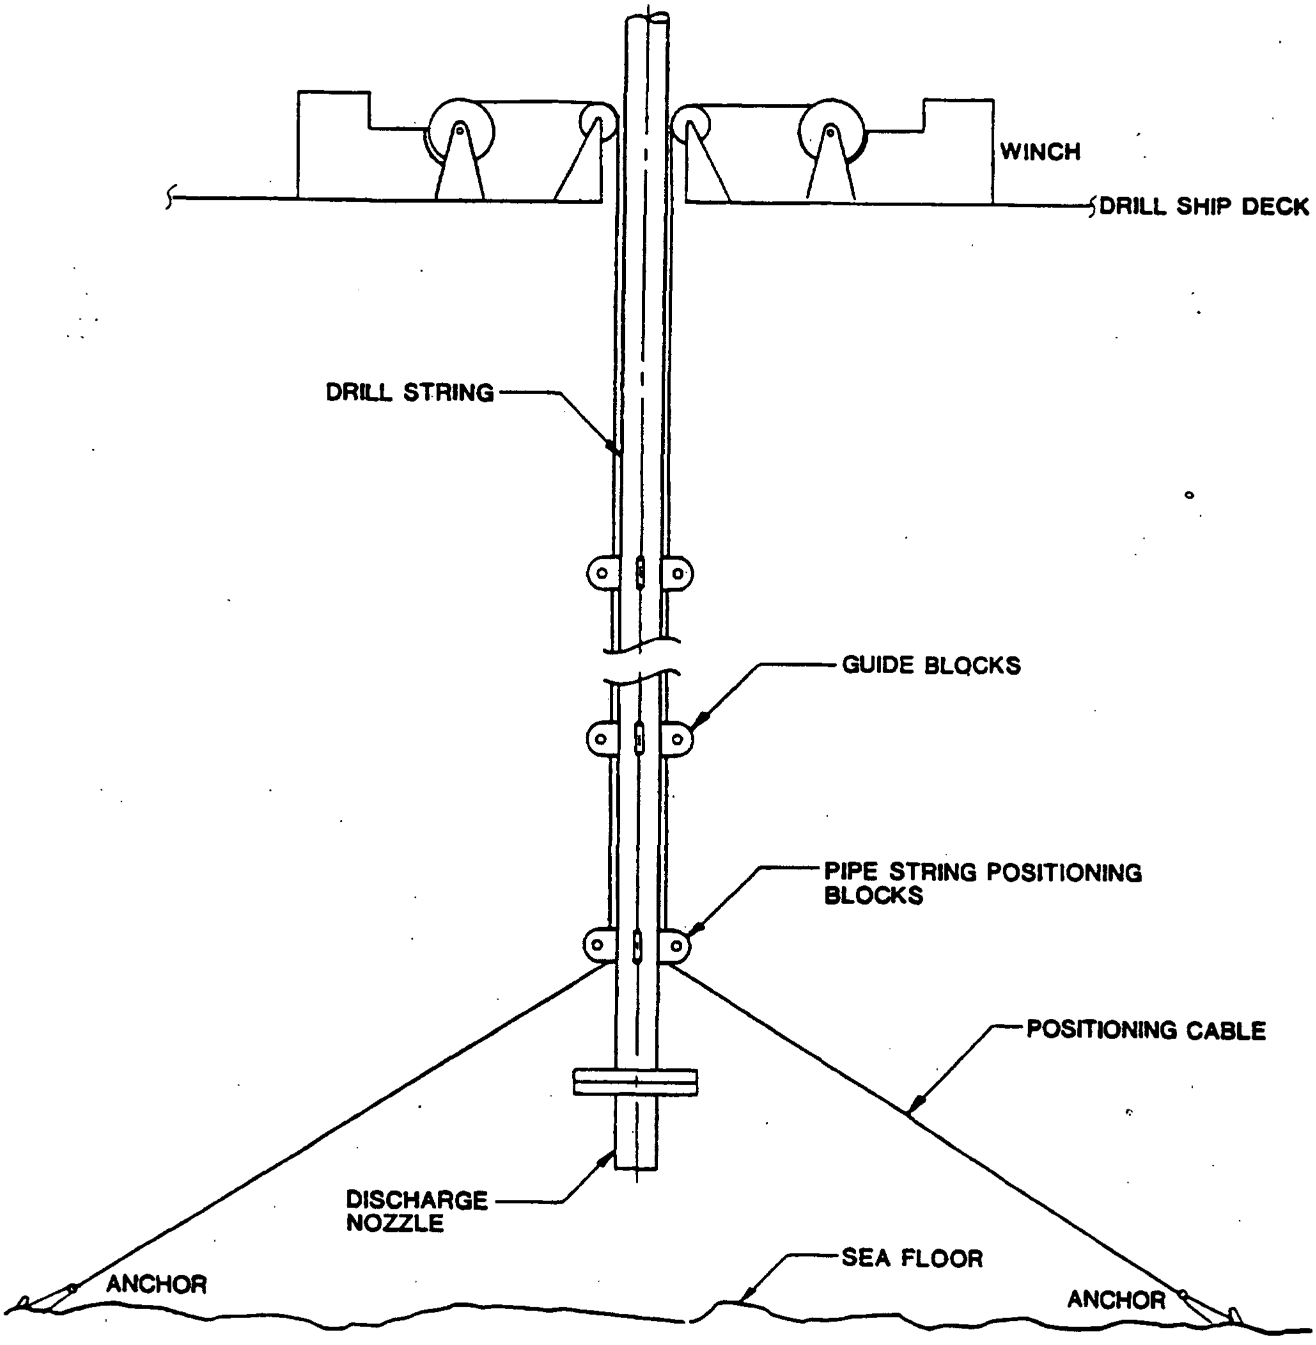

Figure M-3. Drill String Tip Positioning Using Anchors, Cables, Guide Blocks, and Winches Controlled by Positioning System

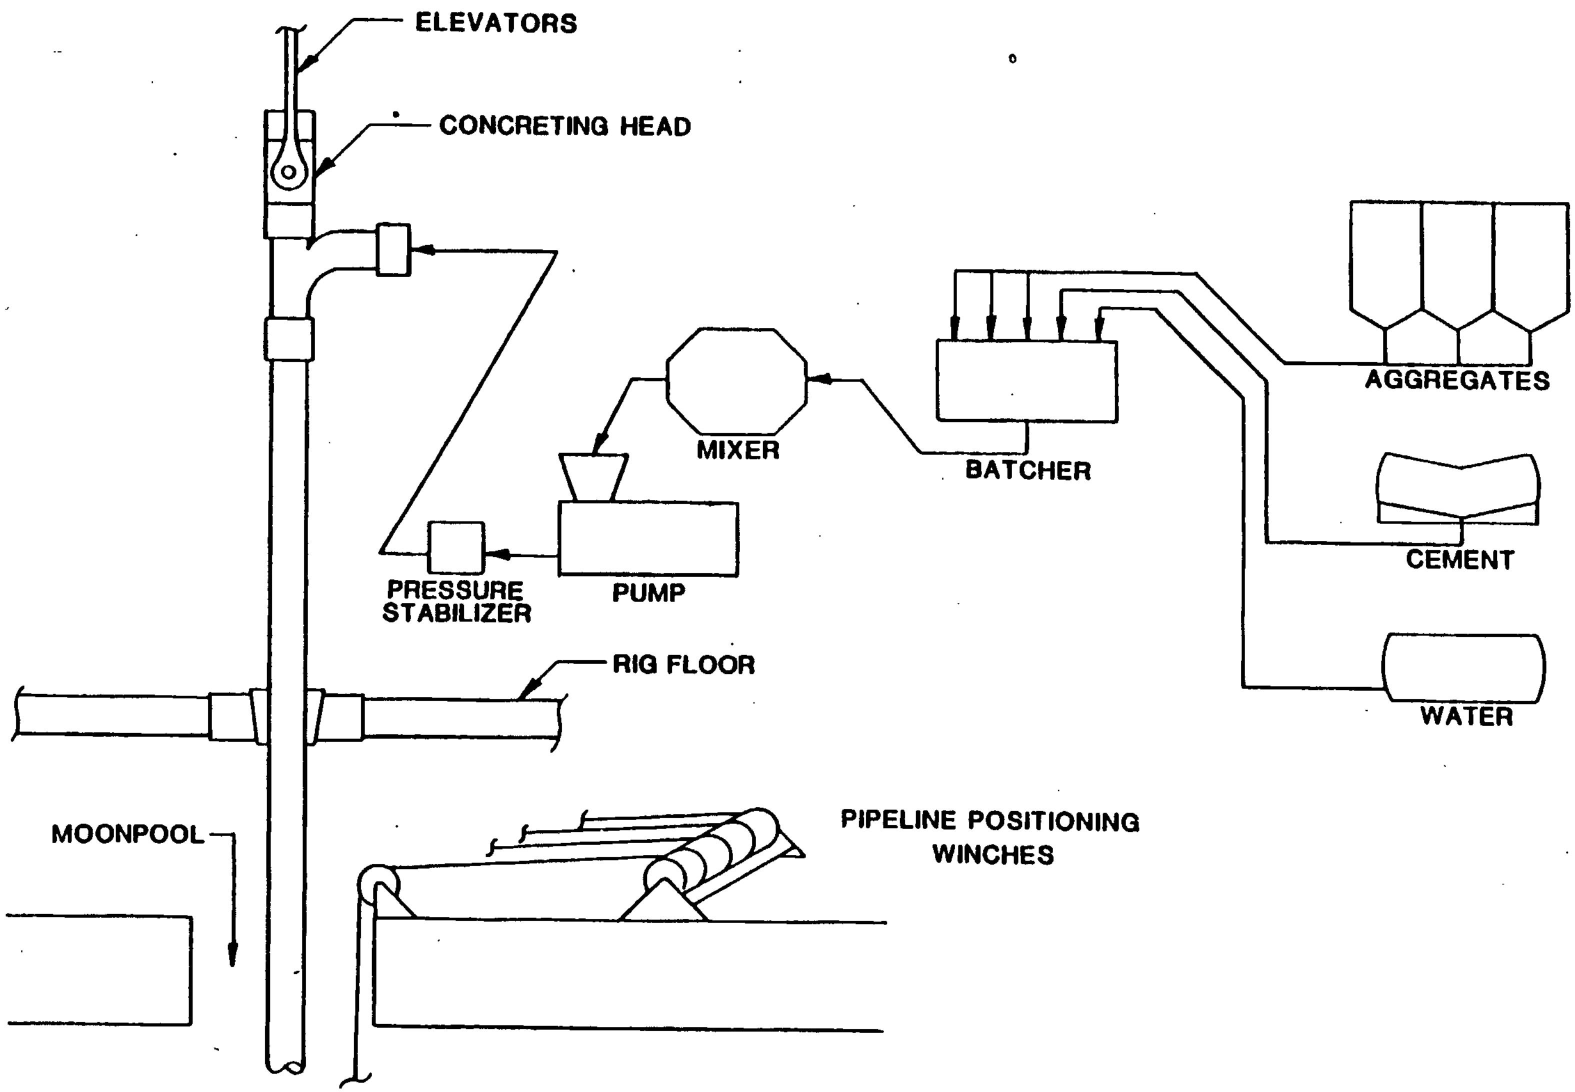

Figure M-4. Central Mix Concrete Plant

TABLE M-1. READY SERVICE MATERIALS REQUIRED ON DRILL SHIP TO ENSURE CONTINUOUS CONCRETE MIXING

	Aggregates	Cement	Water
Weight (lb)	3,600,000	768,000	385,000
Volume (cu yd)	1400	375	230

(5) **Supply barges.** The required resupply of materials would be accomplished through a barge/tug shuttle operated from the nearest port with suitable terminal facilities. The makeup requirements could be met with one barge of approximately 2000 cubic yards capacity per 24-hour day. To meet this requirement for 16 or more days of operation would require four barges and two tugs of about 3000 shaft horsepower size operating on a continuous schedule. This schedule is based on a location approximately 200 nautical miles offshore, a 24-hour offload time at the drill ship, a 24-hour loading time at the terminal, and a tug/barge transit speed of 8 knots.

(6) **Laboratory and engineering support.** In order to ensure a proper concrete mix and the ability to continuously adjust the mix, a portable laboratory would be required on the drill ship. Similar laboratories are utilized at land-based central mix concrete plants for large construction projects. Similarly, on-board engineering support would be required to resolve emergent problems.

c. **Engineering Developments**

(1) **Concrete mix design.** Development of a mix design would be required to achieve the optimum sand and aggregate size graduations and the matching of drill pipe inner diameter to provide proper wall friction forces and resultant flow velocity. This development effort is discussed in References M.2 and M.5.

(2) **Pipe string.** Standard drill pipe appears to be satisfactory for the drill string. However, a technical development program would be required to design a concreting head to supply the pumped concrete to the drill pipe. This equipment is equivalent to the swivel head of a standard drill rig. A second area requiring development would be the discharge or exit diffuser at the tip of the drill string. This device must provide the required back pressure to ensure proper flow in the drill string and may have an additional role in the positioning of the drill pipe through thrust generated by the exiting concrete. This requirement is also discussed in Reference M.2.

d. **Implementation Schedule**

(1) **Engineering development.** Engineering development in the three areas (concrete mix design, drill string hardware, and the positioning system) could be pursued concurrently. It would be necessary to carry out full scale operational tests in water depths of about 2000 feet to verify results. This depth should be adequate to establish steady state concrete flow conditions in the drill pipe while allowing use of readily available equipment. These tests could be executed utilizing small size, barge-mounted equipment such as would be used in local concrete construction. Likewise, small drill rigs exist that could be barge mounted or are installed on small drill ships used for shallow depth coring operations. The required development programs are estimated to require approximately 16 to 24 months.

(2) **Equipment procurement.** The most significant equipment item would be the drill ship itself. Currently, drill ships capable of extending a drill string to the required depths and maintaining the anticipated positioning tolerances are available. It is estimated that approximately 30 days would be required to outfit the drill ship for the concrete placement task.

Procurement of the central mix concrete plant, concrete pump, and support equipment would require from one to three months depending on whether the equipment is leased, purchased used, or purchased new. In any case, the equipment is in current use in the heavy construction industry.

Arrangement for tugs, barges, and port terminal facilities could be made with a minimum amount of lead time, normally one to two months.

(3) **Materials.** The cement, sand, and aggregates in the quantities anticipated for containing a single submarine could be supplied by existing quarry and cement operations. The critical sand and aggregate sizing requirements could, however, impose a greater lead time than for materials used in standard concrete mixes. If special crushing-mill or sand-sizing runs would be required, it is estimated that a lead time of approximately three to six months would be required.

(4) **Organization.** The implementation of the concrete containment plan would require both commercial and U.S. Navy involvement with the probable need for competitive bids for materials, contracting for equipment purchase, and lease hire arrangements for ships, tugs, and barges. It is estimated that a program acquisition organization would be required to be in place for a minimum of 60 to 90 days prior to the start of actual preparations.

(5) **Schedule.** Most of the efforts to develop and implement a concrete containment plan could be executed in overlapping or parallel paths. From the beginning of engineering development through the completion of a containment would require approximately 26 months. If the plan were required to be executed on a succession of submarines, it might be necessary to carry out multiple evolutions requiring several drill ship/concrete plant/tug/barge units.

e. **Cost**

The estimated cost of containment would include engineering development, concrete materials, materials transportation, concrete plant lease, drill ship lease, and engineering and management. Costs are in FY 1983 dollars.

Cost to Contain One Submarine:

Technical Development	$1.6 M
Materials	1.2
Transportation	0.4
Concrete Plant	0.1
Drill Ship	1.8
Engineering and Management	1.3
Total	$6.4 M

The cost of the engineering development, drill ship modifications, and a portion of the engineering management costs are identical for one submarine or for multiple submarines. If more than one submarine were contained, the unit cost would decrease to approximately $3.5 million at five and $3.2 million if a total of ten were contained.

2. Removal

With the horizontal planes removed from the submarine and the longitudinal center of gravity adjusted through addition of gravel, the submarine would descend on an even keel and would bottom within a relatively short displacement from the release point. The rate of descent has been established at about 40 feet per second, which, upon impact, would cause the submarine to penetrate somewhat into the soft bottom. The submarine would subsequently settle farther into the sea floor over a period of time. Depending on the constituent soils in the sea floor, it is possible for the submarine to penetrate up to half of the hull diameter, which would greatly increase the difficulty of later removal and is assumed to be the worst case condition.

According to a Naval Civil Engineering Laboratory study (Reference M.6), the force required to raise a submarine from a one-half diameter position in bottom mud or clay is speed dependent. A fast lift off the bottom (say one hour) might require the application of force equal to twice the submarine weight, but a slow lift over many hours can break out the submarine with a force slightly in excess of the submarine weight. The largest submarine, when flooded and on the bottom, would have a weight in water of approximately 6000 tons. In addition, after retrieval it would be necessary to transport the flooded submarine to another site for further processing.

The Glomar Explorer is an existing asset currently in the U.S. Navy Reserve Fleet. She is a ship approximately 600 feet long with a beam of 116 feet, configured to provide very heavy lifting capabilities through a large midships well. The well measures 199 feet fore and aft and 74 feet athwartships and extends from the keel to the main deck. Over the well, a drill rig type derrick is erected which permits the assembly of drill pipe units into a long string, which may be used as a tension member to raise large weights from the deep ocean. The pipe string with its load can be retrieved at the rate of 6 feet per minute. As presently configured, the Glomar Explorer can raise 4400 tons from a 14,000-foot depth in approximately 40 hours.

Glomar Explorer has the navigational capabilities required to precisely locate a predetermined spot in the disposal area. With the aid of bottom positioned transducers and targets, and an Automatic Station Keeping System, "ASK," the twin screw main propulsion system plus five transverse thrusters have the capability of holding Glomar Explorer to within a very tight circle directly over the predetermined spot. The ASK system can hold the ship within the accuracy of the transponders in fairly rough seas (Sea State of 6. Sea State 6 or less occurs over the Pacific study area about 88.6 percent of the time (Reference M.7)).

There are two options available to provide a retrieval ship which would have both the lifting capacity required and the well size to house a complete submarine. The first method is to lengthen the Glomar Explorer, adding about 140 feet to the mid-body to permit increasing the well size, and to design and fabricate an increased capacity heavy lift system. A new heavier pipe string would also be required. The second method is to design and build a new larger heavy lift ship which would have all the navigational and position-holding capabilities of Glomar Explorer and would have increased lifting capacity and a larger well.

a. Glomar Explorer with Increased Lift Capabilities and Lengthened Well

(1) Description

Increasing both the lift capacity and the size of the well would require that the existing Glomar Explorer be lengthened through the addition of 140 feet of parallel middle body and that a larger heavy lift system be installed. The lifting and well size requirements are the same as those for a new heavy lift ship as discussed below. Additionally, new well closure gates would need to be designed to accommodate the requirements of the larger well. The advantage of this plan is the time and cost savings which might accrue from starting with an existing ship.

(2) Equipment Requirements

The following equipment would be required to be designed, procured, and tested.

(a) The Glomar Explorer itself would require substantial additions to the hull girder to handle the increased bending moments resulting from the increased well length and the heavier lifting loads. The lengthening and strengthening of the hull would be within the state of the art. Sponsons or other means of increasing transverse stability might also be required.

(b) The well closure for the increased length well would need to be redesigned and fabricated, perhaps utilizing a two-stage sliding gate configuration similar to that currently used.

(c) The derrick must be robust enough to handle a "double" made up of two 30-foot pipes welded together from 21-inch diameter pipe with a 6-inch internal diameter. This pipe would weigh a maximum of 1100 pounds per foot or about 70,000 pounds for a double.

(d) The heavy lift system would be required to have a capacity over twice that currently installed aboard Glomar Explorer. To raise a submarine of 6000 long tons from the bottom plus a "claw" with an estimated weight of 3000 long tons would require a pipe string weighing about 5000 long tons in water.

(e) The claw is a device for grappling and holding the submarine. Although a design for this device is not currently available, one could be developed for this application. An estimate of the weight of the claw is 3000 long tons.

(3) **Technical Developments and Implementation Schedule**

(a) Larger pipe size than that previously used by Glomar Explorer must be developed. The largest pipe identified for Glomar Explorer was 15.5 inches in diameter with a 6-inch internal diameter. The largest pipe size that might be required for this operation would be on the order of 21 inches in diameter with a 6-inch internal diameter.

(b) A significant development effort would be required to produce a claw that could be handled from the ship and could raise a 6000 long ton submarine.

(c) The heavy lift system developed for the existing Glomar Explorer was designed for a maximum capacity of 6250 long tons. The new heavy lift system would have to be designed to lift approximately 14,000 long tons.

The time required to develop the engineering to lengthen the ship is estimated to be about nine months and would take about two years to accomplish. This work could be performed in parallel with the technical development efforts. It is estimated that approximately 48 months would be required to implement this plan.

(4) **Estimated Cost of Removing One Submarine**

Development of engineering to lengthen ship	$ 3 M
Technical development of claw	5
Technical development of the heavy lift system	10
Lengthening of Glomar Explorer	144
Fabrication and installation of heavy lift system	60
Fabrication of claw	60
Fabrication of pipe	24
Capital costs (non-recurring)	$306 M
Operating cost for 12 months	36
TOTAL	$342 M

The cost of the technical development of the ship, claw, and heavy lift system as well as the lengthening of the ship and procurement of the pipe string and the preceding items would be identical for removal of one submarine or multiple submarines. If more than one submarine were removed, the unit cost would decrease to approximately $70 million per submarine at five and $40 million per submarine if a total of ten were removed. Costs are for FY 1983.

b. **New Ship Acquisition**

(1) **Description**

(a) This approach would involve the design and construction of a new heavy lift ship which would have the lifting capacity required to raise a complete submarine from 14,000 feet of water. A total lift system capacity of approximately 14,000 long tons would be required. In addition, this ship could bring the submarine into a well and close the well gates under the submarine. The well gates could then be dewatered to provide a seat for the submarine. The submarine would be secured in place for transit to a location where further processing would be implemented (Figure M-5).

(b) The new ship would be about 740 feet long with a beam sized to meet well width and stability requirements. Hull depth of about 55 feet would permit adequate strength to be built in for worst case hull girder bending. The well would measure 340 feet long and about 60 feet wide. The well top would be fitted with hatch covers and the bottom would be closed with hinged buoyant gates. These gates would be opened by flooding and closed by dewatering. The gates would close against gasketing to provide a water-tight closure.

The ship must be equipped with navigational capability at least equal to that existing in Glomar Explorer. Thruster power must be in excess of that provided Glomar Explorer because of the larger profile area of the ship. Position holding equipment must be the equivalent of that installed aboard Glomar Explorer.

(c) The new heavy lift ship would be equipped with the capabilities required to stow and assemble a pipe string of very large diameter pipe. A "claw" similar to that previously used by Glomar Explorer would be used to grapple the submarine. This would increase the total lift required as the weight of the pipe string and the claw must be supported by the heavy lift system.

(2) **Equipment Requirements**

The following equipment would have to be designed, procured, and tested.

(a) The major piece of equipment required would be the ship. This design and procurement would be "state of the art" and would have a very low risk factor. However, equipment to be installed aboard the ship would require considerable development.

(b) The well closure would require some design development to provide a water-tight closure which could be dewatered, and which could also provide adequate strength to support the submarine.

(c) The derrick must be able to handle the same pipe string requirements as the expanded Glomar Explorer. Similarly, the pipe string itself would be the same and would require a storage and handling system of proper size.

(d) The capacity of the heavy lift system would have to be increased to approximately 14,000 long tons. Again, this would require that a new system be designed and fabricated to meet this requirement.

(e) The claw requirements would be the same as for the expanded Glomar Explorer.

(3) **Technical Developments**

The drill pipe string, claw, and increased capacity heavy lift system would be identical to that required for the expanded Glomar Explorer and the technical development requirements and implementation schedule would be unchanged.

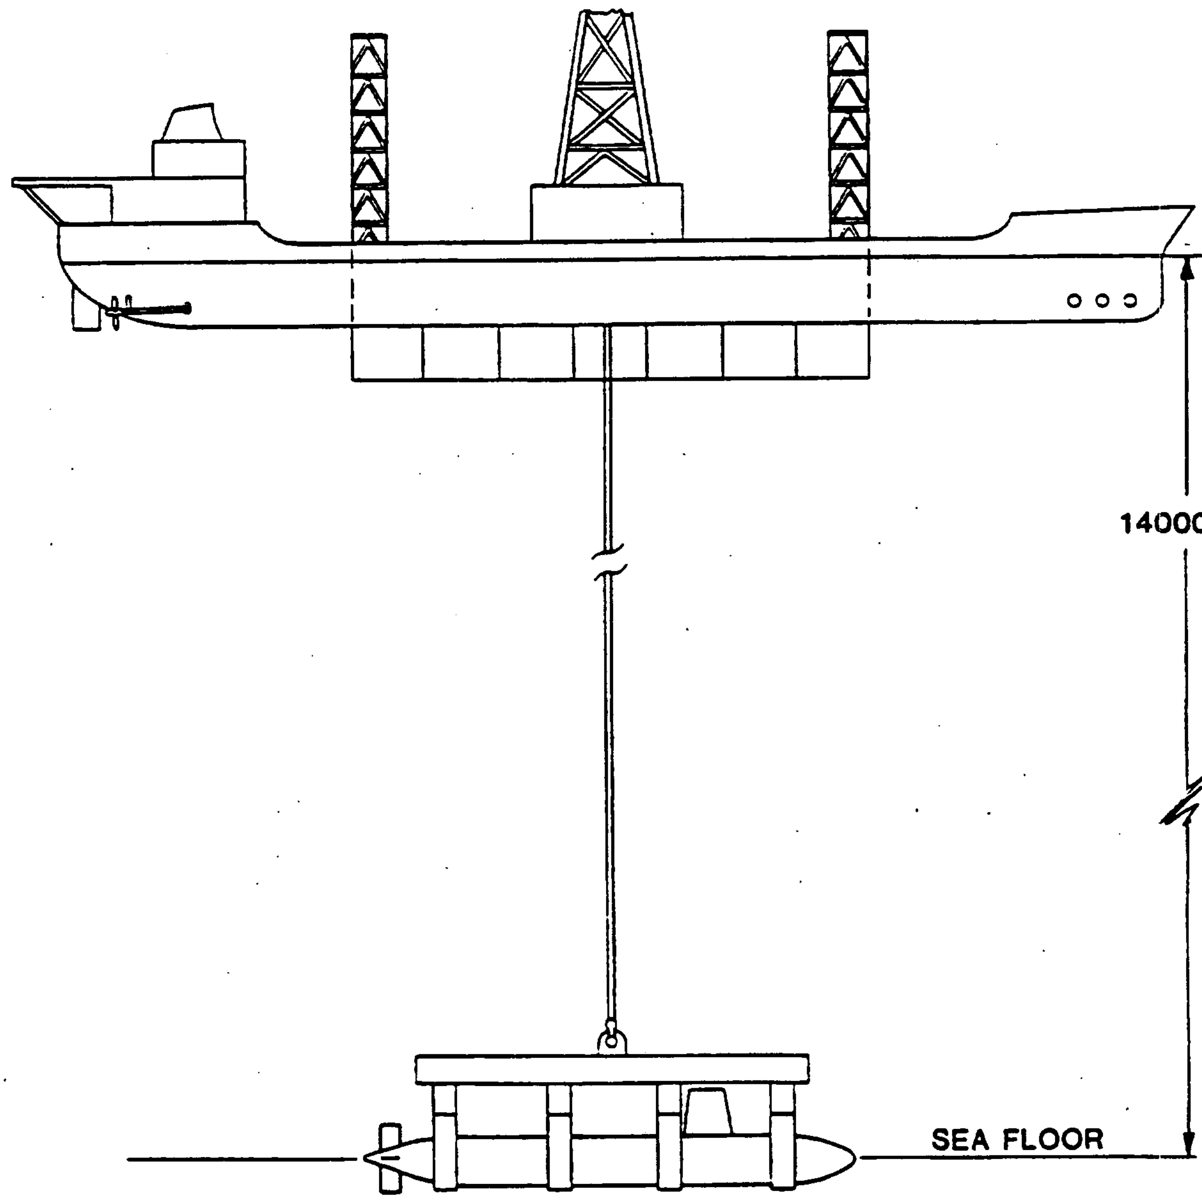

Figure M-5. New Glomar Explorer

(4) **Implementation Schedule**

The implementation plans for design and procurement of the various equipment could be pursued in parallel. From the beginning of preliminary design through detail design and construction of a new Glomar Explorer-type ship would require approximately 60 months.

(5) **Estimated Cost to Remove One Submarine**

Technical development of ship		$ 11 M
Technical development of claw		7
Technical development of heavy lift system		10
Procurement of ship		300
Fabrication and installation of heavy lift system		60
Fabrication of claw		60
Fabrication of pipe		24
Capital costs (non-recurring)		$472 M
Operating costs for 12 months		36
	TOTAL	$508 M

The cost of the technical development of the ship, claw, and heavy lift system as well as the procurement of the ship, pipe string, and the preceding items would be identical for removal of one submarine or multiple submarines. If more than one ship were removed, the unit cost would decrease to approximately $105 million per submarine at five and $57 million per submarine if a total of ten were removed. Costs are for FY 1983.

D. COMPARISON OF COSTS

The high costs associated with the construction and outfitting of a heavy lift ship similar to the Glomar Explorer but with significantly increased lifting capacity, or with the modification of the Glomar Explorer, make the approaches which utilize these options extremely unattractive when compared to the concrete containment method. The costs developed for options using either of the methods are based on realistic current cost data.

Summary of estimated costs for one submarine (FY 1983):

Containment in Freshly Mixed Concrete	**Removal—Modified Glomar Explorer**	**Removal—New Heavy Lift Ship**
$6.4 M	$342 M	$508 M

LIST OF PREPARERS

AUTHORS

Bettis Atomic Power Laboratory

The Bettis Atomic Power Laboratory is operated by the Westinghouse Electric Corporation for the U.S. Department of Energy. In addition to performing research, development, and engineering related to nuclear power for the Department of Energy, the Laboratory conducts research and development for the U.S. Navy in selected areas related to the use of nuclear propulsion in ships. The Laboratory is located in West Mifflin, Pennsylvania.

Carl A. Detrick, BS in Physics, MS and PhD in Nuclear Science and Engineering. Fifteen years experience including nuclear reactor design and analysis; model development; computer programming; evaluation of reactor control systems; reactor refueling, testing and startup; emergency planning; and environmental evaluation. Manager of the group preparing this environmental impact statement.

Arthur L. Baehr, Jr.*, BS in Mathematics, MS in Environmental Studies. Three years experience in environmental analysis and health physics.

Richard F. Beyer, BS in Physics, MS in Nuclear Engineering. Nineteen years experience including experimental reactor physics; neutron and gamma dosimetry; solid and liquid radioactive waste processing; radioactive waste handling, shipping, and disposal; nuclear materials management and safety; reactor testing; and review of federal regulations on radioactive material shipping and waste disposal.

Randy P. Clark, BS in Environmental Engineering. Three years experience including environmental sampling and evaluations of surface waters for chemical, bacteriological, and radiological pollutants; and monitoring for compliance with environmental quality regulations.

Robert H. Giffen, BS, MS, and PhD in Chemical Engineering. Forty years experience including chemical processing of industrial chemicals, plutonium, uranium, thorium, zirconium and hafnium; design and testing of nuclear power plant fluid systems and mechanical components; development of technology in reactor corrosion and coolant chemistry, radioactive corrosion products, and breeder fuel cycles; and environmental evaluation.

Jun Hino, BS, MS, and PhD in Metallurgical Engineering. Thirty-four years experience in nuclear reactor material development, including nuclear reactor fuel, cladding, and control materials; and characterization of the corrosion behavior and physical property characterization of structural materials in steam generators and nuclear plant components.

James L. Rider, BS, MS in Mechanical Engineering. Twenty-seven years experience including reactor plant system design and analysis; radiation shielding design; environmental impact calculations; and development of calculational models and computer programs for predicting reactor plant radiation levels for shield design calculations, for predicting corrosion products behavior in reactor plants, and for estimating atmospheric transport and dose commitments from atmospheric releases.

A. Mercer Sisson, BS in Engineering Physics. Three years experience including computer programming and modeling for environmental applications; calculation of potential environmental effects; and environmental analysis.

Frederick R. Urbanus, BS and MS in Mathematics. Over twenty-five years experience in numerous areas of the naval nuclear propulsion field, including naval reactor core design, analysis, and testing; reactor operator training; nuclear safety; emergency planning; development of techniques for estimating radiation exposure; and analyzing the environmental effects of radiological waste disposal.

*Currently at the University of Delaware, Department of Civil Engineering, Newark, Delaware.

Kenneth H. Vogel, BS in Chemical Engineering, MS and DSc in Chemistry. Thirty-eight years experience including reactor testing; reactor coolant and boiler water chemistry, radiochemistry and radiation chemistry; spent core examination; waste processing and management system design; irradiation test loop design, operation and evaluation; irradiation test assembly thermal and hydraulic design and evaluation; breeder reactor core design; and environmental analysis of breeder reactor fuel cycles from mining to reprocessing and waste management.

Stanley E. Wos, BS in Computer Science. Eleven years experience including computer programming, emergency planning, environmental evaluation, and quality assurance.

Knolls Atomic Power Laboratory

The Knolls Atomic Power Laboratory, located in Schenectady, New York, is operated by the General Electric Company for the U.S. Department of Energy. The Knolls Laboratory conducts research and development in selected areas related to ship nuclear propulsion for the U.S. Navy.

Richard B. Sheldon, BS in Biology, MS in Environmental Engineering. Eight years experience in Naval nuclear propulsion field including nuclear plant operations, initial startup testing, reactor operator training, coolant chemistry control, corrosion of submarine and reactor structural materials, radiological assessment and oceanographic environmental monitoring.

Sherman L. Williams, BS in Chemical Engineering, MS in Physiology and Biochemistry. Over thirty years experience in the nuclear field including reactor coolant system design; radiation and coolant technology; radioecology; and environmental assessment and protection. Manager of the Knolls Laboratory group which contributed to the environmental assessment of the ocean disposal option.

NUS Corporation, Savannah River Center

The NUS Corporation, Savannah River Center is located in Aiken, South Carolina, and is an engineering and environmental consulting firm.

Gary P. Friday, BA, MA in Biology, and PhD in Fisheries and Wildlife. Ten years experience in preparing environmental impact statements and assessments. Certified Wildlife Biologist with broad background in vegetation ecology, wildlife management, and biostatistics.

Sachse Engineering Associates, Inc.

The Sachse Engineering Associates, Inc., is located in La Mesa, California, and is an engineering firm specializing in ocean engineering, deep submergence systems, and marine engineering.

Ronald W. Render, BS, MS in Naval Architecture and Marine Engineering. Eighteen years experience in marine engineering and ship design.

OTHER CONTRIBUTORS

Oregon State University

G. Ross Heath, Dean, School of Oceanography. BS, Honorary BS, and PhD in Oceanography. Extensive experience as Professor of Geological Oceanography. Principal areas of expertise: marine geology, mineralogy, and geochemistry of deep sea sediments and manganese nodules. Involved in site selection and ion migration barriers for subseabed disposal program.

The Oregon State University is located in Corvallis, Oregon.

University of Rhode Island

Edward P. Laine, Assistant Research Professor, Graduate School of Oceanography. BA in Geology, PhD in Oceanography. Ten years experience in integrated studies of deep sea sedimentary environment using geological, geophysical, geotechnical, and oceanographic methods; studies of the influence of climatic change on the characteristics of deep sea sedimentary environment; and specifying site selection criteria for subseabed disposal of high-level nuclear waste.

The University of Rhode Island is located in Narragansett, Rhode Island.

Puget Sound Naval Shipyard

Robert J. Benze, BS in Mechanical Engineering. Twelve years experience in reactor refueling and nuclear facilities design.

James G. Krein, BS in Electrical Engineering. Nineteen years experience in reactor refueling and reactor plant fluid systems.

The Puget Sound Naval Shipyard is located in Bremerton, Washington.

TECHNICAL SUPPORT

A multidisciplinary team of scientists and engineers has contributed to the preparation of this environmental statement, either through direct scientific work to provide the basis for the document or through critical review of the direction or nature of the technical activities. Daniel M. Talbert of the Seabed Programs Division, Sandia National Laboratories has served as the coordinator for a large part of this effort which was performed under subcontract. Specific individuals who have contributed to this work are too numerous to list here but are identified in "Oceanographic Studies to Support the Assessment of Submarine Disposal at Sea," Volume I, SAND 82-1005, D. M. Talbert, September 1982.

TECHNICAL EDITORS

Bettis Atomic Power Laboratory

Thomas G. Coleman, BS in Mathematics. Twelve years experience in writing and editing refueling manuals, reactor plant manuals, technical reports, and safety analysis reports.

Dolores I. Davis, BA in English, MA in Rhetoric and Communications. Six years experience in writing and editing reactor plant manuals, technical reports, and Core Manufacturing Code.

Ellen M. Kerber, BS in Education (English). Five years experience in writing and editing reactor and power plant manuals, Navy training documents, and technical reports.

Roger A. Mesiano, BS in Chemical Engineering. Seventeen years experience in writing and editing reactor and power plant manuals, Navy training documents, technical reports, and safety analysis reports.

Janet B. Skurnick, AS in Science and Business. Six years experience in editing and coordinating reactor plant and training manuals.

GLOSSARY

absorbed dose	When ionizing radiation passes through a material, some of its energy is imparted to the material. The amount of energy retained per unit mass of the material is called the absorbed dose and is measured in rads and usually expressed in rems when referring to the absorbed dose in humans.
abyssal	Pertaining to ocean depths ranging between 4000 and 6000 meters.
abyssal plains	Broad flat areas of fine sediment located at the bottom of the ocean which are typically between ridges, mountain chains, slopes, and other prominent features.
acre-foot	A unit of volume usually used in reference to volumes of water. One acre-foot of water is equal to the amount of water which covers an acre of area and is one foot deep. One acre-foot equals 43,560 cubic feet.
actinide series	The series of chemically similar, mostly synthetic, radioactive elements which have atomic numbers between and including 89 (actinium) and 103 (lawrencium).
activation	The process of making a material radioactive by exposing the material to neutrons, protons, or other nuclear particles. In this statement, a large percentage of the radioactivity present in a defueled nuclear submarine was formed by activating the metal structures in the reactor compartment with neutrons during normal submarine operations. Activation is also referred to as radioactivation.
activation products	The radionuclides formed as a result of a material being activated. For example, Cobalt-60 is an activation product resulting from neutron activation of Cobalt-59.
activity	A measure of the rate at which a material is emitting nuclear radiation. Activity is usually measured in terms of the number of nuclear disintegrations which occur in a quantity of the material over a period of time. The standard unit of activity is the curie (Ci), which is equal to 37 billion (3.7×10^{10}) disintegrations per second.
admixture	Chemical or mineral additives used in concrete or mortar mixes to modify the characteristics of the mix.
adsorption	Taking up of molecules by physical or chemical forces by the surfaces of solids or liquids with which they are in contact; distinguished from absorption.
advection current	A general, prevailing water current.
aft	Toward or close to the rear section of a ship or boat.
aggregates	Sand, gravel, or rock which is used in concrete or mortar mixes to achieve increased strength.
alloy	A mixture of two or more metals.
alluvial fan	A fan-shaped accumulation of sediment on the ocean floor near a land mass which was deposited by flowing water; usually at the mouth of a river.
alpha particle	[Symbol α (alpha)] A positively charged particle emitted by certain radioactive materials. It is made up of two neutrons and two protons bound together, which means it has an electrical charge of +2, and it is identical to the nucleus of the

helium atom. It is the least penetrating of the three common types of ionizing radiation (alpha, beta, and gamma) emitted by radioactive materials and can be stopped by a sheet of paper. It is usually not dangerous to plants, animals, or man unless the material which is emitting alpha particles has entered the body.

aquifer	A geologic unit below the earth's surface which is capable of yielding water to a well or spring.
atomic number	The number of protons in the nucleus of an atom. All atoms of the same element have the same number of protons, whether radioactive or stable.
atomic weight	The average weight of an atom of an element which is usually expressed relative to one atom of the carbon isotope which is taken to have a standard atomic weight of 12.
attitude	The orientation of a ship relative to some reference line or plane.
average individual	An individual who could consume items or occupy areas at rates which would be typical for the population of interest.
background radiation	The radiation which exists in man's natural environment and includes cosmic rays and radiation from naturally-occurring elements, both outside and inside the bodies of humans and animals. Background radiation is also referred to as natural radiation. Typically, an average annual exposure of 100 mrem to the total body occurs from background radiation.
ballast	Any heavy material placed in a ship to enhance stability.
barge	A long, large, usually flat bottomed, unpowered boat which is towed by other craft and is used for water transport of bulky materials or large objects.
barge slip	A docking place for a barge.
base flood	A flood which has a 1 percent chance of occurrence in any given year. Also referred to as a 100-year flood.
bathymetric	Related to the measurement of the depth of large bodies of water.
benthic	Pertaining to the bottom of the ocean.
benthic boundary layer	A zone which separates the water at the deep layers of the ocean from waters directly above. Waters below the benthic boundary layer have relatively greater mixing properties.
best estimate	An estimate in which the factors used in determining the estimate were chosen such that the result approximately represents what would be expected.
beta particle	[Symbol β (beta)] A charged particle emitted by certain radioactive materials. It has a unit electrical charge and a mass which is equal to 1/1837 of a proton. A negatively charged beta particle is identical to an electron and is the more common form of beta activity. A positively charged beta particle is called a positron and is less common. Exposure to large levels of beta particles may cause skin burns, and materials that emit beta particles are harmful if they enter the body. Most beta particles are stopped by a few millimeters of lead or steel.
biofouling	A process in which the growth of plants and animals on the surface of metals causes the corrosion of the metals to increase.

biological half-life	See half-life, biological.
biosphere	All regions of the earth that support self-sustaining and self-regulating ecological systems.
biota	Plant and animal life.
bioturbation	A process in which the upper layers of sediment on the ocean bottom are mixed or disturbed by marine organisms living in or upon the sediment.
bow	The front section of a ship or boat.
bulkhead	An upright, thick, metal partition that divides a ship into compartments.
cement	The principal constituent of concrete, mortar, and grout which effects the bonding of the mixture through hydration. Main ingredient is limestone.
check valve	A device which permits flow in only one direction through pipes or openings.
cladding	A metal casing that surrounds the nuclear fuel.
coagulate	To transform particles which are in a fluid medium into a soft, semisolid, or solid material.
coastal zone	The region along the shore, adjacent to the ocean. A coastal zone is usually defined as the region within three nautical miles of a shoreline.
colloidal	Pertaining to a suspension of particles in water.
concentration factor	A factor which is defined as the concentration of an element or radionuclide in an organism or its tissues divided by the concentration directly available from the organism's environment under equilibrium or steady state conditions.
concrete	A mixture of cement, sand, and aggregate combined with water to form a slurry which hardens through hydration.
concreting head	A device to allow concrete to be pumped into the upper end of a suspended drill pipe.
conservative estimate	An estimate in which the factors used in determining the estimate were chosen such that the result would be unlikely to be exceeded.
containment	The result of enclosing and confining radioactive materials so that the radioactivity cannot be released to the environment.
continental rise	The lower portion of the continental slope.
continental shelf	A generally shallow and relatively flat submerged portion of a continent that extends to a point of steep descent to the ocean floor.
continental slope	The relatively steep area between the continental shelf and the deep-sea floor.
core	The central portion of a nuclear reactor containing the nuclear fuel.
coring	A method for sampling sediments.
corrosion	The process denoting the destruction of metal by chemical or electrochemical action.

corrosion products — The substances produced by corrosion of a metal. Rust is a common corrosion product resulting from the corrosion of iron.

corrosion release rate — Specifies the rate at which corrosion products move away from a corroding surface.

corrosion resistant alloy — An alloy which corrodes slowly compared to ordinary alloys. Stainless steel is an example of a corrosion resistant alloy.

crawler transporter — A large tracked vehicle which is capable of carrying extremely heavy loads either on paved roads or over unpaved terrain.

crinoid — Marine organisms which are characterized by feathery, radiating arms and a stalk by which they attach themselves to a surface. This includes sea lilies, feather stars, and stalked echinoderms.

critical habitat — Specific areas occupied by a species which contain physical or biological features which are essential to the conservation of the species and which may require special management considerations or protection.

critical organ — The limiting organ for evaluating exposure to ionizing radiation. A critical organ is determined by the following criteria: (1) the organ that accumulates the greatest concentration of a radioactive material, (2) the necessity of the organ to the well being of the entire body, (3) the organ most damaged by the entry of a radionuclide into the body, and (4) the organ damaged by the lowest dose. Usually case (1) is the determining factor for choosing the critical organ.

critical pathways — Those pathways which result in the most significant amount of exposure to radiation.

crud — In this statement, the corrosion products which have been activated by passing through the nuclear core during reactor operations and are deposited on and adherent to metal surfaces.

crustacea — Marine organisms which are characterized by a skeleton on the outside of the body and paired, jointed limbs. This includes lobsters, crabs, and shrimp.

curie — [Abbreviation Ci] A unit of radioactivity. One curie of radioactivity in a material results in 37 billion (3.7×10^{10}) nuclear disintegrations per second. This unit does not give any indication of the radiological hazard associated with the disintegration.

decay constant — [Symbol λ (lambda)] A constant which describes the rate at which a radionuclide will undergo the process of radioactive decay. In the equation $N = N_0 e^{-\lambda t}$, N_0 is the initial number of radioactive atoms present, e is the base of the natural system of logarithms, λ is the decay constant, and N is the number of radioactive atoms present after some time t. If N is equal to one-half of N_0, then t is the half-life of the radionuclide.

decay, radioactive — The process of spontaneous transformation of a radioactive nuclide to a different nuclide or different energy state of the same nuclide. Radioactive decay involves the emission of alpha particles, beta particles, or gamma rays from the nuclei of the atoms. If a radioactive nuclide is transformed to a stable nuclide, the process results in a decrease of the number of original radioactive atoms. Radioactive decay is also referred to as radioactive disintegration.

decommission	As used in this statement, to remove a submarine from active service.
defuel	To remove all of the nuclear fuel from a submarine.
demilitarization	The process by which equipment designated for disposal is altered such that any remaining equipment would not reveal any information of military value.
deposited activity	See crud.
detritus	The loose fragments, particles, grains, fecal pellets, or debris which descend to the ocean floor from shallower depths.
diffusion	The process of spreading out or scattering from regions of higher concentration to regions of lower concentration.
diffusivity	See eddy diffusivity.
disintegration, nuclear	A spontaneous nuclear transformation which is characterized by the emission of particles and/or energy from the nucleus of an atom.
dispersion	The process of scattering or distributing over a large region.
diving planes	Horizontal, hinged, movable sections which are mounted on a submarine to control the angle of descent or ascent.
dose	A general term which denotes the quantity of radiation or energy absorbed; usually expressed in rems for doses to man.
dose commitment	The total radiation dose accrued by an individual over a specified period of time due to the exposure of the individual to radiation during a given interval of time. This includes the total time the radioactive material would reside in the body, if ingested or inhaled. Dose commitments are usually expressed in rems and in this EIS generally represent the dose over 70 years following exposure for one year.
dose commitment conversion factor	A factor which converts the quantity of radioactivity taken into the body to the dose to the individual; usually expressed in rems per curie.
dose equivalent	A quantity used to express all radiations on a common scale for calculating the effective absorbed dose. It is defined as the product of the absorbed dose (in rads) and certain modifying factors and is expressed in rems.
dose rate	The amount of radiation dose delivered in a unit amount of time, for example, in rems per hour.
dose rate conversion factor	A factor which converts the exposure to a given radiation level to the dose that an individual could receive. It is usually expressed in rems per hour per curie per cubic meter (or square meter).
dredge spoil	Bottom sediments or materials that have been excavated from a waterway.
drill pipe	A pipe made up of sections used to turn a drilling bit used in the process of drilling into the earth's surface. The pipe may also carry various liquids used in the drilling process.
drogue	A device which is attached to a falling object to retard its speed, for example, a parachute.

dry dock	A large floating or stationary dock from which water can be emptied and is used for maintaining, repairing, or altering a ship.
echinoderms	Phylum of radially symmetrical marine animals consisting of starfishes, sea urchins, and their related forms.
echinoid	Marine organisms which are radially symmetrical and are characterized by a body covered with spines. This includes starfish, sea urchins, and sea cucumbers.
echogram	The mapping of the sea bottom using sound waves to determine the topography of a region.
ecology	The interrelationships between organisms and their environments. Also, the study of these interrelationships.
economic zone	The region of the ocean which is within 200 nautical miles of the shoreline.
ecosystem	A community of plant and animal populations together with their physical environment. An organizational unit which can maintain its biological activities independent of other units.
eddy	A water current that moves contrary to the direction of the main water current.
eddy diffusivity	A term used to describe how eddies, tides, and other processes besides currents affect diffusion or dispersion of materials in the ocean waters.
electron	A negatively charged particle with a mass which is equal to 1/1837 of a proton.
element	A chemical substance that cannot be divided into simpler substances by chemical means. A substance whose atoms all have the same atomic number.
endangered species	A species or subspecies which is in danger of extinction throughout all or a significant portion of its range.
epibenthic	Living on the sea bottom.
erg	A basic unit of work or energy. One erg is equal to approximately 7.4×10^{-8} foot pounds of energy.
excess	The state of being no longer required or of insufficient value for retention.
exposure, external	The subjecting of the outside of the body of an organism to ionizing radiation.
exposure, internal	The subjecting of the inside of the body of an organism to ionizing radiation.
exposure, occupational	The subjecting of an individual to ionizing radiation in the course of employment.
exposure, radiation	The subjecting of a material or organism to ionizing radiation.
fathom	A unit of water depth which is equal to six feet.
fathometer	A trademark for an instrument which is used for determining the depth of water by using sound waves.
fauna	Animals.

filament	As used in this statement, a long shallow section of cool, upwelled water on the ocean surface, extending out from the coast.
fissile	A material whose nucleus is capable of being split (fissioned) by neutrons of all energies.
fission	The splitting of a heavy nucleus into two approximately equal parts which is accompanied by the release of a relatively large amount of energy and generally one or more neutrons.
fission products	The nuclei formed by the splitting (fissioning) of heavy elements, plus the nuclides formed by radioactive decay of the fission products.
floodplain	The lowlands which adjoin inland and coastal waters and relatively flat areas and floodprone areas of offshore islands which are covered with water from a 1 percent or greater chance flood in any given year.
floodplain/wetlands assessment	An evaluation which consists of a description of a proposed action, a discussion of its effects on the floodplain/wetlands, and a consideration of alternatives.
flora	Plants.
food web	The description of the flow of energy and matter between organisms in an ecosystem. Food webs are combinations of several food chains.
fuel	Fissionable material used or useable to produce energy in a nuclear reactor. It may also refer to a mixture, such as natural uranium, in which only part of the atoms are readily fissionable.
g	An abbreviation for the acceleration due to gravity at the earth's surface; also, abbreviation for gram.
gamma ray	[Symbol γ (gamma)] High-energy, short wavelength electromagnetic radiation. Gamma radiation frequently accompanies beta particle emissions. Gamma rays are very penetrating and are stopped most effectively by dense materials such as lead or uranium. They are essentially similar to x-rays but are usually more energetic and originate from the nucleus. Cobalt-60 is an example of a radionuclide that emits gamma rays.
geochemistry	The chemistry of the composition and alterations of the earth's crust.
geology	The study of the origin, history, materials, and structure of the earth.
gross beta activity	Beta particle emissions from a material with no specific identification of the radionuclides present in the material.
groundwater	Water that exists or flows beneath the earth's surface in the zone of saturation between saturated soil and rock.
grout	A mixture of cement and water.
gyre	A circular or spiral form. Used mainly in reference to the circular motion of water in each of the major ocean basins centered in subtropical high pressure regions.
half-life, biological	The time required for a biological system, such as an organ or tissue in an organism, to clear by natural (nonradioactive) processes, half the amount of a substance that has entered it.

half-life, radioactive	The time required for half of the atoms of a radioactive material to decay to another nuclear form.
herpetofauna	Reptiles and amphibians. This includes snakes, lizards, crocodiles, turtles, frogs, toads, and salamanders.
holothurian	A class of echinoderms including the sea cucumbers.
hull	The thick metal casing which forms the outer covering of a submarine.
hydrology	The study of the properties, distribution, and effects of water on the earth's surface, in the soil and underlying rocks, and in the atmosphere.
hydrostatic pressure	The pressure caused by the weight of fluids at rest. In the ocean, hydrostatic pressure increases with increasing depth.
induced activity	See activation.
inner bremsstrahlung	Electromagnetic radiation produced by the sudden retardation of an electrical particle (electron or positron) in the intense electrical field of the atomic nucleus.
ion	An atom or molecule which has acquired an electrical charge by gaining or losing electrons.
ionizing radiation	Any radiation which displaces electrons from atoms or molecules, thereby producing ions. Examples include alpha, beta, and gamma radiation. Exposure to ionizing radiation may produce skin or tissue damage.
irradiate	To expose to radiation.
isotope	One of two or more nuclides which have the same number of protons but have different numbers of neutrons in their nuclei. Therefore, the isotopes of an element have the same atomic number but different atomic weights. Isotopes usually have very nearly the same chemical properties but somewhat different physical properties.
knot	A unit of speed which equals 1 nautical mile per hour or approximately 1.15 statute miles per hour.
land disposal option	A disposal option in which the entire section containing the radioactive portions of the nuclear power plant is cut free from the rest of the submarine and then moved to and buried at a U. S. Department of Energy operated radioactive waste burial site.
leachate	The liquid that has percolated through a material along with the soluble constituents of the material.
list	The tilting of a ship to one side.
lithology	The study of rocks.
long-lived radioactivity	Radioactive nuclides which decay slowly, therefore, having relatively long half-lives. In this statement, it refers to those radionuclides with half-lives that are long in comparison to the expected time required for penetrating their containment; therefore, the following radionuclides are considered long-lived: Carbon-14,

Nickel-59, Molybdenum-93, Niobium-94, and Technetium-99. Nickel-63 is considered an intermediate between short-lived and long-lived radioactivity (see short-lived radioactivity).

LORAN — An acronym for long-range navigation. It is a long-range navigation system based on the use of pulsed radio signals for establishing position by analyzing the time delay between pulses.

low alloy steel — A high strength structural steel which generally contains less than five weight percent of total alloying additions.

manometer — An instrument which is used to measure pressure.

man-rem — A unit used to measure the radiation exposure to an entire group and to compare the effects of different amounts of radiation on groups of people. It is obtained by multiplying the average dose equivalent (measured in rems) to a given organ or tissue by the number of persons in the population of interest.

maximum individual — An individual who could consume items or occupy areas at rates which would be at a maximum for the population of interest.

maximum organ — The organ which receives or could receive the largest amount of exposure to radiation.

mega fauna — Bottom-dwelling marine organisms whose presence and abundance is typically assessed photographically or by capture by trawls and nets.

mesoscale eddies — Eddies which occur over hundreds of kilometers and with time scales of months and longer.

metric ton — [Abbreviation MT] A unit of mass which is equal to 1000 kilograms or approximately 2205 pounds.

MeV — An abbreviation for the energy unit of one million electron volts. One MeV is equal to one million (1×10^6) electron volts or approximately 1.6×10^{-6} ergs.

microcurie — [Abbreviation μCi] A unit of activity which is equal to one-millionth (1×10^{-6}) of a curie.

mil — A unit of length which is equal to one-thousandth (1×10^{-3}) of an inch.

millicurie — [Abbreviation mCi] A unit of activity which is equal to one-thousandth (1×10^{-3}) of a curie.

millirem — [Abbreviation mrem] A special unit for measuring dose equivalents which is equal to one-thousandth (1×10^{-3}) of a rem.

mollusc (or mollusk) — Marine organisms which include oysters, clams, mussels, squids, and octipi.

monitoring, environmental — The periodic or continuous determination of the amount of radioactivity or radioactive contamination present in a region.

mortar — A mixture of cement, sand, and water.

nautical mile — A unit of length which is equal to 1852 meters or approximately 1.15 statute miles.

neutron	[Symbol n] An uncharged particle with a mass slightly greater than that of a proton, found in the nucleus of every atom heavier than hydrogen. Neutrons sustain the fission chain reaction in a nuclear reactor.
neutron activation	The process of making a material radioactive by exposing the material to neutrons.
neutron irradiation	The exposure of a material to neutrons.
nuclear fuel	See fuel.
nuclear reactor	A device in which nuclear fission is initiated and controlled to produce heat which is then used to generate power.
nuclear submarine	A submarine which is propelled by the power produced by a nuclear reactor.
nucleus	The positively charged central region of an atom which is composed of protons and neutrons and contains almost all of the mass of an atom.
nuclide	An atomic form of an element which is distinguished by its atomic number, atomic weight, and the energy state of its nucleus. These factors determine the other properties of the element, including its radioactivity.
oceanography	The study of the ocean and its properties.
organ	A group of tissues which together perform one or more definitive functions in a living body.
organism	Any living plant or animal.
otter trawl	A trawl using otter boards to spread the net. The otter boards are attached to each side of the net's mouth and are caused to flare apart by pressure of the water.
particulate	Pertaining to a very small piece or part of a material.
pathway	In this statement, it refers to the route or course along which radionuclides from disposed and defueled nuclear submarines could reach man.
pathway entry point	In this statement, it refers to the location where a radionuclide could initially enter a pathway.
pelagic	Pertaining to anything which lives or occurs in the open ocean, as opposed to living or occurring in waters adjacent to land or inland waters.
pelagic clay	Clay which is found on the ocean floor.
percolate	To drain or seep through a material.
pH	A measure of the relative acidity or alkalinity of a solution. A neutral solution has a pH of 7, acids have pH's less than 7, and bases have pH's greater than 7.
photon	An indivisible unit of energy generally regarded as a discrete particle which has zero mass and no electrical charge.
picocurie	[Abbreviation pCi] A unit of activity which is equal to one-trillionth (1×10^{-12}) of a curie.

pinger	A device which emits a pinging sound and is attached to an object so the object can be located.
pipe string	A long length of multiple sections of drill pipe.
pitch	The alternate dipping of the bow and stern of a ship.
pitting	A localized corrosion process where the rate of corrosion is greater than the general rate of corrosion; usually resulting in the formation of small openings in the material.
plankton	The generally microscopic plant and animal organisms that float or weakly swim in a body of water.
positron	A positively charged particle with a mass equal to 1/1837 of a proton.
primary system	The portion of a nuclear reactor plant that contains the nuclear fuel and main coolant. The coolant is heated by flowing past the fuel (see secondary system).
protective storage	The storage of a defueled, decommissioned submarine at a location in which it is floating on water, periodically inspected, and guarded to limit personnel access.
proton	A stable, positively charged particle in the nucleus of an atom.
rad	An acronym for radiation absorbed dose. It is the basic unit for measuring the energy absorbed in a material from ionizing radiation. A dose of one rad is equal to the absorption of 100 ergs of radiation energy per gram of absorbing material.
radiation	The emission and propagation of energy through matter or space by means of electromagnetic disturbances which display both wave-like and particle-like behavior. In this context, the "particles" are known as photons. The term has been extended to include streams of fast-moving particles such as alpha and beta particles, free neutrons, and cosmic radiations. Nuclear radiation is that which is emitted from atomic nuclei in various nuclear reactions and includes alpha, beta, and gamma radiation and neutrons.
radiation field	A region where radiation is present.
radiation level	The measured amount of radiation in a region.
radiation survey	The evaluation of an area or object with instruments to detect, identify, and quantify radioactive materials and radiation fields which may be present.
radioactive contamination	The deposition of radioactive material in any place where it may harm persons, invalidate experiments, or make products or equipment unsuitable or unsafe for some specific use. The presence of unwanted radioactive matter.
radioactivity	The process of spontaneous decay or disintegration of an unstable nucleus of an atom; usually accompanied by the emission of ionizing radiation.
radioisotope	An unstable isotope of an element that decays or disintegrates spontaneously and emits radiation. More than 1300 natural and artificial radioisotopes have been identified.
radionuclide	A radioactive nuclide.

reactor compartment	A separate compartment in a nuclear submarine that contains the nuclear reactor and associated structural components and equipment.
reactor vessel (or reactor pressure vessel)	A very strong, thick-walled steel structure which contains the nuclear fuel and cooling water under high pressure during reactor operation.
rem	An acronym for roentgen equivalent man. A special unit for measuring dose equivalents. A rem gives the same biological effects as one roentgen of x-rays. One rem equals approximately one rad for x-ray, gamma, or beta radiation.
river stage	The level of the surface of a river in relation to some reference elevation.
roentgen	[Abbreviation r] A unit of exposure to ionizing radiation. One roentgen equals the amount of gamma rays or x-rays required to produce ions with one electrostatic unit of electrical charge (either positive or negative) in one cubic centimeter of dry air under standard conditions.
roll	To move or rock a ship from side to side.
salinity	The total amount of dissolved salt in seawater.
sea disposal option	A disposal option in which the entire submarine, after appropriate preparations, would be towed to sea and sunk in an area where the water depth exceeds 4000 meters.
sea urchin	Sea animal of somewhat flattened globular form, with a thin brittle shell, covered with sharp movable spines.
secondary system	The portion of a nuclear reactor plant where steam is produced and used to drive a propulsion turbine or turbine generator. The water in the secondary system is heated by the water in the primary system but does not come in contact with the fuel or other radioactive material (see steam generator).
sediment	Particles of organic or inorganic origin that accumulate in loose form.
seismic	Pertaining to an earthquake or earth vibration.
sessile	Staying in the same place.
shear	To deform a material by subjecting it to forces that tend to produce an opposite but parallel sliding motion of the material.
short-lived radioactivity	Radioactive nuclides which decay rapidly, therefore, having relatively short half-lives. In this statement, it refers to those radionuclides with half-lives that are short in comparison to the expected time required for penetrating their containment; therefore, the following radionuclides are considered short-lived: Sulfur-35, Scandium-46, Chromium-51, Manganese-54, Iron-55, Cobalt-58, Iron-59, Cobalt-60, Zirconium-95, and Hafnium-181. Nickel-63 is considered an intermediate between short-lived and long-lived radioactivity.
soluble	Capable of being dissolved. When water is the dissolving medium, it is often defined in operational terms as being the material in water that is able to pass through a filter having openings smaller than 0.45×10^{-6} meters or approximately 1.77×10^{-5} inches.

sonobuoy	A device which floats in water and receives sound waves and is used to locate items or areas.
sorptive	Pertaining to the ability to sorb;* i.e., to take up and hold, as by absorption or adsorption.
special nuclear material	Materials containing nuclides such as Plutonium-239, Uranium-233, or uranium enriched to a higher percentage than normal in the Uranium-235 isotope.
specific activity	The ratio between the amount of radioactive isotope present and the total amount of all other isotopes of that same element, both radioactive and stable. It is usually expressed in microcuries of radioisotope per gram of total element.
sponson	A buoyant section of hull added to an existing ship hull at the waterline and extending approximately 75 percent of the length of the hull.
stable atom	An atom that does not undergo radioactive decay.
statute mile	A unit of length which is equal to 5280 feet.
steam generator	The portion of the nuclear power plant where the heat from the primary system is transferred to the secondary system without physical contact between the water in the two systems.
stern	The rear section of a ship or boat.
submarine canyon	A canyon which exists on the ocean bottom.
survey meter	Any portable instrument which is used to detect radiation and is especially adapted for surveying or inspecting an area to establish the existence and amount of radioactive material present.
swivel head	A device which allows the introduction of liquids at the top of a drill pipe while the pipe is being rotated.
tectonic	Pertaining to or designating the rock structures which result from the deformation of the earth's crust.
thermocline	The zone of rapid temperature change which separates the layers of ocean water nearer the surface, which are subject to periodic variation in temperature, from the deeper layers of the ocean water where temperatures are essentially unvarying over time.
thermoluminescent dosimeter	[Abbreviation TLD] An instrument used to detect and measure accumulated radiation exposure. Commonly used for personnel and environmental monitoring purposes.
threatened species	Any species or subspecies which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.
topography	The detailed physical description of the surface of a region, including the relative elevations of features. The graphical representation of the physical configuration of a region on a map.

tracer	An identifiable substance, such as a dye or radioactive isotope, that can be followed through a physical or biological process to provide information on how the process works.
transfer coefficient	A mathematical factor which describes the rate or probability of movement of a material from one location to another.
transmissivity	A coefficient that relates the volume of flow of a substance through a unit width of groundwater to the driving force (hydraulic potential) that tends to push the volume through the unit width of groundwater. It is a function of the porosity of the medium, the fluid properties, and the saturated thickness of the aquifer.
transmutation	Any process in which a nuclide is transformed into a different nuclide or more specifically into a different element by a nuclear reaction.
transuranic element	An element with an atomic number greater than 92 (uranium). All transuranic elements are produced artificially and are radioactive. They include neptunium, plutonium, americium, curium, berkelium, californium, einsteinium, fermium, mendelevium, nobelium, and lawrencium.
turbidity currents	Ocean water currents caused by slides of sediments down an ocean slope, resulting in the currents being laden with silt. Turbidity currents can reach speeds of up to 50 knots.
upwelling	A process in which the water at lower levels in the ocean moves to higher levels.
uranium	[Symbol U] A natural radioactive element with the atomic number 92 and, as found in natural ores, an average atomic weight of approximately 238. The two principal natural isotopes are Uranium-235 (0.7 percent of natural uranium) and Uranium-238 (99.3 percent of natural uranium). Natural uranium also includes a minute amount of Uranium-234.
vadose zone	The unsaturated region of soil located between the ground surface and water table.
waste, radioactive	Equipment and materials which are radioactive and for which there is no further use. Radioactive wastes are generally classified as high-level waste (those resulting from reprocessing reactor fuel or the used reactor fuel itself), as low-level waste, or as low-level waste containing transuranic elements or Uranium-233.
watershed	The region which drains into a river, river system, or body of water.
water table	The upper surface boundary of an unconfined aquifer, below which groundwater occurs. It is usually defined by the levels at which water stands in wells that barely penetrate the aquifer.
watt	A basic unit of power. One watt is equal to 1×10^7 ergs per second, and approximately 746 watts equals one horsepower.
wetlands	Those areas which are covered by water with a frequency sufficient to support a prevalence of vegetative or aquatic life that requires saturated or seasonally saturated soil conditions for growth and reproduction. Wetlands generally include swamps, marshes, bogs, and similar areas such as sloughs, potholes, wet meadows, river overflow, mudflats, and natural ponds.

x-rays

Penetrating electromagnetic radiations with wavelengths shorter than those of visible light. They are usually produced (as in medical diagnostic x-ray machines) by irradiating a metallic target with large numbers of high-energy electrons. In nuclear reactions, it is customary to refer to photons originating outside the nucleus as x-rays and those originating in the nucleus as gamma rays, even though they are the same.

Tailored to Your Needs!

Selected Research In Microfiche

SRIM® is a tailored information service that delivers complete microfiche copies of government publications based on your needs, automatically, within a few weeks of announcement by NTIS.

SRIM® Saves You Time, Money, and Space!

Automatically, every two weeks, your SRIM® profile is run against all *new* publications received by NTIS and the publications microfiched for your order. Instead of paying approximately $15-30 for each publication, you pay only $2.50 for the microfiche version. Corporate and special libraries love the space-saving convenience of microfiche.

NTIS offers two options for SRIM® selection criteria:

Standard SRIM®–Choose from among 350 pre-chosen subject topics.

Custom SRIM®–For a one-time additional fee, an NTIS analyst can help you develop a keyword strategy to design your Custom SRIM® requirements. Custom SRIM® allows your SRIM® selection to be based upon *specific subject keywords*, not just broad subject topics. Call an NTIS subject specialist at (703) 605-6655 to help you create a profile that will retrieve only those technical reports of interest to you.

SRIM® requires an NTIS Deposit Account. The NTIS employee you speak to will help you set up this account if you don't already have one.

For additional information, call the NTIS Subscriptions Department at 1-800-363-2068 or (703) 605-6060. Or visit the NTIS Web site at *http://www.ntis.gov* and select SRIM® from the pull-down menu.

Abstract: Volume 2 presents comment letters and the records of public meetings conducted by the Navy on the Draft Environmental Impact Statement. The public comment period on the Draft Environmental Impact Statement extended from December 22, 1982 to June 30, 1983; however, all comments received through the end of August 1983 are included. The letters and statements have been reproduced exactly as received from their authors or from the records of the public meetings. Where petitions were submitted, the transmittal letter, a copy of the petition, and the number of signers have been included, but the actual list of signatures has not been reproduced. For handling convenience, the volume is divided into Book 1 and Book 2. Unique identification numbers have been assigned to each letter and statement. The identification numbers correspond to the sequence in which the material was received by the U.S. Navy and, therefore, approximate a chronological correlation. An Author Index and an Exhibit Index are provided at the end of Book 2 of the volume.

i.b

INTRODUCTION

Volume 2 presents comment letters and the records of public meetings conducted by the Navy on the Draft Environmental Impact Statement. The public comment period on the Draft Environmental Impact Statement extended from December 22, 1982 to June 30, 1983; however, all comments received through the end of August 1983 are included. The letters and statements have been reproduced exactly as received from their authors or from the records of the public meetings; however, they are half-size to save space. Where petitions were submitted, the transmittal letter, a copy of the petition, and the number of signers have been included, but the actual list of signatures has not been reproduced. For handling convenience, this volume is divided into Book 1 and Book 2.

Unique identification numbers have been assigned to each letter and statement. The identification numbers correspond to the sequence in which the material was received by the U.S. Navy and, therefore, approximate a chronological correlation. An exception to this chronological order occurs where a respondent provided more than one exhibit. In these cases the identification number for the first submittal was assigned in order and suffix letters have been used with the initial identification number to differentiate submittals.

Exhibits have been sidebarred to identify issues which have been numbered according to the order in which they are presented in Volume 3. The analyses and responses to issues can be located in Volume 3 by using these issue numbers. For example Issue A.1 is the first issue in Section A of Volume 3.

An Author Index and an Exhibit Index are provided at the end of Book 2 of this volume. Both of these indices are comprised of listings of three associated identifiers: (1) name of respondent or organization, (2) identification number assigned to the associated letter or statement, and (3) the page number within Volume 2 where the letter or statement begins. The Author Index lists the letters and statements in alphabetical order by the name of the first author or organization. The Exhibit Index lists each letter or statement by numerical sequence of identification number. The combination of these indices provides a cross reference for readers to readily locate exhibits of a known author and to relate exhibits of interest to respective authors.

CARTERET COUNTY COURT HOUSE

BOARD OF COUNTY COMMISSIONERS

CARTERET COUNTY

BEAUFORT, N.C.

January 5, 1982

Captain Edward F. Wagner
U. S. Navy
Office of the Chief of Naval Operations (OP-22)
Department of the Navy
Washington, D. C. 20350

Subject: Public Comment-Draft Environmental Impact State,
Disposal of Decommissioned Defueled Naval
Submarine Reactor Plants

Dear Captain Wagner:

The Board of County Commissioners of Carteret County has reviewed, discussed and taken formal action on the subject Draft.

While admittedly not experts in the field of nuclear waste disposal and the consequences thereof, we do feel our comments reflect a consensus of feeling among our constituents.

We oppose the Ocean Disposal option for the following reasons:

J.42 1. We do not feel the time factor associated with the USS THRESHER and USS SCORPION (20 years and 15 years respectively) is sufficient to accurately determine the long-term effect of radiation on the surroundings.

L.8 2. We remain unsure as to the cumulative impact of several dozen reactor vessels situated in relatively close proximity.

F.15 3. Being a coastal community, we are familiar with the hazards of ocean towing operations, especially off the notorious Cape Hatteras coast.

L.20 4. Even though preparations will have been made to maximize a controlled sinking situation, it is also true that once the scuttle-cocks have been opened

on the submarines, events afterwards are completely beyond the control of the Navy. Total supervision and control over disposal operations will not be possible as it would be with land disposal. L.20

5. Our community is almost totally ocean oriented. Tourism, commercial fishing and sports fishing is the very essence of our livelyhoods and activities. Our citizens hold a very real concern over any activities which would in any way affect them and future generations. L.53

We favor the Land Disposal option for the following reasons:

1. Land disposal of radioactive is a proven method as experienced by the waste generated from commercial power plants.

2. Disposal sites are available and their use generally accepted.

3. Utilization of only 10 acres of land versus 100 square miles of ocean bottom is advantageous. E.15

4. Transport and disposal operations would not be as sensitive to weather conditions or other unforeseen factors. F.15

5. Supervision and control throughout the total operation would be possible. E.15

We appreciate the opportunity to comment on the Draft. We are confident that the concerns evident within the coastal communities will weigh heavily during the decision-making process.

Yours truly,

Mary Sue Noe

Mary Sue Noe, Chairperson
BOARD OF COUNTY COMMISSIONERS
CARTERET COUNTY, NORTH CAROLINA

cc: Board of County Commissioners
Walter B. Jones, Congressman

#3

PS This letter represents the views of thousands of people (most probably hundreds of thousands) who cannot make/take the time to write. I make the time, since my energy. LISTEN Please respond with a personal letter answering my questions.

Mrs Eleanor Lewallen
Box 372
Navarro Ca 95463
December 29, 1982.

Captain Edward Wagner
US Navy Office of Naval Operations
Dept of Navy. Washington DC 20350

Dear Captain Wagner,

As I write to you, I am recuperating from a hospitalized illness, have a headache & hurting throat, yet the importance of preventing the proposed dumping of radioactive submarine reactor plants causes me to write. I have been reading the information that the Navy, Sandia, & the EPA puts out & have the Draft EIS before me.

I'm going to comment directly to you and I want you to hear with your mind & heart, as an inhabitant of planet earth ~~what~~ the truth of what I am saying.

THE OCEAN IS NOT YOURS TO POISON. YOU HAVE NO RIGHT TO DUMP RADIOACTIVE MATERIALS INTO OUR OCEAN. OUR OCEAN BELONGS TO ALL OF US, PLANET EARTH and ALL OF HER INHABITANTS. IT IS IMMORAL & SHOULD BE ILLEGAL

L.36
L.14

FOR ANYONE (or AGENCY or GOVERNMENT) TO HARM the LIFE FORMS (all of us, fish, sea vegetable, etc) WHO DEPEND ON A HEALTHY UNPOISONED OCEAN for LIFE. Who will take responsibility for the great harm which the navy proposes to do to our ocean? Will you? Does anyone

2

in the navy really care? Or in the EPA? We live here. We make our living from the ocean, but I'd be writing this letter even if that were not the case. I have been a devoted environmentalist and educator for over two decades & much of my energy has gone for protecting the earth.

Our family of four (we have 2 young children) is supported by our small sea vegetable business. We supply hundreds to thousands of people with wholesome, mineral-vitamin-etc filled sea vegetables from the Mendocino county coast. Our business and thousands of other fishermen's businesses will be ruined if you dump those subs. L.53

WHERE IS RESPONSIBILITY for the EARTH and OCEAN. I don't even see how you could consider dumping these man invented monstrosities into the ocean, on which life depends.

I urge you to have & personally come to hearings in Fort Bragg in 1983 & listen to us. Spend some time here & become earth bonded. I believe that most people in the defense department have lost touch with the earth and basic things such as respect for living things, being surrounded by fear and paranoia. Politics would take another whole letter. Look into your heart and soul. Come to see us here. Listen to us. Peace be with you & your family & in our world in 1983. Sincerely, Mrs Eleanor Lewallen

#3b

Box 372
Navarro, Ca 95463
April 6, 1983

Captain Edward F Wagner
Dept. of Navy
Office of Chief of Naval Operations
Washington DC 20350

Dear Captain Wagner,

This letter is a comment on the DEIS and the Navy's proposed plan to dump radioactive submarine reactor plants (or hulls, or any part there of) into the ocean. NO! It is not a good plan. It is a bad, harmful, and frankly unwise plan. [Were I to also add "stupid" that would sound insulting, so skratch that. My intent is not to insult or anger people who propose this plan.] My purpose is simply to say NO, there's a better way AND we need to change our national priorities and stop producing radioactive weapons which soon become poisonous wastes - all with no safe means of disposal.

My older brother Dr. Joel Leventhal who works for the USGS in Colorado who is a geochronologist and works w/ radioactive
H.2 carbon dating, etc suggested that radioactive waste be stored deep in stable areas of the earth - ask him ... Or I suggest, in the
H.4 area of the Nevada or other test site desert unpopulated all ready irradiated areas.

As I write my two young children are playing & interrupting me. It is a calm sunny spring day as I sit by light blue forget me not flowers w/ a variety of bees buzzing around collecting nectar & pollinating flowers. I need to cut wood to keep us warm tonight, but this letter has to come first. I mention this because I do make the time. There are millions of mothers in our country & the world over who cannot make or take the time to write who love their children and the world as much as I - and I know. I am speaking for them and you must listen to us because we are the majority of the world's population who do not

NOTE: Also see Exhibit 3

2

want nuclear war to happen or to harm/kill/maim ANYONE. NO! You don't have our permission. And the sub dumping issue is related to the whole area of nuclear weapons development, manufacture & threat. We are all nuclear hostages now and it is our government as well as the Soviets who are the terrorists, threatening us every day by planning & thinking the unthinkable and the unacceptable. We must make peace, SHALOM & STOP making nuclear & lager war tools immediately. It's insane to go on like this.

Captain Wagner, I'm directing this letter to you and these words to you because of the position you currently hold. [My children want to talk & eat, but I say no, I have to write this now! -]

Enclosed is the book The Hundredth Monkey by Ken Keyes, Jr. Please read it and include it as part of my comments to the DEIS. I would be glad to have anyone read it before including it in the comment packet - on second thought, I'm enclosing 2: one for you & your colleagues, one for the comment section. They are compliments of the Anderson Valley Nuclear Awareness Committee. We have fund raisers & yard sales to raise our funds for education about nuclear issues.

Now: What I really want to say & want all readers of this letter to hear: The oceans cover the majority of the earth's surface. They live and flow as an interconnected entity. The oceans are holy. All life in the oceans are holy and to be respected and revered. Our health, the health of our earth, our oceans depend on how we relate to them. We now have the

F.8 | opportunity to set a world wide precedent:
<u>No</u> <u>ocean</u> <u>dumping</u> <u>of</u> <u>radioactive</u> <u>waste</u>.
The USA can lead the way in this.
Were we (the gov't) to put our energy in a loving direction instead of greed and fear, there is a good chance that we <u>could</u> change the course of the history of our earth and humankind.
There is no need for armageddon or any greed or wars. Our mother earth really does provide — and its our job to protect and nurture her as well as our families and communities.
Captain Wagner, you heard us speak, you met us face to face in Sacramento.* I'm glad you were the person selected to come, because I could see in your eyes and body language that you <u>were</u> <u>hearing</u> <u>us</u>. Next is what you do, having heard the expertise, experience and wisdom from the ocean guardians of (many) all walks of life. You have the choice to heed

* Please send me a copy of testimony given in Sacramento on Feb 24 at the navy's hearing. I urge all readers of this letter to request a copy. It contains expert testimony all criticizing the navy's DEIS. It's a MAJOR commentary.

our wisdom and use every bit of power and influence you have to protect <u>OUR</u> ocean — and this means ~~ag~~ <u>everyone</u> <u>reading</u> <u>this letter</u> or you can choose to disregard it. I wrote <u>many</u> (similar) letters to Anne Gorsuch about the ocean & the navy's plan, specifically, and ~~on~~ being an earth guardian in general. I devoted a lot of time and energy trying to really reach her on the levels of ethics, morality, concern for the earth — using her power & position to do good. She did not heed my letters & now she's out of the E.P.A. Had she followed my most reasonable suggestions, she might have been removed for not following orders of the gov't & big business, but she might have been a heroine — a true earth guardian. What I'm saying is that you have a real opportunity to use your position, knowledge, & caring — to really help the ocean and the American people. Please do that. Your work will be rewarded. We will thank you. The ocean will not be poisoned needlessly — we will be closer to creating a ~~toxic~~ world where we live in peace and reverence for all living things. Finally: we make our living from the ocean. people depend on our sea vegetables for their health and well | L.53
being. If you dump subs, you poison our food & livelihood source — & we can't let that happen! May you move through this well in guidance. Sincerely, [illegible]

MEMORANDUM

To: Captain Edward F. Wagner, U.S. Navy
Office of the Chief of Naval Operations, Washington, D.C.

From: Deputy Director for Environmental Health

Subject: Environmental Impact Statement (EIS) for Disposal of Decommissioned, Defueled Naval Submarine Reactor Plants

Thank you for allowing us to review and comment on the subject EIS. On the basis that the project will comply with all applicable Public Health Regulations, please be informed that we do not have any objections to this project.

We realize that the statements are general in nature due to preliminary plans being the sole source of discussion. We, therefore, reserve the right to impose future environmental restrictions on the project at the time final plans are submitted to this office for review.

1-16-83

Dear Captain Wagner,

Thank you for sending me the Draft Environmental Report Report on the disposal of decommissioned nuclear subs. I must convey to you that I remain deeply concerned about this issue. There is nothing in this report that convinces me of the safety or advisability of dumping this kind of nuclear material into our oceans. From what I understand, there is no possibility of retrieving these submarines should leakage occur. No one knows what the long term harm may be if the ocean becomes contaminated. In my opinion, there is no acceptable "dose commitment" when it comes to radioactive poisoning and that is my point. Good luck on figuring out a sane solution to this insanity

4/18/83

Dear Captain Wagner,

I am writing to you to express my deep concern and opposition to the proposed disposal of nuclear submarines in our ocean. The north Pacific
L.53 ocean is one of the richest fishing grounds in the world. I have yet to see the results of a study that adequately addresses the question of radiation and
L.36 the way in which it can enter
L.20 our food chain. How can leakage be prevented when some of the radioactive elements have a half life of 20,000 years? In case of an accident,
L.57 the results will be devastating and
W.1 irretrievable.

Ocean dumping is a non-solution and does not address the basic problem which is the creation of *more* nuclear weapons and *more* nuclear waste. The manufacturers of nuclear waste must take responsibility for the safe disposal of such. Even this belies the more fundamental truth, this being that there is *no safe place* on this planet for this material. Shoot it up into space if you must but please don't ask me to pay for it! H.16

I request further *local* hearings J.15
to discuss this issue. Please consider Fort Bragg or Eureka as possible locations. The safety of our children may lie in your hands. Please consider.

Thank you,

Ann Bauer

Captain Wagner, Jan 22, 1983

Thank you for sending me your environmental impact statement. It's good to see that much energy is going into this project.

Despite your statement, I still do not feel that nuclear dumping into the ocean is safe. So far, history proves that we have not developed any reliable
L.20 method of containing super dangerous
nuclear waste. Dumping in the ocean is certainly the worst possible method - one that relies heavily on the "out of sight out of mind" theory.

After much reading regarding the past records of the U.S. government and its handling of nuclear matters - it can only be concluded that "gross negligence" best describes many decisions.

I feel that we are being used as
L.36 guinea pigs by our government - a
government that is suppose to protect us.

I, with the rest of my community, would
J.15 greatly appreciate a chance to hold
public hearings in costal areas so over

as the will of the local people may be more fully heard.

We are a group of people who dearly love our land and our sea - a group of people who will fight long and hard to protect whats ours - and our childrens - and also belongs to the residents of the ocean. We have no right to so foully pollute the sea.

Please, Captain Wagner, help stop the Navy from destroying the ocean - find somewhere else to stash hot subs. If they are so harmless, perhaps under the Pentagon would be a good location. You could keep a better watch on them then.

Yours truly,

Daniel Sampson
Box 541

#6a

Mr Lehman, Jan 22, 1983

As a resident of Mendocino County, California, I am understandably upset by the Navy's plans to scuttle her used up nuclear subs off our coast.

Although I am not a scientist, I can read and comprehend what is said about radiation. Lets face it - radiation is the most dangerous toxin so far produced by mankind. What continues to amaze me is the way the United States government goes about denying the dangers of radiation.

I have written several letters to the Navy, to date, about my strong opposition to nuclear subs being dumped in the ocean. What I have gotten back is a huge DEIS. This impressive collection of graphs and words does not one thing to change the fact that radiation is dangerous - and dumping it into the sea makes it no safer.

J.15 I would like to request that you set up public hearings in costal communities in order that the will of the people may be heard. Is this, after all, not the ideal of government - to respond to the will of the people? J.15

Please, Mr. Lehman, help turn this potential catastrophe aside. There is no good way to dispose of these subs but ocean dumping is certainly the poorest choice.

Yours truely

David Sampson

January 25, 1983

Mr. Edward W. Johnson
Office of the Chief of Naval Operations (OPNAV-45)
Department of the Navy
Washington, D.C. 20350

Dear Mr. Johnson:

This refers to the Draft Environmental Impact Statement on the disposal of decommissioned nuclear submarines.

0.34 I have reviewed the DEIS, and have only one comment. The issue of the potential economic impact on tourism in eastern North Carolina should be dealt with. Technically, the risk is completely insignificant. Emotionally, the public fears anything radioactive, whether in fact hazardous or not. This fear, blown out of proportion by the media or anti-nuclear activists, could result in questions sufficient in the minds of tourists that they would choose to vacation somewhere other than on the Outer Banks of North Carolina. While there are those of us permanent residents of this surf and sand country who would just as soon not increase the number of tourists invading our peace and quiet, a more objective position would be that this potential impact on tourism needs to be explored and explained, and made a part of the record.

I am enclosing a copy of the testimony which I presented at the informational hearing held here in Dare County on October 19, 1982. After reviewing the DEIS, my conclusions regarding the proposed sea disposal remain unchanged. I support the Navy's proposal, and ask that this letter and my earlier testimony be made a part of the record in this matter.

Thank you very much. If I can be of any further assistance, please do not hesitate to call on me.

Sincerely,

W A Brobst

TESTIMONY
OF
WILLIAM A. BROBST, CDR, USNR(RET.)

Before the Hearing of the House Committee on Merchant Marine and Fisheries, Manteo, North Carolina, October 19, 1982

* * * *

My name is William A. Brobst. I am a resident of Duck, in Dare County.

I appreciate the opportunity to appear before the House Committee on the subject of sea disposal of nuclear submarines. I appreciate even more your taking the time to come here to inform us about your proposals and to listen to our comments and ideas.

By way of background, I am a retired Naval Reserve Commander. In addition to several years of sea duty, I served in the nuclear weapons testing and storage program, and with the Navy's nuclear propulsion program under Admiral Rickover. I have a baccalaureate degree in chemistry, and my graduate work was in nuclear engineering and radiological physics. I presently serve as an advisor to the U. S. Department of Energy and to the United Nations in nuclear transportation. I am president of a small consulting firm which specializes in the transportation of hazardous materials.

For some months now, we've heard rumors here in Dare County that the Navy was planning to dispose of five nuclear subs off the North Carolina coast. We haven't seen much concrete information on the subject, and it's been hard to find out the facts. The result has been a lot of apprehension and, in some cases, downright fear about the possibility of nuclear waste washing up on our coast. Up until now, we haven't known just what was being considered, and what the potential hazards really are. This hearing will much to clear up that problem.

Because of my background in the Navy's nuclear power program, a lot of local citizens have asked me my opinion about this proposed sea disposal of the nuclear subs. I even gave a talk on the subject at the local Lion's Club. In each case, my listeners have been greatly relieved to learn that the hazards are quite minimal. But the public is generally apprehensive about things nuclear, and many people here in Dare County are still very worried about nuclear subs being dumped off their coast. Considering the lack of hard information in the past, it's no wonder. However, I have found most of my neighbors eager to learn more about the Navy's plans. Their minds are quite open on the subject.

#7 (Cont)

The preparation of a detailed Environmental Impact Statement by the Navy will be a big help in filling this information gap. I encourage the Navy and the Congress to ensure that people here in Dare County not only have an opportunity to review that EIS and to comment on it, but also to participate in its preparation. We want to be in on the planning at an early stage, not just informed of the results. It is heartening to see that the Navy is working closely with the Departments of Energy, Interior, and State, and the Environmental Protection Agency on this project. Being as far out in the boonies as we are, we have to rely to a great extent on receiving fair representation by the other parts of the Federal Government. We and they must ensure that all of the potential environmental effects are considered in depth.

Clearly, the nuclear subs which have become excess must be disposed of. The question is how, not if. Based on my own experience in both sea disposal and land disposal of radioactive wastes, I believe that the environmental impact of the proposed sea disposal of the defuelled nuclear subs will be minimal and acceptable. Even long term protective storage in a shipyard or in mothball anchorage would only be delaying the solution to the problem, without much decrease in the degree of potential risk. So there's little advantage to a long delay in getting rid of our excess nuclear hardware. Let's get on with it.

The world has had over thirty years of experience in sea disposal of nuclear waste. The United States has not done much of this in recent years, but overall we have learned a lot about what happens to this waste once it is committed to the deep. One of the things we've learned is that it's much better to commit it to the deep rather than to the shallow. The volume of chemical and hazardous wastes that have been dumped at sea is phenomenal indeed. Nuclear waste has been but a miniscule part of that total dumping effort.

We have learned that there is very little vertical interchange between deep ocean layers. Waste sitting at the bottom of a 17,000 foot deep ocean trench stays there. A nuclear sub is not going to float to the surface. It, too, will stay where it has sunk, as has been the case with the two nuclear subs that sank with all hands some years ago. There were no adverse environmental effects in those two cases, even with the hundreds of thousands of times more radioactivity on the operating subs than there will be in the empty hulks we're talking about here.

Another reason that the hazards will be minimal is that only low levels of radioactivity will be left in the hulks. These amounts will be within the limits set by the International Atomic Energy Agency for sea disposal of nuclear waste.

The Navy has put a lot of ships out there in that trench already. They've learned that, in many cases, it's cheaper to sink them than to try to cut them up. Sea disposal of the nuclear subs is likely to be very much less expensive than land disposal. The costs of removing the reactor shell and components and cutting them up for land disposal would be extremely high, and would probably significantly increase the total population exposure to

radiation as well. This is a good opportunity to save some tax dollars.

In summary, I support the Navy's efforts to investigate the total environmental effects of both land and sea disposal of the excess nuclear submarines. I appreciate your efforts to keep us informed, and I encourage you to bring us in at an early stage in the study. I believe that the environmental effects of this proposed sea disposal will be minimal, and need be of no concern at all to residents of the Carolina coast. And, if your final decision is to go ahead with this project, I shall support you.

Thank you.

Raleigh, North Carolina

MORNING SESSION

9:16 a.m.

CAPT. WAGNER: Ladies and Gentlemen, my name is Capt. Edward Wagner and I am in the Office of the Deputy Chief of Naval Operations for Submarines. I have been appointed the Navy Hearing Officer for this public hearing. Here with me to present an opening briefing in Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Propulsion Program.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear powered submarine reactor plants after the fuel has been removed and the ships are no longer needed. The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government-owned land disposal sites or placing them on the deep ocean bottom.

On December 22, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement (DEIS) on the disposal of decommissioned, defueled Navy submarine reactor plants. The DEIS contains the results of the Navy's studies of the alternatives available. On the table in the hall as you came in are copies of the Summary of the Draft Environmental Impact Statement. Anyone in the audiehce who would like a complete copy of the DEIS should leave their

name and address on the sheet of paper provided at the registrat: table, and a copy will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient with an interest in this matter in order to provide them with an opportunity to present their views. I am here to today to conduct one of these scheduled public hearings. The purpose of this hearing is to take testimony regarding the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case nor to engage in debate. It is my responsibility to receive statements so that they can be considered in preparing the final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each, and organizational spokesmen are limited to ten minutes, unless additional time has been requested in advance. Time cannot be relinquished from one speaker to another.

In order to ensure all who desire to speak are given an opportunity, each person whould fill out a registration card and provide it to the registration table. All testimony will be recorded so that it can be considered in the development of the Navy's final Environmental Impact Statement.

If you desire to submit written comments rather than speak that is acceptable. You can provide written comments to me or leave them at the registration table. If you desire to provide written comments at a later date, my address is as follows:

Captain Edward P. Wagner
U.S. Navy
Office of the Chief of Naval Operations
(OPNAV-22)
Department of the Navy
Washington, D.C. 20350

You should provide your written comments by March 31, 1983 which as stated in the Federal Register notice is the cut-off date for submitting comments.

Before we begin receiving testimony, I would like to introduce Mr. Mangeno of the Naval Nuclear Propulsion program who will provide a general overview of the issues the Navy is addressing and the content of the DRAFT EIS.

MR. MANGENO: Today's hearing is being conducted as a part of the decision making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an environmental impact statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The environmental impact statement must include the environmental

impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement, or DEIS, on this subject provides the basis for these hearings and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear powered submarines after they are no longer needed. The practical choices are: (1) Bury the radioactive part of the submarine at an existing DOE land disposal facility at the Hanford site in the state of Washington or the Savannah River Plant in South Carolina; or (2) Place the entire submarine on the bottom of the ocean in water more than 2.5 miles deep.

In both choices there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has about 120 nuclear-powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases, as shown in this slide, it is evident that a disposal plan must be prepared for use sometime in the future. This DEIS has been prepared now so that all interested agencies, organizations and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the Uranium and all of the fission products. The removed fuel is handled according to established procedures and is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, to the metal structure supporting the fuel, to the reactor vessel, and to other equipment in the reactor compartment, where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by

the hull of the submarine and by the reactor vessel and coolant piping. In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel, or other metal atoms in the reactor plant. These atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation of the nuclear reactor and the number of Curies of each radionuclide at that time. A curie is a mesure of the amount of radioactivity present, but is not an indication of the possible effect on man or animals. The amount and kinds of radioactive atoms present are described in detail in chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the Federal Government disposal facilities already used for such low level radioactive waste at the Hanford Reservation in the State of Washington or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the-compartment free from the remainder of the submarine, and wld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. Other Government-owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable waterways so that transportation of the reactor compartment to those facilities would be impractical. They Hanford and Savannah River burial grounds are described in Chapter Three.

A transporter of the sort shown in this sketch could then be used to haul the compartment overland to the burial location. There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial, or after burial. This is because radiation outside the compartment would be well below federal limits and the reactor compartment would have been welded shut at the

shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low level radioactive wastes. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burials and would result in no significant additional environmental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot readily be taken into the body. More than 200 years would pass before the reactor compartment bulkhead could be penetrated by corrosion (rust). Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time, exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean in another practical alternative. The maximum radioactivity would be less than the limit specified by international criteria and the triple containment provided by the submarine reactor compartment, by the reactor vessel and piping, and by the radioactive atoms being a part of the metal itself would be an extremely strong and effective disposal containment package.

Locations for possible ocean disposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U.S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site-specific public hearings would be required and the permit process is not part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 160 miles west of Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry and marine biology for very deep ocean locations. The depth of the water in these areas is between 4000 and 5000 meters (13000 and 16000 feet). The scientific information and measurements collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that the environmental impacts could be calculated using realistic data.

Preparation for ocean disposal would be made at one of the shipyards normally servicing nuclear-powered naval vessels. Following defueling, the reactor vessel and the reactor

compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping, and, of course, the metal itself completely intact. The analyses also show that most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping containments or free the atoms from the thick metal.

A comparison of the possible effects on the environment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100 submarine disposals for the year of greatest exposure from both options. This table shows that the radiation exposure would be very small and could have little impact on individuals or the population. These levels are also many times less than any limits established by U.S. regulations or international limits. They are much smaller than the normal fluctuations in annual average background radiation exposure for U.S. residents.

A perspective on radiation exposure can be gained by examining the exposure a person would receive from natural cosmic background radiation if he flew round-trip from New

York City to Los Angeles. That person would receive approximately 2 millirems more radiation than if he had not made the trip because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one-half millirem.

Other environmental impacts are similarly small for both options. The effects on animal life would be small and localized in either case. Land burial of 100 reactor plants would require only about 10 acres of land and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square 10 miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land dispoal would cost about 40% more (about $2 million per submarine more) than sea disposal.

The "No-action" alternative is to place submarines in floating protective storage for an extended period, commonly called "mothballing". However, this would only temporarily delay disposal because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other

alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods and the estimated radiation exposures for the general public would be very small for all available courses of action. Thank you.

CAPTAIN WAGNER: Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing. I will now recess briefly to establish an order for persons who wish to speak. For those people who would like to testify and who have not yet registered, you may do so at this time out at the registration desk in the hallway. We will reconvene the hearing in 5 minutes at 9:40 to receive testimony from the audience.

FROM THE AUDIENCE: Excuse me, sir. Would it be possible to ask any questions about the slide show presentation? I came in a little late.

CAPTAIN WAGNER: We would like to recess now, and we'll come back at 9:40. Thank you.

(At which time a short recess was taken.)

CAPTAIN WAGNER: Ladies and gentlemen, if you'll please take your seats we'll reconvene this hearing. For those of you who got here this morning a little late you might have missed Mr. Mangeno's briefing or my opening statement. I would say again that the summary of the Draft DEIS is available on the front desk registration table. We encourage you to take a copy of that with you. That would answer any or most all questions you might have. If you have some specific question that you don't feel is answered by reading that summary, there is another table at the front hall, and a man by the name of Mr. Anderson, the Chief of Naval Information; if you would please give him your question he will be happy to take it and provide you an answer at a later time.

At this time, simply to establish an order for the statements, I intend to ask individuals representing state government organizations to speak first, in alphabetical order by the speakers last names, followed by individuals representing local government organizations, in alphabetical order by last name of the speaker, and then private organizations and private citizens in alphabetical order by last name of the speaker.

I request your cooperation in providing comments within the time limit so that we may be certain all who wish to speak have an opportunity to do so. Once again, that is five minutes for individual speakers and ten minutes for organizational spokesmen. If your statement is so long that it cannot be given in the time alloted you may summarize in the five or ten minutes, and the entire statement will be included in the record is you submit it in writing.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, proceed

to and use one of the microphones provided, and with the size of the turn-out this morning, we're just going to use this microphone on my left. When you are called and you come to the microphone, state your name and organization, if any. All comments are to be addressed to me.

We are pleased to have as our first speaker this morning Ms. Jane Smith-Patterson, who is the Secretary of the Department of Administration in the state of North Carolina. Ms. Patterson.

#8

MS. PATTERSON: Thank you very much, Captain Wagner. On behalf of the State of North Carolina I would like to welcome you to Raleigh and thank you for coming to Raleigh to hear the concerns of our state and our people on this very important issue.

My comments today will focus on the ocean disposal alternative outlined in the Draft Environmental Impact Statement released by the Navy in December.

The ocean disposal alternative would employ a site about 200 miles off the North Carolina coast. The state of North Carolina has a strong economic interest in this 200 mile zone. Our state depends heavily on the good fishing and clean beaches we now have to keep our coastal economy strong. The state also is concerned about protecting the safety and well-being of her people.

The ocean disposal plan at issue today, if implemented, F.8 L.9 could set a dangerous precedent. The precedent would extend far beyond the risks associated with 100 defueled submarines. That action could lead to renewed dumping of radioactive or other hazardous wastes.

Before any decision on submarine dumping, we must have a comprehensive national ocean use policy - a policy developed openly with full public participation. Sound regulations for the disposal of low-level radioactive wastes in the sea cannot be developed before there is a national ocean use policy. Policy must come first.

L.5 Now, there is no regulatory structure to control the ocean disposal of low-level radioactive wastes. Furthermore, there is not an adequate scientific basis for such a regulator system. L.1 We need scientific data regarding deep water biology and the interrelationships with other marine ecosystems.

Everyone here should understand that the ocean disposal F.2 alternative is now inconsistent with current federal law. Recent amendments to the Ocean Dumping Act call for a two-year moratorium on ocean disposal of low-level radioactive wastes. The amendments also require EPA to establish a regulatory system. The intent of the two-year moratorium is to provide federal officials with time to identify scientific study needs and ultimately to find those answers. Congress acted to ensure that the EPA Administrator will have the right information to determine the full effects of ocean

disposal.

The issue of retrievability of the submarines is also a policy issue as well as a scientific and engineering matter. W.1 The Ocean Dumping Act Amendments specifically call for a monitoring program on the effects of disposal as a requirement for a permit. This requirement presumes that the applicant will be able to detect the effects of the disposal and would be able to reverse the action if the effects were unacceptable J.76 Your EIS does not address retrievability, and that deficiency leads to a conceptual problem that permeates the entire W.1 document. It leads to the notion that the ocean disposal alternative is a "permanent" solution. Without scientific documentation, it is not responsible to state that ocean L.1 disposal of low-level radioactive wastes is an acceptable permanent solution. Without adequate proof, ocean disposal is "out of sight, out of mind" philosophy. This philosophy has failed time and again, and the mistake should not be repeated with ocean disposal.

On the basis of these concerns, it is the policy of the State of North Carolina to oppose the ocean dumping of nuclear submarines until a national ocean use policy has been developed with a consistent and complete regulatory system. L.5 We hold the same position on ocean disposal of any other hazardous wastes.

Because of the issues raised here, we have a general reluctance to accept the proposition that the oceans are the best disposal site for low-level radioactive wastes. We believe the issue is larger than the radiation levels of 100 defueled submarines, and that a decision now on the ocean disposal alternative would be premature.

The issue should be discussed in the context of a national ocean use policy - particularly due to the precedent-setting nature of this action. What other low-level radioactive wastes would be eligible for ocean disposal? What expectations would be raised with other military and private sources of waste? What are the federal government's priorities regarding the proper use of the oceans?

In addition to my comments today, the State of North Carolina will make a formal written response to the Draft EIS and the Navy's determination of the proposal's consistency with the North Carolina Coastal Management Program when it is submitted.

I would like to comment the Navy for entering into the public review process well in advance of the decision date. This allows us all to ask important questions while there is still time to seek answers before a decision is made.

Again, I would like to thank you for this opportunity to present the position of the State of North Carolina. Thank you, Captain Wagner.

CAPTAIN WAGNER: Thank you, Ms. Patterson. Our

next registered speaker is Mr. Edmund B. Welch. Mr. Welch is the Chief Counsel for the House Merchant Marine and Fisheries Committee, and Mr. Welch is representing Congressman Walter Jones, Chairman of the House Merchant Marine and Fisheries Committee.

#9

MR. WELCH: Thank you, Captain. I am Edmund Welch, formerly of Greenville, North Carolina, and presently Chief Counsel of the House Committee on Merchant Marine Fisheries for the U.S. House of Representatives.

Today I am speaking on behalf of Congressman Walter B. Jones, who is not only Chairman of the Merchant Marine and Fisheries Committee, but who also represents North Carolina's First Congressional District, which includes the Outer Banks of North Carolina.

The statement which I will give today represents Congressman Jones' views.

Captain Wagner, I would like to thank you and the Department of the Navy for allowing us to present our comments on the Draft Environmental Impact Statement for the permanent disposal of decommissioned, defueled nuclear submarines. The possible disposal of these submarines at deep ocean sites off the coast of North Carolina is of very serious concern to me and to the citizens of North Carolina. I want to commend you for conducting these field hearings and allowing the residents of North Carolina and other areas to express their concerns to you. I believe that the opportunity for us to comment is of critical importance to guarentee that the process for reaching decisions on these crucial issues is open, balanced, and reliable. I hope that all of us who are interested in the proposal will be provided an ample opportunity to comment and to participate, and in reviewing today's testimony, please remember that Raleigh is some 5 hours from Cape Hatteras, so clearly, many concerned citizens are not able to be present today, especially in view of the traveller's advisories that were broadcast last night.

As you know, in October of last year in Manteo, North Carolina, Congressman Jones convened his Committee on Merchant Marine and Fisheries for hearing on this proposal, and Captain, we appreciate your participation at that hearing. At the hearing witnesses from the Government described their respective responsibilities for licensing and monitoring ocean disposal. Experts in the field also offered impressive analyses for selecting ocean sites and estimating potential hazards. In addition, witnesses from a wide range of commercial and environmental organizations expressed great concern for the potential adverse impacts that such disposal could have on the coastal communities of North Carolina. I share that concern, and believe it to be well founded. I regard this proposal as raising very difficult, complicated issues, and I look to this DEIS to provide guidance to the decision makers on the

scientific and policy questions raised by it.

There are four specific comments on the DEIS that I want to make today. The first addresses the recently adopted amendments to Title I of the of the Marine Protection, Research and Sanctuaries Act which impose new restrictions on ocean disposal of low-level radioactive wastes. The second concerns the analyses of potential impacts on coastal communitie. in North Carolina. The third discusses the site evaluations, and the fourth raises the general issue of credibility, citing specific points in the DEIS where certain revisions may be appropriate.

In December of 1982 Congress passed an amendment to Title I of the Marine Protection, Research and Sanctuaries Act which is commonly known as the Ocean Dumping Act. This amendment may prove to have a significant impact on the disposal of decommissioned nuclear submarines. These amendments had earlier been reported out of the House Committee on Merchant Marine and Fisheries and passed by the House in a package of amendments to Title I of the Ocean Dumping Act, and eventually these changes were passed by the full Congress as part of other legislation. F.2

Frequently referred to as the Anderson amendments, after their primary sponsor in the House, these amendments impose a two-year moritorium on the ocean disposal of any low-level radioactive wastes and substantially modify the permit processes governing such disposal after the moritorium expires. Applicants for permits to dispose of low-level radioactive wastes must submit with their applications a comprehensive radioactive material disposal impact assessment. These assessments must contain, among other things, site specific analyses of potential environmental effects; plans for the removal or containment of the nuclear material if the container leaks or decomposes; consistancy determinations by each affected state; and a comprehensive monitoring plan to occur

F.2

after the disposal is completed. In light of these new requirements, it will be necessary to revise substantially certain portions of this DEIS for it to serve as a later assessment in a permit application to the Environmental Protection Agency (EPA).

Furthermore, if EPA decides to issue a permit for such disposal after the two-year moritorium, it must submit the permit to both Houses of Congress for affirmative Congressional approval. If within 90 days Congress fails to pass a resolution of approval the permit will not take effect, and ocean disposal will not be able to take place.

The provisions of these amendments clearly reflect the seriousness with which Congress views the disposal of radioactive wastes, and they impose upon the potential applicants new and higher standards of study and public

F.2

participation. I would urge the Navy to examine these amendment closely and to modify their program as may be necessary to

comply fully with them.

Therefore, to summarize my point 1, the new law will make it much more difficult to obtain a permit for ocean disposal.

L.53

Secondly, the DEIS fails to address adequately, and in fact virtually ignores the potential impacts that ocean disposal could have on the coastal communities lying adjacent to the disposal areas. Adverse impacts may include both environmental and economic impacts. While the complicated analyses of direct radiation exposures lie beyond my expertise, the summary dismissal of potential adverse impacts on the economies of coastal areas is unsatisfactory. As a matter of fact, there are only three sentences in this entire document that deal with the economic impact of submarine disposal by

O.34

ocean dumping. Although the potential for harmful exposures through, say, swimming on the beach or eating fish from the area may as a point of fact be minimal, the public may nonetheless perceive the potential for harm. That perception, in turn, could severely damage important industries in the coastal areas, such as tourism or fishing. These potential impacts must be examined more closely and factored into the decision making. The economic wellbeing of the Outer Banks depends on the public's perception of them as a safe, unspoiled, natural haven.

To summarize point two, the DEIS is totally inadequate in its study of the economic consequenses of ocean disposal of radioactive wastes off the coast of North Carolina.

My third comment addresses the site specific information on the Hatteras Abyssal Plain area and the lower continental rise area. One runs into difficulty attempting to reconcile the summary comments on the Atlantic sites with the absence of site specific information. The DEIS summarizes that "In general, the Hatteras Abyssal plain study area would likely prove acceptable as an ocean disposal site, based on the site specific selection criteria", and that "Information gathered to date on the lower continental rise study area supports the belief that it would be possible to select an area in the Atlantic on the lower continental rise, within 200 miles of land, and meeting all study area identification guidelines". The technical basis of these admittedly tentative conclusions is not clear, and the potential drawbacks associated with each site should be discussed. Comparative analyses of the sites should be undertaken so that in the end, if ocean disposal is chosen, the most suitable site will be selected. J.9

With regard to the Abyssal Plain site, there is extremely scant data on biological pathways, and too little information on the potential effects of turbidity currents, a potential which the DEIS raises and then dismisses. J.9

As for the lower continental rise area, there is clear evidence of a major submarine canyon system, inter-canyon levee deposits, and the potential for sediment slumping.

The topography of the area could complicate post disposal monitoring, and the dynamic currents within the water column J.77 and on the bottom along the boundary of the continental rise and the Abyssal Plain create further complexity, and again, the lack of deep ocean biological data on the area is evident J.9 in the analyses, throwing into doubt the empirical basis of the pathways analyses.

Finally, the relevence of the 200 mile limit, which has no juridical relationship to ocean disposal, is unclear. Without it, the discussion appears to favor areas beyond 200 miles; yet with it, with the 200 mile criteria, a less suitable site within 200 miles may be unavoidable. Why is the 200 mile limit so critical? The DEIS does not explain it adequately enough. J.18

To summarize point 3, the data on the Atlantic site is still much too sketchy to provide a basis for a decision, and there is no judgement as to which ocean sites are superior to others, and why.

The fourth and final point relates to the overall issue of credibility. Because of the extreme sensitivity of the issue of radioactive waste disposal, it is imperative that the Navy make every effort to present all relevent information on its proposal in an unbiased objective manner. These hearings are an excellent start in fulfilling that objective, but any attempt to skew the analyses one way or the other could do nothing but undermine the public and Congressional confidence that will be crucial to the success of the project. In this respect, portions of the DEIS require revision to examine fully the important policy issues raised by the proposal.

F.8

For instance, in examining the discussion of the effects of the proposal on national policy, it appears less than forthright by skirting the issues raised by the United States resuming ocean disposal of radioactive wastes after espousing a policy of no dumping for well over a decade. The policy shift is important.

L.9

Does a decision in this instance portend further or greater domestic licenses for other radioactive wastes, and if so, for what types of wastes and in what quantities? If a site for this proposal is selected off the North Carolina Outer Banks, what is the probability that it will become the general low-level radioactive waste site for the United States for other wastes produced by the United States? What, then, will be the cumulative effects of this decision on North Carolina? Further, how will the U.S. policy shift affect international ocean disposal practices since other countries are now actively considering disposal?

W.1

Another issue that requires further discussion is that of retrievability. In light of the recently adopted amendments to the Ocean Dumping Law, and the decision by Congress to retain retrievable disposal options for high level wastes in the Nuclear Waste Policy Act of 1982, the issue of retrievability

requires more explicit elaboration as both a technical and policy issue. Retrievability is the Achilles heel of ocean disposal. At least with land disposal, if we decide in the future that we have made a mistake, we have a chance to correct it. But with ocean disposal we cannot correct the error. The choices are irrevocable. Are we willing to gamble today that we cannot make a mistake?

W.1

That concludes my specific comments on the DEIS. In closing, I want to emphasize that I intend to retain an open mind on this matter, knowing that eventually we must dispose of these submarines in some way. But at the same time it is essential that before proceeding with any specific proposal, members of the general public, myself included, must be assured by reasoned scientific evidence that ocean disposal at a specific site is safe, necessary, and the best solution to a difficult problem. The present DEIS does not give that assurance to the people of North Carolina.

Thank you, Captain Wagner.

CAPTAIN WAGNER: Thank you, Mr. Welch. The next registered speaker is Mr. Elbert Felton, who will be speaking on behalf of Congressman Steve Neal.

#10

MR. FELTON: Thank you, Captain Wagner. I will be presenting a statement made by Congressman Steve Neal, the Fifth Congressional District Representative here in North Carolina. I'm on the Congressman's staff, and my name is

Elbert Felton. This is Congressman Neal's statement:

I want to thank the Department of the Navy for affording an opportunity to citizens here in North Carolina to participate in this hearing. The proposals on disposing of decommissioned nuclear submarines are gaining more and more attention and raising more and more questions.

I support the intent of Section 424 of H.R. 5211 calling for restrictions on ocean dumping of low level radioactive wastes and a two year moratorium. The provisions for monitoring, for analysis of economic impact, for retrieval and removal possibilities, and for precise description of dumped material are all reasonable requirements.

There needs to be a compelling reason behind any decision in favor of marine disposal, and that compelling need has not been demonstrated to me. The number one advantage listed in the DEIS is the reported lower immediate cost of this option (page 2-14). In such a controversial situation, this cost difference, even if accurate, does not lead me to conclude that sea disposal is the desired alternative.

I am also concerned about the Navy's earlier reluctance to appear before a hearing of the House Merchant Marine and Fisheries Committee, chaired by Congressman Walter Jones. It is vital that our citizens know exactly what the Navy's plans are, and to have their questions and fears addressed in a direct and timely fashion.

We live on an ocean planet and this predominant feature of our globe should be respected for the impact it has on the entire nation, not just on those narrow sandy beaches of our coastal area.

My staff will be reporting to me on the statements made at the hearing so that I might be aware of the public attitude expressed at this forum. Thank you for allowing my remarks to be a part of the public record. Sincerely, Stephen L. Neal, U.S. Congressman.

Thank you, Captain.

CAPTAIN WAGNER: Thank you, Mr. Felton. The next registered speaker is Mr. John Bone, Executive Vice-President, Outer Banks Chamber of Commerce, Kitty Hawk, North Carolina. Mr. Bone.

#11

MR. BONE: Thank you, Captain Wagner. I also appreciate this opportunity to speak for the Outer Banks Chamber of Commerce.

The Outer Banks Chamber of Commerce at this time reiterates its opposition to disposal of nuclear submarines off the coast of North Carolina. Basically, our business community depends upon either commercial fishing or tourism for its life blood. We can see no benefit or advantage from the disposing of nuclear submarines off our fragile coast.

At the same time, this disposal could be potentially harmful both environmentally and psychologically. Even if we L.53

O.34 could be assured that the disposal would have no environmental effect, we still see a real danger and a misinterpretation which could lead people to choose seafood caught elsewhere over that caught in North Carolina waters near nuclear submarines.

Similarly, this same kind of thinking could cause vacationers to choose alternate vacation sites.

In the absence of any real clear-cut advantage, and conversely much potential harm, the Outer Banks Chamber of Commerce would reemphasize its opposition to nuclear submarine disposal at sea. For these reasons, the Outer Banks Chamber of Commerce encourages the Department of the Navy to reconsider any plan for ocean disposal of nuclear submarines.

Thank you for the opportunity to be here this morning and express our concerns.

CAPTAIN WAGNER: Thank you, Mr. Bone. Our next registered speaker is Mr. Daniel F. Read, representing the Environmental Law Project. Mr. Read.

#12

MR. READ: Good morning, Captain Wagner and fellow North Carolinians. My name is Daniel F. Read and I am representing the Environmental Law Project, which is an independent group of law students at the School of Law at the University of North Carolina in Chapel Hill, North Carolina.

We are particularly concerned with the proposed sea disposal, and I would like to point out what we perceive as

several serious inadequacies in the Draft Environmental Impact Statement. We would urge that the decision making process not go forward until these concerns are resolved.

First, is the lact of thorough site data for many of the parameters listed. J.9 For example, the number of core samples seems severely limited at best: only seven were taken in the Atlantic Ocean study area, which hardly seems to offer more than a few weak scientific generalizations for an area of some 8000 square kilometers. J.28 More importantly, bottom currents are still not fully quantified, being still under study at at least one location, E-11. The available data indicate that although currents are not particularly rapid at the other two sites, there are still currents sufficient to assure a wide distribution of radionuclides in a worst-case scenario. For example, even at the lowest speed measured, which was 0.7 Kilometers per day, the current is sufficient over a one half-life of Nickel-63, which is 92 years, and is one of the more frequently occurring radionuclides in the reactor compartment, to move the radionuclide several thousand kilometers. Ordinarily, a radionuclide is considered detoxified after 10 half-life's, so that's certainly a cause for concern. The data from the Thresher and Scorpion sinkings were showing negligible releases which are summarized in the DEIS offer little consolation, since the very toughness the Navy claims J.42 to have built into these vessels probably means that the

J.42 radiological effects of these comparitively recent events are only just now beginning to be recorded. Given these concerns, ocean dumping should be delayed at a minimum until complete environmental studies have been done.

A second concern we have is the potential effect of an accident during towing of the sub to the site. Accident would also include interference by a third party. The DEIS claims that because of the rugged construction and proven seaworthiness of these vessels, they can be towed to the disposal site with confidence. Similar claims were advanced, one recalls, for other ships including the Titanic. The L.57 absence of any analysis of the results of the sinking of a sub in shallow waters, either accidentally or by an act of God or war or third party negligence, is thus a further inadequacy.

The effects of proposed sea dumping also need to be analized with respect to their effect on providing an implicit F.8 incentive for domestic and foreign producers of waste to join in and increase their own ocena cumping efforts. Additionally, other future military waste disposal at sea is not discussed: L.9 to the extent the military is considering such activity, it should be included in the EIS, since going ahead with this F.8 would probably mean a tacit end to our national policy of no ocean dumping.

S.25 Finally, the EIS provides no illumination with respect to what happens if the projections in the report may be wrong,

and I would reiterate there that all I've seen in this report are projections. There's very little hard analysis of what L.1 we know will happen. Many predictions have been made about disposal of nuclear waste in the past, and many predictions have been wrong. Is there a plan for reducing radionuclide W.1 dispersion is the scenarios listed in the EIS are wrong? The costs set out do not include any such expenses, and that's for a good reason since they would probably be prohibitive, and perforce, the problem would be ignored in the hope that damage would be minimal. "Out of sight, out of mind." That is neither good ecological thinking, nor in accord with the mandate of the National Environmental Policy Act to avoid adverse environmental impacts where possible. Since land disposal would at least offer the chance of repairing or reducing harm from mistaken predictions, it would appear to be the better of the options presented. In any event, the DEIS needs more careful analysis before it can present the kind of basis for rational decision-making contemplated by NEPA. Thank you.

CAPTAIN WAGNER: Thank you, Mr. Read. The next registered speaker is Ms. Joyce Rosenthal, who will be representing Greenpeace. Ms. Rosenthal, please.

#13

MS. ROSENTHAL: Yes, good morning. My name is Joyce Rosenthal, and I will testify here today on behalf of Greenpeace, U.S.A., the passive campaign coordinator for the

*Issues discussed in Ms. Rosenthal's testimony are side barred in Exhibits 13a and 13b.

issue of ocean dumping. Greenpeace is an international environmental organization who's sole purpose is the promotion of the protection of the environment over the long term. Since the inception of Greenpeace in 1971 the oceans have been a central concern of the organization, largely due to our efforts to protect marine life and the ocean environment. Greenpeace presently has over 270,000 contributing members in the United States, and more than a million worldwide.

I am here to address the Navy's examination of the ocean dumping option for the disposal of radioactive nuclear submarines, as outlined in their Draft Environmental Impact Statement released on December 22, and its policy implications. Thank you for this opportunity to comment on this proposal.

Although the Navy's DEIS has not stated a preferred method of submarine disposal, environmentalists, fishermen, scientists, policy-makers and citizens around the country and in other nations have been concerned over the possible resumption of ocean dumping of radioactive wastes by the United States.

Greenpeace opposes the ocean disposal of radioactive wastes. In approaching the question of nuclear waste disposal, we assume the objective goal is to endure the protection of public health and the environment over a very long term. The activity of isotopes present in all categories of nuclear waste, and present in the irradiated reactor compartment,

pressure vessel and steam generator of decommissioned submarines guarantee that levels of radioactivity will persist for thousands of years. To pursue ocean disposal at this time means resuming a practice before the impacts on public health and the marine environment of past radioactive waste ocean dumping are fully understood.

Once dumped, these submarines are irretrievable according to the Navy's DEIS. This is a critical drawback that land storage does not have.

A review of past radioactive waste dumping in this country in comparison to the Navy's proposal elucidates our concern. The DEIS estimates that one defueled submarine reactor plant contains about 62,000 Curies of radioactivity, which is approximately one-half of the entire amount of radioactivity that has been calculated to have occurred in dumping operations off the U.S. coastline between 1946 and 1970. The isotopes in the induced radioactivity in each sub includes: Cobalt 60, nickel 63, cesium 137, nickel 59, and niobium 94. There are 16 different radioactive nuclides in the initial 62,000 Curies and traces of Plutonium 239 and Strontium 90. Half-lives of these isotopes range from 5.26 years for Cobalt 60, to 80,000 years for Nickel 59. With over 100 nuclear submarines scheduled for decommissioning over the next 30 years, choosing the ocean dumping option would result in sea disposal of quantities of radioactive materials that dwarfs the previous U.S. dumping program by comparison. In the over 100,000 containers of nuclear waste and one submarine reactor vessel dumped within the 24-year period of ocean disposal in this country, approximately 120,000 curies of radiation was dumped. These figures on the magnitude of past dumping were recently revised by the EPA, which has been unsuccessful in determining the full extent of past dumping.

The Navy's consideration of ocean dumping as a disposal option stands as a tacit acknowledgement of the failure to fulfill a promise to provide appropriate methods for handling of the waste products from the Nuclear Propulsion Project. A formal request to the EPA to dump radioactive submarines would constitute the most formidable pressure to reverse a 12-year de facto ban on the practice of ocean dumping of nuclear wastes. The practice was halted in 1970 when the Council on Environmental Quality issued a report which concluded that ocean dumping of any radioactive waste presented a very serious and growing threat to the marine environment.

A new policy of considering nuclear waste dumping on a case by case basis by necessity would have to replace the present 2-year moratorium, without developing EPA guidelines. That point was pointed out by many other speakers today. If the Navy pursues the ocean dumping option, that represents an undeniable policy shift that has implications far beyond

the specific proposal. The Navy's DEIS should have assessed the cumulative impacts of ocean scuttling in the context of other past and proposed ocean dumping and other sources of radioactivity.

The Navy is breaking ground here for a great variety of radioactive wastes that could be dumped into the ocean if the EPA permits this practice on a case by case basis. Evidence of this is the February 1 notice by DOE that the ocean dumping option is being considered for disposal of FUSRAP soils, wastes from the Manhattan Project currently being stored in New York. I think the recent Anderson amendments to the Ocean Dumping Act, which place a two-year moratorium on issuance of new ocean dumping permits pending a more detailed study and consideration of their environmental consequences, reflect the spirit of the constituency around the country opposed to renewed nuclear waste ocean dumping.

Politically, the resumption of dumping nuclear wastes is bound to be increasingly unpopular with a growing number of nations that are opposed to this practice, including Pacific Island nations and European nations opposed to the current dumping by the United Kingdom, Belgium and Switzerland into the Northeast Atlantic Ocean. Clearly, the U.S. role in influencing global decision making must be given more consideration. Does the United States want to continually isolate itself in global opinion, as it has recently by not ratifying the Law of the Sea Treaty, and by the United Nations vote, 111 to 1, against a Comprehensive Test Ban Treaty resolution? Japan and Canada are two nations that are watching the development of U.S. policy on this issue very closely in considering their own possible resumption of radioactive waste ocean dumping.

These policy implications of the scuttling plan are why we must examine the entire issue of ocean dumping in judging them; including the under-researched effects of past dumps and potential future dumps of nuclear wastes. An inventory of radioactive materials going into the oceans has never been created, despite recognition by international maritime organizations of it's need.

Ocean dumping is currently subject to review by the more than 50 nations that have signed a treaty called the International Convention on the Prevention of Marine Pollution by Dumping Wastes and Other Matter, better known as the London Dumping Convention. Today is an appropriate day to consider the international aspects of the Navy's scuttling option, as it marks the first day of the seventh meeting of the LDC, and the day that the LDC nations will consider a proposal by Pacific Island nations to ban radioactive waste ocean dumping as an amendment to their treaty.

In light of the current unanswered questions regarding biological and oceanic current transport of radionuclides,

we hope that the LDC nations today will recognize the risks of continued ocean dumping, and support a ban on its practice.

Time constraints in preparation of this testimony following the release of the DEIS do not permit me to engage in a technical review of the Navy's supporting studies on the ocean disposal option, or to review the Navy's studies of possible land burial sites at Hanford, Washington and Savannah River, South Carolina. The 90-day commentary period provided by the Navy is not sufficient for the public to analyze the bulk of technical data and consideration in the scope of this DEIS. Greenpeace has submitted a request as part of a coalition of environmental groups requesting a 90-day extension of public commentary time. We hope the Navy agrees to this for the benefit of the public. North Carolina has barely had time to obtain a copy of the DEIS, much less read the 400-page document and comment on it.

Careful consideration must be given to today's testimony by the Oceanic Society and others as they critique the DEIS on technical grounds. These scientists have pointed to unacceptable gaps of essential information that would be used to predict the transport or fate of radioactivity in the marine environment.

Returning to the question of what to do in order to dispose of obsolete submarines, Greenpeace proposes that the Navy should continue to maintain irradiated submarines in protective storage in naval shipyards where they are decommissioned to allow for the anticipated early rapid decay of short-lived radioisotopes. We have presently asked a technical expert to evaluate data on decay of radioactivity in the subs and hope to present the findings that pinpoint the earliest optimum time for shipping from protective storage to land-based storage. Information in the DEIS indicates that a proper time frame for that shipment would be from 20 to 50 years.

Supporting this recommendation is a statement in the DEIS; "Nuclear submarines can also be placed into storage for a long time without risk to the environment. The submarines would be kept in protective storage. About every 20 years each ship would be taken out of the water for an inspection and repainting to assure continued storage."

The questions we must ask ourselves after that time to assess the differences between land disposal options include: What is the shortest, safest transportation route for these radioactive wastes? Recognizing that shipment is the weakest link in the disposal process, due to the possibility of accidents and public exposure, great consideration must be given to the shortest route. What are the chances of a barge towing accident in case the shipment transverses deep or shallow water and rivers?

What environmental concerns have been raised by the

public near the two land burial sites that the DEIS does not cover? Are there more appropriate burial sites not covered in the DEIS? Can the monitoring plans for a land based burial be developed, as they are not in the DEIS?

In conclusion, I note the problems that every nuclear nation around the world has had in disposing of their radioactive wastes. We must examine our posicies carefully to determine whether it is acceptable to society to continue producing materials for which there exists no environmentally sound disposal practice.

Thank you.

CAPTAIN WAGNER: Thank you, Ms. Rosenthal. The next registered speak is Ms. Jane Sharp, representing the Conservation Council of North Carolina.

#14

MS. SHARP: I am Jane Sharp, President of the Conservation Council of North Carolina. CCNC has about 500 members throughout the state, and 15 member organizations, similarly dispersed. All are interested in the wise use of our national resources and of conservation practices assuring that our children and grandchildren can inherit at least as good an earth as we found here.

Nuclear submarine dumping in the Atlantic Ocean during the '80's and '90's does not seem to be in accord with our ideas of maximum wisdom or conservation. While any nuclear burial only defers the problem, we are impressed with the relative rates of corrosion of metals under sea water and underground, in the Draft EIS, pages F-1 to F-25. Q.12 Experiments show that both water and ocean bacteria contribute to more rapid corrosion under sea water than underground. Because the radioactivity of the disposed materials decays gradually over time, the faster the corrosion, the more active radioactiv is released to the environment in water. L.37 Also, because of the ocean food chain, where radiation can be concentrated 400 to 800 times by bottom-dwelling organisims, which are subsequently consumed by fish, the unwary fisherman may receive a much larger dose than anyone could calculate, based on even dispersio into the environment.

L.53 North Carolina's fishing and tourism industries are among the most important in the state, and would be harmed by O.34 such possibilities lon- before measured amounts of radiation appear in sea water or fish at the surface.

The corrosion rates of the metals involved are slower underground, according to our reading of the DEIS, allowing for greater decay of radioactive metals, and less chance of contact with future populations.

L.9 Our second main point is the temptation of using such a dumping ground for other items than nuclear submarines, given the great resistence to underground disposal of both low level and spent fuel wastes throughout the country, not to mention military reprocessing wastes, which are,

unbelievably, still building up in the United States.

When we pause to determine where we really want this civilization to be heading in the latter twentieth century, we do not see nuclear proliferation as a viable option to the people of any country of which we are aware. The tremendous resistance to land disposal will be equalled by that to ocean disposal, in our view, once the relative corrosion and dispersal rates are studied. And while nuclear proliferation is not the issue today - only how we should dispose of the wastes from past nuclear devices - it becomes clearer with each year, as we return again and again to testify, that the entire nuclear industry is a source of all of these problems. When you try to staunch the flow of a pollutant into the environment, you try to control the source, not merely to mitigate the resulting problem; if you are wise.

Therefore, with all its problems, werecommend the land disposal option over the ocean dumping proposal at this time, but people need to be much more aware of what is happening in order to react at all.

We thank you for allowing us this whole day as an opportunity for us to become more informed ourselves, and also to inform the Navy of our increasing opposition to the ocean dumping option for nuclear submarines.

CAPTAIN WAGNER: Thank you, Ms. Sharp. Our next registered speak is Mr. Thomas C. Jackson, who is representing

#15

the Oceanic Society. Mr. Jackson.

MR. JACKSON: Thank you, Captain Wagner. I am Thomas C. Jackson, vice president of the Oceanic Society, a 60,000 member national marine conservation organization which publishes Oceans magazine as part of a global research, education and conservation program. The Society's principal offices are in Stamford, Connecticut and San Francisco, California with Oceanic Society Chapters in San Francisco, Los Angeles, San Diego, Dallas/Fort Worth, and the Long Island Sound region.

This morning I am speaking on behalf of the Oceanic Society's 60,000 members to address an inadequate Draft Environmental Impact Statement (DEIS) and argue against the sea disposal of obsolete nuclear submarines. A primary fault *W.1 with this "ocean alternative" for worn out subs stems from the irretrievability of these ships once they have been sunk on the deep ocean floor. This alone is sufficient cause under federal law to reject the sea disposal concept.

The draft environmental assessment holds four significant defects:

L.7 1. Cumulative impacts of incremental increases in radioactivity entering the marine environment from these submarines are not considered in the DEIS;

J.76 2. The monitoring program proposed in the DEIS is I.13 inadequate for either sea or land disposal;

L.57 3. Effects of accidental sinking of the submarines on

the Continental Shelf are not adequately considered; and

4. The disposal alternative which minimizes corrosion and hence release of radioactivity - is not even considered in this document. H.3

Based on our consultation with scientists around the country, it appears the most sensible solution is to place reactor compartments in an arid or semi-arid environment. In this alternative, the submarine's reactor compartment would be placed in a trench or left on the ground. Unlike the land alternative considered by the DEIS, the compartment would not be buried. H.3

Scientists believe that by not burying the reactor compartment, corrosion of the submarine's hull and bulkheads would be minimized. Clearly, a compartment which is left exposed to dry air will rust at a much slower rate than one which is buried in the earth. A submarine sunk in salt water will, as shown in the DEIS, corrode at a much faster rate than either of these land disposal options.

We must remember that we are speaking here of placing the entire reactor compartment on land. The reactor compartment is a section of the hull stretching between two watertight bulkheads which contain the reactor, primary piping and steam generator. The uhull and bulkheads are built out of metals strong enough to withstand the high pressure of operating at great depths. Together, the hull and the bulkheads provide

*Other issues discussed by Mr. Jackson are side barred in Exhibits 15a and 37b.

a barrier protecting the environment from radioactivity for a substantial period of time. This hull will last longest, however, if it is not buried or scuttled in the sea.

In revising the DEIS, the Navy must consider this modification of the land disposal alternative. The current text contains neither mention of this option nor any reason for discounting it as a viable solution to the Navy's radioactive waste disposal problem. This inadequacy in the DEIS is just one of our prime concerns.

Both a "Lower Continental Rise Area and a "Hatteras Abyssal Plain Area" of the North Carolina coast have been considered in the DEIS. Published scientic research on the Lower Continental Rise Area suggests a more complete investigation J.28 by the Navy will find bottom current velocities which are, for the deep ocean, significant. In revising the DEIS J.8 assessment of oceanographic data, the Navy must make clear the weight to be given to site selection guidelines developed by Dr. Charles D. Hollister and Dr. G. Ross Heath and reported in Appendix E of the environmental assessment.

L.55 The DEIS must also be revised to consider the "artificial reef effect" scuttled subs are expected to have on the deep ocean ecology. Experience with radioactive waste dumpsites, oil platforms and ships sunk for fishing reefs has established that, on the continental shelf, any such structure attracts and holds new and more abundant communities of fishes and

invertebrates. Whether the subs will serve as an attractive nuisance, attracting new communities of life to the deep sea bottom, must be considered in the DEIS. Estimates of exposure to humans must reflect the "artificial reef effect".

The DEIS must also be expanded to provide a baseline J.9 description of fish and other forms of marine life which inhabit the abyssal plain of North Carolina. Data on trace materials, radionuclides and metel-sequestering proteins should be addressed. Specific attention must be paid to species like the greradier, a fish recognized as the most abundant large organism at these depths, and one which has the potential to serve as a mechanism for horizontal and vertical transport of material released from these submarines.

Sea disposal of radioactive waste is a complex issue. If the Navy really expects informed public comment on this topic, specifically the DEIS, why has it scheduled this hearing only 2 months after the DEIS was released, and why has the Navy limited the comment period to only 90 days?

The DEIS released by the Navy a few days before Christmas is a think and imposing document containing a summary, four chapters of explanatory text and 12 appendices, Two volumes of equal size contain scientific studies compiled to support the DEIS and its conclusions. Both volumes cite an impressive list of references from a myriad of sources. While some of these references are available, others - such as a State

Department press release - are not easily accessible to citizens, conservationists or elected officials. Despite the complexity of this issue and the DEIS, the Navy has alloted only 90 days for public comment on this issue and has not bothered to answer reasonable requests for limited extensions of time.

Many organizations, including the Oceanic Society, have written the Navy to request an expanded comment period and a delay in these hearings. As we noted in our request to Secretary of the Navy John Lehman, it is difficult to assess - let alone promote informed public consideration of - this draft environmental assessment within 90 days. The Navy's refusal to extend the time for public comment raises a fear among those who wonder if this might be because the DEIS cannot withstand prolonged examination.

The Oceanic Society has been concerned about the risks of radioactive waste disposal in the marine environment since 1978. During 1980 we convened a public policy forum in Washington, D.C. to examine the sea disposal of nuclear waste. Two years later we published Nuclear Waste Management: the Ocean Alternative, the first comprehensive text on this issue. We have coordinated scientific testimony before Congressional Committees, followed international standards for radioactive waste disposal at sea and spoken before the National Advisory Committee on Oceans and Atmosphere in this

matter. Yet, we have found it most difficult to assess the DEIS on the tight schedule established by the Navy. By scheduling these hearings in the midst of the 90-day comment period, the Navy has effectively prevented any informed effort to educate the public about the DEIS so they can participate in the hearings.

Our analysis of this DEIS centers on an independent committee of scientists which met in San Francisco on February 3 and 4 to review the document. The committee's report will not be complete until the end of this month. Clearly, we cannot utilize this independent scientific evaluation to help citizens and elected officials understand and then comment intelligently at hearings which conclude next Thursday. The Society urges concerned citizens to submit written comments on the DEIS before the March 31 deadline. We are working with North Carolinians to convene workshops in Winston-Salem and at the Duke Marine Labs March 5 and 6 to help people consider this DEIS. But this is a poor substitute for the degree of informed public participation which could have developed with as few as 60 more days before the hearings began. In the light of Congressman Glenn Anderson's ammendment to the gas tax law, a measure which imposes a 2-year moratorium on sea disposal of any nuclear waste, one has to wonder why the Navy is in such a hurry.

Recent action at the U.S. Environmental Protection Agency have done little to allay these concerns. The current Administration has transferred the man who was in charge of drafting this DEIS for the Navy to direct the EPA office charged with regulating sea disposal of radioactive wastes - and incidentally reviewing this DEIS. This administrator's refusal to allow any EPA staff to assist in our review of the DEIS further weakens the Agency's credibility as a regulatory agency which will protect the public. Rarely has the Reagan Administration provided a clearer example of inviting the fox to guard the hen house.

L.7
J.76

In revising the DEIS, additional attention must be paid to the twin problems of cumulative impact and monitoring. Neither the DEIS not scientific research cited in support of the document consider disposal of decommissioned nuclear submarines within the context of cumulative sources of radioactivity. This is a significant omission which makes it difficult, if not impossible, to adequately consider the incremental increase in radioactivity entailed in land or sea disposal of decommissioned nuclear submarines. Revision of the DEIS must incorporate adequate data, information and discussion to address this issue.

In considering the sea disposal option, consideration of cumulative impacts should begin with development of a comprehensive register of all radioactivity known or reasonably expected to enter the marine environment. This global inventory should include, but not be limited to, past, present and

potential levels of radioactivity from: weapons testing (Atmospheric fallout); historic U.S. and foreign radioactive waste operations; accidental losses of nuclear materials (including submarines); sea disposal of low level wastes under IAEA standards; other U.S. and foreign proposals for low level waste disposal; implacement of high level wastes in the seabed; operation of and/or discharges from civilian and military reactors; scientific experiments; accidental release; and disposal of decommissioned nuclear submarines as well as other military wastes.

This assessment should include an estimate of the marine environment's capacity to assimilate radioactivity without damage. This estimate must be based on sound science and will, in all probability, require additional research. Assessment of cumulative impacts would include descriptions of past, present and projected effects both in terms of human health and specific components of the marine ecosystem.

Consideration of cumulative effects must be complemented by a comprehensive monitoring program. We believe the marine monitoring programs considered in the DEIS are inadequate to gauge environmental effects. Absence of a comprehensive monitoring program prohibits sea disposal of nuclear submarines. In revising the DEIS, the Navy must consider and describe in detail the scope and costs of long-term monitoring of submarines on the deep ocean floor. Specific attention must be given to locating monitoring stations within 25 meters of the reactor compartment and in a network of sites where the plume of radioactivity from a submarine can be monitored. Details of plans for biota sampling, sediment sampling, use of submersibles and development of in situ monitoring equipment must be considered. Costs and assured sources of funds must be clarified.

The best estimate for corrosion described in Appendix G of the DEIS suggests the reactor compartment would be penetrated within 100 years and that bottom currents would begin flowing through the reactor compartment itself within 400 years of disposal. This estimate is used in Figure G-2 to show release of radioactivity to the environment as occurring in +/-100 and +/-400 years. Comprehensive monitoring programs, then, must extend beyond short-term studies to include releases of radioactivity projected for 100 to 400 years from now. Yet the monitoring program described in Appendix K of the DEIS proposes only a $9 million budget for monitoring "during and after the period of active disposal." Further, in Section IV-C, the DEIS states frequency of post-disposal monitoring will be determined by initial results - results from a period when the DEIS predicts no release of radioactivity to the marine environment.

The Deis must also consider instirutional impediments to conducting monitoring programs for a very long (400+ years) period. Experience during the past three decades has

demonstrated the difficulty in retaining records - let alone continuing monitoring programs - of nuclear wastes placed in the marine environment. To a significant degree, records of more than 100,000 curies of radioactive wastes dumped at sea from 1946 to 1970 are inadequate or missing. Research and monitoring of historic sites is virtually non-existent following only limitedly successful and sporadic research and retrieval efforts conducted at high cost.

Effects of accidental sinking of a submarine while the ship is being towed to a sea disposal site also merits additional considertaion. The 0.3 percent probability cited in the DEIS for an accident of a sib makes the likelihood of such a loss much higher than conceded in the document. Hazardous weather conditions frequently found off Cape Hatteras and Cape Mendicino further increase the likelihood of an accident occuring. | L.57 | L.61 | L.58

Neither the DEIS nor the scientific studies cited in support of this document justify selection of the sea disposal option over land disposal. Our inability to retrieve complete submarines from the deep ocean floor combined with the institutional impossibility of guaranteeing support for long term environmental monitoring make the marine environment an unsuitable site for disposal of this waste. | W.1 | J.76, J.79

These factors should combine to compell the Navy to withdraw the DEIS for extensive revision. Concerns expressed at this and other hearings should be considered and reflected in a new DEIS. THat assessment must be written in clear language and use consistent terms to allow citizens a fair opportunity to understand the issue. Release of a revised DEIS should be preceded by a public education effort which allows citizens in states like North Carolina, South Carolina, California and Washington and Oregon to question the scientists whose work supports the Navy's assessment. Then and only then will the Navy mave met the requirement for informed public participation inherent to a democracy.

Land disposal appears to offer a safer, more sensible solution to the dilemma now facing the Navy. If nothing else, the land alternative insures these submarines will not be sent out to sea, out of sight, out of mind.

CAPTAIN WAGNER: Thank you, Mr. Jackson. I previously had a preregistration for the Community Alliance for Nuclear Disarmament by Ms. Melissa Gehrman. Ms. Gerhman has not filled out a registration card this morning. Is there anyone here to represent the Community Alliance?

#16

MS. GERHMAN: I did fill out a card when I came in.

CAPTAIN WAGNER: Fine, Ms. Gerhman, you're the next speaker then.

MS. GERHMAN: Good morning. My name is Melissa Gerhman and I am here today on behalf of the Winston-Salem based Community Alliance for Nuclear Disarmament. We appreciate

the opportunity to participate in this forum today.

CAN-Disarm is a grass-roots organization which provides a resource center and support system for thoes in our community and across North Carolina who are concerned about the ever-increasing threat of nuclear war. This threat is the greatest threat facing our world today, and the proposal to dump these decommissioned nuclear submarines in the ocean is an example of how our priorities have focused on continuation of the arms race rather than pr-serving the earth.

According to my understanding, some of the submarines are being decommissioned because they are old, and others are being decommissioned to make room for new weapons systems such as the Trident. I also am familiar with the statement that the number of submarines to be decommissioned in the next 20 to 30 years is so great that the procedure of mothballing is not feasible for permanent storage. Our concern, however, is that the ocean bottom option for disposal may merely be the most convenient option for the Navy.

It is the contention of the disarmament movement that there are enough nuclear weapons now in the world. Thus, to allow the Navy to use the ocean option because it is the most economical method is to give our permission to continue the arms build-up in the most expedient manner.

This issue clearly shows how nuclear armaments create irreversable environmental problems. There are almost 60,000 nuclear weapons in the world today. As these systems age and become outdated, we must determine how to dispose of them safely. Otherwise, we find ourselves building up armaments in the name of self defense only to end up disposing of them in a manner which threatens the health and lives of the very people they were supposed to protect.

There is much concern that the DEIS glosses over too many problems and that the Navy is willing to go ahead with a plan without recognizing the full impact on the community or the implications the plan has for the future. For example, in the Forward, the statement is made that: "The decision to prepare the DEIS was based on the anticipated high interest in the disposal method decision rather than the expectation that either option would significantly affect the quality of the human environment."

Twelve years ago scientists recommended that the United States halt all radioactive dumping in the ocean because of their inability to determine its effects on the environment. A de facto moritorium was passed then, and recently the Congress passed a law which provided for a 2-year extension of that moratorium.

The ocean option would significantly affect the quality of the human environment because of the precident it would set for future dumping of nuclear wastes in U.S. waters. Once an L.9

ocean site is selected and approved, it will become the object of many more military and commercial requests for nuclear waste disposal.

How much would the North Carolina economy have to suffer in order to be considered significant? On page 4-23, it says that because of the remote location "The economy of coastal areas would not be subjected to limitations on the use of land, water, fisheries or other resources." L.53 On the contrary, the impact on coastal areas would be great. People who eat seafood caught off the North Carolina coast and who vacation there are not going to check out the monitoring data of the Navy before they buy their seafood or make summer reservations. O.34 They will simply take their business elsewhere. This would indeed have a significant affect on the quality of the human environment.

The word "significant" is used frequently in the DEIS, but its definition is no doubt subject to interpretation. Also the words "expected", "anticipated", "undetectable", and "eventual" are words that reflect uncertainty as to the safety of the ocean option. L.39 I site the following examples: On page 4-23, "The radiological consequences to the local sea life population would be undetectable, with no expectation of significant deletorious effects."

On page K-3, "Significant concentrations of radionuclides in the environment near the submarines would not be expected."

On page K-3, "No significant difficulty is anticipated in implementing such a monitoring program as a disposal site."

On page 2-12 it states that, "An unavoidable adverse environmental effect would be the eventual release of about 120 curies of Nickel-59 per submarine."

At the rate of 100 submarines decommissioned and buried over the next 20 to 30 years, that is 12,000 curies of Nickel-59. This certainly seems like a significant amount of radiation when you consider that Nickel-59 has a half-life of 80,000 years.

W.1

It is stated on 2-13 that "Retrievability would not be feasible with current technology." If we make a mistake with this radioactive waste now, will our grandchildren have the technology to retrieve these submarines if they find that the quality of their human environment is being significantly affected?

Other statements that cause doubt about the reliability of the DEIS are the following: On page 4-23, "The overall effects of this action on the local environment and ecology are expected to be negligible."

Same page: "Although a non-recoverable premature sinking is unlikely, it is not impossible."

On page D-1, "Minor damage may be expected to occur upon impact. Breaching of the reactor compartment containment would not be expected."

These conclusions seem to be based on expectations rather than on sound scientific evidence. L.1

Another area of concern is the monitoring of the ocean site. These were some of the statements made about monitoring practices: On page 4-23 in regard to public assurances of safety, "...Since the economies of many coastal regions depend on recreation, tourism and fisheries, an effective environmental monitoring program would be essential to assure the public that no adverse impact had occured."

But in regard to monitoring during active disposal, and on the page where costs are discussed, this is said: "If the initial monitoring surveys performed after commencement of disposal operations confirmed the expectations, the submarine disposals could proceed and the frequency of the monitoring surveys could be reduced." J.76

On the same page, regarding the monitoring of sites after the active disposal period, this is said: "If the analysis presented in this statement were to be corroborated by surveys performed during the period of active disposal, post-disposal surveys would be needed very infrequently."

Would "very infrequent monitoring" be considered "an effective environmental monitoring program" which a few pages back was said to be essential for assuring the public of its safety?

The adverse effects of radioactivity are often not detected until years after exposure, and so in terms of the half-lives of these wastes and corrosion rates of the container it seems that reduced or infrequent monitoring would be inadvisable even under the best of conditions and test results.

The time period of 90 days is extremely short for adequate study of this DEIS. Many of the people who have requested copies of the document have not yet received one, and others in the state are just now applying for one. For these reasons and for the benefit of all concerned North Carolinians, I request an extension of 90 days for the public comment period.

In conclusion, CAN-Disarm is opposed to the ocean option and particularly to the selection of the North Carolina site because:

L.1

1. The DEIS reveals too many uncertainties to believe ocean disposal is an environmentally sound option.

L.9

2. The ocean option sets a precedent for ocean dumping that would lead to extensive use of the North Carolina site by military and commercial waste producers.

3. The ocean option allows the Navy to have an expedient and economical method of disposal of weapons systems which encourages the current pace of the nuclear arms buildup.

Captain Wagner, thank you for allowing me to speak here today. I'm certainly of a differing opinion when discussing the DEIS, but I believe that ultimately we are on the same

side. I know that you and I both are working for the peace and security of our homes and for the future of our children. Thank you.

CAPTAIN WAGNER: Thank you, Ms. Oehrman. I have no further registrations for people representing organizations. Is there anyone registered representing an organization upon whom I have not called? Then I'd like to proceed with the testimony by individuals. Again, I would remind those individuals that we have a 5-minute time limit for individuals, and our first speak is Mr. Bill Barlow from Winston-Salem, North Carolina. Mr. Barlow.

#17

MR. BARLOW: Good morning ladies and gentlemen. My name is Bill Barlow, and I would like to speak as a concerned citizen. I would like to thank those of you who have arranged the opportunity to receive public comment on this controversial delimma of how to dispose of our man-made radioactive wastes. I cherish this democratic forum, and would note that people throughout the world envy it. That is why the decision we make on breaking a 12-year moratorium on ocean dumping of radioactive wastes is so significant, for we as Americans are leaders. Should we choose the ocean dumping option many other ocean dumps will be created throughout the world ocean network, many of which will not even match the integrity of those designed in this proposal. Whereas the ocean is an ever changing environment and a basis for our

F.8

future life on this planet, it is important that we note that what we dispose of now to be released in the next century will be the planning problems we present to our children's children.

I have read the DEIS, and I find within the volume many statements that lead me to doubt that no significant impact A.16 on the environment will be affected by the disposal of these reactor cores. Beside the continual use of phrases like "almost entirely" and "it might be expected", facts like "except for Nickel-63 which exceeds the Class A segregated waste limit by 30 percent...the disposal package...would be required to provide stability of the waste for at least 150 years..." for land disposal burial, and yet we expect a release in 100 years in the sea dumping option. These statements cause me some concern. Even comparisons with television viewing and transcontinental flights do not convince me that the "materials will decay to environmentally innocuous levels within the lifetime of the container." This dissolved L.20 radioactivity of the proposed ocean dumping is an added radioactive contaminant which does affect the delicate balance of nature.

One might view my attitude as one providing no action or no option. I will say I advocate one of the land disposal options at this time. I consider this the most responsible action on the basis of the retrievability. I declare it is

the responsibility of those commercial and military agencies and our federal government who encourages production of fission materials to provide the best method of disposal. I least approve of the military powers being given the priveledge of ducking this responsibility. The land disposal option will do more to encourage development of future long range best disposal method practices. I contend that if the Environmental Protection Agency, the Atomic Energy Commission and the Department of Energy ignore this retrievable aspect they are W.1 also ducking their responsibility and are diminishing the possibility of eventually solving the radioactive waste problems.

I am truely impressed and thoroughly amazed by our country's ability to harness the release of energy from an atomic reactions. However, as may be obvious, I am appalled by the lack of concern for pollution problems associated with its utilization. The current arbitrary designation of low level material locked in the submarine reactor core is merely the tip of the iceburg of the horendous monsters the Navy is cultivating. How many more spent fuel storage pools will be created to accomodate high level wastes from the decommissioning of 100 submarines? How much more Uranium and Plutonium will be processed to make life-threatening mechanisms? And ultimately, how many more new launch tubes will be fabricated for how many new improved multiple warhead missles?

I abhor any promotional avenues for nuclear proliferation, especially in a time of supposed reduction talks.

At least the land option can be viewed as practicing jobs for peace. Training men and women to dismantle nuclear weapons is at least a conforting thought for the extra money spent.

In the same vein, I would like to conclude with a formal request: as the nuclear power industry has not yet been saddled with the responsibility for the costs of effective plant shut-downs and radioactive disposal, I now call on the leaders in the nuclear weapons reduction proposals; Conte, Zablowski, Kennedy, Hatfield and McClosky to demand that these decommissioning costs be directly included in the cost

0.4 estimates for putting new submarines on line. For by agreement, we may only add new launchers as we retire old. Let the cost not be hidden at the bottom of our oceans.

Thank you.

CAPTAIN WAGNER: Thank you, Mr. Barlow. I have no further registrations. Has anyone registered to speak who has not been given the opportunity?

Ladies and gentlemen, additional comments for consideration in the final environmental impact statement may be sent to the address that I gave you earlier, to myself.

There will be two additional hearings today. The next one will be at 1:30 this afternoon, and then there will be one

at 7:30 this evening. You are all invited to attend either or both of those hearings. This hearing is adjourned, and I thank you on behalf of the United States Navy for your participation and interest.

(Whereupon, at 11:00 a.m., the morning session was concluded.)

AFTERNOON SESSION

1:30 p.m.

(At the beginning of the afternoon session, Captain Wagner gave his opening remarks exactly as found in the beginning of this text that he gave at the outset of the morning session. After Captain Wagner's opening remarks, Mr. Mangeno presented his statements and slide presentation, also exactly as found in the beginning of this test, and exactly as he gave them in the morning session. This transcript will commence with Captain Wagner's remarks made at the conclusion of Mr. Mangeno's presentation.)

CAPTAIN WAGNER: Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing. I will now recess briefly to establish an order for persons who wish to speak. For those people who would like to testify and who have not yet registered, you may do so at this time. We will reconvene the hearing in 5 minutes and start testimony at 10 minutes after 2:00.

(At which time a short recess was taken.)

CAPTAIN WAGNER: Simply to establish an order for the testimony, I intend to ask individuals representing state government organizations to speak first, in alphabetical order of the speaker's last names, followed by individuals representing local government organizations, in alphabetical order by last name of the speaker, and then private organizations

and private citizens in alphabetical order by last name of the speaker.

I request your cooperation in providing comments within the time limit so that we may be certain all who wish to speak have an opportunity to do so. Once again, that's five minutes for individual speakers and ten minutes for organizational spokesmen. If your statement is so long that it cannot be given in the time alloted, you may summarize in the five or ten minutes and the entire statement will be included in the record if you submit it in writing.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, proceed to the microphone on my left, state your name, address and organization, if any. All comments are to be addressed to me.

Our registered speaker at the moment is Mr. John Runkle from Chapel Hill, North Carolina, representing the Conservation Council of North Carolina. Mr. Runkle.

#18*

MR. RUNKLE: The president of the Conservation Council of North Carolina spoke at this meeting this morning, Ms. Jane Sharp. I am the coordinator of the Conservation Council, and I'm here to expand on her testimony and raise some other issues that we have with the environmental impact statement. I will preface my remarks by saying that our technical committee is looking very closely at the DEIS, and we will be submitting written comments, but these are sort of

*Other issues discussed by Mr. Runkle are side barred in Exhibit 468.

an outline of the areas that we're having problems with right at this present time. Maybe our technical committee will come up with others.

* F.9

The first thing is that all the way through the DEIS we see that in a lot of places the Navy is relying on the criteria developed under the Law of the Sea. We have a concern that since the Reagan Administration saw fit not to sign the Law of the Sea will the Navy still hold itself to those criteria for the disposal of wastes into the ocean? I'd like to see that in the final DEIS to be clarified. Actually, if the Navy will be following these criteria, whether we have to or not, some kind of statement saying that we are going along with criteria should be included.

We also are concerned as to whether this reactor within the submarine should be classified as low level radioactive waste under 10 CFR 61. This is a definitional problem - looking over how much radioactive material is in it, especially the radioactive Nickel that has a very long half-life - whether this should be considered something else, in fact; gigh level radioactive waste. You know, a reclassification, which would entail new guidelines for disposal of that kind of waste.

The biggest problem our technical committee is having looking at the DEIS, is that the; and we're talking about some hypothetical study areas here. I realize that these are

areas off the coast of North Carolina, but to this point would you not have any idea where the actual sites will take place? I realize that there will be site specific hearings later on, but it seems to me that any decision should be withheld until that time that specific sites can be talked about, so our oceanographers can look at the actual bottom current at that site, and what kind of pressure, what kind of upwellings are at that specific site. We realize that the Navy probably has more extensive surveys done of most of the coastal areas of the United States. We realize also that a lot of this, no doubt, is classified secret, but this kind of information and a specific site might be released, and that will allow us to be able to, and allow you and allow the scientists at the EPA and elsewhere, to look more closely at a specific site. And that's the biggest problem we're having with the whole thing right now.

J.9

J.28

J.31

Q.13

We had some serious questions about the effect of the high pressure and the 13,000 to 16,000 feet; what th- high pressure would be on the corrosion rate. And then it seems to me that there was a study done of an actual corrosion of; well, a study conducted in May of corrosion under that kind of pressure, and what the effect of that pressure would have on the effect of it being so cold on the outside and being radioactive on the inside. The difference between the heat and the cold may do other things to the corrosion; may crack

*Other issues discussed by Mr. Runkle are side barred in Exhibit 468.

things faster.

The biggest problem we have with the dumping off the coast of North Carolina is that first of all there is no monitoring. We will not ever know what has happened to these decommissioned submarines when they are sitting on the bottom of the ocean. We don't know if they are remaining structurally sound for 100 years and will not be releasing radioactive materials within that time. There is no effective monitoring of the submarines. And part of that is the retrievability aspect. If something happens that one of the submarines cracks wide open in the first week of being decommissioned, being disposed of, there is nothing we can do. We can't go down there - practically, we can't go down there and remove that submarine; which is one of the advantages of mothballing. At least in mothballing there is someplace you would have access to the vehicle to monitor this radioactivity in the submarine very closely and retrive them in the long run if necessary, or encase them within another layer if they started releasing radiation into the air.

J.76

L.20

W.1

G.2

Now, I did speak with some of our friends down in South Carolina, the Palmetto Alliance, that's been monitoring the Savannah River Plant for years, and that part of the DEIS is inadequate, and I'm sure that they will comment more in your hearings down there in South Carolina.

We talk in terms of background radiation, and our concerns

are that we are not looking at the cumulative effects of all of the radiation that's going into this Savannah River Plant. The start-up of the L reactor will make that area more radioactive; the new interstate low level radioactive waste compact where wastes from 5 or 6 of the southeastern states is going down to the Savannah River will make that area more radioactive.

E.17

Nuclear power plants in the near future will have to be decommissioned. Where will those reactors go? We pray that they do not be disposed of in the ocean, and if they are disposed of on land in the Savannah River Plant Reservoir we'll have more and more radioactivity in that area.

The Conservation Council of North Carolina has about 600 members across the state, and many of them are down at the coast. Six or eight of our member organizations are coastal groups that have been concerned and have been working on the coast for years, and there's something about our coast of North Carolina that is worth saving. We have the most beautiful beaches in the world, we have beautiful natural areas, we have an extensive tourist industry, and fishing industry - both commercial and sport fishing. Knowing that this radioactivity is off our coast upsets us. In the long run, this is the very thing - I think it will cut down on our industry and cut down on our economics of the coast, and we would like to see the consideration of what the effects of this kind of thing

L.53

O.34

will do to our coastal industry.

As a last question in this hearing, we are talking in terms of roughly 100 submarines that have to be decommissioned in the next 25 to 30 years. This does not take into consideration submarines which may be built starting now, which may be another 100 submarines, another 500 submarines. There's no telling how many nuclear submarines the Navy does want to decommission, and once they start dumping this waste, this radioactive waste off our coast where is it going to stop? We have to stop it right here. We're really concerned about what's happening on the coast of North Carolina.

A.1
N.12

Thank you.

CAPTAIN WAGNER: Thank you. We had a pre-registration for Mr. Doug Guild, representing AMUSE. Is there anyone in the audience to speak for AMUSE this afternoon? I have no further registrations; is there anyone who has registered to speak who I have not yet identified and would like to speak now?

I thank you very much ladies and gentlemen. We will adjourn this hearing, and we will hold another hearing this evening at 7:30. You are all welcome to attend that, and we thank you very much for your interest and testimony this afternoon.

(Whereupon, at 2:22 p.m., the afternoon session was concluded.)

EVENING SESSION

7:45 p.m.

(At the beginning of the evening session, Captain Wagner gave his opening remarks exactly as found in the beginning of this text that he gave at the outset of the morning session and afternoon session. After Captain Wagner's opening remarks, Mr. Mangeno presented his statements and slide presentation, also exactly as found in the beginning of this text, and exactly as he gave them in the morning and afternoon sessions. This transcript will commence with Captain Wagner's remarks made at the conclusion of Mr. Mangeno's presentation.

CAPTAIN WAGNER: Thank you, Mr. Mangeno. Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing.

I will now recess briefly to establish an order for persons who wish to speak. For those people who would like to testify and who have not yet registered, you may do so at this time. We will reconvene the hearing at ten minutes after 8:00 and start testimony at that time.

(At which time a short recess was taken.)

CAPTAIN WAGNER: The hearing will come to order. Simply to establish an order for the statements, I intend to ask individuals representing state government organizations to speak first, in alphabetical order of the speakers' last names, followed by individuals representing local government organizations, in alphabetical order by last name of the speaker, and then private organizations and private citizens in alphabetical order by last name of the speaker.

I request your cooperation in providing comments within the time limit so that we may be certain all who wish to speak have an opportunity to do so. Once again, that's five minutes for individual speakers and ten minutes for organizational speakers. If your statement is so long that it cannot be given in the time alloted, you may summarize in the five or ten minutes, and the entire statement will be included in the record if you submit it in writing.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, proceed to and use one of the microphones provided. State your name, address and organization, if any. All comments are to be addressed to me.

Our first registered speaker is Ms. Jane Ballus, representing the American Friends Service Committee.

#19

MS. BALLUS: I am Jane Ballus representing the American Friends Service Committee, Southeastern Regional Office, Atlanta, Georgia.

Thank you for the opportunity to present this statement tonight regarding the disposal of nuclear submarines at sea. We appreciate the fact that the Navy has an interest to meet here in Raleigh to consider the views of the citizens of

North Carolina.

The disposal of radioactive materials at sea is an issue of major concern, not only for people of coastal areas but for people everywhere who depend on the oceans for both economic and spiritual sustenance. The environmental impact statement has stated that the submarines would be sunk too deep to pose any threat on the ocean ecosystem. We would suggest that more studies are needed on bottom currents, artificial reefing and marine life cycles.

J.9
L.55
L.13

In contrast to the unfounded optimism of the Navy, is the history of ocean dumping of nuclear wastes. Above all else, the main lesson of ocean dumping of nuclear wastes is that no one can accurately predict what will happen in the future, and that adequate monitoring of ocean dumps is extremely difficult, if not impossible.

L.39
J.76

From 1946 to 1970 nearly 90,000 containers of radioactive wastes were dumped in the sea off the U.S. coast. Reports from California and Maryland are now showing that radioactive contaminants from these dump sites are being found in the open water and in marine life. Keep in mind that at the time of the dumping, ocean disposal of radioactive wastes was considered to be quite safe and would pose no future problem.

What we need to emphasize is that once submarines, or any other objects, are dumped into the sea they are virtually impossible to remove or recover, and difficult to monitor;

W.1
J.76

L.20 L.36 T.32

which means that any unanticipated result, such as leaching of contaminants into the sea or uptake by marine life, is likely to be impossible or prohibitively expensive to correct.

One of two assumptions is implicit in this Navy proposal. The Navy either:

1. Expects its analysis and projections are perfect and will perform perfectly; or

2. They are willing to run an experiment in which more studies are needed and which could cause broad reaching impacts.

We reject moving ahead on the basis of either assumption.

F.8

There is also a major policy impact of this proposal. The United States and a number of other countries are reviewing plans for the permanent storage of stockpiled high level nuclear wastes. Here again, several proposals for ocean and seabed disposal of high level radioactive wastes have

L.9

been presented. Again, once placed on the seabed these wastes would be virtually irretrievable. Our concern is that a precedent of dumping nuclear submarines at sea would serve

F.8

as further incentive for ocean disposal of other radioactive wastes. Indeed, U.S. leadership in ocean dumping could provide an added incentive to other coutries to adopt ocean dumping plans. Conversely, U.S. restraint in ocean dumping could provide added weight towards an eventual prohibition on all ocean dumping of nuclear wastes.

For a project of this magnitude it is most essential for the general public to have access to information in order to make an educated review of the possible impacts. The Navy and other arms of the Department of Defense and Department of Energy are notorious for not releasing complete information about nuclear related projects which could have an impact on human and natural environments. A case in point is the construction of a Naval nuclear weapons storage bunker in the flight path of the international airport in Honolulu. The Navy opposed preparation of an Environmental Impact Statement for that project and fought their case all the way to the Supreme Court. The same has been true with accidents involving nuclear weapons; the Department of Defense and Energy have repeatedly avoided disclosure of such accidents and restricted the amount of information released.

A.6

In the case before us it would be most important for the public at large to know specifically the make-up of reactor

L.24

components and other potentially radioactively contaminated parts in order to review their impact. Such a public review can only provide positive results in improving the safety of any proposed actions. As an example, we might point out that for reviewing the long term impact of civilian nuclear reactors, the U.S. Nuclear Regulatory Commission failed to include the impact of radioactive nickel until it was exposed by an independent review by the New York Public Interest Research

Group under the direction of Dr. Marvin Resnikoff. In additicr public review of civilian reactors has resulted in the improvement of reactor safety by requiring the addition of non-standard back-up features. In these cases, the federal agencies involved opposed the public's position initially but later adopted it as a standard practice.

In summary, we offer the following: Ocean disposal of decommissioned nuclear submarines sho-ld be opposed for the following reasons:

W.1

1. Once deposited on the ocean floor the submarines would be virtuallly irretrievable; thus any unforseen occurrences resulting in the release of radioactivity could not be controlled; and

F.8
L.9

2. Ocean disposal of nuclear submarines could serve as additional incentive for ocean disposal of other radioactive materials by the U.S. and othe- countries.

Finally, we urge legislation requiring permanently retrievable land disposal of the decommissioned submarines. Retrievable land disposal is the only sane option for the safe, long-term management of the decommissioned submarines.

H.5

One possibility which we suggest the Navy explore is the dismantling of the radioactively contaminated components for entombment in civilian nuclear reactors scheduled for decommissioning.

Thank you for your consideration of these comments.

#20

CAPTAIN WAGNER: Thank you, Ms. Ballus. The next registered speaker is Mr. Wells Eddleman, representing North Carolina Public Interest Research Group.

MR. EDDLEMAN: Thank you, Captain Wagner. I am Wells Eddleman, staff scientist with the Nort- Carolina Public Interest Research Group.

I was able to receive a copy of the DEIS by telephoning for it. My collogue, Ruffin Slater here, wrote for one and has not gotten it, and we understand that some others haven't gotten theirs either. This reflects, I think, some of the difficulty that some of the public groups and individuals have had in getting hold of information on the study. However, I have gotten the DEIS, and I would like to make the following comments:

First, if the situation really requires no rush, as is repeatedly stated in the DEIS, it appears that the schedule of these hearings is too close to the time of its issuance, and the comment period is too restrictive, and the Public Interest Research Group respectfully joins with those other organizations in requesting an extension of the comment period. I should think, given that the actual disposal of these submarines has been banned by statute now for two years, that an extension of 180 days would be appropriate. There certainly is nothing to be lost by a thorough scientific study of the implications of this project.

I believe that this waste disposal might be characterizeu by saying that want to boldly dump wastes where no one has ever dumped before, and there are some difficulties with that that I don't think have been proved out in practice.

F.20

I was interested to read in the DEIS of tests of sinkin cylinders. However, these weren't strealined like a submarine, and the ones that were sunk with hemispherical heads, even they would have only some of the characteristics of a submarine, and I would think that the effect of impact on the sea bottom should be analysed, not only with respect to the submarine itself, but on to the reactor bulkheads, because the water in the after compartments is independent, really, of the metal of the submarine, and as a person who has worked on crash tests of automobiles, I can tell you that when we have de-coupled impact like this - that is, the vehicle, the sub-marine, is stopped by crashing into the sea bottom but the water still has this momentum, you're dealing with a situation of enormous force, and I'm not sure what that those bulkheads were designed to withstand, and I'm not sure what they will withstand after having been stored for some time. But it should certainly be assured that this will not result in ruptureing the bulkheads.

I would also note that the 62,000 curies of radioactive material in each sub initially, after defueling, is really a substantial amount of radioactivity, particularly when 22,000

of it is that very nast species, Cobalt 60.

In the ocean currents under which the DEIS discussed the dispersal and diffusion of the submarines' radioactive contents, they must go somewhere. There's not just a potential for biological concentration at the site, although the effects of ocean bottom bacteria do not appear to have been adequately explored. But also, this water must upwell at some point, and this may very well be one of these nutrient rich areas, like the Carribean Sea, or our Gulf Stream, or off the Coast of South America, in which you have numerous life forms of many stages, and the hierarchy nad food web which concentrates radioactive materials - and I'm particularly concerned about the Cobalt, because as you know, many forms of marine life have Cobalt based blood.

L.55 Q.12 Q.13 J.31 L.37 L.18

It appears to me that there are a great many unknowns that just are assumed to work out here. For example, the submarines will not leak early. If this is the case then certainly better monitoring of the site is advisable.

L.40 L.20

The DEIS seems to minimize the cost of monitoring, but I think that both the radioactive material and biological activity; the sites need to be very well monitored. It appears that right now, that the monitors to locate the sub when it sinks are adequate, but the monitors for radiation both on sinking and later are not. And I further would question how we could guarantee such monitors for 400 years, which the Navy

J.76 J.79

expects to be the critical time for the release of these materials, and what that would cost. And I'm not just talking about the future dollars to the point where, you know, a million dollars 100 years from now might be worth two cents. I think we need to be realistic about what it might cost.

L.55 Q.12 We also need more information concerning life forms making these submarines their homes. What is their impact on corrosion rates? Would it be possible, for example, for sea bottom gnaqing worms to penetrate corroded areas earlier than the Navy has assumed? What would be the impact of iron-based bacteria that is, that use iron in their biological process - and sulfur - attaching themselves to parts of the submarine where the reactor compartment is, and increasing corrosion?

H.3 It appears that it will be much more desirable to store the defueled reactor plant above ground, preferably in a shed or in some protected area in a dry area. And there are such places. For example, the desert in Hanford.

W.1 I would also question what the cost might be, and feasibility of raising even one submarine from a depth of 4000 or 5000 meters if things have gone wrong. What would be the cost to raise 50 if it were determined that the first sub was leaking as the 51st was being sunk. I would question how marine salvage at such a depth is becomming more or less feasible, and

what its cost might be.

Finally, it appears that the comparisons of radioactive impacts in the DEIS are unrealistic in the sense that they do not integrate all persons and all biological forms that are exposed to this radioactivity. When you consider this cumulative fact of larger areas of submarines, of submarines being disposed, the impact could be substantially greater, very substantially greater than has been supposed. And this has been the case in the past with radioactive disposal in the ocean at other places, and I would urge you to consider these comments in preparing a final impact statement, and I hope that more time will be available for the public and various interested parties to further review this document. L.7

Thank you.

CAPTAIN WAGNER: Thank you. I would like to interject here that I think I mispronounced both names tonight. Please accept my apologies, but rest assured that our reporter will get your name properly for the record.

Our next registered speaker is Mr. Doug Lowe representing People's Alliance. Mr. Lowe.

#21

MR. LOWE: Thank you. My name is Doug Lowe. I am spokesperson for the North Carolina People's Alliance, and I live in Durham, North Carolina, where our citizens organization has a large chapter. The rest of our membership tends to be concentrated in the Triangle area, in Chapel Hill and Raleigh, but we have other members across the state, some of whom are at the coast.

First let me say thank you for holding this hearing, and I know it's a thankless job you have sitting up there and hearing all of this. It's kind of a tough process. I go to hearings a lot because I'm an activist, and you go to hearings a lot because you are paid to hear us, but what we're really after here, I suppose, is a combination of a scientific conference on a report, which I'm not qualified to make; and the process of democracy that says we have to see what the citizens feel and think about this, and unfortunately I suspect that in the process of these environmental impact statements citizens emotions don't count for very much, but let me state a couple of things.

One is that we have had trouble getting a copy of the Draft Environmental Impact Statement also. It was not available in the library in Durham, and so it wasn't convenient for me. And I share the sentiments of our organization that anything of this import certainly needn't be rushed into, and we have your assurances in the Draft EIS in the summary that you are not rushing into it, but you're certainly rushing the hearing process by allowing only 90 days for comment after the DEIS is available.

I first came to North Carolina because of the Outer Banks. I first came here to go to the Outer Banks, and they

are kind of a magical place, and I know magic also doesn't figure in science. I wonder if the environmental impact statement is going to be taking into account impacts in the business environment that have to do with people's image of the Outer Banks changing if they know that there is some radioactive material out there a few hundred miles away. I can assure you as a former advertising man that things like image are very real, and that as most businessmen know, good will or what the public thinks of you can count in dollars and cents, and I don't see really, that you are taking that into account. You offer assurances that it's not going to really affect our fishing industry and other things, but I don't think there's a way; or, there has been very little attempt to measure the cost to the business environment on one of our largest industries, the tourist industry, of sinking a submarine with radioactivity in it out there, because the reality of the matter is just how people perceive it.

L.53

O.34

I'd like to discuss the issue of land versus ocean disposal. It seems to me that your proposal has dollar amounts being in the ocean disposal's favor, and I suppose the Navy is always in favor of dealing with the ocean rather than dealing with land, but you have some other reasons for it that I can't get behind some of your assumptions. There were some words you used that the only feasible way or practical way was to dump it in the ocean. There's no mention of land options other than burial on land. There's no mention, for instance, of this idea just mentioned before me of putting it in the open air, or in the air above ground under a shelter. I happen to have grown up just in the high desert of Washington state, just next door to Hanford where I can testify on the weather conditions up there. And it seems to me that the cost of disposing this on land is artifically inflated when you make it necessary to bury it, when you have an environment there that doesn't require burial, and in fact, being in contact only with the air rather than the ground would keep the metal from corroding. This option would contain a radioactive container much longer than either contact with land or the contact with the sea. And in fact, the sea, if you wanted to choose a natural medium that corroded metals as fast as it could, I don't think you could choose a better one. So some of the logic of this I don't understand, and I wonder how much thought has been given to this, or whether it really has to be buried on land rather than be put above ground. And if you could put it above ground, how much would you save in costs by getting rid of the expense of having to dig the earth and all of that.

H.3

H.3

H.3

It seems to me that some other advantages by having it sitting above ground would be that you can look at it. The monitoring, of course, is very easy and very inexpensive, and as we've already heard, the monitoring that we see in the

objective for the ocean is, or appears to be very inadequate, and even if done adequately, inpractical and incredibly costly. There's no estimate as to what the cost would be, but somehow it seems that keeping it above ground would make it easy to monitor and easy to recover.

J.76

H.3

Again, we're talking about something that's virtually impossible to do - recover a sub from a depth of 4000 or 5000 meters, and we certainly wouldn't want to incur that expense, and we're not really planning on that, but it seems like Murphy's Law would say that if you plan on it, then you should also not plan on it.

W.1

I think there's another advantage to having it on the land, or that may be a disadvantage depending on your point of view, but from my point of view it's an advantage because the whole nation can see, or we have these visual reminders of how much radioactive material we are building up and storing, rather than throwing it away, out of sight, out of mind. And as ecological awareness is teaching all of us, there is no other way - you don't throw anything away, you just put it somewhere else, and it's all connected. By putting it in the ocean it appears to be away, definately out of sight and out of mind. So I want to see it on the ground where I can see it.

H.3

There's a very interesting book written by Garrett Holden called <u>Tragedy of</u> Commons, which says that we cannot divide something that everybody has in common. You know, so we throw our stuff there, and that's away, but that belongs to everybody, and yet the full circle of responsibility says that if you cause a problem or you create a material you should live with it or solve the problem yourself. And so I would say that this material should be disposed of on government land. The government created it and the government should keep it on its land and not put it on the ocean floor that belongs to all the peoples of the world.

F.8

It's very interesting for us to say to all of the people of the world that we've got undesirable materials there, but we don't want them following in our footsteps, if we can help that.

I.9

There wasn't anything in the EIS about the Savannah River site, and I would like to say that it's an above-ground site, or a land site. To me it seems far inferior to the Hanford reserve. And there was some comment made in 1976 included in the DEIS on the Savannah River site saying that it's, you know, very safe for the materials that are beinghandled there. And I've seen something very recently about the degree of radio-

I.4

activity in the ground water, and so I suggest that that be checked into further to see if you are really aware of that latest information that seems to suggest that the Savannah River site is unsafe.

There's also the question of a negligible exposure, and

it's something that's referred to - well, I won't dwell on it, but it is kind of the metaphor, or whatever, of the straw that broke the camel's back. Each straw is negligible, but the last one had an impact, and if you think that law is negligible, it increases our level of radioactivity, and if it's negligible compared to background, compared to television, compared to an airplane flight, at what point do all of those negligibles add up to something that is not negligible. I don't think that question is addressed at all.

L.7

Two final points: I've already referred to Murphy's Law, which as I understand it is that anything that can go wrong will. I see a possibility for two accidents: one which the DEIs mentions briefly - accidents in the towing of the subs to the location you intend on sinking them. It seems that a possibility, in fact, a great possibility, given the seas off the Outer Banks of losing a sub before you get it to where you want it to start sinking it. In other words, the sub may end up on the continental shelf somewhere much closer than the Navy would like it. And therefore that means having to remove it.

L.57
L.60

Also, I gather you're thinking of a much wider or bigger area for sinking the subs in the water than on land, because you want to give plenty of room for those subs to sink and not hit one another. And that's very wise, but this I think - I didn't see anything at all in the DEIS about the probabilitie:

F.23

of one sub hitting another. And it seems that there ought to be some figures on that such as: what are the chances? How much control do you really have in your ability to sink something like that and have it go down and not have one sub accidently hitting another that has already been sunk and causing a rupture and a much earlier dispersion of this radioactivity.

Those are our comments and our concerns. Thank you again for the chance to express them.

CAPTAIN WAGNER: Thank you, Mr. Lowe. I have no further registrations for people representing organizations. Has anyone registered to represent an organization whose name I have not called? At this time, then, we will proceed to testimony by individuals. Again, I would remind that we have a 5-minute time limit for those people speaking for themselves so that everybody will have an opportunity to speak. The same procedure will be used; proceed to the microphone and state your name when I announce it. The next registered speaker is Mr. James F. Berry from Raleigh, North Carolina.

#22

MR. BERRY: How do you do? I'm James Berry, and I want to say also that I appreciate the opportunity to be able to say what I have to say. I'm a retired Colonel with the U.S. Air Force. I've worn a uniform for a large number of years and I understand a little bit about the position you're in. I didn't come to speak in my capacity as a retired colnel;

I'm an ecologist. I've become an ecologist since I've retired, and I want to speak from the standpoint of an ecologist and a North Carolinian.

I would like to support the statements that have previously been made by some respected authorities from the Oceanic Society and from Greenpeace in which they state that they really would like to have some more time to study the DEIS. Others have said the same thing, and I want to repeat that I believe that there is a need that there be more time allowed for study and comment.

I would like to affirm the one great lesson that we have learned in the ecological field in recent years, which is that everything is connected to everything else. Wherever you put these submarines you're going to put them in the middle of a life system. There is a web of life that surrounds the universe. You can't put anything anywhere that you do not interact. So you're going to interact with the earth wherever you put them, and where you're going to put them, if you do put them off the coast of North Carolina two and one-half miles deep, you're going to put them in a place where they are in contact with an earth system and you've got to know what's going to happen to that earth system as a result of their presence there. And you stated in your opening statement that one requirement on you to produce an environmental impact statement is that this will have a significant impact on the environment.

I do affirm, and I think that I can get a lot of support for this, that no matter where you put it you're going to interact with the environment, and I understand that you're trying to find that place that's going to cause the least interaction with the environment, and I say now that there is going to be a life system wherever you put it.

W.1

If you discover, after you have put these, this large number of submarines there, that the interaction with a life system is going to be something very important, or very critical, you're not going to be able to retrieve them and move them.

L.14

I would like to point out also that the impact on the human life system is not the only impact to be considered. The impact on any life system ought to be looked at.

I would like also to point out that mistakes can be made, and we have the horrible circumstances of the things that happened by the way of radiation up in Utah in the salt flats. We had one happen with Agent Orange in Viet Nam; we've had the results of what's happened to all of the chemical dumps where unexpected results have ensued - some of them very bad.

I would like also to state that the study of how to handle the radioactive problem is a study that is receiving a whole lot of attention all of the time. I suppose that sometime science may find out some way to deactivate radioactive waste.

If they do, then you're not going to be able to deactivate that submarine 2 and one-half miles down at the bottom of the sea.

The last thing I want to say is that this is my home. I don't want stuff in my back yard of such potential harm. I think that once you put any radioactive waste in the sea off North Carolina, that then that's going to be a place where people are go-ng to want to put all radioactive wastes. L.9

Thank you very much for the opportunity to speak.

CAPTAIN WAGNER: Thank you, Mr. Berry. Our next registered speaker is Ms. Laura Drey from Durham, North Carolina.

MS. DREY: Could I ask for another couple of minutes? Is there anybody after me?

CAPTAIN WAGNER: Certainly. We'll come back to you after two or three more speakers. The next registered speaker is Mr. Robert Eidus of Raleigh, North Carolina.

#23

MR. EIDUS: Good evening, and how are you doing? I'd like to wish you a happy Valentine's Day gentlemen, if nobody's done that to you today.

Although my remarks are basically critical of the DEIS, I would like to state that these comments should be taken as constructive criticism. They are directed both at the Navy and my opportunity to talk about EPA. I think they are linked. I sincerely hope that these hearings will underscore the concern of many North Carolinians represented here tonight to have our oceans safe and healthy, and that they not be infected by environmental radioactive pollutants.

EPA has changed its role recently, and they are now, so I'm told, involved with enforcement of our environment to a lesser degree, and more with an attitude of industrial compliance. Personally, I think that this is not in the best interests o- the citizens of this country.

I thought that EPA should stand for Environmental Protect: Agency, and that the protection was for all of the citizens of this great country, not for the protection of the polluting industries or the military.

The EPA, to have hired Glenn Sjoblom to review the Draft Environmental Impact Statement, should be held as a blatant inexcusable act. Mr. Sjoblom should have enough ethical character as a U.S. Navy engineer to withdraw from participation in the review process. He should be relieved of his duties if he does not do so, because this report should get a fair and impartial hearing.

I think EPA should refrain from making suggestive stateme-- also in Congress concerning people who were consulted in this matter; that the ocean dumping of nuclear wastes is harmless. We have reports from the EPA that rat-tail fish caught near
U.9 an old dump site near New Jersey were contaminated with levels of radioactivity many times higher than background. And just

because human beings do not eat rat-tail fish does not mean this is not a problem, as EPA thinks.

As Jasques Cousteau advised President Reagan at a White House luncheon on June 23, no dumping which has been; there should be no dumping which has irreversable impact, that that should never be allowed in this country. I contend W.1
that nuclear dumping is known to have irreversable contaminants of the ocean environment, and ultimately on mankind. These studies are known and should be a part of this DEIS. F.12

Now, let's talk about the options stated in the DEIS. The land option proposed has the scrapping of metal, and shows it as a negative cash flow. So why should be even consider it if it has a negative cash flow? Where is the imagination that is necessary for a project of this nature and magnitude to come forth? Why is it not proposed to separate the core section? You could seal it and then take it to the land site, O.10
could open it and fill it with concrete or line it with lead. Then you can take the other sections of the submarine and do with them what you will; take out the intelligence equipment and use it somehow. Take it out to the sea and make a man-made reef out of it, or let the Navy tow it out and blow it up.

The subs at sea are reported by the Navy to be posing no more of a hazard than watching TV or taking a long airplane flight. I'm insulted. There is a big difference. Each individual can choose whether to watch TV or take an airplane ride, but we're not given a choice if you dump the radioactivit into the ocean.

L.40

The point being made is that realistic options were not examined so far, and that the human possibility of error is always there. A case in point is an EPA administrator in the office of toxic wastes who was fired recently, cited with contempt of court for lying under oath; not something that the EPA or the Navy should be proud of. Of course, now, the EPA, they are not dealing with this problem. The sites are not being monitored now. You talk about monitoring sites, but they're not monitored sites. If EPA could mis-represent the hazardues waste situation in this case as it recently has done it abuts our ability to understand what people are trying to protect our interests.

L.6

In the past they have said that there is no problem with the dumping. They went to Massachusets, they opened some barrells and they determined there was no problem with toxic wastes. But they couldn't find the barrells. So, if they couldn't find the barrells then there was no problem with toxic wastes. This does not give the average citizen a deep-seated confidence in EPA that they are really protecting our interests.

L.36

or the interests of people who like to eat seafood.

What I want the Director of EPA right now to do is to turn over the materials Congress wants. This sounds very

suspicious. Are we going to be getting the same presidential executive privilege stuff and national defense rhetoric in the future years? All I can say is that I would like to implore and ask you to consider the future consequences for the sake of the children who will occupy this earth in years to come. It is for them that I come here today to support an international desire to continue the moratorium on dumping; not to pollute the oceans with its fragile ecosystem that we are all so fortunate to enjoy.

Thank you. I hope you have a good evening.

CAPTAIN WAGNER: Our next registered speaker is Mr. Robert B. Ginnis from Cary, North Carolina.

#24

MR. GINNIS: My name is Robert B. Ginnis, and I would like to speak in favor of the ocean disposal matter. I seem to be quite a minority here today.

Basically, it seems rather clear from the Draft Environmental Impact Statement, which by the way, I had no trouble getting - I received it quite promptly in the mail - that all of the impact from either land or ocean disposal would be very minimal, and actually the difference between the two is probably not worth considering.

However, there is one potential problem with the land disposal that I do not see in the impact statement, the draft statement, and that is the potential that at some point down

E.33 the line, the way that I understand the reactor compartment would be prepared, the reactor compartment would fail, would rust through and create a void in the landfill which presents the possibility of water infiltration into the landfill through a broken cover, which would be a problem.

The problem would be less so at the Hanford site than at the Savannah River, basically, and I think that's the only difference between the two, and I believe the cost is sufficient cause in and of itself to justify the ocean disposal.

Thank you.

CAPTAIN WAGNER: Thank you, Mr. Ginnis. I have one remaining individual registered to speak, and that is Ms. Drey. Are you prepared yet, Ms. Drey?

MS. DREY: All right.

CAPTAIN WAGNER: Ms. Drey is from Durham, North Carolina.

#25

MS. DREY: My name is Laura Drey, and I've been out of town for the past week and I didn't expect to get into town until tomorrow, so I wasn't anticipating speaking.

L.36 Mainly what I would like to address is the radioactivity once it gets into the food chain; and I'm not really used to speaking at these hearings. Basically, you know, when you dump radioactive materials into the ocean they get into the food chain like a couple of people have said earlier tonight, and internal damage can be done to people through the

food chain. And, as you know, from studies, I'm sure, radioactive materials can go through the food chain to man through water and soil and water plants, food crops and animals, fish and milk products. And the closer the food is to being irradiated, it's more apt that the irradiated food is to get into people.

Basically, once you dump radioactive materials like the nuclear subs into the bottom of the ocean, they can then be;- the water can evaporate into the air and come back down, and that's how the radioactive materials can get into the food chain. Once that happens - or if, you know, as the ocean mixes, radioactivity can get on the top of the ocean, and when that happens you get the eggs, the fish eggs and stuff are there, and that means that the radioactive materials are then passed on to young fish.

And basically, I guess what I want to say is that as the radioactivity passes, let's say, from small fish to larger fish, as in the case in the ocean, it gets the radioactivity which becomes more and more concentrated as it moves up the food chain. L.37 And I guess that's about it, since I'm not really, you know, prepared to speak. Thank you.

CAPTAIN WAGNER: Thank you very much, Ms. Drey.

Ladies and gentlemen, I have no further registrations. Has anyone registered to speak that I have not yet given you the opportunity? Then I would like to thank you all very much on behalf of the United States Navy and myself for your intere. and your testimony tonight. Thank you again; this hearing is adjourned.

(Whereupon, at 9:00 p.m. the afternoon session was concluded.)

DISPOSAL OF NAVAL SUBMARINES OFF NORTH CAROLINA COAST

My purpose is to present two reasons why, in my opinion, the Navy and government officials ought to be concerned about the ocean being polluted by radioactivity emitted from nuclear submarines that have been disposed of in the ocean.
L.36 first, radioactive materials are passed through the sea food chain to man, and second, radiation causes health problems to man.

L.20 The radio isotopes in the nuclear submarines will not remain contained within the submarines. The reactor vessels are bound to corrode, releasing radio isotopes into the ocean, since the submarines will not be able to outlast the life of some of the radio isotopes. Once the radioactive substances are discharged into the
L.14 marine environment individual organisms, whole populations, and the food chain will be contaminated by radioactive materials.

Radioactive substances are passed through the ocean food chain. Radioactive materials are carried through the sea food chain from tiny floating plants to small crustaceans to intermediate flesh eaters to larger flesh eaters to man.

TABLE 4 APPROXIMATE CONCENTRATION FACTORS OF DIFFERENT ELEMENTS IN MEMBERS OF THE MARINE BIOSPHERE. THE CONCENTRATION FACTORS ARE BASED ON A LIVE WEIGHT BASIS.

Element	Form in Sea water	Concentration in sea water (micrograms/L.)	Algae (Non-calcareous)	Concentration Factors: Invertebrates, Soft	Invertebrates, Skeletal	Vertebrates, Soft	Vertebrates, Skeletal
Na	Ionic	10^7	1	0.5	0	0.07	1
K	Ionic	380,000	25	10	0	5	20
Cs	Ionic	0.5	1	10		10	—
Ca	Ionic	400,000	10	10	1,000	1	200
Si	Ionic	7,000	20	10	1,000	1	200
Zn	Ionic	10	100	5,000	1,000	1,000	10,000
Cu	Ionic	5	100	5,000	5,000	1,000	1, 0
Fe	Particulate	10	20,000	10,000	100,000	1,000	5,000
Ni	Ionic	2	500	200	200	100	—

S	Ionic	900,000	10	5	1	2	—
I	Ionic	50	10,000	100	50	10	—

* Values from Lowman and Thompson (1956).

"The lower or more primitive forms are generally more resistant to ionizing radiation than are the more complex vertebrate forms." (p. 96 National Academy of Science)

> The algae and protozoa are most resistant with LD_{50} values in the order of many thousands of roentgens. The molluscs and crustaceans are somewhat more sensitive, with LD_{50} values of a few thousand roentgens (aquatic insects probably also fall in this category) and the fish are most sensitive with an LD_{50} of about one thousand roentgens- in the same order of magnitude as that of other cold-blooded vertebrates. (p. 96-7 National Academy of Science)

There are factors that determine how radioactive substances work in the sea food chain. The behavior of the radioactive materials depends on the distance between the source of the radioactive contaminant and where the contaminant is taken up in the food chain, and the mixing characteristics of the sea. Radiomaterials act differently in the "three trophic levels: (1) the distribution of elements among the three levels, (2) the concentration factors in different organisms within the same level, and (3) the transport of radiomaterials from one trophic level to another." (p. 76 National Academy of Science)

> In general, the radiomaterials taken up by organisms of the first trophic level will be primarily in the ionized state although a certain amount of particulate radiomaterials will be adsorbed to the body surfaces. When uptake occurs, the rate of uptake will probably be more rapid than the rate of uptake in the other trophic levels.
> Particulate radiomaterials tend to be concentrated in the second trophic level. Findings from the Wigwam and Castle tests (Goldberg, unpublished data) showed that the principal organisms which concentrated particulate radiomaterials were the mucous, ciliary, and pseudopodial feeders among the zooplankters. These organisms contained much more radioactivity per unit weight than either the algae or the petal or rapacious feeders. (p. 77 National Academy of Science)

> The transfer of radiomaterials from one trophic level to another is not only dependent upon the concentration of the radiomaterial in the organism but also is governed by the rate of growth of the organism and the rate of increase in the size of the population. (p. 77 National Academy of Science)

> In any event, there is always a loss in the total amount of radiomaterials in the transfer from one trophic level to another (though not necessarily a decrease in the concentration in individual organisms). Such a loss may be relatively small or it may be very great depending upon the organism and the particular food web involved.
> Not all radiomaterials that enter the first trophic level are passed on to higher levels. At each trophic level there are certain species that, for one reason or another, are not widely used as food by the organisms of higher levels. Also, some of the plants of the first trophic level may die before they are eaten and thus will be returned to the environment

#25a (Cont)

as organic matter. (p. 77 National Academy of Science)

The introduction of radioactive products into the marine environment, like from the dumpin. of nuclear submarines, has the potential to be a serious hazard to man when organisms used for human food are irradiated.

> There are several reasons why:... (1) The radiation recieved from a given quantity of an isotope ingested as food is much greater than the dose from the same quantity in the external environment.[2] (2) Many elements...are concentrated by factors up to several thousands by organisms in the sea; (3) the vertical and horizontal migrations of organisms can result in the transport of radioactive elements and thereby cause distributions different from those that would exist under the influence of physical factors alone; for example, certain elements may be carried from the depths of the sea into the upper mixed layer in greater amounts than could be transported by the physical circulation. (p. 5 Natioanl Academy of Science)

How radiotoxic a radioactive substance is on a person, thus the extent of damage done to a person's health by radioactive substance, is determined by a number of factors. The magnitude of the health effects that are apt to occur to a person who has eaten irradiated food will depend on- 1. the types of radiations emitted, their concentration, and the chemical transformations undergone during various stages of absorption and distribution through the body; 2. the size, location, and types of cells that are exposed by the metabolic pathway the radion took, and the cells sensitivity; 3. the age,[3] sex, and physical condition of the person involved; and 4. the accumulation of the dose which is determined by the decay rate of the radio isotopes, the length of time between exposures, the person's daily intake, the rate of excretion,[4] and the total body dose. "The most important radio isotopes from the stand point of accumulation in organisms are...those (radio isotopes) which are concentrated in a large degree by organisms, are retained by them for relatively long periods of time, and have slow decay rates." (p. 18 National Academy of Science)

There are absorption and distribution rules that radio isotopes follow in the human body. "The uptake of various elements by organisms are not entirely independant of one another." (p. 16 Natioanl Academy of Science)

> The uptake of one radioelement by an organism may be altered by the relative abundace of another element in the environment. In instances in which more than one element is involved, one of three phenomena may be observed: First, elements of similar chemical properties may substitue for one another...Second, some elements may have an inhibitory effect on others...Third, there may be a synergistic effect of one element on another. (pp 73-4 National Academy of Science)

"Elements of similar chemical properties tend to be taken up together very roughly in the same proportions as they exist in the environment." (p. 16 National Academy of Science)

> Since the isotopes of most chemical elements are similar in chemical behavior, it can be assumed that organisms do not appreciabley distinguish between the radioactive and non-radioactive isotopes, and that, to a good degree of approximation, the path of a radioactive element through the biological system is the same as that of its non-radioactive isotopes. (p. 17 National Academy of Science)

A person's eating irradiated food is an example of chronic exposure. The chronic form of exposure is gotten from repeated small doses of the toxic substances over a long period of time. The symptoms of a person who has been chronically exposed does not occur for a long period of time. Chronic exposure to radio isotopes can lead to somatic and genetic injury.

What causes man to have somatic injury from radio isotopes? There are disruptions within the cells, that "may occur at any time of growth and development from conception to adult life,"[5] that affect the cells functions. After individual body cells are exposed to radiation the cells continue to grow or reproduce abnormally: more rapidly than neighboring cells. In addition, somatic injury can be the consequence of membrane damage, enzyme inactivation, and genetic changes. Damage of the cell membrane impairs the transporation of nutrients and other substances to and from the cell. Damaged enzymes within the cell impairs the support role of the cell. This "involves the stimulation or inhibition of active enzyme systems in liver. These (enzyme) systems normally moderate the toxic effects of foreign substances in the body, with the result that modification of the activity of the liver through the effects of one agent may alter its ability to deal with a second agent." (p. 30 Lucas) Since there is damage to the nucleus, especially to the genetic material, the hereditary or germ cells are effected. Within the nucleus are chromosomes, and a component of the chromosomes is DNA, which "directs and controls the normal functioning of the cell," (p. 24 Lucas) therefore with the damage of the nucleus, the cells cease to function properly.

Radiation can indirectly damage individual cells. Radiation effects cells by acting on water that is inside the cells. A fractional amount of the water is decomposed into reactive fragments, called free radicals. These free radicals react readily to form peroxides. Peroxides are capable of moving around for a short time until "they alter a receptive molecule...(then these enzyme) molecules (that have been) modified by radiation may transform 100,000 or more molecules needed for perpetuation of the metabolic activities of the cell."[6] So the effects or radiation are amplified. Changes in the surrounding tissue occur because the cells are bathed in radioactive products.

Tissues vary in their response to radiation. In general, tissues which divide and grow fast, and those dependant upon recieving a large quantity of blood appear to be the most sensitive to radiation. "Consequently the most radiosensitive organs include blood-forming organs such as bone marrow (where white and red blood cells are formed), spleen, growing bone, and the lining of blood vessels and the stomach and the intestines." (p. 68 Schubert) After being effected the skin, the membranes lining the body cavities, and the secreting glands resume normal functioning. However, other parts- muscle, brain, and portions of the kidney and eye are incapable of producing new cells or when they do produce new cells scars, non-healing ulcers, and cancer may develop.[7] Harm to leukocytes, the endocrine system, and the productive organs (examples of what can be damaged) by man's being exposed to radiation will be discussed below.

Leukocytes and a constituent-- lymphocytes, a form of white cells produced in the lymph nodes and spleen, are suceptible to radiation. Once the body has been irradiated, the body is incapable of carrying out the lymphocytes function. This makes a person increasingly susceptible to infections, have a tendency to bleed, and not be as able to repair damaged tissues. Studies show the chance of developing leukemia is higher among people who have relieved an over-exposure of radiation than those who have not. Leukemia is a latent change in a persons blood cell count. According to Webster's New Collegiate Dictionary leukemia is characterized by an abnormal increase in the number of leukocytes in the tissues and often in the blood.

Radiation alters the endocrine system and hormones. The endorcrine system is made up of secreting glands, and secreting glands can be affected by radiation. Most cells in the body are regulated by hormones. Therefore, hormonal imbalance is a response to the impairment of the endocrine glands, the organs responsible for hormones.

Genetic injury (see Appendix 1) varies in its severity. "Radiation can affect the reproductive cells in three ways: (1) it can kill the cells outright; (2) it can break or damage the chromosomes, and (3) it can cause the genes to mutate." (p. 186 Schubert) Genetic injuries are responsible for producing degenerative diseases including crippling disablilities, diabetes, and metabolic deficiences.

Genetic injuries can affect a person's reproductive cells, because "during reproduction there is a transfer of materials from the parent to the offspring." (p. 75 National Academy of Science) Genetic (or hereditary) injuries include

"effects that occur in gonads (the germ cells) and affect the health" (p. 23 Lucas) of subsequent generations when the reproductive cells that have been altered are used in reproduction. Thus there can be a latent period, a delay, between the exposure of an organism to radiation and the time the radiation-induced changes appear.

Radiation is also responsible for evolutionary changes from mutation. "Those mutations involving chromosome aberrations are generally quite drastic and are expressed in the generation immediately following the generation" (p. 30 Lucas) that has been exposed, when the abnormal gene is dominant. Every generation afterwards is affected whenever the abnormal gene is dominant. The reason for this is that a cell that has had a dose of radiation will never fully recover. Therefore, the effect on chromosomes and genes are irreversible. The rule above is broken rarely when further restorative mutation occurs. There is another type of mutation.

> The gene or point mutations, on the other hand, are normally recessive and may be hidden (the person shows no obvious sign, or effect of carrying the recessive gene) in the genetic pool of the population for several generations until an identical mutant is encountered in the conjunction with the sperm and egg cells. (p. 30 Lucas)

Men and women's reproductive capabilities are affected by radiation. Spermatogonia, mature spermatozoa, are especially sensitive to radiation. Men can become permanately sterile with about 500r to 600r, while a lesser dose of radiation may leave men temporarily sterile for two years because the number of spermatogonia are fewer. When an adequate amount of spermatogonia have matured fertility returns.

> Since a female child contains at birth all the ova she will ever use...exposure of the ovaries to radiation affects eggs which may be fertilized in the future. Thus radiation damage is preserved by the ova and may result in defective children. Even if the children appear normal they may carry defects in their hereditary make up (genes) which will be manifest in later generations. (p. 71 Schubert)

With radiation being so harmful to man[8] I suggest no more nuclear submarines be built so the old submarines will not have to be disposed of, creating more nuclear waste. | H.12

Thank you for giving the public the chance to air our views.

Sincerely,

Laura Orey

Concerning disposal of Nuclear Submarines.

Questions/Alternatives

. Of the two alternatives — burial on land (sinking offshore — neither of these are positive alternatives in that both require the ultimate "trashing" of valuable material.

I have two ideas on this subject which I would like to pass along. One fantastic, one pragmatic.

G.3

In the future: before complete defueling, investigate the possibilities of leasing these vessels after complete marine survey of hull and power plant, and sufficient overhauling to ensure safety at shelf depths for 10 yr. periods. These vessels could then be secured to the sea floor and established as undersea research and emergency power stations. Granted the safety aspects of this operation would be involved and under no circumstances should action be taken in this matter until the Navy could establish that these vessels would not be either stolen or sabotaged.

In view of this rather unrealistic view I would like to offer a more practical solution.

Upon defueling, remove entire power plant and lease or sell unit to research facility i.e. Academia/Industry. Undeniably these are some of the world's most concentrated/compact nuclear engines and therefore worthy of study. After defueling remove that section of the submarine contaminated with radioactivity and either store it, or sell it to those firms concerned with the neutralization of low level residual radiation.

As for the remainder of the boat — scrap it. Granted steel prices are low — but certainly making any profit upon sale would be more beneficious than wasteful "throwing away".

10 February 1983

Captain Edward F. Wagner
U.S. Navy
Office of the Chief of Naval Operations (OP 22)
Department of the Navy
Washington, D.C. 20350

Dear Captain Wagner:

Further to my telephone conversation with you last week, and earlier discussions with Lt. Cmdr. Swartz, I am writing to you about deep-sea trenches as potential nuclear waste disposal sites and in particular their possible relevance for the disposal of decommissioned nuclear-powered submarines. As you suggested, I talked with Mr. Mangeno. He advised me that written comments should be sent to you as specified in the December 1982 DEIS on the Disposal of Decommissioned, Defueled Naval Submarine Reactor Plants.

Judging by the thickness of the DEIS, I suspect that you, Mr. Mangeno and others concerned with this problem are not anxious to read additional long documents. I will, therefore, be brief.

J.17

The possibility of using deep-sea trenches (subduction zones) for waste disposal underwent a brief debate about a decade ago and was rather summarily dismissed. Since then trenches have been excluded from any serious consideration with the often repeated statement that nuclear waste should not be placed in such geologically unstable regions. Based on my research and that of others, this is too simple a conclusion and one that could result in possibly overlooking a highly desirable ocean waste disposal site. Trenches may be especially well-suited for the disposal of large items such as submarines. When looked at carefully, I believe they may not only meet the criteria (as set forth in the December 1982 DEIS) for the sea disposal option, but provide certain advantages that other ocean sites do not.

I invite you to review the enclosed document which describes why trenches may be suitable waste disposal sites. It is a copy of a proposal made to a Texas State agency last year that was funded at a modest level. The essential point is that in most trenches large grabens (fault-formed depressions) exist within the oceanic plate that may provide the stable, isolated and remote environment desired for submarine disposal. Please note modified figure 1 of the enclosed proposal in which I suggest the fate of materials placed in trench graben structures. Also enclosed are a separate set of figures which show Pacific-wide distribution of trench graben structures and models of the variations that exist in trench structures.

The time relationship between geologic processes and radioactivity is one that may be better accomodated in trenches than elsewhere in the oceans. Waste volume, which as is noted in the DEIS will eventually be great, could certainly be easily accomodated in trench grabens; they are ubiquitous and very large.

I do not suggest that at this stage we know enough about trenches to conclude that they are the ideal waste disposal site. However, those of us who have been doing research on trenches have learned much that has not generally been considered in the past routine dismissal of trenches as potential sites. It might be worthwhile to include trenches in future ocean disposal considerations.

Should you find any of this of interest I will be happy to provide you with more detailed information. What I have enclosed is only a brief summary of data that exists on the trench regions.

Sincerely yours,

Thomas W.C. Hilde

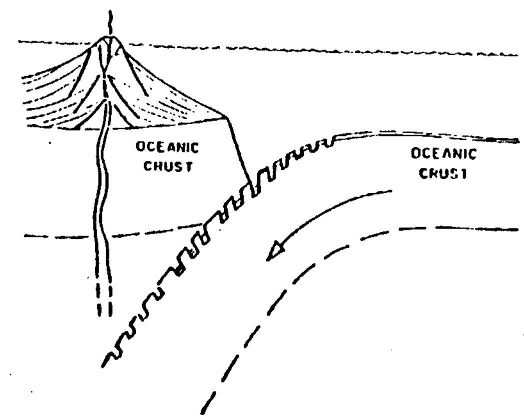
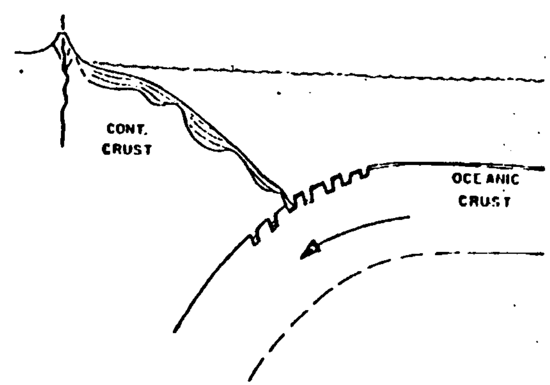
FIGURE 1. Sediment Subduction Models.

A. Sediment subduction within subducting plate grabens where the overriding plate is oceanic. In this case the terrigenous sediment supply is likely to be low and the graben volume exceed the trench axis sediment volume. If the graben volume is greater than the combined terrigenous and pelagic sediment trench axis volume, then all trench axis deposits are likely to be subducted and the lower shoreward trench slope to be devoid of sediments as shown (except for minor *in situ* deposits).

B. Same as A, except the overriding plate is continental. Case shown is for a low terrigenous sediment supply. Therefore, the shoreward slope is covered with relatively thin and undeformed *in situ* deposits.



A.



B.

Figure 1.

FIGURE 2. Sediment Accretion Models.

A. Model of subduction where thick deposits of sediments exist at the trench axis and no graben structures exist within the surface of the subducting plate. These cases generally also involve a shallow angle of initial subduction. Accretion of sediments to the overriding plate may be expected.

B. Same as A, except with grabens. Accretion may still be expected, if sediment volume exceeds graben volume as shown.

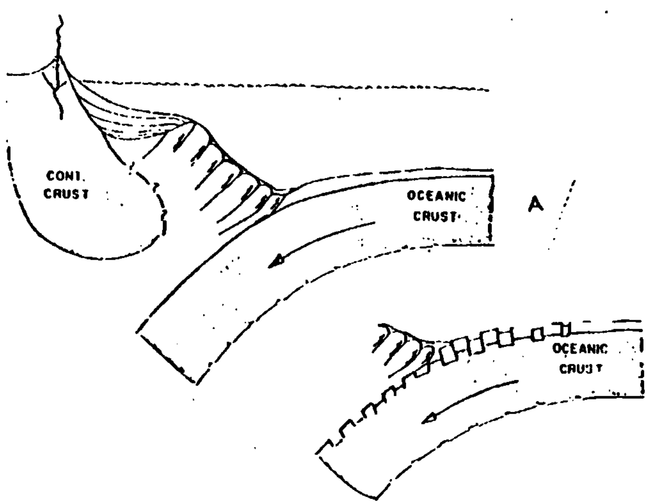


Figure 2.

FIGURE 3.

Distribution of graben fault structures within the subducting oceanic plates around the Pacific. Regions of thick trench axis deposits (where sediment volume exceeds graben volume) are also shown (preliminary).

INTRODUCTION

A major concern associated with the use of nuclear power to meet our future energy needs is what to do with the radioactive waste products that are produced in the process. If this problem can be solved and the solution convincingly demonstrated to society, nuclear power can almost certinaly provide for a major portion of our future energy requirements. Without the provision for essentially permanent waste disposal, and the development of pollution-free mining and safe power generation methods, society is likely to reject nuclear power as a means of providing for our future energy needs.

This proposal deals with one of these concerns, waste disposal. Presently, two broad catagories of sites are under consideration for nuclear waste disposal. These are 1) isolated, massive rock or salt bodies on land, and 2) sedimentary sections in remote regions of the deep ocean basins. Sending nuclear waste off into space has apparently been rejected, at least for now, as a viable option. This leaves the problem squarely within a geologic perspective. Although significant progress has been made in evaluating the above two catagories of potential waste disposal sites, it is my contention that a third type of site, which could prove to be far more desirable in many respects, has been prematurely excluded from proper consideration. These sites are the deep ocean trenches, where the earth's crust is being subducted into the deep interior of the earth. If it can be demonstrated that nuclear waste can be placed into subduction zones, without leakage, they offer something that other sites cannot--permanent disposal.

The reason that trenches have not previously been given serious consideration as disposal sites is because of a lack of knowledge of the actual structures, composition of rocks and processes in these zones. They are tectonic zones and intuitively it was assumed that all tectonic zones were regions where earth movements would make long term, secure containment of nuclear waste impossible. Based on an improved knowledge of the structures, rocks and processes in subduction zones, it now appears that they may be highly desirable sites for nuclear and other types of waste disposal, particularily for any large volumes of waste.

#27 (Cont)

LITERATURE REVIEW

Two, thus far separated, subject areas need to be considered in this study: 1) the general geological conditions for secure, long-term waste isolation, and 2) the detailed geology, structure, tectonic processes and environmental stability of deep-sea trenches and shallow (0-50 kms) portions of subduction zones.

General Geologic Conditons

Since some of the nuclides synthesized in reactors have half lives of over 10^6 years (iodine-135, 1.6×10^7; cesium-135, 2.3×10^6; neptunium-237, 2.1×10^6), the time constants of isolation must be long (Fyfe, 1980). The geological conditions needed to provide this isolation are generally considered to be 1) rock masses of low porosity that are free of fractures, 2) rocks in environmental conditions with little or no fluid transport and that inhibit metal transport, 3) low native radioactivity and minimal heat flow, 4) mineral compositions of the rock that are good for ion exchange or absorption processes, 5) rocks that are resistant to thermal stress, and 6) rocks that are plastic rather than brittle. Additionally, the host rock should not be desirable for other societal needs. Suggested depths of burial vary from 500 m to 15 km based both on technical and societal concerns. The essential point is that nuclear waste must be isolated from the biosphere (Aikin et al., 1977; Bredehoeft et al., 1978; Fyfe and Haq, 1979; Fyfe, 1980; Giletti et al., 1978; Hammond, 1980; Ringwood, 1980; Smith and Roy, 1978; Uffen, 1977; Weinburg, 1980).

Clays and zeolitic volcanic sediments are considered to be among the best sedimentary rocks, on land or in the oceans, in several respects for isolation of nuclear waste; ion exchange or absorption characteristics, plasticity and low porosity. In the oceans, salt water presents a problem because interstitial fluids with high salt concentration will compete with ion exchange on mineral surfaces. Various massive igneous rock bodies are considered on land, which meet some of the above requirements. However, of serious concern is the degree of rock fracture and ground water circulation, which on continents is linked to human and general biosphere consumption. Almost all igneous rocks are fractured to some degree.

Methods presently under consideration for nuclear waste packaging and placement in disposal sites include containerization in glass, inert metals, sintered corundum, natural materials (such as bentonite clays or brucite) and placement by drilling, in mines, or in filled pits (Boulton, 1978; Ringwood, 1980; Fyfe, 1980). If expense and volume were ignored there really would be no problem in building containers that could provide isolation for 10^7 years or longer. However these factors are not being ignored. Therefore method and geological environment of placement, to be determined on both technical and societal grounds, become very important considerations. Recent geological and geophysical studies of subduction zones suggest that these regions may offer better geological sites for nuclear waste disposal than either of the two broad catagories of sites presently being evaluated. Based on recent findings it would seem prudent to undertake an evaluation of subduction zones for their desirability and potential for nuclear waste disposal.

Subduction Zones

The outer rigid shell of the solid earth, called the lithosphere, is broken into several large plates which are in relative motion about the circumference of the earth. Oceanic lithosphere is in the order of 70-100 km thick, and composed of rocks that are more dense than continental rocks. Continental lithosphere is thought to be much thicker, possibly a few 100 kms (An excellent review of the earth's structure and dynamics is contained in LePichon et al., 1973). Where lithospheric plates are in motion toward each other (converging), one of the two plates descends beneath the other, at angles of $\sim 30^\circ$ to vertical, into the earth's mantle below the lithosphere (Isacks and Barazangi, 1977). This process is referred to as subduction (Uyeda, 1982). The two converging plates may both be continental (i.e. India and Asia), one oceanic and one continental (such as along the Peru-Chile Trench), or both oceanic (such as along the Bonin, Mariana and Tonga Trenches). For trenches and extensive subduction to develop, at least one of the two plates must be oceanic. Based on earthquake seismicity we observe that these plates descend to depths in the mantle of as much as 700 km (Isacks and Barazangi, 1977). The rates of plate convergence and subduction range from

#27 (Cont)

a few cms/yr to greater than 10 cm/yr (Minster et al., 1974; Fitch, 1972; Uyeda, 1979). It is at these convergent plate boundaries, where subduction is taking place, that deep-sea trenches are formed.

The possibility of using deep-sea trenches and subduction zones for waste disposal underwent a brief debate about one decade ago (Bostrom and Sherif, 1970; Frances, 1971) and was rather summarily rejected (Silver, 1972). At that time and until four years ago, it was believed that as plates converged at trenches the sediments in trenches were scraped off the descending or subducting plate and transferred to the leading edge of the over-riding plate, with an accompanying great amount of deformation (Karig, 1974; Karig and Sharman, 1975). It was, therefore, concluded that subduction zones were very poor sites for waste disposal. However, my research has shown that in most of the world's trenches the oceanic and trench deposits are not tectonically transferred to the over-riding plate but that these deposits are carried, much of them undeformed, into the deep interior of the earth with the subducting plate (Hilde and Sharman, 1978; Hilde, 1981).

As an oceanic plate bends downward into a subduction zone its upper surface undergoes extensional stress and it is broken by normal faults into horst and graben structures (Hilde and Sharman, 1978; Jones et al., 1978; see Figure 1). This faulting starts when the oceanic plate first starts to bend downward, well seaward of the deep-sea trench and before it begins to be subducted beneath the over-riding plate. In many trenches, by the time the down-going plate reaches the trench axis, displacement on the faults exceeds 500 m and the grabens within the surface of the subducting plate are 500 m to 1 km deep (Hilde and Sharman, 1978; Hilde and Fisher, 1979; and Hilde, 1981). Other typical dimensions of the grabens are 5 to 10 km in cross-section, extending several tens of km along their strike. It appears that in most trenches sediments in the grabens are subducted without being disturbed (Figure 2). As a graben descends beneath the over-riding plate the sediments from the leading horst block, having been temporarily compressed and piled up, are dumped into the graben and cover the sediments that were originally there (Figure 1). This apparently occurs where the volume of the grabens exceeds the volume of the available sediments, which is the case in most trenches (Hilde, 1981). A key point in this process that has particular significance for potential use of the grabens for waste disposal by subduction is that the plane of motion between the subducting and over-riding plate appears to be that defined by the plane connecting the basement surfaces of the horst blocks (see Figure 1). Below this plane (in the grabens) the rocks and sediments are subject to little disturbance. It is quite plausible that waste materials could be placed in a graben just before it starts to be covered with sediment from the leading horst block, that the waste would be sealed with the sediments pushed into the graben and thereafter be carried into the earth's interior with the subducting plate.

OBJECTIVES

The overall objective is to evaluate deep-sea trenches and the subduction process for potential use in the disposal of nuclear and other waste materials. Using existing seismic reflection profiles and bathymetric data the structure and sediment distribution of several circum-Pacific trenches will be evaluated for evidence of the nature and degree of sediment disturbance as trench sediments are initially subducted. This effort will be concentrated on sections of the Mariana, Bonin, Tonga and Peru Trenches for which we have suitable data sets for an initial evaluation. New mapping will be done of the structures in the Mariana Trench, in an E-W corridor between 17°30'N and 18°N, where we have a particularly high density of data and where grabens within the subducting plate are very well developed.

These studies should allow the determination of potential isolation dimensions of hypothetical waste placed within the grabens; amounts of sediment encasing the waste below the plane of subduction, above the igneous basement floor of the grabens and to the normal faults defining the edges of the grabens.

Analysis of sediment samples from these trenches (Deep Sea Drilling Initial Reports, and Shepard, 1981) will be reviewed for composition and physical characteristics that are either desirable or undesirable for sealing

#27 (Cont)

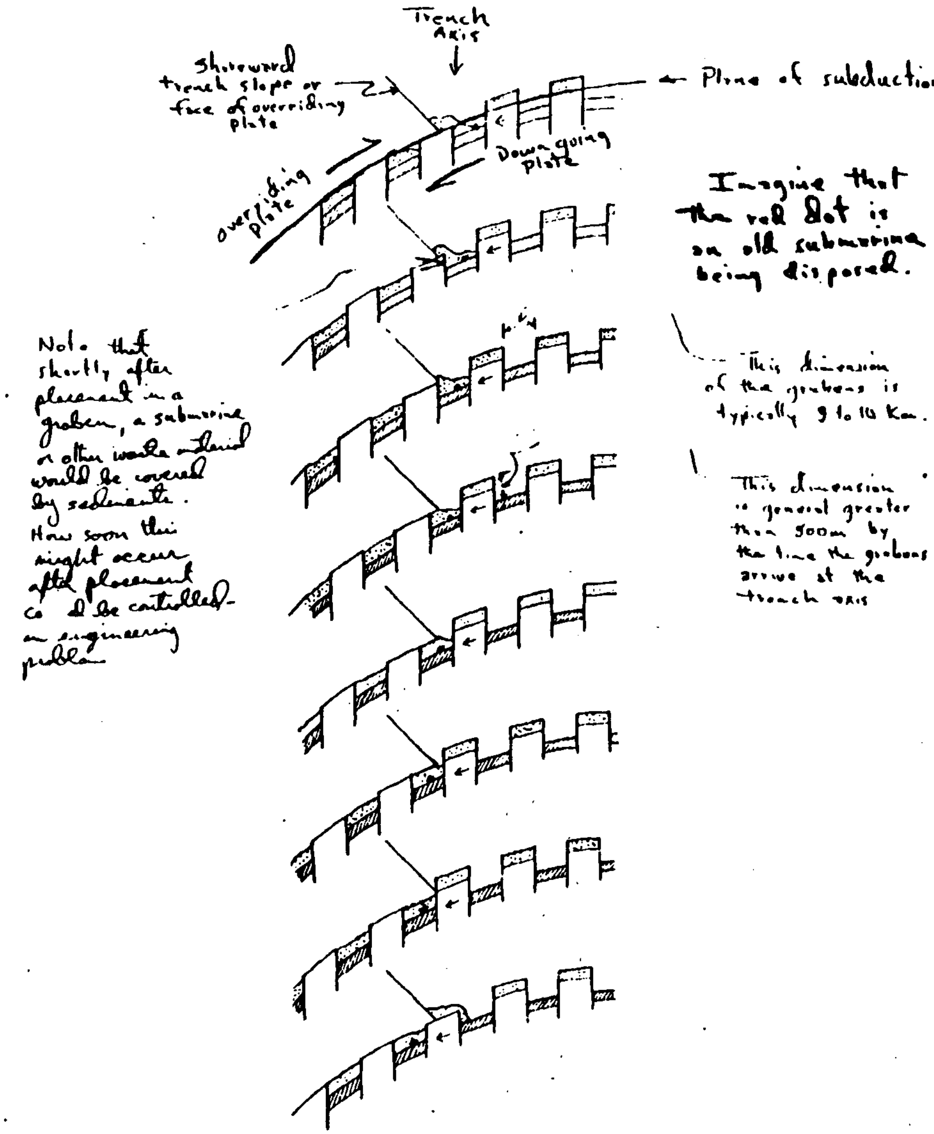

Figure 1. Sequence of trench cross-sections showing progressive subduction (from top to bottom) of an oceanic lithospheric plate that has been broken into graben and horst structures due to bending of the plate into the subduction zone. White area of subducting plate is igneous oceanic basement rock. Sediments on the oceanic plate are shown by dotted and slashed patterns. The different patterns are used not to indicate different type of sediments, but to indicate positions of sediments in the grabens and on the horsts before and after subduction. Note that sediments in the grabens remains undisturbed and that sediments on the horsts are scraped off by the leading edge of the over-riding plate and dumped into the trailing graben. The plane of motion (or subduction) between the subducting and over-riding plate is that which connects the basement surface of the horst blocks. The grabens are protected below that plane.

#27 (Cont)

nuclear waste. It is anticipated, for example, that in certain trenches (such as the Mariana Trench) the sediments will be found to contain large percentages of desirable clay and zeolitic volcanic components.

Environmental aspects of these trenches, such as ocean bottom-water characteristics will also be evaluated for relevance for nuclear waste disposal. Several aspects of the deep-sea are known to have generally stable and desirable characteristics for waste disposal. Deep-sea trenches are regions of the lowest heat flow on earth (Watanabe et al., 1977) and bottom-water temperatures in trenches are around 1°C or less (Reid, 1965), for example. However, while the Pacific Ocean Basin bottom-water residence time is known to be in the order of 1000 - 1500 years (Drake et al., 1978), residence time of bottom-water in trenches may be considerably longer and existing data needs to be evaluated in this regard.

It is anticipated that this study will demonstrate that a more extensive investigation of subduction zones for waste disposal is warranted. The findings from this study will be used as a basis for discussions with relevant government agencies concerned with nuclear and other waste disposal problems and the preparation of proposals for further research. Preliminary discussions have already been held with the National Oceanic and Atmospheric Administration, the U.S. Geological Survey and Sandia Laboratories. The Office of Naval Research (ONR) will be contacted during the early phases of this study to acquaint them with the project. Earlier discussions with officials of ONR revealed a Navy need for the permanent disposal of entire outdated nuclear powered vessels. Placement within grabens of subducting plates may be a solution to their problem. The possibility exists for Navy funding to carry out high resolution bathymetric and geophysical studies of the Mariana Trench in 1981.

SIGNIFICANCE

This research may provide a solution to the problems of nuclear and other waste disposal, including almost any volume of waste imaginable. At subduction rates of 10 cm/yr, a 5 km wide graben would be completely subducted in 50,000 yrs. This is a long time in terms of the needs of present-day society. However, by selecting grabens for waste disposal that are just beginning to subduct, the waste could be instantaneously covered by inducing (an engineering problem) the slumping into the graben of the temporarily accumulated sediment at the base of the over-riding plate (shoreward trench slope). Once this is done the waste would be disposed of and eventually carried deep within the earth.

PROCEDURES

Seismic reflection profiles from the Mariana, Bonin, Tonga and Peru Trenches will be interpreted for cross-sectional distribution of disturbed and undisturbed sediments and their position relative to the grabens in the subducting plate. This will be done for the trench axis regions and the shallow regions of subduction (where the subducting plate has just descended beneath the over-riding plate), to the limits of the reflection data penetration.

In the Mariana Trench, along the corridor mentioned earlier, topographic features will be mapped by compilation and contouring of a high density set of existing echo-sounding data. The contours will then be used, in conjunction with existing seismic reflection data, to identify the distribution of grabens and sedimentary structures along the trench axis. It is anticipated that various stages of convergence and sediment graben filling will be defined in this way.

Sediment and environmental data for these trenches will be compiled from existing reports and analyzed for relevance to acceptable nuclear waste disposal environmental conditions. Sediment samples from the Mariana Trench (DSDP, both shoreward and seaward flanks) will be analyzed for composition and physical properties. Estimates will be made of the radioactive absorption properties of these sediments, possibly including on-campus laboratory radiation experiments.

BUDGET
one year (1982-1983)

A.	**Salaries**	
	Principal Investigator 1 month	$3,640
	Graduate Research Assistant (Ph.D.) 12 months at 50%	$8,242
	Subtotal	$11,882
B.	**Materials and Supplies**	
	Xeroxing and office supplies, drafting and laboratory materials, and photography	$3,000
C.	**Computer Time**	
	1 hour at $720/hour (2nd shift)	$720
D.	**Communications and Shipping**	$500
E.	**Travel**	
	Two trips to ONR (Bay St. Louis, Mississippi) at $500/trip	$1,000
	Two trips to Washington, D.C. at $1000	$2,000
	Subtotal	$3,000
	TOTAL	$20,102

BACKGROUND OF INVESTIGATOR IN PROPOSED AREA

Please note on the following resume the number of publications dealing with trench-arc-back arc systems and subduction processes. These are indicated by an "+". Most of the principal investigator's research over the last several years has been on the tectonics of convergence and the structure of trenches. It is probably reasonable to state that the principal investigator (P.I.) is one of the world's leaders in this area of research. Indication of this is the number of national and international meetings on this subject for which the P.I. has served as convenor, and the special publications on this subject for which the P.I. is editor (see resume).

More than three years accumulated time has been spent at sea doing marine geophysical field work on trench-arc-back arc problems.

The P.I. was the first scientist to use long-range side-scan sonor for studies of trench structures.

B.A., Geology, San Diego State University, 1963
D.Sc., Geophysics, University of Tokyo, 1973

EXPERIENCE:

Laboratory Assistant, Scripps Institution of Oceanography, 1959-1964
Principal Engineering Aid, Scripps Institution of Oceanography, 1964-1967
Oceanographer, U.S. Naval Oceanographic Office, San Diego, 1967-1969
Supervisory Oceanographer, U.S. Naval Oceanographic Office, San Diego, 1969-1970
Scientific Consultant for Oceanographic Development, National Science Council, Republic of China, and Visiting Marine Geophysicist and Lecturer, Institute of Oceanography, National Taiwan University, 1970-1973.
Visiting Marine Geophysicist, Earthquake Research Institute, University of Tokyo, July-December, 1973

HILDE, Thomas Wayne Clark

EXPERIENCE: (Continued)

Consultant for Marine Geology and Geophysics, CCOP, United Nations Bangkok, Thailand, April-October, 1974
Senior Marine Geologist/Geophysicist, CCOP, United Nations, Bangkok, Thailand, March 1975-July 1976
Independent Consultant, San Diego, California, August 1976-June 1977
Associate Professor of Oceanography and Geophysics, and Leader, Geodynamics Research Program, College of Geosciences, Texas A&M University, College Station, Texas, July 1977-present

TEACHING EXPERIENCE:

Texas A&M University, 1977-present
Institute of Oceanography, National Taiwan University, Taipei, Taiwan, 1970-1972
Lectures in Oceanography, Navy ASW Reserve Training School, San Diego, California, 1964-1966

PROFESSIONAL INTERESTS:

Marine geophysics; oceanic, island arc and marginal seas tectonics; research administration

PROFESSIONAL AFFILIATIONS:

The Geological Society of America
American Geophysical Union
American Association for the Advancement of Science
American Geological Institute
Oceanographic Society of Japan
Geological Society of China
Geological Society of Malaysia
Geological Society of Thailand

PROFESSIONAL SERVICE ACTIVITIES:

Member, Western Pacific Working Group and co-chairman, Study Group 1, Inter-Union Commission of Geodynamics, 1974-1980
Member, Ocean Crustal Dynamics Committee, JOI, Inc., 1978 1980
Editor, Western Pacific Final Report, Geodynamics Project, Inter-Union Commission of Geodynamics, present
Member, Gulf Coast Working Group, U.S. Geodynamics Commission Continental Margins Transects Program, 1979-present
Chairman, Commission on Marine Geophysics, and advisor to the Executive for Co-ordination, International Association for the Physical Sciences of the Ocean, 1979-present
Member, JOI Site Survey Planning Committee, 1979-1981
Editor, "Convergence and Subduction", Special Issue, Tectonophysics, in preparation, 1981
Associate Member, Commission for Marine Geology, International Union of Geological Sciences, 1980-present
Corresponding Member, Working Group 8 - Subduction, Collision and Accretion, Inter-Union Commission on the Lithosphere, 1981-present

#27 (Cont)

RECENT AND PLANNED MEETINGS:

International Meeting on Geodynamics of the Western Pacific, Yuzhno-Sakhalinsk, Sakhalin, USSR, 28 May - 6 June, 1981, presentation: "Convergence Tectonics".

OMD Workshop for Synthesis of Region VI, Peru Trench; Hawaii, June 22-27, 1981, presentation: "Peru Trench Axis Tectonics".

OJI International Seminar on Accretion Tectonics; Tomakomai, Hokkaido, Japan, September 10-16, 1981 invited paper. Did not attend. Paper delivered by S. Uyeda: "The relationship between Trench Depth and age of subducting plates" by Hilde and Uyeda.

JOA (Joint Oceanographic Assembly), Halifax, N.S. August 2-23, 1982. Co-convener of Session A-5, "Active Continental Margins" sponsored by SCOR, IAMAP and ILP.

Probably - December 1982 AGU meeting, San Francisco.

PAPERS IN PREPARATION, SUBMITTED OR IN-PRESS:

"Graben Structure and Axial Zone Tectonics of Tonga Trench, Southwest Pacific", T. Hilde and R. Fisher, submitted to International Geodynamics Program, Working Group 1 Final Report, Editor, T. Hilde, (to be jointly published by AGU and GSA).

"Subduction vs. Accretion around the Pacific", T. Hilde, in preparation for a Special Issue of Tectonophysics, Editors, T. Hilde and S. Uyeda.

"Convergence Structures of the Peru Trench Between 10°S and 14°S", W. Warsi, T. Hilde and R. Searle, (same as #2), in preparation.

"Structural Features of the Bonin Arc: Implications for its Convergence History", W. Bandy and T. Hilde, submitted, (same as #2).

"Convergence along the Panama Trench", T. Hilde and R. Searle, in preparation for Geology.

CURRENT PRINCIPAL RESEARCH PROJECTS:

"Peru Trench OMD Synthesis"; extension, from OMD/JOI/NSF, for 1982, $30,947, T. Hilde, 2 students.

"Subduction vs. Accretion"; in preparation for ONR, for 1983, approximately $100,000, T. Hilde, 2 students.

PREVIOUS FUNDED RESEARCH AT TAMU:

"Gulf of Mexico Topographic Feature Study, Subsea Mapping"; BLM, 1 August 1978 - 1 March 1980, $101,702, T. Hilde, R. Rezak and T.K. Treadwell, 3 students.

"Geophysical studies of the Western Pacific"; ONR, Jan. - Dec. 1979; $35,000, T. Hilde and G. Sharman, 2 students.

"Geophysical studies of the Western Pacific"; ONR, Jan. - Dec. 1980; $42,000, T. Hilde and G. Sharman, 2 students.

"Peru Trench OMD Synthesis"; Co-principal investigators D. Hussong, L.D. Kulm and D. Crouch. This research was funded at $173,264 for 1981 by OMD/JOI/NSF ($43,577 to Texas A&M, 2 students).

Public Health Service

Food and Drug Administration
Rockville MD 20857

FEB 10 1983

Captain Edward F. Wagner, USN
Office of Chief of Naval Operations
(OPNAV-22)
Department of the Navy
Washington, DC 20350

Dear Captain Wagner:

The National Center for Devices and Radiological Health staff has reviewed the Draft Environmental Statement (DES) on the Disposal of Decommissioned Defueled Naval Submarine Reactor Plants dated December 1982. Primarily our effort has been directed to an evaluation of the public health and safety impacts associated with the proposed disposal alternatives. We have the following comments to offer:

1. The discussion in Chapter 2 for the land and sea disposal options has provided adequate assurance that the proposed disposal technology would (1) meet State and Federal radiation safety criteria for land burial of radioactive waste, (2) meet international limits on ocean disposal of radioactive waste, and (3) result in radiological exposures that would have little impact on individuals or the population.

2. The environmental exposure pathways identified in Appendix C, Section III, for land disposal and Appendix J, Section III, for ocean disposal adequately cover all possible emission pathways whereby radionuclides could be transferred from the land or ocean burial site to man. The dose computational methodology and models used in the estimation of the dose commitment to individuals and to populations have provided the means to make reasonable estimates of the dose commitments associated with the land and sea disposal of defueled, decommissioned submarine reactor plants. Results of the calculations are summarized in Table 4-11 for the total body exposures and confirm that such exposures are well within current radiation protection standards.

3. The environmental effects of possible accidents incident to land disposal are discussed in Chapter 4, Section I-B. These effects and the calculated doses in Appendix C, Section X, indicate that the immediate and delayed total body exposures to individuals and populations are adequate assessments of the potential health impact. The results are summarized in Table 4-11, and show minimal total body individual and population exposures that are within current radiation protection standards.

The environmental effects of possible accidents incident to the sea disposal option discussed in Chapter 4, Section II-B, together with the exposure estimates presented in Appendix J, Sections III-B, III-C, and III-E are adequate assessments of the potential health impact. The results are summarized in Table J-21 and Table 4-11, and show a minimal radiation dose commitment to individuals and the population that is within current radiation protection standards.

The DES does not contain any specific information on emergency planning and coordination with the States that may be impacted in the unlikely event of an accident. Even though the potential doses are small, it is believed that a section should be added to Chapter 4 that presents the scope of plans and coordination that would be implemented depending upon the disposal option selected. This is of particular importance at this time in view of the concern of the public and State agencies regarding potential exposure to low levels of radiation. N.10

In Chapter 2, Section I-F and Appendix K, Section III, it is stated that the environmental monitoring program for the land disposal option would be the same as those currently conducted by the Department of Energy at the Savannah River Plant and the Hanford Site. These programs have been described in the respective environmental impact statements for waste management operations at the above sites. We have previously reviewed these statements and concluded that the pathway monitoring and analysis for specific radionuclides were sufficiently inclusive to measure the extent of emission from waste disposal activities. Thus, we believe the monitoring program would also be adequate to document any releases to the environment related to the land disposal option.

In Chapter 2, Section II-F and Appendix K, Section IV, it is stated that environmental monitoring would be performed before, during and after the period of disposal in accordance with the requirements established by the EPA based on U.S. and international laws and treaties. The description of the monitoring program presented in Appendix K, Section IV, is considered to be an adequate program for assessing any potential releases of radionuclides to the marine environment that could subsequently make their way to man via the exposure pathways described in Appendix I, Section III, and shown in Figure I-1. We would appreciate receiving copies of the monitoring data collected during the active disposal period, as carried out in accordance with the program outlined in Appendix K, Section IV-B. These data should be capable of documenting the source term applicable to the environmental pathways to man, and of verifying that the dose commitment to individuals and populations meets the current radiation protection standards.

It appears from our review of this DES that the conclusion in Chapter 4, Section IV, which states "Because of these very low radiation related impacts, it is concluded that either option would be acceptable, and that the choice of options should not be based on radiological considerations." is valid from a public health and safety viewpoint and is justified by the technical assessment.

Thank you for the opportunity to review and comment on this Draft Environmental Statement.

Sincerely yours,

John C. Villforth
Director
National Center for Devices
and Radiological Health

I N D E X

(The hearing opened at 9:00 a.m., February 17, 1983.)

CPT WAGNER (HO): I am Captain Edward Wagner. I work in the Office of the Deputy Chief of Naval Operations for Submarines. I have been appointed the Navy's Hearing Officer for this morning's public hearing. Here with me to present an opening briefing is Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program. Also present is Mr. James Gaver, Assistant to the Manager for Public Affairs, the Savannah River Operations Office, Department of Energy.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear powered submarine reactor plants after the fuel has been removed and the ships are no longer needed. The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government-owned land disposal sites or placing them on the deep ocean bottom.

On December 22, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement, or DEIS, on the disposal of decommissioned, defueled Naval submarine reactor plants. The DEIS contains the results of the Navy's studies of the alternatives available. On the registration table are copies of the Summary of the DEIS. Anyone in the audience who would like a complete copy of the DEIS should leave their name and address on the sheet of paper provided at the registration table, and a copy will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient to the people with an interest in this matter, in order to provide them with an opportunity to present their views. I am here today to conduct one of these scheduled public hearings. The purpose of this hearing is to take testimony regarding the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case nor to engage in debate. It is my responsibility to receive comments so that they can be considered in preparing the Final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each, and organizational spokesmen are limited to ten minutes, unless additional time had been scheduled in advance. Time cannot be relinquished from one speaker to another.

In order to ensure all who desire to speak are given an opportunity, each person should fill out a registration card which is located on the registration table as you enter, and provide it to the person at the registration table.

All testimony will be recorded so that it can be considered in the development of the Navy's Final Environmental Impact Statement.

If you desire to submit written comments, rather than speak, that is acceptable. You can provide written comments to me, or you may leave them at the registration table. If you desire to provide written comments at a later date, let me give you my address, and then you can mail that to me at a later time. My address is:

Captain Edward F. Wagner
U. S. Navy
Office of the Chief of Naval
  Operations (OPNAV-22)
Washington, D. C. 20350

You should provide your written comments by March 31, 1983, which, as stated in the Federal Register Notice, is the cut-off date for submitting comments.

Before we begin receiving testimony, I would like to introduce Mr. Mangeno of the Naval Nuclear Propulsion Program, who will provide a general overview of the issue the Navy is addressing and the content of the Draft EIS.

Mr. Mangeno.

MR. MANGENO: Today's hearing is being conducted as a part of the decision-making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an Environmental Impact Statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The Environmental Impact Statement must include the environmental impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement, or DEIS, on this subject provides the basis for these hearings, and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear-powered submarines after they are no longer needed. The practical choices are: Bury the radioactive part of the submarine at an existing DOE land disposal facility at the Hanford Site in the state of Washington, or the Savannah River Plant in South Carolina; or place the entire submarine on the bottom of the ocean in water more than 2.5 miles deep. In both choices there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has about 120 nuclear-powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases, as shown in this slide, it is evident that a disposal plan must be prepared for use sometime in the future. This DEIS has been prepared now so that all interested agencies, organizations, and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the uranium and all of the fission products. The removed fuel is handled according to established procedures and is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, to the metal structure surrounding the fuel, to the reactor vessel, and to other equipment in the reactor compartment, where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by the hull of the submarine and by the reactor vessel and coolant piping. In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel, or other metal atoms in the reactor plant. These

atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation of the nuclear reactor and the number of curies of each radionuclide at that time. A curie is a measure of the amount of radioactivity present, but it is not an indication of the possible effect on man or animals. The amounts and kinds of radioactive atoms present are described in detail in Chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the Federal Government disposal facilities already used for such low-level radioactive waste at the Hanford Reservation in the state of Washington, or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the compartment free from the remainder of the submarine, and weld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal, and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant sites. Other government-owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable waterways, so that transportation of the reactor compartment to those sites would be impractical. The Hanford and Savannah River burial grounds are described in Chapter 3.

A transporter of the sort shown in this sketch could then be used to haul the compartment over land to the burial location. There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial, or after burial. This is because radiation outside the compartment would be well below Federal limits and the reactor compartment would have been welded shut at the shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low-level radioactive wastes. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burials and would result in no significant additional environmental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the body. More than 200 years would pass before the reactor compartment bulkhead

could be penetrated by corrosion (rust). Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time, exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean is another practical alternative. The maximum radioactivity would be less than the limit specified by international criteria; and the triple containment provided by the submarine reactor compartment, by the reactor vessel and piping, and by the radioactive atoms being a part of the metal itself, would be an extremely strong and effective disposal containment package.

Locations for possible ocean disposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U. S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site-specific public hearings would be required and the permit process is not part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 190 miles west of Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry, and marine biology for very deep ocean locations. The depth of the water in these areas is between 4000 and 5000 meters (13,000 to 16,000 feet). The scientific information and measurements collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that the environmental impacts could be calculated using realistic data.

Preparations for ocean disposal would be made at one of the shipyards normally servicing nuclear-powered Naval vessels. Following defueling, the reactor vessel and the reactor compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping, and, of course, the metal itself completely intact. Most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping or free the atoms from the thick metal.

A comparison of the possible effects on the environment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100

submarine disposals for the year of greatest exposure for both options. This table shows that the radiation exposure would be very small and could have little impact on individuals or the population. These levels are also many times less than any limits established by U. S. regulations or international limits. They are much smaller than the normal fluctuations in annual average background radiation exposure for U. S. residents.

A perspective on radiation exposure can be gained by examining the exposure a person would receive from natural cosmic background radiation if he flew round trip from New York City to Los Angeles. That person would receive approximately 2 millirems more radiation than if he had not made the trip, because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one half millirem.

Other environmental impacts are similarly small for both options. The effects on animal life would be small and localized in either case. Land burial of 100 reactor plants would require only about 10 acres of land, and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square 10 miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land disposal would cost about 40% more (about two million dollars per submarine more) than sea disposal.

The "no-action" alternative is to place submarines in floating protective storage for an extended period, commonly called "mothballing." However, this would only temporarily delay disposal, because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods, and the estimated radiation exposures for the general public would be very small for all available courses of action.

Thank you.

CPT WAGNER: Thank you, Mr. Mangeno.

May we have the lights, please.

(The lights have been lowered in order to show the slides during Mr. Mangeno's presentation.)

Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing.

At this time -- we did not previously have any speakers registered for testimony. I understand we do have some speakers registerrd. Would you please bring them forward?

We will proceed right into testimony, and as soon as I receive the registration cards, we will call those people registered.

*Other issues discussed by Mr. Jackson are side barred in Exhibits 15 and 37b.

Simply to establish an order for the statements, I intend to ask individuals representing state government organizations to speak first, in alphabetical order of the speakers' last names, followed by individuals representing local government organizations, private organizations, and then private citizens, and, again, in alphabetical order by last name.

If your statement is so long that it cannot be given in the time allotted, either five or ten minutes, you may summarize in the five or ten minutes, and the entire statement will be included in the record if you submit the statement in writing.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, proceed to and be seated at the testimony table here in front of me. State your name and organization, if any. All comments are to be addressed to me.

Our first registered speaker, then, is Mr. Thomas C. Jackson, representing the Oceanic Society.

Mr. Jackson.

MR. JACKSON: Good morning, Captain Wagner. It is nice to see you again.

CPT WAGNER: Good morning.

MR. JACKSON: I would once again like to thank the Navy for giving us this opportunity to speak about the options for disposal of decommissioned, defueled submarines. #15a

I am Thomas C. Jackson, Vice-President of the Oceanic Society, a 60,000 member national marine conservation organization which publishes OCEANS magazine as part of a global research, education and conservation program. The Society's principal offices are in Stamford, Connecticut, and San Francisco, California. We have Oceanic Society Chapters in San Francisco, Los Angeles, San Diego, Dallas/Fort Worth, and the Long Island Sound region.

This morning, I am speaking on behalf of the Oceanic Society's 60,000 members to address an inadequate Draft Environmental Impact Statement, and argue against the sea disposal of obsolete nuclear
*W.1 submarines. A prime fault with the ocean alternative for worn out subs stems from the irretrievability of these ships once they have been sunk on the deep ocean floor. This alone is sufficient cause under federal law to reject the proposal.

The draft environmental assessment holds four significant defects:

L.7 First, the cumulative impacts of incremental increases in radioactivity entering the marine environment from these submarines are not considered in the DEIS;

J.76
I.13 Second, the monitoring program proposed in the DEIS is inadequate for either the sea or land disposal;

Third, effects of accidental sinking of the submarines
L.57 on the Continental Shelf are not adequately considered; and

Fourth, the disposal alternative which minimizes corrosion
H.3 and, hence, the release of radioactivity is not even considered

in this document.

Based on our consultations with scientists around the country, it appears the most assessible option is to place reactor compartments in an arid or semi-arid environment. In this alternative, the submarine's reactor compartment would be placed in a trench or left on the ground. Unlike the land alternative considered by the DEIS, the compartment would not be buried. H.3

Scientists believe that by not burying the reactor compartment, corrosion of the submarine's hull and bulkhead would be minimized. Clearly, a compartment which is left exposed to dry air will rust at a much slower rate than one which is buried in the earth. A submarine sunk in the salt water will, as shown in the DEIS, corrode at a much faster rate than either of these land disposal options.

I should make it clear at this point that, by definition, it appears the Savannah River site is inappropriate for either the land disposal option considered in the DEIS or the suggestion that we are making today. The amount of rainfall mentioned in the DEIS attending this land site indicates this is truly not an arid or semi-arid site. E.12

We must remember that we are speaking here of placing the entire reactor compartment on the land. The reactor compartment is a section of the hull which stretches between two water-tight bulkheads to provide significant containment to contain radioactivity.

*Other issues discussed by Mr. Jackson are side barred in Exhibits 15 and 37b.

In revising the DEIS, the Navy must consider this modification of the land disposal alternative. The current text contains neither mention of this option nor any reason for discounting it as a viable solution to the Navy's radioactive waste disposal problem. This inadequacy in the DEIS is just one of our prime concerns.

Both a lower continental-rise area and a Hatteras abyssal plain area off the North Carolina coast have been considered in the DEIS. J.28 Published scientific research at one of these sites suggests a more complete investigation by the Navy will find bottom currents which are for the deep ocean considered significant. In revising the DEIS assessment of the oceanographic data, J.8 the Navy officials must make clear the weight to be given to site selection guidelines developed by Doctors Charles Houktross (phonetics) Hollister and G. Ross Heath. They are reported in Appendix E of the environmental assessment.

L.55 The DEIS must also be revised to fully consider the artificial reef effect scuttled subs are expected to have on deep ocean ecology. Experience with radioactive waste dump sites, oil platforms, and ships sunk for fishing reefs, has established that at least on the Continental Shelf, any such structure attracts and holds new and more abundant communities of fish and invertebrates. Whether the subs will serve as an attractive nuisance, attracting new communities of life to the deep sea bottom, must be considered in the DEIS. Estimates of exposure to humans must also reflect this artificial reef effect.

The DEIS plan must also be expanded to provide case-line descriptions of fish and other forms of wild life that inhabit the abyssal plains off these Middle Atlantic States. J.9 Data on trace metals, radionuclides and metal sequestering proteins should be addressed. Specific attention must be paid to the species like Grenadier, a fish recognized in the DEIS as the most abundant large organism at these depths and one which has the potential to serve as a mechanism for horizontal and vertical transport of material released from these submarines.

Sea disposal for radioactive waste is a complex issue. If the Navy really expects informed public comment on this topic, specifically the DEIS, it should not have scheduled this hearing in only two months after the document was released, and specifically should not have limited the comment period to only 90 days.

This DEIS, which was released a few days before Christmas, is a thick and imposing document, containing a summary, four chapters of explanatory text, twelve appendices, and more than 400 pages. A volume of equal size contains scientific studies compiled to support the DEIS and its conclusions. Both volumes cite an impressive list of references from a myriad of sources. While some of these references are available, other, such as a State Department press release, are not easily accessible to citizens, conservationists, or elected officials. Despite the complexity of this issue and the depth of the DEIS, the Navy allotted only 90 days for public comment.

Many conservation groups, including the Oceanic Society, have written the Navy to request expanded comment periods and a delay in these hearings. As we noted in our request to Secretary of the Navy John Lehman, it is difficult to assess, let alone promote, informed public consideration of this draft environmental assessment within the time allotted.

The Oceanic Society has been concerned about the risks of radioactive waste disposal since 1978. We've held public policy forums, published books, and worked with scientists throughout the country, yet we have found it very difficult to analyze and to involve the public in an informed discussion about this issue on the Navy schedule.

Our analysis of this DEIS centers on an independent committee of scientific individuals who met February 3d and 4th to review the document. Our committee report will not be complete until the end of this month. Clearly, we cannot utilize this independent scientific evaluation to help citizens comment on these hearings.

Recent actions at the U. S. Environmental Protection Agency have done little to allay our concerns. The current administration has transferred the man who was in charge of drafting this DEIS for the Navy and placed him in charge of the EPA office, charged with regulating sea disposal of radioactive waste, and incidentally in charge of reviewing this DEIS for that agency. This administrator's refusal to allow any EPA staff to assist in our review

of the DEIS further weakens the agency's credibility as a regulatory agency which protects the public. Rarely has the Reagan Administration provided a clearer example of inviting the fox in to guard the hen house.

In revising the DEIS, additional attention must be paid to the twin problems of cumulative impact and monitoring. Neither the DEIS nor scientific research cited in support of that document consider the disposal of decommissioned nuclear submarines within the context of cumulative sources of radioactivity. This is a significant omission which makes it difficult, if not impossible, to adequately consider incremental increase in radioactivity entailed in land or sea disposal of decommissioned nuclear submarines. Revision of the DEIS must incorporate adequate data, information, and discussions to address this issue.

In considering the sea disposal option, consideration of cumulative impacts should begin with development of a comprehensive register of all radioactivity known or reasonably expected to enter the marine environment. This global inventory should include, but not be limited to, past, present and potential levels of radioactivity from weapons testing, historic U.S. and foreign radioactive waste operations, accidental losses of nuclear material, sea disposal of low level waste under the London Dumping Convention, other U. S. and foreign proposals for waste disposal in the marine environment. L.7

This assessment must include an estimate of the marine environment's capacity to assimilate radioactivity without damage. This estimate must be based on sound science and will, in all probability, require additional research. Assessment of cumulative impacts should include descriptions of past, present and projected efforts, effects, both in terms of human health and specific components of the marine ecosystem.

Consideration of cumulative effects must be complemented by a comprehensive monitoring program. We believe the marine monitoring programs considered in the DEIS are inadequate to gauge environmental affects on either land or sea disposal options. Absence of a comprehensive monitoring program prohibits sea disposal of nuclear submarines. In revising the DEIS, the Navy must consider and describe in detail the scope and cost of long-term monitoring of submarines on the deep ocean floor. Specific attention must be given to locating monitoring stations within 25 meters of the reactor compartment and in a network of sites where the plume of radioactivity from a submarine can be monitored. Details of plans for biota sampling, sediment sampling use of submersibles, and development of <u>in situ</u> monitoring equipment must be considered. Costs and assured sources of funds must be clarified.

The best estimate for corrosion described in Appendix G of the DEIS suggests the reactor compartment would be penetrated within a hundred years and that bottom currents would begin

flowing through the reactor within 400 years of disposal. This estimate is used in Figure G-2 to show release of radioactivity to the environment as occurring in more or less than one hundred and four hundred years. The comprehensive monitoring programs data must extend beyond the short-term studies envisioned in the DEIS, to include monitoring of these projected releases. Unfortunately, the monitoring program described in Appendix K of the DEIS proposed only a nine million dollar budget for monitoring before, during, and after the period of active disposal. Under Section 4c, the DEIS states the frequency of post-disposal monitoring will be determined by measured results, results from a period when the DEIS predicts no release of radioactivity to the marine environment.

The DEIS must also consider institutional impediments to conducting monitoring programs for very long -- I mean, periods of hundreds of years. Experience from the past three decades has demonstrated the difficulty in retaining records, let alone continuing environmental programs, of nuclear waste placed in the marine environment. To a significant degree, records of more than 100,000 curies of radioactive waste dumped in the sea by the United States from 1946 to 1970 are missing today. Research in monitoring of the storage sites is virtually nonexistent, and, in fact, has been cut back by the current administration -- which it is now proposing to do with the sea disposal of radioactive waste. J.79

The effects of accidental sinking of a submarine while

L.57 L.61 the ship is being towed to the sea also merits additional consideration. The DEIS predicts that .3 subs will be sunk for every sub disposed. However, this figure is based upon national statistics. It has not considered the hazardous weather

L.58 conditions proved to be valid off Cape Hatteras and Cape Mendocino.

Neither the DEIS nor the scientific studies cited in support of this document justify selection of the sea disposal option

W.1 over land disposal. Our inability to retrieve complete submarines from the deep ocean floor combined with the institutional im-

J.76 possibility of guaranteeing support for long-term environmental monitoring make the marine environment an unsuitable site for disposal of this waste.

These factors should combine to compel the Navy to withdraw this DEIS for extensive revision. Concerns expressed at this and the other hearings should be considered and reflected in a New Draft Environmental Impact Statement. That assessment must be written in clear language and use consistent terms of reference to allow citizens a fair opportunity to understand and comment upon this issue.

Release of a Revised Draft Environmental Impact Statement should be preceded by public education efforts which allow citizens in states like North and South Carolina, California, and Washington, to question the scientists whose works establish, support, the Navy assessments. Then, and only then, will the Navy have met the requirement for informed public participation

which is inherent in democracy.

Land disposal appears to offer a safer and more sensible solution to the dilemma now facing the Navy. If nothing less, the land alternative insures the submarine will not be sent out to sea, out of sight, and out of mind.

Thank you for this chance to talk again on this issue.

CAPT WAGNER: Thank you for your comments, Mr. Jackson.

Ladies and gentlemen, I know there are a few of you who have parking meter problems. You had to park in a place that has an hour limit. At this time I intend to take a recess so that you can solve that problem, and then we'll come back and resume testimony.

For those of you who would like to testify and have not yet registered, you may do so during the recess.

If you could turn that light off, please, I could see the clock and will set the time for reconvening the hearing.

We'll recess and reconvene at ten minutes of 10:00 -- at 10:00 o'clock. We'll meet at 10:00 o'clock. Thank you.

(The public hearing recessed at 9:50 a.m. and reconvened at 10:00 a.m., 17 February 1983.)

CAPT WAGNER: We are still receiving testimony from persons from organizations, and our next registered speaker is Mr. Michael F. Lowe, who is representing Palmetto Alliance, Incorporated. #29

Mr. Lowe, Please.

MR. LOWE: Good morning, Captain Wagner. I pronounce my name Lowe.

CAPT WAGNER: Excuse me.

MR. LOWE: I appreciate the opportunity for Palmetto Alliance to present its views here for the Navy today.

My name is Michael F. Lowe. I am the Director of Palmettc Alliance. We are a safe energy organization incorporated in South Carolina as a non-profit organization, to promote energy issues, particularly, nuclear waste issues.

Palmetto Alliance opposes ocean dumping of nuclear submarines for reasons so clearly outlined by Mr. Jackson of the Oceanic Society. And I won't go into detail of that.

E.12 Palmetto Alliance also opposes land disposal of these submarines at the Savannah River Plant. The high rainfall rate here relative to the alternative site at Hanford would risk corrosion and leaching of radioactive materials to the environment.

E.13 The location of the plant over the Tuscaloosa-Acquifer in the Southeast also is disadvantageous. We feel Savannah River Plant should never have been located in that position at any rate.

I.8 The fact that the plant is located in a Class III Earthquake Zone should also eliminate the Savannah River Plant as a disposal site for nuclear submarines.

And, finally, the amount of the radioactive waste already at the Savannah River Plant and already at commercial facilities in South Carolina would make it politically unwise for the Navy to choose Savannah River Plant as the site to dispose of nuclear submarines. South Carolinians have already done their part so far as the nuclear program, both commercial and military, for this country. And it is politically unwise, unfair, and unjust to ask us to tolerate more radioactive waste in this state.

I thank you for your time.

CAPT WAGNER: Thank you, Mr. Lowe.

The next registered speaker is Ms. Joyce Rosenthal, representing Greenpeace Association.

MS. ROSENTHAL: Good morning, Captain Wagner.

CPT WAGNER: Good morning.

MS. ROSENTHAL: Thank you very much for this opportunity to testify here today.

My name is Joyce Rosenthal. I will testify here today on behal of Greenpeace USA, in the capacity of Campaign Coordinator to the issue of Ocean Dumping. #13a*

Greenpeace is an international environmental organization whose sole purpose is the promotion of environmental protection over the long term. Our campaigns are designed to foster awareness of the threat of environmental degradation through research, educational efforts, and non-violent direct actions, to prevent destruction of endangered species and critical ecosystems.

Since Greenpeace's beginnings in 1971, the oceans have been a central concern of the organization. Largely due to our efforts to protect marine life and the ocean environment, Greenpeace presently has over 270,000 contributing members in the United States and more than one million worldwide.

I am here to address the Navy's examination of the ocean dumping option for the disposal of irradiated nuclear submarines, as outlined in their Draft Environmental Impact Statement, released December 22, 1982. Although the Navy maintains that they

*Other issues provided by Ms. Rosenthal are side barred in Exhibit 13b.

have not yet selected a preferred method of submarine disposal, environmentalists, fishermen, scientists, policy-makers, state governments, and citizens around the country, and in other nations, have been concerned over the possible resumption of ocean dumping of radioactive waste.

Greenpeace opposes the ocean disposal of radioactive waste. In approaching the question of nuclear waste disposal, we assume the objective goal is to insure the protection of public health and the environment over a very long term. The activity of isotopes present in all categories of nuclear waste, and present in the irradiated reactor compartment, pressure vessel, and steam generator of decommissioned submarines, guarantee that levels of radioactivity will persist for thousands of years.

*L.6 To pursue ocean disposal at this time would mean resuming a practice before the impacts on public health and the marine environment of past radioactive waste ocean dumping are understood.
W.1 Once dumped, these submarines would be irretrievable. This is a critical drawback that land based storage does not have.

A review of past radioactive waste ocean dumping in this country in comparison to the Navy's proposal elucidates part of our concern. The DEIS estimates that one defueled submarine reactor plant contains about 62,000 curies of radioactivity, which is approximately one-half the entire amount of radioactivity that has been calculated to have occurred in dumping operations off the United States coasts between 1946 and 1970. The isotopes

in the induced radioactivity in each sub contains: Cobalt 60, Nickel 63, Cesium 137, Nickel 59, and Niobium 94. There are 16 different radioactive nuclides in the initial 62,000 curies, with half-lives ranging from 5.26 years for Cobalt 60 to 80,000 years for Nickel 59. With over 100 nuclear submarines scheduled for disposal over the next 30 years, choosing the ocean dumping option would result in sea disposal of quantities of radioactive materials that dwarfs the previous U. S. dumping program by comparison.

In the over 100,000 containers of nuclear waste and one submarine reactor vessel dumped into the Atlantic and Pacific Oceans within the 24-year period of ocean dumping was approximately 120,000 curies of radiation. These are the recently revised calculations on the magnitude of past dumping by the Environmental Protection Agency, which has been largely unsuccessful in determining the full extent and location of past dumping.

The Navy's DEIS has not considered the precedent setting nature of this ocean dumping option. A formal request to the EPA to dump radioactive submarines into the ocean would constitute the most formidable pressure to reverse a twelve-year *de facto* ban on the multi-practice of ocean dumping. The practice was halted in 1970 when the Council on Environmental Quality issued a report which concluded that ocean dumping of any radioactive waste presented a very serious and growing threat to the marine environment. F.8 L.9

*Other issues provided by Ms. Rosenthal are side barred in Exhibit 13b.

I think the recent Anderson Amendments to the Ocean Dumping Act, which place a two-year moratorium on issuance of new ocean dumping permits pending a more detailed study of their environmental consequences, reflects the spirit of the constituency around the country that is opposed to renewed nuclear waste dumping into the ocean.

A new policy of considering nuclear waste dumping on a case by case basis, by necessity, would have to replace the present two-year moratorium, without developed EPA guidelines.
L.5 There are also no existing EPA regulations or a national policy
for radioactive waste ocean dumping. If the Navy pursues the
F.8 ocean dumping option, that represents an undeniable policy shift
that has implications far beyond the specific proposal. The
Navy's DEIS should have assessed the cumulative impacts of ocean
L.7 scuttling in the context of other past and proposed ocean dumping
and other sources of radioactivity in the marine environment.

Despite recognition of its needs by international maritime organizations, a complete inventory of radionuclides entering the marine environment has never been created.

The Navy in its proposal is breaking ground for a great variety of radioactive waste that could be dumped into the ocean if the EPA permits this practice on a case by case basis. Evidence of this is the February 1st notice by the Department of Energy that the ocean dumping option is being studied for disposal of FUSRAP soils, wastes from the Manhattan Project currently being stored in New York.

Politically, the resumption of dumping nuclear waste into the ocean is bound to be increasingly unpopular with a growing number of nations that are opposed to this practice, including Pacific Island nations and the European nations opposed to the current dumping by the U.K., Belgium, and Switzerland, into the Northeast Atlantic. Clearly, the U. S. role in influencing global decision making must be given more consideration. In the past two years, we have unfortunately seen the United States relinquish its leadership role in marine protection international to leading the battle cry for a small band of dumping nations.

Ocean dumping is currently subject to review by the more than 50 member nations that have signed a treaty called the "International Convention on the Prevention of Marine Pollution by Dumping Wastes and Other Matter," better known as the London Dumping Convention. This is an appropriate week to consider the international aspects of the Navy's scuttling plans, as it marks the seventh meeting of the London Dumping Convention, where the LDC nations will consider a proposal by the Pacific Island nations to ban radioactive waste ocean dumping as an amendment to that treaty.

In light of the current unanswered questions regarding the biological transport pathways of radionuclides, oceanic currents, and the cumulative effects of past and current dumping operations, we hope that the LDC nations will recognize the risks of continued ocean dumping at this time, and support a ban on its practice.

Japan and other nations are closely watching the development of the U. S. policy on this issue in consideration of their own plans for radioactive dumping. Greenpeace is represented at the LDC meeting as a non-governmental organization and is supporting the proposed ban on all radioactive waste ocean dumping.

These policy implications of the scuttling plan are why we have to examine the entire issue of ocean dumping in judging them, including the under-researched effects of past dumps in this country. Scientific studies contracted by the United States EPA have revealed evidence of radionuclide biocumulation into
U.9 the marine food chain. Specifically, I refer to Dr. William Schell's study of Americium 221 contamination of the rattail fish otherwise known as the grenadier, off the coast of New Jersey and New York, and that is a great cause for concern, especially in light of the almost complete absence of the EPA radioactive waste dumpsite monitoring. Given the current status of the EPA programs, we find that the monitoring plans as outlined for both the ocean and land disposal options in the DEIS are not credible.

Time constraints in preparation of this testimony following the release of the DEIS do not permit me to engage in a technical review of the Navy's supporting scientific studies on the ocean disposal option, or to review the Navy's study of possible land burial sites at Hanford, Washington, and Savannah River, South Carolina. The 90 day commentary period provided by the Navy is not sufficient for the public to analyze the bulk of technical

data and considerations in the scope of this DEIS. Greenpeace has submitted a request as part of a coalition of environmental organizations requesting a 90-day extension of public commentary time. We hope the Navy agrees to this for the benefit of the public, that North and South Carolina have barely had time to obtain a copy of the DEIS, much less analyze this 400-page technical document.

We would also like to note that in addition to not spelling out monitoring plans for land-based disposal, the DEIS did not L.13
take into account the artificial reef effect that nuclear submarines will have on the marine environment. The EPA has found
out that in the deep sea, metal drums used for radioactive waste L.55
disposal in the past produces a reef effect, actually attracting organisms, since the metal containers provide one of the few hard substances to attach to on the ocean floor.

Careful consideration must be given to today's testimony by the Oceanic Society, the Palmetto Alliance, and others, as they critique the DEIS on technical grounds. These people have pointed to unacceptable gaps of essential information that would
be used to predict the transport or fate of radioactivity in the L.1
marine environment.

Returning to the question of how to dispose of obsolete submarines, Greenpeace proposes that the Navy should continue to G.2
maintain irradiated submarines in protective storage in the

naval shipyards where they are decommissioned, to allow for the anticipated early rapid decay of short-lived radioisotopes.

We have presently asked a technical expert to evaluate data on decay of radioactivity in the subs and hope to present findings that pinpoint the earliest optimum time for shipping from protective storage to land-based storage. Information in the DEIS indicates that a proper time-frame for shipment would be from twenty to fifty years.

Supporting this recommendation is a statement in the DEIS: "Nuclear submarines can also be placed into storage for a long time without risk to the environment. The submarines would be kept in protective storage. About every twenty years each ship would be taken out of the water for an inspection and repainting to assure continued storage."

Questions we must ask ourselves after that time to assess the differences between land disposal options include:

E.23 What is the shortest, safest transportation route for these radioactive wastes to the land burial site, or land disposal site? Recognizing that shipment is the weakest link in the disposal process, due to the possibility of accidents and public exposure, great consideration must be given to the shortest and safest route.

L.62 L.57 What are the chances of a barge-towing accident in case the shipment transverses deep or shallow salt water or rivers? The DEIS must consider these possibilities.

What environmental concerns have been raised by the public near the two land disposal sites that the DEIS does not cover? Are there more appropriate burial sites not covered in the DEIS? E.28

Can there be monitoring plans for a land-based disposal site? I.13

In conclusion, I note the Savannah River Plant's relative high rainfall, 47 inches a year. Corrosion is greatly accelerated by moisture, and corrosion is the process by which these radionuclides get into the environment from the reactor compartment. This environment is a factor which would make the Savannah River Plant an unattractive site for these radioactive wastes. E.12 I.9

I also note in conclusion the problems that every nuclear nation around the world has had in disposing of their radioactive wastes. We must examine our policies carefully to determine whether it's acceptable to society to continue producing materials for which there exists no environmentally sound disposal practice.

Thank you, Captain Wagner.

CAPT WAGNER: Thank you, Ms. Rosenthal.

The next registered speaker is Ms. Mary T. Kelly, representing the League of Women Voters in South Carolina. #30

Ms. Kelly.

MS. KELLY: Thank you, Captain Wagner. I appreciate the opportunity to speak.

I don't have a prepared statement, and I would like to reserve the right to submit one at a later date. I just want to go on record for the League as being greatly concerned by this question of both ocean dumping and possible land disposal at the Savannah River Plant. Though, the League of Women Voters is very concerned about the many issues concerning nuclear waste and everything to do with nuclear in South Carolina. Because we are a state excessively impacted both because we have the Savannah River Plant; we've got the Naval Base in Charleston; we have more than the average number of power reactors in this state; we've got a third of the nations high-level waste disposals; we have one of three low-level waste sites. Just from the standpoint of fairness of actually what has happened in South Carolina, it seems to be something that should be considered in this disposal option.

However, we would like to urge you to take into careful account the points that have been raised here since they are
L.1 extremely valid, the many unknowns concerned with deep ocean
L.7 disposal, possible mixing impacts, the cumulative impacts of
J.76 radioactive materials getting into the ecosystem, and the long-range monitoring. The fact that these submarines will be irre-
W.1 trievable is certainly a matter of tremendous importance.

We are also concerned about disposal at the Savannah River Plant because -- we're always concerned about the Savannah River Plant, for the simple reason that long ago when it was sighted -- in hindsight --when we doubt that we'd ever be placed in an area with the geological characteristics of the Savannah River Basin.

That area is in a Class C-3 seismic zone, but we've had a major I.8
earthquake in this state in the past; the possibility of ground
water contamination if this submarine corrodes as we expect it I.9
to. All those are factors that enter in.

We also are a little perturbed at the fact that the time-frame allowed for comment has not really been adequate. I think that governmental organizations really do not comprehend how citizens groups and private citizens operate. We don't have full-time staffs and experts. It takes us a while to come to grips with these things, and we do need more time. We would appreciate that.

Thank you.

CAPT WAGNER: Thank you, Ms. Kelly. We would be pleased to receive your written comments later.

I have no further registrations for people desiring to provide testimony. Is there anyone registered to provide testimony whose name I have not called?

(No response)

CAPT WAGNER: Additional public comments for consideration in the final statement may be sent to me at the address that I announced previously.

I would like, on behalf of the United States Navy, to thank all of you for attending this morning, particularly, those of you who provided testimony.

This hearing is adjourned.

(The morning hearing adjourned at 10:20 a.m., February 17, 1983.)

(The afternoon session of the public hearing convened at 1:33 p.m., February 17, 1983.)

CAPT WAGNER: Ladies and gentlemen, I would like to call this hearing to order.

Is there anyone here this afternoon who did not attend our morning hearing?

(No response)

CAPT WAGNER: I have no registrations for our hearing scheduled this afternoon. Is there anyone in the audience who would like to register and would like to provide testimony?

(No response)

CAPT WAGNER: Then, I will remind everyone that we have a hearing scheduled at 7:30 this evening. We will adjourn at this time and hold a hearing at 7:30 in the evening. Thank you.

(The hearing adjourned at 1:35 p.m., February 17, 1983.)

(The night session of the public hearing convened at 7:45 p.m., February 17, 1983, in Columbia, South Carolina.)

CAPT WAGNER: Good evening, ladies and gentlemen, this hearing is called to order.

I am Captain Edward Wagner, and I work in the Office of the Deputy Chief of Naval Operations for Submarines. I have been appointed the Navy's Hearing Officer for this evening's public hearing. Here with me to present an opening briefing is Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program. Also present is

Mr. James Gaver, Assistant to the Manager for Public Affairs, the Savannah River Operations Office, Department of Energy.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear powered submarine reactor plants after the fuel has been removed and the ships are no longer needed. The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government-owned land disposal sites or placing them on the deep ocean bottom.

On December 22, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement, or DEIS, on the disposal of decommissioned, defueled Naval submarine reactor plants. The DEIS contains the results of the Navy's studies of the alternatives available. On the registration table are copies of the Summary of the Draft Environmental Impact Statement. Anyone in the audience who would like a complete copy of the DEIS, should leave their name and address on the sheet of paper provided at the registration table, and a copy will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient to the people with an interest in this matter, in order to provide them with an opportunity to present their views. I am here today to conduct one of these scheduled public hearings. The purpose of this hearing is to take testimony regarding the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case nor to engage in debate. It is my responsibility to receive statements so that they can be considered in preparing the Final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each, and organizational spokesmen are limited to ten minutes, unless additional time had been requested in advance. Time cannot be relinquished from one speaker to another.

In order to insure all who desire to speak are given an opportunity, each person should fill out a registration card and provide it to the registration table. All testimony will be recorded so that it can be considered in the development of the Navy's Final Environmental Impact Statement.

If you desire to submit written comments rather than to speak, that is acceptable. You can provide written comments to me or leave them at the registration table. If you desire to provide written comments at a later date, my mailing address is:

Captain Edward F. Wagner
U. S. Navy
Office of the Chief of Naval
Operations (OPNAV-22)
Department of the Navy
Washington, D. C. 20350

You should provide your written comments by March 31, 1983, which as stated in the Federal Register Notice, is the

cut-off date for submitting comments.

Before we begin receiving testimony, I would like to at this time introduce Mr. Mangeno of the Naval Nuclear Propulsion Program, who will provide a general overview of the issue the Navy is addressing and the content of the Draft EIS.

Mr. Mangeno.

MR. MANGENO: Today's hearing is being conducted as a part of the decision-making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an Environmental Impact Statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The Environmental Impact Statement must include the environmental impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement, or DEIS, on this subject provides the basis for these hearings, and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear-powered submarines after they are no longer needed. The practical choices are: Bury the radioactive part of the submarine at an existing DOE land disposal facility at the Hanford Site in the state of Washington, or the Savannah River Plant in South Carolina; or place the entire submarine on the bottom of the ocean in water more than 2.5 miles deep. In both choices there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has about 120 nuclear-powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases, as shown in this slide it is evident that a disposal plan must be prepared for use sometime in the future. This DEIS has been prepared now so that all interested agencies, organizations, and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the uranium and all of the fission products. The removed fuel is handled according to established procedures and

is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, to the metal structure supporting the fuel, to the reactor vessel, and to other equipment in the reactor compartment, where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by the hull of the submarine and by the reactor vessel and coolant piping. In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel, or other metal atoms in the reactor plant. These atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation of the nuclear reactor and the number of curies of each radionuclide at that time. A curie is a measure of the amount of radioactivity present, but it is not an indication of the possible effect on man or animals. The amounts and kinds of radioactive atoms present are described in uetail in Chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the federal government disposal facilities already used for such low-level radioactive waste at the Hanford Reservation in the state of Washington, or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the compartment free from the remainder of the submarine, and weld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal, and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. Other government-owned disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable water, so that transportation of the reactor compartment to those sites would be impractical. The Hanford and Savannah River burial grounds are described in Chapter 3.

A transporter of the sort shown in this sketch could then be used to haul the compartment over land to the burial location.

There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial, or after burial. This is because radiation outside the compartment would be well below federal limits, and the reactor compartment would have been welded shut at the shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low-level radioactive wastes. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burials and would result in no significant additional environmental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the body. More than 200 years would pass before the reactor compartment bulkhead could be penetrated by corrosion. Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time, exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean is another practical alternative. The maximum radioactivity would be less than the limit specified by international criteria; and the triple containment provided by the submarine reactor compartment, by the reactor vessel and piping, and by the radioactive atoms being a part of the metal itself, would be an extremely strong and effective disposal containment package.

Locations for possible ocean disposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U. S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site-specific public hearings would be required and the permit process is not a part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 190 miles west of Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry, and marine biology for very deep ocean locations. The depth of the water in these areas is between 4000 and 5000 meters (13,000 to 16,000 feet). The scientific information and measurements collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that the environmental impacts could be calculated using realistic data.

Preparation for ocean disposal would be made at one of the shipyards normally servicing nuclear-powered Naval vessels.

Following defueling, the reactor vessel and the reactor compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping, and, of course, the metal itself completely intact. Most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping or free the atoms from the thick metal.

A comparison of the possible effects on the environment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100 submarine disposals for the year of greatest exposure for both options. This table shows that the radiation exposure would be very small and could have little impact on indivduals or the population. These levels are also many times less than any limits established by U. S. regulations or international limits. They are much smaller than the normal fluctuations in annual average background radiation exposure for U. S. residents.

A perspective on radiation exposure can be gained by examining the exposure a person would receive from natural cosmic background radiation if he flew round-trip from New York City to Los Angeles. That person would receive approximately 2 millirems more radiation than if he had not made the trip, because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one-half millirem.

Other environmental impacts are similarly small for both options. The effects on animal life would be small and localized in either case. Land burial of 100 reactor plants would require only about 10 acres of land, and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square 10 miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land disposal would cost about 40 percent more (about two million dollars per submarine more) than sea disposal.

The "no-action" alternative is to place submarines in floating protective storage for an extended period, commonly called "mothballing." However, this would only temporarily delay disposal, because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods, and the estimated radiation exposures for the general public would be very small

for all available courses of action.

Thank you.

CAPT WAGNER: Thank you, Mr. Mangeno.

Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing. I will now proceed with public testimony.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, please proceed to and be seated at the testimony table in front of me. State your name and organization, if any. All comments are then to be addressed to me.

Our first registered speaker is Ms. Ruth Thomas from Columbia, South Carolina, representing Environmentalists, Inc. #31.

Ms. Thomas.

MS. THOMAS: Thank you, Captain Wagner.

I appreciate this opportunity of being here.

Oh, I should repeat my name: Ruth Thomas with Environmentalists, Incorporated, a Columbia educational organization which has been in existence for over ten years.

I wanted to thank you, too, for holding three sessions, although I didn't know you were going to hold it for me, but I did have two other conflicts. I had a conflict this morning and this afternoon, so I was glad that there was one this evening.

I did receive, or our organization did receive, a copy of the Draft Environmental Impact Statement on the disposal of decommissioned Naval submarine reactor plants, and in looking

this over and in listening to the presentation, I still have
some questions, for example, in relation to the National Environ-
mental Policy Act. It seems as though there are a number of other
H.3 alternatives which have not been included. For example, it would
seem that disposal in an area which is very dry and arid should
be considered.

Another thing is that some of the information appears to
conflict with some factual data. I was surprised, too, that
the National Academy of Scientists reports on radioactive wastes
I.11 were not included as references, or at least I did not find these
as references. For one thing, the National Academy of Science
in their 1966 report indicated that the Savannah River Plant was
not a good area to have radioactive material, and in support of
this they cited the climate, the moist climate, and the water
table which is quite near the surface, and some other problems
with the area.

Of course, with the disposal at sea you are going to have a
lot more water than we have in South Carolina, and the corrosion
problems are a concern, and since this would be the method by
which the radioactivity would be released, I think, too, that we
have to consider that in the future we may be making different
L.36 uses of the ocean than we do now, for more food, and that this
could be a problem having the radioactive material buried at sea.

I.14 I also have with me, which I will leave a copy of, a
report from the U. S. Department of Interior, the geological

survey, and they point out problems at the Savannah River Plant
in relation to having radioactive material and nuclear activity I.14
there. They also point out that monitoring doesn't necessarily
pick up a leaking radioactivity, that the radionuclides can
by-pass monitoring walls and move undetected into a site. And
they point out that if this happens with long-lived radioactivity
that it could be impossible or impractical to take remedial action.

I noticed in the talk that it was mentioned that this would
be classified as low-level radioactive wastes, but as I understand
it, this low-level radioactive waste can include materials that
are radioactive for very long periods of time.

I understand, too, through a study done by Roderick Poole,
that the operation of a nuclear reactor brings about the long-
lived radionuclides, and I believe some of these are mentioned --
I think Lead 59 is one. I couldn't find that report before com-
ing tonight, but I do mention that report and the information
that is contained in that.

The presentation referred to a natural radiation and radia-
tion that we receive from other sources, and since the effects
of radiation are cumulative, it is a concern to think that we
are having this added to the harm that we already receive from
natural radiation. I think we are inclined, because it has been
around so long, to think that maybe natural radiation isn't
harmful, but of course we know that it is.

So, I would like to submit in writing, and I'm sorry that
I didn't have something this evening, but I will do that at a future

date, and I believe by March 31st -- was it?

CAPT WAGNER: That's correct.

MS THOMAS: So that I can refer exactly to the documents that I spoke of and for the basis of our Environmentalists, Inc., recommending that other considerations be given besides those that are included and that we do feel that we would not like to see the disposal at sea, and also would not like to see it buried at the Savannah River Plant. We feel like we have enough there.

Thank you.

CAPT WAGNER: Thank you, Ms. Thomas. We will be happy to receive your written comments when you submit them.

I have no further registrations. So, is anyone registered to speak that I have not yet given them an opportunity?

(No response)

CAPT WAGNER: I would like to again add that the written comment can be mailed to me at the address that I mentioned earlier.

I would like to thank Ms. Thomas for her comments tonight on behalf of the Navy and myself. We appreciate that. And at this time I would like to adjourn the hearing.

(The scheduled night session of the public hearing in Columbia, South Carolina, was adjourned at 8:12 p.m., February 17, 1983.)

CERTIFICATE

March 9, 1983

I hereby certify that the foregoing transcript consisting of 49 pages plus index constitutes a complete and verbatim report of the Public Hearings held on February 17, 1983, at 9:00 a.m., 1:30 p.m., and 7:45 p.m., in Columbia, South Carolina, RE: NAVY'S DRAFT ENVIRONMENTAL IMPACT STATEMENT ON THE DISPOSAL OF DECOMMISSIONED, DEFUELED NAVAL SUBMARINE REACTOR PLANTS, reported and transcribed by me.

COMMENTS
on the
DRAFT ENVIRONMENTAL IMPACT STATEMENT
ON THE
DISPOSAL OF DECOMMISSIONED, DEFUELED
NAVAL SUBMARINE REACTOR PLANTS

By
Marvin Resnikoff, PhD.
Council on Economic Priorities

Prepared for Greenpeace U.S.A.

The Draft Environmental Impact Statement (DEIS) by the Department of the Navy examines the environmental implications of the Navy's plan to dispose of 100 nuclear submarines. Two alternatives are seriously considered: sinking the defueled submarines in the deep ocean and burying the nuclear reactor compartment in near-surface burial grounds at Hanford, Washington and Savannah River, South Carolina. The deferred action alternative preferred by environmental groups, to dispose of the pressure vessel plus radioactive internals in deep underground repositories after a 25 to 50 year storage period is briefly mentioned by the Navy and dismissed.

The Navy DEIS is an ambitious undertaking. It must consider the short and long-term implications of both surface land and deep ocean disposal. However, the DEIS is fatally flawed in its estimates of the initial radioactivity present in the reactor taken out of service. These incorrect estimates lead the Navy to incorrect conclusions about the hazards and method of disposal.

The Navy DEIS understates the curies of cobalt-60 and niobium-94 present in the reactor pressure vessel plus internals. Based on the radioactivity hazard of cobalt-60, submarine reactors should be stored 25 to 50 years, then disposed of in deep underground land repositories rather than in a surface burial ground. Further, the projected occupational exposures in decommissioning a submarine reactor are unsubstantiated and seriously underestimated in the DEIS. Allowing the submarine to remain in safe storage for 25 to 50 years before dismantlement will result in less radiation exposures than if the submarine is immediately dismantled, yet the DEIS holds the opposite. The long-lived gamma radioactivity due to niobium-94 rules out surface burial. These points are discussed in much greater detail below. G.7*

*Other issues provided by Ms. Rosenthal are side barred in Exhibit 13a.

#13b (Cont)

Specific Comments:

A.10

1. The Navy DEIS underestimates the levels of radioactivity of certain radionuclides remaining in a defueled submarine nuclear reactor. This radioactivity is due to the irradiation of the reactor metals by neutrons escaping from the reactor core. We calculate the correct numbers in this section by scaling the levels in a commercial PWR down to the smaller submarine reactor. An exact calculation is impossible because the basic data, such as the power level, capacity factor, geometry and metals (including contaminants) of the submarine reactor are not specified in the DEIS, presumably because of security reasons.

For a rough estimate of the radioactivity in a submarine reactor, we assume that the average submarine reactor has maximum power levels of 125 MW(e) and a capacity factor or 60% for a 30 year period. On average, submarines are at sea 90% of the time, though not operating continuously at full power. The total energy produced is one key parameter determining the radiation levels. Energy is directly proportional to the number of fissions and therefore to the total number of neutrons, a fraction of which escape the reactor core and irradiate the metals. The curie content can then be estimated by linearly scaling the results for a commercial power PWR, as shown in Table 1. We expect that this method underestimates the activation products in a submarine reactor since smaller reactors have a greater fraction of "lost" neutrons, i.e., neutrons which do not interact with uranium-235 and escape the core.

As seen in Table 1, the levels of nickel-59 and -63 estimated by us and the Navy are identical. However, the levels of cobalt-60 estimated by us are greater by a factor of 6; the levels of niobium-94 are greater than the Navy DEIS by a factor of 100. Unless the metals in a Navy reactor are radically different from a commercial PWR, the Navy's estimates for the different radionuclides are inconsistent. Since the NRC values, upon which our projections are based, have been well substantiated in NUREG/CR-0130, we employ them, rather than the Navy's, in further discussions. The Navy has not substantiated its numbers for cobalt-60 and niobium-94 in the DEIS. To do this, it needs to document the contamination levels of Co-59 and Nb-93, the precursors of Co-60 and Nb-94, respectively, and needs to document the total neutron fluence. A.10

These two underestimates by the Navy radically alter the disposal options. Because Co-60 emits penetrating γ radioactivity, higher Co-60 levels imply higher occupational exposures in the case of immediate dismantlement and argue for continued storage, on the order of 25 to 50 years. Higher Nb-94 levels argue for deep underground disposal rather than surface disposal because Nb-94 is also a strong γ emitter and has a 20,000 year half-life. We discuss these points next.

2. Based on projected commercial PWR radiation levels after shutdown, we can estimate radiation levels for the submarine reactor. These are not calculated in the Navy DEIS. Our calculations are shown in Table 2. At reactor shutdown, the radiation levels in the submarine reactor are expected to range as high as 41,500 R/h, due to Co-60 alone. These levels decline to 40.5 R/h, 53 years after sub reactor shutdown. At 1,000 years after reactor B.7

#13b (Cont)

B.7

shutdown, we project the γ radiation levels at the reactor shroud to be 150 mr/h, due almost entirely to Nb-94. These levels exceed the NRC levels for unrestricted release, 2 mr/h, or if a person were continuously present at the reactor for a full year, 0.02 mr/h (170 mr/y). These radiation levels due to Nb-94 necessitate deep underground disposal rather than land surface disposal. Since the half-life of Nb-94 is 20,000 years, these radiation levels will persist for a long period of time. The DEIS claims that the radiation levels will decline to 0.1 mr/h after 53 years (p.1-6) are based more on wishful thinking than the law of physics.

G.6

3. Because of the presence of cobalt-60, the longer the nuclear reactor is stored before dismantlement, the lower will be the worker radiation exposures. For a commercial PWR, with much higher radiation levels, the NRC estimates a 30-year storage period before reactor dismantlement. There appears to be no major reduction in occupation exposure in waiting longer than 30 years (Table 2.8-1, NUREG/CR-0130). The greatest occupational exposures come from immediate dismantlement. Unless submarines have certain design characteristics or methods of dismantlement differing greatly from a commercial PWR, we expect this approximate time period of 30 years to hold for submarines as well. Yet the Navy DEIS comes to a different conclusion.

G.6

4. The Navy opposes interim storage and eventual removal of the reactor pressure vessel, preferring instead to scuttle the entire reactor. It opposes interim storage for two reasons: a) submarine maintenance will be required ever 20 years, and b) there is no reduction in occupational exposures to warrant keeping the submarines in storage.

If submarines are placed in storage, the hull must be maintained every 20 years. The implication in the Navy DEIS is that the hull is corroding. Since the Navy downplays the effects of corrosion if the submarine is sunk, the necessity for maintenance is peculiar. The Navy cannot have it both ways. The Navy claims that once the sub is sunk, thousands of years must pass before water can enter the submarine compartment. G.6 L.23

The Navy claims that the radiation exposures incurred in mothballing a submarine, then burying it in surface burial ground (20 person-rems) is greater than immediate land disposal (17 person-rems). This makes no sense. During a 20-year period, cobalt 60 decays by a factor of 15 and therefore the radiation exposures at the time of dismantlement should be greatly reduced. The DEIS claims that protective storage does not lessen radiation exposures to the public (p. 5-13), yet it does lessen exposures to workers. G.6

5. Because of the longevity of Ni-59 and Nb-94, submarines should neither be buried at sea nor in surface land disposal. According to the EPA interim standards, dose rates should be calculated as if no institutional safeguards were present after 100 years. The Navy did not use this procedure in the DEIS. The presence of Co-60 and Nb-94, in greater amounts than predicted by the Navy DEIS, indicates that the exposures to the public will be greater than calculated by the Navy. Rather than burying the entire reactor compartment in a surface burial ground, it may be preferable to bury the submarine reactor itself in a deep underground repository. The option of deep underground disposal is not considered in the DEIS. This should be remedied in the Final EIS. P.13 A.10 G.7

#13b (Cont)

K.14 G.7

6. Transportation aspects are not properly considered in the DEIS. The barge accident rate should be higher implying that the number of accidents in transporting the reactor compartment to surface land disposal will be greater. According to NUREG-0056 on floating nuclear power stations, the number of accidents per million miles is 9.3. The Navy claims only 5.8. In any case, there is no need to transport the entire reactor compartment, weighing 1000 tons. Only a small component of this 1000 ton mass is radioactive, the reactor pressure vessel plus internals. The difficulties in transporting the reactor compartment up the Savannah River are unnecessary. The reactor itself should go to the final repository, which is not the Savannah River facility.

N.3

7. The costs of deep underground disposal would be considerably greater than for surface land disposal or seabed disposal. Nevertheless, the costs are a small fraction of the full construction and operation costs of a submarine reactor, just as the costs of decommissioning a commercial nuclear reactor are a fraction of the construction and operation costs. The Navy should accept this cost as the commercial sector has for power reactors.

A.10 B.7

8. The DEIS claims that because of radioactive decay, after 100 years there will be no external exposures (p.S-10). This neglects the presence of Nb-94. The DEIS should be revised in light of Table 2 which predicts radiation levels on the order of 143 mr/h.

B.1

9. The population dose commitment does not appear to be correctly evaluated. The Navy definition does not evaluate the radiation exposures over the full hazardous life of these materials. The total number of cancers should be calculated from the total dose to the population over all time.

This concept of dose commitment has been consistently employed by the EPA and should be adopted by the Navy as well.

F.8 L.7

10. Because of the precedent of ocean disposal by the United States and its ramifications on the actions of other countries, it is quite possible that other signatories to the London Dumping Convention will begin to dispose of low level waste by ocean dumping. The Navy should consider the effect of many countries disposing of low level waste and not just the effect of 100 submarines being sunk. This is a reasonable effect of the preferred alternative which the Navy, according to NEPA, must consider.

E.10 E.30

11. The Navy does not consider the full implications of barging the reactor compartment to Savannah River and Hanford. At Savannah River, about 7800 cubic yards of a swamp must be dredged to construct a barge slip. The swamp on the Savannah River is also laced with cesium from the L-reactor. The start-up of the L-reactor would bring more Cs to the swamp. At the Hanford site, the Yakima Indian Nation is opposed to the continued radioactive contamination of the federal preserve. Neither of these two concerns appear in the DEIS.

Table 1. Radionuclides in a Commercial PWR and Submarine Reactor

Radionuclide	Commercial PWR (Ci)[b]	Submarine Estimated (Ci)[c]	Submarine DEIS (Ci)[a]
Cobalt-60	1.84E+6	1.36E+5	2.2E+4[d]
Nickel-59	1.63E+3	1.21E+2	1.2E+2
Niobium-94	9.29	6.88E-1	6.3E-3
Nickel-63	2.43E+5	1.8E+4	1.8E+4

Notes:

[a] From Table 1-1, Navy DEIS, six months after reactor shutdown.

[b] From NUREG/CR-0130, assuming a 3500 MW(t) PWR, operating 40 years at 75% capacity factor. Levels at time of reactor shutdown.

[c] Numbers in Col. 1 multiplied by ratio $\frac{60\% \times 30y \times 125\ MW(e)}{75\% \times 40y \times 1175\ MW(e)} = 1/13.5$

[d] $2.2E+4 = 2.2 \times 10^4 = 22,000$

Table 2. Projected Submarine Exposure Rates*

Radionuclide	One-half year after reactor shutdown (R/h) Shroud	Inner Wall	Fifty-three years after reactor shutdown (R/h) Shroud	Inner Wall	One thousand years after reactor shutdown (R/h) Shroud	Inner Wall
Cobalt-60	4.15E+4	4.00E+1	4.05E+1	3.91E-2	-----	-----
Nickel-59	6.74E-3	1.19E-5	6.74E-3	1.19E-5	6.74E-3	1.19E-5
Niobium-94	1.48E-1	1.26E-2	1.48E-1	1.26E-2	1.43E-1	1.22E-2
Nickel-63	β emitter		β emitter		β emitter	

*Exposure rates obtained from NUREG/CR-0130, scaled down to size of submarine reactor.

QUOTES FROM PERSONS INVOLVED IN OVERSIGHT OF RADIOACTIVE DUMPSITES

"After each dump, a thorough inspection is made of the dump area to ascertain that all containers have sunk. In the rare event of a floating radioactive waste container, it is sunk by gunfire."**
-- U.S. Naval Radiological Defense Laboratory

"First, let us destroy myth that the only materials the United States dumped in the ocean were low-level radioactive wastes...There were over 48,000 radioactive waste containers dumped in the Pacific Ocean, EPA saw approximately 200, and examined the sediment around even fewer... One reason their samples may not be representative is the EPA expeditions never look in the right place."** -- Congressman Glenn M. Anderson 11/20/80

"We never go directly to a dumpsite, some of those places have been in all kinds of use for very long periods of time...it could be deadly dangerous."
-- NOAA official as quoted in "New England Outdoors" Sept '81

"It should be clearly recognized that the information we have collected is not encyclopedic. It does represent a pioneering first step in developing general monitoring programs for both abandoned and active dumpsites, but more information is desireable from a scientific and public health point of view... It is my view that market place, dumpsite, and baseline monitoring should all be done." ** -- Roger J, Mattson,Office of Radiation Programs EPA 11/20/80

"We do not have sufficient data to estimate the level of activity (curies) remaining in the waste after years of radioactive decay." **
-- John F. Ahearne, Nuclear Regulatory Commission 10/1/81

"I feel there ought to be additional monitoring there mainly because ... the fact is that I am not sure we have sufficient information as to what exactly was in those containers... In the absence of the kind of information essential to making a judgement in this area, the Congress should strongly oppose any further resumption of waste dumping in our ocean beds."*
-- Congressman Leon E. Panetta 10/7/81

"It is imperitive that we determine the exact location of these barrels, what kinds of wastes were buried, and what levels of radioactivity was involved." * -- Congressman Robert J. Logomarsino 10/7/81

"...between 1946 and 1970, the AEC issued liscenses for ocean dumping of both low and high-level radioactive waste materials off the Atlantic and Pacific coasts; due to faulty and fragmented record keeping; and an incomplete innacurate monitoring system, it is impossible for us to know the precise location, contents, and amounts of radioactive waste which have been dumped in our oceans. This lack of knowledge poses a threat to the health and safety of our citizens."* -- Congressman Anthony C. Beilenson 10/3/80

"On the question of the need for research and monitoring, we have been frustrated in our attempts to better grapple with the impacts of dumping by the lack of scientific evidence on critical features of the marine environment, and the effects upon it of radioactive materials."**
-- Leslie H. Brown, Bureau of Oceans, Dept.of State 11/20/80

Willits, Cal. 95690

Captain Edward F. Wagner
Office of the Chief of Naval Operations
Dept. of the Navy
Washington, D.C. 20350

Dear Captain Wagner,

Thank you for the copy of the Navy's Draft Environmental Impact Report. I have studied it and would like to respond to it as a citizen
*J.76 of Mendocino County. My main concern is the lack of solid information
reguarding monitoring of Radioactive waste sites. I am aware of the 1980 Scientific Advis ory committee with John Burton which stated that radioactivity had entered the food chain from Nuclear waste dumped off the Farrallon Islands near San Francisco. Also, the Environmental
U.9, Protection Agency studied in the 70's data collected on fish which
L.36 shows a direct pathway of radioactivity to humans from Nuclear waste at the Hudson Canyon dumpsite. No study has been made on an artificial reef
L.55 caused by dumped subs that would attract fish and sea life. As to whether life exists at the bottom of the sea, I have seen photographs of the proposed area, 160 miles off the coast of Cape Mendocino which clearly showed sea cucumber, starfish, Rattail fish (grenadeers), and tracks of sea life on the ocean bottom. The D.E.I.S. states there
J.12 is no significant fishing in the area but two independent tests show that albacore caught in the proposed area numbered highest in one test and second highest in the other. The navy sites cost as a factor in ocean disposal, however after removing the reactor core and welding the sub back together, the cost is similar for both land and sea. Another major
W.1 concern is the lack of retrievability if the subs are sunk into the sea. Without strict testing of this method, untold damage could be done to future generations of humans with no way to correct the mistake. The U.S. Government admits that Radioactive waste is dangerous to life and

*Other issues discussed by Ms. Roberts are side barred in Exhibit 32a.

it is a National problem as to what to do with dangerously radioactive L.53
substances. Mendocino Counto 5th District Supervisor Norman DeVall said, "this is the richest fishing in the world, as 20% of fish protein is caught within the U.S. 200 mile limit. It is obsurd that the U.S.
would consider trashing this area. Fishing is the second largest economic L.14
factor in the County with 400 boats in the Ft. Bragg harbor and a home for all boats from Alaska to San Diego." The U.S. Government must do something about its Nuclear waste build up, and as Supervisor John Cimolino states, "The ocean is not the place to put this waste. We must defeat it and defeat it soundly." Please, Captian Wagner, please consider the future of life to be healthy and free from contamination. It is our Constitutional right to have clean air, safe uncontaminated food, and a healthy Non-Nuclear ocean. Thank-you,

Sinserely,

Beverly Roberts

February 9, 1983

TO: The Honorable John Lehman

Secretary of the Navy
U.S. Department of Defense
The Pentagon Building
Washington, D.C. 95814

REF: Comments regarding the Public Hearing, February 24, Draft EIS, California Water Resources Building, Sacramento, Ca.

SUBJ: Permanent Disposal of Decommissioned Nuclear Submarines in waters off Cape Mendocino.

Dear Mr. Lehman:

As a resident of the North Mendocino Coast I would like to state my opposition to any proposal to dispose of nuclear powered vessels in ocean waters. My reasons are as follows:

1. Local Issue:

a. On-shore, the Mendocino coastal citizens are concurrently dealing with three State mandated projects: State acquisition of private property for public purposes, updating the Mendocino County General Plan (Draft), and certification of the Local Coastal Plan.

b. A review of the respective goals and policies formulated by these projects will serve to point out that the highest priority and maximum commitment is given to the long-term management and protection of our natural environment.

F.8 F.11 | c. As our off-shore waters are a part of the aggregate of surrounding things which we call our natural environment I find that the proposal to dump nuclear wastes off Cape Mendocino is not consistent with the goals and policies cited in para. b., above.

2. National Issue:

F.8 | a. I firmly believe that it is in the best interests of our nation that we preserve the pristine nature of our off-shore waters. Our nation now has the opportunity to set an example for the other nuclear nations to follow, by enacting a permanent moraturium on ocean dumping of Nuclear wastes.

b. A review of the current data available indicates that the on-shore permanent means of disposal of Nuclear wastes is enviromentally acceptable, as compared to ocean dumping methods, which in my judgment is not.

J.15 | I support the fair and reasonable proposals made by our elected representatives that hearings regarding this important issue should be held in the Mendocino North Coast Area.

Sincerely,

D. Paul De Mayo

PROJECT: Draft EIS Submarine Reactor Plants

APPLICANT: U.S. Dept. of the Navy

We have received the "Notification to Clearinghouse of Intent to Apply for Assistance" for the above project, and a review has been completed. The basis of our review of the submitted information is to determine the project's compatibility with Regional goals and objectives. Therefore, the following determination is assigned to the project.

____ The Region R Clearinghouse finds the project to be in keeping with Regional goals and objectives.

____ The Region R Clearinghouse finds the project to be in keeping with Regional goals and objectives; however, the attached comments should be noted.

XX The Region R Clearinghouse finds the project to be in conflict with Regional goals and objectives and/or a duplication of current efforts.

This letter may be used as the official Region R comment to be attached to your application and signifies approval from the Region R Clearinghouse only. The U. S. Official Management and Budget Circular A-95 requires that approval also be obtained from the State Clearinghouse.

Sincerely,

Clearinghouse Coordinator, Region R

A-95 CLEARINGHOUSE PROCESS — SCH# 83-E-0000-5111

FROM: Stephen F. Davenport, Clearinghouse Coordinator, Region R SED

SUBJECT: Draft EIS- Disposal of Decommissioned, Defueled Naval Submarine Reactor Plants

DATE: 2 February, 1983

For A-95 Clearinghouse purposes, please review the attached notification and indicate your response below. If you or your agency require additional information, contact the applicant directly or refer your request to this office.

Please return this response to my attention at the above address by 16 Feb., 1983. If you do not respond by this date, I will assume you have no comment.

RESPONSE: This notification has been reviewed and appropriate response(s) checked below:

____ This project is consistent with local and/or regional goals and objectives and does not duplicate or counter other efforts. (Please note additional comments below).

____ Potential problem areas have been identified. (Please describe below).

____ Applicant has been advised of problem area(s).

____ Problem has been resolved as of ____________ (date).

____ Problem has not been resolved and respondent requests that Clearinghouse arrange a meeting with the applicant.

COMMENTS: (see other side)

REGIONAL A-95 CLEARINGHOUSE REVIEW STATEMENT

Date: February 16, 1983

SCH # 83-E-5113 Decommissioned Submarine Proposal
Project Title/County

N/A (estimated) N/A
Funds Requested Funding Agency

Please attach this form to your application before submitting it to the funding agency.

Applicant: Dept. of the Navy

Project Description:

The Dept. of the Navy and Dept. of Energy have submitted a Draft Environmental Impact Statement for review regarding the disposal of decommissioned, defueled naval submarine reactor plants by land and sea disposal.

REGIONAL REVIEW OF THIS PROJECT IS COMPLETE. The project has been reviewed by and through the Regional A-95 Clearinghouse with comment(s) as follows: (You should proceed to complete formal application for submission to appropriate agency. This statement and its attachments MUST be attached to your formal application.

( ) 1. Project is consistent with regional and local goals, policies, programs, and fiscal resources and is recommended for further development.

( ) 2. Project is recommended for further development with attached recommendations for strengthening it.

( ) 3. Project is recommended for further development if attached specific and major changes are incorporated into project by funding agency.

(X) 4. Project is not recommended for further development based on attached comments.

( ) 5. Project has been waived from A-95 review.

NOTE TO FUNDING AGENCY:

The review and comments for this project are valid until 2/16/84. If the project is considered for funding after this date, please resubmit the application for an additional 30 day review.

February 10, 1983

Mr. Don Eggert
Neuse River Council of Governments
P.O. Box 1717
New Bern, North Carolina 28560

Dear Don:

Craven County is in receipt of your A-95 Review Form for Project No. 83-E-5113, Disposal of Decomissioned Submarines, and make the following observations concerning this proposal.

While this proposal is neither consistent nor inconsistent with any locally adopted plans, programs or policies since there have not been any such programs, plans or policies adopted concerning this type of activity, it is the opinion of Craven County, however, that insufficient information is available concerning any possible long-term negative impacts. As such, it is impossible for the County Commissioners to take a specific position on this proposal.

Based on the above, it is the opinion of Craven County that this proposed project is not consistent with the needs or welfare of Craven County based on information available at this time. I remain,

Sincerely,

Henry E. Dick
County Manager

ON

DRAFT ENVIRONMENTAL

IMPACT STATEMENT

ON THE

DISPOSAL OF DECOMMISSIONED,

DEFUELED NAVAL SUBMARINE

REACTOR PLANTS

AUDITORIUM

OFFICE BUILDING NO. 2

STATE CAPITOL

OLYMPIA, WASHINGTON

9:00 A.M.

TUESDAY

FEBRUARY 22, 1983

IN ATTENDANCE:

On behalf of the U.S. Department of the Navy:

CAPT EDWARD WAGNER, USN, Hearing Officer
MR. JAMES MANGENO, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program

On behalf of the U.S. Department of Energy:

MR. FRANK STANDERFER, Assistant Manager for Defense and Energy Programs, Richland Operations Office

I N D E X

P R O C E E D I N G S

9:15 a.m.

CAPT WAGNER: Please take your seats. This hearing is called to order.

I am Captain Edward Wagner and I work in the Office of the Deputy Chief of Naval Operations for Submarines.

I have been appointed the Navy's Hearing Officer for this morning's public hearing.

Here with me to present an opening briefing is Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program. Also present is Mr. Frank Standerfer, Assistant Manager for Defense and Energy Programs, Richland Operations Office, Department of Energy.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear-powered submarine reactor plants after the fuel has been removed and the ships are no longer needed.

The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government-owned land disposal sites or placing them on the deep ocean bottom.

On December 22nd, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement, or DEIS, on the disposal of decommissioned, defueled Naval submarine reactor plants. The DEIS contains the results of the Navy's studies of the alternatives available. On the registration table as you entered the auditorium, you will find copies of the Summary of the Draft Environmental Impact Statement. Anyone in the audience who would like a complete copy of the DEIS should leave their name and address on the sheet of paper provided at the registration table and a copy will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient to people with an interest in this matter in order to provide them with an opportunity to present their views. I am here today to conduct one of these scheduled public hearings. The purpose of this hearing is to take testimony regarding the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case nor to engage in debate. It is my responsibility to receive statements so that they can be considered in preparing the Final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each, and organizational spokesmen are limited to ten minutes, unless additional time had been requested in advance.

Time cannot be relinquished from one speaker to another.

In order to ensure all who desire to speak are given an opportunity, each person should fill out a registration card and provide it to the registration table. All testimony will be recorded so that it can be considered in the development of the Navy's Final Environmental Impact Statement.

If you desire to submit written comments rather than speak, that is acceptable. You can provide written comments to me or leave them at the registration table. If you desire to provide written comments at a later date, my address is as follows: Captain Edward F. Wagner, U.S. Navy, Office of the Chief of Naval Operations, OPNAV-22, Department of the Navy, Washington, D.C., Zip Code 20350.

You should provide your written comments by March 31st, 1983, which as stated in the Federal Register notice is the cutoff date for submitting comments.

Before we begin receiving testimony this morning, I would like to introduce Mr. Mangeno of the Naval Nuclear Propulsion Program who will provide a general overview of the issue the Navy is addressing and the content of the Draft EIS.

Mr. Mangeno.

MR. MANGENO: Today's hearing is being conducted as a part of the decision-making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an environmental impact statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The environmental impact statement must include the environmental impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement, or DEIS, on this subject provides the basis for these hearings, and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear-powered submarines after they are no longer needed. The practical choices are: bury the radioactive part of the submarine at an existing DOE land disposal facility at the Hanford Site in the State of Washington or the Savannah River Plant in South Carolina; or place the entire submarine on the bottom of the ocean in water more than 2.5 miles deep. In both choices there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has about 120 nuclear-powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases,

as shown in this slide, it is evident that a disposal plan must be prepared for use sometime in the future. This DEIS has been prepared now so that all interested agencies, organizations and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the uranium and all of the fission products. The removed fuel is handled according to established procedures and is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, to the metal structure supporting the fuel, to the reactor vessel and to other equipment in the reactor compartment, where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by the hull of the submarine and by the reactor vessel and coolant piping. In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel, or other metal atoms in the reactor plant. These atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation of the nuclear reactor and the number of curies of each radionuclide at that time. A curie is a measure of the amount of radioactivity present, but it is not an indication of the possible effect on man or animals. The amounts and kinds of radioactive atoms present are described in detail in Chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the Federal Government disposal facilities already used for

such low level radioactive waste at the Hanford Reservation in the State of Washington or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the compartment free from the remainder of the submarine, and weld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal, and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. Other government-owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable waterways so that transportation of the reactor compartment to those sites would be impractical. The Hanford and Savannah River burial grounds are described in Chapter 3.

A transporter of the sort shown in this sketch could then be used to haul the compartment overland to the burial location. There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial, or after burial. This is because radiation outside the compartment would be well below federal limits and the reactor compartment would have been welded shut at the shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low level radioactive wastes. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burials and would result in no significant additional environmental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the body. More than 200 years would pass before the reactor compartment bulkhead could be penetrated by corrosion. Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time, exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean is another practical alternative. The maximum radioactivity would be less than the limit specified by international criteria and the triple containment provided by the submarine reactor compartment, by the reactor

vessel and piping, and by the radioactive atoms being a part of the metal itself would be an extremely strong and effective disposal containment package.

Locations for possible ocean disposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U.S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site-specific public hearings would be required and the permit process is not part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 190 miles west of Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry and marine biology for very deep ocean locations. The depth of the water in these areas is between 4,000 and 5,000 meters, about 13,000 to 16,000 feet. The scientific information and measurements collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that the environmental impacts could be calculated using realistic data.

Preparations for ocean disposal would be made at one of the shipyards normally servicing nuclear-powered naval vessels. Following defueling, the reactor vessel and the reactor compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping, and, of course, the metal itself completely intact. Most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping or free the atoms from the thick metal.

A comparison of the possible effects on the environment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100 submarine disposals for the year of greatest exposure for both options. This table shows that the radiation exposure would be very small and could have little impact on individuals or the population. These levels are also many times less than any limits established by U.S. regulations or international limits. They are much smaller than the normal fluctuations in annual average background radiation exposure for U.S. residents.

A perspective on radiation exposure can be gained by

examining the exposure a person would receive from natural cosmic background radiation if he flew round-trip from New York City to Los Angeles. That person would receive approximately two millirems more radiation than if he had not made the trip because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one-half millirem.

Other environmental impacts are similarly small for both options. The effects on animal life would be small and localized in either case. Land burial of 100 reactor plants would require only about ten acres of land and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square ten miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land disposal would cost about 40 percent more, about two million dollars per submarine more, than sea disposal.

The "no-action" alternative is to place submarines in floating protective storage for an extended period, commonly called mothballing. However, this would only temporarily delay disposal because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods and the estimated radiation exposure for the general public would be very small for all available courses of action.

Thank you.

CAPT WAGNER: Thank you, Mr. Mangeno.

Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing. I will now recess briefly to establish an order for persons who wish to provide testimony. For those people who would like to testify and have not yet registered, you may do so at this time.

We will recess the hearing and reconvene in five minutes and commence testimony at 9:40.

(Short recess.)

CAPT WAGNER: Ladies and gentlemen, if you would please resume your seats, we will reconvene the hearing.

Simply to establish an order for the statements, I intend to ask individuals representing state government organizations to speak first, in alphabetical order of the speakers' last names; followed by individuals representing local government organizations, in alphabetical order by last name of the speakers; and then private organizations; and finally private citizens, also in alphabetical order by last name of the speaker.

I request your cooperation in providing comments within the time limit so that we may be certain all who wish to speak have an opportunity to do so. Once again, that is five minutes for individuals and ten minutes for organizational spokesmen. If your statement is longer than that and it cannot be given in the time allotted, you may summarize in the five or ten minutes and the entire statement will be included in the record if you submit it in writing.

The procedure for public testimony will be as follows. I will announce each registered speaker. When called, proceed to the microphone here in front of me, in the front of the auditorium, and state your name and organization, if any. And even though I announce your name first, please state your name so that our recorder gets that properly for the record.

For those of you who have already registered and you know you are going to be speaking, I encourage you to come down to the front couple of rows here that are reserved for you so we minimize the time coming and going to the microphone.

All comments are to be addressed to me, please.

Our first registered speaker is Ms. Anne Bringloe from Bainbridge Island, Washington. Ms. Bringloe is representing the Sierra Club.

VOICE: Sir?

CAPT WAGNER: Yes.

VOICE: Did you just state that government organizations would go first?

CAPT WAGNER: Yes, if we have government organizations.

VOICE: There are no government organizations?

CAPT WAGNER: I have none registered.

Is Ms. Bringloe here?

#36

MS. ANNE BRINGLOE: Thank you. My name is Anne Bringloe. I am the Conservation Chairman for the Cascade Chapter of the Sierra Club, which is essentially the State of Washington. We have approximately 6,000 members, whose main concern is protecting our environment and using it in a responsible fashion.

The Sierra Club is concerned about several points in the EIS. I think that the main idea that I would like to present is that there is a gamble in assuming that nuclide decay in the reactor compartment will coincide with corrosion rates in the material surrounding the reactor. L.20

Now, if everyone has studied the EIS, they will see that there is some information about the presumed corrosion rates. What we are concerned with is that because of the ionizing radiation's effects on materials such as surround these reactor compartments, the schedule that the Navy EIS suggests may not in fact be what actually happens. If in fact the schedule suggested is different in reality, we may find Q.13

dangerous materials entering the ocean environment much sooner than thought.

Disposing of submarines in the ocean, although it appears to be the most cost-effective plan, it is the embodiment of the idea of dump something and forget about it, because there is not much opportunity for monitoring what is happening after these submarines are disposed of in the ocean. J.76

The Sierra Club would prefer that an option is selected that would make available monitoring. We do not think that disposal in the ocean is the proper choice.

We would hope that the Navy would investigate dry land disposal at some site, not necessarily the Hanford site. The possibility of dry land disposal in a desert environment would hope to be an alternative to ocean dumping. And if the corrosion problem could be minimized by covering of these reactor bodies, it is assumed that it would be a safer substitute. The reactor compartments could be monitored and there would always be the option to dispose of them in some other manner at a future time.

We hope that the Section of the EIS dealing with land burial will be updated and improved and expanded and that this option of land disposal with its monitoring possibilities will be more thoroughly considered.

And I would like to state again that we feel that dumping in the ocean with no possibility of monitoring and no J.76 W.1

possibility of retrieval is not the responsible thing to do in this case. If the Navy cannot come up with a more responsible method for disposing of submarines, perhaps they could consider their submarine building program and really understand the costs of building these submarines when the disposal costs, the real cost to the environment, are added in.

Thank you.

CAPT WAGNER: Thank you, Ms. Bringloe.

The next registered speaker is Dr. Michael J. Herz from San Francisco, California. Dr. Herz is representing the Oceanic Society.

*#37

DR. MICHAEL J. HERZ: Thank you. My name is Dr. Michael J. Herz, Executive Vice President of the Oceanic Society, a 60,000 member non-profit organization devoted to protection of the marine environment. The Society has headquarters in San Francisco and Stamford, Connecticut, and has active chapters along both coasts.

*N.15

Before I begin my testimony, I really must protest the manner in which you public noticed incorrectly this hearing, with no attempt to correct the location. There should have been signs set up in order to have people who went to the first building so that they would find this building correctly. A number of people have gone to the wrong location. There has been no information there. I similarly find that the address listed in the Federal Register announcement for the San

Francisco hearing is incorrect, as well. I would hope that there would be an attempt made to correct in advance that information so people don't have to go to the trouble of wasting a half hour finding the correct hearing place. It just is wrong.

The Oceanic Society is concerned overall with the issue of nuclear waste disposal in the oceans. Although we view with alarm the possibility of the Navy disposing a hundred nuclear submarines in the ocean, it's as much because of the precedent setting nature of this action as it is because of our concern over the potential impact of 6.2 million curies of radioactivity that would ultimately be added to the oceans if these subs are disposed there. L.9

It should be noted that in addition to the Navy's reactor disposal program, the Department of Energy has spent approximately 20 million dollars since 1976 to investigate the use of the seabed off Hawaii as a disposal site for high level nuclear waste. Fuel rods from nuclear power plants. In addition, the Department of Energy is also considering the ocean alternative for the disposal of nuclear waste from the Manhattan Project that produced the first atomic bomb. I should note here too that the so-called FUSRAP Program, the formerly utilized sites remedial action program that is going on right now, was in the Federal Register on February 1st with the hearings being held at the Niagara Falls site on the end L.9

*Other issues discussed by Dr. Herz are side barred in Exhibits 37a, 37b, and 37c.

of last week, hearings being held in Niagara, scoping hearings at the same time as your hearings were being held on the submarine program, at the same time as the London Dumping Convention was meeting. We feel that that is unfortunate because there are a limited number of people in this country who are available to critique these programs and to evaluate the science involved in them, and to have three sets of things happening at the same time is, to say the least, extremely unfortunate because there should be an opportunity for those qualified to comment on these government programs to attend all of the hearings.

The comment period on this Department of Energy Program closes the 25th, the day after the San Francisco hearings on the submarine, making it extremely difficult for people concerned and organizations concerned to track these issues.

Our role, the Oceanic Society's role in evaluating the potential impact of the proposed activities on the marine environment and on land, is to assess science and technology that are presented in support of such proposals. In early February the Oceanic Society convened a scientific committee made up of experts from a variety of disciplines to review the adequacy of the Navy's DEIS and the supporting oceanographic studies. The points raised in the testimony that follows are based on the conclusions from the committee's deliberations.

First of all, it was the committee's conclusion that

the Navy's Draft Environmental Impact Statement is one of the poorest environmental documents any of those committee members had ever reviewed. It is filled with significant information gaps and technical deficiencies and raises a great many issues requiring much additional information. These will be considered and discussed below. But by and large the document reflects poor scholarship, as demonstrated by its author's failure to consider large bodies of pertinent information regarding a number of issues and by the use of old information when significant new information was readily available.

In addition, the DEIS and its oceanographic support documents indicate -- review of it indicates that there are numerous internal inconsistencies, places where the summary of the DEIS misrepresents data presented in the body of the DEIS, and the DEIS and oceanographic studies misrepresent information -- or the summary of the oceanographic study misrepresents information from the total body of the studies. J.21

The most serious deficiencies, though, have to do with the DEIS's consideration of the ocean disposal alternative and the way in which it considers the availability of radioactivity and the possible pathways through which radioactivity might reach humans. The issues that were not addressed or inadequately presented include the following.

First, we feel that there is much additional information required to fully assess the significance of the CRUD

A.12 A.11 J.64 J.34

deposits in the reactor cooling system. The CRUD are the deposits that form on the inside of the cooling pipes because radioactive water has flowed through the cooling system of the reactor. Data from CRUD collected at land-based reactors suggests that this may be one of the most serious sources of radioactivity which can easily become available to the marine environment. Further data on Alpha emitters and CRUD from wrecked and decommissioned nuclear subs is needed. Missing details on sampling sites relative to the location of the reactors from the Thresher and Scorpion accidents makes it impossible to evaluate the Navy's claim that such subs pose no threats to the marine environment or to humans. Sediment, water and organism samples should also be collected from the site of the Soviet sub which the U.S. Government attempted to raise with the Glomar Explorer.

Q.13

We are also concerned because we feel that the projections in the DEIS fail to take into consideration the possibility of galvanic effects, the manner and rate of corrosion at external weld locations and the manner in which the lattice breakdown in the radiated stainless steel will affect corrosion. I might also add the interactions of pressure, the high temperature that the reactors have been subjected to, and the great depths at which disposal would take place do not appear to have been adequately considered in the DEIS.

L.36

Of greatest concern with any disposal alternatives are the potential pathways in which radioactivity might reach

U.9 U.5 L.35

humans. There exists a significant body of literature concerning the migration of radionuclides from waste forms to the water column sediments and to organisms that appears to have been totally ignored in the preparation of the DEIS. The pathway issues that have not been adequately addressed include, first, the studies conducted by the Environmental Protection Agency and others demonstrating possible pathways such as benthic organisms to rattail fish which should serve as a warning that other pathways exist and further investigations are warranted.

L.6

It should be pointed out here that in the late '70s the Environmental Protection Agency collected a great deal of data at the low-level dump sites off of San Francisco at the Farallon Islands and from the Hudson Canyons right off of the East Coast. There were some 13 studies that were released by the EPA in October of 1980 following a great deal of pressure that was applied by a congressional oversight committee. And in fact the strongest of these studies, the one that shows the best evidence of transport from the waste drums into the bottom -- into benthic organisms that live on the bottom and from thence into fish, has not yet been released by the Environmental Protection Agency. None of these were referred to in the DEIS and I cannot understand why.

L.55

Also not considered was the artificial reef effect which has not been investigated in the deep ocean at all, but

L.55 the settling by marine organisms on the subs appears likely and should be investigated, particularly in terms of how it might serve as a pathway in an accident scenario, both at the disposal site or on the continental shelf.

Q.12 Also there was failure to consider the possible role of bacteria in the mobilization of radionuclides. L.57 There also is the feeling that the potential effects of accidents have not been adequately addressed. The Navy estimates .1 accidents per hundred subs scuttled at sea. Because this is a, quote, reasonable probability, unquote, the potential impact of such L.61 an accident on the continental shelf from both an intact sub and from an exposed reactor compartment should be discussed in detail, especially in terms of possible exposure levels of three rems to a population of 30,000 people. A determination on whether this is an acceptable exposure rate should be provided in the DEIS.

U.21 There was feeling by our committee that the worst case calculations in the DEIS are confused and appear to be off by as much as nine orders of magnitude. U.19 Further, the use of EPA standards for drinking water seem to us to be misleading and inappropriate, especially since the correct calculation using the Navy's own data, come to within .1 of that standard.

J.12 The data presented in the DEIS on albacore catches in the vicinity of the proposed Mendocino site are based on 13- to 23-year old information, while more current available

data readily available from the same source, that is, Scripp's Institute of Oceanography, suggest a much more significant fishery in that area. J.9 In addition, there is no information presented on catches on the East Coast, near the East Coast sites.

R.24 There is a lack of consistency throughout the DEIS in terms of worst case and average case scenarios. In order to make discussions of exposure overdoses resulting from accidents a uniform approach to terminology and calculations should be adopted in order to make presentations meaningful.

S.25 A very serious deficiency as perceived by our committee throughout the DEIS is the fact that none of the measurements presented are accompanied by error terms, making it impossible to determine the level of precision or the range or variability of the data presented.

J.9 Although the DEIS states that the location for possible ocean disposal has not been selected, the stated site selection standard suggests that at least the lower continental rise area and possibly the Hatteras abyssal plain area, as well, might be eliminated based on data presented in the oceanographic studies, Volume 2. J.2 It should also be noted that the Cape Hatteras site is outside the U.S. economic zone, outside the 200-mile area, and therefore, I think, will probably not be able to be considered as a dump site.

In addition, through talking with the principal

J.2 investigators at Oregon State University who did the site selection for the generic sites on the West Coast, it appears unlikely that any locations other than the Cape Mendocino area could be found on the West Coast that meet the required selection criteria. J.9 Obviously, if the ocean alternative is chosen, more site-specific data will be required before an evaluation can be made, J.2 but it certainly appears from all the information available that the sites are going to be within the generic sites, and to say that the sites have not been selected, I think, is not totally accurate.

As presented in the DEIS, the monitoring plans for either land or ocean alternatives are inadequate. I.13 With the land alternative the assumption is made that monitoring will be conducted as part of the current and continuing programs at Hanford or Savannah River sites. However, the cost of monitoring is not reflected in estimates presented. There are no cost breakdowns, at least. The sea disposal monitoring presentation is also clearly inadequate, based on inadequate record keeping and the failure of the U.S. Government to conduct any but the most rudimentary monitoring or research at L.6 any of the ocean sites used for disposal of nearly 100,000 curies of waste during the 1946 to '70 period, the program and site documentation must be included as part of the DEIS.

Although the document doesn't contain a cost breakdown, the total amount listed for monitoring appears totally

J.76 inadequate. The committee, our committee, felt that without an adequate monitoring program being presented in the DEIS, the sea disposal option shouldn't receive any further consideration.

W.1 By far the most serious problem with the sea disposal alternative, though, as presented in the DEIS is that F.2 once scuttled the submarines are, by the Navy's admission, irretrievable. Indeed, the Anderson amendment, recently signed into law by the President, requires that radioactive wastes disposed of in the ocean must be retrievable.

Because there are significantly more gaps, deficiencies, unanswered questions and uncertainties regarding the sea disposal alternative, the Oceanic Society's committee concluded, based on the existing information, that a land disposal option is far preferable. Land disposal would minimize corrosion, the principal mechanism producing available radioactivity, and would greatly simplify the monitoring process.

I should point out that the suggestion that was just made or put forth by one of the members of our committee, Dr. Ruth Weiner, who will be testifying following me, but it was her suggestion and it was not considered in the DEIS that the solution, the alternative that would end up with the least amount of radioactivity becoming available to the environment, would be in these reactor compartments on dry land in an arid environment and totally reducing the corrosion to an absolute minimum.

Thank you.

CAPT WAGNER: Thank you, Dr. Herz.

The next registered speaker is Mr. James Puckett from Seattle, Washington, representing Greenpeace.

#38

MR. JAMES PUCKETT: I'm Jim Puckett with Greenpeace Northwest.

Included in the record here today will be technical analyses of data and conclusions. But there are some fundamental questions often lost in technical discussions that deserve full attention.

I would like to focus on the big picture, the political and moral implications of radioactive waste dumping at sea. I testify here on behalf of Greenpeace Northwest as campaign coordinator for the issue of ocean dumping.

Greenpeace is an international environmental organization whose sole purpose is long-range protection of the biosphere, a thin fragile shell around our globe on which all life, present and future, must depend. Seventy-one percent of of this living surface consists of ocean, the womb of all organisms and the great provider of protein for much of the world's human population. About human beings and the ocean, Jacques Cousteau has said, "Each one of the cells in our bodies is a miniature ocean. Poisoning the sea will inevitably poison us."

Greenpeace has long stood for the protection of the

ocean environment. Our continuing success with international treaty organizations such as the International Whaling Commission and efforts to prevent the extermination of marine species is well documented and accounts for our 250,000 members in this country and over a million members worldwide. Greenpeace has become famous for the protection of marine mammals, organisms at the top of the oceanic food chain. It is an obvious step for us to be concerned with the entire food chain of the sea within which we humans are inextricably bound.

Greenpeace opposes all ocean disposal of radioactive wastes. We oppose the U.S. Navy's most recent plans to dispose of over a hundred decommissioned radioactive submarines by sinking them in United States coastal waters. We oppose the United States Environmental Protection Agency's recent advocacy role on the international question of radioactive waste dumping at sea. Opposing all these things, be reminded, we are simply proponents of life and health. The sea disposal of a single submarine cannot be viewed as insignificant. The 25 years of radioactive dumping practiced in this country already represents 95,000 curies of radiation. A single nuclear submarine, minus the core, represents 50,000 curies of radiation from at least 16 different isotopes. But apart from the damage these isotopes would create, apart from the multitude of unanswered questions, crucial to consideration

F.8

of scuttling a single submarine, we are especially concerned over the insidious precedent that would be created by the resumption of U.S. ocean dumping of nuclear waste. Following only the dictates of economy and convenience, the Navy would like to reverse our 13-year defacto dumping ban. If approved, the tyranny of this small decision viewed in a historical perspective could oppress us for a long time to come. Consider the enormous quantities of high-level and low-level radioactive wastes created in this country each year. Hanford Nuclear Reservation last year alone accepted 50,000 cubic meters of radioactive waste. Could the EPA, or anyone, justify granting the Navy dumping permits while disallowing all the other nuclear waste generators? When one considers the entire nuclear world, we are talking about a multiplication of the Navy's Environmental Impact Statement that will make this plant's vast ocean resources look suddenly very small.

L.9

F.8

Worldwide concern over widespread ocean dumping was demonstrated last week when the London Dumping Convention, an international treaty organization, voted 19 to 6 to outlaw the ocean dumping of radioactive waste. The United States, represented by Reagan's EPA, was, in a major policy shift, part of the minority that attempted to block a moratorium. Since January 1st, by a vote of Congress, it is now illegal to dump radioactive waste in U.S. coastal waters. In light of this

fact, Greenpeace seriously questions legality of the EPA in presenting a policy in the international forum that is a direct contradiction of U.S. law. There is good reason to believe that the Navy's sub disposal option was the real hand that voted in London, as it is the only formal proposal, as yet drafted, that would reverse current U.S. practices. The EPA-Navy connection is made more obvious when we follow the career of Glenn Sjoblom, one of the authors of the Draft Environmental Impact Statement we are reviewing today. Glenn Sjoblom, formerly a Navy employee, is now in charge of the department of the EPA that would approve or deny the Navy's dumping permit application under the Marine Protection, Research and Sanctuaries Act. This appears to be more than a conflict of interest involving Mr. Sjoblom, but rather a blatant conflict of interest within the EPA itself which it seems has hired another fox to guard another hen house.

If the Environmental Protection Agency does ignore the London Dumping Convention's moratorium, if the Navy is granted permission to eventually dump over a hundred radioactive submarines, in the eyes of the world the United States will not only be cast as one of the small band of agressive, irresponsible nuclear nations, but as a world leader could be a deplorable yet influential example, opening the doors to other economically competitive nations to act irresponsibly. Countries like Japan, Belgium and South Africa are now watching

F.8 the U.S. closely to see if we intend to ignore and belittle what is now international law.

Although the Navy acknowledges the presence of at least 16 different radionuclides in the irradiated vessels slated for disposal, the Department's reports consistently refer to a single isotope, Cobalt 60, half-life 5.26 years. L.46 Often overlooked are the isotopes Niobium 94 with a half-life of 20,000 years, Nickel 59 with a half-life of 80,000 years, or Technetium 99 with its half-life of 212,000 years. All of these are also radioactive ingredients of decommissioned nuclear submarines that will remain active for hundreds of thousands of years.

The submarines, once dumped, would be irretrievable. W.1 Repeated attempts by both the EPA and the Navy have failed to locate the hulk of the only nuclear submarine deliberately scuttled to date. The Sea Wolf was dumped off the coast of J.85 New Jersey in 1959. Recently, after repeated dives with a research submersible, EPA personnel called off the search for the missing Sea Wolf. The still radioactive submarine could not be found. Ocean dumping of radioactive wastes must be W.1 considered permanent disposal.

If later studies indicate that radioactivity is entering the food chain in significant quantities, there will be nothing we can do. No amount of future monitoring to which the EPA would be committed could reverse the poisoning. The

ocean, once contaminated, could not be cleaned up.

In their Draft Environmental Impact Statement, the authors attempt to make light of the effects of low-level radiation. They define the unit of millirems in terms of the energy required to lift mosquitoes one centimeter. Or the energy necessary to raise body heat two billionths of a degree X.1 centigrade. I would like to remind all present that what we are concerned with today is the manner in which radioactive energy wreaks havoc within living cells and bio-accumulates in the food chain. We are not losing sleep over the possibilities of being crushed by mosquitoes or slowly parboiled.

There has never been a determination of the truly safe level of radioactivity. The standards of yesterday are now considered unsafe and as the long-term cancer statistics are tabulated, experts such as Lowen Mendelsohn of Lawrence-Livermore Laboratories are again questioning the radiation dose limit standards. As the likelihood of exposure to multiple sources of additional radioactivity continue to multiply, L.7 it will become increasingly important for all individuals to avoid all sources of radioactivity that would increase exposure to above-normal background levels. Bio-accumulation, L.36 the process by which radioactive elements are concentrated as they move up the food chain, has been well documented since L.37 the 1950s. And recent investigations by Dr. William Schell,

U.9

contracted by the EPA, have already revealed alarming evidence of radionuclide migration from past ocean dump sites into edible fish. So given that the radionuclides within a decommissioned nuclear submarine will be active for thousands of years, given that the submarines, once dumped, would be irretrievable, and given that the cumulative biological dangers are known but not fully understood, how can we, as part of the human race responsible for creating this dilemma, knowingly pass on to countless future generations the lethal legacies of irreversible radioactive contamination of the biosphere? We today are grossly outnumbered by those of the future. We simply do not have the right under any system of ethics to make such a decision.

G.7

Therefore, Greenpeace requests, first, that we never again dump nuclear waste at sea. We propose that the Navy continue to maintain the irradiated submarines in protective storage in naval shipyards for 25 to 50 years which according to Dr. Marvin Resnikof of the Council of Economic Priorities would be the proper time to allow for the early decay of the short-lived radionuclides. In support of this recommendation I quote from the DEIS. Nuclear submarines can be placed into storage for a long time without risk to the environment. Questions we must ask ourselves after that time to assess the best land disposal options include, are there any unforeseen land disposal alternatives? Recognizing that shipment is the

E.23

weakest link in the land disposal process, subject to accidents and public exposure, what is the shortest, safest route in that all river shipments must traverse deep salt water and run the risk of towing losses, preference must be given to an all land shipment, if feasible. We do not wish to see a precedent of rivers such as the Columbia becoming nuclear highways.

H.3

The subs should be stored in an area with a minimal corrosive environment and adequately monitored. Finally, Greenpeace opposes any water shipment of spent fuel or high-level radiation products. If, after 25 to 50 years, water transport of submarines proves to be the safest method of transport, may this never be interpreted as an endorsement of water shipment of high-level radiation products.

In closing, I would like to quote from Admiral Hyman Rickover, father of the nuclear navy, who recently made the following statement. "Until about two billion years ago it was impossible to have any life on earth. That is, there was so much radiation on earth you couldn't have any life, fish, or anything. Gradually, about two billion years ago the amount of radiation on this planet and probably in the entire system reduced and made it possible for some form of life to begin. It started in the seas, I understand. Now when we go back to using nuclear power we are creating something that nature tried to destroy to make life possible. And I think the human race is going to wreck itself. Therefore, it is important that we get control of this horrible force and try to eliminate it."

Today, we are creating radioactivity, not eliminating it. It is of utmost importance that we, in this uncertain age, act with caution and take seriously our responsibility for handling the threat of radioactivity. By setting a short-sighted international example and precedent, the Navy's plans could send large amounts of lethal radiation back to the sea, the cradle of evolution. If accepted, the Navy's plans to sink their troubles could sink us all.

Thank you.

CAPT WAGNER: Thank you, Mr. Puckett.

Our next registered speaker is Dr. Ruth Weiner from Seattle, Washington, representing the Sierra Club.

#39

DR. RUTH WEINER: I'm Ruth Weiner, I live at 6837 51st Avenue, Northeast, Seattle. I am currently a visiting professor in the Program for Social Management Technology at the University of Washington. And I am here representing the Washington Environmental Council, a statewide organization of approximately 1,100 members at large and 80 organizations. I am chairman of their Radioactive Waste Committee. And the Cascade Chapter of Sierra Club, I am the chair of the Cascade Chapter.

In general we support the position of the Oceanic Society of America and I would like to add a few perspectives to the statements made by Dr. Michael Herz. I would also like

to second Dr. Herz's objection to the foul-up in the place where the hearing was. I was told several times the hearing was in the General Administration Building. The least you could have done was to put signs on the door saying it is not in the General Administration Building. And the fact that the same problem will doubtless occur in San Francisco -- in fact, I have one thing to add. I'm not sure why you are having this hearing in Olympia. It is the state capitol but there is a federal facility in Seattle where plenty of federal hearings are held. If you are going to have it on-site, you should have it in Bremerton, that's where the submarines are. The reason for putting this 60 miles from the population center, forcing people who are interested, many people who are interested, to drive here if they can get here, I just don't understand. N.15*

The Navy has considered three options for disposal of the decommissioned reactor plants. Deep ocean disposal at 4,000 meters, land burial on the low level waste site at Hanford or Savannah River, and leaving the subs moored where they are essentially, or in protective storage.

The nuclides which are of absolutely major concern in this disposal venture, because of the combination of half-life and the amount that each submarine produces are, of course, Cobalt 60, Nickel 63 which has a half-life of 92 years, Iron 55, those three because there is more than 18,000 curies per

*Other issues discussed by Dr. Weiner are side barred in Exhibit 39a.

sub. Nickel 59 and Carbon 14, the last is clearly of concern because it is extremely labile in the environment.

For a hundred submarines, I would like to point out that that is 220,000 curies of Cobalt 60 alone. A curie is a great deal of radioactivity. A curie is 37 billion disintegrations per second. The table from which I have taken these numbers, Table 1.1, goes on to list those nuclides present in less abundance. But even one ten-thousandth of a curie is a lot. You are putting a great deal of radioactive maaterial wherever you put it.

In suggesting ocean disposal the Navy is taking a calculated gamble that the nuclides will have decayed sufficiently by the time the material of the reactor compartment has corroded and sort of dispersed and found its way into the food chain. And by the time that happens you would then no longer have radioactive nuclides. For the nuclides listed above, in particular for Carbon 14, the gamble is that they will never reach the food chain at all. As the Oceanic Society statement has pointed out, combined uncertainties in corrosion rates and dispersion rates make this gamble something much less than an educated guess. Ionizing radiation is known to damage crystal and glass structures. I might add parenthetically that 20 years ago I did my doctoral dissertation on damage to single crystals from ionizing radiation and in particular using Cobalt 60 as a source. So that is not new information. Moreover, the accumulated CRUD in the reactor plants

is just about ignored in the DEIS. The material is far more labile in the environment than the metal of the reactor plant itself.

The Oceanic Society statement points out the uncertainties in the Thresher and Scorpion data. It is also unclear why data from the Glomar Explorer attempt to raise the Russian submarine was not included. This last provides a real case of radioactive material in a submarine in the marine environment. It differs from the Thresher and Scorpion data in that we know where the Russian submarine is. If you look at the data from Thresher and Scorpion in the DEIS, there is only a vague idea of whether they are there at all.

In sum, the marine environment is exceedingly corrosive. Eventual corrosion and dispersion, as the Navy has pointed out, are a certainty, and will in some fashion contribute to the radioactive loading of the ocean. Disposal in the ocean is the alternative with the most uncertain future. Moreover, retrievability is out of the question and monitoring poses enormous problems. The DEIS fails to consider the cumulative effects of old ocean dumps, the FUSRAP program as was mentioned by Dr. Herz, ocean dumping now done or contemplated by other nations. It can be argued that you are dealing with a very large volume in the Atlantic and Pacific Oceans but it can also be argued that we are talking about hundreds and even thousands of years. The comparisons which the DEIS does make to other processes that put radioactive material into the

L.29

environment are often spurious. For example, Table 4-7 of the DEIS compares activity from the reactor plants with activity naturally washed by rivers into the ocean. How natural that process can now be said to be, considering current uranium and coal mining activity, is anybody's guess, of course. But even if it is, this is an apples and oranges comparison. Uranium-234 and 238 and Thorium-232 are compared in the table with Nickel-63, Nickel-59 and Carbon-14. The chemical and biochemical behaviors of the latter three nuclides is completely different from that of the former. This is just another one of those spurious comparisons that we see in all environmental impact statements regarding radioactive waste that you can summarize by saying you are always being told it is no more radioactivity than you are exposed to naturally. It is different. It may not be more or less, that is not the point.

U.6

I would like to make a comment aside now. When are we going to get away, now that we have lots and lots of different radionuclides, from simply considering total activity. The chemical behavior of the radionuclides is the key factor in whether they are incorporated into the human food chain, where they go in the human food chain, what happens to them chemically, what happens to them physically, and so on. We cannot continue to lump uranium with nickel, with carbon, with tritium and hope that we are going to make any sense at all. I didn't really expect the Navy to step out in front on this

and use a specific activity approach in the study of radionuclides but I would hope at some point we could at least get away from this kind of comparison and consider how nuclides that are put into the environment by any given process, these particular nuclides compare with their presence in the natural environment, other things with similar chemical behavior, and so on.

There is not nearly an adequate data base for the costs represented. The Oceanic Society has commented on the costs of marine disposal. I question the cost estimates of the land disposal option, as well, by the way, as other features of the discussion of the land burial option. In particular, the discussion of the Hanford site. The Navy's assessment of that site is based on a 1975 environmental study. At that time the commercial low-level waste site, which I suppose is adjacent to the Department of Energy site that is discussed in the DEIS, was receiving 1,000 cubic meters a year. In 1976 the rate of burial began to increase exponentially and today the rate of burial at the commercial site is about 50,000 cubic meters a year. And it is still going up. Hanford is the only unlimited commercial low-level radioactive waste site in the United States today. Hopefully, by 1986 when the Federal Low-Level Waste Act of 1980 really begins to take effect, the amounts coming to Hanford will be limited by compact but they are not limited now. There are several bills currently pending in the State Legislature, one of which asks for an updated environmental study considering the environmental impact of the current waste storage practices at Hanford, what has gone on between 1976 and now. In addition, of course, the basalt underlying the Hanford site are being considered and are a very good candidate for the first high-level radioactive waste disposal site in the United States. We have just learned that there is a high-level site at Hanford that is leaking 200,000 gallons a day of radioactive liquid and that this has been going on for years. The environmental conditions have changed since 1975, they are changing all the time, and in an environmental impact statement those conditions must be considered as nearly as they can be assessed at the present time. You can't keep on assessing them but you can at least do it now. I might point out with this regard that there is no comprehensive detailed discussion of what kind of continuing monitoring there would be on the Hanford site if that were in fact used as a land burial site.

The estimated costs of land burial are so vaguely addressed that it is impossible to judge whether recent activities have been taken into account or not. The state, for example, now charges a 30 percent burial tax, if you will, on commercial sites. I don't know whether there will be any negotiation with the Federal Government over the submarines or not. Transportation accidents are not adequately addressed.

The Columbia River bar at Astoria is a notorious navigational hazard and an accident in the Columbia could bring radioactive material at least from the CRUD into the food chain immediately. We still fish in the Columbia River.

Section 3, Page B-4, which purports to consider other land burial sites, is particularly vague and sloppy. The sites are barely mentioned and receive no serious consideration at all. Hanford and Savannah River, as usual, are considered because they are already being used as low-level waste sites, or because they are or have ever been particularly suited for that purpose. We keep talking about Hanford as a site because Hanford was the federal reservation that was established during the war, during World War II, and people started storing radioactive waste there. There has never been a study that says Hanford is better or worse than many, many other sites with the same geographic, topographic, geologic and meteorological characteristics.

The Navy has failed to consider, finally, an obvious and quite sensible alternative, disposal above ground in a desert. The Federal Government owns plenty of such land besides Hanford in military reservations: China Lake is one example. The Nevada test site and Alamogordo are two other possibilities. Above ground disposal, possibly covering the plants with plastic sheets that we worry are going to last hundreds of years anyway, in a region of less than eight inches of rainfall a year would minimize corrosion. In this particular instance, we are not dealing with the sort of low level waste that is normally dumped into the Hanford commercial site. This is not material that if you don't bury it and cover it and put it in drums is just going to disperse. This is material, most of which, except the CRUD, will be released by corrosion. So you look at the alternative that gives you the lowest corrosion rate. Above ground storage poses the best situation for both monitoring and retrieval. We are not making an argument for this option at the present time but it must be considered as an alternative in the EIS. Savannah River, I might point out, is clearly not suitable for such an option. And sites in addition to Hanford must also be considered. Also, those sites must be considered from the point of view of transportation difficulties in getting there. I would like to echo Mr. Puckett's statement that we would rather not see the Columbia River become a highway for radioactive waste, although in some senses it already is.

It is easy for environmental groups in other coastal states to make a strong argument against the ocean disposal option and not address land burial. This is not easy or even possible for residents of Washington or South Carolina. The Navy is telling us in Washington that if the reactor plants don't go into the ocean they will go to Hanford, thus leaving us with a Hobson's choice. However, we recognize that reactor

plants must be dealt with and our recommendation on the Environmental Impact Statement is two-fold:

First, revise, update, improve and expand the section of the EIS dealing with land burial, and correct the inadequacies in the current DEIS.

Second, add a thorough discussion and investigation of the above-ground disposal option.

And, I might add, third, once that has been done then I think a second series of public hearings should be held to discuss this option, since it wasn't even addressed.

We support the Oceanic Society's position. We would also like to see the Navy consider its future submarine construction program in the light of the difficulty of disposing of the decommissioned plants.

And, finally, I would like to point out that we do in fact recognize that something has to be done with this material. For my organization, and for myself, I really don't see much point in protected storage for another 50 years. This is a situation where if the short half-life stuff decays it is not going to be corroded out by then anyway. I can't see any other option being made scientifically available over the next 50 years and it is probably going to take some time to work out the actual option, in any case. There is no point in leaving these things in a corrosive environment which the marine environment is. And there really is a point in strongly questioning how many more of them we are going to end up with, anyway.

Thank you, very much.

CAPT WAGNER: Thank you, Dr. Weiner.

I have no further registrations for people representing organizations. Is there anyone registered representing organizations whose name I have not called?

(No response.)

CAPT WAGNER: At this time we will proceed to testimony by individuals. Again, let me stress, please stay within the five minute time limit so everybody has an opportunity to speak.

In order to save some time from people walking back and forth, I am going to announce three individuals at a time. When your name is called, please come forward, have a seat close to the microphone, and then I will announce each speaker to come to the microphone, so we will have three at a time kind of moving in, so that we can give everybody a chance to speak.

The first three individual speakers, then, will be Ms. Kay Bollinger, Mr. Richard Fabry, Mr. Cricket Feringer.

The first of the three, again, Ms. Kay Bollinger, from Seattle, Washington.

#40

MS. KAY BOLLINGER: Hello, I am Iron-55. I have a half-life of 2.6 years. I am easily absorbed into the marine plants and from there into fish. I expect there will be a lot

L.14

of fish and plants around the sunken submarine because any large object in the ocean creates an artificial reef to which organisms are attracted. L.55

CAPT WAGNER: Thank you, Ms. Bollinger.

#41

Mr. Richard Fabry of Seattle, Washington.

MR. RICHARD FABRY: Hi. I am Technetium-99. Talk about long life. My half-life is 212,000 years. Do you know how long 212,000 years is? If people are still around by the time I die out, it won't be thanks to me. I am radioactive and I intend to stay that way (laughing).

CAPT WAGNER: Mr. Cricket Feringer from Seattle, Washington.

#42

MR. CRICKET FERINGER: Today I am also representing Niobium-94. I have a half-life of 20,300 years. According to the recent work of Dr. Marvin Resnikof my presence has been underestimated by a factor of 100. My persistent characteristics will enable me to outlive the reactor chamber. When the corrosive powers of the sea cause the sub's metal to rust away, then my time will begin. I will escape and find a clear pathway through the marine environment into the oceanic food chain. Thank goodness the Navy is not thinking ahead. Their short-sighted thinking will allow me to carry out my long life and demonstrate my destructive potential.

A.10

L.20

L.36

CAPT WAGNER: Thank you, Mr. Feringer.

The next three speakers will be Mr. Pete Hayes and

Mr. Harold Hoey and then Mr. John Hylinger. First, Mr. Pete Hayes from Olympia, Washington.

#43

L.36

MR. PETE HAYES: I don't have a lot to say other than the fact that I am really distressed by the proposal. I think that it is very dangerous to dispose of nuclear waste in the ocean. For the reasons that were given by the previous speakers, I would strongly advocate further considerations of other options, for the same reasons.

I represent a lot of people who couldn't come today, students and other people who have things to do. I don't know if I can say that I represent them, but I would like to think so.

Thank you.

CAPT WAGNER: Thank you, Mr. Hayes.

The next speaker is Mr. Harold J. Hoey, I believe it is. And you will have to announce your location, I can't read the city, sir.

#44

MR. HAROLD HOEY: That's Harold Hoey. I live out here at Lacey.

O.10

I think there is a lot of hysteria in this disposal thing. I can't see dumping these submarines out in the ocean because you are going to lose a lot of valuable material and it may cost the government quite a bit to dismantle these things. But this material will go back into the -- and be remanufactured or the components will be taken out and

installed in ships. I think Hanford is the logical place to put it. We have got the biggest scrapyards in the world in Portland, Oregon and no doubt that it would benefit the economy of Portland and rest of the State of Washington.

Most of the equipment in these submarines is readily reusable, the equipment, most of the equipment in these submarines is reusable without further manufacture. And as far as polluting the Columbia River, it looks to me like there isn't enough radioactive material in these submarines to really bother. All you have to do is bury the things out there in the Hanford desert and put a roof over it so that the moisture can't get to them and they are there forever.

Thank you.

CAPT WAGNER: Thank you, Mr. Hoey.

The next registered speaker is Mr. John Hylinger from Puxuallup, Washington.

MR. JOHN HYLINGER: Puyallup.

CAPT WAGNER: Excuse me.

#45

MR. HYLINGER: I have heard a lot here today about why we can't do this and why we can't do that. So long as we have nuclear energy we are going to have nuclear waste to contend with. It seems to me that nobody has ever come up with a viable nuclear waste dump and I think if we have got one, we have never really used it. In fact, we have got a couple. One is to take nuclear waste in space and fire it into the

H.4

sun. But that is economically unfeasible. So the next closest thing we have got is a container that would live the life of the nuclear waste.

During the '60s -- I think it was the '60s -- we did a lot of underground nuclear testing in the Nevada test facility down near Nellis Air Force Base in Las Vegas. From what I understand, the caverns caused by those nuclear explosions are some 200 feet in diameter and are lined with approximately three feet of what they say is low-grade glass. And they will be there for eons. And why the Navy and the nuclear industry and the Atomic Energy Commission, why they just don't core drill into those with a hole of approximately maybe one foot, maybe six inches, and take your nuclear submarine core and manufacture what I would consider a giant belt sander in an enclosed building and literally grind this nuclear submarine core up into powder and then squeeze the powder into, oh, a ball-shaped object of about the size of a baseball or grapefruit and just drop them down into this cavern. You could do the same thing with nuclear-spent rods. Just make a facility down there and get rid of the high-level nuclear waste in something that is already radioactive as the dickens to begin with.

A.16

Putting it in the ocean has definite disadvantages. If you ground it up into a powder and spread it all over the ocean you would still have the problem. If you sink your

submarines you have still got your problem. The only viable way I can see is either like Dr. -- I don't know what her name was -- she said put it above ground so they don't corrode as fast. But I think if you put them in a glass-lined chambers of the underground nuclear explosions that we had down there, I think that would live just about as long as mankind is going to live around here.

H.4

One thing I would like to say about some of the people that come up here is that they always say you can't do this and you can't do that. The Sierra Club is famous for that. I have heard so many people talk about the Sierra Club. They always come up with reasons why they can't do something. If they can't do it, why don't they come up with a little bit of viable alternatives, what we can do. They never seem to come up with that.

Thank you.

CAPT WAGNER: Thank you, sir.

Next three speakers will be Mr. Carl Deskins and Mr. Ted Mahr and Mr. David Schomer. Mr. Carl R. Deskins from Olympia, Washington.

#46

MR. CARL R. DESKINS: Pretty much that I feel that just a personal statement here, it is important to me because nuclear waste is going to be in my life because it already is, and in my children's life.

I don't understand why we haven't come up with a solution other than dumping it in a riverbed that has a large

H.3

population and a large eco-system. It seems that above ground nuclear storage is a viable solution, just for being able to check on the situation instead of putting it under the rug or under the ocean.

I'm just here to say that I don't appreciate what the Navy has been doing to the world. I have been part of the Navy, I don't appreciate what they do to humans in the Navy. I think that being subjected to military rule and having to be subjected to the dangerous situations and surroundings are wrong for mankind. And I think that the nuclear waste is wrong, also.

Thank you.

CAPT WAGNER: Thank you, sir.

Next registered speaker is Mr. Ted Mahr from Olympia, Washington.

#47

MR. TED MAHR: I want to thank the Navy and other state officials for allowing us citizens to attend this meeting.

However, one comment, sir, and that is, that the meeting really wasn't adequately publicized. I heard about the meeting in December and it was only from a KING Radio broadcast I heard it from. And they told me the meeting would be in the General Administration Building across campus. I went there and no one knew about the meeting. After much difficulty I finally found out it was here. If you do have another meeting in the future I would greatly appreciate it if

N.15

you could adequately publicize it and perhaps put a notice in the Daily Olympian, Seattle Times, Seattle P.I. papers, as well as perhaps holding the meeting at night when more people could participate. I work, I am taking time off work right now and I will have to make up some excuses for my employer when I get back, why I am not there.

Eventually, as to the plan, eventually this radioactivity is going to escape into the environment. There is really no way to keep this material, I believe, isolated for 10,000 or more years from now, the time needed to make sure it is really safe. As a perspective, 250 years ago the United States didn't even exist. And 10,000 years ago we were just entering from a hunting and gathering society into an agriculturally-based society. 10,000 years from now I question whether the United States or really any civilization might exist in order to safeguard the wastes and keep it isolated from the environment.

L.20

What will the ocean be like if the Navy dumps these subs in the Pacific? Well, the Federal Government -- I think we already have a glimpse of what happened -- what might happen. The Federal Government dumped barrels of radioactive waste into the Pacific off San Francisco from the late '40s until 1967. As a result of that dumping, radioactive material is now seeping into the fish and food chain and there is a new species of radioactive sponge as high as this ceiling now

L.36
L.14
L.6

living off the California coast, off the Farallon Islands.

California is attempting to do some studies now as to whether that radiation is seeping into the environment. Unfortunately, they don't have really the budget, the federal funds have been cut by Congress and President Reagan so they can't determine that.

Both alternatives, land and sea burial, are bad but I think the land alternative is much better. But you have to remember because I think it will take much longer for the radiation from these submarines to enter into our food chain and environment.

The real issue is not so much dumping of these subs, whether in the sea or the land, but is to eradicate from the face of the earth forever nuclear weapons and nuclear power reactors. Now, I know in the Navy the job is defense but on the other hand there comes a point when we have got, I think, too much defense.

N.12

Another question you might want to consider is what are we going to do 30 or 40 years from now when the present Trident subs will have to be scuttled. Again, we will have to face the same issue all over again.

Thank you for your time.

CAPT WAGNER: Thank you, sir.

The next registered speaker is Mr. David Schomer from Seattle, Washington.

#48

MR. DAVID SCHOMER: Hi. I'm Dave Schomer and normally I'm a fairly meek and mild-mannered individual, but today I'm Cobalt 60 and that means I'm hot stuff, okay? And that means I'm going to say some pretty hot things because I'm pretty pissed-off.

N.15

Okay, the fact is that the meeting here was very hard to find; I don't find that a mystery at all. The Navy has a long history of ignorance and greed and trying to get things within a budget, do things cheaply without any concern to the public at all, so I'm not surprised. But, as Cobalt 60, I'm the isotope with the most total curies of radiation that will be present in the submarines considered for dumping.

A.10

Still, according to Dr. Marvin Resnikof, the counsel on economic priorities, the levels of my abundant radiation have been underestimated by a factor of six, okay?

G.2

I emit highly penetrating energetic gamma radiation. However, my half-life is relatively short, so I have a small suggestion: If you can keep the subs on a dryland storage or something like that for 30 years until I've done my thing, you'll be a little bit better off.

Thank you.

CAPT WAGNER: Thank you, sir.

Final two registered speakers I have -- and please correct me on this one if I'm wrong -- Swaneagle is the name, following by Mr. Greg Vinson.

Mr. Swaneagle from Colville, Washington? Is that correct?

VOICE: I'm very concerned because --

CAPT WAGNER: Excuse me, ma'am. Would you please state your name properly for the record.

SWANEAGLE: Oh, Swaneagle from Colville.

CAPT WAGNER: Thank you.

#49

SWANEAGLE: I'm very concerned because as of now, my children don't have a healthy future and I feel this situation jeopardizes it even further and it really concerns me that the people that are responsible for such hideous waste are going to leave it to future generations to deal with.

I feel we can do things like make it to the moon, but we can't communicate or find viable solutions for such a horrible situation and I don't see it getting better and I feel we need to concentrate our energy on solutions and on getting along with people all over the planet who do care about their children.

CAPT WAGNER: Thank you.

Next registered speaker is Mr. Greg Vinson from Bellevue, Washington.

#50

MR. GREG VINSON: Hi, I'm Greg Vinson, and I'm today representing Nickel 59.

I emit x-rays and I'll be doing that for quite a while, quite a few generations, as a matter of fact. I've got

a half-life of 80,000 years. The Navy repeatedly ignores my presence, but I'm not going to go away. Not for hundreds of thousands of years. So, pass out the wet blankets and have pleasant dreams. L.46

Thank you.

CAPT WAGNER: Thank you, sir.

I have no further registrations. Has anyone registered in the audience whose name I have not called?

(No response.)

CAPT WAGNER: Ladies and gentlemen, additional public comments for consideration in the final statement may be sent to me at the address that I announced earlier.

I'd like to remind everyone that we have two more scheduled hearings today, one at 1:30 this afternoon, the second at 7:30 this evening. I'd like to thank everyone for their time and particularly for their testimony and comments this morning.

On behalf of the United States Navy, thank you very much.

This hearing is adjourned.

(Whereupon, at 10:50 a.m., the hearing was concluded.)

IN ATTENDANCE:

On behalf of the U.S. Department of the Navy:

CAPT EDWARD WAGNER, USN, Hearing Officer
MR. JAMES MANGENO, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program

On behalf of the U.S. Department of Energy:

MR. FRANK STANDERFER, Assistant Manager for Defense and Energy Programs, Richland Operations Office

I N D E X

P R O C E E D I N G S

1:45 p.m.

CAPT WAGNER: This hearing is called to order.

I am Captain Edward Wagner and I work in the Office of the Deputy Chief of Naval Operations for Submarines.

I have been appointed the Navy's Hearing Officer for this afternoon's public hearing.

Here with me to present an opening briefing is Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program. Also present is Mr. Frank Standerfer, Assistant Manager for Defense and Energy Programs, Richland Operations Office, Department of Energy.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear-powered submarines after the fuel has been removed from the reactor plants and the ships are no longer needed.

The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government-owned land disposal sites or placing them on the deep ocean bottom.

On December 22nd, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement, or DEIS, on the disposal of defueled, decommissioned Naval submarine reactor plants.

The DEIS contains the results of the Navy's studies of the alternatives available. On the registration table are copies of the Summary of the Draft Environmental Impact Statement. Anyone in the audience who would like a complete copy of the DEIS should leave their name and address on the sheet of paper provided at the registration table and a copy will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient to people with an interest in this matter in order to provide them with an opportunity to present their views. I am here today to conduct one of these scheduled public hearings.

The purpose of this hearing is to take testimony regarding the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case, nor to engage in debate. It is my responsibility to receive statements so that they can be considered in preparing the Final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each and organizational spokesmen are limited to ten minutes, unless additional time had been requested in advance. Time cannot be relinquished from one speaker to another.

In order to assure all who desire to speak are given an opportunity, each person should fill out a registration card and provide it to the person at the registration table. All testimony will be recorded so that it can be considered in the development of the Navy's Final Environmental Impact Statement.

If you desire to submit written comments rather than speak, that is acceptable. You can provide written comments to me or leave them at the registration table. If you desire to provide written comments at a later date, my mailing address is as follows: Captain Edward F. Wagner, U.S. Navy, Office of the Chief of Naval Operations, OPNAV-22, Department of the Navy, Washington, D.C., Zip Code 20350.

You should provide your written comments by March 31st, 1983 which, as stated in the Federal Register notice, is the cutoff date for submitting comments.

Before we begin receiving testimony, I would like at this time to introduce Mr. Mangeno of the Naval Nuclear Propulsion Program who will provide a general overview of the issue the Navy is addressing and the content of the Draft EIS.

Mr. Mangeno.

MR. MANGENO: Today's hearing is being conducted as a part of the decision-making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an environmental impact statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The environmental impact statement must include the environmental impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement, or DEIS, on this subject provides the basis for these hearings and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear-powered submarines after they are no longer needed. The practical choices are: bury the radioactive part of the submarine at an existing DOE land disposal facility at the Hanford site in the State of Washington or the Savannah River Plant in South Carolina; or place the entire submarine on the bottom of the ocean in water more than 2.5 miles deep. In both choices there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has about 120 nuclear-powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases,

as shown in this slide, it is evident that a disposal plan must be prepared for use sometime in the future. This DEIS has been prepared now so that all interested agencies, organizations and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the uranium and all of the fission products. The removed fuel is handled according to established procedures and is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, to the metal structure supporting the fuel, to the reactor vessel and to other equipment in the reactor compartment, where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by the hull of the submarine and by the reactor vessel and coolant piping.

In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel or other metal atoms in the reactor plant. These atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation of the nuclear reactor and the number of curies of each radionuclide at that time. A curie is a measure of the amount of radioactivity present, but it is not an indication of the possible effect on man or animals. The amounts and kinds of radioactive atoms present are described in detail in Chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive

material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the Federal Government disposal facilities already used for such low-level radioactive waste at the Hanford Reservation in the State of Washington or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the compartment free from the remainder of the submarine, and weld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. Other government-owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable waterways so that transportation of the reactor compartment to those sites would be impractical. The Hanford and Savannah River burial grounds are described in Chapter 3.

A transporter of the sort shown in this sketch would then be used to haul the compartment overland to the burial location. There is little risk of radiation exposure to any-one in the general public during movement to the burial ground, actual burial or after burial. This is because radiation out-side the compartment would be well below federal limits and the reactor compartment would have been welded shut at the shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low-level radioactive waste. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burials and would result in no significant additional environ-mental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the body. More than 200 years would pass before the reactor com-partment bulkhead could be penetrated by corrosion. Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time, exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean is another practical alternative.

The maximum radioactivity would be less than the limit specified by international criteria and the triple containment provided by the submarine reactor compartment, by the reactor vessel and piping, and by the radioactive atoms being a part of the metal itself would be an extremely strong and effective disposal containment package.

Locations for possible ocean disposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U.S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site specific public hearings would be required and the permit process is not part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 190 miles west of Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry and marine biology for very deep ocean locations. The depth of the water in these areas is between 4,000 and 5,000 meters, 13,000 to 16,000 feet. The scientific information and measure-ments collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that the environmental impacts could be calculated using realistic data.

Preparations for ocean disposal would be made at one of the shipyards normally servicing nuclear-powered naval cessels. Following defueling, the reactor vessel and the reactor compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping and, of course, the metal itself, completely intact. Most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping or free the atoms from the thick metal.

A comparison of the possible effects on the envionment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100 submarine disposals for the year of greatest exposure for both options. This table shows that the radiation exposure would be very small and could have little impact on individuals or the population. These levels are also many times less than any limits established by U.S. regulations or international limits. They are much

smaller than the normal fluctuations in annual average background radiation exposure for U.S. residents.

A perspective on radiation exposure can be gained by examining the exposure a person would receive from natural cosmic background radiation if he flew round-trip from New York City to Los Angeles. That person would receive approximately two millirems more radiation than if he had not made the trip because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one-half millirem.

Other environmental impacts are similarly small and localized in either case. Land burial of 100 reactor plants would require only about ten acres of land and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square ten miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land disposal would cost about 40 per cent more, about two million dollars per submarine more, than sea disposal.

The "no-action" alternative is to place submarines in floating protective storage for an extended period, commonly called mothballing. However, this would only temporarily delay disposal because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods and the estimated radiation exposure for the general public would be very small for all available courses of action.

Thank you.

CAPT WAGNER: Thank you, Mr. Mangeno.

Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of the hearing. I will now recess briefly to establish an order for persons who wish to speak. For those people who have not yet registered and wish to make a statement, you may register at this time.

We will take a recess of five minutes and reconvene the hearing at ten minutes after two.

[Short recess.]

CAPT WAGNER: We will reconvene the hearing.

I do not have any registered speakers for organizations. I mentioned the ten-minute timeframe for organizational spokesmen. Is there anyone who has not registered or

maybe who has registered who I've missed that would like to speak for an organization?

[No response.]

CAPT WAGNER: Then we'll get right into testimony by individuals. The procedure for your public testimony will be as follows. I will call your name. Please come to the microphone right here at the head of the auditorium. Even though I've mentioned your name, I'd like you to please, first of all, state your name in case that I mispronounce it, state your name and then address your comments directly to me.

#51

Our first registered speaker is Mr. Gary DeGraff from Seattle, Washington. Mr. DeGraff.

MR. GARY DeGRAFF: Thank you for your presentation, Captain Edwards -- Captain Wagner, I'm sorry.

I wish to point out that --

CAPT WAGNER: Excuse me, sir. Would you please state your name.

MR. GARY DeGRAFF: Oh, I'm sorry. Gary DeGraff, Seattle, Washington.

CAPT WAGNER: Thank you.

MR. GARY DeGRAFF: I wish to address the fact that here in he United States that us being a superpower, that we're looked upon so much as a nation to set precendents and in some of the literature that I received today, some from the Navy, some from various environmental groups, statements were made here where Japan is prepared this year to make large nuclear waste dumps in the occnas and, in my opinion, Japan relies greatly on the ocean for their survival.

Now, in my years of concern over the whaling issue, Japan has totally ignored the wishes of the International Whaling Commission which is an international organization for the good of huanity and Japan has ignored these things.

F.8

Now, I feel that in this literature where it states that the United States was one of the first -- or, was the first nation -- to form rather a ban on nuclear waste disposal that was very vital to this London Committee for nuclear waste, and I feel that our reversal of our precedences that we have set on this matter, that the amounts or statistics on the amounts of radiation released by our disposed nuclear submarines, that in reality, when this sets a precedent for other nations to say, "Well, the United States, they dump their old nuclear submarines and claim that low-level nuclear wastes are not harmful to the food chain," that here in America where we can speak up on these matters, that's one thing, but what's going to happen with these other countries such as the Soviet Union where citizens are not able to stand before their defense administration and address these matters?

So I feel strongly that, being a citizen of the United States, I wish to voice that I think it's vital that

we set precedents on these kind of things and that since we've created them, let's dispose of them on the land, on our own soil, and I see that a lot of economic issues are raised over this matter and at this present time where the economy could use a little revival, this disposal of removing the reactor out of the submarine, this is in my field of trade, I am presently unemployed, I would like to see some of this work become available, so I wish to just state that I believe in safety, first. Setting precedents for other countries to flllow the examples that we set and, as far as the economic factor, we can use a little work and when it comes to who pays for that work, the Department of the Navy, it says here that people feel that it's the Navy's responsibility, well, my tax dollars is how the Navy exists and myself being a single person and working seven days a week, many hours a day, I get taxed to the hilt, but I'm more concerned with safety, first, even if it does cost me extra dollars and this money factor where safety gets disregarded, I feel that' it's something that we as human beings should really realistically address.

N.3

Thank you, sir.

CAPT WAGNER: Thank you, sir.

The next registered speaker is Mr. Riede Wyatt from Olympia, Washington. Mr. Wyatt.

MR. RIEDE WYATT: Hi. My name is Riede Wyatt.

#52

N.15

This is a public hearing, correct? So why is it that so little effort has been made to inform the public that this hearing is taking place? And, why was the little information given to the public about this hearing false pertaining to location and time of hearing?

Existence of nuclear submarines in the first place stems from the war-like mentality of the United States military. They are built to destroy. So, why should the Navy be concerned with human life and the environment when it comes to dumping old radioactive subs?

That's all I have to say.

CAPT WAGNER: Thank you, sir.

Ladies and gentlemen, I have no further registrations for speakers. Has anyone in the audience registered to speak and I have failed to announce your name?

[No response.]

CAPT WAGNER: Again, I'd like to add that additional public comments for consideration in the final statement may be mailed to me at the address that I gave to you earlier.

I'd like to thank those in the audience for your interest and for the people who provided testimony this afternoon.

Also, I'd like to again re-emphasize that we do have a hearing this evening scheduled for 7:30. Anyone who would like to attend that hearing or if you haven't made

a statement and you would like to consider making one at that time, you're welcome.

On behalf of the United States Navy, I'd like to thank you again for your interest today. This hearing is adjourned.

[Whereupon, at 2:15 p.m., the hearing was concluded.]

On behalf of the U.S. Department of Energy:

MR. FRANK STANDERFER, Assistant Manager for Defense and Energy Programs, Richland Operations Officer

I N D E X

P R O C E E D I N G S

7:45 p.m.

CAPT WAGNER: Good evening, ladies and gentlemen. This hearing is called to order.

I am Captain Edward Wagner and I work in the Office of the Deputy Chief of Naval Operations for Submarines.

I have been appointed the Navy's Hearing Officer for this public hearing.

Here with me to present an opening briefing is Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program. Also present is Mr. Frank Standerfer, Assistant Manager for Defense and Energy Programs, Richland Operations Office, Department of Energy.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear-powered submarine reactor plants after the fuel has been removed and the ships are no longer needed.

The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government owned land disposal sites or placing them on the deep ocean bottom.

On December 22nd, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement, or DEIS, on the disposal of decommissioned, defueled Naval submarine reactor plants.

The DEIS contains the results of the Navy's studies of the alternatives available. On the registration table are copies of the Summary of the Draft Environmental Impact Statement. Anyone in the audience who would like a complete copy of the DEIS should leave their name and address on the sheet of paper provided at the registration table and a copy of the DEIS will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient to people with an interest in this matter in order to provide them with an opportunity to present their views. I am here tonight to conduct one of these scheduled public hearings.

The purpose of this hearing is to take testimony regading the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case, nor to engage in debate. It is my responsibility to receive statements so that they can be considered in preparing the Final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each, and organizational spokesmen are limited to ten minutes, unless additional time had been requested in advance. Time

cannot be relinquished from one speaker to another.

In order to insure all who desire to speak are given an opportunity, each person should fill out a registration card and provide that card to the registration table. All testimony will be recorded so that it can be considered in the development of the Navy's Final Environmental Impact Statement.

If you desire to submit written comments rather than speak, that is acceptable. You can provide written comments to me or you may leave them at the registration table. If you desire to provide written comments at a later date, you may mail those comments to me at the following address: Captain Edward F. Wagner, W-a-g-n-e-r, U.S. Navy, Office of the Chief of Naval Operations, OPNAV-22, Department of the Navy, Washington, D.C., zip Code 20350.

You should provide your written comments by March 31st, 1983 which, as stated in the Federal Register notice, is the cutoff date for submitting comments.

Before we begin receiving testimony, I would like at this time to introduce Mr. Mangeno of the Naval Nuclear Propulsion Program who will provide a general overview of the issue the Navy is addressing and the content of the Draft EIS.

Mr. Mangeno.

MR. MANGENO: Today's hearing is being conducted as a part of the decision-making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an environmental impact statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The environmental impact statement must include the environmental impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement, or DEIS, on this subject provides the basis for these hearings and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear-powered submarines after they are no longer needed. The practical choices are: bury the radioactive part of the submarine in an existing DOE land disposal facility at the Hanford Site in the State of Washingto or the Savannah River Plant in South Carolina; or place the entire submarine on the bottom of the ocean in water more than 2.5 miles deep. In both choices, there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has

about 120 nuclear-powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases, as shown in this slide, it is evident that a disposal plan must be prepared for use sometime in the future. This DEIS has been prepared now so that all interested agencies, organizations and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the uranium and all of the fission products. The removed fuel is handled according to established procedures and is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, to the metal structure supporting the fuel, to the reactor vessel and to other equipment in the reactor compartment, where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by the hull of the submarine and by the reactor vessel and coolant piping.

In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel and other metal atoms in the reactor plant. These atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation of the nuclear reactor and the number of curies of each radionuclide at that time. A curie is a measure of the amount of radioactivity present, but it is not an indication of the possible effect on man or animals. The amounts and kinds of radioactive atoms present are described in detail in Chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless

of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the Federal Government disposal facilities already used for such low level radioactive waste at the Hanford Reservation in the State of Washington or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the compartment free from the remainder of the submarine, and weld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. Other government-owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable waterways so that transportation of the reactor compartment to those sites would be impractical. The Hanford and Savannah River burial grounds are described in

Chapter 3.

A transporter of the sort shown in this sketch could then be used to haul the compartment overland to the burial location. There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial or after burial. This is because radiation outside the compartment would be well below federal limits and the reactor compartment would have been welded shut at the shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low level radioactive waste. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burials and would result in no significant additional environmental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the body. More than 200 years would pass before the reactor compartment bulkhead could be penetrated by corrosion. Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time, exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean is another practical alternative. The maximum radioactivity would be less than the limit specified by international criteria and the triple containment provided by the submarine reactor compartment, by the reactor vessel and piping, and by the radioactive atoms being a part of the metal itself would be an extremely strong and effective disposal containment package.

Locations for possible ocean disposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U.S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site-specific public hearings would be required and the permit process is not part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 190 miles west of Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry and marine biology for very deep ocean locations. The depth of the water in these areas is between 4,000 and 5,000 meters, 13,000 to 16,000 feet. The scientific information and measurements collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that the environmental impacts could be calculated using realistic data.

Preparations for ocean disposal would be made at one of the shipyards normally serving nuclear-powered naval vessels. Following defueling, the reactor vessel and the reactor compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping and, of course, the metal itself, completely intact. Most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping or free the atoms from the thick metal.

A comparison of the possible effects on the environment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100 submarine disposals for the year of greatest exposure for both options. This table shows that the radiation exposure would be very small and could have little impact on individuals or the population. These levels are also many times less than

any limits established by U.S. regulations or international limits. They are much smaller than the normal fluctuations in annual average background radiation exposure for U.S. residents.

A perspective on radiation exposure can be gained by examining the exposure a person would receive from natural cosmic background radiation if he flew round-trip from New York City to Los Angeles. That person would receive approximately two millirems more radiation than if he had not made the trip because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one-half millirem.

Other environmental impacts are similarly small for both options. The effects on animal life would be small and localized in either case. Land burial of 100 reactor plants would require only about ten acres of land and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square ten miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land disposal would cost about 40 percent more, about two million dollars per submarine more, than sea disposal.

The "no-action" alternative is to place submarines in floating protective storage for an extended period, commonly called mothballing. However, this would only temporarily delay disposal because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods and the estimated radiation exposure for the general public would be very small for all available courses of action.

Thank you.

CAPT WAGNER: Thank you, Mr. Mangeno.

Ladies and gentlemen, Mr. Mangeno's presentation concludes our formal portion of tonight's hearing. I will now recess briefly to establish an order for persons who wish to speak. For those people who would like to testify and who have not yet registered, you may do so at this time.

We will recess and reconvene the hearing at ten minutes after eight and start testimony at that time.

VOICE: Will there be an opportunity for questions?

CAPT WAGNER: No, this is a testimony period. As I said earlier, it's not a question-and-answer, it's not a debate session.

[Short recess.]

CAPT WAGNER: Ladies and gentlemen, we'll resume our hearing.

For the gentleman who asked the question on will we have questions and for those of you who might have questions, we do have a lady at the front table who represents the Chief of Naval Information. Her name is Ensign Laurie Ramp. If you have a specific question that you find that the information that we've provided at the registration table does not answer, you may leave that question with her and she will either answer it at the time, if she's able to, or she will find the answer for you and get it to you at a later time.

Simply to establish an order for the statements, I intend to ask individuals representing organizations to speak first. We will do that in alphabetical order by the last name of the speaker. Then we will follow the organizational spokesmen with testimony by individuals, again in alphabetical order by last name of the speaker.

I request your cooperation providing comments within the time limits that we've established so that we may be certain that all who wish to speak have an opportunity to do so.

Once again, that's five minutes for the individual speakers and ten minutes for organizational spokesmen.

If your statement is so long that you feel it cannot be given in the five or ten minutes allotted, then you may submit the entire statement in writing. It will be then entered in the record and you can summarize your entire statement in the five or ten minute period.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, please proceed to the microphone that we have here in the front of the auditorium, state your name and organization, if any, then address all comments to me, please.

I want to re-emphasize, even though I announce your name, please for the record state it. I might mispronounce it and you can then correct it for the record when you start.

Our first registered speaker is Mr. John Schubert from Tacoma, Washington, who is representing the Tahomans for a Healthy Environment.

#53

MR. JOHN SCHUBERT: Thank you, Captain Wagner. My name is John Schubert. I'm a resident of Tacoma, Washington, and my training is in environmental sciences and policy and I'm presenting my views tonight as a representative of Tahomans for a Healthy Environment, or T.H.E.

T.H.E. is a Tacoma citizens' group dedicated to achieving a healthy environment for all people who live and work in Tacoma, yet our concerns extend broader than that from time to time, such as the situation tonight.

I am here to express our opposition to the disposal

of decomissioned and defueled nuclear submarines at sea. My reasons are simple and I believe unassailable. You simply don't put toxic wastes where you can't get at it unless you know it will do no harm and you know you'll never want access to it again. Neither of these conditions are knowable at this time for disposal at sea of radioactive wastes.

W.1

L.39

Too many times we have had passed out of sight and out of mind pollution disposal policies that come back to haunt us. We're in Tacoma unfortunately faced with quite a few of these problems. We've been listed among the top ten toxic waste sites in the country and we're facing very difficult problems in figuring out how to resolve these problems because we put things on the bottom of Commencement Bay, we put things in all sorts of places where there was no ready access to them, now that it's times to do something with it that we never expected to have to do.

As for disposal of these submarines on land, though undesirable in its own right, I believe this option is preferrable. Not only does disposal on land allow retrieval, if necessary or desirable at a future date, but sites in our own back yard such as Hanford and Savannah River serve the public and government well as ever-present reminders of the need to minimize the production of toxic wastes in the first place.

Thank you very much for the opportunity to comment.

#54

CAPT WAGNER: Thank you, sir.

The next registered speaker is Stuart Robert Smith from Olympia, Washington. Mr. Smith is representing the Concerned Citizens of Cooper Point.

MR. STUART SMITH: My name is Stuart Smith and I represent the Concerned Citizens of Cooper Point. The statement here has been quickly drawn up and is not well organized, but I think the points I make are fairly well taken, Captain Wagner.

N.15

One thing I notice was that the public hearing advertisement had the wrong address on it. In the Olympia paper, The Daily Olympian, the address given was the General Administration Building and this, as we know, isn't the General Administration Building; so perhaps there would be more people here if the address was correct.

Secondly, I notice that these public meetings are only taking place in four communities across the entire country: in Sacramento, in Olympia, in Raleigh, North Carolina and Columbia, South Carolina; not well distributed, I'm afraid, and I think perhaps more people would become involved in public meetings if more effort was made to distribute their addresses.

I am a student, I study genetics, and one of the things that I've recently learned about in genetics is something called mutation. Mutation is a change in the structure of a

chromosome which is the basic unit of inheritance in reproduction of animal tissue of humans, eventually. I noticed in looking through the summary of the Draft EIS that you mention millirems and talk about millirems in terms of lifting mosquitoes and I was just wondering if your Department of the EPA ever considered millirems in terms of destroying chromosomes and how much energy it takes to dissociate an active human chromosome.

X.1

I don't have the budget that the Navy does, obviously, to provide a slide show, but I did make some photocopies of human mutations that are not very pretty. They're not as slick as the Navy presentation, I'm afraid, but they do cause one to stop and think very seriously in terms of numbers of millirems or exposure to any radiation at all, not so much in terms of watching television or riding on the airlines, as the Navy chooses to see it, but more in terms of potential biological concentration of mutagens, radioactive nucleotides in the ocean waters that unfortunately can never be removed and we'd have to filter the entire ocean. Once we've polluted these waters, we certainly can't unpollute them.

L.43

L.20

W.1

In fact, Dr. William Schell from the EPA has revealed alarming evidence of radionucleotide migration into edible shellfish from past dump sites. Now, I know that this particular Environmental Impact Statement is not addressing previous dump sites or anything like that, but I think it's something that we might consider, is cleaning up previous waste dumping.

U.9

Now, I know this may seem irrelevant, but in terms of watching television and riding in airplanes, it doesn't seem particularly irrelevant to mention that there is several other ships in the Navy nuclear fleet, for example, the -- oh, let's see, there's the Enterprise, the Kennedy and the Nimitz, which are large carriers I'm sure you're familiar with and the Frigate Long Beach, these are the few that I could come up with, there are cargo ships and many other nuclear ships. For example, the Sea Wolf, which has been sunk off my home state of New Jersey -- at least that's where I was raised; now I'm a resident of Washington -- apparently the Sea Wolf has never been found, which I think is sort of an interesting idea.

I.85

I mean, in one sense, it could be a good argument for the Navy considering that the level of radiation is so low that they've never been able to find it, but in another sense I think it's rather frightening that we can never find out exactly what the effects of the Sea Wolf sinking as our only example of a dumping ocean sunk nuclear vessel.

Anyway, I guess the most frightening thing to me about the Navy wanting to potentially dump spent reactors in the open ocean is that apparently last week the London Dumping Convention, which is I believe an international organization, voted 19 to 6 to outlaw ocean dumping of radioactive

F.5

waste and I think that if the Navy is considering breaking an

international law in dumping nuclear waste in the ocean, that's something -- it's not setting a good precedent for the rest of the world. F.8

I guess I would also mention that the other -- in the Summary Draft Environmental Impact Statement, there is no mention of the potential extent that the radioactive isotopes involved -- talked in terms of half-lives, how long these things will be around. Obviously, they'll be released very slowly into the ocean or into the atmosphere around the land dumping site or anywhere. Technetium-99 was the one that I was particularly impressed by. That's a 212 thousand year half-life, which means half of whatever -- well, half of whatever technetium-99 has produced will be gone after a quarter of a million years. It seems pretty impressive. If any of it is around at all, I imagine it going to be for quite some time.

I guess my main concern is that it seems as if these proceeedings, the EIS proceedngs and Environmental Impact Statement, which of course was drawn up by -- apparently drawn up by an ex-military -- an ex-Navy man, let's see, I have his name here, Sjoblom -- I'm sorry, sir, wherever you are -- who drew up the EPA document, a Navy personnel person, but I guess what I'm most concerned about is the best possible things we could do at this point, I think, is to wait, is to keep the ships in drydock. It seems to be G.2

the least expensive procedure at this point, compared to the others. It adds 3.2 million to a potential 16 million, the most expensive of the procedures. We're not at all sure what the total effects of environmental radiation can be as far as the mutagenic effects and in terms of potential birth defects in our own species and in terms of not fully understanding the storage -- the deep sea dumping procedures that have happened in the past based -- apparently is already leaking out of containment vessels that we were convinced were safe and is already entering our food supply.

L.6

I guess you could just say that I'm concerned. I'm a concerned citizen. And, I certainly hope that the Navy is not whitewashing over their decision to dump the containers, these reactor vessels into the ocean because it's the least expensive thing to do. I'm not someone who has vast credentials or vast experience. I'm young, I'm inexperienced, but I am concerned and that's something that I feel I have a responsibility to represent my children, my grandchildren, your children, your grandchildren here by considering the possible effects of ocean dumping and of land storage and of drydocking.

N.3

Well, I think I've covered most of the points that I wanted to mention. I guess the only thing left to say would be that I certainly hope that you can consider these proceedings very carefully and I certainly hope that you will

*Other issues discussed by Mr. Baird are side barred in Exhibit 55a.

hold public meetings in other communities besides just Sacramento and Olympia and Raleigh, North Carolina and Columbia, South Carolina. I hope it's not too late for the rest of the nation to become aware of what the Navy's plans are. And, I certainly hope that we can undo the damage that we've already done.

J.15

Thank you very much.

CAPT WAGNER: Thank you, Mr. Smith.

(Applause.)

CAPT WAGNER: Ladies and gentlemen, I have no more registrations for organizational spokesmen.

VOICE: I'm here as a representative of the Tatoosh Group of the Sierra Club.

CAPT WAGNER: We had the Sierra Club represented earlier today, so I will give you an opportunity alphabetically with the public. In fact, Mr. Baird -- if you're Mr. Baird, you'll be first. But, the remainder of the cards are alphabetized now with the individual speakers. The same procedure will be used in terms of calling you up to the microphone and I encourage you to please make your comments directly to me, try to stay within the time frames so that we can get everybody who I have listed here tonight an opportunity to speak.

The first individual is Mr. Brian Baird from Tacoma, Washington.

MR. BRIAN BAIRD: My name is Brian Baird. I represent

#55

the Tatoosh Group of the Sierra Club. I'm a conservation chairperson for that organization.

A couple of interesting comments I'd like to begin with. One is I first learned about this meeting quite by accident, actually, although I've been interested in the subject for a couple of years. I happened upon a legal notice in the classified advertising section, which I'm sure you're familiar with the size of those and the frequency with which they're read.

It seems that on something of this magnitude a greater effort could be undertaken to notify the press and the public that something like this is happening. I took it upon myself to call our local newspaper and say, "Hey, did you know this meeting was coming up?" and they were kind enough to publicize it in a slightly larger article, but I have little doubt that many people would be interested in this had the matter been publicized more.

*N.15

Secondly, it has caused some consternation for me to attend the scheduled meeting site and find a notice that the meeting location had been changed, no assistance, particularly, as to how to find the new meeting site, it is raining outside, we came early so as to have a chance to peruse any documents you might have provided for us, ended up getting here about five minutes late after having circumnavigated every building in the nearby vicinity.

*Other issues discussed by Mr. Baird are side barred in Exhibit 55a.

The kinds of minds that are expected to plan disposal of nuclear wastes and nuclear submarines at sea might be expected to provide a map or a better description of the location of a meeting site.

Well, I like to think -- and perhaps it's unjust so because the generations to come might be quite different than these -- but I like to think we're here speaking for people who can't speak because they don't yet exist and, as the gentleman mentioned earlier, that would be my grandchildren and your grandchildren and on for literally thousands of generations who will have to live with whatever we do here today.

I also like to believe that humans are capable of learning from our experience and from our mistakes, but time and again that belief gets challenged by our recurrent stupidity.

The proposal to dump more deadly garbage at sea is another case in point. It exemplifies not only our stupidity, but our arrogance and our short-sightedness. As a resident of Tacoma, like Mr. Schubert, I've seen the effects of short-term solutions to long-term problems. There was a time when industries of Tacoma thought it was perfectly acceptable to dump literally hundreds of thousands of tons of chemical waste in the Bay. Today we're just beginning to see that that works its way up through the food chain and we eat it and it has effects long, long after the actual actions undertaken.

In this case, the waste of concern are only a couple hundred feet deep. Yet, if you attend any of the meetings about how to get those things out or what to do with them, you'll find that it's an incredibly perplexing problem. Certainly it will cost more to eliminate them from the environment where they lay now than it would have to have properly disposed of them at the time.

At any rate, I'm not certain that we'll ever come up with a thoroughly satisfactory solution to that problem, but that's only in a couple hundred feet of water. My understanding is that the proposal for the submarines is in a couple miles deep of water.

W.1

O.26

I'd ask you to really ask yourself seriously -- and I've seen no mention of it in the Environmental Impact Statement -- what if our grand designs and our best-laid plans of mice and men go awry and something happens down there to those reactor vessels? What happens then? How do we get them out? I see no cost estimates for that in the EIS, no even feasibility studies for whether or not that would be possible. The experience at Commencement Bay and hundreds of other sites suggest that that would be a prudent thing to include in any EIS considering ocean dumping sites.

The basic message, as was mentioned earlier, is if

W.1

something's going to be poisonous for an awful long time, you don't dump it where you can't get back at it. But again, I don't think we learn our lessons very well.

I'd like also to make kind of an observation about environmental impacts of the past. There's some questions in addition to the one I just mentioned that might be asked. My observation from the scientific literature that I've had access to which hasn't been vast in this area, but generally there seems to be a great question mark, in fact, that you often read in these studies, so little is known about this area as of yet. We're just beginning to study it. More research is needed.

L.1

J.9

Some questions that I don't think have been adequately addressed include just what organisms are there down there? This is pretty deep water we're talking about and I don't think it's been adequately surveyed. Perhaps I'm mistaken on that. You've already addressed some of the things about long-term effects of the saltwater. I would venture to guess that when the rather rosy picture of possible worst-case -- I won't say "worst-case" because you didn't -- but the possible rosy picture of millirems and how comforting it was to see that in my trip to New York I'll be exposed to more millirems does not consider the worst case incident. If I'm mistaken in that, I'd appreciate correction, but I would certainly guess that if that was the worst possible case of exposure, we wouldn't be having this meeting at all.

The gentleman mentioned earlier that we're talking about half-lives of 20, 30, in some cases hundreds of thousands of years for these things. Again, that was not mentioned in the slide show.

It hearkens back to the time when we were first considering nuclear power and people said, "Hey, this is plenty safe stuff" and at the time we didn't have any real appreciation for the significance of reactor core brittling, we didn't understand the effects of neutron bombardment of some of the vessels, and we went ahead making decisions that really in the long term we're seeing is not particularly appropriate.

So, I'd like to ask just one kind of question, I suppose, in conclusion. We're making decisions that will affect people 20,000 years from now with possibly exposing them to extremely toxic stuff and I would ask just who the hell we think we are. I recognize that that may be viewed by some as an obscenity, but to be frank, I view this proposal to dump things at sea without adequate knowledge as a far greater obscenity and that obscenity is far less, I fear, than the contempt that our progeny may hold for us if we go ahead with that kind of plan.

L.39

Thank you.

CAPT WAGNER: Thank you, Mr. Baird.

(Applause.)

CAPT WAGNER. The next speaker is, I believe, Mr. Scott Elliott -- I might have the first name wrong -- from Olympia, Washington.

#56

MR. SCOTT ELLIOTT: My name is Scott Elliott. I'm a resident of Olympia, Washington.

I believe, pursuant to NEPA, the environmental and scientific data presented is not fully documented within the Environmental Impact Statement. This meeting was not properly publicized. There are insufficient meetings for all members of the public interested to attend. And I think a special area lacking within the EIS pursuant to the NEPA is the social aspects of this that have not been considered.

First of all, the options have not been considered fully with regard to employment. There will be substantially greater employment benefits as a result of land-based disposal. O.11

Secondly, this cannot be considered fully in a vacuum. There are social impacts beyond merely employment, including international law aspects that will impact upon the environment. F.8

One such similar case currently that the United States is involved in is the acid rain controversy involved in the Eastern United States with Canada. That's currently in litigation before the International Court of Justice and that has not been addressed within the Draft Environmental Impact Statement.

F.8

Second is the issue of sovereignty. This will have an effect upon sovereignty and that was not addressed at all in the Draft Environmental Impact Statement. Whenever a government has sovereignty over an area, it can control the environmental impacts that occur there. This will impact sovereignty.

F.8

Third, the international social and legal aspects beyond just sovereignty. Once we start dumping, it will be very hard to stop others from dumping and other nations do not necessarily have the full environmental review processes that we do. Once we set a precedent, that will allow others potentially to dump very high levels of radioactive materials that we will have no control over, we'll not be in a position to comment internationally, and our sovereignty could be potentially violated in the same way as the acid rain situation.

I think it's important that mitigation has not been fully considered, either, as pursuant to NEPA. There are many possible ways of reducing our radioactive contamination of the environment such as immediately decommissioning all nuclear ships. Second, fully decommissioning all nuclear power plants. These are mitigating measures that could be taken if we were to dispose of these at sea.

Another portion of mitigation is land-based disposal could be further improved by processing these further, not just simply welding them shut and dumping them in holes.

E.5

They can be sealed better, they can be processed down. These issues were not properly dealt with in NEPA. Under NEPA you're required to fully consider all the possibilities and all reasonable mitigating measures. I consider slight improvements in the burial processes to be important, significant and economically feasible and they were not dealt with. The Draft Environmental Impact Statement does not meet NEPA. It needs to be fully rewritten, more hearings held at more places, better publicized before a Final Environmental Impact Statement should even be considered.

E.5

My recommendations are beyond just those, that land-based burial be the only option and that full mitigating measures should be taken.

Thank you.

CAPT WAGNER: Thank you, sir.

(Applause.)

CAPT WAGNER: I have two registration cards from Mr. Joe Morin. If we have two people by that name here, let me ask the first man to come up and then --

#57

MR. JOSEPH MORIN: No, they registered once for me. Can I speak --

CAPT WAGNER: Yes, sir. From Olympia, Washington, Mr. Joe Morin.

MR. JOSEPH MORIN: My name is Joseph Morin. I'm a registered voter in the City of Olympia and a citizen of the United States and I came to add my small voice in this Government basement to urge you not to -- to strongly reconsider your proposals to dump nuclear submarines in an ocean site. It would seem rather foolish and perhaps even arrogant that we would lightly make a decision that could affect generations and generations of our families which is not a thing that we should take very lightly.

I'm pleased to see that the Navy has a Draft Environmental Impact Statement, but it doesn't seem to be perhaps as clear as an issue of such vital importance should be before we make such a large decision.

So, basically, I'd just like to add that for the record and strongly urge the Government to take its responsibilities for properly disposing of its waste and not pass that burden on to future generations.

Thank you.

CAPT WAGNER: Thank you, Mr. Morin.

(Applause.)

CAPT WAGNER: The next registered speaker is Mr. Jim Skutt, I believe it is, S-k-u-t-t, --

MR. JAMES SKUTT: You got it.

CAPT WAGNER: -- from Olympia, Washington.

MR. JAMES SKUTT: Good evening. My name is James Skutt and I live here in Olympia. This evening I'm here to offer my comments on the U. S. Navy plan to scuttle spent

nuclear submarines in the ocean.

Earlier today and earlier this evening, you were presented with testimony from a number of environmentally-oriented groups and individuals who pointed out the flaws in the Navy plan and the many ways in which it endangers the existence of the ocean environment.

We also have heard about the dangerous precedent the Navy plan would set in regard to world wide ocean dumping.

I do not feel that I have any further comments to offer that would be of great scientific help. However, I would like to tell you about the way this Navy plan is affecting my impression, my view of the amount of care the Navy and the Government, in general, has for the earth. I'm rapidly getting the impression that the Navy views the ocean as simply a medium for floating their war ships. The earth is the only real world there is. If we continue to poison it, it will die. If it dies, we die, whether we come from America or anywhere else. The earth will not play favorites, the earth will not be selective. The earth, when angry, will be incredibly powerful. Even the Navy higher-ups and the members of the executive branch who are running the united corporation of America will not be able to escape. If the earth's vengeance doesn't come in the form of floods, earthquakes, drastic weather alterations or other spectacular forms, it will come in more insidious and man-caused forms such as radiation in the air and water.

Captain Wagner, you probably find this constant barrage of opposition a bit difficult. Of course, we can't tell because you are trained not to reveal your emotions. But, you have only begun to hear the voice of the people who will be affected by this plan.

The plan to dump nuclear subs in the ocean will lead the way for a new attack on the environment which is, in effect, our mother, and rather than lead the way into oblivion in yet another way, the United States could take action that would, perhaps, be able to lead the world away from darkness. I do not expect the United States Government in its present form to take this action, but, nevertheless, I hope for it.

Thank you for this opportunity.

CAPT WAGNER: Thank you, sir.

(Applause.)

CAPT WAGNER: The next registered speaker is Mr. Eric Simmons from Olympia, Washington.

#59

MR. ERIC SIMMONS: Hello. My name is Eric Simmons and I'm from Olympia, as well. I'd like to comment upon the following falsehood in the DEIS; I quote: "The animal life on or near the sea floor in these study areas is very sparse. None of the animals are used by man or form part of a food chain know to lead to man."

The Prophet Isaiah said, "All flesh is grass" and he was making a point about the transitory nature of life, but in fact he was also stating the basic law of biological communities. The ultimate source of all human and energy upon this planet is the green plant which alone can use the sun's energy to synthesize organic compounds. Plants are not only the primary producers of our world, but also generate the oxygen we breathe. It has been estimated that the free-floating plants of the sea, the phytoplankton, represent 80 percent of the world's annual production of plant material. 80 percent.

Like most plants, phytoplankton require four principal materials to grow. These are water, carbon dioxide, sunlight and certain inorganic nutrient salts such as nitrates and phosphates. In the productive sunlight surface areas, carbon dioxide, sunlight and water are readily available. The limiting factors are the nutrient salts. The vast majority of phytoplankton are unable to fix nitrogen out of the atmosphere. The nitrogen becomes available only through the decomposing done by bacteria. Bacteria turn organic compounds into inorganic, water-soluble nutrients that are suitable for uptake by plants.

This was recognized as long ago as 1865 by Louis Pasteur. Quote, "Life could not exist on earth without not only death, but decomposition." We can see, in crude terms -- I only have five minutes -- the constant recycling of a relatively unchanging amount of nitrogen in the ocean ecosystem. Marine bacteria show a characteristic pattern of vertical distribution in the open waters of the ocean. In the sunlit surface waters, there are relatively few bacteria. Much higher levels are found immediately below the thermocline and the thermocline is the level at which most plant production ceases. It's too dark. The numbers then fall off sharply as one goes deeper, and the intermediate depths of 500 feet and more are relatively devoid of bacteria. By far the greatest numbers of bacteria are found a few centimeters above and within the bottom deposits of the ocean. It is true that most of the bacteria essential to the nitrogen cycle are found. These decomposers are at all depths in all oceans. The nitrates formed are recycled by upwelling and by winter turbulence.

T.24

J.31

You might see the pictures in the EIS of the sea floor, just blank mud, sterile, cold-looking, but should this blank mud, this function cease its activities, the available nitrates would be used up in one bloom of phyto-plankton, that's less than three months.

L.55

Eighty percent of all green plant production on this planet would cease immediately. No animal would survive.

This scenario is probably impossible in nature. However, it must be made very clear to everyone that we are not discussing the extinction of the Snail Darter or some

equally obscure critter that got itself killed by economic considerations. We're talking about the life breath of the planet. Incredibly, no mention has been made of the effects of this dumping on benthic decomposers. You must understand how basic and essential this ocean cycle is. It cannot be ignored.

T.24

L.13

The dumping of only 100 nuclear subs into the sea floor may or may not choke us or starve us. The point is the sea floor is not and must not be considered as a safe place to dump toxants. If you must put them somewhere, put them at Hanford. Do not set such a precedent as this. The interactions in the sea are complicated and very little understood, but the planet's life breath may be more fragile than any of us suspect.

L.9

F.8

L.39

CAPT WAGNER: Thank you, sir.

(Applause.)

CAPT WAGNER: Next registered speaker is Starwater from Colville, Washington.

#60

STARWATER: Thank you, Captain. My name is Starwater. I live in Colville, Washington. And, I honor and respect your position and I would like to believe that the Navy is looking for the best possible solution to this problem. I share the concern in handling these wastes safely and effectively.

Submarines use the ocean; they share it with plant and animal life that live in these waters. We must work together efficiently to serve both the Navy and the ocean life. We cannot dump these deadly poisonous wastes into our living waters. I suggest that before a final decision is made that we continue to look for a beter alternative.

Thank you.

CAPT WAGNER: Thank you.

(Applause.)

CAPT WAGNER: Next registered speaker is Mr. Marcus Tengesdal of Olympia, Washington.

#61

MR. MARCUS TENGESDAL: I am Marcus Tengesdal. I do live in Olympia..

Although saying no without having a viable alternative might seen a little shallow to you, people who aren't technically trained in the area of radioactive disposal need to speak out for what isn't right. Due to the very scanty amount of publicity given for these hearings, I didn't know they were happening until two days ago, which is hardly enough time to do justifiable research into alternatives to ocean disposal.

N.15

Whether planned or not, your tactics of keeping these hearings very low-key and changing buildings at the last minute seem to have succeeded in keeping the public at bay.

Even if your estimates of the maximum amount of radiation levels were correct, who has the right to determine

how many rems we, as living beings, can be exposed to? To say there is no impact on the environment certainly must be an ignorant statement. What about the food chain, to have one example of how it will eventually get to us, even, let alone the animals that are exposed to it immediately? L.36 L.14

When the subs are scuttled, you say they will go down and rest gently on the bottom; how do you know what they're going to do when they get down there? You will be able to watch them? The ocean is the life support system of many cultures and certainly our culture relies upon many products from the sea. How will this radiation be carried by currents throughout the world? J.76 L.53

From going over the DEIS and from testimony heard, I don't see any other option at this point but to dispose of these submarines on the land somewhere in a dry climate. But, at this point, I also haven't heard of a proper mode to do that in and it seems to me the best thing we can do is to wait and someone just may have a better idea and until that point, I think we should just sit tight and leave them where they are. G.2

Thank you.

CAPT WAGNER: Thank you, sir.

(Applause.)

CAPT WAGNER: The next registered speaker is Mr. John Wood of Olympia, Washington.

#62

MR. JOHN WOOD: Good evening, Captain Wagner. My name is John Wood. I'm from Olympia.

The Draft EIS summary in this meeting kind of distressed me. We've heard from about probably twelve people tonight and maybe two this afternoon and four this morning, I believe. That's about eighteen people and eighteen times four is maybe -- we'll call it eighty people across the U. S. who might have said something concerning this disposal of low level nuclear waste. I think that's kind of a sad thing because we will be making decisions that -- you know, this stuff is going to be around for a long time and I think that perhaps in the future -- and I don't know whether this is deliberate or not -- there could have been a bit more planning to make these meetings, one, more accessible and, two, perhaps a bit broader-based because I doubt there's anyone from Hanford here and part of the policy of -- certainly part of this EIS was concern with a land-based disposal system and Hanford was considered and I have a feeling the people in Hanford would have liked to have known about this. And, it seems your minds are already made up.

The summary of the EIS, which I read this afternoon, contained only one single-sentenced paragraph. It was the next to the last paragraph. The sentence read, and I quote, "Sea disposal would seem to be the least costly method.", unquote. Perhaps that should have been the title of the

Draft EIS.

Aren't there other considerations? The report fails to address the need for a national comprehensive policy on the disposal of low level and also high level nuclear waste. Wouldn't that be a good idea? Rather than scatter our waste in areas, and I quote from the Draft EIS again, "cold, dark and tranquil with a sparse population of organisms", end quote, we should develop adequate disposal sites now, disposal sites which incorporate the needs of the future as well as the demands of the present. And, of course, I'm leaving moot the point that perhaps in the future the Navy and perhaps other powers across the world should consider investing in alternative sources of energy for ships, submarines power plants, et cetera. It requires so much time and energy to dispose of and so little time and energy to get started. Most people talk about how little energy is required once things are operating. Well, that's great, but there's so many manhours spent to get rid of the stupid things, it seems as though perhaps we could think a bit more in terms of the future instead of so much in the present. N.3 N.12

That's all I have to say. Good evening.

CAPT WAGNER: Thank you.

(Applause.)

CAPT WAGNER: That concludes the registered people that I have. Is there anyone in the audience who would like to speak who has not registered?

Yes, sir.

VOICE: Yeah.

CAPT WAGNER: I would like you to fill out a registration card for the record if you would, sir, so that we can make sure that we have that.

VOICE: Can I do that on my way out?

CAPT WAGNER: Pardon?

VOICE: Can I do that on my way out?

CAPT WAGNER: Yes, you may.

#63

MR. RICHARD BECK: My name is Richard Beck, and I'm from Olympia, and I just had one thing to say, and that was that so far everybody here tonight has been opposed to dumping them at sea and probably has grave reservations about dumping -- dumping them on the land, too. I mean, there's really nothing to do with these things and we keep making them, but I think that if this has been pretty much the percentage of people that have been opposed to dumping them at sea, that if they go ahead and dump them at sea, it's going to give us a lot of reservations about the whole system for public input, so I just wanted to make that comment on it.

CAPT WAGNER: Thank you, Mr. Beck.

(Applause.)

CAPT WAGNER: Is there anyone else who has not

had an opportunity to speak who would like to do so?

(No response.)

CAPT WAGNER: I'd like to then finally add that additional comments, as I said earlier, may be provided to me at the address that I gave you earlier. If you'd like to make a longer comment, I invite you to do so, and those comments will be considered, as well as those oral comments tonight, in the development of the Final Environmental Impact Statement.

On behalf of the United States Navy, I'd like to thank all of you for your time tonight and particularly for your public testimony.

Thank you very much. This hearing is adjourned.

(Whereupon, at 8:55 p.m., the hearing was concluded.)

#55a*

February 22, 1983,

Public comment regarding disposal of nuclear submarines by the U.S. Navy.

To the hearings officer:

I wish to state at the outset that my comments are offered out of concern for all of the present and future human inhabitants of this planet who may be effected by the proposed disposal of nuclear reactors at sea. Although the proposed project if carried out will likely effect everyone on the planet, not everyone will have the opportunity to express their views about it. Indeed, if past experience is a guide, far more people will come to know of it after the fact, when it is too late to stop the project, and too difficult to remedy it.

I would like to believe that humans are capable of learning from our mistakes, but time and time again that belief is challenged by our recurrent stupidity. The proposal to dump more deadly garbage at sea is another case in point. It exemplifies not only our stupidity, but our arrogance and shortsightedness as well.

As a resident of Tacoma WA. I have seen the effects of short term solutions that have unfortunate long term consequences. There was a time when the industries of Tacoma considered Commencement Bay to be a bottomless toilet, capable of absorbing whatever was dumped into it and in any amount. Over the course of fifty years or so hundreds of thousands of tons of waste products were purposefuly dumped in the bay. The consequences are just beginning to be seen, in diseased fish and other organisms, possibly including humans.

The unfortunate but instructive aspect of the Commencement Bay pollution is that its location makes remediation extremely difficult, if not impossible. Even if it is possible to somehow remove the chemicals from the environment, the cost is likely to be extreme, and almost certainlky will far exceed what it would have cost to dispose of the wastes on land, where it could be more readily accessed.

*W.1 The lesson I hope we could learn is, don't put dangerous things where
they can harm you for years and where you can't do anything about it once they
are there.

That is the lesson I hope we learn, but along comes the Navy with the
A.16 idea that we should dump nuclear submarines at sea, reactor cores and all.

I recognize that there have been environmental impact studies done, but I
J.201 also am aware that the knowledge in this area is exceedingly sparse in
comparison with what we need to know to make a decision of this magnitude.

Just how does the area of the sea in question change over the course of
L.39 tens of thousands of years during which the material will still be dangerous?
Just what organisms live in those locations and what role do they play on
Q.13 other levels of the food chain? What are the long term effects of salt water
and extreme pressure on the submarine and reactor core? Is there any way we
A.16 could remove the material if we find out that it indeed is causing important
damage? How much would that cost? Is it possible that by disposing of the
W.1 material in this way we are unwittingly precluding future use of an area that
may have unique and valuable features?

These are just a few questions to be asked. I am aware that the answer
J.9 will come in the form of best available evidence, but I contend that this is
not yet adequate for a decision of this magnitude. The area of the ocean
floor that is being considered, has been studied very little. In spite of the
EIS and Navy suggestion to the contrary, scientific research studies of the
area consistently contain sugestions that further study is needed and our
knowledge to date is sparse. In view of this is seems far better to store the G.2
material on land than to rush ahead and permanently contaminate an area for
the sake of short term political and economic expediency.

Twenty five years ago, the "best available evidence" did not predict the extent of reactor core brittling that we are finding today, nor was it anticipated that the radioactivity of certain reactor core parts would be higher than is allowable for less costly disposal. These are costly and dangerous mistakes that resulted from our excessive and unnecessary haste. We may not be replicating the specific mistakes with this proposal, but we will certainly be following the same illthought decision procedures, and misplaced priorities that led to them.

If this hearings proposal really has an impact, which I am admittedly not confident that it does, it is difficult to imagine that the submarines will be dumped at sea. I think the public has gradually realized that the ocean is not a toilet, even if the U.S. Navy has not.

Before concluding I would like to note that the public hearing procedure for this EIS was a mockery of the intent of the law. Only four, poorly publicized hearings were held, in locations not necessarily proximal to those which the proposal would impact. Moreover, at the Olympia WA. hearing, the hearing site was changed with exceedingly poor notice regarding the new location of the hearing site. It gave those of us who attended a distinct impression that the Navy did not really want public input into the process.

The EIS itself is, in my judgement, highly inadequate, in the areas
mentioned above, and also in its disregard for worst case scenarios including O.26
costs and consequnces if the plans for this disposal are in error, as
experience has shown they so often are. There should by a new EIS conducted, G.2
or the disposal should be delayed and the submarines mothballed.

In concluding these comments I would like to ask the decision makers who might be inclined to support the dumping at sea proposal, just who in the hell they think they are. What gives them the right to saddle thousands of generations with a potentially deadly threat that they cannot feasibly eliminate. The impression gained at the hearing was that the navy is hell bent on the sea disposal proposal, damn the public input, full speed ahead.

At the Olympia hearing which I attended, the public input was unanimously in opposition to sea dumping. If public input is really important, as a democratic society and NEPA suggest it must be, then there seems to me to be no way the Navy can justify its dumping at sea. The only acceptable course is mothballing, or land disposal. Sea dumping would demonstrate a blatant disregard, not only for the environment and the future, but for the principles of citizen participation in government. The Navy is commissioned to uphold those principles, not circumvent or undermine them.

Thank you for your attention:

Brian N. Baird

Brian Baird

Written comments may be provided on the other side.

The debate over where to dump nuclear waste, highlights the fundamental anarchy which is at the core of the nuclear industry as a whole. Information about the effects of radiation on all living things is readily available to both the public + the military. Lack of knowledge of these disastrous effects is not the issue. Decisions are made not in ignorance of information but in blatant contradiction to that information – to the facts. The reason for such seemingly [illegible] behavior is cost + profit. Facts are manipulated and misconstrued to deceive the public in order to benefit a minority. The public wishes to be dealt with honestly + fairly. Continued resistance to public need and desire will only increase the pressure. A shift in values and perspective is a prerequisite to rational, safe decision making policy re: nuclear waste.

Testimony at the Public Hearing

on the

Draft Environmental Impact Statement

on the

Disposal of Decommissioned Nuclear Submarines

Thursday, February 24, 1983

Department of Water Resources
1416 9th Street
Sacramento, California

Morning Session

Reported By: Theresa French, CSR No. 5750
Ida Ruth Lundsten, CSR No. 5751

Sacramento, California

February 24, 1983

--oOo--

CAPTAIN EDWARD F. WAGNER: Ladies and Gentlemen, if you would please take your seats, we will convene this hearing.

Good morning, ladies and gentlemen. This hearing is called to order. I am Captain Edward Wagner, and I work in the office of the Deputy Chief of Naval Operations for Submarines. I have been appointed the Navy Hearing Officer for this morning's public hearing.

Here with me to present an opening briefing is Mr. James Mangeno, Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program.

This public hearing is being held to receive comments on the Navy's Draft Environmental Impact Statement evaluating alternatives for disposal of nuclear powered submarine reactor plants after the fuel has been removed and the ships are no longer needed. The Navy has conducted studies on the feasibility of burying the defueled reactor plants in government-owned land disposal sites or placing them on the deep ocean bottom.

On December 22, 1982, the Navy announced in the Federal Register the availability of the Draft Environmental Impact Statement or DEIS on the disposal of decommissioned, defueled nuclear powered submarines. The DEIS contains the results of the Navy's studies of the alternatives available. On the registration table, as you entered this auditorium, you'll find copies of the Summary of the Draft Environmental Impact Statement. Anyone in the audience who would like a complete copy of the DEIS should leave their name and address at the registration table on the sheet of paper provided and a copy will be mailed to you.

The Navy's Federal Register announcement also scheduled public hearings at various locations which are convenient to people with an interest in this matter in order to provide them with an opportunity to present their views. I am here today to conduct one of these scheduled public hearings. The purpose of this hearing is to take testimony regarding the Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case nor to engage in debate. It is my responsibility to receive statements so that they can be considered in preparing the Final Environmental Impact Statement.

I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established for this hearing. As set forth in the announcement of the hearing, individual speakers are to limit their testimony to five minutes each, and organizational spokesmen are limited to ten minutes unless additional time had been requested in advance. Time cannot be relinquished from one speaker to another.

In order to insure all who desire to speak are given an opportunity, each person should fill out a registration card and provide it to the registration table. All testimony will be recorded so that it can be considered in the development of the Navy's Final Environmental Impact Statement.

If you desire to submit written comments rather than speak, that is acceptable. You can provide written comments to me or you may leave them at the registration table. If you desire to provide written comments at a later date, you may mail those comments to me at the following address: Captain Edward F. Wagner, W-a-g-n-e-r, U. S. Navy, Office of the Chief of Naval Operations, OPNAV-22, that's O-P-N-A-V dash 22, Department of the Navy, Washington, D.C., zip code 20350.

You should provide your written comments by March 31st of 1983, which as stated in the Federal Register notice is the cutoff date for submitting comments.

Before we begin receiving testimony, I would like at this time to introduce Mr. Mangeno of the Naval Nuclear Propulsion Program who will provide a general overview of the issue the Navy is addressing and the content of the Draft EIS.

--o0o--

CAPTAIN WAGNER: Mr. Mangeno?

JAMES MANGENO,

Deputy Director of Nuclear Technology for the Naval Nuclear Propulsion Program.

Today's hearing is being conducted as a part of the decision-making process required by the National Environmental Policy Act. Under this law, the Navy must prepare an environmental impact statement for any action which could have a significant environmental impact or which might be subject to controversy over the environmental effects. The environmental impact statement must include the environmental impacts for all reasonable alternatives.

The Navy's Draft Environmental Impact Statement or DEIS on this subject provides the basis for these hearings and the slides that follow are from the DEIS. It describes the alternate ways the Department of the Navy, in cooperation with the Department of Energy, is considering for permanently disposing of defueled nuclear powered submarines after they are no longer needed. The practical choices are bury the radioactive part of the submarine at an existing DOE land disposal facility at the Hanford Site in the State of Washington or the Savannah River Plant in South Carolina, or place the

entire submarine on the bottom of the ocean in water more than 2.5 miles deep.

In both choices there would be no nuclear fuel left in the submarine because all of it would be removed before disposal. Nevertheless, there would be some low-level radioactive materials left within the submarine.

Preparation of this Draft Environmental Impact Statement does not mean that the Navy has already decided to dispose of nuclear submarines. The Navy currently has about 120 nuclear powered submarines in operation and five submarines already in protective storage. However, as the number of submarines reaching 25 to 30 years of operation increases, as shown in this slide, it is evident that a disposal plan must be prepared for use sometime in the future.

This DEIS has been prepared now so that all interested agencies, organizations and private citizens can have their views on the available courses of action factored into the Navy's decision. Because this statement has been issued well in advance of any action, there is adequate time for such consideration prior to implementation of any decision.

The submarines are constructed with the nuclear power plant enclosed within a single section of the ship called the reactor compartment. This slide shows a typical submarine with the location of the reactor compartment identified.

Before a ship is taken out of service, the fuel is removed from the submarine in a process called defueling. This defueling removes all of the uranium and all of the fission products. The removed fuel is handled according to established procedures and is not discussed in the DEIS because it would not be included in the disposal of submarines. This defueling removes most of the radioactivity from the ship.

The next slide shows a simplified picture of the nuclear power plant inside the reactor compartment. During operation of the ship, some of the neutrons travel from the fuel, which is installed inside the high-strength steel reactor pressure vessel, the metal structure supporting the fuel to the reactor vessel, and to other equipment in the reactor compartment where they are captured in the metal and cause it to become radioactive. The radioactive atoms which were formed in the metal structures in the reactor compartment would be contained by the hull of the submarine and by the reactor vessel and coolant piping.

In addition to these containments, the radioactive atoms are an inseparable part of the metal and are chemically just like the rest of the iron, nickel or other metal atoms in the reactor plant. These atoms can only be released from the metal by the slow process of corrosion, like the rusting of common iron or steel.

This slide shows the important radionuclides which would remain in the ship six months after the final operation

of the nuclear reactor and the number of curies of each radionuclide at that time. A curie is a measure of the amount of radioactivity present, but it is not an indication of the possible effect on man or animals. The amounts and kinds of radioactive atoms present are described in detail in Chapter 1 of the DEIS.

As shown in this slide, the amount of radioactivity in each submarine will constantly decrease with time, regardless of the method chosen for disposing of the submarine.

One way to permanently dispose of the radioactive material remaining after the fuel is removed would be to bury the metal components inside the reactor compartment at one of the Federal Government disposal facilities already used for such low level radioactive waste at the Hanford Reservation in the State of Washington or at the Savannah River Plant in South Carolina.

The best way to accomplish this would be to leave the radioactive equipment installed in the reactor compartment, cut the compartment free from the remainder of the submarine and weld the reactor pressure vessel and the reactor compartment shut. This would provide an excellent container for permanent disposal and it would avoid the radiation exposure to shipyard personnel that would otherwise be associated with removal of individual parts.

The compartment would be loaded onto a barge and towed to a river landing near the Hanford or the Savannah River Plant site. Other government-owned land disposal sites have been considered for reactor compartment burial, but all except the Hanford and Savannah River Plant sites were eliminated from consideration, primarily because the others were too far from navigable waterways so that transportation of the reactor compartment to those sites would be impractical. The Hanford andSavannah River burial grounds are described in Chapter 1.

A transporter of the sort shown in this sketch would then be used to haul the compartment overland to the burial location. There is little risk of radiation exposure to anyone in the general public during movement to the burial ground, actual burial or after burial. This is because radiation outside the compartment would be well below federal limits and the reactor compartment would have been welded shut at the shipyard to prevent entry.

These compartments could be buried in accordance with existing requirements for burial of low level radioactive wastes. The reactor compartments would be physically larger than packages currently being buried at these locations, but the amounts of radioactivity would be consistent with current burial and would result in no significant additional environmental effects.

Because the radioactive atoms are a part of the structural metal itself, they cannot be readily taken into the

body. More than 200 years would pass before the reactor compartment bulkhead could be penetrated by corrosion, rust. Following the penetration of this exterior containment, the reactor pressure vessel inside would remain intact for a long time exceeding several thousand years. Corrosion of the metal inside the reactor vessel could only then slowly release the remaining radioactive atoms.

Disposal of the reactor plants by sinking the entire submarine into the deep ocean is another practical alternative. The maximum radioactivity would be less than the limit specified by international criteria and the triple containment provided by the submarine reactor compartment, by the reactor vessel and piping, and by the radioactive atoms being a part of the metal itself would be an extremely strong and effective disposal containment package.

Locations for possible oceandisposal have not been selected. If ocean disposal were selected by the Navy, a separate process would be required to obtain a permit from the U. S. Environmental Protection Agency. Part of that permit process would include the selection of ocean disposal sites. Separate site-specific public hearings would be required and the permit process is not part of this DEIS.

However, two study areas in the Atlantic Ocean about 200 miles east of Cape Hatteras, North Carolina, and another in the Pacific Ocean centered approximately 190 miles west of

Cape Mendocino, California, have been used to perform extensive research on currents, sediments, geology, chemistry and marine biology for very deep ocean locations. The depth of the water in these areas is between 4,000 and 5,000 meters, that's 13,000 to 16,000 feet. The scientific information and measurements collected in these areas have been used to make technically well-founded estimates of the potential effects of ocean disposal. The study areas in the Atlantic and Pacific Oceans were also selected to be typical of any site that might be chosen under existing international rules for ocean disposal so that environmental impacts could be calculated using realistic data.

Preparations for ocean disposal would be made at one of the shipyards normally servicing nuclear powered naval vessels. Following defueling, the reactor vessel and the reactor compartment would be filled with water to prevent crushing during sinking and sealed.

Research and analyses have shown that the submarine would reach the deep ocean floor with the containments provided by the hull, the reactor vessel and piping and, of course, the metal itself completely intact. Most of the radioactive atoms imbedded within the metal would have changed to nonradioactive atoms before corrosion could penetrate the hull and piping or free the atoms from the thick metal.

A comparison of the possible effects on the

environment associated with ocean and land disposal has been presented in Chapter 4 of the DEIS. This slide shows the conservative estimates of the possible radiation exposure to a person from 100 submarine disposals for the year of greatest exposure for both options. This table shows that the radiation exposure would be very small and could have little impact on individuals or the population. These levels are also many times less than any limits established by U. S. regulations or international limits. They are much smaller than the normal fluctuations in annual average background radiation exposure for U. S. residents.

A perspective on radiation exposure can be gained by examining the exposure a person would receive from natural cosmic background radiation if he flew round trip from New York City to Los Angeles. That person would receive approximately two millirems more radiation than if he had not made the trip because there is more cosmic radiation at higher altitudes where the atmosphere is less dense.

Another perspective is that the exposure to an individual watching television two hours each day for a year would be approximately one-half millirem.

Other environmental impacts are similarly small for both options. The effects on animal life would be small and localized in either case. Land burial of 100 reactor plants would require only about ten acres of land and disposal at sea would actually occupy about the same area, with the submarines arranged over approximately a square ten miles on a side.

The costs for disposal of a submarine have been estimated and are shown in this slide. The least expensive method for land disposal would cost about forty percent more, about two million dollars per submarine more, than sea disposal.

The "no-action" alternative is to place submarines in floating protective storage for an extended period, commonly called "mothballing." However, this would only temporarily delay disposal because it does not provide a permanent solution and permanent disposal would eventually be required. Protective storage would increase the costs. Since potential exposure to the public would be so small for the other alternatives, there is no advantage to be gained.

In summary, there would be no significant environmental impact from any of the disposal methods, and the estimated radiation exposures for the general public would be very small for all available courses of action.

Thank you.

CAPTAIN WAGNER: Thank you, Mr. Mangeno.

--o0o--

CAPTAIN WAGNER: Ladies and Gentlemen, Mr. Mangeno's presentation concludes our formal portion of this morning's hearing. I will now recess briefly to establish an order for persons who wish to speak. For those people who would like to testify and who have not yet registered, you may do so at this time.

We will now take a ten-minute recess, and we'll reconvene the hearing at 9:45 and start testimony.

(Brief recess)

CAPTAIN WAGNER: Ladies and Gentlemen, if you will please be seated, we will reconvene the hearing.

Ladies and Gentlemen, this hearing is going to reconvene. If I could have your attention, I will explain the order for testimony.

Simply to establish an order for the statements, I intend to ask individuals representing State government organizations to speak first in alphabetical order of the speakers' last names followed by individuals representing local government organizations, also in alphabetical order by last name of the speaker and then private organizations and private citizens in alphabetical order by last name of the speaker.

I request your cooperation in providing comments within the time limits established so that we may be certain all who wish to speak have an opportunity to do so. Once again, that's five minutes for individuals and ten minutes for organizational spokesmen. If your statement is so long that it cannot be provided within those time limits, then you may summarize in the five- or ten-minute period, and the entire statement will be included in the record if you submit it in writing.

The procedure for public testimony will be as follows: I will announce each registered speaker. When called, please proceed to and use the microphone here in the front of the auditorium. We're going to use the one microphone for the convenience of the press this morning. State your name and organization, if any. Even though I announce your name, I'd like you to state it properly for the record and your organization, if any. All comments are to be addressed to me, please.

--o0o--

CAPTAIN WAGNER: I'm honored this morning to announce as our first speaker the Honorable Leo McCarthy, Lieutenant Governor, State of California.

LEO T. McCARTHY,

Lieutenant Governor, State of California.

Thank you, Captain Wagner, and I'm very appreciative first of all of your being here to hold this hearing. Am I at a microphone?

CAPTAIN WAGNER: Yes, sir.

MR. McCARTHY: All right. I'm appreciative of being here to -- that you're even holding this hearing so that those of us in elective office and other citizens of California can give our views on a very critical issue, and you indicated the first capacity in which I appear as Lieutenant Governor of California. I'm here as a co-author of Senator Barry Keene's 1982 resolution in which the legislature directly asked the President and the Congress to ban the dumping of radioactive wastes, specifically including the scuttling of nuclear submarines, in our coastal waters.

It's difficult to approach today's hearing without somehow feeling that we're the targets of an aggression by our own federal representatives. It's difficult to -- and I also find it difficult to accept that those who insist on what

#65

I perceive as a kind of deadly nuclear littering as cost effective as clear public policy thought. It's not difficult to understand the thinking of Congress when it recently voted with bipartisan support for a two-year moratorium on ocean dumping, this after nearly 50,000 barrels of radioactive waste had already been dumped off California's coastline. That two-year moratorium is barely started, and yet here we are seriously discussing plans to go ahead and commit an act of national litterbugging and deliberate disregard of the known and unknown dangers that I think it might cause us, and with all due respect, this is not a decision really to be made just by the United States Navy or in the corridors of the Pentagon. The responsibility must fall where it belongs, on the President and the members of Congress, our elected civilian policy makers. It was to them last year that California's Legislature addressed Senator Keene's resolution which urged no more dumping of radioactive waste off our coast until it has been proven safe by valid and reliable scientific studies. So far, no such studies have been conducted that are known to us. To the contrary, each passing year reveals more evidence seriously questioning the scientific basis for believing ocean dumping to be safe.

L.6

L.6

There were promises that there would be monitoring of the 50,000 barrels of nuclear waste already sitting off our shores. Those promises I don't think have been kept because

the Environmental Protection Agency has changed its program priorities.

So we are told it is cost effective to dump nuclear submarines into the ocean where their radiation can so easily affect the sea life upon which this hungry world depends. And we are also told that it isn't a high priority to check up and see what that radiation is doing.

N.3

L.6

This is clearly another of the growing problem of toxic waste in our society, a danger from which politicians, including me, are supposed to be protecting the public or trying to protect them. If the United States Government can respond so promptly to public concerns over dioxins in Missouri, surely this issue is important enough to warrant some prompt and serious attention by the President and by the members of Congress.

The Navy says its plan to scuttle 100 nuclear subs off the Northern California coast is perfectly safe yet it has chosen an area quite close to geographic fault lines which pose enough of a threat to us on their own without the added ability to unleash a wave of radioactivity along with the next earthquake. They're quite common here as you know.

J.19
F.22

We know there are alternatives for handling decommissioned nuclear submarines. Land disposal of the radioactive elements is one option, not a happy one, but a better option than this one we're considering. Mothballing the submarines for possible

G.2, G.3 later use or later disposal is another option. I suggest to you that this plan is really not an option we should be seriously pursuing.

L.22 Given current evidence that leaking radioactivity does not harmlessly disperse in ocean water but instead it sinks to L.36 be absorbed into the bottom sediment there to become part of the food chain, this ocean disposal is many things. I see it as foolhardy, it's high risk, perhaps ultimately self-destructive. I do not consider it a reasonable option.

The danger of this procedure, in my view, is not eliminated merely by moving it offshore. It is merely disguised, and that may make it all the more dangerous.

J.9 The day may come when scientific research indicates a way to safely use the ocean depths for disposal sites, a day W.1 when we are so certain that we can afford to set a course which is almost irreversible. I don't see that day as having arrived.

The day which has arrived is this one when so many of us are here to deliver to you, in respect, the same message. We will not willingly accept further designation of our coastline as a nuclear garbage disposal. We will not willingly N.3 accept the risk which we are being asked to take in the name of cost effectiveness.

Our message is simple and please listen to us and carry it back. I will represent the responsibility of communicating directly with the President and the members of Congress.

Thank you very much for your courtesy.

CAPTAIN WAGNER: Thank you, Mr. McCarthy.

--o0o--

198

#66

CAPTAIN WAGNER: I am pleased to announce our next registered speaker, Ms. Susan Wade from the U. S. House of Representatives Merchant Marine and Fisheries Committee. Ms. Wade is speaking for Congressman Douglas Bosco and Congresswoman Barbara Boxer.

SUSAN O. WADE

Thank you, Captain Wagner. My name is Susan Wade, and I'm on the staff of the U. S. House of Representatives Committee on Merchant Marine and Fisheries. Our committee maintains legislative jurisdiction over the Marine Protection Research and Sanctuary Acts which governs ocean dumping including low level nuclear waste on the Navy submarines. It is in the capacity of committee observers that I'm attending the hearing today. However, additionally, because they cannot be here, two members of our committee also California Representatives, have requested that I read the testimony which they have prepared for today's hearing. I am pleased to do so. The first will be on behalf of Congresswoman Barbara Boxer. The second on behalf of Congressman Douglas Bosco.

It reads, "Statement for Testimony at U. S. Navy Hearings in Sacramento, February 24, 1983, on Draft Environmental Impact Statement Regarding Disposal of Nuclear

Submarines.

"Nuclear waste disposal is one of the most critical and sensitive issues of our time. The process by which we confront the difficult decisions surrounding this issue has ramifications today and for generations to come.

"Whether we are talking about Cobalt 60 with a half-life of 5.2 years or Plutonium with a half-life of 22,000 years, the issue must be addressed as a whole. Whether we talk about 47,500 fifty-gallon drums which were dumped off the Pacific and Atlantic coasts in the years between 1946 and 1970, or about 100 nuclear submarines each of which would equal fifty percent of all nuclear waste dumped in the sea prior to the present ban, the issue is the same: Where is the safest possible place to store radioactive waste?

"We are treading down a path upon which errors, poor decision-making, inadequate data gathering or dangerous precedent setting would prove most unforgiving in the future. The history of toxic waste disposal -- nuclear or otherwise -- is already rife with examples of bad planning, insufficient monitoring, ill informed decision-making, and consequent health and safety impacts.

"As we prepare to step further down the necessary decision-making path on the nuclear waste disposal issue, the public would like to feel secure in the knowledge that the appropriate steps all have been taken, that all the facts and pieces of the puzzle are in hand before we proceed.

"After review of the DEIS on the proposed ocean alternative for nuclear submarine disposal, I find it inadequate in the following respects:

J.76 "No. 1, the monitoring program proposed in the DEIS

I.13 is inadequate for either sea or land disposal of nuclear submarines.

L.7 "No. 2, cumulative impacts of incremental increases in radioactivity entering the marine environment from these submarines are not considered in the DEIS.

H.3 "No. 3, the disposal alternative which minimizes corrosion and hence release of radioactivity has not been considered in this document. A monitored land disposal option which considers placing the reactor compartments in the least corrosive terrestrial environment -- namely, placing the compartments on land, unburied -- should be considered.

J.76 W.1 "No. 4, placing submarines on the seabed makes monitoring extremelty difficult. Retrieval, if problems arose, would be virtually impossible, according to the Navy's DEIS.

"No. 5, California is home to a multi-million dollar

L.53 fishery. Any potential leakage of radiation and consequent uptake by the flood web could have catastrophic impacts on the economy and potentially on human health.

"No. 6, finally, and of paramount importance, the DEIS states that the key questions and information regarding

L.1 bioaccumulation and ecological transport are still unanswered. Until the scientific community and all the public have all the information on what potential marine impacts and social and biological costs may be, no decision can be made. Fundamental biological answers are the key to decision-makers' questions, and we don't have them.

"In summation, the combined concerns and data gaps as indicated in my testimony bring me to speak against the sea disposal option as presented." Barbara Boxer, Member of Congress.

Miss Boxer invites you to contact her with any questions at her Washington address: 1517 Longworth Building, Washington, D.C. 20515, phone number 202-225-5161.

Now I will read the statement prepared by Honorable Douglas H. Bosco, Representative in Congress from the State of California.

"I appreciate the opportunity to comment today on the Navy's Draft Environmental Impact Statement on the disposal of nuclear submarines. The many serious questions raised by the DEIS demand thorough public review and scrutiny.

"From the outset, however, I wish to express my concern

J.15 over the Navy's refusal to hold public hearings on the DEIS in either Fort Bragg or Eureka, California. Council on Environmental Quality regulations for DEIS preparation state the need to quote, 'describe the environment of the area to be affected or created by the alternatives under consideration.'

"With the designation of an area off Cape Mendocino for generic scientific studies, the residents of the North Coast of California are obviously concerned over the future of their environment. Who is in a better position to describe the many facets of their environment than these residents? They should be afforded the ample opportunity to comment on the ocean disposal option, and the impact such disposal may have on the North Coast.

"As stated in a formal request by all twenty eight Democratic members of the California Congressional delegation, both the time and location of these hearings may prevent access to many concerned citizens. I would hope the Navy reverses its position and expands these hearings for the citizens of Mendocino, Humboldt and Sonoma Counties.

L.9 "Beyond this, I would like to address two basic concerns: the precedent that low-level radioactive waste disposal could set, and the counterproductive nature of this DEIS in alleviating public concerns over ocean disposal.

"As the Navy has stressed, all nuclear fuel and its accompanying uranium and fission products will be removed from each submarine before ocean disposal. The DEIS estimates the radiation exposure to people from remaining materials would be less than natural background radiation. An important variable in this 'low-risk' disposal option, however, is careful site selection. State and local government, as well as

individual citizens, are concerned that conditions making an area acceptable for low level waste disposal will later be viewed as conducive to future high-level waste dumping as well.

"Actual ocean conditions making areas off Cape Mendocino preferable for generic scientific studies or low-level waste disposal will still exist should the Navy or some other governmental department deem further dumping necessary in the future. Unless it is dealt with responsibly, the controversy over the ocean dumping proposal could also result in increased public opposition to alternative means of disposal in the future. L.9

"The unique and delicate nature of California's natural resources is the lifeblood of its major industries. The residents of this area are obviously opposed to making the California coast a dumping ground for national problems. This natural concern of North Coast residents has been exacerbated by several factors associated with the DEIS. It has actually increased fears about offshore dumping rather than allay them.

"First, a detailed environmental impact statement is required for federal actions significantly affecting the quality of the human environment. Yet in defining the very basis for an EIS, the Navy overtly states its bias against very real environmental concerns of the public. The foreword to the DEIS indicates the need for study of the submarine disposal options because of 'anticipated high interest rather than the expectations that either option would significantly affect the quality of the human environment. Potential dangers associated with any release or dispersal of radioactivity place a premium on insuring that all environmental and economic considerations are carefully weighed. Publicly defining the government's expectations before a nonbiased, scientific appraisal of the options can be made does not engender much public confidence in the conclusions reached.

"Also, the highly technical nature of the generic scientific studies used to support the DEIS are difficult for the non-scientist to assess adequately. The selection of areas off Cape Mendocino for generic studies entails technical analysis regarding currents, temperature and geochemistry. Allowing just sixty days for public consumption, analysis and comment will only add to the concerns of many who feel the Navy is not soliciting sufficient local input. With so much at stake, it is important that local government and residents not feel shut out from the impact assessment process because of strict time constraints.

"All involved interests would greatly benefit from well-considered and thorough comments from the public. I would urge that the request of seventeen environmental and citizen organizations be granted in extending the comment period on the DEIS for ninety days to June 10th, 1983. Lack of

sufficient time for public review and comment could seriously jeopardize the Navy's attempt to obtain the cooperation of state and local interests.

"Furthermore, Section 1502.14 of CEQ regulations states the need to present alternatives in the comparative form. The DEIS should define the alternatives in detail, providing a 'clear basis for choice among options by the decisionmaker and the public.'

"While I do not wish to lay claim to any advanced scientific knowledge, detailed analysis appears absent from certain aspects of the ocean dumping alternative. There is certainly inadequate data and analysis, for instance, on possible effects on ocean food chain pathways. Leakage of concentrations of radioactive material into the food chain could have profound and unforeseen consequences. L.36 L.20 There is also insufficient analysis of the abundant marine life located near the Cape Mendocino site where studies were undertaken. J.9 These and other shortcomings in the Navy analysis of ocean dumping cannot be perceived as providing a clear basis for comparison with land disposal. I remain concerned that the 'easiest' and 'cheapest' way to dispose of aging submarines may not be the most environmentally sound. N.3

"In conclusion, I wish to urge the Department of the Navy to consider these factors in evaluating the DEIS on the most appropriate means of disposal. The [illegible], [illegible] and

L.53

environmental way of life of hundreds of coastal communities may be at stake in your decision."

That concludes Congressman Bosco's statement. He too has invited you to contact him with any questions at 1330 Longworth Building, Washington, D.C. 20515, area code 202, 225-3311.

Thank you.

CAPTAIN WAGNER: Thank you, Ms. Wade.

--oOo--

CAPTAIN WAGNER: The next registered speaker is the Honorable Barry Keene, California State Senator.

#67

SENATOR BARRY KEENE

I want to thank you for receiving my testimony today which is really a petition for redress of grievances both past and proposed. Under the Constitution of the United States, in discussing technicological safety, and I hope it won't be regarded as a cheap shot, but I couldn't fail to notice that the system, the sound system in this room was so far from fail-safe this morning at this important hearing at the most -- at the Capitol of the most populace state in the union that it almost drove all these people away, that I want to assure you that for every person out there now there are 100,000 people in California that are equally concerned about this issue. We Californians are very much a Pacific people. Every Californian lives near the shores of the Pacific Ocean. We visit it; we swim in it; we sail on it; we eat seafood from it; we earn our livelihood from it; we depend upon it fully. We're concerned about the fact that the Draft Environmental Impact Statement makes clear that the Navy plans to scuttle its decommissioned nuclear submarines still very highly radioactive probably off of Cape Mendocino in the area that I represent and the area that Congressman Bosco represents

***Other issues discussed by Senator Keene are side barred in Exhibit 67a.**

and the area that other congresspeople represent and the area that the Lieutenant Governor is so concerned about.

*G.2

The conclusion that it's preferable that sea disposal is preferable to burying submarines on land is a very questionable one, and there is the more practical alternative of storing them at land sites where the radioactive reactor vessels can be studied, monitored, and if necessary, retrieved.

L.9

And as concerned as we are about the more than 100 out-moded nuclear submarines, we are more concerned about the additional radioactive garbage that would be dumped in the new Pacific Coast dump site if the Navy initiates dumping there.

F.8

We know that once one federal agency such as the Navy begins dumping at Cape Mendocino or any other site, other federal agencies will follow suit. But worse still, so will other nations, and if that occurs, the same history that will now not let us forget things like the internment of Japanese-Americans in World War II, will not forgive and forget the fact that Americans led the way to making the oceans a nuclear dumping ground, a nuclear sewer, and we can't let that happen because we're too proud of ourselves.

L.7

In the language of federal law, we are concerned about the cumulative impact of all past and future radioactive pollution of the Pacific from the South Pacific nuclear weapons tests, fallout from nuclear explosions around the world, past dumping by this country and other countries, other future

dumping. We're concerned about natural background radiation and all other radiation sources. We're concerned that together they could raise specific ocean radiation to very, very harmful levels.

L.7

A year ago, on February 18th, 1982, I wrote to you, Captain Wagner, to call your attention to the fact that the annotated outline of this report failed to consider the cumulative impact as required by the Federal Council and Environmental Quality Regulations that implement NEPA, a National Environmental Policy Act. The response assured me that the report would "include a consideration of cumulative impacts of action in compliance with the Council on Environmental Quality Regulations."

However, as far as I can tell, that consideration does not appear in this report. In passing Senate Joint Resolution 27 last year, the California Legislature opposed dumping of radioactive wastes in the Pacific until and unless future scientific studies proved it to be safe. This report does not prove that the cumulative impact is safe. It doesn't even try. We cannot comment on its data and its conclusions about the cumulative impact because it presents none. We can only comment on its data and conclusions about the facts of scuttling the more than 100 nuclear submarines that the report does discuss.

Independent scientists who have studied the report

*Other issues discussed by Senator Keene are side barred in Exhibit 67a.

are best qualified to comment on the quality of its research. Some of them will testify later today, Dr. Michael Herz, for example. A biologist with the Oceanic Society will present evidence suggesting that the report relies on skewed data on the rich commercial albacore catch at the Cape Mendocino site.

Other scientists still are conducting their studies of the report and intend to submit written comments before the deadline. I've asked and I ask again now that the deadline be extended until June 30th to allow them to prepare and submit the most useful comments possible on this important question. Commercial fishermen who fish the Cape Mendocino site are best qualified to comment on the data and conclusions about what fish are found at the site and what concentrations; about whether there is significant upwelling that would bring radiation to the surface quickly; about which way and how fast the prevailing currents could carry that radioactive pollution; and about vessel traffic in the area.

J.15 Some of the fishermen will testify later today. More will testify if you grant the request that I and many others have made, and then I repeat now for local public hearings in Fort Bragg and Eureka, the two major fishing towns nearest the Cape Mendocino site.

I do wish to note one more flaw in the data that the report presents to support its conclusion on what the Navy considers the key factor, the turning point on this issue, and

that's dollar cost. In the abstract on the title page and throughout the rest of the report, it concludes again and again that the only reason to prefer scuttling over land burial is its lower cost. The report even fails to consider the exorbitant cost of the eternal monitoring of the scuttle submarine that would be required under existing federal law, J.76 and incredibly the report fails to present any data or calculations to support its conclusion about dollar savings. O.2

Finally, I will also note one other major flaw in the data and conclusions on what I believe to be the key factor, retrievability or the lack of it. The report ambiguously states that retrievability would not be possible with current technology. Now, if you look at those words, the conclusion is very ambiguous. It's undocumented in the first place, but W.1 what does it mean? Does it mean on the one hand that the submarines might become retrievable with some future new technology? If so, we should be able to be informed because we wish to be an informed public in assisting in this decision. We need to know what that new technology is that is contemplated and how much it will cost and add to the cost of ocean dumping. If not, the report should state honestly that the submarines, once sunk, will be irretrievable. We should say clearly that if scuttling later proves to be a mistake, it will be an uncorrectable one and the submarines will be out there emitting radiation into the Pacific Ocean for thousands and thousands of years.

In concluding, let me simply state, and we must remind ourselves of this from time to time, I do, others must, government is charged with protecting, protecting the lives and safety of its people, not creating risks to them. The words of Lincoln -- the words of Lincoln always come to mind. He said it was a government of the people, by the people, for the people, and not a government against the people.

Thank you very much.

CAPTAIN WAGNER: Thank you, Senator Keene.

--o0o--

CAPTAIN WAGNER: Our next registered speaker is Mr. Peter Douglas representing the California Coastal Commission.

#68*

PETER DOUGLAS

Thank you, Captain Edward. My name is Peter Douglas. I'm Chief Deputy Director of the California Coastal Commission, and for the record, I want to indicate that we will be submitting written comments on the Draft Environmental Impact Statement to you within the deadline that exhaustively goes over the various points concerned to us.

The California Coastal Commission is responsible for implementing the California Coastal Act of 1976. This statute is the main component of the California Coastal Management Program which has been approved by the Federal Government for carrying out national coastal policies as well as State coastal policies, and under federal law, the Coastal Zone Management Act, enacted in 1972 -- in fact, a month before the citizens of California passed Proposition 20 -- the Federal Government may not conduct activities which directly affect California's coastal zone unless the federal agency undertaking that activity first determines that the activity would be consistent with the maximum extent practicable with the California Coastal Management Program, and then that determination must be submitted to the California Coastal Commission which would

F.11*

*Other issues discussed by Mr. Douglas are side barred in Exhibit 68a.

either concur or not concur in that determination.

If the Coastal Commission disagrees with the determination of consistency, the activity may not take place unless the federal agency is prohibited by some other federal law from complying with that state law, and I think that's a very important point to make because I notice that there has been no mention made that the State of California does have a vehicle, a handle, through which to review this proposed activity.

The Coastal Commission staff, based on the information that we have been able to review to date, is of the opinion that the activity proposed, the scuttling of nuclear submarines off the coast of California would directly affect California's coastal zone, and that, therefore, a federal consistency determination would have to be made and that consistency determination would have to come to the Coastal Commission for review.

The Coastal Act of California calls for the maintenance, enhancement and restoration of marine resources. Under the Coastal Act, uses of the marine environment shall be carried out in a manner that will sustain the biological productivity of coastal waters and will maintain healthy populations of all species of marine organisms adequate for the long-term commercial, recreational, scientific and educational use of the people.

The effects of any ocean dumping of radioactive wastes would have to be measured against these and other Coastal Act provisions.

I think the main concerns that we have, and I'm not going to go over all these. I have this statement in writing and will submit it to you, but we are concerned about the bio-accumulation of radionuclides through the marine food chain; we're concerned about radiation in marine waters that can affect the fecundity of fish, most especially currently over-exploited fish species; direct and in part perceived in terms of what the impact of the disposal of radioactive materials offshore California would be.

If the consumer knows or feels that fish and shellfish are coming from coastal waters where radioactive wastes have been recently dumped, the purchaser is quite likely to avoid fisheries' products from California. Consumer avoidance or rejection of fisheries' products due to potential radiation damage would devastate coastal fisheries in California.

We think that kind of an impact must be considered and is a direct impact.

The cumulative effects of a disposal of radioactive wastes in the Pacific Ocean must be carefully assessed. Nuclear wastes have been dumped at several locations off the California coast and numerous other places in the Pacific, and accurate records have not been kept. Some monitoring of

NOTE: The issues discussed by Mr. Douglas are side barred in Exhibit 68a.

existing dump sites has been done, but these studies and this monitoring has been quite cursory. Little definitive information has been generated about the fate and effects in the ocean and on the ocean of the various specific types of radioactive wastes that have been dumped.

The Navy's consideration of scuttling nuclear subs off the Mendocino coast is the most immediate and alarming proposal to reestablish the use of California's ocean waters offshore California as a radioactive waste receptacle. One of the most significant issues that has to be addressed, as Senator Keene pointed out, is the retrievability. If serious problems are discovered after the marine disposal of the radioactive wastes, it would be nearly impossible, if not actually impossible, to take any corrective action at that point.

In reviewing a future federal consistency to scuttle nuclear submarines off the California coast, the Coastal Commission would have to consider several -- would expect that several issues be adequately addressed through the provision of adequate information, thorough information that would give us answers about certain -- about these following points: ocean currents, for example. We need a detailed assessment of current conditions and a model projecting the maximum movement of radionuclides dumped where they are dumped. The movement, potential movement of those wastes, is going to be very important to know.

The geology of the earth. What is the seismic history of the area? What is the likelihood of major seismic activity? What effect would an earthquake have on the dumped material?

As to living marine resources, we would need a detailed survey of the plants and animals which inhabit or pass through the dump site. An accurate mapping of all fish breeding and spawning areas is also necessary. This data must be carefully correlated with water movement data to determine potential effects on fishery stocks. How do these particular radionuclides react in seawater? What are the potential synergistic effects? The question of bioaccumulation must be addressed in detail.

Dumping of nuclear wastes in California's ocean waters would certainly affect the public's acceptance, if not the direct productivity and vitality of fisheries offshore. So the fishery, the impact on the fisheries must be addressed.

And then I think one of the most important aspects of it, and that is the precedential effect of such an activity and the cumulative effect of dumping radioactive waste off the shores of California.

In conclusion, the California coastline is the gateway to the Pacific Ocean for millions of visitors from throughout the world. The Pacific is a rich source of food for mankind and an important element in the California and national economy. It is critical to the well-being of California, the nation and the world that the biological health and productivity of ocean waters along the coast be vigorously protected and preserved. The vitality of this rich environment should not be jeopardized by a quick fix solution to the long-term problem of nuclear waste disposal.

Thank you.

CAPTAIN WAGNER: Thank you.

--oOo--

CAPTAIN WAGNER: The next registered speaker is Wesley Chesbro from Humboldt County.

#69

WESLEY CHESBRO

Captain Wagner, as you said, my name is Wesley Chesbro. I'm a member of the Humboldt County Board of Supervisors, and today I am representing a unanimous position of the Board of Supervisors that probably doesn't agree unanimously on anything else. I think you're going to hear perhaps an expert soon from the Mendocino County Board of Supervisors, and I think they could say the same thing, they too are unanimous on this issue.

First of all, thank you very much for the opportunity to present our board's views on the subject of nuclear submarine disposal. Although we appreciate any opportunity to have input, we feel that the Navy is missing out on a full and accurate representation of viewpoints by not holding a hearing on the North Coast where this submarine graveyard is to be proposed. The Humboldt County Board of Supervisors joined with other local governments up and down the coast in asking for hearings in Mendocino and Humboldt Counties. Today we once again formally request that you come to the North Coast and sample the opinions of those who will be most directly affected by this proposal.

J.15

On March 2nd, 1972, the Humboldt County Board of

Supervisors unanimously voted to ask the Federal government to permanently ban the dumping of all nuclear waste, including decommissioned nuclear submarines off of the coast. I have included a copy of that resolution with this testimony which I gave to your reporter. You will note that we based our opposition at that time, and it continues on this basis, to be on the following:

L.53 First, Humboldt County's economic dependence on offshore waters for commercial and recreational fisheries; L.6 and second, past record of radioactive contamination to ocean sediments and the marine environment.

W.1 J.76 Since that time, we have become alarmed at several other aspects of the proposal: the physical inaccessibility of the ocean dump site for both monitoring and for retrieval should problems develop; the failure by the Navy thus far to adequately address the questions of monitoring and retrieval; O.34 and the economic impacts on the tourism and fishing industries of public perception that a hazard exists.

F.22 We are also concerned that the Navy has underestimated the potential for radioactivity resulting from loss of containment due to seismic activity.

I will deal with these points one at a time. First of all, the offshore fishery is a critical element in our local economy. Our economy has been hard hit by the recession in our largest employment sector, the timber industry. And the

fishing industry has been hard hit on a number of fronts, not the least of which is government action and regulation.

Our fishermen are for the most part independent business people who are struggling along in an extremely adverse economic climate to put food on America's dining table. The fisherman does not need, and thus America does not need, for the habitat of this important resource to be threatened by disposal of the Navy's castoff radioactive garbage. You may think that you are considering a proposal to throw these subs away, but let me assure you that there is no "away." What we put down there will come back to haunt us. L.20

The albacore catch data shown on page E-11 of the Draft Environmental Impact Statement is out of date and does not properly reflect the current importance of the proposed dump area to the albacore fishery. J.12 The data is 13 to 21 years old. Substantial changes in the fishing fleet have occurred since then, and the capability of more modern vessels has dramatically increased the importance of the area directly overlying this Pacific Ocean study site to the albacore fishery.

In addition, the grenadier is a fish species that has exhibited uptake of radioactive materials. And the grenadier or rattail fish as it is also known, and I believe it's referred to in the EIS, is commercially important. U.9 Eighty thousand pounds were landed in Humboldt Bay last year. The DEIS fails to discuss this biological pathway, a pathway which T.19 T.20

could substantially increase the availability of radioactivity to the populace.

F.12 There is a bank of data and research on the migration of radionuclides from waste forms to the water column, sediments and to marine life. The DEIS has neglected to cite this important information in its consideration of pathways to humans.

The next major concern that we have is the physical inaccessibility of an ocean dumping ground for monitoring or retrievability. The DEIS states that there is no significant difference between the land disposal option and the ocean disposal option.

Such a statement neglects the obvious, that a land disposal option would allow for a much greater degree of monitoring and mitigation should safety or health threatening situations arise. The DEIS states that 20 years of protective storage or mothballing would reduce the quantity of radioactive material by a factor of four, yet considers this to be no significant advantage. G.2 From the standpoint of public assurances, such storage would seem to be far preferable to immediate disposal.

W.1 It is clear that once these subs are down there, there is no cost effective way to bring them back up should problems develop. This fact alone renders the idea of ocean disposal to the realm of complete nonsense.

Another concern on the north coast is the impact on the economy of our area that will result from the failure of public confidence in the safety of our natural environment and the desirability of one of our most important export products, seafood. These concerns are reflected in the opposition to this proposal by two important north coast business groups: the various associations of commercial fishermen on the one hand and the Redwood Empire Association which is the north coast's leading tourism industry association on the other. And I believe you have received written opposition to the proposal from those organizations, and you'll probably be hearing testimony later today.

From an economic standpoint, public perception among tourists and purchasers of seafood that a hazard exists will be just as bad as the actual exposure. All it takes is for the question to be raised in the mind of the consumer or the traveler for them to reject the north coast and its seafood products in favor of an alternative.

On the question of accidental release of radioactivity, the worse case anlaysis presented in the EIS considers immediate loss of containment from the accidental sinking of one submarine. It is quite conceivable, however, that loss of containment by multiple vessels could occur at the disposal site should the area be subject to some ground-shaking stress. F.22

An estimate of such stresses are shown in the attached

U. S. Geological Survey Open File Report which I have included with the written version of my testimony. The Draft EIS does not contain information to determine whether or not such estimated stress would cause any disruption at the Pacific Area Site, and the final EIS should be amended to include such a discussion and should include a worst-case scenario for loss of containment that might occur due to such an event.

We would recommend adding to the list of disposal site criteria the following: that the site not be subject to J.19 ground-shaking stresses of a magnitude that could trigger sea flow disruption or loss of vessel integrity over the critical period of radioactive decay. We would also recommend adding to the list of pre-site selection monitoring, that seismographic sea floor monitoring be conducted in order to accurately determine the ground-shaking stresses of the site.

L.53 In conclusion, this is a dangerous proposal which threatens our fishing and our tourism industries. There are L.1 many unanswered questions, and the greatest problem with ocean disposal is that it is quite literally an irretrievable act. Once the subs are down there, should the answers to these W.1 questions begin to emerge as threats to the environment and public health, there will be no cost effective way to either assess or mitigate the danger.

Humboldt County does not want to be part of this dangerous experiment. Thanks, but no thanks.

I also have, for the record, a representation from a group that to my knowledge hasn't taken a political stand in years that voted this week to oppose this proposal, and I'd like to submit it for the record.

"Dear Secretary of the Navy Lehman:

"Freshwater Grange #499, P.O. Box 6153, Eureka, California 95501, at their regular meeting on February 22nd, 1983, with a membership of one hundred and forty-nine members, is opposed to any dumping of nuclear submarines off the Northern California Coast."

I'd like to submit that for the record, and I have additional copies of my testimony should they be required.

Thank you very much.

CAPTAIN WAGNER: Thank you, sir.

--oOo--

212

#70

CAPTAIN WAGNER: The next registered speaker is Mr. John Cimolina representing the Mendocino County Supervisors.

JOHN CIMOLINA

Good morning. My name is John Cimolina, and I represent the Fourth District in Mendocino County which is from Fort Bragg to the Humboldt County line, so you know that Cape Mendocino is on my doorstep.

Later on today the Chairman of our board, Dan Hamburg, will be making a formal presentation on our board position, and also Norman deVall who represents the south coast will also be making a more detailed presentation. Mine is a more personal message. All of the people in my district: fishermen, loggers, men, women, children, tourists, sportsmen, are unanimously opposed to any ocean dumping, period.

I am a life-long resident native of Fort Bragg. As a boy I lived a quarter of a mile from the ocean. When I got married and left the homestead, I moved another quarter of a mile east, so I lived in Fort Bragg exactly one-half mile from the ocean.

As a boy I played on the old wharf down where they used to load the tramp steamers with lumber and talk to sailors, and I spent quite a bit of time on the fishing boats at Noyo. I believed the fishermen and I believe them now when they tell

me that whatever you dump into the ocean, sooner or later she will cough it up.

The Navy has put together some of the finest research and development teams in the world. They are proud of these teams and rightly they should be. But the direction of the research of these teams has been directed towards the development of more and better and more sophisticated weaponry.

In the DEIS, what is not addressed and the message that I want you to bring back to your commander in chief is that you redirect the direction of these research development teams towards the development of a safe, permanent method of disposing of nuclear subs and/or radioactive waste so that you won't have to dump in the ocean where it will create a potential for disaster forever.

Thank you.

CAPTAIN WAGNER: Thank you, Mr. Cimolina.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Miss Judith Evered, representing Isla Vista Recreation and Park District.

#71

JUDITH EVERED

As you said, Captain Wagner, my name is Judith Evered, and I have come from Isla Vista, Santa Barbara County to voice our opposition to any more pollution of the ocean or the land. We traveled overnight Monday night to be at the hearings against Diablo -- PG&E's permit to dump radioactive water into the Pacific.

And we at the Isla Vista Recreation and Park District oppose any pollution of this coastline. We have the information now that the ocean is polluted. There was a spill at Humboldt County, PG&E Nuclear Power Plant in about 1975 where 2,000 or more gallons of radioactive water containing cadmium -- which is a cadmium, which is a carcinogenic material was dumped into Humboldt Bay.

L.6 | We know that the barrels of radioactive waste at the Farallon Islands, thirty-five percent of them are leaking.

A.19 | This heat in the ocean attracts fish, especially striped bass fish. And this is a staple diet of people along this coastline.

Off the Santa Barbara Coast are the Islands Channel Islands, Anacapa, and Semequl (ph.) And from the

years of '46 to '51, the Navy dumped waste there.

The manager of our park district went to these islands to try and find out what was happening to this waste. He couldn't find out. We still have to seek this information. We don't know at Santa Barbara if it's safe to swim in the ocean there. We don't know that it's safe to eat the fish that are caught off the coastline.

There are many activists in Santa Barbara. If you should try to put the subs off the Santa Barbara, you would meet just as much opposition as you are getting from the northern states.

And we are here today to speak against the subs being dumped because that would be an irretrievable and irremediable problem for the future. | W.1

We ask for the action of mothballing so that the technology can catch up. | G.2

We are also opposed to Diablo. And I have a -- very personal knowledge of the damage that low radiation can effect because in England, my first son was -- I had an x-ray before he was born -- that was in 1956, and that was just the year that the information was coming out about the bad effects of x-rays before birth. My son died at six years of age from cancer. And we really attribute this to low-level radiation of one x-ray. That's how little it took. So I didn't find this out until after I was a blockader. I was arrested twice in the 1981 blockade of Diablo. That's how strongly I knew and felt that radiation was no good for people.

We will -- I'm on the Defense of Necessity trial. We've a month-long testimony of San Luis Obispo and experts from all over this country came to testify against nuclear power plants. It's all the same problem. Once you get radioactive materials and energy, you have problems. People are going to die. You're committing to death a certain number of people, and you don't know who.

And the unconstitutionality of this is that those people who will be affected by this have no voice and no knowledge of what you're going to do or propose to do. We've already had deaths from nuclear power in this country. We don't know who and we don't know we can't prove that this causes this.

But I ask for a stay of this action until you have incorporated into your testimony works of John Gofman, Ernest Sternglass, Michiokaku, and Dr. Helen Caldicott from Australia, the country of my birth.

We know now that radiation is extremely hazardous. We know that we have a right to live in a safe environment, and we insist that you wait.

And I -- I am also a part of a process which is going to -- in this state called the Public Right to Know. And it's before the Santa Barbara Supervisors now as an

ordinance. And many areas in this state have passed these ordinances, which just means that the public has a right to know of the pollution against this earth.

If you would take note of this book. It's called "Nuclear California, an Investigative Report." It's the truth about the development of nuclear sites, nuclear weapons, nuclear transportation, nuclear dumping, nuclear power plants in this state.

You know, we might think that they have the problems in the east; the commercial fish are already tainted in the east. It's like Russian roulette if you should eat fish over there. Well, it's going to be the same here I'm sure. U.9

The problem is that the research has not been done to find out about the effects of nuclear materials in the ocean here. So I would just like to repeat that the public must be told. The public has a right to a voice. L.1

And I'm very appreciative, Captain Wagner, of your close attention today and the fact that you're taking this testimony and that it will have some impact on the decision makers.

There's a researcher at the University of California Santa Barbara by the name of Adrian Gleena (ph), and he has done research on crabs at San Onofre. And they're finding that the fertility of crabs has been greatly lowered by the fact that the San Onofre nuclear generating plant is admitting radioactive materials into the sea, even though they have a more advanced technology than what is proposed at Diablo Canyon because they have a closed circuit offshore cooling system whereby the radioactive water doesn't supposedly come into contact with the sea.

Now, Diablo Canyon has an open cooling system whereby the water is filtered through the plant and back into the sea. So therefore, Diablo Canyon Nuclear Power Plant is more antiquated in design than San Onofre -- San Onofre nuclear generating plant.

All I can say is first the fish -- first the filter feeders like the zoo plankton, the algae, the mussels who feed by filtering the materials at the bottom of the ocean and then the fish that we feed on feed on those. So it goes up the biological chain to humans. And eventually the humans will be tainted. So we really don't know what's going to happen. And I implore that you -- that more research be done and that you put a hold on every kind of nuclear dumping in the sea. And I'm sure that a lot of it originally was done in ignorance, but it was also done in secrecy.

L.36

And I am very grateful today for all the people that are here and for the government representatives who are voicing opinions of the people. And I begin that the tide is -- is really turning today. And this is an extremely exciting meeting for all of us here. If only -- this last Tuesday we had meetings

here in this same room. There were about a dozen people, and they were talking about the permit for the Diablo Canyon to dump 2.7 billions of water each day into the ocean, some of which will contain the worst pollutants known: mercury, nickel, cadmium, copper, PCBs and so on into the ocean. And people don't know.

So I'm very grateful today that we have had this opportunity and that we're learning what this -- the deleterious effects and the desecration of the ocean could be.

Thank you for your attention.

CAPTAIN WAGNER: Thank you, Miss Evered.

- o0o -

CAPTAIN WAGNER: The next registered speaker is Assemblyman Dan Hauser from the California Assembly.

UNIDENTIFIED SPEAKER: Someone said Dan Hauser, representing the north coast, has been momentarily detained on the Assembly floor and will be here shortly to testify.

CAPTAIN WAGNER: We will proceed with the next registered speaker then; that's Mr. Dan Hamburg, Mendocino County, Chairman of the Board.

*#72

DAN HAMBURG

Thank you. The Mendocino County Board had hoped that we could hold a hearing similar to this up in Mendocino County. We made repeated requests for such a hearing in Fort Bragg. I know the Humboldt County Board wished that a hearing might be held in Eureka. However, we are glad to have this opportunity to address you. We hope that before this thing is over, we will be able to hold some public hearings on our home turf. [*J.15]

I come before you today as the Chairman of the Mendocino County Board of Supervisors, and I'm representing that Board of Supervisors in its position of unanimous opposition to disposal of nuclear wastes in the Pacific Ocean. There is very little comfort for us in the statement that we were sent in a written correspondence from Chapman B. Cox of

the Navy Logistics Section which said that Cape Mendocino has been selected only as a representative study area which may be subsequently designated as the West Coast disposal site. [J.2] We fully realize there are few locations other than Cape Mendocino which would meet the required selection criteria which the Navy and the EPA have outlined.

Beyond our parochial interest that radioactive material not be dumped off our coastline, without our fishery, is the [L.53] larger issue of whether such dumping should occur anywhere off the coast of the United States or any other country's coast. Surely the Navy and the Environmental Protection Agency do not expect the counties and the states located on coastlines to accept this Draft Environmental Impact Statement as evidence of the Federal Government's commitment to a sound nuclear waste disposal program.

I need only draw your attention to the October 1981 General Accounting Office report which admits, and I quote: [L.6] That the Federal government has no complete and accurate catalogue of information on how much, what kind and where low-level radioactive waste has been dumped. End of quote. [L.7]

With this type of record to point to, there should be no surprise in the fact that the Federal government is not trusted to carry forth such a broad and delicate program as the one you propose.

It is the position of the Mendocino County Board of

***Other issues discussed by Mr. Hamburg are side barred in Exhibits 72a and 72b.**

J.20 L.35 L.1

Supervisors unanimously that this DEIS does not adequately address the issue of migration of nucleotides from waste forms to the water column to sediments and organisms.

The critical issue of pathways of radioactivity to humans must be considered in full detail. We note with great

J.12

concern that the data presented in the DEIS on albacore catches in the vicinity of the Mendocino site are based on 20 year-old information; while current data suggests a much more significant fishery in that area.

The Mendocino County Board stands united with our neighboring city councils and board of supervisors, as well as with scores of state and federal elected officials and with millions of citizens across this nation who are opposed to the profligate use of our precious ocean resource as a garbage can for the Federal government and its military establishment.

At this point I want to offer some testimony as an individual supervisor, which goes a bit beyond the position of our Board. I believe the matter before us today is a -- of far greater importance than simply which ocean gets this garbage, whose fishery is polluted, or even whether ocean or land disposal ultimately becomes your preferred option.

The discussion in the DEIS is centered on what to do over the next few years with 100 radioactive submarine hulls. These subs represent only a tiny fraction of the total amount of nuclear waste for which there is no planned disposal method.

This tremendous tonnage of nuclear waste represents only a fraction of the overall problem of waste disposal in this nation.

Of grave concern to me is the message that I'm receiving from the high officials of the Reagan administration that environmental protection in general -- and nuclear and toxic waste disposal in particular -- are being neglected under the guise of deregulation. This administration appears to me to believe that what is good for the military and what's good for the major corporate interests of this country is necessarily good for America. Indicative of this administration's stance that the very agencies which are responsible for environmental protection and for the stewardship of our resources are pushing hard to open our continental shelf to the oil rig and our fishing grounds to the obsolete radioactive sub. Perhaps it is what we might reasonably expect from an administration that dubs its latest multimegaton nuclear weapon "The Peace Keeper."

It's enough to make one believe that your Orwellian nightmare has arrived, and here a full year ahead of schedule.

It is appalling to me that what we have -- ostensibly are doing here is try to figure out how to dump the Polaris in order to make room for the Trident. Does it not occur to this administration in its adherence that is the path of folly? In fact, it is pure arrogance; the worst kind of folly because it threatens the very survival of humankind as species. First we construct weaponry capable of massive unprecedented death and destruction, and then in discarding this weaponry in order to construct ever more potent death machines, we risk tremendous ecological damage. Where is the plan of the Navy and EPA to dispose of the Trident when it's time for burial to come? And what of the kilotons of the other spent weapons and obsolete power plants that litter the earth and spread their radioactive menace? N.12

I believe it's time for an overview. It's time to take stock and redirect our efforts into harmony with other living things on this planet because the earth will digest only so much of our shamelessness before it lays waste to the wastemaker.

Thank you.

How many copies of this did you want?

-o0o--

CAPTAIN WAGNER: The next registered speaker is Mr. Lawrence Espinoza from the California Department of Fish and Game.

Is Mr. Espinoza here?

(Speaker not present.)

CAPTAIN WAGNER: Then we'll proceed with the next registered speaker, Mr. Norman de Vall. Mr. de Vall is representing the Mendocino County Supervisors.

#73

NORMAN de VALL

Mr. Chairman and members of the hearing panel. I had hoped there would be more of you.

Obviously, I support the Mendocino County position, which is a unanimous five-zero position. I'm sorry that there are not more of your colleagues here.

Before I read my brief testimony, I would like to say that I think the Reagan administration and the Navy will regret it is not following the law as passed by the Anderson Amendment to the gas tax which called for a two-year moratorium on this proposal to dispose of spent nuclear submarines in the Pacific Ocean. I think that on a political note that there will be nothing more that will unify and cause people to register and create an issue for the 1984 campaign. F.2

When the administration does not hear the people and when Congress is thwarted in its full efforts to try and support what the people have to say, we will come forward at the grass-root level and we will band together. We will form coalitions, and we are going to stop this proposal.

L.53 The proposal to dispose of spent nuclear submarines within the American Fishery Management Limit or anywhere in a nation's waters or international waters is both foolhardy and incompetent. It puts at risk an existent and viable industry L.36 and jeopardizes the food chain of future generations for an untold period of time.

Very simply, the Government should not design or build that which it will not dispose of safely. Your nuclear submarines fall into the same sphere as nerve gas, dioxanes, and the waste from Three Mile Island.

Under the guise of national security, the proposal to dispose of spent nuclear submarines on the seabed is a harbinger of proposals to come; a disposal plan for other atomic waste that admittedly need a disposal site and method. But that site and method must be safe beyond doubt. Your proposal, sir, is not.

L.53 The DEIS is rift with inconsistencies, incomplete data and skewed statistics. It negates the fact that the Mendocino Escarpment is one of the richest fishing areas known in the world. It is for that reason that Russians, Poles, Germans, Japanese and others as well as Americans choose to

fish there.

The damage being done by this proposal to this industry is phenomenal. It is not understood by your administration. It is not understood by the Navy. It is understood by the people.

Your current data is not yet known satisfactorily by the U. S. Coast Guard. Any of their -- search pattern has a risk factor built into it; the risk to our economy is beyond doubt.

I again repeat, sir, you will contend with us in 1984 when we go to the polls again.

Thank you.

--oOo--

CAPTAIN WAGNER: The next registered speaker is Assemblyman Dan Hauser, California Assembly.

#74*

ASSEMBLYMAN DAN HAUSER

Good morning. Thank you. I also apologize for being late. The legislature was in session this morning, and we just broke up. So --

I would like to address my comments also to the Draft Environmental Impact Statement and to the politics of the north coast. Many of those of us who live on the north coast of California have suspected for some time that one of the major reasons why the Navy has been so interested in our region for its radioactive waste dump site is our relatively sparse population and resultant relative lack of political power. However, it was not until October of last year when the Navy released the report by the Department of Energy Sandia (ph) Laboratories entitled "Oceanographic Study to Support the Assessment of Submarine Disposal at Sea" that we had the proof.

The Sandia report upon which this Draft Environmental Impact Statement is based states that the Cape Mendocino site is less impacted by shipping lines, offers less opportunity per a productive fishery, appears to be characterized by smoother topography and more uniform sedimentation and is a greater distance from major port activity and population centers

than the San Francisco site which was earlier considered and dropped.

I'm here today to tell the Navy that we are capable of generating opposition far beyond our numbers, and we intend to do so. With leaders and spokesmen such as Congressman Doug Bosco, State Senator Barry Keene, we intend to make it impossible for the Navy to turn the ocean that we love into a radioactive dump site.

The income of our entire region depends upon the commercial and recreational fishing industries and the seafood industry which is based in the Ports of Crescent City, Trinidad, Eureka, Fort Bragg, Albion, Port Arena and Bodega Bay. They also depend upon the timber industry which relies on the Port of Humboldt, northwest of Cape Mendocino, to ship many of its products to market. And they depend on the tourism industry, which also is based on the Pacific Ocean and its spectacular coastline. L.53*

This Draft Environmental Impact Statement underestimates and often simply ignores the impacts of radioactive waste dumping on the jobs of those who work in and around these industries. Even public fear of dumping could have a major economic impact; a fact that this DEIS fails to discuss at all. O.34

The California Legislature, however, is not ignoring these threats. Senator Keene and I have introduced Assembly Bill 138, directing the State agencies to use their full legal

***Other issues discussed by Mr. Hauser are side barred in Exhibit 67a.**

powers to prevent any dumping of radioactive waste into the Pacific Ocean unless it would have no adverse impact on the resources and environmental values of the California coast and would be conducted in accordance with all applicable state, federal, and international laws. The agencies directed to cooperate include the California Coastal Commission, which administered the Federal Coastal Zone Management Act in California; the Attorney General's office; the Department of Health Services; the Department of Fish and Game; and the Legislature's Joint Fisheries and Aqua-Culture Committee.

The Navy may think that its sketchy report and contradictory data are enough to roll over the north coast, but the Navy is wrong. The jobs and the health of our people are too important for us to allow that to happen unless it can be proved that it's safe; no one has -- at this point no one can. And we don't intend to allow the dumping to occur.

Thank you.

--o0o--

CAPTAIN WAGNER: Has Mr. Lawrence Espinoza appeared in the hall yet?

(Speaker is not present.)

CAPTAIN WAGNER: Ladies and Gentlemen, I intend to continue with nongovernmental agencies.

Mr. Espinoza is the last registered governmental organizational spokesman, and we will work him in when he does arrive and I have received word that he is here.

The next registered speaker then is Ms. Pat Agnello, representing Redwood Alliance.

PAT AGNELLO

#75

Sorry, I don't appreciate the title too much, but --

CAPTAIN WAGNER: I will make mistakes, and as I said, please repeat your name correctly and it will be proper for the record.

PAT AGNELLO: My name is Patrick Agnello, I'm here representing the Redwood Alliance. We are located up in Arcata, California, on the north coast. We are a group dedicated to educating the public on nuclear issues. We're quite active in the north county. And I'm here to speak for the 1700 or so members that we have. We certainly hope that you listen to the concerns of the north coast constituents, our Congressman Doug Bosco, our State Senator Barry Keene, and

J.15

Dan Hauser our Assemblyman who just spoke and to hold hearings on the north coast. Though we have already had two hearings -- and you weren't present at either one -- we hope that maybe you can be coming up there pretty soon.

The concerns we have are many. First, our major concern is that your desire is to scuttle submarines sold to us as low-level waste off our coast is an effort to circumvent the legal responsibilities of seeking stronger environmental safeguards and injecting a greater degree of accountability in all aspects of radioactive waste dumping.

J.76
L.6

The lack of monitoring procedures and lack of strong commitment to study existing ocean dumps is not consistent with this statement issued by the Environmental Protection Agency. It is a shame that the Reagan administration has withheld the funds for developing monitoring procedures and monitoring studies for ocean dumps. I wonder if the Navy will do the same.

Since 1974, the Federal government has spent only $250,000 studying existing ocean dumps, while spending nearly 10 million dollars to study the sub-seabed and sub -- and the seabed disposal of high-level radioactive waste.

J.76

We have our doubts that the Navy can scientifically monitor these subs at the depth of 15,000 feet. We feel that the Government should spend the extra 250 million dollars required over the next 30 years for the land disposal so that our country will

learn from monitoring and study of these wastes. Our scientists are probably the best in the world and should be given the opportunity to get us out of this radioactive crisis that we are currently facing.

Remember just 200 years ago we were still inventing nice, dandy farm equipment that will help us to, you know, proceed in the future. And now we have 200 years hence in front of us. I think we can probably develop something on the land and try and get rid of this problem.

Our second concern is that with the scuttling of these subs, this is the first penny in the well for the military. These nuclear waste problems far outglow that of the commercial nuclear industry. Once the first sub is sunk followed by the 99 or so others, the rest of the old nuclear navy will likely follow; followed by the waste from the Rocky Flats, followed by Livermore, et cetera.

L.9

And as we sit here today calmly discussing low-level waste, the Defense Department is injecting high-level liquid radwaste into the sub-seabed off the coast of the Marianas in the Pacific. Yet they have failed to file an EIS or address the public. And how long can we depend on you to come to us when you want to dispose of radioactive waste? And how many deals will be made by the commercial nuclear industries with the Government to dispose of their waste also as a secret, easy way out? This is not what we deserve, and it is not what we want, certainly.

Thirdly, we have -- we are concerned by the facts that our friends around the world will follow our lead in dumping their waste into the ocean. Although Norway, Iceland, Canada, Austria and Sweden see the danger of ocean dumping -- and their voices in the London Dumping Conference Convention aren't as strong as those of Britain, the Japanese, the French and the Americans who dump most of the waste. We should become the world leader in radwaste technology, not the world leader in a quick-fix boondoggles.

F.8

Lately -- lastly, I should say, we are concerned that the Draft EIS does not take into account the accidents in dumping that could occur when one sub is sunk by mistake on the body of another sub. This is not addressed in the DEIS.

F.23

The contact that could occur -- though the Navy doesn't feel that such a mishap is possible -- could expose the unit hulls of the sub; that's increasing the corrosion factor. There is no study of any accident or any kind of procedure to remove one sub from another sub if this accident does occur.

We doubt that there is also a ninety-nine percent success rate that the Draft EIS takes into account. You only think that there is only sub -- one mishap that could possibly happen as a worst case scenario. If any agency, the government or otherwise, had a ninety-nine percent success rate, that would be truly a miracle. We would like that you

F.22

show us some reality and responsibility by providing us a scenario of this possible or probable disaster.

On behalf of the Redwood Alliance and our constituents on the north coast, I thank you for the opportunity to provide the input at this public hearing. Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Dr. Jackson Davis, representing the Santa Cruz County Board of Supervisors.

#76

JACKSON DAVIS, Ph.D.

Captain Wagner, members of the press and concerned people, my name is Jackson Davis. I'm a professor of biology at the University of California at Santa Cruz. I'm here to testify on behalf of the Board of Supervisors of Santa Cruz County and also the Farallon Foundation for whom I have analyzed from a scientific standpoint the Environmental Impact Statement prepared by the Navy.

I would like to begin by placing the proposed submarine scuttling program into the context of other past and proposed programs of radioactive waste dumping in the oceans. The Navy said it wants to scuttle 100 submarines between now and the year 2000; each containing 62,500 curies of residual radioactivity. What the Navy does not mention in its DEIS is that it is continuing to manufacture nuclear submarines, each of which will also require scuttling when it wears out.

N.12

In other words, we are talking here about a potentially open-ended dumping program, which if allowed to begin, will continue into the indefinite future for as long as nuclear submarines and other nuclear weapons are manufactured.

The magnitude of this program is staggering. It would involve hundreds of times more radioactivity than past dumping programs. What the Navy is here proposing is by far the largest program ever considered for ocean dumping of radioactive wastes. The Navy has considered -- has suggested that these unprecedented quantities of radioactivity will not harm people because the wastes are bound up in the metal walls of the reactor vessel. But let us look forward in time just one century, by which time even the Navy's calculations indicate that container will be breached. The Navy says that by this time each submarine will contain 10,000 curies of radioactivity; times four submarines per year equals 40,000 curies per year.

R.3

In other words, to proceed with this program, Captain Wagner, is the equivalent of dumping 40,000 curies annually of unpackaged radioactive wastes directly into our grandchildren's laps.

Captain Wagner, I respectfully suggest that this is not a legacy that the people of this state will willingly leave their grandchildren simply because the U. S. Navy says we should.

Let us examine the issues of safety as raised in the DEIS. One of the criterias stated by the Navy in its preliminary scientific evaluation is that "sites should be away from areas containing active geological phenomena such as volcanos."

But according to the Navy's own studies, the Northern

NOTE: This testimony was also submitted (June 28, 1983) as a document which appears in Exhibit 707.

J.19 California dump site lies less than 50 miles from one of the most geologically unstable areas of the sea floor known in any ocean on earth -- the Mendocino fracture zone.

According to the Navy's own data, the report in the preliminary studies, dozens of major earthquakes have been centered along this zone in the past century.

Also according to the Navy, the resulting bottom F.22 shears in the dump site area resulting from these earthquakes and the resultant effects on decayed submarines lying on the bottom are unknown.

Another criterion listed by the Navy as important in choosing a dump site is "sites should be away from areas such as submarine canyons which have a high rate of exchange of the deep ocean waters with surface layers."

But according to the Navy's own studies, there are powerful near-bottom eddy currents in the California dump site that reach velocities of 16 centimeters per second and stir the ocean bottom from top to bottom. Current velocities as J.29 low as 7 centimeters per second -- less than half -- would have been measured -- are capable of suspending and transporting radionuclides.

The Navy also documents a slower southerly current moving at a rate of one kilometer per day. This current could transport suspended radioactivity directly toward the major population of Marin County and the San Francisco Bay Area,

possibly in a matter of months.

The Navy has asserted that animal life in the dump site area is sparse; but when we examined the actual scientific data presented by the Navy in its preliminary scientific study, we find a much different picture. These studies show that all bottom cores from the study areas are "strongly burrow-molted," implying a very active bottom population. All photographs made by the Navy at the bottom in the dump site area show evidence of considerable bottom life.

As also acknowledged in the DEIS, animals are known to concentrate in dump site areas. In short, the dump site area contains abundant bottom life which could rapidly return the dump radionuclides to human beings through the ocean food chain.

The Navy claims that exposures of human beings to radiation dumped at sea would be so small as to be negligible. But it is worth examining how the Navy has arrived at this conclusion.

Their assertions of safety are based upon the use of extremely hypothetical models to calculate possible human exposure. The Navy has ignored all empirical studies of past and present radioactive dump sites, many of which have produced evidence of much higher radiation in seafood than the Navy suggests will occur. F.12

To illustrate: The British discharged 100,000 curies per year into the Irish Sea, resulting in fish that are so radioactive that members of critical consuming groups receive literally quadrillions of times more radioactivity than the Navy claims will result from the submarine scuttling program.

The Navy freely acknowledges the uncertainty inherent in its calculations. On page A-10 of the DEIS, we read the calculations of human radiation exposure by different methods yields different values of, quote -- and this is a quotation of the U. S. Navy -- "The indicated differences are not considered to be significant; rather the real difference is overwhelmed by the magnitudes of the uncertainties in the calculations."

In my considered judgment, Captain Wagner, it is not appropriate to base major public health decisions on hypothetical models and unknown and untested safety factors. The Navy has claimed that the proposed submarine dumping program is consistent with both domestic and international law. This claim was, of course, made prior to the recent domestic legislation facing a two-year moratorium on ocean dumping radioactive waste.

F.2

With respect to international law, I have just returned from the Seventh Consultative Meeting of the London Dumping Convention, which is the sole treaty organization that regulates the disposal of radioactive waste into the ocean.

In this convention, I served as a scientific and technical advisor to the Pacific Island nations on the issue of

radioactive waste dumping at sea. This meeting passed -- by an overwhelming majority, 19 to 6 -- a moratorium on radioactive waste dumping at sea, pending resolution of scientific questions which I and other scientists have raised.

Captain Wagner, I respectfully suggest that the legality of the Navy's proposed dumping program, if not at all established under international law, it would be a matter for all of the contracting parties to this convention to collectively decide at one of our consultative meetings.

F.5

As indicated by the recent vote in London, the nations of the world are not sympathetic to such proposals. The Navy's proposal to dump worn out submarines at sea would be more understandable if there were no alternatives, but there is an alternative; one that is safer, fairer, more cost effective and less politically contentious.

This alternative is the land alternative. Consider first the issue of exposure to human beings to radiation. The Navy's own calculations presented in the DEIS show that human exposure to radiation from sea dumping would be 3 to 40 times greater than the land alternative.

L.47

The Navy claims that these differences are small compared to the uncertainties in the calculations. But we may well ask in return if the uncertainties are large, are not also the inherent risks large?

Knowing as we do that any level of radiation exposure is harmful, it is clear from the Navy's own calculations that the land alternative -- although not without its own risks -- is many times safer than sea dumping.

The second advantage of the land alternative involves monitoring. The Navy has stated that the land burial sites are already monitored on a regular basis, and hence no new monitoring would be required. In contrast, the ocean alternative would require extensive monitoring before, during, and after scuttling operations.

J.76

The first and obvious question to ask is will such monitoring ever in fact take place? Many of us here today recall a congressional investigation on the Farallon nuclear dump site held in October of 1980, at which the U. S. Congress asked responsible federal agencies to monitor the Farallon dump site off of California. Three years have passed since that congressional order was issued. The Farallon site has still not been monitored. Funds to enable such monitoring have still not been allocated, and the people of the Western United States still do not know with certainty whether the seafood harvested at the Farallons contains radionuclides from the dump site there.

L.6

We are obligated to ask whether monitoring of the scuttled nuclear submarines is any more likely to occur.

The chief argument offered by the Navy for preferring the sea option is cost. Close examination of the economics,

however, reveals that the Navy has failed to include several expenses that in total would make sea dumping equally or more expensive than the land alternative. These unaccounted costs include accidents, monitoring, psychological impact, medical expenses, direct economic impact on fisheries and tourism, and the cost of the protracted political struggle which is certain to ensue if the Navy continues with this program.

L.57
O.26
J.76
L.53
O.34

Captain Wagner, there are 70 operational commercial power reactors in the United States at present and 70 more in various stages of planning. If this Navy reactor scuttling program is allowed to proceed, a precedent will be set for dumping worn-out commercial reactors in our coastal waters. I submit that there are too many uncertainties to justify even a small scale sea dumping program, and the nations of the world have agreed with this position in their recent vote. There are scientific uncertainties. There are public health uncertainties. There are economic, social, legal, political, and moral uncertainties. All of these uncertainties have combined to ignite the public's opposition to this proposed submarine scuttling program.

L.9
F.8
L.1

As just one indication of this opposition, the Board of Supervisors of Santa Cruz County has authorized me on behalf of the Farallon Foundation to deliver to this hearing their unanimous resolution opposing the scuttling of decommissioned nuclear submarines in California coastal waters.

As a scientist familiar with the technical issues, as the father of several wonderful children, as a representative of the Pacific Island people whose only natural resource is the sea, and as a representative of the people of Santa Cruz County, I respectfully request that the U. S. Navy immediately abandon this submarine scuttling program.

CAPTAIN WAGNER: Thank you, Dr. Davis.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Mr. George Balding, representing the Fort Bragg Salmon Trollers Marketing Association.

#77*

GEORGE BALDING

Thank you, Mr. Wagner. My name is George Balding. I am a commercial fisherman from Fort Bragg, and I've been elected to the Board of Directors last year. And I was selected unanimously by the Board of Directors to represent the Salmon Trollers Marketing Association of Fort Bragg.

A lot has been said today, and I'm really happy to hear all the emotional quality of the speeches. I've been spending quite a bit of time in the last few weeks making emotional speeches myself to the Pacific Fishing Management Council and recently the legislature. And I'm happy to hear the legislators themselves getting up here and voicing strongly their opposition to this proposal of the earth.

We all -- as Normal de Vall and others have said already -- feel that the Government has a very great lack of concern and in fact a large disregard for the environment. And this environment directly affects our fisheries.

The administration that's currently in power, I think, is probably -- this is the only time that this could possibly happen that I've seen in recent years. Everything that's been -

***Other issues discussed by Mr. Balding are side barred in Exhibit 77a.**

that had been done in 1970 seems to be going backwards now, and we don't like it. Our seasons are being cut down, especially in salmon fishing. In regard to the environment -- the environmental damage being done on all species of fish is becoming irreversible, I would say. Striped bass numbers are down. Steelhead numbers are down, and we can't commercially fish these. Yet the salmon are decreasing at about the same rate, and we are being blamed and restricted from fishing the salmon because of other environmental dangers. And we can't afford any more environmental degradation.

For about six years now we have been under the guise of the Pacific Fishery Management Council, and we've been making input to have some authority given to these people for environmental control. Finally this year, they addressed the issue. They say one of their environmental goals is to use the marine environment in such a way that it will maintain a healthy population of all species. They ask that this happen. They have no authority to enforce this. And we haven't found very many people -- it doesn't seem to me that I've been addressing, including the Department of Fish and Game and others here that are willing to take the responsibility to enforce environmental controls.

Getting to your Draft Environmental Impact Statement. One section of it addressed the disadvantages of ocean disposal. It says the environmental aspects are more

controversial than the land disposal. We are very happy that you people can recognize a controversy when you see it.

You also say that the overwhelming body of scientific research and opinion shows that concerns over the potential public health and environmental consequences posed by past ocean dumping activity are unwarranted and overemphasized. I feel that this is an outright lie.

From what we have gathered from what people are saying here today, I would say that the overwhelming body of scientific research and opinion shows that it is definitely warranted. And we intend to emphasize it.

Mr. Davis just presented a little bit about the radiation getting into the food chain. We are not scientists, we are fishermen. And you yourself say that the submarines are going to produce artificial reefs. Well, anywhere there is a reef, there's a lot of fish activity. The submarines are going to be covered by bacteria, as I understand it. This bacteria will be fed on by other organisms. I don't think anybody here thinks that an organism living right on the submarine isn't going to remain unaffected. And this material is going to become incorporated -- this radiation is going to become incorporated in the food chain. There is no way around it.

I've been fishing for only nine years now, and I know that the ocean is one unit. It's a living organism in itself.

U.5*
L.55
L.36
L.14

*Other issues discussed by Mr. Balding are side barred in Exhibit 77a.

Anything that happens in any part of the ocean is going to somehow -- and possibly in some way it can be spread throughout the entire ocean. It's almost like you people are saying that you're going to put the submarines down there and nothing is going to happen with it; there won't be any interaction with the rest of the ocean. We don't believe that at all.

Very little is said about the socioeconomic effects of L.53 this. As fishermen, we realize that once the public becomes alarmed about having radiation in the fish, they'll stop buying O.34 the fish. That will be the end of the commercial fishing industry as we know it now. And that's going to be a really large financial impact. You're talking of millions of dollars every year, and yet you are worrying about the cost of disposing N.3 of submarines on land. There was no worry about the cost when they were built.

Another part of the Impact Statement that bothers me -- I suggest that the Navy can't even follow their own criteria set up for study guides of the study areas. You say that you will avoid areas of seafood production which is currently used by man. Well, thanks to Dr. Hertz of the Oceanic Society that came to Fort Bragg, I was given an address of the fellow who works for the National Oceanic Atmospheric Administration. It is a national marine fishery service. We got it from J.12 Script Institute 1974, 1976, '77, '78, '80 and '81. There was significant albacore catch directly above the area of the

proposed scuttling. Now, if you're so concerned with these J.12 criteria that you set up, you wouldn't even have considered this area. And it's also been shown by several speakers here J.19 that this is an active area; the fault runs right across there. F.22 Many fishermen who fish that area all their lives have told me that there are upwellings all the time along that fracture J.31 zone and around it caused by the fracture. It's a very productive fishing area. As it's been said before, one of the most productive fishing areas in the world.

I'm not trying to say that you shouldn't dump the nuclear waste in this area. We are just saying that we don't want it in any part of the ocean.

You're saying that you're going to monitor these; yet J.76 your past monitors have been very poor as already testified. L.7

There is, according to your own words -- at the current technology -- they will be unretrievable. You say W.1 that the pathways to humans are not known. You discuss corrosion; I don't think it's covered adequately. Q.13

Another one of my main concerns here has been the Navy's response to public sentiment and also response to politicians who have tried to present opinions and have been refused.

Senator Keene is one example I'm talking about who had the input; who had the backing of California, Oregon, Washington, Idaho, Alaska and Hawaii to represent the Pacific states at the

London Dumping Convention, and he was refused to be a delegate at the convention.

So we, you know, what's -- we feel like what's our input, a public person's input, if you are not listening to our representatives? We don't like that.

L.53

In conclusion, I would just like to say that the success of our industry is based on a quality habitat. The fishing resource is very valuable; it's too valuable to jeopardize it or destroy it. It's important on a worldwide basis. The ocean is used by all Californians for many purposes, and this radiation is going to affect it for tens of thousands of years.

I would just like to say finally that we don't want to have any radioactive waste put in any ocean.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Nat Bingham, representing the Pacific Coast Federation of Fishermen's Association.

#78*

NAT BINGHAM

Captain Wagner, I thank you for the opportunity to appear before you this morning.

I'm a commercial salmon fisherman. I have been a fisherman for 20 years on the north coast of California, and I fished many years in the particular area in question for dumping. I am President of the Pacific Coast Federation of Fishermen's Association, representing 8,000 commercial fishermen in California. I'm also on the Board of Directors in Salmon Trollers Marketing Association in McGeorge.

California's fishing industry was shocked in the autumn of 1981 to learn of the Navy's plans to dispose of 100 obsolete nuclear submarines in the Pacific Ocean, south and west of Cape Mendocino. The men and women of our fishing industry, a north coast economic mainstay, are especially concerned with the effect that dumping program would have on their livelihoods. More than a year has passed since the first terrifying news; a year in which the Navy might have substantially allayed the fears of our citizens of our coastal communities. Instead, the period has been consumed in a

*Other issues discussed by Mr. Bingham are side barred in Exhibit 78a.

desperate struggle for the information about the Navy's plan; a struggle that has been met with Government delays, denials, and silence.

To give voice to the concerns of Californians over the dumping, the fishing industry asked for the introduction of Senate Joint Resolution Number 27, which asked that the scuttling be delayed until valid, reliable scientific studies prove it's safe. With a quarter of the entire California Legislature joining as co-authors, the bill received virtually unanimous support from the Legislature. The Joint Legislature Committee on Fisheries and Agriculture has been assisted by some of California's top marine scientists in an effort to obtain and evaluate information concerning the dangers of dumping radioactive materials into the ocean, as well as regarding the proposed dump site off Cape Mendocino.

The difficulty these scientists have had in obtaining information concerning the Navy programs at times appeared insurmountable.

In June 1982, our north coast State Senator Barry Keene requested copies of specific studies completed by Oregon State University for the Navy; in some cases as early as 1978. He was finally forced to file a Freedom of Information Act request for these publicly-funded materials. It was not until 7 August 1982 that Rear Admiral J. H. Weber responded, claiming that studies had not been summarized and interpreted and would

not therefore be released.

It was October before we received a 686-page report -- Oceanographic Studies to Support the Assessment of Submarine Disposal at Sea.

Up to this point, those responsible for the Navy submarine disposal program have contended that no conclusions have been drawn nor choices made favoring sea disposal over viable sub reactors on land. Our analysis indicated, however, that our fears had been justified. The Oregon State study emphasized the distance of the Cape Mendocino site from major population centers. It downplayed the area's contribution to fisheries' harvest and mistakenly concluded that "no upwelling is present in the study area."

The presence of upwelling, the movement of water from great depths to the ocean's surface in the study area is well-known to north coast fishermen who view the area as a major producer of economically important fish, especially albacore.

I would like to state that I was an active participant in those albacore fisheries that George mentioned. I have been right over the site personally of the dump, and I have enjoyed many very successful days of harvesting albacore.

While albacore themselves are surface-feeding pelagic fish, they are in fact dependent on smaller fish such as needle fish and seriola, which in turn feed on plankton which is feeding T.20*

***Other issues discussed by Mr. Bingham are side barred in Exhibit 78a.**

on upwellings of inorganic and organic materials which come from deep within the water.

I have also participated in the salmon fishery just inshore from that area and have been astounded to catch fish which I don't know the name of because I haven't seen them in any books anywhere. I only know that to me they are sea monsters. They are things that come up from the deep. I have caught them myself; so as far as I am concerned, I am convinced of the unusual nature of the upwellings in this region.

It's not surprising, therefore, that the Navy's Draft Environmental Impact Statement on the disposal of decommissioned, deep-fueled naval submarine reactors, the subject of today's hearing, should prove inadequate developed as it was on an incomplete and in some cases erroneous information.

Let me list some of the deficiencies we see in the DEIS, and let me assure you we will provide more detailed concerns within the period allowed for written comments.

Lack of accumulative impact analysis. In his February 16, 1982 letter to you, Senator Keene specifically pointed out to the Federal Council on Environmental Quality Regulations, implementing the National Environmental Policy Act requires the Navy to analyze how the action proposes to carry out and attribute to accumulative impact of other such actions.

Part 1508.7 of the Federal Regulation defines cumulative

impact as the impact on the environment which results from the incremental impact which -- of the action when added to other past, present and reasonably foreseeable future actions, regardless of what agency undertakes any such action.

Accumulative impact regulations explained can result in individually minor but collectively significant actions taking place over a period of time. Senator Keene suggested this to me. The Navy must address the accumulation of radionuclides in the environment, including fallout from nuclear weapon testing, past dumping of radioactive waste by the United States and foreign countries' background radiations, other future disposal plans where anticipated and all other sources.

In your response, you stated that the Draft Environmental Impact Statement will also include a consideration of cumulative impact of action in compliance with the Council on Environmental Quality Regulations. No such consideration appears in the DEIS. Absence of accumulative impact analysis is in our view a grievous deficiency in the environmental documentation of this Navy's project.

Alternative disposal cost inadequately compare. The DEIS at page S-16 concludes: Sea disposal is seen to be the least costly method. Disposal at sea of entire submarines is priced at 5.2 million per ship; while the cost of land burial of each reactor compartment and sea disposal for the remainder of each sub is estimated to add 2 million to that figure.

Missing from both of these preprogram studies and from the project cost estimate are monitoring activities sufficient to determine the effect of the proposed dumping on the environmental health of the Pacific. Nothing is known of the present radioactivity of the site, and no commitment is made to determine how the actual corrosion rate of the abandoned submarines and the resulting escape of radionuclides in the ocean agri-system will compare with the estimates you used in justifying the Navy's position.

As a fellow boatman -- admittedly on a somewhat smaller scale -- I'm here to tell you that the only way you can keep a boat from falling apart in the ocean is to maintain it. If you let it sink, it's going to come apart. There is absolutely no way that you can keep a man-made object in one piece at the bottom of the ocean.

Were the costs of ocean wandering included, it would likely rule out the Navy's apparently preferred option of disposing entire submarines at sea.

Also missing are estimates of what the economic and social costs of the loss of the entire fishing industry of Northern California would be.

I would at this point suggest as a safe alternative a mothballing of these submarines. We don't want to dispose them on land. It's my conviction that these perhaps in the far

future or in the near future would be more usefully employed in peaceful pursuit, such as oceanographic research, transportation of sensitive materials, whatever. I can't believe that you haven't got any use for those submarines, outside of sinking them. If they are not safe to use -- if in fact they are leaking now, then you've got no business dumping them at the bottom of the ocean.

The DEIS presents estimates at Table 411 of the radioactivity exposure that the general public would experience and concludes that the figure shows no significant difference between the disposal options. In fact, the estimates suggest the public would suffer 42 times more radiation exposure were just one of the submarines slated for sea disposal involved in a handling accident. I refer you to the population exposure column at the table rows B2 and B1: proposed action not identified.

The document before us today is not in fact a Draft Environmental Impact Statement. The pertinent federal regulations clearly require at part 1502.14 that the DEIS identify the proposed action. The document before us, however, concludes that either option could be chosen. Essential purpose of environmental impact statement is that it allows the public to see how by what logic an agency arrives at the preferred alternative. The document which obscures from the public the agency's chosen option defeats the purpose of the DEIS process.

I am sure that the Council on Environmental Quality has this clearly in mind when it adopted Regulation part 1502.14.

I would like to turn from the defects in this specific environmental document to a brief discussion of how the Navy's ocean dumping program fits within the context of existing state and national law and policy. I might suggest at the outset the fit is not particularly natural nor logical. The points which I have to share with you was brought to the attention of the Joint Legislative Fishery Committee at its hearing on the Navy's plan held in San Francisco 7 August 1982.

The State of California has prepared and the Federal government has certified the California Coastal Management Program. The Federal Coastal Management Act prohibits any federal agency from conducting activities which directly affect California's coastal zone unless the federal agency first determines that they -- the activities are consistent with our management plan and the California Coastal Commission concurs in that determination.

The California Coastal Act, the heart of our management program, requires the uses of marine environment should be carried out in a manner that will sustain the biological productivity of the coastal waters and will maintain healthy population of all species of marine organisms adequate for long-term commercial, recreational, scientific and educational

purposes.

We are concerned frankly that radionuclides released by the Navy's dumping program could biocumulate through the marine food chain and cause real or publicly-perceived radiation damage to fish food species. Consumer rejection of California seafood products could devastate our industry and would clearly be inconsistent with our Coastal Management Program.

I would like to add my voice to those of California's congressional delegation, Honorable Lieutenant Governor McCarthy, and Senator Keene in requesting that additional hearings regarding this Draft Environmental Impact Statement be held in Fort Bragg and Eureka, California, in order that those people most directly impacted by the proposed dumping program have the opportunity to adequately express their concerns.

I would like to thank the Navy as it is concerned with the needs of California coastal communities as it is with more heavily represented Raleigh, North Carolina, and Columbia, South Carolina, where field hearings were held last week.

Finally, I would request that the Navy extend the period for receiving public comments on DEIS until at least June 30th of this year.

The effect on the health of our world's oceans from the sort of use proposed here by this Navy, which will make international outlaws of us, will continue for a long, long time. I would urge those responsible for the disposal program to make every effort to seek the best scientific information available to guide their decision. And I would plead with equal urgency that you listen carefully to the fishermen of our coastal communities; those whose health and livelihoods may be changed forever by what you decide in the few months ahead.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Bonnie Blackberry, representing the Citizens for Responsible Government.

#79

BONNIE BLACKBERRY

My name is Bonnie Blackberry, and I'm a resident of Humboldt County. And I came here to represent people that are concerned about the responsibility of their government.

This proposal of dumping the nuclear waste in the ocean is unacceptable. Creating the nuclear waste is unacceptable.

The President -- it appears that the President of this country believes that a nuclear war is a possibility, and they are planning for a nuclear war. Our county and every county in the nation is planning an evacuation plan so that they can respond to this proposed nuclear war.

I believe that -- that these nuclear subs -- that it's a real problem because there's 100 of them; and now they are too radioactive to use. So the proposal is to dump them in the ocean and bring on the Trident. We don't want the Trident. D.5

I would like to talk about Diablo Canyon. As I was here two days ago in this same building talking to the Water Quality Control Board about dumping toxic waste and radioactivity into the ocean.

The PG&E is planning to load the Diablo Canyon plant on .

March 31st, regardless of the environmental impact. Our agencies in the government have been unable to respond to protecting the water -- the quality of the water in our oceans from this. I am very concerned and everyone here is very concerned. And we as the people -- the real people of the United States -- are not going to allow this to happen.

--o0o--

CAPTAIN WAGNER: Ladies and Gentlemen, I think this is a good time to take a break for lunch. What my intentions are -- we'll take a recess until 1:30. For those of you who have already registered, I will continue with testimony alphabetically with you who have registered this morning. We will continue with the nongovernmental organizations. When we complete that, we'll go into the five-minute time frame for individuals. And then, again, I will give priority to those who have registered already over those who might register this afternoon.

I would like to thank all of you; particularly those of you who provided testimony this morning for your testimony. We will reconvene -- and I would also like to thank you -- I should add -- for conforming to the time limits involved. This is a way of assuring that everybody with a representative view has an opportunity to speak.

At this time, we'll recess the hearing and reconvene the hearing at 1:30.

--o0o--

Testimony at the Public Hearing

on the

Draft Environmental Impact Statement

on the

Disposal of Decommissioned Nuclear Submarines

Thursday, February 24, 1983

Department of Water Resources
1416 9th Street
Sacramento, California

Afternoon Session

Reported By: Theresa French, CSR No. 5790
Ida Ruth Lundsten, CSR No. 5791

CAPTAIN WAGNER: If you would please be seated, we will reconvene our hearing.

This hearing is reconvened. I would like to tell you a few things again that I said this morning for the benefit of some of the people that might not have been here this morning.

The purpose of this hearing is take testimony regarding the Draft Environmental Impact Statement on the disposal of the defueled, decommissioned nuclear power submarines. The purpose is neither to plead the Navy's case nor to engage in debate. It is my responsibility to receive statements so that they can be considered in the development of the Navy's final impact statement. I will afford an opportunity to those individuals and organizations who wish to provide oral or written statements to do so within the guidelines established in the hearing. We are providing five minutes time frame for testimony for individual speakers, and ten minutes for those persons representing organizations, unless additional time had been requested in advance. Time cannot be relinquished from one speaker to another.

If you have not filled out a registration card and wish to provide testimony, I ask that you fill out a registration card at the registration desk. And that card then will be added to our alphabetical list for testimony.

Due to the number of registrations this morning, we still have a large number to give an opportunity to speak. As I mentioned before we recessed, I intend to continue with this morning's registration list, and specifically those individuals who registered by 9:00 o'clock, I'm giving them priority. And we are still going through that list. We will continue with nongovernmental organizations that registered before 9:00 o'clock this morning. And from there, we'll move into individual testimony, alphabetically, for those people who registered before 9:00 o'clock this morning.

When we get through with that group, then we'll move on with later registrations.

For the procedure, again, for public testimony, I will announce each registered speaker. When your name is called, please proceed to and use our microphone over here. For the convenience of the press, we'll continue to use one microphone. State your name and organization, if any, even though I call you by name. I want to make sure that the record gets that name and organization correct, in case I mispronounce or whatever. All comments are to be addressed to me.

The next registered speaker is Mr. Lawrence R. Espinoza, who was not here this morning. I want to see if he is here at this time. Representing the California Department of Fish and Game.

Is Mr. Espinoza here now?

(Speaker not present.)

CAPTAIN WAGNER: Then we'll proceed. And the next registered speaker is Mr. Sam Camp from the Environmental Protection Information Center.

--o0o--

THOMAS O'NEIL

#80

I'm with the Environmental Protection Center, but I'm O'Neil, and he had to leave because his wife is sick.

May I speak in his place?

CAPTAIN WAGNER: Yes, Mr. O'Neil, you may. Please state your full name for the record.

MR. O'NEIL: Thomas D. O'Neil, with the Environmental Protection Center.

I would like to start off by saying 20 years ago President and General of the Army Dwight David Eisenhower in his farewell address said, "Beware of the military industrial complex."

I would like to proceed by saying that dealing with that -- this report I found -- I was able to read it. Most of the pertinent areas dealing with ocean dumping, I found it pretty holey in the sense of with holes; particularly lack of footnotes; like the difference with radiation. In other words, the difference in millirems from New York to Denver if you are flying -- which was given this morning in testimony. I don't know where these things came from. Also the terms "very conservative" and "realistic" were used in the report to derive the radiation. They said very conservative. I had the feeling reading it that it was conservative in the sense of the EPA and the Interior Secretary. I feel that conservatism begins with the earth and the planet; conserving the planet. And these terms are being misused, and it's kind of like new speak.

The statistic that was used in the report on page S12 of 0.00000000006 millirems per year exposure to a person most directly to be exposed seems by itself most infinite -- negative magnitude to be absurd and fly in the face of common sense; particularly compared to natural, quote, natural radiation from potassium 40 of 2.4 millirems per year.

It seems that dealing with radiation, the people are expected to take this by -- by faith. And this leap of faith is certainly valid for mystics and other spiritual people. But I don't feel it's valid for scientists and politicians.

I will keep my comments on sea disposal. However, in last week's Newsweek was published a satellite picture of South Carolina, very near where one of the proposed sites for the land dumping. And they are quoted as saying criss-crossed by creeks and rivers. And that's on page 52, Newsweek,

the 21st, 1983. I only hope that this has been taken into satisfactory account. And if you dump them there, that years afterwards reactors there do not become a toxic waste dump.

But even here if -- if these future "realistic" assumptions prove to be an error, it would seem to be possible to clean it up at relatively less cost. How about cleaning W.1
up toxic waste at 14,000 feet below the surface? Here it would seem to be prohibitively expensive.

And my concern -- one of my concerns is that in the future we might find that we might have to clean up this toxic waste dump, and we would have to pay for it. And it will be much more than 2 million dollars per submarine. In other words, O.26
it seems like it's a penny-wise measure but dollar foolish.

Two-thirds of all the radiation per sub is in cobalt 62, which has a half life of five and a fourth years, and nickel 61, which has a half life of ninety-two years. I'm particularly concerned with nickel 63 because it's one-third of the total curies involved in each submarine, and it's an internal exposure hazard.

In other words, it will affect you inside the body L.36
through eating of fish, for instance.

Another one -- and I hope the statistic was right in there -- is this nickel isotope 59, which has a half life of 80,000 years. And both of these seem prime candidates, if L.20
leaked into the oceans, to somehow get into the food chain.

It would seem to me that dumping 120 or more submarines would increase the marine life in the area by providing homes and L.55 cover for all sorts of marine life. We could be creating cities of marine life; especially when the containment walls are breached, probably within 100 years as it was said in the report.

Since most radiation is on the interior surface of the containment vessel when breached, they could become virtual pools of radioactivity where marine life would make their homes. Also would not the forms of life attaching themselves to the Q.13 hulls of submarines accelerate the process of corrosion? And this was never taken into account.

Seismic activity 40 miles away doesn't give me very much F.22 confidence. In the report there were at least, I think, only two to three lines dedicated to this, in very small print; which seems for 40 miles away to be negligence of some form.

Also that area, they mentioned one plate -- tectonic plate, the Gorda Juan de Paruca plate. But there are three plates that join right offshore there: the Juan Paruca plate, the Pacific plate and the North American plate. And of course, the San Andreas fault system is also very close to Cape Mendocino offshore. And very little information is given to the geology of the area relatively close to the dump site.

Incidentally, tectonic plate theories are only just about 20 years old; about the age of the submarines that we want to dump into there. Not much is known, particularly near

their boundaries. It could be found out, for instance, in the next 20 years that 40 miles away from a major fracture zone, instead of being "safe," could well be found to be quite dangerous. And we should leave ourselves open to that possibility.

On the map of page E-31 shows that the dumping site L.53 is less than 50 miles from one of the West Coast's prime fisheries; almost 500 catch per unit effort. Also the 127 degrees longitude eastern boundary -- and that's probably where the dump will take place because within 30 minutes of that you did the core samples. So -- also the map shows on this particular part that the grading goes from less than 10 catch per unit effort all the way up to 100 to 300 catch per unit. It's the only part in the map where you get such a discrete jump in catch areas. So I feel the report is kind of lacking in the research needed for that in the -- in the grading. We need a grading of the fishing. And since I eat the fish -- L.36 and the people I'm involved with eat most of our fish from Shelter Cove, it seems hardly pertinent to us to -- to make sure this is all checked out because I'm concerned about eating.

I'm also concerned about the currents. You have a south, southeast current at 29 meters above the ocean floor, J.28 at about one kilometer per day. It's rather slow, but within 100 days, radioactivity warmed by the current can move 60 miles. Very little is said about upwellings which is always J.31

242

a possibility. There are two major current oceanic surface currents relatively near to the proposed site, and it is possible through upwellings that the radioactivity can be brought much closer to the surface.

One of these is the California current, which is a north-south current in the summer, and it moves pretty well right over that area. But in the winter, there is also a Davidson current, which is a warm water current that moves from south to north in the general area where the California current more closely out to sea. None of this is, of course, mentioned. I had to look into the National Atlas published in 1970.

L.9

If this site is approved, if submarines are dumped, then I feel a precedent will be set that hasn't been set before. And once these submarines are dumped in a 20- to 30- -- 25- to 30-year period, then I would presume that the new Tridents will also be ready to dump. And heaven only knows what the Navy has prepared for us after the Trident; I would imagine a floating Diablo Canyon. You know, one big Captain Nemo submarine with all of the destructive power of all the wars forever and ever. Unless -- Unless of course there is a nuclear war, and then all of that is of course moot, and then -- and so we go on ad infinitum on this nuclear arms race thing, and it all ties together.

And what I've seen here today is such unity of the

north coast area, the whole coastal area and in particular our area that a brother who was working with Mother Teresa in Calcutta called our area God's country. And I -- I think it's the -- to be using the Pacific for war-making materials is a --

UNIDENTIFIED SPEAKER: A sin.

MR. ONEILL: Yes, that's right.

And with that, the only thing that I feel is that if you go ahead with this, I really feel that you will be resisted politically, nonviolently. And I feel in the long run if you -- if we are not listened to that -- that forces could be set up where you might -- that we could have nonviolent direct action off the coast; which means you would -- each submarine would have to cost more than 2 million dollars just to alert the ships to post water hoses on them to keep the fishing boats away.

Thank you very much.

--o0o--

CAPTAIN JAGGER: The next registered speaker is Garrett Connelly, representing Santa Barbara's People for Nuclear Free Future.

--oOo--

#81

GARRETT CONNELLY

Well, I have met an admiral in my life. I met an admiral in my life named Admiral Rickover who worked on submarines, and I had a long talk with the Admiral. And he explained to me exactly how radiation affects life. That the higher the level of radiation, the lower the level of life. It's as simple as that.

Now, you put more radiation in the water, the Santa Barbara -- the people of Santa Barbara, the people of California are not going to stand for it. So there's a problem; The radiation exists. I've read your book. I understand the logic that you're using. And I think we have to understand that this is California, and the people of California have a definite feeling for what life is all about; which is going to have to be understood by the Federal government.

And it goes something like this with regard to radiation: The NRC says that so many rems is so many rems.

And you fly in an airplane, and you get so many rems. You know, so you get your rems one way or you get your rems another way. It doesn't matter, you get your rems.

Well, we know more than that about the world. We've been accused here of being two generations ahead of science by our own Government. And none of us are scientists. We just have a feeling for what life is all about. It's as simple as that.

Now, when you get a rem -- when you get a rem it comes from carbon and that piece of carbon happens to be a hydrocarbon, it's part of your body; that's one kind of rem. And you get a rem flying in an airplane from general radiation out of the solar existence, and that's a general thing that happens day to day out, every way to Sunday.

So the Santa Barbara People for Nuclear Free Future and the people of California who are beginning to resist the constant pressure of absorbing the poisons that are generated by hateful warmongering all over the earth -- the Santa Barbara People for Nuclear Free Future feel that these things should be stored on the land somewhere very hard to reach from the ocean; Somewhere a long way away from a major river. Somewhere like up in the middle of Nevada. Somewhere very difficult; not on the Hanford River land site seven miles from the Columbia River, which is the alternate proposal. The radiation will have to go into the ocean eventually. The longer we can delay that path H.4

in our lifetimes is the best that we can do at this point in time.

N.3

The cost don't really bear in this. I have been in relationship with the Federal government on cost matters on several occasions. Once I saw the Federal government save 23 million dollars by allowing the NRC to give everyone in the country permission to burn all the radioactive rats, to throw all the radioactive shot givers -- hypodermic needles -- in the trash with the normal trash, to take all the radioactive aprons and radioactive pumps and all the radioactive things for another five millirems of specific radiation -- my objection was specific radiation -- as hydrogen and carbon.

So now we are all getting five millirems, an equivalent of a flight from here to New York of hydrogen and carbon; everyone here in this room -- and we are made out of hydrogen and carbon.

The basic attitude, the error, the reason the DEIS went wrong, where it missed the boat and where you'll never be able to convince the Californian that cares about the State is that you forgot to think about the relationship between the purely mechanical realm of pneutonian physics and the wonder of life. And life is magic. It's a magic thing that nobody understands, and you are in a realm here with radioactivity that is fooling with forces that are two generations ahead. You don't understand them. And you can't put it into the ocean

because you can't bring it back.

And so that's my objection from Santa Barbara, and I'll just tell you we are here. We put the Air Force on notice with the highest respect in a nonviolent heart, and the same goes for the Navy; the same goes for anyone that wants to hurt Mother Earth.

CAPTAIN WAGNER: Thank you, Mr. Connelly.

--oOo--

#82

CAPTAIN WAGNER: The next registered speaker is Ramona Crooks, representing Women Against Nuclear Proliferation.

--o0o--

RAMONA CROOKS

I'm Ramona Crooks; I'm from Anchor Bay on the Mendocino County coast. I represent a small group called Women Against Nuclear Proliferation. We're very concerned about ocean nuclear waste dumping for one reason primarily: the lack of proven information on the effects it can have.

According to the Navy, the radiation exposure is expected to be negligible, but expectations have been wrong in the past.

Two hundred and fifty thousand servicemen participated in atmospheric nuclear testing in the past, and no one in the military expected them to develop a higher rate of cancer than normal. Civilians living downwind of the Nevada test sites in the '50's and '60's are now having health problems. The military didn't expect that to happen either because nobody knew about the dangers of radioactive iodine getting into the food chain from fallout. People should never assume anything

because assumptions are so often wrong. And this Draft EIS is full of assumptions. I will assume the military did not expect that American servicemen would be contaminated by Agent Orange in Vietnam. L.40

What assumption is the Navy making about submarine dumping now that may be proved false when it's too late? According to the Navy, the radiation exposure is expected to be negligible. According to John Gotman (ph), a past associate director of the Lawrence Radiation Lab and internationally known for his research on the effects of radioactivity on man and on his environment, "No amount of radiation has ever been proved to be safe."

To my group that means that there is no negligible amount of exposure to radiation. We are very concerned about what you don't know and about what you may be assuming.

Therefore, we are opposed to disposal of nuclear submarines or nuclear waste in any ocean, river, lake, pond or stream.

Thank you.

--o0o--

*#37a

CAPTAIN WAGNER: The next registered speaker is Dr. Michael J. Hertz. Dr. Hertz represents the Oceanic Society.

--o0o--

DR. MICHAEL J. HERTZ

Thank you. I'm Dr. Michael J. Hertz, Executive Vice President of the Oceanic Society, a 60,000-member nonprofit organization devoted to protection of the marine environment to the development of a constituency for the oceans. The society has headquarters in San Francisco and Stamford, Connecticut, and active chapters along both coasts. We have testified at all three of your previous hearings and have been working with states, cities, counties and citizens' groups on both coasts on this issue over the past several years. I'm also delivering this testimony in behalf of the Whale Center, a nonprofit concern for the protection of mammals located in Oakland.

The Oceanic Society has, since it began, been concerned with the issue of ocean disposal of nuclear waste. Although we view with alarm the possibility of the Navy disposing 100 nuclear submarines in the ocean -- it is as much because of the precedent-setting nature of this action as it is because

of our concern over the potential impact of 6.2 million curies of radioactivity that will be added to the seas by the sub. It should be noted that in addition to the Navy's reactor disposal program, the Department of Energy spent over 20 million -- actually closer to 30 million -- since 1976 to investigate the use of the seabed off Hawaii as the disposal site for high-level nuclear waste fuel rods from nuclear power plants.

In addition, the Department of Energy is also considering the ocean alternative for disposal of nuclear waste from the Manhattan project that produced the first atomic bomb. We are concerned that -- the scoping hearings on that project were held last Thursday at the same time as your hearings were held in Savannah, South Carolina, and the same time that the London Dumping Convention was going on, making it extremely difficult for individuals and organizations concerned with this issue to track and testify at all these hearings.

We are also concerned that one of the driving forces behind the Navy's desire to scuttle these subs is that the SALT agreements -- the Strategic Arms Limitations Treaty provisions -- limit the number of subs that any country can have. The alternative for keeping the subs in protective storage or keeping them any place other than scuttled at sea might limit the number of Tridents that could be launched in the coming years. | D.7 *

*Other issues discussed by Dr. Herz are side barred in Exhibits 37, 37b, and 37c.

The Oceanic Society's role in evaluating a potential impact of proposed activities on the marine environment is to assess the science of technology presented in support of such a proposal. In early February, we convened a scientific committee made up of experts from a variety of disciplines around the country to review the adequacy of the Navy's Draft Environmental Impact Statement and the supporting oceanographic studies.

It should be noted too that the title of the oceanographic studies was "Oceanographic Studies in Support of the Assessment of the Sea Disposal of Nuclear Reactors," which leads us to believe that -- that is pretty high on the priority list, and that we are not just looking at the two alternatives; that some decisions may have already been made.

The points raised in the testimony of the file that were based on deliberations of this committee, the final report of our scientific committee, will be completed within the week and will be submitted as written comments to the Navy and will be available for other groups to review.

By far the most serious problem with the sea disposal alternative as presented in the DEIS is once scuttled the submarines are -- by the Navy's admission -- irretrievable. And as has been indicated here by a number of previous speakers, the irretrievability is against the current law. And the Anderson Amendment says any nuclear waste that is put in the

ocean following the two-year moratorium is by law required to be retrievable.

As presented in the DEIS, the monitoring plans for either land or ocean alternatives are inadequate. With the land alternative, the assumption is made that monitoring will be conducted as part of the current and continuing programs of Hanford or Savannah River sites. However, the cost of monitoring is not reflected in estimates presented. The sea disposal monitoring presentation is also clearly inadequate. The adequate -- inadequate record keeping and the failure of the U. S. government to conduct any but the most rudimentary monitoring research at any of the ocean sites -- and there were 50 used for disposal of nearly 100 curies of waste during the '60's, around the '40's and '50's and '60's, does not inspire us with confidence; especially with the grossness around EPA in charge of the permit procedure. Although the Draft Environmental Impact Statement contains no cost breakdown, the total amount listed for monitoring appears to be totally inadequate for materials that will be available for marine environment for many, many millenium. Without that adequate monitoring program, our scientific committee agreed that the sea disposal option should not receive further consideration.

The most serious deficiencies in the DEIS consideration of the ocean disposal alternative concerns the availability of radioactivity and the possible pathways through which available contamination might reach humans.

Issues not addressed or inadequately considered include: Additional information is required to fully assess the significance of the radioactivity contained in the crud deposits in the reactor cooling systems. Data from the crud collected at land base reactors - and that is a technical term, that is crud. That is the material that lines the inside of the cooling pipes that cools the reactor. The data from land base reactors suggests that this might well be one of the most serious sources of radioactivity which can easily become available to the marine environment.

Further data on alpha emitters or crud from decommissioned submarines is also needed. Missing details on the sampling sites relative to the location of the reactors from the Thresher and Scorpion accidents make it impossible to evaluate the Navy's plan that such steps pose no threat to the marine environment or to humans. Sediment, water and organism samples should also be collected from the site of the Soviet sub which the U. S. Government attempted to raise with the Glomar Explorer.

J.42

J.43

J.34

Also we are concerned that the projections presented in the DEIS fail to consider galvanic effects, the manner and rate of corrosion at external well locations, and the manner in which the lattice breakdown in the radiated stainless steel which has been heated from operation of the reactor will

affect corrosion.

Of greatest concern with any disposal alternative are the potential pathways to which the radioactivity might reach humans. There exists a significant body of literature concerning the migration of radionuclides from waste forms to the water column sediments into organisms that appears to have been ignored in the preparation of the Draft Environmental Impact Statement.

Pathway issues not addressed or inadequately considered include: the studies conducted by the Environmental Protection Agency and others demonstrating possible pathways such as benthic organisms to rattail fish which serve as a warning that other pathways or potential pathways exist and that further investigations are warranted.

In that regard, the single most damaging study to the position that says there has been no harm from past dump sites is a study that was done by William Shell and his associates which demonstrated that in the case of the East Coast, the Hudson Canyon site, that migration of radioactivity -- the americium in this case -- has been traced from waste barrels in the bottom sediment in the benthic organisms and then to rattail fish.

You should watch tonight the 20/20 program which will be the first public airing of that set of data because the Environmental Protection Agency has refused to release that information. I think perhaps the Navy could get the information if they requested it.

The artificial reef effect has not been investigated in the deep ocean, but the settling of marine organisms on the subs appears unlikely and should be investigated; particularly in terms of how it might serve as a pathway in an accident scenario both at a disposal site or worse on the continental shelf itself.

Also there has been a failure to consider the possible role in bacteria in the mobilization of radionuclides as a beginning of another pathway to humans.

The potential effect of accidents has not been adequately addressed. The Navy estimates 0.3 accidents per 100 subs scuttled at sea. Because this is a, quote, reasonable probability, the potential impact of such an accident on the continental shelf from both an impact sub and exposed reactor compartment should be discussed in detail, especially in terms of possible exposure level of three rems to a population of 30,000. To determine whether this is an acceptable exposure rate should be provided in the Draft Environmental Impact Statement.

Worse case calculations are confused and appear to be off by as much as nine orders of magnitude.

Further, the use of EPA's standard for drinking water is misleading and inappropriate, especially since the correct

calculations using the Navy's data come to within .1 of that standard.

The data presented in the DEIS on albacore catches in the vicinity of Mendocino sites are based on 15- to 23-year-old information while the more current available data which are available from the same sources at Scripps Institution of Oceanography indicate that in some cases each year the albacore catch is among the highest recorded on the Mendocino Coast. And that data is just as available to the Navy as it is to us to find.

In addition, there is no information presented as to fish catches on the East Coast site. There's a lack of consistency throughout the DEIS in terms of the use of worse and average cases' scenarios. In order to make discussions of exposure doses resulting from accidents, a uniform approach to terminology and calculations should be adopted in order to make presentations more meaningful.

The committee felt that one of the most serious deficiencies throughout the Environmental Impact Statement is the fact that none of the measurements presented are accompanied by air terms, making it impossible to determine the level of precision or the range or variability of the data recorded and a practice that no scientist would use in anything that he attempted to publish.

A serious deficiency throughout the DEIS is the fact --

I'm sorry, I'm repeating myself.

Although the DEIS states that locations for possible ocean disposal have not been selected, the stated site selection standards suggest that the lower continental rise area might be eliminated or possibly be eliminated based on data presented in the Oceanographic Studies Volume 2. That is where it is shown that the currents are some of the fastest seen in the North Atlantic. I think it would be unacceptable in terms of potential for disturbing of the radioactivity. Also the other East Coast site, the Hatteras Plain site, will probably be eliminated because it's just outside the U. S. 200-mile economic zone. And I think our Government could not fly that much in the face of international opinion and dump submarines outside our territorial waters.

In addition, it appears unlikely that locations other than Cape Mendocino area could be found on the West Coast that keep the required selection criteria. Our discussions with Dr. Ross Bek (ph) who is in charge of the Oregon State University studies indicate that the Southern California site that was considered briefly and then discarded as being too close to habitation, fishing, and shipping was the only other site that was really reasonable to be -- to fall into or to meet most of the criteria required; and therefore it looks as if the Mendocino "generic" site is the most likely of the three sites that are covered in the Environmental Impact

Statement for use.

Obviously, more site specific data will be required before an evaluation of the impacts on delineated disposal locations can be made.

Overall, our committee felt that this Navy DEIS is one of the poorest environmental documents that any of the scientific committee members have ever reviewed. It is filled with significant information gaps and technical deficiency and raises a great many issues requiring much additional information.

By and large, the document reflects poor scholarship as demonstrated by its author's failure to consider large bodies of pertinent information regarding a number of issues and by the use of old data when significant new information was readily available.

Also the review of the DEIS in the supporting oceanographic study reveals numerous inconsistencies -- internal inconsistencies -- places where the summary of the DEIS misrepresents data presented in the body of the DEIS, and also where the DEIS and the oceanographic study summary misrepresents information from the oceanographic studies. J.21

Careful reading of the cost data on ocean versus land also indicates the interesting fact that if one looks carefully, the 2 million dollar difference -- the 2 million dollar more expensive land disposal presentation includes within

VINE McKINNON & HALL
SACRAMENTO, CALIFORNIA

it the cost of, after removing the reactor compartments, welding the submarines back together, making them watertight and then towing them out to the ocean. That doesn't seem to be

O.12

part of the ocean -- or the land disposal alternative to us. And if that difference, if that cost of that project is removed, I think that that may eat up much of the difference, leaving cost not one of the principal considerations.

N.3

Our feeling that human health and safety should in any case take precedence over cost.

Because there are significantly more gaps, deficiencies, unanswered questions and uncertainties regarding the sea disposal alternative, the committee concluded based on the existing information that a land disposal option is far preferable. Land disposal would minimize corrosion, the principal mechanism producing available radioactivity and greatly simplify the monitoring process. We do, however, recommend an alternative not presented in the DEIS land

H.3
H.4

disposal alternative discussion, and that is the possible use of something like the Nevada test site which is a very arid environment, leaving the reactor compartments above ground where they would be subject to much less corrosion and minimize the amounts of radioactivity released in the environment.

And finally, we would like to add our support -- and we've already requested it - for an extension of the comment period at least for another 90 days to give people sufficient

time to comment on this proposal.

Thank you very much.

CAPTAIN WAGNER: The next registered speaker is Jeff Hohensee. I'm going to not be able to give the correct organization -- the Alliance for Responsible Energy. And, Mr. Hohensee, would you please correct that organization.

UNIDENTIFIED SPEAKER: There's another speaker here for organizations who is probably going to talk later who's on the list. He came late this morning; I would like to move over to individual speakers --

CAPTAIN WAGNER: Excuse me, sir?

UNIDENTIFIED SPEAKER: -- representing an organization. There is a fellow Yorgos Savides who is going to talk for our organization, and I would like to move my name over to individuals.

CAPTAIN WAGNER: Fine.

UNIDENTIFIED SPEAKER: Thank you.

--o0o--

252

CAPTAIN WAGNER: The next registered speaker then is Mr. Jim Le Cuyer.

MR. SAVIDES: Can I speak then at this point because I represent CARE, that is the organization that Jeff --

CAPTAIN WAGNER: That's fine. I'm sorry, sir.

--oOo--

#83

YORGOS SAVIDES

My name is Yorgos Savides. I represent CARE -- the Cahto Alliance for Responsible Energy. We are a member group of the Abalone Alliance located in Laytonville. And we represent the northernmost portion of inland Mendocino County. I trust that we would welcome a break from sort of the form that the hearing has been taking. I have a poem that offers testimony for our position against the dumping of submarines off the coast. It's entitled "Not Here, Not Anywhere."

"Not here, not anywhere should we meet like this
to discuss what to do with dead atomic submarines.
Not here, not anywhere.
I told them long ago it was a bad idea.
Sooner or later we would have to junk the things

because they would be too hot to handle.
I don't think anybody really cared about it
at that time.
It was just a brilliant new idea.
We were all blinded by the splitting of the
peaceful atom.
Dr. Frankenstein, meet Captain Nemo."

I learned all about the dangers of radiation in the 1950's. A film strip turtle taught me when I was a child in school. Being a turtle, he was very lucky, he could pull his head inside of his shell any time he wanted to escape from reality. He taught us to duck and cover. As soon as you see the blinding light, get under your desk. Clasp your hands on the back of your neck to protect it. Stay indoors and keep the windows closed until the cloud passes. Dump hot nuclear reactors in the ocean far, far away from the centers of population. Dilute them with enough seawater, and their leaking deadly radiation will be harmless. We were told lies then, and we are still being lied to.

And while we are obediently crouched under our desks, you know,I really did feel safe. I remember that as a child I really felt safe under my desk.

Innocent servicemen sat in open trenches in camp desert rock a few thousand feet from ground zero and watched the bones in their hands as if the flesh had melted away as white-coated AEC scientists studied their ability to field strip their M-1s moments after the blast. The green-clad guinea pigs today lie in hospital beds dying of leukemia while the VA turns a deaf ear.

Now, these old subs ain't going to hurt nobody if we can just get them far enough away.

B.4

When they were being built, the radiation from the submarines killed workers. Portsmouth Naval Shipyard, New Hampshire boasted a leukemia rate amongst shipyard workers 450 percent above the national average.

Admiral Rickover was not very eager to let folks know about that one.

The crews on the submarines most likely will fair no better. If they let these subs melt into the ocean floor, it's pretty certain we'll kill some more. I think the strange thing is our enemy may be a lot safer from these subs than we've ever been.

I am angry at America. I am angry at America's unleashed power greed. And I am angry at those who still blindly insist that radiation is a poison that can be diluted with the four sacred elements of our Mother. And that chromosomes will not notice the counterfeit. Those people who still insist this are either serving obscene self-interests or simply have had their heads in the sands of delusion so long they can no longer retrieve them.

We shouldn't be having this meeting. It is an insult to our children.

My neighbor's child contracted leukemia. I must speak from the heart as it is illuminated by the shadow of death.

When the submarines were built, they were dumped on the planet. We cannot dump them now. Not here, not anywhere. There are no hiding places left, and I still trust that we shall find the answers together.

I have a friend who is six years old, his name is Yaro Tager (ph). And he asked me to bring this and deliver it to the Navy today; a little sketch he did. And it's a picture of a submarine underneath the ocean, and a little boy standing on the shore. And I can't read all of it because some of it is written backwards, I think. But the kid's got a smile, and he's saying, "I can't swim." And the submarine has a big X through it.

Thank you for listening.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Mr. Jim Le Cuyer, representing Friends of the Earth.

--o0o--

#84

JIM LE CUYER

I'm Jim Le Cuyer, and I'm here to read a letter from Friends of the Earth, and joining with the Friends of the Earth in approval of that letter is the Marin Center for Peace, Marin Artists for Social Responsibility, International Union for the Conservation of Nature.

It's addressed to you, Captain Wagner.

"Captain Edward F. Wagner, United States Navy, Office of the Chief of Naval Operations.

"Dear Captain Wagner, the proposal to bury obsolete nuclear submarines in the ocean floor is of great concern to Friends of the Earth. We believe the ocean option is the least wise of the choices you have before you. The probability of

L.20 leakage into the biosphere is higher with marine storage than surface storage. A current understanding of the pressure

L.1 effects, corrosion rates and mobilization and geologic action is far inferior to our knowledge of those phenomenon on land.

"A further adequate technique for monitoring leakage

of radioactive materials under the ocean and cleanup of escaping radioactivity will be extremely difficult if not impossible. The application of civilian criteria for a high-level waste disposal to the technique being proposed by the Navy would disqualify this dumping procedure. Burying nuclear submarines on the ocean floor may temporarily solve our generation's problem of what to do with our legacy of radioactive waste, but it's hardly a fair legacy to bequeath to our children and those who follow them.

J.76
W.1
A.16
F.10

"Some radioactive materials remain dangerous far longer than the United States or even human civilization has been in existence, and we must broaden our vision from one lifetime to that of many.

"We recommend that nuclear wastes of all kinds be stored on sites already contaminated with such material until safer alternatives are found. We support efforts to find the safest permanent storage methods that can be developed. Our view is that such methods will probably be land based. The proposed inexpensive scuttling of nuclear submarines will foreclose such options. The ocean bottom alternative that appears financially cheaper for the moment is likely to become costly in monetary terms and irreparable damage to the ocean, their life and perhaps the well-being of the human species.

H.4

N.3

It is our responsibility to assure that the costs of our waste not be laid on the doorsteps of generations to come."

And this is submitted by Jim Redejanic (ph), Assistant to the Chairman of the Friends of the Earth.

I have a few personal comments to make. Captain Wagner, it might surprise you to know that some of us were also in the Navy. I was once a naval officer myself, and probably started about the same time you did -- 1956. I don't know when you began. USN.

I would say you would have to look far and wide right now to find people in California who were sincerely and deeply involved and interested in actually dumping waste in the California ocean here. I think you're convinced of that by now yourself, although I don't know from your face what you are convinced of.

I gave up my Navy career and I became recently a commercial fisherman. And I fish off this coast, and I used to fish off the Farallon Islands until I realized that tens of hundreds of thousands of barrels of radioactive waste had been dumped there. I got a little angry at this and a little worried, and I began to think somebody is wrecking my income. I began to realize that radioactive material as it enters the food chain
L.36 becomes more and more concentrated as it rises higher and higher
L.37 on the food chain. And my fish are about as high as you can get, except for me and other people like me.

When I found out that an estimated one-third of the
L.6 barrels off the Farallons were leaking, I began to wonder if

L.53 there was anything or anybody that could tell me just how radioactive my fish were. I mean, what was I actually catching? And there was nothing. No one could tell me. I began to wonder if I was selling radioactively hot fish to people. And I began to worry about it. So I stopped fishing there. And the reason -- the real reason I stopped is because I know that low-level radioactivity is carcinogenic. And even if you don't think that low-level radioactivity is potentially carcinogenic -- which I think very few people believe -- then you ask someone who believes that to eat a radioactive fish.

I stopped fishing at Farallons also because I've seen how cancer works firsthand. My mother died of it; my grandmother died of it; my uncle and a close friend died of it. It's a very long, slow, painful, horrible death. It drives the victim crazy with pain. I don't believe even the Navy wants anyone to die like that.

I propose three things: One, that hearings be held J.15 in coastal fishing towns at Monterey, San Francisco, Bodega Bay, Fort Bragg and Eureka. You can get a real sense of what the coastal people feel. I'm sure you feel deeply about the ocean yourself.

I propose that until adequate realistic environmental impact studies are undertaken by respected disinterested scientific people, that there be no further dumping of radioactive waste in our ocean.

And I propose -- three -- something that my fellow fishermen might be a little hot about, and no pun intended. That the Farallon Islands be closed to sport and commercial fishing until we know just exactly what we are catching and eating there.

Finally, I want to thank the Navy for offering us the opportunity to come together here. You have allowed a whole variety of sometimes disparate groups -- disparate not desperate -- disparate groups and individuals a welcome chance to come together in an ever greater and more powerful antinuclear movement.

Thank you very much.

--o0o--

UNIDENTIFIED SPEAKER: Merere Paradise asked me to ask you if she could come next. She was promised by you at the lunch break to come after Jackson Davis.

CAPTAIN WAGNER: Ms. Paradise may come next. She represents the Farallon Foundation.

--o0o--

#85

MORERE PARADISE

Good afternoon, Captain Wagner. I'm sorry that we could not meet under more pleasant circumstances. I'm concerned for your well-being as well as mine, otherwise I would not be here. I'm here on behalf of the Farallon Foundation. I have two statements from people that are involved in our organization.

The first one is a letter from Gordon L. Chan, who is a Ph.D. in the Department of Biology. He is also on the Scientific Advisory Board for the Farallon Foundation. The letter starts as follows. It is addressed to Louis Syler, who is the president.

"Dear Mr. Syler, I have read the DEIS for the disposal of defueled naval submarine reactors off our

Mendocino Coast. In summary, I would like to reject this DEIS report for the following reasons: There is no or very little reference of released radionuclides for marine organisms.

T.13 Applying study of terrestrial freshwater organisms to a marine biota is not scientifically applicable in my line of thinking.

L.13 L.43 T.18 J.9 There is no study on accumulative consumption of released radionuclides by benthic or prolific species. What are the effects on the reproductive sequences? What is the population of marine biota in the Mendocino trench area? What are the densities of critical marine species that live in that area?

L.1 Are there any specific marine organisms that are few in numbers and might be endemic to this locality? Could it be possible

J.9 that rare marine species can be eliminated by the release of these nuclides? Until I see such predisposal studies, I would not unload such submarine vessels in the marine habitat. To do so would be a serious mistake in the science of preparatory care of our national resources."

This is signed sincerely, Gordon L. Chan, Ph.D., Biology Department.

Okay. This next letter is from John Harris, Ph.D. in Radiation Biology. He is also an M.D. specialist in oncology; that is cancer studies. He's also on the Scientific Advisory Board for Farallon Foundation.

The letter starts as follows: "As a radiation biologist with over 20 years of research experience on the

effects of radiation, and as a physician whose medical specialty is radiation therapy -- use of radiation for the treatment of cancer patients -- I have an extensive experience with and knowledge of the biological effects of ionization radiation -- excuse me -- ionizing radiation.

"I am a member of many scientific and medical societies and have served, for some years, as the United States representative to the International Atomic Energy Agency working subgroup on modification of radiation therapy in cancer patients. This background provides me with a unique viewpoint from which to comment on the Draft Environmental Impact Statement mentioned above.

"This DEIS argues that disposal of 100 nuclear submarines in the ocean environment is a desirable option because it is cheaper, it is simpler and requires no new regulations relative to other options. It is a seductive document, replete with mathematical models, formulae and graphs which obscure and minimize the real issues. It is pertinent to note in this connection that the authorship includes 13 engineers and mathematicians but only two biologists -- one wildlife biologist Ph.D. and one M.S. in environmental studies with a three-year experience. N.11

"It is critically important that we remember the old adage that those who fail to learn lessons of history are doomed to repeat them. From the unfortunate results of

NOTE: This testimony was also submitted (June 1983) as a document which appears in Exhibit 707.

J.20

T.3

our A bomb experience through the many industrial chemical accidents whose litigations fill our courts, we should have learned by now that government documents which are replete with reassurances of safety based on complicated and calculated scenarios neglect one central fact: Nature does not always understand mathematics;and the calculations, no matter how sophisticated, inevitably are based on incomplete data.

J.20

"When such calculations involve trivial matters, the consequences are often annoying, at best. However, when a potential crisis of the magnitude involved in miscalculations of the consequences of atomic submarine disposal in the ocean environment are involved, then lack of any data may well prove catastrophic.

"The report concludes that the 6 million curies of radioactive materials from 100 submarines would undergo a significant amount of radioactive decay before its containment shell corrodes. They bolster the argument with very short-term data from two sunken submarines and go to great lengths to indicate how secure the calculations can make one feel about the containment, for as long as 200 years.

A.7

L.20

"The fact of the matter is that there would still be as much as 5,000 curies of cobalt 60 alone present even 1,000 years from the disposal time. Surely the mathematicians would not have us believe that the subs will be intact in 1,000 years. It should be apparent that the heartfelt wish that these

L.22

isotopes will not get into the human environment because they would be insoluble is just that -- a wish, not a reality based on any data.

J.20

"The report, for all its mathematical beauty, contains little or no hard data regarding the fate of these various isotopes, by themselves or as changed by the marine environment. In my opinion, it is tantamount to insanity to believe that we can irretrievably dump 100 nuclear submarines -- and one wonders how much more in the future -- with impunity. I think that we are talking about nothing less than potential contamination of the biosphere for future generations, and we are considering this based on cost and very limited data. The land option, while admittedly more expensive, would at least permit ongoing monitoring and possibly retrieval as needed. Experience with and facilities for this option already exist and should be used.

"As a citizen of California, a resident of the Pacific coastline and a scientist and physician who has worked with and researched the effects of radiation for over two decades, I call upon the California State Legislature to take a strong position against this potential insanity and to utilize every means at its command to insure that nuclear wastes are not disposed of in the marine environment."

This letter is signed by John W. Harris, Ph.D., M.D., Associate Professor of Radiation and Oncology.

Captain Wagner, in conclusion, I would like to say as a concerned individual for the well-being of all of humanity, I plead to the United States Navy to not dump into the ocean anywhere in the world and to do further investigation into other viable options such as the land controlled situation where the monitoring could take place.

And I now also plead to the public to educate themselves further and take advantage of these testimonies that have been given here today. Take this opportunity to become active. I strongly urge you to listen to your conscience. Act with expedience and integrity on these issues that can no longer be ignored. We must take responsibility. Many of us have been ignoring this situation for a long time. It is up to the public to change things; to bring about a safe environment; to insure the survival of humanity of our world.

Thank you.

CAPTAIN WAGNER: Thank you, Ms. Paradise.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Scott McCreary, representing Bay Chapter of the Oceanic Society.

--o0o--

#86

SCOTT McCREARY

Thank you very much for the opportunity to speak to you today. I am Scott McCreary, Vice President of the Bay Chapter of the Oceanic Society; one of three chapters in California. I represent a Northern California membership of 1800 people. Today we join with the National Oceanic Society, the Farallon Foundation and others in expressing our opposition to the Navy's plan to scuttle up to 100 obsolete nuclear submarines off Cape Mendocino; thereby adding 6.2 million curies of radioactivity to the oceans.

Our motivation for speaking today is both scientific concern and our philosophical position that nuclear materials produced in the United States should not be disposed in the ocean bottoms. We share the concern of the Oceanic Society's Scientific Advisory Committee whose members critique the Navy's DEIS. We believe the document is flawed, both in the data it fails to present and in the methodology by which conclusions are reached.

Sources of radioactivity are not adequately considered in the Navy's DEIS. Starting with samples from the sites of the Thresher and Scorpion accidents, the Navy should reexamine the statement that subs posed no risk to the marine environment.

A.12 We believe additional data is needed from the so-called crud deposits of nuclear cooling systems.

L.35 Further, the document doesn't take account of corrosion effects that would permit escape of radioactivity to a marine environment. Pathways from waste forms to the marine food chain and to humans are inadequately considered.

U.9 The Navy chose to ignore studies by Shell in the VC for EPA and other studies concerning the migration of waste forms to the water column, sediments, benthic organisms and then to fish.

L.55 Possible pathways associated with the artificial reef effect of organisms settling on subs is not investigated

Q.13 nor is the possible role of bacteria addressed in the mobilization of radionuclides.

Shortcomings in the methodology are numerous. There are basic inconsistencies between the DEIS in supporting oceanographic studies.

S.25 None of the measurements presented are accompanied by error terms, making it impossible to verify the precision or accuracy of the data.

R.24 The construction of worse case scenarios are confused, and we believe inappropriate.

Beyond these fundamental problems with data and computation, I would offer another critique of the Navy's

document. As the principal author of the Draft EIS for the Department of Commerce action on the California coast, I've had firsthand experience being on the other side of the hearing table in this sort of situation.

The President's Council on Environmental Quality drew up some standards for the contents of the Environmental Impact Statement with very specific concepts in mind. One was the idea that irreversible commitments of resources should be examined, and especially closely. The Navy's disposal option appears to be our typical example of an irreversible commitment of resources. The Navy's own statements indicate that once scuttled, the subs would be irretrievable. W.1

This is a direct contradiction of the Anderson Amendment signed into law by President Reagan. F.2

Looking closely at irreversible commitments of resources means careful monitoring to make sure nothing goes wrong.

Both the budget presented in the DEIS and the nature of the disposal program would make adequate monitoring all but impossible. J.76

The second key concept in the CEO guidelines is the insistence that cumulative effects of federal actions be assessed. A proper discussion of cumulative impact should present the Navy's plan in the context of past and future actions. In this case, we must understand cumulative impacts to refer to ocean disposal of radioactive materials through L.7

other programs; both in the country and internationally.

Our own Department of Energy has investigated ocean disposal for spent fuel rods from nuclear power plants and from nuclear waste from the Manhattan project. Ocean disposal of nuclear waste looms as a likely spinoff of the proliferation of so-called many reactors throughout other industrial nations and the third world.

F.8

Given this universal ocean disposal options, the Navy's programs must be viewed as both a symbolic and legal precedent affecting the global ocean continents.

The spector of radioactive waste amounting to as much as 200 billion curies by the year 2000 from nuclear reactors plus additional radioactive waste from military weapons, research, manufacture and disposal makes the thought of ocean disposal truly frightening.

Our decision will be used as the precedent by other nations with nuclear capabilities. This already includes six nuclear weapons powers of today and will likely include over a dozen other nations by the turn of the century. Scores more countries have received radioactive materials for research and power reactors and through clandestine operations. And we are preparing the capabilities to manufacture these materials on their own. Where will the radioactive waste from all this activity be disposed? The precedent that would be set by the United States' ocean dumping our decommissioned

submarines is in itself a critical impact that must be assessed in your environmental impact document.

I would like to raise the nature of this decision process as a concern of my organization. Like the National Oceanic Society, the Bay Chapter is committed to bring the best possible technical data to the decision process. This position has been voiced in our recent statements on the quality of San Francisco Bay offshore drilling and now nuclear dumping at sea.

Last June we convened the first State of the Bay Conference, a quorum of 300 academics and advocates to develop ways of tracking the quality of San Francisco Bay -- this is the document that contains that work.

We presented index numbers for water quality, freshwater inflow into the Bay, fisheries and habitates. These were exposed to cross-examination critique and discussion in an open forum. In contrast, the Navy has provided minimal opportunity for public access to this decision process.

As an organization with interest directly related to the proposal, we are alarmed that not one hearing has been scheduled in a coastal community on the DEIS. Very little effort was made to tap a scientific community or the many users of the marine environment with the direct interest in this issue. In fact, the people in this room today are a more fraction of those with a stake in the outcome of the Navy's

J.15

decision.

As a final point, I would like to raise the issue of the economic justification of an ocean disposal program. Economic calculations are used by the Navy to justify ocean disposal as a preferred alternative. Yet a genuine reckoning of the consequences of high levels of radioactivity finding its way from waste forms to the marine food chain would suggest the other alternative -- land disposal.

N.3

Consider that the oceans and the coastline are common property resources. They belong to all of us. We should ask those likely to be affected by this action how much they would want as compensation before the submarines are scuttled. I suggest that the people of California -- in fact the people in this room -- would ask a very high price indeed.

Thank you for the opportunity to speak.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Jonathan McHugh, representing People for A Nuclear Free Pacific.

--o0o--

#87

JONATHAN McHUGH

Hi. My name is Jon McHugh. I'm with People for A Nuclear Free Pacific, and we represent people all over, around the ocean here, from the United States to Canada, New Zealand, Australia, Japan -- basically ocean people everywhere.

And right now at this hearing, I've noticed that there tends to be an adversarial relationship between the people of this meeting and the Department of the Navy. And I think this is too bad because it's the Navy's duty to protect and defend the American people. And I think the views that are being expressed here is that the Navy is not doing this.

I think that the first question that must be asked at this hearing is why does the Navy want to decommission these Polaris submarines. And one of the reasons is that in order to comply with this Strategic Limitations Talks, in order to put more Tridents into the water, we have got to take some Polaris out. And -- okay.

The introduction of these new class of subs is presumably for the protection of the American people, and presumably that these actions are representing the will of the American people.

Well, in 1982 the express will of the majority of Californians was that we wanted a nuclear freeze. That we considered the continuation of the arms race a threat to our security and not, you know, benefiting our security.

The continuation of the arms race is against the express will of the people of the State, and this continuation is democracy ignored and abused.

We want a freeze on the production of radioactive poisons. These poisons are nonthreshold pollutants that are very much similar to PCB's. And these were outlawed in 1976 because of the problems with nonthreshold pollutants. Basically, they can't be diluted, and -- I mean, they'll still kill people anyway, even if they are diluted.

L.36
L.1
G.2

We depend on the ocean for food, and in the future we may depend on it even more. The dumping of 5 million curies into the ocean doesn't seem prudent when scientific knowledge on transport mechanisms are in their infancy. Therefore it's necessary that the Navy wait and store the subs in dry dock until sufficient knowledge is gathered.

Furthermore that the Navy and Congress make sure that it is the will of the American people that it is our desire to maintain the arms race. I don't believe it is.

The victory of a nuclear freeze initiative in eight of nine states clearly supports this belief.

The atmospheric weapons testing by the Department of Defense has increased the levels of radioactive hydrogen in the ocean by 43 times. The increase in cancer has become endemic, and this is certainly related to radioactive releases into the environment. And I'm sure you're aware of the reasons why atmospheric testing were discontinued. Tritium is only one of the isotopes. Sesium was another one; plutonium.

The Department of Defense is in the business of protecting its citizens, not in the business of killing them.

UNIDENTIFIED SPEAKER: It should be. That was a should be. They should be.

MR. McHUGH: Oh, okay. Okay, the Department of Defense should be in the business of protecting the citizens, and not in the business of killing them.

L.37

When you consider the body concentration effects in the food chain of radionuclides, you realize that what you dump in the ocean will come back to you on your dinner plate. I live in Santa Barbara, and there the Navy has dumped radioactive waste in the submarine trench off the Channel Islands.

L.35
U.5
U.2

Recently a graduate student at UC Santa Barbara has done research on how the radioactive materials get into the food chain even though they are at great depths. And that is the eggs fall into the trench, and then the young fish swim up, and then other fish eat them. So even where there is not upwelling, there is still a possibility of this radioactive materials getting into the food chain.

It took human knowledge to create radioactive waste which endangers the health of the American people, and it will take knowledge to protect ourselves from radioactive waste as well.

We would like you to bring back a message to Washington and the Defense Department that we want to be defended from the threat of nuclear waste. Furthermore that peoples all over the Pacific want our ocean to be kept clean. Remember it is your duty to protect our democracy, and that is the democratic will of the people as expressed through elections -- to halt the production of nuclear weapons and associated waste, even if it is against your own personal views.

We want to rid the planet of nuclear weapons. Let it start here. Let it start now, and let it start with us.

Thank you.

--oOo--

CAPTAIN WAGNER: The next registered speaker is Mr. Tom O'Neil, representing the Environmental Protection Information Center.

MR. O'NEIL: That's okay, I already spoke.

CAPTAIN WAGNER: Fine. Thank you.

Then we'll move onto the next speaker, Mr. Charles Orth, representing Ban the Ocean Nuclear Dumping.

--oOo--

#88

CHARLES ORTH

I'm Mr. Orth, and I do represent BOND here today. Quite a few of our people are also here. I would also like to note that we do have about 40 people that we bused here that left at 4:30 this morning, many of them having drove, oh, an hour to an hour and a half to reach the bus to begin with. They arrived at 10:30, and thereby by your current agenda, they who have to leave by 9:00 o'clock tonight to be able to work tomorrow -- they are already missing a workday today -- I feel you should take into regards those people who did sign up at a later date -- and I'm sure some of the earlier people will waive their rights to testify until a later time. Please regard this.

On behalf of the people of the Mendocino County who are unable to attend this distant hearing site as required by the Department of the Navy, through a verbal testimonial, as ambassador for the coalition of groups calling itself BOND -- Ban Ocean Nuclear Dumping -- I stand before you with a voice full of concern of many thousands; filled with a fear that our Government will not stop the ocean disposal of radioactive waste.

It is the oceans where seventy percent of all oxygen from photosynthesis occurs in the biological process of marine microorganisms. What effect will our disposal of radioactive waste have on these minute organisms that exist in every form and every depth of the ocean environment? We as a people demand to know. L.13

Before you today we speak on the DEIS, on the disposal of decommissioned, defueled naval submarine reactor plants. The sites are in the deep ocean waters off the United States' 200-mile offshore economic zone. How long before other proposals such as the purported sub seabed disposal of low- and medium-level radioactive waste becomes public; as has the proposal to dump without containers of any kind the original radioactive tailings of the Manhattan project? L.9

As an informed group, our comments here today will adhere to all present and future proposals for the dumping of both toxic and radioactive waste in any ocean or naturally occurring body of water. We feel that any water-born program

submits any environment to unacceptable risks as shown by studies done on the Columbia River, the Savannah River and at White Oak Lake near Oakridge, Tennessee.

And I quote from Dr. Robert Pendleton, a nuclear and genetic biologist of the University of Utah, quote: "Very small amounts of radioactive waste were dumped into White Oak Lake. Fish that appeared afterwards were fantastic. They changed into many grotesque shapes and sizes. The most amazing thing was not the genetic mutations but the fact that some fish were found many miles downstream from the lake glowing like Christmas trees," end of quote.

Does the Navy feel that such a result in the rattail fish species of the great ocean depths would be as intriguing as were the Sea Wolf's bluish glowing when it was powered by its now infamous sodium reactor plant? I wonder that with such a beacon effect we still have not found this reactor dumped by the Navy off our East Coast. J.85

Talking about missing or lost material, where are the EPA's studies and film taken of the Farallons' nuclear dump site before the current administration's tenure in office began? Are we to trust the EPA as currently structured to protect and release these documents as part of the final draft on the submarine disposal at sea? They relate to the leaking of radioactive waste into the marine environment. We find no mention of any studies of past sites where any nuclear material L.6

was positively positioned in relationship to any test patterns.

J.42 Specifically, the studies as shown in the current DEIS show only nonnuclear areas, as once again the Navy is unable to show any part of a nuclear reactor plant once placed into a deep ocean environment.

Three such plants exist: the sodium reactor plant which first powered the Sea Wolf and then by accident the fully-fueled reactors of both the Thresher and the Scorpion nuclear subs.

I cite Public Law number 97424 in the Ocean Dumping Act of January 6, 1983, Section J: J.76 "A comprehensive monitoring plan to be carried out by the applicant to determine the full effect of disposal on the marine environment, living resources, or human health."

F.2 Section K(2) requires, I quote: "The administrator shall include in any permit to which paragraph I J is fully implemented, including the analysis by the administrator of the samples required to be taken under this plan."

Section K requires such other information which the administrator may require in order to determine the full effects of such disposal. This law requires a far larger monitoring budget than contained in the DEIS as each and every sub must be monitored fully for faults and/or leaks over a long and extensive time period.

W.1 Also no cost analysis has been done on a plan for the removal or cost of containment of the disposed nuclear material

if the container leaks or decomposes as required in Section E of Public Law 97424. L.53 L.20 Also the current DEIS contains no analysis of testimony about the resulting environmental and economic conditions if the containers fail to contain the radioactive waste material when initially deposited at the specific site as required in Section D of the Public Law 97424.

These additional requirements must be fully addressed in any final Environmental Impact Statement.

The people of Sonoma, Mendocino and Humboldt Counties by their elected representatives at all county, state and federal official levels have requested that additional hearings be held J.15 locally in both Fort Bragg and Eureka. Also the coalition to oppose the ocean dumping of radioactive waste has formally requested the Secretary of the Navy John Lehman a 90-day extension of the comment deadline on the Navy's DEIS for submarine disposal.

The current members of this coalition are in alphabetical order: Ban Nuclear Dumping, Can Disarm, Center for Environmental Education, Committee to Bridge the Gap, Critical Mass and Energy Projects, the Farallon Foundation, Friends of the Earth, Greenpeace, National Audubon Society, Natural Resources Defense Council, Nuclear Free Pacific, Nuclear Information Resource Service, Ocean Education Project, Oceanic Society, Sierra Club, Union of Concerned Scientists and the Wilderness Society.

The depth of our real concerns are here amply shown. And as adequate time has not allowed a full study or even a wide availability of the current DEIS on sub disposal, not to mention the great hardships of a far away workday hearing location, we once again ask for local hearings; these hearings to occur in Fort Bragg and Eureka, and an extension of 90 days on the comment period on DEIS before us today.

L.15

Currently, BOND holds seven percent of the Mendocino community on petition, and I will read this petition to you.

"Petition Against Radioactive Ocean Dumping.

"Because radioactive waste is concentrated in the food chain, increasing its toxicity; because radioactive substances have been shown to cause cancer; because people use the ocean as a source of food, recreation, livelihood and inspiration, we the undersigned demand that the Environmental Protection Agency and the Department of Energy not allow offshore dumping of any radioactive waste."

L.36
L.37
L.53

This petition is about to go national and from there international. So you'll be hearing a lot more about that. These people are stating their opposition to any radioactive waste dumping into any ocean environment and calls for a ban on any such plans or actions.

We do not feel that this hearing addresses the majority of issues still to be put forth by a large part of our interested population or that the time period for public comments allows

for an informed and well-planned review of a critical governmental proposal affecting the future of our offshore ocean environment and/or resource impact.

As we represent a citizens' group, we know the needs of a working population. With time in which to adequately address such a complicated issue due to the effect our environment over hundreds -- due to affect our environment over hundreds and possibly thousands of years.

BOND will submit written comments at a later time.

Thank you.

CAPTAIN WAGNER: Ladies and gentlemen, in order to give our hardworking reporters a few minutes of rest, I want to take a five-minute recess.

We will reconvene the hearing in five minutes.

(Whereupon a brief recess was taken.)

--oOo--

268

CAPTAIN WAGNER: Ladies and gentlemen, if you would resume your seats, please, we will reconvene our hearing.

Ladies and gentlemen, we have two -- if I can have your attention. We have two organizations of school children who have also come a long way today, and so if I have no objections, I would like at this time to have these two organizations of school children come on next so the children can go back home.

The first organization is from the Point Arena Elementary School. Here with Miss Elana Gerstein are some children, and I will introduce each of the children individually and ask them to make their statement at the microphone.

First is Julie Green, please.

--o0o--

#89

JULIE GREEN

Hello. My name is Julie Green, and I come from Mendocino County. And I live in a little town called Anchor Bay. And I go to Point Arena Elementary School, and I'm in eighth grade. And I come here representing my whole class and many other people.

And I want to speak out against the dumping of the nuclear subs off the coastline that I have looked at ever since

I was two years old. I want to say that if the Navy were to dump these nuclear subs, they would lose all of my respect. I have always grown up to believe that the Navy was supposed to protect our ocean. If they dump the subs, they will be contaminating it and harming it. I think that because you built these things, you should think of something better to do with them. I do not want them built so much that I would suffer from them. Like my friends, I care about the effects that it will have on fish and animals of the sea, but I also care about the people that it will affect when the radiation poison leaks out of these subs. It will leak into the sea. Fish that live in the sea will get contaminated; and if people eat this fish, they will be contaminated.

L.14
L.20
L.36

If a pregnant woman ate this fish, her child would probably be born defective. Think of all the children that would be born defective. How could you live with the guilt of ruining a future human life? What if it was your grandchildren or their grandchildren that were harmed by this act? You have the power to save life or destroy it.

I hope you choose life because I want to live safely. That's all I have to say.

--o0o--

#90

CAPTAIN WAGNER: Our next speaker is Elana Gerstein, also from Point Arena Elementary.

--o0o--

ELANA GERSTEIN

My name is Elana Gerstein, and I've come up here from Gualala which is right on the coast of Mendocino County.

This isn't easy for me. I'm only doing this because I really care about what I'm about to say. I really care for the ocean. I love the animals of the sea and all the other things that go along with our beautiful coast. I agree with all that has been said against the dumping of the nuclear subs, and I too am here to speak my feelings on this important subject.

Unlike others, I was lucky enough to come here, and I know a lot of people who care just as much as I do.

We don't know all of the dangers the dumping of subs will cause our ocean. Why are we taking this chance? You people are making a big decision, and your choice is going to affect many. I thought Navy people cared for the ocean, but by dumping the subs, you are actually putting the sea in great danger. You people are meant to protect us, not harm us.

Let's just wait until we have a safe way of getting

rid of these nuclear subs. Why is it that the submarines are run by nuclear power? I feel that we should find a better way so that we don't have to deal with any more of these problems. The submarines cost a lot of money, and we hardly have the money to take care of our own people.

I find it very stupid that we would make such dangerous material when we don't even know how to safely get rid of it. What you are wanting to do is very dangerous, and I don't see how you can even consider it.

Please don't dump the -- Please don't dump the nuclear subs -- Please don't dump the nuclear subs off our coast.

Thank you.

--o0o--

CAPTAIN WAGNER: Our next speaker is Sara Press, from the Point Arena Elementary School.

--o0o--

#91

SARA PRESS

Hi. My name is Sara Press, and I'm from Anchor Bay, which is in Mendocino County. I'm in the seventh grade.

I am speaking for a lot of people at home who couldn't take the day off to come down here.

It's hard to believe that you people in the Navy who have spent so much time on sea can barely see it being destroyed. Who knows what the subs can do after they are dumped into the ocean? I live by the ocean, and I -- and I see the -- I hear the sea lions and other animals. I would not like to see their homes being ruined. L.14

When you were young, did you have to worry about what was going to happen to the earth and the land around you?

Fishing is one of the leading industries in Mendocino County. And the dumping would be near a prime fishing area. That's not very smart. L.53 We should stop making -- We should stop making any more submarines and find a safe way to get rid of the ones that we have. N.3 We shouldn't have even started

to build them until we found a safe way to get rid of them.

The fish and other sea animals can't say what they feel about radioactivity matter being dumped into their homes; so we people have to speak for them: Don't dump the submarines.

--o0o--

CAPTAIN WAGNER: The next speaker is Lea Rude, from the Point Arena Elementary School.

--o0o--

#92

LEA RUDE

Hi. My name is Lea Rude, and I'm in the eighth grade. I live in Point Arena, California, where my home is about two miles from the ocean. It is very hard for me to say what I feel and it is also very hard because I'm not only talking for myself but for many people who live on the coast and many of my friends.

I really love to be by the ocean and see the California gray whales migrating up and down the coast.

I don't know -- I don't know much about nuclear power, but I do know that it may someday destroy our earth. And if nuclear submarines are dumped off the coast, it will destroy sea life, plant life and a vast amount of water. This ocean is the home of many. Please don't destroy it.

--o0o--

CAPTAIN WAGNER: The next speaker is Oona Sherman, from the Point Arena Elementary School.

--o0o--

#93

OONA SHERMAN

Before I say the way I feel, I want you to know that this is a very scary experience for me, and that I'm only doing this because I care about our ocean -- which I live less than a mile from.

My name is Oona Sherman. I'm in seventh grade, and I live in Anchor Bay, which is in Mendocino County.

Just because I'm only 12 doesn't mean I don't care about my ocean or that I don't have the right to speak out. I came down here, missing school, because this is something I believe in.

Dumping these nuclear subs in our coast would ruin our ocean, which would also ruin the world and everything on it. It is also pointless; and I just don't understand why this dumping is being considered.

I realize that you have to get rid of this waste that you made, but I don't think it was very responsible to make dangerous nuclear waste without finding a good way to get rid of it.

I find it really disgusting that you Navy personnel with your obvious respect for the ocean could even consider this. You see, I live so close to the ocean that I can see fish rock while I'm eating breakfast and can hear the sea lions. It really sickens me that this part of life will be set off-balance. And I want everyone here to know that I will do everything I can to stop this world destruction.

This issue is very important to me and a lot of my friends and family, and I don't think that there is even one good reason for it.

Thank you.

--o0o--

CAPTAIN WAGNER: Our final speaker from the Point Arena Elementary School is Brendan Mobert.

--o0o--

#94

BRENDAN MOBERT

My name is Brendan Mobert, and I represent -- I represent the third grade in Point Arena. And this is how I feel about this group and a few other things.

This is an angry group, and they have reason for it. I wish to say that nobody here is wrong, but then again nobody here is right. At this minute, I haven't heard everybody's speech, but I think you are -- I think -- let's see -- that the Navy is endangering the earth and all its life.

I have to live with your mistaken -- I mean their mistakes, and they don't. Everybody's life here is something special about it -- has something special. And I suggest that you remember us and that we count too.

CAPTAIN WAGNER: I would like to thank each of the students from Point Arena Elementary School.

--o0o--

#95

CAPTAIN WAGNER: The next organization -- the next school that is represented is the Fire Creek School.

And the first speaker, I believe, is Susan Powell.

UNIDENTIFIED SPEAKER: Thank you. I think you better come back to Powell.

I just had a few things that I would like to say first, and then some of the children have some things they would like to say also.

I don't have anything really scientific to say, but when I first heard the idea of the submarines being dumped in the ocean, I was so appalled and shocked. And I started to wonder what was it that -- you know, I've almost become hardened to the fact that there is nuclear waste all around us. But what was it that really grabbed me about that? And the more I thought about it, the more I thought it was because the earth -- life on earth came from the ocean. It's the source. And I don't mean just, you know, the little single-celled algae that put oxygen into the atmosphere or even the first vertebrae that crawled up on some beach, you know, way back then. I started thinking about how all of us really come from the ocean because we spend the first nine months of our existence in fluid that is in many respects identical to ocean water. We all come from that same salty womb, I guess. And I think we should respect that. I think we have to really honor that.

And I can't think of anything else. That is really what I wanted to say.

The children have a song that we would like to sing first, and then afterwards some of us have some remarks.

--oOo--

STUDENTS FROM FIRE CREEK SCHOOL

(Song)

"Don't dump your subs in our ocean, our ocean, our
ocean.
Don't dump your subs in our ocean, our ocean's clean.
Don't dump your nukes in our ocean, our ocean, our
ocean.
Don't dump your nukes in our ocean, our ocean's clean.
Don't dump your trash in our ocean, our ocean, our
ocean.
Don't dump your trash in our ocean, our ocean's clean."

UNIDENTIFIED STUDENT SPEAKER: Let us live long in this world. This is the water of the people. And I learned this from an Indian prayer. I do not want to live a nuclear life.

UNIDENTIFIED STUDENT SPEAKER: I wonder if the Navy cares about children's future.

UNIDENTIFIED SPEAKER: Children, why don't you go give him your picture.

Some of the children feel that pictures speak louder than their words.

Thank you.

UNIDENTIFIED SPEAKER: I would like to speak for her. She's 18 months old, and she would like to live a clean life. And she would like not for you to dump these nuclear submarines in our ocean.

CAPTAIN WAGNER: Thank you, all the students of Fire Creek School.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Judith Redwing, representing Women for Survival.

--o0o--

#96

JUDITH REDWING

My name is Judith Redwing. I represent Women for Survival, a group from the Mendocino Coast, which also has a chapter in Santa Fe, New Mexico, which as we all know is where the nuclear fuel cycle began with uranium mining on native peoples' lands.

I come here today to say that there will be no ocean dumping of nuclear submarines or any nuclear waste into any ocean anywhere for all of the valid reasons that many people have spoken here today and will continue to speak to; including the fact that it is not safe. We cannot scientifically, medically, sensibly or truthfully say that radiation is safe. When you say that leaks are possible, that is admitting that, yes, the water may be poisoned; the fish may be poisoned; the people may be poisoned.

L.20

L.36

The first speaker this morning said that radiation in fish and animal life would be "localized." When fishing is a major industry in all parts of the Pacific Ocean, when the ocean floor is riddled with fault lines, and when fish such as whales and others move from one part of the ocean to another, how can we call this potential for disease localized?

F.19 L.20

There is no proof that nuclear submarines when dropped to the floor of the ocean will remain intact. The studies done at the Farallon Islands set proof that there are harmful radioactive leaks from waste dumped that have not even been addressed by this DEIS.

F.2 W.1

And according to the Anderson Amendment, even a test sub dumped will have to be retrievable; and according to your report, that is not possible.

No one is going to die immediately, but one in three people in this country in this planet are dying of cancer right now. It's no coincidence.

Your Draft Environmental Impact Statement says that it is more economically feasible to dump nuclear subs in the ocean. It seems most economically feasible to research methods to stabilize radioactivity in nuclear waste, to develop alternative sources of energy and to spend money on healing this planet and her people rather than destroying it a million times over with nuclear bombs and war toys.

I come here today because I am charged with the pain and the anger and the rage of this earth. Though you and your men in Washington may not understand the concept, the earth, the ocean is the mother of us all, of your children as well as

ours. She will not tolerate your poison, the garbage, the destruction any more. Why do you think there are earthquakes? Why do you think there are volcanoes? When will you learn these lessons?

I come here with the voices and the support of many, many people in Mendocino County and with the inspiration of the children who spoke before me.

And I say to you: (song)

"We ain't gonna let you dump your poison into
the sea, into the sea, into the sea.
Ain't gonna let you dump your poison into the sea.
We are gonna keep on talking,
Keep on fighting until you find another way,
Until you find another way,
And until we hear you say you're gonna stop your
war machine
And stop your death machine
And turn your energy around."

CAPTAIN WAGNER: Thank you, Miss Redwing.

CAPTAIN WAGNER: The next registered speaker is Rella, representing People for A Nuclear Free Future.

RELLA: Captain Wagner, I think that one person has inadvertently been skipped over. Her name is Linda Peters. Before I assume my position at the podium, she can assume hers. Linda Peters.

CAPTAIN WAGNER: I do not have a registration card for her.

MS. PETERS: I called two weeks ago, and I filled out a registration card this morning. And my car is about to go in a tow-away zone at 4:00 o'clock, so --

CAPTAIN WAGNER: Fine.

MS. PETERS: -- I really want to talk right now.

--o0o--

#97

LINDA PETERS

My name is Linda Peters, and I'm here representing the Soroptimists International of Ukiah, of which I'm a member. Our club first became aware of the submarine disposal problem in May of last year, and we felt it was something that the people in our county should be aware of; so we wrote a letter to the Mendocino County Board of Supervisors requesting an

educational nonbiased public hearing on the matter. They in turn joined with the Sonoma County Board of Supervisors and the Humboldt County Supervisors in requesting that the Navy and the EPA hold such a hearing in Fort Bragg since it was part of the DEIS process anyway. They were turned down.

Senator Keene made the same request of the Navy and the EPA and was also turned down. Congressman Bosco along with 27 other congressional representatives in California called for hearings in Eureka and Fort Bragg, and they were also turned down.

Now, we understand your reasoning is that the method is what's to be decided and not the site. I read your letter to one of the organizations, and it seems to us in order to decide between land disposal and sea disposal that you need the input from people that know the sea; not just the scientists, but the people that live and work around the ocean -- Excuse me, sir, can you be quiet while I'm talking?

UNIDENTIFIED SPEAKER: All right.

MS. PETERS: I would like that; thank you.

Okay. We understand your reasoning as of the method is to be decided and not the site. And we feel that in order to decide between ocean disposal and land disposal that you need to have input from people that know the sea; not just the scientists, but also the people that live around the sea and the ones particularly that fish in the ocean.

You've made it very inconvenient for these people to be here today. Being -- and even in your other hearings, they've all been in inland cities. So at the risk of whipping a dead horse, we request once more that the Navy and the EPA hold the hearings in Fort Bragg and other coastal city that has a fishing industry. And we consider that this document is unacceptable unless you do this.

J.15

Now, I want to bring up the subject of cancer. It's been talked about a little bit today. The Soroptimists Club is a service organization made up of businesswomen, and one of the ways we serve our community is by driving cancer victims from Ukiah to Santa Rosa for treatment. Now, no amount of reading on the subject of cancer or studying the statistics has the impact of spending a few moments with someone who is dying of cancer. So we are very concerned about putting any form of carcinogenic substances into the environment.

I have a pamphlet here -- it's from the American Cancer Society, which is a fairly conservative organization. And it's called Cancer Facts and Figures in 1980. I'm sorry it's not 1983, but I got this pamphlet during a seven-month period that I spent with my mother while she was dying with cancer. And I'm sure that the 1983 figures are probably worse than these.

Now, what it says in here -- and these are quotes -- is that one out of four people will get cancer in their

lifetime. This does not include skin cancer, except for melanoma, which is a very deadly form of cancer; probably the most deadly. Two out of three of these people that get the disease will die from it. It used to be four out of five people would die from it. And one might think that modern technology has reduced cancer deaths, but if you read on, you'll find it also says in here that out of every 100,000 people in 1933, 112 died of cancer. Oddly enough, since a few people -- fewer people that get the disease are now dying; in 1977, 133 people of every 100,000 died of cancer. Now that's a nineteen percent increase in the cancer death rate in less than 50 years.

By the way, it also states -- which is appropriate here at this point after hearing the children speak -- that cancer kills more children between the ages of three to fourteen than any other disease.

It also states that the majority of cancer is environmentally related.

Anyone can get this document. It's not very hard to get a hold of. You just go to the American Cancer Society and ask them for a copy.

The environment doesn't change enough in 50 years by itself to cause a nineteen percent increase in the death rate of cancer. And by the way, because fewer people are dying of cancer that get it, what you can deduct from this is that the increase in cancer itself is even greater than nineteen percent. It's only through pollution caused by people that this can be happening. No government agency, no corporation, no business or individual that puts carcinogenic substances in the environment has -- or do I expect will -- step forward to take responsibility for these added cancer deaths.

In fact, just last week, two items were in the news that are along these lines. One was that the EPA has been withholding documents from Congress regarding toxic waste disposal sites. The other item was that women who call themselves the Atomic Widows are now organizing, demanding that the Government and the armed services take responsibility for the deaths of their husbands. Their husbands were used as guinea pigs during atomic testing and have since died of cancer. It was one of the most emotional news items that I ever saw. There were women singing and crying because they missed their husbands. I know we are not supposed to get too emotional here. We are supposed to talk like androids. But this is a very emotional subject.

The Government and the armed services have been trying very hard to ignore these people. Their husbands when they were alive have been saying things to the Government and the armed services, and they haven't gotten anywhere. And now they are dying, and their wives and the children are carrying on.

The EPA and the armed services are rapidly losing the

trust of the American people.

To sum it all up, we Soroptimists feel that the DEIS does not prove to us that either method of disposal is acceptable because they do not absolutely prevent radioactive leakage into the environment. We are particularly concerned about the ocean dumping because it's impossible to retrieve the submarines if necessary. We also feel that this method would most probably affect the fishing industry economically wherever it might take place. We feel you should hold the submarines in storage until you can prove beyond a doubt that you can prevent radioactive leakage into the environment.

L.20
W.1
L.53
G.2

And now speaking as an individual. I'm a mother of two children, and I might guess -- I don't know -- but maybe you're a parent also. And I'm here due to my responsibility to my children and to the future generations of all people. And I think that you have the same responsibility. And I would imagine that if you continue with your job, having to listen to testimony like we've been giving you here today, that it won't be long before you're aligned with us. People in the company of truth have a hard time ignoring it.

Thank you.

--oOo--

#98

CAPTAIN WAGNER: The next registered speaker then is Rella from the People for A Nuclear Free Future.

--oOo--

RELLA

Good day. My name is Rella, and I'm a representative of a very active and very dedicated organization in Fort Bragg with the working people --

UNIDENTIFIED SPEAKER: Would you move closer to the microphone, please?

RELLA: Sure.

Acting locally, thinking locally.

I would like to begin my five-minute presentation with two minutes of silence. And I would like to -- in the process of that silence -- have each of us touch at least one other person. What I would like people to do, if they feel so inclined, I would like them to close their eyes and envision a world of peace; envision a world without nuclear submarines, without nuclear bombs.

(Whereupon there was two minutes of silence.)

I say power to the people. Americans are taught to love. Americans are taught to judge other societies by the

respect their government show for their citizens. We understand that individual rights may not be sacrificed by any authority for the public good. Individual rights are the public good.

But the nuclear age has left our country with a poor record. For example, in the South Pacific, the Navy misled the Bikini islanders into leaving their beautiful island homes so that the island can be used for nuclear weapon test sites; while the South Pacific people were subsequently neglected, degraded, impoverished and poisoned with subsequent suffering of radiation sickness, hair loss, skin lesions, malnutrition, miscarriage and grave sadness as a result of their sacrifice which they were told was "for the good of all humankind."

Meanwhile, the Navy assured them they had nothing to fear. It issued strict and confusing dietary orders, and on occasion warned them not to drink local water; although they often had no alternative.

When the South Pacific people left Bikini, they were too unsophisticated to ask why the United States didn't test this stuff in New York. But after almost 40 years of mistreatment, they are so sophisticated now that they have voted for the first nuclear free constitution.

In our own country, desert bomb tests were made only when the wind blew away from the City of Las Vegas and toward the small town of St. George, Utah. The people of St. George could not believe that their own government would expose them to serious danger, though they too often got cryptic instructions to wash their clothes twice, hose off all cars coming into town, avoid local water and local milk.

The people of St. George have paid a terrible price for their trust in -- in cancer, birth defects and leukemia.

J.6

Now, Cape Mendocino has been selected for the dumping of nuclear submarines possibly, and of course we are assured by the Navy that there is no danger to us or to the ocean environment. But the Navy betrays the truth in rejecting a San Diego site because San Diego has a larger population. And we would be fools not to know what that means. It means that we too are an acceptable sacrifice to a purpose, facilitating the ever-growing nuclear arsenal that a majority of Americans now seriously question.

Forty years of nuclear history and nuclear horrors have not been lost on the American public. The real public good, the human right of each of us to decent treatment by a truthful government must be redeemed.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Cathy Ryan, representing Greenpeace.

--o0o--

#99

CATHY RYAN

Good afternoon, Captain Wagner. My name is Cathy Ryan, and I'm here today on behalf of Greenpeace Pacific Southwest. Greenpeace welcomes this opportunity to address the Navy on land as well as by sea. Thank you very much.

Greenpeace is an international environmental organization. Our purpose is to promote environmental protection over the long term. Our campaigns are designed to foster awareness of the threat of environmental degradation through research, educational programs and nonviolent direct actions.

Since Greenpeace's beginnings in 1971, the oceans have been a central concern of the organization. Largely due to our efforts to protect marine life and the ocean environment, Greenpeace presently has over 240,000 contributing members in the United States, and we represent over 1,000,000 members worldwide.

Before I address the specifics of the Draft EIS, I would also like to add my comments of my concern to those before me. To the fact that this hearing is taking place halfway through the commentary period, which is due to end March 31st, 1983. These comments are taking place now rather than after this period has been completed.

Additionally, over the last six weeks, I have repeatedly heard from concerned individuals who have not been able to obtain a copy of the Draft Environmental Impact Statement; much less analyze and prepare for today critical comments on this 400-page technical document.

The 90-day commentary period the Navy has provided is not sufficient time for the public to analyze the bulk of technical data and considerations of the Draft EIS.

Greenpeace as part of a national coalition has submitted a request for a 90-day extension of public commentary time. We would encourage the Navy to agree to an extension to allow the public the proper time to study a plan with such serious implications.

I would also like to register my organization's concern that these hearings are being conducted in inland cities rather than the -- in the coastal communities that will feel the first impact if the ocean plan does proceed. I would hope that the Navy will recognize the need to hold further public hearings in coastal locations -- particularly Fort Bragg and Eureka, who have for very many months been requesting these hearings from the Navy.

J.15

Today I will address the Navy's examination of the ocean dumping option for the disposal of these radiated nuclear submarines. Although the Navy maintains that they have not yet selected preferred method of submarine disposal, environmentalists, fishermen, scientists, policy makers, state, government and citizens alike around the country and in other nations are concerned that more radioactive waste will be dumped into the ocean.

Greenpeace supports the Anderson Amendment recently passed by Congress which establishes a two-year moratorium on radioactive waste disposal at sea. We also support the interim moratorium adopted last week by the international group at the London Dumping Convention which places a moratorium on rad waste ocean disposal pending further scientific review.

I would point out that the United States was only one of six countries who opposed the moratorium at the London Dumping Convention. Nineteen nations voted in favor. Three of the nineteen nations which voted in favor of the moratorium were nuclear nations.

In the past two years, we've unfortunately seen the United States relinquishing its leadership role in marine protection to leading the battle cry for a diminishing number of dumping nations. Domestically, the Navy's plan is only the beginning for opening the ocean for ocean disposal. This is evidenced by the February 1st release of a notice by the Department of Energy for considering ocean disposal for fuse rap soils left over from the Manhattan project.

Greenpeace opposes the ocean disposal of radioactive waste. We are concerned because ocean dumping this waste means prematurely resuming a practice which could severely impact the public health and the marine environment before the effects of 23 years of past ocean dumping are clearly understood. There are too many scientific unknowns about the fate of radionuclides in the marine environment to add even one defueled submarine reactor plant to the ocean's growing radioactive waste inventory. One submarine reactor alone at 62,000 curies -- that's a DEIS estimate -- represents approximately one-half of the entire amount of radioactivity already estimated to have been dumped by the United States between 1946 and 1970. And the Navy must dispose of over 100 decommissioned nuclear subs.

L.6

L.1

The finding of Dr. Jackson Davis and others indicate that there are many questions that must be answered regarding the biological transport passage of radionuclides, oceanic currents and cumulative effects of passing current dumping operations. Scientific studies contracted by the United States Environmental Protection Agency have revealed evidence of radionuclide bioaccumulation in the marine food chain. Specifically, Dr. William Shell's study of americium 241,

U.9

contamination of rattail fish off the coast of New York and New Jersey is cause for great concern. I understand that that segment will appear tonight on the 20/20 special on ABC at 10:00 o'clock.

Especially in light of the almost complete absence of EPA radioactive waste dump site monitoring, careful consideration must be given to today's testimony by the Oceanic Society and others as they critique the DEIS on technical grounds.

Scientists are pointing to an unacceptable grasp of essential information that could be used to predict the transport of radionuclides in the marine environment. In addition to the lack of scientific review given past ocean dumping, two other concerns are the lack of ability to monitor the radioactivity once it's in the ocean and the irretrievablity of the submarines as stated in the DEIS. Past efforts of the EPA to review waste containers off the Farallon Islands bear this out. Once these subs are dumped, they are on the ocean floor forever. There are 16 different radioactive nuclides in the 62,000 curies that these subs will initially contain. These radioactive isotopes range in half lives of 5.3 years for cobalt 60 to 80,000 years for nickel 59. The steel containment of the waste drums off the Farallon Islands lasted only 20 to 40 years.

J.76
W.1

Comments which have been prepared for Greenpeace USA by

Dr. Marvin Resnicor (ph.)of the Council of Environmental Priorities indicate that the Draft EIS is fatally flawed in its estimates of the initial radioactivity present in the reactors when taken out of service. [A.10] The DEIS understates the curie count of cobalt 60 by a factor of 6, and a curie count of niobium 94 by a factor of 100.

When contrasting the two disposal options, the final solution of ocean disposal versus a responsible program of monitoring and maintenance in protective storage, it seems ludicrous to risk long-term irreversible public and environmental damage when a responsible solution can be developed.

[G.2] Greenpeace proposes that the Navy continue to maintain irradiated submarines in the protective storage in naval shipyards to allow the anticipated early rapid decay of short-lived radioisotopes. Information in the DEIS indicate that a proper time frame will be from 20 to 50 years.

Supporting this recommendation is a statement in the DEIS, and I quote, "Nuclear submarines can also be placed into storage for a long time without risk to the environment. The submarines would be kept in protective storage. About 20 years, each ship would be taken out of the water for an inspection and repainting to assure continued storage."

Furthermore, Greenpeace believes the DEIS must address the following considerations: One, what is the safest

transporation route for these radioactive wastes? Recognizing that shipment is one of the weakest links in the disposal process due to the possibility of accident and public exposure, great consideration must be given to the safest transport route. [E.23]

Two, what environmental concerns have been raised by the public near the two land burial sites that the DEIS does not cover? Are there more appropriate burial sites not covered by the DEIS? [I.2]

And three, can there be monitoring plans for a land base burial site? Can they be developed? The DEIS does not do this at all. [I.13]

In conclusion, ocean dumping is a nonsolution. It forces upon us a permanent means of disposal and precludes any option for safe responsible disposal for this radioactive waste. Given a lack of clear information regarding radioactivity of the submarines themselves, we call for independent verification and accountability of the Navy's nuclear propulsion program, especially in regard to the disposal of decommissioned, defueled nuclear submarines. Checks by the EPA and civilian monitoring agencies are not enough. Based on the lack of retrievability and the inability to monitor the subs once in the ocean as well as the underestimates of actual radioactivity in the subs and life expectancy of the radionuclides and containerization and the inconsistency with U. S. law and global policy, Greenpeace suggests respectfully that the Navy scuttle the ocean disposal plan and redraft a new environmental impact statement computing proper attention to the alternatives to ocean disposal.

For the record, I would also like to acknowledge the number of groups that are present here today. And if you could stand as I read your names. I'll just continue right now. Nationally, the environmental coalition and of environmental groups and public interest grouns include: Ban Ocean Nuclear Dumping -- if you can hold your applause,the list is rather long -- Can Disarm, Center for Environmental Education, Committee to Bridge the Gap -- please stay standing -- Critical Mass Energy Project, the Farallon Foundation, Friends of the Earth, National Audubon Society, Natural Resources Defense Council, Nuclear Free Pacific, Nuclear Information Resource Service, Ocean Education Project, Oceanic Society, Sierra Club, Union of Concerned Scientists, Wilderness Society.

In California these groups also include the Abalone Alliance, Concerned About Ocean Dumping, Defender of Wildlife, Democrats for Peace Conversion, Orange County Alliance for Survival, Orange County Peace Conversion Project, Save our Shore, Southern California Alliance for Survival, Marin Conservation League, Salmon Trollers Marketing Association of Fort Bragg, and Pacific Coast Federation of Fishermen's

Association.

I apologize if I left any of you out -- it's because I haven't spoken with you personally.

Thank you for your time. And I realize that is the fourth time you've heard this in the last two weeks.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Jared L. Rossman, representing Tom Long Watershed Association.

--oOo--

#100

JARED ROSSMAN

I'm Jared Rossman. The Tom Long Watershed Association is a group of about 27 families on the tributary of the Eel River right near where it goes into the Pacific Ocean.

What we seem to be witnessing here is kind of a people's EIS. It seems to me if they took this transcript and with a little of the Navy's help and money edited it, we would have everything we need. We have a People Environmental Impact Statement on exactly what they should do with these submarines.

I would like to ask Captain Wagner kind of a process question. It doesn't seem like there's anybody here -- at least anybody who's not in the Navy's pay -- who is going to speak in favor of this proposal. And I've never seen any kind of unanimity like this in any political endeavor that I've been involved in. And it leads me to ask the following question: Since usually the purpose of a hearing like this is to weigh and balance the remarks that are made in favor of a proposal against the remarks that are made against a proposal

and then come up with a determination; whereas here since we have nobody speaking for the proposal, the only balancing that can really be done is the word of this near unanimous stand of all these groups, officials, organizations and individuals in California, all of whom are experts in living against the Navy's experts in living.

And I'm wondering -- We are going to be watching the results of this hearing really carefully,because if these public hearings in order to provide input into a process are to be meaningful at all, then such an absolutely unanimous stand by a state's people should be absolutely devastating to the conclusions that have already been arrived at in the Draft.

And if it comes back that we really haven't caused any change at all by this unanimous stand, then we are not going to be left with very many options as a united people.

I would like to thank everybody who's given the technical comments as well as those who have given the comments from the heart -- not that the technical ones aren't from the heart, but I know how hard it is to go through these 400-page documents and come up with anything meaningful and stimulating in the way of numbers. So I'm going to not give any more facts, just a few brief feelings about this.

The first is a comment on creatures that befoul their own nests. I'm not -- I don't mean this to be funny at all, and I think it's really actually more scientifically rigorous than it might seem. But the people of the State of California are being put by the Navy in a position, as we have been put time and time again, of toilet training the Federal Government. It's not funny. Humans feel that animals that poison their own nests are crazy. We think that they are aberrant. We think they have rabies or something.

Well, we are fouling our own nest with this; just plain and simple.

Now, earlier in the opening comments, Mr. Mangeno reading for the Navy mentioned what he called quote the natural background radiation as versus the miniscule amounts of radiation that the Navy says we will be getting unnaturally.

I would just like to point out that what he called quote the natural background radiation is not natural. It's the result of all of the bomb tests overground and underground and all of the other ways in which nuclear radioactive isotopes have been put into the environment in the last 30 or 40 years. And it's kind of a telling indication that we are being offered a chance to include these as part of our natural background radiation and then move on from there.

And I just want to ask if we're to accept this, the next time after all of this additional number of curies is added into the environment, are we going to be asked when the next big dumping is going to be proposed to us, we'll look at

the amount of -- are we going to be including what we are dumping now into what we will then call the natural background radiation? It isn't natural. And just because it's there -- because we've made some mistakes in the past, doesn't mean we have to keep putting more of it there.

This leads me to a brief maxim, which is technology that in its uses is too far ahead of its real and total i.e. moral implications and consequences. It's technology that either had to be abandoned or disguised. Let's pretend that dead nuclear submarines are natural features of our landscape. It won't wash.

Captain Wagner, you promoters -- and the Navy is and has been one -- you promoters of nuclear devices have been trying to force upon the people of California one piece of radioactive waste after another for years and for decades. The Navy is forcing us together. It's no longer worth our whiles to fight piecemeal, one by one against each element of the nuclear cycle here in California. From the digging of uranium out of the ground through the testing and manufacture of bombs at Livermore Weapons Lab through the firing off of first strike nuclear missiles from Vandenburg Base through the nuclear power plants that dot the coast and inland of California on through the waste disposal in whatever form it comes out, the entire nuclear cycle is going to come under attack in California. We are going to be working together for a nuclear free California in every respect.

Now, nobody wants this stuff in their backyard; that's what it really comes down to. No community in America any more not in 1983, if it ever did -- is going to vote to accept nuclear waste in its own backyard. No community. And if you think that the ocean doesn't have a community, you're wrong. We are the community of the ocean. It's harder to blockade an ocean dumping of a nuclear submarine than it is to blockade a bomb factory or missile launch or nuclear power plant, but we are going to figure out a way to do it if you push it that far.

Please take the message back to Washington: California is a nuclear free zone. Our land and our soils, we are going to be there to protect them.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Dorothy Ruef from Gualala, representing the Gualala Nuclear Education.

--o0o--

#101

DOROTHY RUEF

My name is Dorothy Ruef. I represent the Gualala Nuclear Education.

UNIDENTIFIED SPEAKER: Louder, please.

MS. RUEF: My name is Dorothy Ruef, and I represent the Gualala Nuclear Education. Gualala being a town in the sub Mendocino Coast.

With all due respect to Captain Wagner from the Navy who came so far to hear us today, I would like to not address him specifically but to address you. I need to talk about the Navy at this moment, however. I think you and I -- I think we all -- tend to hold the Navy in a certain awe. They wear uniforms and have titles; they have ranks. They represent the military with all this power. They are, to a certain extent, foreign to us, and we fear them. And at the hearings today, we feel that they hold somewhat of a life and death decision over us. I think a lot of us have come here and feel to a certain extent like gladiators before the great Roman emperor, and we have to put our best and most valued attempts forward to meet with their approval. And we do it, and then we wait for his sign.

Well, the Navy might like us to think that way, but it's really not true. The U. S. Navy and Captain Wagner will not be making the final decision in this matter. They are not the gods that we have to worry about. The U. S. Navy is not a policy-making branch of the U. S. Government. It may advise them, but it does not make decisions. All the Navy can do is follow orders down through a chain of command. And they get their orders from the President, his administration and Congress.

The Navy will not have its final decision on where to dump anything. That decision is solely the responsibility of the current administration and Congress. My point is that in effect, to a certain degree, we've all been duped. We are wasting our time refuting the Draft EIS. It's not our responsibility to point out its many faults, nor to propose alternatives. And everything we say here today will not matter one iota because the men who need to hear it -- the true Roman emperors -- aren't here today.

Captain Wagner is merely doing his duty as part of the great administration game to draw our fire and to fuse our energies. And we play into his hands and their hands when we get caught up in the Draft EIS. We've all been to carnivals

and country fairs. We've seen the booths where you plunk down your two bits and somebody gives you a gun with ten corks in it, and you shoot at the ducks that are moving across the backdrop.

Well, to a certain extent, this hearing today is a little bit like the carnival, and Captain Wagner is the duck. And we hope that if we hit him, we win something. But the more we shoot at him, the more we are diverted from the real issue, which is to change the policy of the men who run the ducks.

So my advice is to scrap the letters to the Secretary of the Navy John Lehman or to anybody else in the Navy. The Navy already has their orders, and their orders are clear. It's -- obviously, they want to stall us. They want to make it as difficult or as inconvenient for us to talk to them and to present any real communication with the policy makers.

Second, we should forget the letters and the appeals to the EPA. Not only does the EPA display a flagrant disregard for the people and the things it's supposed to protect, but it has somehow managed to mismanage $2,000,000 in the last two years of the funds that were designed to protect the environment -- which by the way is more than enough money to make up the added cost of burying 100 nuclear submarines as safely as possible on land.

Third, we can scratch off appealing to the President or anyone in his Cabinet. You might remember the Sierra Club petition to remove James Watt from office. It garnered 1,000,000 signatures. What did President Reagan do with it? He ignored it.

We have one avenue of approach left, and that is through Congress. We must leave this hearing today with as much energy as we came and direct it all to Congress. It would be easy -- and indeed the Reagan Administration is hoping -- for us all to walk out of here thinking: "Well, I went to the hearing; I spoke to the Navy. I've done as much as I can do. Now, it's up to the Navy."

Don't allow -- Don't allow yourself to be allowed into thinking that this hearing is any more than a superficial influence on the final decision of what to do with the submarines. Our country is reworking its whole rad waste disposal policy, and the ultimate decision on that policy comes from Congress.

So it's now time for us to form grass roots opposition to the Navy's plan. We must each become a lobbyist in his own right and take it upon ourselves to get publicity for this proposal. We must write articles for our newspapers, letters to the editor or create media events. It's time to deluge our Congressmen with letters, phone calls, and mailograms. We must do it repeatedly. We must do it often -- once a week will be just fine. And we must get our friends involved in the process also. We have to get the whole West Coast writing, and we have

to get all the Congressmen aware of the situation and on our side.

In closing, I would like to say it's only through public ignorance and apathy that a ploy such as this irresponsible and dangerous sinking of the submarines can be permitted. And it's our fault -- yours and mine -- if the public remains ignorant and indifferent long enough to permit this.

So pace yourselves and keep your energy up. And if your Congressmen don't hear from you, we may really be duped.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Valerie Sklorevshy, representing Malibu's Ocean Protection.

--o0o--

#102

VALERIE SKLOREVSHY

My name is Valerie Sklorevshy, and I'm a member of MOP. MOPADOP -- Malibu Ocean Protection.

Women of the world have never taken an active role in this race to see all of humanity die. But they have been wiping away the tears and the blood forever. To wipe away the blood and the tears is not enough. The task is to stop it.

We are talking about here nuclear war, the nuclear annihilation of all of creation.

To the folks in the Pentagon, the military industrial complex, the people at Vandenburg, the Navy, the Army, we the people -- the public -- will not submit to the injustice of nuclear weapons destroying us, destroying you, destroying all of creation. It is our living responsibility of being alive and a human being to seriously contest the deadly peril of nuclear weapons: weapons that make cancer the destiny of humanity.

I'm speaking for my friends who were resisters. They

are in jail all over this country. People in this room that I see -- I've seen at blockades all over this country. People are willing to put their lives down and say, "No, we have to speak for the children, the future generations or we won't have any future generations."

I was up in Bangor, Washington for the loading of the Trident submarine this summer. It can destroy 408 cities at one time; the whole northern hemisphere. It has got to stop. If the Navy this summer in Bangor, Washington had 100 ships out there, and they had a lot of men out there and those men all had guns. That's how they faced the peacemakers. We were there with our children, with our hearts speaking for people of the Pacific and people of the world. Where are the men in the Navy today? I look at this one man here, and I'm going, "Are you representing all of the military industrial complex -- the Navy, the Army?"

I went to a meeting in L.A. last week, and it was 300 men for the military industrial complex in that room. There's one man here. We are trying to have our voices heard. Friends in jail are suffering every day, and it started with the native Americans in this land when this Government and the men in the military industrial complex started to mine uranium, and then the people started to die. It's been going on in this country for too long. It's the men in charge of Congress, the men that have always been our presidents, the men that are building the bombs. I am speaking for the women and the children who are not here today. Please. We are trying to love you, to take care of you and to take care of all of creation, which is what women have basically done all our lives. We've tried to take care of life and creation. People here are speaking with their hearts and their souls, and they are pleading "Please hear us."

Who are we talking to? Are we talking to ourselves again? Again? How long will it go on? Do I have an answer -- Do you have an answer for that?

CAPTAIN WAGNER: As I said earlier, Miss Sklorevsky, I'm not here to debate. Your comment is part of the record. The record becomes part of the final transcript for the final EIS. We are here to receive your statements for the record.

MS. SKLOREVSKY: My statement for the record is: No nuclear war. No nuclear insanity. No destroying creation. Please.

--o0o--

CAPTAIN WAGNER: Ladies and gentlemen, we'll take another five-minute recess to allow our reporters to have a slight rest. We'll resume the hearing in five minutes.

(Whereupon a brief recess was taken.)

CAPTAIN WAGNER: Ladies and gentlemen, we have our reporters back, and I would like to reconvene the meeting, please. I have two more organizational spokesmen from this morning's registration, and then when we finish those two individuals, we will move into individual testimony and get as much of that done as we can before we take a dinner break.

The next registered speaker is Mr. Greg Wellish representing Acorn Alliance.

--o0o--

#103

GREG WELLISH

Good afternoon, Captain Wagner and ladies and gentlemen who have been so patient to be here all day even though most of the press has left, and I know most of these people are going to be here late until tonight or however long this hearing goes on and to tomorrow, if that's necessary. I find it a little uncomfortable -- I've been sitting and watching people's backs all morning, and I'll try to address you all, and you, too, specifically, Captain Wagner.

I'm -- my name is Gregory Wellish. I'm representing the Acorn Alliance. We're a citizens' group in southern Humboldt County that is concerned with radiation, with all environmental problems, and we see this as a really big one. It's sort of ironic to me that it's the Navy that is proposing dumping submarines into the ocean; the ocean, the water. That's the Navy's element; that's why the Navy exists because through our history it's been necessary for governments to protect themselves and for commerce to use the ocean. The Navy is the protector of the ocean. That's why I find it extremely strange that now the people have to protect the ocean from the Navy. It's just sort of a bizarre twist. We don't know. You're really saying in this EIS, "We don't know what this is going to do. We don't know now." Now is when you're talking about doing -- you're not saying you want to do it tomorrow, you're saying some point in the future, and that's why this document has been prepared and why future documents are being prepared.

But basically what you're saying in this document is that you don't know what it's going to do. That is totally unacceptable. When these subs are dumped two and a half

W.1

miles into the ocean, they are irretrievable. You say right in here you do not have the technology at this time to retrieve them. There is no excuse for this. The Anderson Amendment states that it can't be done if they are not retrievable.

F.2

The only way that it can be handled for right now is for them to be stored on the land site, not a permanent storage, but to be held in mothballs to be stored until something is known.

G.2

We do not know. We don't know now; we might not know for 20 or 30 years. These submarines that you want to dump in the ocean were commissioned 20, 30 years ago. Thirty years ago, most of them in the '50's and in the late '60's. Now, does this mean that every 30 years you're going to have a new batch of submarines to dump in the ocean? It's going to start to build up. There's no way the people of this country, and especially the people of the State of California, are going to let you do this. It's not going to happen.

I've heard people say here that this is just a ploy; the Navy's here to draw our energy away. I don't care who it is, you, the Congress, the President, any agency. This country is founded on government for and by the people. The people are going to have the final say in this.

Now, there's been very good scientific testimony here today by the experts. The experts that you don't have in this book; the experts that should be in this book: You're saying this is what's known. You don't know, and you don't have the experts saying what they know. It's totally unacceptable. It's just totally out there.

United States has always been a leader in the world, and we still are, and we're going to continue to be. There are other nations currently dumping radioactive waste in the oceans. F.8
This has got to stop. We're not doing it now, and it's holding a balance -- we're holding a balance right here. If the

L.9
F.8

United States, especially starting with the Navy, is allowed to do this, we're going to see this increase all over the world. Greenpeace is already working very hard to stop it where it is going on.

The United States -- we're the leader. The world looks to us for nuclear examples; for all examples. We're the ones that have to say no; we have to say this isn't going to happen. We're not going to let the government do it, we're not going to let private industries do it, and we're not going to let other countries in the world do it.

A few weeks ago the international commission voted, and the United States was one that voted to allow nuclear dumping to continue. It's a sham. The people of the United States don't want these things dumped in the ocean, and it's just totally important that we read this; that we're the ones that show -- that show today, that show in the future what has to happen.

These reactors that Admiral Rickover designed -- a gentleman spoke about Admiral Rickover earlier -- he designed them, and it was a great idea; it worked. Okay. Private industry came along and from his plans they started building reactors. Now, we've got nuclear reactors that are just monstrous, nothing like what Admiral Rickover designed, and it's just going on and on.

The Navy has a special responsibility here because it

was the Navy that started this process of nuclear reactors. Admiral Rickover doesn't approve; lots of people that worked on these reactors don't approve. Why is it going on? I'll ask anyone in the room. Why is it going on?

Yeah -- Yeah, exactly. Dollars, money, industry, the military industrial complex. Submarines -- submarines are going to be dumped in the ocean so that new submarines can be built. So we can look forward to this every 30 years, a new set of submarines because the old ones are obsolete; because the old ones are too hot for men to be on safely. D.4

The submarines -- You say right in here they're too hot to be safely decommissioned. The exposure rate for the people that have to put the concrete in the pipes between the bulkheads are going to be exposed to horrendous amounts of radiation. In -- The atomic veterans who have also been mentioned today, they were exposed to radiation. They did not know the effects. They weren't told what it would do; they were told it was simply harmless; they were told you could stand and watch it; they were told it was beautiful, the sight of a mushroom cloud. We know the effects now. The effects are known. The effects are known by scientists; the effects are known by doctors; and the effects are known in the hearts of the people of this country and very quickly coming up, the people of the world. We're leading. We're leading and the rest of the world is following, and they know what's going on.

We can stand up here and talk to the Navy all day or all year. We can ask them to continue these hearings, and on behalf of my group, I would like to ask them to continue these hearings. There should be an extension of 90 days for public commentary to June 30th, and we strongly feel that hearings should be held in Eureka and Fort Bragg. (J.15) This is where the people are. Not everybody can leave their jobs. I happen to work for very good people who let me come here to Sacramento, 200 miles, over 200 miles to do this. Some of you have come further. A lot of people who wanted to couldn't come because of their families, because of their jobs. I find this sort of interesting that all of us -- over 200 of us -- came here today, and we came from all over California to talk to one man from the Navy who came from Washington. I really don't understand why he could come here and we had to come here, too.

A few politicians are here in Sacramento. The politicians aren't the ones that matter, it's the people, and you've got to talk to the people. You're saying, "We're going to affect your environment by what we plan to do," yet at the same time you're excluding the testimony of the people who are most affected. You're only allowing your leaders to be able to come here to speak. There are fishermen who would have lots of things to tell you, more than that big man and the other gentlemen who spoke for the fishing industry today.

There has to be an extension, and this document has to get out to more people. A lot of people don't understand what the Navy plans to do. They don't know how many submarines, and they don't know that once this starts, it's going to continue. The Navy doesn't intend to just dump 100 submarines. That is just the beginning.

I am for a nuclear free California. I'd like to show you something here. This is a map of nuclear America. There's maps on the back wall and outside. This map has documentation of nuclear reactors, naval facilities, research and development facilities, manufacturing testing sites, deployment sites. California is pockmarked with this. It's cancerous. I've added question marks. One here off of Cape Mendocino and one here off of North Carolina. Are we going to let them continue? They've already pockmarked our country. Are we going to let them continue with the ocean? There's very few spaces left in the country. There's not one state in the country that does not have some sort of nuclear pollution in it. It is not right for the ocean, the ocean which the Navy exists on, exists because of. We're going to dump it in the ocean. I've heard it mentioned today about the food chain and about the (L.36) cumulative effect of radiation, and that's exactly what I'm saying. The cumulative effect. (L.7) Your document speaks only of these particular 100 submarines being dumped in a particular spot, or it's not a particular spot where you choose. It's the

L.9
F.8

cumulative effect. You might be able to dump those submarines without any harm. I don't know. I would be willing to say that it's going to have some effect on the environment, but I do know that if we keep dumping them, if the United States Government starts dumping them and then allows private industry to dump them, the rest of the world is going to keep dumping them.

The point is that we need to start looking at what we are going to do in the future. It's one thing to say I'm going to dump them in the ocean. It's a whole nother thing to say we're going to wait -- we are going to wait until the documentation is in. We're going to wait until we know for sure.

I would like to present this map of the United States in nuclear America as part of my testimony.

CAPTAIN WAGNER: Could I ask you, Mr. Wellish, to summarize, if you may, so that other speakers can get on?

MR. WELLISH: I'll wind up very quickly.

CAPTAIN WAGNER: Thank you.

MR. WELLISH: The Navy is holding these hearings now. Many groups are asking that they be held again. I think it's appropriate that they be held again, but I agree with the woman who spoke earlier, it's not the Navy that's going to have the final decision, it's the people that are going to have the final decision. There's no way the people of this state are going to allow the Navy to dump these submarines in the ocean. If it

comes down to us putting our bodies on the line, that's where they'll be, on the line.

Thank you.

--o0o--

#104

CAPTAIN WAGNER: The next registered speaker is Mr. G. Nelson Wolfe, representing Save Our Shores, Incorporated.

--oOo--

G. NELSON WOLFE

Yes, Captain Wagner, my name is G. Nelson Wolfe testifying today on behalf of Save Our Shores, Incorporated, an organization dedicated to the conservation and protection of the marine environment in Central and Northern California. I'm also testifying as a formal commercial fisherman.

We join with the Oceanic Society, the Farallon Foundation, and all the other organizations' representatives and individuals expressing our grave concern over the educational and scientific process which the Navy has undertaken in considering this proposal.

The dumping of nuclear waste into the oceans must be addressed within the broader context which is the national and international question of what are we going to do with nuclear waste. It's a question which cries out for comprehensive national and international policies. This question belongs not only to the experts, but to the general public. There are moral and political considerations as well

as scientific ones involved. Even supposedly small amounts of increased radioactivity are part of a broader picture and are potentially dangerous precedents.

There are presently proposals on line for the disposal of high-level nuclear waste into deep sea sediments, World War II Manhattan Project wastes, not to mention such waste dumping by France, Great Britain, Switzerland, Japan and others.

Marine organisms and fish recognize no national boundaries nor does radioactivity once it is released. How is it that this proposal can fail to acknowledge this large a context? There's a real question when it comes to what the quote safe levels of radioactivity are. Even small increments in radiation can increase the levels of radiation to which the environment and the world's populations are already exposed. Levels which members of the medical community already suggest are too high. It is estimated that natural radiation exposure alone is responsible for 19,000 cancer deaths each year and between 58,000 and 580,000 genetic deaths each year.

If an irrecoverable decommissioned nuclear submarine were to release even a small additional amount of radioactivity in the poorly understood marine benthic community, and that combined with other exposures were eventually transported to human beings and became responsible for even one additional cancer death, which one of you gentlemen would be responsible for defending this document to that individual?

L.1 W.1 J.76

The contemplation of disposing of such waste in a medium of which we still have relatively little information at a depth which we could neither adequately monitor nor recover if something should go wrong invites only problems at the outset.

F.12 J.9 W.1

Inadequate and incomplete scientific analyses of the shoestring monitoring program and the omission of current and relevant research coupled with the admitted irretrievability of the vessels are all arguments belonging to the Navy's very document suggesting that the ocean disposal option should not be considered further.

N.3

The Navy would like us to believe that the low cost is the most favorable aspect of the ocean disposal option. Yet how can you quantify the potential costs in terms of human health and safety and have you done so?

To proceed with this action before having the adequate scientific information about the disposal environment with which to justify it would be unscientific, unwise and irresponsible. Given the dismal recent history of waste dumping and monitoring for which this nation and the world is only beginning to pay the price, the public cries out for agencies they can trust. We would hope that the appropriate agencies would be moving to correct the grave mistakes represented by the Love Canal, Times Beach or the Farallon Islands; to restore the public's confidence and trust.

L.53 J.9

The potential quote costs with respect to nuclear waste dumping for present and future generations are far too great for the public to accept a hurried, inadequate process which this document and the public education and participation opportunities surrounding it suggest. The inherent bias towards the ocean disposal option and the appointment of the former director of the Navy's Office of Radiation Programs, a known advocate of the ocean disposal option, the permitting authority for ocean dumping at the EPA goes nowhere in assuring the public's true interests are being represented objectively in this matter.

It is essential that such agencies be reminded who your constituency actually is. The Navy works not only for the Navy. The EPA works not only for the EPA and a few big business clients nor really for any particular administration. They must work to protect the health and the safety of the people of this country which by law they are mandated to protect. With this document and with the ocean disposal option as presented, you are clearly not doing the job.

I'd just like to follow up. At the beginning of this long and interesting day, I believe Mr. Mangeno of your office presented a very slick and interesting presentation about the proposal. He stated that the radiation impact and the localization of the -- of any release of radioactivity would be highly localized and minimal. The fact is that he

L.1 really does not have the scientific data to support that statement, and I find it somewhat disgraceful that someone commanded with the education of the public about an issue as serious as this would talk about facts for which he has no evidence. I think he owes it to the people here today; he owes it to the U. S. Navy, and just all the people involved in such a decision as this entails to make it very clear what the facts actually are.

I think it's a far, far better thing to admit and have the courage to admit that which we don't know now rather than coming back later and saying we didn't know.

Thank you very much.

--o0o--

CAPTAIN WAGNER: At this time, ladies and gentlemen, we are going to proceed with testimony by individuals. Again, I would like to ask your cooperation in adhering to the five-minute time limits so that we can hear as many representative views as possible.

--o0o--

CAPTAIN WAGNER: The first individual is Steven Antler. Is Mr. Antler here? Some individuals might have stepped out. I will continue down the list, and if someone is going to get Mr. Antler, let me know when he gets here.

RON GUENTHER: We signed up for a short Sierra Club statement, Redwood Chapter, as an organization.

CAPTAIN WAGNER: Your name, sir?

RON GUENTHER: Ron Guenther.

CAPTAIN WAGNER: Ron Guenther?

RON GUENTHER: Representing the Sierra Club - Redwood Chapter.

CAPTAIN WAGNER: Does anyone object to having Mr. Guenther speak?

--o0o--

#105*

RON GUENTHER

Thank you very much, Captain Wagner, and people. My name is Ron Guenther. I'm chair of the Sierra Club - Redwood Chapter's Executive Committee, and I am here today to represent Redwood Chapter Sierra Club members in California's Del Norte, Humboldt, Mendocino, Sonoma, Solano, Napa, Lake and Siskiyou Counties. I first of all would like to thank

***Other issues discussed by Mr. Guenther are side barred in Exhibit 105a.**

Dorothy Rutherford in reference to, you'll recall, the Watt's Petition. Between 2 and 3 million names have come in on that petition. They're still coming in, and we are still optimistic about replacing Mr. Watt.

First of all, we'd like to go on record as requesting a vastly improved Environmental Impact Statement on this proposal so that the concerned public and decision makers can be completely aware of the actual realistic impact of the proposal before any decisions are made.

We'd also like to go on record as opposing the sea disposal option based on the very limited and inadequate information available to us in the project's Draft EIS simply because of the enormous cumulative ocean radiation totals and because the oceans are so much a source of the planetary life support system. We feel a much better evaluation of this proposal is necessary.

Now, we have a very lengthy written statement in the record. Many of our concerns have already been spoken to in the most eloquent way in this hearing, and what I'd like to do is just simply highlight a few of our very special concerns here.

First of all, we're concerned especially with the very poor evaluation of the so-called artificial reef effect wherein life forms will multiply far beyond the normal numbers when they are near a large sunken object. We're also

concerned with the Navy's denial of life at the site bottom; they're in contradiction to its own photographic evidence record in the EIS itself.

According to the evidence records that we've been looking at, there is marine life at the site leading directly to the human food chain. There's an important upwelling phenomenon at the site. There is a rich fishery that depends upon it that is heavily utilized by people.

It seems quite obvious to us that much more needs to be known about how radioactivity moves through the food chain to the higher life forms, including man.

According to the information that we have, some of the best data on how this radioactive transfer process takes place was the result of testing at the Farallon Islands nuclear dump site. We find it incredible that this data was not included in the Draft EIS, and our request is that it not only be included in the Final EIS, but that it be evaluated and utilized in getting recommendations and decisions coming from the Final EIS. This is the Farallon Islands nuclear dump site test data. F.12*

All right. We're very much concerned with the retrievability issue from a little bit different viewpoint than some of the other speakers. What we're dealing with here is a completely untested process. It may not work. If the reactor plants are ever sunk into this deep ocean here, we

***Other issues discussed by Mr. Guenther are side barred in Exhibit 105a.**

W.1

may desperately want to retrieve them within a very few years, and I would point out on page 213, Section E, that the Navy is not admitting in this Draft EIS that it is impossible to retrieve these nuclear plants once they're dumped into the ocean. The language used here is that it is not feasible using today's technology, and this is not the same thing as saying it's impossible.

And what we are going to request here of you is that if the Navy makes a finding that it's impossible to retrieve them under any conditions, that it ought to unequivocally say so in the Final EIS.

W.1

If a possibility exists for retrievability, what we would request would be a cost and probability analysis of retrievability. In other words, the public has a right to know how much it's going to cost. If it's going to cost 2 to 300 million dollars apiece to raise each reactor plant from the bottom of the ocean, the public has a right to know that. And I might add to that that this kind of a cost figure could have a very devastating effect on the Navy's economic justification for ocean dumping. And we find this one of the most important deficiencies in the EIS and urgently request that it be corrected.

Our final concerns are with cumulative impact which the Draft EIS totally fails to evaluate, in our opinion, and it seems very probable that once we establish an ocean dumping site off the coast, that the pressures are going to be

enormous to dump all kinds of other kinds of radioactive wastes at the site: worn out civilian nuclear power plants, contaminated soils, all kinds of nuclear waste.

F.8

In addition to that, other nations are looking to the U. S. to follow our example, and they will follow us in this nuclear ocean dumping if we resume it. This is one of the most important cumulative impacts that hasn't been dealt with in the EIS, and we request that it be done in the Final EIS.

In addition to that, the Draft EIS fails to evaluate the cumulative effect of the proposed decommissioned submarine reactor plant disposal program on the worldwide nuclear arms buildup. And it seems very clear if we escalate the nuclear arms race to this ocean disposal proposal, other nations could follow our example. A cumulative impact could have devastating effects on the planetary life support systems and simply must be evaluated, in our opinion, before any decisions can be made at all on the reactor plant disposal proposal.

H.12

Finally, the Redwood Chapter has taken a strong position on radioactive waste source reduction. We simply must quit generating nuclear waste if the planetary life support system is to survive, in our opinion, and we would like to recommend a solution to the Navy for its radioactive waste disposal problems -- just quit generating them.

Thank you.

CAPTAIN WAGNER: Ladies and gentlemen, again, I recognize that there are some organizational spokesmen who have not been called. They signed -- or they registered later this morning for this afternoon. I'm still working on the individuals who registered by or prior to 9:00 o'clock, and I'd like to proceed with that list. After the dinner break, we will try to get to the other organizational spokesmen as well.

Next registered speaker is Mr. Steven Antler.

(Speaker is not present.)

Proceed with Mr. Mark Berkich here from Comptche, California.

--oOo--

#106 *

MARK BERKICH

First of all, I would like to say thank you for this opportunity to speak here today. I come from Comptche. It's a small town in Mendocino County. Our community is approximately 16 miles from the Mendocino Coastline. Late last spring I learned of the Navy's plan to dump 100 radioactive submarines off our beautiful coast. At that time I decided that I would set up an information table at the local post office, and I brought some petitions against the dumping and some postcards

addressed to the EPA asking that the EPA not grant permission to the Navy for the radioactive submarine dumping. At the end of the day, over 100 people had come to the post office. They all signed the petitions, they all sent the cards to the EPA. No one was in favor of the Navy's plan to dump the submarines. I was really surprised. I mean, it's kind of a red neck community in a way. I thought there would be someone on the other side, but there wasn't, so I figured I must have been on the right side. My neighbors as well as myself, we eat a lot of fish from this area, and being depressed times, as a matter of fact, a major portion of protein in our diets comes from the nearby ocean.

We're really concerned that the radiation from the scuttled submarines will enter the food chain. Steelhead trout, salmon, they spawn in creeks just 200 feet from where I live. These fish, they live in the ocean, and they feed in the area of the proposed dump site, and then they're going to come back and spawn right where I live. L.36 *

So, you know, I mean, the concern is really there. The Navy says that the dangers of this radiation from the submarines will be gone before the containers disintegrate. Well, radioactive cobalt 60 has a half life of 5,263 years, and radioactive nickel 59 has a half life of 80,000 years. L.20

Now, these are just two of the radioactive substances of many that are going to be dumped, and probably already have

*Another issue discussed by Mr. Berkich is side barred in Exhibit 317.

been dumped. And I'm just a layman, but it's plain to see that this ocean dumping is just out. I mean, no way.

L.6 Virtually no monitoring has been done on the existing rad waste dump sites in the ocean to determine the effect on the sea life and whether or not the radionuclides are making their way through the food chain to humans. This information must be known before any further dumping of rad waste is allowed anywhere in the world's oceans.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Brian Casey Biro from Gualala, California.

--o0o--

#107

BRIAN CASEY BIRO

Hi. I usually go by Brian Casey, but my real last name now is Biro. I'm here mostly just for one reason, and that's fear that we'll make the wrong mistakes again because of past mistakes with the land and air -- making choices of land and air -- how to control pollution. I've really been messed up, and we've got polluted lands everywhere in every state, and the air -- I get a sore throat driving through L.A. with the windows rolled up. It's just real bad, and I don't want the ocean destroyed because -- I mean -- polluted because that's our main source of air, food and a lot of our stuff. And if we destroy the ocean, then all life is practically doomed. And the ocean gives us our food and air. In return we give it nuclear waste, and I don't think that's very fair.

I also think that before the Navy and all the armed forces even made these nuclear weapons, they should have learned how to control them and how to control the waste, and they should find the right way to disoose of the waste instead of the easirst way.

My generation gets to look forward to nuclear war, nuclear waste, pollution, unemployment, and all that stuff. And nuclear waste not disposed of properly isn't going to help my future any, and so I don't want nuclear subs polluting our ocean.

And also I just want to remind everybody that it's the kids of today that have to live with your mistakes tomorrow.

Thank you.

--oOo--

CAPTAIN WAGNER: The next registered speaker is Mr. Doug Boone of Atherton, California.

--oOo--

#108

DOUG BOONE

Hi. My name is Doug Boone.

Fellow residents of the world, neighbors of these United States of America:

The subject we are addressing today is one of highest priority to every living creature on this planet. We must not make foolish decisions which endanger ourselves and/or others. I'm a licensed commercial fisherman, salmon, in the State of Alaska. I was born in California, but I am now a resident and vote in Alaska.

The migratory patterns of salmon take them throughout domestic as well as foreign waters. Thousands of United States citizens are employed on fishing boats and many thousands more in the related processing industries. L.53

Polluting our oceans destroys our food, our jobs, and, therefore, our national security. Our destiny is in jeopardy once again. I voted for the nuclear freeze; I now voice my opinion once again to delay this to be duly represented by my elected officials. Voices cry out throughout this land; we demand to be heard. We do not want nuclear subs dumped in our oceans; we do not want our defenses used against us. We want a reasonable solution to this problem, one that we can live with, not one that will kill our fish and eventually ourselves. We must have honest studies done by the Environmental Protection Agency and other qualified organizations. We must publicly study these reports and use our electoral process to achieve our goals. It is up to our elected representatives to use their influence and power to delay this foolish move until such time as we can arrive at an equitable solution agreeable to all parties.

F.8 We must also consider the implications of our actions in regard to world leadership. We must set an example of our freedom by making wise decisions.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Marlene Boone of Laytonville, California.

--o0o--

#109

MARLENE BOONE

My name is Marlene Boone. I live in Mendocino County with my husband Steve and our two sons. We regularly shop and do our business at Mendocino and Fort Bragg. At times when we are there, our sons delight in wading in the ocean water along the shore. I hope that our future children will also be able to experience the same pleasures without the fear of contamination.

I am deeply concerned over the Navy wanting to dispose of 120 nuclear submarines in the ocean near Cape Mendocino. I am not convinced that it is safe nor am I comfortable with the possible long-term effects. To resume the disposal of more nuclear waste while uncertainties of past irresponsible disposals still linger does not make sense to me. A healthy marine environment is so necessary to our survival. Modern man has a history of interfering with nature which always seems to come back and haunt us. L.6

Let's stop now long enough to be sure that we're not making the worst mistake of all -- threatening the very survival of future generations.

Thank you for allowing me this time to express myself.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Mr. David Booth of Miranda, California.

--o0o--

#110

DAVID BOOTH

Yes, I'm David Booth, a concerned individual, and I'm prepared now to depart from most of my prepared comments because a point Dorothy from Gualala made has the ring of truth to me now. I think she is probably quite right, that you are a sitting duck or the strong man of the Reagan Administration and that this whole affair is a ruse, and perhaps this is a futile attempt to convince you, but I think something has come to me.

I think it's very ironic that perhaps the intent of the administration was to weaken us to dissipate our energies, but unwittingly, they have shown us our strength. Never have I seen such unanimity to one issue, and I'm really impressed, and I know that we are going to fight this demon wherever we find it, and we'll write our Congressmen, and perhaps you do have a disproportionate influence in Washington, and for that reason I make my personal plea to you: To go to Washington and convey our sentiments, but beyond that, I know that I'll keep

306

fighting on this issue wherever necessary, and I know the rest of these people in this audience are not discouraged one bit by what they have learned here today. So it's very ironic, and we'll be back.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Mr. Don Brown of Santa Cruz, California.

Is Mr. Brown here?

(Speaker is not present.)

Then Mr. Sam Camp of Redwood, California.

UNIDENTIFIED SPEAKER: He had to leave.

CAPTAIN WAGNER: He had to leave?

Mr. Derick Cassidy of Sacramento, California.

Garrett Connelly, Santa Barbara, California.

UNIDENTIFIED SPEAKER: He spoke.

CAPTAIN WAGNER: Okay. Thank you.

Jane Corey of Elk, California.

--o0o--

JANE COREY

#111

My name is Jane Corey. I'm a teacher. I have other people's children entrusted to me. I go to many meetings, and I have many conferences with individual parents. The children are always new and exciting to me. Sometimes, however, I feel that I have heard every variety of parental concern, and it becomes difficult to give each parent the fresh hearing and response that he or she deserves.

Sitting in an auditorium for 12 hours is not conducive to fresh responses. I hope, however, that those of you representing the Navy will be able to hear the unanimity among those of us who oppose ocean sub dumping. I hope that you will be able to perceive us as individual voices deserving to be heard with fresh ears.

I live in Elk, a small town on the Mendocino Coast. The feelings I have are shared by my community and my fellow teachers. We think it imperative that you have another hearing in a central location on the coast. We ask you that you extend the deadline for response to the DEIS. We are all of us all too familiar with the increased rate of cancer among friends, relatives and acquaintances. We know that radioactive wastes are carcinogenic; anything dumped into the ocean enters the food chain.

J.15

L.36

It is irresponsible to behave as if hiding toxic substances in the ocean will solve our problems. Decommissioned nuclear submarines with no place to go will be a sore spot and remind us of the responsibility we take on in dealing with nuclear engery.

I own a bottle of Malathion. I no longer believe in using this pesticide, but I am stuck with it in my garage. There's really no place I have to dump it, and I don't want to pass it on to someone else to use. It's a reminder to me

to be a cautious consumer. Dangerous antiques are likewise a reminder to our nation that we need in the future to more carefully consider the long-term effects of our defense experiments.

And I have a statement from my friend Kate Dougherty who couldn't be here today, and she would welcome anyone's response to what she has to say at Kate Dougherty, Box 70, Elk, California 95432.

"As a nation, we have chosen nuclear weapons to defend us. Somehow we feel there is a threat more horrible than the threat of extinction of all life on earth. Or in order to keep off the threat of extinction, we must make larger threats and back these up with facts, with weapons. I don't know if anyone is quite sure which reasoning sustains us, but the fact remains that we have made nuclear weapons; we continue to create them and are planning to continue to do so.

"I live on the coast of Mendocino in a town called Elk. I choose to live here because I wish to live a full life. And then the question, Full life? What is a full life? Of all the sources I have come across, nature has been my best and sometimes all too honest instructor. The sea, among other things, has taught me that there are other communities to which I belong than that of nation. The Pacific Ocean directly affects not only the Mendocino Coast, but all of the coast of California, Washington, Oregon, Canada, Mexico, Guatemala, Nicaragua,

308

Costa Rica, El Salvador, Panama, Colombia, Ecuador, Peru, Chile, the Soviet Union, China, New Guinea, Korea, Australia, Japan, the Philippines, Hawaii, New Zealand, Vietnam.

"The Pacific Ocean is a very important common denominator to the humans living in these countries. Besides connecting life by a common bond, the ocean is itself a vast complex relationship of interconnected communities varying in size from the one-celled algae to the multi-celled sperm whale.

"These communities we call ocean have a major influence upon the life support systems of the entire earth. It is ludicrous for our government to prepare an environmental impact study for the review of the citizens of this state and of this nation when many, many more are affected by the ramifications of this proposal.

"It is morally criminal that we -- and I do mean you and I -- jeopardize the lives of inhabitants off the coasts of the Pacific, the very life of the ocean itself, and the balance of our whole earth because we as a nation have decided this to be the best place to dispose wastes of weapons that defend our particular national way of life.

"The weapons are our weapons. The war is our war. The waste is ours. Each state should take responsibility for disposing portions of it in their own boundaries."

--o0o--

CAPTAIN WAGNER: The next registered speaker is Ruthann Corwin from Novato, California.

--o0o--

#112

RUTHANN CORWIN

Thank you, Captain Wagner. That's Novato, California.

I'm Dr. Ruthann Corwin from Marin County, California. I hold a Ph.D. in applied ecology from the University of California, and I am on the Board of Directors of the San Francisco Chapter of the Oceanic Society. But since you have heard from our designated representative, I am testifying as a concerned citizen with specific expertise in environmental impact assessment and knowledge of the multiple ways in which humans are polluting and disrupting marine habitats.

I would like to begin by expressing my concern that you are only here to take statements; that there is no one here to answer specific technical questions and to have a give and take with the experts on these critical issues.

It is in such debate and in response to questions that the state of knowledge becomes truly apparent. This hearing is only a partial public disclosure process, and I think it is important to note that for the record.

While it is certainly true from all the testimony that we've heard today that it will take political action to finally settle this issue, the legal record's also important, and I think you have been warned that the Environmental Impact Statement which you are considering here today is a seriously deficient document. It does not provide the Navy or the public with a true understanding of the potential effects of the ocean dumping not only of radioactive wastes but also of the other toxic materials such as cadmium, chromium and other heavy metals which are also present in the material to be disposed.

L.7 L.10

Missing from the discussion of environmental effects is any reference to the cumulative effects and possible synergistic effects of this activity along with existing and other potential ocean dumping activities plus other coastal and offshore activities adding pollution to the marine environment.

The effect of this omission is to give rise to a fundamental methodological flaw in your evaluative statements as illustrated by your Table 1 and at many other locations in the Draft Environmental Impact Statement: The continual and inconsistent use of comparative rather than additive assessments to put your rough calculations of exposure into context.

As one example, I call your attention to the statement on page 4-10 with respect to exposure of bottom dwelling sea

life. After calculation of one year's dose to a hypothetical bottom organism from nickel 59, the analysis states, and I quote, an exposure rate of 0.3 rad per year is small compared to the annual internal exposure to the actually-occurring radionuclide polonium 210 that may be received by some midwater dwelling species (600 to 1500 feet in depth).

Reference 4.29 estimates that the natural doses to the most affected organ (hepatopancreas) of certain species of shrimp may be as high as 195 rem per year.

S.25

First of all, no range of errors are given for these figures. If each might be off by one order of magnitude -- and I think we have heard testimony here today that we might look at several orders of magnitude for many of these numbers -- the difference that you are relying on to make this comparison may not be so apparently significant.

L.16

Secondly, the exposure of a hypothetical benthic organism at two to three miles depth is being compared to one measure for one midwater dwelling organism at 600 to 1500 feet of depth which illustrates more than just the fallacy of the comparison itself.

J.20

It also illustrates the appalling lack of data for making a more valid comparison. The estimated exposure rate may be quite significant for the genetic stability of populations of sensitive deep-water species in the vicinity of the dump site.

That is the question that has to be answered, not comparison of species somewhere else.

L.7

Thirdly, the question is not whether one source of exposure is significantly lower than a natural source, it is eventually the total exposure to which marine organisms and eventually people are subjected that is the real issue because it is the total risk we are concerned about, that we are affected by -- not the relative contribution of one source or another.

This is a continuing problem with radioactive or pollution risk assessments. Those who do these studies seem always surprised when people are not willing to accept the level of risk that seems slight, assuming we trust the estimated figures compared to other risks we take daily such as riding on the highway.

What decision makers fail to realize is that we can make a conscious decision whether to be exposed to the risk of driving or flying in an airplane from New York to Los Angeles. When it comes to this kind of radioactive exposure or most marine pollution exposure generally, we have little voluntary choice.

As the sources of such exposure mount in our lives, it is a rational man who says that it is the risk in addition to those he faces daily that he prefers not to face, especially those exposures over which he has no control.

An additional problem is the document's unquestioning assumptions regarding the level of acceptable risk. Biologists have found that each increment in radioactivy to which living cells are exposed produces a direct increment in mutation rate. There are no threshold values for radiation below which mutational damage may not occur. Thus, there is no such thing as a safe dose of radiation.

Since most mutations are detrimental to an organism, it is important to recognize that any and all additions to the radiation load received by an organism, including people, are potentially harmful.

It follows that comparative statements such as those in your summary on pages S-10, S-12, in analyses such as exposure to bottom dwelling sea life which I gave as an example and in the various comparative tables in the text are not valid. The correct framework for understanding effects is not compare potential exposure from this activity with a single other source of exposure such as natural background radiation, rather it would be to add natural exposure plus this potential exposure plus present man-made radioactivity introduced into the environment plus possible additional use of the oceans for disposal of radioactive wastes based on the precedent that this activity may set to get a true picture of the total radioactive burden potentially affecting marine organisms and man.

L.7

L.9

The rivers and coasts of our nation do not carry only natural thorium and uranium isotopes suggested in Table 4-7, but also chronic and accidental contamination from nuclear power plants and nuclear weapons activity.

L.7 At an effluent dispersion conference recently I attended, we were shown profiles of the radioactivity L.6 accumulating in the sediments of the Hudson River downstream from New York nuclear power plants. Radiation from the Hanford facility has been traced in the Columbia River and out into the Pacific Ocean and probably forms part of the background count for the proposed California offshore dump site.

It is likely that background levels or natural levels cited in some of your references contain anthropogenic L.13 radioisotopes from atomic bomb testing as well as land-based sources. The EIS should discuss what is known of the stresses that marine organisms are already being subjected to from these sources. You could make the comparative differences in your tables even more impressive by adding other sources, but the evaluative conclusions that are drawn would still be invalid.

The oceans are a surprising place. The lesson of the British Windscale experience where ocean discharged radionuclides were taken up by seaweeds which then washed L.39 ashore and contaminated the beaches is that we don't know what could happen.

The organisms of the ocean are already being altered

by the activities of man. When you calculate the costs of O.26 these disposal operations for comparison of options, you must also subtract the potential lost value of marine organisms and disturbances of the gene pool, for these are true costs of industrial uses of the ocean which are not being taken into account. No mention is made in the EIS of these values.

Scientists at California universities are only now investigating the chemical structures and properties of unusual metabolic products of California marine life. Chemistry, biochemistry, pharmacology, medicine and agriculture are all benefiting from marine life research, even as the subject of their investigations are threatened by increasing industrialization of the marine environment.

Northern California is one region whose benthic organisms are poorly known, and it is likely that biological surveys of possible dump sites will reveal new and unusual J.9 organisms not yet studied by science. These biological studies should be completed before the EIS is approved.

We threaten our future when we endanger biological resources whose gene pools are the evolutionary heritage of mankind. We are losing species at a rapid rate all over this planet, and we cannot afford to endanger a new area whose potential is unknown.

The fact of increased risk with increased exposure means that no additional exposure is justified. We must stop

312

J.76
W.1

creating more of these life threatening substances now. We must choose to dispose of existing wastes in a way that maximizes our ability to watch them closely and to control them if something goes wrong.

I urge you to revise this inadequate document to illustrate the real risks and costs of radioactive materials disposal, including the specific points I raised above. Our Navy's nuclear submarine program was one of the chief impetuses for development of the nuclear power industry which has spread the potential for radioactive pollution worldwide.

Let the Navy now set a precedent for maximum control of these dangerous wastes. It would be very appropriate for the Navy to lead us away from a technology which we have learned undermines the very security of life and human welfare our armed forces are pledged to protect.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Janet Crone of Willits, California.

--o0o--

#113

JANET CRONE

Can you hear? Okay.

I'm Janet Crone of Willits. I decided to speak -- I hadn't been planning to -- because I care. As a mother of six and a grandmother of one, I care about the future. As a long-time citizen, taxpayer and voter, I care about the actions of my country and its agencies.

L.53
O.34

As a partner in a small business making ocean related decorative items, I care about the future of small businesses whose incomes are tied to ocean tourism which is related to the health of the ocean and even before the health of the ocean is gone, to the public perception of the health of the ocean.

Captain, I hope you have some awareness that the Navy has done you a tremendous disservice. They have prepared a sloppy DEIS, and in a sense, for an essentially immoral plan, and then they have sent you down here ostensibly all alone, you sit there with a lot of empty seats to listen to a lot of irate but very well-prepared individuals take this plan apart.

Perhaps from this you might learn something about the kind of values that are embedded in the opposing views of those who wrote that plan and those who have spoken here today against that plan. A lot of questions have been raised and will continue to be raised concerning the research and the lack of research into the potential environmental effects of putting more radioactivity into the ocean.

L.39 W.1 Given all those unknowns, and given the impossibility of recovering either the waste or the subs from the ocean depths, what is being proposed in an ocean disposal option is a massive experiment with the ocean.

Given that there do exist these wastes and these subs and that there does exist a need to dispose of them, what we are all here saying is that the ocean is not a place for experiments of this magnitude.

G.2 The no action choice, as it is called, is a choice to wait; continue the research for real and lasting solutions is preferred to even the slightest possibility of contaminating the ocean now or 200 years from now or 1,000 years from now.

We are here, a lot of us, with an underlying fear that we will not be heard though we may speak eloquently; that we will not be listened to where it matters though we attest to 100 or 1,000 problems and unanswered questions, and we are

still here, and we've been here all day and still at this hour we are here in these numbers and still we speak with our various degrees of knowledge and fluency. We speak because decisions about the safety of the earth and of future generations are to be made through processes such as these, or at least that's what we are told.

When we have stood at blockades and been arrested for acting in accord with our own convictions, we have been told over and over again that we should use the legal channels, and so we do as we have done for decades, now, because we want to have used every available channel to protest contamination of the ocean and of the earth.

Now, I would say to the Navy, you pride yourselves on the defense of our country and feel sometimes, I think, that our efforts threaten that work; and I believe you need to recognize that we pride ourselves on our defense of the planet and of all life, and we feel that any nuclear activity -- but ocean dumping we are talking about right here -- threatens existence itself, and we find ourselves utterly unable to understand how you can believe it will matter how strongly you defend our country -- it's the only way this can be done is by endangering the ocean which nurishes the country and all of life.

After World War I, there were trials in which people of the free world condemned those that we held responsible for crimes against humanity. We rejected every excuse they came up with. We said that the sanctity of human life is a higher law, and that the daily working decisions of every human being must place those considerations above the dictates of party or nation or project.

Today we stand here in this tribunal of our nation, and we call upon those of our countrymen who will be making this decision about where to put the subs, and we charge you that as representatives of the country which introduced into the world community the concept of those higher laws as operative in your daily actions, that you make those decisions in accord with these laws; laws which say that even the defense of our own country, even trying to find a cheaper solution, does not give us the right to experiment with the ocean or with life.

N.3

Yes, we must deal with the existing waste, but no, we do not have to take chances on disposal techniques. We need to use the no-action option, and we must change it from a no-action option to one which becomes a massive and well-funded search for real solutions that have been promised to us for almost 40 years and which as yet have not been found.

--o0o--

CAPTAIN WAGNER: The next registered speaker is William Crooks of Gualala, California.

--o0o--

#114

WILLIAM CROOKS

That's a tough act to follow. My name is William Crooks, and I live on the Mendocino Coast at Anchor Bay. I'm an engineer retired after 21 years of employment by IBM.

Upon hearing that the Navy wants to scrap upwards of 100 nuclear powered submarines over the next few years, some questions obviously come to mind. I'd like to address three of those:

Why dispose of the subs? Why not retrofit or modify to keep them in service to assist us in keeping down the cost of our ultra costly arms race?

G.3

I'm not convinced that the Navy is cost effective with planned expenditures of 14.2 billion, and I repeat, 14.2 billion dollars by the Navy for FFG-7 missile frigates and 7.9 billion for Trident Missile I's.

It behooves the use of any and all equipment for longer periods of time to allow us for safe disposal.

Two, if disposal in the oceans of the reactor

J.7

components are so inert and so harmless for the report by the Department of the Navy, why not dump them in many sites off all coasts to save money towing the subs thousands and thousands of miles?

The answer, of course, is that this material is not harmless.

Third, why can't we allow ocean dumping of nuclear or radioactive material to be resumed? There are two basic reasons for not allowing the resumption of the dumping of nuclear radioactive material in the ocean.

L.9

First, if the Navy is allowed to start dumping, then other and probably all agencies will want to do the same. I'm sure that other agencies can prepare the same arguments that appear in the Navy's current report which is questionable at best.

Second, the other point to be made is that the nuclear -- that the reactor components should be buried in the Navy land, or in the designated land sites so that they may be retrieved when science finds a method to neutralize nuclear radioactive material.

Science will find the solution, as it must, and then the reactor compartments can be made harmless.

In summary, I make the following representation: Bury the reactor components in the designated land sites for monitoring; and last but not least, deposit the remainder of

the dismantled subs in the closest proposed land site to save the cost of transportation.

J.15

Thank you for allowing me to speak before you, Captain Wagner. We hope you will follow up with more meetings on the coast. We'd like for you to come on over. A Navy captain shouldn't be so far from the water, anyway.

Thank you.

--o0o--

316

CAPTAIN WAGNER: Next registered speaker is Mr. Jeff Hohensee of Laytonville, California.

UNIDENTIFIED SPEAKER: Excuse me, sir, aren't these supposed to go in alphabetical order?

CAPTAIN WAGNER: Yes, they are.

UNIDENTIFIED SPEAKER: My name is Ronald Glick, and I was here at 9:00 o'clock in the morning, and I signed up to speak.

CAPTAIN WAGNER: My cards are not alphabetized properly.

Mr. Hohensee, if you would please allow Mr. Glick -- Ron Glick of McKinleyville, California.

--o0o--

#115

RONALD GLICK

Thank you. It's been a long day. I'm a citizen of the United States of America as I trust you are, Captain. My name is Ron Glick. I'm a citizen of the United States of America, and I trust that you are, as you are in the Navy, and I trust that the Commander in Chief of the Armed Forces is also a citizen, otherwise he couldn't have got the job.

And when I was trying to figure this thing all out, I

tried to see what logic the Commander in Chief would have and what logic the Navy would have for doing this, and this is what I came up with.

It is in our national security interest to have nuclear submarines. Well, part of having those nuclear submarines means eventually we have to do something with them when they're obsolete or too radioactive to handle or whatever.

So what the Navy has decided, or the Commander in Chief or somebody has decided, that what we ought to do is sink 'em in Davy Jones' Locker. Well, by the Environmental Impact Statement, the Draft that the Navy has published, they have calculated that there will be no significant risk, but any radiation is bad. We know this, that none of it is good. It causes mutations, cancer, leukemia and maybe other things, for all I know. And so even this little insignificant bit is in addition to whatever else there is in the environment, and it is bad, and it is bad for the people that it comes in contact with. L.7

Now, the Navy and the President in their desire for national security has decided we -- or is proposing that we sink these things off the coast near where I live, and as an individual, I am -- thereby, my health is thereby more endangered by their presence than would they not be there.

So in essence, what they're saying to me is that for the betterment of the United States of America, the people of the United States of America, the national security of the people of the United States of America, that we're going to put these things here, and we're sorry, Ron, but that's the way it goes.

Well, I would like to take issue with that and to express the gravity of how dangerous this is. I would like to read a short passage which will be less than all told five minutes from Beneto Mussolini's "Fascism Doctrine and Institutions."

"Anti-individualistic, the fascist conception of life, stresses the importance of the state and accepts the individual only insofar as his interests coincide with those of the state which stands for the conscious and universal will of man and with historic entity. It is opposed to classical liberalism which arose as a reaction to absolutism and exhausted its historical function when the state became the expression of the conscience and the will of the people. Liberalism denied the state in the name of the individual. Fascism reasserts the right of the state as expressing the real essence of the individual, and if liberty is to be the attribute of living men and not of abstract dummies invested by individualistic liberalism, then fascism stands for liberty and for the only liberty worth having, the liberty of the state and of the individual within the state."

Now, there's been some question raised here as to whethe

there's any point in us being here; is this just some ritual that we go through as a nation to provide public comments?

And as one citizen who cherishes democracy to another citizen who, I think, does because you took the time to allow the children to speak because it is a lesson in democracy for them to come here and be able to speak.

I urge you to go back to Washington and explain to the people at the top, and if that means you have to go into the office of the Commander in Chief and give him the message: How dangerous an act this is to go against the will of the people.

Thank you.

--o0o--

CAPTAIN WAGNER: Jeff Hohensee.

--oOo--

#116

JEFF HOHENSEE

Thank you. As between the artificial lights and the artificial air and everything else in here --

As a concerned citizen, I worry about our government's actions. The people of the United States have a cavalier attitude toward natural resources which is quickly pulling us toward dependence on foreign sources. On either end of the nuclear bulkhead are potentially recycleable materials. As our resources dwindle more and more, things become feasible to recycle. Today that scrap metal may be economically unretrievable. Has any economist ever read accurately 20 years down the road? Once nuclear submarines are dumped into the ocean, they are basically unretrievable. Their fate is up to the ocean, and to quote an old sailor's antidote, "The ocean does not forgive your mistakes." W.1

The nuclear waste disposal problem is new to our generation. We inherited it from a society whose faith in technology was boundless. Technology today is nowhere near

curing all the havoc it's created. Technology, like man, its creator, is imperfect. Mistake is an integral part of his existence. Can we guarantee our grandchildren that we aren't perpetrating a disaster on them? We don't have any idea how the embedment of steel will affect the longevity of the holding capacity of the bulkheads. We don't have the technology to dump anything, let alone nuclear submarines intact to the depths we are proposing. We don't even have the ability to monitor them once they're there. Q.13 J.76

In college we are taught to bend statistics to tell any truth. We know statistics speak with forked tongues. What if in our pompous ignorance we do unleash a nuclear genocide?

Can we hide behind our rhetoric when people are being born mutants. Throughout the EIS, the word "assumption" is weaved into most of the predictions. What if our assumptions are false? What if at some point nuclear waste is released in the environment? What can I tell my children when they look me in the eye and ask me, "Why did you let the Navy do it, Daddy? Was it because it was easy? Because you were in a hurry"? L.43 L.40 L.20

We live in a generation where convenience at any cost has been the bottom line. Well, maybe dumping nuclear waste in the ocean is the most expedient way to deal with it today, but what about tomorrow? We owe it to our future to take firmer N.3

steps when we're dancing in the arms of nuclear waste. An ounce of prevention is worth a pound of cure. Only as much nuclear waste needs to be disposed of as we create. Please stop nuclear waste.

--o0o--

CAPTAIN WAGNER: Ladies and gentlemen, we are going to take a recess now for dinner. We're going to reconvene the hearing at 7:30. I'm told that the building has to be closed during the time that we're gone. It will be reopened at 7:15, so we will recess at this time and reconvene at 7:30.

--o0o--

Testimony at the Public Hearing

on the

Draft Environmental Impact Statement

on the

Disposal of Decommissioned Nuclear Submarines

Thursday, February 24, 1983

Department of Water Resources
1416 9th Street
Sacramento, California

Evening Session

Reported by: Theresa French, CSR No. 5790
Ida Ruth Lundsten, CSR No. 5791

CAPTAIN WAGNER: Ladies and gentlemen, we'll reconvene the hearing.

Is there anyone in the audience who was not here this afternoon when we recessed? Let me just for a minute set the procedure.

I'm Captain Edward Wagner. I'm here as the Navy's hearing officer to conduct one of the scheduled public hearings on the Navy's Draft Environmental Impact Statement on the disposal of decommissioned, defueled nuclear powered submarine reactor plants.

The purpose of this hearing is to take testimony regarding the Navy's Draft Environmental Impact Statement. The purpose is neither to plead the Navy's case nor to engage in debate. My responsibility is to receive statements in the form of testimony so that they can be considered in preparing the Navy's Final Environmental Impact Statement.

I'm affording those individuals and organizations an opportunity to provide testimony. We are in the process of listening to individual testimony from individual speakers, and the time limit on the individual so that everyone will have an opportunity to express their views is five minutes.

The procedure for public testimony is as follows: I will announce each registered speaker. You need to register if you want to provide testimony. And if you haven't already registered, you should fill out a registration card at the registration desk to accomplish that.

When you are called, proceed to the microphone. Please state your name. And if we get back to organizational spokesmen tonight, please list your organization if any -- even though I call your name, I want to make sure that the record gets that name correctly in case I mispronounce or we have misspellings or whatever.

Please address your comments to me. Again, if your statement is so long that it's going to exceed the time limit that we've established, I remind you that you can submit that statement in writing. It will be entered into the record in its full content. And you can summarize your statement in the five-minute period.

So let's proceed with the first registered speaker -- or the next registered speaker, who is Elizabeth Ann Halfcock (ph) from Redway, California.

Is Miss Halfcock here?

(Speaker not present.)

CAPTAIN WAGNER: I believe we will move to the next speaker. I believe this is Lori Kern from Willits, California, or it could be Lori Kim from Willits, California.

(Speaker not present.)

CAPTAIN WAGNER: And then let's ask Mr. Edward Martinez from Santa Cruz, California -- or I could have the last name wrong, it could be Martiner from Santa Cruz, California.

(Speaker not present.)

CAPTAIN WAGNER: Brendan Mobert from Gualala, California.

UNIDENTIFIED SPEAKER: Brendan has spoken.

BRENDAN MOBERT: I have already spoken.

CAPTAIN WAGNER: Thank you.

Kenneth L. Mobert from Gualala, California.

--o0o--

MARY MOBERT

#117

My name is Mary Mobert, I speak for my husband. Sir, it is very hard for me to understand as a student of physics why this artificial discussion is going on in the first place. There is no lack of data establishing the absolute folly of dumping toxic waste anywhere -- let alone the ocean.

If you apply the notions of criminal negligence or for that matter criminal insanity to this Environmental Impact Statement, I believe that any of its preparers would be quickly led away.

L.20

We are not discussing some abstract concept but the very survival of life on this planet. What manner of idiot would say that a container of lethal waste could be safely stored

322

L.20

for 50,000 years? I am sure that by the time this letter is read, plenty of arguments both emotional and logical will have been made.

The bone that I would like to pick is just who do you think you are kidding in the first place? It is clearly obvious that this meeting is a fraud and quite likely illegal. This so-called meeting was carefully constructed to make it difficult -- if not impossible -- for the people it affects most to have any say in it. Though I have legal -- little legal experience, I am -- I am reasonably sure that a good constitutional lawyer would have little trouble bringing suit against both the Navy and the Government.

In short, this meeting is a carefully planned farce with deadly serious possibilities.

There has never been a crime more villainous than the murder of a whole world.

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Kirk R. Mobert from Gualala, California.

--o0o--

#118

KIRK R. MOBERT

Hello, I'm Kirk R. Mobert. And believe it or not, I wrote a speech but I folded it and put it in my pocket, so it's a little ruined. I'll have to wing this one.

First of all, I live in Gualala. And I swim in the ocean down at the beach and, you know, I dive and the whole thing. And I'm glad I'm -- I wasn't one of the unfortunate ones to find any fish -- you know, any messed up fish like some fishermen here before.

But I would just like to say that nuclear ocean dumping is sort of a waste. And putting -- putting the subs in -- well, in the oceans is pretty bad -- pretty bad too. Kind of crazy.

I just also would like to say that as Brian Casey said before: If you make mistakes, I have to live with it and so do my children and my grandchildren.

That's pretty much all I have to say.

--o0o--

CAPTAIN WAGNER: The next registered speaker -- excuse me -- is Mary Mobert who just spoke for her husband.

Would you like to speak for yourself? From Gualala, California.

--o0o--

#119

MARY MOBERT

Thank you. My name is Mary Mobert. I'm a nobody.

UNIDENTIFIED SPEAKER: Louder, please.

MS. MOBERT: Thank you.

I'm a nobody as were most of the people here. I live a quiet life, most days filled with parenting and paying bills and keeping life and limb together, as do most of the people here.

So why didn't I keep my nose in my business? Why did I waste two days getting here and sitting here to spend at the most five minutes talking to people who I feel chances are won't be listening anyway?

I haven't been to a protest since the Vietnam War days. The years have proven that these protests sent ripples through society right to the top and eventually changed things. I'm adding my small voice to other voices -- large and small --

that have been telling you that all these nuclear toys you boys have been insisting upon playing with expede a high price that will be paid in full, not by you, but by your children and their children's children.

We are beginning to see it in the environment now. Animals, birds and fish are showing the effects of poison we have dumped on them. The earth has begun to revolt against the way we are treating her and her children. The weather is changing and experts on the subject can't say what will happen next.

The Navy sits in Washington clothed in its brass-plated pride, gazing down on all us reactionaries, ignoring 30 years of evidence and testimony and asking the question: To dump or not to dump and on whom?

You have the gall to print a 400-page tome that says, "All will be well; just trust us." I know a man who trusted you in the early '50's. He signed onto a ship and wound up in the Marshalls standing on deck as did all MSTS civilian personnel aboard, facing away from the blast of the first H bomb testing. He was never told where he was going nor did he give his permission to be a guinea pig in your experiment. He has had no children since -- and though he tried several times. He is now a retired merchantile Marine, and he is fighting a losing battle with cancer. That man is my father-in-law. And you cared about your effects on his life about as much as you care about the lives of the people who have been sitting here today.

You think you have the right to suck our life's blood and to pay for your flesh-melting, soul-crushing, life-destroying toys. You think you have the right to reek slow insidious poisonous death on our progeny without our permission; to litter the world's backyard with your cast-off, deadly dolls. Well, think again.

This meeting is just not one of two to add to a thin coat of democratic varnish to your already carefully laid plans. It's one of a long line of meetings that will hopefully break the deadly chain that will change opinions.

We will win. Set your mind on it. For we outnumber you. We tell you"Wake up." You're dancing a dangerous dance with a very dangerous lady. You've lulled yourself into believing that you are safe through your strength and your power -- Be aware.

You can't continue this diluted game of slap and tickle, hide and seek with this woman. Her clock was wound at creation's inception and will continue to tick beyond this planet's demise. If you continue your folly of throwing caution in her face, the price the world will pay will be beyond the imagining of men. When that Geiger clock strikes, Lady Death will impose her will on us all, and you in your air conditioned, comfortable bunker and I on my hill with

my goats will be burnt up; in my hiding place or not and in your hiding place or not.

Many of us have taken the trouble to bring our children here as a part of the educative process on both sides. We wanted them to see you in action. We wanted you to hear from those whom you will affect the most; their thoughts and concerns in their own voice. We wanted you to look them in the face and remember those faces as you decide to what degree you -- with your cold-blooded calculation -- will murder them.

The Navy is used to the no-action syndrome. You've been sitting on your proverbial poop deck in the nonaction attitude for years.

So please, for the sake of my kids and for those kids who were here, keep sitting on that nonaction syndrome, and it will be very much appreciated.

Thank you.

--o0o--

#120

CAPTAIN WAGNER: The next registered speaker is Morning Star from Willits, California.

--o0o--

MORNING STAR

My name is Morning Star, and I come from Willits. This is a ceremony that we are doing here, and, therefore, I will use my ceremonial name. And I, Morning Star Rainbow Medicine Woman Bridge of Life Protected by the Golden Eagle, will call on all the power in all of the people in this room to thank the Navy, our brothers, and the brothers and sisters in this room for sharing in this ceremony.

I wish to speak to the DEIS from my heart as a nature person. The earth is alive. We are part of a delicate balance. To see humankind as above this balance and therefore to believe that we can safely control it is foolish. To see humankind as superior to all other life limits the vision of mankind. This limited vision is reflected in scientific theory; limited to belief in only the existence of that which can been seen or in some way proven.

Atoms existed for eons before man saw them. The earth as a living being exists whether or not mankind knows it and

acknowledges it. I don't need scientific proof to know that we are part of the earth and that nuclear waste dumped into the ocean is a desecration of our sacred waters, seriously disturbing the balance of life.

I ask all the people in this room to focus their attention on the moment when their hearts opened and they awakened to this reality. And I ask them to join me in prayer for all our brothers in the Pentagon that their hearts may too be opened to feel their oneness with our earth.

Thank you.

--o0o--

326

CAPTAIN WAGNER: The next speaker is Ede Morris of Redwood Valley, California.

LEWIS KORN: Pardon me, I'm Lewis Korn and I think that you -- the Ms come after the Ks. I didn't hear my name called.

CAPTAIN WAGNER: We are working, sir, on the registrations that occurred prior to or at 9:00 o'clock this morning. If you registered after that time, we haven't got to those yet.

MR. KORN: I believe I did come at 9:00.

CAPTAIN WAGNER: We'll bring you next, sir.

--o0o--

#121

EDE MORRIS

My name is Ede Morris, and I left my husband and two small children in Redwood Valley which is in Mendocino County so I could come here today and sing a song for you. It has to do with the history of the coastline in California and the destruction that is taking place here.

(This is a song.)

On the golden shore of the Pacific Ocean the
Spaniards came for gold

and the Padres brought the cross of Jesus to
the Indians who were sold
as slaves to the conquering white man who
robbed them of their gods
and took their land till they made a stand on the
coast of California.
The white man came to the land of the sun
he took what he wanted left the Indians none
The Great Spirit warned them that the power
would come
now the Earth is in pain and there's nowhere
we can run.
The settlers came in search of Freedom not
knowing it was lost
and the hunters killed the buffalo but the
Indians paid the cost
of their brave young men and land that had been
theirs for so long
they were driven to the hills so far away
from the coast of California.
The white man came to the land of the sun
he took what he wanted left the Indians none
The Great Spirit warned them that the power
would come
now the Earth is in pain and there's nowhere

we can run.
The cities grew till the air was black from
the cars and factory smoke
and the kings and queens of Hollywood found
Jesus as their hope
for all the sins of their indulgence in the
myre of booze and drugs
they sit and wait for the big earthquake on
the coast of California.
The white man came to the land of the sun
he took what he wanted left the Indians none
The Great Spirit warned them that the power
would come
now the Earth is in pain and there's nowhere
we can run.
On the golden shore of the Pacific Ocean
they're drillin' for more oil
You can see the rigs suckin' up the juice from
the coastline they will spill
And blackness filled the water where blue ocean
once had been
and the people lost their fine shore lots on
the coast of California.
The white man came to the land of the sun
he took what he wanted left the Indians none

The Great Spirit warned them that the power
would come
now the Earth is in pain and there's nowhere
we can run.
Power companies built nuclear plants on the
center of a fault
so the people said they'd go to jail if the
destruction didn't halt
and radiation filled the ocean where clear water
once had been
and the Indian bones have lost their homes on
the coast of California.
The white man came to the land of the sun
he took what he wanted left the Indians none
The Great Spirit warned them that the power
would come
now the Earth is in pain and there's nowhere
we can run.
Now the Navy wants to dump nuclear subs
to make room for the deadlier Trident
They'll make the ocean their permanent home
a radioactive environment
But the people said they don't want them
for the ocean is our source
We must all join hands

and take a stand
on the coast of California.
We must all join hands
and take a stand
on the coast of California.

Well, I'm really glad I got to do this. I waited all day, and I was pretty tense. But I want to let you know again that as a founding member of the Abalone Alliance, I know how fast grass-roots movements grow, and this movement is going to grow and be very powerful.

And I recommend that you listen to what's been said today; take heed to what we told you, and please don't dump the subs or the waste in the ocean.

Thank you.

--o0o--

#122

LEWIS KORN

I've prepared a speech which I'm not going to read. Thank you. I'm not going to read my speech because everybody said everything I wanted to say, but I need to say something.

Can you hear me?

CAPTAIN WAGNER: Could you please state your name, sir?

MR. KORN: I'm Lewis Korn, I live in Willits.

And I want to say to all of you who has the staying power to stay so long, for coming many of you so far --

I just want to say a few things. The environmental burdens become body burdens. Toxics, pesticides, hazardous chemicals, nuclear radiation are becoming intolerable burdens. Some terrible but illuminating experiments are performed.

Frogs dropped into scalding water will, if they can, immediately jump out. When placed into cool water that is gradually heated to boiling, they make no effort to escape until they are too weakened and cannot move. We must learn from the poor frogs so that we do not follow their example. We must learn to not do that to frogs and to ourselves.

You know, we are really one life. And if we understood that, we wouldn't be doing this to ourselves. And it's biologically true that we are one life. If you take the single cell and it divided in half and both halves are the same life in two cells. And when you -- when they divide in half, you've got the same life in four. And when -- when they evolve, you have the same life in different forms.

Why should we be doing this to each other? That's all.

--o0o--

CAPTAIN WAGNER: The next speaker is Lee O'Bryant from Fort Bragg, California.

UNIDENTIFIED SPEAKER: Miss O'Bryant had to leave -- Mrs. O'Bryant.

CAPTAIN WAGNER: Thank you.

LYNNE HARPER: Excuse me. I'm not Mrs. O'Bryant -- and I'm sure I missed out. I'm wondering if you could backtrack? Did you already do Lynne Harper?

CAPTAIN WAGNER: No. You may speak next, Ms. Harper.

--o0o--

LYNNE HARPER

#123

My name is Lynne Harper, and I'm from the hills outside of Covelo. And I don't recognize -- and I don't represent any big group. But I know how my friends and neighbors feel. And I know that we are upset enough about it to drive for seven hours to get here and to wait around all day.

And I have a little son, and I don't want you to dump nuclear waste in his world and mess it up.

--o0o--

330

#124

SAM: Excuse me, I signed up at around 9:00 and haven't been able to speak yet. I don't want to say very much, so --

CAPTAIN WAGNER: Go right ahead.

--o0o--

SAM *

Okay, great. I want to remind everybody that these are the same people that are saying that nuclear war is not --

UNIDENTIFIED SPEAKER: Your name?

SAM: What? Oh, my name is Sam, and I live ten miles from Cape Mendocino. And tonight we're speaking with people that think nuclear war is winnable. And I feel like anybody that -- that thinks it's safe to dump radioactive subs in the ocean needs to see a psychiatrist.

Thank you.

--o0o--

*Believed to be Mr. Sam Camp.

#88a*

CAPTAIN WAGNER: The next registered speaker is Charles Orth of Willits, California.

--o0o--

CHARLES ORTH

I'm sure you all know me from earlier today. Actually, I'm not going to hold you to taking verbal testimony as I am going to be using sounds I don't think you can recreate in your little punches.

The issue today is this little shell and the way we can feel about this little shell. And it's called reverence for life. And the issue here is black and white. It is a challenge to that reverance; that's why we see so many people here who have traveled so far. And why I don't feel you will be in Fort Bragg and Eureka, because you will not confront our reverence for our lives and the lives of things such as this shell -- that it may be a bone of something that lived. But it did live and it was whole and has been worked by the ocean and moved by the ocean, and it has intermingled in that environment. And we are part of that intermingling.

So I will now wish to call upon all of our concern that has been in this room today. And I call upon that which

*Issues discussed by Mr. Orth are side barred in Exhibit 88.

is silent so much you know us.

(Whereupon the speaker recited Indian chants.)

Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Will Reed of Gualala, California.

--o0o--

#125

WILL REED

I am Will Reed from Anchor Bay, and persistence does win out every once in awhile.

I wanted first of all to say thank you everyone who is here. Thank you, Captain. And that I also put some time in the service. I was part of the Navy. However, it was called the Needy Navy -- the Coast Guard.

And I do -- I do believe in some of the values of our country, and I believe that we are among all -- a lot of folks in this world -- we're probably in the vanguard of trying to get back to something that was lost somewhere. And that's what I want to talk about.

I had -- like everyone else, I had these, you know, compiled notes. And so many others -- I'm speaking slowly -- so many other people have expressed their views more succinctly and more clearly than I can.

But what I want to touch on is something that is always reoccurring in whatever we all say -- witness brother's chant just a moment ago. It's a reoccurring theme of harmony. It's the integration of everything that is here and that we are a part of it. And if -- to think that we aren't is totally beyond conception for most of us here.

And it's basically a theme of just common sense, you know? It's this -- this spirituality, this level of awareness has always existed. It has always been around. It is what the generations -- the millennium the people have been talking about, and it's something that's more heartfelt than mentally felt. It's there in your heart. And it's -- There's a song -- I don't know if it's from a play -- it's called "On A Clear Day You Can See Forever."

And when you are not involved in something, you generally have the perspection of looking over at it, and most of us are a product.

I was -- I tell people I was born when they weren't making cars and trucks. They weren't; they were making tanks and bombs. I was born in 1944. And most of us are products of after that era. And we don't come from the -- have that same perspection like the purview of paranoia that the present administration is operating from, which is kind of a -- let's see -- a reality that didn't -- that existed 40 years ago and no longer exists.

And we can see that real clearly. And we are trying to express that that feeling -- it's a matter of trust. And it's

a matter of openness in one's heart. And that is growing. It's becoming a larger base. And witness in here a lot of us -- you know, I mean it's not the hardest travails that anyone in history has made, but we have made an effort to be here and we've been talking about it for a long time now and not just on this particular issue.

And we -- it's our children. Like, I think, someone said, you know, the children, they belong to the future. Well, we cannot know, and we don't want to pass on this legacy of -- I don't know -- just total lack of respect for what is in nature, in that harmony that exists within it.

And this -- this reality, this level of awareness that is growing is -- it's almost like up until the overriding ruling power or consensus has been to use up and abuse, and when it's -- when you are all done with it, you kind of just sort of, you know, shovel it off somewhere where no one else can see it, and you move on.

Well, we're moving on throughout the entire world practically, and the world is also running out of lackeys I mean, the third worlds are saying, "Hey, forget this; we don't like this -- you know, we don't want to do it any more."

And that's kind of what's going on.

And it's going on here and it's the younger people. And it's not just the younger people, but there's becoming more and more younger people that are seeing this as being a pretty obvious -- I mean, why else look at it in any other way?

And I may be beating a dead dog here, but that's kind of off the top.

What I wanted to talk about -- and just coincidentally, there was a wonderful woman who was from the Soroptimists who spoke earlier, and she was telling about the forgotten people from another era. Well, I just came from although I'm from Massachusetts years ago -- I came from Southern California. I just got back from taking care of my near-invalid father, who is dying of emphysema because he worked in the -- I'm having - wait a minute, let me get a hold of it.

He worked in shipyards during the war as a welder, and he now has asbestosis and was forced into retirement 20 years ago. And the Government does not want -- he's too young to get Social Security, and the Government doesn't want to give him a pension.

So he is another one of these people that kind of got swept aside. And there's lots of people like that, and we don't want to do that any more. We don't want children to have that to happen.

And it is -- and I don't come here as -- you know -- I don't feel like you're an adversary and, you know, it's us against you. We are all in this. And this is more of an appeal. And there she is right, the appeal should go to the elected people -- I mean, our elected officials.

It's compassion, and that's about all I have to say.

CAPTAIN WAGNER: The next registered speaker is Beverly Roberts of Willits, California.

--oOo--

BEVERLY ROBERTS

Hello, my name is Beverly Roberts, I'm from Willits, California. And I feel that everyone here feels the same. They are all my friends, and I can tell you how I feel.

I originally wanted to come and talk because I was afraid. And I was afraid of many things, the main one being afraid of radiation.

When I first felt this fear of radiation, I wanted to find out more about it. So I looked at books, and I went through films. And the more I found out about it, the less afraid I became.

But there are other fears too. I'm afraid for people -- for the human race. I'm afraid for my children. I'm afraid for generations to come. I'm afraid for the people in the Marshall Islands. I'm afraid of the lies that I'm told by the Government. I have all these different things that make me afraid.

And the only thing that I can do to combat that fear

is to educate myself and to educate others so that they'll know the facts; we'll know the truth that will take away those fears.

I help teach in a third grade class. And before I came to the hearing, I talked to those children about emotional problems that they have in the classroom when some children aren't getting along with other children. And we talked about our fears, and we talked about the fears of friendship, of not having friends.

But I don't have that now because I see all my friends. And so after we talked, I said: "I won't be here next week because I'm going to Sacramento; going to Sacramento to talk to the Navy because the Navy has plans to -- to dispose of 120 decommissioned nuclear submarines in the ocean right outside Cape Mendocino."

And these children said, "Can we write to the Navy?"

And I said, "Yes, I see no reason why you can't write to the Navy."

And that's all I told them. The next day I picked my son up at noon and the third grade teacher gave me these letters, which I would like to read to you. They are all addressed to the Honorable Captain Wagner, Department of the Navy.

This is from a little girl eight years old: I don't feel good at all about the idea of dumping the radioactive

*L.14
L.36

submarines in the ocean because it can wipe out millions of fish and whales and sharks for miles around; and it can hurt people also. I enjoy going to the ocean and playing in the waves, and I don't want to see it destroyed. Also it might pollute the air, even if a little bit escapes. I don't know who came up with the idea to dump them in the ocean, but I don't think it's a good idea. And please don't do it. Emily Stoik (ph.).

Jason Patterson: I feel very, very bad about you dumping these submarines into the ocean. It would kill a lot of fish and people, and it would ruin our food and could even kill you.

I feel that you aren't respecting us, and it can kill us -- which I don't want. We can't go to the beach; it stays for a long, long time. David Lockman.

Willie Riggs: If you guys let them go, you guys could give us cancer. Number one, they blow up. Number two, they give us cancer. Number three, they kill fish. We don't want to get cancer because we don't want to die.

E.33

Reef Roberts: I think you should put the old subs in the desert and bury them with cement and iron casings. And I mean it. No thanks.

BEVERLY ROBERTS: This is by Steven Allen: Don't do it because someone might eat the radioactive fish and die. I don't think you would punish us in that way and destroy our food.

BEVERLY ROBERTS: These children are eight years old.

Jeff Smith: I feel bad that you are dropping the submarines in the ocean. It will kill lots of fish and things. It might ruin our food. It can kill people.

BEVERLY ROBERTS: This is by Seth: I don't like the subs being dumped in the ocean because they will kill the fish. It will make our food dull. It will kill people. I think they should throw them in the ocean because they can poison lots of fish -- I don't think they should throw them in the ocean because they could poison lots of fish, and I or other people could eat the fish and get very sick. Number one: kill fish. Number two: ruin the ocean. Number three: hurt -

*Other issues discussed by Ms. Roberts are side barred in Exhibit 32.

California.

BEVERLY ROBERTS: This is by Maurine Paula Marris: "I think you should empty the subs and put them in the park. Number one: People will die. Number two: You will ruin our ocean.

"Patrick Simpson: I feel threatened. The subs should not be dumped in the sea."

BEVERLY ROBERTS: This is from Murissa: "I think that the subs can kill more than half of our earth. I do not want the subs dumped in the ocean -- this is underlined twice with three exclamation points.

"I feel that if you put them in the ocean, we would not have any fish. I feel if you dump them in the ocean, you could kill animals and lots of people." This is by Kevin.

"I don't think you should dump the subs in the ocean,

you could kill a lot of people and a lot of babies and fish and whales and animals. And there wouldn't be no ocean. It could make a lot of air stink."

This is a little picture -- no submarines in the ocean.

"I feel very bad that you are doing this, and I think you shouldn't put them in the sea because it will pollute it. And the nuclear bombs will kill the children." This is by Amber.

Thank you.

You can have this, and we'll mail you these. Thank you.

I want to say one more thing. Tomorrow morning when I get back to Willits, I am going to go back to the third grade class, and I'm going to tell them the things that I experienced here, and we'll talk again. And then we'll mail the letters in. Thank you.

--o0o--

CAPTAIN WAGNER: The next registered speaker is Dan Roberts from Willits, California.

--oOo--

#126

DAN ROBERTS

My name is Dan Roberts. My son is Reef Roberts and he means it.

The first thing I would like to say is thank you for helping us organize. I played basketball in high school, and I know before a game if we had a real good pep rally, we always won. And this has been the best pep rally I've ever been to.

I've learned a lot from this, and I hope you have too.

One question that came up that wasn't in what I wrote was that what would happen to a Trident submarine if it was loaded and exploded in the ocean. I know you can't answer that question, but that's a lot more serious than dumping submarines that's had the fuel lines taken out of it, right? Okay.

Don't poison my waters. I live 230 miles in a straight line from where you want to dump the submarines. I eat the fish from there. My wife eats the fish from there. My children eat the fish from there. My friends eat the fish from there.

My children's children will eat the fish from there, and they'll probably eat it even if you dump it in there and it's slightly radioactive because that's the way people are. You eat from there. Your wife and children eat from there. Your great-grandchildren will eat from there. You and I both know that sooner or later that radiation will leak out and get in the food chain.

L.20
L.36

Are we crazy? What kind of desperate people would poison their own food? And for thousands of years? Irretrievable. Irretrievable.

W.1

My great-grandchildren will stand there and shake their heads and go, "How could they? What were they thinking?" It's not an us-and-them situation -- it's us, everybody.

These subs must be disposed of where they will not enter the food chain or the water. What we really need is a way to stabilize the radioactive nature of the waste; make it not radioactive. There is surely a way. Some day it will be discovered. Spend a fortune now hiring scientists to work day and night on this critical situation. Learn how to make it inert, stable, not radioactive. Then the danger will be gone. Give a billion dollar award to whoever can figure it out. We can afford it. It's not as desperate as dumping them in the ocean where inevitably they will enter the food chain.

Please find a way to stabilize these wastes soon --

real soon, before you think about dumping them again. Make them not radioactive, inert, stable.
