

## NHC Forecast Verification Summary

Miles B. Lawrence and Joel W. Cline  
National Hurricane Center

The National Hurricane Center issues a 72-hour track and intensity forecast, every six hours, for all tropical cyclones in the Atlantic and eastern Pacific basins. Forecasts for all tropical storms and hurricanes are verified by comparison with a best-track post analysis of all available track and intensity data.

Table 1 lists the official track forecast errors, by storm, for the Atlantic and Table 3 does so for the eastern Pacific. In both basins, the official forecasts were somewhat smaller than the previous 10-year averages. In particular, note that the errors for Hurricane Hugo were quite small, as is normally the case for a smooth storm track.

Tables 2 and 4 list homogeneous comparisons of track forecast errors for a variety of guidance models, for the Atlantic and eastern Pacific, respectively. In the Atlantic, after 24 hours, all of the guidance models performed slightly better than CLIPER, the climatology/persistence control model. NHC83 was the best performer by a small margin, but BAM did as well at 72 hours in spite of its large errors at the earlier forecast periods. These large early errors are the result of BAM not properly incorporating the initial storm motion and it is impressive that it can overcome this poor start. In the eastern Pacific, there is little model improvement over EPCL84.

Finally, Table 5 lists one-minute wind speed forecast errors for both basins for the official forecasts and for the SHIFOR/EPSHIF climatology/persistence models.

Table 1. Official track forecast errors (average in nautical miles), Atlantic, 1989.

storm	forecast period (hours)					
	0	12	24	36	48	72
Allison (no. of cases)	15 (4)	39 (4)	80 (2)	- (0)	- (0)	- (0)
