

NATIONAL HURRICANE CENTER VERIFICATION FOR 1991

Miles B. Lawrence

Abstract

The National Hurricane Center issues a 72-hour track and intensity forecast, every six hours, for all tropical cyclones in the Atlantic and eastern Pacific basins. Forecasts are verified by comparison with a best-track post analysis of all available track and intensity data. Verification statistics for 1991 are presented.

1. Atlantic

Table 1.1 lists average official track forecast errors by storm for the Atlantic for 1991 for tropical storms and hurricanes and Table 1.2 compares 1991 with the previous ten-year average. The 1991 averages at 12 and 24 hours are somewhat larger than the previous ten years, while the 0-, 48- and 72-hour errors are less than the previous ten-year average. The small number of cases (only 21 at 72 hours) for 1991 precludes making any meaningful generalizations about this year's errors. Table 1.3 shows that 72-hour track forecast errors for tropical depressions for 1991 are 30 percent larger than those of tropical storms and hurricanes.

Track forecast errors for all forecasts for operational guidance models are given in Table 1.4 and model comparisons for homogeneous data sets are given in Tables 1.5 and 1.6. The QLM model has the smallest errors at 24, 36 and 48 hours and NHC90 has the smallest at 72 hours, although the number of cases is very small when the QLM is included. Also, The QLM is not available as guidance until after the Aviation Model run is complete. It is of interest that the CLIPER errors for 1991 in Table 1.4 are the largest for this model since 1978. This suggests a high difficulty level for this year's track forecasts. VICBAR track forecast errors are not available for this report, but are reported on by Aberson and DeMaria in the research presentations.

Official wind speed forecast errors are listed in Table 1.7. The mean wind speed errors show a positive bias at all forecast periods while the previous ten-year average is a negative bias. The mean absolute errors for 1991 beyond 12 hours are larger than the corresponding previous ten-year averages.

2. Eastern Pacific

Statistics similar to those described above are given for the eastern Pacific in Tables 2.1 through 2.6. This is the fourth season that the National Hurricane Center has been responsible for issuing advisories for the eastern Pacific. Track forecast errors for 1991 compare nicely with the previous three years with only the 72-hour errors for 1988 being smaller than this year's errors (Table 2.2).

Homogeneous model comparisons (Tables 2.4 and 2.5) show that the old PSDE and PSS (statistical-dynamical and statistical-synoptic) models compete favorably with CLIPER, as do the deep and medium BAM after 24 hours. The new statistical-dynamical P91E also improves on CLIPER.

The official mean wind speed errors (Table 2.6) continue to show a negative bias, but not quite as much as the previous three years. Mean absolute errors show little change from the previous three years.
