### DISCLAIMER

This report was prepared by ALSTOM Power Plant Laboratories with support in part by a grant from both the Ohio Coal Development Office/Ohio Department of Development and the United States Government. Neither the State of Ohio, the United States Government, nor any of their agencies, nor any person acting on their behalf:

- 1. Make any warranty or representation, express or implied, with respect to the accuracy, completeness, or usefulness of the information contained in this report, or that the use of any information, apparatus, method or process disclosed in this report may not infringe privately-owned rights; or
- 2. Assume any liabilities with respect to the use of, or damages resulting from the use of, any information, apparatus, method or process disclosed in this report.

References herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise, does not necessarily constitute or imply its endorsement, recommendation, or favoring; nor do the view and opinions of authors expressed herein necessarily state or reflect those of the State of Ohio, the United States Government or their agencies.

## ACKNOWLEDGMENTS

The authors appreciatively acknowledge the following people for their contributions to the successful performance of the work presented herein: Mark Borman and Tom Ross of AEP Conesville Plant for providing field unit information; Lorraine Miemiec, and Roland Tetreault of ALSTOM Power's Boiler Segment for providing boiler performance prediction, and design graphics, respectively; and Alan DelPaggio of CRI Catalyst Company for De-oxy catalyst process development. The financial support of this project by OCDO (Contract No CDO/D-98-8), DOE National Energy Technology Laboratory (Contract No DE-FC26-99FT40576), ALSTOM Power Inc. and ABB Lummus Global Inc. is also appreciated. The in-kind financial support of the project by American Electric Power is greatly appreciated

# PUBLIC ABSTRACT

ALSTOM Power Inc.'s Power Plant Laboratories (ALSTOM) has teamed with American Electric Power (AEP), ABB Lummus Global Inc. (ABB), the US Department of Energy National Energy Technology Laboratory (DOE NETL), and the Ohio Coal Development Office (OCDO) to conduct a comprehensive study evaluating the technical feasibility and economics of alternate  $CO_2$  capture and sequestration technologies applied to an existing US coal-fired electric generation power plant.

The motivation for this study was to provide input to potential US electric utility actions concerning GHG emissions reduction. If the US decides to reduce  $CO_2$  emissions, action would need to be taken to address existing power plants. Although fuel switching from coal to natural gas may be one scenario, it will not necessarily be a sufficient measure and some form of  $CO_2$  capture for use or disposal may also be required. The output of this  $CO_2$  capture study will enhance the public's understanding of control options and influence decisions and actions by government, regulators, and power plant owners in considering the costs of reducing greenhouse gas  $CO_2$  emissions.

The total work breakdown structure is encompassed within three major reports, namely: (1) Literature Survey, (2) AEP's Conesville Unit #5 Retrofit Study, and (3) Bench-Scale Testing and CFD Evaluation. The report on the literature survey results was issued earlier by Bozzuto, et al. (2000). Reports entitled "AEP's Conesville Unit #5 Retrofit Study" and "Bench-Scale Testing and CFD Evaluation" are provided as companion volumes, denoted Volumes I and II, respectively, of the final report. The work performed, results obtained, and conclusions and recommendations derived therefrom are summarized below.

### Volume I

The Volume I report discusses three retrofit technology concepts, which were evaluated in conjunction with AEP's Conesville Unit #5, namely:

- **Concept A:** Coal combustion in air, followed by CO<sub>2</sub> separation with Kerr-McGee/ABB Lummus Global's commercial MEA-based absorption/stripping process
- **Concept B:** Coal combustion with O<sub>2</sub> firing and flue gas recycle (oxy-fuel firing)
- **Concept C:** Coal Combustion in air with oxygen removal and CO<sub>2</sub> separation by a mixture of primary and tertiary amines, i.e., monoethanolamine (MEA)/methyldiethanolamine (MDEA).

Each of these technologies was evaluated against a baseline case, the existing design without  $CO_2$  capture, from the standpoints of performance, impacts on power generating cost, and  $CO_2$  emissions. AEP's 450 MW Conesville Unit No. 5, located in Conesville, Ohio, was used for the power plant case study. All technical performance and cost results associated with the available options were evaluated in a comparative manner.

### **Major conclusions:**

- No major technical barriers exist for retrofitting AEP's Conesville Unit #5 to capture CO<sub>2</sub> for any of the three concepts considered under this study.
- Concept B (oxygen firing with flue gas recycle) appears clearly to be the best alternative of the three concepts studied from both an efficiency and incremental COE viewpoint for systems designed for very high CO<sub>2</sub> capture (i.e. > 90%). If lower CO<sub>2</sub> capture fractions are considered, it appears that Concept A would likely be the best alternative for capture fractions below some as yet undetermined value. Concept C would also improve considerably with lower capture fractions.
- This study has confirmed two important issues related to firing coal in a CO<sub>2</sub>-rich flue gas / O<sub>2</sub> mixture:
  - Modifications to the existing steam generator unit pressure arts are not required, and as such will also allow the unit to continue to operate in the conventional air- fired mode.
  - CO<sub>2</sub>-rich flue gas can be cleaned and compressed with a relatively simple system to provide high purity CO<sub>2</sub> for usage or sequestration.

- Energy requirements and power consumption are high for all three concepts, resulting in significant decreases in overall power plant efficiencies (HHV basis), ranging from efficiencies of 20.5 to 22.5%, as compared to 35.0% for the Base case (air firing without CO<sub>2</sub> capture), which is equivalent to an energy penalty ranging from 36% to 41%. That is, the net power plant output was reduced to 77% 59%.
- The MEA/MDEA mixture of Concept C requires about 28% less energy per pound of CO<sub>2</sub> captured to regenerate the solvent as compared to the MEA used in Concept A.
- Specific investment costs are high, ranging from about 800 to1800 \$/kW and from 1000 to 2200 \$/kW, corresponding to scenarios with and without replacement power, respectively.
- All cases studied indicate significant increases to the COE as a result of CO<sub>2</sub> capture. The incremental COE as compared to the Base case (air firing without CO<sub>2</sub> capture) ranges from 3.4 to 8.4 ¢/kWh. Similarly CO<sub>2</sub> mitigation costs range from about 42-98 \$/ton of CO<sub>2</sub> avoided for the range of cases studied.
- Specific carbon dioxide emissions were reduced from about 2 lbm/kWh for the Base case to 0.13 0.27 lbm/kWh for the study cases. Recovery or capture of CO<sub>2</sub> ranged from 91 to 96%.
- Nominally, 5-8 acres of new equipment space is needed for Unit #5 alone on the existing 200-acre power plant site, which accommodates a total of 6 units with a total power generating capacity of 2,080 MW.

### Major recommendations:

- A sensitivity study, for Concepts A and C, showing the impact of reducing CO<sub>2</sub> capture percentage on plant efficiency, investment cost, emissions, and cost of electricity. The current work utilized 90% CO<sub>2</sub> capture (nominal). The sensitivity study would investigate nominal CO<sub>2</sub> capture percentages of 70% and 50%.
- Detailed analysis of the existing steam turbine for Concept A: In Concept A about 79% of the steam leaving the intermediate-pressure (IP) turbine is extracted from the IP/LP crossover pipe for solvent regeneration. The capability of the existing low-pressure (LP) turbine to operate under these conditions of very low steam flow o ver the load range should be investigated in detail, preferably by the original equipment manufacturer (OEM).
- Optimization of the amine system reboiler steam pressure for Concepts A and C.
- Concept B detailed boiler system analysis: A startup/shutdown procedure and system design, particularly the transition from air to oxygen firing (including transient conditions) should be developed. Detailed metal temperature analysis for all heat exchanger sections, including operation at part loads should be analyzed. This should also include furnace wall metal temperatures and analysis of the circulation system. The existing fans should be checked (preferably by the OEM's) for operation under the new conditions. The feasibility of operating the boiler under a slight positive pressure to eliminate air infiltration should also be investigated.
- Investigation of Improved oxygen production systems for Concept B, in line with the membrane-based air separation research being conducted by various research groups (e.g., Praxair, Air Products, Norsk Hydro). Also optimization of an integrated boiler and oxygen production system.
- Measurement of furnace heat transfer in CO<sub>2</sub>/O<sub>2</sub> environments in a proof of concept boiler simulation facility.
- Improved solvents, which require lower regeneration energy requirements and/or can be regenerated at a lower temperature level, similar to MHI's KS1 system, but for coal-firing application.
- Hybrid process using oxygen-enriched combustion and amine based CO<sub>2</sub> absorption, to accrue, simultaneously, both CO<sub>2</sub> capture and drastic NOx emissions reduction.
- Investigation of a new novel high risk CO<sub>2</sub> capture process that would reduce efficiency penalty and retrofit investment cost. This would likely not utilize the existing boiler.

### Volume II

The bench-scale testing consisted primarily of drop-tube (DTFS-1) and thermo-gravimetric analyses (TGA). Three cases were investigated: (1) an air-fired case (Base case); (2) a case in which the  $N_2$  was replaced by an equal mass of CO<sub>2</sub> (Constant Mass case); and (3) a case in which the  $N_2$  volume was replaced by an equal volume of CO<sub>2</sub> (Constant Volume case). The Constant Mass case represents the appropriate retrofit scenario in a commercial pulverized coal firing application, albeit without flue gas recycling.

### **Major conclusions:**

### (a) Based on TGA results

• Both the Conesville Unit #5 and Pittsburgh Seam #8 coals have, for air (Base case) and O<sub>2</sub>/CO<sub>2</sub> environments (Constant Mass/Volume cases), similar burning characteristics, as they both go to completion within the same temperature range (550-575 oC). Burning either of the coals in air or any of the O<sub>2</sub>/CO<sub>2</sub> mixture ratios used here would produce virtually identical results; and (2) both coals have similar reactivity characteristics.

### (b) Based on DTFS-1 results

- Residence time, as expected, has a significant impact on the overall coal combustion efficiency, and hence, on the unburned carbon emission in the fly ash for both coals under consideration. That is, while the combustion efficiency for both coals is only about 80% (dry-ash-free coal basis) at 0.2 sec., it is more than 98% at greater than 0.5 sec. Correspondingly, unburned carbon emissions range from about 65% to about 2% (dry fly ash basis).
- The impact of reaction medium is also significant. While the overall combustion efficiencies do not seem to exhibit significant differences between the baseline and Constant Mass firing, the more sensitive parameter, unburned carbon (UBC) in the fly ash, on the other hand, clearly shows better performance for the Constant Mass case. That is, the UBC at the furnace outlet was about a factor of 4.5 lower for the Constant Mass case (~2% vs. 9%). This is believed to be due to higher reactant gas temperature, and yet longer residence (0.77 sec. vs. 0.57 sec.). It appears, from the shape of the UBC profiles, that, if given enough residence time, these differences would narrow down considerably, implying that the ultimate performance in both mediums would be similar.
- The coal sample from Conesville Unit #5 appears to perform better than the sample from Pittsburgh seam #8 coal (e.g., 9% vs. 12.5% UBC for the air firing case). However, based on the shape of the UBC profiles, it can be seen that if given additional residence time, they would both be expected to perform similarly.
- NOx emission from oxy-fuel firing is about a factor of 3 (0.73 vs. 2.25 lb/MMBtu) lower than that of the Base Case. Correspondingly, sulfur dioxide is lower by about 19% (3.6 vs. 4.3 lb/MMBtu), and CO is significantly lower (0.09 lb/MMBtu vs. a negligible amount).

### (c) Based on CFD results

- The baseline case exhibits higher carbon-in-ash (by 1.6 percentage points), higher outlet NOx emissions (by a factor of 2), and higher outlet CO (by a factor of 2) than the Concept-B case. These same computational trends are also qualitatively exhibited by the bench-scale testing.
- The baseline case exhibits a slightly higher peak gas temperature (maximum difference of about 200 °F), and a correspondingly higher average (cross-sectional) gas temperature (difference of 90 °F at the HFOT), than that of the Concept-B case.
- The net wall absorption in the furnace region for the baseline case is larger (by less than 1%) than that of the Concept-B case. However, A significant variation in both calculated and experimental irradiation to the wall between baseline and oxy-firing scenarios was also found in the literature (e.g., +6 to -18%). Differences may be partially attributed to the sensitivity of the irradiation and local emissivities to the aerodynamic and flame patterns, which are, in turn, a function of the furnace and firing system. It is suggested that radiatively absorbing gas species can either enhance or inhibit the irradiation in the vicinity of the wall, depending upon their local temperature and their relative spatial placement.

### Major recommendations:

- Carry out a systematic coal fundamentals study concerning this field of endeavor. This study should be geared toward the creation of a database of information depicting the impact of coal nature (using coals of various rank coming from both domestic and international sources) when fired in an oxy-fuel environment on:
  - > Coal devolatilization and char oxidation kinetics, and unburned carbon emissions in the fly ash
  - Acid rain-related gaseous (NOx, SO<sub>2</sub>, and CO) emissions
  - Air toxics, particularly, mercury (Hg), volatile organic compounds (VOC's), and particulate emissions.
- Derive furnace heat transfer data from natural gas and coal firing in an oxy-fired pilot-scale furnace, which simulates the temperature/time history of a boiler. Use first the data from natural gas firing to validate the CFD code, without the complication of burning particles transiting the boiler. Apply the experience learned from modeling a natural gas fired boiler to model the coal-fired boiler.

# APPENDIX I- DRAWINGS148APPENDIX II- EQUIPMENT LISTS173

# **EXECUTIVE SUMMARY**

### Background

International discussions continue to debate the need for reductions in emission levels of greenhouse gases (GHG). Because fossil fuel fired power plants are among the largest and most concentrated producers of  $CO_2$  emissions, it stands to reason that recovery of  $CO_2$  from the flue gas of such plants has been identified as one of the primary means for reducing  $CO_2$  emissions.

ALSTOM Power Inc.'s Power Plant Laboratories (referred to herein as ALSTOM) teamed with American Electric Power (AEP), ABB Lummus Global Inc. (referred to herein as ABB), the US Department of Energy National Energy Technology Laboratory (DOE NETL), and the Ohio Coal Development Office (OCDO) to conduct a comprehensive study evaluating the technical and economic feasibility of three alternate  $CO_2$  capture technologies applied to an existing US coal-fired electric generation power plant. The steam generator analyzed in this study is the Conesville No. 5 unit, operated by American Electric Power (AEP) of Columbus, Ohio. This steam generator is a nominal 450 MW, coal-fired, subcritical pressure, controlled circulation unit. It has a single cell furnace that employs corner-fired, tilting, tangential burners and which fires bituminous coal from the state of Ohio. The flue gas leaving the boiler system is cleaned of particulate matter in an electrostatic precipitator (ESP) and of  $SO_2$  in a lime-based flue gas desulfurization (FGD) system before being discharged to the atmosphere.

ALSTOM is managing and performing the subject study from its Power Plant Laboratories office in Windsor, CT. ABB, from its offices in Houston, Texas, is participating as a sub-contractor. AEP is participating by offering their Conesville Generating Station as the case study and cost sharing consultation, along with relevant technical and cost data. AEP is one of the largest US utilities, and as the largest consumer of Ohio coal, is bringing considerable value to the project. Similarly, ALSTOM and ABB are well established as global leaders in the design and manufacturing of steam generating equipment, petrochemical, and  $CO_2$  separation technology. The DOE National Energy Technology Laboratory and the Ohio Coal Development Office provided consultation and funding. All participants contributed to the cost share of this project.

### **Objectives**

The motivation for this study was to provide input to potential US electric utility actions concerning GHG emissions reduction. If the US decides to reduce  $CO_2$  emissions, action would need to be taken to address existing power plants. Although fuel switching from coal to natural gas may be one scenario, it will not necessarily be a sufficient measure and some form of  $CO_2$  capture for use or disposal may also be required. The output of this  $CO_2$  capture study will enhance the public's understanding of control options and influence decisions and actions by government, regulators, and power plant owners in considering the costs of reducing greenhouse gas  $CO_2$  emissions.

The key goals of the study were to evaluate the impacts on the plant output, efficiency, and  $CO_2$  emissions, resulting from the addition of the  $CO_2$ -capture systems. Cost estimates were developed for the systems required to produce, extract, clean and compress the  $CO_2$ , which could then be available for use in enhanced oil or gas recovery or sequestration. Additionally, the impact of  $CO_2$  capture on the cost of electricity (COE) and on the mitigation cost for  $CO_2$  (\$/ton of  $CO_2$  avoided) was also evaluated.

### Work Scope

The total work breakdown structure is encompassed within three major reports, namely: (1) Literature Survey, (2) AEP's Conesville Unit #5 Retrofit Study, and (3) Bench-Scale Testing and CFD Evaluation. The report on the literature survey results was issued earlier by Bozzuto, et al. (2000). The report entitled "Bench-Scale Testing and CFD Evaluation" constitutes Volume II of the final report.

Work on AEP's Conesville Unit #5 Retrofit Study is presented here as <u>Volume I</u> report. The work performed, results obtained, and conclusions and recommendations derived therefrom are summarized below.

### System Descriptions

The three retrofit  $CO_2$  capture technology concepts evaluated in this study are listed below:

- **Concept A**: Coal combustion in air, followed by CO<sub>2</sub> separation with Kerr-McGee/ABB Lummus Global's commercial MEA-based absorption/stripping process
- **Concept B**: Coal combustion with O<sub>2</sub> firing and flue gas recycle (oxy-fuel firing)
- **Concept C**: Coal combustion in air with oxygen removal and CO<sub>2</sub> separation by a mixture of primary and tertiary amines

The results from each of these three evaluations were compared to the Base Case, which represents the "business as usual" operating scenario for the existing plant without  $CO_2$  capture.

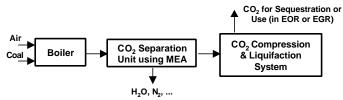

The CO<sub>2</sub> capture systems were designed for a minimum of 90% CO<sub>2</sub> capture. The Dakota Gasification Company's CO<sub>2</sub> specification (DGC WebPages, 2001) for EOR, given in the following table, was used as the basis for the CO<sub>2</sub> capture system design. A very low concentration of oxygen, in particular, is specified for meeting current pipeline operating practices, due to the corrosive nature of the oxygen. Hence, for Concept B, whereby the final CO<sub>2</sub> liquid product was found to contain about 9300 vppm of O<sub>2</sub>, the design of the transport pipe to an EOR site for example would have to take this characteristic under consideration.

Component	Unit	Concentration	
CO2	Vol.%	96.0	
H₂S	Vol.%	0.9	
CH4	Vol.%	0.7	
C2+HCs	Vol.%	2.3	
со	Vol.%	0.1	
N <sub>2</sub>	vppm	< 300	
H <sub>2</sub> O	vppm	< 20	
0 <sub>2</sub>	vppm	< 50	

## Dakota Gasification Project's CO2 Specification for EOR

Concepts A and C are both low temperature  $CO_2$  absorption systems located downstream of the FGD system and as such do not impact the operation of the boiler.

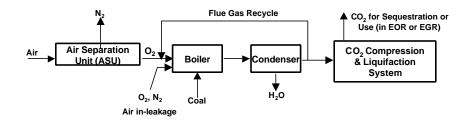

In **Concept A** Coal is burned conventionally in air as schematically depicted below. The flue gases leaving the modified FGD system (a secondary absorber is added to reduce the  $SO_2$  concentration for MEA system) are cooled with a direct contact cooler and ducted to the MEA system where more than 96% of the  $CO_2$  is removed, compressed, and liquefied for usage or sequestration. The remaining flue gases leaving the new MEA system, consisting of primarily oxygen, nitrogen, water vapor and a relatively small amount of sulfur dioxide and carbon dioxide, are discharged to the atmosphere.

Although boiler performance is identical to the Base Case in Concept A, there is a major impact to the steam cycle system where low-pressure steam is extracted to provide the energy for solvent regeneration. About 79% of the

intermediate pressure (IP) turbine exhaust is extracted from the IP/LP crossover pipe. This steam is expanded from 200 psia to 65 psia through a new steam turbine. The exhaust from the new turbine provides the heat requirement for solvent regeneration in the reboiler's of the MEA  $CO_2$  recovery system. Solvent regeneration requires about  $4.7 \times 10^6$  Btu/Ton  $CO_2$ . The condensate from the reboilers is pumped to the existing deaerator. The remaining 21% of the IP turbine exhaust is expanded in the existing low-pressure turbine before being exhausted to the existing condenser. The total output from both the existing and new generators is 331,422 kW. This represents a gross output reduction of 132,056 kW (about 28%) as compared to the Base Case.

The basic concept of the overall system for **Concept B** is to replace air with oxygen for combustion in the furnace, thus directly producing a high  $CO_2$  content flue gas. In designing the Concept B system, emphasis was placed on utilizing as much as possible of the existing equipment, minimizing boiler modifications required, and providing operational flexibility to permit switching to the conventional mode of operation if desired. This process is depicted schematically below.

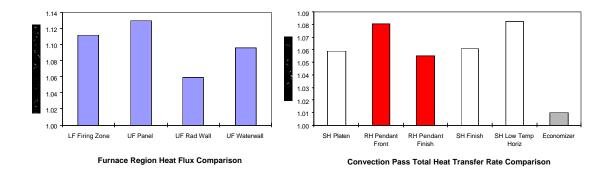

The proposed combustion system uses a mixture of nearly pure oxygen with recycled flue gas. A conventional cryogenic Air Separation Unit (ASU) supplies the oxygen. The recycle flow rate is established by the need to maintain a thermal balance between the radiant and convective heat transfer surfaces of the existing steam generator. The quantity of the recirculated gas is approximately equal to the quantity of nitrogen contained in the combustion air that would have been supplied to the steam generator as part of the oxidant. Inherent in the flue gas recirculation process is the build-up of carbon dioxide and water vapor content in the flue gas. This increased concentration produces significant changes in the thermal and mechanical properties of the flue gas. These gas property differences cause significant differences in the heat transfer processes, which occur within the steam generator unit. Analyses were made to determine the impact of the heat transfer differences on boiler behavior.

Heat transfer in the lower and upper furnace regions is compared in the figure to the left below. The figure on the left compares heat fluxes (Btu/hr-ft<sup>2</sup>) in the lower and upper furnace region between air firing and oxygen firing. Lower furnace results show firing zone heat flux to be about 11% higher with oxygen firing. Upper furnace region results show the reheat radiant wall is about 6% higher and the superheat panels are about 13% higher with oxygen firing. Similarly, the upper furnace waterwall region is about 10% higher.

Convective heat transfer in utility steam generator units is dependent upon many of the transport properties of the flue gas (viscosity, thermal conductivity, density, specific heat and others). Additionally, convection depends strongly on gas velocity. With this system, there are significant changes in the flue gas analysis as compared with air firing. These gas analysis changes cause both transport property and gas velocity changes throughout the unit. Significant differences in non-luminous radiant heat transfer are also expected. Of the gases produced by the complete combustion of a fuel, only carbon dioxide, water vapor and sulfur dioxide emit radiation over a sufficiently wide band of wavelengths to warrant consideration. With this system the primary change in the flue gas as compared to air firing is the large increase in the  $CO_2$  content and decrease in  $N_2$  content. The total heat transfer rates (convective + non-luminous radiation) for the convection pass are shown in the figure on the right, below. Increases are calculated to be in the range of 1 to 8% for oxygen firing over the values with air firing.

# Steam Generator Heat Transfer Comparison

(Oxygen and Air Firing)

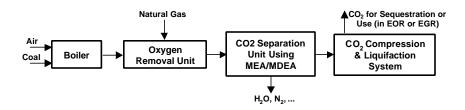

Despite these heat transfer changes, boiler performance is achieved with the existing steam temperature control system that includes burner tilts and desuperheating sprays. Although more detailed analysis are needed, no boiler pressure parts modifications appear to be required.

The products of combustion that exit the furnace are cooled in a series of heat exchangers. Two of these heat exchangers, located downstream of the existing air heater, are new. The first heat exchanger is provided to preheat the oxygen required for combustion. The second heat exchanger recovers additional heat from the flue gas in a low temperature economizer installed in parallel with the low-pressure extraction feedwater heaters. This heat exchanger was necessary as a result of reduced air heater performance with oxygen firing.

The steam cycle system for Concept B is very similar to the Base Case. The only modification was the addition of a low-pressure feedwater heater arrangement in parallel with two low-pressure extraction feedwater heaters. The modified steam cycle system produces almost exactly the same output as the Base Case.

In **Concept C**, coal is burned conventionally in air. A process comprising an optimized mixture of monoethanolamine (MEA) and methydiethanolamine (MDEA), installed downstream of the flue gas desulfurization unit, is integrated into the power plant to strip  $CO_2$  from the effluent gas stream. The mixture of MEA and MDEA cannot be made to be oxygen-resistant. Therefore, while this process potentially offers an improved system from the standpoint of solvent regeneration energy requirement, it is necessary that the excess oxygen in the flue gas be converted to  $CO_2$  by combustion with natural gas over a De-Oxy catalyst upstream of the solvent contactor. Solvent regeneration requires about  $3.4 \times 10^6$  Btu/Ton  $CO_2$  (about 72% of that required for Concept A). High temperature heat recovery is provided in the De-Oxy system by the generation of high pressure superheated steam for power generation and solvent regeneration. Concept C is depicted schematically below.

Boiler performance for Concept C is again identical to the Base Case. There is a major impact to the steam cycle system, similar to Concept A, where low-pressure steam is extracted from the existing steam turbine to provide energy for solvent regeneration. In this case, about 45% of the IP turbine exhaust is extracted from the IP/LP crossover pipe. This steam is expanded from 200 psia to about 65 psia through a new low-pressure steam turbine. The exhaust from

4

the new turbine provides most of the heat requirements for solvent regeneration in the reboiler's of the MEA/MDEA  $CO_2$  capture system. The high-pressure steam generated in the De-Oxy heat recovery system is expanded through a new high-pressure steam turbine for additional power generation. The exhaust from this turbine provides about 20% of the energy requirement for the reboilers. Low temperature heat recovery is provided in the De-Oxy system with a low-pressure feedwater heater which is located in a feedwater stream which is in parallel with the three existing low pressure extraction feedwater heaters. The total output from the modified steam cycle is 431,290 kW. This represents a gross output reduction of 32,188 kW, which represents about 7% of the Base Case output.

### **Performance Analysis Results**

The table shown below summarizes the performance differences between the cases. The primary design constraint among all cases was the supply of an equivalent main steam flow to the existing steam turbine.

	(units)	Original Plant (Base)	Concept A MEA	Concept B O2 Fired	Concept C MEA-MDEA
Fuel Paramaters					
Coal Heat Input (HHV)	(10 <sup>6</sup> Btu/hr)	4228.7	4228.7	4140.0	4228.7
Natural Gas Heat Input (HHV)	(10 <sup>6</sup> Btu/hr)		17.7	11.4	885.9
Total Fuel Heat Input (HHV)	(10 <sup>6</sup> Btu/hr)	4228.7	4246.4	4151.5	5114.6
Steam Cycle Paramaters					
Existing Steam Turbine Generator Output	(kW)	463478	269341	463056	357196
CO2 Removal System Turbine Generator Output	(kW)	0	62081	0	36343
De-Oxy System Turbine Generator Output (Concept C)	(kW)	0	0	0	37751
Total Turbine Generator Output	(kW)	463478	331422	463056	431290
Total Auxiliary Power	(kW)	29700	76007	189709	95317
Net Plant Output	(kW)	433778	255414	273347	335973
Overall Plant Performance Paramaters					
Net Plant Efficiency (HHV)	(fraction)	0.3501	0.2053	0.2247	0.2242
Net Plant Efficiency (LHV)	(fraction)	0.3666	0.2150	0.2354	0.2371
Normalized Efficiency (HHV; Relative to Base Case)	(fraction)	1.0000	0.5864	0.6419	0.6404
Net Plant Heat Rate (HHV)	(Btu/kwhr)	9749	16626	15188	15223
Net Plant Heat Rate (LHV)	(Btu/kwhr)	9309	15872	14500	14395

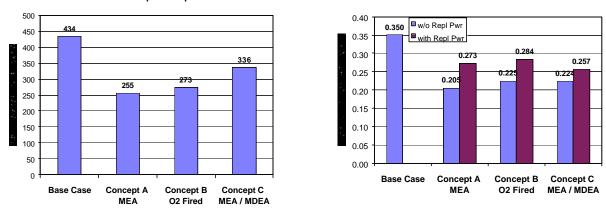

As described above, significant reductions in Net Plant Output are incurred as a result of the  $CO_2$  capture systems (refer to the figure to the left below). Therefore, each case was also analyzed with replacement power to make up this difference. For cases with replacement power, it was assumed to be generated with a state-of-the-art natural gas fired combined cycle (NGCC) plant. The NGCC plant was analyzed without capturing the  $CO_2$  from its flue gas. The NGCC plant was assumed to generate power with an efficiency of 57.1 percent (LHV basis). The additional  $CO_2$  emitted from the NGCC was 0.762 lbm/kWh.

Net plant efficiency is reduced from about 35% (HHV basis) for the Base Case to about 20.5% for Concept A and about 22.5% for Concepts B and C (without replacement power) as shown in the figure on the right below. These efficiencies represent energy penalties of 41% and 36%, respectively. The efficiency reductions for Concepts A and C are due to large reductions in the existing steam turbine output and significant auxiliary power requirement increases. Concept C additionally utilizes a large quantity of natural gas in the de-oxy system increasing the total fuel heat input by about 21%. The steam turbine output reductions for Concepts A and C result from solvent regeneration energy requirements, which are provided by low-pressure steam extraction. The auxiliary power increases are due to the  $CO_2$  compression and liquefaction system. Concept B, with a gross output essentially the same as the Base Case, suffers from high auxiliary power primarily from the ASU and the  $CO_2$  compression and liquefaction system.

The efficiencies for these cases including replacement power are also shown on this figure and range from about 26% to 28% (HHV basis) with Concept B being the most efficient.

Net Plant Output Comparison

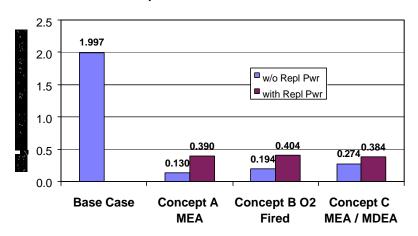

Plant Thermal Efficiency Comparison (HHV Basis)

#### Plant CO<sub>2</sub> Emissions

Specific carbon dioxide emissions were reduced from about 2 lbm/kWh for the Base Case to between 0.13 - 0.27 lbm/kWh for the study cases as shown in the following table and figure (without replacement power). Recovery of CO<sub>2</sub> ranged from 91 to 96%. The CO<sub>2</sub> emissions with replacement power are also indicated on the figure below.

		Original Plant (Base)	Concept A MEA	Concept B O2 Fired	Concept C MEA-MDEA
	(units)				
Plant CO <sub>2</sub> Emissions					
Carbon Dioxide Produced	(lbm/hr)	866102	868137	849255	967806
Carbon Dioxide Recovered	(lbm/hr)	0	835053	796238	875653
Carbon Dioxide Emissions	(lbm/hr)	866102	33084	53016	92153
Fraction of Carbon Dioxide Recovered	(fraction)	0	0.962	0.938	0.905
Specific Carbon Dioxide Emissions	(lbm/kwhr)	1.997	0.130	0.194	0.274
Normalized Specific CO <sub>2</sub> Emissions (Relative to Base Case)	(fraction)	1.00	0.065	0.097	0.137
Avoided Carbon Dioxide Emissions (as compared to Base)	(lbm/kwhr)		1.867	1.803	1.722

### Specific CO<sub>2</sub> Emissions

# **Project Costs**

The project capital cost estimates, including construction, are shown in the following table and figure. These costs include all required equipment such as the amine based  $CO_2$  scrubbing systems of Concepts A and C, the modified FGD system of Concept A, the de-Oxy system of Concept C, the  $CO_2$  compression and liquefaction systems for all three concepts, steam cycle modifications for all concepts, the air separation unit and the boiler island modifications of Concept B. Boiler island modifications for Concept B are relatively small and include costs for such items as air and gas ducts and dampers, booster fans, parallel feedwater heaters and piping,  $O_2$  heater, and controls and instrumentation.

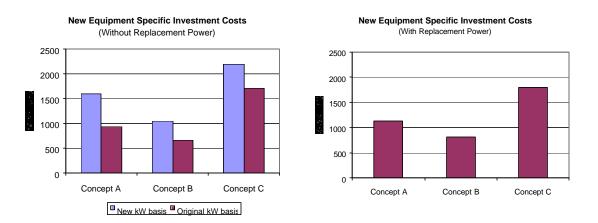

All these  $CO_2$  capture options produce less net plant output than the original plant (Base Case). Therefore, each case was also analyzed with replacement power to make up this difference. For cases with replacement power, it was assumed to be generated with a state-of-the-art natural gas fired combined cycle (NGCC) plant. The NGCC plant was analyzed without capturing the  $CO_2$  from its flue gas. The NGCC plant was assumed to cost \$450/kW, installed and its efficiency (LHV basis) was 57.1 percent. The additional  $CO_2$  emitted from the NGCC was 0.762 lbm/kWh.

Two sets of costs are shown for each Concept in the table, one without replacement power and one including replacement power. The figure on the left shows new equipment specific investment costs (\$/kW net) for the three concepts, without replacement power, based on both the original and modified net output. The figure on the right shows new equipment specific investment costs (\$/kW net) for the three concepts, with replacement power, and therefore based on the original net output.

CO <sub>2</sub> Capture Concept	Units	w/o Repl Pwr	with Repl Pwr
Concept A	10 <sup>6</sup> US\$	409	489
	\$/kW	1602	1128
Concept B	10 <sup>6</sup> US\$	285	357
	\$/kW	1042	823
Concept C	10 <sup>6</sup> US\$	738	782
	\$/kW	2197	1803

<b>Total Retrofit Investme</b>	ent Capital Costs
--------------------------------	-------------------

**Note:** The specific costs (\$/kW) shown above for cases without replacement power are based on the new net kW output.

Operating and maintenance (O&M) costs were calculated for all systems. The O&M costs for the Base Case were provided by AEP. The fixed O&M costs (FOM) for the existing plant were about \$16/kW (0.27 Cents/kWh using the base parameter assumptions) and the variable O&M costs (VOM) were about 0.45 Cents/kWh. The VOM costs are

comprised exclusively of the lime cost required for the FGD system and the costs for fly ash, bottom ash and FGD system waste disposal.

For the retrofit  $CO_2$  capture system evaluations, additional O&M costs were calculated for the new equipment. The VOM costs for the new equipment included such categories as chemicals and desiccants, waste handling, maintenance material and labor, and contracted services. The FOM costs for the new equipment includes operating labor only.

For the variable ranges considered in the economic sensitivity study, total FOM costs for the retrofit systems, including existing and new equipment, ranged from about 0.4 to 0.6 Cents/kWh and VOM costs ranged from about 0.9 to 2.3 Cents/kWh.

### **Economic Evaluation**

A total of 66 CO<sub>2</sub> capture cases were compared in the reported sensitivity studies. All cases studied indicate significant increases to the COE as a result of CO<sub>2</sub> capture. The incremental COE as compared to the Base Case (air firing without CO<sub>2</sub> capture) ranges from 1.5 to 9.8 Cents/kWh. Similarly CO<sub>2</sub> mitigation costs range from about 17-113 \$/Ton of CO<sub>2</sub> avoided for the range of cases studied. The following table and figures summarize the economic analysis results for the six primary cases using base parameter values (i.e.; Coal Cost = 1.32\$/10<sup>6</sup> Btu, Natural Gas Cost = 4.0\$/10<sup>6</sup> Btu, Capacity Factor = 67%, CO<sub>2</sub> Byproduct Sell Price = 0.0\$/Ton, Investment Cost = As Estimated).

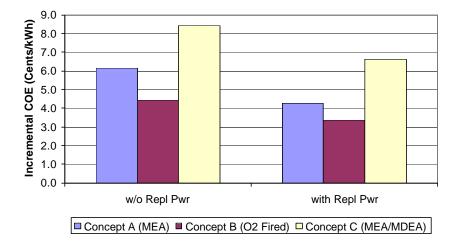

### Summary of Economic Analysis Results

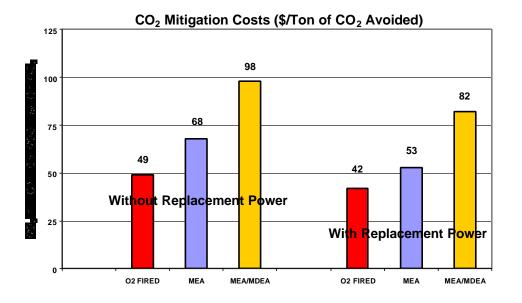

(Using base parameter values)

Parameter	Units	Concept A		Concept B		Concept C	
		w/o Repl Pwr	with Repl Pwr	w/o Repl Pwr	with Repl Pwr	w/o Repl Pwr	with Repl Pwr
Incremental COE	Cents/kWh	6.2	4.3	4.4	3.4	8.4	6.6
CO2 Mitigation Cost	\$/Ton	68	53	49	42	98	82

## **Incremental Cost of Electricity**

(Using base parameter values)

Concept B (oxygen firing with flue gas recycle) appears to clearly be the best alternative of the three concepts studied based on incremental COE or mitigation cost evaluation criteria. Using the base parameters of the sensitivity study for Concept B yields incremental COE values of 3.4 and 4.6 Cents/kWh for cases with and without replacement power respectively. The actual COE values for Concept B are 19% and 12% lower than the corresponding values for Concept C for cases with and without replacement power respectively. Similar results are also obtained when comparing mitigation costs.

If  $CO_2$  byproduct were sold for \$20/ton, incremental COE values would be reduced to 1.59 and 1.64 Cents/kWh respectively. Additional reductions would be possible with capacity factor increases, investment cost decreases or system efficiency increases as quantified in the sensitivity studies. Significant investment cost decreases and efficiency increases may be possible as oxygen transport membrane technology develops. Previous studies, Liljedahl, et al. (1999), have shown membrane technology to provide specific investment cost (\$/kW) reductions of about 30% and net plant heat rate improvements greater than 20%.

## **Conclusions and Recommendations**

No major technical barriers exist for retrofitting AEP's Conesville Unit #5 to capture  $CO_2$  with any of the three concepts considered under this study. Nominally, 5-8 acres of new equipment plan area is needed. For this site, new equipment is located approximately 1500 feet north of the Unit #5 stack on the existing ~200 acre power plant site which accommodates a total of 6 units with a total power generating capability of 2,080 MW.

Energy requirements and power consumption are high, resulting in significant decreases in overall power plant efficiencies (HHV basis), ranging from about 21 to 23% as compared to 35% for the Base Case. The MEA/MDEA mixture of Concept C requires about 28% less energy per pound of  $CO_2$  captured to regenerate the solvent as compared to the MEA used for Concept A.

Specific investment costs are also high ranging from about 1000 to 2200 k without replacement power, and from about 800 to 1800 k with replacement power. All cases studied indicate significant increases to the COE as a result of CO<sub>2</sub> capture. The incremental COE as compared to the Base case (air firing without CO<sub>2</sub> capture) ranges from 3.4 to 8.4 k wh. Similarly CO<sub>2</sub> mitigation costs range from about 42-98 f of CO<sub>2</sub> avoided for the range of cases studied.

Specific carbon dioxide emissions were reduced from about 2.0 lbm/kWh for the Base Case to 0.13, 0.19, and 0.27 lbm/kWh for study cases A, B, and C, respectively. Recovery of CO<sub>2</sub> ranged from 91 to 96%.

Concept B (oxygen firing with flue gas recycle) appears to clearly be the best alternative of the three concepts studied from both an efficiency and incremental COE viewpoint for systems designed for very high CO<sub>2</sub> capture (i.e. > 90%). If lower CO<sub>2</sub> capture fractions are considered, it appears that Concept A would likely be the best alternative for capture fractions below some as yet undetermined value. Concept C would also improve considerably with lower capture fractions. This study has confirmed two important issues related to firing coal in a CO<sub>2</sub> rich flue gas /O<sub>2</sub> mixture:

- Modifications to the existing steam generator unit pressure parts may not be required, and as such will also allow the unit to continue to operate in the conventional air fired mode. This is an important consideration as it is unlikely that much new coal-fired capacity can be built in the short term.
- CO<sub>2</sub> rich flue gas can be cleaned and compressed with a relatively simple system to provide high purity CO<sub>2</sub> for usage or sequestration.

While overall plant performance penalty and costs are high, the integration of power generation, air separation, and  $CO_2$  separation, compression and liquifaction systems may significantly improve the overall system efficiency and economics. The major cost item in Concept B is in the air separation plant, both from a capital and an operating cost point of view. While in recent years advances have been made in air separation technology which have steadily improved the costs, new membrane based technologies are being researched which promise to provide greatly reduced auxiliary power requirements and investment costs which will significantly improve the overall system efficiency and economics. Previous studies, Liljedahl, et al. (1999), have shown membrane technology to provide specific investment cost (kW) reductions of about 30% and net plant heat rate improvements greater than 20%.

Barring governmental mandates, it is clear that none of these three retrofit concepts will be acceptable to the electric utility industry from the standpoint of cost competitiveness.

Recommendations for Future Work are listed below:

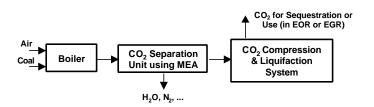

- A sensitivity study, for Concepts A and C, showing the impact of reducing CO<sub>2</sub> capture percentage on plant efficiency, investment cost, emissions, and cost of electricity. The current work utilized 90% CO<sub>2</sub> capture (nominal). The sensitivity study would investigate nominal CO<sub>2</sub> capture percentages of 70% and 50%.
- Detailed analysis of the existing steam turbine for Concept A: In Concept A about 79% of the steam leaving the intermediate-pressure (IP) turbine is extracted from the IP/LP crossover pipe for solvent regeneration. The capability of the existing low-pressure (LP) turbine to operate under these conditions of very low steam flow should be investigated in detail, preferably by the original equipment manufacturer (OEM).
- Optimization of the amine system reboiler steam pressure for Concepts A and C.
- Concept B detailed boiler system analysis: A startup/shutdown procedure and system design, particularly the transition from air to oxygen firing (including transient conditions) should be developed. Detailed metal temperature analysis for all heat exchanger sections, including operation at part loads should be analyzed. This should also include furnace wall metal temperatures and analysis of the circulation system. The existing fans should be checked (preferably by the OEM's) for operation under the new conditions. The feasibility of operating the boiler under a slight positive pressure to eliminate air infiltration should also be investigated.
- Investigation of Improved oxygen production systems for Concept B, in line with the membrane-based air separation work being conducted by various research groups (e.g., Praxair, Air Products, Norsk Hydro). Also optimization of an integrated boiler and oxygen production system.
- Measurement of furnace heat transfer in CO<sub>2</sub>/O<sub>2</sub> environments in a proof of concept boiler simulation facility.

- Improved solvents, which require lower regeneration energy requirements and/or can be regenerated at a lower temperature level, similar to MHI's KS-1 and KS-2 solvents (Iijima, et al., Feb. 1998), but for coal-firing application.
- Hybrid process using oxygen-enriched combustion and amine based CO<sub>2</sub> absorption, to accrue, simultaneously, both CO<sub>2</sub> capture and drastic NOx emissions reduction.
- Investigation of a new novel high risk CO<sub>2</sub> capture process that would reduce efficiency penalty and retrofit investment cost. This would likely not utilize the existing boiler.

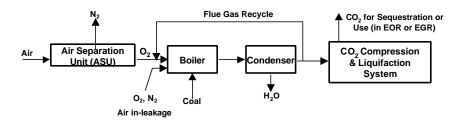

# 1.0 INTRODUCTION

ALSTOM Power Inc. teamed with American Electric Power, ABB Lummus Global Inc., the US DOE NETL, and the Ohio Coal Development Office to conduct a comprehensive study evaluating the technical feasibility and economics of alternate  $CO_2$  capture and sequestration technologies applied to an existing US coal-fired electric generation power plant. The three retrofit technology concepts being evaluated are shown below.

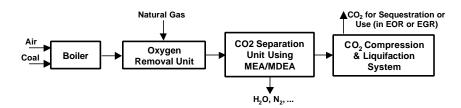

• Concept A: Coal combustion in air, followed by CO<sub>2</sub> separation from flue gas with Kerr-McGee/ABB Lummus Global's commercial MEA-based absorption/stripping process.

• Concept B: Coal combustion with O<sub>2</sub> firing and flue gas recycle.

• Concept C: Coal combustion in air with oxygen removal and CO<sub>2</sub> separation from flue gas by a mixture of primary and tertiary Amines

Each of these technologies was evaluated against a Base Case from the standpoints of performance and impacts on power generating cost. The Base Case represents the "business as usual" operation scenario for the plant without  $CO_2$  capture. A typical existing US domestic pulverized coal-fired power plant is being used in this evaluation. Specifically, American Electric Power's (AEP's) 450 MW Conesville Unit No. 5, located in Conesville, Ohio is the power plant case study. All technical performance and cost results associated with these options are being evaluated in comparative manner.

ALSTOM Power Inc. is managing and performing the subject study from its US Power Plant Laboratories office in Windsor, CT. ABB Lummus Global, from its offices in Houston, Texas, is participating as a sub-contractor. American Electric Power is participating by offering their Conesville Generating Station as the case study and cost sharing consultation, and relevant technical and cost data. AEP is one of the largest US utilities and is the largest consumer of Ohio coal, and as such, is bringing considerable value to the project. Similarly, ALSTOM Power and ABB Lummus Global are well established as global leaders in the design and manufacture of power generation equipment, petrochemical and  $CO_2$  separation technology. ALSTOM Power Performance Projects and Environmental Business Units are world leaders in providing equipment and services for boilers and power plant environmental control, respectively, and are providing their expertise to this project. The US Department of Energy (US DOE) National Energy Technology Laboratory (NETL) and the Ohio Coal Development Office (OCDO) provided consultation and funding. All participants provided cost share to this project.

The motivation for this study was to provide input to potential US electric utility actions to meet Kyoto protocol targets. If the US decides to reduce  $CO_2$  emissions consistent with the Kyoto protocol, action would need to be taken to address existing power plants. Although fuel switching from coal to gas is a likely scenario, it will not be a sufficient measure and some form of  $CO_2$  capture for use or disposal may also be required. The output of this  $CO_2$  capture study will enhance the public's understanding of control options and influence decisions and actions by government, regulators, and power plant owners to reduce their greenhouse gas  $CO_2$  emissions.

The key objectives of the study were to evaluate the impacts on the plant output, efficiency,  $CO_2$  emissions, investment costs, and the cost of generating electricity resulting from the addition of the  $CO_2$  capture systems. All technical performance and cost results associated with these options are being evaluated in comparative manner. Technical and economic issues being evaluated include:

- Boiler performance and plant efficiency
- Purity of O<sub>2</sub> produced and flue gas recycled
- Heat transfer into the radiant and convective sections of the boiler
- NO<sub>X</sub>, SO<sub>2</sub>, CO and unburned carbon emissions
- Heat transfer surface materials
- Steam temperature control
- Boiler and Steam Cycle modifications
- Electrostatic Precipitator system performance
- Flue Gas Desulfurization system performance
- Plant systems integration and control
- Retrofit investment cost and cost of electricity (COE)
- CO<sub>2</sub> Mitigation Costs

Each of the  $CO_2$  capture systems are designed for a minimum of 90%  $CO_2$  capture. Cost estimates were developed for all the systems required to produce, extract, clean, compress and liquefy the  $CO_2$ , to a product quality acceptable for pipeline transport. The Dakota Gasification Company's  $CO_2$  specification (2) for EOR, given in the following table, was used as the basis for the  $CO_2$  capture system design.

Component	Unit	Concentration
CO <sub>2</sub>	Vol.%	96.0
H₂S	Vol.%	0.9
CH4	Vol.%	0.7
C2+HCs	Vol.%	2.3
со	Vol.%	0.1
N <sub>2</sub>	vppm	< 300
H₂O	vppm	< 20
O <sub>2</sub>	vppm	< 50

## Dakota Gasification Project's CO<sub>2</sub> Specification for EOR

The  $CO_2$  product could then be available for usage in enhanced oil or gas recovery or sequestration. Additionally, an economic evaluation, showing the impact of  $CO_2$  capture on the cost of electricity (COE), was developed for each concept. Included in the economic evaluation was a sensitivity study showing the effects of coal cost, natural gas cost, plant capacity factor,  $CO_2$  byproduct sell price, investment cost, and replacement power, on the incremental cost of electricity and on the mitigation cost for the  $CO_2$  (\$/ton of  $CO_2$  avoided).

13

# 2.0 STUDY UNIT SELECTION, DESCRIPTION AND PERFORMANCE

This section includes the criteria used for selection of the study unit, and provides a brief description of the selected unit. Additionally, the Base Case is defined as the unmodified existing unit firing coal at full load, utilizing air as the oxidant, without capture of  $CO_2$  from the flue gas. This represents the "business as usual" operating scenario and is used as the basis of comparison for the three  $CO_2$  removal options investigated in this study. The overall performance of the Base Case is presented in Section 2.3.

### 2.1 Study Unit Selection

A decision was required at the end of Task 2 (Site Selection/Plant Evaluation) regarding the selection of either unit #5 or #6 of AEP's Conesville, Ohio, Power Generating Station, as the study unit for our retrofit evaluations.

To provide the necessary background to facilitate this selection, a trip was made to the Conesville site on April 20, 2000. This visit provided the opportunity to gather operating data for unit #5, overall site information for both units #5 and 6, and additionally, to make arrangements for collecting a raw coal sample for Bench-Scale Testing (Task 4a).

It was learned from the operators and plant maintenance personnel that both twin units #5 and #6 operate nearly identically, and that no renovations had been made to either unit aside from replacement in kind. AEP, OCDO and Alstom personnel conducted a walk down of both units. Site drawings were provided and photographs were taken to document the footprints of both units. This information was used to evaluate space availability for the various new equipment that would be required for the three  $CO_2$  capture systems being evaluated in this study. Figure 2.1.1 shows several potential areas for new equipment placement in the neighborhood of units #5 and #6. A large amount of additional land area (about 10 acres) is available in a location about 1,500 feet northeast of the common stack used for units #5 and #6 (upper right corner of Figure 2.1.1).

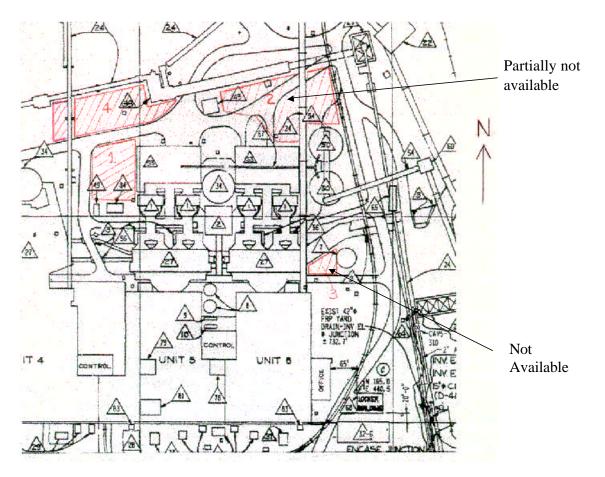

The approximate size of the four areas in the immediate vicinity of units #5 and #6 for locating some of the new equipment on the ground are listed below:

<u>Area #</u>	Approximate Size (square feet)	
1	13,000 (Available)	
2	29,000 (Partially available)	
3	2,600 (Not available)	
4	25,000 (Available)	

Additionally, consideration was given for hanging some of the equipment, where appropriate, in the space between the far end of the ESP and the boiler: fifth floor and up.

The major new equipment envisioned for the three retrofit concepts for this study include:

- An Air Separation Unit of about 9,000 tons of O<sub>2</sub> per day (Concept B),
- An MEA system for removal of about 10,000 tons of CO<sub>2</sub> per day from the flue gas (Concept A),
- An MEA/MDEA system for removal of about than 10,500 tons of CO<sub>2</sub> per day from the flue gas (Concept C),
- A flue gas oxygen removal system upstream of the MEA/MDEA system (Concept C),
- A CO<sub>2</sub> Compression and Liquefaction system (required for all 3 concepts),
- Various other ancillary equipment

### Figure 2.1. 1: Plan View of AEP's Conesville, Ohio, Power Generating Station Site Showing Area Occupied by Units #5 and #6

The four areas identified previously and shown in Figure 2.1.1 indicate the following:

- These areas, even combined, are not large enough to locate all the equipment required for any one of these CO<sub>2</sub> removal concepts. They may however be useful for location of various ancillary equipment.
- Areas 1 and 4, which are in the vicinity of unit #5 total to ~38,000 square feet
- Areas 2 and 3, which are in the vicinity of unit #6, total ~31,000 square feet, of which less than 28,000 square feet are available.
- Furthermore, conveniently we already had performance data from unit #5.
- Although we could have obtained data from unit #6, this step could be eliminated with the selection of unit #5. Hence, it made more sense to use unit #5 in this initial evaluation. If there is in the future a desire to evaluate unit #6, then a further re-examination of areas #2 and #3 would be warranted and performance data from unit #6 could be obtained.

In summary, the preceding information indicated that:

• Unit #5 offers more "on-the-ground" area near the unit for erecting new equipment than does unit #6.

- Both units #5 and #6 are equally accessible for erecting new equipment in the space between the boiler and the far end of the ESP, fifth floor and up.
- Both units #5 and #6 are equally accessible to the large area available about 1,500 feet northeast of the unit #5/#6 stack.
- Both units #5 and #6 perform similarly with respect to power generation.

Considering the totality of the information given above, we concluded that unit #5 offered a relatively more costeffective scenario for our retrofit evaluation. Cognizant personnel of the Conesville Power Generating Station were in complete agreement with these findings and Conesville Unit #5 was selected as the study unit.

### 2.2 Study Unit Description

The steam generator unit analyzed in this study was American Electric Power's Conesville Unit #5. A sectional side elevation drawing of the study unit is shown in Figure 2.2.1. This unit can be described as a nominal 450 MW-gross, tangentially coal fired, subcritical pressure, controlled circulation, radiant reheat wall unit. The furnace is a single cell design utilizing five elevations of tilting tangential coal burners. The unit fires mid-western bituminous coal. The coal is supplied to the five elevations with five RP-903 coal pulverizers. The unit is configured in a "Conventional Arch" type design and is representative in many ways of a large number of coal fired units in use today. The unit is designed to generate about  $3.1 \times 10^6$  lbm/hr of steam at 2400 psi and 1005 F with reheat also to 1005 F. These represent the most common steam cycle operating conditions for existing utility scale power generation systems. Outlet steam temperature control is provided with de-superheating spray and burner tilt.

The furnace is tangentially fired and is of the single cell design. It is about 51.67 ft wide, 44.33 ft deep and 171.67 ft high. The superheater is divided into four major sections. Saturated steam leaving the steam drum first cools the roof and rear pass walls before supplying the low temperature superheater section. The low temperature superheater section is located in the rear pass of the unit and is a horizontal section with the outlet tubes in a vertical orientation adjacent to the finishing superheater section. Steam leaving the low temperature superheater section. The division panels are located in the upper furnace directly above the combustion zone of the lower furnace. Steam leaving the panels flows to the superheater platen section, which is a more closely spaced vertical section located between the panels and the finishing pendant reheater. Steam leaving the platens flows into the finishing superheater section in the rear pass of the unit. Steam leaving the finishing superheater is piped to the high-pressure turbine where it is expanded to reheat pressure and then returned to the reheat de-superheater is piped to the high-pressure turbine where it is expanded to reheat pressure and then returned to the reheat de-superheating spray station.

The reheater is divided into two sections, a low temperature radiant wall section followed by a spaced finishing pendent section. Steam is supplied to the reheater radiant wall from the de-superheating spray station, which is fed from the high-pressure turbine exhaust. The reheater radiant wall section is located in the upper furnace and covers the entire front wall and most of the two sidewalls of the upper furnace. The pendant finishing reheat section is located above the arch between the superheat platen and superheat finishing sections. Steam leaving the finishing reheater is returned to the intermediate pressure turbine where it continues its expansion through the intermediate and low-pressure turbines before being exhausted to the condenser.

The gases leaving the low temperature superheater section are then further cooled in an economizer section. The economizer is comprised of four banks of spiral finned tubes (2 fins/inch) which heats high-pressure boiler feedwater before it is supplied to the steam drum. The feedwater supplying the economizer comes from the final extraction feedwater heater.

Finally, a Lungstrom trisector regenerative air heater is used to heat both the primary and secondary air streams prior to combustion in the lower furnace. Particulate matter is removed from the cooled flue gas leaving the air heater in an electrostatic precipitator and sulfur dioxide is removed in a lime based flue gas de-sulfurization system. The flue gas

is then exhausted to the atmosphere through the stack. The induced draft and forced draft fans are controlled to operate the unit in a balanced draft mode with the furnace maintained at a slightly negative pressure (typically -0.5 inwg).

The high pressure superheated steam leaving the finishing superheater is expanded through the high pressure steam turbine, reheated in the two stage reheater and returned to the intermediate pressure turbine. The steam continues its expansion through the low-pressure turbine sections where it expands to condenser pressure. The generator produces about 463 MW of electric power at Maximum Continuous Rating (MCR). The steam cycle utilizes seven feedwater heaters (three low-pressure heaters, a deaerator, and three high-pressure heaters) where the feedwater is preheated to about 493 F before entering the economizer of the steam generator unit. The boiler feed pump is steam turbine driven with steam provided from the intermediate pressure turbine exhaust and expanded to condenser pressure.

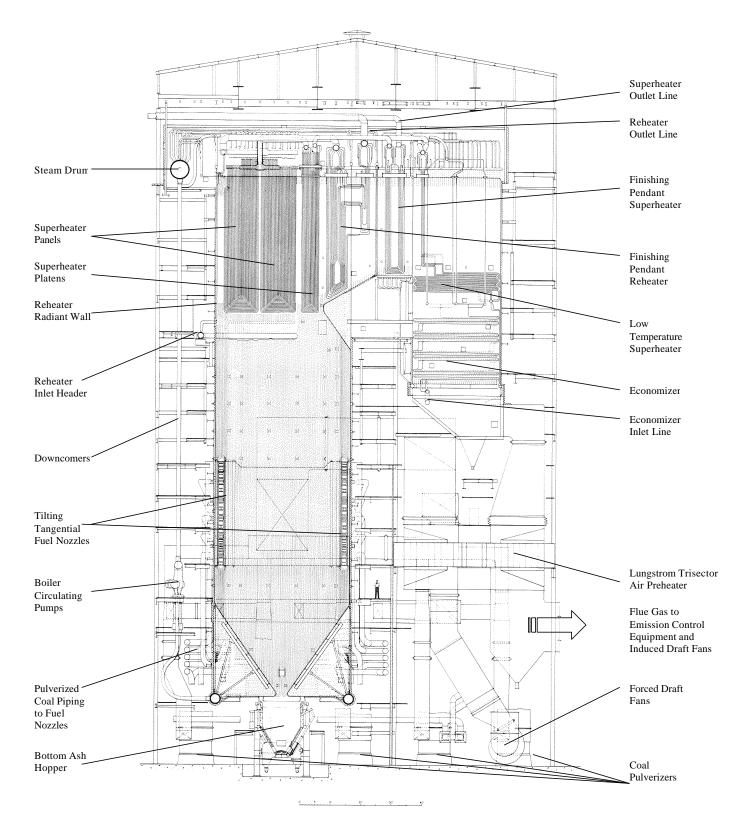

Figure 2.1. 2: Study Unit (Existing Conesville Unit #5 Steam Genertor)

### 2.3 Base Case Performance Analysis

The Base Case can be described as the unmodified existing unit firing coal at full load and utilizing air as the oxidant without capture of  $CO_2$  from the flue gas. This represents the "business as usual" operating scenario and is used as the basis of comparison for the three the  $CO_2$  removal options investigated in this study. The first step in the development of a Base Case was to set up a computer model of the boiler. Using test data from the existing unit, the computer model was then calibrated. The calibrated boiler model was then used for analysis of the Base Case and the three  $CO_2$  removal concepts.

### 2.3.1 Calibration of Boiler Computer Model

The first step in the calculation of a Base Case was to set up a steady state performance computer model of the Conesville #5 steam generator unit. This involves calculating or obtaining all the geometric information for the unit as required by the proprietary Reheat Boiler Program (RHBP). The RHBP provides an integrated, steady state performance model of the Boiler Island including, in addition to the steam generator unit, pulverizers, air heater, and steam temperature control logic. The RHBP is used to size components and/or predict performance of existing components. In this study, since the boiler island component sizes are known, the RHBP was used exclusively for calculating unit performance.

The next step in the heat transfer analysis of the Base Case was to calibrate the RHBP model of the unit. This involves obtaining test data (with air firing) for the existing unit and "adjusting" the performance model to match the test data. The required test data includes steam temperatures entering and leaving each major heat exchanger section in the unit, steam pressures, coal analysis, flue gas oxygen content, etc. The "adjustments or calibration factors" for the model are in the form of "surface effectiveness factors" and "fouling factors" for the various heat exchanger sections throughout the unit. Unfortunately, the test data used for calibration of this model was not totally complete and several assumptions were required in the calibration process. Although all the required data was not available, primarily due to existing instrumentation limitations, a satisfactory calibrated model was obtained.

Using the calibrated boiler model and providing it with new steam side inputs (mass flows, temperatures, and pressures) from the agreed upon MCR steam turbine material and energy balance, the model was run and performance was calculated for the Base Case. The performance for the overall power plant system is described in Section 2.3.2 with the boiler performance shown in Section 2.3.3 and the steam turbine performance in Section 2.3.4.

### 2.3.2 Overall System Description and Material and Energy Balance

The simplified gas side process flow diagram for the Base Case is shown in Figure 2.3.1 and the associated material and energy balance for this case is shown in Table 2.3.1. Overall plant performance is summarized in Table 2.3.2. This system is described previously in Section 2.2. Boiler efficiency is calculated to be 88.13 percent. The net plant heat rate is calculated to be 9,749 Btu/kwhr for this case as shown in Table 2.3.2. Auxiliary power is 29,700 kw and the net plant output is 433,778 kw. Carbon dioxide emissions are 866,156 lbm/hr or about 2.00 lbm/kwhr.

# Table 2.3.2: Overall Plant Performance Summary (Base Case)

#### 2.3.3 Boiler Analysis Results

The main steam flow for this case and all other cases in this study is 3,131,619 lbm/hr. The cold reheat flow leaving the high-pressure turbine for this case and all other cases in this study is 2,766,780 lbm/hr. The hot reheat flow (including de-superheating spray) returning to the intermediate pressure turbine for this case is 2,853,590 lbm/hr. The overall steam conditions produced by the existing Conesville #5 steam generator unit are shown in Table 2.3.3 below. To produce these conditions, the superheat circuit requires about 3.6 percent spray and the reheat circuit requires about 3.1 percent spray to maintain required steam outlet temperatures. The burner tilts are -10 degrees (the minimum value the customer uses). The boiler was fired with 15 percent excess air and the resulting boiler efficiency calculated for this case was 88.13 percent with an air heater exit gas temperature of 311 F.

#### 2.3.4 Steam Cycle Performance

The steam cycle for the Base Case is shown schematically in Figure 2.3.2. Figure 2.3.3 shows the associated Mollier diagram which illustrates the process on enthalpy - entropy coordinates. The high pressure turbine expands about 3.1 x  $10^6$  lbm/hr of steam at 2535 psia and 1005 F. Reheat steam is returned to the intermediate pressure turbine at 591 psia and 1005 F. These conditions (temperatures, pressures) represent the most common steam cycle operating conditions for existing utility scale power generation systems in use today. The condenser pressure used for the Base Case and all other cases in this study was 2.5 in Hga. The steam turbine performance analysis results show the generator produces 463,478 kw output and the steam turbine heat rate is about 7999 Btu/kwhr.

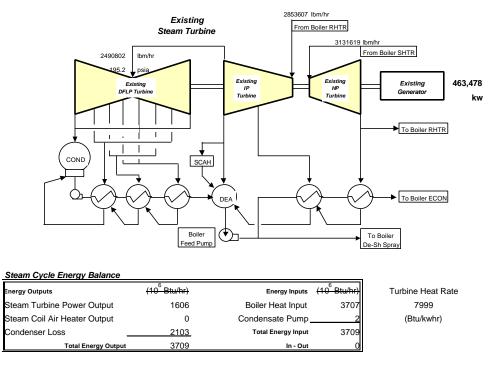

Figure 2.3. 2: Base Case Steam Cycle Diagram and Performance

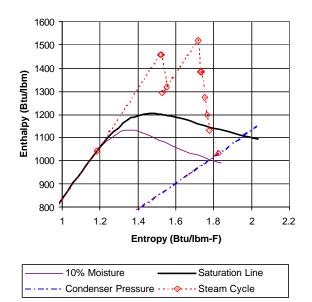

Figure 2.3. 3: Base Case Steam Cycle Mollier Diagram

#### 2.3.5 Flue Gas Desulfurization System Analysis

Figure 2.3.4 shows the process flow diagram for the existing Flue Gas Desulfurization System. The stream numbers in Figure 2.3.4 also correspond to stream numbers shown in Figure 2.3.1 and Table 2.3.1. The flue gas leaving the ID fan (Stream 7) is delivered to the Absorber, which consists of a tray followed by a two-stage spray system. The incoming gas is saturated as it passes through the scrubbing slurry contained on the tray and through the two spray levels. The active component of the scrubbing slurry is calcium oxide (Stream 8a), which reacts with sulfur dioxide to form calcium bisulfite (Stream 9). The scrubbing slurry is circulated from the reagent feed tank that forms the base of the scrubber to the spray levels. The solids loading in the scrubbing slurry controls the blowdown from the reaction tank to byproduct disposal. The flue gas passes through chevron type mist eliminators that remove entrained liquid before exiting the scrubber (Stream 10). The water utilized in spray washing the mist eliminators also serves as make-up (Stream 8b).

Table 2.3.4 identifies the assumptions that were made in predicting the FGD performance. Table 2.3.5 shows the gas constituents at the existing Absorber inlet and outlet locations. Results show a  $CO_2/SO_2$  mole ratio of 63 and an  $SO_2$  removal efficiency of 94.8%, corresponding to a value of 104 vppm at the outlet of the absorber.

# Table 2.3.5:FGD Performance

# 3.0 CO<sub>2</sub> REMOVAL SYSTEMS

The following three basic process options were studied:

- **Concept A**: Coal combustion in air, followed by CO<sub>2</sub> separation with Kerr-McGee/ABB Lummus Global's commercial MEA-based absorption/stripping process
- **Concept B**: Coal combustion with O<sub>2</sub> firing and flue gas recycle (oxy-fuel firing)
- **Concept C**: Coal combustion in air with oxygen removal and CO<sub>2</sub> separation

The Capture of  $CO_2$  from the flue gas for Concept A is accomplished using the Kerr-McGeee / ABB Lummus Global oxygen inhibited MEA technology. Only Kerr-McGee/ ABB Lummus oxygen inhibited amine was studied. It is the most commercially proven process evaluated in this study.

Concept B utilizes oxygen firing with the recycle of flue gas to bring the firing and heat transfer characteristics of the boiler back close to original design. The oxygen firing is used to produce a flue gas stream with high enough  $CO_2$  content such that simple compression, refrigeration, and rectification can produce a suitable  $CO_2$  liquid product. Optimizations in various areas such as oxygen purity, air leakage into the boiler and associated equipment operating below atmospheric pressure, and flue gas recycle ratio have been made. On the liquefaction side, an optimization of the flow scheme to remove the inerts while maintaining  $CO_2$  recovery at the lowest energy consumption was made.

For Concept C,  $CO_2$  recovery from the flue gas is accomplished by using generic amines (i.e. MEA, MDEA). However, if more efficient and cost effective, proprietary amines may be used. The difference between the amines used in this case and in Concept A is that the amines are not oxygen resistant. Hence, the oxygen is converted to  $CO_2$ by combustion with methane over a de-oxy catalyst upstream of the amine contactor.

Although triethanolamine (TEA) was first proposed for use for Concept C, due to its relatively low energy requirement for solvent regeneration, the literature survey conducted earlier in the present study, Bozzuto, et al. (2000), revealed that the TEA had a very low recovery of CO<sub>2</sub> when operating at near atmospheric pressure. Operating at higher pressures to improve recoveries is not economically feasible as the carbon dioxide concentration in the flue gas is less than 13% and compressing the entire flue gas stream to 200 psig would require approximately 250,000 hp. Therefore, only generic amines and proprietary amines that absorb efficiently at atmospheric pressure were evaluated for this case. Specifically, the amines evaluated were monoethanolamine/ methyldiethanolamime (MEA /MDEA) blend, BASF activated MDEA, and Mitsubishi Heavy Industries amines (Iijima, et al., 1998; Iijima, 1998). Since these amines are required to be oxygen resistant, de-oxygenation via catalytic combustion is required upstream of the amine unit. Neither the de-oxy catalyst nor any of these amines have been tested in coal fired power plant flue gas streams.

# 3.1 CO<sub>2</sub> Removal Systems Design Basis

# 3.1.1 Site Data

Listed below is the summary of the bases used for this design:

- Plant is located in Connesville, Ohio, elevation 744 feet.
- Atmospheric pressure is 29.92 inches of Hg.
- Ambient temperature for air cooler design is 80 °F.
- Wet bulb temperature for cooling tower design is 75 °F.
- Electric power may be available from the existing facilities. Auxiliary power, 7-8% of the gross, is provided through auxiliary transformers at 4160-volt bus and is reduced down to 480 volts.

- Flue gas is high in halides (chlorides and fluorides) as well as SO<sub>3</sub> so that stainless steel 316L can be used as the material of construction for the flue gas cooling system.
- Pressure of liquid product CO<sub>2</sub> is 2000 psig.

# 3.1.2 Battery Limit Definition

The  $CO_2$  recovery and liquefaction sections are located approximately 1200 feet north of the Unit #5 stack (Figure 3.1.1). The new cooling tower is at a different location, which is about 1900 feet southwest of the  $CO_2$  recovery and liquefaction equipment. The  $CO_2$  recovery and liquefaction equipment, for Concepts A and C, actually receives cooling water from both the existing plants cooling system and the new cooling tower. This is due to the fact that the existing plant cooling water capacity will be partially available as a result of the amine system reboiler's consumption of steam for solvent regeneration. This steam was previously exhausted from the existing low-pressure turbine and condensed in the existing power plant surface condensers.

The new cooling tower section receives frequent deliveries of sodium hypochlorite. It is also periodically attended by cooling tower chemical service such as Betz or Nalco. They bring with them the required dispersant, pH control, and corrosion inhibitors. However, their visits do not totally relieve the power plant personnel from taking samples themselves at least once per shift. The blowdown from the cooling tower must be treated with sodium bisulfite to dechlorinate it. Sodium bisulfite will be unloaded from drums into the injection package. Concept A, which makes use of an existing cooling water make-up stream must have its blowdown filtered to reduce the suspended solids to within acceptable limits. Backwash from the sand filters will go back to the existing cooling tower blowdown disposal system. Concepts B and C require significant amounts of cooling tower make up water. Thus, river water taken from existing pumps will be sent to a new clarifier. It is expected that this clarifier will eliminate suspended solids to the extent that there will be no need for sand filters on the cooling tower blowdown. Blowdown from the clarifier will be sent to an existing clarifier blow down system.

The new  $CO_2$  recovery and liquefaction section comprises another section of the power plant. It has its own control room and motor control center (MCC). In addition to the flue gas, which serves as the feed to the unit, it must also receive the required utilities and chemicals. Caustic, if available from existing facilities, can be used to maintain levels in this facilities day tanks. Otherwise it can be offloaded from trucks into the day tanks. Diatomaceous earth will be off loaded on skids. The spent diatomaceous earth leaves the plant in drums. Reclaimer effluent will be collected in a tank truck parked at one end of the unit. Potable water for eyewashes and cooling tower make-up water for hose down will be routed along side the feed gas duct and 180 psig steam. Corrosion inhibitor to provide oxygen resistance to the amine in Concept A will be directly from drums into an injection package.

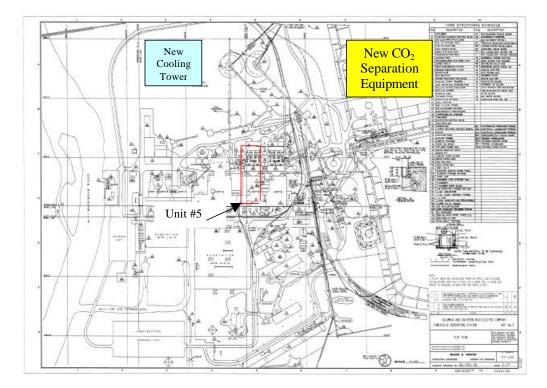

Figure 3.1. 1: AEP Conesville, Ohio, Electric Power Generating Station Site

The design of the  $CO_2$  recovery and liquefaction sections has been based on the flue gas data leaving the Flue Gas Desulfurization System, shown in Table 3.1.1.

Commonant	Concept A	Concept D	Concept C
Component	Concept A	Concept B	Concept C
	Mole %	Mole %	Mole %
O2	2.94	2.91	2.94
N2	68.45	5.03	68.45

$CO_2$	12.83	73.04	12.83
SO2	<10 ppmv	0.01	106 ppmv
MW	28.61	37.92	28.61
T (°F)	136	144	136
P (psig)	1	0	1

# 3.1.3 CO<sub>2</sub> Product Specification

The product specification for sequeststration (Orr, 2001) is shown in Table 3.1.2. This composition is what can be obtained from the liquefaction scheme for Concept B. Its hydrate locus was verified to be sufficiently close to that of pure  $CO_2$  which is the criterion used by one of the world's foremost  $CO_2$  sequestration experts, Lynn Orr of Stanford University.

2015

# Table 3.1.2:Specification for Sequestration

Table 3.1.3 represents the specification required for Enhanced Oil Recovery (EOR). It was compiled by comparing the Dakota Gas specification supplied by AEP and contracts signed through Kinder Morgan  $CO_2$  company and taking the strictest specification of the two.

Table 3.1. 3:	Specification for EOR

Component	Specification
0	10 might and marine of the CO
$O_2$	10 weight ppm maximum of the $CO_2$
$N_2$	300 ppmv maximum
$H_2O$	20 ppmv maximum
$CO_2$	96% minimum
$H_2S$	20 weight ppm of the $CO_2$
CO	0.1% maximum
C <sub>2</sub> + Hydrocarbons	2.3 mole % max
Methane	0.7 % maximum
T (°F)	120 F max

A product pressure of 2000 psig was used in the designs that follow.

# 3.1.4 Chemicals

This section provides data for the chemicals available on site and used by the  $CO_2$  Recovery systems. Conditions for liquid chemicals are specified at grade level.

	Pressure at B.L. psig	Temperature °F
Minimum	• •	
Normal	15	ambient
Maximum		
Mechanical	50	125
Design		

Table 3.1.4:	Caustic (NaOH)
--------------	----------------

- Available for reclaiming MEA (Concept A)
- The import and dilution facilities will be used to keep a day tank in the process area at desirable levels.

# 3.1.5 Utilities

The data below applies to both Concepts A and C except where noted. For cooling water, new utility systems will have to be provided and are included in the cost estimate. For steam, obviously the export of 195 psia steam to an external process represents a change from the current operation. It was decided to use extraction steam from the turbine rather than build additional facilities. The reason for this decision comes from plant efficiency, investment cost, and plot considerations. Conditions for all liquid utilities are given at grade level.

#### Steam:

#### Low Pressure Steam (LP) (Concepts A and C) Used mainly for process heating

	Pressure at B.L.	Temperature
	psig	°F
Minimum (for process design)		700
Normal	180	716
Maximum	200	
Mechanical Design	250 /FV	775

#### Water:

#### Cooling Water (Concepts A, B, and C) Source: New Cooling Tower

Source. New Cooling	TOWEI	
CW Supply:	Pressure at B.L.	Temperature
	psig	°F
Minimum

Maximum		
Mechanical Design	100	175

# Surface Condensate (Concept C process cooling, Concept A and C amine make-up)

	Pressure at B.L. psig	Temperature °F
Minimum		
Normal	300	109
Maximum		
Mechanical Design	350	200

#### Raw Water (Fresh Water)

Distributed for general use at hose stations (Concepts A and C). The source of this is a clarifier for cooling tower make-up. The capacity of this clarifier is sufficient for make up for Concept A, but not B or C. Its quality is as follows:

Components	Unit	Specifications
Si	ppm.	22
Iron (as Fe)	ppm.	0.18
Copper (as Cu)	ppm	0.05

Suspended Solids	ppm	15
Chlorine	11	100-180
	ppm	
Alkalinity	ppm	100
Na	ppm	100

For Concepts B and C water from the Muskingum River must be sent to a new clarifier. The specifications for this water are as follows:

	Unit	Specification
Suspended Solids	ppm	10 to many hundreds
Turbidity	ppm	5 to 300

# Potable Water (Concepts A and C)

	Pressure at B.L.	Temperature
	Psig	°F

	Pressure at OSBL psig	Temperature °F
Minimum	1 0	
Normal	50	Ambient
Maximum		
Mechanical Design	100	150

# **Power Supply:**

All of the required power (100%) for the  $CO_2$  Recovery Unit will be provided by AEP either from the local supply or from the Ohio Grid.

(Concepts A, B, C)

Service	Voltage	Phase
Auxiliary plant power system	4160	3-phase
Large Motors	4160	3-phase
Small Motors	480	3-phase
Instruments, Lighting etc	480 / 230	3/1-phase

# 3.1.6 Equipment Design

**Equipment Numbering:** 

Equipment numbering will be based on Lummus standards.

Sparing Philosophy:

A sparing philosophy was employed to reduce investment. Therefore, spares were spread out upon multiple trains or provide 50% or 33% sized spares when possible. Small pumps (e.g. metering pumps) and equipment related to protection of major equipment (e.g. lube oil pumps) may be spared.

Mechanical Design Conditions:

ABBLGI practices will be followed (page 24, T3.1.TP07.402 in "Relief and Flare Systems" manual).

# **3.2** Concept A: CO<sub>2</sub> Separation with Monoethanolamine Absorption

Concept A is defined as a system designed for the removal and recovery of  $CO_2$  from the boiler flue gas using an amine scrubbing system. The amine system selected was the Kerr-McGeee / ABB Lummus Global oxygen inhibited MEA technology.

# 3.2.1 Overall System Description and Material and Energy Balance

A simplified process flow diagram for the modified unit is shown in Figure 3.2.1. The operation and performance of the existing Boiler and ESP systems are identical to the Base Case and are not affected by the addition of the MEA based  $CO_2$  removal system. The FGD system is modified with the addition of a secondary absorber to reduce the  $SO_2$  content to about 10 ppmv (See Section 3.2.4). The overall material and energy balance for the system shown in Figure 3.2.1 is shown in Table 3.2.1. The flue gases leaving the modified FGD system are ducted to the new MEA system where ~94 percent of the  $CO_2$  is removed, compressed, and liquefied for usage or sequestration. The remaining flue gases leaving the new MEA system, consisting of primarily oxygen, nitrogen, water vapor and a relatively small amount of sulfur dioxide and carbon dioxide, is discharged to the atmosphere.

Boiler efficiency is calculated to be 88.13 percent (HHV Basis), the same as for the Base Case. The net plant heat rate is increased significantly to 16,626 Btu/kwhr (HHV Basis) for this option as shown in Table 3.2.2 which also includes the Base Case for comparison. The plant thermal efficiency for Concept A (20.53%, HHV basis) is about 59 percent of the Base Case value (35.01%), indicating an energy penalty of ~41%. Auxiliary power is increased to 76,007 kw and the net plant output is reduced to 254,414 kw. Carbon dioxide emissions are 33,084 lbm/hr or about 0.13 lbm/kwhr.

# 3.2.2 Boiler Analysis

The boiler performance in Concept A is identical to that of the Base Case described previously in Section 2.3 and will not be repeated here.

# 3.2.3 Steam Cycle Modifications and Performance

The steam cycle system for Concept A is modified as shown in Figure 3.2.2 while Figure 3.2.3 shows the associated Mollier diagram. About 79 percent of the IP turbine exhaust is extracted from the IP/LP crossover pipe. This steam is expanded to about 65 psia through a new steam turbine generating 62,081 kw. The exhaust from the new turbine, at about 478 F, is de-superheated and then provides the energy requirement for the solvent regeneration done in the reboiler's of the MEA  $CO_2$  removal system. The condensate from the reboiler's is pumped to the Deaerator. The modified existing steam cycle system produces 269,341 kw. The total output from both generators is 331,422 kw. This represents a gross output reduction of 132,056 kw (about 28.5%) as compared to the Base Case. A yet unsolved uncertainty is whether the existing low-pressure turbine can be operated over the required load range with the such a small fraction of the original design steam mass flow rate. The answer to this question was beyond the scope of the current project.

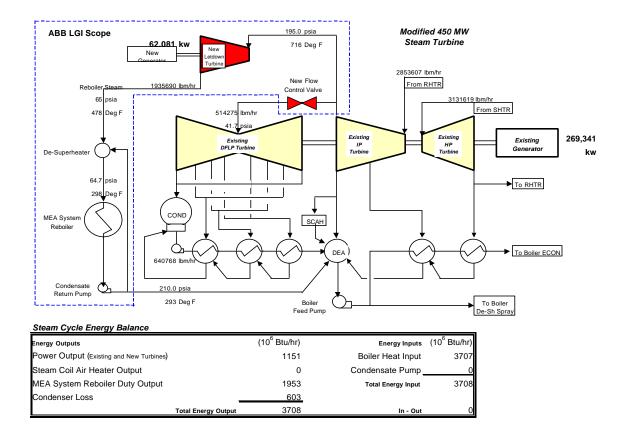

Figure 3.2. 2: Modified Steam Cycle Diagram and Performance (Concept A)

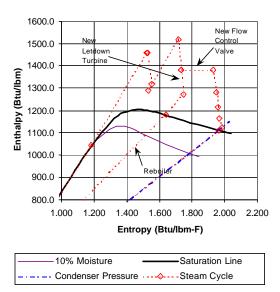

Figure 3.2. 3: Modified Steam Cycle Mollier Diagram (Concept A)

# 3.2.4 Flue Gas Desulfurization System Analysis

The FGD system for Concept A is modified with the addition of a secondary absorber to reduce the  $SO_2$  content to 10 vppm or less as required by the amine system downstream. The principle of operation is as briefly described previously in Section 2.3.5. In this case, however, the flue gas leaving the existing FGD system's absorber is supplied to the new secondary absorber and the flue gas leaving the secondary absorber provides the feed stream for the amine  $CO_2$  absorption system, as discussed later in Section 3.2.5. Additional piping and ductwork is required as is shown in Figure 3.2.4 process flow diagram.

Table 3.2.3 identifies the assumptions that were made in predicting the FGD performance.

Table 3.2.4 shows the gas constituents at the existing Absorber inlet and secondary Absorber outlet. Results show a  $CO_2/SO_2$  mole ratio of 63 and an  $SO_2$  removal efficiency of 99.7%, corresponding to a value of 6.5 vppm at the outlet of the secondary absorber.

# 3.2.5 Carbon Dioxide Separation and Compression System

The Kerr-McGee/ABB Lummus amine technology is used for the Concept A  $CO_2$  removal system. This system is the most proven of the three processes analyzed in this study. An important feature of this  $CO_2$  recovery technology is its flexibility to operate with boilers or co-generation systems that fire fuels ranging from natural gas to high-sulfur coal and coke. The process tolerates oxygen in the flue gas as well as limited amount of sulfur dioxide. Low corrosion rates and minimal loss of the circulating solvent used to absorb  $CO_2$  ensure economical and reliable operation.

Kerr-McGee started up their 800 TPD  $CO_2$  recovery unit in 1978. The Trona unit has been fed flue gases from boilers fired with natural gas, coal and coke. During its first several years of operation, the installation was improved in terms of reliability and cost effectiveness. As of January 1992, three units have been licensed using this technology. They are:

1.) Applied Energy Systems, Poteau, Oklahoma. This 300 MW coal-fired co-generation plant incorporates a 200 TPD food-grade liquid  $CO_2$  unit as the steam host. Startup was completed in January 1991. Lummus Crest was responsible for engineering, procurement, and construction of the entire facility, including the power plant. Lummus Crest made several design improvements to the AES facility.

2.) Soda Ash Botswana, Pty. Ltd., Sue Pan, Botswana. This soda ash facility, incorporating a 300 TPD  $CO_2$  unit, started up in March 1991.

3.) AES Corporation is building a second food grade  $CO_2$  plant in Warrior run, Pennsylvania using the Kerr-McGee / Lummus technology. This is a 150 short tons/day liquid  $CO_2$  plant, using flue gas from coal fired circulating fluidized bed (CFB) boilers, was commissioned in 1999.

In late 1990, Kerr-McGee and Lummus Global concluded a joint licensing agreement whereby Lummus gained worldwide exclusive marketing rights to Kerr-McGee's  $CO_2$  recovery technology and became responsible for marketing and basic engineering. Kerr-McGee maintains a continuing role in technology transfer, process improvement, quality control of new designs, operator training, and licensing. In addition to providing an experience list for the amine part of the process, these plants also contain  $CO_2$  compression and liquefaction facilities. These plants compress the  $CO_2$  to a slightly higher pressure and utilize ammonia refrigeration. Many of these plants make food grade  $CO_2$ .

# 3.2.5.1 Introduction

The CO<sub>2</sub> Recovery Unit for Concept A is comprised of the following sections:

- Flue Gas Pretreatment
- Absorption
- Stripping
- CO<sub>2</sub> Compression and Liquefaction
- Drying

The flue gas pretreatment section cools and conditions the flue gas, which is then fed to the  $CO_2$  Absorber (or  $CO_2$  contactor as it is often called). In the Absorber,  $CO_2$  is removed from the gas by contacting it, in countercurrent fashion, with monoethanolamine (MEA). The recovered  $CO_2$  is then stripped off in the Stripper (or Regenerator) from where the lean solvent is recycled back to the Absorber. Solvent regeneration for Concept A requires about  $4.7 \times 10^6$  Btu/Ton  $CO_2$ . The overhead vapor from the Stripper is cooled to condense most of the water vapor. The condensate is used as reflux in the Stripper and the wet  $CO_2$  stream is fed forward to the  $CO_2$  Compression and Liquefaction System. Here the  $CO_2$  product is compressed and dried so it can be pumped to its final destination. No specific destination has been chosen for the product pipeline. It has been assumed to end at the battery limit for costing purposes.

A brief description of the processing scheme for Concept A is given in the following paragraphs. Description of the package units is indicative only and may vary for the chosen supplier of the package unit

# 3.2.5.2 Process Description

This section refers to the following process flow diagrams, which are shown in Section 3.2.5.3:

# PROCESS FLOW DIAGRAMS - CONCEPT A:

- Figure 3.2.5:Drawing D 09484-01001R-0: Flue Gas Cooling and CO<sub>2</sub> Absorption
- Figure 3.2.6:Drawing D 09484-01002R-0: Solvent Stripping
- Figure 3.2.7:Drawing D 09484-01003R-0: CO<sub>2</sub> Compression and Liquefaction

The designs include several process trains. Only one train is shown. The note section of the PFD tells how many trains are included in the complete system. To avoid confusion, suffixes have been used to indicate parallel equipment. These are mainly for spared pumps and drier vessels in parallel. Even if there are several trains, only one drawing (typical) has been prepared to represent all of the trains. On these drawings, flow splits to the other parallel trains have been shown. Similarly, flows coming from other parallel trains and converging to a single common stream have also been shown.

A note about stream numbering convention is also necessary. The stream numbers have not been tagged with "A", "B", etc. to indicate which train they belong to. Instead, the flow rate given in the material balance for each stream is the actual flow rate for the stream within the train. The combined flow from all of the trains leaving a process step shows the total flow going to the next process step. As an example, stream 8 (Drawing D 09484-01001R-0) is the Rich Amine stream leaving one train of the absorber process step, and comprises 1/5 of the total rich amine. Stream 9A is the total rich amine going to the Solvent Stripping process step. Stream 9A appears on both the absorber and solvent stripper PFD's. After the rich amine flow sheet continuation block, the stream splits 9 ways for the 9 stripping trains. Then stream 9 continues for processing on the solvent stripper PFD (Drawing D 09484-01002R-0), with 1/9 of the flow entering the rich-lean solvent exchanger (EA-2205). The numbering practice for Concept C is the same as for Concept A.

# Flue Gas Pretreatment:

The pressure profile of the  $CO_2$  capture equipment is contained in the material balance. Since the flue gas pretreatment equipment flow scheme includes a blower, the pressure profile of the existing power generation equipment does not change from today's operation. To force the flue gas from the secondary FGD through the  $CO_2$ 

39

Absorber, the pressure of the flue gas after sulfur removal is boosted to 1.5 psig by a motor driven fan. As the power consumption of the fan is considerable, the duct size must be chosen not to add excessive pressure drop for the 1200 feet it takes to get to the absorbers. The blower will run at constant speed. Each blower, provided as part of the boiler flue gas conditioning equipment, is equipped with its own suction and a discharge damper operated pneumatically. The suction damper controls the suction pressure to adjust for the flow variation resulting from the power plant performance. The suction pressure control will avoid any surges to blower. The discharge damper is an isolation damper.

# Direct Contact Cooling (Refer to Drawing No. D 09484-01001R-0):

The Direct Contact flue gas Cooler (DCC) is a packed column where the hot flue gas flowing up is brought into an intimate contact with cold water which is fed to the top of the bed and flows down the tower. Physically, DA-2101 and DA-2102 have been combined into a single, albeit compartmentalized tower. DA-2101 is the lower one and is designed to support DA-2102 so that the top head of DA-2101 is the bottom head of DA-102. Effectively, this dividing head acts as a chimney tray with a number of upward extending chimneys which provide passages for the flue gas to flow directly from the DCC into the Absorber.

Theoretically, a direct contact cooler is capable of cooling the gas to a very close approach in a short bed. When the hot gas enters the DCC, the gas contains water but is highly superheated. At the bottom end of the bed, the gas is quickly cooled to a temperature known as the "Adiabatic Saturation Temperature" (AST). This is the temperature the gas reaches when some of its own heat content has been used to vaporize just the exact amount of water to saturate the gas.

Up to the point when the AST is reached, the mass flow of the gas stream increases due to evaporation of water. At the AST, water vapor contained in the gas begins to condense. And, as the gas travels up the column and cools further, more and more water is condensed. This internal refluxing increases the V/L traffic at the bottom end of the bed significantly beyond the external flows and must be considered in the hydraulic design.

The water stream that leaves the bottom of the DCC contains the water fed to the top as well as any water that has condensed out of the flue gas. The condensed water may be somewhat corrosive due to sulfur and nitrogen oxides that may be present in the flue gas. Therefore, instead of using the condensate in the process, it will be blown down from the system. For the DCC to be effective, the temperature of the leaving water must always be lower than the AST.

Most of the water leaving the bottom of the DCC is circulated back to the top of the direct contact cooler by DCC Water Pump GA-2102 A/B. However, before sending it back to the column the water stream is first filtered in DCC Water Filter FD-2101 and then cooled in DCC Water Cooler EA-2101 against the water from the new cooling tower. Temperature of the cooled water is controlled by a cascade loop which maintains a constant flue gas exit temperature (Absorber feed temperature). Because of the relatively low cooling water temperature at the plant, the circulating water is cooled down to 95 °F which, in turn, easily cools the gas down to 115 °F.

Filtration is necessary to remove any particulate matter that may enter the DCC in the flue gas. The blowdown is taken out after the filter but before the cooler and mixed into the return water of cooler EA-2101. This way the cooler does not have to handle the extra duty that would otherwise be imposed by the blowdown stream.

# Absorption:

# CO<sub>2</sub> Absorber DA-2102 (Refer to Drawing No. D 09484-01001R-0):

From the DCC the cooled flue gas enters the bottom of the  $CO_2$  Absorber and flows up the tower countercurrent to a stream of 20-wt.% monoethanolamine (MEA) solution. The lean MEA solution (LAM) enters the top of the column and heats up gradually as more and more  $CO_2$  is absorbed. By the time the stream leaves the bottom of the tower it has gained approximately 28 °F. The tower has been designed to remove 94% of the  $CO_2$  in the incoming gas. The  $CO_2$  loading in LAM is 0.215 mol  $CO_2$  / mol MEA while the loading of the rich amine leaving the bottom is 0.44 mol  $CO_2$  / mol MEA. These values are consistent with the values reported by Rochelle (2000).

To maintain water balance in the process, it is imperative that the temperature of the LAM feed be very close to that of the feed gas stream. Thus, with feed gas temperature fixed at 115 °F, the temperature of the LAM stream must also be

close to 115 °F, preferably within 10 °F. If the feed gas comes in at a higher temperature than the LAM, it brings in excess moisture, which condenses in the Absorber and becomes excess water. Unless this water is purged from the system, the concentration of MEA will decrease and the performance of the system will suffer. If, on the other hand, the gas feed is colder than the LAM, it heats up in the tower and picks up extra moisture that is then carried out of the system by the vent gas. The result is a water deficiency situation because more water is removed than what comes into the system.

For the reasons explained above, it is essential that both the temperature of the flue gas and that of the LAM be accurately controlled. In fact, it is best to control one temperature and adjust the temperature of the other to maintain a fixed temperature difference. The design difference is approximately 10 °F. The LAM temperature was chosen to be the "master" and the gas temperature to be the "slave".

The rich MEA solvent solution from the bottom of the absorber at 133 °F is heated to 204 °F by heat exchange with lean MEA solvent solution returning from the stripping column. The rich MEA solvent is then fed to the top of the stripping column. The lean MEA solvent solution thus partially cooled to 143 °F is further cooled to 105 °F by exchange with cooling water and fed back to the absorber to complete the circuit.

 $CO_2$  Absorber DA-2102 is a packed tower which contains two beds of structured packing and a third bed, the so called "Wash Zone", at the very top of the column. There is also a liquid distributor at the top of each of bed. The distributors for the main beds are of high-quality design. There are several reasons for selecting structured packing for this service:

- Very low pressure drop which minimizes fan horsepower
- High contact efficiency / low packing height
- Good tolerance for maldistribution in a large tower
- Smallest possible tower diameter
- Light weight

At the bottom of the tower, there is the equivalent of a chimney tray, which serves as the bottom sump for the Absorber. Instead of being flat like a typical chimney tray, it is a standard dished head with chimneys. The hold-up volume of the bottom sump is sufficient to accept all the liquid held up in the packing both in the  $CO_2$  Absorber and in the Wash Zone. Rich Solvent Pump GA-2103 A/D takes suction from the chimney tray.

# Absorber Wash Zone (Refer to Drawing. No. D 09484-01001R-0):

The purpose of the Wash Zone at the top of the tower is to minimize MEA losses both due to mechanical entrainment and also due to evaporation. This is achieved by circulating wash water in this section to scrub most of the MEA from the lean gas exiting the Absorber. The key to minimizing MEA carryover is a mist separator pad between the wash section and the Absorber. But, the demister can not stop losses of gaseous MEA carried in the flue gas. This is accomplished by scrubbing the gas with countercurrent flow of water. Wash Water Pump GA-2101 takes water from the bottom of the wash zone and circulates it back to the top of the bed. Circulation rate has been chosen to irrigate the packing sufficiently for efficient operation.

The key to successful scrubbing is to maintain a low concentration of MEA in the circulating water. The higher the concentration, the higher the vapor pressure of MEA and, consequently, the higher the MEA losses. Therefore, relatively clean water must be fed to the wash zone as make-up while an equal amount of MEA laden water is drawn out. A simple gooseneck seal accomplishes this and maintains a level on the chimney tray at the bottom of the wash section. Overflow goes to the main absorber. Make-up water comes from the overhead system of the Solvent Stripper.

The lean flue gas leaving the wash zone is released to atmosphere. The top of the tower has been designed as stack which is made high enough to ensure proper dispersion of the exiting gas.

# Rich/Lean Solvent Exchanger EA-2205 (Refer to Drawing No. D 09484-01002R-0):

The Rich/Lean Solvent Exchanger is a plate type exchanger with rich solution on one side and lean solution on the other. The purpose of the exchanger is to recover as much heat as possible from the hot lean solvent from the bottom

of the Solvent Stripper by heating the rich solvent feeding the Solvent Stripper. This reduces the duty of the Solvent Stripper Reboiler. This exchanger is the single most important item in the energy economy of the entire  $CO_2$  Recovery Unit. For this study, 10°F approach was chosen to maximize the heat recovery. An air cooler (EC-2201) was added on the lean amine stream leaving the Solvent Stripper. This was to reduce the plot space requirement (compared to placing the air cooler downstream of the rich/ lean exchanger) and overall cost of the project. A study was performed to determine that heat transfer via the plate frame type lean/ rich exchanger is relatively cheap which justifies tight temperature approaches with this type of exchanger.

# Stripping:

Solvent Stripper DA-2201 (Refer to Drawing No. D 09484-01002R-0):

The solvent Stripper is a packed tower which contains two beds of structured packing and a third bed, so called the "wash zone" at the very top of the column. The purpose of the Solvent Stripper is to separate the  $CO_2$  (contained in the rich solvent) from the bottom stream of the  $CO_2$  Absorber that is feeding the stripper. As the solvent flows down, the bottom hot vapor from the reboiler continues to strip the  $CO_2$  from the solution. The final stripping action occurs in the reboiler. The hot wet vapors from the top of the stripper contain the  $CO_2$ , along with water vapor, and solvent vapor. The overhead vapors are cooled by Solvent Stripper CW Condenser (EA-2206) where most of the water and solvent vapors condense. The  $CO_2$  does not condense. The condensed overhead liquid and gaseous  $CO_2$  are separated in a reflux drum (FA-2201).  $CO_2$  flows to the  $CO_2$  purification section on pressure control and the liquid (called reflux) is returned via Solvent Stripper Reflux Pump (GA-2202A/B) to the top bed in the stripper. The top bed of the stripper is a water wash zone designed to limit the amount of solvent (MEA) vapors entering the stripper overhead system.

# Solvent Stripper Reboiler EA-2201 (Refer to Drawing No. D 09484-01002R-0):

The steam-heated reboiler is a vertical shell and tube thermosyphon type exchanger using inside coated high flux tubing proprietary of UOP. Circulation of the solvent solution through the reboiler is natural and is driven by gravity and density differences. The reboiler tube side handles the solvent solution and the shell side handles the steam. The energy requirement for the removal of  $CO_2$  is about 2.6 tons of steam per ton of  $CO_2$  for Concept A.

# Solvent Reclaimer EA-2203 (Refer to Drawing No. D 09484-01002R-0):

The Solvent Stripper Reclaimer is a horizontal heat exchanger. Certain acidic gases, present in the flue gas feeding the  $CO_2$  absorber, form compounds with the MEA in the solvent solution that cannot be regenerated by application of heat in the solvent stripper reboiler. These materials are referred to as "Heat Stable Salts" (HSS). A small slipstream of the lean solvent from the discharge of the Solvent Stripper Bottoms Pump (GA-2201A/B/C) is fed to the Solvent Reclaimer. The reclaimer restores the MEA usefulness by removing the high boiling and nonvolatile impurities, such as HSS, suspended solids, acids and iron products from the circulating solvent solution. Caustic is added into the reclaimer to free MEA up from its bond with sulfur oxides by its stronger basic attribute. This allows the MEA to be vaporized back into the circulating mixture, minimizing MEA loss. This process is important in reducing corrosion, and fouling in the solvent system. The reclaimer bottoms are cooled (EA-2204) and are supplied to a tank truck without any interim storage.

# Solvent Stripper Condenser EA-2206 (Refer to Drawing No. D 09484-01002R-0):

EA-2206 is a water-cooled shell and tube exchanger. The purpose of the condenser is to completely condense all components contained in the overhead vapor stream that can condense under the operating conditions, with the use of cooling water as the condensing medium. Components that do not condense include nitrogen, carbon dioxide, oxygen, nitrogen oxides and carbon monoxide. The water vapor and MEA solvent vapor will condense and the condensed water will dissolve some carbon dioxide. This exchanger uses cooling water capacity freed up due to the reduced load on the existing surface condensers of the power plant. The same is true for the lean solvent cooler (EA-2202).

# Solvent Stripper Reflux Drum, FA-2201 (Refer to Drawing No. D 09484-01002R-0):

The purpose of the reflux drum is to provide space and time for the separation of liquid and gases and also provide liquid hold-up volume for suction to the reflux pumps and also provides surge for pre-coat filter. The separation is not perfect, as a small amount of carbon dioxide is left in the liquid being returned to the stripper and the  $CO_2$ , saturated with water, is routed to the  $CO_2$  compression and liquefaction system.

Solvent Stripper Reflux Pump, GA-2202 (Refer to Drawing No. D 09484-01002R-0): This pump takes suction from the reflux drum and discharges on flow control to the stripper top tray as reflux.

Solvent Filtration Package, PA-2251 (Refer to Drawing No. D 09484-01002R-0):

Precoat Filter PA-2251 is no ordinary filter; it is a small system. The main component is a pressure vessel that has a number of so called "leaves" through which MEA flows. The leaves have a thin (1/8 inch) coating of silica powder which acts to filter off any solids. For the purposes of such application the powder is called "filter aid".

To cover the leaves with the filter aid, the filter must be "precoated" before putting it into service. This is accomplished by mixing filter aid in water in a predetermined ratio (typically 10-wt %) to prepare a slurry. This takes place in an agitated tank. A pump, which takes its suction from this tank, is then operated to pump the slurry into the filter. Provided the flow rate is high enough, the filter aid is deposited on the leaves while water passes through and can be recycled back to the tank. This is continued until the water in the tank becomes clear indicating that all the filter aid has been transferred.

The volume of a single batch in the tank is typically 125% of the filter volume because there must be enough to fill the vessel and have some excess left over so level in the tank is maintained and circulation can continue. In this design, water from the Stripper overhead will be used as make-up water to fill the tank. This way the water balance of the plant is not affected.

During normal operation, it is often beneficial to add so-called "body" which is the same material as the precoat but may be of different particle size. The body is also slurried in water but is continually added to the filter during operation. This keeps the filter coating porous and prevents rapid plugging and loss of capacity. As the description suggests, an agitated tank is needed to prepare the batch. A metering pump is then used to add the body at preset rate to the filter.

When the filter is exhausted (as indicated by pressure drop), it is taken off line so the dirty filter aid can be removed and replaced with fresh material. To accomplish this, the filter must be drained. This is accomplished by pressurizing the filter vessel with nitrogen and pushing the MEA solution out of the filter. After this step, the filter is depressurized. Then, a motor is started to rotate the leaves so a set of scrapers will wipe the filter cake off the leaves. The loosened cake then falls off into a conveyor trough in the bottom of the vessel. This motor operated conveyor then pushes the used cake out of the vessel and into a disposal container (oil drum or similar). The rejected cake has the consistency of toothpaste. This design is called "dry cake" filter and minimizes the amount of waste produced.

For this application, some 2% of the circulating MEA will be forced to flow through the filter. In fact, Filter Circulating Pump GA-2203 draws the liquid through the filter as it has been installed downstream of the filter. The advantage of placing the pump on the outlet side of the filter is reduced design pressure of the filter vessel and associated piping. In spite of the restriction on its suction side, ample NPSH is still available for the pump. Flow is controlled on the downstream side of the pump.

# Corrosion Inhibitor (Refer to Drawing No. D 09484-01002R-0):

Corrosion inhibitor chemical is injected into the process constantly to help control the rate of corrosion throughout the  $CO_2$  recovery plant system. Since rates of corrosion increase with high MEA concentrations and elevated temperatures, the inhibitor is injected at appropriate points to minimize the corrosion potential. The inhibitor is stored in a tank (Part of the Package, not shown) and is injected into the system via injection pump (Part of the Package, not shown). The pump is a diaphragm-metering pump.

The selection of metallurgy in different parts of the plant is based on the performance feedback obtained from our similar commercial units in operation over a long period of time.

# CO<sub>2</sub> Compression and Liquefaction:

# (Refer to Drawing. No. D 09484-01003R-0):

 $CO_2$  from the solvent stripper reflux drum, GA-2201, saturated with water, is compressed in a three stage centrifugal compressor using the air and cooling water from the new cooling tower for interstage and after compression cooling.

The interstage coolers for first and second stage are designed to supply 95 °F  $CO_2$  to the compressor to minimize the compression power requirements.

Most of the water in the wet  $CO_2$  stream is knocked out during compression and is removed from intermediate suction drums. A  $CO_2$  drier is located after the third stage to meet the water specifications for the  $CO_2$  product. The water-free  $CO_2$  is liquefied after the third stage of compression at about 194 psig pressure and is further pumped with a  $CO_2$  pump (GA-2301) to the required battery limit pressure of 2000 psig.

# Drying:

CO<sub>2</sub> DRIER, FF-2351 (Refer to Drawing No. D 09484-01003R-0):

The purpose of the  $CO_2$  drier is to reduce the moisture content of the  $CO_2$  product to less than 20 vppm to meet pipeline transport specifications. The drier package, FF-2351, includes four drier vessels, three of which are in service while one is being regenerated or is on standby. The package also includes a natural gas fired regeneration heater and a cooled regeneration cooler. The exchanger will have a knock out cooler downstream for separating the condensed water. The drier size used as a basis for cost estimate is good for 10 hour run length based on 3A molecular sieve.

The drier is located on the discharge side of the 3rd Stage of the  $CO_2$  Compressor. Considering the cost of the vessel and the performance of the desiccant, this is the location favored by vendors. The temperature of the  $CO_2$  stream entering the drier is 90 °F.

Once a bed is exhausted, it is taken off line and a slipstream of effluent from the on line beds is directed into this drier after being boosted in pressure by a compressor. Before the slipstream enters the bed that is to be regenerated, it is heated to a high temperature. Under this high temperature, moisture is released from the bed and carried away in the  $CO_2$  stream. The regeneration gas is then cooled to the feed gas temperature to condense any excess moisture. After this, the regeneration gas stream is mixed with the feed gas upstream of the third stage knockout drum.

All the regeneration operations are controlled by a PLC that switches the position of several valves to direct the flow to the proper drier. It also controls the regeneration compressor, heater, and cooler. Because the regeneration gas has the same composition as the feed gas, it also contains some moisture. Thus, it is primarily the heat ("temperature swing") that regenerates the bed.

# 3.2.5.3 Process Flow Diagrams

The processes described above are illustrated in the following process flow diagrams:

- Figure 3.2.5: Drawing D 09484-01001R-0: Flue Gas Cooling and CO<sub>2</sub> Absorption
- Figure 3.2.6: Drawing D 09484-01002R-0: Solvent Stripping
- Figure 3.2.7: Drawing D 09484-01003R-0: CO<sub>2</sub> Compression and Liquefaction

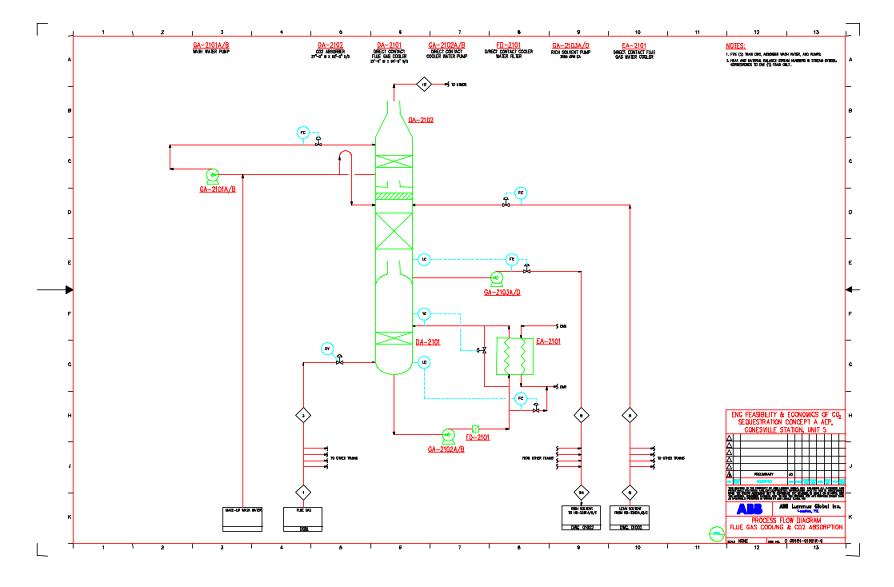

Figure 3.2. 5: Process Flow Diagram for Concept A: Flue Gas Cooling and CO<sub>2</sub> Absorption

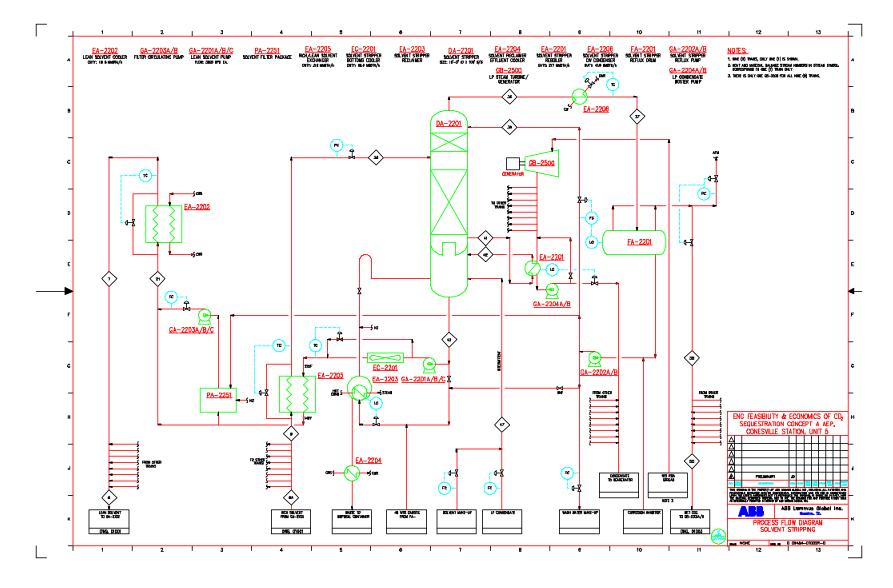

Figure 3.2. 6: Process Flow Diagram for Concept A: Solvent Stripping

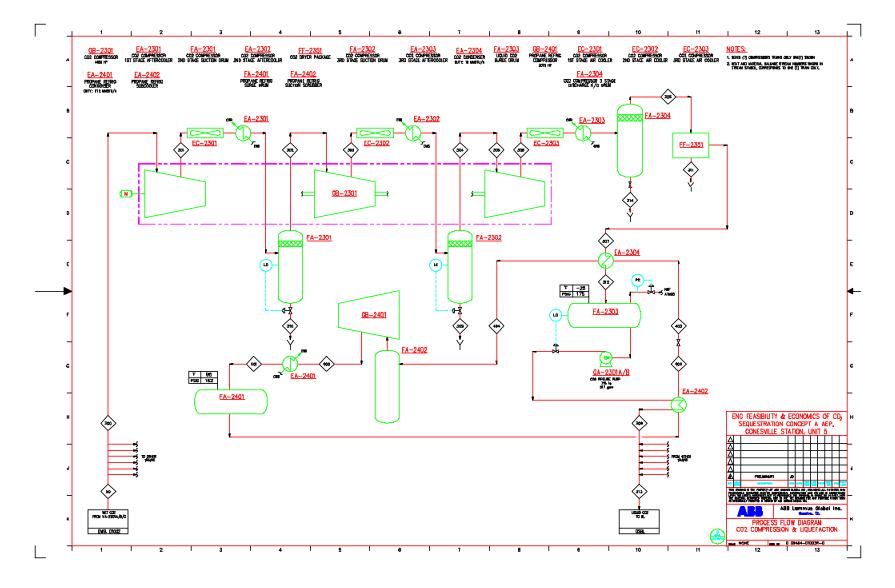

Figure 3.2. 7: Process Flow Diagram for Concept A: CO<sub>2</sub> Compression and Liquefaction

# 3.2.5.4 Overall Material and Energy Balance

The material balances (Tables 3.2.5 and 3.2.6) were run on two process simulators: Hysim and Amsim. Amsim was used for the Absorption/Stripping systems while Hysim was used for the conventional systems as follows:

•	Flue Gas feed	Hysim
-		11,01111

- SO<sub>2</sub> scrubber ALSTOM Power Program
- Absorber and Stripper Amsim
- Compression Hysim
- Heat Pumps Hysim

The two simulators use a different reference enthalpy. They also use slightly different calculation methods for determining water saturation quantities. There is no simple way to normalize the enthalpies to the same reference. Thus, the enthalpies given in the balance are the values copied directly from the simulation. This creates a discontinuity at the interface between Hysim and Amsim simulations. Take for example the wet  $CO_2$  flow to the  $CO_2$  compressor. The stream comes from the Stripper overhead system, which was simulated with Amsim and enters the  $CO_2$  compressor, which was simulated using Hysim. For this particular stream, the enthalpy value given in the balance comes from Hysim. Lastly, convergence algorithms allow the programs to slightly alter input streams. Thus some leniency and care should be exercised when using such interface streams for heat balance checks.

This section contains heat and material balances for Concept A. See the comments under "Process Flow Diagrams" (Section 3.2.5.3) for comments about stream numbering philosophies.

# 3.2.5.5 Equipment List with Data

Equipment data for Concept A, provided in Appendix II, has been presented in the so-called "short spec" format which provides adequate data for a factored cost estimate.

3.2.5.6 Consumption of Utilities

The following utilities from outside boundary limits (OSBL) are required in the CO<sub>2</sub> Recovery Unit.

- Steam
- High Pressure (HP) Steam
- Low Pressure (LP) Steam
- Water
- Demineralized Water
- Raw Water (Fresh Water) (Cooling tower make-up)
- Potable Water (hoses, etc.)
- Air
- Plant Air (maintenance, etc.)
- Instrument Air
- Electric Power
- Natural Gas

Note: The CO<sub>2</sub> Recovery Plant includes cooling water pumps that supply all the cooling water required by this unit.

Concept A utility consumption is presented in Table 3.2.7.

		Utility	Amount Consumed	Units	_	
	N	latural Gas	.42	MMSCFD

#### 3.2.5.7 Consumption of Chemicals and Desiccants

The consumption of chemicals and desiccants for Concept A are identified in Table 3.2.8 shown below.

Chemical	Consumption per day (lbs.)
Caustic (100%)	3600
MEA	14000
Corrosion inhibitor	1140
Diatomaceous earth	916
Molecular sieve	257
Sodium hypochlorite	3590
Sodium bisulfite	13.8

 Table 3.2.8:
 Concept A Chemical s and Desiccants Consumption

This total does not include chemicals provided by the cooling tower service people nor disposal of waste. These are handled as a component of operating costs referred to as contracted services and waste handling, respectively.

# 3.2.5.8 Design Considerations

The following parameters were optimized for Concept A with the objective of reducing the overall unit cost and energy requirements.

- Solvent Concentration
- Lean Amine Loading
- Rich Amine Loading
- Absorber Temperature
- Rich /Lean Exchanger approach
- CO<sub>2</sub> Compressor inter-stage temperatures
- CO<sub>2</sub> Refrigeration Pressure and Temperature

A minimum of 90%  $CO_2$  recovery was targeted. The above parameters were adjusted to increase the recovery until a significant increase in equipment size and/ or energy consumption was observed. AES Corporation owns and operates a 200 STPD food grade  $CO_2$  production plant in Oklahoma. This plant was designed and built by ABB Lummus

Global as a part of the larger power station complex using coal fired boilers. This plant was started up in 1990 and has been operating satisfactorily with lower than designed MEA losses. The key process parameters from the present design for Concept A are compared with those from the AES plant (Barchas and Davis, 1992) in Table 3.2.9.

PROCESS PARAMETER	AEP DESIGN (Concept A)	AES DESIGN
	0000	200
PLANT CAPACITY TPD	9888	200
$CO_2$ in Feed, % mol	13.9	14.7
$O_2$ in Feed, % mol	3.2	3.4
$SO_2$ in Feed, % mol	100 ppm	10 PPMV (Max)
SOLVENT	MEA	MEA
SOLVENT CONC. %WT	20	15 (Actual 17-18%Wt)
LEAN LOADING	0.21	0.10
RICH LOADING	0.44	0.41
STRIPPER FEED TEMP , F	210	194
STRIPPER BOTTOM TEMP F	250	245
FEED TEMP TO ABSORBER, F	105	108
CO <sub>2</sub> RECOVERY %	95	90 (ACTUAL 96-97%)
ABSORBER PRESSURE DROP psi	1	1.4
STRIPPER PRESSURE DROP psi	0.6	4.35
R/L EXCHANGER APPROACH,F	10	50
CO <sub>2</sub> COMPRESSOR I/STG TEMP F	105	115
LIQUID CO <sub>2</sub> TEMP F	82	-13
STEM CONSUMPTION (T steam/ T CO2)	2.6	3.45
LIQUID CO <sub>2</sub> PRESSURE psi (A)	2015	247

# Table 3.2.9: Concept A Key Process Parameters Comparison

#### 3.2.5.9 OSBL Systems

# Reclaimer Bottoms (Concept A):

The reclaimer bottoms are generated during the process of recovering MEA from heat stable salts (HSS), which are produced from the reaction of MEA with  $SO_2$  and  $NO_2$ . The HSS accumulate in the reclaimer during the lean amine feed portion of the reclaiming cycle. The volume of reclaimer bottoms generated will depend on the quantity of  $SO_2$  and  $NO_2$  that is not removed in the Flue Gas Scrubber. A typical composition of the waste is presented in Table 3.2.10.

MEA	9.5 wt.%
NH <sub>3</sub>	0.02 wt.%
NaCl	0.6 wt.%
$Na_2SO_4$	6.6 wt.%
Na <sub>2</sub> CO <sub>3</sub>	1.7 wt.%
Insolubles	1.3 wt.%
Total Nitrogen	5.6 wt.%
Total Organic Carbon	15.6 wt.%
РН	10.7
Specific Gravity	1.14

53

Table 3.2. 10:	<b>Reclaimer Bottoms</b>	Composition

June 30, 2001

#### Filter Residues:

A pressure leaf filter filters a slipstream of lean amine. Diatomaceous earth is used as a filter-aid for pre-coating the leaves and as a body feed. Filter cycles depend on the rate of flow through the filter, the amount of filter aid applied, and the quantity of contaminants in the solvent. A typical composition of the filter residue is provided in Table 3.2.11 below. These will be disposed of by a contracted service hauling away the drums of spent cake.

MEA	2.6 wt.%
Total Organic Carbon	1.5 wt.%
SiO <sub>2</sub>	0.03 wt.%
Insolubles	0.03 wt.%
РН	10.0
Specific Gravity	1.0

# Table 3.2.11: Filter Residue Composition

# Excess Solvent Stripper Reflux Water:

The  $CO_2$  Recovery Facility has been designed to operate in a manner to avoid accumulation of water in the Absorber / Stripper system. Conversely, no continuous make-up stream of water is required, either. By controlling the temperature of the scrubbed flue gas to the absorber, water balance of the MEA system can be kept in check. Excess water can accumulate in the Stripper Reflux Drum and can be reused once the system is corrected to operate in a balanced manner. Should water need to be discarded, contaminants will include  $CO_2$  and MEA.

#### Secondary FGD Absorber Effluent:

The existing plant uses lime in its flue gas desulfurizer. In the cost estimate of this plant, it has been assumed that the existing plant disposal facilities can include the relatively small additional load of the secondary regenerator.

# Cooling Tower Blowdown:

The composition limits on cooling tower blowdown are shown in Table 3.2.12.

Component	Specification
Suspended Solids	30 ppm monthly, 100 ppm daily
PH	6.5 to 9
Oil and Grease	15 ppm maximum monthly, 20 ppm maximum daily
Free Chlorine	0.035 ppm

# Table 3.2. 12: Cooling Tower Blowdown Composition Limitations

There is a thermal limit specification for the entire river. However, the blowdown volume is too small to affect it significantly.

# Relief Requirements:

The relief valve discharges from the  $CO_2$  Recovery Unit are discharged to atmosphere. No tie-ins to any flare header are necessary.

# 3.2.5.10 Plant Layout

The new equipment required for Concept A covers about 7 acres of plot area. Plant layout drawings prepared for the Concept A  $CO_2$  Recovery System are as follows:

These drawings are shown in Appendix I.

Plot Plan – Overall Site before CO<sub>2</sub> Unit Addition

U01-D-0208 Plot Plan – Concept A: Flue Gas Cooling & CO<sub>2</sub> Absorption U01-D-0214 Plot Plan – Concept A: Solvent Stripping U01-D-0204 Plot Plan – Concept A: CO<sub>2</sub> Compression & Liquefaction U01-D-0211 Plot Plan – Concept A: Overall Layout Conceptual Plan U01-D-0200R Plot Plan – Concept A: Modified Overall Site Plan

Plant layout has been designed in accordance with a spacing chart called "Oil and Chemical Plant Layout and Spacing" Section IM.2.5.2 issued by Industrial Risk Insurers (IRI).

When reviewing the layout, the first thing to observe is that no highly flammable materials are handled within the  $CO_2$ Recovery Unit. The open cup flash point of MEA is 200 °F and, therefore, will not easily ignite. In addition to MEA, the corrosion inhibitor is the only other hydrocarbon liquid within the battery limits. The flash point of this material is higher than that of MEA and is handled in small quantities.

As the chemicals used in the process present no fire hazard, there is an opportunity to reduce the minimum spacing between equipment from that normally considered acceptable in hydrocarbon handling plants. Regardless, for the drawings that follow, standard spacing requirements, as imposed by IRI have been followed.

The plot area available for the installation of the desired equipment is small. Some equipment items are placed on structures to allow other pieces of equipment to be placed underneath them. This way pumps and other equipment associated with the Absorber can be located under the structure. Locating the pumps under the structure has been considered acceptable because the fluids being pumped are not flammable.

Noise is an issue with the flue gas fan as much as it is with compressors. Discussions with vendors suggest that it will be possible to provide insulation on the fan casing to limit noise to acceptable levels. Therefore, it has been assumed that no building needs to be provided for noise reasons.

Having economized on the required plot space as noted above, it was judged not to be practical to divide up the absorbers and strippers that are required into the relatively small plot areas initially offered for this purpose (refer to Section 2.1 and Figure 2.1.1). Eventually it was agreed that the units would be placed in an area about 1200 feet north of the Unit #5 stack (refer to Figure 3.1.1). By locating the units on a single site, the flue gas duct length and MEA piping between the absorber and stripper could be minimized, although the latter impact is not nearly as important as the flue gas routing.

The corrosion inhibitor must be protected against freezing during winter. The caustic solution will not freeze but will become very viscous when it gets cold. Therefore, a heated shed has been provided for housing the Corrosion Inhibitor and the Caustic injection packages.

The plot plan shows a substation in the Stripper area but none for the Absorber area. The assumption is that because the electrical consumption of the Absorber equipment is small (0.23 MW) compared to the Stripper equipment, the equipment can be run directly from the auxiliary power 480 volt power system.

55

For the Rich/Lean Solvent Exchanger which is a plate and frame type exchanger, area estimates received from vendors based on similar conditions suggest that five units/ train would be sufficient for the specified service.

# 3.3 Concept B: CO<sub>2</sub> Separation with Oxygen Firing and Flue Gas Recirculation

The basic idea of the overall system for Concept B is to replace air with oxygen for combustion in the furnace in order to produces a high carbon dioxide content flue gas stream leaving the boiler island. A stream of re-circulated flue gas to the furnace is required to maintain thermal balance in the existing boiler between the lower furnace region where evaporation takes place and the convective heat transfer surfaces where steam is superheated and reheated to the required temperature level. This arrangement produces a high carbon dioxide content flue gas that after leaving the boiler system, is processed to provide high-pressure carbon dioxide liquid product for sequestration, enhanced oil recovery (EOR) or other uses.

#### 3.3.1 Overall System Description and Material and Energy Balance

A simplified system diagram for the modified unit is shown in Figure 3.3.1. The system was designed to provide maximum flexibility of operation and to facilitate combustion of coal in either air or oxygen and recirculated flue gas mixture environment.

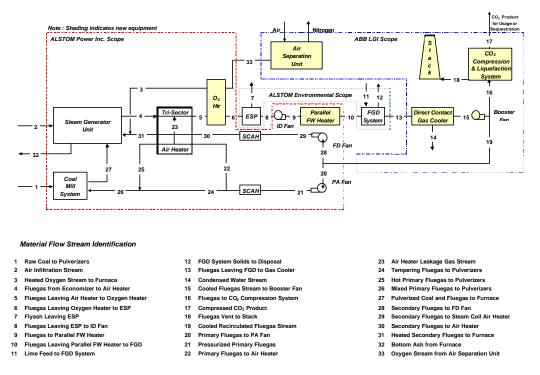

Figure 3.3. 1: Simplified Gas Side Process Flow Diagram for CO<sub>2</sub> Separation with Oxygen Firing

Raw coal (Stream 1) from the coal bunkers is supplied to the existing coal mills where it is pulverized and transported with recycled flue gas (Stream 27) to the furnace. The air separation unit (ASU) supplies the oxidant for the existing boiler. There is no air supply to the boiler except for air infiltration (Stream 2). The oxygen produced, about 8,924 tons per day, (Stream 33) flows through a heat exchanger where it is preheated by cooling the flue gas leaving the existing air heater (Stream 5). The pulverized coal is combusted in the furnace with a mixture of preheated oxygen (Stream 3) and preheated recycled flue gas (Stream 31).

The products of combustion leave the furnace and are cooled in a series of heat exchangers. The gas leaving the furnace first enters the existing convection pass of the unit where steam generated in the existing furnace walls is superheated and reheated in the existing convection pass heat exchangers. The flue gas leaves the convection pass (Stream 4) and is further cooled in the existing air heater of the unit. The air heater, however, is now used to heat recycled flue gas since air is no longer supplied to the unit in this mode of operation. The flue gas stream leaving the air heater (Stream 5) flows through the oxygen heater, electrostatic precipitator, induced draft fan, parallel feedwater

heater, flue gas de-sulfurization unit, gas cooler and booster fan, in series, before it is split into two streams. One stream (Stream 16) represents the exhaust gas stream leaving the boiler island. This stream provides the feed stream for the Carbon Dioxide Separation and Compression System (described in detail in Section 3.3.7). The remaining flue gas (Stream 19), which is roughly twice as large as Stream 16, is recycled back to the unit with the forced draft and primary air fans. Figure 3.3.2 shows the cooling curve for the flue gas leaving the existing boiler.

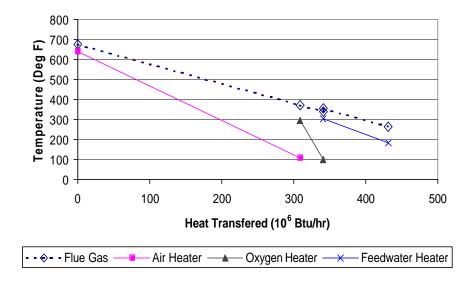

Figure 3.3. 2: Boiler Flue Gas Cooling Curve

The primary reason for the large recycle stream is to maintain the thermal balance between heat transferred in the radiant furnace and the convective heat transfer surfaces, and to generate required boiler performance. In addition, gas temperatures throughout the unit must be low enough to assure the ash, which is contained within the fuel, is maintained in a state where cleanability of the unit is not compromised. Additionally, the integrity of the existing metallurgy in the furnace walls and convective pass heat exchangers must be ensured. The recycled flue gas is supplied to the unit through a combination of new ducts and the existing air ducts. These recycle streams (Streams 29, 30, 31, 21, 22, 24, 25, and 26) provide the primary and secondary "air" streams for the air heater as well as the tempering "air" stream for outlet temperature control of the pulverizers. The modified system was designed to generate approximately  $3.1 \times 10^6$  lbm/hr of steam, which represents the Maximum Continuous Rating (MCR) for the unit.

Table 3.3.1, below, shows constituent mass flows, temperatures, pressures, enthalpies, and energy values (chemical, sensible, latent, and total) for all the points shown in the system diagram of Figure 3.3.1 This table therefore provides the gas side energy and material balance for the system. Two of the key assumptions used in the development of this material and energy balance were an oxygen stream purity of 99 percent by weight, and an air infiltration rate equivalent to one percent of the total oxygen required for the process. For the definition of state points 17 and 18, (not defined in Table 3.3.1) refer to Section 3.3.7.4, which provides the complete material and energy balance for the  $CO_2$  Compression and Liquifaction System.

Boiler efficiency for the modified system is calculated to be 90.47 percent (HHV basis). This is increased significantly as compared to the Base Case (88.13 percent) due to Oxygen firing and the addition of the Oxygen Heater and Parallel Feedwater Heaters. The net plant heat rate (HHV basis) is increased significantly to 15,188 Btu/kwhr for this option as shown in Table 3.3.2, which also includes the Base Case for comparison. The plant thermal efficiency (HHV basis) for Concept B (22.47%) is about 64 percent of the Base Case value of 35.01%. This case represents the highest efficiency of the three CO<sub>2</sub> removal cases studied in this project. Auxiliary power is increased to 189,709 kW as a result of the added Air Separation Unit and the CO<sub>2</sub> Compression and Liquefaction System. Net plant output is reduced to 273,347 kW. Carbon dioxide emissions are 53,016 lbm/hr or about 0.194 lbm/kWh which is about 9.7% of the Base Case value of 1.997 lbm/kWh.

#### 3.3.2 Air Separation Unit

Concept B uses nearly pure oxygen instead of air for combustion of coal and therefore requires an Air Separation Unit (ASU) to provide the supply of oxygen to the furnace. The ASU selected is a cryogenic type design because of the large capacity required.

#### 3.3.2.1 Background

As stated above in Section 3.3.1, AEP's Conesville Unit #5 requires 8,924 standard tons of 99% purity  $O_2$  per day (T/D) when fired at 100% of the maximum continuous rating (MCR). Hence it was necessary to design an Air Separation Unit (ASU) that would be capable of producing at least this amount of oxygen. Initial discussions between ABB and air separation plant vendors were about using two 3685 T/D of oxygen trains and one 1600 T/D train for a total of 8950 T/D. This is due to the fact that a 3685 T/D is the largest plant, which could be comfortably offered at this time. After factoring in capital cost considerations, it was decided to design an overall plant comprised of two-3930 T/D trains and two-550 T/D trains, for a total capacity of 8,960 T/D. A variety of practical and technical issues are discussed below. A process flow diagram of a typical cryogenic air separation unit (BOC Webpage) showing all its major components is shown in Figure 3.3.3.

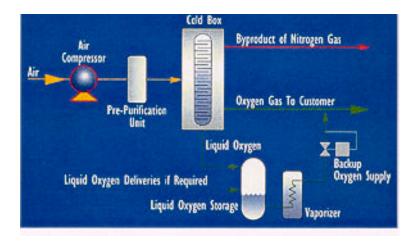

Figure 3.3. 3: Process Flow Diagram of a BOC Improved Air Separation Unit

## 3.3.2.2 Oxygen Purity Considerations

Oxygen purities above 98% have significant impacts on the cryogenic portion of the process.  $O_2$  purities below 95% do not benefit in a cost reduction due to reduction in main air compressor discharge pressure requirements. The purities below 95% often require a frame size increase due to higher inlet volumetric flow rates. It also increases the size of the air adsorber system. The reduced discharge pressure requirements do save on energy of the main air compressor, but other process duties increase due to the higher flow rate of oxygen product. The overall energy consumption could increase if the product is gaseous oxygen with a significant battery limit pressure requirement.

#### 3.3.2.3 Bottlenecks for building plants larger than 3685 ST/D

The current largest single ASU in operation is 3500 ST/D at Rozenburg, The Netherlands. However, sizes up to 4950 ST/D have been designed on paper. Usually, larger size plants are cheaper than smaller plants due to economy of scale. However, it is believed that a break point somewhere near 3685 T/D is where increased plant size will actually cost more for the following reasons:

- The compressor size, driver size, motor sizes, and line voltage drop at start-up are potential hurdles. The largest compressor sizes that ASU manufacturers have experience with are in the 40000-hp range. There may not be any significant aspects of the larger compressors that would create problems over the voltage drop to the compressor if it is motor driven, however, there is no actual experience among the major manufacturers with compressors and drivers exceeding this size.
- Columns larger than 20 feet in diameter create transportation problems for the part of the trip, which is over land. Plants located adjacent to navigable bodies of water would not have any limitation like this. The impact could translate to the need to field fabricate the column.
- Large size pipe and valves become more job specific which create the loss of pricing economies of scale which can be attained when pipe and valve sizes fit many units being built at the same time.

#### 3.3.2.4 Major Vendors Experience

A plant size of 3685 ST/D  $O_2$  production is larger than any vendor had operating as of May 2000. The following list represents the largest operating plant size that the three vendors had running at that time:

Vendor	Largest size operating plant
	(ST/D O <sub>2</sub> )
Air Liquide	3190
Air Products	3500
BOC	2640

## 3.3.2.5 Power Consumption

The Air Separation unit (ASU) includes a cryogenic plant for air separation. Economic considerations for this application favored the selection of oxygen stream purity of 99 percent by weight. As stated above, four trains were required to produce the required oxygen mass flow rate of about 8924 tons per day. This system consumes 95,822 kW of electric power or about 21 percent of the generator output. This energy consumption is equivalent to about 260 kWh/ton of  $O_2$  produced. By contrast, Kobayashi and Prasad (Kobayashi and Prasad, 1999) state that the thermodynamic minimum energy requirement is about 40 kWh/ton of  $O_2$  produced. If this limit could be approached, it would represent a breakthrough technology that would enable Concept B to become nearly cost competitive with "business as usual" (coal-fired in air without  $CO_2$  capture) electricity generation.

## 3.3.2.6 Plot Plan Requirements

The required plot plan areas, supplied by Air Products, are 185 feet by 250 feet and 125 feet by 150 feet for the 3930 T/D and 550 T/D plants, respectively. When the areas for storage and oxygen compressions are included, the required total plot plan amounts to 555 feet by 620 feet. Refer to Appendix I for the plant layout drawings for Concept B.

## 3.3.2.7 Investment and Operation and Maintenance Costs

The investment, and operation and maintenance costs of the Air Separation Unit are presented in Section 5.3.2.

## 3.3.3 Boiler Heat Transfer Analysis

The primary objective of the systems analysis task for Concept B was to develop a system, which would produce high carbon dioxide content flue gas from an existing coal, fired boiler without requiring major pressure part modifications to the boiler. In order to access whether pressure part modifications would be necessary an accurate heat transfer analysis of the existing boiler was required.

The first step was to set up a steady state performance model of the Conesville #5 steam generator unit. This involved calculating or obtaining all the geometric information for the unit as required by the proprietary Reheat Boiler Program (RHBP). The RHBP provides an integrated performance model of the boiler island including, in addition to the steam generator unit, pulverizers, air heater, and steam temperature control logic. The RHBP is used to size components and/or predict performance of existing components. In this study, since the boiler island component sizes are known, the RHBP was used exclusively for calculating unit performance.

The next step in the heat transfer analysis of the system was to calibrate the RHBP model of the unit. This involved obtaining a set of test data (with air firing) for the existing unit and adjusting the performance model to match the test data. The required test data includes steam temperatures entering and leaving each major heat exchanger section in the unit, steam pressures, coal analysis, flue gas oxygen content, etc. The adjustments to the model are in the form of "surface effectiveness factors" and "fouling factors".

After the model was calibrated, additional adjustments were required in order to obtain an accurate heat transfer analysis with the high carbon dioxide content flue gas of the Concept B system. The combustion process occurs in a non-conventional environment, which produces gases of different physical and thermal properties. These gas property differences cause significant differences in the heat transfer processes, which occur within the steam generator unit. Analyses were made to determine the impact of the heat transfer differences on boiler behavior.

The RHBP accounts for three modes of heat transfer in the upper furnace and convective pass of the unit (direct radiation, non-luminous radiation and convection). The direct radiation is emitted from the furnace "fire-ball" and is absorbed in various areas of the unit depending on the geometry of the tube banks and the proximity to the "fire-ball". Since the distribution of direct radiation is only a function of geometry, no formulation modifications were necessary for this component of the heat transfer analysis. Investigation of the non-luminous radiation formulations within the RHBP indicated that current equations (based on the Hottel curves, 1957) would be accurate and formulation modifications would not be required. The convection formulations, however, were not set up with the capability of

accurately analyzing convective heat transfer for flue gases which were this much different than the typical range of boiler flue gases. The appropriate corrections were made to properly model the convection process in the RHBP with oxygen firing.

#### 3.3.3.1 Furnace Analysis

Initially, it was expected that heat fluxes to the furnace walls might be increased or decreased somewhat for Concept B (oxygen firing) due to the higher  $CO_2$  and  $H_2O$  content of the flue gas relative to the air fired Base Case for the following reasons:

- Higher gas emissivity and absorptivity of  $CO_2$  and  $H_2O$  relative to  $N_2$ . For an equivalent local gas temperature, the higher emissivity of  $CO_2$  and  $H_2O$ , relative to the optically transparent  $N_2$ , should serve to increase the absorption coefficient and hence, the radiation to the walls in the recycled flue gas case (Concept-B) relative to the Base Case.
- Higher specific heat of CO<sub>2</sub> and H<sub>2</sub>O relative to N<sub>2</sub>. For an equivalent local heat release and heat transfer, the higher specific heat of carbon dioxide will serve to decrease the overall flame temperatures of the recycled flue gas mixture in the Concept-B case, relative to the baseline case. This would tend to compensate for the higher gas emissivity.

In preparation for the Concept B furnace performance analysis, a review of pertinent literature and CFD furnace analysis results developed for this project (Bozzuto, et al., 2000) were completed. Explanations for the observed trends must rely on physical property differences between nitrogen, which dominates in the Base Case, and carbon dioxide, which largely supplants nitrogen in Concept-B.

## Literature review:

The first step in the furnace analysis was to review applicable results obtained from the literature regarding combustion of coal in an environment where  $CO_2$  displaces the  $N_2$  in the combustion air. Several investigators (Thambimuthu, 1998; Kiga, et al., 1997; and Weller, at al., 1985) have found from pilot-scale testing that when coal is burned in  $O_2/CO_2$  environment whereby  $CO_2$  displaces the  $N_2$  in the combustion air (i.e., in ~30%  $O_2/70\%$   $CO_2$  mixture, by volume), the heat absorption in the lower furnace is not significantly impacted.

To illustrate this point, the results of re-analyses of Thambimuthu's (Thambimuthu, 1998) data concerning the combustion of a subbituminous coal sample from Western Canada are presented in Figure 3.3.4. As can be seen in this figure, the radiative heat fluxes into the lower furnace were, for the three cases studied (air, 28%  $O_2/72\%$   $CO_2$ , and 35%  $O_2/65\%$   $CO_2$ ), roughly similar at gas temperatures greater than 1275 °C.

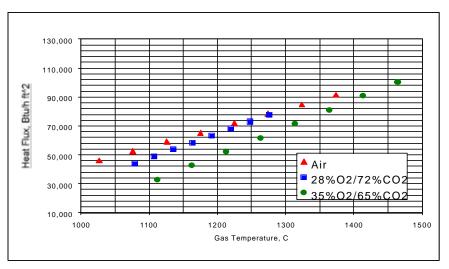

Figure 3.3. 4: Variation of Radiative Heat Flux with Gas Temperature During Combustion in Air and O<sub>2</sub>/CO<sub>2</sub> Mixtures (from Thambimuthu, 1998)

Results from a similar experiment, Chui, et al., (2001), were also investigated, in somewhat more detail, in order to assess the apparent overall change in gas emissive power that would occur in a furnace when switching from air-firing to a high  $CO_2$ - $O_2$  environment. The test facility, the same one used previously by Thambimuthu et.al.(1998), is a pilot-scale, 0.3 MW facility and consists of a cylindrical, down-fired vertical combustor (0.61 m I.D. and 6.7 m in length). The most relevant tests from the literature source are designated as Case-1 (baseline condition with air firing and a burner swirl setting of 11) and Case-2 (dry recycle with burner swirl setting of 10). The dry recycle case is representative of an oxygen fired case similar to Concept B with 28%  $O_2 / 72\%$  CO<sub>2</sub> by volume. The principal conclusion of the work by Chui, et al., based on both experimental and simulated results, was that the dry recycle case demonstrated a distinct decrease in the incident radiant heat flux to the wall (by about 18%) relative to the baseline case (Case-1).

The intent of the present re-analysis of this data was to utilize the incident heat flux measurements and measured centerline gas temperatures for the cases reported by Chui, et al., and then back-calculate the apparent gas emissivity for the furnace as a function of the longitudinal position. The desire was to verify whether the apparent emissivity differences between the baseline and dry recycle cases mirrored the known physical differences in radiative absorption properties between N<sub>2</sub> and CO<sub>2</sub> (corresponding to the baseline and dry recycle cases, respectively). The comparison of Case-1 and Case-2, which have similar swirl settings (and thus similar flow patterns), should isolate the effects of gas emissive properties without introducing the strong effects of flow pattern changes as observed by Chui and reconfirmed by our analysis. Based on the incident heat flux measurements and the measured centerline gas temperatures, apparent gas emissivities for the furnace were calculated. These values are tabulated in Table 3.3.3 and plotted in Figure 3.3.5.

Axial Distance (m)	Case-1 (Air Firing) Gas Emissivity	Case-2 (Oxy-Firing) Gas Emissivity
0.95	0.685	0.782
1.55	0.657	0.737
2.15	0.611	0.796
2.77	0.562	0.829
3.40	0.532	0.766

 Table 3.3.3:
 Apparent Combustor Gas Emissivities

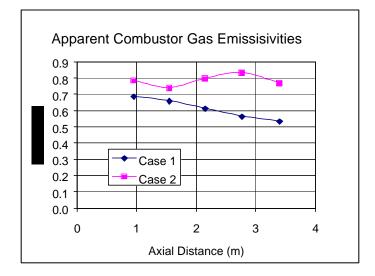

Figure 3.3. 5: Apparent Combustor Gas Emissivities as a Function of Axial Distance

As shown in Figure 3.3.5, the apparent emissivity of the dry recycle case (Case-2) is higher than that of the baseline case (Case-1). Based on the substitution of the radiating gas  $CO_2$  for non-radiating nitrogen in the dry recycle case, the observed shift is what would be expected. It should be understood, however, that these results are only to be expected for cases with identical or similar flow patterns. The other test cases reported in Chui, et al. (2001) with swirl settings and corresponding aerodynamic and flame patterns that were different from those of Case-1 and Case-2, showed that such flow patterns have a dominant influence on the apparent gas radiative properties.

Another interesting aspect of the combustor results are the measured centerline gas temperatures. Table 3.3.4 tabulates the corresponding temperatures measured in the Chui, et al. combustor, along with the Case-1 to Case-2 shift. The temperature shifts are plotted in Figure 3.3.6. The mean gas temperature shift, averaged over all measurement locations, is -214 °F.

Axial Distance (m)	Case-1 Centerline Gas Temperature, °F	Case-2 Centerline Gas Temperature, °F	Temperature Shift, °F (Case 2 - Case 1)
0.95	2664	2419	-245
1.55	2552	2367	-185
2.15	2421	2215	-205
2.77	2284	2041	-243
3.40	2143	1953	-191

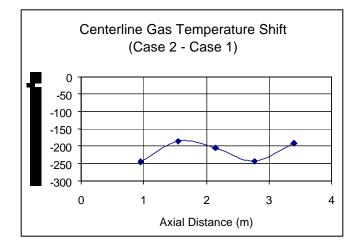

Figure 3.3. 6: Centerline Gas Temperature Shift as a Function of Axial Distance

Calculations of adiabatic flame temperature  $(T_{ad})$  were performed for coal firing in AEP's Conesville Unit #5 at maximum continuous rating (MCR). A number of scenarios were considered, namely: (1) Base Case (i.e., coal firing in air); (2) Constant Mass Case (i.e., the mass of nitrogen in air was replaced by the mass of CO<sub>2</sub> in the flue gas recycle (FGR); and (3) Various CO<sub>2</sub>/O<sub>2</sub> Mole Ratio Cases. Results (Figure 3.3.7) indicated that the  $T_{ad}$  for air firing was approximately 180 °F higher than for the Constant Mass Case. This difference is due to differences in specific heat (Cp) between N<sub>2</sub> and CO<sub>2</sub> (i.e., CO<sub>2</sub> Cp > N<sub>2</sub> Cp at elevated temperatures, Figure 3.3.8). One implication is that the ultimate combustion efficiency difference between air firing and O<sub>2</sub>/FGR firing could be governed by opposing phenomena, i.e., potentially lower reaction rate, but longer residence time in O<sub>2</sub>/FGR than in air. Thermo-gravimetric analysis (TGA) and Drop Tube Furnace System-1 (DTFS-1) results -- obtained from combustion firing of both Conesville Unit #5 and Pittsburgh Seam #8 coals other (See Volume II Report of this work, Bozzuto, et al., 2001) -- indicate that these two phenomena indeed virtually cancel each other.

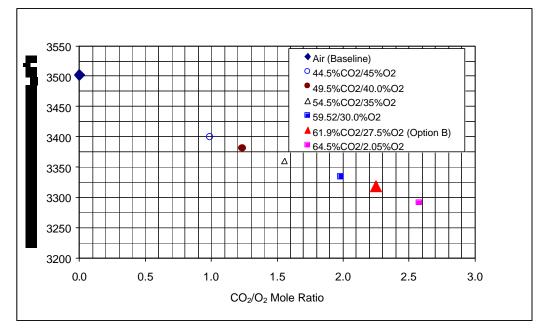

Figure 3.3. 7: Calculated Adiabatic Flame Temperature as a Function of CO2/O2 Mole Ratio for Conevsville Unit #5

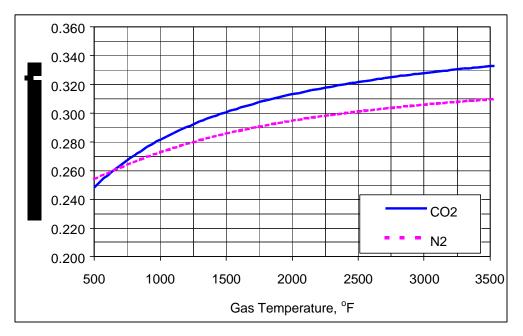

Figure 3.3. 8: Specific Heats (Cp) of Nitrogen and Carbon Dioxide as a Function of Temperature

## **CFD Furnace Model Results and Conclusions:**

Review of the CFD analysis results (Bozzuto, et al., 2001) which were developed for this project indicated the following with respect to furnace heat transfer:

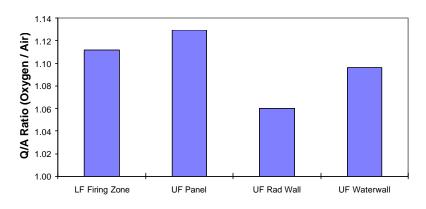

The baseline case (or Base Case) exhibits a slightly higher peak gas temperature (maximum difference of about 200 °F), and a correspondingly higher average (cross-sectional) gas temperature (difference of 90 °F at the HFOT), than that of the Concept-B case. This result compares favorably with the approximate -214 °F shift found by Chui et.al.

Note, however, that this close correspondence may be somewhat fortuitous, particularly since the two furnaces are so different. Nevertheless, the correspondence may indicate that the baseline air case may be expected to exhibit consistently higher peak and averaged post-flame temperatures than an oxy-fired case (with similar flow and flame patterns).

The net wall absorption in the furnace region for the baseline case is larger (by less than 1%) than that of the Concept-B case. Conversely, the net wall absorption for the baseline calculation with the proprietary in house Reheat Boiler Program (RHBP), as described below, was found to be about 6% lower than the Concept-B case calculated by the RHBP. The higher specific heat of the carbon dioxide, and the associated lower gas temperatures in the Concept-B case, will tend to offset somewhat or compensate for the expected increase in the wall absorption (i.e., anticipated due to the enhanced emissivity of the  $CO_2$ .) Furthermore, the spatial distribution of the carbon dioxide across the cross-section may be important; it is hypothesized that high concentrations of  $CO_2$  in the cooler gas mixtures between the wall and the flame may actually act to inhibit the net radiative flux to the walls.

## Performance Model (RHBP) Results:

The present study for Concept B involves coal combustion in a medium with  $\sim 31\%O_2/69\%$  CO<sub>2</sub> volume ratio. Heat transfer in the lower and upper furnace regions as calculated by the RHBP is compared in Figure 3.3.9. This figure compares heat fluxes (Btu/hr-ft2) in selected lower and upper furnace regions for air firing and oxygen firing. Lower furnace region results show firing zone heat flux to be about 11 percent higher with oxygen firing. Upper furnace region results show the reheat radiant wall is about 6 percent higher and the superheat division panels are about 13 percent higher with oxygen firing. Similarly, the upper furnace waterwall area is about 10 percent higher. The overall lower furnace heat absorption for Concept B was about 6% higher than for the air fired Base Case. The horizontal furnace outlet temperature (HFOT) for Concept B was calculated to be 123 °F lower than for the Base Case.

The trend calculated by the CFD code, with respect to the furnace temperature at the HFOP, appears to be qualitatively aligned with the trend calculated by the in-house RHBP code. However, the difference in wall absorption for the Concept-B case relative to the baseline case, calculated by FLUENT (change of -1%), does not fully agree with the results of the RHBP (change of +6%). Computed and/or experimental trends that indicate that oxy-firing may induce either an increase in wall absorption or a decrease in wall absorption, relative to the baseline case, are supported in the literature. It is suggested that the absorptive properties of a local CO<sub>2</sub>-containing gas mixture in the vicinity of the wall may either act to enhance or inhibit the incident radiative flux to the wall, depending upon its relative spatial location and mixture temperature. For example, a low-temperature, CO<sub>2</sub>-rich mixture near the wall would absorb the radiative flux from the interior "fireball" region; a portion of the energy would be re-emitted at the lower gas temperature, and the remainder of the energy would be used to heat up the gas. The result would be a net reduction in the incident radiative flux to the wall. Conversely, a high-temperature, CO<sub>2</sub>-rich mixture near the wall would emit at its local gas temperature, thus enhancing the incident radiative flux to the wall. Therefore, it is suggested that the relative spatial relationships of the cool and hot gas mixtures, the relative composition of the absorbing media, and the proximity of that media to the wall (as induced by the furnace and firing

system aerodynamics), may significantly impact the gas-phase irradiation to the wall. Indeed, the aerodynamic and flame patterns that prevail in a given air-fired or oxy-fired furnace may conceivably have as strong an impact on the net wall absorption as the physical property differences themselves (gas-phase emissivity, specific heat, etc.)

The results of computational tools (such as CFD and the RHBP) should be viewed with some skepticism, particularly when they are asked to produce calculations outside of the experience base for which they have been validated. Certainly, the gas-phase and particle-phase radiation property sub-models could be enhanced in both codes, and the impact of spatial gradients (caused by the interleaving of hot and cool regions of varying CO<sub>2</sub> composition) on radiative wall flux needs to be investigated more fully. CFD computations have been utilized to gain a more in-depth qualitative understanding of aerodynamic and flame patterns in combustion systems, but have not yet been integrated into routine boiler design procedures. At the present time, the ALSTOM design standards are based upon the experience and expertise built into the RHBP and other design protocols, and those standards must be adhered to in any new design project in order to mitigate risk. Therefore, the results of the RHBP, as reported in this work, must be regarded as the current standard, both from an engineering experience viewpoint and from a rules-based design viewpoint. However, additional validation work needs to be done in order to confirm the trends for oxy-firing scenarios.

Although differences in physical properties of the transport gases (e.g., air-firing versus oxy-firing) may initially induce undesirable deviations from the performance goals of an existing field unit, the designer and engineer views such alterations as challenges rather than insurmountable obstacles. Much can be done in the way of operating condition optimization (e.g., spray, nozzle tilt, and amount of gas recirculation), without major modifications to the unit, to realign steam temperatures and wall absorption with their desired, target values. Design parameters are often in conflict, and the intelligent designer must work to balance various parameters and operating conditions to achieve the desired outcome. The CFD work performed here was based on certain constraints to maintain equivalency for comparison purposes, which would not necessarily be the case in the field. For example, a potential decrease in furnace wall absorption of several percentage points could be nullified through manipulation of the various operating parameters available.

## 3.3.3.2 Convection Pass Analysis

Figures 3.3.10, 3.3.11 and 3.3.12 show the comparison of convective, non-luminous, and total heat transfer rates between air firing and oxygen firing for all the major sections contained in the existing convection pass of the unit at full load operating conditions as calculated by the RHBP.

Convective heat transfer in utility steam generator units is dependent upon many of the transport properties of the flue gas (viscosity, thermal conductivity, density, specific heat and others). Additionally, convection depends strongly on gas velocity. With the Concept B system there are significant changes in the flue gas analysis as compared with air firing. These gas analysis changes cause both transport property and gas velocity changes throughout the unit. The resulting convective heat transfer rates, as shown in Figure 3.3.10, ranged from about 80 to 105 percent as compared to air firing.

Significant differences in non-luminous radiant heat transfer are also expected. Of the gases produced by the complete combustion of a fuel, only carbon dioxide, water vapor and sulfur dioxide emit radiation over a sufficiently wide band of wave lengths to warrant consideration. With this system the primary change in the flue gas as compared to air firing is the large increase in the  $CO_2$  content and decrease in  $N_2$  content. The resulting enhancement in non-luminous heat transfer rates range from about 26 to 28 percent greater than air firing as shown in Figure 3.3.11.

Ultimately the convection pass total heat transfer rates, shown in Figure 3.3.12, were increased in the range of 1 to 8 percent over the values with air firing.

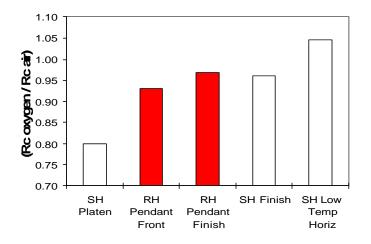

Figure 3.3. 10: Convective Heat Transfer Rate Comparison

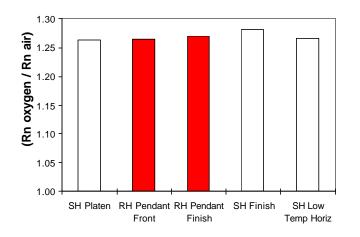

Figure 3.3. 11: Non-luminous Heat Transfer Rate Comparison

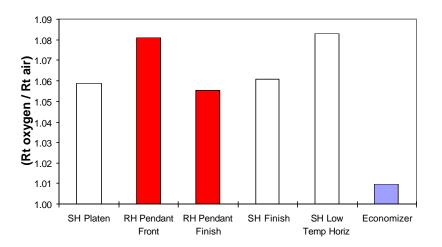

Figure 3.3. 12: Total Heat Transfer Rate Comparison

Steam temperature control was achieved through the use of burner tilt and reheat spray. The performance analysis results indicated the reheater circuit required about 1.45 percent spray to maintain the reheat outlet temperature at the design value. The superheater circuit required about 0.34 percent spray to maintain the superheat outlet temperature at the design value. The burner tilt was set at -10 degrees, the minimum value the customer uses. The overall steam conditions produced are shown in Table 3.3.5 below. Furthermore, with this recycle gas system, flue gas recirculation is also available as an additional steam temperature control variable. In this study however, we did not utilize this as an additional steam temperature control variable. We decided, as a first approximation, to set the flue gas recirculation rate at a value such that the flue gas flow to coal flow ratio was the same as with air firing. As it turned out, this was an acceptable setting for the gas recirculation rate.

	SHO	FWI	ECO	RHO	RHI
Flow (lbm/hr)	3131619	3131619	3131619	2808511	2808511
Pressure (psia)	2535	3165	3070	590.8	656.5
Temperature (F)	1000	493	622	1000	631

With the increased heat transfer rates with oxygen firing and similar steam temperature profiles, there was concern regarding metal temperatures throughout the unit. A detailed analysis using the Metal Temperature Program (MTP) was however, beyond the scope of this study. The MTP, using thermal inputs from the RHBP, calculates steam and metal temperatures at any selected point along the length of the tube. All tubes of each heat exchanger bank are modeled. A very brief review of metal temperatures at only a few selected points was done in this study. In general, for the points investigated, the metal temperatures were found to be the same or slightly lower than with air firing. The primary reason for this result was that although the heat transfer rates were slightly higher and the steam temperature profile was similar, the gas temperatures were lower. This combination yields similar heat flux conditions and ultimately similar metal temperatures.

## 3.3.4 Boiler System Modifications

Listed below are the basic modifications required for the Conesville No.5 unit to support firing with oxygen as required in Concept B.

## 3.3.4.1 Boiler

The Boiler Island should be inspected for potential air leaks into the system and should be sealed to minimize any infiltration. Special attention should be given to all penetrations including seal boxes for convective surfaces, sootblowers, wallblowers, expansion joints, ductwork, fuel piping, fans and windbox.

## 3.3.4.2 Ducts and Dampers and Fans

Refer to the Duct and Damper Diagram (Figure 3.3.13) shown below for the required duct arrangement and associated cross-sectional areas for this system. New flue gas ductwork is required for the Oxygen Heater. Part of the existing ductwork from the Air Heater flue gas exit to the Electrostatic Precipitator inlet must be removed and replaced with new ductwork that accommodates the new Oxygen Heater. Additionally, oxygen supply ductwork from the ASU to

the Oxygen Heater is required and hot oxygen supply ductwork from the Oxygen Heater to the existing secondary "air" duct must be provided. Similarly, New flue gas ductwork is required for the Parallel Feedwater Heater. Part of the existing ductwork from the Induced Draft fan outlet to the Scrubber inlet must be removed and replaced with new ductwork that accommodates the new Parallel Feedwater Heater. New ductwork and dampers are also required for the recycle flue gas streams that feed the existing Forced Draft and Primary Air fans.

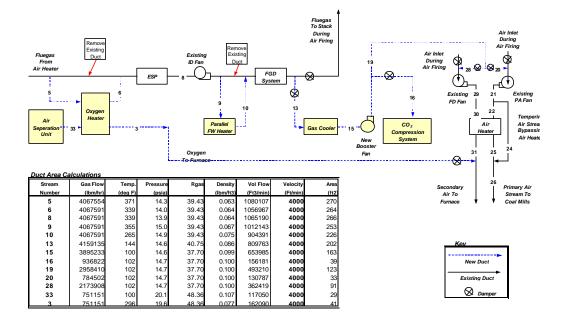

Figure 3.3. 13: Duct and Damper Diagram for Concept B

A new booster fan will be required as a minimum. The booster fan is required to overcome the added draft loss of the various new heat exchanger components shown in Figure 3.3.1 previously. Specifications for the booster fan are shown in Table 3.3.6 below. The existing Induced Draft, Forced Draft and Primary Air fans should eventually be checked with the suppliers to see if they can handle the new conditions (Note: The molecular weight is now 37.7 for the FD and PA fans and 39.4 for the ID fan). For this study we have assumed that both fans are acceptable.

Table 3.3.6:Booster Fan Specification

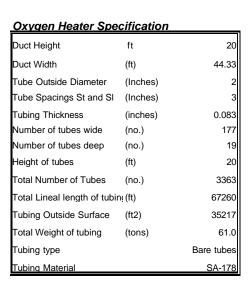

## 3.3.4.3 Oxygen Heater

The flue gas exiting the Air Heater is at 371 °F. A large quantity of sensible heat is still available in this gas stream. The Oxygen heater is used to recover additional sensible heat in the flue gas as a result of reduced air heater performance with oxygen firing. This heat is partially recovered in the Oxygen Heater where cold O2 from the Air

Separation Unit is preheated before being mixed with the gas recirculation stream prior to furnace injection. Part of the existing ductwork connecting the existing Air Heater flue gas exit stream to the Precipitator inlet is removed. New ductwork, which accommodates the addition of the new Oxygen Heater, is installed. Performance requirements and gas analyses for the Oxygen Heater are shown in Table 3.3.7. Table 3.3.8 shows the Oxygen Heater specifications. It should be noted that the flue gas stream, which provides the heat source for this heat exchanger, contains flyash, as the Oxygen Heater is located between the Air Heater and the Electrostatic Precipitator (ESP). A simple sketch of the oxygen heater, which is similar in design to a tubular air heater, is shown in Figure 3.3.14. Refer to Appendix I Concept B Boiler modification drawings for the proposed arrangement of this equipment.

# 3.3.4.4 Parallel Low Pressure Feedwater Heater

A parallel low-pressure feedwater heater (PFWH) is facilitated to remove remaining useful sensible heat in the flue gas. This heater is installed in a parallel feedwater stream with the existing extraction low-pressure feedwater heaters number 52 and 53. The heat source for the PFWH is flue gas leaving the ID fan as shown on the system diagram (Figure 3.3.1). In actuality, there are two ID fans on this unit and therefore two PFWH's are used. The flue gas

temperature leaving the induced draft fans is 355 F. The PFWH cools the flue gases down to 265 F by heating feedwater in a parallel stream with the feedwater being heated in the extraction feedwater heaters No. 52 and 53 as shown in Figure 3.3.15. About 29 percent of the total low-pressure feedwater flow leaving the No. 51 low-pressure feedwater heater is heated in the new PFWH. This heat exchanger is essentially a low temperature economizer section that is designed similar to Heat Recovery Steam Generator (HRSG) tube banks with finned tubing. The fin pitch can be quite high (6 fins/inch) since the flue gas at this point is particulate free.

These new components recover about 26,458 kW [90.3 x 106 Btu/hr]. This causes the steam extractions to heaters No. 52 and No. 53 to be reduced proportionally and the steam flow through the low-pressure section of the existing steam turbine to be increased by approximately two percent. This increases the generator output proportionally. Performance requirements and specifications for the PFWH are shown in Tables 3.3.9 and 3.3.10. Figure 3.3.16 shows a simple sketch of the new component. Refer to Appendix I Concept B Boiler modification drawings for the proposed arrangement of this equipment.

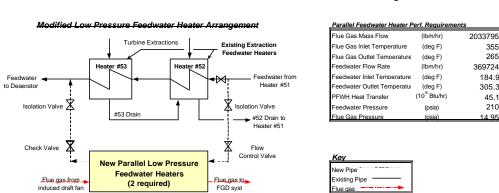

Figure 3.3. 15: Parallel Feedwater Heater Arrangement

 Table 3.3.10:
 Parallel Feedwater Heater Specification

Figure 3.3. 16: Parallel Feedwater Heater Sketch

Table 3.3.11 shows the specifications for the PFWH headers and piping. The piping runs from the feedwater pipe entering existing feedwater heater #52 to the two PFWH unit inlet headers and returns from the to PFWH outlet headers to the feedwater pipe leaving existing feedwater heater #53.

Table 3.3.11:	<b>PFWH Header and Piping Specifications</b>
---------------	----------------------------------------------

## 3.3.4.5 Controls and Instrumentation:

Additional controls and instrumentation will be required for the new components and systems described. The transition between air firing and oxygen firing needs careful consideration.

## 3.3.4.6 Modified Boiler Drawings

Drawings of the modified boiler showing the existing and new equipment are listed below and contained in Appendix I.

U00-E-0551R General Arrangement - Side Elevation for Concept B U00-E-0552R General Arrangement - Plan View "B-B" for Concept B U00-E-0585R General Arrangement - Plan View "A-A" for Concept B

## 3.3.5 Steam Cycle System

The steam cycle system for Concept B is modified slightly with the addition of a low-pressure feedwater heater arrangement in parallel with extraction feedwater heaters # 52 and 53 as described in Section 3.3.4.4. The parallel feedwater heaters are used to recover additional sensible heat in the flue gas as a result of reduced air heater performance with oxygen firing. The modified steam cycle is shown in Figure 3.3.17. The associated Mollier diagram showing the modified steam cycle on enthalpy vs entropy coordinates is shown in Figure 3.3.18. The modified steam cycle system produces 463,056 kw with a steam turbine heat rate of 8089 Btu/kwhr.

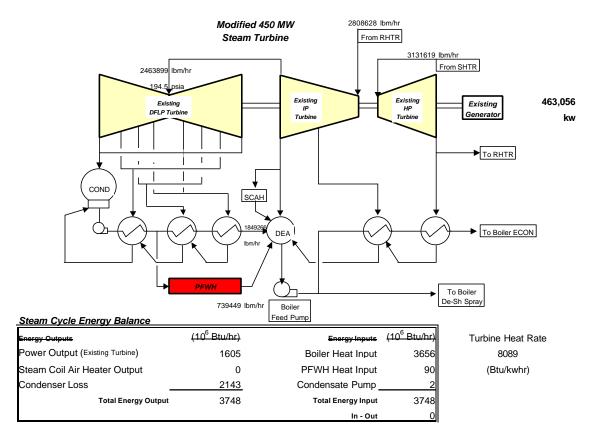

Figure 3.3. 17: Modified Steam Cycle Diagram and Performance for Concept B

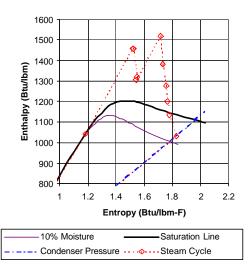

Figure 3.3. 18: Modified Steam Cycle Mollier Diagram for Concept B

#### 3.3.6 Flue Gas Desulfurization and Electrostatic Precipitator Systems Performance Issues

Because the flue gas for Concept B was significantly different in composition from the Base Case due to combustion with oxygen as opposed to air, analysis of the Flue Gas Desulfurization System (FGD) system and the Electrostatic Precipitator (ESP) system performance with these new conditions was investigated. The most noticeable differences regarding the flue gas composition for this case is that it contains significantly more  $CO_2$  and less  $N_2$  than with air firing. The overall mass flow rates for both cases are nearly identical. The effects of operating the Flue Gas Desulfurization System and the ESP with the high  $CO_2$  content flue gas of Concept B are discussed in this section.

#### 3.3.6.1 Flue Gas Desulfurization System Performance Issues

Table 3.3.12 identifies the assumptions that were made in predicting the FGD system performance. Table 3.2.13 shows the gas constituents at the existing Absorber inlet and outlet locations. It should be noted that the  $CO_2/SO_2$  mole ratio is 199, as opposed to the value of 63 encountered previously for the Base Case and Concept A (refer to Section 3.2.4). Hence, it was necessary to assess the impact of high  $CO_2$  content in the flue gas on the performance of FGD System. It is important to note that  $SO_2$  forms a much stronger acid than  $CO_2$  (with a dissociation constant of 7.8E-3 vs. 5.2E-7). Additionally,  $SO_2$  is about 35 times more soluble in water than  $CO_2$ . The absorbed  $SO_2$  will drop the pH of the scrubbing solution to about 4.5. At this level, the  $CO_2$  is basically insoluble in water. ALSTOM Power's Environmental Systems group predicted that, under these circumstances, the flue gas desulfurization systems  $SO_2$  capture efficiency would decrease by approximately 2%.

#### 3.3.6.2 Electrostatic Precipitator (ESP) System Performance Issues

The effects of operating the Electrostatic Precipitator (ESP) in the high  $CO_2$  content flue gas environment of Concept B are discussed in this section.

The electrostatic precipitation process can be characterized as four stages.

- Corona generation and flue gas ionization
- Particle charging resulting from ionization
- Migration of particles under the influence of the electric field
- Removal of particle cake from collecting electrodes

Background From White, J. "Industrial Electrostatic Precipitation" (1962):

Corona discharge is vital to the electrical separation of particles from the gas stream. The dominant ion production mechanism in the corona is ionization by electron impact, in which free electrons in the gas acquire energy from an applied electric field and collide violently with gas molecules, literally knocking electrons out of the molecules. The net result is free electrons and positively charged gas ions.

The unipolar corona, used in electrical precipitation, is a stable, self-maintaining gas discharge between an emitting electrode and a receiving electrode. The ionization processes are confined to or near the glow region in the strong electric field adjacent to the emitting electrode. Most of the ionization is produced by free electrons that are accelerated to fairly high energies in this region and ionize by collision with molecules.

With negative corona free electrons from the ionization zone, upon entering the low-field region of the corona, combine with molecules of the gas to form negative ions. The ability to form negative ions is a fundamental property of the molecular species. Some gases such as nitrogen, hydrogen, helium, neon and argon, if sufficiently pure, have no affinity for electrons and hence do not form negative ions. Negative corona does not occur in these gases. Instead, when the voltage is raised to a point that would correspond to the corona onset point, spark over occurs. On the other hand, oxygen, chlorine, sulfur dioxide, and many other gases do have strong electron affinities, and, as would be expected, they produce highly stable negative coronas. Negative corona is possible only in gases, or mixtures of gases, that exhibit appreciable electron attachment. Consequently negative corona characteristics are highly sensitive to gas composition and can range from no corona to highly stable corona.

Fortunately practically all industrial furnaces, boilers and process gases as well as air contain electro-negative gases such as oxygen, water vapor, carbon dioxide and frequently sulfur dioxide. Electron attachment is the process by

which electrons combine with neutral molecules to form negative ions. The probability of attachment varies greatly with the gas composition. It is zero for gases such as nitrogen and hydrogen, very small for ammonia, and relatively high for chlorine.

Theory and experiment show that the molecular composition of the gas profoundly influences its negative-corona characteristics (Please refer to Figures 3.3.19, 3.3.20 and 3.3.21 below, extracted from White, 1962). The general conclusion is that gases such as nitrogen that in the pure state have zero electron affinity, are incapable of supporting negative corona, and gases of the  $CO_2$  type that have moderate electron affinity do have considerable negative corona, and gases of the  $SO_2$  type have a very wide range of negative corona.

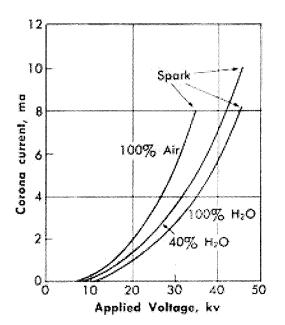

Figure 3.3. 19: Negative Corona Curves for Ai r-water Vapor Mixtures at 400F; Atmospheric Pressure; 3-in. Tube; 0.010-in. Wire

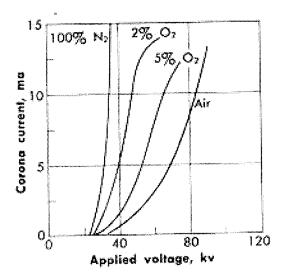

Figure 3.3. 20: Negative Corona Characteristics for Nitrogen-Oxygen Mixtures; 6-in Tube; 0.109-in Wire

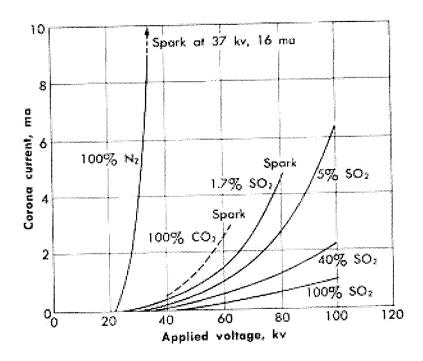

Figure 3.3. 21: Negative Corona Curves for Nitrogen-Sulfur Dioxide Mixtures; 6-in. Tube; 0.019-in. Wire

Conditions with recycled flue gas:

Table 3.3.14 gives a comparison of the flue gas analysis for air firing and  $O_2$ /Recycled flue gas firing. The high nitrogen content, 73.7%, found with the air firing is reduced to 5.3% where as the  $CO_2$  increases from 13.9% to 77.2%. There is also a small increase in the moisture content from 9% to 14.1% and  $SO_2$  content from 2212 vppm to 3887 vppm.

Species	Unit	Air Firing: (ESP Inlet Gas Composition)	O <sub>2</sub> /Recycled Flue Gas Firing: (ESP Inlet Gas Composition)
O <sub>2</sub>	Vol.%	3.1	3.1
$N_2$	Vol.%	73.7	5.27
$H_2O$	Vol.%	9.0	14.1
$\dot{CO}_2$	Vol.%	13.9	77.2
$SO_2$	vppm	2212	3887

 Table 3.3.14:
 Composition of Flue Gases Entering the Electrostatic Precipitator (ESP)

If the gas was 100% Nitrogen, the negative corona precipitation process could not occur. Nitrogen has no affinity for electrons and hence cannot form negative ions. When the voltage is raised to a point that would correspond to the corona onset point, spark over occurs. Figure 3.3.20 shows that the introduction of  $O_2$  allows an increase in voltage to take place creating a stronger electrical field prior to spark over. Figure 3.3.21 shows again the 100% nitrogen gas and the effects of various levels of the electro-negative gas  $SO_2$ . Also a comparison curve is given for 100%  $CO_2$ . It can be seen that  $CO_2$  has electron affinity resulting in a significant increase in voltage, beyond corona onset voltage, before spark break down occurs. The curve tends to the improved characteristic that is obtained with the presence of a small percentage of  $SO_2$ .

Hence with all other gas components remaining constant the replacement of nitrogen by  $CO_2$  will result in a gas that is more beneficial for negative corona precipitation.

In Conclusion, for the gas analysis of Concept B shown above in Table 3.3.14, no ESP performance degradation is expected as a result of firing coal in  $O_2$ /Recycled flue gas environment.

#### 3.3.7 Carbon Dioxide Separation and Compression System

This system processes the flue gas stream leaving the oxygen fired boiler system of Concept B to provide a liquid product  $CO_2$  stream with suitable conditions for sequestration or usage.

#### 3.3.7.1 Introduction:

Traditionally, amine scrubbing has been used on industrial scale to recover  $CO_2$  from boiler flue gases. Monoethanolamine (MEA) is one of the most effective absorbents but reclamation of the absorbed  $CO_2$  from MEA solution consumes large amounts of energy. Therefore, a search is on for more energy efficient methods for recovering  $CO_2$  from flue gas streams. One proposed method is to replace combustion air of a power plant with nearly pure oxygen. Theoretically, the flue gas from such a plant would consist of only  $CO_2$  and water vapor. Because water can be separated from this gas relatively easily (by condensation) this method seems to offer a promising way to recover  $CO_2$  by simply compressing it to a high enough pressure so it can be disposed of or recovered for some useful purpose. Practically however, the stream leaving the Boiler Island contains many other components other than just  $CO_2$  and water vapor, which must be fully considered in the system design for Concept B.

## 3.3.7.2 Process Description:

Figure 3.3.22 (Refer to Section 3.3.7.3) shows the Flue Gas Cooling process flow diagram and Figure 3.3.23 shows the Flue Gas Compression and Liquefaction process flow diagram.

The following describes a  $CO_2$  recovery system that cools and then compresses a  $CO_2$  rich flue gas stream from an oxygen-fired boiler to a pressure high enough so  $CO_2$  can be liquefied. The resulting liquid  $CO_2$  is passed through a  $CO_2$  Stripper to reduce the  $N_2/O_2$  content to an acceptable level. Then the liquid  $CO_2$  is pumped to a high pressure so it can be economically transported for sequestration or usage. Pressure in the transport pipeline will be maintained above the critical pressure of  $CO_2$  to avoid 2-phase flow. The overhead gas from the  $CO_2$  Stripper is vented to atmosphere.

The key process parameters (pressures, temperatures, duties etc.) are shown on the process schematics and will not be repeated here except in selected instances.

Later in this report there is a section titled "Design Considerations" (Section 3.3.7.8). This section covers design issues that are not discussed in the Process Description below.

## Flue Gas Cooling:

Please refer to Figure 3.3.22 (drawing D 09484-01005R-0).

The feed to the  $CO_2$  Recovery System is the flue gas stream that leaves the FGD system of the Boiler Island. At this point, the flue gas is at the dew point of H<sub>2</sub>O. All of the flue gas leaving the boiler is cooled to 100 °F in Gas Cooler DA-101 A/B/C which operates essentially under atmospheric pressure. A significant amount of water condenses out in this cooler. Approximately 2/3 of the gas is then recycled back to the boiler while 1/3 is fed forward to the  $CO_2$  compression area. The recycle stream is required to maintain thermal balance in the existing Conesville #5 steam generator unit in order to avoid major pressure part modifications to the boiler. The Gas Cooler minimizes the volumetric flow rate to, and the resulting power consumption of, the Flue Gas Compression equipment located downstream. Excess condensate is blown down to the cooling water system. Three vessels have been provided for these coolers because a single vessel would be too large.

The Gas Cooler is configured in a packed tower arrangement where the flue gas is contacted with cold water in countercurrent fashion. Warm water from the bottom of the contactor is recycled back to the top of the contactor by

Water Pump GA-101 A/B/C/D after first cooling it in an external water cooled heat exchanger, Water Cooler EB-101 (plate and frame exchanger). The cooling water for this exchanger comes from the new cooling tower.

Because the flue gas may carry a small amount of fly ash, the circulating water is filtered in Water Filter FD-101 to prevent solids build-up in the circulating water. Condensate blowdown is filtered and is taken out downstream of the filter. However, the stream is not cooled and is split off before EB-101. Thus the heat load to the cooling tower is minimized.

From the Gas Cooler, the flue gas stream enters a series of booster blowers that are located adjacent to the Gas Cooler. This design was developed to minimize the length of ducting operating at a slight vacuum and to minimize the temperature of the gas being recycled back to the boiler. This arrangement also minimizes energy consumption, as it does not needlessly over boost the pressure of the stream to be recycled back to the boiler. It is only necessary to boost the pressure of the flue gas flow that proceeds to compression and liquefaction to overcome the pressure drop of the duct which is about 1200 feet long.

#### Three-Stage Gas Compression System:

Please refer to Figure 3.3.23 (drawing D 09484-01004R-0).

The compression section, where  $CO_2$  is compressed to 365 psig by a three-stage centrifugal compressor, includes Flue Gas Compressor GB-101. After the aftercoolers, the stream is then chilled in a propane chiller to a temperature of -21 °F. Note that both the trim cooling water and water for the propane condenser come from the new cooling tower. At this pressure and temperature, about 80 mole % of the stream can be condensed. The flash vapors contain approximately 80 weight % of the inlet oxygen and nitrogen, but also 12 weight % of the  $CO_2$ . Therefore, a rectifier tower has been provided to reduce the loss of  $CO_2$  to an acceptable level (about 6 weight %). Then the pressure of the liquid is boosted to 2000 psig by  $CO_2$  Pipeline Pump GA-103. This stream is now available for sequestration or usage.

The volumetric flow to the compressor inlet is about 80,000 ACFM to each of the two trains and only a single frame is required in each train. The discharge pressures of the stages have been balanced to give reasonable power distribution and discharge temperatures across the various stages. They are:

1st Stage	28 psig
2nd Stage	108 psig
3rd Stage	365 psig

Power consumption for this large compressor has been estimated assuming adiabatic efficiency of 75%.

The hot gas from each stage is first cooled in an air cooler to 120  $^{\circ}$ F (Flue Gas Compressor 1st/ 2nd / 3rd Stage Aftercooler EC-101/2/3) and then further cooled by a water-cooled heat exchanger to 95  $^{\circ}$ F (Flue Gas Compressor 1st/ 2nd Stage Trim Cooler EA-101/2). The flue gas compressor 3rd stage cooler (EA-103) cools the gas down to 90  $^{\circ}$ F to reduce the size of the dryers. Due to their large size, many of these heat exchangers consist of multiple shells. Because of highly corrosive conditions, the process side of the coolers must be stainless steel.

Because the flue gas stream leaving DA-101 is wet, some water condenses out in the three aftercoolers. The sour condensate is separated in knockout drums (FA-101/2/3) equipped with mist eliminator pads. Condensate from these drums is drained to the cooling tower or to waste water treatment. To prevent corrosion, these drums have a stainless steel liner.

Flue gas leaving the 3rd stage discharge knockout drum (FA-103) is fed to Flue Gas Drier FF-101 A/G where additional moisture is removed.

#### Gas Drying:

Please refer to Figure 3.3.23 (drawing D 09484-01004R-0).

It is necessary to dry the  $CO_2$  stream to meet the product specification. A mole sieve drier has been selected.

The performance of a fixed-bed drier improves as pressure increases. This favors locating the drier at the discharge of the compressor. However, as the operating pressure of the drier increases, so does the design pressure of the equipment. This favors low-pressure operation. But, at low pressure the diameter or number of the drier vessels grows, increasing the cost of the vessel. Having to process the recycle gas from the rectifier condenser cooling would also increase the diameter of the vessel. However, this is less than 10% of the forward flow. For this design the drier has been optimally located downstream of the 3rd stage compressor. The CO<sub>2</sub> Drier system consists of six vessels; FF-101 A/G. One vessel is on line while the others are being regenerated. Flow direction is down during operation and up during regeneration.

The drier is regenerated with the non-condensable vent gas from the rectifier after it exits the third stage discharge trim cooler in a simple once through scheme. During regeneration, the gas is heated in Regeneration Heater FH-101 before passing it through the exhausted drier. After regeneration, heating is stopped while the gas flow continues. This cools the bed down to the normal operating range. The regeneration gas and the impurities contained in it are vented to the atmosphere.

Regeneration of a mole sieve bed requires relatively high temperature and, because HP steam pressure may fluctuate, a gas-fired heater has been specified for this service.

Flue Gas Filter FD-102 has been provided at the drier outlet to remove any fines that the gas stream may pick up from the desiccant bed.

## <u>CO<sub>2</sub> Condensation and Stripping:</u>

Please refer to Figure 3.3.23 (drawing D 09484-01004R-0).

From the  $CO_2$  Drier, the gas stream is cooled down further to -21 F with propane refrigeration in  $CO_2$  Condenser EA-104. From EA-104 the partially condensed flue gas stream continues on to  $CO_2$  Rectifier DA-102.

At this pressure and temperature 80 mole % of the stream can be condensed. The flash vapors contain approximately 80 weight % of the inlet oxygen and nitrogen, but also 12 weight % of the  $CO_2$ . Therefore, as mentioned, a rectifier tower has been provided to reduced the loss of  $CO_2$  to an acceptable level. The pressure of the liquid is boosted to 2000 psig by  $CO_2$  Pipeline Pump GA-103 for delivery to a sequestration or usage location.

The vapors in the feed to the rectifier contain the nitrogen and the oxygen that flashed from the liquid  $CO_2$ . To keep the  $CO_2$  loss to the minimum, the rectifier also has an overhead condenser,  $CO_2$  Rectifier Condenser EA-107. This is a floodback type condenser installed on top of the Rectifier. It cools the overhead vapor from the tower down to -48 °F. The condensed  $CO_2$  acts as cold reflux in the  $CO_2$  Rectifier.

Taking a slipstream from the inert-free liquid  $CO_2$  from the Rectifier bottoms and letting it down to the Flue Gas Compressor 3rd stage suction pressure cools EA-107. At this pressure,  $CO_2$  liquid boils at -55 °F thus providing the refrigeration necessary to condense some of the  $CO_2$  from the Stripper overhead gas. The process has been designed to achieve at least 94%  $CO_2$  recovery. The vaporized  $CO_2$  from the cold side of EA-107 is fed to the suction of the Flue Gas Compressor 3rd stage.

Any system containing liquefied gas such as  $CO_2$  is potentially subject to very low temperatures if the system is depressurized to atmospheric pressure while the system contains cryogenic liquid. If the  $CO_2$  Rectifier (and all other associated equipment that may contain liquid  $CO_2$ ) were to be designed for such a contingency, it would have to be made of stainless steel. However, through proper operating procedures and instrumentation such a scenario can be avoided and low temperature carbon steel (LTCS) can be used instead. Our choice here is LTCS. However, the condenser section will be made from stainless steel.

## CO<sub>2</sub> Pumping and CO<sub>2</sub> Pipeline:

Please refer to Figure 3.3.23 (drawing D 09484-01004R-0).

The  $CO_2$  product must be increased in pressure to 2000 psig. A multistage heavy-duty pump (GA-103A/B) is required for this service. This is a highly reliable derivative of an API-class boiler feed-water pump.

It is important that the pipeline pressure be always maintained above the critical pressure of  $CO_2$  such that singlephase (dense-phase) flow is guaranteed. Therefore, pressure in the line should be controlled with a pressure controller and the associated control valve located at the destination end of the line.

## Offgas:

Please refer to Figure 3.3.23 (drawing D 09484-01004R-0).

The vent gas from the  $CO_2$  Rectifier overhead is at high pressure and there is an opportunity for power recovery using turbo-expanders. Because the gas cools down in the expansion process, there is also an opportunity for cold recovery. Heat recovery from the stream after let down via an expander was examined and it was determined that the amount of duty that could be recovered without the carbon dioxide in the stream freezing was small. Thus heat recovery could not be justified. The offgas leaves the Rectifier at -48 °F approximately. The refrigeration recovery to condense  $CO_2$  was the best use for this cold since it also produces a reasonable temperature regeneration gas for the dryers.

3.3.7.3 Process Flow Diagrams

Two process flow diagrams are shown below for these systems:

- Figure 3.3.22 (drawing D 09484-01005R-0) Flue Gas Cooling PFD
- Figure 3.3.23 (drawing D 09484-01004R-0) CO<sub>2</sub> Compression and Liquefaction PFD

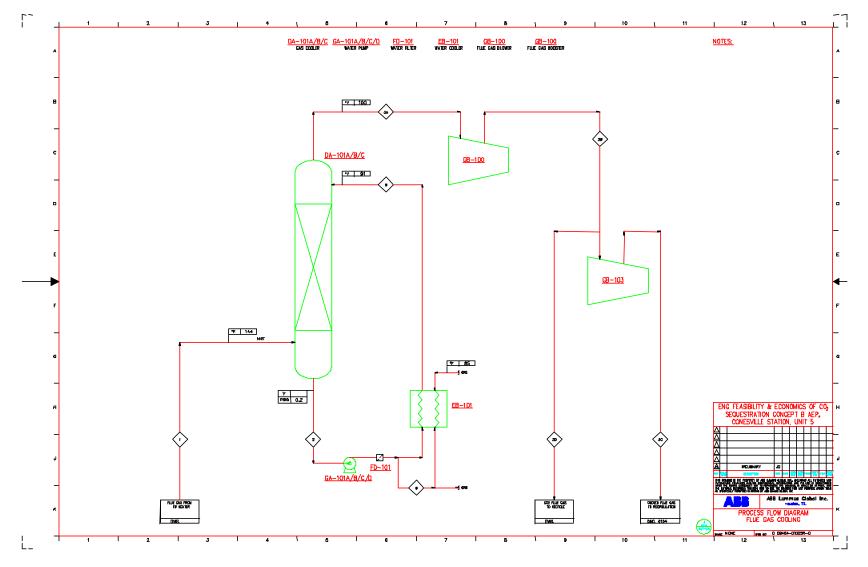

Figure 3.3. 22: Process Flow Diagram for Concept B: Flue Gas Cooling

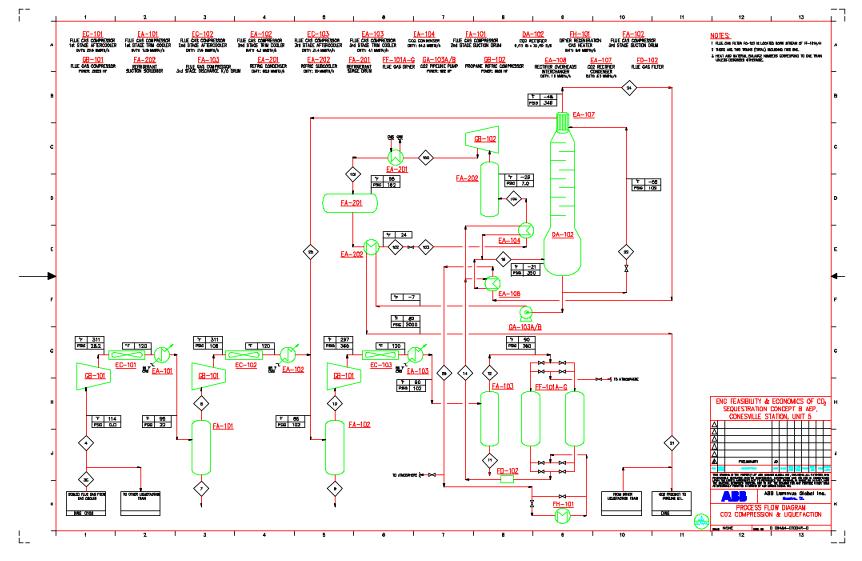

Figure 3.3. 23: Process Flow Diagram for Concept B: CO<sub>2</sub> Compression and Liquefaction

#### 3.3.7.4 Overall Material and Energy Balance

Table 3.3.15 contains the overall material balance for the Flue Gas Cooling System and the  $CO_2$  Compression and Liquefaction System. It is based on 94% recovery of  $CO_2$ .

| STREAM NAME                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 91                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |     

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 0.0
