                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | 

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | bottol           conde           2:    

              

   

            ## Table 3.3.15: Material and Energy Balance for Flue Gas Cooling, CO2 Compression and Liquefaction

## 3.3.7.5 Equipment List with Data

Equipment data for Concept B, summarized in Appendix II, has been tabulated in the so-called "short spec" format which provides adequate data for a factored cost estimate.

#### 3.3.7.6 Consumption of Utilities

In addition to the primary utilities listed below (Table 3.3.16), the plant will also need a supply of other utilities such as instrument air, plant air, process water, nitrogen etc. However, these needs are minor and in many cases are for maintenance purposes only. Consumption of these utilities has not been estimated.

	Utility	Amount Consumed	Units		
	Natural Steam Cooling water	0	MMSCFD Lb/hr Gpm	_	
				Power (ea)	
			Number	including	
Number of	Item		Operating	0.95	Total
Trains	Number	Service	per train	motor eff	all trains
			1	(kW)	(kW)
2	EC-101	Flue Gas Compressor 1st	1	81	163
		Stage Aftercooler			
2	EC-102	Flue Gas Compressor 2nd	1	69	138

2	EC-103	Flue Gas Compressor 3rd	1	68	137
		Stage Aftercooler			
1	PA-101A/B	Large Air Separation Unit	2	40255	80511
1	PA-102	Small Air Separation Unit	1	15311	15311
1	PA-103	Cooling Tower	1	4074	4074
2	GB-101	1 Stage	1	6416	12831
2		2 Stage	1	6675	13349
2		3 Stage	1	6718	13436
2	GB-102	1 stage	1	2362	4724
2		2 stage	1	5204	10408
1	GB-100	Flue Gas Blower	1	2173	2173
1	GB-103	Flue Gas Booster	1	396	396
1		Water	2	104	311
1	GA-101 A/B/C/D	Water pump	3		
2	GA-103A/B	CO2 Pipeline pump	1	1045	2089
		Total			160051

#### Table 3.3.16: Concept B Utility Consumption

#### 3.3.7.7 Consumption of Chemical and Desiccants

The  $CO_2$  compression system does not need any chemicals for its operation. Naturally, there will be a minor demand of lube oil and similar supplies. These have not been estimated.

It has been assumed that the mole sieve desiccant in the  $CO_2$  Drier must be replaced once every 3 years. The estimated consumption of mole sieve and other chemicals can be found Table 3.3.17.

Table 3.3. 17:	<b>Concept B Chemical and Desiccant Consumption</b>
----------------	-----------------------------------------------------

Chemical	Consumption per day (lbs.)
Sodium Hypochlorite	15300
Sodium Bisulfite	86
Mole Sieves	136

The totals shown in Table 3.3.17 do not include chemicals provided by the cooling tower service personnel. This is handled as a component of operating costs referred to as contracted services. It also does not include air separation plant chemicals and lubricants that were presented as monetary value only. They will appear in the operating expense break down.

#### 3.3.7.8 Design Considerations

The process and equipment specifications presented for Concept B were the result of a number of optimizations. The areas of optimizations in the CO<sub>2</sub> Compression and Liquifaction System were:

- O<sub>2</sub> purity
- CO<sub>2</sub> purity
- CO<sub>2</sub> condensation pressure and temperature

#### $O_2$ Purity:

Initial analysis included an Air Separation Unit (ASU) producing oxygen of 95% purity. Additionally, 5% of the total oxygen demand was assumed to be from infiltration of ambient air into the boiler which is typical for a boiler of this type and age. These operating conditions combined with the need for nominally 15% excess oxygen for combustion, resulted in almost 15-wt% of nitrogen and oxygen in the flue gas. This concentration is much higher than typically accepted for EOR applications. The conclusion then was that the bulk of the inerts must be separated from  $CO_2$  before it can be used for EOR. Thus, direct compression to the pipeline is not an option. Instead,  $CO_2$  would have to be condensed so the inerts could be separated.

It soon became obvious that it is impossible to condense  $CO_2$  from such a mixture at pressures below the critical pressure of  $CO_2$  and temperatures achievable with cooling water. This is illustrated by Figure 3.3.24 which shows the achievable  $CO_2$  recovery (the ratio of pure  $CO_2$  product recovered to the  $CO_2$  in the flue gas entering the system) as a function of pressure and temperature. Pressure was limited to 1000 psig, which is just slightly below the critical pressure of  $CO_2$  (1070 psia).

CO2 Recovery - Original Basis (14.69wt% N2 - Dry Basis)

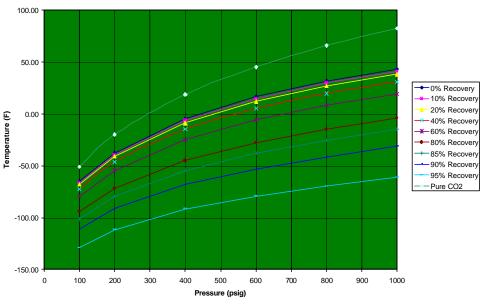

Figure 3.3. 24: CO<sub>2</sub> Recovery from Boiler Flue Gas (Combustion with 95% Pure O<sub>2</sub> and 5% Air Infiltration)

Because the combustion process requires excess oxygen (typically 15-20% with coal firing), the flue gas will always contain at least some oxygen. Furthermore, it is not easy to completely eliminate nitrogen. Some infiltration of air will always occur as long as the combustion chamber of the boiler operates under slight vacuum, as is the current practice with coal firing, thus some  $N_2$  will also be present. Additionally, increasing oxygen purity from the ASU beyond 99% is expensive because the remaining 1% is mainly argon and the separation becomes more difficult.

Because the inert gases have a strong effect on the dew point of the flue gas, the only way to condense a substantial fraction of the  $CO_2$  is by refrigeration. One should keep in mind that the critical temperature of  $CO_2$  is approximately 88 F and condensation of  $CO_2$  without some form of refrigeration may not be feasible in the warmer regions of the world even when inerts are not present in the  $CO_2$  stream.

Figure 3.3.25 shows the achievable  $CO_2$  recovery as a function of pressure and temperature using 99% pure  $O_2$  and 1% air infiltration as combustion process assumptions. One comparison which emphasizes the impact of flue gas purity is that with 95%  $O_2$  purity, the temperature for 95% recovery at 1000 psig is -60°F (Figure 3.3.24) whereas it is 30 °F (Figure 3.3.25) with 99% pure oxygen.

CO2 Recovery - Revised Basis (3.56 wt% N2 - Dry Basis)

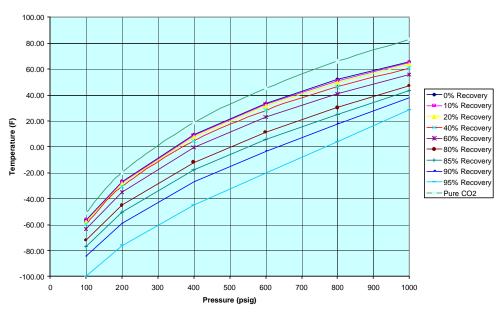

Figure 3.3. 25: CO<sub>2</sub> Recovery Boiler Flue Gas (Combustion with 99% Pure O<sub>2</sub> and 1% Air Infiltration)

#### $CO_2$ purity:

Simulations were made to evaluate modifications to the liquefaction flow scheme presented in Sections 3.3.7.2 & 3.3.7.3 for this concept. The alternate schemes evaluated included total product condensation and having a reboiler on the rectifier (turning it into a complete distillation column). The result was that total condensation, even with the use of 99% pure oxygen, left the product with approximately 11% inerts, which cast doubt according to experts that it could be sequestered in a body of water. The result of having a reboiler on the bottom of the rectifier showed that it improved the CO<sub>2</sub> product purity, but could never be feasibly made to produce a product which contained less than 10 ppm O<sub>2</sub> which would be required for EOR applications. The reason that a reboiler was not presented in the final design was that all of the heat of reboiling was added to the condenser, which required refrigeration at a much lower temperature than the refrigeration which was recovered in the reboiler. The result was a significant work of liquefaction increase.

#### *CO*<sub>2</sub> *condensation pressure and temperature:*

The range of condensation pressures evaluated ranged from 995 psia to 70 psia. The range of condensation temperatures evaluated ranged from 41 °F to -69 °F. The optimum was found to be 350 psig and -22 °F.

#### 3.3.7.9 OSBL Systems

Concept B has equipment associated with the liquefaction of  $CO_2$  in four different areas. The areas include the cooling tower, flue gas cooling section, air separation plant, and the compression and liquefaction equipment.

For this Concept, all of the cooling water must come from a new cooling tower since there is no diversion of steam to supply process heat. The clarifier producing make-up water for the cooling tower produces a blowdown sludge that must be sent to the existing clarifier blowdown handling system. The blowdown from the cooling tower itself can be discharged to the river after the free chlorine is removed by injection of sodium bisulfite.

The air separation plant utilizes the bulk of the cooling water. It also consumes electric power. The original design of the air separation plant involved the consumption of steam for molecular sieve drier regeneration. This duty was converted to an electric load to get the  $CO_2$  recovery process isolated from swings in steam pressures that can occur with changes in throughput. The only other utility it takes in is instrument air.

The  $CO_2$  compression and liquefaction section requires less supplemental utilities and chemicals than its amine counterparts. Only cooling water and electric power are required. Once every three years the molecular sieve in the dryers may need to be replaced.

## 3.3.7.10 Plant Layout

The gas from the flue gas desulfurizer arrives at the nozzles of the flue gas coolers at atmospheric pressure. In order to avoid any additional inflow of oxygen, the flue gas coolers must be placed as close to the power boilers as possible. The coolers are located just west of the existing FGD system.

Initially there were concerns about the piping between the air separation plant and the power boiler. The oxygen is produced at the air separation plant at 5 psig. Therefore it should not be subject to more than 3 psi of frictional pressure loss in the duct connecting it to the power boiler. Calculations reveal that two 36-inch supply lines can carry the oxygen from the ASU to the Boiler, a distance of about 1500 feet. The wall thickness of standard pipe should provide more than enough protection from most incidents that could be envisioned for a pipe spanning this distance. There may be even scope to reduce the wall thickness to less than standard wall if calculations permit. Air Products also had concerns about putting the Air Separation plant too close to the power plant where the inlet air may be high in  $CO_2$ . This  $CO_2$  could affect the drier operation. Due to the fact that this  $CO_2$  liquefaction unit reduces gases going up the stack, there should be no problem.

The layout of the compression and liquefaction unit offers few areas to comment on. At the low-pressure section of the plant, elbows are quite large making spacing allowances on the plot plan difficult without a rigorous design being made.

Plant layout drawings for Concept B (listed below) are included in Appendix I. This new equipment requires about 5.5 acres of plot area.

#### 3.4 Concept C: CO<sub>2</sub> Separation by MEA/MDEA Absorption and De-Oxy Catalyst

Concept C is defined as a system designed for the removal and recovery of CO<sub>2</sub> from the boiler flue gas using MEA/MDEA blended amine technology. The difference between the amines used in this case and in Case A is that the mixture of amines are not oxygen resistant. Therefore, the oxygen in the flue gas is converted to  $CO_2$  by combustion with methane over a de-oxy catalyst upstream of the amine contactor.

#### 3.4.1 Overall System Description and Material and Energy Balance

A simplified process flow diagram for the modified unit is shown in Figure 3.4.1. The operation and performance of the existing Boiler, ESP, and FGD systems are identical to the Base Case and are not affected by the addition of the MEA/MDEA based  $CO_2$  removal system. The gas side material and energy balance for the Boiler Island system is shown in Table 3.4.1 below. The flue gases leaving the existing FGD system are ducted to the new de-oxy system. The de-oxy system converts the remaining oxygen contained in the flue gas to  $CO_2$  using two stages of catalytic combustion with natural gas as the fuel source. High temperature heat recovery is provided in the de-oxy system by generation of high pressure superheated steam, which is expanded through a new steam turbine for additional power generation. The exhaust from this turbine provides part of the feed for solvent regeneration in the re-boilers of the MEA/MDEA system. The de-oxygenated flue gas leaving the de-oxy system is supplied to the MEA/MDEA system where about 91 percent of the  $CO_2$  is removed, compressed, and is available for usage or sequestration. The remaining flue gases leaving the new MEA/MDEA system absorber, consisting of primarily, nitrogen, water vapor, carbon dioxide, and relatively small amounts of sulfur dioxide and methane, is discharged to the atmosphere through stacks above the absorbers.

Boiler efficiency is calculated to be 88.13 percent, the same as for the Base Case and Case A. The net plant heat rate is increased significantly to 15,223 Btu/kwhr for this case as shown in Table 3.4.2 which also includes the Base Case for comparison. The plant thermal efficiency for Case C (22.42%) is about 64 percent of the Base Case value (35.01%). Auxiliary power is increased to 95,317 kW and the net plant output is reduced to 335,973 kw. Fuel heat input to the overall system is increased by about 21 percent as compared to the Base Case due to the natural gas consumption of the de-oxy system. The fuel heat input to the boiler is the same as in the Base Case and Concept A. Carbon dioxide emissions are 92,153 lbm/hr or about 0.274 lbm/kWh which is about 13.7% of the Base Case value.

#### 3.4.2 Boiler Analysis

The existing boiler system performance in Case C is identical to that of the Base Case described previously in Section 2.3 and will not be repeated here.

#### 3.4.3 Steam Cycle Modifications and Performance

The steam cycle system for Concept C is modified as shown in Figure 3.4.2. Figure 3.4.3 shows the associated Mollier diagram for this system. About 45 percent of the IP turbine exhaust is extracted from the IP/LP crossover pipe. This steam is expanded to about 65 psia through a new letdown steam turbine generating 36,343 kw. The exhaust from the letdown turbine, at about 478 °F, is de-superheated and then provides most of the heat requirement for solvent regeneration in the re-boilers of the MEA/MDEA CO<sub>2</sub> removal system. The condensate leaving the re-boilers is split. About 20 percent of the condensate provides feedwater for the de-oxy system heat recovery steam generator system. The remainder is pumped to the Deaerator of the existing steam cycle. High temperature heat

recovery is provided in the de-oxy by the generation of high pressure superheated steam. This steam is then expanded through a second new steam turbine for additional power generation. This turbine generates 37,751 kw. The exhaust from this turbine provides about 20 percent of the feed for the re-boilers of the MEA/MDEA system. Low temperature heat recovery is provided in the de-oxy system with a low pressure feedwater heater which is located in a feedwater stream which is in parallel with the three existing low pressure extraction feedwater heaters. This heat exchanger is located in the gas stream leaving the gas to gas heat exchanger. About 92 percent of the low-pressure feedwater leaving the main condenser flows through this new heat exchanger with the remainder flowing through the existing extraction feedwater heaters. The modified existing steam cycle system produces 357,196 kw. The total output from the modified steam cycle is 431,290 kw. This represents a gross output reduction of 32,188 kW (about 7%) as compared to the Base Case.

3.4.4 Flue Gas Desulfurization System Analysis

The Flue Gas Desulfurization System performance in Case C is identical to that of the Base Case described previously in Section 2.3.5 and will not be repeated here. Table 3.4.3 identifies the assumptions that were made in predicting the FGD performance. Table 3.4.4 shows the gas constituents at the existing Absorber inlet and outlet locations. Results show a  $CO_2/SO_2$  mole ratio of 63 and an  $SO_2$  removal efficiency of 94.8%, corresponding to a value of 104 vppm at the outlet of the absorber.

## 3.4.5 Carbon Dioxide Separation and Compression System

One important aspect of this project was to evaluate a new technology to separate the  $CO_2$  with the intent of finding a more cost-effective process. Initially triethanolamine (TEA) was proposed for the solvent due to its low energy requirement to remove the absorbed  $CO_2$ . Preliminary calculations made on TEA showed that it had poor performance removing  $CO_2$  at atmospheric pressure. Calculations made on compressing the flue gas stream in order to use TEA showed that energy requirements were excessive and that a different solvent should be found. The result was that a 10/25-weight % mixture of monoethanolamine (MEA) and methyldiethanolamine (MDEA) was to be employed. This combination has the benefit of the low energy requirement for  $CO_2$  stripping of a tertiary amine with the aggressiveness to capture  $CO_2$  at atmospheric pressure of MEA. The energy requirement for the removal of  $CO_2$  (about 3.4x10<sup>6</sup> Btu per ton of  $CO_2$ ) is about 72% of what was required for Concept A with MEA. However, MDEA lacked both oxygen resistance and  $SO_2$  resistance. Thus a process had to be developed to reduce both of these components to very low levels.

Burner manufacturers, Corporate Development Labs, and Catalyst Vendors were contacted. In the end only one catalyst vendor was willing to put forth the resources to demonstrate that they could meet our process requirements. CRI Catalyst, affiliated with the Shell Oil Company, modified their NOx reduction catalyst to create a low-pressure drop surface to promote the reaction between the excess oxygen present in the flue gas and natural gas added to the mixture. In reality the bench tests were done with ethylene instead of natural gas due to availability at the testing facility. However, identical results for oxygen removal (to below 100 ppmv) with natural gas were promised by CRI. The resulting process, reflected in the following pages, shows the most thermally efficient process to get the flue gas heated above its minimum inlet temperature, 550 °F, by the use of a feed/effluent exchanger.

#### 3.4.5.1 Process Description

The numbering practice for Concept C is the same as for Concept A. The process description for the amine absorption and stripping in Concept C is essentially the same as of Concept A except that Concept C uses a less energy intensive amine than Concept A. Thus the reboiler duty will be less per unit of  $CO_2$  absorption. Also prior to selecting which amine was to be used for Concept C, it was decided to remove essentially all of the oxygen in the flue gas stream. Tertiary amines cannot tolerate oxygen and form oxalic, acetic, propionic, glycolic, and formic acids, which are corrosive. Thus, there will be no chemical injection package for Concept C. Besides the process differences, the oxygen removal steps have an impact on the material balance. The de-oxy catalyst reactor enables the injection of methane to combine with the 2.94% of the flue gas stream that is oxygen. The process of combusting methane creates 11 % more  $CO_2$  than in Concept A and also requires the addition of additional heat recovery equipment. The hydraulics of the equipment sized in Concept A were such that this volume of gas can be tolerated in the same size equipment. The hydraulics in this Concept are also helped by the fact that there is less liquid circulation required due to the higher amine concentration.

Thus the process flow for Concept C proceeds as follows:

# Flue Gas De-Oxygenation and Cooling Systems:

# Please refer to Figures 3.4.4 and 3.4.5 (drawings D 09484-01006R-0; D 09484-01007R-0)

Flue gas supplied from the existing Flue Gas Desulfurizer (FGD) is at 14.7 psia and 136 F. It goes through the Flue Gas Blower, GB-301 where it is boosted by 2.4 psi which increases its temperature to 173 °F. The flue gas is then delivered to the Bottom Direct Contact Cooler DA-2103 to be cooled to 140 °F. The heat from this process stream goes to the new cooling tower. This is done because the flow to one train is at the maximum capacity of the largest skid built by the Flue Gas Scrubber manufacturer with which there is the most experience. The gas then proceeds to Flue Gas Scrubber, D-301X, a two stage scrubbing system. The active component of the scrubbing solution is sodium sulfite, which reacts with sulfur dioxide to form sodium bisulfite. The resulting bisulfite is converted sodium sulfite with make-up caustic prior to recirculation to the scrubber. It is also equipped with a pressure control damper that maintains a constant inlet pressure to the scrubber. The scrubbing liquid used in this stage is fed to a common manifold that feeds the quench and the first stage of scrubbing. Flue gas traverses through the two-stage scrubber. The first stage includes three baffles and a Chevron type mist eliminator. In the second stage, three more baffles are encountered and scrubbing with sodium sulfite is introduced at a constant pH. The liquid level controller is used to control blowdown from the second stage to the first stage. Each section has separate pH controllers for caustic addition. The water spray in spray washing the mist eliminators also serves as make-up. The purpose of this equipment is to reduce the inlet SO<sub>2</sub> level from 108 ppmv down to 1 ppmv.

The gas then flows to a feed/ effluent exchanger, EA-301, where it exchanges heat with the de-oxy catalyst reactor effluent. Next the gas proceeds to a mixing chamber where the stochiometric quantity of natural gas required for the complete combustion of the oxygen is flow ratio controlled into the flue gas stream. A temperature of 628 °F is sufficient to start the reaction with the natural gas. The heat from the exothermic reaction is not available until the reaction has been established, so a start-up heater is also required. This heater, FH-302 is placed in series with the feed/ effluent exchanger, but it is normally turned off. It has 33 % of the duty of the feed/ effluent exchanger and is designed to initially heat the reactors using 33% of the design flow rate. The other 67 % of the flow continues to flow up the stack until the reactors reach operating temperature. However, as the gas leaving the de-oxy catalyst reactor increases in temperature as the reactors absorb the heat from the start-up heater, a larger gas flow can be put through the heater. Note that during the start-up mode natural gas is not mixed in with the flue gas.

All of the piping downstream of the feed/effluent exchanger through the start-up heater and reactor loop back to the other side of the feed effluent exchanger is refractory lined. The De-oxy Catalyst Reactor, DA-301, is refractory lined also. It is actually two reactors in parallel. This reactor is in a vertical orientation and contains two catalyst beds, each 5 feet deep, which create a pressure drop of 0.5 psi for each reactor vessel. The flow goes into the middle of each reactor and is split into to 50% streams by having symmetrical external piping and identical internals in the reactors. Half of the flow goes through the upper bed and half of the flow goes through the lower bed. The catalyst is a hollow cylinder 6-mm OD x 2.5-mm ID x 6-mm long. The de-oxygenated flue gas exits the reactor at 1209 °F. The outlet of the exchanger is cooled back to 840°F in the EA-303 and EA-304, Reactor Effluent/ Steam Superheater & Steam Generator, respectively. These heat exchangers are similar to a Heat Recovery Steam Generator (HRSG) type heat exchanger and only have about 6 inches of water pressure drop. The pressure of the steam generated is 1800 psia due to the desire to generate power. The effluent from the steam turbine, which drives the generator, provides part of the reboiler steam for solvent regeneration in the amine stripper. The flow passes from the steam generating heat exchangers to the Feed/ Effluent Exchanger, EA-301, where it cools by exchanging heat with the flue gas coming from the Flue Gas Scrubber. The effluent outlet temperature from EA-301supplies 42.4 MM-Btu/h heat to preheat the boiler feed water in each of the five trains. This heat is used to preheat low-pressure feedwater before supplying the power plant deaerator. The heat exchange takes place in the Dry Flue Gas Cooler EA-305. The gas is further cooled in Direct Contact Cooler (DCC) Flue Gas Cooler DA-2101. From the DCC cooler the gas then continues on to the CO<sub>2</sub> Absorber.

The DCC Flue Gas Cooler DA-2101 is a packed column where the hot flue gas flowing up is brought into an intimate contact with cold water which is fed to the top of the bed and flows down the tower. Physically, DA-2101, DA-2102,

and DA-2103 have been combined into a single, albeit compartmentalized tower. DA-2103 is the bottom one and will be designed to support the top portion of this column. However, since there is intervening equipment between this equipment and the DCC Flue Gas cooler, DA-2101, the top head must have an outlet nozzle added to it so that the outlet pipe can exist through the section of skirt between these two vessel sections. The top of the DCC Flue Gas Cooler is configured differently. Since the flow from it proceeds directly to the amine absorption section above it, the top head of this section serves as the bottom head for the  $CO_2$  Absorber. Effectively, this dividing head acts as a chimney tray with a number of upward extending chimneys which provide passages so the flue gas may flow directly from the DCC into the Absorber.

Theoretically, a direct contact cooler is capable of cooling the gas to a very close approach in a short bed. When the hot gas enters the DCC, it contains water but is highly superheated. At the bottom end of the bed, the gas quickly cools down to a temperature called the "Adiabatic Saturation Temperature" (AST). The AST is the temperature the gas reaches when some of its own heat content has been used to vaporize just the exact amount of water to saturate the gas.

Up to the point when the AST is reached, the mass flow of the gas stream increases due to evaporation of water. At the AST, water begins to condense. And, as the gas travels up the column and cools down further, more and more water is condensed. This internal refluxing increases the V/L traffic at the bottom end of the bed significantly beyond the external flows and must be considered in the hydraulic design.

The water stream which leaves the bottom of the DCC contains the water fed to the top as well as any water which has condensed out of the flue gas. The condensed water may be somewhat corrosive due to sulfur and nitrogen oxides that may be present in the flue gas. Therefore, instead of using the condensate in the process, it will be blown down from the system. For the DCC to be effective, the temperature of the leaving water must always be lower than the AST.

DCC Water Pump GA-2102A/B circulates most of the water leaving the bottom of the DCC back to the top of the direct contact cooler. However, before sending it back to the column the water stream is first filtered in DCC Water Filter FD-2101 and then cooled in DCC Water Cooler EA-2101. The source of this cooling water is the new cooling tower. Temperature of the cooled water is controlled by a cascade loop which maintains a constant flue gas exit temperature (Absorber feed temperature). The circulating water is cooled to 95 °F, which in turn, easily cools the gas to 115 °F.

Filtration is necessary to remove any particulate matter that may enter the DCC in the flue gas. The blowdown is taken out after the filter but before the cooler and mixed into the return water of cooler EA-2101. This way the cooler does not have to handle the extra duty that would otherwise be imposed by the blowdown.

The process description of all other equipment (CO<sub>2</sub> absorption, solvent stripping, and CO<sub>2</sub> compression and liquefaction) is essentially the same as in Concept A and will not be repeated here. Refer to Section 3.2.5.2 for the process description of this equipment. One small exception to note is a difference in the lean amine cooling. In Concept C the lean amine is cooled in two steps against cooling water downstream of the lean-rich exchanger. The warmest cooling water exchanger (EA-2208) is fed from the new cooling tower. The final cooler (EA-2202) is fed from the existing plant cooling tower. The solvent stripper CW condenser (EA-2206) also gets water from the existing plant cooling tower. Another exception for Concept C is the lean and rich amine loading. For Concept C the loadings are 0.148 mole CO<sub>2</sub>/mole of amine and 0.445 mole CO<sub>2</sub>/mole of amine for the lean and rich streams respectively. Please refer to Figures 3.4.6 and 3.4.7 (drawings D 09484-01008R-0; D 09484-01009R-0) for process flow diagrams of these systems for Concept C.

# 3.4.5.2 Process Flow Diagrams:

The processes described above for Concept C are illustrated in the following Process Flow Diagrams.

Figure 3.4.4: Drawing D 09484-01006R-0: De-Oxy System Figure 3.4.5: Drawing D 09484-01007R-0: Flue Gas Cooling and Absorption Figure 3.4.6: Drawing D 09484-01008R-0: Solvent Stripping Figure 3.4.7: Drawing D 09484-01009R-0: CO<sub>2</sub> Compression and Liquefaction

#### 3.4.5.6 Consumption of Chemicals and Desiccants

Consumption of Chemicals and Desiccants for Concept C is defined in Table 3.4.9.

Chemical	Consumption per day (lbs.)
Caustic (100%)	25200
MEA	700
Corrosion inhibitor	0
Diatomaceous earth	916
Molecular sieve	282
Sodium hypochlorite	10300
Sodium bisulfite	30

#### Table 3.4.9: Chemicals and Desiccants Consumption f or Concept C

This total does not include chemicals provided by the cooling tower service people nor disposal of waste. These are handled as a component of operating costs referred to as contracted services and waste handling, respectively.

#### 3.4.5.7 Design Considerations

The following parameters were optimized for Concept C with the objective of reducing the overall unit cost and energy requirements.

- Solvent Concentration
- Lean Amine Loading
- Rich Amine Loading
- Stripper Feed Temperature
- Absorber Temperature
- Rich /Lean Exchanger approach
- CO<sub>2</sub> Compressor interstage temperatures
- CO<sub>2</sub> Refrigeration Pressure and Temperature

A minimum of 90% recovery was targeted. The above parameters were adjusted to increase the recovery until a significant increase in equipment size and/ or energy consumption was observed. AES Corporation owns and operates a 200 STPD food grade  $CO_2$  production plant in Oklahoma. This plant was designed and built by ABB Lummus Global as a part of the larger power station complex using coal fired boilers. This plant was started up in 1990 and has been operating satisfactorily with lower than designed MEA losses. Table 3.4.10 compares key process parameters for the Concept C design with the AES design.

PROCESS PARAMETER	AEP DESIGN	AES DESIGN
	(Concept C)	
PLANT CAPACITY TPD	10372	200
CO <sub>2</sub> in Feed, % mol	15.7	14.7
O <sub>2</sub> in Feed, % mol	100 ppm	3.4
$SO_2$ in Feed, % mol	1 ppm	10 PPMV (Max)
SOLVENT	MEA/ MDEA	MEA
SOLVENT CONC. %WT	10/25	15 (Actual 17-18%Wt)

## Table 3.4.10: Key Process Parameters Comparison

#### 3.4.5.8 OSBL Systems

#### Filter Residues:

A pressure leaf filter filters a slipstream of lean amine. Diatomaceous earth is used as a filter-aid for pre-coating the leaves and as a body feed. Filter cycles depend on the rate of flow through the filter, the amount of filter aid applied, and the quantity of contaminants in the solvent. A typical composition of the filter residue is provided in Table 3.4.11 below. These will be disposed of by a contracted service hauling away the drums of spent cake.

#### Table 3.4.11: Filter Residue Composition

MEA	2.6 wt.%
Total Organic Carbon	1.5 wt.%
SiO2	0.03 wt.%
Insolubles	0.03 wt.%
РН	10.0
Specific Gravity	1.0

## Excess Solvent Stripper Reflux Water:

The  $CO_2$  Recovery Facility has been designed to operate in a manner to avoid accumulation of water in the Absorber / Stripper system. Conversely, a continuous make-up stream of water is not required either. By controlling the temperature of the scrubbed flue gas to the absorber, water balance of the MEA/MDEA system can be kept in check. Excess water can accumulate in the Stripper Reflux Drum and can be reused once the system is corrected to operate in a balanced manner. Should water need to be discarded, contaminants will include  $CO_2$  and MEA/MDEA.

#### Secondary Absorber Effluent:

The existing plant uses lime in its flue gas desulfurizer. In the cost estimate of this plant, it has been assumed that the existing plant disposal facilities can include the additional load of the secondary absorber (D-301X).

#### Cooling Tower Blowdown:

The composition limits on cooling tower blowdown are shown in Table 3.4.12:

Component	Specification
Suspended Solids	30 ppm monthly, 100 ppm daily
pH	6.5 to 9
Oil and Grease	15 ppm maximum monthly, 20 ppm maximum daily
Free Chlorine	0.035 ppm

Table 3.4. 12: Filter Residue Composition

There is a thermal limit specification for the entire river. However, the blowdown volume is too small to affect it significantly.

The relief valve discharges from the  $CO_2$  Recovery Unit are discharged to atmosphere. No tie-ins to any flare header are necessary.

#### 3.4.5.9 Plant Layout

The Concept C Plant Layout Drawings listed below are shown in Appendix I. This equipment requires about 8 acres of plot area.

U01-D-0207 Plot Plan – Concept C: De-Oxy Catalyst & Cooling U01-D-0210 Plot Plan – Concept C: Flue Gas Cooling & CO<sub>2</sub> Absorption U01-D-0215 Plot Plan – Concept C: Solvent Stripping U01-D-0206 Plot Plan – Concept C: CO<sub>2</sub> Compression & Liquefaction U01-D-0213 Plot Plan – Concept C: Overall Layout Conceptual Plan U01-D-0202R Plot Plan – Concept C: Modified Overall Site Plan

Plant layout has been designed in accordance with a spacing chart called "Oil and Chemical Plant Layout and Spacing" Section IM.2.5.2 issued by Industrial Risk Insurers.

When discussing layout, the first thing to observe is that no highly flammable materials are handled within the  $CO_2$ Recovery Unit. The open cup flash point of MEA is 200 °F and, therefore, will not easily ignite. In addition to MEA, the corrosion inhibitor is the only hydrocarbon liquid within the battery limits. The flash point of this material is higher than that of MEA and is handled in small quantities.

As the chemicals used in the process present no fire hazard, there is an opportunity to reduce the minimum spacing between equipment from that normally considered acceptable in hydrocarbon handling plants. Regardless, for the drawings that follow, standard spacing requirements, as imposed by IRI have been followed.

The plot area available for the installation of the desired equipment is small. Some equipment items are placed on structures to allow other pieces of equipment to be placed underneath them. This way pumps and other equipment associated with the Absorber can be located under the structure. Locating the pumps under the structure has been considered acceptable because the fluids being pumped are not flammable.

Noise is an issue with the flue gas fan as much as it is with compressors. Discussions with vendors suggest that it will be possible to provide insulation on the fan casing to limit noise to acceptable level. Therefore, it has been assumed that no building needs to be provided for noise reasons.

Having economized on the required plot space as noted above, it was judged not to be practical to divide up the absorbers and strippers that are required into the plot areas initially offered for this purpose (refer to Section 2.1, Figure 2.1.1). Eventually it was agreed that the units would be placed in the northeast corner of the site, about 1200-ft from the Unit 5/6 stack. By having the units all together, the flue gas duct length and MEA piping between the absorber and stripper could be minimized, although the latter impact is not nearly as important as the flue gas routing.

The caustic solution will not freeze but will become very viscous when it gets cold. It will be electric traced.

The plot plan shows a substation in the Stripper area but none for the Absorber area. The assumption is that because the electrical consumption of the Absorber equipment is small (0.23 MW) compared to the Stripper equipment, the equipment can be run directly from the auxiliary power 480 volt power system.

For the Rich/Lean Solvent Exchanger which is a plate and frame type exchanger, area estimates received from vendors based on similar conditions suggest that five units/ train be sufficient for the specified service.

# 4.0 SUMMARY OF SYSTEMS PERFORMANCE AND CARBON DIOXIDE EMISSIONS

This section summarizes overall system performance and  $CO_2$  emissions. Table 4.0.1 shows a comparison of plant performance and emissions for the three  $CO_2$  recovery concepts and the Base Case that has no  $CO_2$  recovery system.

# Table 4.0.1: Overall Plant Performance and CO<sub>2</sub> Emissions Comparison

Several comparisons have been made in this table and throughout the report. Some of the more important comparisons are summarized in this section.

#### **Boiler Performance**

All four cases were analyzed and designed based on the boiler producing a main steam flow of 3,131,619 lbm/hr at conditions of 1000 F and 2535 psia at the turbine. This main steam flow represents the maximum continuous rating (MCR) for the unit. All four cases also provided reheat steam to the turbine at conditions of 1000 °F and 590.8 psia. The boiler performance for the Base Case, Case A, and Case C was identical. Case B, while producing the same main steam flow as the other cases had a slightly lower reheat steam flow because there was less reheat spray required for this case. Boiler efficiency for Case B (90.47%) was somewhat higher than the other cases (88.13%) due primarily to the oxygen firing and the addition of the new oxygen heater and parallel feedwater heater.

#### Steam Cycles

The steam cycles for the four cases were all very different. The Base Case steam cycle is a typical steam cycle with nominal conditions of 2535 psia /  $1000 \,^{\circ}\text{F}$  /  $1000 \,^{\circ}\text{F}$ . Six extraction feedwater heaters are used. The generator in this case produces 463,478 kW.

Case A differs from the Base Case in that it extracts a large portion of steam from the IP/LP crossover pipe. The extracted steam, at about 200 psia is expanded through a new turbine generating power before exhausting into the reboilers of the  $CO_2$  recovery plant at 65 psia. The modified existing steam turbine generator produces 269,341 kW and the new turbine produces 62,081 kW for a total of 331,422 kW. The gross output is reduced by 132,056 kW, about 28 percent, for this case.

The steam cycle for Case B is quite similar to the Base Case. The system is modified slightly with the addition of a new low-pressure feedwater heater in parallel with existing extraction feedwater heaters # 52 and #53 as described in Section 3.1.2. The parallel feedwater heater (PFWH) was used to recover additional sensible heat in the flue gas as a result of reduced air heater performance with oxygen firing. The modified steam cycle system of Case B produces 463,056 kW. This is 422 kW lower than for the Base Case. The gross output for Case B is slightly lower than the Base Case due to less reheat spray being required. Nearly offsetting this is the increased output resulting from the addition of the PFWH.

Case C differs from the Base Case in that a large portion of steam is extracted from the IP/LP crossover pipe that is ultimately used for the solvent regeneration in the reboilers similar to Case A. The amount of steam extracted is however, less for Case C due to two reasons. First, less steam is required per unit of  $CO_2$  recovered and secondly, additional steam is being provided to the reboilers from the de-oxy system. The steam extracted from the existing steam turbine is expanded through a new turbine generating 36,343 kW before exhausting into the reboilers of the  $CO_2$  recovery plant at 65 psia. The high-pressure steam generated in the de-oxy system is expanded through a new turbine providing 37,751 kW of output. A parallel low-pressure feedwater heater, arranged similar to the one used in Case B, is used for low level heat recovery in the de-oxy system. The modified existing steam turbine generator produces 357,196 kW for a total gross output of 431,290 kW. The gross output is reduced by 32,188 kW, about 7 percent, for Case C as compared to the Base Case.

#### **Auxiliary Power and Net Plant Output**

The auxiliary power required for the Base Case is 29,700 kW or about 6.4 percent of the gross output. Net plant output is 433,778 kW. All three  $CO_2$  capture options require large amounts of additional auxiliary power. For Concept A (MEA) auxiliary power is increased to 76,007 kW due primarily to the addition of the  $CO_2$  compression and liquefaction system which delivers the  $CO_2$  as a liquid at 2000 psig. This system consumes 50,355 kW. The total amount of auxiliary power represents about 23 percent of the gross output. Net plant output is reduced to 255,414 kW or about 59 percent of the Base Case output. For Concept B (oxygen fired) auxiliary power is increased to 189,709 kW due primarily to the addition of the air separation unit, which consumes 95,822 kW, and the  $CO_2$  compression and liquefaction system which consumes 64,229 kW. The total amount of auxiliary power represents about 41 percent of the gross output. Net plant output is reduced to 273,347 kW or about 64 percent of the Base Case output. For Concept C (MEA/MDEA) auxiliary power is increased to 95,317 kW due primarily to the addition of the  $CO_2$  compression and liquefaction system which consumes 67,477 kW. The total amount of auxiliary power for Concept C

represents about 22 percent of the gross output. Net plant output is reduced to 335,973 kW or about 77 percent of the Base Case output. Net Plant Output values are compared below in Figure 4.0.1.

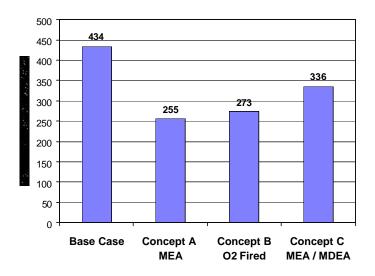

Figure 4.0. 1: Net Plant Electrical Output (Mw)

# Net Plant Heat Rate and Thermal Efficiency

Because of the large energy requirements and/or auxiliary power demands for the new equipment required for the  $CO_2$  capture systems, net plant heat rate and thermal efficiency are degraded substantially relative to the Base Case as shown in Figure 4.0.2. The Base Case plant thermal efficiency (HHV Basis) is about 35.0%, which equates to a net plant heat rate of 9,749 Btu/kwhr. Concept A, with large amounts of steam extracted for solvent regeneration and increased auxiliary power for the  $CO_2$  compression and liquefaction system, has plant thermal efficiency degraded to about 20.5% (16,626 Btu/kwhr). Concept B, with large amounts of auxiliary power for the air separation unit and the  $CO_2$  compression and liquefaction system, has plant thermal efficiency degraded to about 22.5% (15,187 Btu/kwhr). Concept C, with less steam extracted than Concept A for solvent regeneration and increased auxiliary power for the  $CO_2$  compression and liquefaction system, has plant thermal efficiency degraded to about 22.5% (15,223 Btu/kwhr). These results correspond to energy penalties of 41%, 36%, and 36% for Concepts A, B, and C, respectively.

As shown in figure 4.0.1 plant output is reduced significantly with the addition of the  $CO_2$  capture systems. Therefore replacement power is required to restore the original capacity of the unit. For cases with replacement power, it was assumed to be generated with a state-of-the-art natural gas fired combined cycle (NGCC) plant. The NGCC plant was analyzed without capturing the  $CO_2$  from its flue gas. The NGCC plant was assumed to generate power with an efficiency of 57.1 percent (LHV basis). The additional  $CO_2$  emitted from the NGCC was 0.762 lbm/kWh. The thermal efficiency of the three concepts including the replacement power systems is also shown in Figure 4.0.2. The efficiencies (HHV basis) range from about 26% to 28% with Concept B being the highest at 28.4%.

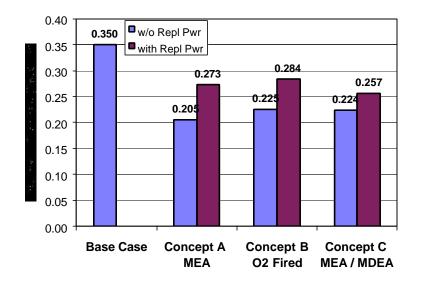

Figure 4.0. 2: Plant Thermal Efficiency (HHV Basis)

# CO<sub>2</sub> Emissions

 $CO_2$  emissions are summarized in Table 4.0.1 for the cases without replacement power. Specific carbon dioxide emissions were reduced from 1.997 lbm/kWh for the Base Case to 0.130, 0.194, and 0.274 lbm/kWh for Concepts A, B, and C, respectively. Figure 4.0.3 illustrates this comparison while also showing the  $CO_2$  captured and the avoided emissions. Figure 4.0.4 compares specific  $CO_2$  emissions both with and without replacement power. Recovery of  $CO_2$  ranged from 91 to 96%. Normalized specific  $CO_2$  emissions for Concepts A, B, and C respectively (without Replacement Power), were 6.5, 9.7, and 13.7 percent of the Base Case value.

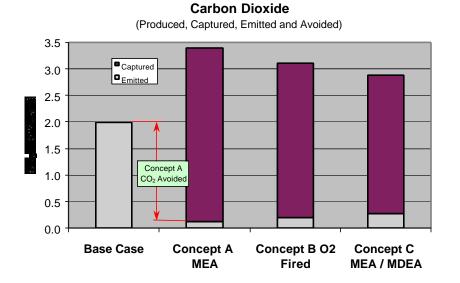

Figure 4.0. 3: Carbon Dioxide Distribution (without replacement power)

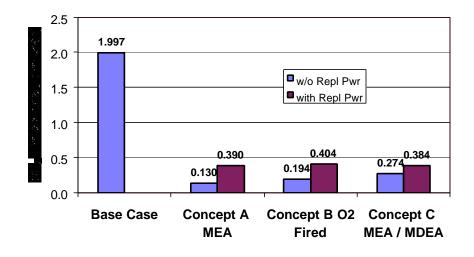

Figure 4.0. 4: Specific Carbon Dioxide Emissions

# 5.0 COST ANALYSIS

The project capital cost estimates, including engineering, procurement and construction (EPC basis), are shown in this section. These costs include all required equipment such as the amine-based  $CO_2$  scrubbing systems of Concepts A and C, the modified FGD system of Concept A, the De-Oxy system of Concept C, the  $CO_2$  compression and liquefaction systems for all three concepts, steam cycle modifications for all concepts, and the air separation unit and the boiler island modifications of Concept B. Boiler island modifications for Concept B are relatively small and include costs for such items as oxygen and gas ducts and dampers, booster fans, parallel feedwater heaters and piping, oxygen heater, and controls and instrumentation.

All these  $CO_2$  capture options produce less net plant power output than the original plant (Base Case). Therefore, costs for replacement power to make up this difference were also calculated. Economic analyses discussed in Section 6 were done both with and without replacement power. For cases with replacement power, it was assumed to be generated with a state-of-the-art natural gas fired combined cycle (NGCC) plant. The NGCC plant cost and performance were developed without capturing the  $CO_2$  from its flue gas.

Operating and maintenance (O&M) costs were calculated for all systems. The O&M costs for the Base Case were provided by American Electric Power (AEP). For the retrofit CO<sub>2</sub> capture system evaluations, additional O&M costs were calculated for the new equipment. The variable operating and maintenance (VOM) costs for the new equipment included such categories as chemicals and desiccants, waste handling, maintenance material and labor, and contracted services. The fixed operating and maintenance (FOM) costs for the new equipment includes operating labor only.

# 5.1 Cost Estimation Basis

The following assumptions were made in developing these cost estimates for each concept evaluated:

- Outdoor installation
- Investment in new utility systems is outside the scope
- CO<sub>2</sub> pipeline is outside the scope
- No special limitations for transportation of large equipment
- No protection against unusual airborne contaminants (dust, salt, etc.)
- No unusual wind storms
- No earthquakes
- No piling required
- All releases can go to atmosphere no flare provided
- CO<sub>2</sub> Pump designed to API standards, all other pumps conform to ANSI
- All heat exchangers designed to TEMA "C"
- All vessels are designed to ASME Section VIII, Div 1.
- Annual operating time is 5870 h/yr.
- The investment cost estimate was developed as a factored estimate based on in-house data for the major equipment. Such an estimate can be expected to have accuracy of +/-30%.
- No purchases of utilities or charges for shutdown time have been charged against the project.

Other exclusions from the cost estimate are as follows:

- Soil investigation
- Environmental Permits
- Disposal of hazardous or toxic waste
- Disposal of existing materials
- Custom's and Import duties
- Sales/ Use tax.
- Forward Escalation
- Capital spare parts
- Chemical loading facilities

- Buildings except for Compressor building and electrical substation.
- Financing cost
- Owners cost
- Guards during construction
- Site Medical and Ambulance service
- Cost & Fees of Authorities
- Overhead High voltage feed lines
- Cost to run a natural gas pipeline to the plant (Concept 3C)
- Excessive piling
- Contingency and risk

# 5.2 Boiler Modification Costs

Boiler modification costs for these three  $CO_2$  capture options are relatively minor as compared to the other new equipment required. For this project the Boiler Scope is defined as everything on the gas side upstream of the FGD System. Therefore it includes equipment such as fans, ductwork, ESP, air heater, steam generator, pulverizers, coal and ash handling systems, etc. Not included in the boiler scope is the FGD system. The FGD system modification costs are shown separately in Section 5.4. For Concepts A and C, the Boiler Scope is not modified from the Base Case configuration and as such there are no costs in this category. Concept B Boiler Scope modifications were described in Section 3.3.4 and include such items as sealing the boiler for air leaks, new ductwork dampers and fans for the recirculated flue gas, oxygen heater, parallel low-pressure feedwater heater, and modified controls and instrumentation. The total cost required for the boiler scope modifications of Concept B is \$7,000,000. This estimate includes material, engineering and construction. The expected level of accuracy for this budget level cost estimate is +/-30%.

# 5.3 Carbon Dioxide Separation and Compression System Costs

5.3.1 Concept A

#### **Investment Cost**

Table 5.3.1 shows investment costs for the Concept A  $CO_2$  Separation and Compression System. Included in this table (Acc't. Code - 14200) are the steam cycle modification costs as well as the new letdown turbine and associated electric generator. The steam cycle modifications were described in Section 3.2.3. The Total Installed Cost (TIC) of this equipment is \$393,325,000. The expected level of accuracy for this budget level cost estimate is +/- 30%.

Operating Labor**	0	1,380,000**
Contracted Services	1,202,000	
Column Totals	25,155,920	1,380,000
Total (Fixed + Variable)		26,535,920

\*Included with heat rate reduction, operating expense included with power plant modifications operating cost. \*\* Operating labor is 365 days/ year, all other numbers are variable costs and are based on 245 days/ yr.

#### 5.4 Flue Gas Desulfurization System Modification Costs

Flue Gas Desulfurization System modification costs for these three  $CO_2$  capture options are relatively minor as compared to the other new equipment required. For Concepts B and C, the existing Flue Gas Desulfurization System is not modified from the Base Case configuration and as such there are no costs in this category. The Concept A Flue Gas Desulfurization System modifications, which include the addition of a secondary absorber island, building, booster fan, and ductwork, are described in Section 3.2.4. The total cost required for the Flue Gas Desulfurization System scope modifications of Concept A is \$15,800,000. This estimate includes material, engineering and construction. The expected level of accuracy for this cost estimate is +/-10%.

# 5.5 Charges for Loss of Power during Construction and Operation of the Modified Power Plant System

During the construction period it is assumed the existing Unit No. 5 power plant will be operated in its normal way. The new  $CO_2$  capture equipment is being located some 1500 feet from the Unit No. 5/6 stack (see Appendix I for plant layout drawings) and as such will not impede operation of Unit No. 5 or any of the other units on site. Once construction is completed it has been assumed the final connections between the  $CO_2$  capture systems and the existing power plant can be completed during the annual outage for the unit. Final shake down testing will be completed after the outage.

During plant operation, all these  $CO_2$  capture options produce less net plant output at full load than the original plant (Base Case). Therefore, each concept was analyzed with replacement power to make up for this difference. For cases with replacement power, it was assumed to be generated with a state-of-the-art natural gas fired combined cycle (NGCC) plant. The NGCC plant performance and cost was calculated assuming the  $CO_2$  from its flue gas was not captured. The NGCC plant was assumed to cost \$450/kW, installed. Table 5.5.1 shows the NGCC outputs and costs for the three  $CO_2$  capture concepts.

	Concept A	Concept B	Concept C
NGCC Power Output (kW)	178,363	160,430	97,805
NGCC Installed Cost (\$ x 1000)	80,264	72,194	44,012

Table 5.5.1:	NGCC Outputs and Costs for Replacement Power
--------------	----------------------------------------------

# 5.6 Summary of Total Plant Investment Costs

Table 5.6.1 summarizes the total retrofit investment costs required for each of the three Concepts. Two costs are shown for each concept, one with and one without replacement power. Figure 5.6.1 shows the specific investment costs (\$/kW) for the three concepts without replacement power. Two costs are given for each of the three concepts in this figure. The bars on the left are relative to the new plant output and the bars on the right are relative to the original plant output. Figure 5.6.2 shows the specific investment costs (\$/kW) for the three concepts with replacement power These costs were used in the economic evaluation (Section 6) to develop incremental Cost of Electricity values and comparisons.

CO <sub>2</sub> Capture Concept	Units	w/o Repl Pwr	with Repl Pwr	
Concept A	10 <sup>6</sup> US\$	409	489	
	\$/kW	1602	1128	
Concept B	10 <sup>6</sup> US\$	285	357	
	\$/kW	1042	823	
Concept C	10 <sup>6</sup> US\$	738	782	
	\$/kW	2197	1803	

 Table 5.6.1:
 Total Retrofit Investment Capital Costs

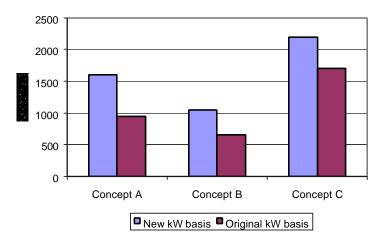

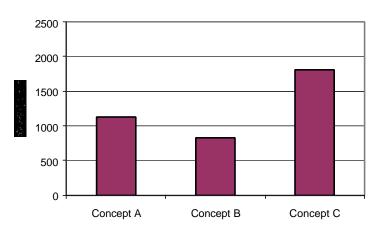

Figure 5.6. 1: New Equipment Specific Investment Costs (Without Replacement Power)

# 6.0 ECONOMIC ANALYSIS

A comprehensive economic evaluation comparing the Base Case study unit and the three retrofit CO<sub>2</sub> capture concepts (A - MEA absorption,  $B - O_2$  Fired with flue gas recycle, and C - MEA/MDEA absorption) was performed. The purpose of the evaluation was to quantify the impact of CO<sub>2</sub> capture on the Cost of Electricity (COE) of this existing coal fired unit. CO<sub>2</sub> mitigation costs were also determined in this analysis. The economic evaluation results are presented as incremental Costs of Electricity (first full year of operation basis). The first year basis is quite representative (at least for the input assumptions used in this study) as the post modification COE for year 10 is only about 7% greater than for year 1. The incremental costs of electricity are incremental relative to the Base Case (air fired without CO<sub>2</sub> capture, i.e., business as usual). Each CO<sub>2</sub> capture option was evaluated both with and without replacement power. Since all these CO<sub>2</sub> capture options produce less net plant output than the original plant (Base Case), the replacement power exactly represents this difference. For cases with replacement power, it was assumed to be generated with a state-of-the-art natural gas fired combined cycle (NGCC) plant. The NGCC plant was analyzed without CO<sub>2</sub> capture from its flue gases. Additionally, economic sensitivity studies were developed for the six primary cases (each of the CO<sub>2</sub> capture options with and without replacement power) to highlight which parameters affected the COE to the greatest extent. A total of 66 economic evaluation cases are reported.

The model used to perform the economic evaluations was the proprietary ALSTOM Power Plant Laboratories' Project Economic Evaluation Pro-Forma. This cash flow model, developed by the Company's Project & Trade Finance group, has the capability to analyze the economic effects of different technologies based on differing capital costs, operating and maintenance costs, fuel costs, and cost of capital assumptions. Various categories of results are available from the model. In addition to cost of electricity, net present value, project internal rate of return, payback period, and other evaluation parameters are available.

In performing the economic evaluations, numerous assumptions were required. Table 6.0.1 lists the primary assumptions used in this analysis.

<b>-</b>								
Economic Assumptions			Financing Terms					
NPV Cash Discount Rate	percent	12.0	Equity	percent	50.0			
Depreciable Life	years	15	Debt	percent	50.0			
			Interest on Loan (APR)	percent	9.0			
Project Schedule			Term of Loan	years	15			
Project Start	date	9/1/01	Return on Equity	percent	12.0			
Construction Period	months	30						
Evaluation Period	years	15	Fuel Information					
			Coal Cost	\$/10 <sup>6</sup> Btu	1.32			
Variable Operating Costs	(Non-Fuel)		Natural Gas Cost	\$/10 <sup>6</sup> Btu	4.00			
Lime Cost (Delivered)	\$/Ton	60						
Ash Disposal Cost	\$/Ton	14						
			Plant Information					
Revenue Information			Capacity Factor	percent	67.0			
Electricity Price	\$/MWhr	32.00	Remaining Operating Life	years	20			
CO <sub>2</sub> Market Price	\$/Ton	0.0	Fixed O&M Costs	\$/kw	16.0			

Table 6.0.1:	<b>Economic Evaluation Study Assumptions</b>
--------------	----------------------------------------------

The following list defines additional assumptions used in all Replacement Power Cases.

- Power Generation Technology: Natural Gas fired Combined Cycle (NGCC) without CO<sub>2</sub> capture
- NGCC Net Plant Heat Rate (HHV basis): 6640 Btu/kWh (GTW, 1998-1999)
- NGCC Net Plant Efficiency (LHV basis): 57.1 percent
- NGCC Investment Cost; Engineered, Procured, Constructed basis (EPC): 450 \$/kW
- NGCC Fixed O&M Cost: 16.92 \$/kW-yr
- NGCC Variable O&M Cost: 0.01 Cents/kWh

As is evident from the above list, the NGCC replacement power calculations were identical for all cases with the only difference between cases being the scaling of various items required for the economic evaluation as a function of output requirement. In other words a "rubber NGCC" was assumed with performance, O&M costs, and specific investment costs assumed constant and not a function of output. This was done such that all economic differences between the cases would be completely attributable to the  $CO_2$  capture technology employed and not influenced by changes in NGCC specific costs, or performance, resulting from economy of scale.

The Economic Sensitivity Study was performed for each of six primary cases. The six primary cases include two cases each for Concepts A, B, and C (one case with and one case without replacement power). The sensitivity study shows the effect on incremental COE and on  $CO_2$  mitigation cost of variations in five parameters of interest.  $CO_2$  mitigation costs were calculated according to Equation (6.1) below. The five parameters varied in this study were investment cost (which included the new  $CO_2$  capture equipment, replacement power equipment, and the book value of the existing plant), coal cost, natural gas cost, capacity factor, and  $CO_2$  byproduct sell price. Eleven evaluations were done for each of the six cases providing a total of 66 economic evaluations from the overall sensitivity study. Table 6.0.2 shows the ranges for each of the five parameters varied in the sensitivity study. Three points were calculated for each parameter (Base Value, Minimum, and Maximum).

$$Mitigation \ Cost = (COE_{Cp} - COE_{Ref}) / (CO_{2 \ Ref} - CO_{2 \ Cp})$$
(6.1)

Where:

Mitigation Cost = \$/Ton of CO<sub>2</sub> Avoided COE = Cost of Electricity (\$/kWh) CO<sub>2</sub> = Carbon Dioxide Emitted (Ton/kWh) Cp = Capture Plant Ref = Reference Plant

Parameter	Units	Base Value	Minimum	Maximum
Investment Cost	\$	as estimated	Base - 25%	Base + 25%
Fuel Cost (Coal)	\$/MMBtu	1.32	1.00	1.60
Fuel Cost (Natural Gas)	\$/MMBtu	4.00	3.00	5.00
Capacity Factor	Fraction	0.67	0.60	0.75
CO <sub>2</sub> Byproduct Sell Price	\$/ton	0.00	10.00	20.00

 Economic Sensitivity Study Parameters

# 6.1 Concept A Results: CO<sub>2</sub> Separation with Monoethanolamine (MEA) Absorption

This section shows the economic analysis results for Concept A,  $CO_2$  separation with Monoethanolamine Absorption. Results both with and without replacement power are reported including sensitivity results.

#### 6.1.1 Concept A Results without Replacement Power

Figure 6.1.1 shows the economic analysis results using the base parameter values for Concept A (MEA) as compared with the Base Case (air fired without  $CO_2$  capture). This analysis was done without replacement power. The first year incremental cost of electricity for this case was about 6.17 Cents/kWh greater than the Base Case COE.

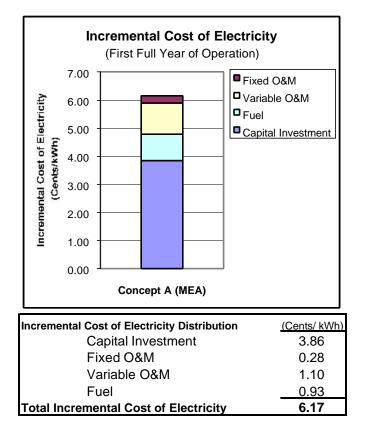

Figure 6.1. 1: Concept A (MEA) Economic Results without Replacement Power

Results for the Concept A sensitivity study, without replacement power, are shown in Table 6.1.1 and Figure 6.1.2. This table and the associated figure show the sensitivity of incremental COE to coal cost, natural gas cost, capacity factor,  $CO_2$  byproduct sell price, and new equipment installed capital cost. Results for the Base parameter values (i.e., Coal Cost =  $1.32 \ \text{s}/10^6$  Btu, Natural Gas Cost =  $4.0 \ \text{s}/10^6$  Btu, Capacity Factor = 67%,  $CO_2$  Byproduct Sell Price =  $0.0 \ \text{s}/\text{Ton}$ , Investment Cost = As Estimated) are shown above in Figure 6.1.1. The base parameter values also represent the point in Figure 6.1.2 where all the sensitivity curves intersect (point 0.0, 0.0). Incremental COE ranges from a low of 2.90 to a high of 7.25 cents/kWh. The most sensitive parameters are  $CO_2$  byproduct sell price, capital cost and capacity factor, in that order, with coal cost and natural gas cost showing significantly less impact on incremental COE.  $CO_2$  mitigation costs ranged from 31-73 \$/Ton of  $CO_2$  avoided with the baseline value at 66 \$/Ton of  $CO_2$  avoided.

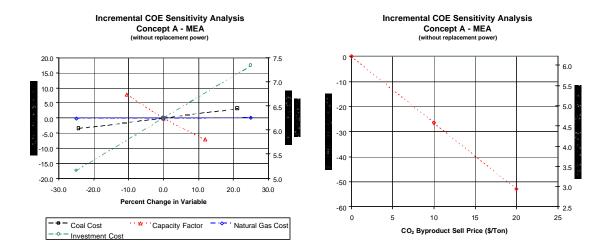

Figure 6.1. 2: Concept A (MEA) Economic Sensitivity Results without Replacement Power

## 6.1.2 Concept A Results with Replacement Power

Figure 6.1.3 shows the economic analysis results using the base parameter values for Concept A (MEA) with replacement power as compared with the Base Case. The first year incremental cost of electricity for this case was about 4.25 Cents/kWh greater than the Base Case COE.

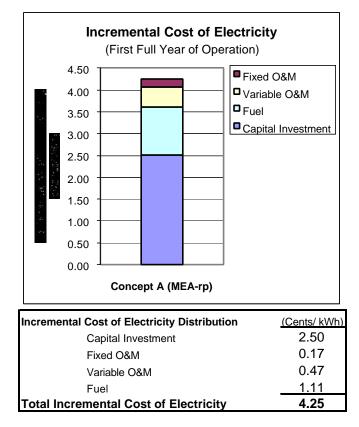

Figure 6.1. 3: Concept A (MEA) Economic Results with Replacement Power

Results for the Concept A sensitivity study, with replacement power, are shown in Table 6.1.2 and Figure 6.1.4. Incremental COE ranges from a low of 2.33 to a high of 4.99 cents/kWh. The most sensitive parameters again are  $CO_2$  byproduct sell price, investment cost and capacity factor, in that order. Natural gas cost shows significantly more impact on incremental COE when replacement power is included as would be expected with the NGCC being used to generate the replacement power. Coal cost, on the other hand, has no impact on incremental COE with replacement power since both the Base Case and Concept A use the same amount of coal and the net electrical output is also the same.  $CO_2$  mitigation costs ranged from 29-73 \$/Ton of  $CO_2$  avoided with the baseline value at 53 \$/Ton of  $CO_2$  avoided.

# 6.2 Concept B Results: CO<sub>2</sub> Separation with Oxygen Firing and Flue Gas Re-circulation

This section shows the economic analysis results for Concept B, CO<sub>2</sub> Separation with Oxygen Firing and Flue Gas Re-circulation. Results both with and without replacement power are also reported along with sensitivity results.

6.2.1 Concept B Results without Replacement Power

Figure 6.2.1 shows the economic analysis results using the base parameter values for Concept B (Oxygen Fired) as compared with the Base Case (air fired without  $CO_2$  capture). This analysis was done without replacement power. The first year incremental cost of electricity for this case was about 4.45 Cents/kWh greater than the Base Case COE.

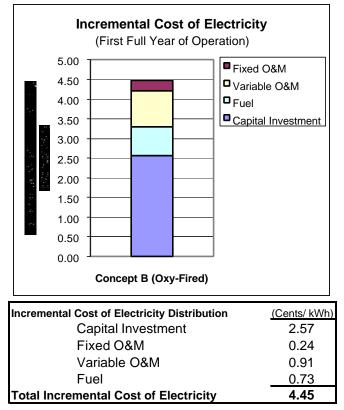

Figure 6.2. 1: Concept B (Oxygen Fired) Economic Results without Replacement Power

Results for the Concept B sensitivity study, without replacement power, are shown in Table 6.2.1 and Figure 6.2.2. Incremental COE ranges from a low of 1.53 to a high of 5.20 cents/kWh. The most sensitive parameters are, again,  $CO_2$  byproduct sell price, investment cost and capacity factor, in that order, with coal cost and natural gas cost showing significantly less impact on incremental COE.  $CO_2$  mitigation costs ranged from 17-58 \$/Ton of  $CO_2$  avoided with the baseline value at 49 \$/Ton of  $CO_2$  avoided.

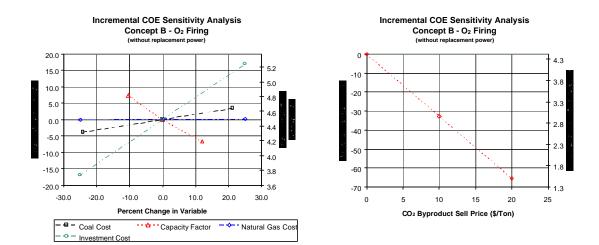

Figure 6.2. 2: Concept B (Oxygen Firing) Economic Sensitivity Results without Replacement Power

## 6.2.2 Concept B Results with Replacement Power

Figure 6.2.3 shows the economic analysis results using the base parameter values for Concept B (Oxygen Firing) with replacement power as compared with the Base Case. The first year incremental cost of electricity for this case was about 3.35 Cents/kWh greater than the Base Case COE.

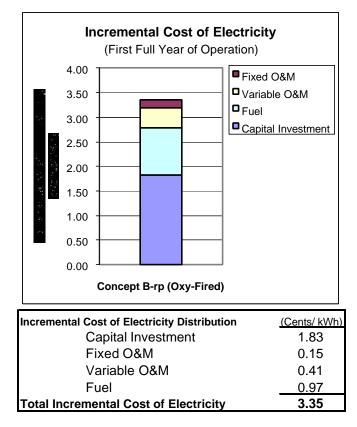

Figure 6.2. 3: Concept B (Oxygen Firing) Economic Results with Replacement Power

Results for the Concept B sensitivity study, with replacement power, are shown in Table 6.2.2 and Figure 6.2.4. Incremental COE ranges from a low of 1.52 to a high of 3.92 cents/kWh. The most sensitive parameters, again, are  $CO_2$  byproduct sell price, investment cost and capacity factor, in that order. Natural gas cost shows significantly more impact on incremental COE when replacement power is included as would be expected with the NGCC being used to generate the replacement power. Coal cost, on the other hand, shows minimal impact on incremental COE with replacement power since both the Base Case and Case A use nearly the same amount of coal and the net electrical output is exactly the same.  $CO_2$  mitigation costs ranged from 19-49 \$/Ton of  $CO_2$  avoided with the baseline value at 42 \$/Ton of  $CO_2$  avoided.

## 6.3 Concept C Results: CO<sub>2</sub> Separation with MEA / MDEA

This section shows the economic analysis results for Concept C, CO<sub>2</sub> Separation with MEA / MDEA absorption. Results both with and without replacement power are reported along with sensitivity results. 6.3.1 Concept C Results without Replacement Power

Figure 6.3.1 shows the economic results using the base parameter values for Concept C (MEA /MDEA) as compared with the Base Case (air fired without  $CO_2$  capture). This analysis was done without replacement power. The first

year incremental cost of electricity for this case was about 8.41 Cents/kWh greater than the Base Case COE.

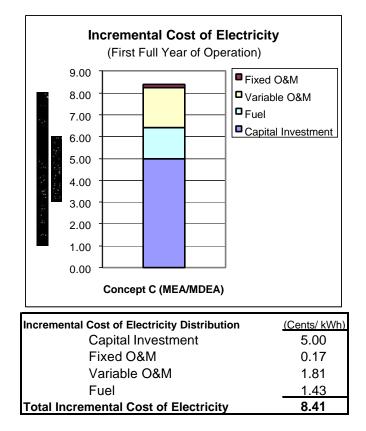

Figure 6.3. 1: Concept C (MEA/MDEA) Economic Results without Replacement Power

Results for the Concept C sensitivity study, without replacement power, are shown in Table 6.3.1 and Figure 6.3.2. Incremental COE ranges from a low of 5.93 to a high of 9.77 cents/kWh. The most sensitive parameters are  $CO_2$  byproduct sell price, investment cost and capacity factor with coal cost and natural gas cost showing significantly less impact on incremental COE.

CO<sub>2</sub> mitigation costs ranged from 69-113 \$/Ton of CO<sub>2</sub> avoided with the baseline value at 98 \$/Ton of CO<sub>2</sub> avoided.

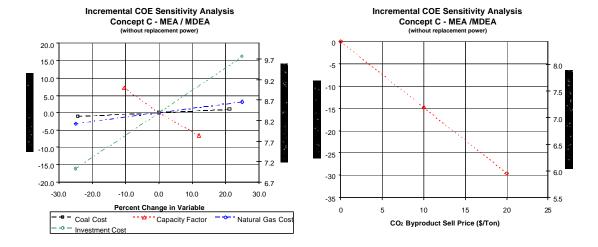

Figure 6.3. 2: Concept C (MEA/MDEA) Economic Sensitivity Results without Replacement Power

## 6.3.2 Concept C Results with Replacement Power

Figure 6.3.3 shows the economic analysis results using the base parameter values for Concept C (MEA / MDEA) with replacement power as compared with the Base Case. The first year incremental cost of electricity for this case was about 6.61 Cents/kWh greater than the Base Case COE.

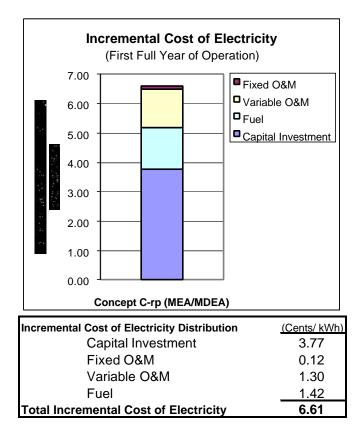

Figure 6.3. 3: Concept C (MEA/MDEA) Economic Results with Replacement Power

Results for the Concept C sensitivity study with replacement power are shown in Table 6.3.2 and Figure 6.3.4. Incremental COE ranges from a low of 4.69 to a high of 7.66 cents/kWh. The most sensitive parameters again are  $CO_2$  byproduct sell price, investment cost and capacity factor. Natural gas cost shows significantly more impact on incremental COE when replacement power is included as would be expected with the NGCC being used to generate the replacement power. Coal cost, on the other hand, shows minimal impact on incremental COE with replacement power since both the Base Case and Case A use the same amount of coal and the net electrical output is exactly the same.

CO<sub>2</sub> mitigation costs ranged from 58-95 \$/Ton of CO<sub>2</sub> avoided with the baseline value at 82 \$/Ton of CO<sub>2</sub> avoided.

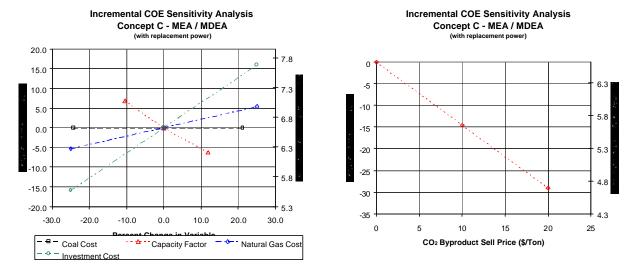

Figure 6.3. 4: Concept C (MEA/MDEA) Economic Sensitivity Results with Replacement Power

## 6.4 Economic Study Summary and Conclusions

A total of 66 CO<sub>2</sub> capture cases were compared in the reported sensitivity studies. All cases studied indicate significant increases to the COE as a result of CO<sub>2</sub> capture. The incremental COE as compared to the Base Case (air firing without CO<sub>2</sub> capture) ranges from 1.52 to 9.77 Cents/kWh. Similarly CO<sub>2</sub> mitigation costs range from about 17-113 \$/Ton of CO<sub>2</sub> avoided for the range of cases studied. Table 6.4.1 summarizes the economic analysis results for the six primary cases using base parameter values (i.e.; Coal Cost =  $1.32 \,$ \$/10<sup>6</sup> Btu, Natural Gas Cost =  $4.0 \,$ \$/10<sup>6</sup> Btu, Capacity Factor = 67%, CO<sub>2</sub> Byproduct Sell Price = 0.0 \$/Ton, Investment Cost = As Estimated). Figure 6.4.1 shows the incremental COE values for these cases and similarly, Figure 6.4.2 shows the associated CO<sub>2</sub> mitigation costs.

 Table 6.4.1:

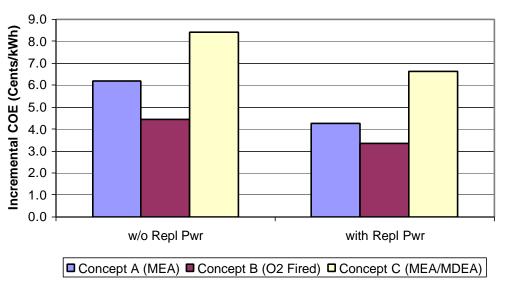

Figure 6.4. 1: Incremental Cost of Electricity (Using Base Parameter Values)

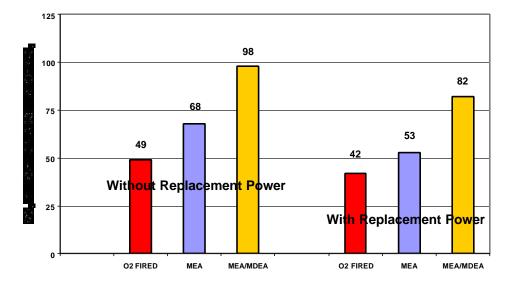

Figure 6.4. 2: Co<sub>2</sub> Mitigation Costs (Using Base Parameter Values)

Concept B (oxygen firing with flue gas recycle) appears to clearly be the best alternative of the three concepts studied based on incremental COE evaluation criteria. Using the base parameters of the sensitivity study for Concept B yields incremental COE values of 3.35 and 4.45 Cents/kWh for cases with and without replacement power, respectively. The actual COE values for Concept B are 20% and 13% lower than the corresponding values for Concept A and 47% and 51% lower than the corresponding values for Concept C for cases with and without replacement power respectively. If  $CO_2$  byproduct can be sold at \$20/ton, incremental COE values are reduced to 1.53 and 1.52 Cents/kWh, respectively. Additional reductions would be possible with capacity factor increases, investment cost decreases or system efficiency increases. Significant investment cost decreases and efficiency increases may be possible as oxygen transport membrane technology develops. Previous internal studies (Liljedahl, et al., 1999) have shown membrane technology to provide specific investment cost (\$/kW) reductions of about 30% and net plant heat rate improvements greater than 20%.

Barring governmental mandates, it is clear that none of these three retrofit concepts will be acceptable to the electric utility industry from the standpoint of cost competitiveness.

# 7.0 COMPARISONS WITH PRIOR WORK

This section provides a comparison of the basic performance,  $CO_2$  emissions, investment costs, and cost of electricity results of this study with selected results from the literature (David and Herzog, 2000; Palkes, et al., 1999; and Liljedahl, et al., 1999). Table 7.0.1 summarizes the pertinent technical results determined in this study (Marion, et al., 2001; Griffin, et al., 2001; and Liljedahl, et al., 2001).

Figures 7.0.1 and 7.0.2 compare net plant heat rates and  $CO_2$  emissions for this study with selected results from the literature (David and Herzog, 2000; Palkes, et al., 1999; and Liljedahl, et al., 1999). This study shows a significantly greater impact on net plant heat rate, for the MEA process, than David and Herzog show. David and Herzog show about a 33% increase in net plant heat rate (e.g. 8,277 vs. 11,037 Btu/kWh; LHV basis) corresponding to an energy penalty of about 25%. This study shows about a 70% increase in net plant heat rate for the MEA system (e.g. 9,309 vs. 15,872 Btu/kWh; LHV basis) corresponding to an energy penalty of about 41%. A partial explanation for this difference can be seen in Figure 7.0.2, which shows specific  $CO_2$  emissions. The present work shows significantly higher  $CO_2$  removal (e.g., 0.906 to 0.059 kg/kWh) than David and Herzog show (e.g. 0.789 to 0.105 kg/kWh). Using the  $CO_2$  emission and heat rate values from these figures, it can be determined that the  $CO_2$  captured for the David and Herzog study is about 23% more  $CO_2$  per unit of original net electrical output). Additionally, this study produced a liquid  $CO_2$  product stream at 2000 psig with product purity meeting the Dakota Gasification Project specification for EOR (Dakota Gasification WebPages). The David and Herzog product stream was reported at 1470 psia and the details regarding purity are not given although purity is probably similar in both cases. Both these differences would help explain at least partially, the efficiency penalty deviation between the two studies.

## Table 7.0.1: Summary of Performance for Original Plant and CO<sub>2</sub> Capture Study Cases

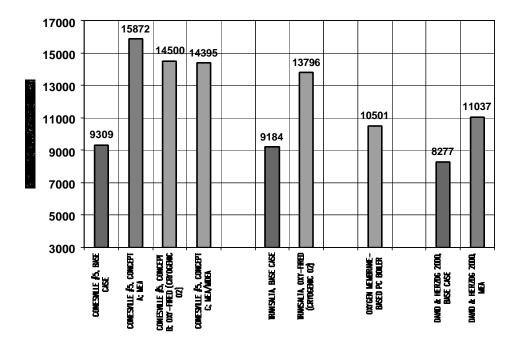

Figure 7.0. 1: Comparative Net Plant Heat Rate Results for Coal Fired Power Plants

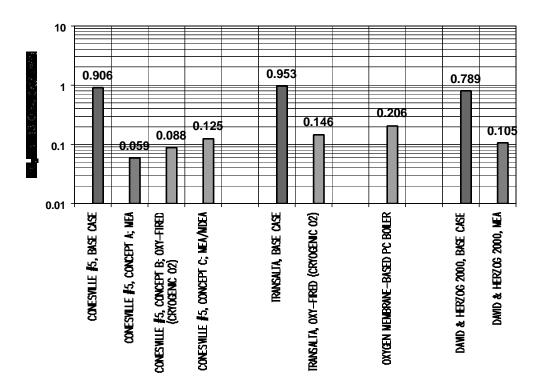

Figure 7.0. 2: Comparative CO<sub>2</sub> Emissions for Coal Fired Power Plants

Investment costs are also significantly different between the studies. David and Herzog (2000) show the cost of the  $CO_2$  processing plant to be about 529 \$/kg/hr of  $CO_2$ . This study shows 1,037 \$/kg/hr of  $CO_2$  for this equipment. The differences in the  $CO_2$  product conditions and purity, discussed above, may represent part of this deviation. Additionally, for this retrofit study, the steam extracted from the existing steam turbine at the IP/LP crossover pipe had to be further expanded in a new letdown turbine before being exhausted to the reboilers for solvent regeneration. The David and Herzog study was for a new plant and therefore may not have required this letdown turbine/generator and the investment cost associated with it. Not enough information is given in their paper to determine if a letdown turbine is used in their particular system. Other savings may also possible for a new plant designed specifically for  $CO_2$  removal. The steam turbine and generator may be significantly less expensive than for a reference plant designed for the same steam flow as a result of the large quantity of extracted low-pressure steam. The low-pressure feedwater heaters and condenser would also be significantly smaller and less expensive. David and Herzog show the incremental capital cost for a new plant, as compared to the reference plant without  $CO_2$  capture, to be about 940 \$/kW as compared to this study, for a retrofit situation, which shows about 1,600 \$/kW.

Ultimately David and Herzog show the incremental cost of electricity to be about 3.3 Cents/kWh as compared to Concept A (MEA) of this study, which shows about 6.2 Cents/kWh. Financial assumptions, while probably not identical for both cases, would likely not cause a large impact on this difference.

With respect to oxy-fuel firing (Palkes, et al., 1999; Liljedahl, et al., 1999), it is seen that producing the oxygen in a ceramic membrane system leads to an improvement in net plant heat rate of more than 20% over the cases whereby the cryogenic method is used to produce oxygen (e.g., 10,501 vs. 13,796 Btu/kWh).  $CO_2$  emissions are somewhat higher with the membrane system (e.g. 0.206 vs. 0.146 kg/kWh) due to natural gas firing in the membrane system air heater. Investment costs were shown to be more than 30% lower. Cost of electricity was not reported in this study.

# 8.0 CONCLUSIONS AND RECOMMENDATIONS FOR FUTURE WORK

## **Conclusions:**

No major technical barriers exist for retrofitting AEP's Conesville Unit #5 to capture  $CO_2$  for any of the three concepts considered under this study. Nominally, 5-8 acres of new equipment space is needed and is located approximately 1500 feet north of the Unit #5 stack on the existing 200-acre power plant site which accommodates a total of 6 units. If all 6 units on this site were converted to  $CO_2$  capture, it would be difficult if not impossible to accommodate all the new  $CO_2$  capture equipment on the existing site. Energy requirements and power consumption are high, resulting in significant decrease in overall power plant efficiencies, ranging from about 20.5 to 23% as compared to 35% (all HHV basis) for the Base Case. Specific carbon dioxide emissions were reduced from about 2 lbm/kWh for the Base Case to 0.12 - 0.26 lbm/kWh for the study cases. Recovery of  $CO_2$  ranged from 91 to 96%.

Specific investment costs are also high ranging from about 1000 to 2200 k without replacement power, and from about 800 to 1800 k with replacement power. All cases studied indicate significant increases to the COE as a result of CO<sub>2</sub> capture. The incremental COE as compared to the Base case (air firing without CO<sub>2</sub> capture) ranges from 3.4 to 8.4 k wh. Similarly CO<sub>2</sub> mitigation costs range from about 42-98 t of CO<sub>2</sub> avoided for the range of cases studied.

Concept B (oxygen firing with flue gas recycle) appears to clearly be the best alternative of the three concepts studied from both an efficiency and incremental COE viewpoint for systems designed for very high CO<sub>2</sub> capture (i.e. > 90%). If lower CO<sub>2</sub> capture fractions are considered, it appears that Concept A would likely be the best alternative with capture fractions below some as yet undetermined value. Concept C would also improve considerably with lower capture fractions. This study has confirmed two important issues related to firing coal in a CO<sub>2</sub> -rich flue gas /O<sub>2</sub> mixture:

- Modifications to the existing steam generator unit pressure parts are not required, and as such will also allow the unit to continue to operate in the conventional air fired mode. This is an important consideration as it is unlikely that much new coal-fired capacity can be built in the short term.
- CO<sub>2</sub>-rich flue gas can be cleaned and compressed with a relatively simple system to provide high purity CO<sub>2</sub> for usage or sequestration.

While overall plant performance penalty and investment costs are high, an optimum integration of power generation, air separation, and  $CO_2$  separation and compression systems may significantly improve the overall system efficiency and economics. The major cost item for Concept B is the air separation plant, both from a capital and an operating cost point of view. While in recent years advances have been made in air separation technology which have steadily improved the costs, new membrane based technologies are being researched which promise to provide greatly reduced auxiliary power requirements and investment costs which will significantly improve the overall system efficiency and economics. Previous studies (Liljedahl, et al., 1999) have shown membrane technology, applied to coal-fired boilers, to provide specific investment cost (k/kW) reductions of about 30% and net plant heat rate improvements greater than 20% as compared to cryogenic based air separation.

## **Recommendations for Future Work:**

- A sensitivity study, for Concepts A and C, showing the impact of reducing CO<sub>2</sub> capture percentage on plant efficiency, investment cost, emissions, and cost of electricity. The current work utilized 90% CO<sub>2</sub> capture (nominal). The sensitivity study would investigate nominal CO<sub>2</sub> capture percentages of 70% and 50%.
- Detailed analysis of the existing steam turbine for Concept A: In Concept A about 79% of the steam leaving the intermediate-pressure (IP) turbine is extracted from the IP/LP crossover pipe for solvent regeneration. The capability of the existing low-pressure (LP) turbine to operate under these conditions of very low steam flow should be investigated in detail, preferably by the original equipment manufacturer (OEM).

- Optimization of the amine system reboiler steam pressure for Concepts A and C.
- Concept B detailed boiler system analysis: A startup/shutdown procedure and system design, particularly the transition from air to oxygen firing (including transient conditions) should be developed. Detailed metal temperature analysis for all heat exchanger sections, including operation at part loads should be analyzed. This should also include furnace wall metal temperatures and analysis of the circulation system. The existing fans should be checked (preferably by the OEM's) for operation under the new conditions. The feasibility of operating the boiler under a slight positive pressure to eliminate air infiltration should also be investigated.
- Investigation of Improved oxygen production systems for Concept B, in line with the membrane-based air separation research being conducted by various research groups (e.g., Praxair, Air Products, Norsk Hydro). Also optimization of an integrated boiler and oxygen production system.
- Measurement of furnace heat transfer in  $CO_2/O_2$  environments in a proof of concept boiler simulation facility.
- Improved solvents, which require lower regeneration energy requirements and/or can be regenerated at a lower temperature level.
- Hybrid process using oxygen-enriched combustion and amine based CO<sub>2</sub> absorption, to accrue, simultaneously, both CO<sub>2</sub> capture and drastic NOx emissions reduction.
- Investigation of a new novel high risk CO<sub>2</sub> capture process that would reduce efficiency penalty and retrofit investment cost. This would likely not utilize the existing boiler.

## APPENDIX I - DRAWINGS

This appendix contains all drawings developed for this project for Concepts A, B, and C and also includes a plot plan of the existing site.

## **Existing Plant:**

66-530.00 Plot Plan – Existing Overall Site before CO<sub>2</sub> Unit Addition

## Concept A:

U01-D-0208Plot Plan – Concept A: Flue Gas Cooling & CO2 AbsorptionU01-D-0214Plot Plan – Concept A: Solvent StrippingU01-D-0204Plot Plan – Concept A: CO2 Compression & LiquefactionU01-D-0211Plot Plan – Concept A: Overall Layout Conceptual PlanU01-D-0200RPlot Plan – Concept A: Modified Overall Site Plan

## Concept B:

U01-D-0203 Plot Plan – Concept B: Air Separation Plants
U01-D-0209 Plot Plan – Concept B: Flue Gas Cooling
U01-D-0205 Plot Plan – Concept B: CO<sub>2</sub> Compression & Liquefaction
U01-D-0212 Plot Plan – Concept B: Overall Layout Conceptual Plan
U01-D-0201R Plot Plan – Concept B: Modified Overall Site Plan

#### **Boiler Modifications:**

U00-E-0551R General Arrangement - Side Elevation for Concept B U00-E-0552R General Arrangement - Plan View "B-B" for Concept B U00-E-0585R General Arrangement - Plan View "A-A" for Concept B

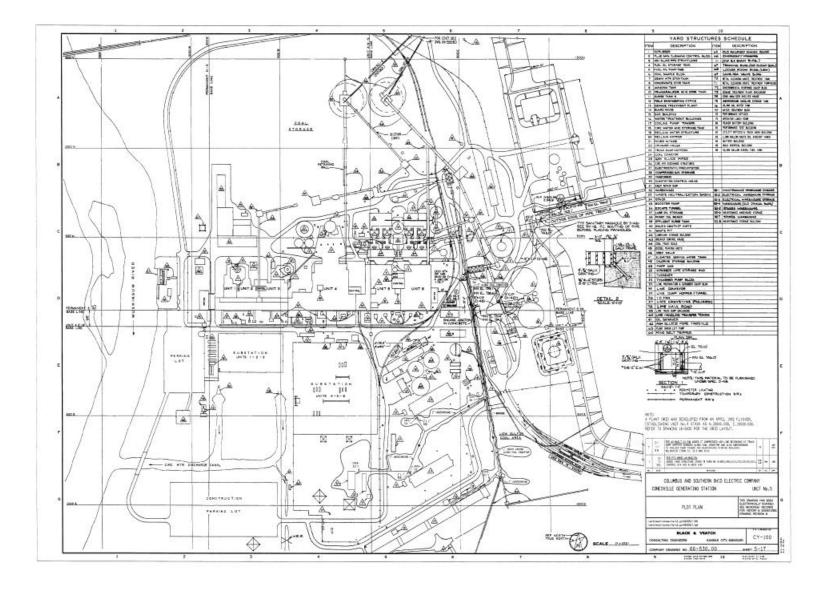

## Concept C:

U01-D-0207 Plot Plan – Concept C: De-Oxy Catalyst & Cooling
U01-D-0210 Plot Plan – Concept C: Flue Gas Cooling & CO<sub>2</sub> Absorption
U01-D-0215 Plot Plan – Concept C: Solvent Stripping
U01-D-0206 Plot Plan – Concept C: CO<sub>2</sub> Compression & Liquefaction
U01-D-0213 Plot Plan – Concept C: Overall Layout Conceptual Plan
U01-D-0202R Plot Plan – Concept C: Modified Overall Site Plan

# **Existing Plant:**

The existing plant site drawing is shown below:

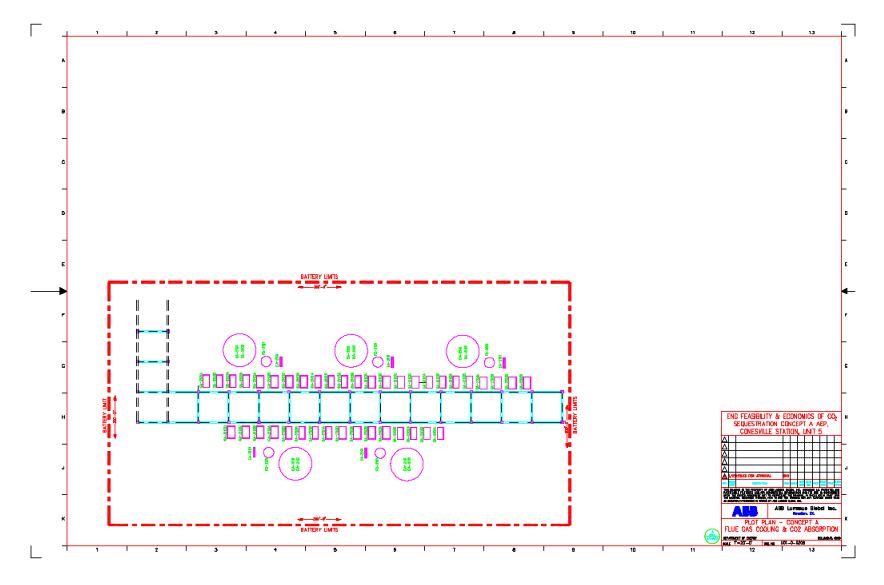

66-530.00 Plot Plan – Existing Overall Site before  $CO_2$  Unit Addition

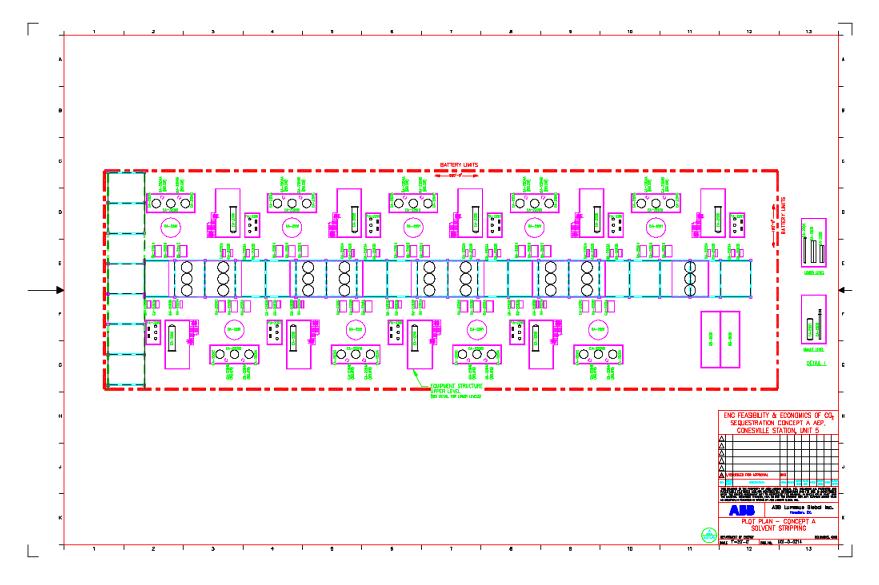

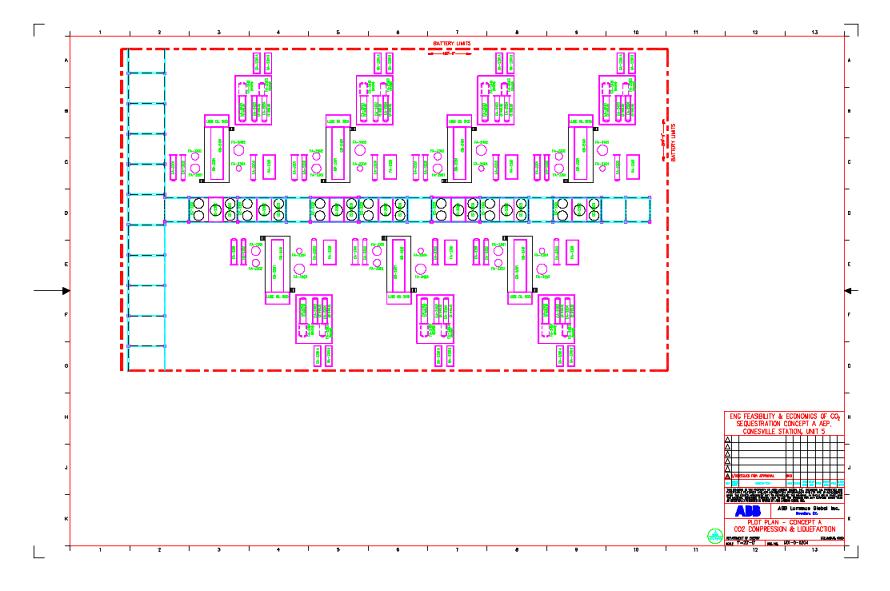

# Concept A:

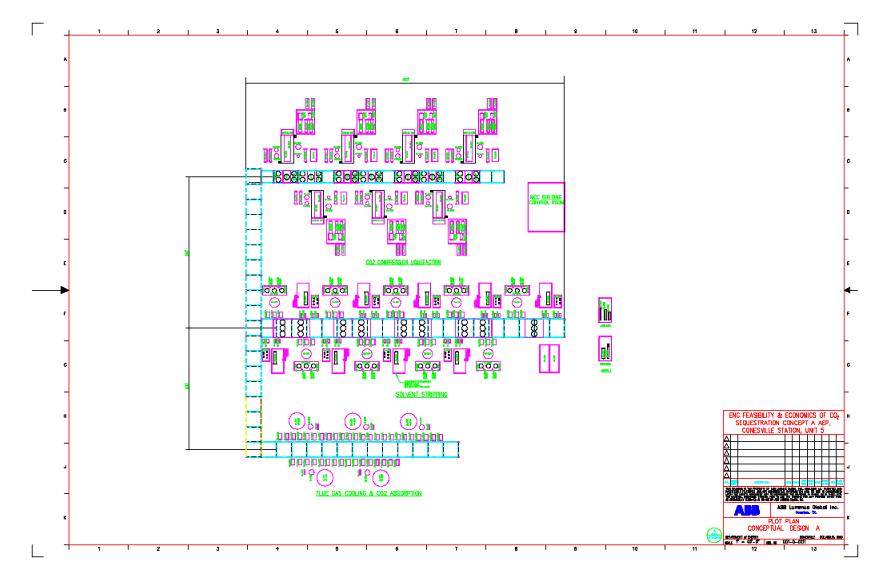

The plant layout drawings prepared for the Concept A CO<sub>2</sub> Recovery System are as follows:

U01-D-0208 Plot Plan – Concept A: Flue Gas Cooling & CO<sub>2</sub> Absorption U01-D-0214 Plot Plan – Concept A: Solvent Stripping U01-D-0204 Plot Plan – Concept A: CO<sub>2</sub> Compression & Liquefaction U01-D-0211 Plot Plan – Concept A: Overall Layout Conceptual Plan U01-D-0200 Plot Plan – Concept A: Modified Overall Site Plan

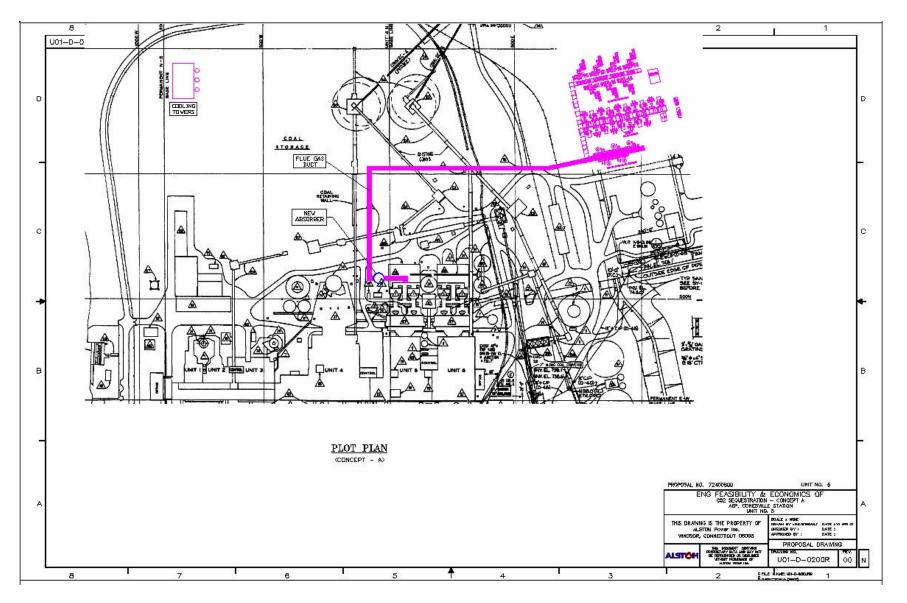

# VOLUME I. AMERICAN ELECTRIC POWER'S CONESVILLE POWER PLANT UNIT NO. 5 $\rm CO_2$ CAPTURE RETROFIT STUDY

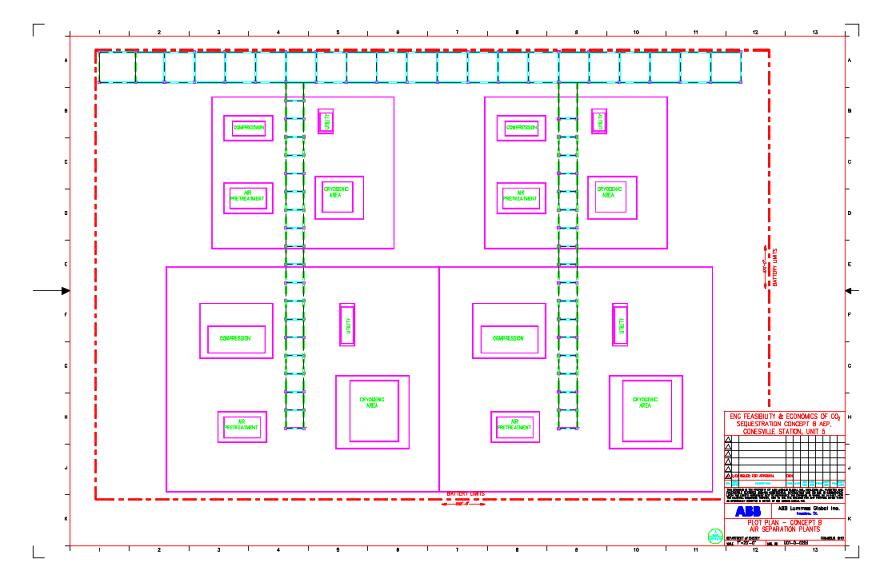

# Concept B:

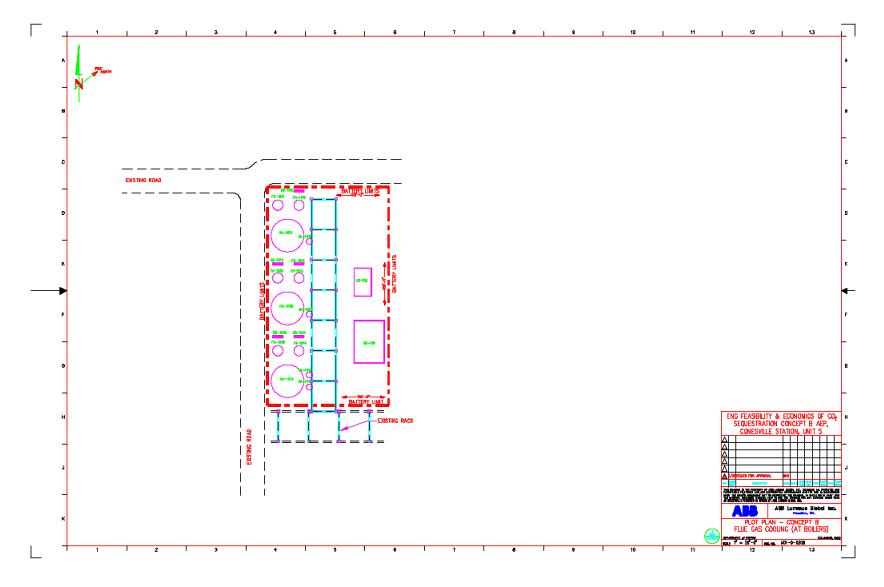

The plant layout drawings prepared for the Concept B Air Separation Unit & CO<sub>2</sub> Recovery System are as follows:

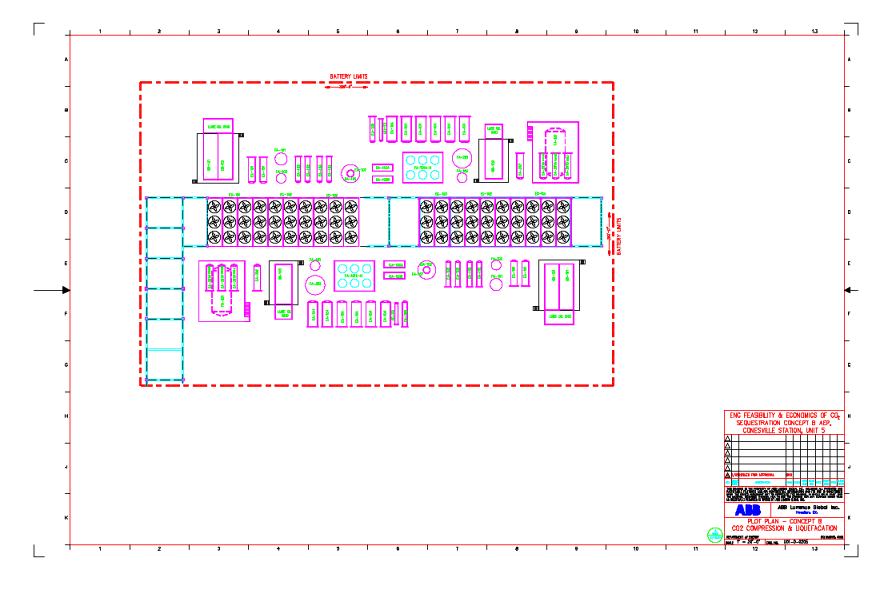

U01-D-0203 Plot Plan – Concept B: Air Separation Plants U01-D-0209 Plot Plan – Concept B: Flue Gas Cooling U01-D-0205 Plot Plan – Concept B: CO<sub>2</sub> Compression & Liquefaction U01-D-0212 Plot Plan – Concept B: Overall Layout Conceptual Plan U01-D-0201 Plot Plan – Concept B: Modified Overall Site Plan

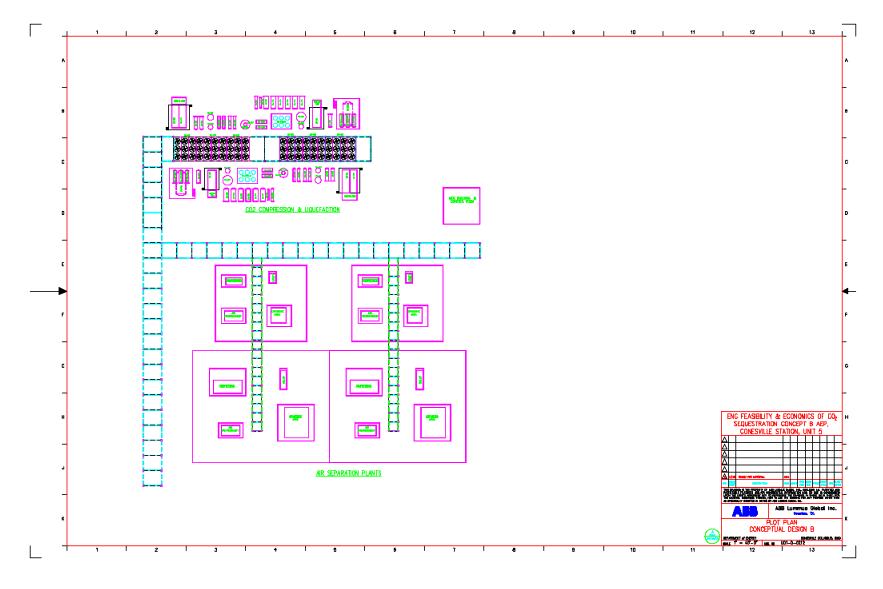

The boiler modification drawings prepared for the Concept B are as follows:

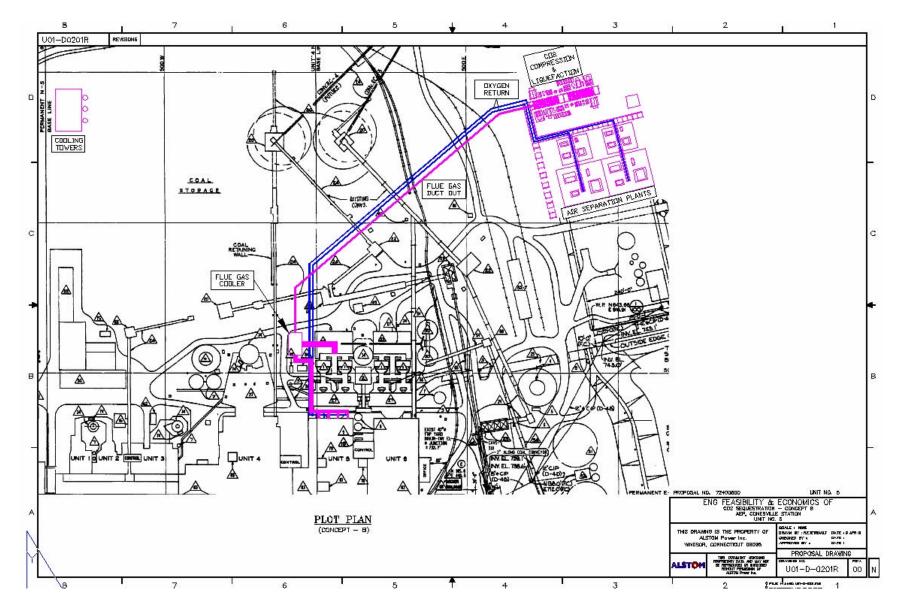

U00-E-0551- General Arrangement - Side Elevation for "Concept B" U00-E-0552 - General Arrangement - Plan View "B-B" for "Concept B" U00-E-0585 - General Arrangement - Plan View "A-A" for "Concept

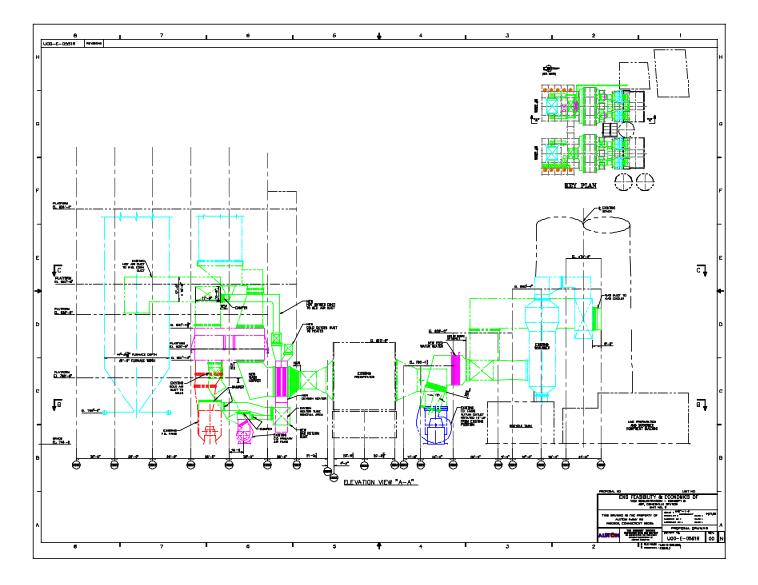

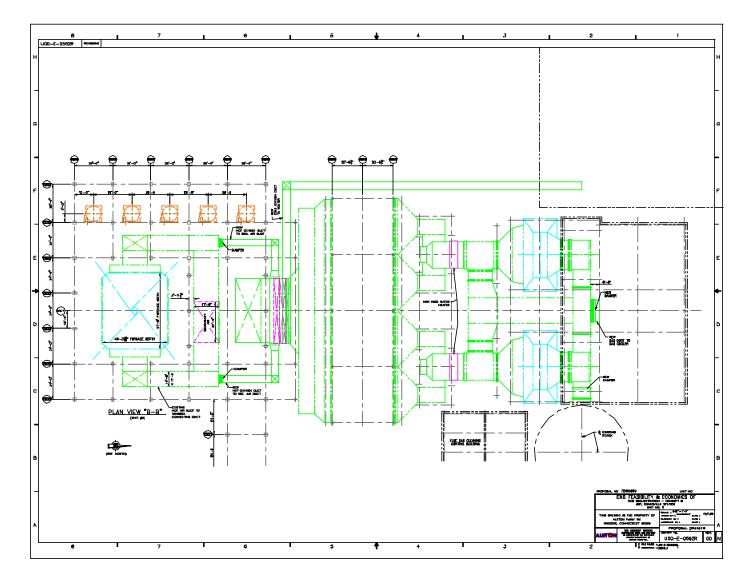

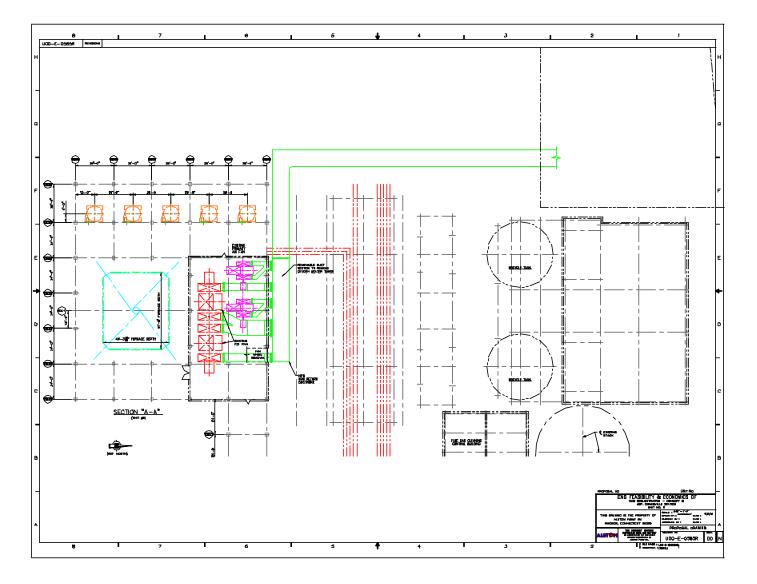

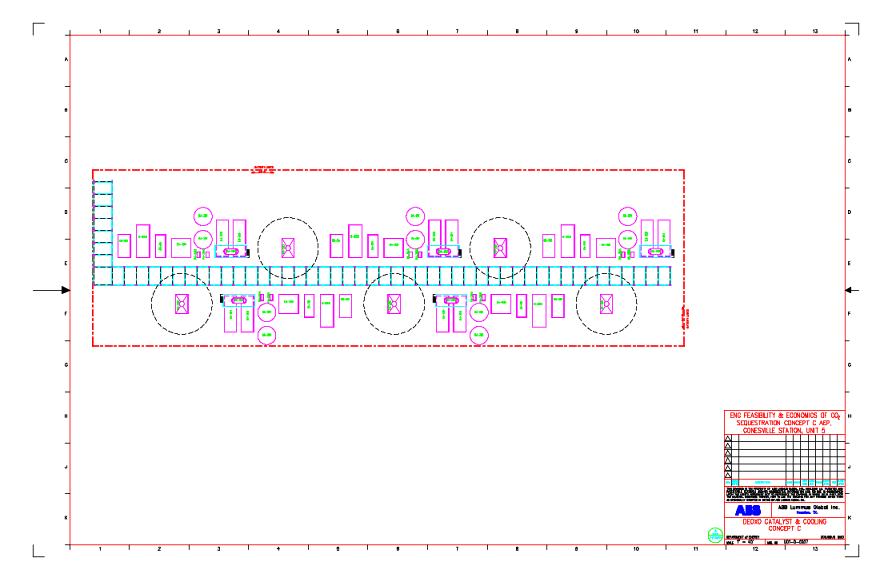

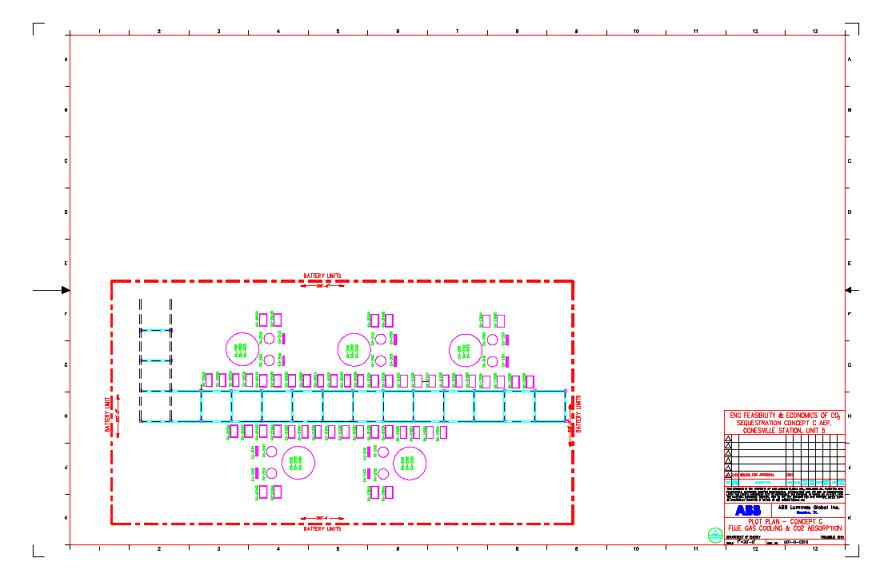

# **Concept C:**

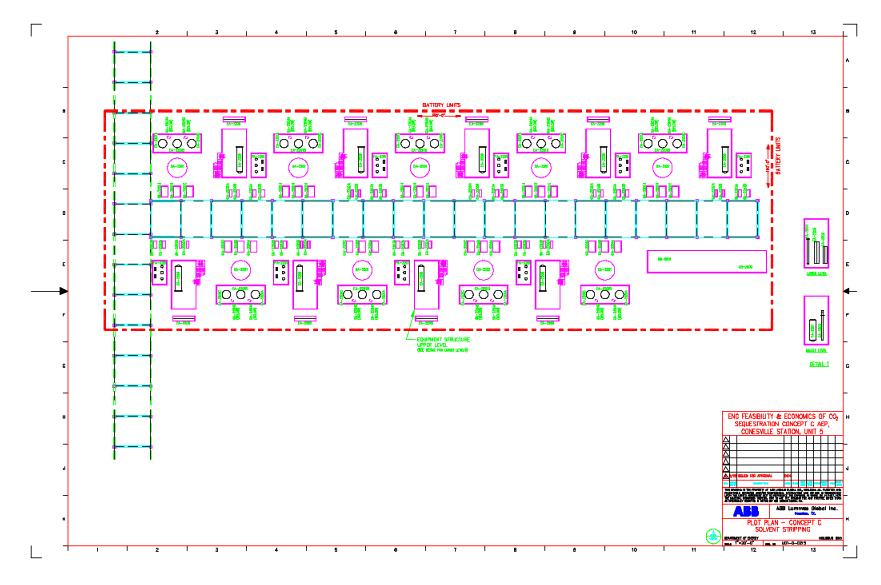

The plant layout drawings prepared for the Concept C CO<sub>2</sub> Recovery System are as follows:

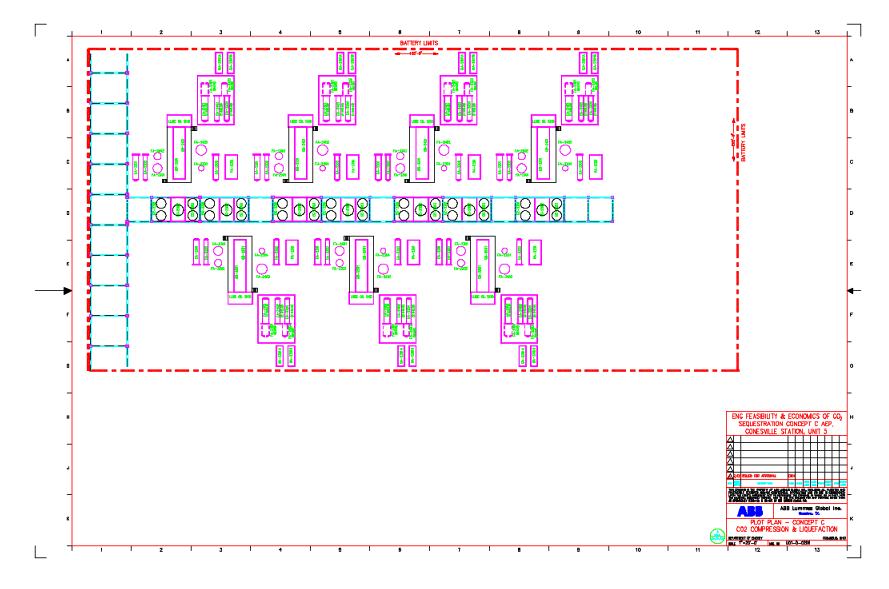

U01-D-0207 Plot Plan – Concept C: De-Oxy Catalyst & Cooling U01-D-0210 Plot Plan – Concept C: Flue Gas Cooling & CO<sub>2</sub> Absorption U01-D-0215 Plot Plan – Concept C: Solvent Stripping U01-D-0206 Plot Plan – Concept C: CO<sub>2</sub> Compression & Liquefaction U01-D-0213 Plot Plan – Concept C: Overall Layout Conceptual Plan U01-D-0202 Plot Plan – Concept C: Modified Overall Site Plan

# APPENDIX II - EQUIPMENT LISTS

This appendix contains equipment lists for the CO<sub>2</sub> Capture Systems of Concepts A, B, and C.

Concept A E	quipment List	and Data:
-------------	---------------	-----------

Number of Trains	Tag no.	Description	Size Parameters	Material
5	DA-2101	Direct Contact Flue Gas Cooler	27' ID x 34' S/S, DP 2.5 psig/ 0.7 psi vac	CS/SS
5	DA-2102	CO2 Absorber	27' ID x 92' S/S, DP 2.5 psig/ 0.7 psi vac	CS/SS
9	DA-2201	Solvent Stripper	16' ID x 100' S/S, DP 35 psig/ FV	CS/SS
9	EA-2201	Solvent Stripper Reboiler	217 MMBTU/HR DP S/T, 50 psig/ 60 psig	CS/SS
9	EA-2203	Solvent Stripper Reclaimer	5.6 MMBTU/HR, DP S/T, 120 psig/ 190 psig	CS/TI
9	EA-2204	Solvent Reclaimer Effluent Cooler	5 MMBTU/HR, DP S/T, 125 psig, 100 psig	CS/TI
9	EA-2206	Solvent Stripper CW Condenser	41.6 MMBTU/HR, DP S/T, 35 psig/ 100 psig	SS/TI
7	EA-2301	CO2 Compr. 1st Stage Aftercooler	1.9 MMBTU/HR, DP S/T, 75 psig/ 100 psig	SS/TI
7	EA-2302	CO2 Compr. 2nd Stage Aftercooler	1.3 MMBTU/HR, DP S/T, 125 psig/ 100 psig	SS/TI
7	EA-2303	CO2 Compr. 3rd Stage Aftercooler	1 MMBTU/HR, DP S/T, 235 psig/ 100 psig	CS/TI
7	EA-2304	CO2 Condenser	19 MMBTU/hr DP S/T, 235 psig/ 300 psig	CS/TI
5	EA-2101	Direct Contact Flue Gas Water Clr	4.8 MMBTU/HR, DP P/U, 50 psig/ 100 psig	TI
9	EA-2205	Rich / Lean Solvent Exchanger		SS316
9	EA-2202	Lean Solvent Cooler	101.8 MMBTU/HR, DP P/U 135 psig/ 100 psig	TI
7	EA-2401	Propane Refrig Condenser	20.45 MMBTU/HR, DP S/T, 300 psig/ 100 psig	CS/CS
7	EA-2402	Propane Refrig Subcooler	5.9 MMBTU/HR, DP S/T, 300 psig/ 2500 psig	CS/LTCS
7	EC-2301	CO2 compressor 1st stage air cooler	2.94 MMBTU/HR, DP 75 psig	SS
7	EC-2302	CO2 compressor 2nd stage air cooler	3.1 MMBTU/HR, DP 125 psig	SS
7	EC-2303	CO2 compressor 3rd stage air cooler	4.6 MMBTU/HR, DP 235 psig	SS
9	EC-2201	Solvent stripper bottoms cooler	80.3 MMBTU/HR, DP 135 psig	SS
9	FA-2201	Solvent Stripper Reflux Drum	5' ID x 16' S/S, DP 35 psig/ FV	304L
7	FA-2301	CO2 Compressor 2st Stage Suction Drum	7'- 6" ID x 10' S/S, DP 75 psig	CS/SS
7	FA-2302	CO2 Compressor 3rd Stage	6' ID x 10' S/S, DP 125 psig	CS/SS

		Suction Drum		
7	FA-2303	Liquid CO2 Surge Drum	4'- 6" ID x 14' S/S, DP 235 psig	KCS
7	FA-2304	CO2 Compressor 3rd stage	4' 6" ID x 10' S/S, DP 235 psig	CS/SS
		Discharge KO Drum		
7	FA-2401	Propane Refrig Surge Drum	10' ID x 30' S/S, DP 300 psig	CS
7	FA-2402	Propane Refrig Suction Scubber	8' 6" ID x 12' S/S, DP 300 psig	LTCS
3	FB-2503	Caustic day tank	2' ID x 4' S/S, DP atm	CS
5	FD-2101	DCC Water Filter	205 gpm, DP 35 psig	SS
5	GA-2101	Wash Water Pump	1425 gpm, DP 29 psi	DI/SS
	A/B			
5	GA-2102 A/B	Direct Contact Cooler Water Pump	205 gpm, DP 36 psi	SS/SS
5	GA-2103	Rich Solvent Pump	3450 gpm, DP 92 psi	SS/SS
0	A/B/C/D	Lasar Calasar Damar	2000 and DD 95 mi	00/00
9	GA- 2201A/B/ C	Lean Solvent Pump	3000 gpm, DP 85 psi	SS/SS
9	GA-2202	Solvent Stripper Reflux Pump	310 gpm, DP 75 psi	DI/SS
	A/B	Sorvent Surpper Rentax Fump	sto gpin, Di 75 psi	01/00
9	GA-2203 A/B	Filter Circ. Pump	290 gpm, DP 91 psi S	
9	GA-2204	LP Condensate Booster Pump	512 gpm, DP 237 psi	CI/SS
_	A/B			
7	GA-2301 A/B	CO2 Pipeline Pump	217 gpm, DP 1815 psi	CS/CS
3	GA-2501	Caustic metering pump	.45 gpm, DP 50 psi	SS
5	011 2501	Cuusile metering pump	. to gpin, Dr 50 psi	55
7	GB-2301	CO2 Compressor (Motor driven)	4480 hp	SS wheels
7	GB-2401	Propane Refrig Compressor	3075 hp	LTCS
1	GB-2500	LP steam turbine/ generator	83365 hp	
9	PA-2551	Corrosion Inhibitor Package	Metering, 25 lb/ hr	
9	PA-2251	Solvent Filter Package	140 gpm	
7	PA-2351	CO2 Dryer Package	4 driers, 200 hp compressor, elec hea	ater, cooler
1		Crane for Compr. Bldg.	· · · · · · · · · · · · · · · · · · ·	,
		Flue gas ducting		
1	PA-2551	Cooling Tower	22000 gpm, includes basin, pumps injection	, chlorine
1	PA-2552	Cooling tower blowdown	100 gpm sand filters and dechlor	rinator,
		treatment package	hypochlorite	,
			storage tank

7	FA-2302	CO2 Compressor 3rd Stage Suction Drum	6' ID x 10' S/S, DP 125 psig	CS/SS
7	FA-2303	Liquid CO2 Surge Drum	4'- 6" ID x 14' S/S, DP 235 psig	KCS
7	FA-2304	CO2 Compressor 3rd stage Discharge KO Drum	4' 6" ID x 10' S/S, DP 235 psig	CS/SS
7	FA-2401	Propane Refrig Surge Drum	10' ID x 30' S/S, DP 300 psig	CS
7	FA-2402	Propane Refrig Suction Scubber	8' 6" ID x 12' S/S, DP 300 psig	LTCS
3	FB-2503	Caustic day tank	2' ID x 4' S/S, DP atm	CS
5	FD- 2101A/B	DCC Water Filter	1645 gpm each, DP 35 psig	SS
5	FH- 302	Start-up heater	54.6 MMBTU/HR	CS
5	GA-301 A/B	HP Condensate Booster pumps	163 gpm, DP 1500 psi	DI/SS
5	GA-2101 A/B	Wash Water Pump	1425 gpm, DP 29 psi	DI/SS
5	GA-2102 A/B	Direct Contact Cooler Water Pump	3289 gpm, DP 36 psi	SS/SS
5	GA-2103 A/B/C/D	Rich Solvent Pump	2435 gpm, DP 92 psi	SS/SS
5	GA-2104 A/B	Bottom Direct Contact Cooler Water Pump	325 gpm, DP 36 psi	SS/SS
9	GA- 2201A/B/C	Lean Solvent Pump	2095 gpm, DP 85 psi	SS/SS
9	GA-2202 A/B	Solvent Stripper Reflux Pump	310 gpm, DP 75 psi	DI/SS
9	GA-2203 A/B	Filter Circ. Pump	290 gpm, DP 91 psi	SS/SS
9	GA-2204 A/B	LP Condensate Booster Pump	395 gpm, DP 237 psi	DI/SS
7	GA-2301 A/B	CO2 Pipeline Pump	228 gpm, DP 1815 psi	CS/CS
3	GA-2501	Caustic metering pump	.45 gpm, DP 50 psi	SS
5	GB-301	Flue Gas Blower	3350 hp	SS
7	GB-2301	CO2 Compressor (Motor driven)	4750 hp	SS wheels
7	GB-2401	Propane Refrig Compressor	3225 hp	LTCS
1	GB-2500	LP steam turbine/ generator	48809 hp	
1	GB-2501	HP steam turbine/ generator	52421 hp	

9 7	PA-2251 PA-2351	Solvent Filter Package CO2 Dryer Package	140 gpm 4 dryers, 200 hp compressor, fired heater, cooler
1		Crane for Compr. Flue gas ducting	
1	PA-2551	Cooling Tower	67500 gpm, includes basin, pumps, chlorine injection
1	PA-2552	Make-up water purification package	1570 gpm clarifier w/ b/d sump and pump, and CT b/d dechlorinator, hypochlorite storage tank

VOLUME I. AMERICAN ELECTRIC POWER'S CONESVILLE POWER PLANT UNIT NO. 5  ${\rm CO}_2$  CAPTURE RETROFIT STUDY

# VOLUME II

# ENGINEERING FEASIBILITY AND ECONOMICS OF $CO_2$ CAPTURE ON AN EXISTING COAL-FIRED POWER PLANT

#### FINAL REPORT

#### VOLUME II BENCH-SCALE TESTING AND COMPUTATIONAL FLUID DYNAMICS (CFD) EVALUATION

#### SUBMITTED BY

ALSTOM POWER INC. POWER PLANT LABORATORIES 2000 DAY HILL ROAD WINDSOR, CT 06095 (860) 688-1911

#### **REPORT SUBMITTAL DATE: JUNE 29, 2001**

#### PROJECT PERFORMANCE PERIOD: NOVEMBER 11, 1999 - JUNE 30, 2001

#### PPL REPORT NO. PPL-01-CT-10

#### Disclamer

This report was prepared by <u>ALSTOM Power Plant Laboratories</u> with support in part by a grant from both the Ohio Coal Development Office/Ohio Department of Development and the United States Government. Neither the State of Ohio, the United States Government, nor any of their agencies, nor any person acting on their behalf:

- 1. Make any warranty or representation, express or implied, with respect to the accuracy, completeness, or usefulness of the information contained in this report, or that the use of any information, apparatus, method or process disclosed in this report may not infringe privately-owned rights; or
- 2. Assume any liabilities with respect to the use of, or damages resulting from the use of, any information, apparatus, method or process disclosed in this report.

References herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise, does not necessarily constitute or imply its endorsement, recommendation, or favoring; nor do the view and opinions of authors expressed herein necessarily state or reflect those of the State of Ohio, the United States Government or their agencies.

#### Acknowledgements

The authors appreciatively acknowledge the following people for their contributions to the successful performance of the work presented herein: Gregory A. Burns for setting up and running all the Drop Tube Furnace System-1 (DTFS-1) tests; Kurt W. Johnson and the Chemical Analytical Services Laboratory personnel for providing all fuel analyses; John Holmes and all the Electrical and Controls Services personnel for providing computer and instrumentation support; and Woodrow A. Fiveland for his leadership and counsel on the CFD computations. The financial support of this project by OCDO (Contract NO. CDO/D-98-8), DOE National Energy Technology Laboratory (Contract NO. DE-FC26-99FT40576), ALSTOM Power Inc. and ABB Lummus Global Inc. is also appreciated. The in-kind financial support of the project by American Electric Power is greatly appreciated.

#### Public Abstract

ALSTOM Power Inc.'s Power Plant Laboratories (ALSTOM) has teamed with American Electric Power (AEP), ABB Lummus Global Inc. (ABB), the US Department of Energy National Energy Technology Laboratory (DOE NETL), and the Ohio Coal Development Office (OCDO) to conduct a comprehensive study evaluating the technical feasibility and economics of alternate  $CO_2$  capture and sequestration technologies applied to an existing US coal-fired electric generation power plant.

The motivation for this study was to provide input to potential US electric utility actions concerning GHG emissions reduction. If the US decides to reduce  $CO_2$  emissions, action would need to be taken to address existing power plants. Although fuel switching from coal to natural gas may be one scenario, it will not necessarily be a sufficient measure and some form of  $CO_2$  capture for use or disposal may also be required. The output of this  $CO_2$  capture study will enhance the public's understanding of control options and influence decisions and actions by government, regulators, and power plant owners in considering the costs of reducing greenhouse gas  $CO_2$  emissions.

The total work breakdown structure is encompassed within three major reports, namely: (1) Literature Survey, (2) AEP's Conesville Unit #5 Retrofit Study, and (3) Bench-Scale Testing and CFD Evaluation. The report on the literature survey results was issued earlier by Bozzuto, et al. (2000). Reports entitled "AEP's Conesville Unit #5 Retrofit Study" and "Bench-Scale Testing and CFD Evaluation" are provided as companion volumes, denoted Volumes I and II, respectively, of the final report. The work performed, results obtained, and conclusions and recommendations derived therefrom are summarized below.

#### Volume I

The Volume I report discusses three retrofit technology concepts, which were evaluated in conjunction with AEP's Conesville Unit #5, namely:

- **Concept A:** Coal combustion in air, followed by CO<sub>2</sub> separation with Kerr-McGee/ABB Lummus Global's commercial MEA-based absorption/stripping process
- **Concept B:** Coal combustion with O<sub>2</sub> firing and flue gas recycle (oxy-fuel firing)
- **Concept C:** Coal combustion in air with oxygen removal and CO<sub>2</sub> separation by a mixture of primary and tertiary amines, i.e., monoethanolamine (MEA)/methyldiethanolamine (MDEA).

Each of these technologies was evaluated against a baseline case, without  $CO_2$  capture, from the standpoints of performance, impacts on power generating cost, and  $CO_2$  emissions. AEP's 450 MW Conesville Unit No. 5, located in Conesville, Ohio, was used for the power plant case study. All technical performance and cost results associated with the available options were evaluated in a comparative manner.

#### **Major conclusions:**

- No major technical barriers exist for retrofitting AEP's Conesville Unit #5 to capture CO<sub>2</sub> for any of the three concepts considered under this study.
- Concept B (oxygen firing with flue gas recycle) appears clearly to be <u>the best</u> alternative of the three concepts studied from both an efficiency and incremental COE viewpoint. This study has confirmed two important issues related to firing coal in a CO<sub>2</sub>-rich flue gas / O<sub>2</sub> mixture:
  - Modifications to the existing steam generator unit pressure arts are not required, and as such will also allow the unit to continue to operate in the conventional air- fired mode.
- CO<sub>2</sub>-rich flue gas can be cleaned and compressed with a relatively simple system to provide high purity CO<sub>2</sub> for usage or sequestration.
- Energy requirements and power consumption are high, resulting in significant decreases in overall power plant efficiencies (HHV basis), ranging from efficiencies of 20.5 to 22.5%, as compared to 35.0% for the Base case (air

firing without  $CO_2$  capture), which is equivalent to an energy penalty ranging from 36% to 41%. That is, the net power plant output was reduced to 77% - 59%.

- Specific investment costs are high, ranging from about 800 to1800 \$/kW and from 1000 to 2200 \$/kW, corresponding to scenarios with and without replacement power, respectively.
- All cases studied indicate significant increases to the COE as a result of CO<sub>2</sub> capture. The incremental COE as compared to the Base case (air firing without CO<sub>2</sub> capture) ranges from 3.4 to 8.4 ¢/kWh. Similarly CO<sub>2</sub> mitigation costs range from about 42-98 \$/ton of CO<sub>2</sub> avoided for the range of cases studied.
- Specific carbon dioxide emissions were reduced from about  $2 lb_m/kWh$  for the Base case to  $0.13 0.27 lb_m/kWh$  for the study cases. Recovery or capture of CO<sub>2</sub> ranged from 91 to 96%.
- Nominally, 5-8 acres of new equipment space is needed for Unit #5 alone on the existing 200-acre power plant site, which accommodates a total of 6 units with a total power generating capacity of 2,080 MW.

#### Major recommendations:

- A sensitivity study, for Concepts A and C, showing the impact of reducing CO<sub>2</sub> capture percentage on plant efficiency, investment cost, emissions, and cost of electricity. The current work utilized 90% CO<sub>2</sub> capture (nominal). The sensitivity study would investigate nominal CO<sub>2</sub> capture percentages of 70% and 50%.
- Detailed analysis of the existing steam turbine for Concept A: In Concept A about 79% of the steam leaving the intermediate-pressure (IP) turbine is extracted from the IP/LP crossover pipe for solvent regeneration. The capability of the existing low-pressure (LP) turbine to operate under these conditions of very low steam flow over the load range should be investigated in detail, preferably by the original equipment manufacturer (OEM).
- Optimization of the amine system reboiler steam pressure for Concepts A and C.
- Concept B detailed boiler system analysis: A startup/shutdown procedure and system design, particularly the transition from air to oxygen firing (including transient conditions) should be developed. Detailed metal temperature analysis for all heat exchanger sections, including operation at part loads should be analyzed. This should also include furnace wall metal temperatures and analysis of the circulation system. The existing fans should be checked (preferably by the OEM's) for operation under the new conditions. The feasibility of operating the boiler under a slight positive pressure to eliminate air infiltration should also be investigated.
- Investigation of Improved oxygen production systems for Concept B, in line with the membrane-based air separation research being conducted by various research groups (e.g., Praxair, Air Products, Norsk Hydro). Also optimization of an integrated boiler and oxygen production system.
- Measurement of furnace heat transfer in CO<sub>2</sub>/O<sub>2</sub> environments in a proof of concept boiler simulation facility.
- Improved solvents, which require lower regeneration energy requirements and/or can be regenerated at a lower temperature level, similar to MHI's KS1 system, but for coal-firing application.
- Hybrid process using oxygen-enriched combustion and amine based CO<sub>2</sub> absorption, to accrue, simultaneously, both CO<sub>2</sub> capture and drastic NOx emissions reduction.
- Investigation of a new novel high risk CO<sub>2</sub> capture process that would reduce efficiency penalty and retrofit investment cost. This would likely not utilize the existing boiler.

#### Volume II

ALSTOM Power Inc.

The bench-scale testing consisted primarily of drop-tube (DTFS-1) and thermo-gravimetric analyses (TGA). Three cases were investigated: (1) an air-fired case (Base case); (2) a case in which the  $N_2$  was replaced by an equal mass of CO<sub>2</sub> (Constant Mass case); and (3) a case in which the  $N_2$  volume was replaced by an equal volume of CO<sub>2</sub> (Constant Volume case). The Constant Mass case represents the appropriate retrofit scenario in a commercial pulverized coal firing application, albeit without flue gas recycling.

#### Major conclusions:

#### (a) Based on TGA results

• *B*oth the Conesville Unit #5 and Pittsburgh Seam #8 coals have, for air (Base case) and O<sub>2</sub>/CO<sub>2</sub> environments (Constant Mass/Volume cases), similar burning characteristics, as they both go to completion within the same temperature range (550-575 °C). Burning either of the coals in air or any of the O<sub>2</sub>/CO<sub>2</sub> mixture ratios used here would produce virtually identical results; and (2) both coals have similar reactivity characteristics.

#### (b) Based on DTFS-1 results

- Residence time, as expected, has a significant impact on the overall coal combustion efficiency, and hence, on the unburned carbon emission in the fly ash for both coals under consideration. That is, while the combustion efficiency for both coals is only about 80% (dry-ash-free coal basis) at 0.2 sec., it is more than 98% at greater than 0.5 sec. Correspondingly, unburned carbon emissions range from about 65% to about 2% (dry fly ash basis).
- The impact of reaction medium is also significant. While the overall combustion efficiencies do not seem to exhibit significant differences between the baseline and Constant Mass firing, the more sensitive parameter, unburned carbon (UBC) in the fly ash, on the other hand, clearly shows better performance for the Constant Mass case. That is, the UBC at the furnace outlet was about a factor of 4.5 lower for the Constant Mass case (~2% vs. 9%). This is believed to be due to higher reactant gas temperature, and yet longer residence (0.77 sec. vs. 0.57 sec.). It appears, from the shape of the UBC profiles, that, if given enough residence time, these differences would narrow down considerably, implying that the ultimate performance in both mediums would be similar.
- The coal sample from Conesville Unit #5 appears to perform better than the sample from Pittsburgh seam #8 coal (e.g., 9% vs. 12.5% UBC for the air firing case). However, based on the shape of the UBC profiles, it can be seen that if given additional residence time, they would both be expected to perform similarly.
- NOx emission from oxy-fuel firing is about a factor of 3 (0.73 vs. 2.25 lb/MMBtu) lower than that of the Base case. Correspondingly, sulfur dioxide is lower by about 19% (3.6 vs. 4.3 lb/MMBtu), and CO is significantly lower (0.09 lb/MMBtu vs. a negligible amount).

#### (c) Based on CFD results

- The baseline case exhibits higher carbon-in-ash (by 1.6 percentage points), higher outlet NOx emissions (by a factor of 2), and higher outlet CO (by a factor of 2) than the Concept-B case. These same computational trends are also qualitatively exhibited by the bench-scale testing.
- The baseline case exhibits a slightly higher peak gas temperature (maximum difference of about 200 °F), and a correspondingly higher average (cross-sectional) gas temperature (difference of 90 °F at the HFOT), than that of the Concept-B case.
- The net wall absorption in the furnace region for the baseline case is larger (by less than 1%) than that of the Concept-B case. However, a significant variation in both calculated and experimental irradiation to the wall between baseline and oxy-firing scenarios was also found in the literature (e.g., +6 to -18%). Differences may be partially attributed to the sensitivity of the irradiation and local emissivities to the aerodynamic and flame patterns, which are, in turn, a function of the furnace and firing system. It is suggested that radiatively absorbing gas species can either enhance or inhibit the irradiation in the vicinity of the wall, depending upon their local temperature and their relative spatial placement.

#### Major recommendations:

- Carry out a systematic coal fundamentals study concerning this field of endeavor. This study should be geared toward the creation of a database of information depicting the impact of coal nature (using coals of various rank coming from both domestic and international sources) when fired in an oxy-fuel environment on:
  - > Coal devolatilization and char oxidation kinetics, and unburned carbon emissions in the fly ash
  - Acid rain-related gaseous (NOx, SO<sub>2</sub>, and CO) emissions
  - > Air toxics, particularly, mercury (Hg), volatile organic compounds (VOCs), and particulate emissions.
- Derive furnace heat transfer data from natural gas and coal firing in an oxy-fired pilot-scale furnace, which simulates the temperature/time history of a boiler. Use first the data from natural gas firing to validate the CFD code, without the complication of burning particles transiting the boiler. Apply the experience learned from modeling a natural gas fired boiler to model the coal-fired boiler.

# **Executive Summary**

#### Background

International discussions continue to debate the need for reductions in emission levels of green house gases (GHG). Because fossil fuel fired power plants are among the largest and most concentrated producers of  $CO_2$  emissions, it stands to reason that recovery of  $CO_2$  from the flue gas of such plants has been identified as one of the primary means for reducing  $CO_2$  emissions.

ALSTOM Power Inc.'s Power Plant Laboratories (ALSTOM) teamed with American Electric Power (AEP), ABB Lummus Global Inc. (ABB), the US Department of Energy National Energy Technology Laboratory (DOE NETL), and the Ohio Coal Development Office (OCDO) to conduct a comprehensive study evaluating the technical and economic feasibility of three alternate  $CO_2$  capture technologies applied to an existing US coal-fired electric generation power plant. The steam generator analyzed in this study is the Conesville No. 5 unit, operated by American Electric Power (AEP) of Columbus, Ohio. This steam generator is a nominal 450 MW, coal-fired, subcritical pressure, controlled circulation unit. It has a single cell furnace that employs corner-fired, tilting, tangential burners and which fires bituminous coal from the state of Ohio. The flue gas leaving the boiler system is cleaned of particulate matter in an electrostatic precipitator (ESP) and of  $SO_2$  in a lime-based flue gas desulfurization (FGD) system before being discharged to the atmosphere.

ALSTOM is managing and performing the subject study from its US Power Plant Laboratories office in Windsor, CT. ABB, from its offices in Houston, Texas, is participating as a sub-contractor. AEP is participating by offering their Conesville Generating Station as the case study and cost sharing consultation, along with relevant technical and cost data. AEP is one of the largest US utilities, and as the largest consumer of Ohio coal, is bringing considerable value to the project. Similarly, ALSTOM and ABB are well established as global leaders in the design and manufacturing of steam generating equipment, petrochemical, and  $CO_2$  separation technology. The DOE National Energy Technology Laboratory and the Ohio Coal Development Office provided consultation and funding. All participants contributed to the cost share of this project.

#### Objectives

The motivation for this study was to provide input to potential US electric utility actions concerning GHG emissions reduction. If the US decides to reduce  $CO_2$  emissions, action would need to be taken to address existing power plants. Although fuel switching from coal to natural gas may be one scenario, it will not necessarily be a sufficient measure and some form of  $CO_2$  capture for use or disposal may also be required. The output of this  $CO_2$  capture study will enhance the public's understanding of control options and influence decisions and actions by government, regulators, and power plant owners in considering the costs of reducing greenhouse gas  $CO_2$  emissions.

The key goals of the study were to evaluate the impacts on the plant output, efficiency, and  $CO_2$  emissions, resulting from the addition of the  $CO_2$ -capture systems. Cost estimates were developed for the systems required to produce, extract, clean and compress the  $CO_2$ , which could then be available for use in enhanced oil or gas recovery or sequestration. Additionally, the impact of  $CO_2$  capture on the cost of electricity (COE) and on the mitigation cost for  $CO_2$  (\$/ton of  $CO_2$  avoided) was also evaluated.

#### Work Scope

The total work breakdown structure is encompassed within three major reports, namely: (1) Literature Survey, (2) AEP's Conesville Unit #5 Retrofit Study, and (3) Bench-Scale Testing and CFD Evaluation. The report on the literature survey results was issued earlier by Bozzuto, et al. (2000). The report entitled "AEP's Conesville Unit #5 Retrofit Study" constitutes Volume I of the final report.

"Bench-Scale Testing and CFD Evaluation" is presented herein as the Volume II report. The work performed, results obtained, and conclusions and recommendations derived therefrom are summarized in the sections that follow.

#### **Bench-Scale Testing**

The overall objective of the (Volume II) work segment was to provide critical technical information for evaluating a single option, selected from the three retrofit technology options available, which had the highest probability of realizability. The final option selected was that denoted as: "Coal Combustion in an  $O_2/CO_2$  Environment with  $CO_2$  Recycle." Specific objectives were two-fold: (1) bench-scale testing was to provide experimental combustion and emissions performance data on a specific Ohio coal under conditions where the fuel was to be burned in mixtures of  $CO_2$  and  $O_2$ ; and (2) a computational fluid dynamics (CFD) modeling effort was to utilize design and operating information from a commercial boiler burning Ohio coal in order to establish a calculation for the conventional burning of coal (in air), and then to evaluate performance in the same commercial unit for the burning of the same coal in mixtures of  $CO_2$  and  $O_2$ .

Bench-scale results provided surrogate combustion kinetics, NOx, CO, SO<sub>2</sub> and unburned carbon results on the coal that is presently burned in the Conesville Boilers Units #5 and 6 under conditions that represent conventional combustion (in air) and in various mixtures of  $CO_2$  and  $O_2$ . A knowledge of the actual combustion and emissions data from Conesville Unit #5 provided a means whereby the baseline bench-scale results in air were referenced and interpreted; in a sense, it allowed "calibration" of the bench-scale experimental facility to a given point of reference. Referencing the baseline bench-scale results to the actual furnace emissions data allowed a more accurate interpretation of the bench-scale results of the  $CO_2$ - $O_2$  mixtures and permitted a more reliable/extrapolation of how an actual retrofitted boiler would respond to the same  $CO_2$ - $O_2$  mixtures.

The completed literature survey, performed under an initial task of this project (Bozzuto, et al., 2000), indicated that no fundamental combustion performance had been carried out on any coal in  $CO_2/O_2$  media. Hence, the work scope provided first-of-a-kind information to the project. Information derivation and application was carried out as follows:

- First, bench-scale testing of the Conesville coal was carried out in both air (to provide baseline information) and in two mixtures of CO<sub>2</sub> and O<sub>2</sub>.
- A comparison of the information on combustion performance in air with information from ALSTOM's proprietary database permitted ALSTOM to select char oxidation kinetic parameters to be used on a surrogate basis during the calibration of the CFD cases.

#### **Coal Characteristics**

ASTM standard analyses and ash chemistry analyses were performed for coal samples from AEP's Conesville Unit #5 and Pittsburgh #8 seam. Both of these coal samples are typical of good Eastern US bituminous steaming coals, with fuel values (i.e., FC/VM ratios) of 1.4 and 1.3, respectively. Both coals have high sulfur contents and exhibit medium potentials for slagging the boiler waterwall and convective pass.

#### **TGA Results**

The coal samples were size graded to 200x400 mesh. These size-graded materials were subsequently tested in the thermo-gravimetric analyzer (TGA) and the drop-tube furnace system (DTFS-1) equipment to determine their reactivities and unburned carbon emission propensities.

Three cases were evaluated for each coal. The Base case consisted of burning the coal in air. The Constant Mass case consisted of burning the coal in an  $O_2/CO_2$  mixture, such that the mass of  $O_2$  used in the Base case was maintained and the mass of  $N_2$  used in the Base case was replaced with an equal mass of  $CO_2$ . The Constant Volume case consisted burning the coal in  $O_2/CO_2$  mixture, such that the mass of  $O_2$  used in the Base case was again maintained and the volume of  $N_2$  used in the Base case was replaced with an equal volume of  $CO_2$ .

The combustion efficiency profiles from the TGA indicate that both the Conesville and Pittsburgh #8 coals, for both the air (Base case) and  $O_2/CO_2$  environments (Constant Mass/Volume cases), have similar burning characteristics, as they both go to completion within the same temperature range (550-575°C). Additional analysis of the weight loss as a function of time, as well as the temperature at which the maximum reaction rate occurs, confirms that: (1) burning either of the coals in air or any of the  $O_2/CO_2$  mixture ratios used will produce virtually identical results; and (2) both coals have similar reactivity characteristics.

### **Drop-Tube Combustion Furnace System-1 Results**

The DTFS-1 testing was used to derive quantitative information on the impact of various operating parameters such as particle size, stoichiometry and temperature/time history on unburned carbon loss and gaseous (NOx, CO and SO<sub>2</sub>) emissions. The coal feed rate was adjusted for each coal such that the overall stoichiometry ( $\lambda$ ) was ~2.50, which is the stoichiometry required to achieve reasonably low unburned carbon emissions in the drop tube. The DTFS-1 was operated in a laminar flow regime, with a Reynolds number in the 150-225 range; the maximum residence time for the conditions evaluated was about 0.8 seconds. DTFS-1 results showed the following:

- Residence time has, as expected, a significant impact on the overall coal combustion efficiency, and hence, on the unburned carbon emission in the fly ash for both coals under consideration. That is, while the combustion efficiency for both coals is only about 80% (dry-ash-free coal basis) at 0.2 sec residence time, it is more than 98% at greater than 0.5 sec. residence times. Correspondingly, unburned carbon emissions range from about 65% to less about 2% (dry fly ash basis) for the same residence times.
- The impact of reaction medium is also significant. While the overall combustion efficiencies do not seem to exhibit significant differences between the baseline and Constant Mass firing, the more sensitive parameter, unburned carbon (UBC) in the fly ash, on the other hand, clearly shows better performance for the Constant Mass case. That is, the UBC at the furnace outlet was more than a factor of 4.5 lower for the Constant Mass case (~2% vs. 9%). This is believed to be due to higher reaction temperature, and yet longer residence time (0.77 sec. vs. 0.57 sec.). It appears, from the shape of the UBC profiles, that, if given enough residence time, these differences would considerably narrow down, implying that the performance in both mediums would be similar.
- The coal sample from Conesville Unit #5 appears to perform better than the sample from Pittsburgh seam #8 coal (e.g., 9% vs. 12.5% UBC for the air firing case). However, based on the shape of the UBC profiles, it can be seen that if given additional residence times, they would both be expected to perform similarly.
- NOx emission from oxy-fuel firing is about a factor of 3 (0.73 vs. 2.25 lb/MMBtu) lower than that of the Base case. Correspondingly, sulfur dioxide is lower by about 19% (3.6 vs. 4.3 lb/MMBtu), and CO is significantly lower (0.09 lb/MMBtu vs. a negligible amount).
- The gaseous emission trends are consistent with results reported by others (Thambimuthu, et al.; 1998; Weller, et al., 1985) and by the CFD results of the present study (Section 3.0, below).

# **CFD** Analysis

ALSTOM Power uses a commercial CFD code (denoted FLUENT<sup>TM</sup>) from Fluent Inc. for its simulations of furnaces and auxiliary equipment. Case preparation of a boiler for the Fluent code was initiated with the collection of the geometry data (from blueprints and schematics), the free areas of the nozzles, and the operating conditions. A CFD grid or mesh was prepared using a combination of EXCEL spreadsheets and a grid-generation package (denoted GAMBIT<sup>TM</sup>) supplied by Fluent Inc. The total number of cells in the grid was approximately 315,000.

Two cases have been compared using the FLUENT<sup>™</sup> CFD code – a baseline, nominal 15% excess air case (Case 1 or Base case), and a recirculated flue gas, oxy-fired case (Case 2 or Concept-B case). In the Concept-B case, the nitrogen was largely replaced by carbon dioxide. The cases have been compared on the basis of equivalent nozzle/inlet areas, as well as an equivalent coal-to-oxygen feed ratio (by mass).

The baseline case was calibrated to known furnace performance and operating conditions. Calibration is required because of the uncertainty associated with wall fouling factors, particle reactivities, etc. "Implicit" boundary conditions that were matched during the baseline calibration included:

- the unburned carbon (UBC) in the fly ash (i.e., carbon-in-ash value) at the outlet of the computational domain
- the outlet NOx emissions value at the outlet of the computational domain
- the "horizontal furnace outlet temperature (HFOT)," which is the mass-weighted average temperature across the plane at the apex of the arch (i.e. the horizontal furnace outlet plane or HFOP).

Both the UBC and NOx emissions values were derived from experimental measurements (usually taken downstream of the air preheater). The HFOT value was calculated by an in-house, proprietary design package denoted the Reheat Boiler Program (RHBP). An iterative trial-and-error method was used to calibrate the baseline case by changing the input parameters for char oxidation, NOx, and waterwall conduction resistance, until (after a number of runs) the code calculations matched the desired UBC, the NOx value, and the HFOT, respectively.

Lateral and vertical waterwall heat flux or absorption distributions, as well as the overall heat transfer in the lower and upper furnace, were extracted from the CFD calculations. Total and sectional (area-weighted) waterwall heat absorption rates, in addition to peak heat absorption values, were used to quantify the heat absorption rates that constitute one of the metrics used as a basis of comparison between the cases. Metrics utilized to compare the cases include:

- the unburned carbon (UBC) in the fly ash at the outlet of the computational domain
- the outlet NOx emissions value at the outlet of the computational domain
- the horizontal (and/or vertical) furnace outlet temperature(s) (FOT)
- the outlet CO emissions value at the outlet of the computational domain
- total, sectional, and peak waterwall heat flux or absorption rates

Some of the metrics for the two cases, such as NOx, were compared on a basis that is scaled or referenced to the baseline value, since relative trends may be a more reliable indicator of the expected performance than the absolute magnitudes of the metrics. Line and contour plots for variables of interest were prepared at selected horizontal or vertical planes, as appropriate.

The predictions provided a relative indication of the changes that occurred in the oxy-firing case as a result of deviation from the baseline operating conditions. The difference in inlet nozzle velocities, mixture specific heats, and radiative properties between  $CO_2$  and  $N_2$  had a visible impact on the performance criteria and metrics of interest, e.g., HFOT, waterwall heat flux distributions, NOx emissions, and unburned carbon in the fly ash. Overall, the CFD runs served to provide insight into the flow and reaction patterns of the lower furnace, as well as to provide relative changes in emissions and residual carbon values at the exit plane as a result of changes in operating conditions.

# **CFD Results and Conclusions**

The following computational results have been highlighted:

- The baseline case exhibits higher carbon-in-ash (by 1.6 percentage points), higher outlet NOx emissions (by a factor of 2), and higher outlet CO (by a factor of 2) than the Concept-B case. These same computational trends are also qualitatively exhibited by the bench-scale testing.
- The baseline case exhibits a slightly higher peak gas temperature (maximum difference of about 200 °F), and a correspondingly higher average (cross-sectional) gas temperature (difference of 90 °F at the HFOT), than that of the Concept-B case.
- The net wall absorption in the furnace region for the baseline case is larger (by less than 1%) than that of the Concept-B case. (Conversely, the net wall absorption for the baseline calculation with the RHBP was found to be about 6% lower than the Concept-B case calculated by the RHBP.)

Explanations for the observed trends must rely on physical property differences between the nitrogen, which dominates in the baseline case, and carbon dioxide, which largely supplants the nitrogen in the Concept-B case. The physical species properties and the anticipated consequences are itemized below:

- 1. <u>Higher molecular weight of CO<sub>2</sub> relative to N<sub>2</sub></u>. For equivalent inlet areas, and as a result of the molecular weight and associated density differences, the baseline case will exhibit larger inlet velocities and a higher penetration capability than the Concept-B case. The inlet velocity differences will further serve to impact the aerodynamic, particle trajectory, mixing, and flame patterns.
- 2. <u>Higher specific heat of  $CO_2$  relative to  $N_2$ </u>. For an equivalent local heat release and heat transfer, the higher specific heat of carbon dioxide will serve to decrease the overall flame temperatures of the recycled flue gas mixture in the Concept-B case, relative to the baseline case.
- 3. <u>Higher gas emissivity and absorptance of  $CO_2$  relative to  $N_2$ </u>. For an equivalent local gas temperature, the higher emissivity of  $CO_2$ , relative to the optically transparent  $N_2$ , should serve to increase the absorption coefficient (and the irradiation to the wall) in the recycled flue gas case (Concept-B) relative to the baseline case.

The three physical properties listed above may have compensatory rather than cumulative effects. In the present CFD calculations, the resultant, local gas temperatures are not equivalent in the two cases. The higher specific heat of the carbon dioxide, and the associated lower gas temperatures in the Concept-B case, will tend to offset somewhat or compensate for the expected increase in the wall absorption (i.e., anticipated due to the enhanced emissivity of the  $CO_2$ .) Furthermore, the spatial distribution of the carbon dioxide across the cross-section may be important; it is hypothesized that high concentrations of  $CO_2$  in the cooler gas mixtures between the wall and the flame may actually act to inhibit the net radiative flux to the walls.

The trend calculated by the CFD code, with respect to the furnace temperature at the HFOP, appears to be qualitatively aligned with the trend calculated by the in-house RHBP code. However, the difference in wall absorption for the Concept-B case relative to the baseline case, calculated by FLUENT<sup>M</sup> (change of -1%), does not fully agree with the results of the RHBP (change of +6%). Computed and/or experimental trends that indicate that oxy-firing may induce either an increase in wall absorption (+6%) or a decrease in wall absorption (-18%), relative to the baseline case, are supported in the literature. It is suggested that the absorptive properties of a local CO<sub>2</sub>-containing gas mixture in the vicinity of the wall may either act to enhance or inhibit the incident radiative flux to the wall, depending upon its relative spatial placement and mixture temperature. For example, a low-temperature, CO<sub>2</sub>-rich mixture near the wall would absorb the radiative flux from the interior "fireball" region; a portion of the energy would be re-emitted at the lower gas temperature, and the remainder of the energy would be used to heat up the gas. The result would be a net reduction in the incident radiative flux to the wall. Conversely, a high-temperature, CO<sub>2</sub>-rich mixture near the wall would emit at its local gas temperature, thus enhancing the incident radiative flux to the wall. Therefore, it is suggested that the relative spatial relationships of the cool and hot gas mixtures, the relative composition of the absorbing media, and the proximity of that media to the wall (as induced by the furnace and firing system aerodynamics), may significantly impact the gas-phase irradiation to the wall. Indeed, the aerodynamic and flame patterns that prevail in a given air-fired or oxy-fired furnace may conceivably have as strong an impact on the net wall absorption as the physical property differences themselves (gas-phase emissivity, specific heat, etc.)

The results of computational tools (such as CFD and the RHBP) should be viewed as being qualitative in nature, particularly when they are asked to produce calculations outside of the experience base for which they have been validated. Certainly, the gas-phase and particle-phase radiation property submodels could be enhanced in both codes, and the impact of spatial gradients (caused by the interleaving of hot and cool regions of varying CO<sub>2</sub> composition) on radiative wall flux needs to be investigated more fully. CFD computations have been utilized to gain a more in-depth qualitative understanding of aerodynamic and flame patterns in combustion systems, but have not yet been integrated into routine boiler design procedures. At the present time, the ALSTOM design standards are based upon the experience and expertise built into the RHBP and other design protocols, and those standards must be adhered to in any new design project in order to mitigate risk. Therefore, the results of the RHBP must be regarded as the default standard, both from an engineering experience viewpoint and from a rules-based design viewpoint. However, additional validation work needs to be done in order to confirm the trends for oxy-firing scenarios.

Although differences in physical properties of the transport gases (e.g., air-firing versus oxy-firing) may initially induce undesirable deviations from the performance goals of a field unit, the designer and engineer views such alterations as challenges rather than insurmountable obstacles. Much can be done in the way of operating condition optimization (e.g., spray and nozzle tilt), without major retrofits, to realign steam temperatures and wall absorptions with their desired, target values. Design parameters are often in conflict, and the intelligent designer must work to balance various parameters and operating conditions to achieve the desired outcome. The CFD work performed here was based on certain constraints to maintain equivalency for comparison purposes, which would not necessarily be the case in the field. For example, a potential decrease in furnace wall absorption of several percentage points could be nullified through manipulation of various operating parameters. If required, firing system retrofits and surface modifications could be performed to handle more severe decreases in absorption; certainly new unit design could easily accommodate any necessary alterations in design philosophy.

#### **Recommendations for Future Work**

There is, to the authors' knowledge, no fundamental coal combustion work being carried out elsewhere to determine the impact of coal nature in an oxy-fuel environment on unburned carbon and gaseous and particulate emissions. Hence, the following is recommended:

- Carry out a systematic coal fundamentals study concerning this field of endeavor. This study should be geared toward the creation of a database of information depicting the impact of coal nature (using coals of various rank coming from both domestic and international sources) when fired in an oxy-fuel environment on:
  - > Coal devolatilization and char oxidation kinetics, and unburned carbon emissions in the fly ash
  - Acid rain-related gaseous (NOx, SO<sub>2</sub>, and CO) emissions
  - > Air toxics, particularly mercury (Hg), volatile organic compounds (VOCs), and particulate emissions.
- Derive furnace heat transfer data from natural gas and coal firing in an oxy-fired pilot-scale furnace, which simulates the temperature/time history of a boiler. Use first the data from natural gas firing to validate the CFD code, without the complication of burning particles transiting the boiler. Apply the experience learned from modeling a natural gas-fired boiler to model the coal-fired boiler.

# 1.0 BACKGROUND/OBJECTIVES

ALSTOM Power Inc.'s Power Plant Laboratories led a team, which performed a study titled "Engineering Feasibility and Economics of  $CO_2$  Capture on an Existing Coal-Fired Power Plant," under the auspices of the OCDO and DOE NETL. The other team members were ABB Lummus Global Inc. and American Electric Power (AEP).

The overall objective of this project was to evaluate the technical feasibility and the economics of alternate  $CO_2$  capture and sequestration/use technologies for retrofitting an existing coal-fired power plant. Three alternate  $CO_2$  capture systems (see Section 3 of Volume I) were evaluated, with attention being given to the impact of such systems on an existing boiler, the auxiliary components of the boiler, the boiler and overall plant performance, and the power plant costs, including the cost of electricity.

The overall objective of this work segment was to provide critical technical information for evaluating one of the three retrofit technology options, namely "Coal Combustion in an  $O_2/CO_2$  Environment with  $CO_2$  Recycle." Specific objectives were two-fold: (1) bench-scale testing was to provide experimental combustion and emissions performance data on a specific Ohio coal under conditions where the fuel was to be burned in mixtures of  $CO_2$  and  $O_2$ ; and (2) a computational fluid dynamics (CFD) modeling effort was to utilize design and operating information from a commercial boiler burning Ohio coal in order to establish a calculation for the conventional burning of coal (in air), and then to evaluate performance in the same commercial unit for the burning of the same coal in mixtures of  $CO_2$  and  $O_2$ .

Bench-scale results provided surrogate combustion kinetics, NOx, CO, SO<sub>2</sub> and unburned carbon results on the coal that is presently burned in the Conesville Boilers Units #5 and 6 under conditions that represent conventional combustion (in air) and in various mixtures of  $CO_2$  and  $O_2$ . A knowledge of the actual combustion and emissions data from Conesville Unit #5 provided a means whereby the baseline bench-scale results in air were referenced and interpreted; in a sense, it allowed "calibration" of the bench-scale experimental facility to a given point of reference. Referencing the baseline bench-scale results to the actual furnace emissions data allowed a more accurate interpretation of the bench-scale results of the  $CO_2$ - $O_2$  mixtures and permitted a more reliable/extrapolation of how an actual retrofitted boiler would respond to the same  $CO_2$ - $O_2$  mixtures.

The completed literature survey, performed under an initial task of this project (Bozzuto, et al., 2000), indicated that no fundamental combustion performance had been carried out on any coal in  $CO_2/O_2$  media. Hence, the work scope provided first-of-a-kind information to the project. Information derivation and application was carried out as follows:

- First, bench-scale testing of the Conesville coal was carried out in both air (to provide baseline information) and in various mixtures of CO<sub>2</sub> and O<sub>2</sub>.
- A comparison of the information on combustion performance in air with information from ALSTOM's proprietary database permitted ALSTOM to select char oxidation kinetic parameters to be used on a surrogate basis during the calibration of the CFD cases.

# 2.0 BENCH-SCALE TESTING

# 2.1 Introductory Remarks

ALSTOM Power's DTFS-1 has been used extensively over the years to derive, among other things, the following information (Nsakala, et al., 1986; Nsakala, et al., 1991; Thornock, et al., 1993):

- High temperature volatile matter yields from coals over the whole ASTM rank spectrum and from various synthetic solid fuels (petroleum cokes, refused-derived fuels, process coal gasification chars, beneficiated coal-based fuels, etc.).
- Fuel nitrogen conversion from coals over the whole ASTM rank spectrum and from the same various synthetic solid fuels given above.
- Gasification and devolatilization kinetic parameters for coals over the whole ASTM rank spectrum and for the same various synthetic solid fuels given above.
- Oxidation kinetic parameters of chars prepared from coals over the whole ASTM rank spectrum and from the same various synthetic solid fuels given above.

This information is used, where appropriate, in conjunction with coal combustion modeling with CFD and other proprietary in-house codes for the purpose of predicting (principally) unburned carbon loss and NOx emissions in pulverized fuel fired utility power boilers.

# 2.2 Analysis of Test Coals

Tables 2.1 and 2.2 present the ASTM standard analyses and ash chemistries of coal samples from AEP's Conesville Unit #5 and Pittsburgh #8 seam. Both of these coal samples are typical of good Eastern US bituminous steaming coals, with fuel values (i.e., FC/VM ratios) of 1.4 and 1.3, respectively. Consistent with the majority of the coal samples from this geological province, they have high sulfur contents (2.4 and 3.5 lb<sub>m</sub> S/MMBtu, respectively). Their coal ashes are typical of "Eastern" coal ashes, in which the iron contents are greater than the sums of alkali and alkaline earth contents. Based on the commonly used ash slagging and fouling indices, in conjunction with ash contents and fusibility temperatures, these coal ashes have only medium potentials of slagging the boiler waterwall and convective pass. The plant personnel from Conesville Generating Station confirmed this behavior, with respect to their Unit #5.

The coal samples in Table 2.1 were size graded to 200x400 mesh. These size-graded materials (Table 2.3) were subsequently tested in the TGA and DTFS-1 equipment to determine their reactivities and unburned carbon emission propensities. It is important to note that the chemical compositions of these size fractions are comparatively consistent with those of the parent coal samples they were prepared from.

# Table 2. 3: Proximate and Ultimate Analyses of Size Graded Coal Samples

# 2.3 Combustion Evaluation of Size-Graded Coal Samples

The coal samples, whose analyses are given in Table 2.3, were combustion tested in both a Thermo-Gravimetric Analysis (TGA) apparatus and a Drop Tube Furnace System-1 (DTFS-1). The equipment, experimental procedures, and conclusions are presented in the succeeding sections.

# 2.3.1 Thermo-Gravimetric Analysis (TGA)

The TGA apparatus, experimental procedure, and results are presented below.

# 2.3.1.1 TGA Description and Procedure

ALSTOM uses a Perkin-Elmer TGA Model 7 (Figure 2.1) to obtain specific reactivity parameters of fuels and limestones, among other things. The TGA is also used to derive the "micro-proximate" analyses of coals and coal chars, based on a test protocol developed in-house. Testing was conducted as follows. About 4-6 mg of sample was placed in the TGA sample pan. The sample amount was such that it distributed over the bottom of the pan almost as a monolayer, thus minimizing  $O_2$  mass transfer control phenomenon during combustion. Equal amounts of nitrogen (which serves to protect the balance) and air is allowed to pass through the reaction tube containing the coal sample. The temperature control mechanism is actuated, such that the heating rate is maintained at 10 °C/min from room temperature to the completion of combustion. Both weight loss and rate of rate of weight loss are monitored and recorded throughout the combustion process. The information from this testing is used, as shown in the next section, to derive combustion efficiency curves, and "pseudo" surface reaction kinetic parameters of the test coals as a function of reaction medium.

Three cases were evaluated for each coal. Fifty cc/min of  $N_2$  gas were admitted into the balance compartment to protect it from over-heating. The Base case consisted of burning the coal in 50 cc/min of air. The Constant Mass case consisted of burning the coal in an  $O_2/CO_2$  mixture, such that the mass of  $O_2$  used in the Base case was maintained and the mass of  $N_2$  used in the Base case was replaced with an equal mass of  $CO_2$ . The Constant

Volume case consisted of burning the coal in  $O_2/CO_2$  mixture, such that the mass of  $O_2$  used in the Base case was again maintained and the volume of N<sub>2</sub> used in the Base case was replaced with an equal volume of CO<sub>2</sub>.

## 2.3.3.2 TGA Results

As stated in Section 2.2, the TGA evaluation was carried out on the 200x400-mesh samples identified in Table 2.3. Results from this evaluation are presented in Figures 2.2 to 2.4.

The combustion efficiency profiles, shown in Figure 2.2, indicate that some subtle differences seem to exist between coal firing in air and  $O_2/CO_2$  mediums. A close examination of the data, however, shows that these differences are within experimental error for this type of testing. The results further indicate that both coals have similar burning characteristics, as they both go to completion within the same temperature range (550-575 °C).

The differential thermo-gravimetric analysis profiles, derived from the first derivative of weight loss with time (i.e., -dW/dt) are shown in Figure 2.3. One of the parameters traditionally used to interpret these curves is the Tkp. This parameter is, by definition, the temperature at which maximum heat evolution or reaction rate occurs. The values for the Conesville Unit #5 coal range from 472 to 479 °C; the corresponding values for Pittsburgh #8 coal fall in the 462 to 479 °C range. Clearly, these numbers are in such a narrow range that it can be concluded that: (1) burning either of the coals in air or any of the  $O_2/CO_2$  mixture ratios used will produce virtually identical results; and (2) both coals have similar reactivity characteristics. These results are consistent with those reported in Figure 2.2.

The combustion efficiency curves in Figure 2.2 were used to derive first-order reaction kinetic parameters, assuming that the effects of  $O_2$  mass transfer in the fixed-bed TGA were minimal and could be neglected. Results are plotted in Figure 2.4 as logKs versus 1000/, where Ks is the "pseudo" surface reactivity rate parameter (sec<sup>-1</sup>), and T (°K) is the reaction temperature. These results are consistent with those reported in Figures 2.2 and 2.3.

# 2.3.2 Drop Tube Furnace System-1 (DTFS-1) Testing

The test facility, testing procedures used, and results obtained therefrom are discussed in the following sections.

## 2.3.2.1 DTFS-1 Description and Testing Procedure

ALSTOM's Drop Tube Furnace System-1 (DTFS-1) (Figure 2.5) is comprised of a 1-inch inner diameter, horizontal tube, gas pre-heater and a 2-inch inner diameter, vertical tube, test furnace for providing controlled temperature conditions to study devolatilization, gasification and/or combustion phenomena. This entrained flow reactor, which is electrically heated with silicon carbide elements, is capable of heating reacting particles to temperatures of up to 2700 °F and sustaining particle residence times of up to about one second to simulate the suspension firing conditions encountered in pulverized coal-fired boilers.

The DTFS-1 testing procedure entails the following: (1) the fuel is fed at a precisely known rate through a water-cooled injector into the test furnace reaction zone; (2) the fuel and its carrier gas are allowed to rapidly mix with a pre-heated down-flowing secondary gas stream; (3) devolatilization, gasification, or combustion is allowed to occur for a specific time (dictated by the transit distance); (4) reactions are rapidly quenched by aspirating the mixture into a water-cooled sampling probe; (5) the solids are separated from gaseous products in a filter medium; and (6) an aliquot of the effluent gas stream is sent to a dedicated Gas Analysis System (GAS) for on-line determination of NOx, SO<sub>2</sub>, O<sub>2</sub>, CO<sub>2</sub>, CO, and THC (total hydrocarbons) concentrations. Minor gaseous components (HCN, NH<sub>1</sub>, CH<sub>1</sub>, VOCs, PAHs, etc.) can be measured, if required, with existing ancillary equipment (a gas chromatograph and / or a Fourier transform infrared spectrometer). A LabView-based data acquisition system records, on demand, all relevant test data for subsequent retrieval and processing. The LabView software package is also used to control the gas flow rates into the furnace.

An ash tracer technique (Nsakala, et al., 1977; Nsakala, et. Al., 1986) is used in conjunction with the proximate analyses of feed samples and chars subsequently generated in the DTFS-1 to calculate the devolatilization, gasification or combustion efficiency as a function of operational parameters (particle temperature, particle residence time, fuel fineness, reaction medium, etc.). A proprietary software package can, alternatively, use the information on concentrations of  $CO_2$ , CO, and THC (if available) in the effluent gas streams to calculate carbon conversion rates under prevailing conditions.

The DTFS-1 testing is normally used to derive quantitative information on the impact of various operating parameters such as particle size, stoichiometry and temperature/time history on unburned carbon loss and gaseous (NOx, CO and  $SO_2$ ) emissions.

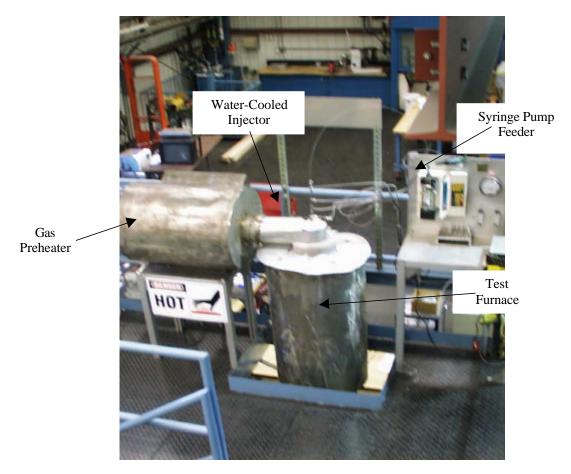

Figure 2.5: ALSTOM Power's Drop-Tube Furnace System-1 (DTFS-1)

Three cases were evaluated for each coal (Table 2.5). The Base case consisted of burning the coal in 15 l/min of air. The Constant Mass case consisted of burning the coal in an  $O_2/CO_2$  mixture, such that the mass of  $O_2$  used in the Base case was maintained and the mass of  $N_2$  used in the Base case was replaced with an equal mass of  $CO_2$ . The Constant Volume case consisted of burning the coal in an  $O_2/CO_2$  mixture, such that the mass of  $O_2$  used in the Base case was again maintained and the volume of  $N_2$  used in the Base case was replaced with an equal volume of  $CO_2$ .

The rationale for selecting these three test cases is as follows. The Base case represents coal combustion in air, consistent with a "business as usual" scenario. The Constant Mass case represents a realistic scenario if coal were to be fired in an  $O_2$ /recycled flue gas environment. The Constant Volume case also represents coal combustion in an  $O_2$ /recycled flue gas environment, although in this case the  $CO_2$  volume is conserved vis-à-vis the  $N_2$  it would displace from the air. Table 2.5 shows that the total gas volumetric flow rates for the Constant Mass and Constant Volume cases are, respectively, lower than and equal to that of the Base case (10.7 l/min and 15.0 l/min versus 15.0 l/min, at 25 °C and 1 atm.). Hence, all other things being equal, the gas residence times in the furnace for the Constant Mass and Constant Volume cases would be, respectively, longer than and equal to the gas residence time for the Base case.

The coal feed rate was adjusted for each coal such that the overall stoichiometry (1) was ~2.50. This value is more than a factor of 2 higher than the typical value encountered in pulverized coal firing applications. It was known, from previous experience, that in order to achieve reasonably low unburned carbon emissions in the drop tube, it was necessary to conduct these experiments in such oxygen-rich environments. This mode of operation is necessitated for two principal reasons, namely: (1) the DTFS-1 operates in a laminar flow regime,

with a Reynolds number in the 150-225 range; and (2) the maximum residence time for the conditions evaluated was about 0.8 seconds.

## 2.3.2.2 Reactant Gas Temperature Measurements

A suction pyrometer was used to measure, for each of the three study cases, the gas temperature profile along the axis of the DTFS-1 reaction chamber. In addition to the in-furnace measurements, heat transfer calculations were performed for each case to predict the impact of the reactant gas characteristics on its temperature profile along the axis of the DTFS-1 reaction chamber. The predictions were based on the exact DTFS-1 operating conditions for the same three study cases. The measurements (Figure 2.6) indicate the following gas temperature profile trend:  $T_{Base case} < T_{Constant}$  volume case  $< T_{Constant Mass case}$ . The reason for this occurrence is that CO<sub>2</sub>, unlike N<sub>2</sub>, is capable of absorbing energy radiated from the furnace walls. CO<sub>2</sub> has a greater specific heat than N<sub>2</sub> (Figure 2.7), but as is evident from the Constant Mass case, the ability of the CO<sub>2</sub> to absorb/emit radiation dominates and causes the CO<sub>2</sub>-rich gas to achieve higher temperatures than the N<sub>2</sub>-rich case. The trends exhibited by the theoretical heat transfer model, developed to predict gas temperatures, supported those found experimentally (Figure 2.6).

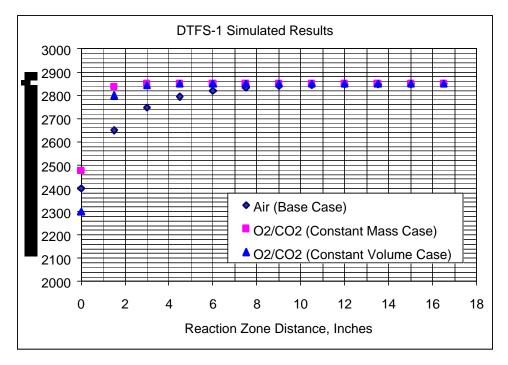

Figure 2.6: Measured and Predicted Gas Temperatures in the DTFS-1

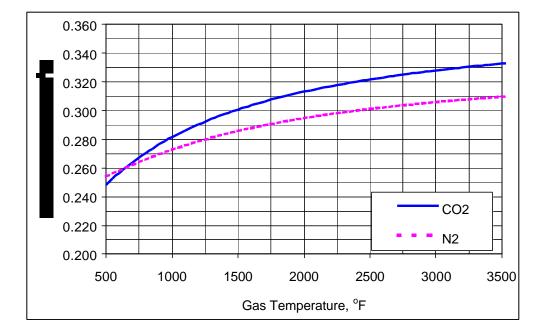

Figure 2.7: Specific Heats of Nitrogen and Carbon Dioxide as a Function of Temperature

It should be borne in mind that the heat transfer calculations were made only to validate the trends of the gas temperatures measured in the DTFS-1. No attempts were made to calibrate those calculations to the measurements.

When gas mass flow rates, temperatures, and furnace geometry are taken into consideration together the corresponding gas residence times (t) indicated the following trend:  $t_{Constant Volume case} < t_{Base case} < t_{Constant Mass case}$ . The impacts of these trends or lack thereof, on unburned carbon and gaseous emissions, will be discussed in Section 2.3.2.3.

# 2.3.2.3 Unburned Carbon and Gaseous Emission Results

It is important to reiterate at the outset (See Section 2.3.2.1) that: (1) the DTFS-1 is operated in a laminar flow regime, with a Reynolds number in the 150-225 range; and (2) the maximum residence time for the conditions evaluated was about 0.8 sec. Hence, in order to achieve reasonably low unburned carbon emissions at the furnace outlet, the DTFS-1 was operated at a rather high overall oxygen/fuel stoichiometric ratio (i.e.,  $\mathbf{1} \sim 2.5$  versus the typical value of ~1.2 encountered in pulverized coal firing applications). Consequently, the unburned carbon and gaseous emission results reported here should be interpreted strictly on a relative basis only, as no attempt was made to correlate them with field (i.e., Conesville Unit #5) performance results.

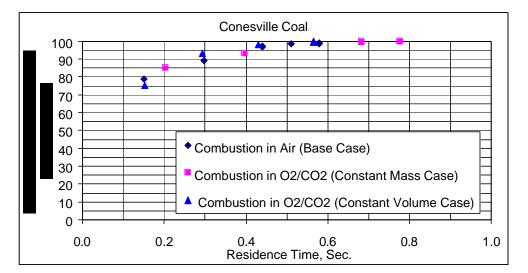

Table 2.6 summarizes the unburned carbon (UBC) results obtained from firing the coal samples from Conesville Unit #5 and Pittsburgh #8 seam under the three study cases discussed above. Figures 2.8 and 2.9 are plots of coal combustion efficiency and unburned carbon in fly ash as a function of gas residence time.

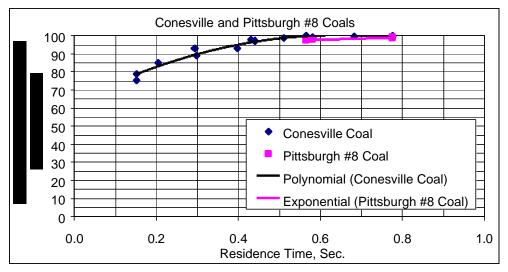

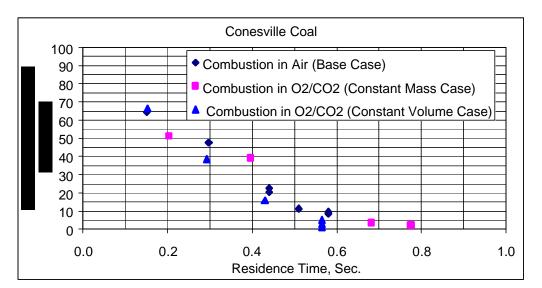

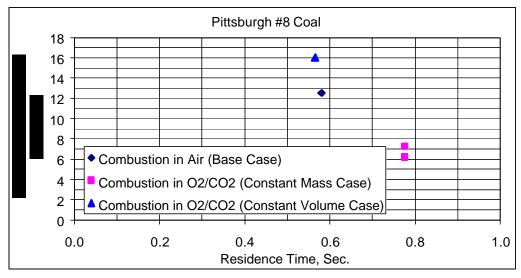

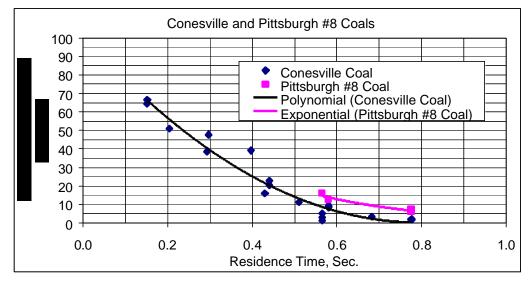

Figure 2.8: DTFS-1 Generated Coal Combustion Efficiency Profiles

ALSTOM Power Inc.

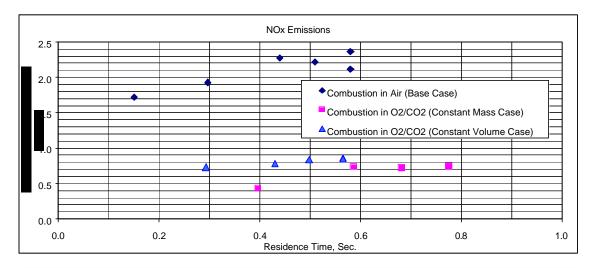

ALSTOM Power Inc.

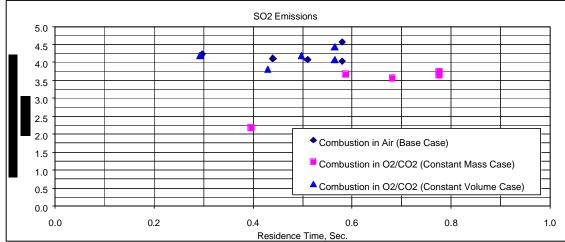

Figures 2.8 and 2.9 indicate that residence time has, as expected, a significant impact on the overall coal combustion efficiency, and hence, on the unburned carbon emission in the fly ash for both coals under consideration. That is, while the combustion efficiency for both coals is only about 80% (dry-ash-free coal basis) at 0.2 sec residence time, it is more than 98% at 0.8 sec. residence time. Correspondingly, unburned carbon emissions range from about 65% to less about 2% (dry fly ash basis) for the same residence times. The second point that can be made is that for the given thermal regime in the DTFS-1, the impact of reaction medium is significant. While the overall combustion efficiencies do not seem to exhibit significant differences between the baseline and Constant Mass firing, the more sensitive parameter, unburned carbon (UBC) in the fly ash, on the other hand, clearly shows better performance for the Constant Mass case. That is, the UBC at the furnace outlet was more than a factor of 4.5 lower for the Constant Mass case (~2% vs. 9%). This is believed to be due to higher reaction temperature, and yet longer residence by 35% (0.77 sec. vs. 0.57 sec.). It appears, from the shape of the UBC profiles, that, if given enough residence times, these differences would considerably narrow down. Finally, it appears that the coal sample from Conesville Unit #5 performs better than the sample from Pittsburgh #8 coal seam (e.g., 9% vs. 12.5% UBC for the air firing case). However, if given additional residence times, they would both be expected to perform similarly.

The ultimate conclusion is that unburned carbon emission for the Constant Mass case, which represents the appropriate retrofit scenario in a commercial pulverized coal firing application (i.e., the mass of  $CO_2$  in the  $O_2/CO_2$  combustion medium displaces the same mass of  $N_2$  in the combustion air), provides a significant advantage over air firing. This is, presumably, because of the relatively higher temperature, and yet longer combustion process time that the Constant Mass case provides.

Table 2.2.7 and Figure 2.10 show gaseous (NOx, CO, and SO<sub>2</sub>) emissions results obtained from burning the coal sample from Conesville Unit #5 in air and O<sub>2</sub>/CO<sub>2</sub> combustion mediums. These results indicate significant increases in NOx, slight increases in SO<sub>2</sub>, and significant decreases in CO emissions as a function of increasing residence time. This is due to, as expected, correspondingly improved overall coal combustion efficiency with time. The NOx emission reduction from air firing (Base case) to oxy-fuel firing (i.e., O<sub>2</sub>/CO<sub>2</sub> combustion mediums) is about a factor of 3 (0.73 vs. 2.25 lb/MMBtu). The trend is consistent with results reported by others (Thambimuthu, et al.; 1998; Weller, et al., 1985) and by the CFD results of the present study (Section 3.0, below). However, Thambimuthu, et al. and Weller, et al. reported reductions ranging up to only about 30%. Hence, it is not clear whether the superstoichiometry utilized in the present experiment ( $\lambda \sim 2.5$ ) exaggerates the difference. Sulfur dioxide for oxy-fuel firing is lower by about 19% than the corresponding value for air firing (3.6 vs. 4.3 lb/MMBtu). CO for oxy-fuel firing was lower than the corresponding values for air firing (0.09 lb/MMBtu vs. a negligible amount).

The ultimate conclusion from gaseous emission findings is that the Constant Mass case does seem to provide (1) a significant advantage over air firing, with respect to NOx and CO emissions; and (2) a slight advantage over air firing, with respect to  $SO_2$  emission.

# 2.3.3 Conclusions and Recommendations for Future Work

The conclusions and recommendations that were derived from this bench-scale testing campaign are given below.

## 2.3.3.1 Conclusions

A series of conclusions can be drawn from the results from combustion testing of the coal samples from Conesville Unit #5 and Pittsburgh #8 seam in both TGA and DTFS-1 equipment, namely:

- TGA results indicate that subtle differences exist between: (1) coal firing in air and in O<sub>2</sub>/CO<sub>2</sub> mediums; and (2) Conesville Unit #5 coal and Pittsburgh Seam #8 coal. A close examination of the data, however, indicates that these differences are within experimental errors. Hence, it can be concluded that both coals can be expected to perform similarly under the experimental constraints specified in this study.
- DTFS-1 results showed the following:
  - Residence time has, as expected, a significant impact on the overall coal combustion efficiency, and hence, on the unburned carbon emission in the fly ash for both coals under consideration. That is, while the combustion efficiency for both coals is only about 80% (dry-ash-free coal basis) at 0.2 sec residence time, it is more than 98% at greater than 0.5 sec. residence times. Correspondingly, unburned carbon emissions range from about 65% to less about 2% (dry fly ash basis) for the same residence times.
  - The impact of reaction medium is also significant. While the overall combustion efficiencies do not seem to exhibit significant differences between the baseline and Constant Mass firing, the more sensitive parameter, unburned carbon (UBC) in the fly ash, on the other hand, clearly shows better performance for the Constant Mass case. That is, the UBC at the furnace outlet was more than a factor of 4.5 lower for the Constant Mass case (~2% vs. 9%). This is believed to be due to higher reaction temperature, and yet longer residence (0.77 sec. vs. 0.57 sec.). It appears, from the shape of the UBC profiles, that, if given enough residence times, these differences would considerably narrow down, implying that the performance in both mediums would be similar.
  - The coal sample from Conesville Unit #5 appears to perform better than the sample from Pittsburgh seam #8 coal (e.g., 9% vs. 12.5% UBC for the air firing case). However, base on the shape of the UBC profiles, it can be seen that if given additional residence times, they would both be expected to perform similarly.
  - NOx emission from oxy-fuel firing is about a factor of ~3 (0.73 vs. 2.25 lb/MMBtu) lower than that of Base case. Correspondingly, sulfur dioxide is lower by about 19% (3.6 vs. 4.3 lb/MMBtu), and CO is significantly lower (0.09 lb/MMBtu vs. a negligible amount).
  - The gaseous emission trends are consistent with results reported by others (Thambimuthu, et al.; 1998; Weller, et al., 1985) and by the CFD results of the present study (Section 3.0, below).

#### 2.3.3.2 Recommendations for Future Work

There is, to the authors' knowledge, no fundamental coal combustion work being carried out elsewhere to determine the impact of coal nature in an oxy-fuel environment on unburned carbon and gaseous and particulate emissions. Hence, the following is recommended:

- Carry out a systematic coal fundamentals study concerning this field of endeavor. This study should be geared toward the creation of a database of information depicting the impact of coal nature (using coals of various rank coming from both domestic and international sources) when fired in an oxy-fuel environment on:
  - > Coal devolatilization and char oxidation kinetics, and unburned carbon emissions in the fly ash

- Acid rain-related gaseous (NOx, SO<sub>2</sub>, and CO) emissions
- > Air toxics, particularly mercury (Hg), volatile organic compounds (VOCs), and particulate emissions.
- Derive furnace heat transfer data from natural gas and coal firing in a pilot-scale furnace, which simulates the temperature/time history of a boiler. Use first the data from natural gas firing to validate the CFD code, without the complication of burning particles transiting the boiler. Apply the experience learned from modeling a natural gas flame to model the coal-fired flame.

# 3.0 CFD Evaluation Of Conesville Boiler No. 5

## 3.1 Introduction

ALSTOM Power has made a strong commitment to computational fluid dynamics (CFD) and has effectively used CFD in many applications, e.g., design and optimization of coal-, oil-, and gas-fired boilers, pulverizers, air heaters, electrostatic precipitators, cyclones, and scrubbers. At any given time, there are 8 to 10 individuals performing CFD simulations on approximately 40 CPU's, including both workstations and multi-processor servers.

With respect to boiler performance, significant CFD and combustion modeling research efforts have been conducted at ALSTOM Power to characterize and optimize the performance of tangentially-fired and wall-fired furnaces. These projects have demonstrated the impact of fluid dynamics, gas phase stoichiometry, and heat input on the combustion efficiency and boiler emissions for a variety of commercial boiler applications. Synopses of recent studies that have been permitted to enter the public domain include the prediction of furnace gas temperatures and species concentrations for NOx reduction with recirculated flue gas (Richards, et al., 1997), furnace waterwall species concentrations for improvement to deposition and slagging performance (Hart, et al., 1998), and design of a low NOx burner (Haynes, et al., 1996). (Overview papers on CFD at ALSTOM Power include Marion, et al., 1995 and Fiveland, 2000.)

CFD modeling is considered to be the most cost-effective approach to assess flow and mixing related phenomena for reacting flow conditions, and was therefore proposed for this work.

# 3.2 Grid Preparation

American Electric Power's Conesville Unit #5 boiler has been described in detail in Volume I of this report (Bozzuto, et al., 2001); however, certain features will be reviewed below to introduce the grid and case preparation.

In general, the Conesville unit can be described as a nominal 450 MW-gross, tangentially coal fired, subcritical pressure, controlled circulation, radiant reheat unit. The furnace is a single cell design utilizing five elevations of tilting tangential coal burners. The unit fires a mid-western bituminous coal. The coal is supplied to the five elevations with five RP-903 coal pulverizers. The unit is designed to generate about  $3.1 \times 10^6$  lbm/hr of steam at 2400 psi and 1005 °F with reheat also to 1005 °F. The boiler is equipped with a number of superheater surfaces, including a low temperature superheater (horizontal), finishing superheater, a radiant superheat division panel section, and the superheater platen section. The reheater consists of a low temperature radiant wall section followed by a spaced finishing section. The economizer section consists of four banks of spiral finned tubes. Outlet steam temperature control is provided with desuperheating spray and burner tilt. The dimensions of the boiler unit are 51' 8" in width, 44' 3-15/16" in depth (to the rear wall), and 170' 10-1/4" in height. A sectional side view of this boiler is shown in Figure 3.1.

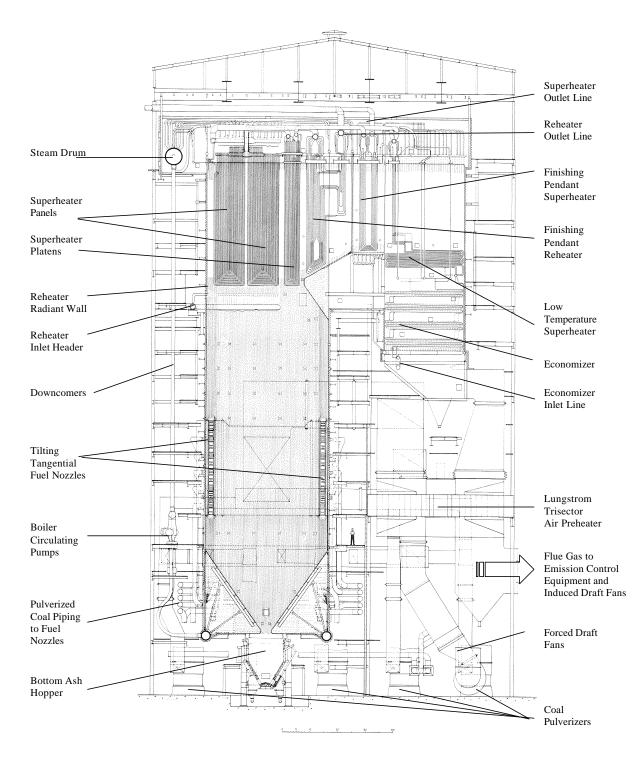

Figure 3.1: Sectional Side View of the Conesville Unit #5 Steam Generator

ALSTOM Power uses a commercial CFD code (denoted FLUENT<sup>™</sup>) from Fluent Inc. (Lebanon, NH) for its simulations of furnaces and auxiliary equipment. Case preparation of a boiler for the Fluent code is initiated with the collection of the geometry data (from blueprints and schematics), the free areas of the nozzles, and the operating conditions. A CFD grid or mesh is prepared using a combination of EXCEL spreadsheets and a grid-generation package (denoted GAMBIT<sup>™</sup>) supplied by Fluent Inc. Skeletal and external isometric views of the computational domain are shown in Figure 3.2.

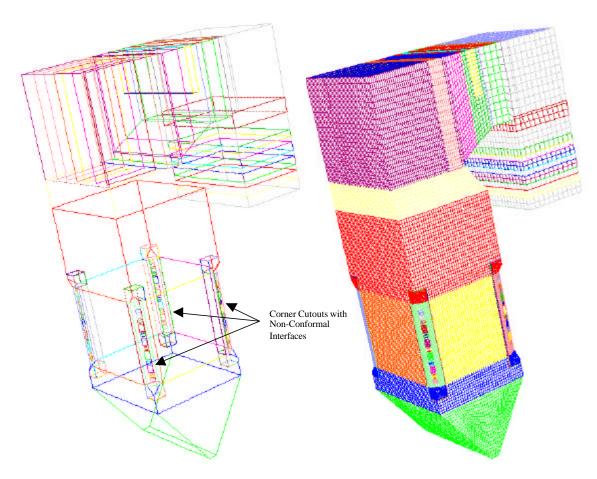

Figure 3.2: Isometric Views of the Conesville Unit #5 Computational Domain

The framework or skeletal view above shows square cutouts in the corners that encompass the windboxes. These square cutouts contain cells that are smaller (by a factor of 2 in each coordinate direction) than the cells in the interior of the domain, thus allowing the windbox region to receive a greater concentration of cells than in the interior. The enhanced cell concentration in the windbox region permits greater resolution of the relatively small nozzle openings and the high gradient regions associated with discrete jets. The interfaces between each of the corner cutouts and the domain interior are referred to (by Fluent Inc.) as "non-conformal" interfaces. Such interfaces permit grids of dissimilar type and size to seamlessly interact with each other along any given plane and preserve the conservation of all relevant quantities (e.g., mass, momentum, and energy).

Close-ups of the grid from a side view of the boiler are shown in Figure 3.3. Besides the non-conformal interfaces around the windboxes, another non-conformal grid interface is utilized in the convective pass, permitting the grid to coarsen (by a factor of 2 in each coordinate direction) into the backpass. The grid in the computational domain is composed primarily of hexahedral elements. Tetrahedral elements are utilized only at the top and bottom of the windbox to assist in a geometric transition. Pyramidal elements are used at the interface between the tetrahedrons and the hexahedrons. The total number of cells in the grid is 314,176.

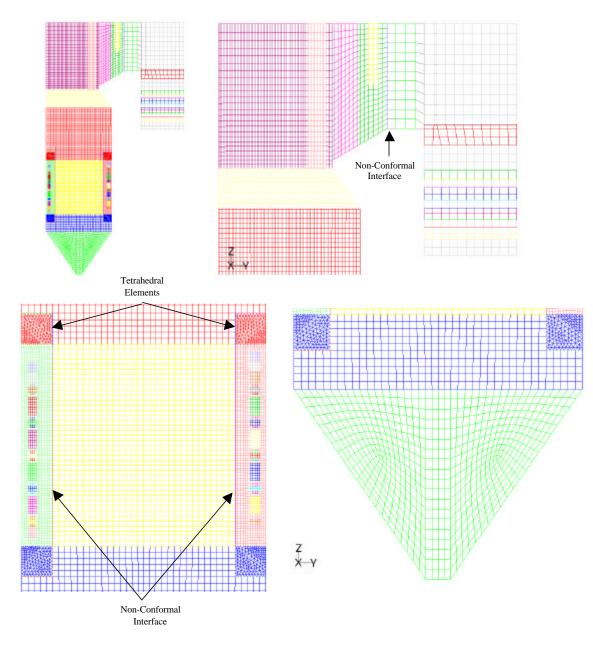

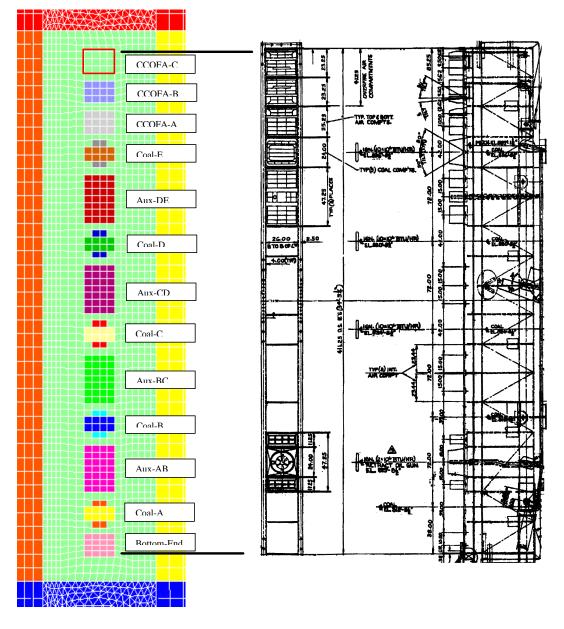

Figure 3. 3: Side Views of the Conesville Unit #5 Exterior Grid

Conesville Unit No. 5 is equipped with a tangential firing system, consisting of 3 close-coupled overfire air (CCOFA) register elevations, and 5 coal nozzle elevations. The main and CCOFA windbox widths are equal to 26 inches and the coal nozzle ID is equal to 19.25 inches. The tip/nozzle free areas were extracted from the firing system windbox selection sheets and the nozzle elevations were calculated from the available blueprints. A computational representation of the windbox and nozzles, which is necessarily crude in comparison to the details of the actual hardware, is shown in Figure 3.4. The computational inlet designations (i.e., CCOFA-C, etc.) are also shown. The small inlets on the top and bottom of each computational coal nozzle represent the flow area associated with the fuel-air stream, which in actuality, flows into the furnace around the periphery of the primary coal pipe/tip.

# Figure 3.4: Detailed Drawing of Windbox and Corresponding Side View of Grid Depicting Nozzle Openings

The direction of swirl rotation in Conesville Unit 5 (as viewed from the top of the boiler), is shown below in Figure 3.5. The direction of the "fireball rotation" is counter-clockwise. The normal firing angles are at 44 degrees and at 36 degrees for the pairs of opposed jets.

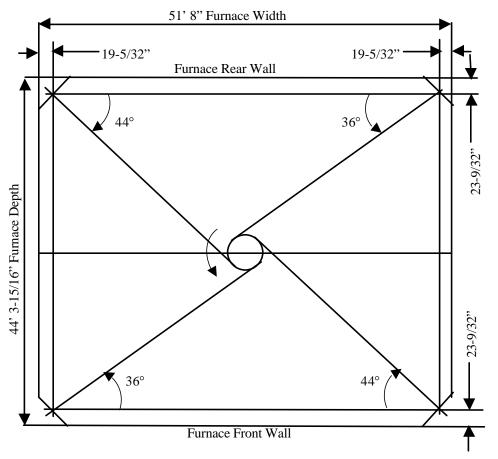

Figure 3. 5: Cross-Sectional View of Normal Firing Angles for Conesville Unit 5

The corresponding grid on the cross-section, in the vicinity of the windbox, is shown in Figure 3.6. As explained before, a 2:1 change in cell dimension occurs across the non-conformal interface in the windbox region, thus allowing a greater grid density to be concentrated in the immediate vicinity of the nozzle inlets. The grid in the windbox region consists of hexahedral cells, although they may be slightly skewed to accommodate the corner fillets (comprising the windbox).

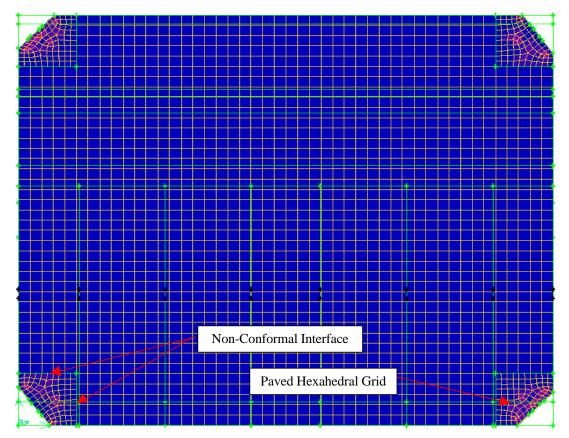

Figure 3. 6: Cross-Sectional View of Grid, in the Vicinity of the Windbox, for Conesville Unit 5

# 3.3 Baseline Calibration Procedure and Strategy

Typically, in an applications project, as in the present study, the first CFD case that is prepared and run is used to evaluate the furnace performance under its baseline combustion conditions. Many of the boundary conditions, such as velocity and temperature, constitute "explicit" boundary conditions and are defined as part of the input. However, a few boundary conditions (or equality constraints) are "implicitly" defined and are derived either from experimental measurements or external calculations. While "implicit" boundary conditions are not explicitly defined as inputs, it is understood that such boundary conditions must nevertheless be matched by the post-run results. Such "implicit" boundary conditions include:

- the unburned carbon (UBC) in the fly ash (i.e., carbon-in-ash value) at the outlet of the computational domain
- the outlet NOx emissions value at the outlet of the computational domain
- the "horizontal furnace outlet temperature (HFOT)," which is the mass-weighted average temperature across the plane at the apex of the arch (i.e. the horizontal furnace outlet plane or HFOP).

Both the UBC and NOx emissions values originate from experimental measurements (usually taken downstream of the air preheater). The HFOT value is calculated by an in-house, proprietary design package denoted the Reheat Boiler Program (RHBP). The Reheat Boiler Program, running in its reverse/calibration mode, is fed the excess air, windbox nozzle tilts, all known steam-side parameters, the fuel flow rate, and other general and geometric parameters, and in turn, calculates the HFOT (as well as the wall heat transfer fouling factors, the tube bank surface effectiveness factors, the gas flow rates, and the amount of superheat/reheat spray, if applicable).

In the CFD calculation, the char oxidation input parameters control the final amount of residual carbon in the fly ash, the NOx kinetic input parameters largely control the outlet NOx values, and the overall resistance to heat transfer through the waterwall and superheater surfaces and deposits controls the HFOT. An iterative trial-and-error method is used to calibrate the baseline case by changing the input parameters for char oxidation, NOx, and waterwall conduction resistance, until (after a number of runs) the code calculations match the desired UBC, the NOx value, and the HFOT, respectively. Such an iterative procedure for calibration is required since many of the input parameters and boundary conditions are not known with sufficient accuracy to be specified in an *a priori* manner, and calibration tends to compensate for the accrued uncertainty.

In the present study, the above procedure was used to calibrate the baseline case to the desired UBC (as dictated by experimental field data) and to the desired HFOT (as dictated by the RHBP results). Since the CFD code (i.e., the FLUENT<sup>TM</sup> code) did not provide sufficient access to the NOx kinetic parameters, the calculated baseline NOx results were scaled to the baseline experimental values.

# 3.4 CFD Test Matrix

Two main cases were analyzed in this CFD modeling study. The scope of the modeling work consisted of the baseline case and one subsequent case entailing oxy-firing (i.e., firing the coal in  $O_2$ - and  $CO_2$ -rich recycled flue gas. A description of each of the cases is provided in Table 3.1.

Case	Case Description	Nominal Inlet O <sub>2</sub> Mole Percent (Dry)	Nominal Inlet CO <sub>2</sub> Mole Percent (Dry)	Nominal Inlet N <sub>2</sub> Mole Percent (Dry)
1	Base Case: Nominally 15% Excess Air	21	0	79
2	Concept B Case: FGR / Oxy-Firing	29	65	6

Table 3. 1: Matrix of CFD Cases

Case 1 is the Base case or baseline case, which corresponds to a nominal 15% excess air and maximum continuous rating (MCR) load conditions. As discussed above, specific input parameters have been iteratively modified until calibration with the selected implicit boundary conditions was achieved to a reasonable approximation.

The FLUENT<sup>TM</sup> code, calibrated with the baseline combustion conditions, was subsequently used to evaluate the impact of oxy-firing the coal, with a prescribed  $CO_2/O_2$  mole ratio. In comparison with the baseline run (Case 1), the Concept-B case (Case 2) displaces the mass of  $N_2$  by an equivalent mass of  $CO_2$  (approximately). Since the molecular weight of  $CO_2$  is greater than that of  $N_2$  by a factor of approximately 1.57, the density of  $CO_2$  will be correspondingly greater than that of  $N_2$ , and the velocity of the recirculated flue gas streams through the windbox nozzles will therefore be smaller (by, e.g., 36% for pure streams) than that of the baseline case (for the same nozzle free area). Based on the presumption that windbox retrofits should not be required in any application of the proposed advanced FGR technology, a decision was made to preserve the same (computational) inlet nozzle area for both cases; therefore, both cases were compared on an equivalent inlet-area basis, rather than on an equivalent inlet-velocity basis.

Lateral and vertical waterwall heat flux or absorption distributions, as well as the overall heat transfer in the lower and upper furnace, have been extracted from the CFD calculations. Total and sectional (area-weighted) waterwall heat absorption rates, in addition to peak heat absorption values, have been used to quantify the heat absorption rates that constitute one of the metrics used as a basis of comparison between the cases. Metrics utilized to compare the cases include:

- the unburned carbon (UBC) in the fly ash at the outlet of the computational domain
- the outlet NOx emissions value at the outlet of the computational domain
- the horizontal (and/or vertical) furnace outlet temperature(s) (FOT)
- the outlet CO emissions value at the outlet of the computational domain
- total, sectional, and peak waterwall heat flux or absorption rates

ALSTOM Power Inc.

Some of the metrics for the two cases, such as NOx, will be compared on a basis that is scaled or referenced to the baseline value, since relative trends may be a more reliable indicator of the expected performance than the absolute magnitudes of the metrics. Line and contour plots for variables of interest will be shown at selected horizontal or vertical planes, as appropriate.

The predictions provide a relative indication of the changes that may occur as a result of deviation from the baseline operating conditions. The difference in inlet nozzle velocities, mixture specific heats, and radiative properties between  $CO_2$  and  $N_2$  have an impact on the performance criteria and metrics of interest, e.g., HFOT, waterwall heat flux distributions, NOx emissions, and unburned carbon in the fly ash. Overall, the CFD runs serve to provide insight into the flow and reaction patterns of the lower furnace, as well as to provide relative changes in emissions and residual carbon values at the exit plane as a result of changes in operating conditions.

# 3.5 Input and Boundary Conditions

The case selected as the "Base case" is not strictly a replication of the experimental test data at one operating condition of the Conesville Unit No. 5. Rather, the Base case is defined as being a composite case which is representative of the available control room or board data over multiple test days. The board data encompasses variations in excess air conditions (14.1% to 18.1%), tilts, and burners designated as being out of service (BOOS)). From the array of operating conditions available in the board data, specific operating parameters were selected, which collectively constituted the "Base case" operating conditions. A RHBP simulation of the selected Base case test conditions helped to further delineate and refine some of the operating condition parameters.

Based on the project goals and requirements for flue gas recirculation and oxy-firing, the operating conditions of the Concept-B case were also subsequently defined. A RHBP run was conducted to study and evaluate the Concept-B case.

The mass flow rates, excess air conditions, inlet temperatures, tilts, etc. calculated in the RHBP runs were utilized directly in the CFD runs. A summary of the overall input parameters applied to the two cases are shown in Table 3.2.

	Base Case	Comport D Cogo	
Parameters	(15% Excess Air)	Concept B Case (Oxy-Firing)	
	(	(- <b>,</b> 8/	
Total Secondary Gas $(lb_m/hr) =$	2,968,935	2,933,877	
Total Primary Gas (lb <sub>m</sub> /hr) =	724,580	671,503	
Total Gas (lb <sub>m</sub> /hr) =	3,693,515	3,605,380	
Total (As Rec'd) Coal $(lb_m/hr) =$	374,455	366,603	
Total (Moisture-Free) Coal $(lb_m/hr) =$	336,635	329,576	
Total (DAF) Coal (lb <sub>m</sub> /hr) =	294,322	288,150

Table 3. 5:	Mass Flow	Rates for	the Secondary	<b>Gas Feed Streams</b>
-------------	-----------	-----------	---------------	-------------------------

The damper positions for the top two CCOFAs were extracted from field board data. The other damper positions were estimated, based upon ALSTOM Power's experience. A proprietary EXCEL spreadsheet calculator, denoted the Firing Zone Stoichiometry Calculations (FZSC) spreadsheet, was used to modify the damper positions slightly until the desired windbox-to-furnace  $\Delta p$  of 6.4 inches-of-water-gauge and the desired excess air (XA) were achieved. (The desired windbox-to-furnace  $\Delta p$  of 6.4 inches-of-water-gauge corresponds to a field measurement from the Conesville Unit No. 5 board data at a relatively low excess air condition of 14.1%.)

The mass flow rates for the primary gas and coal feed streams are shown in Table 3.6.

# Table 3. 6: Mass Flow Rates for the Primary Gas and Coal Feed Streams

It should be noted that the bottom coal elevation (Coal A) has been designated as being out of service (OOS) for these two cases. For the Coal-A nozzle, the coal mass flow rate is completely turned off and only a small amount (e.g., 5% of the normal allocation) of air or gas is permitted to pass through the coal nozzle (i.e., to help purge and cool the nozzle).

The inlet turbulence intensity was arbitrarily set at 10% of the mean velocity. The dissipation length scale for the turbulence was calculated using an effective hydraulic diameter for the inlet.

As mentioned previously, the overall wall absorption and the HFOT constitute implicit boundary conditions. The RHBP is the external resource which is used to provide values for the tube bank heat extraction, the overall wall absorption, and the HFOT. The overall resistance to wall heat transfer in the CFD computation is iteratively changed until the calculated implicit boundary condition constraint (i.e., wall absorption and HFOT) matches the RHBP values to within acceptable accuracy. Since the wall absorption computed by the CFD must ultimately match the wall absorption calculated by the RHBP, a brief tutorial of the RHBP nomenclature is required. The RHBP arbitrarily divides the furnace and convective pass into the sections shown in Figure 3.7.

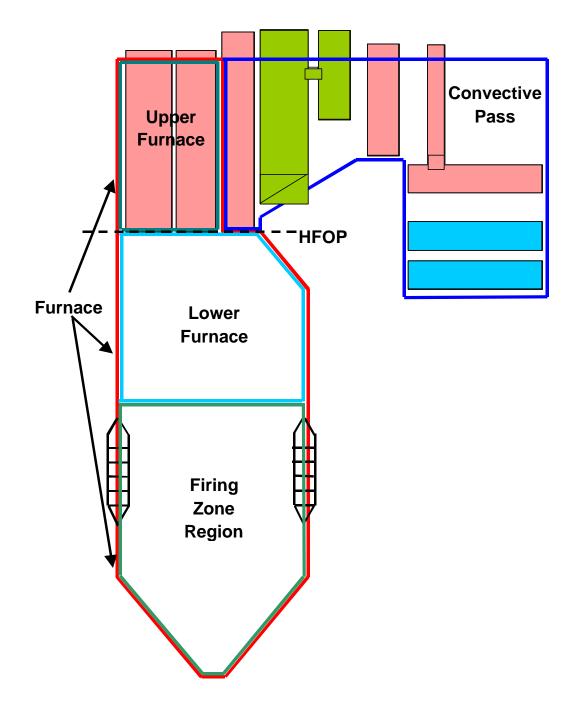

Figure 3.7: Furnace and Backpass Sections Specific to the RHBP

The "furnace" volume (outlined in Figure 3.7) is defined within the RHBP to include most of the radiant wall sections and extends from the bottom of the coutant to the roof of the upper furnace; it does not include the convective pass section, nor the superheater platen tube bank. The "furnace" volume encompasses 3 partitioned sections. The first section is the "firing zone" region, which extends from the bottom of the coutant to several feet above the top coal elevation. The "lower furnace" section extends from the top of the firing zone section to the HFOT plane. The "upper furnace" section extends from the HFOT to the roof and encompasses the superheater division panels, but not the superheater pendant platens. For all surfaces in the "furnace" volume, the RHBP generates the appropriate fouling factors.

The convective pass and backpass volume is defined by the RHBP to encompass all of the tube banks and their bounding surfaces, with the exception of the division panels. For convenience sake, the RHBP treats the convective pass volume differently than it does the furnace volume. For the convective section, the RHBP generates surface effectiveness factors, rather than fouling factors.

The HFOP is at the apex of the arch. The VFOP (not shown) is defined by the RHBP as being at the inlet to the superheater platen (both along the top and along the bottom of the platen), but this definition will be modified later on. The nomenclature utilized by the RHBP (with the exception of the VFOP definition), will be adhered to in the ensuing discussion.

The material properties and relative amounts of slag and fouling deposits found locally on the superheater division panels and the bounding tube walls are usually not known *a priori*. Consequently, the surface resistance to heat transfer in the CFD computation must be iteratively adjusted throughout the furnace volume in order to match the horizontal furnace outlet temperature (HFOT) calculated by the RHBP. For heat transfer to the computational waterwalls, radiant reheat surfaces, and superheat surfaces, the boundary conditions were prescribed using an effective overall surface resistance (or overall fouling factor) and a back-side (steam) temperature. It should be noted that the fouling factors calculated by the RHBP are not utilized directly in the CFD computation. Since the radiation and heat transfer submodels in the RHBP are significantly different than those found in a CFD code, it follows that the fouling factors and emissivities generated by the RHBP may also be quite different from those calculated by the CFD code.

In the waterwalls, the backside (two-phase) steam-water temperature corresponds to saturated conditions and was assigned a temperature of 680 °F. Since the fouling factor must be iteratively changed in the CFD calculation in order to calibrate the wall absorption and HFOT to the RHBP value, all of the backside steam temperatures were equated to the (constant) saturation steam temperature, including the radiant reheat and superheat surfaces. Although the superheat temperatures in the bounding surfaces will be higher than the saturation temperature, the goal of the calibration exercise was principally to match the overall absorption in the furnace proper, the convective pass being secondary, and the approximation was thought to be acceptable. The wall heat transfer parameters found to calibrate the Base case to the RHBP results are shown in Table 3.7.

Interior Wall Surface	Internal Wall Emissivity	Overall Fouling Factor (hr-ft <sup>2</sup> -°F/Btu)
Coutant and Wall Below Windbox Firing Zone Lower Furnace Waterwall (Above Windbox) Radiant Reheat Walls (Lower Furnace) Upper Furnace Waterwalls/Radiant Reheat Upper Furnace Roof Superheater Division Panels Convective Pass and Backpass Roof of Convective Pass and Backpass	0.80 0.75 0.75 0.65 0.65 0.65 0.75	$\begin{array}{c} 0.0175\\ 0.0232\\ 0.0258\\ 0.0247\\ 0.0378\\ 0.0258\\ 0.0378\\ 0.0232\\ 0.0142 \end{array}$
Backside Wall / Steam Temperature (°F) =	680	

# Table 3. 7: Wall Heat Transfer Parameters in the CFD Cases

One of the quantifiable metrics selected as a means of comparing the Base case and the Concept-B case is the overall wall absorption. In order to compare the two cases on an equivalent basis, it was deemed necessary to maintain the same fouling factors throughout the "furnace" volume in both cases. Therefore, the two corresponding RHBP runs were generated with the same fouling factors. However, convective section surface effectiveness factors and tube bank absorptions could not also be forced to be identical for the two cases in order to permit the RHBP to converge to a physical solution based on its solution constraints (i.e., prescribed superheat and reheat temperatures).

The tube banks are approximated as porous media in the CFD cases; parameters describing the pressure drop through each tube bank are calculated from industry design standards. The RHBP is used to evaluate the steam side performance and to estimate the furnace outlet temperature and the heat duty of the various tube bank sections. The amount of heat extracted from each tube bank, as calculated from the RHBP, with the exception of the superheater division panels (which are calculated with the resistance and backside temperature approach), are shown in Table 3.8. The tube bank absorption quantities also include the absorption through any nearby screen tubes.

	Base Case (15% Excess Air)	Concept B Case (Oxy-Firing)
Tube Bank	Heat Transferred to Steam in Banks (Btu/hr)	Heat Transferred to Steam in Banks (Btu/hr)
Superheater Pendant Platen Reheater Pendant Platen (Front) Assemblies Reheater Finishing Section Superheater Finishing Section Superheater Low Temp (Vertical) Pendant Section Superheater Horizontal Spaced Rear Assemblies Economizer Assembly	3.957E+08 1.424E+08 2.397E+08	2.942E+08 3.753E+08 1.286E+08 2.194E+08 1.253E+08 2.807E+08 4.594E+08
Totals:	2.012E+09	1.883E+09

## Table 3. 8: Energy Extracted from Tube Banks

Although the fouling factors in the "furnace" volume were forced to be identical in the two RHBP cases, the heat absorption through each tube bank in the convective pass was allowed to self-adjust to meet the RHBP solution and convergence criteria. Therefore, the tube bank heat extractions for the two cases are somewhat different. The tube bank absorption for the Concept-B case is generally lower than (but within 10% of) the tube bank absorption in the Base case.

The above absorptions were specified in the CFD calculation for each tube bank in the form of a sink term to the energy transport equation.

## 3.6 Submodel Parameters and Case Preparation

Calculations of the two Conesville cases were run using FLUENT<sup>™</sup> Version 5.4.8. FLUENT<sup>™</sup> is a general purpose CFD code with a range of physical model capabilities. For these simulations, the important fluid flow, heat transfer, gas and solid phase combustion processes were represented in a steady-state calculation. Submodel selections and their parameter settings are described below.

The SIMPLE pressure-correction algorithm was used with first-order upwind differencing. The turbulence model was the traditional or standard k-ɛ turbulence model. The turbulence-chemistry interaction was modeled using the composite Magnussen eddy-breakup (mixing-limited / fast-chemistry) and Arrhenius rates (kinetically-limited) combustion submodel, in which the smaller of the two rates (eddy-breakup or Arrhenius rates) takes local precedence. The gas-phase chemistry was based on two, irreversible, global steps: (1) volatile combining with oxygen to form carbon monoxide, water, nitrogen, and sulfur dioxide, and (2) carbon monoxide combining with oxygen to form carbon dioxide.

The Discrete Ordinates radiation model was used to calculate the local radiative fluxes. The particle absorption and scattering efficiencies were specified via a proprietary user-defined function (UDF). An implementation inconsistency was found in the weighted-sum-grey-gas (WSGGM) model in the FLUENT<sup>™</sup> code (which ultimately forced the CFD

runs to be repeated and delayed the final report). To circumvent the use of the WSGGM submodel, a gas-phase absorption coefficient, calculated from the Edwards wide-band model, was calculated and utilized instead. Unfortunately, the polynomial prescriptions for the gas-phase absorption coefficient in the FLUENT<sup>TM</sup> input permitted the coefficient to be a function of local temperature only, whereas it should ideally be a dual function of both local concentration and temperature. Consequently, the gas-phase absorption coefficient was input as a linear function of temperature, calculated from a single CO<sub>2</sub> and H<sub>2</sub>O partial pressure that prevailed in the computed upper furnace region. (While the complete wide-band model cannot be incorporated in the time frame required to impact the present CFD runs, a recommendation will subsequently be made to Fluent Inc. to upgrade their gas-phase radiative properties submodel to incorporate a full and reliable wide-band model.)

The particles were modeled as discrete trajectories using the stochastic Lagrangian particle model. Particles were injected from 16 inlet surfaces (8 cells per injection surface), corresponding to each of the primary coal inlets (4 coal elevations), with 10 particle size bins per distribution and 6 stochastic tries, for a total of 7,680 discrete particles that were tracked through the domain. Conesville Unit No. 5 mill classifier or sieve analysis data was available, which were averaged to produce a composite analysis with 98.35% through 50 mesh and 88.55% through 100 mesh. A Rosin-Rammler fit of the data produced a mean particle diameter of 66 microns and a slope/spread parameter of near unity. Maximum and minimum particle sizes were chosen as 200 microns and 1 micron, respectively. This information was utilized to calculate the particle size distribution through the Rosin-Rammler utility in FLUENT<sup>™</sup>.

Each of the particles followed a stochastic particle trajectory, progressing through the sequential stages of heating, devolatilization and char oxidation according to local flame conditions. The mill module, one of the modules within the company proprietary Reheat Boiler Program (RHBP), estimated that the amount of moisture in the as-fired coal would be approximately 4.5% (from an as-received moisture value of 10.1%). However, to simplify the CFD calculations, all of the coal moisture was presumed to have evaporated completely in the mill and was given to the primary transport air. Devolatilization was calculated from the Kobayashi-type two-competing-rates submodel. The high-temperature volatile yield parameter was estimated using the commercially available Niksa Energy Associates (NEA) PC COAL LAB software (i.e., FLASHCHAIN model). The high-temperature volatile yield was specified to be 67.6% on a DAF basis (as calculated for 55 micron particles at 25 °C entrained in nitrogen at 1600 °C in a furnace at 1700 °C and atmospheric pressure). The same high-temperature volatile yield was specified for all particle sizes. Based on the results of an inhouse, proprietary study, the Kobayashi devolatilization parameters were modified somewhat to give accelerated devolatilization rates which more closely approximated the FLASHCHAIN rates.

Parameters for the char oxidation kinetics of the mid-western bituminous coal fired in Conesville Unit No. 5 were set initially through comparison of the proximate and ultimate analyses of the coal with other coals tabulated in an inhouse, drop-tube, kinetics database. Based on a comparison with the database, a reasonable surrogate fuel was found to be Pittsburgh No. 8. Consequently the database kinetics for Pittsburgh No. 8 were used for the Conesville case. The activation energy was not subsequently changed, but the pre-exponential factor was iteratively adjusted as necessary to match the desired unburned carbon in the ash at the exit (of approximately 2%) for the baseline case. The char oxidation submodel in FLUENT<sup>TM</sup> is a composite kinetics/diffusion-limited char combustion model. In the char oxidation submodel, the char is oxidized via heterogeneous reaction to form CO, which is then oxidized further in the gas phase to form CO<sub>2</sub>.

The species (gaseous) properties, such as thermal conductivity, viscosity, and specific heat, were calculated at each cell in the domain based on polynomial functions of temperature. The species specific heats did not account for dissociative effects. The gas mixture properties were based on composition dependent formulations of the properties of the pure species.

The NOx model is run in a post-processor fashion. NOx predictions were performed for a combination of both thermal and fuel NOx submodels. Destruction through the reburn mechanism is permitted only for the presumed probability distribution function (PDF) combustion model, which was not utilized in this case. For thermal NOx, the partial equilibrium assumption was activated for atomic oxygen, and a beta function PDF was utilized for the convolution over temperature. For the fuel NOx model, atomic nitrogen fractions in both the volatile and the char were specified. The char nitrogen was presumed to go to HCN, rather than directly to NO. NOx and CO emissions are typically more difficult to predict than gross flow features or overall heat release because they are more sensitive to accurate calculations of local temperature and require more detailed chemistry. Consequently the NOx predictions were ultimately scaled to the measured Base case value.

Further grid refinement or adaption of the grid was not performed for the two cases. It is not known to what extent numerical diffusion, typically associated with coarse or skewed meshes, has impacted the quantitative accuracy in the present study. Since the focus of the present investigation was to discriminate between the two cases on a relative basis only, the present grid was presumed to be acceptable.

# 3.7 Calculation Results

The baseline case (Case 1) and the Concept-B case (Case 2) will be compared on the basis of the metrics discussed previously in Section 3.3. All of the gas-phase, planar integrated scalars, such as temperature and species, will be reported on a mass-averaged basis.

The calculated residual carbon in the fly ash, as well as the NOx and CO emissions are shown in Table 3.9.

	Base Case (15% Excess Air)	Concept B Case (Oxy-Firing)		
Residual Carbon in Ash (%)	2.4	0.8		
NOx (ppmm, uncorrected, dry) [Note 1]	190	104		
CO (ppmv, dry)	141	82		
Note 1:	Baseline value was scaled to measurement			

Table 3. 9: Comparison of Predicted Residual Carbon and Emissions for Cases 1 and 2

The carbon-in-ash measured in the field was between 2% and 3%; therefore for the baseline case, the pre-exponential factor for the char oxidation kinetics was adjusted until such a representative value was calculated. Relative to the baseline case, the carbon-in-ash value for the Concept-B case was calculated to be significantly lower. The same trend is also exhibited by the emissions calculations. If the calculated NOx value is scaled to the representative measured value of approximately 190 ppm, and assuming that the Concept-B calculated value can be proportionately scaled as well, then the Concept-B NOx value may be expected to decrease by about a factor of two relative to the baseline value. The calculated CO value for Concept-B is also much lower than its baseline counterpart. Since experimental CO values were reported as being "under range", and are therefore not available, and since the inclusion of reliable CO kinetics within the CFD computation is not considered to be practical at present, the CO results, as well as the unburned carbon results, may be taken as an indication of the extent of mixing, the temperature history, and the residence time differences between the two cases.

The planar temperatures at the HFOP, VFOP, and economizer outlet plane constitute implicit boundary conditions or target temperatures, provided by the RHBP, that the CFD calculations attempts to match through modification of its wall heat transfer boundary conditions. The aforementioned planes are depicted in Figure 3.8, to show their relative positioning.

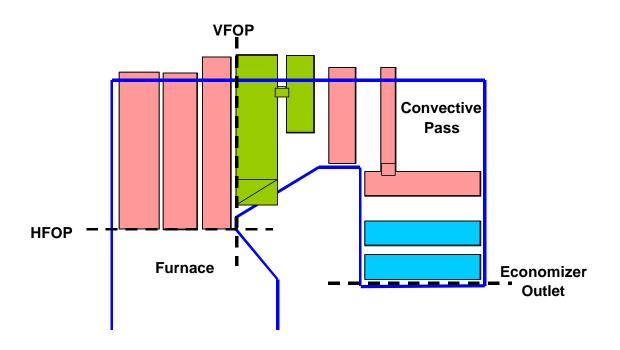

Figure 3.8: Depictions of Specific Planes for Comparisons of Averaged Temperatures

The temperatures at various cross-sections, as well as the integrated wall absorption over various furnace wall sections (largely in accordance with the RHBP partitioning and definitions in Figure 3.7), are shown in Table 3.10. The definition of the "upper furnace" section, prescribed by the RHBP to exclude the superheater platen, is inconvenient for CFD computations. Hence, the term has been modified in the table below, such that the heat extracted in the superheater platen (via a sink term to the energy equation), and its bounding surfaces, is now included in the definition of the "upper furnace" term.

	 Base Case (15% Excess Air)			Concept B Case (Oxy-Firing)		
	 RHBP	FLUENT™		RHBP	FLUENT™	
Average Planar Temperature (°F):						
HFOP VFOP [Note 1]	 2,756 2,185	2,765 2,125		2,729 2,027	2,676 2,040

### Table 3. 10: Comparison of Predicted Gas Temperature and Sectional Wall Absorption Values for Cases 1 and 2

The wall absorption throughout the furnace dictates the resultant temperatures at the HFOP and VFOP. (The domain outlet temperature is a less reliable indicator, since the heat extracted from the tube banks is different for the two cases.) The FLUENT<sup>M</sup> code does not presently permit the user to interrogate the net radiative flux through an arbitrary interior plane, so it is difficult to know to what extent radiation losses through each section, and through the porous media (representing the tube banks), are impacting the above results. Therefore, while it may not be possible to fully ascertain the energy entering and leaving each section in the CFD computation, and thus provide a more detailed explanation as to the magnitudes of the temperatures and fluxes, some general conclusions about the relative trends may be drawn.

In the baseline case, the HFOT and wall absorptions were calibrated to the RHBP values (as shown above in Table 3.10). Although the individual absorptions in the firing zone region and the lower furnace region are not duplicated, the total absorption below the HFOP, as well as the total absorption in the upper furnace are matched to an acceptable degree. The reason that the individual absorptions in the firing zone and lower furnace regions are not matched is because the CFD computation is much more sensitive to the location of the burner-out-of-service (BOOS) than the RHBP (as will be apparent later when the absorption profiles are shown). Since the lowest coal elevation has been dictated to be out of service (OOS), a smaller number of burning particle trajectories traverse the coutant region than would occur if the lowest coal elevation were in service; hence the heat release and wall absorption in the region below the windbox is also commensurately less. Alternatively, the RHBP effectively treats all of the firing zone region (below

the "lower furnace") as a single, well-mixed, global volume (with an allowance for a radiation boundary layer). Since the RHBP has a long history of successful designs that encompass a wide variation in firing system configurations, it is suspected, although not proven, that the CFD computation may be overly sensitive to the location of the BOOS.

When the RHBP run for Case 1 is compared with the RHBP run of Case 2, it is evident from the calculations that the HFOT for Concept-B decreases by 29 °F and the VFOT decreases by 158 °F (for an average decrease of about 94 °F) from the corresponding baseline values. The overall furnace wall absorption for Concept-B is expected to increase over that of the baseline (by 5.8%). This result is in accordance with a literature source (Wilkinson, et al., 2001) for refinery gas fired into a wall-fired boiler, in which a one-dimensional, slice-type model (i.e., RHBP-type model) was used to perform the analysis. The authors found that the oxyfuel concept experienced an increase in the incident radiative heat flux of about 4% to 6%, and a corresponding increase in the furnace heat absorption of approximately 9%, relative to the baseline air concept. This increase was attributed by the authors to "the increase in radiative power of the carbon dioxide and water-rich combustion gases".

The CFD computations exhibited a similar temperature trend to that of the RHBP. Both the HFOT and VFOT for the Concept-B case decreased by 85 and 89 °F, respectively, relative to the baseline results. On the other hand, the CFD cases exhibited a trend in wall absorption which was not as strong as the RHBP results. The wall absorption for the Concept-B case decreased by less than 1% relative to the furnace absorption of the baseline CFD case. Additional CFD runs, in which the fuel was changed from coal to an equivalent gas-only fuel (i.e., volatile), confirmed the trend (i.e., the Concept-B absorption was slightly lower than the baseline absorption). This same CFD trend is partially supported in the literature (Chui, et al., 2001) for coal burned in a cylindrical, down-fired vertical combustor, in which both CFD and experimental data were utilized to assess performance. The authors found that both the CFD calculation and the measured data showed that the oxygen-enriched, recycle-gas case exhibited a significant decrease of about 18% in the incident radiant flux, relative to the baseline case. Chui, et al. attributed this decrease to:

- (a) the change in aerodynamic and temperature patterns due to the lower inlet velocity and penetration of the recycled flue gas (i.e., due to the higher molecular weight of  $CO_2$  relative to  $N_2$ ),
- (b) a decrease in the overall flame temperatures of the recycled flue gas case due to the higher specific heat of  $CO_2$  relative to  $N_2$ , and principally to
- (c) the increase in the absorption coefficient in the recycled flue gas case because of the higher concentrations of the optically absorbing  $CO_2$  and  $H_2O$ , relative to the optically transparent  $N_2$ .

The analysts of both the (1) one-dimensional/slice or global mixing codes (like the RHBP) and the (2) CFD codes rely on the enhanced radiative absorption coefficient associated with  $CO_2$  to partially explain the furnace absorption results, although the calculated trends exhibit different apparent sensitivities for the two types of codes. Apart from differences in the gas-phase radiation properties themselves, a potential explanation for this apparent dichotomy is not readily available. However, in the CFD calculations, the high flame temperatures and patterns are a function of the local aerodynamics and may be effectively isolated from the wall by a significant presence of colder gases. Any  $CO_2$  (and  $H_2O$ ) in the near-wall gases will absorb radiative energy at the higher temperature of the "fireball", but will re-emit at the lower near-wall temperature, thus acting to increase the temperature of the near-wall gases and decreasing the net wall heat absorption. Slice or global-mixing codes will try to mimic this same effect and may, for example, presume a uniform firing zone or slice temperature radiating through a (colder) "radiation boundary layer" adjacent to the wall. The quantitative impact of the near-wall or "radiation boundary layer" gases on the net radiative flux to the wall may be significantly different between the two types of codes. The CFD computations may simply exhibit a greater "insulative" effect to radiation in the near-wall regions than that provided in RHBP-type models due to aerodynamic (case-specific) and submodel differences.

As discussed earlier, due to an implementation inconsistency in the FLUENT<sup>TM</sup> code, the gas-phase radiation absorption coefficient utilized in the CFD computational was a linear function of local temperature only, and not a function of concentration. While it is anticipated that the gas-phase absorption coefficient will be sensitive to the local concentrations of CO<sub>2</sub> and H<sub>2</sub>O, it is not known at this juncture whether the difference in overall wall absorption between the two cases would increase or decrease relative to its present values, and what the difference in magnitude would be. The calculations should be repeated with a gas-phase radiation absorption coefficient submodel that uses the full wide-band model (and that is more reliable than the WSGGM model presently in FLUENT<sup>TM</sup>).

Vertical profiles of the maximum and average net wall heat flux for the baseline case and the Concept-B case are shown in Figures 3.9 and 3.10, respectively. At any given elevation, the net wall heat flux value represents the area-weighted average of all the cells positioned "circumferentially" around the furnace (at that elevation). The maximum local net wall heat flux is simply the maximum value of all of the "circumferential" cells (at a given elevation). The radiative portion of the net wall heat flux, the portion of the net wall heat flux due to conduction, and the incident radiative flux are also shown. A geometry profile is also provided, showing the coutant bendline, the windbox, and the arch bendline. The recessed line in the geometry profile represents the windbox, while the slanted line with the positive slope represents the coutant, and the slanted line with the negative slope represents the arch bendline. The maximum and average values of the net wall heat flux calculated from "idealized" in-house design standards correspond to the base case conditions only (on both Figures 3.9 and 3.10) and are provided simply for comparative reference purposes.

# ENGINEERING FEASIBILITY AND ECONOMICS OF CO2 ON AN EXISTING COAL-FIRED POWER PLANT

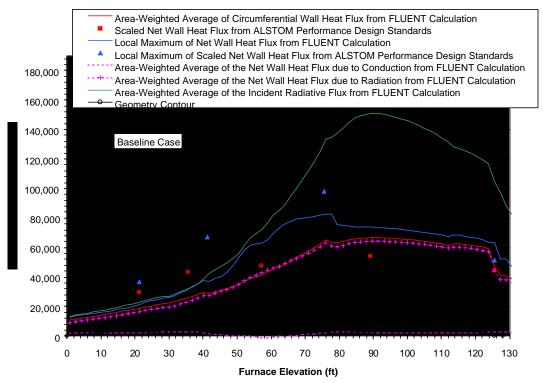

Figure 3.9: Vertical Profiles of the Local Peak and Area-Weighted Net Wall Heat Flux for the Base Case

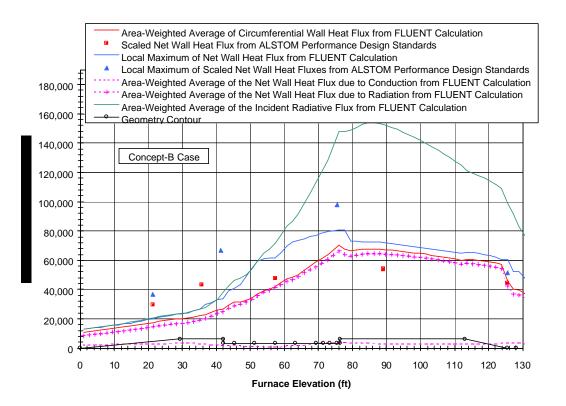

Figure 3. 10: Vertical Profiles of the Local Peak and Area-Weighted Net Wall Heat Flux for the Concept-B Case

ALSTOM Power Inc.

For the Base case (Figure 3.9), it can be seen that the CFD-calculated average net wall heat flux is less than the idealized design standard in the furnace volume below the windbox, and is above the design standard in the furnace volume above the windbox. This is due again to the fact that the lower coal is OOS, which means that fewer particles are carried down toward the bottom of the furnace, and the heat release generated in the coutant region is correspondingly smaller than it otherwise would be. (Computational runs with the lower coal in service show a heat release in the coutant region which is similar in magnitude to the design standard profile.)

In a comparison of Figures 3.9 and 3.10, it can be seen that the Base case has a slightly higher peak and average wall heat flux, over most of the furnace elevation, than the Concept-B case, as has already been established. However, differences in the overall absorption between the two cases are rather small (i.e., less than 1%) and may perhaps be construed to be part of the "noise" in the CFD calculations.

Vertical profiles of the peak, standard deviation, and mass-averaged, planar, gas temperatures are provided in Figures 3.11 and 3.12. The area-averaged interior wall temperature is also shown in both figures. The peak temperatures and standard deviations of the local gas temperature (i.e., a type of unmixedness) for the baseline case are somewhat higher than those of the Concept-B case. The peak temperature differences are higher in the windbox region, with a delta of approximately 200 °F or more for the peak temperature in the mid-windbox region, which then diminishes slightly to about 150 °F as the arch elevation is approached. The standard deviation of the local gas temperature for the baseline case is about 150 °F higher than that of the Concept-B case in the windbox region, although the difference then diminishes and becomes negligibly small as the HFOP is approached. (It is difficult to say whether the difference in standard deviation between the two cases reflects a significant difference in mixing efficiencies or simply a difference in local peak temperature values.) Over most of the furnace height, except in the immediate vicinity of the CCOFA jets, the mean temperature and the interior wall temperature are generally higher in the baseline case than in the Concept-B case. (Table 3.10 shows that the baseline HFOT is approximately 90 °F higher than that of Concept-B.)

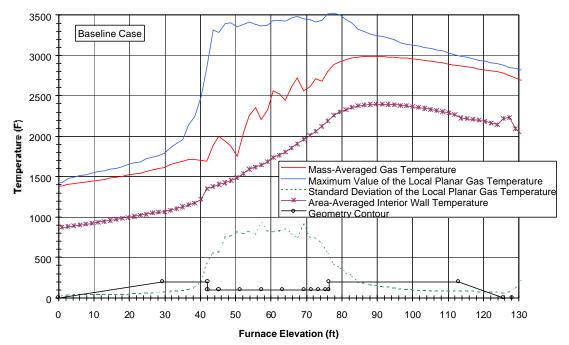

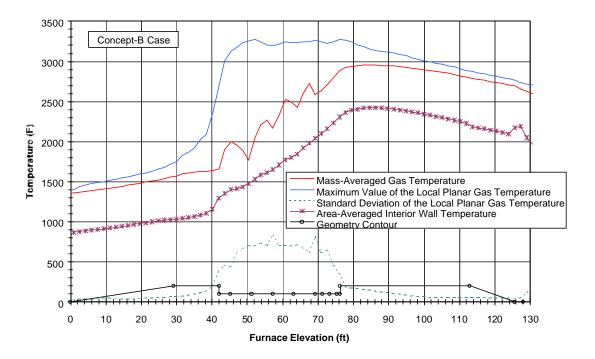

Figure 3.11: Vertical Profiles of the Local Peak and Mass-Averaged Gas Temperatures for the Base Case

The specific heat of  $CO_2$  is about 6% to 7% greater than that of  $N_2$  over the range of 1340 °F (1000 K) to 3140 °F (2000 K). Therefore, for equivalent heat release and wall absorption, the Concept-B case would be expected to have a slightly

lower mean gas temperature. The specific heat of  $H_2O$  (gaseous) is a factor of 2 to 3 times that of  $CO_2$ , but the mass fraction of  $H_2O$  in the inlet mixtures of the Concept-B case is only about a percentage point higher than that in the baseline case; thus its impact on lowering the Concept-B HFOT is minimal. Consequently, it is expected that the specific heat consideration of  $CO_2$  (alone) should be a factor which would ordinarily cause the HFOT for the Concept-B case to decrease relative to that of the baseline case.

## 3.8 Contour Plots

Contour plots of temperature at selected elevations are given in Figure 3.13. The plots show reasonable symmetry of the flowfield, with a relatively cool inner core, surrounded by an annular, high-temperature region. In certain regions, cooler near-wall temperatures may separate the high-temperature annular "ring" from the walls.

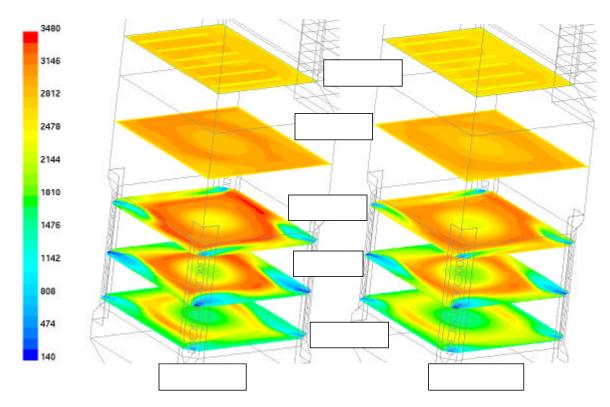

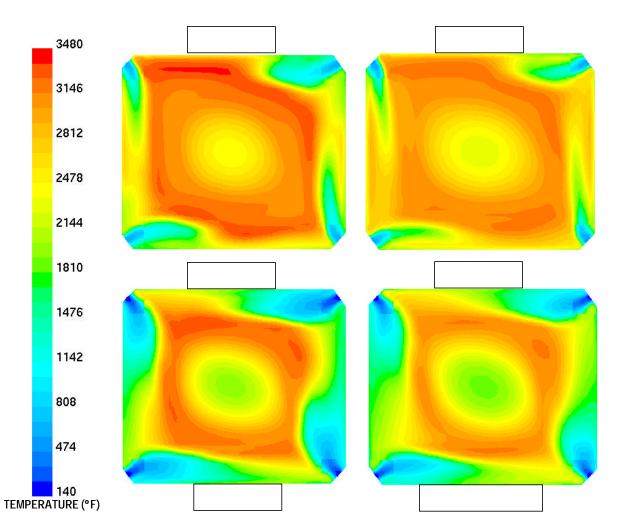

Figure 3. 13: Planar Contour Plots of Temperature at Various Elevations for the Base Case and Concept-B Case

#### A cross-sectional view of the temperature contours at two planes is given in Figure 3.14.

#### Figure 3. 14: Planar Contour Plots of Temperature at two Elevations for the Base Case and Concept-B Case

As can be seen in Figure 3.14, the aerodynamics and flame regions are rather similar in shape and appearance, with minor differences in temperature magnitude. The higher inlet velocities and penetration of the baseline case (see Tables 3.5 and 3.6) are apparent, in that a longer traverse distance is required before the jet is either swept upward out of the plane or mixed out to equivalent temperatures. The swirl is sufficiently strong to prevent the jets from penetrating radially to the core; rather the jets are quickly "bent over" in the direction of the swirl crossflow vectors (in the cross-sectional plane) and any residual jet penetration is in that same direction. It should be noted that although the difference in inlet velocities between the two jets is a factor in the resultant aerodynamic penetration, a perhaps equally influential factor is the velocity acceleration due to combustion. The coal jets, for example, enter the domain at 96.2 ft/s and 60.8 ft/s, for the baseline case and the Concept-B case respectively, but the jets are rapidly accelerated to approximately 170 ft/s (figure not shown) within a few nozzle diameters of the entrance.

The peak temperatures in the annular high-temperature annular "ring" are higher in the baseline case than in the Concept-B case. By the time the CCOFA is reached, the core temperature of the baseline case also appears to be higher than that in the Concept-B case (contributing ultimately to a higher HFOT for the Base case).

Temperature plots at the mid-plane of the x-coordinate direction are shown in Figure 3.15. The plots are again qualitatively very similar in appearance.

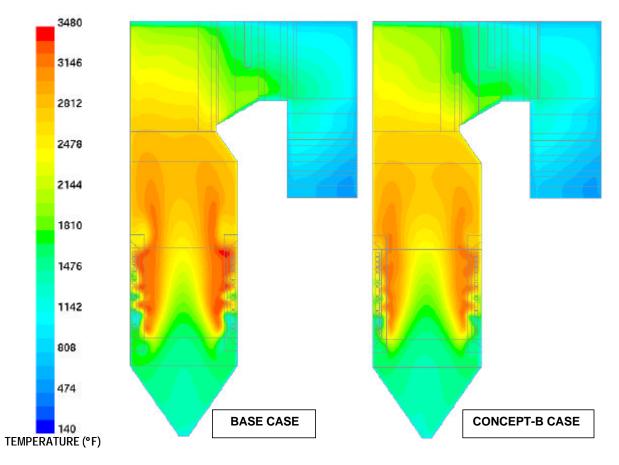

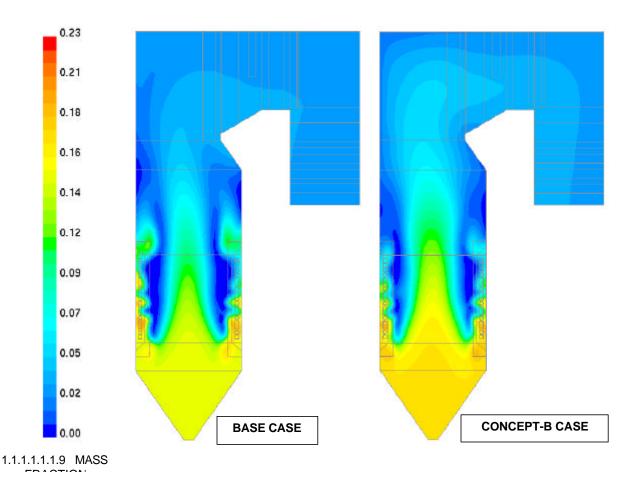

Figure 3. 15: Planar Contour Plots of Temperature at the X-Mid-Plane for the Base Case and Concept-B Case

The corresponding contour plots of the oxygen mass fraction (wet) at the x-mid-plane are shown in Figure 3.16.

#### Figure 3. 16: Contour Plots of O<sub>2</sub> Mass Fraction (Wet) at the X-Mid-Plane for the Base Case and Concept-B Case

The Concept-B case appears to have a slightly greater concentration of oxygen in the coutant region and in the furnace core than the Base case does. The amount of oxygen will be partially controlled by the relative local concentrations of the particles and the gas, as well as the particle burning rates and trajectory history. Assuming complete combustion, the exit  $O_2$  concentrations on a mass fraction basis are almost equivalent (see Table 3.2); on a molar basis, the Concept-B case will have a higher exit mole fraction (3.6%, dry) compared to that of the Base case (2.6%, dry). Since the composite kinetic/diffusion surface reaction rate model for char oxidation in FLUENT<sup>TM</sup> is a direct function of the partial pressure of oxygen, assuming an equivalent particle distribution, the higher oxygen mole fraction in the Concept-B case should help the particles to burn out more completely than the particles in the Base case (as shown in Table 3.9).

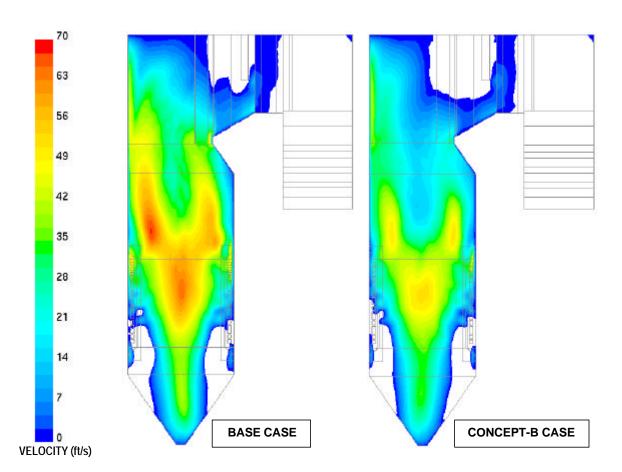

Figure 3.17 shows the z-component (i.e., the upward component) of velocity on the mid-plane.

Figure 3. 17: Contour Plots of the (Upward) Z-Velocity at the X-Mid-Plane for the Base Case and Concept-B Case

In Figure 3.17, only the positive (upward) z-component velocity is shown. The upward velocity appears to be somewhat greater in the core of the furnace for the baseline case than for the Concept-B case. For an equivalent upward mass flow rate, at any cross-section, it would be expected that the baseline case velocity would be higher than that of the Concept-B case due simply to the difference in molecular weights (between  $CO_2$  and  $N_2$ ) and the associated densities. In addition, the baseline case has higher peak temperatures which would also accelerate the local velocity field. However, the presence of a higher velocity does not necessarily mean that the integrated planar flow rates are higher. The CFD results also show that between the bottom of the coutant and the top of the windbox, the planar integrals (not shown) of negative mass flow rate, positive mass flow rate, and absolute mass flow rate are on the order of 10% greater for the Concept-B case than for the baseline case. Above the windbox, the differences in integrated mass flow rate become small (since they simply reflect the nearly equivalent overall inlet flow rates).

Both cases evidence the presence of an adverse pressure gradient (i.e., low velocity region) in the core between the arch-bendline elevation and the top-of-the-windbox elevation. However, the higher upward core velocities associated with the baseline case appear to almost overcome the low-velocity, adverse pressure gradient region. Planar integrals of the swirl number (not shown) indicate that the Concept-B case has a slightly higher swirl magnitude at all elevations except over the upper windbox region. As a result, the Concept-B case appears to be closer to incipient reverse flow zone formation than the baseline case in the upper core region below the arch bendline.

The net wall heat flux is shown in Figure 3.18. (It should be noted that the wall absorption of greatest magnitude is represented by the blue color (i.e., value on the order of -70,000).)

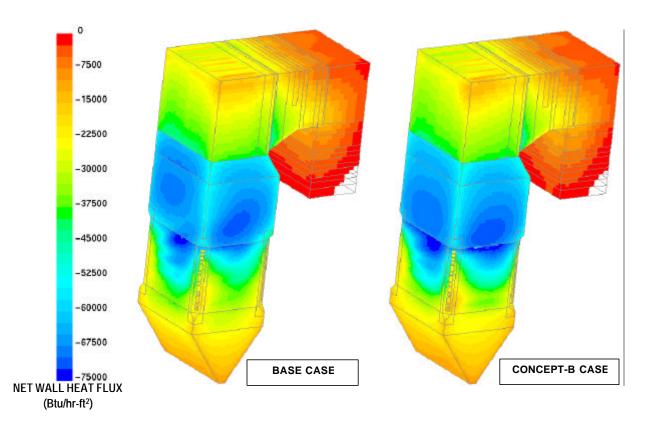

Figure 3. 18: Net Wall Heat Flux for the Base Case and Concept-B Case

As discussed earlier, the wall absorption is very similar for both cases. The peak net wall heat flux is between the top coal nozzle elevation and the arch bendline, in the mid-span region of the waterwall.

# 3.9 Conclusions

Two cases have been compared using the FLUENT<sup>™</sup> CFD code -- a baseline, nominal 15% excess air case (Case 1 or Base case), and a recirculated flue gas, oxy-fired case (Case 2 or Concept-B case). In the Concept-B case, the nitrogen was largely replaced by carbon dioxide. The cases have been compared on the basis of equivalent nozzle/inlet areas, as well as an equivalent coal-to-oxygen feed ratio (by mass). The following computational results have been highlighted:

- The baseline case exhibits higher carbon-in-ash (by 1.6 percentage points), higher outlet NOx emissions (by a factor of 2), and higher outlet CO (by a factor of 2) than the Concept-B case. These same computational trends are also qualitatively exhibited by the bench-scale testing.
- The baseline case exhibits a slightly higher peak gas temperature (maximum difference of about 200 °F), and a correspondingly higher average (cross-sectional) gas temperature (difference of 90 °F at the HFOT), than that of the Concept-B case.
- The net wall absorption in the furnace region for the baseline case is larger (by less than 1%) than that of the Concept-B case. (Conversely, the net wall absorption for the baseline calculation with the RHBP was found to be about 6% lower than the Concept-B case calculated by the RHBP.)

Explanations for the observed trends must rely on physical property differences between the nitrogen, which dominates in the baseline case, and carbon dioxide, which largely supplants the nitrogen in the Concept-B case. The physical species properties and the anticipated consequences are itemized below:

- (1) <u>Higher molecular weight of  $CO_2$  relative to  $N_2$ </u>. For equivalent inlet areas, and as a result of the molecular weight and associated density differences, the baseline case will exhibit larger inlet velocities and a higher penetration capability than the Concept-B case. The inlet velocity differences will further serve to impact the aerodynamic, particle trajectory, mixing, and flame patterns.
- (2) <u>Higher specific heat of CO<sub>2</sub> relative to N<sub>2</sub></u>. For an equivalent local heat release and heat transfer, the higher specific heat of carbon dioxide will serve to decrease the overall flame temperatures of the recycled flue gas mixture in the Concept-B case, relative to the baseline case.
- (3) <u>Higher gas emissivity and absorptance of  $CO_2$  relative to  $N_2$ </u>. For an equivalent local gas temperature, the higher emissivity of  $CO_2$ , relative to the optically transparent  $N_2$ , should serve to increase the absorption coefficient (and the irradiation to the wall) in the recycled flue gas case (Concept-B) relative to the baseline case.

The three physical properties listed above may have compensatory rather than cumulative effects. In the present CFD calculations, the resultant, local gas temperatures are not equivalent in the two cases. The higher specific heat of the carbon dioxide, and the associated lower gas temperatures in the Concept-B case, will tend to offset somewhat or compensate for the expected increase in the wall absorption (i.e., anticipated due to the enhanced emissivity of the  $CO_2$ .) Furthermore, the spatial distribution of the carbon dioxide across the cross-section may be important; it is hypothesized that high concentrations of  $CO_2$  in the cooler gas mixtures between the wall and the flame may actually act to inhibit the net radiative flux to the walls.

The trend calculated by the CFD code, with respect to the furnace temperature at the HFOP, appears to be qualitatively aligned with the trend calculated by the in-house RHBP code. However, the difference in wall absorption for the Concept-B case relative to the baseline case, calculated by FLUENT<sup>M</sup> (change of -1%), does not fully agree with the results of the RHBP (change of +6%). Computed and/or experimental trends that indicate that oxy-firing may induce either an increase in wall absorption (+6%) or a decrease in wall absorption (-18%), relative to the baseline case, are supported in the literature. It is suggested that the absorptive properties of a local CO<sub>2</sub>-containing gas mixture in the vicinity of the wall may either act to enhance or inhibit the incident radiative flux to the wall, depending upon its relative spatial placement and mixture temperature. For example, a low-temperature, CO<sub>2</sub>-rich mixture near the wall would absorb the radiative flux from the interior "fireball" region; a portion of the energy would be re-emitted at the lower gas temperature, and the remainder of the energy would be used to heat up the gas. The result would be a net reduction in the incident radiative flux to the wall. Conversely, a high-temperature, CO<sub>2</sub>-rich mixture near the wall would emit at its local gas temperature, thus enhancing the incident radiative flux to the wall. Therefore, it is suggested that the relative spatial relationships of the cool and hot gas mixtures, the relative composition of the absorbing media, and the proximity of that media to the wall (as induced by the furnace and firing system aerodynamics), may significantly impact the gas-phase irradiation to the wall. Indeed, the aerodynamic and flame patterns that prevail in a given air-fired or oxy-fired furnace may conceivably have as strong an impact on the net wall absorption as the physical property differences themselves (gas-phase emissivity, specific heat, etc.)

The results of computational tools (such as CFD and the RHBP) should be viewed as being qualitative in nature, particularly when they are asked to produce calculations outside of the experience base for which they have been validated. Certainly, the gas-phase and particle-phase radiation property submodels could be enhanced in both codes, and the impact of spatial gradients (caused by the interleaving of hot and cool regions of varying CO<sub>2</sub> composition) on radiative wall flux needs to be investigated more fully. CFD computations have been utilized to gain a more in-depth qualitative understanding of aerodynamic and flame patterns in combustion systems, but have not yet been integrated into routine boiler design procedures. At the present time, the ALSTOM design standards are based upon the experience and expertise built into the RHBP and other design protocols, and those standards must be adhered to in any new design project in order to mitigate risk. Therefore, the results of the RHBP must be regarded as the default standard, both from an engineering experience viewpoint and from a rules-based design viewpoint. However, additional validation work needs to be done in order to confirm the trends for oxy-firing scenarios.

Although differences in physical properties of the transport gases (e.g., air-firing versus oxy-firing) may initially induce undesirable deviations from the performance goals of a field unit, the designer and engineer views such alterations as challenges rather than insurmountable obstacles. Much can be done in the way of operating condition optimization (e.g., spray and nozzle tilt), without major retrofits, to realign steam temperatures and wall absorptions with their desired, target values. Design parameters are often in conflict, and the intelligent designer must work to balance various parameters and operating conditions to achieve the desired outcome. The CFD work performed here was based on

certain constraints to maintain equivalency for comparison purposes, which would not necessarily be the case in the field. For example, a potential decrease in furnace wall absorption of several percentage points could be nullified through manipulation of various operating parameters. If required, firing system retrofits and surface modifications could be performed to handle more severe decreases in absorption; certainly new unit design could easily accommodate any necessary alterations in design philosophy.
