# Preface

## Scope and purpose of the HIV molecular immunology database

*HIV Molecular Immunology* is a companion volume to *HIV Sequence Compendium*. This publication, the 2008 edition, is the PDF version, suitable for printing, of the web-based HIV Immunology Database (<http://www.hiv.lanl.gov/content/immunology/>). The web interface for this relational database has many search options, as well as interactive tools to help immunologists design reagents and interpret their results.

In the HIV Immunology Database, HIV-specific B-cell and T-cell responses are summarized and annotated. Immunological responses are divided into three parts, CTL, T helper, and antibody. Within these parts, defined epitopes are organized by protein and binding sites within each protein, moving from left to right through the coding regions spanning the HIV genome. We include human responses to natural HIV infections, as well as vaccine studies in a range of animal models and human trials. Responses that are not specifically defined, such as responses to whole proteins or monoclonal antibody responses to discontinuous epitopes, are summarized at the end of each protein section. Studies describing general HIV responses to the virus, but not to any specific protein, are included at the end of each part.

The annotation includes information such as cross-reactivity, escape mutations, antibody sequence, TCR usage, functional domains that overlap with an epitope, immune response associations with rates of progression and therapy, and how specific epitopes were experimentally defined. Basic information such as HLA specificities for T-cell epitopes, isotypes of monoclonal antibodies, and epitope sequences are included whenever possible. All studies that we can find that incorporate the use of a specific monoclonal antibody are included in the entry for that antibody. A single T-cell epitope can have multiple entries, generally one entry per study.

Finally, maps of all defined linear epitopes relative to the HXB2 reference proteins are provided. Alignments of CTL, helper T-cell, and antibody epitopes are available through the search interface on our web site at <http://www.hiv.lanl.gov/content/immunology>.

Only responses to HIV-1 and HIV-2 are included in the database. CTL responses to SIVs are periodically summarized in our review section by Dr. David Watkins and colleagues. Dr. Christian Brander and colleagues annually provide a concise listing of optimally defined CTL epitopes. Reviews from previous years can

be found at <http://www.hiv.lanl.gov/content/sequence/HIV/REVIEWS/reviews.html>.

Questions regarding the database can be sent via email to [immuno@lanl.gov](mailto:immuno@lanl.gov).

## About the data

At the time of this publication, the HIV Immunology Database contained over 4900 CTL/CD8+ epitopes, over 1000 Helper/CD4+ epitopes, over 1400 unique antibody epitopes, and a total bibliography of over 2100 references (Figure 1). To illustrate the distribution of the epitopes, we have plotted them by position in the HIV proteome (Figure 2).

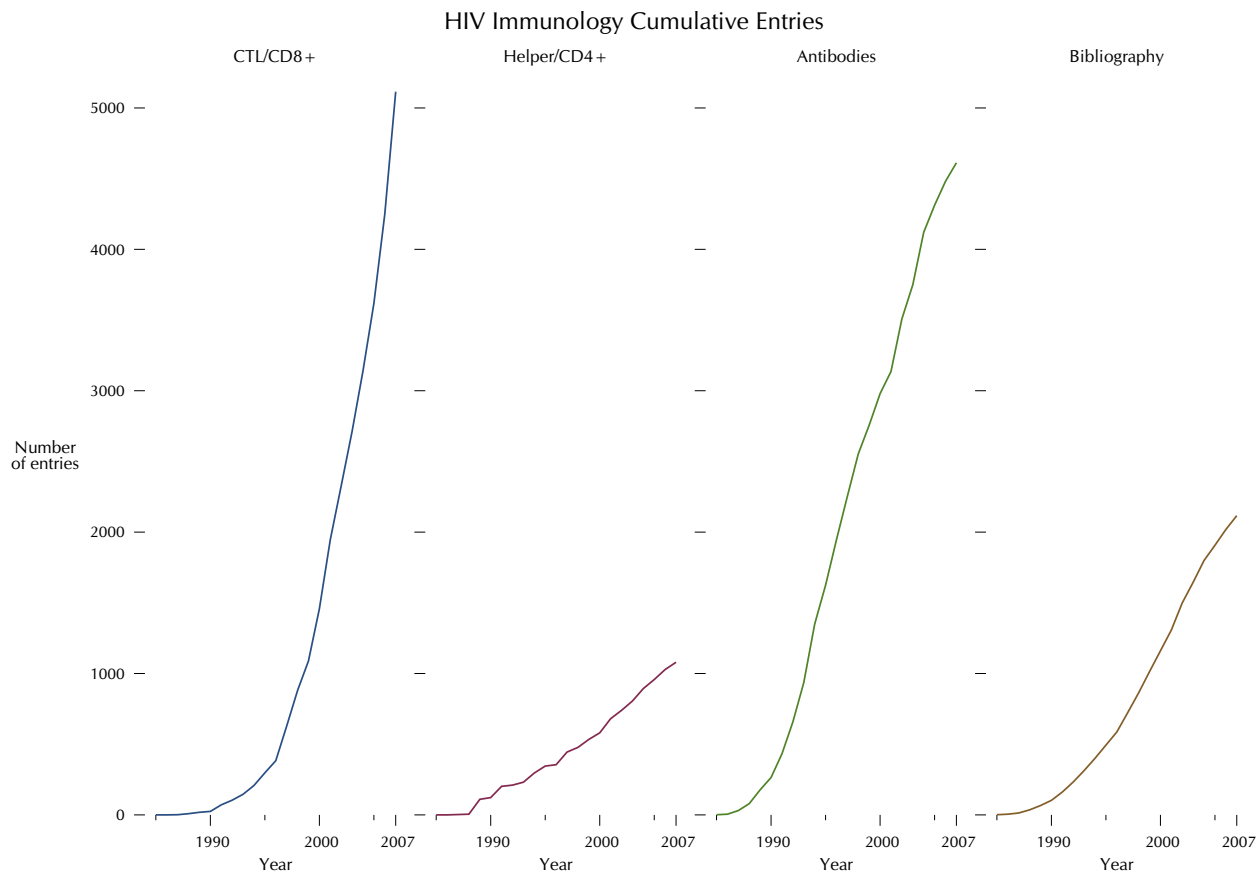

For T-cell epitopes, the density of epitopes by position reflects the density of defined epitopes in the database, which in turn roughly reflects the density of responses, as judged by EliSpot assays from natural infection. Both CTL/CD8+ T-cell (maroon) and Helper/CD4+ T-cell (green) responses are most commonly detected in Gag and Nef, and the database has the highest density of epitopes captured from the literature in these regions.

In contrast, the antibody epitope database density (blue) is less meaningfully captured in this graph, because only continuous epitopes are included. Many antibody responses defined in the database are to discontinuous epitopes, or are defined regionally or by competition experiments, and other database entries are polyclonal responses with multiple antibodies binding to multiple regions; these are not included in this map. The database entries have other biases in frequency. For example, the database is based on retrieval of information from the literature, and so a region like the V3 loop of HIV-1, which is of particular interest to investigators, has been studied with great intensity, and this high level of interest accounts for the large spike of antibody entries in gp120.

## Citing the database

This publication may be cited as

*HIV Molecular Immunology* 2008. Bette T. M. Korber, Christian Brander, Barton F. Haynes, Richard Koup, John P. Moore, Bruce D. Walker, and David I. Watkins, editors. Publisher: Los Alamos National Laboratory, Theoretical Biology and Biophysics, Los Alamos, New Mexico.

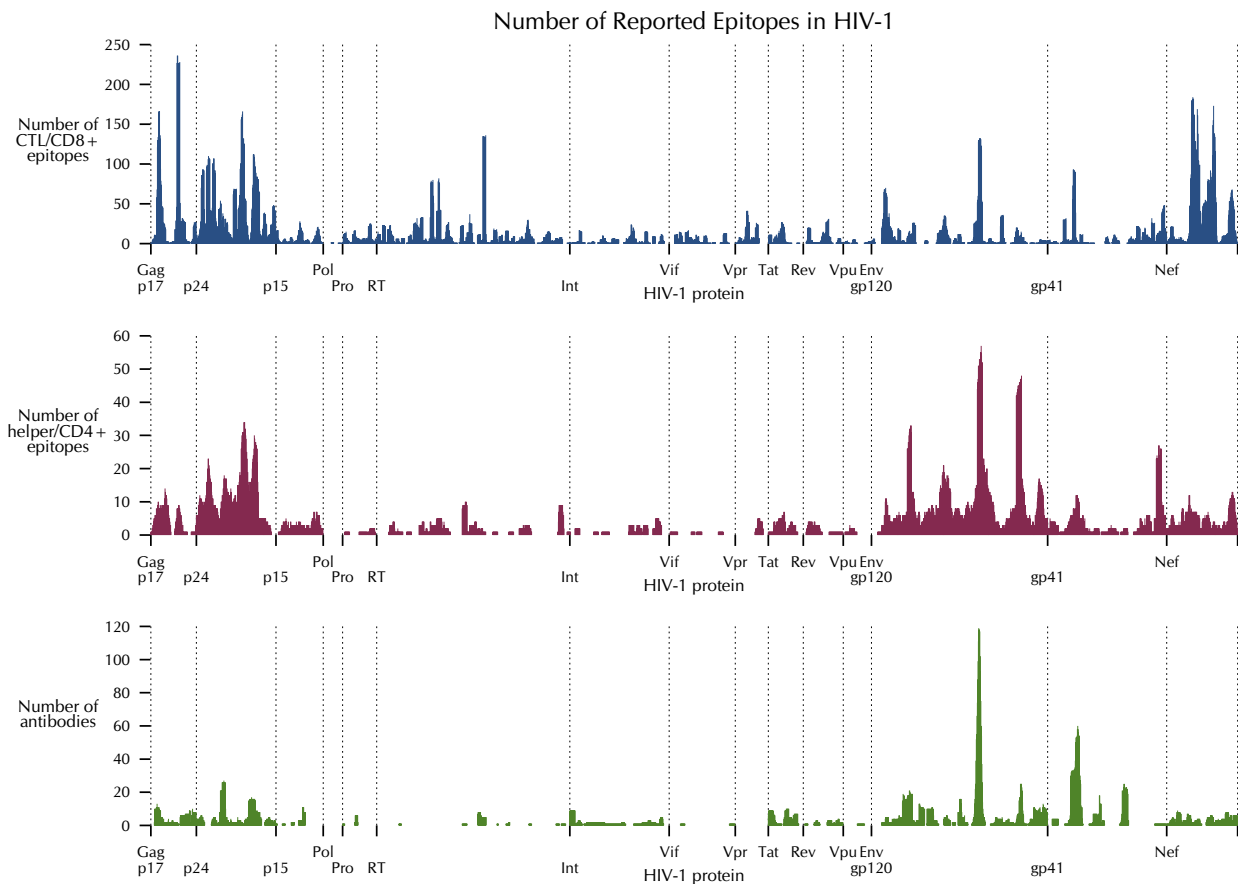

**Figure 1:** HIV immunology database cumulative entries. The CTL, T Helper and Antibodies plots show the total number of epitope entries described in the database at the denoted point in time. If an epitope is described in 5 papers then it is considered to be 5 entries. Thus the number of unique epitopes is lower than the plotted number. Although all 4 plots begin at 1985, the earliest CTL and Helper epitopes were described in 1987.

## About the PDF

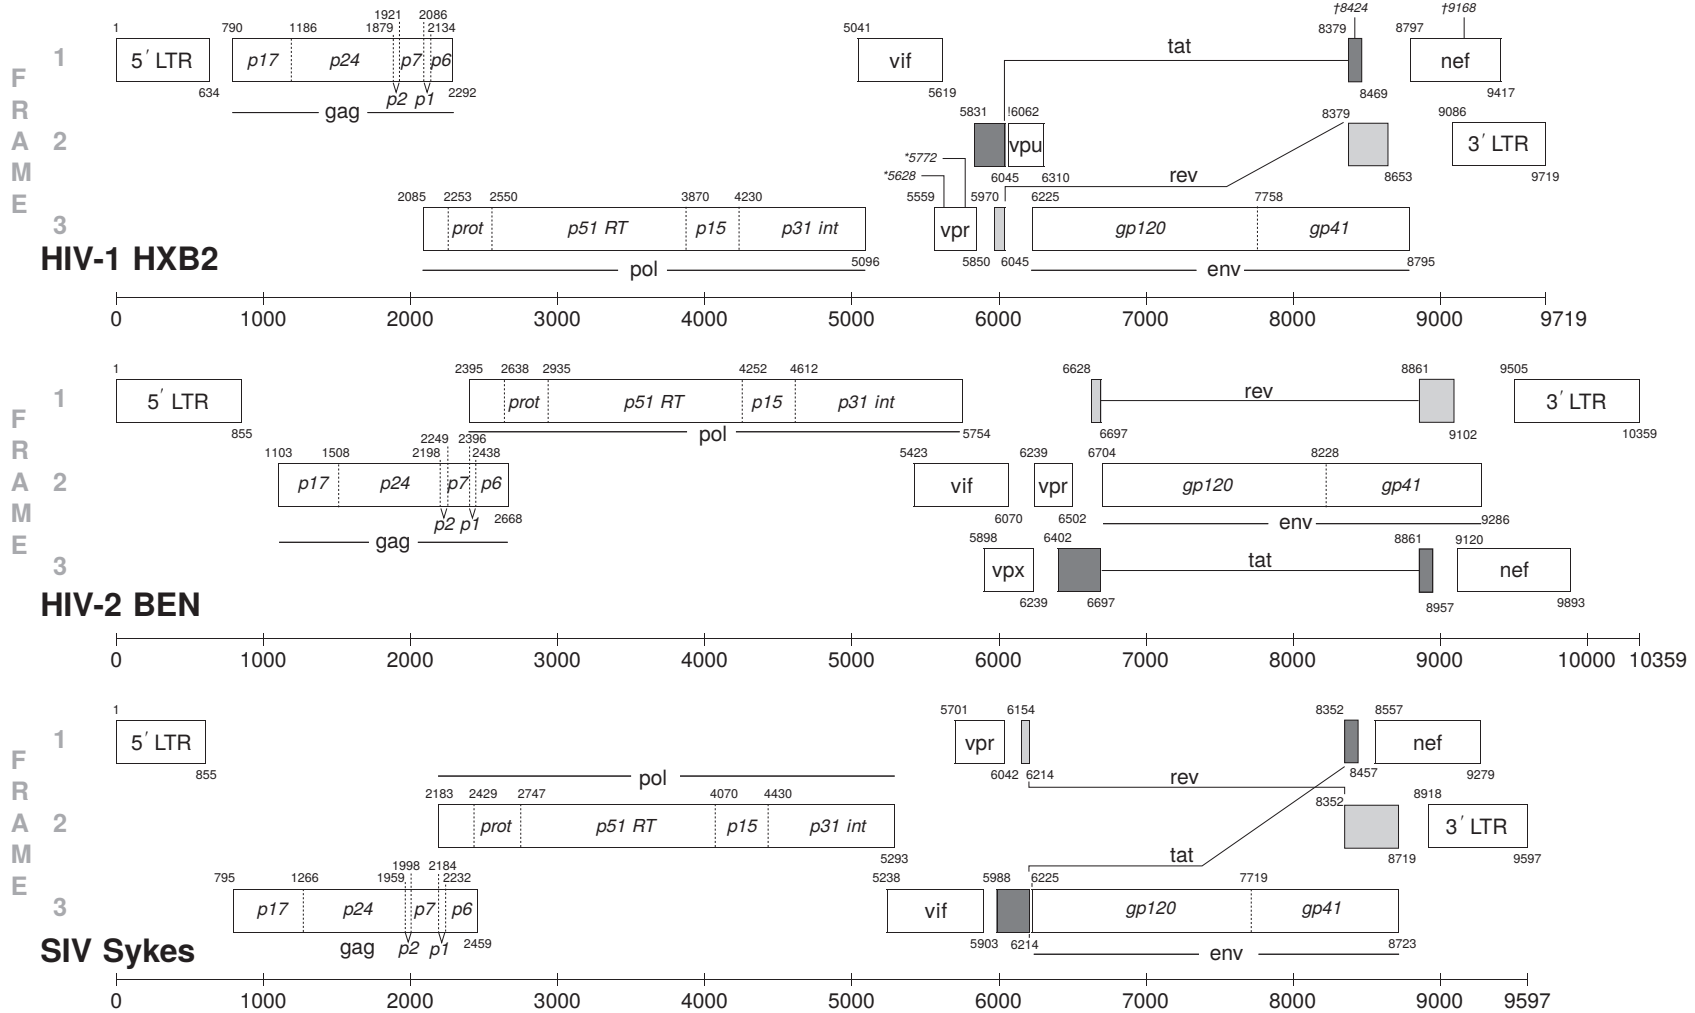

The complete *HIV Molecular Immunology 2008* is available in Adobe Portable Document Format (PDF) from our website, <http://www.hiv.lanl.gov/content/immunology>. The PDF version is hypertext enabled and features 'clickable' table-of-contents, indexes, references and links to external web sites.

This volume is typeset using  $\text{\LaTeX}$ . The immunology data tables and epitope maps are produced automatically from the SQL database by a series of Perl programs.

**Figure 2:** The number of unique epitopes included in the database that span each position in the HIV proteome.

## Genome maps

**Landmarks of the HIV-1, HIV-2, and SIV genomes.** The gene start, indicated by the small number in the upper left corner of each rectangle, normally records the position of the a in the atg start codon for that gene while the number in the lower right records the last position of the stop codon. For *pol*, the start is taken to be the first t in the sequence ttttttag which forms part of the stem loop that potentiates ribosomal slippage on the RNA and a resulting -1 frameshift and the translation of the Gag-Pol polyprotein. The *tat* and *rev* spliced exons are shown as shaded rectangles. In HXB2, \*5628 and \*5772 mark positions of frameshifts in the *vpr* gene; †6062 indicates a defective acg start codon in *vpu*; †8424 and †9168 mark premature stop codons in *tat* and *nef*. See Korber *et al.*, Numbering Positions in HIV Relative to HXB2CG, in *Human Retroviruses and AIDS*, 1998, p. 102. Available from <http://www.hiv.lanl.gov/content/sequence/HIV/REVIEWS/HXB2.html>

## HIV/SIV proteins

Name	Size	Function	Localization
Gag MA	p17	membrane anchoring; env interaction; nuclear transport of viral core (myristylated protein)	virion
CA	p24	core capsid	virion
NC	p7	nucleocapsid, binds RNA	virion
	p6	binds Vpr	virion
Protease (PR)	p15	gag/pol cleavage and maturation	virion
Reverse Transcriptase (RT)	p66, p51	reverse transcription	virion
RNase H	(heterodimer)	RNase H activity	virion
Integrase (IN)		DNA provirus integration	virion
Env	gp120/gp41	external viral glycoproteins bind to CD4 and chemokine co-receptors	plasma membrane, virion envelope
Tat	p16/p14	viral transcriptional transactivator	primarily in nucleolus/nucleus
Rev	p19	RNA transport, stability and utilization factor (phosphoprotein)	primarily in nucleolus/nucleus shuttling between nucleolus and cytoplasm
Vif	p23	viral infectivity factor, inhibits minus-strand viral DNA hypermutation	cytoplasm (cytosol, membranes), virion
Vpr	p10-15	promotes nuclear localization of preintegration complex, inhibits cell division, arrests infected cells at G2/M	virion nucleus (nuclear membrane?)
Vpu	p16	promotes extracellular release of viral particles; degrades CD4 in the ER; (phosphoprotein only in HIV-1 and SIVcpz)	integral membrane protein
Nef	p27-p25	CD4 and class I downregulation (myristylated protein)	plasma membrane, cytoplasm, (virion?)
Vpx	p12-16	Vpr homolog present in HIV-2 and some SIVs, absent in HIV-1	virion (nucleus?)
Tev	p28	tripartite tat-env-rev protein (also named Tnv)	primarily in nucleolus/nucleus

## Abbreviations

Abbreviations and acronyms used in this database.

Abbrev.	Meaning
AA	amino acid
AAV	adeno-associated virus
Ab	antibody
ACTG	AIDS clinical trial group
ADC	AIDS dementia complex
ADCC	antibody-dependent cell-mediated cytotoxicity
ADE	antibody-dependent enhancement
ADRA	Antiviral Drug Resistance Analysis: a program that analyzes your sequences for mutations known to confer drug resistance and links to the records in the database
AIDS	acquired immunodeficiency syndrome
ANN	artificial neural networks
APC	antigen presenting cell
ARC	AIDS related complex
ART	anti-retroviral therapy
AZT	azidothymidine
BIMAS	BioInformatics and Molecular Analysis Section
BIV	bovine immunodeficiency virus
BLAST	Basic Local Alignment Search Tool
CAEV	caprine arthritis/encephalitis virus
CD4BS	CD4 binding site
CD4i	antibody that has enhanced binding to gp120 in the presence of SCD4 (CD4 induced)
CDC	Centers for Disease Control and Prevention
CDR	complementary determining regions
CFA	complete Freund's adjuvant
CHI	Center for HIV Information
CMI	cell-mediated immunity
CMV	cytomegaliovirus
CNS	central nervous system
CP	canary pox
CRF	circulating recombinant form
CsA	cyclosporine A
CSF	cerebrospinal fluid
CTL	cytotoxic T lymphocyte
CTL <sub>e</sub>	CTL effector
CTL <sub>p</sub>	CTL precursor
CyPA	cyclophilin A
DC	dendritic cell
DDDP	DNA-dependent DNA polymerase
DHH	U. S. Department of Health and Human Services
dMM	deopymannojirimycin
dpc	days post challenge
DTT	dithiothrietol

Abbrev.	Meaning
EIA	enzyme immuno assay
EIAV	equine infectious anemia virus
ELF	Epitope Location Finder
ELISA	Enzyme Linked ImmunoSorbent Assay
ER	endoplasmic reticulum
Fabs	fragment antigen binding-univalent antibody fragment
FATT-CTL	Fluorescent antigen-transfected target cell-CTL
FIV	feline immunodeficiency virus
FP	fowl pox
FSW	female sex worker
GALT	gut-associated lymphoid tissues
GDE format	Genetic Data Environment
gp	glycoprotein
GRIV	genetic resistance to HIV
HAART	highly-active anti-retroviral therapy
HCV	hepatitis C virus
HEPS	HIV-exposed persistently seronegative
HIV	human immunodeficiency virus
HIVD	HIV-1 dementia
HLA	human leukocyte antigens
HLA-MHC	human leukocyte antigens-major histocompatibility complex
HMM	hidden Markov models
IAVI	International AIDS Vaccine Initiative
IDE	immunodominant epitope
IE genes	immediate early genes
IFA	incomplete Freund's adjuvant
IFN	interferon
IG format	IntelliGenetics format
Ig	immunoglobulin
IL	interleukin
INHI	immunologically normal HIV-infected
iscom	immunostimulating complex
KLH	keyhole limpet hemocyanin
LANL	Los Alamos National Laboratory
LDA	limiting dilution assay
LN	lymph node
LPR	lymphoproliferative response
LT	labile enterotoxin
LTNP	long-term non-progressor
LTR	long terminal repeat
LTS	long term survivor
mAb	monoclonal antibody
MBL	mannose-binding lectin
MCMC	Markov chain Monte Carlo
MDP	muramyl dipeptide
MEI	multiple epitope immunogen
MHC	major histocompatibility complex
MHR	major homology region
ML	maximum likelihood
MLV	murine leukemia virus

Abbrev.	Meaning
MP	maximum parsimony
mpc	months post challenge
MPER	membrane-proximal external region
MRC	Medical Research Council, UK
MSF	multiple sequence alignment format of the GCG sequence analysis package
MV	measles vector
MVA vector	modified vaccinia virus Ankara
Nab	neutralizing antibody
NCBI	National Center for Biotechnology Information
NIAID	National Institute of Allergies and Infectious Diseases
NIBSC	National Institute for Biological Standards and Control, UK
NIH	National Institutes of Health
NIST	National Institute of Standards and Technology
NJ	neighbor joining
NLS	nuclear localization signal
NRP	non-rapid progressor
NSI	non-synctium-inducing protein
p	protein
PB	peripheral blood
PBL	peripheral blood lymphocyte
PBMC	peripheral blood mononuclear cell
PCOORD	principal coordinate analysis
PCR	polymerase chain reaction
PERV	porcine endogenous retrovirus
PHYLP	Phylogeny Inference Package
PL	proteoliposome
RAC	ricin A chain
RDDP	RNA-dependent DNA polymerase
rec/r	recombinant
RIP	Recombinant Identification Program: a program for detecting evidence of inter-subtype recombination
RIPA	Radio Immuno Precipitation Assay
RP	rapid progressor
RRE	Rev-responsive element
rsgp160	recombinant soluble gp160
RSV	Rous sarcoma virus
SAM	Sequence Alignment and Modeling program
SAP	sequential antigen panning
sCD4	soluble CD4
scFv	single-chain variable fragment
SDS	sodium dodecyl sulfate
SFV	Semliki Forest virus
SI	synctium inducing
SIV	simian immunodeficiency virus

Abbrev.	Meaning
SIVE	SIV encephalitis
SLE	systemic lupus erythematosis
SNAP	synonymous-nonsynonymous analysis program
STI	supervised treatment interruption (also seen as structured treatment interruption and standard treatment interruption)
TCLA	T cell line adapted
TCR	T-cell receptor
Th	T-helper cell
TNF	tumor necrosis factor
VEE	Venezuelan equine encephalitis
VESPA	Viral Epidemiology Signature Pattern Analysis
VIP	vasoactive intestinal peptide
VL	viral load
VLP	virus like particle, assembled from p55 gag
VSV	vesicular stomatitis virus
VV	vaccinia virus
WB	Western Blot

### Amino Acid Codes

A	Alanine
B	Aspartic Acid or Asparagine
C	Cysteine
D	Aspartic Acid
E	Glutamic Acid
F	Phenylalanine
G	Glycine
H	Histidine
I	Isoleucine
K	Lysine
L	Leucine
M	Methionine
N	Asparagine
P	Proline
Q	Glutamine
R	Arginine
S	Serine
T	Threonine
V	Valine
W	Tryptophan
X	unknown or "other" amino acid
Y	Tyrosine
Z	Glutamic Acid or Glutamine
.	gap
-	identity

## I-A

# Identification and Optimal Definition of HIV-Derived Cytotoxic T Lymphocyte (CTL) Epitopes for the Study of CTL Escape, Functional Avidity and Viral Evolution

Nicole Frahm<sup>a</sup>, Brett Baker<sup>a</sup>, Christian Brander<sup>a</sup>

## I-A-1 Associations between T cell specificity and viral control: cause or effect?

Despite ongoing efforts into the characterization of immune correlates of controlled HIV infection, the impact of antigen specificity, viral sequence variation and variant cross-recognition on the control of viral replication and HIV disease progression remains unknown. While a steadily growing number of reports confirm the association between T cell responses directed against the HIV Gag protein and reduced viral load [Zuñiga *et al.*, 2006; Brumme *et al.*, 2008; Kiepiela *et al.*, 2007; Masemola *et al.*, 2004a; Rolland *et al.*, 2008], and despite some reports showing a rapid re-presentation of Gag-derived antigen from the incoming virus [Sacha *et al.*, 2007], it remains unclear whether a) these associations reflect the cause or the consequences of otherwise controlled infection and b) whether, and if so, which regions outside of Gag would present effective targets of the host cellular immune response to HIV. Similarly, although a number of recent reports have established strong associations between reduced viral replicative fitness and specific viral sequence changes in Gag epitopes restricted by HLA alleles associated with relative protection [Brockman *et al.*, 2007; Schneidewind *et al.*, 2007; Martinez-Picado *et al.*, 2006], these analyses urgently need to be expanded to other, broadly distributed HLA alleles and targets located in viral proteins other than Gag. In addition, the consequences of sequence variation on T cell recognition, often assumed to reflect effective T cell escape,

will need to be more carefully assessed, ideally including approaches such as viral inhibition assays and testing for different T cell effector functions to discriminate between partial agonistic variants, antagonistic or superagonistic sequence changes, or true CTL escape due to abrogated HLA binding, missing TCR interaction or severely impaired antigen processing.

## I-A-2 The role of functional avidity in the control of highly variable pathogens

A rapidly growing number of reports have also started to assess the role of T cell receptor repertoire diversity, TCR functional avidity and variant recognition [Price *et al.*, 2005; Turnbull *et al.*, 2006; Messaoudi *et al.*, 2002]. Recently published data in HCV infection has linked the presence of T cell responses of high functional avidity with a superior ability to cross-react with sequence variants [Yerly *et al.*, 2008]. Although these high avidity HCV-specific T cell populations were mainly found in subjects that spontaneously cleared HCV infection, it remains unclear whether individuals who went on to become chronically infected initially also had such high avidity responses which, for unknown reasons, got lost over time, similarly to what has recently been described in longitudinal analyses in HIV infection. Emerging data in HIV infection confirms the analyses in HCV as Frahm *et al.* (unpublished data) and likely others have identified particularly highly avid and broadly cross-reactive T cell populations in HIV controllers, but less so in individuals with progressive HIV disease. It thus appears likely that an effective HIV vaccine (and HCV, too) would likely profit from the induction of such high avidity responses.

### I-A-3 Refined HLA footprint analyses and the identification of novel CTL epitopes and HLA binding motifs

Aside from determining the roles of functional avidity and TCR repertoires, the analysis of viral evolution as a consequence of cytotoxic T lymphocyte (CTL) mediated immune pressure has given rise to a flurry of publications over the last few years [Moore *et al.*, 2002; McMichael & Klenerman, 2002]. Since the initial description of these HLA footprints in the HIV sequence, refined approaches have now been developed that take into consideration potentially confounding effects of the phylogeny of the analyzed sequences and HLA linkage disequilibrium [Brumme *et al.*, 2008; Bhattacharya *et al.*, 2007; Brumme *et al.*, 2007]. These analyses have also allowed for the identification of novel T cell epitopes by a sort of a “reversed” genetic approach that points towards the existence of novel T cell epitopes at or close to sites of strong associations between specific HLA alleles and recurrent viral sequence polymorphisms. With larger cohorts being generated and comprehensively analyzed in different geographic regions of the world with populations of considerably different host genetics and circulating viral populations, such HLA footprint analyses now also allow to assess the global effects of viral adaptation to HLA restricted T cell mediated immune pressure [Rousseau *et al.*, 2008]. Taking into consideration the balancing effects of forward mutations and reversion to pre-infection sequence, large cohort based analyses, together with detailed *in vitro* viral fitness studies, may also allow to determine the relative strength of the CTL mediated immune pressure and the effectiveness of an epitope specific CTL response. Especially for these kinds of studies, however, it is necessary to define the precise epitope so that the effectiveness of CTL escape and its potential different mechanisms (processing escape versus abrogated HLA binding, etc.) can correctly be assessed.

With more studies moving into populations where less well-characterized HLA alleles are more prevalent, epitope definition becomes more difficult (due to less well known binding motifs for instance) but also more informative for the relevant populations. Especially for such less well characterized alleles, the inference of binding motifs and subsequent identification of optimal epitopes through the analysis of HLA sequence positions lining the binding pockets has proven quite effective [Honeyborne *et al.*, 2007; Frahm *et al.*, 2005, 2006]. At the same time, our own analyses on promiscuously presented HIV epitopes clearly indicate that the current description of allele-specific motifs is still incomplete, and that the identification of truly optimally defined epitopes, viral or not, will help to amend and more accurately define existing binding motifs [Frahm *et al.*, 2007]. This would obviously

not only facilitate the work in HIV but also in other viral infections, cancer and autoimmunity.

### I-A-4 Are current criteria for the definition of “optimal” epitopes helpful to the community

As in past years, the present listing is based on the inclusion of epitopes that fulfill a number of criteria intended to ensuring reliable description of the optimal length epitope and correct assignment of the restricting HLA class I allele(s) [Brander & Walker, 1995, 1996]. Nevertheless, there may still be occasions where the data reported here conflict with data in other laboratories and we would like to encourage any investigator who observes discrepancies in his/her own data with what is reported here to bring this to our attention. In addition, we have still adhered to the previously described inclusion criteria, being aware that some epitopes may fail one or more of these tests although they may indeed represent optimal epitopes [Schellens *et al.*, 2008; Mueller *et al.*, 2007]. In particular, we and others are moving towards the use of single HLA allele transfected cell lines for HLA restriction analyses. While this approach would seemingly define the presenting allele directly, it is possible that stabilization of the allele on the cell surface may be sufficient to trigger a response, even though the allele is not the truly restricting one. We would thus like to suggest that each class I allele expressed by the subject from whom the effector cells were obtained be tested, either as single allele expressing cell lines or as a negative control antigen presenting cell line that matches as many of the presumably non-restricting alleles as possible. Alternatively, a known good binding epitope different from the one that is to be mapped could be used to exclude unspecific reaction due to high peptide concentration in the assay. High peptide concentration may also be a factor for the elicitation of responses in the Elispot assay that are however unable to inhibit viral replication [Valentine *et al.*, 2008]. While such cases may indeed identify epitopes with likely little contribution to effective viral control *in vivo*, their identification is still necessary to allow for their exclusion from potential immunogen sequences.

## I-A-5 Table of optimal HIV-1 CTL epitopes

Table I-A.1: Best defined HIV CTL epitopes.

### I-A-6 Map of optimal HIV-1 CTL epitopes

The location and HLA restriction elements of CTL epitopes are indicated on protein sequences of HXB2. These maps are meant to provide the relative location of defined epitopes on a given protein, but the HXB2 sequence may not actually carry the epitope of interest, as it may vary relative to the sequence for which the epitope was defined.

## I-A-7 Acknowledgments

We would like to express our gratitude to the large number of researchers in the field who continuously contribute to this database. We very much welcome any criticism, comments and additions to this list since we are sure that some epitopes will unintentionally escape our attention, despite close monitoring of the literature. Also, we would like to especially invite suggestions as to the use of alternative or additional selection criteria to define optimal epitopes as we strive to make this listing as extensive and useful to the community as possible, while maintaining its integrity. Please write or call us with any comments you may have at:

**Part II**

# **HIV CTL/CD8 + Epitopes**

CTL CD8+

## II-A

# Summary

This part includes tables, maps, and associated references of HIV-specific CTL epitopes found in the literature arranged sequentially according to the location of the proteins in the HIV-1 genome. We attempted to make this part as comprehensive as possible, requiring that the epitope be contained within a defined region of a maximum of 30 amino acids, but not that the optimal boundaries be defined. Studies that were based on the analysis of whole proteins are described at the end of each protein section. The same epitope can have multiple entries, as each entry represents a single publication in this part of the database. For more recent updates, epitope sequence alignments, and useful search capabilities, please see our web site: <http://www.hiv.lanl.gov/content/immunology>. For a concise listing of only the best defined CTL epitopes, see the summary by Nicole Frahm, Brett Baker and Christian Brander on page 3 in Part I of this compendium. CTL responses to proteins with no defined epitopes are listed at the end of each protein section.

Recent studies utilize multiple functions attributed to T cells to define responses, and the simple distinctions of cytotoxic T-cell and helper T-cells have become blurred as more is learned about the range of responses triggered in CD4 and CD8 positive T-cells responding to antigenic stimulus. When adding the most recent studies to the database, we have tried to place T cell responses in a reasonable manner into our traditional helper T cell and CTL parts, and to specify the assay used to measure the response in each study.

### II-A-1 Epitope tables

Each CTL reference has a multi-part basic entry:

**HXB2 location:** The viral strain HXB2 (GenBank Accession Number K03455) is used as a reference strain throughout this publication. The position of the defined epitope location relative to the sequence of the HXB2 protein is indicated. The numbering in this table corresponds to the protein maps. Because of HIV-1 variation the epitope may not actually be present in HXB2; rather, the position in HXB2 indicates the position aligned to the epitope. HXB2 was selected as the reference strain because so many studies use HXB2, and because crystal structures for HXB2-related proteins are often available. The precise positions of an

epitope on the HXB2 reference strain can be readily obtained using the interactive position locator at our web site: <http://www.hiv.lanl.gov/content/sequence/LOCATE/locate.html>.

**Author location:** The amino acid positions of the epitope boundaries and the reference sequence are listed as given in the primary publication. Frequently, these positions as published are imprecise, and do not truly correspond to the numbering of the sequence, but they provide a reasonable guide to the peptide's approximate location in the protein. Also, in many cases the reference sequence identification was not provided, and in such cases it is not possible to use these numbers to specify precise locations.

**Epitope:** The amino acid sequence of the epitope of interest as defined in the reference, based on the reference strain used in the study defining the epitope. On occasions when only the position numbers and not the actual peptide sequence were specified in the original publication, we tried to fill in the peptide sequence based on the position numbers and reference strain. If the sequences were numbered inaccurately by the primary authors, or if we made a mistake in this process, we may have misrepresented the binding site's amino acid sequence. Because of this uncertainty, epitopes that were not explicitly written in the primary publication, that we determined by looking up the reference strain and the numbered location, are followed by a question mark in the table.

**Epitope name:** If the epitope has a name attributed by the publication, it is recorded here, e.g. "SL9".

**Subtype:** The subtype under study, if specified in the primary publication; this is generally not specified for B subtype.

**Immunogen:** The antigenic stimulus of the CTL response. Often this is an HIV-1 infection. If a vaccine was used as the original antigenic stimulation, not a natural infection, this is noted, and additional information about the vaccine antigen is provided as available.

**Species (MHC):** The species responding and MHC or HLA specificity of the epitope.

**Donor MHC:** The HLA genotype of the individual that responded to the epitope.

**Country:** The country where the samples were obtained; this is generally not specified if the study was conducted in the United States.

**Assay type:** Assays used to characterize the response.

**Keywords:** Keywords are a searchable field for the web interface that is included in the T-cell sections of the printed version to help identify entries of particular interest.

**Reference:** The primary reference (sometimes two or more directly related studies are included). Details for some of the earlier references are in Part V.

Following the entry for a given CTL epitope brief comments explain the context in which the epitope was studied and what was learned about the epitope in a given study.

## II-A-2 HIV protein epitope maps

All HIV CTL epitopes mapped to within a region of 14 amino acids or less are indicated on the HIV protein epitope maps. The location and HLA restriction elements of CTL epitopes are indicated on protein sequences of HXB2. These maps are meant to provide the relative location of defined epitopes on a given protein, but the HXB2 sequence may not actually carry the epitope of interest, as it may vary relative to the sequence for which the epitope was defined. Epitopes with identical boundaries and HLA fields are included in the maps only once. If one laboratory determines HLA presenting molecules at the serotype level (example: A2) and another at the genotype level (example: A\*0201) both will be included in the map. MHC specificities are indicative of the host species; when no MHC presenting molecule is defined, the host species is noted.

## II-A-3 Alignments

To conserve space, no epitope alignments are provided in this book, but they can be generated using the CTL epitope search tool at <http://www.hiv.lanl.gov/content/immunology>. The master protein sequence alignment files from which the epitope alignments were created are available at our web site at <http://www.hiv.lanl.gov/content/sequence/NEWALIGN/align.html>.

## II-B

# HIV CTL/CD8+ Epitope Tables

All HIV CTL epitopes are arranged by protein position. The table entries are sorted in a nested way—first by protein, then by HXB2 start location, and finally by HLA presenting molecule. CTL reactions against proteins with undefined epitopes are listed at the end of the protein that stimulated the response.

### II-B-1 Gag p17 CTL/CD8+ epitopes

**HXB2 Location** p17 (1–10)  
**Author Location** Gag  
**Epitope** MGARASVLSG  
**Subtype** CRF01\_AE  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A11.1)  
**Country** Thailand  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay  
**Keywords** optimal epitope  
**References** Kantakamalakul *et al.* 2006

- T cell responses in CRF01\_AE infected individuals from Thailand were studied.
- This single peptide elicited IFN-gamma responses from three subjects and may be an A\*1101 binding peptide.

**HXB2 Location** p17 (5–13)  
**Author Location** Gag (5–13 SUMA)  
**Epitope** ASVLSGGEL  
**Epitope name** Gag AL9  
**Subtype** B  
**Immunogen** HIV-1 infection  
**Species (MHC)** human  
**Donor MHC** A\*1103, A\*2402, B\*1402, B\*1501, Cw\*0802  
**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay  
**Keywords** dynamics, acute/early infection, characterizing CD8+ T cells  
**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.

- The patient SUMA maintained low viral loads and stable CD4 T-cell counts through 7 years of followup. In contrast to more rapid progressors WEAU and BORI, SUMA had a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only 4 epitopes acquired escape mutations in SUMA over time, and this was 1 of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

**HXB2 Location** p17 (5–15)  
**Author Location** Gag (5–15)  
**Epitope** ASILRGGKLDK  
**Subtype** C  
**Immunogen** HIV-1 infection  
**Species (MHC)** human  
**Country** India  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay  
**Keywords** subtype comparisons  
**References** Kaushik *et al.* 2005

- T cell responses to Gag consensus C peptides were studied in C-infected patients from India. CD8+ responses were stronger and broader than CD4+ responses. IFN- $\gamma$  response was higher in both CD8+ and CD4+ T cells than corresponding IL-2 response, that was detectable only in CD4+ T cells.
- 1/25 patients responded to this peptide (IFN- $\gamma$  CD8+ response). An IL-2 response was not detectable.

**HXB2 Location** p17 (5–19)  
**Author Location** p17 (5–19)  
**Epitope** ASVLSGGELDRWEKI  
**Epitope name** AI14  
**Subtype** B  
**Immunogen** HIV-1 infection  
**Species (MHC)** human  
**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other  
**Keywords** binding affinity, subtype comparisons, acute/early infection  
**References** Malhotra *et al.* 2007b

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants

are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.

- This peptide, ASVLSGGELDRWEKI contains the CON clade-B putative epitope AI14. No cross-recognition of variants was seen across clades or intra-clade central sequences. Variant ASVLSGGkLdaWEKI was seen in clade A and M-group; variant ASiLrGGkLdkWEKI in clade C; ASVLSG-GkLdkWEKI in clade-B ANC; and variant ASVLSGGELDKWEKI in clade-B COT.

**HXB2 Location** p17 (6–15)

**Author Location** Gag (Henan isolate)

**Epitope** SVLSGGQLDR

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11)

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.

**HXB2 Location** p17 (8–18)

**Author Location** Gag (8–18)

**Epitope** LSGGELDRWEK

**Epitope name** Gag 1.2

**Immunogen** vaccine

*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* B clade  
*HIV component:* Env, Gag, Protease, Rev, RT, Tat, Vpu

**Species (MHC)** macaque

**Assay type** T-cell Elispot, Intracellular cytokine staining

**Keywords** subtype comparisons, variant cross-recognition or cross-neutralization, memory cells

**References** Amara *et al.* 2005

- A clade B DNA/MVA HIV vaccine was shown to raise a broad cross-reactive cellular immune response for peptides based on the CRF02\_AG consensus Gag in macaques. The activity was better conserved for CD8 than CD4 T cells.
- All 5 CD8 and 4/8 of the CD4 epitopes that were recognized in vaccinated macaques have also been reported for human infections, indicating cross-species conservation. The similar reported human epitope in this case is GELDRWEKI. HLA restriction: B\*4002, B62
- Conservation across other clades: none. The form that is most common in CRF02, LSGGkLdaWEK, does not cross-react with the B clade elicited response.

**HXB2 Location** p17 (11–19)

**Author Location**

**Epitope** GELDRWEKI

**Epitope name** Gag-GI9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*4002)

**Donor MHC** 01RCH46: A\*0201, A\*0217, B\*0801, B\*4002, Cw\*0303, Cw\*0701

**Keywords** HAART, ART

**References** Sabbaj *et al.* 2003

- This study monitored epitope responses in HIV-1 infected minority women living in the United States.
- 24 epitopes were described – 8 were novel, 8 used new restricting elements but were previously defined epitopes, and 8 were previously described.
- Serial peptide truncations were used to define optimal epitopes for CTL cell lines isolated from 12 individuals, assayed by a Cr-release.
- This epitope was newly defined in this study.
- Patient 01RCH46 was Hispanic, on HAART, and had a viral load of 21000 and CD4 count of 623 – she also recognized KETINEEAA p24(70-78), HLA B\*4002, and TAFTIPSI, RT(128-135), HLA A\*0217.
- Among HIV+ individuals who carried HLA B40, 2/5 (40%) recognized this epitope.

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion

**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.

- The escape variant geldrwKki was detected in 10/10 maternal clones from a B40-positive mother, but was absent in all sequences from her B40-negative infant, sampled at months 2, 4, and 11, suggesting either transmission of a minority wild-type variant, or rapid reversion in the absence of continued CTL pressure.
- geldrwKki elicited lower responder cell frequencies than GELDRWEKI.

**HXB2 Location** p17 (11–19)

**Author Location** p15

**Epitope** GELDRWEKI

**Epitope name** B40-GI9(p15)

**Immunogen** HIV-1 infection

**Species (MHC)** human (B40)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** p17 (11–30)

**Author Location** Gag (11–30)

**Epitope** GELDRWEKIRLRPGGKKKYK

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B62)

**Donor MHC** A2, A32, B27, B62

**Assay type** Chromium-release assay

**Keywords** genital and mucosal immunity

**References** Musey *et al.* 2003

- CTL clones from blood, semen, cervix and rectum samples from 12 individuals were compared. CTL clones derived from blood and mucosal samples had similar high lysis efficiency, primarily perforin dependent, and TCR $\beta$  VDJ region sequencing revealed cases of expansion of the same clone in different compartments.
- CD8+ T cell clones directed at this epitope were derived from blood and semen.

**HXB2 Location** p17 (12–21)

**Author Location** p17

**Epitope** ELDRWEKIRL

**Subtype** B, C

**Immunogen** HIV-1 infection

**Species (MHC)** human (B63)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- This is a putative HLA B63 epitope containing the B58 super-type binding motif embedded in a reactive peptide. There is no evidence for B57/B58 cross-presentation of this epitope.

**HXB2 Location** p17 (16–30)

**Author Location** p17 (16–30 HXB2)

**Epitope** WEKIRLRPGGKKKYK

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Assay type** T-cell Elispot

**Keywords** immunodominance, early treatment

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**HXB2 Location** p17 (17–34)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but

the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.

- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, EKIRLRPGGKKKYKCLKHI, had an overall frequency of recognition of 16.7% - 22% AA, 15.4% C, 15.9% H, 4.8% WI.

**HXB2 Location** p17 (18–26)  
**Author Location** p17 (18–26 IIIB)  
**Epitope** KIRLRPGGK

**Keywords** escape, acute/early infection, variant cross-recognition or cross-neutralization  
**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. CTL escape variants were often transmitted. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those

epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient.

- A\*0301 epitopes RLRPGGKKK and KIRLRPGGK, and B\*0801 epitope GGKKKYRL, overlap. In 1 donor, the transmitted virus carried the escape form for 2 of these epitopes. The double substitution kirlrpggR results in escape from response in the donor. Similarly, the double substitution ggRkkyKl results in escape for this epitope.
- The escape mutation kirlrpggR in this epitope resulted in 74% reduction in HLA binding affinity. The other variant tested, kirlrQggR, resulted in 90% reduction.

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.

- 8/14 HLA-A3 positive individuals had detectable A3-restricted responses during acute infection. Only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 7/8 individuals with acute responses had specific responses for this epitope.
- KIRLRPGGK and RLRPGGKKK were the most commonly recognized HLA-A3 epitopes during acute infection, after 1 year of treatment, and after STI. RLRPGGKKK was immunodominant.

- KK9 and RK9 overlap, are presented by HLA-A3, and are frequently immunodominant and involved in acute-phase primary responses. A mutation in the C-terminal flanking residue of KK9 (K to Q) (kirlrpkkq-Q) inhibits processing of the immunodominant gag KK9 epitope, resulting in rapid decline in the KK9 specific CD8+ T-cell response. At the same time it abrogates the response to RK9 through the embedded mutation rlrpggkQk. Transmission of this mutation to patients expressing HLA-A3 prevents acute-phase response to these epitopes, although the mutation can eventually revert to wild-type allowing a delayed response to the epitope.

**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion

**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.

- The escape variant kirlrpggR was present in 10/10 clones from an A3+ mother, was transmitted to her infant, and present in 10/10 clones at months 2 and 4, but decreased to 0/10 clones by 15 months of age in her A3- child.

**Keywords** HAART, ART, escape, viral fitness and reversion  
**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate escape rate for this epitope, KIRLRPGGKK, was 0.002 (SE 0.006), and best estimate reversion rate was 0/day with a SE of 0.
- The variant K26R confers escape in A\*0301+ individuals. On transmission to an HLA A\*0301-negative recipient, the mutation did not revert to wild type over a period of 1 year.

**Keywords** rate of progression, escape

**References** Gao *et al.* 2005

- Three distinct HLA alleles known to alter the rate of AIDS progression were studied. B\*57-mediated protection occurs early in infection and the protective effect of this allele subsides after CD4 cell count drops. In contrast, B\*27 shows no protection against progression to CD4<200, but rather delays progression to an AIDS-defining illness after the CD4 counts have dropped. B\*35-mediated rapid progression to AIDS is probably a function of early decline in CD4 counts.
- KK10 escape occurs late and was shown to precede a sharp increase in viral load. The authors hypothesize the B27 benefit may arise due to enduring HLA restriction after escape from many other allotype responses has occurred.

**Keywords** escape

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- One subject responded to peptide KK15 which had a K26R mutation, KIRLRPGGKrKYKLLK, in a minority of plasma virus clones.

**References** Feeney *et al.* 2004

- Viral load in a perinatally infected child remained low until emergence of an escape variant (kTwiilglnk) in the immunodominant CTL epitope KRWILGLNK when the child was 7.4 years old. The emergence of this escape mutation was followed by an increase in viremia and an increase in the number of targeted CTL epitopes, measured again when the child was 9.2 years old. A low level response to IK9 was the only other epitope recognized prior to the loss of immune control and broadening of the response, and was detected in the 7.4 year sample.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, RK9 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen with both C- and A-clades. Anchor residues are at positions 2 and 9; while the C-clade variant contains a change at position 9 to RLRPGGKKh. Typically, magnitude and avidity of binding for T-cell responses were much lower to the C-clade variant.

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load was also found.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWILGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

- IFN $\gamma$  T-cell responses in breast milk of 5 HIV-1 infected women from the US and 6 from Zambia were tested using Elispot. 11/11 women responded to Gag, 8/11 responded to Pol, 7/11 women to Nef, and 2/5 women to Env peptide pools. These responses were shown to be primarily due to CD8+ T-cells in one woman, and another woman had cytolytic responses measured by Cr-release.
- Tetramer analysis of breast milk and peripheral blood samples of one volunteer showed responses to RLRPGGKKK in both compartments, 0.65% of CD3+/CD8+ cells in breast milk, and 0.22% of CD3+/CD8+ cells in peripheral blood cells.
- The frequencies of responses in the two compartments differed, and 2/4 women who responded to epitopes in Nef 101-205 and Pol 601-710 showed responses in breast milk but no detectable responses in peripheral blood cells.

- Patients with acute or early infection were shown to preferentially target variable peptides with higher entropy while those with chronic infection showed responses towards more conserved peptides with lower entropy. In longitudinally followed subjects, responses to variable proteins declined over time while responses to conserved proteins increased. The decline is suggested to be due to CTL escape.
- rlrpggkkQ escape mutant showed drastically reduced avidity. The response to this peptide was not apparent until month 20, by month 32 the escape variant was present.

**HXB2 Location** p17 (20–28)**Author Location** p17**Epitope** RLRPGGKKK**Subtype** A**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0301)**Donor MHC** A\*0101, A\*0301, B\*0801; A\*0201, A\*3101, B\*3501, B\*3905**Country** United Kingdom**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** escape, acute/early infection, variant cross-recognition or cross-neutralization**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. CTL escape variants were often transmitted. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient.
- Certain escape mutations in RLRPGGKKK, rlrpggkkQ, rlrpggkkR and rlrpggkkT, resulted in nearly complete reduction in binding affinity for A\*0301. The form that was transmitted in one of the donor pairs was rlrpggRkk, and it binds to A\*0301 with comparable affinity to RLRPGGKKK. However, an escape variant was on the rise in the donor near the time of transmission, rlrpggRkT, which eventually came to fixation in the donor, illustrating the importance of the timing of transmission regarding which variant is transmitted.
- A\*0301 epitopes RLRPGGKKK and KIRLRPGGK, and B\*0801 epitope GGKKKYRL, overlap. In 1 donor, the transmitted virus carried the escape form for 2 of these epitopes. The double substitution kirlrpggR results in escape from response in the donor. Similarly, the double substitution ggRkkyKl results in escape for this epitope.

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, RLRPGGKKK, was found to be 0.032/day, with SE of 0.008.
- The K28T substitution conferred escape from CTL responses of both the RLRPGGKKK and GGKKKYRL epitopes.

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, A3-RLR (that has no association with accelerated or delayed progression to AIDS) and its natural variants are not cross-recognized. Its alanine-substituted variants were extremely inconsistent between individuals showing very efficient or poor cross-reactivity.

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06 was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.

- 8/14 HLA-A3 positive individuals had detectable A3-restricted responses during acute infection. Only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 7/8 individuals with acute responses had specific responses for this epitope.
- KIRLRPGGK and RLRPGGKKK were the most commonly recognized HLA-A3 epitopes during acute infection, after 1 year of treatment, and after STI. RLRPGGKKK was immunodominant during acute infection and throughout the study period in the 5/6 individuals who targeted it.

**Keywords** class I down-regulation by Nef

**References** Lewinsohn *et al.* 2002

- CTL kill targets through releasing perforin, that forms pores in the plasma membrane, and granzymes, that induce apoptosis.
- Vpr is capable of arresting infected cells in the G2 phase, and it was hypothesized that Vpr may inhibit CTL-mediated apoptosis because it interacts with the granzyme B molecular complex.
- Vpr expression in the target cell did not inhibit epitope specific lysis – neither perforin or granzyme mediated events were inhibited, as measured by a Chromium release assay and a TUNEL assay.
- In contrast, deletion of Nef, which is thought to protect primary HIV infected cells by down-regulating cell-surface expression of MHC class I complexes, increased the susceptibility of HIV-1 infected cells to CTL mediated killing 2-fold using the TUNEL assay.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- This epitope was recognized in four individuals during early infection, each time presented by A3.
- All HIV-1 proteins except Vpu were recognized, and responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay  
**Keywords** immunodominance, escape, acute/early infection, characterizing CD8+ T cells, viral fitness and reversion  
**References** Allen *et al.* 2004
- KK9 and RK9 overlap, are presented by HLA-A3, and are frequently immunodominant and involved in acute-phase primary responses. A mutation in the C-terminal flanking residue of KK9 (K to Q) (kirlrpkkg-Q) inhibits processing of the immunodominant gag KK9 epitope, resulting in rapid decline in the KK9 specific CD8+ T-cell response. At the same time it abrogates the response to RK9 through the embedded mutation rlrpggkQk. Transmission of this mutation to patients expressing HLA-A3 prevents acute-phase response to these epitopes, although the mutation can eventually revert to wild-type allowing a delayed response to the epitope.

**Epitope** RLRPGGKKK  
**Epitope name** RK9  
**Immunogen**  
**Species (MHC)** (A3)  
**Keywords** review, immunodominance, escape, acute/early infection, early-expressed proteins, kinetics, viral fitness and reversion  
**References** Lichterfeld *et al.* 2005
- This review discusses the importance of 3 factors that impact the selection of immunodominant epitopes in acute HIV infection: i) the kinetics of viral protein expression, ii) the HLA class I background of the infected individual, and iii) the autologous sequence of the infecting virus. This is 1 of 12 peptides listed as immunodominant in acute HIV-1 infection.
- HXB2 Location** p17 (20–28)  
**Author Location** p17  
**Epitope** RLRPGGKKK  
**Epitope name** A3-RK9(p17)  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A3)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion  
**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- RLRPGGKKKY was recognized in 2 mothers, and is an A\*30 epitope. The variant RLRPGGKKqY was found in 9/10 of 1 mother's sequences. This form was transmitted to her child, and 10/10 clones were this variant at months 2 and 6 in the infant; by month 12, 9/10 were RLRPGGKKqY. RLRPGGKKrY was the form found in the other mother. The variant gradually diminished in frequency in her child, 10/10 sequences at 2 months, 9/10 at 4 months, and 6/10 at 12 months.

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The RY10 variant RLRPGGrKKY was the only form of the epitope detected over a 5 year time period in this person. Elispot reactions were stronger to the autologous form than to RLRPGGKKKY, the B clade consensus form.

**References** Weekes *et al.* 2006

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced clonal efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, LRPGGKKKYKLNHIV, was found to be -0.001/day (upper bound on rate of escape = 0.085), with SE of 0.003.
- In the subject studied, K26R grew out steadily to 95% frequency, but then there was a progressive re-emergence of the wild type. If data from all time points were fitted, then the mutant actually had a negative growth rate because it was eventually out-competed by the wild type.

**References** Geldmacher *et al.* 2007b

- The objectives of this study were to find antiviral epitopic determinants of Gag HIV-specific CTL response and to find 'host HLA-CTL response' correlations. By studying 56 ART-naive subjects including low viral load (LVL) responders, the authors show that subjects expressing the above "protective" HLA have broader Gag epitope recognition which may be abrogated if co-expressed with HLA-B alleles associated with rapid AIDS progression. Also, a negative linear relation was seen between Gag epitope numbers recognized and plasma viral load while a positive relationship was seen with CD4 T-cell count. Finally, LVL subjects recognized specific Gag regions at the N- and C-termini of the protein more often than peptides in the middle of the protein.
- Epitope RPPGKKKYML, presented by HLA-B\*0702 and B\*4201 is strongly associated with LVL. However, the last position RPPGKKKYMI is highly variable.

**References** Geels *et al.* 2005

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse

correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.

- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence had an K5N change, RPPGnKKYKL.

- The variants 7R: GGKKKYRL, 7Q: GGKKKYQL, 5R: GGKKRYKL, and 3R: GGRKKYKL, were studied.
- Crystal structures were obtained to study these peptides in the context of HLA-B8, and CTL binding and activity were determined.
- 3R has been detected in 3 patients, and it abolishes recognition causing extensive conformational changes upon binding including MHC main chain movement.
- 7Q and 7R alter the TCR exposed surface, and retain some recognition.
- Reactivity of 5R depends on the T cell clone, this amino acid is embedded in the C pocket of B8 when the peptide is bound.
- Optimal peptide is 8-mer, not 9-mer, and positions 3, 5, and 8 are the anchor residues.

**Keywords** subtype comparisons

**References** Geels *et al.* 2005

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence had an L8M change, GGKKKYKm.

**Keywords** responses in children, mother-to-infant transmission, escape, characterizing CD8+ T cells, viral fitness and reversion

**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in

the infant over time was determined by infant HLA haplotype and viral fitness.

- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- Variant sequence ggRkkykl was present in 10/10 clones from a B8-positive mother, but decreased to 0/10 clones by 15 months of age in her B8-negative child.
- The variant ggRkkykl was present in 10/10 clones from a B8+ mother, was transmitted to her infant, and present in 10/10 clones at months 2 and 4, but decreased to 0/10 clones by 15 months of age in her B8- child.

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Gag epitope GGKKKYKf (p17-31F) presumed escape variant was transmitted from a B8 positive donor to a B8 negative recipient. Reversions to GGKKKYKl were found in the recipient.

**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B8-GGK and its alanine-substituted variants are very weakly cross-recognized and reactive.

- PBMCs from HIV-1 infected Indian subjects were tested for HIV-1 Gag (with C clade peptides), Nef (with B clade peptides), and Env (clade unspecified) specific T-cell responses. 5 immunodominant regions conserved across clades were identified in Gag and Nef. 3 antigenic regions were found to be recognized by CTLs in the Indian subjects; these regions were not identified as immunodominant in studies from Africa.
- 26 epitopes were predicted within reactive peptides, of which 90% were clustered in the conserved immunodominant regions of Gag and Nef.
- 3 of the epitopes were highly conserved across clades, and 7 novel epitopes were found.
- Epitope KRYMIKHLV was conserved only across clade C.

**HXB2 Location** p17 (28–36)**Author Location** (C consensus)**Epitope** HYMLKHIVW**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (A\*2301)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, optimal epitope**References** Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- Mutational patterns in the M in the third residue HYMLKHIVW are associated with the presence of the HLA presenting molecule in the host.

**HXB2 Location** p17 (28–36)**Author Location** Gag (28–36)**Epitope** HYMLKHIVW**Subtype** A, C**Immunogen** HIV-1 infection**Species (MHC)** human (A\*2301)**Country** Tanzania**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** subtype comparisons, immunodominance**References** Geldmacher *et al.* 2007a

- To assess whether T-cell specific responses to Gag and Nef are biased towards infecting subtype recombination, 56 ART-naive subjects were studied using six overlapping peptide sets consisting 15-mer peptides, covering both proteins completely. A multi-region hybridization assay was employed. Overall, the best recognized epitope variant in terms of magnitude and breadth corresponded to infecting subtype, in this case usually type-C. Hot spots of CTL recognition in Gag were in p24, p17

and p15; hotspots against Nef were in its central, conserved region.

- Epitope variants hYmLKHIVW, kYrLKHIVW and qYrLKHIVW were studied as peptide sequences GKK-hYmLKHIVW-ASR (subtype C), GKK-kYrLKHIVW-ASR (subtype A) and GKK-qYrLKHIVW-ASR with 21% responders. Subtype C epitopes were best recognized.

**HXB2 Location** p17 (28–36)**Author Location** (C consensus)**Epitope** HYMLKHLVW**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (A\*2301, A\*2402)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** cross-presentation by different HLA, characterizing CD8+ T cells**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** p17 (28–36)**Author Location** p17 (28–36 LAI)**Epitope** KYLKLKHIVW**Subtype** B**Immunogen****Species (MHC)** human (A\*2402)**Keywords** optimal epitope**References** Frahm *et al.* 2008

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-A24+ individuals that had a CTL response to this epitope broken down by group: 0/0 group 1, 2/3 group 2, and 0/0 group 3.

**HXB2 Location** p17 (28–36)**Author Location** p17 (28–36 93TH253 subtype CRF01)**Epitope** KYCLKHIVW**Subtype** CRF01\_AE**Immunogen** HIV-1 infection**Species (MHC)** human (A24)**Keywords** subtype comparisons**References** Bond *et al.* 2001

- More than half of a cohort of HIV+ female sex workers (FSW) from Northern Thailand were HLA-A11 positive, and this study concentrated on A11 epitopes in this group, although E clade versions of previously defined B-clade A2 and A24 epitopes were also tested.
- The only HLA-A24 FSWs tested did not recognize the E clade version of this epitope KYKMKHLVW, which differs from the previously defined B clade version by two amino acids, KYCLKHIVW.

**HXB2 Location** p17 (28–36)**Author Location** p17**Epitope** KYCLKHIVW**Epitope name** KW9**Immunogen** HIV-1 infection**Species (MHC)** human (A24)**Donor MHC** A2, A24, B38, B60, Cw12, Cw2**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** supervised treatment interruptions (STI), acute/early infection**References** Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion

**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.

- qYKCLKHIVW is an escape variant of the A\*24 epitope KYKCLKHIVW, found in 9/10 clones from the mother. It was transmitted to her infant, and persisted for 15 months. Both the mother and child are A\*24+.
- qYKCLKHIVW elicited lower responder cell frequencies than KYKCLKHIVW.

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**References** Geldmacher *et al.* 2007b

- The objectives of this study were to find antiviral epitopic determinants of Gag HIV-specific CTL response and to find 'host HLA-CTL response' correlations. By studying 56 ART-naive subjects including low viral load (LVL) responders, the authors show that subjects expressing the above "protective" HLA have broader Gag epitope recognition which may be abrogated if co-expressed with HLA-B alleles associated with rapid AIDS progression. Also, a negative linear relation was seen between Gag epitope numbers recognized and plasma viral load while a positive relationship was seen with CD4 T-cell count. Finally, LVL subjects recognized specific Gag regions at the N- and C-termini of the protein more often than peptides in the middle of the protein.
- Epitope HYMLNHIVW is overrepresented for recognition within the LVL group. However, this immunodominant epitope is most variable of all.

**References** Kaul *et al.* 2001a

- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-Cw4 women, 2/2 HEPS and 7/11 HIV-1 infected women recognized this epitope.
- The dominant response to this HLA allele was to this epitope in both of the 2/2 HEPS cases and in 3 of the 7/11 HIV-1 infected women.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, KHIVWASRELERFAV, had an overall frequency of recognition of 16.7% - 23.7% AA, 19.2% C, 9.1% H, 4.8% WI.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved

peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J. Virol.* 76:8757–68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This overlapping peptide, ASRELERFAVNPGLL, was differentially targeted across ethnic groups and had an overall frequency of recognition of 13.3% - 6.8% AA, 26.9% C, 20.5% H, 0% WI (P value = 0.0068).

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- This is a putative HLA-B63 epitope is contained within a reactive peptide containing the B58 supertype binding motif. There is no evidence for B57/B58 cross-presentation of this epitope.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.

- This epitope, QLQPSLQTGS, was detected within overlapping peptides QLQPSLQTGSEELRSly and EGCRQILQLQPSLQTGS.

**Subtype B****Immunogen** HIV-1 infection**Species (MHC)** human (A\*01)**Donor MHC** A\*02, B\*08**Country** United States**Assay type** Intracellular cytokine staining, Other**Keywords** rate of progression, escape, immune evasion**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naïve subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- In one patient, this epitope GSEELRSLY varied at Y79F to GSEELRSLF, at an anchor position, conferring potent viral escape. One other variant seen was GSEELRSLc.

**HXB2 Location** p17 (71–79)**Author Location** p17**Epitope** GTEELRSLY**Subtype** A**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0101)**Donor MHC** A\*0101, A\*0301, B\*0801; A\*0201, A\*3101, B\*3501, B\*3905**Country** United Kingdom**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** escape, acute/early infection, characterizing CD8+ T cells**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- Escape mutation gteelrslF in this epitope resulted in 98% reduction in HLA binding affinity, and was the transmitted variant.

**HXB2 Location** p17 (71–79)**Author Location** p17**Epitope** GSEELRSLY**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0101)**Donor MHC** A\*0101, A\*0301, B\*0801, B\*5101; A\*0101, B\*0801**Country** United Kingdom**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** escape, acute/early infection, characterizing CD8+ T cells**References** Milicic *et al.* 2005

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence had dramatic changes, the epitope GSEELRSly peptide was GtegiKSLh, and so likely not the actual reactive epitope in the larger peptide.

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 were chronically infected and treated; 22 started treatment during acute infection; 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.

- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.

- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- 17 perinatally HIV-1 infected children (0.08–16 years) were evaluated for HLA-A2-restricted IFN-gamma CD8+ CTL responses against 4 immunodominant peptides that carry HLA-A2 epitopes. Two peptides were from gp120 (one at position 112, one from the V3 loop), and one each was from gp41 and Gag. 15/17 patients responded to the Gag peptide, 13/17 to the gp41 and the non-V3 gp120 peptides, and 11/17 responded to the V3 loop. 4 children recognized all 4 peptides.
- In 10/14 children, addition of exogenous IL-15 induced increased frequencies of SFCs to the Gag peptide. IL-2 and IL-7 did not increase SFCs, however IL-2, IL-7 and IL 15 could all increase the intensity of the spots in some patients. In 4 children, IL-15 addition brought the SFC response up to the level of detection.

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence ELRSLYNTV had dramatic changes, the epitope peptide was gikSLhNTV, and so likely not the actual reactive epitope in the larger peptide.

- HLA-A\*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN- $\gamma$  staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A\*0201/\*3002 B\*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A\*3002/ B53/\*5801 Cw4/7) an African-Caribbean.
- In both HLA-A\*3002 individuals the response to RSLYNTVATLY was dominant.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41).
- HLA-A\*3001-positive targets do not present RSLYNTVATLY.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8+ T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.

- Treatment interruption following HAART resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.

- This is a putative HLA-B63/57/58 epitope containing the B58 supertype binding motif. Peptide reactivity was enriched for those that carry B63, with a trend for those that carry B57/B58. Optimal epitope was defined in an individual that was B\*1517(B63)/B58 positive.

**References** Liu *et al.* 2006a

- An SIV Gag DNA vaccine was studied in mice in order to enhance subdominant immune responses to the KV9 epitope, without compromising its immunodominant response to the Gag AL11 epitope. Both epitopes share a common MHC restricting allele. Novel vaccine strategies including anatomic separation and heterologous prime-boost were investigated to expand vaccine-elicited CTL responses. This was the first study of its kind using DNA gene-based vaccines.
- This epitope, KSLYNTVCV (KV9), was the subdominant epitope studied, but it was capable of eliciting a response of comparable magnitude to the immunodominant epitope, AL11, in the absence of AL11 during vaccine priming.
- This subdominant epitope KV9 had an augmented response even in the presence of immunodominant AL11, making their responses codominant, when vaccine administration used anatomic separation or heterologous boost strategies.

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- The major p17 Gag SL9 epitope, SLYNTVATL, varied to SLYNTiATL with change V82I at position 6 and SLfNTiATL with an additional change Y79F at position 3. The 79F mutant elicited lower magnitude and functional avidity responses than 82I and 79F82I mutants. Even so, in time most variants were Y79F which showed positive selection. This Y79F mutant was seen combined with upstream changes E62G/V/A. In combination with 62E and 62G however, the Y79F mutant did

not propagate successfully. Later, in combination with 62A the 79F mutant coincided with increasing viral load.

- The impact of Nef on antiviral activity was studied. CTL-targeting epitopes were susceptible to the effects of Nef, both in late (Gag, RT, Env) and in early proteins (Rev, Nef), although to a lesser degree in early proteins. However, HLA-C-restricted CTLs (unlike HLA-A and HLA-B) were unaffected by Nef both in early (Nef) and late (Env) proteins.
- Late protein Gag epitope SLYNTVATL-recognizing CTLs were affected by Nef.

- Maturation phenotypes of CTLs were compared between HIV-1 Controller and Progressor subjects. Controllers were found to recognize a median of 18 epitopes compared to 15 by Progressors. While Controllers certainly had higher frequencies of terminally differentiated effector CTLs (CD45RA+/CCR7-), Progressors had higher mean frequencies of CD45RA-/CCR7- effector memory, CD45RA-/CCR7+ central memory (statistically significant) and CD45RA+/CCR7+ naive CTLs. No correlation was seen between CTL effector phenotype and either HLA-type or epitope.

- A\*02-restricted epitope SLYNTVATL does not correlate with any particular CTL maturation phenotype.

- To assess whether T-cell specific responses to Gag and Nef are biased towards infecting subtype recombination, 56 ART-naive subjects were studied using six overlapping peptide sets consisting 15-mer peptides, covering both proteins completely. A multi-region hybridization assay was employed. Overall, the best recognized epitope variant in terms of magnitude and breadth corresponded to infecting subtype, in this case usually type-C. Hot spots of CTL recognition in Gag were in p24, p17 and p15; hotspots against Nef were in its central, conserved region.
- Epitope variants SLYNTvATL and SLfNTiATL were studied as peptide sequences SLYNTvATL-YCVHEK (subtypes C, A, D), SLfNTiATL-YCVHEK and SLfNTiATL-WCVHQR with 18% responders. Subtype C epitopes were best recognized.

- Based on two papers, Iversen 2006 and Frahm 2006, the authors point out that in choosing epitopes for use in AIDS vaccines not only immunogenicity but fitness cost of escape mutations must be considered. Thus immunization may be made to both wild-type and common escape variants. Also, while epitopes that lack sequence variation may form good targets, so would subdominant epitopes.
- Iversen *et al.* found 2 pathways of conservative residue change that affect CTL epitope contacts with HLA-A\*02 - one acquiring escape mutations (SLfNTiAvL) and the other retaining or reverting to index residues in Gag protein's SLYNTVATL (SL9) epitope.
- Since viral loads in patients with escape mutations in SL9 are typically lower, it is suggested that CTL responses to subdominant epitopes in such patients may be involved in replication control. Frahm *et al.* showed subdominant epitopes of an HLA-B\*1503 restricted response to HIV were able to reduce viremia.

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** acute/early infection

**References** Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T-cells and viral load was also found.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWIIIGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

 • HIV was scanned for all peptides which carried the A2-supermotif pattern conserved in more than 50% of B clade sequences – 233 peptides met this criteria, and 30 of these bound to HLA-A\*0201 – 20/30 bound to at least 3/5 of HLA-A2 supertype alleles tested.  
 • Three additional previously described HLA-A2 epitopes were added to the set of 20, including p17 SL9, and 18/22 chronically infected HLA-A2 individuals had CTL that recognized at least one of the 23 peptides (median of 2 and maximum of 6), while 6/12 acute infected individuals recognized at least 1 (median of 1 and maximum of 2).  
 • p17 SL9 was recognized in 12/22 patients with chronic HIV-1 infection.

- Only 1/13 patients with acute HIV-1 infection recognized p17 SL9.

- This paper describes a comparison of results of different CTL assays, a SL9 tetramer assay and IFN-gamma ELISPOT, using 7 HIV-positive patients.
- The IFN-gamma ELISPOT assay was compared using the single SL9, a pool of overlapping 20 mers, and recombinant vaccinia encoding Gag as antigen – pooled peptides gave the highest number of spot forming cells, vaccinia gave high background.
- A correlation with results of the tetramer assay was found only for ELISPOT using the Gag epitope as antigen, but the tetramer assay detected a 10-fold higher number of cells than could produce IFN-gamma in the ELISPOT assay – the authors suggest not all tetramer-positive cells may produce IFN-gamma, some may be undergoing apoptosis, some may be producing other cytokines.
- The tetramer assay could detect a reaction to SLYNTVATL in most of the HLA-A\*0201 chronically HIV-1 infected study subjects.

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using tetramer staining or CD8+ cell IFN $\gamma$  production to measure responses.
  - In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
  - Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

**References** Propato *et al.* 2001
- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
  - Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
  - A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
  - Tetramer staining with A2, beta2microglobulin, and either SLYNTVATL, KLVGKLNWA, or LTFGWCFKL revealed that tetramers detected more HIV-specific sells in LTNP than in progressors, activated effector cells were the minority population, and ELISPOT correlated better with the effector cell subpopulation than the total tetramer stained population.

**References** Ostrowski *et al.* 2000
- The role of CD4+ T-cell help in expansion of virus-specific memory CTL was studied through co-culture *ex vivo*.
  - Optimal expansion of HIV-1-specific memory CTL depended on CD4+ T cell help in 9/10 patients – CD40 ligand trimer (CD40LT) could enhance CTL in the absence of CD4+ T cell help to a variable degree in most of patients.

- Those CTL that didn't respond to CD40LT could expand with IL2 present, and IL15 produced by dendritic cells also contributes.
- The T-helper epitope used for CD4+ T cell stimulation was the universal tetanus helper epitope TET830-843 (QYIKAN-SKFIGITE).

**Keywords** binding affinity, vaccine-specific epitope characteristics, immunodominance

**References** Peter *et al.* 2001

- The stability of peptide binding to HLA-A2.1 was determined for six HLA-A2.1 peptides included in this vaccine study – ILKEPVHGV (RT), SLYNTVATL (p17), SLLNATDIAV (gp41) and LLWKGEAV (RT) all bound with high affinity comparable to a influenza epitope reference (GILGFVFTL), while RGPGRFVTI and VIYQYMDDL bound with a lower affinity (relative binding activity = 0.01).
- The four high-affinity peptides formed stable complexes with half-lives ranging between 8 and 32 hours, while the low affinity peptides had half lives of less than an hour.
- HLA-A2.1 transgenic mice were immunized with the six HIV-1 peptides and P30, as a universal T-helper epitope, with IFA or Montanide or microspheres as adjuvants.
- All peptides except VIYQYMDDL induced a strong CTL response in Cr-release assays - stronger responses were observed when peptides were delivered alone, indicating immunodominance when the combination was used.

- When HIV-1 peptides were used to vaccinate HLA-A2.1 transgenic A2-Kb mice, strong responses to five peptides were observed when the peptides were given individually, but immunodominance limited the response to some of the peptides when they were given in combination Peter *et al.* [2001]. IL-12 can counteract immunodominance in BALB/c mice, so it was given with the multiple epitope vaccination, and was instead found to specifically eliminate the HLA-A2.1-epitope CTL responses, but not Kb CTL responses. This was possibly a consequence of transient depletion of T-cells, B cells and macrophages in the spleen.

**References** Schönbach *et al.* 2002

- Computational methods (artificial neural networks [ANN], hidden Markov models [HMM], binding matrices based on HLA association rates BIMAS) were used to identify HLA-A\*0201 and HLA-B\*3501 HIV T-cell epitope candidates from 533 Gag, Env and Pol sequences of which 374 were derived from HIV-1, 97 were derived from HIV-2 and 62 from SIV. Comparisons to known epitopes and between clades were made.
- The SLYNTVATL epitope received focused discussion. SLYNTVATL, sIFntvatl, slyntvaVI, and slyntIaVI are all recognized variants, ANN predicts all four variants would be recognized, while BIMAS only predicts SLYNTVATL and sIFntvatl would be recognized. However, Sewell *et al.* [1997] suggested certain substitutions may be antagonistic, including sIFntvatl, and vaccines do not stimulate SLYNTVATL responses as well as natural infections. The authors note these kinds of issues complicate the application of computational predictions of epitopes to vaccine design.

**References** Imami *et al.* 2002b

- 70 patients with chronic disease progression, 10 clinical non-progressors, and 3 immunologically discordant progressors (individuals who controlled viremia but had progressive CD4+ T-cell decline) were analyzed for their T-helper cell responses to p24 and cytokine profile. Long term non-progressors had much stronger Th responses, particularly to p24 peptides, and they tended to be balanced between Th1, IL-2 producing and Th2, IL-4 producing responses.
- One of the immunologically discordant progressors became symptomatic during the course of the study, and he had a rapid drop in proliferative response to all antigens and also a shift from a Th1 to a Th2 response. To find out if the CD8 response also shifted in cytokine production, the CD8+ T-cell response to SLYNTVATL in this patient was also tested. It too was found to shift, from IFN $\gamma$  to IL-4 producing in Eli-spot, and using a bioassay of indicator lines, from IL-2 to IL-4 production.

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- Only 1/10 HLA A\*02 carrying individuals in this study recognized SLYNTVATL.
- All HIV-1 proteins except Vpu were recognized, and responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**HXB2 Location** p17 (77-85)**Author Location****Epitope** SLYNTVATL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0201)**Assay type** Cytokine production, proliferation, Tetramer binding, Intracellular cytokine staining, Chromium-release assay**References** Dagarag *et al.* 2003

- Telomere length is short in the CD8+ T-cell compartment of HIV-1 infected people, indicating excessive CTL activation and premature senescence. Here human telomerase RT (hTERT) transduction of HIV-1-specific CTL was used to study the functional impact of telomerase. Telomerase expression enhanced proliferative capacity, as well as cytolytic and antiviral capabilities; cytokine production was unchanged. hTERT transduced CTLs were 10-fold more efficient in controlling HIV-1 replication in culture. Thus telomerase transduction can restore CTL mediated cytolysis, and may have therapeutic potential.
- Three polyclonal CD8+ T-cell lines derived from an HIV-1, HLA A\*0201 positive patient were used in this study, including one specific for this epitope.

- Alanine substitutions of VIYQYMDDL were tested for importance of each amino acid for HLA-A2.1 binding. Peptide variant (vLyqymddV) showed an 8 fold higher MHC binding affinity than wild type. YLyqymddV had an even higher binding affinity, but the Y at position one blocked TCR recognition. The higher affinity form of vLyqymddV induced CTL *in vivo* that could protect against a vaccinia virus expressing RT and the wild type epitope.
- SLYNTVATL was included as a control.

**HXB2 Location** p17 (77-85)**Author Location** Gag (77-85)**Epitope** SLYNTVATL**Epitope name** SL9**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0201)**Assay type** Tetramer binding**Keywords** genital and mucosal immunity**References** Shacklett *et al.* 2003

- Lymphocytes from rectal biopsies were used to characterize the CD8+ T cell response to HIV in GALT, Gut-associated lymphoid tissues. Patients were selected on the basis of being HLA-A2+ and having detectable SLYNTVATL and ILKEPVHGV tetramer responses in PBMC. SLYNTVATL frequency was increased in GALT relative to PBMC in 6/7 patients studied, while a control response to a CMV-peptide was diminished in GALT. Only two patients had ILKEPVHGV CD8+ T cell responses, and both had slightly higher frequencies in GALT than PBMC.
- HIV may perturb lymphocyte retention in GALT, suggested by an overall reduction of GALT CD8+ cells expressing alphaEbeta7. GALT HIV-specific CD8+ T cells expressed alphaEbeta7, suggesting mucosal priming.

- Epitope escape mutations in chronically infected individuals developed over several years indicating selective advantage of escape mutants. The maturation state of CTLs appear to affect the rate of epitope mutation and CTL decay.
- In two patients, SL9-specific CTL peaked at 2-4 years post-infection; at that point the escape mutations began to dominate followed by CTL decline with a 6 month lag, suggesting CTL decline resulted as a consequence of escape. In a third patient, the initial response was 1/2 as strong and mutations did not

arise until 6-7 years post-infection; in that case the decline in SL9 CTL preceded epitope mutation.

- Two patients HLA-A\*0201 started out with a non-consensus sequence, sIFntvatl. In one of the patients, a transient reversion to the consensus was observed after 4 years, that did not reappear until the 11th year, suggesting the possibility that a reversion to the consensus form occurred, but a CTL response may have limited it so that this more fit form could not reassert itself until the patient had a more severely compromised immune response.

- SL9-specific CTLs were shown to be primed by immature DCs and independent of help from CD4+ or exogenous IL2, and sensitive to paracrine IL-2 induced apoptosis. The authors suggest that the reason SL9 responses are not seen during acute infection is the high level of innate immune responses resulting in cytokine-induced apoptosis, but that these CD8+ T-cells would come to dominate later infection when CD4 help is diminished.

- This paper is a review of the role of CTL in HIV infection, and it uses SL9 as an example of an epitope that is not responded to early in infection, yet 75% of HIV+ people respond to SL9 during chronic infection. Despite the delay in response, strong SL9 responses have been associated with lower viral loads, and escape mutations arise.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- Patients with acute or early infection were shown to preferentially target variable peptides with higher entropy while those with chronic infection showed responses towards more conserved peptides with lower entropy. In longitudinally followed subjects, responses to variable proteins declined over time while responses to conserved proteins increased. The decline is suggested to be due to CTL escape.
- The response to this peptide was not apparent until month 20, by month 32 a T to V change was dominant, but the slyntiV1 mutant showed comparable avidity.

**References** Boggiano *et al.* 2005

- A combinatorial library was used to identify epitope mimics of HLA-A2 restricted CTL epitope SL9.
- 19 HIV+ HLA-A\*0201 subjects were tested for their ability to bind to peptide variants. 11/19 could bind to SLYNTVATL. Nine epitope mimics were recognized by more than a third of the subjects, and 1 subject recognized 17/20 variants tested. Some SL9 mimics were up to an order of magnitude better at stimulating CTL responses in PBMC than was SL9.

- Compared to the original SL9 sequence, some SL9 variants recognized by HLA-A\*0201 patients induced superior SL9 immune responses in HLA-A\*0201 transgenic mice.

- A novel technique for subtractive analysis of HIV-1 specific CTLs was developed, including depletion of peptide-specific CTLs by stimulating PBMCs with the specific peptide in the presence of 5-FU, followed by TCR spectratyping for clonal breadth analysis. In analysis of infected individuals using this technique, it was found that HIV-1 specific responses range from two to 10 different T-cell clones per epitope.
- The SL9 responses in one individual were complex, with TCR in multiple families, including: Vbeta12.2, Vbeta17, Vbeta23.3 and Vbeta22.
- This paper provides further evidence for the polyclonal nature of epitope-specific responses. Polyclonal responses may be able to better inhibit escape and may play a beneficial role in progression.

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.

- The best estimate of escape rate for this epitope, SLYNTVATL, was found to be 0.006/day (upper bound on rate of escape = 0.008), with SE of 0.001.
- Four variants were shown to confer escape (Y79F, Y79F-V82I, Y79F-T84V, V82I-T84V), and variant A83V was also present but untested for CTL response.

**References** Laugel *et al.* 2007a

- It was found that CD8 co-receptor differentially fine tunes CTL function via cytokine/chemokine production (MCP-1, MIP1-beta, MIP1-alpha, TNF-alpha, RANTES, IFN-gamma, IL-2 and IL-4). Differential CD8 action was controlled by abrogating its engagement using point-mutated HLA Class I molecules in 4 CTL clones specific for 3 different epitopes from HIV-1 and hTERT.
- 2 HLA-A\*0201 restricted CTL clones, SLY-10 and 003, specific for HIV-1 Gag epitope SLYNTVATL were stimulated with cognate antigen and found to have different diversities as well as hierarchies of cyto/chemokine production. Epitope variants 3H (SLHNTVATL), 3S (SLSNTVATL) and 3F (SLFNTVATL) also selectively blocked effector functions for each clone. CD8 co-receptor requirement was minimally affected for the index ligand SLYNTVATL recognition by CTL, but weaker agonists viz. the epitope variants depended more on co-receptor binding. However, MIP1-beta and IL-2 were consistently the least- and most-CD8 dependent effector secretions.
- This is the first documentation of secretion of MCP-1 by T cells. It seems to require high antigen and co-receptor dependency for release.

- The evolution of SLYNTVATL epitope was analyzed over 10 to 20 years in 76 patients and it was found that two opposing selective forces act on the epitope in HLA-A2+ patients. One is caused by an effective CTL pressure, resulting in escape. The main escape mutations were in positions 3, 6 and 8 of the epitope. The other force is selection for optimal viral growth, where the wild-type epitope's index amino acids are selected for. These common evolutionary pathways for the epitope were conserved across several HIV subtypes; while the balance between the opposing evolutionary pathways is suggested to determine variants in a patient at any given time. Fitness cost to SL9 variant generation leading to CTL escape also contributes to lower viral loads in such patients.
- Most variation in this epitope affects TCR recognition as shown by binding studies. Heterogenous CTL responses in patients to viral epitope variants also suggest that the advantage of any single mutation in SL9 is host (and HLA) dependent.
- CTL selection can differ between compartments as seen in compartmentalization of epitope variants between blood and cervix samples.

- Standard assays like ELISpot, ICS and tetramer staining do not measure antiviral activity of HIV-infected CTLs, but use exogenous synthetic peptides on uninfected cells or HLA tetramers. Similarly, functional avidity assesses CTL activity against uninfected target cells. Here functional avidity is compared to the efficiency of actual infected cells' recognition and killing, revealing a sharp threshold between CTL immune antiviral activity and lack of infected cell recognition.
- As previously shown, epitopes and their variants spanned orders of magnitude of SD50. Likewise, CTL clearance of infected cells varied from 0 to 100% with epitope sequence variation. Moreover, direct suppression of HIV-1 replication by CTLs also varied with epitope variant.
- When killing efficiency (KE) using virus-infected cells was compared to functional avidity using synthetic peptides, there was a narrow threshold separating maximal killing from almost none. Since different SL9-specific clones had similar KEs, which were vastly different from RL10-specific CTL KEs, it was obvious that KEs varied with epitope sequence too. Finally, a strong correlation between KE and inhibition of viral replication was also seen.
- This epitope, SLYNTVATL, showed marked differences in its functional avidity, killing efficiency, as well as inhibition of viral replication when compared to its variants SLFNTVATL, SLfNTiATL, SLYNTiAvL, SLYNTiATL, SLYNaVATL and SLYNIVAvL.

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert *et al.* J. Exp. Med. 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.
- This epitope, SL9, showed discordant epitope evolution between the twins, and both alpha and beta TCR chains recruited were entirely different between them.

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative

**Species (MHC)** human (A2)

**Keywords** subtype comparisons, HIV exposed persistently seronegative (HEPS), immunodominance

**References** Kaul *et al.* 2001a

- Variants SL(F/Y)NTVATL are A/B clade specific.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A2 women, 1/10 HEPS and 22/26 HIV-1 infected women recognized this epitope, likelihood ratio 18.3, *p* value < 0.003, and ILK(D/E)PVHGV tended to be more reactive in HEPS women, SL(F/Y)NTVATL in infected women.
- The dominant response to this HLA allele was to this epitope in the 1/10 HEPS case and in 18 of the 22/26 HIV-1 infected women that responded.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Subject ML 1250 had an A2 response to ILK(D/E)PVHGV prior to seroconversion, which switched to SL(F/Y)NTVATL post-seroconversion.
- Subjects ML 1575 and ML 1592 had no response to SL(F/Y)NTVATL prior to seroconversion, but made responses post-seroconversion.
- Subject ML 1760 had an A2 response to ILK(D/E)PVHGV prior to seroconversion, and gained responses to epitopes A2 SL(F/Y)NTVATL and B27 KRWII(L/M)GLNK post-seroconversion.

**References** Cohen *et al.* 2002

- The antigen presentation of two A2-restricted epitopes was compared, SLYNTVATL (p17) and ILKEPVHGV (RT). HIV-1 infected cells were more sensitive to lysis by SLYNTVATL-specific CTL than by ILKEPVHGV-specific CTL, because of a higher density of SLYNTVATL-A2 resulting from differences in processing.
- Incubation with a T1-cell proteolytic extract showed that by four hours, 25% of a p17 peptide had a C-term Leu-85 and were SLYNTVATL-precursors, while ILKEPVHGV-precursors were far less frequent (6.8%) even with four times more proteolytic extract after 30 hours.
- p17 was preferentially cleaved between Leu85 and Tyr86, while appropriate Val484 and Tyr485 cleavage was minor for RT.
- In a competition experiment, RSLYNTVATL bound TAP 3.7-fold more efficiently than RT peptides.
- No difference in CTL avidity was detected in six patients with HLA-A2-restricted responses to these epitopes.
- No significant difference in HLA-A2 binding to p17 or RT epitopes was observed.

**HXB2 Location** p17 (77–85)

- Transgenic mice expressing a HLA-A2/Kb chimeric protein were vaccinated with either a p17-p24-p51 fusion protein (vG/P-92) or the Gag-Pol precursor protein (vVK1).
- Compared to vVK1, vG/P-92 induced a significant increase in Gag and Pol induced IFN $\gamma$  production and CTL responses, and to the epitopes SLYNTVATL and ILKEPVHGV, as determined by Elispot and 51Cr-release assays.

**HXB2 Location** p17 (77–85)**Author Location** Gag (77–85)**Epitope** SLYNTVATL**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Donor MHC** A2, A3, B7, Bw6**Keywords** HAART, ART**References** Appay *et al.* 2002

- Four HIV patients with prolonged clinically successful antiviral therapy but with ongoing evidence of replication and Nef mRNA transcription, showed specific T-cell responses by Elispot and Tetramer staining, maintained for 2–4 years after initiation of HAART.
- Nef epitope recognition was detected in all 4 subjects, gp120, Pol and Gag-specific in 1 or 2 subjects.
- The HIV-specific CD8+ T-cells had an intermediate maturation phenotype characterized by low levels of perforin and high levels of CD27 expression.

**HXB2 Location** p17 (77–85)**Author Location** p17 (77–85 NL-43)**Epitope** SLYNTVATL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Keywords** class I down-regulation by Nef, escape**References** Ali *et al.* 2003

- NL43 was passaged in the presence of Nef KEKGGLEGL-specific CTL clones STD11 and KM3, giving rise to rapid selection of escape mutations, including E93G, E93K, K94N+G99R, G95R+G99R, E98K, E98D, G99R, G99E, L100P, and L100I; insertions, deletions, frameshifts and an early stop codon. 34/36 (94%) of sequences carried mutations in the epitope by seven days, 36/36 (100%) by 14 days.
- Several mutations selected by KEKGGLEGL-specific CTL were shown to impair the down regulation of class I MHC by Nef, in particular E93G, E93K, and a truncation mutation at position 51.
- Nef deletion mutants increased 100-fold NL-43 susceptibility to inhibition by CTL specific for epitopes in other proteins, the A2 epitopes ILKEPVHGV in RT and SLYNTVATL in p17 Gag.

**HXB2 Location** p17 (77–85)**Author Location** Gag**Epitope** SLYNTVATL**Epitope name** SL9**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Assay type** Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** class I down-regulation by Nef**References** Bobbitt *et al.* 2003

- Nef, through Nef-mediated MHC-1 down-regulation, is not the only viral protein to influence levels of HIV-specific CTL recognition. The Rev L60F mutation, a common natural variant, can decrease CTL recognition of late gene products. The Rev mutation impacts the early to late gene switch, reducing late gene product production (Gag, Pol, Env, Vpu, Vpr and Vif), while increasing Nef production, both of which reduce the impact CTL recognition of late gene products. As expected, Rev L60F rendered HIV infected cells more resistant to CTL that recognized epitopes from the late proteins Env and Gag. Gag expression is reduced more than Env, and Gag-specific CTL were more profoundly affected. Conversely CTL against an epitope in an early gene product, Tat, were more efficiently recognized when infected with viruses carrying the Rev L60F mutation.
- Patients in the asymptomatic phase with active immune responses had more CTL resistant viruses, with lower Rev activity, lower Gag expression and greater resistance to Gag-specific CTL killing, while viruses isolated from people with AIDS were more sensitive to CTL killing.

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A\*0204, immunogenicity in HLA-A\*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This epitope was one of the previously identified HLA-A2 epitopes studied.
- 10/17 HIV-infected HLA-A2+ people in this study recognized this epitope, and CTL and CD8+ T cells responses were elicited by immunization of transgenic mice with this peptide.

**References** Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

**Keywords** responses in children

**References** Sandberg *et al.* 2003

- 65 vertically HIV-1 infected children, ages 1–16, the majority undergoing ART, were analyzed in regard to their plasma viremia and CD4+ and CD8+ T-cell counts, and CD8+ T-cell responses.
- Using vaccinia expressed Gag, Pol, Env, Rev, Nef in target cells in an Elispot assay, 85% of the children recognized at least one HIV antigen. Strong CD8+ T-cell responses were directed against Pol, followed by Gag and Nef. Children younger than 4 had significantly weaker responses (7/14 had no response) than older children (only 1/32 had no response, and responses were greater in magnitude).

- SLYNTVATL and ILKEPVHGV tetramers were used to quantitate specific responses. 49 children in an expanded cohort carried HLA-A2. 1/11 children under 3 years of age had detectable CD8+ T-cell responses to SLYNTVATL, 2/11 to ILKEPVHGV. Among children over 3, 11/38 recognized SLYNTVATL and 9/38 recognized ILKEPVHGV.
- Older children that maintained a CD4 count greater than 400 cells/ $\mu$ l tended to have stronger CTL responses.

**Keywords** assay standardization/improvement, memory cells

**References** Sun *et al.* 2003

- This study compares assay methods for testing CTL responses using samples from 20 HIV+ patients. The study compares ELISpot, tetramer-binding, and intracellular IFN- $\gamma$ . Tetramer-binding analysis was performed with Gag (SLYNTVATL) or Pol (ILKEPVHGV) tetramers. Antigen presentation using recombinant vaccinia viruses (rVVs) encoding HIV-LAI Gag, Pol, Env, Nef, Tat and Vif proteins was compared to peptide panels. HIV antigen recognition in memory CTLs was measured by chromium release assay and compared to effector/memory CD8+ T-cells in an IFN- $\gamma$  ELISpot assay.
- Results: IFN- $\gamma$  Elispot and flow cytometry gave similar frequencies of HIV specific CD8+ T-cells. Tetramer-binding analysis was most sensitive. Pools of peptides and the sum of frequencies of individual peptides were comparable. Elispot assays using peptides were more sensitive than assays using vaccinia expressed proteins. Cr release and Elispot against rVVs gave comparable memory cell responses 2/3s of the time.
- 3/7 HLA-A2+ patients recognized this epitope.

**HXB2 Location** p17 (77–85)

**Epitope** SLYNTVATL

**Epitope name** SL9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2)

**Assay type** Chromium-release assay, CTL suppression of replication

**Keywords** escape, TCR usage

**References** Yang *et al.* 2003a

- Virus was cultured in the presence of CTL lines specific for 5 different epitopes (SLYNTVATL, ILKEPVHGV, IEIKDTKEAL, SEGATPQDL, and KEKGGLEGL) to study the emergence of escape mutations. Escape varied between clones for the same epitope, and between different epitopes. Gag and RT epitope escape, if it occurred at all, tended to

be monoclonal and within the epitope, indicating strong fitness constraints, while the Nef epitope escape was rapid, polyclonal, and sometimes the result of upstream frameshifts.

- Three CTL clones were studied that recognized SLYNTVATL, 161JxA14, 18030D23, and 115DEC4. The different TCR usage on the CTL clones resulted in different patterns of recognition and escape. 161JxA14 suppressed the variant sIFntvatl, 18030D23 did not; conversely the variants sIFntIaV1 and sIFntIatI were suppressed by 18030D23, but not 161JxA14.
- After two weeks of passage the predominant escape mutant from 161JxA14 was slyntIatI. Amino acid residues flanking SL9 were unchanged. Escape mutations did not occur within two weeks for the two additional SL9-specific CTL clones 18030D23 and 115DEC4.

**Keywords** variant cross-recognition or cross-neutralization

**References** Draenert *et al.* 2004c

- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2–39) epitopic regions were targeted in an average of 6 proteins (range, 1–8). HAART resulted in decrease in antigen and reduction in gamma IFN EliSpot responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that persistent CTL through late disease do not exert strong immune selection pressure, yet the Elispot assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.

- 3 subjects recognized this epitope with high functional avidity. Relative to consensus, 2 individuals that had the SLYNTVATL epitope carried a R -> K mutation proximal to but outside the epitope; possible processing implications were not studied here.

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 3/14 CTL T-cell clones tested were specific for Gag/p17-SL9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 range for Gag/p17-SL9 was 1,000 - 20,000 pg/ml.

**References** Lichterfeld *et al.* 2004a

- HIV-1 specific CD8+ T-cells in acute and long-term nonprogressive HIV-1 infection show strong ex-vivo proliferative capacities which are rapidly lost in chronic HIV-1 infection. The loss of CD8+ T-cell function is closely linked with the loss of HIV-1 specific, IL2 secreting CD4+ T-cells. The function can be rescued in vitro and in vivo by restoring the specific CD4+ T-cell help.
- Despite being detectable at high frequencies, CD8+ T-cells specific for SL9 epitope were shown to entirely lose their proliferative capacity in chronic HIV-1 infection. This activity

could be restored by co-stimulation with CD4+ T cells isolated from acute infection in an IL-2 dependent manner.

- CD8+ T cells from HIV-2 infected patients had more polyclonal TCR responses than HIV-1 infected patients, who tended to have oligoclonal responses. This results in limited plasticity of T cell responses to amino acid substitutions within epitopes in HIV-1 infections. HIV-2-specific CD8+ T-cells showed a more diverse TCR usage associated with enhanced CD8 expansion and IFN-gamma production on cross-recognition of variant epitopes.
- Responses to this epitope were characterized in detail. One patient's response to SL9 A2-SLYNTVATL tetramers was shown to have only Vbeta5.1 clonotypes. The naturally-occurring HIV-2 variant: sIFntvCVI, was not recognized well by this response or by the SLYNTVATL reactive CD8+ T cells in four additional A2+ HIV infected asymptomatic individuals. The subtype A variant, sIFntvatl was also poorly recognized, and 4/5 Ala substitutions abrogated responses. All variants bound to HLA-A2 with higher affinity than the index peptide except slyntAatl, which was slightly reduced, so the lack of cross-reactivity must have been due to the TCR.

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0–80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.

- This epitope was one of six epitopes found to be under positive selection for escape mutations and was completely replaced by escape variants between days 327 and 635 (sLYntvatl and sLYnAvatl).

**HXB2 Location** p17 (77–85)**Author Location** Gag**Epitope** SLYNTVATL**Epitope name** SL9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- Two escape mutations, at positions 3 and 8, sIFntvatl and slyntvaVI, were found in the most polymorphic residues in the epitope. These were shared between clades B and C. One escape mutation, at position 6, slyntlatl, was found not to correspond to the most polymorphic residue in the epitope.

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
- This was 1 of 4 A2 gag/pol epitopes tested. Transgenic mice immunized with the deleted construct induced more potent EliSpot reactions to this epitope than those immunized with full length Gag/Pol.

- CD8+ T-cells from HIV-1 CRF02\_AG-infected Ivorians could recognize clade B epitopes. No difference was observed in the number of recognized peptide pools between nine French subtype B infected study subjects, and nine CRF02\_AG infected Ivorian subjects.
- This epitope was recognized by 3/9 CRF02\_AG-infected patients, and by 2/9 B-infected patients.

**HXB2 Location** p17 (77–85)**Author Location** Gag**Epitope** SLYNTVATL**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Country** Netherlands**Assay type** Tetramer binding, Flow cytometric T-cell cytokine assay**Keywords** binding affinity, rate of progression, escape, characterizing CD8+ T cells**References** Jansen *et al.* 2005

- HLA-B57 has been associated with long term non-progression in HIV+ people. The number and responsiveness of CD8 T-cells directed to different Gag peptides presented by HLA-A2, -B8 and B57 were compared. T cells specific for the HLA-B57 epitope KAFSPEVIPMF responded to a higher extent and more readily to antigenic stimulation than those specific for the A2 epitope SLYNTVATL and the B8 epitope EIYKRWII.
- In 3/4 A2 subjects that were sequenced, epitope variants dominated: 2 subjects carried sIFntvatl, and the other slyntlatl.
- Tetramer decay experiments indicate that the HLA-B57 peptide has a higher half-life than the A2 and B8 peptides. The authors point out that CD8+ T cells with high binding affinity may require less help.

**HXB2 Location** p17 (77–85)**Author Location** Gag (77–85)**Epitope** SLYNTVATL**Epitope name** SL9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Donor MHC** A\*02, A\*68, B\*14, B\*52, Cw\*08, Cw\*12**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** escape, optimal epitope**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- Elispot responses to the consensus form of this epitope, SLYNTVATL, were much more intense than to the most common variants of the epitope found over time in this individual, SLfNTiATL and SLfNTVAvL; these may be escape variants. The strong response to the consensus form persisted, despite the fact it was not observed among the autologous sequences during 6 years of chronic infection.

- CD8 T-cell responses were studied in individuals who remained seronegative in spite of being mucosally (group 1) or intravenously (group 2) exposed to HIV-1. A similar proportion of subjects from each group recognized at least 1 HIV peptide, and they recognized peptides with similar cumulative intensity. The proportion of responding individuals in both groups was significantly greater than in a low-risk, negative control group. One exposed uninfected subject recognized 7 epitopes.
- HLA-A\*0201 epitopes that are immunodominant in chronically infected individuals were rarely stimulatory in exposed uninfected individuals. SLYNTVATL was recognized by one HLA A2+ individual in each group (1/11 vs 1/5), while none of the exposed uninfected individuals tested responded to ILKEPVHGV. In contrast, chronically infected subjects recognized these epitopes at a frequency of 69% and 31%, respectively.

- CTL responses to 3 HLA-A2-restricted epitopes were investigated in 51 HIV-1 infected HLA-A2+ individuals. The most prevalent response was seen for IV9, followed by SL9. The VL9 epitope was not recognized. There was a significant correlation of CTL activity to the CD8 counts in peripheral blood, but no correlation to CD4 counts, viral load, or antiviral therapy.
- SL9 was only recognized in 13.7% of the individuals tested.

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** p17 (77–85)  
**Author Location** p17 (77–85)  
**Epitope** SLYNTVATL  
**Epitope name** SL9  
**Subtype** B  
**Immunogen** peptide-HLA interaction

**Assay type** Chromium-release assay, HLA binding  
**Keywords** escape, TCR usage, structure, optimal epitope  
**References** Martinez-Hackert *et al.* 2006

- Several natural SL9 variants were shown to bind comparably well to soluble HLA-A2 and D3 TCR. All variants had remarkably similar peptide conformations as evidenced by high resolution crystal structures of soluble interacting proteins. These structures were shown to differ from other peptide-MHC-TCR structures. SL9 variation was shown to be partially restricted by its context in the HIV p17 matrix protein, and the preservation of peptide conformation despite epitope variation may contribute to the persistence of SL9-mediated immune responses.

- 11 Natural variants of SLYNTVATL were tested. They were SLYNTiATL (SL9-6I), SLYNTiAvL (SL9-6I/8V), SLYNTVAvL (SL9-8V), SLfNTVATL (SL9-3F), SLfNTiAvL (SL9-3F/6I/8V), SLfNTiATL (SL9-3F/6I), SLfNTVAvL (SL9-3F/8V), SLYNaVATL (SL9-5A), SLYNsVATL (SL9-5S), SLYNaiATL (SL9-5A/6I), SLYNIVAvL (SL9-5L/8V). Only variants at P5 where Threonine is substituted by Alanine or Leucine abrogated activity, while all others variants were active. No natural variants had substitutions at P4, while P1, P2 and P9 were also conserved. 9 synthetic variants were also tested.
- This degenerate recognition of the HIV Gag epitope by CTL is different from other viral peptide-degeneracies in that several CTL clones can perform equally well in recognition of the SL9 pMHC, and there is not necessarily one dominant recognition.

**References** Kan-Mitchell *et al.* 2006

- A synthetic combinatorial nonapeptide library was screened with ex-vivo-primed SL9-specific T-cells and an agonist variant of the SL9, p41 SLYNTVAA<sub>L</sub>, was identified. p41 immunized SL9-cross-reactive CTLs from donors ex vivo and double knockout mice expressing a chimeric HLA I molecule. p41-primed CTLs were also found to require less costimulation from APCs and (unlike SL9-CTLs, they required exogenous IL-2 to proliferate, suggesting they would have better immune memory) less need for exogenous IL-2 to proliferate. The loss of SL9 T-cells was minimized with p41, and the TCR clonotype was shown to be able to develop into either help-dependent or help-independent CTLs.

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish

even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

- Since it is suggested that a single response to B27-KK10 epitope may be responsible for the association of HLA-B\*2705 patients with AIDS-free survival, B27-KK10-specific CTLs were compared to other HLA-specific CTLs in phenotype, function, clonal diversity, and antigen sensitivity in 47 treatment-naive infected slow or nonprogressing patients.
- cVL, the cell-associated viral load (number of infected cells harboring HIV DNA) correlated inversely with Gag-specific CTLs. This was most significant in HLA-B27 donors, and KK10 was identified as the peptide generating strongest CTL responses.
- B27-KK10-specific CTLs had no significant phenotypic differences from other epitope-specific CTLs upon testing a large panel of markers; however, they released higher proportions of IFN-gamma, TNF-alpha, MIP-1beta and CD107a upon antigenic stimulation.
- Both B27-KK10-specific and other HLA-specific CTLs had strikingly consistent domination of single clonotypes, as shown by analyses of TCRB gene expression. B27-KK10-specific CTLs showed no preferential usage of CDR3 motifs, indicating that they could be recognized by diverse clonotypes with differing binding properties. Over several years, B27-KK10-specific CTLs changed their dominant clonotype as compared to other CTLs. This temporal dominant clonal turnover was attributed to a decline in replicative capacity of the dominant clonotype as seen by increases in CD57 expression, which is linked to replicative senescence.
- Studies involving functional avidity and different HLA-restricted responses proved that B27-KK10 responses had highest avidity. An inverse correlation between patient cVL and functional avidity of both dominant and highest subdominant responses suggested that functional avidity correlates with capacity to control HIV replication via infected cell elimination.
- Using the example seen in one patient, the authors stress the importance of maintaining protective stimulating activity of CTLs. When control by dominant clonotypes is lost, as in viral escape, ensuing viral replication is rapid.
- SLYNTVATL, was a dominant epitope found in non-B27-KK10 CTL responses.

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.
- SLYNTVAVL was recognized by 61% HLA-A2-positive individuals.

**References** Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, SLYNTVATL (SL9), is restricted by HLA-A02. A variant that arose was SLYNTVAvL.

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated

impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

- Seven HIV-positive subjects tended to make their strongest CD8+ T-cell response against Gag; these responses had varying breadth and magnitude that were unrelated to disease progression.
- Patient TX7 primarily recognized SL9 during a three year study period and used six T-cell clonotypes for this recognition.
- SLYNTVATL was the only form of the epitope found initially, but three alternate forms eventually appeared: SLYNTVAVL, SLYNTIATL, and most commonly SLYNTI AVL. These distinct forms bind A2, but have distinct abilities to stimulate different T-cell clonotypes.
- In subject TX7, the observed mutations of SL9 failed to escape overall CTL recognition, presumably because the six T-cell clonotypes allowed a more flexible response.
- The BV17 T-cell clone recognized SL9 but not SLYNTI AVL, and BV17 became undetectable at week 20 when SLYNTI AVL predominated. Subsequently BV17 became the second most common clone. Thus the relative frequency of the T-cell clonotypes varied with respect to each other and to epitope variation.

**Keywords** binding affinity, co-receptor

**References** Laugel *et al.* 2007b

- To interrogate why epitope variant-related T-cell activations differ in degree of CD8 coreceptor dependence, the authors set up a system to examine pMHC/CD8 interactions upon binding of antigenic ligands by CTLs. 2 previous hypotheses to explain coreceptor dependence are those of Holler and Kranz suggesting it is inversely correlated to TCR/pMHC affinity, or it is related to the geometry of TCR engagement. The former hypothesis was supported, since the CD8 coreceptor may optimize T-cell polyspecificity by improving low to intermediate binding affinities of pMHC for TCR.
- Most studies were performed using clones specific for an hTERT or HTLV-1 peptide. SLYNTVATL was used with clones 003 and SLY-10, both derived from HIV-infected donors, to show that binding to pMHC tetramers was greater in the presence of WT rather than null CD8 coreceptors.

**Keywords** vaccine-induced epitopes

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was contained in the vaccine, the vaccinated patient recognized it both before and after infection.
- PBMCs from reacting individual failed to bind the HLA-A2/SLYNTVATL tetramer. The optimal epitope turned to be newly defined LYNTVATL, restricted by HLA-C14, not previously shown to restrict HIV-1 epitopes, and T cells recognizing LYNTVATL were of high avidity.

**Country** Barbados, Haiti, United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, SLYNTVATLYCVHQRIEV, had an overall frequency of recognition of 25.3% - 30.5% AA, 26.9% C, 22.7% H, 9.5% WI. This peptide is included in a 34 aa Gag-p17 highly reactive region to be used for vaccine design.

**Immunogen** HIV-1 infection

**Species (MHC)** human (A24)

**Donor MHC** A23, A24, B35, B58, Cw4, Cw7

**Country** Democratic Republic of the Congo

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, computational epitope prediction

**References** Geels *et al.* 2005

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- Predicted epitope based on a patient with an HLA motif embedded in a reactive peptide from a person carrying a D clade Gag.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Flow cytometric T-cell cytokine assay

**Keywords** vaccine-induced epitopes

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was contained in the vaccine, the vaccinated patient recognized it both before and after infection.
- This epitope was contained in SLYNTVATL epitope, but PBMCs from reacting individual failed to bind the HLA-A2/SLYNTVATL tetramer. The optimal epitope turned to be newly defined LYNTVATL, restricted by HLA-C14, not previously shown to restrict HIV-1 epitopes, and T cells recognizing LYNTVATL were of high avidity.

**Keywords** HLA associated polymorphism

**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- All HIV-1 subtype C protein sequences were analysed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. **Assay type** CD8 T-cell Elispot - IFN $\gamma$ , CD4 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Chromium-release assay

**Keywords** subtype comparisons, epitope processing, immunodominance, cross-presentation by different HLA

**References** Masemola *et al.* 2004b

- Highly targeted regions in Gag for CD8+ T-cells were defined for individuals with C clade infections in South Africa. 9 specific epitopes within the most reactive regions were characterized. This is 1 of 5 novel epitopes that were found among subtype C HIV-1 from African patients who hadn't previously been identified in B clade infections. Some epitopes were shown to be promiscuous, presented by multiple class I restricting alleles.
- LYNTVATLY was presented by A\*2902 and B\*4403. B\*44 is more common among Caucasians than Zulus (allele frequency 0.149 versus 0.107), while A\*29 is more common in Zulus (0.045 versus 0.125).

**HXB2 Location** p17 (78–86)

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** characterizing CD8+ T cells

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11)

**Keywords** subtype comparisons

**References** Bond *et al.* 2001

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This epitope was predicted by the EpiMatrix method to be likely to bind to A11, and it served as an epitope in the FSWs, it was one of the six A11 epitopes that had been previously defined.
- 3/8 tested FSWs recognized this epitope.
- This epitope was not conserved in other subtypes, and exact matches were uncommon.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** assay standardization/improvement, optimal epitope

**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This putative epitope, ATLYCVHQR, was detected and confirmed within overlapping peptides TGSEELRSLYNTVATLY and SLYNTVATLYCVHQRIEV.

**HXB2 Location** p17 (83–91)

**Author Location** Gag (Henan isolate)

**Epitope** AVLYCVHQR

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11)

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.

**HXB2 Location** p17 (84–91)

**Author Location** Gag (83–90)

**Epitope** TLYCVHQR

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*1101)

**Keywords** subtype comparisons, TCR usage

**References** Fukada *et al.* 2002

- Counterparts for eight known clade B HLA A\*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A\*1101 epitopes was recognized in a clade specific manner. Two other HLA A\*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- TLYCVHQR was found to elicit clade-specific responses in clade B (TLYCVHQR is most common, and is also common in clade A – the variant tlycvhqK is common in clade B) and clade E (tIWcvhqr is most common). TLYCVHQR was not recognized by any CTL, tlycvhqK was recognized by CTL from 1/5 B clade infected Japanese subjects, and tIWcvhqr was not recognized by CTL from infected Thai subjects, so this seems to be a B clade exclusive epitope.
- The binding of the variant peptides to HLA A\*1101 was comparable, but CTL that recognized tlycvhqK did not cross-recognize the other forms, implicating TCR interaction differences.

**HXB2 Location** p17 (84–91)

**Author Location** p17 (83–91)

**Epitope** TLYCVHQR

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11)

**Keywords** escape

**References** Harrer *et al.* 1998

- Two overlapping epitopes were recognized in a long-term survivor, restricted by two different HLA molecules, HLA-A11(TLYCVHQR) and HLA-A2 (SLYNTVATL)

- Viral sequence substitutions were present in this individual which did not affect viral replication and did not alter CTL-recognition of the A2 epitope, but reduced recognition of the A11 epitope, indicative of immune escape.
- A Q90E substitution resulted in a loss of the ability of the peptide to induce lysis, a R91K substitution was still reactive, and a R91Q substitution showed a reduced ability to stimulate lysis.

**Keywords** dynamics, acute/early infection, characterizing CD8+ T cells

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T-cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

**References** Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, IDIKDTKEAL (IL10) was restricted by HLA-B\*4001.

**References** Altfeld *et al.* 2006
- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
  - The most frequently recognised epitopes also elicited the greatest CTL response.

- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- Virus was cultured in the presence of CTL lines specific for 5 different epitopes (SLYNTVATL, ILKEPVHGV, IEIKDTKEAL, SEGATPQDL, and KEKGGLEGL) to study the emergence of escape mutations. Escape varied between clones for the same epitope, and between different epitopes. Gag and RT epitope escape, if it occurred at all, tended to be monoclonal and within the epitope, indicating strong fitness constraints, while the Nef epitope escape was rapid, polyclonal, and sometimes the result of upstream frameshifts.

- There was one cloned cell line that recognized IEIKDTKEAL, 161JD27. After 2 weeks of passaging HIV-1 in the presence of 161JD27, no mutations were observed within the epitope in 10 sequences; one of the 10 had a single E → K substitution 6 amino acids beyond the C-terminal end of the epitope.

**References** Brainard *et al.* 2004

- HIV-1 gp120 is shown to suppress the ability of antigen-specific CTLs to migrate or remain at sites of high viral replication by concentration-dependent chemotaxis and fugetaxis. Directional T-cell movement is shown to depend on the interaction of the V2 and V3 loops with the CXCR4 receptor. X4 HIV-1 gp120 causes the migration of T-cells, including HIV-1 specific CTL, away from infected target cells, another potential mechanism for immune evasion.

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 1/14 CTL T-cell clones tested were specific for Gag/p17-IL10. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 value for the Gag/p17-IL10 clone was 8,000 pg/ml.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses

detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

- A minor response was detected against an E93D variant of this epitope, dVKDTKEAL. However, CTL responses effectively eliminated cells with this viral variant. Upstream of this epitope, EVKDTKEAL, an R91G mutation was seen that is suggested to affect processing of this EL9 epitope, such that this mutant viral population evaded immune responses restricted by HLAs A\*01, A\*02 and B\*08. Other variants detected were EiKDTKEAL, kVKDTKEAL and EVKDTKgAL.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- There was a weak response to this epitope during acute and early infection, and the epitope sequence did not vary during the first year of the infection.

**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- The second donor in the study shares A\*0101 and B\*0801 with his partner. The epitope EVKDTKEAL has an escape variant in the donor that does not react in an Elispot assay, DvkGtkeal, but the Dvkdtkcal form was the transmitted variant. The transmitted form and EVKDTKEAL bind with equal affinity to B\*0801.
- The recipient mounted a response to the Dvkdtkcal form of the epitope. The variant DvRdtkeal was detected by 32 weeks post infection.

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, AADTGNSSQ, was found to be 0.119/day, with SE of 0.021.
- A number of mutations in this epitope (Gag AQ9) abolished recognition completely. Gag AQ9 overlapped with a second epitope (Gag NP10), and a number of mutations conferring escape from the AQ9 directed response were shown to confer escape from NP10 responses as well. This will lead to an overestimate of the importance of a single CTL response. Escape at NP10 was not quantified separately on the grounds that it was insufficiently independent from escape at AQ9.

- The crystal structure of this epitope bound to HLA-B\*3501 shows that a serine can fit into the B pocket, which is shared between B35 and B53, with the hydroxyl group of the P2 serine occupying a position almost identical to the P2 proline that was previously considered the anchor motif.
- Novel B53 epitopes (DTINEEAAEW and QATQEVKNNM) were defined in this study that showed that A and T can also serve as P2 anchor residues for the B pocket of HLA-B35 and B53 – while S, T, and P could all fit into the B pocket and

form a hydrogen bond, A would not form a bond, so the authors propose compensatory interactions account for the high affinity of QATQEVKNNM for B53.

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWILLGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGIEY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

## II-B-2 Gag p17-p24 CTL/CD8+ epitopes

**HXB2 Location** p17-p24 (119–3)

**Author Location** p17-p24

**Epitope** AADTGNSSQVSQNYPIV

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11, A25)

**Country** Barbados, Haiti, United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved

peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This overlapping peptide, AADTGNSSQVSQNYPIV, was differentially targeted across ethnic groups and had an overall frequency of recognition of 2.7% - 0% AA, 15.4% C, 0% H, 0% WI (P value = 0.001).

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Donor MHC** A\*2902, B\*1402, Cw\*0802

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** dynamics, immunodominance, escape, acute/early infection, characterizing CD8+ T cells, viral fitness and reversion

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified.
- 10 variants in the NSSQVSQNY epitope were found in the patient BORI, the first appearing at day 35, NgSQVSQNY, with new variants continuing to arise through day 556. This is an extremely variable epitope, and changed not only by base substitution but by insertion and deletion. All variants tested conferred some degree of escape by diminishing the CTL response.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
  - 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
  - Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
  - This peptide, EKIRLRPGGKKkYrLKHL differs from the consensus C sequence KIRLRPGGKKhYmLKHL at 2 amino acid positions, i.e. by 11.1%.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
  - The most frequently recognised epitopes also elicited the greatest CTL response.
  - HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
  - HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
  - In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.
- HXB2 Location** p17-p24 (127–3)
- Author Location** p17
- Epitope** QVSQNYPIV
- Epitope name** A68-QV9

- Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Flow cytometric T-cell cytokine assay
- Keywords** rate of progression, escape, acute/early infection, antibody generation, co-receptor, immune evasion
- References** Streeck *et al.* 2007b

- A subject with acute and rapid disease progression to AIDS showed no neutralizing antibody activity and rapid decline in HIV-specific CTL response by 6 months post-infection. Virus from this rapid progressor was resistant to neutralization by plasma from a long-term progressor. Viral epitopes did not vary much. This suggests viral immune evasion in the absence of viral sequence variation.
- This epitope, QVSQNYPIV, elicited a sub-dominant CTL response, not detectable after 6 months post-infection. QV9 and its flanking sequences NSSQVSQNYPIVQNL showed one escape mutation in the flanking sequence to sSSQVSQNYPIVQNL by 6 months post-infection.

**HXB2 Location** p17-p24 (129–7)

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining

**Keywords** epitope processing, immune evasion, viral fitness and reversion, HLA associated polymorphism

**References** Honeyborne *et al.* 2007

- To determine whether HLA-B\*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B\*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B\*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.
- Variants of this epitope, VQNLQGQMV, were seen at positions 4, 7 and 9. A closer look at sequences just upstream and downstream of the optimal epitope, QNPVQNLQGQMVHQaiSPRTLNAWVKVEE, show that residues 146 and 147 show most change. In association with HLA-B\*57/5801, the epitope ISPRTLNAW (Gag, 147-155) may vary; whilst the HLA-B\*1510-restricted epitope VHQAIISPRTL (Gag, 143-152) varies at A146P to VHQpISPRTL. Such mutations may be seen  $\geq$  4 residues downstream of the epitope C terminus.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** subtype comparisons, immunodominance

**References** Geldmacher *et al.* 2007a

- To assess whether T-cell specific responses to Gag and Nef are biased towards infecting subtype recombination, 56 ART-naive subjects were studied using six overlapping peptide sets consisting 15-mer peptides, covering both proteins completely. A multi-region hybridization assay was employed. Overall, the best recognized epitope variant in terms of magnitude and breadth corresponded to infecting subtype, in this case usually type-C. Hot spots of CTL recognition in Gag were in p24, p17 and p15; hotspots against Nef were in its central, conserved region.
- Epitope variants GQMVHQaiSP, GQMVHQslSP and GQMVHQalSP were studied as peptide sequences GQMVHQaiSP-RTLNA (subtypes C and D), NLQ-GQMVHQslSP-RT (subtype A) and NAQ-GQMVHQalSP-RT with 16% responders. Frame-of-epitope effects prevented conclusions about such point mutations, but subtype C was best recognized.

**References** Barugahare *et al.* 2005
- T-cell immune responses were examined in HIV-1 infected Ugandans. Similar levels of cross-clade responses for Gag, Env and Nef were observed. Higher frequencies of responses in conserved regions were found for Gag within a single clade, while areas with higher viral sequence variation had fewer detectable responses. Differential interclade sequence homologies between the Gag regions did not affect the respective level of cross-clade recognition.
  - The sequence contains a known B7/B8 epitope, but the subjects recognizing it are B7- and B8-negative. The viral sequences isolated from the subjects were qmThqNlsprtlaw and qmvhqAlsprtlaw, and the peptide was recognized.

**References** Hossain *et al.* 2003
- HLA-A\*3303 is a common HLA allele in east and southeast Asia. Pol, Gag and Nef SF2 proteins were scanned for potential A\*3303 epitopes. 99 potential epitopes were synthesized, and 52/99 bound to A\*3303. Six of these served as peptide-targets for lysis by PBMC from infected individual, and clones derived from 4 of these 6 could lyse HIV-vaccinia infected target cells, indicating proper processing.
  - This epitope is one of the 4 that are properly processed.

**Epitope** MVHQAI SPR  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A3 supertype)  
**Keywords** supertype, rate of progression  
**References** Propato *et al.* 2001
- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
  - Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.

- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind 5/5 HLA-A3 supertype alleles (A\*0301, A\*1101, A\*3101, A\*3301 and A\*6801).

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
  - This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 29% of the study subjects, and it was the third most frequently recognized peptide.

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Amino acid site in the third position potentially experienced positive selection. QAISPRTLNAW CTL escape mutant was found.

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
  - Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 1 allele previously known to be associated (A25) and 5 additional alleles (A23, A68, B44, Cw04, Cw07).

#### References Bailey *et al.* 2007

- In this study the entire HIV-1 genome was analyzed before and after virologic escape for the first time and escape mutations were temporarily associated with an increased viremia in an otherwise B\*57-elite controller of viral load. It is suggested that HLA-B\*57-restricted CTL mutations were the major cause of escape because other multiple drug resistance mutations in Pol and RT (M184V and T215Y) did not result in a marked increase in viral replication capacity in vitro.
- CTLs detecting this Gag epitope, ISPRTLNAW, were detectable and levels remained unchanged over 20 months. Most clones developed an A-P mutation in the position preceding IW9 which is a well-characterized processing escape mutation.

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- There was nearly equivalent IFN- $\gamma$  response to [i/m]SPRTLNAW and to [i/l]SPRTLNAW in several subjects, compared to the wild type.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, IW9 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen with both C- and A-clades. Anchor residues are at positions 2 and 9; while the A-clade variant contains a change at position 1 to ISPRTLNAW.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- One patient showed an I147L mutation in the HLA-B57 restricted epitope ISPRTLNAW, to ISPRTLNAW.

**HXB2 Location** p24 (15–23)**Author Location** p24 (15–23)**Epitope** ISPRTLNAW**Epitope name** IW9**Immunogen** HIV-1 infection**Species (MHC)** human (B\*57)**Country** United Kingdom, Kenya**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** TCR usage, structure, characterizing CD8+ T cells**References** Gillespie *et al.* 2006

- CD8+ T cell repertoire recognizing KAFSPEVIPMF [KF11] and variants and the structure of individual B\*57-peptide complexes were studied.
- In addition, immunodominance of the previously mapped B\*57 epitopes during chronic infection was assessed. KGFN-PEVIPMF and ISPRTLNAW were immunodominant both in frequency and magnitude of recognition.

**HXB2 Location** p24 (15–23)**Author Location** Gag (144–152)**Epitope** ISPRTLNAW**Subtype** A, C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*57, B\*58)**Country** Tanzania**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** subtype comparisons, immunodominance**References** Geldmacher *et al.* 2007a

- To assess whether T-cell specific responses to Gag and Nef are biased towards infecting subtype recombination, 56 ART-naive subjects were studied using six overlapping peptide sets consisting 15-mer peptides, covering both proteins completely. A multi-region hybridization assay was employed. Overall, the best recognized epitope variant in terms of magnitude and breadth corresponded to infecting subtype, in this case usually type-C. Hot spots of CTL recognition in Gag were in p24, p17 and p15; hotspots against Nef were in its central, conserved region.
- Epitope variants iSPRTLNAW and ISPRTLNAW were studied as peptide sequences HQA-iSPRTLNAW-YKV (subtype C), QMVHQS-ISPRTLNAW and QMVHQA-ISPRTLNAW with 20% responders. Frame-of-epitope effects prevented conclusions about such point mutations, but subtypes A and D were best recognized.

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80

tetramers in complex with epitopes to KIR3DS1 transiently expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.

- This epitope, ISPRTLNAW (MHC Class I restriction, serotype Bw4Ile80) complexed with MHC B\*5701 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C.

**HXB2 Location** p24 (15–23)**Author Location** p24 (15–23)**Epitope** ISPRTLNAW**Epitope name** ISP**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5701)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** rate of progression, TCR usage, variant cross-recognition or cross-neutralization, characterizing CD8+ T cells**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B57-ISP, is very strongly associated with delayed progression to AIDS, and its natural variants were less efficiently cross-recognized. Its alanine-substituted variants were poorly cross-recognized.

**References** Pillay *et al.* 2005

- HIV-specific CTLs in infants were shown to be able to select for viral escape variants early in life, despite a lack of escape with the same CTL specificity in the mother. Infant CTL responses may be compromised by transmission of escape variants that arose in the mother and also those that arose in the father, if the father was the source of the mother's infection.
- ISPRTLNAW is the C consensus form of the epitope and was the autologous form in the mother, and was transmitted to her infant. By 33 weeks a new dominant form of the epitope had emerged in the infant, mSPRTLNAW, and two additional variants had arisen, one with a substitution proximal to the epitope, pISPRTLNAW, and ISPRTLNAW.

**HXB2 Location** p24 (15–23)

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate reversion rate for this epitope, ISPRTLNAW, was found to be -0.005/day with a SE of 0.
- An A14P substitution in the flanking region of this B57-restricted epitope prevented correct processing of the epitope and conferred CTL escape. On transfer of this variant to an HLA-B57- individual, the frequency of the escape mutant actually increased giving a negative reversion rate of -0.005/day. This is consistent with in vitro replication and competition assays as well as with the accumulation of this mutation in the population, suggesting that A14P does not carry a fitness cost.

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.
- ISPRTLNAW was recognized more often in children than in adults, and was the most frequently recognized B57 epitope in children. Escape variants of this epitope arose in 2 children: an A->P change proximal to the epitope, pISPRTLNAW, and an I1L change, ISPRTLNAW. In both cases the mother carried AISPRTLNAW.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, SPRTLNAWV, was predicted to be restricted by HLA B\*0702, B\*3501, B\*5102, B\*5103, B\*5301, B\*5401 and B\*5502 as well.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** supertype, cross-presentation by different HLA

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (B07), an additional HLA (B42) was statistically predicted to be associated with this epitope.

**Keywords** rate of progression, acute/early infection

**References** Day *et al.* 2001

- The CTL response to optimally defined CTL epitopes restricted by HLA class I A and B alleles in individuals who coexpressed HLA A2, A3, and B7 was studied in eight HIV-1-infected subjects, two with acute infection, five with chronic, and one long-term non-progressor (LTNP).
- 2 to 17 epitopes were recognized in a given individual, A2-restricted CTL response tended to be narrow and never dominated the response, and 25/27 epitopes were targeted by at least one person.
- Subjects with chronic HIV-1 infection recognized between 2-8 out of 11 B7-restricted epitopes.

- An acute seroconverter homozygous for the B7 allele recognized five B7-restricted epitopes.
- The other acute seroconverter failed to recognize any of the 11 B7-restricted epitopes tested.
- The B7-restricted CTL response was highly variable and there was no clearly dominant epitope.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
- This was 1 of 4 A2 gag/pol epitopes tested. Transgenic mice immunized with the deleted construct induced more potent EliSpot reactions to this epitope than those immunized with full length Gag/Pol.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- There was a weak response to this epitope during acute and early infection, and the epitope sequence did not vary during the first year of the infection.

**References** Kiepiela *et al.* 2004
  - HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
  - This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** subtype comparisons, rate of progression, immunodominance  
**References** Frahm *et al.* 2006
- CTL responses restricted by HLA-B\*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B\*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects inspite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominant CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
  - VKVVEEKAF of clade B is a potential HLA-B\*1503-restricted epitope, with epitope VKViEEKAF found in clade C.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Other  
**Keywords** escape, viral fitness and reversion, drug resistance

**References** Bailey *et al.* 2007

- In this study the entire HIV-1 genome was analyzed before and after virologic escape for the first time and escape mutations were temporarily associated with an increased viremia in an otherwise B\*57-elite controller of viral load. It is suggested that HLA-B\*57-restricted CTL mutations were the major cause of escape because other multiple drug resistance mutations in Pol and RT (M184V and T215Y) did not result in a marked increase in viral replication capacity in vitro.
- CTLs detecting this Gag epitope, ISPRTLNAW, were detectable and levels remained unchanged over 20 months. No mutations developed in the KF11 epitope.

**Keywords** subtype comparisons, escape, viral fitness and reversion, optimal epitope  
**References** Leslie *et al.* 2005
- An escape mutation, A2G (KgFSPEVIPMF), is suggested to be a result of selection pressure from the HLA-B\*57 allele, and can be transmitted and stable in the absence of HLA-B\*57. Evidence indicated that the mechanism of escape was an increased off-rate.
- HXB2 Location** p24 (30–40)  
**Author Location** Gag  
**Epitope** KAFSPEVIPMF  
**Epitope name** KF11  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (B\*57)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** escape  
**References** Bailey *et al.* 2006b
  - Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
  - A163S mutation in this epitope can potentially act as a CTL escape mutation.

**HXB2 Location** p24 (30–40)

**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other  
**Keywords** binding affinity, subtype comparisons, acute/early infection  
**References** Malhotra *et al.* 2007b
  - T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.

- This epitope, KAFSPEVIPMF, is invariant across CON A, B, C and M-Group sequences, as well as clade B COT and ANC sequences.

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*5701)

**Keywords** rate of progression, immunodominance

**References** Migueles & Connors 2001

- HLA B\*5701 was found in a very high frequency in HIV-1 infected non-progressors, 11/13 (85%) versus 19/200 (9.5%) of progressors. Non-progressors tended to have an immune response that was highly focused on four p24 epitopes that were presented by B\*5701, ISPRTLNAW, KAFSPEVIPMF, TSTLQEQIGW, and QASQEVKNW.
- Attempts to make all for HLA B\*5701-epitope tetramers were made, but only the HLA B\*5701-KAFSPEVIPMF tetramer folded properly. The percentage of CD8+ T cells staining with this HLA B\*57 gag tetramer and the fraction of CD69+IFN-γ cells responding to autologous B cells pulsed with KAFSPEVIPMF was highly correlated ( $r = 0.84$ ;  $P = 0.005$ ). The percent of CD8+ T cells that stain with the A\*2 gag SLYNTVATL tetramer was low (0–0.31%) in a A2+ B57+ LTNP, emphasizing the focus of the immune response on the B\*5701 epitopes.

**HXB2 Location** p24 (30–40)

**Author Location**

**Epitope** KAFSPEVIPMF

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*5701)

**Keywords** rate of progression, immunodominance

**References** Migueles & Connors 2001

- CTL activity was monitored in 27 individuals, including 10 LTNP with an over-expression of HLA B\*5701 – these individuals have viral loads below the threshold of infection without therapy, and their immune response tends to be focused on peptides that contain B\*5701 epitopes ISPRTLNAW, KAFSPEVIPMF, TSTLQEQIGW, and QASQEVKNW.
- CTL responses are broader in B\*5701+ individuals with progressive viremia than those that control viremia.
- The HLA-A\*0201 SLYNTVATL epitope response was not as strong in individuals that carried both A2 and B57.

**HXB2 Location** p24 (30–40)

**Assay type** Intracellular cytokine staining, Flow cytometric T-cell cytokine assay

**Keywords** rate of progression, escape

**References** Migueles *et al.* 2003

- cDNA Gag sequences from a set of 17 HLA-B\*5701+ progressors and 10 LTNPs were obtained, and the variation in four p24 B\*5701 epitopes examined. Sequence variants were more common ( $p < 0.01$ ) in the epitopes in the progressors (median 3, range 1–7) than LTNPs (median 2, range 0–4).
- In general, use of the autologous protein in a target cell did not diminish the overall CD8+ T-cell responses.
- This epitope tends to be quantitatively immunodominant in B57+ people, including in some of the individuals in this study. It was extremely well conserved in the sequences obtained here, despite strong immune pressure, suggesting fitness constraints.

**Immunogen** peptide-HLA interaction

**Species (MHC)** human (B\*5701)

**Assay type** Tetramer binding

**Keywords** binding affinity

**References** Gillespie *et al.* 2007

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80 tetramers in complex with epitopes to KIR3DS1 transiently

expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.

- This epitope, KAFSPEVIPMF (MHC Class I restriction, serotype Bw4Ile80) complexed with MHC B\*5701 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C. However, the complex B\*57-KAFSPEVIPMF does bind inhibitory KIR3DL1 subtype KIR3DL1\*005.

**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B57-KAF that is strongly associated with delayed progression to AIDS and its natural as well as alanine-substituted variants are efficiently cross-recognized. At lower peptide concentrations, efficiency of variant cross-recognition was reduced, even while interepitopic differences in variant cross-recognition efficiency were maintained. CTLs responding to this epitope expressed the same predominant TCR

Vbeta family, but individuals whose CTLs predominantly used TCR Vbeta 17 had less efficient variant cross-reactivity.

**References** Gillespie *et al.* 2002

- CTL responses of eight HIV+ slow progressors from Nairobi Kenya or Oxford, UK who were B\*5701 or B\*5703 were studied, as B\*57 is associated with slow progression.
- This epitope is located between the structurally conserved alpha-helix 1 and alpha-helix 2 (H1-H2) region of the p24 capsid protein, and tends to elicit strong reactions in B\*57 individuals.
- Broad heterogeneous cross-clade reactivity to 6 clade variants of the KAFS peptide sequence were observed in one B\*5701 and 5 B\*5703 HLA-restricted patients, measured by IFN- $\gamma$  production Elispot assays as well as tetramer binding. The clade variants were: KAFSPEVIPMF (clades A and B), kGfNpevipmf (clades A/AC); kaLspevipmf (clade A); kafspevipVf (clade A); kafNpelipmf (group O); kafspeIipmf (A/C); kafsQevipmf (A/C); and kaLspevipmf KNFSPEVIPMF A/G). Not all variants were well recognized in all patients, for example kafsQevipmf was not able to induce IFN gamma production in 3/6 tested, and had a diminished capacity to sensitize target cells for lysis.

**References** Yu *et al.* 2007a

- To study the contributions of HLA alleles and TCRs to the prevention of viral escape, HLAs B\*5701 and B\*5703 that differ at only 2 residues were followed with epitope KF11 and variants. B\*5701-KF11 allowed fewer viral mutations along with a narrow TCR repertoire while B\*5703-KF11 had a greater repertoire of TCR but also greater numbers of escape mutations. Therefore extensive TCR diversity is not a prerequisite to the prevention of viral mutations. More heterogeneous TCR-beta chains were also seen in the HLA-B\*5703-KF11 situation and greater numbers of KF11 variants arose especially in clade C-infected subjects.
- For both Clades B and C HIV-1, this epitope KAFSPEVPMF (wt) i.e. KF11 spawned variants KgFSPEVPMF (A2G), KnFSPEVPMF (A2N), KsFSPEVPMF (A2S), KsFnPEVPMF (A2S-S4N) and KsFSPEiPMF (A2S-V7I). In addition, Clade C also allowed variants KgFnPEVPMF (A2G-S4(N/K)) and KgFkPEVPMF (A2G-S4(N/K)). Overall, HLA-B\*5703 subjects showed more of these sequence variants than HLA-B\*5701 possessing subjects did.

**Keywords** rate of progression, HLA associated polymorphism

**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- This Gag epitope KF11 is highly variant in the African cohort when restricted by B\*5703, but is conserved in the Caucasian B\*5701-positive cohort.

- Using previously defined epitopes Oxenius *et al.* [2000, 2001a] in an IFN $\gamma$  Elispot assay, 13 chronically HIV-1 infected patients were studied over a period including therapy with standard treatment interruptions (STI).
- STIs induced increased recognition of CTL epitopes, but there was no correlation between CTL responses with viral rebound rates, plateau viral loads, or clearance rates.

**HXB2 Location** p24 (30–40)**Author Location** p24 (30–40)**Epitope** KAFSPEVPMF**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B57)**Donor MHC** A\*0201, A3, B44, B57, Cw5, Cw6**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** acute/early infection, early-expressed proteins**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most

avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- All HIV-1 proteins except Vpu were recognized, and responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- Alleles A3, B35, B57, and B62 were more frequently recognized than alleles A1, A2, A30, and A44 e.g., during primary infection. 2/10 patients, 1372 and 1397, recognized A2-restricted epitopes. The common A2-restricted epitopes Gag SL9 and Pol IV9 were not recognized in peptide tetramer-binding assays.

**Keywords** TCR usage

**References** Betts *et al.* 2004

- Both cytokine production and degranulation in HIV-1 specific and CMV specific CD8+ T-cells occurs at high peptide concentrations together with TCR downregulation. Only degranulation is observed at lower peptide concentrations with no observed TCR downregulation. Thus the nature of CTL response depends not on the specific T cell clonotype or antigen, but on the concentration of Ag presented on APCs.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** variant cross-recognition or cross-neutralization

**References** Draenert *et al.* 2004c

- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2-39) epitopic regions were targeted in an average of 6 proteins (range, 1-8). HAART resulted in decrease in antigen and reduction in gamma IFN EliSpot responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that persistent CTL through late disease do not exert strong immune selection pressure, yet the Elispot assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.
- 2 subjects recognized this epitope, 1 with high functional avidity, 1 with intermediate. Autologous sequence revealed no substitutions in this epitope compared to the B consensus.

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.
- 7/7 patients recognized this epitope.

- This study characterizes an escape mutation in a C-terminal flanking residue of the HLA-A3 gag p17 KK9 epitope that inhibits processing, and is embedded in the overlapping HLA-A3 RK9 epitope.
- The immune response was tracked in subject AC-38. The acute immunodominant response was to the B57 TW10 epitope; this response declined following viral escape (tsNIqeqigw) by day 64. The p17 KK9 and RK9 became immunodominant, but then declined as the escape mutation arose. FK11 is 1 of 3 other strong responses that persisted, along with 1 sub-dominant response.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- Acute HIV-1 infection induces massive activation of HIV-specific and non-HIV-specific CD8+ T-cells resulting in differentiation of these cells. High differentiation of CD8+ T-cells is correlated with disease progression. Differentiation is a natural process but it can be driven by elevated immune activation, such as in HIV infection.

- HLA-B57 has been associated with long term non-progression in HIV+ people. The number and responsiveness of CD8 T-cells directed to different Gag peptides presented by HLA-A2, -B8 and B57 were compared. T cells specific for the HLA-B57 epitope KAFSPEVIPMF responded to a higher extent and more readily to antigenic stimulation than those specific for the A2 epitope SLYNTVATL and the B8 epitope EIYKRWII.
- Tetramer decay experiments indicate that the HLA-B57 peptide has a higher half-life than the A2 and B8 peptides. The authors point out that CD8+ T cells with high binding affinity may require less help.
- Variant forms of the HLA-B57 epitope KAFSPEVIPMF were found in the 3/5 HLA B57+ individuals sequenced, but the variants were always a minor form.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- To characterize HIV-1 proteome areas that are targeted in early, effective CTL responses, two cohorts were studied. Responses in early infection were against fewer epitopes and of lower magnitude than during chronic infection. While no region of the proteome was favored, Nef was the predominant target based on length of proteins. When based on the expression of protective versus nonprotective HLA I alleles, it was found that HLA-B27 and -57 possessing slow progressors to disease directed the majority of their responses to Gag in early infection, as opposed to those with HLA-B\*3501 or B\*3502, i.e. rapid progressors to AIDS, who had negligible responses to Gag. As compared with HLA-B57-/B27-subjects and HLA-B35 subjects, HLA-B57+/27+ subjects responded most to the p24 component of Gag. By using overlapping peptides within Gag p24, two were picked as being consistently targeted, and both contained previously described epitopes TW10 and KK10.
- IVLPEKDSW, i.e. epitope IW9 of RT protein was targeted in 62% of B57+ non-progressors to disease.

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.
- KAFSPEVIPMF was frequently recognized in children and in adults.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype G Gag. The autologous epitope sequence in this person matched the known epitope.

- Differences in early versus chronic AIDS include a decline in CTL number accompanied by a reducing viremia. Comparative analysis of such CTLs in this study show that early infection is characterized by a different clonotypic composition and higher functional avidity of CTLs followed by their selective depletion during transition to chronic disease. The total magnitude of CTL cytokine production is lower in early infection. Intraindividual, early CTLs' functional avidity for the same epitope decreases concomitantly with a reduction in clonotypic TCR repertoire especially of strongly activated and CD127lo, CD38+, Ki-67hi CTLs while progressing to chronic infection states.
- None of the target epitopes, including this epitope KAFSPEVIPMF seen in 1 patient, underwent sequence changes.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided, it appears to be HXB2.
- Responses to this peptide were detected in 22% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187–2200 (2004)].
- This peptide, sqVSQNYPIVQNLQGMV differs from the consensus C sequence kVSQNYPIVQNLQGMV at 2 amino acid positions, i.e. by 11.1%.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3

frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.

- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, AFSPEVPMFSALSEGA, had an overall frequency of recognition of 15.3% - 16.9% AA, 11.5% C, 18.2% H, 9.5% WI. This peptide is included in a 49 aa Gag-p24 highly reactive region to be used for vaccine design. It is also part of 'Region III', PRTLNAWVKVVEEKAFSPEVPMFSALSEGA, a 31 aa region recognized by >90% of subjects across ethnic groups.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** cross-presentation by different HLA, optimal epitope

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.

- This is a putative HLA-B63/57/58 epitope containing the B58 supertype binding motif. Significantly more often recognized by B63+ and B57/58+ subjects than by negative subjects. Optimal epitope defined.

**Keywords** binding affinity, subtype comparisons, rate of progression, immunodominance, escape, cross-presentation by different HLA, variant cross-recognition or cross-neutralization

**References** Kawashima *et al.* 2005

- A\*26 is associated with slow progression to disease and is common in Asian populations (about 20%). 31/110 HIV peptides that carried the A\*2603 motif ([VTILP] at P2, [ML] at the C-terminus) bound to HLA-A\*2603. Only 2 of these were epitopes and could induce specific CD8 T-cell responses in PBMC from HLA-A\*2603 positive subjects.
- This epitope induced specific CD8+ T cells in chronically infected individuals with either A\*2603 or A\*2601. It is an immunodominant epitope.
- 3 common B clade variants were synthesized. EVIPMFaAL and EVIPMFtAL bound to A\*2603 with equal affinity as the consensus form, EVIPMFSA, but could not be recognized by an EVIPMFSA-specific T-cell clone so may mediate TCR escape. The other common variant, kVIPMFSA, did not bind to A\*2603.
- EVIPMFSA is the most common form in clades A, B, D, and E (CRF01), but EVIPMFtAL is the most common form in clade C.

**References** Zhao *et al.* 2007

- 46 ART-naïve subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, PMFsALSEGATPQDLNTM differs from the consensus C sequence PMFtALSEGATPQDLNTM at 1 amino acid position, i.e. by 5.6%.

**References** Frahm *et al.* 2004
- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
  - Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
  - In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
  - This immunodominant, frequently targeted overlapping peptide, PMFSALSEGATPQDLNTM, had an overall frequency of recognition of 16% - 20.3% AA, 15.4% C, 13.6% H, 4.8% WI. This peptide is included in a 49 aa Gag-p24 highly reactive region to be used for vaccine design. It is also part of 'Region III', PRTLNAWVKVVEEKAFSPEVPMFSALSEGA, a 31 aa region recognized by >90% of subjects across ethnic groups.

**HXB2 Location** p24 (42–52)**Author Location** Gag (343–353)**Epitope** ALSEGATPQDL**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human**Country** India**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** subtype comparisons**References** Kaushik *et al.* 2005

- T cell responses to Gag consensus C peptides were studied in C-infected patients from India. CD8+ responses were stronger and broader than CD4+ responses. IFN- $\gamma$  response was higher in both CD8+ and CD4+ T cells than corresponding IL-2 response, that was detectable only in CD4+ T cells.
- 1/25 patients responded to this peptide (IFN- $\gamma$  CD8+ response). An IL-2 response was not detectable.

**HXB2 Location** p24 (43–52)**Author Location** Gag (175–184 WEAU)**Epitope** LSEGATPQDL**Epitope name** Gag LL10**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*4403)**Donor MHC** A\*2902, B\*0801, B\*4403**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay**Keywords** dynamics, immunodominance, escape, kinetics, characterizing CD8+ T cells, viral fitness and reversion**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- There was a weak response to this epitope during acute and early infection, and the epitope sequence did not vary during the first year of the infection.

**HXB2 Location** p24 (43–52)**Author Location** p24 (subtype A)**Epitope** LSEGATPQDL**Subtype** A**Immunogen** HIV-1 infection**Species (MHC)** human (B42, B44)**Keywords** subtype comparisons**References** Cao *et al.* 2000

- HIV-1 subtypes A and D dominate the Ugandan epidemic, and a vaccine trial using B clade antigen is underway – this study addresses relative levels of cross-reactive CTL responses in Ugandans to A, D, and B clade recombinant vaccinia viruses expressing Gag, Env, Pol, RT or Nef from HIV-1 clades A, B, and D.
- Proteins corresponding to the subtype of the infecting strains tended to trigger higher levels of CTL response measured by percent specific lysis, but there was extensive inter-subtype cross-reactivity with B clade proteins and the co-circulating subtype.
- This optimal epitope sequence, recognized by CTL derived from a Ugandan with an A subtype infection (patient SP 511), is cross-reactive with subtypes A, B and D peptides.

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**References** Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were

fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

**References** Yang *et al.* 2003b

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 1/14 CTL T-cell clones tested were specific for Gag/p24-SL9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 value for Gag/p24-SL9 was 30 pg/ml, it was among the peptides with the highest avidity.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J.Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, GATPQDLNMLNTVGGH, had an overall frequency of recognition of 20% - 18.6% AA, 11.5% C, 18.2% H, 4.8% WI. This peptide is included in a 49 aa Gag-p24 highly reactive region to be used for vaccine design. It is also part of 'Region III', PRTLNAWVKVVEEKAFSPEVIMFMSALSEGA, a 31 aa region recognized by >90% of subjects across ethnic groups.

**References** Geels *et al.* 2005

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell

responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.

- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence in this person matched the known epitope.

- Highly targeted regions in Gag for CD8+ T-cells were defined for individuals with C clade infections in South Africa. 9 specific epitopes within the most reactive regions were characterized. Some epitopes were shown to be promiscuous, presented by multiple class I restricting alleles.
- TPQDLNTML was presented by B\*4201 and B\*8101. B\*44 is more common among Caucasians than Zulus (allele frequency 0.149 versus 0.107), while A\*29 is more common in Zulus (0.045 versus 0.125). This epitope had previously identified in B clade infections.

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity was correlated with selection pressure observed in HLA allele-epitope restriction.
- TL9 selection pressure was evidenced by studying changing epitope variants associated with HLAs of the B7 supertype.
- Higher level of polymorphism variation, escape mutations and TCR diversity was associated with the B\*8101 allele.

- In 3 B-supertype alleles studied, B\*4201, B\*8101 and B\*3910, the variant at the seventh position, TPQDLN $\gamma$ ML, was most common. Several more variants are listed in the paper.

- The objectives of this study were to find antiviral epitopic determinants of Gag HIV-specific CTL response and to find 'host HLA-CTL response' correlations. By studying 56 ART-naive subjects including low viral load (LVL) responders, the authors show that subjects expressing the above "protective" HLA have broader Gag epitope recognition which may be abrogated if co-expressed with HLA-B alleles associated with rapid AIDS progression. Also, a negative linear relation was seen between Gag epitope numbers recognized and plasma viral load while a positive relationship was seen with CD4 T-cell count. Finally, LVL subjects recognized specific Gag regions at the N- and C-termini of the protein more often than peptides in the middle of the protein.
- Epitope TPQDLNTML elicits a strong CTL-response and was targeted with high magnitude by 41% of the subjects. TL9 is highly conserved in subtype C and shows no evidence of viral escape by point mutations. The authors however, find no evidence of this immunodominant response having a substantial role, as subjects with B\*8101 who do target TL9 have high viral loads.

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80 tetramers in complex with epitopes to KIR3DS1 transiently expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.
- This epitope, TPQDLNMML (MHC Class I restriction, serotype Bw4Ile80) complexed with MHC B\*53C1 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C.

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.

- Variants TPDLNTML and TPQDLNsML at positions 3 and 7 were the predominant polymorphisms found.

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 4 alleles previously known to be associated (B07, B42, B53, B81) and 3 additional alleles (A02, A24, B14).

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- CD8 T-cell responses were evaluated and compared in HIV-1 and HIV-2 infected individuals living in the Gambia. A significantly greater magnitude and breadth of Gag-specific responses were found in HIV-1 infected individuals, possibly because of low or undetectable viral loads in HIV-2 infected

individuals. This finding suggests that responses in HIV-2 infection reflect antigen load in plasma, as is the case in HIV-1 infection. No correlation was found between immune control of HIV-2 and the frequency of perforin-expressing virus-specific CD8 T-cells.

- 5/7 HIV-1-infected B53-positive subjects recognized TPQDL-NMML, the HIV-1 version of this epitope. 3/3 HIV-2-infected B53-positive subjects responded to TPYDINQML, the HIV-2 version of the epitope.

**Epitope** TPQDLNTML

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** rate of progression, acute/early infection

**References** Day *et al.* 2001

- The CTL response to optimally defined CTL epitopes restricted by HLA class I A and B alleles in individuals who coexpressed HLA A2, A3, and B7 was studied in eight HIV-1-infected subjects, two with acute infection, five with chronic, and one long-term non-progressor (LTNP)
- 2 to 17 epitopes were recognized in a given individual, A2-restricted CTL response tended to be narrow and never dominated the response, and 25/27 epitopes were targeted by at least one person.
- Subjects with chronic HIV-1 infection recognized between 2–8 out of 11 B7-restricted epitopes.
- An acute seroconverter homozygous for the B7 allele recognized five B7-restricted epitopes.
- The other acute seroconverter failed to recognize any of the 11 B7-restricted epitopes tested.
- The B7-restricted CTL response was highly variable and there was no clearly dominant epitope.

**Species (MHC)** human (B7)

**Donor MHC** A3, B7, Cw7

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.

- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 1/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 1/4 individuals had detectable responses to this epitope after STI.

**References** Altfield *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8+ T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient A displayed the greatest response to epitope B14-EL9(gp41), a strong response to B7-TL9(p24), and responses to B7-TM9(Nef) and A32-PW10(RT).

**Epitope** TPQDLNTML?

**Epitope name** TL9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B81)

**Country** United States, South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding

**Keywords** memory cells

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.

- The B consensus form of this epitope, TPQDLNTML, persisted throughout 6 years of chronic infection in 1 individual.

**References** Beattie *et al.* 2004

- This study compared CD8+ T-cell EliSpot responses to 58 Gag peptides that were optimal epitopes, with responses to overlapping 15 mers that spanned Gag. When screening for HIV-1-specific CD8+ T-cell responses from 49 HIV+ people, overlapping 15-mer peptide pools revealed several novel responses that would have been missed using predefined CD8 epitopes. However, the 15-mer pools often missed low-level responses to predefined epitopes, especially when the epitope was located centrally in the 15-mer peptide, and the overall level of response to the 15 mers was generally lower (mean 1.4 five fold dilutions lower, range 0-3).
- The response to TPQDLNTML was used as an example of a titration curve. When comparing the peptide TPQDLNTML to the 15 mer EGATPQDLNTMLNTV, the 15 mer had a diminished response to the same amount of peptide.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype G Gag. The autologous epitope sequence in this person differed from the known epitope in one position, Q7T, TPQDLNtMLNTV

**HXB2 Location** p24 (48–62)**Author Location** p24 (48–56)**Epitope** TPQDLNMMLNIVGGH**Subtype** A, D**Immunogen** HIV-1 infection**Species (MHC)** human**Donor MHC** A\*0201, A\*2902, B\*1402, B\*1503; A\*0101, A\*7401, B\*5801**Country** Uganda**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, variant cross-recognition or cross-neutralization**References** Barugahare *et al.* 2005

- T-cell immune responses were examined in HIV-1 infected Ugandans. Similar levels of cross-clade responses for Gag, Env and Nef were observed. Higher frequencies of responses in conserved regions were found for Gag within a single clade, while areas with higher viral sequence variation had fewer detectable responses. Differential interclade sequence homologies between the Gag regions did not affect the respective level of cross-clade recognition.
- This sequence contains a known B7 and B53 epitope, but the subjects recognizing it are B7- and B53-negative. It was conserved in the two people that recognized the peptide.

**Keywords** HAART, ART

**References** Mollet *et al.* 2000

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using CD8+ cell IFN $\gamma$  production to measure responses.
- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

**HXB2 Location** p24 (51–59)

**Author Location** p24 (183–191)

**Epitope** DLNMLNIV

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative

**Species (MHC)** human (B14)

**Keywords** HIV exposed persistently seronegative (HEPS), immunodominance

**References** Kaul *et al.* 2001a

- Variants DLNMLNIV/DLNTMLNVV are specific for clades A/B.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B14 women, 4/4 HEPS and 3/7 HIV-1 infected women recognized this epitope, likelihood ratio 4.8, p value 0.1, and HEPS women tended to respond to DLNMLNIV/DLNTMLNVV, while infected women tended to respond to DRF(F/W)KTLRA.
- The dominant response to this HLA allele was to this epitope for all 4/4 HEPS cases and in only one of the 3/7 HIV-1 infected women.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Four epitopes were considered to be “resistant epitopes”, as they were preferentially reactive in HEPS women and so may confer resistance, and these were found in three different proteins: A2 ILK(D/E)PVHGV in RT, A\*6802 DTVLEDINL in Protease, B14 DLN(M/T)LN(I/V)V in p24 and B18 FRDYV-DRF(Y/F)K also in p24.

**Epitope** DLNMLNIV  
**Subtype** B  
**Immunogen** HIV-1 exposed seronegative  
**Species (MHC)** human (B\*1402, Cw8)  
**Keywords** subtype comparisons  
**References** Rowland-Jones *et al.* 1998b

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi – these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.
- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among B and D clade viruses.
- The Clade A version of the epitope, DLNMLNIV, was preferentially recognized by CTL.
- Recent evidence indicates this is a Cw8 epitope; B14 and Cw8 are in linkage disequilibrium and the HLA presenting molecule is hard to distinguish (P. Goulder, personal communication).

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** assay standardization/improvement, optimal epitope  
**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, GHQAAMQMLKE, was detected within overlapping peptide GGHQAAMQMLKETINEEA.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** subtype comparisons, immunodominance  
**References** Zhao *et al.* 2007
- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
  - 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
  - Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
  - 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
  - This peptide, GHQAAMQMLKeTINEEAA differs from the consensus C sequence GHQAAMQMLKdTINEEAA at 1 amino acid position, i.e. by 5.6%.

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
  - 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
  - A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
  - The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
  - Responses to this peptide were detected in 22% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- Different HIV strains were used for different regions: Env IIIIB, Gag HXB2.
- BALB/c mice were vaccinated with rec vesicular stomatitis virus (rVSV) expressing either HIV-1 Gag, Env, or both, and compared to using rec Env and Gag in vaccinia virus (rVVs). The primary response was determined by cell lysis, cytokine production and tetramer staining.
- Primary CTL responses to the immunodominant Gag (AMQMLKETI) epitope peaked in 7 days for GAG-rVSV, 3% of the cells were tetramer positive, and this response was 8-fold higher than for Gag-rVV.
- Vaccinating with GagEnv-rVSV carrying both Gag and Env allowed recognition of both HIV-1 proteins, but at reduced levels compared to either Gag-rVSV or Env-rVSV alone.
- Intranasal immunization with Env-rVSV yielded CTL responses that were strong but reduced compared to an intraperitoneal route.

**Species (MHC)** mouse (H-2K<sup>d</sup>)

**Keywords** immunodominance

**References** Haglund *et al.* 2002b

- Different HIV strains were used for different regions: Env IIIIB, Gag HXB2.
- BALB/c mice were vaccinated with rec vesicular stomatitis virus (rVSV) expressing either HIV-1 Gag or Env, or both, and retention of memory responses and recall responses were studied by tetramer staining and IFN-gamma production.
- Seven months after vaccination with Env-rVSV, 6% of the CD8+ cells were tetramer positive for the immunodominant Env epitope; these cells had a memory phenotype, CD44-Hi positive.
- Env in rec vaccinia virus (Env-rVV) elicited a strong recall response, with up to 45% of the CD8+ T-cell population tetramer positive and activated (expressing CD62L-Lo), and capable of IFN-gamma production.
- A prime with Env-rVSV and heterologous boost of Env-rVV gave remarkably high levels of memory cells, with approximately 1/3 of the CD8+ splenocytes being Env specific memory cells 150 days after the boost.
- A Gag-rVSV or EnvGag-rVSV prime and with a heterologous Gag-rVV or EnvGag-rVV boost combination gave 40% tetramer positive CD8+ cells, but the fraction of IFN-gamma producing cells was only about 25%. Still the heterologous vector prime-boost combination showed a profound benefit.
- A HIV-1 protein rVSV prime, rVV boost was a more potent combination than a vector reversal of a rVV prime and rVSV boost.

**References** Wild *et al.* 2004

- A codon optimized gag DNA vaccine was compared to a myristylation defective gag and p24 alone, both of which lack signals for secretion from transfected cells. Gag-derived immunogens that were secreted as VLPs and those that remained intracellular (p24) each produced strong CTL responses, and neither the size of antigen nor cellular trafficking and localization significantly influenced the strength of humoral and cellular immune activation. The formation and release of VLPs was not essential for eliciting strong CTL. BALB/c mice were given the DNA vaccine by i.m. administration of plasmid DNA for the prime and boost.
- Linking the region encoding the V3 immunodominant epitope to the gag gene did not diminish the response to the Gag p24 epitope A9I, but did enable a response to the V3 epitope.
- Minigenes were made incorporating just 1 epitope, minitopes, carrying 1 of 3 murine class I epitopes linked to the Ad2-E3 protein-derived signal peptide to allow access of the epitope to the ER. Weak induction of cellular immune responses was observed, in contrast to the complex polyprotein.

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- After immunization with Clades A or C vaccines, both containing Epitope G, AMQMLKDTI, T cells responded well to this index epitope, but poorly to Clade B variant AMQMLKeTI, and intermediately to variant AMQiLKDTI. Induction by Clade B vaccine, containing epitope AMQMLKETI, generated good responses to both Clade B and A variants, but not to variant AMQiLKDTI.

- Intranasal immunization triggered CTL response in the nasal-associated lymphoid tissue (NALT), posterior cervical lymph nodes (pCLNs) and the spleen, but not in the mesenteric lymph nodes (MLNs). Rectal immunization elicited CTL responses only in the MLNs. By immunizing mice nasally following rectal immunization, CTL responses were detected in NALT, pCLNs, spleen and MLNs. Epitope-specific CD8+ T-cells were primarily located in NALT after 6 days and in pCLNs after 2 months.
  - The strongest specific lysis was induced by NALT-specific CTL clones. pCLNs derived memory CTL clones originated from NALT CTL clones, as determined by T-cell receptor V $\beta$  usage.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, LKeTINEEAAEWDR LHPV differs from the consensus C sequence LKdTINEEAAEWDR LHPV at 1 amino acid position, i.e. by 5.6%.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, KETINEEAA, was detected within overlapping peptideS GGHQAAMQMLKETINEEA, LKETINEEAAEWDR LHPV and AAEWDR LHPVHAGPIA.

**Species (MHC)** human (B53)

**Keywords** HIV exposed persistently seronegative (HEPS)

**References** Kaul *et al.* 2001a

- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B53 women, 0/2 HEPS and 7/9 HIV-1 infected women recognized this epitope.
- The dominant response to this HLA allele was to this epitope in 4 of the 7/9 responsive HIV-1 infected women.

**HXB2 Location** p24 (71–80)

**Author Location** p24 (203–212 subtype A consensus)

**Epitope** DTINEEAAEW

**Subtype** A

**Immunogen** HIV-1 infection

**Species (MHC)** human (B53)

**Keywords** binding affinity, subtype comparisons, epitope processing

**References** Dorrell *et al.* 2001

- In clade A infected Gambians, three HLA-B53 epitopes were defined in Gag p24 using ELISPOT, tetramer, and cytotoxicity assays.
- Two of the new epitopes lacked the predicted P2 anchors, DTINEEAAEW and QATQEVKNM, and bound to B53 with high affinity, thus extending the anchor residue motif for B53 and the related B35.
- Two overlapping 20 mer peptides carry this complete epitope, but only one stimulates recognition, which could be due to different peptide processing.
- DTINEEAAEW was recognized in only 2/7 HLA-B53 subjects.
- DTINEEAAEW was not A subtype specific and there was cross-recognition although diminished, of the subtype B, C, and D variant, ETINEEAAEW.
- In one of the two subjects there was cross-recognition of the HIV-2 version of the epitope, EIINEEAADW.

**References** Geels *et al.* 2005
- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
  - This previously described B53 epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype A Gag. The autologous epitope sequence in this person differed from the known epitope by one amino acid, E1D, dTINEEAAEW. It was also recognized in a person carrying a subtype D gag, and in this case the autologous sequence matched the epitope. This was also predicted to possibly be a B58 cross-presented epitope in another subtype D Gag infected person based on peptide reactivity and a known B58 motif.

**Keywords** vaccine-induced epitopes  
**References** Horton *et al.* 2006b
- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
  - None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
  - Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
  - This epitope was contained in the vaccine, the vaccinated patient recognized it after infection.

**References** Yang *et al.* 2005b
- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
  - The response to the epitope EEAAEWDV was found in the patient before superinfection and diminished afterwards; the initial infecting and superinfecting strain carried EEAAEWDRI.

**Keywords** binding affinity, immunodominance  
**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, AAEDRLHPVHAGPIA, had an overall frequency of recognition of 20% - 18.6% AA, 23.1% C, 25% H, 9.5% WI. This peptide is included in a 41 aa Gag-p17 highly reactive region to be used for vaccine design.

**Keywords** rate of progression, escape  
**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relative efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive epitopes found not to vary over time.

**References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.
- AEWDLHPV was among 5 mostly recognized epitopes (69%).

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.

- This epitope, AEWDRLHPV, was detected within overlapping peptides LKETINEEAAEWDRHPV and AAEWDRHPVHAGPIA.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
  - Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
  - This HIV-1 epitope, LHPVHAGPI, is similar to human protein PTPRE, sequence LnPVHAGPIV and human protein T cell leukemia Homeobox 1, sequence LHPgHAePIV.

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses

implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

**Epitope name** B7-HA9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Donor MHC** A3, B7, Cw7

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 1/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection—10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 3/4 individuals had detectable responses to this epitope after STI.

**Donor MHC** A03, B07, Cw7

**Assay type** Cytokine production, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** assay standardization/improvement, memory cells, characterizing CD8+ T cells

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Keywords** assay standardization/improvement, optimal epitope

**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, HPVHAGPIAPGQMREPR, was detected within overlapping peptides LHPVHAGPIAPGQMREPR, LKETINEEAAEWDRHPV and AAEWDRHPVHAGPIA.

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*02 restricted epitope, HAGPIAPGQMREPRG was mutated to qAGPIAPGQMREPRG in the daughter D2 isolate.

**References** Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- An early response to this peptide was detected that waned prior to superinfection. The embedded epitope and HLA presenting molecule were not resolved. The initial and superinfecting strains carried a perfect match to the peptide sequence.

- To find the factors involved in attenuated disease course and long term non-progression, HIV-2 and immune control were studied. HIV-2 viral load was used as a predictor of patient survival. HIV-2 viral load correlated inversely with magnitude of IFN-gamma response, relative dominance of Gag-specific peptides' responses over other proteins' responses, and the breadth of different peptide-specific immune responses. The most frequently recognized peptides were in Gag protein, followed by Env and Pol, while Nef and accessory proteins (Vif, Vpx, Vpr, Tat and Rev) rarely elicited responses. The 6 most

recognized peptides were clustered in a highly conserved region of Gag.

- This peptide, SDIAGTTSTVDEQIQWMY, was recognized by 10 out of 65 subjects. It is found in the 149 amino-acid long HIV-2 proteome region of Gag 175-323.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, TW10 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen only to the C-clade variant. Anchor residues are at positions 2 and 10; while the A-clade variant contains a non-conservative change at position 4 to TSTpQE-QIGW, and the C-clade variant has a semi-conservative substitution at position 9 to TSTLQEQIaW. Reduced avidity was seen with the clade-C variant.

**Keywords** rate of progression, HLA associated polymorphism

**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA I in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.

- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variants TSnLQEQIGW and TSTLQEQIaW at positions 3 and 9, were present in 86.7% of HLA-matched patients and 28.3% of HLA-unmatched patients. Phylogenetic analysis identified the threonine at position 3 to be under strong positive selective pressure.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*5701)

**Keywords** rate of progression, immunodominance

**References** Migueles & Connors 2001

- CTL activity was monitored in 27 individuals, including 10 LTNP with an over-expression of HLA B\*5701 – these individuals have viral loads below the threshold of infection without therapy, and their immune response tends to be focused on peptides that contain B\*5701 epitopes ISPRTLNAW, KAFSPEVIPMF, TSTLQEQIGW, and QASQEVKNW.
- CTL responses are broader in B\*5701+ individuals with progressive viremia than those that control viremia.
- The HLA-A\*0201 SLYNTVATL epitope response was not as strong in individuals that carried both A2, B57.

**Country** Australia

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape, HLA associated polymorphism

**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, Science 296:1439 2002) were found

to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.

- The third position of this epitope TStLQEIQGW has a mutational pattern that is correlated with the host carrying HLA B\*5701.

**Keywords** rate of progression, TCR usage, variant cross-recognition or cross-neutralization, characterizing CD8+ T cells  
**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B57-TST (that is strongly associated with delayed progression to AIDS) and its alanine-substituted variants are efficiently cross-recognized.

**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- TSTLQEIQAW was a previously defined B\*5701/B\*5801 presented epitope that encompassed a B\*57/B\*5801 associated polymorphism, TStLQEIQAW, in the third position.

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variant TSnLQEIQGW at position 3 was often found in conjunction with a second polymorphism at positions 5, 8 or 9.

- CD8 T-cell responses were evaluated and compared in HIV-1 and HIV-2 infected individuals. A significantly greater magnitude and breadth of Gag-specific responses were found in HIV-1 infected individuals, possibly because of undetectable viral load in HIV-2 infected individuals. This finding suggests that responses in HIV-2 infection reflect antigen load in plasma, as is the case in HIV-1 infection. No correlation was found between immune control of HIV-2 and the frequency of perforin-expressing virus-specific CD8 T-cells.
- 4/5 HIV-2-infected B\*5801-positive subjects recognized TSTVEEQIQW, the HIV-2 version of this epitope. 0/4 HIV-1-infected B\*5801-positive subjects responded to TSTLQE-QIGW, the HIV-1 version of this epitope.

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80 tetramers in complex with epitopes to KIR3DS1 transiently

expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.

- This epitope, TSTLQEQIGW (MHC Class I restriction, serotype Bw4Ile80) complexed with MHC B\*5801 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C.

- To characterize HIV-1 proteome areas that are targeted in early, effective CTL responses, two cohorts were studied. Responses in early infection were against fewer epitopes and of lower magnitude than during chronic infection. While no region of the proteome was favored, Nef was the predominant target based on length of proteins. When based on the expression of protective versus nonprotective HLA I alleles, it was found that HLA-B27 and -57 possessing slow progressors to disease directed the majority of their responses to Gag in early infection, as opposed to those with HLA-B\*3501 or B\*3502, i.e. rapid progressors to AIDS, who had negligible responses to Gag. As compared with HLA-B57-/B27-subjects and HLA-B35 subjects, HLA-B57+/27+ subjects responded most to the p24 component of Gag. By using overlapping peptides within Gag p24, two were picked as being consistently targeted, and both contained previously described epitopes TW10 and KK10.

- TSTLQEQIGW, i.e. epitope TW10 is one of two immunodominant epitopes targeted during early infection in long term non-progressors to AIDS. After the acute phase of infection most subjects develop a variant, TSnLQEQIGW. Reversion to wild type is seen rapidly upon viral transmission to an HLA-B57- individual.

- TSTLQEIQIAW (the consensus form in the C clade) responses dominate the immune response in HLA-B57 individuals, and this epitope is also recognized in HLA-B5801 individuals. TSnLQEIQIAW is shown to be an escape mutant correlated with HLA-B57 and HLA-B5801 alleles. The variant can be transmitted to HLA-B57/B5801 negative individuals, but reverts to wild-type in those. A second escape mutation within the epitope is, however, maintained after transmission; TSNLQEIQIGW is the most common form of the epitope in the B clade, and a G substitution to some other amino acid, often A, was frequently noted in B57+ individuals; transmission of these variants persist in the new host.

- References** Gao *et al.* 2005
- Three distinct HLA alleles known to alter the rate of AIDS progression were studied. B\*57-mediated protection occurs early in infection and the protective effect of this allele subsides after CD4 cell count drops. In contrast, B\*27 shows no protection against progression to CD4<200, but rather delays progression to an AIDS-defining illness after the CD4 counts have dropped. B\*35-mediated rapid progression to AIDS is probably a function of early decline in CD4 counts.
  - TW10 is typically the immunodominant B57 epitope. TW10 responses are rapid, and escape occurs but presumably with a fitness cost, because reversion occurs after the escape variant is transmitted to a B57- person. High CD4 counts may be maintained in individuals because of immune selection for a less fit form of the virus.

- HIV-specific CTLs in infants were shown to be able to select for viral escape variants early in life, despite a lack of escape with the same CTL specificity in the mother. Infant CTL responses may be compromised by transmission of escape variants that arose in the mother and also those that arose in the father, if the father was the source of the mother's infection.
  - TSTLQEIQIAW is the C consensus form of the epitope and the autologous form in the mother was TSTLQEIQItW, and this was the form transmitted to her infant. The mother does not carry B57, and the B57 escape footprint was inherited paternally. By 33 weeks a new dominant form of the epitope had emerged in the infant, TSnLQEIQIAW, and the consensus form was also present in the infant.

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.
- This epitope, TSTLQEIQGW (TW10), elicits the HLA-B57 restricted response that is most dominant of the immune responses generated.

**References** Goulder & Watkins 2004

- This paper is a review of the role of CTL in HIV infection, and it uses the TW10 epitope as an example. HLA B\*57 and B\*5801 both can present this epitope, and are associated with successful containment of HIV infection. The early response to TW10 is immunodominant, and often followed by rapid escape due to the T->N substitution, tsNlqeqigw. Some long term survivors do not carry the escape form, possibly because the CTL response to this epitope is able to suppress viremia. Others do carry the N escape form, and presumably control viremia due to viral attenuation; in support of this the N rapidly back mutates to T in a new host, so there is likely to

be a high fitness cost. In contrast, the epitope sometimes contains a G-> A substitution at position 9, and the A can persist in a new host after transmission.

**Keywords** responses in children, mother-to-infant transmission, escape

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children did not respond to TSTLQEIQGW but showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.
- TW10 was found to be more frequently recognized by adults than by children. Among B57-positive subjects, TW10 was recognized by 10 out of 12 acutely infected adults, 11/22 chronically infected adults, and only 1/14 infected children. All 14 children carried mutations of this epitope, commonly T3N and G9A (TSnLQEIQaW), but the children were able to recognize the autologous variant. These mutations were rare in adults. One child carried T3N, Q5A, and G9A, and also recognized the autologous variant, TSnLaEQIaW.

- References** Cao *et al.* 2003
- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
  - This epitope was recognized in three of the acutely infected individuals and was presented by both HLA-B57 and B58.
  - More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.
  - All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

- References** Lopes *et al.* 2003
- CD8+ T cells from HIV-2 infected patients had more polyclonal TCR responses than HIV-1 infected patients, who tended to have oligoclonal responses. This results in limited plasticity of T cell responses to amino acid substitutions within epitopes in HIV-1 infections. HIV-2-specific CD8+ T-cells showed a more diverse TCR usage associated with enhanced CD8 expansion and IFN-gamma production on cross-recognition of variant epitopes.
  - This peptide was recognized by a CD8+ T-cell clonotype with Vbeta5.1 usage in one HIV-1 infected patient, and all HIV-1 patients had narrow TCR usage, while HIV-2 patients used multiple TCR Vbeta chains. The HIV-2 variant of this peptide is: tstVEeqiQw. 5/6 HIV-2 infected individuals could recognize both the HIV-1 and HIV-2 peptides, while 0/5 HIV-1 infected patients that could react with the HIV-1 peptide could also react with the HIV-2 peptide.

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
  - This epitope was recognized by 30% of B63-positive subjects and 22% of B57/58-positive subjects.

**Keywords** HAART, ART, escape, viral fitness and reversion

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate reversion rates for this epitope, TSTLQEQIGW, in 3 different subjects were found to be 0.016, 0, and 0.005/day with SEs of 0.007, 0, and 0.001 respectively.
- Gag p24 T110N confers escape in subjects expressing HLA-B57 and HLA-B5801. On transmission from an HLA-B57+ donor to an B57/B5801- recipient, the mutation rapidly reverted to wild type (a=0.016/day). Gag p24 G116A confers escape in subjects expressing B57 and B5801. On transmission from an HLA-B57+ donor to an B57/B5801- recipient, the mutation did not revert to wild type over the 8-year observation period, suggesting that the mutation was neutral (a=0/day). The escape variant in Gag p24 T110N was studied in a further HLA-B57+ to HLA-B57/B5801- transmission pair where it reverted to wild type (a=0.005/day).

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
  - Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
  - In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
  - This frequently targeted overlapping peptide, WMTNNPIPVPVGEIYKRWI, was differentially targeted across ethnic groups and had an overall frequency of recognition of 16% - 25.4% AA, 23.1% C, 2.3% H, 9.5% WI (P value = 0.0035). This peptide is included in a 41 aa Gag-p24 highly reactive region to be used for vaccine design.

**References** Leligdowicz *et al.* 2007
- To find the factors involved in attenuated disease course and long term non-progression, HIV-2 and immune control were studied. HIV-2 viral load was used as a predictor of patient survival. HIV-2 viral load correlated inversely with magnitude of IFN-gamma response, relative dominance of Gag-specific peptides' responses over other proteins' responses, and the breadth of different peptide-specific immune responses. The most frequently recognized peptides were in Gag protein, followed by Env and Pol, while Nef and accessory proteins (Vif, Vpx, Vpr, Tat and Rev) rarely elicited responses. The 6 most recognized peptides were clustered in a highly conserved region of Gag.
  - This peptide, MYRQQNPVPVGNIRRWI, was recognized by 11 out of 65 subjects. It is found in the 149 amino-acid long HIV-2 proteome region of Gag 175-323.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
  - This epitope, HPVHAGPIAPGQMREPR, was detected within overlapping peptideS LHPVHAGPIAPGQMREPR, LKETINEEAAEWDR LHPV and AAEWDR LHPVHAGPIA.

*Vector/Type:* DNA, peptide *Adjuvant:* Incomplete Freund's Adjuvant (IFA)**Species (MHC)** human, mouse (A\*0201)**Assay type** Cytokine production, T-cell Elispot**Keywords** subtype comparisons, computational epitope prediction, escape, TCR usage, variant cross-recognition or cross-neutralization**References** McKinney *et al.* 2004

- This study examined variant recognition of epitopes presented by A\*0201 and A\*1101. Numerous amino acid substitutions can be introduced into epitopes without disrupting their recognition by CTLs, although epitopes with multiple substitutions were less recognized. An algorithm was constructed for prediction of epitopes capable of inducing responses to a great number of variant epitopes.
- MTSNPPIPV form is most common in subtype C while MTnNPPIPV form is mostly found in subtype B.
- A total of 14 variant forms of Gag 271 were identified. Immunization with MTSNPPIPV form induced CTLs recognizing 11 of the variant forms while MTnNPPIPV form induced CTLs recognizing only 3 of the epitope variants.

**HXB2 Location** p24 (118–126)**Author Location** p24 (118–126)**Epitope** MTNPPPIPV**Epitope name** MV9**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Donor MHC** A\*02, A\*23, B\*07, B\*51, Cw\*15**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- The mother was A02- and carried a variant form of the epitope, MThNPPIPV, which she passed to her A02+ child. This form persisted in her child for 12 months.

**HXB2 Location** p24 (118–126)**Author Location** Gag (282–290)**Epitope** MTNPPPIPV**Immunogen** HIV-1 infection**Species (MHC)** human (A2 supertype)**Keywords** supertype, rate of progression**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertype alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STL.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- To characterize HIV-1 proteome areas that are targeted in early, effective CTL responses, two cohorts were studied. Responses in early infection were against fewer epitopes and of lower magnitude than during chronic infection. While no region of the proteome was favored, Nef was the predominant target based on length of proteins. When based on the expression of protective versus nonprotective HLA I alleles, it was found that HLA-B27 and -57 possessing slow progressors to disease directed the majority of their responses to Gag in early infection, as opposed to those with HLA-B\*3501 or B\*3502, i.e. rapid progressors to AIDS, who had negligible responses to Gag. As compared with HLA-B57-/B27-subjects and HLA-B35 subjects, HLA-B57+/27+ subjects responded most to the p24 component of Gag. By using overlapping peptides within Gag p24, two were picked as being consistently targeted, and both contained previously described epitopes TW10 and KK10.
- PPIPVGDIY, i.e. epitope PY9 was targeted in 10% of rapid progressors to disease.

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polypeptide string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polypeptide string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  ELISPOT assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polypeptide region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polypeptide string Wee *et al.* [2002].

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence in this person matched the known epitope. In another D subtype infected individual, it was predicted to be a B53 epitope based on HLA typing of the individual and motifs within the reactive peptide.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J.Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.

- This frequently targeted overlapping peptide, PVGEIYKRWI-ILGLNKIV, was differentially targeted across ethnic groups and had an overall frequency of recognition of 22% - 30.5% AA, 42.3% C, 9.1% H, 4.8% WI (P value = 0.001). This peptide is included in a 41 aa Gag-p24 highly reactive region to be used for vaccine design.

**Keywords** rate of progression, optimal epitope, HIV-2

**References** Leligdowicz *et al.* 2007

- To find the factors involved in attenuated disease course and long term non-progression, HIV-2 and immune control were studied. HIV-2 viral load was used as a predictor of patient survival. HIV-2 viral load correlated inversely with magnitude of IFN-gamma response, relative dominance of Gag-specific peptides' responses over other proteins' responses, and the breadth of different peptide-specific immune responses. The most frequently recognized peptides were in Gag protein, followed by Env and Pol, while Nef and accessory proteins (Vif, Vpx, Vpr, Tat and Rev) rarely elicited responses. The 6 most recognized peptides were clustered in a highly conserved region of Gag.
- This peptide, PVGNIYRRWIQIGLQKCV, was recognized by 9 out of 65 subjects. It is found in the 149 amino-acid long HIV-2 proteome region of Gag 175-323.

**Keywords** supervised treatment interruptions (STI), immunodominance, early treatment

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.

- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.

- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B8-GEI, that is associated with rapid progression to AIDS, and its natural as well as alanine-substituted variants are either not cross-recognized or show high inter-patient variability in cross-recognition. At lower peptide concentrations, efficiency of variant cross-recognition was reduced, even while interepitopic differences in variant cross-recognition efficiency were maintained. CTLs responding to this epitope expressed the same predominant TCR Vbeta family.

- Only 20% of CD8+ T-cells produce IFN- $\gamma$  and granzyme B simultaneously (Tc1a). Two additional subpopulations of HIV specific CD8 cells are found, each one constituting 30-40% of the CD8 cell pool. One of these (Tc1b) secretes IFN- $\gamma$  only, and the other one (Tc1c) secretes GzB only.
  - None of three patients responded to this peptide with GzB producing cells and one of the patients responded with IFN- $\gamma$  producing cells.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence matched the peptide.

- This study monitored epitope responses in HIV-1 infected minority women living in the United States.
- 24 epitopes were described – 8 were novel, 8 used new restricting elements but were previously defined epitopes, and 8 were previously described.

- Serial peptide truncations were used to define optimal epitopes for CTL cell lines isolated from 12 individuals, assayed by a Cr-release.
- Among HIV+ individuals who carried HLA B08, 3/6 (50%) recognized this epitope.

**HXB2 Location** p24 (128–135)**Author Location** p24 (128–135)**Epitope** EIYKRWII**Epitope name** EI8**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*08)**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** binding affinity, subtype comparisons, acute/early infection**References** Malhotra *et al.* 2007b

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, EI8 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen to both A- and C-clade variants. Anchor residues are at positions 4 and 5; while both A- and C- variants contain a change at position 1 to dIYKRWII.

- Maturation phenotypes of CTLs were compared between HIV-1 Controller and Progressor subjects. Controllers were found to recognize a median of 18 epitopes compared to 15 by Progressors. While Controllers certainly had higher frequencies of terminally differentiated effector CTLs (CD45RA+/CCR7-), Progressors had higher mean frequencies of CD45RA-/CCR7- effector memory, CD45RA-/CCR7+ central memory (statistically significant) and CD45RA+/CCR7+ naive CTLs. No correlation was seen between CTL effector phenotype and either HLA-type or epitope.

- B\*08-restricted epitope EIYKRWII does not correlate with any particular CTL maturation phenotype.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80 tetramers in complex with epitopes to KIR3DS1 transiently expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.
- This epitope, DIYKRWII (MHC Class I restriction, serotype Bw6) complexed with MHC B\*0801 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C.

- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2–39) epitopic regions were targeted in an average of 6 proteins (range, 1–8). HAART resulted in decrease in antigen and reduction in gamma IFN Elispot responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that

persistent CTL through late disease do not exert strong immune selection pressure, yet the Elispot assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.

- 3 subjects recognized this epitope with intermediate functional avidity. Autologous sequence revealed one substitution, Diyrkwil, in 1 of the 3; this version of the epitope also had intermediate functional avidity with the donor's cells.

**HXB2 Location** p24 (128–135)**Author Location** Gag**Epitope** EIYKRWII**Immunogen** HIV-1 infection**Species (MHC)** human (B8)**Country** Netherlands**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** HIV exposed persistently seronegative (HEPS)**References** Koning *et al.* 2004

- A high-risk seronegative group of 29 homosexual men showed reduced cellular in vitro susceptibility for HIV infection and enhanced production of RANTES compared to 15 men who went on to seroconvert. Significantly higher frequencies of HLA A\*11, A\*31 and Cw\*15 were also found in the high risk seronegative men. Both groups of men had low frequencies of HIV-1 specific CD8+ T-cells, which may signify exposure more than protection from infection.
- 3/9 HLA B8+ infection-resistant men, compared to 1/3 pre-seroconversion men who went on to become infected, reacted to this epitope.

**References** Jansen *et al.* 2005

- Number and responsiveness of CD8 T-cells directed to different Gag peptides presented by HLA-A2, -B8 and B57 were compared. It was shown that T-cells specific for an HLA-B57 peptide responded to a higher extent and more readily to antigenic stimulation than those specific for HLA-A2 and -B8 peptides did. Moreover, it was shown that the higher functionality of B57-restricted T-cells was not correlated to higher

number of epitope escape mutations in A2- and B8-restricted T-cells.

- Tetramer decay experiments indicate that the HLA-B57 peptide has a higher half-life than the A2 and B8 peptides. The authors point out that CD8+ T cells with high binding affinity may require less help.
- In 1/2 B8+ individuals that were sequenced, 2 epitope variants were present: E1YKRWII and r1YKRWII, but the form E1YKRWII was found most often.

**Country** United States, South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding

**Keywords** memory cells

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**Keywords** vaccine-induced epitopes

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.

- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.

- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was contained in the vaccine, the vaccinated patient recognized it after infection.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, acute/early infection

**References** Lichterfeld *et al.* 2007b

- Differences in early versus chronic AIDS include a decline in CTL number accompanied by a reducing viremia. Comparative analysis of such CTLs in this study show that early infection is characterized by a different clonotypic composition and higher functional avidity of CTLs followed by their selective depletion during transition to chronic disease. The total magnitude of CTL cytokine production is lower in early infection. Intraindividual, early CTLs' functional avidity for the same epitope decreases concomitantly with a reduction in clonotypic TCR repertoire especially of strongly activated and CD127lo, CD38+, Ki-67hi CTLs while progressing to chronic infection states.
- None of the target epitopes, including this epitope EIYKRWII seen in 2 patients, underwent sequence changes.

**Keywords** dynamics, acute/early infection, characterizing CD8+ T cells

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.

- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence in this person matched the known epitope.

**Keywords** escape

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- Epitope KRWILGLNK is B\*27-, non-B\*57-restricted.
- An N271H variant, KRWILGLhK, was found in resting CD4+ T cells and could elicit immune responses.
- An L268M variant, KRWIImGLNK, found in plasma virus elicited at least as great immune response as wild type virus.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- This epitope, KRWILGLNK, is invariant across CON A, B, C and M-Group sequences, as well as clade B COT and ANC sequences.

**HXB2 Location** p24 (131–140)**Author Location** p24 (131–140)**Epitope** KRWILGLNK**Epitope name** KK10**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*27)**Country** Switzerland**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** rate of progression, HLA associated polymorphism**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variants KkWIILGLNK and KRWIImGLNK/KRWIiGLNK at positions 2 and 6 were found. Phylogenetic analysis identified the leucine at position 6 to be under strong positive selective pressure.

**HXB2 Location** p24 (131–140)**Author Location****Epitope** KRWIILGLNK**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*27)**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** characterizing CD8+ T cells**References** Addo *et al.* 2007

- Maturation phenotypes of CTLs were compared between HIV-1 Controller and Progressor subjects. Controllers were found to recognize a median of 18 epitopes compared to 15 by Progressors. While Controllers certainly had higher frequencies of terminally differentiated effector CTLs (CD45RA+/CCR7-), Progressors had higher mean frequencies of CD45RA-/CCR7- effector memory, CD45RA-/CCR7+ central memory (statistically significant) and CD45RA+/CCR7+ naive CTLs. No correlation was seen between CTL effector phenotype and either HLA-type or epitope.
- B\*27-restricted epitope KRWILGLNK does not correlate with any particular CTL maturation phenotype even though Controllers had similar viral loads.

**HXB2 Location** p24 (131–140)**Author Location** p24 (131–140)**Epitope** KRWIILGLNK**Epitope name** KK10**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A\*02, B\*27)**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other**Keywords** rate of progression, acute/early infection, memory cells**References** Sabbaj *et al.* 2007

- CD127 hi memory CTLs were correlated with different patient groups - subjects with chronic HIV-1 infection or controllers or those treated early with ART. For patients with chronic infection, CD127 hi CTL levels decrease greatly. Early ART treatment alone maintained these long-lived memory T cells.
- In response to epitope KK10, KRWIILGLNK, IFN-gamma was produced by CD127 lo cells in chronic patients without viremia. IL-2 and TNF-alpha were not secreted. In patients with early ART, IFN-gamma was secreted by both CD127 hi and lo cells before treatment but was maintained in CD127 hi cells after treatment. CD127 hi cells were responsible for producing IL-2 and TNF-alpha after ART.

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**References** Betts *et al.* 2005

- A vaccinated HIV-negative individual exhibited features predicted to be necessary for vaccine-induced protection: killing ability, cytokine production, multifunctionality, proliferative capacity, polyclonality, memory phenotype, and a CD8 T-cell response directed against a highly immunodominant epitope correlated with long-term nonprogression. In spite of this, the subject became infected with HIV through homosexual contact. The subject progressed more rapidly than expected for an HLA-B27-positive individual.
- After infection, CD4+ and CD8+ T cells acquired functional characteristics typical of chronic HIV infection. The infecting virus escaped the vaccine-induced T-cell response with an R264G substitution, KgWIIILGLNK, which diminishes binding to B27, between the second and third year of infection.

**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B27-KRW is very strongly associated with delayed disease progression and its alanine-substituted variants are highly efficiently cross-recognized.

**Keywords** binding affinity, escape, dendritic cells, immune evasion  
**References** Lichterfeld *et al.* 2007a

- A variant of this epitope KK10, KRWIImGLNK (L6M), arises due to CTL escape and increases binding to Immunoglobulin-like transcript-4 (ILT4), leading to functional inhibition of DCs. Not only was KK10-L6M not recognized by CTLs but other variants like R2K and R2T were. During chronic infection, this variant recruited an alternative TCR $\alpha$  and  $\beta$ , being immunogenic enough to elicit a de novo CTL response. Finally, enhanced binding of this HLA-B\*2705-KK10-L6M complex to ILT4 occurred, resulting in an impairment of DC function as measured by the markers HLA-DR, CD83, CD40, CD180 and CD86.

 • HLA-B\*2705 is associated with slow HIV disease progression.  
 • 11/11 HLA-B\*2705 donors make a response to this epitope, usually an immunodominant response.

- This is a highly conserved epitope.
- The HLA-B\*2705 binding motif includes R at position 2, and L in the C-term position.
- Goulder *et al.* [1997a] is a review on CTL immune escape that discusses this epitope in the context of the difficulty in detection of immune escape – KRWIILGLNK and an R2K change, KKWIILGLNK, show little difference in titration curves, yet the K2 variants fail to bind to targets for more than 1 hour, while the R2 form can sensitize lysis by CTL for over 24 hours – minigene transfection experiments confirmed the importance of this for the CTL response.

- 85% of B27+ adults have CTL that recognize this epitope, but only 2/6 children did.
- Responses to this dominant B27-restricted Gag epitope are present during the time of decreasing viral load in acute infection.
- Three children who shared B27 with their mothers did not respond to this epitope and inherited escape mutations from their mothers.
- A transmitted R132T anchor residue mutation abrogated binding to B27.
- In the three children infected with the non-binding KK10 variants, the dominant CTL specificity was still HLA-B27-restricted, but it was directed against an epitope in p17, IRL-RPGGKK, only rarely recognized in adults when KRWIIILGLNK is the dominant response.

- Mutations in this epitope were observed in autologous clones of subjects who were B27-positive with a higher frequency than those who were B27-negative ( $P = 0.0005$ )
- These mutations are being sexually transmitted in adult infections.

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.

- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.

- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.

- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.

- Breakdowns of epitope responses were shown for 4 individuals. Patient C displayed the greatest response to B27-KK10(p24), and in decreasing order also responded to A24-RW8(Nef), B7-IL9(gp41), A24-RL9(gp41), A24-YL8(gp41), and B7-TM9(Nef). Patient D also displayed the greatest response to B27-KK10(p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

- Viral load in a perinatally infected child remained low until emergence of an escape variant (kTwiiIgLnk) in the immunodominant CTL epitope KRWIIILGLNK when the child was 7.4 years old. The emergence of this escape mutation was followed by an increase in viremia and an increase in the number of targeted CTL epitopes, measured again when the child was 9.2 years old. The timing suggests that the loss of recognition of this epitope may have resulted in the subsequent loss of immune control.
- The mutation krwiiMglnk has been suggested to be compensatory and required for the emergence of the previously described escape mutation kKwiiMglnk (Kelleher 2001). The L136M mutation does appear in this child, but not in conjunction with the R132T escape mutation.

**References** Pillay *et al.* 2005

- HIV-specific CTLs in infants were shown to be able to select for viral escape variants early in life, despite a lack of escape with the same CTL specificity in the mother. Infant CTL responses may be compromised by transmission of escape variants that arose in the mother and also those that arose in the father, if the father was the source of the mother's infection.
- A B27 escape footprint was passed from a B27+ father to his partner, who then passed the variant to their child. KRWIIILGLNK is the B consensus form of this epitope, the paternal form was KqWIIiGLNK, the maternal form, KqWvImGLNK, and this was the form passed on to the child.

- B27-positive subjects have an immunodominant response to Gag epitope KRWILGLNK, with R264 KrWILGLNK being a crucial anchor residue. Among a group of 20 long-term non-progressive B27-positive subjects, 14 carried wild-type sequence, 5 carried known escape mutants (K264 or G264), and 1 carried a novel Q264 mutant. This mutant was also shown to be a likely escape mutation. These escape mutations all lower the affinity for B27 binding; the Q264 variant has 30-fold lower binding affinity.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognized epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.
- This epitope, KRWILGLNK (KK10), elicits the HLA-B27 restricted response that is most dominant of the immune responses generated.

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rates for this epitope, KRWIIMGLNK, were found in 3 subjects to be 0.002, 0.001 and 0.010/day, with SEs of 0.003, 0.003 and 0.011 respectively.
- The escape mutation was R132K in all cases.

- Since it is suggested that a single response to B27-KK10 epitope may be responsible for the association of HLA-B\*2705 patients with AIDS-free survival, B27-KK10-specific CTLs were compared to other HLA-specific CTLs in phenotype, function, clonal diversity, and antigen sensitivity in 47 treatment-naive infected slow or nonprogressing patients.
- cVL, the cell-associated viral load (number of infected cells harboring HIV DNA) correlated inversely with Gag-specific CTLs. This was most significant in HLA-B27 donors, and KK10 was identified as the peptide generating strongest CTL responses.
- B27-KK10-specific CTLs had no significant phenotypic differences from other epitope-specific CTLs upon testing a large panel of markers; however, they released higher proportions of IFN-gamma, TNF-alpha, MIP-1beta and CD107a upon antigenic stimulation.
- Both B27-KK10-specific and other HLA-specific CTLs had strikingly consistent domination of single clonotypes, as shown by analyses of TCRB gene expression. B27-KK10-specific CTLs showed no preferential usage of CDR3 motifs, indicating that they could be recognized by diverse clonotypes with differing binding properties. Over several years, B27-KK10-specific CTLs changed their dominant clonotype as compared to other CTLs. This temporal dominant clonal turnover was attributed to a decline in replicative capacity of

the dominant clonotype as seen by increases in CD57 expression, which is linked to replicative senescence.

- Studies involving functional avidity and different HLA-restricted responses proved that B27-KK10 responses had highest avidity. An inverse correlation between patient cVL and functional avidity of both dominant and highest subdominant responses suggested that functional avidity correlates with capacity to control HIV replication via infected cell elimination.
- Using the example seen in one patient, the authors stress the importance of maintaining protective stimulating activity of CTLs. When control by dominant clonotypes is lost, as in viral escape, ensuing viral replication is rapid.
- In one B27-positive patient studied, the dominantly-targeted epitope sequence changed over time from KRWIIMGLHK to KRWIILGLNK.

- To characterize HIV-1 proteome areas that are targeted in early, effective CTL responses, two cohorts were studied. Responses in early infection were against fewer epitopes and of lower magnitude than during chronic infection. While no region of the proteome was favored, Nef was the predominant target based on length of proteins. When based on the expression of protective versus nonprotective HLA I alleles, it was found that HLA-B27 and -57 possessing slow progressors to disease directed the majority of their responses to Gag in early infection, as opposed to those with HLA-B\*3501 or B\*3502, i.e. rapid progressors to AIDS, who had negligible responses to Gag. As compared with HLA-B57-/B27-subjects and HLA-B35 subjects, HLA-B57+/27+ subjects responded most to the p24 component of Gag. By using overlapping peptides within Gag p24, two were picked as being consistently targeted, and both contained previously described epitopes TW10 and KK10.
- KRWIILGLNK, epitope KK10, is one of two immunodominant epitopes targeted during early infection in long term non-progressors to AIDS. Only in later phases of infection, after accumulation of compensatory mutations do most subjects develop variants.

- This commentary summarizes work by Lichtenfeld *et al.* [JEM Vol. 204: 2785-7 (2007)]. HLA-B27 restricted CTLs presented with epitope KK10 (KRWIILGLNK) are known to keep infection at bay in LTPs. However, a triple mutation resulting in viral escape can occur after several years. The mutations are L268M, R264K(T/G) and S173A. L268M occurs early in infection and becomes fixed when bound to HLA-B27, conferring unknown viral advantage that is suggested to be due to its 3-fold higher affinity for ILT4. This may result in impaired DC and monocyte function. It is thought that the triple mutations compensate for each other, stabilizing them.

- Differences in early versus chronic AIDS include a decline in CTL number accompanied by a reducing viremia. Comparative analysis of such CTLs in this study show that early infection is characterized by a different clonotypic composition and higher functional avidity of CTLs followed by their selective depletion during transition to chronic disease. The total magnitude of CTL cytokine production is lower in early infection. Intraindividual, early CTLs' functional avidity for the same epitope decreases concomitantly with a reduction in clonotypic TCR repertoire especially of strongly activated and CD127lo, CD38+, Ki-67hi CTLs while progressing to chronic infection states.
  - None of the target epitopes, including this epitope KRWIILGLNK seen in 1 patient, underwent sequence changes.

- Epitope KK10 in HLA-B27 slow progressors to disease varies late in infection, leading to AIDS. The predominant escape mutation for this epitope is R264K, and it severely compromises virus replication, late in reverse transcription but unrelated to capsid stability. This can be restored by an in vivo upstream compensatory mutation, S173A and modulation of CypA binding in the presence of cyclosporine A. However, the first mutation to arise is the L268M, a prerequisite compensatory mutation to R264K.
  - Four HLA-B27 subjects' virus were sequenced longitudinally to find that the KK10 epitope mutates from KRWIILGLNK (WT) to KkWIILGLNK (R264K), KRWIILGmNK (L268M), KkWIImGLNK (R264K/L268M), KRWIILGLNK (S173A), KkWIILGLNK (S173A/R264K), KkWIImGLNK (S173A/R264K/L268M) and KkWIImGLNK (A237T on R264K/L268M).

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

**HXB2 Location** p24 (134–142)**Author Location** Gag (Henan isolate)**Epitope** IILGLNKIV**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Country** China**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.

- After injection of an anti-HIV-1 lipopeptide vaccine and the booster injections, a response was observed in >85% of 28 volunteers, and a long-term immune response was observed in >50% of the volunteers. A positive effect of QS21 adjuvant was found for B- and CD4+T-cell responses. A higher number of CD8+ T-cell epitopes was induced after a fourth boost injection. This epitope was one of the 31 epitopes that the vaccinated volunteers responded to.

**HXB2 Location** p24 (134–143)**Author Location** p24 (subtype B)**Epitope** IILGLNKIVR**Subtype** B**Immunogen** HIV-1 exposed seronegative**Species (MHC)** human (A33)**Keywords** subtype comparisons**References** Rowland-Jones *et al.* 1998b

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi – these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.
- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among A, B and D clade viruses.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, ILGLNKIV, was detected within overlapping peptide PVGEIYKRWIIILGLNKIV.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized—the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized. A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- This epitope, GLNKIVRMY, is invariant across CON A, B, C and M-Group sequences, as well as clade B COT and ANC sequences.

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.

- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.

- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, GLNKIVRMY, was predicted to be restricted by HLA A\*0203, A1, B\*1501.

- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2-39) epitopic regions were targeted in an average of 6 proteins (range, 1-8). HAART resulted in decrease in antigen and reduction in gamma IFN ELISPOT responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that

persistent CTL through late disease do not exert strong immune selection pressure, yet the Elispot assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.

- 1 subject recognized this epitope with intermediate functional avidity. The autologous sequence matched the B consensus.

- CTL epitope responses were mapped in 21 men within 15–92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN- $\gamma$  secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.

- The autologous form of the GY9 matched the B clade consensus form of the epitope, GLNKIVRMY, throughout the 5 years of study.

**Epitope** GLNKIVRMY  
**Subtype** B, CRF01\_AE  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (B62)  
**Country** Viet Nam  
**Assay type** HLA binding  
**Keywords** subtype comparisons, computational epitope prediction, vaccine antigen design  
**References** Lazaro *et al.* 2005

- The most common HLA-alleles in the Vietnamese population were found to be HLA-A11, A02, A33, B75, B46, and B62. Several epitopes cluster in short regions in Gag and Nef that are presented by these HLA molecules; these epitopes may be useful targets for vaccine antigens. In a comparison of CRF01\_AE sequences to HXB2, 14 mutations were found in epitopes in these Gag and Nef pluriepitopic regions; 7 did not affect the HLA binding score, 3 increased it, and 4 reduced it.
- GLNKIVRMY is the epitope in the HXB2 reference strain sequence, and is also the most common form in CRF01.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, DIRQGPKEPFR, was detected within overlapping peptides SILDIRQGPKEPFRDYV and GPKEPFRDYVDRFYKTLR.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].

- This peptide, GPKEPFRDYVDRFYKTLR differs from the consensus C sequence GPKEPFRDYVDRFfKTLR at 1 amino acid position, i.e. by 5.6%.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, GPKEPFRDYVDRFYKTLR, had an overall frequency of recognition of 16.7% - 18.6% AA, 11.5% C, 15.9% H, 14.3% WI. This peptide is included in a 43 aa Gag-p24 highly reactive region to be used for vaccine design.

- A codon optimized gag DNA vaccine was compared to a myristylation defective gag and p24 alone, both of which lack signals for secretion from transfected cells. Gag-derived immunogens that were secreted as VLPs and those that remained intracellular (p24) each produced strong CTL responses, and neither the size of antigen nor cellular trafficking and localization significantly influenced the strength of humoral and cellular immune activation. The formation and release of VLPs was not essential for eliciting strong CTL. BALB/c mice were given the DNA vaccine by i.m. administration of plasmid DNA for the prime and boost.
  - Minigenes were made incorporating just 1 epitope, minitopes, carrying 1 of 3 murine class I epitopes linked to the Ad2-E3 protein-derived signal peptide to allow access of the epitope to the ER. Weak induction of cellular immune responses was observed, in contrast to the complex polyprotein. The E10F minigene did not produce a detectable CTL response.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, EPFRDYVDRF, is similar to human protein COPINE 5, sequence vPFRDYVDR.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*81)

**Country** Tanzania

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** subtype comparisons, immunodominance

**References** Geldmacher *et al.* 2007a

- To assess whether T-cell specific responses to Gag and Nef are biased towards infecting subtype recombination, 56 ART-naive subjects were studied using six overlapping peptide sets consisting 15-mer peptides, covering both proteins completely. A multi-region hybridization assay was employed. Overall, the best recognized epitope variant in terms of magnitude and breadth corresponded to infecting subtype, in this case usually type-C. Hot spots of CTL recognition in Gag were in p24, p17 and p15; hotspots against Nef were in its central, conserved region.
- Epitope variants EPFRDYVDRFf and EPFRDYVDRFy were studied as peptide sequences PK-EPFRDYVDRFf-KT (subtypes C and A) and PK-EPFRDYVDRFy-KT (subtype D) with 12.5% responders. Subtypes C and A were best recognized.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , CD4 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Chromium-release assay

**Keywords** subtype comparisons, epitope processing, immunodominance, cross-presentation by different HLA

**References** Masemola *et al.* 2004b

- Highly targeted regions in Gag for CD8+ T-cells were defined for individuals with C clade infections in South Africa. 9 specific epitopes within the most reactive regions were characterized. This is 1 of 5 novel epitopes that were found among subtype C HIV-1 from African patients who hadn't previously been identified in B clade infections. Some epitopes were shown to be promiscuous, presented by multiple class I restricting alleles. The HLA restricting element for this optimal epitope was not determined due to limited material.

**Keywords** characterizing CD8+ T cells  
**References** Kiepiela *et al.* 2004
- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
  - This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** Liu *et al.* 2006b
- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

**Author Location** p24 (293–302)  
**Epitope** FRDYVDRFYK  
**Immunogen** HIV-1 infection, HIV-1 exposed seronegative  
**Species (MHC)** human (B18)  
**Keywords** HIV exposed persistently seronegative (HEPS)  
**References** Kaul *et al.* 2001a
- Variants FRDYVDRF(Y/F)K are specific for the B,D/A,C clades.
  - ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.

- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B18 women, 3/4 HEPS and 1/9 HIV-1 infected women recognized this epitope, likelihood ratio 5.3, p value 0.04, and HEPS women tended to respond to FRDYVDRFY/FK, while infected women tended to respond to YPLTFGWCY/F.
- The dominant response to this HLA allele was to this epitope for all 3/4 HEPS cases and for the single HIV-1 infected women that responded to this epitope.
- Four epitopes were considered to be “resistant epitopes”, as they were preferentially reactive in HEPS women and so may confer resistance, and these were found in three different proteins: A2 ILK(D/E)PVHGV in RT, A\*6802 DTVLEDINL in Protease, B14 DLNM/TLN(I/V)V in p24 and B18 FRDYVDRF(Y/F)K also in p24.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.

*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade  
*HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human, macaque (B18)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**Species (MHC)** human

**Assay type** T-cell Elispot

**Keywords** supervised treatment interruptions (STI), immunodominance, early treatment

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- T-cell immune responses were examined in HIV-1 infected Ugandans. Similar levels of cross-clade responses for Gag, Env and Nef were observed. Higher frequencies of responses in conserved regions were found for Gag within a single clade, while areas with higher viral sequence variation had fewer detectable responses. Differential interclade sequence homologies between the Gag regions did not affect the respective level of cross-clade recognition.
  - The sequence contains a known epitope (FRDYVDRFYKTL), but the subject recognizing it does not carry HLAs of the previously-defined restriction. The isolated viral sequence was frdyvdrfykVlrae, from the patient that could recognize the peptide.

- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2-39) epitopic regions were targeted in an average of 6 proteins (range, 1-8). HAART resulted in decrease in antigen and reduction in gamma IFN ELISPOT responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that persistent CTL through late disease do not exert strong immune selection pressure, yet the ELISPOT assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.
- 1 subject recognized this epitope with low functional avidity. The autologous sequence matched the B consensus.

**Keywords** dynamics, acute/early infection, characterizing CD8+ T cells

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

**References** Hossain *et al.* 2003

- HLA-A\*3303 is a common HLA allele in east and southeast Asia. Pol, Gag and Nef SF2 proteins were scanned for potential A\*3303 epitopes. 99 potential epitopes were synthesized, and 52/99 bound to A\*3303. Six of these served as peptide-targets for lysis by PBMC from infected individual, and clones derived from 4 of these 6 could lyse HIV-vaccinia infected target cells, indicating proper processing.
- This epitope is one of the 2/6 peptides that could induce CTL responses in the PBMC of infected individuals, but was not properly processed in a vaccinia-HIV infected target cell.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, YVDRFYKTL, was detected within overlapping peptides SILDIRQGPKPEFRDYV and GPKEPFRDYV-DRFYKTLR.

- Cross-reactive responses were found in PBMC isolated from individuals infected with either B or CRF01\_AE clade viruses, as determined by Elispot assays of target cells expressing recombinant vaccinia viruses expressing HIV-1 gag, env, nef and pol from many clades.
- The Thai subject VAIP-4 demonstrated broad CTL cross-reactivity towards gag constructs derived from subtypes A, B, C, D, F, G, H, and CRF-01\_AE. Sequence alignments of this epitope showed conservation for clades B and D, and Y->F substitutions at position 6 for subtypes A, C, CDR01-AE, F, G, and H. YVDRFYKTL and the variant epitope YVDRFFKTL are recognized equally well.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, YVDRFFKTL, was predicted to be restricted by HLA A\*0203, A\*0204, A\*0207, A\*2601 and B\*3801.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was one of two used to illustrate how specific epitopes were characterized with regard to defining the optimal epitope and the HLA restricting element. HLA allelic associations in the population with peptide recognition was highly predictive of the epitope within the 15 mer.

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated

impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, YVDRFYKTLRAEQASQeV differs from the consensus C sequence YVDRFfKTLRAEQAtQdV at 3 amino acid positions, i.e. by 16.7%.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but

the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.

- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, YVDRFYKTLRAEQASQEV, had an overall frequency of recognition of 25.3% - 22% AA, 30.8% C, 31.8% H, 14.3% WI. This peptide is included in a 43 aa Gag-p24 highly reactive region to be used for vaccine design.

**References** Leligdowicz *et al.* 2007

- To find the factors involved in attenuated disease course and long term non-progression, HIV-2 and immune control were studied. HIV-2 viral load was used as a predictor of patient survival. HIV-2 viral load correlated inversely with magnitude of IFN-gamma response, relative dominance of Gag-specific peptides' responses over other proteins' responses, and the breadth of different peptide-specific immune responses. The most frequently recognized peptides were in Gag protein, followed by Env and Pol, while Nef and accessory proteins (Vif, Vpx, Vpr, Tat and Rev) rarely elicited responses. The 6 most recognized peptides were clustered in a highly conserved region of Gag.
- This peptide, YVDRFYKSLRAEQTDPVAV, was most frequently recognized at 20 out of 65 different subjects. Its responses can be both CD8 and CD4 T cell restricted.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, VS14 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen to both A- and C-clade variants. An anchor residue is at position 9; while both A- and C- variants contain a change at position 14 to VDRFYKTLRAEQAT.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**HXB2 Location** p24 (165–179)

**Author Location****Epitope** VDRFYKTLRAEQASQ**Immunogen** HIV-1 infection**Species (MHC)** human**Donor MHC** A3, A32; B38, B64**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** vaccine-induced epitopes**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was recognized by a placebo patient after infection.

**HXB2 Location** p24 (165–184)**Author Location** Gag (297–311)**Epitope** VDRFYKTLRAEQASQ**Epitope name** VQ15**Immunogen** HIV-1 infection**Species (MHC)** human (B\*57)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** escape**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- One subject responded to peptide VQ15, a non-B\*57-restricted peptide.

**HXB2 Location** p24 (166–174)**Author Location** p24 (166–174)**Epitope** DRFYKLTRA**Epitope name** DA9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*14)**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** binding affinity, subtype comparisons, acute/early infection**References** Malhotra *et al.* 2007b

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, DA9 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen to both A- and C-clade variants. An anchor residue is at position 2; while both A- and C- variants contain a change at position 4 to DRFFKLTRA.

**Keywords** vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naïve individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naïve T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, DRFFKTLRA, was predicted to be restricted by HLA B\*1402, B\*2701, B\*2702, B\*2703, B\*2704, B\*2705 and B\*2709.

- Variants DRF(F/W)KTLRA are specific for clades A/B.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B14 women, 0/4 HEPS and 6/7 HIV-1 infected women recognized this epitope, likelihood ratio 14.4, p value 0.004 and HEPS women tended to respond to DLNMMMLNIV/DLNTMLNVV, while infected women tended to respond to DRF(F/W)KTLRA.
- The dominant response to this HLA allele was to this epitope for all of the 6/7 HIV-1 infected women.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.

- References** Cao *et al.* 2003
- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
  - This epitope was recognized in two subjects early in infection, presented by B14 in each case.
  - All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
  - More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 1/14 CTL T-cell clones tested were specific for Gag/p24-DA9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 value for Gag/p24-DA9 was 100,000 pg/ml, it had the lowest avidity of the 14 tested.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** p24 (166–174)**Author Location** (B consensus)**Epitope** DRFYKTLRA**Epitope name** DA9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B14)**Donor MHC** A28, A29, B14, B44, Cw8; A25, A32, B08, B14, Cw7, Cw8; A03, B14, B60, Cw3, Cw7**Country** United States**Assay type** Cytokine production, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** assay standardization/improvement, memory cells, characterizing CD8+ T cells**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 3/9 individuals recognized this epitope, presented by HLA-B14.

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- This epitope was reactive, but escape mutations did not accrue in it over time.

**HXB2 Location** p24 (166–174)**Author Location** Gag (298–306)**Epitope** DRFYKTLRA**Epitope name** DA9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B14)**Donor MHC** A\*02, A\*68, B\*14, B\*52, Cw\*08, Cw\*12**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** escape, optimal epitope**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- A form of this epitope that elicited a diminished Elispot response, DRFYrTLRA, dominated the viral sequence for several years, and then reverted back to the B consensus form, DRFYKTLRA.

**HXB2 Location** p24 (166–174)**Author Location** p24**Epitope** DRFYKTLRA**Epitope name** DA9**Immunogen****Species (MHC)** (B14)**Keywords** review, immunodominance, escape, acute/early infection, early-expressed proteins, kinetics, viral fitness and reversion**References** Lichterfeld *et al.* 2005

- This review discusses the importance of 3 factors that impact the selection of immunodominant epitopes in acute HIV infection: i) the kinetics of viral protein expression, ii) the HLA class I background of the infected individual, and iii) the autologous sequence of the infecting virus. This is 1 of 12 peptides listed as immunodominant in acute HIV-1 infection.

**HXB2 Location** p24 (166–174)**Author Location** p24**Epitope** DRFYKTLRA**Epitope name** B14-DA9(p24)**Immunogen** HIV-1 infection**Species (MHC)** human (B14)**Assay type** CD8 T-cell Elispot - IFN $\gamma$

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi – these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.
- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among B and D clade viruses.

- The Clade A version of the epitope, DRFFKLTRA, was preferentially recognized by CTL.
- This epitope was recognized by two different exposed and uninfected prostitutes.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified.
- DRFYKTLRAEQ didn't vary. There was no response in acute infection to this epitope, but the response was detectable by early infection.

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm et al. [J. Virol. 78:2187-2200 (2004)].
- This peptide, LRAEQAsQeVKNWMTeTL differs from the consensus C sequence LRAEQAtQdVKNWMTdTL at 3 amino acid positions, i.e. by 16.7%.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, LRAEQASQEVEKNWMTETL, had an overall frequency of recognition of 22.7% - 20.3% AA, 46.2% C, 18.2% H, 9.5% WI. This peptide is included in a 43 aa Gag-p24 highly reactive region to be used for vaccine design.

- To find the factors involved in attenuated disease course and long term non-progression, HIV-2 and immune control were studied. HIV-2 viral load was used as a predictor of patient survival. HIV-2 viral load correlated inversely with magnitude of IFN-gamma response, relative dominance of Gag-specific peptides' responses over other proteins' responses, and the breadth of different peptide-specific immune responses. The most frequently recognized peptides were in Gag protein, followed by Env and Pol, while Nef and accessory proteins (Vif, Vpx, Vpr, Tat and Rev) rarely elicited responses. The 6 most recognized peptides were clustered in a highly conserved region of Gag.
- This peptide, LRAEQTDPVKNWMTQTL, was recognized by 11 out of 65 subjects. It is found in the 149 amino-acid long HIV-2 proteome region of Gag 175-323.

 • The ability of CTL effector cells was studied by expanding autologous HIV-1 Gag-specific CTL *in vitro*, and adoptively transferring them.  
 • The transferred CTLs migrated to the lymph nodes and transiently reduced circulating productively infected CD4+ T cells, showing that CTL move to appropriate target sites and mediate anti-viral effects.

 • A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using CD8+ cell IFNgamma production to measure responses.

- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient B displayed the greatest response to epitope B44-AW11(p24) and also responded to A32-PW10(RT) in both PB and LN samples, while a third response against epitope A32-RW10(gp120) was only detected in the LN sample.

**Keywords** variant cross-recognition or cross-neutralization  
**References** Draenert *et al.* 2004c
- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2-39) epitopic regions were targeted in an average of 6 proteins (range, 1-8). HAART resulted in decrease in antigen and reduction in gamma IFN Elispot responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that persistent CTL through late disease do not exert strong immune selection pressure, yet the Elispot assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.
  - 1 subject recognized this epitope with low functional avidity. The autologous sequence matched the B consensus.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype D Gag. The autologous epitope sequence had an D7E change, AEQASQeVKNW.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- HLA B\*5701 was found in a very high frequency in HIV-1 infected non-progressors, 11/13 (85%) versus 19/200 (9.5%) of progressors. Non-progressors tended to have an immune response that was highly focused on four p24 epitopes that were presented by B\*5701, ISPRTLNAW, KAFSPEVIPMF, TSTLQEIQGW, and QASQEVKNW.
- Only QASQEVKNW was recognized in all of the LTNP's tested.

**HXB2 Location** p24 (176–184)**Author Location****Epitope** QASQEVKNW**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5701)**Keywords** rate of progression, immunodominance**References** Migueles & Connors 2001

- CTL activity was monitored in 27 individuals, including 10 LTNP with an over-expression of HLA B\*5701 – these individuals have viral loads below the threshold of infection without therapy, and their CD8+ T-cell response tends to be focused on peptides that contain B\*5701 epitopes ISPRTLNAW, KAFSPEVIPMF, TSTLQEIQGW, or QASQEVKNW.
- CTL responses are broader in B\*5701+ individuals with progressive viremia than those that control viremia.
- The HLA-A\*0201 SLYNTVATL epitope response was not as strong in individuals that carried both A2, B57.

**HXB2 Location** p24 (176–184)**Author Location** Gag (308–316)**Epitope** QASQEVKNW**Epitope name** QW9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5701)**Assay type** Intracellular cytokine staining, Flow cytometric T-cell cytokine assay**Keywords** rate of progression, escape**References** Migueles *et al.* 2003

- cDNA Gag sequences from a set of 17 HLA-B\*5701+ progressors and 10 LTNPs were obtained, and the variation in four p24 B\*5701 epitopes examined. Sequence variants were more common ( $p < 0.01$ ) in the epitopes in the progressors (median 3, range 1-7) than LTNPs (median 2, range 0-4).
- In general use of the autologous protein in a target cell did not diminish the overall CD8+ T-cell responses.
- The substitution E312D (qasqDvknw) was common in progressors (8/17) and rare in LTNP (1/8) ( $p = 0.06$ ). qasqDvknw and qasqEvknw peptides were made; this mutation does not affect binding to B\*57. 2/4 progressors that carried only the D variant could not recognize the D variant peptide, but could recognize the E variant peptide, demonstrating immune escape.

**HXB2 Location** p24 (176–184)**Author Location** p24 (176–184)**Epitope** QASQEVKNW**Epitope name** QAS**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5701)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** rate of progression, TCR usage, variant cross-recognition or cross-neutralization, characterizing CD8+ T cells**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B57-QAS, that is very strongly associated with delayed progression to AIDS, and its alanine-substituted variants are weakly cross-recognized.

**HXB2 Location** p24 (176–184)**Author Location** (C consensus)**Epitope** QATQDVKNW**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5801)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** characterizing CD8+ T cells**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** p24 (176–184)**Author Location** Gag (308–316)**Epitope** QASQEVKNW**Epitope name** QAS**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5801, B53)**Country** Gambia**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** cross-presentation by different HLA, characterizing CD8+ T cells, HIV-2**References** Gillespie *et al.* 2005

- CD8 T-cell responses were evaluated and compared in HIV-1 and HIV-2 infected individuals. A significantly greater magnitude and breadth of Gag-specific responses were found in HIV-1 infected individuals, possibly because undetectable viral load in HIV-2 infected individuals. This study suggests that responses in HIV-2 infection reflect antigen load in plasma, as is the case in HIV-1 infection. No correlation was found between immune control of HIV-2 and the frequency of perforin-expressing virus-specific CD8 T-cells.
- QASQEVKNW is a HIV-1 epitope cross-presented by B53 and B\*5801. It was recognized in 4/4 B\*5801+ HIV-1 infected individuals, and 7/7 B53+ HIV-1 infected individuals. HIV-2 infected individuals preferentially recognized the B58 HIV-2 epitope TSTVEEQIQW, and B53 epitope TPYDIN-QML.

**References** Buseyne *et al.* 2001

- Exogenous presentation or cross-presentation of epitopes by antigen presenting cells (APC) without protein synthesis is an alternative pathway for CTL epitope processing that may be important in the initial generation of viral specific CTL.
- Dendritic cells treated with AZT to inhibit protein synthesis were able to elicit a strong specific CTL response in QASQEVKNW specific CTL clone 141 without protein synthesis, while macrophages demonstrated a decreased presentation efficiency.
- Exogenous Gag epitope presentation was Env-dependent and required receptor-dependent fusion.

**Epitope** QATQEVKNW

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative

**Species (MHC)** human (B53)

**Keywords** HIV exposed persistently seronegative (HEPS)

**References** Kaul *et al.* 2001a

- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B53 women, 1/2 HEPS and 7/9 HIV-1 infected women recognized this epitope.

**Author Location** p24 (308–316 subtype A consensus)

**Epitope** QATQEVKNM

**Subtype** A

**Immunogen** HIV-1 infection

**Species (MHC)** human (B53)

**Keywords** binding affinity, subtype comparisons

**References** Dorrell *et al.* 2001

- In clade A infected Gambians, three HLA-B53 epitopes were defined in Gag p24 using ELISPOT, tetramer, and cytotoxicity assays.
- Two of the new epitopes lacked the predicted P2 anchors, DTI-NEEAAEW and QATQEVKNM, and bound to B53 with high affinity, thus extending the anchor residue motif for B53 and the related B35.
- While S, T, and P could all fit into the HLA-B35 or HLA-B53 B pocket and form a hydrogen bond, A would not form a bond, so the authors propose compensatory interactions account for the high affinity of QATQEVKNM for B53.
- QATQEVKNM was recognized in 6/7 HLA-B53 subjects.
- Cross-recognition of QATQEVKNM was not studied here, but it was noted that both the A, QATQEVKNM, and B, QASQD-VKNW, subtype version of this epitope, are also presented by HLA-B57 and B58, common HLA alleles in Africans.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B53)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.

- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** binding affinity, immunodominance, optimal epitope

**References** Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope QASQEVKNN when restricted by HLA-B53, elicited a magnitude of response of 595 SFC with a functional avidity of 0.1nM and binding affinity of 9.7nM. When restricted by HLA-B57, it elicited a magnitude of response of 350 SFC with a functional avidity of 10nM and binding affinity of 157nM. When restricted by HLA-Cw04, it elicited a magnitude of response of 755 SFC with a functional avidity of 0.05nM.

**References** Draenert *et al.* 2004c

- CD8+ T-cell responses that persisted in individuals with advanced disease were studied; most of the optimal epitopes defined were recognized with intermediate to high avidity. On average 13 (range, 2-39) epitopic regions were targeted in an average of 6 proteins (range, 1-8). HAART resulted in decrease in antigen and reduction in gamma IFN EliSpot responses, suggesting active responses to autologous virus. The lack of mutations within most viral epitopes suggest that persistent CTL through late disease do not exert strong immune selection pressure, yet the Elispot assays show robust responses, suggesting to the authors that gamma IFN-based screening methods may not reveal functional CD8+ T-cell impairment in patients with AIDS.
- 2 subjects recognized this epitope with high functional avidity. Autologous sequence revealed no substitutions in this epitope compared to the B consensus.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** responses in children, mother-to-infant transmission

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from two infected people carrying subtype D Gag. The epitope sequence in one person matched the peptide, in the other had an E5D change, QASQdVKNW.

- This study compared CD8+ T cell EliSpot responses to 58 Gag peptides that were optimal epitopes, with responses to overlapping 15 mers that spanned Gag. When screening for HIV-1-specific CD8 T-cell responses from 49 HIV+ people, overlapping 15-mer peptide pools revealed several novel responses that would have been missed using predefined CD8 epitopes. However, the 15-mer pools often missed low-level responses

to predefined epitopes, especially when the epitope was located centrally in the 15-mer peptide, and the overall level of response to the 15 mers was generally lower (mean 1.4 fivefold dilutions lower, range 0–3).

- In one individual, a response to QASQEVKNW could be detected at a concentration of 0.2  $\mu$ g/ml, while a response to RAEQASQEVKNWMTE required 25  $\mu$ g/ml for detection.

- An SIV Gag DNA vaccine was studied in mice in order to enhance subdominant immune responses to the KV9 epitope, without compromising its immunodominant response to the Gag AL11 epitope. Both epitopes share a common MHC restricting allele. Novel vaccine strategies including anatomic separation and heterologous prime-boost were investigated to expand vaccine-elicited CTL responses. This was the first study of its kind using DNA gene-based vaccines.
- This immunodominant epitope, AAVKNWMTQTL (AL11), was omitted from the initial vaccination administered, rendering the mouse incapable of recognizing it or the mutated peptide AAVKaWMTQTL, and allowing instead a dramatic, sustained response to the subdominant epitope studied.
- The immunodomination of AL11 over the subdominant epitope (KV9) was found to be a local rather than systemic mechanism, depending on anatomic the site of vaccine administration.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- Epitope sequences for this epitope, VV11 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen only to the A-clade variant. Anchor residues are at positions 2, 9 and 10; while the C-clade variant contains a semi-conservative change at position 7 to VKNWMTdTLV.

**Assay type** Chromium-release assay  
**Keywords** epitope processing, escape  
**References** Yokomaku *et al.* 2004

- Epitope variants escaped from being killed by CTLs in an endogenous expression system although they were recognized when corresponding synthetic peptides were exogenously loaded onto the cells. Escape is thus probably due to changes that occur during the processing and the presentation of epitopes in infected cells.
- Epitope variant nSnpdckNi was not recognized when added exogenously or when processed endogenously, but the mutations were in anchor residues and presumably inhibited binding to B\*5101.

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occurred sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these epitopes, but this increased over time.

- T cell immune responses following STI were monitored in two chronically HIV-1 infected partners (A and B) who had contracted HIV-1 during 1992. STI induced strong transitory CD4+ and CD8+ T cell responses in both patients. The viruses remained very closely related over 10 years, despite the two individuals having different HLA types; the authors suggest the maintained similarity does not support a strong role for HLA driven HIV diversity as has been claimed in Moore *et al.* (Science 2002).
  - During the second treatment stop, patient A developed a strong proliferative response to p24, and multiple strong CD8+ T cell responses to Env, Pol, Gag and Nef. This patient was able to control viral load for two years follow up without therapy. Patient B developed a very weak CD4+ T cell response against p24 during breaks in therapy, and had CD8+ responses to two epitopes. Patient A: A01, A32, B\*1410, B15; Patient B: A\*3101, A68, B\*4403, B51.

**Keywords** rate of progression, escape  
**References** Oxenius *et al.* 2004b
- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0–80% as efficiently as the index peptide, and the relative efficiency of the variant epitopes increased using

PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.

- This was one of 8 reactive epitopes found not to vary over time.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
  - Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
  - This HIV-1 epitope, PDCKTILKA, is similar to human protein Deltex 4 homolog, sequence HPDCKTI.

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.

- The objectives of this study were to find antiviral epitopic determinants of Gag HIV-specific CTL response and to find 'host HLA-CTL response' correlations. By studying 56 ART-naive subjects including low viral load (LVL) responders, the authors show that subjects expressing the above "protective" HLA have broader Gag epitope recognition which may be abrogated if co-expressed with HLA-B alleles associated with rapid AIDS progression. Also, a negative linear relation was seen between Gag epitope numbers recognized and plasma viral load while a positive relationship was seen with CD4 T-cell count. Finally, LVL subjects recognized specific Gag regions at the N- and C-termini of the protein more often than peptides in the middle of the protein.
  - Epitope GPGATLEEM, supposedly presented by HLA-B\*8101 is strongly associated with LVL. However, the second position GpGATLEEM is highly variable.

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpr, Vpu and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, aAtLEEMMTACQGVGGPSH differs from the consensus C sequence gAsLEEMMTACQGVGGPSH at 2 amino acid positions, i.e. by 10.5%.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.

- Epitope sequences for this epitope, AK11 are invariant between CON B, COT B, ANC B and M-group. Cross-recognition is seen only to the A-clade variant. An anchor residue is at position 11; while the C-clade variant contains a semi-conservative change at position 9 to ACQGVGGPShk.

**References** Fukada *et al.* 2002

- Counterparts for eight known clade B HLA A\*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A\*1101 epitopes was recognized in a clade specific manner. Two other HLA A\*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- ACQGVGGPGHK was found to elicit clade-specific responses in clade B (ACQGVGGPGHK is most common in clades A and B) and clade E (acqvggpgshk is most common and is also common in clades C and D). ACQGVGGPGHK was recognized by CTL from 4/5 B clade infected Japanese

subjects, and acqgvggpShk from 3/7 E clade infected Thai subjects.

- The binding of the two variants to HLA A\*1101 was almost identical, but bulk CTL generated from individuals did not cross-react with the cross-clade peptides, indicating the lack of cross-reactivity was due to TCR specificity.

**Keywords** dynamics, acute/early infection, characterizing CD8+ T cells

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- GPSHKARVL is an optimal epitope.

**HXB2 Location** p24 (223–231)**Author Location** (224–232)**Epitope** GPSHKARVL**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*0702)**Assay type** Other**Keywords** HLA associated polymorphism**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- GPSHKARVL was a previously defined B\*0702 presented epitope that encompassed a B\*07- associated polymorphism, GPsHKARVL, in the third position.

**HXB2 Location** p24 (223–231)**Author Location** p24 (1858–)**Epitope** GPGHKARVL**Immunogen** HIV-1 infection**Species (MHC)** human (B\*0702)**Country** Australia**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** escape, HLA associated polymorphism**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore et al., *Science* 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The third position of this epitope GPgHKARVL has a mutational pattern that is correlated HLA B\*0702. This epitope was experimentally tested using IFN-gamma Elispot and functional avidity studies.

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- A strong negative association between B\*0702 and conservation of sequence is observed.

- To assess whether T-cell specific responses to Gag and Nef are biased towards infecting subtype recombination, 56 ART-naive subjects were studied using six overlapping peptide sets consisting 15-mer peptides, covering both proteins completely. A multi-region hybridization assay was employed. Overall,

the best recognized epitope variant in terms of magnitude and breadth corresponded to infecting subtype, in this case usually type-C. Hot spots of CTL recognition in Gag were in p24, p17 and p15; hotspots against Nef were in its central, conserved region.

- Epitope variants GPgHKARVL and GPgHKARVL were studied as peptide sequences ACQGVG-GPgHKARVL (subtypes C and D) and ACQGVG-GPgHKARVL (subtype A) with 12.5% responders. Subtypes C and D were best recognized.

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (B07), an additional HLA (B40) was statistically predicted to be associated with this epitope.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- Predicted epitope based on an HLA motif embedded in a reactive peptide from a person carrying a D clade Gag.

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- Only two epitopes were detected during acute infection in patient AC-06, B7 restricted gp41 epitope IPRRIRQGL and Gag GPGHKARVL. GPGHKARVL was the first targeted peptide, and remained immunodominant through the 34 month study period.
- 3/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 1/4 individuals had detectable responses to this epitope after STI.

**References** Almeida *et al.* 2007

- Since it is suggested that a single response to B27-KK10 epitope may be responsible for the association of HLA-B\*2705 patients with AIDS-free survival, B27-KK10-specific CTLs were compared to other HLA-specific CTLs in phenotype, function, clonal diversity, and antigen sensitivity in 47 treatment-naïve infected slow or nonprogressing patients.
- cVL, the cell-associated viral load (number of infected cells harboring HIV DNA) correlated inversely with Gag-specific CTLs. This was most significant in HLA-B27 donors, and KK10 was identified as the peptide generating strongest CTL responses.
- B27-KK10-specific CTLs had no significant phenotypic differences from other epitope-specific CTLs upon testing a large panel of markers; however, they released higher proportions of IFN- $\gamma$ , TNF- $\alpha$ , MIP-1 $\beta$  and CD107a upon antigenic stimulation.
- Both B27-KK10-specific and other HLA-specific CTLs had strikingly consistent domination of single clonotypes, as shown by analyses of TCRB gene expression. B27-KK10-specific CTLs showed no preferential usage of CDR3 motifs, indicating that they could be recognized by diverse clonotypes with differing binding properties. Over several years, B27-KK10-specific CTLs changed their dominant clonotype as compared to other CTLs. This temporal dominant clonal turnover was attributed to a decline in replicative capacity of the dominant clonotype as seen by increases in CD57 expression, which is linked to replicative senescence.
- Studies involving functional avidity and different HLA-restricted responses proved that B27-KK10 responses had highest avidity. An inverse correlation between patient cVL and functional avidity of both dominant and highest subdominant responses suggested that functional avidity correlates with capacity to control HIV replication via infected cell elimination.
- Using the example seen in one patient, the authors stress the importance of maintaining protective stimulating activity of

CTLs. When control by dominant clonotypes is lost, as in viral escape, ensuing viral replication is rapid.

- GPGHKARVL, was a dominant epitope found in non-B27-KK10 CTL responses.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

**Epitope** VLAEAMSQV

**Epitope name** Gag-VV9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2)

**References** Sabbaj *et al.* 2003

- Among HIV+ individuals who carried HLA A02, 3/29 (10%) recognized this epitope.

- HXB2 Location** p24-p2p7p1p6 (230–7)  
**Author Location** Gag (362–)  
**Epitope** VLAEAMSQV  
**Epitope name** Gag362(9L)  
**Immunogen** HIV-1 infection, vaccine  
*Vector/Type:* peptide *Adjuvant:* Incomplete Freund's Adjuvant (IFA)
- Species (MHC)** human, transgenic mouse (A2)  
**Assay type** T-cell Elispot, Chromium-release assay, Flow cytometric T-cell cytokine assay  
**Keywords** binding affinity, subtype comparisons, computational epitope prediction  
**References** Corbet *et al.* 2003
- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A\*0204, immunogenicity in HLA-A\*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
  - This peptide was a good A2 binder that induced CTL and CD8+ T-cell IFN gamma responses in mice. Responses were detected in 1/17 HIV+ HLA-A2 subjects.
  - The variant vlaeamsqA was also immunogenic in A2 transgenic mice, eliciting a CD8+ T-cell response, as was recognized in 3/17 HIV+ people, including the person that recognized the vlaeamsqV variant.

**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion  
**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- The mother was A02+ and carried a variant form of the epitope, VLAEAMShV, which she passed to her A02- child. This form persisted in her child for 15 months.

- HXB2 Location** p24-p2p7p1p6 (230–7)  
**Author Location** p24  
**Epitope** VLAEAMSQV  
**Epitope name** A2-VV9(gp24)  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A2)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** rate of progression, immunodominance, early-expressed proteins  
**References** Altfeld *et al.* 2006
- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
  - The most frequently recognised epitopes also elicited the greatest CTL response.
  - HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
  - HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
  - In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- HXB2 Location** p24-p2p7p1p6 (230–7)  
**Author Location** p2p7p1p6 (362–370 Henan isolate)  
**Epitope** VLAEAMSQV

**Immunogen** HIV-1 infection  
**Species (MHC)** human (A2)  
**Country** China  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**References** Gong *et al.* 2006
- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.

- While VLAEAMSQV was described previously to have strong CTL response in HLA-A2 individuals, in this study 8 of 13 (61%) A2-positive individuals demonstrated moderate response to this peptide.

**HXB2 Location** p24-p2p7p1p6 (230–7)

**Author Location** Gag (397–405)

**Epitope** VLAEAMSQV

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind all five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802)

**HXB2 Location** p24-p2p7p1p6 (230–8)

**Species (MHC)** human (A2)

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding

**References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.
- VLAEAMSQVT was among 5 most recognized peptides (69%).

## II-B-5 Gag p2p7p1p6 CTL/CD8+ epitopes

**HXB2 Location** p2p7p1p6 (1–10)

**Author Location** p2p7p1p6 (1903–)

**Epitope** AEAMSQVTNS

**Epitope name** A\*3101 KR9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*4002)

**Country** Australia

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape, HLA associated polymorphism

**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- Mutational patterns in the ninth position, AEAMSQVTnS, in this epitope are correlated with the host carrying HLA B\*4002.

**Species (MHC)** human (A\*02)

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** assay standardization/improvement, optimal epitope

**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, SQVTNSATI, was detected within overlapping peptide EAMSQVTNSATIMMQR.

**HXB2 Location** p2p7p1p6 (5–13)

**Author Location** Gag (SF2)

**Epitope** SQVTNPANI

**Immunogen** vaccine

*Strain:* B clade SF2 *HIV component:* Gag

**Species (MHC)** mouse (H-2D<sup>b</sup>)

**References** Paliard *et al.* 1998

- HIV-1 (SF2)p55gag vaccination of H-2 mice activates a CTL response against this epitope.

- CTL that recognized SQVTNPANI in the context of H-2D<sup>b</sup> cross-reacted with H-2 alloantigens H-2L<sup>d</sup> and an unidentified self-peptide.
- A postulate: heterozygosity at the MHC level could prevent the maturation of some T cell receptor combinations for foreign peptide and self-MHC constructs because of thymic depletion and tolerance.

**HXB2 Location** p2p7p1p6 (8–17)

**Author Location** Gag

**Epitope** TNSANIMMQR

**Epitope name** TR10

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Donor MHC** A28, A29, B14, B44, Cw8

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion

**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 5, tnsaSimmqr, was found in the most polymorphic residues in the epitope. One escape mutation, at position 2, tTsanimmqr, was found not to correspond to the most polymorphic residues in the epitope. This is a novel partially mapped epitope.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** vaccine-induced epitopes

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85–86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

- Cross-clade CTL responses in 10 non-B HIV-1 infected individuals were evaluated. T-cell reactivity was tested against peptide pools of clade B Gag, Pol, Nef, Rev and Tat. Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- This previously described epitope was embedded in a B clade peptide that was recognized by T-cells from an infected person carrying subtype G Gag. The autologous epitope sequence had 2 changes, an E8T substitution and a two amino acid insertion, QG at position 10, that could impact the anchor: HQMKDC-NtRqgQAN.

- T-cell responses to clade B Gag peptides were tested using sequences based on consensus (CON), most recent common ancestor (CON) and center of tree (COT); as well as CON sequences from clade A, clade C and M-group Gag. It was found that Gag-specific cross-clade T-cell IFN-gamma responses are detectable during primary infection, and there was no significant difference in breadth or magnitude of responses with the different peptide sets. While several epitopes in low diversity domains are invariant across clades, other recognized variants are seen outside HLA anchor positions. T-cell immunity often tolerates conservative or semi-conservative amino acid substitutions but changes presumed to be in TCR contact sites may abrogate epitope recognition.
- This epitope, CTERQANFL, is invariant across CON A, B, C and M-Group sequences, as well as clade B COT and ANC sequences.

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was contained in the vaccine, the vaccinated patient recognized it both before and after infection.

- To determine whether HLA-B\*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B\*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B\*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.
- Mutations in this epitope, RQANFLGKI, were seen at K436R i.e. to RQANFLGRi as well as at I437VLM i.e. to RQANFLGKv, RQANFLGKI and RQANFLGKm. These C-terminii variants may compromise viral fitness by interference with protease cleavage between p7 and p1.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757–68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.

- This immunodominant, frequently targeted overlapping peptide, RQANFLGKIWPSHKGR, had an overall frequency of recognition of 23.3% - 18.6% AA, 30.8% C, 31.8% H, 9.5% WI. This peptide is included in a 27 aa Gag-p15 highly reactive region to be used for vaccine design.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Two patients developed responses to epitope FLGKIWPSHK during primary infection and one after primary, during early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, *Science* 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The seventh position (K), KIWPSYkGR, is an HLA-A\*3101 correlated amino acid. The susceptible form of this epitope is KIWPSYKGR, whilst the escape form is KIWPSYrGR, as indicated by the mutational patterns; this was validated experimentally using IFN-gamma Elispot and functional avidity studies.

**Epitope** GNFLQSRPTAPPF  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A2)  
**Country** Spain  
**Assay type** proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay  
**Keywords** HAART, ART, supervised treatment interruptions (STI), immune dysfunction  
**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.
- Less than 2 of 19 patients recognized this epitope.

**HXB2 Location** p2p7p1p6 (83–97)  
**Author Location** Gag (453–462 BH10, LAI)  
**Epitope** GNFLQSRPEPTAPPF  
**Immunogen** HIV-1 infection  
**Species (MHC)** human  
**References** Maksiutov *et al.* 2002

- This study employs an antigenic similarity matrix to compare HIV-1 antigenic determinants with human proteins.
- This CTL epitope (the HIV-1 LAI fragment with high similarity to a human protein overlapping this epitope is PEP-TAPPFLQ) has similarity with the T-cell surface glycoprotein CD5, fragment PEPTAPPRLQ.

**HXB2 Location** p2p7p1p6 (85–94)  
**Author Location** Gag (448–457 Henan isolate)  
**Epitope** FLQSRPEPTA  
**Subtype** B  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A2)  
**Country** China  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding  
**References** Gong *et al.* 2006

- CTL responses were studied in treated and untreated donors from China, using Gag peptides from Henan isolate. All peptides were predicted to have A2 or A11 restriction (two of the most prominent alleles in Chinese population) and HLA restriction was further analyzed by CTL recognition in patients carrying corresponding allele. Among treated donors, HLA-A2 donors had higher CTL response than HLA-A11 donors. Chronically infected untreated individuals had higher magnitude of CTL response than treated ones.
- Newly identified HLA-A2-restricted epitope.
- FLQSRPEPTA was among 5 mostly recognized peptides (77%).

**References** Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- A response to this epitope was detected before superinfection but diminished afterward. The epitope in the infecting and superinfecting strain had the sequence: kelyplAsl. The second infecting strain had a 4-amino acid insertion proximal to the epitope, RGIDkelyplAsl.

**Keywords** escape, HLA associated polymorphism

**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, *Science* 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The mutational patterns in the second position in the HLA B\*4001 epitope KELYPLTSL are correlated with the host carrying HLA B\*4001.

**HXB2 Location** p2p7p1p6 (118–126)**Author Location** Gag p6 (481–489)**Epitope** KELYPLTSL**Epitope name** KL9**Immunogen** HIV-1 infection**Species (MHC)** human (B40)**Donor MHC** A\*02, A\*32, B\*07, B\*40, Cw\*03, Cw\*07**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- A B40+ mother carried the KEmYPLaSL variant of the epitope and transmitted it to her B40- infant. The variant form continued to dominate the infant's sequences at months 3 and 15.

**HXB2 Location** p2p7p1p6 (118–126)**Author Location** p15**Epitope** KELYPLTSL**Epitope name** B40-KL9(p15)**Immunogen** HIV-1 infection**Species (MHC)** human (B40)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, immunodominance, early-expressed proteins**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.

- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** p2p7p1p6 (118–126)**Author Location** p15 (118–126 SF2)**Epitope** KELYPLTSL**Epitope name** p15-24**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B60)**Keywords** immunodominance, cross-presentation by different HLA**References** Yu *et al.* 2002b

- 26/57 HIV-1 infected subjects displayed Gag p15-specific CD8+ T-cell IFN $\gamma$  responses were measured by Elispot and intracellular staining. The immunodominant regions targeted by CD8+ T cells were mapped to three functional domains: the zinc finger structures, the protease cleavage site p7/p1, and to the Vpr binding site in p6.
- p15 contributed on average 17% of the total Gag response (range 0-100%).
- 3 optimal CTL epitopes were mapped within p15: KELYPLTSL, CRAPRKKGC, and FLGKIWPSYK.
- Four patients who were HLA-B60+ recognized KELYPLTSL.
- The binding motif for B60 is C-term Leu and 2nd position Glu.
- Four patients who did not carry HLA-B60 also recognized the 15 amino acid long peptide carrying KELYPLTSL, suggesting other epitopes in this immediate region can be presented by other HLA class I molecules.

Nine individuals demonstrated cross-reactive T-cell responses to clade A, B, and C Gag pools; 6/7 patients that responded to Nef-B also reacted to clade A and C Nef pools. An inverse correlation was observed between the sequence divergence of the HLA class I restricted epitopes and the height of the T-cell responses, which in Gag could be explained through variations in the HLA-anchor residues. 42% of the responses were directed to regions containing new epitopes.
- Predicted epitope based on an HLA motif embedded in a reactive peptide from a person carrying a D clade Gag.

## II-B-6 Gag CTL/CD8+ epitopes

**HXB2 Location** Gag

**Author Location**

**Epitope**

**Immunogen** computer prediction

**Species (MHC)** (A\*0201, B\*3501)

**Keywords** subtype comparisons, computational epitope prediction

**References** Schönbach *et al.* 2002

- Computational methods (artificial neural networks, hidden Markov models, binding matrices based on HLA association rates) were used to identify HLA-A\*0201 and HLA-B\*3501 HIV T-cell epitope candidates from 533 Gag, Env and Pol sequences of which 374 were derived from HIV-1, 97 were derived from HIV-2 and 62 from SIV. Comparisons to known epitopes and between clades were made.

**HXB2 Location** Gag

**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human (A\*0201, Cw\*08)**References** Shacklett *et al.* 2000

- HIV-1 specific, MHC class I-restricted CTL killing was detected in duodenal and rectal gut associated lymphoid tissue (GALT) sites from three infected individuals – the distribution of class I restricted CTL was different in the peripheral blood samples and GALT samples.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Assay type** Tetramer binding, Flow cytometric T-cell cytokine assay**Keywords** assay standardization/improvement**References** Wu *et al.* 2005

- A flow cytometric assay for validation of HIV-1 gag- or pol-specific- CD8/HLA-A2 T-cells was shown to be sensitive and specific, being able to detect HIV-1 CTL at the single T-cell level. An inverse correlation between HIV plasma viremia and gag- and pol-specific-CD8/HLA-A2 T-cells was observed.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*35)**Keywords** rate of progression**References** Jin *et al.* 2002

- Patients with HLA-B\*35 variants B\*3502, B\*3503, B\*3504, and B\*5301 tend to proceed to AIDS more quickly than those with B\*3501.
- Of 32 patients with HLA-B\*35 alleles CD8+ CTL responses were quantified using an intracellular cytokine staining assay – 75% had responses to Pol, 69% to Gag, 50% to Nef, and 41% to Env.
- The overall magnitude of CTL responses did not differ between those bearing B\*3501 and the others. A higher percentage of Gag responses was observed in those that had lower RNA levels that carried B\*3501, and there was a negative association with viral load and CTL activity. The data is consistent with higher levels of CTL responses contributing to protection in B\*3501 individuals, but not in B\*3502, B\*3503, B\*3504, and B\*5301 individuals.

**HXB2 Location** Gag**Author Location****Epitope****Subtype** A, B, C**Immunogen** vaccine

**Vector/Type:** canarypox prime with gp120 boost, canarypox prime with gp160 boost  
**Strain:** B clade LAI, B clade MN, B clade SF2  
**HIV component:** Gag, gp120, gp41, Nef, Pol

**Species (MHC)** human (B60)**Keywords** subtype comparisons, vaccine-specific epitope characteristics**References** Ferrari *et al.* 2001

- Different HIV strains were used for different regions: gp41 LAI, Gag LAI, gp120 MN, gp120 SF2
- HLA-B60 responses dominated the responses against an Gag vaccine in an individual (022G0Z) who was HLA A1, A11, B8, B60. The strongest response was against the MN peptide 107-136. Low level Gag responses were observed against B8 and A11 epitopes, no response was observed against A1 epitopes.
- Vaccinee 202T7 (HLA A2, B27, C25) made the strongest response to an epitope at positions 131-140 of Gag. The response was highly cross-reactive with D clade Gag expressed from vaccinia, less so with C, and only minimally cross-reactive with A and CRF01.

**HXB2 Location** Gag**Author Location** p24**Epitope****Immunogen** vaccine

**Species (MHC)** mouse (H-2<sup>bxd</sup>)**References** Otten *et al.* 2000

- CB6F1 were primed with gag DNA by im injection and challenged with vaccinia expressing Gag/Pol (rVVgag-pol)
- Gag-specific CTL responses were detected by IFN $\gamma$  secretion in the spleen, independent of the route (intraperitoneal, intranasal or intrarectal) of rVV gag-pol challenge.
- The gag DNA vaccine induced CTL responses in 4/4 monkeys 2 weeks post immunization, but antibody responses were detected in only 1/4 monkeys after 3 immunizations.
- CTL cross-reactivity against Gag sequences 1-80, 254-323, and 421-496 was observed, suggesting multiple CTL epitope recognition.

**HXB2 Location** Gag**Author Location** p24**Epitope****Immunogen** vaccine

**Vector/Type:** DNA  
**HIV component:** Gag

**Species (MHC)** mouse (H-2<sup>d</sup>)

**References** Qiu *et al.* 2000

- Mice were injected with plasmid DNA at 0, 2 and 4 weeks and lymphocyte proliferation was measured after 6 weeks with recombinant p24 protein.
- Secreted HIV-1 Gag expression vectors generated a stronger response than standard Gag or cytoplasmic Gag expression vectors.
- IFN-gamma levels were increased compared to an undetectable IL-4 response.
- CTL levels were also increased in secreted Gag expression vaccination studies.

**HXB2 Location** Gag**Author Location** Gag (SF2)**Epitope****Immunogen** vaccine*Vector/Type:* vaccinia *Strain:* B clade SF2  
*HIV component:* Gag, Protease**Species (MHC)** macaque, mouse (H-2<sup>d</sup>)**References** zur Megede *et al.* 2000

- Sequence-modified Rev-independent gag and gag-protease gene constructs lead to increased expression levels and elevated CTL and antibody immunogenicity in BALB/c and CB6F1 mice.
- A CTL response in mice could be detected after a single immunization with codon-optimized gag, using 2 ng of plasmid; wild type gag required 200 ng to detect a response.
- Recognition of 3 different Gag peptide pools was observed, indicating a polyclonal CTL response.
- Significant gag-specific CTL responses were detected in 4/4 rhesus monkeys, in contrast to 1/4 using wildtype gag.

**HXB2 Location** Gag**Author Location** p24**Epitope****Immunogen** vaccine*Vector/Type:* coxsackievirus *HIV component:* p24 Gag**Species (MHC)** mouse (H-2<sup>d</sup>)**References** Halim *et al.* 2000

- An avirulent recombinant coxsackievirus (CB4-P) construct was generated that can express p24 Gag sequences – CB4-P is attenuated even in immunodeficient mice and T help responses can be elicited from peptides embedded in a surface loop of the VP1 capsid.
- This paper describes the vaccine strategy and generation of constructs, and employs amino-terminal fusion of Gag sequences to the viral polyprotein with subsequent cleavage to elicit CTL responses via MHC class I presentation in BALB/c mice.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** vaccine*Vector/Type:* DNA *Strain:* B clade HXB2, B clade NL43 *HIV component:* Gag, Pol**Species (MHC)** mouse (H-2<sup>d</sup>)**References** Huang *et al.* 2001

- Different HIV strains were used for different regions: gag HXB2, pol NL43
- Mice were immunized with four humanized DNA constructs: GagPol, that would form a pseudoparticle carrying Gag and Pol, Gag, Pol or a GagPol fusion construct.
- The GagPol pseudoparticle, Gag and GagPol fusion construct all elicited strong anti-Gag CTL, but only the GagPol fusion construct elicited strong anti-Pol CTL.

**HXB2 Location** Gag**Author Location** Gag (HXB)**Epitope****Immunogen** vaccine*Vector/Type:* Listeria monocytogenes

*Vector/Type:* virus-like particle (VLP) *HIV component:* Gag

**Species (MHC)** macaque**References** Paliard *et al.* 2000

- CTLs primed by HIV-1 p55 gag virus-like particle (VLP) vaccination recognized epitopes in four different 20 amino acid peptides p17/4, p17/8, p24/13 and p14/9.
- Cytotoxic T cell response lasted greater than 8.5 months.

**HXB2 Location** Gag**Author Location** Gag (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human

**Keywords** rate of progression, Th1

**References** Wasik *et al.* 2000

- HIV+ infants that progressed rapidly to AIDS had lower Th1 responses and decreased production of beta-chemokines and IL-2 relative to other HIV+ infants.
- HIV+ infants had no demonstrable CTL at birth, but Th1 responses accompanied by CTL responses developed in children with slowly progressive disease, and not in rapid progressors.
- CTLp frequencies were determined by limiting dilution using autologous B cells infected with vaccina/HIV constructs.

**HXB2 Location** Gag**Author Location** Gag (LAI)**Epitope****Subtype** B**Immunogen** vaccine

*Vector/Type:* canarypox *Strain:* B clade LAI, B clade MN *HIV component:* Gag, gp41, Protease, V3

**Species (MHC)** human**References** Salmon-Ceron *et al.* 1999

- The vaccine used was a rec canarypox with HIV-1 gp120 MN, tm/gag/protease LAI (vCP205), alone or with p24E-V3 MN synthetic peptide (CLTB-36)
- Twenty HIV negative subjects were vaccinated in phase I trial with combinations of vCP205 and CLTB-36.
- Immunization with vCP205 induced HIV-1-specific ABs to gp120, V3, and p24 antigens, and CTL immune responses against vCP205 were detected after the fourth immunization in 33% of the subjects against Env, Gag and Pol, but the CLTB-36 peptide did not produce AB or CTL immune responses against p24 or gp160.

**HXB2 Location** Gag**Author Location** p24**Epitope****Immunogen** vaccine

*Vector/Type:* virus-like particle (VLP) *HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human**References** Klein *et al.* 1997

- Immunization of HIV+ people with an HIV-1 p17/p24 Ty virus-like particle (p24-VLP) resulted in a marginal, short-lived increased proliferative response to p24 and p17 and a transient elevation in viral load.

- Two of four subjects that received 500 or 1000 µg of p24-VLP had an increase in gag-specific CTL.

**HXB2 Location** Gag**Author Location** p24 (SF2)**Epitope****Immunogen** vaccine

*Vector/Type:* DNA *Strain:* B clade SF2 *HIV component:* gp120, p24 Gag *Adjuvant:* MF59, PLG

**Species (MHC)** mouse, baboon**References** O'Hagan *et al.* 2000

- PLG (Polylactide co-glycolide polymer) microparticles administered in MF59 emulsion induced gp120 Ab responses and CTL immune responses against p24 gag.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Lubaki *et al.* 1999

- Three strategies were used to analyze CTL activity: area under the net HIV-specific lysis curve (ACU), linear regression (LR) of net specific lysis, and the standard method, lytic units (LU20)
- A correlation between low HIV plasma viral load and increased levels of HIV-specific Gag and Nef CTL activity was observed using ACU and LR, but not LU20.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Kalams *et al.* 1999a

- The presence of HIV-1 p24-specific proliferative responses was positively correlated with Gag-specific memory CTL and negatively correlated with viral load in untreated subjects.
- Gag proliferative responses were the most readily detected – Gag CTL responses were the only responses with a significant correlation with Gag stimulated help, although there was a positive trend with Nef, Env and RT.

**HXB2 Location** Gag**Author Location** p55 (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Greenough *et al.* 1999

- 7/128 HIV-1 infected hemophiliac were identified as long-term non-progressors (LTNPs) and were monitored for viral and host immune parameters over 15 years – LTNPs maintained a low viral load, high frequencies of CTL precursors directed against Gag antigen and low levels of HIV-specific effector CTL activity – effector cell activity suggests low level ongoing viral replication.

**HXB2 Location** Gag**Author Location** Gag

**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Trickett *et al.* 1998

- Twelve HIV-1 infected patients were re-infused with their own lymphocytes, cryopreserved from an earlier time point in the infection.
- Improvement in CD4+ and CD8+ T cells was seen in 7/12, and an increase in the CTL response to Gag was seen in one patient.

**HXB2 Location** Gag**Author Location** Gag (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** rate of progression**References** Betts *et al.* 1999

- This study demonstrated an inverse correlation between HIV Type I plasma viral load and CTL activity directed against HIV-1 Pol, and stronger combined effects of Pol- and Env-specific CTL, in long-term survivors (LTS) of HIV-1 infection.

**HXB2 Location** Gag**Author Location** Gag (LAI)**Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**References** Legrand *et al.* 1997

- Seventeen recently infected patients were tested for CTL response to HIV proteins Env, Gag, Pol, Rev, Nef, Vif and Tat.
- An early response (within a month following PI) was noted in 87% of the subjects to Gag, 75% to Env, and 50% to Nef.
- Early responses to Pol, Rev, Vif and Tat were rare.

**HXB2 Location** Gag**Author Location** Gag (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** subtype comparisons**References** Betts *et al.* 1997

- 6/8 individuals from Zambia infected with C clade virus had CTL that were able to make response to B clade HIV-1 IIIB vaccinia-expressed Gag, Pol and Env proteins.
- A vigorous cross-clade response was not limited to a particular protein, and the level of recognition of different proteins varied among the six patients.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** De Maria *et al.* 1997

- CD3+ cells that also carry a natural killer cell receptor (NKR+) can exhibit down regulation of T cell function.

- Anti-NKR IgM MAb masked this inhibitory function and increased HIV-1 specific CTL activity in phytohemagglutinin-activated PBMC cultured in the presence of IL-2 from 3/5 patients, and in one other case anti-NKR MAb brought HIV-1 specific CTL activity to detectable levels.

- A general test of CD8 anti-viral activity was developed based on proviral load of coculture of autologous CD8+ cells with CD4+ cells after homogeneous superinfection with NSI virus.
- Significantly decreased the CD4+ T-cell proviral loads were found in 12 HIV+ slow progressors relative to 10 rapid progressors.
- Significant CD8+ mediated cytotoxicity directed against autologous cells infected with vaccinia carrying the HIV-1 gag gene was observed in slow progressors in contrast to rapid progressors, but no correlation was found between plasma viral load in 22/22 asymptomatic HIV infected individuals.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Young *et al.* 2001

- Addition of recombinant rec human IL12 (rhIL12) to cultures increased HIV-specific lysis of HIV-Gag, Pol and gp120 vaccinia expressed antigens (11/15 tested increased lysis by > 5%) if the culture was derived from HIV+ individuals who had CD4 cells/ul > 500.
- 2/10 individuals with <200 CD4 cells/ul, and 3/10 individuals with 200-500 CD4cells/ul, had an increase of >5% upon treatment of the culture with rhIL12, so a few individuals in late stage disease had CD8 cells that maintained responsiveness to rhIL12.

**HXB2 Location** Gag**Author Location** p24**Epitope****Immunogen** HIV-1 infection**Species (MHC)** mouse**References** de Quiros *et al.* 2000

- CB-17 SCID-Hu mice engrafted with peripheral blood mononuclear cells of four long-term nonprogressors (viral load < 50 copies/ml) displayed resistance to challenge with HIV-1 SF162, mediated by CD8+ T-cells and associated with proliferation in response to p24 – these patients did not have a higher level of HIV-1 specific immunity *in vitro*, so the mechanism is unknown.

**HXB2 Location** Gag**Author Location** Gag (subtype A, B, D)**Epitope****Subtype** A, B, D**Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** subtype comparisons**References** Cao *et al.* 2000

- HIV-1 subtypes A and D dominate the Ugandan epidemic, and a vaccine trial using B clade antigen is underway – this study addresses relative levels of cross-reactive CTL responses in HIV infected Ugandans to A, D, and B clade recombinant vaccinia viruses expressing Gag, Env, RT or Nef from HIV-1 clades A, B, and D.
- Proteins corresponding to the subtype of the infecting strains tended to trigger higher levels of CTL response measured by percent specific lysis, but there was extensive inter-subtype cross-reactivity with B clade proteins and the co-circulating subtype.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** White *et al.* 2001

- HIV-specific CTL activity was detected in the female reproductive tract of only 1/3 HIV-infected women who underwent a hysterectomy, although CTL could be identified in the PBMC of all three women.

**HXB2 Location** Gag**Author Location** Gag (HXB2)**Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**References** Chun *et al.* 2001

- Suppression of viral replication in the resting CD4+ T-cell reservoir by autologous CD8+ T-cells via CD4+/CD8+ cell contacts was observed in long-term nonprogressors and patients undergoing antiretroviral treatment, but this activity appears to be independent of Gag-specific CTL activity.

**HXB2 Location** Gag**Author Location** Gag (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** rate of progression

**References** Jin *et al.* 2000a

- The CTL precursor level (CTLp) was measured in long term non-progressors (LTNP) with low viral load using limiting dilution analysis and measuring CTL against Env Gag and Pol expressed in vaccinia in autologous targets.
- LTNPs have high memory CTL numbers and low viral load.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 exposed seronegative**Species (MHC)** human**Keywords** review, HIV exposed persistently seronegative (HEPS)**References** Rowland-Jones *et al.* 2001

- This is a review that summarizes observations about HIV-specific CTL found in the HIV-1 exposed persistently seronegative (HEPS) population.
- The CTL responses assayed by ELISPOT and by CTL precursor frequencies by limiting dilution analysis indicate that CTL in HEPS individuals tend to be of a lower magnitude than in chronic HIV-1 infections – the responses in HEPS cases are below the level of detection by tetramer assays.
- CD8+ CTL responses tend to be detectable in HEPS subjects only if they are recently exposed, and the response diminishes if exposure is reduced – it is not clear if there is a stable memory population in HEPS cases.
- CD8+ CTL responses in the HEPS population are associated with HIV-1 specific CD4+ T cell responses, assayed by proliferation assays, IL-2 secretion, and ELISPOT, and the authors consider the possibility that HIV-1-specific T-help responses improve the "quality" of the CD8+ response in HEPS individuals relative to HIV-1 infected individuals, who tend to have a poor HIV-1-specific T-help response.
- HIV-1 specific CD8+ CTL responses in HIV-1 infected individuals show reduced levels of perforin, and the T cells may not mature properly, and although similar studies have not been conducted in HEPS individuals this is considered as a possible difference in the CTL immune response in HEPS and HIV-1 infected people.

**HXB2 Location** Gag**Author Location****Epitope****Subtype** B**Immunogen** vaccine*Vector/Type:* DNA *HIV component:* Env, Gag, Pol**Species (MHC)** mouse**Keywords** review, vaccine-specific epitope characteristics**References** Nabel 2002

- Using DNA that had humanized codon usage, CTL responses to DNA vaccines containing either Gag, Pol, Gag-Pol fusion protein, or Gag-Pol pseudoparticles suggested that the greatest breadth and most potent response was to the Gag-Pol fusion protein. The Gag-Pol fusion lacks the Gag precursor protein required for viral assemble, so does not form releaseable particles; the author speculates that longer retention of the Gag-Pol protein within the cell may enhance antigen presentation.

- 2/3 infants infected in utero had detectable HIV-1 Gag and Env specific CTL responses, one by 4 months, one by 11 months of age. Levels of the responses varied at different time point. Pol responses were not detected.
- 2/4 infants infected intrapartum had detectable responses, one note until 11 months, one not until 42 months.
- HIV-specific CTL were not detected in ten HIV- infants that were born to HIV+ mothers.

**HXB2 Location** Gag**Author Location****Epitope****Immunogen** vaccine*Vector/Type:* canarypox prime with gp120*boost Strain:* B clade LAI, B clade MN*HIV component:* Env, Gag**Species (MHC)** human**References** Gupta *et al.* 2002

- Different HIV strains were used for different regions: Gag, LAI; gp120, MN; and gp41, LAI
- A safety and immunogenicity study of a vaccine dosing schedule was studied in a trial conducted in high and low risk study subjects. There was a 76% cumulative probability of detecting a Gag or Env CTL response by day 728.

**HXB2 Location** Gag**Author Location****Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** HAART, ART, responses in children**References** Scott *et al.* 2001

- CTL responses before and after initiation of ART were studied in 13 HIV-1 vertically infected infants <6 months of age, and 4 that were >6 months of age.
- Before ART 2/13 infants <6 months of age showed IFN $\gamma$  Elispot CD8+ T-cell responses, one to Nef and one to Env and Nef, and these responses became undetectable after successful therapy– 3 infants were coinfecting with CMV and all 3 had CMV-specific CD8+ T-cell responses.
- One older infant, at 23 months, had CTL responses against all for proteins tested, Gag, Pol, Nef and Env, and had the lowest plasma viremia of the study group. 3/4 infants older than 6 months of age responded to either Nef or Pol.

- Administration of ART over 48 weeks broadened the HIV-1-specific CTL response in 2/4 of the older children that were incomplete responders.

**HXB2 Location** Gag**Author Location** (IIIB, MN)**Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** dendritic cells**References** Larsson *et al.* 2002a

- Dendritic cells acquire and present HIV-1 antigens derived from dead, apoptotic cells or from non-infectious, fusion-competent HIV-1 virions, and these DC cells could stimulate CD4+ and CD8+ T-cells resulting in IFN $\gamma$  production in an Elispot assay. Both HLA Class I and class II molecules were used for presentation. This may be an important aspect of the initial immune response to HIV-1 infection of CD4+ cells in the mucosal subepithelia.

**HXB2 Location** Gag**Author Location** (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** HAART, ART, supervised treatment interruptions (STI)**References** Ortiz *et al.* 2001

- Immune responses in eight chronically HIV-1 infected patients undergoing HAART therapy structured treatment interruptions (STI) were studied. STI boosted HIV-1 specific CTL responses and elevated CTL responses were maintained up to 22 weeks after the last treatment interruption, but viral load rebound to pretreatment levels and CD4 T-cell count decline was observed. CD8 responses in PBMC were measured by cytokine flow cytometry with gp160, Gag p55, RT-Pol and Nef expressed in vaccinia.

**HXB2 Location** Gag**Author Location** Gag**Epitope****Subtype** AG, B**Immunogen****Species (MHC)** human**References****HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen****Species (MHC)** human**References****HXB2 Location** Gag**Author Location** Gag**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Assay type** Intracellular cytokine staining

**Keywords** HAART, ART, computational epitope prediction, supervised treatment interruptions (STI)

**References** Amicosante *et al.* 2002

- A new assay was developed to detect CTL responses to HIV using 28 pooled 15-mer peptides from conserved regions in Gag that were selected to be rich in HLA class I motifs, carrying potential epitopes for more than 90% of HLA class I haplotypes, and to be conserved between subtypes. Some peptide variants were included, expanding the potential for cross-clade recognition. 12 Caucasians, even those on successful HAART, had detectable CTL responses using this assay, and as did five Africans. People with either B subtype or A-G recombinant infections all reacted.
- The Gag peptide ICS assay was more sensitive to picking up CTL reactivity than whole Gag in HAART treated people. Initiation of STI increased the number of IFN-gamma producing CD8+ T-cells detected using the peptide assay.

- 3 rhesus macaques were given oral immunizations with an enteric-coated mixture of adenoviral vectors expressing HIV-1 gag and a string of conserved env peptides representing broadly cross-reactive CD4+ and CD8+ epitopes. The macaques were boosted intranasally with a mixture of 6 HIV-1 envelope peptides plus cholera toxin adjuvant.
- The immunizations increased cellular immune responses, including antigen-specific IFN $\gamma$ -producing CD4+ and CD8+ effector memory T cells in the intestine. After only the oral immunization, there were no EliSpot responses to env peptides or to gag. After the intranasal boost, EliSpot responses against env peptides and against inactivated HIV were markedly increased, but gag responses were not.

**HXB2 Location** Gag

**Author Location** Gag (HXB2)

**Epitope**

**Subtype** B

**Immunogen** vaccine

*Vector/Type:* DNA prime with vaccinia boost *Strain:* B clade HXB2 *HIV component:* Gag

**Species (MHC)** mouse

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, CD4 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Chromium-release assay

**Keywords** vaccine-induced epitopes, Th1

**References** Arruda *et al.* 2006

- p55 Gag cellular trafficking of two chimeras (DNA plasmid with either lysosomal-associated membrane protein LAMP/gag or human dendritic cell CD-LAMP/gag) was studied in mice. Both produces potent T and B cell immune responses, but DC-LAMP produces stronger Th1 response. The chimeras produces also significant responses to cryptic epitopes that were not recognized after immunization with native gag DNA.

**HXB2 Location** Gag

**Author Location**

**Epitope**

**Subtype** B

**Immunogen** vaccine

*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* B clade

**Species (MHC)** macaque

**Assay type** Intracellular cytokine staining

**Keywords** subtype comparisons, vaccine antigen design

**References** Smith *et al.* 2005

- Macaques were immunized with a clade B HIV vaccine and tested for responses to pools of clade B and A/G Env and Gag peptides. While CD4 responses were more frequent than CD8 responses, higher cross-clade responses were found for CD8 responses. The authors suggest that the better cross-clade reactivity of the CD8 responses reflects the size difference between CD8 and CD4 epitopes; the smaller CD8 epitopes provide a smaller target for mutation.
- For both B and A/G Env and Gag peptides, 3/5 pools produced CD8+ T cells, suggesting the existence of 2 or 3 cross-reactive CD8 epitopes.

## II-B-7 Gag/Pol CTL/CD8+ epitopes

**HXB2 Location** Gag/Pol

**Author Location** Gag/Pol (ARV-2 SF2)

**Epitope**

**Immunogen** vaccine

*Vector/Type:* fowlpoxvirus *Strain:* B clade ARV-2, B clade SF2 *HIV component:* Gag, Pol *Adjuvant:* IFN $\gamma$

**Species (MHC)** macaque

**References** Kent *et al.* 2000

- Vaccination with FPV Gag/Pol-IFN-gamma increased HIV-1 specific CTL and T cell proliferative responses to Gag/Pol antigens, respectively, in infected *Macaca nemestrina*.
- HIV-1 viral loads remained low and unchanged following vaccinations.

**HXB2 Location** Gag/Pol

**Author Location** RT

**Epitope**

**Immunogen** vaccine

*Vector/Type:* DNA *HIV component:* Env, Gag, Pol, Vif *Adjuvant:* B7, IL-12

**Species (MHC)** mouse

**References** Kim *et al.* 1997d

- A Gag/Pol or Env DNA vaccine, when delivered in conjunction with the plasmid encoding the co-stimulatory molecules CD86, gave a dramatic increase in both the cytotoxic and proliferative responses in mice.
- When CD86 was present, CTL response could be detected even without *in vitro* stimulation.

**HXB2 Location** Gag/Pol

**Author Location** RT

**Epitope**

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Keywords** TCR usage

**References** Gamberg *et al.* 1999

- 13/13 subjects with advanced HIV infections showed CD8 T cell proliferation and differentiation of CTL *in vitro*, and six individuals showed HIV-specific responses to Gag, Pol, Env or Nef antigens.
- Data suggests that the functional and genetic integrity of the CD8 T cell repertoire (TCR V $\beta$  gene intrafamily genetic diversity) remains intact through advanced HIV infection, although HIV-specific CTL activity decreases.

**HXB2 Location** Gag/Pol

**Author Location**

**Epitope**

**Immunogen** vaccine

*Vector/Type:* adenovirus *HIV component:* Gag-Pol, Nef, Vpr

**Species (MHC)** mouse

**References** Muthumani *et al.* 2002

- Vpr can cause cells to go into G2 arrest, and it suppresses immune cell activation and inflammatory cytokine production, so co-immunization of BALB/c mice with recombinant adenovirus expressing Vpr and HIV-1 antigens Nef or Gag/Pol was tested to see if Vpr reduced the immune response to the other HIV antigens.
- Vpr compromised CD8+ T-cell lytic responses and T-helper proliferative responses in mice co-immunized with Vpr and Nef or Gag/Pol.
- *In vitro*, Vpr reduced T-cell cytokine production of IL-12 and TNF $\alpha$ , indicative of Vpr-mediated immune suppression.

## II-B-8 Gag/Pol TF CTL/CD8+ epitopes

**HXB2 Location** Gag/Pol TF (24–31)

**Author Location**

**Epitope** NSPTRREL

**Epitope name** NL8

**HXB2 Location** Gag/Pol TF (24–31)

**Author Location** p6 (35–42 HXB2)

**Epitope** NSPTRREL

**Epitope name** NL8

**Subtype B****Immunogen** HIV-1 infection**Species (MHC)** human (Cw\*0102)**Donor MHC** A\*0201, A\*2501, B\*1801, B\*5101, Cw\*0102, Cw\*1203**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** escape, immune evasion, optimal epitope**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Position 4 in the epitope had potentially experienced positive selection. NspTRREL and tSPTRREL escape variants were found.

**HXB2 Location** Gag/Pol TF (44–52)**Author Location** Pol (C-96BW15C05)**Epitope** AGAERQGTL**Epitope name** C**Subtype** C**Immunogen** vaccine*Vector/Type:* DNA, alphavirus replicon*Strain:* C clade C-96BW04.09, C clade C-96BW15C05 *HIV component:* Gag, Gag-Pol, Pol**Species (MHC)** mouse (H-2d)**Assay type** Flow cytometric T-cell cytokine assay**Keywords** vaccine-induced epitopes, vaccine antigen design**References** Megede *et al.* 2006

- HIV clade C gag, pol and fusion gagpol vaccines were compared in mice. Breadth of T cell responses was improved in mice immunized with gagpol fusion genes, compared to single antigen constructs. 5 new murine CD8+ T cell epitopes were mapped.
- This is a novel epitope.

**II-B-9 Gag/Pol TF-Protease CTL/CD8+ epitopes****HXB2 Location** Gag/Pol TF-Protease (54–6)**Author Location** Pol**Epitope** FSFPQITLW**Epitope name** FW9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Donor MHC** A11, A2, B18, B44, Cw12, Cw5**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- An escape mutation at position 2, fNfpqitlw, was found in the most polymorphic residue in the epitope. This is a novel partially mapped epitope.

**II-B-10 Protease CTL/CD8+ epitopes****HXB2 Location** Protease (2–19)**Author Location** (C consensus)**Epitope** QITLWQRPLVSIKVGQI**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (Cw\*0801)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression**References** Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.

**HXB2 Location** Protease (3–11)**Author Location** RT (71–79 subtype A, B, D)**Epitope** ITLWQRPLV**Subtype** A, B, D**Immunogen****Species (MHC)** human (A\*6802)**Keywords** optimal epitope**References** Frahm *et al.* 2008

- C. Brander notes this is an A\*6802 epitope.

**HXB2 Location** Protease (3–11)**Author Location** Pol**Epitope** ITLWQRPLV**Subtype** A, B, C, D**Immunogen** HIV-1 infection, vaccine*Vector/Type:* DNA prime with modified vac-*cinia Ankara (MVA) boost* *Strain:* A clade*HIV component:* p17 Gag, p24 Gag**Species (MHC)** human (A\*6802)**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polypeptide string of conserved, often immunodominant epitopes that were selected to

have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].

- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  ELISPOT assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**HXB2 Location** Protease (29–43)**Author Location****Epitope** DDTVLEEMSLPGRWK**Immunogen** HIV-1 infection, vaccine*Vector/Type:* canarypox prime with gp120 boost, polyepitope *Strain:* B clade LAI, B clade MN *HIV component:* Gag, gp120, gp41, Nef, Pol, Protease**Species (MHC)** human**Donor MHC** A\*3001, A\*3002; B\*4201/02, B\*4403/26/30**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** vaccine-induced epitopes**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.

- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

**HXB2 Location** Protease (30–38)

**Author Location** Pol (subtype B)

**Epitope** DTVLEEMNL

**Subtype** B

**Immunogen** HIV-1 exposed seronegative

**Species (MHC)** human (A\*6802)

**Keywords** subtype comparisons

**References** Rowland-Jones *et al.* 1998b

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi—these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.
- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among B and D clade viruses.
- The Clade A version of the epitope: DTVLEDINL.
- This epitope was recognized by two different exposed and uninfected prostitutes.
- This epitope was identified by screening 49 HIV-1 peptides with the predicted A\*6802 anchor residue motif x(VT)xxxxxx(VL)

**HXB2 Location** Protease (30–38)

**Author Location** Pol (subtype A)

**Epitope** DTVLEDINL

**Subtype** A

**Keywords** HIV exposed persistently seronegative (HEPS), escape

**References** Kaul *et al.* 2001c

- This study examines CTL responses in HIV exposed, persistently seronegative individuals, HEPS, who eventually seroconverted – 11/114 HEPS Nairobi sex workers eventually seroconverted, and for six of these HIV CTL reactive epitopes had been defined while seronegative.
- DTVLEDINL was recognized in 3 of the 6 women (ML857, ML1203, and ML1707), and the response was present in the last available sample prior to seroconversion, 3-7 months.
- In each of the three women, 20/20 sequences of the infecting strain had no substitutions in this epitope, all were DTVLEDINL, so there was no evidence for escape.
- The epidemiological factor associated with seroconversion was stopping sex work. HIV-specific CTL activity declined when HEPS sex workers stopped working for a period or retired.
- This epitope was recognized in 3/22 HEPS sex worker controls, ML851, ML1432, and ML1601.

**HXB2 Location** Protease (30–38)

**Epitope** DTVLEDINL

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative

**Species (MHC)** human (A\*6802)

**Keywords** HIV exposed persistently seronegative (HEPS), immunodominance

**References** Kaul *et al.* 2001a

- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A\*6802 women, 11/12 HEPS and 6/11 HIV-1 infected women recognized this epitope likelihood ratio 4.4, p value 0.08, and HEPS women tended to respond to DTVLEDINL, infected women tended to ETAYFILKL.
- The dominant response to this HLA allele was to this epitope in 10 of the 11/12 HEPS cases, but in only 4 of the 6/11 HIV-1 infected women.

- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Four epitopes were considered to be “resistant epitopes”, as they were preferentially reactive in HEPS women and so may confer resistance, and these were found in three different proteins: A2 ILK(D/E)PVHGV in RT, A\*6802 DTVLEDINL in Protease, B14 DLN(M/T)LN(I/V)V in p24 and B18 FRDYV-DRF(Y/F)K also in p24.
- Subject ML 857 shifted from a A\*6802 DTVLEDINL and B35 (H/N)PDIVIIYQY response prior to seroconversion to a B35 PPIPVGDIY and B35 VPLRPMTY response post-seroconversion, and the loss of the pre-seroconversion response was not due to sequence variation within these epitopes.
- Subject ML 1203 started with CTL responses to A\*6802 DTVLEDINL and B7 FPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A\*6802 ETAYFILKL which became dominant, B7 TPGPGV/IRYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.
- Subject ML 1707 started with a CTL response to A\*6802 DTVLEDINL prior to seroconversion, and switched to A\*6802 ETAYFILKL and A24 RDYVDRFFKTL post-seroconversion, and the loss of the pre-seroconversion response was not due to sequence variation within the epitope.
- Subject ML 1830 made no detectable response prior to seroconversion, but responded to A\*6802 DTVLEDINL and A\*6802 ETAYFILKL post-seroconversion.

- Neisseria gonorrhoea cervicitis in 9 HIV+ Kenyan sex workers caused a functional deficiency in IFN-gamma production in HIV-1 epitope-specific CD8+ T-cells, detected by intracellular cytokine production and tetramer assays, while not affecting the total number of epitope-specific CTLs.
- Ghonorrhoea caused the weaker HIV-1 specific CTL responses in 4 HIV-1 exposed persistently seronegative (HEPS) women to become undetectable by Elispot and tetramer assays, and CMV-specific CTL in 2 HEPS subjects were shown to have impaired function with regard to IFN-gamma production.

**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- This epitope was reactive, but escape mutations did not accrue in it over time.

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

**Epitope** EEINLPGKW**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*44)**Assay type** Other**Keywords** HLA associated polymorphism**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- EEINLPGKW was a previously defined B\*44 presented epitope that encompassed an associated polymorphism, EeINLPGKW, in the second position.

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The fourth position of the epitope EEMnLPGRW has a mutational pattern that is correlated the host carrying HLA B\*4402.

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- This HLA-B\*4403 HIV mutation association was only picked up using statistics that incorporate the phylogeny. The second position, EeMNLPGRW, is the anchor residue association.

**HXB2 Location** Protease (34–42)**Author Location** Protease (34–42)**Epitope** EEMNLPGRW**Immunogen****Species (MHC)** human (B44)**Keywords** optimal epitope**References** Frahm *et al.* 2008**HXB2 Location** Protease (34–42)**Author Location** Protease**Epitope** EEMNLPGRW**Epitope name** EW9**Immunogen** HIV-1 infection**Species (MHC)** human (B44)**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** epitope processing, supervised treatment interruptions (STI), immunodominance**References** Rodriguez *et al.* 2004

- Protease and integrase are shown to be frequently targeted by CD8 T-cell responses (23% and 68% of 56 HIV+ patients, respectively). Responses tend to cluster in conserved regions of Int, although 1 high conserved region had no responses. CTL frequencies per unit protein length for Pro and Int were similar to other HIV non-structural proteins. Three novel HLA class I-restricted optimal epitopes were found and characterized with fine mapping.
- The epitope includes residue M36, which is a known accessory mutation site in individuals treated with PIs.

**HXB2 Location** Protease (34–42)**Author Location** Protease (34–42)**Epitope** EEMNLPGRW**Epitope name** EW9**Subtype** multiple**Immunogen** HIV-1 infection**Species (MHC)** human (B18, B40, B44)**Country** Germany**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** immune evasion, drug resistance**References** Mueller *et al.* 2007

- To assess HIV-1-specific CTL influence on development and patterns of drug resistance in protease (PR) 94 HLA-typed patients were analyzed. Statistical analyses performed were univariate (Fisher's exact test) and were verified with biological assays. 10 new CTL epitopes were defined and 26 correlations (positive and negative) between HLA class-I alleles and PR mutations - some leading to escape mutations - were detected, demonstrating that CTL epitopes can be predicted based on HLA-amino acid substitution associations.
- Some patient CTL escape mutations were detectable by other CTLs of the same patient. Correlations between resistance mutations, polymorphisms and specific PR inhibitors were not detected.
- HLA-B had the strongest impact on PR sequence change, though HLAs-A and -C also had some impact.
- The authors suggest that CTL escape is active in developing drug-resistance related polymorphisms as well as major and minor mutations in HIV-1 infected persons.
- HIV-1 subtype breakdown in this cohort was follows - 83/94 patients infected with subtype B virus, 3 with subtype C, 4 CRF01\_AE, 1 CRF03\_AB, 1 CRF15\_01B and 2 subtype Ds.
- This highly immunogenic index epitope, EEMNLPGRW, EW9, developed variants EEiNLPGRW, EW9 M/I, EEMdLPGRW, EW9 N/D, EdMNLPGRW, EW9 E/D, EdiNLPGRW, EW9 D/I, EEMNLPgkW, EW9 R/K, EEMNLsGRW, EW9 P/S. E35D and P39S mutants were located in the previously reported HLA-B44 restricted epitope EEMSLPGRW (EW9). Correlation between minor drug mutation E35D and B44 was strong, standing up to Bonferroni's correction, while that of B44 with P39S was weak. E35D mutations induced a strong decrease in CTL recognition, but few patient samples did mount specific responses against it giving a negative correlation between this mutation and HLA-B44. A novel association between the E35D mutant and HLA-B18 was also found.
- Cross-reactivity of CTL recognition of EW9 and variants occurred for most patients. This showed that cells from several patients mount oligoclonal CTL responses, indicating immune system reactions to escape by recruitment of CTLs with new TCR specificities. On the other hand, most patients showed mutually exclusive recognition of variant epitopes containing either E35D or E35E; HLA-B44 subtypes and other factors tested could not explain this phenomenon.
- EW9 epitope and variant peptides include the S37N substitution when compared to HXB2 strain sequences.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

**HXB2 Location** Protease (45–54)

**Species (MHC)** humanized mouse (A\*0201)

**Assay type** Intracellular cytokine staining

**Keywords** epitope processing, vaccine-specific epitope characteristics, immunodominance, variant cross-recognition or cross-neutralization, vaccine antigen design

**References** Singh & Barry 2004

- When A\*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteasome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.
- The drug resistant variant of this epitope, kViVgiggi, was tested. WT and CO vaccines produced low level CD8+ T-cell responses against the B clade form as well as against drug resistant variant, but the ELI vaccine produced much more intense responses against both the WT and the variant, including after boosting.

**HXB2 Location** Protease (45–54)

**Author Location** Pol (125–134)

**Epitope** KMIGGIGGFI

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

- To determine whether HLA-B\*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B\*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B\*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.

**Keywords** immune evasion, drug resistance

**References** Mueller *et al.* 2007

- To assess HIV-1-specific CTL influence on development and patterns of drug resistance in protease (PR) 94 HLA-typed patients were analyzed. Statistical analyses performed were univariate (Fisher's exact test) and were verified with biological assays. 10 new CTL epitopes were defined and 26 correlations (positive and negative) between HLA class-I alleles and PR mutations - some leading to escape mutations - were detected, demonstrating that CTL epitopes can be predicted based on HLA-amino acid substitution associations.
- Some patient CTL escape mutations were detectable by other CTLs of the same patient. Correlations between resistance mutations, polymorphisms and specific PR inhibitors were not detected.
- HLA-B had the strongest impact on PR sequence change, though HLAs-A and -C also had some impact.
- The authors suggest that CTL escape is active in developing drug-resistance related polymorphisms as well as major and minor mutations in HIV-1 infected persons.
- HIV-1 subtype breakdown in this cohort was follows - 83/94 patients infected with subtype B virus, 3 with subtype C, 4 CRF01\_AE, 1 CRF03\_AB, 1 CRF15\_01B and 2 subtype Ds.
- This newly defined B13-associated epitope, RQYDQIPiEI, RI10, shows drug-induced mutations at I62V, RQYDQvPIEI. RI10 does not have a published HLA-binding motif yet, but it overlaps with the Cw4-restricted epitope QYDQIPiEI, and

shows similarity at the putative anchor binding positions of the B13-restricted Nef epitope, RQDILDWLWI.

**References** Yang *et al.* 2005a

- CTL responses were evaluated in identical twins infected with HIV-1 from the same blood source. Targeting of the CTL was similar in the 2 patients, while their TCR profiles were highly dissimilar. It is suggested that CTL targeting is predominately genetically determined, while T-cell generation is a stochastic process; the responding CTLs differ at the TCR molecular level, leaving the viral escape and CTL efficacy unpredictable.
- HKAIGTVLVGPTPVN was the immunodominant epitope in each twin, but was recognized by T cells with distinctly different TCRs. The epitope was not defined within the epitope. The twins had very different patterns of HIV evolution in this region, with one carrying HKveGsVLiGPTPVN and the other HKAIGaVLiGPTPVN.

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- HLA-B63/57/58 epitope containing the B58 supertype binding motif. Significantly more often recognized by B63-positive subjects than by negative subjects. Optimal epitope was defined in a person who was B57+.

**HXB2 Location** Protease (75–84)**Author Location** Protease (75–84 MN)**Epitope** VLVGPTPVNI**Immunogen** in vitro stimulation or selection**Species (MHC)** human (A\*0201)**Keywords** binding affinity**References** Konya *et al.* 1997

- Peptide predicted to be reactive based on HLA-A\*0201 binding motif.
- Peptide could stimulate CTL in PBMC from 5/6 seronegative donors.
- Peptide located in a highly conserved region of protease.
- Both 9-mer and 10-mer could stimulate CTL: VLVGPTPVNI and LVGPTPVNI.
- Binding affinity to A\*0201 was measured,  $C_{1/2 \max} \mu\text{M} = 6$  for 10-mer, 3 for 9-mer.
- MAL variant of Pr(75-84 MN), with substitutions V77, G78, and P79, gave reduced binding and CTL recognition.

- Immunization of HLA-A\*0201-transgenic mice with synthetic genes encoding clusters of human A\*0201 CTL epitopes located at the sites of drug resistance mutations, induced RT-specific cellular responses indicating the immunogenicity of these constructs. This vaccine strategy may be a first step towards a therapeutic vaccine against drug-resistant strains.
- This was one of five HLA-A\*0201 epitopes from the RT or protease proteins that was included in the polyepitope vaccine. When the transgenic HLA A\*0202 mice were vaccinated with the polyepitope construct or with a mixture of RT peptides, a sustained low level CD8+ T-cell gamma IFN response was

observed, in contrast to when an intact RT gene was used for vaccination.

**HXB2 Location** Protease (75–84)**Author Location** Pol (75–84 IIIB)**Epitope** VLVGPTPVNI**Epitope name** pol75-84**Subtype** B**Immunogen** vaccine*Vector/Type:* DNA *Strain:* B clade IIIB  
*HIV component:* Gag-Pol**Species (MHC)** humanized mouse (A\*0201)**Assay type** Intracellular cytokine staining**Keywords** epitope processing, vaccine-specific epitope characteristics, immunodominance, variant cross-recognition or cross-neutralization, vaccine antigen design**References** Singh & Barry 2004

- When A\*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteasome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.
- The drug resistant variant of this epitope, vlvgptpTnV, was tested. WT and CO vaccines produced low level CD8+ T-cell responses against the B clade form as well as against drug resistant variant, but the ELI vaccine produced much more intense responses against both the WT and the variant, including after boosting.

**HXB2 Location** Protease (75–84)**Author Location** Protease (75–84)**Epitope** VLVGPTPVNI**Immunogen** vaccine*Vector/Type:* peptide, Other *Strain:* multiple epitope immunogen *HIV component:* Protease *Adjuvant:* Incomplete Freund's Adjuvant (IFA), Other**Species (MHC)** transgenic mouse (A\*0201)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** vaccine-specific epitope characteristics, drug resistance**References** Boberg *et al.* 2006

- Binding of a protease epitope and its variants caused by drug-resistance mutations to HLA-A0201 and CTL responses in transgenic mice immunized with this epitope were analyzed. It was found that both the wild-type and resistance variants of the epitope bound well to HLA-A0201 and were strongly immunogenic in HLA-A0201 transgenic mice. Immunological cross-reactivity between different variants of the peptide was observed, suggesting that immunization with drug-resistance mutated epitopes could induce a broad immune response, which may cause a better outcome of antiretroviral therapy in HIV-1 infected individuals.

- An interesting epitope from the HIV-1 protease (PR) protein was found VLVGPTPVNI, and mutant variants - VLVGPT-PaNI, VLVGPTPfNI, VLVGPTPVNv, VLVGPTPfNv. The epitope, VLVGPTPVNI, and its drug-induced mutant version VLVGPTPfNv, were studied and were able to elicit responses both by peptide constructs and multi-CTL epitope constructs.

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naïve subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

**HXB2 Location** Protease (76–84)

**Author Location** Pol (163–)

**Epitope** LVGPTPVNI

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naïve individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naïve T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, LVGPTPVNI, was predicted to be restricted by HLA A\*0201, A\*0202, A\*0205, A\*0209, B\*1501 and B\*1516.

**Assay type** Intracellular cytokine staining, Chromium-release assay

**Keywords** HAART, ART, escape

**References** Karlsson *et al.* 2003

- This epitope contains two positions that are commonly associated with protease inhibitor escape, lvgptpAni (V82A) and lvgptpvnV (I84V). 29 HIV-1 infected patients (15 were HLA-A2+) with a history of protease inhibitor failure were screened for mutations within the protease gene and CD8+ T cells recognition of the wt and V82A variant peptides. CTL pressure alone, despite high functional avidity, did not drive the V82A substitution. Surprisingly V82A was found more frequently among HLA-A2- individuals (10/14) than HLA-A2+ (7/15), despite the mutation conferring not only drug resistance but CTL escape.

- 8/15 HLA-A2+ patients carried had a Val at position 82; 7/8 of these recognized the WT peptide, but only 3/8 could also recognize V82A.

- 7/15 had the V82A substitution; 2/7 recognized the wt and the V82A mutation, 1/7 recognized only the peptide with the V82A substitution.

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- Clade-B vaccination induced recognition of index epitope VGPTPVNII and variant VGPTPiNII.

**HXB2 Location** Protease (77–85)

**Author Location** Protease (C-96BW15C05)

**Epitope** IGPTPVNII

**Epitope name** D

**Subtype** C

**Immunogen** vaccine

*Vector/Type:* DNA, alphavirus replicon *Strain:* C clade C-96BW04.09, C clade C-96BW15C05 *HIV component:* Gag, Gag-Pol, Pol

**Species (MHC)** mouse (H-2d)

**Assay type** Flow cytometric T-cell cytokine assay

**Keywords** vaccine-induced epitopes, vaccine antigen design

**References** Megede *et al.* 2006

- HIV clade C gag, pol and fusion gagpol vaccines were compared in mice. Breadth of T cell responses was improved in mice immunized with gagpol fusion genes, compared to single antigen constructs. 5 new murine CD8+ T cell epitopes were mapped.
- This is a novel epitope.

**HXB2 Location** Protease (79–89)

**Author Location** Protease

**Epitope** PTPVNIIGRNL

**Subtype** B, C

**Immunogen** HIV-1 infection

**Species (MHC)** human (B63)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** cross-presentation by different HLA, optimal epitope

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- Putative HLA-B63/57/58 epitope containing the B58 super-type binding motif. Significantly more often recognized by B63-positive subjects than by negative subjects, trend towards being more often recognized in those with B57/B58.

**HXB2 Location** Protease (80–90)

**Author Location** (C consensus)

**Epitope** TPVNIIGRNMML

**Subtype** C

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*8101)

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, optimal epitope

**References** Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- TPVNIIGRNMML is an optimal epitope.

**HXB2 Location** Protease (80–90)

**Author Location** Protease (80–90)

**Epitope** TPVNIIGRNMML

**Epitope name** TL11

**Subtype** C

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*8101)

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Other

**Keywords** supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction

**HXB2 Location** Protease (80–90)

**HXB2 Location** Protease (91–99)

**Author Location** Pol (2529–)

**Epitope** TQIGCTLNF

**Epitope name** B\*1501 TF9

**Subtype** B, C, CRF01\_AE

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*1501)

**Country** Australia

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape, HLA associated polymorphism

**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore et al., Science 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- The mutational pattern in the third position in this epitope TQIGCTLNF, is correlated with the host carrying HLA B\*1501.
- This epitope was experimentally tested using Interferon-g Elispot and functional avidity studies. For one of six patients tested, the form TQ(L)GCTLNF showed decreased functional avidity relative to TQIGCTLNF. In all other patients, the form TQ(L)GCTLNF had greater functional avidity than the form TQIGCTLNF.

**HXB2 Location** Protease (91–99)

**Author Location** Protease

**Epitope** TQIGCTLNF

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*1503)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, rate of progression, immunodominance

**References** Frahm *et al.* 2006

- CTL responses restricted by HLA-B\*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B\*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects in spite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominant CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
- TQIGCTLNF of clade B is a potential HLA-B\*1503-restricted epitope, with epitope TQIGCTLNF found in clade C.

**HXB2 Location** Protease (91–99)

**Author Location** Protease (91–99)

**Epitope** TQICGTLNF

**Epitope name** TF9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B62, Cw3)

**Country** Germany

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** immune evasion, drug resistance

**References** Mueller *et al.* 2007

- To assess HIV-1-specific CTL influence on development and patterns of drug resistance in protease (PR) 94 HLA-typed patients were analyzed. Statistical analyses performed were univariate (Fisher's exact test) and were verified with biological assays. 10 new CTL epitopes were defined and 26 correlations

(positive and negative) between HLA class-I alleles and PR mutations - some leading to escape mutations - were detected, demonstrating that CTL epitopes can be predicted based on HLA-amino acid substitution associations.

- Some patient CTL escape mutations were detectable by other CTLs of the same patient. Correlations between resistance mutations, polymorphisms and specific PR inhibitors were not detected.
- HLA-B had the strongest impact on PR sequence change, though HLAs-A and -C also had some impact.
- The authors suggest that CTL escape is active in developing drug-resistance related polymorphisms as well as major and minor mutations in HIV-1 infected persons.
- HIV-1 subtype breakdown in this cohort was follows - 83/94 patients infected with subtype B virus, 3 with subtype C, 4 CRF01\_AE, 1 CRF03\_AB, 1 CRF15\_01B and 2 subtype Ds.
- This newly defined epitope, TQICGTLNF, TF9, spawns minor B62 and Cw3-associated mutations at I93L, viz. TQICGTLNF.

## II-B-11 Protease-RT CTL/CD8+ epitopes

**HXB2 Location** Protease-RT (95–5)

**Author Location** Gag (175–184)

**Epitope** CTLNFPISPI

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- The epitope starts in Protease and ends in RT.
- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind all five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802)

**HXB2 Location** Protease-RT (96–5)

**Author Location** Pol (176–184)

**Epitope** TLNFPISPI

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.

- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNP to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

- HXB2 Location** Protease-RT (96–5)  
**Author Location** Pol (152–160)  
**Epitope** TLNFPISPI  
**Immunogen** HIV-1 infection  
**Species (MHC)** human  
**Assay type** Cytokine production, CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Other, HLA binding  
**Keywords** vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism  
**References** Reche *et al.* 2006
- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
  - A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
  - This epitope, TLNFPISPI, was predicted to be restricted by HLA A\*0201 and A\*0207.

## II-B-12 RT CTL/CD8+ epitopes

**Country** United States  
**Assay type** Intracellular cytokine staining, Other  
**Keywords** rate of progression, escape, immune evasion  
**References** Karlsson *et al.* 2007
- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variants SsIETVPVKL and SPIkTVPVKL at positions 2 and 4 were the predominant polymorphisms found.

**HXB2 Location** RT (3–12)

**Author Location** Pol

**Species (MHC)** human (B40)

**Assay type** Other

**Keywords** escape, TCR usage, immune evasion

**References** Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert *et al.* J. Exp. Med. 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.
- This epitope, IL8, showed discordant epitope evolution between the twins, and both alpha and beta TCR chains recruited were entirely different between them.

**References** Zarling *et al.* 1999

- This study compares the ability of macrophages and dendritic cells to stimulate primary responses in CD8+ lymphocytes isolated from HLA-appropriate HIV-uninfected donors using peptide-pulsed APC – the dendritic cells performed better as APC for the stimulation of primary responses.
- Strong CTL responses were elicited by the epitopes DRFYK-TLRA and GEIYKRWII when presented by either immature or mature dendritic cells – macrophages were not able to prime a CTL response against DRFYKTLRA.
- A weak response to KLTPLCVSL was stimulated using macrophages as the APC.
- No detectable response was observed for the following previously-defined HIV epitopes: KIRLRPGGK, ILKEPVHGV, IRLRPGGK, GPKVKQWPL.

**Immunogen** HIV-1 infection  
**Species (MHC)** human (B8)  
**Keywords** HAART, ART, supervised treatment interruptions (STI), immunodominance, escape, acute/early infection  
**References** Oxenius *et al.* 2000

- Patients who started therapy at acute HIV-1 infection (three with sustained therapy, two with limited therapy upon early infection) had strong HIV specific CD4 proliferative responses and were able to maintain a CTL response even with undetectable viral load – three patients that had delayed initiation of HAART had no HIV specific CD4 proliferative responses and lost their CTL responses when HAART was eventually given and their viral loads became undetectable.
- Two of the 7/8 study subjects that were HLA B8+ recognized this epitope.
- Patient SC2 (HLA A1, B7/8, Cw0701/0702, DR4/53, DQ7) had CTL responsiveness against epitopes FLKEKGGL, GPKVKQWPL, and GEIYKRWII peptides – FLKEKGGL tetramer staining steadily declined and at day 1340 the FLKEKGGL stained cells were no longer detected and the escape mutant FLKENGGI was found in 8/10 clones.
- Patient SC11 (HLA A1, B8, Cw0201, DR3/11, DR52, DQ2/7) started therapy early, remained on therapy for 40 days, then reinitiated HAART at day 640 had a CTL response to FLKEKGGL, GPKVKQWPL, and GEIYKRWII throughout and received a benefit from the early limited course therapy.

**Keywords** escape, variant cross-recognition or cross-neutralization, optimal epitope  
**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The GL9 variant GPrVKQWPL was essentially the only form of the epitope detected over a 5-year period in this person. Elispot reactions were roughly equivalent between the autologous form and the B clade consensus form, GPKVKQWPL. A single variant was observed in 1/8 clones at the 5-year time point, GPrVKQgPL.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- In one patient, initially the consensus sequence ALVEICTEM was not found. Instead the 35I variant ALiEICTEM was seen, followed by the emergence of the 35M variant, ALmEICTEM, and finally, emergence of the consensus B sequence, ALvEICTEM. Strongest immune responses were detected to the 35M variant and weaker responses to the 35I variant, while negligible responses were seen to the consensus, ALVEICTEM. This is an example of CTL-responses against variant epitopes causing virus evolution to the consensus B sequence. Other variants that emerged were ALtEICTEM, ALiEICTEt, ALiEICTdM, ALmkICTEM and ALmEiCaEM.
- Responses to epitope ALVEICTEM were seen in early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

- This epitope contains the mutation M41L, a mutation induced by nucleoside reverse transcriptase inhibitors.
- Patient 201#5, (A\*0201), was found by ELISPOT to recognize the mutated peptide after zidovudine treatment, but not the wild-type peptide – the mutation M41L gave an increased A2 binding score ([http://bimas.dcrn.nih.gov/molbio/hla\\_bind](http://bimas.dcrn.nih.gov/molbio/hla_bind)) compared to the wildtype RT sequence.

- Three additional A\*0201 individuals and one B27 individual did not respond to this epitope before or after treatment.
- M41L occurred at anchor positions p2 and p9 in several computer predicted RT epitopes (33-41, 32-41, and 40-49) ([http://bimas.dcrn.nih.gov/molbio/hla\\_bind](http://bimas.dcrn.nih.gov/molbio/hla_bind)), and increased the predicted binding affinity for 6 HLA molecules (B2705, B5102, C3, A0201, B2705 and B3901)

**HXB2 Location** RT (33–41)**Author Location** RT (33–41 MN)**Epitope** ALVEICTEM**Subtype** B**Immunogen** vaccine*Vector/Type:* DNA, polyepitope *Strain:* B clade MN *HIV component:* gp120, Protease, RT *Adjuvant:* Incomplete Freund's Adjuvant (IFA)**Species (MHC)** humanized mouse (A\*0201)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** epitope processing, vaccine-specific epitope characteristics, immunodominance, immunotherapy**References** Isaguliants *et al.* 2004

- Immunization of HLA-A\*0201-transgenic mice with synthetic genes encoding clusters of human A\*0201 CTL epitopes located at the sites of drug resistance mutations, induced RT-specific cellular responses indicating the immunogenicity of these constructs. This vaccine strategy may be a first step towards a therapeutic vaccine against drug-resistant strains.
- This was one of five HLA-A\*0201 epitopes from the RT or protease proteins that was included in the polyepitope vaccine. When the transgenic HLA A\*0202 mice were vaccinated with the polyepitope construct or with a mixture of RT peptides, a sustained low level CD8+ T-cell gamma IFN response was observed, in contrast to when an intact RT gene was used for vaccination.

**HXB2 Location** RT (33–41)**Author Location** Pol (132–140 IIIB)**Epitope** ALVEICTEM**Epitope name** pol132-140**Subtype** B**Immunogen** vaccine*Vector/Type:* DNA *Strain:* B clade IIIB *HIV component:* Gag-Pol**Species (MHC)** humanized mouse (A\*0201)**Assay type** Intracellular cytokine staining**Keywords** subtype comparisons, vaccine-specific epitope characteristics, immunodominance, variant cross-recognition or cross-neutralization, vaccine antigen design**References** Singh & Barry 2004

- When A\*0201-C3H/J transgenic mice were immunized with plasmids encoding wild-type gag-pol, codon-optimized (CO) gag-pol, and an expression library vaccine expressing 16 fragments of gag-pol fused with ubiquitin for proteasome targeting (ELI), the ELI vaccine produced up to 10-fold higher CD8 T-cell responses than the other two vaccines. In contrast to the wt and CO vaccines, which tended to augment only immunodominant responses, boosting with the ELI vaccine resulted in

many CD8 responses against variant epitopes from different HIV-1 clades, and against drug-resistant variants.

- Different variants of this epitope from different clades were tested. WT and CO vaccines produced low level CD8+ T-cell responses against the B clade form as well as against variants from other clades, but the ELI vaccine produced much more intense responses against the B clade and all variants tested, including after boosting. The variants were: clade A, atTDictem; clade C, atTAicEem; and clade D, alleicSem.

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.

- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*02 restricted epitope, ALVEICTEM was mutated to ALiEICTEM in the daughter D2 isolate.

**Species (MHC)** mouse (H-2K<sup>k</sup>)  
**References** Leggatt *et al.* 1998

- Epitope variants were examined for CTL response in concert with H-2K<sup>k</sup> MHC class I binding – all of the following combinations were observed: (i) two single mutations which did not alone abrogate CTL activity did abrogate activity when combined, (ii) loss of recognition of a single substitution could be restored by an additional substitution, and (iii) sometimes there was recognition of two single substitutions as well as the combination of those substitutions.
- 2E and 9I are anchor residues for H-2K<sup>k</sup>—if you have M in the third position, it enhances H-2K<sup>k</sup> binding 10-fold, but polymorphism at this site is important for the overall conformation of the peptide and can influence T cell recognition.

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naïve individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naïve T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.

- This epitope, EKEGKISKI, was predicted to be restricted by HLA B\*2701, B\*3801, B\*3901, B\*3909, B\*4402, B\*5101, B8.

**Keywords** escape  
**References** Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occurred sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these epitopes, but this increased over time.

- CD8 T-cells targeting epitopes spanning drug resistance induced mutations were detected in 3/25 individuals harboring multidrug-resistant HIV-1. Novel CD8 T-cell responses were detected against epitopes with common protease inhibitor fitness mutations. T-cell immunity to drug-resistant variants was confirmed in SHIV-infected macaques, where CD8 and CD4 immune responses to RT and protease resistance mutations were elicited using peptide-based immunotherapy.
- The immune response to this peptide was cross-reactive for both the wild type and RT drug resistance mutation K65R, and NTPVFAIKK and ntpvfaikR stimulated CD8 T-cell responses with equal efficiency. The C-terminal R or K is required for a full response; NTPVFAIK stimulated a much weaker response.
- The 3 people that responded to the drug resistant forms of the virus were among those that had the highest levels of CD4 and CD8 T-cell responses, indicating that they were among the most immunocompetent.

**HXB2 Location** RT (57–65)

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, NTPVFAIKKK, is similar to human protein HERV, sequence SPwNTPVFvIKKK.

**Epitope name** P248-257

**Subtype** CRF01\_AE

**Immunogen** HIV-1 exposed seronegative

**Species (MHC)** human (A11)

**Keywords** HIV exposed persistently seronegative (HEPS)

**References** Sriwanthana *et al.* 2001

- This was a study of HIV-1 exposed persistently seronegative (HEPS) female sex workers in Chiang Mai, northern Thailand.
- HLA-A11 is very common in this population, and was enriched among the HEPS sexworkers - weak CTL responses were detected in 4/7 HEPS women, and CTL responses were found in 8/8 HIV+ controls, and 0/9 HIV- women that were not exposed.
- This epitope was weakly reactive in the HEPS study subject 265 who was HLA A2/A11 and after a second stimulation *in vitro* gave a strong response in HEPS study subject 128 who was HLA A11/A33.

**HXB2 Location** RT (93–102)

- Patients with acute or early infection were shown to preferentially target variable peptides with higher entropy while those with chronic infection showed responses towards more conserved peptides with lower entropy. In longitudinally followed subjects, responses to variable proteins declined over time while responses to conserved proteins increased. The decline is suggested to be due to CTL escape.
- The response to this epitope was not evident until month 20, and increased over time.

**HXB2 Location** RT (107–115)**Author Location** RT (107–115)**Epitope** TVLDVGDY**Immunogen** HIV-1 infection**Species (MHC)** human (B\*3501)**Assay type** Cytokine production, CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Other, HLA binding

**Keywords** vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, TVLDVGDAY, was predicted to be restricted by HLA B0702, B3501, B5102, B5103, B5301, B5401 and B5502 as well. B\*1501, B\*3501, B\*5701, C\*0304.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.

- The most frequently recognised epitopes also elicited the greatest CTL response.

- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.

- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).

- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** RT (108–118)

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*02)

**Country** United States

**Assay type** Intracellular cytokine staining, Other

**Keywords** rate of progression, escape, immune evasion

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** RT (118–127)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15–92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**Keywords** escape, TCR usage, immune evasion

**References** Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert *et al.* J. Exp. Med. 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain

repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.

- This epitope, YV9, showed discordant epitope evolution between the twins, and both alpha and beta TCR chains recruited were entirely different between them.

**Keywords** rate of progression, HLA associated polymorphism

**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.

- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- TAFTIPSI escapes very soon after seroconversion to the variant TAFTIPSt with change at its carboxyl terminus, position 8, which has been identified by phylogenetic analysis to be under strong positive selection pressure. It was present in 7/8 of HLA-matched patients and 21/57 of HLA-unmatched patients.

**References** Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- TAFTIPSI was one of two epitopes characterized in detail. C-terminal I135x substitutions were associated with people who carried HLA-B5 – 39/40 (98%) of HLA-B\*5101 individuals had substitutions in this position, while only 127/431 (29%) who did not have HLA-B\*5101 did. The predominant substitution was kytaftipsT, and this mutation is predicted to abrogate binding to HLA-B\*5101.

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Last position (8) of the epitope had potentially experienced positive selection. TAFTIPSt, TAFTIPSt and TAFTIPStv escape variants were found.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*5101)

**Assay type** Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay, CTL suppression of replication

**Keywords** binding affinity, class I down-regulation by Nef, rate of progression

**References** Tomiyama *et al.* 2005

- HLA-B\*5101 associated with slow progression to the disease state was studied as related to Nef-mediated HLA class I downregulation. It was shown that different CTLs have different ranges of ability to kill HIV-1 infected CD4+ T cells and suppress HIV-1 replication. This was found to be a function

of the specific HIV-1 epitope presented by the corresponding HLA allele to the CTL.

- Certain epitope recognising CTL clones or lines were therefore, capable of killing HIV-1 infected cells even in the presence of Nef-mediated MHC 1 downregulation, while other CTL clones recognising different epitopes were not so capable.
- There was no significant difference in cytokine production or cytokine producing cells between CTLs that were capable of killing CD4+ T-cells infected with HIV-1 and those CTLs that could not kill such HIV-1 infected cells.
- On the basis of studies involving binding abilities and cytolytic activities for four different epitopes that correlate with HLA-B\*5101-restricted CTLs, it is suggested that the ability of CTLs to kill infected CD4+ T cells is due to the number of epitopes presented by the HLA on the surface of the CD4+ T cells rather than the ability of TCR to recognise the epitope.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B51)

**Keywords** review

**References** Menendez-Arias *et al.* 1998; Sipsas *et al.* 1997

- HIV IIIB proteins were used to define the range of CTL epitopes recognized by 3 lab workers accidentally infected with HIV-1 IIIB.
- TAFTIPST, a variant found in HIV-1 CAM1, was also recognized but 100-fold more peptide was needed.
- TAFTIPSV, a variant found in HIV-1 VE1RT, was also recognized, but 10-fold more peptide was needed.
- TVFTIPSI, a variant found in HIV-1 MANC, was also recognized.
- Menendez-Arias *et al.* [1998], in a review, notes that this epitope includes a region near the active site of RT – the substitution of the position two conservative change from A to V decreases CTL recognition.

**HXB2 Location** RT (128–135)

**Epitope name** TAF

**Immunogen** HIV-1 infection

**Species (MHC)** human (B51)

**Keywords** HAART, ART, acute/early infection

**References** Oxenius *et al.* 2000

- Patients who started therapy at acute HIV-1 infection (three with sustained therapy, two with limited therapy upon early infection) had strong HIV specific CD4 proliferative responses and were able to maintain a CTL response even with undetectable viral load – three patients that had delayed initiation of HAART had no HIV specific CD4 proliferative responses and lost their CTL responses when HAART was eventually given and their viral loads became undetectable.
- None of the 8 study subjects recognized this epitope but none were HLA B51+

**HXB2 Location** RT (128–135)

**Author Location** RT (295–302 LAI)

**Epitope** TAFTIPSI

**Epitope name** P5

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B51)

**Keywords** HAART, ART

**References** Mollet *et al.* 2000

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using CD8+ cell IFN $\gamma$  production to measure responses.
- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

**References** Sabbaj *et al.* 2002

- IFN $\gamma$  T-cell responses in breast milk of 5 HIV-1 infected women from the US and 6 from Zambia were tested with using Elispot. 11/11 women responded to Gag, 8/11 responded to Pol, 7/11 women to Nef, and 2/5 women to Env peptide pools. These responses were shown to be primarily due to CD8+ T-cells in one woman, and another woman had cytolytic responses measured by Cr-release.
- T-cells in breast milk from a volunteer who was HLA A3, A11, B35, B51 induced IFN $\gamma$  after stimulation with either of two overlapping peptides that carry known B51 epitope TAFTIPSI.

- The frequencies of responses in the two compartments differed, and 2/4 women that responded to epitopes in Nef 101-205 and Pol 601-710 showed responses in breast milk but no detectable responses in peripheral blood cells.

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**Keywords** rate of progression, escape

**References** Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occurred sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 5 epitopes from this individual that varied over time where the internal mutations became fixed; a dramatic decrease in CTL activity against the wild type epitope was observed as the mutation arose. The taftipsT variant residue found at 47 months postseroconversion.

**References** Casazza *et al.* 2005

- Evidence of continued viral evolution during HAART therapy despite low viral load was found in 1/5 patients studied. This epitope provided the best evidence for apparent immune escape during HAART.
- Prior to the initiation of therapy, taftipsT variant was found in 24/24 clones. At week 14 of therapy, this variant was completely replaced with taftipsI. By week 19, a complete replacement occurred again, this time to taftipsM. The change at nucleotide level suggests a stepwise progression from ACA to ATA to ATG.
- The taftipsT and taftipsM variants had lower avidity than the taftipsI variant, but this wasn't evident at saturating conditions; only careful titrations revealed the difference. HLA-B51 stabilization studies revealed the increased stabilization with the taftipsI form. Also, CD3 down-regulation was larger in response to taftipsI.
- The viral shift to the taftipsM variant during HAART was predicted to have minimal or undetectable effect on drug sensitivity.

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in

vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.

- The best estimate of escape rate for this epitope, YF-PDWQDYT, was found to be 0.002/day (optimistic escape rate = 0.012), with SE of 0.001.
- In the subject studied, the monotonic outgrowth of a I290T mutation in Pol was observed over a period of 817 days.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- SPAIFQSSM was a previously defined B\*07 presented epitope that encompassed a B\*0702-associated polymorphism, SPAIFQsSM, in the seventh position.

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction
- Only B\*0702 was found to be associated with polymorphism.

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** Menendez-Arias *et al.* 1998; Shiga *et al.* 1996

- Binds HLA-B\*3501.
- Menendez-Arias *et al.* [1998], in a review, notes that this epitope includes catalytic residues in the active site of RT.

**HXB2 Location** RT (156–164)

**Author Location** Pol (311–319)

**Epitope** SPAIFQSSM

**Immunogen** HIV-1 infection

**Species (MHC)** human (B35)

**References** Ferrari *et al.* 2000

- One of the 51 HIV-1 epitopes selected by Ferrari *et al.* as good candidate CTL epitopes for vaccines by virtue of being conserved and presented by common HLA alleles.

**HXB2 Location** RT (156–164)

**Author Location** RT Pol (311–319)

**Epitope** SPAIFQSSM

**Immunogen** HIV-1 infection

**Species (MHC)** human (B35)

**Country** Spain

**Assay type** proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** HAART, ART, supervised treatment interruptions (STI), immune dysfunction

**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.
- 5/9 patients recognized this epitope.

**HXB2 Location** RT (156–164)

**Author Location** Pol (156–164 HXB2)

**Epitope** SPAIFQSSM

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** rate of progression, immunodominance

**References** Hay *et al.* 1999

- CTL response to IPRRIRQGL was the immunodominant response in a rapid progressor – there was a subdominant response to SPAIFQSSM in Pol, and interestingly, no response to commonly immunodominant HLA A\*0201 epitope SLYNTVATL, although this individual was HLA A\*0201.
- The individual showed a strong initial CTL response at the time of the initial drop in viremia, but it was quickly lost, although memory cells persisted.
- Despite the initial narrow response to two epitopes, no other CTL responses developed.
- No HIV-specific lymphoproliferative responses were detected in this patient, and neutralizing antibody response was weak.
- Variants of this epitopes were observed *in vivo* (spaifqCsm, spSifqssm), but the binding motifs for B7 were preserved (P2, and C-term aromatic or hydrophobic)

**HXB2 Location** RT (156–164)

**Author Location** Pol

**Epitope** SPAIFQSSM

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** rate of progression, acute/early infection

**References** Islam *et al.* 2001

- Subject 053i was followed longitudinally from acute infection through death, and had rapid progression to AIDS.
- This individual had a dominant response to IPRRIRQGL with strong *in vivo* activated responses and *in vitro* stimulated memory responses and a subdominant response to SPAIFQSSM – during the course of disease progression (4 Years), the functional CTL responses were lost and no sequence variation occurred with in both epitopes, but CTL clones specific for IPRRIRQGL persisted throughout.

**HXB2 Location** RT (156–164)

**Author Location** RT (323–331 SF2)

**Epitope** SPAIFQSSM

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** HAART, ART, acute/early infection

**References** Altfeld *et al.* 2001b

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-B7+ individuals that had a CTL response to this epitope broken down by group: 0/4 group 1, 0/3 group 2, and 1/1 group 3.

**HXB2 Location** RT (156–164)

**Author Location** RT (156–164)

**Epitope** SPAIFQSSM

**Epitope name** B7-SM9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Donor MHC** A3, B7, Cw7

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 1/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 3/4 individuals had detectable responses to this epitope after STI.

**HXB2 Location** RT (156–164)

**Epitope** SPAIFQSSM

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** assay standardization/improvement, epitope processing

**References** Draenert *et al.* 2004a

- 96% of optimally defined epitopes have one of only nine amino acids serving as the C-terminal anchor position. Seven amino acids are never found in this position and four are only present in 4% of cases. CD8 T-cell response to an epitope is shown to be best detected when the epitope is situated at the C-terminal end of a longer peptide, and authors suggest that Elispot reagents would be better designed if peptides ended on known C-terminal anchors.
- SPAIFQSSM is suggested to be the optimal epitope instead of SPAIFQSSMT.

**HXB2 Location** RT (156–164)

**Author Location** (B consensus)

**Epitope** SPAIFQSSM

**Epitope name** SM9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Donor MHC** A03, B07, Cw7

**Assay type** Cytokine production, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** assay standardization/improvement, memory cells, characterizing CD8+ T cells

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between

HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.

- 1/9 individuals recognized this epitope.

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**References** Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- HLA-B7+ individuals with a S162x (18/33) substitution had higher viral loads than those that did not, suggesting escape was associated with diminished immune control of viremia.

*HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human, macaque (A\*0301, A11, A33)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This epitope was predicted by the EpiMatrix method to be likely to bind to A11, and it served as an epitope in the FSWs, it was one of the six A11 epitopes that had been previously defined.

- 6/8 tested FSWs recognized this epitope.
- An HLA-A11 tetramer was made for this epitope, which was recognized by two subjects – and both subjects had expanded tetramer staining T-cell populations after *in vitro* stimulation.
- This epitope was highly conserved in other subtypes, and exact matches were common.

**Epitope** AIFQSSMTK

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11)

**Keywords** epitope processing, escape

**References** Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- HLA-A11+ individuals with a K166x (4/19) substitution had higher viral loads than those that did not, suggesting escape was associated with diminished immune control of viremia.

**Keywords** escape, optimal epitope

**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences *in vivo*. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The AK9 variant AIFQSSMT<sub>r</sub> was essentially the only form of the epitope detected over a 5-year period in this person. Elispot reactions indicated the T-cell clones only recognized the autologous form, not the B clade consensus, AIFQSSMTK. Two rare variants were observed at the 5-year time point, tIFQSSMT<sub>r</sub> and AIFQSSMar.

**Epitope** IFQSSMTKI  
**Epitope name** E  
**Subtype** C  
**Immunogen** vaccine  
*Vector/Type:* DNA, alphavirus replicon  
*Strain:* C clade C-96BW04.09, C clade C-96BW15C05 *HIV component:* Gag, Gag-Pol, Pol
- Species (MHC)** mouse (H-2d)  
**Assay type** Flow cytometric T-cell cytokine assay  
**Keywords** vaccine-induced epitopes, vaccine antigen design
- References** Megede *et al.* 2006
- HIV clade C gag, pol and fusion gagpol vaccines were compared in mice. Breadth of T cell responses was improved in mice immunized with gagpol fusion genes, compared to single antigen constructs. 5 new murine CD8+ T cell epitopes were mapped.
  - This is a novel epitope.
- HXB2 Location** RT (164–172)  
**Author Location** RT (1645–172)  
**Epitope** MTKILEPFR  
**Epitope name** MR9  
**Immunogen**  
**Species (MHC)** human (A\*0301)  
**References** Zimbwa *et al.* 2007

- E169D is a processing mutation for HLA-B\*0702 restricted SPAIFQSSM (SM9) as well as an epitope variation for HLA-A\*0301 restricted MTKILEPFR (MR9).
- CTL recognition of MR9 was detected 5 days post-infection with wild type (169E) HIV-1, but not with mutant 169D virus bearing epitope MTKILdPFR.
- Binding assays found a 44% reduction in binding to HLA-A\*0301 by the variant epitope MTKILdPFR.
- Mutation 169D lies within MR9. In vitro proteasome processing assays showed that both wild type or variant 27-mer synthetic peptide QGWKGGSPAIFQSSMTKILE(d)PFRKQNPd released appropriate MR9-intermediate peptides within 6 h.

**HXB2 Location** RT (164–172)

**Author Location** Pol (343–351)

**Epitope** MTKILEPFR

**Immunogen** HIV-1 infection

**Species (MHC)** human (A3 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind 4/5 HLA-A3 supertype alleles (A\*0301, A\*1101, A\*3101, A\*3301 and A\*6801).

**Immunogen** HIV-1 infection, peptide-HLA interaction

**Species (MHC)** human

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** immunodominance

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, MTKILEPFR, is similar to human protein Piwi-like 2, sequence MTKILEPc and human protein SON DNA Binding protein, sequence sMTKILdSF.

**Keywords** optimal epitope  
**References** Frahm *et al.* 2008; Goulder *et al.* 2001a  
 • C. Brander notes this is an A\*3002 epitope.

**HXB2 Location** RT (173–181)  
**Author Location** RT  
**Epitope** KQNPDIIVY  
**Epitope name** KY9 (RT-53)  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A\*3002)  
**References** Goulder *et al.* 2001a  
 • HLA-A\*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.  
 • A rapid method was developed combining ELISPOT with intracellular IFN- $\gamma$  staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.  
 • Two individuals were studied: Subject 199 (HLA A\*0201/\*3002 B\*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A\*3002/ B53/\*5801 Cw4/7) an African-Caribbean.  
 • In both HLA-A\*3002 individuals the response to RSLYNT-VATLY was dominant.  
 • In subject 199 four additional A\*3002 epitopes were identified.  
 • Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

**References** Kiepiela *et al.* 2004  
 • HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.  
 • This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** RT (173–181)  
**Author Location**  
**Epitope** KQNPDIIVY  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A30)  
**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** supertype, cross-presentation by different HLA  
**References** Frahm *et al.* 2007

• 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.  
 • In addition to its known HLA association (A30), an additional HLA (A6801) was statistically predicted to be associated with this epitope.

**Epitope** KQNPDIIVY  
**Subtype** B  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (B\*1503)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** subtype comparisons, rate of progression, immunodominance  
**References** Frahm *et al.* 2006  
 • CTL responses restricted by HLA-B\*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B\*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects in spite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominant CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.  
 • KQNPDIIVY of clade B is a potential HLA-B\*1503-restricted epitope, with epitope KQNPEIIVY found in clade C.

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- NPDIIVYQY was one of two epitopes characterized in detail. D177x substitutions are known to specifically abrogate binding to HLA-B\*3501, and not other B\*35 subtypes. D177x substitutions were associated with people who carried HLA-B\*3501 and not other B\*35 subtypes; considering high resolution typing generally strengthened the B\*35 associations.

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ INF- $\gamma$  T-cell responses in 21 men within 15-92days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of INF- $\gamma$

secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**Keywords** escape, acute/early infection

**References** Bansal *et al.* 2005

- Patients with acute or early infection were shown to preferentially target variable peptides with higher entropy while those with chronic infection showed responses towards more conserved peptides with lower entropy. In longitudinally followed subjects, responses to variable proteins declined over time while responses to conserved proteins increased. The decline is suggested to be due to CTL escape.
- The response to this epitope was not detected until month 25.

**References** Kaul *et al.* 2001c

- This study examines CTL responses in HIV exposed, persistently seronegative individuals, HEPS, who eventually seroconverted – 11/114 HEPS Nairobi sex workers eventually seroconverted, and for six of these HIV CTL reactive epitopes had been defined while seronegative.
- HPDIVIYQY or NPDIVIYQY was recognized in 1 of the 6 women (ML857), and the response was present in the last available sample prior to seroconversion, 7 months.
- 20/20 sequences of the infecting strain had three substitutions in this epitope, all 20 were NpQiIiyqy, and this form was not recognized by CTL from ML 857 – this was the only case in the study where a virus carrying an unrecognized form of the epitope broke through.
- The epidemiological factor associated with seroconversion was stopping sex work. HIV-specific CTL activity declined when HEPS sex workers stopped working for a period or retired.
- NPDIVIYQY was recognized by 1/22 HEPS control sex workers, ML887.

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative  
**Species (MHC)** human (B35)  
**Keywords** HIV exposed persistently seronegative (HEPS), immunodominance

**References** Kaul *et al.* 2001a

- Variants (H/N)PDIVIYQY are specific for the A/B clades.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B35 women, 2/3 HEPS and 1/4 HIV-1 infected women recognized this epitope.
- The dominant response to this HLA allele was to this epitope in only one of the 2/3 HEPS cases, and was not to this epitope in the one responsive HIV-1 infected women.
- Subject ML 857 shifted from a A\*6802 DTVLEDINL and B35 (H/N)PDIVIYQY response prior to seroconversion to a B35 PPIPVGDIY and B35 VPLRPMTY response post-seroconversion and the loss of the pre-seroconversion response was not due to sequence variation within these epitopes.

**Keywords** mother-to-infant transmission

**References** Sabbaj *et al.* 2002

- IFN $\gamma$  T-cell responses in breast milk of 5 HIV-1 infected women from the US and 6 from Zambia were tested with using Elispot. 11/11 women responded to Gag, 8/11 responded to Pol, 7/11 women to Nef, and 2/5 women to Env peptide pools. These responses were shown to be primarily due to CD8+ T-cells in one woman, and another woman had cytolytic responses measured by Cr-release.
- T-cells in breast milk from a volunteer who was HLA A3, A11, B35, B51 induced IFN $\gamma$  after stimulation with a peptide that carries known B35 epitope NPDIVIYQY.

- The frequencies of responses in the two compartments differed, and 2/4 women that responded to epitopes in Nef 101-205 and Pol 601-710 showed responses in breast milk but no detectable responses in peripheral blood cells.

**HXB2 Location** RT (175–183)

**Author Location** Pol

**Epitope** HPDIVIYQY

**Subtype** A

**Immunogen** HIV-1 infection, vaccine

*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade  
*HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human, macaque (B35)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

**Keywords** assay standardization/improvement, optimal epitope

**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, VIVQYMDDL, was detected within overlapping peptide RKQNPDIVIVQYMDDLIV.

**HXB2 Location** RT (179–187)

**Epitope** VIYQYMDDL

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** epitope processing, immunodominance, escape

**References** Sewell *et al.* 1999

- Proteasome regulation influences epitope processing and could influence patterns of immunodominance.
- The proteasome is inhibited by lactacystin treatment, and gamma IFN induces expression of proteasome subunits, LMP2 and LMP7, which combine with the proteasome to create an immunoproteasome.
- IFN-gamma induction of the immunoproteasome and lactacystin inhibition increases the presentation of the A\*0201 VIYQYMDDL epitope, but decreases the presentation of the A\*0201 ILKEPVHGV epitope, which is immunodominant

within pol proteins, showing the two epitopes are processed by different pathways.

- ILKEPVHGV seems to be processed by the classical proteasome pathway, while VIYQYMDDL appears to be destroyed by this pathway.

- This epitope contains the catalytic site (YMDD) of RT, a conserved sequence in HIV-1 which restricts escape mutants.

**References** Dela Cruz *et al.* 2000

- Integration of HIV RT CTL epitopes into the N-terminus of the HLA-A2 heavy chain, or tethering the epitopes to the target chain, resulted in epitope-specific lysis by CD8+ CTL.
- These antigens could also be used to stimulate primary responses *in vitro*.

**HXB2 Location** RT (179–187)

**Author Location** Pol (346–354)

**Epitope** VIYQYMDDL

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** epitope processing, immunodominance

**References** Sewell *et al.* 2002

- Epitope processing of three different HLA-A\*0201 HIV epitopes was shown to use different pathways, which might influence patterns of immunodominance. .174 cells were used that lack TAP1 and TAP2 genes, as well as the LMP2 and LMP7 genes that encode the beta-subunits of the immunoproteasome. These genes could be added back through transfection to study processing.
- ILKEPVHGV was efficiently presented in TAP-1 and -2 transfected cells while VIYQYMDDL and SLYNTVATL were not. VIYQYMDDL was destroyed by the MB1 subunit of the protease, and could be expressed in the presence of the protease inhibitor lactacystin, but SLYNTVATL expression was not restored. SLYNTVATL expression was unaltered by lactacystin in a wild type cell line.

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*02/A\*0201 restricted epitope, VIYQYMDDL was mutated to cIYQYMDDL in the daughter D2 isolate.

**Keywords** HAART, ART, epitope processing

**References** Kelleher *et al.* 2001a

- Ritonavir (RTV) inhibits chymotryptic activity in the 20S proteasome *in vitro*, as does Saquinavir (SQV) to a lesser extent; Indinavir (IDV) does not. Thus there is concern protease inhibitors may adversely effect CTL epitope processing, but this paper indicates that processing is not inhibited at therapeutically relevant concentrations of RTV when the proteasome is functioning in an intracellular context.
- RTV did not alter the presentation two RT A2 epitopes processed by distinct pathways: ILKEPVHGV, generated by the constitutive proteasome containing the MB1 beta subunit, and VIYQYMDDL which is dependent on IFN $\gamma$  induction of LMP7 which replaces MB1 in the immunoproteasome, and is destroyed by MB1 in the constitutive proteasome.
- RTV did not inhibit the processing and assembly of HLA-B35 or -A2, which are assembled with a rapid and moderate time course, respectively, or of HLA-A3, -B27 and -B39.

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The

modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.

- This was 1 of 4 A2 gag/pol epitopes tested. Transgenic mice immunized with the deleted construct induced more potent EliSpot reactions to this epitope than those immunized with full length Gag/Pol.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Two patients developed responses to epitope YQYMDDL during primary infection and in early chronic infection.

**Keywords** binding affinity, immunodominance  
**References** Frahm *et al.* 2004
- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
  - Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
  - In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
  - This overlapping peptide, KIEELRQHLLRWGFTTPDK, was differentially targeted across ethnic groups and had an overall frequency of recognition of 13.3% - 5.1% AA, 23.1% C, 25% H, 0% WI (P value = 0.0018).

**Immunogen** HIV-1 infection  
**Species (MHC)** human (B\*4001)  
**Donor MHC** A\*0201, A\*2402, B\*4001, B\*5001, Cw03, Cw04

- Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining  
**Keywords** immunodominance, escape, variant cross-recognition or cross-neutralization  
**References** Draenert *et al.* 2006
- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their sero-conversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
  - This epitope, IEELRQHLL (IL9) restricted by HLA-B\*4001, was one of two immunodominant responses. Variants that arose were vEELReHLL and IEELReHLL.

**Epitope** IEELRQHLL  
**Epitope name** B40-IL9(RT)  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (B40)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** rate of progression, immunodominance, early-expressed proteins  
**References** Altfeld *et al.* 2006
- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
  - The most frequently recognised epitopes also elicited the greatest CTL response.
  - HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
  - HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
  - In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- HXB2 Location** RT (202–210)

**Epitope** IEELRQHLL  
**Epitope name** IL-9  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (B40)  
**Assay type** Other  
**Keywords** escape, TCR usage, immune evasion  
**References** Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance

of CTL response [Draenert et al. *J. Exp. Med.* 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.

- This epitope, IL9, showed concordant epitope evolution between the twins, but both alpha and beta TCR chains recruited were entirely different between them.

**Species (MHC)** human (B40)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** supertype, cross-presentation by different HLA

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (B40), an additional HLA (B37) was statistically predicted to be associated with this epitope.

**HXB2 Location** RT (202–210)

**Epitope** IEELRQHLL

**Immunogen** HIV-1 infection

**Species (MHC)** human (B60)

**Keywords** HAART, ART, acute/early infection

**References** Altfeld *et al.* 2001b

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-B60+ individuals that had a CTL response to this epitope broken down by group: 0/2 group 1, 1/1 group 2, and 0/0 group 3.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** HAART, ART, supervised treatment interruptions (STI), early treatment

**References** Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Arnedo-Valero *et al.* 2004

- T cell immune responses following STI were monitored in two chronically HIV-1 infected partners (A and B) who had contracted HIV-1 during 1992. Both were heterozygous for the CCR5 delta32, and had different HLAs and treatment histories. STI induced strong transitory CD4+ and CD8+ T cell responses in both patients. Patient A displayed broad

CD8+ T cell responses directed against Env, Pol, Gag, and Nef HIV-1 antigens. CTL responses in patient B were mainly directed against two epitopes: Gag(p24)NANPDSKTI and Pol(RT)EELRQHLLRW.

- Despite the host differences, both patients had similar dynamics of viral evolution and CD4+ T-cells, suggesting that good immune responses to STI may be more related to the virus than host characteristics in these cases.

**Keywords** HAART, ART, supervised treatment interruptions (STI), immune dysfunction

**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.

- 9/11 patients recognized this epitope; of three B\*44 epitopes tested, this was the only one that was recognized by more than 2/11 patients.

- T cell immune responses following STI were monitored in two chronically HIV-1 infected partners (A and B) who had contracted HIV-1 during 1992. STI induced strong transitory CD4+ and CD8+ T cell responses in both patients. The viruses remained very closely related over 10 years, despite the two individuals having different HLA types; the authors suggest the maintained similarity does not support a strong role for HLA driven HIV diversity as has been claimed in Moore *et al.* (Science 2002).

- During the second treatment stop, patient A developed a strong proliferative response to p24, and multiple strong CD8+ T cell responses to Env, Pol, Gag and Nef. This patient was able to control viral load for two years follow up without therapy. Patient B developed a very weak CD4+ T cell response against p24 during breaks in therapy, and had CD8+ responses

to two epitopes. Patient A: A01, A32, B\*1410, B15; Patient B: A\*3101, A68, B\*4403, B51.

**References** Mason *et al.* 2005

- CTL responses against the IP-30 signal peptide associated with autoimmunity were shown to be elicited by stimulation of PBMCs from HIV-1 infected individuals with HIV protease peptide 76-84. In vitro stimulation with HIV PR 76-84 or the IP-30 signal peptide was shown to activate a comparable population of cross-reactive effector cells. None of the peptides activated CTL in non-HIV-infected individuals. IP-30 signal peptide was shown to have lower avidity T-cell interactions than the HIV peptide.
- As a control, responses to A2-restricted HIV epitopes ALVEICTEM, EELRQHLLRW, and LSPRTLNAW were shown not to give IP-30 responses.

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Position 8 in the epitope had potentially experienced positive selection. ELRQHLLkW escape variant was found.

**References** Larke *et al.* 2007

- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.
- After immunization with Clade A vaccine containing RT1, RAHLLSWGf, this index epitope was not recognized. Clade B vaccine containing RQHLLRWGL generated T cells that recognized its index epitope as well as variants RaHLLSWGf (Clade A index), RkHLLkWGf (Clade C index), RaHLLRWGf, RQHLLRWGf, ReHLLkWGf, ReHLLRWGf, RgHLLkWGf, RkHLLSWGf at lower levels. C Clade vaccine with index epitope RKHLLKWGF resulted in T cells that recognized that epitope, and Clade B index epitope RqHLLrWGL, and epitope RKHLLsWGf at 53%.

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
