**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**Epitope** IVLPEKDSW

**Epitope name** IW9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- HLA-B\*57-restricted optimal epitope IVLPEKDSW was tested for immune response.
- No loss of recognition was seen for variants I147L (IVLPEKDSW) and I147M (mVLPEKDSW) in several subjects, none of whom had the I147M mutation.
- I146P variant, iVLPEKDSW, blocks presentation of epitope IW9.

- An early-expressed Nef protein was modified to contain Env and Pol epitopes to enable the study the effect of expression kinetics on CTL mediated suppression of replication. The "EpiNef" construct was inserted into a recombinant vaccinia virus which was used to infect a target cell line; the target cells were lysed by CTL clones specific for the Env and Pol epitopes indicating that they were properly processed.

**HXB2 Location** RT (244–252)**Author Location** RT (244–252 ACH320.2A.2.1)**Epitope** IVLPEKDSW**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** (B57)**Keywords** acute/early infection, early-expressed proteins, kinetics**References** van Baalen *et al.* 2002

- Tat, Rev and Nef are the first HIV proteins expressed upon acute infection of T-cells (< 6 hours), and RT is not expressed until after 24 hours. The B14-restricted Rev-SAEPVPLQL specific CD8 T-cell clone TCC108, and the B57-restricted RT-IVLPEKDSW specific CD8 T-cell clone TCL1C11 were co-incubated with CD4+ cultures inoculated with HIV-1 at low MOI. Co-incubation with the Rev-specific CTL resulted in two logs less HIV-1 production in ten days of culture. When the RT epitope was cloned into the Nef gene of the infecting strain, another early expressed protein, it proved as effective as the Rev epitope at inhibiting viral production. A mathematical model of CTL-target interactions suggest early proteins are important for vaccine design.

**HXB2 Location** RT (244–252)**Author Location** Pol**Epitope** IVLPEKDSW**Epitope name** IW9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B57)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.

- One escape mutation, at position 2, was found in the most polymorphic residue in the epitope. This was shared between clades B and C. The position 2 mutation was significantly more common among persons expressing HLA-B57.

**HXB2 Location** RT (244–252)**Author Location** RT**Epitope** IVLPEKDSW**Epitope name** B57-IW9(RT)**Immunogen** HIV-1 infection**Species (MHC)** human (B57)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, immunodominance, early-expressed proteins**References** Altfield *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**References** Streeck *et al.* 2007a

- To characterize HIV-1 proteome areas that are targeted in early, effective CTL responses, two cohorts were studied. Responses in early infection were against fewer epitopes and of lower magnitude than during chronic infection. While no region of the proteome was favored, Nef was the predominant target based on length of proteins. When based on the expression of protective versus nonprotective HLA I alleles, it was found that HLA-B27 and -57 possessing slow progressors to disease directed the majority of their responses to Gag in early infection, as opposed to those with HLA-B\*3501 or B\*3502, i.e. rapid progressors to AIDS, who had negligible responses to Gag. As compared with HLA-B57-/B27-subjects and HLA-B35 subjects, HLA-B57+/27+ subjects responded most to the p24 component of Gag. By using overlapping peptides within Gag p24, two were picked as being consistently targeted, and both contained previously described epitopes TW10 and KK10.
- IVLPEKDSW, i.e. epitope IW9 of RT protein was targeted in 62% of B57+ non-progressors to disease.

**Keywords** responses in children, mother-to-infant transmission, escape

**References** Feeny *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

**HXB2 Location** RT (245–252)

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.

- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNP to clear virus.
- This epitope can bind four of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).
- Tetramer staining with A2, beta2microglobulin, and either SLYNTVATL, KLVGKLNWA, or LTFGWCFKL revealed that tetramers detected more HIV-specific cells in LTNP than in progressors, activated effector cells were the minority population, and ELISPOT correlated better with the effector cell subpopulation than the total tetramer stained population.

- HLA-A\*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN- $\gamma$  staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A\*0201/\*3002 B\*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A\*3002/ B53/\*5801 Cw4/7) an African-Caribbean.
- In both HLA-A\*3002 individuals the response to RSLYNT-VATLY was dominant.
- In subject 199 four additional A\*3002 epitopes were identified.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

**HXB2 Location** RT (263–271)**Author Location** (C consensus)**Epitope** KLNWASQIY**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (A\*3002)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** characterizing CD8+ T cells**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** RT (263–271)**Author Location** (C consensus)**Epitope** KLNWASQIY**Subtype C****Immunogen** HIV-1 infection**Species (MHC)** human (A\*3002)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, optimal epitope**References** Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- KLNWASQIY is an optimal epitope.

**HXB2 Location** RT (263–271)**Author Location** RT**Epitope** KLNWASQIY**Epitope name** A30-KY11(RT)**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A30)**Donor MHC** A30, A32, B18, B27**Keywords** HAART, ART, supervised treatment interruptions (STI)**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- HLA, viral sequence, and Elispot data was obtained from 105 HIV-1 positive Botswanans; Elispot data was obtained from between 55 and 64 subjects for each HIV protein.
- Nef and p24 had the highest percentage of reactive peptides, and p24 had the highest magnitude of HIV-1 responses.
- This peptide was among the 28 most reactive C clade peptides from among over 350 tested spanning all HIV proteins.

**HXB2 Location** RT (268–282)**Author Location** RT (SF2)**Epitope** SQIYPGKIKVRQLCKL**Immunogen** HIV-1 infection**Species (MHC)** human**References** Altfeld *et al.* 2001a

- HIV+ individual AC-06 was tested for reactive overlapping peptides spanning all HIV-1 proteins in an ELISPOT and was found to react with 12 peptides from 7 proteins, suggesting that the breadth of CTL responses are underestimated if accessory proteins are not included in the study.
- RT peptides SQIYPGKIKVRQLCKL and WKG-SPAIFQSSMTKI were recognized.

**HXB2 Location** RT (269–277)**Author Location** (LAI)**Epitope** QIYPGKIKVR**Subtype** B**Immunogen****Species (MHC)** human (A\*0301)**Keywords** optimal epitope**References** Altfeld 2000; Frahm *et al.* 2008**HXB2 Location** RT (269–277)**Author Location** RT (269–277)**Epitope** QIYPGKIKVR**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0301)**Assay type** Other**Keywords** HLA associated polymorphism**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- QIYPGKIKVR was a previously defined A\*0301 presented epitope that encompassed an A\*03- associated polymorphism, QIYPGKIKVrIQ, in the last position. This epitope was embedded in a previously determined CTL immunoreactive region.

**HXB2 Location** RT (269–277)**Author Location** Pol (424–432)**Epitope** QIYAGIKVK**Subtype** B, CRF01\_AE**Immunogen** HIV-1 infection**Species (MHC)** human (A\*1101)**Keywords** binding affinity, subtype comparisons**References** Fukada *et al.* 2002

- binding affinity, inter-clade comparisons.
- Counterparts for eight known clade B HLA A\*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A\*1101 epitopes was recognized in a clade specific manner. Two other HLA A\*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- QIYAGIKVK is commonly found in viruses representing subtypes A, B and E. It was strongly recognized by CTL from 1/5 B clade infected Japanese subjects, and 5/7 E clade infected Thai subjects.
- QIYAGIKVK had the highest A\*1101 binding affinity, but qiyagikvR and qiyPgikvR (the most common C and D clade variant both bound to A\*1101). QIYAGIKVK and qiyagikvR were both cross-presented by a clone from a B clade infection, but qiyPgikvR was not.

**HXB2 Location** RT (269–277)**Author Location** (B consensus)**Epitope** QIYAGIKVK**Epitope name** QVK9**Immunogen** HIV-1 infection**Species (MHC)** human (A11)**Donor MHC** A02, A11, B18, B44, Cw12, Cw5**Country** United States**Assay type** Cytokine production, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** assay standardization/improvement, memory cells, characterizing CD8+ T cells

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- A strong association between B\*4201 and variation in the epitope was found.

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**References** Ueno *et al.* 2004b

- Two different clonotypes of CD8+ T-cells with specificity for this epitope were isolated from a chronic HIV+ patient. The clonotype with the relatively high affinity TCR had no cytolytic activity, cytokine production or proliferation in response to HIV-infected cells, while the moderate affinity clonotype had strong reactions. More than 3-fold increased duration in tetramer 1/2 life was observed with the defective clonotype. The TCRs from the two clonotypes preserved the phenotype when transduced into primary CD8+ T cells, suggesting the TCR with higher affinity was directly associated with impaired T-cell reactivity of the cells.
- The high affinity impaired TCR was Valpha1.1/Vbeta13.3, the moderate affinity active TCR was Valpha12.1/Vbeta5.6.

**Donor MHC** A\*2402, A\*2601, B\*3501, B\*5101

**Country** Japan

**Assay type** Cytokine production, Tetramer binding, Chromium-release assay

**Keywords** binding affinity, cross-presentation by different HLA, immunotherapy, TCR usage, characterizing CD8+ T cells

**References** Ueno *et al.* 2004a

- This paper described the transduction of HIV specific clone TCR genes Valpha12.1/Vbeta5.6 into primary CD8+ T cells. Epitope fine specificity and appropriate effector functions were observed in the transduced cells, although functional avidity could change due to different densities of TCR on the surface of the transduced cells. No allogenic responses were detected. This methodology could have immunotherapeutic applications.

**HXB2 Location** RT (293–301)

**Author Location** Pol (448–456 SF2-24)

**Epitope** IPLTEEAEL

**Epitope name** HIV-B35-SF2-24

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*3501, B\*5101)

**References** Tomiyama *et al.* 2000b

- This epitope is naturally processed and presented by both HLA-B\*3501 and HLA-B\*5101 and is cross-recognized by a single CTL clone.
- IPLTEEAEL binds approximately four times more tightly to HLA-B\*3501 than HLA-B\*5101.

**HXB2 Location** RT (293–301)

**Author Location** Pol (489–456)

**Epitope** IPLTEEAEL

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*0702, B\*3501, B\*5101, B\*5301)

**Donor MHC** A24, A26, B35, B51, Cw3

**Keywords** supertype, cross-presentation by different HLA, TCR usage

**References** Ueno *et al.* 2002

- The IPLTEEAEL epitope was known to be presented by both HLA-B\*3501 and -B\*5101 to a dual specific CTL clone. A single TCR complex bearing Valpha12.1 and Vβ5.6 was shown recognize the epitope in either HLA-B\*3501 and -B\*5101. Furthermore, this TCR also recognized the peptide presented by B\*5301 and B\*0702 in cytolytic CTL assays, demonstrating that this single TCR complex recognizes the same peptide presented by a range of HLA class I molecules.

**Country** Netherlands

**Assay type** CD8 T-cell Elispot - IFNγ, Flow cytometric T-cell cytokine assay

**Keywords** rate of progression, escape

**References** Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occurred sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these epitopes, but this increased over time.

**Assay type** CD8 T-cell Elispot - IFNγ, Tetramer binding, CD4 T-cell Elispot - IFNγ

**Keywords** rate of progression, immunodominance, escape

**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- The IPL epitope was found to be under positive selection for escape mutations and it was replaced by first variant between days 297 and 369, ipltGaeI. This new variant was subsequently replaced by 2 further variants, that were even more resistant to CD8+ T cell recognition between days 369 and 635, ipltAeaeI and ipltVeaeI.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This overlapping peptide, ASRELERFAVNPGLL, was differentially targeted across ethnic groups and had an overall frequency of recognition of 13.3% - 6.8% AA, 26.9% C, 20.5% H, 0% WI (P value = 0.0028).

**Assay type** Intracellular cytokine staining, Other

**Keywords** rate of progression, escape, immune evasion

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Responses to epitope IV9 were seen in early chronic infection.

**HXB2 Location** RT (309–317)

**Author Location** RT (309–317)

**Epitope** ILKEPVHGV

**Epitope name** IV9

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*02)

**Assay type** CTL suppression of replication

**Keywords** class I down-regulation by Nef

**References** Adnan *et al.* 2006

- The impact of Nef on antiviral activity was studied. CTL-targeting epitopes were susceptible to the effects of Nef, both in late (Gag, RT, Env) and in early proteins (Rev, Nef), although to a lesser degree in early proteins. However, HLA-C-restricted CTLs (unlike HLA-A and HLA-B) were unaffected by Nef both in early (Nef) and late (Env) proteins.
- Late protein RT epitope ILKEPVHGV-recognizing CTLs were affected by Nef.

**References** Wick *et al.* 2005

- Experimental and mathematical models were used to estimate the number of HIV-infected cells that can be killed by CD8+ T-cells. On average, CTLs can kill from 0.7 to 3.0 cells/day.
- CTL clone 68A62 recognizes epitope ILKEPVHGV and was used to study the inhibition of HIV-1 replication in acutely infected cells in vitro.

**HXB2 Location** RT (309–317)

**Author Location**

**Epitope** ILKEPVHGV

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** acute/early infection

**References** Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and a close temporal relationship between the number of circulating HIV-specific T cells and viral load.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWILGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

**Epitope** ILKEPVHGV

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** epitope processing, immunodominance

**References** Sewell *et al.* 1999

- Proteasome regulation influences epitope processing and could influence immunodominance.
- The proteasome is inhibited by lactacystin treatment, and gamma IFN induces expression of proteasome subunits, LMP2 and LMP7, which combine with the proteasome to create an immunoproteasome.
- IFN-gamma induction of the immunoproteasome and lactacystin inhibition increases the presentation of the A\*0201 VIYQYMDDL epitope, but decreases the presentation of the A\*0201 ILKEPVHGV epitope, which is immunodominant within pol proteins, showing the two epitopes are processed by different pathways.
- ILKEPVHGV seems to be processed by the classical proteasome pathway, while VIYQYMDDL appears to be destroyed by this pathway.
- This epitope contains the catalytic site (YMDD) of RT, a conserved sequence in HIV-1 which restricts escape mutants.

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**References** Altman *et al.* 1996

- This paper introduces the tetramer methodology which permits quantification of specific CTL based on expression of specific TCRs—HLA-A2 tetramers were prepared that can stain CTL lines specific for ILKEPVHGV and SLYNTVATL, and can quantify HIV-specific CD8+ cell lines in freshly isolated PBMCs.
- Three patients only stained the Gag epitope SLYNTVATL, one patient had the highest frequency of tetramer staining to the Pol epitope (0.77%), less to the Gag epitope (0.28%)
- The A2-Pol CD8+ clones were CD45RO positive and HLA-DR and CD38 negative, suggesting a memory rather than effector phenotype.

**References** Peter *et al.* 2002

- When HIV-1 peptides were used to vaccinate HLA-A2.1 transgenic A2-Kb mice, strong responses to five peptides were observed when the peptides were given individually, but immunodominance limited the response to some of the peptides when they were given in combination Peter *et al.* [2001]. IL-12 can counteract immunodominance in BALB/c mice, so it

was given with the multiple epitope vaccination, and was instead found to specifically eliminate the HLA-A2.1-epitope CTL responses, but not Kb CTL responses. This was possibly a consequence of transient depletion of T-cells, B cells and macrophages in the spleen.

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFNgamma Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**Species (MHC)** human (A\*0201)

**Keywords** epitope processing, dendritic cells

**References** Andrieu *et al.* 2003

- This study demonstrates that lipopeptides carrying epitopes can be taken up by human dendritic cells, processed using different pathways, and recognized by epitope-specific CD8+ T-cells originally derived from HIV+ individuals. The RT ILKEPVHGV peptide was embedded in a longer peptide fragment in the lipopeptide, and was internalized by endocytosis and processed in the cytosol by proteasomal cleavage by following an endosome-to-cytosol pathway for processing and presentation. Administration of epoxomicin, a proteasome inhibitor, completely abrogated epitope presentation to a CD8+ T-cell line, while monensin, an inhibitor of acid-dependent endosomal enzyme activity did not.
- In contrast to the RT epitope, dendritic cell presentation of the Nef epitope QVPLRPMTYK embedded in a longer peptide in a lipopeptide was not inhibited by epoxomicin, but was inhibited by monensin, indicative of endocytotic epitope processing.

**References** Dagarag *et al.* 2003

- Telomer length is short in the CD8+ T-cell compartment of HIV-1 infected people, indicating excessive CTL activation and premature senescence. Here human telomerase RT (hTERT) transduction of HIV-1-specific CTL was used to study the functional impact of telomerase. Telomerase expression enhanced proliferative capacity, as well as cytolytic and antiviral capabilities; cytokine production was unchanged. hTERT transduced CTLs were 10-fold more efficient in controlling HIV-1 replication in culture. Thus telomerase transduction can restore CTL mediated cytolysis, and may have therapeutic potential.
- Three polyclonal CD8+ T-cell lines derived from an HIV-1, HLA A\*0201 positive patient were used in this study, including one specific for this epitope. An IV9-specific monoclonal cell line, 68A62 was also generated.

**Epitope name** IV9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding

**Keywords** HAART, ART, responses in children, dendritic cells

**References** Zhang *et al.* 2006

- Immune responses in HIV-1 infected children either undergoing HAART or not were analysed. HIV-specific CTLs were lower in children responding to HAART than in non-responders and HAART-naive children. CTL frequency was correlated with myeloid DC frequency in treatment-naive patients, and inversely correlated with duration of virus suppression following treatment.
- 11 of the 22 children had significant responses to SL9.

**References** Mollet *et al.* 2000

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using tetramer staining or CD8+ cell IFN $\gamma$  production to measure responses.
- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

**References** Bennett *et al.* 2007

- Standard assays like ELISpot, ICS and tetramer staining do not measure antiviral activity of HIV-infected CTLs, but use exogenous synthetic peptides on uninfected cells or HLA tetramers. Similarly, functional avidity assesses CTL activity against uninfected target cells. Here functional avidity is compared to the efficiency of actual infected cells' recognition and killing, revealing a sharp threshold between CTL immune antiviral activity and lack of infected cell recognition.
- As previously shown, epitopes and their variants spanned orders of magnitude of SD50. Likewise, CTL clearance of infected cells varied from 0 to 100% with epitope sequence variation. Moreover, direct suppression of HIV-1 replication by CTLs also varied with epitope variant.
- When killing efficiency (KE) using virus-infected cells was compared to functional avidity using synthetic peptides, there was a narrow threshold separating maximal killing from almost none. Since different SL9-specific clones had similar KEs, which were vastly different from RL10-specific CTL KEs, it was obvious that KEs varied with epitope sequence too. Finally, a strong correlation between KE and inhibition of viral replication was also seen.
- This epitope, ILKEPVHGV, showed marked differences in its functional avidity as well as killing efficiency, when compared to its variants ILKdPVHGV, ILKnPVHGV, ILKdPVHG<sub>a</sub>, ILKtPVHGV, ILrPVHGV, ILKEsVHGV, ILKEtVHGV, ILKEPVHG<sub>a</sub>, ILKEPVHeV, ILKqPVHGV, liKEPVHGV, ILrtPVHGV, ILKEPVHrV, ILKEPIHGV, kLKEPVHGV and ILKEIVHGV.

**Keywords** binding affinity  
**References** Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope ILKEPVHGV elicited a magnitude of response of 110 SFC with a functional avidity of 0.01nM.

**HXB2 Location** RT (309–317)

**Epitope** ILKEPVHGV  
**Immunogen** vaccine  
*Vector/Type:* vaccinia  
**Species (MHC)** human (A2)  
**References** Woodberry *et al.* 1999

- A polyepitope vaccine was generated in a vaccinia construct that contiguously encoded seven epitopes, all presented by HLA A-2.
- HHD mice have a transgene of HLA A2 linked to the transmembrane and cytotoxic domains of H-2D<sup>d</sup> – this transgene is the only MHC molecule expressed in the mice.

- CTL responses to Gag (77-85) SLYNTVATL, Pol (476-484) ILKEPVHGV, gp120 (120-128) KLTPLCVTL, and Nef (190-198) AFHHVAREL were observed in HIV polytope HHD-vaccinated mice, and these responses were enhanced with vaccination boost.
- No CTL immune responses were generated against HLA A2-restricted HIV epitopes Nef 157-166 (PLTFGWYCYKL), Pol 346-354 (VIYQYMDDL), and Nef 180-189 (VLEWRFD-SRL)
- Sixteen HLA A2+ patients were tested for their ability to make CTL responses by peptide restimulation in culture with the epitopes selected for inclusion in the polytope – one individual recognized all seven of these epitopes; 7 patients had CTL cultures able to recognize at least one of the epitopes, and 6 of those 7 recognized more than one epitope, but they were not able to test all peptides for all patients; many patients only had three peptides tested.
- ILKEPVHGV was recognized by 2 of the patients.

**Keywords** subtype comparisons, HIV exposed persistently seronegative (HEPS), immunodominance

**References** Kaul *et al.* 2001a

- Variants ILK(D/E)PVHGV are A/B clade specific.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A2 women, 7/10 HEPS and 14/26 HIV-1 infected women recognized this epitope, and ILK(D/E)PVHGV tended to be more reactive in HEPS women, SL(F/Y)NTVATL in infected women.

- The dominant response to this HLA allele was to this epitope in all 7/10 HEPS cases but in only 5 of the 14/26 HIV-1 infected women.
- Four epitopes were considered to be “resistant epitopes”, as they were preferentially reactive in HEPS women and so may confer resistance, and these were found in three different proteins: A2 ILK(D/E)PVHGV in RT, A\*6802 DTVLEDINL in Protease, B14 DLN(M/T)LN(I/V)V in p24 and B18 FRDYV-DRF(Y/F)K also in p24.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Subject ML 1250 had an A2 response to ILK(D/E)PVHGV prior to seroconversion, which switched to SL(F/Y)NTVATL post-seroconversion.
- Subject ML 1760 had an A2 response to ILK(D/E)PVHGV prior to seroconversion, and gained responses to epitopes A2 SL(F/Y)NTVATL and B27 KRWII(L/M)GLNK post-seroconversion.

**References** Kelleher *et al.* 2001a
- Ritonavir (RTV) inhibits chymotryptic activity in the 20S proteasome *in vitro*, as does Saquinavir (SQV) to a lesser extent; Indinavir (IDV) does not. Thus there is concern protease inhibitors may adversely effect CTL epitope processing, but this paper indicates that processing is not inhibited at therapeutically relevant concentrations of RTV when the proteasome is functioning in an intracellular context.
  - RTV did not alter the presentation two RT A2 epitopes processed by distinct pathways: ILKEPVHGV, generated by the constitutive proteasome containing the MB1 beta subunit, and VIYQYMDDL which is dependent on IFN $\gamma$  induction of LMP7 which replaces MB1 in the immunoproteasome, and is destroyed by MB1 in the constitutive proteasome.
  - RTV did not inhibit the processing and assembly of HLA-B35 or -A2, which are assembled with a rapid and moderate time course, respectively, or of HLA-A3, -B27 and -B39.

**Keywords** class I down-regulation by Nef  
**References** Yang *et al.* 2002
- Nef down-modulates class I protein expression, and this study demonstrates directly that Nef-deleted HIV-1 NL-43 can be more effectively killed *in vitro* than NL-43 with an intact Nef. The effect was shown to be specific for class I presentation of epitopes, and unlike Nef, deleting Vpr did not alter CTL susceptibility of NL-43 infected cells. The CTL clone 68A62, specific for the class I A2 presented ILKEPVHGV epitope, was one of four used in this study.

**References** Cohen *et al.* 2002
- The antigen presentation of two A2-restricted epitopes was compared, SLYNTVATL (p17) and ILKEPVHGV (RT). HIV-1 infected cells were more sensitive to lysis by SLYNTVATL-specific CTL than by ILKEPVHGV-specific CTL, because of a higher density of SLYNTVATL-A2 resulting from differences in processing.
  - Incubation with a T1-cell proteolytic extract showed that by four hours, 25% of a p17 peptide had a C-term Leu-85 and were SLYNTVATL-precursors, while ILKEPVHGV-precursors were far less frequent (6.8%) even with four times more proteolytic extract after 30 hours.
  - p17 was preferentially cleaved between Leu85 and Tyr86, while appropriate Val484 and Tyr485 cleavage was minor for RT.
  - In a competition experiment, RSLYNTVATL bound TAP 3.7-fold more efficiently than RT peptides.
  - No difference in CTL avidity was detected in six patients with HLA-A2-restricted responses to these epitopes.
  - No significant difference in HLA-A2 binding of to p17 or RT epitopes was observed.

- BALB/c mice immunized with the p9 peptide, ILKEPVHGV, elicited specific lymphocyte proliferation activity.
- Exposure of lymphocytes from HIV-negative, HLA-A2 positive people to p9-RNA stimulated lymphocyte proliferation activity to p9. Anti-p9 CTL activity in human lymphocytes incubated with RNA extracted from lymphoid organs of p9-vaccinated mice could be more intensely stimulated.
- This murine RNA also mediated RNA-dependent protein kinase (PKR) and NFkappaB activation in the human lymphocytes, which may be driving the enhanced CTL stimulation in the human cells.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Flow cytometric T-cell cytokine assay  
**Keywords** responses in children  
**References** Sandberg *et al.* 2003
- 65 vertically HIV-1 infected children, ages 1-16, the majority undergoing ART, were analyzed in regard to their plasma viremia and CD4+ and CD8+ T cell counts, and CD8+ T cell responses.
  - Using vaccinia expressed Gag, Pol, Env, Rev, Nef in target cells in an Elispot assay, 85% of the children recognized at least one HIV antigen. The strong CD8+ T cell responses were directed against Pol, followed by Gag and Nef. Children younger than 4 had significantly weaker responses (7/14 had no response) than older children (only 1/32 had no response, and responses were greater in magnitude).
  - SLYNTVATL and ILKEPVHGV tetramers were used to quantify specific responses. 49 children in an expanded cohort carried HLA-A2. 1/11 children under 3 years of age had detectable CD8+ T-cell responses to SLYNTVATL, 2/11 to ILKEPVHGV. Among children over 3, 11/38 recognized SLYNTVATL and 9/38 recognized ILKEPVHGV.
  - Older children that maintained a CD4 count greater than 400 cells/ul tended to have stronger CTL responses.

**References** Sun *et al.* 2003
- This study compares assay methods for testing CTL responses using samples from 20 HIV+ patients. The study compares ELISpot, tetramer-binding, and intracellular IFN- $\gamma$ . Tetramer-binding analysis was performed with Gag (SLYNTVATL) or Pol (ILKEPVHGV) tetramers. Antigen presentation using recombinant vaccinia viruses (rVVs) encoding HIV-LAI Gag, Pol, Env, Nef, Tat and Vif proteins was compared to peptide panels. HIV antigen recognition in memory CTLs was measured by chromium release assay and compared to effector/memory CD8+ T cells in an IFN- $\gamma$  ELISpot assay.
  - Results: IFN- $\gamma$  Elispot and flow cytometry gave similar frequencies of HIV specific CD8+ T cells. Tetramer-binding analysis was most sensitive. Pools of peptides and the sum of frequencies of individual peptides were comparable. Elispot assays using peptides were more sensitive than assays using vaccinia expressed proteins. Cr release and Elispot against rVVs gave comparable memory cell responses 2/3s of the time.

- 3/7 HLA-A2+ patients recognized this epitope.

**Keywords** escape  
**References** Yang *et al.* 2003a
- Virus was cultured in the presence of CTL lines specific for 4 different epitopes (SLYNTVATL, ILKEPVHGV, IEIKDTKEAL, and KEKGGLEGL) to study the emergence of escape mutations. Escape varied between clones for the same epitope, and between different epitopes. Gag and RT epitope escape, if it occurred at all, tended to be monoclonal and within the epitope, indicating strong fitness constraints, while the Nef epitope escape was rapid, polyclonal, and sometimes the result of upstream frameshifts.
  - There was one cloned cell line that recognized ILKEPVHGV, 68A62. After 2 weeks of passaging HIV-1 in the presence of 68A62, the mutated epitope ilkeLvghv was found in 6/12 sequences.

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 2/14 CTL T-cell clones tested were specific for RT/IV9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 values for the two RT/IV9 clones were very different, 50 and 20,000 pg/ml.

**Epitope** ILKEPVHGV

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

**HXB2 Location** RT (309–317)

**Author Location** Pol (subtype B)

**Epitope** ILKEPVHGV

**Subtype B****Immunogen** HIV-1 exposed seronegative**Species (MHC)** human (A\*0202, A2)**Keywords** subtype comparisons**References** Rowland-Jones *et al.* 1998b

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi – these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.
- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among B and D clade viruses.
- Clade A version of the epitope, ILKDPVHGV, was preferentially recognized by CTL.

**HXB2 Location** RT (309–317)**Author Location** RT (309–317)**Epitope** ILKEPVHGV**Epitope name** RT2**Immunogen** vaccine, *in vitro* stimulation or selection*Vector/Type:* HIV-1 peptide in filamentous bacteriophage major coat protein *HIV component:* RT**Species (MHC)** human, mouse (A2, A2 transgenic)**Keywords** epitope processing**References** De Berardinis *et al.* 2000

- Phage display of the CTL epitope, ILKEPVHGV coupled with T helper epitope KDSWTVNDIQKLVGK, elicited specific CTL responses *in vitro* in PBMC from HIV negative individuals in and *in vivo* in immunization of HLA-A2 transgenic mice.
- Bacteriophage presentation of peptides is generally used for stimulation of antibodies, and this novel discovery of CTL epitope processing and presentation suggests new possibilities for these vectors.

**HXB2 Location** RT (309–317)**Author Location** RT (476–484 LAI)**Epitope** ILKEPVHGV**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Donor MHC** A\*0201**Keywords** HAART, ART, responses in children**References** Luzuriaga *et al.* 2000

- Longitudinal study of 8 infants with prolonged viral suppression due to combination antiretroviral therapy showed no HIV-1 specific CTL responses in peripheral blood cells. 6/8 were studied using a Chromium release assay and no response was detected using Gag expressed in vaccinia in the target cells. Three HLA-A\*0201 children were tested using SLYNT-VATL or ILKEPVHGV HLA A\*0201 tetramers and again no HIV-specific response was detected, either using PBMC specimens, or PBMC which had been stimulated *in vitro* for a week.
- In contrast, one of the children with suppressed HIV viral replication who was co-infected with HIV and EBV, while HIV-tetramer negative, had EBV-tetramer staining cells at a frequency of 0.14% in the PBMC.

**HXB2 Location** RT (309–317)**Author Location****Epitope** ILKEPVHGV**Immunogen** HIV-1 infection**Species (MHC)** human**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other**Keywords** binding affinity, acute/early infection**References** Lichterfeld *et al.* 2007b

- Differences in early versus chronic AIDS include a decline in CTL number accompanied by a reducing viremia. Comparative analysis of such CTLs in this study show that early infection is characterized by a different clonotypic composition and higher functional avidity of CTLs followed by their selective depletion during transition to chronic disease. The total magnitude of CTL cytokine production is lower in early infection. Intraindividual, early CTLs' functional avidity for the same epitope decreases concomitantly with a reduction in clonotypic TCR repertoire especially of strongly activated and CD127<sup>lo</sup>, CD38<sup>+</sup>, Ki-67<sup>hi</sup> CTLs while progressing to chronic infection states.
- None of the target epitopes, including this epitope ILKEPVHGV seen in 1 patient, underwent sequence changes.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade HIV component: p17 Gag, p24 Gag

**Species (MHC)** human (B62)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**Keywords** epitope processing, immune evasion, viral fitness and reversion, HLA associated polymorphism
- References** Honeyborne *et al.* 2007
- To determine whether HLA-B\*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B\*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B\*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.

**References** Bond *et al.* 2001

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This epitope was not predicted by the EpiMatrix method to be likely to bind to A11, though it served as an epitope in the FSWs, and it was one of the six A11 epitopes that had been previously defined.
- 5/8 tested FSWs recognized this epitope.
- This epitope was highly conserved in other subtypes, although exact matches were not very common.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, FKNLKTGKY, is similar to human protein Str Spe Recognition protein, sequence FKNsKTG.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 21% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.

- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187–2200 (2004)].
- This peptide, QKIAtESIWIWGKTPKFK differs from the consensus C sequence QKIAmESIWIWGKTPKFKr at 2 amino acid positions, i.e. by 10.5%.

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757–68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, QKIATESIWIWGKTPKFK, had an overall frequency of recognition of 16% - 22% AA, 15.4% C, 9.1% H, 14.3% WI.

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient A displayed the greatest response to epitope B14-EL9(gp41), a strong response to B7-TL9(p24), and responses to B7-TM9(Nef) and A32-PW10(RT). Patient B displayed the greatest response to epitope B44-AW11(p24) and also responded to A32-PW10(RT) in both PB and LN samples, while a third response against epitope A32-RW10(gp120) was only detected in the LN sample. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** binding affinity, immunodominance, optimal epitope

**References** Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope PIQKETWETW elicited a magnitude of response of 88 SFC with a functional avidity of 1nM.

**Keywords** supertype, cross-presentation by different HLA

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (A32), an additional HLA (A24) was statistically predicted to be associated with this epitope.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** characterizing CD8+ T cells

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, SPRTLNAWV, was predicted to be restricted by HLA A\*1101.

**Keywords** supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Country** Barbados, Haiti, United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J.Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.

- This immunodominant, frequently targeted overlapping peptide, QLEKEPIVGAETFYVDGA, had an overall frequency of recognition of 15.3% - 22% AA, 11.5% C, 4.5% H, 23.8% WI.

**HXB2 Location** RT (436–445)

**Author Location** RT (591–600 IIIB)

**Epitope** GAETFYVDGA

**Immunogen** HIV-1 infection

**Species (MHC)** human (B45)

**References** Menendez-Arias *et al.* 1998

- This epitope spans the Pol p66 RT – p15 (RNase) domain.

**HXB2 Location** RT (436–445)

**Author Location** Pol (591–600 IIIB)

**Epitope** GVETFYVDGA

**Immunogen** HIV-1 infection

**Species (MHC)** human (B45)

**Keywords** responses in children, mother-to-infant transmission, escape

**References** Wilson *et al.* 1999a

- This study describes maternal CTL responses in the context of mother-to-infant transmission.
- Detection of CTL escape mutants in the mother was associated with transmission, but the CTL-susceptible forms of the virus tended to be found in infected infants.
- No variants of this epitope were found in a non-transmitting mother who had a CTL response to it.
- This epitope spans the Pol p66 RT – p15 (RNase) domain.

**HXB2 Location** RT (436–452)

**Author Location** (C consensus)

**Epitope** GAETFYVDGAANRETKI

**Subtype** C

**Immunogen** HIV-1 infection

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Country** Barbados, Haiti, United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, GAETFYVDGAANRETKL, had an overall frequency of recognition of 18% - 20.3% AA, 11.5% C, 18.2% H, 19% WI.

**Keywords** rate of progression, immunodominance, early-expressed proteins  
**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- References** Hossain *et al.* 2003
- HLA-A\*3303 is a common HLA allele in east and southeast Asia. Pol, Gag and Nef SF2 proteins were scanned for potential A\*3303 epitopes. 99 potential epitopes were synthesized, and 52/99 bound to A\*3303. Six of these served as peptide-targets for lysis by PBMC from infected individual, and clones derived from 4 of these 6 could lyse HIV-vaccinia infected target cells, indicating proper processing.
  - This epitope is one of the 4 that are properly processed.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, ALQDSGLEV, was detected within overlapping peptides QKTELQAIHLALQDSGL and IHLALQDSGLEVNIV.

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
  - This was 1 of 4 A2 gag/pol epitopes tested. Transgenic mice immunized with the deleted construct induced more potent EliSpot reactions to this epitope than those immunized with full length Gag/Pol.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, VNIVTDSQYA, is similar to human protein HERV, sequence VNIyTDSQYA and human protein Thrombospondin 3 precursor, sequence VNtVTDDdYA.

**HXB2 Location** RT (496–505)

**Author Location** Pol (651–660)

**Epitope** VTDSQYALGI

**Epitope name** VII10

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B14)

**Donor MHC** A\*02, A\*68, B\*14, B\*52, Cw\*08, Cw\*12

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** escape, optimal epitope

**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The B consensus form of this epitope, VTDSQYALGI, persisted throughout 6 years of chronic infection in 1 individual.

**HXB2 Location** RT (496–505)

**Author Location** Pol (subtype B)

**Epitope** VTDSQYALGI

**Subtype** B

**Immunogen** HIV-1 exposed seronegative

**Species (MHC)** human (B\*1402, B14)

**Keywords** subtype comparisons

**References** Rowland-Jones *et al.* 1998b

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi – these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.
- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among A, B and D clade viruses.

**HXB2 Location** RT (496–505)

**Author Location** RT (663–672 IIIB)

**Epitope** VTDSQYALGI

**Immunogen** HIV-1 infection

**Species (MHC)** human (Cw8)

**References** Brander & Walker 1996

- Unpublished, P. Johnson.
- Published in this database in 1995 as B14, but B14 transfected cells did not present the peptide and it is thought to be presented by the genetically linked Cw8 molecule instead Brander & Walker [1996]
- This epitope occurs in the p15 (RNase) domain of Pol p66 RT.

**HXB2 Location** RT (496–505)

**Author Location** RT

**Epitope** VTDSQYALGI

- Immunogen** HIV-1 exposed seronegative  
**Species (MHC)** human (Cw8)  
**Keywords** subtype comparisons, HIV exposed persistently seronegative (HEPS)  
**References** Rowland-Jones *et al.* 1998a
- A CTL response was found in exposed but uninfected prostitutes from Nairobi using previously-defined B clade epitopes that tended to be conserved in A and D clades – such cross-reactivity could protect against both A and D and confer protection in Nairobi where both subtypes are circulating.
  - The A and D subtype consensus are identical to the B clade epitope.
  - Thought to be HLA-Cw8 restricted, not B14 as originally reported (C. Brander, B. Walker, and S. Rowland-Jones, personal communication)
  - This epitope occurs in the p15 (RNase) domain of Pol p66 RT.
- HXB2 Location** RT (497–512)

**Epitope** QIIEQLIKK  
**Subtype** B, CRF01\_AE  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A\*1101)  
**Keywords** subtype comparisons, TCR usage

**References** Fukada *et al.* 2002

- Counterparts for eight known clade B HLA A\*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A\*1101 epitopes was recognized in a clade specific manner. Two other HLA A\*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- QIIEQLIKK was found to elicit clade-specific responses in clade B (QIIEQLIKK is most common) and clade E (qiieElikk is most common). QIIEQLIKK was strongly recognized by CTL from 1/5 B clade infected Japanese subjects, and qiieElikk from 3/7 E clade infected Thai subjects. The variant qiieKliEk, common in the A subtype, was also recognized in 2/7 E clade infected Thai subjects.
- The binding of QIIEQLIKK, qiieElikk and qiieKliEk to HLA A\*1101 was similar, but CTL clones from individuals did not cross-react with the cross-clade peptides indicating that the substitutions inhibited TCR interaction.

**Keywords** vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.

- This epitope, RAMASDFNL, was predicted to be restricted by HLA A\*0201, B\*2709 and C\*0304

**HXB2 Location** Integrase (20–28)

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** Integrase (28–36)

**Country** South Africa  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Other  
**Keywords** supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- A strong association between B\*4201 and variation in this epitope was found.

**HXB2 Location** Integrase (28–36)**Author Location** Integrase (28–36)**Epitope** LPPIVAKEI**Epitope name** LI9**Immunogen** peptide-HLA interaction**Species (MHC)** human (B\*4201)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, HLA binding**Keywords** optimal epitope**References** Honeyborne *et al.* 2006

- Novel epitopes are defined for four HLA-alleles common in South African Zulu/Xhosa populations: B\*3910, B\*4201, B\*8101 and Cw\*1801, by motif inference. HLA-A\*2902 was found to overlap those of A1 and A24 superotypes.
- LPPIVAKEI (LI9) was the optimal epitope for HLA-B\*4201 with variants LPPIVAKE, PPIVAKEI, LPPIVAKEIv, nLPPIVAKEI having been tested.

**HXB2 Location** Integrase (28–36)**Author Location** Integrase**Epitope** LPPIVAKEI**Epitope name** LI9**Immunogen** HIV-1 infection**Species (MHC)** human (B\*51)**Country** Australia**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** escape, HLA associated polymorphism**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, *Science* 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- There are two variant forms of this B57/B5801 epitope at the second position, LPPIVAKEI and LPPVVAKEI. Leslie *et al.*, *J Exp Med.* 201:891 (2005) suggest that the escape form LPPVVAKEI may have come to dominate the B clade lineage over

time due to higher HLA B51 frequencies in B clade epidemic regions. Bhattacharya suggests lineage effects are also playing an important role in the observed amino acid frequencies, and note that the ratio of I/V has not change over time, and that the frequency of I/V in different epidemic populations does not correlate with HLA B51 allele frequency.

**HXB2 Location** Integrase (28–36)**Author Location** Pol (743–751 SF2)**Epitope** LPPVVAKEI**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5101)**Keywords** subtype comparisons, rate of progression**References** Tomiyama *et al.* 1999

- HLA-B27, -B51, and -B57 are associated with slow progression to AIDS, while HLA-B35, -B8, -B24 are associated with a rapid progression to AIDS (*Nat. Med.* 2:405, 1996; *Lancet* 22:1187, 1986; *Hum Immunol* 22:73, 1988; *Hum Immunol* 44:156, 1995)
- 15% of Japanese populations carry HLA-B51 while HLA-B27 and -B57 are detected in less than 0.3%
- Of the 172 HIV-1 peptides with HLA-B\*5101 anchor residues, 33 bound to HLA-B\*5101, seven of these peptides were reactive with CTL from 3 B\*5101 positive individuals, and six were properly processed.
- Four of the six epitopes were highly conserved among B subtype sequences – LPPVVAKEI is highly conserved.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

**Keywords** binding affinity, class I down-regulation by Nef, rate of progression

**References** Tomiyama *et al.* 2005

- HLA-B\*5101 associated with slow progression to the disease state was studied as related to Nef-mediated HLA class I downregulation. It was shown that different CTLs have different ranges of ability to kill HIV-1 infected CD4+ T cells and suppress HIV-1 replication. This was found to be a function of the specific HIV-1 epitope presented by the corresponding HLA allele to the CTL.
- Certain epitope-recognising CTL clones or lines were therefore capable of killing HIV-1 infected cells even in the presence of Nef-mediated MHC 1 downregulation, while other CTL clones recognising different epitopes were not so capable.
- There was no significant difference in cytokine production or cytokine producing cells between CTLs that were capable of killing CD4+ T-cells infected with HIV-1 and those CTLs that could not kill such HIV-1 infected cells.
- On the basis of studies involving binding abilities and cytolytic activities for four different epitopes that correlate with HLA-B\*5101-restricted CTLs, it is suggested that the ability of CTLs to kill infected CD4+ T cells is due to the number of epitopes presented by the HLA on the surface of the CD4+ T cells rather than the ability of TCR to recognise the epitope.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, QVDCSPGI, of unknown HLA restriction, was detected within overlapping peptides LKGEAMHGQVDCSPGIW and GQVDCSPGIWQLDCTHL.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
  - Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
  - This HIV-1 epitope, YIEAEVIPA, is similar to an unnamed human protein, sequence gYIEAaVIPAG and human protein p53 inducible protein, sequence EIEAEV.

- ETAYFILKL cross-reacts with clades A, B and D.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A\*6802 women, 3/12 HEPS and 9/11 HIV-1 infected women recognized this epitope likelihood ratio 7.9, p value 0.01, and HEPS women tended to respond to DTVLEDINL, while infected women to ETAYFILKL.
- The dominant response to this HLA allele was to this epitope in 2 of the 3/12 HEPS cases and in all 9/11 HIV-1 infected women that responded to the epitope.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.
- Subject ML 1203 started with CTL responses to A\*6802 DTVLEDINL and to B7 FPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A\*6802 ETAYFILKL which became dominant, B7 TPGPG(V/I)RYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.
- Subject ML 1707 started with a CTL response to A\*6802 DTVLEDINL prior to seroconversion, and switched to A\*6802 ETAYFILKL and A24 RDYVDRFFKTL post-seroconversion.
- Subject ML 1830 made no detectable response prior to seroconversion, but responded to A\*6802 DTVLEDINL and A\*6802 ETAYFILKL post-seroconversion.

**Epitope name** SW10

**Immunogen** HIV-1 infection

**Species (MHC)** human (B57)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** epitope processing, supervised treatment interruptions (STI), rate of progression, immunodominance

**References** Rodriguez *et al.* 2004

- Protease and integrase are shown to be frequently targeted by CD8 T-cell responses (23% and 68% of 56 HIV+ patients, respectively). Responses tend to cluster in conserved regions of Int, although 1 high conserved region had no responses. CTL frequencies per unit protein length for Pro and Int were similar to other HIV non-structural proteins. Three novel HLA class I-restricted optimal epitopes were found and characterized with fine mapping.
- All 5 HLA-B57 patients recognized this epitope and were long-term nonprogressors.

**Epitope name** SW10

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion

**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- Two escape mutations, at positions 2 and 3, were found in the most polymorphic residue in the epitope. These were shared between clades B and C. The T840N mutation at residue 2,

sNtvkaacww, was significantly more common in persons expressing HLA-B57, often in conjunction with T841A or V sT[A/V]kaacww.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Integrase (123–132)

**Epitope** STTVKAACWW

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*5801, B57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** responses in children, mother-to-infant transmission, characterizing CD8+ T cells

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

**HXB2 Location** Integrase (127–135)

**Author Location** Pol (869–877)

**Epitope** KAACWWAGI

**Immunogen** HIV-1 infection

**Species (MHC)** human (A2 supertype)

**Keywords** supertype, rate of progression

**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, AVFIHNFKR, was predicted to be restricted by HLA A\*0301, A\*1101, A\*3101, A\*3301, A\*6601 and A\*6801.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This putative epitope, AVFIHNFKRK, was detected and confirmed within overlapping peptides AVFIHNFKRKGGIG-GYSA and RKGIGGYSAGERIVDII.

**Keywords** HIV exposed persistently seronegative (HEPS)

**References** Bond *et al.* 2001

- This was a study of HIV-1 exposed persistently seronegative (HEPS) female sex workers in Chiang Mai, northern Thailand.
- HLA-A11 is very common in this population, and was enriched among the HEPS sexworkers – weak CTL responses were detected in 4/7 HEPS women, and CTL responses were found in 8/8 HIV+ controls, and 0/9 HIV- women that were not exposed.
- This epitope was weakly reactive in the HEPS study subjects 265 who was HLA A2/A11 and 128 who was HLA A11/A33, and had been predicted to be a possible A11 epitope using Epimer in Bond *et al.* [2001]

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognized epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).

- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 0/14 HLA-A3 positive individuals had detectable A3-restricted responses to this epitope during acute infection, but only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 1/7 individuals began to have detectable responses to this epitope after STI.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
  - This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** HLA associated polymorphism  
**References** Boutwell & Essex 2007
- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12%

of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.

- FKRKGGIGGY was a previously defined B\*1503 presented epitope that encompassed a polymorphism, FKRkGGIGGY, in the fourth position.

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 21% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, KIQNFRVYY, was predicted to be restricted by HLA A1 and A\*3002.

**Keywords** binding affinity, vaccine-specific epitope characteristics, immunodominance

**References** Peter *et al.* 2001

- The stability of peptide binding to HLA-A2.1 was determined for six HLA-A2.1 peptides included in this vaccine study – ILKEPVHGV (RT), SLYNTVATL (p17), SLLNATDIAV (gp41) and LLWKGEAV (RT) all bound with high affinity comparable to a influenza epitope reference (GILGFVFTL), while RGPGRFVVTI and VIYQYMDDL bound with a lower affinity (relative binding activity = 0.01).
- The four high-affinity peptides formed stable complexes with half-lives ranging between 8 and 32 hours, while the low affinity peptides had half lives of less than an hour.
- HLA-A2.1 transgenic mice were immunized with the six HIV-1 peptides and P30, as a universal T-helper epitope, with IFA or Montanide or microspheres as adjuvants.
- All peptides except VIYQYMDDL induced a strong CTL response in Cr-release assays - stronger responses were observed when peptides were delivered alone, indicating immunodominance when the combination was used.

- When HIV-1 peptides were used to vaccinate HLA-A2.1 transgenic A2-Kb mice, strong responses to five peptides were observed when the peptides were given individually, but immunodominance limited the response to some of the peptides when they were given in combination Peter *et al.* [2001]. IL-12 can counteract immunodominance in BALB/c mice, so it was given with the multiple epitope vaccination, and was instead found to specifically eliminate the HLA-A2.1-epitope CTL responses, but not Kb CTL responses. This was possibly a consequence of transient depletion of T-cells, B cells and macrophages in the spleen.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.

- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, LLWKGEAV, was predicted to be restricted by HLA A\*0201, A\*0204, A\*0205 and A\*0209.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, KVVPRRKAKIIRDYQKQM, had an overall frequency of recognition of 15.3% - 20.3% AA, 7.7% C, 9.1% H, 19% WI.

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms

were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.

- VPRRKVKII was a previously defined B\*42 presented epitope that was associated with a polymorphism, VPRRKVKIIk seen just after the last position in that epitope.

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**References** Kiepiela *et al.* 2004
- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
  - This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** Frahm *et al.* 2006
- CTL responses restricted by HLA-B\*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B\*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects in spite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominant CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.

- RKAKIIRDY of clade B is a potential HLA-B\*1503-restricted epitope, with epitope RKAKIIRDY found in clade C.

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction

**II-B-15 Pol CTL/CD8+ epitopes****HXB2 Location** Pol**Author Location****Epitope****Immunogen** computer prediction**Species (MHC)** (A\*0201, B\*3501)**Keywords** subtype comparisons, computational epitope prediction**References** Schönbach *et al.* 2002

- Computational methods (artificial neural networks, hidden Markov models, binding matrices based on HLA association rates) were used to identify HLA-A\*0201 and HLA-B\*3501 HIV T-cell epitope candidates from 533 Gag, Env and Pol sequences of which 374 were derived from HIV-1, 97 were derived from HIV-2 and 62 from SIV. **HXB2 Location** Pol**Author Location** RT (IIIB)**Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Keywords** epitope processing, escape**References** Moore *et al.* 2002b

- HIV polymorphisms in the RT protein were examined relation to HLA alleles found in a population of 473 participants in the Western Australian HIV Cohort Study. 64 significant associations between polymorphisms at particular positions and HLA alleles were detected, for HLA-B7, -B12, -B35 and -B15. Fifteen of these were in positions with known epitopes, 4 in anchor residues, 11 in other positions. Six additional polymorphic sites associated with particular HLA molecules flanked known epitopes and may relate to processing.
- 25 negative associations were also found between polymorphism and HLA alleles. The authors propose this is due to escape mutations in epitopes presented by common HLA types dominating in the population, and give examples of five amino acids which are in the consensus and tend to be stable in those with the most common HLA allele, HLA-A2.

**HXB2 Location** Pol**Author Location** Pol**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Assay type** Tetramer binding, Flow cytometric T-cell cytokine assay**Keywords** assay standardization/improvement**References** Wu *et al.* 2005

- A flow cytometric assay for validation of HIV-1 gag- or pol-specific- CD8/HLA-A2 T-cells was shown to be sensitive and specific, being able to detect HIV-1 CTL at the single T-cell level. An inverse correlation between HIV plasma viremia and gag- and pol-specific-CD8/HLA-A2 T-cells was observed.

**HXB2 Location** Pol

**Author Location** Pol**Epitope****Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*35)**Keywords** rate of progression**References** Jin *et al.* 2002

- Patients with HLA-B\*35 variants B\*3502, B\*3503, B\*3504, and B\*5301 tend to proceed to AIDS more quickly than those with B\*3501.
- Of 32 patients with HLA-B\*35 alleles CD8+ CTL responses were quantified using an intracellular cytokine staining assay – 75% had responses to Pol, 69% to Gag, 50% to Nef, and 41% to Env.
- The overall magnitude of CTL responses did not differ between those bearing B\*3501 and the others. A higher percentage of Gag responses was observed in those that had lower RNA levels that carried B\*3501, and there was a negative association with viral load and CTL activity. The data is consistent with higher levels of CTL responses contributing to protection in B\*3501 individuals, but not in B\*3502, B\*3503, B\*3504, and B\*5301 individuals.

- Twelve HIV-1 infected patients were re-infused with their own lymphocytes, cryopreserved from an earlier time point in the infection.
- Improvement in CD4+ and CD8+ T cells were seen in 7/12, and an increase in the CTL response to Pol was seen in one patient.

**HXB2 Location** Pol**Author Location** RT**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** rate of progression**References** Froebel *et al.* 1997

- Two HIV-1 infected children with contrasting disease courses were followed longitudinally – one died of AIDS, the other is a long-term non-progressor.
- Reactivity against Gag, Pol, Env and Tat proteins was tested by PBMC bulk cultured cells reacting with protein expressed in vaccinia constructs in autologous EBV transformed B cells.
- The child who progressed consistently had CTL against Pol and Tat.
- The long-term non-progressing child had no detectable CTL, but was heterozygous for a mutation in the CCR5 receptor and for HLA-B49, which has been shown to be associated with slower progression.

**HXB2 Location** Pol**Author Location** Pol (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** subtype comparisons**References** Betts *et al.* 1997

- 6/8 individuals from Zambia infected with C clade virus had CTL that were able to make response to B clade HIV-1 IIIB vaccinia-expressed Gag, Pol and Env proteins.
- A vigorous cross-clade response was not limited to a particular protein, and the level of recognition of different proteins varied among the six patients.

**HXB2 Location** Pol**Author Location** RT**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** De Maria *et al.* 1997

- CD3+ cells that also carry a natural killer cell receptor (NKR+) can exhibit down regulation of T cell function.
- Anti-NKR IgM MAb masked this inhibitory function and increased HIV-1 specific CTL activity in phytohemagglutinin-activated PBMC cultured in the presence of IL-2 from 3/5 patients, and in one other case anti-NKR MAb brought HIV-1 specific CTL activity to detectable levels.

**HXB2 Location** Pol**Author Location** Pol (LAI, MN)

**Epitope****Immunogen** HIV-1 exposed seronegative**Species (MHC)** human**References** Goh *et al.* 1999

- 13/37 exposed uninfected individuals with repeated high-risk sexual exposure had HIV-1 specific CTL against Env, Gag, Pol, or a combination of proteins – CTL activity was correlated with a CCR5 wildtype genotype.
- In this group, the highest CTLp frequencies were directed at Gag, but the most common response was to Env and four individuals had responses to multiple HIV-1 proteins.

**HXB2 Location** Pol**Author Location** Pol (LAI)**Epitope****Subtype** B**Immunogen** vaccine*Vector/Type:* canarypox *HIV component:* Gag, gp120, gp41, Nef, Protease, RT**Species (MHC)** human**References** Evans *et al.* 1999

- A Canarypox vaccine expressing gp120, gp41, Gag, Protease, Nef and Pol CTL epitopes gave rise to CTL that could be detected in 61% of the volunteers – responses to Gag, Env, Nef and Pol were detected 3-6 months after the last vaccination.

**HXB2 Location** Pol**Author Location** Gag/Pol (MN)**Epitope****Immunogen** vaccine*Vector/Type:* DNA *HIV component:* Env, Gag, Pol *Adjuvant:* CD80, CD86**Species (MHC)** chimpanzee**References** Kim *et al.* 1998

- The study explores the use of co-stimulatory molecules co-expressed with an HIV-1 immunogen in a DNA vaccine to enhance the immune response – co-expression of CD86, but not CD80, dramatically increased both HIV Env and Gag/Pol specific CTL and Th proliferative responses.

**HXB2 Location** Pol**Author Location** Pol (IIIB)**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Jin *et al.* 1998a

- CTL precursor frequencies were determined in HIV-1 infected pregnant women, and significantly higher CTLp frequencies to Pol and Nef were found in non-transmitting mothers than in transmitting mothers;

**HXB2 Location** Pol**Author Location** Pol**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** Young *et al.* 2001

- Addition of recombinant rec human IL12 (rhIL12) to cultures increased HIV-specific lysis of HIV-Gag, Pol and gp120 vaccinia expressed antigens (11/15 tested increased lysis by > 5%) if the culture was derived from HIV+ individuals who had CD4 cells/ul > 500.
- 2/10 individuals with <200 CD4 cells/ul, and 3/10 individuals with 200-500 CD4cells/ul, had an increase of >5% upon treatment of the culture with rhIL12, so a few individuals in late stage disease had CD8 cells that maintained responsiveness to rhIL12.

**HXB2 Location** Pol**Author Location** RT (subtype A, B, D)**Epitope****Subtype** A, B, D**Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** subtype comparisons**References** Cao *et al.* 2000

- HIV-1 subtypes A and D dominate the Ugandan epidemic, and a vaccine trial using B clade antigen is underway – this study addresses relative levels of cross-reactive CTL responses in HIV infected Ugandans to A, D, and B clade recombinant vaccinia viruses expressing Gag, Env, Pol, RT or Nef from HIV-1 clades A, B, and D.
- Proteins corresponding to the subtype of the infecting strains tended to trigger higher levels of CTL response measured by percent specific lysis, but there was extensive inter-subtype cross-reactivity with B clade proteins and the co-circulating subtype.

**HXB2 Location** Pol**Author Location** Pol**Epitope****Immunogen** HIV-1 infection**Species (MHC)** human**References** White *et al.* 2001

- HIV-specific CTL activity was detected in the female reproductive tract of only 1/3 HIV-infected women who underwent a hysterectomy, although CTL could be identified in the PBMC of all three women.

- The CTL precursor level (CTLp) was measured in long term non-progressors (LTNP) with low viral load using limiting dilution analysis and measuring CTL against Env Gag and Pol expressed in vaccinia in autologous targets.
- LTNPs have high memory CTL numbers and low viral load.

**HXB2 Location** Pol**Author Location** Pol**Epitope****Immunogen** HIV-1 exposed seronegative**Species (MHC)** human

**Keywords** review, HIV exposed persistently seronegative (HEPS)

**References** Rowland-Jones *et al.* 2001

- This is a review that summarizes observations about HIV-specific CTL found in the HIV-1 exposed persistently seronegative (HEPS) population.
- The CTL responses assayed by ELISPOT and by CTL precursor frequencies by limiting dilution analysis indicate that CTL in HEPS individuals tend to be of a lower magnitude than in chronic HIV-1 infections – the responses in HEPS cases are below the level of detection by tetramer assays.
- CD8+ CTL responses tend to be detectable in HEPS subjects only if they are recently exposed, and the response diminishes if exposure is reduced – it is not clear if there is a stable memory population in HEPS cases.
- CD8+ CTL responses in the HEPS population are associated with HIV-1 specific CD4+ T cell responses, assayed by proliferation assays, IL-2 secretion, and ELISPOT, and the authors consider the possibility that HIV-1-specific T-help responses improve the "quality" of the CD8+ response in HEPS individuals relative to HIV-1 infected individuals, who tend to have a poor HIV-1-specific T-help response.
- HIV-1 specific CD8+ CTL responses in HIV-1 infected individuals show reduced levels of perforin, and the T cells may not mature properly, and although similar studies have not been conducted in HEPS individuals this is considered as a possible difference in the CTL immune response in HEPS and HIV-1 infected people.

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed; however, epitopes were not found that span the invariant, most highly conserved regions of RT and Protease. This might be due to the virus evolving conserved features that disallow the CTL responses in these most conserved regions, as functional constraints for enzyme function would not tolerate change, and normal capacity for immune escape by rapid evolution is lost in these domains.

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 6, rirtwNslvk, was found not to correspond to the most polymorphic residue in the epitope.

**HXB2 Location** Vif (17–26)**Author Location** Vif**Epitope** RIRTWKSLVK**Epitope name** A3-RK10(Vif)**Immunogen** HIV-1 infection**Species (MHC)** human (A3)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, immunodominance, early-expressed proteins**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognized epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Vif (17–26)**Author Location****Epitope** RIRTWKSLVK**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** epitope processing, escape**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.

- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.

- 0/14 HLA-A3 positive individuals had detectable A3-restricted responses to this epitope during acute infection, but only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 2/7 individuals had detectable responses to this epitope after STI.

**Epitope name** IF9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- HLA-B\*57-restricted optimal epitope ISKKAKGWF was tested for immune response.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** responses in children, mother-to-infant transmission, escape

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Keywords** epitope processing, escape

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction

**Keywords** vaccine-induced epitopes

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

**Epitope** LVITTYWGLHTGERDWHL

**Epitope name** VIF-09

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, immunodominance

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.

- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, LVITTYWGLHTGERDWHL differs from the consensus C sequence LVIKTYWGLqtGERDWHL at 3 amino acid positions, i.e. by 16.7%.

**Keywords** acute/early infection, variant cross-recognition or cross-neutralization, superinfection

**References** Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- The response to this epitope, HTGERDWHL, was present before superinfection but waned afterward. The epitope from the first strain had the substitution hPgerdwhl, while the second strain matched the test peptide.

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was one of two used to illustrate how specific epitopes were characterized with regard to defining the optimal epitope and the HLA restricting element. HLA allelic associations in the population with peptide recognition was generally high predictive of the epitope within the 15 mer.

**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.

- WHLGHGVS I was a previously defined B\*1510 presented epitope that was associated with a polymorphism, dIWHLGHGVS I, in the first position before that epitope. This epitope was embedded in a previously identified CTL immunoreactive region.

**Keywords** epitope processing, escape

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.

- Epitope KTKPPLPSVKK elicited a magnitude of response of 580 SFC with a functional avidity of 0.05nM and binding affinity of 1.4nM.

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

**Species (MHC)** human (A3)

**Donor MHC** A3, B7, Cw7

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 0/14 HLA-A3 positive individuals had detectable A3-restricted responses to this epitope during acute infection, but only 5/15 of HLA-A3 epitopes tested were targeted during acute infection. 2/7 individuals had detectable responses to this epitope after STI.

**Species (MHC)** human  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** immunodominance  
**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, DQGPQREPY, is similar to human protein Carcinoma associated protein, sequence qRP-DQGPQRPP, and human proline-rich protein, sequence DQG-PQRpP.

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.

- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, GPQREPYNEWTLLELLEEL differs from the consensus C sequence GPQREPYNEWTLLELLEEL at 0 amino acid positions, i.e. the two clades' peptides are identical.

**Keywords** epitope processing, escape

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 17% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but

the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.

- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. *J.Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, ELKNEAVRHFPRIWLHSL, had an overall frequency of recognition of 25.3% - 32.2% AA, 19.2% C, 20.5% H, 23.8% WI. This peptide is included in a 27 aa Vpr highly reactive region to be used for vaccine design.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- Last position (9) in the epitope had potentially experienced positive selection. EAVRHFPRI and EAVRHFPRI escape variants were found.

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN- $\gamma$  secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

**Epitope** AVRHFPRIW

**Epitope name** AW9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- HLA-B\*57-restricted optimal epitope AVRHFPRIW was tested for immune response.

**HXB2 Location** Vpr (30–38)

**Keywords** responses in children, mother-to-infant transmission, escape

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

**Keywords** epitope processing, escape

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

**Keywords** supertype, cross-presentation by different HLA, TCR usage  
**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction
- Only B\*0702 was associated with variation within this epitope.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A\*0204, immunogenicity in HLA-A\*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This peptide was a good A2 binder, and induced CTL and CD8+ T-cell IFN gamma responses in mice. Responses to the peptide were not detected in 17 HIV+ HLA-A2 subjects.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** vaccine-induced epitopes

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was recognized by a placebo patient after infection.

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid

with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.

- ETYGDWTGV was a previously defined A\*6802 presented epitope that encompassed a supertype A\*2 associated polymorphism, YleTYGDWTGV, in the first position of that epitope.
- The epitope YleTYGDWTGV is partially embedded in a CTL immunodominant region.

**Keywords** acute/early infection, early-expressed proteins  
**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15–92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**Species (MHC)** human (A\*0201)  
**Keywords** acute/early infection  
**References** Altfeld *et al.* 2001a

- CTL responses against HIV-1 Vpr, Vpu, and Vif were analyzed in multiple HIV-1-infected individuals.
- This epitope was recognized by 8/24 individuals expressing A\*0201 allele.

- Epitope is located within a highly conserved alpha helix in Vpr.
- Individuals with long-term nonprogressive and treated chronic HIV-1 infection targeted Vpr more frequently than individuals with treated acute infection.
- Vpr is a frequent target of HIV-1 specific CD8+ T-cells – a response was detected in 45% of individuals tested and Vpr and p17 were the most preferentially targeted proteins per unit length by CD8+ T-cells.
- The A2 epitopes Vpr AIIRLLQQL and p17 SLYNTVATL do not account for the dominance of Vpr and p17, the result holds even when HLA-A2+ individuals are excluded.

**HXB2 Location** Vpr (59–67)

**Author Location** Vpr (59–)

**Epitope** AIIRILQQL

**Epitope name** Vpr-59

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** binding affinity, subtype comparisons, super-type, computational epitope prediction, immunodominance

**References** Altfeld *et al.* 2001c

- HIV was scanned for all peptides which carried the A2-supermotif pattern conserved in more than 50% of B clade sequences – 233 peptides met this criteria, and 30 of these bound to HLA-A\*0201 – 20/30 bound to at least 3/5 of HLA-A2 supertype alleles tested.
- Three additional previously described HLA-A2 epitopes were added to the set of 20, and 18/22 chronically infected HLA-A2 individuals had CTL that recognized at least one of the 23 peptides (median of 2 and maximum of 6), while 6/12 acute infected individuals recognized at least 1 (median of 1 and maximum of 2)
- AIIRILQQL binds to four HLA-A2 supertype alleles: A\*0203, A\*0201, A\*0206 and A\*6802 (highest affinity), but not A\*0202.
- 5/22 individuals with chronic HIV-1 infection recognized this epitope, but with low magnitude responses in ELISPOT.
- 2/12 HLA-A2 patients with acute HIV-1 infection responded strongly to this peptide, but during chronic infection SL9 and Gag-386 tended to be immunodominant while Vpr-59 was weak and sub-dominant.
- One of the the acutely infected individuals, AC13, was HLA A\*0201/68 B44/14 and also had a strong acute response to gp41 epitope SV10 LLNATDIAV.
- This peptide was shown to be properly processed and presented in TAP-competent B-cell lines *in vitro*.

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*0201 restricted epitope, AIIRILQQL, was mutated to AI(L)RILQQL in the daughter D2 isolate.

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 5, ALIRsLQQL, was found in the most polymorphic residue in the epitope. One escape mutation, at position 3, ALtRILQQL was found not to correspond to the most polymorphic residue in the epitope.

**HXB2 Location** Vpr (59–67)**Author Location** Vpr (59–67)**Epitope** ALIRILQQL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, HLA binding**Keywords** escape, acute/early infection, variant cross-recognition or cross-neutralization, optimal epitope**References** Altfeld *et al.* 2005

- The most frequently targeted HLA-A2-restricted CD8+ T-cell epitopes in chronic infection were significantly less frequently recognized during primary infection. This epitope was recognized both in acute and chronic infection, but slightly more frequently in chronic infection.
- A less common form of this epitope, with the I to L change in the second position, ALIRILQQL binds to HLA-A2 at lower concentrations and can serve as an HLA-A2 epitope during acute infection. It binds well to A\*0201, A\*0202, A\*0203, and A\*0206. This is an example of a less immunogenic form of the epitope, AiRILQQL becoming the most common circulating form.

**HXB2 Location** Vpr (59–67)**Author Location** Vpr**Epitope** AIIRILQQL**Epitope name** A2-AL9(Vpr)**Immunogen** HIV-1 infection**Species (MHC)** human (A2)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, immunodominance, early-expressed proteins**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.

- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Vpr (59–67)**Author Location** Vpr (59–67)**Epitope** AIIRILQQL**Immunogen** HIV-1 infection**Species (MHC)** human (A2 supertype)**Keywords** supertype, rate of progression**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind four of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

**HXB2 Location** Vpr (59–67)**Author Location****Epitope** AIIRILQQL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Keywords** epitope processing, escape**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.

- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- This study examined variant recognition of epitopes presented by A\*0201 and A\*1101. Numerous amino acid substitutions can be introduced into epitopes without disrupting their recognition by CTLs, although epitopes with multiple substitutions were less recognized. An algorithm was constructed for prediction of epitopes capable of inducing responses to a great number of variant epitopes.
- A total of 23 variant forms of Vpr 62 were identified. More than 95% of the variant epitopes were recognized by CTLs from mice immunized with the parental form.
- Vpr 62 epitope (parent or variant form) was present in 96% of HIV sequences of many M group subtypes.

**Keywords** rate of progression, immunodominance, early-expressed proteins  
**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Vpr (62–70)**Author Location** Vpr (62–70)**Epitope** RILQQLLFI**Immunogen** HIV-1 infection**Species (MHC)** human (A2 supertype)**Keywords** supertype, rate of progression**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind three of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

Gag-Pol, Nef, Vpr

**Species (MHC)** mouse**References** Muthumani *et al.* 2002

- Vpr can cause cells to go into G2 arrest, and it suppresses immune cell activation and inflammatory cytokine production, so co-immunization of BALB/c mice with recombinant adenovirus expressing Vpr and HIV-1 antigens Nef or Gag/Pol was tested to see if Vpr reduced the immune response to the other HIV antigens.
- Vpr compromised CD8+ T-cell lytic responses and T-helper proliferative responses in mice co-immunized with Vpr and Nef or Gag/Pol.
- In vitro, Vpr reduced T-cell cytokine production of IL-12 and TNFalpha, indicative of Vpr-mediated immune suppression.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** Tat (2–11)**Author Location** (C consensus)**Epitope** EPVDPNLEPW**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*5301)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, optimal epitope**References** Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- EPVDPNLEPW is an optimal epitope.

**HXB2 Location** Tat (2–11)**Author Location** Tat (2–11 BRU)**Epitope** EPVDPRLPEPW**Epitope name** Tat 1**Immunogen** HIV-1 infection**Species (MHC)** human (B53)**References** Addo *et al.* 2001

- Rev and Tat are expressed early in the virus life cycle and thus may be important targets for CTL against HIV early in infection and for vaccines – therefore CTL responses against Tat and Rev were screened using overlapping peptides.
- 11/57 (19.3%) HIV-1 + individuals recognized at least 1 Tat peptide, and 21/57 (37%) responded to at least 1 Rev peptide.

- EPVDPRLEPW was recognized by four individuals, but only two were B53, thus this epitope can probably be presented by other HLA alleles.

**Species (MHC)** human (B53)

**Assay type** Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** class I down-regulation by Nef

**References** Bobbitt *et al.* 2003

- Nef, through Nef-mediated MHC-1 down-regulation, is not the only viral protein to influence levels of HIV-specific CTL recognition. The Rev L60F mutation, a common natural variant, can decrease CTL recognition of late gene products. The Rev mutation impacts the early to late gene switch, reducing late gene product production (Gag, Pol, Env, Vpu, Vpr and Vif), while increasing Nef production, both of which reduce the impact CTL recognition of late gene products. As expected, Rev L60F rendered HIV infected cells more resistant to CTL that recognized epitopes from the late proteins Env and Gag. Gag expression is reduced more than Env, and Gag-specific CTL were more profoundly affected. Conversely CTL against an epitope in an early gene product, Tat, were more efficiently recognized when infected with viruses carrying the Rev L60F mutation.
- Patients in the asymptomatic phase with active immune responses had more CTL resistant viruses, with lower Rev activity, lower Gag expression and greater resistance to Gag-specific CTL killing, while viruses isolated from people with AIDS were more sensitive to CTL killing.

**Keywords** epitope processing, escape

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Positions 5 and 7 in the epitope had potentially experienced positive selection. PVD-PRLdPW, PVDPsLEPW and PVDPkLEPW escape variants were found.

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host

proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.

- This HIV-1 epitope, PKTACTNCY, is similar to human protein Zinc finger protein, sequence SQPKsACgNCY.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** HAART, ART, escape, viral fitness and reversion

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rates for this epitope, NCYCK-KCCF, were found to be 0.047 and 0.006/day (optimistic escape rates = 0.051 and 0.013), with SE of 0.054 and 0.004 respectively.
- In the first subject, 3 mutations in this Tat epitope (N24K, N24K+K29R, N24K+K29Q) were all shown to confer escape. In the second subject, peptide recognition was not tested, but by analogy with another patient it was suggested that a N to K mutation at position 1 of the epitope Tat 24-32 conferred escape. An additional N to T mutation at position 1 was also considered likely to be an escape mutation.

**References** Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- A early response to this peptide KCCFHCQVCFTTKGL was detected that waned prior to superinfection. The embedded epitope and HLA presenting molecule were not resolved. The initial and superinfecting strains had different versions of the peptide, oCCFHCQVCFTTKGL and KCCIHCQVCFTTKGL respectively.

- 4/14 optimal HIV-1 T-cell epitopes in a subject underwent mutation associated with dramatic loss of the original CD8 response. For 1 of the escape variants, a novel CD8 T-cell response equal in magnitude to the wildtype, was generated. CD8 T-cell recognizing the variant epitope utilized a distinct T-cell receptor and did not exhibit any cross-reactivity against the wildtype.
- A mutation occurred at position 3 of this epitope, ccMhcqvc, but significant cross-recognition was observed between the escape variant and the wildtype epitope.

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 3, CCIHCQVC, was found in the most polymorphic residue in the epitope.

**HXB2 Location** Tat (30–37)**Author Location** Tat**Epitope** CCFHCQVC**Epitope name** CC8**Immunogen****Species (MHC)** (Cw\*12)**Keywords** review, immunodominance, escape, acute/early infection, early-expressed proteins, kinetics, viral fitness and reversion**References** Lichtenfeld *et al.* 2005

- This review discusses the importance of 3 factors that impact the selection of immunodominant epitopes in acute HIV infection: i) the kinetics of viral protein expression, ii) the HLA class I background of the infected individual, and iii) the autologous sequence of the infecting virus. This is 1 of 12 peptides listed as immunodominant in acute HIV-1 infection.

**HXB2 Location** Tat (30–37)**Author Location** Tat (30–37)**Epitope** CCFHCQVC**Immunogen** HIV-1 infection**Species (MHC)** human (Cw\*1203)**Donor MHC** A26, A3, B\*3801, B7, Cw\*0702, Cw\*1203; A\*0201, A\*2501, B18, B51, Cw\*0102, Cw\*1203**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** acute/early infection, early treatment**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN- $\gamma$  secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- Two individuals recognized this epitope both presented by Cw\*1203.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at

high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

- Position 3 in the epitope had potentially experienced positive selection. CCIHCQVC and CCFHCQsC escape variants were found.

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85–86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

- A longitudinal study from primary infection to 5 years postinfection was conducted to determine Tat and Rev gene evolution. 2/4 patients showed Tat gene evolution. It was found that though Tat evolved by mostly nonsynonymous, non-random sequence changes, there was no increase in transactivating capacity or size of Tat protein. Sequence evolution occurred mostly in predicted epitopes that are MHC I restricted.
- Tat and Rev seem to evolve due to CTL pressure later in infection, after seroconversion, and possibly during viral replication.
- The predicted epitope C(I)HCQVCFI, had a variant CfHCQVCFI in the second position.

**References** Jones *et al.* 2004
- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
  - The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
  - Only four epitopes were found to acquire escape mutations in SUMA over time. Early in infection, three overlapping epitopes in Tat carried mutations: FHCQVCFMTK, VCFMTKGLGI, and MTKGLGISY. An M->T substitution was evident during acute infection in the first sample, at four days of the onset of symptoms, and a rare second variant was seen at day 20 that added a K->E substitution. The M->T substitution abrogated responses to FHCQVCFrTK, VCFrTKGLGI, but not in the third epitope rTKGLGISY. By day 69 a double mutation was evident that persisted through day 435, F->L and T->K. Variants IHCQVCFmKk, VCFmKkGLGI were not recognized, and impact processing of the MkkKGLGISY epitope.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding  
**Keywords** HAART, ART, escape, viral fitness and reversion  
**References** Asquith *et al.* 2006
- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is

made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.

- The best estimate of escape rate for this epitope, FHCQVCFITK, was found to be 0.066 (optimistic escape rate = 0.189) per day, with SE of 0.032.
- In this region of Tat there were 3 overlapping CTL epitopes. A T to K mutation at Tat 32 completely abolished in vitro CTL lysis against all three epitopes. In addition, an M to T mutation at Tat 31 completely abolished recognition of two of the epitopes (third not tested). Quantifying the outgrowth of both of the mutations will overestimate the efficiency of a single CTL response.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were

not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.

- This immunodominant, frequently targeted overlapping peptide, FHCQVCFTTKGLGISYGR, had an overall frequency of recognition of 16.7% - 16.9% AA, 15.4% C, 20.5% H, 9.5% WI.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, VCFTTKGLGI, was detected within overlapping peptides FHCQVCFTTKGLGISYGR and TKGLGISYGRKKRRQRRR.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- CTL responses restricted by HLA-B\*1503 were analyzed in HIV-1 subtype B and C-infected patients. An association between HLA-B\*1503 and reduced viral loads in individuals infected with clade B was found. No such correlation was found in clade C infected subjects in spite of the same immunodominant responses in subjects infected with either subtype. Clade B viral control was associated with several subdominant CTL epitopes lacking in clade C, suggesting that subdominant responses can contribute to viral control.
- FQTKGLGISY of clade C is a potential HLA-B\*1503 restricted epitope.

**HXB2 Location** Tat (38–47)**Author Location** Tat**Epitope** FQTKGLGISY**Epitope name** B15-FY10(Tat)**Immunogen** HIV-1 infection**Species (MHC)** human (B15)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, immunodominance, early-expressed proteins**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Tat (39–47)**Author Location** Tat (39–47) SUMA)**Epitope** MTKGLGISY**Epitope name** Tat MY9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*1501)**Donor MHC** A\*1103, A\*2402, B\*1402, B\*1501, Cw\*0802**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay**Keywords** dynamics, epitope processing, immunodominance, escape, acute/early infection, kinetics, characterizing CD8+ T cells, viral fitness and reversion**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time. Early in infection, three overlapping epitopes in Tat carried mutations: FHCQVCFMTK, VCFMTKGLGI, and MTKGLGISY. An M->T substitution was evident during acute infection in the first sample, at four days of the onset of symptoms, and a rare second variant was seen at day 20 that added a K->E substitution. The M->T substitution abrogated responses to FHCQVCFrTK, VCFrTKGLGI, but not in the third epitope tTKGLGISY. By day 69 a double mutation was evident that persisted through day 435, F->L and T->K. Variants IHCQVCFMkK, VCFMkKGLGI were not recognized, but the CTL response was strong to MkKGLGISY. The authors provide evidence that the F->L and T->K substitutions impact processing of the MTKGLGISY epitope, as the mutations don't abrogate a CTL response to the peptide, but Tat expressed in target cells doesn't allow recognition of the Tat variant.
- MTKGLGISY was the highest level response in acute and early infection.

**HXB2 Location** Tat (39–47)**Author Location** Tat (39–47)**Epitope** ITKALGISY**Immunogen** HIV-1 infection**Species (MHC)** human**Donor MHC** A\*1103, A\*2402, B\*1402, B\*1501**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** HAART, ART, escape, viral fitness and reversion**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate

for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.

- The best estimate of escape rate for this epitope, VC-FITKALGI, was found to be 0.066 (optimistic escape rate = 0.189) per day, with SE of 0.032.
- In this region of Tat there were 3 overlapping CTL epitopes. A T to K mutation at Tat 32 completely abolished in vitro CTL lysis against all three epitopes. In addition, an M to T mutation at Tat 31 completely abolished recognition of two of the epitopes (third not tested). Quantifying the outgrowth of both of the mutations will overestimate the efficiency of a single CTL response.

**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and

the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.

- This was one of 8 reactive epitopes found not to vary over time.

**References** Gostick *et al.* 2007

- HLA-A\*6801 was studied because of its unusual property of weak binding to CD8. Several peptide variants were followed in a CTL clone grown from an A\*68 expressing patient who responded to his autologous "index" peptide iTKgLGISYGR. His founder epitope was suggested to be TTKALGISYGR, the "reference" sequence, with variants ITKaLGISYGR and tTKGLGISYGR. The reference sequence TTKALGISYGR is a better agonist in cytokine and degranulation assays than the index peptide iTKgLGISYGR. Surface plasmon resonance shows that both index and reference peptides bind soluble TCR within normal ranges. A mutant HLA-A68 that increases CD8 interaction was found to recognize CTL at lower peptide concentrations and increase cytokine production (IFN-g, MIP-1b, RANTES). However its pattern of variant recognition was not changed. Thus "normalization" of HLA-A\*6801 interaction with CD8 does not induce non-specific activation, but does enhance agonist peptide recognition and immune response.

**Keywords** epitope processing, escape  
**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome

in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.

- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, EELLKTVRL, is similar to human protein nucleolar RNA associated protein, sequence EEL-LKeVRL, and a human protein, sequence LLKTVRLIRLL.

**Keywords** TCR usage, structure, characterizing CD8+ T cells

**References** Gillespie *et al.* 2006

- CD8+ T cell repertoire recognizing KAFSPEVIPMF [KF11] and variants and the structure of individual B\*57-peptide complexes were studied.
- In addition, immunodominancy of the previously mapped B\*57 epitopes during chronic infection was assessed. KGFN-PEVIPMF and ISPRTLNAW were immunodominant both in frequency and magnitude of recognition.

**Species (MHC)** human (B\*5801, B57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** responses in children, mother-to-infant transmission

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.
- This epitope was recognized less frequently in children than in adults.

**Species (MHC)** human (B57, B58, B63)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, cross-presentation by different HLA, optimal epitope

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment.

Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.

- This epitope was recognized by 20% of B63-positive subjects and 12% of B57/58-positive subjects.

**Epitope** KAVRLIKFLY

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Keywords** epitope processing, escape

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated, traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** superinfection, characterizing CD8+ T cells

**References** Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- The response to this epitope, TVRLIKFLY, was present only after superinfection. The epitope from the first infecting strain had the substitutions tvKlikfly relative to the test peptide, while the second strain shared the sequence TVRLIKFLY.

**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- The second donor in the study shares A\*0101 and B\*0801 with his partner. The escape variant iserilStF was transmitted, and it abrogates binding to A\*0101.

**Assay type** CTL suppression of replication

**Keywords** class I down-regulation by Nef

**References** Adnan *et al.* 2006

- The impact of Nef on antiviral activity was studied. CTL-targeting epitopes were susceptible to the effects of Nef, both in late (Gag, RT, Env) and in early proteins (Rev, Nef), although to a lesser degree in early proteins. However, HLA-C-restricted CTLs (unlike HLA-A and HLA-B) were unaffected by Nef both in early (Nef) and late (Env) proteins.
- Late protein Rev epitope RPAEPVPLQL-recognizing CTLs were affected by Nef.

**Assay type** Chromium-release assay, Other

**Keywords** binding affinity

**References** Bennett *et al.* 2007

- Standard assays like ELISpot, ICS and tetramer staining do not measure antiviral activity of HIV-infected CTLs, but use exogenous synthetic peptides on uninfected cells or HLA tetramers. Similarly, functional avidity assesses CTL activity against uninfected target cells. Here functional avidity is compared to the efficiency of actual infected cells' recognition and killing, revealing a sharp threshold between CTL immune antiviral activity and lack of infected cell recognition.
- As previously shown, epitopes and their variants spanned orders of magnitude of SD50. Likewise, CTL clearance of infected cells varied from 0 to 100% with epitope sequence variation. Moreover, direct suppression of HIV-1 replication by CTLs also varied with epitope variant.
- When killing efficiency (KE) using virus-infected cells was compared to functional avidity using synthetic peptides, there was a narrow threshold separating maximal killing from almost none. Since different SL9-specific clones had similar KEs, which were vastly different from RL10-specific CTL KEs, it was obvious that KEs varied with epitope sequence too. Finally, a strong correlation between KE and inhibition of viral replication was also seen.
- This epitope, RPAEPVPLQL, showed marked differences in its functional avidity, killing efficiency, as well as inhibition of viral replication when compared to its variants RsAEPVPLQL, RPtEPVPLQL, RPeEPVPLQL, RPAqPVPVPLQL, RPAEPVPLhL, RPAEPVPfQL, RPvEPVPLQL, RPeEPVPfQL, RPeEPVPLpL, RPAEPVPfhL, RPtEPVPfQL, RPtEPVPLeL, RPqEPVPLIL and RPtEPVPfhL.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining

**Keywords** epitope processing, immune evasion, viral fitness and reversion, HLA associated polymorphism

**References** Honeyborne *et al.* 2007

- To determine whether HLA-B\*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B\*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B\*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.
- An HLA-B\*13-restricted epitope was found within the above overlapping peptide sequences, but the optimal epitope was not confirmed.

- Molecularly cloned primary NSI macrophage tropic strain 2.1 and SI non-macrophage tropic strain 1.2 were isolated from study participant ACH320 and used to infect irradiated XID mice that had been reconstituted with human PBMC from B14+ seronegative donors – results indicate CTL may favor selective outgrowth of macrophage tropic strains.
- The CTL clone TCC108 specific for SAEPVPLQL, previously described by van Baalen 1997, and van Baalen 1998, was stimulated *in vitro* and given to the mice to apply specific CTL pressure.
- The macrophage-tropic HIV-1 strain #2.1 escaped CTL pressure more efficiently (7/14 animals) than its non-macrophage-tropic counterpart #1.2(SI) – the latter isolate was suppressed in 13/14 animals – macrophage may serve as a CTL sanctuary and reduced pressure on macrophage tropic HIV strains may allow additional replication to assist with acquisition of escape.
- Specific HIV-1 variants selectively induced by TCC108 were for strain 1.2: SEEPVPLQL, and for strain 2.1: SAEHVPLQL, SAESVPLQL, SVEPVPLQL, SLEPVPLQL, SAEPVPFQL, and SAEPVPFQL.

**Keywords** acute/early infection, early-expressed proteins, kinetics

**References** van Baalen *et al.* 2002

- Tat, Rev and Nef are the first HIV proteins expressed upon acute infection of T-cells (< 6 hours), and RT is not expressed until after 24 hours. The B14-restricted Rev-SAEVPLQL specific CD8 T-cell clone TCC108, and the B57-restricted RT-IVLPEKDSW specific CD8 T-cell clone TCL1C11 were co-cultured with CD4+ cultures inoculated with HIV-1 at low MOI. Co-incubation with the Rev-specific CTL resulted in two logs less HIV-1 production in ten days of culture. When the RT epitope was cloned into the Nef gene of the infecting strain, another early expressed protein, it proved as effective as the Rev epitope at inhibiting viral production. A mathematical model of CTL-target interactions suggest early proteins are important for vaccine design.

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Rev (67–75)

**Author Location** Rev (67–75 IIIB)

**Epitope** SAEPVPLQL

**Immunogen** HIV-1 infection

**Species (MHC)** human (B14, Cw8)

**References** van Baalen *et al.* 1998

- The Rev-specific CTL response studied here was from an individual infected with HIV-1 for more than 12 years without developing symptoms – Rev and Tat are expressed early and CTL activity against these proteins has been correlated with long-term survival.
- The CTL clone TCC108 specific for this epitope was studied *in vitro*.
- CTLs added immediately after infection suppressed viral production, indicative of CTL interference with viral production prior to lysis – CTL-mediated lysis occurred after the onset of progeny viral release, but prior to peak viral production.
- Rapid selection of a E69K mutation, which abolished CTL, recognition was observed.
- The epitope was originally listed as B14, but Cw8 and B14 are in linkage disequilibrium, and in this case were not distinguished (pers. comm., Christian Brander, 1999)

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes was characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.
- What was learned from proteins where many epitopes have been defined (Gag, Pol, Env and Nef) was used to develop an algorithm to predict where epitopes would be localized in Rev, Tat, Vif, and Vpr. Predictions were made blinded, and then compared to the first 15 epitopes defined in these proteins; the epitopes were concentrated in the predicted regions.

**Keywords** binding affinity, subtype comparisons, computational epitope prediction

**References** Corbet *et al.* 2003

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A\*0204, immunogenicity in HLA-A\*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This peptide was an intermediate A2 binder, and induced a CD8+ T-cell IFN gamma response in 1/6 mice. Responses were detected in 1/17 HIV+ HLA-A2 subjects.
- The variant gVgspqilv did not elicit a CD8+ T-cell IFN gamma response in transgenic mice, and bound to A2 with low affinity.

**HXB2 Location** Rev (98–116)

**Keywords** assay standardization/improvement, optimal epitope  
**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method

of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.

- This epitope, ILVESP AVL, was detected within overlapping peptide TQGVGSPQILVESP AVL.

**References** De Groot *et al.* 2003

- Epitopes defined using sequence parsing and matching algorithm Conservatrix, and epitope prediction tool EpiMatrix, were shown to be conserved in a broad range of HIV-1 sequences derived from different parts of the world. 31 novel highly conserved HIV-1 epitopes were found, among which four were recognized as promiscuous epitopes and five as MHC supertypes.
- Estimated binding probability for LVILAIVALV: 6%

**HXB2 Location** Vpu (7–15)

**Author Location** Vpu (7–15)

**Epitope** LAIVALVVA

**Subtype** B

**Immunogen** HIV-1 infection, peptide-HLA interaction

**Species (MHC)** human

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** immunodominance

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, LAIVALVVA, is similar to human protein Trypsin-domain protein, sequence aVALVVApL, and human small inducible cytokine 28 protein, sequence LAIVALaV.

**HXB2 Location** Vpu (13–21)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** escape, immune evasion, optimal epitope  
**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Last position (9) in the epitope had potentially experienced positive selection. HAPWD-VNDm escape variant was found.

**HXB2 Location** Vpu  
**Author Location** Vpu  
**Epitope**  
**Immunogen** vaccine  
*Vector/Type:* DNA *HIV component:* Nef, Vif, Vpu  
**Species (MHC)** mouse (H-2<sup>d</sup>)  
**Keywords** subtype comparisons, Th1  
**References** Ayyavoo *et al.* 2000

- Splenocytes from BALB/c mice immunized with pVVN-P DNA were incubated with Vif, Vpu or Nef antigens for 3 days and assayed for IL-4 and IFN-gamma levels.
- Antigen stimulation increased IFN-gamma production in pVVN-P immunized mice, indicating a Th1 response.
- IL-4 production was not significantly changed after antigen stimulation compared to control levels.
- Cross-clade CTL activity was also observed: A, B clade, CRF01(AE) clade antigens could serve as targets for the B clade immunization-stimulated CTL – an HIV-1 AC recombinant, however, did not stimulate a CTL response, but was expressed at lower levels on the target cell.

## II-B-21 gp160 CTL/CD8+ epitopes

**Assay type** proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** HAART, ART, supervised treatment interruptions (STI), immune dysfunction

**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load..
- Less than 2 of 11 patients recognized this epitope.

**HXB2 Location** gp160 (30–40)  
**Author Location** gp160  
**Epitope** AENLWVTVYY

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, immunodominance

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, aaeNLWVTVYYGVPVWK differs from the consensus C sequence vggNLWVTVYYGVPVWK at 3 amino acid positions, i.e. by 17.6%.

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

**Keywords** rate of progression, escape

**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using

PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.

- This was one of 8 reactive peptides found not to vary over time. It was one of four epitopes that were not precisely defined.

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Position 1 in the epitope had potentially experienced positive selection. AdNLWVTVY, tDNLWVTVY, tEdLWVTVY, eEdLWVTVY and AEdsWVTVY escape variants were found.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- This was the immunodominant response in acute infection in WEAU, and there was rapid escape in the epitope AENLWVTVY, with three variants observed by day 30 from the onset of symptoms. Additional mutations continued to develop, so that there were 9 different forms observed through the course of sampling. The variants all conferred different levels of reduction in CTL response, double mutations or anchor mutations tended to cause the greatest reduction: AaNLWV-TaY, tNkWVTVY, AgNLWVTVY, AkNLWVTVY, although the double mutant tENLWVTiY elicited a very strong CTL response, suggesting it might not be an escape form.

- AC2 is a B44 restricted CTL clone that recognizes AENLWVTYV.
- CTL could be activated by a fusion protein of an HIV protein and anthrax lethal factor (LFn-HIV) that promotes antigen presenting cell uptake of exogenous protein and allows processing through the MHC class I pathway. This strategy for CTL detection could allow antigen presentation without generation of cells by the standard methods of using live viral vectors carrying a protein, or by loading the cells with peptides and by-passing processing.

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope AENLWVTYV elicited a magnitude of response of 160 SFC with a functional avidity of 5nM.

**HXB2 Location** gp160 (31–39)**Author Location** gp160 (31–39)**Epitope** AENLWVTYV**Immunogen** HIV-1 infection**Species (MHC)** human**Donor MHC** A1, A29, B44, B8**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** HAART, ART, escape, viral fitness and reversion**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, AENLWVTYV, was found to be 0.048/day (upper bound on rate of escape = 0.053), with SE of 0.022.
- Mutations at position 30 (E30G and E30A) were shown to confer escape.

- 21% (40/187) of Thai adults that received ALVAC-HIV with or without gp120 or oligomeric gp160 had a CD8+ T-cell response. HLA-B44 was positively associated with CTL responses, and A33 had a borderline significance association with response. A33/B44/DRB1\*0701 is the most common haplotype in Thailand. B46, present in 30% of the population, was negatively associated with CTL responses, although it did not reach significance. HLA class I serotypes A11, A24, A33, B46 and B75 were the most common found in 245 Thai volunteers.
- 9/11 cases of pCTL activity to Env were in people with B44. The authors suggest some of the response may be directed at the previously mapped B44 Env epitope AENLWVTVYY in HXB2, DNLWVTVYY in their CRF01 ALAVC vaccine 92TH023. B\*4403 is the most common B44 allele among Thais, while B\*4402 is more common among Caucasians; a prior study had shown that B\*4403 may be able to present a broader spectrum of epitopes than B\*4402.

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

**HXB2 Location** gp160 (33–42)

- Ten HIV-1 + HLA A2 asymptomatic individuals were given two courses of HIV-1 MN rgp160 vaccine over a 2 year period.
- Two hundred and fifty three HIV-1 peptides of 9 or 10 aa possessing the HLA-A2.1 binding motif (Leu at position 2, Val at the C terminus) were identified in gp160, of which 25 had a high or intermediate binding affinity.
- Eleven peptides were studied that had high HLA-A2 binding affinity – a CTL response was detected to 9/11 peptides in at least 1 individual.
- CTL responses after reimmunization may include recall responses – only individuals with vaccine cross-reactive sequences prior to vaccination showed detectable CTL responses.

**HXB2 Location** gp160 (33–42)**Author Location** Env**Epitope** KLWVTVYYGV**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0201, A\*19, B\*3501, B\*44, Cw\*07, Cw\*16)**Donor MHC** A\*01, A\*19, B\*14, B\*44, Cw\*08, Cw\*16**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*02/A2.1 restricted epitope, KLWVTVYYGV was mutated to nWVTVYYGV in the daughter D2 isolate.

- Telomere length is short in the CD8+ T-cell compartment of HIV-1 infected people, indicating excessive CTL activation and premature senescence. Here human telomerase RT (hTERT) transduction of HIV-1-specific CTL was used to study the functional impact of telomerase. Telomerase expression enhanced proliferative capacity, as well as cytolytic and antiviral capabilities; cytokine production was unchanged. hTERT transduced CTLs were 10-fold more efficient in controlling HIV-1 replication in culture. Thus telomerase transduction can restore CTL mediated cytolysis, and may have therapeutic potential.
- Three polyclonal CD8+ T-cell lines derived from an HIV-1, HLA A\*0201 positive patient were used in this study, including one specific for this epitope.

Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.

- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*02 restricted epitope, LWVTVYYGVPVWKEATTLFCA was mutated to wWVTVYYGVPVWKEATnTLFCA in the daughter D2 isolate.

**Epitope** VTVYYGVPV

**Epitope name** Env35

**Immunogen** HIV-1 infection, vaccine

*Vector/Type:* peptide *HIV component:* Env

*Adjuvant:* Incomplete Freund's Adjuvant (IFA)

**Species (MHC)** human (A2)

**Assay type** CD4 T-cell ELISpot - IFN $\gamma$ , Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** binding affinity, subtype comparisons, computational epitope prediction

**References** Corbet *et al.* 2003

- HLA-A2-restricted HIV-1 CTL epitopes were computationally predicted. Binding affinities for HLA-A\*0204, immunogenicity in HLA-A\*0201 transgenic mice, and responses to the peptides in 17 HIV-1 infected patients were tested. 31 novel conserved A2 epitopes were detected. An average of 4 epitopes were recognized per patient.
- This peptide was a good A2 binder, and induced a CD8+ T-cell IFN gamma response in 1/6 mice. Responses to the peptide were not detected in 17 HIV+ HLA-A2 subjects.

**HXB2 Location** gp160 (36–46)

**Vector/Type:** DNA, peptide **Adjuvant:** Incomplete Freund's Adjuvant (IFA)

**Species (MHC)** human, mouse (A\*1101)

**Assay type** Cytokine production, T-cell Elispot

**Keywords** subtype comparisons, computational epitope prediction, escape, TCR usage, variant cross-recognition or cross-neutralization

**References** McKinney *et al.* 2004

- This study examined variant recognition of epitopes presented by A\*0201 and A\*1101. Numerous amino acid substitutions can be introduced into epitopes without disrupting their recognition by CTLs, although epitopes with multiple substitutions were less recognized. An algorithm was constructed for prediction of epitopes capable of inducing responses to a great number of variant epitopes.
- A total of 9 variant forms of Env 47 were identified. More than 95% of the variant epitopes were recognized by CTLs from mice immunized with the parental form.
- Env 47 epitope (parent or variant form) was present in 82% of HIV sequences of many M group subtypes.

**Author Location** gp120 (36–46 CM243 subtype CRF01)

**Epitope** VTVYYGVPVWR

**Subtype** CRF01\_AE

**Immunogen** HIV-1 infection

**Species (MHC)** human (A11)

**Keywords** subtype comparisons

**References** Bond *et al.* 2001

- HLA-A11 CRF01 (called subtype E in Bond *et al.*) epitopes were identified that stimulated CTL from HIV+ female sex workers (FSW) from Northern Thailand, of whom more than half were HLA-A11 positive.
- 77 possible HLA-A11 epitopes were first defined using EpiMatrix, these were screened for binding to A11 finding and 26 bound, and 12 of these were epitopes for CTL responses from 8 HLA-A11 positive FSWs, six were novel, six were previously identified.
- This epitope was not predicted by the EpiMatrix method to be likely to bind to A11, though it served as an epitope in the FSWs, and it was one of the six A11 epitopes that had been previously defined.
- 1/8 tested FSWs recognized this epitope.
- This epitope was only conserved in CRF01 and subtypes B and C, and exact matches were uncommon.

**Country** Kenya

**Assay type** Cytokine production, proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** assay standardization/improvement

**References** McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.

- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 4 variants of this index epitope TVYYGVPVW, TW9, were tested - TiYYGVPVW, TVYYGiPVW, TVYYGVPPrW, TVYYGVPmW. This index peptide, TW9, and its variants show a high proportion of instances where IFN-gamma ELISPOT and proliferation correspond well.

**References** McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. TVYYGVPVW responses were detected in 2 women who reacted to all clades tested, A, B, C, and D, and the sequence was identical in all clades.

**Keywords** acute/early infection  
**References** Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load was also found.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWIIIGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.

- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PIIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**References** Zhao *et al.* 2007
- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
  - 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
  - Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
  - 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
  - This peptide, TVYYGVPVWKEA $\dagger$ TTTLF differs from the consensus C sequence TVYYGVPVWKEAkTTTLF at 1 amino acid position, i.e. by 5.9%.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3

- frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
  - In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
  - This immunodominant, frequently targeted overlapping peptide, TVYYGVPVWKEATTTLF, had an overall frequency of recognition of 22.7% - 25.4% AA, 19.2% C, 18.2% H, 28.6% WI. This peptide is included in a 41 aa gp120 highly reactive region to be used for vaccine design.

**References** Nehete *et al.* 1998a
- Three long-term non-progressors and one asymptomatic HIV+ individual were studied and found to have HLA class I C-restricted CD8+ Env-specific CTLs – Cw7 specific CTL were found against three peptides, including this one.
  - HLA-C antigens are expressed on lymphoid cells to a lesser extent than either HLA-A or -B.
  - HLA-C confers protection against lysis by natural killer cells and by non-MHC-restricted effector T cells and Cw7 directly governs this resistance to lysis – the authors hypothesize that pathogens that inhibit antigen expression and class I expression may particularly down regulate Cw7, thus triggering non-MHC restricted killing.

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** rate of progression, escape

**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0–80% as efficiently as the index peptide, and the relative efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive peptides found not to vary over time. It was one of four epitopes that were not precisely defined.

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, TLFCASDAK, was predicted to be restricted by HLA A\*0301, A\*1101, A\*3101, A\*3301, A\*6601 and A\*6801.

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope LFCASDAKAY elicited a magnitude of response of 240 SFC with a functional avidity of 5nM.

- A\*26 is associated with slow progression to disease and is common in Asian populations (about 20%). 31/110 HIV peptides that carried the A\*2603 motif ([VTILP] at P2, [ML] at the C-terminus) bound to HLA-A\*2603. Only 2 of these were epitopes and could induce specific CD8 T-cell responses in PBMC from HLA-A\*2603 positive subjects.
- This epitope induced specific CD8+ T cells in chronically infected individuals with A\*2603, but not A\*2601.
- 5 common B clade variants were synthesized. EVHNVWATHA and EVHNiWATHA bound to A\*2603 with equal affinity. EiHNVWATHA and EaHNVWATHA bound to A\*2603 with reduced affinity. EmHNVWATHA and EkHNVWATHA could not bind to A\*2603. A CTL clone that recognized EVHNVWATHA was able kill cells prepulsed with the 3 peptide variants that could bind to A\*2602.
- EVHNVWATHA is the most common form in clades A, B, C, and E (CRF01), but EaHNiWATHA is the most common form in clade D.

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, ACVPTDPNP, was found to be 0.023/day, with SE of 0.016.
- Five mutations at the fifth position of Env gp41 73-81 were all shown to confer limited CTL escape.

- CTL specific responses were measured over a 1.3 to 1.5 year period in members of the Sydney Blood Bank Cohort (SBBC) who had been infected with a natural attenuated strain of HIV-1 which was Nef-defective.
- Some of these patients had prolonged high levels of CTL effector and memory cells despite low viral load.

**HXB2 Location** gp160 (78–86)**Author Location****Epitope** DPNPQEVVL**Immunogen** HIV-1 infection**Species (MHC)** human (B35)**Keywords** acute/early infection**References** Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and a close temporal relationship between the number of circulating HIV-specific T cells and viral load.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWIILGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** rate of progression, immunodominance, escape

**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This epitope was one of six epitopes found to be under positive selection for escape mutations, and was mostly replaced by an escape variant between days 66 and 369 (dpnpqeAal) and then replaced by a new escape variant (dpnpqevPl) by day 635.

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.

- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. VTEEFNMWK responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; a VnEEFNMWK variant was in clade B and D, and the clade C Env carried VnEEFNWWe. One woman also reacted with RAIEAQQHL, the other with KNCSFNMTT.
- Both women that reacted with VTEEFNMWK carried HLA-B\*5301, the only common HLA allele.

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.

- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- This epitope was contained in the vaccine, the vaccinated patient recognized it after infection.

**References** Kmiecik *et al.* 1998a

- CTL responses in six patients to four Env epitopes were studied: D2: LLNATAIAV, 5.3: RLRDLLLLIV, D1: KLTPLCVTL, and 4.3: QMHEDIISL – all have A2 anchor residues.
- The C terminal epitopes (D2 and 5.3) were highly variable and the variability was considered responsible for limited CTL response, while D1 and 4.3, N-terminal epitopes, were much more conserved and gave evidence of high levels of CTL response *in vitro*.
- Peptides 4.3 and D1 bound HLA-A\*0201 molecules with high affinity.
- Peptides 4.3 and D1 stimulated CTL with a relatively limited TCR V $\beta$  repertoire.

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- One patient developed a response to epitope KLTPLCVTL after primary infection at early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

**References** Zarling *et al.* 1999

- This study compares the ability of macrophages and dendritic cells to stimulate primary responses in CD8+ lymphocytes isolated from HLA-appropriate HIV-uninfected donors using peptide-pulsed APC – the dendritic cells performed better as APC for the stimulation of primary responses.
- Strong CTL responses were elicited by the epitopes DRFYK-TLRA and GEIYKRWII when presented by either immature or mature dendritic cells – macrophages were not able to prime a CTL response against DRFYKTLRA.
- A weak response to KLTPLCVSL was stimulated using macrophages as the APC.
- No detectable response was observed for the following previously-defined HIV epitopes: KIRLRPGGK, ILKEPVHGV, IRLRPGGK, GPKVKQWPL.

- Transgenic mice expressing a HLA-A2/Kb chimeric protein were vaccinated with a full length gp160 or with gp160deltaV3, with the V3 loop deleted. Mice given gp160deltaV3 had a broader immune response than those given gp160, with increased responses to conserved HLA-A2 epitopes in the C1 region of gp120, KLTPLCVTL, and the C-term region of gp41, SLLNATAIAV.
- Greater resistance was conferred by the gp160deltaV3 than the gp160 vaccine to a challenge of vaccinia expressing heterologous gp160 from primary isolates (VI-06 and 89.6), and the resistance was conferred by CD8+ T-cells.

- Immunization of transgenic mice with a codon-optimized hGagp17p24-Polp51 DNA plasmid, consisting of clusters of highly conserved CTL epitopes presented by multiple MHC class I alleles, induced 2- to 5-fold higher CD8+ T-cell responses than the corresponding full-length proteins. The modified proteins had the ribosomal frameshift deleted, as well as the potentially immunosuppressive p15, and protease and integrase. This correlated with higher protection against challenge with Gag and Pol expressing recombinant vaccinia virus. Mice immunized with the hGagp17p24-Polp51 also showed an elevated level of type 1 cytokine production as well as an increased titer of p24- and RT-specific IgG2 antibody responses.
- Four A2 gag/pol epitopes were tested, and this Env A2 epitope was used as a negative control.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** gp160 (121–129)**Author Location** Env (134–142)**Epitope** KLTPLCVTL**Immunogen** HIV-1 infection**Species (MHC)** human (A2 supertype)**Keywords** supertype, rate of progression**References** Propato *et al.* 2001

- Long-term nonprogressors (LTNPs) had strong memory resting CD8+ T-cell responses against the majority of epitopes tested, (18 for the A2 supertype, 16 for the A3 supertype) while the effector cells of long-term nonprogressors recognized far fewer epitopes.
- Progressors had memory resting CD8+ T-cells that recognized far fewer epitopes than LTNPs.
- A positive correlation between effector CD8+ T-cells and plasma viremia and a negative correlation between CD8+ effector T-cells and CD4+ T-cells was observed, which may contribute to the inability of LTNPs to clear virus.
- This epitope can bind four of the five HLA-A2 supertypes alleles (A\*0201, A\*0202, A\*0203, A\*0206 and A\*6802).

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. VTEEFNMWK responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; a VnEEFNMWK variant was in clade B and D, and the clade C Env carried VnEEFNMWK. One woman also reacted with RAIEAQQHL, the other one with KNCSFNMTT. KNCSFNMTT was identical in clades A and C, while clade B carried KNCSFNMis, clade D carried KNISFNMTT.

**HXB2 Location** gp160 (156–165)**Author Location** gp120 (156–165)**Epitope** NCSFNISTSI**Immunogen** HIV-1 infection**Species (MHC)** human (Cw\*08)**Keywords** epitope processing**References** Ferris *et al.* 1999

- Recognized by CTL clone LWF A5, isolated from a lab worker exposed to HIV-1 in 1985.
- The processing of this epitope is TAP1/2-dependent, as are most Env epitopes, and it contains two N-linked glycosylation sites that are glycosylated in Env.
- Only peptide that has been deglycosylated, a process that changes asparagine (N) to aspartic acid (D) was recognized: the aspartic acid at position 5 was critical, position 1 could be either D or N.
- This peptide also contains a Cys involved in a disulfide linkage but reducing conditions did not effect recognition by CTL clone LWF A5.
- The HIV-1 Env epitopes are typically processed by a TAP1/2 dependent mechanism, which involves cotranslational translocation into the ER, glycosylation, export back into the cytosol, and deglycosylation for processing, and retransport into the ER for the association with class I molecules.
- The particular pathway of generating an epitope may have an impact on the presentation of that epitope, quantitatively as well as qualitatively.

**HXB2 Location** gp160 (156–165)**Author Location** gp120 (156–165 IIIB)**Epitope** NCSFNISTSI**Immunogen** HIV-1 infection**Species (MHC)** human (Cw8)**References** Sipsas *et al.* 1997

- HIV IIIB proteins were used to define the range of CTL epitopes recognized by 3 lab workers accidentally infected with HIV-1 IIIB.
- NCSFNITTSI, a variant found in HIV-1 MN, was not recognized, thus this epitope was type-specific.
- NCSFNISTSI contains two potential N-linked glycosylation sites and cysteine residue, possibly related to the requirement for a high sensitizing dose of peptide for CTL activity.

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, SYKLTSCNTSVITQACPKV, was found to be 0.005/day, with SE of 0.001.

- In the subject studied, the monotonic outgrowth of a Q199K mutation in Env gp41 was observed over a period of 1,028 days.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but

the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.

- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, YRLISCNTSVITQACPKV, had an overall frequency of recognition of 15.3% - 11.9% AA, 23.1% C, 18.2% H, 9.5% WI.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol.

Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0-80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive epitopes found not to vary over time.

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This putative epitope, SVITQACPK, was detected and confirmed within overlapping peptide YRLISC-NTSVITQACPKV.

- Counterparts for eight known clade B HLA A\*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A\*1101 epitopes was recognized in a clade specific manner. Two other HLA A\*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- SVITQACPK was found to elicit clade-specific responses in clade B (SVITQACPK is most common, sAitqacpk is most common variant in clade A, C and D) and clade E (saiKqacpk is most common). SVITQACPK was recognized by CTL from 3/5 B clade infected Japanese subjects, and aiKqacpk by CTL from 0/7 E clade infected Thai subjects, so this seems to be a B clade exclusive epitope.
- The binding of the three variant peptides to HLA A\*1101 was comparable, implicating TCR interaction differences.

- A vaccine study with B clade Envs in mice was undertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of HIV gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.
- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, ITQACPKVSFEPIPI.

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

**References** Brown *et al.* 2006

- A vaccine study with B clade Envs in mice was undertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.

- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, PKVS-FEPIPIHYCAP.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined, WEAU and BORI, had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape. This epitope was recognized in both patients.

- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified. The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.

- Four escape variants to the SFPEPIPIHY epitope were found in the patient BORI. SFdPIPIHY came up first, at day 55 from onset of symptoms, and caused a reduced cytotoxic response. By day 218, two rare forms were found, SIEPIPIHf and SiEPIPIHf. By day 556, only tFEPIPIHY was found. The weakest response was detected in the double mutant, SiEPIPIHf, yet tFEPIPIHY was the form that persisted.
- In WEAU, a minor variant, SsEPIPIHY was present at day 41. The SIEPIPIHf variant first came up day 136, gave a reduced CTL response, and then came to be the dominant form. Other variants were SFPEPIInY and SFPEPIIdf.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- Two subjects recognized this epitope during primary infection, both in the context of A29.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimates of escape rate for this epitope, SFPEIPIHY, were found to be 0.072 and 0.041/day (optimistic escape rate = 0.13), with SEs of 0.041 and 0.005 respectively, in 2 subjects.
- In the first subject, rapid loss of wild type at this epitope (primarily due to a E211D mutation) was observed. In the second subject, a Y217F mutation grew out over time.

**HXB2 Location** gp160 (217–226)**Author Location** gp120 (217–226 HIV-MN)**Epitope** YCAPAGFAIL**Epitope name** YL10**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (Cw\*0102)**Donor MHC** A\*0201, A\*2501, B\*1801, B\*5101, Cw\*0102, Cw\*1203**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** escape, immune evasion, optimal epitope**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Last position (10) in the epitope had potentially experienced positive selection. YCAPAGFAIi escape variant was found.

**HXB2 Location** gp160 (218–228)**Author Location** Env (218–228)**Epitope** CTPAGYAILKC**Subtype** CRF01\_AE**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0201, A\*0206, A\*0207)**Country** Thailand**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay**Keywords** optimal epitope**References** Kantakamalakul *et al.* 2006

- T cell responses in CRF01\_AE infected individuals from Thailand were studied.
- Based on two overlapping peptide sequences that were both reactive, as well as conserved anchor residues, this peptide is suggested to contain an epitope.

**HXB2 Location** gp160 (237–246)**Author Location** Env**Epitope** GPCKNVSTVQ**Immunogen****Species (MHC)** human (B56)**References** De Groot *et al.* 2001

- The program Epimatrix was used in conjunction with the program Conservatrix to identify conserved regions of HIV that might serve as epitopes.
- A subset of the potential epitopes was identified that could bind to the appropriate HLA-allele, and 15 predicted B7 superfamily (HLA B7, B8, and B58) epitopes were identified that could stimulate IFN $\gamma$  production in an ELISPOT assay.

- GPCKNVSTVQ was newly defined as an epitope in this study, was shown to stimulate an ELISPOT response, and to bind to HLA-B7.

**HXB2 Location** gp160 (239–247)**Author Location** Env**Epitope** CTNVSTVQC**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0201, A\*19, B\*3501, B\*44, Cw\*07, Cw\*16)**Donor MHC** A\*01, A\*19, B\*14, B\*44, Cw\*08, Cw\*16**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-Cw8 restricted epitope, CTNVSTVQC was mutated to CqNVSTVQC in the daughter D2 isolate.

**HXB2 Location** gp160 (239–247)**Author Location** gp160 (237–245 BORI)**Epitope** CKNVSTVQC**Epitope name** gp160 CC9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (Cw\*0802)**Donor MHC** A\*2902, B\*1402, Cw\*0802**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay**Keywords** dynamics, immunodominance, escape, acute/early infection, kinetics, characterizing CD8+ T cells, viral fitness and reversion**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three

patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.

- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified.
- Four variants of the CKNVSTVQC epitope were found in the patient BORI. CeNVSTVQC and cCeNVSTVhC came up first, at day 6 from onset of symptoms. The CeNVSTVQC form was the form that persisted, with a second rare variant present at day 35, CgNVSTVQC. These variants were not tested for their impact on escape.

**Country** Kenya

**Assay type** Cytokine production, proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** assay standardization/improvement

**References** McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 4 variants of this index epitope RPNNNTRKS, RS9, were tested in vitro - RPsNNTRKS, RPyNNTRKS, RPyNNTRqS, RPNNNTRrS. Autologous variants RPNNNTRrg and RPNNNTRtS were also detected. The rare variant RPyNNTRqS, found almost exclusively in clade B HIV (but absent in all subjects in this study), showed both proliferative as well as ELIspot responses. However, the intermediate RPyNNTRKS showed only a slight increase in proliferation but not in ELIspot detection.

**References** Ferris *et al.* 1999; Hammond *et al.* 1995

- The processing of this epitope is TAP1/2-dependent, as are most Env epitopes, and it contains an N-linked glycosylation site that is glycosylated in Env.
- Peptide that had been deglycosylated, a process that changes asparagine (N) to aspartic acid (D) (RPNDNTRKSI) was recognized a 100-fold more efficiently than either glycosylated or non-glycosylated RPNNNTRKSI.
- Position 5 is not involved with HLA B\*07 binding, so is probably important for TCR recognition.
- HIV-1 Env epitopes are typically processed by a TAP1/2 dependent mechanism, which involves cotranslational translocation into the ER, glycosylation, export back into the cytosol, and deglycosylation for processing, and retransport into the ER for the association with class I molecules.
- The particular pathway of generating an epitope may have an impact on the presentation of that epitope, quantitatively as well as qualitatively.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- The extent of CTL interclade cross-reactivity from CTL isolated from individuals newly infected with B clade virus was studied, and extensive cross-reactivity was observed.
- Two HLA B7 individuals had CTL response to B\_LAI, A\_92UG037 and C\_92BR025 gp160, but were B clade strain MN non-responders – the authors note that the B7 epitope RPNNNTRKSI is immunodominant, conserved between the LAI and clade A and C strains, but is very divergent in MN (RPNYNKRKRI), and that this epitope might be dominating the specificity of the response in the HLA B7 individuals.

**References** Altfeld *et al.* 2001b
- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
  - The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
  - Previously described and newly defined optimal epitopes were tested for CTL response.
  - Number of HLA-B7+ individuals that had a CTL response to this epitope broken down by group: 0/4 group 1, 1/3 group 2, and 1/1 group 3.

- The CTL response to optimally defined CTL epitopes restricted by HLA class I A and B alleles in individuals who coexpressed HLA A2, A3, and B7 was studied in eight HIV-1-infected subjects, two with acute infection, five with chronic, and one long-term non-progressor (LTNP)
  - 2 to 17 epitopes were recognized in a given individual, A2-restricted CTL response tended to be narrow and never dominated the response, and 25/27 epitopes were targeted by at least one person.
  - Subjects with chronic HIV-1 infection recognized between 2-8 out of 11 B7-restricted epitopes.
  - An acute seroconverter homozygous for the B7 allele recognized five B7-restricted epitopes.
  - The other acute seroconverter failed to recognize any of the 11 B7-restricted epitopes tested.
  - The B7-restricted CTL response was highly variable and there was no clearly dominant epitope.
- HXB2 Location** gp160 (298–307)

**Epitope name** B7-RI10**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Donor MHC** A3, B7, Cw7**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 4/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 1/4 individuals had detectable responses to this epitope after STI.

**HXB2 Location** gp160 (298–307)**Author Location** gp120**Epitope** RPNNNTRKSI**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Donor MHC** A2, A3, B7, Bw6**Keywords** HAART, ART**References** Appay *et al.* 2002

- Four HIV patients with prolonged clinically successful antiviral therapy but with ongoing evidence of replication and Nef mRNA transcription, showed specific T-cell responses by Elispot and Tetramer staining, maintained for 2-4 years after initiation of HAART.
- Nef epitope recognition was detected in all 4 subjects, gp120, Pol and Gag-specific in 1 or 2 subjects.
- The HIV-specific CD8+ T-cells had an intermediate maturation phenotype characterized by low levels of perforin and high levels of CD27 expression.

**HXB2 Location** gp160 (298–307)**Author Location** gp160 (298–307)**Epitope** RPNNNTRRGI**Epitope name** B7-RI10 Env**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** supervised treatment interruptions (STI), escape, early treatment, superinfection**References** Altfeld *et al.* 2002a

- An HIV+ individual given acute ARV and undergoing STI developed a strong CTL immune response, but despite this was shown to be superinfected with second B clade virus. Some epitope variants of the second infecting virus were resistant to the initial CTL response.

- The first infecting strain had the variant rpSnntrKSi, and the CTL response was higher to the second variant, RPNNNTR-RGI.

**HXB2 Location** gp160 (298–307)**Author Location** gp120**Epitope** RPNNNTRKSI**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Country** Netherlands**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** HIV exposed persistently seronegative (HEPS)**References** Koning *et al.* 2004

- A high-risk seronegative group of 29 homosexual men showed reduced cellular in vitro susceptibility for HIV infection and enhanced production of RANTES compared to 15 men who went on to seroconvert. Significantly higher frequencies of HLA A\*11, A\*31 and Cw\*15 were also found in the high risk seronegative men. Both groups of men had low frequencies of HIV-1 specific CD8+ T-cells, which may signify exposure more than protection from infection.
- No one pre-seroconversion, 0/9 HLA A2+ infection-resistant men, and 0/4 pre-seroconversion men who went on to become infected, reacted to this epitope.

**HXB2 Location** gp160 (298–307)**Author Location** Env (302–311)**Epitope** RPNNNTRKSI**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Country** Spain**Assay type** proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay**Keywords** HAART, ART, supervised treatment interruptions (STI), immune dysfunction**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.
- 3/7 patients recognized this epitope.

**References** Ahlers *et al.* 2001

- BALB/c and A.AL were immunized with an Env-peptide vaccine construct containing the CTL epitope P18IIIB and the T helper epitope T1, KQIINMWQEVGKAMYA.

- Substitution of Glu (wt) to Ala in T1, kqiiimwqAvgkamya, caused increased affinity for MHC class II Ek, resulting in the upregulation of CD40L in the responding Th cells, and shifting the response towards Th1. Increased Th responses stimulated DCs to produce higher levels of IL-12, and B7-1 and B7-2, and enhanced CTL responses to P18.
- The modified epitope, T1A, elicited stronger protection against increasing doses of viral challenge with vaccinia expressing HIV-1 IIIB gp120 compared to the wt epitope T1.

- A discistronic IL-2 gp120 expression vector gave a weaker CTL response than gp120 alone in the expression vector, however co-administration of an IL-2/IgG fusion protein enhanced the immune response and administration of a IL-2/IgG plasmid had a response that depended on the timing of administration.
- This study showed that a response to an HIV-1 DNA vaccine could be either augmented or suppressed by plasmid Cytokine/Ig administration.

**HXB2 Location** gp160 (308–322)**Author Location** Env (308–322 IIIB)**Epitope** RIQRGPGRAFVTIGK**Epitope name** P18**Immunogen** vaccine*Vector/Type:* peptide *Strain:* B clade IIIB*HIV component:* V3 *Adjuvant:* B7, CpG immunostimulatory sequence (ISS), in vivo electroporation**Species (MHC)** mouse (H-2<sup>d</sup>)**Keywords** Th1**References** Uno-Furuta *et al.* 2001

- Peptide immunization usually doesn't elicit a good CTL response because epitopes are not internalized and processed and presented, so vaccination with electric pulsing was tried (i.m. injection followed by 8 electric pulses), to enhance peptide uptake through electroporation.
- BALB/c immunized with HIV P18 or hepatitis C P17 peptides with an electric pulse elicited a CTL response, those that did not receive the pulse did not.
- The CTL response was enhanced by addition of immunostimulatory sequences ISS in the plasmid pCMV-LacZ, that contains hexamers GACGTC, AGCGCT, AACGCT, sequences common in prokaryotic genomes but rare in eukaryotic genomes that elicit Th1 cytokines and result in B cell and T-cell proliferation.
- The CTL response was also enhanced by addition of B7-1 cDNA – the B7 family of proteins transduce co-stimulatory signals through interaction with CD28.

*HIV component:* V3 *Adjuvant:* Cholera toxin (CT), GM-CSF, IL-12, IL-18, IL-1 $\alpha$

**Species (MHC)** mouse (H-2D<sup>d</sup>)

**References** Staats *et al.* 2001

- Cholera toxin (CT) is a potent adjuvant used in animal studies that is not safe in humans, so combinations of cytokines were used in nasal immunization of BALB/c mice V3 peptides to attempt to replace CT as a potent adjuvant.
- Peptide vaccine induced CTL activity was significantly increased by IL-1 $\alpha$ , IL-18, and GM-CSF given alone as adjuvant, but CT gave more potent CTL activity than any single cytokine.
- Combinations of cytokines could be more potent than CT as an adjuvant. The highest tetramer binding of H-2D<sup>d</sup> peptide-specific PBMC after nasal immunization was observed with IL-1 $\alpha$  plus IL-18 as adjuvant.
- Nasal immunization with HIV peptide in the presence of IL-1 $\alpha$ , IL-12 and GM-CSF induced IFN- $\gamma$ -secreting cells in the cervical lymph node, the lung and the spleen, and was associated with upregulation of MHC class II and B7.1 on nonlymphocytes in NALT/nasal mucosal cells.
- Consistent results were obtained for the IIIB and the MN peptides.

**Keywords** vaccine-specific epitope characteristics  
**References** Moore *et al.* 2002a

- Intramuscular immunization of BALB/c mice with DNA vaccines carrying either gp160 or Nef in the expression vector plasmid pNGVL gave different responses – gp160 induced strong gp160-specific CTL and IFN-responses and low-titer humoral responses, and Nef generated humoral (IgG1, IgG2a) responses and IFN-responses but little CTL activity.
- Co-injection of DNA plasmids encoding cytokines and/or hematopoietic growth factors, IL2, IL-12, IL-15, Flt3 ligand (FL), and GMCSF tended to give responses that were enhanced quantitatively, but not altered qualitatively.
- Co-administration of GMCSF most strongly enhanced CTL and IFN-responses against pNGVL-gp160.
- Repeated immunization with pNGVL-Nef failed to induce CTL responses. Co-administration of IL-12 most strongly enhanced humoral and IFN $\gamma$  responses.
- FL, which enhances innate immune responses, in combination with IL-2, IL-12 or IL-15 generated with most potent Nef responses.

**References** Jones *et al.* 2004
- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
  - The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
  - This was one of five reasonably strong responses in early infection in the patient WEAU, and the epitope sequence did not vary during the first year of the infection.

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naïve subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.

**Species (MHC)** mouse (A\*0201)

**Keywords** binding affinity, vaccine-specific epitope characteristics, immunodominance

**References** Peter *et al.* 2001

- The stability of peptide binding to HLA-A2.1 was determined for six HLA-A2.1 peptides included in this vaccine study – ILKEPVHGV (RT), SLYNTVATL (p17), SLLNATDIAV (gp41) and LLWKGEAV (RT) all bound with high affinity comparable to a influenza epitope reference (GILGFVFTL), while RGPGRGFVTI and VIYQMDDL bound with a lower affinity (relative binding activity = 0.01).
- The four high-affinity peptides formed stable complexes with half-lives ranging between 8 and 32 hours, while the low affinity peptides had half lives of less than an hour.
- HLA-A2.1 transgenic mice were immunized with the six HIV-1 peptides and P30, as a universal T-helper epitope, with IFA or Montanide or microspheres as adjuvants.
- All peptides except VIYQMDDL induced a strong CTL response in Cr-release assays - stronger responses were observed when peptides were delivered alone, indicating immunodominance when the combination was used.

**References** Altfield *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.

- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- Different HIV strains were used for different regions: Env IIIB, Gag HXB2
- BALB/c mice were vaccinated with rec vesicular stomatitis virus (rVSV) expressing either HIV-1 Gag or Env, or both, and retention of memory responses and recall responses were studied by tetramer staining and IFN-gamma production.
- Seven months after vaccination with Env-rVSV, 6% of the CD8+ cells were tetramer positive for the immunodominant Env epitope; these cells had a memory phenotype, CD44-Hi positive.
- Env in rec vaccinia virus (Env-rVV) elicited a strong recall response, with up to 45% to the CD8+ T-cell population tetramer positive and activated (expressing CD62L-Lo), and capable of IFN-gamma production.
- A prime with Env-rVSV and heterologous boost of Env-rVV gave remarkably high levels of memory cells, with approximately 1/3 of the CD8+ splenocytes being Env specific memory cells 150 days after the boost.
- A Gag-rVSV or EnvGag-rVSV prime and with a heterologous Gag-rVV or EnvGag-rVV boost combination gave 40% tetramer positive CD8+ cells, but the fraction of IFN-gamma producing cells was only about 25%. Still the heterologous vector prime-boost combination showed a profound benefit.
- A HIV-1 protein rVSV prime, rVV boost was a more potent combination than a vector reversal of a rVV prime and rVSV boost.

**HXB2 Location** gp160 (311–320)

**Immunogen** vaccine

*Vector/Type:* peptide *Strain:* B clade IIIB *HIV component:* V3 *Adjuvant:* Cholera toxin (CT), GM-CSF, IL-12, IL-18, IL-1 $\alpha$

**Species (MHC)** mouse (H-2D<sup>d</sup>)

**References** Staats *et al.* 2001

- Cholera toxin (CT) is a potent adjuvant used in animal studies that is not safe in humans, so combinations of cytokines were used in nasal immunization of BALB/c mice V3 peptides to attempt to replace CT as a potent adjuvant.
- Peptide vaccine induced CTL activity was significantly increased by IL-1 $\alpha$ , IL-18, and GMCSF given alone as adjuvant, but CT gave more potent CTL activity than any single cytokine.
- Combinations of cytokines could be more potent than CT as an adjuvant. The highest tetramer binding of H-2Dd peptide-specific PBMC after nasal immunization was observed with IL-1 $\alpha$  plus IL-18 as adjuvant.
- Nasal immunization with HIV peptide in the presence of IL-1 $\alpha$ , IL-12 and GM-CSF induced IFN-gamma-secreting cells in the cervical lymph node, the lung and the spleen, and was associated with upregulation of MHC class II and B7.1 on nonlymphocytes in NALT/nasal mucosal cells.
- Consistent results were obtained for the IIIB and the MN peptides.

*Vector/Type:* DNA prime with vaccinia boost *Strain:* B clade IIIB *HIV component:* gp160 *Adjuvant:* beta-glucan lentinan, IL-2/Ig, liposome, PLG

**Species (MHC)** mouse (H-2D<sup>d</sup>)

**Keywords** immunodominance

**References** Wierzbicki *et al.* 2002

- BALB/c mice were given an oral immunization with (PLG)-encapsulated plasmid DNA expressing gp160 and a boost of rec gp160 vaccinia vectors (rVV) with addition of murine IL-2/Ig plasmid or lentinan-associated liposomes. Lentinan increased CTL activity as measured by Cr-release assays against the immunodominant epitope RGPGRAFVTI, but didn't alter Ab responses. IL-2/Ig increased both type I and II activities, and increased Env specific CTL and Abs. Administration of liposomes and PLG microparticles with adjuvants facilitated gastrointestinal uptake.

**Immunogen** vaccine

*Vector/Type:* protein *Strain:* B clade LAI *HIV component:* Gag, gp120 *Adjuvant:* CpG immunostimulatory sequence (ISS)

**Species (MHC)** mouse (H-2D<sup>d</sup>)

**References** Horner *et al.* 2001

- Immunostimulatory sequences (ISS), also known as CpG motifs, stimulate innate immunity and enhance vaccine-specific immune responses.
- Intranasal immunization (i.n.) of BALB/c mice was more effective than intradermal (i.d.), and immunization with a gp120-ISS conjugate was more potent than immunizing with gp120 and separate ISS molecule – increased IgG1, IgG2a,

IFN-gamma, MIP1-alpha and MIP1-beta production was observed, and only i.n. immunization gave IgA responses.

- The highest mucosal CTL activity in both the Lamina Propria and the Peyer's Patch was observed following intranasal delivery with the gp120/ISS conjugate.
- Cytokine, chemokine and CTL responses following gp120/ISS conjugate vaccination were CD4+ T-cell independent; gp120 specific antibodies were dependent on helper T cells.

**References** Wild *et al.* 2004

- A codon optimized gag DNA vaccine was compared to a myristylation defective gag and p24 alone, both of which lack signals for secretion from transfected cells. Gag-derived immunogens that were secreted as VLPs and those that remained intracellular (p24) each produced strong CTL responses, and neither the size of antigen nor cellular trafficking and localization significantly influenced the strength of humoral and cellular immune activation. The formation and release of VLPs was not essential for eliciting strong CTL. BALB/c mice were given the DNA vaccine by i.m. administration of plasmid DNA for the prime and boost.

- Linking the region encoding the V3 immunodominant epitope to the gag gene did not diminish the response to the Gag p24 epitope A9I, but did enable a response to the V3 epitope.
- Minigenes were made incorporating just 1 epitope, minitopes, carrying 1 of 3 murine class I epitopes linked to the Ad2-E3 protein-derived signal peptide to allow access of the epitope to the ER. Weak induction of cellular immune responses was observed, in contrast to the complex polyprotein.

- To study the critical amino acids of both TCR and MHC that interact with peptide P18-I10 of HIV-1 IIIB, the authors used a series of mutant substituted peptides. Peptides substituted with Ala at various positions showed that positions 322R, 324F and 327I were essential for binding to H2-D<sup>d</sup>. Residue 325V was critical for interacting with TCR. By employing D-amino acid derived peptides as mutants in order to avoid charge, size and molecular weight differences, they also show that 325V is necessary for CTL-induced cytotoxic activity. Using two distinct CTL clones and molecular modeling they determined that TCR sequences of CDR1 and not CDR3 critically interact with 325V.
- This 10-residue minimally active peptide lies within the immunodominant epitope, RIQRGPGRAFVTIGK, that belongs to gp160, the hypervariable region of Env. Substituted peptides used in this study were RGPGRAFiTI, RGPGRAFITi, RGPGRAFaTi, RGPGRAFyTi, RGPGRAFfTi, RGPGRAFhTi, RGPGRAFrTi, RGPGRAFsTi, RGPGRAFeTi, RGPGRAFkTi, RGPGRAFrTi and RGPGRAFpTi. In addition, D-amino acid variants of the residues in parentheses were used - (r)GPGRAFVtI, RG(p)GRAFVtI, RGPg(r)AFVtI, RGPGR(a)FVtI, RGPGRa(f)VtI, RGPGRAF(v)tI, RGPGRAFV(t)i, RGPGRAFVt(i), RGPGRAF(i)tI, RGPGRAF(I)tI, RGPGRAF(a)tI, RGPGRAF(y)tI, RGPGRAF(f)tI, RGPGRAF(h)tI and RGPGRAF(t)tI.

- HIV-epitope, RGPGRAFVTI, was fused to a Hepatitis B core antigen (HBcAg) gene in order to improve immunogenicity of an epitope-based vaccine in mice. A vaccine containing hybrid HBcAg-epitope linked to an HIV-specific T helper epitope induced significantly higher responses than a hybrid HBcAg-epitope vaccine which performed better than epitope alone. The authors suggest that HBcAg could be a better carrier of foreign epitopes than even Hepatitis B surface antigen (HBsAg) - (previously studied).
- This work also deals with a multi-epitope SIV-based vaccine in non-human primates.

**Assay type** Tetramer binding, Other

**Keywords** memory cells

**References** Ramsburg *et al.* 2007

- The requirement for CD4 T cell help in primary versus memory CTL responses was examined. Since a VSV vector encoding HIV Env was used as vaccine, responses specific to HIV-1 Env epitope RGPGRAFTVTI as well as VSV epitope N were tested. Both primary and memory responses to the Env epitope did not require Th help. However, primary CTL responses to Env were 2-3 fold higher in the presence of CD4 T cells, while memory responses were tested until 3 months post-priming. Thus memory CTL maintenance dependency on CD4 T cell help is epitope-dependent.

**Keywords** vaccine-specific epitope characteristics, immunodominance

**References** Vázquez Blomquist *et al.* 2002

- BALB/c mice were vaccinated with a polyepitope V3 vaccine in a fowlpoxvirus carrying concatenated 15 mer sections of the V3 loops of HIV-1 isolates LR150, JY1, RF, MN, BRVA and IIIB with 5-aa linkers between, fused to the N-term of p64K protein from *Neisseria meningitidis*.
- Intraperitoneal immunization elicited the strongest V3-specific IFN-gamma response in splenocytes, compared to intravenous and subcutaneous immunization. Intraperitoneal immunization conferred protection in a recombinant vaccinia virus challenge model.
- The immunodominant response was directed against the IIIB peptide (the IIIB immunizing peptide was SIRIQRGP-GRFVFTI, the peptide used to probe the response by Elispot was GPGRFVFTI).
- Low CTL responses were also detected to the LR150 (SRGIRIGPGRAILAT) and RF (RKRTMGPRVYYTT) peptides, no responses were detected to the JY1 (RQSTPIGLGQ-ALYTT), BRVA (RKSITKGPGRVIYAT), or MN (RKRIHIGPGRAFYTT) peptides.

**Species (MHC)** mouse (H-2<sup>d</sup>)

**Assay type** Cytokine production, CD8 T-cell Elispot - IFN $\gamma$

**Keywords** Th1

**References** Gómez *et al.* 2004

- Priming of mice with DNA-TAB vector, a polyepitope string carrying 8 different V3 loop sequences, followed by a booster with VV-TAB or MVA-TAB, induced humoral responses, as well as a CD8+ T-cell response against V3 epitopes from three different subtype B HIV isolates. The highest values of specific CD8+ T-cell response were achieved when priming with DNA-TAB and a DNA vector expressing IFN-gamma, followed by a MVA-TAB boost. The T-cell response was Th1.
- The eight V3 loops were linked with an A-G-G-G-A sequence. The three peptides that elicited a response were LR150, SRGIRIGPGRAIL; MN, RKRIHIGPGRAFY; and IIIB, SIRIQRGPGRFVFTI. These peptides were located at the beginning, middle and end of the polyepitope, indicating all parts were able to be processed. It is not known if there is an H-2d epitope in the other five V3 loop variants that did not elicit a response.

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Positions 1, 5 and 10 (last) in the epitope had potentially experienced positive selection. qIIGDIRQAY, dIIGDIRQAh, EIIGnIRQAh and EIIGDIRQAh escape variants were found.

**Country** United States

**Assay type** Cytokine production

**Keywords** subtype comparisons, immunodominance

**References** Brown *et al.* 2006

- A vaccine study with B clade Envs in mice was undertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.
- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, IIGDIRQAHCNISRE.

**Keywords** dynamics, immunodominance, escape, kinetics, characterizing CD8+ T cells, viral fitness and reversion

- References** Jones *et al.* 2004
- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
  - The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
  - WEAU had a reaction to an epitope within this peptide, and there was very rapid accumulation of substitutions; variation continued through the last sample collected.

**Epitope** SFNCGGEFFY

**Epitope name** SY10

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (A29)

**Donor MHC** A28, A29, B14, B44, Cw8

**Country** United States

**Assay type** Cytokine production, Intracellular cytokine staining, Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** assay standardization/improvement, memory cells, characterizing CD8+ T cells

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN-gamma and TNF-alpha exhibit stronger cytotoxic activity than those secreting only IFN-gamma. These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 1/9 individuals recognized this epitope.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

**HXB2 Location** gp160 (404–420)**Author Location** gp120**Epitope** GSNNTVGNPIILPCRI**Subtype** A, B, C, D**Immunogen** vaccine*Vector/Type:* DNA prime with vaccinia boost, protein *Strain:* B clade 1007, B clade 1035**Species (MHC)** human**Assay type** Cytokine production**Keywords** subtype comparisons, immunodominance**References** Brown *et al.* 2006

- A vaccine study with B clade Envs in mice was undertaken to assess a subtype-specificity of responses. Four T-cell hybridomas responsive to subtype B envelope proteins were tested against 20 different subtype B envelope proteins and a protein each from subtypes A, C and D. IL-2 production was measured.
- No consistent correlation was found between T cell specificity towards epitopes from a certain (B) subtype or lack of specificity towards other (A, C, D) subtype.
- Not only did T-cell specificity not vary with subtype, but pairwise sequence comparisons of gp120 envelope sequences showed that some US-derived sequences were more similar to sequences from distant countries than to each other.
- Changes in core epitopes, flanking and distant regions, all affected responsiveness of the hybridomas to different subtype Env epitopes, showing that it is not only core changes that can eliminate T cell reactivity to an epitope.
- The above findings were substantiated by database analyses showing that epitope distributions are not necessarily dictated by subtype.
- This paper lists several variants of the epitope above, GSNNTVGNPIILPCRI.

**HXB2 Location** gp160 (410–429)**Author Location** gp120 (410–429 PV22)**Epitope** GSDTITLPCRIKQFINMWQE**Immunogen** in vitro stimulation or selection**Species (MHC)** human (DRA CD4+)**References** Bouhdoud *et al.* 2000

- CTL were studied through PBMC stimulation *in vitro* by gp120 pulsed autologous monocytes.
- Human CD4+ CTL clone (Een217) is an MHC class II HLA-DRA restricted CTL clone that can lyse antigen presenting HLA-DRA-transfected murine L cells – natural variants of the epitope resulted in an anergic response.
- Low concentrations of the HXB2-derived variant (GSDTITLPCRIKQIINMWQK) induced T cell anergy – higher concentrations could induce proliferation and cytotoxic activity.
- CDC42 (TGDITLPCRIKQII-NRWQV), Eli (TNTNITLQCRKQIIMVAG) and Z3 (CTGNITLPCRIKQIIM-NWQE) variants did not induce proliferation, cytotoxic or anergic responses.

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient B displayed the greatest response to epitope B44-AW11(p24) and also responded to A32-PW10(RT) in both PB and LN samples, while a third response against epitope A32-RW10(gp120) was only detected in the LN sample. Patient D displayed the greatest response to B27-KK10 (p24), and also responded to A30-RY11(p17), A32-PW10(RT), A30-KY11(RT), A32-RW10(gp120), and B18-YY9(Nef).

 of progression, kinetics, memory cells, char-  
 acterizing CD8+ T cells  
**References** Davenport *et al.* 2004

- Activation and expansion of antigen-specific CD8+ T-cells shows a delay following infection that allows early viral replication. Until day 10, the kinetics of CD8+ T-cell expansion was the same in vaccinated and control macaques. An increase in virus-specific CD8+ T-cell numbers around day 10 in vaccinated macaques coincides with a slowing in viral replication. This indicates that while cytotoxic T-lymphocyte-inducing vaccines may have a long-term benefit in controlling viral replication and preventing disease progression, they cannot prevent infection.

**References** Barouch *et al.* 2000; Shen & Siliciano 2000

- Different HIV strains were used for different regions: SIV-mac239 Gag and HIV-1 89.6P Env
- Monkeys that received the DNA vaccines augmented with IL-2/Ig were infected when challenged with pathogenic SHIV-89.6P, but had potent CTL responses, stable CD4+ T-cell counts, preserved virus-specific CD4+ T-cell responses, low to undetectable viral loads, and no evidence of disease or mortality by day 140 after challenge – monkeys that got a sham vaccine had high viral load, progressed to disease, and were half were dead by day 140.
- IL2/Ig consisting of interleukin-2 (IL-2) for immune stimulation, and the Fc portion of immunoglobulin G (IgG) for stability, was delivered either as protein or as DNA – both enhance the CTL response to vaccination, DNA IL2/Ig giving the most intense response.
- Responses to a dominant Mamu A\*01 gag epitope SIV Gag p11C (CTPYDINQM) and a subdominant epitope HIV-1 Env p41A (YAPPISGQI) were tracked and had good durability prior to challenge, and the higher the prechallenge peak p11C CTL response, the lower the post-challenge viral load.
- No NAb responses were detected in the vaccinated monkeys prior to challenge, and comparable peak NAb titers developed in vaccinated monkeys and control monkeys with preserved CD4+ T-cells.
- Shen *et al.* 2000 is an accompanying commentary.

**Species (MHC)** human

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** immunodominance

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, NWRSELYKY, is similar to human protein peroxysomal acylCoA thioesterase, sequence hNWRSELY.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.
- Only four epitopes were found to acquire escape mutations in SUMA over time, and this was one of the 20 that remained invariant. A low level response was detected at acute infection that persisted through early infection.

- Three long-term non-progressors and one asymptomatic HIV+ individual were studied and found to have HLA class I C-restricted CD8+ Env-specific CTLs – Cw7 specific CTL were found against three peptides, including this one.
  - HLA-C antigens are expressed on lymphoid cells to a lesser extent, 10% of either HLA-A or HLA-B.
  - HLA-C confers protection against lysis by natural killer cells and by non-MHC-restricted effector T cells and Cw7 directly governs this resistance to lysis – the authors hypothesize that pathogens that inhibit antigen expression and class I expression may particularly down regulate Cw7, thus triggering non-MHC restricted killing.

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, IVQQSNLLRAIEAQQHL differs from the consensus C sequence IVQQSNLLRAIEAQQHL at 0 amino acid positions, i.e. the two clades' peptides are identical.

**Keywords** optimal epitope  
**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, RAIEAQQHL, was predicted to be restricted by HLA B\*1501, B\*1517, B\*5101 and C\*0304.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** rate of progression, escape

**References** Geels *et al.* 2003

- Both stable potential epitopes and epitopes with escape mutations were found in a patient with increasing viral load over a time period of 4 years. Fixation of escape mutations occurred sequentially and correlated with the rise in viral load and with the increased number of productively infected cells.
- This is one of 17 potential epitopes from this individual, defined based on previously identified epitopes presented by appropriate HLA molecules. Full length genome sequence did not reveal changes in time in any of these epitopes over a four year period. Peptide pools initially revealed very little response to these epitopes, but this increased over time.

**HXB2 Location** gp160 (557–565)

**Author Location** gp41 (557–565 LAI)

**Epitope** RAIEAQQHL

**Epitope name** E3

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B51)

**Keywords** HAART, ART

**References** Mollet *et al.* 2000

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using CD8+ cell IFN $\gamma$  production to measure responses.
- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

**HXB2 Location** gp160 (557–565)

**Author Location** gp41

**Epitope** RAIEAQQHL

**Epitope name** B51-RL9(qp41)

**Immunogen** HIV-1 infection

**Species (MHC)** human (B51)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).

- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** gp160 (557–565)

**Author Location** gp41

**Epitope** RAIEAQQHL

**Subtype** B, C

**Immunogen** HIV-1 infection

**Species (MHC)** human (B57, B58, B63)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** cross-presentation by different HLA, optimal epitope

**References** Frahm *et al.* 2005

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- This is a putative HLA-B63/57/58 epitope containing the B58 supertype binding motif. Significantly more often recognized by B63+ and B57/58+ subjects than by negative subjects.

**HXB2 Location** gp160 (557–565)

**Author Location** gp41 (46–54)

**Epitope** RAIEAQQHL

**Epitope name** RL9

**Immunogen** HIV-1 infection

**Species (MHC)** human (C\*03, C\*15)

**Assay type** CTL suppression of replication

**Keywords** class I down-regulation by Nef

**References** Adnan *et al.* 2006

- The impact of Nef on antiviral activity was studied. CTL-targeting epitopes were susceptible to the effects of Nef, both in late (Gag, RT, Env) and in early proteins (Rev, Nef), although to a lesser degree in early proteins. However, HLA-C-restricted CTLs (unlike HLA-A and HLA-B) were unaffected by Nef both in early (Nef) and late (Env) proteins.
- Env epitope RAIEAQQHL-recognizing HLA-C restricted CTLs were unaffected by Nef.

**HXB2 Location** gp160 (557–565)

**Author Location** gp41 (557–565)

**Country** Kenya

**Assay type** Cytokine production, proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** assay standardization/improvement

**References** McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTS as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 5 variants of this index epitope RAIEAQQHL, RL9, were tested - RAIEAQQHm, RAIEAQQqm, RAIEvQQHL, RAIEgQQHL, RAIEtQQHL. The index peptide RAIEAQQHL and variant RAIEAQQHm while being most prevalent, are commonly recognized in ELISPOT but do not elicit proliferation. Conversely, the relatively rare variant RAIEvQQHL had proliferative responses more often than it was recognized by ELISpot.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** assay standardization/improvement, optimal epitope

**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, RAIEAQQHL, was detected within overlapping peptides IVQQNNLLRAIEAQQHL and LRAIEAQQHLQLTVWGI.

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (Cw03, Cw15) and 4 additional alleles (A02, A30, B58, Cw04).

**Keywords** subtype comparisons, variant cross-recognition or cross-neutralization

**References** McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than one clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. VTEEFNMWK responses were detected in 2 women that had Env responses to all 4 clades, and clade A gave the highest responses; a VnEEFNMWK variant was in clade B and D, and the clade C Env carried VnEEFNMWK. One woman also reacted with RAIEAQQHL, the other with KNCSFNMTT. RAIEAQQHL was identical in clades A, B, and D, while C carried RAIEAQQHm.

**HXB2 Location** gp160 (557–566)**Author Location** Env (557–566)**Epitope** RAIEAQQHML**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (A\*69, B\*40)**Country** India**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, computational epitope prediction, immunodominance**References** Thakar *et al.* 2005

- PBMCs from HIV-1 infected Indian subjects were tested for HIV-1 Gag (with C clade peptides), Nef (with B clade peptides), and Env (clade unspecified) specific T-cell responses. 5 immunodominant regions conserved across clades were identified in Gag and Nef. 3 antigenic regions were found to be recognized by CTLs in the Indian subjects; these regions were not identified as immunodominant in studies from Africa.
- 26 epitopes were predicted within reactive peptides, of which 90% were clustered in the conserved immunodominant regions of Gag and Nef. 3
- of the epitopes were highly conserved across clades, and 7 novel epitopes were found.
- Epitope RAIEAQQHML had >50% conservation across clades B and non-Indian C, but showed no conservation to subtype A.

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.

- This HLA-B\*14 restricted epitope, VERYLKDQQL was mutated to VERYLrDQQL in the daughter D2 isolate.

- A panel of 16 epitopes covering 15 class I alleles was tested in 14 HIV+ patients from an unselected Caucasian population treated with HAART, using CD8+ cell IFN $\gamma$  production to measure responses.

- In general, during the first month of treatment viral load decreased and frequencies of HIV-specific CTL tripled and broadened – eight new HIV specificities that were not previously detectable were newly detected, as were CMV specific CD8+ PBL – but with continued viral suppression, HIV-specific responses diminished.
- Viral rebounds gave different patterns of response: increases or decreases in pre-existing response, new specificities, or no change.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure

imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.

- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**References** McKinnon *et al.* 2007

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTs as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 6 variants of this index epitope ERYLKDQQL, EL9, were tested - ERYLqDQQL, EsYLqDQQL, EsYLKDQQL, ERYLrDQQL, ERYLtDQQL, ERYLsDQQL.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient BORI had high viral loads and rapid CD4 decline. BORI mounted 8 detected responses. BORI did not control viral replication well, and escape mutations occurred early and in most epitopes, 6/7 that were precisely identified.
- The patient SUMA maintained low viral loads and stable CD4 T cell counts through seven years of follow up. In contrast to more rapid progressors, WEAU and BORI, SUMA a broad response to 24 epitopes, with little immunodominance. Two peptides were somewhat more intensely recognized in acute infection, but this response leveled out early on.

- Eleven variants in the ERYLKDQQL epitope were found in the patient BORI. ERYLKeQQp came up first at day 17 from onset of symptoms, but wasn't tested for escape properties. ERYLrDQQL came up next, by day 31, but didn't confer escape in a Cr release assay. By day 218, three variants were found, all of which gave a diminished response: ERYLrDQQL, ERYLqDQQL, and ERYLsDQQL. By day 556 a complex mixture was present, also including the ERYLmDQQL variant that gave a further reduction in the response, and many double mutants: ERYLmDQrL, ERYLmDrQL, ERYLmDQlL, ERYLrDQrL and ERYrDQrL.
- In SUMA, the only variation found in the 24 epitopes was in three overlapping epitopes in Tat, and in this gp160 epitope; variation accumulated early in infection in the Tat epitopes, but this epitope was stable until a sample 736 days post-infection, when only the ERYLqDQQL variant was detected. This variant was not tested with CTL from SUMA, but gave a diminished response in BORI.

**Donor MHC** A32, B14, B7

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient A displayed the greatest response to epitope B14-EL9(gp41), a strong response to B7-TL9(p24), and responses to B7-TM9(Nef) and A32-PW10(RT).

**Subtype** A, B, C, D

**Immunogen** HIV-1 infection, vaccine

*VectorType:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade  
*HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human (B14)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**References** Yang *et al.* 2003b

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 4/14 CTL T-cell clones tested were specific for Env EL9. Under conditions of excess peptide (100 $\mu$ g/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 range for Env EL9 was 5,000 - 60,000 pg/ml.

**Keywords** assay standardization/improvement, memory cells, characterizing CD8+ T cells

**References** Lichterfeld *et al.* 2004c

- Using a flow-cytometric cytotoxicity assay based on caspase-3 activation in dying target cells, it was shown that the subset of HIV-1-specific CD8+ T cells secreting both IFN- $\gamma$  and TNF- $\alpha$  exhibit stronger cytotoxic activity than those secreting only IFN- $\gamma$ . These cells also exhibited stronger intracellular perforin expression. No association between HIV-1-specific CD8+ T-cell maturation phenotypes and intracellular perforin expression was found.
- 2/9 individuals recognized this epitope, presented by HLA-B14.

**References** Koibuchi *et al.* 2005

- HIV-1-specific CD8 T-cell responses were persistent in the chronic phase of HIV-1 infection, although the responses to some of the epitopes declined despite the persistence of the targeted sequences in vivo. Only 4/14 epitopes were potential CTL escape variants, although strong responses to these epitopes persisted for 6 years. This indicates limited viral evolution within targeted CD8 T-cell epitopes during the chronic phase of infection.
- The variant ERYLqDQQL was the only form of the epitope detected over a 6-year period in this person. Elispot reactions were reduced to the autologous form relative to the B clade consensus form, ERYLKDQQL.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

- CD8+ T-cell function induced by HIV-1 immunogens and natural infection was compared. Natural infections consisted of early, chronic, and long term nonprogressors.
- B27- and B57-restricted CD8+ T cells from nonprogressors exhibited greater expansion than those restricted by other alleles, providing an explanation for the observed association between HLA-B27/B57 and control of HIV-1 infection.

**HXB2 Location** gp160 (584–592)**Author Location** gp41 (subtype B)**Epitope** ERYLKDQQL**Subtype** B**Immunogen** HIV-1 exposed seronegative**Species (MHC)** human (B\*1402, B14)**Keywords** subtype comparisons**References** Rowland-Jones *et al.* 1998b

- HIV-specific CTL were found in exposed seronegative prostitutes from Nairobi – these CTL may confer protection.
- Seroprevalence in this cohort is 90-95% and their HIV-1 exposure is among the highest in the world.

- Most isolated HIV strains are clade A in Nairobi, although clades C and D are also found – B clade epitopes are often cross-reactive, however stronger responses are frequently observed using A or D clade versions of epitopes.
- This epitope is conserved among B and D clade viruses.
- The Clade A version of the epitope is ERYLRDQQL.

- Three out of five patients with HIV-1 symptomatic infection controlled their viral infection well and mounted an early, strong HIV-1 specific MHC restricted CTL response.
- One of the three, study subject BORI, specifically recognized this peptide.

**HXB2 Location** gp160 (584–592)**Author Location** gp160**Epitope** ERYLRDQQL**Subtype** A, B, C, D**Immunogen** HIV-1 infection, vaccine*Vector/Type:* vaccinia *Strain:* A clade, B clade, D clade NDK, C clade consensus *HIV component:* Env**Species (MHC)** human**Donor MHC** A\*0202, A\*7401, B\*1503, B\*5802, Cw\*0202, Cw\*0602; A\*0201, A\*3009, B\*4501, B\*5802, Cw\*0202, Cw\*1601**Country** Kenya**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other**Keywords** subtype comparisons, variant cross-recognition or cross-neutralization**References** McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. ERYLRDQQL responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; a ERYLkDQQL variant was in clade B and

C, and the clade D Env carried ERsLkDQQL. The epitope VS-GFLALAW was also recognized by 1 of the women.

- HLA-B\*5802 was the only HLA common to both women who reacted with ERYLRDQQL, so may be the presenting allele.

**References** Horton *et al.* 2006b

- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
- None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85–86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
- Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
- ERYLKDQQL was recognized by a placebo patient after infection.

- CTL epitope responses were mapped in 21 men within 15–92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope RYLKDQQLL elicited a magnitude of response of 80 SFC with a functional avidity of 5nM.

**HXB2 Location** gp160 (585–593)

**Epitope** RYLKDQQLL

**Immunogen** HIV-1 infection

**Species (MHC)** human (A24)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** supertype, cross-presentation by different HLA

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- In addition to its known HLA association (A24), an additional HLA (A23) was statistically predicted to be associated with this epitope.

**HXB2 Location** gp160 (585–595)

**Author Location** gp41 (584–591 SF2)

**Epitope** RYLKDQQLLGI

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*2402)

**References** Ikeda-Moore *et al.* 1997

- Defined using reverse immunogenetics – 59 HLA-A\*2402 binding peptides were predicted by searching for A\*2402 anchors in HIV proteins (Tyr at 2, and Phe, Leu or Ile at the C term) – 53 of the 59 peptides bound A\*2402.
- This peptide induced CTL in 4/4 HIV-1 + people tested.
- RYLKDQQLLGI bound to A\*2402 with medium strength, the epitope can be processed in a vaccinia construct and presented – two specific CTL clones were obtained.

**HXB2 Location** gp160 (585–595)

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative

**Species (MHC)** human (A24)

**Keywords** subtype comparisons, HIV exposed persistently seronegative (HEPS), immunodominance

**References** Kaul *et al.* 2001a

- Variants (R)YL(R/K)DQQLL are specific for the A/B clade.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-A24 women, 3/4 HEPS and 10/10 HIV-1 infected women recognized this epitope, and (R)YL(R/K)DQQLL tended to be reactive in HEPS and infected women, RDYVDRFFKTL in infected women only.
- The dominant response to this HLA allele was to this epitope in all 3/4 HEPS cases but in only 4 of the 10/10 HIV-1 infected women.
- Differences in epitope specificity were only seen for responses restricted by class I HLA alleles A2, A24, A\*6802, B14, and B18, previously shown to be associated with resistance to HIV-1 in this cohort.

**References** Altfield *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognized epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Subtype** A

**Immunogen** HIV-1 infection, vaccine

*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade  
*HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human, macaque (A24, B8)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** escape, acute/early infection, variant cross-recognition or cross-neutralization

**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- The second donor in the study shares A\*0101 and B\*0801 with his partner. Escape variant yLQdqql was transmitted, and it reduces binding to B\*0801 by 92% relative to YLKDQQLL.

**Keywords** binding affinity, acute/early infection, early-expressed proteins  
**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially a showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.

- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A2.1 restricted epitope, WLWYIKIFI was the only one mutated, to WLWYIrIFI in the mother M2 isolate.

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.

- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, WYIKIFIMI, was predicted to be restricted by HLA A\*0203, A\*0206, A\*2402.

- HLA-A33 a very common allele in Asian, with HLA-A\*3303 the most common among the Japanese. New A\*3303 epitopes were defined to better characterize the immune response in this population.
- The anchor motif for HLA\*3303 (A, I, L, V, F, Y in position 2 (F and Y bind most strongly), and R (K is also tolerated) in the C-terminal position) was used to define 82 potentially reactive peptides in Env; 37/82 peptides bound to A\*3303; 3/37 peptides could induce peptide-specific CTL in bulk PBMC cultures from 1/3 HLA A\*3303 positive individuals tested.
- CTL clones were isolated that killed target cells in a concentration dependent manner after pulsing with the VFAVLSIVNR peptide, that could also kill cells transfected with env expressed from a vaccinia vector. Bulk cultures were tested from six additional people, and only 1/6 reacted with this peptide, but the peptide is in a highly variable region.

- HLA-A\*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
- A rapid method was developed combining ELISPOT with intracellular IFN- $\gamma$  staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
- Two individuals were studied: Subject 199 (HLA A\*0201/\*3002 B\*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A\*3002/ B53/\*5801 Cw4/7) an African-Caribbean.
- In both HLA-A\*3002 individuals the response to RSLYNT-VATLY was dominant.
- In subject 199 four additional A\*3002 epitopes were identified.
- Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Last position (9) in the epitope had potentially experienced positive selection. YSPLSLQTr escape variant was found.

**References** McKinnon *et al.* 2005

- Interclade cross-reactivity of clades A, B, C, and D was tested using recombinant vaccinia-based IFN-gamma Elispot assay. 47/74 women had a positive Elispot response to at least one clade, and cross-clade responses were frequent. Clade A responses were most frequent, as expected, as clade A dominates the Kenyan epidemic (85% of the 47 women responded to clade A Env, 74% to B, 62% to C, and 43% to D). Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. ERYLRDQQL responses were detected in 2 women who had Env responses to all 4 clades, and clade A gave the highest responses; an ERYLRDQQL variant was in clade B and C, and the clade D Env carried ERsLkDQQL. The epitope VSGFLALAW was also recognized by 1 of the women; A and C clade were identical, while clade B carried VnGsLiLAW, clade D VnGIsAiAW.

**References** Weekes *et al.* 2006
- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

**Keywords** binding affinity, acute/early infection, early-expressed proteins  
**References** Cao *et al.* 2003
- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later

- in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
  - More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**Vector/Type:** DNA with CMV promoter, modified vaccinia Ankara (MVA), DNA prime with modified vaccinia Ankara (MVA) boost **Strain:** A clade **HIV component:** Env, Gag, Nef, RT  
**Species (MHC)** mouse (H-2K<sup>d</sup>)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other  
**Keywords** subtype comparisons, vaccine-induced epitopes, variant cross-recognition or cross-neutralization, antagonism  
**References** Larke *et al.* 2007
- Cross-clade vaccine recognition was studied using either single-, multi or several anatomically separated single-clade vaccines. Limited cross-clade response was seen with single-clade administrations. Multi-clade vaccines gave immune interference (antagonism and original antigenic sin), reducing CTL response. Simultaneously administered but anatomically separated vaccines from clades A, B, C decreased antagonism and increased immune responses.

- After immunization with Clade A vaccine containing Epitope E, SYHRLRDFI, T cells were able to respond to epitope variant SYHRLRDFv, as well as variants SYHRLRDci, SYHRLRDii and SYHRLRDli at <50% magnitude. Variants SYrhLRDFI, iYHhLRDii and SYrhLRDii were not recognized.

**Species (MHC)** human (A03, A31)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding  
**Keywords** binding affinity, immunodominance, optimal epitope  
**References** Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope RLRDLLLIVTR when restricted by HLA-A03 elicited a magnitude of response of 450 SFC with a functional avidity of 0.5nM and binding affinity of 9.6nM. When restricted by HLA-A31, it elicited a magnitude of response of 450 SFC with a functional avidity of 0.05nM and binding affinity of 3.8nM.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** supertype, cross-presentation by different HLA  
**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (A03, A31) and 4 additional alleles (A02, A74, B44, Cw04).

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes was characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**References** Goulder *et al.* 2001a
- HLA-A\*3002 is very common in African populations, 50% of Zimbabweans express HLA-A30, 44% in African Zulu, so five new HIV epitopes were characterized that are presented by this HLA molecule.
  - A rapid method was developed combining ELISPOT with intracellular IFN- $\gamma$  staining of PBMCs to map optimal epitopes, then HLA presenting molecules were defined – this method was completed within 48 to 72 hours of receipt of blood.
  - Two individuals were studied: Subject 199 (HLA A\*0201/\*3002 B\*4402/51 Cw2/5), a Caucasian, and Subject 6007 (HLA A\*3002/ B53/\*5801 Cw4/7) an African-Caribbean.
  - In both HLA-A\*3002 individuals the response to RSLYNT-VATLY was dominant.
  - In subject 199 four additional A\*3002 epitopes were identified.
  - Three quantitative assays, ELISPOT, precursor frequency and chromium release, confirmed a hierarchy of response: RY11 (p17) > KY9 (gp41) > KY9 (RT-53) > IY9 (gp41)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding  
**Keywords** memory cells  
**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**References** Draenert *et al.* 2006

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, QELKNSAVSL (QL10) was restricted by HLA-B\*4001. A variant that arose was QELKkSAVSL.

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- Responses to epitope SLLNATAIAV were seen in early chronic infection. This was one of the epitopes targeted by broad HLA-A2-restricted CTL responses.

**References** Peter *et al.* 2001

- The stability of peptide binding to HLA-A2.1 was determined for six HLA-A2.1 peptides included in this vaccine study – ILKEPVHGV (RT), SLYNTVATL (p17), SLLNATDIAV (gp41) and LLWKGEAV (RT) all bound with high affinity comparable to a influenza epitope reference (GILGFVFTL), while RGPGRAFVTI and VIYQYMDDL bound with a lower affinity (relative binding activity = 0.01).
- The four high-affinity peptides formed stable complexes with half-lives ranging between 8 and 32 hours, while the low affinity peptides had half lives of less than an hour.
- HLA-A2.1 transgenic mice were immunized with the six HIV-1 peptides and P30, as a universal T-helper epitope, with IFA or Montanide or microspheres as adjuvants.
- All peptides except VIYQYMDDL induced a strong CTL response in Cr-release assays - stronger responses were observed when peptides were delivered alone, indicating immunodominance when the combination was used.

**References** Peter *et al.* 2002

- When HIV-1 peptides were used to vaccinate HLA-A2.1 transgenic A2-Kb mice, strong responses to five peptides were observed when the peptides were given individually, but immunodominance limited the response to some of the peptides when they were given in combination Peter *et al.* [2001]. IL-12 can counteract immunodominance in BALB/c mice, so it was given with the multiple epitope vaccination, and was instead found to specifically eliminate the HLA-A2.1-epitope CTL responses, but not Kb CTL responses. This was possibly a consequence of transient depletion of T-cells, B cells and macrophages in the spleen.

**References** Chitnis *et al.* 2003

- 17 perinatally HIV-1 infected children (0.08–16 years) were evaluated for HLA-A2-restricted IFN-gamma CD8+ CTL responses against 4 immunodominant peptides that carry HLA-A2 epitopes. Two peptides were from gp120 (one at position 112, one from the V3 loop), and one each was from gp41 and Gag. 15/17 patients responded to the Gag peptide, 13/17 to the gp41 and the non-V3 gp120 peptides, and 11/17 responded to the V3 loop. 4 children recognized all 4 peptides.

**Epitope** LLNATAIAV

**Immunogen** HIV-1 infection

**Species (MHC)** human (A\*0201)

**Keywords** binding affinity

**References** Kmiecik *et al.* 1998a

- CTL responses in six patients to four Env epitopes were studied: D2: LLNATAIAV, 5.3: RLRDLLLIV, D1: KLTPLCVTL, and 4.3: QMHEDIISL—all have A2 anchor residues.
- The C terminal epitopes (D2 and 5.3) were highly variable and the variability was considered responsible for limited CTL response, while D1 and 4.3, N-terminal epitopes, were much more conserved and gave evidence of high levels of CTL response *in vitro*.
- Peptides 5.3 and D2 bound to HLA A\*0201 with low affinity and were variable, particularly D2.
- Substitutions in peptide D2: llnTiAiav did not abrogate the response, but diminished it.
- In a longitudinal study, the CTL response to the variable D2 epitope diminished over time, while the response to the conserved epitope D1 stayed higher.

**Keywords** characterizing CD8+ T cells

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background

and HIV-1 epitope-immune response interaction account for nonprogression of disease.

- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This HLA-A\*02/A\*0201 restricted epitope, LLNATAIAV was mutated to LLNAiAIAV in the daughter D2 isolate.

**References** Jones *et al.* 2004

- Primary CD8+ T-cell response to Env, Tat and Gag and the extent, kinetics and mechanisms of viral escape were examined in three patients. Rapid escape, within weeks from infection, from HIV specific CTL responses was observed in all three patients, but the kinetics and extent of the escape differed depending on the breadth and co-dominant distribution of CTL-mediated pressure. The two patients that rapidly declined had more focused immunodominant responses, while the single patient that had low viral load and stable CD4 counts for seven years had a broad co-dominant response and less escape.
- The patient WEAU had high viral loads and rapid CD4 decline. WEAU mounted 14 detected CTL responses, with distinct patterns of immunodominance. WEAU did not control viral replication well, and escape mutations occurred early and 4/14 had changes that could have resulted in escape, and two were confirmed as escape.
- This was one of five reasonably strong responses in early infection in the patient WEAU, and the epitope sequence did not vary during the first year of the infection.

- A combined VLP-based vaccine, CombiHIVvac, was designed comprising TBI with 4 T-cell epitopes and 5 B-cell epitopes, as well as TCI with over 80 T-cell epitopes from Env, Gag, Pol and Nef conserved across A, B and C HIV-1 subtypes. The vaccine induced humoral and cellular immunity in mice infected with 3 HIV-1 strains. Virus-neutralizing activity was as efficient as HIV-1 patient sera inhibition of viral replication. IFN-gamma and IL-2 ELISpot showed that CTL responses were induced, though at 2 & 10 times lower than T-helper responses as measured by IL-4 ELISpot. Toxicity studies showed the vaccine to be promising with no allergenic properties.
- This multiple class I restricted peptide, DRVIEVVQ-GAYRAIR, is from the TCI component of the vaccine. It induced CTL responses as measured by ELISpot.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, HIPRRIRQGLERALL, had an overall frequency of recognition of 16.7% - 15.3% AA, 23.1% C, 15.9% H, 14.3% WI.

- The authors suggest that epitope variation has different effects on the HIV- specific immune responses of effector memory T cells (Tem) and central memory T cells (Tcm). They show a lack of correlation between IFN-gamma ELISPOT (Tem typical) and proliferation (Tcm typical) assays for specific epitopes in subjects. Since proliferating CTL also correlate with high intracellular IFN-gamma levels, they surmise that proliferating Tcm differentiate to express Tem functions.
- They also show that proliferating CTL numbers correlate with higher CD4 cell counts.
- Several patients responded strongly to epitope variants that were not part of their autologous HIV-1 sequences. Thus they suggest more comprehensive functional characterizations than the usual overnight IFN-gamma ELISPOTS as well as assessments of Tem versus Tcm specific responses rather than general CTL immune responses.
- 4 variants of this index epitope IPRRRIRQGF, IF9, were tested - IPtRIRQGI, IPRRRIRQGa, IPtRIRQGF, IPvRIRQGI. Variant IPRRRIRQGa that is relatively rare induced a high proliferation rate in T cells.

**HXB2 Location** gp160 (843–851)

**Author Location** gp41 (332–340)

**Epitope** IPRRRIRQGL

**Epitope name** IL9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*07)

**Assay type** CTL suppression of replication

**Keywords** class I down-regulation by Nef

**References** Adnan *et al.* 2006

- The impact of Nef on antiviral activity was studied. CTL-targeting epitopes were susceptible to the effects of Nef, both in late (Gag, RT, Env) and in early proteins (Rev, Nef), although to a lesser degree in early proteins. However, HLA-C-restricted CTLs (unlike HLA-A and HLA-B) were unaffected by Nef both in early (Nef) and late (Env) proteins.
- Late protein Env epitope IPRRRIRQGL-recognizing CTLs were affected by Nef.

**Keywords** binding affinity, immunodominance, optimal epitope

**References** Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope IPRRRIRQGL elicited a magnitude of response of 163 SFC with a functional avidity of 1nM and binding affinity of 8.3nM.

**Keywords** rate of progression, immunodominance  
**References** Hay *et al.* 1999

- CTL response to IPRRIRQGL was the immunodominant response in a rapid progressor – there was a subdominant response to SPAIFQSSM in Pol, and interestingly, no response to commonly immunodominant HLA A\*0201 epitope SLYNTVATL, although this individual was HLA A\*0201.
- The individual showed a strong initial CTL response at the time of the initial drop in viremia, but it was quickly lost, although memory cells persisted.
- Despite the initial narrow response to two epitopes, no other CTL responses developed.
- No HIV-specific lymphoproliferative responses were detected in this patient, and neutralizing antibody response was weak.

- Variants were observed *in vivo*, the most common form of the viral epitope at presentation at 3 months was the only form that did not elicit a CTL response: iprTrqgl; the other forms detected were iprrirqgF, iprrLqgF, VprirqgF and they could elicit a CTL response although the response to iprrLqgF was reduced.
- A second rapid progressor had a detectable CTL response exclusively to this epitope.

**References** Kaul *et al.* 2001a

- IPRRIRQGL cross-reacts with clades A, B and D.
- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.
- Among HLA-B7 women, 2/5 HEPS and 5/6 HIV-1 infected women recognized this epitope.
- The dominant response to this HLA allele was to this epitope in 2 of the 5/6 HIV-1 infected women that responded to the epitope, but in neither of the 2/5 HEPS cases.
- Subject ML 1203 started with CTL responses to A\*6802 DTVLEDINL and to B7 FVPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A\*6802 ETAYFILKL which became dominant, B7 TPGPGV/IRYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient C displayed the greatest response to B27-KK10(p24), and in decreasing order also responded to A24-RW8(Nef), B7-IL9(gp41), A24-RL9(gp41), A24-YL8(gp41), and B7-TM9(Nef).

**HXB2 Location** gp160 (843–851)**Author Location** Env**Epitope** IPRRRIRQGL**Epitope name** EW10**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Assay type** Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** class I down-regulation by Nef**References** Bobbitt *et al.* 2003

- Nef, through Nef-mediated MHC-1 down-regulation, is not the only viral protein to influence levels of HIV-specific CTL recognition. The Rev L60F mutation, a common natural variant, can decrease CTL recognition of late gene products. The Rev mutation impacts the early to late gene switch, reducing late gene product production (Gag, Pol, Env, Vpu, Vpr and Vif), while increasing Nef production, both of which reduce the impact CTL recognition of late gene products. As expected, Rev L60F rendered HIV infected cells more resistant to CTL that recognized epitopes from the late proteins Env and Gag. Gag expression is reduced more than Env, and Gag-specific CTL were more profoundly affected. Conversely CTL

against an epitope in an early gene product, Tat, were more efficiently recognized when infected with viruses carrying the Rev L60F mutation.

- Patients in the asymptomatic phase with active immune responses had more CTL resistant viruses, with lower Rev activity, lower Gag expression and greater resistance to Gag-specific CTL killing, while viruses isolated from people with AIDS were more sensitive to CTL killing.

**HXB2 Location** gp160 (843–851)**Author Location** gp41 (843–851)**Epitope** IPRRRIRQGL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Donor MHC** A1, A3, B14, B7, Cw\*0702, Cw\*0802**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** binding affinity, acute/early infection, early-expressed proteins**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**HXB2 Location** gp160 (843–851)**Author Location** gp41**Epitope** IPRRRIRQGL**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Country** Netherlands**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** HIV exposed persistently seronegative (HEPS)**References** Koning *et al.* 2004

- A high-risk seronegative group of 29 homosexual men showed reduced cellular in vitro susceptibility for HIV infection and enhanced production of RANTES compared to 15 men who went on to seroconvert. Significantly higher frequencies of HLA A\*11, A\*31 and Cw\*15 were also found in the high risk seronegative men. Both groups of men had low frequencies

of HIV-1 specific CD8+ T-cells, which may signify exposure more than protection from infection.

- 3/9 HLA B7+ infection-resistant men, compared to 0/4 pre-seroconversion men who went on to become infected, reacted to this epitope.

**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0–80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- This was one of 8 reactive epitopes found not to vary over time.

Cross-clade CD8 T-cell responses were common and directed at conserved epitopes.
- There was a greater magnitude of response to A clade peptides in individuals who responded to more than 1 clade; a 2-fold higher response was observed in clade A in 36% (9/25) of these individuals, and the response to A peptides was never lower. An IPRRIRQGL response was detected in a woman who had Env responses to 3 clades, A, B, and C, and clade A and B gave the highest responses. IPRRIRQGL was identical in A and B, had the form IPRRIRQGL in C, and IvRRIRQGL in D.

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance

of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.

- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**Assay type** Tetramer binding, Flow cytometric T-cell cytokine assay  
**Keywords** vaccine-specific epitope characteristics, immunodominance, vaccine antigen design  
**References** Subbramanian *et al.* 2006

- Multiepitope plasmid DNA vaccine constructs were shown to elicit CTL populations that do not show skewing of recognition of dominant epitopes in macaques, but repeated boosting of the vaccinated macaques uncovered and amplified the usual CTL epitope dominance hierarchy. This study suggests that heterologous prime-boost regimens can be effective in augmenting the magnitude of CTL responses, but cannot alter the dominance hierarchy established immediately after the exposure to antigen.
- Also, for live recombinant boost studies, results of in vitro peptide stimulation of PMBCs predict reliably the actual breadth of CTL responses that would expand out in antigen-primed T-cell populations.

**HXB2 Location** Env  
**Author Location** Env (SIV)

**Immunogen** HIV-1 exposed seronegative

**Species (MHC)** human

**Keywords** review, HIV exposed persistently seronegative (HEPS)

**References** Rowland-Jones *et al.* 2001

- This is a review that summarizes observations about HIV-specific CTL found in the HIV-1 exposed persistently seronegative (HEPS) population.
- The CTL responses assayed by ELISPOT and by CTL precursor frequencies by limiting dilution analysis indicate that CTL in HEPS individuals tend to be of a lower magnitude than in chronic HIV-1 infections – the responses in HEPS cases are below the level of detection by tetramer assays.
- CD8+ CTL responses tend to be detectable in HEPS subjects only if they are recently exposed, and the response diminishes if exposure is reduced – it is not clear if there is a stable memory population in HEPS cases.
- CD8+ CTL responses in the HEPS population are associated with HIV-1 specific CD4+ T cell responses, assayed by proliferation assays, IL-2 secretion, and ELISPOT, and the authors consider the possibility that HIV-1-specific T-help responses improve the "quality" of the CD8+ response in HEPS individuals relative to HIV-1 infected individuals, who tend to have a poor HIV-1-specific T-help response.
- HIV-1 specific CD8+ CTL responses in HIV-1 infected individuals show reduced levels of perforin, and the T cells may not mature properly, and although similar studies have not been conducted in HEPS individuals this is considered as a possible difference in the CTL immune response in HEPS and HIV-1 infected people.

**Keywords** epitope processing, escape  
**References** Yusim *et al.* 2002

- Epitopes that have been described in the literature and included in this database tend to cluster in conserved regions and be absent or rarely found in highly variable regions in Nef, Env, and p17.
- While the uneven distribution of epitopes may be in part due to a limited cross-recognition of specific responses because of differences between peptides used to probe the immune response and autologous strains, regions with a paucity of defined epitopes also had higher frequencies of amino acids that tend to not be found in C-terminal positions of epitopes, and had lower cleavage prediction scores for epitope processing. This suggests that in the regions of the virus where variation is best tolerated traces of immune escape have left an imprint on the viral population. Epitopes also were concentrated in alpha-helix and turn regions in the proteins.
- In the more conserved p24, and Pol proteins RT and Protease, epitopes are more evenly distributed.

**References** Scott *et al.* 2001

- CTL responses before and after initiation of ART were studied in 13 HIV-1 vertically infected infants <6 months of age, and 4 that were >6 months of age.
- Before ART 2/13 infants <6 months of age showed IFN $\gamma$  ELISPOT CD8+ T-cell responses, one to Nef and one to Env and Nef, and these responses became undetectable after successful therapy— 3 infants were coinfecting with CMV and all 3 had CMV-specific CD8+ T-cell responses.
- One older infant, at 23 months, had CTL responses against all for proteins tested, Gag, Pol, Nef and Env, and had the lowest plasma viremia of the study group. 3/4 infants older than 6 months of age responded to either Nef or Pol.
- Administration of ART over 48 weeks broadened the HIV-1-specific CTL response in 2/4 of the older children that were incomplete responders.

**Author Location** (IIB)

**Epitope**

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Ortiz *et al.* 2001

- Immune responses in eight chronically HIV-1 infected patients undergoing HAART therapy structured treatment interruptions (STI) were studied. STI boosted HIV-1 specific CTL responses and elevated CTL responses were maintained up to 22 weeks after the last treatment interruption, but viral load rebound to pretreatment levels and CD4 T-cell count decline was observed. CD8 responses in PBMC were measured by cytokine flow cytometry with gp160, Gag p55, RT-Pol and Nef expressed in vaccinia.
- One of seven subjects with a detectable NAb response had an augmented neutralization titer in response to STI.

**Species (MHC)** macaque

**References** Akahata *et al.* 2003

- Four monkeys were injected i.m. with a SHIV plasmid (SHIV-NM-3rn ZF1\*) which encodes all viral proteins driven by the SIV LTR promoter. Infectivity is prevented by the introduction of mutations within the zinc-finger motifs of the nucleocapsid (NC) that prevents RNA packaging. An original NC ZF1 mutant plasmid was constructed using NL43 (Akahata 275:116-124 (2000) – the SHIV construct was made as an alternative to get improved expression in macaques using an SIV promoter. CTL were detected by lysis of HIV-1 Env IIB or SIV Gag mac239 expressing target cells, and a T cell proliferative response to Env was observed. Env-directed antibodies were detected by ELISA. All vaccinated macaques had a low peak viral loads that fell below the level of detection within 6 weeks post-challenge with autologous SHIV SHIV-NM-3rn.

**References** Currier *et al.* 2003

- CD8-cellular immune responses from 21 HIV-1 infected patients from Kenya infected with subtype A, C, D, and unique recombinants were studied for cross-recognition of Gag, Env, and Nef vaccinia-expressed proteins representing subtypes A-H, including CRF01.
- Both subtype-specific and cross-reactive CTL were observed, with a skewing of responses towards the infecting subtype in the nine subjects with full length sequence available. The magnitude of the responses to Gag were the highest, less to Nef, and still less to Env.
- For Gag, 8/21 subjects responded to at least 7/8 different subtype proteins, 7 had a mixed response, recognizing some subtypes but not others, and 6 responded to only one or none of the different subtype proteins. For Env, 4/19 subjects responded to at least 7/8 subtypes, 8 had a mixed response, and 7 responded to one or none. For Nef, 5/19 subjects responded to at least 7/8 subtypes, 8 had a mixed response, and 6 responded to one or none.

- Reduced perforin-and granzyme- containing Env-specific CD8+ T cells were observed in ART treated individuals indicating that antiretroviral drugs might directly interfere with the production of perforin and granzymes, inhibiting CTL killing. Immunomodulants may be needed to enable CTL to become fully functional during ART.

**HXB2 Location** Env**Author Location** gp140**Epitope****Immunogen** vaccine*Vector/Type:* protein, peptide in liposome*Strain:* B clade IIIB *HIV component:*gp140, gp160, oligomeric gp140 *Adjuvant:*

CpG immunostimulatory sequence (ISS), liposome

**Species (MHC)** mouse**Donor MHC** H-2d**Assay type** Cytokine production, proliferation, Chromium-release assay**Keywords** Th1, Th2, adjuvant comparison, vaccine antigen design**References** Rao *et al.* 2004

- Administration of ogp140 in liposomes containing lipid A (LA) induces high antibody titers which are increased by adding CpG ODN. Priming and boosting of BALB/c mice with ogp140+LA induces mixed Th1/Th2 immune response, while adding CpG ODN switches the immune response to a Th1 type. Mixing ogp140 with liposomes containing lipid A yielded excellent proliferative and CTL specific responses; CpG did not affect CTL responses. The antigen did not need to be encapsulated in the liposome to induce strong responses with LA as an adjuvant.

- Macaques were immunized with a clade B HIV vaccine and tested for responses to pools of clade B and A/G Env and Gag peptides. While CD4 responses were more frequent than CD8 responses, higher cross-clade responses were found for CD8 responses. The authors suggest that the better cross-clade reactivity of the CD8 responses reflects the size difference between CD8 and CD4 epitopes; the smaller CD8 epitopes provide a smaller target for mutation.
- For both B and A/G Env and Gag peptides, 3/5 pools produced CD8+ T cells, suggesting the existence of 2 or 3 cross-reactive CD8 epitopes.

## II-B-23 Nef CTL/CD8+ epitopes

**Keywords** escape, immune evasion, optimal epitope

**References** Liu *et al.* 2006b

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- This is a newly defined epitope. Positions 4 and 6 in the epitope had potentially experienced positive selection. WSKtSIIGW and WSKSSmIGW escape variants were found.

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- SVVGWPaVRERMRA is a previously unpublished epitope that varies from the consensus at position 7.

**Keywords** characterizing CD8+ T cells  
**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** Nef (13–20)  
**Author Location** Nef  
**Epitope** WPTVRERM  
**Subtype** B  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (B\*0801)  
**Donor MHC** A\*0101, B\*0801  
**Country** United Kingdom  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding  
**Keywords** escape, acute/early infection  
**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- The recipient mounted an acute CTL response to this epitope, and the escape variant wpAvrKrm emerged in the recipient soon after.

**HXB2 Location** Nef (13–20)

**Author Location** (C consensus)

**Epitope** WPAIRERM

**Subtype** C

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*0801)

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, optimal epitope

**References** Kiepiela *et al.* 2007

- A comprehensive analysis of 160 class I T cell responses in 578 individuals from KwaZulu-Natal, South Africa was performed. Gag-specific responses were associated with lowering viremia, while Env, accessory and regulatory protein-specific responses were associated with higher viremia.
- WPAIRERM is an optimal epitope.

**HXB2 Location** Nef (13–20)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection, viral fitness and reversion

**References** Sanchez-Merino *et al.* 2005

- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- The variant WnTVRERM was present in 10/10 clones from a B8+ mother, was transmitted to her B8- infant, and present in 10/10 clones at months 2, 4, and 15.

**HXB2 Location** Nef (13–20)

**Immunogen** HIV-1 infection

**Species (MHC)** human (B8)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Nef (13–20)

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, WPTVRERMRAEPAA was mutated in the daughter D2 isolate to WPaVRdRMR-RAEPAA.

**HXB2 Location** Nef (15–23)

**Keywords** immunodominance

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, TVRERMRRRA, is similar to human protein Rhomboid protein, sequence TTVRsRMRRRA.

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes was characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.

- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** rate of progression, acute/early infection, memory cells

**References** Sabbaj *et al.* 2007

- CD127 hi memory CTLs were correlated with different patient groups - subjects with chronic HIV-1 infection or controllers or those treated early with ART. For patients with chronic infection, CD127 hi CTL levels decrease greatly. Early ART treatment alone maintained these long-lived memory T cells.
- In response to peptide GI-15, IFN-gamma and IL-2 were produced by CD127 hi cells in patients given early ART. TNF-alpha was secreted by CD127 lo cells. Longitudinally, in one patient, IFN-gamma was secreted by both CD127 hi and lo cells before treatment but was maintained in CD127 hi cells after treatment. CD127 hi cells were responsible for producing IL-2 and TNF-alpha after ART.

**Species (MHC)** human

**Donor MHC** A24, A3, B7

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** computational epitope prediction, vaccine-induced epitopes

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- This peptide AVSRDLERHGAISS is a previously unpublished epitope that varies from the consensus at position 8.

**Species (MHC)** mouse (H-2<sup>b</sup>)  
**References** Liang *et al.* 2002
- BALB/c, C3H/HeN and C57BL/6 mice were given intramuscular immunization with Nef DNA constructs – C57BL/6 responded to this epitope.

- The Nef mutant that lacked the myristylation site (G→A) at position 2, and the dileucine motif (L → A at positions 174 and 175) was impaired in terms of its ability to elicit induction of Nef-specific CD4+ and CD8+ T-cell responses. The myristylation site is critical for Nef membrane localization and function, and the di-leucine motif for the down-regulation of surface CD4 molecules, and the mutation of these regions could yield a safer vaccine.
- N-terminal addition of human tissue plasminogen activator (TPA) to Nef, enhanced CD8+ T-cell responses and could compensate for the G2A, L174A, L175A mutations – this enhanced immunogenicity correlated with enhanced levels of protein expression in transfected cells.

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Donor MHC** A24, A3, B7

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** computational epitope prediction, vaccine-induced epitopes

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- This peptide, EEEVGFPVKPQVPLR, varies at position 9 from the consensus.

**HXB2 Location** Nef (64–74)

**Author Location** Nef (C consensus)

**Keywords** escape, viral fitness and reversion

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- People who carried B45 tended to carry a variant of this epitope, while people who did not almost always carried the consensus form.
- B\*4501 was one of the HLA types associated with having a high viral load.

**HXB2 Location** Nef (65–82)

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Country** China

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** subtype comparisons, immunodominance

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, EVGFVPRPQVPLRPMTYK differs from the consensus C sequence EVGFVPRPQVPLRPMTfK at 1 amino acid position, i.e. by 5.6%.

**HXB2 Location** Nef (65–82)

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved

peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- EVGFVPRPQVPLRPMTYK is the most frequently targeted across ethnicities. It is immunodominant, and had an overall frequency of recognition of 44.7% - 52.5% AA, 50% C, 34.1% H, 38.1% WI. This peptide is included in a 58 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region I', EVGFVPRPQVPLRPMTYKAAVDLSHFLKEKGGLEGLIYSQK, a 41 aa region recognized by >90% of subjects across ethnic groups.

**Immunogen** HIV-1 infection  
**Species (MHC)** human (B\*0702)  
**Assay type** Other  
**Keywords** HLA associated polymorphism  
**References** Boutwell & Essex 2007

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- FPVRPQVPL was a previously defined B\*0702 presented epitope that encompassed a B\*07 associated polymorphism, FPVrPQVPL, in the fourth position.

**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** acute/early infection, variant cross-recognition or cross-neutralization, superinfection  
**References** Yang *et al.* 2005b

- An individual infected with a drug-resistant strain of HIV-1 subtype B with controlled viremia became superinfected with another subtype B strain. The second strain outgrew the first despite lower replication capacity and the same viral phenotype. The strains showed differences in their epitope sequences. The CTL responses to the first strain declined after superinfection, followed by some adaptation of targeting to the new epitopes of the second strain. Differences in the recognized epitopes were suggested to have contributed to the poor immune containment of the second strain.
- This epitope FPVRPQVPL was identical in the initial and superinfecting strains, and the CTL response persisted in the patient before and after superinfection.

**HXB2 Location** Nef (68–76)

**Assay type** Cytokine production, CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Other, HLA binding  
**Keywords** vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism

- References** Reche *et al.* 2006
- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naïve individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
  - A more detailed evaluation of HIV-naïve T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
  - This epitope, FPVRPQVPL, was predicted to be restricted by HLA A\*2902, B\*0702, B\*3501, B\*5101, B\*5102, B\*5103, B\*5301 and B\*5401.

- This study examines CTL responses in HIV exposed, persistently seronegative individuals, HEPS, who eventually seroconverted – 11/114 HEPS Nairobi sex workers eventually seroconverted, and for six of these HIV CTL reactive epitopes had been defined while seronegative.

- FPVTPQVPLR was recognized in 1 of the 6 women (ML1203), and the response was present in the last available sample prior to seroconversion, 7 months.
- 20/20 sequences of the infecting strain had no substitutions in this epitope, all were FPVTPQVPLR, so there was no evidence for escape.
- The epidemiological factor associated with seroconversion was stopping sex work. HIV-specific CTL activity declined when HEPS sex workers stopped working for a period or retired.
- This epitope was recognized in 1/22 HEPS sex worker controls, ML851.

**HXB2 Location** Nef (68–77)

**Author Location** Nef (66–75)

**Epitope** FPVTPQVPLR

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**References** Ferrari *et al.* 2000

- One of the 51 HIV-1 epitopes selected by Ferrari *et al.* as good candidate CTL epitopes for vaccines by virtue of being conserved and presented by common HLA alleles.

**HXB2 Location** Nef (68–77)

**Author Location** Nef (68–77 SF2)

**Epitope** FPVTPQVPLR

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** HAART, ART, acute/early infection

**References** Altfeld *et al.* 2001b

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.
- Number of HLA-B7+ individuals that had a CTL response to this epitope broken down by group: 0/4 group 1, 0/3 group 2, and 1/1 group 3.

**HXB2 Location** Nef (68–77)

**Author Location** Nef (68–77)

**Immunogen** HIV-1 infection, HIV-1 exposed seronegative

**Species (MHC)** human (B7)

**Keywords** HIV exposed persistently seronegative (HEPS)

**References** Kaul *et al.* 2001a

- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.

- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.

- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.

- Subject ML 1203 started with CTL responses to A\*6802 DTVLEDINL and to B7 FPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A\*6802 ETAYFILKL which became dominant, B7 TPGPG(V/I)RYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.

**Author Location** Nef (68–77)

**Epitope** FPVTPQVPLR

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** rate of progression, acute/early infection

**References** Day *et al.* 2001

- The CTL response to optimally defined CTL epitopes restricted by HLA class I A and B alleles in individuals who coexpressed HLA A2, A3, and B7 was studied in eight HIV-1-infected subjects, two with acute infection, five with chronic, and one long-term non-progressor (LTNP)
- 2 to 17 epitopes were recognized in a given individual, A2-restricted CTL response tended to be narrow and never dominated the response, and 25/27 epitopes were targeted by at least one person.
- Subjects with chronic HIV-1 infection recognized between 2–8 out of 11 B7-restricted epitopes.
- An acute seroconverter homozygous for the B7 allele recognized five B7-restricted epitopes.
- The other acute seroconverter failed to recognize any of the 11 B7-restricted epitopes tested.
- The B7-restricted CTL response was highly variable and there was no clearly dominant epitope.

**Author Location** Nef (68–76)

**Epitope** FPVTPQVPLR

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Donor MHC** A3, B7, Cw7

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.

- 0/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. Also, none of 4 individuals had detectable responses to this epitope after STI.

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, PVRPQVPLRPMTYKA was mutated in the daughter D2 isolate to PVRPQVPLRPMTfKA.

**HXB2 Location** Nef (70–84)

**Author Location** Nef (70–84 HXB2)

**Epitope** VTPQVPLRPMTYKAA

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Assay type** T-cell Elispot

**Keywords** supervised treatment interruptions (STI), immunodominance, early treatment

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.

- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 34% of the study subjects, and it was the second most frequently recognized peptide.

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Other

**Keywords** supertype, escape, cross-presentation by different HLA, TCR usage, HLA associated polymorphism

**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction.
- For this epitope, RM9, selection pressure was evidenced by studying changing epitope variants associated with HLAs of the B7 supertype.
- Higher level of sequence variation and escape mutations were associated with the B\*8101 and B\*0702 alleles.

- In 3 B-supertype alleles studied, B\*4201, B\*8101 and B\*0702, two variants were most common - one at the first position, kPQVPLRPM and the other at the sixth position, RPQVPvRPM. Several more variants are listed in the paper.

**Keywords** rate of progression, HLA associated polymorphism

**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variant RPQVPvRPM at position 6 was the predominant polymorphism found.

**Author Location** Nef (71–79 BRU)

**Epitope** TPQVPLRPM

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B35)

**Keywords** binding affinity, epitope processing

**References** Chopin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.

- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- TPQVPLRPM was recognized in 1/10 (10%) of individuals with HLA B7, and 1/10 (10%) of individuals with HLA B35. It was a moderate affinity HLA binder.

**Country** United States, South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding

**Keywords** memory cells

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** binding affinity, epitope processing

**References** Chopin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- TPQVPLRPM was recognized in 1/10 (10%) of individuals with HLA B7, and 1/10 (10%) individuals with HLA B35. It was a moderate affinity HLA binder.

**Epitope** TPQVPLRPM

**Epitope name** B7-TM9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Donor MHC** A3, B7, Cw7

**Keywords** dynamics, supervised treatment interruptions (STI), acute/early infection

**References** Yu *et al.* 2002a

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI

this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.

- 0/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 2/4 individuals had detectable responses to this epitope after STI.

**Keywords** HAART, ART, supervised treatment interruptions (STI)

**References** Altfeld *et al.* 2002b

- Peripheral blood (PB) and lymph node (LN) CD8+ T-cell responses were compared in 15 asymptomatic HIV-1 infected patients using all known optimal CTL epitopes (<http://hiv-web.lanl.gov/content/hiv-db/REVIEWS/brander2001.html>) for each person's class I HLA alleles.
- 60 epitope responses were detected in both PB and LN samples of the 15 patients, and an additional 8 responses were detected only in LN. The total magnitude of the response was similar in LN and PB, but the percentage of CD8+ T cells in the LN is lower so the number of HIV-specific cells per million CD8+ T-cells is higher in the LN.
- 1 year post-HAART treatment in five patients studied, the magnitude of the CD8 T-cell response was decreased in both LN and PB, but more dramatically in PB, and 13/25 epitope responses in the PB became undetectable, in contrast to 5/26 in the LN.
- Treatment interruption following HAART induced resulted in increased viremia accompanied by the restoration of the detection of 13 epitopes that had become undetectable in the PB, and the addition of 9 novel epitope responses.
- Breakdowns of epitope responses were shown for 4 individuals. Patient A displayed the greatest response to epitope B14-EL9(gp41), a strong response to B7-TL9(p24), and responses to B7-TM9(Nef) and A32-PW10(RT). Patient C displayed the greatest response to B27-KK10(p24), and in decreasing order also responded to A24-RW8(Nef), B7-IL9(gp41), A24-RL9(gp41), A24-YL8(gp41), and B7-TM9(Nef).

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- This epitope was reactive, but escape mutations did not accrue in it over time.

**Species (MHC)** human (B7)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**Country** South Africa  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** escape, cross-presentation by different HLA  
**References** Kiepiela *et al.* 2004
- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
  - People who carried either B07 or B81 tended to carry a variant of this epitope, while people who did not almost always carried the consensus form.
  - B\*4201 may also present this epitope, as the allele is enriched in people who react with the peptide that contains the epitope, and it is known from the database to be also presented by B\*4201.

**References** Wherry *et al.* 2006

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated

impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

*HIV component:* p17 Gag, p24 Gag

**Species (MHC)** human, macaque (B51)

**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance

**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost

vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].

- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- This peptide, KPQVPLRPMTYKAAV, is a variant of the consensus peptide QVPLRPMTYKAAVDL.

- This study demonstrates that lipopeptides carrying epitopes can be taken up by human dendritic cells, processed using different pathways, and recognized by epitope-specific CD8+ T-cells originally derived from HIV+ individuals. The RT ILKEPVHGV peptide was embedded in a longer peptide fragment in the lipopeptide, and was internalized by endocytosis and processed in the cytosol by proteasomal cleavage by following an endosome-to-cytosol pathway for processing and presentation. Administration of epoxomycin, a proteasome inhibitor, completely abrogated epitope presentation to a CD8+ T-cell line, while monensin, an inhibitor of acid-dependent endosomal enzyme activity did not.
- In contrast to the RT epitope, dendritic cell presentation of the Nef epitope QVPLRPMTYK embedded in a longer peptide in a lipopeptide was not inhibited by epoxomycin, but was inhibited by monensin, indicative of endocytotic epitope processing.

**HXB2 Location** Nef (73–82)**Author Location** Nef**Epitope** QVPLRPMTYK**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (A\*0301)**Donor MHC** A\*0101, A\*0301, B\*0801, B\*5101**Country** United Kingdom**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding**Keywords** escape**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient. In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.
- Two variants of this epitope, QVPvRPMTYK and QaPLRPMTYK, were found in 1 donor. The QaPLRPMTYK substitution reduced the binding affinity for A\*0301 by 52%.

**Epitope name** QVP  
**Immunogen** HIV-1 infection  
**Species (MHC)** human (A\*0301)  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay  
**Keywords** rate of progression, TCR usage, variant cross-recognition or cross-neutralization, characterizing CD8+ T cells  
**References** Turnbull *et al.* 2006
- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
  - This epitope, A3-QVP (that has no association with accelerated or delayed progression to AIDS) and its natural variants are less efficiently cross-recognized. Its alanine-substituted variants were inconsistent between individuals showing very efficient or poor cross-reactivity. CTLs responding to this epitope expressed the same predominant TCR V $\beta$  family, but individuals whose CTLs predominantly used TCR V $\beta$  13.6 had poor cross-recognition of alanine substituted variants.

**Epitope** QVPLRPMTYK  
**Subtype** A, B, D  
**Immunogen** HIV-1 infection, vaccine  
*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade  
*HIV component:* p17 Gag, p24 Gag  
**Species (MHC)** human, macaque (A\*0301, A11)  
**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance  
**References** Hanke & McMichael 2000; Wee *et al.* 2002
- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
  - Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5

macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**References** Wang *et al.* 2007
- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
  - This putative epitope, QVPLRPMTYK, was detected and confirmed within overlapping peptides EVGFPVRPQVPLRPMTYK and YKAAVDLSHFLKEKGGL. It was the immunodominant HLA-A\*11 restricted epitope in 10 subjects tested.

**References** Gillespie *et al.* 2007

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80 tetramers in complex with epitopes to KIR3DS1 transiently expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.
- This epitope, QVPLRPMTYK (MHC Class I restriction, serotype Bw6) complexed with MHC A03 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C.

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.
- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (A03, A11) and 4 additional alleles (A02, A33, B44, Cw07).
- In addition to its known HLA associations (A03, A11), an additional HLA (A34) was statistically predicted to be associated with this epitope.

- The effect of HAART on the population size, phenotype and function of HIV- and HCMV-specific CTL clones was analyzed. It was determined that the clonal composition of gag and env HIV-specific CD8 T-cells did not change after HAART. Following HAART, the size of immunodominant HIV-specific CD8 T-cell clones was found to diminish even with the relative preservation of functional memory responses. Maintenance of such strong functional responses implied the preferential loss of HIV-specific cells that have reduced cloning efficiency in vitro. HCMV-specific CTL clones had different kinetics and phenotypes than HIV-specific CTL clones in the same subject.

**References** Altfeld *et al.* 2001b

- Therapy provided during acute infection resulted in a narrower CTL response, stronger T help response, and a less diverse viral population than was seen in individuals treated during chronic infection.
- The breadth and specificity of the response was determined using ELISPOT by studying 19 individuals with pre-seroconversion therapy (Group 1), 11 individuals with primary infection but post-seroconversion therapy (Group 2), and 10 individuals who responded to HAART given during chronic infection (Group 3), using 259 overlapping peptides spanning p17, p24, RT, gp41, gp120 and Nef.
- Previously described and newly defined optimal epitopes were tested for CTL response.

- Number of HLA-A3+ individuals that had a CTL response to this epitope broken down by group: 3/7 group 1, 1/4 group 2, and 1/2 group 3.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** binding affinity, acute/early infection, early-expressed proteins

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** HAART, ART, escape, viral fitness and reversion

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.

- The best estimates of escape rate for this epitope, QVPLRRM-TYK, were found to be 0.022 and 0.003/day (upper bound on rate of escape = 0.05 and 0.011), with SEs of 0.013 and 0.003 respectively, in 2 subjects.
- In the first subject, a number of mutations arose in Nef 73-82; all but one of these (V74A) elicited a very weak ELISpot response compared to the wild type. In the second subject, large epitope deletions and a V74I substitution in the recognized epitope were selected for.

**References** Lichterfeld *et al.* 2004a

- HIV-1 specific CD8+ T-cells in acute and long-term nonprogressive HIV-1 infection show strong ex-vivo proliferative capacities which are rapidly lost in chronic HIV-1 infection. The loss of CD8+ T-cell function is closely linked with the loss of HIV-1 specific, IL2 secreting CD4+ T-cells. The function can be rescued in vitro and in vivo by restoring the specific CD4+ T-cell help.
- Full CD8+ T-cell responses to this epitope were dependent on co-stimulation with a CD4+ T cell dependent epitope from T-cells harvested during acute infection. The CD8+ T-cell response to this epitope was immunodominant in one study individual.

**References** Lichterfeld *et al.* 2007b

- Differences in early versus chronic AIDS include a decline in CTL number accompanied by a reducing viremia. Comparative analysis of such CTLs in this study show that early infection is characterized by a different clonotypic composition and higher functional avidity of CTLs followed by their selective depletion during transition to chronic disease. The total magnitude of CTL cytokine production is lower in early infection. Intraindividual, early CTLs' functional avidity for the same epitope decreases concomitantly with a reduction in clonotypic TCR repertoire especially of strongly activated and CD127lo, CD38+, Ki-67hi CTLs while progressing to chronic infection states.
- None of the target epitopes, including this epitope QVPLRPMTYK seen in 1 patient, underwent sequence changes.

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains.

Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.

- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, QVPLRPMTYKAAVDL was mutated in the daughter D2 isolate to QVPLRPMTfKAAVDL.

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, QVPLRPMTYKAAVDLSHF, had an overall frequency of recognition of 34% - 40.7% AA, 38.5% C, 29.5% H, 19% WI. This peptide is included in a 58 aa Nef highly reactive region to be used for vaccine design. It is also

part of 'Region I', EVGFPVVRPQVPLRPMTYKAAVDLSHF-FLKEKGGLEGLIYSQK, a 41 aa region recognized by >90% of subjects across ethnic groups.

**Species (MHC)** human (B\*3501)

**Keywords** dendritic cells

**References** Ostrowski *et al.* 2000

- The role of CD4+ T-cell help in expansion of virus-specific memory CTL was studied through co-culture *ex vivo*
- Optimal expansion of HIV-1-specific memory CTL depended on CD4+ T cell help in 9 of 10 patients – CD40 ligand trimer (CD40LT) could enhance CTL in the absence of CD4+ T cell help to a variable degree in most of patients.
- Those CTL that didn't respond to CD40LT could expand with IL2 present, and IL15 produced by dendritic cells also contributes.
- The T-helper epitope used for CD4+ T cell stimulation was the universal tetanus helper epitope TET830-843 (QYIKAN-SKFIGITE)

**HXB2 Location** Nef (74–81)**Author Location** Nef (74–81)**Epitope** VPLRPMTY**Epitope name** VY8**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B\*3501)**Donor MHC** A\*0201, A\*0301, B\*3501, B\*51, Cw\*04, Cw\*06**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Chromium-release assay**Keywords** escape, acute/early infection**References** Bansal *et al.* 2005

- Patients with acute or early infection were shown to preferentially target variable peptides with higher entropy while those with chronic infection showed responses towards more conserved peptides with lower entropy. In longitudinally followed subjects, responses to variable proteins declined over time while responses to conserved proteins increased. The decline is suggested to be due to CTL escape.
- Point mutation of epitope at position 8 (Y to F, VPLRPMTf) was detected at a chronic infection timepoint. The CTL response was strong in early infection, but diminished by month 13. This mutation had reduced avidity.

**HXB2 Location** Nef (74–81)**Author Location** Nef**Epitope** VPLRPMTY**Immunogen** HIV-1 infection**Species (MHC)** human (B\*4201, B\*4202)**Country** Kenya**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, Flow cytometric T-cell cytokine assay**Keywords** subtype comparisons, cross-presentation by different HLA, variant cross-recognition or cross-neutralization**References** Currier *et al.* 2006

- The pattern of immunodominance and epitope clustering within Gag and Nef proteins in subtype A infected individuals was similar to that seen in subtype B and C infections. An immunodominant HLA-C restricted epitope, YVDRF-FKTL (YL9 from Gag protein) was observed and restricted to Cw0304.

- The sequences fpvrpqVPLRPMTYk is associated with HLA-B\*4201/02 and HLA-B\*5301 and contains the epitope VPLRPMTY.

**HXB2 Location** Nef (74–81)**Author Location** Nef (subtype B)**Epitope** VPLRPMTY**Subtype** B**Immunogen** HIV-1 exposed seronegative**Species (MHC)** human (B35)**References** Kaul *et al.* 2000

- 11/16 heavily HIV exposed but persistently seronegative sex-workers in Nairobi had HIV-specific CD8 gamma-IFN responses in the cervix – systemic CD8+ T cell responses tended to be to the same epitopes but at generally lower levels than cervical CD8+ T cell responses.
- Low risk individuals did not have such CD8+ cells.
- CD8+ T cell epitopes: DTVLEDINL (3 individuals), SLYNT-VATL (4 individuals), LSPRTLNAW (3 individuals) and YPLTFGWCF (4 individuals) were most commonly recognized by the HIV-resistant women.

**HXB2 Location** Nef (74–81)**Author Location** Nef**Epitope** VPLRPMTY**Immunogen** HIV-1 infection**Species (MHC)** human (B35)**Keywords** acute/early infection**References** Wilson *et al.* 2000a

- Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load was also found.
- All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B2705; and A\*0201, A\*0301, B2705, B39.
- ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWIIIGGLNK.
- The subject with A\*0201 had a moderately strong response to SLYNTVATL.
- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

**HXB2 Location** Nef (74–81)**Author Location** Nef (74–81 BRU)**Epitope** VPLRPMTY**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B35)**Keywords** binding affinity, epitope processing**References** Choppin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- VPLRPMTY was recognized in 5/16 (31%) of individuals with HLA B35, and it was a moderate affinity HLA binder. Cleavage at the C-term Y was frequent *in vitro*.

**HXB2 Location** Nef (74–81)**Author Location****Epitope** VPLRPMTY**Subtype** A, B, D**Immunogen** HIV-1 infection, vaccine*Vector/Type:* DNA prime with modified vaccinia Ankara (MVA) boost *Strain:* A clade HIV component: p17 Gag, p24 Gag**Species (MHC)** human, macaque (B35)**Keywords** subtype comparisons, epitope processing, vaccine-specific epitope characteristics, immunodominance**References** Hanke & McMichael 2000; Wee *et al.* 2002

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

**HXB2 Location** Nef (74–81)**Author Location** Nef (74–81)**Epitope** VPLRPMTY**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B35)**Donor MHC** A1, A3, B35, B8**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** acute/early infection, early treatment**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. SubjectBroadcast message from root Thu May 27 21:34:36 2004...n of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma vBattery Low Notification from APM BIOS (8% 0:12) or the frequency of IFN $\gamma$  secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**HXB2 Location** Nef (74–81)**Author Location** Nef (72–79)**Epitope** VPLRPMTY**Immunogen** HIV-1 infection

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , CD4 T-cell Elispot - IFN $\gamma$   
**Keywords** rate of progression, immunodominance, escape  
**References** Oxenius *et al.* 2004b
- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes were recognized 0–80% as efficiently as the index peptide, and the relatively efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.
- VPL epitope was one of six that were largely or completely replaced by escape variants, with the two escape forms coming up between days 172 and 635, vplrpmSy and vplrmpTF.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** computational epitope prediction, vaccine-induced epitopes  
**References** Li *et al.* 2006b
- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that

vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.

- This epitope, IPLRPMTYK<sub>g</sub>AIDLS, varies from the consensus peptide at positions 10 and 12.

- Subjects with chronic HIV-1 infection recognized between 2-8 out of 11 B7-restricted epitopes.

- An acute seroconverter homozygous for the B7 allele recognized five B7-restricted epitopes.
- The other acute seroconverter failed to recognize any of the 11 B7-restricted epitopes tested.
- The B7-restricted CTL response was highly variable and there was no clearly dominant epitope.

**Epitope** RPMTYKAAV

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Keywords** binding affinity, epitope processing

**References** Choppin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- RPMTYKAAV was recognized in 7/10 (70%) of individuals with HLA B7, and 0/3 (0%) of individuals with HLA B35. It was a moderate affinity HLA binder.

- CTL responses in 18 acutely HIV-infected HLA-A3 (n=7) or -B7 (n=4) or both -A3 and B7 (n=7) positive individuals were studied.
- One individual, AC-06, was homozygous at all three class I alleles (A3, B7, Cw7), was treated during acute infection and had supervised treatment interruptions (STI). He had only two detectable CTL responses during acute infection, but after STI this broadened to 27 distinct epitopes including 15 restricted by HLA-A3, 11 by HLA-B7, and 1 by HLA-Cw7.
- 3/11 HLA-B7 individuals had detectable B7-restricted responses to this epitope during acute infection – 10/15 of HLA-B7 epitopes tested were targeted by at least one person during acute infection. 2/4 individuals had detectable responses to this epitope after STI.

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.
- 3/7 patients recognized this epitope.

**HXB2 Location** Nef (77–85)**Author Location** Nef (75–83)**Epitope** RPMTYKGAL**Epitope name** RPM**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Donor MHC** A2, A68.1, B\*07, B\*3503, Cw\*0401, Cw\*0702, DQ2, DQ6, DR15, DR17, DR51, DR52**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, CD4 T-cell Elispot - IFN $\gamma$ **Keywords** rate of progression, immunodominance, escape**References** Oxenius *et al.* 2004b

- The increase in plasma viral load in a patient that progressed rapidly was preceded by positive selection of viral escape mutations in epitopes targeted by dominant HIV-1-specific CD8+ T-cell responses, and a decrease in HIV-1-specific CD4+ and CD8+ T-cell frequencies. Overall, escape variant epitopes

were recognized 0-80% as efficiently as the index peptide, and the relative efficiency of the variant epitopes increased using PBLs collected after their appearance. No changes were found in viral tropism, replication kinetics and neutralizing antibody titers, so the rapid decline of the patient was attributed to loss of HIV containment due to CTL escape.

- This epitope was one of six epitopes found to be under positive selection for escape mutations and was completely replaced by escape variants between days 172 and 635 (rpmtFkgal, rpm-SykAal, rpmtkygaV, rpmtkyAal). The first two were the most common at day 635, and experimentally shown to be escape.

**HXB2 Location** Nef (77–85)**Author Location** Nef**Epitope** RPMTYKGAL**Epitope name** RL9**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Donor MHC** A1, A3, B57, B7, Cw6, Cw7**Country** United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, escape, characterizing CD8+ T cells, viral fitness and reversion**References** Allen *et al.* 2005a

- Two-thirds of all mutations arising in non-envelope proteins during the transition from acute to chronic infection were found to be due to either CD8 T-cell-associated selective pressures or reversion of HLA-I-associated mutations selected in a previous host. The predominance of escape mutations at highly polymorphic sites was observed across different HIV-1 clades.
- One escape mutation, at position 4, RPMnYKGAL, was found not to correspond to the most polymorphic residue in the epitope.

**HXB2 Location** Nef (77–85)**Author Location** Nef (77–85 BRU)**Epitope** RPMTYKAAV**Subtype** B, CRF02\_AG**Immunogen** HIV-1 infection**Species (MHC)** human (B7)**Country** Cote D'Ivoire**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons**References** Inwoley *et al.* 2005

- CD8+ T-cells from HIV-1 CRF02\_AG-infected Ivorians could recognize clade B epitopes. No difference was observed in the number of recognized peptide pools between nine French subtype B infected study subjects, and nine CRF02\_AG infected Ivorian subjects.
- This epitope was recognized by 0/9 CRF02\_AG-infected Ivorians, and 2/9 B-infected French subjects.
- One of the B-clade infected subjects that recognized this peptide was not sequenced, the other had one amino acid change: RPMTYKAAI. A variant form was in 3/5 B clade infection sequences. 8/8 CRF01 infected individuals had a variant of this peptide.

**Keywords** responses in children, mother-to-infant transmission, escape, characterizing CD8+ T cells, viral fitness and reversion  
**References** Sanchez-Merino *et al.* 2005
- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.
  - Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
  - The variant RPTMThqAAW was present in 10/10 clones from a B7- mother, was transmitted to her B7+ infant, and present in 29/30 clones at months 2, 6, and 152.

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, RPMTYKAAVDLSHFL was mutated in the daughter D2 isolate to RPMTfKAAVDLSHFL.

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 47% of the study subjects, and it was the most frequently recognized peptide.

**Subtype** B

**Immunogen** HIV-1 infection**Species (MHC)** human**Country** China**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** subtype comparisons, immunodominance**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, yKGAIDLShFLKEKGGGL differs from the consensus C sequence fKGAfDLSfFLKEKGGGL at 3 amino acid positions, i.e. by 17.6%.

**HXB2 Location** Nef (81–97)**Author Location** Nef**Epitope** YKAAVDLSHFLKEKGGGL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human**Country** Barbados, Haiti, United States**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other**Keywords** binding affinity, immunodominance**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved

peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, YKAAVDLSHFLKEKGGGL, had an overall frequency of recognition of 30% - 33.9% AA, 30.8% C, 31.8% H, 14.3% WI. This peptide is included in a 58 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region I', EVGFVPRPQVPLRPMTYKAAVDLSHFLKEKGGGLEGLIYSQK, a 41 aa region recognized by >90% of subjects across ethnic groups.

**HXB2 Location** Nef (82–90)**Author Location** (C consensus)**Epitope** KGAFDLSFF**Subtype** C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*57)**Country** South Africa**Assay type** CD8 T-cell Elispot - IFN $\gamma$ **Keywords** characterizing CD8+ T cells**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** Nef (82–90)**Author Location** Nef (82–90)**Epitope** KAAVDLSHF**Epitope name** KF9**Subtype** B, C**Immunogen** HIV-1 infection**Species (MHC)** human (B\*57, B\*5801)**Country** Australia**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay, HLA binding**Keywords** subtype comparisons, computational epitope prediction, mother-to-infant transmission, escape, viral fitness and reversion, optimal epitope**References** Leslie *et al.* 2005

- KAAVDLSHF is the susceptible optimal form of the epitope, and KgAVDLSHF an escape variant. The KgAVDLSHF form of the epitope was shown to be an escape mutation by virtue of an increased off-rate; however Elispot reactions to both forms are positive. The escape form was shown to be transmitted, and the most common form of the epitope in a B clade infected population in Perth, Australia (52%).

**References** Bhattacharya *et al.* 2007

- Host HLA associated mutational patterns in HIV can be a consequence of immune escape, but to cleanly resolve whether or not such patterns are the result of lineage effects or immune pressure, it is helpful to incorporate the phylogenetic history of the virus into the test statistics. Most of the HLA associations that appeared to result from immune escape in an earlier study (Moore *et al.*, *Science* 296:1439 2002) were found to be a consequence of the phylogenetic history of the virus, not immune escape. Other HLA associations were validated, and some additional HLA-associated mutations were identified through incorporating the viral phylogenetic tree in the analysis.
- There are two variant forms of this B57/B5801 epitope at the second position KaAFDLSFF and KgAFDLSFF. Leslie *et al.*, *J Exp Med.* 2005 201:891 suggest that the escape form KgAFDLSFF may have come to dominate the C clade lineage over time due to higher HLA B57/B5801 frequencies in southern Africa. Bhattacharya suggests lineage effects are also playing an important role in the observed amino acid frequencies, and note that the ratio of G/A has not change over time, and that the frequency of G/A in different epidemic populations does not correlate with HLA B57/B5801 allele frequency.

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- The AL9 epitope AAVDLSHFL elicited a potent CTL response while its minor variant AAVDiSHFL containing substitution L87I at position 5 elicited a less intense response, resulting in the L87I variant later dominating the viral population. This is a novel viral adaptation to an HLA-A2 restricted immune response discovered in Nef epitope AL9. In later longitudinal studies, more variants were seen either linked - AAVDirHFL - or not linked with the L87I mutant. Two new mutants seen were the A83G at position 1, gAIDLSHFL and gArDLSHFL; and the V85L at position 3, AAIDLSHFL, AAIDiSHFL, AAIDiSHIL. Amino acid positions 83, 85, 97 and 91 were under positive selection pressure.
- Responses to AL9 were seen in early chronic infection.

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.

- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- AAVDLSHFL was recognized in 3/18 (17%) of individuals with HLA A2. It was a low affinity HLA binder.

**HXB2 Location** Nef (83–91)

**Author Location** Nef (83–91)

**Epitope** AAVDLSHFL

**Subtype** B

**Immunogen** vaccine

*Vector/Type:* lipopeptide *Strain:* B clade LAI *HIV component:* Env, Gag, Nef *Adjuvant:* QS21

**Species (MHC)** human (A2)

**Assay type** proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** vaccine-induced epitopes, variant cross-recognition or cross-neutralization

**References** Gahéry-Ségard *et al.* 2003

- After injection of an anti-HIV-1 lipopeptide vaccine and the booster injections, a response was observed in >85% of 28 volunteers, and a long-term immune response was observed in >50% of the volunteers. A positive effect of QS21 adjuvant was found for B- and CD4+T-cell responses. A higher number of CD8+ T-cell epitopes was induced after a fourth boost injection. This epitope was one of 31 that the vaccinated volunteers responded to.

**HXB2 Location** Nef (83–91)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** responses in children, immunodominance, characterizing CD8+ T cells

**References** Chandwani *et al.* 2004

- Responses to five HLA-A2 presented epitopes in Nef were characterized in a population of 19 HIV infected adults and 21 children. The CD8 T-cell response to Nef was stronger and broader in adults than children, averaging 652 and 87 SFCs/10<sup>6</sup> PBMC, and 2.6 and 0.9 recognized epitopes per person, respectively.
- The novel AALDLSHFL Nef epitope was the most frequently and most strongly recognized epitope in this study, making it a possible immunodominant epitope.
- This is one of three novel Nef epitopes previously identified in HLA-A2 transgenic mice, shown to induce CD8 T-cell response in humans.

**Species (MHC)** human (A2)  
**Country** Viet Nam  
**Assay type** HLA binding  
**Keywords** subtype comparisons, computational epitope prediction, escape, variant cross-recognition or cross-neutralization, vaccine antigen design  
**References** Lazaro *et al.* 2005
- The most common HLA-alleles in the Vietnamese population were found to be HLA-A11, A02, A33, B75, B46, and B62. Several epitopes cluster in short regions in Gag and Nef that are presented by these HLA molecules; these epitopes may be useful targets for vaccine antigens. In a comparison of CRF01\_AE sequences to HXB2, 14 mutations were found in epitopes in these Gag and Nef pluriepitopic regions; 7 did not affect the HLA binding score, 3 increased it, and 4 reduced it.
  - The CRF01\_AE variant GaFdsFfl had a higher HLA-A2 binding score than the HXB2 epitope.

**Country** United States  
**Assay type** CD8 T-cell Elispot - IFN $\gamma$   
**Keywords** responses in children, mother-to-infant transmission, escape, characterizing CD8+ T cells, viral fitness and reversion  
**References** Sanchez-Merino *et al.* 2005
- CD8 T-cell responses were examined in mother-infant pairs. Escape variants were commonly detected in maternal plasma. Early infant plasma viruses showed heterogeneity of gag and nef gene sequences as well as mother-to-child transmission of CD8 T-cell escape variants. The stability of escape mutants in the infant over time was determined by infant HLA haplotype and viral fitness.

- Sequential plasma specimens from infants showed changes in CD8 T-cell epitope sequences, suggesting that infants are capable of generating virus-specific CD8 T-cell responses.
- An escape form of the A2 epitope, AAVDmSHFL, was transmitted from an A2- mother to her A2+ infant, where it persisted in 29/29 sequences sampled over 11 months.
- Another form of this A2 epitope, gAIDLSHFL, was transmitted by an A2+ mother to an A2- infant, where it persisted in 30/30 sequences sampled over 15 months.
- AAVDmSHFL was shown to have lower responder cell frequencies than AAVDLSHFL.

**Epitope name** A68-AL(Nef)

**Immunogen** HIV-1 infection

**Species (MHC)** human (A68)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Nef (83–91)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** acute/early infection, early treatment

**References** Cao *et al.* 2003

- All proteins were scanned and optimal epitopes were mapped in a study of CD8+ gamma IFN T-cell responses in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized did not tend to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- Four different individuals recognized this epitope during a primary infection, and it was shown to be presented by HLA B60, B62, C2\*0802, and Cw8.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently utilized than A1, A2, A30, and A44.

**HXB2 Location** Nef (83–91)

**Author Location** Nef (83–91)

- Counterparts for eight known clade B HLA A\*1101 epitopes were generated for clade E (CRF01). Three epitopes, identical among clade A-E, were cross-reactive and recognized by clade E infected individuals. The clade E and B analogs to three more HLA A\*1101 epitopes was recognized in a clade specific manner. Two other HLA A\*1101 clade B defined epitopes were found not to have stimulated a response in clade E infected individuals.
- AVDLSHFLK was found to elicit clade-specific responses in clade B (AVDLSHFLK is most common, aLdlshflk is a common variant also found in clade A) and clade E (aFdlsFflk is most common and is also common in clade C). AVDLSHFLK was strongly recognized by CTL from 2/5 B clade infected Japanese subjects, as was aLdlshflk, and aFdlsFflk by CTL from 5/7 E clade infected Thai subjects.
- The binding of aFdlsFflk to HLA A\*1101 was 10-50 times lower than the other variants, and bulk CTL generated from individuals did not cross-react with the cross-clade peptides.

**Immunogen** HIV-1 infection

**Species (MHC)** human (A03, A11)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** binding affinity, immunodominance, optimal epitope

**References** Bihl *et al.* 2006

- CTL responses were tested for both HIV-1 and EBV derived epitopes restricted by HLA-A, -B and -C alleles. HLA-B alleles more frequently induce detectable responses and that the responses are generally of greater magnitude than those for HLA-A and -C alleles.
- The magnitude and frequency of CTL recognition were related to each other and that TCR avidity for HLA/peptide complexes is a more important determinant for magnitude of response than peptide binding affinity to HLA.
- EBV response patterns were not significantly altered by HIV coinfection.
- Epitope AVDLSHFLK when restricted by HLA-A03 elicited a magnitude of response of 620 SFC with a functional avidity of 0.5nM and binding affinity of 0.65nM. When restricted by HLA-A11, it elicited a magnitude of response of 50 SFC with a functional avidity of 0.5nM and binding affinity of 5.9nM.

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the

presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.

- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (A03 and A11) and 4 additional alleles (A02, A23, A30, B44).

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, VDLSHFLKEKGGLEG was mutated in the daughter D2 isolate to VDLSHFLKEmGGLdG.

- Species (MHC)** human (A11, A3)  
**Country** Viet Nam  
**Assay type** HLA binding  
**Keywords** subtype comparisons, computational epitope prediction, variant cross-recognition or cross-neutralization, vaccine antigen design  
**References** Lazaro *et al.* 2005
- The most common HLA-alleles in the Vietnamese population were found to be HLA-A11, A02, A33, B75, B46, and B62. Several epitopes cluster in short regions in Gag and Nef that are presented by these HLA molecules; these epitopes may be useful targets for vaccine antigens. In a comparison of CRF01\_AE sequences to HXB2, 14 mutations were found in epitopes in these Gag and Nef pluriepitopic regions; 7 did not affect the HLA binding score, 3 increased it, and 4 reduced it.
  - The CRF01\_AE variant dlsFflkek had same HLA-binding score as the HXB2 epitope.

**Keywords** subtype comparisons, immunodominance

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, ShFLKEKGGLEGLIYSqK differs from the consensus C sequence SfFLKEKGGLEGLIYSkK at 2 amino acid positions, i.e. by 11.1%.

### Subtype B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Country** Barbados, Haiti, United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining, Other

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, SHFLKEKGGLEGLIYSQK, had an overall frequency of recognition of 18% - 20.3% AA, 30.8% C, 15.9% H, 0% WI. This peptide is included in a 58 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region I', EVGFPVVRPQVPLRPMTYKAAVDLSHFLKEKGGLEGLIYSQK, a 41 aa region recognized by >90% of subjects across ethnic groups.

**Keywords** HAART, ART, mother-to-infant transmission, rate of progression, co-receptor, immune evasion, HLA associated polymorphism

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, HFLKEKGGLEGLIYS was mutated in the daughter D2 isolate to HFLKEmGGLdGLIYS.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Tetramer binding, Chromium-release assay, Flow cytometric T-cell cytokine assay

**Keywords** rate of progression, escape, TCR usage, characterizing CD8+ T cells

**References** Dong *et al.* 2004

- In 4 donors with delayed disease progression, the response to the FL8 Nef epitope was dominated by V-beta-13.2 TCR expressing CTLs with an unusually long CDR3 region. These CTLs were shown to be resistant to apoptosis and able to recognize escape variants of the FL8 Nef epitope. Thus, selection of these CTLs may be related to better clinical outcome.

- The Q5 variant flkeQggl was rapidly selected in a donor that responded to the FLKEKGGL epitope. The FLKEKGGL peptide and the variant flkeQggl HLA-B8 complexes bound to the Vbeta13.2 FLKEKGGL TCR with equal affinity, while the Vbeta6 FLKEKGGL TCR had reduced affinity for the FLKEKGGL form and did not recognize the Q5 variant. Other variants (T5, N5, and M5 as well as Q5) were recognized by Vbeta13.2 clones from all 4 donors. One clone from donor 046 that was not Vbeta13.2 could only recognize the index variant.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**Country** United Kingdom

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , HLA binding

**Keywords** escape, acute/early infection

**References** Milicic *et al.* 2005

- CTL responses and escape were analyzed in 4 homosexual couples where blood samples were available within weeks of estimated transmission. When the recipient had the same HLA type as the donor, CTL escape variants prevented a CTL response to those epitopes in the recipient. Even when the HLA alleles were different in the transmitting couple, a single escape mutation in one epitope can abolish CTL recognition of an overlapping epitope of distinct restriction in the recipient.

In an early acute infection of the donor, the precise timing of transmission determines the viral variants transmitted.

- The recipient mounted an acute CTL response to this epitope, and the escape variant flkeQggl emerged soon after.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** rate of progression, TCR usage, variant cross-recognition or cross-neutralization, characterizing CD8+ T cells

**References** Turnbull *et al.* 2006

- Functional cross-reactivity of CD8 responses to HIV-1 epitopes restricted by different HLA-alleles was analyzed. It was shown that epitope-specific responses with the most efficient cross-recognition were strongly associated with delayed disease progression. Variant-cross recognition efficiency was linked to the dominant TCRs used for epitope recognition. Epitopes restricted by the same HLA-allele did not show similar variant cross-recognition efficiency, suggesting that the rate of disease progression might be associated with the quality of responses to certain critical epitopes.
- This epitope, B8-FLK that is associated with more rapid progression to AIDS and its natural as well as alanine-substituted variants were quite weakly cross-recognized. CTLs responding to this epitope expressed the same predominant TCR Vbeta family.

**References** Oxenius *et al.* 2000

- Patients who started therapy at acute HIV-1 infection (three with sustained therapy, two with limited therapy upon early infection) had strong HIV specific CD4 proliferative responses and were able to maintain a CTL response even with undetectable viral load – three patients that had delayed initiation of HAART had no HIV specific CD4 proliferative responses and lost their CTL responses when HAART was eventually given and their viral loads became undetectable.
- Six of the 7/8 study subjects that were HLA B8 recognized this early dominant CTL epitope.

- Patient SC2 (HLA A1, B7/8, Cw0701/0702, DR4/53, DQ7) had CTL responsiveness against epitopes FLKEKGGL, GP-KVKQWPL, and GEIYKRWII peptides – FLKEKGGL tetramer staining steadily declined and at day 1340 the FLKEKGGL stained cells were no longer detected and the escape mutant FLKENGGI was found in 8/10 clones.
- Patient SC9 (HLA A1/2, B8/13, Cw0/0701, DR2/11, DQ6/7) had a CTL response against epitopes FLKEKGGL, ILKEPVHGV, SQRRQDILDWYHTQGYFPDWQNY, and GEIYKRWII peptides and all responses declined during therapy initiated at day 390 but were restored when therapy became intermittent.
- Patient SC19 (HLA A11/12, B8/44, Cw06/0701, DR3/7, DR52/53, DQ 2/8) had a CTL response to epitopes FLKEKGGL, GEIYKRWII, ACQGVGGPGHK, AVDLSH-FLK, and FNCGGEFFY that declined during therapy initiated at day 197.
- Patient SC10 (HLA A1/3, B8/35, DR1/8, DQ 4/5) had sustained therapy started during acute infection and maintained an immunodominant response to FLKEKGGL and a response to GEIYKRWII through day 1088.
- Patient SC12 (HLA A1, B8/39, Cw0701/0702, DR2/3, DR51/52, DQ2/6) had sustained therapy started during acute infection and maintained an immunodominant response to FLKEKGGL throughout and minor responses to GEIYKRWII, DCKTILKAL, GGKKKYKLLK – GEIYKRWII and GGKKKYKLLK responses were stimulated by a brief period off therapy.
- Patient SC11 (HLA A1, B8, Cw0201, DR3/11, DR52, DQ2/7) started therapy early, remained on therapy for 40 days, then reinitiated HAART at day 640 had a CTL response to FLKEKGGL, GPKVKQWPL, and GEIYKRWII throughout and received a benefit from the early limited course therapy.

- HLA tetramers to six epitopes were used to study HLA-A2, B8 and B57 CTL in 54 patients – HIV-specific tetramer positive cells were inversely correlated with viral load in patients with high CD4, but in patients with CD4 T-cells below 400 high tetramer frequencies were found despite high viral load.
- Most patients have high levels of HIV-specific T-cell expansions, but many of these cells aren't functional.
- In 15 of the patients, the proportion of IFN gamma producing tetramer cells correlated with AIDS-free survival.
- Stimulation with HLA-B8 p24 and Nef epitopes significantly increased Nef-specific T-cell numbers in 2 patients (748 and 1113)
- There were more functional IFN-gamma producing Nef-specific T-cells within the T-cell population than there were active p24 Gag-specific T-cells.
- No correlation between elevated numbers of Nef-specific CTL cells and plasma viral load was observed.

- Tetramer assays were compared with three functional assays in 42 people with chronic HIV infection: ELISPOT, intracellular cytokine staining, and precursor frequency (limiting dilution assay [LDA])
- HIV-specific tetramer staining CTLs appeared to be active, and inert CTL were not found to play a significant role in chronic pediatric or adult HIV infection.

**HXB2 Location** Nef (90–97)**Author Location** Nef (90–97 BRU)**Epitope** FLKEKGGL**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B8)**Keywords** binding affinity, epitope processing**References** Choppin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- FLKEKGGL was recognized in 12/14 (86%) of individuals with HLA B8, and it was a high affinity HLA binder.

**HXB2 Location** Nef (90–97)**Author Location** Nef**Epitope** FLKEKGGL**Epitope name** FLK**Immunogen** HIV-1 infection**Species (MHC)** human (B8)**Keywords** HAART, ART, supervised treatment interruptions (STI)**References** Oxenius *et al.* 2002b

- Using previously defined epitopes Oxenius *et al.* [2000, 2001a] in an IFN $\gamma$  Elispot assay, 13 chronically HIV-1 infected patients were studied over a period including therapy with standard treatment interruptions (STI).
- STIs induced increased recognition of CTL epitopes, but there was no correlation between CTL responses with viral rebound rates, plateau viral loads, or clearance rates.

- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].

- Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  Elispot assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polypeptide region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polypeptide string Wee *et al.* [2002].

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN- $\gamma$  secreting cells was observed, and there was no correlation between the functional avidity of a response and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a response to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**References** da Silva 2003

- Evidence of the evolutionary adaptation of HIV-1 to the specific neutralizing antibody response and CTL detection is reviewed. Both SIV and HIV epitopes are discussed, with a detailed summary of one patient's response and CTL escape in the FLKEKGGL epitope. The three C-terminal amino acids were left unchanged, and it may be due to high fitness costs as these are putatively involved in CD4 down-regulation and formation of a hydrophobic pocket in Nef. The N terminal residue is involved in binding to protein tyrosine kinases.
- Immediately after infection the susceptible epitope FLKEKGGL was found in 20/20 viral sequences. Six months later, it was only found in 4/44 sequences. The flkeNggL form was most common, 24/44 cases; it bound poorly to HLA B08 and was poorly recognized by CTL. Two minor variants were found 3/44 times, flkeEggl and flkeQggl; both bound poorly to B08, but the K->Q substitution was still well recognized. A variant flkDkggl was found in 4/44 sequences; it bound B08 moderately well, but was poorly recognized. 3 double mutants were found once each, and were not recognized by CTL: flkeNggL, flEeNggL, and flkGNggL.

**References** Lichterfeld *et al.* 2004a

- HIV-1 specific CD8+ T-cells in acute and long-term nonprogressive HIV-1 infection show strong ex-vivo proliferative capacities which are rapidly lost in chronic HIV-1 infection. The loss of CD8+ T-cell function is closely linked with the loss of HIV-1 specific, IL2 secreting CD4+ T-cells. The function can be rescued in vitro and in vivo by restoring the specific CD4+ T-cell help.
- Full CD8+ T-cell responses to this epitope were dependent on co-stimulation with a CD4+ T cell dependent epitope from T-cells harvested during acute infection. The CD8+ T-cell response to this epitope was immunodominant in one study individual.

- T-cell immunity and the impact of selection were longitudinally studied in a patient from the time of transmission. New epitopes were detected at sites that were shown to be under positive selection. Env was found to be the major target of CTLs and most of the new epitopes were found here. One third of the sites examined were associated with epitope escape mutations from CTL. Acquisition of mutations found at high frequency in the database was suggested to be a result of reversion of CTL epitopes in the absence of immune targeting.
- A Nef epitope FLKEeGGL (Nef-94E) presumed escape variant was transmitted from a B8 positive donor to a B8 negative recipient. FLKEgGGL, FLKgeGGL variants as well as FLKEkGGL reversions were found in the recipient subject.

- Cohorts of HIV-infected subjects from the US and South Africa were screened for CD8+ EliSpot responses. Tetramer assays were performed for 13 frequently targeted HIV epitopes and compared to Flu, vaccinia, and EBV epitopes assayed in non-HIV-infected subjects. HIV tetramer+ CD8 T cells expressed less CD127, and this reduction was pervasive across all epitopes and alleles tested. These results indicated impaired HIV-specific memory CD8 T cell differentiation, regardless of level of control of viremia, epitopes targeted, or HLA alleles.

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs *in vivo*. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, FLKEKGGL, was found to be 0.049/day, with SE of 0.012.
- In the subject studied, a number of variants arose in the Nef epitope 90-97 (including complete epitope deletion) that were poorly recognized by CTL or escaped recognition completely.

**References** Lichterfeld *et al.* 2007b

- Differences in early versus chronic AIDS include a decline in CTL number accompanied by a reducing viremia. Comparative analysis of such CTLs in this study show that early infection is characterized by a different clonotypic composition and higher functional avidity of CTLs followed by their selective depletion during transition to chronic disease. The total magnitude of CTL cytokine production is lower in early infection. Intraindividual, early CTLs' functional avidity for the same epitope decreases concomitantly with a reduction in clonotypic TCR repertoire especially of strongly activated and CD127lo, CD38+, Ki-67hi CTLs while progressing to chronic infection states.
- None of the target epitopes, including this epitope FLKEKGGL seen in 4 patients, underwent sequence changes.

**Species (MHC)** human (A2)  
**Keywords** binding affinity, epitope processing  
**References** Choppin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- FLKEKGGLEGL was recognized in 8/12 (67%) of individuals with HLA A2. It was a low affinity HLA A2 binder.

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- Responses to this peptide were detected in 16% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**References** Wang *et al.* 2007

- HLA-A11-restricted CTL epitopes in 2 male Han Chinese subjects (one ART naive and one receiving HAART) were determined. A novel epitope was discovered and 5 other putative epitopes confirmed using 425 overlapping peptides spanning the entire HIV-1 clade B proteome. By employing intracellular cytokine staining, the authors developed a new method of mapping optimal epitopes and defining their HLA restriction efficiently. In spite of its being the most common HLA type in China, A\*11-restricted epitopes were recognized less frequently than other epitopes, and A\*11-restricted responses formed a mean of only 13% of the responses against HIV.
- This epitope, KEKGGLEGL, was detected within overlapping peptide SHFLKEKGGLEGLIYSQK.

**References** Karlsson *et al.* 2007

- To correlate evolving HIV-1 populations with HLA-A2 restricted immune responses for epitopes in Gag, Pol, Env and Nef, 11 treatment-naive subjects were longitudinally studied. Results show that increased viral load is often associated with broad CTL responses early in infection that persist as an "immunological footprint". Conversely, early, restricted responses may help limit viral load. Phylogenetic and functional evidence of viral escape is seen in Gag, Nef and Pol. Gag and Nef show flanking epitope changes restricted by non-HLA-A2 alleles. As far as modes of viral adaptation, CTL responses were seen to develop both against static viral populations resulting in viral evolution to HLA-A2 as well as against existing mutants resulting in reselection of consensus B-like variants. This study reinforces that CTL immune responses detected are not necessarily beneficial to patients, but may be "footprints" from early effective responses that the virus has since escaped.
- A minor response was detected against an E98D variant of this epitope, KEKGGGLdGL.

- HIV-specific cellular and humoral immune responses were examined in monozygotic male twins infected simultaneously with the same virus. 15 of 17 targeted epitopes were identical in the twins, including two immunodominant responses. 3 of 4 declining responses in the twins showed mutations at the same residue. Evolving antibody responses cross-neutralized the other twin's virus. The results were compared with a third brother, infected by the twins' virus 13 months after their seroconversion. The data show similarity in disease course in persons of identical genetic background infected with the same strain of HIV-1.
- This epitope, KEKGGLEGL (KL9) restricted by HLA-B\*4001, was one of two immunodominant responses.

**Keywords** escape, TCR usage, immune evasion

**References** Yu *et al.* 2007b

- The dependence of TCR clonotype recruitment on genetic background was determined by studying monozygotic twins infected with the same HIV-1 strain. After an early, initial correlation in the magnitude, specificity and immunodominance of CTL response [Draenert *et al.* *J. Exp. Med.* 203:529-539(2006)], subsequent disease was mixed with respect to CTL epitopes' mutational escape. TCR alpha and beta chain repertoires were analyzed and it was found that their clonotypes in HIV-specific CTLs were broadly heterogeneous for both concordant and discordant epitope sequence evolution between the twins. Therefore initial TCR recruitment appears to be an entirely random process independent of genetic background of the infected individual.
- This epitope, KL9, showed concordant epitope evolution between the twins, but both alpha and beta TCR chains recruited were entirely different between them.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** supervised treatment interruptions (STI), early treatment

**References** Montefiori *et al.* 2003

- HIV-1 + patient AC10 underwent early HAART treatment, which was discontinued 1.5 years later. At this timepoint potent NAb responses against autologous virus were detected. Treatment interruption initially induced weak CD8+ responses directed against 5 epitopes. By days 873d and 923d the CTL response had broadened to target 22 epitopes; of these six were fully characterized. Eventually the virus escaped the NAb response, but escape was not accompanied by a rise in viral load, and the authors suggest the virus was contained by the CTL response.

**Epitope** KEKGGLEGL

**Epitope name** KL9

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B60)

**Assay type** Chromium-release assay, CTL suppression of replication

**Keywords** escape

**References** Yang *et al.* 2003a

- Virus was cultured in the presence of CTL lines specific for 5 different epitopes (SLYNTVATL, ILKEPVHGV, IEIKDTKEAL, SEGATPQDL, and KEKGGLEGL) to study the emergence of escape mutations. Escape varied between clones for the same epitope, and between different epitopes. Gag and RT epitope escape, if it occurred at all, tended to be monoclonal and within the epitope, indicating strong fitness constraints, while the Nef epitope escape was rapid, polyclonal, and sometimes the result of upstream frameshifts.
- Two cloned CTL lines recognized KEKGGLEGL, STD11 and KM3. Highly resistant clones emerged after a single round of passage with both CTL clones, and multiple substitutions accrued including frameshifts and stop codons, reflecting the dispensability of Nef in viral culture.
- The following epitope variants were observed after passaging with clone STD11 for one week: kekggegl, kKkggegl, and 12/20 frameshifts and 1 early stop. By two weeks, a more complex polyclonal mixture was observed including:

kekggegl, kKkggegl kekggeP, kekggeEl, kekggeRl, kekRgeRl, keNggeRl, and 11/22 frameshifts.

**Keywords** binding affinity, TCR usage, characterizing CD8+ T cells

**References** Yang *et al.* 2003b

- Killing efficiency of CTLs and their ability to suppress viral replication is shown to depend more on epitope specificity than to antigenic avidity. Different clones recognizing the same epitope had similar killing efficiency despite their variation in avidity. Nef specific CTL clones tended to be most inhibitory, followed by Gag, then by RT specific clones, regardless of avidity.
- 2/14 CTL T-cell clones tested were specific for Nef KL9. Under conditions of excess peptide (100ug/ml), there was no difference in their lytic potential; all possessed similar effector capacity. Avidity was measured as the sensitizing dose of peptide required for 50% of maximal killing (SD50), which varied from 20 pg/ml to 100 ng/ml, over four orders of magnitude for all 14 epitopes. The SD50 range for Nef KL9 was 20-30 pg/ml, both high avidity. These clones were among the most efficient at inhibiting viral replication in the set tested, but because of the general lack of correlation between avidity and viral inhibition efficiency in this study, the authors attribute other reasons to Nefs ability to inhibit viral replication that pertain to presentation like kinetics and expression levels.

**HXB2 Location** Nef (92–100)

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISPOT studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, EKGGLEGLIYSQKRQ was mutated in the daughter D2 isolate to EmGGLdGLIYSQrRQ.

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [*J. Virol.* 78:2187-2200 (2004)].
- This peptide, GLEGLIYSqKRQdILDLDLW differs from the consensus C sequence GLEGLIYSkKRQeILDLDLW at 2 amino acid positions, i.e. by 11.1%.

**Keywords** immunodominance

**References** Rolland *et al.* 2007b

- Resemblance between viral and host peptides may preclude immune reactivity against such epitopes. This was shown using ELISpot to test recognition against the entire viral genome in 314 HIV-infected subjects. Also, 944 overlapping Nef variants were tested for 30 patients. This inverse relationship between similarity of HIV epitope to host proteome and its immunogenicity has implications in vaccine design.
- Other factors, however, like entropy effects and forbidden residue usage or even hydrophobicity or disorder prediction scores were more influential than this similarity to self, with regards to immunogenicity of HIV-1. Also, forbidden aa ratios at the C-terminus of CTL epitopes and similarity to host proteins are positively correlated. Low disorder peptides elicit broader CTL responses and are better recognized.
- This HIV-1 epitope, IYSQKRQDI, is similar to human protein Ig heavy chain variable region, sequence tYSQKfQDI.

**Keywords** computational epitope prediction, vaccine-induced epitopes

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- The peptide, IYSQKRQDILDLDLWiY, is a variant of the consensus peptide IYSQKRQDILDLDLVY.

**Keywords** vaccine-induced epitopes  
**References** Horton *et al.* 2006b
- T cell responses during early infection in individuals previously enrolled in HIV vaccine trials were compared with those of nonvaccinated subjects.
  - None of the breakthrough infections possessed vaccine-induced T-cell responses preinfection and 85-86% of vaccinees and nonvaccinees with primary infection developed T-cell responses postinfection, indicating that vaccinees' ability to mount T-cell response postinfection is not compromised by previous immunization.
  - Breakthrough subjects recognized 43 T-cell epitopes, 8 of them novel, and 25% were present in the vaccine.
  - This epitope was not contained in the vaccine, the vaccinated patient recognized it after infection.

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, QKRQDILDWVYHTQGYF, had an overall frequency of recognition of 26% - 28.8% AA, 26.9% C, 25% H, 19% WI. This peptide is included in a 54 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region II', QKRQDILDWVYHTQGYFPDWQNYTPGP-GIRYPLTFGWCFKLVPEPEKVEEAN, a 54 aa region recognized by >90% of subjects across ethnic groups.

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** Nef (105–115)

**Author Location** Nef (C consensus)

**Epitope** KKQEILDLWVY

**Subtype** C

**Immunogen** HIV-1 infection

**Species (MHC)** human (Cw7)

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- People who carried Cw07 often carried a variant of this epitope, while the susceptible form of the epitope was highly conserved among those who did not.

**HXB2 Location** Nef (105–119)

**Author Location** Nef (105–119 HXB2)

**Epitope** RRQDILDLWIYHTQG

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Assay type** T-cell Elispot

**Keywords** supervised treatment interruptions (STI), immunodominance, early treatment

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2–42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 19% of the study subjects, and it was one of the 25 most frequently recognized peptides.

**HXB2 Location** Nef (106–114)

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*13)

**Donor MHC** A\*0301, A\*3001, B\*1301, B\*1402, Cw\*0602, Cw\*0802

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Intracellular cytokine staining

**Keywords** epitope processing, immune evasion, viral fitness and reversion, HLA associated polymorphism

**References** Honeyborne *et al.* 2007

- To determine whether HLA-B\*13-restricted CTL responses could partially explain low viremic loads in patients, a cohort of chronic C-clade infected subjects was studied. 6 novel B\*13-restricted CTL epitopes were defined from both C- and B-clade viruses, 3 of which were within Gag. B\*13-restricted CTL responses correlated with lower viremia, with most immunity targeted against Gag epitopes (p15, p17, p24). Gag epitope escape variants may exact a high viral fitness cost, mutations being seen within and around the optimal epitope.

**HXB2 Location** Nef (106–114)

**Author Location** Nef (106–114)

**Epitope** RQDILDLWI

**Epitope name** RI9

**Immunogen** HIV-1 infection

**Species (MHC)** human (B13)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, escape, variant cross-recognition or cross-neutralization, optimal epitope

**References** Harrer *et al.* 2005

- An HLA-B13-restricted optimal epitope was defined in Nef, RI9. The frequency of CTLs specific for this epitope in B13-positive patients exceeded the number of CTLs against other epitopes, indicating that this is a dominant epitope in B13-positive subjects. Three B13-positive patients who had an immunodominant response to this epitope were good controllers of their infection, with low viral loads over long periods.
- In B13-positive patients with a previous diagnosis of AIDS, an RrDILDLWI escape variant was found.

- This is a well conserved epitope but natural variants were tested. Peptide titration experiments indicate a V91 RQDILDLWv variant and RQDILDLWI are equally well recognized. Other natural substitutions are less well recognized: RkDILDLWI, RQeILDLWI, aQDILDLWI, RQaILDLWI, RrDILDLWv.

**Immunogen** HIV-1 infection

**Species (MHC)** human (B7)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** rate of progression, immunodominance, early-expressed proteins

**References** Altfeld *et al.* 2006

- Immunodominant HIV epitopes in early, primary infection of CTLs were identified and the relative contribution of immune responses restricted to individual HLA class I molecules were studied.
- The most frequently recognised epitopes also elicited the greatest CTL response.
- HIV-1 Epitope sequence variability was not correlated with immunodominant versus immune sub-dominant responses.
- HLA-B57 and HLA-B27 restricted responses were the strongest in these early and acute infections - due to dominant responses to a single epitope in each case (TW10 for B57 and KK10 for B27).
- In the presence of HLA-B57 and HLA-B27 restricted responses, the relative contribution of other restricting HLA dropped greatly.

**HXB2 Location** Nef (106–115)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** computational epitope prediction, vaccine-induced epitopes

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- This epitope, RQEILDLWVYHTQGY, varies at position 3 from the consensus peptide KRQDILDLWVYHTQG.

**References** Cao *et al.* 2003

- CTL epitope responses were mapped in 21 men within 15-92 days post-HIV-1 infection. Subjects initially showed narrow immune responses with a mean of 2.3 epitopes recognized per patient. The immune response broadened later in infection. No correlation between the plasma viral load and the number of recognized epitopes or the frequency of IFN-gamma secreting cells was observed, and there was no correlation between the functional avidity of a responses and the abundance of IFN-secreting cells that recognized the epitope. The first epitopes to be recognized tended not to be the most avid, and earliest responses tended to be directed against Nef, Tat, Vpr, and Env.
- All HIV-1 proteins except Vpu were recognized, and a responses to a total of 41 optimal epitopes were characterized; 24 had been identified previously. 48% of the total T-cell responses were directed against Nef and 43% were directed against Gag.
- More common HLA alleles were less frequently used in primary infection than less common alleles, for example A3, B35, B57, and B62 were more frequently recognized than A1, A2, A30, and A44.

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* J.Virol. 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.

- This immunodominant, frequently targeted overlapping peptide, LWVYHTQGYFPDWQNY, had an overall frequency of recognition of 30% - 25.4% AA, 38.5% C, 31.8% H, 28.6% WI. This peptide is included in a 54 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region II', QKRQDILDLWVYHTQGYFPDWQNYTPGP-GIRYPLTFGWCFKLVPEPEKVEEAN, a 54 aa region recognized by >90% of subjects across ethnic groups.

**Keywords** assay standardization/improvement, epitope processing  
**References** Draenert *et al.* 2004a

- 96% of optimally defined epitopes have one of only nine amino acids serving as the C-terminal anchor position. Seven amino acids are never found in this position and four are only present in 4% of cases. CD8 T-cell response to an epitope is shown to be best detected when the epitope is situated at the C-terminal end of a longer peptide, and authors suggest that Elispot reagents would be better designed if peptides ended on known C-terminal anchors.
- HTQGYFPDW is suggested to be the optimal epitope instead of HTQGYFPDWQ since Gln is not described as a C-terminal anchor residue in any of the other optimally defined epitopes. HTQGYFPDW was also found to be recognized at two times lower peptide concentrations than HTQGYFPDWQ.

**Country** South Africa

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** responses in children, mother-to-infant transmission, escape, acute/early infection

**References** Pillay *et al.* 2005

- HIV-specific CTLs in infants were shown to be able to select for viral escape variants early in life, despite a lack of escape with the same CTL specificity in the mother. Infant CTL responses may be compromised by transmission of escape variants that arose in the mother and also those that arose in the father, if the father was the source of the mother's infection.
- HTQGYFPDW is the C consensus form of the epitope; the autologous form in the mother was HTQGfFPDW, and this was transmitted to her infant. By 33 weeks a new dominant form of the epitope had emerged in the infant: nTQGfFPDW.

**Keywords** responses in children, mother-to-infant transmission, escape, characterizing CD8+ T cells

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.
- While 2 mothers carried the form HTQGYFPDW, their children carried the escape H1N variant nTQGYFPDW.

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- HLA-B\*57-restricted optimal epitope HTQGYFPDWQ was tested for immune response.

**Country** Switzerland

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Other

**Keywords** rate of progression, HLA associated polymorphism

**References** Frater *et al.* 2007

- To study whether CTL responses restricted by "good" HLA I molecules exert stronger immune selection than "other" HLA I molecules, 54 and 70 optimal epitopes within HIV-1 Gag, Pol and Nef genes for Caucasian and African cohorts were tested in patients over a mean of 14 months. "Good", advantageous HLA allele-restricted epitopes were much more polymorphic than epitopes restricted by "other", non-advantageous HLA in patients, suggesting that benefits associated with HLA Class I alleles of elite controllers of disease progression are epitope-specific. Such "driver" epitopes with high polymorphism had high frequency of immune response, allowing them to be ranked for recognition and polymorphism.
- Patients with higher proportions of mutated epitopes also showed lower plasma viral loads, and mean epitope variability correlated negatively with relative hazard of disease progression.
- Variant nTQGYFPDWQ at position 1 was found in 100% of HLA-matched patients and in 28.8% of HLA-unmatched patients.

**HXB2 Location** Nef (116–125)

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.
- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, QGYFPDWQNYTPGPgRf differs from the consensus C sequence QGYFPDWQNYTPGPvRy at 2 amino acid positions, i.e. by 11.1%.

**Keywords** binding affinity, immunodominance

**References** Frahm *et al.* 2004

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved

peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim et al. *J. Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.

- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, QGYFPDWQNYTPGPGIRY, had an overall frequency of recognition of 30.7% - 23.7% AA, 38.5% C, 40.9% H, 19% WI. This peptide is included in a 54 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region II', QKRQDILDWVYHTQG YFPDWQNYTPGPGIRYPLTFGWCFKLVPEPEKVEEAN, a 54 aa region recognized by >90% of subjects across ethnic groups.

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** cross-presentation by different HLA, characterizing CD8+ T cells

**References** Kiepiela *et al.* 2004

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

**HXB2 Location** Nef (120–127)

**Author Location**

**Epitope** YFPDWQNY

**Immunogen** HIV-1 infection

**Species (MHC)** human (A29)

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** assay standardization/improvement, epitope processing

**References** Draenert *et al.* 2004a

- 96% of optimally defined epitopes have one of only nine amino acids serving as the C-terminal anchor position. Seven amino acids are never found in this position and four are only present in 4% of cases. CD8 T-cell response to an epitope is shown to be best detected when the epitope is situated at the C-terminal end of a longer peptide, and authors suggest that Elispot reagents would be better designed if peptides ended on known C-terminal anchors.
- Instead of YFPDWQNYT, YFPDWQNY was found to be the optimal epitope in one patient.

**HXB2 Location** Nef (120–127)

**Author Location**

**Epitope** YFPDWQNY

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*5801, B57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$ , Chromium-release assay

**Keywords** responses in children, mother-to-infant transmission, escape

**References** Feeney *et al.* 2005

- Escape mutations in TW10 and other B57-restricted epitopes were shown to arise early in infants following perinatal infection. Some escape variants were likely to have been transmitted vertically, from HLA-B57/5801 positive HIV-1 infected mothers, while others arose during infancy in cases where the children inherited the B57/5801 allele paternally. In contrast to adults, the majority of children showed a robust response to the escape variants, suggesting that infants are able to mount

functional immune responses and drive immune escape and that a developing immune system may exhibit greater plasticity in recognizing viral variants.

- YFPDWQNY responses were somewhat more frequent in adults.

**Keywords** vaccine-specific epitope characteristics, cross-presentation by different HLA, HLA associated polymorphism

**References** Reche *et al.* 2006

- 25 CTL epitopes with sequence conservation were studied. Population protection coverage (PPC) for 5 different ethnic groups in the US was estimated by combining HLA binding predictions and known HLA frequencies. HIV-1-naive individuals mounted a better response to the epitope pools than HIV-1 infected individuals.
- A more detailed evaluation of HIV-naive T-cell responses was undertaken, limiting the study to only those peptides that are restricted to A\*0201. Though the peptides could cross-recognize and bind different HLA, they were able to specifically lyse only cells of the same (A\*0201) HLA-restriction. Thus, the CTL response was less degenerate than peptide binding to MHC.
- This epitope, SPRTLNAWV, was predicted to be restricted by A1, B\*3701 and B\*5701.

**Keywords** supertype, cross-presentation by different HLA

**References** Frahm *et al.* 2007

- 100 HIV-infected subjects were tested for response to optimally-defined CTL epitopes regardless of the subject's HLA type. Half of all detected responses were seen in the absence of the originally reported restricting HLA class I allele, and only 3% of epitopes were recognized exclusively in the presence of their original allele. Statistical and experimental methods were used to define additional HLA alleles associated with the epitopes.

- Based on a prediction of the minimum number of HLA alleles needed to cover the HLA representation in all responders to this epitope, a minimum set of 6 alleles was found: 2 alleles previously known to be associated (B37, B57) and 5 additional alleles (A01, A02, A23, Cw02, Cw06).

**References** Asquith *et al.* 2006

- In order to reconcile apparent conflicts between a CTL-protective role as suggested by HLA-1 alleles associated with different rates of progression to AIDS, and a CTL non-protective role as suggested by the fact that virus clearance following ART is not impaired in advanced AIDS, a model is made that quantifies the efficiency of HIV-1-specific CTLs in vivo. As a surrogate for the actual rate of CTL-killing of infected cells, the model rests on calculating virus escape rate for an epitope and subtracting its reversion rate upon transmission to a non-restricting HLA bearing host. It is shown that CTLs recognizing a single epitope kill only 2% of productively infected CD4+ cells. The rate of CTL lysis was found to be significantly faster during primary infection than in chronic infection. However, the authors suggest that small differences in CTL lysis rate can translate into large differences in terms of absolute numbers of infected cells killed, which are likely to be clinically relevant.
- The best estimate of escape rate for this epitope, YFPDWQDYT, was found to be 0.002/day (optimistic escape rate = 0.012), with SE of 0.001.
- In the subject studied, the fluctuating outgrowth of a Q125D mutation in Nef was observed over a period of 1,361 days.

**References** Reinis *et al.* 2007

- HIV-1 mother-to-child transmission is studied for LTNPs by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, FPDWQNYTPGPGIRY was mutated in the daughter D2 isolate to FPDWQNYTPGPGtRf.

**Country** United States

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** computational epitope prediction, vaccine-induced epitopes

**References** Li *et al.* 2006b

- To assess the efficiency of vaccine-elicited T-cell responses to epitopes in circulating strains of HIV-1 rather than to consensus or ancestor epitope sequences, the authors used potential T-cell epitopes (PTEs) from Gag, Pol, Nef and Env proteins, to construct an epitope prediction model for peptide selection. Evaluation in their method was conducted by testing Nef-specific CTL responses in four HIV-1 subtype B infected subjects. It was found that peptides autologous to HIV-1 immunogen sequence were the best for vaccine design and that vaccine response evaluation was better performed using peptide sets from circulating strains of HIV-1.
- This peptide has identity with the consensus peptide FPDWQNYTPGPGIRY.

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, QNYTPGPGIRYPLTF was mutated in the daughter D2 isolate to QNYTPGPGIRfPLTF.

**Keywords** subtype comparisons, immunodominance

**References** Zhao *et al.* 2007

- 46 ART-naive subjects with HIV-B infection were used to study CTL cross-responses between HIV clade B and C peptide sequences. 204/826 overlapping peptide epitopes tested were common between both clades in eliciting CTL responses that were of similar magnitude and frequency in both HIV-B

and -C. Higher magnitudes and frequencies of responses were detected with peptides from Gag, Pol, Env and Nef proteins, while peptides from Rev, Vif, Vpu, Vpr and Tat were recognized less often.

- 27 peptides from immunodominant regions of higher inter-clade homology in Gag, Nef, Pol, Vpr, Env and Vif were found to be common between both clades in eliciting the greatest CTL responses. Although these 27 peptides differed by up to 39% between clades, CTL responsiveness was not affected.
- Cross-recognized peptides had a lower entropy of recognition than clade-B specific variants, suggesting that published conserved clade-B sequences are also more conserved between clades. Consensus sequences therefore occurred in virus regions of low intra-clade entropy and high inter-clade homology.
- 18/27 highly immunogenic clusters were previously reported by Frahm *et al.* [J. Virol. 78:2187-2200 (2004)].
- This peptide, QNYTPGPGRfPLTFGWCF differs from the consensus C sequence QNYTPGPGvRyPLTFGWCF at 2 amino acid positions, i.e. by 10.5%.

**Keywords** binding affinity, epitope processing

**References** Chopin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- NYTPGPGVRY was recognized in 3/10 (30%) of individuals with HLA A24. It was a moderate affinity HLA-A24 binder.

- To identify HLA-independent immunodominant regions in HIV clade B across different ethnicities, the authors analyzed CTL responses to HIV in African-American (AA), Caucasian (C), Hispanic (H) and West Indian (WI) cohorts, and analyzed factors influencing immune dominance. Host HLA-A11 and -A25 distributions differed among ethnicities significantly; but the virus regions most targeted by CTLs in breadth and magnitude were in Gag, Nef and Int proteins (Nef-76, most targeted). Pro was the least targeted. 88% of peptides across the entire HIV sequence elicited CTL responses. 6 peptides tested were most differentially targeted between ethnicities. 3 frequently targeted and 10 highly CTL-reactive regions across all 4 ethnicities were noted for vaccine design purposes.
- Suppressive treatment rather than treatment itself was found to diminish CTL responses, whose breadth and magnitude correlates with CD4 count and not viral load. Factors found to determine peptide recognition by CTLs were (i) conserved peptides displaying low entropy (ii) low fraction of forbidden amino acids and (iii) high proteasomal cleavage score, confirming previous informatic studies [Yusim *et al.* *J.Virol.* 76:8757-68 (2002)]. These 3 variables did not correlate with each other but an inverse trend was seen between cleavage score and entropy.
- In addition, since all ethnicities were able to mount CTL responses to every HIV protein and only <12% of peptides were not recognized by any subject, the consensus sequence-based approach to vaccine design is substantiated.
- This immunodominant, frequently targeted overlapping peptide, NYTPGPGIRYPLTFGWCF, had an overall frequency of recognition of 37.3% - 42.4% AA, 38.5% C, 31.8% H, 33.3% WI. This peptide is included in a 54 aa Nef highly reactive region to be used for vaccine design. It is also part of 'Region II', QKRQDILDWVYHTQGYFPDWQNYTPGPGIRYPLTFGWCFKLVPEPEKVEEAN, a 54 aa region recognized by >90% of subjects across ethnic groups.

- HLA-B63-positive subjects were shown to be able to generate CTL responses early in acute HIV infection and to control HIV replication in the absence of antiretroviral treatment. Since HLA-B63 shares the epitope binding motif of HLA-B57 and -B58, it was shown that HLA-B63-positive individuals mounted CTL responses to previously identified B57-restricted epitopes, as well as novel, B63-restricted epitopes. Moreover, these novel B63-restricted epitopes can also be presented by HLA-B57 and -B58.
- This is a putative HLA-B63/57/58 epitope containing the B58 supertype binding motif. The optimal epitope was defined in a person carrying B57, and reactivity to the peptide was enriched in those with B57/B58, just a trend for B63.

**Keywords** supertype, cross-presentation by different HLA, TCR usage, HLA associated polymorphism  
**References** Leslie *et al.* 2006

- 14 promiscuous HIV-specific CTL epitopes presented by B7 supertype alleles were described. It was shown that CTLs targeting an identical epitope that are restricted by closely related but different HLA alleles differ in several ways: by occurrence of distinct HLA-specific escape mutations, by recruitment of distinct TCRs by peptide/MHC complexes, and by functional avidity of CTLs. Since there were no differences in the frequency, magnitude or immunodominance of the CTL responses restricted by different HLA alleles, it is suggested that the unique peptide/MHC complexes generated by closely related HLA induce qualitatively different CTL responses.
- Functional avidity is correlated with selection pressure observed in HLA allele-epitope restriction
- Only B\*0702 was found to be associated with polymorphism.

  - Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.
  - 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
  - TPGPGVRYPL was recognized in 8/16 (50%) of individuals with HLA B7, and 1/9 (11%) of individuals with HLA B35. It was a high affinity HLA binder.

**Immunogen** HIV-1 infection  
**Species (MHC)** human (B7)  
**Keywords** acute/early infection  
**References** Wilson *et al.* 2000a
  - Three individuals with highly focused HIV-specific CTL responses were studied during acute infection using tetramers – high frequencies of HIV-1-specific CD8+ T cells were found prior to seroconversion, and there was a close temporal relationship between the number of circulating HIV-specific T cells and viral load was also found.
  - All three patients were B\*2705, with HLA alleles: A1, A30/31, B\*2705, B35; A1, A\*0301, B7, B\*2705; and A\*0201, A\*0301, B\*2705, B39.
  - ELISPOT was used to test a panel of CTL epitopes that had been defined earlier and were appropriate for the HLA haplotypes of the study subjects – 3/3 subjects showed a dominant response to the B\*2705 epitope KRWILGGLNK.
  - The subject with A\*0201 had a moderately strong response to SLYNTVATL.

- Weak responses were observed to A\*301-RLRPGGKKK, A\*301-QVPLRPMTYK, and B7-TPGPGVRYPL in the subject who was HLA A1, A\*0301, B7, B\*2705.
- No acute response was detected to the following epitopes: A\*201-ILKEPVHGV, A\*301-KIRLRPGGK, A\*301-AIFQSSMTK, A\*301-TVYYGVPVWK, B35-EPIVGAETF, B35-HPDIVIYQY, B35-PPIPVGEIY, B35-NSSKVSQNY, B35-VPLRPMTY, B35-DPNPQEVVL.

**References** Kaul *et al.* 2001a

- ELISPOT was used to study CTL responses to a panel of 54 predefined HIV-1 epitopes in 91 HIV-1-exposed, persistently seronegative (HEPS) and 87 HIV-1-infected female Nairobi sex workers.
- Responses in HEPS women tended to be lower, and focused on different epitopes with HLA presenting molecules that have previously been associated with reduced risk of infection, and there was a shift in the response in the HEPS women upon late seroconversion to epitopes recognized by the HIV-1 infected women.
- 43/91 HEPS women had CD8+ responses and detection of HIV-1-specific CTL in HEPS women increased with the duration of viral exposure.

- Among HLA-B7 women, 4/5 HEPS and 5/6 HIV-1 infected women recognized this epitope.
- The dominant response to this HLA allele was to this epitope in 3 of the 4/5 HEPS cases and in 2 of the 5/6 HIV-1 infected women.
- Subject ML 1203 started with CTL responses to A\*6802 DTVLEDINL and to B7 FVPVTPQVPLR prior to seroconversion, and upon seroconversion acquired additional responses to A\*6802 ETAYFILKL which became dominant, B7 TPGPG(V/I)RYPL, B7 IPRRIRQGL, and B7 SPRTLNAWV.

**References** Hanke & McMichael 2000; Wee *et al.* 2002
- The HIV-1 subtype A focused vaccine HIVA contains p24 and p17, in a reversed order relative to the Gag polyprotein to prevent myristylation of p17, which could direct the protein to the cell membrane and inhibit efficient peptide processing and class I presentation, as well as a polyepitope string of conserved, often immunodominant epitopes that were selected to have particularly good cross-reactive potential for the A-clade epidemic in Nairobi, Kenya. A DNA and MVA prime-boost vaccination protocol using the HIVA antigen will be used in a phase III clinical trial in Kenya. This epitope is included in the polyepitope string Hanke & McMichael [2000].
  - Multiple CD4+ or CD8+ T-cell vaccine-induced responses to peptide pools were detected using intracellular cytokine staining and IFN $\gamma$  ELISPOT assays after vaccination of 5 macaques. The response to the Mamu A\*01 SIV p27 epitope p11C (CTPYDINQM), included in the polyepitope region, was not immunodominant in the Mamu A\*01 vaccinated macaques, possibly because of processing limitations in context of the artificial polyepitope string Wee *et al.* [2002].

- HIV-1 mother-to-child transmission is studied for LTNP by comparing entire genomes from 2 mother (M1, M2) and 2 daughter (D1, D2) RNA samples of a mother-child pair over 11 years. Genetic distance was 94% between subjects' strains. Divergence in sequences was attributed to distinct HLA selection pressures as ds/dn was larger for intra- rather than inter-person sequences. 10 new mutations in D2 were found related to unique daughter HLA alleles.
- Functional ELISpot studies using D2 and Nef peptides reveal strong associations between CTL responses and escape variants, contributing to delayed progression.
- LTNP status was not related to defective virus since all viral genes were intact and CTL response did not effectively control viral load. It is supposed that genetic HLA background and HIV-1 epitope-immune response interaction account for nonprogression of disease.
- All isolates contained R77Q in Vpr, a variation associated with reduction of cellular apoptosis.
- This Nef overlapping peptide, PGPGRYPLTFGWCF was mutated in the daughter D2 isolate to PGPGRfRfPLTFGWCF.

- The peptide PGPGIRYPLcFGWCF varies at position 10 from the consensus peptide IRYPLTFGWCFKLVP.

**HXB2 Location** Nef (130–139)**Author Location** Nef (130–139 BRU)**Epitope** GPGVRYPLTF**Subtype** B**Immunogen** HIV-1 infection**Species (MHC)** human (B35)**Keywords** binding affinity, epitope processing**References** Choppin *et al.* 2001

- Seventy-three 8-11 mer peptides were generated based on putative anchor motifs in the Nef BRU sequence for HLA A2, A3, A24, B7, B8, and B35; these 73 peptides had 81 motifs. 54% bound to the predicted HLA molecule, particularly A2, B7/35, and B8. The strength of HLA-peptide binding was not directly related to the number of individuals that recognized a protein.

- 20s proteasome cleavage of the Nef protein positions 66-100 showed a large fraction of peptides were cleaved ending at: 87L, 83A, 81Y, 71P, 68F and 67G. The frequency of recognition may be in part dictated by the cleavage step in processing.
- GPGVRYPLTF was recognized in 0/10 (0%) of individuals with HLA B7, and 1/11 (9%) of individuals with HLA B35, although it was a high affinity HLA binder.

**HXB2 Location** Nef (130–143)

**Author Location** Nef (130–143 LAI)

**Epitope** GPGVRYPLTFGWCY

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*57)

**References** Goulder *et al.* 1996b

- CTL response to this epitope observed in 4 long-term survivors.
- Peptide defined on the basis of B\*5801 binding motif, yet not cross-restricted except at high concentrations.

**HXB2 Location** Nef (130–143)

**Author Location**

**Epitope** GPGIRYPLTFGWCF

**Epitope name** GF14

**Immunogen** HIV-1 infection

**Species (MHC)** human (B\*57)

**Assay type** CD8 T-cell Elispot - IFN $\gamma$

**Keywords** escape

**References** Bailey *et al.* 2006b

- Impact of CTL escape mutations in HLA-B57 positive elite suppressors was examined. Escape mutations in B57-restricted Gag epitopes were present in all viruses derived from plasma but were lacking in proviruses, suggesting a strong selective pressure acting upon virus in plasma. IFN-gamma responses were detected to both wild-type epitopes and mutant plasma virus epitopes. In some individuals, CD8 IL-2 secretion, rather than IFN-gamma responses, showed better correlation with the plasma viral variants.
- HLA-B\*57-restricted peptide GPGIRYPLTFGWCF was tested for immune response.

**HXB2 Location** Nef (130–143)

**Author Location** Nef (121–141)

**Epitope** GPGVRYPLTFGWCY

**Immunogen** HIV-1 infection

**Species (MHC)** human (B57)

**References** Ferrari *et al.* 2000

- One of the 51 HIV-1 epitopes selected by Ferrari *et al.* as good candidate CTL epitopes for vaccines by virtue of being conserved and presented by common HLA alleles.

**HXB2 Location** Nef (130–143)

**Author Location** Nef (128–141)

**Epitope** GPGVRYPLTFGWCY

**Immunogen** HIV-1 infection

**Species (MHC)** human (B57)

**Country** Spain

**Assay type** proliferation, CD8 T-cell Elispot - IFN $\gamma$ , Flow cytometric T-cell cytokine assay

**Keywords** HAART, ART, supervised treatment interruptions (STI), immune dysfunction

**References** Plana *et al.* 2004

- Structured treatment interruption (STI) alone is not able to control viral replication in chronically infected patients, probably due to lack of strong, maintained T-helper cell responses. HIV-1 specific CD8+ T-cell responses were shown to increase significantly until the end of the follow up, but were not correlated with viral load.
- 7/7 patients recognized this epitope.

**HXB2 Location** Nef (130–144)

**Author Location** Nef (130–144 HXB2)

**Epitope** GPGVRYPLTFGWCYK

**Subtype** B

**Immunogen** HIV-1 infection

**Species (MHC)** human

**Assay type** T-cell Elispot

**Keywords** supervised treatment interruptions (STI), immunodominance, early treatment

**References** Addo *et al.* 2003

- Comprehensive Elispot screening of 504 overlapping peptides that spanned all HIV-1 proteins in 57 HIV-1 infected individuals. Four groups of patients were compared: 23 were untreated; 12 patients were chronically infected and treated; 22 started treatment during acute infection, 11 continuously treated and 11 with STI.
- 63% of the peptides were recognized - the most frequent responses were directed against Nef (95%) and p24-Gag (88%). p17 was the most frequently recognized protein after correction for protein length. A median of 18 peptides (range 2-42) were recognized per person. The most frequently (>20%) recognized peptides were located in conserved regions within clade B sequences. Vpu was rarely recognized.
- A decrease in the total magnitude and in the breadth of CTL responses was detected in patients with treated acute infection in comparison to chronically infected treated or untreated individuals. No correlation between plasma viral load and HIV-1 specific T-cell responses was observed.
- The authors did not note the reference strain, but based on the peptide sequences provided it appears to be HXB2.
- Responses to this peptide were detected in 24% of the study subjects, and it was one of the 25 most frequently recognized peptides.

- HLA class I restricted CD8+ T-cell responses against HIV-1 were analyzed in African patients. Significantly more responses were shown to be HLA-B restricted. Viral load, CD4 count, and thus rate of disease progression were also associated with HLA-B alleles. In addition, the selection pressure imposed on HIV-1 by HLA-B alleles was shown to be substantially greater than by other alleles.
- This epitope was suggested to be the epitope within a longer reactive peptide based on correspondence with a known epitope in the HIV database. Also, a significantly higher frequency of people in the Durban cohort who reacted with the peptide had this HLA type.

- All HIV-1 subtype C protein sequences were analyzed, and 94 HLA-associated amino acid polymorphisms were found that were well distributed throughout the proteome. These sequences were compiled from publicly available databases and originated in South Africa and Botswana. Many polymorphisms were associated with multiple HLA allele classes. 12% of negative associations were found as well, where there was an association of virus expression of the consensus amino acid with a specific HLA allele. HLA-B alleles were involved in most of the associations. 19 HLA-associated polymorphisms were embedded in previously defined epitopes presented by an appropriate HLA restricting molecule.
- RYPLTFGW was a previously defined A\*2402 presented epitope that encompassed an A\*24 associated polymorphism, RYPLTFGW, in the second position.

**HXB2 Location** Nef (134–141)**Author Location** Nef**Epitope** RYPLTFGW**Immunogen** peptide-HLA interaction**Species (MHC)** human (A\*2402)**Assay type** Tetramer binding**Keywords** binding affinity**References** Gillespie *et al.* 2007

- MHC can exert a protective effect on HIV-1 disease progression by the interaction of MHC Class I molecules with Killer Inhibitory Receptors (KIR) of the innate immune system. Here, KIR3DS1, a putative stimulatory receptor and allele of the inhibitory KIR3DL1, is studied. Bw4 MHC Class I proteins were implicated in this KIR's ligand specificity, but the authors were unable to generate binding of Bw4Ile80 tetramers in complex with epitopes to KIR3DS1 transiently expressed on 293-T cells, using a panel of HIV-epitopes differing at p7 and p8.
- This epitope, RYPLTFGW (MHC Class I restriction, serotype Bw4) complexed with MHC A\*2402 as a tetramer was unable to bind KIR3DS1 at 4, 20 and 37C. However, the A\*2402-KYKLLKHIVW complex does bind inhibitory KIR3DL1 subtype KIR3DL1\*005.
