#### PREFACE

This catalog is a summary of the location, size, and species composition of seabird colonies along the coast and interior marine waters of Washington. Eighteen species are discussed in more than 440 nesting sites with an estimated total population of about 300,000 birds.

The catalog is one of 10 catalogs or regional atlases published in the U.S. Fish and Wildlife Service's Biological Report Program and contains detailed information on the natural history, distribution, and abundance of seabirds. It will be useful to planning, management, and regulatory agencies closely connected to resource decisionmaking that impacts seabirds (e.g., oil and gas leasing, coastal ecosystems and Outer Continental Shelf development).

#### ACKNOWLEDGMENTS

Many persons have contributed to this catalog, both as observers and collectors. They are listed in alphabetical order in the Reference section. To a large extent, the sum of their efforts makes this catalog possible and gives it historical and area-wide depth.

The following persons were very helpful, responding to inquiries for information with field notes, unpublished observations, and in some cases manuscripts: E. R. Cummins, J. G. Galusha, Jr., D. Hancock, W. Hoffman, D. Α. Manuwal, K. McAllister, G. Monson, D. R. Paulson, R. L. Pitman, F. Richardson, K. O. Richter, Ε. Rodrick, A. S. Thoresen, R. S. Widrig, and U. W. Wilson. The detailed field notes of G. Eddy and W. Harrington-Tweit were particularly valuable.

The many observations contained in the files of the Natural Heritage Data System, Nongame Wildlife Program, Washington Department of Game, were made available to us. The help of K. McAllister, т. Owen, and Ε. Rodrick in assisting our use of these files is gratefully acknowledged.

We also acknowledge the past and continuing efforts of the collectors, assistants, managers, and curators of the collections listed below. We appreciate and thank them for devoting the time and resources required to respond

to our requests for pertinent data on eggs, specimens, and field notes on marine birds breeding in Washington. The information provided to us of specimens, eggs, and field notes held and maintained at great cost by museums has given this catalog a completeness and value otherwise not Certain individuals possible. were particularly helpful in assisting us, and they are listed parenthetically following the names of their respective museums. The museums are: Academy of Natural Sciences, Philadelphia (M. B. Robbins); American Museum of Natural History, New York (M. LeCroy; unidentified assistant); Bird and Mammal Collection, Department of Biology, University of California, Los Angeles (J. R. Northern); British Museum, Natural History, Tring (I. с. J. Galbraith, М. Walters); Thomas Burke Memorial Washington State Museum, University of Washington, Seattle (D. R. Paulson, J. Rodzilsky); Carnegie Museum of Natural History, Pittsburgh (J. M. Loughlin); Conner Museum, Washington State University, Pullman (R. E. Johnson); Delaware Museum of Natural History, Greenville (D. M. Niles); Denver Museum of Natural History, Denver (D. C. Lowell); Field Museum of History, Chicago Natural (D. Willard); Pacific Lutheran University Museum, Tacoma; Museum of Comparative Zoology, Harvard University, Cambridge (R. Α. Paynter, Jr.; G. B. Cabe); Museum of Natural History, Oregon State

University, Corvallis; Museum of Natural History, University of Puget Sound, Tacoma (G. D. Bird Collection, Alcorn); Department of Biology, Western Washington University, Bellingham; Museum of Vertebrate Zoology, University of California, Berkeley (S. F. Bailey); Museum of Zoology, Louisiana State University, Baton Rouge (J. V. Remsen); National Museum of Natural History (Smithsoniam Institution), Washington, D. C. (M. R. Browning, M. S. Foster); Natural History Museum of Los Angeles County, Los Angeles (K. L. Garrett); Natural History Museum, San Diego Society of Natural History, San Diego (S. Liston); Peabody Museum of Natural History, Yale University, New Haven (E. H. Stickney); Western Foundation of Vertebrate Zoology, Los Angeles (L. L. Kiff); and Whatcom Museum of History and Art, Bellingham (J. Burghoffer).

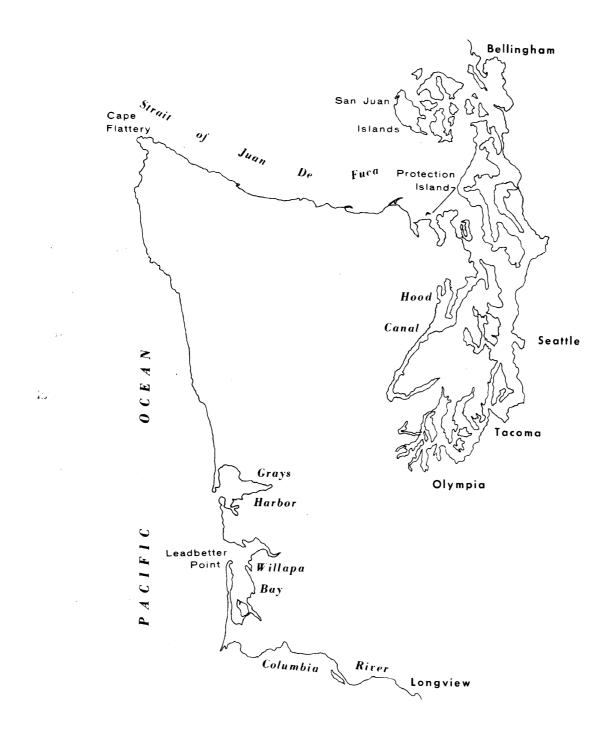

We thank the staffs of the Washington State Library, Olympia, Library, and the Suzallo University of Washington, Seattle, for their help in our review of literature. The assistance given us in finding historical documents by Washington State Library personnel is especially appreciated, as was further assistance given by the staff of the Map Library, Huxley College of Environmental the Sciences, and Archives Wilson Library, at Department, Washington University, Western Bellingham.

The Bird Banding Laboratory, Patuxent, provided valuable listings of banding records of the species covered in this catalog.

We thank W.B. Hesselbart, Refuge Nisqually National Manager, Wildlife Refuge, for making available to us the records of colony We surveys by refuge personnel. also acknowledge his issuance to us of Special Use Permits for surveys of refuge islands during past studies, which provided data for this catalog. Joe Welch, Refuge Manager, Willapa National Wildlife Refuge, also made records of past surveys available to us. Ulrich Wilson, biologist, Willapa National Wildlife Refuge, has been very helpful in providing us with the results of his thorough and careful surveys of coastal islands.

G.A. Clark, Jr., and E.R. Long expertly reviewed parts of the text material and their comments were very helpful. E. Cummins, S.G. Herman, and R.L. Pitman provided photographs of some colony sites. Jay F. Watson supplied extensive assistance and patience as Reviewer and Project Officer for this production.

Illustrations and maps were provided by Richard E. Huxley, Mary Peterson, and Dan Hayes. Special thanks is given to Karen Shumaker for her careful typing of the numerous drafts of this catalog.

#### INTRODUCTION

This catalog is one of a series describing the seabird colonies of shorelines the marine of the United States. The Pacific Coast of North America has been divided following State into areas boundaries. Seabird colonies in Alaska have been documented by and et al. (1978) in Sowls California by Sowls et al. (1980). catalog of colony sites in Α Oregon is now in preparation and, with this catalog of Washington colonies, will appear in the Biological Report series (formerly FWS/OBS series), published by the U.S. Fish and Wildlife Service. A similar catalog of British Columbia, Canada, colony sites has been published (Drent and Guiguet 1961) by the British Columbia Provincial Museum, Victoria, and is currently being updated. Thus an inventory of all reported seabird colonies of the Pacific Coast of North America north of Mexico will be available soon. catalogs establish These а historical baseline description of a valuable and interesting marine resource--the breeding seabirds of the eastern North Pacific ocean. A list of published catalogs and atlases is included as Appendix E.

several important There are reasons why the preparation of catalog was undertaken. this First, as mentioned above, it brings together in one source all the most recent information on breeding species, their numbers, and breeding sites in Washington and establishes a baseline in time. In this catalog the baseline period includes the years 1978 through 1982, as a complete census of all sites in the State in 1 or 2 years has never been undertaken, Also, 1978 marked the beginning of intensive efforts to census all colony sites in the State, in part in conjunction with a study of seasonal populations of all marine birds of the northern inland marine waters of Washington (Manuwal et al. 1979; Wahl et al. 1981).

The second objective of this catalog is to present the best possible reconstruction of the history of all breeding marine birds at all known sites in Washington. This includes all historical breeding sites. data-points Original this in catalog span the period from May 1792 through the summer of 1982: 191 nesting seasons.

Third, this catalog is intended source document for as а administrators, regulatory agency wildlife biologists, personnel, researchers, bird-watchers, and others interested in nature. Thus we have documented the source and location of present every reference in this catalog. We have also included an appendix which gives viewpoints from which number of colonies can be а observed without causing disturbance to the birds (Appendix B).

It is our hope that the catalog will aid in the understanding and conservation of this resource, element of Washington's this marine ecosystem. Future study, censusing, and long-term monitoring can be undertaken with а better understanding of the recent and past status of all species and sites. Changes in numbers and sites and species can be understood and placed in a better perspective.

From its beginning, this catalog was destined to be incomplete by the very nature of its purposes. Without doubt we have overlooked some references, museum holdings of specimens, eggs, field notes, correspondence, historical files and archives, photographs, agency files, observations of innumerable persons, and many other possible sources of information. In a few cases we were unable to track down sources or elicit response from observers in time for publication. Please bring other errors to our attention.

This catalog documents more than 440 nesting areas of 16 species, with a total of more than 300,000 birds within the marine shoreline habitats of Washington. Two more species are also included: one which recently nested in Washington but presumably does not now, and one which does presently nest there but in very small numbers. There are two species of stormpetrels (Fork-tailed and Leach's), three cormorants (Double-crested, Brandt's, and Pelagic), one shorebird (American Black **Oyster**catcher), three gulls (Western, Glaucous-winged, and Ring-billed), two terns (Arctic and Caspian), and seven alcids (Common Murre, Pigeon Guillemot, Marbled Murrelet, Ancient Murrelet, Cassin's Auklet, Rhinoceros Auklet, and Tufted Puffin). In addition to population information in the maps and tables, species accounts discuss aspects of the natural history of these species, emphasizing status within Washington. Species accounts were after modified Sowls et al. <u>Cataloq</u> <u>California</u> <u>Seabird</u> <u>of</u> (1980), Colonies which this catalog parallels.

We point out that this report only documents nesting sites, and only of these species. Large numbers of nonbreeding birds of these species also reside yearround in marine habitats. There are other species not considered "seabirds" which are also resident and which are regularly, significantly involved with the marine ecosystem in Washington. These include Great Blue Heron (Ardea <u>herodias</u>), Bald Eagle (<u>Haliaeetus</u> <u>leucocephalus</u>, Belted Kingfisher (<u>Ceryle alcyon</u>), and American/ "Northwestern" Crow (Corvus caurinus).

In addition to these residents, large numbers of non-nesting birds migrate through coastal Washington in spring and fall and many more birds of many species winter along the coast and in protected waters. These include shearwaters from as far away as Tasmania, New Zealand, and Chile; many species of loons; shorebirds and waterfowl from arctic Alaska and Canada; gulls from the Arctic and from Mexico; inland-nesting and species of grebes and gulls. Oil spills and other disturbances could severely affect populations of many species that constitute an international resource and must be managed and protected as such.

#### METHODS

This catalog summarizes the results of the efforts of numerous investigators and observers over many years. It is not the result of a specifically designed survey project which ultimately led to this report.

Data used in this catalog were obtained from many sources. A nearly complete survey was made of the major ornithological journals as well as regional journals, particularly <u>The Murrelet</u>.

books, regional Relevant dissertations, monographs, and theses were sought out and Unpublished reviewed. manuscripts, field notes, surveys, correspondence, etc., searched for in were several Washington museums, libraries. archives, State and Federal files. and private libraries. Field notes were also obtained from other museums.

Letters of inquiry were sent to major museums most in North America requesting information on specimens and eggs of breeding details of birds, notes on breeding from specimen labels and egg cards, and for field notes from Washington. Correspondence was carried out with the British Museum of Natural History for the specimens and notes from voyage of Vancouver in 1972 to Puget Sound.

Considerable effort was devoted correspondence with various to observers, requesting details of observations, A11 their etc. sources obtained were checked for other references, both for additional observers and collections, and also for literature Every effort was made citations. to follow any leads which developed.

Data presented in this catalog were acquired through a wide range of survey techniques. Methods of obtaining numbers of breeding birds vary among sites, species, period observers, and of collection. We have judged all the data presented here to be reasonable in that numbers of each species reported breeding at a given site probably did indeed do Ultimately it is up to the so.

user of this report to decide whether any given data set is usable for any given project.

In reviewing data collected we eliminated data sets where (1) it was indeterminable whether numbers of a given species were nesting at a reported site, (2) the site was not reported, (3) the site could not be distinguished from others (as in islands reported as а group), (4) the date of the data could not be determined, or (5) there were other problems with the data set which raised serious doubts as to its validity.

Specimen records were assumed to represent birds nesting at the site of collection if this seemed reasonable to us on the basis of knowledge of the species and the This was strengthened if site. there was a history of the species using that site. In some cases, breeding information on specimen tags clarified nesting status. In our request to museums for information we asked that specimen label and egg card comments be sent to us. In many cases this was done, but in others a lack of museum personnel prevented this.

We attempted to reference all citations in the completely catalog, whether from the literature, correspondence, field notes, reports, or museums. We identified the have present location of all data sources as well as possible. For specimens and eggs, the museum holding the indicated. specimen(s) is Literature citations are standard. The present location of correspondence, field notes, and reports is indicated. Several reports and personal communications from various observers are presented here for the first time, and are otherwise contained only in our personal files, as indicated.

For many sites, species data are outlined in a "box" at the head of the site listing. Data in these boxes represent the best data, usually the latest, for each species at the site, collected from 1978 through 1982. Sites lacking species data outlined in a box have not to our knowledge been censused during this period.

The user of this catalog should be aware that the totals given for burrowing species, especially those entering and leaving burrows nocturnally, are not usually the result of direct counts. These totals are often the result of grid samples extrapolated to cover the entire suitable habitat at the This procedure in itself ces tremendous potential site. introduces variance in reported totals. In addition, burrow samples signify different things to different investigators, or even the same investigator at different times or locations. In some cases the estimated total of nocturnal, burrowing species may represent all burrows observed. In other cases it may represent active burrows, burrows with eqqs, burrows with chicks, or even just burrows that produce young. Some serious users of this catalog will undoubtedly to want review personally the original source documents.

#### THE NATURE OF SEABIRDS

Seabirds have relatively long lifespans, low adult mortality rates, relatively late sexual maturity, and small clutch sizes.

Lifespans of seabirds are imperthey fectly known, but are certainly long in comparison to most terrestrial birds. There are records of several species of seabirds reaching 20 and even 30 vears of age in the wild. Glaucous-winged Gulls banded as chicks in the San Juan Islands in Washington have been seen on the nesting colonies up to 25 years later (T. Wahl, unpubl. obs.). Long lifespans in a species imply low annual rate of adult а mortality, and annual mortality rates below 20% are common in (Ashmole 1971; seabirds Henny 1972). Some albatrosses may have annual mortality rates of as low as 3% (Lack 1954) whereas many passerines, at the other extreme, have annual mortality rates from 40 to 70% (Lack 1954; Henny 1972). If mortality rates remain constant with increasing age, large seabirds with very low annual mortality rates may attain а breeding life of 50 years or more (Ashmole 1971). In addition, recruitment of birds into the breeding population is often slow Before attaining and delayed. maturity, many seabirds spend at least 2 years, and more commonly 3-5, and up to 9 years as nonbreeders (Ashmole 1971; Speich and Manuwal 1974). Long breeding lives, low recruitment rates, and delayed maturity could delay the detection of effects on successive breeding populations for several years.

The clutch size of seabirds is usually low. Storm-petrels and other Procellariiformes lay one egg, alcids lay one or two eggs, and pelicans and gulls lay one to three eggs. Cormorants may lay up to seven eggs, though clutches of four or five are more common. By contrast, species of land birds lay from 7 to 15 eggs per clutch, and many produce two or more broods each year.

Because seabirds reproduce at a slow rate but over a long lifetime, the effects of an oil spill or other disaster and the potentially more dangerous effects of long-term, chronic pollution, habitat loss, and other disturbances demand careful and frequent monitoring of seabird populations.

Seabirds tend to be of two types: those which spend most of their time near shore and usually on shore (including roost cormorants, pelicans, and gulls), and those which come to land only during the breeding season or sometimes intermittently during other times of the year (including storm-petrels and alcids). Of the truly pelagic seabirds, several are nocturnal on the breeding or leaving grounds, entering only at night. colonies Tn Washington storm-petrels, the Marbled Murrelet, Cassin's and Rhinoceros auklets are nocturnal in their visits to nest sites.

The colony site is a very habitat for seabirds critical thus reproduction and because continuation of species depend on these sites. Here the population will reach its annual low, just before young are hatched, and its annual high, just after hatching. other times of the At year, seabirds may be able to avoid problems, such as disruption of food supplies and perhaps even large oil spills, simply by flying somewhere else, but for successful reproduction they are limited to the area around the colony.

In following sections, we point out some of the problems which face seabirds. We hope an awareness of these will alert coastal planners and, indeed, all others to the kinds of problems that may be encountered.

#### THREATS TO SEABIRDS

#### DISTURBANCE

In Washington, especially in the areas east of Cape Flattery, in Puget Sound and the San Juan disturbance-induced Islands, stress and mortality are probably important most long-term the affecting marine bird factors The effects of populations. disturbance are often subtle and easily overlooked by the casual are often but observer, devastating to the birds. Impacts range from slight disruption of courtship behavior, incubation, feeding of nestlings by and adults, to outright mortality of nestlings from exposure to heat or cold, and induced predation by conspecific adults or by other species.

The effects of a disturbance event depend on many factors, including the species involved, stage of nesting, type and time of disturbance and its duration and intensity. The long-term summation of all disturbance events is of great concern. Although individual events mav appear innocuous separately, together they may be sufficient to lower the mean success of the species' population in the area. Each species is vulnerable in different ways, and each species tolerance to has its own disturbance events below a level significantly its affecting Our view is that reproduction.

the continued existence, especially of many of the birds nesting in Puget Sound and the San Juan Islands, is already being seriously jeopardized by disturbance.

Major forms of disturbance and their potentially detrimental effects on breeding marine birds in Washington include the following:

#### <u>Recreation</u>

Boating. The spring and summer are popular boating periods which, of course, coincide with the greatest nesting activity and vulnerability to disturbance of nesting seabirds. Our observations indicate that most disturbance occurs indirectly with water recreation and is unintentional and unknown to the persons involved. Only when boats are taken near colony sites is disturbance likely to result. Many boaters usually stay far from rocks, islands, and shorelines, but others seek out such areas as a matter of curiosity or as a place to spend the day or night. The waters immediately adjacent to colonies are often good fishing spots. These close visits near colonies constitute the problem with boating. Often, even when islands are posted as U.S. Fish and Wildlife Refuges, persons land on colonies, walk about, sunbathe, picnic, or run dogs. These activities can be extremely detrimental to nesting birds, disrupting their breeding biology.

The presence of humans or dogs in colonies causes adult birds to leave nests, exposing eggs and young to the weather and predatory species. Boats and their occupants brought close to colonies can also result in adults leaving their nests unprotected. Exposed eggs and small young are often eaten whole by gulls which boldly approach unprotected nests during disturbances. Crows can break and carry off eggs and remove small young. Eggs and young left unprotected may expire from exposure to the sun's heat or chill on cold days. When young are larger and able to move about, disturbance can cause young birds to leave nest sites or territories in panic. Young gulls may be killed by neighboring adults or fall off cliffs into the water and be unable to return to the nest. Young cormorants may be eaten by gulls and crows or be frightened into the water prematurely.

The problems of disturbance are not unique to Washington and are recognized from many other areas; e.g., Baja California, Mexico (Anderson and Keith 1980); and California colonies (S. Speich pers. obs.).

Boating in foraging areas, although perhaps less disturbing to marine birds, can affect nesting birds by reducing foraging opportunities and efficiency. This is thus far undocumented for Washington, but it may prove to be significant in the future, particularly in inland marine waters.

Diving is <u>Scuba</u> Diving. an increasingly popular sport in Washington's inland marine waters. Dive boats operating in the San Juan Islands often anchor near seabird colonies. The proximity of the boat, its occupants, and their activities cause cormorants especially to desert nests, leaving young or eggs unattended. Tufted Puffins are also easily disturbed. Activity near the colony for long periods can be fatal to eggs and young birds due to exposure or predation. Divers often leave the water and land on the islands, compounding the disturbance and its effects.

#### Search and Rescue

Although there is no question as to the need for search and rescue operations by United States and Canadian Coast Guard units in Washington, these nevertheless can affect seabirds. These operations often bring vessels, air-cushion craft, and helicopters very near Helicopters and aircolonies. cushion craft are noisy and scare large numbers of birds from nests. Night operations combine noise with powerful searchlights that sweep the colonies, causing great confusion and panic among adults and nestlings. Adults frightened from colonies may not return for hours. Conventional Coast Guard pose search-and-rescue vessels similar disturbance threats as pleasure craft do during daylight hours. The potential impacts on seabird colonies of searchlights at night, especially when employed vessels air-cushion by and helicopters, can be extreme.

#### Military Operations

Several islands along the outer coast of Washington, as well as islands in Rosario Strait, have been used as bombing targets in the past. Fortunately these activities have been halted in the inland marine waters and are very limited on the outer coast.

Another source of disturbance is close overflights of seabird colonies by a variety of military aircraft. Sudden loud noise panics nesting birds from nest sites: Common Murres often figuratively explode from the cliffs and loss of eggs (held between the legs of incubating birds) may be extremely high.

The use of strobe lights and high-powered searchlights on or near nesting colonies accompanied by engine noise and the firing of cannon constitutes another disturbance hazard to nesting seabirds.

Cormorants, Common Murres, and Tufted Puffins are the species probably most affected by these activities.

#### Domestic Animals

introduction of domestic The animals into a nesting colony can Dogs especially be disastrous. extremely disruptive of are nesting birds. They not only disrupt nesting activities, but a single dog can easily kill many nestlings and even adult nocturnal birds such as the Rhinoceros Auklet (see Manuwal 1978).

The Pigeon Guillemot is now probably being excluded from many beach areas because of the presence of free-running dogs. Guillemot nests under beach logs and other objects are easily found by dogs.

Many intertidal areas are important foraging areas for gulls, crows, and herons at lower tide stages. Dogs can effectively eliminate these areas from use by foraging nesting birds, as we have observed on numerous occasions. This pressure may be effective in essentially eliminating foraging areas in heavily populated regions or at recreation sites.

#### LOSS OF HABITAT

Loss of habitat can take many forms. Some have already been noted above, as where habitat is rendered unsuitable due to disturbance. When discussing nesting marine birds, we tend to think generally of only the actual nesting site and give little attention to the birds' habitat requirements throughout the year and their life cycles.

#### Nesting Sites

It is of course critical that nesting sites be preserved. Tn Washington nearly all colony sites are now in public ownership, and there is presently little threat development. of loss due to However, as discussed above, disturbance has the potential to render sites unusable for some species of birds. Pigeon Guillemots and Glaucous-winged Gulls are now probably excluded from some shoreline areas due to disturbance from people and dogs. Marbled Murrelets, if they indeed nest exclusively in trees in Washington, may now have less nesting habitat available than in pre-logging days, but we have no way to evaluate historical population changes or current levels.

#### Foraging Areas

It is important that foraging areas be preserved and prey species populations maintained at levels which will in turn support marine bird populations (see Commercial Fishing). Each species preferences, has habitat and individuals within species have favored localities in which they tend to forage. The outright alteration of these habitats can eliminate or reduce the support capability, the "carrying capacity," of the habitat. The filling of inter-tidal areas and destruction of bottom and infaunal communities through dredging, filling, and pollution are examples of drastic alteration. And, of course, constant disturbance from people, boating traffic, and domestic animals can also effectively eliminate a site as a foraging area.

#### <u>Roosting Sites</u>

All birds require sites to rest, and different species have different site requirements. Some species use upland sites to roost while others use water sites, or both. Roosting sites are important for resting and preening. For cormorants, roost sites, both during daytime and nighttime hours, are critically important for the essential drying of the birds' plumage.

Roost sites, like nesting and foraging areas, must be free from disturbance and secure from predators or perceived predators such as domestic dogs. These sites are important throughout the year.

During winter storms, periods of high stress and energy consumption, secure roosting sites become even more important as places of safety and shelter. Breeding seabirds must be considered on an annual basis: survival requirements must be met throughout the year.

#### <u>Wintering Areas</u>

There are very few data on the actual wintering areas of marine birds that breed in Washington, though some general patterns are known. These wintering areas need to be identified and preserved where necessary. Storm-petrels remain at sea during the winter. Tufted Puffins disperse over the North Pacific at this time, with young birds remaining there until old enough to breed. Presumably cormorants breeding in Washington stay in Washington waters; at least, many individuals of each species are present in winter. American Black Oystercatchers probably remain in Washington and are often found in large flocks. Rhinoceros Auklets appear to go south along the coast to winter off California. Cassin's Auklets from are present offshore Washington during the winter, but most birds may go farther south; we simply do not know. Large numbers of Marbled Murrelets are present during the winter, but we have no information on their origin. At least some Common Murres breeding in Washington may leave the outer coastal waters and enter the inland marine waters during the winter. Although young Glaucous-winged Gulls may disperse up and down the Pacific Coast, adults probably stay in the area during the winter. Caspian Terns probably move south to the waters off Central and South America.

It is essential for the survival of the breeding populations that wintering areas continue to be adequate. Many of the birds breeding in Washington probably leave and winter at sea or along the coasts of Oregon, California, and farther south, but more definite evidence on winter areas is needed. Within Washington we can only directly ensure that winter habitats for roosting and foraging are maintained for local wintering birds.

#### COMMERCIAL FISHING

There are two major ways that commercial fishing operations can affect marine birds. First, and the most obvious, is the direct mortality of birds caught in fishing nets. In Washington mortality occurs primarily during gill net operations. This mortality from gill nets is poorly documented, but observations and reports from fishermen indicate it occurs locally and in some cases involves many birds. Much gillnetting is done in the shallower bays and estuaries where bird densities are usually highest. Western Grebes (Aechmorphorus <u>occidentalis</u>) the are chief victims observed; however, Common Murres and Marbled Murrelets are also reported to be frequently drowned in nets. A large gill net fishery is in the middle of the Strait of Juan de Fuca, and its impact on the annual large influx of Common Murres in late summer should be investigated. Gill nets staked across rivers may also kill numbers of birds. Lost gill nets have killed large numbers of seabirds on the high seas (see DeGange and Newby 1980), but the mortality from lost nets in Washington is unknown. Gillnetting occurs primarily at night, and the elimination of seabird mortality appears very difficult under many circumstances.

Purse-seining is the other primary type of commercial fishing which affects bird populations. It is conducted during daylight and, as it can be considered an "active" type of netting which attempts to select fish schools, would appear to catch fewer birds. However, we have observed Western Grebes and Common Murres caught in nets, and numbers of dead birds are occasionally seen floating or beached near locations where purse-seining is extensive. Our observations lead to the suggestion that mortality from purse-seining may be reduced by modifications of net design or fishing strategy.

A second way fishing may affect bird populations is in overfishing or reducing fish to a level where stocks of predators, including seabirds and mammals, may also be Some bird species may reduced. not be able to switch to alternative prey items because of specializations in behavior or diet requirements. In Washington, overfishing could happen, particularly in the case of herring-roe extremely fisheries or other localized and intensive fisheries. Overfishing is a concern for both summer breeding populations and populations of marine birds wintering in Washington.

#### OIL POLLUTION

There are several ways that petroleum (e.g., solvents, gasoline, fuel oil, lubricating oils, bunker oil, and crude oil) arrives in the marine environment. These include at one extreme massive oil spills, such as when an oil tanker is wrecked. Less petroleum catastrophic events include small local spills such as both occur at fuel docks, commercial and recreational, during fueling of vessels. Fuel may be spilled during transfer between barges or vessels and shore facilities. Crude oil may be spilled during transfer at refineries, by accidents within refineries, or through damage or failure of oil pipelines. Small quantities of petroleum products lost daily through bilge are pumping, small spills at fuel docks, and other accidents. And of significance in the large urban areas are petroleum products, i.e., various oils and greases, which are flushed into storm drains from roadways and into marine waters during rains.

In Washington, it is fortunate that no large oil spills, such as an oil tanker wreck, have occurred date. The wreck of the to freighter Seagate on the outer coast of Washington on September 6, 1956, released fuel that led to the death of several thousand White-winged Scoters (<u>Melanitta</u> and Common Murres <u>fusca</u>) (Richardson 1956). There is a potential, however, for large oil spills in Washington. There is regular and frequent tanker traffic offshore along the outer Alaska coast between and California and ports in Central America. There is traffic also in the Strait of Juan de Fuca and through Rosario Strait to major refineries at Cherry Point in Whatcom County and March Point in Skagit County. These tanker routes pass almost all the major seabird colonies in the State, with ships passing particularly close to several colonies in Rosario Strait.

Chronic, low-level introduction of petroleum products into the marine environment is a serious concern. However, to date, little evidence indicates significant impact on marine bird populations in Washington. Surveys of beaches in areas east of Cape Flattery in 1978 and 1979 revealed few dead birds that were obviously marked with oil (Speich and Wahl 1986). Nevertheless, the potential effects of chronic low-level oil pollution should not be underestimated. Only a small fraction of actual numbers of dead birds, oiled or unoiled, may reach shore (Hope Jones et al. 1970), leading to underestimates of mortality.

Oil in the marine environment can affect marine birds in several ways and at varying magnitudes. Marine oil spills leave the most obvious effects, easily visible in the form of oiled birds. Because of the habits particular to each species, such as sites and methods of roosting, feeding, and nesting, different species are affected differently. Generally the species most severely impacted are those divers that spend nearly all their time, including hours of darkness, on the water surface. After oil spills in other areas, species of loons, grebes, and alcids occur at high rates on beaches, often heavily oiled and beyond rescue (Smail et al. 1972; Powers and Rumage 1978; Mead and Baillie 1981). These swimming birds are more likely to encounter and be fouled by oil and to be more heavily oiled than species that fly more frequently or roost ashore at night (Powers and Rumage 1978). Gulls observed after the Argo Merchant oil spill tended to have less surface area oiled than did alcids (Powers and Rumage 1978; see also Levy 1980).

Crude oil and crude oil derivatives can affect birds several ways. The most direct is through oiling of feathers which

reduces  $\mathtt{the}$ buoyancy and insulation of the plumage. This increases body heat loss and the swimming and decreases foraging efficiency of affected birds, leading to a greater energy demand and decreased ability to meet that demand. This combination can be fatal, particularly during times of environmental stress. Gulls that were oiled only slightly following the wreck of the Argo Merchant apparently died from being weakened due to oiling and to environmental stress (Levy 1980). Clearly birds that are extensively oiled, especially in cases where oil-matted feathers allow direct contact of the body surface with cold water, have very much reduced chances of survival.

When oil adheres to feathers of a bird, its reaction is to preen and restore the feathers to their natural state. The process of result preening can in the ingestion of oil. Oil can also enter the digestive system by ingestion of contaminated food items. Oil fractions are differentially absorbed within the bird and can cause severe, even fatal physiological disruptions (Hartung and Hunt 1966; Powers and Rumage 1978; see also Stickel and Dieter 1979). Hemolytic anemia in marine birds is a primary toxic effect of ingestion of the crude oil (Leighton et al. 1983).

Ingestion of oil, especially during critical periods of egg formation, can cause depression of laying and rates of hatching, as shown in studies of Cassin's Auklet (Ainley et al. 1981; see also Stickel and Dieter 1979). This can reduce the reproductive efficiency of the population as late nesting birds are less likely to be successful in fledging their young than birds reproducing on a normal schedule. If birds produce infertile eggs due to physiological disruption caused by ingestion of oil, results on the population may be severe. Birds attempting to incubate eggs that fail to hatch may be effectively eliminated from reproducing that season.

Oil on the feathers of adult birds can be a threat not only to them, but in the case of nesting birds, to their eggs and young. Laboratory studies which simulated the oiling of eggs by oiled parents returning to a nest showed marked decreases in hatching and fledging rates. Treatment of the eggs of nesting Great Black-backed Gulls (<u>Larus marinus</u>) confirmed this in the field. Free-ranging, incubating Laughing Gulls (L. atricilla) were captured and 2.5 ml of No. 2 fuel oil was applied to their feathers around the brood patch. After 5 days of incubation, embryo death was significantly greater in the experimental groups (Stickel and Dieter 1979). These experiments demonstrate that even small amounts of oil on a bird's plumage can seriously reduce productivity. Chronic low-level petroleum pollution of the marine environment potentially can, and may be already, reducing reproductive output. In the longreducing term, chronic low-level pollution by petroleum products may be more significant in impacting populations than less frequent and yet obvious and dramatic more major pollution events like spills.

Several species of alcids nest in Washington in large numbers; included are two important colonies of Rhinoceros Auklets.

In the event of a major spill in staging foraging or areas. especially during the summer breeding period, there could be very high mortality. During late summer there are perhaps as many million Common one-quarter as including flightless Murres, adults and chicks, in the Strait Juan de Fuca moving from of nesting sites in Washington, perhaps Oregon, and northern California to wintering areas in inland marine waters of the State. An oil spill then and there could result in the loss of huge numbers of birds.

There is little information on the response in general of birds to the presence of oil in foraging areas. Some species are more easily oiled than others. But it known with certainty is not birds will effectively whether shift to new foraging areas free from oil (and unexploited by other populations or species). Observations of oiled birds suggest that in at least cases some habitat or location shifts do not However, following the occur. IXTOC I spill along the Texas coastline, part of the shorebird populations left polluted beaches and returned only after the oil was gone (Getter et al. 1981).

#### TOXIC SUBSTANCES

been general There has а perception by the public that the waters of Washington, including Puget Sound, are "clean." Huge quantities of marine organisms are annually for human taken consumption within the region. However, recent studies of Puget Sound revealed that heavy metals, hydrocarbons, and aromatic synthetic organic compounds occur

throughout the area. Highest concentrations were recorded in samples of marine organisms and sediments from bays near urban These areas include the areas. bays and waterways of the industrial areas of Seattle and Tacoma, particularly, and Bremerton and These findings have Bellingham. led the U.S. Environmental Protection Agency to include the nearshore and tideflat areas of Commencement Bay (Tacoma) within the list of the top ten priority toxic waste dump sites in the country requiring remedial action. Contaminants recently found in high concentrations include chlorobiphenyls (PCB's), chloro-(CBD's), butadienes various aromatic hydrocarbons, and metals such as mercury, lead, arsenic, and cadmium (see Long 1982 for a review of recent findings).

Recent studies have shown that certain sites within Puget Sound are significantly contaminated (Long 1982; Malins et al. 1982). Apparently areas outside of Puget Sound are relatively "clean"; however, none of the parts of Puget Sound studied thus far have been found to be contaminant free (Malins et al. 1982). Parts of the outer coast of Washington are the most removed from sources of contamination, but there are apparently few or no data available from the area for comparisons with other regions.

There are several examples of the effects of metals and man-made chemicals on the survival of adult birds and their ability to reproduce successfully. Effects include physiological disorders and egg-shell thinning (Peakall 1970 1975; and Hays and Riseborough 1972) that have been observed in several species. The pattern of reproductive failure and its apparent reversal in the the Brown Pelican case of occidentalis) in (Pelecanus is and California well known documented (Gress et al. 1973; Anderson et al. 1975). Doublecrested Cormorants also experienced depressed reproductive success during the same period (Gress et al. 1973). The thinning of eggshells of the Ashy Storm-Petrel (Oceanodroma homochroa) and Farallon Common Murre on the Islands has been linked to contaminants (Coulter and Riseborough 1973; Gress et al. 1973), as was the case of the Western Gull in southern California (Hunt and Hunt 1973). For a discussion of eggshell thinning patterns in Oregon seabirds, see Henny et al. (1982).

Samples of birds collected in 1982 from the Seattle and Tacoma marine water areas contained metals and high concentrations of PCB's (Riley et al. 1983). Birds tend to accumulate mercury and contaminants, organic but not The egg of one Pigeon others. Guillemot PCB contained concentrations at a level known to be lethal to chicken embryos, but apparently little is known of the interactive pathways of PCB's. Samples away from Tacoma and Seattle contained lower levels of pollutants. Although there are high levels of contaminants near these cities, few marine birds breed in the area. Fewer than 1% of the total of all marine birds nesting in Washington breed in the inland waters south of Admiralty However, this apparent Inlet. remoteness of major breeding populations does not necessarily mean remoteness of these birds from contaminants. Birds breeding in relatively clean areas may winter in contaminated areas, as in the case of Common Murres wintering in Puget Sound. A Forktailed Storm-Petrel egg collected in coastal Oregon contained high levels of DDE and PCB's (Henny et al. 1982). This species generally feeds offshore, over deep water. Birds can pick up contaminants at any time of the year at any location. But we must point out that we do not yet have any evidence that Puget Sound marine birds are suffering from exposure to or the uptake of contaminants.

#### LIMITATIONS OF THE DATA BASE

There are many variables that limit the accuracy and reliability of the data that are available and presented in this catalog of the breeding marine birds of Washington. These limits are of two kinds and must be considered when using data from the catalog. There are, first, the reliability and accuracy of the data available from the viewpoint of observer shortcomings in collecting and data. recording the Second, intrinsic in the nesting habits of each species is great variability in the species' observability and the researcher's ability to obtain a number that reflects the actual number of individuals of a species nesting at any given site.

## RELIABILITY AND ACCURACY OF DATA

All data presented are affected by the reliability and accuracy of the observer. Factors range from the observer's ability to identify a species accurately and determine whether it is nesting, to the recording of observations in a clear, complete, and concise format. Other important factors include the observer's competence in knowing and recording the exact location of observation.

recorded Unfortunately, most observations are incomplete and a considerable number cannot be used because of ambiguity or lack of location, species data on identification, or species nesting Insufficient documenstatus. recording and of tation observations has occurred since the first explorations of this region in the 1780's and 1790's, and continues to this day. It is distressing to consider the amount of time and resources spent by numerous individuals, various personnel, agency persons associated with colleges and universities, etc., and the poor quality of recorded observations that have often resulted from their efforts. And, in almost all cases, apparently little thought given and little effort was expended to insure the availability of recorded observations to later workers. There is an almost universal lack of recording of observations in formal field notes in the format of or even vaguely similar to that of the late Joseph Grinnell of the Museum Vertebrate Zoology (Herman of Most recorded data are 1980). fragmentary, often on scraps of in letters, recorded in paper, tables without comments, or contained in the literature in A lack of maps brief form. locations obserdepicting of vations has been particularly limiting in many cases.

Specimens and egg sets are known sites from many colony in In using these Washington. necessary to specimens, it is "trust" the accuracy of the collectors, particularly in regard

to locations. With egg sets it is virtually certain the species was nesting. However, unless specimens are of pre-fledgling young, we can only assume the individual was nesting at the site of collection. This assumption is reinforced if there is a recorded history of nesting at the site by the species, or if the collector has made notes on the tag indicating the specimen or species was nesting.

### SPECIES-SPECIFIC PROBLEMS IN COLLECTING DATA

Although species treated in this catalog are breeding marine birds, their natural history, including their manner of nesting, varies Because of this, considerably. different methods must be used to determine numbers nesting of each species, and even for the same species at different sites (i.e., Nettleship 1976). see The confidence a user can put in the numbers recorded as nesting is This is in part thus varied. reflected in the Data Quality codes, a code system based upon the proportion of actual nests But the Data Quality counted. code is thus limited, as it may be possible to obtain a very accurate determination by counting, for example, the individual birds at a site.

NUMBERS OF BREEDING WASHINGTON SEABIRDS--SUMMARY

Eighteen species of marine birds, with minimum total populations of about 303,000 breeding birds, are discussed in It is likely that this catalog. all major colonies within the

State are presently known, though the actual sizes of populations of some species using these colonies imperfectly are very known. Although most minor colonies or nest sites are also likely known, there are almost certainly many more locations where species that nest as single pairs, particularly hole-nesters, breeding. are Species accounts (below) qive totals for these species breeding along the marine shorelines of the State, but do not include populations of any which might breed on fresh water, particularly east of Cascade Mountains. the Ringbilled Gulls and California Gulls <u>californicus</u>), in (<u>Larus</u> particular, nest in colonies in eastern Washington. The species accounts point out which species population totals are believed to be accurate. For those species that we consider existing data to be inadequate, we include of estimates actual numbers breeding in the marine habitats. estimates We feel these are realistically reasonable and conservative, and consequently we estimate a total of about 423,000 marine birds may be nesting within the area covered by this catalog.

The species accounts also indicate that the lack of sufficient historical data for virtually all species precludes any assessment of long-term population changes within the State. Only in the cases of relatively late-arriving species such as Ring-billed Gull and Caspian Tern is there information to show changes, though informed speculation can be made on populations of a number of other species.

Seven species constitute 81% of the breeding marine birds covered in this catalog. Cassin's and

Rhinoceros auklets, Leach's Storm-Petrel, Glaucous-winged and Western gulls (numbers combined-accounts), see species Common Murre and Tufted Puffin make up this group (Figure 1). This proportion uniform, is not however, throughout the various regions of the State. Four of these species breed predominantly on the outer coast, often in a few large colonies, and these species are absent or scarce east of Cape Flattery; therefore, a number of the remaining nine species become relatively much more important as nesting birds in the inland marine waters.

Figure 2 indicates where colonies of the more populous species are concentrated. Over 72% of the total estimated birds breed along the outer coast north from about Point Grenville to Seal and Sail Rocks near Neah Bay.

There are a number of colonies throughout the area generally known as the San Juan Islands and adjacent waters, and in total these form an important nesting area and are, indeed for several species, the primary known nesting area within the State.

The major nesting site in the inland waters is Protection Island, where 16% of all birds in the catalog area nest. The importance of this site (species totals are shown separately in Species Accounts Figures and in Figure 3) is evident in species accounts and the site descriptions below.

The shoreline south of Point Grenville on the outer coast has limited nesting habitat available except for accreted sand islands in Grays Harbor and Willapa Bay and the rock cliff face at the mouth of the Columbia River.

of south The inland waters Admiralty Inlet, including Puget and Hood Canal, have Sound relatively few breeding marine birds, and these are concentrated few sites which were in а unintentionally provided as а result of human activities. Nest except sites, Pigeon for limited here, Guillemots, are though factors of marine productivity and disturbance may also explain low numbers of nesting seabirds in this most highly developed and densely populated part of the State.

Although a number of species essentially nest throughout the in suitable habitats, State several species are confined to the outer coast exclusively, and this gives the State a "split personality" as far as its marine birds are concerned. Seven species breed along the coast but not in inland habitats, while none breed exclusively in the inland Some species are waters area. likely restricted to outer coast sites because suitable nesting habitat is unavailable elsewhere, but some also likely require nest sites near pelagic foraging areas.

Six species, including the least abundant species breeding in the area, Ring-billed Gull, and the abundant nesting bird, most Cassin's Auklet, are known to nest fewer than ten locations. at Fork-tailed Storm-Petrel, Brandt's Cormorant, Caspian Tern, and Rhinoceros Auklet (the second-most are also abundant species) restricted to very few nesting sites. At the other extreme, the Guillemot is the most Pigeon

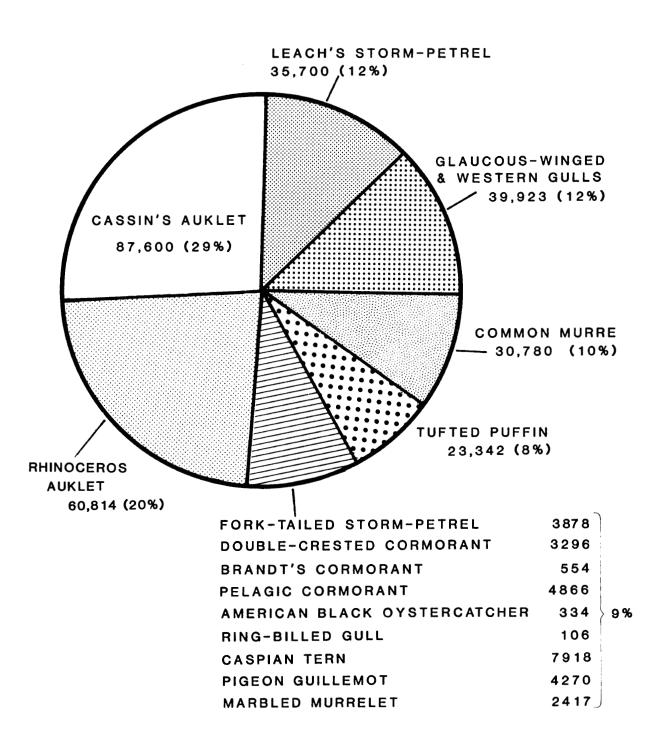

Figure 1. Populations of breeding seabirds and percentages of total aggregate population in Washington.

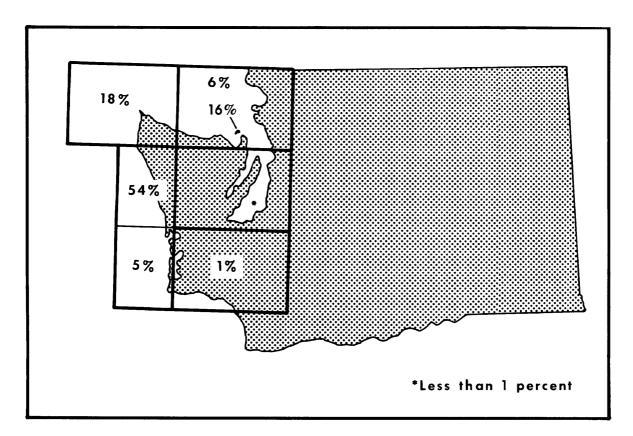

Figure 2. Percentage of breeding seabirds along the marine shorelines of Washington.

widespread nesting species, being recorded here in 148 locations but possibly actually nesting in 200 or more. Other relatively widespread species are Pelagic Cormorant, American Black Oystercatcher (with one of the lowest total nesting populations in the State for the species considered in this study), Glaucous-winged and Western gulls, and presumably, Marbled Murrelet.

If Glaucous-winged and Western gulls are considered one species or closely related species (see species account), and exceptions are made for Ring-billed Gull

(essentially an inland-nesting species) and Caspian Tern (of southern origin), species breeding in Washington's marine habitats also nest along the Pacific coast of North America from approximately northern California to This species composition Alaska. reflects similarities in climate and habitats within this long stretch of coastline.

Although breeding distribution of different species of seabirds has been related to oceanography and biological productivity in various parts of the world (e.g., Sowls et al. 1980), little attention has been given to these relationships in Washington. The associations between great variations in breeding success and variations in climatic oceanographic and to date conditions also have little received attention in Washington.

Thus far, most long-term changes in breeding seabird populations in Washington have been attributed to factors such as land use and human activity patterns and waste disposal. The species accounts below will suggest some possible Additionally, associations. studies are required on effects of pollution and fishing activities on seabird populations and implications for bird reproduction in the State.

Although historical data are minimal, there is evidence that a nesting in number of sites Washington have changed in vegetative cover over time, likely affecting nesting birds. Burrownesting birds can accelerate soil erosion and make a site unsuitable over time. Removal or loss of trees or shrub cover can eliminate soil by erosion and thus make an island unusable by burrow-nesting species while possibly benefiting species which nest on bare rock. Fire, whether from lightning strikes or human-caused accidents, habitat nesting transform can within a brief period of time. Erosion by the sea itself is occurring, continually and а number of islands used by nesting birds in Washington have shown significant changes during recent years.

Knowledge of nesting marine bird populations in Washington, particularly in any areas other than nest sites and species composition, is in early stages and there is much to learn. However, with many of the nesting sites in the State now under State or Federal ownership and management, with public interest in protecting our natural and preserving heritage highly evident, and with regulations enforcement of shoreline regarding use and discharge of pollutants, there is reason for optimism regarding the future of marine birds here. With public proper concern and education and judicious use of other resources that the birds may also require, we can meet the basic needs of the birds for food sufficient and foraging areas, roosting habitat, nesting and freedom from disturbance, and a clean environment. Populations of breeding seabirds can thus be maintained.

## **SPECIES ACCOUNTS**

Willoughby Rock (174017) 19 June 1979 S.M. Speich.

Fork-tailed Storm-Petrel (Oceanodroma furcata)

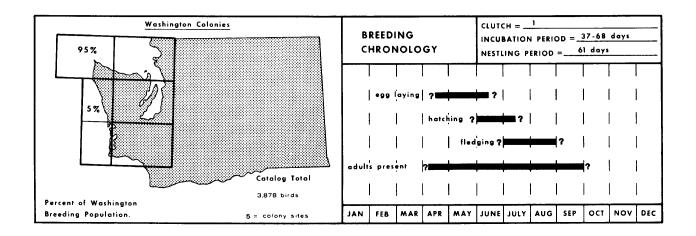

Fork-tailed Storm-Petrels are among the smallest seabirds, yet they range far from land over the mid-ocean waters. They usually feed on surface plankton, but they follow fishing vessels and forage on oil and offal when the opportunity arises. They are abundant over large areas of the cooler waters of the North Pacific and are frequently seen over the outer continental shelf waters of Washington and pelagic waters farther offshore.

Fork-tailed Storm-Petrels breed on offshore islands where they are secure from land-based predators. Throughout their range they nest in both rocky crevices and, to a lesser extent, in burrows in soil.

To avoid diurnal predators, colony activity occurs during the darkest hours of the night. Adults mate, exchange incubation and brooding duties, and feed chicks only during the night, remaining in the burrow or returning offshore by day. For this reason, storm-petrels are seldom seen near breeding colonies Their nocturnal during the day. habits make detection of colonies difficult estimation and of populations imprecise.

#### WASHINGTON COLONIES

Fork-tailed Storm-Petrels have been found breeding at five sites in Washington, all of them along the outer coast. It is possible the species is breeding at other sites, but confirmation of this is lacking because of the difficulty surveying nesting sites on of Washington's outer coast and the difficulty of finding all nests of burrowing species in general. The largest known colony is on Carroll Island where about 1,600 birds are estimated to be nesting in burrows

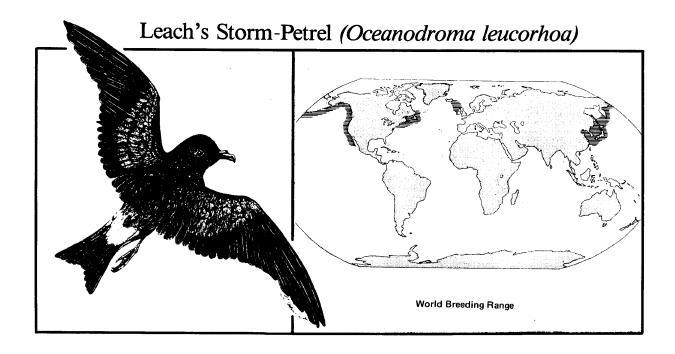

under grassy slopes. An estimated 1,900 breed on two of the Bodelteh Island group, and about 200 breed on both Alexander and Tatoosh Islands. On the Bodeltehs the birds nest extensively under deciduous shrub cover on northfacing slopes.

#### HISTORICAL STATUS AND VULNERABILITY

Virtually nothing is known of historical trends in populations Storm-Petrels of Fork-tailed nesting in Washington. Many of the seabird colonies, especially those along the outer coast in particular, have been entered only few times during the known а history of the State (some rocks with nesting colonies apparently have never been landed upon by seabird biologists), and fragmentary reports and casual estimates make meaningful comparisons impossible. However, based on recent field surveying work available habitat, we feel it is unlikely that there could be more than 3,000 additional Fork-tailed Storm-Petrels nesting in Washington.

Fork-tailed Storm-Petrels readily desert their nests if disturbed by humans during incubation or while parents are brooding recently hatched chicks. Evidence from studies of an Alaskan population shows that extremely unfavorable weather conditions or insufficient food supplies will cause parents to temporarily abandon eggs and chicks (Boersma et al. 1980). temporary Such abandonment of nests reduces viability of eggs, causes death among chicks, and lengthens the breeding season (Boersma and Wheelright 1979; Boersma et al. 1980).

These storm-petrels are most vulnerable to oil pollution during the summer months when the birds are distributed close to continents due to breeding activities (Lensink et al. 1978; Weins et al. 1978). They could be severely impacted by pollution of marine food webs at this time when they are "tied" to colony sites, though loss of prey species could have severe effects at other times. They are also vulnerable to predation at colonies by animals like river otters (Lutra candensis) when colonies are close to the mainland (Speich and Pitman 1984).

Leach's Storm-Petrels are an abundant species with an extensive breeding range around the perimeter of the North Pacific They range widely at sea Ocean. during the nonbreeding season, with birds to ranging south tropical waters both in the Pacific and Atlantic Oceans (Palmer 1962). Although they are numerous nesting а bird on Washington's outer coastal offshore islands, this species is infrequently seen away from the colonies during daylight hours.

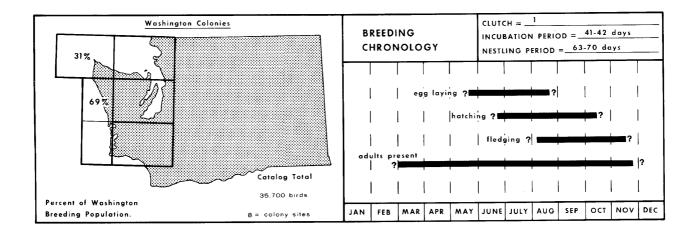

Like all storm-petrels, Leach's Storm-Petrels are nocturnal on the breeding colonies, an adaptation which reduces their susceptibility to diurnal predators such as qulls. Nests are usually located in burrows or, less frequently, in rock crevices (Palmer 1962). Like other species of Prothe cellariiformes, this one has a well-developed olfactory system (Bang 1966; Stager 1967), and

Grubb (1973, 1974) has suggested that these birds, which sometimes nest in forests, may locate their burrows by odor.

Like most seabirds, Leach's Storm-Petrels exhibit relatively long lifespans and low mortality rates for their size. Individuals that survive the hazardous first year of life can live up to 24 years and possibly longer (Graham 1980). Additional references on this well-studied species include Gross (1935), Ainslie and Atkinson (1937), Huntington (1963), Wilbur (1969), Harris (1974), Threlfall (1974), Ainley et al. (1974, 1976) and Morse and Buchheister (1979).

#### WASHINGTON COLONIES

While Leach's Storm-Petrels are known to nest in 11 colonies in Washington, there may be as many as 20 or 25 locations where nesting takes place. They burrow

under tussocks on grassy slopes, and this habitat exists where surveys have not yet been adequate or even attempted off Washington. The largest known colonies are 20,000 birds on Jagged Island and 10,000 on Carroll Island. Dhuoyautzachtahl (Petrel Rock) is estimated to have 2,600 birds nesting, Alexander Island 2,000, and while Kohchaa(uh) is listed as having "hundreds," olfactory impressions to observers approaching but unable to land on this island suggested that possibly thousands may nest there. Likewise, Cake and Rounded Islands may have thousands of nests. It is possible there may be 50,000 or more Leach's Storm-Petrels nesting in Washington.

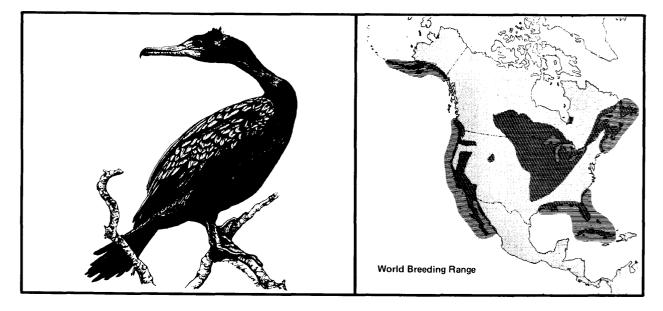

#### HISTORICAL STATUS AND VULNERABILITY

As in the case of the Forktailed Storm-Petrel and other burrowing species, infrequent and incomplete surveys and inconsistent censusing methods make assessment of historical trends of species difficult this if not impossible. Furthermore, while they are obviously more abundant as nesting birds, Leach's Stormmuch less Petrels are seen frequently than Fork-tailed Stormon boat trips off the Petrels coast during the nesting season, presumably because their preferred foraging habitat is far offshore and possibly because the species is more nocturnal in habits. This virtual lack of nearshore at-sea data offers no help in locating colonies or in making historical comparisons.

Leach's Storm-Petrels appear to forage farther offshore and over warmer waters than Fork-tailed Storm-Petrels (Wahl 1975). Their later nesting season in Washington is apparently a response to seasonal oceanographic conditions: the warm waters of the West Wind Drift come closest to the continent during July and August when young birds are hatching and being fed by adults.

Predators such as river otters can impact storm-petrel colonies along the Washington coast (Speich and Pitman 1984). Like other seabirds, Leach's Storm-Petrels are vulnerable to contamination by oil. While they may forage far offshore during the nesting season, their use of the coastal waters is only partially known (waters near nesting colonies have not been adequately sampled), and nocturnal foraging habits would

make present sampling methods inadequate in any case. They appear to be absent from Washington waters in winter, the season of greatest storms and hazards to shipping.

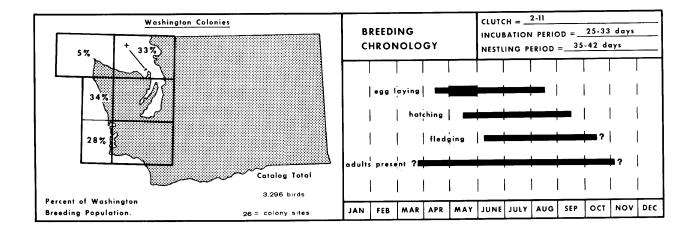

# Double-crested Cormorant (Phalacrocorax auritus)

Double-crested Cormorants are the most widespread of North They are American cormorants. the only species in the United States and Canada regularly found in freshwater habitats. Tn Washington, Double-crested Cormorants are found breeding in limited numbers inland (Jewett et al. 1953), but by far the largest numbers breed in marine habitats near and around the San Juan Islands, along the outer coast, and in Grays Harbor.

Double-crested Cormorants nest in a variety of habitats. Along the coast they nest on the exposed tops of offshore rocks, in Gravs Harbor on low sand islands around the periphery of dune grass areas, and in some though not in coastal areas, Washington, occasionally in dead trees. Those nesting inland nest in trees or snags or on islands in lakes. This species constructs nests of sticks, with inlandnesting bird also using matted vegetation gathered near the colony.

Double-crested Cormorants are sleek and strong swimmers that prey on shallow-water fish (Robertson 1974). After their sessions, fishing they are frequently seen perched on logs or rocks, extending their wings to dry. Cormorant feathers become completely saturated during underwater swimming and require periodic drying (Rijke 1968). Many Double-crested Cormorants which nest on coastal rocks and islands feed in nearby bays and rivers on the mainland. There are impressive flights of cormorants between colonies and roosts in the San Juans and the estuaries of the Skagit and other rivers in Washington (Wahl et al. 1981).

# WASHINGTON COLONIES

Double-crested Cormorants nest at about 30 locations in Wash-The marine population of ington. about 3,300 breeding birds is concentrated in three regions. About 900 nest in Grays Harbor on Goose Island. Approximately 1,100 nest along the northern outer coast at 14 locations. Another 1,100 nest in the northern inland waters at nine locations, though three colonies at the southern end of Strait--Colville Rosario Island and its adjacent "annex," Bird Rocks, and Williamson Rocks-account for almost all the nesting population. The estimate of total nesting population size is probably reasonably accurate, though shifts in colony locations can make errors possible.

#### HISTORICAL STATUS AND VULNERABILITY

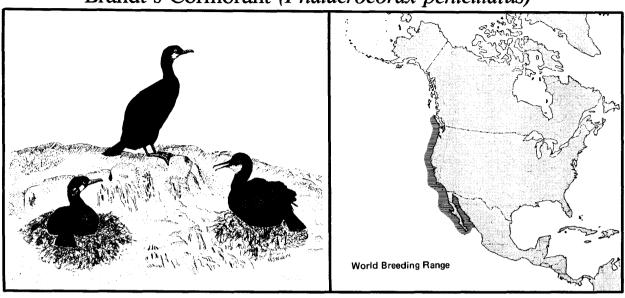

Cormorants are well known for moving nesting colonies from one location to another, and this is also true in Washington's marine waters. There are some locations where Double-crested and Pelagic cormorants are present each year, but others may have large numbers for a few years and none for another period of time. Cormorants also may shift colony sites in the middle of a nesting season. The reasons for this are unknown but could relate to human disturbance in some cases.

Numbers of nesting Double-crested Cormorants in Washington appear to However, lack of be increasing. consistent censusing over time and the shifts of cormorant colonies mean that caution is required in interpreting census numbers, even in the case of large, conspicuous birds like cormorants. Changes in availability of prey due to variations in oceanographic conditions from year to year have been suggested as explanations for very large variations in nesting 1976) numbers (Ainley in cycles California and similar undoubtedly occur in Washington.

While eggshell thinning due to pesticide contamination decreased reproductive success of cormorants in California (Gress et al. 1973), this threat has not been documented in Washington. Until recent decades, cormorants were officially persecuted as suspected predators on commercial fishes and, while policies have long been changed to protection, a bomb set off in 1980 on Bird Rocks which killed a number of Double-crested Cormorants suggests that old attitudes die hard. Since the few colonies in inland marine waters are concentrated within a very few square kilometers and are easily accessible by small boat, this type of persecution, along with disturbance due to boating, fishing, and diving, poses a potentially real danger to the nesting there. birds Human of disturbance Double-crested Cormorant colonies can be very

destructive (Ayers 1975). Cormorant eggs and chicks are vulnerable to gull predation when adults are frightened off their nests by human intrusion (Kury and Gochfeld 1975).

Little is known of the vulnerability of cormorants to oil, but few oiled birds have been found after spills in California (Smail et al. 1972). Cormorants are mobile, and it is likely they can avoid oil spills to some degree. Unlike many other seabirds, cormorants spend large amounts of time out of the water and would thus be less exposed to oil.

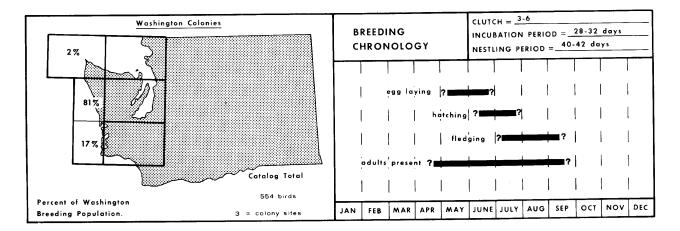

Brandt's Cormorant (Phalacrocorax penicillatus)

Brandt's Cormorants are among the most conspicuous seabirds in Washington waters during most of the year, but this species is one of the least numerous breeding birds in the State. Large numbers breed along the Pacific coast of Baja California, California, and Oregon. The northernmost sizeable colonies in the species' range are found on the western side of Vancouver Island, British Columbia (Hatler et al. 1978). There has been a small colony at Prince William Sound, Alaska, since 1972 (Kessell and Gibson 1978). Birds from these colonies apparently winter in the coastal waters and the deeper channels and passages of the protected waters of Washington. A few nonbreeders are found locally during the summer in the State, roosting and foraging in traditional cormorant habitats (Wahl et al. 1981).

Brandt's Cormorants usually nest on offshore islands or, less frequently, on inaccessible mainland bluffs and wide cliff ledges near the water above the splash zone. During the breeding season, these cormorants present a striking appearance with their bright blue throat pouches and white feather plumes on the sides of their heads. At colonies, Brandt's Cormorants are opportunistic gatherers of nesting material (Hunt et al. 1979). They collect nearby herbaceous plants and pluck seaweeds from close tidal rocks. Once nests are constructed, continual additions are made, often with material stolen from neighboring nests (Palmer 1962).

Young Brandt's Cormorants are born without feathers but soon are covered with coal-black down. Nestlings feed by inserting their heads down the throats of their parents and removing partly digested fish remains.

swimmers divers, Strong and prey Brandt's Cormorants on various species of fish (Hubbs et al. 1970; Scott 1973; Baltz and (1911) Morejohn 1977). Clay Brandt's reported Cormorants caught in fishing nets at depths as great as 70 meters. These cormorants often feed in large flocks in deep waters with strong tidal currents and frequently feed with loons, gulls, murres, and other alcids (Wahl et al. 1981).

## WASHINGTON COLONIES

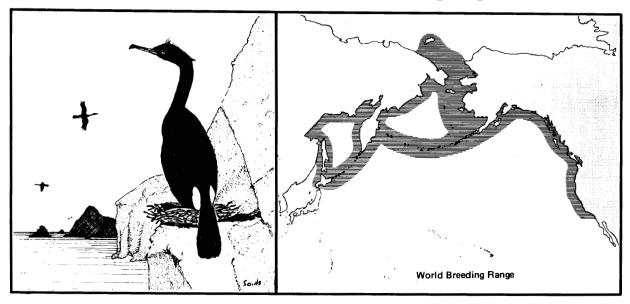

While Brandt's Cormorants often large colonies elsewhere, form they nest in small numbers in Washington. There are only four sites recently used for nesting by this species in Washington, all on These include the outer coast. the cliffs at Cape Disappointment, Paahwoke-it, Willoughby Island, The estimated and Split Rock. number of Brandt's total Cormorants nesting in Washington is probably reasonably accurate.

#### HISTORICAL STATUS AND VULNERABILITY

This species apparently has never been numerous or widespread as a breeding bird in Washington. Historically, there are reports of birds nesting at Paawoke-it and Grenville Arch and Sea Lion Rock in 1906/1907 (Dawson 1908) in small numbers.

Brandt's Cormorants are believed have suffered reproductive to failure from thin eggshells caused pesticide accumulation of by (Hunt et al. 1979), residues though whether the same situation may have occurred in Washington is unknown. Cormorants in North have generally been America by human disturbance, affected nesting during the especially Adults flush from their season. nests readily when approached by low flying aircraft, or boats, humans on foot. Once parents are away from the nests, gulls are able to prey upon eggs and chicks. Repeated disturbance can cause permanent colony desertion.

Observed cormorant deaths from oil spills are not frequent (Wahl et al. 1981), and it may be that cormorants, which spend proportionately more time out of the water than other diving birds, avoid oil spills more easily. However, the relatively low numbers of oiled cormorants found on beaches could be due to a sink because they lack the water-greater tendency of cormorants to proof plumage of other seabirds.

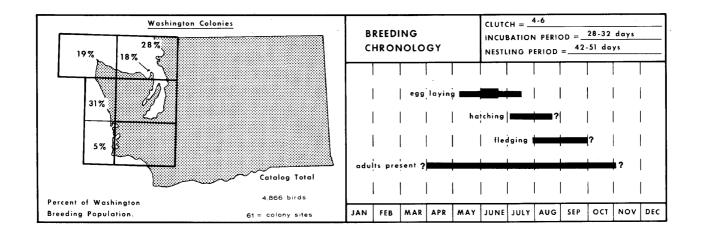

Pelagic Cormorant (Phalacrocorax pelagicus)

Pelagic Cormorants are the most widespread nesting cormorants in Washington and, while they are seldom seen in large flocks like Brandt's Cormorants or Doublecrested Cormorants, they are commonly seen foraging in many areas along the outer coast and inland marine waters of Wash-These small cormorants ington. can be seen at any season along rocky shorelines around kelp beds and tidal channels where they propel themselves underwater with their strong webbed feet in pursuit of fish and shrimp (Robertson 1974; Hatler et al. 1978). Clay (1911) reported that Pelagic Cormorants are capable of diving to depths of up to 140 meters.

Pelagic Cormorants nest in solitary pairs, scattered groups, and colonies of up to hundreds. While some sites appear to be traditional and are occupied each year, the locations of others may

shift from one year to the next (Benz and Garrett 1978; Nysewander and Barbour 1979). With nests anywhere from hundreds of feet above the ocean to just within the zone, Pelagic Cormorants spray raise their young in platform nests of seaweed built on small outcrops and ledges. These cliffside colonies stand out because of the summer whitewash they receive and can be seen for great distances. In Washington, Pelagic Cormorants also nest inside sea caves on narrow ledges, on vertical cliff faces, on top of dolphins (at Port Angeles), on abandoned piers, and on an offshore navigation marker tower.

Pelagic Cormorants often are found nesting other near cormorants. In these locations, direct competition is apparently by staggered reduced nesting by differences in chronologies, nest site selection, behavior, and

in selection of food types, sizes, and feeding locations (Robertson 1974; Benz and Garrett 1978).

## WASHINGTON COLONIES

Pelagic Cormorants nest in suitable locations along the entire coast of Washington, from the northern San Juan Islands and the Strait of Juan de Fuca south along the outer coast to Cape Disappointment at the mouth of the Columbia River. They nest at 63 locations, most of them on offshore rocks, islands and humanmade structures; relatively few nest on mainland cliffs. While there are many small colonies, a few larger ones at Cape Disappointment, Paahwoke-it, Tatoosh, Protection, Smith, Colville, and Castle Islands make up almost onehalf of the total nesting population. The total estimated nesting population is likely reasonably close to actual numbers.

HISTORICAL STATUS AND VULNERABILITY

Pelagic Cormorants were noted by the earliest of the naturalists who visited Washington. The colony at Cape Disappointment, for example, appears to have been active for over 100 years. However, the tendency of this and other cormorant species to shift breeding locations makes interpretation of historical records, which lack simultaneous, statewide coverage, difficult if not impossible.

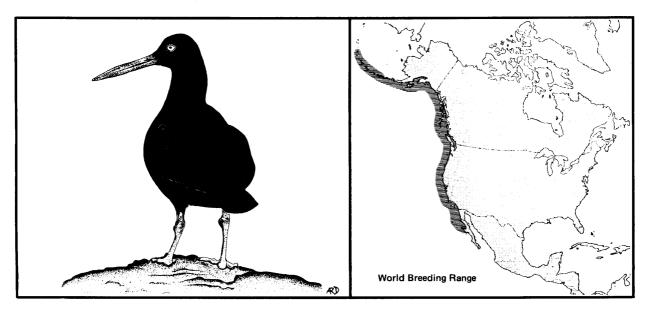

This species and the Doublecrested Cormorant both suffered depressed populations in the past when cormorants were not protected because they were considered a menace to commercial fishing.

Shoreline use and development pose threats to cormorants. They can be easily disturbed by any activity human near colonies. Approach to nesting birds by aircraft, boats, and humans on foot may force adults off their and young leaving eggs nests, chicks unprotected. Chicks and eggs may be knocked from nests by with gulls, frightened adults, crows, and ravens then preying on eggs or young. Eagles also visit colonies in Washington frequently and, while they are mobbed by

gulls on such occasions, they may prey on young cormorants.

Pelagic Cormorants, like other members of the order Pelecaniformes, may be vulnerable to pesticide pollution. The eggshell thinning, egg breakage, and subsequent nesting failure and population declines experienced by other species in California (Gress et al. 1973) have not been documented for this species (Hunt et al. 1979).

Oil spills have resulted in few known cormorant deaths to date in Washington (Richardson 1956). Because of their widespread distribution and ability to shift colony sites, Pelagic Cormorant populations may be relatively resistant to localized oil slicks. Their habit of spending nights and much of the day roosting out of the water may reduce vulnerability to oil pollution (Smail et al. 1972).

Black Oystercatcher (Haematopus bachmani)

Black Oystercatchers are distinctive shorebirds inhabiting the rocky shorelines of the coast from Baja California to the western Islands. Adults Aleutian establish breeding territories on offshore rocks and islands and occasionally on mainland rocky beaches. An oystercatcher nest, composed of a scrape lined with and shell fragments, pebbles is difficult to find. One to cryptically-colored three eggs are placed directly on the pebbles.

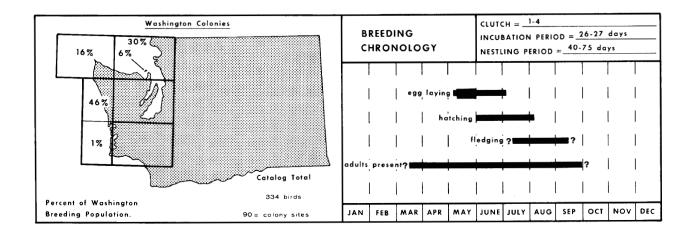

The young oystercatchers are precocial and may leave the nest within hours of hatching. A1though they remain near the nest the first few days, chicks later follow adults to intertidal foraging areas. The food consists of mussels (Hunt et al. 1979), limpets, and chitons; chicks may crabs (Hartwick 1976; be fed Helbing 1977).

Mortality among eggs and chicks is apparently high. Hartwick (1974) lists gull predation as an important cause of mortality. In addition, chicks and eggs are frequently "washed overboard" from nests by storm waves.

During the winter, oystercatchers are gregarious (Wahl et al. 1981), and flocks may be found roosting in some localities. In the San the entire popu-Juan Islands, lation may gather into three or four such flocks (Wahl et al. strange, With their 1981). vermillion-colored bills, pale pink feet, and loud, distinctive crow-sized black calls, the oystercatchers are a characteristic species of exposed rocky shorelines in Washington.

## WASHINGTON COLONIES

Black Oystercatchers are a noncolonial nesting species nesting

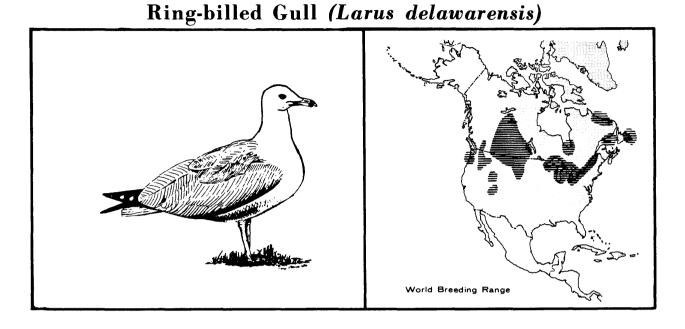

at about 100 different locations in Washington. They are usually found on the same offshore islands and rocks as colonial nesting species. They establish large nesting and feeding territories distribute and thus themselves along the available coastal habitat. While censusing nesting oystercatchers can be difficult because approach must be close enough to initiate a reaction from territorial adults, the catalog total for the inland marine waters is probably quite accurate because calm waters and limited size of the study coverage area made thorough. Numbers for the exposed outer coast are probably less accurate due to more rigorous conditions and lower sampling effort there. We feel the total breeding population for the State is unlikely to be more than 400 birds.

# HISTORICAL STATUS AND VULNERABILITY

The Black Oystercatcher was among the first birds reported in Washington when Menzies (1792) found and ate birds on Smith Islands on 6 June 1792. Black Oystercatcher populations in Washington have probably been relatively stable over historical time, though numbers may be somewhat higher on the outer coast due to abandonment of lighthouse stations and other human uses of islands under now refuge protection. Numbers in inside waters may have declined due to increased human activities, but reports of nesting attempts at sites where the species had previously been unreported may mean the species is reoccupying its original range or expanding into new areas.

These birds require clean and undisturbed rocky coastlines for nesting and feeding. то the extent that these areas are disturbed by humans, reproductive success will be reduced. Oil spills, which foul rocky coastlines where oystercatchers feed within the narrow band of intertidal exposure, could seriously affect their food supplies, but losses from direct oiling would probably be low. Long-term degradation of intertidal habitat would almost certainly cause population decline.

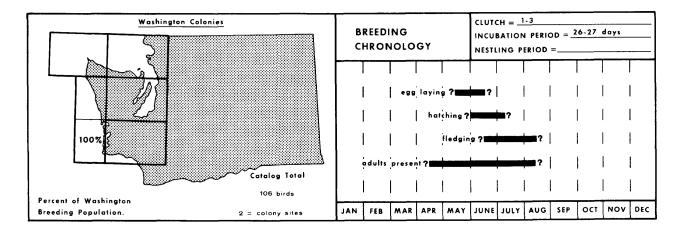

Ring-billed Gulls nest throughout much of inland North America, but they are a relatively recent addition to the list of seabirds marine habitats nesting in in Washington. They nested in the Columbia Basin areas in central Washington as early as 1930 (see Jewett et al. 1953) but have been recorded nesting in Willapa Bay (Penland since 1976 and only This Jeffries 1977). lightblack wingtipped gull mantled, with yellow legs is a relatively common migrant in inland marine in Washington. Ringwaters billed Gulls nest colonially offshore on low-lying sandy islands that are relatively secure land-based predators from and disturbance. They have shown less adaptability in nest site selection than Glaucous-winged and Western Gulls and are much more restricted in breeding range in Washington.

Like other gulls, Ring-billed Gulls feed on almost anything, including fish and other aquatic organisms, and insects and grubs foraged in plowed fields, sewage, and garbage. They may land in trees to eat fruit. This species fields is more often seen in in during the winter western Washington than in marine habitats.

# WASHINGTON COLONIES

Ring-billed Gulls on Gunpowder Island nest in a densely packed group in the middle of the Glaucous-winged Gull colony near Caspian Terns. Penland and noted Jeffries (1977)birds nesting in the tern colony itself on Ellen Sands. The existing colony is somewhat precarious as are all those on the exposed, lowlying sandy islands in Willapa Bay

and Grays Harbor, which may be altered or destroyed by winter storms. The estimate of numbers of breeding birds in western Washington is likely quite accurate at the time of the most recent survey. The species may also nest at Sand Island, though their recent status there is unknown.

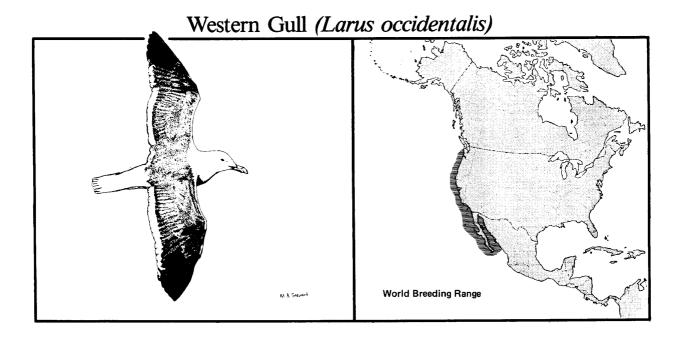

HISTORICAL STATUS AND VULNERABILITY

Like other species "large" of gulls, Ring-billed Gulls are adaptable, gregarious, and opportunistic. have They increased in numbers as garbage and sewage from human populations have increased, and have exploited new food supplies resulting from agricultural operations and the

prey populations of insects and other animals provided by massive irrigation projects in what were deserts prior to the 1930's.

Ring-billed Gulls are sensitive to disturbance on nesting sites, though these sites at present are generally secure in western Washington because of relative inaccessibility to humans. Like other species using the accreted sand and gravel spits, they can be severely impacted during nesting by storm waves flooding nests or even obliterating nesting islands.

While studies to date have not determined the extent of competition for nest sites with larger Glaucous-winged and Western Gulls, this may limit the population growth of this species in western Washington.

Western Gulls reach the northern edge of their breeding range on the outer coast of Washington at about Destruction Island. However, Glaucous-winged Gulls are sympatric with Western Gulls, and hybrids of the two are found well to the north and into the inland marine waters of the State (see Hoffman et al. 1978).

Western Gulls nest in a variety of habitats, but in Washington the most frequently used nest sites are on offshore rocks and islands, and on several accreted, low, sandy islands in Grays Harbor and Willapa Bay. Birds nesting on the mainland select areas, such as steep slopes and cliff faces, inaccessible to predators. The nests are substantial and usually made from vegetation collected The normal clutch is nearby. three eggs.

Like most of the large gulls, Western Gulls feed on a variety of prey, including fish, euphausids and other plankton, and fishing discards and offal. They are opportunistic feeders, of course, and forage readily at garbage dumps and fish-processing plants.

#### WASHINGTON COLONIES

Western Gulls are concentrated at colonies along the southern Wash-However, we have ington coast. not separated Western Gulls from Glaucous-winged Gulls in population estimates, and thus numbers the latter species for given large proportion of include a Western Gulls, at least in the colonies from Destruction Island south to the Columbia River. This is due to the fact that, though Dawson (1908b) recognized that different forms were present, few have since then observers differentiated between the two, perhaps because the extent of hybridization (see Hoffman et al.

1978) makes identification of many individuals difficult. Observer variability and differences in what are considered "pure" forms and "hybrid" forms further add to the confusion of field deter-This subject minations. is discussed at length by Hoffman et al. (1978), and K. Richter (pers. comm.) gives additional ideas of proportions of the two species or forms at the colony at East Sand The population of large Island. gulls nesting from Destruction Island south, about 12,000 birds, might include about 6,000 to 8,000 Western Gulls.

#### HISTORICAL STATUS AND VULNERABILITY

Western Gulls and Glaucouswinged Gulls are probably the least likely of Washington population seabirds to suffer declines as a result of human Their populations activities. substantially over have grown recorded history (Thoreson and Galusha 1971); and while changes in human garbage and sewage disposal methods may limit these food sources, gull populations remain at a high level and may still be increasing. Increases in numbers of large gulls may cause safety problems around airports, and gull predation and competition may reduce populations of other seabirds.

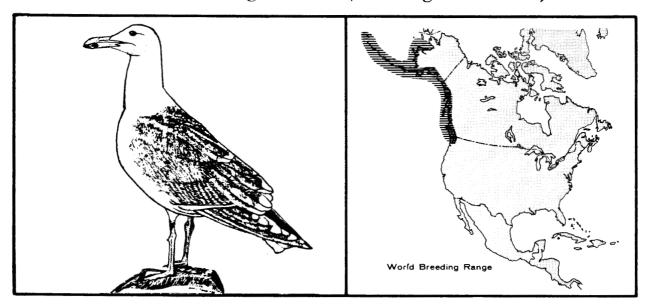

Increases in the size of several populations of large gulls have been attributed to the availability of human food wastes and sewage (Vermeer 1963; Kadlec and Drury 1968; Drury 1979). Both Herring Gulls (<u>Larus argentatus</u>) and Great Black-backed Gulls (<u>Larus marinus</u>) in eastern North America have increased in number and caused substantial damage to tern and Atlantic Puffin (<u>Frater-</u> <u>cula arctica</u>) colonies by usurping optimal nesting habitat, stealing food, and eating eggs and chicks (Nettleship 1972; Nisbet 1973).

Populations of Western Gulls in Washington appear to have increased during the past 100 years, but there are no data to support this from the early explorations on.

The effects of gull populations on other seabirds are difficult to Western Gulls are the assess. most important predators on stormpetrels and Cassin's Auklets on the Farallon Islands in California (Manuwal 1974b; Ainley et al. the situation in 1974), and Washington is likely similar. Large gulls kleptoparasitize cormorants, Rhinoceros Auklets, and probably Tufted Puffins. Rates of incidence are unknown, but are probably higher and effects on other seabird populations more severe at present than in the past when gulls were less abundant.

Large gulls are probably less vulnerable to oil spills than other seabird species nesting in They are highly Washington. mobile and frequently return to land to rest and roost. They are susceptible, like other surfacenesting birds, to disturbances while nesting. Disturbance in a particularly dense colony may result in intraspecific pirating of eggs and cannibalism. Chicks frightened from their territories may be killed by neighboring gulls lost or become and starve. However, with many nesting sites either in refuge status or inaccessible, populations of the large gulls nesting in Washington will probably continue at high

levels. relatively	high reproductive	ability to feed on a wide variety of prey, the large gulls would
potential, nonbreeding	an excess of adults, and their	likely make a rapid recovery from any decline.

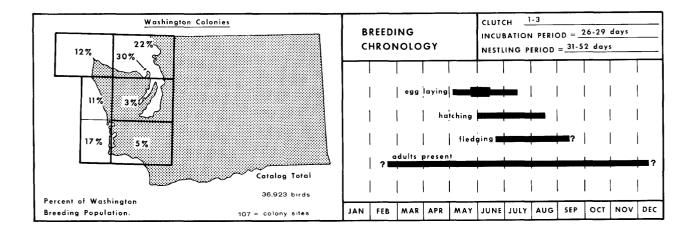

Glaucous-winged Gull (Larus glaucescens)

The Glaucous-winged Gulls nest around the perimeter of the North Pacific Ocean, from the area of Destruction Island off Washington to northern Japan. They are the most abundant and widespread gull nesting in Washington and the one most familiar to most people. Glaucous-winged Gulls and Western Gulls hybridize, and the varied plumage characteristic of many large gulls hatched in Washington display this to the confusion of many observers.

Like Western Gulls, Glaucouswinged Gulls nest in many different habitats and situations, from rocky islands off the coast to accreted gravel spits, roofs of downtown buildings in Seattle, abandoned piers, inaccessible dolphins at ferry docks, and log piles at sorting yards. Some of the largest seabird colonies in Washington are those of the Glaucous-winged Gull. The combined colonies of this species and the Western Gull total up to more sites than any species except the Pigeon Guillemot.

Glaucous-winged Gulls are omnivorous in their feeding habits and range from open-ocean diets of fish and other natural foods to fishing vessel discards, anchovies, and intertidal organisms like starfish, crabs, They have become and clams. accustomed to foraging at garbage dumps, sewage ponds, and outfalls and to following plows for grubs and organisms. Glaucousother winged Gulls commonly feed on earthworms that come to the surface in farm fields and athletic fields saturated by winter precipitation. They have become closely associated with humans in many situations and boldly approach picnic tables, fishing piers, and bird feeders in many places in western Washington.

#### WASHINGTON COLONIES

Glaucous-winged Gulls breed at virtually any suitable location along the shoreline of the State. They are essentially absent as nesting birds along the exposed sand beaches from North Head, near the Columbia to Point River, Grenville the coastline where becomes suitable. They do not nest along the Strait of Juan de Fuca between Seal and Sail Rocks And, while there and Dungeness. are colonies on piers and other waterfront situations in Seattle, Olympia, Tacoma, and Shelton, there are very few nesting in Puget Sound in "natural" situations south of Colvos Rock at the The entrance to Hood Canal. largest colonies in the State, a number of which include Western Gulls and intergrades between the two species, are at Protection, Gunpowder, Tatoosh, East Sand, Colville, Smith and Minor, Carroll, and Destruction Islands.

#### HISTORICAL STATUS AND VULNERABILITY

Glaucous-winged Gulls steal food from other seabirds, particularly

They also birds nesting nearby. young birds of many prey on alcids species, including and Oystercatchers. Con-Black have probably sequently, they suppressed populations of other species as Western Gulls have in California (Sowls et al. 1980) and large gulls have in eastern North America (Nettleship 1972; Nisbet 1973).

Like the closely related Western Gull, this species has increased in recorded in numbers time. taking advantage of increased food availability in the form of garbage, waste and discards from fisheries activity and sewage, and protection through from also shooting, feather collecting, egging, automation of lighthouses, and establishment of refuges for nesting of areas. maintenance While population data are limincreases in nesting ited. populations at several inland Washington colonies are documented (Thoreson and Galusha 1971), and qualitative observations by many observers indicate the trend has been area-wide.

Glaucous-winged Gulls appear to be less vulnerable to effects of oil spills than other, more specialized marine birds, which spend more of their lives in the water, which dive for prey, and are less adaptable to changing conditions. However, the species, like all surface-nesting birds, is vulnerable to disturbance while nesting; and high mortality may result from entry of humans and dogs into colonies during times when there are chicks in the nests. Disturbance at this time

can easily result in chilling of eggs or chicks, chicks leaving home territories and being killed by neighboring gulls, and eggs being stolen by crows. For the most part, however, since large gulls are adaptable, opportunistic, and aggressive, populations of large gulls in Washington appear likely to be maintained at current levels, at least for the foreseeable future.

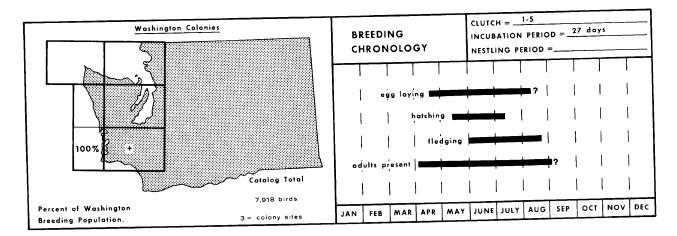

Caspian Tern (Sterna caspia)

Caspian Terns are one of the largest and most widespread species of terns in the world. They are found in both the temperate Northern and Southern hemispheres. On the west coast of North America they nest as far north as Grays Harbor in Washington and inland as far north as Great Slave Lake in Canada. The nesting population in Washington is now by far the largest on the west coast north of Mexico, with only a few hundred birds recorded breeding in California (Sowls et al. 1980).

The species was recorded nesting in central Washington near Moses Lake in 1930 (see Jewett et al. 1953). About 1957 it was found nesting in Grays Harbor (Alcorn 1958) and has become established one of the most abundant as nesting marine birds in Willapa Bay and Grays Harbor since then. The spread of this species has been remarkable, both as a nesting bird and as nonbreeders and postbreeding dispersants. Godfrey (1966), for example, felt it unusual in British Columbia; in recent years, however, adultplumaged birds are numerous in spring and early summer in many locations in western Washington and British Columbia.

Caspian Terns nest on low sand or gravel islands accreted by wave action and usually with a minimum of vegetative cover. Two to four eggs are laid in a small depression in the sand lined with bits of vegetation. Like other terns and gulls, this species is a colonial nester, and it nests near gulls in many situations.

This large tern apparently feeds almost exclusively on fish, which it catches by plunging from several meters above the surface, frequently submerging in order to secure the prey. Smith and Mudd (1978) found Caspian Terns had

delivered small perch, chum salmon, staghorn sculpin, and other fishes to nestlings in Grays Harbor in May and June. The birds probably also feed on species like anchovies which are extremely abundant at other seasons in the area.

#### WASHINGTON COLONIES

Since the discovery of nesting Caspian Terns in Washington, the species has shifted colony sites, likely due to changes in available nest site habitat. Goose Island, site of the first known colony, Sand and Whitcomb Islands in Grays Harbor, and Gunpowder Island in Bay Willapa have all been occupied, but the terns recently (1982) nested only on Sand and Gunpowder Islands. It is possible earlier in the species nested western Washington as it has been recorded for many years (Jewett et al. 1953) during the summer in marine habitats.

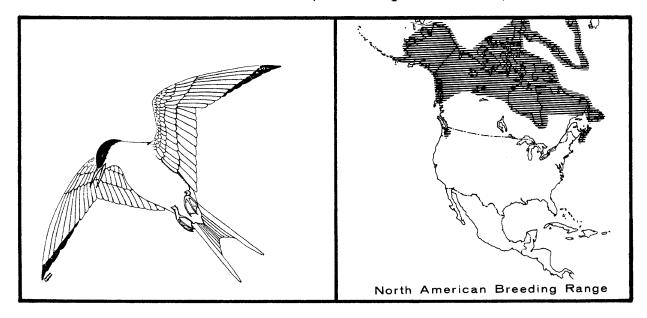

# HISTORICAL STATUS AND VULNERABILITY

The Caspian Tern is present in relatively large numbers in

during the Washington western Its harsh cries nesting season. and the begging call of chicks following adults are now among the most conspicuous seabird sounds in Grays Harbor and Willapa Bay summer and into during the September. However, while Caspian have increased at rates Terns probably greater than Glaucouswinged or Western Gulls in recent years, they are much more precarious in their existence as nesting birds in Washington. This is due to their being much more vulnerable to disturbance on the nesting colonies, to habitat loss, and to disruption of food webs. Most colony sites are protected, but entry by boaters, fishermen, sightseers, and researchers with unfamiliar biology and behavior of terns are potential The islands used for threats. nesting are vulnerable to ravages of winter storm waves which have created, moved, and eliminated the sites over time. Caspian Tern during their even colonies, brief history in relatively Washington, have relocated several sometimes inexplicably. times, The first known colony on Goose Island peaked in numbers in 1970, and no birds were found there Whitcomb Island after 1976.

presumably received the Goose Island population starting in 1974, with numbers building to 2,000 by 1976, but by 1981 the terns were gone from there. Sand Island was chosen in 1976, with large numbers present in 1982, when 3,000 birds were also found on Gunpowder Island in Willapa Bay. While food resources appear to be adequate and stable for this species, disruption or contamination of these could have profound effects on the status and abundance of nesting populations using Washington's marine waters.

Arctic Tern (Sterna paradisaea)

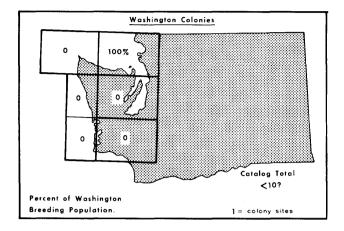

Arctic Terns generally nest in western North America in Alaska and northern Canada and migrate at sea to winter in the Southern Hemisphere. They appear on the list birds nesting in of Washington's marine habitats due to an extremely unusual nesting in 1977 occurrence and 1978 et al. (Manuwal 1979a). It appears that the species does not nest in the State at the present time.

Arctic Terns are small terns, generally gregarious in nesting habits and in foraging behavior and migration. They nest in open areas on tundra, sand and gravel shorelines, or islands, laying two eggs in a scrape. They are aggressive in nest defense and attempt to drive off suspected predators with harsh calls and diving attacks, sometimes striking vigorously.

Like other similar small terns, this species seeks its prey of planktonic fish and small organisms by searching above the sea surface, hovering and plunging to strike below the surface, and emerging quickly to take flight Unlike gulls, terns (even again. pelagic species like this one) seldom are seen resting on the water. During their migration at sea, Arctic Terns may be seen resting on floating logs and debris.

## WASHINGTON COLONIES

A small group of Arctic Terns nesting at the gull colony on Jetty Island, a dredge-spoil island off Everett harbor, in 1977-1978 represented the southern-most known colony of this species in western North America (Manuwal et al. 1979a).

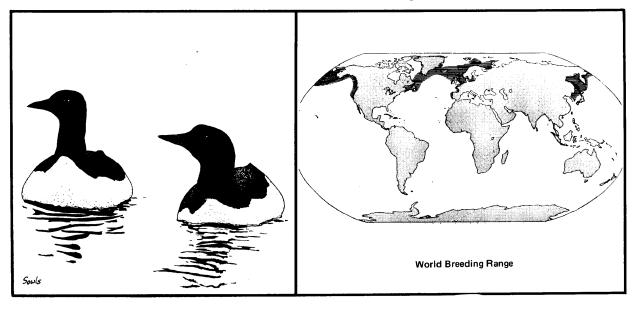

# HISTORICAL STATUS AND VULNERABILITY

Checks of the Jetty Island colony site subsequent to 1978 (Richter, pers. comm.) have failed to find Arctic Terns there, and it is doubtful the species is nesting in Washington presently. Whether or not Arctic Terns reoccupy this site may depend on its preservation in suitable form.

Terns are extremely vulnerable to disturbance on nest sites, and wholesale flights and colony abandonment are recorded, resulting from what might be minimal disturbance to other species like gulls. It is unknown whether disturbance from recreation caused abandonment of one Washington colony or the whether this small outlier colony, far outside the species' normal simply range, was abandoned. Because terns feed principally on fish other marine small and organisms and apparently do not shift to other foods, they are much more vulnerable to perturbations in food supply or to contamination of food webs.

Common Murre (Uria aalge)

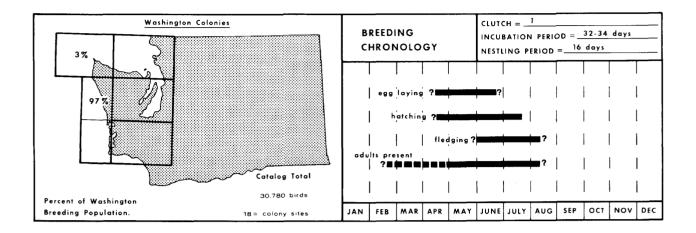

Common Murres are among the most colonial of seabirds. highly Their colonies, usually on rocky offshore islands, are often densely packed with noisy birds, nesting just out of the pecking range of neighbors. Common Murres occur in both the North Pacific and North Atlantic Oceans and are among the most numerous seabirds in the northern hemisphere.

Common Murres prefer to nest on wide, flat cliff ledges and the tops of islands, but they also nest on narrow ledges of vertical A large, single egg is cliffs. laid on bare rock or soil. It is narrowly pointed on one end and broad and rounded on the other. Murre eggs vary greatly in color, ranging from white to buff, brown, reddish, blue, or green. They are almost always marked with dark dots, blotches, or intricate scribbling (Harrison 1978). The unique pattern of each eqq probably aids individual recognition by adults (Johnson 1941).

Murre chicks are fed by both parents and jump from the colonies to the waters below when only partly grown (Tschanz 1968). They are accompanied at sea by only one parent, usually the male (Varoujean in Sowls et al. 1980), swimming from the nesting area to wintering grounds. Observations suggest this may be from colonies along the Oregon coast to Puget Sound in Washington.

Common Murres are strong fliers and are capable of foraging long distances from their colonies. They dive to considerable depths and include fish, crustaceans, and cephalopods in their diet (Ogi and 1977). Common Tsujita 1973, Murres may be seen along the outer coast of Washington during all Larger year. the months of present from fall numbers are

through winter when numbers also are present in the deeper habitats of the inland marine waters.

# WASHINGTON COLONIES

Common Murres nest at 18 locations along Washington's outer coast from Erin's Bride north to Tatoosh Island at the entrance to the Strait of Juan de Fuca. The largest numbers found are at Willoughby Rock (5,300), Split Rock (10,400), Grenville Arch (5,000), and Rounded Island (2,200). While these larger colonies are probably used each year, murres also appear to shift nesting colony sites; assessments of populations require monitoring of all possible locations.

Colonies of murres are easy to find but are difficult to census. Variables such as time of year, time of day, and the unknown breeding status of many individuals complicate the task. The estimates of murre numbers presented in this catalog represent the number actually counted and make no allowance for members of breeding pairs that may be away from the colony. Ainley (1976) estimated that two-thirds of the total number of birds actually nesting may he away Thus our during some censuses. estimated totals may be somewhat We feel, however, that all low. sizeable nesting sites have been found. The Common Murre is much less numerous, perhaps as а function availability of of suitable nesting habitat, as а breeding bird in Washington than it is in California, Oregon, British Columbia, or Alaska.

## HISTORICAL STATUS AND VULNERABILITY

Due to very infrequent surveys in until recent years, trends of populations nesting Common Murres in Washington are not Differences in census known. methods and incomplete coverage of the coastline by many observers impossible. make comparisons While in the case of Tatoosh Island there is less human presence due to automation of the light station, themurre population there is relatively small in comparison with the larger colonies elsewhere. The amount of egging carried out on murre colonies in the past is unknown, but this could have depressed populations in the State as it did elsewhere.

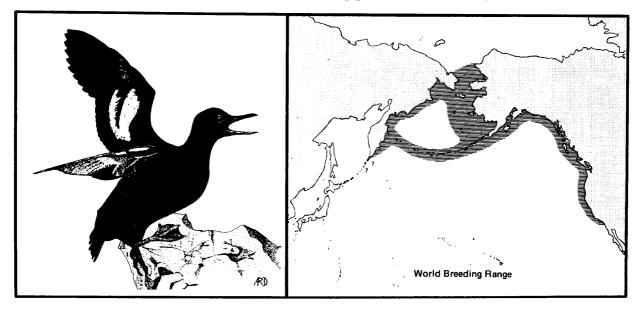

Nesting Common Murres are very sensitive to disturbance by boats, low-flying aircraft, and humans on foot. When disturbed, adults flush from the colonies and may knock eggs and chicks from nest The remaining chicks and sites. eggs are subject to increased predation from gulls, ravens, and Common Murres are highly crows. vulnerable to oil contamination and were some of the most frequently oiled birds in the 1971

San Francisco oil spill (Smail et They are common in al. 1972). outer coastal waters off Washington throughout the year and in inside waters in winter. Since they spend virtually all their nonbreeding lives in the water, forage by diving, and congregate both around colonies on the water and in flocks during the rest of the year, they are among the most vulnerable of marine birds to oil spills. Murres also have suffered heavy mortality in gill nets (see DeGange and Newby 1980). Net mortality to murres has been observed in Washington, but the magnitude and impact on local nesting populations is unknown.

# FIELD NOTES

The authors would appreciate copies of your field notes for updates

Pigeon Guillemot (Cepphus columba)

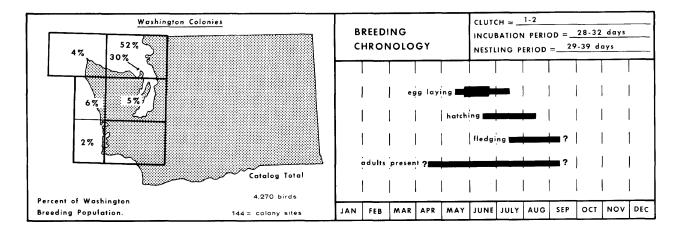

Pigeon Guillemots inhabit the relatively shallow nearshore zone and are usually found along stretches of rocky shoreline. They are most easily observed in the early morning, before the egg laying season, when both members of each pair frequent waters adjacent to their colonies.

This species usually nests in natural rock crevices, talus, and boulder beaches (Thoreson and Booth 1958; Drent 1965). In the inland marine waters of Washington, birds also frequently nest under drift logs on beaches that are relatively undisturbed and free from land predators. They also use burrows dug into loose conglomerate bluffs and artificial structures such as wharf timbers and drain pipes. On one island formerly used for practice bombing, they have nested in spent bomb casings.

The Pigeon Guillemot is one of the few alcids which regularly lays two eggs (Bent 1946; Thoreson and Booth 1958; Drent 1965). Eggs are laid on bare rock, soil, or sometimes on a bed of pebbles and shell fragments. Guillemots usually feed close to shore, and the feeding the proximity of grounds to the colonies may explain their ability to sometimes raise two chicks. Pigeon Guillemots, like all members of the family Alcidae, dive for food by using wings for their propulsion. Fish the are principal food of guillemots.

Following breeding, Pigeon Guillemots apparently move away from some areas where they are common during the summer. Winter distribution is presently uncertainly known, and determination of the seasonal range of this important breeding species is highly desirable.

#### WASHINGTON COLONIES

In Washington, Pigeon Guillemots are perhaps the most widespread nesting seabird. While they are absent from shallow estuaries and sandy beaches, they are opportunistic and take advantage of suitable nesting possibilities like crevices in the jetties at the Grays Harbor entrance. While there are sizeable breeding "colonies" or aggregations at well-known sites like Protection and Sucia Island Island, many quillemots nest in scattered locations and often in small numbers. Delimiting concentrations for much of Washington's coastline is difficult; while we have described this species' subsurface nesting locations as precisely as possible, we have also given breeding-season population size and location by subregions (bays or stretches of coastline) without reference to precise nesting locations in order to show relative abundance and estimate total breeding popula-(see tions Appendix С for estimates derived from two surveys conducted in inland waters).

The catalog total for this species in Washington is 4,270.

While given censuses or subregion totals may be high or low, we feel the overall total is conservative because of birds missed during Censusing Pigeon censusing. Guillemots is an inexact science at best and is complicated by many factors (see Methods). We have used the best recent estimates here, though we feel there may be about 33% more nesting in the inland waters, particularly in the San Juan's and adjacent areas, and perhaps 50%-75% more nesting along the outer coast than are listed There may be about 6,000 here. Pigeon Guillemots breeding in Washington.

#### HISTORICAL STATUS AND VULNERABILITY

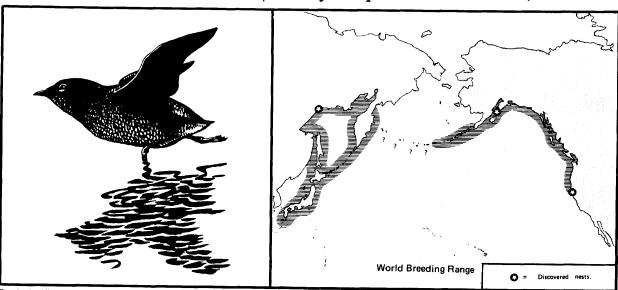

While there are many records for many years many sites over Pigeon Guillemot describing populations--the first breeding nesting observations date to May (Menzies 1792)--it is 1792 difficult to determine actual population trends because of problems involved in field censusing, timing, geographic coverage, and access.

Compared to other seabirds such as murres and cormorants, Pigeon Guillemot populations are not highly prone to disturbance, primarily because of their comparatively low nesting densities and inaccessible nest sites. However, individual pairs will readily desert their nests if disturbed during nesting or brooding.

Like murres and other alcids, Pigeon Guillemots are very

vulnerable to oil pollution. Guillemots spend large amounts of time on the water, usually close to shorelines and in shallow waters where oil development, transfer, and processing take place. While local populations could be severely impacted, the wide distribution of the species would likely mean impacts would be less than in the case of some other species. FIELD NOTES

## Marbled Murrelet (Brachyramphus marmoratus)

Drawing by Allan Brooks, compliments of The Murrelet, A Journal of Northwest Ornithology and Mammalogy.

#### NOTE

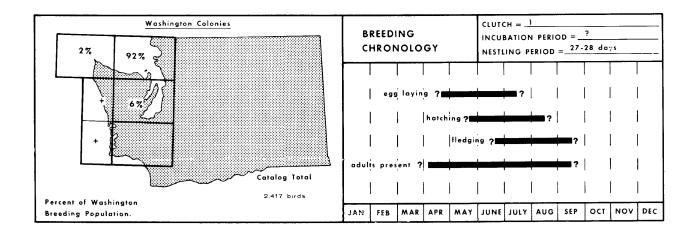

On January 15, 1988, the U.S. Fish and Wildlife Service received a petition from the National Audubon Society to add the Marbled Murrelet in California, Oregon, and Washington to the List of Endangered and Threatened Wildlife and Plants. A preliminary finding that the petitioned action may be warranted was published in the *Federal Register* on October 17, 1988. Further review is pending.

For additional information on this species, consult the following:

Marshall, D.B. 1988. Status of the Marbled Murrelet in North America: with special emphasis on populations in California, Oregon, and Washington. U.S. Fish and Wildlife Service Biological Report 88(30). 19 pp.

Copies of the publication may be obtained from the Publications Unit, U.S. Fish and Wildlife Service, Washington, DC 20240, or may be purchased from the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, VA 22161.

Marbled Murrelets are the least known, as to their breeding habits, of all the birds nesting in Washington. One of the earliest clues of their nesting habitat resulted from an egg found in Whatcom County, Washington (see Kiff 1981), but they remain for all intents and purposes "mystery birds" in the State. Only four nests have been found throughout the species' wide range around the perimeter of the North Pacific. One was found in Siberia (Kuzyakin 1963), one in California (Binford et al. 1975; Singer and Verardo

1975), and two in the Barren Islands in Alaska (Simon 1980; Hirsch et al. 1981). Kiff (1981) recently reviewed the known eggs and nests of this species.

Of the four nests, both the Siberian and California nests were found in trees, but the Alaskan nests were found on the tundra of a treeless island. The Siberian nest was found in the upper branch of a larch (Larix dehurica) 6.8 meters above the ground (Kuzyakin The California nest was 1963). found 45 meters above the ground on a moss-covered limb of a douglas-fir (Pseudotsuga menziesii) in northern California (Binford et al. 1975). This nest contained a Marbled Murrelet chick sitting in a small depression encircled by droppings.

Binford et al.(1975) theorized that the pale green egg, the cinnamon brown breeding plumage of the adult, and the light brown nestling are cryptic adaptations for nesting in trees. The entire breeding population of this species in California is suspected to nest in trees; and while this is likely also for Washington, the use of talus slopes or other ground sites cannot be ruled out.

Marbled Murrelets seen offshore are almost always in pairs and within about one kilometer of the shoreline. This is true all year, though they aggregate in foraging areas during the summer and in winter have been seen in large flocks, including one of over 5,000 birds passing Point Roberts, Washington (Wahl et al. 1981). Breeding birds return to their nests in the evening and depart at 1980), and dawn (Sowls et al. birds over flights of calling forests in inland coastal California are similar to reports in Washington (e.g., Dawson and Bowles 1909).

Marbled Murrelets, like all other alcids, spend a large percentage of the time on the water. They feed on fish and less frequently on crustaceans (Sealy 1975).

#### WASHINGTON POPULATION

Marbled Murrelets are present during the breeding season along almost all of Washington's marine

shoreline, but they are concentrated in certain areas. These concentrations likely are related to foraging opportunities, but the locations are also frequently near forested areas relatively undisturbed by humans. These include the Olympia Peninsula, particularly near Tongue Point and Voice of America, the south shore of Island, the Lopez southwestern shoreline of Lummi Island, and Obstruction/Peavine Passes between Orcas and Blakely Islands in the San Juan's. Marbled Murrelets also gather in loose but sizeable aggregations where fish runs appear to be heavy, as in Hale Pass, Whatcom County, during the Pacific season when herring (<u>Clupea harenqus</u>) are spawning near Cherry Point.

Estimating numbers of Marbled Murrelets in Washington present at any season, including the breeding season, is difficult, considerably more so than in the case of the Pigeon Guillemot. We have treated it here similarly to that species and have estimated numbers by geographic subregion (see Appendix Numbers are likely under-C). estimated as censusing was often done from fast-moving small boats or aircraft, and Marbled Murrelets in breeding plumage are inconspicuous under many conditions of observation. Data are almost completely lacking for areas along the outer coast of Washington, small concentrations along the northern section of the coast (Speich, pers. obs.), and numbers are observed often along the shoreline near Ocean Shores and in the Grays Harbor channel during the breeding season (Wahl, pers. obs.). The estimates presented here are intended to aid further

investigations into the biology of this species. These estimates are based on our systematic censuses only, and many reports from other sources are useful in specific investigations of this littleknown species. While the catalog total estimate is 2,417 breeding birds, insufficient coverage and difficulties of censusing lead us to believe as many as 5,000 Marbled Murrelets may nest in Washington.

#### HISTORICAL STATUS AND VULNERABILITY

There is virtually no information on the historical status of Marbled Murrelet breeding populations in Washington, though birds in breeding condition were collected in Puget Sound in the 1850's.

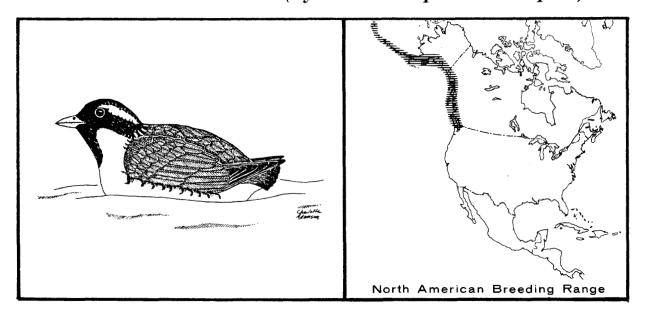

Disturbance to nesting birds probably has been will and continue to be primarily through the destruction of nesting habitat, particularly if, as strongly suspected, they nest in trees. Populations may have been reduced by the reduction of oldgrowth coastal forests. We suspect Marbled Murrelets may have formerly been more abundant than they are today.

Marbled Murrelets are vulnerable to oil contamination since they are often found very close inshore, feeding in tidal fronts and other places where their prey concentrates. This impact can be considered in perspective by referring to subregion estimates indicate which areas of concentration.

FIELD NOTES

The authors would appreciate copies of your field notes for updates

## Ancient Murrelet (Synthliboramphus antiquus)

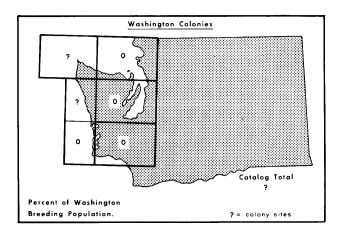

The Ancient Murrelets are an abundant and widespread species breeding north from the Queen Charlotte Islands, British Columbia around the northern North Pacific Ocean. They are numerous in offshore habitats in Washington during the winter, but they may be the rarest breeding seabird in the State, if indeed they nest here at all.

This cleanly marked species nests in colonies on coastal islands, in burrows or crevices, beneath stones, roots, or fallen logs on grassy or wooded slopes. Clutch size is usually two eggs, often elongate in shape and large for the size of the bird, variable in color from bluish-white through cream or buff, marked with different shades of brown and bluish-grays. Young birds leave the nest when very small, unlike many other alcids, perhaps when only one to two days old and follow the calls from adults leading them to water at night.

Ancient Murrelets are more pelagic than Marbled Murrelets, being found farther at sea, and are more gregarious, with flocks of up to 30 birds not uncommon in winter in Washington. Birds often plunge directly from flight to pursue prey underwater in areas of tidal fronts and strong currents. alcids, Like other Ancient Murrelets feed on small fish and marine invertebrates.

#### WASHINGTON COLONIES

The breeding distribution of this Washington species in has apparently always been limited. It was breeding 9 May 1924 on Carroll Island (Hoffman 1924), and this represents the only record. In 1978, 12 certain adults were observed near LaPush,

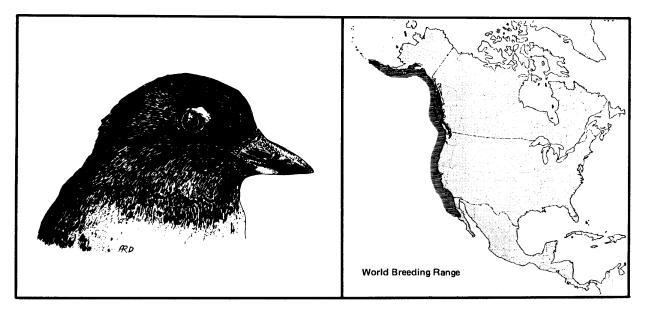

and a fledgling was seen near Island (Speich Alexander and Pitman, pers. obs.). There are of sightings birds off the Washington coast during the summer from at least the area of Grays Canyon (Wahl, pers. obs.) north, though these could be stragglers from colonies much farther north. However, the evidence suggests that small numbers of Ancient Murrelets may nest in Washington.

#### HISTORICAL STATUS AND VULNERABILITY

There is no certain breeding record for Ancient Murrelets in Washington since 1924. Sightings of birds during the breeding season are few enough that the breeding population would have to be very localized, small, and difficult to locate.

Like many marine birds, Ancient Murrelets are vulnerable to loss of breeding habitat, contamination by oiling, and disruption of food Oiling would seem to be a webs. greater hazard during winter when environmental stress is the greater, but the population of Ancient Murrelets wintering in Washington undoubtedly consists of birds breeding elsewhere.

# Cassin's Auklet (Ptychoramphus aleuticus)

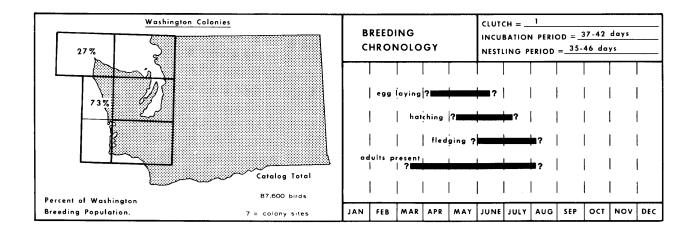

The Cassin's Auklet is one of the most widespread members of the family Alcidae in the North Pacific. Cassin's Auklets build their nests in burrows on offshore islands that have a sufficient mantle of soil. These tiny alcids are nocturnal at their breeding colonies and are likely to be among the most pelagic of alcids at that season when they are found well offshore at the outer edge of the continental shelf and the shelf edge (Wahl 1975).

Throughout their range, Cassin's Auklets usually nest in burrows but may also use rock crevices, debris piles, cracks under buildings, andlarge caves (Thoreson 1964). In Washington they are known to nest in burrows under trees and open salal and salmonberry shrub areas. Each female lays a single, creamy-white egg, but may lay a second egg if the first is destroyed (Manuwal

Adult Cassin's Auklets 1974a). develop two incubation patches on the body, one beneath each wing (Manuwal 1974a). These incubation found patches are only among several species of alcids, Xantus' including Murrelets, Auklets, Rhinoceros and Tufted Cassin's Auklets also Puffins. develop a gular pouch used to store food for young that are fed by regurgitation at night (Speich and Manuwal 1974). Small fish and pelagic crustaceans form the mainstay of the diet of Cassin's Auklets (Manuwal 1974a; Hunt et al. 1979).

#### WASHINGTON COLONIES

Cassin's Auklets are the most numerous breeding seabirds in Washington, though they are seldom seen near shore because they visit colonies nocturnally and forage well offshore. The species nests

in just eight known locations, though some additional sites are likely. The largest colony is on Alexander Island where approximately 55,000 are estimated to nest. Jagged Island, Carroll Island, and the Bodeltehs have large colonies which make up most of the rest of the known population. We feel it is possible that as many as 20,000 additional birds could be nesting in Washington on other sites.

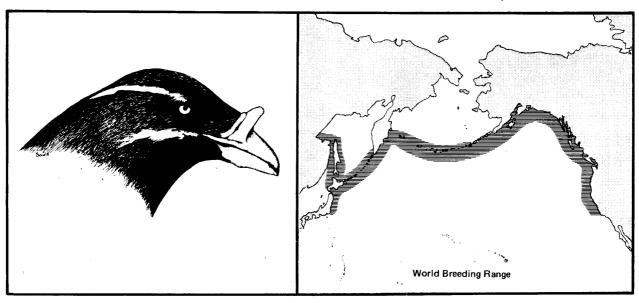

#### HISTORICAL STATUS AND VULNERABILITY

This species was recorded at several sites in 1906 and 1907 (Dawson 1908b), including Alexander and Carroll Islands and was apparently as common on those colonies as it is today. It is not known if Cassin's Auklets were nesting on Tatoosh Island in 1906-07, but it is now.

In California, Western Gulls prey heavily on Cassin's Auklets at colony sites (Thoreson 1964). Chicks are pulled from shallow burrows by gulls, and adults are killed at night when they unfortunately land at the feet of roosting gulls (Thoreson 1964).

Cassin's Auklets are vulnerable to disturbance and to the depredations of introduced predators like cats. Cassin's Auklets may desert their nests if disturbed during incubation, and their burrows can easily be caved in by unwary visitors to their colonies. Fortunately, Washington colonies are protected by refuge status.

Cassin's Auklets feed from the ocean surface in flocks, concentrating in areas where their food is abundant but where they are susceptible to contamination by oil (Hunt et al. 1979). In Washington, Cassin's Auklets are vulnerable especially near nesting colonies and on foraging areas over the outer continental shelf.

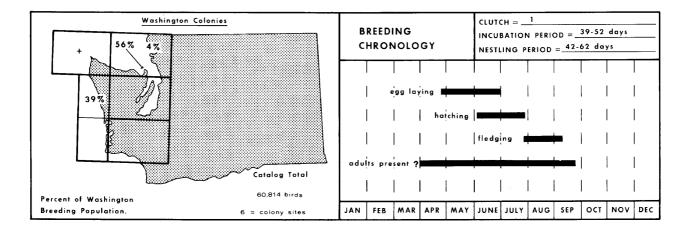

Rhinoceros Auklet (Cerorhinca monocerata)

Rhinoceros Auklets are one of the most abundant seabirds breeding in Washington, where their southernmost large colonies in the eastern North Pacific are located. While the species breeds from California north around the rim of the Pacific from the Aleutians to northern Japan, it is abundant only around a few large colonies in Washington, British Columbia, southeastern Alaska, and Kamchatka, Siberia, and Hokkaido, Japan (Udvardy 1963).

The species derives its name from the keratinous "horn" found on its bill during the breeding Although this species' season. common name implies it is an auklet, it is more closely related puffins. to the Rhinoceros Auklets are excellent divers and feed on small fish and cephalopods (Heath 1915; Richardson 1961; Leschner 1976).

Rhinoceros Auklets nest primarily in burrows dug into the ground in forested and unforested both islands. Burrows may be up to six meters in length and often fork two or three times before ending in a nesting cavity (Heath 1915; The recent dis-Willett 1915). covery of Rhinoceros Auklets at Sea Lion Caves, Oregon (Scott et al. 1974; Varoujean and Pitman 1979), and at caves in the concliffs at Point glomerate Arguello, California (Sowls et al. 1980), indicates that this species may also nest in rocky mainland habitats.

Rhinoceros Auklets almost always enter and leave colonies at night chicks. when feeding This predominantly nocturnal behavior may have evolved as a means of reducing kleptoparasitism by qulls. In California and Oregon, Rhinoceros Auklets may often be observed on or near colonies

during the day; but north of Washington they appear to be strictly nocturnal in visits to colonies, although some birds may be seen foraging near the colonies. This difference remains unexplained but may be related to the availability of food and its proximity to the colonies.

#### WASHINGTON COLONIES

Rhinoceros Auklets nest at three main sites in Washington: Protection Island (34, 216),Destruction Island (23,600), and Smith Island (2, 588). In addition, small numbers nest at Tatoosh Island, Alexander Island, and East Bodelteh. Reports of small colonies in other parts of the inland waters, particularly southern Puget Sound, have not been verified in recent field surveys (Wahl and Speich 1984). While a few more pairs nest in the State in limited suitable habitat, the total estimated nesting population is relatively accurate.

#### HISTORICAL STATUS AND VULNERABILITY

Rhinoceros Auklets are conspicuous in inland marine

Washington near waters of the Protection Island colony in particular and have been mentioned from the early days of field ornithology in Washington. Suckley and Cooper (1860) reported species on the was nesting Protection 1854. Island in However, little data are available as to population size in most sites and, while local residents state that the colony on Protection Island is larger than in the past, no census data exist prior to about 1956 (Richardson 1961). Certainly there have been variations in population size due to natural and human factors alike.

Rhinoceros Auklets are very sensitive to disturbance during the nesting period. Adults will readily desert their nests if disturbed during incubation or brooding. Their burrows are often near the surface of the ground and are easily collapsed.

This species has suffered in the past from ground predators introduced onto nesting colonies. Dogs brought by lighthouse personnel killed many birds (see Manuwal 1978), and while automated light stations have changed this situation, potential introduction of dogs and other predators into Washington colonies is a serious concern.

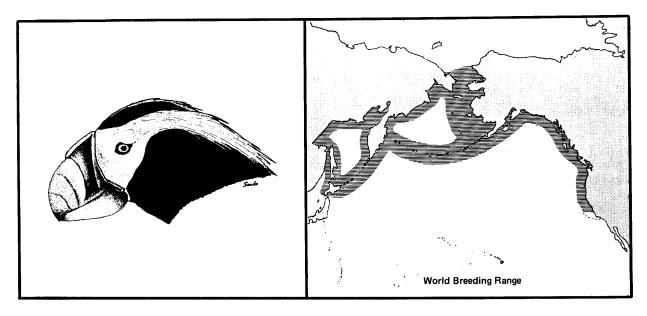

Like all alcids, Rhinoceros Auklets are extremely vulnerable oil spills. to During the breeding season they concentrate around colonies at night, and they tend to forage in large flocks in areas of strong tidal currents, particularly in inshore waters where oil spills are perhaps of greater likelihood. During the winter, when Rhinoceros Auklets are present only in low numbers in Washington waters, large numbers of this species, presumably many from Washington colonies, are present along the California coastline (Speich, pers. obs.).

While there are indications this species is increasing along the west coast of North America (see Sowls et al. 1980), and while it may be that more Rhinoceros Auklets nest on Protection Island now than in 1956, there is no evidence in Washington that there have been any significant new colonies established. Populations in Washington may be reaching the limit available of nesting habitat.

## FIELD NOTES

The authors would appreciate copies of your field notes for updates

Tufted Puffin (Lunda cirrhata)

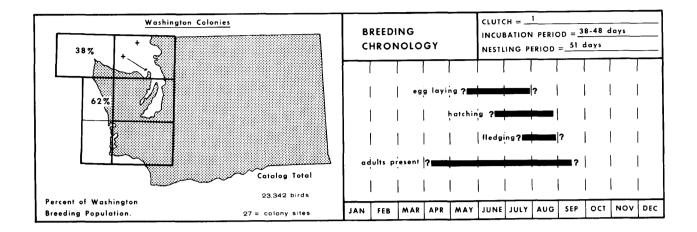

Tufted Puffins are among the most abundant and conspicuous seabirds nesting around the North Pacific rim, with the center of abundance apparently in the western Gulf of Alaska and the Aleutian Islands (Sowls et al. 1980). Their spectacular appearance and their as yet unexplained habit of circling and investigating vessels at sea helps make the "sea parrots" among the most well known of seabirds. At colonies they can often be seen standing in front of their nesting burrows.

Tufted Puffins usually nest in earth burrows at the edges of cliffs or on the grassy slopes of islands. In Washington they nest on open, grassy slopes and near the top of vertical cliffs where edges erode. Habitat is limited or unavailable on many islands suitable for other species; consequently, in inland waters in particular, puffins have probably always been restricted in nesting distribution in Washington.

Tufted Puffins can sometimes be observed carrying fish (up to 12 or more) crosswise in their bills chicks at colonies. to their small include Preferred foods fish, cephalopods, and crustaceans (Hatch et al. 1979). Although diurnal, Puffins are Tufted fledglings apparently leave their burrows and go to sea under cover darkness. In fall. adult of puffins brightly lose their sheathes. colored bill Both fledglings and adults head far offshore to winter in mid-ocean and during winters are only occasionally seen near land.

#### WASHINGTON COLONIES

Although Tufted Puffins are among the least-frequently noted

seabirds breeding in Washington, this attractive species is actually one of the most abundant. inland marine Few nest in the areas where most boating takes place, but on the outer coast there are large colonies. A11 the species breeds at 29 told, known locations with all but five of these along the outer coast from Tatoosh Island to the Point Grenville area. largest The colonies are on Jagged Island where 7,800 breeding birds are estimated and Alexander Island where 4,000 nest. In the inland waters the species nests only at Seal and Sail Rocks, Protection Island. Smith Island. and at Colville Islands. and Bare Because of inaccessibility of many sites where puffins nest along the outer coast and the fact that, though birds may be seen from a boat circling colony sites. standing outside burrows numbers seen compared with numbers actually present or foraging away from the islands may be at convariance. siderable We feel actual numbers of nesting puffins in Washington may be 50% or more larger than the total estimated populations given here.

#### HISTORICAL STATUS AND VULNERABILITY

Tufted Puffins, like many other diving seabirds with specialized diets, are vulnerable to oiling and to contamination of food webs. nesting Human disturbance on colonies is another potential threat. Most of the colonies occupied by puffins in Washington are protected as wildlife refuges, and those on the outer coast are The relatively inaccessible. colony sites in the inland waters vulnerable to are much more disturbance by boaters, sightseers, and birdwatchers approaching too closely.

Puffins, like puffins Tufted elsewhere (Nettleship 1972; Nisbet may have decreased in 1973), numbers in Washington as populations of large gulls have increased over time. recorded Gulls prey on chicks at burrow entrances, steal fish from adults approaching the burrows, and can severely reduce the reproductive success of puffins. As late as the 1940's, puffins apparently nested at several locations (e.g., Viti Rocks) where they no longer

do. However, there have been a few more sightings in recent years near some old sites and, particularly since refuge status

protects islands in the San Juan Islands, small numbers of Tufted Puffins may reestablish themselves as nesting birds there.

S.G. Herman Sand Island (174024) 1977 Caspian Tern chick and egg.

Catalog of Washington

Seabird Colonies

# MAPS AND TABLES

#### HOW TO USE MAPS AND TABLES

The tables in this catalog are all standardized, using the same format and codes throughout. With only a few minor differences they are the same as the tables and codes used in the <u>Catalog of</u> <u>California Seabird Colonies</u> (Sowls et al. 1980). The codes and fields as used in this catalog are explained and terms are defined below.

#### <u>Map Area</u>

The Map Areas used in this catalog are based upon the United States Geological Survey (USGS) National Topographic map series, scale 1:250,000. The maps have been numbered by the U.S. Fish and Wildlife Service and cover the United States. Each standard Map Area is normally one degree latitude high and two degrees longitude wide. In Washington there are five such Map Areas that cover all the marine shoreline of The general geographic the State. location of the Map Areas in Washington and Map Area Numbers appear on the Map Index page (below).

#### Map Area Numbers

These are the numbers that have been assigned to each Map Area. This number appears at the top of each page in the Maps and Tables section.

#### Map Area Names

These are the names that appear on the USGS 1:250,000 topographic maps; they appear on the top of each page in the Maps and Tables section, immediately after the Map Area Number.

#### Colony Numbers

Each site of breeding, potential breeding, or past breeding by marine birds in Washington is given a Colony Number. Many of the Colony Numbers used in this catalog were first assigned by Varoujean (1979). If his numbers are not used, explanation is given. We assigned Colony Numbers in each Map Area to appropriate sites by using numbers coming immediately after those assigned by Varoujean (1979). He did not assign numbers in all Map Areas.

The Colony Number is made up of two parts. The first three digits correspond to the Map Area number of the Map Area in which the colony site is found. The last three digits are numbers assigned in consecutive order by, in some cases, Varoujean (1979) and, in the remainder, by us to each site in the Map Area. In the tables the number in the circle is the Site Number within the Map Area number that appears at the top of each page. The Site Numbers also appear in the circles labeling sites on the maps on the right hand pages of the Maps and Tables section.

#### <u>Colony Names</u>

Each site is given a Colony Name. Many site names were assigned by Varoujean (1979), and they are retained. Other site names were assigned by us. The Colony Name immediately follows the Colony Number on the top of the tables. Colony Names that are not in quotation marks are derived

from the names found on standard USGS topographic maps, generally 1:24,000 series maps. Names that appear in quotation marks do not appear on these maps for the referred-to sites and locations. Lower case sites and location name description modifiers also do not appear on these maps. Names in quotation marks are derived from National Oceanic and Atmo-(1) spheric Administration, National Ocean Survey, Nautical Charts; (2) local use; (3) the literature; (4) previous investigators; or (5) assignment by authors. the Several sites have the same Colony Name, and we have made no attempt eliminate duplications, to as names are generally derived from the USGS topographic maps. An alphabetical listing of sites is contained in Appendix A, Gazetteer of Localities.

#### Latitude-Longitudes

The latitude and longitude were determined for every site in this catalog, and coordinates previously determined by Varoujean (1979) were redone. Since it is difficult to make determinations of latitude and longitude from the USGS topographic maps, all determinations were made from NOAA Nautical Charts using the largest scale chart available for every Determinations were made site. with calipers as best as possible within the limits of the size of the site and the scale of the nautical charts.

#### Species Names

There are 18 species of "marine birds" that are breeding or have bred in marine habitats in Washington, and they are documented by this catalog. Species names follow those found in the <u>Thirty-fourth Supplement to</u> the American Ornithologists' Union <u>Check-list of North American Birds</u> (1982), with one exception: the American Black Oystercatcher is called Black Oystercatcher here to save space in the tables.

#### Number of Breeding Birds

the field in tables This contains the probable number of <u>individuals</u> of each breeding species at each Colony Site on (See Data Quality each survey. below for comments on the accuracy of these figures.) Other symbols also appear in this field combined with numbers of individuals or alone. The definitions of these symbols as they are used here follow:

- X = Definitely present and breeding, but numbers breeding are not available or cannot be determined from the data available.
- P = Present and probably nesting, but status cannot be definitely determined, either in the field or from the information in the source document.
- B = Indicates that the number of adults present, such as Ring-billed Gulls or Glaucous-winged Gulls, was estimated from the number of young pre-fledgling birds banded at the ratio of 1.5 banded young equal two adult breeding birds.
- ? = The breeding status of the birds present cannot be determined, either in the field or in source documents.

N = Birds may be present, but in any case the species probably is not breeding at the site. This code is generally not used except in special cases; i.e., where there is particular reason to document the breeding absence of the species at the site. This generally used for is with species small populations in the State to document their absence from previous, suspected, potential sites of or breeding.

When a species' data line in a colony table is in reference to specimens or eggs (see Survey Type field), the numbers in this field refer, in the case of eggs, to the number of sets collected with two adults being recorded for each egg set. For specimens, the number refers to the actual number of specimens collected.

#### Sources

This field identifies the sources from which the data of breeding birds for the sites were obtained. There is a large range of data sources used in this Sources that include a catalog. date in the field refer to publications of various types. Names without dates refer to a variety of sources that include collectors, agencies, field notes of investigators, and personal communications. Full details of each source are found in the Reference section of the catalog. The Reference Numbers at the far right of the tables correspond to the sources that appear in the Source field and help to specifically identify each source in the Reference section.

Where possible, have we identified where reference material can be found when not in standard journals or government documents. Thus reference to collectors of eggs and specimens are identified the museum holding the referred-to specimens at the time of our survey. Other sources are identified as the library or museum holding material such as field notes and correspondence.

#### Survey Date

The survey date is when observations of the referred-to species were made. For specimens this is the date of collection, and for banding, the date the banding took place. In many cases, it is not possible to determine the exact date of observations, collecting, banding, etc., and we have then made the best determination possible. Thus, many dates include a date range: several days, the month or months, the time of year, the year alone, or a range of years. Our accuracy for determining dates is limited by the accuracy of the observers in the recording of their data in their notes, on specimen labels, or in published articles.

#### Survey Type

The code in this column describes the platform of observation and method employed in acquiring the data given in estimates of numbers of birds present. This designation reflects the Data Quality below.

- A = Aerial. Survey conducted from an airplane or helicopter.
- B = Boat. Survey conducted from a boat, ranging in

size from Washington State Ferries to a small Zodiac.

- M = Mainland. Survey made of the site from the mainland or another nearby island.
- L = Land. Survey made of the site on foot.
- S = Specimen. This code indicates that one or more specimens were collected. See the number of Breeding Birds field for the number of specimens collected.
- E = Egg. This code indicates that a one or more egg sets were collected. See Number of Breeding Birds field for the number of sets collected; two adult birds were recorded for each egg set taken.

#### Data Quality

This field's codes quality the data collected, specifically the number of each species determined to be nesting at the site. The codes all relate to the observing of nests and the proportion of the actual total number of nests that were observed. The code definitions are as follows:

- I = The numbers represent a total count of all nests of the subject species; no nests were omitted from the survey.
- II = Some nests were missed in
   the survey or misiden tified; the error in
   numbers is small.
- III = Only a small sample of nests was obtained, and

the nesting individuals were extrapolated from the sample over the area of appropriate habitat at the Most estimates of site. the number of burrowing birds were obtained in this manner, usually through a small number of grid samples in the colony. Nocturnal burrowing species were estimated in this manner at several sites. For diurnal burrowing species, such as the Tufted Puffin, birds were sometimes counted in front of their burrows on the colony slopes.

For species such as the Glaucous-winged Gull, many entries of breeding numbers are coded "III" even though all birds on the site were counted. The Data Quality codes refer to nests only and are allow used here to conformity with the seabird catalogs for California and Oregon.

- = There were no data available.
- ? = The accuracy of the observations could not be determined.

#### <u>Reference Number</u>

This number is assigned to the source of data used to obtain the species status on the respective lines of the table. Use of these numbers allows for more precise determination of the reference source (investigator) in the Reference section of the catalog.

#### THE CATALOG MAPS

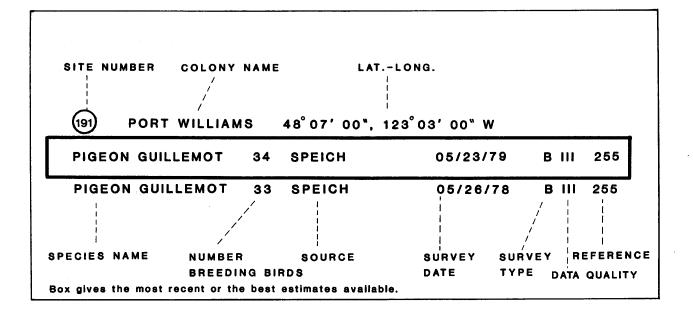

#### <u>Area Maps</u>

At the front of every Map Area section, an index map of the Map Area appears. A11 active sites, those with nesting birds reported from the period 1978 through 1982, are located on this map. The Site Numbers of each of the respective colonies appear in circle, the circle size а reflecting the total number of nesting at the site birds indicated.

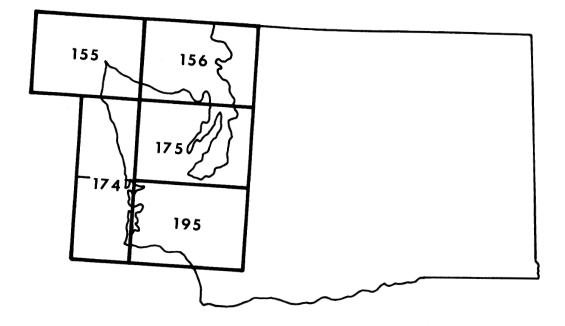

#### <u>Site Maps</u>

Within the Maps and Tables section of the catalog, the tables

corresponding Site Maps and All tables start on the appear. left-hand-facing page, and the corresponding Site Maps appear on the right-hand-facing page. These maps are cut from the USGS topographic maps, generally 1:24,000 scale series. The Site Numbers appear in circles, and the actual size is indicated by a bracket, or boundary pointer, drawn on the map pieces. The Map Name the map cut-out was taken from appears in the box within the map cut-out.

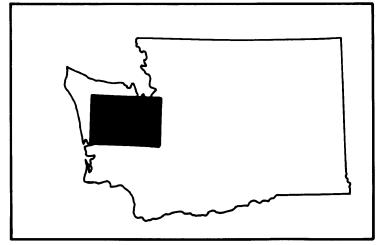

MAP INDEX:

AREA 175, Seattle (cont'd.)

175

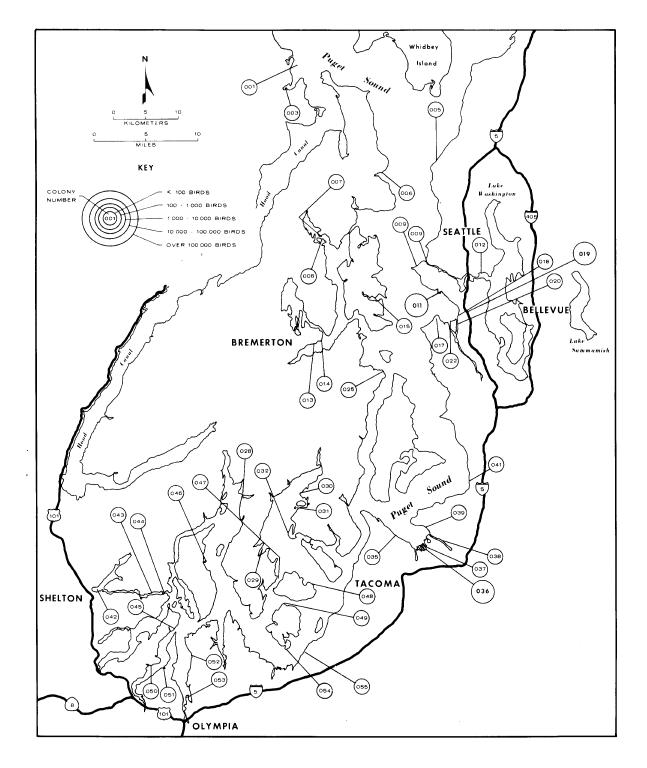

Seattle

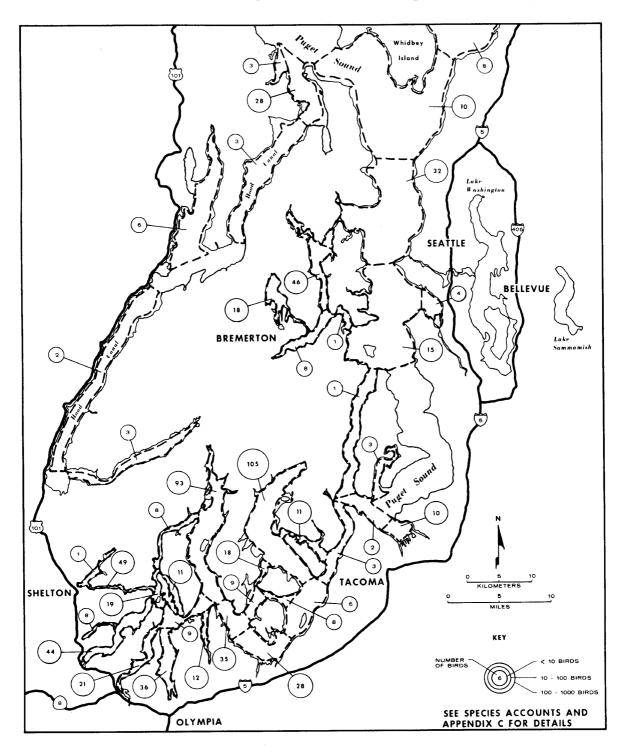

The map on the facing page is an index to the locations of colonies within map 175, Seattle. On the pages following this map, all colonies are listed sequentially and a detailed map of each is provided.

Numbers of breeding seabirds will vary from year to year. Below are the approximate numbers of breeding seabirds within this region.

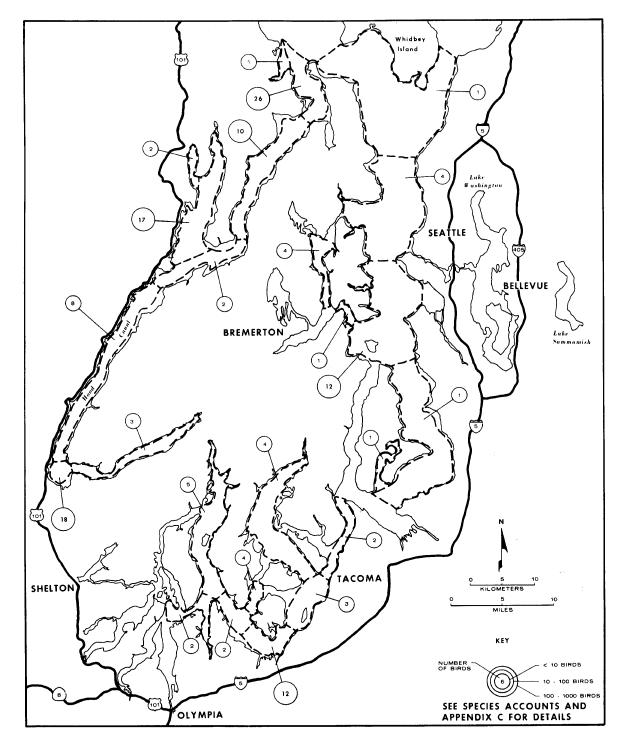

Glaucous-winged and Western gulls	1,100
Pigeon Guillemot	220
Marbled Murrelet	150

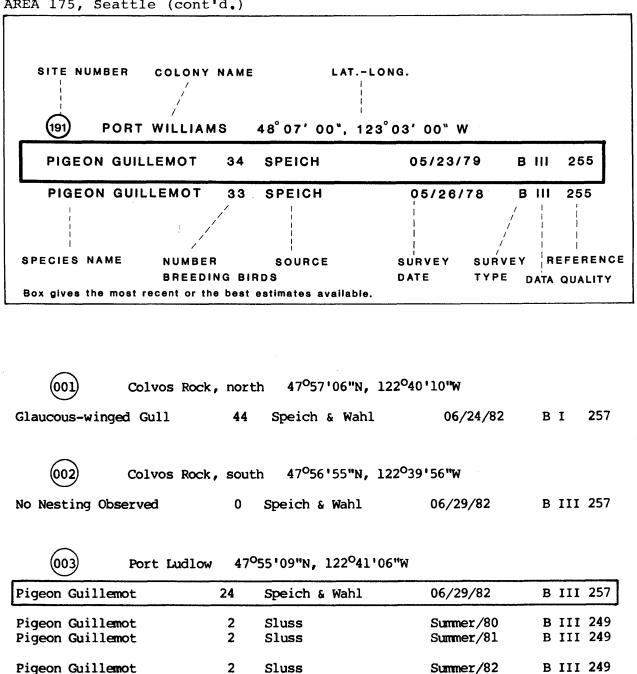

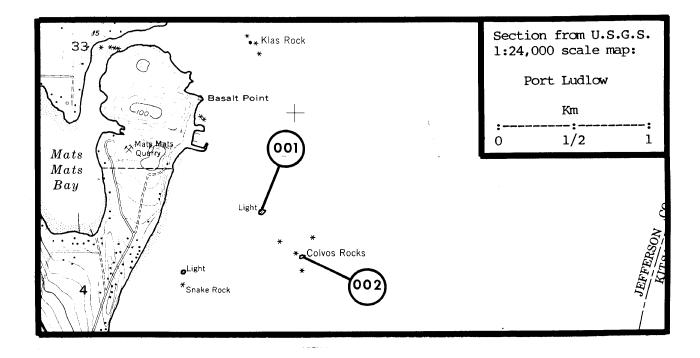

Relative distribution for Pigeon Guillemots in map area 175, Seattle.

156 Victoria

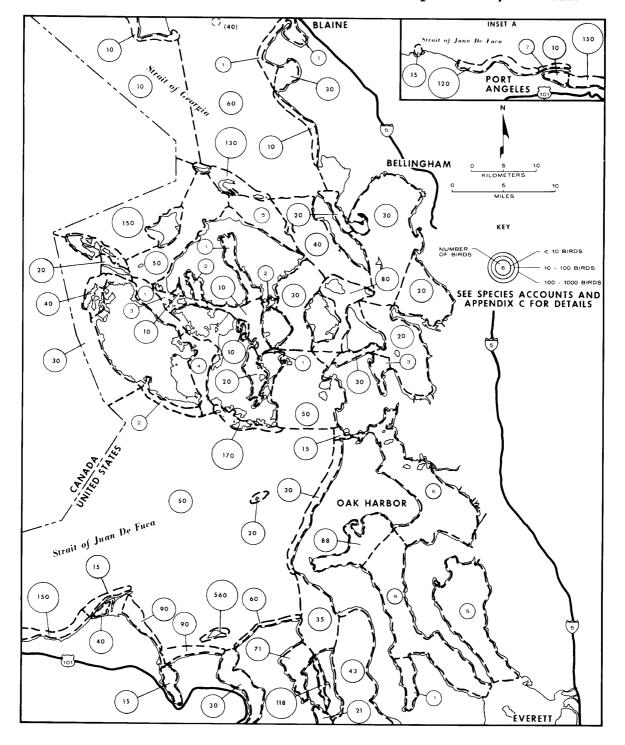

The map on the facing page is an index to the locations of colonies within map 156, Victoria. Note that all colonies on the map are not numbered consecutively from north to south, or west to east, since many previously unreported sites have been added since initial colony numbers were assigned by Varoujean (1979). On the pages following this map, all colonies are listed sequentially and a detailed map of each is provided.

Numbers of breeding seabirds vary from year to year. Below are the approximate numbers of breeding seabirds within this region.

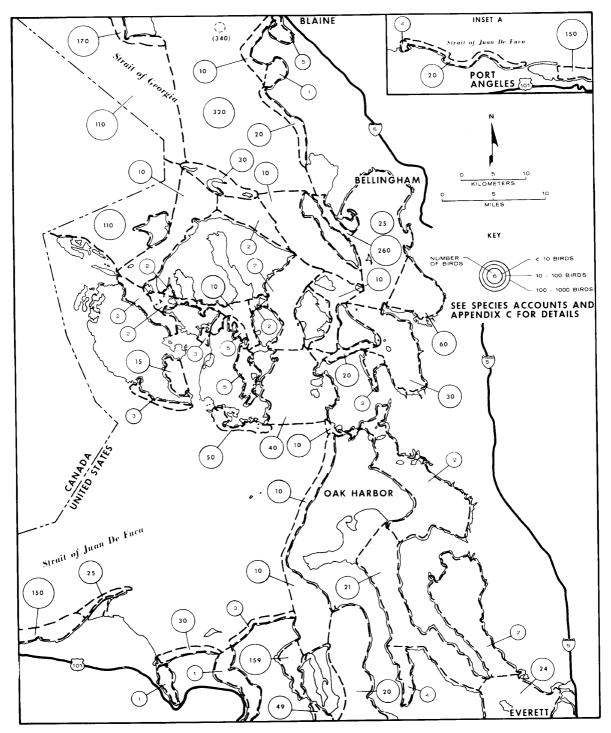

Double-crested Cormorant	1,100
Pelagic Cormorant	2,200
American Black Oystercatcher	120
Glaucous-winged and Western gulls	19,000
Pigeon Guillemot	3,500
Marbled Murrelet	2,200
Rhinoceros Auklet	37,000
Tufted Puffin	60

## **156 VICTORIA**

Relative distribution for Pigeon Guillemots in map area 156, Victoria.

# Cape Flattery

The map on the facing page is an index to the locations of the colonies within Map 155, Cape Flattery. Note that all colonies on the map are not numbered consecutively from north to south, since many previously unreported sites have been added since initial colony numbers were assigned by Varoujean (1979). On the pages following this map, all colonies are listed sequentially and a detailed map of each is provided.

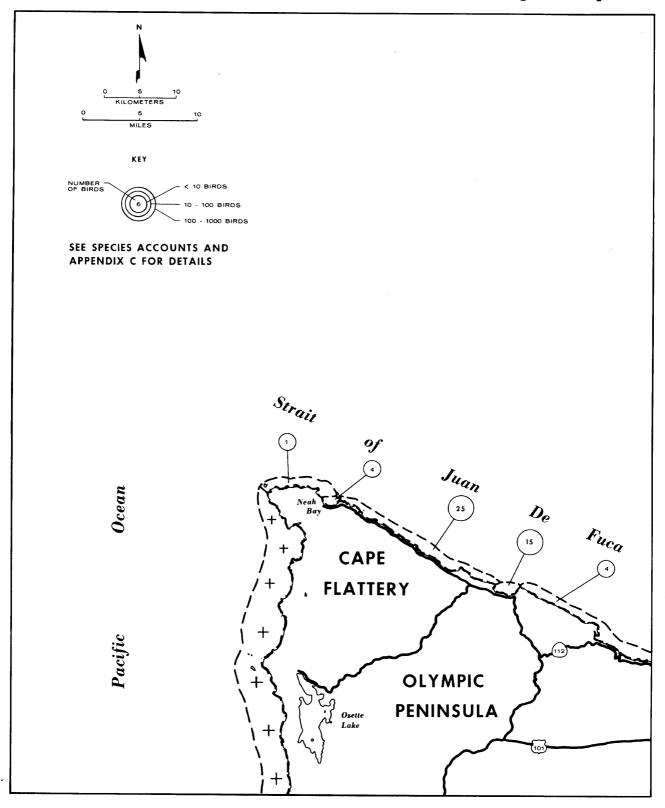

Numbers of breeding seabirds will vary from year to year. Below are the approximate numbers of breeding seabirds within this region.

Fork-tailed Storm-Petrel	3,700
Leach's Storm-Petrel	11,000
Double-crested Cormorant	150
Brandt's Cormorant	10
Pelagic Cormorant	900
American Black Oystercatcher	60
Glaucous-winged and Western gulls	4,400
Common Murre	900
Pigeon Guillemot	150
Marbled Murrelet	50
Cassin's Auklet	24,000
Rhinoceros Auklet	200
Tufted Puffin	8,700

"Paahwoke-it" (155070) 27 June 1979 S.M. Speich

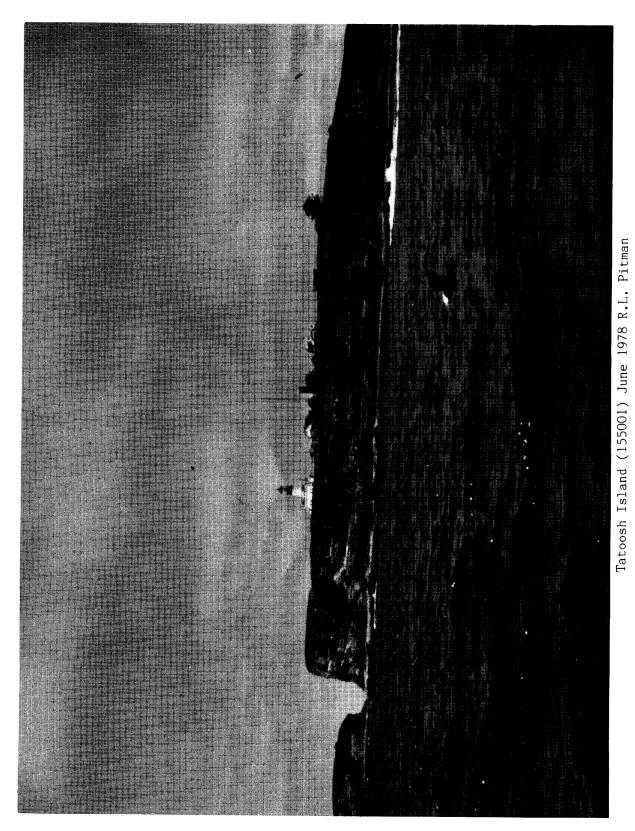

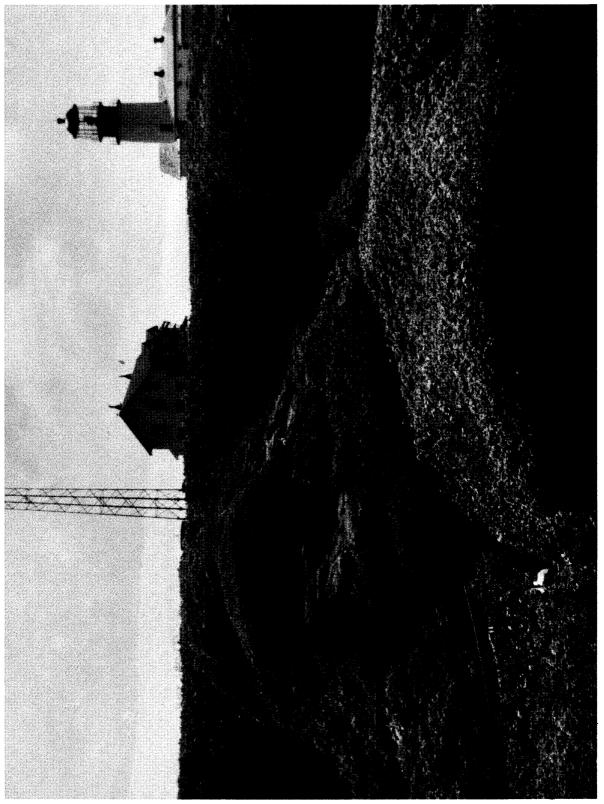

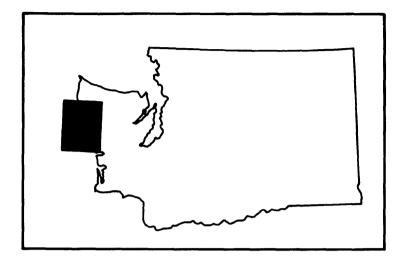

AREA 155, Cape Flatterv (cont'd,)

Tatoosh Island (155001) June 1978 R.L. Pitman

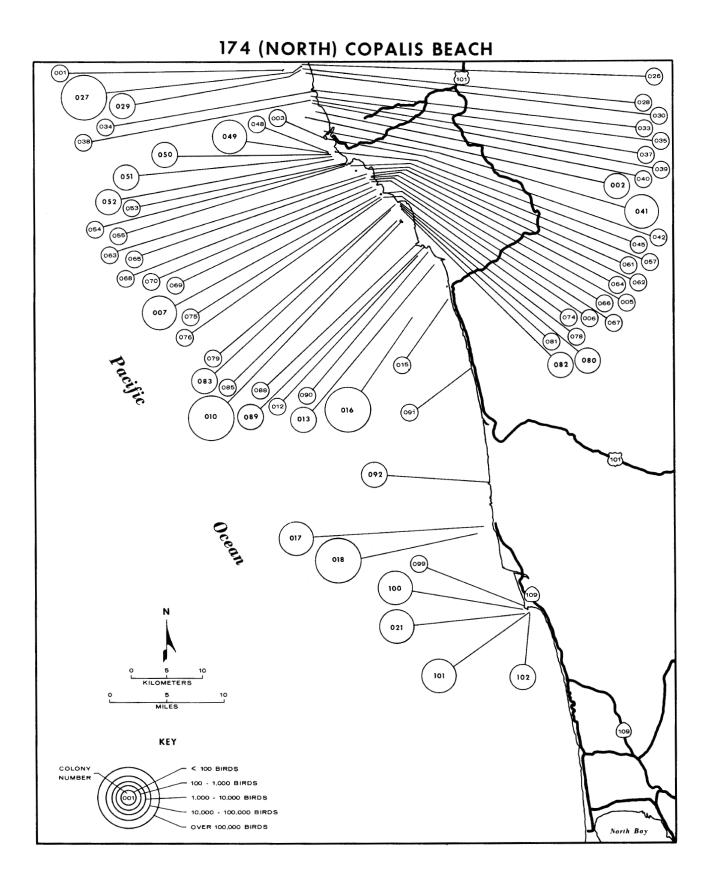

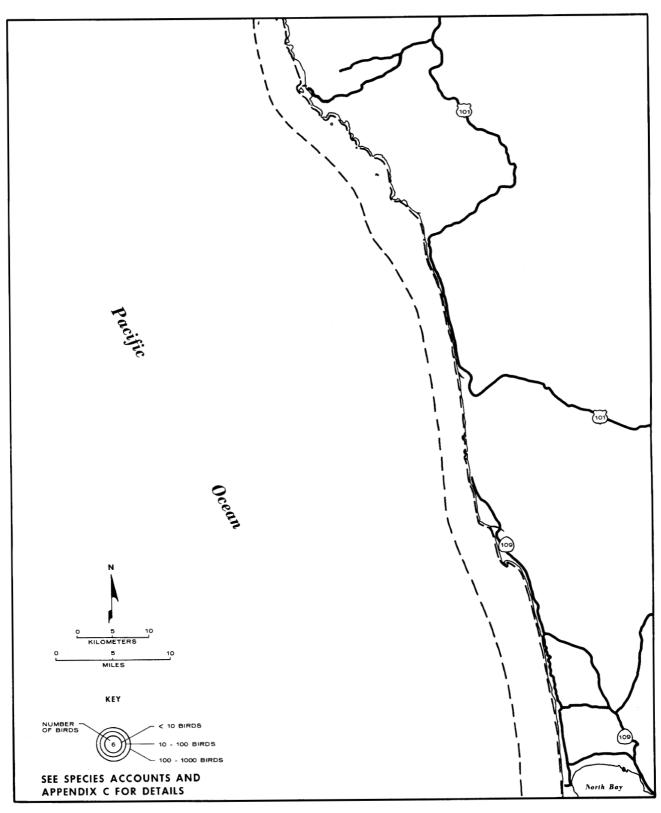

174 Copalis Beach (North)

The map on the facing page is an index to the location of colonies within map 174, Copalis Beach, North. Note that all colonies on the map are not numbered consecutively from north to south, since many previously unreported sites have been added since initial colony numbers were assigned by Varoujean (1979). On the pages following this map, all colonies are listed sequentially and a detailed map of each is provided.

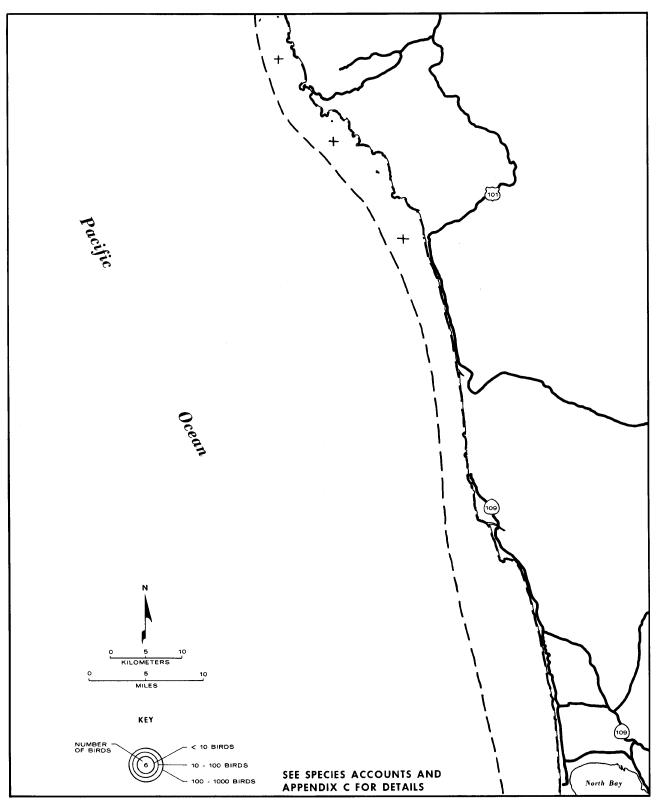

Numbers of breeding seabirds will vary from year to year. Below are the approximate numbers of breeding seabirds within this region.

Fork-tailed Storm-Petrel	200
Leach's Storm-Petrel	25,000
Double-crested Cormorant	1,100
Brandt's Cormorant	450
Pelagic Cormorant	1,500
American Black Oystercatcher	160
Glaucous-winged and Western gulls	3,900
Common Murre	30,000
Pigeon Guillemot	280
Marbled Murrelet	no estimate
Cassin's Auklet	64,000
Rhinoceros Auklet	24,000
Tufted Puffin	15,000

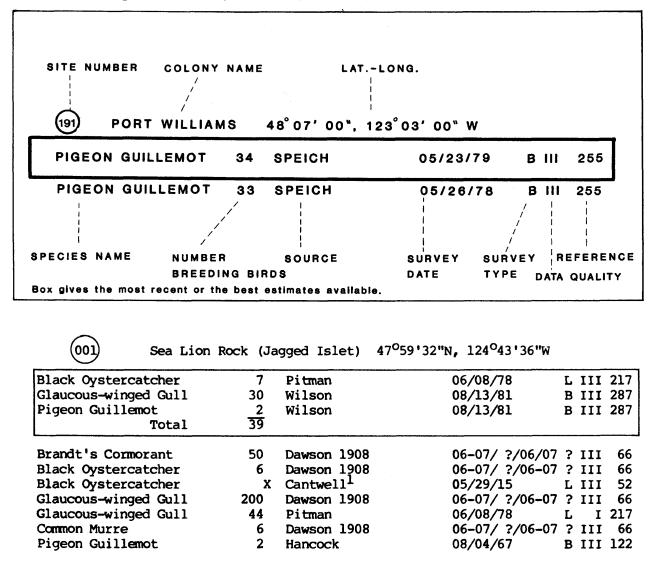

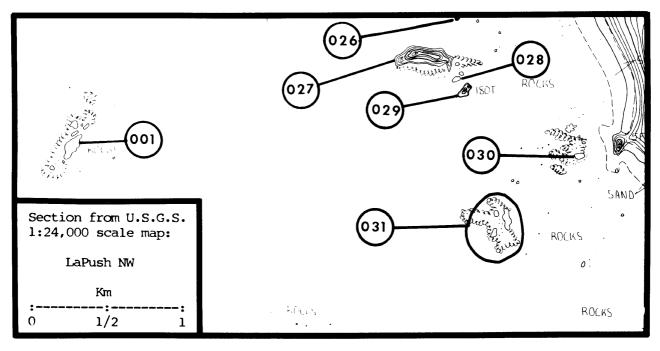

Relative distribution for Pigeon Guillemots in map area 174 (North) Copalis Beach.

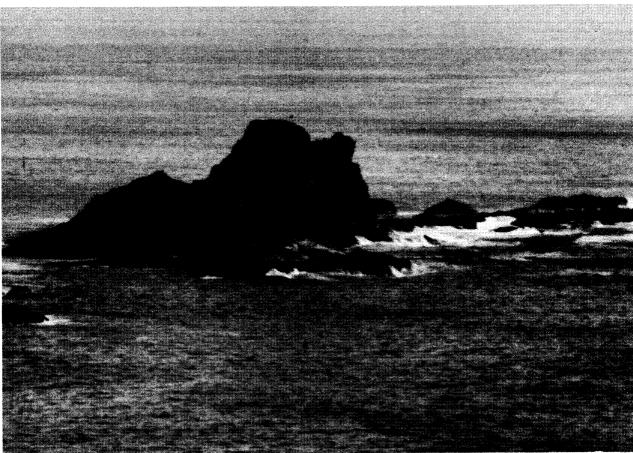

Relative distribution for Marbled Murrelets in map area 174 (North) Copalis Beach.

<sup>1</sup>Location not definite.

174 Copalis Beach (South)

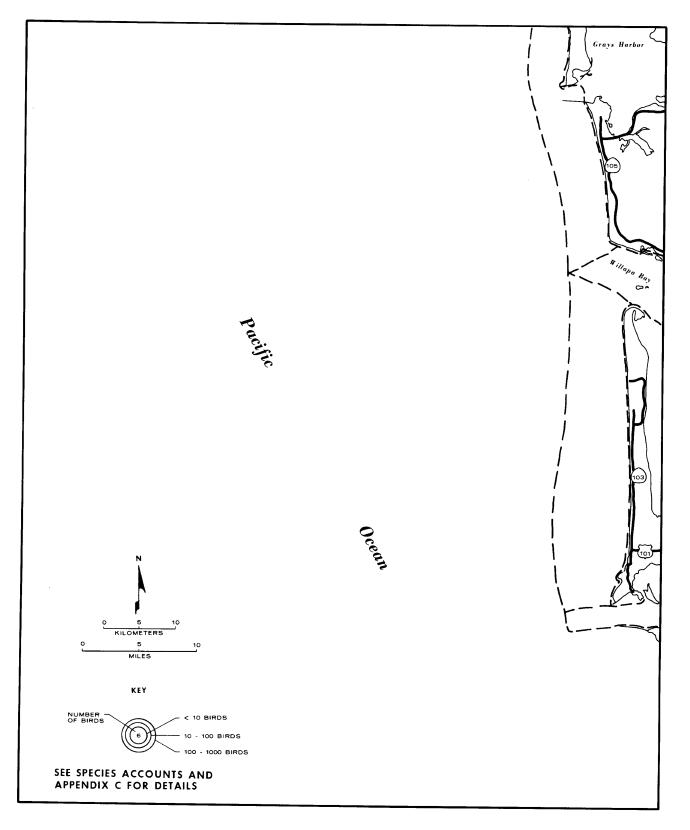

The map on the facing page is an index to the locations of colonies within map 174, Copalis Beach, South. Note that all colonies on the map are not numbered consecutively from north to south, since many previously unreported sites have been added since initial colony numbers were assigned by Varoujean (1979). On the pages following this map, all colonies are listed sequentially and a detailed map of each is provided.

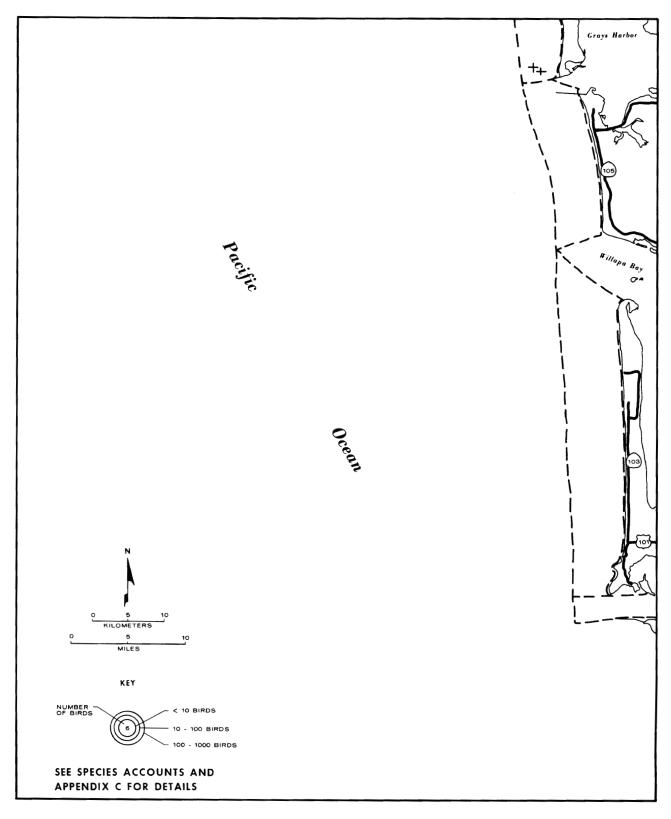

Numbers of breeding seabirds will vary from year to year. Below are the approximate numbers of breeding seabirds within this region.

Double-crested Cormorant	900
Brandt's Cormorant	100
Pelagic Cormorant	240
American Black Oystercatcher	2
Glaucous-winged and Western gulls	6,300
Ring-billed Gull	110
Caspian Tern	7,900
Pigeon Guillemot	70
Marbled Murrelet	no estimate

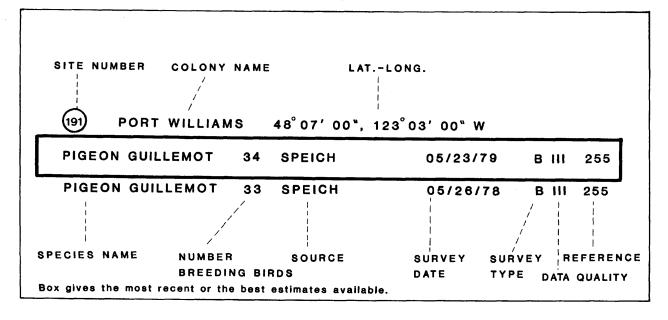

Relative distribution for Pigeon Guillemots in map area 174 (South) Copalis Beach.

Relative distribution for Marbled Murrelets in map area 174 (South) Copalis Beach.

<sup>1</sup>Ellen Sands is defined here as to include Ellen Sands, Snag Island, and Pine Island. These sand islands are not stable; there is confusion in their names and locations on various maps; and investigators are not always specific as

<sup>2</sup>Attributed to Snag Island. <sup>3</sup>Attributed to Pine Island.

#### APPENDIX A

# GAZETTEER OF LOCALITIES

The sites of seabird colonies and other locations in this catalog are listed below. Names given are as they appear on U.S. Geological Survey topographic maps unless they are in quotation marks. Names in quotation marks for the referred-to sites and locations do not appear on these maps nor do lower case site-and-location name description modifiers. Names in quotation marks are derived from (1) National Oceanic and Atmospheric Administration, National Ocean Survey, Nautical Charts; (2) local use; (3) the literature; (4) previous investigators; or (5) were assigned by the authors.

Abbey Island		
	174 014	47°42'58"N, 124°25'10"W
Agate Bay	156 182	48°09'30"N, 123°44'00"W
Aleck Rocks	156 162	48°25'23"N, 122°50'48"W
Alexander Island	174 010	47°47'52"N, 124°30'16"W
Allan Island	156 170	48°27'55"N, 122°42'12"W

# APPENDIX B

# OBSERVATION POINTS FOR SEABIRD COLONIES

Bird-watching, birding, or nature observation has become a major non-consumptive recreational pursuit in North America, and people often travel great distances to see hard-to-find species or rarities from other parts of the world. This is true in Washington situation and the exists not only for birds in general but also for species breeding in the State.

With this greatly increased interest and awareness of the natural world, more and more people are attempting to see seabirds, particularly where they nest. A few years ago a Horned Puffin appeared on one relatively accessible colony in Washington, and within a short period of time bird-watchers converged on the area, having chartered boats in order to try to add the species to their "Washington list." It is with this experience in mind and with concern for the welfare of the birds and their reproductive success that include we this section. Some cautions are also introduced here for the welfare of persons viewing seabirds.

Seabird colonies in Washington, as elsewhere, tend to be in inaccessible because of the need of the birds for security from predation and disturbance. Thus many colonies are offshore and

must be viewed at a distance, usually with a telescope, or must be approached in a boat. The preferable method is former because possibilities for disturbance are minimal. The use of boats allows close approach but also introduces possible distur-bance stress and this is not only undesirable but is illegal in some Many nesting islands are cases. wildlife refuges and entry is forbidden. Maintaining a distance of perhaps 100-200 yards from a colony is necessary in many cases to prevent birds being frightened, taking flight, and causing loss of eggs or young to predators or A further cause being crushed. for caution in using small boats in Washington is that in many it can be extremely areas hazardous. Along the outer coast, there are very few places where boats can be rented or launched--Neah Bay, LaPush, Grays Harbor, Willapa Bay, and Ilwaco--and only the first two are near colonies. Even in the summer, sea conditions can change within a few minutes heavy swells or fog can and quickly create dangerous circumstances around rocks and islands or make entry into harbor impossible. In the inside waters, particularly in the San Juans, navigation near rocks can be very hazardous due to very strong tidal and inexperienced currents, sailors are well advised to be extremely cautious, even during ideal weather. There are a number of places in the State where the summer resident seabirds can be observed, perhaps even better than on the colonies themselves. Most of these are included in Wahl and Paulson (1981) and full details are given there.

Trips to view pelagic birds on ocean encounter not only the nesting species, including stormpetrels and Cassin's Auklets not visible from shore, but also such species as Black-footed Albatrosses (Diomedea nigripes), Northern Fulmars (Fulmarus glacialis), and several species of shearwaters. Details can be obtained through the Seattle Audubon Society.

Ocean jetties at Ocean Shores, Westport, and Ilwaco (north jetty of the Columbia River) extend out from shore and allow, in good excellent views of conditions, Birds rest on and seabirds. forage around the jetties, and vast numbers pass by during Pigeon migration. Guillemots often nest in crevices in the jetties themselves, and large numbers of gulls, cormorants, sea ducks, rock shorebirds, and other species can be seen in season.

The lighthouse site at Point Wilson, Fort Worden State Park, near Port Townsend is an excellent location all year. Rhinoceros Auklets from Protection Island feed offshore, and large numbers of many species of birds forage in the strong tidal currents off the point.

Point Roberts, reached through Canada, is the extreme northwestern tip of Whatcom County. Lighthouse Park, at the southwest tip of the Point, is an excellent place to see seabirds close to shore, especially when the tide is running.

Green Point, in Washington Park, overlooks Rosario Anacortes, Strait and, while Bird Rocks can be seen by telescope in the distance, this spot is best known spectacular flights of for cormorants moving between roosts and foraging areas and for large numbers of Common Murres and many in the other species feeding tidal convergences.

Deception Pass, at the north end of Whidbey Island is reached by entering Deception Pass State Park and also has large flocks of birds feeding in strong tidal currents. Pigeon Guillemots, cormorants, loons, and many other species are often present.

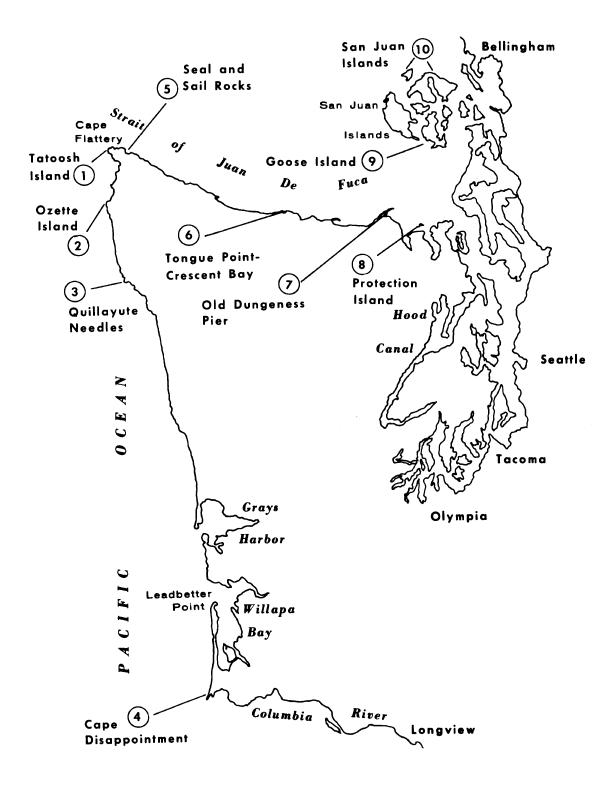

Washington also has what many other places do not--passenger and ferries traveling through car waters where there are many seabirds to observe in the appropriate season. While the routes in the southern inland waters of Puget Sound do not often encounter many birds, two Washington State Ferry routes do have abundant The "Keystone Ferry" birds. between Whidbey Island and Port Townsend crosses the tidal fronts of Admiralty Inlet, which drains most of Puget Sound into the Strait of Juan de Fuca and the While large Pacific Ocean. numbers of birds of many species may be seen during the 35-minute most abundant crossing, the species are Rhinoceros Auklets in summer, and Common Murres in winter, and qulls during all Thousands of Rhinoceros seasons. from the colonies at Auklets, Smith Protection Island and

Island, can be seen particularly on the west side of Admiralty Inlet. Tufted Puffins are also possible here.

The other ferry route with good bird observation possibilities is the ferry from Anacortes to Friday Sidney, Harbor or British Columbia. The ferry passes, at distance, some number a of important colonies. Foraging birds and others moving from one feeding area to another are often seen close to the vessel. The ferry to Sidney normally passes close to Mandarte Island, B.C., which has hundreds of nesting cormorants, thousands of nesting gulls, as well as Pigeon Guillemots and Black **Oyster**catchers. This is one of the largest colonies in the inside waters of Washington and British Columbia. Bald Eagles are often seen in the San Juans and Gulf Islands, with largest numbers in winter.

excellent location for One viewing nesting seabirds is not listed below. That is Point Grenville, where the many offshore rocks and islands can be seen well from the lighthouse site. However, the access to this former Coast Guard station is question-The property able at present. itself is now under Ouinault Tribal jurisdiction and Indian access has not been allowed recently, at least at writing of this catalog.

Hiking the outer coastal beaches of the Olympic National Park has been a popular form of recreation for years. Many of the offshore nesting colonies may be seen from along the shore, though a telescope is necessary and transporting the necessary equipment while back-packing makes this out of the question for most people.

# VIEW POINT: Cape Flattery

COLONY: Tatoosh Island

ACCESS

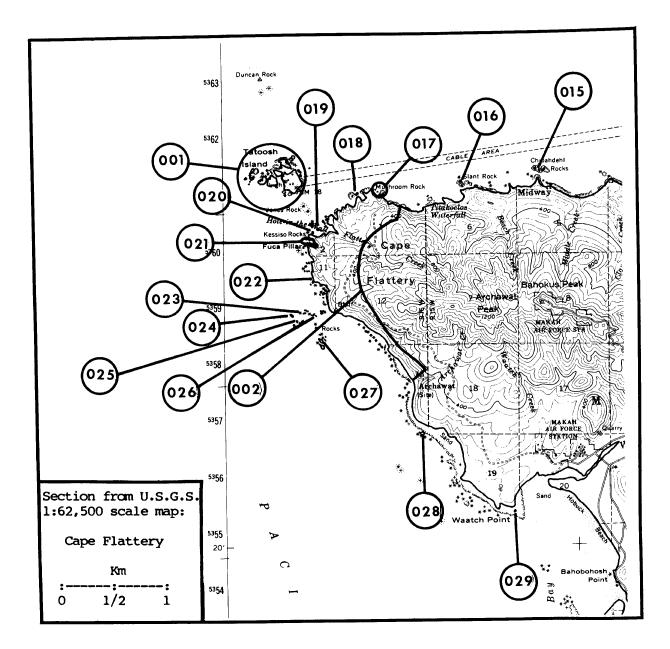

1

Follow the signs in "Cape Neah Bay to Flattery." The road from the west end of Neah Bay circles the Cape itself. The parking area for the trail to the Cape Flattery viewpoint on the cliffs is about 5 miles from Neah Bay. It is about one-half mile down a trail, with some stepping over tree roots under the forest, to the edge of the cliffs.

#### SEABIRD SPECIES:

From the viewpoint at the edge of the cliffs--caution is advised: do not get too close to the edge--

Tatoosh Island is visible offshore, and with a telescope, birds can be seen on nesting territories or flying to and from foraging areas offshore. Pelagic Cormorants, Black Oystercatchers, Glaucous-winged Gulls, Common Murres, Pigeon Guillemots, and Tufted Puffins may be clearly, if distantly, seen. Leach's and Fork-tailed Storm-Petrels and Cassin's Auklets nest here, too, but are strictly nocturnal and only infrequently seen near the island during daylight hours. Pelagic Cormorants and Black Oystercatchers also nest on sea stacks closer to Cape Flattery and can be seen there also. A great amount of bird activity can often be seen from Cape Flattery, from vast flocks of shearwaters feeding at the entrance to the Strait of Juan de Fuca, to flocks of migrating Brants and hawks passing in the spring. Gray Whales may be seen during their spring migration, with some passing directly under the cliff view point.

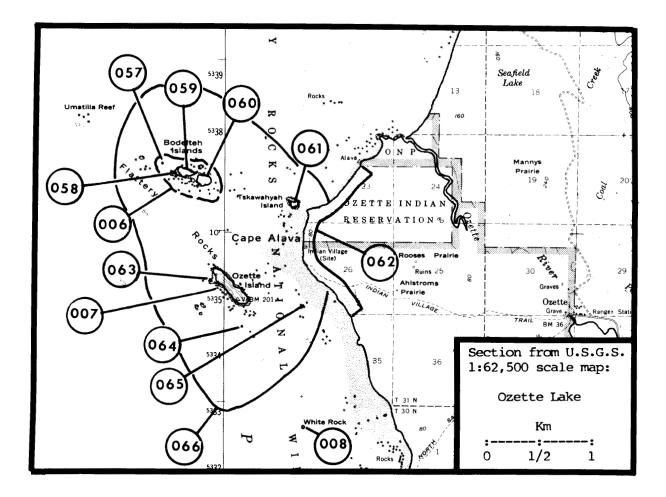

# VIEW POINT: Cape Alava

COLONY: Bodelteh Islands, Ozette Island

ACCESS: The Cape Alava trail is 3.3 miles long, from Lake Ozette to the Cape. The trail is reached by a road leaving Highway 110 west of Sekiu.

#### SEABIRD SPECIES:

Pelagic Cormorants, Black Oystercatchers, Glaucous-winged Gulls, Common Murres, Pigeon Guillemots and Tufted Puffins can be seen by telescope on the islands offshore. In addition, storm-petrels and Cassin's Auklets nest there. One of the few places in the State where Sea Otters may be seen from shore is near Ozette Island, to the south of Cape Alava.

VIEW POINT: Rialto Beach or LaPush

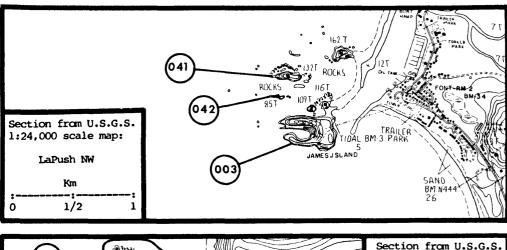

COLONY: Quillayute Needles

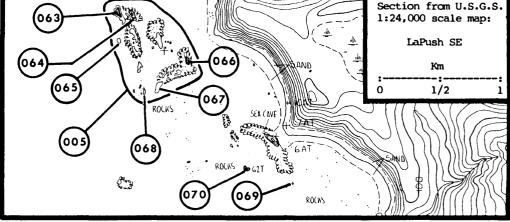

3

ACCESS: Leave Highway 101 just north of Forks, go about 10.5 miles where the right fork in the road goes to Mora Campground, Olympia National Park, and then to Rialto Beach, just the river across from LaPush. The left fork goes to the town of LaPush.

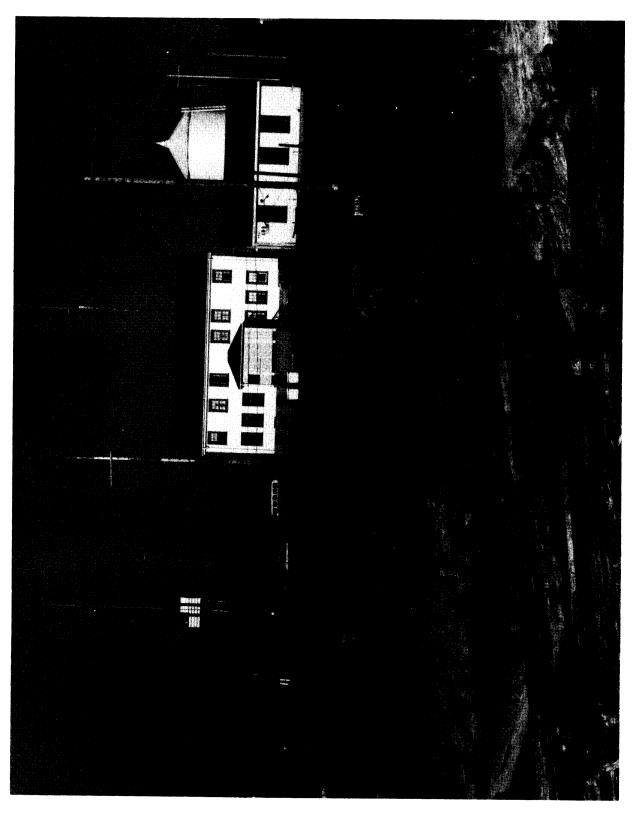

### SEABIRD SPECIES:

the Rialto Beach, From Quillayute Needles are visible just beyond wooded James Island. With a telescope, nesting murres, guillemots, and Tufted Puffins, may be seen along with many other species, including Harlequin Ducks histronicus), (<u>Histrionicus</u> scoters, Bald Eagles (<u>Haliaectus</u> and shorebirds. <u>leucocephalus</u>), For better views of the Quillayute Needles colonies, take the road to LaPush (left-hand fork). From LaPush it is possible to walk the beach south and from there to look at the offshore islands and their colonies.

VIEW POINT: Cape Disappointment Interpretive Center overlook, lighthouse

COLONY: Cape Disappointment

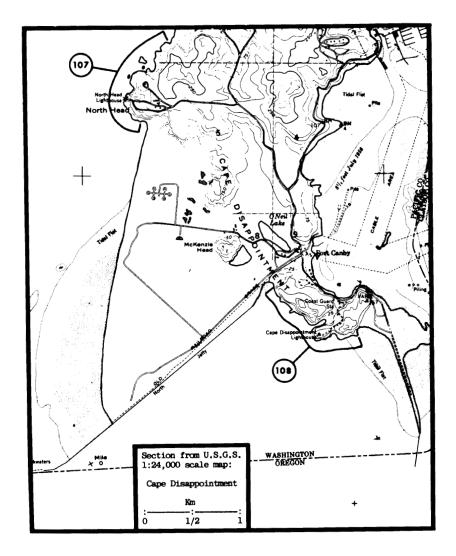

ACCESS:

4

Reach the Lewis and Clark Interpretive Center by following directions from Ilwaco. The access trail to the Cape Disappointment lighthouse is also marked.

#### SEABIRD SPECIES:

The nesting Brandt's and Pelagic cormorants can be seen by peering over the edge of the cliff at the interpretative center (stay behind the fence!) or from the lighthouse site with a telescope. This is one of only four known locations where Brandt's Cormorants nest in Washington and views here are good.

VIEW POINT: Highway 112 east of Neah Bay

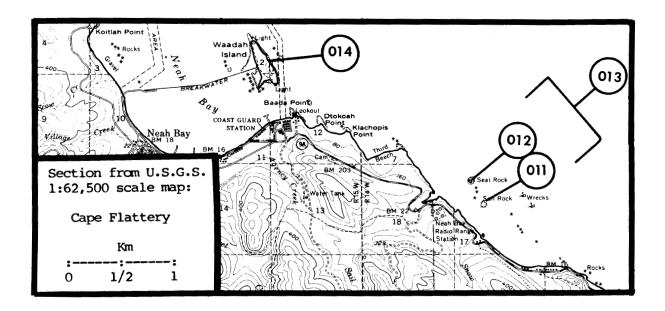

COLONY: Seal and Sail Rocks

ACCESS: Pull off where space permits. Can be viewed by small boat from a distance.

[5]

# SEABIRD SPECIES:

Cormorants, Black Oystercatchers, Glaucous-winged Gulls, Pigeon Guillemots, and Tufted Puffins can be seen by telescope on these rocks: the only sizeable colony between Cape Flattery and Port Angeles.

VIEW POINT: Tongue Point, Salt Creek Recreation Area

COLONY: Tongue Point-Crescent Bay

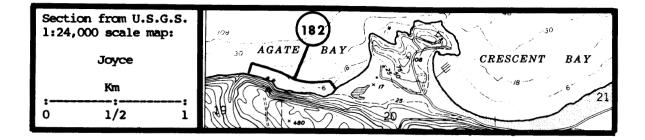

ACCESS:

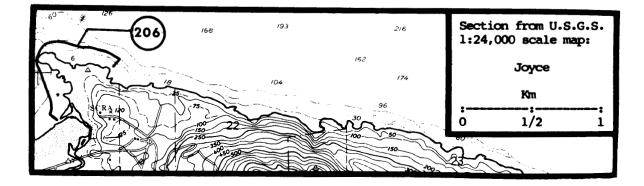

(6)

Leave Highway 112 about 13 miles west of Port Angeles at signs from Salt Creek Recreation Area (Clallam County Park). Follow the road through the camping area to Tongue Point.

# SEABIRD SPECIES:

While this is not a "colony" as such, it is a good place to see Black Oystercatchers and Pigeon Guillemots at close range during the nesting season. Marbled Murrelets are usually here, too.

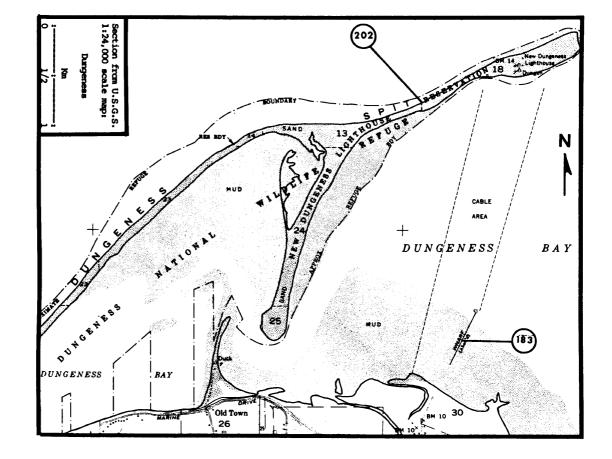

- VIEW POINT: Old Dungeness ("3 Crabs")
- COLONY: Abandoned pier

ACCESS: Limited parking is available at the end of the road next to the 3 Crabs Restaurant (do not use the restaurant parking lot). SEABIRD SPECIES:

The old pier offshore is used by nesting Pelagic Cormorants and Glaucous-winged Gulls, which can be seen quite closely by telescope.

VIEW POINT: Boat

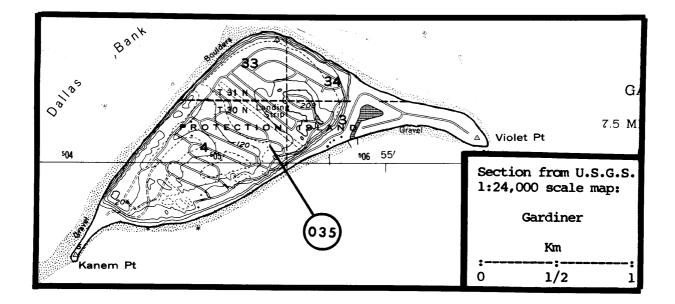

COLONY: Protection Island

ACCESS: Boats may be rented or larger vessels chartered in Port Townsend.

#### SEABIRD SPECIES:

This colony contains the largest number of Rhinoceros Auklets in Washington, along with impressive concentrations of Black Oystercatchers, gulls, Pigeon Guillemots, and Tufted Puffins. However, this colony is included in this section only because it is so well known and accessible, and compared to the open ocean coast, it is in relatively sheltered waters. Because of possible disturbance of nesting cormorants,

puffins, and hauled-out harbor seals, close approach is ill-The north side of the advised. island is fraught with navigational hazards and puffins in chased off be particular can cliffs on the south side. Most of the nesting seabirds can be seen much better at foraging areas. Rhinoceros Auklets can be seen close at hand at dusk offshore from the west end of the island as they bring food to chicks. Thousands of Rhinos feed during the daytime in Admiralty Inlet and can be seen from Point Wilson and the Keystone Ferry. The completion acquisition of of Protection Island by the U.S. Fish and Wildlife Service as a refuge subsequent and development of facilities interpretive and programs will minimize disturbance to animals and provide viewing possibilities in the future.

VIEW POINT: Cattle Point

COLONY: Goose Island

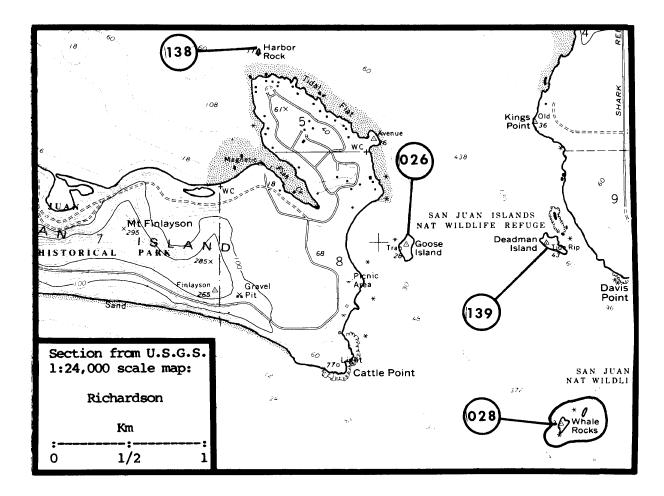

ACCESS:

9

Drive from Friday Harbor on San Juan Island to Cattle Point at the south end. There is a State Department of Natural Resources park on the site of an old lighthouse generator station.

#### SEABIRD SPECIES:

Goose Island is a small island offshore from Cattle Point, in the narrow entrance to San Juan Glaucous-winged Gulls Channel. and Black Oystercatchers nest here, and many other seabirds can be seen foraging in the tidal currents and along the shorelines. Whale Rocks and Mummy Rocks are visible to the east, near Lopez These are very important Island. cormorant roosting sites. Sea lions may be seen near them in the winter, and Minke Whales may be seen in the passage. Bald Eagles are also numerous in the area, and river otters may be seen.

VIEW POINT: Boat

COLONY: Colonies in San Juan Islands area

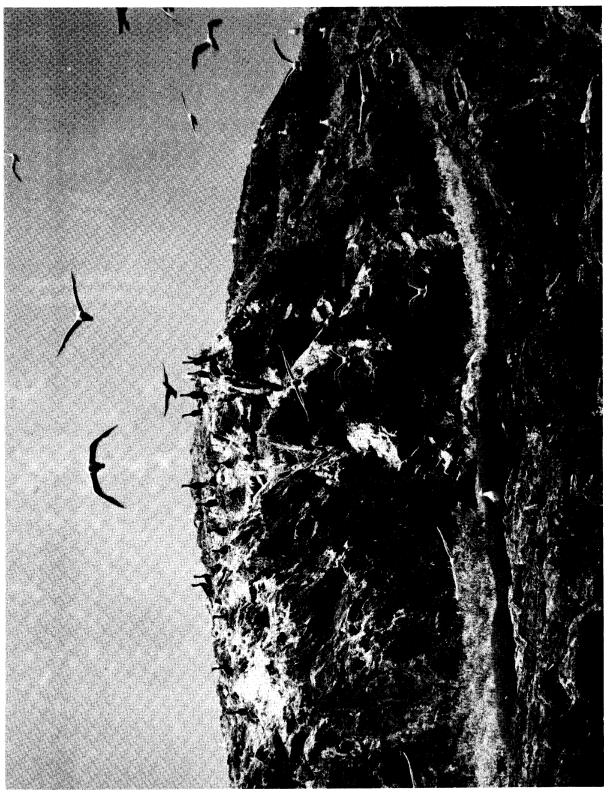

ACCESS: Small boats may be chartered in Anacortes and Friday Harbor.

# SEABIRD SPECIES:

There are many accessible small islands throughout the San Juan Islands. Almost all of these already have a great deal of disturbance due to small boats, scuba diving, and other

activities, however, and close approach is not advised.

Species nesting in the San Juans include Double-crested and Pelagic cormorants, Black Oystercatcher, Glaucous-winged Gulls, Pigeon Guillemot, and very few Tufted Puffins. Refer to individual site maps and listings for specifics. Marbled Murrelets may be seen in numbers at several locations in the San Juan Islands. The shoreline of Lopez Island near Point Colville and Watmough Head, Peavine Pass, and Obstruction Pass between Orcas and Blakely Islands, and the southwestern shoreline of Lummi Island are among the best places.

Colville Island (156032) D. Marshall

# APPENDIX C

#### NUMBERS OF PIGEON GUILLEMOTS AND MARBLED MURRELETS

All of the marine waters east of Cape Flattery have been systematically surveyed for the presence of marine birds during the summer breeding period. Marine waters of the Strait of Juan de Fuca, San Juan Islands, Georgia Strait, and the northeastern bays were surveyed during June of 1978 and 1979, using a variety of platforms of observation, such as a small airplane, а small boat, the Washington State Ferry, and land sites (see Manuwal et al. 1979b and Wahl et al. 1981 for details of sites, transect routes, and census methods). The results of these surveys for Pigeon Guillemots and Marbled Murrelets are summarized in Appendix Table 1.

The marine waters of Puget Sound (waters south of Admiralty Inlet) and Hood Canal were first systematically surveyed in summer 1982. During this survey, the entire marine shoreline was sampled from a small boat, a small airplane, in some cases, from shore and, (see Wahl and Speich 1984 for details). All open waters were also sampled. The numbers of Pigeon Guillemots Marbled and Murrelets observed are listed in Appendix Table 2.

As pointed out in the Species Accounts, these surveys are only samples; actual numbers of breeding individuals of each species are likely larger.

Censuses are sensitive to variety of factors. Environmental conditions such as sun glare and area, water surface glare condition, and tidal stage all affect the detectability of birds during censuses. The activity patterns of the species determine their presence on the water surface during surveys. Pigeon Guillemots often loaf on shore beaches, rocks, logs, and cliff ledges, making detection difficult, especially from aircraft. Censuses made during feeding periods likely will fail to detect birds beneath the water Birds may also dive to surface. avoid the approaching boat or aircraft and go undetected. During incubation period, the the incubating adult in the nest would of course also go unobserved.

There have been no systematic surveys along the outer coast of Washington, sensitive to Pigeon Guillemots and Marbled Murrelets, which would allow quantification of their numbers. Numerous pelagic trips out of Westport over the continental slope have shown the species to be rare in deep waters (Wahl, pers. obs.). Pigeon Guillemots are found all along the coast where suitable nesting habitat is found. These observations are recorded in the colony-site tables in this catalog. Apparently, few if any birds nest along the long stretches of

beaches south of Pt. Grenville, except as observed in the rocks of the jetties at the entrance to Grays Harbor and the cliffs of Cape Disappointment. Marbled Murrelets have been observed along the entire nearshore area of the outer coast. Birds are often seen in the entrance channels of Grays Harbor and Willapa Bay. Birds have been observed in the shallow coastal waters north of the Grays Harbor entrance. During surveys

of the north coastal islands between Pt. Grenville and Cape Flattery, during the summers of 1978 and 1979, Marbled Murrelets were often observed. However, these observations were from a Zodiac and were incidental to colony surveys. Marbled Murrelets appear to stay in shallow waters, and within 1 or 2 miles of shore. Comments on numbers are found in the Species Accounts.

NOTES:					

Table 1. Co	ncluded
-------------	---------

- a. Refers to Marine Ecosystem Analysis Program, National Oceanic and Atmospheric Administration, Seattle, Washington. For full details of this extensive project see Wahl et al. 1981.
- b. These are MESA subregion numbers. Many numbers were assigned during the MESA project. The numbering system was then subsequently extended to cover all marine waters of Washington (Wahl and Speich 1980). Subregion boundaries, although arbitrary, generally follow natural geographic and oceanographic features. Subregion boundaries and numbers are shown in maps on pages 502-507.
- c. The surface area,  $km^2$ , of the subregion.
- d. These are projected totals based on the mean density calculated from all censuses in the subregions in June of 1978 and 1979. The mean density was extended to the Subregion Area to obtain the projected totals. For full details see Wahl et al. (1981).
- e. This subregion consists entirely of offshore waters, greater than 20 m deep. See Wahl et al. (1981) for full details. If no comments are made, the subregion consists entirely or primarily of nearshore waters less than 20 m deep.
- f. This subregion contains nearshore waters and significant proportions of offshore waters. See Appendix A in Wahl et al. 1981 for full details.
- g. Number present indeterminant but probably small.

Table 2. Numbers of Pigeon Guillemots and Marbled Murrelets observed during censuses of Puget Sound nearshore waters, Summer 1982. All nearshore areas were surveyed 100% except for Admiralty Inlet (0401) with only 20% of the nearshore area surveyed and Penn Cove/Crescent Harbor (1402) with only 75% of the nearshore area surveyed.

Table 2. Conclude
-------------------

a. These are MESA subregion numbers. Many numbers were assigned during the MESA project. The numbering system was then subsequently extended to cover all marine waters of Washington (Wahl and Speich 1980). Subregion boundaries, although arbitrary, generally follow natural geographic and oceanographic features. Subregion boundaries and numbers are shown in maps on pages 501-506.

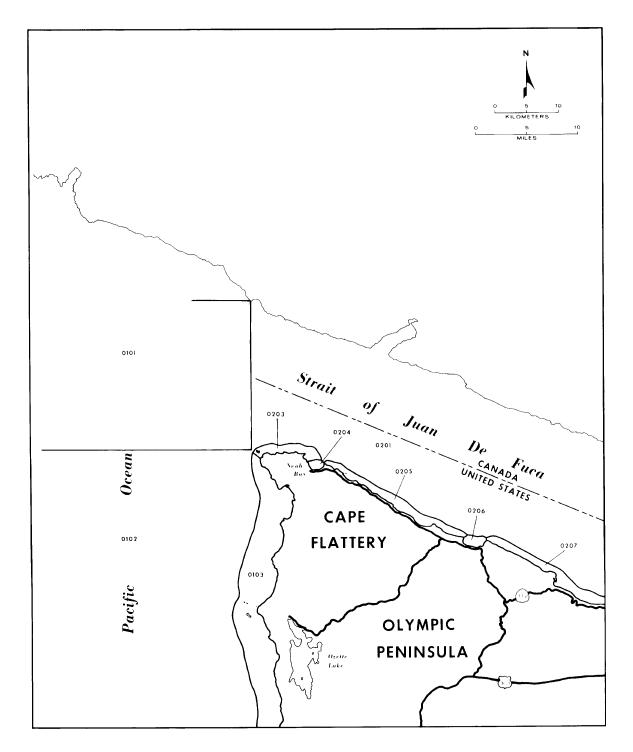

b. Survey type (observation platform) codes: A = airplane; B = small boat (and Washington State Ferry); and S = shoreline.

## APPENDIX D. Concluded

#### APPENDIX E

## AVAILABILITY AND PUBLISHING STATUS OF WATERBIRD ATLASES AND CATALOGS

Most of the listed atlases or catalogs are no longer available from the U.S. Fish and Wildlife Service, but may be found in the Federal Documents section in some libraries under the Superintendent of Documents code I 49.89/2 (see your local librarian for the location of the nearest library designated as a Federal Depository). Most may also be ordered from the National Technical Information Service (NTIS) at a cost (NTIS/U.S. Department of Commerce/5285 Port Royal Road/Springfield, VA 22161).

### ATLANTIC COAST:

- Erwin, R.M., and C.E. Korschgen. 1979. Coastal waterbird colonies: Maine to Virginia, 1977. An atlas showing colony locations and species composition. U.S. Fish Wildl. Serv. FWS/OBS-79/08. 647 pp. NTIS PB80 147 945
- Osborn, R.G., and T.W. Custer. 1978. Herons and their allies: atlas of Atlantic coast colonies, 1975 and 1976. U.S. Fish Wildl. Serv. FWS/OBS-77/08. 211 pp. NTIS PB297 864
- Portnoy, J.W., R.M. Erwin, and T.W. Custer. 1981. Atlas of gull and tern colonies: North Carolina to Key West, Florida (including pelicans, cormorants, and skimmers). U.S. Fish Wildl. Serv. FWS/OBS-80/05. 121 pp. NTIS PB82 116 054

## FLORIDA:

Nesbitt, S.A., J.C. Ogden, H.W. Kale II, B.W. Patty, and L.W. Rowse. 1982. Florida atlas of breeding sites for herons and their allies: 1976-78. U.S. Fish Wildl. Serv. FWS/OBS-81/49. 449 pp. NTIS PB83 138 438

GULF COAST:

Portnoy, J.W. 1977. Nesting colonies of seabirds and wading birds coastal Louisiana, Mississippi, and Alabama. U.S. Fish Wildl. Serv. FWS/OBS-77/07. 126 pp. NTIS PB 286 216

509

## TEXAS:

Texas Colonial Waterbird Society. 1982. An atlas and census of Texas waterbird colonies 1973-1980. Caesar Kleberg Wildlife Research Institute, Texas A&I University, Kingsville. 358 pp. (not available from USFWS)

## GREAT LAKES:

Scharf, W.C. 1978. Colonial birds nesting on man-made and natural sites in the U.S. Great Lakes. U.S. Army Eng. Waterways Exp. Stn., Vicksburg, Miss. Tech. Rep. 0-78-10, and U.S. Fish Wildl. Serv. FWS/OBS-78/15. 136 pp. + appendixes. NTIS AD A061 818

#### CALIFORNIA:

Sowls, A.L., A.R. DeGange, J.W. Nelson, and G.S. Lester. 1980. Catalog of California seabird colonies. U.S. Fish Wildl. Serv. FWS/OBS-80/37. 371 pp. NTIS PB81 212 599

#### OREGON:

Pitman, R.L, J. Hodder, M.R. Graybill, and D.H. Varoujean. 1988. Catalog of Oregon seabird colonies. U.S. Fish Wildl. Serv. Biol. Rep. 88(7). (Unpubl)

## ALASKA:

Sowls, A.L., S.A. Hatch, and C.J. Lensink. 1978. Catalog of Alaska seabird colonies. U.S. Fish Wildl. Serv. FWS/OBS-78/78. 153 pp. + appendixes.

UNITED STATES:

Spendelow, J.A., and S.R. Patton. 1988. National atlas of coastal waterbird colonies in the contiguous United States: 1976-82. U.S. Fish Wildl. Serv. Biol. Rep. 88(5). x +326 pp.

OPTIONAL FORM 272 (4–77) (Formerly NTIS–35) Department of Commerce As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.
