

General Characteristics		
1	<b>Abstract of Model Capabilities</b>	<p>MATHEW/ADPIC are the core codes for the DOE Atmospheric Release Advisory Capability (ARAC) program at Lawrence Livermore National Laboratory (LLNL), Livermore, Calif. The models are used to simulate dispersion from a wide variety of releases of hazardous material in the atmosphere. The ARAC models can be used to make both real-time responses as well as assessments of radiological or chemical releases using sequential time-varying meteorological and source term inputs. The diagnostic models are applicable to all mesoscale meteorological and topographic settings (domain of a few km to thousands of km). The ARAC Model Set consists of the following 6 codes which are available in the public domain version:</p> <p>TOPOG - Topographic grid generation code  MEDIC - Meteorological data interpolation code  CG-MATHEW - Conjugate-Gradient Mass-Adjusted Three-Dimensional Wind Field  ADPIC - Atmospheric Dispersion by Particle-in-Cell  PLCNT - A graphical contour plot generator  TIMHIS - A Time History statistical analysis of ADPIC output values at individual receptors with optional comparison with measurement data.</p> <p>Several databases and programs to automatically initialize each of the 6 codes reside on the LLNL ARAC system, but are not included in the public domain version. These include terrain, geography, model parameter, default sources, chemical properties, dose conversion factors, chemical and radiological consequence guideline databases, a chemical source model, and real-time meteorological data feeds.</p>

4	<b>Life-Cycle</b>	<p>The MATHEW/ADPIC models were initially developed at LLNL in the mid-1970s as the basis for the Atmospheric Release Advisory Capability (ARAC) emergency response system. The initial version of the ARAC system (ARAC-1) became operational shortly before the Three Mile Island incident in 1979. From 1982-1985, the entire system was reengineered to run on DEC-VAX to support acquisition of global meteorological, topographic, and geographic data (ARAC-2). The ARAC-2 models underwent a major restructuring in the early 1990s. In 1994, MATHEW's numerical method and handling of boundary conditions were greatly improved (CG-MATHEW). In 1995, the ADPIC dispersion code was extended to include a cell-independent, purely Lagrangian Monte Carlo approach to modeling diffusion. CG-MATHEW/ADPIC Version 5.0 was frozen for public release in February, 1997. In 1996, LLNL began building the third generation system (ARAC-3). The MATHEW/ADPIC models will be replaced with new diagnostic meteorological (Atmospheric Data Assimilation and Parameterization Techniques-ADAPT) model and a new Lagrangian dispersion (Livermore Operational Dispersion Integrator-LODI) model that have a continuous terrain representation, variable 3-Dimensional grids, and prognostic model inputs. The system is being re-engineered to be independent of operating system, use of third-party software, and have a fully graphical user interface.</p>

5	<b>Model Description Summary</b>	<p>A typical run stream for the ARAC dispersion model set involves a sequence of 5 codes: TOPOG, MEDIC, MATHEW, ADPIC, and PLCNT. TOPOG produces a Eulerian grid of block-form terrain cell heights for the lower boundary of the model system. Meteorological observations or gridded data are input into MEDIC which performs an initial inverse-distance-squared weighting interpolation over the grid using. CG-MATHEW generates a mass-consistent wind field by a minimal adjustment of the interpolated MEDIC wind field. CG-MATHEW adjusts wind vectors using a finite-difference stencil for the Poisson equation and a conjugate gradient solution of the Euler-Lagrange equations. Vertical velocities are generated by enforcing the continuity equation on each grid cell. Flow either travels over or around or is blocked by terrain according to atmospheric stability. ADPIC provides the dispersion physics for a wide range of emissions, such as neutrally buoyant gases, and/or particles, including radioactive materials and chemicals. Up to 100,000 marker particles are available to represent as many as 9 different sources or species in a single model run. Each source may have its own release rate, particle-size distribution, deposition velocity, and plume-rise characteristics. Sources may be either instantaneous puffs or continuous plumes with any initial point, line, area, or volume geometry and time-varying release rates. First-order chemical, radioactive or ultraviolet light decay, particle-size-dependent gravitational settling, dry deposition, and precipitation scavenging can be computed during each time step for each source. Four inner nested grids with 2, 4, 8, and 16 times the resolution of the primary grid cell provide higher resolution near sources. ADPIC uses the wind fields from CG-MATHEW for the transport component of dispersion. The diffusion component in ADPIC is based on K-theory parameterizations of horizontal and vertical eddy diffusivities. ADPIC solves the advection-diffusion equation using one of two options -- the original hybrid Eulerian-Lagrangian particle-in-cell technique or the newer Random Displacement Method (RDM). RDM, a purely Lagrangian Monte Carlo statistical approach, is the preferred option. PLCNT produces a variety of contoured outputs on geographic map coordinates. Typical model results include plots of material deposited on the ground, instantaneous and time-integrated doses, or air concentrations (instantaneous, time-averaged, integrated, or composite peak over a period) at selected levels above the ground. Species or sources may be combined as required and contoured according to user-specified isopleth values.</p>
6	<b>Application Limitation</b>	<p>MATHEW's diagnostic wind field is controlled by wind and user inputs. Interpolation of sparse data can be a limitation. ADPIC does not perform chemical transformations.</p>
7	<b>Strengths/ Limitations</b>	<p><b>Strengths:</b> The code is very robust and has been applied to thousands of assessments, responses and exercises over a 20-year period.</p> <p><b>Limitations:</b> The model uses a block cell representation of terrain, which can result in limited spatial resolution depending on terrain steepness and the number and size of grid cells used in the domain.</p>

10	<b>Output Summary</b>	<p>Each of the six codes produces graphical outputs in the form of GKS graphics files --Topographic cell heights, wind profiles and vector fields, marker particle overhead and cross-section views, and contour isopleth plots. All inputs are also echoed in output files. The user can also produce arrays of output values.</p> <p>Note: The VAX/VMS version includes GKS graphics; no attempt has been made to make this capability work in the UNIX environment. The ARAC-2 models augment the strict definition of GKS graphics and use a particular implementation of a CGM standard for graphics metafiles. Some development effort will be necessary to use the ARAC graphics code. All graphics calls in the source code can be removed with differential compile logic. Unix users may use other graphics packages such as PV-Wave or IDL.</p>
11	<b>Applications</b>	<p>MATHEW/ADPIC has been applied to thousands of assessments, safety analyses, responses to accidental releases and emergencies, and exercises throughout the world.</p> <p>Some of the over 80 responses include:</p> <ul style="list-style-type: none"> <li>! Material processing and transportation accidents <ul style="list-style-type: none"> <li>-1986 Sequoyah Fuels Plant UF6 accident, Gore, Oklahoma, several tritium releases</li> </ul> </li> <li>! Industrial chemical accidents <ul style="list-style-type: none"> <li>- 1991 Metam sodium spill into Sacramento River, Calif.</li> <li>- 1993 Sulfuric acid release from overheated oleum tank car, Richmond, Calif.</li> <li>- 1996 Bogalusa, Louisiana nitrogen tetroxide tank car</li> <li>- 1996 Cajon Pass, Calif. rail accident, multiple chemicals</li> </ul> </li> </ul>
12	<b>User-Friendliness</b>	<p>No graphical user interface is provided for the public version. To create input files the user must edit FORTRAN namelist files. To execute each of the codes the user must enter individual run commands.</p>

13	<b>Hardware-Software Interface Constraints/ Requirements</b>	<p><b>Computer operating system:</b> The ARAC-2 CG-MATHEW/ADPIC Version 5.0 set of six codes is available for public distribution via the DOE Energy Science and Technology Software Center (ESTSC) in Oak Ridge, TN. Two versions of the software are provided in separate file groupings - the native DEC-VMS operating system and a differential compile for UNIX platforms. The VMS grouping has the full sources as they exist in the ARAC system, along with the MMS files used to build different versions of the models on the VMS system. The UNIX version covers the necessary details for installing the models in a UNIX environment. The UNIX versions have been installed under Solaris, Digital UNIX, IRIX and UNICOS.</p> <p><b>Other Programming or Operating Information or Restrictions:</b>      Compiling the source code requires a Fortran-77 compiler with extensions for namelist I/O, long variable names and include files. Graphics output requires a GKS library, although all graphics can be removed via differential compilation. The full package also includes some DEC-Pascal routines but these can also be removed via differential compilation.</p> <p>Memory requirements vary with various compiled parameters such as the grid dimensions. For example, for a MATHEW grid of 51x51x15 and an ADPIC grid of 41x41x15 the codes have the following memory requirements in a VAX/VMS environment:      TOPOG - 31 Megabytes      MEDIC - 122 Megabytes      MATHEW- 19 Megabytes      ADPIC - 47 Megabytes      PLCNT - 16 Megabytes      TIMEHIS - 123 Megabytes</p> <p><b>Computer platform:</b> DEC VAX or any Unix platform</p> <p><b>Disk space requirements:</b>      Disk requirements vary with the run time and frequency of graphics, etc.</p> <p><b>Run execution time</b> (for a typical problem): Run time is dependent upon modeling time and several user-selected parameters (such as the number of marker particles used in ADPIC). A typical one-hour simulation (TOPOG through PLCNT) using 5000 marker particles completes in less than 2 CPU minutes on a VAX 6610.</p> <p><b>Programming language:</b> FORTRAN, Pascal</p> <p><b>Other computer peripheral information:</b> No information provided.</p>
14	<b>Operational Parameters</b>	<p><b>Identify whether the code has any error diagnostic messages to assist the user in troubleshooting operational problems:</b> Range checking and some input error diagnostics are available. There are limited run-time diagnostics; FORTRAN trace-back error statements are the basic method for determining model crashes.</p> <p><b>Set up time for:</b> <b>Typical times are:</b> <b>first-time user:</b> VAX-VMS version 2-3 months Unix version: 1 month <b>experienced user:</b> VAX-VMS version: 1 month Unix version: a few days, especially on Sun workstation under Solaris operating system</p>

15	<b>Surety Considerations</b>	<p><b>All quality assurance documentation:</b> Atmospheric Release Advisory Capability (ARAC) 1997: Users Guide to the CG-MATHEW/ADPIC Models, Version 5.0. ARAC, Lawrence Livermore National Laboratory UCRL-MA-103581 Rev. 5.                  Sugiyama, G., Lee, R.L., and Walker, H., 1994: Conjugate Gradient MATHEW, Lawrence Livermore National Laboratory Report UCRL-ID-118629.                  Ermak, D.L., J.S. Nasstrom, and A.G. Taylor, 1995: Implementation of a Random Displacement Method (RDM) in the ADPIC Model Framework, Lawrence Livermore National Laboratory UCRL-ID-121742. The codes have been run many thousands of times. Each new update is documented and tested before implemented. Over 1000 software change requests for revisions or fixes have been resolved through a formal system of prioritization, documentation and tracking.</p> <p><b>Benchmark runs:</b> In addition to testing the wind field against a potential flow field around a semi-hemispheric hill, the following 6 field tracer experiments are used to statistically benchmark model improvements:</p> <table border="0"> <thead> <tr> <th>Sponsor</th> <th>Project-Location</th> <th>Date</th> </tr> </thead> <tbody> <tr> <td>USAF</td> <td>Project Prairie Grass, O'NEILL, NB</td> <td>1957</td> </tr> <tr> <td>AEC</td> <td>Roller Coaster (explosions), NTS, NV</td> <td>1963</td> </tr> <tr> <td>EPRI</td> <td>Plume Model Validation - Kincaid, IL</td> <td>1980</td> </tr> <tr> <td>DOE</td> <td>MATS-Savannah River Plant, SC</td> <td>1983</td> </tr> <tr> <td>PG&amp;E</td> <td>DOPPTEX - Diablo Canyon NPP, CA</td> <td>1986</td> </tr> <tr> <td>CEC-IAEA-WMO</td> <td>ATMES (Chernobyl)</td> <td>1991</td> </tr> </tbody> </table> <p><b>Validation calculations:</b> Validation is achieved based on a significant number of model verifications or evaluations; see below.</p> <p><b>Verification with field experiments that has been performed with respect to this code:</b>                  The model has been evaluated against hundreds of tracer data sets from over 20 field programs in a wide variety of settings and scales from a few to thousands of km.</p> <table border="0"> <thead> <tr> <th>Sponsor</th> <th>Project-Location</th> <th>Date</th> </tr> </thead> <tbody> <tr> <td colspan="3">Up to 100 km</td> </tr> <tr> <td>USAF</td> <td>Project Prairie Grass, O'NEILL, NB</td> <td>1957</td> </tr> <tr> <td>AEC</td> <td>Roller Coaster (explosions), NTS, NV</td> <td>1963</td> </tr> <tr> <td>NOAA</td> <td>I-131 - Idaho Natl. <b>Part B: Dispersion Submodel Type</b>		
B1	<b>Gaussian</b>	<input type="checkbox"/> Straight-line plume <input type="checkbox"/> Segmented plume <input type="checkbox"/> Statistical plume <input type="checkbox"/> Statistical puff
B2	<b>Similarity</b>	<input checked="" type="checkbox"/> Plume <input checked="" type="checkbox"/> Puff
B3	<b>Stochastic</b>	<input checked="" type="checkbox"/> Monte Carlo <input checked="" type="checkbox"/> Random walk
B4	<b>Gradient Transport or K-Theory</b>	ADPIC is based on K-theory parameterizations of horizontal and vertical eddy diffusivities -- similarity theory for vertical diffusivity and horizontal diffusivity from sigma theta inputs and DraxlerOs (1976) parameterization. Draxler, R.R., 1976: Determination of atmospheric diffusion parameters. <i>Atmospheric Environment</i> , Vol. 10, pp. 99-105.
B5	<b>Particle-In-Cell</b>	The original ADPIC Eulerian-Lagrangian particle-in-cell technique has been replaced with a newer, preferred, purely Lagrangian Random Displacement Method (RDM) (See Item 8 below)
B8	<b>Particle</b>	ADPIC (Atmospheric Dispersion by Particle-in-Cell) is a numerical, 3-D particle-diffusion code which calculates the time-dependent distribution of air pollutants under many conditions including distorted wind fields, calm conditions, wet and dry deposition, radioactive decay, and space- and time-variable turbulence parameters. ADPIC solves the advection-diffusion equation using one of two options -- the original Eulerian-Lagrangian particle-in-cell technique or the newer Random Displacement Method (RDM). RDM, a purely Lagrangian Monte Carlo statistical approach, is the preferred option.
<b>Part C: Transport Submodel Type</b>		
C1	<b>Prognostic</b>	CG-MATHEW can produce prognostic results if the wind fields supplied to MEDIC are from another prognostic model.
C2	<b>Deterministic</b>	Two codes, MEDIC and CG-MATHEW, are used to create a transport wind field from either observations or gridded wind inputs. The user may input single or multiple surface and upper air observational data or gridded analyses or prognostic model data into MEDIC for each user-specified averaging time. Three separate layers of the atmosphere (surface, boundary, and geostrophic) are used to construct the 3-D wind field. The surface layer is the lowest layer in which surface effects predominate and no direction shear with height is allowed. The boundary layer is the region where both speed and directional shear can occur between the surface and geostrophic layers. The highest layer, the geostrophic layer, is the region of the atmosphere where surface effects have disappeared and the winds reflect larger-scale synoptic flow. MEDIC initially interpolates the data over the grid using an inverse-distance-squared weighting. The user controls the influence of meteorological input data on the vertical interpolation in the boundary layer. In

C2	<b>Deterministic (Cont.)</b>	sparse data regions, interpolation controlled by power-law profiles is preferred whereas in more dense data regions, extrapolating the input data is preferred. CG-MATHEW generates a 3-D mass-consistent wind field by a minimal adjustment of the purely horizontal (2-D) wind field supplied by MEDIC. A functional is formulated which minimizes the variance between input and output winds subject to a non-divergence constraint, mass-flow boundary conditions on lateral and top faces, and the requirement of zero normal wind-field components at terrain surfaces. The requirement of minimal adjustment maintains consistency with available meteorological measurements, while atmospheric stability governs the relative amounts of change in the vertical and horizontal wind components. The adjustment is irrational and neither momentum balance nor energy conservation is imposed. Velocity components are defined on staggered grid faces so that the mass-consistency constraint is cell-flux rather than grid-point based. The problem then reduces to the solution of the Poisson equation in the Lagrange multiplier, with the adjusted winds derived from the corresponding Euler-Lagrange equations.
C4	<b>Frame of Reference</b>	<input checked="" type="checkbox"/> Eulerian <input type="checkbox"/> Lagrangian <input type="checkbox"/> Hybrid <input type="checkbox"/> Eulerian-Lagrangian
<b>Part D: Fire Submodel Type</b> (Not Applicable)		
<b>Part E: Energetic Events Submodel Type</b>		
E2	<b>Dust Explosions</b>	Not explicitly treated, but may be simulated with an initial mushroom-shaped fixed source geometry.
E3	<b>Deflagrations</b>	Not explicitly treated, but may be simulated with an initial mushroom-shaped fixed source geometry.
E4	<b>Detonations</b>	<p>Two options are available:</p> <ul style="list-style-type: none"> <li>! An initial mushroom-shaped fixed source geometry.</li> <li>! A time-dependent explosive cloud rise module.</li> </ul> <p>The explosive cloud rise submodel in ADPIC provides a time evolution of the physical and thermodynamic properties of a buoyant cloud formed when a chemical explosive is detonated. This module generates additional vertical and horizontal components of motion applied to each ADPIC marker particle while under the influence of the rising thermal from the detonation. The code is based on integrating the 3-D conservation equations of mass, momentum, and energy over the cloud's cross section. With some simplifying assumptions the integral equations reduce to a set of ordinary differential equations which can be solved for the cloud radius, centerline height, temperature, and velocity as a function of time.</p> <p>The code is patterned after Boughton and Delaurentis (1987) with implementation details in Foster, <i>et. al.</i> (1990).</p> <p>Boughton, B.A., J.M. Delaurentis, and W.E. Dunn 1987: A stochastic model of particle dispersion in the atmosphere, <i>Boundary-Layer Meteorology</i>, Vol. <b>40</b>, pp. 147-163.</p> <p>Foster, K.T., R. Freis, J.S. Nasstrom, 1990: Incorporation of an explosive cloud rise code into ARAC's ADPIC transport and diffusion model. Lawrence Livermore National Laboratory Report UCRL-ID-103443.</p>
E5	<b>Vapor Cloud Explosions</b>	Not explicitly treated, but may be simulated with an initial mushroom-shaped fixed source geometry.
E6	<b>Boiling Liquid Expanding Vapor Explosions (BLEVEs)</b>	Not explicitly treated, but may be simulated with an initial mushroom-shaped fixed source geometry.
E7	<b>Missile Generation</b>	Not explicitly treated, but may be simulated with an initial mushroom-shaped fixed source geometry.
E8	<b>High Explosives</b>	See Item number 4.

E9	<b>Nuclear Detonations</b>	Not treated.

H11	Resuspension	The user can specify a deposited area source as a resuspension source.
H12	Radionuclide Ingrowth and Decay	Yes.
H13	Temporally and Spatially Variant Mesoscale Processes	Urban heat island: As diagnosed from observations. Canopies: Complex terrain (land) effects: <input type="checkbox"/> mountain-valley wind reversals <input type="checkbox"/> anabatic winds <input type="checkbox"/> katabaic winds Complex terrain (land-water) effects: <input type="checkbox"/> seabreeze airflow trajectory reversals <input type="checkbox"/> Thermally Induced Boundary Layer definition <input type="checkbox"/> seabreeze fumigation <input type="checkbox"/> landbreeze fumigation Thunderstorm outflow: Temporally variant winds: High velocity wind phenomena: <input type="checkbox"/> tornado <input type="checkbox"/> hurricane <input type="checkbox"/> supercane <input type="checkbox"/> microburst
<b>Part I: Model Input Requirements</b>		
I1	Radio(chemical) and Weapon Release Parameters	Release rate: <input checked="" type="checkbox"/> Continuous <input checked="" type="checkbox"/> Time dependent <input checked="" type="checkbox"/> Instantaneous Release container characteristics: <input type="checkbox"/> vapor temperature <input type="checkbox"/> tank diameter <input type="checkbox"/> tank height <input type="checkbox"/> tank temperature <input type="checkbox"/> tank pressure <input type="checkbox"/> nozzle diameter <input type="checkbox"/> pipe length (The ARAC chemical source model which uses container characteristics to model source terms is not included in the public domain codes.) Jet release: <input checked="" type="checkbox"/> initial size <input checked="" type="checkbox"/> shape <input type="checkbox"/> concentration profile at end of jet affected zone Release dimensions: <input checked="" type="checkbox"/> point <input checked="" type="checkbox"/> line <input checked="" type="checkbox"/> area Release elevation: <input checked="" type="checkbox"/> ground <input checked="" type="checkbox"/> roof <input checked="" type="checkbox"/> stack

12	Meteorological Parameters	<p>Wind speed and wind direction: <input checked="" type="checkbox"/> single point    <input type="checkbox"/> single tower/multiple point  <input checked="" type="checkbox"/> multiple towers</p> <p>Temperature: <input checked="" type="checkbox"/> single point                    <input checked="" type="checkbox"/> single tower/multiple point    <input checked="" type="checkbox"/> multiple towers</p> <p>Dew point temperature: <input type="checkbox"/> single point    <input type="checkbox"/> single tower/multiple point  <input type="checkbox"/> multiple towers</p> <p>Precipitation: <input checked="" type="checkbox"/> single point                    <input checked="" type="checkbox"/> single tower/multiple point    <input checked="" type="checkbox"/> multiple towers</p> <p>Turbulence typing parameters: <input type="checkbox"/> temperature difference    <input checked="" type="checkbox"/> sigma theta  <input checked="" type="checkbox"/> sigma phi            <input checked="" type="checkbox"/> Monin-Obukhov length    <input checked="" type="checkbox"/> roughness length  <input checked="" type="checkbox"/> cloud cover            <input checked="" type="checkbox"/> incoming solar radiation                    <input checked="" type="checkbox"/> user-specified</p> <p>Four dimensional meteorological fields from prognostic model: MEDIC accepts wind fields from any prognostic model.</p>
<b>Part J: Model Output Capabilities</b>		
J1	Hazard Zone	User specified contours.
J2	Graphic Contours and Resolution	Yes. Resolution depends on model grid and location of 4 inner grid nests, each of which are half the horizontal dimension of the specified grid cell.
J3	Concentration Versus Time Plots	Yes
J4	Tabular at Fixed Downwind Locations	Yes
J5	Health Effects	<input checked="" type="checkbox"/> toxicity indices [e.g., ERPG's, PAG's] <input type="checkbox"/> potential fatalities <input type="checkbox"/> cancers <input type="checkbox"/> other adverse effects
J6	Number of People Affected, Calculated at What Resolution?	<input type="checkbox"/> block <input type="checkbox"/> block group <input type="checkbox"/> country Not provided with public domain codes, but can be incorporated.
J9	Commerical Off-the-Shelf (COTS) Geographic Information System (GIS) Used	Not provided with public domain codes, but can be incorporated.
J11	Accuracy of Output, Calculated in Terms of Percentages of Population Impacted More Than Predicted at one, two, and three Standard Deviations in Urban and Rural Areas	Accuracy of model output is summarized in ARAC model evaluation papers. The models have been evaluated in both urban and rural areas. One common statistic used in these evaluations is the ratio of observed to modeled concentrations. Results of many model calculations paired in space and time with all available observations show that the MATHEW/ADPIC models estimate the air concentrations of the tracer to within a factor of 2 of the measured values 20 to 50% of the time, and to within a factor of 5 about 35 to 85% of the time. The lower performance is during complex meteorological conditions or complex terrain, or elevated release heights. The higher performances is in simpler settings and shorter distances.

Part K: Model Usage Considerations		
K1	<p><b>Ease of Model Use</b></p>	<p><b>Training required to run the model: 4 _ background (years of education)</b>  <b>__ training time needed on the model to be able to exercise all model capabilities</b>                      Recommend minimum of BS in meteorology with knowledge of FORTRAN.</p> <p><b>Training required to continue development of the model:</b>  <b>Min. 6 months _ background (years of education)</b>                      Recommend Ph. D. in atmospheric sciences.  <b>6 months _ training time needed on the model to be able to exercise all model capabilities</b>                      See above.</p>
K2	<p><b>Time to Process From Notification of Release (including data acquisition) to Production of Product Listed in #K1, Listed for Platforms for Which the Program is Already Compiled</b></p>	<p>When fully implemented with automated meteorological data acquisition on a workstation, the time to produce contour plots from when input files are completed is 2-5 min. See: Lawver, B.S., T.J. Sullivan, R.L. Baskett. 1993. A real-time monitoring/emergency response workstation using a 3-D numerical model initialized with sodar. American Nuclear Society Topical Meeting on Environment Transport and Dosimetry, ANS, Chicago. Also LLNL UCRL JC-113042.</p>
K3	<p><b>Ease of Use of Output, Evaluated as the Time Needed to Train a College Graduate in the Use of the Output</b></p>	<p>The ARAC plot format for the VAX/VMS version using GKS Graphics presents a contoured map of the user-specified consequences, associated health consequence description and appropriate source and timing labels. ARAC plots have been used by many emergency response managers for many years and are intended for interpretation without training.</p>
