## NOAA Technical Memorandum NMFS

The National Marine Fisheries Service's Alaska Fisheries Science Center uses the NOAA Technical Memorandum series to issue informal scientific and technical publications when complete formal review and editorial processing are not appropriate or feasible. Documents within this series reflect sound professional work and may be referenced in the formal scientific and technical literature.

The NMFS-AFSC Technical Memorandum series of the Alaska Fisheries Science Center continues the NMFS-F/NWC series established in 1970 by the Northwest Fisheries Center. The NMFS-NWFSC series is currently used by the Northwest Fisheries Science Center.

## **Abstract**

The Resource Assessment and Conservation Engineering Division of the Alaska Fisheries Science Center conducts annual bottom trawl surveys to monitor the condition of the demersal fish and crab stocks of the eastern Bering Sea continental shelf. The standard study area, surveyed each year since 1979, encompasses a major portion of the eastern Bering Sea shelf between the 20-m and the 200-m isobaths and from the Alaska Peninsula north to approximately the latitude of St. Matthew Island ( $60^{\circ}50'N$ ). In 2007, two chartered trawlers, the 40-m FV *Arcturus* and the 40-m FV *Aldebaran* surveyed this area.

Demersal populations were sampled by trawling for 30 minutes at stations centered within  $20 \times 20$  nautical mile grids covering the survey area. At each station, species composition of the catch was determined. Length distributions and age structure samples were collected from ecologically and commercially important species.

All 356 standard survey stations were sampled successfully. Twenty additional survey stations were sampled northwest of the standard survey area primarily to investigate the distribution and abundance of walleye pollock and opilio crabs. Walleye pollock, yellowfin sole, and rock sole dominated fish biomass estimates (8.3 million metric tons combined). A total of 179 invertebrate species were identified to the species level in the survey.

Survey results presented in this report include abundance estimates for fish and invertebrates, geographic distributions of important fish species and size composition of principal fish species, and contour plots of surface and bottom temperatures during the survey sampling period.

Appendices provide station data, summarized catch data by station, species listings, and detailed analyses of abundance and biological data of the sampled populations.

## **Introduction**

The eastern Bering Sea continental shelf supports one of the most productive groundfish and crab fisheries in the world (Bakkala 1993). Since 1970, groundfish such as walleye pollock (*Theragra chalcogramma*), yellowfin sole (*Limanda aspera*) and Pacific cod (*Gadus macrocephalus*) have been the primary target species among commercial catches. Although many species of groundfish are caught commercially, walleye pollock is the most abundant with catches ranging from 1.2 to 1.5 million metric tons (t) per year for the past 30 years, and marketed products represent 40% of the global whitefish market (Ianelli et al. 2007).

Since 1971, the National Marine Fisheries Service (NMFS) Resource Assessment and Conservation Engineering (RACE) Division of the Alaska Fisheries Science Center (AFSC) has conducted an annual bottom trawl survey in the eastern Bering Sea to determine the distribution and abundance of groundfish and crab resources.

The first large-scale survey of the eastern Bering Sea shelf was conducted in 1975 under contract from the Bureau of Land Management in response to a need for baseline data to assess the potential impact of proposed offshore oil exploration and development on fishery resources (Pereyra et al. 1976). During this baseline survey, sampling was conducted over the eastern Bering Sea shelf between the 20-m and 200-m isobaths from the Alaska Peninsula north to approximately 62°N.

In subsequent years, the area coverage of the annual surveys was reduced until 1979 when the most comprehensive survey of the Bering Sea shelf was undertaken in cooperation with the Japan Fisheries Agency (Bakkala and Wakabayashi 1985). That survey encompassed the entire region sampled in the 1975 baseline study plus the continental slope waters between

St. Matthew and St. Lawrence Islands. A hydroacoustic survey was also conducted in 1979 to assess the midwater component of the walleye pollock population.

Subsequent annual bottom trawl surveys have essentially resampled the stations established during the 1975 survey, with slight modifications each year. This region encompasses the major portion of economically important eastern Bering Sea groundfish and crab populations, except those primarily located in the deep continental slope waters. Commercial crab stocks managed by the Alaska Department of Fish and Game (ADF&G), are covered by the North Pacific Fishery Management Council's Fishery (NPFMC) Management Plan for the Commercial King and Tanner Crab Fisheries in the Bering Sea and Aleutian Islands Regions. Crab species of interest include Tanner crab (*Chionoecetes bairdi*), snow crab (*C. opilio*), two stocks of blue king crab (*Paralithodes platypus*), red king crab (*P. camtschaticus*), and hair crab (*Erimacrus isenbeckii*). Detailed results from the most recent crab survey are available in Rugolo et al. (2006).

Beginning in 1979 and on a triennial basis through 1991, the survey was extended to include bottom trawl sampling of the continental slope and in the region between St. Matthew and St. Lawrence Islands. The continental slope was not surveyed in 1994 or 1997 but the survey was resumed in 2000 as an independent bottom trawl survey series that is surveyed on a biennial basis. The most recent continental slope survey was conducted in 2004 (Hoff and Britt 2005).

The groundfish information gathered by the annual biological surveys serves to: 1) provide annual fishery-independent estimates of abundance and biological condition of commercially exploited stocks to the NPFMC; 2) provide updates on the distribution and abundance information to commercial fishermen; and 3) continue a time-series database critical

to our improved understanding of the population dynamics and interactions of groundfish species. This report presents information collected by the AFSC on the eastern Bering Sea shelf during the 2007 bottom trawl survey, which represents the twenty-sixth contribution to the time series.

## Methods

### **Survey area and sampling design**

The standard station pattern for the eastern Bering Sea survey is based on 356 systematic  $37.04 \times 37.04$  km ( $20 \times 20$  nautical mile) grids with a fixed sampling station at the center of each grid square (Fig. 1). In areas surrounding St. Matthew and the Pribilof Islands, a high-density sampling of “corner stations” was implemented to better assess local blue king crab concentrations (Fig. 1). The original sampling design includes 356 sampling stations that have been sampled annually since 1982. An additional 20 stations were sampled northwest of the standard area primarily to investigate the distribution and abundance of opilio crabs and the northern distribution of walleye pollock (Fig. 2). For all 376 stations, a general description of the fish and invertebrate species caught by trawl is presented in the results section and a detailed list in Appendix A. Other than relative abundance for the top 25 fish species in the 20 northwest stations, all data analyses presented in the results section include only the 356 standard survey stations.

### **Sampling logistics and stratification scheme**

Survey trawl sampling began in Bristol Bay and stations were sampled along alternate, longitudinal columns (Fig. 2). When possible, using two vessels, this pattern of sampling

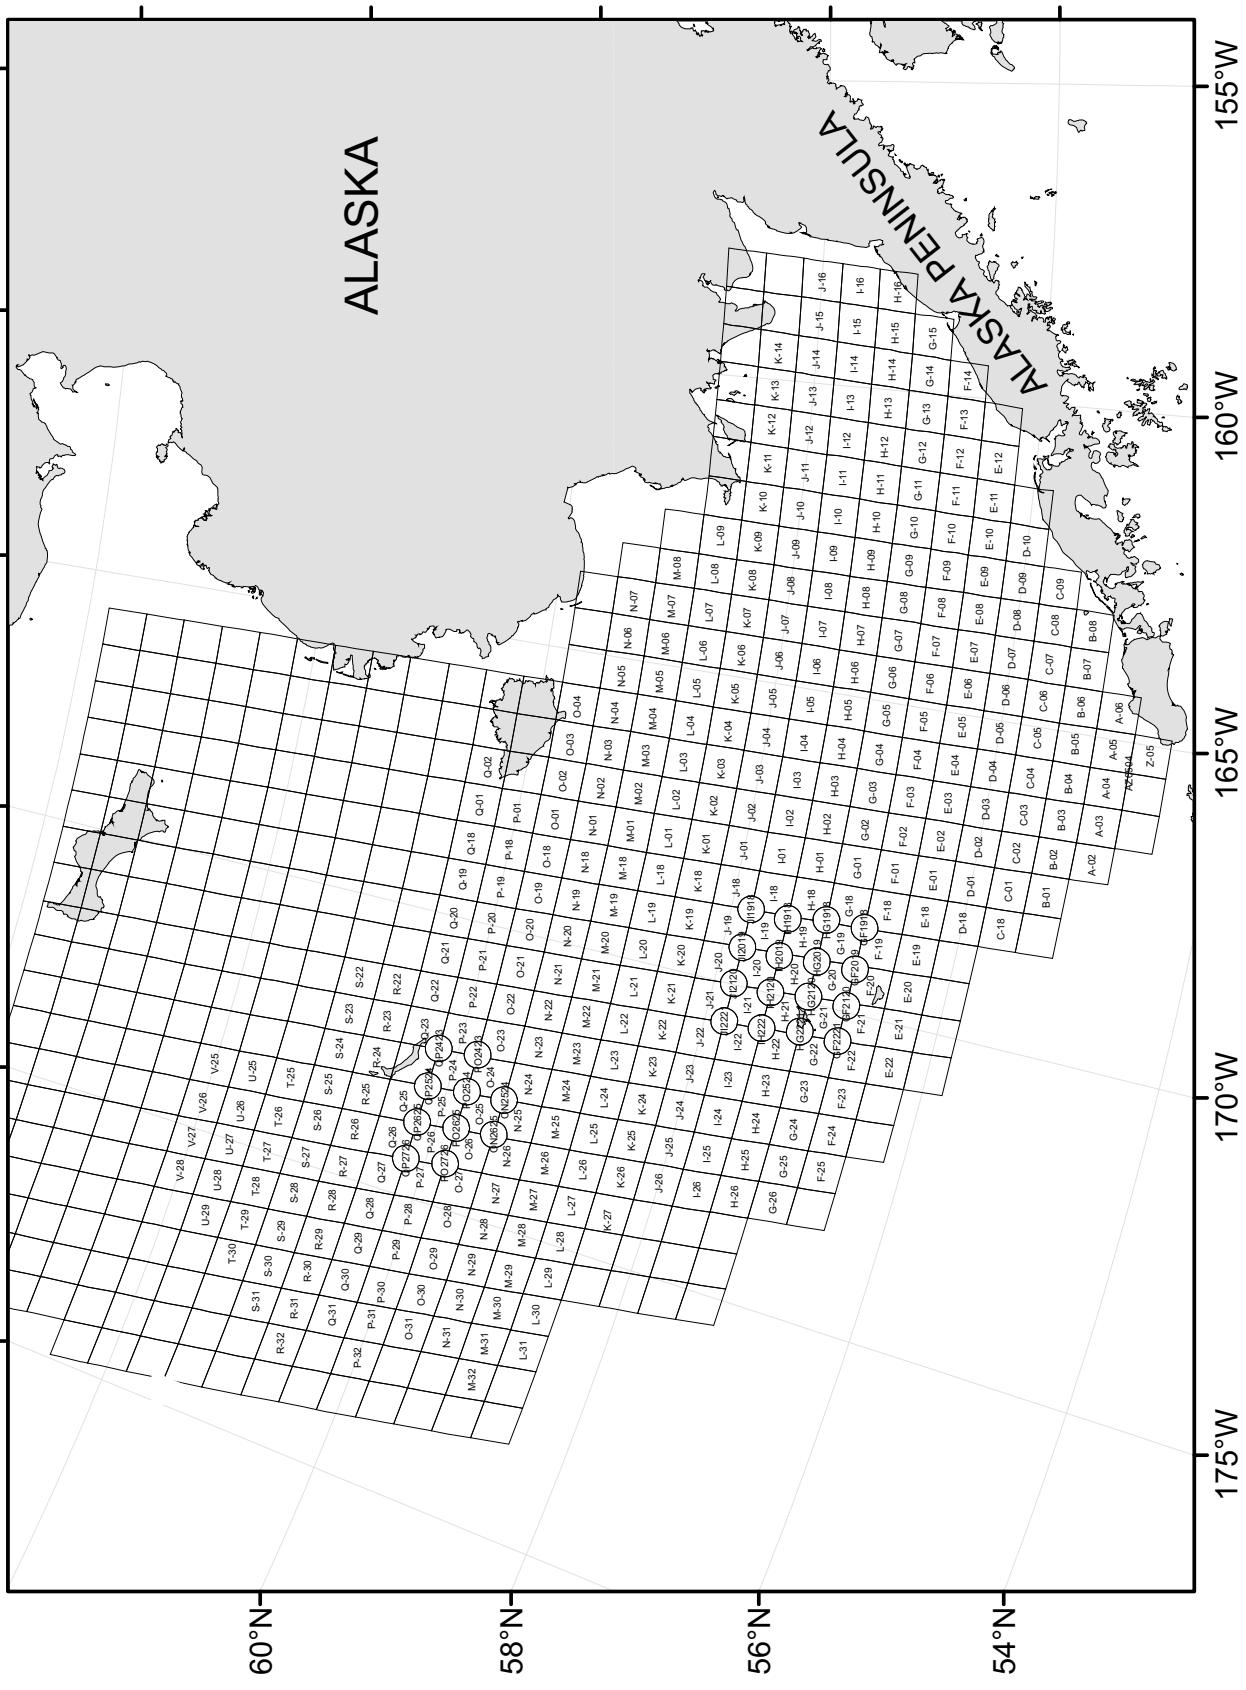

Figure 1. -- Grid map of sample stations for the eastern Bering Sea continental shelf trawl survey.

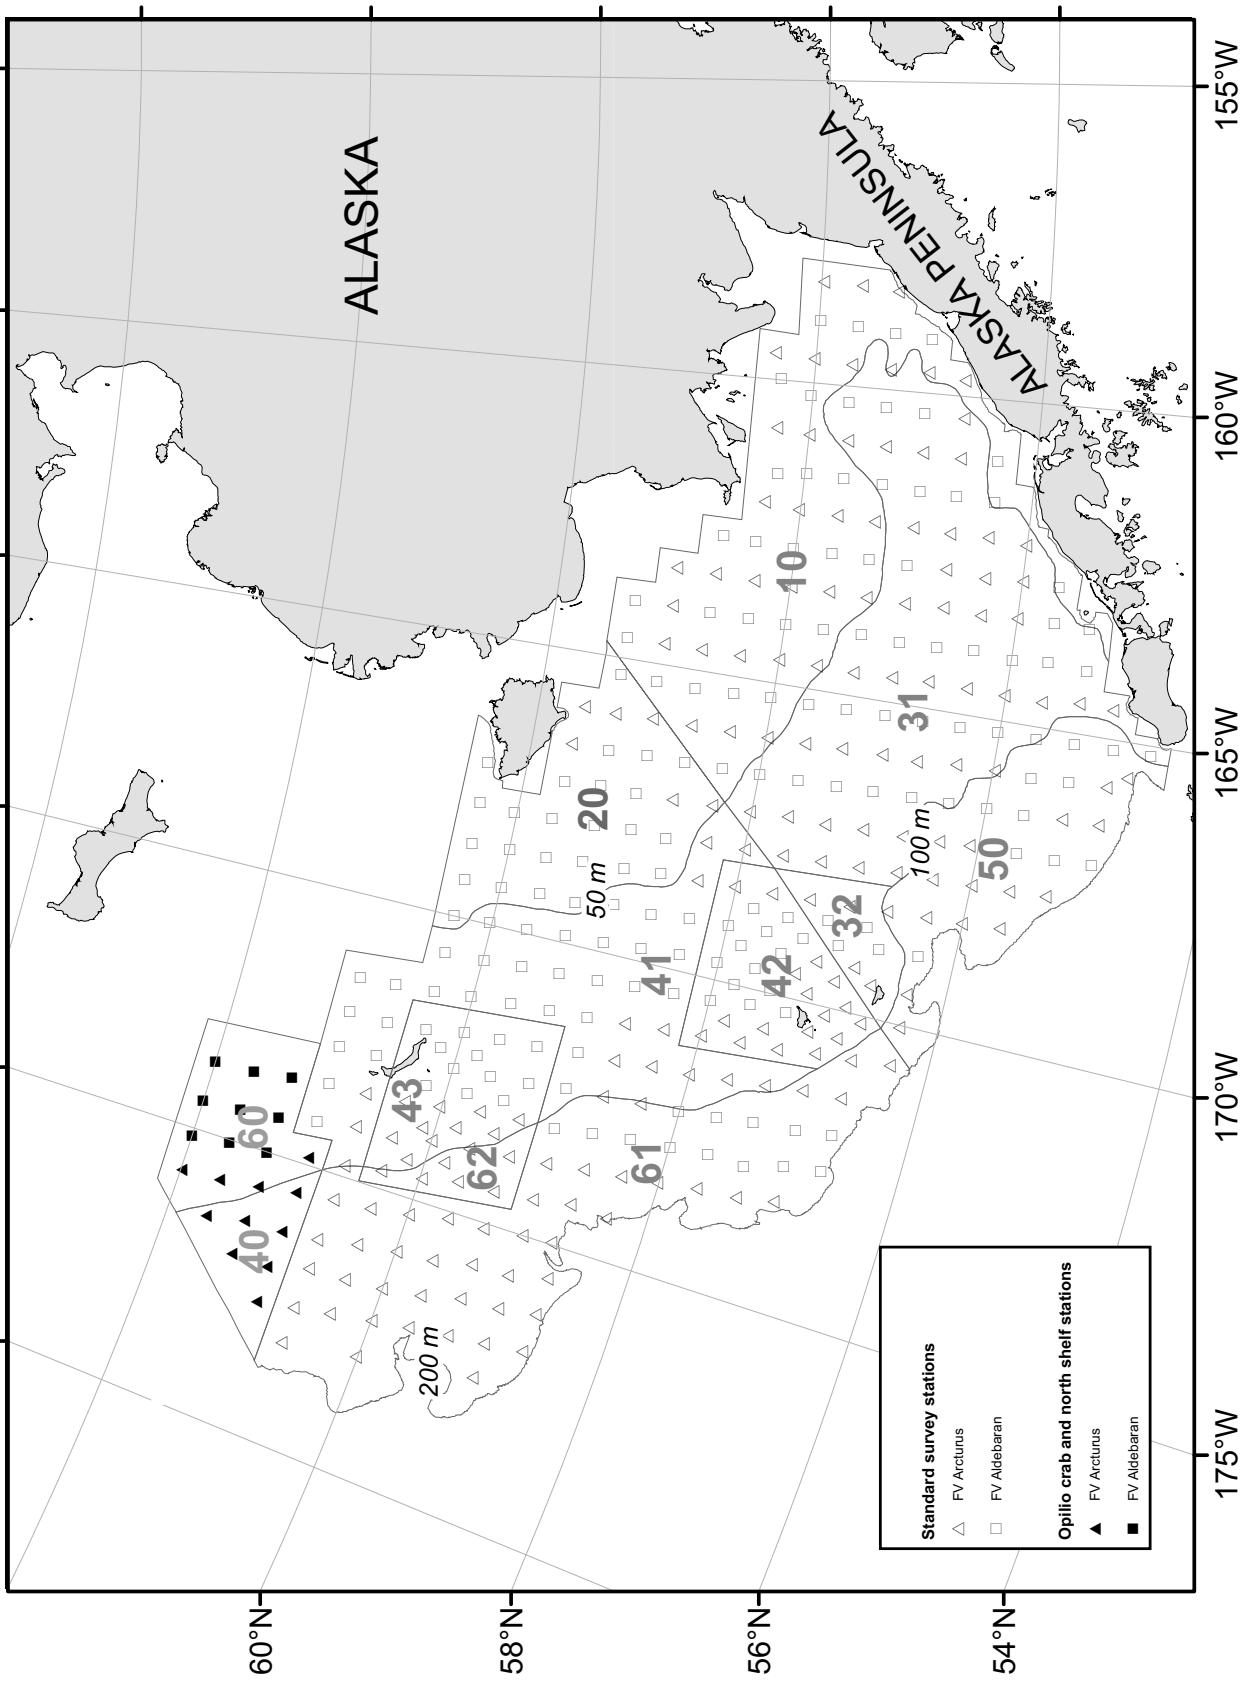

Figure 2. -- Sampled survey stations by vessel and the stratification scheme used for data analysis of the 2007 eastern Bering Sea bottom trawl survey.

proceeded westward to the shelf edge. This practice is designed to balance the coverage of the survey area between vessels. The progression from east to west was established in response to movements by yellowfin sole and perhaps other species, which may be migrating eastward during the course of the survey (Smith and Bakkala 1982).

For catch analysis, the survey region was divided into six strata bounded by the 50-m, 100-m, and 200-m isobaths and into two geographic strata that separate the northwest and southeast portions of the study area (Fig. 2). This stratification scheme best reflects the differences observed in Bering Sea groundfish across the different oceanographic domains, and the intention of the design was to reduce the variances of population and biomass estimates (Bakkala 1993). Localized high-density sampling for blue king crab in Strata 30, 40, and 60 necessitated a further subdivision into high-density and standard-density sample strata, resulting in a total of 10 strata.

The overall sampling density for the entire survey area was one station per 1,313 km<sup>2</sup> (Table 1). However, because of the high-density sampling in Strata 30, 40, and 60, and the irregular stratum boundaries, sampling density within the 10 subdivided strata varied from one station per 775 km<sup>2</sup> (Stratum 42) to one per 1,494 km<sup>2</sup> (Stratum 61).

### **Survey vessels and sampling gear**

From 4 June to 2 August 2007, the survey was conducted aboard the chartered commercial stern-trawlers FV *Arcturus* and FV *Aldebaran*. All fishing operations were conducted in strict compliance to national and regional protocols detailed in Stauffer (2004). Both vessels were equipped with standard 83-112 Eastern otter trawls, which have 25.3-m (83 ft) headropes and 34.1-m (112 ft) footropes (Fig. 3). These nets were attached to tail chains with

## 83/112 EASTERN

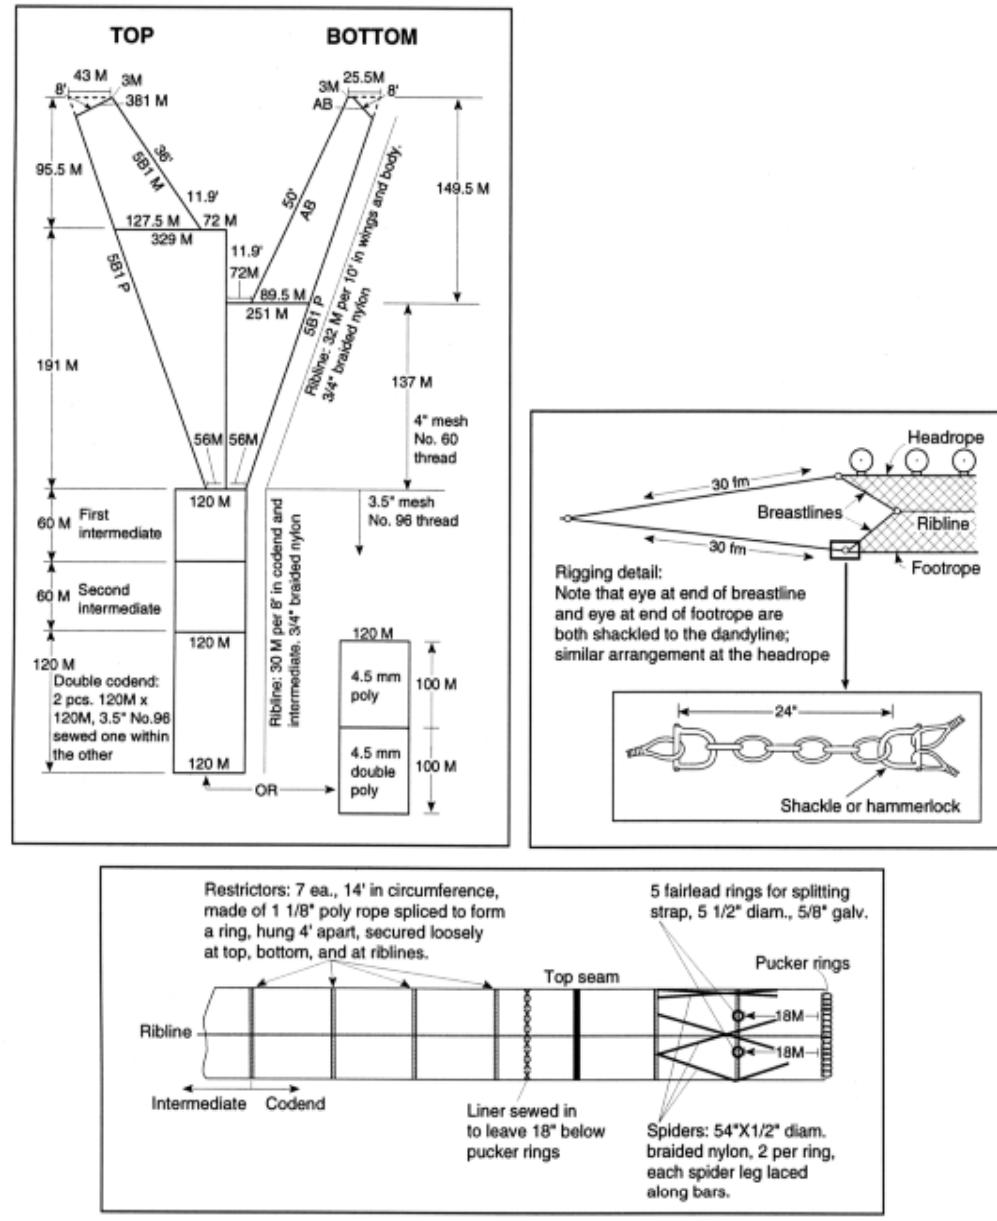

Figure 3. -- Schematic diagram of 83/112 Eastern otter trawl net used during the 2007 eastern Bering Sea bottom trawl survey.

54.9-m (30 fathom) paired dandylines. Each lower dandyline had a 0.61-m chain extension connected to the lower wing edge to improve bottom-tending characteristics. Steel "V"-doors measuring  $1.8 \times 2.7$  m and weighing 816 kg each were used.

Netmind net mensuration systems (Northstar Technical Inc., St. John's, Newfoundland) were used aboard each vessel to monitor and record net height and width during fishing operations. Net width was measured as the distance between two sensors attached to the upper starboard and port dandylines, about 0.61 m in front of the net, and net height was measured from the headrope to the seafloor bottom. Estimates of mean net width were used in calculations of the area-swept per tow (Rose and Walters 1990). For tows without observed net width values a mean net width-inverse scope regression (Zar 1999) was used because it accounts for a majority of the variation for the eastern Bering Sea standard survey trawl (Rose and Walters 1990; Fig. 4).

### **Catch sampling procedures**

Detailed sampling procedures used in RACE eastern Bering Sea assessment surveys are described in detail by Wakabayashi et al. (1985) and Stauffer (2004). A brief summary of sampling procedures is outlined in this section.

Samples were collected by trawling near the center of each  $37.04 \times 37.04$  km grid square (or corner station, in the case of high-density strata) for a target fishing time of 30 minutes and towing at a speed of 1.54 m/sec (3 knots). If the seafloor appeared to be untrawlable at the specified location, the nearest trawlable site within the same grid square was used. If the net was damaged or the net impacted by bottom structure during the trawl, the catch was discarded and a new sample obtained.

Catches estimated to be less than 1,150 kg (2,500 lb) were enumerated entirely while larger catches were subsampled. After sorting the subsample, individual species were weighed in aggregate and counted and these weights and numbers were expanded to the total catch.

Fishes and invertebrates were identified and sorted to the lowest taxonomic level practicable. Similar morphological features between flathead sole (*Hippoglossoides elassodon*) and Bering flounder (*H. robustus*) make accurate identification of these species difficult in areas where the two species overlap; thus, in the analysis for this report these species are grouped by genus (*Hippoglossoides* spp.). Due to low abundance (believed to be < 1%) of southern rock sole (*Lepidopsetta bilineata*) and its morphological similarities to northern rock sole (*L. polyxystra*; Orr and Matarese 2000), these species were also grouped by genus (*Lepidopsetta* spp.) for this report.

Catch weights and numbers by species or species group were either estimated directly when subsampled, or estimated by extrapolating the proportion in the subsample to that of the entire catch weight. Pacific halibut (*Hippoglossus stenolepis*), Greenland turbot (*Reinhardtius hippoglossoides*), skates, and commercial crab species were weighed and enumerated from the entire catch. Depending on size and catch composition, other fish species (such as certain sculpins, rarely encountered species, sharks) may have been completely sorted from the catch as well.

A random sample of approximately 200 fish of each selected abundant species was set aside for length measurements. Size composition data was collected for each commercially important groundfish species and many co-occurring species (Table 2). Length measurements were collected from randomly chosen samples of each species. The sex of each specimen was determined then each was measured to the nearest centimeter from the tip of the snout to the end

of the middle rays of the caudal fin (fork length measurement). Unless retained for sampling by the International Pacific Halibut Commission (IPHC) for management purposes, Pacific halibut were measured immediately upon capture and returned to the sea in an effort to reduce mortality; weights were estimated using an IPHC regression.

Sagittal otoliths were collected from 12 fish species in both the northwestern and southeastern divisions of the survey area (Table 3). The eastern Bering Sea was divided into low and high density strata for pollock otolith sampling. This division was based on historical pollock density data and a depth contour of approximately 70 m. Otoliths were collected from all hauls in which total number of pollock was 20 or more. Walleye pollock samples for otolith collection were selected at random from fish samples prior to sex determination. Six pairs of otoliths were collected in high-density strata and four otoliths in low-density strata. Three otolith pairs per sex-centimeter interval per vessel (six pairs total) were collected for Pacific cod, Greenland turbot (*Reinhardtius hippoglossoides*), Bering flounder (*Hippoglossoides robustus*), marbled eelpout (*Lycodes raridens*), and yellow Irish lord (*Hemilepidotus jordani*). Five otolith pairs per sex-centimeter interval by vessel (10 pairs total) were collected for yellowfin sole (*Limanda aspera*). Northern rock sole (*Lepidopsetta polyxystra*), flathead sole (*Hippoglossoides elassodon*), and Alaska plaice (*Pleuronectes quadrituberculatus*) were also collected at five otolith pairs per sex-centimeter interval, but on only one vessel. Pacific halibut otoliths were collected by the IPHC for population and growth analyses.

Individual fish weights were collected for all species for which age structures were taken. Age structures for roundfish were preserved in 70% ethanol; flatfish otoliths were preserved in 50% glycerol-thymol solution.

<sup>a</sup>Age structure collection analyzed and managed by the International Pacific Halibut Commission (IPHC); data were not tallied by strata.

Surface and bottom water temperatures, as well as temperature and depth profiles, were taken at each station using a Sea-Bird SBE-39 datalogger (Sea-Bird Electronics Inc., Bellevue, WA) attached to the headrope of the net. Depth to bottom was obtained by adding net height to headrope depth.

## **Data analysis**

Several analyses were performed on RACE survey data which included estimates of: 1) relative abundance; 2) population biomass; 3) population numbers, and 4) population abundance by size class. A brief description of the procedures used in the analysis of RACE Bering Sea survey data follows (for a detailed description see Wakabayashi et al. 1985). Note: some of the species collected were grouped by family for data analysis because of their limited commercial value or uncertain identification.

Mean catch per unit effort (CPUE) values for each species were calculated in kilograms per hectare ( $1 \text{ ha} = 10,000 \text{ m}^2$ ) and number per hectare for each of the 10 strata; area swept (hectares) was computed as the distance towed multiplied by the mean net width (Alverson and Pereyra 1969). Mean CPUE values were calculated for individual strata and for the overall survey area. Biomass and population estimates were derived for each stratum by multiplying the stratum mean CPUE by the stratum area. Stratum totals were then summed to produce estimates for each of the six main strata and the total survey area.

In estimating the population size composition of principal commercial species, the proportion of fish at each length interval (from subsamples at each station) was weighted by CPUE (number of fish/ha) and then expanded to the stratum population. Stratum estimates were

summed to derive the estimated size composition for each of the six main strata and for the overall survey area.

Except for Pacific halibut, otolith samples collected during the survey were read by staff of the Age and Growth Program of the AFSC's Resource Ecology and Fisheries Management (REFM) Division. Age, growth, and population analyses will be presented in separate reports (e.g., Ianelli et al. 2007).

### **Additional research projects**

In addition to the operations involved with the core sampling, there were 26 additional research projects undertaken during the 2007 survey (Table 4). The RACE Division projects included studies of: 1) gear performance and monitoring; 2) fish behavior in response to light and vessel noise; 3) fish and crab reproduction and pathology; 4) summer zooplankton biomass; 5) octopus populations, and 5) additional biological sampling of Bering flounder, eelpouts, and miscellaneous fish species. The REFM Division and the AFSC's Auke Bay Laboratories (ABL) special studies projects included: 1) fish stomach scans and collections (Table 5); 2) a seabird survey; 3) biological sampling of sculpins and forage fishes; 4) collections of fish prey for stable isotope analysis, and 5) tissue collections for a DNA-based identification library. The two projects from outside the agency involved halibut otolith, tag and size collections by the International Pacific Halibut Commission (IPHC), and collection of fish specimens for stable isotope analysis of fur seal prey by the University of Alaska Fairbanks (UAF).

## **Results and Discussion**

### **Station data**

A total of 376 stations were successfully sampled in 2007, which included 356 stations in the standard survey area and an additional 20 stations northwest of the standard survey area (Fig. 2). The additional northwest stations are in Strata 82 and 90 and they have been sampled annually since 1987. In order to maintain the time series for the longest possible period, the 20 northwest stations are excluded as part of the standard survey area. Data from all 376 stations from the 2007 survey are listed in Appendix B. Relevant information such as position, tow parameters (net width, depth, distance fished, and duration of haul), time, and environmental measurements (surface and gear temperatures) are listed for each vessel for all standard bottom trawl stations used in the analyses.

Any hauls that experienced significant gear damage or debris such as discarded crab pots were re-sampled immediately following the original haul. There were no stations skipped in 2007; however, 32 stations in Bristol Bay were resampled by the FV *Aldebaran* for crab at the end of the survey to allow additional time for female red king crab to molt successfully and develop clutches of eggs. A minimum threshold population of 8.4 million female red king crab  $\geq 90$  mm carapace length must be present for the fishery to remain open. The delayed spawning may have been in response to lower water temperatures at the onset of the survey (Dew in review).

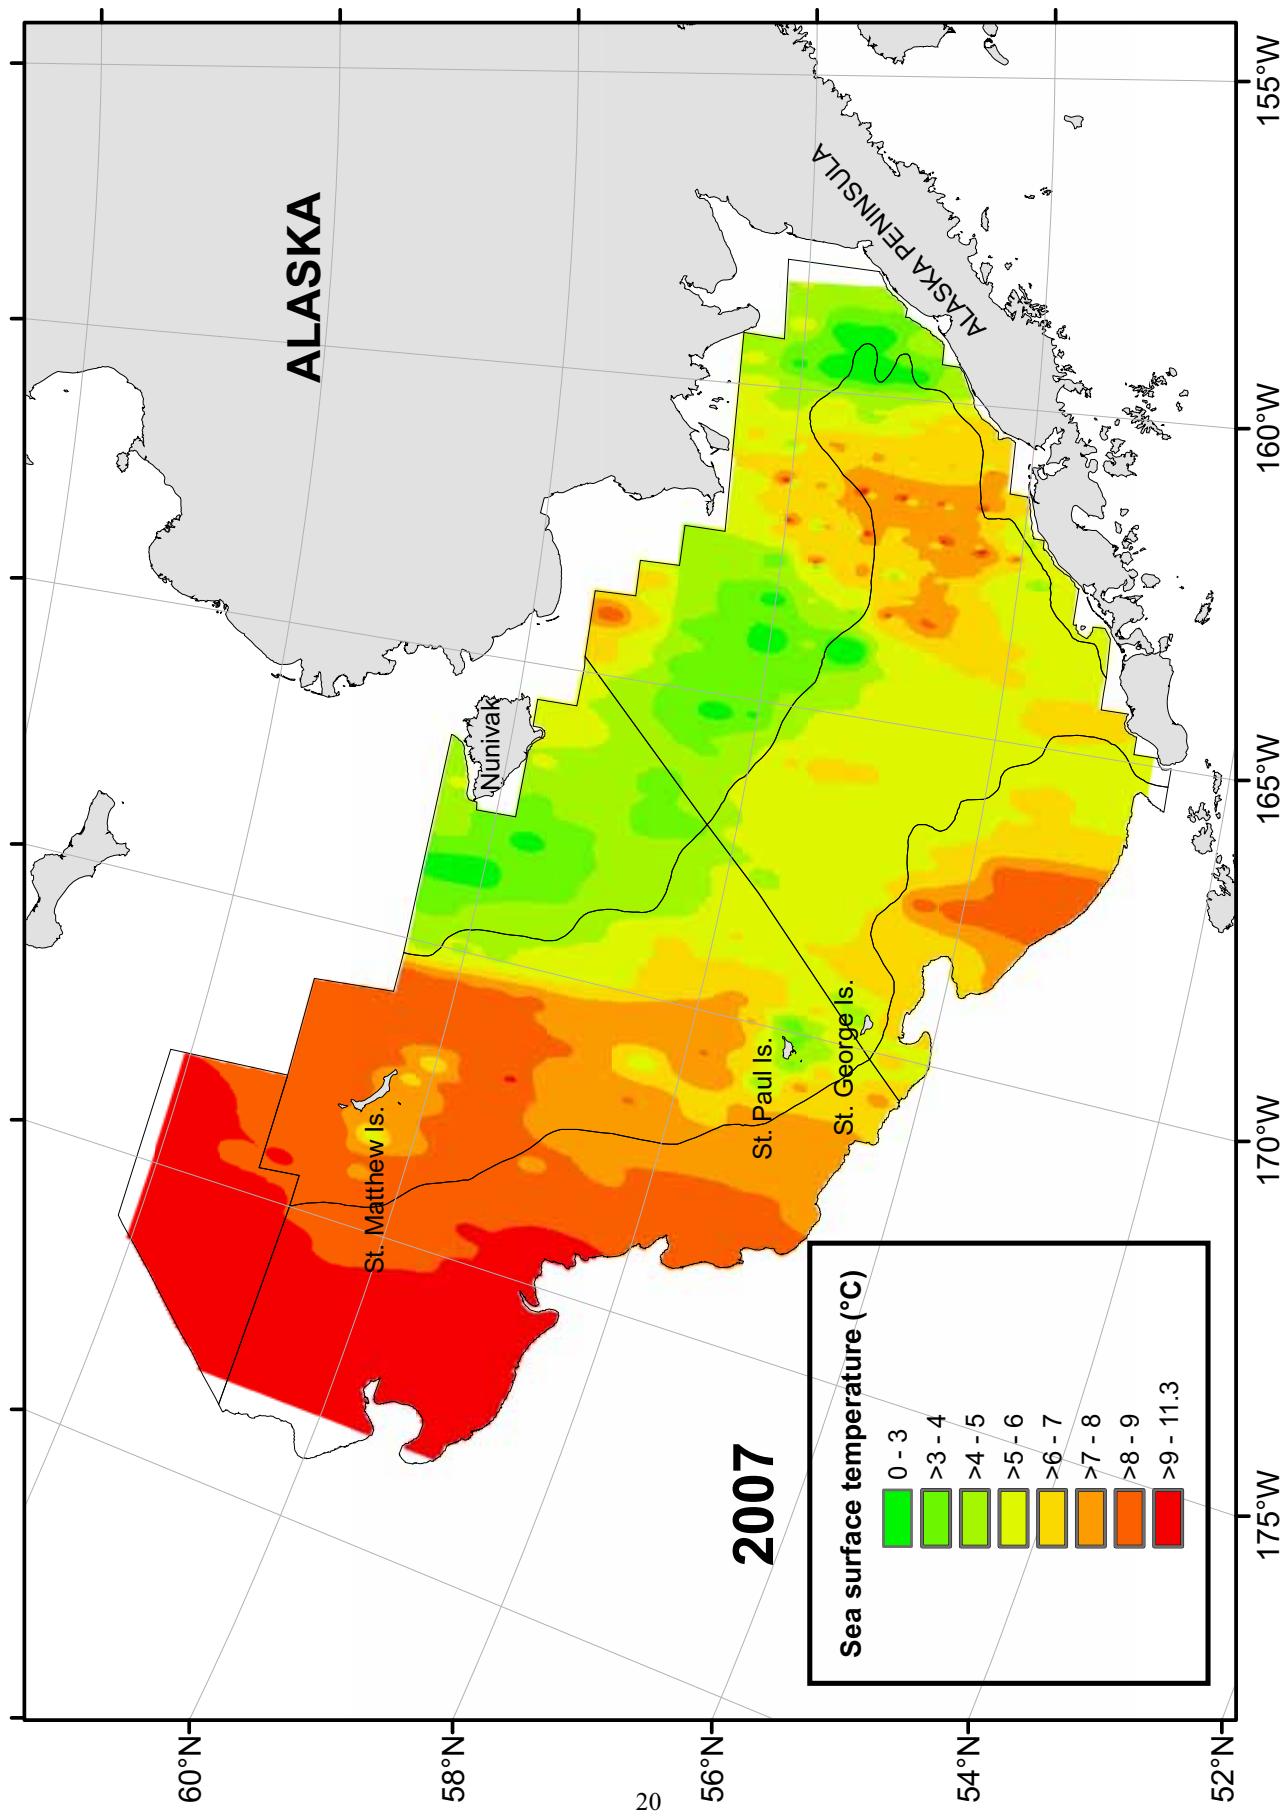

Figure 5. -- Distribution of sea surface water temperatures ( $^{\circ}\text{C}$ ) observed during the 2007 eastern Bering Sea bottom trawl survey.

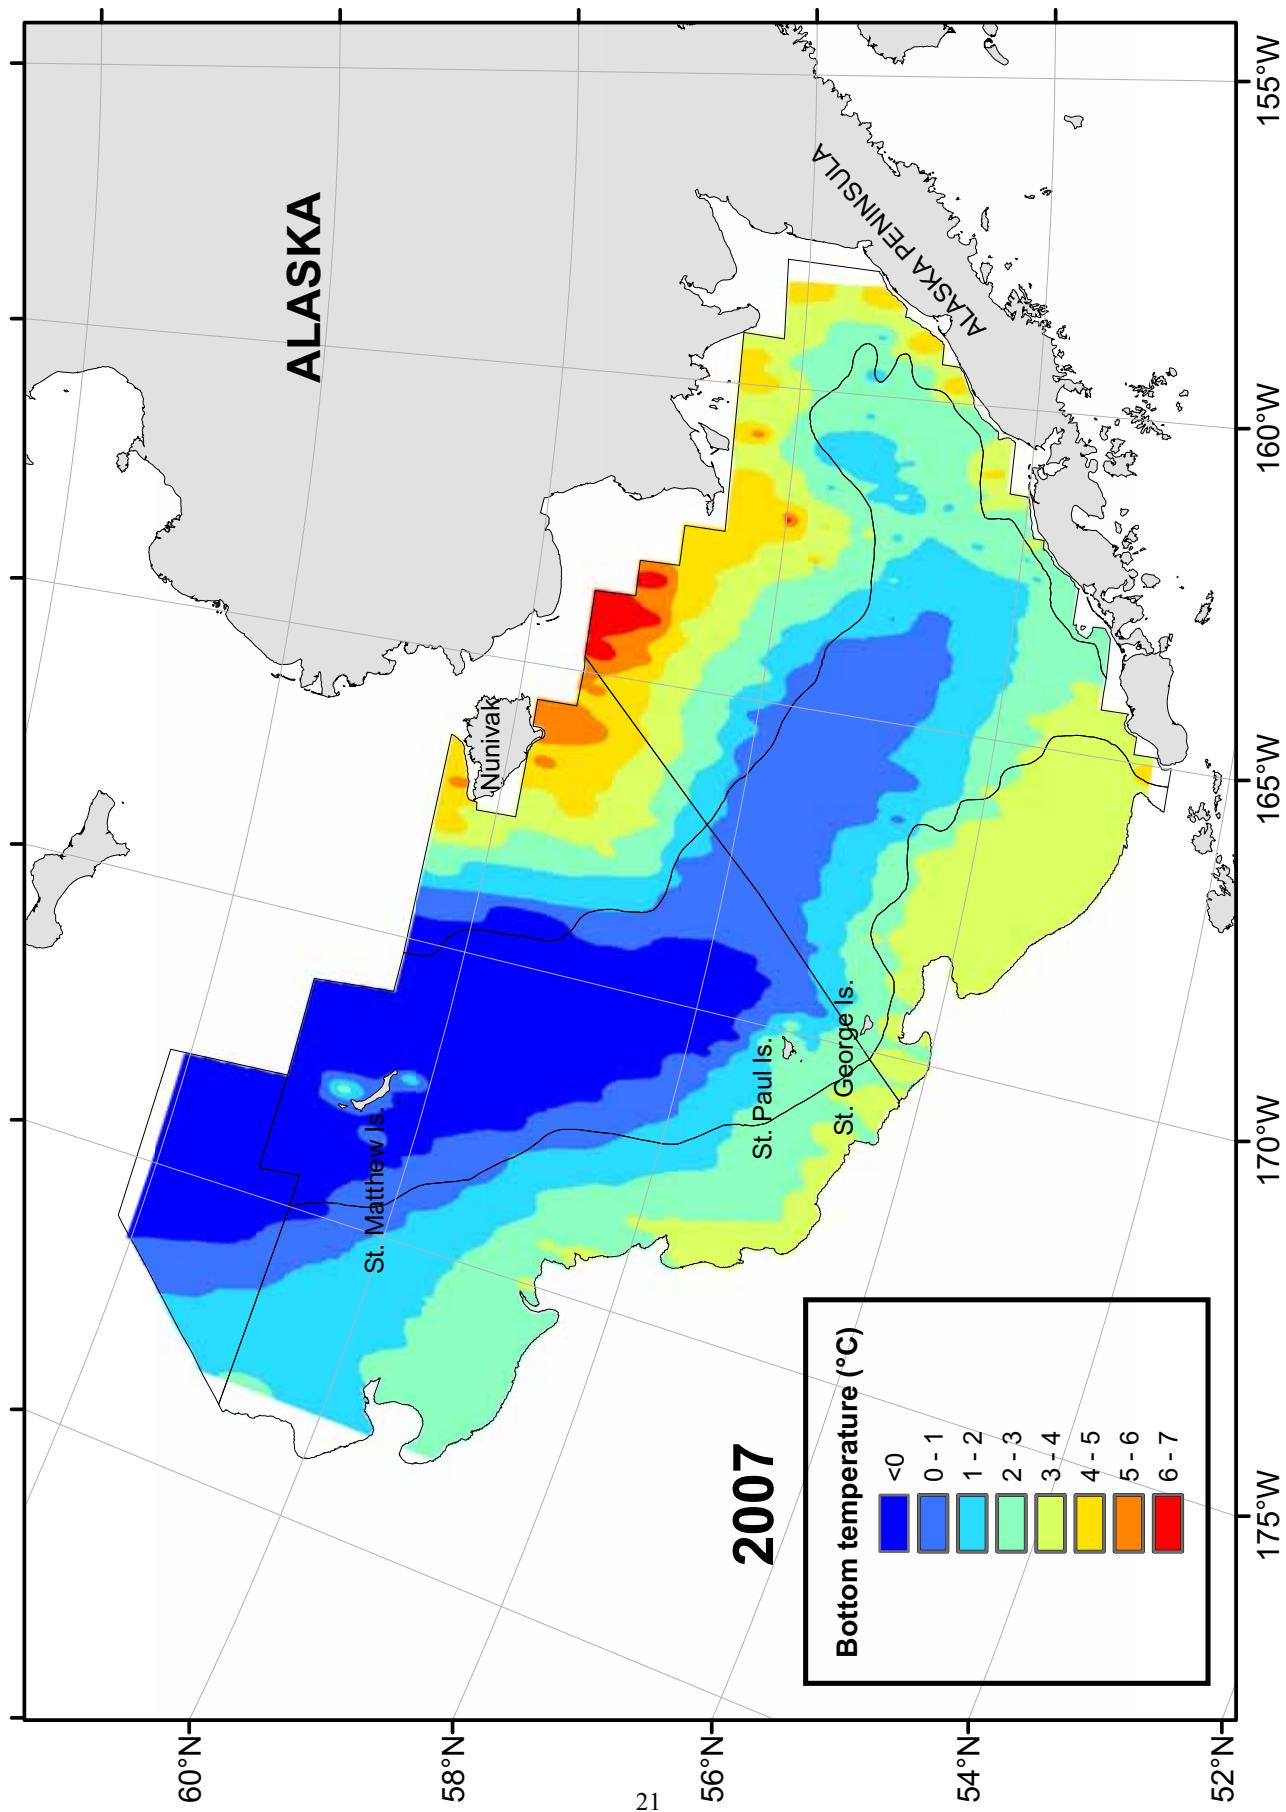

Figure 6. -- Distribution of bottom water temperatures (°C) observed during the 2007 eastern Bering Sea bottom trawl survey.

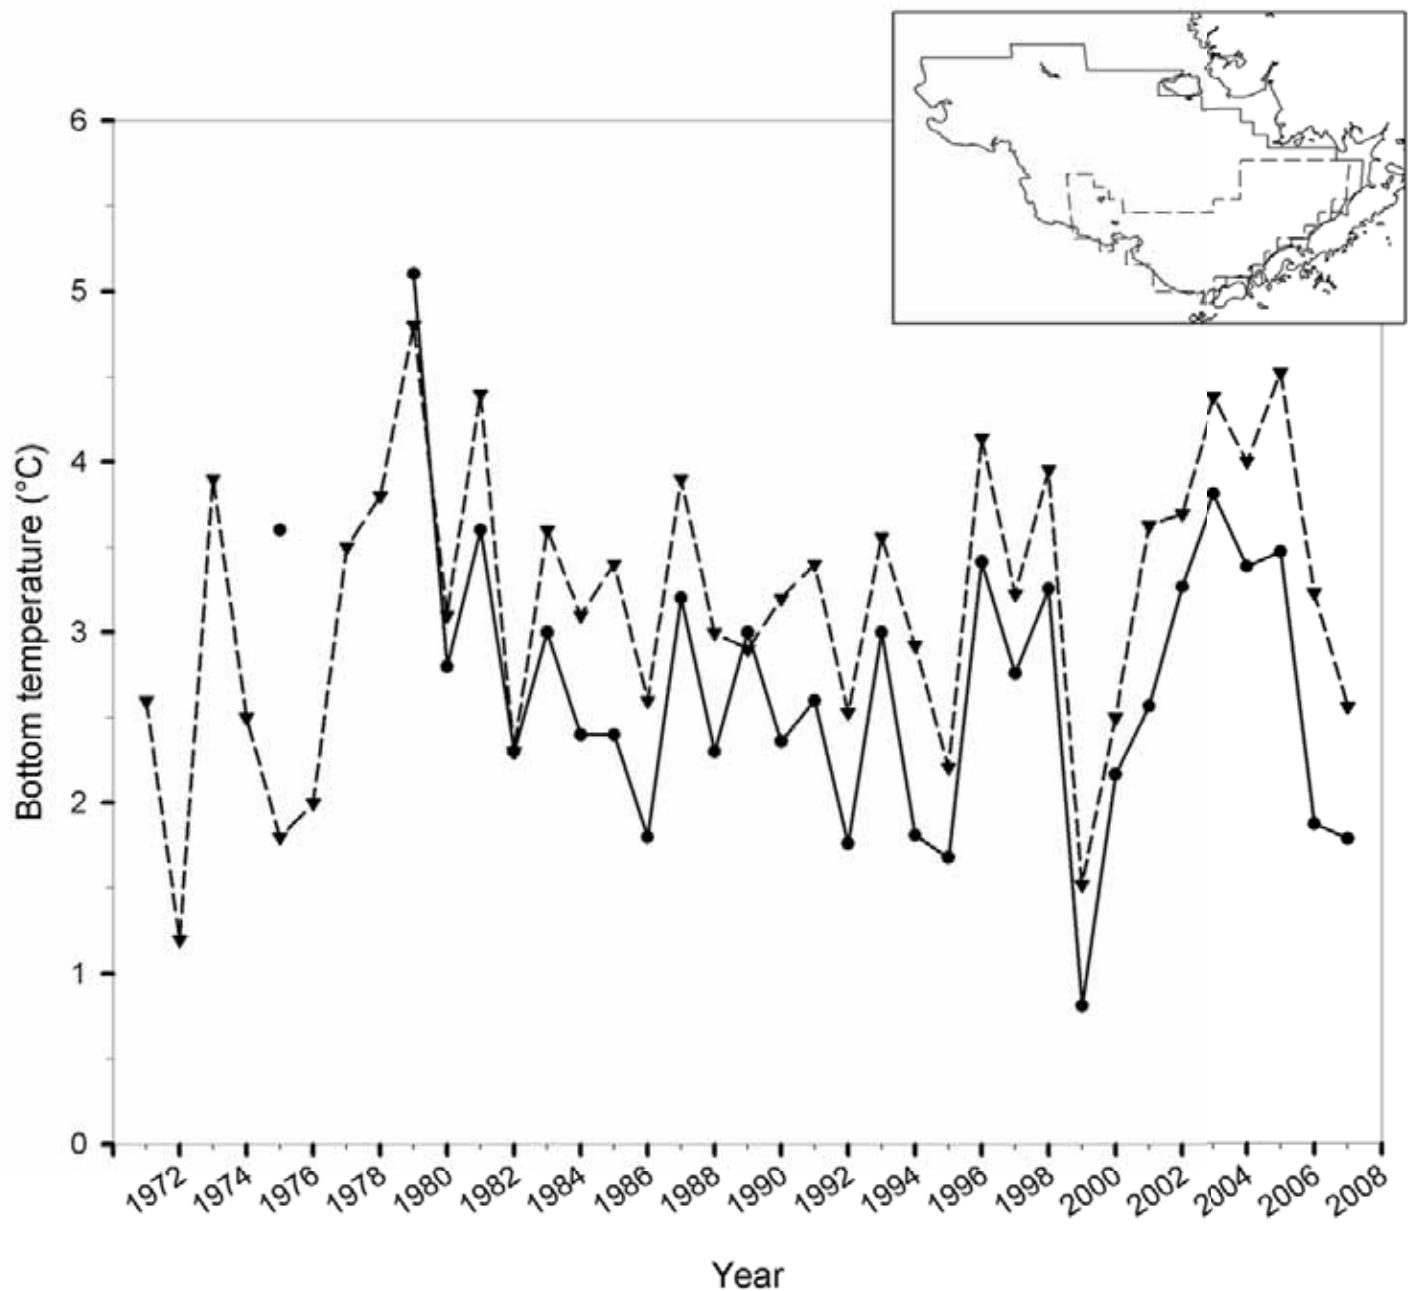

Figure 7. -- Mean summer bottom temperatures based on expendable bathythermograph casts or dataloggers attached to the net headrope during the Alaska Fisheries Science Center bottom trawl surveys. The 1971-2007 means (dashed line) are from southeast Bering Sea (see insert) and the 1975 and 1979-2007 means (solid line) are from the larger survey area outlined on the inset. The 1975 data point for the overall survey area is based on data collected from August through September, while those in all other years and areas were collected from June through early August.

## **Environmental conditions**

Sea surface temperatures recorded during the survey ranged from 1.8° to 11.3°C (Fig. 5).

As in most previous surveys, surface temperature increased from east to west across the shelf, reflecting the progression of summer warming as the survey proceeded from east to west.

Sea bottom temperatures ranged from –1.6° to 8.2°C (Fig. 6). Warmer bottom temperatures (above 3.0° C) occurred along the inner shelf from the northern portion of Bristol Bay to Nunivak Island, and most of the outer shelf west of the Pribilof Islands. A cold pool (<2°C) occupied most of the mid-shelf at depths between 50 and 100 m and extended south to the Alaska Peninsula and into Bristol Bay.

In general, water temperatures were lower than the long-term mean from 1982 to 2007. The 2007 sea surface temperature averaged 6.31°C; lower than the long-term mean of 6.71°C. Mean bottom temperature was 0.08°C lower than 2006 with an average of 1.79 °C (Fig. 7), and approximately 0.8°C cooler than the long-term average of 2.59°C.

## **Relative fishing powers of survey vessels**

Historically, two vessels, fishing alternate columns, have been used to conduct the eastern Bering Sea shelf bottom-trawl survey. Fishing power corrections (FPC) have been applied when statistical differences of mean CPUE values were detected between the two vessels (Kappenman 1992). The underlying assumption for using an FPC is that one survey vessel was less efficient at catching fish than the other survey vessel (e.g., speed effects, operator effects, fishing gear effects) and this systematic error needed to be corrected. Table 6 shows the calculated FPCs, by fish species, which were applied to CPUE estimates for the less-efficient survey vessel for survey years 1982–2005. Due to uncertainties of the FPC and the risk of

Table 6. --Calculated fishing power corrections (FPC), by fish species, that were applied to CPUE estimates for the less-efficient survey vessel for survey years 1982-2005.

increasing overall error in CPUE estimates (Munro 1998), the application of an FPC was discontinued starting in 2006.

Applying these FPCs may have corrected for systematic bias, however, their application did not guarantee a lower overall error, even when the differences between mean CPUE values were statistically significant (Munro 1998). Moreover, application of an FPC to the eastern Bering Sea trawl survey data does not take into account recent advances to reduce systematic errors between vessels using improved monitoring of survey trawls (Somerton and Weinberg 2001, Zimmerman et al. 2003), and recent knowledge from scientific studies regarding gear performance and survey trawl catching efficiency (Weinberg and Kotwicki in review, Weinberg 2003, Kotwicki and Weinberg 2005, Kotwicki et al. 2006, Somerton et al. 2007, Weinberg and Somerton 2006). Furthermore, real spatial and temporal differences can occur between alternate columns, and the application of FPCs can potentially mask these differences.

The RACE Groundfish Assessment Program is currently investigating sources for systematic errors in area swept calculations and developing methods for improving the precision and accuracy of area-swept estimates of abundance. Another critical aspect currently underway is the development of a relational database that will enable staff to analyze data using the improved methods. Until the methods under investigation are reviewed and finalized and the new database is fully operational, the FPC adjustments to catch for years prior to 2006 will remain unchanged.

## **Relative abundance**

The relative abundance of the 11 most abundant species and species groups of fishes are presented in Figure 8. These taxa accounted for 74.9% (238.4 kg/ha) of total catch mean CPUE

## Relative abundance

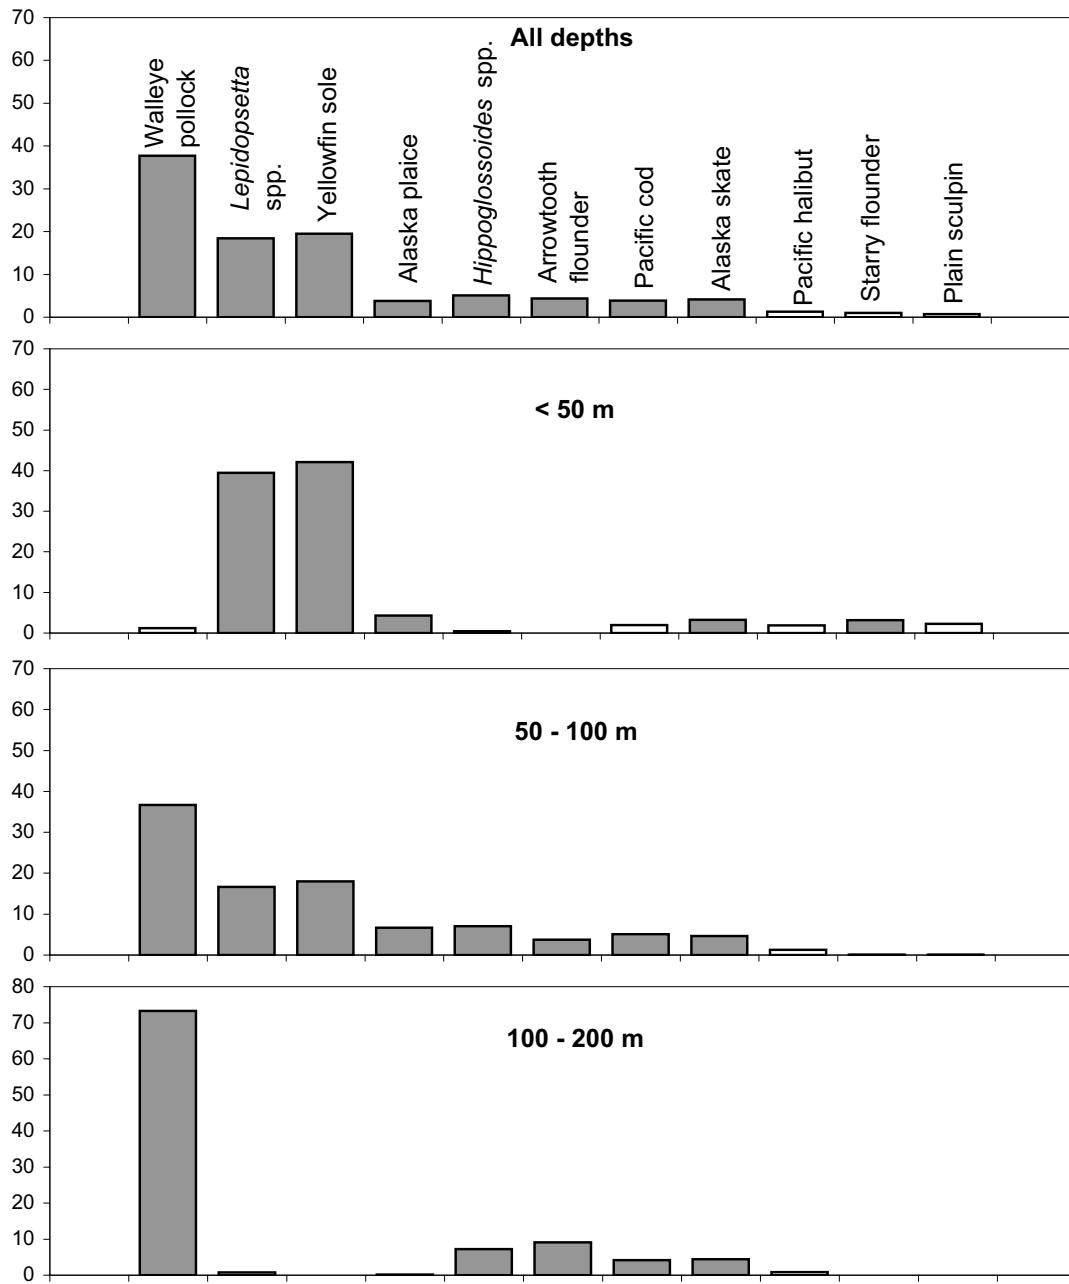

Figure 8. -- Relative abundance (%CPUE in kg/ha) of principal groundfish species (top 11 for all depths combined) by depth zones and for all depths combined for the 2007 eastern Bering Sea bottom trawl survey.

(318.3 kg/ha) and 96.6% of total fish mean CPUE (246.7 kg/ha). The walleye pollock mean CPUE for all areas combined was 89.7 kg/ha. Walleye pollock was the dominant groundfish species at depths between 50 and 200 m. This species was encountered at nearly all sampling stations, with the largest mean catches observed in the outer shelf stations. Pacific cod were also caught primarily in the 50-200 m-depth zone with an overall mean CPUE of 9.1 kg/ha. Both northern and southern rock sole, as well as yellowfin sole with overall mean catch rates of 44.0 and 46.5 kg/ha, respectively, were abundant in water less than 70 m. Snow crab was the most abundant commercially important crab species encountered, with a total average catch rate of 5.7 kg/ha. Red king crab and Bairdi Tanner crab mean CPUEs were slightly less at 2.0 kg/ha and 2.7 kg/ha, while blue king crab had the lowest overall catch rate at 0.2 kg/ha. See Appendix C for a descending rank of all organisms caught.

### **Biomass, abundance, distribution, CPUE, and size composition of principal species and species groups**

A total of 89 species of fish representing 16 families and 60 genera were identified in the catches from the entire survey area, including the 20 northwest stations (Appendix A1). In addition a total of 281 individual invertebrate taxa were identified from 15 phyla with 178 identified to the species level (Appendix A2).

Total demersal animal biomass for the standard survey area was estimated at 15.4 million t, of which fish species accounted for 77% (11.8 million t; Table 7) and invertebrates 23% (3.6 million t; Table 8). Greatest concentrations of fish biomass were located in Bristol Bay, along the Alaska Peninsula, around the Pribilof Islands, and in the outer shelf north of the Pribilofs (Fig. 9). The fish biomass was dominated by pleuronectids (6.4 million t)

and gadids (4.6 million t; Table 7). The biomass of invertebrates was composed primarily of crustaceans (1.4 million t), echinoderms (1.3 million t), and crab (1.3 million t; Table 8). Fish catches from the 20 northwest stations were similar to the rest of the survey also dominated by pleuronectids and gadids (Table 9).

Geographic distributions, population numbers, biomass estimates, and size composition are presented in Figures 10 - 28 and Tables 11 - 20 for each of the following commercially important eastern Bering Sea groundfish: walleye pollock; Pacific cod; yellowfin sole; northern and southern rock sole grouped (*Lepidopsetta* spp.); flathead sole and Bering flounder grouped (*Hippoglossoides* spp.); Alaska plaice; Greenland turbot; arrowtooth flounder; Kamchatka flounder (*Atheresthes evermanni*); and Pacific halibut. Estimates are given separately for each of the 10 geographic strata used in the analysis (Table 1).

Estimated biomass, population numbers, and mean size (by length and weight) are summarized by stratum and the entire survey area. Size composition data are illustrated in histograms relating the population percentage by 1 cm interval of length for each stratum and in population numbers for the total survey area. Catch-per-unit-effort (CPUE), population, and biomass estimates and associated variances and confidence limits are listed for each species by stratum.

Appendices to the report contain detailed results of the survey including population estimates by sex and size classes, and rank of fish and invertebrate taxa by unweighted total CPUE (kg/ha).

## **Walleye pollock**

The total biomass and abundance of walleye pollock for the entire survey area was 4.16 million t and 6.61 billion fish and individual walleye pollock weighed an average of 0.63 kg and averaged 39.5 cm in length (Table 10a). The 2007 biomass estimate was higher than the 2006 estimate of 2.85 million t (Lauth and Acuna 2007). This estimate may in part be due to a shift of the population away from the survey area caused by the colder than average water temperatures on the Bering Sea shelf during 2007 (Ianelli et al. 2007, Kotwicki et al. 2005).

Walleye pollock were captured at 95% of the standard survey stations (Fig. 10). Catch rates were lowest on the inner shelf compared to the middle and outer shelves and the highest densities were north of the Alaska Peninsula, around the Pribilof Islands, and along the outer shelf (Fig. 10). Stratum 62 had the highest catch rate of walleye pollock compared to all other strata (Table 10b). Length measurement data collected from 334 hauls showed higher proportion of smaller walleye pollock in Strata 10, 20, and 40 compared to the outer shelf strata (Fig. 11).

## **Pacific cod**

Like walleye pollock, Pacific cod was also broadly distributed across the shelf being observed in 98% of the trawls (Fig. 12). The highest catch rates of Pacific cod were observed in the northwestern half of the shelf in Stratum 60 (Table 11a), especially in Strata 42, 43, and 62 around St. Matthew Island and the Pribilof Islands (Table 11b; Fig. 12). Similar to walleye pollock, the highest proportions of juvenile Pacific cod were along the inner shelf in Stratum 10 (Fig. 13).

Compared to 2006, there was a decrease in Pacific cod biomass from 0.52 to 0.42 million t, however, population size increased from 394 to 733 million while length measurement data collected from 348 hauls showed that the average fish length decreased from 37.9 to 24.8 cm suggesting a strong incoming year class (Table 11b).

### **Yellowfin sole**

The highest catch rates of yellowfin sole occurred on the inner shelf (Table 12a; Fig. 14). The lowest catch rates were in the vicinity of St. Matthew Island and the Pribilof Islands. Yellowfin sole were very low in abundance or absent from Strata 50 and 60 (Table 12b). Yellowfin sole in the 10-20 cm length range were found on the inner shelf and were mostly absent from the middle shelf strata (Fig. 15).

The biomass of yellowfin sole in 2007 was 2.15 million t and the population was 8.51 billion (Table 12a), remaining relatively unchanged from 2006. There was also little change in mean weight of yellowfin sole (+0.01 kg) or the mean length (-0.4 cm) (Table 12a).

### **Northern and southern rock sole**

The distribution of rock sole was very similar to that of yellowfin sole except rock sole occurred at higher densities around the Pribilof Islands (Stratum 42) and the distribution extended onto the outer shelf (Tables 13a and 13b; Fig. 16). The composition of rock sole shifted from smaller to larger sizes from inshore to offshore strata (Fig. 17).

Biomass decreased slightly from 2.2 to 2.0 million t and population numbers decreased from 15.1 to about 11.0 billion (Table 13a). Compared to 2006, mean weight and length of rock

sole increased from 0.15 to 0.19 kg and from 20.8 to 22.7 cm (Table 13a). Length measurements were collected from 316 hauls (Table 13b).

### **Flathead and Bering sole**

Flathead and Bering sole (*Hippoglossoides* spp.) were distributed on the middle and outer eastern Bering Sea shelf. The highest CPUEs were in the northwest outer shelf (Stratum 60), near the Pribilof Islands (Stratum 42), and in the southern middle shelf region (Stratum 31) (Tables 14a and 14b; Fig. 18). Most *Hippoglossoides* spp. ranged in size between 10 and 50 cm and length distributions were somewhat bimodal which may be partly due to the combination of species within the genus (Fig. 19).

Biomass decreased from 0.64 million t in 2006 to 0.56 million t in 2007 with a proportional decrease in population from 2.1 to 1.9 billion (Table 14a). The overall mean length and mean weight remained virtually unchanged 2006 to 2007 (Table 14a).

### **Alaska plaice**

Alaska plaice was most abundant on the inner and middle shelf centering along the 50 m contour with lower densities occurring on the shallow inner shelf stations and deeper middle shelf stations (Fig. 20). Stratum 30 had the highest proportion of biomass of all the strata (Table 15a) and Stratum 41 had the highest catch rate by weight compared to other strata (Table 15b). Smaller Alaska plaice (< 20 cm) occurred in Strata 10 and 20, while the deeper strata had higher percentages of plaice > 40 cm (Fig. 21).

Biomass decreased from 0.64 million t to 0.42 million t, and the population from 1.0 billion to 0.8 billion (Table 15a). The mean length of 35.1 cm decreased to 32.3 in 2007 and mean weight decreased from 0.62 kg to 0.52 kg (Table 15a). Length measurements were collected from 253 hauls (Table 15b).

### **Greenland turbot**

Greenland turbot is an arctic flatfish species inhabiting the upper continental slope, although juveniles may spend several years on the continental shelf (Alton et al. 1988). Greenland turbot were captured in 67 out of 356 tows, and most of these tows were in the northwest part of the outer shelf (Fig. 22). Greenland turbot were absent in strata 10 and 20 while present only in low numbers in strata 30 and 40 (Table 16a; Fig. 23).

Biomass estimates in 2007 decreased slightly from 17.5 thousand t in 2006 to 13.0 thousand t in 2007 (Table 16a), however, population numbers increased from 7.9 to 9.3 million. The mean size and weight of turbot decreased from 54.8 cm and 2.2 kg in 2006 to 40.8 cm and 1.7 kg in 2007 (Table 16a). Stratum 61 had the highest mean CPUE by weight and stratum 62 had the highest mean CPUE by number (Table 16b).

### **Arrowtooth flounder**

Arrowtooth flounder were observed all along the outer shelf and on the middle shelf south of latitude 58°N (Fig. 24). Catch rates were generally higher at the deeper more southern stations (Fig. 24) and no arrowtooth flounder were present in Stratum 20 (Table 17a; Fig. 25). Estimates of both biomass and population size decreased in 2007 compared to 2006; biomass decreased from 0.61 to 0.48 million t and population from 1.3 to 1.0 billion (Table 17a). Stratum

50 had the highest proportion of biomass and the highest CPUEs of any strata for both weight and number (Table 17b).

### **Kamchatka flounder**

Kamchatka flounder were observed at all but two of the outer shelf stations but were absent in Strata 10 and 20 (Table 18a; Fig. 26). The highest catch rates on the outer shelf were observed north of latitude 56°N in Stratum 61 (Table 18b; Fig. 26). Compared to 2006, the biomass increased from 60.4 to 64.3 thousand t and the population decreased from 187 to 144 million fish. There was an increase in both mean weight (0.32 to 0.44 kg) and length (31.3 to 34.1 cm) (Table 18a). Length measurements were collected from 127 hauls (Table 18b).

### **Pacific halibut**

Pacific halibut were widely distributed and captured at 80% of the stations, but were generally absent in trawl catches at or north of 60°N (Fig. 28). Pacific halibut were present in all strata, with juveniles prevalent along the coast of the inner strata 10 and 20 and southern edge of strata 30 (Fig. 29). Estimated biomass and population decreased from 156 thousand t and 134 million halibut in 2006 to 144 thousand t and 119 million in 2007 (Table 19a). Catch rates in terms of weight and numbers were lower in the outer shelf Strata 50, 61, and 62 (Table 19b) however, this is where the largest specimens were observed on the outer shelf with a mean weight and length of 1.2 kg and 39.3 cm (Table 19a).

## **Other fishes**

Geographic distributions for some common ecologically important fish species are presented in Figures 30-44 and Tables 21-31. These species are Bering skate (*Bathyraja interrupta*), Alaska skate, warty sculpin, great sculpin, plain sculpin, bigmouth sculpin, wattled eelpout (*Lycodes palearis*), shortfin eelpout (*L. brevipes*), marbled eelpout, sturgeon poacher, Bering poacher (*Occella dodecaedron*), butterfly sculpin, eulachon (*Thaleichthys pacificus*), capelin (*Mallotus villosus*), and Pacific herring (*Clupea pallasii*), respectively.

Biomass and population estimates, as well as mean weight per individual, are given by stratum and total area. These tables are not provided for the pelagic species such as eulachon, capelin, and Pacific herring due to the bottom sampling nature of the survey. These species may be inadequately represented in the samples; however, plots are shown to give approximate geographic distribution.

## Butterfly sculpin

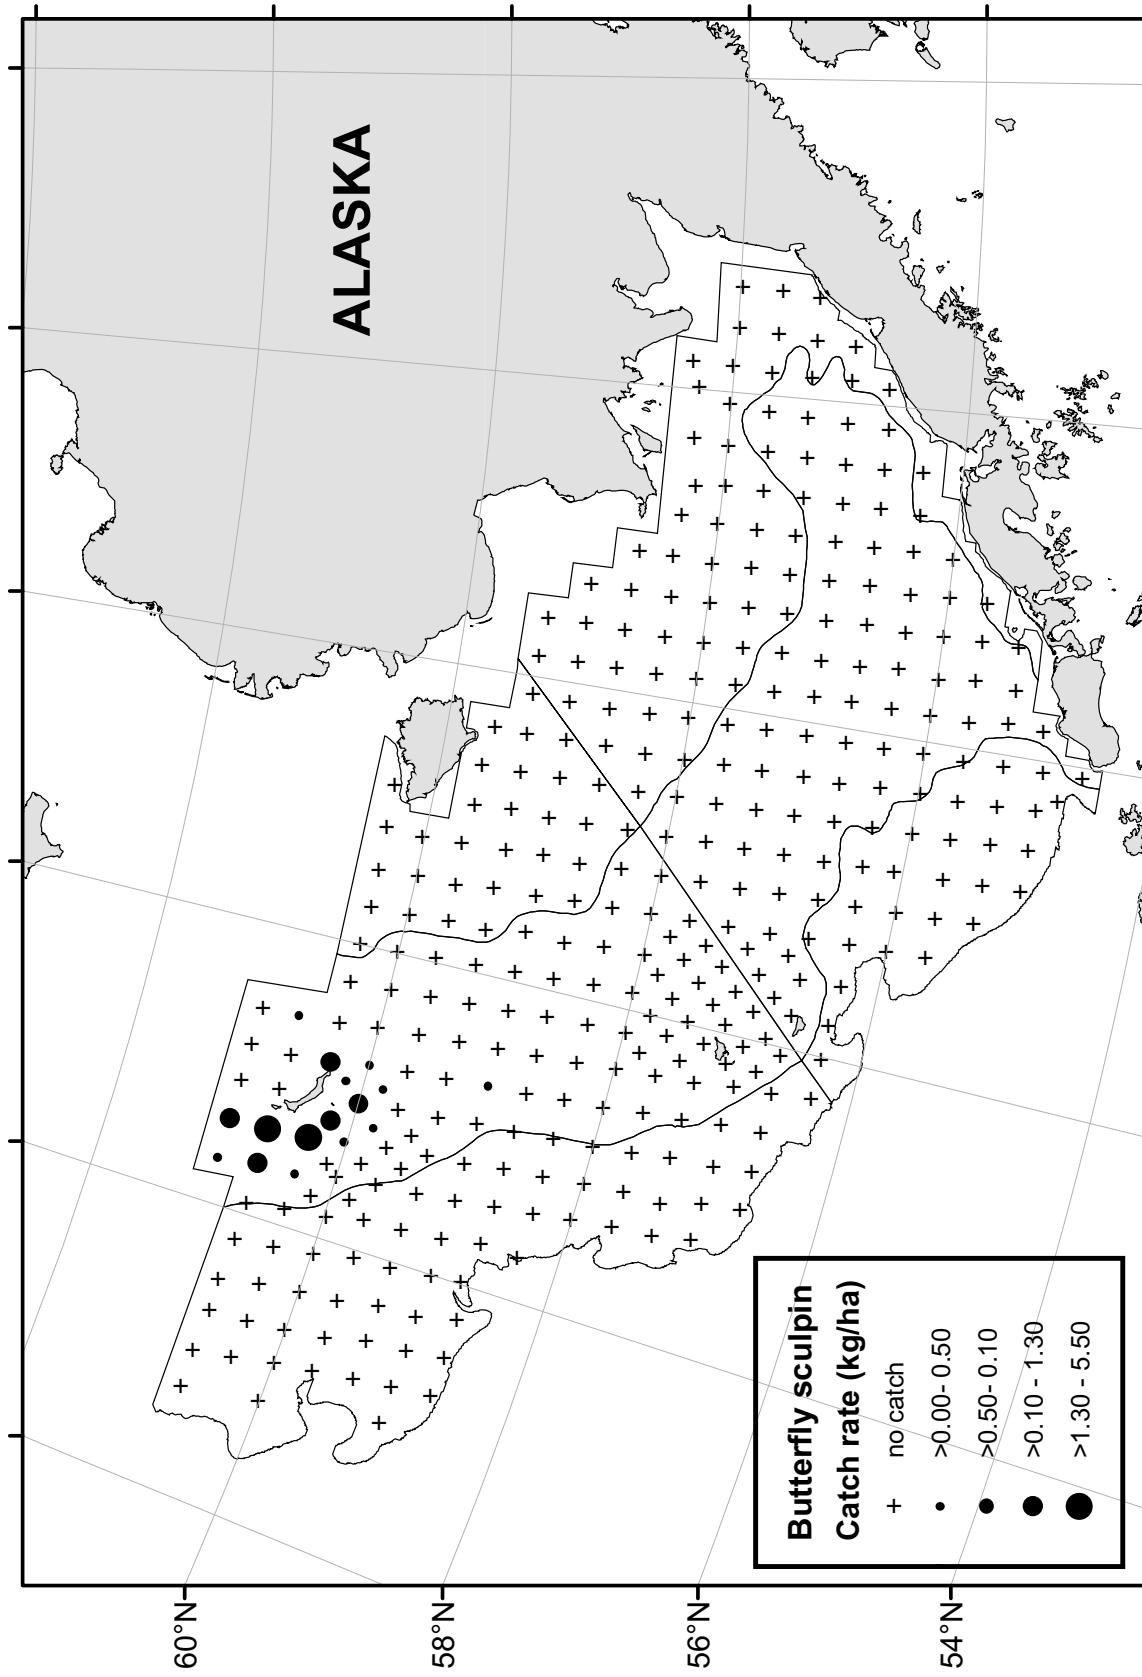

Figure 41. -- Distribution and relative abundance (kg/ha) of butterfly sculpin (*Hemilepidotus peltatus*) for the 2007 eastern Bering Sea bottom trawl survey.

# Eulachon

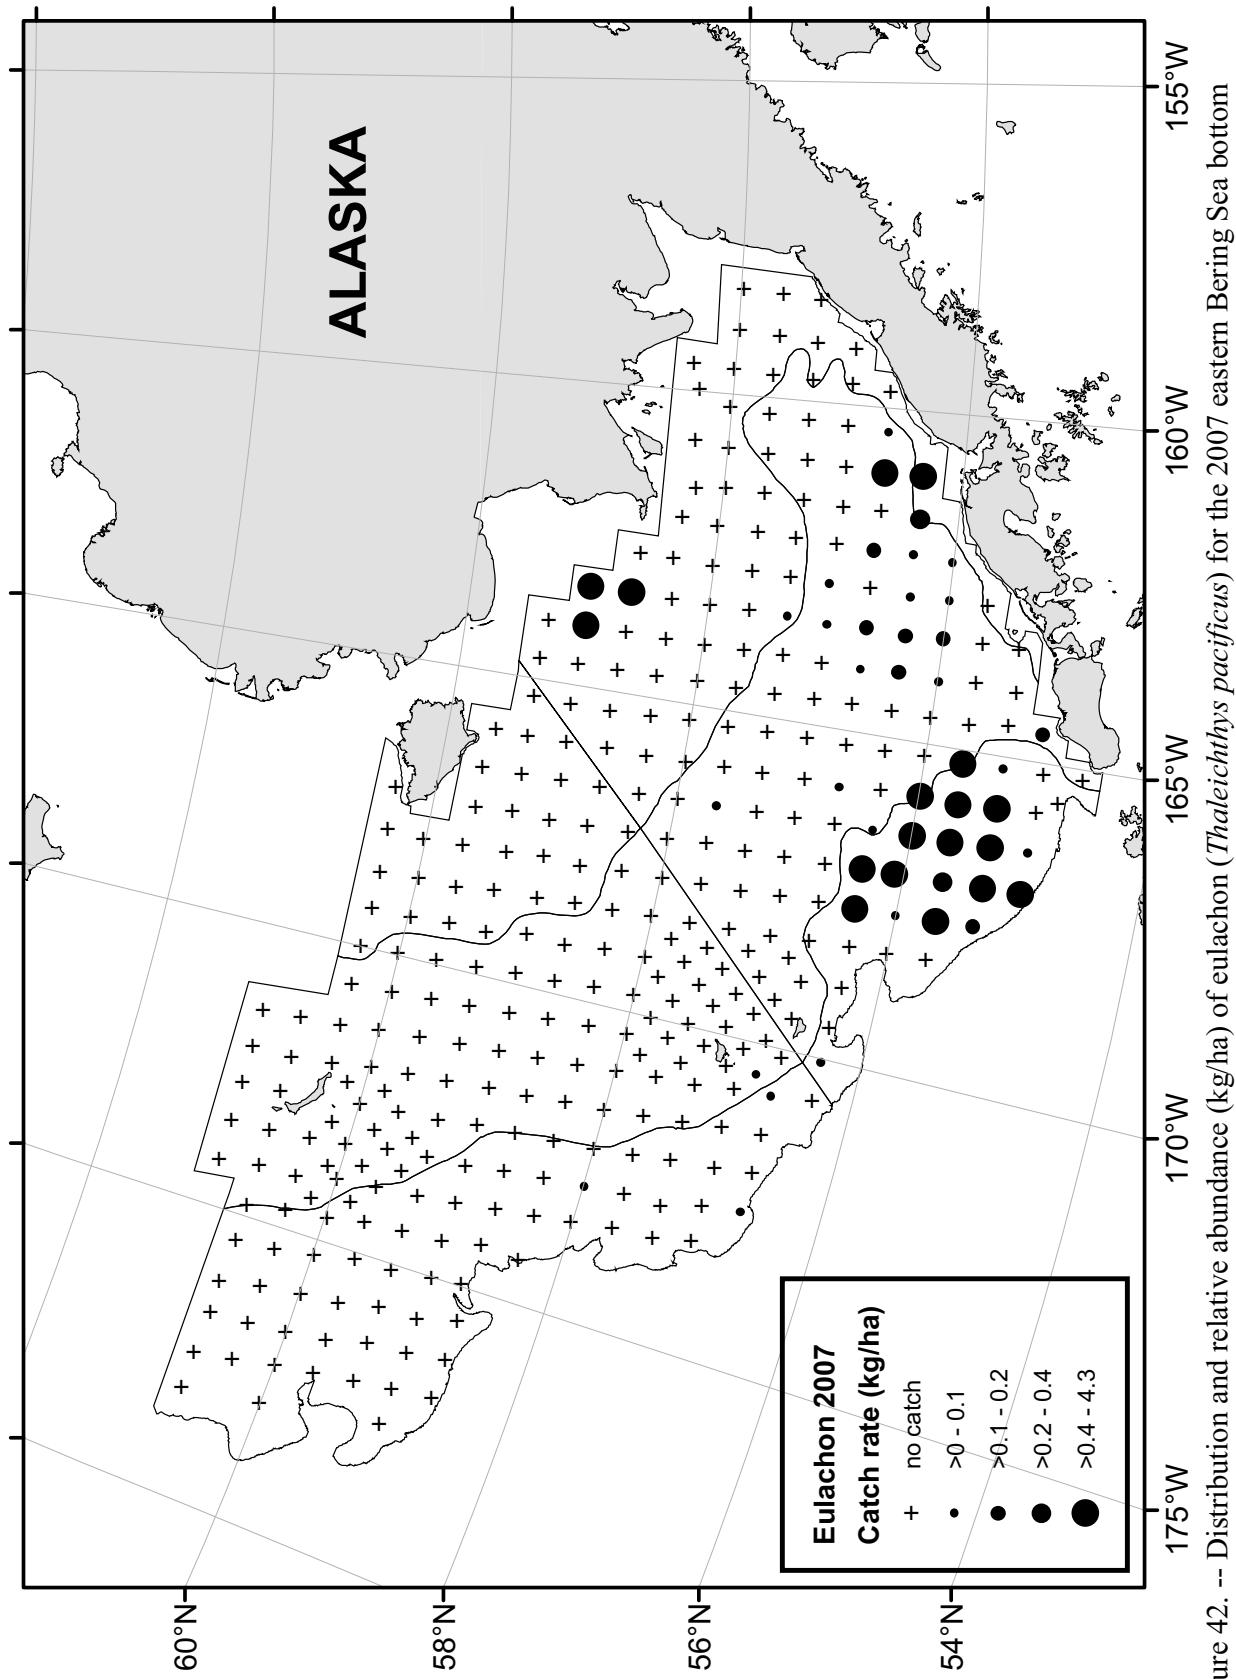

Figure 42. -- Distribution and relative abundance (kg/ha) of eulachon (*Thaleichthys pacificus*) for the 2007 eastern Bering Sea bottom trawl survey.

# Capelin

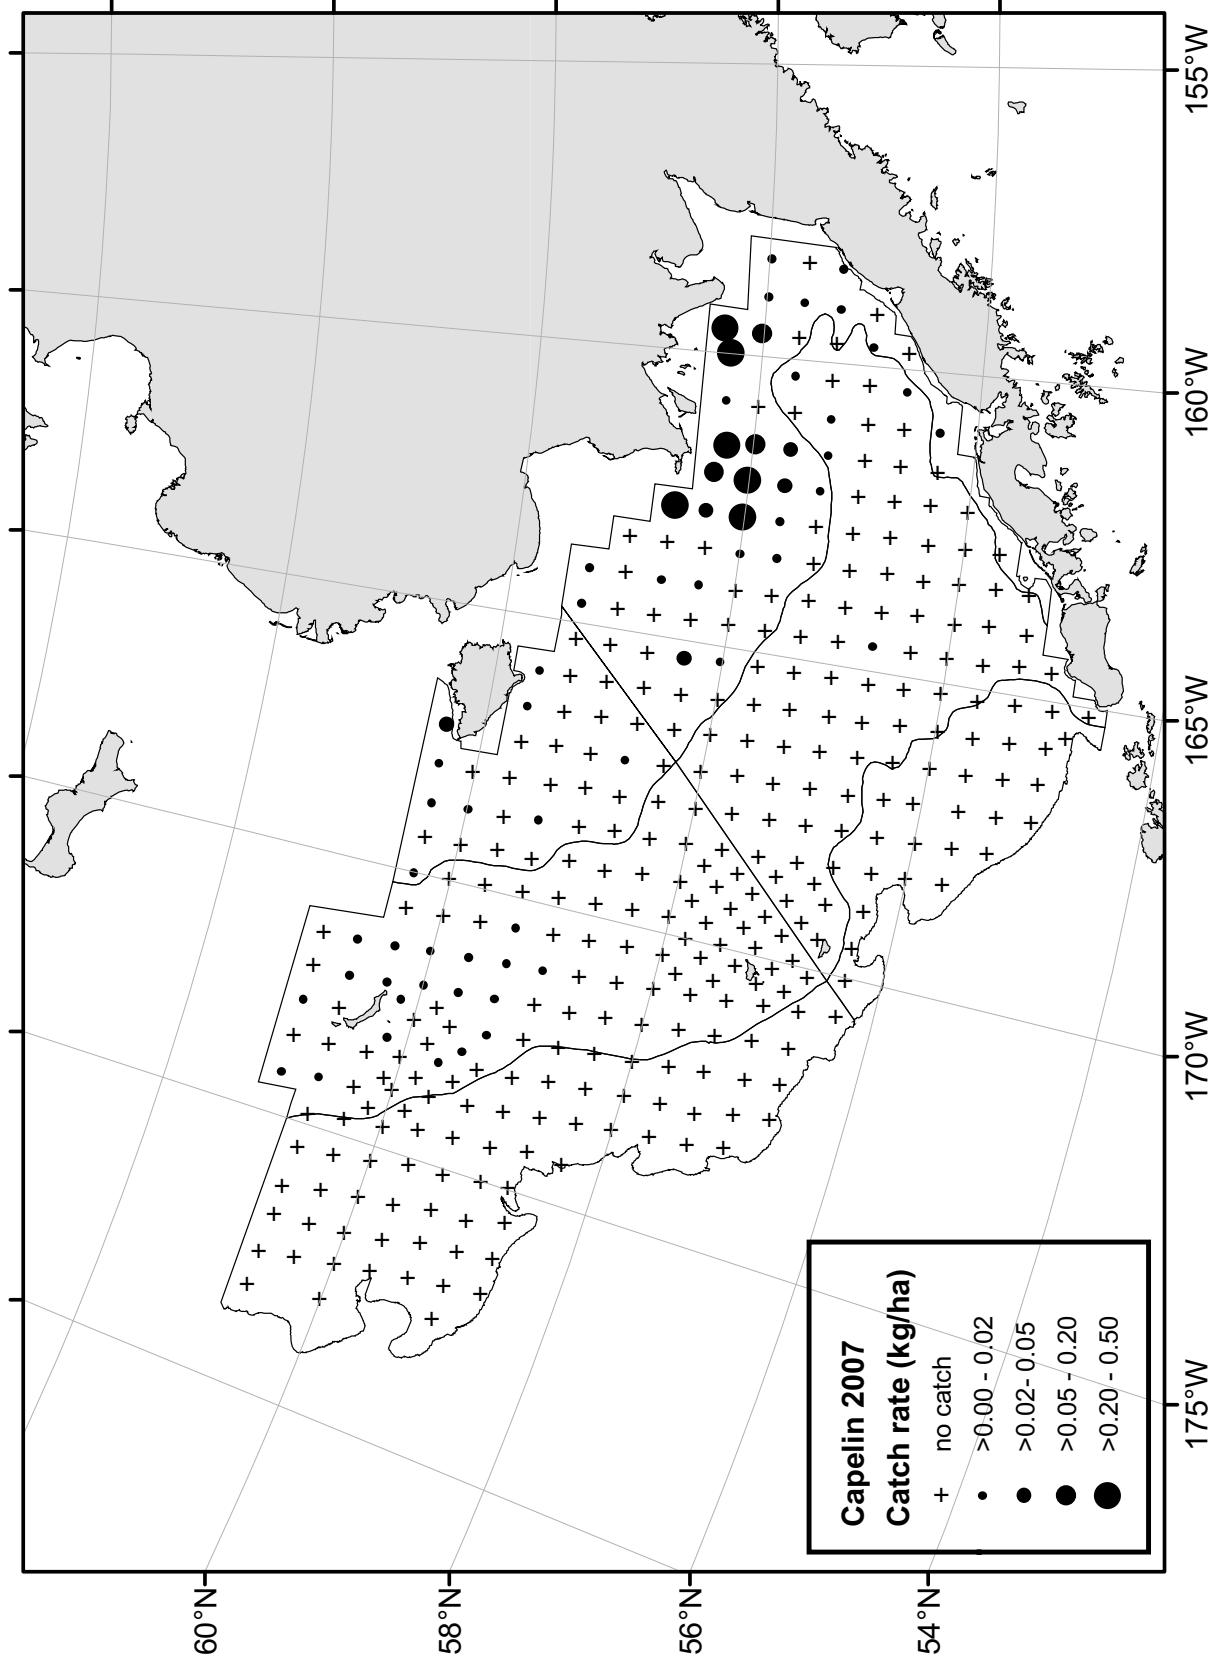

Figure 43. -- Distribution and relative abundance (kg/ha) of capelin (*Mallotus villosus*) for the 2007 eastern Bering Sea bottom trawl survey.

## Pacific herring

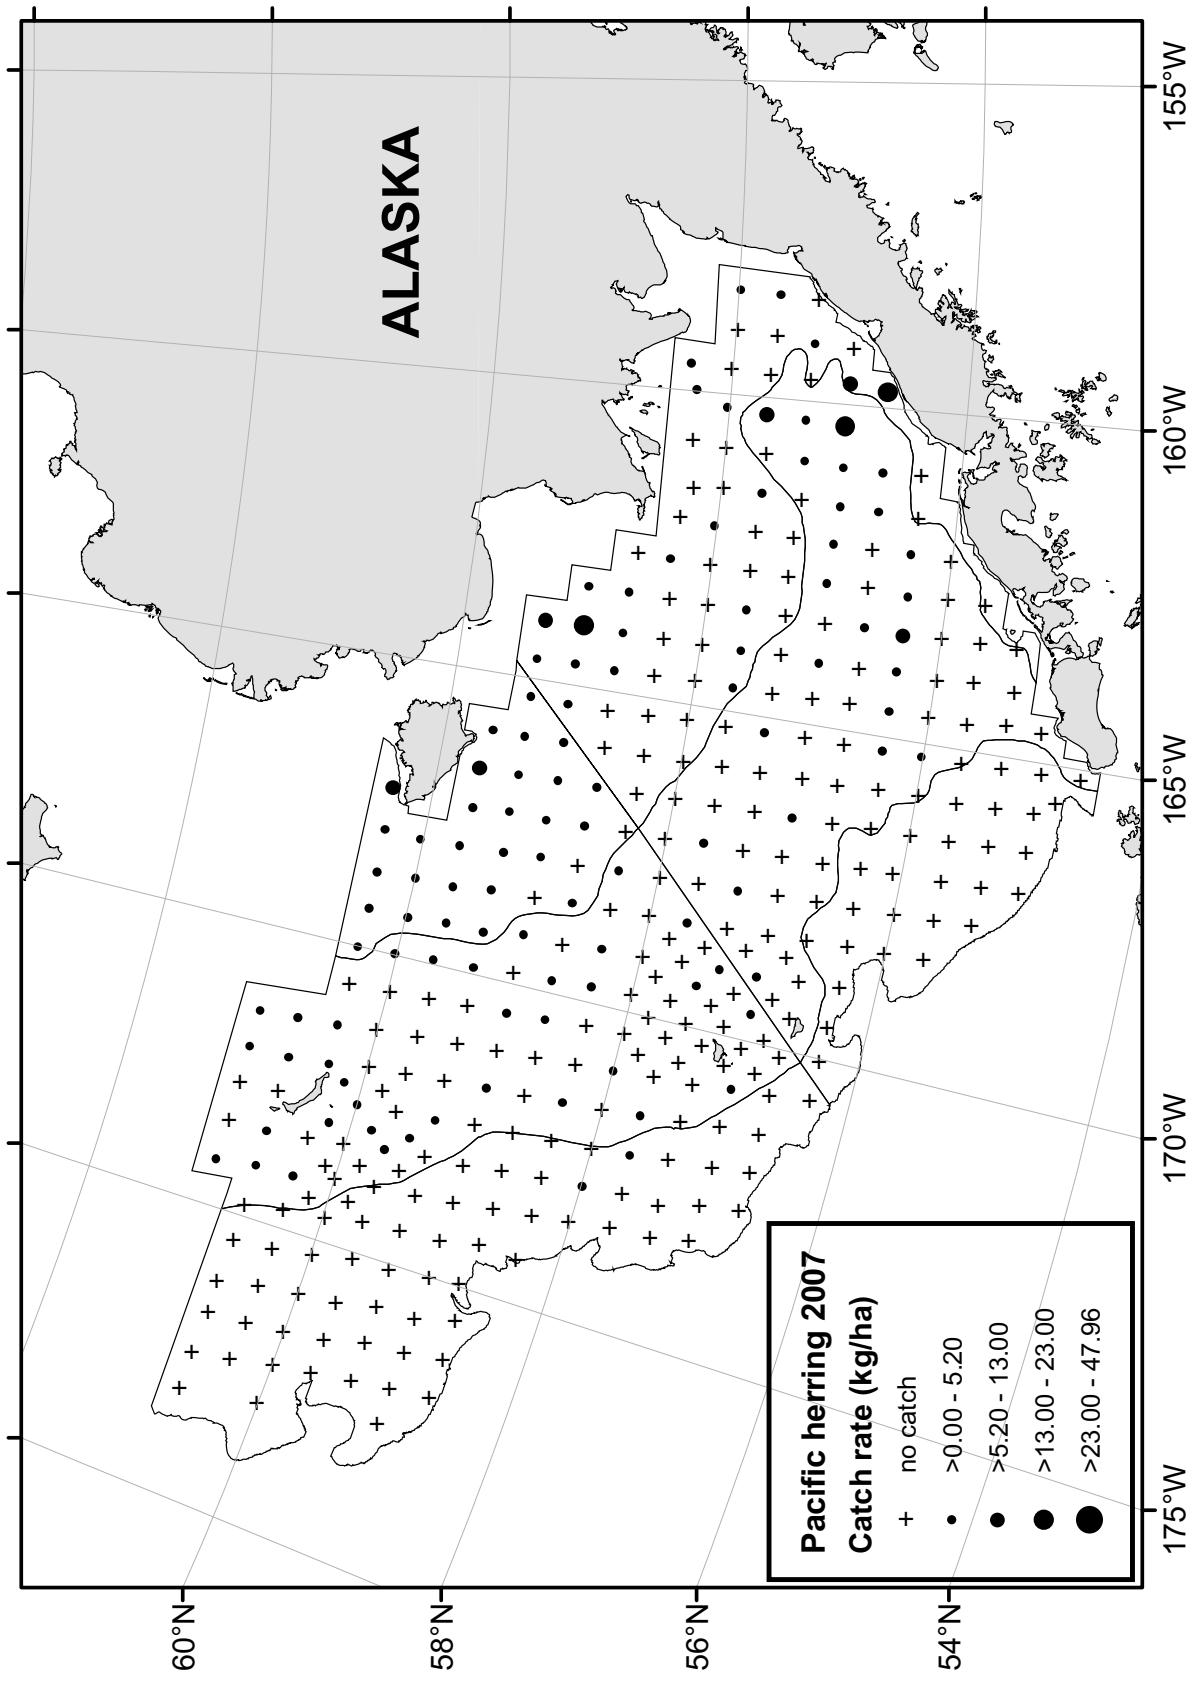

Figure 44. -- Distribution and relative abundance (kg/ha) of Pacific herring (*Clupea pallasii*) for the 2007 eastern Bering Sea bottom trawl survey.

### **Acknowledgements**

Recognition and appreciation is extended to the captains and crew of the F/V *Aldebaran* and F/V *Arcturus* who without their expertise, goodwill, and sacrifice this survey would not be possible. Thank you to the Trident Corporation for making the vessels available and always maintaining safety as a top priority. Great appreciation is also extended to all the scientists, researchers, and interns who worked tirelessly aboard each vessel to complete the survey in a safe and successful manner. We also thank the survey support team who provided us with technical and scientific equipment. Finally appreciation is extended to the reviewers of this document whose excellent comments and suggestions greatly improved this document.

## **Appendix B: Station Data, 2007 Eastern Bering Sea Trawl Survey**

Appendix B contains station data by vessel for the 376 successfully completed standard survey stations. In using the tables, the following should be noted:

1. Time represents the nearest hour and minute at the start of the haul.
2. Haul numbers are not always sequential because unsatisfactory hauls were omitted.
3. All longitudes are in the Western Hemisphere and latitudes in the Northern

Hemisphere. Starting and ending positions for each haul are displayed as degrees and decimal minutes.

4. Net measured codes are as follows:

Y = Net width was measured by net mensuration gear.

N = Net width was estimated from a function of wire out or wire out.

5. Catch weights are displayed in total kilograms

### **List of Tables**

**Appendix B Table 1** – Haul data for stations sampled by the FV *Arcturus*.

**Appendix B Table 2** – Haul data for stations sampled by the FV *Aldebaran*.

Appendix B Table 1.-- Haul and catch data for successfully completed tows by FV *Archirus* during the 2007 eastern Bering Sea bottom trawl survey.

### **Appendix C: Rank Order of Relative Abundance of Fishes and Invertebrates**

Appendix C ranks all fishes and invertebrates identified during the 2007 eastern Bering Sea bottom trawl survey by descending unweighted CPUE (kg/ha).

Appendix C Table 1. -- Rank of fish and invertebrate taxa by unweighted total CPUE (kg/ha) from the 2007 eastern Bering Sea bottom trawl survey.

Rank	Species code	Mean CPUE (kg/ha)	Variance	95% Confidence limits	Proportion	Cumulative proportion	Scientific name

## **Appendix D: Population Estimates by Sex and Size Groups for Principal Fish Species**

Appendix D presents estimates of the numbers of individuals within the overall survey area by sex and size group for principal fish species.

### **List of Tables**

Population estimates by sex and size group from the 2007 eastern Bering Sea bottom trawl survey.

**Appendix D Table 1** – walleye pollock

**Appendix D Table 2** – Pacific cod

**Appendix D Table 3** – yellowfin sole

**Appendix D Table 4** – northern and southern rock sole grouped

**Appendix D Table 5** – flathead sole and Bering flounder grouped

**Appendix D Table 6** – Alaska plaice

**Appendix D Table 7** – Greenland turbot

**Appendix D Table 8** – arrowtooth flounder

**Appendix D Table 9** – Kamchatka flounder

**Appendix D Table 10** – Pacific halibut

Appendix D Table 1. -- Population estimates by sex and size for **walleye pollock** (*Theragra chalcogramma*) from the 2007 eastern Bering Sea bottom trawl survey.
