

TROPICAL CYCLONE STRUCTURE

ERIC BLAKE
FLORIDA GOVERNOR'S HURRICANE CONFERENCE
MAY 13, 2008

Outline

- Initial stages of development
- Lifecycle
- Mature hurricane structural differences
- Identifying hurricane characteristics using radar and satellite

Precursors of a tropical cyclone...

Typical Tropical Cyclone Size Lifecycle

In general, as the system increases in strength, it gets larger. Additionally, as the system gets to higher latitudes, the wind field also expands.

THE WARM CORE IS A CONSEQUENCE OF BOTH LATENT HEAT
RELEASE AND WARMING BY SUBSIDENCE

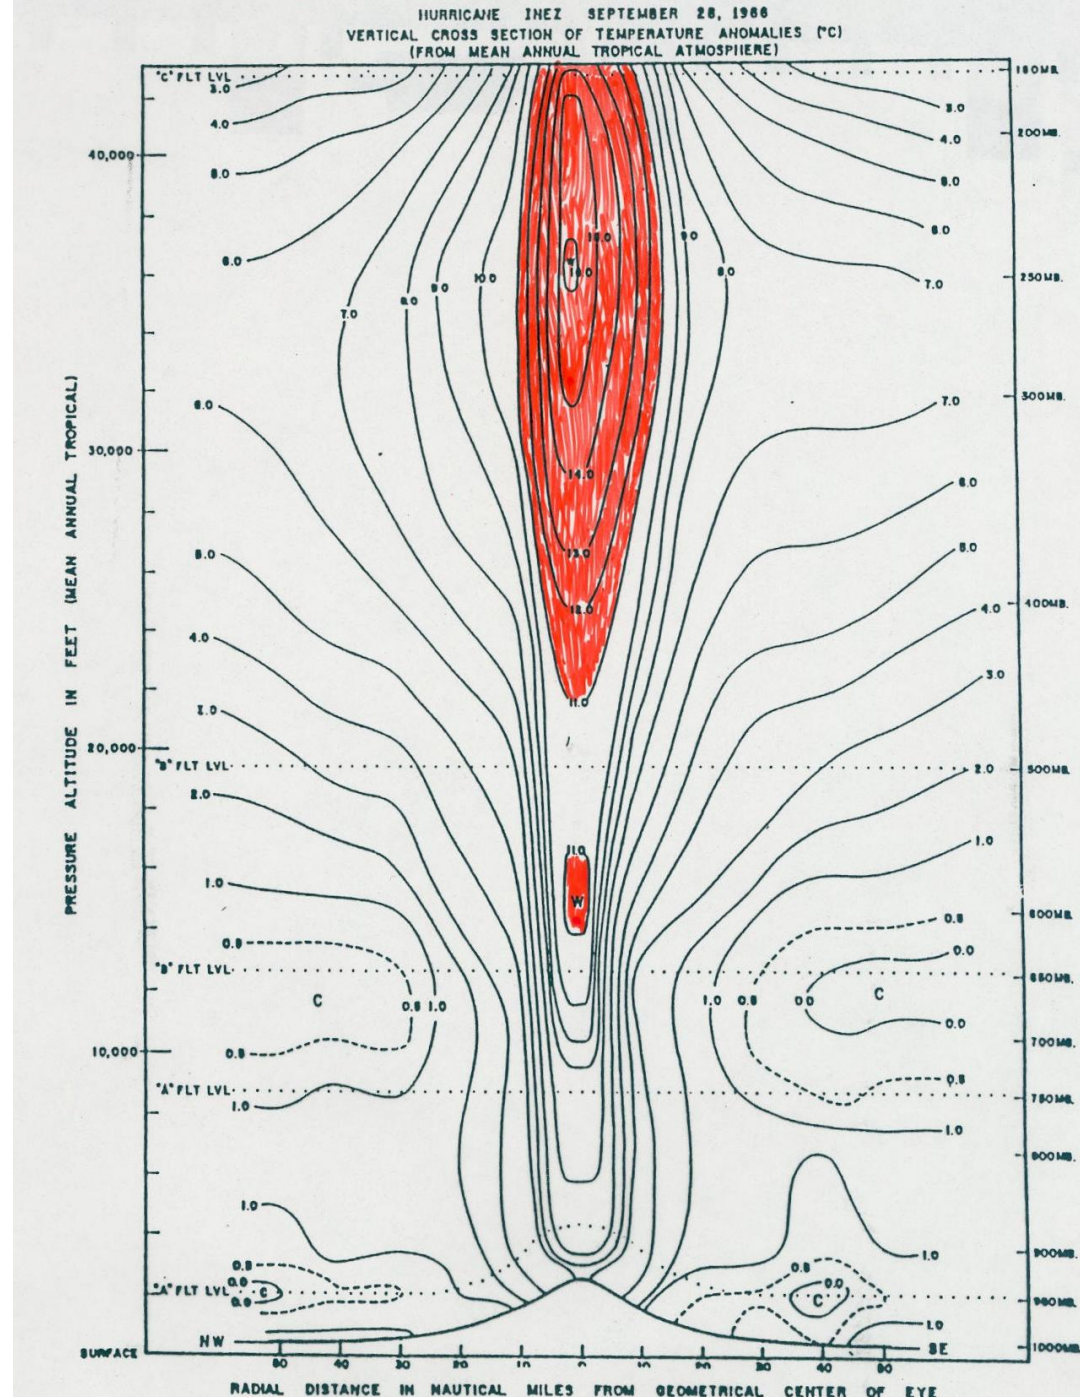

THE WARM CORE IS A CONSEQUENCE OF BOTH LATENT HEAT
RELEASE AND WARMING BY SUBSIDENCE

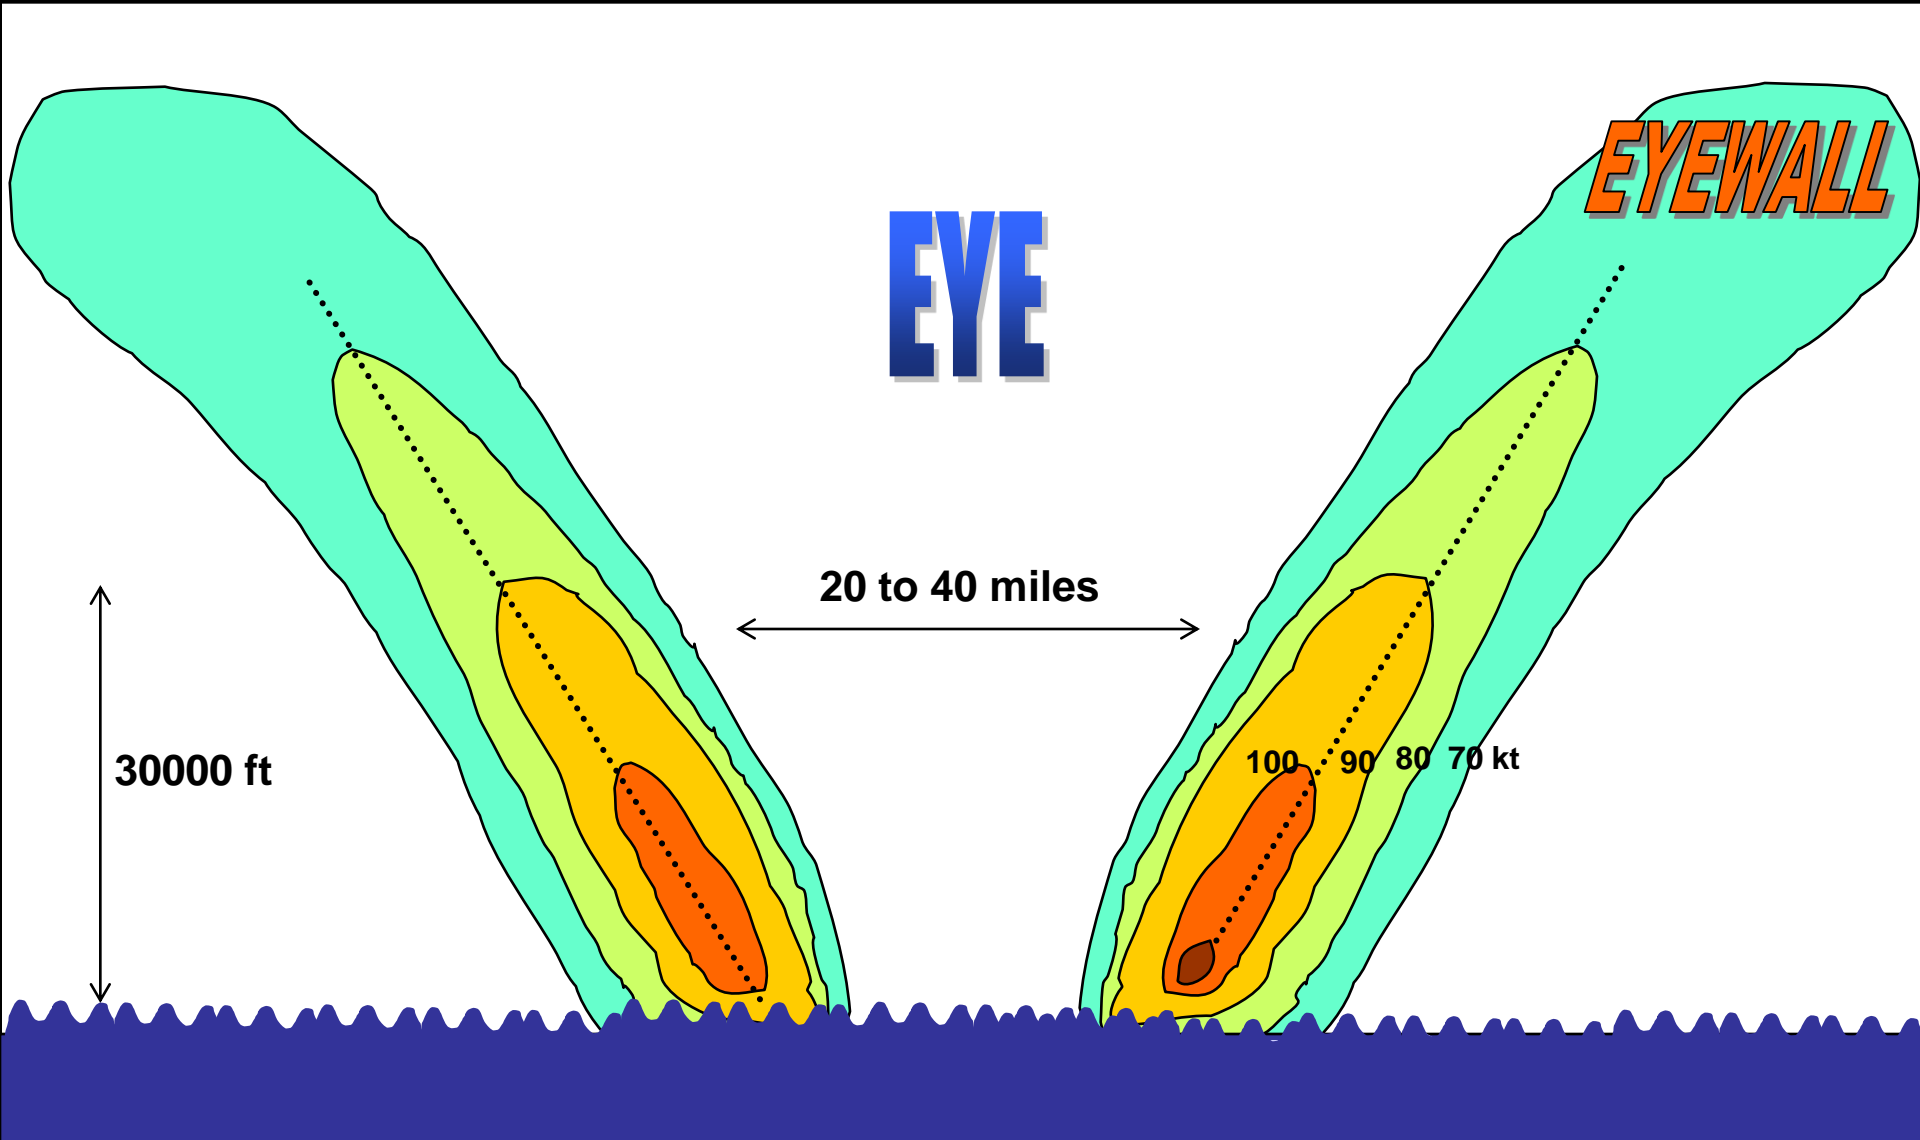

Characteristics of a hurricane:

- Intense warm core aloft: Can be 25F warmer than normal tropical values.
- Winds decrease with height and maximize just above the surface.
- Highest wind and rain are concentrated in a narrow ring of storms around the center—the eyewall.

EYEWALL SCHEMATIC

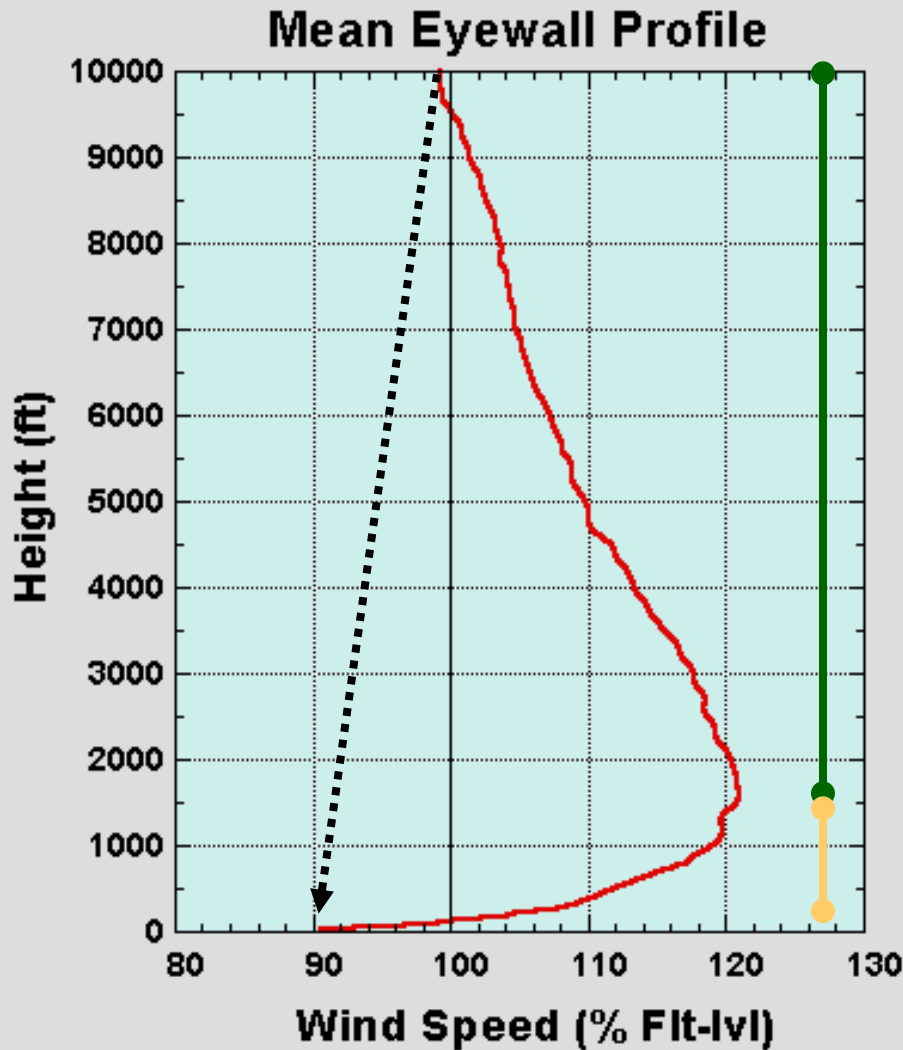

GPS Nominal Constellation
24 Satellites in 6 Orbital Planes
4 Satellites in each Plane
20,200 km Altitudes, 55 Degree Inclination

GPS DROPWINDSONDE

- **Developed in conjunction with the NOAA Gulfstream-IV jet aircraft. First systematic use for intensity was in 1998's Hurricane Bonnie.**
- **GPS dropsondes provide direct measurements of the winds at low levels in the hurricane eyewall.**
- **Dropsonde data reveal that the structure of the eyewall is very complex, and can vary tremendously from storm to storm.**

Because the hurricane is “warm-core”, winds increase downward from flight-level (10000 ft).

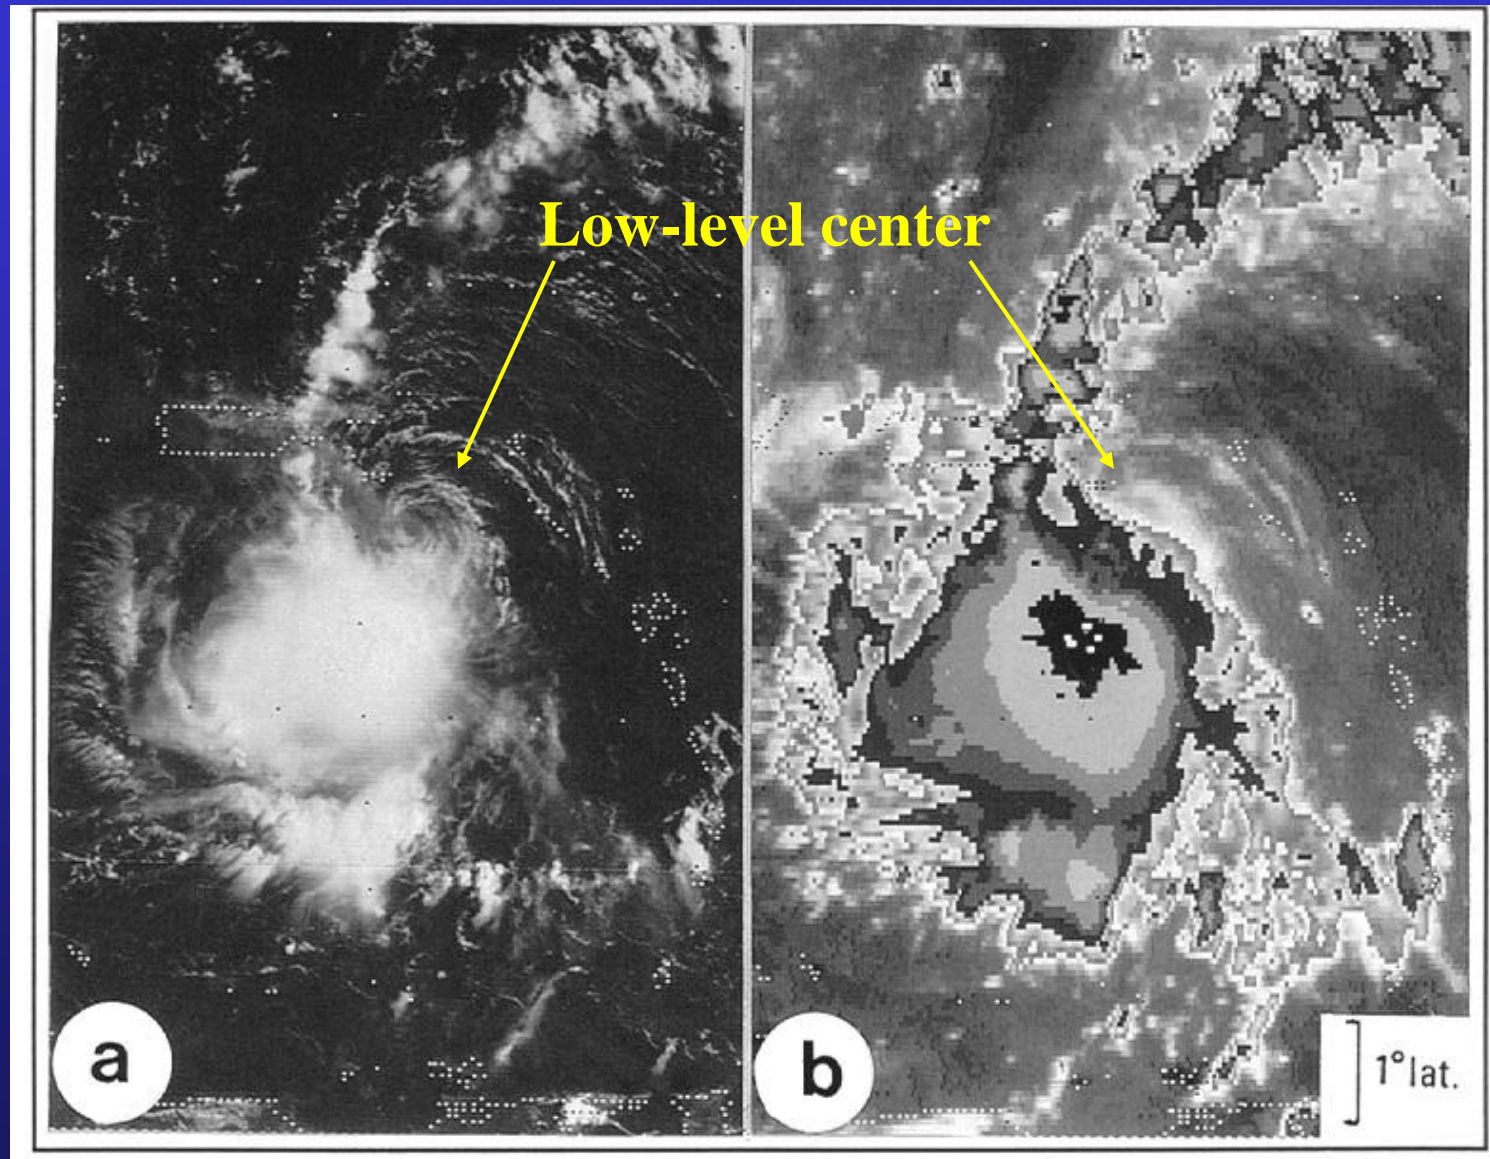

Friction decreases wind in the lowest 1500 ft of the eyewall.

Dvorak Technique Premise

- **Tropical cyclones have characteristic evolutions of cloud patterns that correspond to stages of development and certain intensities.**

During the loop, watch for a near complete eyewall at first, followed by the eyewall breaking down, then a reformation.

EYEWALL REPLACEMENT CYCLES:

INTENSITY CHANGE IS OFTEN CONTROLLED BY EYEWALL REPLACEMENT CYCLES (EYEWALL SUCCESSIONS) IN STRONG HURRICANES.

- **AS THE EYEWALL CONTRACTS, THE CYCLONE DEEPENS (INTENSIFIES).**
- **AROUND THE TIME THE CYCLONE REACHES A PEAK IN INTENSITY, AN OUTER EYEWALL FORMS.**
- **THE INNER EYEWALL BEGINS TO DISSIPATE, RESULTING IN A LARGER EYE, AND THE CYCLONE FILLS (WEAKENS).**
- **THE NEW EYEWALL CAN CONTRACT, RESULTING IN A RESTRENGTHENING AND POSSIBLE REPETITION OF THE CYCLE.**
- **TIME SCALE OF ONE CYCLE CAN RANGE FROM A FEW HOURS, AS WAS THE CASE OF HURRICANE ANDREW (1992), TO MORE THAN A DAY, AS IN THE CASE OF ALLEN (1980).**

Images of Helene

Hurricane Emily Landfall

Note the inner eyewall rotating inside the larger eyewall. This is toward the end of an eyewall cycle.

Eventually the inner eyewall breaks up, and the outer eyewall becomes better-defined, right near the time of landfall.

C.N.A.

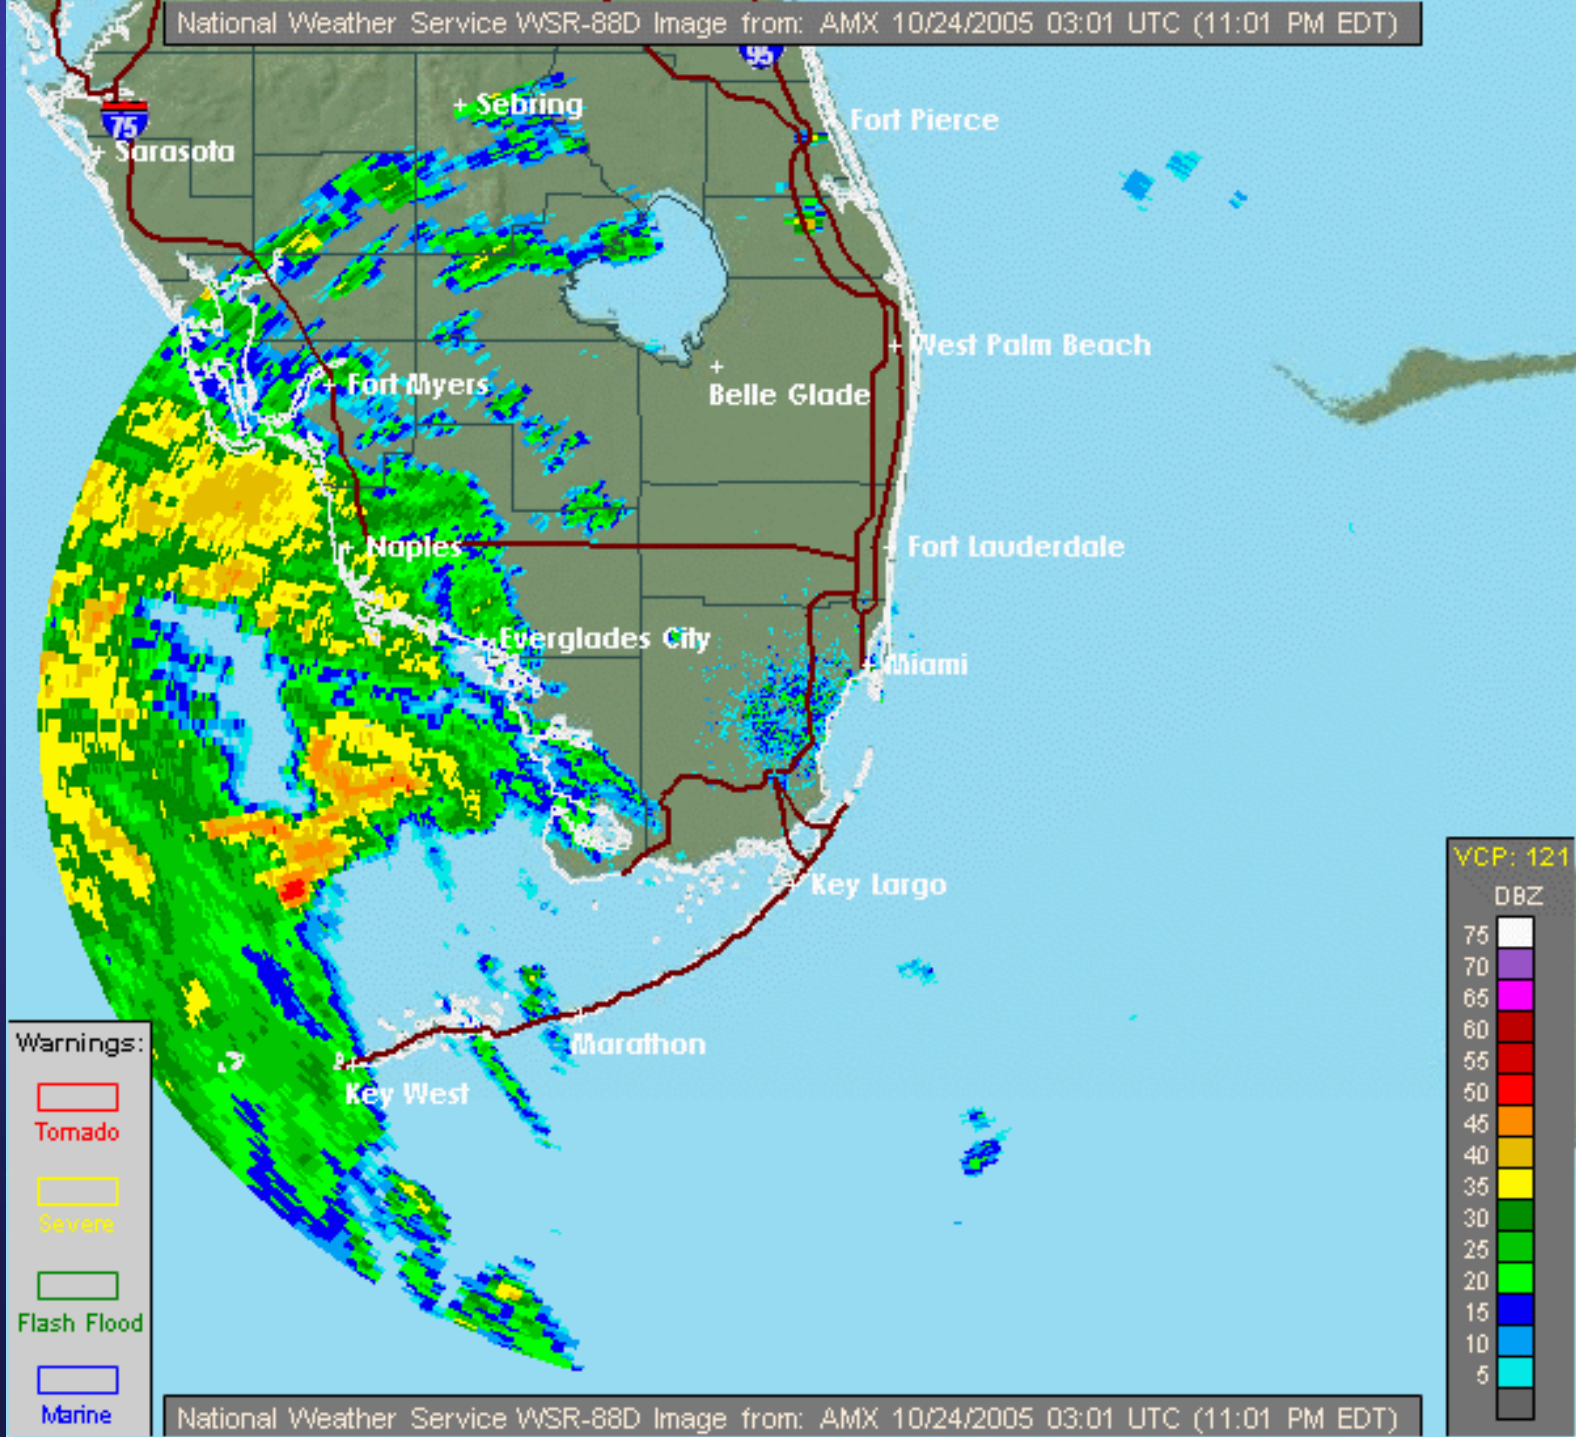

One eyewall is present at first. As Wilma approaches Yucatan, a larger eyewall forms.

Only fragments of the inner eyewall remain by the time Wilma emerges over the Gulf of Mexico.

Wilma keeps this larger eye for its Florida landfall.

Summary

- Hurricanes come in many different sizes, recently ranging from Charley in 2004 to Katrina in 2005.
- Size is somewhat related to intensity, but the relationship is weak.
- During the major hurricane phase, eyewall replacement cycles can cause big intensity changes without any apparent external forcing. The causes for these cycles are poorly understood and a major source of error in intensity forecasts.
