Experiments on Interrupted Mating
of E. coli.

Collaboration with Luca Cavalli April – June 1958.

5·3·58

E.COLI Specific Projects 1400

P 1. Mathematical Theory of mating

P 2. Entry vs. Pairing

DIPLOIDS ; RETRIEVAL OF UNP. MARKERS; BLENDING S/ INTERRUPTION; ABORTIVE RECMB'TS ; DNA LEAKAGE AND VIABILITY ; DIFF'L INHIB'n (AZIDE RESISTANCE)

P 3 PARAMETRIC DETAILS : PULSE EXPTS. VARIATION IN ENTRY; DIFF'L TEMP. EFFECTS ON MATING-VS. ENTRY; INTEGRATION; POST-EL. MARKERS ; SPONT. INTERRUPTION; Lp$^+$ TRANSFER.

P 4. MAPPING : LAC ; GAL ; Lp ; Gal exogenote ; OTHER HFR'S; RAPID METH

P 5. OTHER ISSUES: (Hfr × F$^-$) F$^+$; Holoclonal F$^+$; Enumerate Hfr mutants ; complementary crossing-over;

P 6. Nutrition of W3060... Use of M$^-$ × TL$^-$ for pulse (s sm!).

1401

TIMED MATING WITH $11/T_2$.

(1) Non pulsed. Scored approx every 10'. TL+. Gal+, T_1
3000 × 3084

(2) Pulsed. Scored every 5'. TL+ Gal+ but T_1
3000 × 3084

(3) Non pulsed. Scored every 5'. T+, TL+, Pr+. other markers Gal+ as
3050 × 3052 for T_1

1402

(4) PULSE

(1) 3000 × 3084 - Various relations tested by pairing 4a with 1
Each of 4 strains was treated 2x every 1' with
and 30' interval

(2) 3000 × 3084 10x, 1x, 1x, 4 testing - Effect noted may be due to first 30' incubation

(3) 3000, 1895 × 3084. pulse with 5bn ion, 2d, Decrease in colony and zone
min delete mating negative effect of pulse.

(4) 3000 × 3084 room. 3x, 1a. conc. kept at 1' one zone, then put for
after 1' pulse. No effect of pulse.

(5) 3000 × 3084 - 3rd, same as 1402, 2. pulse 1' → some decrease in
pulse effective

(5) 3000 × 3084. same as 1402, 1895 pulse 1' then transf to Pen
and comparison with unrelated. Very small effect of pulse. B.A

3060's
Temp. Conf Effect

May 9 19 58

REF:

2 days ago, sparse growth from dilute streakes on DO (No B1) were suspended in little water (i.e., from lg + sm colony streakes) & streaked ☐ "same" amount of inoculum on DO & incubated @ 30 & 37 C.

	30 C	37 C
@ 20 Hrs:		
Large	Sparse growth in brush	ea
Small	"	few (~10) sm. col.
@ 2 Days:		
Large	Good growth	Good growth
Small	Good growth	Few lg col, + few tiny satellites

1 lg colony from each of above streaks was picked + put in 9 ml saline on rotator @ 37 C. End of day:

10⁻⁶ dilutions of each spread on B lac and DO & incubated @ 30 + 37. Ditto in DO + DO + B1 (ie, @ 30 + 37).

MICROBIAL
GENETICS

3060's

May 5 1958

REF:

"Prototrophic" 3060 (from Goffhil) plated on B lac to ~ 100 col/plate, which was replicated to DO and to DO B1, Sm & W3064 for Hfr testing. All colonies were prototrophic, and about 2/3 were Hfr. Next pick + streak one Hfr and one non-Hfr to single colony test for Hfr + prototrophy.

8 Hfr −'s → NOIN Hfr and prototrophic (on agar)

8 Hfr +'s → Hfr and prototrophic

but dilute inocula grew on DO·B1 and not on DO unsupplemented.

Also: streak of 3060 (water suspension from same slant as broth for above was prepared from) grew very poorly - few large colonies plus few satellites. Both streaked on B lac (no morphological difference). Both made from 5 c of 10 cm. Now test on DO + DO B1, both liquid + agar D.Ho for 3870 (difference on DO not so pronounced).

		Liquid		Agar		Dilute	
		DO	DO+B1	DO	DO+B1	DO	DO + B1
3870	Large	.400	.630	+	+	+	goodish
"	Small	.454	.620	+	+	+	sl
3060	Large	.527	.530	+	+	+	poorish
"	Small	.408	.590	+	+	+	sl

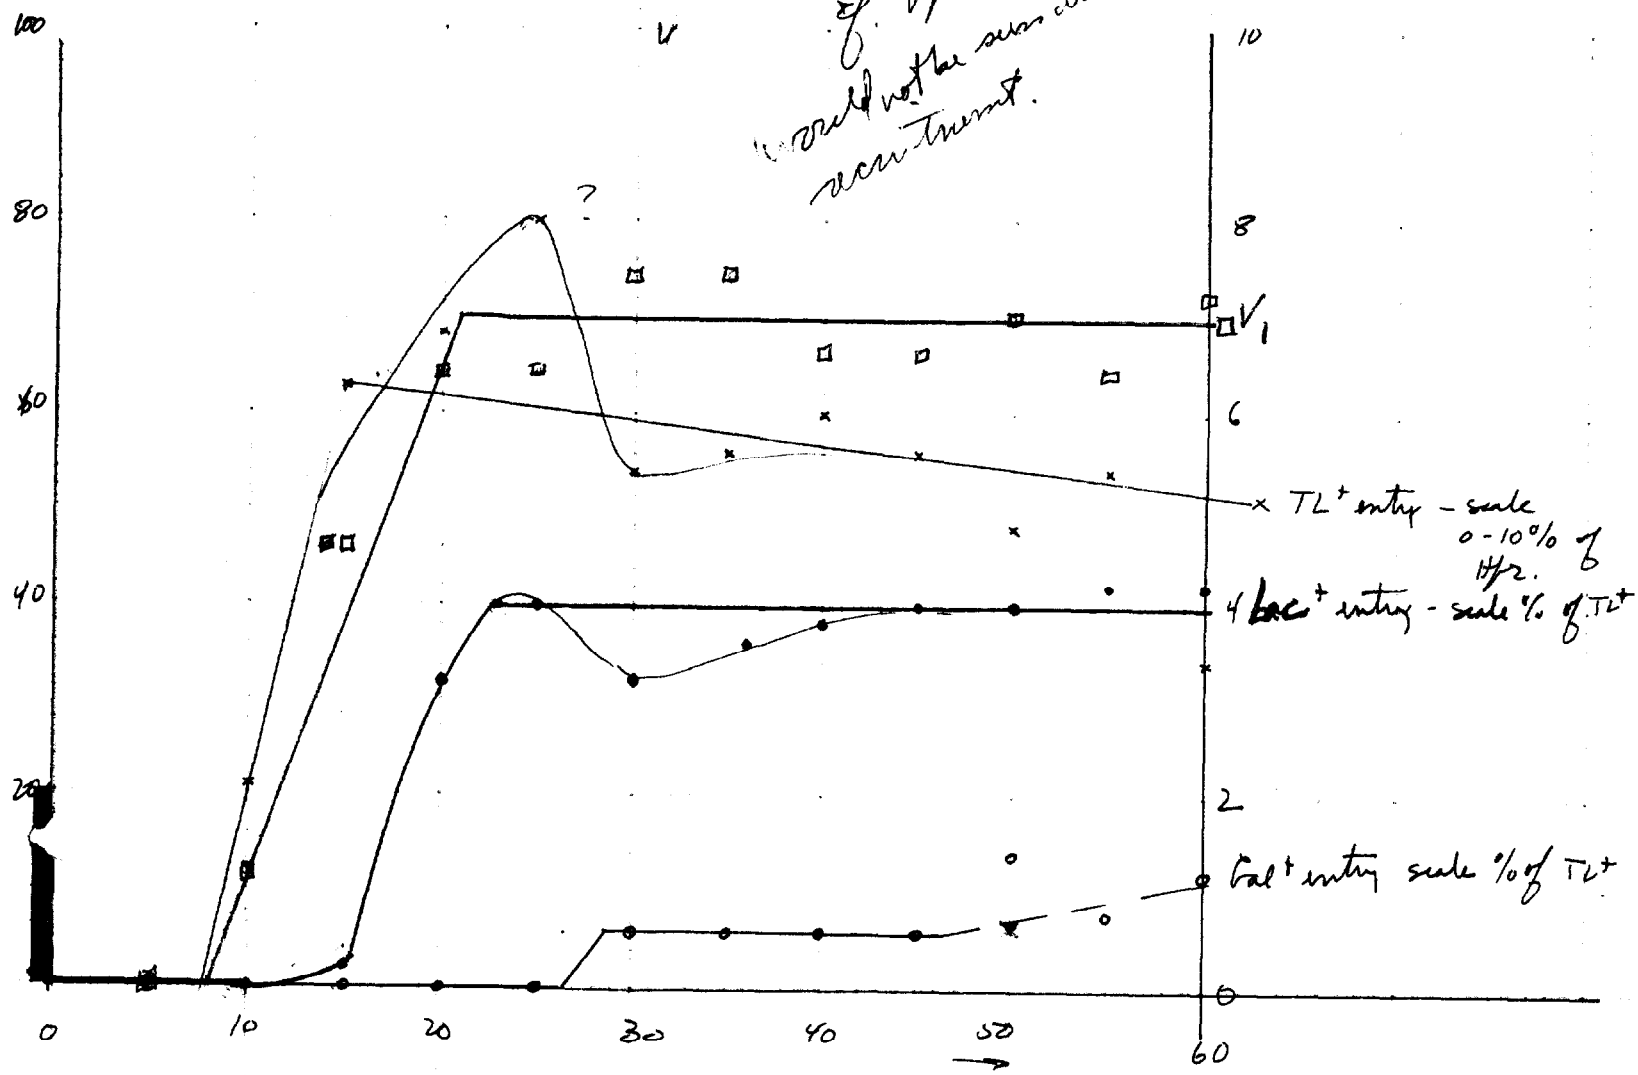
1401/2

% of Lac, Gal, T_1
based on first samples of
50 colonies each.

? Is this a real inflection?
- Lethal effect of hy^+ on hy^+?
of hy^s + hy^s.
would not be seen with continuous recruitment.



1401-2

Conclusions. 5'-10' Pulse is an efficient procedure for raising No. of recombinants.

Dilution of 1/100 at least after pulse if further damage must be avoided. Segregation ratios unaffected, provided dilution is carried out with 1 ml. pipettes. 0.1 ml pipettes unreliable. Interruption on simple dilution in Exp. 1401 probably due to chilling, or plating.

Experiment 1403, not successful because of selection of F+ isolate from Hfr, must be repeated

RECHECK ON PULSE

1hr exponential cultures of W3060, W3064 - (1 + 7.5 ml Pen).
Spun, resuspended in 3 ml for ♂, 0.3 ml for ♀. Kept ice cold until warmed for use.

For resuspension: 1) BGA old type.
2) Penassay.

Mating mixtures equal amounts of suspensions, concentrated and diluted 1/100, 1/10.000. From concentrated; dilute 1/100, 1/10.000 in same medium after 1'.

A conc. mixture D 1/100 dil. E 1/10.000 dil.
↓ 1' purge
B 1/100
↓
C 1/10.000

Plating: after 20' from A dil 1/10.000 0.05
[for D(from B,)] B dil 1/100 0.05
C ~~dil~~ → 0.05
D dil 1/100 0.1
E → 0.05

same after 80' for BGA and

A-E letters refer to BGA
similarly F, G, H, I, J for Penassay, with equal mix. meanings (A=F, B=G etc.).

U.W.
MICROBIAL
GENETICS

19 REF: 1402/4

	1	2	3	4	5	6	7	8	9	10
		60' broken Highs 60'	1' Pen → ½' Highs 1' 1:100 60'	½' Pen → ¼' Highs 1' 1:10⁴	½' 60' 1:100 60'	½' 60' 10⁻² 10⁻⁴ 60'				
	BGA.	A	B	C	D	E				
plate	20'	4	0	0	~~15~~ 0	0		Plate counts		
	~~86~~	52	28	++ not spread	15	0			Pen	BGA
			~2%/1½					10^{-2}	2	1

		F	G	H	I	J				
	20	8	9	9	7	2				
	~~86~~	28	55	43	51	29				

10^{-4} in BGA might work for pulsing: 1' pulse followed by 10^{-4} in BGA gave 2% yield. But cross may be delayed.

10^{-2} in BGA not enough to limit mating (D)
No valid test of 10^{-4} dilution in BGA. This is adequate predilution (E) to prevent further mating, ~~and~~ but there is no measure of pulse : post pulse mating (a/c C being n.g.)

19 May 26th, 1958. REF: 1402/5

PULSE I

(P).

Experiment identical to 1401/2, except for dilutions employed and times.

Samplings every 20', samples chilled, blended, plated (0.05) and also 1/10 dilutions plated (0.05) on D(from B_1).

Note: 3064 strain is extremely soupy and very difficult to resuspend in Penassay.

(D). From same suspensions as P, diluted each 1/5000, a mixture of equal parts of 1/5000 dilutions incubated, sampled and plated exactly as for P.

DATE: PLATING BY FLOODING. REF: 1403-3

12.30, 1 ml + 10 ml — rotation, # 3060, 3064.

13.30, 2 ml + 2 ml of exponential cultures mixed, incubated in water bath for 5', then diluted in warmed broth ~~from~~ 1/100, and kept in water bath.

After 10' since dilution:

1/100 Broth → .05 on B_1 plate } undil.

1/100 → .05 "

DW → 1 ml flooded plate on B_1 } 1/100

1/1000 → .05 on B_1

DW → 1 ml flooded plate } 1/1000

1/10.000 → 1 ml flooded plate } 1/10.000

Dilutions: first with 0.2 ml pipette, then 1 ml.

Mixing after dilution, by transfer to dry tube and back

After 20' same, except that first dilution in DW is 1/10 instead of 1/100; rest unchanged.

After 60' same.

Flooded plates have been inverted 5-10 minutes after preparation - Some liquid still floating

STABILITY OF PAIRS TO PLATING.

To check if 2323 or 2735 are more resistant than 3060 x 3064 to interruption by plating.

Saturated o.r.c. of 2323, 2735, 3060, 3064 mixed in equal amounts:

After 20' ~~plated~~ diluted 1/1000 and { 0.1 / 0.05 } plated on min/ft B,

		Counts:	0.1	0.02
A	3060 x 3064		5	0
B	3060 x 2735		0	0
C	2323 x 3064		0	0
D	2323 x 2735		6	0

Not picked for Lac segregation -

What's wrong with this experiment?

5 May 1958 REF: ~~1401-2~~.

C -O area mess. Mal⁻ doesn't allow for decent scoring of F character! Will have to use another system, perhaps Hfr₂ ara⁻.

E.G. Hfr₂ ara⁻ T⁺L⁺ S^s
F⁺ ara⁺ M⁻ S^s × T⁻L⁻ S^R gal⁻ or lac⁻ ? F⁻

and discriminate on basis of ara character which is closely linked to T⁺⁺.

Wait for W4062 to be lysogenized.

{ F+ x F−
{ Hfr x F− } Cross infertile mogh.

1404 A.

DATE: March 24, 1958 REF: 1322, AKC 4.1

9/56

If futility of F+ depends on the mutation to Hfr, F+ x F− should not be uniformly F− except by reinfection. Expt. to determine whether the recombinants from Hfr x F− are inherited in presence of F+ x F−. Use excess F− and measure incidence of F+ conversions via it.

Basic setup Hfr V_6^2 M− = W3273 (cf. AKC as best linked to lac).

F+ V_1^2 M− = Y40

W3089 = Lac− Mal− S^R. (Use S^R — can terminate mating by sm ?)

Previous history of Lac linkage

Also retrieve stocks of W1979 = W1895 V_1^2; W3262 (but V_6^2 not linked to lac); W1632: F+ V_6^2.

P23 (A) Sm cultures. N24 Sm 1:10 is necessary rotate 37° rotate.

Better not to rotate ??

1:15 PM (Est dens. ~ 5×10^8/ml) Make following mixtures.

			Counts P26
1	W3089	1 ml	0, 0
2	W3273	1 ml · dil 10^{-3} (↓)	
3	Y40	1 ml	
4	W3089	1 + W3273 .1	41, 43
5	W3089	1 + Y40 .1	1, 1
6	W3089	1 + W3273.1 + Y40 .1	22, 27

too low!

Incubate standing.

2:45 PM. Add .1 ml of sm (2 mg/ml) per tube → 200 r/ml.

Add 10 ml water (room temp.) to dilute

Plate 0.1 ml samples on M lac. 1 = W3089 + .1 ml(2) + .1 ml(3) added after the dilutions of 1. This tests plate recombinants.

Plate out #6 on EMB Mal for infertile rate of W3089. — test only the Mal−

Crosses n.g. — not enough from F+. Repeat c/ new 3089 also.

1404A W1632 ($V_1^S V_6^R$ × W3089)

PROTOPLASTS.

Exp 1405-I is repeated, but after bursting in DW, mixtures are either plated or kept in the waterbath until completion of 60' since the beginning of the expt. In addition, a pulse of 10' is given to the mixture.

9.05 am. 1 ml 3060 overnight aerated + 9 ml broth → Rot.
10.30 1 ml 3060 expon. + 9 ml I_2
12.10 coarse granular growth. Agitated, 10^3 Pen u/ml added.
14.40 centrifuged.

Algo: 14.20 3064 2 ml + 10 ml Broth.
14.40 Centrifuged.

3060 ♂, 3064 resuspended in 1.2 + 1 ml I_2; = 10 ×
0.3 ml in water bath.
3060 ♂ 10 × → 0.1 ml + 0.9 ml DW → 0.1 on B Lac.
→ 0.1 + 1.9 ml formalin 1% → Count (all burst out?)
3064 10 × → 0.5 } X
→ 0.5 }
→ 0.1 + 1.9 ml formalin 1% → Count = 9×10^8/ml

X and ♂ ♀ (diff. in I_2 of 3060 ♂) incubated in water bath for 10', then: diluted 20 × with I_2 medium warmed.

(X) → 0': 1 ml + 9 ml DW → plate 0.05 and 0.01 on minST B_1.
↓ + 10 ml broth, water bath. (= 0/60') → plate 0.05 / 0.01
10' water bath: same as above → = 10
20' " " = 10/50.
30' " "
45' " "
60' " 1/10 DW → = X-60 (pl. 0.05, 0.01)
→ + 10 ml broth → = 60/0 (pl. 0.05, 0.01)

DATE: REF: 1405-III

LEDERBERG, ESTHER M., University of Wisconsin, Madison, Wis.--Fine structure of the Gal loci in Escherichia coli K-12.---A distinctive recon (one of a group of closely linked loci separable by recombination) has been assigned to each of ten independently occurring Gal$^-$ (galactose nonfermenting) mutants. All the mutants were obtained after UV irradiation except Gal$_3$ which was spontaneous. Allelism was tested by large scale matings and by transduction analysis.---Prophage-linked transduction via Hfr λ, where practically every phage particle may result in a transductional event, produced heterogenotic clones when donor and recipient bore distinctive recons. The heterogenotes were unstable, segregating the two input and two crossover classes (Morse, Lederberg and Lederberg 1956). Two cistrons (cis-trans position effect groups) had been demonstrated: trans heterogenotes with members of the same cistron are phenotypically mutant. Galactokinase was missing in mutants of one cistron (Gal 2,8) while UDP transferase activity was absent in the other (Gal 1, 4, 6, 7), a defect corresponding to human congenital galactosemia, (Kalckar, Kurahashi 1957). Gal$_3^-$ and Gal$_9^-$ are genetically cistronic with <u>both</u> of the foregoing groups; they have not yet been successfully analysed for their enzymatic defect. Among two hundred new mutants, no recons identical with the first ten have recurred. Most have been assigned to either of the first two cistronic groups, but a small number which would represent a fourth genetic group have given only normal galactose-positive heterogenotes with every standard Gal$^-$ tested. A few mutants were not transformable by λ but were found to carry other modifiers including that of hexose metabolism which obscure their relationship to the Gal$^-$ group.---An attempt was made to map the Gal markers in linear sequence by their relationship to the Lp locus. Intercrosses of Hfr M$^-$ Gal$_x^-$ x F$^-$ Gal$_y^-$ were made on a medium which selected efficiently for M$^+$Gal$_x^+$Gal$_y^+$ recombinants, and these were then scored for the segregation of an Lp marker. However, the linkage of Gal-Lp proved to be not close enough to compensate for the perturbations of segmental loss from the Hfr parent, and the data were indecisive.

10th International Congress of Genetics, Montreal, 1958.

19 May 16, 1958 REF: 1408/5

GAL PREUM TIMING: Hfr3, Hfr4.

1 hr rotated cultures of ♂4 and ♂13, ♀ 3908.
♂'s same as in exp 1408/3. - Cultures started with 2 ml ea. ♂, 1 ml ♀
Centrifuged, resuspended in 4 ml (2×), and mixed in flask.
4 ml ♂2× + 8 ml ♀2×.
Sampled at 10' intervals, chilled, blended, plated .05 & .1 on 5th Gal fin Meth Prot.

Controls: .03 of ♂ + .09 of ♀

19 June 18, 1957 REF: 1408/15.

Hfr₂ Timing of Gal₄, Gal₂, Gal₃.

Exactly as 1408/14, but:

1) ♀ parents were Gal₄, Gal₂, Gal₃, and they were seeded in this order.

2) ♀ 3 was grown after Gal₄ and Gal₂ had been harvested, as a substitute for Gal₄ which was supposed to be tested today and was found to be St^s. ♀ 3 was found to be slightly less concentrated than the other two females and these two were collected into two, thus reaching 1.5 × conc. for this ♀.

3) Mating mixture: .5 ml ♂ + 12 ml ♀.

Plate counts. (48 hrs) (72 hrs)

Time	Gal₄	Gal₃		Gal₂
0	(35), 7	2, 0	13,	0, 0
15	7, 1	0, 3	11,	0, 0
18	2, 9	3.	27, 27	0, 1

" " + 0.1 colchicine solution 1%.

1h rotation -

CO: mixed equal amounts of colchicined broths, + 0.1 ml. colchicine/ml.

I: mixed equal amounts of (Control)* broths, 0.1 ml colchicine water added per ml.

C: mixed equal amounts of (Control)* broths 0.1 ml water added per ml.

10' incubation in water bath, then dilution 1/100 in broth, incubation 20', then:

1/10 DW → 0.05 mixSt B1

↓

1/10 DW → same

↓

1/100 DW → 0.05 B lac.

	CROSSES 1/10	1/100	B Lac Lac+	Lac-
CO	152	6	6	17
I	69	7	6	14
C	146	14	6	15

Conclusions: There is perhaps a small decrease in No of prototrophs adding colchicine to the mating mixture (but not adding it in advance to the cultures: adaptive enzyme destroying colchicine?) -

Freezing mating cultures

U.W. MICROBIAL GENETICS

1412

April 26 1958 REF: 1401-2.

ORF = overnight aerated cultures.

W3060 (overnight) 3X 10ml → 3
W3064S (rotated) 30X 10ml → 0.3 ml. in fresh prewarmed } .2 .2 mixed.

Prewarmed cultures mixed in a 125 ml flask. After 60 seconds added 19.6 ml prewarmed broth for 1:20 dilution. Mix gently in flask.

[A2] Add 1 ml samples to prechilled tubes in CO_2-acetone bath.

[A1] Dilute 1 + 3 ml 20% glycerol and freeze. = glycerol-freeze.

Dilute 1:250 in broth, incubate 15 minutes. Chill in ice bath.

[B] Sample 1+3 ml glycerol & freeze.

Blend 30 seconds.

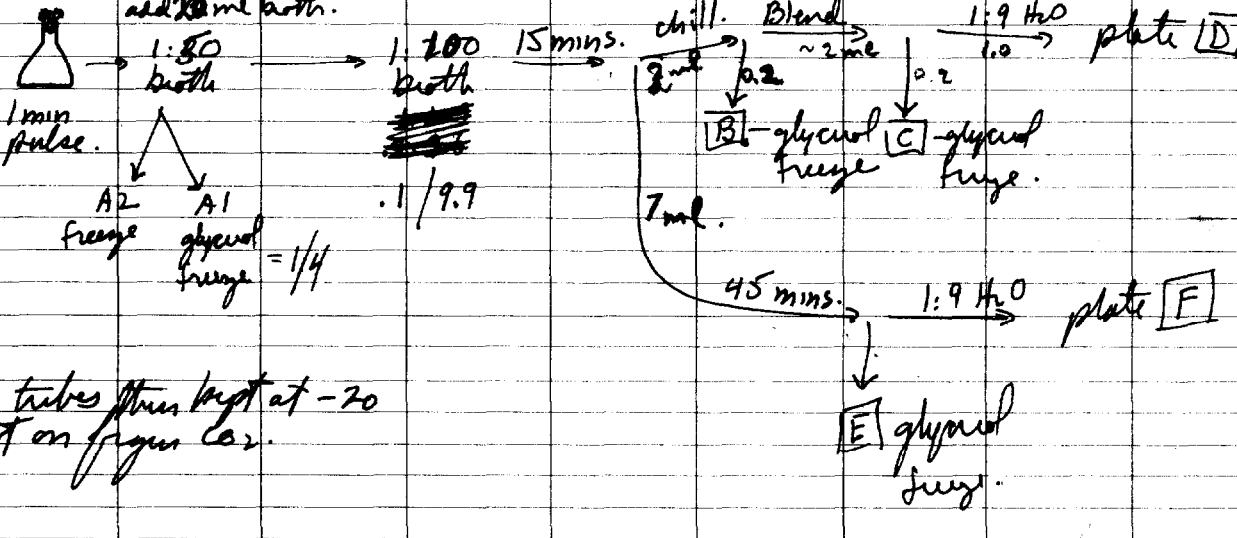
[C] glycerol-freeze

Dilute 1/9 in water and plate [D].

Incubate 45 minutes further

[E] glycerol freeze [F] dilute 1/9 in water and plate.

D and F plated .05 and .1 ml on DB, sm and B bac.



frozen tubes stored at -70 not on frozen CO_2.

addendum: Drosophila eggs and larvae in agar/10% glycerol. Chill in ice water & freeze quickly in CO_2 acetone. — proved workable.

See Luca's notes: he finds that freezing interrupts pairs; yields of recombinants are about 50% of non-frozen controls. Technique is usable subject to some possible bias; may be good way to interrupt (contra first diluting in chilled saline.)

(over)

3060 x 3064.

(1412)

5 1 ml samples.

1 ml. A.

Pulse 1 minute. 1:20 ~~dilution~~ dilution = 20 ml.

fuge 1 sample.

incubate 1:~~200~~ dilution

→ 15 minutes

- fuge 1 sample – 1 ml. B
- ~~dilute 1:10~~ blend dilute 1:10 → fuge 1 sample C → count
- ~~dilute 1:10~~ blend dilute 1:10 → plate 1 sample D → count
- incubate 45 m. → fuge 1 sample E → count
- incubate 45 m. → plate 1 sample F. → count

---

1. – F. interruption by fusing as TL+ count.

B – F interruption by bac ratio.

~~B~~ –

C – D viability of zygotes.

C – E interruption by bac ratio

B, CE vs D, F viability of zygotes as TL count.

C, E vs DF viability of input.

storage; methods of thawing

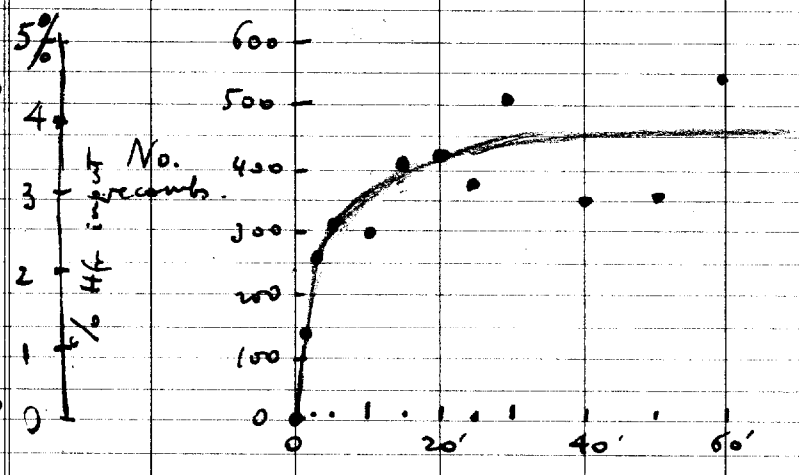
40'	345	55	5	!
50'	356	53	not done	
60'	540	43	"	



Note: 0' is not an accurate definition as it merely measures plate recombinants. A better 0' would have been 60' incubation of parents diluted 1/10.000 and mixed.

Conclusions.

t_{37} about 5'; to have 95% mated 15' are necessary. this time is too long.* In order to reduce it to about 1/3 try:

1. temperature decrease
2. DNP.

* as confronted with rate of entry of chromosomes. It is desired to have this time %

smaller than the difference, in time of entry, between T1 and last which is about 8'.

1414B

D0 - versees D20 shows lacenty. Is this due to

(1) reverting of Hfr × F⁻ despite blending + dilution
(2) F⁺ × F⁺ owing to preferentiation of F⁻
(3) Resumption of pairing is interrupted Hfr × F⁻ under influence of F⁺.

suggest: use W1306 ($H^- F^+ V_1^r V_6^r$) to distinguish (2).
control: reincubate after blending + dilution to distinguish (1).

U.W.
MICROBIAL
GENETICS

19 May 9th, 1958. REF: 1415/3.

W 3060 (Esther's transfer) : 1 ml + 7.5 ml Penassay, 8 cult.
W 3064 " : 0.5 ml + " 10 " .
3 hrs rotation. Spun, resusp. in water 1 ml, pooled different cultures, distributed each strain in equal amounts in two tubes, spun again, of each strain one tube resusp in 0.5 ml. (Concentration about 80 x) of D(aspartic). *, and the other in D(aspatic + azide 10^{-4}).

*: to 10 ml of D(M): .1 of 20% glucose and .02 of 10 mg/ml aspartic acid. pH 7.0.

Azide and non azide parents incubated at 37° for 5', then:

(AB) Parents in non-azide D(asp) mixed, 0.2 ml + 0.2 ml and pulsed for 2½ minutes, then diluted as follows:
A. .1 ml in 10 ml D(asp)
B. same + azide .1 of 1% solution.

(CD) Parents in D(asp) azide 10^{-4}, 0.2 ml + 0.2 ml, and pulsed for 2½ minutes, then diluted as follows:
C. .1 ml in 10 ml D(asp)
D. same + azide .1 ml of 1% solution.

(E_1) Unpulsed recombination control 10^{-2}: .05 of each parents, 80 x conc. to 10 ml of D(asp) at 37°, 40'. Dilute 1/100, plate .05.

(E_2) Unpulsed recomb. control 10^{-4}: .05 of 1/100 dilution of each parent to 10 ml of D(asp at 37° for 40'. plate .05

A and C : after 40' from pulse, dilute 1/100 in water, plate .05 in min/sm B_1

B and D :

B_1, D_1 : .1 ml to 10 ml water, plate as above

B_2, D_2 : .1 ml to D(appo) 10 ml, 40' in water bath, plate .05 on min/sm B_1.

Plate recombination

10^{-4} dilution of parental suspensions, .025 of each to min/sm B_1 plate

Counts : photometry at 650 mμ of 1/100 dilution of concentrated parents :

3060	50%	= 240 × 10^6/ml
3064	52%	= 320 × 10^6/ml

10^{-7} dilution, .05 on B Lac :

3060 : 100, 139

3064 : 159, 164

Original conc. suspensions : 24 × 10^9/ml ; 32 × 10^9/ml resp.

Plate counts: Numbers were too high for accurate counts.

A_1 : ~800

B_1 : same

B_2 : same

C_1 : ~500

D_1 : ~500

D_2 : ~800

E_1 : 250

E_2 : 140.

Plate records: 0, 0 -

Conclusions: too many recombinants in the unpulsed controls for any valid conclusions to be drawn. Due to use of D (aspartic) instead of BGA? Azide is however almost ineffective. Try higher concentrations.

Conclusions

Matings probably stopped by Az 3%, DNP M/200 or more. Action apparently reversible, but new recruitment may have taken place (although G 1/1000 and G2 1/10 show equal numbers): nos. of prototrophs have considerably increased and it is unlikely that they were all blocked before TL at the 12'.

AZIDE RES-: OPTIMAL AZIDE CONC.

O.r.c. cultures of W3050, 3064, 3947, 3935 - spun and resuspended in diluted ~~fol~~ ~~ma~~ Broth-

Mixtures as in exp 1415/6, then 0.9 of mixture per tube, to which 0.1 of the following conc. of azide in Penassay were added:

3%, 1%, 0.3%, 0.1%, 0.

Called 1 2 3 4 5 -

45' incubation, then dilution 1/1000, plating of 0.05 on D(str B,)-

	1	2	3	4	5
A	0	0	7	57	38
B	0	1	6	18	44
C	0	1	43	108	~400
D	1	10	41	118	318

No discrimination.

DNP.

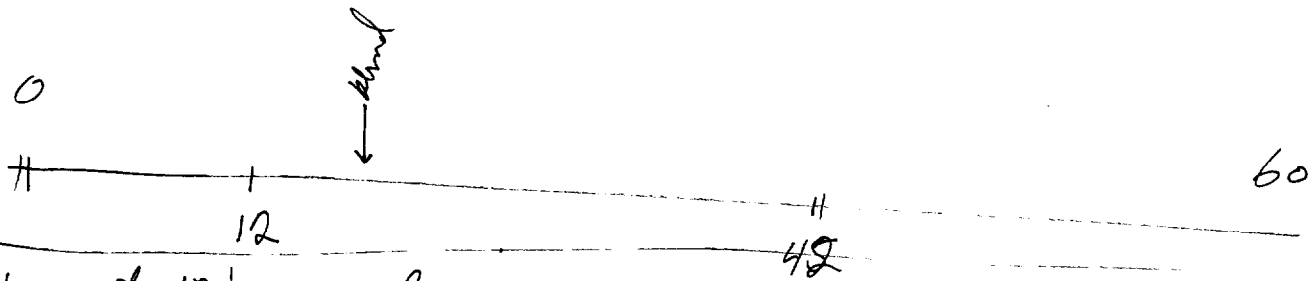
14/15

Pulse — 12 minutes.

1. Blend & plate.
2. Blend in DNP
3. DNP reversibility.

4. Incubate + 30 minutes. Blend + plate.

(2) add DNP. Blend. Incubate (in DNP) 1 hour and overnight.



1. at 12' d + pl.

2: at 12' add DNP. Incubate 30 minutes in DNP. → 3

3. Blend + plate. 4. Dilute (to remove DNP), Incubate 30 minutes.

↳ 5 after 5 minutes, blend. → incubate in DNP {30 minutes / overnight}

↳ dilute
incubate 30 minutes

(4/15)

I Effect on mating

plate after 60 m: = I A - B - C - D. at 10^{55}

II Effect on injection: $10^{15} - 11^{15}$ dilute 1:100 in B & A.

↳ plate A

plate B at 12^{15}

IV.

---

5 May.

14/15

3060 - 3064. ~ ½ ml 100x. chilled.

NaN_3 - now have 10 mg/ml. Use at 100γ/ml.
Need to dilute 100x at least.

avoiding orange.

---

(1) Do these compounds inhibit mating?
(2) Do they inhibit injection once started? 12 minutes.
(3) are they reversible.

(A) mating: add .1ml cells each parent + .2ml inhibitor.
pulse 1 minute. dilute ~~+ 1000 in~~ 1:10,000 in BOA.
warm BOA. 95° Plate on DSMB, at 60 minutes.

(B). Also dilute (C) sample 1:100 in BOA. at 12 minutes add inhibitor. Incubate 30 minutes ~~& plate~~ dilute 1:100 blend & plate. (Another sample chilled 30 mins.). Enzyme A chilled.

(C) after 30 minute dilute 1:100, incubate 30 minutes +, blend & plate.

B(A - D)
4 tubes. 1 ml each. $10^{0.3}$ PM warmed.
at 10½ chilled and add 1 ml of inhibitors. - Warm and incubate ~~+2 minutes~~.

Azide effects on mating

14154

5 May 1958 REF:

Ultimate purpose: compare azide effects with Az^+ O^+ v O^-.

Below: A = —; B = Azide 100 r/ml C = acridine orange 60 r/ml D = DNP $\frac{M}{1000}$
[Note: agglutination of 0550 in C.] Make up 2 x in BOA.

Design: Effects on mating (during pulse) I; effects on entry (after pulse) II; Reversibility III.

I Pretreat each parent before and during mixing; dilute, incubate & plate.

II Dilute untreated pulse into inhibitor soln. Incubate.

III Redilute these and incubate further.

Pulse 1 min. | Dilute & Incubate

Treated → BOA 1 hour. Plate: I

Untreated → (12 min.) treatment 1 hour → Plate: II

A / B / C / D chilled

Dilute into BOA → Incubate 1 hour. Plate IV

→ Plate III.

Reversibility of inhibited entry is tested after 12 minutes.

8 PM ff. W3060, W3064 refreshed from ORC 5 tubes each harvested into 0.5 ml (ice) in BOA. Chilled until used. Timing by chilling in ice water.

M1. But Mergers present

I Add 0.1 ml each parent + .1 ml inhibitor (2X). Mix and incubate 1 minute (pulse)
Dilute 1/10,000 in warm BOA & plate at 60 m. (10^{55} AM). : I: A, B, C, D.

II. Tube A at t_1 (1:100) and dispense 1 ml to each of 5 tubes. Chill at t_{12}. (Plate III)
AO - keep chilled. A, B, C, D add equal vol. inhibitors and incubate 10^{20} - 11^{15}

III ~~Plate after~~ 1:50 dilution at 11^{05} → plate II
Incubate 1 hour + plate III.

Note: water bath went to 43° at 11 PM.

Counts: IA - 0 prototrophs. II and III zeros all 0!

IB { 25 prototrophs
36
36

Faulty IA? Are the "inhibitors" encourage mating? If they do not inhibit mating they do appear to inhibit entry and according to B reversibly.

U.W.
MICROBIAL
GENETICS

Azide at. on entry.

1415 B.

6 May 1958

REF:

Repeat 1415 in view of 43° incident. Change designation to measure entry of T2.

Use same cells as yesterday (chilled at 100X).

Pulse (1:1:2ml fresh BOA) 7 minutes at 37°. Chill and dilute 1:100 in BOA

disperse 1 ml volumes of dilutions. Add 1 ml of inhibitor. AO = chilled A (not inc.

Incubate 30 minutes. (Plate semis at at 1:50 dilu.) Dilute all samples 1:100 in

warm BOA and incubate 60 mn. Plate 0.1 ml.

.05 ml samples plated.

1 Plate A only at t_0

2 Plate AO, A, B, C, D at t = 50.

3 Plate AOABCD at t = 110

4

Needs reincubation, counting, and full scoring. Gal as T_1

semis 2 shows inhibition of entry

3 its reversibility.

U.W. MICROBIAL GENETICS

PULSATION

design 1420A

June 1 1958 REF:

Kinetic experiments based on pulsed mating have been unsatisfactory until now on account of an unsatisfactory separation of recruitment and entry phases. In previous control experiments, extent of recruitment varied as approximately the 1/2 power of cell density (instead of expected square), so that subsequent recruitment accounted for 5-25% of total yields. This is quite unsatisfactory.

In this experiment, screen for reagents which may impede mating without preventing further entry.

Following are suggested:

1. pH range in .5 units from 4.5 to 9 Adjust D(0) by HCl or NaOH
2. tris
3. versene
4. thioglycollate
5. ethanolamine
6. dead and live S^s F^-
7. fluorouracil deoxyriboside ↓ not available today
8. periodate M/100 M/1000 M/10.000
9. D(0) ∅ Mg

Experimental design: Mate ORC W-3060 and W-3064 (washed and resuspended in cold penassay) at sat'd cell density for 5 minutes at 37°. Dilute 1:10 into indicated solutions (made up in D(0) unless indicated, and incubate to 60'. Dilute 1:100 for plating .05 ml on SGalThSm. The pulse matings should gave a baseline count of ~~prem~~ SRP including some 10% Gal+.

Toxicity will be indicated by a loss of SRP

Inhibition of entry will be indicated by failure of Gal+ among SRP

No inhibition will be indicated by marked rise in SRP

Inhibition of mating ∅ inh. of entry will be indicated by stabilization of SRP with establishment of Gal+.

Controls needed: Plate recombinants (plate mixture after dilution))
Early interruption: plate mating at 5';)
1:1000 dilution at 5'; plate at 5' 15' and 60') Dilute in D(0).....
1:10 dilution: plate at 5' 15' and 60')

Dilution only 1:10 from penassay!

Criticism: may have already been pulsed by high density. Luca's conclusions: pH 5 to 8.5 no effect. 4.5 gradual reduction or slight 4 no effect. 2,3 not tried

D(0)-Mg no effect. periodate negative (partial interruption and null-recruitment)

6B no effect! But 6A

19 June 4, 1958. REF: 1420 B

PULSATION WITH PERIODATE

Parents: W3060, W3064

ORC cultures, 4pm, susp in chilled water 20 x until used then diluted in: Penassay, 1/20,

DM (D(M) + asparagine 1‰)

DO (D(O) + " + glucose .5%)

α1 Pulse 2' in Penassay, mixing equal amounts of parents: 1 ml each in a flask, starting from chilled susp mixed while chilled. Dilute after 2' in DM periodate M/2000, 1/100, incubate and sample every 5' until 40', dilute sample of 0.2 ml in 1.8 ml, plate and plate on D(Sm B_1) 0.05 ml.; for 20' amounts also further 1/5 dil. plated

α10 From pulse dilute in D(M) 1/100, without periodate; sample only after 40' and plate 1/5 and 1/25 .05 → D(Sm B_1)

There were no colonies except in α10 (where there were 4 colonies).

F+ reversion of W3060 ?

Moreover while this part of the experiment showed contamination with staph, the second part of this same exp., which used the same cultures, showed no or less contamination, but was also sterile.

Does dilution into periodate give a pulse? Possibility that M/2000 periodate is toxic if not neutralized? Should try adding thioglycollate at various times, providing thioglycollate does neutralize. M/2000 periodate was not toxic in 15 minutes with a heavier cell suspension (1420B). Again will neutralize periodate. Q questions.

No colonies! Presumably reacted Fx!

0	20	−	0

Tests by shifting

(1-6 diluted, via 0(m) rather than H_2O.

at M/2000, inactivation maybe differential.

Preliminary results are very promising (for periodate as a de-sorting agent). Could the aeration phenomena have been oxidation of surface receptors? If so should reverse Hpoise.

See 1420 for origin of this experiment. Periodate is of course known to affect the receptors of animal cells for influenza virus. (Will flu agglutinate any bacteria?).

Try other oxidants? Ferricyanide?

Conclusion (within limit of test): sexual competence is destroyed by periodate, ♂♂ more sensitive than ♀♀. [Viral kinetic and viability controls.] 1421B shows M/200 periodate is toxic; M/2000 is not.

If Hpoise inactive, will periodate/Protein deactivate ♂♂?

June 3 19 58 REF: 1420;1421

Harvest CSC W-3060, W-3064 3x7 ml each into 1 ml water. (Keep chilled during day before beginning experiment about 7PM. 1421 suggested differential effect of periodate. This is essentially a repetition with some added controls for viability and reproducibility.

In each case, add 0.1 ml cell suspension to 0.5 ml treatment solution (in D(m)). Treat 10 mins. at 37; neutralise 5 mins. by addition of 4.5 ml penassay+1% glycerol. Mate for 15' by mixing .5 ml each suspension. Then chill, dilute 1/100 and plate 0.1 ml on D-B$_1$sm agar: duplicate plates. Also dilute 10^{-6} and plate mk 0.1 ml on EMB Lac for viability.

	Treatment: (periodate conc.)		Viability		SRP counts	
	♂	♀	Lac+	-		
1	-	-	28,29	60,38	27	27
2	M/10000	-	49	78	20	15
3	5000	-	32	85	7	8
4	2000	-	30	71	0	0
5	200	-	2	104	0	0
6	-	10000	107	84	25	60sm.
7	-	5000	30	62	47	23
8	-	2000	36	52	38	37
9	-	200	53	1	0	0
10	2000P	-	43	68	102	55
11	-	2000P	22	71	50 sm	23

(A few SRP counts were slightly distorted by smearing)

These counts reflect a substantial pipetting error, but not enough to weaken the experiment.

Tubes #0-11 (P) had periodate neutralised by penassay-glycerol/prior for 5' to addition of the cells

CONCLUSIONS: M/200 periodate is toxic; M/2000 and less is not.

M/2000 periodate differentially inactivates fertility of ♂♂, with no perceptible effect on fertility of ♀♀ or viability. M/5000 has a partial inhibitory effect; M/10.000 is doubtful. Must explore possibility that mild treatment of ♀♀ enhances fertility; try especially neutralised M/2000 or M/10000. This might be explained if there is a phase of periodate treatment with slows the separation of the pairs.

Also need a more careful study now of effects on interruption and on speed of effects.

Periodate and other oxidant effect on Hfs. Regeneration of receptors

1421 D

5 June 1958 RE 1421

As 1421A. — Pretreatments of W3060.

Incubate at 37 C unless otherwise stated

20x cells diluted .1 + .4 ml into treatments, Neutralize by pronase - glyc 10 m. 5 m.

Mate + Equal volume W3060 / 15 min., dilute 1:200 and plate .05 ml. (3B 1:1000)

				Counts	
Periodate	M/2000	37	10m.	~~46~~	0
"	"	at 0°C.	10m.	0	4
"	M/200	37°	5 m.	43	43 : [19, 37, ~45] should be 1/5
"	M/2000	37°	5 m.	~~83~~	2
Ferricyanide	M/10000	37	5m.		36
	M/1000		10		24
	M/100	"			22
Dichromate	M/10000				15
	1,000			~~20~~	
	100	"			2
Bubble oxygen		37	10 m.		2
		37	30 m.		4
		0°	30 m.		9

(.1 ml 20x oxalate + 2 ml D(m) — these 2.5 ml pronase equiv. to 1 ml in other.)

Regeneration: Use samples of ① after neutralization.

This is now at .1/5 = 1/50 x 20x = .4x (i.e. .4 of saturating concentration).

Dilute further 1:10 in pronase. F(t) take 0.2 ml + .75 ml of 1x Bg, incubate 12 m. (test titration) dilute dilute 1:10 + plate

0 minutes — postpone.

Control counts not very satisfactory and no control on plate count titration.

Conclude: periodate effect complete; incomplete at 0° and < 10 minutes.

Ferricyanide has no effect on fertility at M/100. (tests for viability!) (May generate a useful indicator). Dichromate effective only at M/100! (presumably viability).

Bubbling oxygen for 10 minutes reduces F phenocopy! Should also be regenerated.

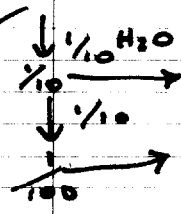
19 June 13, 1958. REF: 1423 B

POURED AGAR AS A MEANS OF DELAYING INTERRUPTION AND AVOIDING PLATE RECOMB.

ORC W3870, W3064, Spun, resusp in chilled water 20x. ♀ Susp. had to be blended because of coarse agglutination.

0': plate recombination. 0.1 ml ♂ + 0.1 ml ♀ + 4 ml broth, in ice bath → .05 plated on DSMB$_1$, surface and poured agar.



incubated in waterbath and* sampled at:

13', 40', 120', 240'.

0.1 ml samples diluted 1/100 in chilled water and a fraction blended. Unblended and blended fractions plated, .05 in DSMB$_1$, on surface and poured.

	Spread	Pour	B spr.	B pour
13	0 0	(14) (11)	1 0	0 0
40	41 49	40, 60	40 49	40 35
120	104		(115)	
240	223		223 (sic)	

Spread equivalent to blend!

	Spread	Complete	
	(196, 212)	~~292~~	44, 64
0 1/10	1, 0	0, 1	
0 1/100	1, 0	0, 0	

∴ pour plating gives some diminution in plate recombinants (possibly convergent) but not breaking up nonspecific agglutinations) but not a great deal. This is not a serious problem with these particular crosses. (of 1/100 dilutions of 13' stk)

Note linear increase of recombinants per ml

Further dilution of Sp. (Blend) Sp. (Blend) Pour Pour

			216	27/Σ						
	240	P	237	16/94	.17	14/16		28/79		
			256							

Conclusions: the 4 treatments (blend or not) · (pour vs. surface) are concordant for SRP and Cal ratio except:

① : SRP, pour, unblended is consistently ≧, esp at 120 minutes.

② The Cal ratio of this class at 13' is exceptionally high

③ at 13' only this class shows a SRP – others presumably interrupted very nearly at "first entry" of Ta++.

④ Plate recombinants show Cal ratio about equal to 120' and << 240'

⑤ Plate recombination is negligible at $\frac{1}{10}$ and $\frac{1}{100}$ dilutions ($\frac{1}{100}$ was expt'l plating dilution)

⑥ Non-visible effect of plating on increasing the Cal ratio, e.g. at 40' or at 0'. ∴ no evidence of prolonged entry

⑦ High (expected) prevalence of Lac+ among Cal+ crossed class of alternate interr

The following were also n.p. tested for Mal, Xyl, Mtl^{-} and were all $^{-}$ $^{-}$ $^{+}$ ...

Psmic:	#tested
0	18
40	1
120	3
120B	5
240	20
240	8
240B	32

These markers are very low (>0?) even with prolonged entry, under conditions of SP selection.

unclustered = plate records.

Σ = replica test of surface plates to B Cal B, Sm. Others individually streaked to B Cal. From these, only Cal+ tested for Lac. Replica test better for Lac.

For further study:

reality of: (1) High Cal compared to 13' pour plate compared to 0'
(2) continued increase of Cal+ (reduction?)
(3) true function of Lac ratio among Cal+. 0S and 240S both have
(4) other markers, especially 0 and 240. a rather lower Lac ratio than, say, 240P.

parents ORC prepassage, 20× shell of .1 + .1 + 4 ml. dispense 1 ml to each of 4 tubes. Time by transfer 0° → 37° → 0° (1 hr at each temp.: 0', 10', 20', 30'. 0' is undiluted (plate use.) 10-20-30 dilute 1:100 and plate .05 ml on H Cal B, 5mm (as on hand).

\+ > 10 ++ ~ 100 Recombinants as rather small papillae in most cases.

#11,0 #16 and #7 appear most promising on this screening: note that both show a considerable decrease after 10 minutes. This might be due to the segregation of H⁻ in absence of methionine. Spreading and elimination of late recombinants may have been important in this crude screening trial.

Purpose: for mapping Cal it would be best to have an Hfr that shows early entry of Cal. W3991 gives very weak Cal⁺. Try W3119

Note - Cattus says W2945 (Hfr 6) is high on all Cal × except Cal 3 !

? Does Hfr go to Gal end? Any markers very late? TL entry is at about 60 minutes! (Could test chloramphenicol hive smigby by SRP count if desired) Gal ratio at this time must be very low, or 0.

Note: use of D(0) may have reduced yields.

notes send ✓ Phrases Thermofax 1-2. June 30 1958

1401-2 Best pulse for T, L, V, Lac. Good test of interruptors.

-3 P^+ selection; also delay in T, L. ?Different F^- different patterns. These were one-hour cultures! Cannot be ascribed to non-freshness. [discussion of Ag^+ in temperature equilibrium and initiation of male fertility

-4 Compared 3052 v. 3064 as F^-: no difference in time. Separately and a differential (ara, $^-$) marker test

-5 Hfr_1 v. Hfr_2 x W3052. Preliminary. P-I-T comparisons. But the 15' time for Hfr_1 was irregular + rejected. t(T)=5' t(L)=7' t(P)=12-13'. Leucine-sensitivity?

-6 Repetition.

1402- Pulsing

1. Various concentrations of cells. Reducing "0" is predilution. Unselected markers dilution and incubation does not interrupt at 1:100 dilution, mating was only 10^{-1} less. No emphasis with product.

2. Try to concentrate above "standard". Some increase noted but not product. 10x conc. → 4x recombinants.

5/14 3. Pulse in various media (various cultures). Buffers, penassay, predilution controls .... (many experiments were not properly controlled.) Hfr_1: very few recombinants – expt. n.g. Pulsing gave lower yields. Overcast conditions are inhibitory. Cells were conc'd into penassay and resp'd. Too high conc. (?) makes this a poor test of optimum medium.

5/21 4. Repeat, keeping cells cold. Compared penassay BBA (buffer, glucose, asparagine) and ~~Hfr~~ etc. No great difference. But too many recombinants were observed even at 10^{-4} dilution for accurate pulsing. Clarification of ABCDE on record. No difference possible for BBA. penassay failure at 10^{-4}!

1402-5 Attempted repetition of pulse for step of Tc^+. But 5x increase of X^+ 20'-60'! Was under misconception of pulse in 140(2-F1.) 140(2-F1 may have been pulsed by saturation.

5/29. -6. Trial improvement by using BFA for entry after necessary mating. No evident effect on step 20'-40'.

1403- 1 Manipulations. $Hfr \rightarrow F^+$ N.C.

2 See protocol

3 How to plate s/ interruptions. See also 1423B

4 Do strains vary in stability to plating? See 1410-1. ~~Thanks~~

1404 F^+. Hfr. F^- Test for cross infection of F^- progeny on plates. So far mechanisms a/c too low for stability of F^+ and poor design of F testing.

1405 Protoplasts ♂ and ♀

1. Interruption by lysis of ♂ protoplasts. Preliminary
2. 4 combinations of (♂ ♀)(P. B). $Hfr \rightarrow F^+$ n.g.

4.14. 3 Repeat 1. Best experiment! Do protoplasts show delay in Cal (and Lac) or spontaneous interruptions and lysis before Cal? Cal remained 0 to 60' See 1405-6

4/11 4. protoplast × protoplast. Based on auxotrophy of W3060. An interesting result: crosses on sucrose B, gave very high male medians (poor conditions of selection). Worry again about nutrition of W3060.

1405-5. Protoplast crosses. Repeat 1405-4. High residual viability. Still selecting on sucrose B$_1$. No conclusions

4.19.58 -6 Repeat -3. Effect of incubating shocked suspensions. No effect on enlarged scale. Good for interruption by lysis

-7 Osmotic shocks on rods. No interruptions of rods e.g. (rods only).

-8 repeat -4

1406. +/B1 Conditions of mating: age of cells.

4.16. No difference between fresh and old (3 yield; not obvious for timing either.

1407 EML Transfer of Hp$^+$

1408 -1 EML JL. Cal timing. -1 washout.

-2 Showed linkage of try - gal. (because know of Hfr - try linkage).

3 Various Hfr's — intensity of linkage of Cal - try.

4 Cal timing. Hfr$_2$ Preliminary only.

5 Hfr$_2$. Close timing. Discarded a/c contamination

6 Hfr$_{4,13}$. Preliminary. Try enters at 15'

7 Hfr$_{13}$ More accurate. " " " 13'. Exponential kinetics

8 Hfr$_2$ Try - Cal mapping. ? Two modes of entry.

9 Early rise, later more rapid.

10 Hfr$_2$ Cal$_2$. See disc. of two modes of entry.

11 Hfr$_1$: Cal timing. Very late entry.

12. Repeat: no effect

1408-13 Hfr 2 – compare two Cals. Low numbers: F+ rev. Cal 2 < Cal 1.

..... Current Caltimings in EML hands

-20 No evidence of early slow rise in titre. Probably was due to growth of plate recomb.

1409-1 Enzymes on protoplasts.

-2 " " mating. (?? slight effect of lysozyme).

1410 – Diploids send interpretative summary when ready.

1411 – Colchicine no effect.

1412 – Freezing. Parents OK.
Need to summarize and compare B1-B2.

1413-1 Reblending — differential F⁻
See record. Plate Rec. probably occt. for the protoplasts seen.
But unselected markers showed interruption.

-2 Two stage transfer.

-3 Exhaust males by excess F⁻? (to use them for 2' stage transfer to a new batch.) Required 20' to exhaust, which is too long to use most convenient available markers

-4 Increase recruitment s/entry. Temperature. 37° optimal. zero rate at 0°.

-5 } Crosses were altogether – N.C. W3060 → F+.

-6 } N.C. " " "

-7 Check selection for Lac+ S^R; Gal+ S^R on W2323 Blackson. Rather few!

-8. Test for suppression. (Reconstruction).

-9 Repeat -1. No reblend recombinants.

-10 Repeat 2. Two stage transfer. Negative.

1415 – Need to evaluate notes Azide

General conclusion: no differential effect.

No definite verification of reversible inhibition.

–3 concentration too low, no effect. Azide .2% in Difco gelatole

–4 necessary conc. to inhibit. Some effect at 10^{-4} – 10^{-3}. Still no prevention of F^+ entry. Cal excluded. (slow action?)

–5 Azide + DNP – 3% inhibits mating. DNP – M/200. maybe reversible (no evidence new recruitment).

–6 R x S; S x R. Inconclusive. Graded effect. Counts too high in controls

–7 Differential concentration lost on F^-. Stratified fertility of crosses!

– Nothing mean Azide-resistance!

DNP^R — See record. – low degree of resistance. .2–.5 ml/2 cm loop of M/20 DNP see 1419.

1416 – DNA leakage. – some leakage in every case.

240–260 mμ difference.

1417 – Timing of Hfr_1. TL: ~20'

–2 TL ~<20' Th very late ~ 60' Cf 1401–5. Thr 35–40'. In Progress

–3 (JZ) – Time entry of Mal, Xyl...; effect of chloramphenicol

1418 – DNA → F^+ mating with F^- prototrophs.

1419 – DNP-resistance

1420 – Pulsation.

–B – periodate "pulse" } e.g. $Hfr \rightarrow F^+$

–C " " }

–D. Effect of F^- cells. (High density!) Apparent interruptions

–E " " (lower density). Confused?? Cells does not interrupt, pipetting control does!

- E. Cal counted on Stalson B's. Good internal consistency - Luca repeat!

1421 - Periodate I.S.

C - will be finished by I.S. Collate protocols
- treatment of F^+; and effect on F infection etc. - look to plates

D. - Other oxidants. Rather low yields

E. - RDE. No Ca^{++} used see 1422
RDE may still be open question. Not yet used Eric Frank's.

F. -

1422. RDE + Ca^{++} No yields: inconclusive

1423 Delay interruption c/ chloramphenicol.
A. 50r/ml. Maybe bactericidal; no prolifération. No evidence of any effect on Cal and Lac entry. Part II OK.
B. Over plating to delay interruption. No interruptions; no prolongation

1424

Yudkin's E. coli: to make protoplasts L2, double strength; 300 - 1000 u/ml pc.
Burst more readily. (to prepare DNA from W3514 S^R).
→ W___.

See 1410 deploids for bulk of experiments of May - June 1958. Then 1426 1427.

U.W. MICROBIAL GENETICS

Analysis of Gal$^+$ × Gal$^-$ diploid

Relationship of two modes of segregation

Segregation of 1410F48.

[1410C] [1426 ←]

1 July 1958

REF: 1410C1T(1-7)

7 Gal$^+$ heterogenotes have been isolated from 1410C1. Label these, 1426 A-G. Each derives from an Ara^v colony picked to D(Ara B,) and retrospectively verified as Gal$^+$. From the same streaks, Gal$^-$ were picked to EMB ara to verify (qualitatively) independence of Gal and Ara segregation. Results: (of Gal$^-$ tested)

B 5/5 ara$^-$ . . Ara^v Gal$^{t\,v}$ → Ara^v Gal^{t-}

C 4/6 → Ara$^-$ Gal^{t-}

D 3/6

E 1/3

F 5/9.

Ara$^-$ Gal$^{t\,v}$ presumed from consequences of earlier streaking.

The new labels (1426 (A-G)) now refer to the D(ara) broths mentioned above. all are still Gal$^+$ Ara^v

1 July: plate out A and B on Bara.

2 July: Streak out individual Ara^v on Bara for examination of single, discrete segments.

Pick 4 groups of 4 ara$^-$ from each ara^v streak out → Bgal. (see next page (1 July))

also from first plating, ara$^-$ pick to Bgal and Blac.

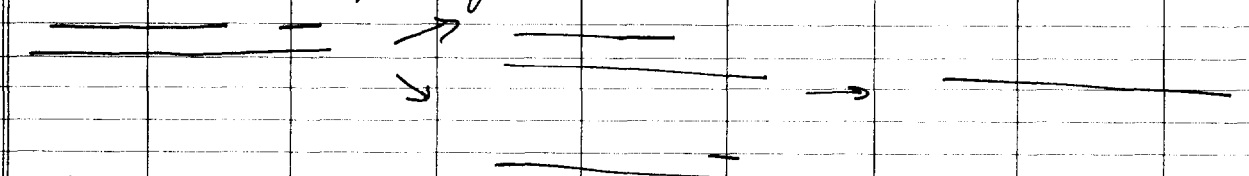
	G	L		G	L		G	L
A 1	+	−	B	−	−	8 B	+	−
2	+	−		+	+	9	−	−
3	+	−		+	−	10	−	−
4	+	−		+	v	11	−	−
5	+	v → lac^v Ara^v		+	−	12	−	−
6	+	−		+	−	13	+	v → lac$^+$ ara$^-$
7	+	v → lac$^-$ ara^v		+	−	14	+	v → lac^v Ara^v

? - partials for purity.

Three most Ara$^-$ lines are lac$^-$

Ara^v are these lac^v rarely ara$^-$? On streak out, 1 was ara$^-$ lac$^+$ 3 were ara^v lac^v and had been simply misjudged as ara$^-$. There may be some position effect as some Ara^v have microscopic central spots.

Conclusions (two pp.) Segregation of heterozygote + segregate occur independently, as if



Data are not sufficient to establish statistical independence. Among Ara$^-$ incidence of Gal$^-$ was 3/144 and 12/184 respectively in segregations of single Ara^v colonies. No data for the Ara^v pairs in same colonies. Much higher incidence of Gal$^-$ Ara^v in several both segregations (2/13; 13/32). Defer this problem to a more suitable marked diploid + subtract a Gal$^-$ hemi 2340 etc!

analysis of a heterogenotic heterozygote:

$\frac{\text{ara}^{TLP}}{\text{Gal}_2\ S}$ / $\frac{+}{+}$

U.W. MICROBIAL GENETICS

1426.

July 4 1958. REF:

Analysis of A and B. Is there linkage of the Gal factors to lac or ara?

A. 13 Ara^V / B. 32 Ara^V Stock cultures were plated on B ara. Single ara^V were streaked out on B Ara, and 4 ara^- isolates picked from each streak out to B Gal, together with mass bunch.

A: 2/13 ara^V were pure Gal^- (already segregated). Of the other 11, there was one $3^+:1^-$ and one $2^+:2^-$ split among the 4-sets of ara^-. ∴ Total incidence of Gal^- among Ara^- (recently derived from Ara^V) was 3/44.

B. 11/32 ara^V were pure Gal^-. Where 4-set derived from $ara^V Gal^+$ (21 sets), the following splits:

$4^+ 0^-$	$3^+ 1^-$	$2^+ 2^-$	$1^+ 3^-$	$0^+ 4^-$
10	10	1	0	0

and total incidence of $^-$ here is 12/84. This suggests that B is somewhat less stable a heterogenote than A (or that A gives significant Gal^+ segregants) but needs this may be selection. It is evident that $Ara^V Gal^V$ $\overset{V-}{\nearrow}\searrow$ $\searrow\nearrow$ $\overset{-+}{\longrightarrow}$ — at least qualitatively, independently. Replica plate to lac to determine if there is any linkage of Gal^+ to lac (viz. interaction in segregation when both have segregated. This tells little about linkage of the exogenote to Gal since all viable cells presumably have the same Gal factor.

Replica plate to EMB Lac. A

Gal^-: 24-sets pure Gal^- are pure lac^-; $Gal^- ara^V$ is $lac^\pm$

Each Gal^-: 3 all lac^- $Gal^+ ara^-$: All but 3 are also lac^-. These 3 are $(Ara^- Lac^+ Gal^+)$ two from a 2:2 split; 1 from a 1:3. ∴ The A-sets are

2 $Ara^V Gal^- Lac^\pm$: 4 sets $Ara^- Gal^- Lac^-$

1 $Ara^V Gal^V Lac^V$: 3 $Ara^- Gal^+ Lac^-$: 1 $Ara^- Gal^+ Lac^+$

1 " : 2 $Ara^- Gal^+ Lac^-$: 2 $Ara^- Gal^+ Lac^+$

7 $Ara^V Gal^V Lac^V$: 4 $Ara^- Gal^+ Lac^-$: 0 ——

(over)

B sets: all but 1 4-set are pure lac⁻ This one has following elements
(Gal⁺ara⁺lac⁺); 1 ara⁻gal⁻lac⁻; 1 ara⁻gal⁺lac⁻; 2 ara⁻gal⁺lac⁺
see below. one of these is ara⁺!

∴ again almost all ara⁻ are lac⁻.

These diploids are not optimal to study segregation in any more detail; wait for development of more suitable markers (V_1; V_6; AZ) But it might be worthwhile saving a set of sibling lac⁺ and lac⁻, ara⁻ for typing for ara. Spot these on B ara.

∴ lac ratio among ara⁻ (among all abscissates from ara⁺ colonies)

is	corrected (see below)
A) 3⁺/41⁻	~~2⁺/44⁻~~ 2⁺/41⁻
B) 2⁺/128⁻	1⁺/126⁻

→ But on recheck, The 4-set from A was ara⁺lac⁺: ara⁻lac⁺ (1); 2 ara⁻lac⁻ (2, 3)
B: ara⁻lac⁺ (1); ara⁺lac⁺ (2); ara⁻lac⁻gal⁺ (3); ara⁻lac⁻gal⁻

See 1410K for typing:
The two lac⁺ are ara_3^-
The four lac⁻ are ara_2^-.
This further confirms the structure of this diploid $\frac{ara_2^- lac^-}{ara_3^- lac^+}$.
no special bearing on Gal.

1410 X
2 July 58

Plans for further diploids:

1. additional markers should be segregating: V_1, V_6 and perhaps Az. Possibly leave P free to segregate? These will help rapid screening of heterozygosity.
2. Include possibility of selecting for Gal^V? (Introduce Gal^- into a parent).
3. Time more precisely: perhaps pulse. Measure bac and Gal concurrently
4. Select some Hfr diploids? (Maynard B, $^+$ isolate!) — should cross to get me!

5. Set up for Ara ristin preliminaries
6. Effect of streptomycin in disturbing appearance of Gal ek.?

Plans for present diploids:

11 ~~#~~. Reexamine 2 stated pure bac^+, say F26 and F31.
Reexamine the 2 $Gal^+ bac^V$ F5, F12 | G10, 3, 13
Examine zygosity of Gal, then bac in C2, F21, F22, F23, 27, 28, 30; G1, 2, 8, 21, 24 * *
Defer linkage + segregation studies. Complete F37, 38. Trace F30

12. Get an $Ara^- bac^V Gal^-$ autoinict to use as F^- for secondary nondisjunction: Or use $Ara^V bac^-$, selecting bac^+? This is messy with Gal^-, and bac not balanced. In any case, polarity of bac^+ would encourage formation of bac^+ prototrophs.

13. Other Ara tests? What to save from 1410H?

14 In C, examine for bp^h.

Also H plans.

* to D (and B,)!

JULY 20, 1958. terminal notes for resumption of work in the fall

It is now clear that Hfr_2 crosses tend to give both Lac^v and Lac^- hemizygotes. It is probably not profitable to attempt to categorize more of the Lac^- from the 1410 series; it may be worthwhile doing a time sequence experiment for the production of diploids, though it is reasonably clear that the occurrence of Lac^+ is related to the production of Lac^v, while the Lac^- are hemizygous, in supp ort of the progressive entry hypothesis. But the nonoccurrence of Gal^v (compared to Gal^+ is enigmatic, and probably some more Gal^v or $^+$ should be looked for

However, in orddr to distinguish Gal^+ hemizgous from homozygous, it will be necessayy to use complementary Gal mutants, allowing either Gal^1 or Gal^0 to be analysed by reversion. This will also afford the opportunity of using Gal/Gal selection for Gal heterozygosity.

Therefore the main programs are:.

1. Time sequence on heterozygote isolations, to complete that picture. Include segregation of Az, V1 and V6 as now available.
2. Gal x Gal selections of diploids a) are there any Galv; b)Ara2,4 pos.eff.

3. Complementary to 2: crosses of diploid x haploid

4. Nay be worthwhile to look for automictic derivatives of Lac^v diploids as a Lac^- homozygotes would probably be a preferable ^{0}.

5. Time exogenote entry in crosses of Hfr heterogenotes.

Probably first item will be the review the accumulated Gal^- stocks for identity and complementarity to Gal_2.

Dec. 16 19 58 REF:

From Ara plates

Plate 1:	2-34	#33	lgt	1-3	, dark 4-6 , pap 7-8
	2-34	#37	lgt	1-5	, dark 6-10
Plate 2	3-16	#9	lgt	1-5	, dark 6-10
	4-1	#13	lgt	1-5	, dark 6-10
Plate 3	4-1	#16	small	1-4	large 5-10
	4-1	#35	lgt	1-4	, dark 5-8 , v 9-10
Plate 4	4-6	#31	lgt	1-4	, dark 5-8 , pap 9-10
	5-20	#21	lgt	1-4	dark 5-6
Plate 5	5-20	#26	lgt	1-4	dark 5-8
	5-20	#41	lgt	1-4	, dark 5-9

Since some "single" colony isolates gave ambiguous results in Ara typing (see 50 M), they were restreaked from little penassay on B Ara. They manifested colonial differences, (see below), so representative types were retested for Lac and Ara types.

On B Ara (2 days)

2-34	#33	mostly orange -, few light -, 2 sl. pap.
	#37	as above
3-16	#9	as above
4-1	#13	as above
	#16	no good color dif; few small col, mostly larger
	#35	more light than orange, few v?
4-6	#31	mostly orange, some light, some pap (large center area)
5-20	#21	mostly lgt, very few dark
	#26	mostly orange, few lgt
	#41	mostly lgt, few dark ?

Reversions and arrangements in 5-57.

19 REF:

Sing. col. of Lac Reversions of (5-57) were streaked on B Lac, B Ara

	B Lac	B Ara
5-57-1 light Lac Rev a	+	−
b	+, −, V	− but "segregating"
c	+	−
5-57-2 dark Lac Rev a	+ but "segregating"	+, −, V
b	+	−
c	+ but "segregating"	+, −, V
d	+	+, −, V

5-57 is Lac⁻ Ara^V, Gal⁻, which yields on Lac heavily mottled

of Lac^V → Lac⁺: (1) Ara^V pure Lac^V (mostly Lac⁺ & Lac⁻ sectors) but better

(2) Ara^V (Ara⁺ & Ara⁻ sectors), Lac⁺ mottled.

Ara^V Lac⁻ Gal⁻ —select Lac⁺→ Ara⁻ Lac^V Gal⁻ — confirmation mystery!

→ Ara^V Lac⁺ Gal⁻ — Lac is sectors Lac⁺/Lac± no Lac⁻

Expt 50 P = V from 5-57-1b and 5-57-2a on Gal, Lac, Ara
from Lac and from Ara

Restored Ara^V: two types found.

Ara^V Lac⁻^V (light on BAra).

Ara^V Lac^V (+/−)
