# Declines in Teenage Birth Rates, 1991-97: National and State Patterns 

by Stephanie J. Ventura, M.A.; T. J. Mathews, M.S.; and Sally C. Curtin, M.A., Division of Vital Statistics

#### Abstract

This report presents data on the numbers of teenage births and teenage birth rates for the United States for the period 1950-97 and State-specific birth rates for teenagers for 1991-96. After increasing sharply in the late 1980's, birth rates declined for American teenagers from 1991 through 1997. Rates fell overall by 16 percent for teenagers 15-17 years and by 11 percent for teenagers 18-19 years. Declines were reported for all race and ethnic origin groups, with the largest declines found for black teenagers, especially those aged 15-17 years.

Particularly noteworthy has been the 21-percent decline in the rate of second births for teenagers who have had one child. Rates have fallen for first births as well, but the reductions are more modest, about 6 percent. Teenage mothers and their babies continue to be at greater risk of adverse health consequences compared with older mothers, including higher rates of preterm birth and low birthweight.

While teenage birth rates vary considerably by State, rates fell in all States in the 1990's with nearly all declines statistically significant. Rates for black and non-Hispanic white teenagers dropped in most States from 1991 to 1996. Birth rate trends for Hispanic teenagers by State were not consistent. The proportion of second and higher order births among all teenage births declined substantially in most States. Data are from the National Center for Health Statistics' (NCHS) National Vital Statistics System.

Keywords: teenage fertility • State-specific birth rates • fertility trends • teenage pregnancy

## Acknowledgments

This report was prepared in the Division of Vital Statistics (DVS). The authors appreciate the helpful comments of Kenneth G. Keppel, Acting Branch Chief, Reproductive Statistics Branch, DVS. This report was edited by Demarius V. Miller, typeset by Jacqueline M. Davis, and graphics produced by Jarmila Ogburn of the Publications Branch, Division of Data Services.

Figure 1. Birth rates for teenagers by age: United States, 1950-97

## Teenage birth rate down 15 percent since 1991; rates still higher than in early 1980's

The birth rate for U.S. teenagers in 1997 was 52.9 live births per 1,000 women aged 15-19 years, 3 percent lower than in 1996, and 15 percent lower than in 1991 (table 1 and figure 1). The rate of 62.1 reported for 1991 was the highest level recorded in 20 years ( 64.5 in 1971). While the teenage birth rate has fallen steadily in the 1990's, the rate in 1997 remains higher than the rates in the mid-1980's, when they were at their lowest point ever ( 50 to 51 per 1,000).

The teenage birth rate declined fairly steadily from the late 1950's to the mid-1980's. Rates in the late 1950's were the highest ever recorded with the peak rate reported in 1957, at 96.3 births per 1,000. After reaching a low point in the mid-1980's, the teenage birth rate climbed steeply, with an overall increase of 24 percent between 1986 ( 50.2 per 1,000) and 1991 (62.1). The current downward trend represents a reversal of that increase.

While several measures are appropriate for examining patterns of teenage childbearing, the most useful measure is the birth rate, defined as the number of live births per 1,000 teenagers. This measure enables us to compare levels and trends in teenage childbearing among different population groups and over time for the same group, because all rates are computed on the basis of 1,000 women. For example, the birth rate for teenagers 15-17 years in 1997 was 32.6 births per 1,000 women aged 15-17 years. That rate was 38.7 in 1991. The rate for this age group has dropped 16 percent from 1991 to 1997 (table A). The number of births indicates how many teenagers gave birth in a given year. It is affected by the birth rate for a given age group (that is, the proportion of teenagers giving birth) and the number of females of that age. Looking again at teenagers 15-17 years, the number of births in 1997 was 183,324 , compared with 188,226 in 1991, a modest reduction of about 3 percent. The number of births did not fall as much as the birth rate because the number of female teenagers in the population increased 16 percent from 1991 to 1997 (1).

## Unmarried births are larger proportion of all teenage births as teenagers now less likely to marry

Teenagers have never married in large numbers; however, the proportion who are married now is at a record low. In 1970 about

10 percent of female teenagers were married; a quarter century later, this proportion fell to less than 5 percent $(2,3)$. Since 1970 the birth rate for married teenagers declined more than 20 percent (from 443.7 per 1,000 married women aged 15-19 years in 1970 to 344.3 in 1996). At the same time the birth rate for unmarried teenagers doubled, with most of the increase coming in the 1980's. The rate rose from 22.4 per 1,000 in 1970 to 46.4 in 1994, and has since declined 8 percent (42.9 in 1996). Because of these changes in marriage patterns among teenagers and birth rates for unmarried and married teenagers, the proportion of teenage births occurring to unmarried women has risen steeply (figure 2). For example, among teenage mothers 15-17 years, the proportion unmarried more than doubled, from 43 percent in 1970 to 87 percent in 1997. Similarly, among teenage mothers 18-19 years, the proportion unmarried more than tripled from 22 percent in 1970 to 72 percent in 1997.

These major changes in marriage and marital and nonmarital birth rates are not unique to teenagers. In fact, relatively fewer women in all age groups are married nowadays, and birth rates have increased sharply for unmarried women in all age groups. As a consequence, while most births to teenagers are nonmarital, teenagers do not account for the majority of all births to unmarried women. As recently as 1975, more than half of all births to unmarried women were to teenagers; by 1997, the proportion under age 20 was only 31 percent.

## Teenage birth and pregnancy rates fall

In order to examine trends in pregnancies among teenagers, data on live births must be combined with data on induced abortions and fetal losses. Because information on abortion and fetal loss is not as current as information on live births, this report focuses on trends and variations in live births and live birth rates. However, recent abortion data indicate that the current decline in teenage birth rates has been accompanied by declines in abortion rates as well $(4,5)$; thus teenage pregnancy rates have fallen in the 1990's. According to the most recent complete estimates, the teenage pregnancy rate declined 12 percent from 1991 to 1995. The pregnancy rate for 1995 was 103 pregnancies per 1,000 women aged 15-19 years, nearly twice the birth rate in that year (56.8). In 1976 these rates were 101 (pregnancy) and 53 (live birth) (6).

[Birth rates per 1,000 women in specified age group]

[^0]

Figure 2. Percent of births to unmarried teenagers by age: United States, 1950-97

## Birth rates decline for teenagers in all age groups

The live birth rate for the youngest teenagers, 10-14 years, fell to 1.2 per 1,000 in 1997 (table 2). This rate declined from 1.4 in 1990-94 to 1.3 in 1995 and 1.2 in 1996-97. Concurrent with the decline in the birth rate, the number of births to this age group has fallen as well, dropping from an average of 12,000-13,000 per year in 1991-95, to under 11,000 in 1997 (table A).

The birth rate for teenagers 15-17 years fell 4 percent between 1996 and 1997 to 32.6 per 1,000. Overall, this rate fell 16 percent from 1991 (38.7) to 1997. Sixty percent of the decline occurred from 1995 to 1997. The long-term trend for this age group has not been as steady as for older teenagers (figure 1). The rate generally declined from the early 1970's to the mid-1980's, before climbing 27 percent from 1986 to 1991, and then declining to its current level. The number of births to teenagers 15-17 years totaled 183,324 in 1997. This number did not begin to decline steadily until after $1994(195,169)$. The decline in the number of births is smaller than the decline in the birth rate because, as noted earlier, the number of female teenagers in the population has increased by 16 percent, since 1991.

The birth rate for teenagers 18-19 years declined 2 percent from 1996 to 1997 to 84.4 per 1,000. This rate fell 11 percent from 1991 to 1997. The birth rate for 18-19-year-olds declined rapidly from 1960 ( 166.7 per 1,000 ) to the late 1970's, where it stabilized at about 80 per

1,000, less than half the 1960 rate. Beginning in the late 1980's, this rate began to increase, rising 20 percent during 1987-92, and then falling again. The number of births to teenagers 18-19 years was 305,886 in 1997, about the same as in $1996(305,856)$. This number declined from $1990(338,499)$.

The number of births to teenagers, like the teenage birth rate, was substantially higher several decades ago than now. The peak number of births was reported in 1970, with 644,708 babies born to women aged 15-19 years. The 1970 total is nearly a third higher than in 1997.

## Despite declines, black and Hispanic teenage birth rates are still high

Birth rates have dropped sharply for black teenagers (by 23 percent) from 115.5 per 1,000 aged 15-19 years in 1991 to 89.5 in 1997. The rate for Hispanic teenagers has declined since 1994, by 8 percent. Birth rates for black and Hispanic teenagers continue to be substantially higher than for other racial groups (table 2 and figure 3 ). All race and Hispanic origin groups have experienced declines in teenage birth rates in the 1990's. Declines for non-Hispanic white and American Indian teenagers were 16 percent each to 36.4 and 71.8 per 1,000 , respectively. The rate for Asian or Pacific Islander teenagers, already the lowest of all, declined 10 percent since 1991-to 24.8 per 1,000.

In general, rates fell more for younger than for older teenagers. The largest reduction of all was the rate for black teenagers 15-17 years,

Figure 3. Birth rate for teenagers $15-19$ by race and Hispanic origin: United States, 1980-97
dropping 26 percent from 84.1 to 62.3. Rates by age for Hispanic and Asian or Pacific Islander teenagers declined more for older than for younger women. Beginning in 1994, Hispanic teenagers had higher birth rates than any other group (figure 3).

## Fewer teenagers have their first baby

Birth rates for teenagers can also be calculated for teenagers who have not had a live birth and for teenagers with a previous live birth. The birth rate for teenagers who have not had a live birth describes the proportion of teenagers who give birth for the first time. More commonly, first birth rates are computed by relating first births to all women in a given age group, regardless of whether or not they have had any children. The rate for childless women enables us to measure precisely changes in first time childbearing among teenagers who have not yet had a child. It is thus a refinement of the first birth rate. For teenagers, the differences between the first birth rate and the birth rate for childless teenagers are relatively small and the trends are fairly similar, because most teenagers have not had any children. For example, the first birth rate for teenagers 15-19 years declined from 46.5 in 1991 to 42.5 in 1996, a reduction of 9 percent. The birth rate for childless teenagers declined from 49.6 in 1991 to 46.7 in 1996, a reduction of 6 percent.

Birth rates for teenagers who have not had a live birth increase sharply with age, as would be expected. The rate for childless teenagers 15 years was 17.1 per 1,000 in 1996, compared with a rate of 77.4 for childless teenagers 19 years (table 3). Unlike the overall teenage birth rate which has fallen steadily since 1991, the rate for childless teenagers did not begin to fall consistently until after 1994.

## Even fewer teenagers have second child

In contrast to the modest declines in birth rates for teenagers who have not had a live birth, repeat childbearing, that is, the rate of second births to teenagers who have already had one child has fallen substantially since 1991. Repeat births are of particular concern; a teenager with two or more children is at greater risk for a host of difficulties (7). The rate of second order births to teenagers who have had one child dropped 21 percent to 174 per 1,000 aged 15-19 years in 1996, from 221 per 1,000 in 1991. To put it another way, 17 percent of teenagers who have had one child gave birth to a second child in 1996, compared with 22 percent in 1991. Rates fell for teenagers at each age 16 through 19 years, with the reductions much steeper for the youngest teenagers (table 3 and figure 4). (The most recent year for which birth rates can be computed according to the number of previous births to the mother is 1996.)

Twenty-two percent of teenage births were second and higher order births in 1997, compared with 25 percent in 1991. Despite the reduction in repeat childbearing, over 100,000 teenagers gave birth to their second or higher order child in 1997.

The proportion of repeat births for young teenagers 15-17 years fell 20 percent from 1991 to 1997, from 15 to 12 percent; for young black teenagers, the proportion fell by 27 percent, from 22 percent to 16 percent. The proportion of second and higher order births for older teenagers 18-19 years declined 10 percent (from 31 to 28 percent); again, the proportion fell more for black teenagers, by 14 percent (from 42 to 36 percent).

Figure 4. Rate of second births to teenagers who have had a first birth, 1985-96

## Teenage childbearing has serious health consequences

Teenage mothers and their babies are at greater risk of adverse health consequences compared with older mothers. Most teenage mothers are not ready for the emotional, psychological, and financial responsibilities and challenges of parenthood (7). The vast majority of teenage pregnancies are unintended (8). Teenagers who become pregnant are less likely to receive timely prenatal care and more likely to begin care in the third trimester or have no care at all (figure 5). They are also more likely to smoke during pregnancy. Moreover, a recent report showed that in contrast to declines in smoking for older women, smoking has increased among pregnant teenagers in the mid-1990's, concurrent with increases reported for all teenagers $(9,10)$. As a consequence of these and other factors, infants born to teenagers are more likely to be born preterm, that is, at less than 37 completed weeks of gestation, and more likely to be low birthweight (less than 5 lb 8 oz ), and thus are at greater risk of serious and long-term illness, developmental delays, and of dying in the first year of life $(11,12)$.

## Teenage birth rates vary greatly by State

Birth rates by State vary substantially (tables 4-6 and figure 6). In 1996, the most recent year for which State-level rates can be computed, rates varied from 28.6 for New Hampshire to 75.5 for

Figure 5. Selected characteristics for teenage mothers and mothers aged 20 years and over: United States, 1996

Mississippi; the rate for the District of Columbia was 102.1. The highest rate was reported for Guam (116.8). The wide variation in rates by State reflects in part the differences in the composition of the teenage population by race and Hispanic origin. As noted earlier, rates are much higher for Hispanic and black teenagers than for nonHispanic white teenagers (table 2). Therefore, States with relatively high proportions of Hispanic and/or black teenagers would be expected to have higher overall teenage birth rates. These compositional differences should be kept in mind when comparing teenage birth rates across States (13).

## Teenage birth rates decline in all States

Birth rates for teenagers 15-19 years fell from 1991 to 1996 in all States and the District of Columbia (figure 7). Declines in all but three States (Delaware, North Dakota, and Rhode Island) were statistically significant. Rates fell as well for teenage subgroups, with statistically significant declines recorded for all but 13 States for teenagers 15-17 years and for all but 9 States for teenagers 18-19 years (table 4). (Declines for the District of Columbia and Puerto Rico for teenagers 18-19 years were not statistically significant. Rates increased in Guam.)

## Steep reductions in State-level rates for black teenagers

Echoing the reductions in national birth rates for black teenagers, rates by State declined substantially as well (table 6). Trends in the rates for black teenagers could be reliably computed for 40 States and the District of Columbia for both 1991 and 1996. Rates fell in all States except for the District of Columbia; all declines were statistically significant except for West Virginia.

Rates for non-Hispanic white teenagers declined in all States. Reductions were statistically significant in all but four States and the District of Columbia.

Statistically reliable rates for Hispanic teenagers for both 1991 and 1996 were available for 38 States. Statistically significant increases were reported for 15 States, with declines found for 10 States. These modest changes reflect the fact that birth rates for Hispanic teenagers have declined in the United States only since 1994.

## First birth rates decline and proportions of repeat births fall sharply across the country

State-specific populations of childless teenagers are not available. Therefore, first birth rates in this section are based on all teenagers 15-19 years, regardless of whether or not they have had any children. First birth rates by State in 1996 ranged from 24.9 per 1,000 aged 15-19 years in New Hampshire to 57.6 in Arkansas; the rate in the District of Columbia was 69.4 (table 7). Between 1991 and 1996, the first birth rate in the United States declined by 9 percent, from 46.5 to 42.5 per 1,000. Statistically significant declines were reported for all but 11 States. The decline in rates ranged from 4 percent (Texas) to 26 percent (Alaska). Rates increased in Puerto Rico and Guam.

Second order birth rates for teenagers "at risk," that is, for those who have had one child, cannot be computed at the State level because State-specific populations of teenagers according to the number of children they have had are not available. However, the impact of second and higher order births on all teenage births can be approximated by computing the proportion of teenage births that are second and higher order. These proportions are shown in table 7. Overall, the proportion of second and higher order births declined from 25.1 percent (1991) to 21.9 percent (1996), a drop of 13 percent. Statistically significant declines were found for all but seven States and the District of Columbia.

Figure 6. Teenage birth rates, ages 15-19, by State, 1996

Figure 7. Percent decline in teenage birth rates, ages 15-19, by State, 1991 to 1996

Declines were 20.0 percent or greater in eight States. The proportion of second and higher order births increased in Guam, but the rise was not statistically significant.

## Declines in sexual activity and increases in condom use are key factors

The declines in birth and pregnancy rates for teenagers across the country since 1991 reflect changes in a number of demographic and behavioral factors. First, three separate surveys have shown that the proportion of teenagers who are sexually experienced has stabilized and declined in the 1990's, reversing the steady increases over the past two decades. According to results from the 1995 National Survey of Family Growth (NSFG), conducted by the National Center for Health Statistics, and the National Survey of Adolescent Males (NSAM), the proportion of teenagers who are sexually experienced has fallen in the 1990's $(14,15)$. More recently, results from the Youth Risk Behavior Surveillance Survey, conducted by the Centers for Disease Control and Prevention, show that among teenagers attending school, sexual activity has declined in the 1990's through 1997 (16). Moreover, teenagers are more likely to use contraceptives at first intercourse, especially condoms. In addition, some teenagers, especially black teenagers, are using injectable and implant contraceptives (14-17). These changes in contraceptive use in particular are probably important factors in the decline in rates for second births to women who already have one child.

Teenage pregnancy has been the subject of a great deal of public interest and concern, especially since the late 1980's when rates increased rapidly. As a result, a variety of national, State, and local initiatives and strategies have been developed to reduce teenage pregnancy (18). Only a few programs have been rigorously evaluated (19) and no single approach has been identified. However, findings from the National Longitudinal Study on Adolescent Health (Add Health), a large-scale, congressionally mandated survey of students in grades 7 through 12, have suggested that enhancing the connections of teenagers to their family and home, their school, and their community is essential for protecting teenagers from a vast array of risky behaviors, including sexual activity (20).

## .- Data not available.

${ }^{1}$ Includes races other than white and black.
${ }^{2}$ Data for 1997 are preliminary; figures are based on weighted data rounded to the nearest individual, so categories may not add to total; see Technical notes.
NOTE: Figures for 1950-75 are by race of child; see reference 11.

Table 2. Birth rates for women under 20 years, by age, race, and Hispanic origin: United States, 1990-97, and percent change in rates, 1991-97

* Figure does not meet standards of reliability or precision (based on fewer than 20 births or fewer than 1,000 women in specified group).

Includes all persons of Hispanic origin of any race.
NOTES: Rates by race and Hispanic origin cannot be computed for Puerto Rico, Virgin Islands, and Guam because populations are not available by race and Hispanic origin for these areas. Birth rates shown in this table are based on population estimates provided by the U.S. Bureau of the Census and, therefore, the rates shown here may differ from rates computed on the basis of other population estimates.

## Technical notes

Data shown in this report for 1996 and earlier years are based on 100 percent of the birth certificates registered in all States and the District of Columbia. More than 99 percent of births occurring in this country are registered. Data shown for 1997 are preliminary, based on a sample file of 99 percent of births for that year (21). Tabulations by State also include Puerto Rico, the Virgin Islands, and Guam. However, totals shown for the United States do not include these areas.

Tabulations by race and Hispanic origin of mother are based on this information as reported on the birth certificate. Race and Hispanic origin are reported independently on the birth certificate. Although the overwhelming majority of Hispanic births ( 97 percent) are to white women, there are substantial differences in teenage childbearing patterns between Hispanic and non-Hispanic white women. Therefore, data are shown separately for these groups.

Population data for computing birth rates were provided by the U.S. Bureau of the Census $(1,22,23)$. Rates by State shown here may differ from rates computed on the basis of other population estimates. State rates are based on mother's place of residence. Population estimates by race and Hispanic origin are not available for Puerto Rico, Virgin Islands, and Guam.

Rates were not computed if there were fewer than 20 births in the numerator or fewer than 1,000 women in the specified group in the denominator. An asterisk is shown in place of the rate.

Data on first birth rates and birth rates for women who have not had a live birth (i.e., childless women) are included in this report. The rate for childless women enables us to measure precisely changes in first-time childbearing among teenagers who have not yet had a child. It is thus a refinement of the first birth rate, which relates first births to all teenagers, regardless of whether they have had any children. For teenagers, the differences between the first birth rate and the birth rate for childless women are relatively small and the trends are fairly similar, because most teenagers have not had any children. For example, the first birth rate for teenagers 15-19 years declined from 46.5 in 1991 to 42.5 in 1996, a reduction of 9 percent. The birth rate for childless teenagers declined from 49.6 in 1991 to 46.7 in 1996, a reduction of 6 percent.

Additional information on the tabulation of birth data by race, random variation, and relative standard error is provided in earlier reports $(11,13)$.
