SUMMARY OF WORK (200 words or less - underline keywords) <p>Our aim is to study the distribution of <u>nicotinic acetylcholine receptors</u> in intact and cultured tissues of the <u>peripheral and central nervous system</u> in relationship to the development and function of synapses. To this purpose histochemical localization of <u>α-bungarotoxin</u> bound to the receptors is used in conjunction with <u>light and electron microscopy</u>. In the past year we have used an <u>α-bungarotoxin-horseradish peroxidase conjugate</u> to identify the <u>synaptic sites</u> of nicotinic acetylcholine receptors in the chicken <u>retina</u> and studied the control of nicotinic acetylcholine receptor aggregation on <u>cultured skeletal muscle cells</u> by <u>neuroblastoma-glioma hybrid cells</u> and by substances secreted by these cells.</p>																				

Project Description:

Methods Employed: We have used indirect immunoperoxidase staining of monolayer cultured cells to which α BT has been bound, and peroxidase staining of tissue incubated in vivo with peroxidase-labeled α BT. These materials are subsequently examined by light and electron microscopy.

Major Findings: (1) Horseradish peroxidase was crosslinked to α BT to form a conjugate which retained the specific affinity of α BT for nicotinic acetylcholine receptors. This conjugate bound to 5-7% of the synapses in the inner synaptic layer of the chicken retina. Amacrine cell and bipolar cell synapses bound conjugate, indicating that some synapses of both types have nicotinic acetylcholine receptors. (2) Co-culture of mouse muscle fibers with neuroblastoma-glioma hybrid cells (which form synapses with the muscle cells) increased the number of nicotinic acetylcholine receptor clusters 2-4 fold. A similar increase was obtained by adding cell-free conditioned medium from hybrid cell cultures to the muscle cell cultures. The effect did not depend on the synthesis of new receptors.

Significance to Biomedical Research: Knowledge of ultrastructural distribution of acetylcholine receptors is of clear importance in any attempt to understand the role of neurotransmitters and their receptors in the function and development of the nervous system. The α -bungarotoxin-immunoperoxidase technique already has shown promise for the diagnosis and analysis of mechanisms in human neuromuscular disorders.

The results obtained with chick retina (1) represent the first direct demonstration of the synaptic localization of neurotransmitter receptors in the central nervous system, and should lead to a better understanding of neuronal specificity in the CNS.

The cultured muscle studies (2) may lead to a better understanding of the mechanism whereby neurons control the distribution of receptors on muscle cells and on other neurons.

Proposed Course: (1) We will extend the study of cholinergic synapses in retina to: a) further analyze the pattern of cholinergic synaptic transmission, b) follow the course of receptor accumulation at synapses during development. (2) We will attempt to characterize the factor(s) in hybrid cell conditioned medium which promotes the aggregation of receptors on muscle cell membranes and to determine its mechanism of action.
