ABSTRACT

The methodology of indirect impact measurement utilized in the IXTOC I and BURMAH AGATE oil spill study involved the use of economic relationships developed in an input-output analysis of the coastal economies of Texas.

Regional input-output models were constructed because they permit a detailed examination of the economic relationships between the endogenous (internal) sectors of an economy and between these endogenous sectors and the sector(s) or event(s) considered external to the regional economy. For instance, an oil spill is an external event that impacts on the internal sectors of a region's economy.

The basic tabloid of an input-output model is the transactions table, which is a summary account of the many sales and purchase transactions that take place between all the sectors of the economy under study for some specified time period. Other important tables are derived from the transactions table that provide the sector impact multipliers for economic impact assessment purposes.

Eighteen regional input-output models, each containing 65 economic sectors, were constructed for the oil impact study. The construction of the eighteen input-output models reflects 1) the delineation of six impact study areas, comprising the total nineteen-county study region and five subregional divisions within the total study region, and 2) the establishment of a 3-year study period, 1979-81.

The construction of input-output models requires an enormous compilation of economic information, such as information on imports/exports, interindustry transactions, sector gross sales, and personal income by sector. Such information, especially at the regional level, either does not exist or is in a form not useful for the construction of regional input-output models. Therefore, the modeler must decide between a massive survey approach for model construction purposes or the use of secondary estimating techniques to derive a regional input-output model from a larger-scaled geographic model, such as a national input-outptut model. Oftentimes, budget constraints preclude the survey approach, especially for small regional studies. Useful and satisfactory estimating techniques have been developed to derive regional input-output models from the larger-scaled geographic models.

The eighteen regional input-output models used in the oil impact study to measure the indirect economic impacts associated with the oil spills were derived from the 1972 Texas Input-Output Model.[1] The Texas model was modified to reflect the

Texas coastal economies for the 1979-81 study period. The report, <u>Input-Output Model for Economic Analysis</u>, explains 1) methods for deriving regional input-output models from larger-scaled geographic models and 2) how regional input-output models can be used to assess the indirect economic effects associated with some external event, such as an oil spill.

SECTION I

INTRODUCTION

I. INTRODUCTION

The methodology of <u>indirect</u> impact measurement utilized in the IXTOC I and BURMAH AGATE oil spill study involved the use of economic relationships developed in an input-output analysis of the economies of the coastal counties of Texas. Regional input-output models were derived from the 1972 Texas Input-Output Model.[1] The derivation of these models involved 1) up-dating the 1972 Texas model for the 1979-81 study period and 2) regionalizing the state model to reflect the Texas coastal-county economies. The basic purpose of this manual is to explain, with illustrations, the development and application of input-output models for oil impact assessment purposes.

This Manual is divided into four sections: In the first section, input-output techniques are discussed in such a way that the nontechnical user can understand input-output application and interpretation. This discussion will focus on a "collapsed" version of the 66-sector input-output model developed for the crude oil impact study region. The methods in which the Texas input-output model was regionalized, described in the second section, are presented so that a user can duplicate these techniques. The third section presents, in a useful manner, the updating procedure. The input-output tables for the study areas are presented in the final section along with an application of the output multipliers for the commercial fishing sector.

Understanding Input-Output Models

At the outset, the reader should be aware of (1) the designated study area used in the development of an input-output model, that is, a regional economy vs. a national economy and (2) the distinction between a static model and a dynamic model. In view of the study's requirements, the discussion will focus entirely on input-output modeling for regional economies. In addition, the discussion will be limited to a static analysis of interindustry relationships. Thus, the identified structure of a region's economy, with all its components (producing sectors), represents an economic snapshot for a particular time, but will not systematically reveal the dynamic characteristics of the region's economy. Like a picture, the economic snapshot will not indicate how the region's producing sectors developed to their current state. In practice, inadequate data at the regional level precludes the construction of dynamic regional input-output models, which explains why static input-output models are periodically updated to capture current changes in the structure of the region's economy, which are due mainly to changes in plant investment activity and/or technology.

---

[1]<u>The Texas Input-Output Model, 1972</u>, Texas Department of Water Resources, LP-24, March, 1978.

The usual set of tables that make up a regional input-output model are the transactions table, the direct requirements table, and the total requirements table.[2]

The transactions table, which will be discussed first, is a system of economic accounts for the region, which makes it a descriptive table, similar but not identical to the typical system of accounts used in business. The direct and total requirements tables are referred to as analytical tables since they are derived from the transactions table. These tables form what is commonly referred to as a regional input-output model. In short, a regional input-output model is a compilation of certain analytical tables.

Transactions Table

Viewing the transactions table as a system of accounts, its single most important feature is the systematic classification of interindustry transactions. This feature will become evident with the discussion of Table 1, which presents, in schematic fashion, a transaction table's format.

Quadrant I. Quadrant I of the transactions table contains the producing, processing, trading, and servicing sectors of the economy, among which are agricultural production, forestry, fishing, mining, manufacturing, trade, services, transportation, finance, insurance, real estate, utilities, construction, and households. These sectors, which represent groupings of similar business establishments, are involved in the Quadrant I portion of Table 1 by row and column headings. A customary feature of Quadrant I is that the row order for listing the producing sectors is the same as the column order for the same sectors.

The individual cell values of Quadrant I indicate the economic relationships between the producing sectors and can be expressed in monetary units or physical units. However, monetary units generally are used. Reading across a sector's row shows sales by that sector to the designated sector columns. Reading down a sector's column shows the purchases by that sector from the designated sector rows. This row-and-column interpretation means than an input-output transactions table is a double entry bookkeeping system of accounts.

Quadrant II. All of the columns in Quadrant II, which extend into Quadrant IV, are referred to collectively as the final demand component of the transactions table. The final demand sectors make up the autonomous portion of the

---

[2]The usual practice in the construction of a set of input-output tables is to calculate two basic total requirements tables due to the treatment of the household sector. In the construction of one of the total requirements tables, the household sector is treated as a component of final demand,

Table 1

Basic Format of Transactions Table

| The Endogenous and Exogenous parts of the Transactions Table | | | PURCHASING SECTORS | | | | | | | | EXTERNAL SECTORS (Final Demand) | | | | | |
| | | | INTERNAL SECTORS | | | | | | | | | | | | | |
			Agricultural Sectors	Fishing	Mining, Gas Petroleum	Construction Sectors	Manufacturing Sectors	Non-Commodity Sectors	Household	State-local Government	Federal Government	Private Capital Formation	Net Inventory Change	Exports	Total (Gross Outlay)

		Households													
	EXTERNAL SECTORS (Other Payments)	State-local Gov't Federal Gov't Depreciation Imports & Other Expenses													
		Total (Gross Outlay)			QUADRANT III							QUADRANT IV			

transactions table, that is, the structural part of a region's economy in which the initial changes occur that are transmitted throughout the rest of the region's economy. For illustrative purposes, the final demand portion of Table 1 includes: state and local governments, federal governments, gross private capital formation, net changes in inventories, and exports. The state and local government sector represents purchases by various agencies of state and local government from the sectors indicated along the left-hand side of the table. The column headed gross private capital formation records the sales on capital account by capital producing sectors. To avoid confusion later, it is important to note here that sales to the gross private capital formation sector represent capital expenditures and, therefore, do not represent expenditures for current consumption. The net inventory column records net changes in the inventory of produced items during the accounting period. Finally, the export column records sales by the region's producing sectors to buyers located outside the region. Sales to federal government agencies are excluded from the export category since a separate federal government sector is used. Importantly, given particular study requirements, the final demand sectors are collapsed into a single final demand category. The input-output models developed for the oil impact study region contain a single final demand category (sector).

Quadrant III. The rows in Quadrant III of the transactions table, which extend through Quadrant IV, are referred to collectively as the other payments sectors. State and local government, federal government, depreciation, and imports and other expenses are illustrated in Table 1 as the other payments sectors. Payments to government sectors represent tax payments made during the accounting period, and cell entries for the depreciation row record the amount of calculated capital "used up" during the production period. Finally, the imports and other expenses row represents, for the most part, the purchase of goods and service from producers located outside the region. Other kinds of payments not recorded elsewhere, such as retained earnings, association dues, and donations to charitable and nonprofit organizations, are shown in Table 1 in the imports and other expenses row. Depending upon the availability of data, these types of expenses can be disaggregated to form additional other payments sectors. As with final demand, study requirements oftentimes do not require a detailed break-out of other payments. In the case of the oil impact study, a single row is used for other payments. The ability to disaggregate other payments (and final demand) on the basis of secondary data sources is extremely limited. Thus, if the study

---

meaning that the economic effects of changes in household incomes are not included in economic impact estimates. With the inclusion of households in a producing sector in the second total requirements table, any economic effects associated with the household income changes are measured. The discussion that follows treats households as a producing sector.

requirements will permit, it is desirable to aggregate other payments and final demand.

Quadrant IV. Quadrant IV of the transactions table records the intersector transactions between the other payments sectors and the final demand sectors. For instance, a figure recorded in the cell representing the intersection of the federal government column with the state and local government row would indicate a transfer of federal revenue to state and local government. Quadrant IV plays no direct role in impact estimates, but its purpose is simply to complete the regional system of accounts.

Total Output. The last row of Table 1 records the total gross outlay by each of the producing sectors and the final demand sectors. By definition, the total gross outlay of each producing sector equals its total gross output, adjusted for changes in inventory. It is not the case, however, that row and column totals for sectors common to both the final demand and other payments portions of the table should be equal.

Table 2 represents a gross consolidation of the input-output transactions table for the 19-county study region. The data in Table 2 represent 1972 transactions, reflecting a regionalization of the 1972 Texas Input-Output Model,[3] used here simply for illustrative purposes. These transactions were updated to the 1979-81 period for purposes of the study requirements. Table 2 is presented here to use in the discussion of the direct and total requirements tables. For Table 2, the study region's economy is consolidated into 12 producing sectors: agriculture and forestry products; commercial fishing; mining, gas, and petroleum; construction; manufacturing; transportation and communication; utilities; wholesale; retail; finance, insurance, and real estate (FIRE) group; services; and households. The total gross output of each sector is evaluated in monetary terms in millions of dollars. Final demand and other payments are shown as a single sector.

Rows 1 through 12 of Table 2 detail the distribution of the producing sectors' outputs. Columns 1 through 12 detail their purchases. Column 13 records the producing sectors' sales to final demand, and row 13 lists, by sector, other payments expenses. Quadrant I, which is the most important component of an input-output transactions table, consists of the 12 rows and columns of Table 2.

Direct Requirements Table

The direct requirements table is derived from the accompanying transactions table and will be illustrated with the

use of Table 2. A direct requirements table is calculated on the basis of the information contained in Quadrant I of the accompanying transactions table, and the total gross outlay figures for the producing sector's purchases, which are identified by reading down its column, are calculated by its total gross outlay. While items included under other payments represent purchases, these payments are usually excluded in the derivation of a direct requirements table because they do not represent the region's production of goods and services.

Table 3 is the direct requirements table for the input-output transactions table of Table 2. Illustrating its interpretation, commercial fishing (sector two) purchased, on the average, approximately 13 cents from the region's manufacturers to produce $1.00 of commercial fish for 1972 ($10.89/84.99 = 0.128). In addition, commercial fishing purchased directly an average of 1 cent from commercial fishing; 0.1 cent from utilities; 4 cents from wholesale; 0.1 cent from retail; 4.8 cents from FIRE; 0.5 cent from services; and paid out 30 cents to regional households for labor; returns on capital investments, and the like, for a total of 56 cents of regional-produced inputs in order to produce $1.00 of output. As illustrated, the information contained in a direct requirements table is interpreted by reading down the columns. The input coefficients or direct requirements coefficients of Table 3 are average relationships. If they are used to estimate the direct purchases needed by a column sector to produce an additional quantity of output, it is important to recognize that these average relationships are being assumed. Additional assumptions that are crucial to a correct interpretation of the results of input-output analysis will be noted later.

Total Requirements Table

The great advantage of an input-output system of accounts comes from the derivation of a total requirements table, as illustrated in Table 4. The total requirements table is algebraiclally derived from the direct requirements table, which in turn is derived from the transactions table. Hence, the algebraic explanation of the derivation of the total requirements table begins with the following accounting equation, reflecting the interindustry transactions recorded in a transactions table.

$$(1) \quad X_i = \sum_{j=1}^{n} x_{ij} + Y_i \quad (j = 1,2,\ldots\ldots,n)$$

This accounting equation shows that the total output of a producing sector X_i is equal to the sum of its sales to all producing sectors

$$\sum_{j=1}^{n} x_{ij}$$

plus sales to final demand Y_i. In short, equation No. 1 represents the individual producing sector rows of a

transactions table.

The algebraic formulation of the coefficients of a direct requirements table is equally straightforward.

Let

$$a_{ij} = x_{ij}/X_j$$

where a_{ij} expresses the per dollar requirements of column sector j for sector i.

From the definition of a_{ij}, it is apparent that x_{ij} is equal to $a_{ij}X_j$. Therefore, equation No. 1 can be rewritten as

$$(2) \quad X_i = \sum_{j=1}^{n} a_{ij}X_i + Y_i \qquad (j = 1,2,\ldots,n)$$

The only purpose for rewriting equation No. 1 as equation No. 2 is to carry out the algebraic derivation of the total requirements table.

A system of equations of the type shown as equation No. 2 above exists, one equation for each producing sector. The output totals of this system form a matrix, and the final demand sectors can be aggregated to form a column vector. In matrix algebra, this system of equations can be formulated as:

$$
\begin{vmatrix} X_1 \\ X_2 \\ X_3 \\ \cdot \\ \cdot \\ \cdot \\ X_n \end{vmatrix}
=

$$

Lettering $\underline{X}$ represents the column vector of output totals, $\underline{A}$ represents the matrix of input coefficients, and $\underline{Y}$ represents the column vector of final demand, the total set of equations, can be written as:

(3) $X = AX + Y$

The total requirements table, which is derived from the above set of equations, measures regional economic impact due to some change in regional sales to final demand. Therefore, equation No. 3 is reformulated to express regional output as a function of final demand. Employing the use of the identity matrix and matrix algebra, equation No. 3 is converted to:

(4) $\quad X = (I - A)^{-1} Y$

where $(I - A)^{-1}$ is the matrix of total requirements.

Turning to interpretation, the total requirements table shows the total transactions (that is, the direct and indirect requirements) for each of the producing sectors to deliver $1.00 of output to final demand. More specifically, the columns show the total requirements that are necessary for the column sector to produce and sell an additional $1.00 of output to final demand.[4] For example, the total requirements table (Table 4) shows that for the commercial fishing sector to increase its sales to final demand by $1.00, a total of $2.30 (or 2.295) of activity is generated in the regional economy for 1972. The $2.30 represents the column's sum for commercial fishing of 2.295 rounded to the nearest cent. Included in the total of $2.30 is the $1.00 of increased commercial fishing sales to final demand. (Recall that final demand included sales to exports, state and local government, federal government, and the like). The individual sector amounts that make up the sum of $2.30 show how each producing sector was affected by commercial fishing's sale of $1.00 to final demand. For example, the commercial fishing sector had to increase its total activity by $1.01 (or 1.010 from the commercial fishing sector column of Table 4). However, as already indicated, $1.00 of this amount represents commercial fishing's increased sale of $1.00 to final demand. The difference of 1 cent ($1.01 - $1.00) represents direct and indirect requirements for the commercial fishing sector's initial sale of an additional $1.00 of output to final demand. This shows how an initial change in one producing sector (for example, commercial fishing) creates responsive changes in output levels (that is, the column sum of each producing sector of Table 4 reflects the total of direct and indirect effects associated with the producing sector, increasing its sales to final demand by $1.00).

As discussed above, final demand multipliers, measured in terms of gross transactions, come directly from the direct requirements table. To reiterate, a total requirements table gives the total of direct and indirect requirements that stem from a producing sector's sales of $1.00 of output to final demand. To review this important point, $1.00 of sales to final demand is a dollar's worth of sector output. Understandably, the sector had to purchase various inputs to produce the dollar's worth of output. These inputs are called direct requirements, and they make up the direct requirements table (Table 3). To move one step further, these inputs of direct requirements are outputs of other producing and supplying sectors, and suppliers had to purchase inputs in order to produce outputs. At this stage, only transactions that are "one

---

[4]By convention, the entries in a total requirements table are developed to reflect a $1.00 sale to final demand. Hence, the unit of measurement is $1.00 of sales to final demand by

round" removed from the initial sector selling to final demand are being considered, and these transactions, or inputs, are called indirect requirements. But only one round of indirect requirements beyond the initial direct requirements has been noted. In reality, numerous rounds of spending and respending accompany the production and distribution of a product to final demand, which means that a multiplying effect occurs within the economy as a result of increased sales to final demand. The multiplying effect is measured by means of the derivation of the total requirements table (Table 4), which summarizes the direct and indirect requirements associated with a producing sector's sale of $1.00 of output to final demand.

Now, the household sector is treated as a producing sector in the derivation of the total requirements table because the household row of the transactions table records the amount of wages, salary, dividends, interest, and rent paid, by sector, to regional households for their labor and financial contributions to production. Next, the household row of the direct requirements table averages the amount of income paid to households per $1.00 of sector output. This payment is a direct requirement for production, which means that it is similar, but not identical to, the purchase of material and/or service inputs for production purposes. Adding the household row to the group of producing sectors for the derivation of the total requirements table incorporates the rounds of spending and respending of household incomes, which have a multiplying effect similar to the spending and respending effects noted earlier for the inputs of goods and services used up in production.

Since Table 4 includes households as a producing sector, the multiplying effects recorded in this table summarize the combined spending and respending effects of goods and services inputs for production and household incomes. The contribution that the spending and respending of household incomes makes to the total multiplying effect can be measured by the derivation of a second total requirements table that excludes the household sectors from the group of producing sectors (Table 5). The summarized multiplying effects recorded in Table 5 will be less than those of the first total requirements table (Table 4) by an amount equal to the multiplying effects of household incomes. The final demand multiplier (without households) for the commercial fishing sector in Table 5 is 1.369 (or $1.37). The difference between the final demand multiplier (without households, Table 5) for the commercial fishing sector is the household income effect, or $0.93.

_____

each individual producing sector. This means that the entries in the total requirements can be easily applied to a producing sector's actual change in sales in final demand (increase/decrease) to determine the total economic impact of this change on the region's economy.

Output Multipliers. Useful for impact assessment purposes are the output multipliers that can be derived from the total requirements table. Basically, they are derived by dividing the cell values in each column of the total requirements table by that column's total requirement figure that has the same row and column heading; for example, the commercial fishing column of Table 4. The total requirements figure in the commercial fishing column with the same row and column heading is 1.010, which is divided into each of the cell values for the commercial fishing column and provides the commercial fishing column for Table 6. (To give another example, the total requirements figure for the manufacturing column with the same row and column heading is 1.262. This figure is divided into each of the cell values for the manufacturing column, and the manufacturing column is formed for Table 6). To complete Table 6, this procedure is repeated for the other producing sectors defined in Table 4. Table 7 also contains output multipliers, but the household sector has been excluded from the group of producing sectors because the exclusion of the household sector makes it possible to measure interindustry effects apart from the household income effects.

Although output multipliers and final demand multipliers are both determined from a total requirements table, an interpretative difference exists and can be made clear by taking a closer look at the final demand multiplier for the commercial fishing sector (2.295). This figure was determined by summing the cell figures for the commercial fishing column and gives the total requirements (transactions) associated with $1.00 of sales to final demand by the commercial fishing sector. Of particular importance is the cell value of 1.010, which means that in order for the commercial fishing sector to sell $1.00 of its output to final demand in 1972, it produced $1.01 of output. Thus, the actual $1.01 output produced exceeded the amount sold to $1.00 final demand by the increase in internal demands that stemmed from the commercial fishing sector's sales of $1.00 of its output to final demand. To illustrate further, as noted from the manufacturing sector column of Table 4, the manufacturing sector must produce approximately $1.26 (or 1.262) in order to sell $1.00 of its product to final demand generated an additional demand of approximately 26 cents. With an understanding as to why the actual output of the commercial fishing sector (or the manufacturing sector) exceeds its $1.00 of sales to final demand, all figures in the commercial fishing sector column of Table 4 can be logically scaled down to give the total requirements associated with $1.00 of the commercial fishing sector's output. The method for scaling down the column figures has already been indicated where this procedure is based on the assumption of a proportional relationship between input and output.

Turning now to the output multiplier for the commercial fishing sector in Table 6, 2.272 represents the amount of activity generated in the regional economy when the commercial fishing sector produced $1.00 of output in 1972. Similarly, the

Source: Derived from Table 5

output multiplier for the manufacturing sector represents 1.680 of activity generated in the region's economy for 1972, when manufacturing produced $1.00 of output.

Several uses can be made of output multipliers. Suppose, for illustrative purposes, that due to, say, adverse weather conditions, the commercial fishing sector lost $1.2 million of output. The total economic impact of this loss on the region's economy can now be estimated by multiplying $1.2 times the output multiplier for the commercial fishing sector ($1.2 x 2.272 = $2,726,400). The aggregate impact figure of $2.726 million can be disaggregated simply by multiplying the individual cell values of the commercial fishing column of Table 6 times the loss of $1.2 million. For example, the economic loss to the manufacturing sector was $0.276 million ($1.2 x 0.230 = $0.276). This loss (or impact) occurred <u>indirectly</u> as a result of the <u>direct</u> loss of $1.2 million of output of the commercial fishing sector. This simple illustration exemplifies the method used in this study to estimate the indirect economic effects associated with any direct effects in the activities of the commercial fishing, tourism, and recreation sectors within the study region due to the oil spills.

<u>Assumptions and Valid Estimates</u>. Most of the application of input-output models is by way of the various sector multipliers derived from the total requirements table. Several important <u>assumptions</u> are involved in the analytical derivation of the total requirements table, and for a proper use of sector multipliers, these assumptions should be known. First, as discussed earlier, the direct requirement coefficients, or input coefficients, are average relationships. Next, the relationship between input and output is proportional; therefore, if the quantity of each input is doubled, the output is also doubled. Finally, production factors are not substituted; and at the regional level the input coefficients are not the same as technical input coefficients.

Because of the substantial amount of trade with other regions, regional input coefficients are, in fact, trade coefficients. That is, for any column in the direct requirements table, each input coefficient shows the amount the producing sector purchased from the region in order to produce $1.00 of output, but an additional amount of the same input may have been purchased from outside the region. The amount purchased from within the region plus the amount purchased outside the region per $1.00 of output approximates the technical input coefficient for that input. But the assumption of "no substitution" means that regional input sources are not substitutable for "outside" input sources, and vice versa, which may not be a reasonable assumption for small areas. Generally speaking, a small area (for example, a county) is likely to show a greater variation in its trade pattern over time than will a multistate region.

The reliability of input-output multipliers is based on the

reliability of the assumptions used to convert the input-output transactions table to an analytical model. To review, these assumptions are: (1) that a proportional relationship exists between inputs and output; (2) that the input coefficients are average relationships; and (3) that there is no substitution of production factors. For discussion purposes, these related assumptions can be reduced to one basic assumption, that of fixed factor proportions.

The validity of the more general assumption of fixed factor proportions is related to the degree of industry aggregation used in the construction of the input-output transactions table. Industry aggregation, as used here, refers to the grouping of producing units (for example, establishments) into producing industries or sectors. At one extreme, complete aggregation of all producing units would result in an input-output transactions table with one producing sector only. The sector row of the transactions table would show the distribution of final output to households, government, investment, and export. The sector column would show the way in which factor payments are distributed among wages, rent, depreciation, taxes, and profits. Such a table would not show interindustry transactions, and hence interindustry relations.

At the other extreme, each producing unit of the region would be shown in the input-output transactions table as a separate producing sector. The number of rows and columns in the producing quadrant of the transactions table would equal the number of producing units in the region. While this detailed input-output transactions table would give a complete picture of interindustry relations, it would produce confusion by its sheer complexity. Obviously, neither extreme is used in the construction of an input-output transactions table. The first task is to determine the degree of aggregation that will make the best use of obtainable statistical information on the one hand, and render validity to the assumption of fixed factor proportions on the other. Since the availability and quality of data, along with industry aggregation, affect the accuracy of the results, the intent here is to concentrate on the association between the validity of the assumptions and the degree of industry aggregation. To this end, the discussion will focus on the major conditions that need to be satisfied to render validity to the basic assumption of fixed factor proportions.

One condition is that the substitution of one input factor for another must be negligible. A very fine classification of industry groups may result in closely substitutable produced inputs put into different industry categories. If input substitution occurs because of, say, a price change, the interindustry relations after the substitution would differ from the industry relations before the price change. The possibility can be largely avoided by classifying closely substitutable inputs in the same industry category.

A second condition is that no significant excess capacity exists in the industry group. This is an important condition because with excess capacity or very large inventories of some inputs, it may be possible for output to be increased without proportional increases in these inputs. A larger degree of industry aggregation would mean that excess stocks of inputs by some establishments would tend to be cancelled by depleted stocks of other establishments.

A third condition that is similar but not identical to excess stocks, is input indivisibilities. An indivisible input is one in which a unit of input suffices over a range of output, thus disproving the fixed factor proportions assumptions. Sufficient industry aggregation will minimize this problem, as some establishments in the industry group will purchase indivisible inputs to expand production while others will be able to expand output without an increase in such outputs. Thus, the average input requirements for the industry group will tend to be more proportional to the increase in output if a large number of establishments are in the industry group.

As a fourth condition, changes in technology must not occur. Obviously, this is an unrealistic condition, but again the broader the industry classification, the more likely the effects of different technologies will cancel.

The fifth condition is that constant returns to scale exist for the industry group. This is a realistic condition because aggregation will tend to average out internal differences of economies of scale. Within the industry group, some establishments may be enjoying internal economies of scale; that is, lower average production costs with higher levels of output. The assumption of fixed factor proportions is not valid in this case, but other producers of the same industry group may be experiencing internal diseconomies of scale; that is, higher average productions costs with higher levels of output. An aggregation of establishments with reversed average cost schedules would tend to cause a cancellation, and hence the average cost schedule for the industry group would approximate the fixed input-output relationship that is assumed in input-output analysis.

A final condition that underlies the basic assumption of fixed factor proportions is a constant interregional trade pattern. The degree of industry aggregation has, however, little effect upon the pattern of interregional trade. The constancy of interregional trade is mainly related to the size of the region under study. As said earlier, a county is likely to show a greater variation in its trade pattern than a multistate region.

Knowledge of how aggregation affects the validity of the basic assumption of fixed factor proportions is helpful in two ways. First, this knowledge aids the analyst in determining the degree of aggregation which best meets the above conditions that

underlie the basic assumptions. Second, and equally important, such knowledge provides an awareness of how changes in, for instance, resource prices may affect input-output relations. Equipped with an understanding of what the basic input-output assumptions imply, the researcher can make his adjustments in his/her final estimates where these adjustments reflect some known change in the region's economic structure.

SECTION II

CONSTRUCTING INPUT-OUPUT MODELS FROM SECONDARY INFORMATION SOURCES

II. CONSTRUCTING INPUT-OUTPUT MODELS FROM SECONDARY INFORMATION SOURCES

This section of the manual contains an explanation of the methodology used in the construction of input-output models for the entire 19-county study region and also for each of the five subregions (hereafter called the six study areas). Hypothetical data sets will accompany the text in order to illustrate the application of the methodology. It should be noted at the outset that this methodology is being widely practiced by those who construct input-output models from secondary information sources.

Data Constraints

The application of the methodology in the development of input-output models for the six study areas reflects the lack of existing input-output models for the study areas and the data constraints specified in the study contract, meaning that the research team needed to rely almost entirely on existing data sources and analytical models that could be modified to reflect the economic structures of the study areas. In view of these constraints, the 1972 Texas Input-Output Model, which is the latest model currently available for Texas, was chosen as the basic input-output model for the study areas.[5] The Texas model contains 175 producing sectors, seven final payment sectors, and eight final demand sectors. Table 8 is a complete listing of these sectors along with the SIC industries included in each of the sectors. For the six study areas, the 176 producing sectors were deflated to 64 sectors, retaining the household sector as a single sector. All final demand sectors were deflated to a single column sector, and similarly, all primary payments sectors rows were reduced to a single row sector. See Table 9 for a listing and description of these sectors.

---

[5]In 1978, the Coastal Zone Management Office of Texas published five multicounty input-output models for the Texas coastal counties. These five models were derived from the 1972 Texas Input-Output Model, which is maintained by the Texas Department of Water Resources.

In the early formative stages of this study's methodology, it was believed that the five Coastal Zone Management input-output models, reflecting 1972 interindustry relationships, could be modified to meet the needs of the oil impact study. After some initial attempts to modify these models to conform, for instance, to the county configurations of the oil impact study areas, it seemed desirable to revert to the 1972 Texas model to derive our area specific input-output models.

Table 8

Texas Input-Output Model:
Input-Output Sector Names and Definitions, 1972

SECTOR NUMBER	SECTOR NAME	SIC CODE OR DESCRIPTION

Other Manufacturing

173	Ordnance and ordnance accessories	3482, 3483, 3484, 3489, 3761, 3795

Other Services

**174	Outdoor recreation	The Total Public funds spent in the operation and administration of outdoor recreation facilities by the Texas Parks and Wildlife Department, plus those funds spent by counties, cities, and municipalities for the same purpose.
175	Scrap	Used and second hand goods.

Final Payments

176	Households	Wages, salaries, rents, interest, and dividends paid to households and personal incomes of sole proprietors.
177	Property payments (residual)	Total revenue minus total expenditures (residual income, retained earnings, etc.).
**178	Federal Government	Taxes and other payments to Federal Government.
**179	State Government	Taxes and other payments to State Gov't.

Table 8, cont'd.

SECTOR NUMBER	SECTOR NAME	SIC CODE OR DESCRIPTION
**180	Local Government	Taxes and other payments to Local Gov't.
181	Depreciation	Capital consumption allowances for plant and equipment current production.
182	Imports	Payments for goods and services produced outside Texas.

Final Demand

183	Households	Purchases by individual consumers.
**184	Federal Government Defense	Expenditures of the Department of Defense.
**185	Federal Government Non-Defense	Federal expenditures other than DOD expenditures.
**186	State Government	State Government expenditure.
**187	Local Government	Expenditures of Local government
188	Exports	Out-of-State sales of goods and services produced in Texas, including sales in Texas to out-of-state buyers.
189	Capital formation	Value of capital purchased by Texas sectors that will be depreciated in future years.

Table 8, cont'd.

SECTOR NUMBER	SECTOR NAME	SIC CODE OR DESCRIPTION
190	Inventory change	If negative, the current sales made from inventory; if positive, the value of production added to inventory.

*This sector contains both Private and Government-owned established.
**This sector contains only Government-owned establishments.

Matrix Deflation

To facilitate the deflation of the Texas input-output model to fewer rows and columns required the computerization of the Texas model. Once the model was computerized, the deflating routine was a very simple operation. The following hypothetical illustration shows the basic procedure for collapsing input-output transactions tables.

Assume that Table 10 represents the complete 1972 Texas Input-Output Transactions table. Table 10 contains six producing sectors, one final demand sector, and one primary payments sector. Based on the following instruction, Table 10 is to be collapsed to three producing sectors (Table 11) while maintaining the original final demand sector (column) and primary payments sector (row). The collapsing instructions are:

1. Sector 1
   1.1 Collapse columns 1 and 2. The new sector is to be named Sector 1.
   1.2 Collapse rows 1 and 2. The new row sector is to be named Sector 1.

2. Sector 2
   2.1 Collapse columns 3, 4, and 5. The new column sector is to be named Sector 2.
   2.2 Collapse rows 3, 4, and 5. The new row sector is to be named Sector 2.

3. Sector 3
   3.1 Rename column sector 6 to column Sector 3.
   3.2 Rename row sector 6 to row Sector 3.

The Regionalization Process

One basic procedure in the development of a regional input-output model from a state (or multistate) input-output model is to regionalize the a_{ij} direct-input coefficients. The regionalization process deflates the a_{ij} coefficients to reflect increased imports at the substate level. Generally speaking, a state will import a smaller proportion of goods and services to total gross state product than the comparable proportion imported by some substate region. On the other hand, a substate area is generally more dependent on the importation of goods and services for production and consumption purposes than is the state economy.

The following hypothetical illlustration (Figure 1) more specifically explains the need for adjusting the a_{ij} coefficients for import differences. As hypothetically shown, the fabricated metals sector used $30 worth of primary metals products. Assume that this input-output relationship reflects the current state of technology in the production of fabricated metals, Thus, the technical input coefficient A_{ij} is 0.30 ($30/$100 = 0.30). Assume, however, that the regional economy

Table 10

Hypothetical Technical Input Requirement

From \ To		Fabricated Metals	
Primary Metals		30	
Total Outlay		100	

where the fabricated metals sector is located can supply locally only $20 of the $30 of required primary metals, and the difference of $10 is imported. The regional input coefficient a_{ij} becomes 0.20 ($20/$100 = 0.20). In short, the technical input coefficient A_{ij} has been regionalized to reflect the availability of regionally produced goods and services.

While the Texas input-output model coefficients are not exactly technical input coefficients, meaning that Texas also imports goods and services for production and consumption purposes, the a_{ij}'s at the state level will be generally larger than the corresponding a_{ij}'s for a substate area.

A common procedure for adjusting a_{ij}'s for local (or substate) interindustry trade relationships is the location quotient technique. The location quotient is formulated in the following way, using in this case, Texas as the base economy.

$$LQ_i^t = \frac{R_i \ / \ R}{T_i \ / \ T} \qquad (1)$$

where

LQ_i^t = location quotient for sector i for time period t;

R_i = the economic activity of sector i in region R for time period t;

R = the total economic activity of region R for time period t;

T_i = the economic activity of sector i for Texas for time period t; and

T = the total level of economic activity for Texas for time period t.

(Note: Economic activity can be measured either in terms of employment, gross shipments, or value added.)

As constructed, the location quotient (LQ) will range in value from zero to, theoretically, infinity. Based on the assumptions that no spatial variation in consumption patterns exists, no spatial variation in labor productivity exists, and each sector produces a single and homogenous product, the location quotient can be interpreted in the following manner. If the LQ ratio for sector i is greater than one, the sector is producing a quantity of output that exceeds regional demand. Conversely, if the LQ ratio for sector i is less than one, the sector is not meeting the total regional demand for its product. Therefore, the region is importing some amount of the goods. Finally, if the LQ ratio for sector i is one, the quantity produced by regional

sector i is exactly equal to the amount necessary to satisfy regional demand for the good.

As already indicated, a strict interpretation of the location quotient is based on three quite specific assumptions. It would be unrealistic to believe that these assumptions always hold and, therefore, always yield totally valid results. It seems plausible, however, to expect that they will be more nearly correct when the technique is applied to some substate area where the state is used as the base economy. Greater spatial variation in consumption patterns, labor productivity, and the like can be expected at the national level than at the state level. Finally, if interindustry trade data were available, the location quotient technique would not be used to develop regional input coefficients. Clearly, the use of the location quotient technique introduces some degree of error in the formulation of the a_{ij} coefficients.

A computer routine was developed to calculate the LQ's used in the derivation of the a_{ij}'s for the input-output models for the six study areas. To reiterate, the study area level a_{ij}'s were calculated on the basis of the Texas A_{ij} coefficients, adjusted for interindustry trade differences. The a_{ij} adjustment routine is based on the following two basic rules:

1. If LQ $\geq$ 1

$$a_{ij} = A_{ij}$$

> meaning that the study area level a_{ij}'s are equal to the state A_{ij}'s.

2. If LQ < 1

$$a_{ij} = (LQ_i)\ (A_{ij})$$

> meaning that the study area level a_{ij}'s are adjusted from the state A_{ij}'s in relation to the substate area's degree of self-sufficiency of good i.

The application of the location quotient technique for adjusting a_{ij} coefficients is not difficult. To illustrate the application, the hypothetical (collapsed version) Texas Transactions Table (Table 12) will be used. However, to apply the LQ technique for this purpose, the transactions table must be converted to a direct requirements table (i.e., converted to a matrix of a_{ij} coefficients). Table 13 provides the a_{ij} matrix for a hypothetical Texas model; however, the a_{ij} matrix is calculated only for the Quadrant I portion of the transactions table.

Sector One	0.237	0.327	0.167
Sector Two	0.342	0.288	0.278
Sector Three	0.026	0.038	0.056

Source: Derived from Table 12.

The employment of the location quotient technique also requires sector output totals for both the base economy (e.g., the state economy) and the region under study. For illustrative purposes, consider the following sector output totals, where the sector totals at the state level are extracted from Table 12.

The calculated location quotients are shown in the last column of Table 14. Based on the previous interpretation of the

LQ's only, Sector Two is producing at a level of output sufficient to meet the region's total demand for that sector's product.

Table 14

Hypothetical
Sector Output Totals and Location Quotients

SECTOR	STATE	REGION	LOCATION QUOTIENT
Sector One	$ 38	$10	0.86
Sector Two	52	19	1.21
Sector Three	18	4	0.71
TOTAL	$108	$33	

Table 15 illustrates the application of the location quotient technique to the hypothetical Texas input coefficients of Table 13. Because the LQ ratio for Sector Two was at least the value one, the a_{ij} coefficients in the Sector row were not adjusted.

The adjusted (or regionalized) a_{ij}'s, when multiplied by the regional sector output totals, yield the Quadrant I portion of the transactions table. This step was not necessary for meeting the requirements of the oil impact study, however. Impact assessments require the derivation of impact multipliers, such as the output multiplier, which are derived directly from the direct requirements table (for example, Table 13).

Table 15

Regional Direct Requirements Table
With Adjusted Trade Area

SECTOR	SECTOR ONE	SECTOR TWO	SECTOR THREE
Sector One	(0.237)(0.86) = 0.204	(0.327)(0.86) = 0.281	(0.167)(0.86) = 0.144

Table 15, con't.

SECTOR	SECTOR ONE	SECTOR TWO	SECTOR THREE
Sector Two	0.342	0.288	0.278
Sector Three	(0.026)(0.71) = 0.018	(0.038)(0.71) = 0.027	(0.056)(0.71) = 0.040

Source: Derived from Tables 13 and 14.

The location quotient technique just illustrated was used to develop regional input-output models for each of the six study areas. Table 16 indicates the coastal counties included in each of the six study areas. Using sector gross output estimates, location quotients were calculated for each of the 65 producing sectors, as defined in Table 9, for each of the six study areas. Sector gross output data for the state were obtained from the collapsed 66-sector version of the 1972 Texas Input-Output Model. Comparable sector output data at the study level were estimated on the basis of each area's percent share of state economic activity by sector. Percentages were calculated on the basis of county level employment data that are reported in County Business Patterns on a Standard Industrial Classification (SIC) basis.[6] This circuitous way of estimating sector output totals for the study area was necessary because detailed industry-level output information is not available at the county level. Table 17 presents the 1972 sector output totals for the state and for each of the six study areas. These figures were used in computing the locations quotients used in developing the input-output models for the six study areas.

SECTION III

III

UPDATING INPUT-OUTPUT MODELS

III. UPDATING INPUT-OUTPUT MODELS

The practice of updating input-output models reflects several important considerations.

High Cost of Model Construction

First, as a general matter, it reflects a response to the high cost of constructing a primary input-output model each time the need arises to calculate an economic impact. The cost of constructing primary input-output models is enormous because primary models are based almost entirely on industry surveys. However, like all static input-output models, primary models soon become "dated" models. The practical solution to this problem is to select an existing primary input-output model and adjust its economic structure to reflect the time period and the geographic area under study. (See an earlier section entitled "Constructing Input-Output Models from Secondary Information Sources" for a discussion of a conventional procedure for regionalizing input-output models.) The necessity for constructing primary input-output models is, then, reduced to a time frequency of, say, every three or five years and a single state (or regional) model can be modified to handle substate economic impact calculations.

Second, and related to the first consideration, updating practices reflect known changes in the interindustry stucture of the economy. Structural changes reflect relative price changes, technological changes in production and distribution, and/or relative changes in trade patterns. Discussing each of these sources in reverse order, changes in relative trade patterns reflect a gradual process of change in a region's competitive position with other regions. Regions, like nations, compete for industry and engage in interregional trade. Active regional competition for industry and trade means, in a technical sense, that the region's a_{ij} coefficients will change over time. Thus, the practice of updating a regional input-output model should include adjustments in the regional a_{ij} coefficients to reflect changes in the region's trade patterns. This is rarely done, however, because the adjustment process would require detailed information on industrial location and interregional trade patterns for the region. Currently, such information does not exist.

As for the effect of technological change on the a_{ij} coefficients, new technologies can affect changes in production processes, and changes in production processes affect input-output relationships among industries. Thus, the region's a_{ij} coefficients have changed. Adjustments are then called for in these a_{ij} coefficients. Such adjustments, however, are not easily made. In fact, they are rarely made a part of the practice of updating input-output models. As before, the lack of appropriate information precludes the development of systematic procedures for treating the effects of technological

change on the a_{ij} coefficients. At the industry level, however, technological change occurs only slowly over time. Thus, the need for updating a_{ij}'s for technological reasons is generally not as critical as is the need for adjusting coefficients for relative price changes.

Although input-output relationships reflect <u>physical</u> quantities (levels) of goods (services) used for production purposes, these relationships typically are expressed in <u>monetary</u> terms. Monetary measures permit the aggregation of closely substitutable items, such as screws and bolts, in order to form a common industry group (sector), such as fabricated metal products. (Recall that product aggregation is an important procedure in the construction of input-output models. See the section entitled "Assumptions and Valid Estimates" for a discussion of product aggregation). Monetary measures, however, are subject to price inflation over time. Consider, for example, the use of diesel fuel to power commercial fishing boats. Assume that 15 gallons of diesel fuel are needed to catch 7,500 pounds of finfish. The physical input-output relationship is 0.002 gallon of diesel fuel to one pound of fish (15/7,500 = 0.002). This input-output relationship in monetary terms, where, in 1978 diesel fuel was 78 cents a gallon and the dock price of finfish was 15 cents a pound, yields a direct requirement coefficient of 0.0104. Suppose, now, that this a_{ij} coefficient is being recomputed for 1980. Prices have changed, but more importantly, there has been a relative price change between diesel fuel and finfish. Assume that diesel fuel in 1980 was 95 cents a gallon and the dock price for finfish was 15-1/2 cents per pound. Nothing else changed, meaning that the same amount of diesel fuel was required to catch 7,500 pounds of finfish, on the average. What changed was the relative price between diesel fuel and finfish, and this change needs to be reflected in the updated a_{ij} coefficient. Expressed in monetary terms, the a_{ij} coefficient is now 0.0123 (15 gallons x $0.95)/(7,500)($0.155) = 0.0123.

Procedure

What has just been shown as a way for updating an input coefficient represents a common procedure for updating input-output models to reflect changes in relative prices. The method is simply extended to handle a complete table of input-output relationships, which is the input-output transactions table. To see this extension, the previous example of the fishing and fuels sectors will constitute two of the four producing sectors in the hypothetical input-output transactions table of Table 18. Assume that Table 19 reflects 1978 prices to be consistent with the 1978 prices used in the previous illustration.

The usual input-output price updating procedure, although identical to that viewed in the fishing example, used price indexes (by sector) rather than actual prices. Of course, price indexes reflect actual price information, and more importantly, they reflect price changes. Notice, for instance, that the

Table 18

Hypothetical Transactions Table

SECTORS	AGRICULTURE	FISHING	FUELS	OTHER	FINAL DEMAND	TOTAL
Agriculture	100.00	0.00	0.00	500.00	200.00	800.00
Fishing	0.00	5.00	0.00	400.00	720.00	1,125.00
Fuels	100.00	11.70	40.00	100.00	48.30	300.00
Other	300.00	400.00	210.00	300.00	190.00	1,400.00
Primary Payments	300.00	708.00	50.00	100.00	100.00	1,258.30
Total	800.00	1,125.00	300.00	1,400.00	1,258.00	4,883.30

Table 19

Hypothetical Price Indexes

SECTOR NAME	INDEX (1978 = 100)
Agriculture	108.2
Fishing	103.3
Fuels	121.8
Other	112.6

price indexes for both diesel fuel and finfish (Table 19) reflect the assumed 1978 market prices for finfish and diesel fuel. More specifically, the fuels index of 121.8 reflects the fuels price ration of $0.95/$0.78 = 1.218. To express this index in conventional form, 1.218 is multiplied by 100, or 121.8%. Like all price indexes, the price index of 121.8% has a base price which, in this case, is the fuels price for 1978. Thus, the index of 121.8% means that the price of diesel fuel in 1980 was 1.218 times the base price, or 1.218 x $0.78 = $0.95.

The price updating procedure involves two basic steps. First, the price indexes for the producing sectors (Table 19) are multiplied by the respective row values of the original input-output transactions table (Table 18), as illustrated in Table 20. Notice from Table 21 that the calculation of updated sector row totals is part of the first step. The second step is to divide each sector's column of transactions (purchases) by that same sector's updated row total. The second step is illustrated in Table 20 by focusing on the agriculture sector. The numerator figures of Table 20 are the updated column figures for the agriculture sector of Table 22, and the denominator figure of each ratio in Table 20 is the updated agriculture sector row total from Table 22. The coefficient form of these ratios is the price updated a_{ij} coefficients. These coefficients are shown in Table 20 for the agriculture sector.

Table 20

Price Updating, Illustrated

SECTORS	AGRICULTURE
Agriculture	108.20/865.60 = 0.1250
Fishing	0.00/865.60 = 0.0000
Fuels	121.80/865.60 = 0.1407
Other	337.80/865.60 = 0.3902

Source: Table 22

This 2-step process is repeated for each of the remaining producing sectors identified in the transportation table. The result is a price updated direct requirements table, which is shown as Table 21. Notice how the updated a_{ij} coefficients of Table 21 differ from the original a_{ij} coefficients of Table 23. These differences reflect relative price changes from 1978 to 1980.

The updated direct requirements, Table 21 can now be used to generate updated total requirements table. Recall from an earlier section of this manual that the important data used in impact assessment estimates are the various sector multipliers. The foregoing price adjustment procedure and the resulting price adjusted a_{ij} matrix (Table 21) form the basic matrix for calculating the updated sector multipliers. Recall that sector multipliers are derived from the $(I - A)^{-1}$ matrix. The $(I - A)^{-1}$ matrix for the above hypothetical illustration will not be shown here as it would serve no useful purpose.

Table 24 presents the 1979 update of the direct requirements table of Table 3. Recall that the a_{ij} coefficients of Table 3 reflect 1972 prices since the Texas Input-Output Model was constructed for 1972. Recall, also, that Table 3 is a collapsed 12-sector version of the 66-sector input-output model constructed for the 19-county study region. The inclusion of a 1979 update (Table 24) of Table 3 is to show a realistic example of a price-adjusted direct requirements table. The price indexes used for Table 24 and given in Table 25 are aggregates of the price indexes used for updating the 66-sector input-output models. The detailed price indexes are given in Table 26.

SECTION IV

THE STUDY AREA'S INPUT-OUTPUT MODELS

IV

IV. THE STUDY AREA'S INPUT-OUTPUT MODELS

The study areas include the 19-county study region and five subregional areas for a total of six study areas. The study period includes the years 1979, 1980, and 1981. Six area input-output models were constructed for each year or a total of 18 models for the 3-year study period. Moreover, each input-output model consists of three tables--direct requirements table, total requirements table (with households), and total requirements table (without households). These 54 input-output tables presented in Appendices A-F are arranged in the order as indicated by the following outline:

Total Study Region	1979	Direct Requirements Table

Using Output Multipliers

Disaggregated output multipliers for the commercial fishing sector for the 19-county study region for the 1979-1981 period are presented in Tables 27 and 28. To illustrate the use of these tables and, more generally, to illustrate the use of output multipliers, let it be assumed that due to some adverse event the commercial fishing sector's total output for 1979 declined by an estimated 15% from the expected output level of $158.952 million. The result is a $23,842,800 loss in output for commercial fisheries ($158,952,000 x 0.15 = $23,842,800).

This loss affects directly and indirectly the activities of other producing sectors within the region. The total of these effects, measured in dollars, can be calculated with the use of the 1979 output multipliers for the commercial fishing sector. A summary of the hypothetical impact estimates is given below in Table 29. A detailed breakdown of this hypothetical economic impact is presented in Table 30. The practical value of a table like Table 30 is that it identifies those sectors within the study region that would be most affected by a sudden change in the output of commercial fisheries.

Presenting the Input-Output Tables

The 54 input-output tables are presented below in the order indicated in the outline at the beginning of this section. An interpretation of any of the tables follows the explanation of input-output models and updating procedures discussed in earlier parts of this manual.

For convenience, sector descriptions (Table 31) and county composition (Table 32) of the study areas are repeated below from earlier tables.

Table 27

The Department of the Interior Mission

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering sound use of our land and water resources; protecting our fish, wildlife, and biological diversity; preserving the environmental and cultural values of our national parks and historical places; and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to ensure that their development is in the best interests of all our people by encouraging stewardship and citizen participation in their care. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.

The Minerals Management Service Mission

As a bureau of the Department of the Interior, the Minerals Management Service's (MMS) primary responsibilities are to manage the mineral resources located on the Nation's Outer Continental Shelf (OCS), collect revenue from the Federal OCS and onshore Federal and Indian lands, and distribute those revenues.

Moreover, in working to meet its responsibilities, the **Offshore Minerals Management Program** administers the OCS competitive leasing program and oversees the safe and environmentally sound exploration and production of our Nation's offshore natural gas, oil and other mineral resources. The MMS **Minerals Revenue Management** meets its responsibilities by ensuring the efficient, timely and accurate collection and disbursement of revenue from mineral leasing and production due to Indian tribes and allottees, States and the U.S. Treasury.

The MMS strives to fulfill its responsibilities through the general guiding principles of: (1) being responsive to the public's concerns and interests by maintaining a dialogue with all potentially affected parties and (2) carrying out its programs with an emphasis on working to enhance the quality of life for all Americans by lending MMS assistance and expertise to economic development and environmental protection.
