

1992 NATIONAL HURRICANE CENTER FORECAST VERIFICATION

Miles Lawrence and James Gross

Abstract

The National Hurricane Center issues a 72-hour track and intensity forecast, every six hours, for all tropical cyclones in the Atlantic and eastern Pacific basins. Forecasts are verified by comparison with a best-track post analysis of all available track and intensity data. Verification statistics for 1992 are presented.

1. Atlantic

Official track errors by storm are listed in Table 1.1 along with the yearly average for all storms and a comparison with the previous ten-year average. This year's track errors are smaller than the previous ten-year average for all forecast periods. Also note that the average errors for Hurricane Andrew were quite small at all forecast periods.

Tables 1.2.1 and 1.2.2 are homogeneous comparisons of various track guidance models. Table 1.2.1 does not include the GFDL model and has a larger number of cases. The Aviation model has the smallest errors except at 12 hours and the BAM medium layer model has the next smaller errors. The smaller sample in Table 1.2.1 shows the GFDL model with very small errors at 12 and 24 hours and it also performs well at longer forecast periods.

Official maximum one-minute wind speed forecast errors are given in Table 1.3. The average bias for the year is slightly positive at all forecast periods compared to a larger negative bias for the previous ten years. The average absolute wind speed errors are somewhat larger than the previous ten years after 24 hours. Tables 1.4.1 and 1.4.2 are homogeneous comparisons of various intensity guidance models. The newer SHIPS model has about the same errors as SHIFOR except a little smaller at 72 hours. The GFDL model performs rather well for this limited sample.

2. Eastern Pacific

Tables 2.1 through 2.3 are similar verification statistics for the eastern Pacific basin. The 1992 average official track errors are similar to the 1988-1991 averages (the NHC started advisories in the eastern Pacific in 1988) except the 1992 errors at 72 hours are slightly larger. P91E, a statistical/dynamical model, has the lowest guidance model errors except at 72 hours in a homogeneous comparison, but is followed closely by the QLM and The BAM medium layer model. Note that improvement over the CLIPER model is more difficult to achieve in the eastern Pacific than in the Atlantic.

The 1992 official wind speed bias error is smaller than in prior years and the mean absolute errors are slightly less than the 1988-1991 average.

Table 1.1. Official track forecast errors (average in nautical miles), Atlantic, 1992.

| storm | forecast period (hours) | | | | | |
|---|-------------------------|-------------|-------------|--------------|--------------|--------------|
| | 0 | 12 | 24 | 36 | 48 | 72 |
| Subtropical One (no. of cases) | 15 (5) | 61 (5) | 124 (5) | 196 (5) | 290 (3) | - (0) |
