## The June Review

As we come to press, the catastrophic hurricanes of 2005 are still a vivid memory. Michael L. Dolfman, Solidelle Fortier Wasser, and Bruce Bergman investigate the effects of Hurricane Katrina on the economy and labor market of New Orleans. They find that despite significant job losses almost across the board, the three key industries in the New Orleans economy survived. By surviving, tourism, port operations (including at-sea petroleum mining), and educational services provide a base for the city's eventual recovery.

Paul E. Gabriel and Susanne Schmitz analyze gender differences among workers' occupations and employment patterns. They find that differences in occupational distributions have remained fairly stable and that shifts across occupational lines are not much different than they were in the past. When they did a more detailed examination of those shifts, Gabriel and Schmitz discovered that to reach a more gender-neutral occupational distribution, women would have to move in large numbers from white- to blue-collar jobs. They conclude, "This is unlikely, however, in light of recent occupational employment patterns and choice by gender. Thus, U.S. women in their thirties and forties do not appear to encounter significant levels of involuntary segregation across broad occupational categories."

## Families and employment

Among married-couple families, 83.8 percent had an employed member in

2006 , unchanged from 2005 . The proportion of married-couple families in which only the husband worked declined to 19.8 percent in 2006 from 20.2 percent in 2005. The proportion of married-couple families in which only the wife worked remained at 6.5 percent. The proportion that was dualworker couples (both husband and wife employed) rose from 51.3 percent to 51.8 percent. The proportion of married-family couples in which no family member was employed was 16.2 percent in both 2005 and 2006.

## Multifactor productivity

In the private business sector, multifactor productivity-output per combined units of labor and capital inputs-grew at an annual rate of 1.1 percent in 2006. The multifactor productivity gain in 2006 reflected a 3.8 -percent increase in output and a 2.7-percent increase in the combined inputs of capital and labor. Capital services grew 3.0 percent. Labor input posted an increase of 2.6 percent, as both hours worked and labor composition rose. A change in multifactor productivity reflects the change in output that cannot be accounted for by the change in combined inputs of labor and capital. To learn more, see "Preliminary Multifactor Productivity Trends, 2006," news release USDL 07-0758.

## Time use

On an average weekday in the 20032005 period, full-time university and college students spent 3.1 hours engaged in educational activities. Students spent 8.5 hours sleeping, 4.1 hours in leisure and sports activities,
and 2.7 hours working, on average. Traveling took 1.5 hours of the average student day, eating and drinking took 1.0 hour, and grooming, 0.7 hour. All other activities combined averaged 2.4 hours out of the 24 -hour weekday.

Married women ages 25 to 54 who were employed full time and lived with a child under 6 spent fewer hours per weekday in 2005 caring for household children than women who were not employed or only worked part time. Women who worked full time also spent fewer hours engaged in leisure and sports activities, household activities, and sleeping than women who were not employed or only worked part time. (Household activities include housework, food preparation and cleanup, lawn and garden care, and household management.)

In 2005, employed individuals age 65 and older spent 2.4 fewer hours on average per day engaged in leisure time activities than those who were not employed. Those who were not employed spent most of their additional leisure time watching TV ( 1.3 hours) and reading ( 0.5 hour). Watching TV was the most common leisure activity for both groups.

To learn more about how people in various groups spent their time, see Charts from the American Time Use Survey online at www.bls.gov/tus

## Combined July/August issue

To maintain our publication goals for this year, Monthly Labor Review plans to consolidate its July and August issues. The combined issue will be available online at the end of August.

# The effects of Hurricane Katrina on the New Orleans economy 

Hurricane Katrina devastated the New Orleans economy; tourism, port operations, and educational services, the foundation of the city's economy, survived, offering a base for recovery

Michael L. Dolfman, Solidelle Fortier Wasser,
and Bruce Bergman

Michael L. Dolfman is Regional Commissioner, Solidelle Fortier Wasser is a senior economist, and Bruce Bergman is an economist, all in the Bureau of Labor Statistics, New York regional office. E-mail: dolfman.michael@bls. gov

On August 29, 2005, Hurricane Katrina made landfall on the gulf coast of the United States, east of New Orleans, ${ }^{1}$ with the storm's eye passing within 10 to 15 miles of the city. The effect on New Orleans, as well as on the entire coastal region, was devastating.

In the aftermath of the storm, about 80 percent of the city (much of which is below sea level) was flooded. A recent article estimated damages in excess of $\$ 200$ billion, making Katrina one of the most economically costly hurricanes ever to strike the United States. ${ }^{2}$ Reacting to the widespread destruction, the 109th Congress enacted two supplementary appropriation bills totaling $\$ 62.3$ billion for emergency response and recovery needs. ${ }^{3}$ The death toll has been estimated at more than $1,200 .{ }^{4}$ In addition, tens of thousands of citizens were evacuated to other parts of the Nation.

Besides taking its toll on the human, social, and psychological fabric of the city, the storm had a notable effect on the city's economy, its labor market dynamics, and its individual businesses. Just what these effects were has been the subject of some discussion. This article joins the discussion in its analysis of employment and wage data.

In what follows, trends in employment and wage patterns based on data provided by the

Quarterly Census of Employment and Wages (QCEW) program of the Bureau of Labor Statistics (BLS, the Bureau) are compared before and after the storm to measure the extent of the losses during the first 10 months (September 2005 to June 2006) following Katrina.

The findings indicate the extensive effect of Katrina on the New Orleans labor market.The over-the-year loss to the city economy averaged 95,000 jobs during the first 10 months after the hurricane. The job-loss trough occurred in November 2005, when the employment total was 105,300 below what it had been a year earlier. Ten months after the hurricane, in June 2006, the over-the-year job loss had diminished to 92,900 . The loss in wages during the 10 months following Katrina was approximately $\$ 2.9$ billion, with 76 percent of it, or $\$ 2.2$ billion, associated with the private sector. ${ }^{5}$

## The New Orleans economy

In order to understand fully the economic impact of Hurricane Katrina on New Orleans, it is important to assess the impact of the economic forces driving the city. In making this assessment, two approaches offer insights.

The first approach, which occupies the next section and to which the analysis returns at the end of the article, evaluates the diver-
sity within the New Orleans economy compared with that of the Nation. This comparative and static approach uses location quotients based on employment concentration by industry sector; it points out which industrial sectors of the New Orleans economy have a higher concentration of jobs compared with those same industrial sectors of the national economy. (If a New Orleans industry has a greater share than expected, compared with the U.S. share of that industry, then the industry, with its "extra" employment, is assumed to be "basic," or an export industry, because those additional jobs are above what a local economy needs to serve local needs. Basic New Orleans industries become particularly relevant in assessing New Orleans opportunities for recovery, because it is those industries which connect New Orleans to the rest of the Nation.)

Generalizing the analysis from industry concentration to include the total New Orleans economy, the second analytic approach is a time-focused comparison of changes in the total number of jobs, total wages, and average weekly wages, which together define the New Orleans' labor market. Assessing these changes affords additional insights, because they represent New Orleans at two different points in time and underscore temporary population displacement and its effect on the local economy. This approach, which provides a basis for assessing the effects of Katrina, will be utilized throughout the rest of the article.

## Export industries of New Orleans

As can be seen in table 1, the New Orleans economy can be compared to a three-legged stool, with tourism, port operations, and education serving as the legs of the stool and thereby providing its foundation.

Tourism (arts, entertainment, and recreation; accommodation and food service). As is widely recognized, New Orleans is, or at least has been, among the most visited cities in the United States. Besides the attraction of its French Quarter, its internationally renowned restaurants, and its firstclass accommodations, a series of celebrations, including Mardi Gras, the New Orleans Bowl, the Sugar Bowl, and the New Orleans Jazz and Heritage Festival, has drawn thousands of tourists to the city.

Port operations (mining; transportation and warehousing). Less recognized than tourism is the importance of the Port of New Orleans. In combination with the Port of South Louisiana located in nearby LaPlace, the Port of New Orleans handles the most bulk tonnage in the world.

About 5,000 ships from nearly 60 countries dock at the Port of New Orleans each year. Chief exports-to other countries and different regions of the Nation-include grain and foodstuffs produced by Midwestern farmers and petroleum products mined in the Gulf of Mexico. Among the port's leading imports are chemicals, petroleum, coffee, and cocoa beans. The port handles more trade with Latin America than any other U.S. gateway. ${ }^{6}$

Educational services. Also less recognized than tourism is the role of New Orleans as a center of higher education. Located within the city are Tulane University, the University of New Orleans, Loyola University New Orleans, Xavier University of New Orleans, Southern University of New Orleans, Dillard University, and the Louisiana State University Medical School. In addition, a number of community colleges and technical schools lie within the city's boundaries. Of special note is the fact that Dillard, Xavier, and Southern University-all serving predominantly Afri-can-American students-have educated significant numbers of professionals who have resided in the city.

## Pre-Katrina

From 1990 to 2000, the U.S. economy, as measured by total employment, grew by 19.5 percent, or 21.4 million jobs. During the same period, the country's population increased by 13.1 percent, or 32.7 million people. ${ }^{7}$ In New Orleans, however, the results were different: during the decade, the city lost both jobs and population (as regards the latter, more than 12,000 residents, or 2.5 percent of the city's population base).

In 1990, almost half of employment in New Orleans ( 48.5 percent) was associated with four sectors: accommodation and food services ( 10.9 percent), retail trade ( 9.3 percent), health care and social assistance ( 9.2 percent), and government (19.1 percent). In the aggregate, these four sectors provided 39.8 percent of the total wages generated in the city.

Accommodation and food services, a significant part of the "three-legged stool," is also an export New Orleans industry. By contrast, in local industries, such as retail trade and health care and social assistance, job levels are related to the local population size and reflect the needs of that population.

The 1990 New Orleans average weekly wage in private industry, $\$ 424$, was 2.1 percent below the national average of $\$ 433$, due to fact that a high percentage of New Orleans jobs were in the lowest paying sectors, namely, accommodation and food services, and retail trade. ${ }^{8}$ Despite

Table 1. Second-quarter employment location quotients, Orleans Parish, 1990, 2000, and 2004

| Industry |  |  |
| :--- | ---: | ---: | ---: |
|  |  |  |
|  |  |  |

this relatively low average wage, a defining strength of the city's economy was its wide distribution of industries providing employment opportunities. Other than tourism, which represented 12.2 percent of employment, and government, which, as mentioned earlier, accounted for 19.1 percent of jobs, no individual sector dominated the economic landscape.

By 2000, a shift had taken place in the New Orleans employment base: the city lost 2.3 percent of its 1990 pri-vate-sector job base. (See table 2.) But this loss was only part of the story. During the decade, the tourism industry increased in importance until, by 2000, it represented 16.0 percent of employment and 8.0 percent of the total wages generated in the city. Government also increased in significance and represented 20.8 percent of all jobs and 24.7 percent of total wages. In 2000, 1 out of 5 people working in New Orleans was employed by Federal, State or local government, 1 out of 6 in tourism, and 1 out of 10 in health care.

In 10 years, the national average weekly wage in private industry had increased to $\$ 648$, 13.1 percent higher than in New Orleans. ${ }^{9}$ Thus, in terms of average wages, the gap between New Orleans and the Nation had widened. Both the level and the change in average wage underscore the importance of the "three-legged stool" to the New Orleans economy. Although the average New Orleans
wage was below that of the United States, the city did have an array of high-paying industries. Table 3 shows the 10 highest average weekly wages among New Orleans subsectors in 1990 and 2004. Oil and gas extraction, water transportation, and warehousing and storage-all important elements of the "three-legged stool"-were among the highest ranked industries in the city.

Similarly, despite job losses and relatively low average wages in the city, a number of subsectors experienced notable increases in wages between 1990 and 2004. Five of the 10 industries with the largest increases during this period were from the "three-legged stool" sectors, as indicated in table 4. In all of these subsectors, wages grew at a rate that was almost 2 times the all-industry average for the city.
Job and population losses in New Orleans, identified during the 1990s, continued into the 21st century. By 2004, the New Orleans economy had lost more than 16,000 jobs ( 6.2 percent) since 2000. (See table 5.) The city's population declined by an additional 23,000 residents, or 4.7 percent, during the same period.

By comparison, during this same timeframe U.S. population increased by 4.1 percent, or 11.5 million. Employment in the country, however, remained relatively fixed, declining by about 860,000 jobs, or less than 1 percent. ${ }^{10}$ The average weekly wage in New Orleans private industry increased to $\$ 643$, while in the Nation the average weekly

Table 2. Second-quarter employment and wages, Orleans Parish, 2000

wage rose to $\$ 712$, about 11.0 percent higher than the New Orleans figure. Tourism maintained its importance in the city's economy, representing 16.0 percent of jobs and 10.0 percent of total wages.

Despite the overall decrease in the city's employment base compared with 2000, jobs in professional and technical services increased by 3.3 percent from 2000 to 2004. With average weekly wages of $\$ 964$, this was one of the highest paying sectors among the city's private establishments and represented 7.9 percent of total wages, second only to health care and social assistance.

By the end of June 2005, private-sector employment in New Orleans continued its decline. The second-quarter average figure of 191,701 jobs represented a further decrease of about 3,500 jobs, or 1.8 percent, compared with the figure for the same quarter the previous year.

## Post-Katrina

To gain a clear picture of the effect of Katrina, this section presents a series of charts that display various monthly time series of over-the-year employment changes from 2004 to 2006. Monthly data from January 2004 to June 2006 summarize employment and total pay (exclusive of benefits) of workers covered by State and Federal unemployment insurance. Coverage is broad and is estimated at 97.0 percent of all wage and salary employees working in New Orleans during the 2004-06 period.

The methodology presented compares employment levels in the current month with those of the same month in the previous year. (The 42 data points are thus reduced to 30 in each chart.) This approach overcomes problems associated with seasonal patterns in employ-

| Table 3. Subsectors with the highest second-quarter |  |
| :---: | ---: | ---: |
| average weekly wage, Orleans Parish, 1990 |  |
| and 2004 |  |

ment data that are not seasonally adjusted.
Not all industries were affected to the same extent by the hurricane, because the economic circumstance of each sector varied. Before Katrina, some industries were grow-
ing and others were contracting. To evaluate the impact of Katrina on rates of growth (or decline), as well as to assess the magnitude of the loss, a trend line was inferred from January 2003 to August 2005. The deviation from this trend line during the subsequent months indicates the impact of Katrina, not only in terms of job loss, but also on the rate of sector growth, and both of these were considered in evaluating the economic effects of the hurricane.

## Describing the loss

Chart 1 presents a picture of job losses in the New Orleans economy from January 2004 to June 2006. Both the gradual, but steady, loss of jobs-from January 2004 to August 2005-and the dynamic and catastrophic loss of jobs-from September 2005 to June 2006-are represented. The trend line extrapolates what the New Orleans economy would likely have looked like had Katrina not occurred. ${ }^{11}$ As stated previously, the findings indicate Katrina's devastating effect on New Orleans' labor market. During the first 10 months after the hurricane, the city suffered an over-the-year average loss of 95,000 jobs. At the trough of the job loss, in November 2005, employment was 105,300 below the previous year's November figure. By June 2006, the over-the-year job loss, though smaller, was still substantial $(92,900)$. Lost wages over the 10-month period from September 2005 to June 2006 were about $\$ 2.9$ billion, with 76 percent of the loss attributable to the private sector.

## Job losses by sector: a visualization

To provide additional information about the effects of Katrina, this section examines separate sectors of the New Orleans economy to see how they responded to the storm and its aftermath.

Tourism. As noted earlier, tourism had been one of the bright spots in the New Orleans economy in terms of employment. Between 1990 and 2004, jobs grew by 33.0 percent $(10,715)$ in the sector, and they continued to grow in the months preceding the hurricane. As chart 2 shows, the industry was particularly hard hit by Katrina. First, tourism experienced the largest job loss among all sectors; second, tourism would have shown further gains in employment had the hurricane not struck the city.

During the 10 -month period studied, the tourism industry lost approximately 22,900 jobs. Over the 10 months following the hurricane, the loss in wages in the sector was about $\$ 382.7$ million.

Table 5. Second-quarter employment and wages, Orleans Parish, 2004

| Industry | Average monthly employment (thousands) | Percent of Orleans Parish employment | Percent change in employment, 2000-04 | Total wages (millions) | Percent of Orleans Parish total wages | Average weekly wage |

| Local government ........................... | 22.6 | 9.0 | -2.1 | 191.0 | 8.7 | 650 |

[^0]Port operations. Chart 3 points up the effects of Katrina on port operations. As the chart shows, employment was severely affected by Katrina, the sector having added jobs prior to the hurricane. After a precipitous decline commencing in August 2005, the sector started to rebound. However, the rebound was short lived, and due to the higher wages paid in the sector, the overall financial impact of the jobs that were lost was disproportionately higher than the impact in the tourism sector. During the 10 -month period, port operations saw about 3,500 jobs disappear and lost wages amounted to approximately \$136.1 million.

Professional, scientific, and technical services. In 2005, prior to the hurricane, the professional, scientific, and technical services sector recorded a loss of jobs during most of the year. Like the entire New Orleans economy, the sector experienced a precipitous decline after August 2005, but demonstrated a marked improvement begin-
ning in September. As chart 4 shows, the professional and technical services sector was one of the bright spots in the New Orleans economy, returning to its pre-Katrina employment trend line by mid-2006. During the 10-month period, the sector lost approximately 1,680 jobs overall. The loss of wages was about $\$ 84.6$ million.

Construction. The construction sector has been the one industry registering job gains in the New Orleans economy. Immediately following the hurricane, job losses were registered, but as recovery efforts began and then took hold, there was an overall increase in employment during the 10 -month period examined. (See chart 5.) The sector posted a net gain of 4,927 construction jobs, adding $\$ 1.8$ million to the city's economy.

Educational services. The educational services sector had experienced volatility in employment even before Katrina devastated the city. In the aftermath of the

## Chart 1. Over-the-year changes in employment, New Orleans, January 2004 to June 2006

## Chart 5. Over-the-year changes in employment in the construction sector, New Orleans, January 2004 to June 2006

hurricane, the sector reached its nadir in job losses in November 2005, after which it began a steady recovery. By May 2006, educational services had almost reached pre-Katrina employment levels; however, employment losses began again soon after. (See chart 6.) During the 10 -month period, educational services lost approximately 1,910 jobs, amounting to $\$ 66.4$ million in lost wages.

Health care and social services. Job losses in the health care and social services sector mirrored those of the New Orleans economy as a whole. That is, precipitous losses occurred immediately following Katrina, and significant losses continued throughout the 10 -month period studied. (See chart 7.) During that period, health care and social services posted a loss of 13,418 jobs, with $\$ 377.8$ million in lost wages.

## Employment and wages

As shown in charts 2-7, Katrina's devastating effect on the New Orleans economy was not shared equally by
all sectors. In assessing the 10 -month aftermath of the hurricane, it becomes apparent that sectors having the lowest average weekly wage were hardest hit. Besides eliminating jobs from the New Orleans economy, the loss of these lower paying jobs had an effect on the entire economic structure by raising the average weekly wage for the city. In order to further a more complete understanding of that effect, this section divides the post-Katrina period into three specific quarters and analyzes the economic impact of the storm during each quarter.

Fourth quarter, 2005. For the months of October, November, and December 2005-the timeframe that immediately followed the hurricane-average over-the-year job losses were 103,316, or 41.7 percent of the city's fourth-quarter, 2004, job base. (See table 6.) An examination of these job losses reveals that 46.1 percent were centered in just three sectors: retail trade, which lost 12,140 jobs, or 62.8 percent of its job base; accommodation and food services, in which 21,133 jobs, or 59.3 percent of its job base, were eliminated; and health care and social assistance, which lost 14,330 jobs, or 56.4 percent

of its job base. As data from table 5 indicate, these sectors were among the lowest paid in the entire New Orleans economy. Because of the disproportionate loss of jobs in all three sectors, the average weekly wage for those jobs remaining in the city rose 29.4 percent.

Although retail trade, accommodation and food services, and health care and social assistance bore the brunt of the job losses due to Katrina, practically all sectors of the New Orleans economy suffered notable job losses that, in effect, paralyzed most of the city. (In the utilities and mining sectors, in which the number of jobs was relatively small, employment was static on an over-theyear basis).

Job losses during the fourth quarter were due to two
factors: the destruction of the city's infrastructure, thereby eliminating places of employment; and the destruction of homes and the subsequent public-health crisis, which together forced large segments of the employed population to leave the city.

First quarter, 2006. For the months of January, February, and March 2006, a slight improvement in New Orleans' economic structure began to emerge. The average over-the-year loss of jobs during the quarter was 99,114 , or 41.0 percent of the city's first-quarter, 2005, base. (See table 7.) Over the quarter, 44.1 percent of all job losses were associated with retail trade ( 10,955 jobs, or 58.0 percent of the industry's job base), accommodation

and food services ( 19,244 jobs, or 53.6 percent of the industry's job base), and health care and social assistance ( 13,517 jobs, or 58.3 percent of the industry's job base). As a result of this continued disproportionate number of job losses at the lower end of the wage scale, the average weekly wage for those jobs which remained in the city increased by 33.7 percent.

Significant job losses continued throughout many of the sectors making up the New Orleans economy. However, some rays of light had begun to emerge. On an over-the-year basis, employment in the construction sector increased by 31.2 percent (about 1,700 jobs) as the city began the initial steps to rebuild. A revival in business activity also was indicated by a slowing of job losses in the
professional, scientific, and technical sector (the sector lost just 8.8 percent of its job base on an over-the-year basis), with average monthly employment increasing from the previous quarter. Clearly, the city's economy was still desperate, but some signs of slight improvement were visible.

Second quarter, 2006. During April, May, and June 2006, the intensity of job loss continued to abate. By the end of the quarter, losses stood at 93,594 jobs, or 38.3 percent of the city's second-quarter, 2005, job base. (See table 8.) Of all the job losses in the New Orleans economy over the quarter, 44.4 percent were associated with retail trade (about 9,770 jobs, or 51.4 percent of the industry's

[^1]Note: Percentage bases include the approximately 0.3 percent of private employment with nonclassifiable industries.
job base), accommodation and food services (18,070 jobs, or 49.1 percent of the industry's job base), and health care and social assistance ( 13,718 jobs, or 57.9 percent of the industry's job base). As a result of these job losses, the average weekly wage for all jobs rose 28.2 percent.

Although grim, the economic climate in the city was improving. Employment in the construction sector continued to grow, increasing, on average, by an additional 2,000 jobs compared with the previous quarter's figure. On an over-the-year basis, employment in the sector increased by 27.0 percent, or 1,580 jobs. Employment in the professional, scientific, and technical sector held steady at 12,500 jobs, but, on an
over-the-year basis, registered a 7.3-percent decline of 988 jobs.

## Over-the-year comparison

As noted, the two most significant effects of Katrina were a massive loss of jobs and a significant rise in the city's average weekly wage. On an over-the-year basis, average weekly wages increased 28.2 percent, to $\$ 887$. The loss of jobs changed the city's employment patterns, but did not alter the relation of the local to the base (export) economy. By the second quarter of 2006, 81.4 percent of those jobs which remained in the city were associated with the private sector; previously, private-sector
employment had accounted for 78.4 percent of all jobs.
Within the private sector itself, however, a redistribution in employment had taken place. Whereas in the second quarter of 2005 accommodation and food services, the largest employer in New Orleans, accounted for 15.0 percent of all jobs, a year later the sector represented 12.4 percent of employment (still the largest in the economy, though). Employment shares for health care and social assistance had decreased from 9.7 percent to 6.6 percent, while those for retail trade had decreased from 7.8 percent to 6.1 percent. By contrast, the following sectors increased their employment shares: professional, scientific, and technical, from 5.5 percent to 8.3 percent; and educational services, from 3.5 percent to 5.3 percent.

The rise in the proportion of private-sector jobs was the result of a notable loss of government jobs: 46.7 percent, or 24,584 jobs, from the second quarter of 2005 to the same quarter of 2006. All segments of government experienced significant reductions in employment. Federal employment was reduced by 22.8 percent ( 2,838 jobs), and State employment decreased by 36.6 percent ( 6,944 jobs). However, it was in the local governmental sector that massive job losses occurred: on an over-the-year basis, the city reduced its governmental workforce by 69.6 percent, or 14,802 jobs.

## Ten-month assessment

Over the 10 -month period studied, 1 out of every 4 private-sector jobs lost ( 25.4 percent) was in the accommodation and food services sector. (See table 9.) Due to lower-than-average wages associated with the sector, those lost jobs accounted for just 1 out of every 7 dollars ( 14.5 percent) lost in total wages in the New Orleans economy. About 1 out of every 6 jobs lost (17.9 percent), amounting to 1 out of every 5 dollars in lost wages ( 19.6 percent), was associated with the health care and social services sector, while 1 out of every 7 jobs lost ( 14.3 percent) and 1 out of every 10 dollars in lost wages ( 10.5 percent) were associated with the retail trade sector.

Thus, in terms of its effect on the private sector, about 6 out of every 10 jobs lost ( 57.6 percent) and nearly half of all dollars in lost wages ( 44.6 percent) were associated with just three sectors: accommodation and food services, health care and social assistance, and retail trade.

THE NEW ORLEANS ECONOMY CAN BE COMPARED to a three legged stool, with tourism, port operations,

| Table 9. Share of Orleans Parish <br>  2005 to June 2006) priva <br> and wage loss, post-Kat | 10-month (S ate-industry ina | ember ployment |

and education serving as the legs of the stool and thereby providing its foundation. Of interest is how Katrina, with its effect on the employment and wage dynamics of the city, may have altered that foundation. In particular, what influence has the loss of so many jobs, concentrated in a few specific industry sectors, exerted on New Orleans's overall economic picture?

Examining the 2-year change in location quotients (from the second quarter of 2004 to the second quarter of 2006) affords a number of insights into this issue. Despite the extensive loss of jobs in the accommodation and food services sector, tourism, with a 2006 location quotient of 1.60 (down from 1.90 in 2004) remains a basic (that is, export) component of the New Orleans economy. (See table 10.) Port operations, with a location quotient of 2.22 (compared with 1.80 in 2004), has increased in importance, as has educational services, with a 2006 location quotient of 3.30, compared with 2.52 in 2004.

Of special note is the increase in strength recorded in the professional, scientific, and technical sector (which

| Table 10. Second-quarter employme quotients, Orleans Parish, 200 |  |

moved from a location quotient of 1.15 in 2004 to 1.57 in 2006), along with the weakening registered in health care and social assistance (which dropped from a location quotient of 1.04 in 2004 to 0.63 in 2006). Significant job losses in this sector clearly weakened its influence in the city's economy and may indicate a real deterioration in the availability of social services, which are, of course, critical during a time of recovery from a disaster.

Within the New Orleans economy, the location quotient for oil and gas extraction increased from 13.7 in 2001 to 14.0 in the second quarter of 2006 , and that for the related industry of marine cargo handling rose from 18.5 to 20.6 over the same period. Advances in technology have increased the proportion of exploratory wells,
enhanced offshore drilling capacities, and extended the productive, useful life of existing wells. The supplies of oil and gas, nonrenewable resources, depend heavily on their price, which has fluctuated.

In addition, the overall New Orleans tourist industry has been based not only on the presence of physical structures, but also on the manifestation of the city's history in the lives of its people. Prior to the hurricanes, the unique heritage of New Orleans as a former French colony had lived on in its museums (with a location quotient of 2.32) and in the French tradition of converting the experiences of daily life into song and music (musical groups and artists had a location quotient of 3.91). ${ }^{12}$ These location quotients show that, despite the shock to the New Orleans economy as a result of Hurricane Katrina, industries associated with the "three-legged stool" (that is, tourism, port operations, and educational services) have maintained their relative strength. Moreover, the employment outlook overall for these sectors is favorable. ${ }^{13}$

National numbers project that, over the next decade, overall employment in colleges and universities is expected to rise by 34.3 percent, with increases of 25.1 percent in arts, entertainment, and recreation and 16.6 percent in accommodation and food services. ${ }^{14}$ Thus, despite a lackluster economy prior to Katrina, the structure of the New Orleans economy has a triumvirate source of economic strength-tourism, port operations, and education-that bodes well for the future. Current data indicate that the rebuilding of New Orleans has resulted in steady, continuing employment growth.

Chart 8 presents two trend lines. ${ }^{15}$ The top line, commencing in January 2004, projects the long-term employment level in New Orleans had Katrina not devastated the city. The bottom line, starting in October 2006, after the initial destruction and amidst job losses, is projected forward. After having hit its low point of 137,785 jobs in January 2006, the New Orleans employment level continues to increase, suggesting that there is a base for recovery. in the post-Katrina New Orleans labor economy.

Employment

## Notes

Acknowledgment: The authors would like to thank their colleagues from the BLS Dallas regional office for their assistance in the preparation of this article.
${ }^{1}$ For the purposes of this article, "New Orleans" refers to the city of New Orleans (Orleans Parish), as opposed to the larger metropoli$\tan$ area composed of 12 parishes. The city's employment and wage losses were just part of the total economic damage caused by Katrina. The analytic framework presented herein will focus on second-quarter data to maintain consistency with the latest quarter (the second quarter of 2006) for which data are available for New Orleans.
${ }^{2}$ Roger D. Congleton, "The Story of Katrina: New Orleans and the Political Economy of Catastrophe," Public Choice, vol. 127, April 2006, pp. 5-30, especially pp. 5, 6.
${ }^{3}$ Congressional Research Service, Library of Congress, May 16, 2006, RS22239.
${ }^{4}$ See Congleton, "Story of Katrina," p. 5.
${ }^{5}$ To avoid the effects of seasonal fluctuation, estimates of employment and wage loss were based on year-to-year differences in monthly employment before and after Hurricane Katrina. Within a given quarter, monthly employment differences were multiplied by the base quarter's average weekly wage. In evaluating the relative shares of the private-sector loss among industry sectors, this analysis was performed at the North American Industry Classification System (NAICS) sector level. Because the over-the-year loss spanned into higher employment in previous years (annual levels of employment had been declining in New Orleans every year since 2001), this method may have slightly overstated the overall employment loss. The wage loss, however, may have been understated, because it was based on year-old average wage levels. The base-quarter average wage, as opposed to the more recent wage, more accurately re-
flects the occupation and industry mix of the prehurricane economy. Therefore, estimates of employment and wages lost to the hurricane are likely conservative.

${ }^{7}$ Statistical Abstract of the United States: 2006, 125th ed. (U.S. Census Bureau, 2007), table 1, p. 8 .
${ }^{8}$ The wage figures are from the BLS QCEW program.
${ }^{9}$ Ibid.
${ }^{10}$ Ibid.
${ }^{11}$ The trend line represents the least square fit based on values from January 2004 to August 2005, assuming that over-the-year employment change is linear. Linear trend lines were used throughout this analysis, for both total and sector employment.
${ }^{12}$ Location quotients are from the BLS QCEW Program.
${ }^{13}$ See Career Guide to Industries, 2006-2007, Bulletin 2601 (Bureau of Labor Statistics, 2007). The arts, entertainment, and recreation sector is projected to increase by 25 percent (p.248), food services and drinking places by 16 percent (p.255), and educational services by 17 percent. With an increase of more than 12 percent, the port facility operations sector is projected within the average range of 14 percent for all industries. Oil and gas extraction is projected to grow worldwide, with the U.S. contribution heavily dependent on relative supplies and prices.
${ }^{14}$ Projections data are for 2004-14 and are from the BLS Employment Projections Program.
${ }^{15}$ Employment levels from January 2004 through August 2005 and from January 2006 through June 2006 were projected forward with the use of simple linear trend lines.

# Gender differences in occupational distributions among workers 

An investigation of gender differences in occupational attainment of prime-age U.S. workers reveals that such differences do exist, especially among women, but apparently are the results of voluntary choices and long-term changes in the labor market

Paul E. Gabriel<br>and<br>Susanne Schmitz

[^2]Recent analyses of gender employment patterns suggest that occupational differences between men and women are a persistent presence in the U.S. labor market. Traditional blue-collar occupations such as operatives and craft continue to be male dominated, while women remain concentrated in service and clerical occupations. (See table 1.) Other occupations, such as managerial, professional and technical, and sales appear to be distributed almost evenly by gender. For women, the most popular occupations are clerical (a traditionally female-dominated occupation) and professional and technical; for men, the most popular occupations are production and craft, professional and technical, and managerial. Table 1 also presents a well-known measure of the disparity in occupational distributions: the Index of Dissimilarity (ID). This index, based on the absolute deviation in the percentages of men and women across occupations, is defined as

$$
\begin{equation*}
\mathrm{ID}=\frac{1}{2} \sum_{j=1}^{J}\left|P_{j}^{M}-P_{j}^{W}\right| \tag{1}
\end{equation*}
$$

where $P_{j}^{M, W}$ measures the percentage of men $(M)$ or women $(W)$ in occupational category $j$. The ID ranges from 0 to 100 , with its numerical value indicating the percentage of men, women, or some combination of the
two that need to shift occupations in order for the two distributions to equalize. An ID of 0 means equal occupational representation by gender, whereas a value of 100 denotes complete gender segregation across occupations. Thus, the data in table 1 indicate that, in 2001, 31 percent of men or women (or a combination of percentages that adds up to 31 percent) would have to change occupations for there to be complete gender equality in occupational distributions. This percentage is consistent with other estimates of occupational employment patterns reported from a variety of labor market data. ${ }^{1}$

Although the occupational differences reported in table 1 are well known, researchers continue to investigate whether these employment disparities result from gender differences in occupational choice, from differences in characteristics, or from market distortions such as occupational segregation. Occupational segregation occurs when workers are excluded from certain jobs, and overrepresented in others, for reasons such as race, gender, or national origin. Since the early 1960s, researchers have been interested in the measurement and consequences of occupational segregation in the labor market. Recent empirical work has employed dis-crete-choice, qualitative-response models of occupational attainment to investigate differences in occupational structures across groups of workers. These qualitative-response models

Table 1. Employed persons 20 years and older in the civilian labor force, by occupation and gender, 2001

| Occupation | Percentage of occupation that are men | Percentage of occupation that are women | Men |  | Women |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Number (in thousands) | Percentage of all men employed in each occupation | Number (in thousands) | Percentage of all women employed in each occupation |
| Total................... | ... | ... | 67,334 | 100.0 | 59,787 | 100.0 |
| Managerial ........................... | 54 | 46 | 11,005 | 16.3 | 9,387 | 15.7 |
| Professional and technical ....... | 46 | 54 | 12,063 | 17.9 | 13,952 | 23.3 |
| Sales .................................. | 52 | 48 | 7,601 | 11.3 | 6,953 | 11.6 |

| Operatives ............................ | 76 | 24 | 9,302 | 13.8 | 3,007 | 5.0 |
| Laborers ............................... | 78 | 22 | 3,631 | 5.4 | 1,011 | 1.7 |

Note: The Index of Dissimilarity across all occupations in 2001 was 31.1.
of occupational attainment were developed initially to predict the likelihood that workers are employed in a specified occupational category, given their individual traits. ${ }^{2}$ The occupational segregation literature has adapted the models to determine whether, after controlling for differences in characteristics such as human capital variables, certain workers face unequal prospects for occupational achievement. ${ }^{3}$

This article assesses recent occupational distributions of prime-working-age ("prime-age") men and women in the U.S. labor market. The objective is to determine the extent of gender differences in occupations that are due to discrimination-based segregation, or due to other factors such as differences in human capital characteristics and labor market choices.

## Empirical model

Occupational attainment refers to the net outcome of the processes that ultimately determine a worker's occupation. The demand side of occupational labor markets is influenced by employer-established requirements for jobs in terms of training, education, and experience and by other labor market factors, such as product demand and labor productivity. On the supply side, a worker's background, demographic characteristics, ability, and aptitude will influence occupational choice and placement. Empirical models of occupational attainment are therefore reducedform specifications that attempt to incorporate both sup-
ply- and demand-side factors. This analysis uses a well-established occupational attainment model to estimate the statistical link between a worker's characteristics and the likelihood that he or she is employed in a given occupation. In our specification, we assume that the probability that a worker is employed in the $j$ th occupation $(j=1, \ldots, j)$ can be expressed as the logistic conditional probability function

$$
\begin{equation*}
P_{i j} \left\lvert\, X_{i}=\frac{e^{\delta_{j} X_{i}}}{\sum_{j} e^{\delta_{j} X_{i}}}\right. \tag{2}
\end{equation*}
$$

where $P_{i j}$ is the expected probability that the $i$ th individual $(i=1, \ldots, N)$ is employed in the $j$ th occupation, $X_{i}$ is a vector of individual characteristics, and $\delta_{j}$ is a vector of coefficients to be estimated. The logistic model in (1) can be expressed in linear terms as the log of an odds ratio:

$$
\begin{equation*}
\ln \left(P_{i j} / P_{J}\right)=\hat{\delta}_{j} X_{i} \tag{3}
\end{equation*}
$$

Estimating the parameters in $\delta_{j}$ yields an occupational structure in which the net influence on a worker's occupation is expressed as a function of personal characteristics that are statistically linked to occupational attainment. ${ }^{4}$

We can use equation (3) to investigate whether women face different prospects for occupational attainment than
their male counterparts. The initial step in this process is to estimate the parameter coefficients of (3) for men. Next, these estimated coefficients are applied to workers' characteristics from the women's sample. This step yields an estimated probability that a woman is employed in an occupation, given that her personal traits are evaluated according to the estimated occupational structure for men:

$$
\begin{equation*}
\hat{P}_{i j}^{W}=\frac{e^{\hat{\delta}_{j}^{M} X^{W}}}{\sum_{j} e^{\hat{\delta}_{j}^{M} X^{W}}} \tag{4}
\end{equation*}
$$

Equation (4) can be used to derive the expected percentage of women in occupation $j$, assuming that they are assigned to occupations on the basis of their characteristics and qualifications in a fashion similar to the way men are. ${ }^{5}$ The expected occupational distribution for women can be compared with their actual distribution to determine whether there are noticeable differences.

To compare the actual occupational distribution of men with the actual and expected occupational distributions of women, we calculate (1) the ID for the actual occupational distributions of men and women, and (2) the ID for the actual men's distribution and the expected women's distribution. A significant decline in the index from (1) to (2) suggests that if the characteristics of women are evaluated as though they were men, the occupational distributions of the two groups become more similar. This idea supports the notion of discrimination-based occupational segregation against women, assuming that men and women have similar tastes with respect to occupational choice. The approach assumes implicitly that any remaining disparity in occupational distributions, once the expected female distribution is determined, results from differences in occupational choice patterns by gender. ${ }^{6}$ Thus, the empirical model used in this article is based on the standard neoclassical labor market approach to gender discrimination, ${ }^{7}$ an approach which asserts that unequal labor market outcomes between men and women are due primarily to gender differences in skills, qualifications, and choice, as well as to labor market imperfections such as discrimination. ${ }^{8}$

## Data and empirical results

Because the analysis that follows focuses on recent labor market outcomes for prime-age workers, two waves from the 1979 cohort of the National Longitudinal Survey of Youth (NLSY79) were selected: 1994 and 2000. ${ }^{9}$ Longitudinal data sets are an excellent source of demographic information on individual workers and allow the speci-
fication of a relatively complete set of independent variables for the occupational attainment model given by equations (3) and (4). However, a potential drawback of the NLSY79 is the impossibility of constructing a representative nationwide sample of workers. For instance, in 2000, the NLSY79 comprised workers between the ages of 35 and 43. Although not representative of the entire U.S. labor force, prime-age workers are important to study because these workers are just entering their peak earnings years within their chosen professions. ${ }^{10}$ In addition, this age group represents a significant portion of the labor market, accounting for approximately 27 percent of the U.S. civilian labor force in $2000 .{ }^{11}$ The samples presented consist of nonagricultural workers who reported positive wage and salary income. Excluded are full-time military personnel, individuals who are enrolled in school, and those with missing information on their occupational status. The occupational categories are described more fully in exhibit 1, and the independent variables used to estimate the logit model of occupational attainment ( $X_{i}$ ) are described in exhibit 2.

Table 2 compares the occupational distributions of prime-age men and women in 1994 and 2000. ${ }^{12}$ In 1994, the gender disparity in occupational distributions, as measured by the ID, was 37.4 . Thus, 37 percent of men or women, or a combination of the two, would have had to shift occupations in order for the two distributions to converge. By 2000, gender differences in the occupational distributions declined slightly, to 36.1. These results are comparable to estimates of gender disparities in employment patterns reported in table 1 and elsewhere. ${ }^{13}$ Thus, the overall gender disparity in occupational distributions among prime-age workers remained relatively stable during the late 1990s.

Table 2 also compares the actual occupational distribution of men with the expected occupational distribution of women, derived from equation (4). The ID for 1994 declines by 33.6 points when the expected occupational distribution for women is compared with the actual male distribution. In other words, if women were assigned to occupations on the basis of their education, experience, and other characteristics according to the male occupational structure, the overall gender disparity in occupations declines by approximately 90 percent. For 2000, the change in the ID when the expected women's occupational distribution is compared with the actual men's is 31 points, a reduction of 86 percent. One interpretation of these findings is that unexplained differences in the occupational distributions of men and women fell, albeit slightly from 1994 to 2000. One also may interpret these findings as indicating that women continue to face significant

Table 2. Comparison of actual and expected occupational distributions for men and women, 1994 and 2000 National Longitudinal Survey of Youth
[In percent]

| Occupation | 1994 |  |  |  | 2000 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Service ................ | 11.2 | 18.7 | 12.0 | 9.3 | 17.2 | 10.2 |
| Laborers | 10.0 | 1.4 | 10.5 | 7.9 | 1.9 | 8.8 |
| Clerical | 7.4 | 31.2 | 8.5 | 5.4 | 25.2 | 6.3 |
| Operatives .... | 17.1 | 8.7 | 15.3 | 16.9 | 7.9 | 15.6 |
| Craft ............................... | 19.8 | 2.4 | 18.9 | 21.5 | 2.5 | 19.9 |
| Sales ... | 4.5 | 3.5 | 4.6 | 3.8 | 4.7 | 3.8 |
| Managerial | 14.6 | 12.6 | 13.4 | 18.3 | 16.2 | 16.2 |
| Professional and technical ..... | 15.5 | 21.6 | 16.7 | 16.8 | 24.2 | 19.3 |
| Sample size ........................ | 3,221 | 2,888 | $\ldots$ | 3,021 | 2,851 | $\ldots$ |

Note: The Index of Dissimilarity across men's actual and women's actual occupational distributions was 37.4 in 1994 and 36.1
in 2000. The Index of Dissimilarity across men's actual and women's expected occupational distributions was 3.8 in 1994 and 5.1 in 2000.
obstacles to occupational mobility than their predecessors did, even with more education and fewer children and with the presence of antidiscrimination laws.

However, a more detailed look at the data in table 2 reveals certain gender differences in occupational distributions that work to mitigate the segregation interpretation. For instance, suppose we consider occupations to be overrepresented by women if the expected percentage of an occupational category is lower than the actual percentage by more than 25 percent. Similarly, underrepresented occupations are those for which the opposite is true (that is, the expected percentage exceeds the actual percentage by more than 25 percent). According to these criteria, women appear to be overrepresented in the service, clerical, and professional and technical occupations, and underrepresented in the craft, operatives, and laborers categories in both 1994 and 2000. This implies that most of the hypothetical "shifting" in occupations between the actual and expected women's distributions results in women moving from service, clerical, and professional jobs into more traditional, blue-collar occupations. If women tend to avoid blue-collar occupations, it is unlikely that such hypothetical shifts are due to differential treatment in the labor market. Rather, these results are consistent with the notion that many women may prefer occupations that offer more flexible work arrangements
and scheduling with better nonwage amenities, regardless of their human capital and other traits. ${ }^{14}$ Our results are also consistent with those of John Robst and Jennifer Van Gilder, who find that women who choose "female" occupations incur lower wage penalties for intermittent labor force participation than women employed in predominantly "male" occupations. ${ }^{15}$ Thus, the reluctance of women to choose blue-collar occupations may result from a rational assessment of the potential labor market losses from activities such as child rearing.

Recent work from the sociology literature also supports the finding of stable gender differences in occupational employment patterns. Robert Blackburn and colleagues find that the persistence of gender employment differences in occupational structures is common in more developed countries such as Britain and the United States. ${ }^{16}$ They attribute this phenomenon to several factors. One factor is the long-term change in occupational labor markets in which the growth in women's labor force participation is correlated with the relative increase in the proportion of white-collar occupations in the labor force. Thus, as more women have entered the labor market with education levels that equal or surpass their male colleagues, they have found employment in the rapidly growing white-collar occupations in the professional, technical , and clerical fields.

Do WOMEN AND MEN ENCOUNTER unequal employment prospects across occupations, given their personal characteristics? Empirical evidence presented in this article indicates that gender differences in occupational distributions remained stable during the 1990s at levels comparable to those of the 1980s. The multinomial logit model of occupational attainment set forth here also detected a significant shift of women across occupational categories if their characteristics are evaluated according to the men's occupational structure. These shifts did not change significantly throughout the 1990s and are similar to comparable estimates from the late 1970s and 1980s. A more detailed examination of the occupational shifts

Volker, "On the Determination of Occupational Attainment and Mobility," Journal of Human Resources, spring 1985, pp. 197-213; Andrew M. Gill, "Incorporating the Causes of Occupational Differences in Studies of Racial Wage Differentials," Journal of Human Resources, winter 1994, pp. 20-41; and Paul E. Gabriel, Susanne Schmitz, and Donald R. Williams, "The Relative Occupational Attainment of Young Blacks, Whites, and Hispanics," Southern Economic Journal, July 1990, pp. 35-46.
${ }^{4}$ Schmidt and Strauss, "The Prediction of Occupation"; and Gabriel and others, "The Relative Occupational Attainment."
${ }^{5}$ Following the standard approach, equation (4) is based on the assumption that men, as a group, encounter the "discrimination-free" occupational structure. The expected occupational distribution of women is obtained by summing the estimates from (4) across all workers in the women's sample. (For a discussion of this approach, see Miller and Volker, "On the Determination of Occupational Attainment"; and Gabriel and others, "The Relative Occupational Attainment.")
${ }^{6}$ Miller and Volker, "On the Determination of Occupational Attainment"; and Schmidt and Strauss, "The Prediction of Occupation."
${ }^{7}$ Gary S. Becker, The Economics of Discrimination, 2d ed. (Chicago, University of Chicago Press, 1971); and Polacheck, "Occupational Self-selection."
reveals that the expected ("discrimination-free") women's occupational distribution predicts a movement of women from white-collar to blue-collar jobs. This is unlikely, however, especially in light of recent literature on occupational employment patterns and choice by gender. Thus, U.S. women in their thirties and forties do not appear to encounter significant levels of involuntary segregation across broad occupational categories. Although gender differences in occupational attainment persist, they apparently result from voluntary choices of men and women and from long-term changes in labor markets, such as the simultaneous growth of white-collar occupations and women's labor force participation rates.
${ }^{8}$ For a summary of alternative explanations of gender employment patterns based on sociological theories of labor market outcomes, see Robert M. Blackburn, Jude Browne, Bradley Brooks, and Jennifer Jarman, "Explaining Gender Segregation," British Journal of Sociology, December 2002, pp. 513-36.
${ }^{9}$ The 1994 wave of the NLSY79 was selected because it is the last of the annual surveys; beginning in 1994, the NLSY was conducted on a biannual basis. Thus, 1994 represents the last year in which we have continuous information on labor force participation. The year 2000 was selected because it is the most recent wave available.
${ }^{10}$ The age distribution (35-43 years) of the NLSY sample used in this analysis falls within the standard classification of "prime-age" workers (generally considered to be between 35 and 54 years old).
${ }^{11}$ Employment and Earnings (Bureau of Labor Statistics, 2002), pp. 209-10.
${ }^{12}$ The multinomial logit estimates used to derive the expected occupational distributions in table 2 are available from the authors upon request. For a discussion of the multinomial logit estimation technique, see G. S. Maddala, Limited-Dependent and Qualitative Variables in Econometrics (New York, Cambridge University Press, 1983). Also, the Index of Dissimilarity value for 2001 (in table 1) refers to the entire U.S. labor force (age 20 and older). The figures for 1994 and 2000 (in table 2) are based on samples drawn from the National Longitudinal Survey of Youth (ages 34-43). Thus, the Index of Dissimilarity values for 2001 are not directly comparable with those for 1994 and 2000.

Exhibit 1. Occupational categories

| Occupation | Occupations included |
| :--- | :--- |
| Service | Service, including private household |
| Laborers | Handlers, equipment cleaners, helpers, and laborers |
| Clerical | Administrative support |
| Operatives | Machine operators, assemblers, inspectors, material movers |
| Craft | Precision production, craft, and repair |
| Sales | Sales |
| Managerial | Executive, administrative, and managerial |
| Professional and technical | Professional specialty; technicians and related support |

## Exhibit 2. Independent variables $\left(X_{j}\right)$ for the multiple logit occupational attainment model

|  | Individual characteristic |
| :---: | :---: |
| HIGRADE: | Highest grade of schooling completed by respondent in survey year. |
| YRFTEXP: | Total years of year-round full-time equivalent labor market experience since 1979calculated as (total annual hours of labor market activity)/1,750. |
| DISAB: | Set equal to 1 if an individual reports a disability that limits labor force participation, 0 otherwise. |
| MSP: | Set equal to 1 if an individual is married with spouse present, 0 otherwise. |
| AFQT: | Percentile score on the Armed Forces Qualifications Test, administered in 1980. |
| MHGRADE: | Highest grade of schooling completed by respondent's mother. |
| FHGRADE: | Highest grade of schooling completed by respondent's father. |
| SMSA: | Equal to 1 if an individual lives within a Standard Metropolitan Statistical area, 0 otherwise. |
| UNION: | Set equal to 1 if an individual reports that his or her workplace is covered by a collective bargaining agreement, 0 otherwise. |
| BLACK: | Set equal to 1 if an individual is black, and non-Hispanic, 0 otherwise. |
| HISPANIC: | Set equal to 1 if an individual is Hispanic, 0 otherwise. |

## The negative saving rate

The personal saving rate in the United States has been declining for decades; since 2005, it has been negative. This trend suggests increased personal debt and lower living standards in the long run. In a recent study in the Federal Reserve Bank of New York's Current Issues in Economics and Finance (May 2007), Charles Steindel examines some of the factors contributing to the decline in personal saving, as well some of its feared results.

Steindel begins by explaining the life cycle-permanent income model. According to the model, people effectively project their real-dollar income over their entire lifetime, borrowing when they are young, saving during their most productive working years, and consuming saved assets when they are retired. Thus, a persistent decline in saving could negatively impact household well-being in the future. But Steindel argues that "increases in wealth (assets such as stocks and houses, less debt) relative to disposable income" over the last several decades might have "worked to boost spending relative to income," thus reducing the personal saving rate. He further notes that if households predict that their permanent (future) income greatly exceeds their current (disposable) income, they might choose to save less now, counting on their ability to save more later.

Steindel notes that the data from the Bureau of Economic Analysis are preliminary. In the 1970s, early readings of reduced personal saving were later revised upward. Thus, the recent declines could be reversed later. Also, he attributes some of the recent decline in saving to the surge in energy prices in 2005 and 2006. Steindel broadens the definition of saving to include share repurchases paid to stockholders and constructs
a measure of "gross saving" that includes personal saving, undistributed corporate profits, depreciation, and government saving. By this measure, saving actually increased slightly during the past decade. Aggregate household wealth increased as well. Overall, Steindel finds little evidence to support the notion that the current low personal saving rate will jeopardize the future economic well-being of U.S. households.

## The rise in the highest incomes

Much has been written about the increase in recent decades in the inequality of the income distribution in the United States. What is behind the rise in the incomes of those at the very top of the distribution?

In "Wall Street and Main Street: What Contributes to the Rise in the Highest Incomes?" (NBER Working Paper 13270), Steven N. Kaplan and Joshua Rauh of the Graduate School of Business at the University of Chicago consider this question. They look at four groups of highly compensated individuals: top executives of firms that are not in the finance sector; financial service sector employees from investment banks and fund companies; lawyers; and professional athletes and celebrities. Kaplan and Rauh refer to the first and second groups, for short, as "Main Street" and "Wall Street."

Their evidence indicates that these
four groups account for somewhere between 15.0 percent to 26.5 percent of those who make up the very highest adjusted gross income categories (such as the top 0.1 percent, 0.01 percent and so on). The researchers believe that their assumptions are conservative and that these groups may represent even larger fractions of
these categories.
According to Kaplan and Rauh, their evidence provides support for three theories about the increase in inequality. One is the theory of skillbased technological change, which "predicts that inequality will increase if technological progress raises the productivity of skilled workers relative to unskilled workers and/or raises the price of goods made by skilled workers relative to those made by unskilled workers." As an example, they mention that computers and related advances in technology may complement skilled labor (and also substitute for unskilled labor). The complementary relationship may help to explain pay gains of professional athletes, who are able to reach more consumers because of technology, and Wall Street investors, who can acquire information and trade large amounts more efficiently.

A second theory involves the scale of companies. Dramatically increased revenues may help explain the higher compensation of some employees. A third theory is what has been called the "superstar" theory. As Kaplan and Rauh put it, this theory, first introduced by Sherwin Rosen, "can be viewed as a combination of the previous two explanations in that the individuals and firms who benefit from the technological change are likely to get larger."

## Overtime law and whitecollar workers

"Time and a Half's the American Way": A History of the Exclusion of WhiteCollar Workers from Overtime Regulation, 1868-2004. By Marc Linder, Fanpihua Press, Iowa City, Iowa, 2004, 1,342 pp., \$20/paperback.

In intricate yet luminously flowing sentences reminiscent at times of Marcel Proust, and with a fervent sense of justice rivaling that of Charles Dickens, Marc Linder has written a definitive study of a critical provision of federal labor law whose enormous impact deprives over 30 million employees of the right to minimum wage as well as time and one-half overtime pay for any work in excess of 40 hours in a workweek. The provision, a part of the Fair Labor Standards Act (FLSA) administered and enforced by the U.S. Department of Labor (DOL), says merely that the minimum wage and overtime provisions shall not apply to "any employee employed in a bona fide executive, administrative, or professional capacity
." What is most astounding about this provision, as Linder makes clear, is that there is no indication in any of the Congressional debates or committee reports on the FLSA that offers any clue what Congress intended in enacting this so-called white-collar exemption (even though Congress directed DOL to issue regulations defining the scope of the exemption).

As part of what he calls "terminological prolegomena," Linder notes the rich irony of calling this provision an exemption rather than an exclusion. In common parlance under the FLSA a professional economist, for example, would be described as "entitled to the exemption" -thus suggesting that it is the employee who derives some benefit as a result. But quite
to the contrary, since an exemption is relief from a requirement or liability, it is the employer who enjoys the benefit by being excused from paying minimum wage and overtime pay. It would hence be more accurate to say that the employee is excluded from the FLSA's protections. Linder, a law professor at the University of Iowa and arguably the country's preeminent authority on the FLSA, has written a very lengthy book that puts the white-collar exemption in its full historical context. He examines various bills passed (or at least debated) before the enactment of the FLSA in 1938 that carved out exceptions for white-collar workers; he explores the treatment of white-collar workers in the federal government; he reviews the laws of foreign countries on the subject; and, most importantly, he analyzes in great detail the various regulations that DOL issued between 1938 and 2004 that try to clarify the meaning of this provision. Linder's prodigious learning and indefatigable pursuit of facts, including numerous interviews and archival research, represent a stunning intellectual achievement.

A detailed analysis of the various DOL regulations implementing the FLSA exemption is the heart of the book, culminating in over a hundred pages that describe the gestation and birth of the latest regulatory changes in 2004. These 2004 revisions were so controversial that Congress, for the first time in the nearly 70-year history of the FLSA, sought-unsuccessfully, as it turned out-to prevent them from coming into force.

In looking at legislation before the FLSA was enacted, Linder seeks some understanding of what Congress may have had in mind in creating the FLSA's white-collar exemption. This examination includes, most importantly, state minimum wage and overtime laws and the National Industrial

Recovery Act of 1933 (NIRA), as well as various alien contract labor immigration laws and even several treaties -International Labor Organization conventions-relating to hours of work. These earlier white-collar exclusions unfortunately offer few if any clues. The numerous National Recovery Administration (NRA) codes of fair competition under the NIRA are a prime example. These codes-in effect, regulations fleshing out the NIRA-restricted working hours in various industries in order to encourage the hiring of the unemployed during the Great Depression. But the restrictions in the codes had various exceptions, such as permitting extra hours during peak periods of work and excluding certain white-collar employees completely from the hours limitations. After an extensive analysis of the many NRA hearings on fair competition codes for various industries, Linder finds little consistency in the white-collar exclusion rules that were adopted. As he notes, few unions were trying to organize white-collar workers when the codes were being developed, and indeed unions at that time often regarded office workers as potential spies for management. As a result, white-collar workers-even clerical workers, many of whom were unem-ployed-had few advocates for limited hours. The NRA codes accordingly offer almost no guidance that would illuminate the meaning of the FLSA's white-collar exemption. Thus, when DOL set out in 1938 to issue FLSA regulations fleshing out the meaning of "executive," "administrative," and "professional" employee, it truly had a tabula rasa.

The purposes of the minimum wage and overtime pay provisions are explained in the FLSA's legislative history, and for this reason-so Linder asserts-they offer some indication of how Congress must have intended
to limit the scope of the white-collar exemption. Minimum wages are intended to assure tolerable compensation for workers; overtime pay is intended to put pressure on employers to hire more workers rather than requiring those already on the payroll to work over 40 hours per week. One approach to fulfilling these purposes, even in the face of a provision that excludes white-collar workers from the FLSA's protections, is to limit the scope of the exemption to only those executive, administrative, and professional job categories in which unemployment is very low. To use a simple example, if many mid-level executives in the automobile industry are laid off, then the exemption should arguably not apply to them because otherwise the auto industry would be under no "time and onehalf" financial pressure to discourage it from forcing the mid-level executives still on the payroll to work even longer hours. Linder gives various other examples of how the regulations defining the scope of the exemption could be crafted, taking into account the basic purposes of the FLSA's standard wage requirement. These suggestions, however, seem to overlook the fact that many exemptions in the FLSA, though claimed to have various and elaborate rationales, at bottom have little more purpose than to save an employer some money without any regard to the adverse effect of the exemption on affected employees. In any event, DOL did not adopt this approach that Linder discusses.

The original white-collar regulations, issued in October 1938, generated so much interest that they were printed in full on the front page of The New York Times. They contained a two-part test for exempt status. First, there was a description of various duties that defined who was exempt, distinguishing white-collar employees from clerical employees,
technicians, and working foremen and others. (In the original regulations the definitions of executive and administrative employee were the same, because DOL regarded administrative employees as administrators or managers and thus essentially synonymous with executive employees.) Second, the regulations established a minimal salary of $\$ 30$ per week. The rationale for this requirement was that compensation is the best indicator of the importance of an employee to an employer and that white-collar employees are overwhelmingly paid on a salary basis. (The minimal-salary requirement did not apply to professional employees.) Professional employees were required for the first time in 1940 to be paid a specified minimal compensation on a salary or fee basis, but this test did not apply to lawyers or doctors.

This two-part "duties test/salary test" for exempt status has remained, in broadest outline, more or less the same since 1938. Two important regulatory changes to the salary test have occurred since then. In 1940, a second, higher-level salary was established, and employees who were paid at the higher level had fewer specified duties they had to perform in order to be exempt. The theory underlying this short test of duties, commonly called just the short test, was that employees who are paid a higher salary are more likely to be exempt and hence have fewer duties requirements. The 1940 regulations set the short test salary minimum at $\$ 100$, whereas the salary for the long test of duties (the "long test" salary) was $\$ 55$ for executive and administrative employees and $\$ 75$ for professional employees. At irregular intervals from 1940 until 2004 the salaries were adjusted upward, in order to reflect rising salaries for whitecollar employees; but the duties tests remained essentially the same.

The other important regulatory change occurred in 2004, when both the salary test and the duties tests were revamped. The long test salary was set at $\$ 455$ per week (the equivalent of $\$ 11.38$ per hour for a 40 -hour week and $\$ 23,660$ per year). The short test salary required that the employee be paid at least $\$ 100,000$ per year ( $\$ 1,923$ per week, of which at least $\$ 455$ per week had to be paid on a salary or fee basis). The rest could be paid by commissions or other nondiscretionary compensation. And for both the long test and the short test the list of duties that had to be performed was shortened. Specifically, duties required under the long test for the executive exemption were reduced from 5 to 3 , for the administrative exemption from 4 to 2 , and for the professional exemption from 4 to 1 . As for the short test duties, they were reduced from 2 to 1 (except for professional employees engaged in artistic or similarly creative or imaginative work, who even under the pre-2004 short test had to meet only 1 duty requirement).

The effect of the 2004 regulatory changes deeply troubles Linder for many reasons. He contends that the \$455 per week salary under the long test is far too low. If all of the long test salaries established in the past are adjusted for inflation using the consumer price index, the current $\$ 455$ per week is the lowest salary in nearly 50 years. As he points out, the weekly salary minimums for the long test established in 1959-\$100 for executive and administrative employees and $\$ 115$ for professional employees -in 2004 are the equivalent of $\$ 614$ and $\$ 707$, respectively, when adjusted for inflation.

Linder also believes that the revisions of the duties under the long test will make more employees exempt. A graphic example is that, before 2004, the long test required that in order
to be exempt an executive employee could not spend more than 20 percent of working time doing non-executive work (or 40 percent in the case of an employee of a retail or service establishment); a similar 20 percent limit applied to an administrative employee.(These so-called tolerances for nonexempt work recognized the fact that even executives might have to spend some time doing their own photocopying, filing, and other less exalted work.) These requirements were significantly relaxed under the long test in the 2004 regulations so that there is now a 50 percent tolerance for nonexempt work.

It remains to be seen whether the 2004 regulatory changes will have the many adverse effects on employees that Linder foresees. The new regulations have been in effect for only three years so there are not yet enough court decisions to make a definitive judgment. Nevertheless, there is little doubt that the regulations, mainly because of the reduction in the number of duties tests, will make it easier than in the past for employers to claim successfully that their white-collar employees satisfy the duties tests.

## The credit trap

Debt for Sale. By Brett Williams, University of Pennsylvania Press, Philadelphia, Pennsylvania, 2004, 131 pp., $\$ 19.95 /$ paperback.

Brett Williams, a professor of Anthropology at American University, has done extensive research of the credit industry. In this book she analyzes the marked changes that have taken place in the lives of Americans
since credit cards first began making a major impact in the 1970s. She makes an impressive case against banks and finance service companies, who, she says, pursue profits in highinterest credit cards; student loans; and "predatory lending" or marketing to the poor, less educated, more vulnerable in society. The result, she says, has been "the fall of the middle class, the strangling of small business, the exploitation of college students and the battering of the poor."

Indebtedness among Americans is proliferating. According to Professor Williams, between 1980 and 1990 the amount of our indebtedness more than doubled, from $\$ 300$ billion to $\$ 795$ billion. In 1995 , issuers of credit cards sent out 2.4 billion unsolicited credit offers and collected $\$ 65$ billion in interest, more than the GNP of Egypt. By 2003, personal debt had grown to 130 percent of disposable income, nearly one-third more than was the case in 1995. Simultaneously, some Americans have become less and less able to pay their bills, as service jobs replaced higher paying manufacturing jobs.

In the 1980 s , credit card interest and fees became the primary profit source for banks. According to Williams, the banks initially sought middle class "installment users," people who "intend to pay their bills each month but never quite manage," flooding them with a barrage of enticements. Once that market became saturated, banks focused on college and high school students and the poor. Since the 1990s, Williams claims that credit card solicitors have specifically targeted college students with ads such as "Visa: accepted at more places than you were." The bait is a low introductory interest rate, but once it expires even the "preferred" interest rate is much higher. When you are late, bounce a check, or go over your limit there are penalties, and any time
you don't pay off the balance in full, you pay interest on interest. A 1991 survey found that only 18 percent of students paid off their balances each month. By 1995, for every 100,000 college students, credit card issuers earned more than $\$ 16.5$ million a year; of this, $\$ 10$ million was interest. The next group that may be heavily targeted for credit cards could be high school students. "Within five years, your typical 15-year old will have at least a $\$ 300$ credit limit on a major card," was the prediction of one analyst cited by Williams.

Concurrently, Williams explains, finance service companies began marketing credit cards to the poor and uneducated. One method of doing this is the payday loan. This is how it works: in return for $\$ 100$, a customer writes a check for $\$ 130$ to be cashed when the customer gets paid a week or two later. The loan shop typically earns an annual interest rate of more than 1,200 percent on such loans. By 1999, there were an estimated 8,000 payday loan shops. The number of pawn shops, where interest rates approximate 200 percent, doubled during the 1980s; nationwide, there were around 14,000 shops by 2002. Other methods of offering high-cost credit to the poor include rent-to-own stores, where customers may pay 5 times the retail price, and income tax anticipation loans that can charge interest exceeding 700 percent on an annualized basis.

So, what can be done? Williams offers a number of solutions including:

1. Raise the reserve requirements for banks engaging in predatory lending.
2. Tax short-term gains and give credit for long-term holdings to encourage the creation of jobs that pay a living wage.
3. Create a nationwide usury cap onall types oflending and enforceit.
4. Loan money directly to students rather than through banks and intermediaries, offer amnesty on student loans in return for public service, and consider making a college education the type of entitlement it is in many European countries.
5. Requirebanks to provide lowcost banking services to the poor.

Brett Williams is "right on the money," both in her analysis of the problem and the solutions that she suggests above. But, to be fair, it should also be noted that Williams barely touches upon the benefit credit cards provide to responsible users. Does anyone really want to go back to the days when traveling required carrying large sums of
money and/or traveler's checks?
To those interested in purchasing this book she offers some good advice: "Don't Charge This Book!"

This section of the Review presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

## General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables $1-14,17-21,48$, and 52 . Seasonally adjusted labor force data in tables 1 and 4-9 were revised in the February 2005 issue of the Review. Seasonally adjusted establishment survey data shown in tables $1,12-14$, and 17 were revised in the March 2005 Review. A brief explanation of the seasonal adjustment methodology appears in "Notes on the data."

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average AllItems CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data-such as the "real" earnings shown in table 14-are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100 . For example, given a current hourly wage rate of $\$ 3$ and a current price index number of 150 , where $1982=100$, the hourly
rate expressed in 1982 dollars is $\$ 2(\$ 3 / 150$ $\mathrm{x} 100=\$ 2$ ). The $\$ 2$ (or any other resulting values) are described as "real," "constant," or "1982" dollars.

## Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see BLS Handbook of Methods, Bulletin 2490. Users also may wish to consult Major Programs of the Bureau of Labor Statistics, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau's monthly publication, Employment and Earnings. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet: www.bls.gov/cps/ Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:
www.bls.gov/ces/
Additional information on labor force data for areas below the national level are provided in the BLS annual report, Geographic Profile of Employment and Unemployment.

For a comprehensive discussion of the Employment Cost Index, see Employment Cost Indexes and Levels, 1975-95, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: Employee Benefits in Medium and Large Firms; Employee Benefits in Small Private Establishments; and Employee Benefits in State and Local Governments.

More detailed data on consumer and producer prices are published in the monthly periodicals, The CPI Detailed Report and Producer Price Indexes. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the Monthly Labor Review. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

## www.bls.gov/lpc/

For additional information on international comparisons data, see Interna-
tional Comparisons of Unemployment, Bulletin 1979.

Detailed data on the occupational injury and illness series are published in Occupational Injuries and Illnesses in the United States, by Industry, a BLS annual bulletin.

Finally, the Monthly Labor Review carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

## Comparative Indicators

## (Tables 1-3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on changes in compensation, prices, and productivity are presented in table 2. Measures of rates of change of compensation
and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

## Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

## Employment and Unemployment Data

(Tables 1; 4-29)

## Household survey data

## Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

## Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12 th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding

4 weeks. Persons who did not look for work because they were on layoff are also counted among the unemployed. The unemployment rate represents the number unemployed as a percent of the civilian labor force.

The civilian labor force consists of all employed or unemployed persons in the civilian noninstitutional population. Persons not in the labor force are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The civilian noninstitutional population comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The civilian labor force participation rate is the proportion of the civilian noninstitutional population that is in the labor force. The employment-population ratio is employment as a percent of the civilian noninstitutional population.

## Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of Employment and Earnings. For a discussion of changes introduced in January 2003, see "Revisions to the Current Population Survey Effective in January 2003" in the February 2003 issue of Employment and Earnings (available on the BLS Web site at www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See "Revision of Seasonally Adjusted Labor Force Series in 2003," in the February 2003 issue of Employment and Earnings (available on the BLS Web site at www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the

January-June period. The historical seasonally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July-December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691-6378.

## Establishment survey data

## Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2002 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

## Definitions

An establishment is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goodsproducing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private service-providing industries, data are collected for nonsupervisory workers, which include most employees except those
in executive, managerial, and supervisory positions. Those workers mentioned in tables 11-16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private ser-vice-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. Real earnings are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. Overtime hours represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the $1-, 3-$, and $6-$ month spans are seasonally adjusted, while those for the 12 -month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

## Notes on the data

Establishment survey data are annually adjusted to comprehensive counts of employment (called "benchmarks"). The March 2003 benchmark was introduced in February 2004 with the release of data for January 2004, published in the March 2004 issue of the Review. With the release in June 2003, CES completed a conversion from the Standard Industrial Classification (SIC) system to the North American Industry Classification System (NAICS) and completed the transition from its original quota sample design to a probability-based sample design. The indus-try-coding update included reconstruction of historical estimates in order to preserve
time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of Employment and Earnings and "Recent changes in the national Current Employment Statistics survey," Montbly Labor Review, June 2003, pp. 3-13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of Employment and Earnings, and "Recent changes in the State and Metropolitan Area CES survey," Monthly Labor Review, June 2003, pp. 14-19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4 - versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12-17 in the Review). When all returns have been received, the estimates are revised and published as "final" (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are published as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on
establishment survey data, contact the Division of Current Employment Statistics: (202) 691-6555.

## Unemployment data by State

## Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

## Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691-6392 (table 10) or (202) 691-6559 (table 11).

## Quarterly Census of Employment and Wages

## Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (ucfe) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES202 data, are the most complete enumeration of employment and wage information by industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor
market trends and major industry developments.

## Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of covered workers who worked during, or received pay for, the pay period that included the 12th day of the month. Covered private industry employment includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each uI-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An establishment is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the predominant reporting unit or statistical
entity for reporting employment and wages data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly ur report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the uI report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the installation: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into size categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level.It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total wages paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify that wages be reported for, or based on the
period during which services are performed rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as $401(\mathrm{k})$ plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

## Notes on the data

Beginning with the release of data for 2001, publications presenting data from the Covered Employment and Wages program have switched to the 2002 version of the North

American Industry Classification System (NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because coun-ty-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The necma for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1 . The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

For additional information on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691-6567.

## Job Openings and Labor Turnover Survey

## Description of the series

Data for the Job Openings and Labor Turnover Survey (JoLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JoLTS program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JoLTS sample design is a random sample
drawn from a universe of more than eight million establishments compiled as part of the operations of the Quarterly Census of Employment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JoLTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

## Definitions

Establishments submit job openings in-for-mation for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and
job openings, and multiplying that quotient by 100 .

Hires are the total number of additions to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and parttime, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100 .

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation-quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100 . The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100 .

## Notes on the data

The Jolts data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supplemental panels of establishments needed to create NAICS estimates were not completely
enrolled until May 2003. The data collected up until those points are from less than a full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled units were reporting data at that time.

In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JolTs hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12th of the
month, while the reference period for hires and separations is the calendar month; and (2) payroll employment can vary from month to month simply because part-time and oncall workers may not always work during the pay period that includes the 12th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961-5870.

## Compensation and Wage Data

(Tables 1-3; 30-37)
The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

## Employment Cost Index

## Description of the series

The Employment Cost Index (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2002 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into
about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are combined to represent one of ten intermediate aggregations, such as professional and related occupations, or one of five higher level aggregations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series-civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current eci sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

## Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

## Notes on the data

The ECI data in these tables reflect the con-version to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational
purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries in the private nonfarm economy was published beginning in 1975. Changes in total compensation cost-wages and salaries and benefits combined-were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December $2005=100$ ) are available on the Internet: www.bls.gov/ect/

ADDITIONAL INFORMATION on the Employment Cost Index is available at http://www.bls.gov/ncs/ect/home.htm or by telephone at (202) 691-6199.

National Compensation Survey Benefit Measures

Description of the series
NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

## Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having access to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as participating in an insurance or retirement plan if they have paid required
contributions and fulfilled any applicable service requirement. Employees in noncontributory plans are counted as participating regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

## Notes on the data

ADDITIONAL INFORMATION ON THE NCS benefit measures is available at http://www. bls.gov/ncs/ebs/home.htm or by telephone at (202) 691-6199.

## Work stoppages

(Table 37)

## Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

## Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate
number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

## Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stop-pages data is available at http://www. bls.gov/cba/home.htm or by telephone at (202) 691-6199.

## Price Data

(Tables 2; 38-46)
Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base pe-riod-December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982-84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 $=100$ for International Price Indexes.

## Consumer Price Indexes

## Description of the series

The Consumer Price Index (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers,
the CPI-U covers professional, managerial, and technical workers, the self-employed, shortterm workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 39. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

## Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are meaured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691-7000.

## Producer Price Indexes

## Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by
class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the 2002 North American Industry Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13 th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

## International Price Indexes

## Description of the series

The International Price Program produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price
data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

## Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691-7155.

## Productivity Data

(Tables 2; 47-50)

## Business and major sectors

## Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour, output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

## Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. Output per unit of capital services (capital productivity) is the quantity of goods and services produced per unit of capital services input. Multifactor productivity is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no selfemployed). Real compensation per hour is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. Unit nonlabor payments include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the com-
ponents of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures, land, and inventories-weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

## Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47-50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

FOR ADDITIONAL INFORMATION on this productivity series, contact the Division of Productivity Research: (202) 691-5606.

## Industry productivity measures

## Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

## Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, output indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The labor input series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. Labor compensation includes payroll as well as supplemental payments, including both legally required expenditures and payments
for voluntary programs.
Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. Combined inputs include capital, labor, and intermediate purchases. The measure of capital input represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures, land, and inventories. The measure of intermediate purchases is a combination of purchased materials, services, fuels, and electricity.

## Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Industry Productivity Studies: (202) 691-5618, or visit the Web site at: www.bls.gov/lpc/home. htm

## International Comparisons

(Tables 51-53)

## Labor force and unemployment

## Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment approximating U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For additional information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" Monthly Labor Review, June 2000, pp. 3-20 (available on the BLS Web site at:
www.bls.gov/opub/mlr/2000/06/art1full. pdf).

## Definitions

For the principal U.S. definitions of the labor
force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

## Notes on the data

The foreign country data are adjusted as closely as possible to U.S. concepts, with the exception of lower age limits and the treatment of layoffs. These adjustments include, but are not limited to: including older persons in the labor force by imposing no upper age limit, adding unemployed students to the unemployed, excluding the military and family workers working fewer than 15 hours from the employed, and excluding persons engaged in passive job search from the unemployed.

Data for the United States relate to the population 16 years of age and older. The U.S. concept of the working age population has no upper age limit. The adjusted to U.S. concepts statistics have been adapted, insofar as possible, to the age at which compulsory schooling ends in each country, and the Swedish statistics have been adjusted to include persons older than the Swedish upper age limit of 64 years. The adjusted statistics presented here relate to the population 16 years of age and older in France, Sweden, and the United Kingdom; 15 years of age and older in Australia, Japan, Germany, Italy, and the Netherlands. An exception to this rule is that the Canadian statistics are adjusted to cover the population 16 years of age and older, whereas the age at which compulsory schooling ends remains at 15 years. In the labor force participation rates and employ-ment-population ratios, the denominator is the civilian noninstitutionalized working age population, except for Japan and Germany, which include the institutionalized working age population.

In the United States, the unemployed include persons who are not employed and who were actively seeking work during the reference period, as well as persons on layoff. In the United States, as in Australia and Japan, passive job seekers are not in the labor force; job search must be active, such as placing or answering advertisements, contacting employers directly, or registering with an employment agency (simply reading ads is not enough to qualify as active search). Canada and the European countries classify passive jobseekers as unemployed. An adjustment is made to exclude them in Canada, but not in the European countries where the phenomenon is less prevalent. In some countries, persons on layoff are classified as employed due to their strong job attachment. No adjustment is made for
the countries that classify those on layoff as employed. Persons without work and waiting to start a new job are counted as unemployed under U.S. concepts if they were actively seeking work during the reference period; if they were not actively seeking work, they are not counted in the labor force. Persons without work and waiting to start a new job are counted among the unemployed for all other countries, whether or not they were actively seeking work.
For more qualifications and historical annual data, see Comparative Civilian Labor Force Statistics, Ten Countries, on the Internet at http:/www.bls.gov/fls/flscomparelf.htm

FOR ADDITIONAL INFORMATION on this series, contact the Division of Foreign Labor Statistics: (202) 691-5654 or flshelp@ bls.gov

## Manufacturing Productivity and Labor Costs

## Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity), output, total hours, compensation per hour, and unit labor costs for the United States, Australia, Canada, Japan, Korea, Taiwan, and 10 European countries. These measures are trend comparisons-that is, series that measure changes over timerather than level comparisons. BLS does not recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures-output, total labor hours, and total compensation. The hours and compensation measures refer to all employed persons (wage and salary earners plus self-employed persons and unpaid family workers) with the exception of Belgium and Taiwan, where only employees (wage and salary earners), are counted.

## Definitions

Output, for most economies, is real value added in manufacturing taken from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 is from an index of industrial production. Manufacturing value added for the United Kingdom is essentially identical to its indexes of industrial production.

Real output for manufacturing in the United States is the chain-weighted index of real gross product originating (deflated value added), produced by the Bureau of Economic

Analysis of the U.S. Department of Commerce. Most of the other economics now also use chain-weighted as opposed to fixed-year weights that are periodically updated.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). For the United States and Canada, it is defined according to the North American Industry Classification System (NAICS 97).

To preserve the comparability of the U.S. measures with those for other economies, BLS uses gross product originating in manufacturing for the United States. The gross product originating series differs from the manufacturing output series that BLS publishes in its quarterly news releases on U.S. productivity and costs (and that underlies the measures that appear in tables 48 and 50 in this section). The quarterly measures are on a "sectoral output" basis, rather than a valueadded basis. Sectoral output is gross output less intrasector transactions.

Total hours refer to hours worked in all economies. The measures are developed from statistics of manufacturing employment and average hours. For most other economies, recent years' aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, and Sweden, compensation is increased to account for other significant taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for employment-related subsidies. Self-employed workers are included in the all-employed persons measures by assuming that their compensation is equal to the average for wage and salary employees.

Unit labor costs are the costs of labor input required to produce one unit of output. They are computed as compensation in norminal terms divided by real output. Unit labor costs can also be computed by dividing hourly compensation by output per hour, that is, by labor productivity.

## Notes on the data

In general, the measures relate to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France include parts of mining as well.

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

For additional information on these series, go to http://www.bls.gov/news. release/prod4.toc.htm or contact the Division of Foreign Labor Statistics: (202) 691-5654.

## Occupational Injury and IIIness Data

(Tables 54-55)

## Survey of Occupational Injuries and IIInesses

## Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers' job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

## Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such
as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

## Notes on the data

The definitions of occupational injuries and illnesses are from Recordkeeping Guidelines for Occupational Injuries and Illnesses (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not
adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, Occupational Injuries and Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at: http://www.bls. gov/iif/

## Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events.

The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

## Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

## Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 6916175, or the Internet at: www.bls.gov/iif/

${ }^{1}$ Quarterly data seasonally adjusted.
2 Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter.
${ }^{3}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
${ }^{4}$ Excludes Federal and private household workers.
${ }^{5}$ Goods-producing industries include mining, construction, and manufacturing. Serviceproviding industries include all other private sector industries.

NOTE: Beginning in January 2003, household survey data reflect revised population controls. Nonfarm data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC based data.
2. Annual and quarterly percent changes in compensation, prices, and productivity

${ }^{1}$ Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter. Compensation and price data are not seasonally adjusted, and the price data are not compounded.
${ }^{2}$ Excludes Federal and private household workers.
${ }^{3}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes
only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
${ }^{4}$ Annual rates of change are computed by comparing annual averages. Quarterly percent changes reflect annual rates of change in quarterly indexes. The data are seasonally adjusted
${ }^{5}$ Output per hour of all employees.
3. Alternative measures of wage and compensation changes

1 Seasonally adjusted. "Quarterly average" is percent change from a quarter ago, at an annual rate.
${ }^{2}$ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard

Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NaICS and soc became the official BLS estimates starting in March 2006.
${ }^{3}$ Excludes Federal and private household workers.
4. Employment status of the population, by sex, age, race, and Hispanic origin, monthly data seasonally adjusted

${ }^{1}$ The population figures are not seasonally adjusted.
${ }^{2}$ Civilian employment as a percent of the civilian noninstitutional population.
${ }^{3}$ Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

${ }^{1}$ Average weekly wages were calculated using unrounded data.
2 Percent changes were computed from quarterly employment and pay data
adjusted for noneconomic county reclassifications. See Notes on Current Labor Statistics.

3 Totals for the United States do not include data for Puerto Rico or the

Virgin Islands.
${ }^{4}$ Data do not meet BLS or State agency disclosure standards.
NOTE: Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs. Data are preliminary.

## 29. Annual data: Average hours and earnings of production or nonsupervisory workers on nonfarm

 payrolls, by industry

NOTE: Data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC-based data
30. Employment Cost Index, compensation, by occupation and industry group

Note: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and sOC data shown prior
to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.
33. Employment Cost Index, private industry workers by bargaining status and region
[December $2005=100]$

1 The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the Monthly Labor Review Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

Note: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

${ }^{1}$ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:
M-Every month.
1-January, March, May, July, September, and November.
2-February, April, June, August, October, and December.
${ }^{2}$ Regions defined as the four Census regions.
${ }^{3}$ Indexes on a December 1996 = 100 base.
${ }^{4}$ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.
${ }^{5}$ Indexes on a December 1986 = 100 base.
${ }^{6}$ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the CPI Detailed

Report: Anchorage, AK; Cincinnatti, OH-KY-IN; Kansas City, MO-KS; Milwaukee-Racine, WI; Minneapolis-St. Paul, MN-WI; Pittsburgh, PA; Port-land-Salem, OR-WA; St Louis, MO-IL; San Diego, CA; Tampa-St. Petersburg-Clearwater, FL.
${ }^{7}$ Indexes on a November $1996=100$ base.
NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.
40. Annual data: Consumer Price Index, U.S. city average, all items and major groups

51. Unemployment rates, approximating U.S. concepts, nine countries, seasonally adjusted [Percent]

| Country | Annual Averages |  | 2005 |  |  |  | 2006 |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 2005 | 2006 | I | II | III | IV | I | II | III | IV |
| United States. | 5.1 | 4.6 | 5.3 | 5.1 | 5.0 | 5.0 | 4.7 | 4.7 | 4.7 | 4.5 |
| Canada. | 6.0 | 5.5 | 6.2 | 6.0 | 6.0 | 5.8 | 5.7 | 5.5 | 5.6 | 5.4 |
| Australia. | 5.1 | 4.9 | 5.1 | 5.1 | 5.0 | 5.2 | 5.2 | 5.0 | 4.8 | 4.6 |
| Japan.. | 4.5 | 4.2 | 4.6 | 4.4 | 4.4 | 4.5 | 4.3 | 4.2 | 4.2 | 4.1 |
| France. | 9.9 | 9.7 | 9.8 | 9.9 | 9.9 | 10.0 | 10.0 | 9.8 | 9.6 | 9.3 |
| Germany.............. | 11.2 | 10.3 | 11.4 | 11.4 | 11.2 | 10.9 | 10.9 | 10.5 | 10.0 | 9.6 |
| Italy.................... | 7.8 | 6.9 | 7.9 | 7.9 | 7.7 | 7.7 | 7.3 | 7.0 | 6.8 | 6.6 |
| Sweden.............. | 7.7 | 7.0 |  |  |  |  | - | - | - | - |
| United Kingdom.... | 4.8 | 5.5 | 4.7 | 4.8 | 4.8 | 5.1 | 5.3 | 5.5 | 5.6 | 5.5 |
| NOTE: Dash indicates data not available. Quarterly figures for France, Germany, and Italy are calculated by applying annual adjustment factors to current published data, and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures. There are breaks in series for Germany (2005) and Sweden (2005). For details on breaks in series, see the technical notes of the report Comparative Civilian Labor Force Statistics, Ten Countries, 19602006 (Bureau of Labor Statistics, March 19, 2007), available on the Internet at http://www.bls.gov/fis/flscomparelf.htm. For further qualifications and historical annual data, see the full report, also available at this site. |  |  |  |  | For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the report Unemployment rates in nine countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted, 1995-2007, (Bureau of Labor Statistics), available on the Internet at ftp://ftp.bls.gov/pub/special.requests/ForeignLabor/flsjec.txt. Data may differ between the two reports mentioned, because the former is updated on a bi-annual basis, whereas the latter is updated monthly and reflects the most recent revisions in source data. |  |  |  |  |  |

52. Annual data: employment status of the working-age population, approximating U.S. concepts, 10 countries
[Numbers in thousands]

| Employment status and country | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 |

${ }^{1}$ Labor force as a percent of the working-age population.
${ }^{2}$ Employment as a percent of the working-age population.
NOTE: Dash indicates data not available. There are breaks in series for the United States (1997, 1998, 1999, 2000, 2003, 2004), Australia (2001), Germany (1999, 2005), and
Sweden (2005). For details on breaks in series, see the technical notes of the report Comparative Civilian Labor Force Statistics, Ten Countries, 1960-2006
(Bureau of Labor Statistics, March 19, 2007), available on the Internet at http://www.bls.gov/fis/flscomparelf.htm. For further qualifications and historical annual data, see the full report, also available at this site. Data in this report may not be consistent with data in Unemployment rates in nine countries, civilian labor force basis, approximating U.S. concepts, seasonally adjusted, 1995-2007, (Bureau of Labor Statistics), because the former is updated on a bi-annual basis, whereas the latter is updated monthly and reflects the most recent revisions in source data.

[^16]$\mathrm{N}=$ number of injuries and illnesses or lost workdays;
$\mathrm{EH}=$ total hours worked by all employees during the calendar year; and
$200,000=$ base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).
${ }^{4}$ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.
${ }^{5}$ Excludes farms with fewer than 11 employees since 1976.
NOTE: Dash indicates data not available.

1 Based on the 1992 BLS Occupational Injury and IIIness Classification Manual.
2 Excludes fatalities from the Sept. 11, 2001, terrorist attacks.
3 The BLS news release of August 10, 2006, reported a total of 5,702 fatal work injuries for calendar year 2005. Since then, an additional 32 job-related fatalities were identified, bringing the total job-related fatality count for 2005 to 5,734 .
NOTE: Totals for all years are revised and final. Totals for major categories may include subcategories not shown separately. Dashes indicate no data reported or data that do not meet publication criteria. N.e.c. means "not elsewhere classified."

[^16]:    ${ }^{1}$ Data for 1989 and subsequent years are based on the Standard Industrial Classification Manual, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985-88, which were based on the Standard Industrial Classification Manual, 1972 Edition, 1977 Supplement.
    ${ }^{2}$ Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.
    ${ }^{3}$ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:
