Foreword

The National Standard Reference Data System provides effective access to the quantitative data of physical science, critically evaluated and compiled for convenience, and readily accessible through a variety of distribution channels. The System was established in 1963 by action of the President's Office of Science and Technology and the Federal Council for Science and Technology, with responsibility to administer it assigned to the National Bureau of Standards.

The System now comprises a complex of data centers and other activities, carried on in academic institutions and other laboratories both in and out of government. The independent operational status of existing critical data projects is maintained and encouraged. Data centers that are components of the NSRDS produce compilations of critically evaluated data, critical reviews of the state of quantitative knowledge in specialized areas, and computations of useful functions derived from standard reference data. In addition, the centers and projects establish criteria for evaluation and compilation of data and make recommendations on needed improvements in experimental techniques. They are nornally closely associated with active research in the relevant field.

The technical scope of the NSRDS is indicated by the principal categories of data compilation projects now active or being planned: nuclear properties, atomic and molecular properties, solid state properties, thermodynamic and transport properties, chemical kinetics, and colloid and surface properties.

The NSDRS receives advice and planning assistance from the National Research Council of the National Academy of Sciences-National Academy of Engineering. An overall Review Committee considers the program as a whole and makes recommendations on policy, long-term planning, and international collaboration. Advisory Panels, each concerned with a single technical area, meet regularly to examine major portions of the program, assign relative priorities, and identify specific key problems in need of further attention. For selected specific topics, the Advisory Panels sponsor subpanels which make detailed studies of users' needs, the present state of knowledge, and existing data resources as a basis for recommending one or more data compilation activities. This assembly of advisory services contributes greatly to the guidance of NSRDS activities.

The NSRDS–NBS series of publications is intended primarily to include evaluated reference data and critical reviews of long-term interest to the scientific and technical community.

The JANAF Thermochemical Tables Project, sponsored and monitored by agencies of the Defense Department, has been considered an important part of the National Standard Reference Data System. The tables have found wide utility in technical areas far removed from those for which the work was initiated. Consequently, when plans for a Second Edition of the JANAF Thermochemical Tables were under discussion, a suggestion was made that they be incorporated into the NSRDS–NBS publication series. This suggestion was accepted, and the present volume, NSRDS–NBS 37, is the outcome. It is hoped that this publication channel will lead to even wider distribution and greater use of these very valuable tables.

LEWIS M. BRANSCOMB, *Director*

PREFACE TO THE FIRST EDITION

Beginning in the mid-1950's, when elements other than the conventional carbon, hydrogen, oxygen, nitrogen, chlorine, and fluorine came into consideration as rocket propellant ingredients, formidable difficulties were encountered in conducting rigorous theoretical performance calculations for these new propellants. The first major problem was calculational techniques. The second was the lack of accurate thermodynamic data.

By the end of 1959, the calculational technique problem had been substantially resolved by applying the method of minimization of free energy to large, high-speed digital computers. At this point the calculations became as accurate as the thermodynamic data upon which they were based. However, serious gaps were present in the available data. For propellant ingredients, only the standard heat of formation is required to conduct a performance calculation. However, this must be known to a high degree of accuracy. For combustion products, the enthalpy and entropy must be known, as a function of temperature, in addition to the standard heat of formation.

In order to resolve the problem, a substantial experimental thermodynamic research program was initiated under the sponsorship and technical direction of Project PRINCIPIA of the Advanced Research Projects Agency. Simultaneously, a project was initiated to critically evaluate and compile consistent tables of thermodynamic properties of propellant combustion products for use by the aerospace industry. This project, known as the "JANAF Thermochemical Tables," was undertaken by the Dow Chemical Company. Since the objective of the project was to have one single source of "best available data" prepared for use by the entire industry, the JANAF Thermochemical Panel undertook the task of furnishing a critical review of the Tables prior to their publication and distribution. This approach was designed to insure that the Tables be of the highest possible quality.

PREFACE TO THE SECOND EDITION

It is appropriate to call attention to some of the reasons for the phenomenal success of the JANAF Thermochemical Tables in achieving, first, the initial limited objective of providing the standard data for the chemical rocket propulsion industry, and later, upon publication, world-wide recognition as thermodynamic reference data of the highest quality and timeliness.

First, and most obvious, there was the selection and continued support of a highly competent evaluation team, themselves engaged in a broad specturm of thermodynamic research. The personnel of the Thermal Research Laboratory of the Dow Chemical Company, under the direction of Dr. D. R. Stull and Dr. H. Prophet, have filled this role to a degree of excellence not likely to be exceeded anywhere. Moreover, the group has heroically remained productive in spite of many battles to retain continuing support, and the actual sharp reduction of funding over the past two years to a less-than-viable level.

A second important factor is the unusual approach to format, evaluation, and distribution of the Tables, as it has been followed since their inception. The primary distribution is in frequently issued loose-leaf supplements. Each previously issued table may thus be revised as often as necessary to take account of improved data. Each loose-leaf table is accompanied on its reverse side by a complete explanation of the selection of the key data, together with all references.

The third vital distinction of these Tables has been the existence of a continuing cognizant working group composed of technological users of data, thermodynamicists, and government sponsors of both research and development. Independent prepublication review of the Tables has been an important contribution of some of the members of this group; but its annual technical meetings have resulted in even more far-reaching benefits. Together, the users and generators of data have been able to establish realistic priorities for the species to be included in the Tables; at the same time the course of experimental research has been guided by the demonstration of absence or inadequacy of needed data. Although the working group no longer enjoys official recognition, the members and participants have enthusiastically volunteered to continue meeting in this important work.

Special words of appreciation are due to Dr. Charles W. Beckett, who has lined up all the technical presentations at the last six annual meetings of the working group; and to Mr. Curtis C. Selph who has served with wisdom and insight as the Air Force project monitor for the JANAF Thermochemical Tables contracts.

JOSEPH F. MASI
Air Force Office of Scientific Research

Arlington, Virginia
October, 1970

Members of the JANAF Thermochemical Panel (1959-1961) and the JANAF Thermochemical Working Group (1961-1964) were:

- T. O. Dobbins, Advanced Research Projects Agency (Past Chairman)
- W. H. Jones, Institute for Defense Analysis; Aerospace Corporation (Past Chairman)
- W. G. May, Institute for Defense Analyses; Esso Research and Engineering Company (Past Chairman)
- C. W. Beckett, National Bureau of Standards (Vice Chairman)
- G. W. Avery, Chemical Propulsion Information Agency (Past Secretary)
- B. K. Farris, Chemical Propulsion Information Agency (Past Secretary)
- T. L. Reedy, Chemical Propulsion Information Agency (Secretary)
- B. J. Alley, Army Materiel Command
- P. W. Bender, University of Wisconsin
- W. A. Bernett, Bureau of Naval Weapons
- B. Brown, Hercules Powder Company
- C. L. Funk, Jet Propulsion Laboratory
- J. S. Gordon, Thiokol Chemical Corporation
- L. J. Gordon, Aerojet-General Corporation
- S. A. Greene, North American Aviation, Incorporated
- C. B. Henderson, Atlantic Research Corporation
- D. L. Hildenbrand, Philco Corporation
- J. L. Margrave, University of Wisconsin
- J. P. McCullough, U.S. Bureau of Mines
- P. L. Nichols, Jr., Jet Propulsion Laboratory
- C. C. Selph, Air Force Systems Command
- D. R. Stull, Dow Chemical Company

The Thermochemical Working Group of the Interagency Chemical Rocket Propulsion Group (ICRPG) has consisted of the following at various times during its existence (1964-1969).

Members

- J. F. Masi, Air Force Office of Scientific Research (Chairman)
- C. W. Beckett, National Bureau of Standards (Vice Chairman)
- T. O. Dobbins, Advanced Research Projects Agency
- S. Gordon, National Aeronautics and Space Administration
- R. Jackel, Office of Naval Research
- J. Murrin, Naval Ordnance Systems Command
- R. Odom, Army Materiel Command
- C. E. Selph, Air Force Rocket Propulsion Laboratory
- D. Squire, Army Research Office

Participants

- G. S. Bahn, Marquardt Corporation
- B. Brown, Hercules, Incorporated
- H. F. Calcote, AeroChem Research Laboratories
- J. P. Coughlin, Aerojet-General Corporation
- J. S. Gordon, Atlantic Research Corporation
- D. R. Douslin, U.S. Bureau of Mines
- M. Farber, Space Sciences, Incorporated
- R. M. Fristrom, Applied Physics Laboratory
- C. B. Henderson, Atlantic Research Corporation
- D. L. Hildenbrand, Douglas Aircraft Company
- J. L. Margrave, Rice University

W. G. May, Esso Research and Engineering Company
W. Mitchell, Thiokol Chemical Corporation
C. F. Robillard, Jet Propulsion Laboratory
L. Schieler, Aerospace Corporation
C. H. Shomate, Naval Weapons Center
D. R. Stull, Dow Chemical Company
M. Zimmer, Naval Ordnance Station

Secretariat (Chemical Propulsion Information Agency)

T. Gilliland
M. McCormack
T. L. Reedy

Project Personnel

The Tables began under the direction of Daniel R. Stull in 1959. Major contributions in the first two years were made by Thomas E. Dergazarian, Samuel Levine and Louis A. DuPlessis. In the years from 1961 to 1969 the major contributors were Jing Chao, Harold Prophet, Alan N. Syverud and Andrew T. Hu. In 1969 Harold Prophet succeeded Daniel R. Stull as project director. At present Alan N. Syverud, Andrew T. Hu and Jerry L. Curnutt are the principal contributors.

Special mention must be made of Alan N. Syverud for his help in the technical editing of the Tables. Also G. C. Sinke has aided the project on numerous occasions with criticism, advice and tables.

We also wish to acknowledge the valuable asssistance of Norma Dumont 1959-64, Viola E. Harrington 1964-66, Carol S. Scheffler 1966-67, Wildene B. Harris 1967-68 and Mary J. Walter since 1968 in the typing of these Tables. Isabel Carr has provided valuable services to the group in abstracting, searching and ordering documents, and proof reading the Tables.

We also wish to thank the staff of the Computation Research Laboratory for their assistance in the many facets of the production of these Tables.

DANIEL R. STULL
HAROLD PROPHET

Library of Congress Catalog Card Number: 77-611423

CONSTANTS USED

The fundamental constants are those recommended by the International Union of Pure and Applied Chemistry as reported by F. D. Rossini, Pure and Applied Chemistry, 9, 453 (1964). The physical scale based on the atomic mass of $^{12}C = 12$ reported by A. E. Cameron and E. Wichers, J. Am. Chem. Soc. 84, 4175 (1962) is employed. The temperature scale is nominally the 1948 International Practical Temperature Scale for measured quantities and nominally the thermodynamic temperature scale for calculated gaseous quantities. The probable errors between these scales and the 1968 International Practical Temperature Scale are given by T. B. Douglas, J. Research Natl. Bur. Std. 73A, 451 (1969).

Fundamental Constants

Name	Symbol	Value	Units
Velocity of Light	c	2.997925×10^{10}	cm s^{-1}
Planck Constant	h	6.6256×10^{-27}	erg s
Avogadro Constant	N	6.02252×10^{23}	mol^{-1}
Faraday Constant	$\mathcal{F}$	96,487.0	C mol^{-1}
Absolute temperature of the "ice point", 0°C	$T_{0°C}$	273.1500	K
Molar volume of ideal gas	$V_{0°C}$ (1 atm)	22,413.6	cm^3 mol^{-1}
Pressure-Volume product for a mole of gas at 0°C and zero pressure	$(PV)^{P=0}_{T_{0°C}}$	2271.06	J mol^{-1}
Electronic Charge	e	1.60210×10^{-19}	C
Gas constant	R	8.3143 1.987165	J deg^{-1} mol^{-1} cal deg^{-1} mol^{-1}
Boltzmann Constant	k	1.38054×10^{-16}	erg deg^{-1} $molecule^{-1}$
Second radiation constant	c_2	1.43879	cm deg
Constant relating wave number and energy per mole E, in the relation $(\Delta E)=Nhc(\Delta\nu)=Z(\Delta\nu)$	Z	11.96255	J cm mol^{-1}

Defined Constants

Name	Symbol	Value	Units
Standard gravity	g	980.665	cm s^{-2}
Standard atmosphere	atm	101 325	N m^{-2}
Standard millimeter of mercury pressure	mmHg	1/760	atm
Thermochemical calorie	cal	4.1840	J

SYMBOLS AND TERMINOLOGY

Throughout these tables, the symbols used are defined as follows:

amorph.	Amorphous state
B	The rotational constant for diatomic or linear molecules
C_p	Molar heat capacity at constant pressure
c	Crystalline state
D	Centrifugal distortion constant
D_0	Dissociation energy required to break a bond at 0°K
E	Internal or intrinsic energy
G or F	Gibbs energy = E + PV - TS = H - TS
g_i	Quantum weight of electronic states
( )	Parentheses following a vibrational frequency are used to indicate the degeneracy
g	Gaseous state, or statistical weight
GFW	Gram Formula Mass
gls	Glassy state
H	Enthalpy (or heat content) = E + PV
I_A, I_B, I_C	Principal moments of inertia of a molecule
$I_AI_BI_C$	Product of the principal moments of inertia of a molecule
K	Equilibrium constant
k	Hooke's Law force constant
liq. or ℓ	Liquid state
ln	Logarithm to the base e (e = 2.7182818)
log	Logarithm to the base 10
n	Number of potential maxima in an internal rotation
P	Pressure in atmospheres
r	Internuclear distance
S	Entropy
T	Temperature in degrees Kelvin (T° = t° + 273.15°)
t	Temperature in degrees Celsius
V	Volume
V_o	Potential barrier
x	First order vibrational anharmonicity constant
y	Second order vibrational anharmonicity constant
α	Vibrational-rotational interaction constant
ε	Electronic energy level
μ	Reduced mass of the molecule
ρ	Density
σ	Symmetry number
ω	Vibrational frequency
[ ]	Square brackets enclose estimated quantities

Subscripts

a	Atomization
b	Boiling point at one atmosphere pressure
c	Combustion, or critical state
d	Dissociation
e	Equilibrium position
f	Formation from elements in their standard states
i	The i th quantity
m	Melting
p	Constant pressure
r	Reaction
s	Sublimation
t	Transition
v	Vaporization

In addition to the above symbols, the spectroscopic symbols and terminology employed by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., and "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., New York, are adopted.

Circular superscript, °, indicates the thermodynamic standard state.

Numerical subscript, as $_{298.15}$, denotes temperature in Kelvins.

Δ indicates the increment in a given property for a given process or reaction, taken as the value for the final state (or sum for the products) less that for the initial state (or sum for reactants).

ΔH, ΔG, ΔS, ΔC_p equal the increment in enthalpy, Gibbs energy, entropy and heat capacity, respectively, for a process or reaction.

ΔH_f° represents the standard enthalpy of formation, which is the increment in enthalpy associated with the reaction of forming the given compound from its elements, with each substance in its thermodynamic standard state at the given temperature.

$\Delta H^\circ_{c\ 298.15}$ symbolizes the enthalpy of combustion of a given substance, in gaseous oxygen to completely oxidized products at 25°C. and constant pressure, with all reactants and products in their appropriate standard states.

SYMBOLS AND TERMINOLOGY

$\Delta H^\circ_{r\ 298.15}$ represents the enthalpy change in a given reaction at 25°C and constant pressure with all the reactants and products in their appropriate standard states.

When the reaction or process evolves heat, the sign of the change in enthalpy is negative. Conversely, when the reaction or process absorbs heat, the sign of the change in enthalpy is positive.

ΔG°_f or ΔF°_f denotes the standard Gibbs energy of formation, which is the increment in Gibbs energy associated with the reaction of forming the given compound from its elements, with each substance in its thermodynamic standard state at the given temperature.

$\mathrm{Log}_{10}K_p$ stands for the logarithm (to the base 10) of the thermodynamic equilibrium constant of formation for the reaction of forming the given compound from its elements at the indicated temperature.

$(H^\circ_T - H^\circ_{298.15})$ indicates the enthalpy (or heat content) in the standard state at the temperature T less the enthalpy in the standard state at 298.15 K.

$(G^\circ_T - H^\circ_{298.15})/T$ or $(F^\circ_T - H^\circ_{298.15})/T$ denotes the Gibbs energy function in the standard state at temperature T, and is defined as $-S^\circ_T + (H^\circ_T - H^\circ_{298.15})/T$.

S°_T represents the absolute entropy of the thermodynamic standard state at the absolute temperature T, omitting contributions from nuclear spins.

The Standard State is taken as the state at one atmosphere pressure and the temperature under consideration for the solid, liquid, and ideal gas. Only homogeneous substances are considered here.

The Reference State applies to elements in their stable standard state. Consequently the Reference State tables presented here are either single phase or polyphase tables.

CHANGES IN SYMBOLS ON TABLES DATED 6-30-66 OR LATER

The following symbols are used, without periods, to indicate units as follows:

Symbol	Unit	Symbol	Unit
Å	angstrom	eu	calories per degree-mole
atm	atmosphere	g	gram
cal	calorie	J	joule
deg	degree (temperature)	kcal	kilocalorie
°C	degree Celsius	mm	millimeter
°K	degree Kelvin	mol	mole
eV	electron volt	gibbs	calories per degree

Subscripts as defined earlier are used as symbol modifiers but are placed on the same line, thus, heat capacity is abbreviated as Cp°, enthalpy of formation as ΔHf°, etc.

RELATIONSHIP TO SI UNITS

The symbols cal. $\mathrm{mole}^{-1}\ \mathrm{deg}^{-1}$ and gibbs/mol are identical and refer to units of calories per degree-mole. These units can be converted to SI units of joules per degree-mole by multiplying the tabulated values by 4.184. Similarly values in kilocalories per mole can be converted to joules per mole by multiplying with the factor 4184. For further discussions of the SI system and for conversions from other units the reader should consult Pure and Applied Chemistry, 21, 1 (1970).

EVALUATION OF THERMODYNAMIC DATA

A. Interconsistency

The basic aim of these thermodynamic property tables is to provide a related and consistent set of enthalpies and Gibbs energies of formation. This allows the prediction of the enthalpy and gibbs energy changes of any reaction among the constituent of the tables. Since the enthalpy and Gibbs energy of formation are related to each other by the entropy of formation we may choose to make consistent any two of these quantities. The entropy, which is an absolute quantity in thermochemical calculations is ideal for this purpose. Since the enthalpy of reaction is the most common link between different materials, we adopt it as the other consistent quantity. Unfortunately enthalpies are not absolute quantities and in order to achieve consistency it is necessary to provide a consistent base. This is done by referring all enthalpies of formation to the elements in their reference states. By convention the enthalpy of formation of an element in its reference state is zero at all temperatures.

The reference state may be single phase or multiphase and examples of both kinds are found in this compilation. In these tables we have generally chosen the ideal diatomic gas for the reference state of permanent gases such as O_2, N_2, Cl_2 etc. For elements which are solid at room temperature we adopt the solid state up to the melting point, then the liquid up to the boiling point, and then the gas phase. These choices are arbitrary and vary in different compilations. Enthalpies or Gibbs energies of formation taken from different sources should be checked to ensure that the reference states are the same.

The choice of reference states is the first step in any scheme for interconsistency, and is the relation of all quantities to comparable bases. The next step in obtaining an interconsistent set of values, ideally, would be to take all the measured values of enthalpies, Gibbs energies and entropies of reaction and, after adjustment to the proper reference states, to solve the whole set simultaneously. This would provide values for enthalpies, Gibbs energies and entropies which when combined would yield the minimum overall deviations from the measured values. We have already taken this approach in a limited sense by treating grou of interrelated fluorides simultaneously. Hopefully with even larger memories in computers we shall be able to move towards the ultimate goal. As an interim solution it is necessary to fix, simultaneously when possible, certain key values for common reactants such as water, hydrochloric acid, etc., these can then be used to help fix smaller groups of interrelated compounds.

Because of the several revisions of these tables we do not claim to maintain perfect interconsistency. However, the consistency of the tables is a prime concern and a cause for revision if the effects are of the same order of magnitude as the stated uncertainties. As an example, over 100 fluoride tables have been revised since a new HF gas table was adopted in December 1968.

Another type of consistency is involved in systems where properties must be estimated. For example the estimation of certai properties of a series of halides must be done so that the proper graduation in properties occurs from fluoride to iodide and from polyhalide to monohalide. Similarly the evaluation of experimental data must be done in a consistent manner, and this is discussed in the next section.

B. General Evaluation Techniques

1. The Second-Law Method

Starting from the equation $\Delta G° = -T\ell nK$, by differentiation with respect to T and substitution of $d(\Delta G°)/dT = -\Delta S°$, we obtain $\Delta H° = RT^2 d(\ell nK)/dT$, the well known van't Hoff equation. By substituting $dT = -T^2 d(1/T)$ one obtains $\Delta H° = -Rd(\ell nK)/d(1/T)$, thus, the slope of a ℓnK versus $1/T$ plot is $-\Delta H°/R$. If $\Delta H°$ is constant then the slope is constant and the plot is a straight line. Since the variation of $\Delta H°$ with temperature is often quite small it is customary to assume a straight line relationship. This method of obtaining heats of reaction from equilibrium measurements is known as a "second-law" calculation. However, it should be noted that for greatest accuracy the equilibrium measurements should extend over a wide range of temperature, and in this case $\Delta H°$ is probably not constant. Curvature corrections can be applied by assuming a specific form for the variation of $\Delta H°$ with temperature, however, the effects of such corrections are of significance only with very precise measurements. It should be noted that the second law cannot be applied to a single observation, but the third-law method, which is described below, can be used. The second-law method can be applied when only relative values of the equilibrium constant are available, for example, from mass-spectroscopic intensity measurements.

2. The Third-Law Method

The third-law method is based on a knowledge of the absolute entropy of the reactants and products. It allows the calculatio of a reaction enthalpy from each data point when the change in the Gibbs-energy function for the reaction is known. The Gibbs-energy function is defined as $gef_T = (G°_T - H°_{ref})/T$ and is easily calculated from the relation

$$S°_T = -(G°_T - H°_T)/T = (H°_T - H°_{ref})/T - (G°_T - H°_{ref})/T$$

thus,

$$gef_T = -S°_T + (H°_T - H°_{ref})/T.$$

From the definition we can write for the change in a reaction

$$\Delta G°/T = \Delta gef_T + \Delta H°_{ref}/T = -R\ell nKp$$

thus,

$$\Delta H°_{ref}/T = -R\ell nKp - \Delta gef_T$$

where Δ signifies Σ products $-\Sigma$ reactants.

In the JANAF Thermochemical Tables, Gibbs-energy functions are based on 298 K and, thus, yield enthalpies at 298 K regardless of the temperature of the reaction. It should be noted that, since most of these tables are single phase tables, the Gibbs-energy functions of liquids are based on liquid at 298 K even though it may not exist at 298 K. This differs from the usual convention of combining all condensed phases into one table; in this case the enthalpy of reaction refers to the state stable at the base temperature. In these tables the functions always refer to the state of the table at 298 K regardless of its stability. For example, if the vapor pressure over liquid copper is analysed using Cu(ℓ) Gibbs-energy functions the enthalpy of vaporization at 298 K will result. To calculate the enthalpy of sublimation of Cu it is necessary to add the heat of melting at 298 K, which is the difference in the heat of formation of Cu(ℓ) and Cu(c) at 298 K. It should also be noted that Gibbs-energy functions are always negative, thus the function $-(G^\circ_T-H^\circ_T)/T$ is usually tabulated and the proper sign must be remembered when using these functions.

The analysis of data by the third law is generally considered superior to the second-law analysis. It is definitely superior if the Gibbs-energy functions are measured, because each data point is independent of the others. Thus, third-law analysis will often reveal trends in the equilibrium constants of a set of data that indicate nonequilibrium or erroneous values. We have found a combination of the two methods to be so valuable that a third-law calculation is always accompanied by a second-law treatment of the same data. The calculation is done in ascending temperature order to give ΔH_{298} and its deviation from the mean, δ, and the calculated log K_p and its deviation from the least-squares line. Third-law analyses enables bad points to be seen as deviations from the general trend of the differences; thus the method can be used even when the Gibbs-energy functions are estimated. If these bad points are located on the ends of the data set, the second-law line often fits quite well through them and by itself does not arouse suspicion. Moreover, the dropping of such points can bring widely discordant slopes into agreement with each other and often with the third-law values. The data sets given in Table 1 illustrate these comments. The first set of data contains all the reported points and is in disagreement with earlier values around 54 kcal/mole. The third-law analysis indicates the first two points are poor, and the effect of dropping these two is shown in the second set of data. This latter second-law slope has changed considerably; the heat is in good agreement with the earlier data and with the third law. The size of the third-law deviations in the second set indicates that the data are not very reproducible. A deviation of 0.5 kcal at 1000°K represents an uncertainty of 30% in the measured equilibrium constants.

If measured Gibbs-energy functions are available, third-law analysis is preferred; however, if the data are good, the second-law value should agree. When the Gibbs-energy functions are estimated, the third-law values derived from them must be handled carefully. Values that are constant and that agree with the second-law enthalpy indicate that the Gibbs-energy functions and equilibrium data are mutually consistent. A drift with temperature of the third-law values indicates errors in either the data or the functions. The magnitude of such drifts is often given in the table write-up and represents the entropy change required to bring the second- and third-law values into agreement. If the drift is within the experimental entropy uncertainty then the data are acceptable. Drifts which are much larger than reasonable entropy errors generally indicate failure to attain equilibrium.

Table 1. Analysis of Equilibrium Data

3. Heat Capacities

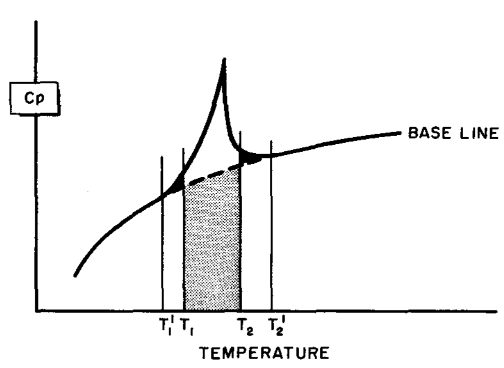
The evaluation of reported values is a relatively subjective procedure, but the analysis should be as objective as possible and therefore certain ground rules must be laid. The first step is the fitting by orthogonal polynomials and the computer-generated plotting of all information so that a general idea of the agreement can be visually obtained. If certain data sets differ from the majority, they are examined for possible causes of the difference. Calibration data, sample purity, and experimental scatter are checked. If the source of error can be located, the data are given appropriately less weight. Otherwise all data of equal reliability are considered equal, even if they disagree. Such data are then smoothed by a weighted orthogonal polynomial curvefit. Enthalpy data are smoothed similarly and heat capacities are derived directly from the differentiated polynomial. The smoothing of enthalpy data requires constraining the fit so that it passes through zero at the reference temperature. Additional constraints are often used to fix the heat capacity at 298 K, or to join enthalpy data smoothly with low-temperature heat capacities.

4. Transitions

The evaluation of solid state transitions involves first the recognition of the type of transition, which may not always be obvious. A first-order transition such as fusion involves a change of enthalpy and entropy at the transition point, whereas second-order transitions involve only discontinuities in heat capacity. Because of impurities and other factors, all first-orde transitions do not occur at one temperature; rather, they spread a little on either side and are sometimes difficult to distinquish from λ-type second-order transitions. In order to evaluate the enthalpy of a first-order transition from heat-capacity data, an enthalpy change $(H_{T_2} - H_{T_1})$ from T_1 to T_2°K must be reported on either side of the transition. The normal heat-capacit curve is extended forward and backward to the temperature of the transition-heat-capacity maximum to form a base line. If T_1' a T_2' are the temperatures at which the transitional heat capacity curve leaves and rejoins the base line, and ubl and obl designa under and over the base line, the heat of transition given by

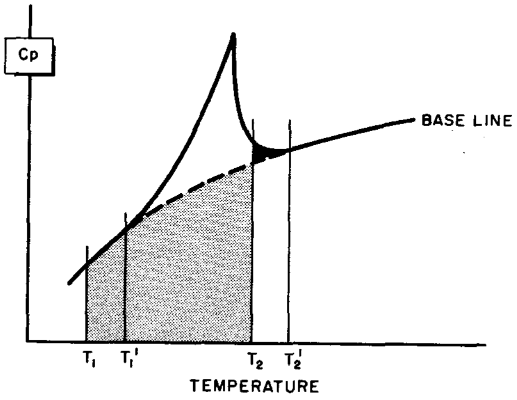
$$\Delta H_t = (H_{T_2} - H_{T_1}) - (H_{T_2} - H_{T_1})_{ubl} + (H_{T_1'} - H_{T_1})_{obl} + (H_{T_2} - H_{T_2'})_{obl}$$

Figures 1 and 2 show two possible cases. The shaded areas represent the enthalpy over the base line and cross-hatched areas the enthalpy under the base line.



EVALUATION OF TRANSITIONAL ENTHALPIES

FIGURE 1



EVALUATION OF TRANSITIONAL ENTHALPIES

FIGURE 2

Many enthalpies of fusion and enthalpies of solid-state transitions are obtained from enthalpy measurements and therefore require different treatment. Here the heats are given directly by the difference in enthalpy at the transition temperature. Normally, the enthalpy above and below can be smoothly extended to the temperature of transition, although the transition temperature may not be clearly obtainable from the enthalpy data.

The heats of the remaining transitions, vaporization and sublimation, are evaluated from equilibrium data by the second- and third-law methods just described except when calorimetric measurements are available.

5. Equilibrium

Perhaps the most significant factors to be established in evaluating equilibrium data are that equilibrium was attained and that the process was properly described. For example, in a sublimation process the most accurate measurements are valueless if the vapor phase is not uniquely defined. If polymerization or breakdown might have occurred, the first order of business is to establish the exact reaction. Because mass spectroscopy has shown that vapor phases are often extremely complex, it is almost a requirement that before equilibrium data can be accepted the vapor phases must be examined by a mass spectrometer to ensure their composition. Some methods of measurement are less accurate than others and should be given less weight. For example, equilibria determined in a mass spectrometer are usually quite rough because many approximations and uncertainties are involved in obtaining an absolute pressure measurement. On the other hand, measurements of the electromotive force of reversible cells can have great accuracy. Once the system is defined and equilibrium data are available, the data are analyzed by the second- and third-law methods.

CONSTRUCTION OF THE TABLES

1. Solid Phase

To produce a final table after all of the data have been evaluated or estimated, the enthalpy of formation, the entropy at 298 K, and the heat capacity at reasonable intervals through the temperature range of interest are needed. The enthalpy is obtained from the heat capacity by evaluating $\int_{298}^{T} C_p dT$. The entropy is similarly obtained from the heat capacity by evaluating $\int_{298}^{T} (C_p/T)dT$. The Gibbs energy function is then obtained from the relation $(G^\circ_T - H^\circ_{ref})/T = -S^\circ_T + (H^\circ_T - H^\circ_{ref})/T$. Enthalpies of formation at temperatures other than 298 K require a knowledge of the enthalpies of the reference elements:

$$\Delta Hf^\circ_T = \Delta Hf^\circ_{298} + (H_T - H_{298})_{compd} - \Sigma(H_T - H_{298})_{elements}$$

The Gibbs energy of formation is readily calculated from the heat of formation when the entropies of the elements are known. Thus

$$\Delta Gf^\circ_T = \Delta Hf^\circ_T - T[S_T(compd) - \Sigma S_T(elements)]$$

The logarithm of the equilibrium constant of formation is then found from the relation $\Delta Gf^\circ_T = -4.5756T \log K_p$.

Until now, we have only considered the calculation of values above 298 K; however, it is desirable to have data all the way to absolute zero. The temperature 0 K is a natural base for measurements involving gases in their lowest energy state, and values are needed in order to convert to the thermochemical reference temperature of 298 K. There is no basic difference in evaluating low-temperature data, but many more heat-capacity points are needed because of the large curvature. It is also necessary to evaluate the starting entropy at some temperature above 0 K because data rarely extend to below 5 K. In order to evaluate enthalpy it is necessary to start with a value above zero and integrate up to 298 K; then the value at 298 K is subtracted from the intermediate values, giving negative values below 298 K.

The tables extend to well above the normal melting point to facilitate the use of the tables by computers which can then interpolate values accurately right at the melting point. Dotted and solid lines indicate the end of the phase stability and solid-state transitions respectively.

2. Liquid Phase

The construction is identical with that used for the solid phase; however, the required data at 298 K are not usually readily available. The data are obtained by calculating a preliminary table using the chosen heat capacities with zero values for ΔHf°_{298} and S°_{298}. The correct starting values are then determined by comparing the values from the tables of crystal and liquid, using the following equations:

$$\Delta Hm^\circ = \Delta Hf^\circ_{Tm}(\ell) - \Delta Hf^\circ_{Tm}(c)$$

$$\Delta Sm^\circ = \frac{\Delta Hm^\circ}{Tm} = S^\circ_{Tm}(\ell) - S^\circ_{Tm}(c)$$

The correct values at 298 K may be obtained from the above relations. A typical liquid table is extrapolated both below the melting point and above the boiling point to facilitate interpolation near the phase boundaries.

3. Gas Phase

The data required for the various types of molecules are summarized below. The equations used are given in the section on Calculational Methods. All molecules require the gram formula mass and enthalpy of formation at 298 K.

Additionally, monatomic species require: $\varepsilon_0, \varepsilon_1 \ldots \varepsilon_n$ and $g_0, g_1 \ldots g_n$

Diatomic species require: $B_e, \sigma, x_e, \omega_e, \alpha_e, \varepsilon_i, g_i$ (i = 0,... n)

Linear polyatomic species require: B_e, σ, ω_i (i = 1,... 3N-5), ε_i, g_i (i = 0,... n)

Nonlinear polyatomic species require: σ, $\log I_A I_B I_C$, ω_i (i = 1,... 3N-6), ε_i, g_i (i = 0,... n)

ε_i is the energy of the i th electronic level
g_i is the statistical weight of the i th electronic level
B_e is the rotational constant
σ is the symmetry number
x_e is the anharmonicity correction = $\omega_e x_e/\omega_e$
ω_e is the fundamental frequency of a diatomic molecule
ω_i is a fundamental frequency of a polyatomic molecule
α_e is the rotational vibrational interaction constant
N is the number of atoms in the molecule
$I_A I_B I_C$ is the product of the moments of inertia

Monatomic species often have a large number of electronic levels; it is usual to average the higher levels taking account of the individual multiplicities. Diatomic and polyatomic species sometimes have several excited states which are low enough to make appreciable contributions. These states are treated by direct summation over the individual partition functions using anharmonic-oscillator approximations for each state. If vibrational and rotational constants for the higher states are not available the calculations are simplified by assuming the ground state values for each state.

4. Multiphase Tables

Tables which show only values for the real phases at one atmosphere pressure are multiphase tables. In this compilation they are generally reference state tables, though some solid phase tables include more than one phase. Multiphase tables can always be recognized by the presence of solid lines, indicating phase transitions, on the table. They are prepared in a manner similar to tables for condensed phases. The functions are evaluated in the same manner as for a solid up to the first transition point; then the heat and entropy of transition are added and the integration is continued using the second-phase heat capacities. At each phase boundary the above process is repeated.

USE OF TABLES

The rapid proliferation of thermodynamic tabulations in recent years brings with it the possibility of serious abuse of th information in them. First, as we explained earlier, not all tabulations are based on the same reference states. To avoid thi pitfall it is helpful to write down the reaction and check the value and state of each component. It is even better to utilize only a single compilation whenever possible, because values from different compilations may not be consistent or compatible. Second, the base temperatures of compilations differ between 0 and 298 K. Only enthalpies and Gibbs-energy functions are affected, but they can result in serious errors if used indiscriminately.

A different type of error is caused by misunderstanding the significance of negative Gibbs-energy changes. For example, m species in the JANAF Thermochemical Tables have large negative Gibbs energies of formation at 6000 K. This does not necessaril imply that the species are stable, but only that the Gibbs-energy change from the elemental reference state is negative. In fa nearly all the elements are monatomic gases at 6000 K, and the reference states are generally unstable with respect to the atom Similarly, a negative Gibbs-energy change does not mean a reaction will occur, but means only that the reaction is favorable as written. For example, at 298 K

$$C + O_2 \rightarrow CO + 1/2\ O_2 \qquad \Delta G_{298} = -32.8 \text{ kcal/mole}$$

However, at normal pressures this reaction would generally be recognized as unlikely in view of

$$C + O_2 \rightarrow CO_2 \qquad \Delta G_{298} = -94.3 \text{ kcal/mole}$$

Similarly, in combining free energies of reaction, one should be careful not to combine impossible reactions with possible ones to obtain an over-all favorability:

$$4C + H_2 + O_2 \rightarrow C_2H_2 + 2CO \qquad \Delta G = -15.6 \text{ kcal/mole}$$

This equation is impossible because we cannot combine the reactions

$$2C + H_2 \rightarrow C_2H_2 \qquad \Delta G = +50.0 \text{ kcal/mole}$$

and

$$2C + O_2 \rightarrow 2CO \qquad \Delta G = -65.5 \text{ kcal/mole}$$

by simple addition. Both reactions must be written so that they are possible. They then become

$$C_2H_2 \rightarrow 2C + H_2 \qquad \Delta G = -50.0 \text{ kcal/mole}$$

$$2C + O_2 \rightarrow 2CO \qquad \Delta G = -65.6 \text{ kcal/mole}$$

Then by simple addition

$$C_2H_2 + O_2 \rightarrow 2CO + H_2 \qquad \Delta G = -115.6 \text{ kcal/mole}$$

Although these tables have been continuously revised it is not possible to keep all the tables fully revised with the latest da Thus, each table indicates the dates of each revision at the foot of the tabular values. The latest date is most important sin information generated after that date has not been incorporated. The frequency of revisions often indicates the level of resea activity on the compound and may indicate further changes in the future.

CALCULATIONAL METHODS

The presentation of Mayer and Mayer "Statistical Mechanics", John Wiley & Sons, Inc., New York, (1940) forms the basis for the expressions given below for the ideal gas state. The calculations have been carried out by a Burroughs B5500 electronic computer.

I. Ideal Monatomic gas

(a) Translation

$(H^\circ - H_0^\circ)/T = C_p^\circ = 4.967913$ cal deg^{-1} mol^{-1}.

$-(G^\circ - H_0^\circ)/T = 6.863426 \log M + 11.439043 \log T - 7.282868$ cal deg^{-1} mol^{-1}.

$S^\circ = 6.863426 \log M + 11.439043 \log T - 2.314954$ cal deg^{-1} mol^{-1}.

(b) Electronic

$$C_p^\circ = \frac{4.113664}{T^2}\left[\frac{\sum \varepsilon_i^2 g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}} - \left(\frac{\sum \varepsilon_i g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}}\right)^2\right] \text{cal deg}^{-1}\text{ mol}^{-1}.$$

$$(H^\circ - H_0^\circ)/T = \frac{2.859114}{T}\,\frac{\sum \varepsilon_i g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}} \quad \text{cal deg}^{-1}\text{ mol}^{-1}.$$

$$-(G^\circ - H_0^\circ)/T = 4.575617 \log \sum g_i e^{-\frac{1.438790\,\varepsilon_i}{T}} \quad \text{cal deg}^{-1}\text{ mol}^{-1}.$$

$$S^\circ = \frac{2.859114}{T}\,\frac{\sum \varepsilon_i g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}}{\sum g_i e^{-\frac{1.438790\,\varepsilon_i}{T}}} + 4.575617 \log \sum g_i e^{-\frac{1.438790\,\varepsilon_i}{T}} \quad \text{cal deg}^{-1}\text{ mol}^{-1}.$$

II. Ideal Diatomic Gas

(a) Translation and Rotation

$C_p^\circ = 6.955079 + 0.0914148\,(B/T)^2$ cal deg^{-1} mol^{-1}.

$(H^\circ - H_0^\circ)/T = 6.955079 - 0.953038\,(B/T) - 0.0914148\,(B/T)^2$ cal deg^{-1} mol^{-1}.

$-(G^\circ - H_0^\circ)/T = 6.863426 \log M + 11.439043 \log T - 4.575617 \log (B\sigma/T) + 0.953038\,(B/T) + 0.0457074\,(B/T)^2 - 8.005804$ cal deg^{-1} mol^{-1}.

$S^\circ = 6.863426 \log M + 11.439043 \log T - 4.575617 \log (B\sigma/T) - 0.0457074\,(B/T)^2 - 1.050725$ cal deg^{-1} mol^{-1}.

where $B = (B_e - \alpha_e/2)$ when spectroscopic constants are available.

$B = \frac{2.799076 \times 10^{-39}}{I}$ when calculated from a molecular model, (I in g cm^2)

(b) Vibration

$C_p^\circ = 1.987165\, u^2 e^{-u}/(1-e^{-u})^2$ cal deg^{-1} mol^{-1}.

$(H - H_0^\circ)/T = 1.987165\, u e^{-u}/(1-e^{-u})$ cal deg^{-1} mol^{-1}.

$-(G^\circ - H_0^\circ)/T = -4.575617 \log (1-e^{-u})$ cal deg^{-1} mol^{-1}.

$S^\circ = 1.987165\, u e^{-u}/(1-e^{-u}) - 4.575617 \log (1-e^{-u})$ cal deg^{-1} mol^{-1}.

where $u = (1.438790/T) \cdot (\omega_e - 2\omega_e x_e)$ when spectroscopic constants are available.

$u = (1.438790/T)\omega$ where ω is the fundamental wave number of a harmonic oscillator.

(c) Electronic

Same as I(b) when the i th-state vibrational partition function, Q_v^i and the i th-state rotational partition function, Q_r^i, are equal to the respective ground state partition functions. In this case the partition function $Q = Q_t Q_v Q_r \sum_i Q_e^i$, otherwise all the thermodynamic functions are derived from $Q = Q_t \sum_i Q_e^i Q_v^i Q_r^i$, where Q_t is the translational partition function and $Q_e^i = g_i \exp(\varepsilon_i/kT)$.

(d) Anharmonicity Corrections

$$C_p{}^\circ = 1.987615 \left[\frac{16\gamma}{u} - \frac{\delta u^2 e^u}{(e^u - 1)^2} + \frac{u^2 e^u (2\delta e^u - 4Xu - 8X)}{(e^u - 1)^3} + \frac{12Xu^3 e^{2u}}{(e^u - 1)^4}\right] \text{cal deg}^{-1} \text{ mol}^{-1}.$$

$$(H^\circ - H_0^\circ)/T = 1.987165 \left[\frac{8\gamma}{u} + \frac{u(\delta e^u - 2X)}{(e^u - 1)^2} + \frac{4Xu^2 e^u}{(e^u - 1)^3}\right] \text{cal deg}^{-1} \text{ mol}^{-1}.$$

$$-(G^\circ - H_0^\circ)/T = 1.987165 \left[\frac{8\gamma}{u} + \frac{\delta}{(e^u - 1)} + \frac{2Xu}{(e^u - 1)^2}\right] \text{cal deg}^{-1} \text{ mol}^{-1}.$$

$$S^\circ = 1.987165 \left[\frac{16\gamma}{u} + \frac{\delta}{(e^u - 1)} + \frac{\delta u e^u}{(e^u - 1)^2} + \frac{4Xu^2 e^u}{(e^u - 1)^3}\right] \text{cal deg}^{-1} \text{ mol}^{-1}.$$

where u is $(\omega_e - 2\omega_e x_e) \cdot 1.438790/T$

$X = (\omega_e x_e)/\omega_e$; $\delta = \alpha_e/B_e$; $\gamma = B_e/\omega_e$.

III. Linear Polyatomic Molecule

(a) Translation and rotation same as for II (a).

(b) Vibration same as II (b) for 3N-5 vibrational degrees of freedom.

(c) Electronic same as II (c) where levels and quantum weight are known.

(d) Anharmonic corrections neglected.

IV. Nonlinear Polyatomic Molecule (Rigid Rotator, Harmonic Oscillator).

(a) Translation and Rotation

$C_p{}^\circ = 7.948662$ cal deg^{-1} mol^{-1}.

$(H^\circ - H_0^\circ)/T = 7.948662$ cal deg^{-1} mol^{-1}.

$$-(G^\circ - H_0^\circ)/T = 6.863426 \log M + 18.302469 \log T - 4.575617 \log \sigma + 2.287809 \log I_A I_B I_C \times 10^{117} - 10.297926 \text{ cal deg}^{-1} \text{ mol}^{-1}.$$

$$S^\circ = 6.863426 \log M + 18.302469 \log T - 4.575617 \log \sigma + 2.287809 \log I_A I_B I_C \times 10^{117} - 2.349265 \text{ cal deg}^{-1} \text{ mol}^{-1}$$

(b) Vibration same as II (b) for 3N-6 vibrational degrees of freedom.

(c) Electronic same as II (c) where levels and quantum weight are known.

(d) Anharmonic corrections neglected.

V. Condensed States

Evaluation of thermodynamic data for condensed states rests upon either measured or estimated information. Heat-capacity data are plotted, smoothed, and data for calculations read back at regular temperature intervals. Integration of this smoothed heat capacity data is carried out with the relations

$$H_T^\circ - H_{298.15}^\circ = \int_{298.15}^{T} C_p^\circ \, dT \qquad S_T^\circ = \int_0^T \frac{C_p^\circ}{T} \, dT$$

by machine, three points at a time. The computer calculates the constants for a parabolic equation through the three points, and employs the constants to integrate the first temperature interval. The lowest point is discarded; the next higher point is combined with the two retained points; and a new set of parabolic constants calculated and used for integrating the next higher temperature interval. This recurrent procedure is well suited to this type of calculation. At the appropriate temperatures, transition enthalpies are added to the enthalpy total, while the quotient of the transition enthalpy divided by the absolute temperature is added to the entropy total.

NOTES

1. Indexing

The modified Hill indexing system, J. Am. Chem. Soc. 22, 478-94 (1900), for Chemical Compounds as used by Chemical Abstracts and the Classification Division of the U. S. Patent Office is used to index the chemical compounds in this data collection. The arrangement of atomic symbols in chemical formulas is alphabetical except for carbon compounds. Thus, the indexing of chemical compounds is as follows: Ac (actinium compounds), Ag (silver compounds), Al (aluminum compounds), Am (americium compounds), Ar (argon), As (arsenic compounds), Au (gold compounds), B (boron compounds), Ba (barium compounds), Be (beryllium compounds), and so on throughout the alphabet. Once the correct order of the elements in the formula is deduced, the location of a compound within the group is easily accomplished. This obviates the need for pagination, and the index page indicates the correct order.

Organic (carbon) compounds represent a gigantic group, so that for convenience this one class of compounds presents the exceptions to the alphabetical rule. In carbon compounds the C always comes first, followed immediately by H if hydrogen is present, and then followed by any other elements present in their normal alphabetical order. The number of atoms of the element indexed first also influences the order of indexing the compound; e.g., all formulas with C (one carbon atom only) come before those with C_2 (two carbon atoms), followed by C_3 compounds, and so on. Thus: $CHBF_4O$ (formyl fluoride, compound with BF_3), $CHCl_3$ (chloroform), CH_2F_3P (trifluoromethylphosphine), CH_3NO_3 (methyl nitrate), CH_4Cl_2Si (dichloromethylsilane), $CH_{10}N_4O_3$ (hydrazine carbonate), CO (carbon monoxide), CO_2 (carbon dioxide), CO_3Zn (zinc carbonate), CZr (zirconium carbide), C_2Ba (barium acetylide), C_2BrClF_2 (bromochlorodifluoroethylene), C_2Ca (calcium carbide), and so on. See any formula index of Chemical Abstracts for further details and examples.

2. Selection of Enthalpy Reference Temperature

Since no enthalpy measurements can be made in the sense of an absolute quantity, and since all enthalpy measurements are made as a difference between an initial and a final state, it is necessary to select the thermodynamic state to which all other thermodynamic states will be referred. For these tables, the thermodynamic state selected is chosen as the state at one atmosphere total pressure tabulated at 298.15 K. Note that the temperature 298 K listed in the table actually refers to 298.15 K., but decimals have been omitted in the temperature column. Usage in theoretical work indicates the selection of the state existing at absolute zero, which is a hypothetical state that is even approached by relatively few measurements. Values of the difference in heat between 298.15 and 0 K will permit theoretical workers to use these tables, so it was decided to tabulate values at 0 K. Modern usage of thermodynamic data sometimes requires application to conditions below ambient, so the decision was made to tabulate values at 0, 100, and 200 K where the information is available.

3. Limitations of Calculated Quantities

Calculation of the contributions of rotation and translation involves the use of quantum statistics, but to obtain a numerical solution the quantum statistics are usually replaced by classical statistics at temperatures above about 100 K. Attempts to employ these methods below 100 K lead into a temperature range where the approximation afforded by classical statistics no longer holds. For this reason the equations presented under "Calculational Methods" fail in the vicinity of 0 K. In agreement with the third law concept, C_p° and S° are zero at 0 K. For a reference element, log K_p is zero at 0 K, while for compounds the absolute values of the free energy function and log K_p become infinite at 0 K.

4. Reference State of an Element

A related set of thermodynamic property tables requires that there be a reference table of the thermodynamic properties for each element to which all other forms of that element or any compound involving that element may be referred. If the temperature range of interest (6000 K here) can be represented by a single phase for that material (say hydrogen) the tabulated values in the reference table will be smooth and regular. If the temperature range of interest includes more than one phase (say magnesium) there will be a solid phase (from 0 to 922 K, the melting point), a liquid phase (922 to 1378 K, where the vapor pressure reaches one atmosphere), and a gas phase (1378 to 6000 K), the tabulated values in the reference table will be discontinuous at these phase boundaries. Practical usage dictates that in so far as possible the phase most stable at one atmosphere pressure (that is, the form most easily worked with) be selected. This practice is followed in these tables, and does lead to discontinuities in the thermodynamic functions. Attention is called to these discontinuities in the polyphase reference-state tables by insertion of a solid line at the temperature of a phase transition. The phase transitions considered are: first-order solid-state transformations from one crystal type to some other, solid to liquid, and solid or liquid to gas at one atmosphere.

5. Single-Phase Table

It is expected that these tables will be employed on various problems solved by automatic machine computation. Such calculations are carried out in numerous ways, and vary from one installation to another. Programs to perform these calculations are simplified if the thermodynamic functions are smooth and extend beyond the actual range of use permitting a wide latitude in iterative procedures. For this reason, most tables other than elemental reference states are tabulated as single-phase tables. Thus, tables for the solid state are extrapolated well past the melting point; those for the liquid state are extrapolated below the melting point (into the supercooled-liquid range to 298.15 K) and well above the atmospheric boiling point, while gas tables are tabulated from 0 K to 6000 K. Care has been taken to preserve the correct free energy relationships between the extrapolated-phase functions and the functions of the real phase. Attention is called to these extrapolations by insertion of a dotted line at the temperature where the indicated phase meets an adjacent more stable phase, but for reasons mentioned above the indicated phase is extrapolated into a temperature range where it is thermodynamically unstable.

NOTES

6. Mole

With each table and text there is listed either the atomic, molecular, or gram formula mass. It is generally understood that this mass in grams refers to Avogadro's number of atoms or molecules, and will be referred to simply as a "mole".

7. Point Groups and Ground-State Configurations

Throughout these tables the nomenclature and definition of the ground-state configurations and point groups are those in use by C. E. Moore, U. S. National Bureau of Standards Circular 467, (1949), and G. Herzberg, "Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, (1950), and "Molecular Spectra and Molecular Structure, II. Infrared and Raman Spectra", D. Van Nostrand Co., New York, (1945).

8. Decimal Places

Three decimal places have been arbitrarily carried in the tables even though *in numerous cases the data do not warrant* this accuracy. This has been done to preserve the proper relationship of the thermodynamic functions, and to facilitate machine interpolation of these values.

9. Higher Electronic Terms

A single electronic term of 30,000 cm^{-1} and above contributes a negligible amount to the thermodynamic functions at temperatures of 6000 K and below. On the other hand, a number of such terms cannot be neglected. In these cases, the number of terms and their values have been summed and their contribution included.

10. Estimated Vibrational Frequencies

Some vibrational frequencies have been estimated by analogy with related molecules. Occasionally, more than one frequency has been averaged at the same value. This is not to be confused with a true degeneracy which is indicated by placing the degeneracy value in parentheses following the frequency. However, when the information has been taken from another compilation, the degeneracies indicated by the compiler have been retained.

11. Quantum Weight

The term quantum weight is also referred to as statistical weight by many authors. The quantity is the product of the spin multiplicity and state degeneracy of the electronic level under consideration.

12. Isotope Effects

The functions calculated for gases from molecular constants are, in general, obtained from constants which have been corrected to the natural isotopic abundance.

INDEX TO TABLES

Filing Order	Table Title
$BClF$	Boron Chloride Fluoride (g)
$BClF_2$	Boron Chloride Difluoride (g)
$BClO$	Boron Oxide Chloride (g)
BCl_2	Boron Dichloride (g)
BCl_2^+	Boron Dichloride Unipositive Ion (g)
BCl_2^-	Boron Dichloride Uninegative Ion (g)
BCl_2F	Boron Dichloride Fluoride (g)
BCl_2H	Boron Dichloride Hydride (g)
BCl_3	Boron Trichloride (g)
BF	Boron Monofluoride (g)
BFO	Boron Oxide Fluoride (g)
BF_2	Boron Difluoride (g)
BF_2^+	Boron Difluoride Unipositive Ion (g)
BF_2^-	Boron Difluoride Uninegative Ion (g)
BF_2H	Difluoroborane (g)
BF_2HO	Boron Hydroxide Difluoride (g)
BF_2O	Boron Oxide Difluoride (g)
BF_3	Boron Trifluoride (g)
BF_4K	Potassium Tetrafluoroborate (c)
BF_4K	Potassium Tetrafluoroborate (ℓ)
BF_4K	Potassium Tetrafluoroborate (g)
BH	Boron Monohydride (g)
BHO	Boron Oxide Hydride (g)
BHO^+	Boron Oxide Hydride Unipositive Ion (g)
BHO_2	Metaboric Acid (c)
BHO_2	Metaboric Acid (g)
BH_2	Boron Dihydride (g)
BH_2O_2	Boron Dihydroxide (g)

Dec. 31, 1960; Dec. 31, 1965; June 30, 1967

ALUMINUM (Al) (LIQUID) AT. WT. = 26.9815

$S°_{298.15}$ = 8.42 gibbs/mol

Tm° = 933°K

Tb° = 2766.8°K

$\Delta Hf°_{298.15}$ = 2.072 kcal/mol

ΔHm° = 2.56 ± 0.05 kcal/mol

ΔHv° = 69.497 kcal/mol

Heat of Formation

The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between $H°_{933} - H°_{298}$ for (c) and (ℓ).

Heat Capacity and Entropy

The heat capacity is adopted from the enthalpy measurements of R. A. McDonald, private communication, Thermal Research Laboratory, The Dow Chemical Company, Midland, Michigan, Oct. 1965. The liquid enthalpies were determined in crucibles of BN and TiB_2 sealed in a platinum-rhodium capsule. The liquid enthalpies are in agreement with the determination of J. W. Awberry and E. Griffiths, Proc. Phys. Soc. (London) 38, 378 (1926) and higher, by as much as 12 percent, than those of F. Wust, A. Meuthen and R. Dorrer, Forsch. Arb. Ver. Deut. Ing. No 204 (1918) and S. Umino, Sci. Repts. Tohoku. Imp. Univ. Ser 1, 15, 597 (1926). The enthalpy data is adequately represented by a constant heat capacity. The entropy is calculated from that of the crystal in a manner analogous to the heat of formation.

Melting Data

See Al(c) for details.

Vaporization Data

The temperature of boiling and the heat of vaporization are derived from the adopted functions and the heat of sublimation in order to maintain thermodynamic consistency.

Heat of Formation.

The heat of sublimation of aluminum has been derived from a second and third law analysis of the vapor pressure data of several investigators; the results are tabulated below.

				ΔH_{298} subl. kcal. mole^{-1}		Drift
Ref.	Range °K.	Method	Points	2nd law	3rd law	cal. deg.$^{-1}$ mole^{-1}
1	1273-1473	Knudsen	10*	76.3 ± 2.3	75.32 ± 0.7	-0.8 ± 1.7
2	1734-2237	Boiling	4	83.1 ± 0.3	74.58 ± 1.8	-4.3 ± 0.2
3	1383-1468	Knudsen	10	89.8 ± 32.9	77.29 ± 3.7	-9.0 ± 23.3
4	1410-1468	Knudsen	6	71.9 ± 19.2	78.4 ± 1.3	4.5 ± 13.2
5	1511-1723	Mass Spec	11	77.2 ± 2		
6	2473	Boiling	1		70.5	
7	1476	Knudsen	1		77.35	
8	1400-1611	Torsion	104	80.3 ± 1.2	79.5 ± 0.3	-0.3 ± 0.8

*1 point rejected due to failure of statistical test.

It is apparent that there is little real agreement in the data; in Ref. 3 some of this is due to diffusion of liquid Al through the TaC crucibles, while Ref. 8 reports surface oxidation of the sample. The data for Ref. 5 have been reworked since they corrected their data using ΔC_p between (l) and (g) of -2 cal. deg.$^{-1}$ mole^{-1}, where our tables give a value of -2.62 cal. deg.$^{-1}$ mole^{-1}. Ref. 8 has obtained by far the largest number of data points all of which are in good agreement, show no trend and little scatter. Ref. 1 has gone to a great deal of trouble to ensure uniform heating, total collection of effusate and good Knudsen conditions and also has no trend. It is difficult to imagine why these two series differ by a factor of 3 in the pressure. An intermediate value of the heat of sublimation has been adopted at 78 ± 2 kcal. mole^{-1}. This choice is also indicated by the decomposition of AlN(c) to Al(g) and 1/2 N_2(g), which has been well established as 153.7 ± 0.8 kcal. mole^{-1}, combined with the heat of formation of AlN(c) = -76 ± 0.3 kcal. mole^{-1}, to yield ΔH°_{sub} Al = 77.7 ± 0.9 kcal. mole^{-1}.

Heat Capacity and Entropy.

The electronic ground state configuration and the higher electronic levels are taken from C. E. Moore, Natl. Bur. Stds. Circular 467, "Atomic Energy Levels" Washington 1949.

85479.0	5	95547.9	5
91271.2	3	95548.8	3

Heat of Formation.

The heat of formation was calculated from the equation: $Al(g) - e^- \rightarrow Al^+(g)$ with the JANAF auxiliary value for Al(g); using an I.P. = 4.827916 X 10^4 cm^{-1} (138.047 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore loc. cit. The electronic levels above 1 X 10^5 cm^{-1} were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.481 kcal./mole.

ALUMINUM BORON DIOXIDE ($AlBO_2$)   (IDEAL GAS)   GFW = 69.7913

Point Group [C_s] ΔHf°_0 = -128.8 ± 4 kcal/mol

$S^\circ_{298.15}$ = [64.4] gibbs/mol $\Delta Hf^\circ_{298.15}$ = -129.4 ± 4 kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[2000](1)	[600](1)
[1000](1)	[350](1)
[600](1)	[800](1)

Bond Distance: Al-O = [1.66] Å   O-B = [1.36] Å   B=O = [1.20] Å

Bond Angle: Al-O-B = [145]°   O-B=O = [180]° $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C$ = [6.65357] X 10^{-115} g^3 cm^6

Heat of Formation.

The heat of formation, ΔHf°_{298} ($AlBO_2$, g) = -129.4 ± 4 kcal/mol, was calculated from the heat of reaction, ΔHr°_{1500} = -14.7 ± 3.2 kcal/mol for 1/2 Al_2O(g) + 1/2 B_2O_3(g) = $AlBO_2$(g), with all JANAF auxiliary data. The value of ΔHr°_{1500} was obtained from the mass spectrometric determination of ion intensity ratios by A. Büchler, P. E. Blackburn and J. L. Stauffer, "Thermodynamics of Vaporization in the Aluminum Oxide-Boron Oxide System," ARPA Order No 315-62, Arthur D. Little, Inc., Cambridge, Mass.

Heat Capacity and Entropy.

The bent molecular structure, the bond distances O-B and B=O, and the bond angle O-B-O were assumed to be the same as those in $LiBO_2$(g). The bond distance Al-O and the bond angle Al-O-(BO) were estimated to be the same as those in Al_2O(g). The three principal moments of inertia are I_A = 0.7255 X 10^{-39}, I_B = 29.9238 X 10^{-39}, and I_C = 30.6493 X 10^{-39} g cm^2.

The vibrational frequencies were estimated by comparison with those in $LiBO_2$(g), Al_2O(g), B_2O_3(g), and AlCl(g).

Heat of Formation.

S. A. Semenkovich, Zh. Prikl, Khim. 30, 933 (1957) measured the vapor pressure of the reaction $Al(l) + NaBr(l) \rightarrow Na(g) + AlBr(g)$ at 1175°K. By the third law method the heat of reaction ($\Delta H_{r\ 298.15}^\circ$) was evaluated to be 108.31 kcal. mole^{-1}. The value of $\Delta H_{f\ 298.15}^\circ$ for AlBr(g) was calculated as 3.6 ± 5.0 kcal. mole^{-1}. Based on this value the dissociation energy (D_0°) was derived to be 4.3 ± 0.2 e.v. which is in excellent agreement with the value, $D_0^\circ = 4.3 \pm 0.2$ e.v., reported by A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The dissociation energy (D_0°) of AlBr(g) was reported to be 2.4 e.v. and 105 kcal. mole^{-1} (4.55 e.v.) by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950 and R. F. Barrow, Trans, Faraday Soc. 56, 952 (1960), respectively. However, using these D_0° values, the corresponding values of $\Delta H_{f\ 298.15}^\circ$ for AlBr(g) were found to be 48.55 and -1.11 kcal. mole^{-1}. The adopted value was calculated from the vapor pressure data reported by S. A. Semenkovich, loc. cit.

Heat Capacity and Entropy.

The spectroscopic constants were taken from G. Herzberg, loc. cit. and corrected to the average isotopic species.

Dec. 31, 1961; June 30, 1964; June 30, 1967

ALUMINUM TRIBROMIDE ($AlBr_3$) (CRYSTAL) GFW = 266.7085

ΔHf°_0 = -121.4 ± 3 kcal/mol

$S^\circ_{298.15}$ = 43.08 ± 0.25 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -126.0 ± 3 kcal/mol

Tm = 370.6°K

ΔHm° = 2.89 kcal/mol

Heat of Formation

The value of ΔHf°_{298} for $AlBr_3(c)$ is that selected by the National Bureau of Standards (1). The methods and auxiliary data used to obtain their value are not given. Their result is apparently based on the heats of reaction of aqueous solutions of $AlBr_3$ measured by Berthelot (2).

Heat Capacity and Entropy

The heat capacity of $AlBr_3(c)$ has been measured from 11.6° to 308.1°K by Justice (3) and the enthalpy from 337° to 367°K by Fischer (4). The heat capacities used are deirved from curve fits of these data. The Cp values above 370.6°K are obtained by graphical extrapolation. Justice (3) reported the value of S°_{298}, based on S°_{12} = 0.951 eu.

Melting Data

Fischer (4) determined the melting temperature (Tm) of $AlBr_3(c)$. The heat of melting (ΔHm°) is calculated from the enthalpies of $AlBr_3(c)$ and $AlBr_3(\ell)$ at the melting temperature. The enthalpy of the crystal at the melting point was determined from the curve used for the heat capacity calculations. The enthalpy of the liquid at the melting point was determined from a linear least squares fit to the enthalpy data for $AlBr_3(\ell)$ reported by Fischer (4).

Dec. 31, 1961; June 30, 1964; June 30, 1967

ALUMINUM TRIBROMIDE ($AlBr_3$)   (LIQUID)   GFW = 266.7085

$S^\circ_{298.15}$ = 49.352 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -123.633 ± 3 kcal/mol

Tm = 370.6°K   ΔHm° = 2.69 kcal/mol

Tb = 529°K (to dimer gas)   ΔHv° = 5.92 kcal/mol (to dimer gas)

Heat of Formation

The heat of formation (ΔHf°_{298}) of $AlBr_3(\ell)$ is calculated from ΔHf°_{298} of $AlBr_3(c)$ plus the heat of melting (ΔHm°) and the enthalpy differences ($H_{370.6} - H_{298}$) of the crystal and liquid.

Heat Capacity and Entropy

Fischer (1) has measured the enthalpy of $AlBr_3(\ell)$ from 371° to 406°K. The heat capacity used is derived from a linear least squares fit to his data. The resulting constant value for the heat capacity is adopted for temperatures above 406°K. The entropy (S°_{298}) of $AlBr_3(2)$ was determined in a manner analogous to that for the heat of formation.

Melting Data

See $AlBr_3(c)$ table for details.

Vaporization Data

The heat of vaporization (ΔHv°) of $AlBr_3(\ell)$ is determined from the work of Fischer et al. (2). The boiling temperature (Tb) was calculated from their vapor pressure data. See $Al_2Br_6(g)$ table for details.

ALUMINUM TRIBROMIDE (AlBr$_3$) (IDEAL GAS) GFW = 266.7085

Point Group [D_{3h}]

$S°_{298.15}$ = 84.5 gibbs/mol

Ground State Quantum Weight = [1]

$\Delta Hf°_0$ = -95.7 ± 4 kcal/mol

$\Delta Hf°_{298.15}$ = -101.1 ± 4 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
[215] (1)	[100] (2)
[109] (1)	[418] (2)

Bond Distance: Al-Br = [2.27] Å

Bond Angle: Br-Al-Br = [120°]

σ = [6]

Product of the Moments of Inertia: $I_A I_B I_C$ = 2.16 x 10^{-111} g^3 cm^6

Heat of Formation

Fischer et al. (1) have determined the equilibrium constants for the reaction $2AlBr_3(g) = Al_2Br_6(g)$ from vapor density measurements. The heats of reaction are calculated from these data using both second law and third law methods. The adopted value of $\Delta Hf°_{298}$ is -101.1 ± 4 kcal/mol. The results of the calculations are as follows:

Range T°K	No. Pts.	$\Delta Hr°_{298}$ kcal/mol Second Law	Third Law	Drift, eu	*$Hf°_{298}$ kcal/mol
613-846	4	-29.73	-29.39	0.16 ± 1.33	-98.4
605-854	7	-29.32	-29.35	-0.20 ± 0.67	-98.5

*Calculation based on the third law value of $\Delta Hr°_{298}$.

Heat Capacity and Entropy

The molecular structure of $AlBr_3(g)$ is assumed to be the same as that of $AlF_3(g)$. The bond distance was estimated by Heise and Wieland (2). The vibrational frequencies are estimated from the force constants of $BBr_3(g)$ (3) and then adjusted so that the values of $\Delta Hr°_{298}$ obtained by the second and third law methods are in good agreement. The principal moments of inertia are: $I_A = I_B = 1.03 \times 10^{-37}$, and $I_C = 2.05 \times 10^{-37}$ g cm^2.

ALUMINUM MONOCHLORIDE (AlCl) (IDEAL GAS) GFW = 62.4345

Ground State Configuration $^1\Sigma^+$ $\Delta Hf^\circ_0 = -12.34 \pm 1.0$ kcal/mol

$S^\circ_{298.15} = 54.455 \pm 0.02$ gibbs/mol $\Delta Hf^\circ_{298.15} = -12.30 \pm 1.0$ kcal/mol

Electronic Levels and Quantum Weight

ε_i, cm^{-1}	0	24541	24615	24680
g_i	1	2	2	2

$\omega_e = 480.0$ cm^{-1} $\omega_e x_e = 1.94$ cm^{-1} $\sigma = 1$

$B_e = 0.24262$ cm^{-1} $\alpha_e = 0.00159$ cm^{-1} $r_e = 2.1298$ Å

Heat of Formation

Equilibrium constants as a function of temperature for the reaction $2Al(\ell) + AlCl_3(g) \rightarrow 3AlCl(g)$ have been reported by many investigators. The data were subjected to second and third law analyses with results as follows [ΔHr at 298.15°K refers to $2Al(c) + AlCl_3(g) \rightarrow 3AlCl(g)$]:

Investigator(s)	Temp. Range °K	Number of Data Points	$\Delta Hr^\circ_{298.15}$ kcal/mol $AlCl_3$ 2nd Law	3rd Law	Drift eu
Rao and Dadape (1)	1125-1425	11	102.3±1.6	102.8±0.8	0.3±1.3
Frisch et al. (2)	931-1034	9	99.7±1.1	106.7±0.5	7.2±1.0
Gross et al. (3)	1225-1278	7	a	109.7±2.8	
Ginsberg et al. (4)	1423-1500	8	91.4±1.8	104.7±0.8	9.1±1.2
Semenkovich (5)	1223-1473	6	89.2±0.4	98.5±1.3	6.8±0.3
Heimgartner (6)	978-1383	13	58.8±2.5	100.0±9.5	33.0±2.2
Weiss (7)	1273-1473	3	93.1±3.4	86.3±1.2	-5.2±2.7
Pinchuk et al. (8)	1173-1373	3	86.0±7.5	95.0±1.9	7.6±5.8
Mitani et al. (9)	1273-1473	b	88.9	99.1±2.1	7.4
Kikuchi et al. (10)	1273-1523	b	78.7	98.7±5.0	14.3
Tanabe et al. (11)	1173-1573	b	93.3	94.6±0.5	0.9
Russell et al. (12)	1388	1		103.8	

[a] Temperature range too small for significant second law calculation.

[b] These data available only as equations as given in Chemical Abstracts.

Unfortunately, most of the data are very discordant and of no help in defining ΔHf(AlCl, g). The results of Rao and Dadape (1) cover a temperature range of 300°K, show good compatibility with the thermodynamic functions, are near an average of all the data, and are judged most acceptable. The third-law heat of reaction derived from their data is adopted and combined with the heat of formation of $AlCl_3(g)$ to give $\Delta Hf^\circ_{298.15}(AlCl, g) = -12.30 \pm 1.0$ kcal/mol.

Gross et al. (3) reported equilibrium constants for the reaction of aluminum with sodium chloride and potassium chloride and Pinchuk et al. (8) determined equilibrium constants for reaction of aluminum with sodium chloride and magnesium chloride. The results of Pinchuk et al. (8) are suspect in that the partial pressures of sodium and magnesium chlorides they calculate from their data exceed the saturation pressures calculated from JANAF data. The data of Gross et al. (3) were recalculated to allow for effects of dimer in sodium chloride and potassium chloride vapors (JANAF data):

Reaction	T, °K	Kp(atm^2)	$\Delta Hr_{298.15}$ kcal/mol	$\Delta Hf^\circ_{298.15}$(AlCl, g) kcal/mol
$NaCl(s) + Al(\ell) \rightarrow AlCl(g) + Na(g)$	1043	4.178×10^{-10}	109.24	-12.7 ± 1.0
$NaCl(\ell) + Al(\ell) \rightarrow AlCl(g) + Na(g)$	1243	1.138×10^{-6}	102.31	-13.6 ± 1.5
$KCl(s) + Al(\ell) \rightarrow AlCl(g) + K(g)$	1023	5.141×10^{-11}	110.47	-13.1 ± 1.5

The result for NaCl(s) is the average of 12 experiments whereas the NaCl(ℓ) and KCl(s) are based on 5 and 3 experiments, respectively, and the NaCl(s) value is considered the most reliable. The derived heat of formation is in good agreement with the value selected on the basis of the Rao and Dadape data.

Barrow (13) has compared thermochemical and spectroscopic dissociation energies for monohalides of B, Al, Ga, In, and Tl. A short extrapolation of vibrational levels gives $D_0'' = 124.1$ kcal/mol for AlCl while predissociation indicates $D_0'' \leq 120.1$ kcal/mol. The maximum predissociation value gives $\Delta Hf^\circ_{298.15}(AlCl, g) = -14.1$ kcal/mol, in reasonable agreement with the selected value. Barrow (13) speculates that a potential maximum occurs in the $A^1\Pi$ state of AlF and AlCl which causes extrapolation of vibrational levels to give erroneous heats of dissociation.

Heat Capacity and Entropy

The vibrational frequency and anharmonicity constants were taken from Herzberg (14) and the structural constants are based on microwave spectroscopy by Lide (15). The electronic levels were reported by Sharma (16).

Heat of Formation

D. L. Hildenbrand, E. Murad, L. P. Theard and F. Ju, Aeronutronic Report No. U-3197, July 30, 1965, under contract AF 04(611)-10743, reported an appearance potential of 9.4 ± 0.4eV for $AlCl^+$. They suggested that the magnitude of the value indicated formation by direct ionization of AlCl(g).

R. F. Porter and E. E. Zeller, J. Chem. Phys. 33, 858 (1960), obtained an appearance potential of 19.7 ± 0.5eV for $AlCl^+$ which they attributed to formation from $AlCl_3(g)$. Assuming the process to be $AlCl_3(g) + e^- \rightarrow AlCl^+(g) + 2Cl(g) + 2e^-$ ΔH = 454 kcal, one obtains $\Delta Hf^\circ_{298}(AlCl^+)$ = 257 kcal/mol, or an ionization potential of 11.6eV. This would almost certainly represent an upper limit, since the fragments could easily contain excess kinetic energy.

We adopt the ionization potential of 9.4 ± 0.4eV obtained by Hildenbrand et al., which yields $\Delta Hf^\circ_{298}(AlCl^+, g)$ = 205 ± 10 kcal/mol.

Heat Capacity and Entropy

$AlCl^+$ is isoelectronic with MgCl, and the electronic configuration of the ground state and first excited state are estimated to be those for MgCl. The vibrational frequency, anharmonicity constant and bond length are estimated by comparison with those for MgCl and AlCl. The rotational constant is calculated from the bond length and atomic masses, and α_e is calculated from the other constants assuming a Morse potential function.

The enthalpy at 0°K is -2.236 kcal/mol.

Dec. 31, 1960; Sept. 30, 1964

ALUMINUM CHLORIDE FLUORIDE (AlClF) (IDEAL GAS) MOL. WT. = 81.437

Point Group C_s

$\Delta H_{f\ 0}^\circ = [-120 \pm 20]$ kcal. mole⁻¹

$S_{298.15}^\circ = [67.388]$ cal. deg.⁻¹ mole⁻¹

$\Delta H_{f\ 298.15}^\circ = [-120 \pm 20]$ kcal. mole⁻¹

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm.⁻¹
[590] (1)
[220] (1)
[730] (1)

Bond Distance: Al-F = [1.63] Å Al-Cl = [2.14] Å

Bond Angle: Cl-Al-F = [120]°

$\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C = [1.48427 \times 10^{-114}]$ g.³ cm.⁶

Heat of Formation.

The value of $\Delta H_{f\ 298.15}^\circ$ for AlClF(g) was calculated based on an assumption that $\Delta H_r^\circ = 0$ for the reaction $AlF_2(g) + AlCl_2(g) = 2AlClF(g)$. The $\Delta H_{f\ 298.15}^\circ$ values for $AlF_2(g)$ and $AlCl_2(g)$ used for calculation are -165.0 and -75.0 kcal. mole⁻¹, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated to be consistent with those for $AlF_2(g)$ and $AlCl_2(g)$. The bond distances of Al-F and Al-Cl were estimated to be the same as those in $AlF_3(g)$ and $AlCl_3(g)$, respectively. The bond angle and ground state quantum weight were estimated to be consistent with those for $AlF_2(g)$ molecule. The three principal moments of inertia are: $I_A = 2.41078 \times 10^{-38}$, $I_B = 2.3289 \times 10^{-39}$ and $I_C = 2.64367 \times 10^{-38}$ g. cm.²

Aluminum Chloride Difluoride ($AlClF_2$)

Bond Distance: Al-F = [1.65]Å Al-Cl = [2.14]Å

Bond Angle: Cl-Al-F = [120]° F-Al-F = [120]°

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 1.47245 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ was calculated based on an assumption that $\Delta H^\circ_r = 0$ for the reaction $AlCl_3(g) + 2AlF_3(g) = 3AlClF_2(g)$. The values of $\Delta H^\circ_{f\ 298.15}$ for $AlF_3(g)$ and $AlCl_3(g)$ used for calculation are -286.5 and -139.7 kcal. mole^{-1}, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for $AlF_3(g)$ and $AlCl_3(g)$. The bond distances of Al-F and Al-Cl atoms were assumed to be the same as those in $AlF_3(g)$ and $AlCl_3(g)$, respectively. The bond angles and ground state quantum weight were estimated by comparison with those for $AlF_3(g)$. The three principal moments of inertia are 1.28827×10^{-38}, 2.79746×10^{-38} and 4.08573×10^{-38} g. cm.^{2}

ALUMINUM OXIDE CHLORIDE (AlOCl) (CRYSTAL) MOL. WT. = 78.437

$S^\circ_{298.15}$ = [13 ± 1] cal. deg.$^{-1}$ mole^{-1}

T_m = Unknown

T_d = [500]°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -189.6 ± 0.3 kcal. mole^{-1}

ΔH°_m = Unknown

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for AlOCl(c) was calculated from $\Delta H^\circ_{r\ 298}$ = 21.05 kcal. mole^{-1} for the reaction $AlOCl(c) + Cl_2(g) = AlCl_3(c) + 1/2\ O_2(g)$ reported by H. Schafer, F. E. Wittig, and W. Wilborn, Z. anorg. allgem. Chem. 297, 48 (1958). This reaction is the overall reaction of the following four separate reactions.

Chemical Reaction	$\Delta H^\circ_{r\ 298}$, kcal. mole^{-1}
$AlOCl(c) + 2(HCl\cdot 299.5\ H_2O) = AlCl_3\cdot 600\ H_2O(l)$	-46.9
$AlCl_3\cdot 600\ H_2O(l) = AlCl_3(c) + 600\ H_2O(l)$	+79.3
$H_2(g) + Cl_2(g) + 599\ H_2O(l) = 2(HCl\cdot 299.5\ H_2O)$	-79.67
$H_2O(l) = H_2(g) + 1/2\ O_2(g)$	+68.32
$AlOCl(c) + Cl_2(g) = AlCl_3(c) + 1/2\ O_2(g)$	+21.05

Heat Capacity and Entropy.

The heat capacities for AlOCl(c) were estimated based on the assumption that ΔC_p = 0 for the reaction $AlCl_3(c) + Al_2O_3(c) = 3AlOCl(c)$. $S^\circ_{298.15}$ was estimated by H. Schafer, F. E. Wittig, and W. Wilborn, loc. cit.

Temperature of Decomposition.

T_d is estimated as the temperature at which the free energy change of the reaction $6AlOCl(c) \rightarrow 3Al_2O_3(c) + Al_2Cl_6(g)$ approaches zero.

Heat of Formation.

The free energy change of the reaction 1/3 Al_2O_3(l) + 1/3 $AlCl_3$(g) = AlOCl(g), $\Delta F_r^\circ{}_{2400^\circ K.}$ = 28 ± 3 kcal. mole^{-1}, has been determined by M. A. Greenbaum, et al., Maremont Corporation, California, private communication, August 26, 1964. Incorporating appropriate auxiliary data the heat of reaction was derived to be 82.9 kcal. mole^{-1}, yielding $\Delta H_f^\circ{}_{298.15}$ = -83.2 ± 5 kcal. mole^{-1} for AlOCl(g).

Heat Capacity and Entropy.

Point group, ground state quantum weight and vibrational frequencies were obtained from J. Hilsenrath, W. H. Evans and H. W. Woolley, National Bureau of Standards Report 6484, "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum and Their Compounds with Hydrogen, Oxygen, Nitrogen, Fluorine and Chlorine", July 1, 1959. The bond distances of r_{O-Al} and r_{Al-Cl} were assumed to be the same as those in AlO(g) and AlCl(g) molecules, respectively. The three principal moments of inertia are: I_A = 0 and $I_B = I_C$ = 2.86467 X 10^{-38} g. cm.^{2}

ALUMINUM DICHLORIDE (AlCl$_2$) (IDEAL GAS) MOL. WT. = 97.894

Point Group C_{2v}

$\Delta H^\circ_{f\ 0}$ = [-75 ± 20] kcal. mole^{-1}

$S^\circ_{298.15}$ = [68.815] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-75 ± 20] kcal. mole^{-1}

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[430] (1)
[210] (1)
[540] (1)

Bond Distance: Al-Cl = [2.14]Å

Bond Angle: Cl-Al-Cl = [120]°

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [6.62845 X 10^{-114}] g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for AlCl$_2$(g) was calculated based on an assumption that $\Delta H^\circ_r = 0$ for the reaction AlCl(g) + AlCl$_3$(g) = 2AlCl$_2$(g). The values of $\Delta H^\circ_{f\ 298.15}$ for AlCl(g) and AlCl$_3$(g) used for calculation are -11.2 and -139.7 kcal. mole^{-1}, respectively.

Heat Capacity and Entropies.

The vibrational frequencies were calculated by valence force field method described by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950, using force constants , k_1 = 2.05 X 10^5 and k_δ/l^2 = 0.25 X 10^5 dynes/cm., estimated from those for AlCl(g) and other similar compounds. The bond distance was assumed to be the same as that for AlCl(g). The bond angle and ground state quantum weight were estimated to be consistent with those for AlF$_2$(g). The three principal moments of inertia are I_A = 4.04243 X 10^{-38}, I_B = 3.7149 X 10^{-39} and I_C = 4.41392 X 10^{-38} g. cm.^{2}

Heat of Formation

R. F. Porter and E. E. Zeller, J. Chem. Phys. 33, 858 (1960), reported an appearance potential of 13.4 ± 0.5eV (309 ± 12 kcal) for $AlCl_2^+$; they indicated that $AlCl_3(g)$ was the probable parent molecule. Assuming the formation reaction to be $AlCl_3 + e^- \rightarrow AlCl_2^+ + Cl + 2\ e^-$, we obtain $\Delta Hf^\circ_{298}(AlCl_2^+, g)$ = 140 kcal/mol or an ionization potential of 215 kcal or 9.3eV. Since there is a possibility of the fragments containing excess kinetic energy, the ionization potential represents an upper limit to the true value. A comparison of the ionization potentials of BF_x and BCl_x indicates that the chloride is lower by ~1eV per atom; on this basis we would obtain an ionization potential of 7eV using the value for AlF_2 of 9eV.

The National Bureau of Standards Report No. 8628, Jan. 1, 1965, gives an estimate of 8 ± 1eV (185 ± 25 kcal); we adopt this value as being representative of the probable range of values. The adopted ionization potential yields $\Delta Hf^\circ_{298.15}(AlCl_2^+, g)$ = 110 ± 40 kcal/mol in conjunction with $\Delta Hf^\circ_{298}(AlCl_2, g)$ = -75 ± 20 kcal/mol.

Heat Capacity and Entropy

$AlCl_2^+$ is isoelectronic with $MgCl_2$ and on this basis we assume the ground state to be singlet and linear in accordance with the predictions of A. D. Walsh, J. Chem. Soc. 2266 (1953). The vibrational frequencies are estimated to lie between those for $AlCl_2$ and $MgCl_2$. The bond length is estimated as the sum of the covalent radii of the atoms.

The enthalpy at 0°K is -3.128 kcal/mol.

Bond Distance: Al-Cl = [2.14] Å

Bond Angle: Cl-Al-Cl = [120°]

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [6.634 x 100^{-114}] g^3 cm^6

Heat of Formation

$AlCl_2^-$ is isoelectronic with $SiCl_2$, and an estimate of its heat of formation may be obtained by assuming the binding energy to be the same in the two molecules. This leads to $\Delta Hf^\circ_{298}(AlCl_2^-, g)$ = -80 kcal/mol or an electron affinity of 5 kcal. An alternative route assumes that the heat of reaction is identical for the processes $AlCl_3(g) \rightarrow AlCl_2^-(g) + Cl^+(g)$ and $AlCl(g) \rightarrow Al^-(g) + Cl^+(g)$. Using the electron affinity of Al(g) given in National Bureau of Standards Report No. 8628, Jan. 1, 1965, we obtain $\Delta Hf^\circ_{298}(AlCl_2^-, g)$ = -63 kcal/mol or an electron affinity of -12 kcal. In addition, using the correlation diagrams of A. D. Walsh, J. Chem. Soc. 2266 (1953), the electron must go into a non-bonding orbital; thus the binding energy should be close to that of $AlCl_2$. The dissociation energy of $AlCl_2$ is 211 kcal which leads to $\Delta Hf^\circ_{298}(AlCl_2^-, g)$ = -87 kcal/mol, or an electron affinity of 12 kcal. We adopt an intermediate value for the electron affinity of 5 ± 20 kcal/mol, or $\Delta Hf^\circ_{298}(AlCl_2^-, g)$ = -80 ± 40 kcal/mol using $\Delta Hf^\circ_{298}(AlCl_2, g)$ = -75 ± 20 kcal/mol.

Heat Capacity and Entropy

As noted earlier, $AlCl_2^-$ is isoelectronic with $SiCl_2$ and, with 18 valence electrons, should be definitely bent according to the correlation scheme of A. D. Walsh, loc. cit. The vibrational frequencies are estimated to lie between those of $SiCl_2$ and $AlCl_2$. The bond length and angle are estimated as equal to those for $AlCl_2(g)$. By analogy with SiF_2 (see G. Herzberg "Electronic Spectra of Polyatomic Molecules," D. Van Nostrand Company Inc., New York, 1966) we do not expect any low lying electronic levels.

The enthalpy at 0°K is -3.006 kcal/mol. The three principal moments of inertia are: $I_A = 3.7155 \times 10^{-39}$, $I_B = 4.0438 \times 10^{-38}$, and $I_C = 4.4154 \times 10^{-38}$ g cm^2.

Dec. 31, 1960; Sept. 30, 1964

ALUMINUM DICHLORIDE FLUORIDE ($AlCl_2F$) (IDEAL GAS) MOL. WT. = 116.894

Point Group C_{2v}

$\Delta H^\circ_{f\ 0}$ = [-188.0 ± 20] kcal. mole^{-1}

$S^\circ_{298.15}$ = [74.356] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-188.6 ± 20] kcal. mole^{-1}

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
[420] (1)	[200] (1)
[260] (1)	[650] (1)
[150] (1)	[820] (1)

Bond Distance: Al-F = [1.65]Å Al-Cl = [2.14]Å

Bond Angle: F-Al-Cl = [120]° Cl-Al-Cl = [120]° $\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.64645 X 10^{-113}] g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ was calculated based on an assumption the $\Delta H^\circ_r = 0$ for the reaction $AlF_3(g) + 2AlCl_3(g) = 3AlCl_2F(g)$. The values of $\Delta H^\circ_{f\ 298.15}$ for $AlF_3(g)$ and $AlCl_3(g)$ used for calculation are -286.5 and -139.7 kcal. mole^{-1}, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for $AlF_3(g)$ and $AlCl_3(g)$. The bond distances of Al-F and Al-Cl atoms were assumed to be the same as those in $AlF_3(g)$ and $AlCl_3(g)$, respectively. The bond angles and ground state quantum weight were estimated by comparison with those for $AlF_3(g)$. The three principal moments of inertia are 4.04374 X 10^{-38}, 1.92508 X 10^{-38} and 5.96882 X 10^{-38} g.^{3} cm.^{6}

Dec. 31, 1960; June 30, 1961; June 30, 1963; Mar. 31, 1964; June 30, 1970

ALUMINUM TRICHLORIDE ($AlCl_3$) (CRYSTAL) GFW = 133.341

$S^\circ_{298.15}$ = 26.12 ± 0.10 gibbs/mol

Tm = 465.7 ± 0.2°K

Ts (to dimer) = 454.3°K

ΔHf°_0 = -168.32 ± 0.20 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -168.65 ± 0.20 kcal/mol

ΔHm° = 8.45 ± 0.2 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to dimer) = 27.66 kcal/mol dimer

Heat of Formation

Gross and Hayman (1) measured the enthalpy of direct combination of "spectrographically pure" aluminum and carefully purified chlorine and derived $\Delta Hf^\circ_{298.15}$ = -168.80 ± 0.16 kcal/mol. Siemonsen (2) also reported the enthalpy of direct combination and is in agreement at -167.5 kcal/mol within his relatively large uncertainty interval of ±1.1 kcal/mol.

Coughlin (3) determined the enthalpy of solution of 99.99+% pure Al in 4.360 m HCl and also (4) the enthalpy of solution of anhydrous $AlCl_3$ in the same solvent. Enthalpies of mixing were measured to close a thermochemical cycle at 303.15°K (adjusted to 1961 at. wts.):

	Reaction	$\Delta H^\circ_{303.15}$, cal.
(1)	$Al(c) + 3H^+(sol) = Al^{+++}(sol) + 3/2\ H_2(g)$	-127,057 ± 120
(2)	$3(HCl\cdot 12.731\ H_2O)(\ell) = 3H^+(sol) + 3Cl^-(sol) + 38.193\ H_2O(sol)$	0 ± 10
(3)	$AlCl_3(c) = Al^{+++}(sol) + 3Cl^-(sol)$	-72,504 ± 50
(4)	$38.193\ H_2O(\ell) = 38.193\ H_2O(sol)$	-3,050 ± 20
(5)	$Al(c) + 3(HCl\cdot 12.731\ H_2O)(\ell) = AlCl_3(c) + 38.193\ H_2O(\ell) + 3/2\ H_2(g)$	-51,503 ± 140

With heat capacity data for Al, $AlCl_3$, and H_2 from the JANAF tables and for $HCl[12.731\ H_2O]$ from Parker (5), the enthalpy of reaction 5 at 298.15°K is -51,910 ± 140 cal/mol $AlCl_3$. Interpolation of data for $\Delta Hf^\circ_{298.15}$(HCl, aq) selected by Wagman et al. (6) yields $\Delta Hf^\circ_{298.15}(AlCl_3, c)$ = -168.37 kcal/mol. The overall uncertainty is estimated as 300 cal/mol.

Earlier investigations on the enthalpies of solution of Al were adjusted to the conditions of Coughlin's experiments by means of the data of Smith and Bass (7) for the effects of HCl concentration and H_2O dilution on $\Delta Hf(AlCl_3, aq)$ and estimates of ΔCp of solution of Al of +20 gibbs/mol.

Investigator(s)	ΔH(soln) as reported kcal/mol Al	ΔHsoln adjusted kcal/mol Al
Young (8)	-126.83	-126.79
Roth and Wolf (9)	-124.01	-127.29
Canneri and Rossi (10)	-125.40	-126.80
Somermeier (11)	-128.36	-126.42
Richards and Burgess (12)	-126.00	-124.06

Only Richards and Burgess deviate more than expected; they report a value for Mg in good agreement with modern values and it seems likely their sample of Al was impure.

Several values for the enthalpy of solution of $AlCl_3(c)$ in water have also been published and are listed here along with Coughlin's value recalculated to solution in pure water at 20°C.

Investigator(s)	ΔH(soln) in H_2O at 20°C (kcal/mol $AlCl_3$)
Coughlin (3)	-78.22 (adjusted)
Thomsen (13)	-76.85
Berthelot (13)	-76.3
Baud (13)	-77.6
Sabatier (13)	-78.
Roth and Büchner (14)	-77.9
Roth and Börger (15)	-79.3
Klemm and Tanke (16)	-77.7 (adjusted)

Klemm and Tanke (16) measured the enthalpy of solution of $AlCl_3$ in $HCl\cdot 20\ H_2O$ at 0°C. A weighted average of the values of Gross and Hayman (1) and of Coughlin (4) is adopted for $\Delta Hf^\circ_{298.15}(AlCl_3, c)$ = -168.65 ± 0.20 kcal/mol.

Heat Capacity and Entropy

Justice (17) reported low temperature heat capacity data (13° to 310°K) and presented smoothed thermodynamic functions, including $S^\circ_{298.15}$ = 26.12 gibbs/mol, of which 0.086 gibbs/mol is extrapolation below 13°K. Heat content relative to 273.15°K was measured by Fischer (18) from 298°K to 504°K and heat content relative to 298.15°K was measured by McDonald (19) from 310° to 493°K. The heat content data for the crystal can be fit within about 2% by integration of Cp(c) (gibbs/mol) = 15.52 + 0.021T, which is an extrapolation of Cp data reported by Justice (17).

Melting Data

See table for $AlCl_3(\ell)$.

Sublimation Data

See table for $Al_2Cl_6(g)$.

Dec. 31, 1960; June 30, 1961; Mar. 31, 1964; June 30, 1970

ALUMINUM TRICHLORIDE ($AlCl_3$) (LIQUID) GFW = 133.341

$S^\circ_{298.15}$ = 41.326 ± 0.5 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -161.28 ± 0.40 kcal/mol

Tm = 465.7 ± 0.2°K ΔHm = 8.45 ± 0.20 kcal/mol

Heat of Formation

$\Delta Hf^\circ_{298.15}(\ell)$ was obtained from $\Delta Hf^\circ_{298.15}(c)$ by adding ΔHm and the difference between $(H_{465.7}-H_{298.15})$ for crystal and liquid.

Melting Point

Kendall et al. (1) observed $AlCl_3$ to melt "sharply" at 463.4°K, Foster (2) noted that $AlCl_3$ began melting and melted completely in the range 465.7 ± 0.2°K, Nisel'son et al. (3) reported Tm = 467.2°K, and Ostrikova et al. (4) reported Tm = 466°K. Smits and Meijering (5) and Treadwell and Terebesi (6) derived triple point temperatures of 465.8°K and 466.5°K, respectively, from intersection of vapor pressure curves for crystal and liquid. The value of Foster is adopted as most accurate. The vapor pressure at the triple point is 2.3 atm.

Heat of Fusion and Heat Capacity

Fischer (7) and McDonald (8) measured heat content data for the liquid over a short range (473°-504°K) of temperature. Their data can be represented within 2% by the heat capacity equation derived for the crystal [see $AlCl_3$(c) table], a heat of fusion of 8.45 kcal/mol, and a liquid heat capacity of 30.0 gibbs/mol. Fischer's data are high, while McDonald's points lie below the selected values.

Point Group D_{3h}

$\Delta Hf^\circ_0 = -139.27 \pm 0.70$ kcal/mol

$S^\circ_{298.15} = 75.118 \pm 1.0$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -139.70 \pm 0.70$ kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
371 (1)	146 (2)
[185] (1)	610 (2)

Bond Distance: Al-Cl = 2.06 Å

Bond Angle: Cl-Al-Cl = 120° $\sigma = 6$

Product of the Moments of Inertia: $I_AI_BI_C = 1.0518 \times 10^{-112}\ g^3\ cm^6$

Heat of Formation

The heat of formation is calculated from the value adopted for Al_2Cl_6(g) and the heat of dissociation of Al_2Cl_6, derived from equilibrium P-V-T data on aluminum chloride vapor as listed below.

Investigator(s)	Temp. Range °K	Number of Data Points	$\Delta Hr_{298.15}$(kcal/mol Al_2Cl_6) 2nd Law	3rd Law
Smits and Meijering (1)	669-816	6	29.28	30.12
Fischer et al. (2)	647-869	16[a]	30.82	30.35
Vrieland and Stull (3)	669-825	19[b]	30.22	30.40

[a] Twenty three points reported, points at 938, 881, 944, 734, 805, 605, and 688°K rejected by statistical test.

[b] Twenty six points reported, points at 627.9, 643.1, 671.3, 638.4, 671.6, 722.5, and 686.9°K rejected by statistical test.

The three investigations are in reasonable agreement. Giving consideration also to equilibrium data on the reaction of $AlCl_3$(g) and Al(ℓ) to form AlCl(g) [see AlCl(g) table], there is selected as a best value $\Delta Hr^\circ_{298.15}$ = 30.24 kcal/mol Al_2Cl_6, which yields $\Delta Hf^\circ_{298.15}(AlCl_3, g) = -139.70$ kcal/mol.

Heat Capacity and Entropy

Zasorin and Rambidi (4) carried out electron diffraction experiments on aluminum chloride vapor at 800°K where the monomer should predominate. They found a planar symmetrical structure with Al-Cl = 2.06 ± 0.01 Å and Cl-Al-Cl angles of 120°. The individual moments of inertia are $I_A = I_B = 3.7466 \times 10^{-38}$ g cm^2 and $I_C = 7.4932 \times 10^{-38}$ g cm^2. For aluminum chloride vapor at high temperatures (monomer predominant), Klemperer (5) observed a band at 610 cm^{-1} in the infrared spectrum and Beattie and Horder (6) reported Raman bands at 371 cm^{-1} and 146 cm^{-1}. The remaining frequency should be infrared active but presumably was beyond the range of Klemperer's measurements. Zasorin and Rambidi (7) give 95 ± 15 cm^{-1} based on amplitudes of vibration observed in electron diffraction measurements. However, this frequency gives thermodynamic functions clearly not compatible with the equilibrium P-V-T data. Force constant ratios in the boron halides also suggest a higher wavenumber. An estimate of 185 cm^{-1} was therefore adopted as an optimum value for fitting both the Al_2Cl_6 dissociation data and the equilibrium data for $AlCl_3(g) + 2Al(\ell) \rightarrow 3AlCl(g)$ [see AlCl(g) table].

POTASSIUM TETRACHLOROALUMINATE ($KAlCl_4$) (CRYSTAL) MOL. WT. = 207.908

$S^\circ_{298.15}$ = [47 ± 2] cal. deg.$^{-1}$ mole^{-1}

T_m = 529°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -286.0 ± 2.5 kcal. mole^{-1}

ΔH°_m = Unknown

Heat of Formation.

The heat of reaction of aluminum chloride and potassium chloride was measured by E. Baud, Ann. Chim. Phys. 1, 8 (1904). From ΔH°_r = -26.38 kcal. mole^{-1} for the reaction: $Al_2Cl_6(c) + 2KCl(c) = 2KAlCl_4(c)$, the value of $\Delta H^\circ_{f\ 298.15}$ for $KAlCl_4(c)$ was calculated to be -286 kcal. mole^{-1}.

Heat Capacity and Entropy.

Heat capacities were estimated by comparison with those for $KMgCl_3(c)$, reported by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). $S^\circ_{298.15}$ was estimated according to the methods suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, 1958 and K. K. Kelley, private communication, June, 1960.

Temperature of Melting.

T_m was reported by W. Fischer and A.-L. Simon, Z. anorg. allgem. Chem. 306, 1 (1960).

TRIPOTASSIUM HEXACHLOROALUMINATE (K_3AlCl_6) (CRYSTAL) MOL. WT. = 357.022

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [90 ± 2] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -500 ± 1 kcal. mole^{-1}

T_m = [800]°K.

ΔH_m° = Unknown

Heat of Formation.

The heat of formation at 298.15°K. was recalculated from the same quantity given in National Bureau of Standards (U. S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952. The latter value was derived from the enthalpy change for the reaction $Al_2Cl_6(c) + 6KCl(c) = 2K_3AlCl_6(c)$ measured by E. Baud, Ann. chim. phys. 1, 8 (1904).

Heat Capacity and Entropy.

Both C_p and $S^\circ_{298.15}$ were estimated by comparison with the corresponding values of the sum of the constituent halides for $Na_3AlF_6(c)$.

Temperature of Melting.

T_m was estimated by comparison with that for $K_3AlF_6(c)$.

Trisodium Hexachloroaluminate (Na_3AlCl_6)

Heat of Formation

There have been several studies of the interaction of Al with AlF_3 to produce AlF(g) and the results of 2nd and 3rd law analyses are given below.

Ref.		Range °K	Reaction	Points	$\Delta Hr^\circ_{298.15}$ kcal/mol 2nd law	$\Delta Hr^\circ_{298.15}$ kcal/mol 3rd law	Drift eu	$\Delta Hf^\circ_{298.15}$(AlF, g) kcal/mol

* 1 point rejected due to statistical test. ** Value given by original author.

A) $AlF_3(c) + 2\ Al(c) = 3\ AlF(g)$ B) $AlF_3(c) + 2\ Al(\ell) = 3\ AlF(g)$ C) $AlF_3(g) + 2\ Al(\ell) = 3\ AlF(g)$

It is apparent that the runs with least drift are in close agreement at -63.4 kcal/mol and we adopt this value.

This value is confirmed by Gross et al. (6) who report the heat of reaction A as 172.9 kcal/mol or ΔHf°_{298}(AlF, g) = -62.96 kcal/mol. Also the data of Hildenbrand et al. (7) on the reaction $BeF_2(g) + Al(c) = Be(c) + 2\ AlF(g)$ yield ΔHr°_{298} = 59.25 ± 0.5 kcal/mol which gives ΔHf°_{298}(AlF, g) = -64.12 ± 1.7 kcal/mol. The highest observed levels in the $A^1\Pi$ state of AlF correspond to an absolute minimum of 156.4 kcal for the dissociation energy of AlF. Barrow et al. (8) indicate that normal extrapolation of the levels would yield a dissociation energy of 167.0 kcal. The dissociation energy corresponding to the adopted heat of formation is 159.2 kcal which may indicate a potential hump in the $A^1\Pi$ state.

Heat Capacity and Entropy

The rotational, vibrational constants and electronic levels are from the analyses of Naude and Hugo (9), Barrow et al. (8) and Lide (10).

June 30, 1968

ALUMINUM MONOFLUORIDE UNIPOSITIVE ION (AlF^+) (IDEAL GAS) GFW = 45.9794

Ground State Configuration [$^2\Sigma$]

ΔHf°_0 = 161 ± 12 kcal/mol

$S^\circ_{298.15}$ = [52.95 ± 0.5] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 161 ± 12 kcal/mol

Electronic Levels and Quantum Weights

ε_i, cm^{-1}	g_i
0	[2]
[28000]	[4]
[37000]	[2]
[45000]	[2]

ω_e = [740] cm^{-1}

$\omega_e x_e$ = [6] cm^{-1}

σ = 1

B_e = [0.5232] cm^{-1}

α_e = [0.0053] cm^{-1}

r_e = [1.7] Å

Heat of Formation

T. C. Ehlert, G. D. Blue, J. W. Green, and J. L. Margrave, J. Chem. Phys. 41, 2250 (1964) reported the ionization potential of AlF as 9.7 ± 0.5eV (224 ± 12 kcal). The magnitude of the value has been confirmed by R. F. Porter, J. Chem. Phys. 33, 951 (1960) who found it between 9 and 10eV. Using the above value in conjunction with ΔHf°_{298}(AlF, g) = -62.5 kcal/mol, and the equation $AlF(g) \rightarrow AlF^+(g) + e^-$ yields $\Delta Hf^\circ_{298}(AlF^+, g)$ = 161 ± 12 kcal/mol.

Heat Capacity and Entropy

AlF^+ is isoelectronic with MgF, and the electronic configuration of the ground and excited states we estimate to be those for MgF(g). The vibrational frequency, anharmonicity constant and bond length we estimate by comparison with those for MgF and AlF. The rotational constant is calculated from the bond length and atomic masses, and α_e is calculated from the other constants assuming a Morse potential function.

The enthalpy at 0°K is -2.139 kcal.

Aluminum Oxide Fluoride (AlOF)

(Ideal Gas) Mol. Wt. = 61.98

ALUMINUM OXIDE FLUORIDE (AlOF) (IDEAL GAS) MOL. WT. = 61.98

Point Group $C_{\infty v}$

$S^\circ_{298.15}$ = [55.986] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = -139.5 ± 2.6 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -140.2 ± 2.6 kcal. mole^{-1}

<u>Vibrational Frequencies and Degeneracies</u>

<u>ω, cm.$^{-1}$</u>

[900](1)
[500](2)
[750](1)

Bond Distance: O=Al = [1.62] Å   Al-F = [1.65] Å

Bond Angle: O-Al-F = [180]° σ = 1

Rotational Constant: B_0 = [0.180806] cm.$^{-1}$

Heat of Formation.

The equilibrium constants (2200-2225°K.) of the chemical reaction Al_2O_3 (c) + AlF_3 (g) = 3AlOF (g) were measured by M. Farber and H. L. Petersen, Trans. Faraday Soc. 59, 836 (1963). Using this data, the heat of reaction at 298.15°K. was calculated by the third law method to be 266.2 ± 1.7 kcal. mole^{-1}. The value of $\Delta H^\circ_{f\ 298.15}$ for AlOF (g) was then derived.

Heat Capacity and Entropy.

The bond distances of Al-O and Al-F were estimated to be the same as those for AlO (g) and AlF (g), respectively. The point group, ground state quantum weight and vibrational frequencies were obtained from W. H. Evans, J. Hilsenrath and H. W. Woolley, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element Compounds," National Bureau of Standards Report 6928, July 1, 1960. The moment of inertia is 1.54800 x 10^{-38} g. cm.^{2}

[750](1)

Bond Distance: Al-F = [1.65]Å

Bond Angle: F-Al-F =[120°]

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ =[3.367909 X 10^{-115}]g.^{3} cm.^{6}

Heat of Formation.

The selected heat of formation, -165 ± 20 kcal. mole^{-1} is the weighted average of two estimates (a) [-163 ± 20 kcal. mole^{-1}] and (b) [-175 ± 30 kcal. mole^{-1}]. The first estimate (a) is based upon appearance potentials reported by T. C. Ehlert and J. L. Margrave, J. Am. Chem. Soc. 86, 3901 (1964).

(1) $AlF_3(g) \rightarrow AlF_2^+(ion) + F(g)$ 15.2 ± 0.3 e.v.

(2) $AlF_2^+(ion) \rightarrow AlF_2(g)$ -9 ± 1 e.v.

(3) (1) + (2) or $AlF_3(g) \rightarrow AlF_2(g) + F(g)$ 6.2 ± 1.3 e.v.

The second estimate (b) is based upon the average Al-F bond strength of $AlF_3(g)$ and AlF(g). i.e.

(4) $AlF_3(g) + AlF(g) \rightarrow 2\ AlF_2(g)$ $\Delta H_{r\ 298} = 0$

Heat Capacity and Entropy.

The bond distance, 1.65Å, was estimated from a consideration of the Al-F distance 1.63 and 1.655Å in $AlF_3(g)$ and AlF(g). The bent configuration and bond angle estimates were based on the correlations of A. D. Walsh, J. Chem. Soc., 2266, (1953). From the molecular constants the principal moments of inertia were found to be I_A = 1.7829 X 10^{-39}, I_B = 12.8817 X 10^{-39}, and I_C = 14.6646 X 10^{-39} g. cm.^{2}. The vibrational frequencies were calculated assuming valence forces, [G. Herzberg, "Molecular Spectra and Molecular Structure II", D. Van Nostrand Co., 1945] and using force constants calculated from $AlF_3(g)$.

ALUMINUM DIFLUORIDE UNIPOSITIVE ION (AlF_2^+) (IDEAL GAS) GFW = 64.9778

Point Group [$D_{\infty h}$]

ΔHf°_0 = [42.3 ± 10] kcal/mol

$S^\circ_{298.15}$ = [57.8 ± 2.0] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [42 ± 10] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[850] (1)
[240] (2)
[500] (1)

Bond Distance: Al-F = [1.7] Å

Bond Angle: F-Al-F = [180°]

σ = 2

Rotational Constant: B_0 = [0.1535] cm^{-1}

Heat of Formation

T. C. Ehlert, G. D. Blue, J. W. Green and J. L. Margrave, J. Chem. Phys. 41, 2250 (1964) report the appearance potential of AlF_2^+ from AlF_3 as 15.2 ± 0.3eV. Assuming the reaction to be $AlF_3(g) + e^- \rightarrow AlF_2^+ + F + 2e^-$ ΔH = 350.5 ± 7 kcal we calculate $\Delta Hf^\circ_{298}(AlF_2^+, g)$ = 42 ± 10 kcal/mol, or an ionization potential for AlF_2 of 9eV. Due to the neglect of any kinetic energy of the fragments this probably is an upper limit.

Heat Capacity and Entropy

The linear configuration is estimated from the correlation diagrams of A. D. Walsh, J. Chem. Soc. 2266 (1953), however, it should be noted that the isoelectronic MgF_2 is considered to be bent. The vibrational frequencies are estimated to lie between those for AlF_2 and MgF_2. The bond distance is estimated by comparison with AlF and AlF_3.

The enthalpy at 0°K is -2.883 kcal/mol.

ALUMINUM DIFLUORIDE UNINEGATIVE ION (AlF_2^-) (IDEAL GAS) GFW = 64.9788

Point Group [C_{2v}] ΔHf_0° = [-174.5 ± 40] kcal/mol

$S^\circ_{298.15}$ = [61.4 ± 0.5] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [-175 ± 40] kcal/mol

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies
ω, cm^{-1}
[820] (1)
[320] (1)
[900] (1)

Bond Distance: [1.65] Å

Bond Angle: F-Al-F = [120°] σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.368 x 10^{-115}] g^3 cm^6

Heat of Formation

AlF_2^- is isoelectronic with SiF_2 and an estimate of its heat of formation may be obtained by assuming the binding energy to be the same; this yields $\Delta Hf^\circ_{298}(AlF_2^-, g)$ = -191 kcal/mol, or an electron affinity for AlF_2 of 26 kcal/mol.

The binding energy should be close to that of AlF_2 since the extra electron should go into a non-bonding orbital according to the correlation diagrams of A. D. Walsh, J. Chem. Soc. 2266 (1953); using this approach yields $\Delta Hf^\circ_{298}(AlF_2^-, g)$ = -177 kcal/mol or an electron affinity for AlF_2 of 12 kcal. Another method of estimation assumes that the heats are identical for the two reactions $AlF_3 \rightarrow AlF_2^- + F^+$ and $AlF \rightarrow Al^- + F^+$ which yields $\Delta Hf^\circ_{298}(AlF_2^-, g)$ = -161 kcal/mol or an electron affinity for AlF_2 of -4 kcal.

We adopt a median value for the electron affinity for AlF_2 of 10 ± 20 kcal, which leads to $\Delta Hf^\circ_{298}(AlF_2^-, g)$ = -175 ± 40 kcal/mol when combined with $\Delta Hf^\circ_{298}(AlF_2, g)$ = -165 ± 20 kcal/mol.

Heat Capacity and Entropy

According to the predictions of A. D. Walsh, loc. cit., there is no doubt that the molecule is bent; the bond length is assumed to lie between those of AlF and AlF_3, the angle is that in AlF_3. The vibrational frequencies are estimated between those for SiF_2 and AlF_2. By analogy with SiF_2 no low electronic levels are expected (G. Herzberg, "Electronic Spectra of Polyatomic Molecules," D. Van Nostrand Co., Inc., New York 1966).

The enthalpy at 0°K is -2.698 kcal/mol.

The individual principal moments of inertia are $I_A = 1.783 \times 10^{-39}$ g cm^2, $I_B = 12.882 \times 10^{-39}$ g cm^2 and $I_C = 14.665 \times 10^{-39}$ g cm^2.

Aluminum Trifluoride (AlF_3)

Heat of Formation

The adopted value is from separate calorimetric studies of combustion in fluorine of aluminum (1) and aluminum-Teflon mixtures (2). More extensive auxiliary data (2) for Teflon bring the aluminum-Teflon study into exact agreement with the aluminum study (1). Calorimetric data relating AlF_3 to PbF_2 (1, 3) tend to confirm this value, but PbF_2 is probably more uncertain than is AlF_3.

Solid-state emf data (4) relating AlF_3 to MgF_2 via ThF_4 gave $\Delta Gf^\circ = -305.7$ kcal/mol for AlF_3(c) at 600°C. The adopted ΔHf° yields $\Delta Gf^\circ = -306.5$ kcal/mol; this is more negative by 0.8 kcal/mol. The adopted ΔHf° is also 2.4 kcal/mol more negative than indicated by entrainment data (5) for $2/3\ AlF_3(c) + H_2O(g) \rightarrow 1/3\ Al_2O_3(\alpha, c) + 2HF(g)$ in the range from 849° to 1312°K. Analysis of the equilibrium constants yields $\Delta Hr^\circ_{298.15} = 33.11 \pm 0.2$ kcal/mol (3rd law) and 33.33 ± 0.22 kcal/mol (2nd law) with an insignificant entropy difference, $\Delta Sr^\circ(\text{2nd law}) - \Delta Sr^\circ(\text{3rd law}) = 0.2 \pm 0.2$ gibbs/mol. It has been suggested (1) that interaction of the condensed phases caused the equilibria to deviate from the standard-state reaction assumed above. An alternative may be that the reaction with water vapor produced Al_2O_3 in a metastable form; such forms require ignition temperatures greater than 1400°K for complete conversion to α-Al_2O_3 (6).

Heat Capacity and Entropy

Cp° and S°_{298} are taken from Douglas and Ditmars (7), whose tables are based on heat capacity measurements from 54° to 298°K (8) and relative enthalpy measurements from 323° to 1173°K (7). The enthalpy data confirm earlier data (401°-1401°K) of O'Brien and Kelley (9) rather than the adjusted values proposed by Frank (10). Douglas and Ditmars (7) gave a detailed comparison with other data. The entropy is derived from Cp° using the extrapolation $S^\circ_{50} = 0.53 \pm 0.06$ gibbs/mol.

Transition Data

Tt and ΔHt° are from Douglas and Ditmars (7). The values were obtained from extensive enthalpy data for the transition region assuming the presence of a very small amount of impurity in solid solution.

Sublimation Data

Ts is the temperature at which the calculated total pressure (monomer plus dimer) reaches one atm; the mole fraction of dimer is calculated as 0.109 at Ts. Sublimation temperatures of 1533° and 1566°K were obtained in two sublimation-pressure studies (11, 12) at the Technische Hochschule, Breslau. The selected enthalpies of sublimation to $AlF_3(g)$ and $Al_2F_6(g)$ reproduce closely the entrainment data of Krause and Douglas (13). Selection of these values of ΔHs° and comparisons with other vapor-pressure data are discussed on the gas-phase tables.

Dec. 31, 1960; Sept. 30, 1963; Sept. 30, 1965; June 30, 1970

ALUMINUM TRIFLUORIDE (AlF_3) (IDEAL GAS) GFW = 83.9767

Point Group D_{3h}

$S°_{298.15}$ = 66.15 ± 0.2 gibbs/mol

Ground State Quantum Weight = 1

$\Delta Hf°_0 = -288.14 \pm 0.6$ kcal/mol

$\Delta Hf°_{298.15} = -289.035 \pm 0.6$ kcal/mol

Vibrational Frequencies and Degeneracies, ω, cm^{-1}

[650] (1) 297 (1) 935 (2) 263 (2)

Bond Distance: Al-F = 1.63 ± 0.01 Å

Bond Angle: F-Al-F = 120° σ = 6

Product of the Moments of Inertia: $I_AI_BI_C = 3.9742 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

ΔHf° is calculated from that of the crystal by use of $\Delta Hs°_{298.15}$ = 71.965 ± 0.5 kcal/mol. Sublimation studies by mass-spectrometric and entrainment techniques suggest the presence of a small amount of dimer in the saturated vapor. These studies are reviewed on the table for $Al_2F_6(g)$. ΔHs(monomer) and ΔHs(dimer) are selected by adopting (a) the JANAF entropies for crystal, monomer and dimer, (b) the mass spectrometric value of 2 ΔHs(monomer) - ΔHs(dimer) = -49 kcal/mol at 1000°K, and (c) the entrainment data of Krause and Douglas (1). The resulting calculated pressures deviate by <0.5% from the entrainment data (1), by <10% from the mass-spectrometric equation (3) and by <3% from the mass-effusion equation (4).

Further comparisons with experimental data are given below. The adopted values favor the later (11) of two sublimation-point studies (11, 12); both show considerable scatter and similar deviations from the calculated dP/dT. Torsion-effusion data suggest the possibility of more serious discrepancy. Although data of Witt and Barrow (9) are consistent with the JANAF pressures, Hildenbrand et al. (7, 8) noted a trend toward increasing pressure with decreasing orifice area. They concluded (7) that the condensation coefficient <0.06, based on **eightfold** variation in the product of Clausing factor x orifice area. JANAF predictions for the pressure are 60 to 80% of the adjusted torsion values (7) and the discrepancy corresponds roughly to the ratios used in the adjustment. In contrast, the JANAF predictions agree closely with mass-effusion data of Ko et al. (4), who reported no significant effect from a **twelvefold** variation in orifice area.

Comparison of Calculated and Observed Total Pressures over $AlF_3(c)$

[a] Magnitude and sign of the difference, calculated minus observed, in dP/dT. [b] Absolute pressures of monomer were obtained by integration of the ion intensity during total sublimation. [c] Based on P calculated from the torsion pressure Pt by the equation given.

Heat Capacity and Entropy

The molecular structure is that derived from electron-diffraction data by Akishin et al. (13). Observed vibrational frequencies are those reported by Büchler et al. (14) from infrared spectra of the vapor at 1000-1200°K. These frequencies are confirmed by infrared spectra of AlF_3 isolated in matrices of neon, argon and krypton (15). The Raman-active fundamental ν_1 is estimated as 650 ± 50 cm^{-1} by three methods: (a) calculation of the force constant k_1 from ν_3 and ν_4; (b) comparison of $k_1(XY_3)/k(XY)$ for X = B, Al and Y = F, Cl and Br; and (c) extrapolation of $\nu_1(BY_3)/\nu_1(AlY_3)$ to Y = F from Y = Cl, Br and I, using recent gas-phase Raman data (16) for AlY_3. Principal moments of inertia are $I_A=I_B=12.572\times10^{-39}$ and $I_C=25.144\times10^{-39}$ g cm^2.

Bond Distance: Al-F = [1.69] Å LiF = [1.8] Å

Bond Angle: F-Al-F = [109.47°] σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.0109 x 10^{-113}] g^3 cm^6

Heat of Formation

Mass spectrometric studies (1) of the two-phase systems LiF + Li_3AlF_6 and Li_3AlF_6 + AlF_3 suggested that the vapor contains small amounts of Li_2AlF_5 and $Li_2(AlF_4)_2$ but that $LiAlF_4$(g) constitutes of the order of 90%. Hildenbrand et al. (2) reported torsion effusion pressures for the compositions 3LiF·AlF_3 and LiF·AlF_3; as a first approximation, these total pressures should correspond to the reactions (A) Li_3AlF_6(c) → $LiAlF_4$(g) + 2LiF(c), and (B) 1/3 Li_3AlF_6(c) + 2/3 AlF_3(c) → $LiAlF_4$(g). Porter and Zeller (3) reported mass spectrometric equilibrium constants for the reaction (C) Li_2F_2 + AlF_3(g) → LiF(g) + $LiAlF_4$(g). Second- and third-law analyses of these data are summarized below. Kuxmann and Tillessen (4) reported total vapor pressures over molten nLiF·AlF_3 (0.81 ≤ n ≤ 3), but we have made no attempt to establish the liquid phase activities necessary for use of these data.

The adopted ΔHf° is derived from reaction (B) which exhibits entropy deviations (δS) and orifice area effects which are relatively minor. Data for reaction (A) yield a ΔHf° that is more negative by 1.5 kcal/mol, but the very large entropy deviation suggests the presence of systematic uncertainties. Combination of (B) and (A) into the reaction 3LiF(c) + AlF_3(c) → Li_3AlF_6(c) gives ΔHr_{298} = -3.3 kcal/mol, which is fairly consistent with the calorimetric value (5) of ΔHr°_{298} = -5.4 ± 0.5 kcal/mol. Sidorov and Kolosov (6) suggested that the equilibrium constants for reaction (C) should be considered as lower limits since AlF_3 and $LiAlF_4$ are probably both precursors of AlF_2^+.

Heat Capacity and Entropy

The point group and molecular structure are assumed to be similar to those adopted for $NaAlF_4$. A discussion of the incomplete structural evidence is given on the table for $NaAlF_4$(g). The adopted structure consists of tetrahedral AlF_4 combined with Li to form a planar ring, AlF_2Li, through coordination with two fluorines. The Al-F distance is assumed to be equal to that observed in $NaAlF_4$, while the Li-F distance is estimated by comparison of the M-F distances in MF(g), M_2F_2(g), M_3AlF_6(c) (M = Li and Na) with that in $NaAlF_4$(g). The principal moments of inertia are I_A = 24.026 x 10^{-39} and I_B = I_C = 28.930 x 10^{-39} g cm^2.

Snelson (7) observed eight fundamentals in the infrared spectra of $LiAlF_4$ isolated in rare gas matrices. He estimated gas phase fundamentals by assuming a constant shift of about 15 cm^{-1} from the value in a neon matrix to the value in the gas. McCory et al. (8) found absorptions near 778 and 866 cm^{-1} in the infrared spectra of the vapor at high temperatures. We adopt average values of 800 and 890 cm^{-1} for these two fundamentals and Snelson's values for the other six. The four additional fundamentals necessary for C_{2v} symmetry are estimated by comparison with Li_2F_2, Al_2F_6, AlF_3 and $AlCl_4^-$. Sidorov and Kolosov (6), using somewhat different estimates for fundamental frequencies and structural parameters, calculated S°_{1000} = 114 ± 2 gibbs/mol. The JANAF value is 112.7 ± 2 gibbs/mol.

Bond Distance: Al-F = 1.69 ± 0.02 Å Na-F = 2.11 ± 0.02 Å

Bond Angle: F-Al-F = 109.47° σ = [2]

Product of the Moments of Inertia: $I_AI_BI_C = 4.79396 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation

ΔHf° is based on $\Delta Hr^\circ_{298.15}$ = 69.36 kcal/mol for the reaction $Na_3AlF_6(c) \rightarrow NaAlF_4(g) + 2NaF(c)$. ΔHr° is calculated by third law analysis of the pressure equation reported for this reaction by Sidorov and Kolosov (1). The second law ΔHr° = 70.5 kcal/mol and the entropy deviation is 1.1 gibbs/mol. Sidorov and Kolosov obtained their pressure equation by combination of the temperature variation of ion intensities with integration of intensities during total sublimation at 931°K (2).

Sidorov et al. (2) concluded that the pressure of the dimer $(NaAlF_4)_2$ at 931°K is almost half of the monomer pressure over the two-phase system $Na_5Al_3F_{14}$-AlF_3. In contrast, Büchler et al. (3) reported the approximate vapor composition of 97% monomer, 1% dimer, 1% Na_2AlF_5, and 1% AlF_3 over the same condensed phases at 833°K. The latter composition was obtained from a mass spectrometric study by the twin crucible method.

Vapor pressures over melts in the NaF-AlF_3 system have been measured by the entrainment and boiling point techniques (4-7). We have made no attempt to establish the liquid phase activities necessary for use of these data.

Heat Capacity and Entropy

The adopted structure (C_{2v} symmetry) consists of tetrahedral AlF_4 combined with Na to form a planar ring, AlF_2Na, through coordination with two fluorines. Experimental evidence available for $NaAlF_4$ and $LiAlF_4$ does not distinguish conclusively between this structure and the alternatives which have been seriously considered. Alternatives include a C_s structure, in which the ring is non-planar, and two C_{3v} structures, in which Na (or Li) is coordinated to one or three fluorines instead of two.

Electron diffraction data (8) for the vapor gave the adopted bond distances and showed that the AlF_4 group is essentially tetrahedral. Wave error at small scattering angles precluded the calculation of accurate non-bonded distances for Na.

Snelson (9) observed the infrared spectra of $LiAlF_4$ and $NaAlF_4$ isolated in matrices of neon and argon. Eight fundamentals were found above 200 cm^{-1} for $LiAlF_4$ and six for $NaAlF_4$. Snelson chose a C_{3v} structure for $LiAlF_4$ on the basis of Redlich-Teller product-rule calculations for istopic shifts due to Li.

Neither the infrared data nor the electron-diffraction data are conclusive so we apply these qualitative arguments. Coordination of Na to three fluorines seems less likely, since there are no known examples of this behavior. The C_{2v} structure, as suggested by Büchler and Berkowitz-Mattuck (3), is likely because it is a hybrid between the accepted structures of Na_2F_2 and Al_2F_6. C_{2v} symmetry (σ = 2) is a compromise which has an entropy effect intermediate between the other alternatives. The principal moments of inertia of the C_{2v} structure are $I_A = 24.026 \times 10^{-39}$ and $I_B = I_C = 44.669 \times 10^{-39}$ g cm^2.

The fundamental vibrations of 800 and 890 cm^{-1} are average values from gas phase (10) and matrix (9) spectra. Four other observed values are from the matrix data. Six fundamentals are estimated by comparisons similar to those used for $LiAlF_4(g)$.

June 30, 1962; Sept. 30, 1963; Dec. 31, 1963

TRIPOTASSIUM HEXAFLUOROALUMINATE (K_3AlF_6) (CRYSTAL) MOL. WT. = 258.28

$\Delta H^\circ_{f\ 0}$ = Unknown

$S^\circ_{298.15}$ = [68.0 ± 1.0] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-795 ± 5] kcal. mole^{-1}

T_m = 1293°K.

ΔH°_m = Unknown

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ adopted was calculated based upon $\Delta H^\circ_r = -30.2$ kcal. mole^{-1} for the reaction, $AlF_3(c) + 3KF(c) = K_3AlF_6(c)$, which was estimated by comparison with the values of ΔH°_r of the similar reactions for $Na_3AlF_6(c)$, $Na_3AlCl_6(c)$ and $K_3AlCl_6(c)$.

Heat Capacity and Entropy.

Both C_p and $S^\circ_{298.15}$ were estimated by the addition of a correction term, $3(M_{KF}-M_{NaF})$, to the corresponding values for $Na_3AlF_6(c)$, where M denotes either C_p or $S^\circ_{298.15}$.

Temperature of Melting.

T_m was obtained from F. P. Hall and H. Insley, J. Am. Ceram. Soc. 21, 113 (1938).

TRILITHIUM HEXAFLUOROALUMINATE (Li_3AlF_6) (CRYSTAL) GFW = 161.7889

ΔHf°_0 = -805.6 ± 1.1 kcal/mol

$S^\circ_{298.15}$ = 44.907 ± 0.05 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -808.7 ± 1.1 kcal/mol

Tt_1 = 748 K ($\beta \rightarrow \gamma$)

ΔHt°_1 = [0.5] kcal/mol

Tt_2 = 848 K ($\gamma \rightarrow \delta$)

ΔHt°_2 = [0.3] kcal/mol

Tt_3 = 978 K ($\delta \rightarrow \epsilon$)

ΔHt°_3 = [0.1] kcal/mol

Tm = 1058 ± 3 K

ΔHm° = 20.6 ± 1.0 kcal/mol

Heat of Formation

ΔHf° is derived from ΔHr° = -5.4 ± 0.5 kcal/mol at 298.15 K for the reaction 3 LiF(c) + AlF_3(c) → Li_3AlF_6 (α, β mixture). Greene et al. (1) obtained this result by heating the fluorides under standardized conditions in a small electrical furnace contained in their calorimeter at 25°C. ΔHr° includes a small endothermic effect observed during heating of the reaction product. The authors suggest that the enthalpy of conversion between the α- and β-forms is small and thus their result should apply to both forms.

Heat Capacity and Entropy

Furukawa et al. (2) measured Cp°(15-370 K) using a sample prepared by fusion of stoichiometric proportions of LiF and AlF_3 in graphite. X-ray diffraction and petrographic examination of separate portions of the sample indicated a single phase identified as β-Li_3AlF_6. The authors tabulated values of Cp° and S° based on their data and the extrapolation S°_{15} = 0.042 gibbs/mol. These values are adopted.

Douglas and Neufer (3) reported relative enthalpy data (323-973 K) for part of the same sample used in measurement of Cp° (2). Their study was made prior to discovery of the five crystalline phases, and their drop-calorimetric data reveal only the transition near 748 K. Reinterpretation of the data above 748 K is complicated by the proximity of the furnace temperatures to the transition temperatures and by the tendency of high-temperature forms to revert to both α- and β-forms under different conditions of cooling. Björge and Jenssen (4) and Rolin et al. (5) also reported crystalline enthalpy data, but these are relatively imprecise and include similar uncertainties in the final state after the drop. These difficulties preclude the derivation of accurate heat capacities for the high-temperature forms.

Cp° for the β-form is adopted from (2, 3), since the two methods are in good agreement. The curve is extrapolated linearly above 748 K to obtain Cp° for the high-temperature forms. Obvious differences in Cp° are not apparent in the observed data for the different forms, so this should be an adequate approximation.

Transition Data

Existence of five polymorphic forms was shown by high-temperature X-ray diffraction (1, 6, 7) and differential thermal analysis (6, 7). Both α- and β-forms persisted at room temperature, but the α-form appeared only on quenching of high-temperature forms (1). The α-form transformed to β near 490 K (1, 6), but the reverse transformation was not observed. Single-crystal X-ray diffraction showed the α-form to be orthorhombic (8).

The adopted values of Tt are the lowest temperatures at which the high-temperature form was observed growing at the expense of the low-temperature form (1). DTA data (6, 7) were higher by roughly 30° for Tt_1 and 25° for Tt_2. Combination of the observed enthalpies (3) with the adopted Cp° yields ΔHt°_1 = 0.76 and ΔHt°_2 = 0.03 or 0.15 kcal/mol; however, we prefer to adopt ΔHt° values (0.5 and 0.3 kcal/mol) which are more consistent with the areas of peaks in the DTA curve (7). Evidence suggests that ΔHt°_3 is small, so we estimate 0.1 kcal/mol.

Melting Data

See the table for the liquid.

TRILITHIUM HEXAFLUOROALUMINATE (Li_3AlF_6) (LIQUID) GFW = 161.7889

$S^\circ_{298.15}$ = 58.758 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -792.935 kcal/mol

Tm = 1058 ± 3 K

ΔHm° = 20.6 ± 1.0 kcal/mol

Heat of Formation

$\Delta Hf^\circ_{298.15}$ is calculated from that of the crystal by addition of ΔHm° and the difference of ($H^\circ_{1058}-H^\circ_{298.15}$) for the crystal and liquid.

Heat Capacity and Entropy

Relative enthalpy data were measured by Björge and Jenssen (1) from 1065 to 1088 K and by Rolin et al. (2) from about 1075 to 1145 K. The data are consistent with liquid heat capacities in the range from roughly 82 to 92 gibbs/mol. We adopt the mean value of 86 gibbs/mol and extrapolate this to higher and lower temperatures. A glass transition is assumed at 700 K and Cp° at lower temperatures is taken to be the same as that of β-Li_3AlF_6. S°_{298} is calculated in a manner analogous to that of the heat of formation.

Melting Data

Tm was observed at 780°C (3), 782°C (2, 4), 783°C (5, 8) and 785°C (1). The last and highest value is adopted for this table. Combination of the observed liquid enthalpies with the adopted crystal enthalpies yields values for ΔHm° of 19.7 kcal/mol (1, authors gave 20.2 ± 1.0) and 21.5 ± 0.3 kcal/mol (2, authors gave 21.5). We adopt the mean value of 20.6 kcal/mol which is confirmed by values of 20.7 (8), 20.8 (4), 22.2 (4), 20.1 (4) and 22.0 (2) derived from crystal-liquid phase data for binary systems. The agreement among values for ΔHm° seemingly excludes the possibility of large dicrepancies in the enthalpies due to formation of the α-phase instead of β during drop-calorimetry from high temperatures.

Vaporization Data

Li_3AlF_6 vaporizes mainly to $LiAlF_4$(g) with small contributions from species such as Li_2AlF_5(g), Li_2F_2(g) and LiF(g) (6, 7).

CRYOLITE (Na_3AlF_6) (CRYSTAL) GFW = 209.9413

$S°_{298.15}$ = 56.99 ± 0.40 gibbs/mol
Tt ($\alpha \rightarrow \beta$) = 838°K
Tt ($\beta \rightarrow \gamma$) = 1153°K
Tm = 1285°K

$\Delta Hf°_0$ = -788 ± 1 kcal/mol
$\Delta Hf°_{298.15}$ = -791 ± 1 kcal/mol
$\Delta Ht°(\alpha \rightarrow \beta)$ = 1.97 ± 0.40 kcal/mol
$\Delta Ht°(\beta \rightarrow \gamma)$ = 0.09 ± 0.10 kcal/mol
$\Delta Hm°$ = 25.64 kcal/mol

Heat of Formation

The heats of solution of Al(c), NaCl(c), and Na_3AlF_6(c) in 4.36 M HCl acid solution were determined at 303.15°K by Coughlin (1). The enthalpy change for the reaction Al(c) + 2.96 NaCl(c) + 5.96 (HF·5.716 H_2O) + 3.617 $H_2O(\ell)$ = $Na_{2.96}AlF_{5.96}$(c) + 2.96 (HCl·12.731 H_2O) + 3/2 H_2(g) was derived as $\Delta Hr°_{298.15}$ = -153.22 ± 0.14 kcal/mol. Using the $\Delta Hf°_{298}$ data on $H_2O(\ell)$, HCl and HF solution from (2, 3) and NaCl from JANAF Table (4), we calculate the value $\Delta Hf°_{298}$ = -791.2 ± 0.7 kcal/mol for Na_3AlF_6(c).

Baud (5) reported ΔHr° = -40.7 kcal/mol for the reaction $2AlF_3(c) + 6NaF(c) = 2Na_3AlF_6(c)$. Based on JANAF $\Delta Hf°_{298}$ values for AlF_3(c) and NaF(c), we obtain $\Delta Hf°_{298}(Na_3AlF_6, c)$ = -793.7 ± 2 kcal/mol.

Mashovets and Yudin (6) determined the equilibrium constants in the temperature range 1101-1239°K for the reaction $2/3\ Na_3AlF_6(c) + H_2O(g) = 1/3\ Al_2O_3(c) + 2HF(g) + 2NaF(c)$, using the transpiration method. Based on the reported Kp values, we evaluate $\Delta Hr°_{298}$ = 48.1 ± 0.8 and 46.6 kcal/mol by the second and third law methods, respectively. From the third law $\Delta Hr°_{298}$ value, we calculate $\Delta Hf°_{298}(Na_3AlF_6, c)$ = -791.3 kcal/mol.

The equilibrium pressures of sodium vapor in the reaction $2NaF(c) + 1/3\ Al(\ell) = Na(g) + 1/3\ Na_3AlF_6(c)$ at temperatures 1020 - 1150°K were determined by Ono et al. (7), employing differential thermal analysis and X-ray analysis. Since the reported vapor pressures are the total pressures of Na(g) and Na_2(g), we calculate the partial pressures of Na(g) by use of the equilibrium constants for the reaction $Na_2(g) = 2Na(g)$ derived from JANAF functions for Na_2(g) and Na(g). Based on the calculated Na(g) pressures we evaluate the enthalpy change of the above reaction by the third law method to be 109.2 kcal/mol, yielding $\Delta Hf°_{298}(Na_3AlF_6, c)$ = -791.1 kcal/mol.

The amounts of sodium over the mixtures of cryolite and aluminum were measured in the temperature range 1023 - 1373°K by the ultraviolet absorption method by Stokes and Frank (8). The enthalpy change for the reaction $6NaF(\ell) + Al(\ell) = 3Na(g) + Na_3AlF_6(\ell)$ is not evaluated due to lack of appropriate data on the activities of $NaF(\ell)$ and $Na_3AlF_6(\ell)$.

The heat of formation (298°K) for cryolite(c) is adopted as -791 ± 1 kcal/mol.

Heat Capacity and Entropy

The low temperature heat capacities, 53.66 - 296.00°K, were measured by King (9). The values of Cp below 53.66°K are extrapolated using the Cp equation given by King. $S°_{298}$ is derived based on the adopted low temperature heat capacities.

The high temperature enthalpies, 401.3 - 1370.5°K, determined by O'Brien and Kelley (10), are adopted to derive the heat capacities which join smoothly at 298°K with the low temperature Cp's. The heat capacity of $Na_3AlF_6(\gamma)$ is estimated such that the calculated enthalpy at 1200.5°K is consistent with the measured value reported by O'Brien and Kelley. The heat capacity above the melting point is obtained by linear extrapolation.

Frank (21) commented that the enthalpies reported by O'Brien and Kelley were incorrect due to an apparent error in temperature measurement. However, his reported corrected enthalpy values are not used here (see NaF(c) table for details). The high temperature enthalpies have also been measured by the following investigators: Joly, 284.5 - 373.3°K (11); Baud, 289 - 328°K (12); Roth and Bertram, 369 - 1371°K(13); Krestovnikov and Karetnikov, 573 - 1273°K (14); Lyshenko, 290 - 1217°K (15); and Albright, 350.0 - 1311.8°K (16). Their data are not used for evaluation due to inconsistencies among the reported values.

Transition Data

Landon and Ubbelohde (17) determined the electrical conductance (σ) of crystals and melt of cryolite, and observed two transition temperatures from a plot of log σ vs 1/T, i.e. Tt($\alpha \rightarrow \beta$) = 838°K and Tt($\beta \rightarrow \gamma$) = 1153°K, which are adopted here. Other values of Tt($\alpha \rightarrow \beta$) reported are (°K): 823 (16), 833 (18), 834 (19), 835 (20), and 838 (13).

The values of $\Delta Ht°(\alpha \rightarrow \beta)$ and $\Delta Ht°(\beta \rightarrow \gamma)$ are calculated as the difference between the adopted enthalpies for α and β at 838°K and β and γ at 1153°K, respectively. The value of $\Delta Ht°(\alpha \rightarrow \beta)$ has also been reported as (kcal/mol): 1.24 (13), 2.16 (10), 2.24 (20), and 2.38 (16). Landon and Ubbelohde (17) estimated that $\Delta Ht°(\beta \rightarrow \gamma)$ = 0.01 x ΔHm = 0.2 kcal/mol.

The cause of the discrepancies among the reported values for Tt, ΔHt° and the high temperature enthalpies may be due to differences in the sample composition.

Melting Data

See the $Na_3AlF_6(\ell)$ table for details.

Dec. 31, 1968

CRYOLITE (Na_3AlF_6) (LIQUID) GFW = 209.9413

$S^\circ_{298.15}$ = 68.544 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -774.052 kcal/mol

Tm = 1285°K ΔHm° = 25.64 kcal/mol

Heat of Formation

The $\Delta Hf^\circ_{298}(\ell)$ is obtained from $\Delta Hf^\circ_{298}(c)$ by adding ΔHm° and the difference between $H^\circ_{1285} - H^\circ_{298}$ for crystal and liquid.

Yudin and Mashovets (1) studied the dissociation of cryolite and reported $K_{1300} = 2.23\times10^{-5}$ for the reaction $Na_3AlF_6(\ell) = 3NaF(\ell) + AlF_3(c)$. Based on this K_{1300} value, we evaluated the enthalpy change by the third law method as 24.3 kcal/mol. Using ΔHf°_{298} = -360.8 and -130.6 kcal/mol for $AlF_3(c)$ and $NaF(\ell)$, respectively, we obtain $\Delta Hf^\circ_{298} = -776.7 \pm 3$ kcal/mol for $Na_3AlF_6(\ell)$.

Heat Capacity and Entropy

The high temperature enthalpies, 1285.5 - 1370.5°K, were measured by O'Brien and Kelley (2). Using their data we derive a constant Cp, 94.7 gibbs/mol, for $Na_3AlF_6(\ell)$. A glass transition temperature is assumed at 800°K., and the heat capacities below 800°K are taken to be the same as those of the $Na_3AlF_6(c)$. The Cp values above 1370.5°K are obtained by linear extrapolation. The entropy, S°_{298}, is calculated in a manner analogous to that of the heat of formation.

Albright (3) measured the high temperature enthalpies of $Na_3AlF_6(\ell)$ in the temperature range 1298.1 - 1311.8°K. However, his data are systematically higher (about 4.9%) than the values determined by O'Brien and Kelley (2), which is also true for the other sets of enthalpy data measured using this calorimeter. Therefore Albright's enthalpy data is not used for evaluation.

Melting Data

The melting point of cryolite has been reported as (°K): 1273 (4), 1279 (3), 1281 (5), 1282 (6, 7), 1293 (9), and 1300 (2). The value of Tm adopted is that determined by Landon and Ubbelohde (8). This value is corrected from the original measured value 1286°K, due to the thermocouple standardization against the freezing points of assay gold giving a gold point of 1064.2 ± 0.15°C compared with the fixed value of 1063.0°C.

The value of ΔHm° is calculated as the difference between the enthalpies at Tm for crystal and liquid. Other reported values of ΔHm° are (in kcal/mol): 16.64 (4), 26.6 (10), 27.64 (2), and 27.91 (3).

ALUMINUM MONOHYDRIDE (AlH) (IDEAL GAS) MOL. WT. = 27.988

Ground State Configuration $^1\Sigma^+$

$\Delta H^\circ_{f\ 0}$ = 62.0 ± 5.0 kcal mole^{-1}

$S^\circ_{298.15}$ = 44.875 cal deg^{-1} mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 62.0 ± 5.0 kcal mole^{-1}

Electronic Levels and Multiplicities

ε, cm^{-1}	g_i
0	1

ω_e = 1682.56 cm^{-1}

$\omega_e x_e$ = 28.09 cm^{-1}

σ = 1

B_e = 6.3907 cm^{-1}

α_e = 0.1858 cm^{-1}

r_e = 1.6477 Å

Heat of Formation

A. G. Gaydon, "Dissociation Energies", 2nd Ed., Chapman Hall, Ltd., London (1953), extrapolated the available $X^1\Sigma$ vibrational levels and also considered predissociation in the $A^1\Pi$ state and concluded that the best value of D_0° was 2.9 ± 0.2 e.v. The linear Birge-Sponer extrapolation gave a value of 3.05 e.v. while the predissociation limit was 3.07 e.v. Gaydon's recommended value is adopted here and leads to a vlaue of $\Delta H^\circ_{f\ 298.15}$ = 62.16 ± 5.0 kcal mole^{-1} using JANAF auxiliary data.

Heat Capacity and Entropy

P. B. Zeeman and G. J. Ritter, Can. J. Phys. 32, 555 (1954) examined the UV band system of AlH under high resolution and reported the molecular constants adopted above.

ALUMINUM OXIDE HYDRIDE (HAlO) (IDEAL GAS) MOL. WT. = 43.988

Point Group [$C_{\infty v}$]

$S^\circ_{298.15}$ = [51.464] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H_f^\circ{}_0$ = [9 ± 20] kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = [8 ± 20] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[900] (1)
[1000] (2)
[1600] (1)

Bond Distance: Al=O = [1.62] Å Al-H = [1.64] Å

Bond Angle: H-Al-O = [180°]

σ = 1

B_0 = [0.5271] cm.$^{-1}$

Heat of Formation.

The heat of formation was estimated by summing the constituent bond energies. The Al=O was taken as that in AlO(g) and the Al-H bond was taken as that in AlH(g), this gave a heat of atomization of 182 kcal.

Heat Capacity and Entropy.

Vibrational frequencies, bond lengths and angles and point group were taken from National Bureau of Standards Report 6297, Jan. 1, 1959, "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum, and Their Compounds with Oxygen, Hydrogen, Fluorine, and Chlorine".

Heat of Formation

From a mass-spectrometric investigation of the equilibrium

$$1/3Al_2O_3(c) + 1/3Al(g) + 1/2D_2(g) = AlOD(g)$$

M. Farber et al. (1) report second law heats of reaction of 56.7 ± 0.6 kcal at 1980°K, 57.1 ± 2.8 kcal at 2060°K and 62.7 ± 1.4 kcal at 2000°K. Using JANAF auxilliary data, assuming AlOD to be AlOH, we obtain ΔHf°_{298}(AlOD, g) = -44.6 ± 1, -44.0 ± 3.2 and -38.6 ± 1.8 kcal/mol. A second equilibrium in the same investigation was

$$Al_2O(g) + D_2O(g) = 2AlOD(g)$$

for which second law heats of reaction of 6.3 ± 2.1 kcal at 2060°K and 5.7 ± 0.8 kcal at 2000°K were reported. Farber et al. also measured the heat of reaction

$$1/3Al_2O_3(c) + 4/3\ Al(g) = Al_2O(g)$$

at the same temperatures as -10.7 ± 2.8 kcal at 2060° and -10.3 ± 10.2 kcal at 2000°K. Combining these reactions and eliminating $Al_2O(g)$ yields ΔHr_{2060} = -4.4 ± 5.0 kcal and ΔH_{2000} = -5 ± 11 kcal for the reaction

$$1/3Al_2O_3(c) + 4/3Al(g) + D_2O(g) = 2AlOD(g).$$

Using auxiliary JANAF values for $Al_2O_3(c)$ and Al(g), $\Delta Hf^\circ_{298}(D_2O, g)$ = -59.56 kcal/mol (2), and functions for $D_2O(g)$ from Friedman and Haar (3) we obtain ΔHf°_{298}(AlOD, g) = -43.9 ± 6 kcal/mol and -43.4 ± 3 kcal/mol. From all the above results we adopt a value of ΔHf°_{298}(AlOD, g) = -44 ± 3 kcal/mol, assuming that AlOH is less stable than AlOD by 1 kcal/mol as is the case for H_2O, HDO and D_2O, we obtain ΔHf°_{298}(AlOH, g) = -43 ± 3 kcal/mol.

Farber et al. (1) also performed weight loss experiments under molecular flow conditions by allowing hydrogen to flow over $Al_2O_3(c)$. The products assumed were AlOH(g), Al(g), $Al_2O(g)$, H(g) and $H_2O(g)$ and the equilibrium amounts of H(g), Al(g) and $Al_2O(g)$ were assumed to be those predicted by the free energies from the JANAF tables. A 3rd law analysis of the equilibrium constants given by Farber for the reaction $2H_2(g) + Al_2O_3(c) = 2AlOH(g) + H_2O(g)$ yields ΔHr°_{298} = 238 ± 12 kcal/mol and ΔHf°_{298}(AlOH, g) = -52 ± 6 kcal/mol. However, the assumed equilibria involving $Al_2O(g)$ and Al(g) may be significantly in error and thus the ΔHf°_{298} should be considered as simply confirming the magnitude determined mass-spectrometrically.

Heat Capacity and Entropy

The vibrational frequencies are estimated by using the AlO(g) fundamental as approximately the Al-O stretch; the O-H stretch is that in $H_2O(g)$; and the bending frequency is approximately the OH bend in $CD_3OH(g)$ reported by T. Shimanouchi, U. S. Natl. Bur. Std. NSRDS-NBS 6, 1967.

The AlO bond length was taken from U. S. Natl. Bur. Std. Report No. 6297, Jan. 1, 1959, and the OH bond length is assumed to be that in $H_2O(g)$. The bond angle is assumed to be 180° using the prediction of A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953), for "HAB" molecules with less than 11 valence electrons. Confirmation of this prediction is scanty for molecules having A more electronegative than B; however, R. L. Kuczkowski, D. R. Lide, Jr., and L. C. Krishner, J. Chem. Phys. 44, 3131 (1966), have confirmed the linearity of KOH and CsOH which have 8 valence electrons.

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(AlOH, g) and its ionization potential, which is estimated to be 7.5 ± 1 eV (173 ± 23 kcal). The ionization potential is estimated from a reported value of 7.5 eV for the appearance potential of $AlOD^+$, presumably from the parent AlOD, by M. Farber, M. A. Frisch, G. Grenier, and H. C. Ko, Space Sciences, Inc., Final Report under USAF contract F04611-67-C-0010, AFRPL-TR-67-244, November, 1967.

Heat Capacity and Entropy

According to the correlation diagram given by A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953), for "HAB" molecules, a compound with 9 valence electrons would have the three outermost electrons in an unfilled Π orbital. Thus, it would be a $^2\Pi$ state since the molecule ought to be linear if it has less than 11 valence electrons. The outermost orbital is a bonding orbital and thus the loss of an electron from it would weaken the bonding. The vibrational frequencies are estimated from those for AlOH(g) with somewhat lower frequencies due to the weaker bonding. Similarly, the Al-O bond length is slightly increased over that in AlOH(g). The enthalpy at 0°K is -2.138 kcal/mol.

Product of the moments of Inertia: $I_A I_B I_C$ = [4.554×10^{-117}] g^3 cm^6

Heat of Formation

The heat of formation is obtained from ΔHf°_{298}(AlOH, g) and its electron affinity, which is estimated to be 0.5 ± 0.9 eV (12 ± 20 kcal). The electron affinity is estimated to be small, or even negative, since the additional electron must go into an antibonding orbital, according to the correlation diagram of A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953).

Heat Capacity and Entropy

Since the molecule now has 11 valence electrons, the Walsh correlation diagram predicts a bent molecule. The extra electron is antibonding thus making the bonds weaker than in AlOH(g). Thus the vibrational frequencies and bond lengths are taken to be the same as in $AlOH^+$(g), which is also less strongly bound than AlOH(g). The bond angle is arbitrarily chosen as 120°. The principal moments of inertia are $I_A = 6.536 \times 10^{-39}$ g cm^2, $I_B = 0.105 \times 10^{-39}$ g cm^2 and $I_C = 6.641 \times 10^{-39}$ g cm^2. The enthalpy at 0°K is -2.419 kcal/mol.

[3400] (1)	[700] (1)
[1200] (1)	[500] (1)
[1100] (1)	[400] (1)

Bond Distances: Al=O = [1.62] Å Al-O = [1.87] Å O-H = [0.94] Å

Bond Angles: O-Al-O = [180°] Al-O-H = [105°]

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = [37.349 \times 10^{-117}]\ g^3\ cm^6$

Heat of Formation

The hydroxyl group can often be considered as intermediate between F and Cl as is illustrated by the following examples of bond energies from these tables.

D(F-H) = 136 kcal, D(Cl-H) = 103 kcal and D(HO-H) = 119 kcal; also

D(F-BO) = 163 kcal, D(Cl-BO) = 105 kcal and D(HO-BO) = 143 kcal. Thus from

D(F-AlO) = 181 kcal and D(Cl-AlO) = 134 kcal we estimate D(HO-AlO) = 158 ± 20 kcal. This yields $\Delta Hf°_{298}$(HOAlO, g) = -127 ± 20 kcal/mol.

Consider also D(FB-O) = 175 kcal and D(ClB-O) = 169 kcal; and D(FAl-O) = 138 kcal and D(ClAl-O) = 132 kcal; it is evident that the substituent F or Cl has little effect on the B-O and Al-O bonds. Thus, we assume that D(HOAl-O) = 135 ± 10 kcal/mol which leads to $\Delta Hf°_{298}$(HOAlO, g) = -119 ± 10 kcal/mol.

M. Farber, M. A. Frisch, G. Grenier, and H. C. Ko, "Investigation of the Thermodynamic Properties of Rocket Combustion Products," AFRPL-TR-67-244, Nov. 1967, found no evidence for the ion $DOAlO^+$ when reacting $D_2O(g) + Al_2O_3(c)$. From estimates of the pressure needed to ensure detection of DOAlO and a knowledge of the D_2O pressure, they calculated the most negative value of $\Delta Hf°_{298}$(HOAlO, g) = -104 ± 10 kcal/mol. The absence of $DOAlO^+$ may be caused by fragmentation by the ionizing electrons and thus the value quoted may not be a real limit.

We adopt $\Delta Hf°_{298}$(HOAlO, g) = -110 ± 15 kcal/mol which encompasses all the values.

Heat Capacity and Entropy

Vibrational frequencies, bond distances, bond angles, and the product of the moments of inertia were taken from "Preliminary Report on the Thermodynamic Properties of Lithium, Beryllium, Magnesium, Aluminum, and Their Compounds with Oxygen, Hydrogen, Fluorine, and Chlorine," National Bureau of Standards Report No. 6297, January 1, 1959. The individual moments of inertia are : $I_A = 0.13 \times 10^{-39}\ g\ cm^2$, $I_B = 16.9 \times 10^{-39}\ g\ cm^2$, and $I_C = 17.0 \times 10^{-39}\ g\ cm^2$.

LITHIUM TETRAHYDROALUMINATE ($LiAlH_4$) (CRYSTAL) MOL. WT. = 37.952

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [21.0 ± 2.0] $\Delta H_f^\circ{}_{298.15}$ = -28.0 ± 2.0 kcal. mole^{-1}

T_d = [410 ± 10]°K.

Heat of Formation.

The heats of solution of $LiAlH_4(c)$ in HCl(aq.) were measured calorimetrically by the following investigators: W. D. Davis, L. S. Mason and G. Stegeman, J. Am. Chem. Soc. 71, 2775 (1949), L. G. Fasolino, et al., "Heat of Formation of Lithium Aluminum Hydride," Special Report, National Research Corporation, Ma., April 26, 1963, and M. B. Smith and G. E. Bass, Jr., J. Chem. Eng. Data, 8, 342 (1963). The results are given in the following table.

Investigator		Chemical Reaction	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1}
Davis, et al.	(1)	$LiAlH_4(c) + 10(HCl\cdot 50H_2O) \rightarrow (LiCl + AlCl_3 + 6HCl)\cdot 500H_2O + 4H_2(g)$	-165.87
	(2)	$(AlCl_3 + LiCl + 6HCl)\cdot 500\ H_2O + 41020\ H_2O(l) \rightarrow (AlCl_3 + LiCl + 6HCl)\cdot 41520\ H_2O$	-4.43
	(3)	$(AlCl_3 + LiCl + 6HCl)\cdot 41520\ H_2O \rightarrow AlCl_3\cdot 5190\ H_2O + LiCl\cdot 5190\ H_2O + 6(HCl\cdot 5190\ H_2O)$	0.00(assumed)
		(1) + (2) + (3)	-170.30
Fasolino, et al.	(4)	$Al + 60(HCl\cdot 14H_2O) \rightarrow (AlCl_3 + 57\ HCl)\cdot 840\ H_2O + 3/2\ H_2$	-128.14
	(5)	$Li + 60(HCl\cdot 14H_2O) \rightarrow (LiCl + 59\ HCl)\cdot 840\ H_2O + 1/2\ H_2$	-67.05
	(6)	$LiAlH_4 + 60(HCl\cdot 14\ H_2O) \rightarrow (LiCl + AlCl_3 + 56\ HCl)\cdot 840\ H_2O + 4H_2$	-170.52
		(4) + (5) - (6)	-24.67
Smith and Bass	(7)	$LiAlH_4(c) + 39.715(HCl\cdot 11.624\ H_2O) \rightarrow [LiCl + AlCl_3 + 35.715\ (HCl\cdot 12.926\ H_2O)] + 4H_2(g)$	-164.6
	(8)	$LiCl(c) + [AlCl_3 + 35.715(HCl\cdot 12.926\ H_2O)] \rightarrow [LiCl + AlCl_3 + 35.715\ (HCl\cdot 12.926\ H_2O)]$	-6.75
		(7) - (8)	-157.85

Incorporating appropriate auxiliary thermal data, the heats of formation ($\Delta H_f^\circ{}_{298.15}$) for $LiAlH_4(c)$ were derived as -28.51 (recalculated value, by Smith and Bass, loc. cit.), -24.67 ± 1.31 and -28.4 ± 1.5 kcal. mole^{-1}, resp. The adopted value, -28.0 ± 2.0 kcal. mole^{-1}, is the weighted average of the above three values.

Heat Capacity and Entropy.

Heat capacities were estimated by comparison with those for $LiBH_4(c)$, $LiBO_2(c)$ and $LiAlO_2(c)$. The entropy value ($S^\circ_{298.15}$) was calculated from that for $LiBH_4(c)$ by the substitution of the entropy contribution of B atom by that of Al atom in the $LiAlH_4(c)$ molecule. The entropy values of the constituent B and Al atoms in crystalline compounds were taken from O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958.

Temperature of Decomposition.

T_d was reported by A. E. Finholt, A. C. Bond, Jr. and H. I. Schlesinger, J. Am. Chem. Soc. 69, 1199 (1947). The decomposition products are aluminum, hydrogen, and lithium hydride. This reaction is apparently kinetically controlled since the free energy for the decomposition is negative even at room temperature.

Dec. 31, 1961; Sept. 30, 1964

ALUMINUM MONOIODIDE (AlI) (IDEAL GAS) MOL. WT. = 153.89

Ground State Configuration $^1\Sigma^+$

$\Delta H_{f\ 0}^\circ = 14.6 \pm 2.0$ kcal. mole⁻¹

$S^\circ_{298.15} = [59.243]$ cal. deg.⁻¹ mole⁻¹

$\Delta H^\circ_{f\ 298.15} = 14.3 \pm 2.0$ kcal. mole⁻¹

Electronic Levels and Quantum Weight

ϵ_1, cm.⁻¹	g_1
0	1

$\omega_e = 316.1$ cm.⁻¹

$\omega_e x_e = 1.0$ cm.⁻¹

$\sigma = 1$

$B_e = [0.1156]$ cm.⁻¹

$\alpha_e = [0.000492]$ cm.⁻¹

$r_e = [2.56]$ Å

Heat of Formation.

The dissociation energy (D_0°) of AlI(g) was reported by A. G. Gaydon [1], R. F. Barrow [2], and G. Herzberg [3], respectively. Hence the corresponding values of $\Delta H^\circ_{f\ 298.15}$ for AlI(g) were derived. The results are given as follows.

Investigator	D_0° e.v.	D_0° kcal. mole⁻¹	$\Delta H^\circ_{f\ 298.15}$ kcal. mole⁻¹
Gaydon [1]	3.92	90.4	12.7
Barrow [2]	—	87.0	16.0
Herzberg [3]	2.9	66.9	36.2

[1] A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall Ltd., London, 1953.
[2] R. F. Barrow, Trans. Faraday Soc. 56, 952 (1960).
[3] G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950.

The adopted value of $\Delta H^\circ_{f\ 298.15}$ for AlI(g) is the average of the first two $\Delta H^\circ_{f\ 298.15}$ values listed in the above table.

Heat Capacity and Entropy.

The spectroscopic constants, ω_e and $\omega_e x_e$, and ground state configuration were taken from G. Herzberg, loc. cit. The values of B_e and α_e were estimated. The bond length (r_e) was estimated by comparison with those for Al_2I_6(g) reported by K. J. Palmer and N. Elliott, J. Am. Chem. Soc. 60, 1852 (1938).

Dec. 31, 1961; June 30, 1964

ALUMINUM TRIIODIDE (AlI_3) (CRYSTAL) MOL. WT. = 407.71

$S^\circ_{298.15}$ = [45.3 ± 2.0] cal. deg.$^{-1}$ mole^{-1}

T_m = 464.15°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -73.9 ± 1.5 kcal. mole^{-1}

ΔH°_m = 3.8 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ (to dimer) = 28.8 ± 1.8 kcal. mole^{-1}

Heat of Formation.

J. D. Corbett and N. W. Gregory, J. Am. Chem. Soc. 76, 1446 (1954) reported the free energy change, $\Delta F^\circ_{298.15}$ = -8.7 ± 0.2 kcal. mole^{-1}, for the reaction $AlI_3(c) + 3HCl(g) \rightarrow AlCl_3(c) + 3HI(g)$. By the relationship $\Delta H = \Delta F + T\Delta S$ the value of $\Delta H^\circ_{r\ 298.15}$ was derived as -10.1 ± 0.2 kcal. mole^{-1}. The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for $AlI_3(c)$ was evaluated to be -73.66 ± 0.30 kcal. mole^{-1}. The heat of solution of $AlI_3(c)$ in water was measured by D. J. A. Dear and D. D. Eley, J. Chem. Soc., 4684 (1954). From the value, $\Delta H^\circ_{r\ 298.15}$ = -91.4 ± 1.5 kcal. mole^{-1} for the reaction $AlI_3(c) \rightarrow Al^{+++}(aq.) + 3I^-(aq.)$, the heat of formation for $AlI_3(c)$ was calculated to be -74.1 ± 1.5 kcal. mole^{-1}. The adopted value of $\Delta H^\circ_{f\ 298.15}$ for $AlI_3(c)$ is the average of the above two values.

Heat Capacity and Entropy.

The heat capacities, 298.15-464°K., were taken from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). They were derived from the enthalpy data measured by W. Fischer, Z. anorg. Chem. 200, 332 (1931). Above 464°K. the C_p values were obtained by graphical extrapolation. The entropy, $S^\circ_{298.15}$, for $AlI_3(c)$ was calculated from $S^\circ_{298.15}$ for $AlI_3(l)$ by subtracting ΔS°_m and the difference between $S^\circ_{464.15}-S^\circ_{298.15}$ for crystal and liquid.

Melting Data.

Temperature and heat of melting were reported by W. Fischer, loc. cit.

Heat of Sublimation.

Heat of sublimation was calculated from vapor pressure data reported by W. Fischer, O. Rahlfs, and B. Benze, Z. anorg. allgem. Chemie, 205, 1 (1932), by both the second and third law methods. See $Al_2I_6(g)$ table for details.

Dec. 31, 1961; June 30, 1964

AlI_3

ALUMINUM TRIIODIDE (AlI_3) (LIQUID) MOL. WT. = 407.71

$S^\circ_{298.15}$ = [52.45] cal. deg.$^{-1}$ mole^{-1} ΔH_f° 298.15 = -70.77 ± 1.5 kcal. mole^{-1}

T_m = 464.15°K. ΔH_m° = 3.8 kcal. mole^{-1}

Heat of Formation.

ΔH_f° 298.15(l) was obtained from ΔH_f° 298.15(c) by adding ΔH_m° and the difference between $H^\circ_{464.15}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity, 464-500°K., was obtained from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). It was derived based on the enthalpy data measured by W. Fischer, Z. anorg. Chem. 200, 332 (1931). The C_p values above 500°K. were assumed to be the same as that at 500°K. The entropy, $S^\circ_{298.15}$, was estimated so that the values of ΔH_v° calculated from vapor pressure data by the second and third law methods were in reasonable agreement.

Melting Data.

T_m and ΔH_m° were reported by W. Fischer, loc. cit.

Dec. 31, 1961; June 30, 1964

ALUMINUM TRIIODIDE (AlI_3) (IDEAL GAS) MOL. WT. = 407.71

Point Group [D_{3h}]

$S^\circ_{298.15}$ = [86.776] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = -47.5 ± 1.8 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -49.0 ± 1.8 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
[210] (1)	[95] (1)
[170] (1)	[450] (2)

Bond Distance: Al-I = 2.44 ± 0.02 Å

Bond Angle: I-Al-I = [120]°K.

σ = 6

Product of the Moments of Inertia: $I_AI_BI_C = 1.33213 \times 10^{-110}$ g.^{3} cm.^{6}

Heat of Formation.

The equilibrium pressures of the reaction $Al_2I_6(g) \rightarrow 2AlI_3(g)$ at several temperatures were determined by W. Fischer, O. Rahlfs and B. Benze, Z. anorg. allgem. Chem. 205, 1 (1932). The heats of dissociation of $Al_2I_6(g)$ were calculated by both second and third law methods. The heats of vaporization, i.e. $AlI_3(l) \rightarrow AlI_3(g)$, were also evaluated using the calculated partial pressure of $AlI_3(g)$ over $AlI_3(l)$. See $Al_2I_6(g)$ table for detail. The results obtained are summarized as follows:

Chemical Reaction or Process	Temperature Range (°K.)	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	$\Delta H^\circ_{f\ 298.15}(AlI_3, g)$ Kcal. Mole^{-1}
$Al_2I_6(g) \rightarrow 2AlI_3(g)$	614 - 744	25.18	23.34	-47.9
$Al_2I_6(g) \rightarrow 2AlI_3(g)$	482.8 - 578.0	23.07	23.34	-49.0
$AlI_3(l) \rightarrow AlI_3(g)$	493.8 - 645.2	21.45	22.69	-49.2

The three $\Delta H^\circ_{f\ 298.15}(AlI_3, g)$ values were calculated using the respective second law values of $\Delta H^\circ_{r\ 298.15}$. The adopted value, $\Delta H^\circ_{f\ 298.15}$ = -49.0 ± 1.8 kcal. mole^{-1}, is the weighted average of the above three values.

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were obtained from P. A. Akishin, N. G. Rambidi, and E. L. Zosorin, Kristallografiya, 4, 186 (1959). The vibrational frequencies were estimated such that the values of ΔH°_r obtained by the third law method are in reasonable agreement with the corresponding values calculated by the second law method. The three principal moments of inertia are: $I_A = I_B = 1.8815 \times 10^{-37}$ and $I_C = 3.7630 \times 10^{-37}$ g. cm.^{2}.

LITHIUM ALUMINATE ($LiAlO_2$) (CRYSTAL) MOL. WT. = 65.92

ΔH_{f0}° = -282.78 kcal. mole^{-1}

T_m = 1883°K

ΔH_f° 298.15 = -284.33 ± .20 kcal. mole^{-1}

$S^\circ_{298.15}$ = 12.75 cal. deg.$^{-1}$ mole^{-1}

ΔH_m = [6000] cal. mole^{-1}

Heat of Formation.

ΔH_f° 298.15 was measured by J. P. Coughlin, J. Am. Chem. Soc. 79, 2397 (1957).

Heat Capacity and Extrapolation.

Thermodynamic functions are based on the low temperature heat capacity data of E. G. King, J. Am. Chem. Soc. 77, 3189 (1955), and on the high temperature heat content results of A. O. Christensen, K. O. Conway, and K. K. Kelley, U. S. Bur. Mines Rept. Invest. 5565 (1960).

Melting.

R. Ballo and E. Dittler, Z. anorg. u allgem. Chem. 76, 39 (1912), list the melting point as between 1900° to 2000°K. More recently, K. H. Kim and F. A. Hummel, J. Am. Ceram. Soc. 43, 611 (1960), determined the melting point as 1883° ± 15°K. by rapidly heating a small sample on a Pt-Rh strip furnace. The value, which was used in this report, was derived from an average of ten measurements by Kim and Hummel.

H. Prophet, The Dow Chemical Company, private communication March 9, 1961, using an arc-image furnace reports the melting point to be about 1975°K. After seven successive runs on the same sample the melting point approached that of Al_2O_3 at 2308°K. The sample, therefore is decomposed upon fusion to Li_2O vapor and Al_2O_3(c). See O. N. Salmon and L. Marcus J. Am. Ceram. Soc. 43, 549 (1960), and F. A. Hummel, B. S. R. Sastry and D. Watring, Ibid, 41, 88 (1958).

Dec. 31, 1960; Dec. 31, 1961; Dec. 31, 1962

ALUMINUM NITRIDE (AlN) (CRYSTAL) MOL. WT. = 40.988

$\Delta H_{f\ 0}^\circ = -74.8 \pm 0.3$ kcal. mole^{-1}

$T_d = [2790°K]$

$\Delta H_{f\ 298.15}^\circ = -76.0 \pm 0.3$ kcal. mole^{-1}

$S_{298.15}^\circ = 4.816$ cal. deg.$^{-1}$ mole^{-1}

Heat of Formation.

The selected heat of formation is the average of two independent calorimetric determinations. The heat of formation was reported to be -76.5 ± 0.2 kcal. mole^{-1} and -75.6 ± 0.4 kcal. mole^{-1}. The former value was reported by C. A. Neugebauer and J. L. Margrave, Z. Anorg. Allgem. Chem. 290, 82 (1957). The later value was reported by A. D. Mah, E. G. King, W. W. Weller, and A. V. Christensen, U. S. Bureau of Mines Report of Investigations 5716 (1961).

Vapor pressure measurements agree with the selected heat of formation. For instance $\Delta H_{f\ 298.15} = -75.5$ kcal. mole^{-1} for AlN(c) was calculated from the heat for the reaction $2AlN(c) \rightarrow 2Al(g) + N_2(g)$ and the heat of sublimation, 78.0 kcal. mole^{-1}, for Al(c). This heat of reaction was obtained from a third law calculation using JANAF values for the free energy functions and torsion effusion pressures measured by D. L. Hildenbrand and L. P. Theard, Aeronutronic Technical Report U-1497 (1961). Vapor pressure measurements with a microbalance in a vacuum system by L. H. Dreger, V. V. Dadape, and J. L. Margrave, J. Phys. Chem. 66, 1556 (1962) agree with the selected $\Delta H_{f\ 298.15}^\circ$. When recalculated with the sublimation coefficient ($\alpha \approx 2.2 \times 10^{-3}$) reported by Hildenbrand and Theard, some of the Knudsen cell measurements by M. Hoch and D. White, "The Vaporization of Boron Nitride and Aluminum Nitride," ASTIA Unclassified Report 142616, October 29, 1956, agree with the selected heat of formation.

Earlier determinations of the heat of formation which apparently are in error are summarized by C. A. Neugebauer and J. L. Margrave (loc. cit.) and by L. H. Dreger et al. (loc. cit.).

Heat Capacity and Entropy.

The heat capacity and entropy were reported by A. D. Mah et al. (loc. cit.). They measured the low temperature (51-298.15°K) and high temperature (298.15-1800°K) heat capacities and extrapolated the heat capacity from 0 to 51°K using the T^3 law. A smooth extrapolation of the heat capacity was made from 1800° to 3000°K. The heat content of AlN(c) was recently determined from 300 to 1200°K by R. Mezaki, "Heat Contents of Inorganic Substances at High Temperatures," M. S. Thesis, University of Wisconsin (1961). The enthalpies reported by Mezaki are about 1% greater than those of Mah et al.

Decomposition Data.

P. O. Schissel and W. S. Williams, Bull. Am. Phys. Soc. II, 4, 139 (1959) studied the vaporization of AlN with the mass spectrometer and detected only the gaseous species Al and N_2. The temperature at which the ΔF_f° of AlN(c) and Al(g) were equal, 2788.9°K, was taken as the temperature of decomposition.

$r_e = [1.65]$ Å

Heat of Formation.

The heat of formation is calculated from the estimated ω_e and $\omega_e x_e$, using $D_0 = \omega_e{}^2/4\omega_e x_e$, as 89 kcal/mol. J. L. Margrave and P. Staphitanonda, J. Phys. Chem. 59, 1231 (1955) estimated values of the bond length as 1.23 - 1.65 Å and calculated from an ionic model D_0 values of 137 - 82 kcal/mol. Using an estimated bond length of 1.65 Å and a D_0 = 87 kcal/mol leads to ΔHf°_{298} = 104 kcal/mol.

Heat Capacity and Entropy.

The bond length is estimated as 1.65 Å from a comparison with the bond lengths of SO, PO, SiO, AlO, MgO, S_2, SiS, AlS, PN, SiN, and the sums of covalent radii. This bond length is then used with Guggenheimer's Relation [K. M. Guggenheimer, Proc. Phys. Soc. (London), 58, 456 (1946)] to calculate a value for ω_e. By analogy with SiN(g) it is taken to closely approach the multiple bonding case, which gives ω_e = 960 cm^{-1}. The anharmonicity correction x_e is calculated by assuming the product $x_e\mu^{1/2}$ equal to that for AlO(g). The value of α_e is calculated using the relation:

$$\alpha_e = 6[(\omega_e x_e B_e{}^3)^{1/2} - B_e{}^2]/\omega_e$$

Sodium Aluminate ($NaAlO_2$)

Dec. 31, 1960; Mar. 31, 1963

SODIUM ALUMINATE ($NaAlO_2$) (CRYSTAL) MOL. WT. = 81.971

$\Delta H_{f\ 0}^\circ = -268.97 \pm 0.17$ kcal. mole^{-1}

$S_{298.15}^\circ = 16.826$ cal. deg.$^{-1}$ mole^{-1} $\Delta H_{f\ 298.15}^\circ = -270.84 \pm 0.17$ kcal. mole^{-1}

$T_t = 740$°K. $\Delta H_t = 0.310$ kcal. mole^{-1}

T_m = above 1923°K. ΔH_m° = Unknown

Heat of Formation.

$\Delta H_{f\ 298.15}^\circ$ was reported by J. P. Coughlin, J. Am. Chem. Soc. 79, 2397 (1957). The value was calculated from the measured heat of solution of $NaAlO_2$(c) at 303.15°K. in 4.360m hydrochloric acid solution.

Heat Capacity and Entropy.

The low temperature heat capacities, below 350°K., were measured by E. F. Westrum, University of Michigan, Ann Arbor, Michigan, private communication, May 19, 1960. Heat capacities above 350°K, 399.4 — 1698.6°K., were measured by A. U. Christensen, K. C. Conway, and K. K. Kelley, U. S. Bur. Mines Rept. Invest. 5565 (1960). These two sets of C_p data were plotted graphically and joined smoothly at 350°K. Low temperature heat capacities 51°-298°K., were also determined by E. G. King, J. Am. Chem. Soc. 77, 3189 (1955), which agree very well with those reported by E. F. Westrum, loc. cit. $S_{298.15}^\circ$ was reported by E. F. Westrum, loc. cit., using S_{10}°(extrap.) = 0.01 cal. deg.$^{-1}$ mole^{-1}.

Transition Data.

T_t and ΔH_t° were obtained from A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit.

Temperature of Melting.

T_m was taken from K. Kammermeyer and A. B. Peck, J. Am. Ceram. Soc. 16, 363 (1933).

Heat of Formation

The vibrational quanta of the ground and first excited states can be linearly extrapolated to obtain approximate dissociation energies of 98.3 and 106.5 kcal/mol. Both these states can correlate with ground state atoms and we assume, with a high degree of confidence, that these are the products of the dissociation. Hildenbrand (1) has shown that improved values from ground state extrapolations can be obtained by correcting the extrapolation for the ionicity of the state. The corrected value is obtained from D°_0 = D(linear extrapolation)[0.365(r_x/r_e)+0.448] eV where r_x = 14.4/(IP-EA) and IP-EA is the difference, in eV, between the ionization potential of the electropositive element and EA is the electron affinity of the more electronegative element. This approach yields a corrected value of 114.7 kcal for the ground state dissociation energy. The second and higher excited states all have extrapolations of the same magnitude as the ground state but involve excited products, thus, they do not add materially to the knowledge of the dissociation energy.

Drowart et al. (2) have determined the partial pressures of Al(g), O(g) and AlO(g) over Al_2O_3, by mass-spectrometry in the temperature range 2000-2500°K. A similar experiment has also been reported by Efimenko (3) over a mixture of Be and Al_2O_3. An analysis of this data for the reaction AlO(g) → Al(g) + O(g) by the 2nd and 3rd law methods is given below.

Reference	Points	Range °K	ΔHr_{298}, kcal/mol		Drift	ΔHf°_{298}(AlO, g)
			2nd law	3rd law	eu	kcal/mol
2. Mo cell	15	2036-2466	114.7 ± 7.0	116.0 ± 2.6	0.4 ± 3.1	21.6
2. W cell	15*	2188-2514	122.1 ± 5.0	114.7 ± 1.9	-3.2 ± 2.2	22.9
3. W cell	10*	1511-1743	68.4 ± 7.3	75.2 ± 1.9	3.7 ± 4.4	62.4

*2 or 3 points rejected due to failure of a statistical test.

In addition Tyte (4) has obtained a value for the onset of continuous absorption, which he interprets as the dissociation of AlO, of 36630 cm^{-1} or 104.73 kcal. However, McDonald and Innes (5) conclude that Tyte was seeing continuous absorption from the $A^2\Pi$ state, since bands of two systems terminating in this state were seen by Tyte. On this basis they conclude that the best value of the dissociation energy should be 41912 cm^{-1} or 119.83 kcal/mol, which corresponds to ΔHf°_{298}(AlO, g) = 16.57 kcal/mol. Many other values have been reported for ΔHf°_{298}(AlO, g), including 9.3 kcal/mol (6), -0.7 kcal/mol (7), 48.7 kcal/mol (8) and 20.3 ± 3 kcal/mol (9).

The situation is not clearly resolved, and so a median value of D°_0 = 116.3 ± 4 kcal is adopted which corresponds to ΔHf°_{298}(AlO, g) = 20 ± 4 kcal/mol.

Heat Capacity and Entropy

The thermodynamic functions were calculated by summing over the individual partition functions for the separate states. The ground and B state constants were obtained from Lagerqvist et al. (10), the A and E state constants from McDonald and Innes (5), the C state constants from McDonald et al. (11), and the D state constants are from Krishnamachari et al. (12). Estimated quantities are obtained by comparison with other states and from combination of references (5) and (13) for ω_e of the E state. Several other sets of data exist but are no longer considered significant to the analysis. References to them may be found in the adopted studies.

Heat of Formation

The ionization potential of AlO has been reported as 9.5 ± 0.5eV(219 kcal) by J. Drowart, G. DeMaria, R. P. Burns, and M. G. Inghram, J. Chem. Phys. 32, 1366 (1960), and by G. DeMaria, J. Drowart and M. G. Inghram, J. Chem. Phys. 30, 318 (1959). Using this value in conjunction with ΔHf°_{298}(AlO, g) = 20 ± 4 kcal/mol, we obtain ΔHf°_{298}(AlO$^+$) = 239 ± 15 kcal/mol.

Heat Capacity and Entropy

AlO$^+$ is isoelectronic with MgO and we estimated the electronic ground state and excited states by comparison with those for MgO as reported by W. G. Richards, G. Verhaegen and C. M. Moser, J. Chem. Phys. 45, 3226 (1966). The bond length is estimated to be longer than that in AlO, since the dissociation energy of AlO$^+$ is less than that of AlO. The vibrational frequency and anharmonicity are estimated between those for MgO and AlO and the rotational constant, α_e, is derived from the above quantities assuming a Morse potential function.

The enthalpy at 0°K is -2.118 kcal/mol.

Bond Angle: O-Al-O = [180°]

Rotational Constant: B_0 = [0.1912] cm^{-1}

Heat of Formation

The OH bond strength in H_2O is 119 kcal and in HOBO it is 118 kcal. Thus, it appears very reasonable to assume 118 kcal for the value in HOAlO. This assumption leads to $\Delta Hf^\circ_{298}(AlO_2, g)$ = -44 ± 20 kcal/mol, using the JANAF ΔHf°_{298}(HOAlO, g) = -110 kcal/mol. This value is consistent with the independently estimated $\Delta Hf^\circ_{298}(AlO_2^-, g)$ = -130 ± 15 kcal/mol, since it yields an electron affinity for AlO_2 of 86 kcal in good agreement with the value 98 kcal for BO_2.

Heat Capacity and Entropy

The electronic ground and excited states and molecular configuration are estimated to be similar to those for BO_2. The AlO bond length is assumed to be equal to that in Al_2O. The vibrational frequencies are estimated from a valence force field treatment using k_1 from BO_2 modified by the ratio k(AlO)/k(BO) and using the same ratio of bending to stretch force constants as in BO_2.

The adopted molecular configuration and electronic ground state are in accord with the predictions of A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953).

[320] (2)
[1200] (1)

Bond Distance: Al-O = [1.66] Å

Bond Angle: O-Al-O = [180°] σ = 2

Rotational Constant: B_0 = [0.1912] cm^{-1}

Heat of Formation

The heat of formation of AlO_2^- is estimated from the following considerations. The heats of the following reactions are calculated from the tables:

$BO_2^- \rightarrow B^- + 2O$ ΔH = 411 kcal
$CO_2 \rightarrow C + 2O$ ΔH = 384 kcal
$BO_2^- \rightarrow B + O + O^-$ ΔH = 382 kcal
$BOF \rightarrow B + O + F$ ΔH = 355 kcal

It is apparent that the heat of dissociation of BO_2^- is closely predicted by use of the corresponding isoelectronic decomposition. Thus using

$SiO_2 \rightarrow Si + 2O$ ΔH = 299
we predict $AlO_2^- \rightarrow Al^- + 2O$ ΔH = [320]
and using $AlOF \rightarrow Al + O + F$ ΔH = 297
we predict $AlO_2^- \rightarrow Al + O + O^-$ ΔH = [320]

From these two reactions we estimate ΔHf(AlO_2^-, g) = -158 and -135 kcal/mol and we adopt the value -145 ± 15 kcal/mol. From the value adopted for AlO_2(g) we obtain an electron affinity of 4.38 ev (101 kcal) which is comparable to that for BO_2(g).

Heat Capacity and Entropy

The configuration of the molecule is assumed to be linear using the correlations of Walsh, (1) for 16 electron XY_2 molecules; the ground state is assumed to be $^1\Sigma$ from the same correlation diagrams. The bond length is taken to be that in Al_2O and the vibrational frequencies are estimated between those for AlO_2 and SiO_2.

The enthalpy at 0°K is -2.630 kcal/mol.

Heat of Formation.

The dissociation energy of 4.1 e.v. was calculated by adding 17% to the dissociation energy obtained from a linear extrapolation of the vibrational levels, 3.5 e.v. This was done by analogy with the molecule AlO(g) whose observed D_0 is 17% larger than the linear extrapolation. The adopted value of 4.1 e.v. corresponds to a heat of formation of 48 kcal. mole^{-1}.

Heat Capacity and Entropy.

The vibrational and rotational constants were reported by C. N. McKinney and K. K. Innes, J. Mol. Spect. 3, 235 (1959) from an analysis of 6 bands of the $A^2\Sigma^+$-$X^2\Sigma^+$ system.

Mar. 31, 1962; Sept. 30, 1964

BERYLLIUM ALUMINATE ($BeAl_2O_4$) (CRYSTAL) MOL. WT. = 126.973

$\Delta H_{f\ 0}^\circ = -541 \pm 5$ kcal. mole⁻¹

$S_{298.15}^\circ = 15.84$ cal. deg.⁻¹ mole⁻¹

$\Delta H_{f\ 298.15}^\circ = -545 \pm 5$ kcal. mole⁻¹

$T_m^\circ = 2143$°K.

$\Delta H_m^\circ = [42]$ kcal. mole⁻¹

Heat of Formation.

W. A. Young, J. Phys. Chem. 64, 1003 (1960) studied the equilibria

$$BeO(c) + H_2O(g) \rightarrow Be(OH)_2(g)$$

$$1.5\ BeAl_2O_4 + H_2O(g) \rightarrow 0.5\ BeAl_6O_{10}(c) + Be(OH)_2(g)$$

$$BeAl_6O_{10}(c) + H_2O(g) \rightarrow 3Al_2O_3(c) + Be(OH)_2(g)$$

from his results one obtains $\Delta F_{f\ 1673}^\circ = -379$ kcal. mole⁻¹, which corresponds to $\Delta H_{f\ 298}^\circ = -545$ kcal. mole⁻¹.

Heat Capacity and Entropy.

G. T. Furawaka and W. G. Saba, and T. B. Douglas and W. H. Payne, National Bureau of Standards Report 8186, Jan. 1964 have measured the low temperature heat capacities and the high temperature enthalpy in the range 15 - 1173°K.

Melting Data.

The temperature of melting was taken from National Bureau of Standards Circular 500, Washington (1952).

The heat of melting was estimated as the sum of the ΔH_{fusion}° of the constituent oxides at 2100°K.

Bond Distances: Al-Br = 2.21 ± 0.4 Å $Al\text{-}Br_{bridge}$ = 2.33 ± 0.4 Å

Bond Angles: Br-Al-Br = 114° 38' $Br_{bridge}\text{-}Al\text{-}Br_{bridge}$ = 86° 44' σ = 4

Product of the Moments of Inertia: $I_AI_BI_C = 8.80123 \times 10^{-110}\ g^3\ cm^6$

Heat of Formation

The vapor pressures of $AlBr_3$(c) and $AlBr_3$(ℓ) have been measured by Dunne and Gregory (1) and Fischer et al. (2), respectively. Using these data, the heats of vaporization were calculated by both second and third law methods. The adopted value of ΔHf°_{298} for Al_2Br_6(g) is -231.5 ± 7 kcal/mol. The results of these calculations are as follows with reaction (A) corresponding to $2AlBr_3(c) = Al_2Br_6(c)$ and reaction (B) corresponding to $2AlBr_3(\ell) = Al_2Br_6(g)$:

Source	Reac.	Method	No. Pts.	Range T°K	ΔHr°_{298}, kcal/mol 2nd Law	3rd Law	Drift, eu	*ΔHf°_{298}
1	A	Effusion	3	273-310	19.7±0.7	20.25	2.2±2.4	-231.7
2	B	Weight Loss	18**	413-523	15.6±0.1	15.61	0.1±0.1	-231.5
2	B	Transport	4	396-471	16.1±0.2	15.60	-1.0±0.3	-231.5

*Calculation based on third law ΔHr°_{298}.

**One point rejected due to failure of a statistical test.

Heat Capacity and Entropy

The molecular structure, bond distances and angles were obtained from the electron diffraction work of Palmer and Elliott (3). The bond distances and angles have also been reported by Akishin et al. (4), and these values are in good agreement with those given by Palmer and Elliott (3). The principal moments of inertia are $I_A = 5.36492 \times 10^{-37}$, $I_B = 2.51547 \times 10^{-37}$, and $I_C = 6.52171 \times 10^{-37}$ g cm^2. It has been established that the condensed phases of $AlBr_3$ are dimeric (5), (6), thus spectroscopic studies of the crystal and liquid pertain to the structure of Al_2Br_6(g). Gerding and Smit (7) have studied the Raman spectra of Al_2Br_6(ℓ). The eighteen fundamental vibrational frequencies of Al_2Br_6(g) have been predicted by Miller (8) based on seven of the frequencies reported by Gerding and Smit (7). Webb (9) has measured the infrared spectra of Al_2Br_6(c) in the 40-600 cm^{-1} region, the results being in general accord with the predictions of Miller (8). The vibrational frequencies used are adjusted so that the values of ΔHv°_{298} obtained by the third law method are in agreement with the corresponding second law values. These adjustments are based on the assumption that vibrations with a wave number below 300 cm^{-1} have a lower wave number in the gas phase than they have in the condensed phases.

Bond Lengths: Al-Cl = 2.05 Å, $Al\text{-}Cl_{bridge}$ = 2.23 Å

Bond Angles: Cl-Al-Cl = 120°, $Cl_{bridge}\text{-}Al\text{-}Cl_{bridge}$ = 83° σ = 4

Product of the Moments of Inertia: $I_AI_BI_C = 5.986 \times 10^{-111}\ g^3\ cm^6$

Heat of Formation

The heat of formation is calculated from the value adopted for $AlCl_3$(c) and the heat of sublimation as derived from vapor pressure data. Vapor pressures were corrected for vapor non-ideality by means of the equation $\Delta G°/T = -R\ell nP - BP/T$. The Berthelot equation of state and critical constants T_c = 625.7°K and P_c = 26.1 atm reported by Denisova and Baskova (1) were used to calculate B. Boston et al. (2) and Nisel'son and Sokolova (3) confirm T_c within ±2°K. The corrected vapor pressures were used to derive $\Delta Hs°_{298.15}$ by both second law and third law methods.

Investigator(s)	Temp. Range °K	Number of Data Points	$\Delta Hs°_{298.15}$ (kcal/mol Al_2Cl_6) 2nd Law	3rd Law	Drift eu

[a] Nine points reported, points at 420.8° and 433.5°K rejected by statistical test.
[b] Fourteen points reported, points at 395.2 and 441.3°K rejected by statistical test.
[c] Thirteen points reported, point at 472.2°K rejected by statistical test.
[d] Nine points reported, point at 342.0°K rejected by statistical test.
[e] Individual points not reported; their vapor pressure equation was used to calculate 2 points at extremes of temperature range covered.

The first seven data sets show good agreement between second and third law values and an average of $\Delta Hs°_{298.15}$ = 27.66 ± 0.55 kcal/mol Al_2Cl_6 is adopted. The remaining data sets show serious discrepancies between second and third law values, indicating temperature dependent errors in measurement, and are given no weight.

Heat Capacity and Entropy

Electron diffraction data by Palmer and Elliott (11) and by Akishin et al. (12) are in agreement within experimental error and average values for bond angles and distances as given above are selected. The principal moments of inertia are: $I_A = 2.2172 \times 10^{-37}$, $I_B = 9.991 \times 10^{-38}$, and $I_C = 2.7023 \times 10^{-37}\ g\ cm^2$. Klemperer (13) observed three frequencies in the infrared spectrum of Al_2Cl_6 vapor, Beattie and Horder (14) and Maroni et al. (15) reported gas phase Raman spectra, and Gerding and Smit (16) and Pershina and Raskin (17) measured liquid phase Raman frequencies. With previous vibrational assignments and normal coordinate calculations by Onishi and Shimanouchi (18), Miller (19), and Maroni et al. (15) as a starting point, a new assignment was made (see above) which incorporates additional frequencies observed by Beattie and Horder (14) and Pershina and Raskin (17). Raman and infrared spectra of Al_2Br_6 and Al_2I_6 determined by Beattie, et al. (20) were very helpful. The new assignment differs with earlier calculations primarily in the assumption that the frequencies at 36 cm^{-1} and 19 cm^{-1} observed by Pershina and Raskin in the liquid can be assigned to modes not ordinarily Raman active. This assumption is supported by the compatibility of thermodynamic functions based on the new assignment with vapor pressure data as listed above. Use of the frequencies 88 cm^{-1} and 56 cm^{-1} of Miller (19) gives 3rd law heats of sublimation nearly 2 kcal/mol Al_2Cl_6 higher than the average of 2nd law values.

TRIPOTASSIUM NONACHLOROALUMINATE ($K_3Al_2Cl_9$) (CRYSTAL) MOL. WT. = 490.373

$\Delta H^\circ_{f\ 0}$ = Unknown

$S^\circ_{298.15}$ = [112] cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15}$ = -683.6 ± 3 kcal. mole^{-1}

T_m = Unknown ΔH°_m = Unknown

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for $K_3Al_2Cl_9$(c) was calculated from the heat of solution, ΔH°_r = -112.07 kcal. mole^{-1}, of $K_3Al_2Cl_9$(c) in water (one mole of solute in 36 l. of water) determined by E. Baud, Ann. chim. phys. 1, 8 (1904).

Heat Capacity and Entropy.

Heat capacities and $S^\circ_{298.15}$ were estimated based on an assumption that the property of the mixed chloride ($2AlCl_3 \cdot 3KCl$) is the sum of the corresponding values for its component chlorides, i.e. $AlCl_3$(c) and KCl(c).

Bond Distance: Al-F [1.63] Å Al-F' = [1.80] Å (F is external, F' is in the bridge)
Bond Angle: F-Al-F = [120°] F'-Al-F' = [90°] σ = [4]
Angle between F'-Al-F' plane and F-Al-F plane = [90°]
Product of the Moments of Inertia: $I_AI_BI_C$ = [2.669 x 10^{-112}] g^3 cm^6

Heat of Formation

The existence of small amounts of dimer in the saturated vapor was inferred from the intensities of AlF_2^+, AlF_3^+ and $Al_2F_5^+$ observed by mass spectrometry (1, 2, 3). Büchler et al. (1) concluded that the precursor of the first two ions was mainly AlF_3, while the dimer was the precursor of $Al_2F_5^+$. Intensities of $Al_2F_5^+$ relative to those of AlF_2^+ were observed as 0.0057 (1), 0.007 (2) and 0.025 (3) at ionizing energies of 60, 90 and 100 V for vapor at 1025, 1100 and 1025°K, respectively.

The temperature dependence of ion intensities was used to derive 2nd-law values of ΔHs° for monomer and dimer (1, 2) and a value of ΔH(dimerization) based on an estimate for the entropy of dimerization (3). The absolute pressure of the monomer was obtained (2) from integration of the intensity of AlF_2^+ during total sublimation at 1100°K, then the pressure of dimer was estimated from the relative ion intensity assuming a relative ionization cross section equal to two and neglecting other effects. Krause and Douglas (4) reported ΔHs°(monomer) plus ΔH° and ΔS° for dimerization; these were derived by combination of ΔHs°(dimer) (1) with precise sublimation pressures from entrainment data near 1200°K, where the dimer is more abundant. After reduction to 1000 K with JANAF functions, these results may be summarized as follows:

Source	Method	ΔHr°, kcal/mol*			ΔSr°, gibbs/mol*		
		c → m	2c → d	2m → d	c → m	2c → d	2m → d
Krause (4)	Entrainment	68.1 ± 0.4	[86]	-50 ± 3	[44.04]	---	-35 ± 3
Büchler (1)	Ion Intensities	67.3 ± 3	85.8 ± 3	-48.8 ± 3	---	---	---
Erokhin (2)	Ion Intensities	70.5	92.1	-49.0	46.4	55.1	-37.7
Porter (3)	Ion Intensities	---	---	-48.0 ± 4	---	---	[-32 ± 3]
JANAF	Adopted	68.4	87.8	[-49]	[44.37]	[52.83]	[-35.9]

* Reactions are abbreviated by c = crystal, d = dimer gas and m = monomer gas. Brackets enclose those values assumed in deriving the other values.

JANAF values are given in the last line. These are based on JANAF entropies, on ΔH°(dimerization) = -49 kcal/mol for which there is close agreement, and on the entrainment pressures of Krause and Douglas (4). Reduction of the dimer value to 298.15°K gives ΔHs° = 92.55 ± 4 and ΔHf° = -629.45 ± 4 kcal/mol. The table for AlF_3(g) gives a detailed comparison of observed and predicted total pressures along with predictions of the mole fraction of dimer in the saturated vapor. The latter are reasonably consistent with the relative ion intensities.

Heat Capacity and Entropy

The molecular structure is assumed to be similar to that of Al_2Cl_6. Bond distances and bond angles are estimated by comparison with AlF_3 (5), $AlCl_3$ (6) and Al_2Cl_6 (5, 6). Principal moments of inertia are I_A = 35.36 x 10^{-39}, I_B = 79.74 x 10^{-39} and I_C = 94.66 x 10^{-39} g cm^2.

Six observed vibrational frequencies are from infrared spectra of the dimer isolated in rare-gas matrices (7). Unobserved fundamentals (2 in infrared, 9 in Raman and 1 inactive) are estimated such that the entropy is consistent with the result of Krause and Douglas (4) as given above. The estimated fundamentals are based on comparisons with Al_2Cl_6, Al_2Br_6 and Al_2I_6 which have been restudied extensively (8-11) since the calculations of Miller (12). Assignments used in the comparisons are minor modifications of those given by Beattie et al. (8).

Bond Distance: Al-I = 2.53 Å Al-I_{bridge} = 2.58 Å

Bond Angle: I-Al-I = 112 ± 1° I_{bridge}-Al-I_{bridge} = 68 ± 1° σ = 4

Product of the Moments of Inertia: $I_AI_BI_C$ = 5.21725 X 10^{-109} g.^{3} cm.^{6}

Heat of Formation.

W. Fischer, O. Rahlfs and B. Benze, Z. anorg. allgem. Chem. 205, 1 (1932) measured the vapor pressure of $AlI_3(l)$. The vapor consists of both $Al_2I_6(g)$ and $AlI_3(g)$ species. The partial pressures of $Al_2I_6(g)$ and $AlI_3(g)$ at different temperatures for the equilibrium $Al_2I_6(g) \rightarrow 2AlI_3(g)$ were determined by W. Fischer, O. Rahlfs and B. Benze, loc. cit. From these partial pressures the mole ratios of $Al_2I_6(g)$ and $AlI_3(g)$ at other temperatures were estimated. The partial pressures of $Al_2I_6(g)$ over $AlI_3(l)$ were calculated from the total pressure using the estimated mole ratio values. The heat of vaporization, $\Delta H^\circ_{v\ 298.15}$ = 20.5 ± 1.0 kcal. mole^{-1}, was evaluated employing the vapor pressures obtained by second law method. The corresponding third law value is 22.4 kcal. mole^{-1}. It was not used due to the uncertainties involved in the estimation of the vibrational frequencies. The heat of formation for $Al_2I_6(g)$ was calculated from $\Delta H_f^\circ(l)$ and ΔH_v° obtained.

Heat Capacity and Entropy.

Molecular structure, bond distances and angles were reported by K. J. Palmer and N. Elliott, J. Am. Chem. Soc. 60, 1852 (1938). Five vibrational frequencies (344, 146, 94, 53 and 410 cm.$^{-1}$) were adopted from the Raman spectrum of $Al_2I_6(l)$ measured by H. Gerding and E. Smit, Z. physik. Chem. 50B, 171 (1941). The remaining ones were estimated by comparison with those for $Al_2Cl_6(g)$ and $Al_2Br_6(g)$ and adjusted so that the value of $\Delta H_{s\ 298.15}$ obtained by the third law method is in reasonable agreement with the corresponding second law value. The three principal moments of inertia are: I_A = 9.32506 X 10^{-37}, I_B = 4.60265 X 10^{-37}, and I_C = 1.21558 X 10^{-36} g. cm.^{2}.

Magnesium Aluminate ($MgAl_2O_4$)

Dec. 31, 1960; Mar. 31, 1963

MAGNESIUM ALUMINATE ($MgAl_2O_4$) (CRYSTAL) MOL. WT. = 142.28

$\Delta H_{f\ 0}^\circ = -547.3 \pm 1.9$ kcal. mole^{-1}

$S_{298.15}^\circ = 19.27 \pm 0.10$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ = -551.2 \pm 1.9$ kcal. mole^{-1}

$T_m = 2408$°K.

ΔH_m° = Unknown

Heat of Formation.

The value of $\Delta H_{f\ 298.15}^\circ$ was calculated from $\Delta H_{r\ 298.15}^\circ = 124.6 \pm 1.5$ kcal. mole^{-1} for the reaction: $4MgO(c) + 2Al(l) = MgAl_2O_4(c) + 3Mg(g)$. The value of $\Delta H_{r\ 298.15}^\circ$ was obtained by the third-law method, using vapor pressure data reported by K. Grjotheim, O. Herstad, and J. M. Toguri, Can. J. Chem. 39, 443 (1961). From the Knudsen experiments with $MgAl_2O_4(c)$, R. L. Altman, J. Phys. Chem., 67, 366 (1963) calculated the value of $\Delta H_{f\ 298.15}^\circ$ as -552 kcal. mole^{-1} which agrees with the value used.

Heat Capacity and Entropy.

The low temperature heat capacity, 53-296°K., was measured by E. G. King, J. Phys. Chem. 59, 218 (1955). The high temperature heat capacity, 400°-1800°K., was reported by K. R. Bonnickson, J. Phys. Chem. 59, 220 (1955). These two sets of data were joined smoothly and extrapolated to 3000°K. $S_{298.15}^\circ$ was reported by E. G. King, loc. cit., based on S_{51}°(extrap.) = 0.32 cal. deg.$^{-1}$ mole^{-1}.

Temperature of Melting.

T_m was taken from "Data on Chemicals for Ceramic Use," U. S. National Research Council Bulletin 118, 1949.

[238] (1)
994 (1)

Bond Distance: Al-O = 1.66 Å

Bond Angle: Al-O-Al = 145°

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 263.2477 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H_f^\circ{}_{298}$ = -31.4 ± 7 kcal. mole^{-1} for $Al_2O(g)$ was calculated from $\Delta H_r^\circ{}_{298}$ = 247 ± 7 kcal. mole^{-1} for the reaction $Al_2O(g) = 2Al(g) + O(g)$; and $\Delta H_r^\circ{}_{298}$ = 131 ± 7 kcal. mole^{-1} for the reaction $Al_2O(g) = AlO(g) + Al(g)$. The values of $\Delta H_r^\circ{}_{298}$ were obtained by the third law method, using the partial pressure data reported by J. Drowart, G. DeMaria, R. Burns and M. Inghram, J. Chem. Phys. 32, 1366 (1960). (The second law values which are in poor agreement with the third law values, are $\Delta H_r^\circ{}_{298}$ = 271 ± 10 kcal. mole^{-1} and ΔH_r° = 154 ± 10 kcal. mole^{-1}, respectively.) L. Brewer and A. Searcy, J. Am. Chem. Soc., 73, 5308 (1951), reported that under reducing condition, Al_2O_3 vaporizes mostly to $Al_2O(g)$, but under neutral condition $AlO(g)$ and $O(g)$ are the major products. Brewer and Searcy also measured the vapor pressures of the $Al-Al_2O_3$ system by Knudsen effusion method, and obtained the heat of formation of $Al_2O(g)$ from gaseous atoms as ΔH°_{298} = -248 kcal. mole^{-1}. This value leads the heat of formation for $Al_2O(g)$, $\Delta H_f^\circ{}_{298}$ = -32.4 ± 7, which agrees with the value selected.

Heat Capacity and Entropy.

The matrix isolation of high temperature vapors for the investigation of the infrared spectrum of Al_2O has been used to determined the bond distance, angle and vibrational frequencies by M. Linevsky, D. White and D. Mann, J. Chem. Phys., 41, 542 (1964). These reported data have been adopted in this table. The symmetric structure Al-O-Al instead of Al-Al-O for $Al_2O(g)$ was chosen for two reasons: (1) The dissociation energy of $Al_2O(g)$, D°_{298} = 247 ± 7 kcal/mole, is approximately twice the dissociation energy of $AlO(g)$, D°_{298} = 115 ± 5 kcal. mole^{-1}, which implies that the symmetric structure is more reasonable. (2) The dissociation energy of $Al_2(g)$ has been estimated to be only 39 kcal. mole^{-1} by J. Drowart and R. Honig, J. Phys. Chem., 61, 980 (1957). This implies that the Al-O bond energy in "Al-Al-O" structure would be as large as 208 kcal. mole^{-1} if D°Al-Al = 39 kcal. mole^{-1}. Therefore $Al_2O(g)$ must have a symmetric structure. Linevsky et al., loc. cit., have also concluded the bent symmetric structure (instead of a linear one) and the calculated ω_2 from the observed infrared spectra and the reanalysis of the ultraviolet spectra. The three principal moments of inertia are I_A = 0.5105 X 10^{-39}, I_B = 22.4539 X 10^{-39} and I_C = 22.9644 X 10^{-39} g. cm.^{2}

Drowart, et al. (loc. cit.), also postulated a bent symmetric molecule for $Al_2O(g)$, and estimated the bond distance Al-O = [1.0176] Å and angle Al-O-Al = [110]° and the vibrational frequencies as [1079] cm.$^{-1}$, [351] cm.$^{-1}$ and [921] cm.$^{-1}$

The National Bureau of Standards Report No. 6484 "Preliminary Report on the Thermodynamic Properties of Li, Be, Mg, Al and Their Compounds with Hydrogen, Oxygen, Nitrogen, Fluorine and Chlorine" July, 1959, has proposed a trigonal structure for $Al_2O(g)$ with bond distance Al-O = [1.87] Å, and Al-Al = [2.0] Å. Its vibration frequencies were estimated as [450] cm.$^{-1}$, [1000] cm.$^{-1}$ and [1000] cm.$^{-1}$.

Bond Distance: Al-O = [1.66] Å

Bond Angle: Al-O-Al = [155°]

σ = 2

Product of the Moments of Inertia: $I_A I_B I_C$ = [1.481 x 10^{-115}] g^3 cm^6

Heat of Formation

The ionization potential of Al_2O has been reported as 7.7 ± 0.2eV (177.6 kcal) by R. F. Porter, P. Schissel, and M. G. Inghram, J. Chem. Phys. 23, 339 (1955), and has been confirmed as 7.7 ± 0.5eV by G. DeMaria, J. Drowart, M. G. Inghram, J. Chem. Phys. 30, 318 (1959). Using this value with $\Delta Hf^\circ_{298}(Al_2O, g)$ = -31.4 kcal/mol, we obtain $\Delta Hf^\circ_{298}(Al_2O^+, g)$ = 146 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecule is assumed to be bent by analogy with Al_2O, although both these molecules are predicted to be linear according to A. D. Walsh, J. Chem. Soc. 2266 (1953). The electronic ground state is doublet, since there is an odd number of electrons. The bond length is estimated to be the same as that in Al_2O and the vibrational frequencies are also assumed to be close to those for Al_2O. Since normally the molecule Al_2O ought to be linear, the bending must occur due to the occupancy of an outermost orbital with strong angular variation. Presumably this orbital is occupied by a pair of electrons, one of which will be removed in Al_2O^+, thus causing an opening of the bond angle. On this basis the angle is estimated to be greater than that in Al_2O. The individual moments of inertia are: $I_A = 2.645 \times 10^{-40}$ g cm^2, $I_B = 2.353 \times 10^{-38}$ g cm^2 and $I_C = 2.380 \times 10^{-38}$ g cm^2.

The enthalpy at 0°K is -2.769 kcal/mol.

Aluminum Monoxide, Dimeric (Al_2O_2)

Dec. 31, 1960; Sept. 30, 1961; Dec. 31, 1961; Sept. 30, 1965

ALUMINUM MONOXIDE, DIMERIC $((AlO)_2)$ (IDEAL GAS) MOL. WT. = 85.9618

Point Group $[V_h]$

$\Delta H^\circ_{f\ 0} = -95.7 \pm 7$ kcal. mole^{-1}

$S^\circ_{298.15} = [63.7]$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15} = -97.0 \pm 7$ kcal. mole^{-1}

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
[200] [1]	[930] [1]
[600] [1]	[1000] [1]
[930] [1]	[1000] [1]

Bond Distance: Al-O = [1.60] Å

Bond Angle: Al-O-Al = [90]°, O-Al-O = [90]°

$\sigma = [4]$

Products of the Moments of Inertia: $I_AI_BI_C = [1.4246 \times 10^{-114}]$ g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298} = -97 \pm 7$ kcal. mole^{-1} for $Al_2O_2(g)$ was calculated from $\Delta H^\circ_{r\ 298} = 372 \pm 7$ kcal. mole^{-1} for the reaction $Al_2O_2(g) = 2Al(g) + 2O(g)$. The value of $\Delta H^\circ_{r\ 298}$ was obtained by the third law method, using the partial pressure data reported by J. Drowart, G. DeMaria, R. Burns and M. Inghram, J. Chem. Phys. 32, 1366 (1960). (The second law value for ΔH°_r, which is in poor agreement with the third law value, is 451 ± 25 kcal. mole.)

Heat Capacity and Entropy.

The molecular structure (plane cyclic model) and vibrational frequencies of $Al_2O_2(g)$ were obtained from Drowart, et al., J. Chem. Phys., 32, 1366 (1960). The bond distance Al-O in Al_2O_2 was assumed to be the same as that in AlO (g). The three principal moments of inertia are $I_A = 6.8005 \times 10^{-39}$, $I_B = 11.4674 \times 10^{-39}$ and $I_C = 18.2679 \times 10^{-39}$ g. cm.^{2}

The configuration was proposed by Drowart, et al., instead of the alternate linear structure OAl-AlO for the reason discussed below. The OB-BO bond ^{1,2} compares to the B_2 dissociation energy ^{3,4} in the same way as the NC-CN bond compares to the C-C single bond. However, for $Al_2O_2(g)$, the relationship between OAl-AlO and Al_2 would be quite different.

Bond Distance: Al-O = [1.66] Å

Bond Angle: O-Al-O = [90°] Al-O-Al = [90°] σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.777 x 10^{-114}] g^3 cm^6

Heat of Formation

G. DeMaria, J. Drowart, and M. G. Inghram, J. Chem. Phys. 30, 318 (1959), have reported an ionization potential for Al_2O_2 of 9.9 ± 0.5eV(228 kcal). Using this value in conjunction with $\Delta Hf^\circ_{298}(Al_2O_2, g)$ = -97 kcal/mol, we obtain $\Delta Hf^\circ_{298}(Al_2O_2^+, g)$ = 131 ± 20 kcal/mol.

Heat Capacity and Entropy

The molecular configuration is assumed to be the same as that used for Al_2O_2. The bond length is assumed to be longer than that in Al_2O_2 and is made equal to that reported for Al_2O. The bond angle is arbitrarily estimated to be the same as that in Al_2O_2. The vibrational frequencies are estimated to be slightly lower than those for Al_2O_2, since the $Al_2O_2^+$ molecule should be less rigidly bound. The ground state is assumed to be doublet, since there is an odd number of electrons.

The individual moments of inertia are $I_A = 7.32 \times 10^{-39}$ g cm^2, $I_B = 1.234 \times 10^{-38}$ g cm^2, and $I_C = 1.966 \times 10^{-38}$ g cm^2.

The enthalpy at 0°K is -3.010 kcal/mole.

Dec. 31, 1960; Sept. 30, 1961; Mar. 31, 1964

ALUMINUM OXIDE (ALPHA Al_2O_3) (CRYSTAL) MOL. WT. = 101.960

$S^\circ_{298.15}$ = 12.174 cal. deg.$^{-1}$ mole^{-1}

T_m = 2315°K.

$\Delta H^\circ_{f\ 0}$ = -397.5 ± 0.3 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -400.4 ± 0.3 kcal. mole^{-1}

ΔH_m = 28.30 ± 0.55 kcal. mole^{-1}

Heat of Formation.

The value of ΔH_f derived from the direct combustion of pure aluminum in oxygen was taken from A. D. Mah, J. Phys. Chem. 61, 1572 (1957). Other values for ΔH_f obtained in the same way are: -399.04 ± .24 kcal. mole^{-1} reported by P. E. Snyder and H. Seltz, J. Am. Chem. Soc. 67, 683 (1945); -400.4 ± .3 kcal. mole^{-1} reported by C. E. Holley, Jr., and E. J. Huber, Jr., J. Am. Chem. Soc. 73, 5577 (1951); and -402 ± 2 kcal. mole^{-1} reported by A. Schneider and G. Gattow, Z. anorg. u. allgem. Chem. 277, 41 (1954).

Heat Capacity and Entropy.

The heat capacity measurements reported by G. T. Furukawa, T. B. Douglas, R. E. McCoskey, and D. C. Ginnings, (15° to 1200°K.), J. Research Natl. Bur. Standards 57, 67 (1956), were employed in this table. Low temperature measurements were also made by F. Simon and R. C. Swain (30-280°K.), Z. Physik. Chem. 28B, 189 (1935); E. C. Kerr, H. L. Johnston, and N. C. Hallett (20° to 295°K.), J. Am. Chem. Soc. 72, 4740 (1950); J. W. Edwards and G. L. Kingston (53-291°K.), Trans. Faraday Soc. 58, 1313-22 (1962); E. N. Rodigina and K. Z. Gomel'skii, (100-900°K.), Zhur. Fiz. Khim. 32, 1859-62 (1958); B. E. Walker, J. A. Grand, and R. R. Miller (300-900°K.), J. Phys. Chem. 60, 231-3 (1956); R. Dawson, E. B. Brackett, and T. E. Brackett (700-1400°K.), J. Phys. Chem. 67, 1669 (1963), and L. Terebesi (0-1300°K.), Helv. Chim. Acta. 17, 804 (1934). All of the above low temperature data are in good agreement with Furukawa's work.

The heat capacities above 1200°K. (1200-2500°K.) were taken from the enthalpy measurements of P. B. Kantor, L. S. Lazareva, V. V. Kandyba, and E. M. Fomichov, Ukr. Fiz. Zh. 7, 205-10 (1962). The heat capacity values above 2500°K. were extrapolated. High temperature measurements were also made by the following investigators: V. Ya. Chekhovskoi (500-2000°K.), Inzh. Fiz. Zh., Akad. Nauk. Belorussk SSR 5, 62-5 (1962); A. Ferrier and M. Olette (1100-2300°K.), Compt. Rend. 254, 4293-95 (1962); C. H. Shomate and B. F. Naylor (500-1800°K.), J. Am. Chem. Soc. 67, 72 (1945) and H. L Johnston and M. Hoch (1000-2000°K.), J. Phys. Chem. 65, 1184-5 (1961); and V. A. Kirillin, A. E. Sheidlin, and V. Ya. Chekhovskii (500-2000°K.), Doklady Akad. Nauk. SSSR 135, 125-8 (1960). Numerical values were not available from Kirillin, et al., but graphical values were in close agreement with an extrapolation of Furukawa's data. The entropy at 298.15 was reported by T. Furukawa, et al., loc. cit., using S°_{15} = 0.0105 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The melting data were obtained from the measurements of P. B. Kantor, L. S. Lazareva, V. V. Kandyba, and E. M. Fomichov, loc. cit. S. J. Schneider "Compilation of the Melting Points of the Metal Oxides," NBS Monograph 68, p. 6, Oct. 10, 1963, gives a review of the melting points that range from 2267 to 2345°K.

Dec. 31, 1965

ALUMINUM OXIDE, GAMMA (γ- Al_2O_3)   (CRYSTAL)   MOL. WT. = 101.9612

$\Delta H^\circ_{f\ 0}$ = Unknown

$S^\circ_{298.15}$ = [12.55] cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15}$ = [-396.0 ± 0.5] kcal. mole^{-1}

T_m = 2323°K. ΔH°_m = [20.9] kcal. mole^{-1}

Heat of Formation.

The enthalpy change (ΔH°_t) for the transition $Al_2O_3(\gamma, c) \rightarrow Al_2O_3(\alpha, c)$ has been determined by (1) V. Kostomaroff and M. Rey, Silicates Ind. 28, 9 (1963); and (2) T. Yokokawa and O. J. Kleppa, J. Phys. Chem. 68, 3246 (1964). The results obtained are presented in the table. The enthalpies of solution for $Al_2O_3(\gamma, c)$ and Al(c) in 2N KOH(aq.) have been measured by (3) K. K. Kelley, C. H. Shomate, F. E. Young, B. F. Naylor, A. E. Salo and E. H. Huffman, U. S. Bur. Mines Tech. Rept. 688 (1946). Based on their reported values, -16.13 ± 1.0 and -196.02 ± 0.25 kcal. mole^{-1}, respectively, the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for $Al_2O_3(\gamma, c)$ was evaluated to be -384.84 ± 1.1 kcal. mole^{-1}. Hence, the enthalpy of transition ($\gamma \rightarrow \alpha$) was calculated as -15.6 ± 1.1 kcal. mole^{-1}, using $\Delta H^\circ_{f\ 298.15}$ (Al_2O_3, α, c) = -400.4 kcal. mole^{-1}.

Source	Method	Temperature, °K.	ΔH°_t, kcal. mole^{-1}	$\Delta H^\circ_{t\ 298.15}$, kcal. mole^{-1}
(2)	solution calorimetry	978	-5.3	-4.4
(1)	differential thermal analysis	1473	-11.0	-9.4
(3)	solution calorimetry	298.15	-15.6	-15.6

The heat of formation for $Al_2O_3(\gamma, c)$ was calculated from that for $Al_2O_3(\alpha, c)$ and the ΔH°_t value reported by Yokokawa and Kleppa, loc. cit., which was arbitrarily selected.

Heat Capacity and Entropy.

The heat capacities were assumed to be larger than those for $Al_2O_3(\alpha, c)$ by 5% at each temperature. The value of $S^\circ_{298.15}$ was estimated such that at T_m, ΔF°_f (Al_2O_3, γ, c) > ΔF°_f (Al_2O_3, α, c).

Melting Data.

T_m was reported by M. Plummer, J. Appl. Chem. 8, 35 (1958). The difference between ΔH°_f for Al_2O_3 (γ, c) and Al_2O_3 (l) at T_m is ΔH°_m.

ALUMINUM OXIDE (Al_2O_3) (LIQUID) MOL. WT. = 101.96

$S^\circ_{298.15}$ = [23.728] cal. deg.$^{-1}$ mole^{-1}

T_m = 2315°K.

$\Delta H^\circ_{f\ 298.15}$ = [373.356] kcal. mole^{-1}

ΔH°_m = 28.30 ± 0.55 kcal. mole^{-1}

Heat of Formation.

The heat of formation for the liquid was obtained from $\Delta H_{f\ 298.15}$ for α crystal by adding on ΔH_m plus the difference between $H_{2315}-H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacities of the liquid alpha-Al_2O_3 was taken from the crystal heat capacities up to 1600°K. where a glass transition was assumed. From 1600°K. to 3500°K. the heat capacities were assumed to be the constant value of 34.623 measured by P. B. Kantor, L. S. Lazareva, V. V. Kandyba and E. M. Fomichov (2300-2500°K.) Ukr. Fiz. Zh. 7, 205-10 (1962).

The entropy at 298.15°K. was obtained in a manner analogous to the heat of formation.

Melting Data.

The melting data was taken from the measurements of P. B. Kantor, et al., loc. cit. S. J. Schneider, "Compilation of the Melting Points of the Metal Oxides," NBS Monograph 68 p. 6, Oct. 10, 1963, gives a review of the melting points that range from 2267 to 2345°K.

SILLIMANITE (Al_2SiO_5) (CRYSTAL) GFW = 162.046

ΔHf°_0 = -614.83 ± 0.5 kcal/mol

$S^\circ_{298.15}$ = 22.987 ±0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -618.81 ± 0.5 kcal/mol

Heat of Formation

The heat of the reaction $Al_2O_3(\alpha) + SiO_2$ (quartz) $\rightarrow Al_2SiO_5$ (sillimanite) has been determined at 968°K by J. L. Holm and O. J. Kleppa, J. Phys. Chem. 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be -1.51 ± 0.15 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to ΔHr°_{298} = -0.71 kcal/mol, which is used to calculate the adopted value.

The above value is in serious disagreement with the solution data of F. Neumann, Z. Anorg. Allgem. Chem. 145, 193 (1925); this work, however, has recently been questioned by several workers. H. Flood and W. J. Knapp, J. Am. Ceram. Soc. 40, 206 (1957) suggested that ΔHr° was between 0 and -10 kcal/mol. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964, conclude that ΔHr° should lie between 0 and -6 kcal/mol. C. R. Waldbaum, Am. Mineralogist 50, 186 (1965), calculated ΔHr° = -0.356 kcal/mol from high temperature - high pressure equilibria. These later values are all in good agreement with the adopted calorimetric value.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 54.4° to 296.5°K by S. S. Todd, J. Am. Chem. Soc. 72, 4742 (1950). The entropy is based on S°_{51} = 0.73 gibbs/mol. The high temperature enthalpy has been measured to 1500°K by L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964. The low and high temperature data were joined smoothly together by means of a Shomate function plot [C. H. Shomate, J. Phys. Chem. 58, 368 (1964)]. The crystal structure of sillimanite, L. Bragg and G. F. Claringbull, "Crystal Structure of Minerals," Vol. IV, G. Bell and Sons Ltd., London, 1965, indicates that there is no mixing of the tetra-coordinated aluminum and silicon atoms. Thus there should be no residual entropy at 0°K.

ANDALUSITE (Al_2SiO_5) (CRYSTAL) GFW = 162.046

ΔHf°_0 = -615.46 ± 0.5 kcal/mol

$S^\circ_{298.15}$ = 22.28 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -619.52 ± 0.5 kcal/mol

Heat of Formation

The heat of the reaction $Al_2O_3(\alpha) + SiO_2(\text{quartz}) \rightarrow Al_2SiO_5(\text{andalusite})$ has been determined at 968°K by J. L. Holm and O. J. Kleppa, J. Phys. Chem. 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be -1.99 ± 0.17 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to ΔHr°_{298} = -1.42 kcal/mol, which is used to calculate the adopted value.

The above value is in serious disagreement with the solution data of F. Neumann, Z. Anorg. Allgem. Chem. 145, 193 (1925); this work, however, has recently been questioned by several workers. H. Flood and W. J. Knapp, J. Am. Ceram. Soc. 40, 206 (1957), suggested that ΔHr° was between 0 and -10 kcal/mol. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964, conclude that ΔHr° should lie between 0 and -6 kcal/mol. C. R. Waldbaum, Am. Mineralogist 50, 186 (1965), calculated ΔHr° = -1.108 kcal/mol from high temperature - high pressure equilibria. These latter values are all in good agreement with the adopted calorimetric value.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 54.9° to 296.2°K by S. S. Todd, J. Am. Chem. Soc. 72, 4742 (1950). The entropy is based on S°_{51} = 0.62 gibbs/mol. The high temperature enthalpy has been measured to 1600°K by L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964. The low and high temperature data were joined smoothly together by means of a Shomate function plot [C. H. Shomate, J. Phys. Chem. 58, 368 (1954)]. Since all the aluminum and silicon atoms occupy differently coordinated sites, there is no possibility of any residual entropy of mixing in this polymorph.

KYANITE (Al_2SiO_5) (CRYSTAL) GFW = 162.046

ΔHf_0° = -615.75 ± 0.5 kcal/mol

$S^\circ_{298.15}$ = 20.032 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -620.06 ± 0.5 kcal/mol

Heat of Formation

The heat of the reaction $Al_2O_3(\alpha) + SiO_2(\text{quartz}) \rightarrow Al_2SiO_5(\text{kyanite})$ has been determined at 968° by J. L. Holm and O. J. Kleppa, J. Phys. Chem. 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be -2.37 ± 0.15 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to ΔHr°_{298} = -1.96 kcal/mol, which is used to calculate the adopted value.

The above value is in serious disagreement with the solution data of F. Neumann, Z. Anorg. Allgem. Chem. 145, 193 (1925); this work, however, has recently been questioned by several workers. H. Flood and W. J. Knapp, J. Am. Ceram. Soc. 40, 206 (1957), suggested that ΔHr° was between 0 and -10 kcal/mol. L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964, conclude that ΔHr° should lie between 0 and -6 kcal/mol. R. W. Haskell and R. C. DeVries, J. Am. Ceram. Soc. 47, 202 (1964), from phase equilibria obtained ΔHr° = -2 ± 7 kcal/mol. C. R. Waldbaum, Am. Mineralogist 50, 186 (1965), calculated ΔHr° = -0.622 kcal/mol from high temperature - high pressure equilibria. These latter values are all in good agreement with the adopted calorimetric value.

Heat Capacity and Entropy

The low temperature heat capacity has been measured from 54.8° to 296.3° by S. S. Todd, J. Am. Chem. Soc. 724742 (1950). The entropy is based on S°_{51} = 0.33 gibbs/mol. The high temperature enthalpy has been measured to 1500°K by L. B. Pankratz and K. K. Kelley, U. S. Bur. Mines RI 6370, 1964. The low and high temperature data were joined smoothly together by means of a Shomate function plot [C. H. Shomate, J. Phys. Chem. 58, 368 (1954)]. The high temperature heat capacity has been measured between 100° and 1200°C by V. Ya. Leonidov, Yu. P. Barskii and N. I. Khitarov, Geochemistry (English Transl.) 1964, 409 (1964). The values reported are in excellent agreement with the adopted functions. Since the aluminum atoms and the silicon atoms occupy different types of sites there is no possibility of any residual entropy of mixing in this polymorph.

MULLITE ($Al_6Si_2O_{13}$) (CRYSTAL) GFW = 426.053

$\Delta Hf^\circ_0 = -1619.25 \pm 1.5$ kcal/mol

$S^\circ_{298.15} = 65.7 \pm 3$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -1629.83 \pm 1.5$ kcal/mol

$Tm = 2023°K$

Heat of Formation

The heat of the reaction $3Al_2O_3(\alpha) + 2SiO_2(\text{quartz}) \rightarrow Al_6Si_2O_{13}$ has been determined at 968°K by J. L. Holm and O. J. Kleppa, J. Phys. Chem. 70, 1690 (1966) and Am. Mineralogist 51, 1608 (1966), to be +5.44 ± 0.35 kcal/mol. This value was obtained from heat of solution measurements in a high temperature oxide melt calorimeter. Using the JANAF functions, this reduces to $\Delta Hr^\circ_{298} = +4.11$ kcal/mol, which is used to calculate the adopted value.

Heat Capacity and Entropy

The low temperature heat capacity and high temperature enthalpy of mullite have been measured by L. B. Pankratz, W. W. Weller and K. K. Kelley, U. S. Bur. Mines RI 6287, 1963. The low temperature investigations extended from 53.5°K to 296.4°K; the Debye-Einstein equation 3D(182/T) + 15E(350/T) + 10E(502/T) + 15E(897/T) represented the data from 53.5° to 114.6°K within 1.4 percent and gave a smooth extrapolation to zero. From this equation the entropy at 51°K was found to be 2.17 gibbs/mol as opposed to the value 1.96 gibbs/mol found by Pankratz et al. However, since it is known that mullite has some of its Al atoms on Si sites, there will be configurational entropy remaining at 0°K. This is borne out by the free energy determinations of R. H. Rein and J. Chipman, Trans. Met. Soc. AIME 233, 415 (1965), and D. A. R. Kay and J. Taylor, Trans. Faraday Soc. 56, 1372 (1960), who obtain $\Delta Gr^\circ_{1823} = -5.7 \pm 0.1$ kcal/mol for the formation from oxide. If the entropies and enthalpies reported by Pankratz et al. are used with the heat of formation, they yield $\Delta Gr^\circ_{1823} = +2.9$ kcal/mol. Holm and Kleppa, loc. cit., calculate that random mixing of tetra-coordinated aluminum and silicon atoms could produce 7 eu residual entropy. We have added 4.7 eu in order to match the measured ΔGr°_{1823}.

A review of the enthalpy determination indicated that the values might easily be 2 percent low if as little as 4 percent of kyanite remained unchanged in the sample used for measurement. Since X-ray could not detect this amount, it is not an unreasonable assumption. Accordingly we have checked the effect of increasing the heat capacity above 298°K by 2 percent; this then gives $\Delta Gr^\circ_{1823} = -2.10$ kcal/mol. In order to bring this within reasonable agreement with the observations a residual configurational entropy of 2 gibbs/mol would be needed. Thus the uncertainty in the residual entropy is of the order of 2 eu due to possible uncertainty in the high temperature heat capacity.

Melting Data

The congruent melting point of mullite was reported by S. Aramaki and R. Roy, Nature 184, 631 (1959).

Dec. 31, 1960; Dec. 31, 1964

BORON, BETA-RHOMBOHEDRAL (B) (CRYSTAL) AT. WT. = 10.82

$\Delta H^\circ_{f\ 0}$ = 0 kcal. mole^{-1}

$S^\circ_{298.15}$ = 1.403 ± 0.01 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 0 kcal. mole^{-1}

T_m = 2450 ± 20 °K.

ΔH°_m = [5.39] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 132.8 ± 4.0 kcal. mole^{-1}

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Low temperature heat capacities, 16.90 - 303.71°K., were measured by H. L. Johnston, H. N. Hersh and E. C. Kerr, J. Am. Chem. Soc. 73, 1112 (1951). The high temperature heat capacities, 282.8 - 1667.8°K., were measured by R. A. McDonald and D. R. Stull, J. Chem. Eng. Data, 7, 84 (1962). These two sets of data were joined smoothly at 298.15°K. by graphical method. The heat capacity values above 1667.8°K. were estimated by graphical extrapolation. The high temperature C_p, 530 - 800°K., were also determined by S. S. Wise, J. L. Margrave and R. L. Altman, J. Phys. Chem. 64, 915 (1960). The other principal investigators are: (1) J. A. Robertson, Ph. D. Thesis, Cornell University, 1944; (2) A. Magnus and H. Danz, Ann. Phys. [4] 81, 407 (1926); (3) H. Moissan and H. Gautier, Compt. rend. 116, 924 (1893); (4) H. F. Weber, Ann. Phys. [2] 154, 367, 553 (1875); (5) H. Kopp, Trans. Roy. Soc. [London] 155, 71 (1865); and (6) V. Regnault, Ann. chim. et phys. [3] 63, 5 (1861) and Phil. Mag. [4] 23, 103 (1862). The value of $S^\circ_{298.15}$ was obtained from H. L. Johnston, H. N. Hersh and E. C. Kerr, loc. cit., based on S°_{17} = 0.00139 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The melting point (T_m) of B(c) has been measured by many investigators. The values of T_m reported are in the range 2273 - 2673°K. Based on the relationship between the values of T_m determined and the purities of the boron sample used, the value T_m = 2450 ± 20°K. was estimated. The data employed for estimation are those reported by C. F. Cline, J. Electrochem. Soc. 106 (4), 332 (1959), and A. W. Searcy and C. E. Myers, J. Phys. Chem. 61, 957 (1957). The estimated value for T_m is in agreement with the value taken by H. L. Schick, et al., "Thermodynamics of Certain Refractory Compounds", ASD-TR-61-260, Part I, Vol. 1, May 1962, in which the reported melting points of boron were reviewed. The heat of melting was calculated assuming entropy of melting is 2.2 cal. deg.$^{-1}$ mole^{-1} at 2450°K.

Heat of Sublimation.

The adopted value of $\Delta H^\circ_{s\ 298.15}$ is the weighted average of eight $\Delta H^\circ_{s\ 298.15}$ values derived from vapor pressure data. See B(g) table for details.

Dec. 31, 1960; Dec. 31, 1964

BORON (B) (LIQUID) AT. WT. = 10.82

$S^\circ_{298.15}$ = [3.533] cal. deg.$^{-1}$ mole^{-1}

T_m = [2450 ± 20]°K.

T_b = [3931]°K.

$\Delta H^\circ_{f\ 298.15}$ = [5.260] kcal. mole^{-1}

ΔH°_m = [5.39] kcal. mole^{-1}

ΔH°_v = [121.3 ± 4] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ for B(l) was obtained from $\Delta H^\circ_{f\ 298.15}$ for B(c) by adding ΔH°_m and the difference between $H^\circ_{Tm} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of liquid was estimated by comparison with the heat capacity of solid at the melting temperature. The value of $S^\circ_{298.15}$ was obtained in a manner analogous to that of the heat of formation. A glass transition temperature at 1600°K. is assumed.

Melting Data.

See B(c) table for details.

Vaporization Data.

The boiling point was calculated as the temperature at which the free energies of formation (ΔF°_f) for both B(l) and B(g) are equal. The difference in heat of formation (ΔH°_f) of B(l) and B(g) at the boiling point is the heat of vaporization (ΔH°_v).

Heat of Formation.

The vapor pressures of B(g) over condensed phases B(c) and $B_4C(c)$, respectively, were determined by many investigators. Using the vapor pressure data reported, the corresponding heats of sublimation and decomposition were evaluated by both the third and second law methods. The values of $\Delta H^\circ_{f\ 298.15}$ for B(g) were then calculated. The results obtained are listed as follows (all calculations were made employing JANAF functions).

Investigator	Process or Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H^\circ_{f\ 298.15}$,* kcal. mole^{-1}
Hildenbrand and Hall[1]	$0.25CB_4(c) \rightarrow 0.25C(c) + B(g)$	138.5	137.6 ± 1.2	135.3 ± 1.3
Hildenbrand[2]	$B(c) \rightarrow B(g)$	136.1	136.3 ± 3	136.1 ± 0.3
Paule and Margrave[3]	$B(c) \rightarrow B(g)$	136.4	135.4 ± 1.6	136.4 ± 1.0
Robson and Gilles[4]	$0.25CB_4(c) \rightarrow 0.25C(c) + B(g)$	137.7	142 ± 4	134.5 ± 1.3
Searcy and Myers[5]	$B(c) \rightarrow B(g)$	139.1	148.4 ± 8.4	139.1 ± 2.5
Schissel and Williams[6]	$B(c) \rightarrow B(g)$	—	129 ± 5	129 ± 5
Chupka[7]	$B(c) \rightarrow B(g)$	129.2	131.7	129.2
Akishin et al.[8]	$B(c) \rightarrow B(g)$	131.7	—	131.7 ± 5
Verhaegen and Drowart[9]	$B(am.) \rightarrow B(g)$	—	129.1 ± 5	130.3 ± 5**
	$0.25CB_4(c) \rightarrow 0.25C(c) + B(g)$	—	134.4 ± 5	131.2 ± 5
Linevsky, et al.[10]	$B(c) \rightarrow B(g)$	—	131.4	131.4
Schissel and Trulson[11]	$B(c) \rightarrow B(g)$	—	132.8 ± 1.4	132.8 ± 1.4

*Calculation based on the third law values available.
**Based on a heat of transition of 1.2 kcal. mole^{-1} for B(c) to B(am.).

1 D. L. Hildenbrand and W. F. Hall, J. Phys. Chem. 68, 989 (1964) - 2374-2615°K. - torsion-effusion.

2 D. L. Hildenbrand, "Thermodynamic Properties of Propellant Combustion Products", QLR-64-10, Philco Corporation, California, 1950-2140°K., torsion-Langmuir method. Listed $\Delta H^\circ_{f\ 298.15}$ value is the average of three reported values.

3 R. G. Paule and J. L. Margrave, J. Phys. Chem 67, 1368 (1963) - 1781-2152°K. - free-evaporation.

4 H. E. Robson and P. W. Gilles, J. Phys. Chem. 68, 983 (1964) - 2184-2522°K. - Knudsen-effusion.

5 A. W. Searcy and C. E. Myers, J. Phys. Chem. 61, 957 (1957) - 2115-2413°K. - Knudsen-effusion.

6 P. O. Schissel and W. S. Williams, Bull, Am. Phys. Soc. 4, 139 (1959). The quoted value of ΔH°_r was derived from vapor pressure data determined by the mass spectrometer-effusion method.

7 The third and second law values of $\Delta H^\circ_{r\ 298.15}$ were calculated from the respective values of $\Delta H^\circ_{r\ 0}$ quoted by G. Verhaegen and J. Drowart, J. Chem. Phys. 37, 1367 (1962). Vapor pressure data obtained by mass spectrometer-effusion method.

8 P. A. Akishin, D. O. Hikitin and L. N. Gorokhov, Proc. Acad. Sci., USSR, 129, 1075 (1959). The vapor pressure data (2024 - 2231°K.) were determined by the mass spectrometric method.

9 The two second law values were recalculated from $\Delta H^\circ_{r\ 2060}$ = 127.4 and $\Delta H^\circ_{r\ 2080}$ = 133.1 kcal. mole^{-1} for the first and second reactions in the above table, respectively. The data were reported by G. Verhaegen and J. Drowart, J. Phys. Chem. 37, 1367 (1962), which were derived from vapor pressures determined by the mass spectrometric method.

10 M. J. Linevsky, G. M. Kibler, T. F. Lyon and V. J. DeSantis, "Refractory materials Research", WADD-TR-60-646, Part IV, August 1964, General Electric Co., Ohio.

11 P. O. Schissel and O. C. Trulson, J. Phys. Chem. 66, 1492 (1962).

The adopted value of $\Delta H^\circ_{f\ 298.15}$ for B(g) is the weighted average of the 12 $\Delta H^\circ_{f\ 298.15}$ values given in the above table.

Heat Capacity and Entropy.

The electronic levels and quantum weights used were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, National Bureau of Standards Circular 467, 1949.

Heat of Formation

We calculate the heat of formation at 0°K from the reaction $B(g) - e^-(g) \rightarrow B^+(g)$ using the JANAF auxiliary value for B(g) and an ionization potential of 191.314 kcal/mol from C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, Vol. I, 1949.

Heat Capacity and Entropy

We obtain the electronic levels and quantum weights from C. E. Moore, loc. cit. $H^\circ_0 - H^\circ_{298} = -1.481$ kcal/mol at 0°K.

Beryllium Boron Dioxide ($BeBO_2$)

[900](1)	[800](1)

Bond Distance: Be-O = [1.40] Å O-B = [1.36] Å B=O = [1.20] Å

Bond Angle: Be-O-B = [120]° O-B=O = [180]° σ = [1]

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.450656] X 10^{-115} g^3 cm^6

Heat of Formation.

Since P. E. Blackburn and A. Büchler, J. Phys. Chem. 69, 4250 (1965), have postulated that the BO_2^- group has the pseudochloride character in bond strength, the heat of formation of $BeBO_2(g)$ is estimated by adding the difference of the heats of formation of BeCl(g) and AlCl(g) to the heat of formation of $AlBO_2(g)$, using all JANAF values ΔHf°_{298} (BeCl, g) = 3.0, ΔHf°_{298} (AlCl, g) = -11.2 and ΔHf°_{298} ($AlBO_2$, g) = -129.4 kcal/mol.

Heat Capacity and Entropy.

All molecular constants are estimated by comparison with those in $LiBO_2(g)$, $AlBO_2(g)$ $B_2O_3(g)$ and BeCl(g). The three principal moments of inertia are I_A = 1.1015 X 10^{-39}, I_B = 14.3751 X 10^{-39} and I_C = 15.4766 X 10^{-39} g cm^2.

σ = 1

B_e = 0.497 cm.$^{-1}$

α_e = 0.0036 cm.$^{-1}$

r_e = 1.887 Å

Heat of Formation.

G. Herzberg, "Spectra of Diatomic Molecules" D. Van Nostrand Co. New York 1950 reports a D_0° of 4.1 e.v. which corresponds to a heat of formation of 64 kcal. mole^{-1} A. G. Gaydon "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall, London 1953, gives essentially the same value, with a rider that the value is unrealiable due to the ionic nature of the bonding. R. F. Barrow, Trans. Farad. Soc. 56, 952 (1960) made a critical evaluation of the bond dissociation energies of the group III halides and concluded D_0 BBr = 103.5 which gives ΔH_f° = 56 kcal. mole^{-1}. An estimate of the dissociation energy by taking the ratio $D(BF)/(\Delta H_a(BF_3)/3) = 1.177$ and applying this to BBr_3 yields D(BBr) = 103 kcal. mole^{-1}, this was the value adopted.

Heat Capacity and Entropy.

The vibrational and rotational constants were all taken from National Bureau Standards Report 7093, Jan. 1, 1962.

BORON BROMIDE CHLORIDE (BBrCl) (IDEAL GAS) MOL. WT. = 126.193

Point Group C_s

$S^\circ_{298.15}$ = [69.056] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [2]

$\Delta H^\circ_{f\ 0}$ = [-1.0 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-2.5 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[660](1)
[195](1)
[905](1)

Bond Distance: B-Cl = [1.73] Å B-Br = [1.87] Å

Bond Angle: Cl-B-Br = [120°] $\sigma = 1$

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.192176] X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_r = 0$ for the reaction $BCl_2 + BBr_2 \rightarrow 2BBrCl$.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for BBr_2 and BCl_2. The bond distances, angles, and quantum weight were assumed the same as in the dihalides. The individual moments of inertia were $I_A = 1.2997 \times 10^{-39}$ g. cm.^{2}, $I_B = 40.4239 \times 10^{-39}$ g. cm.^{2} and $I_C = 41.7236 \times 10^{-39}$ g. cm.^{2}

Boron Bromide Dichloride ($BBrCl_2$)

Sept. 30, 1962; Dec. 31, 1964

BORON BROMIDE DICHLORIDE ($BBrCl_2$) (IDEAL GAS) MOL. WT. = 161.65

Point Group C_{2v}

$S^\circ_{298.15}$ = 74.163 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [1]

$\Delta H_f^\circ{}_0$ = -78.5 ± 10 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -80.5 ± 10 kcal. mole^{-1}

<u>Vibrational Frequencies and Degeneracies</u>

ω, cm.$^{-1}$	ω, cm.$^{-1}$
885(1)	959 (1)
406(1)	[208](1)
218(1)	433 (1)

Bond Distance: B-Cl = 1.73 Å B-Br = 1.87 Å

Bond Angle: Cl-B-Cl = [120°] Br-B-Cl = [120°] σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 9.19303 X 10^{-113} g.^{3} cm.^{6}

<u>Heat of Formation</u>.

The heat of formation was estimated by assuming ΔH_r = 0 for the reaction

$$BBr_3 + 2BCl_3 \rightarrow 3BBrCl_2$$

<u>Heat Capacity and Entropy</u>.

Vibrational frequencies were obtained from L. P. Lindeman and M. K. Wilson, J. Chem. Phys. <u>24</u>, 242 (1956). The b_1 mode was the only unobserved frequency and was calculated from a normal coordinate treatment. Bond distances were reported by T. Wentink and V. H. Tiensuu, J. Chem. Phys. <u>28</u>, 826 (1958). Bond angles were estimated by analogy with the other trihalides of boron. The individual moments of inertia were I_A = 26.4242 X 10^{-39} g. cm.^{2}, I_B = 47.2327 X 10^{-39} g. cm.^{2} and I_C = 73.6569 X 10^{-39} g. cm.^{2}

BORON BROMIDE FLUORIDE (BBrF) (IDEAL GAS) MOL. WT. = 109.736

Point Group C_s

$S^\circ_{298.15}$ = [65.887] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [2]

$\Delta H^\circ_{f\ 0}$ = [56 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [57.5 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[860](1)
[310](1)
[1140](1)

Bond Distance: B-F = [1.3] Å B-Br = [1.87] Å

Bond Angle: Br-B-F = [120°]

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [4.13196] X 10^{-115} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_r = 0$ for the reaction $BBr_2 + BF_2 \rightarrow 2BBrF$.

Heat Capacity and Entropy.

The vibrational frequencies, bond lengths, angles and quantum weight were estimated by comparison with the respective dihalides. The individual moments of inertia were $I_A = 0.8407 \times 10^{-39}$ g. cm.^{2}, $I_B = 21.7537 \times 10^{-39}$ g. cm.^{2} and $I_C = 22.5944 \times 10^{-39}$ g. cm.^{2}

Sept. 30, 1962; Dec. 31, 1964

BORON BROMIDE DIFLUORIDE ($BBrF_2$) (IDEAL GAS) MOL. WT. = 128.736

Point Group C_{2v}

$S^\circ_{298.15}$ = 68.424 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [1]

$\Delta H^\circ_{f\ 0}$ = [-193.7 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-196.0 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
1215 (1)	1427 (1)
633 (1)	[346](1)
[330](1)	573 (1)

Bond Distance: B-F = 1.295 Å B-Br = 1.87 Å

Bond Angle: F-B-F = [120°] Br-B-F = [120°]

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 8.46916 X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_r = 0$ for the reaction $2BF_3 + BBr_3 \rightarrow 3BBrF_2$.

Heat Capacity and Entropy.

All but two of the vibrational frequencies have been observed and assigned by L. P. Lindeman and M. K. Wilson J. Chem. Phys. 24, 242 (1956), the two remaining frequencies were calculated by a normal coordinate treatment. The bond distances were reported by T. Wentink and V. H. Tiensuu, J. Chem. Phys. 28, 826 (1958). The bond angles were estimated by analogy with the other boron trihalides. The individual moments of inertia were I_A = 7.9349 X 10^{-39} g. cm.^{2}, I_B = 28.9426 X 10^{-29} X 10^{-29} g. cm.^{2} and I_C = 36.8775 X 10^{-39} g. cm.^{2}

[370] (2)
[1800] (1)

Bond Distance: O=B = [1.20] Å B-Br = [1.87] Å

Bond Angle: O-B-Br = [180]°

Rotation Constant: B_0 = [0.11742] cm.$^{-1}$

σ = 1

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for BOBr (g) was calculated based on an assumption that D(BO-Br) = 92.5 kcal. mole^{-1} which was estimated by comparison with the following related bond energy values: D(BF_2-F) = 159, D(BO-F) = 169, D(BCl_2-Cl) = 105, D(BO-Cl) = 110 and D(BBr_2-Br) = 90.5 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The vibrational frequencies (ω) were estimated from the ω values calculated by the valence force method described by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., 1945, using estimated force constants, $k_1 = 4.2 \times 10^5$, $k_2 = 16.9 \times 10^5$ dynes cm.$^{-1}$ and $k_\delta = 0.37 \times 10^{-11}$ dynes cm. rad.$^{-1}$ The B=O and B-F bond distances were assumed to be the same as those in BO(g) and BBr_3(g), respectively. The moment of inertia is 2.38357×10^{-38} g. cm.^{2}

Mar. 31, 1962; Dec. 31, 1962; Dec. 31, 1964

BORON DIBROMIDE (BBr_2) (IDEAL GAS) MOL. WT. = 170.652

Point Group [C_{2v}]

$S^\circ_{298.15}$ = [70.402] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [2]

$\Delta H^\circ_{f\ 0}$ = [18.2 ± 15] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [15.0 ± 15] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$

[600](1)
[150](1)
[830](1)

Bond Distance: [1.87] Å

Bond Angle: [120°]

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 7.26584 X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by analogy with BF_3, specifically the ratio

$$\Delta H_r(BX_3 \rightarrow BX_2 + X) / \Delta H_r(BX_3 \rightarrow B + 3X)$$

was taken as 0.347.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from force constants transferred from the trihalide given by G. Herzberg "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., (1945). The bond length was taken between those of the mono and trihalide and the angle was estimated to be the same as that in the trihalides. The ground state quantum weight was taken as two on account of the one unpaired electron.

The individual moments of inertia were I_B = 1.4708 X 10^{-39} g. cm.^{2}, I_A = 69.5532 X 10^{-39} g. cm.^{2} and I_C = 71.0240 X 10^{-39} g. cm.^{2}

Boron Dibromide Chloride (BBr_2Cl)

Sept. 30, 1962; Dec. 31, 1964

BORON DIBROMIDE CHLORIDE (BBr_2Cl) (IDEAL GAS) MOL. WT. = 206.109

Point Group C_{2v}

$S^\circ_{298.15}$ = 76.909 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [1]

$\Delta H^\circ_{f\ 0}$ = [-61.4 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-65 ± 10] kcal. mole^{-1}

Vibrational Levels and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
925(1)	834(1)
344(1)	195(1)
166(1)	409(1)

Bond Distance: B-Br = 1.87 Å B-Cl = 1.75 Å

Bond Angle: Br-B-Br = [120°] Cl-B-Br = [120°]

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 2.55478 X 10^{-112} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_r = 0$ for the reaction

$$2BBr_3 + BCl_3 \rightarrow 3BBr_2Cl$$

Heat Capacity and Entropy.

The vibrational frequencies have all been observed and assigned by L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956). The bond lengths were reported by T. Wentink and V. H. Tiensuu, J. Chem. Phys., 28, 826 (1958). Bond angles were estimated by analogy with the other trihalides of boron. Individual moments of inertia are I_B = 35.0734 X 10^{-39} g. cm.^{2}, I_A = 69.5934 X 10^{-39} g. cm.^{2} and I_C = 104.6668 X 10^{-39} g. cm.^{2}

Bond Distance: B-Br = 1.87 Å B-Cl = 1.295 Å

Bond Angle: Br-B-Br = [120°] Br-B-F = [120°]

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 8.72359 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_r = 0$ for the reaction $2BBr_3 + BF_3 \rightarrow 3BBr_2F$.

Heat Capacity and Entropy.

Two of the vibrational frequencies were observed and assigned by L. P. Lindeman and M. K Wilson, J. Chem. Phys. 24, 242 (1956), the remaining frequencies were calculated by a normal coordinate treatment using force constants obtained by comparison with the other mixed trihalides. The bond distances were reported by T. Wentink and V. H. Tiensuu, J. Chem. Phys. 28, 826 (1958). The bond angles were estimated by analogy with the other trihalides. The individual moments of inertia were $I_B = 14.8452 \times 10^{-39}$ g. cm.^{2}, $I_A = 69.5934 \times 10^{-39}$ g. cm.^{2} and $I_C = 84.4386 \times 10^{-39}$ g. cm.^{2}

Bond Distance : B-H = 1.20 Å B-Br = [1.87] Å

Bond Angle: Br-B-Br = 119.3 ± 2° Br-B-H = 120.3 ± 1°

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 1.08645 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H_f^\circ{}_{298.15}$ (BBr_2H, g) was derived by assuming the B-H bond strength to be 92 kcal. mole^{-1}, the same as that in BCl_2H(g).

Heat Capacity and Entropy.

The molecular structure, B-H bond distance and bond angle were obtained from L. Lynds and C. D. Bass, J. Chem. Phys. 41, 3165 (1964). The B-Br bond distance was taken from that in BBr_3(g) molecule. The vibrational frequencies adopted and corrected to the average isotopic species were assigned by O. Brieux de Mandirola and J. F. Westerkamp, Spectrochim. Acta, 21, 1101 (1965), from infrared spectrum. The values in brackets are calculated by the Wilson's FG-method. Infrared spectrum of BBr_2H(g) was also reported by S. K. Wason and R. F. Porter, J. Phys. Chem. 69, 2461 (1965), and three frequencies, ν_1, ν_4 and ν_5, were assigned. The three principal moments of inertia are: $I_A = 6.87842 \times 10^{-38}$, $I_B = 2.2244 \times 10^{-39}$ and $I_C = 7.10086 \times 10^{-38}$ g. cm.^{2}

BORON TRIBROMIDE (BBr_3) (LIQUID) MOL. WT. = 250.568

$S^\circ_{298.15}$ = 54.7 cal. deg.$^{-1}$ mole^{-1}

T_m = 227.2°K

T_b = 364.4°K

ΔH_f° 298.15 = -57.0 ± 0.2 kcal. mole^{-1}

ΔH_m° = Unknown

ΔH_v° = 7.30 kcal. mole^{-1}

Heat of Formation.

The heat of formation of boron tribromide liquid has been determined by H. A. Skinner and N. B. Smith, Trans. Farad. Soc. 51, 19 (1955) by hydrolysis to H_3BO_3 and HBr. The adopted heat of formation was calculated from Skinners hydrolysis data using ΔH_f° H_3BO_3(c) from these tables, ΔH_{soln} H_3BO_3 from L. G. Fasilino, National Research Corporation Special Report NONR-3608 (00) June 2, 1964, with the dilution data of J. Smisko and L. S. Mason, J. Am. Chem. Soc. 72, 3679 (1950). The ΔH_f° HBr(aq) was taken from W. H. Evans, Appendix III, Natl. Bureau of Standards Report 8504, 1 July 1964.

Heat Capacity and Entropy.

The heat capacity was estimated from that of the gas by K. K. Kelley USBM Bulletin 383. The entropy was back calculated from that of the gas by adjusting the free energy functions to give the best fit of the vapor pressure data.

Melting Data.

The temperature of melting was reported by J. Goubeau and H. Keller, Z. anorg. allgem. Chem. 267, 1 (1951) and A. Stock and E. Kuss, Ber. 47, 3113 (1914). This value was recently confirmed by the triple point measurement of 227.31°K by W. F. Barber, C. F. Boynton and P. E. Gallagher J. Chem. Eng. Data 9, 137 (1964).

Boiling Data.

The boiling point is from the data of Stock and Kuss, loc. cit. A second and third law analysis of the vapor pressure data of Stock and Kuss (1) and Barber et. al. (2) loc. cit. indicated that the data of Stock gave the best agreement as indicated below.

ΔH_v 298.15 kcal. mole^{-1}

	Second Law	Third Law	
		S°_{298} = 54.7	S°_{298} = 54.26
Ref 1.	8.175 ± 0.03	8.222 (-0.02)	8.361 (0.42)
Ref 2.	8.229 ± 0.03	8.203 (-0.44)	8.347 (0.00)

Ref. 1. had the first eight data points rejected due to a statistical test on the third law values. The values in parentheses are values of the third law drift measured as $\Delta(\Delta H)$ / ΔT. The second law entropy also confirmed the choice of the data of ref. 1 and an entropy of 54.7 cal. deg.$^{-1}$ mole^{-1}.

BORON TRIBROMIDE (BBr_3) (IDEAL GAS) MOL. WT. = 250.568

Point Group D_{3h}

$\Delta H_f^\circ{}_0 = -43.5 \pm 0.22$ kcal. mole^{-1}

$S^\circ_{298.15} = 77.487$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -48.8 \pm 0.22$ kcal. mole^{-1}

Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
278 (1)
379 (1)
827 (2)
150 (2)

Bond Distance: B-Br = 1.87 ± 0.02 Å

Bond Angle: Br-B-Br = 120° ± 6°

$\sigma = 6$

Product of the Moments of Inertia: $I_A I_B I_C = 6.74115 \times 10^{-112}$ g.^{3} cm.^{6}

Heat of Formation.

$\Delta H_f^\circ{}_{298}$ was obtained from the heat of formation of the liquid plus the heat of vaporization at 298°K, taken as 8.20 kcal. mole^{-1} as the average second and third law value derived from the vapor pressures of A. Stock and E. Kuss, Ber. 47, 3113 (1914). See BBr_3(l) for details.

Heat Capacity and Entropy.

Vibrational frequencies were obtained from T. Wentink, Jr., and V. H. Tiensuu, J. Chem. Phys., 28, 825 (1958) modified for the natural isotopic abundances (B^{10} 18.83%, B^{11} 81.17%) given by J. R. Bradford, "Handbook of Chemistry and Physics", Chemical Rubber Publishing Co., 1956. B-Br bond distance was reported by T. Wentink, Jr., and V. H. Tiensuu, loc. cit. Br-B-Br angle was taken from L. E. Sutton (editor), "Tables of Interatomic Distances and Configuration in Molecules and Ions," Special Publication No. 11, The Chemical Society, London, 1958. The individual moments of inertia were $I_A = I_B = 419.187 \times 10^{-39}$ g. cm.^{2}, $I_C = 838.375 \times 10^{-39}$ g. cm.^{2}

BORON MONOCHLORIDE (BCl) (IDEAL GAS) MOL. WT. = 46.277

Ground State Configuration $^1\Sigma$

$S^\circ_{298.15}$ = 50.942 cal deg^{-1} mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 33.1 ± 4.0 kcal mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 33.8 ± 4.0 kcal mole^{-1}

Electronic Levels and Quantum Weight

ϵ_i, cm^{-1}	g_i
0	1

ω_e = 843.65 cm^{-1}

$\omega_e x_e$ = 5.167 cm^{-1}

σ = 1

B_e = 0.6914 cm^{-1}

α_e = 0.00657 cm^{-1}

r_e = 1.7157 Å

Heat of Formation

The dissociation energy (D_0°) of BCl(g) has been reported by G. Herzberg[1], A. G. Gaydon[2] and R. F. Barrow[3], respectively. Hence the corresponding values of $\Delta H^\circ_{f\ 298.15}$ for BCl(g) were derived. The results are given as follows.

	D_0°		$\Delta H^\circ_{f\ 298.15}$
Investigator	e.v.	kcal mole^{-1}	kcal mole^{-1}
Herzberg[1]	4.2	96.9	62.6
Gaydon[2]	5.1 ± 0.4	117.6 ± 9.2	41.8 ± 9.2
Barrow[3]	---	127	33.8 ± 4

[1] G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950.

[2] A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953.

[3] R. F. Barrow, Trans. Faraday Soc. 56, 952 (1960).

The last value of $\Delta H^\circ_{f\ 298.15}$ listed in the above table is adopted. Using the bond energy, D°(B-Cl), obtained from BCl_3(g) molecule, the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for BCl(g) was calculated as 37.8 kcal mole^{-1} employing the same ratio of D°(B-X)/ average bond energy of BX_3 as found in BF(g) and BF_3(g), which is within the uncertainty of the value evaluated from dissociation energy.

Heat Capacity and Entropy

The spectroscopic constants were obtained from G. Herzberg, loc. cit. and corrected to the average isotopic species. The principal moment of inertia (I) is 4.0514 x 10^{-39} g cm^2.

α_e = [0.0056] cm^{-1}

σ = 1

r_e = [1.73] Å

Heat of Formation

Several values of the appearance potential of BCl^+ from BCl_3 have been reported. Osberghaus (1) gave 19.2eV, Marriott and Craggs (2) reported 18.54 ± 0.07eV, and Koski et al. (3) obtained two values of 17.2 ± 0.2eV and 20 ± 0.2eV. We make the presumption that the higher values, 19.2 and 20, refer to the reaction $BCl_3(g) + e^- \rightarrow BCl^+ + 2Cl(g) + 2e^-$ and the other values to $BCl_3(g) + e^- \rightarrow BCl^+ + Cl_2(g) + 2e^-$. Using the lower value in each case to help eliminate any excess kinetic energy, we obtain $\Delta Hf^\circ_{298}(BCl^+, g)$ = 289 and 300 kcal/mol, respectively. We adopt an average value of $\Delta Hf^\circ_{298}(BCl^+, g)$ = 295 ± 10 kcal/mol, which corresponds to an ionization potential for BCl(g) of 11.3 ± 0.3eV.

Heat Capacity and Entropy

BCl^+ is isoelectronic with BeCl,and the ground state configuration and electronic levels are estimated by comparison with BeCl. The bond length, frequency and anharmonicity constant are estimated between the values for BCl and BeCl; the rotational constant is calculated from the bond length and atomic masses, and α_e is obtained from the above constants assuming a Morse potential function.

The enthalpy at 0°K is -2.118 kcal/mol.

BORON CHLORIDE FLUORIDE (BClF) (IDEAL GAS) MOL. WT. = 65.277

Point Group C_s

$S^\circ_{298.15}$ = [63.229] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [2]

$\Delta H^\circ_{f\ 0}$ = [-75.2 ± 7.0] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-75.0 ± 7.0] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[920] (1)
[360] (1)
[1220] (1)

Bond Distance: B-Cl = [1.73] Å B-F = [1.295] Å

Bond Angle: F-B-Cl = [120]°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.81165 X 10^{-115}] g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for BClF(g) was estimated based on an assumption that ΔH°_r = 0 for the reaction $BCl_2(g)$ + $BF_2(g)$ = 2BClF(g). The values of $\Delta H^\circ_{f\ 298.15}$ of $BCl_2(g)$ and $BF_2(g)$, used for calculation, are -20 and -130 kcal. mole^{-1}, respectively.

Heat Capacity and Entropy.

The ground state quantum weight and bond angle were assumed to be the same as those for $BF_2(g)$. The bond distances of B-Cl and B-F were estimated by comparison with those in $BCl_3(g)$ and $BF_3(g)$ molecules, respectively. The vibrational frequencies were estimated from the corresponding values for $BCl_2(g)$ and $BF_2(g)$. The three principal moments of inertia are: I_A = 1.48569 X 10^{-38}, I_B = 7.7980 X 10^{-40} and I_C = 1.56367 X 10^{-38} g. cm.^{2}

Bond Distance: B-Cl = [1.73] Å B-F = [1.295] Å

Bond Angle: F-B-Cl = [120°] F-B-F = [120°]

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 3567.6 \times 10^{-117}$ g.^{3} cm.^{6}

Heat of Formation.

The values for BCl_2F and $BClF_2$ of $\Delta H^\circ_{f\ 298.15} = -154$ and $\Delta H^\circ_{f\ 298.15} = -211.6$ kcal. mole^{-1}, respectively, are obtained from the average bond energies of BF_3 and BCl_3. The calculated values were each made less negative by about 0.8 kcal. mole^{-1} in order to make them consistent with the equilibrium measurements of T. H. S. Higgins, E. C. Leisegang, C. J. G. Raw, and A. J. Rossouw, J. Chem. Phys. 23, 1544 (1955) and S. R. Gunn and R. H. Sanborn, J. Chem. Phys. 33, 955 (1960) for the reaction

$$BF_3(g) + BCl_3(g) \rightarrow BClF_2(g) + BCl_2F(g).$$

Values for the heat of reaction are $\Delta H_{298.15} = +1.68$ kcal. mole^{-1} and $\Delta H_{298.15} = 1.1$ (uncertainty of -0.5 to +0.8) kcal. mole^{-1}, the former calculated from the measured equilibrium constant and the statistical entropy change and the latter obtained from the variation of the equilibrium constant with temperature. Selection of $\Delta H_{298.15} = 1.6$ kcal. mole^{-1} fixes the sum of the heats of formation of $BClF_2$ and BCl_2F as -365.6 kcal. mole^{-1}, but it does not determine the individual values. Thus, the selected heats of formation are only as accurate as the average bond energy calculations on which they are based. A reasonable estimate of the uncertainty would be ± 5 kcal. mole^{-1}.

Heat Capacity and Entropy.

The observed frequencies of L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956), were adjusted to the normal isotopic composition of 81.2% ^{10}B and 18.8% ^{11}B. The bond angles were assumed to be 120° and the bond lengths were taken to be the same as in the respective trihalides. As a result, the principal moments of inertia are: $I_A = 17.6044 \times 10^{-39}$, $I_B = 7.935 \times 10^{-39}$, and $I_C = 25.5394 \times 10^{-39}$ g. cm.^{2}.

Rotational Constant: B_0 = [0.16504] cm.$^{-1}$

σ = 1

Heat of Formation.

The vapor-phase equilbria existing in the $B_2O_3 + BCl_3$ system were determined by an effusion method in the temperature range 1234-1389°K. by J. Blauer and M. Farber, Trans. Faraday Soc. 60, 301 (1964). Based on the equilibrium constants reported for the reaction $1/3\ B_2O_3(l) + 1/3\ BCl_3(g) = BOCl(g)$, the second and third law values of $\Delta H^\circ_{r\ 298.15}$ were evaluated as 57.7 and 56.3 kcal. mole^{-1}, respectively. The third law value for $\Delta H^\circ_{r\ 298.15}$ was adopted for the calculation of the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for BOCl(g).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The vibrational frequencies (ω) were estimated from the ω values calculated by the valence force method described by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., 1945, using estimated force constants, $k_1 = 5.2 \times 10^5$, $k_2 = 16.7 \times 10^5$ dynes cm.$^{-1}$ and $k_\delta = 0.40 \times 10^{-11}$ dynes cm. rad.$^{-1}$ The B=O and B-Cl bond distances were assumed to be the same as those in BO(g) and $BCl_3(g)$, respectively. The moment of inertia is 1.6958×10^{-38} g. cm.^{2}

BORON DICHLORIDE (BCl_2) (IDEAL GAS) MOL. WT. = 81.734

Point Group [C_{2v}]

$S^\circ_{298.15}$ = [64.956] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight [2]

$\Delta H_f^\circ{}_0$ = [-20.3 ± 15] kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = [-20 ± 15] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[720](1)
[240](1)
[980](1)

Bond Distance: B-Cl = [1.73] Å

Bond Angle: Cl-B-Cl = [120°]

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ =[8.49841 X 10^{-115}]g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by analogy with BF_3, specifically the ratio

$$\Delta H_r(BX_3 \rightarrow BX_2 + X) \;/\; \Delta H_r(BX_3 \rightarrow B + 3X)$$

was taken as 0.347.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from force constants transferred from the trichloride given by G. Herzberg "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., (1945). The bond length was taken between those of the mono and trichlorides and the angle was estimated to be the same as that in the trihalides. The ground state quantum weight was taken as two on account of the one unpaired electron.

The individual moments of inertia were I_B = 1.1661 X 10^{-39} g. cm.^{2}, I_A = 26.4189 X 10^{-39} g. cm.^{2} and I_C = 27.5851 X 10^{-39} g. cm.^{2}

Boron Dichloride Unipositive Ion (BCl_2^+)

[500] (1)
[150] (2)
[800] (1)

Bond Distance: B-Cl = [1.74] Å

Bond Angle: Cl-B-Cl = [180°] σ = 2

Rotational Constant: B_0 = [0.0785] cm^{-1}

Heat of Formation

The appearance potential (AP) of the positive ion fragment BCl_2^+(g) from BCl_3(g) was determined mass spectrometrically by Osberghaus (1), Marriott (2), and Koski (3) as 13.2 ± 0.5, 13.01 ± 0.02, and 11.8 ± 0.2 eV, respectively. From the reaction $BCl_3 + e^- = BCl_2^+ + Cl + 2e^-$, the corresponding values of ΔHf°_{298} for BCl_2^+(g) are derived to be 180.4 ± 11.5, 176.0 ± 0.5, and 148.1 ± 4.6 kcal/ mol, using ΔHf°_0 = -96.078 and 28.520 kcal/mol for BCl_3(g) and Cl(g). The value of ΔHf°_{298} for BCl_2^+(g) is adopted as 148 ± 5 kcal/mol, since the lowest value is likely to have the least excess kinetic energy in the fragments.

Heat Capacity and Entropy

The molecular structure is assumed to be linear using the Walsh (4) predictions for 16 valence electron XY_2 molecules. The electronic states, levels and vibrational frequenceis are estimated by comparison with those for CO_2 (5). The B-Cl bond distance is estimated using the method of Krasnov (6). The moment of inertia is 3.564 x 10^{-38} g cm^2. The enthalpy at 0°K is -3.07 kcal/mol.

Bond Distance: B-Cl = [1.74] Å

Bond Angle: Cl-B-Cl = [120°]

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = [8.798 \times 10^{-115}]\ g^3\ cm^6$

Heat of Formation

The electron captured by BCl_2 should go into a non-bonding orbital according to the correlation diagrams of Walsh (1), thus one expects a small electron affinity. In fact one reasonable estimate of the dissociation energy yields a negative electron affinity (EA). Consider the isoelectronic reactions $BCl_2^- \rightarrow B^- + 2Cl$ and $CCl_2 \rightarrow C + 2Cl$, if we make the assumption that these binding energies are the same then $\Delta Hf°_{298}(BCl_2^-, g) = 12$ kcal/mol or $EA(BCl_2) = -32$ kcal. Another possible estimate is obtained from the isoelectronic reactions $BCl_2^- \rightarrow BCl + Cl^-$ and $BClAr \rightarrow BCl + Ar$, although the latter reaction is unknown we expect a zero bond strength; applying this to the first reaction yields $\Delta Hf°_{298}(BCl_2^-, g) = -22$ kcal/mol or $EA(BCl_2) = 2$ kcal.

In consideration of the above arguments we choose $EA(BCl_2) = EA(B, g) = 6$ kcal (2) which gives $\Delta Hf°_{298}(BCl_2^-, g) = -26$ kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be bent using the correlations of A. D. Walsh (1) for 18 valence electron XY_2 molecules. The B-Cl bond distance is estimated using the method of Krasnov (3). The Cl-B-Cl bond angle is taken as 120°. The electronic levels, quantum weights and vibrational frequencies are estimated by comparison with those for CF_2(4) and other related isoelectronic molecules. The three principal moments of inertia are $I_A = 1.179 \times 10^{-39}$, $I_B = 2.673 \times 10^{-38}$ and $I_C = 2.791 \times 10^{-38}$ g cm². The enthalpy at 0°K is -2.76 kcal/mol.

1320 (1)	1000 (1)
[554] (1)	[339] (1)
[266] (1)	528 (1)

Bond Distance: B-Cl = [1.73] Å B-F = [1.295] Å

Bond Angle: Cl-B-Cl = [120°] F-B-Cl = [120°] σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 12020 X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

The values for BCl_2F and $BClF_2$ of $\Delta H_f^\circ{}_{298.15}$ = -154 and $\Delta H_f^\circ{}_{298.15}$ = -211.6 kcal. mole^{-1}, respectively, are obtained from the average bond energies of BF_3 and BCl_3. The calculated values were each made less negative by about 0.8 kcal. mole^{-1} in order to make them consistent with the equilibrium measurements of T. H. S. Higgins, E. C. Leisegang, C. J. G. Raw, and A. J. Rossouw, J. Chem. Phys. 23, 1544 (1955) and S. R. Gunn and R. H. Sanborn, J. Chem. Phys. 33, 955 (1960) for the reaction

$$BF_3(g) + BCl_3(g) \rightarrow BClF_2(g) + BCl_2F(g).$$

Values for the heat of reaction are $\Delta H_{298.15}$ = +1.68 kcal. mole^{-1} and $\Delta H_{298.15}$ = 1.1 (uncertainty of -0.5 to +0.8) kcal. mole^{-1}, the former calculated from the measured equilibrium constant and the statistical entropy change and the latter obtained from the variation of the equilibrium constant with temperature. Selection of $\Delta H_{298.15}$ = 1.6 kcal. mole^{-1} fixes the sum of the heats of formation of $BClF_2$ and BCl_2F as -365.6 kcal. mole^{-1}, but it does not determine the individual values. Thus, the selected heats of formation are only as accurate as the average bond energy calculations on which they are based. A reasonable estimate of the uncertainty would be ± 5 kcal. mole^{-1}.

Heat Capacity and Entropy.

The spectroscopic constants are based on the work of L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956), who observed ν_1, ν_4, and ν_6 and calculated ν_2, ν_3, and ν_5. The frequencies were adjusted to the normal isotopic composition of 81.2% ^{11}B and 18.8% ^{10}B. The bond angles were taken to be 120° while the bond lengths were assumed to be the same as in the respective trihalides. As a result, the principal moments of inertia are I_A = 11.8748 X 10^{-39}, I_B = 26.4268 X 10^{-39}, and I_C = 38.3016 X 10^{-39} g. cm.^{2}.

BORON DICHLORIDE HYDRIDE (BCl_2H) (IDEAL GAS) MOL. WT. = 82.72497

Point Group C_{2v}

$S^\circ_{298.15}$ = [64.1] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 1

$\Delta H_f^\circ{}_0$ = -58.6 ± 1 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -59.3 ± 1 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
[2610](1)	1091 (1)
744 (1)	[894](1)
[287](1)	786 (1)

Bond Distance: B-H = 1.13 ± 0.2 Å B-Cl = [1.75] Å

Bond Angle: Cl-B-Cl = 119.7 ± 3° Cl-B-H = 120.15 ± 1.5° σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = 1.39215 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The chemical equilibria for the following two reactions: (A) $BCl_3(g) + H_2(g) = BHCl_2(g) + HCl(g)$, and (B) $6BHCl_2(g) = B_2H_6(g) + 4BCl_3(l, g)$ were investigated by (1) J. H. Murib, D. Horvitz, and C. A. Bonecutter, Ind. Eng. Chem. Prod. Res. Develop. 4, 273 (1965); (2) P. H. Mook, G. R. Seiler, and E. R. Watson, "Process Development, Prepilot and Pilot Plant Investigations - High Energy Boron Fuels," ASDTR 62-7-558 A, Vol. IV, March 1962; and (3) L. Lynds and C. D. Bass, Inorg. Chem. 3, 1147 (1964). Using the reported equilibrium constants, the corresponding enthalpy changes and the respective $\Delta H_f^\circ{}_{298.15}$ values were evaluated. The results obtained are presented as follows.

Reaction	Temperature, °K.	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1} Third Law Value	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1} Second Law Value	$\Delta H_f^\circ{}_{298.15}$* kcal. mole^{-1}	Reference
A	873 - 973	16.19	15.57 ± 0.8	-58.06 ± 0.5	(1)
A	1073 -1273	13.91	13.50 ± 3.0	-60.3 ± 0.7	(2)
B	273	-17.85	——	-59.6	(1)
B	298	-19.09	——	-59.4	(3)

*Based on the third law value of $\Delta H_r^\circ{}_{298.15}$.

The value of $\Delta H_f^\circ{}_{298.15}$ for $BHCl_2(g)$ is selected as -59.3 ± 1 kcal. mole^{-1}.

Heat Capacity and Entropy.

The molecular structure, B-H bond distance and Cl-B-Cl bond angle were obtained from L. Lynds and C. D. Bass, J. Chem. Phys. 40, 1590 (1964). The B-Cl bond distance was assumed to be the same as that in $BCl_3(g)$. The vibrational frequencies adopted were reported by C. D. Bass, L. Lynds, T. Wolfram, and R. E. DeWames, J. Chem. Phys. 40, 3611 (1964), and corrected to the average isotopic species. It has been pointed out that the complete assignment of the infrared spectra of $HBCl_2(g)$ is quite difficult due to the unavoidable presence of $BCl_3(g)$. The adopted frequencies were obtained using the Green's function and partitioning techniques, taking $HBCl_2$ as an "isotopic" species of BCl_3. An excellent agreement between the calculated and observed spectra reported by L. Lynds and C. D. Bass, loc. cit. was claimed. Spectra of the mixture of BCl_3, $HBCl_2$ and $DBCl_2$ are quite complex and have been observed by L. Lynds and D. R. Stern, J. Am. Chem. Soc. 81, 5006 (1959), H. G. Nadean and D. M. Oaks, Jr., Anal. Chem. 32, 1481 (1961), and H. W. Mayers and R. F. Putnam, Inorg. Chem. 2, 655 (1963) and only three bands were correlated with $HBCl_2$. Analysis of infrared data from previous works, according to the conventional Wilson's method of symmetry coordinates, has been undertaken by O. B. de Mandirola and J. F. Westerkamp, Spectrochim. Acta, 20, 1633 (1964). Based on four observed frequencies, a set of six frequencies was derived and assigned. The three principal moments of inertia are: $I_A = 2.6960 \times 10^{-38}$, $I_B = 1.7957 \times 10^{-39}$ and $I_C = 2.87557 \times 10^{-38}$ g. cm.^{2}

Heat of Formation.

The enthalpy change ($\Delta H_r^\circ{}_{298.15}$) of the reaction B(amorph) + 3/2 $Cl_2(g) = BCl_3(g)$ has been determined in a calorimeter by W. H. Johnson, R. G. Miller and E. J. Prosen, J. Res. Natl. Bur. Std. 62, 213 (1959). From the reported value, $\Delta H_r^\circ{}_{298.15} = -97.51 \pm 0.32$ kcal. mole^{-1}, the heat of formation ($\Delta H_f^\circ{}_{298.15}$) for $BCl_3(g)$ was derived as -96.31 ± 0.50 kcal. mole^{-1}, using $\Delta H_r^\circ{}_{298.15} = 1.20 \pm 0.40$ kcal. mole^{-1} for the reaction B(c) = B(amorph). Some other related heats of reaction reported by previous investigators are presented as follows.

Investigator	Reaction	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1}	$\Delta H_f^\circ{}_{298.15}$, kcal.mole^{-1}
Gal'chenko, et al.[1]	B(am.) + 3/2 $Cl_2(g) = BCl_3(g)$ B(am.) + 3/2 $Cl_2(g) = BCl_3(l)$	-97.4 ± 0.7 -103.3 ∓ 0.6	-96.2 ± 0.8 -96.5 ∓ 0.7
J. R. Lacher, et al.[2]	$B_2H_6(g) + 6\ Cl_2(g) = 2\ BCl_3(g) + 6\ HCl(g)$	-342.9	-100.4 ± 5.0
Skinner and Smith[3]	$BCl_3(l) + (n+3)H_2O(l) = (H_3BO_3+3HCl)\cdot n\ H_2O$ (Sol.)	-69.2 ± 1.0	-97.2 ± 1.0
Gunn and Green[4]	$BCl_3(l) + 2403\ H_2O(l) = (H_3BO_3+3HCl)\cdot 2400H_2O$ (Sol.)	-68.68 ± 0.06	-96.3 ± 0.2
Fasolino[5]	$BCl_3(l) + 593\ H_2O(l) = (H_3BO_3+3HCl)\cdot 590\ H_2O$ (Sol.)	-69.12 ± 0.11	-95.44 ± 0.39

[1] G. L. Gal'chenko, B. I. Timofeev and S. M. Skuratov, Russ. J. Inorg. Chem. 5,1279 (1960). $\Delta H_f^\circ{}_{298.15}$ were derived from $\Delta H_r^\circ{}_{298.15}$ using $\Delta H_r^\circ = -1.2 \pm 0.4$ kcal. mole^{-1} for B(am.) = B(c) and $\Delta H_v^\circ{}_{298.15}(BCl_3, l) = 5.6$ kcal. mole^{-1}.

[2] J. R. Lacher, R. E. Scruby and J. D. Park, J. Am. Chem. Soc. 74, 5292 (1952). The $\Delta H_f^\circ{}_{298.15}$ value was calculated based on $\Delta H_f^\circ{}_{298.15} = 9.80$ kcal. mole^{-1} for $B_2H_6(g)$.

The heats of formation for $BCl_3(l)$ derived from the heats of hydrolysis reported by other investigators were reviewed by W. H. Johnson, R. G. Miller and E. J. Prosen, loc. cit.

Heat Capacity and Entropy.

The bond distance of B and Cl atoms has been reported to be 1.73 ± 0.02, 1.76 ± 0.02 and 1.75 Å by H. A. Levy and L. O. Brockway, J. Am. Chem. Soc. 59, 2085 (1937), A. H. Gregg, G. C. Hampson and G. I. Jenkins, P. L. F. Jones and L. E. Sutton, Trans. Faraday Soc. 33, 852 (1937), and C. Spencer and W. N. Lipscomb, J. Chem. Phys. 28, 355 (1958), respectively. The last value is adopted. The values of vibrational frequencies used were reported by L. P. Lindeman and M. K. Wilson, J. Chem. Phys. 24, 242 (1956). The vibrational frequencies were also determined by A. B. D. Cassie, Proc. Roy. Soc. A148, 87 (1935), T. F. Anderson, E. N. Lassettre and D. M. Yost, J. Chem. Phys. 4, 703 (1936), and R. E. Scruby, J. R. Lacher and J. D. Park, J. Chem. Phys. 19, 386 (1951). The molecular structure was given by H. A. Levy, et al., loc. cit. The three principal moments of inertia are: $I_A = I_B = 2.7042 \times 10^{-38}$ and $I_C = 5.4085 \times 10^{-38}$ g. cm.^{2}

Heat of Formation.

The equilibria of the reaction 2/3 B(c) + 1/3 $BF_3(g)$ = BF(g) were studied by J. Blauer, M. A. Greenbaum and M. Farber[1], by means of transpiration at pressures below 300μ. The values of log K_p at 1375 and 1476°K. were reported as -3.99 ± 0.02 and -3.30 ± 0.05, respectively. By the third law method the value of $\Delta H^\circ_{r\ 298.15}$ for the reaction was derived to be 61.38 kcal. mole^{-1}, yielding $\Delta H^\circ_{f\ 298.15}$ = -28.7 ± 2.6 kcal. mole^{-1} for BF(g). The system B + CaF_2 was studied mass spectrometrically in a graphite Knudsen cell by D. L. Hildenbrand. The equilibria involving BF(g) were observed. Intensity measurements were made at temperatures, 1583-1734°K. From the third law value, $\Delta H^\circ_{r\ 298.15}$ = 12.2 ± 0.3 kcal. mole^{-1}, for the reaction $BF_3(g)$ + Ca(g) = BF(g) + $CaF_2(g)$, the value of $\Delta H^\circ_{f\ 298.15}$ for BF(g) was derived as -26.7 ± 2 kcal. mole^{-1}. The dissociation energy (D_0°) of BF(g) molecule has been reported by G. Herzberg[2], A. G. Gaydon[3] and R. F. Barrow[4], respectively. Hence the corresponding values of $\Delta H^\circ_{f\ 298.15}$ for BF(g) were derived. The results are compared with those obtained from equilibrium data as follows.

Investigator	Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1}	$\Delta H^\circ_{f\ 298.15}$, kcal. mole^{-1}
Farber, et al.[1]	2/3 B(c) + 1/3 $BF_3(g)$ = BF(g)	61.38	-28.7 ± 2.6
Herzberg[2]	BF(g) = B(g) + F(g)	100.2	+51.5
Gaydon[3]	BF(g) = B(g) + F(g)	197.0	-45.3 ± 11.5
Barrow[4]	BF(g) = B(g) + F(g)	186.0	-34.3
Gross, et al.[5]	2/3 B(c) + 1/3 $BF_3(g)$ = BF(g)	—	-28 ± 3
Hildenbrand[6]	$BF_3(g)$ + Ca(g) = BF(g) + $CaF_2(g)$	12.2	-26.7 ± 2

[2] G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, New York, 1950. $\Delta H^\circ_{r\ 298.15}$ was calculated based on D_0° = 4.3 e.v.

[3] A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. $\Delta H^\circ_{r\ 298.15}$ was derived from D_0° = 8.5 ± 0.5 e.v.

[4] R. F. Barrow, Trans. Faraday Soc. 56, 952 (1960). $\Delta H^\circ_{r\ 298.15}$ was calculated based on D_0° = 185 kcal. mole^{-1}.

[5] P. Gross, C. Hayman, D. L. Levi and R. H. Lewin, "Stability of Lower Boron Halides", Final Technical Report, August 22, 1963, Fulmer Research Institute Limited, England. The reported value, $\Delta H^\circ_{f\ 298.15}$ = -28 ± 3 kcal. mole^{-1}, is a preliminary estimated one.

[6] D. L. Hildenbrand, "Thermodynamic Properties of Propellant Combustion Products", QLR-65-3, Philco Corporation, California.

The value of $\Delta H^\circ_{f\ 298.15}$ adopted is the average of the first and last $\Delta H^\circ_{f\ 298.15}$ values listed in the above table.

Heat Capacity and Entropy.

The spectroscopic constants used were obtained from R. Onaka, J. Chem. Phys. 27, 374 (1957) and corrected to the average isotopic species. Spectroscopic constants for BF(g) were also reported by G. Herzberg, loc. cit. The moment of inertia (I) is 1.8321 X 10^{-39} g. cm.^{2}

Bond Distance: B-F = [1.30] Å B-O = [1.20] Å

Bond Angle: O-B-F = [180°]

σ = 1

B_0 = [0.30939] cm.$^{-1}$

Heat of Formation.

The equilibrium constants for the reaction $B_2O_3(l) + BF_3(g) = 3BOF(g)$ in the temperature range 1054-1253°K. were determined by M. Farber and J. Blauer, Trans. Faraday Soc. 58, 2090 (1962), using the so-called Molecular Flow Reaction Method. The value of ΔH°_r for this reaction was evaluated by both the second and third law methods, using the equilibrium constants corrected for the trimer and correcting K_p at 1200°K. from 9.6 X 10^{-11} to 9.6 X 10^{-10}. D. L. Hildenbrand, L. P. Theard and A. M. Saul, J. Chem. Phys. 39, 1973 (1963) analyzed the vapor above mixture of MgF_2 and B_2O_3 contained in a Knudsen cell with a mass spectrometer and found that in the temperature range 980-1230°K. the vapor is composed of $BF_3(g)$, $(BOF)_3(g)$ and $BOF(g)$ species. From the reported temperature dependence of appropriate ion intensities the enthalpy change of the reaction $(BOF)_3(g) = 3BOF(g)$ was derived by the second law method as 127.9 kcal. mole^{-1} at 1115°K. or 129.75 kcal. mole^{-1} at 298.15°K. The results obtained are presented as follows, using JANAF free energy functions and auxiliary data.

Investigator	Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second law value	Third law value	$\Delta H^\circ_{f\ 298.15}$ kcal. mole^{-1}
Farber and Blauer	$B_2O_3(l) + BF_3(g) = 3BOF(g)$	150.2 ± 16.6	149.0	-140.1 ± 6*
Hildenbrand, et al.	$(BOF)_3(g) = 3BOF(g)$	129.8 ± 3	——	-145.2 ± 1.5

*Calculation based on the third law value and one point rejected due to statistical test.

The adopted value of $\Delta H^\circ_{f\ 298.15}$ for BOF(g) is the weighted average of the two $\Delta H^\circ_{f\ 298.15}$ values listed above.

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The vibrational frequencies (ω) were estimated from the ω values calculated by the valence force method described by G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., 1945, using estimated force constants, k_1 = 10 X 10^5, k_2 = 25.6 X 10^5 dynes cm.$^{-1}$ and k_δ = 0.47 X 10^{-11} dynes cm. rad.$^{-1}$. The B-O and B-F bond distances were assumed to be the same as those in BO(g) and $BF_3(g)$ molecules. The moment of inertia is 9.0464 X 10^{-39} g. cm.^{2}

Heat of Formation.

The heat of formation ($\Delta H_f^\circ{}_{298.15}$) was obtained from J. L. Margrave, J. Phys. Chem. 66, 1209 (1962), from appearance potentials.

Heat Capacity and Entropy.

The bond distance and angle were assumed to be the same as those in BF_3(g) molecule. The vibrational frequencies were calculated using force constants transferred from those for BF_3(g) given by G. Herzberg, "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., 1945. The three principal moments of inertia are: $I_A = 7.9278 \times 10^{-39}$, $I_B = 5.8710 \times 10^{-40}$ and $I_C = 8.5149 \times 10^{-39}$ g. cm.^{2}

[1550] (1)

Bonc Distance: B-F = [1.31] Å

Bond Angle: F-B-F = [180°] σ = 2

Rotational Constant: B_0 = [0.2585] cm^{-1}

Heat of Formation

The electron impact reaction at low pressure in BF_3(g) has been studied with a mass spectrometer by Osberghaus (1), Law (2), and Marriott (3). From the reported appearance potentials 17.0 ± 0.5, 16.2 ± 0.2, and 16.7 ± 0.05 eV and assumed process $BF_3 + e^- = BF_2^+ + F + 2e^-$, we calculate the corresponding values of ΔHf°_{298} (BF_2^+, g) as 102.8 ± 11.5, 84.4 ± 4.6, and 83.7 ± 1.2 kcal/mol, using ΔHf_0° = 270.977 and 18.357 kcal/mol for BF_3 (g) and F (g). The adopted value of ΔHf°_{298} for BF_2^+ (g) is 84 ± 2 kcal/mol, since the lower values are likely to have the least excess kinetic energy in the fragments.

Heat Capacity and Entropy

The molecular structure is assumed to be linear using the Walsh (4) prediction for 16 valence electron XY_2 molecules. The electronic states and levels, and vibrational frequencies are estimated by comparision with those for CO_2(5). The B-F bond distance is calculated by the method recommended by Krasnov (6). The moment of inertia is 1.083×10^{-38} g cm^2. The enthalpy at 0°K is -2.54 kcal/mol.

BORON DIFLUORIDE UNINEGATIVE ION (BF_2^-) (IDEAL GAS) GFW = 48.80835

Point Group [C_{2v}]

ΔHf°_0 = [-136 ± 30] kcal/mol

$S^\circ_{298.15}$ = [57.5 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-136 ± 30] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	1
[6000]	3
[28000]	1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[1000] (1)
[570] (1)
[1100] (1)

Bond Distance: B-F = [1.30] Å

Bond Angle: F-B-F = [120°]

σ = 2

Product of the Moments of Inertia: $I_A I_B I_C$ = [4.054 x 10^{-116}] g^3 cm^6

Heat of Formation

The electron captured by BF_2 should go into a non-bonding orbital according to the correlation diagrams of Walsh (1), thus we would expect a small electron affinity. Two estimates of the dissociation energy of BF_2^- indicate a negative electron affinity (EA); consider the isoelectronic reactions $BF_2^- \rightarrow B^- + 2F$ and $CF_2 \rightarrow C + 2F$ if we make the reasonable assumption that the atomization energies are the same then $\Delta Hf^\circ_{298}(BF_2^-, g)$ = -86 kcal/mol, or $EA(BF_2)$ = -44 kcal. Another approach is to consider the isoelectronic reactions $BF_2^- \rightarrow BF + F^-$ and $BFNe \rightarrow BF + Ne$, although the latter reaction is unknown we would expect zero bond strength, and if used in the first reaction this yields $\Delta Hf^\circ_{298}(BF_2^-, g)$ = -90 kcal/mol, or $EA(BF_2)$ = -40 kcal.

In consideration of the above we choose $EA(BF_2) = EA(B, g)$ = 6 kcal (2), which gives $\Delta Hf^\circ_{298}(BF_2^-, g)$ = -136 kcal/mol.

Heat Capacity and Entropy

The molecular structure and B-F bond distance are assumed to be the same as those for the $BF_2(g)$ molecule. The electronic levels, quantum weights and vibrational frequencies are estimated by comparison with those for CF_2(3) which is isoelectronic with BF_2^-. The three principal moments of inertia are: $I_A = 5.904 \times 10^{-40}$, $I_B = 7.997 \times 10^{-39}$ and $I_C = 8.587 \times 10^{-39}$ g cm^2. The enthalpy at 0°K is -2.52 kcal/mol.

DIFLUOROBORANE (BHF_2) (IDEAL GAS) MOL. WT. = 49.81577

Point Group C_{2v}

$S^\circ_{298.15}$ = 58.3 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = -174.5 ± 0.8 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -175.4 ± 0.8 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
2640 (1)	1411 (1)
1174 (1)	[1158](1)
544 (1)	928 (1)

Bond Distance: B-H = 1.15 Å B-F = 1.30 ± 0.15 Å

Bond Angle: F-B-F = 120 ± 5° F-B-H = 120 ± 2.5° σ = 2

Product of the Moments of Inertia: $I_AI_BI_C$ = 7.5168 X 10^{-116} g.^{3} cm.^{6}

Heat of Formation.

The equilibrium pressures at 296 and 360°K. for the reaction 1/6 $B_2H_6(g)$ + 2/3 $BF_3(g)$ = $HBF_2(g)$ were determined by R. F. Porter and S. K. Wason, J. Phys. Chem. 69, 2208 (1965). By the third law method, the enthalpy change was evaluated to be 3.06 ± 0.33 kcal. mole^{-1}. Based on the values of $\Delta H^\circ_{f\ 298.15}$ for $B_2H_6(g)$ and $BF_3(g)$ as 9.8 and -270.1 kcal. mole^{-1}, respectively, the heat of formation for $BHF_2(g)$ was derived to be -175.4 ± 0.8 kcal. mole^{-1}. The drift in the third law heat of reaction is 3.6 e.u.

Heat Capacity and Entropy.

The infrared spectrum of $BHF_2(g)$ has been observed by the following investigators:

T. D. Coyle, J. J. Ritter and T. C. Farrar, Proc. Chem. Soc. 25 (1964).
M. Perec and L. N. Becka, J. Chem. Phys. 43, 721 (1965).
L Lynds, J. Chem. Phys. 42, 1124 (1965).
R. F. Porter and S. K. Wason, J. Phys. Chem. 69, 2208 (1965).

The vibrational frequencies, except ν_5, were obtained from Porter and Wason, and corrected to the average isotopic species. The value of ν_5 was estimated by comparison with the same value reported by other investigators. The molecular structure, bond distances and angle were obtained from Perec and Becka, loc. cit. The three principal moments of inertia are: I_A = 7.9959 X 10^{-39}, I_B = 1.0404 X 10^{-39} and I_C = 9.0362 X 10^{-39} g. cm.^{2}

The vibrational-rotational spectrum of $BHF_2(g)$ has been studied by L. Lynds and C. D. Bass, J. Chem. Phys. 43, 4357 (1965). The values of ν_1, ν_2, ν_3 and ν_6 were assigned as 1164.2, 2620.8, 541.5 and 923.5 cm.$^{-1}$, respectively, which are in fair agreement with the adopted values reported by Porter and Wason, loc. cit.

Bond Distance: B-F = [1.30] Å B-O = [1.36] Å O-H = [0.96] Å

Bond Angle: F-B-F = [120]° F-B-O = [120]° B-O-H = [105]° σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.05094 X 10^{-114}] g.^{3} cm.^{6}

Heat of Formation.

The value of heat of formation ($\Delta H^\circ_{f\ 298.15}$) was calculated based on an assumption that $\Delta H^\circ_{r\ 298.15}$ = 0 for the reaction 2/3 $BF_3(g)$ + 1/3 $B(OH)_3(g)$ = $BOHF_2(g)$.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from J. S. Gordon, Astrosystems International, Inc., private communication, November 2, 1962. The B-F and O-H bond distances were assumed to be the same as those in $BF_3(g)$ and $H_2O(g)$ molecules, respectively. The B-O bond distance and the bond angles were estimated from related molecules. The three principal moments of inertia are: I_A = 7.8114 X 10^{-39}, I_B = 8.3333 X 10^{-39} and I_C = 1.61447 X 10^{-38} g. cm.^{2}

Bond Distance : B-F = 1.30 ± 0.05 Å   B-O = 1.40 ± 0.05 Å

Bond Angle: F-B-O = 117 ± 5°   F-B-F = 126 ± 5° $\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 9.9464 \times 10^{-115}\ g^3\ cm^6$

Heat of Formation.

The molecule $BF_2O(g)$ is similar to $BO_2(g)$ in that both have an extra electron. Based on an assumption that $D^\circ_0(F_2B\text{-}O) = D^\circ_0(OB\text{-}O) - 10 = 134.3$ kcal/mol, where the quantity -10 kcal/mol is estimated as the resonance stabilization energy in $BO_2(g)$, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $BF_2O(g)$ is calculated to be -206 kcal/mol.

Assuming $D^\circ_0(F_2BO\text{-}H) = D^\circ_0(HO\text{-}H) = 118$ kcal/mol, the value of $\Delta Hf^\circ_{298.15}(F_2BO,g)$ is evaluated as -191.6 kcal/mol, using $\Delta Hf^\circ_0 = 51.63$ and -257.35 kcal/mol for H(g) and $F_2BOH(g)$, respectively.

The value of $\Delta Hf^\circ_{298.15}$ for $BOF_2(g)$ is tentatively adopted as -200 ± 15 kcal/mol.

Heat Capacity and Entropy.

The 4465-Å emission spectrum was observed in a discharge through BF_3 and O_2 by C. W. Mathews, J. Mol. Spectry. 19, 203 (1966). The emitter of the discharge was shown to be either the planar BOF_2 molecule or molecule-ion BOF_2^+. No experimental evidence has been found to distinguish between them. The molecular structure, bond distances and angles were reported by Mathews, based on a rotational analysis of the emission spectrum. These values are adopted here.

Three vibrational frequencies for both $^{11}B^{16}OF_2$ and $^{10}B^{16}OF_2$ molecules (or ions) were determined by vibrational analysis of the 5800 - Å bands of the emission spectrum by C. W. Mathews and K. K. Innes, J. Mol. Spectry. 15, 199 (1965). These values are corrected to the average isotopic species and adopted. The last three frequencies are estimated from values calculated by the valence-force method, using force constants transferred from $COF_2(g)$.

The ground state quantum weight is taken as 2 because of the extra electron. The other two electronic levels are estimated from the band systems at 5800 and 4465 Å, assuming that two systems have a common lower state, i.e. the ground state.

The three principal moments of inertia are: $I_A = 8.4647 \times 10^{-39}$, $I_B = 7.4045 \times 10^{-39}$ and $I_C = 1.5869 \times 10^{-38}\ g\ cm^2$.

BORON TRIFLUORIDE (BF_3) (IDEAL GAS) GFW = 67.8062

Point Group D_{3h}

ΔHf_0° = -270.7 ± 0.4 kcal/mol

$S^\circ_{298.15}$ = 60.77 ± 0.01 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -271.42 ± 0.4 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	
888	(1)
696.7	(1)
1463.3	(2)
480.7	(2)

Bond Distance: B-F = 1.307 ± 0.002 Å

Bond Angle: F-B-F = 120°

σ = 6

Products of the Moments of Inertia: $I_AI_BI_C = 1.0563 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

The adopted heat of formation was selected by a simultaneous adjustment of several interrelated pieces of data relating to the heat of formation of HF (see HF, g table 12-31-68). The data which were considered relating directly to BF_3 were as follows.

A. $NF_3(g) + B(c, \beta) \rightarrow BF_3(g) + 0.5\ N_2$ $\Delta Hr^\circ_{298} = -239.46 \pm 1.2$ kcal/mol

Ludwig and Cooper (1) report the above value after correction for 0.44 percent impurities in the boron. As much as 5 percent unburned boron was determined by analysis.

B. $1.5\ F_2(g) + B(c, \beta) \rightarrow BF_3(g)$

Wise et al. (2) originally reported $\Delta Hr^\circ_{298} = -270.1 \pm 0.24$ kcal/mol but later reanalysis (3) of the impurities and due allowance for their effect changed this to -271.6 ± 0.9 kcal/mol. Johnson et al. (3) using zone refined boron obtained $\Delta Hr^\circ_{298} = -271.65 \pm 0.22$ kcal/mol after correction for 0.12 percent impurities. Domalski and Armstrong (4) obtained $\Delta Hr^\circ_{298} = -271.03 \pm 0.51$ kcal/mol from a combustion in the presence of Teflon, the boron contained 0.32 percent impurities and corrections were included. The above reaction constituted about 0.35 of the total energy measured. The measurements of Gross et al. (5), although on a zone refined sample, did not include a complete purity analysis and their data were not included since probable impurities could introduce serious errors.

C. $3HF(50\ H_2O) + B(c, \beta) + 0.75\ O_2(g) \rightarrow BF_3(g) + 1.5\ H_2O(\ell)$

From the measurements of Gunn (6) on the reaction of $BF_3(g) + 15.67\ HF(3.747\ H_2O) \rightarrow$ [solution] and Good and Mänsson (7) for the reaction $B(c, \beta) + 0.75\ O_2(g) + 18.57\ HF(3.065\ H_2O) \rightarrow$ [solution] $+ 1.5\ H_2O(\ell)$, where the resulting solutions have the same composition, we obtain $\Delta Hr^\circ_{298} = -142.77 \pm 0.5$ kcal/mol. Further details of the simultaneous solution are given by Syverud (8).

Heat Capacity and Entropy

The fundamental frequencies were selected from the measurements of Lindeman and Wilson (9), McKean (10), Nielsen (11), Anderson et al. (12) and Yost et al. (13). The bond lengths and structure are those reported by Gin et al. (14) which are in agreement with those of Kuchitsu and Konaka (15) from gas phase electron diffraction. These measurements disagree with the earlier determinations of Nielson (11) and Levy and Brockway (16) but are considerably more precise and are adopted.

The individual moments of inertia are $I_A = I_B = 8.083 \times 10^{-39}\ g\ cm^2$ and $I_C = 16.166 \times 10^{-39}\ g\ cm^2$.

POTASSIUM TETRAFLUOROBORATE (KBF_4) (CRYSTAL) GFW = 125.907

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = 32.00 ± 4.0 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -451.0 ± 1 kcal/mol

Tt = 556°K

ΔHt° = 3.36 ± 0.04 kcal/mol

Tm = 843°K

ΔHm° = 4.22 ± 0.04 kcal/mol

$\Delta Hs^\circ_{298.15}$ = [80] kcal/mol

Heat of Formation

Bills and Cotton (1) measured the enthalpies of several reactions at 25°C which led to the following result:

$$H_3BO_3(c) + 4(HF\cdot 23\ H_2O) + KNO_3(c) \rightarrow KBF_4(c) + HNO_3\cdot 92\ H_2O + 3H_2O.$$
$$\Delta Hr = -19.26 \pm 0.6 \text{ kcal/mol}$$

Combining this result with the following heat of formation data,

$\Delta Hf^\circ(H_3BO_3, c) = -261.47 \pm 0.2$ kcal/mol (2)
$\Delta Hf^\circ(HF\cdot 23\ H_2O) = -76.75 \pm 0.1$ kcal/mol (3)
$\Delta Hf^\circ(KNO_3, c) = -118.22$ kcal/mol (4)
$\Delta Hf^\circ(HNO_3\cdot 92\ H_2O) = -49.44$ kcal/mol (5)
$\Delta Hf^\circ(H_2O, \ell) = -68.315$ kcal/mol (5)

we derive, $\Delta Hf^\circ(KBF_4, c) = -451.6 \pm 1.2$ kcal/mol.

Gross, Hayman, and Joël (6) recently measured the following heats of reaction:

$NaF(c) + BF_3(g) \rightarrow NaBF_4(c)$ $\Delta Hr = -32.04 \pm 0.12$ kcal/mol

$\left\{\begin{matrix} KBF_4 \\ + \\ NaF \end{matrix}\right\}_c + HF(aq.) \rightarrow \text{Soln A}$ $\Delta Hs = +8.14 \pm 0.18$ kcal/mol

$\left\{\begin{matrix} NaBF_4 \\ + \\ KF \end{matrix}\right\}_c + HF(aq.) \rightarrow \text{Soln A}$ $\Delta Hs = -2.94 \pm 0.13$ kcal/mol.

These data combine to give, $\Delta Hr = -43.13 \pm 0.22$ kcal/mol, for the reaction

$KF(c) + BF_3(g) \rightarrow KBF_4(c)$.

Combining this result with the following heats of formation,

$\Delta Hf^\circ(KF, c) = -135.9 \pm 0.1$ kcal/mol (7)
$\Delta Hf^\circ(BF_3, g) = -271.42 \pm 0.4$ kcal/mol (7)

we derive, $\Delta Hf^\circ(KBF_4, c) = -450.5 \pm 0.7$ kcal/mol. An average value, $\Delta Hf^\circ(KBF_4, c) = -451.0 \pm 1$ kcal/mol, of these two results is adopted here.

Heat Capacity and Entropy

The heat capacity data are calculated from the high temperature enthalpy data of Dworkin and Bredig (8). S°_{298} is chosen such that a third-law analysis of the equilibrium data for the reaction

$$KBF_4(c, \ell) \rightleftarrows KF(c, \ell) + BF_3(g)$$

reported by de Boer and van Liempt (9) gives the experimentally determined heat of reaction at 25°C (6).

Transition Data

Tt is from the high temperature studies of Dworkin and Bredig (8). ΔHt° is calculated from their high temperature enthalpy data.

Melting Data

Tm has been reported as 803°K by de Boer and van Liempt (9) and 843°K by Dworkin and Bredig (8). Dworkin and Bredig's value is adopted here. ΔHm° is calculated from their high temperature enthalpy data.

Sublimation Data

ΔHs°_{298} is estimated by comparison with data for $LiAlF_4(c)$ reported by Hildenbrand and Theard (10).

Dec. 31, 1969

POTASSIUM TETRAFLUOROBORATE (KBF_4) (LIQUID) GFW = 125.907

ΔHf_0° = Unknown

$S^\circ_{298.15}$ = 35.88 ± 4.0 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -446.8 ± 1.5 kcal/mol

Tm = 843°K

ΔHm° = 4.22 ± 0.04 kcal/mol

Heat of Formation

$\Delta Hf^\circ(\ell)$ is calculated from $\Delta Hf^\circ(c)$ by adding the heat of melting and the difference in $H_{843}-H_{298}$ between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity data are calculated from the high temperature enthalpy data of Dworkin and Bredig (1). S°_{298} is calculated in a manner analogous to the heat of formation.

Melting Data

Tm has been reported as 803°K by de Boer and van Liempt (2) and 843°K by Dworkin and Bredig (1). Dworkin and Bredig's value is adopted here. ΔHm° is calculated from their high temperature enthalpy data.

Bond Distance: B-F = 1.380 Å K-F = 2.752 Å B-K = [2.863] Å

Bond Angle: F-B-F = 109°28' $F_{ax.}$-B-K = [180°]

σ = [3]

Product of Moments of Inertia: $I_AI_BI_C = [4.529 \times 10^{-113}]\ g^3\ cm^6$

Heat of Formation

ΔHf°(g) is calculated from ΔHf°(c) and the estimated heat of sublimation.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with data for BF_4^-, BF_3, KF, and K_2F_2. The infrared and Raman spectra of BF_4^- in various phases have been reported by (1, 2, 3, 4). The molecular structure is assumed to be the same as for $LiAlF_4$ as discussed by Porter and Zeller (5). The B-F and K-F bond lengths and F-B-F bond angle are average values of the crystallographic data recently reported by Clark and Lynton (6). The B-K bond length is calculated from the above structural data according to the assumed molecular model. The individual moments of inertia are $I_A = I_B = 5.292 \times 10^{-38}\ g\ cm^2$ and $I_C = 1.617 \times 10^{-38}\ g\ cm^2$.

BORON MONOHYDRIDE (BH) (IDEAL GAS) MOL. WT. = 11.828

Ground State Configuration $^1\Sigma^+$

$\Delta H^\circ_{f\ 0}$ = 105.0 ± 2.0 kcal. mole^{-1}

$S^\circ_{298.15}$ = [41.047] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 105.8 ± 2.0 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ_i, cm.$^{-1}$	g_i
0	1

ω_e = [2368] cm.$^{-1}$ $\omega_e x_e$ = [49] cm.$^{-1}$ σ = 1

B_e = 12.036 cm.$^{-1}$ α_e = .413 cm.$^{-1}$ r_e = 1.2325 Å

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was calculated from D_0 (BH) = 3.39 ± 0.04 e.v. reported by A. C. Hurley, Proc. Royal Soc. (London), A261, 237 (1961). Hurley stated "by combining an analysis of the spectroscopic data with theoretical calculations we obtain a greatly improved estimate of D_0 (BH)". This value and the other D_0 (BH) values which are tabulated below are based on the same spectroscopic data but differ due to different methods of analysis.

D_0 (BH)	Method	Reference
3.0 ± 0.4 e.v.	Birge-Sponer extrapolations	A. G. Gaydon "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall, Ltd., London, 1953.
3.5 e.v.	Observed predissociation by rotation in BH, A$^1\Pi$ and deduced D_0(BH).	G. M. Almy and R. B. Horsfall Jr., Phys. Rev., 51, 491 (1937).
< 3.51 e.v.	Pre-dissociation limit. This is only an upper limit due to a maximum in the potential Curve of the A$^1\Pi$ state.	G. Herzberg and L. G. Mundie, J. Chem. Phys. 8, 263 (1940) and G. Herzberg "Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950.
3.38 ± 0.04 e.v.	The potential energy curve of the A$^1\Pi$ state was determined and was found to have a maximum and a minimum in agreement with Herzberg and Mundie (loc. cit.)	The selected D_0 (BH) value as reported by Hurley (loc. cit.).

Heat Capacity and Entropy.

The molecular constants from G. Herzberg (loc. cit.) were adjusted for the natural abundance of B^{10} and B^{11}. Because the constants ω_e and $\omega_e x_e$ could not be determined directly from the spectrum, Almy and Horsfall (loc. cit.) obtained estimates for the ground state X $^1\Sigma^+$ from the rotational constants for this state and the relations $D_e = 4 B_e^3/\omega_e^2$ and $\omega_e x_e/\omega_e = 0.6\ \alpha_e/B_e$.

Point Group $C_{\infty v}$

$S^\circ_{298.15}$ = [50.236] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = [-20 ± 20] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-20 ± 20] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[1900](1)
[700](2)
[2300](1)

Bond Distance: H-B = [1.23] Å B=O = [1.20] Å

Bond Angle: H-B-O = [180]°

Rotational Constants: B_0 = [1.3011] cm.$^{-1}$

σ = 1

Heat of Formation.

The heat of formation of the hypothetical species HBO(g) is controversial. Using $\Delta H^\circ_{r\ 298.15}$ = [255] kcal. mole^{-1} for the reaction HBO(g) = H(g) + B(g) + O(g), the value of $\Delta H^\circ_{f\ 298.15}$ for HBO(g) is calculated as [-13] kcal. mole^{-1}. The value of $\Delta H^\circ_{r\ 298.15}$ is the sum of the constituent bond energies, i.e. D(H-B) = 87 and D(B=O) = 168 kcal. mole^{-1}. The D(H-B) value is derived from the dissociation of BH_3(g) and D(B=O) value is calculated as the average value of the B=O bond energies, 175 and 161 kcal. mole^{-1}, in BO(g) and BO_2(g) molecules, respectively.

However, by comparison with the following dissociation reactions:

$(FBO)_3$ (g) → 3 FBO (g) $\Delta H^\circ_{r\ 298.15}$ = 135 kcal. mole^{-1} or 45 kcal. mole^{-1} per mole of FBO(g)

$(HOBO)_3$(g) → 3 HOBO(g) $\Delta H^\circ_{r\ 298.15}$ = 141.8 kcal. mole^{-1} or 47 kcal. mole^{-1} per mole of HOBO(g)

$(ClBO)_3$(g) → 3 ClBO(g) $\Delta H^\circ_{r\ 298.15}$ = 170.6 kcal. mole^{-1} or 57 kcal. mole^{-1} per mole of ClBO(g)

it is estimated $\Delta H^\circ_{r\ 298.15}$ = [70] kcal. mole^{-1} for the reaction 1/3$(HBO)_3$(g) → HBO(g), based on the electronegativity difference among the F, Cl and H atoms. Hence the value of $\Delta H^\circ_{f\ 298.15}$ for HBO(g) is calculated to be -27 kcal. mole^{-1}. The adopted value of $\Delta H^\circ_{f\ 298.15}$ for HBO(g) is 1/2(-13 -27) = -20 kcal. mole^{-1}. The uncertainty is given as ± 20 kcal. mole^{-1}. Other methods of estimation have been tried such as the comparison of the difference in $\Delta H^\circ_{f\ 298.15}$ between H-CH_3 and HO-CH_3 with the corresponding difference between H-BO and HO-BO, etc. They lead to very large negative values for $H^\circ_{f\ 298.15}$(HBO, g). However, a value of 260 ± 15 kcal. mole^{-1} for the atomization of HBO(g) was used by L. V. Gurveech, et al., "Thermodynamic Properties of Individual Substances," Vol. I, Academy of Science, USSR, Moscow, 1962, which was obtained by comparison with the dissociation energies for BO, BH, CN, CH and HCN molecules.

Heat Capacity and Entropy.

The vibrational frequencies and molecular structure were obtained from W. H. Evans, private communication, October 6, 1960. The bond lengths of H-B and B=O in the HBO(g) molecule were assumed to be the same as those in the BH(g) and BO(g) molecules, respectively. The moment of inertia (I) is calculated as 2.1561 X 10^{-39} g. cm.^{2}

Bond Distance: B-H = [1.25] Å   B-O = [1.25] Å

Bond Angle: H-B-O = [180°]   σ = 1

Rotational Constant: B_0 = [1.208] cm^{-1}

Heat of Formation

Using the correlations developed by A. D. Walsh, J. Chem. Soc. 2288 (1953) for HAB molecules the electron removed by ionization ought to be a bonding electron. This indicates a high ionization potential and also the bond dissociation energy of $BO\text{-}H^+$ should be significantly less than BO-H. Assuming a decrease of 40 kcal we obtain $\Delta Hf^\circ_{298}(HBO^+, g)$ = 335 ± 20 kcal/mol which corresponds to an ionization potential of 355 kcal or 15.4 ± 1eV. This is in accord with the ionization potential of BO, 12.8eV, from National Bureau of Standards Report 8628, Jan. 1, 1965, which should be less than HBO since the electron in BO is unpaired.

Heat Capacity and Entropy

According to the correlations of Walsh loc.cit., the molecule should be linear and since the unpaired electron is in a pi orbital, the ground state should be $^2\Pi$. A first excited state is estimated at 20000 cm^{-1} to be $^2\Sigma$ by analogy with the isoelectronic molecule CO^+. Since HBO^+ is lacking a bonding electron compared to HBO, we assume that the bond lengths will be slightly longer than in HBO. The vibrational frequencies are also estimated from those in HBO by assuming all values to be 10 per cent lower due to the weaker bonding.

The enthalpy at 0°K is -2.275 kcal/mol.

METABORIC ACID (HBO_2) (CRYSTAL) MOL. WT. = 43.828

$S^\circ_{298.15}$ = [11.7 ± 1.0] cal. deg.$^{-1}$ mole^{-1}

T_m = 509 ± 1°K

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -191.87 ± 0.20 kcal. mole^{-1}

ΔH°_m = Unknown

$\Delta H^\circ_{s\ 298.15}$ = 57.9 ± 1.0 kcal. mole^{-1}

Heat of Formation.

The enthalpy change (ΔH°_r) of the reaction HBO_2 (c, I) + H_2O(l) = H_3BO_3(c) has been determined by M. V. Kilday and E. J. Prosen, J. Am. Chem. Soc. 82, 5508 (1960). From the value, $\Delta H^\circ_{r\ 298.15}$ = -1.28 kcal. mole^{-1}, the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for HBO_2 (c, I) is derived to be -191.87 ± 0.20 kcal. mole^{-1} which is adopted. The heats of solution of HBO_2 (c, I) in H_2O(l) was measured by N. D. Sokolova, S. M. Skuratov, A. M. Shemonaeva and V. M. Yuldasheva, Russ. J. Inorg. Chem. 6, 395 (1961). Based on the reported value, $\Delta H^\circ_{r\ 298.15}$ = 1.76 ± 0.01 kcal. mole^{-1} for the reaction HBO_2(c, I) + 501 H_2O(l) = $H_3BO_3 \cdot 500\ H_2O$(Sol.), the heat of formation for HBO_2(c, I) was derived as -189.46 ± 0.20 kcal. mole^{-1}, using $\Delta H^\circ_{f\ 298.15}$($H_2O$, l) = -68.317 and $\Delta H^\circ_{f\ 298.15}$($H_3BO_3 \cdot 500\ H_2O$, Sol.) = -256.02 ± 0.20 kcal. mole^{-1}.

Heat Capacity and Entropy.

The values of heat capacity for HBO_2(c, I) were estimated by comparison with those of its constituent oxides. $S^\circ_{298.15}$ was calculated as the sum of the entropy contributions from H^+ and BO_2^- in HBO_2(c) suggested by K. K. Kelley, private communication, June 1960, and O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry", Pergamon Press, New York, 1958.

Melting Data.

F. C. Kracek, G. W. Morey and H. E. Merwin, Am. J. Sci. [5] 35A, 143 (1938) reported the existence of three crystal forms of HBO_2(c), namely HBO_2(c, I), m.p. 509 ± 1°K; HBO_2(c, II), m.p. 474.1 ± 0.5°K; and HBO_2(c, III), m.p. 449.2 ± 0.2°K. However, there was no solid phase equilibrium found among these three crystals. N. D. Sokolova, S. M. Skuratov, A. M. Shemonaeva and V. M. Yuldasheva, loc. cit., measured the heats of solution in water of HBO_2(c, I) and HBO_2(c, II) and derived the heat of transition as $\Delta H^\circ_{t\ 298.15}$(II → I) = 1.29 kcal. mole^{-1}.

Heat of Sublimation.

The value of $\Delta H^\circ_{s\ 298.15}$ was calculated as the difference between the $\Delta H^\circ_{f\ 298.15}$ values for HBO_2(g) and HBO_2(c).

Heat of Formation.

The equilibrium pressures of the reaction $1/2\ B_2O_3(l) + 1/2\ H_2O(g) = HBO_2(g)$ have been measured by several investigators. Using the equilibrium data reported, the heats of reaction ($\Delta H^\circ_{r\ 298.15}$) were evaluated by both the second and third law methods. The corresponding heats of formation for $HBO_2(g)$ were derived based on the $\Delta H^\circ_{r\ 298.15}$ values obtained by the third law method. The results obtained are presented as follows.

Investigator	Temperature, °K.	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	$\Delta H^\circ_{f\ 298.15}$ kcal. mole^{-1}

	1148	——	43.2	-135.3 ± 0.4

*The value not used for the calculation of the weighted average of $\Delta H^\circ_{f\ 298.15}$ for $HBO_2(g)$

[1] D. J. Meschi, W. A. Chupka and J. Berkowitz, J. Chem. Phys. 33, 530 (1960). The $\Delta H^\circ_{r\ 298.15}$ values, 0.25 ± 6.0 and -5.15 kcal. mole^{-1}, were obtained based on the reaction $1/2\ B_2O_3(g) + 1/2\ H_2O(g) = HBO_2(g)$.

[2] D. White, D. E. Mann, P. N. Walsh and A. Sommer, J. Chem. Phys. 32, 488 (1960). The $\Delta H^\circ_{f\ 298.15}$ value was derived using $\Delta H^\circ_{r\ 298.15}$ obtained by the second law method.

[3] S. P. Randall and J. L. Margrave, J. Inorg. Nucl. Chem. 16, 29 (1960). The partial pressure of $HBO_2(g)$, $P_{HBO_2} = 3.813 \times 10^{-4}$ atm., was calculated from the total pressure by the relation $P_{HBO_2} = P_{total} - 3\ P_{H_3BO_3} - 3\ P_{H_3B_3O_6}$ where $P_{H_3BO_3} = 3.030 \times 10^{-5}$ and $P_{H_3B_3O_6} = 2.1466 \times 10^{-5}$ atm.

[4] M. Farber, et al., "Thermodynamics of Reactions Involving Light Metal Oxides and Propellant Gases", QR-1987-5, May 9 - Aug 9, 1961; QR-1987-7, Nov. 9 - Feb. 9, 1962 and Final Report, May 9, 1960 through June 30, 1962, Rocket Power, Inc., California. The first and last sets of data were determined by the Molecular Flow Method and the rest, by Effusion Method.

The value of $\Delta H^\circ_{f\ 298.15}$ for $HBO_2(g)$ adopted is the weighted average of the $\Delta H^\circ_{f\ 298.15}$ value listed above.

Heat Capacity and Entropy.

All molecular and spectroscopic constants were taken from D. White, D. E. Mann, P. N. Walsh and A. Sommer, loc. cit. The three principal moments of inertia are: $I_A = 1.155 \times 10^{-40}$, $I_B = 9.1050 \times 10^{-39}$ and $I_C = 9.2205 \times 10^{-39}$ g. cm.^{2}

BORON DIHYDRIDE (BH_2) (IDEAL GAS) MOL. WT. = 12.836

Point Group [$D_{\infty h}$]

$S_{298.15}$ = [43.045] cal. deg.⁻¹ mole⁻¹

Ground State Quantum Weight = [2]

$\Delta H_f^\circ{}_0$ = 48 ± 15 kcal. mole⁻¹

$\Delta H_f^\circ{}_{298.15}$ = 48 ± 15 kcal. mole⁻¹

Vibrational Frequencies and Degeneracies

ω, cm.⁻¹	ω, cm.⁻¹	ω, cm.⁻¹
[2430](1)	[840](2)	[2650](1)

Bond Distance: B-H = [1.20 Å]

Bond Angle: H-B-H = [180°]

Rotational Constant: B_0 = 5.80683 cm.⁻¹

σ = 2

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ was calculated from appearance potentials reported by T. P. Fehlner and W. S. Koski, J. Am. Chem. Soc. 86, 2733 (1964) and the JANAF ($B_2H_6(g)$) $\Delta H_f{}_{298.15}$ = +9.8 kcal. mole⁻¹. For example

	$\Delta H_r^\circ{}_0$
$B_2H_6(g) \rightarrow BH_2^+(ion) + BH_2(g) + H_2(g)$	13.4 e.v.
$BH_2(g) \rightarrow BH_2^+(ion)$	9.8 e.v.
$B_2H_6(g) \rightarrow 2BH_2(g) + H_2(g)$	3.6 e.v.

The ΔH_f data is summarized below.

Investigator	Method	$\Delta H_f^\circ{}_{298.15}$ kcal. mole⁻¹
T. P. Fehlner and W. S. Koski (loc. cit.)	Appearance Potentials	48
C. J. O'Brien and J. R. Perrin, Marquardt Corp., Van Nuys, Calif. and J. Perine, Olin Mathieson Chemical Corp., New York 22, N.Y., "Estimation of the Heats of Formation of Gaseous Combustion Product Molecules", October 1959.	Estimate	66
P. C. H. Jordan and H. C. Longuet-Higgins, Mol. Phys. 5, 121 (1962).	Estimate	93

Heat Capacity and Entropy.

The bond distance B-H = 1.20 Å was estimated from a consideration of BH(g), $BH_3(g)$ and other molecules. The bond angle H-B-H = 180° and the electronic configuration of the ground state [$^2A_2$] were estimated by P. C. H. Jordan and H. C. Longuet-Higgins (loc. cit.). The frequencies were estimated assuming valance forces [G. Herzberg, "Molecular Spectra and Molecular Structure II Infrared and Raman Spectra of Polyatomic Molecules" D. Van Nostrand Co. Inc., N. Y. (1945) page 172] and using force constants, $k_1 = 3.5 \times 10^5$ dynes cm.⁻¹ and $k_\delta l^{-1} = 0.35 \times 10^5$ dynes cm.⁻¹, estimated from BH_3, (see A. Shepp and S. H. Bauer, J. Am. Chem. Soc. 76, 265 (1954)).

Bond Distance: B-O = [1.27] Å O-H = [0.97] Å

Bond Angle: H-O-B = [105]° O-B-O = [180]°

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.42627 X 10^{-116}] g.^{3} cm.^{6}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for $B(OH)_2(g)$ was calculated by using the bond energy, D°(B-OH) = 132.7 kcal. mole^{-1}, and the heats of formation for B(g) and OH(g) as 132.80 and 9.33 kcal. mole^{-1}, respectively.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for $BO_2(g)$, $B(OH)_3(g)$ and other related molecules. The bond distances and angles were estimated by comparison with those for $BO_2(g)$ and $H_2O_2(g)$ molecules. The molecular configuration is assumed to be trans which is considered as more stable than the cis-form. The three principal moments of inertia are: I_A = 2.6870 X 10^{-40}, I_B = 9.3682 X 10^{-39} and I_C = 9.6369 X 10^{-39} g. cm.^{2}

Bond Distance: B-H = [1.16 Å]

Bond Angle: H-B-H = [120°]

σ = 6

Product of the Moments of Inertia: $I_AI_BI_C$ =[7.71 X 10^{-119}]g.^{3} cm.^{6}

Heat of Formation:

$\Delta H^\circ_{f\ 298.15}$ was calculated from appearance potentials reported by T. P. Fehlner and W. S. Koski J. Am. Chem. Soc. 86, 2733 (1964). For example

$B_2H_6(g) \rightarrow BH_3^+(ion) + BH_3(g)$	13.1 e.v.
BH_3 +(ion) $\rightarrow BH_3(g)$	-11.4 e.v.
$B_2H_6(g) \rightarrow 2BH_3(g)$	1.7 e.v.

The heat of formation data is summarized below.

Reaction: $B_2H_6(g) \rightarrow 2BH_3(g)$*

*The auxiliary $\Delta H^\circ_{f\ 298.15}(B_2H_6)$ was from the JANAF Table dated Dec. 31, 1964

Investigators	Method	$\Delta H^\circ_{r\ 0}$	$\Delta H^\circ_{f\ 298.15}$*

Heat Capacity and Entropy.

The molecular comfiguration, [planar, H-B-H angle = 120°], was estimated by A. Shepp and S. H. Bauer, J. Am. Chem. Soc. 76, 265 (1954) as well as by P. C. H. Jordan and H. C. Longuet-Higgins, (loc. cit.). In addition Shepp and Bauer estimated the bond distance and the vibrational frequencies. Jordan and Longuet-Higgins estimated the electronic configuration [$^1A_1'$]. The principal moments of inertia calculated from these molecular constants are, $I_A = I_B$ = 3.378 X 10^{-40} and I_C = 6.756 X 10^{-40} g. cm.^{2}

Sept. 30, 1962; Dec. 31, 1964

BORIC ACID (H_3BO_3) (CRYSTAL) MOL. WT. = 61.844

$\Delta H^\circ_{f\ 0} = -258.23 \pm 0.20$ kcal mole^{-1}

$S^\circ_{298.15} = 21.21 \pm 0.1$ cal deg^{-1} mole^{-1}

$\Delta H^\circ_{f\ 298.15} = -261.47 \pm 0.20$ kcal mole^{-1}

$T_m = 444.1 \pm 0.2$°K

ΔH°_m = Unknown

$T_d = [330]$°K

$\Delta H^\circ_{s\ 298.15} = 24.3 \pm 0.7$ kcal mole^{-1}

Heat of Formation

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) of $H_3BO_3(c)$ was taken from W. D. Good, M. Mansson and J. P. McCullough, Quarterly Technical Report No. 9, Nov. 4, 1963, U. S. Bur. Mines, Bartlesville, Oklahoma. The value was derived based on the following measurements

	$\Delta H^\circ_{r\ 298.15}$, kcal mole^{-1}
$B(c) + 0.75\ O_2(g) + 18.674\ HF\cdot 57.219\ H_2O(\ell) = HBF_4\cdot 14.674\ HF\cdot 58.719\ H_2O(\ell)$	-173.4 ± 0.2
$H_3BO_3(c) + 18.674\ HF\cdot 55.719\ H_2O(\ell) = HBF_4\cdot 14.675\ HF\cdot 58.719\ H_2O(\ell)$	$+14.6 \pm 0.1$

The heats of solution of $H_3BO_3(c)$ in water have been measured by many investigators. L. G. Fasolino, "Heat of Formation of $B_2O_3(c)$ and B_2O_3(am.)," NONR-3608 (00), June 2, 1964, National Research Corporation, Massachusetts, obtained the value, $\Delta H^\circ_{r\ 298.15} = 5.45 \pm 0.01$ kcal mole^{-1} for the reaction $H_3BO_3(c) + 504\ H_2O(\ell) = H_3BO_3\cdot 504\ H_2O$(sol.) which leads to $\Delta H^\circ_{f\ 298.15}$ ($H_3BO_3\cdot 504\ H_2O$, sol.) = -256.02 kcal mole^{-1}. The $\Delta H^\circ_{r\ 298.15}$ value is in reasonable agreement with the value reported by J. Smisko and L. S. Mason, J. Am. Chem. Soc. 72, 3679 (1950) in which the heats of solution and dilution of $H_3BO_3(c)$ were given. The heats of solution of $H_3BO_3(c)$ in water measured by other previous investigators were reviewed by L. G. Fasolino, loc. cit.

Heat Capacity and Entropy

The low temperature (16-296°K) heat capacities were reported by H. L. Johnston and E. C. Kerr, J. Am. Chem. Soc. 72, 4733 (1950). The heat capacities above 300°K were estimated by comparison with those of its constituent oxides. $S^\circ_{298.15}$ was obtained from H. L. Johnston and E. C. Kerr. loc. cit., using $S^\circ_{17} = 0.18$ cal deg^{-1} mole^{-1}.

Melting Data

The value of T_m was taken from F. C. Kracek, G. W. Morey and H. E. Merwin, Am. J. Sci. [5] 35A, 143 (1938). However, $H_3BO_3(c)$ is in a metastable state at T_m. Measurements of the decomposition pressure of $H_3BO_3(c)$ to form HBO_2(c, II or III) and $H_2O(g)$ have been made by H. Menzel, H. Schulz and H. Deckert, Z. anorg. allgem. Chem 220, 49 (1934); A. Thiel and H. Siebeneck, Z. anorg. allgem. Chem. 220, 236 (1934); M. V. Stackelberg. F. Quatram and J. Dressel, Z. Elektrochem. 43, 14 (1937); S. Bezzi, Gass. chim. ital. 65, 766 (1935); and H. Tazaki, J. Sci. Hiroshima Univ. Ser. A 10, 37, 55, 63, 109, 113 (1939). The decomposition pressures of the system $H_3BO_3(c) = H_2O(g) + HBO_2$(c, I), at the temperatures of 312 to 352°K, have been reported by E. D. West, "The properties of Boron Compounds", ARL Technical Report 60-276, May 1960, National Bureau of Standards.

Temperature of Decomposition

The decomposition temperature (T_d) is calculated as the temperature at which the free energy change of the reaction $H_3BO_3(c) \rightarrow HBO_2(c) + H_2O(g)$ approaches zero.

Heat of Sublimation

The heat of sublimation ($\Delta H^\circ_{s\ 298.15}$) is derived as the difference between the $\Delta H^\circ_{f\ 298.15}$ values for $H_3BO_3(g)$ and $H_3BO_3(c)$.

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.15684 X 10^{-114}] g.^{3} cm.^{6}

Heat of Formation.

The vapor pressures of H_3BO_3(c), 109 - 140°C, were measured by M. V. Stackelberg, F. Quatram and J. Dressel, Z. Elecktrochem. 43, 14 (1937). Using the vapor pressures reported, the heats of sublimation of H_3BO_3(c) were evaluated to be 24.4 ± 0.6 and 24.22 kcal. mole^{-1} by the second and third law methods, respectively. The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for H_3BO_3(g) was calculated from the $\Delta H^\circ_{f\ 298.15}$ and $\Delta H^\circ_{s\ 298.15}$ for H_3BO_3(c). The $\Delta H^\circ_{s\ 298.15}$ value adopted is the average of the second and third law values mentioned previously.

Heat Capacity and Entropy.

The molecular structure and constants were taken from C. W. F. T. Pistorius, J. Chem. Phys. 31, 1454 (1959) based on an X-ray diffraction study on H_3BO_3(c) by W. H. Zachariasen, Acta Cryst. 7, 305 (1954). The O-H bond distance was reestimated as 0.96 Å instead of 0.88 Å reported. From the existing infrared and Raman spectra data on H_3BO_3(c) and its aqueous solution C. W. F. T. Pistorius, loc. cit., carried out a normal coordinate treatment by means of Wilson's F-G matrix method and calculated the fifteeen fundamental frequencies for H_3BO_3(c). For H_3BO_3(g) twelve reported frequencies were used and corrected to the average isotopic species. The three torsional frequencies, 824(1) and 209(2) cm.$^{-1}$, were not used based on an assumption that there are three internal rotations, i.e. three OH groups, each rotates about its own B-O bond. Employing the model of having three free rotating OH tops, the value of S°_{400} was evaluated statistically as 75.522 cal. deg.$^{-1}$ mole^{-1}. The corresponding value obtained by using the second law value of ΔS°_{400}, 48.39 ± 1.42 cal. deg.$^{-1}$ mole^{-1}, for the reaction H_3BO_3(c) = H_3BO_3(g), is 75.97 ± 1.42 cal. deg.$^{-1}$ mole^{-1} which is in good agreement with the S°_{400} value based on a model having three free rotating groups. Thus the assumed model is adopted to evaluate the thermodynamic functions. The three principal moments of inertia are: $I_A = I_C$ = 8.3320 X 10^{-39} g. cm.^{2} and I_B = 1.6664 X 10^{-38} g. cm.^{2} The reduced moment of inertia for OH top is I_r = 1.15321 X 10^{-40} g. cm.^{2} The infrared absorption spectrum of H_3BO_3(g) was observed under conditions where one atmosphere of water vapor with a path length of approximately one meter as background, by F. T. Greene, G. E. Leroi, S. P. Randall, J. R. Soulen, L. H. Spinar and J. L. Margrave, "Spectra and Thermodynamic Properties of Light-Element Oxides and Hydroxides", Proceedings of the Conference on Propellant Thermodynamics and Handling, Columbus, Ohio, July, 1959. The following fundamentals were obtained: 3220 cm.$^{-1}$ S., 1490 cm.$^{-1}$ S., 1199 cm.$^{-1}$ S., 881 cm.$^{-1}$ W., and 669 cm.$^{-1}$ W.

POTASSIUM TETRAHYDROBORATE (KBH_4) (CRYSTAL) MOL. WT. = 53.952

$\Delta H^\circ_{f\ 0} = -52.15 \pm .55$ kcal. mole^{-1}

$S^\circ_{298.15} = 25.48$ cal. deg.$^{-1}$ mole $\Delta H^\circ_{f\ 298.15} = -54.23 \pm .55$ kcal. mole^{-1}

$T_d = [770]^\circ K$

Heat of Formation.

The heat of reaction of $KBH_4(c)$ with hydrochloric acid has been measured by solution calorimetry and reported by W. H. Johnson, R. H. Schumm, I. H. Wilson, and E. J. Prosen, J. Res. Nat'l. Bur. Std. 65A, 97 (1961)

$$KBH_4(c) + HCl(g) + 3H_2O(liq) \rightarrow KCl(c) + H_3BO_3(c) + 4H_2(g) \qquad \Delta Hr = -84.62 \pm .44 \text{ kcal. mole}$$

The $\Delta H_{f\ 298.15}$ values for HCl(g) and $H_3BO_3(c)$ were obtained from the JANAF Tables. The $\Delta H_{f\ 298.15}$ value for KCl(c) was calculated from $\Delta H_{f\ 298.15}\ K^+ = -60.32$ kcal. mole^{-1}, $\Delta H_{f\ 298.15}\ Cl^- = -39.952$ kcal. mole^{-1} and ΔH dilution = 4.12 kcal. mole^{-1} obtained from NBS. Rept. 8504, 1 July 1964 - Appendix III by W. H. Evans. $\Delta H_{f\ 298.15}$ for $H_2O(liq)$ was obtained from W. H. Evans, loc. cit. Unpublished data of The Dow Chemical Company Thermal Laboratory give a value of $\Delta H_{f\ 298.15} = -55.0 \pm 1.0$ kcal. mole^{-1} by solution calorimetry.

Heat Capacity and Entropy.

C_p and S° at temperatures below 298.15°K were reported by G. T. Furukawa, M. L. Reilly, and J. H. Piccirelli, J. Res. Nat'l. Bur Std. 68A, 651 (1964). The values of C_p in the range from 298.15 to 700°K were obtained from T. B. Douglas and A. W. Harman, J. Res. Nat'l. Bur. Std. 60, 117 (1958). These two sets of C_p data were plotted and joined smoothly at 298.15°K. The values of C_p above 700°K were estimated by graphical extrapolation.

Temperature of Decomposition.

The temperature of decomposition (into constituent elements) was estimated according to a report by T. B. Douglas and A. W. Harman, loc. cit.

$S^\circ_{298.15}$ = 18.120 cal. deg.$^{-1}$ mole^{-1}

T_m = [750°K.]

$\Delta H_f^\circ{}_0$ = -43.105 ± 0.05 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -45.522 ± 0.05 kcal. mole^{-1}

ΔH_m° = Unknown

Heat of Formation.

The heat of formation of $LiBH_4(c)$ was calculated from the solution calorimetry of W. D. Davis, L. S. Mason, and G. Stegeman J. Am. Chem. Soc. 71, 2775 (1949). The heats of reaction were measured for the following reactions:

$LiBH_4(c) + 1.25(HCl\cdot 200\ H_2O) + 3\ H_2O(l) \rightarrow (NaCl + H_3BO_3 + 0.25\ HCl)\cdot 247\ H_2O + 4\ H_2(g)$ $\quad \Delta H_{1\,298.15}$ = -72.14 kcal.

$LiCl\cdot 60\ H_2O + H_3BO_3\cdot 60\ H_2O + 0.25(HCl\cdot 508\ H_2O) \rightarrow (LiCl + H_3BO_3 + 0.25\ HCl)\cdot 247\ H_2O$ $\quad \Delta H_{2\,298.15}$ = 0.00 kcal. (assumed)

$H_3BO_3\cdot 60\ H_2O + \infty\ H_2O \rightarrow H_3BO_3\cdot\infty H_2O$ $\quad {}^*\Delta H_{3\,298.15}$ = 0.200 kcal.

The summation of the above reactions yields:

$LiBH_4(c) + 1.25(HCl\cdot 200\ H_2O) + 3\ H_2O(l) + \infty\ H_2O \rightarrow LiCl\cdot 60\ H_2O + H_3BO_3\cdot\infty H_2O$
$+ 0.25(HCl\cdot 508\ H_2O) + 4\ H_2(g)$ $\quad \Delta H_{298}$ = -71.94

The heat of formation of Lithium Borohydride crystal was calculated to be -45.522 kcal. mole^{-1} with the following auxiliary data:

Compound	Heat of Formation at 298.15	Reference
HCl (508 H_2O)	-39.815	HCl(g) JANAF; Dilution data from NBS. Rept. 8504, 1 July 1964 Appendix III by W. H. Evans
HCl (200 H_2O)	-39.696	HCl(g) JANAF; Dilution data from W. H. Evans, loc. cit.
LiCl (60 H_2O)	-106.023	Li^+ see $NaBH_4$ table; Cl^- and dilution data W. H. Evans, loc. cit.
H_3BO_3 (∞H_2O)	-256.05	JANAF $H_3BO_3(c)$ and dilution data from J. Smisko and L. S. Mason. J. of Am. Chem. Soc. 72, 3679 (1950)

*This $\Delta H_{r\ 298.15}$ value was obtained from J. Smisko and L. S. Mason loc. cit.

Heat Capacity and Entropy.

The low temperature heat capacities, 15.72 - 302.88 °K were obtained from the measurements by N.C. Hallett and H. L. Johnston, J. Am. Chem. Soc., 75, 1496 (1953). The C_p values above 298.15°K were estimated by comparison with the C_p's for $NaBH_4$.

The entropy was based on S°_{15} (extrap) = 0.0874 reported by N. C. Hallett and H. L. Johnston loc. cit.

Melting Data.

T_m was estimated by comparison with the T_m for $NaBH_4$.

$\Delta H^\circ_{f\ 0}$ = -43.86 ± .07 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -45.85 ± .07 kcal. mole^{-1}

$\Delta H^\circ_{t_1}$ = 0.2388 kcal. mole^{-1}

ΔH°_m = Unknown

Heat of Formation.

The heat of formation was calculated from the solution calorimetry of W. D. Davis, L. S. Mason and G. Stegeman, J. Am. Chem. Soc. 71, 2775 (1949). The heats of reaction and mixing were measured for the following reactions:

$NaBH_4 + 1.25(HCl\cdot 200H_2O) \rightarrow (NaCl + H_3BO_3 + 0.25HCl)\cdot 247H_2O + 4H_2$ ΔHr = -63.880 kcal. mole^{-1}

$NaCl\cdot 60H_2O + H_3BO_3\cdot 60H_2O \rightarrow (NaCl + H_3BO_3)\ 120H_2O$ ΔHr = -0.026 kcal. mole^{-1}

$NaCl + (H_3BO_3)\cdot 120H_2O + 0.25(HCl\cdot 508H_2O) \rightarrow (NaCl + H_3BO_3 + 0.25HCl)\cdot 247H_2O$ ΔHr = +0.083 kcal. mole^{-1}

$H_3BO_3\cdot 60H_2O + \infty H_2O \rightarrow H_3BO_3\cdot \infty H_2O$ ΔHr = +0.068 kcal. mole^{-1}

The summation of the above equations yields:

$NaBH_4(c) + 1.25(HCl\cdot 200H_2O) + 3H_2O(l) + \infty H_2O \rightarrow NaCl\cdot 60H_2O + H_3BO_3\cdot \infty H_2O + 0.25(HCl\cdot 508H_2O) + 4H_2(g)$

ΔHr = -63.869 kcal. mole^{-1}

The $\Delta H_{f\ 298.15}$ values for HCl were obtained from JANAF value for HCl(g) and heat of dilution data of NBS. Rept. 8504, 1 July 1964 - Appendix III by W. H. Evans. The $\Delta H_{f\ 298.15}$ $H_2O(l)$ value was obtained from W. H. Evans loc. cit. The $\Delta H_{f\ 298.15}$ value for NaCl was obtained from JANAF value of NaCl(c) together with dilution data from W. H. Evans, loc. cit. The $\Delta H_{f\ 298.15}$ value for H_3BO_3 was obtained from JANAF value for $H_3BO_3(c)$ together with dilution data of J. Smisko and L. S. Mason, J. of Am. Chem. Soc. 72, 3679 (1950).

Heat Capacity and Entropy.

The low temperature heat capacity (15.76 - 301.26) was obtained from H. L. Johnston and N. C. Hallett, J. Am. Chem. Soc. 75, 1467 (1953). In the area of transition (169-193.5°K) the average ΔH = 635.3 cal./mole and the average ΔS = 3.35 cal./mole °K were adopted from H. L. Johnston and N. C. Hallett, loc. cit. Using the present base line these ΔH and ΔS values yield a heat of transition of 0.2388 kcal. mole^{-1}. The low temperature heat capacity was fitted with the smoothed heat capacity data (298.15 - 700°K) of T. B. Douglas and A. W. Harman, J. Research Natl. Bur. Standards 60, 117 (1958). The heat capacity above 700°K was extrapolated from the plot of both sets of data.

Transition Data.

The temperature and heat of transition were obtained from H. L. Johnston and N. C. Hallett loc. cit.

Melting Data.

The melting data was obtained from T. B. Douglas and A. W. Harman loc. cit.

June 30, 1963; Dec. 31, 1963; Dec. 31, 1964

BORON MONOIODIDE (BI) (IDEAL GAS) MOL. WT. = 137.73

Ground State Configuration [$^1\Sigma^+$]

$\Delta H^\circ_{f\ 0}$ = [72.7 ± 10] kcal. mole^{-1}

$S^\circ_{298.15}$ = [55.604] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [73.0 ± 10] kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ_i, cm.$^{-1}$	g_i
0	[1]

ω_e = [600] cm.$^{-1}$

$\omega_e x_e$ = [3.04] cm.$^{-1}$

σ = 1

B_e = [0.3912] cm.$^{-1}$

α_e = [0.0027] cm.$^{-1}$

r_e = [2.08] Å

Heat of Formation.

The ratio D(BF) / ($\Delta H_a(BF_3)/3$) = 1.177, where ΔH_a signifies the heat of atomization, was applied to BI_3 giving D(BI) = 84.4 kcal. mole^{-1} and $\Delta H^\circ_{f\ 298}$ = 73 ± 10 kcal. mole^{-1}.

Heat Capacity and Entropy.

The bond length was first estimated by comparison with the ratio of the bond lengths in the other boron trihalides and monohalides. The vibrational frquency was then calculated using Guggenheimer's Relation [Proc. Phys. Soc. (London) 58, 456 (1946)] which was checked using BBr and shown to give an excellent fit. The quantity $x_e\mu^{1/2}$, where μ is the reduced mass, has been shown to be constant for similar molecules and its value was transferred from BBr to give x_e and $\omega_e x_e$ for BI. α_e was then calculated using the Morse potential function and B_e was determined from the bond length. The ground state configuration was assumed to be the same as that in BBr.

$\Delta H_{f\ 0}^\circ$ = [58.5 ± 15] kcal. mole^{-1}

$S^\circ_{298.15}$ = [73.964] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = [58.0 ± 15] kcal. mole^{-1}

Ground State Quantum Weight [2]

Vibrational Levels and Degeneracies

ω, cm.$^{-1}$
[550](1)
[110](1)
[770](1)

Bond Distance: B-I = [2.06] Å

Bond Angle: I-B-I = [120°]

$\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 3.33503 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was estimated by analogy with BF_3, specifically the ratio

$$\Delta H_r(BX_3 \rightarrow BX_2 + X) \ / \ \Delta H_r(BX_3 \rightarrow B + 3X)$$

was taken as 0.347.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from force constants transferred from the trihalide given by G. Herzberg "Infrared and Raman Spectra of Polyatomic Molecules", D. Van Nostrand, Inc., (1945). The bond length was taken between those of the mono and trihalide and the angle was estimated to be the same as that in the trihalides. The ground state quantum weight was taken as two on account of the one unpaired electron.

The individual moments of inertia were $I_B = 1.8278 \times 10^{-39}$ g. cm.^{2}, $I_A = 134.1670 \times 10^{-39}$ g. cm.^{2} and $I_C = 135.9948 \times 10^{-39}$ g. cm.^{2}

Boron Triiodide (BI_3)

Bond Distance: B-I = [2.03 ± 0.03] Å

Bond Angle: I-B-I = [120°]

$\sigma = 6$

Product of the Moments of Inertia = [4.418202] X 10^{-111} g.^{3} cm.^{6}

Heat of Formation.

W. S. Koski, J. J. Kaufman and C. F. Pachuki, J. Am. Chem. Soc. 81, 1326 (1959) measured the appearance potential of the B^+ ion from BI_3. Assuming the reaction

$$BI_3 + e \rightarrow B^+ + 3I + 2e$$

one can calculate the heat of atomization of BI_3 as 8.31 ± 0.5 e.v. The analagous reaction for BBr_3 can be checked independently and shows the process to be valid. This value leads to a $\Delta H^\circ_{f\ 298}$ = 17.0 ± 12 kcal. mole^{-1}, if the process is assumed to occur at 298°K.

Heat Capacity and Entropy.

Vibrational frequencies were taken from T. Wentink and V. H. Tiensuu, J. Chem. Phys. 28, 826 (1958) modified according to the natural abundance of boron. The B-I distance was estimated by Koski et al., loc. cit., and the angle was estimated by analogy with the other boron trihalides. The three principal moments of inertia are: $I_A = I_B$ = 1.30238 X 10^{-37} and I_C = 2.60476 X 10^{-37} g. cm.^{2}

June 30, 1961; Dec. 31, 1964

LITHIUM METABORATE ($LiBO_2$) (CRYSTAL) MOL. WT. = 49.76

$S^\circ_{298.15}$ = 12.351 cal. deg.$^{-1}$ mole^{-1}

T_m = 1117 ± 1°K.

$\Delta H^\circ_{f\ 0}$ = -241.96 ± .20 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -243.29 ± .20 kcal. mole^{-1}

ΔH_m = 8.093 ± .10 kcal. mole^{-1}

Heat of Formation.

G. C. Sinke, Thermal Research Laboratory, The Dow Chemical Co., private communication, July 1960 has measured $\Delta H_{r\ 298.15}$ for the following reaction:

$$LiBO_2(c) + HNO_3 \cdot 111H_2O(Sol.) + H_2O(l) \rightarrow LiNO_3 \cdot 112H_2O(Sol.) + H_3BO_3 \cdot 112H_2O(Sol.)$$

$\Delta H_{r\ 298.15}$ = -10.93 ± 0.05 kcal. mole^{-1}

From this heat of reaction the $\Delta H_{f\ 298.15}$ for $LiBO_2(c)$ is calculated to be -243.29 kcal. mole^{-1} with the following auxiliary heats of formation:

	$\Delta H_{f\ 298.15}$(Kcal. mole^{-1})	Source
$H_3BO_3 \cdot 112\ H_2O$	-256.23	Dilution data from J. Smisko and L. S. Mason, J. of Am. Chem. Soc. 72, 3679 (1950)
$HNO_3 \cdot 111\ H_2O$	-49.44	NBS. Rept. 8504, 1 July 1964 - Appendix III by W. H. Evans
$H_2O(l)$	-68.315	W. H. Evans, loc. cit.
$LiNO_3 \cdot 112\ H_2O$	-115.747	*S. R. Gunn and L. G. Green, J. Am. Chem. Soc. 80, 4782 (1958); correction S. R. Gunn Lawrence Radiation Lab. UCRL-7992, 5, July, (1964).

**Dilution and other auxiliary data from W. H. Evans, loc. cit.

L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27 (1954), measured the heats of solution in nitric acid of various Li_2O-B_2O_3 glasses and crystalline mixtures containing 0 to 48 mole % Li_2O. These results were extrapolated to 50 mole % and yielded $\Delta H_{r\ 298.15}$ = -45.20 kcal. for the following reaction:

$$Li_2O(c) + B_2O_3(c) \rightarrow 2\ LiBO_2(c)$$

With JANAF values for $Li_2O(c)$ and $B_2O_3(c)$ the $\Delta H_{f\ 298.15}$ for $LiBO_2(c)$ was calculated to be -245.97 ± .80 kcal. mole^{-1}. This value is in fair agreement with the value adopted for the table.

*$Li(c) + H_2O(l) \rightarrow LiOH \cdot 1000\ H_2O(Sol.) + 1/2\ H_2$	$\Delta H_{r\ 298.15}$ = -53.115 ± 0.019 kcal. mole^{-1}
**$LiOH \cdot 1000\ H_2O(Sol.) \rightarrow LiOH\ \infty\ H_2O$	$\Delta H_{dilution\ 298.15}$ = +.102 kcal. mole^{-1}
$LiOH(\infty H_2O) \rightarrow Li^+(\infty H_2O) + OH^-(\infty H_2O)$	$\Delta H_{r\ 298.15}$ = 0.00
$LiNO_3(\infty H_2O) \rightarrow Li^+(\infty H_2O) + NO_3^-(\infty H_2O)$	$\Delta H_{r\ 298.15}$ = 0.00
$LiNO_3(\infty H_2O) \rightarrow LiNO_3 \cdot 112\ H_2O$	ΔH_{r} dilution = .171 kcal. mole^{-1}

Heat Capacity and Entropy.

F. L. Oetting and W. E. Hatton, The Dow Chemical Company, private communication, April, 1961, have measured C_p from 13° to 326°K. R. A. McDonald, Thermal Research Laboratory The Dow Chemical Company, private communication, April, 1961 has measured H_T-$H_{298.15}$ from 288° to 1116°K. The above data were adopted for the table. The C_p values above T_m were obtained by graphical extrapolation.

The entropy was based on S° = .013 cal. mole^{-1} deg.$^{-1}$ at 15°K. calculated from the low temperature C_p values of F. L. Oetting and W. E. Hatton loc. cit.

Melting Data.

The T_m and ΔH_m adopted for this table were obtained from R. A. McDonald loc. cit. The following cryoscopic data have been published: C. Petit and M. Jaeger, Compt. rend. 244, 1734 (1957), T_m = 1109°K., ΔH_m = 7.4 kcal. mole^{-1}; G. Zarzychi, colloques intern, centre, nat'l. recherche sci. (Paris) 39, Electrolyse C34-C37 (1952), ΔH_m = 8.3 ± 0.6 kcal. mole^{-1}. C. Sutra, Compt. rend. 234, 1283 (1952), T_m =1113°K. and ΔH_m = 8.3 kcal. mole^{-1}.

June 30, 1961; Dec. 31, 1964

LITHIUM METABORATE $(LiBO_2)$ (LIQUID) MOL. WT. = 49.76

$S^\circ_{298.15}$ = [15.591] cal. deg.$^{-1}$ mole^{-1}

T_m = 1117 ± 1°K.

T_b = [2264]°K.

ΔH°_f 298.15 = [-238.819] kcal. mole^{-1}

ΔH°_m = 8.09 ± .10 kcal. mole^{-1}

ΔH°_v = [50.79] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_f(l)$ was obtained from $\Delta H^\circ_f(c)$ by addition of ΔH°_m and difference between $(H^\circ_{1117} - H^\circ_{298.15})$ for the crystal and liquid.

Heat Capacity and Entropy.

R. A. McDonald, Thermal Research Laboratory, The Dow Chemical Company, private communication, April 1961, has measured $H_T - H_{298.15}$ from 1118° to 1707°K. The constant value of C_p measured between 1118° and 1707°K. has been extrapolated above and below this range. Lithium metaborate is assumed to have a glass transformation temperature at 745°K. below which C_p of the glass is assumed equal to that of the cyrstal.

The entropy of the liquid was calculated from the entropy of the crystal in a manner analogous to the heat of formation.

Melting Data.

The ΔH_m and T_m values were obtained from R. A. McDonald loc. cit.

Vaporization Data.

The boiling point was found from graphing the ΔF_f's of the liquid and gas. The heat of vaporization was found from the difference in ΔH_f's of the liquid and gas at T_b.

Bond Distances: Li-O = 1.82 Å, O-B = 1.36 Å, B=O = 1.20 Å

Bond Angles: LiOB = 100°, O-B=O = 180°

Product of the Moments of Inertia: $I_AI_BI_C$ = 4.01933 X 10^{-115} g.^{3} cm.^{6}

Heat of Formation.

The adopted heat of formation at 298.15 was evaluated by the third-law method using vapor pressure data reported by D. L. Hildenbrand, W. F. Hall and N. D. Potter, J. Chem. Phys. 39, No. 2, 296 (1963). The heat of reaction at 298.15 was found to be 82.908 kcal. mole^{-1} thus giving the value $\Delta H_{f\ 298.15}$ = -160.382 kcal. mole^{-1}. A second-law method was also used on the data of D. L. Hildenbrand et. al., loc. cit. and yielded a $\Delta H_{r\ 298.15}$ = 81.375 kcal. mole^{-1} thus giving $\Delta H_{f\ 298.15}$ = -161.915 kcal. mole^{-1}. A. Büchler and J. B. Berkowitz-Mattuck, J. Chem. Phys. 39, No. 2, 286 (1963), have measured the vaporization of lithium metaborate mass spectrometrically in an effusion cell. The second law value reported by A. Büchler and J. B. Berkowitz-Mattuck, loc. cit. for $\Delta H_{r\ 1060}$ was 79 ± 3 kcal. mole^{-1} which yields $\Delta H_{r\ 298.15}$ = 84.078 kcal. mole^{-1} thus giving $\Delta H_{f\ 298.15}$ = -159.212 kcal. mole^{-1} with JANAF auxiliary values.

Heat Capacity and Entropy.

A. Büchler and E. P. Marram, J. Chem Phys. 39, No. 2, 292, (1963), observed and assigned two vibrational frequencies to lithium metaborate which were adopted for this table. The other vibrational frequencies were estimated by comparison with similar molecules. D. White, Ohio State University, in a private communication quoted in D. L. Hildenbrand et. al. loc. cit. assigned vibrational frequencies from matrix-isolation experiments. When these frequencies were used in a third and second law analysis of Hildenbrand's data, the drift in the third law was much larger and the agreement between the second and third law was also much poorer than that using the frequencies employed in this table. The molecular constants were obtained from P. A. Akishin and V. P. Spiridonov, Zhur. Strukt. Khim. 2, 63 (1961). The individual moments of inertia are: I_A = 1.22164 X 10^{-38} g. cm.^{2}, I_B = 2.2710 X 10^{-39} g. cm.^{2}, and I_C = 1.44875 X 10^{-38} g. cm.^{2}.

BORON NITRIDE (BN) (CRYSTAL) GFW = 24.8177

$\Delta Hf^\circ_0 = -59.27 \pm 0.37$ kcal/mol

$S^\circ_{298.15} = 3.536$ gibbs/mol

$\Delta Hf^\circ_{298} = -59.97 \pm 0.37$ kcal/mol

Td = 2600 ± 100°K

Heat of Formation.

The adopted heat of formation was determined by Wise et al. using combustion in fluorine. Other recent calorimetric values are in good agreement as summarized below. Torsion-effusion studies of the decomposition $BN(c) \rightarrow B(am) + 0.5\ N_2(g)$ by D. L.Hildenbrand and W. F. Hall, J. Phys. Chem. 67, 888 (1963), yield essentially the same ΔHf° and indicate that the condensation coefficient, α, is $< 6\times10^{-3}$ for $N_2(g)$ on the surface of the sample. Use of $\alpha = 6 \times 10^{-3}$ brings the following decomposition studies into reasonable agreement: Langmuir studies by L. H. Dreger, V. V. Dadape and J. L. Margrave, J. Phys. Chem 66, 1556 (1962); mass spectrometric studies by P. O. Schissel and W. S. Williams, Bull. Am. Phys. Soc., II, 4, 139 (1959); and Knudsen effusion studies by M. Hoch and D. White, Technical Research Report MCC-1023-TR-214, Ohio State University Research Foundation, Columbus, Ohio, October, 1956.

Heat Capacity and Entropy.

The low temperature heat capacity was taken from E. F. Westrum, Jr., private communication, May 19, 1960. The intermediate heat capacity (300-1650°C) was obtained from R. A. McDonald and D. R. Stull, J. Phys. Chem. 65, 1918 (1961). The high temperature Cp was taken from H. Prophet and D. R. Stull, J. Chem. Eng. Data 8, No. 1, 78, January 1963. The heat capacities in the three temperature ranges were plotted and then graphically smoothed. A. S. Dworkin, D. J. Sasmor, and A. R. Van Artsdalen, loc cit., also reported heat capacity (50-300°K) not employed in this table.

The entropy was obtained by integration of the heat capacity data from E. F. Westrum, Jr., loc. cit., based upon $S^\circ_{10} = 0.0028$ eu.

Temperature of Decomposition.

Observations by The Dow Chemical Company under Contract No. AF 33(616)-6149 show decomposition to elements at 1 atm total pressure at 2600 ± 100°K. The decomposition temperature calculated from these tables is 2832°K; presumably this discrepancy is associated with uncertainties in the high temperature enthalpies of BN(c), B(c) and B(l) and the enthalpy of melting of B(c).

Heat of Formation.

The heat of formation is based on D_o = 5.7 eV which was calculated from ω_e and $\omega_e x_e$ observed by A. E. Douglas and G. Herzberg, Can. J. Research 18A, 179 (1940). An uncertainty of ± 1.3 eV was assigned from consideration of other information, which places the dissociation energy between 4 and 7 eV. The value D_o = 4.0 ± 0.5 eV was selected by A. G. Gaydon, "Dissociation Energies," second edition, Chapman and Hall Ltd, London, 1953, from his own extrapolation of the spectroscopic data. An upper limit of $D_0 \leqslant$ 7.0 eV results from the upper limit for the pressure of BN(c) → BN(g) obtained from the B^+ ion intensity at 1600°C observed by P.A.Akishin and Yu. S. Klodeev, Zh. Neorgan. Khim. 7, 941 (1962). It is likely that the BN(g) pressure is even smaller, since it is known that BN(c) → B(s) + 0.5 N_2(g) and Akishin's pressure limit are the same magnitude as that of B(s) → B(g). V. V. Fesenko, Poroshkovaya Met., Akad. Nauk Ukr. S. S. R. 1, No. 4, 80-5 (1961) [cf. Chem. Abs. 56, 10997 (1962)], reports a standard heat of sublimation of 160 kcal/mol for BN(c) → BN(g) and also gives pressures for BN(g) at 2500 and 3000°K which are stated to be two orders less than the equilibrium pressure of nitrogen. Fesenko's original article is not yet available to us and it is not clear from the abstract whether the values are based on new data or are mere calculations. The reported pressures yield D_o = 6.2 eV, but here again the BN(g) pressures are of the same magnitude as the JANAF values for B(s) → B(g).

Some estimated values for D_o (ranging from 5.4 to 6.4 eV) are summarized below along with the experimental evidence.

Source	D_o (eV)	ΔHs°_{298} (kcal/mol)	ΔHf°_{298} (kcal/mol)
Gaydon's extrapolation of spectroscopic data	4.0 ± 0.5	213	153
Linear Birge-Sponer extrapolation	5.7	174	114
Fesenko's "BN(g) pressures"	6.2	161	101
Akishin's upper limit for BN(g) pressure	7.0	145	85
Estimate from geometric mean of D_o for B_2 and N_2	5.4	180	120
Estimate from D_o for series N_2, CN, BN, BeN	5.6	177	117
Estimate $M_2 + N_2$ = 2 MN for M=B from M=C	6.0	166	106
Estimate from arithmetic mean of D_o for B_2 and N_2	6.4	158	98

Heat Capacity and Entropy.

The molecular constants are based on emission spectra of the $^3\Pi$ - $^3\Pi$ transition obtained by Douglas and Herzberg, loc. cit. Observation of the same triplet in absorption by B. A. Thrush, Nature 160, 1044 (1960), strongly suggests that the ground state of BN is $^3\Pi$ in contrast to $^1\Sigma$, as observed for the isoelectronic molecules BeO and C_2. Electronic levels for the $^3\Pi$ states are taken from Douglas and Herzberg, while values for $^1\Sigma+$ and $^1\Pi$ have been estimated from the SCF calculations of J. L. Masse and M. Bärlocher, Helv. Chim. Acta 47, 314 (1964).

Dec. 31, 1960; Mar. 31, 1965

SODIUM METABORATE ($NaBO_2$) (CRYSTAL) MOL. WT. = 65.811

$\Delta H_f^\circ{}_0 = -232.9$ kcal. mole⁻¹

$S^\circ_{298.15} = 17.573$ cal. deg.⁻¹ mole⁻¹

$\Delta H^\circ_{f\ 298.15} = -234 \pm 2$ kcal. mole⁻¹

$T_m = 1239°K.$

$\Delta H_m^\circ = 8.66$ kcal. mole⁻¹

$\Delta H^\circ_{s\ 298.15} = 77.00$ kcal. mole⁻¹

Heat of Formation.

W. H. Evans, D. D. Wagman and E. J. Prosen in NBS Report No. 4943, "Thermodynamic Properties of Some Boron Compounds", August, 1956, extrapolated from the graph of L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27 (1954) the heat of solution to be -25.4 kcal. mole⁻¹ for the first reaction in 2N nitric acid. G. Grenier and D. White, J. Chem. Phys. 61, 1681 (1957) measured the heat of solution at 273.15°K. in 2N nitric acid for the first reaction and found a value of -20.43 kcal. mole⁻¹. The heats of solution for the second and third reactions were obtained from L. Shartsis and W. Capps, loc. cit.

1. $Na_2O \cdot B_2O_3(c)$ + Solvent I = end Solution 1
2. $B_2O_3(c)$ + Solvent II = end Solution 1 $\Delta H_2 = -3.64$ kcal./mole
3. $Na_2O(c)$ + Solvent I = Solvent II $\Delta H_3 = -83.9$ kcal./mole

The combination of the above reactions yields:

$Na_2O(c) + B_2O_3(c) = Na_2O \cdot B_2O_3(c)$

$1/2\ Na_2O(c) + 1/2\ B_2O_3(c) = NaBO_2(c)$

The $\Delta H^\circ_{f\ 298.15}$'s for Na_2O and B_2O_3 are JANAF values. The $\Delta H^\circ_{f\ 298.15}$ value of -234.000 kcal. mole⁻¹ employed in this table was obtained by taking the average of the values given above for reaction 1. Since there were uncertainties in the extrapolation and in assuming no correction for the measurements at 273.15°K., an average value was considered preferable.

Heat Capacity and Entropy.

The low temperature heat capacities (5-298.15°K.) and $S^\circ_{298.15}$ were obtained from G. Grenier and E. F. Westrum, J. Am. Chem. Soc. 78, 6226 (1956). The heat capacities at the higher temperatures were altered slightly from the estimate of K. K. Kelley, U. S. Bureau of Mines Bulletin 393 (1936).

Melting Data.

The T_m was obtained from H. S. Van Klooster, Z. Anorg. Chem. 69, 122 (1911). The adopted ΔH_m° was calculated by K. K. Kelley loc. cit. from H. S. Van Klooster's work. K. K. Kelley also calculated a ΔH_m° of 9.3 kcal. mole⁻¹ from M. H. LeChatelier, Compt. rend. 118, 800 (1894).

Sublimation Data.

The ΔH_s was obtained from the mass spectrometric investigations of A. Büchler and J. B. Berkowitz-Mattuck, J. Chem. Phys. 39, 286 (1963).

Dec. 31, 1960; Mar. 31, 1965

SODIUM METABORATE (NaBO$_2$) (LIQUID) MOL. WT. = 65.811

$S^\circ_{298.15}$ = 20.560 cal. deg.$^{-1}$ mole^{-1}

ΔH°_f 298.15 = [-229.339] kcal. mole^{-1}

T_m = 1239°K.

ΔH°_m = 8.66 kcal. mole^{-1}

Heat of Formation.

ΔH°_f 298.15(l) was obtained from ΔH°_f(c) by addition of ΔH°_m and difference between $(H^\circ_{1239}-H^\circ_{298.15})$ for the crystal and liquid.

Heat Capacity and Entropy.

Sodium metaborate is assumed to have a glass transformation at 826°K. below which C_p of the glass is assumed equal to that of the crystal. Above 826°K. the heat capacity was estimated as a constant value by assuming 8.75 calories contribution from each atom. The $S^\circ_{298.15}$ was obtained in a manner analogous with ΔH°_f 298.15.

Melting Data.

See crystal table.

Bond Distance: Na-O = 2.14 Å, O-B = 1.36 Å, B=O = 1.20 Å

Bond Angle: NaOB = 100°, O-B=O = 180°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 2.566657 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was calculated from the heat of sublimation of 73 ± 3 kcal. mole^{-1} measured mass spectrometrically at 1070°K. by A. Büchler and J. B. Berkowitz - Mattuck, J. of Chem. Phys. 39, 286 (1963) by addition of the difference between $(H^\circ_{1070} - H^\circ_{298.15})$ for the crystal and gas.

Heat Capacity and Entropy.

A. Büchler and E. P. Marram, J. Chem. Phys. 39, No. 2, 292, (1963), observed and assigned two vibrational metaborate frequencies, which were adopted for this table. The other vibrational frequencies were estimated by comparison with lithium metaborate. The molecular constants were obtained from P. A. Akishin and V. P. Spiridonov, Zhur. Strukt. Khim. 2, 63 (1961). The individual moments of inertia are: $I_A = 4.2923 \times 10^{-39}$, $I_B = 22.4009 \times 10^{-39}$, and $I_C = 26.6933 \times 10^{-39}$ g. cm.^{2}

BORON MONOXIDE (BO) (IDEAL GAS) GFW = 26.8104

Ground State Configuration $^2\Sigma^+$

$\Delta Hf_0^\circ = -0.7 \pm 2$ kcal/mol

$S^\circ_{298.15} = 48.60 \pm 0.01$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 0 \pm 2$ kcal/mol

Electronic Levels and Quantum Weights

	ϵ_i, cm^{-1}	g_i
$X^2\Sigma^+$	0	2
$A^2\Pi$	23836	2
$A^2\Pi$	23959	2
$B'^2\Sigma$	39957	2
$B^2\Sigma^+$	43175	2

$\omega_e = 1895.66$ cm^{-1} $\omega_e x_e = 11.90$ cm^{-1} $\sigma = 1$

$B_e = 1.800$ cm^{-1} $\alpha_e = 0.01676$ cm^{-1} $r_e = 1.2049$ Å

Heat of Formation

The heat of formation has recently been determined by several workers whose values are in close agreement. P. E. Blackburn, A. Buchler, and J. L. Stauffer, J. Phys. Chem. 70, 2469 (1966), measured the ion currents corresponding to BO^+ and $B_2O_2^+$ as a function of temperature in a mass spectrometer. From a least squares fit of the data they report $\Delta H = 56.6 \pm 1.8$ kcal for the reaction $1/2B_2O_2(g) \rightarrow BO(g)$; this yields $\Delta Hf^\circ_{298}(BO, g) = 2.1 \pm 2.8$ kcal/mol using $\Delta Hf^\circ_{298}(B_2O_2, g) = -109 \pm 2$ kcal/mol.

L. De Galan, Physica, 31, 1286 (1965), from flame photometric measurements reports $D_0^\circ(BO) = 8.3$eV(191.4 kcal), which corresponds to $\Delta Hf^\circ_{298}(BO, g) = -0.1$ kcal/mol.

P. Coppens, S. Smoes and J. Drowart, Trans. Faraday Soc. 64, 630 (1968), from a mass spectrometric study of several isomolecular exchange reactions, conclude that $D_0^\circ(BO) = 8.29 \pm 0.1$eV(191.2 ± 2.3 kcal) or $\Delta Hf^\circ_{298}(BO, g) = 0.1 \pm 2.3$ kcal/mol.

M. Farber, M. A. Frisch, G. Grenier and H. C. Ko, Rocket Power, Inc., Report No. AFRPL-TR-67-244, Final Report under Contract F04611-67-C-0010, Nov. 1967 (available as AD830237), investigated the same reaction as Blackburn et al. and report $\Delta Hr^\circ_{1800} = 53.8 \pm 1.9$ kcal, which yields $\Delta Hf^\circ_{298}(BO, g) = 0.9 \pm 2.9$ kcal/mol.

We adopt a median value of 0 ± 2 kcal/mol which includes all the determinations.

Heat Capacity and Entropy

The molecular and vibrational constants for the ground state are from G. Herzberg "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950. The electronic levels are also given by Herzberg with the exception of the level at 39957, a $^2\Sigma$ level designated B' by A. A. Mal'tsev and D. I. Kataev, Vestn. Mosk, Univ. Serv. II 22, 2 (1967). The molecular constants were all adjusted to reflect normal isotopic abundancies.

$^2\pi_g$	149	2
$^2\pi_u$	18291.6	4
$^2\Sigma_u^+$	24508.0	2

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
1056 (1)
454 (2)
1321.7 (1)

Bond Distance: B-O = 1.263 Å

Bond Angle: O-B-O = 180° σ = 2

Rotational Constant: B_0 = 0.3303 cm^{-1}

Heat of Formation

Greene (1) measured the vapor pressure of B_2O_3 and examined the infrared absorption spectra of B_2O_3, B_2O_2 and BO_2. The isotope shift and oxygen and temperature dependencies of the boric acid fluctuation bands were studied. The enthalpy change, $\Delta Hr^\circ_{2100°K}$ = 76 ± 2 kcal/mol, for the reaction $1/2B_2O_3(\ell) + 1/4\ O_2(g) = BO_2(g)$, was obtained spectroscopically. Based on this data and $\Delta Hf^\circ_{2100°K}(B_2O_3,\ \ell)$ = -291.05 kcal/mol, we derive $\Delta Hf^\circ_{298}(BO_2,\ g)$ = -68.4 ± 2 kcal/mol.

Rusin (2) determined the equilibrium constant of the reaction $HBO_2(g) + OH(g) = BO_2(g) + H_2O(g)$ by simultaneously recording the pressure and spectra at 3000 - 3200°K of HBO_2 and BO_2, which were produced from the combustion in a bomb of mixtures of H, O, CO and a small amount of B_2H_6. Using the experimental value Kp_{3100} = 0.9, and JANAF free energy functions for the reactants and products, we obtain ΔHr°_{298} = 0.53 kcal/mol for that reaction. Employing ΔHf°_{298} = -134.00, 9.43 and -57.80 kcal/mol for $HBO_2(g)$, OH(g) and $H_2O(g)$, respectively, we derive the value $\Delta Hf^\circ_{298}(BO_2,\ g)$ = -66.24 kcal/mol.

In a study of gases from flames containing trimethylborate stabilized on flat porous metal burners, Kaskan (3) obtained data consistent with the bands being due to the molecule $BO_2(g)$. The temperature dependence of the equilibrium constants for the reaction $OH(g) + HBO_2(g) = H_2O(g) + BO_2(g)$ was investigated and the data were reported to be consistent with a value $\Delta Hr^\circ_{1800°K}$ = -16 kcal/mol. Based on this ΔHr°_{1800} value, we calculate the heat of formation at 298°K for $BO_2(g)$ to be -83.62 kcal/mol. Kaskan (4) has studied the effect of oxygen on the intensity of absorption (5470 Å) in the green or "fluctuation" bands of the gas phase in equilibrium with $B_2O_3(\ell)$. At constant temperature the absorptivity was found to depend on the 1/4 power of the oxygen pressure. This is interpreted as evidence that the absorbing species is $BO_2(g)$. The reaction $1/2B_2O_3(\ell) + 1/4\ O_2(g) = BO_2(g)$ was found to be 70 kcal/mol endothermic in the temperature range 1660 - 1950°K, yielding $\Delta Hf^\circ_{298}(BO_2,\ g)$ = -75.28 kcal/mol. Rusin et al. (2) discussed the discrepancy between their results and those of the above two investigations and commented that the results of Kaskan (3, 4) were derived based on the assumption that Beer's law was obeyed over the temperature range 1400 - 2200°K. Actually, the relative population α of the principal electronic state $X^2\pi$ of the BO_2 molecule changes greatly over this temperature range. Therefore the expression for the dependence of the optical density on the concentration of BO_2 must be corrected to allow for the variation of α with temperature.

The heat of formation of $BO_2(g)$ at 298°K is selected as -68 ± 2 kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from Johns (5). Vibrational frequencies, bond distance and rotational constant were reported by Johns (5), Sommer (6), and Snowden (7). The values adopted are those determined by Snowden (7). Snowden used a (1:1) mixture of KBF_4 and B_2O_3 placed in a 13 mm Vycor tube. The mixture was heated to produce a vapor which passed through an external electrodeless discharge. The intense emission spectrum of the BO_2 molecule was observed. The fluorescence spectrum obtained by Johns was too weak for a full characterization of the electronic ground state. The moment of inertia is 8.4743×10^{-39} g cm^2.

Heat of Formation

D. E. Jensen, AeroChem TP-187A, Dec. 1968, AeroChem Research Laboratories, Inc., Princeton, N. J., has obtained equilibrium constants for the reaction $HBO_2 + e^- \rightarrow H + BO_2^-$. This involves several assumptions the most basic of which is that boron added to $H_2/N_2/O_2$ flames is converted completely to HBO_2. The free electrons are produced by addition of potassium to the flame, and their concentration is measured directly by a microwave cavity resonance method. The hydrogen atom concentration is taken from previous studies on such flames. The BO_2^- concentration is obtained from the difference between the K^+ concentration and the free electron measurement. The K^+ concentration is measured by an electrostatic probe.

By 2nd and 3rd law analysis of the data, 11 points read back from a plot, we obtain ΔHr_{298}(II) = 27.5 ± 4 kcal and ΔHr_{298}(III) = 20 ± 2 kcal with a drift of -3.7 ± 1.5 eu. The third law value yields $\Delta Hf^\circ_{298}(BO_2^-)$ = -166 ± 6 kcal/mol where the uncertainty includes possible errors in the functions. This corresponds to an electron affinity of BO_2 equal to 98 ± 6 kcal/mol (4.25 eV).

Heat Capacity and Entropy

The molecular structure is assumed to be linear using the Walsh (1) prediction for 16 valence electron XY_2 molecules. The electronic states are taken from those for $CO_2(g)$ (2), which is isoelectronic with $BO_2^-(g)$. The electronic level 35000 cm^{-1} and vibrational frequencies are estimated by comparison with the corresponding values for CO_2, CO_2^+, and BO_2, and, the data of Vasco and Srb (3) on the BO_2^- ion in alkali halide lattices. The B-O bond distance in $BO_2^-(g)$ is assumed to be smaller than the B-O bond in $BO_2(g)$, because the $BO_2^-(g)$ molecule has one more bonding electron than the $BO_2(g)$ molecule. The moment of inertia is 8.302×10^{-39} g cm^2. The enthalpy at 0°K is -2.30 kcal/mol.

BORON MONOSULFIDE (BS) (IDEAL GAS) MOL. WT. = 42.89

Ground State Configuration $^2\Sigma$

$S^\circ_{298.15}$ = 51.645 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 79 ± 18 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 80 ± 18 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ, cm.$^{-1}$	g_i
0	2

ω_e = 1188.23 cm.$^{-1}$

$\omega_e x_e$ = 6.396 cm.$^{-1}$

σ = 1

B_e = 0.80596 cm.$^{-1}$

α_e = 0.00618 cm.$^{-1}$

r_e = 1.609 Å

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for BS(g) was calculated based on D°_0 = 5.1 ± 0.8 e.v. for BS(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy.

The ground state configuration, ω_e, $\omega_e x_e$, B_e, α_e and r_e were reported by P. B. Zeeman, Can. J. Phys. 29, 336 (1951). The molecular constants used for calculation were corrected to the average isotopic species. The moment of inertia is 3.47762 X 10^{-39} g. cm.^{2}

Mar. 31, 1963; June 30, 1965

TITANIUM MONOBORIDE (TiB) (CRYSTAL) MOL. WT. = 58.711

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [8.3 ± 1.5] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -38.3 ± 9 kcal. mole^{-1}

T_d = [2500]°K.

Heat of Formation.

P. O. Schissel and O. C. Trulson, J. Phys. Chem., 66, 1492 (1962) used a mass spectrometer with Knudsen cells to study the vaporization of the titanium-boron system and obtained ΔF°_{2340} = -118.54 kcal. mole^{-1} for the reaction TiB(c) = Ti(g) + B(g). This corresponds to $\Delta F_f^\circ{}_{2340}$(TiB(c)) = -33.266 ± 9 kcal. mole^{-1}, where 4 kcal. mole^{-1} of the uncertainty is due to the heat of sublimation of boron. When this is reduced to 298°K. one obtains $\Delta H_f^\circ{}_{298}$(TiB(c)) = -38.3 ± 9 kcal. mole^{-1}. This value implies a high stability for TiB. This is also indicated by the phase studies of H. Nowotny, F. Benesovsky, C. Brukl and O. Schob, Monatshefte fur Chemie 92, 403 (1961).

Heat Capacity and Entropy.

The heat capacities from 298 to 1200°K. were estimated from that of TiB_2 by assuming the difference to be the same as that between CrB and CrB_2 as determined by R. Mezaki, E. W. Tilleux, D. W. Barnes and J. L. Margrave (Paper presented at the International Symposium on Nuclear Materials, Vienna, May 1962). A linear extrapolation was assumed above 1200°K.

The heat capacities above 298°K. were also estimated from the relationship C_p(Ti) + C_p(2B) - C_p(TiB_2) = 2/3 [C_p(Ti) + C_p(B) - C_p(TiB)]. This estimation agreed with the above to 4% over the temperature range 400 to 1000°K.

S°_{298}(TiB, c) = 8.3 cal. mole^{-1} deg.$^{-1}$ was calculated by the method of W. M. Latimer, J. Am. Chem. Soc., 73, 1480 (1951). Using JANAF S°_{298}(TiB_2, c) = 6.8 cal. mole^{-1} deg.$^{-1}$ and Latimer's value of 9.8 e.u. for the entropy contribution of Ti, an entropy contribution of -1.5 e.u. per Boron atom was calculated.

Decomposition Data.

The phase diagram given in, "The Metallurgy of the Rarer Metals - No. 4 Titanium", by A. D. McQuillan and M. K. McQuillan, Academic Press, New York (1956) was used to estimate the decomposition temperature. This diagram shows the decomposition products are TiB_2 and Ti_2B. However, Nowotny et al. (loc. cit.) have shown Ti_2B to be nonexistent and so the decomposition products are not defined, probably a eutectic of TiB and TiB_2 is involved.

BORON, DIATOMIC (B_2) (IDEAL GAS) MOL. WT. = 21.64

Ground State Configuration $^3\Sigma_g^-$

$S^\circ_{298.15}$ = 48.228 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 193.5 ± 6.4 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 195.0 ± 6.4 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ_i, cm.$^{-1}$	g_i
0	3

ω_e = 1061.0 cm.$^{-1}$

B_e = 1.235 cm.$^{-1}$

$\omega_e x_e$ = 9.58 cm.$^{-1}$

α_e = 0.0144 cm.$^{-1}$

σ = 2

r_e = 1.589 Å

Heat of Formation.

The equilibrium vapor pressure of the reaction $B_2(g) \rightarrow B(g) + B(c)$ was determined by G. Verhaegen and J. Drowart, J. Chem. Phys. 37, 1367 (1962). Using the value, $P_{B_2(g)}/P_{B(g)} = 9 \times 10^{-5}$ at 2330°K. where P is partial pressure, the heat of reaction ($\Delta H^\circ_{r\ 298.15}$) was evaluated to be -62.2 ± 5.0 kcal mole^{-1}. This leads to $\Delta H^\circ_{f\ 298.15}$ = 195.0 ± 6.4 kcal. mole^{-1} for $B_2(g)$ or D_0° = 3.0 e.v. which is in excellent agreement with the value, D_0° = 3.0 ± 0.5 e.v. reported by A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The value, D_0° = 3.6 e.v., estimated by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., 1950, yields $\Delta H^\circ_{f\ 298.15}$ = 181.6 kcal. mole^{-1} for $B_2(g)$ which is not used.

Heat Capacity and Entropy.

Molecular and spectroscopic constants were obtained from G. Herzberg, loc. cit. and corrected to the average isotopic species. The principal moment of inertia (I) is 2.26779×10^{-39} g. cm.^{2}

Beryllium Diborate (BeB_2O_4)

Bond Angle: O=B-O = [180°] O-Be-O = [180°] B-O-Be = [95°]

$\sigma = 2$

Product of Moments of Inertia: $I_AI_BI_C = 5.3801 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was obtained from mass spectrometric studies; the following reactions at 1500°K. were reported by P. E. Blackburn and A. Büchler, Interim Technical Report No. 1, March 1965:

1. $B_2O_3(l) \rightarrow B_2O_3(g)$ ΔH_1 = 92.226 kcal/mole
2. $1/3\ Be_3B_2O_6(c) + 2/3\ B_2O_3(l) \rightarrow Be(BO_2)_2(g)$ $\Delta H_2 = 118 \pm 2$ kcal/mole
3. $Be_3B_2O_6(c) \rightarrow 3BeO(c) + B_2O_3(g)$ $\Delta H_3 = 112 \pm 1$ kcal/mole
4. $Be_3B_2O_6(c) \rightarrow 2BeO(c) + Be(BO_2)_2(g)$ $\Delta H_4 = 137 \pm 3$ kcal/mole
5. $3BeO(c) + B_2O_3(l) \rightarrow Be_3B_2O_6(c)$ ΔH_5 = -23 kcal/mole
6. $BeO(c) + B_2O_3(g) \rightarrow Be(BO_2)_2(g)$ ΔH_6 = 22 kcal/mole

The value of ΔH_1 was obtained from JANAF values for $B_2O_3(l)$ and $B_2O_3(g)$. The values for ΔH_2, ΔH_3 and ΔH_4 were obtained from P. E. Blackburn and A. Büchler loc. cit. The value for ΔH_5 was obtained by taking the average of ΔH_5 = -20 kcal/mole in a weight loss experiment, $\Delta H_5 = \Delta H_1 - \Delta H_3$ = -19.774 kcal/mole, and $\Delta H_5 = 3/2\ (\Delta H_2 - \Delta H_4)$ = -28.5 kcal/mole. The ΔH_6 value was obtained by taking the average of $\Delta H_6 = \Delta H_4 - \Delta H_3$ = 25 kcal/mole and $\Delta H_6 = \Delta H_2 - \Delta H_1 + 1/3\ \Delta H_5$ = 18.107 kcal/mole. The $\Delta H_{f\ 298.15}$ of BeB_2O_4 was calculated from reaction 6 with auxiliary JANAF values.

Heat Capacity and Entropy.

The vibrational frequencies estimated by comparison with B_2O_3, were adjusted to obtain an S°_{1500} = 127 obtained in a manner analogous with ΔH_f from the report of P. E. Blackburn and A. Büchler loc. cit. The frequencies listed are not in point group order. All other molecular constants were estimated by comparison with related boron oxide molecules. The individual moments of inertia are $I_A = 8.5561 \times 10^{-39}$ g. cm.^{2}, $I_B = 75.1345 \times 10^{-39}$ g. cm.^{2} and $I_C = 83.6909 \times 10^{-39}$ g. cm.^{2}

Triberyllium Diborate ($Be_3B_2O_6$)

Sept. 30, 1966

TRIBERYLLIUM DIBORATE ($Be_3B_2O_6$) (CRYSTAL) GFW = 144.655

$S^\circ_{298.15}$ = [24 ± 3] gibbs/mol

Tm = 1768 ± 5°K

ΔHf° = Unknown

$\Delta Hf^\circ_{298.15}$ = -741.96 ± 2 kcal/mol

ΔHm° = Unknown

Heat of Formation.

The adopted $\Delta Hf^\circ_{298.15}$ = -741.96 ± 2 kcal/mol was calculated from $\Delta Hr^\circ_{298.15}$ = -13.38 ± 0.5 kcal/mol for 3 BeO (c) + B_2O_3(gl) = $Be_3B_2O_6$(c) measured calorimetrically by P. Gross, Fulmer Research Institute, Administration Report No. 5, Stoke Poges, England, January - April 1966. From equilibrium data relating to the same reaction at 1500°K, P. E. Blackburn and A. Buchler, J. Phys. Chem. 69, 4250 (1965), report heats of reaction of -21 ± 2 and -28.5 ± 5 kcal/mol, which correspond to -21.7 and -29.2 kcal/mol at 298°K. The discepancy of 8 to 16 kcal is attributed primarily to the equilibrium values. These values result from differences between 2nd law heats of reaction derived from the variation with temperature of intensities for $B_2O_3^+$ and $Be(BO_2)_2^+$, respectively, over the systems B_2O_3(l) - $Be_3B_2O_6$(c) and $Be_3B_2O_6$(c) - BeO(c). The reported reactions and their heats are:

	Reactions	ΔHr°_{1500} (kcal/mol)
(a)	$B_2O_3(l) \rightarrow B_2O_3(g)$	91 ± 0.5
(b)	$Be_3B_2O_6(c) \rightarrow 3\ BeO(c) + B_2O_3(g)$	112 ± 1
(c)	$1/3\ Be_3B_2O_6(c) + 2/3\ B_2O_3(l) \rightarrow Be(BO_2)_2(g)$	118 ± 2
(d)	$Be_3B_2O_6(g) \rightarrow 2\ BeO(c) + Be(BO_2)_2(g)$	137 ± 3

Heat Capacity and Entropy.

The heat capacity was estimated from that for BeO(c) and B_2O_3(c). The adopted $S^\circ_{298.15}$ = 24 ± 3 eu is an average value from the following three estimates. Blackburn and Buchler, loc. cit., report Kp = 2.7×10^{-5} and Kp = 9.3×10^{-6} atm at 1500°K for reactions a and b (see heat of formation) based on vacuum balance data and ion intensities, respectively. These Kp's yield ΔGr°_{1500} = -3.17 kcal/mol for 3 BeO(c) + B_2O_3(l) → $Be_3B_2O_6$(c). Combining this with the JANAF value for ΔHr°_{1500} = -12.64 kcal/mol, we get ΔSr°_{1500} = -6.3 and S°_{298} ($Be_3B_2O_6$,c) = 22.9 eu. This entropy agrees with 23 eu estimated from the sum of entropies for the component oxides; however, the entropy for $Ca_3B_2O_6$(c), observed by K. K. Kelley, S. S. Todd and C. H. Shomate, J. Am. Chem. Soc. 70, 1350 (1948), is larger than that of the component oxides by 2.5 eu. Use of this increment gives 25.5 eu for $Be_3B_2O_6$(c).

Melting Data.

Tm was obtained from P. E. Blackburn and A. Buchler, loc. cit.

Bond Distance: B-Cl = 1.73 ± 0.02 Å B-B = 1.75 ± 0.01 Å

$\sigma = 4$

Bond Angle: Cl-B-Cl = 120 ± 2°

Dihedral angle between two BCl_2 planes = 90°

Product of the Moments of Inertia: $I_AI_BI_C = 5.33449 \times 10^{-112}$ g.^{3} cm.^{6}

Heat of Formation.

S. R. Gunn, L. G. Green and A. I. Von Egidy, J. Phys. Chem. 63, 1787 (1959) determined the enthalpy change (ΔH_r°) of the reaction $B_2Cl_4(l) + Cl_2(g) = 2BCl_3(g)$. From the value, $\Delta H_{r\ 298.15}^\circ = -67.3 \pm 0.6$ kcal. mole^{-1}, the heat of formation for $B_2Cl_4(l)$ was calculated as -125.32 ± 1.20 kcal. mole^{-1}. Based on $\Delta H_{v\ 338.7}^\circ = 8.029$ kcal. mole^{-1} reported by G. Urry, T. Wartik, R. E. Moore and H. I. Schlesinger, J. Am. Chem. Soc. 76, 5293 (1954), the heat of formation for $B_2Cl_4(g)$ was derived to be -116.9 ± 1.2 kcal. mole^{-1}.

Heat Capacity and Entropy.

The vibrational frequencies, molecular structure and constants were taken from D. E. Mann and L. Fano, J. Chem. Phys. 26, 1665 (1957). The barrier restricting internal rotation about the B-B single bond is fixed at 1.53 ± 0.60 kcal. mole^{-1} obtained from E. A. Mason and M. M. Kreevoy, J. Am. Chem. Soc. 77, 5808 (1955). The three principal moments of inertia are: $I_A = 1.00465 \times 10^{-37}$, $I_B = 5.28520 \times 10^{-38}$ and $I_C = 1.00465 \times 10^{-37}$ g. cm.^{2} The reduced moment of inertia for BCl_2 top is $I_r = 1.3213 \times 10^{-38}$ g. cm.^{2}

Product of the Moments of Inertia: $I_AI_BI_C = 2.50147 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation was calculated based on the value, $\Delta H_r^\circ = -82.0 \pm 1.0$ kcal. mole^{-1} for the reaction $B_2F_4(g) + Cl_2(g) = 0.92\ BF_3(g) + 0.46\ BF_2Cl(g) + 0.32\ BFCl_2(g) + 0.30\ BCl_3(g)$ reported by S. R. Gunn and L. G. Green, J. Phys. Chem. 65, 178 (1961).

Heat Capacity and Entropy.

The molecular and spectroscopic constants were obtained from J. N. Gayles and J. Self, J. Chem. Phys. 40, 3530 (1964). The vibrational frequencies were corrected to the average isotopic species. The molecular configuration was reported to be staggered, analogous to that observed for $B_2Cl_4(g)$. The angle between two B-BF_2 planes is approximately 90°. The thermodynamic functions were evaluated based on an assumption that there is free rotation at B-B bond between the two BF_2 rotating tops. The internal moment of inertia is 4.12218×10^{-39} g. cm.^{2} The three principal moments of inertia are: $I_A = 3.89497 \times 10^{-38}$, $I_B = 1.64887 \times 10^{-38}$ and $I_C = 3.89497 \times 10^{-38}$ g. cm.^{2} The reduced moment of inertia for BF_2 top is $I_r = 4.12218 \times 10^{-39}$ g. cm.^{2}

BORON DIHYDROXIDE, DIMERIC ($B_2(OH)_4$)   (CRYSTAL)   MOL. WT. = 89.65148

$S^\circ_{298.15}$ = [30 ± 1] cal. deg.$^{-1}$ mole^{-1}

T_m = Unknown

$\Delta H_f^\circ{}_0$ = Unknown

$\Delta H_f^\circ{}_{298.15}$ = -337.1 ± 2.0 kcal. mole^{-1}

ΔH_m° = Unknown

$\Delta H_s^\circ{}_{298.15}$ = [30.1] kcal. mole^{-1}

Heat of Formation.

The enthalpy change, $\Delta H_r^\circ{}_{298.15}$ = -91.3 ± 1.0 kcal. mole^{-1}, for the reaction $B_2(OH)_4(c) + (m + 2)\cdot AgNO_3(aq.) + (n + 2)\cdot H_2O(l) = 2Ag(c) + [2H_3BO_3 + 2HNO_3 + mAgNO_3]\cdot nH_2O(aq.)$ was determined calorimetrically by A. Finch, P. J. Gardner and I. J. Hyams, Trans. Faraday Soc. 61, 649 (1965). The heat of formation of $B_2(OH)_4(c)$ was reported to be -335.1 kcal. mole^{-1}. This value was corrected to be -337.1 ± 2 kcal. mole^{-1} by use of more recent data on the $\Delta H_f^\circ{}_{298.15}$ values used for calculation.

Heat Capacity and Entropy.

The heat capacity for $B_2(OH)_4(c)$ was estimated by comparison with those for $B(OH)_3(c)$. The value of $S^\circ_{298.15}$ was calculated based on 3 cal. deg.$^{-1}$ mole^{-1} per atom for $B_2(OH)_4(c)$, which was obtained from the corresponding values for $HBO_2(c)$ and $B(OH)_3(c)$.

Heat of Sublimation.

The value, $\Delta H_s^\circ{}_{298.15}$, was calculated as the difference between $\Delta H_f^\circ{}_{298.15}$ for $B_2(OH)_4(g)$ and $B_2(OH)_4(c)$.

Boron Dihydroxide, Dimeric ($B_2(OH)_4$)

Bond Distance: B-B = [1.67] Å B-O = [1.36] Å B-H = [0.96] Å

Bond Angle: H-O-B = [114]° O-B-O = [120]° O-B-B = [120]° σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = [2.2995 \times 10^{-113}]$ g.^{3} cm.^{6}

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for $B_2(OH)_4(g)$ was calculated, using bond energies, D(B-OH) = 132 and D(B-B) = 78 kcal. mole^{-1}. The bond energy D(B-OH) was taken from that in $B(OH)_3(g)$ and D(B-B) was estimated by comparison with that in $B_2F_4(g)$.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that for $B_2F_4(g)$, i.e. the two $B(OH)_2$ units have staggered configuration, and free rotation about B-B bond. The B-B bond distance was taken as that in B_2F_4 molecule. Those for B-O and B-H bond and bond angles were adopted from H_3BO_3 molecule. Eleven vibrational frequencies were assumed to be the same as those for $B_2F_4(g)$. In addition to these were added four OH torsion frequencies, 824(2) and 209(2), four OH stretching, 3200(4), and four B-O-H bending frequencies, 1200(2) and 880(2). The thermodynamic functions were evaluated based on a molecular model having free internal rotation of two $B(OH)_2$ groups about B-B bond. The reduced moment of inertia for the rotation is calculated as 4.10146×10^{-39} g. cm.^{2} The three principal moments of inertia are: $I_A = 1.64037 \times 10^{-38}$ and $I_B = I_C = 3.7441 \times 10^{-38}$ g. cm.^{2}

Bond Angles: H_t - B - H_t = 120.2 ± 1.6°

$\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C = 2.46622 \times 10^{-116}$ g.^{3} cm.^{6}

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ is a weighted average of the following data. The older data of W. A. Roth et al.(8) deviates from the rest of the investigations and is not included.

Investigator		Reaction	ΔH_r° 298.15 (kcal. mole^{-1})	ΔH_f° 298.15 (kcal. mole^{-1})
Gunn and Green(1)		$B_2H_6(g) \rightarrow 2B(am) + 3H_2(g)$	-5.0	7.4
E. J. Prosen et al.(2)		$B_2H_6(g) \rightarrow 2B(am) + 3H_2(g)$	-6.73	9.13
J. R. Lacher et al.(3)		$B_2H_6(g) + 6Cl_2 \rightarrow 2BCl_3(g) + 6HCl(g)$	-342.3	17.3
E. J. Prosen et al.(4)		$B_2H_6(g) + 6H_2O(l) + [2000H_2O](l) \rightarrow 2[H_3BO_3 + 1000H_2O](soln.) + 6H_2(g)$	-111.46 ± 0.54	9.32
Gunn and Green(7)	(a)	$B_2H_6(g) + 2006H_2O \rightarrow 2(H_3BO_3 + 1000H_2O) + 6H_2(g)$	-112.22 ± 0.10	10.08
Gunn and Green(7)	(b)	$BCl_3(l) + 130.3H_2O \rightarrow (H_3BO_3 + 1000H_2O) + 3(HCl + 100H_2O)$	-68.14	——
(a) - 2(b) =	(c)	$B_2H_6(g) + 6(HCl\cdot 100H_2O) \rightarrow 2BCl_3(l) + 6H_2(g)$	+24.06	10.06
Gunn (9)		$(CH_3)_3N(g) + 1/2\ B_2H_6(g) \rightarrow (CH_3)_3N{:}BH_3(c)$	-32.33 ± 0.06	8.3
McCoy and Bauer(13)		$(CH_3)_3N(g) + 1/2\ B_2H_6(g) \rightarrow (CH_3)_3N{:}BH_3(c)$	-31.40	6.5

Sources of Auxiliary data: From the JANAF tables, $\Delta H_f^\circ{}_{298.15}$ = 1.2, -96.31, -22.063 kcal. mole^{-1} of B(am), $BCl_3(g)$ and HCl(g) respectively. From F. D. Rossini et al. (11) The $\Delta H_v^\circ{}_{298.15}$ = 5.6 kcal. mole^{-1} of BCl_3. From D. D. Wagman(12) the $\Delta H_f^\circ{}_{298.15}$ of $(HCl + 100H_2O)$ = -39.657 kcal. mole^{-1}. From Good et al.(5) the $\Delta H_f^\circ{}_{298.15}$ of $H_3BO_3(c)$ = -261.47 ± 0.20 kcal. mole^{-1} and the H_3BO_3 solution data of Fasolino(6). $\Delta H_f^\circ{}_{298.15}$ of $(CH_3)_3N(g)$ = -5.9 ± 0.4 kcal. mole^{-1} from I Jaffe(10).

Heat Capacity and Entropy.

The molecular constants reported by B. L. Carroll, "Electron Diffraction Investigation of Diborane and Boron-alkyls", Thesis, Iowa State University of Science and Technology, 1963, were selected. They agree well with those reported by K. Hedberg, and V. Schomaker, J. Chem. Phys. 22, 985 (1954). The principal moments are $I_A = 1.0578 \times 10^{-39}$, $I_B = 4.6416 \times 10^{-39}$, and $I_C = 5.0229 \times 10^{-39}$ g. cm.^{2}

The vibrational frequencies for $B_2^{11}H_6$ were those listed by E. C. Wu, Thesis, University of Minn. 1962, "Assignments and Force Constants of Diborane and Isotopic Derivatives" except for ν_8, ν_{10} and ν_{14} which were taken from the calculated frequency column of table VIII-1 page 55 of the Thesis.

MAGNESIUM DIBORIDE (MgB_2) (CRYSTAL) MOL. WT. = 45.96

$\Delta H_{f\ 0}^\circ = -21.8 \pm 2.0$ kcal. mole^{-1}

$S^\circ_{298.15} = 8.60 \pm 0.04$ cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15} = -22.0 \pm 2.0$ kcal. mole^{-1}

$T_d = [1320]^\circ K$

Heat of Formation.

The equilibrium constants (993 - 1108°K.) for the reaction $2MgB_2(c) = Mg(g) + MgB_4(c)$ were determined by M. Wright and P. N. Walsh, "The Vaporization of $MgB_4(c)$", Technical Research Report OMCC-HEF-55, Jan. 9, 1958, Ohio State University Research Foundation. The corresponding second and third law values of $\Delta H^\circ_{r\ 298.15}$ for this reaction were derived as 53.1 ± 4.7 and 54.1 kcal. mole^{-1}, respectively. Using the third law value obtained, i.e. $\Delta H^\circ_{r\ 298.15} = 54.1$ kcal. mole^{-1}, for the reaction, the $\Delta H^\circ_{f\ 298.15}$ for $MgB_2(c)$ was evaluated as -22.0 ± 2.0 kcal. mole .

Heat Capacity and Entropy.

The low temperature (21.12 - 304.22°K.) heat capacities were measured by R. M. Swift and D. White, J. Am. Chem. Soc. 79, 3641 (1957). Above 298.15°K. the values of C_p were estimated by comparison with those of other related borides. $S^\circ_{298.15}$ was reported by R. M. Swift and D. White, loc. cit., using S°_{20} (extrap.) = 0.005 cal. deg.$^{-1}$ mole^{-1}.

Temperature of Decomposition.

T_d was taken from L. Y. Markovsky, Y. D. Kondrashev, and G. V. Kaputovskaya, Zhur. Obshchei Khim., 25, 409 (1955). On heating to high temperatures $MgB_2(c)$ decomposes into boride phases A, B, and C with the separation of Mg. The composition of phase A is close to MgB_6 and that of C is close to MgB_{12}.

Heat of Formation.

The heat of formation was calculated from the estimated heat of reaction ΔHr°_0 = 300 ± 25 kcal/mol for $B_2O(g) \rightarrow 2B(g) + O(g)$, using the JANAF auxiliary data for B(g) and O(g). The value of ΔHr°_0 was assumed to be the sum of the heats of dissociation, 120 kcal/mol for $B_2O(g) \rightarrow BO(g) + B(g)$ and 180 kcal/mol for $BO(g) \rightarrow B(g) + O(g)$. The former was estimated and the latter was derived from the JANAF values.

The possible existence of $B_2O(g)$ in the burning of boron under reducing conditions was discussed by Gilbert S. Bahn in a paper presented at the Combustion Institute, at University of Denver, Apr. 25-27, 1966. He estimated the heat of formation to lie between -27 and +23 kcal/mol, but favored the value of +23 kcal/mol in the theoretical calculations of boron burning in air.

Heat Capacity and Entropy.

The bent molecular structure and the molecular constants were estimated by comparison with those in BO(g), AlO(g) and $Al_2O(g)$. The three principal moments of inertia are I_A = 0.1624 X 10^{-39}, I_B = 5.318 X 10^{-39} and I_C = 5.4804 X 10^{-39} g cm^2.

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for $B_2O_2(g)$ adopted is the weighted average of three $\Delta H^\circ_{f\ 298.15}$ values derived from two different chemical reactions. The chemical reactions related to the production of $B_2O_2(g)$ have been studied by several investigators. Using the equilibrium vapor pressure data, the respective values of $\Delta H^\circ_{r\ 298.15}$ were evaluated by both the second and third law methods. The results obtained are based on the latter and presented as follows.

Investigator	Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Third Law Value	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second Law Value	$\Delta H^\circ_{f\ 298.15}$ kcal. mole^{-1}
Inghram, et al.[1]	$2/3\ B(c) + 2/3\ B_2O_3(l) = B_2O_2(g)$	94.0	91.8 ± 2.2	-105.5 ± 0.7*
	$2/3\ B(c) + 2/3\ B_2O_3(g) = B_2O_2(g)$	24.8	25.4 ± 0.2	-108.0 ± 0.5
Searcy and Myers[2]	$2MgO(c) + 2B(c) = 2Mg(g) + B_2O_2(g)$	255.4	—	-102.6 ± 10*
Scheer[3]	$2/3\ B(c) + 2/3\ B_2O_3(l) = B_2O_2(g)$	89.3	77.9 ± 0.2	-110.2 ± 0.9
Rentzepis, et al.[4]	$B_2O_3(l) + 3C(c) = 3CO(g) + 2B(c)$	—	—	-108.5 ± 1.5
	$B_2O_3(l) + C(c) = B_2O_2(g) + CO(g)$	—	—	

*The value not used for the calculation of the weighted average of $\Delta H^\circ_{f\ 298.15}$ for $B_2O_2(g)$.

BORON OXIDE (B_2O_3) (CRYSTAL) MOL. WT. = 69.64

$S^\circ_{298.15}$ = 12.87 ± 0.10 cal. deg.$^{-1}$ mole^{-1}

T_m = 723 ± 2°K.

$\Delta H^\circ_{f\ 0}$ = -302.16 ± 0.40 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -303.64 ± 0.40 kcal. mole^{-1}

ΔH°_m = 5.26 ± 0.02 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 104.5 ± 0.6 kcal. mole^{-1}

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) for B_2O_3(c) has been reported by many investigators. However, the values obtained were not in good agreement. The value of $\Delta H^\circ_{f\ 298.15}$ for B_2O_3(c) adopted was taken from L. G. Fasolino, "Heats of Formation of B_2O_3(c) and B_2O_3(am.)". NONR-3608 (00), National Research Corporation, Massachusetts, June 2, 1964. The other derived values of $\Delta H^\circ_{f\ 298.15}$ for B_2O_3(c) are listed in the following table.

Investigator	Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1}	$\Delta H^\circ_{f\ 298.15}$, kcal. mole^{-1}
Roth[1]	$B_2O_3(gl) + 3\ H_2O(l) = 2\ H_3BO_3(c)$	-18.15	-304.2 ± 0.4
Eggersgluess et al.[2]	$2B(am.) + 3/2\ O_2(g) = B_2O_3(gl.)$	-281.1 ± 3.1	-283.1 ± 3.1
Artsdalen and Anderson[3]	$1/2\ B_2O_3(am.) + 3/2\ H_2O(l) = H_3BO_3(c)$	-9.13± 0.04	-304.1 ± 0.4
Eckstein and Artsdalen[4]	$2B(c) + 3/2\ O_2(g) = B_2O_3(gl.)$	-304.6 ± 4.2	-309.0 ± 4.2
Gal'chenko et al.[5]	$2B(am.) + 3/2\ O_2(g) = B_2O_3(gl.)$	-298.7 ± 1.8	-300.7 ± 2.0
Fasolino	$B_2O_3(c) + 348\ H_2O(l) = 2\ H_3BO_3 \cdot 345\ H_2O(Sol.)$	-3.45± 0.03	-303.64± 0.40

[1] W. A. Roth, Z. Naturforsch, 1, 574 (1946).

[2] W. Eggersgluess, A. G. Monroe and W. G. Parker, Trans. Faraday Soc. 45, 661 (1949).

[3] E. R. Van Artsdalen and K. P. Anderson, J. Am. Chem. Soc. 73, 579 (1951).

[4] B. H. Eckstein and E. R. Van Artsdalen, J. Am. Chem. Soc. 80, 1352 (1958).

[5] G. L. Gal'chenko, A. N. Kornilov and S. M. Skuratov, Russ. J. Inorg. Chem. 5, 1039 (1960).

In order to evaluate the values of $\Delta H^\circ_{f\ 298.15}$ for B_2O_3(c) from the corresponding $\Delta H^\circ_{r\ 298.15}$ values, the following auxiliary data (298.15°K) were used: ΔH°_f(B,am.) = 1.2 ± 0.4 kcal. mole^{-1}, ΔH°_r = 4.36 kcal. mole^{-1} for the reaction $B_2O_3(c) = B_2O_3(gl.)$, $\Delta H^\circ_f(H_3BO_3, c)$ = -261.47 ± 0.20 kcal. mole^{-1}, $\Delta H^\circ_f(2\ H_3BO_3 \cdot 345\ H_2O, Sol.)$ = -512.04 ± 0.40 kcal. mole^{-1} and $\Delta H^\circ_f(H_2O, l)$ = -68.317 kcal. mole^{-1}.

Heat Capacity and Entropy.

The low temperature (18.08 - 296.60°K.) heat capacities used were reported by E. C. Kerr, H. N. Hersh and H. L. Johnston, J. Am. Chem. Soc. 72, 4738 (1950). The high temperature (350.6 - 718.4°K.) heat capacities were derived from the heat content measurements determined by J. C. Southard, J. Am. Chem. Soc. 63, 3147 (1941). These two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 718.4°K. were estimated by graphical extrapolation. $S^\circ_{298.15}$ was obtained from E. C. Kerr, H. N. Hersh and H. L. Johnston, loc. cit., based on S°_{18} = 0.027 cal. deg.$^{-1}$ mole^{-1}. The specific heats of B_2O_3(c) in the temperature range 51 to 298°K. were also determined by K. K. Kelley, J. Am. Chem. Soc. 63, 1137 (1941). The C_p values reported are in good agreement with the values adopted.

Melting Data.

Melting temperature (T_m) was taken from F. C. Kracek, G. W. Morey and H. E. Merwin, Am. J. Sci. [5] 35A, 143 (1938). The heat of melting (ΔH°_m) was converted from $\Delta H^\circ_{m\ 298.15}$ = 4.36 ± 0.02 kcal. mole^{-1} reported by J. C. Southard, loc. cit.

Heat of Sublimation.

The value of heat of sublimation ($\Delta H^\circ_{s\ 298.15}$) was calculated as the difference in the heats of formation ($\Delta H^\circ_{f\ 298.15}$) for B_2O_3(g) and B_2O_3(c).

Dec. 31, 1960; Dec. 31, 1964

BOROŃ OXIDE (B_2O_3) (LIQUID) MOL. WT. = 69.64

$S^\circ_{298.15}$ = 18.739 cal. deg.$^{-1}$ mole^{-1}

T_m = 723 ± 2°K.

T_b = 2316°K.

$\Delta H^\circ_{f\ 298.15}$ = -299.28 ± 0.40 kcal. mole^{-1}

ΔH°_m = 5.26 ± 0.02 kcal. mole^{-1}

ΔH°_v = 87.55 kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ for $B_2O_3(l)$ was obtained from $\Delta H^\circ_{f\ 298.15}$ for $B_2O_3(c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m}$ - $H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat content (H°_t - $H^\circ_{298.15}$) measurements on B_2O_3(glass) and $B_2O_3(l)$ were determined, from 381.7 to 1776.8°K., by J. C. Southard, J. Am. Chem. Soc. 63, 3147 (1941) and, from 1015 to 2154°K., by R. M. Krasovitskaya, P. B. Kantor, L. S. Kan, V. V. Kandyba, L. M. Kutsyna and E. N. Fomichev, Russ. J. Phys. Chem. 35, 737 (1961). Based on these data the corresponding heat capacities (C_p) were derived. The C_p values thus obtained were plotted and joined smoothly, assuming a glass transition temperature at 550°K. The heat capacities above 2154°K. were estimated by graphical extrapolation. The entropy was obtained in a manner analogous to that of the heat of formation. The heat capacities of B_2O_3 glass and liquid have also been measured between 35 and 350°C with a radiation calorimeter by S. B. Thomas and G. S. Parks, J. Phys. Chem. 35, 2091 (1931). The heat capacity curves obtained have been compared and discussed.

Melting Data.

See the $B_2O_3(c)$ table.

Vaporization Data.

The boiling point (T_b) was calculated as the temperature at which the difference in ΔF°_f values for $B_2O_3(g)$ and $B_2O_3(l)$ becomes zero. The corresponding difference in ΔH°_f values at T_b is the heat of vaporization (ΔH°_v).

Heat of Formation.

The heat of formation ($\Delta H_f^\circ{}_{298.15}$) for $B_2O_3(g)$ was calculated from the values of $\Delta H_f^\circ{}_{298.15}$ and $\Delta H_v^\circ{}_{298.15}$ for $B_2O_3(l)$. The $\Delta H_v^\circ{}_{298.15}$ value was obtained from the analyses of the vapor pressure data of $B_2O_3(l)$ by both the second and third law methods. Ten sets vapor pressure data were employed for examination. The results obtained are presented as follows.

Investigator	Temperature, °K.	$\Delta H_v^\circ{}_{298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H_f^\circ{}_{298.15}$* kcal. mole^{-1}
Cole and Taylor[1]	1473 - 1673	87.77	72.92 ± 2.3	-211.51
Speiser, et al.[2]	1331 - 1642	99.25	87.10 ± 1.8	-200.03
Soulen, et al.[3]	1567 - 1808	98.49	65.87 ± 7.8	-200.79
Searcy and Myers[4]	1501 - 1566	98.70	101.3 ±12.5	-200.58
Scheer[5]	1414 - 1621	101.89	95.25 ± 0.9	-197.39
Nesmeyanov and Firsova[6]	1299 - 1515	98.86	82.36 ± 2.9	-200.42
White, et al.[7]	1220 - 1641	99.36	90.52 ± 0.6	-199.92
Sommer[8]	1228 - 1641	99.63	93.08 ± 0.7	-199.65

The free energy functions of $B_2O_3(g)$ used for calculation are obtained using two estimated vibrational frequencies, 172 and 460 cm.$^{-1}$. Similar evaluations were made using 259 and 460 cm.$^{-1}$ instead, each corresponding third law values of ΔH_v° obtained was lower by more than 1 kcal. mole^{-1} than that of the previous ones. The value of $\Delta H_v^\circ{}_{298.15}$ for $B_2O_3(g)$ adopted is the third law value based on the vapor pressures reported by D. L. Hildenbrand, W. F. Hall and N. D. Potter, loc. cit.

Heat Capacity and Entropy.

The bond distances were reported by P. A. Akishin and V. P. Spridinov, Doklady Akad. Nauk. S.S.S.R. 131, 557 (1960). The bond angle was taken from W. Weltner, Jr. and J. R. W. Warn, J. Chem. Phys. 37, 292 (1962). The vibrational frequencies were obtained from A. Sommer, D. White, M. J. Linevsky and D. E. Mann, J. Chem. Phys. 38, 87 (1963) and corrected to the average isotopic species. The three principal moments of inertia are: I_A = 3.10959 X 10^{-38}, I_B = 2.9758 X 10^{-39} and I_C = 3.40717 X 10^{-38} g. cm.^{2}

LEAD DIBORATE (PbB_2O_4) (CRYSTAL) MOL. WT. = 292.85

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [31.2 ± 3] cal. deg.$^{-1}$ mole^{-1} $\Delta H_f^\circ{}_{298.15}$ = -372 ± 1.5 kcal. mole^{-1}

Heat of Formation.

W. H. Evans in NBS Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system. L. Shartsis and E. Newman, J. Am. Ceram. Soc. 31, 213 (1948) measured heats of solution of the lead borate glasses in 2 N HNO_3. In their phase studies C. Mazzetti and F. De Carli, Gazz. chim. ital. 56, 19 (1926) established that the compounds formed were $PbO\cdot B_2O_3$, $PbO\cdot 2B_2O_3$, $PbO\cdot 3B_2O_3$ and 2 $PbO\cdot 5B_2O_3$. From the Shartsis and Newman paper loc. cit. Evans obtained the following:

$$PbO(c) + B_2O_3(c) \rightarrow PbO\cdot B_2O_3(gls.) \qquad \Delta H_r = -16.2 \text{ kcal. mole}^{-1}$$

and estimated a $\Delta H_{298.15}$ of 7.0 kcal. mole^{-1} for the conversion to the $PbO\cdot B_2O_3$(crystal). With auxiliary JANAF values the $\Delta H_f^\circ{}_{298.15}$ was calculated to be -372 kcal./mole. The results of B. M. Lepinskikh and O. A. Esin, Zhur. Neorg. Khim. 6, 1223 (1961) studying the lead borate system at 1000°K. with cells of the type $Pb(liq.)/PbO,B_2O_3/$ $/Pt/ O_2(g)$ were in fair agreement with the results of Shartsis and Newman.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of the heat capacities for B_2O_3 and PbO.

The entropy at 298.15 was obtained from a consideration of the entropies of sodium and calcium borates and those of the consituent oxides, as given by K. K. Kelley and E. G. King, Bureau of Mines Bull. 592 (1961). These indicate for the reaction:

$$MO + B_2O_3 \rightarrow MO\cdot B_2O_3$$

that the simple addition of entropies will give values at least 2.7 e.u. too low for the reaction. The reason for this is propably structural, the $B_2O_4^{--}$ ion is a flexible chain. Therefore, the $S^\circ_{298.15}$ for PbB_2O_4 was obtained from the summation of JANAF $S^\circ_{298.15}$ for constituent oxides and the addition of 2.7 e.u.

Sept. 30, 1962; Dec. 31, 1962; June 30, 1965

TITANIUM DIBORIDE (TiB_2) (CRYSTAL) MOL. WT. = 69.522

$\Delta H^\circ_{f\ 0}$ = -66.4 ± 4.0 kcal. mole^{-1}

$S^\circ_{298.15}$ = 6.808 ± 0.1 cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15}$ = -66.8 ± 4.0 kcal. mole^{-1}

T_m = 3193°K. ΔH°_m = [24] kcal. mole^{-1}

Heat of Formation.

G. M. Kibler, T. F. Lyon, M. J. Linevsky, and V. J. DeSantis, General Electric Co., report No. WADD-TR-60-646, Part IV (August 1964) studied the vapor pressure of the reaction $TiB_2(c) + 1/2\ C(c) = Ti(g) + 1/2\ B_4C(c)$ by comparing the absorption intensity of the 3371.45Å Ti resonance line of the above reaction at temperature T_1 to Ti (g) over pure titanium metal at temperature T_2. Using JANAF auxiliary data ΔF°_{2475} = 81.612 kcal. mole^{-1} for the above reaction and $\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -66.9 kcal. mole^{-1} were calculated.

W. S. Williams, J. Phys. Chem. 65, 2213 (1961) found 2150 ± 25°K. to be the temperature at which $TiB_2(c)$ was formed from a mixture of TiN(c) and BN(c). If ΔF°_{2150} = 0 is assumed for the reaction $TiN(c) + 2BN(c) = TiB_2(c) + 3/2\ N_2(g)$ then $\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -70.7 kcal. mole^{-1}. If, however, $N_2(g)$ is 1/2 atm. then ΔF°_{2150} = 4.4 kcal. mole^{-1} and $\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -66.3 kcal. mole^{-1}. He has also shown by stability comparisons that ΔF and $\Delta H > 0$ for the reaction $TiB_2 + 3/2C = TiC + 1/2B_4C$. Thus $\Delta H^\circ_{f\ 298}\ TiB_2 < -51$ kcal. mole^{-1}.

P. O. Schissel and O. C. Trulson, J. Phys. Chem. 66, 1492 (1962) used a mass spectrometer with Knudsen cells to study the vaporization of the titanium-boron system. Only the set of measurements without excess boron or titanium was used. The value ΔF°_{2261} = 194.9 kcal. mole^{-1} for the reaction $TiB_2(c) = Ti(g) + 2B(g)$ was obtained. This corresponds to $\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -62.9 kcal. mole^{-1} using JANAF auxiliary data.

V. A. Epel'baum and M. I. Starostina, Bor Trudy Konf. Khim. Bora i Ego Soedinenii 97 (1955-pub.1958) report $\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -66.85 ± 2.7 kcal. mole^{-1} from combustion calorimetry.

C. E. Lowell and W. S. Williams, Rev. Sci. Inst. 32, 1120 (1961) used high temperature calorimetry to obtain the heat of formation of $TiB_2(c)$. From their data and JANAF auxiliary data $\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -48.2 ± 5 kcal. mole^{-1} was calculated. We question the adiabaticity of the experiment and believe their value is an upper limit.

$\Delta H^\circ_{f\ 298}(TiB_2(c))$ = -66.8 ± 4 kcal. mole^{-1} was chosen as representative of the first four investigations.

Heat Capacity and Entropy.

The heat capacity of $TiB_2(c)$ has been determined by the following investigators:

Investigator	Method	Temperature Range
Westrum[1]	Adiabatic Calorimetry	5- 850°K.
Walker et al.[2]	Drop calorimeter	373- 977°K.
Southern Research Institute[3]	Drop type ice calorimeter	586-2689°K.
Mezaki[4]	Copper-block drop calorimeter	420-1180°K.
Prophet[5]	Arc-imaging furnace	1300-2150°K.
Barriault et al.[6]	Pulse-method	1733-2417°K.

[1] L. Kaufman and E. V. Clougherty, Technical Documentary Report No. RTD-TDR-63-4096 Part 1 p. 239 (Dec. 1963).

[2] B. E. Walker, C. T. Ewing, and R. R. Miller, J. Phys. Chem. 61, 1682 (1957).

[3] Southern Research Institute, Technical Documentary Report No. ASD-TDR-62-675 p. 253 (Jan. 1963).

[4] R. Mezaki, M. S. Thesis, University of Wisconsin (1961).

[5] H. Prophet, Annual Report for 1962 of the Dow Chemical Co. to ARPA under Contract AF 04(611)7554.

[6] R. J. Barriault et al., Thermodynamics of Certain Refractory Compounds, AVCO Corporation, report ASD-TR-61-260, Part I, Vol. 1, (May 1962).

The low temperature data of Westrum[1] and the medium range data of Walker et al.[2] were used to obtain the C_p's of this tabulation. Their data were fitted to a Shomate plot and extrapolated to 4000°K.

$S^\circ_{298.15}$ = 6.808 cal. deg.$^{-1}$ mole^{-1} was determined by Westrum[1].

Melting Data.

The melting point has been reported as 3063°, 3193°, and 3203°K. by F. W. Glaser, Trans. AIME 194, 391 (1952), B. Post, F. W. Glaser, and D. Moskowitz, Acta. Met. 2, 20 (1954), and by G. V. Samsonov and G. V. Petrash, Metallovedi Obrabotka Metalov No. 4, 19 (1955) respectively. The heat of melting is derived from an estimated ΔS_m = 2.5 cal. deg.$^{-1}$ g. atom^{-1} at 3193°K. It should be pointed out that an error of 0.5 cal. deg.$^{-1}$ g. atom^{-1} in the estimation of ΔS_m is 5 kcal. mole^{-1} in ΔH°_m.

Titanium Diboride (TiB_2)

Sept. 30, 1962; Dec. 31, 1962; June 30, 1965

TITANIUM DIBORIDE (TiB_2) (LIQUID) MOL. WT. = 69.522

$S^\circ_{298.15}$ = [13.455] cal. deg.$^{-1}$ mole^{-1}

T_m = 3193°K.

T_d = [4250]°K.

$\Delta H^\circ_{f\ 298.15}$ = [-44.99] kcal. mole^{-1}

ΔH°_m [24] kcal. mole^{-1}

<u>Heat of Formation</u>.

$\Delta H^\circ_{f\ 298.15}(l)$ was calculated from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_{Tm} and the difference between $\Delta H^\circ_{Tm}-H^\circ_{298.15}$ for crystal and liquid.

<u>Heat Capacity and Entropy</u>.

A glass transition is assumed at 2100°K. $C_p(l)$ at and below 2100°K. were assumed to be equal to those of $TiB_2(c)$. Above 2100°K. the heat capacities were estimated to be constant. $S^\circ_{298.15}(l)$ is calculated based on $S^\circ_{298.15}(c)$ and an estimated ΔS°_m = 2.5 cal. deg.$^{-1}$ gm. atom^{-1}.

<u>Melting Data</u>.

See $TiB_2(c)$ table for details.

<u>Decomposition Data</u>.

T_d estimated from ΔF°_{Td} = 0 for the reaction $TiB_2(l) = Ti(g) + 2B(g)$.

Sept. 30, 1962; Mar. 31, 1963; June 30, 1965

ZIRCONIUM DIBORIDE (ZrB_2)   (CRYSTAL)   MOL. Wt. = 112.842

$\Delta H^\circ_{f\ 0}$ = -76.8 ± 1.6 kcal. mole^{-1}

$S^\circ_{298.15}$ = 8.59 ± 0.01 cal. deg.$^{-1}$ mole^{-1} $\Delta H^\circ_{f\ 298.15}$ = -77.1 ± 1.6 kcal. mole^{-1}

T_m = 3323°K. ΔH°_m = [25] kcal. mole^{-1}

Heat of Formation.

G. K. Johnson, Argonne National Laboratory, private communication, May 1965, reported $\Delta H^\circ_{f\ 298}$ ($ZrB_{1.999\ \pm\ 0.006}$) = -78.7 ± 1.5 kcal. mole^{-1}. Their value was obtained by fluorine bomb calorimetry and was based on their recently redetermined value of $\Delta H^\circ_{f\ 298}(BF_3(g))$ = -271.80 ± 0.20 kcal. mole^{-1}.

G. M. Kibler, T. F. Lyon, M. J. Linevsky, and V. J. De Santis, General Electric Co., report No. WADD-TR-60-646, Part IV (August 1964) studied the vaporization of $ZrB_{1.931}$ by the Knudsen effusion method. Over the range 2260 to 2500°K., log K_p = 22.038 - $\frac{10.164 \times 10^4}{T}$ for the reaction $ZrB_{1.931}$ (c) = Zr (g) + 1.931 B (g). JANAF auxiliary data were used to calculate $\Delta H^\circ_{r\ 298}$ = 478.5 ± 1.5 kcal. mole^{-1} by the 3rd law method and $\Delta H^\circ_{f\ 298}$ ($ZrB_{1.931}$(c)) = -76.7 ± 3.2 kcal. mole^{-1}.

O. C. Trulson and H. W. Goldstein, Union Carbide Res. Inst., report No. C-25 (October 1964), investigated the decomposition vapor pressure of the reaction ZrB_2 (c) = Zr (g) + 2B (g) and reported $\Delta H^\circ_{f\ 298}$ (ZrB_2(c)) = -72.1 ± 5.3 kcal. mole^{-1}. They also reported $\Delta H^\circ_{r\ 298}$ = 289.7 kcal. mole^{-1} for the reaction ZrB_2(c) + C (c) = ZrC(c) + 2B (g). Using the JANAF $\Delta H^\circ_{f\ 298}$ (ZrC(c)) = -47.0 ± 3 kcal. mole^{-1}, $\Delta H^\circ_{f\ 298}$ (ZrB_2(c)) = -76.1 ± 3 kcal. mole^{-1} was calculated. JANAF values for $\Delta H^\circ_{v\ 298}$ B (g) and Zr (g) were not used since their independent determinations serve to cancel instrumental constants.

From oxygen bomb calorimetry, E. J. Huber, Jr., E. L. Head, and C. E. Holley, Jr., J. Phys. Chem. 68, 3040 (1964) reported $\Delta H^\circ_{f\ 298}$(ZrB_2(c)) = -77.2 ± 1.2 kcal. mole^{-1}.

$\Delta H^\circ_{f\ 298}$(ZrB_2(c)) = -77.1 ± 1.6 was chosen as a value representative of the above.

Heat Capacity and Entropy.

The heat capacity of ZrB_2(c) has been determined by the following investigators:

Investigator	Method	Temperature Range
Westrum and Feick[1]	Adiabatic calorimetry	5- 350°K.
Valentine et al.[2]	Copper-block drop calorimeter	410-1125°K.
Mezaki[3]	Copper-block drop calorimeter	430-1170°K.
Prophet[4]	Arc-imaging furnace	1300-2150°K.
Barriault et al.[5]	Pulse-method	1740-2520°K.
Southern Research Institute[6]	Drop type ice calorimeter	500-2500°K.

[2] R. H. Valentine, T. F. Jambois, and J. L. Margrave, J. Chem. Eng. Data 9(2), 182 (1964).

[3] R. Mezaki, M. S. Thesis, University of Wisconsin (1961).

[4] H. Prophet, Annual Report for 1962 of the Dow Chemical Co. to ARPA under Contract AF 04(611)7554.

[5] R. J. Barriault et al., Thermodynamics of Certain Refractory Compounds, AVCO Corporation, report ASD-TR-61-260, Part I, Vol. 1, (May 1962).

[6] D. Neel, C. Pears, and S. Oglesby, Southern Research Institute, report ASD-TRD-62-675 (August 1962).

Westrum and Feick's[1] C_p values were adopted to 350°K. The disparities in heat capacities above room temperatures seem too great to be errors in measurement and are probably due to sample differences. Since the samples used by Westrum and Feick[1] and by Valentine et al.[2] were from the same batch, Valentine's data were used above 350°K. The two sets of data were fitted to a Shomate plot which was extrapolated to 4000°K. However, in consideration of the results of Mezaki[3], Prophet[4] and Southern Research Institute[6], the C_p extrapolation ran somewhat higher than a direct extrapolation of Valentine's data would yield.

$S^\circ_{298.15}(ZrB_2)$ = 8.59 cal. mole^{-1} °K.$^{-1}$ was determined by Westrum[1].

Melting Data.

The melting point has been reported as 3313°, 3323°, and 3265°K. by F. Glaser and B. Post, J. of Metals, 5, 1117 (1953), B. Post, F. Glaser, and D. W. Moskowitz, Acta. Met. 2, 70 (1954) and H. Greenwood, Engineer 187, 349 (1949) respectively. The heat of melting is derived from an estimated ΔS_m = 2.5 cal. deg.$^{-1}$ g. atom^{-1} at 3323°K. It should be pointed out that an error of 0.5 cal. deg.$^{-1}$ g. atom^{-1} in the estimation of ΔS_m is 5 kcal. mole^{-1} in ΔH°_m.

Sept. 30, 1962; Dec. 31, 1962; June 30, 1965

ZIRCONIUM DIBORIDE (ZrB_2) (LIQUID) MOL. WT. = 112.842

$S^\circ_{298.15}$ = [15.448] cal. deg.$^{-1}$ mole^{-1}

T_m = 3323°K.

T_d = [4466]°K.

$\Delta H^\circ_{f\ 298.15}$ = [-54.194] kcal. mole^{-1}

ΔH°_m = [25] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}(l)$ was calculated from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_{Tm} and the difference between $\Delta H^\circ_{Tm}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition is assumed at 2200°K. $C_p(l)$ at and below 2200°K. were assumed to be equal to those of $ZrB_2(c)$. Above 2200°K. the heat capacities were estimated to be constant. $S^\circ_{298.15}$ (c) and an estimated ΔS°_m = 2.5 cal. deg.$^{-1}$ gm. atom^{-1}.

Melting Data.

See $ZrB_2(c)$ table for details.

Decomposition Data.

T_d estimated from ΔF°_{Td} = 0 for the reaction $ZrB_2(l) = Zr(g) + 2B(g)$.

Bond Distance: B-Cl = [1.75]Å B-O = [1.36]Å

Bond Angle: Cl-B-O = [120°] B-O-B = [120°] $\sigma = 6$

Product of the Moments of Inertia: $I_AI_BI_C = [1.86850 \times 10^{-111}]$ g.^{3} cm.^{6}

Heat of Formation.

The equilibrium constants for the reaction $B_2O_3(l) + BCl_3(g) = (BOCl)_3(g)$ were determined in the temperature range 536-825°K. by a transpiration method by J. Blauer and M. Farber, J. Chem. Phys. 39, 158 (1963); and in the temperature range 1234-1309°K. by an effusion method by the same investigators, Trans. Faraday Soc. 60, 301 (1964). Using the reported equilibrium constants, the enthalpy changes for this reaction were evaluated by both the second and third law methods. The results obtained are given in the following table.

Method Used	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H^\circ_{f\ 298.15}$* kcal. mole^{-1}
Transpiration	5.31	5.07 ± 0.4	-390 ± 2
Effusion	12.57	5.85 ± 3.3	-386 ± 3

*Based on the third law values

By a mass spectroscopic method the enthalpy change, $\Delta H^\circ_{r\ 1000} = 16.6 \pm 2.5$ kcal. mole^{-1}, for the reaction $BCl_3(g) + B_2O_3(l) = (BOCl)_3(g)$ was determined by R. F. Porter and S. K. Gupta, J. Phys. Chem. 68, 280 (1964). The $\Delta H^\circ_{f\ 298.15}$ value for $(BOCl)_3(g)$ was derived as -377 ± 3 kcal. mole^{-1}. However, it is possible that the intensity of $B_3O_3Cl_3^+$, employed to plot the ion ratios $I(B_3O_3Cl_3^+)/I(BCl_2^+)$ versus $\frac{1}{T}$, does not fully reflect the concentration of $B_3O_3Cl_3$ especially at the highest temperatures, due to changes in the fragmentation pattern with temperature.

The value of $\Delta H^\circ_{f\ 298.15}$ adopted for $(BOCl)_3(g)$ is -390 ± 2 kcal. mole^{-1} derived from transpiration data. The effusion data were measured in the temperature range where Porter and Gupta, loc. cit. found the presence of $(BOCl)_4(g)$. However, this point was not taken into consideration in the report. Hence, the corresponding $\Delta H^\circ_{f\ 298.15}$ value was not adopted.

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with related molecules such as $B_3O_3F_3(g)$ and $(BH_2O)_3(g)$. The B-Cl bond distance was assumed to be the same as that in $BCl_3(g)$. The B-O bond distance and all bond angles were estimated. The three principal moments of inertia are: $I_A = I_B = 9.77585 \times 10^{-38}$ and $I_C = 1.95517 \times 10^{-37}$ g. cm.^{2}

Heat of Formation.

The equilibrium constants (K), 1246-1326°K, for the two reactions $2B_3O_3F_2H(g) = B_3O_3FH_2(g) + B_3O_3F_3(g)$ and $2B_3O_3FH_2(g) = B_3O_3H_3(g) + B_3O_3F_2H(g)$ were reported by F. R. Porter and W. P. Sholette, J. Chem. Phys. 37, 198 (1962). The $\Delta H^\circ_{f\ 298.15}$ for $B_3O_3H_2F(g)$ adopted was evaluated by use of K values slightly outside the ranges given by Porter and Sholette. See the table for $B_3O_3F_2H(g)$ for details.

Heat Capacity and Entropy.

The structure was assumed to be a planar six membered ring structure of C_{2v} symmetry, which has 21 vibrations of the type $8A_1$, $7B_1$, $2A_2$, and $4B_2$. These frequencies were estimated from the values for boroxin and trifluoroboroxin, the symmetry being reduced from D_{3h} as follows: $3A_1' \rightarrow 3A_1$, $2A_2' \rightarrow 2B_1$, $5E' \rightarrow 5A_1 + 5B_1$, $2A_2 \rightarrow 2B_2$ and $2E'' \rightarrow 2A_2 + 2B_2$.

The B-F distance was taken as approximately equal to that in $(CH_3)_2O\cdot BF_3$ reported by S. H. Bauer, G. R. Findlay and A. W. Laubengayer, J. Am. Chem. Soc. 67, 339 (1945). The other bond lengths and angles were taken equal to those in boroxin. The individual moments of inertia were calculated to be $I_A = 32.995 \times 10^{-39}$, $I_B = 13.973 \times 10^{-39}$, and $I_C = 46.968 \times 10^{-39}$ g. cm.^{2}

Heat of Formation.

The stabilities of gaseous boroxin ($B_3O_3H_3$) and its fluoro derivatives have been studied by R. F. Porter and W. P. Sholette, J. Chem. Phys. 37, 198 (1962). From the mass spectra of the gaseous reaction products generated by reaction of an H_2-BF_3 mixture on B_2O_3 at 1250°K., the equilibrium constants (K) for the following proposed reactions were reported.

	Reaction	Temperature, °K.	K	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1}
(1)	$H_2(g) + B_3O_3F_3(g) = HF(g) + B_3O_3F_2H\ (g)$	1246 - 1326	4.2 X 10^{-3} - 2.3 X 10^{-2}	20.45 - 17.17
(2)	$2B_3O_3F_2H(g) = B_3O_3FH_2(g) + B_3O_3F_3(g)$	1246 - 1326	0.62 - 0.46	1.28 - 2.15
(3)	$2B_3O_3FH_2(g) = B_3O_3H_3(g) + B_3O_3F_2H(g)$	1246 - 1326	1.0 - 0.63	-2.56 - -1.51

Using these reported K values the corresponding enthalpy changes ($\Delta H_r^\circ{}_{298.15}$) were evaluated by the third law method. The results obtained are listed in the above table. Based on $\Delta H_f^\circ{}_{298.15}$ = -565.3 and -64.8 kcal. mole^{-1} for $B_3O_3F_3(g)$ and HF(g), respectively, the value of $\Delta H_f^\circ{}_{298.15}$ for $B_3O_3F_2H(g)$ was calculated from Reaction (1) as -482 kcal. mole^{-1}. From Reaction (2), the $\Delta H_f^\circ{}_{298.15}$ value for $B_3O_3FH_2(g)$ was calculated as -397 kcal. mole^{-1}. However, employing $\Delta H_f^\circ{}_{298.15}(B_3O_3H_3,\ g)$ = -291 kcal. mole^{-1}, the values of $\Delta H_f^\circ{}_{298.15}$ for $B_3O_3FH_2(g)$ and $B_3O_3F_2H(g)$ thus obtained do not fit properly for Reaction (3). Therefore the $\Delta H_f^\circ{}_{298.15}$ for $B_3O_3FH_2(g)$ and $B_3O_3F_2H(g)$ adopted were evaluated by use of K values slightly outside the ranges given by Porter and Sholette.

Heat Capacity and Entropy.

The vibrational frequencies were obtained by comparison with $B_3O_3F_3(g)$ and $B_3H_3O_3(g)$. The types of vibration and symmetry are identical to those given for $B_3O_3H_2F(g)$. The bond angles and lengths were taken equal to those for $B_3O_3H_2F(g)$. The individual moments of inertia were calculated to be I_A = 22.051 X 10^{-39}, I_B = 48.659 X 10^{-39} and I_C = 70.710 X 10^{-39} g. cm.^{2}

Sept. 30, 1962; Mar. 31, 1965

BORON OXIDE FLUORIDE, TRIMERIC $((BOF)_3)$ (CRYSTAL) MOL. WT. = 137.46

$S^\circ_{298.15}$ = [52] cal. deg.$^{-1}$ mole^{-1}

T_m = 353°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -586.5 ± 3.0 kcal. mole^{-1}

ΔH°_m = Unknown

$\Delta H^\circ_{s\ 298.15}$ = 21.2 ± 3.2 kcal. mole^{-1}

Heat of Formation.

The heats of solution of the compounds: $B_2O_3(gl)$, $BF_3(g)$ and $(BOF)_3(c)$ in water and methanol, respectively, were reported by E. M. Magee, J. Inorg. Nucl. Chem. 22, 156 (1961). The corresponding enthalpy changes for the reaction $B_2O_3(gl) + BF_3(g) = (BOF)_3(c)$ were derived as -19.8 and -14.4 kcal. mole^{-1}, yielding $\Delta H^\circ_{f\ 298.15}$ for $(BOF)_3(c)$ -589.18 and -583.78 kcal. mole^{-1}, respectively. The adopted value of $\Delta H^\circ_{f\ 298.15}$ for $(BOF)_3(c)$ is the average of these two values obtained.

Heat Capacity and Entropy.

The heat capacities (C_p) for $(BOF)_3(c)$ were estimated from the C_p values for $B_2O_3(c)$ and $BF_3(g)$, according to the method suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry", Pergamon Press, New York, 1958. $S^\circ_{298.15}$ for $(BOF)_3(c)$ was estimated by E. M. Magee, loc. cit.

Melting Data.

The value of T_m was reported by E. M. Magee, loc. cit.

Heat of Sublimation.

The heat of sublimation ($\Delta H^\circ_{s\ 298.15}$) for $(BOF)_3(c)$ is calculated as the difference between $\Delta H^\circ_{f\ 298.15}$ for crystal and gas.

Bond Distance: B-F = [1.3] Å B-O = [1.36] Å

Bond Angle: F-B-O = [120°] B-O-B = [120°] O-B-O = [120°] σ = 6

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.9254 X 10^{-112}]g.^{3} cm.^{6}

Heat of Formation.

The enthalpy changes (ΔH°_r) of the reaction $B_2O_3(l) + BF_3(g) = (BOF)_3(g)$ were derived by both the second and third law methods, using the equilibrium constant data reported by several investigators. The results are given as follows.

Investigator	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H^\circ_{f\ 298.15}$* kcal. mole^{-1}
Hildenbrand, et al.[1]	4.06	4.01 ± 0.3	-565.32 ± 1.0
Fisher, et al.[2]	3.41	6.45 ± 0.6	-565.97 ± 1.5

[2] H. D. Fisher, J. Kiehl and A. Cane, Report HTC-61-90, June 1961, Hughes Tool Company, Culver City, California

[3] D. D. Smith and R. W. Lawrence, Aerojet Report No. 1952, February 1961, Aerojet-General Corporation.

[4] M. Farber, J. Chem. Phys. 36, 661 (1962). The first $\Delta H^\circ_{r\ 298.15}$ value was evaluated based on K_{1000} = 11.8. The second $\Delta H^\circ_{r\ 298.15}$ values refer to the reaction $B_2O_3(c) + BF_3(g) = (BOF)_3(g)$.

[5] R. F. Porter, D. R. Bidinosti and K. F. Watterson, J. Chem. Phys. 36, 2104 (1962). The $\Delta H^\circ_{r\ 298.15}$ value was derived from $\Delta H^\circ_{r\ 700}$ = 3.46 ± 0.30 kcal. mole^{-1}.

The adopted value of $\Delta H^\circ_{f\ 298.15}$ for $(BOF)_3(g)$ is the weighted average of the six $\Delta H^\circ_{f\ 298.15}$ values listed above.

Heat Capacity and Entropy.

The infra-red spectrum has been reported by D. D. Smith and R. L. Lawrence, loc. cit., and by H. D. Fisher, W. J. Lehmann, and I. Shapiro, J. Phys. Chem. 65, 1166 (1961) who also made a partial assignment. The unassigned bands at 1280 and 1233 from Fisher, et al., can be assigned to the A_2' and A_1' species which may be observed if the selection rules are not rigorously obeyed in the solid. All the unobserved frequencies were estimated by comparison with $B_3O_3(OH)_3$, $B_3O_3(OD)_3$ from J. L. Parsons, J. Chem. Phys. 33, 1860 (1960) and $B_3O_3H_3$ and $B_3O_3D_3$ from S. K. Gupta and R. F. Porter, J. Phys. Chem. 67, 1286 (1963) and G. H. Lee, W. H. Bauer and S. E. Wiberley, J. Phys. Chem. 67, 1742 (1963). The D_{3h} assumed symmetry has 14 vibrations of the type $3A_1'$, $2A_2'$, 5E', $2A_2''$ and 2E" which are given in order above. The B-F bond distance was assumed to be the same as that in BF_3. The B-O bond distance was estimated by comparison with other related compounds. The three principal moments of inertia are: $I_A = I_B$ = 4.5832 X 10^{-38} and I_C = 9.1664 X 10^{-38} g. cm.^{2}

BOROXIN ($B_3O_3H_3$) **(CRYSTAL)** **MOL. WT. = 83.484**

$S^\circ_{298.15}$ = [40 ± 10] cal. deg.$^{-1}$ mole^{-1}

T_m = Unknown

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -301.7 ± 10 kcal. mole^{-1}

ΔH°_m = Unknown

$\Delta H^\circ_{s\ 298.15}$ = 10.7 ± 0.5 kcal. mole^{-1}

Heat of Formation.

The value of $\Delta H^\circ_{f\ 298.15}$ for $B_3O_3H_3$(c) was calculated from the $\Delta H^\circ_{f\ 298.15}$ for $B_3O_3H_3$(g) and $\Delta H^\circ_{s\ 298.15}$ for $B_3O_3H_3$(c) reported by R. F. Porter and S. K. Gupta, J. Phys. Chem. 68, 280 (1964).

Heat Capacity and Entropy.

The heat capacities (C_p) were estimated from those for B_2O_3(c) and 1/2 B_2H_6(g), according to the method suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry", Pergamon Press, New York, 1958. The value of $S^\circ_{298.15}$ for $B_3O_3H_3$(c) was calculated based on $\Delta S^\circ_{r\ 298.15}$ = 6.6 cal. deg.$^{-1}$ mole^{-1} for the reaction $B_3O_3H_3$(c) = B_2O_3(am) + 1/2 B_2H_6(g), which was obtained from the calculated $\Delta H^\circ_{r\ 298.15}$ and measured $\Delta F^\circ_{r\ 298.15}$ evaluated from the vapor pressure reported by W. P. Sholette and R. F. Porter, J. Phys. Chem. 67, 177 (1963).

Heat of Sublimation.

$\Delta H^\circ_{s\ 298.15}$ was taken from R. F. Porter and S. K. Gupta, loc. cit.

Bond Angle: B-O-B = [120°] O-B-H = [120°]

σ = [6]

Product of the Moments of Inertia: $I_AI_BI_C$ = [5.4563] X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

The equilibrium constants (1290-1481°K.) for the reaction (1) $3/2\ H_2(g) + B(am) + B_2O_3(l) = B_3O_3H_3(g)$ were determined by W. P. Sholette and R. F. Porter, J. Phys. Chem. 67, 177 (1963). The equilibrium pressures of $B_2H_6(g)$ and $B_3O_3H_3(g)$ for the reaction (2) $B_3O_3H_3(g) = 1/2\ B_2H_6(g) + B_2O_3(c)$ were measured at 300°K. by R. F. Porter and S. K. Gupta, J. Phys. Chem. 68, 280 (1964). The equilibrium constants (1246-1326°K.) for the reaction (3) $2B_3O_3FH_2(g) = B_3O_3H_3(g) + B_3O_3F_2H(g)$ were reported by R. F. Porter and W. P. Sholette, J. Chem. Phys. 37, 198 (1962). Using these data the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Reaction	$\Delta H_r^\circ{}_{298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H_f^\circ{}_{298.15}$* kcal. mole^{-1}
(1)	-5.90	+6.52 ± 4.5	-304.0 ± 5.0
(2)**	-11.11	——	-287.6 ± 2.0
	-12.21	——	-282.5 ± 2.0
(3)	-2.0	——	-314 ± 12.0

*Calculation based on the third law values.

**The initial system for the first set of measurements was $B_2H_6(g) + B(OH)_3(c)$. That for the second set was $B_2H_6(g) + B_2O_3(gl)$.

The value of $\Delta H_f^\circ{}_{298.15}$ for $B_3O_3H_3(g)$ adopted is a weighted average of these $\Delta H_f^\circ{}_{298.15}$ values listed.

Heat Capacity and Entropy.

The infra-red spectrum of solid boroxin has been determined by S. K. Gupta and R. F. Porter, J. Phys. Chem. 67, 1286 (1963) and a partial assignment was made. The infra-red spectra of the gas has also been reported by G. H. Lee, W. H. Bauer, and S. E. Wiberley, J. Phys. Chem. 67, 1742 (1963) and is in essential agreement with the solid. The assignment of the frequencies has been changed slightly due to the non-appearance of the band at 1115 cm.$^{-1}$ in the gas phase. The assumed D_{3h} symmetry has 14 vibrations of the type $3A_1'$, $2A_2'$, $5E'$, $2A_2''$, and $2E''$, the 7 estimated frequencies were obtained by comparison with $B_3O_6H_3$, by J. L. Parsons, J. Chem. Phys. 33, 1860 (1960).

The point group, bond angles and bond lengths were assumed to be the same as for $(BOF)_3(g)$. The B-H bond length was taken as the sum of the single covalent radii of the atoms. The individual moments of inertia were calculated to be $I_A = I_B = 13.973 \times 10^{-39}$, and $I_C = 27.949 \times 10^{-39}$ g.^{3} cm.^{6}

The equilibrium constant, $K_{p\ 1451} = 0.9$, for the reaction $H_3BO_3(l) + B_2O_3(l) = (HBO_2)_3(g)$ was reported by D. J. Meschi, W. A. Chupka and J. Berkowitz, J. Chem. Phys. 33, 530 (1960), which was determined by means of mass spectrometry. The equilibrium constants of the reactions between water vapor and liquid B_2O_3 were determined at 1147°K. by J. A. Blauer and M. Farber, J. Phys. Chem. 68, 2357 (1964), by use of a transpiration method. From the reported value, $1.5\ K_2 + 0.5\ K_3 = 0.0342 \pm 0.0095$, the equilibrium constant, K_2, for the reaction $1.5\ B_2O_3(l) + 1.5\ H_2O(g) = (HBO_2)_3(g)$ was derived as 0.0168, using $K_3 = 0.0181$ for the reaction $0.5\ B_2O_3(l) + 1.5\ H_2O(g) = H_3BO_3(g)$ evaluated by use of JANAF values of ΔF°_f for $B_2O_3(l)$, $H_2O(g)$ and $H_3BO_3(g)$. Employing the equilibrium constants obtained the respective enthalpy changes ($\Delta H^\circ_{r\ 298.15}$) for the two reactions were calculated by the third law method. The corresponding values of $\Delta H^\circ_{f\ 298.15}$ for $(HBO_2)_3(g)$ were also derived. The results are presented as follows.

Investigator	Chemical Reaction	$\Delta H^\circ_{r\ 298.15}$ kcal. mole^{-1}	$\Delta H^\circ_{f\ 298.15}$ kcal. mole^{-1}
Meschi, et al.	$H_3BO_3(l) + B_2O_3(l) = (HBO_2)_3(g)$	-7.31	-543.8
Blauer and Farber	$1.5\ B_2O_3(l) + 1.5\ H_2O(g) = (HBO_2)_3(g)$	-6.67	-542.3

The adopted value of $\Delta H^\circ_{f\ 298.15}$ for $(HBO_2)_3(g)$ is the average of these two listed in the above table. The equilibrium constants for the same reactions between $B_2O_3(l)$ and $H_2O(g)$ were also determined by a transpiration method in the temperature region 1000°-1273°K. by S. P. Randall and J. L. Margrave, J. Inorg. Nucl. Chem. 16, 29 (1960). The reported value, $\Delta H^\circ_{f\ 0} = -537.5 \pm 3$ kcal. mole^{-1} for $(HBO_2)_3(g)$, is in good agreement with the value adopted.

Heat Capacity and Entropy.

All the molecular and spectroscopic constants were estimated by D. White, D. E. Mann, P. N. Walsh and A. Sommer, J. Chem. Phys. 32, 488 (1960). The three principal moments of inertia are: $I_A = I_B = 4.4623 \times 10^{-38}$ and $I_C = 8.9247 \times 10^{-38}$ g. cm.^{2} The infrared absorption spectra for $B_3O_3(OH)_3(c)$ in the 430 to 4000 cm.$^{-1}$ was reported by L. J. Parsons, J. Chem. Phys. 33, 1860 (1960). A partial Raman spectrum was also given.

Bond Distance: B-N = 1.44 Å B-H = 1.20 Å H-N = 1.02 Å

Bond Angle: N-B-N = 120° B-N-B = 120° N-B-H = 120° $\sigma = 6$

Product of Moments of Inertia: $I_AI_BI_C = 8.3303 \times 10^{-14}$ g.^{3} cm.^{6}

Heat of Formation.

The heat of combustion for the reaction $B_3N_3H_6(l) + 15/4\ O_2(g) + 3/2\ H_2O(l) = 3\ H_3BO_3(c) + 3/2\ N_2(g)$ was reported to be -552.9 ± 3.0 kcal. mole^{-1} by M. V. Kilday, W. H. Johnson and E. J. Prosen, J. Res. Natl. Bur. Std. 65 A, 101 (1961). $\Delta H^\circ_{f\ 298.15}\ H_2O(l) = -68.317$ kcal. mole^{-1} from Natl. Bur. Std. Circ. 500, "Selected Values of Chemical Thermodynamic Properties", 1952 and $\Delta H^\circ_{f\ 298.15}\ H_3BO_3(c) = -261.47$ kcal. mole^{-1} from JANAF tables were used to calculate $\Delta H^\circ_{f\ 298.15}\ B_3N_3H_6(l) = -129.0 \pm 3.0$ kcal. mole^{-1}. Vapor pressure data on $B_3N_3H_6(l)$ reported by A. Stock and E. Pohland, Ber. 59, 2215 (1926) were fitted to a linear least squares. $\Delta C_p(l\text{-}g)$ for borazine was approximated by benzene to calculate a 2nd law $\Delta H_{v\ 298} = 7.1 \pm 0.1$ kcal. mole^{-1}.

Heat Capacity and Entropy.

The fundamental frequency assignment was made by B. L. Crawford, Jr. and J. T. Edsall, J. Chem. Phys. 7, 223 (1939). The three frequencies enclosed by brackets are calculated values. The moments of inertia were calculated from molecular constants given by S. H. Bauer, J. Am. Chem. Soc. 60, 524 (1938). The three principal moments of inertia are: $I_A = I_B = 16.09 \times 10^{-39}$ and $I_C = 32.18 \times 10^{-39}$ g. cm.^{2}.

March 31, 1963

DIPOTASSIUM TETRABORATE $(K_2B_4O_7)$ (CRYSTAL) MOL. WT. = 233.44

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [49.8 ± 1.5] cal. deg.$^{-1}$ mole^{-1} $\Delta H_f^\circ{}_{298.15}$ = -796.9 kcal. mole^{-1}

T_m = 1088°K. ΔH_m = 24.9 ± 1 kcal. mole^{-1}

Heat of Formation.

$\Delta H_f^\circ{}_{298.15}$ was recalculated from the experimental data of L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954). They studied the heat of solution of various alkali borates in 2N nitric acid. Average molecular weights were used for physical mixtures of the oxides B_2O_3 and R_2O (where R is either Li, Na, or K) rather than for the borate compounds $R_2O \cdot nB_2O_3$ present. These incorrect molecular weights led to spurious correlations and faulty conclusions. In reinterpreting the data, the steps followed were: (1) The calculation of the correct molecular weights and molar heats of reaction; (2) The establishment that the heat of formation of the borates from the oxides is linear with the mole fraction of B_2O_3 in the total original moles of oxides for the reactions

$R_2O(c) + nB_2O_3(gl) \rightarrow R_2O \cdot nB_2O_3(gl)$ (I)

and $R_2O(c) + nB_2O_3(gl) \rightarrow R_2O \cdot nB_2O_3(c)$ (II)

with the heat of formation being zero at 100 percent R_2O; (3) The evaluation of the least square fit of the line through the heat of reaction data for reaction I and for reaction II; (4) The use of the proper weighting factors in applying least squares to adjust for both the sample size and the molecular weight of the mixture of borates used in each solution experiment.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic. 59-2916, in the range 298-973°K were smoothed graphically and were used to obtain a smooth set of C_p data. The heat capacity was extrapolated smoothly above this region. The entropy at 298°K was estimated from that of $Na_2B_4O_7(c)$ by using an average entropy change of 4.5 ± 1.5 cal. deg.$^{-1}$ mole^{-1} on substituting Na_2 by K_2.

Melting Data.

T_m was given by A. P. Rollet, Comp. Rend. 200, 1763 (1935). The heat of melting was obtained from the heats of formation of the crystal and glass at 298°K combined with the enthalpy differences between 298 and 1088°K. This involves a slight extrapolation of the crystal data and an uncertainty of about 1.0 kcal. mole^{-1}.

March 31, 1963

DIPOTASSIUM TETRABORATE ($K_2B_4O_7$) (LIQUID) MOL. WT. = 233.44

$S^\circ_{298.15}$ = [56.7 ± 2.5] cal. deg.$^{-1}$ mole^{-1}

T_m = 1088°K.

ΔH_f° 298.15 = -786.1 kcal. mole^{-1}

ΔH_m = 24.9 ± 1 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from reaction (1) given on the crystal table.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1373°K on the glass and liquid were smoothed graphically and used to determine C_p. There is a discontinuity (glass transition) in the C_p curve at 676°K. Above 1373°K the C_p values were extrapolated smoothly.

The entropy at 298°K was obtained from that of the crystal by adding ΔS_m° and the difference between S_{1088}-S_{298} for crystal and liquid.

Melting Data.

See the crystal table.

Mar. 31, 1962; Dec. 31, 1962; June 30, 1965

DILITHIUM TETRABORATE ($Li_2B_4O_7$) (CRYSTAL) MOL. WT. = 169.1178

$\Delta H_f^\circ{}_0$ = Unknown

$S_{298.15}^\circ = [37.2 \pm 1.0]$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = -803.6 \pm 1.5$ kcal. mole^{-1}

$T_m = 1190 \pm 2$°K.

$\Delta H_m^\circ = 28.8 \pm 1.5$ kcal. mole^{-1}

Heat of Formation.

The heat of formation was calculated from $\Delta H_r^\circ{}_{298} = -12.2$ kcal. for the reaction $Li_2B_4O_7(c) + 2HNO_3(aq.) + 5H_2O(l) = 4H_3BO_3(aq.) + 2LiNO_3(aq.)$. The heat of solution ($\Delta H_r^\circ$) was interpolated from the heat of solution data of L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27 (1954). Auxilliary data are from National Bureau of Standards Circular 500 (1952).

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph. D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1190°K. were smoothed graphically and used to determine C_p. A linear extrapolation of C_p was used from 1190 to 2000°K.

S_{298}° was estimated by three routes: (1) S_{298}° ($Li_2B_4O_7$) = 37.3 cal. mole^{-1} deg.$^{-1}$ based on JANAF S_{298}° ($Na_2B_4O_7$) = 45.3 and ΔS_{298}° (2Na-2Li) = 8 cal. deg.$^{-1}$ from W. M. Latimer, J. Am. Chem. Soc. 73, 1480 (1951); (2) S_{298}° ($Li_2B_4O_7$) = 36.7 cal. mole^{-1} deg.$^{-1}$ in a similar manner based on ΔS_{298}° ($2Na^+-2Li^+$) = 8.6 cal. deg.$^{-1}$ from K. K Kelley, Bureau of Mines, private communication, June 1960; and (3) S_{298}° ($Li_2B_4O_7$) = 37.6 cal. mole^{-1} deg.$^{-1}$ based on addition of the JANAF entropies for $2LiBO_2$ and B_2O_3. The value adopted is an average of these estimates.

Melting Data.

The value for T_m is from B. S. R. Sastry and F. A. Hummel, J. Am. Chem. Soc. 42, 216 (1959). A. P. Rollet and R. Bouaziz, Compt. rend. 240, 2417 (1955) earlier reported T_m = 1188°K. ΔH_m = 28.8 kcal. mole^{-1} is from G. S. Smith loc. cit.

Mar. 31, 1962; Dec. 31, 1962; June 30, 1965

DILITHIUM TETRABORATE ($Li_2B_4O_7$) (LIQUID) MOL. WT. = 169.1178

$S^\circ_{298.15}$ = [41.564 ± 1.5] cal. deg.$^{-1}$ mole^{-1}

T_m = 1190 ± 2°K.

$\Delta H^\circ_{f\ 298.15}$ = -792.79 ± 1.5 kcal. mole^{-1}

ΔH°_m = 26.3 ± 1.5 kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}(l)$ was calculated from $\Delta H^\circ_{f\ 298.15}(c)$ by adding $\Delta H^\circ_{T_m}$ and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph. D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1373°K. were smoothed graphically and used to determine C_p. The C_p data have a discontinuity at about 756°K. A linear extrapolation of C_p was used from 1373 to 3000°K.

The entropy at 298°K. is set so that ΔF is equal at T_m for the crystal and liquid.

Melting Data.

See crystal table for details.

MAGNESIUM TETRABORIDE (MgB_4) (CRYSTAL) MOL. WT. = 67.60

$\Delta H_f^\circ{}_0 = -25.0 \pm 2.0$ kcal. mole^{-1}

$S^\circ_{298.15} = 12.41 \pm 0.06$ cal. deg.$^{-1}$ mole^{-1} $\Delta H_f^\circ{}_{298.15} = -25.1 \pm 2.0$ kcal. mole^{-1}

$T_d = [1100]$°K.

Heat of Formation.

The equilibrium pressures (1169-1177°K.) of the reaction $MgB_4(c) \rightarrow Mg(g) + 4B(c)$ were measured by M. Wright and P. N. Walsh, "The Vaporization of $MgB_4(c)$", Technical Research Report OMCC-HEF-55, Jan. 9, 1958, Ohio State University Research Foundation. The third law value of $\Delta H_r^\circ{}_{298.15}$ for this reaction was derived as 60.40 ± 1.5 kcal. mole^{-1}. This leads to a $\Delta H_f^\circ{}_{298.15} = -25.1 \pm 2.0$ kcal. mole^{-1} for $MgB_4(c)$. The unit of equilibrium pressures reported should be in atmosphere not in mm Hg as printed. The diameter of the hole drilled through the center of the lid served as the effusion orifice should be 1/16 inch rather than the reported value 1/6 inch.

Heat Capacity and Entropy.

The low temperature (17.34-299.53°K.) heat capacities were measured by R. M. Swift and D. White, J. Am. Chem. Soc. 79, 3641 (1957). Above 298.15°K. the C_p values were estimated by comparison with those of other related borides. $S^\circ_{298.15}$ was reported by R. M. Swift and D. White, loc. cit., using S°_{20}(extrap.) = 0.022 cal. deg.$^{-1}$ mole^{-1}.

Temperature of Decomposition.

T_d was estimated from the decomposition reaction reported by M. Wright and P. N. Walsh, loc. cit.

DISODIUM TETRABORATE ($Na_2B_4O_7$) (CRYSTAL) MOL. WT. = 201.262

$S^\circ_{298.15}$ = 45.289 cal. deg.$^{-1}$ mole^{-1}

T_m = 1015.6°K

$\Delta H^\circ_{f\ 0}$ = -778.91 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -783.16 ± 2.0 kcal. mole^{-1}

ΔH°_m = 19.4 ± 1.5 kcal. mole^{-1}

Heat of Formation.

The heat of the reaction $Na_2O(c) + 2B_2O_3(l) \rightarrow Na_2B_4O_7(c)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $Na_2O(c)$ (June 30, 1962). The above ΔH°_r = -85.2 kcal. mole^{-1}.

Heat Capacity and Entropy.

In the low temperature region (5-344°K) the C_p values are those determined by E. F. Westrum, Jr., and G. Grenier, J. Am. Chem. Soc. 79, 1799 (1957). The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1015.6°K were smoothed graphically and used to determine C_p; the values did not join smoothly with those of Westrum and Grenier and the low temperature values were given greater weight. Above T_m the heat capacity was extrapolated. $S^\circ_{298.15}$ was derived from low temperature heat capacities.

Melting.

The value for T_m is from G. W. Morey and H. E. Merwin, J. Am. Chem. Soc. 58, 2248 (1936). Other reported values for T_m are: 1008 ± 5°K by S. S. Coles, S. R. Scholes, and C. R. Amberg, J. Am. Ceram. Soc. 18, 58 (1935); 1011°K by H. Menzel, Z. anorg. Chem., 224, 1 (1935); 1005°K by J. F. Ponomareff, Z. anorg. Chem. 89, 383 (1924); 1015°K by A. L. Day and E. T. Allen, "The Isomorphism and Thermal Properties of the Feldspars", Carnegie Inst. of Washington, Publ. No. 31 (1905) p. 29; and 1064°K by C. H. Burgess and A. Holt, Proc. Roy. Soc. (London) 74, 285 (1904). ΔH°_m was obtained from the values of ΔH°_f for $Na_2B_4O_7(c)$ and $Na_2B_4O_7(l)$ at 298°K as described above and the difference between $H_{1015}-H_{298}$ for crystal and liquid.

DISODIUM TETRABORATE ($Na_2B_4O_7$) (LIQUID) MOL. WT. = 201.262

$S^\circ_{298.15}$ = 47.513 ± 1.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 1015.6°K.

ΔH_f° 298.15 = -778.36 ± 2.0 kcal. mole^{-1}

ΔH_m° = 19.4 ± 1.5 kcal. mole^{-1}

Heat of Formation.

The heat of reaction $Na_2O(c) + 2B_2O_3(l) \rightarrow Na_2B_4O_7(l)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $Na_2O(c)$ (June 30, 1962). The above ΔH_r° = -80.4 kcal. mole^{-1}.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916, in the range 298 to 1373°K, were smoothed graphically and used to determine C_p. These were joined smoothly with the low temperature data of E. F. Westrum and G. Grenier, J. Am. Chem. Soc. 79, 1799 (1957). At 743°K a glass transition was observed and above this temperature the C_p adopted as constant.

The entropy at 298°K obtained from that of the crystal by adding ΔS_m° and the difference between $S_{1015}-S_{298}$ for crystal and liquid.

Melting.

See the crystal for details.

LEAD TETRABORATE (PbB_4O_7) (CRYSTAL) MOL. WT. = 362.49

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [39.9 ± 3] cal. deg.$^{-1}$ mole^{-1} $\Delta H_f^\circ{}_{298.15}$ = -683 ± 1.5 kcal. mole^{-1}

Heat of Formation.

See lead diborate table for the complete writeup. W. H. Evans in NBS Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system based upon Shartsis and Newman's heats of solution and Mazzetti and DeCarli's phase studies. From the Shartsis and Newman paper Evans obtained the following:

$$PbO(c) + 2B_2O_3(c) \rightarrow PbO\cdot 2B_2O_3(gls.) \qquad \Delta H_r = -11.9 \text{ kcal. mole}^{-1}$$

and estimated a ΔH_{298} of 11.4 kcal. mole^{-1} for the conversion to the $PbO\cdot 2B_2O_3$(crystal). With auxiliary JANAF values the $\Delta H_f^\circ{}_{298.15}$ was calculated to be -683.00 kcal./mole.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of the heat capacities of the constituent oxides.

The entropy at 298.15 was obtained from a consideration of the entropies of sodium and calcium borates and those of the constituent oxides, as given by K. K. Kelley and E. G. King, Bureau of Mines Bull. 592 (1961). These indicate for the reaction:

$$MO\cdot B_2O_3 + B_2O_3 \rightarrow MO\cdot 2B_2O_3$$

that the simple addition of entropies will give values at least 2.7 e.u. in the case of Na borates and 5.7 e.u. for Ca borates too high for the reaction. The reason for this is probably structural, the $B_4O_7^{--}$ ion is a rigid chain of rings. It was assumed that additional B_2O_3 would extend the ring structure into a rigid plane and thus the average entropy difference of 4.2 for the reaction was assumed to hold for each additional mole of B_2O_3. Therefore the entropy at 298.15 was obtained from $S^\circ_{298.15}$ for PbB_2O_4 and B_2O_3 and the subtraction of 4.2 e.u.

Dec. 31, 1962; Mar. 31, 1965

PENTABORANE (B_5H_9) (LIQUID) MOL. WT. = 63.172

$S^\circ_{298.15}$ = 44.056

$\Delta H^\circ_{f\ 298.15}$ = 10.240 ± 1.6 kcal. mole^{-1}

T_m = 226.34°K.

ΔH°_m = 1.466 kcal. mole^{-1}

T_b = 335°K.

ΔH°_v = 6.79 kcal. mole^{-1}

Heat of Formation.

The vapor pressures of B_5H_9(l) were measured by H. E. Wirth and E. D. Palmer, J. Phys. Chem. 60, 914 (1956) and H. L. Johnston, E. C. Kerr, J. T. Clarke and N. C. Hallett, "Calorimetric Investigation with the Condensed Gas Calorimeter. IV. The Heat Capacities, Latent Heats and Entropies of Pentaborane from 13 to 296°K.; Heats of Transition, Fusion and Vaporization; Vapor Pressures of the Liquid", TR-6, July 8, 1949, The Ohio State University. By use of both the second and third law methods, the respective heats of vaporization ($\Delta H^\circ_{v\ 298.15}$) were evaluated. The $\Delta H^\circ_{f\ 298.15}$ values for B_5H_9(l) were calculated from $\Delta H^\circ_{f\ 298.15}$ for B_5H_9(g) and $\Delta H^\circ_{v\ 298.15}$ for B_5H_9(l) obtained previously. The results are presented as follows.

Investigator	$\Delta H^\circ_{v\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	$\Delta H^\circ_{f\ 298.15}$* kcal. mole^{-1}
Wirth and Palmer	7.26 ± 0.02	7.26	10.24 ± 1.6
Johnston, et al.	7.23 ± 0.04	7.25	10.23 ± 1.6

*Calculation based on the third law $\Delta H^\circ_{v\ 298.15}$ values.

The adopted value is the average of the two $\Delta H^\circ_{f\ 298.15}$ values obtained.

Heat Capacity and Entropy.

The heat capacities (C_p), 231.34 - 290.19°K., for B_5H_9(l) were measured by Johnston, Kerr, Clarke and Hallett, loc. cit. The C_p values above 290.19°K. were estimated by graphical extrapolation of the C_p curve plotted using the experimental data. The value of $S^\circ_{298.15}$ was derived based on the low temperature C_p, 13.29 - 221.61°K., and ΔH°_m for B_5H_9(c) reported by Johnston, Kerr, Clarke and Hallett, loc. cit. and C_p values, 226.34 - 298.15°K., for B_5H_9(l), using $S^\circ_{13.29}$ = 0.236 cal. deg.$^{-1}$ mole^{-1} for B_5H_9(c).

Melting Data.

The values of T_m and ΔH°_m were taken from Johnston, Kerr, Clarke and Hallett, loc. cit.

Vaporization Data.

The boiling point (T_b) is calculated as the temperature at which the free energy change of the reaction $B_5H_9(l) \rightarrow B_5H_9(g)$ becomes zero. The enthalpy change of the reaction at T_b is heat of vaporization (ΔH°_v).

B-H_{bridge}-B = 83° 37' B-B-B = 90°
Angle between B_{apex}BB plane and BBH_{bridge} plane = 196 ± 2°

Product of the Moments of Inertia: $I_AI_BI_C = 2.3693 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The enthalpy change ($\Delta H_r^\circ{}_{298.15}$) of the reaction $B_5H_9(g) \rightarrow 5B(am.) + 9/2\ H_2(g)$ was reported to be -12.99 ± 0.39 and -9.9 ± 1 kcal. mole^{-1} by E. J. Prosen, W. H. Johnson and F. Y. Pergiel, J. Res. Natl. Bur. Std. 61, 247 (1958) and S. R. Gunn and L. G. Green, J. Phys. Chem. 65, 2173 (1961), respectively. Using $\Delta H_r^\circ{}_{298.15} = 1.2 \pm 0.4$ kcal. mole^{-1} for the reaction $B(c) \rightarrow B(am.)$, the corresponding $\Delta H_f^\circ{}_{298.15}$ values for $B_5H_9(g)$ were derived as 18.99 and 15.9 kcal. mole^{-1}. The adopted value is the average of these two.

Heat Capacity and Entropy.

The molecular structure, a tetragonal pyramid of boron atoms, and constants were obtained from H. J. Hrostowski and R. J. Myers, J. Chem. Phys. 22, 262 (1954). The vibrational frequencies were reported by H. J. Hrostowski and G. C. Pimentel, J. Am. Chem. Soc. 76, 998 (1954). The earlier models of pentaborane were assumed to have a hydro carbon - like structure of low symmetry by S. H. Bauer and L. Pauling, J. Am. Chem. Soc. 58, 2403 (1936) and K. S. Pitzer, J. Am. Chem. Soc. 67, 1126 (1945). However, the electron diffraction and X-ray data by K. Hedberg, M. E. Jones and V. Schomaker, Proc. Natl. Acad. Sci., U. S. 38, 679 (1952) and W. J. Dulmage and W. N. Lipscomb, Acta Cryst. 5, 260 (1952) revealed an unusual pyramidal structure of C_{4v} symmetry. The Raman spectrum of liquid B_5H_9 and the infrared spectrum of the gas B_5H_9 from 3 to 25 microns have been obtained by W. J. Taylor, C. W. Beckett, J. Y. Tung, R. B. Holden and H. L. Johnston, Phys. Rev. 79, 234 (1950). The near infrared spectrum of $B_5H_9(l)$ have been examined at high resolution by P. R. Pondy and H. C. Beachell, J. Chem. Phys. 25, 238 (1956). Ten bands were observed. The three principal moments of inertia are: $I_A = I_B = 1.18344 \times 10^{-38}$ and $I_C = 1.69172 \times 10^{-38}$ g. cm.^{2}

DIPOTASSIUM HEXABORATE ($K_2B_6O_{10}$) (CRYSTAL) MOL. WT. = 303.12

$S^\circ_{298.15}$ = [60 ± 3] cal. deg.$^{-1}$ mole^{-1}

T_d = 1098°K

$\Delta H_f^\circ{}_0$ = Unknown

$\Delta H_f^\circ{}_{298.15}$ = -1,107.44 ± 2.4 kcal. mole^{-1}

Heat of Formation.

The heat of reaction $K_2O(c) + 3B_2O_3(l) \rightarrow K_2B_6O_{10}(c)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $K_2O(c)$ (June 30, 1963). The above ΔH_r° = -122.8 kcal. mole^{-1}.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 973°K were graphically smoothed and used to determine C_p. Above this range C_p was extrapolated.

The entropy at 298°K was obtained from a consideration of the entropies of sodium and calcium borates and those of the constituent oxides, as given by K. K. Kelley and E. G. King, Bureau of Mines Bull. 592 (1961). These indicate that for the reactions

$MO + B_2O_3 \rightarrow MO.B_2O_3$ (1)

$MO.B_2O_3 + B_2O_3 \rightarrow MO.2B_2O_3$ (2)

the simple addition of entropies will give values at least 2.7 e.u. too low for reaction (1) and at least 2.7 e.u. too high for reaction (2). The reason for this is probably structural, the $B_2O_4^{--}$ ion being a flexible chain while the $B_4O_7^{--}$ ion probably is a rigid chain of rings. It was assumed that additional B_2O_3 would extend the ring structure into a rigid plane and thus the entropy difference for reaction (2) was assumed to hold for each additional mole of B_2O_3 added. Thus a value for $Na_2B_6O_{10}$ was estimated to be 55.5 ± 1.5 and then using an average value of 4.5 ± 1.5 e.u. for the difference between K_2 and Na_2 gave 60 ± 3 e.u. for the entropy of $K_2B_6O_{10}$.

Decomposition Temperature.

The incongruent melting point was given by A.-P. Rollet, Comp. rend. 200, 1763 (1935), the decomposition products being $K_2B_4O_7(l)$ and $K_2B_8O_{13}(c)$.

Mar. 31, 1962; Dec. 31, 1962; Mar. 31, 1965

DILITHIUM HEXABORATE ($Li_2B_6O_{10}$) (CRYSTAL) MOL. WT. = 238.80

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [45.0 ± 1.0] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -1,113.74 ± 2.40 kcal. mole^{-1}

T_d = 1107 ± 4°K.

Heat of Formation.

The heat of reaction $Li_2O(c) + 3B_2O_3(l) \rightarrow Li_2B_6O_{10}(c)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and $Li_2O(c)$ (March 31, 1964). The above ΔH_r° = -72.80 kcal. mole^{-1}.

Heat Capacity and Entropy.

The enthalpy measurement of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 823°K. were used to determine C_p. Above this range C_p is extrapolated. Entropy at 298°K. is estimated from that of the component oxides and the difference from the oxides observed for twice $LiBO_2(c)$.

Temperature of Decomposition.

The incongruent melting point reported by B. S. R. Sastry and F. A. Hummel, J. Am. Ceram. Soc. 42, 216-8 (1959) is used here.

LEAD HEXABORATE (PbB_6O_{10}) (CRYSTAL) MOL. WT. = 432.13

$\Delta H^\circ_{f\ 0}$ = Unknown

$S^\circ_{298.15}$ = [48.6 ± 3] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -1003 ± 2.0 kcal mole^{-1}

Heat of Formation.

See lead diborate table for the complete writeup. W. H. Evans in NBS Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system based upon Shartsis and Newman's heats of solution and Mazzetti and De Carli's phase studies. From the Shartsis and Newman paper Evans obtained the following:

$PbO(c) + 3B_2O_3(c) \rightarrow PbO\cdot 3B_2O_3(gls.)$ ΔH_r = -24.5 kcal./mole

and estimated a ΔH_{298} of 16.0 kcal. mole^{-1} for the conversion to the $PbO\cdot 3B_2O_3$(crystal). With auxiliary JANAF values the $\Delta H^\circ_{f\ 298.15}$ was calculated to be -1003.00 kcal./mole.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of heat capacities of the constituent oxides.

The entropy at 298.15 was obtained in the manner described in the PbB_4O_7 table from $S^\circ_{298.15}$ for PbB_4O_7 and B_2O_3 and the subtraction of 4.2 e.u.

DIPOTASSIUM OCTABORATE ($K_2B_8O_{13}$) (CRYSTAL) MOL. WT. = 372.76

$S^\circ_{298.15}$ = [70.2 ± 4] cal. deg.$^{-1}$ mole^{-1}

T_m = 1130°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = -1,420.92 ± 1.4 kcal. mole^{-1}

ΔH°_m = 29.9 ± 1.0 kcal. mole^{-1}

Heat of Formation.

The heat of reaction $K_2O(c) + 4B_2O_3(l) \rightarrow K_2B_8O_{13}(c)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $K_2O(c)$ (June 30, 1963). The above ΔH°_r = -137.00 kcal. mole^{-1}.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1130°K were smoothed graphically and used to determine C_p. Above this range C_p is extrapolated.

The entropy at 298°K was obtained by estimating the entropy of $Na_2B_8O_{13}(c)$ as 65.7 ± 2.5 e.u., as described on the table for $K_2B_6O_{10}(c)$ and then using an average value of 4.5 ± 1.5 e.u., for the replacement of Na_2 by K_2.

Melting Data.

T_m is given by A.-P. Rollet, Comp. rend., 200, 1763 (1935). ΔH°_m was obtained from the values of ΔH°_f for $K_2B_8O_{13}(c)$ and $K_2B_8O_{13}(l)$ at 298°K reported above and the enthalpy of the crystal and liquid at T_m.

Mar. 31, 1963; Mar. 31, 1965

DIPOTASSIUM OCTABORATE ($K_2B_8O_{13}$) (LIQUID) MOL. WT. = 372.76

$S^\circ_{298.15}$ = [71.295] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -1,403.57 ± 2.4 kcal. mole^{-1}

T_m = 1130°K.

ΔH_m = 29.9 ± 1.0 kcal. mole^{-1}

Heat of Formation.

The heat of reaction $K_2O(c) + 4B_2O_3(l) \rightarrow K_2B_8O_{13}(l)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $K_2O(c)$ (June 30, 1963). The above ΔH_r° = -119.65 kcal. mole^{-1}.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range 298 to 1373°K on the glass and liquid were smoothed graphically and used to determine C_p. There is a discontinuity in the C_p curve, a glass transition at about 673°K. Above 673°K the C_p values were estimated to be constant.

The entropy was obtained from that of the crystal by adding ΔS_m° and the difference between $S_{1130}-S_{298}$ for crystal and liquid.

Melting Data.

See the crystal table.

DILITHIUM OCTABORATE ($Li_2B_8O_{13}$) (CRYSTAL) MOL. WT. = 308.44

$S^\circ_{298.15}$ = [63.4 ± 1.0] cal. deg.$^{-1}$ mole^{-1}

T_d = 908 ± 10°K.

ΔH_f° = Unknown

ΔH_f° 298.15 = -1413.57 ± 2.50 kcal. mole^{-1}

Heat of Formation.

The heat of the reaction $Li_2O(c) + 4B_2O_3(l) \rightarrow Li_2B_8O_{13}(c)$ was reported by L. Shartsis and W. Capps, J. Am. Ceram. Soc. 37, 27-32 (1954) from their heats of solution measurements. Their values for the heat of reaction of the oxides have been converted to the heats of formation using JANAF values for $B_2O_3(l)$ (Dec. 31, 1964) and for $Li_2O(c)$ (March 31, 1964). The above ΔH_r° = -73.35 kcal. mole^{-1}.

Heat Capacity and Entropy.

The enthalpy measurements of G. S. Smith, Ph.D. Thesis, Penn. State Univ., Jan. 1959, L. C. Card No. Mic 59-2916 in the range of 298 to 823°K. were used to determine C_p. Above this range C_p is extrapolated. Entropy at 298°K. is estimated from that of the component oxides and the difference from the oxides observed for twice $LiBO_2(c)$.

Temperature of Decomposition. The incongruent melting point reported by B. S. R. Sastry and F. A. Hummel, J. Am. Ceram. Soc. 42, 216-8 (1959) is used here.

Sept. 30, 1962; Dec. 31, 1964

DECABORANE (B_{10} H_{14}) (CRYSTAL) MOL. WT. = 122.312

$\Delta H^\circ_{f\ 0}$ = 3.4 ± 4.5 kcal. mole^{-1}

$S^\circ_{298.15}$ = 42.20 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -6.9 ± 4.5 kcal. mole^{-1}

T_m = 371.93°K

ΔH°_m = 5.25 ± 0.01 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298}$ = 18.2 ± 0.2 kcal. mole^{-1}

Heat of Formation.

The enthalpy change ($\Delta H^\circ_{r\ 298.15}$) of the reaction $B_{10}H_{14}(c) \rightarrow 10B(am) + 7H_2(g)$ was reported to be 19.8 ± 1.4 and 18.0 ± 1.0 kcal. mole^{-1} by W. H. Johnson, M. V. Kilday and E. J. Prosen, J. Res. Natl. Bur. Std. 64A, 521 (1960) and G. L. Gal'chenko, B. I. Timofeev and S. M. Skuratov, Doklady Akademii Nauk. USSR, 142, 1077 (1962), respectively. Using $\Delta H^\circ_{r\ 298.15}$ = 1.2 ± 0.4 kcal. mole^{-1} for the reaction $B(c) \rightarrow B(am)$, the corresponding $\Delta H^\circ_{f\ 298.15}$ values for $B_{10}H_{14}(c)$ were calculated to be -7.8 and -6.0 kcal. mole^{-1}. The adopted value of $\Delta H^\circ_{f\ 298.15}$ for $B_{10}H_{14}(c)$ is the average of these two.

Heat Capacity and Entropy.

C_p (60° to 371.93°K.) was given by G. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Standards, 55, 255 (1955). The heat capacity above 371.93° was estimated by comparison with that of the liquid decaborane. Heat capacity (14° to 205°K.) was also reported by E. C. Kerr, N. C. Hallett and H. L. Johnston, J. Am. Chem. Soc., 73, 1117 (1951). The value of $S^\circ_{298.15}$ was taken from G. T. Furukawa and R. P. Park, loc. cit.

Melting Data.

T_m and ΔH°_m were obtained from G. T. Furukawa and R. P. Park, loc. cit.

Heat of Sublimation.

$\Delta H^\circ_{s\ 298.15}$ was calculated from free energy functions and vapor pressure reported by G. T. Furukawa and R. P. Park, loc. cit. See $B_{10}H_{14}(g)$ table for details.

DECABORANE ($B_{10}H_{14}$) (LIQUID) MOL. WT. = 122.312

$S^\circ_{298.15}$ = 56.299 cal. deg.$^{-1}$ mole^{-1}

T_m = 371.93°K.

T_b = [492]°K.

$\Delta H^\circ_{f\ 298.15}$ = -1.7 ± 2.0 kcal. mole^{-1}

ΔH°_m = 5.25 ± 0.01 kcal. mole^{-1}

ΔH°_v = [10.3] kcal. mole^{-1}

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$ was calculated from $\Delta H^\circ_{f\ 298.15}$ for $B_{10}H_{14}$(c) and ΔH°_m reported by G. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Standards, 55, 255 (1955) and the difference $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p (371.93° to 380°K) was measured by G. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Standards, 55, 255 (1955). Heat capacities below 371.93° and above 380°K. were estimated by comparison with that of the gaseous decaborane. $S^\circ_{298.15}$ was calculated from that of crystal in a manner analogous to that of the heat of formation.

Melting and Vaporization Data.

T_m and ΔH°_m were obtained from G. T. Furukawa and R. P. Park, loc. cit. T_b and ΔH°_v were calculated from functions for $B_{10}H_{14}$(l) and $B_{10}H_{14}$(g), respectively.

Decaborane ($B_{10}H_{14}$)

Bond Distance: B-B = 1.762 Å $B\text{-}B_{apex}$ = 1.773 Å

$B\text{-}H_{bridge}$ = 1.394 Å B-H = 1.256 Å

σ = 2

Bond Angle: B-B-B = 108° $B\text{-}B_{apex}\text{-}B$ = 59° 34' $B\text{-}B\text{-}B_{apex}$ = 60° 13'

$B\text{-}H_{bridge}\text{-}B$ = 46° 17' $B_{apex}\text{-}B\text{-}H$ = 87° 42' $B_{center}\text{-}B_{center}\text{-}H$ = 120°

Product of the Moments of Inertia: $I_A I_B I_C = 8.6710 \times 10^{-113}$ g.^{3} cm.^{6}

Heat of Formation.

The vapor pressures of decaborane ($B_{10}H_{14}$) were measured by G. T. Furukawa and R. P. Park, J. Res. Natl. Bur. Std. 55, 255 (1955) and G. A. Miller, J. Phys. Chem. 67, 1363(1963). The heats of vaporization (ΔH_v°) were derived by both the second and third law methods. Using the average value of ΔH_v°, the respective heats of formation ($\Delta H_f^\circ{}_{298.15}$) for $B_{10}H_{14}$(g) were calculated. The results are presented as follows.

		$\Delta H_v^\circ{}_{298.15}$, kcal. mole^{-1}		$\Delta H_f^\circ{}_{298.15}$
Investigator	Process	Third Law Value	Second Law Value	kcal. mole^{-1}
Furukawa and Park	$B_{10}H_{14}(c) \rightarrow B_{10}H_{14}(g)$	18.20	16.63 ± 0.93	10.52 ± 4.5
	$B_{10}H_{14}(l) \rightarrow B_{10}H_{14}(g)$	13.06	13.28 ± 0.06	11.47 ± 4.5
Miller	$B_{10}H_{14}(c) \rightarrow B_{10}H_{14}(g)$	18.27	17.81 ± 0.01	11.14 ± 4.5

The adopted value of $\Delta H_f^\circ{}_{298.15}$ for $B_{10}H_{14}$(g) is the weighted average of the three $\Delta H_f^\circ{}_{298.15}$ values listed in the above table.

Heat Capacity and Entropy.

The molecular structure of $B_{10}H_{14}$(c) were reported by J. S. Kasper, C. M. Lucht and D. Harker, Acta Cryst. 3, 436 (1950); E. B. Moore, Jr., R. E. Dickerson and W. N. Lipscomb, J. Chem. Phys. 27, 209 (1957) and W. N. Lipscomb, "Boron Hydrides", W. A. Benjamin, Inc., New York, 1963. For the calculation of the moments of inertia for $B_{10}H_{14}$(g) a simplified molecular model is adopted. The molecule is assumed to be composed of two regular pentagonal pyramids with a common base edge. The angle between the base planes of those pyramids is 73° 30'. Each of 10 H atoms is attached to a single B atom above the base plane. The remaining 4 H atoms, each bridge two B atoms. The vibrational frequencies were obtained from W. H. Evans, National Bureau of Standards Report 7093 (Jan. 1, 1961), which were derived based on the infrared and Raman spectra reported by J. E. Stewart, National Bureau of Standards, private communication, 1957 and W. E. Keller and H. L. Johnston, J. Chem. Phys. 20, 1749 (1952). The three principal moments of inertia are: $I_A = 4.53825 \times 10^{-38}$, $I_B = 3.51508 \times 10^{-38}$ and $I_C = 5.43559 \times 10^{-38}$ g. cm.^{2}

DILEAD DECABORATE ($Pb_2B_{10}O_{17}$) (CRYSTAL) MOL. WT. = 794.62

$\Delta H_f^\circ{}_0$ = Unknown

$S^\circ_{298.15}$ = [84.3 ± 3] cal. deg.$^{-1}$ mole^{-1} $\Delta H_f^\circ{}_{298.15} = -1694 \pm 3$ kcal. mole^{-1}

Heat of Formation.

See lead diborate for the complete writeup. W. H. Evans in NBS. Report 7192, July 1, 1961, analysed the heats of formation of the lead borate system based upon Shartsis and Newman's heats of solution and Mazzetti and DeCarli's phase studies. From the Shartsis and Newman paper Evans obtained the following:

$$2PbO(c) + 5B_2O_3(c) \rightarrow 2PBO\cdot 5B_2O_3(gls.) \qquad \Delta H_r = -45.2 \text{ kcal./mole}$$

and estimated a ΔH_{298} of 26.8 kcal. mole^{-1} for the conversion to the $2PbO\cdot 5B_2O_3$(crystal). With auxiliary JANAF values the $\Delta H_f^\circ{}_{298.15}$ was calculated to be -1694.00 kcal./mole.

Heat Capacity and Entropy.

The heat capacity employed in this table was obtained by graphically smoothing the summation of the heat capacities of the constituent oxides.

The entropy at 298.15 was obtained in the manner described in the PbB_4O_7 table from $S^\circ_{298.15}$'s of $Pb\cdot 2B_2O_3$ and $Pb\cdot 3B_2O_3$ and the subtraction of 4.2 e.u.

BERYLLIUM (Be) (REFERENCE STATE) MOL. WT. = 9.013

Solid state to the melting point 1556°K.

Liquid state from 1556°K. to the boiling point 2757°K.

Ideal monatomic gas state above 2757°K.

See Crystal, Liquid, Ideal Monatomic gas for details.

September 30, 1961

BERYLLIUM (Be) (CRYSTAL) MOL. WT. = 9.013

$\Delta H_{f0}^\circ = 0$

$\Delta H_s^\circ = 78.254$ kcal. mole^{-1}

$T_m = 1556$°K.

ΔH_f° $_{298.15} = 0$

$S^\circ_{298.15} = 2.280$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_m = 2800 \pm 500$ cal. mole^{-1}

Heat of Formation.

Zero by definition.

Heat Capacity and Extrapolation.

Heat capacity measurements have been reported by F. Simon and M. Ruheman, (71° to 79°K.), Z. physik. Chem. 129, 321 (1935); S. Cristescu and F. Simon, (10° to 300°K.), Z. physik. Chem. 25B, 273 (1934); E. J. Lewis, (97° to 463°K.), Phys. Rev. 34, 1575 (1929); D. C. Ginnings, T. B. Douglas and A. F. Ball, (0° to 900°C.), J. Am. Chem. Soc. 73, 1236 (1951), and R. W. Hill and P. L. Smith, (4° to 300°K.), Phil. Mag. 44, 636 (1953).

A five constant equation was fit to both sets of data adopted from Ginnings and co-workers by the method of least squares, standard deviation ± 0.017, and joined smoothly with the C_p values of Hill and Smith. C_p from 1200°K. to the melting point was extrapolated.

P. B. Kantor, R. M. Krasovitskaya and A. N. Kisel, Fiz. Metal. i Metalloved., Akad. Nauk. S.S.S.R. 10, 835 (1960), report enthalpy data for pure beryllium, purity not given, from 600° to 1560°K. (crystal) and from 1560° to 2200°K. (liquid). Their values for the crystal are too high.

Entropy.

Third law entropy calculated from C_p.

Melting.

Data from O. Kubaschewski, P. Brizgys, O. Huchler, R. Jauch, and K. Reinartz, Z. Elektrochem. 54, 275 (1950).

Heat of Sublimation.

ΔH_s $_{298.15}$ was derived from a third law analysis of the vapor pressure data of E. A. Gulbransen and K. F. Andrew, J. Electrochem. Soc. 97, 383 (1952), and of R. B. Holden, R. Speiser, and H. L. Johnston, J. Am. Chem. Soc. 70, 3897 (1948) which are in good agreement. The results of R. Schuman and A. B. Garrett, J. Am. Chem. Soc. 66, 442 (1944), are too low, and the values given by E. Baur and R. Brunner, Helv. Chim. Acta 17, 958 (1934), have a wrong temperature dependence.

BERYLLIUM (Be) (LIQUID) MOL. WT. = 9.013

$\Delta H_{f\ 298.15}^\circ$ = [2.881] kcal. mole^{-1}

T_m = 1556°K.

T_b = 2757°K.

$S_{298.15}^\circ$ = [3.954] cal. deg.$^{-1}$ mole^{-1}

ΔH_m° = 2800 ± 500 cal. mole^{-1}

ΔH_v = 71.137 kcal. mole^{-1}

Heat of Formation.

Obtained from ΔH_m 1556°K.

Heat Capacity and Extrapolation.

Heat capacity from T_m to 2200°K. taken from P. B. Kantor, R. M. Krasovitskaya and A. N. Kisel, Fiz. Metal. i Metalloved., Akad. Nauk S.S.S.R. 10, 835 (1960). C_p values below T_m and above 2200°K. were extrapolated.

Entropy.

Third law entropies between T_m and T_b extrapolated in both directions by means of extrapolated heat capacities.

Vaporization Phenomena.

T_b and ΔH_v derived from a third law analysis of the vapor pressure data of E. A. Gulbransen and K. F. Andrew, J. Electrochem. Soc. 97, 383 (1952), and of R. B. Holden, R. Speiser, and H. L. Johnston, J. Am. Chem. Soc. 70, 3897 (1948).

A mass spectrometric study and review undertaken by O. T. Nikitin and L. N. Gorokhov, Zhur. Neorg. Khim. 6, 224 (1961), on the composition of beryllium vapor reveals that beryllium vaporizing both below and above the melting point, 1556°K., consists only of monatomic Be.

Beryllium (Be)

BERYLLIUM UNIPOSITIVE ION (Be^+) (IDEAL GAS) MOL. WT. = 9.01165

Ground State Configuration $^2S_{1/2}$

$\Delta H_{f\ 0}^\circ = 292.2 \pm .5$ kcal/mole

$S_{298.15}^\circ = 33.922$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ = 294.7 \pm .5$ kcal/mole

Electronic Levels and Quantum Weight

$\mathcal{E}_1$, cm.$^{-1}$	g_1
0.0	2
31928.8	2
31935.4	4
88231.2	2
96496.4	2
96498.2	4
98053.2	10

Heat of Formation.

The heat of formation was calculated from the equation: $Be(g) - e^- \rightarrow Be^+(g)$ with the JANAF auxiliary value for Be(g); using an I.P. = 7.519229 X 10^4 cm^{-1} (215.001 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore loc. cit. The electronic levels above 1 X 10^5 cm^{-1} were omitted because their contribution is negligible below 6000°K.. The $H^\circ-H_{298}^\circ$ value at 0°K. is -1.481 kcal./mole.

B_e = [0.53780] cm.$^{-1}$

α_e = [0.00293] cm.$^{-1}$

r_e = [1.97] Å

Heat of Formation.

The dissociation energy was estimated from the experimental energies for BeF(g), BeCl(g), and the gaseous lithium halides. The resulting value, 97.1 kcal. mole^{-1}, was combined with JANAF heats of formation for Be(g) and Br(g) in arriving at $\Delta H_{f\ 298.15}^\circ$.

Heat Capacity and Entropy.

The vibrational frequency was estimated from those of BeF(g), BeCl(g), and the gaseous lithium halides. The ground term was assumed to be similar to that of BeCl(g) and BeF(g), tabulated by G. Herzberg, "Molecular Spectra and Molecular Structure I. Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950. A correlation of the interatomic distances for the alkali halides, BeF(g), and BeCl(g) was employed in deriving r_e.

Dec. 31, 1961; June 30, 1965

BERYLLIUM DIBROMIDE ($BeBr_2$) (CRYSTAL) MOL. WT. = 168.8302

$S^\circ_{298.15}$ = [25.4 ± 2.0] cal. mole^{-1} deg.$^{-1}$

T_m = 761°K.

$\Delta H_f^\circ{}_0$ = Unknown

$\Delta H_f^\circ{}_{298.15}$ = [-88.4 ± 8] kcal. mole^{-1}

ΔH_m° = [4.5] kcal. mole^{-1}

$\Delta H_s^\circ{}_{298.15}$ = 29.8 ± 1.5 kcal. mole^{-1}

Heat of Formation.

The heat of formation was estimated from the work of W. Biltz and C. Messerknecht, Z. Anorg. Chem. 148, 157 (1925) and Biltz, Klatte and Rahlfs, Z. Anorg. Chem. 166, 339 (1927) as reported in N. B. S. Circular 500, Washington, 1952. They measured the heat of solution of $BeBr_2$ in aq. HCl to an unknown concentration. This value was apparently adjusted and used with Be^{++} and $2Br^-$ to obtain ΔH_f° of the crystal. However Be^{++} was estimated by N. B. S. An uncertainty of 8 kcal. is thought to be realistic.

Heat Capacity and Entropy.

The heat capacity was estimated graphically by comparison with $BeCl_2$ and BeF_2. The entropy was also estimated by comparing with α-$BeCl_2$ and BeF_2 and using additive entropy values for the halide ions.

Melting Data.

The melting point has been reported by O. Rahlfs and W. Fischer, Z. Anorg. Chem. 211, 351 (1933) and by Lebean, Ann. Chim. Phys. 16, 472 (1899) as reported in N. B. S. Circular 500, Washington, 1952. The heat of melting was estimated by comparison with the sum of the heat of transition and melting for BeF_2 and $BeCl_2$.

Sublimation Data.

The heat of sublimation was obtained from an analysis of the vapor pressure data of Rahlfs and Fischer, loc. cit. from 624-695°K. The 3rd law analysis gave $\Delta H_{sub\ 298}$ = 29.78 with a drift of -2.1 ± 0.8 cal. mole^{-1} deg.$^{-1}$ A 2nd law analysis gave $\Delta H_{sub\ 298}$ = 31.1 ± 0.5 kcal. mole^{-1}. The 2nd law result was adopted in order to yield a real liquid region, no attempt was made to eliminate the drift since this would have caused the liquid region to become unreal.

Dec. 31, 1961; June 30, 1965

BERYLLIUM DIBROMIDE ($BeBr_2$) (LIQUID) MOL. WT. = 168.8302

$S^\circ_{298.15}$ = [28.07] cal. $mole^{-1}$ $deg.^{-1}$

T_m = 761°K.

T_b = [794]°K.

$\Delta H^\circ_{f\ 298.15}$ = [-85.88 ± 3] kcal. $mole^{-1}$

ΔH°_m = [4.5] kcal. $mole^{-1}$

ΔH°_v = [23.9] kcal. $mole^{-1}$

Heat of Formation.

The heat of formation was obtained from that of $BeBr_2$(c) by adding ΔH°_m and the difference between H_{761} H_{298} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated by comparison with the measured value for $BeCl_2$. A glass transition was assumed at 500°K. below which the heat capacity is that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See $BeBr_2$(c) table for details.

Vaporization Data.

The temperature and heat of vaporization were calculated from the cross over between $BeBr_2$(l) and (g).

Dec. 31, 1961; June 30, 1965

BERYLLIUM DIBROMIDE ($BeBr_2$) (IDEAL GAS) MOL. WT. = 168.8302

Point Group $D_{\infty h}$

$S^\circ_{298.15}$ = [66.4 ± 2] cal. mole^{-1} deg.$^{-1}$

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = [-54.2 ± 9.5] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-57.3 ± 9.5] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[205] (1)
[180] (2)
[890] (1)

Bond Distance: Be-Br = 1.90Å

Bond Angle: Br-Be-Br = [180°]

Rotational Constant: B_o = 0.02922 cm.$^{-1}$

σ = 2

Heat of Formation.

The heat of formation was obtained from that of the crystal plus $\Delta H^\circ_{s\ 298.15}$, see $BeBr_2$(c) for details.

Heat Capacity and Entropy.

The linear structure was assumed by analogy with $BeCl_2$. The bond length was reported by P. A. Akishin, V. P. Spirodinov and G. A. Sobelev, Dokl. Akad. Nauk. SSSR 118, 1134 (1958) from electron diffraction measurements. The vibrational frequencies were estimated by assuming a set of force constants k_1 for the BeF_2, $BeCl_2$, $BeBr_2$, BeI_2 series and also assuming $k_1/k_\delta/l^2$ = 50 as for BeF_2. The principal moment of inertia is 95.7984 x 10^{-39} g. cm.^{2}

BERYLLIUM MONOCHLORIDE (BeCl) (IDEAL GAS) GFW = 44.4652

Ground State Configuration $^2\Sigma^+$

ΔHf°_0 = 13.9 ± 3.0 kcal/mol

$S^\circ_{298.15}$ = 51.984 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 14.5 ± 3.0 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	2
27970	4

ω_e = 845.29 cm^{-1} $\omega_e x_e$ = 4.831 cm^{-1} σ = 1

B_e = [0.769] cm^{-1} α_e = [0.0063] r_e = [1.75] Å

Heat of Formation.

Novikov[1] measured 39 bands in the ultraviolet spectrum of BeCl(g). A linear extrapolation leads to a ground state dissociation energy of 36,555 cm $^{-1}$. The authors assumed that the non-crossing rule applied and that the ground and first excited states had a common dissociation limit. However, in the analogous case of BeF, treated in the same way by the above authors, it was shown by Mann[2] that these assumptions were not correct. If it is assumed that the excited state dissociates $A^2\pi \rightarrow Be(^3P) + F(^2P)$ and the ground state $X^2\Sigma \rightarrow Be(^1SO) + F(^2P)$, then ν_{oo} + D' should equal D" + excitation energy of Be atom. We find ν_{oo} + D' = 27,960 + 30,390 = 58,350 and D" + E_{Be} = 36,555 + 21,981 = 58,536 which is in excellent agreement. Thus the dissociation energy to ground state atoms is taken as 104.5 kcal/mol, which leads to a heat of formation of 3 kcal/mol using reaction a.

Greenbaum et al.[3] report equilibrium constants for reaction b in the temperature range 1573 - 1724°K using the molecular flow effusion method. Also Hildenbrand et al.[4] report equilibrium constants for reactions c and d which were calculated from mass spectrometric ion intensities. The $\Delta Hr^\circ_{298.15}$ values by second and third law analysis for these data and the corresponding $\Delta Hf^\circ_{298.15}$ values are listed below.

Author	Method	Reaction	T°K	$\Delta Hr^\circ_{298.15}$ kcal/mol Second Law	Third Law	Drift eu	$\Delta Hf^\circ_{298.15}$ Kcal/mol
1. Novikov	Spectroscopic	(a) BeCl(g) → Be(g) + Cl(g)		104.5			2.7
3. Greenbaum	Kp	(b) $BeCl_2$(g) + Be(l) →	1573-1724	93.56 ± 7			5.2
		2 BeCl(g)			85.87	-4.521	1.3
4. Hildenbrand	Kp from Mass	(c) Be(g) + AlCl(g) →	1382-1554	27.5 ± 2			16.5 ± 3
	Spectroscopy	BeCl(g) + Al(g)			26.25	- .779	15.3 ± 2
		(d) Be(g) + $BeCl_2$(g) →	1382-1536	33.41± 8			12.8 ± 5
		2 BeCl(g)			36.08	2.198	14.1 ± 2.5

The equilibrium data of Greenbaum et al.[3] was not weighted, since calculations indicated the possibility of reaction of BeCl(g) with the Al_2O_3 tube at the temperatures and pressures used. The data of Hildenbrand et al.[4], which reflect the true gas phase equilibria and appear consistent with each other, were adopted, yielding $\Delta Hf^\circ_{298.15}$ = 14.5 kcal/mol.

Heat Capacity and Entropy.

The vibrational constants used to calculate the functions were derived by Novikov[1] from a two constant equation $[\omega''_o - (2\nu'' + 1)\,\omega''_o x''_o = \Delta G''_o(\nu'')]$. The electronic levels were obtained from Herzberg[5]. B_e was obtained from the estimated bond length, which was taken to be slightly less than that in $BeCl_2$(g), and α_e was estimated from the Morse potential function.

BERYLLIUM MONOCHLORIDE UNIPOSITIVE ION ($BeCl^+$) (IDEAL GAS) GFW = 44.46465

Ground State Configuration $[^1\Sigma_g^+]$ ΔHf_0° = [233 ± 20] kcal/mol

$S^\circ_{298.15}$ = [50.9 ± 2] gibbs/mol ΔHf_0° = [234 ± 20] kcal/mol

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$^1\Sigma_g^+$	0	1
$^3\pi_u$	[10000]	6
$^1\pi_u$	[15000]	2
$^3\Sigma_g^-$	[30000]	3
$^1\Delta$	[35000]	2
$^1\Sigma^+$	[40000]	1

ω_e = [700] cm^{-1} $\omega_e x_e$ = [4.8] cm^{-1} σ = 1

B_e = [0.7241] cm^{-1} α_e = [0.0071] cm^{-1} r_e = [1.8] Å

Heat of Formation

Krasnov (1) has reported calculations of the ionization potentials(IP) for the monohalides (MX, where X = F, Cl, Br, and I) of Group IIA elements (M = Mg, Ca, Sr, and Ba). Based on his data we obtain graphically the value IP(BeCl, g) = 8.9 ± 0.5 eV. The value of $\Delta Hf^\circ_{298}(BeCl^+, g)$ is derived as 219 ± 15 kcal/mol, using $\Delta Hf^\circ_0(BeCl, g)$ = 13.9 kcal/mol. Beckett (2) reported the ionization potential of BeCl(g) to be approximately 9 ± 1 eV, yielding $\Delta Hf^\circ_{298}(BeCl^+, g)$ = 222 ± 23 kcal/mol. Hildenbrand (9) measured the appearance potential (AP) of $BeCl^+(g)$ to be 9.5 ± 0.7 eV which is on the same order of the above IP values, and assumed that $IP(BeCl^+, g) = AP(BeCl^+, g)$ = 9.5 ± 0.7 eV. Using this IP value, we obtain $\Delta Hf^\circ_{298}(BeCl^+, g)$ = 234 ± 20 kcal/mol which is adopted.

Heat Capacity and Entropy

The six electronic states are obtained from Fougere (3). The electronic levels are estimated by comparison with those of the isoelectronic molecules, BeS (4), BeO (5, 6), and MgO (5, 7). The values of ω_e, $\omega_e x_e$ are estimated by comparison with those for BeCl(g) and LiCl(g). B_e and α_e are calculated using the method suggested by Herzberg (5). The bond distance is estimated (8). The moment of inertia is 3.865×10^{-39} g cm^2. The enthalpy at 0°K is -2.15 kcal/mol.

Dec. 31, 1960; June 30, 1965

BERYLLIUM CHLORIDE FLUORIDE (BeClF) **(IDEAL GAS)** **MOL. WT. = 63.4636**

Point Group $[C_{\infty v}]$

$S^\circ_{298.15}$ = [58.89] cal. mole^{-1} deg.$^{-1}$

Ground State Quantum Weight = 1

$\Delta H^\circ_{f\ 0}$ = [-137.2 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-137 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[500](1)
[270](2)
[1300](1)

Bond Distance: Be-Cl = [1.77]Å

Be-F = [1.43]Å

Bond Angle: Cl-Be-F = [180°]

σ = 1

Rotational Constant: B_o = 0.12970 cm.$^{-1}$

Heat of Formation.

The heat of formation was estimated by assuming $\Delta H_r = 0$ for the reaction $BeF_2 + BeCl_2 \rightarrow 2BeClF$

Heat Capacity and Entropy.

The structure, bond lengths and frequencies were all estimated from the properties of $BeCl_2$ and BeF_2. The principal moment of inertia is 21.579 x 10^{-39} g. cm.^{2}

Beryllium Dichloride, Alpha (α-$BeCl_2$)

BERYLLIUM DICHLORIDE, ALPHA (α-$BeCl_2$)   (CRYSTAL)   MOL. WT. = 79.9182

$S_{298.15}^\circ = 19.76 \pm 0.06$ cal. mole^{-1} deg.$^{-1}$

$T_m = 688$°K.

$\Delta H_{f\ 0}^\circ = -117.5 \pm 0.8$ kcal. mole^{-1}

$\Delta H_{f\ 298.15}^\circ = -117.3 \pm 0.8$ kcal. mole^{-1}

$\Delta H_m^\circ = 2.07 \pm 0.06$ kcal. mole^{-1}

$\Delta H_{s\ 298.15}^\circ = 31.3$ kcal. mole^{-1}

Heat of Formation.

W. H. Johnson and A. A. Gilliland, J. Res. Nat'l. Bur. Stand. 65A, 59 (1961) have directly reacted beryllium and chlorine and obtained $\Delta H_f^\circ = -118.03 \pm 0.56$ though the crystal form of the product was unknown. P. Gross, C. Hayman, P. D. Greene and J. T. Bingham, Fulmer Research Institute, Report R. 163/SR.1/Sept. 1964 under Contract AF61(052)-447 also by direct combustion of the elements obtain $\Delta H_f^\circ = -117.1 \pm 0.4$ kcal. mole^{-1}. The crystal form of the sample was deduced to be α' by a comparison experiment, the assumption is made here that α and α' are identical. C. J. Thompson, G. C. Sinke and D. R. Stull, J. Chem. Eng. Data 7, 380 (1962) by solution calorimetry report a $\Delta H_f^\circ = -118.25 \pm 0.5$ kcal. mole^{-1}. Initially this sample was reported to be of unknown crystal form. However, G. C. Sinke, private communication February 1965, reports that an x-ray of the sample used has been reinterpreted, in the light of more recent data, as being approximately 50% α' and 50% β. Using the heats of transition adopted for these tables heats of formation of -117.3 ± 0.8 kcal. mole^{-1} for α and -118.6 ± 0.8 kcal. mole^{-1} for β have been adopted as being the most consistent with all measurements.

Heat Capacity and Entropy.

R. A. McDonald and F. L. Oetting, J. Phys. Chem. scheduled for publication in the Nov. 1965 issue have measured the heat capacity of the α' form from 13° to 304°K. and the enthalpy (relative to the α' form) from 676° to 688°K. The assumption has been made that the α and α' forms are identical and the heat capacity curve between 304° and 676°K. has been estimated graphically. The entropy was obtained by integration of the heat capacity curve assuming $S_{13} = 0.16$ cal. mole^{-1} deg.$^{-1}$. The sample was identified as α' by x-ray diffraction both before and after the experiments.

Melting Data.

The temperature and heat of melting were reported by McDonald and Oetting, loc. cit. Several investigations of the melting point are in disagreement mainly due to the uncertainty of the crystal form of the material and a solid state transition just below the pure α-liquid melting point.

Sublimation Data.

The adopted heat of sublimation was derived from that of the β form and heat of the α-β transition at 298°K.

June 30, 1965

BERYLLIUM DICHLORIDE, BETA (β-$BeCl_2$) (CRYSTAL) MOL. WT. = 79.9182

$S^\circ_{298.15}$ = 18.12 ± 0.05 cal. mole^{-1} deg.$^{-1}$

T°_m = [682°K.]

T°_t = 676°K ($\beta \rightarrow \alpha$)

$\Delta H^\circ_{f\ 0}$ = -118.7 ± 0.8 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -118.6 ± 0.8 kcal. mole^{-1}

ΔH°_m = [3.65] ± 0.15 kcal. mole^{-1}

ΔH°_t = [1.63]-± 0.15 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 32.5 kcal. mole^{-1}

Heat of Formation.

See table for α-$BeCl_2$ for details.

Heat Capacity and Entropy.

R. A. McDonald and F. L. Oetting, J. Phys. Chem. scheduled for publication in the November 1965 issue have measured the heat capacity of the β-form from 13 to 304°K. and the enthalpy of the β-form from 298° to 676°K. The entropy was obtained by integration of the heat capacity curve based on S_{13} = 0.06 cal. mole^{-1} deg.$^{-1}$ The sample was identified as β-$BeCl_2$ both before and after the low temperature experiments.

Melting Data.

The temperature and heat of melting were obtained from cross over point of the tables for β-$BeCl_2$ and liquid $BeCl_2$.

Transition Data.

The temperature of the β to α transition was obtained from McDonald and Oetting, loc. cit. The heat of the transition is a function of the heat capacity curve chosen for α-$BeCl_2$ between 298 and 676°K. A straight line interpolation was used by McDonald and Oetting, which gives a different result (1.49 kcal. mole^{-1}) than the curve employed here. It should also be noted that the transitional heat is not included in this table, which is for B-$BeCl_2$ only.

Sublimation Data.

The heat of sublimation was determined by 2nd and 3rd law analysis of vapor pressure data as described fully on the table for $BeCl_2$ (g).

Sept. 30, 1961; June 30, 1965

BERYLLIUM DICHLORIDE ($BeCl_2$) (LIQUID) MOL. WT. = 79.9182

$S^\circ_{298.15}$ = 19.065 ± 1 cal. mole^{-1} deg.$^{-1}$

T_m = 688°K.

T_b = 805°K.

$\Delta H^\circ_f\ _{298.15}$ = -117.4 ± 1.5 kcal. mole^{-1}

ΔH°_m = 2.07 ± 0.06 kcal. mole^{-1}

ΔH°_v = 25.0 ± 2 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from that of the α-$BeCl_2$ plus ΔH°_m plus the difference of $H_{688}-H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

R. A. McDonald and F. L. Oetting, J. Phys. Chem. scheduled for publication in the November 1965 issue have measured the enthalpy of the liquid, relative to α-$BeCl_2$, from 688° to 713°K. The heat capacity was assumed constant above this point and also below the melting point to 460°K. where a glass transition was assumed. Below 416°K. the heat capacity was assumed to be that of β-$BeCl_2$. The entropy was calculated in a manner analagous to the heat of formation.

Melting Data.

See the table for α-$BeCl_2$ (c) for details.

Vaporization Data.

The boiling point and heat of vaporization were obtained from the cross over point of the $BeCl_2$ (l) and (g) tables. The analysis of the liquid vapor pressure data is given on the table for $BeCl_2$ (g).

Bond Angle: Cl-Be-Cl = 180°

Rotational Constant: B_o = 0.0759 cm.$^{-1}$

σ = 2

Heat of Formation.

The vapor pressure data over the crystal was assumed to be for the β-form. The 2nd and 3rd law analyses of the data are summarized below after conversion to a common process. The data were also analyzed using gaseous free energy functions based on a bending frequency of 170 cm.$^{-1}$ but no significant improvement of the results was noted.

It is obvious that there is no real agreement between the data sets, and some of this is undoubtedly due to the difficulty of keeping a single crystal form throughout a series of measurements. It is also doubtful that water vapor was adequately excluded in some experiments. We have adopted the only piece of work which shows adequate 2nd and 3rd law agreement, and no third law trend, that is ΔH_{sub} = 32.5 ± 1 kcal. mole^{-1} from ref. 4. It is interesting to note that all the other data can be made much more precise and its drift removed if a constant pressure is added to all points. The addition which varied from 20-30% of the lowest pressure in each data set serves to indicate the magnitude of possible systematic errors.

Heat Capacity and Entropy.

The linear structure of $BeCl_2(g)$ has been confirmed by the electric deflection experiments of A. Büchler, A. D. Little, Inc. Progress Report No. 8, 31st Dec. 1963 under contract No. DA-19-020-ORD-5584. The bond length was obtained from the electron diffraction data of P. A. Akishin, V. P. Spirodinov and G. A. Sobelev, Dokl. Akad, Nauk SSSR 118, 1134 (1958). A Büchler and W. Klemperer, J. Chem. Phys. 29, 121 (1958) have reported the infra-red spectrum and assigned 1113 as the asymmetric stretch ν_3 and 482 as the bending frequency ν_2. However, A. Snelson, IIT Research Institute, Report No. IITRI-C6013-4 May 1964 under Contract No. DA-31-124-ARO(D)-111 using matrix isolation experiments has shown this second band to be due to beryllium chloride solid. The unobserved frequencies were estimated from a valence force field treatment by assuming that the ratio of stretching to bending force constant was 50:1 the same as for $BeF_2(g)$. This gives 230 cm.$^{-1}$ for ν_2 and 375 cm.$^{-1}$ for the symmetric stretch. The principal moment of inertia is 36.884 X 10^{-39} g. cm.^{2}

α_e = 0.01685 cm.$^{-1}$

r_e = 1.361 Å

Heat of Formation.

The selected $\Delta H^\circ_{f\ 298.15}$ was calculated from the experimental data of M. A. Greenbaum, R. E. Yates, M. L. Arin, M. Arshadi, J. Weiher, and M. Farber, J. Phys. Chem. 67, 703 (1963). A molecular flow effusion method was employed by Farber, et al., for the reaction: $BeF_2(g) + Be(c, l) = 2BeF(g)$ from 1425°-1675°K. Using the data reported by Farber, et al. partial pressures, and equilibrium constants were calculated and used to obtain a third law heat for this reaction. From this third law heat the selected $\Delta H^\circ_{f\ 298.15}$ was calculated. The following auxiliary data was used: $\Delta H^\circ_{f\ 298.15}$ = -188 ± 3 kcal. mole and free energy functions from the JANAF Table for $BeF_2(g)$, dated June 30, 1963.

The vapor pressure of an equal mixture of Be powder and $BeF_2(c)$ was measured in a graphite cell by a torsion-effusion method over the temperature range 800°-900°K by D. L. Hildenbrand, L. P. Theard, and N. D. Potter, Aeronutronic Technical Report U-1606, March 15, 1962. No vapor pressure increase over pure BeF_2 was detected. Assuming a detection limit of 20% of the BeF_2 vapor pressure they calculated that $D_0^\circ < 6.8$ e.v. for BeF. In a similar manner mass spectrometric and effusion pressure measurements on a BeF_2-Al system by D. L. Hildenbrand, L. P. Theard, and F. Ju, Aeronutronic Technical Report U-1988, Jan. 31, 1963, and D. L. Hildenbrand, Aeronutronic, private communication, April 19, 1963 lead to a $D_0^\circ < 6.7$ e.v. for BeF.

J. L. Margrave and co-workers, University of Wisconsin, private communication, Dec. 13, 1962, have mass spectrometrically measured the species formed when a reducing agent (Al) was added to BaF_2, SrF_2, CaF_2, and MgF_2. The D_0° values found for the species, BaF, SrF, CaF, and MgF, suggested to Margrave that the D_0° of BeF was likely to be in the range 5 ± 1 e.v.

V. M. Tatevskii, L. N. Tunitskii, and M. M. Navikov, Optics and Spectroscopy 5, 521 (1958), measured the emission spectra of BeF. On the basis of their analysis of the vibrational structure they gave a rather high value (8.0 ± 0.5 e.v.) for the D_0° of BeF. In a recent report on the dissociation energy of BeF, D. E. Mann, National Bureau of Standards Preliminary Report No. 7587, July 1, 1962, has analyzed the spectral data in the literature including the Russian work and concludes that a $D_0^\circ \simeq 6.2$ e.v. is probable.

A. G. Gaydon, Imperial College, London, private communication, Sept. 5, 1962, and W. C. Price, Kings College, London, private communication, March 1, 1963, suggested the Russians have chosen the wrong dissociation products. Therefore, the D_0° value they reported was about 2.5 e.v. too high.

Heats of formation and D_0° values for BeF(g) are summarized as follows:

D_0°	$\Delta H^\circ_{f\ 298.15}$	Remarks
5 ± 1 e.v.	-19.2 kcal. mole^{-1}	J. L. Margrave (loc. cit.)
5.5 e.v.	-30.7 kcal. mole^{-1}	A. G. Gaydon (loc. cit.) and W. C. Price) (loc. cit.)
6.2 e.v.	-46.8 kcal. mole^{-1}	D. E. Mann (loc. cit.)
6.3 e.v.	-48.3 ± 2.5 kcal. mole^{-1}	Calculated from the 2nd law ΔH_r of Farber, et al.
6.3 e.v.	-49.7 ± 2.0 kcal. mole^{-1}	The selected value.
$<$6.7 e.v.	$>$-58 kcal. mole^{-1}	Vapor Pressure of a BeF_2-Al system. Hildenbrand, et al.
$<$6.8 e.v.	$>$-60 kcal. mole^{-1}	Vapor pressure of a BeF_2-Be system. Hildenbrand, et al.
8.0 ± 0.5 e.v.	-88.3 kcal. mole^{-1}	V. M. Tatenskii et al., (loc. cit.)

Heat Capacity and Entropy.

The molecular constants used for this table were taken from G. Herzberg, "Molecular Spectra and Structure I. Spectra of Diatomic Molecules," D. van Nostrand Co., Inc., New York, 1950. To facilitate a comparison with Herzberg's constants, the molecular constants reported by Tatenskii, et al., were changed to the equilibrium state. The two sets of constants showed very slight differences.

BERYLLIUM DIFLUORIDE (BeF_2) (CRYSTAL) GFW = 47.009

ΔHf°_0 = -244.8 ± 1.0 kcal/mol

$S^\circ_{298.15}$ = 12.752 ± 0.04 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -245.4 ± 1.0 kcal/mol

Tt = 500°K (low quartz → high quartz)

ΔHt° = 0.0526 kcal/mol

Tm = 825°K

ΔHm° = 1.137 kcal/mol

$\Delta Hs^\circ_{298.15}$ = 55.15 kcal/mol

Heat of Formation

ΔHf° is the value selected by Parker (1), based on a thorough review of data for BeF_2(c, vitreous, aqueous) and BeO(c). Parker's analysis remains essentially unchanged for BeO(c) and BeF_2(c), even though the results for BeF_2(HF, aqueous) become more negative by 0.93 kcal/mol due to JANAF selections for HF(aqueous). Three values derived by Parker for BeF_2(c) from PbF_2(c) are changed due to JANAF auxiliary data; these values become -246.9, -246.0 and -247.2 for the three paths used by Parker.

The adopted ΔHf° was derived by combination of calorimetric data for Be(c) + F_2(g) → BeF_2(vitreous) and BeF_2(c) → BeF_2(vitreous). Churney and Armstrong (2) obtained $\Delta Hf^\circ_{298.15}$ = -244.32 ± 0.8 kcal/mol for vitreous BeF_2 by combustion in fluorine of polytetrafluoroethylene and mixtures of Be(c) with polytetrafluoroethylene. $\Delta Hr^\circ_{298.15}$(c → vitreous) = 1.125 ± 0.016 kcal/mol was measured via solution calorimetry by Taylor and Gardner (3).

Heat Capacity and Entropy

Cp° is based on JANAF curve fits of measurements by adiabatic calorimetry (8-300°K) and by ice calorimetry (354-776°K) as reported by Taylor and Gardner (3). The sample was estimated as approximately 99.5% BeF_2. Analyses indicated that the major impurity was about 0.3% oxygen, mainly in the form of absorbed water. Petrographic examination and X-ray diffraction showed the sample to be composed almost completely of quartz-type crystals. The entropy is derived from the smoothed Cp° based on the extrapolation S°_8 = 0.0065 gibbs/mol. The adopted Cp° above 300°K agrees closely with the relative enthalpy data and shows a remarkable similarity to that of SiO_2 (low quartz, high quartz).

Transition Data

Tt is the value selected by Taylor and Gardner (3) from their relative enthalpy data. ΔHt° is the corresponding difference in relative enthalpy from the JANAF curve fits for the two crystalline forms. Levina (4) studied the polymorphism of BeF_2 by observing the peaks in Cp near the transition temperatures. For low quartz → high quartz, Levina's peak began near 438°K, was complete near 503°K, and gave ΔHt = 0.17 kcal/mol. Levina found a second transition attributed to a form analogous to tridymite; this began above 670°K, was complete by 740°K, and gave ΔHt = 0.24 kcal/mol. There is no evidence for this transition in the relative enthalpy data, so we suspect that its occurrence may be due to impurities in Levina's sample. Levina also found that the cristobalite-like phase transformed in the region 380 to 420°K with ΔHt = 1.27 kcal/mol.

Melting Data

See the table for BeF_2(ℓ).

Heat of Sublimation

See the table for BeF_2(g).

BERYLLIUM DIFLUORIDE (BeF_2) (LIQUID) GFW = 47.009

$S^\circ_{298.15}$ = 14.321 gibbs/mol $\Delta Hf^\circ_{298.15}$ = -244.275 ± 1.0 kcal/mol

Tm = 825°K ΔHm° = 1.137 kcal/mol

Tb = 1448.2°K ΔHv° = 47.646 kcal/mol

Heat of Formation

ΔHf° is obtained from that of the crystal by means of ΔHr° = 1.125 ± 0.016 kcal/mol for BeF_2(c) → BeF_2(vitreous) at 298.15°K. Further details are given in the section on Melting Data. ΔHf°(ℓ) actually is based on the direct determination of ΔHf°(vitreous) by Churney and Armstrong (1) as discussed on the crystal table.

Heat Capacity and Entropy

Cp° is based on a JANAF curve fit of relative enthalpies of Taylor and Gardner (2) for the liquid (828-1183°K) and vitreous (320-473°K) forms of BeF_2. The combined data yield a normal Cp° curve and reveal no need for a glass transition. Scatter in the data is somewhat larger than for the crystal, presumably due to minor variations in the vitreous state at the conclusion of each drop. $S^\circ_{298.15}(\ell)$ is calculated from that of the crystal by addition of ΔSm° and the difference for crystal and liquid of $(S^\circ_{825}-S^\circ_{298.15})$.

Melting Data

Tm is the value selected by Taylor and Gardner (2) from their relative enthalpy data. These showed premelting starting near 804°K and complete melting above 828°K. Cooling of the liquid produced the vitreous state. Tm has also been reported as 815 (3), 821 (4), 818 (5) and 816 ± 5°K (6).

Solution calorimetry (2) gave ΔHr° = 1.125 ± 0.016 kcal/mol for BeF_2(low quartz) → BeF_2(vitreous) at 298.15°K. Confirmation of this result came from transposed temperature-drop calorimetry (7) and calorimetric conversion (8). These gave 1.1 ± 0.2 and 1.1 ± 0.5 kcal/mol, respectively. Combination of ΔHr° = 1.125 with JANAF enthalpies yields ΔHm° = 1.137 kcal/mol.

Vaporization Data

Tb is the calculated temperature at which ΔGr° = 0 for BeF_2(ℓ) → BeF_2(g). ΔHv° is the corresponding value of ΔHr°. These calculations neglect the presence of dimer, which is assumed to be negligible based on extrapolation of the equations of Belousov (9). Cantor (10) obtained Tb = 1442°K by extrapolation of his vapor pressures (1146-1372°K).

BERYLLIUM DIFLUORIDE (BeF_2) (IDEAL GAS) GFW = 47.009

Point Group $D_{\infty h}$

ΔHf°_0 = -190.3 ± 1.0 kcal/mol

$S^\circ_{298.15}$ = 54.36 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -190.25 ± 1.0 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
[670] (1)	345 (2)	1530 (1)

Bond Distance: Be-F = 1.40 ± 0.03 Å

Bond Angle: F-Be-F = 180°

σ = 2

Rotational Constant: B_0 = 0.22635 cm^{-1}

Heat of Formation

ΔHf° is calculated from that of the crystal by means of $\Delta Hs^\circ_{298.15}$ = 55.15 ± 0.1 kcal/mol. The selected value of ΔHs° is an average of those obtained by third-law analysis of vapor pressures measured by manometry (3), torsion effusion (4) and entrainment (8-10). Mass-spectrometric data (1, 2) are in reasonable agreement and so is the average of two Knudsen-effusion studies (6, 7). Several techniques (2, 4, 6) were used to show that the amount of dimer in the vapor is negligible up to at least 1000°K. JANAF analyses of the vaporization data are summarized as follows:

Source	Method	Range T, °K	δS* gibbs/mol	$\Delta Hs^\circ_{298.15}$, kcal/mol 2nd Law	3rd Law

*δS = ΔSr°(2nd law) - ΔSr°(3rd law)

Heat Capacity and Entropy

The bond length and angle are those derived by Akishin et al. (11) from electron-diffraction data for the vapor. Linearity of BeF_2 was confirmed by electric-deflection studies (12) of the vapor and by infrared studies (13) of matrix-isolated BeF_2. Infrared absorptions were found near 330 and 1540 cm^{-1} in neon matrices, leading to gas-phase estimates of 345 and 1555 cm^{-1} (13). The latter absorption was observed (14) at 1520 cm^{-1} in the infrared spectra of the vapor at 1000°C. We adopt a compromise of 1530 cm^{-1} and use this value in the valence-force-field approximation to estimate 670 cm^{-1} for the symmetric stretching mode.

LITHIUM TRIFLUOROBERYLLATE ($LiBeF_3$) (CRYSTAL) GFW = 72.9464

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = (21.3 ± 2) gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -390.2 ± 0.7 kcal/mol

Tm = 633°K

ΔHm° = Unknown

Heat of Formation.

The $\Delta Hf^\circ_{298.15}$ = -390.2 ± 0.7 kcal/mol was calculated from the $\Delta Hr^\circ_{298.15}$ = -2.24 ± 0.08 kcal/mol of the reaction $LiF(c) + LiBeF_3(c) = Li_2BeF_4(c)$ measured (calorimetrically) by P. Gross, Fulmer Research Institute, Administrative Report No. 4, January 1966.

Heat Capacity and Entropy.

The heat capacity (298 - 1100°K) was estimated from the difference of the Cp° values for $Li_2BeF_4(c)$ and LiF(c). Above 1100°K the values were extrapolated graphically. The entropy was estimated by addition of S°_{298} for $BeF_2(c)$ and LiF(c).

Melting Data.

Tm was obtained from the phase diagram of a mixture of LiF(c) and $BeF_2(c)$ reported by A. L. Mathews and C. F. Baes, Jr., ORNL-TM 1129, May 1965.

LITHIUM TRIFLUOROBERYLLATE ($LiBeF_3$) (Ideal Gas)

Mol. Wt. = 72.953

$\Delta H_{f\ 298.15}^\circ$ = -212 kcal. mole⁻¹

$S_{298.15}^\circ$ = [64] cal. deg.⁻¹ mole⁻¹

Point Group [C_{3v}]

Vibrational Frequencies and Degeneracies

ω, cm.⁻¹	ω, cm.⁻¹
[1530] (1)	[485] (2)
[820] (2)	[800] (3)
[700] (1)	

Bond distance: Be-F = [1.40] Å Li-Be = [1.209] Å

Li-F = [1.85] Å

Bond angle: F-Be-F = [120]° Li-Be-F = [90]°

Moment of inertia: $I_AI_BI_C$ = 2.1604 X 10^{-114} g.³ cm.⁶ σ = [3]

Heat of Formation. $\Delta H_{f\ 298.15}^\circ$ was calculated from $\Delta H_{r\ 900}^\circ$ = 53 kcal. mole for the reaction: $LiF(g) + BeF_2(g) = LiBeF_3(g)$ reported by J. Berkowitz and W. A. Chupka, Ann, N. Y. Acad. Sci., 79, 1073 (1960).

Heat Capacity and Entropy. The molecular structure was assumed to be pyramidal with Li atom at the top and BeF_3 located at the bottom. Beryllium atom was taken at the center of the equilaternal triangle formed by the three F atoms. The Be-F distance was estimated from that of BeF(g). The bond distance of Li-F was taken from R. F. Porter and E. E. Zeller, J. Chem. Phys., 33, 858 (1960). Vibrational frequencies were estimated by comparison with related fluorides.

Dilithium Tetrafluoroberyllate (Li_2BeF_4)

June 30, 1966

DILITHIUM TETRAFLUOROBERYLLATE (Li_2BeF_4) (CRYSTAL) GFW = 98.8838

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [29.8 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -539.0 ± 1.3 kcal/mol

Tm = 745°K

ΔHm° = 10.606 kcal/mol

Heat of Formation.

The $\Delta Hf^\circ_{298.15}$ = -539.0 ± 1.3 kcal/mol was calculated from the $\Delta Hr^\circ_{298.15}$ = -5.05 ± 0.06 kcal/mol of the reaction $2LiF(c) + BeF_2(gl) = Li_2BeF_4(c)$ measured (calorimetrically) by P. Gross, Fulmer Research Institute, R.163/23/May 1966. A value of ΔHr°_{298} = 1.17 kcal/mol was used for $BeF_2(c) \rightarrow BeF_2(gl)$.

Heat Capacity and Entropy.

The heat capacity is based on the enthalpy data (323-723°K) of T. B. Douglas and W. H. Payne, Natl. Bur. Std. Report 8186, January, 1964. The entropy was estimated by addition of values for the component fluorides.

Melting Data.

Tm and ΔHm° were obtained from Douglas et al., loc. cit., who measured the high temperature enthalpies.

June 30, 1966

DILITHIUM TETRAFLUOROBERYLLATE (Li_2BeF_4) (LIQUID) GFW = 98.8838

$S^\circ_{298.15}$ = [39.3 ± 2] gibbs/mol

Tm = 745°K

$\Delta Hf^\circ_{298.15}$ = -531.2 ± 1.3 kcal/mol

ΔHm° = 10.606 kcal/mol

Heat of Formation.

The $\Delta Hf^\circ_{298.15}$ was obtained from $\Delta Hf^\circ_{298.15}$(c) by adding ΔHm° and the difference between $H^\circ_{Tm}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 500°K. The heat capacity below 500°K was obtained from the heat capacity of the crystal. Above 500°K the heat capacity was assumed constant at 55.5 gibbs/mol calculated from the liquid enthalpy equation given by T. B. Douglas and W. H. Payne, Natl. Bur. Std. Report No. 8186, Washington, 1964. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See Li_2BeF_4(c) table.

α_e = 0.300 cm.$^{-1}$

r_e = 1.3431 Å

Heat of Formation.

Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall Ltd., London, 1953, selected a value of 2.3 ± 0.3 e.v. (53 ± 7 kcal. mole^{-1}) for D_0. Herzberg, "Molecular Spectra and Molecular Structure I. Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950, estimated D_0 as being 2.2 e.v. (50.7 kcal. mole^{-1}). Gaydon's value was used in this table.

Heat Capacity and Entropy.

Molecular constants were found in Herzberg, op. cit.

B_e = 10.7996 cm^{-1}

$\omega_e x_e$ = 39.79 cm^{-1}

α_e = 0.2935 cm^{-1}

σ = 1

r_e = 1.31216 Å

Heat of Formation.

The heat of formation was calculated from the equation $BeH(g) \rightarrow BeH^+(g) + e^-$ with the JANAF auxiliary data for BeH(g), using an ionization potential = 8.6 ± 0.4 eV (198.34 ± 9.23 kcal/mol) obtained from C. W. Beckett, NBS Report 8628, Jan. 1, 1965.

The dissociation energy, D_0 (Be^+-H) = 3.2 ± 0.2 eV (73.8 kcal/mol), has been reported by A. G. Gaydon, "Dissociation Energies," 2nd Ed., Chapman and Hall Ltd., London, 1953. This yields $\Delta Hf°_0$ (BeH^+, g) = 270.0 kcal/mol, which is in agreement with the value adopted.

Heat Capacity and Entropy.

The molecular constants were obtained from the ultraviolet spectroscopic studies by W. W. Watson and R. F. Humphreys, Phys. Rev. 52, 318 (1937).

The ground state configuration was given by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, New York, 1950. The estimated electronic level and quantum weight were obtained by assuming that a $^3\Sigma$ level lies below the first observed excited state ($^1\Sigma$) at 40,000 cm^{-1}.

BERYLLIUM MONOHYDROXIDE (BeOH) (IDEAL GAS) MOL. WT. = 26.021

Point Group [C_s]

$S^\circ_{298.15}$ = [53.28] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [2]

$\Delta H^\circ_{f\ 0}$ = -25 ± 10 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -25 ± 10 kcal. mole^{-1}

Vibrational Frequencies and Multiplicities

ω, cm.$^{-1}$
[1500] (1)
[1200] (1)
[3600] (1)

Bond Distance: Be-O = [1.4] Å O-H = [0.96] Å

Bond Angle: Be-O-H = [120°] σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [0.447] X 10^{-117} g.^{3} cm.^{6}

Heat of Formation.

D. L. Hildenbrand, L. P. Theard, and F. Ju, Ford Motor Co., Aeronutronic Division, Third Quarterly Report, U-2231, April-June, 1963, studied the equilibrium $Be_2O(g) + H_2O(g) \rightarrow 2BeOH(g)$ in a mass spectrometer. Using the JANAF values for the free energy functions and heats of formation yielded $\Delta H^\circ_{f\ 298}$ BeOH(g) = -24.8 ± 10 kcal. mole^{-1}, which was rounded to -25 ± 10 kcal. mole^{-1}. This value is a minimum one, that is, it is the most negative possible value.

Heat Capacity and Entropy.

The molecule was assumed to be nonlinear, the OH stretch was estimated as 3600 cm.$^{-1}$, the Be-O stretch as 1500 cm.$^{-1}$, from BeO(g), and the bending frequency as 1200 cm.$^{-1}$ The Be-O bond length was taken as a little larger than in BeO(g) while the O-H bond length is that in $H_2O(g)$. The bond angle was taken arbitrarily to be 120° and changes in this will have negligible effect on the functions unless it goes to 180°. The molecule contains one free electron and so was assumed to have a statistical weight of 2.

BERYLLIUM MONOHYDROXIDE UNIPOSITIVE ION ($BeOH^+$) (IDEAL GAS) GFW = 26.01902

Point Group [$C_{\infty v}$]

$S^\circ_{298.15}$ = [48.0] gibbs/mol

Ground State Quantum Weight = [1]

ΔHf°_0 = [194 ± 30] kcal/mol

$\Delta Hf^\circ_{298.15}$ = [194 ± 30] kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[1300] (1)
[1100] (2)
[3500] (1)

Bond Distance: Be-O = [1.4] Å O-H = [0.96] Å

Bond Angle: Be-O-H = [180°]

Rotational Constant: B_0 = [1.2602] cm^{-1}

σ = 1

Heat of Formation

The ionization potential (IP) of BeOH(g) is estimated as 9.5 ± 1 eV by comparison with the values IP(BeF, g) = 9.1 ± 0.5, IP(MgF, g) = 7.8 ± 0.3 (1) and IP(MgOH, g) = 8.5 eV. (JANAF value). Based on IP(BeOH, g) = 9.5 eV or 219 kcal/mol and ΔHf°_0(BeOH, g) = -25 ± 10 kcal/mol, we derive the heat of formation at 298°K for $BeOH^+$(g) as 194 ± 30 kcal/mol, which is tentatively adopted.

Heat Capacity and Entropy

The $BeOH^+$(g) molecule has eight valence electrons. Based on the criterion given by Walsh (2) that ABH molecules (H = hydrogen atom) containing ten or less valence electrons will be linear in their ground state, we assume that the structure of $BeOH^+$(g) is linear. The vibrational frequencies are estimated by comparison with those for BeOH(g) and LiOH(g). The Be-O and O-H bond distances are assumed to be the same as those in BeOH and H_2O molecules, respectively. The ground state quantum weight of $BeOH^+$(g) is assumed to be the same as that of the isoelectronic molecule LiOH(g). The moment of inertia is 2.221×10^{-39} g cm^2. The enthalpy at 0°K is -2.11 kcal/mol.

BERYLLIUM DIHYDROXIDE, ALPHA (α-$Be(OH)_2$) (CRYSTAL) GFW = 43.02694

$\Delta Hf°_0$ = Unknown

$S°_{298.15}$ = [11.8 ± 2] gibbs/mol

$\Delta Hf°_{298.15}$ = -215.75 ± 0.5 kcal/mol

Td = [407]°K

Heat of Formation.

The heat of formation is based on $\Delta Hr°_{298.15} = -79.16 \pm 0.5$ kcal/mol for the reaction $Be(c) + 2H_2O(l) = Be(OH)_2(\alpha,c) + H_2(g)$. The heat of this reaction is obtained by combination of the calorimetric heats of solution for pure beryllium metal and α-$Be(OH)_2$ in aqueous HF, measured by I. J. Bear and A. G. Turnbull, J. Phys. Chem. 69, 2828-33 (1965).

Heat Capacity and Entropy.

The heat capacity was assumed the same as that of the beta phase. The entropy is calculated from the value of $\Delta G°_{298.15} = -0.50$ kcal/mol for the change $\alpha\text{-}Be(OH)_2 \rightarrow \beta\text{-}Be(OH)_2$ which is obtained from the solubilities in concentrated alkali measured by R. Fricke and H. Humme, Z. Anorg. Allgem. Chem. 178, 400 (1929). This is combined with the $\Delta Hf°_{298.15}$ difference and gives a change in entropy, $\Delta S°_{298.15} = -0.8$ eu and an entropy of α-$Be(OH)_2$, $S°_{298.15} = 11.8 \pm 2$ eu.

Decomposition Data.

Td is calculated as the temperature at which $\Delta Gr°$ equals zero for $Be(OH)_2(\alpha,c) = BeO(c) + H_2O(g)$.

BERYLLIUM DIHYDROXIDE, BETA (β-Be(OH)$_2$) (CRYSTAL) GFW = 43.02694

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [11.0 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -216.50 ± 0.5 kcal/mol

Td = [417] °K

Heat of Formation.

The heat of formation is based on $\Delta Hr^\circ_{298.15}$ = -79.89 ± 0.5 kcal/mol for the reaction $Be(c) + 2H_2O(l) = Be(OH)_2(\beta,c) + H_2(g)$. The heat of this reaction is obtained by combination of the calorimetric heats of solution measured by Bear and Turnbull for pure beryllium metal and β-Be(OH)$_2$ in aqueous HF. Third law analyses of two studies of the decomposition pressure of water vapor over the β-phase are in good agreement with the selected heat of formation, as summarized below. Fricke and Severin observed a decomposition temperature of 105°C at a pressure of 100 mm, while Baur and Lecocq found 223°C for equilibrium with saturated water vapor at 24.2 atm. We have reduced the latter data to a standard state value of $\Delta G^\circ_{496.15}$ = -3028 cal/mol for the decomposition reaction given below.

	Source	Method	Reaction	T, °K	$\Delta Hr^\circ_{298.15}$ kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol
1	Bear & Turnbull	Calorimetric	$Be(c) + 2H_2O(l) \rightarrow Be(OH)_2(\beta,c) + H_2(g)$	294	-79.89	-216.52 ± 0.5
2	Fricke & Severin	Kp	$Be(OH)_2(\beta,c) \rightarrow BeO(c) + H_2O(g)$	378	15.68	-216.58
3	Baur & Lecocq	Kp	"	496	15.44	-216.34

Heat Capacity and Entropy.

The heat capacity is estimated from that for Mg(OH)$_2$ by subtracting the values for MgO and adding those for BeO.

The entropy is estimated by extrapolation to beryllium of the differences in S°_{298} between the chlorides and hydroxides of magnesium and calcium. Entropies of Mg(OH)$_2$, $MgCl_2$ and $BeCl_2$ are taken from the JANAF tables, while those of Ca(OH)$_2$ and $CaCl_2$ are taken to be 19.9 ± 0.1 and 25.0 ± 1.0 eu, respectively. [Recent low temperature data for $SrCl_2$ and $BaCl_2$ suggest that the $CaCl_2$ extrapolation should be S°_{50} = 2.4 ± 1.0 eu rather than the original value of S°_{50} = 4.59 eu used by K. K. Kelley and G. E. Moore, J. Am. Chem. Soc. 65, 782 (1943)]. Confirmation of the adopted entropy is obtained from the good agreement between the calorimetric heat of formation and the third law values derived from the equilibrium data.

Decomposition Data.

Td is calculated as the temperature at which ΔGr° equals zero for $Be(OH)_2(\beta,c) = BeO(c) + H_2O(g)$.

Bond Distances: Be-O = [1.35] Å O-H = [0.97] Å

Bond Angles: Be-O-H = [100°] O-B-O = [180°]

σ = 2

Angle between Be-O-H planes = [95°]

Product of the Moments of Inertia: $I_AI_BI_C = [32.26] \times 10^{-117}\ g^3cm^6$

Heat of Formation.

The equilibrium reaction (A) $BeO(c) + H_2O(g) \rightarrow Be(OH)_2(g)$ has been studied by several investigators; all of them inferred that $Be(OH)_2(g)$ was the major product, but there has been no direct proof of this. D. F. Hildenbrand, L. P. Theard and F. Ju, Aeronutronic, 3rd Quarterly Technical Report No. U-2231, Contract AF 04(611)-8523, 31 July 1963, have examined the $BeO-H_2O$ system at 2300°C mass-spectroscopically and report only BeOH and $Be(OH)_2$. They report a maximum value of the equilibrium constant for reaction (B) $BeO(g) + H_2O(g) \rightarrow Be(OH)_2$ of 3.5×10^5 atm^{-1} at 2327°K; this yields $\Delta Hf^\circ_{298.15}\ (Be(OH)_2,g) \geq -157.7 \pm 10$ kcal/mol using JANAF functions.

L. I. Grossweiner and R. L. Seifert, J. Am. Chem. Soc. 74, 2701 (1952); W. A. Young, J. Phys. Chem. 64, 1003 (1960); and W. I. Stuart and G. H. Price, J. Nucl. Mater. 14, 417 (1964), have all studied reaction (A) under similar conditions. Each of these investigators varied and $H_2O(g)$ flow rate without detectable change of K_p values. However, Grossweiner and Seifert used a considerably larger flow rate than the other investigators, and the reaction that they studied may not have been quite at equilibrium. The residence times in all cases were quite comparable. A second and third law analysis of the above data are shown below.

J. Blauer, M. A. Greenbaum and M. Farber, J. Phys. Chem. 70, 973 (1966), have also studied reaction (A) using the molecular flow effusion technique. They obtained a large variation of Kp with surface area, although the sample area and size were comparable to that in the earlier investigations. They operated at 300μ pressure, which is at the upper limits of the molecular flow regime. Also encountered was an unexpected variation of the blank experiments with sample size. All the samples investigated were relatively coarse with surface areas <60 cm^2/g; it seems likely that surface area effects would have been found in the three earlier investigations with up to threefold variation in sample weights. We conclude that the variation observed by Blauer et al. is not wholly caused by sample size. A second and third law analysis of the data are shown below.

G.R.B. Elliott, UCRL 1831 (1952), has also investigated reaction (A), but details of the sample are not available and the results show considerable scatter.

A. Baur and A. Lecocq, Comm. Energie At. (France), Rappt. CEA-R2611, Direction des Materiaux et Combustibles Nucleaires, Nov. 1964, cite the results of Morize, Roudier and Bisson, DM/948, in equation form.

*calculated using the 3rd law ΔHr°_{298}.

$\Delta Hf^\circ_{298}(Be(OH)_2,g) = -156.4 \pm 5$ kcal/mol is adopted, with a large uncertainty to cover errors due to the functions as well as the experimental uncertainty.

Heat Capacity and Entropy.

The structure is that assumed by R. L. Altman, J. Chem. Eng. Data 8, 534 (1963). One vibrational frequency was reported by M. Farber, M. A. Greenbaum, M. A. Frisch et al., Rocket Power, Inc., Final Report AFRPL-TR-66-220, Contract AF 04(611)-10929, September 1966. The remaining frequencies were estimated and adjusted to give reasonable agreement between the second and third law heats of reaction. The three principal moments of inertia are $I_A = 2.865 \times 10^{-40}$, $I_B = 10.60 \times 10^{-39}$, and $I_C = 10.62 \times 10^{-39}$ g cm^2.

r_e = [2.19] Å

Heat of Formation.

The dissociation energy was estimated from the experimental energies for BeF(g), BeCl(g), and the gaseous lithium halides. The resulting value, 79.1 kcal. mole^{-1}, was combined with JANAF heats of formation for Be(g) and I(g) in arriving at $\Delta H_f^\circ{}_{298.15}$.

Heat Capacity and Entropy.

The vibrational frequency was estimated from those of BeF(g), BeCl(g), and the gaseous lithium halides. The ground term was assumed to be similar to that of BeCl(g) and BeF(g), tabulated by G. Herzberg, "Molecular Spectra and Molecular Structure I. Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., New York, 1950. A correlation of the interatomic distances for the alkali halides, BeF(g), and BeCl(g) was employed in deriving r_e.

Dec. 31, 1961; June 30, 1965

BERYLLIUM DIIODIDE (BeI_2) (CRYSTAL) MOL. WT. = 262.821

$S^\circ_{298.15}$ = [28.8 ± 2] cal. mole^{-1} deg.$^{-1}$

T_m° = 753°K.

$\Delta H^\circ_{f\ 0}$ = Unknown

$\Delta H^\circ_{f\ 298.15}$ = [-50.6 ± 8] kcal. mole^{-1}

ΔH°_m = [5] kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 30.3 ± 2.0 kcal. mole^{-1}

Heat of Formation.

The heat of formation was estimated from the work of W. Biltz and C. Messerknecht, Z. anorg. Chem. 148, 157 (1925) and Biltz, Klatte and Rahlfs, Z. anorg. Chem. 166, 339 (1927) as reported in N.B.S. Circular 500, Washington 1952. They measured the heat of solution of BeI_2 in aq. HCl to an unknown concentration. This value was apparently adjusted and used with Be^{++} and $2I^-$ to obtain ΔH_f° of the crystal. However Be^{++} was estimated by the Bureau and a total uncertainty of 8 kcal. is thought to be realistic.

Heat Capacity and Entropy.

The heat capacity was estimated graphically by comparison with $BeCl_2$ and BeF_2. The entropy was also estimated by comparing with α-$BeCl_2$ and BeF_2 and using additive entropy values for the halide ions. K. N. Semenenko and T. N. Naumova, Zhur. Strukt. Khim. 4, 67 (1963) have reported that between 563 and 643°C BeI_2 exists in a β' form and above 643°C a β form and an unknown form also exist. No allowance has been made for these modifications in the present table.

Melting Data.

The melting point was reported by O. Rahlfs and W. Fischer, Z. anorg. Chem. 211, 351 (1933). The heat of melting was estimated by comparison with the heats of transition and melting for $BeCl_2$ and BeF_2.

Sublimation Data.

The heat of sublimation was obtained from a third law analysis of the vapor pressure data of Rahlfs and Fischer, loc. cit. from 578-703°K. This gave $\Delta H^\circ_{s\ 298}$ = 30.34 kcal. mole^{-1} with a drift of 3.2 ± 1.1 cal. mole^{-1} deg.$^{-1}$ A second law analysis gave $\Delta H^\circ_{s\ 298}$ = 28.1 ± 0.7 kcal. mole^{-1}. No attempt was made to change the functions to eliminate the drift, since a correlation with $BeCl_2$, $BeBr_2$ and BeI_2 indicated that the drift was probably due to the data rather than the functions.

BERYLLIUM DIIODIDE (BeI_2) (LIQUID) MOL. WT. = 262.821

$S^\circ_{298.15}$ = [32.4] cal. mole^{-1} deg.$^{-1}$

T°_m = 753°K.

T°_b = [755]°K.

ΔH°_f 298.15 = [-47.45 ± 3] kcal. mole^{-1}

ΔH°_m = [5] kcal. mole^{-1}

ΔH°_v = [23] kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from that of the crystal by adding ΔH°_m and the difference between H_{753}-H_{298} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated by comparison with the measured value for $BeCl_2$. A glass transition was assumed at 500°K. below which the heat capacity was that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See BeI_2(c) table for details.

Vaporizaton Data.

The temperature and heat of vaporization were calculated from the cross over point BeI_2(l) and (g).

Bond Distance: Be-I = 2.12Å

Bond Angle: I-Be-I = [180°]

σ = 2

Rotational Constant: B_o = 0.01478 cm.$^{-1}$

Heat of Formation.

The heat of formation was obtained from that of the crystal plus $\Delta H_{s\ 298}$, see BeI_2 (c) table for details.

Heat Capacity and Entropy.

The linear structure was assumed by analogy with $BeCl_2$. The bond length was reported by P. A. Akishin, V. P. Spirodinov and G. A. Sobelev, Dokl. Akad. Nauk SSSR, 118, 1134 (1958) from electron diffraction measurements. The vibrational frequencies were estimated by assuming a set of force constants k_1, for the BeF_2, $BeCl_2$, $BeBr_2$ and BeI_2 series and also assuming $k_1/k/l^2 = 50$ as for BeF_2. The principal moment of inertia is 189.402 x 10^{-39} g. cm.^{2}

BERYLLIUM NITRIDE (BeN) (IDEAL GAS) MOL. WT. = 23.021

Ground State Configuration $[^2\Pi]$

$\Delta H_{f\ 0}^\circ = [101]$ kcal mole^{-1}

$S_{298.15}^\circ = [49.87]$ cal deg^{-1} mole^{-1}

$\Delta H_{f\ 298.15}^\circ = [102]$ kcal mole^{-1}

Electronic Levels and Multiplicities

ϵ_i, cm^{-1}	g_i
0	[4]

$\omega_e = [1194]$ cm^{-1} $\omega_e x_e = [12.4]$ cm^{-1} $\sigma = 1$

$B_e = [1.555]$ cm^{-1} $\alpha_e = [0.019]$ cm^{-1} $r_e = [1.406]$ Å

Heat of Formation

The heat of formation was estimated by J. S. Gordon, Astrosystems International, Livingston, New Jersey, private communication, April 25, 1963.

Molecular Constants

The molecular constants were taken from J. S. Gordon, loc. cit.

Dec. 31, 1960; Sept. 30, 1963

BERYLLIUM OXIDE (BeO) (CRYSTAL) MOL. WT. = 25.013

$S^\circ_{298.15}$ = 3.38 ± 0.05 cal. deg.$^{-1}$ mole^{-1}

T_{t_1} = 2325°K.

T_m = 2820°K.

$\Delta H^\circ_{f\ 0}$ = -142.3 ± 0.1 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -143.1 ± 0.1 kcal. mole^{-1}

$\Delta H^\circ_{t_1}$ = 0.06 ± 1.0 kcal. mole^{-1}

ΔH°_m = 15.1 ± 0.4 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 174.1 ± 3.0 kcal. mole^{-1}

Heat of Formation.

L. A. Cosgrove and P. E. Snyder, J. Am. Chem. Soc. 75, 3102 (1953) have reviewed earlier determinations of the heat of formation and have made a very careful oxygen bomb calorimeter determination, their value is adopted here.

Heat Capacity and Entropy.

The high temperature enthalpy of BeO(c) has been reported by A. Magnus and H. Danz, Ann. Physik. [4] 81, 407 (1926) up to 1172°K; E. N. Rodigina and K. Z. Gomel'skii, Zhur. Fiz. Khim. 35, 1828 (1961) up to 1128°K; V. V. Kandyba, P. B. Kantor, R. M. Krasovitskaya and E. N. Fomichev, Doklady. Akad. Nauk. S.S.S.R. 131, 566 (1960) up to 2840°K; B. E. Walker, C. T. Ewing, and R. R. Miller, private communication, U. S. Naval Research Laboratory 18th April 1963 up to 1100°K; A. C. Victor and T. B. Douglas, J. Res. Natl. Bureau Standards 67A, 325 (1963) up to 1173°K. A high temperature phase transition has been reported by S. B. Austerman, Bull. Am. Physical Soc. II7 (1), 28 (1962) and has been confirmed using high temperature X-rays by T. W. Baker and P. J. Baldock, Nature 193, 1172 (1962). K. K. Kelley, J. Am. Chem. Soc. 61, 1217 (1939) has reported the low temperature heat capacities from 55.5 to 292.4°K. The heat capacity was assumed to follow the T^3 law below 55.5°K. and this gave $S_{55.5}$ = 0.045 cal. deg.$^{-1}$ mole^{-1}. The high temperature enthalpy data was smoothed using both 18 and 27 point groupings and was assumed to be discontinuous at 2325°K. The heat capacity obtained from the smoothed enthalpy was itself smoothed graphically so as to fit with the low temperature heat capacity. The data of Kandyba, et al., show no effect of the transition at 2325° and a value of 0.06 kcal. mole^{-1} was adopted simply to provide a somewhat improved fit of the data above 2325°K. The data above 2700°K. were not included because of apparent premelting effects and the heat capacity curve from 2700 to 2820°K. is extrapolated.

Transition Data.

See heat capacity and entropy.

Melting Data.

Obtained from the enthalpy measurements of Kandyba, et al., loc. cit.

Heat of Sublimation.

The gas above BeO(c) is complex and the value given is for the reaction BeO(c) → BeO(g) and simply read from the respective tables.

Dec. 31, 1960; Sept. 30, 1963

BERYLLIUM OXIDE (BeO) (LIQUID) MOL. WT. = 25.013

$S^\circ_{298.15}$ = 8.04 cal. deg.$^{-1}$ mole^{-1}

T_m = 2820°K.

T_b = [4060]°K.

ΔH°_f 298.15 = -129.562 ± 0.5 kcal. mole^{-1}

ΔH°_m = 15.1 ± 0.4 kcal. mole^{-1}

Heat of Formation.

The heat of formation was obtained from that of the crystal by adding ΔH°_m and the difference between H_{2820}-H_{298} for crystal and liquid.

Heat Capacity and Entropy.

The enthalpy of three points in the liquid phase was determined by V. V. Kandyba, P. B. Kantor, R. M. Krasovitskaya and E. N. Fomichev, Dokl. Akad. Nauk. S.S.S.R. 131, 566 (1960). These values were used to obtain a heat capacity for the liquid which was assumed constant. At 1900°K. a glass transition was assumed below which the heat capacity was that of the solid. The entropy at 298°K. was obtained in a manner analogous to the heat of formation.

Melting Data.

See the table for BeO(c).

Vaporization Data.

The vapor composition over BeO(c) at say 2300°K. is composed of Be(g), O(g), BeO(g), $(BeO)_2(g)$, $(BeO)_3(g)$, $(BeO)_4(g)$, $(BeO)_5(g)$, $(BeO)_6(g)$, $Be_2O(g)$ and other species and thus a boiling point becomes almost meaningless and the value given here is the point at which the total pressure reaches 1 atm.

Beryllium Oxide (BeO)

σ = 1

B_e = 1.6510 cm.$^{-1}$

α_e = 0.0190 cm.$^{-1}$

r_e = 1.3308 Å

<u>Heat of Formation</u>.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. <u>30</u>, 827 (1959) obtained a value of 106 ± 3 kcal. mole^{-1} for D_0, from the reactions $BeO(g) \rightarrow Be(g) + O(g)$ and $BeO(g) + O(g) \rightarrow Be(g) + O_2(g)$. The reactions were followed mass spectrometrically at low electron energies in order to eliminate fragmentation of higher polymers. A Lagerqvist, Arkiv. Fysik <u>7</u>, 473 (1954) had previously reported a value for D_0 = 110 ± 10 kcal. mole^{-1} based on the dissociation limit of the lowest $^1\Pi$ state which was assumed to dissociate to $Be(^1s)$ and $O(^1D)$. The $\Delta H_f^\circ{}_{298}$ BeO(g) = 31 ± 3 kcal. mole^{-1} from D_0 = 106 ± 3 kcal. mole^{-1} was adopted.

<u>Heat Capacity and Entropy</u>.

The spectroscopic constants are from G. Herzberg, "Molecular Spectra and Molecular Structure. I. Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York 1950. The ground state configuration has been confirmed by B. A. Thrush, Proc. Chem. Soc. (London), 339 (1960) using absorption spectroscopy.

Sept. 30, 1966

BERYLLIUM SULFATE (α - $BeSO_4$) (CRYSTAL) GFW = 105.0738

$S^\circ_{298.15}$ = 18.635 gibbs/mol

Tt_1 = 863°K

Tt_2 = 908°K

ΔHf°_0 = -284.4 ± 0.8 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -287.0 ± 0.8 kcal/mol

ΔHt°_1 = [0.266] kcal/mol

ΔHt°_2 = [4.673] kcal/mol

Heat of Formation.

Bear et al. measured the heats of solution of Be(c) and $BeSO_4$(α) in concentrated HF and the heat of reaction of H_2SO_4 (aq) with $BeSO_4$ (aq HF). Combination of these yields reaction (a) below. Taylor et al. measured heats of solution of Be(c) and $BeSO_4$(α) in H_2SO_4 (aq) which yields reaction (b). Marchal measured the total vapor pressure of $BeSO_4$(c) in the temperature range 863-1103°K. Partial pressures of SO_3(g) were calculated from Marchal's data using JANAF values for the SO_3 - SO_2 equilibrium. Third law analysis of these data yields ΔHr° for reaction (c) as given below. This was converted to ΔHf° for α- $BeSO_4$ using JANAF heats of transition.

Author	Method	Reaction	T°K	ΔHr_T kcal/mol	$\Delta Hf^\circ_{298.15}$ kcal/mol
1. Bear (1966)	Calorimetric	(a) $Be(c) + H_2SO_4(109\ H_2O) = H_2(g) + \alpha\text{-}BeSO_4$	294	-74.47	-286.65 ± 0.5
2. Taylor (1966)	Calorimetric	(b) $Be(c) + H_2SO_4(47.849\ H_2O) = H_2(g) + \alpha\text{-}BeSO_4$	298	-76.38	-287.55 ± 0.13
3. Marchal (1925)	Kp (973-1083°K)	(c) $BeSO_4(\gamma) \rightarrow BeO(c) + SO_3(g)$	298	+43.92	-286.55 ± 0.5

References: 1. I. J. Bear and A. G. Turnbull, J. Phys. Chem. 70, 711-17 (1966).
2. A. R. Taylor, Jr., B. B. Letson and D. F. Smith, U. S. Bureau of Mines, Report No. 6724, 1966.
3. G. Marchal, J. Chim. Phys. 22, 502 (1925).

The adopted $\Delta Hf^\circ_{298.15}$ = -287.0 ± 0.8 is an average value of reactions(a) and (b). This value is for relatively finely divided crystals of $BeSO_4$ as was indicated by Bear et al.

Heat Capacity and Entropy.

Low temperature heat capacities (12-301°K) and high temperature enthalpies (366-864°K) were measured by A. R. Taylor, Jr., T. E. Gardner and D. F. Smith, U. S. Bureau of Mines, Report No. 6240, 1963. These data were joined smoothly at 298°K and extrapolated graphically above 864°K. The entropy was obtained from the heat capacities using $S^\circ_{12.56}$ = 0.034 eu.

Transition Data.

I. I. Bosik, A. V. Novoselova and Yu. P. Simanov, Russ. J. Inorg. Chem. 6, 1295 (1961), observed two endothermic effects at 863-883°K and 908-913°K on the heating and cooling curves of $BeSO_4$(c); thus we have adopted Tt ($\alpha \rightarrow \beta$) = 863°K and Tt ($\beta \rightarrow \gamma$) = 908°K. ΔHt° ($\alpha \rightarrow \beta$) = 0.266 kcal/mol was obtained from the single enthalpy point at 863.9°K observed by Taylor, Gardner and Smith. ΔHt° ($\beta \rightarrow \gamma$) = 4.673 kcal/mol was chosen in order to give good agreement with the equilibrium data of Marchal, loc. cit.

BERYLLIUM TUNGSTATE ($BeWO_4$) (CRYSTAL) GFW = 256.8598

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [21.12 ± 2] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-361.7 ± 15] kcal/mol

Tm = Unknown

ΔHm° = Unknown

Heat of Formation.

The heat of formation, $\Delta Hf^\circ_{298}(BeWO_4,c) = -361.7$ kcal/mol, is calculated from $\Delta Hr^\circ_{298} = -17.1$ kcal/mol for $BeO(c) + WO_3(c) \rightarrow BeWO_4(c)$. The value of ΔHr°_{298} is assumed to be the same as that for $MgO(c) + WO_3(c) \rightarrow MgWO_4(c)$, using -143.7, -143.1, -201.5 and -362.3 kcal/mol for the heats of formation of MgO(c), BeO(c), $WO_3(c)$ and $MgWO_4(c)$, respectively.

Heat Capacity and Entropy.

Heat capacities are estimated by comparison with those of $CaWO_4(c)$[1], BeO(c)[2], and CaO(c)[3].

The entropy, $S^\circ_{298} = 21.12$ eu, is calculated from $\Delta S^\circ_{298} = -0.4$ eu for $BeO(c) + WO_3(c) \rightarrow BeWO_4(c)$. The value of ΔS°_{298} is assumed to be the same as that for $MgO(c) + WO_3(c) \rightarrow MgWO_4(c)$, using 6.44, 3.38, 18.14 and 24.18 eu for MgO(c), BeO(c), $WO_3(c)$ and $MgWO_4(c)$, respectively.

Bond Distance: Be-Cl = [1.7]Å

Be-Cl' (in ring) = [1.8]Å

Bond Angle: Cl'-Be-Cl' (in ring) = [88°]

Cl'-Be-Cl = [136°]

σ = 4

Product of the Moments of Inertia: $I_AI_BI_C$ = 2.62616 x 10^{-112} g.³ cm.⁶

Heat of Formation.

The heat of formation was estimated by assuming that the concentration of dimer in equilibrium with the monomer was ~5% at 500°K. as reported by D. L. Hildenbrand, L. P. Theard, E. Murad and F. Ju, Aeronutronic Div. of Philco Corp., Report U-3068, April 1965 under contract AF 04(611)-8523, giving an effective K_p = 5.5 x 10^{-4} for $2BeCl_2(g) \rightarrow Be_2Cl_4$ at 500°K.

Heat Capacity and Entropy.

The structure was assumed planar with a D_{2h} symmetry, the bond lengths were estimated from the values for $BeCl_2$ (g), a lengthening being assumed in the ring. The frequencies were estimated using K_2Cl_2 as a basis for the ring vibrations. Two polymeric frequencies had been observed by A. Snelson, IIT Research Institute, Report No. IITRI-C6013-4, May 1964, under Contract No. DA-31-124-ARO(D)-111. These were observed in matrix isolated $BeCl_2$ gas and were ascribed to polymeric species on account of their warm up behavior. They are here assigned to the B_{3u} asymmetric stretching mode and the B_{1u} symmetric out of plane wag of the non ring chlorines. The order of the frequencies listed above is arbitrary and not related to their specie types. The individual moments of inertia are: I_A = 18.396 x 10^{-39} g. cm.², I_B = 110.638 x 10^{-39} g. cm.² and I_C = 129.034 g. cm.²

Diberyllium Oxide Difluoride (Be_2OF_2)

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.5543474] X 10^{-114} g^3 cm^6

Heat of Formation.

J. Efimenko, NBS Report 8186, Jan. 1964, has studied mass spectrometrically the reaction $BeO(c) + BeF_2(g) \rightarrow Be_2OF_2(g)$ and also reported two sets of equilibrium constants. Using JANAF thermodynamic functions, the heat of reaction has been calculated from those reported equilibrium constants by the second law and the third law methods.

	Number of Measurements	Temperature Range (°K)	ΔHr°_{298} kcal/mol 2nd law value	ΔHr°_{298} kcal/mol 3rd law value	3rd law Drift (eu)
1st Set	13	1570-1891	41.448 ± 3.04	41.981	0.408 ± 1.726
2nd Set	21*	1872-2195	42.553 ± 0.70	42.714	0.015 ± 0.359

*Four points are rejected due to failure of statistical test.

A weighted average value, ΔHr°_{298} = 42.70 kcal/mol, was chosen for the heat of reaction. The heat of formation, ΔHf°_{298} (Be_2OF_2, g) = -287.9 ± 5 kcal/mol, was calculated from the selected heat of reaction, using ΔHf°_{298} (BeO, c) = 143.1 kcal/mol and ΔHf°_{298} (BeF_2, g) = -187.5 kcal/mol.

Heat Capacity and Entropy.

The adopted "V" shape molecular structure with nine fundamental vibrational frequencies was obtained from an estimation by D. E. Mann, NBS Report 8186, Jan. 1, 1964. The bond distances Be-O and Be-F were estimated to be the same as those in BeO(g) and $BeF_2(g)$, respectively. The three principal moments of inertia are I_A = 1.0103 X 10^{-39}, I_B = 49.7805 X 10^{-39} and I_C = 50.7908 X 10^{-39} g cm^2.

Bond distance: Be-O = [1.4] Å

Bond Angle: Be-O-Be = [180°]

σ = 2

Moment of Inertia: I_A = 5.8656 X 10^{-39} g. cm.^{2}

Heat of Formation.

D. L. Hildenbrand, L. P. Theard, and F. Ju, Ford Motor Co., Aeronutronic Division, Third Quarterly Technical Report U-2231, April-June 1963, have reported the heat of formation. Equilibrium constants were determined in a mass spectrometer for the reactions $2BeO(c) \rightarrow Be_2O(g) + O(g)$ - (1) $2BeO(g) \rightarrow Be_2O(g) + O(g)$ - (2) and $Be_2O_2(g) \rightarrow Be_2O(g) + O(g)$ - (3). Using our own free energy functions we obtain $\Delta H^\circ_{f\ 298}$ $Be_2O(g)$ = -13.1, -14.5, and -16.7 kcal. mole^{-1}, all ± 10; the 2nd law treatment of reaction 1 gives -18.3 ± 10 kcal. mole^{-1}. We adopt a median value -15 ± 10 kcal. mole^{-1}.

Heat Capacity and Entropy.

A. Buchler, J. L. Stauffer, W. Klemperer and C. Wharton, A. D. Little, Inc., Interim Technical Report No. 5, 1963, have shown Li_2O to be linear. Also A. D. Walsh, J. Chem. Soc. London 2269 (1953) preducted that AB_2 molecules with less than 16 bonding electrons would be linear. Thus Be_2O was taken to be linear and symmetrical, with a Be-O bond length of 1.4 Å, which is a little longer than in BeO(g). The vibrational frequencies were estimated by taking ω_3 to be larger than the stretch in BeO(g) and then calculating ω_1 from the valence force field assumption. The bending force constant was estimated as 1/20th of the stretching force constant. The two outermost electrons were considered unpaired and so gave a $^3\Sigma$ ground state.

Beryllium Oxide, Dimeric (Be_2O_2)

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) studied the temperature dependence of the $(BeO)_2^+$ ion in a mass spectrometer and obtained a second law heat of vaporization of 172 ± 8 kcal. mole^{-1} at 2150°K. No correction was made for fragmentation of higher polymers and this is reflected in the uncertainty. We adopted a heat of sublimation of 178 kcal. mole^{-1} in order to match more closely the equilibrium constant found by Chupka, et al. However, it was not possible to alter either the heat or entropy sufficiently to obtain exact agreement, the predicted pressure being too high by a factor of 20.

Heat Capacity and Entropy.

A planar ring configuration was assumed which has six vibrational frequencies of the type $2A_{1g}$, B_{1g}, B_{1u}, B_{2u}, and B_{3u}. These were estimated by comparison with $(LiO)_2$ for which values have been calculated by D. White, K. Seshadri, D. F. Dever, D. E. Mann, and M. J. Linevsky, prepublication communication, July, 1963. It seems unlikely that any other structure than that of a ring is possible, as, in order to approach the observed equilibrium constant an even lower entropy is needed. A non-linear chain would have a higher entropy due to the change in symmetry number and the two odd electrons. A linear chain would have approximately the same entropy due to cancellation of opposite effects. The vibrational frequencies were also made as high as possible by normalizing them using B_{3u} equal to the BeO stretch in BeO(g). The bond length was taken as the sum of the covalent radii of O and Be, which is in general agreement with other polymeric structures which generally increase in bond length by 10-20% in going from monomer to polymer. The bond angle was chosen arbitrarily, however, changes in the angle would change the entropy less than 1 eu.

The individual moments of inertia were $I_A = 7.057$, $I_B = 3.976$, and $I_C = 11.033 \times 10^{-39}$ g. cm.^{2}

Sept. 30, 1961; June 30, 1965

BERYLLIUM ORTHOSILICATE (Be_2SiO_4) (CRYSTAL) MOL. WT. = 110.108

$\Delta H_f^\circ{}_0 = -503.1 \pm 7$ kcal. mole^{-1}

$S^\circ_{298.15} = 15.342 \pm 0.1$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H_f^\circ{}_{298.15} = [-506.0 \pm 7]$ kcal. mole^{-1}

$T_m = 1833$°K.

Heat of Formation.

The $\Delta H_f^\circ{}_{298.15}$ was estimated from the $\Delta H_r^\circ{}_{298.15}$ of Mg, Ca and Ba oxides with SiO_2 given by K. K. Kelley in the report of investigations 5901, U. S. Department of the Interior, Bureau of Mines 1962, and from the $\Delta H_f^\circ{}_{298.15}$ of BeO(c) (Sept. 30, 1963) and SiO_2(c) (Dec. 31, 1962) in JANAF tables. The $\Delta H_r^\circ{}_{298.15} = 0 \pm 7$ kcal. mole^{-1} was estimated for the reaction $2BeO(c) + SiO_2(c) \rightarrow Be_2SiO_4(c)$.

Heat Capacity and Entropy.

At low temperatures C_p was used from K. K. Kelley, J. Am. Chem. Soc., 61, 1217 (1939). Above 298.15°K. C_p values were estimated by summation of the component oxides using JANAF tables, BeO (Sept. 30, 1963) and SiO_2 (Dec. 31, 1962). The entropy was calculated at 54.7°K. using the Debye and Planck-Einstein functions $D(\frac{422}{T}) + 2E(\frac{527}{T})$ given by K. K. Kelley, J. Am. Chem. Soc., 61, 1217 (1939). The value of $S^\circ_{54.7} = 13.59$ cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

The incongruent melting point was taken from Kubaschewski and Evans, "Metallurgical Thermochemistry" 3rd edition, Pergamon Press., New York 1958.

BERYLLIUM NITRIDE, ALPHA (α-Be_3N_2) (CRYSTAL) GFW = 55.050

$\Delta Hf°_0$ = -138.8 ± 0.3 kcal/mol

$S°_{298.15}$ = 8.157 gibbs/mol

$\Delta Hf°_{298.15}$ = -140.6 ± 0.3 kcal/mol

Tm = 2473°K

ΔHm° = [30.9] kcal/mol

Heat of Formation.

P. Gross, C. Hayman, P. D. Greene and J. T. Bingham, Trans. Faraday Soc. 62, 2719 (1966), have measured the heat of chlorination of α-Be_3N_2 to α-$BeCl_2$, and the heat of reaction of Be with ammonia. The chlorination reaction (A) $\alpha\text{-}Be_3N_2(c) + 3Cl_2(g) \rightarrow 3\ \alpha\text{-}BeCl_2(c) + N_2(g)$ had a $\Delta Hr°_{298}$ = -210.3 ± 1.1 kcal/mol, which, combined with the value of -117.1 ± 0.4 kcal/mol for α-$BeCl_2$ reported in the same paper, yields $\Delta Hf°_{298}(\alpha\text{-}Be_3N_2,c)$ = -141.0 ± 1.6 kcal/mol. Reaction (B) $3\ Be(c) + 2\ NH_3(g) = \alpha\text{-}Be_3N_2(c) + 3\ H_2(g)$ had a $\Delta Hr°_{298}$ = -214.6 ± 0.3 kcal/mol, which, combined with the JANAF value for $NH_3(g)$, yields $\Delta Hf°_{298}(\alpha\text{-}Be_3N_2,c)$ = -140.3 ± 0.3 kcal/mol. A weighted mean value of the above two determinations is adopted.

The decomposition $Be_3N_2(c) = 3\ Be(g) + N_2(g)$ has been studied by R. E. Yates, M. A. Greenbaum and M. Farber, J. Phys. Chem. 68, 2682 (1964), using the torsion effusion technique. The same decomposition has also been investigated by C. L. Hoenig, UCRL-7521, April 1964, using the Knudsen technique. An analysis of these data sets by 2nd and 3rd law methods is given below.

	Range		$\Delta Hr°_{298}$ kcal/mol		Drift	$^{**}\Delta Hf°_{298.15}$ Be_3N_2

*Points rejected due to failure of statistical test.

**Calculated from 3rd law $\Delta Hr°_{298}$.

The data of Yates et al. are seen to be in good agreement with the adopted $\Delta Hf°_{298}$.

Heat Capacity and Entropy.

The low temperature heat capacity of α-Be_3N_2 has been measured, from 25° - 310°K, by B. H. Justice, The Dow Chemical Co., 1st Quarterly Report under Contract AF04611-67-C-0009, April 1967. These measurements are joined smoothly with the high temperature enthalpies reported by T. B. Douglas and W. H. Payne, Natl. Bur. Std. Report 7587, July 1962. Above 1200°K the values were smoothly extrapolated to a limiting value of 6.2 gibbs/g-atom. The entropy at 298° was calculated by integration of the low temperature data based on S_{25} = 0.002 eu.

Melting Data.

See $Be_3N_2(l)$ for details.

Dec. 31, 1960; Mar. 31, 1963; Sept. 30, 1964; Mar. 31, 1967

BERYLLIUM NITRIDE (Be_3N_2) (LIQUID) GFW = 55.050

$S^\circ_{298.15}$ = [9.425] gibbs/mol

Tm = 2473°K

$\Delta Hf^\circ_{298.15}$ = [-116.4] kcal/mol

ΔHm° = [30.9] kcal/mol

Heat of Formation.

The heat of formation of $Be_3N_2(l)$ is calculated from ΔHf°_{298} $Be_2N_2(c)$ by adding ΔHm° and the difference between $H_{2473} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity is estimated to be constant and slightly greater than the maximum for $Be_3N_2(c)$. The entropy at 298°K is estimated in a manner analogous to that of the heat of formation.

Melting Data.

The melting point was reported by F. Fichter and E. Brunner, Z. Anorg. Allgem. Chem. 93, 84 (1915). The heat of melting was calculated on the assumption that each g-atom contributed 2.5 gibbs to ΔSm°.

Bond Distance: Be-O = [1.63] Å

σ = [6]

Bond Angle: Be-O-Be = [120°] O-Be-O = [120°]

Product of the Moments of Inertia: $I_AI_BI_C$ = [9.0658] X 10^{-114} g.^{3} cm.^{6}

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) measured the change in the intensity of the $(BeO)_3^+$ ion with temperature and obtained a second law heat of vaporization of 161 ± 6 kcal. mole^{-1} at 2150°K. The uncertainty is large because of an approximate correction of 8 kcal. mole^{-1} and the neglect of fragmentation effects. We adopted a heat of sublimation at 2150°K. of 163 kcal. mole^{-1} in order to bring the equilibrium vapor pressure into agreement with that measured by Chupka, et al.

Heat Capacity and Entropy.

The assumed D_{3h} symmetry implies eight vibrational frequencies of the types $2A_1'$, A_2', A_2'', 3E', and E_2''. The frequencies were estimated by comparison with the values for the $B_3O_3(O^-)_3$ skeleton as given by J. L. Parsons, J. Chem. Phys. 33, 1860 (1960) and the partial assignment of Boroxine by S. K. Gupta and R. F. Porter, J. Phys. Chem. 67, 1286 (1963). The bond length was taken as that in $Be_2O_2(g)$, while the bond angle was arbitrarily taken as 120°. The individual moments of inertia were $I_A = I_B$ = 16.550, I_C = 33.010 X 10^{-39} g. cm.^{2}

Bond Distance: Be-O = [1.63] Å

σ = [8]

Bond Angle: Be-O-Be = [115°] O-Be-O = [155°]

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.11656] X 10^{-112} g.^{3} cm.^{6}

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) measured the variation of intensity of the $(BeO)_4^+$ ion with temperature in a mass spectrometer. They reported a second law heat of vaporization of 177 ± 8 kcal. mole^{-1} at 2150°K., which included an approximate correction of 9 kcal. mole^{-1}, and this value was adopted here.

Heat Capacity and Entropy.

The assumed D_{4h} structure has 14 vibrational frequencies of the type $2A_{1g}$, A_{2g}, $2B_{1g}$, $2B_{2g}$, E_g, A_{2u}, B_{2u}, B_{1u}, and $3E_u$. The frequencies were estimated by comparison with $(BeO)_3$ and cyclobutane from G. W. Rathjens, N. K. Freeman, W. D. Gwinn, and K. S. Pitzer, J. Am. Chem. Soc. 75, 5634 (1953). The estimated structure and frequencies gave an entropy which was in excellent agreement with the experimental heat and equilibrium constant determined by Chupka, et al.

The bond lengths were taken equal to those in $Be_2O_2(g)$ and the angles were chosen so that O-Be-O was almost linear. The individual moments of inertia were calculated to be $I_A = I_B$ = 38.219, I_C = 76.438 X 10^{-39} g. cm.^{2}

Beryllium Oxide, Pentameric (Be$_5$O$_5$)

Product of the Moment of Inertia: $I_AI_BI_C$ = [6.9653] X 10^{-112} g.^{3} cm.^{6}

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) measured the variation in intensity of the $(BeO)_5^+$ ion with temperature in a mass spectrometer. They calculated a second law heat of vaporization of 193 ± 12 kcal. mole^{-1} at 2150°K., the uncertainty reflects the inclusion of an approximate correction of 10 kcal. mole^{-1}. This value was adopted here.

Heat Capacity and Entropy.

The assumed D_{5h} structure has 14 vibrations of the type $2A_1'$, A_2', $3E_1'$, $4E_2'$, A_2'', E_1'', and $2E_2''$. These were estimated by comparison with similar motions in other ring structures including $(BeO)_3$ and $(BeO)_4$. The estimated structure and frequencies gave an entropy in good agreement with the experimental heat and equilibrium constant determined by Chupka, et al.

The bond length was assumed to be the same as in Be_2O_2(g) and the angles were chosen so as to make O-Be-O almost linear. The individual moments of inertia are calculated to be $I_A = I_B$ = 70.356, I_C = 140.713 X 10^{-39} g. cm.^{2}

Bond Distance: Be-O = [1.63] Å

σ = [12]

Bond Angle: Be-O-Be = [110°] O-Be-O = [190°]

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.1266] X 10^{-111} g.^{3} cm.^{6}

Heat of Formation.

W. A. Chupka, J. Berkowitz, and C. F. Giese, J. Chem. Phys. 30, 827 (1959) measured the temperature dependence of the $(BeO)_6^+$ ion in a mass spectrometer. They calculated a second law heat of vaporization of 203 ± 15 kcal. mole^{-1} which was adopted here. The uncertainty reflects in part an approximate correction of 10 kcal. mole^{-1} and the small observed intensities.

Heat Capacity and Entropy.

The assumed symmetry D_{6h} has 20 vibrational frequencies of the type $2A_{1g}$, A_{2g}, B_{1g}, B_{2g}, E_{1g}, $4E_{2g}$, A_{2u}, $2B_{1u}$, $2B_{2u}$, $3E_{1u}$, and $2E_{2u}$. The frequencies were estimated by comparison with similar motions in other ring molecules including benzene, $(BeO)_3$ and $(BeO)_4$. The assumed structure and vibrational frequencies gave an entropy in good agreement with the heat and equilibrium constant determined by Chupka, et al. The bond length was taken equal to that in Be_2O_2(s) the angles were chosen so that the O-Be-O angle was almost linear but with the Be-O-Be angle less than 120°. The individual moments of inertia were calculated to be $I_A = I_B$ = 116.059, I_C = 232.118 X 10^{-39} g. cm.^{2}

Thermodynamic Functions.

Thermodynamic functions were calculated using electronic levels and multiplicities listed by C. E. Moore [Natl. Bur. Standards Circ. 467 (1949)]. Higher levels were averaged. The results are in good agreement with W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 147 (1955)], who used essentially the same data.

Heat of Formation.

The heat of formation is calculated from the dissociation energy of bromine selected by Evans, Munson, and Wagman (loc. cit.) and the heat of sublimation derived for diatomic bromine. Evans, Munson, and Wagman list experimental vapor density measurements from the literature which agree with the spectroscopic value within their estimated uncertainty.

Sept. 30, 1962; Sept. 30, 1965

BROMINE MONOCHLORIDE (BrCl) (IDEAL GAS) MOL. WT. = 115.362

Ground State Configuration $^1\Sigma^+$

$S^\circ_{298.15}$ = 57.337 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = 5.28 ± 0.30 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = 3.50 ± 0.3 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ, cm.$^{-1}$	g_i
0	1

ω_e = 443.1 cm.$^{-1}$

B_e = 0.150797 cm.$^{-1}$

$\omega_e x_e$ = 1.8 cm.$^{-1}$

α_e = 0.0007597 cm.$^{-1}$

σ = 1

r_e = 2.136 Å

Heat of Formation.

The average $\Delta H^\circ_{r\ 298.15}$ = -0.406 kcal. mole^{-1} for the reaction $Br_2(g) + Cl_2(g) = 2BrCl(g)$ and the $\Delta H^\circ_{f\ 298.15}$ = 3.694 kcal. mole^{-1} for 1/2 $Br_2(g)$ from JANAF tables were used to calculate the $\Delta H^\circ_{f\ 298.15}$ = 3.5 ± 0.3 kcal. mole^{-1}. Other equilibrium measurements not included below have been summarized by Beeson and Yost, loc. cit.

Heat Capacity and Entropy.

All spectroscopic and molecular constants were obtained from W. H. Evans, T. R. Munson and D. D. Wagman, J. Res. Natl. Bur. of Standards, 55, 147 (1955) except r_e which was calculated from B_e. The value of r_e was reported to be 2.13 Å and 2.11 Å by C. M. Beeson and D. M. Yost, J. Am. Chem. Soc. 61, 1432 (1939) and L. G. Cole and G. W. Elverum Jr., J. Chem. Phys., 20, 1543 (1952), respectively. Ground state configuration was taken from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

BROMINE MONOFLUORIDE (BrF)   (IDEAL GAS)   MOL. WT. = 98.9074

Ground State Configuration $^1\Sigma^+$

$S^\circ_{298.15}$ = 54.700 cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = -12.1 ± 0.4 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -14.0 ± 0.4 kcal. mole^{-1}

Electronic Levels and Quantum Weight

ϵ, cm.$^{-1}$	g_1
0	1

ω_e = 673 cm.$^{-1}$ $\omega_e x_e$ = 4 cm.$^{-1}$ σ = 1

B_e = 0.356319 cm.$^{-1}$ α_e = 0.005206 cm.$^{-1}$ r_e = 1.7555 Å

Heat of Formation.

The equilibrium constant for the reaction $Br_2(g) + BrF_3(g) = 3BrF(g)$ has been measured over the temperature range 328-380°K. by R. K. Steunenberg, R. C. Vogel and J. Fischer, J. Am. Chem. Soc. 79, 1320 (1957). Third law analysis of the data yields a $\Delta H^\circ_{r\ 298}$ = 11.785 ± 0.2 kcal. mole^{-1}, with a drift of -0.6 ± 1.2 cal. mole^{-1} deg.$^{-1}$. Second law analysis yields $\Delta H^\circ_{r\ 298}$ = 11.98 ± 0.45 kcal. mole^{-1}, thus it is obvious that the data is thermodynamically self consistent. There is an uncertainty in the entropy of $BrF_3(g)$ of ± 1 cal. mole^{-1} deg.$^{-1}$ but this corresponds only to ± 0.35 kcal. mole^{-1} in $\Delta H^\circ_{r\ 298}$, thus a best value of $\Delta H^\circ_{r\ 298}$ = 11.78 ± 0.5 kcal. mole^{-1} is adopted. This yields $\Delta H^\circ_{f\ 298}$ BrF = -13.973 ± 0.4 kcal. mole^{-1}, the uncertainty in the heat of formation being a maximum value comprising the sum of the uncertainties in Br_2, BrF_3 and ΔH°_r.

Attempts have been made to analyse the spectra of BrF to obtain a D°_o value. P. H. Brodersen and J. E. Sicre, Z. Physik 141, 515 (1955) obtained two dissociation limits for BrF of 65.52 kcal. mole^{-1} and 54.98 kcal. mole^{-1}. The difference corresponds to the $Br(^2P_{1/2}) - Br(^2P_{3/2})$ excitation energy, indicating that the upper state goes to $F(^2P_{3/2})$ and $Br(^2P_{1/2})$. This yields a heat of formation of BrF of -10.23 kcal. mole^{-1}. Since this value is well outside the possible uncertainty limits of the equilibrium data we must conclude that the extrapolation is in error. W. H. Evans, T. R. Munson and D. D. Wagman, J. Res. Natl. Bur. Std. 55, 147 (1955) have also analysed the spectra and conclude that a heat of formation of -14.4 kcal. mole^{-1} is possible. However W. H. Evans, private communication Nov. 1965, now believes that the dissociating state was too strongly perturbed for meaningful extrapolation.

Heat Capacity and Entropy.

All molecular constants were obtained from W. H. Evans, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bur. of Standards 55, 147 (1955) except r_e and ground state configuration which were taken from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

Product of the Moment of Inertia: $I_AI_BI_C = 4.519225 \times 10^{-114}$ g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15} = -61.087 \pm 0.7$ kcal. mole^{-1} is from L. Stein, J. Phys. Chem. 66, 288 (1962) and was derived from heats of reaction of F_2 with Br_2 which were measured in an adiabatic calorimeter. Stein's value for the $\Delta H^\circ_{f\ 298.15} = -64.78$ kcal. mole^{-1} was based upon gaseous Br_2, which has been adjusted to the liquid Br_2 reference state at 298.15°K.

Heat Capacity and Entropy.

D. W. Magnuson, Report No. K-1179, Carbide and Carbon Chemicals Co., K-25 plant, Oak Ridge, Tennessee (December, 1954) determined the moments of inertia and quadrupole coupling coefficients of both $Br^{79}F_3$ and $Br^{81}F_3$ from a number of microwave transitions. From the moment of inertia the bromine trifluoride molecule was found to have a distorted -"T" structure with one short, 1.721 Å, and two long, 1.810 Å Br-F bonds. The FBrF angle was found to be 86° 12.6'.

H. H. Claassen, B. Weinstock, and J. G. Malm, J. Chem. Phys. 28, 285 (1958), observed two of the six vibrational levels in the vapor, and calculated the other four levels from a normal coordinate treatment of the molecule. They also obtained a measured entropy of $BrF_3(g)$, from low temperature data combined with vapor pressure data and an approximate correction for dimerization. This value is 71.9 e.u. at 316.27°K. compared with a value of 70.82 e.u. from this table, the difference is probably within the uncertainty of the data. The three principal moments of inertia are: $I_A = 7.7514 \times 10^{-39}$, $I_B = 2.05791 \times 10^{-38}$ and $I_C = 2.83306 \times 10^{-38}$ g. cm.^{2}

Bond Distance: $Br\text{-}F_{(equatorial)} = 1.79$ Å $Br\text{-}F_{(axial)} = 1.68$ Å

Bond Angle: $F_{(equatorial)}\text{-}Br\text{-}F_{(equatorial)} = [90°]$ and $F_{(axial)}\text{-}Br\text{-}F_{(equatorial)} = [90°]$ $\sigma = 4$

Product of the Moment of Inertia: $I_AI_BI_C$ = 3.2035 X 10^{-113} g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\,298.15}$ = -102.466 ± 0.5 kcal. mole^{-1} is from L. Stein J. Phys. Chem. 66, 288 (1962) and was derived from heats of reaction of F_2 with Br_2 which were measured in an adiabatic calorimeter. Stein's value for the $\Delta H^\circ_{f\,298.15}$ = -106.16 kcal. mole^{-1} was based upon gaseous Br_2 which has been adjusted to the liquid Br_2 reference state at 298.15°K.

Heat Capacity and Entropy.

G. M. Begun, W. H. Fletcher and D. F. Smith, J. Chem. Phys. 42, 2236 (1965) report the infrared (gas phase) and Raman (liquid phase) spectra and correlate the observations by means of normal coordinate calculations for the similar molecules BrF_5, IF_5, ClF_5 and $XeOF_4$. The fundamental frequencies are taken from Begun, et al., except for ν_9 which was beyond the range of their infrared measurements. The value ν_9 = 245 cm.$^{-1}$ for the gas has been observed by R. S. McDowell and L. B. Asprey, J. Chem. Phys. 37, 165 (1962) and is confirmed by 237 cm.$^{-1}$ found in the Raman spectra of the liquid. Raman values from the liquid were used for the infrared inactive fundamentals ν_4 and ν_6. One Raman active frequency, persumably ν_5, is not observed in any of the four molecules. The value ν_5 = 281 cm.$^{-1}$ was obtained from the normal coordinate calculation. Previous Raman studies were reported by C. V. Stephenson and E. A. Jones, J. Chem. Phys. 20, 1830 (1952).

A tetragonal pyramidal structure (C_{4v} symmetry) with the above parameters was used by Begun, et al., in the analysis of the spectra. This symmetry is consistent with the NMR spectra of H. S. Gutowsky and C. J. Hoffman, J. Chem. Phys. 19, 1259 (1951), with the dipole moment determined by M. T. Rogers, R. D. Pruett, H. B. Thompson and J. L. Speirs, J. Am. Chem. Soc. 78, 44 (1956), and with the X-ray crystal structure obtained by R. D. Burbank and F. N. Bensey, Jr., J. Chem. Phys. 27, 982 (1957). Bond distances were based on those in the crystal and the bond angle was assumed to be 90°, slightly larger than those in the crystal (80.5-86.5°). Begun, et al., indicate that the angle in the gaseous molecule is probably not exactly 90° but that the normal coordinate calculations are not sensitive to this angle. The three principal moments of inertia are: $I_A = 2.81497 \times 10^{-38}$, $I_B = 2.81497 \times 10^{-38}$ and $I_C = 4.04277 \times 10^{-38}$ g. cm.^{2}

Heat of Formation.

The enthalpy change, $\Delta H^\circ_{r\ 376.2} = -12.47 \pm 0.13$ kcal. mole^{-1}, for the reaction (1) 1/2 $H_2(g)$ + 1/2 $Br_2(g)$ = HBr(g) was reported by J. R. Lacher, L. Casali and J. D. Park, J. Phys. Chem. 60, 608 (1956). Using $\Delta H^\circ_{f\ 298.15}$ (Br_2, g) = 7.39 kcal. mole^{-1}, the $\Delta H^\circ_{f\ 298.15}$ (HBr, g) was derived as -8.71 ± 0.13 kcal. mole^{-1}.

The heat of oxidation of aqueous sulfur dioxide with gaseous chlorine and liquid bromine were determined by calorimetric methods by W. H. Johnson and J. R. Ambrose, J. Res. Natl. Bur. Std. 67A, 427 (1963) and W. H. Johnson and S. Sunner, Acta Chem. Scand., 17, 1917 (1963), respectively. The results were given as $\Delta H^\circ_{r\ 298.15} = -77.28 \pm$ 0.14 kcal. mole^{-1} ($X_2 = Cl_2(g)$) and -55.47 ± 0.11 kcal. mole^{-1} ($X_2 = Br_2(l)$) for the reaction $X_2 + SO_2\cdot2500\ H_2O$ + 2 $H_2O(l) = H_2SO_4\cdot2500\ H_2O$ + 2 (HX·1250 H_2O). The enthalpy change for the reaction $Cl_2(g)$ + 2 (HBr·1250 H_2O = $Br_2(l)$ + 2 (HCl·1250 H_2O) was calculated to be -21.82 ± 0.18 kcal. mole^{-1}. Using $\Delta H^\circ_{f\ 298.15}$ (HCl·1250 H_2O) = -39.93 ± 0.05 kcal. mole^{-1}, the heat of formation for HBr·1250 H_2O was derived to be -28.932 ± 0.10 kcal. mole^{-1}. Employing ΔH° (HBr·1250 H_2O → HBr·∞H_2O) = -0.084 kcal. mole^{-1}, leads to $\Delta H^\circ_{f\ 298.15}$ (HBr·∞H_2O) = -29.016 ± 0.10 kcal. mole^{-1}. Based on the value, $\Delta H^\circ_{r\ 298.15} = -20.350 \pm 0.012$ kcal. mole^{-1} for the reaction HBr(g) = HBr (∞ H_2O) reported by C. E. Vanderzee and J. D. Nutter, J. Phys. Chem. 67, 2521 (1963), the heat of formation ($\Delta H^\circ_{f\ 298.15}$) for HBr(g) was evaluated as -8.67 ± 0.10 kcal. mole^{-1}.

The heats of oxidation of As_2O_3 to As_2O_5 in aqueous solution with $Br_2(l)$ and $Cl_2(g)$ were measured by L. Bjellerup, S. Sunner and I. Wadsö, Acta Chem. Scand. 11, 1761 (1957) and S. Sunner and S. Thoren, Symposium on Thermodynamics and Thermochemistry, Lund, Sweden, July, 1963. Using the values $\Delta H^\circ_r = -56.61 \pm 0.11$ kcal. mole^{-1} ($X_2 = Br_2(l)$) and -100.09 ± 0.08 kcal. mole^{-1} ($X_2 = Cl_2$ (g)) for the reaction As_2O_3(aq.) + 2X_2 + 2 H_2O(aq.) → As_2O_5(aq.) + 4 HX(aq.) obtained from H. A. Skinner, Pure Appl. Chem. 8, 95 (1964), the ethalpy change for the reaction 2Br_2(l) + 4HCl(aq.) = 2Cl_2 + 4HBr(aq.) was calculated to be +43.48 ± 0.14 kcal. mole^{-1}. Based on $\Delta H^\circ_{f\ 298.15}$ (HCl, ∞ H_2O) = -39.93 ± 0.05 kcal. mole^{-1}, the value of $\Delta H^\circ_{f\ 298.15}$ (HBr, ∞ H_2O) was derived to be -29.06 ± 0.06 kcal. mole^{-1}, yielding $\Delta H^\circ_{f\ 298.15}$ (HBr, g) = -8.71 ± 0.06 kcal. mole^{-1}.

The value of $\Delta H^\circ_{f\ 298.15}$ (HBr, g) adopted is -8.71 ± 0.10 kcal. mole^{-1}.

Heat Capacity and Entropy.

The values of ω_e, $\omega_e x_e$, B_e and α_e were taken from T. C. James and R. J. Thibault, J. Chem. Phys. 42, 1450 (1965), and corrected to the average isotopic species. Submillimeter-wave spectra of HBr were measured by G. Jones and W. Gordy, Phys. Rev. 136, A 1229 (1964). The molecular constants derived were close to the values adopted. The ground state configuration was obtained from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950, in which molecular constants for HBr(g) were also given. A precise measurement of the infrared fundamental bands of HBr has been made by E. K. Plyler, J. Res. Natl. Bur. Std., 64, 377 (1960). The corresponding rotational and vibrational constants have been calculated from the observed data. The moment of inertia is 3.30614 X 10^{-40} g. cm.^{2}

$\Delta H^\circ_{f\ 298.15}$ = -64.9 ± 0.3 kcal. mole^{-1}

ΔH°_t = 0.77 kcal. mole^{-1}

ΔH°_m = Unknown

Heat of Formation.

The equilibrium pressures for the reaction $NH_4Br(c) \rightarrow NH_3(g) + HBr(g)$ have been measured by several investigators. Using the densi-tensimeter, A. Smits and R. Purcell, J. Chem. Soc 2944 (1928), determined both the equilibrium pressures and vapor densities of the decomposition products, simultaneously, at several temperatures. In order to check the density values obtained, the authors applied the "extrapolation method", from which it was calculated that the corresponding vapor density agreed with complete dissociation. Based on this conclusion, the reported equilibrium pressures were employed to evaluate the enthalpy changes (ΔH°_r) of the decomposition reaction by both the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K.	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Second Law Value	Third Law Value	Equipment Used
Smith and Calvert (1)	576.40-676.02	45.12 ± 0.13	44.93	Isoteniscope
Smits and Purcell (2)	604.95-668.15	45.50 ∓ 0.17	45.08	Densi-tensimeter
Johnson (3)	573.15-667.75	45.41 ∓ 0.44	44.85	Spiral Manometer

(1) A. Smith and R. P. Calvert, J. Am. Chem. Soc. 36, 1363 (1914).
(2) A. Smits and R. Purcell, J. Chem. Soc. 2944 (1928).
(3) F. M. G. Johnson, Z. physik. Chem. 65, 38 (1909).

The value of $\Delta H^\circ_{r\ 298.15}$ adopted is 45.2 ± 0.2 kcal. mole^{-1}. Using $\Delta H^\circ_{f\ 298.15}$ = -10.97 and -8.71 kcal. mole^{-1} for $NH_3(g)$ and HBr(g), respectively, the value of $\Delta H^\circ_{f\ 298.15}$ for $NH_4Br(c)$ is evaluated as -64.9 ± 0.3 kcal. mole^{-1}. The corresponding $\Delta H^\circ_{r\ 298.15}$ value evaluated from solution data, selected by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NSRDS-NBS2, National Bureau of Standards, April 1, 1965, is 45.5 ± 0.2 kcal. mole^{-1}.

The vapor densities (573-661°K.) of dissociation products of $NH_4Br(c)$ were also measured by A. Smith and R. H. Lombard, J. Am. Chem. Soc. 37, 38 (1915). Using the equilibrium pressures reported by A. Smith and R. P. Calvert, loc. cit, they derived the corresponding degrees of dissociation of $NH_4Br(c)$ at different temperatures. The calculated results indicated that only 48% of $NH_4Br(c)$ decomposed at 573°K. and as reaction temperatures increased to 661°K. the degree of dissociation decreased to 10%. This conclusion was stated to be erroneous by Smits and Purcell, loc. cit., probably because of incorrect density determinations.

Heat Capacity and Entropy.

The low temperature (13-305°K.) heat capacities and $S^\circ_{298.15}$ were obtained from M. Sorai, H. Suga and S. Seki, Bull. Chem. Soc. Japan, 38, 1125 (1965). The C_p values above 305°K. were estimated by comparison with those for NaCl(c), NaBr(c) and $NH_4Cl(c)$. The low temperature heat capacities were also measured by R. Ewald, Ann. Physik, 44, 1213 (1914), 139-301°K., and F. Simon, C. V. Simson and M. Ruhemann, Z. phys. Chem. 129, 339 (1927), 201.2-277.1°K.

Transition Data.

The temperature (T_t) and heat of transition (ΔH°_t) were given by P. W. Bridgman, Proc. Am. Acad. Arts Sci. 52, 91 (1916-17). T_t = 419.5 ± 0.6°K. was reported by M. M. Markowitz and D. A. Boryta, J. Phys. Chem. 66, 1477 (1962), which was determined by differential thermal analysis. According to Sorai, Suga and Seki, loc. cit., there are 3 solid phase transitions, namely Phase IV (CsCl) → Phase III (tetragonal) at 108°K., Phase III (tetragonal) → Phase II (CsCl) at 235°K. and Phase II (CsCl) → Phase I (NaCl) at 411°K.

Melting Temperature.

The value of T_m was taken from H. Rassow, Z. anorg. Chem. 114, 117 (1920), determined under pressure.

Temperature of Decomposition.

The temperature of decomposition (T_d) was calculated as the temperature at which the total pressure of the decomposition products for the reaction $NH_4Br(c) \rightarrow NH_3(g) + HBr(g)$ equals 1 atm. T_d = 674 and 668.4°K. were reported by N. W. Luft, Ind. Chemist, 31, 502 (1955) and M. M. Markowitz and D. A Boryta, loc. cit., respectively.

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives 0.7 ± 0.4 e.v. for the dissociation energy into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from K. Wieland, Zeits. f. Electrochemie 64, 761 (1960) were weighted according to their natural isotopic abundances. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York, 1950. The bond length was estimated to be 0.965 of the mercuric bond length by analogy with the mercury chlorides.

IODINE MONOBROMIDE (IBr) (IDEAL GAS) GFW = 206.8134

Ground State Configuration $^1\Sigma^+$

$S^\circ_{298.15}$ = 61.86 gibbs/mol

ΔHf°_0 = 11.91 ± 0.02 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 9.77 ± 0.02 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i	ϵ_i, cm^{-1}	g_i
0	1	16880	1
12230	6	[51677]	2
[16155]	5	[56349]	2

ω_e = 267.38 cm^{-1} $\omega_e X_e$ = 0.774 cm^{-1} σ = 1

B_e = 0.05568 cm^{-1} α_e = 0.00034 cm^{-1} r_e = 2.485 Å

Heat of Formation.

The equilibrium constants for the reaction (A) $I_2(g) + Br_2(g) = 2\ IBr(g)$ were determined to be 0.01124 and 0.01303 at 547.7 and 578°K, respectively, by W. Müller, Z. Physik. Chem. 123, 1 (1926), who studied the rate of reaction between $H_2(g)$ and $Br_2(g)$ in the presence of $I_2(g)$. M. Bodenstein and A. Schmidt, Z. Physik. Chem. 123, 28 (1926), derived two values of the equilibrium constants at 1495°K for the same reaction by vapor density studies on the system I_2, I, Br_2, Br and BrI. The equilibrium between $CuBr_2(c)$, $I_2(g)$, CuBr(c) and IBr(g) was investigated by J. McMorris and D. M. Yost, J. Am. Chem. Soc. 53, 2625 (1931), and the equilibrium constants at 115.0, 151.2 and 176.0°C for reaction (A) were evaluated. Based on these reported equilibrium constants, the corresponding enthalpy changes for reaction (A) are calculated by both the second and third law methods.

R. M. Badger and D. M. Yost, Phys. Rev. 37, 1548 (1931), observed the infrared bands of IBr and classified them as the $A^3\pi_2 \leftarrow X'\Sigma$ transition. They have shown that the dissociation products of the upper state are normal atoms.
W. G. Brown, Phys. Rev. 42 355 (1932), assigned a faint set of bands in the red as the $B^3\pi_{0^+} \leftarrow X'\Sigma$ system. By means of a vibrational analysis he found that the absorption spectrum of IBr is analogous to that of ICl. The heat of dissociation for IBr was evaluated to be 14,660 ± 5 cm^{-1} or 1.817 eV. Hence the enthalpy change for the reaction (B) $IBr(g) = I(g) + Br(g)$ is calculated as 41.92 kcal/mol.

The heats of formation for BrI(g) derived from the enthalpy changes for reaction (A) and (B) are presented in the following table. The value of $\Delta Hf^\circ_{298.15}$(IBr,g) adopted is 9.77 ± 0.02 kcal/mol.

Investigator	Reaction	Temperature °K	No. of Points	$\Delta Hr^\circ_{298.15}$, kcal/mol Second Law Value	Third Law Value	Drift eu	$\Delta Hf^\circ_{298.15}$* kcal/mol
Müller (1926)	(A)	547.7, 578	2	-3.07	-3.38	-0.55	9.47
Bodenstein and Schmidt (1926)	"	1495	1	-	-2.92	-	9.70
McMorris and Yost (1931)	"	388.2-449.2	14	-2.46	-2.85	-0.9 ± 0.4	9.73
Brown (1932)	(B)	298	-	-	41.92**		9.77**

*Calculation based on third law $\Delta Hr^\circ_{298.15}$ value.

**The value is derived from D°_0(I-Br).

Heat Capacity and Entropy.

The ground state configuration, electronic levels, quantum weights, ω_e and $\omega_e X_e$ are obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand, Inc., New York, 1950. The values of B_e, α_e (corrected to the average isotopic species) and r_e were reported by T. S. Jaseja, J. Mol. Spectry. 5, 445 (1960), who analyzed the microwave spectrum of IBr, corresponding to the transitions J = 4 → 5 and J = 5 → 6, for the two isotopic species, $I^{127}Br^{79}$ and $I^{127}Br^{81}$. The moment of inertia is 5.007 x 10^{-38} g cm^2.

The infrared absorption spectrum of IBr at 8000 - 6800 Å, associated with a $^3\pi_1 \leftarrow X^1\Sigma^+$ transition, was observed by L. E. Selin, Arkiv Fysik 21, 479 (1962). The derived rotational constants are different from those reported by Jaseja, loc. cit.

Dec. 31, 1961; Mar. 31, 1967

POTASSIUM BROMIDE (KBr) (CRYSTAL) GFW = 119.011

$S^\circ_{298.15}$ = 22.93 ± 0.01 gibbs/mol

Tm = 1007°K

ΔHf°_0 = -92.42 ± 0.1 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -94.12 ± 0.1 kcal/mol

ΔHm° = 6.1 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to monomer) = 51.08 kcal/mol

$\Delta Hs^\circ_{298.15}$ (to dimer) = 59.04 kcal/mol

Heat of Formation.

The heat of solution (ΔHsoln) of KBr(c) in $H_2O(l)$ has been measured by many investigators. The results were reviewed in detail by V. B. Parker, U. S. Natl. Bur. Std. NSRDS-NBS 2, 1965. Eight pertinent ΔH°_∞ values are reproduced in the table below. Adopting the best value, ΔHr°_{298} = 4.75 ± 0.02 kcal/mol, for the reaction KBr(c) = $K^+(\infty H_2O) + Br^-(\infty H_2O)$, we derive ΔHf°_{298} = -94.12 kcal/mol for KBr(c). The auxiliary values ΔHf°_{298} = -60.32 and -29.05 kcal/mol for $K^+(\infty H_2O)$ and $Br^-(\infty H_2O)$, respectively, are obtained from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965.

*Values are adjusted to 298.15°K and to infinite dilution.

**Lowest experimental molality.

Heat Capacity and Entropy.

The low temperature heat capacities, 2.9 - 272.2°K, were measured by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) A 242, 467 (1957), using an adiabatic calorimeter. The high temperature heat capacities, 325.25 - 711.75°K, are taken from A. Mustajoki, Ann. Acad. Sci. Fennicae, Ser. A I, 98, 7 (1951). These two sets of Cp data are joined smoothly at 298°K. The Cp values at temperatures, 720 - 1007°K, are extrapolated graphically, so that the derived enthalpy change ($H^\circ_{1007} - H^\circ_{298}$) = 9.9 kcal/mol agrees with that determined by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tennessee, Dec. 1, 1964. The derived enthalpies at 700, 800 and 900°K are also in good agreement with those measured by S. M. Skuratov and S. A. Lapushkin, J. Gen. Chem. USSR (Eng. Transl.) 21, 2485 (1951). The Cp values above 1007°K are obtained by graphical extrapolation.

The S°_{298} is calculated from the adopted low temperature Cp, based on $S^\circ_{2.9}$ = 0.0015 eu.

The heat capacities of KBr(c) were also measured by W. Nernst and F. A. Lindemann, Z. Elektrochem. 17, 817 (1911), 78.7 - 89.2°K; F. Koref, Ann. Physik 4, 49 (1911), 137 - 234°K; and K. Clusius, J. Goldmann, and A. Perlick, Z. Naturforsch. 4A, 424 (1949). The enthalpies of KBr(c) were determined by A. Magnus, Phys. Z. 14, 5 (1913), and C. B. Cooper, J. Chem. Phys. 21, 777 (1953). The results are in reasonable agreement with the adopted functions except for those reported by Cooper.

Melting Data.

See KBr(l) table for details.

Heat of Sublimation.

The heats of sublimation to monomer and dimer are calculated as the enthalpy changes for the following two reactions: KBr(c) = KBr(g) and 2 KBr(c) = $K_2Br_2(g)$.

Dec. 31, 1961; Mar. 31, 1967

POTASSIUM BROMIDE (KBr) (LIQUID) GFW = 119.011

$S^\circ_{298.15}$ = 25.225 gibbs/mol

Tm = 1007°K

Tb = 1671°K

$\Delta Hf^\circ_{298.15}$ = -89.984 kcal/mol

ΔHm° = 6.1 kcal/mol

ΔHv° = 35.65 kcal/mol

Heat of Formation.

The heat of formation (ΔHf°_{298}) for KBr(l) is obtained from ΔHf°_{298}(KBr, c) by adding ΔHm° and the difference between $H^\circ_{1007} - H^\circ_{298}$ for crystal and liquid.

J. Toguri, H. Flood and T. Forland, Acta Chem. Scand. 17, 1502 (1963), studied the chemical equilibrium for the reaction KBr(l) + HCl(g) = KCl(l) + HBr(g). They obtained ΔGr°_{1073} = 3.50 ± 0.08 and 3.54 kcal/mol from partial pressure data and emf data, respectively. The corresponding value calculated from these tables is 3.78 kcal/mol. Combination of the experimental results with JANAF auxiliary data leads to -89.70 and -89.74 kcal/mol for ΔHf°_{298}.

Heat Capacity and Entropy.

The heat capacity of 16.7 gibbs/mol was derived by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tennessee, Dec. 1, 1964, from enthalpy data in the range 1010 - 1100°K. This Cp value is adopted here for the temperature range 298 - 2500°K.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data.

The adopted Tm and ΔHm° were determined by J. W. Johnson and M. A. Bredig, J. Phys. Chem. 62, 604 (1958), and A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960), respectively.

Heats of melting of 6.2 kcal/mol from phase diagram studies and 6.7 kcal/mol from calorimetric measurements were obtained by E. Aukrust, B. Bjørge, H. Flood, and T. Forland, Annals of the New York Academy of Sciences 79, Art. 11, 830 (1960).

Vaporization Data.

The boiling point, Tb = 1671°K, is calculated as the temperature at which the sum of the partial pressures of KBr(g) and K_2Br_2(g) over KBr(l) equals one atmosphere. The value of ΔHv° is calculated as the heat required to produce one mole of vapor mixture, which contains 19.5% dimer (K_2Br_2) and 80.5% monomer (KBr).

Tb was reported to be 1648 and 1668°K by H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), and O. Ruff and S. Mugdan, Z. Anorg. Chem. 117, 147 (1921), respectively.

Heat of Formation.

The heat of formation is derived from the sublimation and vaporization data analyzed below. Numerous investigators have obtained total pressures by static methods or "apparent" pressures by effusion or transpiration. These pressures are converted to monomer pressures by use of functions [see $K_2Br_2(g)$ table] which are consistent with the dimer-monomer equilibrium data of Hagemark et al.(6). Second and third law analyses of the monomer pressures show remarkable consistency over temperatures from 637 to 1668°K. The selected value of ΔHf°_{298} = -43.0 ± 0.5 kcal/mol may be compared with -43.8 kcal/mol derived from D°_0 = 3.95 eV which is reported by Gaydon(14) based on atomic fluorescence data.

*Based on the third law ΔHr°_{298} value. (A) KBr(l) = KBr (g), (B) KBr(c) = KBr(g).

Heat Capacity and Entropy.

Rusk and Gordy(10) have investigated the pure rotational spectra of KBr in the 1.5 to 5.0 mm range of the microwave region by millimeter wave molecular beam spectroscopy. The reported values of ω_e, $\omega_e x_e$, B_e and r_e are adopted here and corrected to the average isotopic species. The value of α_e is obtained from Fabricand et al.(11). Molecular constants for KBr(g) have also been reported by Herzberg(12) and Rice and Klemperer(13). They are in good agreement with the values adopted. Herzberg(12) also lists an A state at 31770 cm^{-1} based on observed electronic spectra. The moment of inertia is 3.4604 x 10^{-38} g cm^2.

Sept. 30, 1961; June 30, 1966

LITHIUM BROMIDE (LiBr) (CRYSTAL) GFW = 86.848

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [17.7] gibbs/mol

$\Delta Hf^\circ_{298.15} = -83.87 \pm 0.1$ kcal/mol

Tm = 823°K

$\Delta Hm^\circ = 4.22$ kcal/mol

Heat of Formation.

The heat of formation, ΔHf°_{298} (LiBr,c) = -83.87 kcal/mol, was calculated from the heat of solution of lithium bromide (c) at infinite dilution and the ionic heats of formation of $Li^+(\infty H_2O)$ and $Br^-(\infty H_2O)$.

V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS 2, April 1, 1965, reviewed the heat of solution data in the literature and gave the "best" value, $\Delta H^\circ_\infty = -11,670 \pm 50$ cal/mol for $LiBr(c) \rightarrow LiBr(\infty H_2O)$ at 298.15°K. The ionic heat of formation, ΔHf°_{298} $(Li^+ \cdot \infty H_2O)$ = -66.49 kcal/mol, was calculated from ΔHf°_{298} $(LiOH \cdot \infty H_2O)$ = -121.46 kcal/mol (see JANAF LiOH(c) table, Mar. 31, 1966) with ΔHf°_{298} $(OH^- \cdot \infty H_2O)$ = -54.97 kcal/mol from NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Oct. 1, 1965. The value ΔHf°_{298} $(Br^- \cdot \infty H_2O)$ = -29.05 kcal/mol was also obtained from NBS Technical Note 270-1. Combination of the ionic heats of formation of $Li^+(\infty H_2O)$ and $Br^-(\infty H_2O)$ gives the heat of formation of $LiBr(\infty H_2O)$, ΔHf°_{298} = -95.54 kcal/mol.

Heat Capacity and Entropy.

A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1964, has measured the enthalpy changes by the drop method (723-883°K), yielding $H_{823}-H_{298}$ = 7.0 kcal/mol for the crystal at the melting point. Heat capacities derived from his data were $Cp_{773°}$ = 15.1 and $Cp_{853°}$ = 15.6 gibbs/mol for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of LiCl(c), NaCl(c) and NaBr(c).

The entropy, $S^\circ_{298.15}$ = 17.7 eu, was estimated by adding the entropy difference between NaBr(c) and NaCl(c) to the entropy of lithium chloride (c) at 298.15°K. Comparisons with other alkali halides give results within ± 0.5 eu of this value. K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) and 592 (1961), has estimated the heat capacities ($Cp = 11.50 + 3.02 \times 10^{-3}T$ gibbs/mol) and the entropy ($S^\circ_{298} = 16.0 \pm 0.5$ eu)

Melting Data.

The selected heat of fusion (ΔH°_{823} = 4.22 kcal/mol) was obtained from enthalpy measurements in a drop calorimeter by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

K. K. Kelley, U. S. Bur. Mines Bull. 393 (1936), reviewed some phase diagram studies of the lithium bromide system in the literature, and gave the heat of fusion ΔH°_{825} = 2.90 kcal/mol. M. Blanc, Compt. rend. 246, 570 (1958), reported the heat of fusion ΔH°_{819} = 3.095 kcal/mol by a cryoscopic method. Both values are too low.

Sept. 30, 1961; June 30, 1966

LITHIUM BROMIDE (LiBr) (LIQUID) GFW = 86.848

$S^\circ_{298.15}$ = [20.220] gibbs/mol

Tm = 823°K

Tb(to equilibrium mixture) = 1562°K

Tb(to monomer only) = [1611]°K

$\Delta Hf^\circ_{298.15}$ = -80.839 kcal/mol

ΔHm°=4.22 kcal/mol

ΔHv°(to equilibrium mixture) = 25.6 kcal/mol

ΔHv°(to monomer only) = [35.2] kcal/mol

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding the heat of fusion and the difference between $H^\circ_{823}-H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1964, has derived the heat capacity (Cp = 15.6 gibbs/mol) from enthalpy measurements (823° - 883°K) by the drop method. The liquid heat capacity was assumed to be a constant, 15.6 gibbs/mol. The entropy (S°_{298} = 20.220 eu) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiBr(c) table for detail.

Vaporization Data.

Tb (to monomer only) is taken as the temperature at which the calculated Gibbs energy change is zero for LiBr(l) → LiBr(g), while ΔHv°(to monomer only) is the corresponding heat of reaction.

Tb (to equilibrium mixture) is taken as the temperature at which the sum of the calculated partial vapor pressures of LiBr(g) and $Li_2Br_2(g)$ reaches one atmosphere (trimer and higher polymers have been neglected in calculation). This value (1562°K) is in good agreement with the boiling point of 1583°K obtained from total vapor pressure measurements by H. von Wartenberg and H. Schulz, Z. Elektrochem. 27, 568 (1921), and also the boiling point of 1538°K by O. Ruff and S. Mugdan, Z. anorg. Chem. 117, 147 (1921). ΔHv°(to equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 29.23 mole percent of dimer. For detailed information see LiBr(g) and $Li_2Br_2(g)$ table.

Heat of Formation.

The heat of formation (ΔHf°_{298} (LiBr, g) = -36.8 ± 3 kcal/mol) was calculated from the selected heat of vaporization and the heat of formation for lithium bromide (1). Lithium bromide vaporizes to a mixture of monomeric and dimeric gases. (Higher polymers have been neglected in the calculation.) The heats of vaporization to monomer and to dimer were chosen to satisfy (1) the total vapor pressure data measured by H. von Wartenberg and H. Schulz, Z. Elektrochem. 27, 568 (1921), and O. Ruff and S. Mugdan, Z. anorg Chem. 117, 147 (1921); (2) the partial vapor pressures of monomer and dimer derived from R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956), 28, 981 (1958), in an analysis of the velocity distribution of molecules in alkali halide vapor. The selected heats of vaporization are ΔHv°_{298}(to monomer) = 44.0 ± 3 kcal/mol and ΔHv°_{298}(to dimer) = 42.0 ± 5 kcal/mol which combine with the heat of formation of lithium bromide (1) (ΔHf°_{298} = -80.84 kcal/mol) to give the standard heats of formation of LiBr(g) and Li_2Br_2(g) -36.8 and -119.7 kcal/mol, respectively. The derived heat of dissociation is ΔH°_{298} = 46.0 kcal/mol for $Li_2Br_2(g) \rightarrow 2LiBr(g)$.

J. Berkowitz, H. A. Tasman and W. A. Chupka, J. Chem. Phys. 36, 2170 (1962), have measured mass-spectrometrically the heat of dissociation ΔH°_{850} = 45.9 kcal/mol (ΔH°_{298} = 46.9 kcal/mol) for $Li_2Br_2(g) \rightarrow 2LiBr(g)$ in a double oven apparatus by the second law method. D. L. Hildenbrand, L. P. Theard, W. F. Hall and N. D. Potter, Philco Report U-2289, under Contract NOw61-0905-C, Sept. 15, 1963, have determined mass-spectrometrically the heats of sublimation of lithium bromide by the second law method as ΔHs°_{740} (to monomer) = 46.9 and ΔHs°_{740} (to dimer) = 45.0 kcal/mol (equivalent to ΔHv°_{298} (to monomer) = 45.82 kcal/mol and ΔHv°_{298} (to dimer) = 41.93 kcal/mol). These values are in reasonable agreement with those selected in the tabulation.

Heat Capacity and Entropy.

The bond distance (r_e) was obtained from the microwave studies by A. Honig, M. Mandel, M. L. Stitch and C. H. Townes, Phys. Rev. 96, 629 (1954). The vibrational constants (ω_e and $\omega_e x_e$) were determined from the infrared spectrum by W. Klemperer, W. G. Norris, A. Büchler, and A. G. Emslie, J. Chem. Phys. 33, 1534 (1960). The rotational constants which have been corrected to the average isotopic species were obtained by A. J. Herbert, F. W. Breivogel, Jr., and K. Street, Jr., J. Chem. Phys. 41, 2368 (1964), using microwave spectra. Their data are in good agreement with those reported by Honig et al., loc. cit., and J. R. Rusk and W. Gordy, Phys. Rev. 127, 817 (1962).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by R. L. Wilkins, J. Chem. Eng. Data 5, 337 (1960), who used slightly different molecular constants.

MAGNESIUM MONOBROMIDE (MgBr) (IDEAL GAS) GFW = 104.221

Ground State Configuration $^2\Sigma$

ΔHf°_0 = -11 kcal/mol

$S^\circ_{298.15}$ = 58.481 ± 0.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -13 ± 7 kcal/mol

Electronic Levels and Quantum Weights

ϵ, cm^{-1}	g_i
0	2
25800	4
39200	4

ω_e = 373.8 cm^{-1}

$\omega_e x_e$ = 1.34 cm^{-1}

σ = 1

B_e = [0.165162] cm^{-1}

α_e = [0.000809] cm^{-1}

r_e = [2.34] Å

Heat of Formation.

The heat of formation was calculated from that of $MgBr_2(g)$ using the relation $D(MgBr)/\Delta Hatom\ (MgBr_2) = 0.46 \pm 0.04$ which has been shown to apply to several dihalides. This results in $\Delta Hf^\circ_{298} = -13 \pm 7$ and $D_0 = 74.4 \pm 7$ kcal/mol. The selected value is in good agreement with $D_0 \leqslant 77$ kcal/mol obtained from predissociation by G. Herzberg, "Spectra of Diatomic Molecules," second edition, D. van Nostrand Co., Inc., New York, 1950, and with the linear Birge-Sponer extrapolation of D_0 = 74 kcal/mol given by A. G. Gaydon, "Dissociation Energies," second edition, Chapman and Hall Ltd, London, 1953. Gaydon's selected value of $D_0 = 58 \pm 23$ kcal/mol was discounted since it would require the unlikely ratio $D(MgBr)/\Delta Hatom(MgBr_2) = 0.28$.

Heat Capacity and Entropy.

The molecular constants ω_e, $\omega_e x_e$ and ground state configuration ($^2\Sigma$) were taken from G. Herzberg, loc. cit., while α_e was calculated from the above constants. The bond distance was estimated to be the same as in $MgBr_2(g)$.

December 31, 1962

NITROGEN MONOBROMIDE (NBr) (IDEAL GAS) MOL. WT. = 93.924

$\Delta H_{f\ 0}^\circ = 73.7 \pm 5$ kcal. mole^{-1}

$\Delta H_{f\ 298.15}^\circ = 71.9 \pm 5$ kcal. mole^{-1}

Ground State Configuration $^3\Sigma^-$

$S^\circ_{298.15} = 56.25 \pm 0.1$ cal. deg.$^{-1}$ mole^{-1}

Electronic Level and Multiplicity

ϵ, cm.$^{-1}$	g_1
0	3

$\omega_e = 699.1$ cm.$^{-1}$

$\omega_e x_e = 4.7$ cm.$^{-1}$

$\sigma = 1$

$B_e = 0.443$ cm.$^{-1}$

$\alpha_e = 0.00399$ cm.$^{-1}$

$r_e = 1.79$ Å

Heat of Formation.

E. R. V. Miller and H. B. Dunford, J. Chem. Phys. 35, 1202 (1961) have extrapolated the ground state vibrational levels and obtain $D_0^\circ = 67 \pm 5$ kcal. mole^{-1} or $\Delta H_{f\ 0}^\circ = 73.7 \pm 5$ kcal. mole^{-1}.

Heat Capacity and Entropy.

Miller and Dunford loc. cit. give all the vibrational and rotational constants, which have been adjusted to the normally occurring isotopic mixture for bromine.

Bond Distance: O-N = 1.15 ± 0.04 Å N-Br = 2.14 ± 0.02 Å

Bond Angle: O-N-Br = 117 ± 3° σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 5.1631 \times 10^{-115}\ g^3\ cm^6$

Heat of Formation.

The chemical equilibrium of the reaction $2NO(g) + Br_2(g) = 2NOBr(g)$ has been studied by Trautz and Dalal[1], Blair, Brass and Yost[2], and Krauss[3], respectively. Using the reported equilibrium constants, the enthalpy changes ($\Delta Hr^\circ_{298.15}$) of this reaction are evaluated by both the second and third law methods. Based on the third law $\Delta Hr^\circ_{298.15}$ values, the heats of formation for NOBr(g) are derived. The results obtained are presented in the table below. The value of $\Delta Hf^\circ_{298.15}$ (NOBr,g) adopted is 19.63 ± 0.2 kcal/mol.

			$\Delta Hr^\circ_{298.15}$, kcal/mol

2. Blair et al.	30	296.9 - 502.9	-11.74 + 0.07	-11.26	1.3 ± 0.2	19.64
3. Krauss	23	264.0 - 290.1	-13.46 + 0.30	- 9.62	-13.7 ± 1.1	20.46

*The data points employed for evaluation are calculated from a given equation.

1. M. Trautz and V. P. Dalal, Z. Anorg. Chem. 110, 1 (1920).
2. C. M. Blair, Jr., P.D. Brass and D. M. Yost, J. Am. Chem. Soc. 56, 1916 (1934).
3. W. Krauss, Z. Physik. Chem. A175, 295 (1936).

Heat Capacity and Entropy.

The molecular structure of NOBr(g) has been determined by electron diffraction by J. A. A. Ketelaar and K. J. Palmer, J. Am. Chem. Soc. 59, 2629 (1937). The results were confirmed later by T. L. Weatherly and Q. Williams, J Chem. Phys. 25, 717 (1956), who studied the microwave spectrum of NOBr(g) in the region 20,000 - 40,000 Mc/sec and analyzed the J = 2→3 transition. The values of bond length and angle adopted are obtained from Ketelaar and Palmer, loc. cit. The infrared absorption spectrum of NOBr(g) has been examined from 400 to 5303 cm^{-1} by W. G. Burns and H. J. Bernstein, J. Chem. Phys. 18, 1669 (1950). The authors observed the first two fundamental vibrational frequencies and obtained the third from combination and overtones. These assignments are adopted. The three principal moments of inertia are: $I_A = 9.404 \times 10^{-40}$, $I_B = 2.2965 \times 10^{-38}$ and $I_C = 2.3906 \times 10^{-38}\ g\ cm^2$.

Sept. 30, 1964

SODIUM BROMIDE (NaBr) (CRYSTAL) MOL. WT. = 102.907

$S^\circ_{298.15}$ = 20.75 ± 0.06 cal. deg.$^{-1}$ mole^{-1}

T_m = 1020°K.

$\Delta H^\circ_{f\ 0}$ = -84.68 ± 0.10 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -86.38 ± 0.10 kcal. mole^{-1}

ΔH°_m = 6.24 kcal. mole^{-1}

$\Delta H^\circ_{s\ 298.15}$ = 51.98 kcal. mole^{-1} to monomer gas

Heat of Formation.

The heat of solution of NaBr(c) in water has been measured by F. A. Askew, E. Bullock, H. T. Smith, R. K. Tinkler, O. Gatty and J. H. Wolfenden, J. Chem. Soc. 1368 (1934) and W. E. Wallace, J. Am. Chem. Soc. 71, 2485 (1949) to be +0.01 and -0.144 kcal. mole^{-1}, respectively. Using $\Delta H^\circ_{f\ 298.15}$ (Na^+, aq.) = -57.39 and $\Delta H^\circ_{f\ 298.15}$ (Br^-, aq.) = -29.05 kcal. mole^{-1}, obtained from D. D. Wagman, National Bureau of Standards, private communication, July 2, 1964, the respective value of $\Delta H^\circ_{f\ 298.15}$ for NaBr(c) was found to be -86.3 and -86.45 kcal. mole^{-1}. The adopted value is the average of these two.

Heat Capacity and Entropy.

The low temperature heat capacities (7.21 - 301.63°K.) were measured by T. E. Gardner and A. R. Taylor, Jr., U. S. Bur. Mines RI 6435 (1964). The high temperature enthalpy changes (290 - 645, 290 - 816°K.) were determined by A. Magnus, Phys. Z. 14, 5 (1913). Based upon the latter data the high temperature heat capacities were derived. The two sets of C_p data were joined smoothly at 298°K. by graphical method. $S^\circ_{298.15}$ was obtained from T. E. Gardner and A. R. Taylor, Jr., loc. cit., using S°_{10} = 0.034 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

T_m and ΔH°_m were reported by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960). The values, T_m = 1014°K. and ΔH°_m = 5.52 kcal. mole^{-1}, reported by M. Blanc, Compt. Rend., 246, 570 (1958), were not used.

Heat of Sublimation.

The value of $\Delta H^\circ_{s\ 298.15}$ was derived from six sets of vapor pressure data by both the second and third law methods. See NaBr(g) table for detail.

Sept. 30, 1964

SODIUM BROMIDE (NaBr) (LIQUID) MOL. WT. = 102.907

$S^\circ_{298.15}$ = [24.940] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-81.105] kcal. mole^{-1}

T_m = 1020°K.

ΔH°_m = 6.24 kcal. mole^{-1}

T_b = [1720]°K. to monomer gas

ΔH°_v = 38.42 kcal. mole^{-1} to monomer gas

Heat of Formation.

$\Delta H^\circ_{f\ 298.15}$(l) was obtained from $\Delta H^\circ_{f\ 298.15}$(c) by adding ΔH°_m and the difference between $H^\circ - H^\circ_{298.15}$ for crystal and liquid. The equilibrium constant of the reaction NaBr(l) + HCl(g) = NaCl(l) + HBr(g) has been determined by J. Toguri, H. Flood and T. Forland, Acta Chem. Scand. 17, 1502 (1963). From the reported data, $\ln K_{800°C} = -1.19 \pm 0.01$, the heat of reaction ($\Delta H^\circ_{r\ 298.15}$) was derived to be 2.11 kcal. mole^{-1}. Using $\Delta H^\circ_{f\ 298.15}$ (HCl,g) = -22.062, $\Delta H^\circ_{f\ 298.15}$ (NaCl, l) = -92.24 and $\Delta H^\circ_{f\ 298.15}$ (HBr, g) = -8.70 kcal. mole^{-1}, the value of $\Delta H^\circ_{f\ 298.15}$ for NaBr(l) was evaluated to be -81.0 ± 0.5 kcal. mole^{-1} which is in reasonable agreement with the value adopted. The values of $\Delta H^\circ_{f\ 298.15}$ for HCl(g) and HBr(g) were obtained from D. D. Wagman, National Bureau of Standards, private communication, July 2, 1964.

Heat Capacity and Entropy.

Heat capacity for NaBr(l) was estimated by comparison with those for NaCl(c), AgCl(c) and AgCl(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH°_m were reported by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960). The values, T_m = 1014°K. and ΔH°_m = 5.52 kcal. mole^{-1}, reported by M. Blanc, Compt. Rend., 246, 570 (1958), were not used.

Vaporization Data.

The boiling point, T_b, was calculated as the temperature at which the value of ΔF°_r becomes zero for the reaction NaBr(l) → NaBr(g). The difference between ΔH°_f for NaBr(l) and NaBr(g) at T_b is the heat of vaporization, ΔH°_v.

Heat of Formation.

The heat of formation ($\Delta H^\circ_{f\ 298.15}$) was calculated from $\Delta H^\circ_{f\ 298.15}$ and $\Delta H^\circ_{s\ 298.15}$ for NaBr(c). The latter was derived from six sets of corrected vapor pressure data, due to the presence of dimeric species in the vapor, by both the second and third law methods. The results are listed as follows.

Investigator	Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H^\circ_{f\ 298.15}$* kcal. mole^{-1}
Niwa[1]	NaBr(c) → NaBr(g)	51.97	50.31	-35.24
Cogin and Kimball[2]	NaBr(c) → NaBr(g)	52.26	52.14	-34.18
Mayer and Wintner[3]	NaBr(c) → NaBr(g)	52.59	65.30	-33.79**
Ruff and Mugdan[4]	NaBr(l) → NaBr(g)	46.43	47.48	-34.15
Wartenberg and Albrecht[5]	NaBr(l) → NaBr(g)	46.38	47.54	-34.15
Bloom et al.[6]	NaBr(l) → NaBr(g)	46.23	51.53	-34.88**

*Based on the average of the second and third law values.

**Only the third law value being used.

[6] H. Bloom, J. O'M. Bockris, N. E. Richards and R. G. Taylor, J. Am. Chem. Soc. 80, 2044 (1958).

The value of $\Delta H^\circ_{f\ 298.15}$ for NaBr(g) adopted is the average value of the six $\Delta H^\circ_{f\ 298.15}$ values listed in the above table. The dissociation energy (D°_0) was calculated to be 86.28 kcal. mole^{-1} or 3.74 e.v. which is in good agreement with the values, $D^\circ_0 = 3.84 \pm 1$ and 3.85 e.v., reported by A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953 and G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, New York, 1950, respectively. According to L. Brewer, private communication, October 23, 1964, Gaydon's original reported value, $D^\circ_0 = 3.8$, is an average of the value of 3.84 e.v. from atomic fluorescence and the value of 3.75 e.v. calculated for Gaydon by Brewer from pressure data available at that time.

Heat Capacity and Entropy.

The values of ω_e, $\omega_e x_e$, B_e and α_e were taken from S. A. Rice and W. Klemperer, J. Chem. Phys. 27, 573 (1957). The adopted bond distance (r_e) was reported by A. Honig, M. Mandel, M. L. Stitch and C. H. Townes, Phys. Rev. 96, 629 (1954), which was derived from microwave spectrum. By electron-diffraction method, the Na-Br bond distance was determined as 2.64 ± 0.01 Å by L. R. Maxwell, S. B. Hendricks and V. M. Mosley, Phys. Rev. 52, 968 (1937). The discrepancy may be due to the presence of a large proportion of dimer at the higher pressures used in the electron-diffraction determination. The ground state configuration was reported by G. Herzberg, loc. cit.

June 30, 1963; Dec. 31, 1963

PHOSPHORUS MONOBROMIDE (PBr) (IDEAL GAS) MOL. WT. = 110.891

Ground State Configuration $[{}^3\Sigma]$

$S^\circ_{298.15}$ = [59.5] cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 0}$ = [45] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [43] kcal. mole^{-1}

Electronic Levels and Multiplicities

ϵ_i, cm.$^{-1}$	g_i
0	[3]

ω_e = [400] cm.$^{-1}$

$\omega_e x_e$ = [1.5] cm.$^{-1}$

σ = 1

B_e = [0.1519] cm.$^{-1}$

α_e = [0.0008] cm.$^{-1}$

r_e = [2.23] Å

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was estimated as 40.8 kcal. mole^{-1} by J. S. Gordon, Astrosystems International, Livingston, New Jersey, private communication, August 25, 1961. This $\Delta H^\circ_{f\ 298.15}$ was changed from the white (α) to red (V) phosphorus reference state.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit.

Lead Monobromide (PbBr)

(Ideal Gas) Mol. Wt. = 287.13

June 30, 1962

Lead Monobromide (PbBr) (Ideal Gas)

Mol. Wt. = 287.13

$\Delta H_f^\circ{}_{298.15} = 13.3 \pm 9.2$ kcal. mole^{-1}

$S^\circ_{298.15} = 64.936$ cal. deg.$^{-1}$ mole^{-1}

Ground State Configuration $^2\Pi_{1/2}$

Electronic Levels and Multiplicities

ϵ, cm.$^{-1}$	g_i
0	2
[8000]	2

$\omega_e = 207.5$ cm.$^{-1}$ $\omega_e x_e = 0.50$ cm.$^{-1}$

$B_e = [0.04874]$ cm.$^{-1}$ $\alpha_e = [0.00016]$ cm.$^{-1}$

$\sigma = 1$

Heat of Formation. $\Delta H_f^\circ{}_{298.15}$ was calculated from the dissociation energy of PbBr(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e and $\omega_e x_e$ were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York (1950). B_e and α_e were estimated by J. S. Gordon, Astrosystems, Inc., private communication, May, 1962. Electronic levels and multiplicities were estimated from those for PbF(g).

Heat of Formation

The heat of formation, ΔHf°_{298}, of TiBr (g) is calculated from the dissociation energy, D°_0, which is estimated as 104 kcal/mol. This estimate is obtained from the relation $D(TiBr_4) < D^\circ_0(TiBr) < D(TiBr_3)$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF_2(g) by Zmbov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e, and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interatomic distance is estimated from Guggenheimer's relation (2). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti^+ (3). α_e is estimated from the Morse potential function.

TUNGSTEN MONOBROMIDE (WBr)   (IDEAL GAS)   GFW = 263.759

Ground State Configuration [$^2\Delta$] ΔHf°_0 = [141.9 ± 20] kcal/mol

$S^\circ_{298.15}$ = [65.1] gibbs/mol $\Delta Hf^\circ_{298.15}$ = [140.1 ± 20] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	[4]
[5000]	[2]
[15000]	[20]

ω_e = [321.4] cm^{-1} $\omega_e x_e$ = [0.80] cm^{-1} σ = 1

B_e = [0.05254] cm^{-1} α_e = [0.00015] cm^{-1} r_e = [2.40] Å

Heat of Formation

The heat of formation, ΔHf°_{298}(WBr, g) = 140.1 kcal/mol, is calculated from the bond dissociation energy, D°_{298}(W-Br) = 90 ± 20 kcal/mol. This value of D°_{298} is estimated to be slightly higher than the average bond dissociation energy of WBr_6(g), by analogy with the WCl_x system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WBr_6(g). This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency, ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 456 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4(D^\circ_0 + 0.5\ \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is 53.27×10^{-39} g cm^2.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for WF(g). See WF(g) table (March 31, 1967) for details.

$B_e = [0.065]$ cm^{-1} $\alpha_e = [0.00018]$ cm^{-1} $r = [2.47]$ Å

Heat of Formation

The heat of formation, ΔHf°_{298}(ZrBr, g) = 72 kcal/mol, is derived from the estimated bond dissociation energy, D°_{298}(Zr-Br) = 103.5 ± 10 kcal/mol. The value of D°_{298}(Zr-Br) is calculated from the relation D°_{298}(Zr-Br)/D°_{298}(Ti-Br) = D°_{298}(Zr-Br_4)/D°_{298}(Ti-Br_4) where the average bond dissociation energies, D°_{298}(Zr-Br_4) = 102.2 kcal/mol, D°_{298}(Ti-Br_4) = 87.9 kcal/mol and D°_{298}(Ti-Cl) = 89.0 kcal/mol, all calculated from JANAF ΔHf°_{298} for $ZrBr_4$(g), $TiBr_4$(g), TiCl(g), Zr(g), Ti(g) and Br(g).

Heat Capacity and Entropy

The bond distance is assumed to be the same as that in $ZrBr_4$(g), which was estimated as 2.47 Å by Godnev, Aleksandrovskaia and Rigina, Optics and Spectroscopy, 7, 172 (1959). The estimated bond distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental frequency ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 416 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4\ (D^\circ_0 + 0.5\ \omega_e) = 0.0021$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is 42.1488×10^{-39} g cm^2.

The ground state configuration is taken from the ground state multiplet of Zr^+ reported by C. E. Moore, "Atomic Energy Levels," Vol. II, Natl. Bur. Std. Circ. 467, 1952. The electronic levels and quantum weights are estimated to be the same as those of ZrF(g).

0°K to 265.90°K	Crystal
265.90°K to 332.62°K	Liquid
332.62°K to 6000°K	Ideal Diatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal and Liquid.

Low temperature thermal data have been adopted from the work of D. L. Hildenbrand, W. R. Kramer, R. A. McDonald, and D. R. Stull [J. Am. Chem. Soc. 80, 4129 (1958)]. References to older work are given by Hildenbrand, et al., and are not given any weight here.

Heat of Melting and Melting Point.

Hildenbrand, et al., (loc. cit.) report T_m = 265.90°K and ΔH_m = 2.527 kcal. mole^{-1}.

Heat of Sublimation, Ideal Gas Functions.

See ideal gas tables for details.

The heat of formation at 298.15°K is zero by definition.

__Heat Capacity.__

The liquid heat capacity data of D. L. Hildenbrand, W. R. Kramer, R. A. McDonald, and D. R. Stull [J. Am. Chem. Soc. __80__, 4129 (1958)] were extrapolated to a constant value of 18.0 cal. mole^{-1} deg.$^{-1}$

__Entropy.__

The entropy is that given by Hildenbrand, et al., (loc. cit.) for liquid bromine at 298.15°K.

__Vaporization.__

See ideal gas tables for details.

December 31, 1961

BROMINE, DIATOMIC (Br_2) (IDEAL GAS) MOL. WT. = 159.832

$\Delta H^\circ_{f0} = 10.922 \pm .030$ kcal. mole^{-1}

$\Delta H^\circ_{f\ 298} = 7.387$ kcal. mole^{-1}

Ground State = $^1\Sigma$

$S^\circ_{298} = 58.647$ cal. deg.$^{-1}$ mole^{-1}

$\omega_e = 323.22$ cm.$^{-1}$

$\omega_e x_e = 1.070$ cm.$^{-1}$

$B_e = 0.08092$ cm.$^{-1}$

$\alpha_e = 0.000275$ cm.$^{-1}$

$\sigma = 2$

Thermodynamic Functions.

Spectroscopic data listed by G. Herzberg [Spectra of Diatomic Molecules, D. Van Nostrand Company, New York, 1950] have been adjusted to the isotopic mixture (50.52% Br^{79}, 49.48% Br^{81}). The calculated functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 147 (1955)] who used the same spectroscopic data.

Heat of Formation.

The heat of vaporization at 298.15°K was reported by D. L. Hildenbrand, W. R. Kramer, R. A. McDonald, and D. R. Stull [J. Am. Chem. Soc. 80, 4129 (1958)] as 7.387 ± .027 kcal. mole^{-1}, which calculates to 10.922 kcal. mole^{-1} at 0°K. Vapor pressure data from the literature and the above adopted thermodynamic functions for liquid and gas were used to calculate ΔH°_0 as follows:

	ΔH°_0, kcal. mole^{-1}
Liquid range	
Fischer and Bingle[1] (298° to 389°K)	10.905 ± .019
Ramsay and Young[2] (265° to 329°K)	10.924 ± .008
Scheffer and Voogd[3] (270° to 362°K)	10.906 ± .018
Solid range	
Frey and Gregory[4] (177° to 195°K)	10.941 ± .029
Henglein, Rosenberg, and Muchlinski[5] (177° to 241°K)	10.912 ± .034
Ramsay and Young[2] (256° to 262°K)	10.986 ± .014
Scheffer and Voogd[3] (253° to 264°K)	10.961 ± .014

For the liquid range, the data of Fischer and Bingle as well as that of Scheffer and Voogd show a decided decrease with increasing temperature, starting at about 10.94 and decreasing to 10.87 kcal. mole^{-1}. The data of Ramsay and Young show only a small trend with temperature and are in good agreement with the calorimetric value. For the solid range, the data are too scattered to be conclusive. The calorimetric value, as supported by Ramsay and Young, is adopted as the heat of formation of the ideal gas.

Sept. 30, 1966

IRON DIBROMIDE ($FeBr_2$) (CRYSTAL) GFW = 215.665

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = 33.62 ± 0.3 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -59.5 ± 0.5 kcal/mol

Tt = 650°K

ΔHt° = 0.1 kcal/mol

Tm = 964°K

ΔHm° = [12 ± 3] kcal/mol

$\Delta Hs^\circ_{298.15}$ (to monomer) = [49.6] kcal/mol

$\Delta Hs^\circ_{298.15}$ (to dimer) = [58.5] kcal/mol

Heat of Formation.

The heats of solution of Fe(c), Br_2(l) and $FeBr_2$(c) in Br_2-KBr aqueous solution were measured by use of ice calorimeter by (1) W. Hieber and A. Woerner, Z. Elektrochem. 40, 287 (1934). From the results obtained the heat of formation for $FeBr_2$(c) was reported to be -59.87 kcal/mol.

The heats of solution of $FeBr_2$(c) in water were determined by (2) J. C. M. Li and N. W. Gregory, J. Am. Chem. Soc. 74, 4670 (1952) and (3) P. Paoletti, Trans. Faraday Soc. 61, 219 (1965), to be -20.1 ± 0.4 and -20.06 ± 0.06 kcal/mol, respectively. Using $\Delta Hf^\circ_{298.15}$ = -29.05 and -21.3 kcal/mol for Br^-(aq) and Fe^{++}(aq), the corresponding heats of formation for $FeBr_2$(c) were calculated as -59.3 and -59.34 kcal/mol. The value of $\Delta Hf^\circ_{298.15}$ (Br^-, aq) was taken from "Selected Values of Chemical Thermodynamic Properties," Part I, Technical Note 270-1, by D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, National Bureau of Standards, 1965. The value of $\Delta Hf^\circ_{298.15}$ (Fe^{++}, aq) was derived from heats of solution and formation for $FeCl_2$(c) using $\Delta Hf^\circ_{298.15}$(Cl^-,aq) = -39.952 kcal/mol from the same source as $\Delta Hf^\circ_{298.15}$ (Br^-, aq)

The value of $\Delta Hf^\circ_{298.15}$ ($FeBr_2$,c) adopted is -59.5 ± 0.5 kcal/mol.

Heat Capacity and Entropy.

The heat capacities, 323-633°K, were measured by N. W. Gregory and H. E. O'Neal, J. Am. Chem. Soc. 81, 2649 (1959). Those for temperatures below 323°K and above 633°K were estimated by linear extrapolation. Low temperature heat capacities, 12-110°K, were reported by G. Miljutin and N. Nachimowitsch, Phys. Trans. Ukrain. Acad. Sci. 9, 71 (1940). However, these data are inadequate for obtaining an accurate entropy at 298°K. The adopted $S^\circ_{298.15}$ value was reported by N. W. Gregory and R. O. MacLaren, J. Phys. Chem. 59, 110 (1955). It was obtained from E. F. Westrum, Jr., University of Michigan, Ann Arbor, Michigan, by private communication. A magnetic transition at 11°K was reported by H. Bizette, C. Terrier, and B. Tsai, Compt. rend. 245, 507 (1957).

Transition Data.

Tt and ΔHt° were taken from N. W. Gregory and H. E. O'Neal, loc. cit.

Melting Data.

Tm adopted was reported by R. O. MacLaren and N. W. Gregory, J. Phys. Chem. 59, 184 (1955). The value was calculated from the vapor pressure equations and is slightly above the previously reported value, 684°C (957°K), by A. Ferrari, A. Celeri and F. Giorgi, Atti accad. Nazl. Lincei 9, 782,1134 (1929). However, it agrees well with 962 ± 2 °K obtained by the differential thermocouple cooling curve analysis by the same authors. The ΔHm° value was estimated from the vapor pressure data in order to obtain good agreement between the second and third law heats of vaporization. See the $FeBr_2$(g) table for details.

Heat of Sublimation.

$\Delta Hs^\circ_{298.15}$ (to monomer) is calculated as the difference between $\Delta Hf^\circ_{298.15}$ for $FeBr_2$(g) and $FeBr_2$(c). $\Delta Hs^\circ_{298.15}$(to dimer) is calculated as the difference between those for Fe_2Br_4(g) and 2 $FeBr_2$(c).

Sept. 30, 1966

IRON DIBROMIDE ($FeBr_2$) (LIQUID) GFW = 215.665

$S°_{298.15}$ = [40.483] gibbs/mol $\Delta Hf°_{298.15}$ =[-50.431] kcal/mol

Tm = 964°K $\Delta H\dot{m}$ = [12 + 3] kcal/mol

Tb = [1207] °K $\Delta H\dot{v}$ =[29.4] kcal/mol

Heat of Formation.

The value of $\Delta Hf°_{298.15}$ (l) was obtained from $\Delta Hf°_{298.15}$ (c) by adding ΔHm° and the difference between $H°_{Tm}-H°_{298.15}$ for $FeBr_2$(c) and $FeBr_2$(l).

Heat Capacity and Entropy.

The heat capacity was assumed to be constant in the temperature range from 298.15 to 2000°K and was estimated on the basis of 8.5 gibbs/g-atom. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $FeBr_2$(c) table for details.

Vaporization Data.

Tb is calculated as the temperature at which the total pressure of $FeBr_2$(g) and Fe_2Br_4(g) over $FeBr_2$(l) equals one atmosphere. Based on the vapor composition and the values of $\Delta H\dot{v}$ for both the monomer and dimer at Tb, the heat of vaporization is derived.

Rotational Constant: B_o = [0.02102] cm^{-1}

Heat of Formation.

The vapor pressures of $FeBr_2(c)$ and $FeBr_2(l)$ have been measured in the temperature range from 623.15 to 962.15°K by several investigators. Using the reported data the corresponding enthalpy changes (ΔHr°) for the reactions (A) $FeBr_2(c) = FeBr_2(g)$ and (B) $FeBr_2(l) = FeBr_2(g)$ were evaluated by both the second and third law methods. The results obtained are presented in the following table. The values of $\Delta Hf^\circ_{298.15}$ for $FeBr_2(g)$ are calculated based on the third law values for $\Delta Hr^\circ_{298.15}$. The value of $\Delta Hf^\circ_{298.15}$ for $FeBr_2(g)$ adopted is -9.9 ± 0.5 kcal/mol.

Reference	Reaction	Temperature, °K	Method	$\Delta Hr^\circ_{298.15}$, kcal/mol Second Law Value	$\Delta Hr^\circ_{298.15}$, kcal/mol Third Law Value	Drift eu	$\Delta Hf^\circ_{298.15}$ kcal/mol

1	(B)	962.15-1182.15	Diaphragm	39.77	40.84	+ 0.93	- 9.59

1. R. O. MacLaren and N. W. Gregory, J. Phys. Chem. 59, 184 (1955).
2. R. J. Sime and N. W. Gregory, J. Phys. Chem. 64, 86 (1960).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The electronic levels and quantum weights were estimated by comparison with those for $FeCl_2(g)$ reported by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The bond distance was estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The vibrational frequencies were estimated in order to obtain good agreement between the second and third law heats of sublimation and vaporization. The moment of inertia is 1.33148 x 10^{-37} g cm^2.

Br_2Hg

MERCURY DIBROMIDE ($HgBr_2$) (Crystal)

Mol. Wt. = 360.442

$\Delta H_f^\circ{}_{298.15} = -40.500 \pm 0.5$ kcal. mole^{-1}

$S^\circ_{298.15} = [40.706] \pm 1.5$ cal. deg.$^{-1}$ mole^{-1}

$T_m = 514$°K

$\Delta H_m = 4.280 \pm 0.08$ kcal. mole^{-1}

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952).

Heat Capacity and Entropy. C_p was assumed to be a linear function of temperature and was fitted to the data of M. Guinchant, Comp. Rend. 145, 320 (1907) and G. J. Janz and J. Goodkin, J. Phys. Chem. 63, 1975 (1959). The entropy was estimated by adjusting its value until the melting, sublimation and vaporization data were in agreement.

Melting. T_m was taken from National Bureau of Standards (U.S.) Circular 500 (loc. cit.). ΔH_m was given by G. J. Janz and J. Goodkin (loc. cit.).

MERCURY DIBROMIDE ($HgBr_2$) (Liquid)

Mol. Wt. = 360.442

ΔH_f° 298.15 = -37.158 ± 0.58 kcal. mole^{-1}

$S^\circ_{298.15}$ = [46.797] ± 1.5 cal. deg.$^{-1}$ mole^{-1}

T_m = 514°K

ΔH_m = 4.280 ± 0.08 kcal. mole^{-1}

T_b = 592°K

ΔH_v = 14.148 ± 0.25 kcal. mole^{-1}

Heat of Formation. Calculated from $\Delta H_f^\circ(c)$.

Heat Capacity and Entropy. C_p obtained from the data of G. J. Janz and J. Goodkin, J. Phys. Chem. 63, 1975 (1959) in the range 507-544°K, it was assumed constant above and below this value. A glass type transition was assumed at 343°K below which the heat capacity was equal to that of the crystal. The entropy was obtained from S°(c), the entropy of fusion and the estimated heat capacity.

Melting and Vaporization. T_m and T_b were taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952). ΔH_m was given by G. J. Janz and J. Goodkin (loc. cit.) and ΔH_v was obtained from the data of E. B. R. Prideaux, J. Chem. Soc. (London) 97, 2032 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

MERCURY DIBROMIDE ($HgBr_2$) (Ideal Gas)

Mol. Wt. = 360.442

ΔH_f° 298.15 = -20.424 ± 2.0 kcal. mole^{-1}

$S^\circ_{298.15}$ = 76.511 cal. deg.$^{-1}$ mole^{-1}

Point Group = $D_{\infty h}$

Vibrational Levels and Multiplicities

ω, cm.$^{-1}$
225 (1)
41 (2)
293 (1)

Hg-Br distance = 2.41 Å

Moment of Inertia = 154.12 X 10^{-39} g. cm.^{2} σ = 2

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952, was combined with the 3rd law heat of sublimation at 298°K from the data of K. Niwa and Z. Shibata, J. Fac. Sci. Hokkaido Imp. Univ. Ser III 2, 183 (1938) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The bond length is an average of the values given by H. Braune and S. Knoke, Zeits. phys. Chemie B23, 163 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. F. Jones and L. E. Sutton, Trans. Farad. Soc. 33, 852, (1937) and P. A. Akishin, V. P. Spiridinov and A. N. Khodchenkov, Zhur. Fiz. Khim. 33, 20 (1959).

Mercury Monobromide, Dimeric (Hg_2Br_2)

March 31, 1962

MERCURY MONOBROMIDE, DIMERIC (Hg_2Br_2) (Crystal)

Mol. Wt. = 561.052

$\Delta H_f^\circ{}_{298.15} = -48.800 \pm 0.2$ kcal. mole^{-1}

$S^\circ_{298.15} = 52.283 \pm 0.75$ cal. deg.$^{-1}$ mole^{-1}

$T_{sub} = 666°K$ (decomp.)

Heat of Formation. The average of the values obtained from the cell measurements of T. W. Dakin and D. T. Ewing, J. Am. Chem. Soc. 62, 2280 (1940) and those of F. Ishikawa and Y. Ueda, J. Chem. Soc. Japan 51, 59 (1930) was adopted.

Heat Capacity and Entropy. The heat capacity was estimated by analogy with mercurous chloride. The entropy of formation was obtained from the free energy and heat of formation data listed under heat of formation.

Sublimation. The vapor pressure over mercurous bromide reaches one atmosphere at 666°K according to G. Jung and W. Ziegler Zeits. f. physik. Chem. A150, 139 (1930). At this point the vapor is dissociated into Hg(g) and $HgBr_2$(g).

Bond Distances: K-Br = [3.07]Å K-K = [1.94]Å Br-Br = [2.39]Å

Bond Angles: Br-K-Br = [102]° K-Br-K = [78]° σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.473 x 10^{-111}] g^3 cm^6

Heat of Formation.

Vapor densities and vapor pressures of KBr were measured, using a liquid gold isoteniscope, by K. I. Hagemark, M. Blander, and E. B. Luchsinger, J. Phys. Chem. 70, 276 (1966), and K. I. Hagemark, private communication, 3M Company, St. Paul, Minn., Feb. 6, 1967. Based on the equilibrium constants for the reaction 2KBr(g) = K_2Br_2(g) in the temperature range 1267 - 1434°K, the enthalpy change (ΔHr°_{298}) of this reaction is evaluated by the second and third law methods to be -42.80 ± 4.26 and -43.12 kcal/mol, respectively. The heat of formation for K_2Br_2(g) is calculated to be -129.2 ± 4 kcal/mol, using the third law ΔHr°_{298} value and ΔHf°_{298}(KBr,g) = -43.04 kcal/mol. The drift in the third law ΔHr°_{298} values is 0.01 ± 3.2 eu.

Heat Capacity and Entropy.

The molecular structure and bond distances were estimated by J. Berkowitz, J. Chem. Phys. 29, 1386 (1958), and are tentatively adopted. J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), has calculated vibrational frequencies on the basis of the potential function for an ionic model. These values are adjusted so that the third law ΔHr°_{298} value for the reaction 2KBr(g) = K_2Br_2(g) agrees with the second law value. The three principal moments of inertia are: I_A = 4.867 x 10^{-38}, I_B = 1.513 x 10^{-37} and I_C = 2.000 x 10^{-37} g cm^2.

Bond Distance: Li-Br = 2.35 Å Li-Li = 2.70 Å

Bond Angle: Br-Li-Br = 110° $\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C = 4.220745 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation.

This was obtained from the heat of formation of the liquid and the selected heat of vaporization to the dimer, which derivation has been given in the LiBr(g) table.

Heat Capacity and Entropy.

J. Berkowitz, J. Chem. Phys. 29, 1386 (1958), 32, 1519 (1960), has calculated the molecular structure and vibrational frequencies based on an ionic model. The planar rhombic structure for dimeric lithium bromide, proposed by Berkowitz, has been confirmed by the lack of polarity in electric deflection by A. Büchler, J. L. Stauffer and W. Klemperer, J. Am. Chem. Soc. 86, 4544 (1964). The selected bond distances and angle were obtained from the electron diffraction studies of monomer-dimer vapor by P. A. Akischin and N. G. Rambidi, Z. Physik Chem. 213, 111 (1960). The bond distances ($r_{Br-Br} = 4.20$ Å and $r_{Li-Li} = 2.60$ Å) calculated by Berkowitz are in reasonable agreement with those selected. The three principal moments of inertia are $I_A = 4.1866 \times 10^{-39}$, $I_B = 98.3352 \times 10^{-39}$ and $I_C = 102.5218 \times 10^{-39}\ g\ cm^2$

S. H. Bauer, T. Ino and R. F. Porter, J. Chem. Phys. 33, 685 (1960), have estimated six vibrational frequencies (576, 576, 202, 230, 329 and 365 cm $^{-1}$) for $Li_2Br_2(g)$ in the electron diffraction studies of $Li_2Cl_2(g)$. W. Klemperer and W. G. Norris, J. Chem. Phys. 34, 1071 (1961), have observed two fundamental vibrational frequencies (413 and 295 cm $^{-1}$) in the infrared spectrum and tentatively assigned them as B_{2u} and B_{3u} modes; and these have been adopted in the tabulation. The remaining four vibrational frequencies were obtained from J. Berkowitz, loc. cit., because his model and derivation are self-consistent.

ΔHf_0° = Unknown

$S_{298.15}^\circ$ = [28.5 ± 2] gibbs/mol

$\Delta Hf_{298.15}^\circ$ = -124.0 ± 1 kcal/mol

Tm = 984°K

ΔHm° = 8.3 ± 2 kcal/mol

Heat of Formation

The heat of formation was calculated from ΔHf° values for Mg^{++}(H_2O) and Br^-(H_2O) and ΔHsol°(H_2O) for $MgBr_2$(c). The value for Br^- was obtained from D. D. Wagman et al., NBS Tech. Note 270-1, Natl. Bur. of Std., Washington, D.C., 1965. Values for Mg^{++} and ΔHsol° were taken from F. D. Rossini et al., NBS Circ. 500, Natl. Bur. of Std., Washington, D.C., 1952, since a survey of the literature revealed no new data which would significantly change these values. ΔHsol° is based on measurements of Beketoff, Bull. acad. sci. Russ. 34, 291 (1892), while Mg^{++} is presumably based on data for $MgCl_2$.

The selected heat of formation is confirmed by ΔGr_{1073}° = -0.267 kcal/mol for $MgBr_2(l) + HCl(g) = MgCl_2(l) + HBr(g)$ observed by J. Toguri, H. Flood and T. Forland, Acta Chem. Scand. 7, 1502 (1963). Based on JANAF functions, this leads to ΔHf_{298}° = -124.9 kcal/mol for $MgBr_2$(c).

Heat Capacity and Entropy

The entropy and heat capacity were estimated by comparison with the corresponding values for $MgCl_2$, NaCl and NaBr. W. M. Latimer, "Oxidation Potentials," 2nd Edition, Prentice-Hall, Inc., New York, 1952, has estimated S_{298}° = 29.4 eu which is also a reasonable value. Use of 29.4 eu would give almost exact agreement between the selected ΔHf° and the equilibrium data of Toguri et al., but this may be fortuitous because of uncertainties in the enthalpy and heat of melting for $MgBr_2$.

Melting Data

Tm and ΔHm° are the values obtained by K. K. Kelley, USBM Bulletin 393, 1936, from phase diagrams for the systems $MgBr_2$ - NaBr and $MgBr_2$ - KBr studied by G. Kellner, Z. Anorg. Chem. 99, 137 (1912), and for $MgBr_2$ - LiBr studied by A. Ferrari and C. Colla, Atti accad. Lencei, ser. 6, 13, 78 (1931).

June 30, 1966

MAGNESIUM DIBROMIDE ($MgBr_2$) (LIQUID) GFW = 184.130

$S^\circ_{298.15}$ = [31.968] gibbs/mol

Tm = 984°K

Tb = [1557]°K

$\Delta Hf^\circ_{298.15}$ = [-118.337] kcal/mol

ΔHm° = 8.3 kcal/mol

ΔHv° = [32.9] kcal/mol

Heat of Formation.

The $\Delta Hf^\circ_{298.15}$ was obtained from $\Delta Hf^\circ_{298.15}(c)$ by adding ΔHm° and the difference between $H^\circ_{Tm} - H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was assumed constant and estimated as 23.25 gibbs/mol using 7.75 gibbs/g-atom as suggested by O. Kubaschewski and E. Ll. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $MgBr_2(c)$ table.

Vaporization Data.

Tb was calculated as the temperature at which ΔGr° = 0 for $MgBr_2(c) \rightarrow MgBr_2(g)$. ΔHv° is the corresponding enthalpy change.

June 30, 1966

MAGNESIUM DIBROMIDE ($MgBr_2$) (IDEAL GAS) GFW = 184.130

Point Group $D_{\infty h}$

$S^\circ_{298.15}$ = [67.5 ± 2] gibbs/mol

Ground State Quantum Weight = [1]

ΔHf°_0 = -70.8 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -74.6 ± 3 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
[179](1)
[220](2)
491 (1)

Bond Distance: Mg-Br = 2.34 Å

Bond Angle: Br-Mg-Br = 180°

Rotational Constant: B = 0.019264 cm^{-1}

$\sigma = 2$

Heat of Formation.

The $\Delta Hf^\circ_{298.15}$ was calculated from the $\Delta Hr^\circ_{298.15}$ = 49.4 kcal/mol for the reaction $MgBr_2(c) = MgBr_2(g)$, based on third law analysis of pressures at 798 and 842°K determined from Knudsen effusion - mass spectrometric studies by J. Berkowitz and J. R. Marquert, J. Chem. Phys. 37, 1853 (1962). Second law analysis of ion intensities (635 - 850°K) gave ΔHr° = 50.3 kcal/mol at 727°K, corresponding to ΔHr° = 52.2 kcal/mol at 298.15°K. The absolute pressure at 842°K was calibrated by integrating the ion current during complete volatilization of the sample. Data for $(MgBr_2)_2$ indicate that the dimer mole fraction (about 0.04 at 842°K) over the crystal increases with increasing temperature; this behavior is similar to that of the alkali halides.

Heat Capacity and Entropy.

Bond distance and bond angle were taken from the electron diffraction studies of P. A. Akishin, V. P. Spiridonov, G. A. Sobolev and V. A. Naumov, Zhur. Fiz. Khim. 31, 461 (1957). Electric deflection experiments of A. Büchler, J. L. Stauffer and W. Klemperer, J. Am. Chem. Soc. 86, 4544 (1964), also suggest a linear structure for $MgBr_2$ within the sensitivity of the measurements. The antisymmetric stretching vibration ν_3 is that observed in the infrared spectra of the vapor by S. P. Randall, F. T. Greene and J. L. Margrave, J. Phys. Chem. 63, 758 (1959). The other frequencies were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963), from a valence force model using k = 1.5 and $k\delta/l^2$ = 0.15 md/Å.

[120] (1)	[188] (1)
[207] (1)	[228] (1)

Bond Distance: Na-Br = [2.75] Å

Bond Angle: Na-Br-Na = [71]° Br-Na-Br = [109]° $\sigma = 4$

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.97701 X 10^{-112}] g.^{3} cm.^{6}

Heat of Formation.

The temperature dependence of the equilibrium constants (1293-1434°K.) for the reaction $(NaBr)_2(g) \rightleftarrows 2NaBr(g)$ has been studied by S. Datz, W. T. Smith, Jr. and E. H. Taylor, J. Chem. Phys. 34, 558 (1961). The dissociation energy ($\Delta E_{1300°K.}$) was evaluated to be 42.9 ± 1.3 kcal. mole^{-1}. The vapor mixture contains 37 to 17% of dimers in the temperature range of 1293 to 1434°K. Hence the vapor pressure data on NaBr(g) reported by the previous investigators were reexamined. In other words, the reported vapor pressure of NaBr(g) is the sum of the partial pressures of both the monomer (NaBr) and the dimer (Na_2Br_2). The partial pressures of $Na_2Br_2(g)$ thus obtained were used to evaluate the heats of vaporization by both the second and third law methods. The values of $\Delta H^\circ_{f\ 298.15}$ for $Na_2Br_2(g)$ were then calculated. The results are presented as follows.

Investigator	Reaction	$\Delta H^\circ_{r\ 298.15}$, kcal. mole^{-1} Third Law Value	Second Law Value	$\Delta H^\circ_{f\ 298.15}$* kcal. mole^{-1}
Niwa[1]	$2NaBr(c) \rightarrow Na_2Br_2(g)$	56.51	54.84	-117.08
Cogin and Kimball[2]	$2NaBr(c) \rightarrow Na_2Br_2(g)$	56.80	56.69	-116.01
Mayer and Wintner[3]	$2NaBr(c) \rightarrow Na_2Br_2(g)$	57.13	68.78	-115.63**
Ruff and Mugdan[4]	$2NaBr(l) \rightarrow Na_2Br_2(g)$	45.70	46.71	-116.00
Wartenberg and Albrecht[5]	$2NaBr(l) \rightarrow Na_2Br_2(g)$	45.64	46.77	-116.00
Bloom et al.[6]	$2NaBr(l) \rightarrow Na_2Br_2(g)$	45.49	51.17	-116.72**

*Based on the average of the second and third law values.

**Only the third law value being used.

[1] K. Niwa, J. Fac. Sci., Hokkaido Univ., Ser. III, 2 201 (1938).

[2] G. E. Cogin and G. E. Kimball, J. Chem. Phys. 16, 1035 (1948).

[3] J. E. Mayer and I. H. Wintner, J. Chem. Phys., 6, 301 (1938).

[4] O. Ruff and S. Mugdan, Z. anorg. allgem. Chem., 117, 147 (1921).

[5] H. von Wartenberg and P. Albrecht, Z. Electrochem., 27, 162 (1921).

[6] H. Bloom, J. O'M. Bockris, N. E. Richards and R. G. Taylor, J. Am. Chem. Soc. 80, 2044 (1958).

The value of $\Delta H^\circ_{f\ 298.15}$ for $Na_2Br_2(g)$ adopted is the average of the six $\Delta H^\circ_{f\ 298.15}$ values listed in the above table.

Heat Capacity and Entropy.

Bond distance and angles were calculated based on the related data reported by J. Berkowitz, J. Chem. Phys. 29, 1386 (1958). The vibrational frequencies were calculated by J. Berkowitz, J. Chem. Phys., 32, 1519 (1960), from an assumed model. The ground state quantum weight was estimated. The three principal moments of inertia are I_A = 1.94452 X 10^{-38}, I_B = 1.33619 X 10^{-37} and I_C = 1.53065 X 10^{-37} g. cm.^{2}

Lead Dibromide (PbBr$_2$) (Crystal)

Mol. Wt. = 367.04

ΔH_f° 298.15 = -66.07 ± 0.20 kcal. mole^{-1}

$S^\circ_{298.15}$ = 38.66 ± 0.5 cal. deg.$^{-1}$ mole^{-1}

ΔH_s° 298.15 = 41.90 ± 0.17 kcal. mole^{-1}

T_m = 640°K.

ΔH_m = 4.96 kcal. mole^{-1}

Heat of Formation. Recalculated from the data reported by H. Braune and F. Koref, Z. anorg. Chem., 87, 175 (1914) and C. Krahmer, Z. Elektrochem., 26, 97 (1920).

Heat Capacity, Entropy, and Melting Data. C_p (18.4° to 297.0°K.) reported by W. M. Latimer and H. D. Hoenshel, J. Am. Chem. Soc., 48, 19 (1926). Above 298.15°K., C_p given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used. T_m and ΔH_m° obtained from M. Blanc and G. Petit, Compt. rend., 248, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of H. Bloom, J. O'M. Bockris, N. E. Richards and R. G. Taylor, J. Am. Chem. Soc., 80, 2044 (1958), H. von Wartenberg and O. Bosse, Z. Elektrochem., 28, 384 (1922), F. Volmer, Phys. Z., 30, 590 (1929), and B. Greiner and K. Jellinek, Z. physik. Chem., A165, 97 (1933) which are in good agreement.

Lead Dibromide $(PbBr_2)$

$\Delta H_f^\circ{}_{298.15}$ = [-63.00 ± 0.20] kcal. mole^{-1}

$S^\circ_{298.15}$ = [42.699] cal. deg.$^{-1}$ mole^{-1}

T_m = 640°K.

ΔH_m° = 4.96 kcal. mole^{-1}

T_b = 1187°K.

ΔH_v° = 27.44 ± 0.17 kcal. mole^{-1}

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p obtained from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960). T_m and ΔH_m° reported by M. Blanc and G. Petit, Compt. rend. 248, 1305-6 (1959). A glass transition temperature of 400°K. is assumed.

Vaporization Phenomena. T_b and ΔH_v° calculated from $\Delta H_s^\circ{}_{298.15}$ and free energy functions for condensed and gaseous states.

TITANIUM DIBROMIDE ($TiBr_2$) (CRYSTAL) GFW = 207.718

ΔHf°_0 = unknown

$S^\circ_{298.15}$ = [25.9 ± 2.0] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -96.9 ± 5.0 kcal/mol

Ts = [1208.8]°K

ΔHs° = [49.29] kcal/mol

Heat of Formation

The heat of formation of $TiBr_2$ crystal is derived from the data of Hall and Blocher (1) for the reaction $2TiBr_3(c) = TiBr_4(g) + TiBr_2(c)$. Second and third law analyses of these data are not useful because of the formation of solid solutions in the above process. Hall and Blocher obtained a value of ΔHr°_{800} of 31.3 kcal/mol for the reaction by integrating the incremental free energy changes over varying compositions of the solid solutions. The coresponding ΔHr°_{298} and ΔHf°_{298} are calculated as 34.6 kcal/mol and -96.9 kcal/mol, respectively, using auxiliary JANAF heats of formation and enthalpy data.

Heat Capacity and Entropy

The heat capacity of $TiBr_2(c)$ was estimated by Kelley (2). The value of $S^\circ_{298.15}$ is estimated from that of $TiCl_2(c)$ and the difference between ionic entropy contributions of Cl^- and Br^-.

Heat of Sublimation

The heat of sublimation of $TiBr_2(c)$ is taken as the difference in the heats of formation of $TiBr_2(c)$ and $TiBr_2(g)$ at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta Gr^\circ = 0$ for the reaction $TiBr_2(c) = TiBr_2(g)$. The heat of formation of $TiBr_2(g)$, upon which these quantities depend, is an estimated quantity.

Bond Angle: Br-Ti-Br = [180°] σ = 2

Rotational Constant: B_0 = [0.0183] cm^{-1}

Heat of Formation

The heat of formation of $TiBr_2(g)$ is calculated from the estimated Ti-Br bond energy. The bond energy is estimated as being the same as the average Ti-Cl bond energy of $TiCl_2(g)$. This estimate is used because the measured average bond energies of $TiBr_3(g)$ and $TiCl_3(g)$ and those of $TiBr_4(g)$ and $TiCl_4(g)$ are very nearly equal.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $TiCl_2(g)$, $TiCl_4(g)$ and $TiBr_4(g)$. The vibrational frequencies are estimated from a valence force field model. The force constant k is estimated as 1.2 millidynes Å^{-1}, and the constant k_δ/ℓ^2 is assumed to be 0.06 millidynes Å^{-1}. These values are derived by a correlation with other dihalides.

The electronic levels are assumed to be the same as $TiCl_2(g)$. The levels of $TiCl_2(g)$ are estimated by assuming that they correspond to the inverted states of $NiCl_2(g)$ (1). The linear configuration is adopted since experimental evidence indicates that other transition metal dihalides are linear (2, 3, 4, 5).

Mar. 31, 1962; June 30, 1970

ZIRCONIUM DIBROMIDE ($ZrBr_2$) (CRYSTAL) GFW = 251.038

ΔHf°_0 = Unknown

$S^\circ_{298.15}$ = [27.7 ± 3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-96.7 ± 10] kcal/mol

Tm = [900]°K

ΔHm° = [15.0 ± 10] kcal/mol

$\Delta Hs^\circ_{298.15}$ = [55.0 ± 5] kcal/mol

Heat of Formation

The value of $\Delta Hf^\circ_{298}(ZrBr_2, c) = -96.7$ kcal/mol is calculated from the estimated $\Delta Hs^\circ_{298} = 55 \pm 5$ kcal/mol for $ZrBr_2(c) \rightarrow ZrBr_2(g)$, using $\Delta Hf^\circ_{298}(ZrBr_2, g) = -41.7$ kcal/mol (1). The estimated ΔHs°_{298} is obtained as an average of the heats of sublimation at 298°K for $CrBr_2$, $MnBr_2$, $CoBr_2$, $NiBr_2$ given by Brewer, Somayajulu and Brackett (2) and $TiBr_2$ and $FeBr_2$ listed in JANAF tables (3).

Heat Capacity and Entropy

The heat capacities of $ZrBr_2(c)$ are estimated from $TiBr_2(c)$ (3), based on the assumption $Cp(ZrBr_2) = Cp(TiBr_2) + 3/2\ R\ln[(\text{at. wt. of Zr})/(\text{at. wt. of Ti})]$. The entropy, $S^\circ_{298} = 27.7$ eu, is estimated in a similar manner based on $TiCl_2(c)$ (4) and $TiBr_2(c)$ (3).

Melting Data

The heat of fusion is roughly estimated, so that the entropy of vaporization is about 20 eu. The melting point was estimated by Brewer (5).

Mar. 31, 1962; June 30, 1970

ZIRCONIUM DIBROMIDE ($ZrBr_2$) (LIQUID) GFW = 251.038

$S°_{298.15}$ = [43.983] gibbs/mol

$\Delta Hf°_{298.15}$ = [-81.820] kcal/mol

Tm = [900]°K

ΔHm° = [15.0 ± 10] kcal/mol

Tb = [1555.1]°K

ΔHv° = [31.5] kcal/mol

Heat of Formation

The $\Delta Hf°_{298}(ZrBr_2, \ell)$ is calculated from $\Delta Hf°_{298}(ZrBr_2, c)$ by adding ΔHm° and the difference between $H_{900}-H_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

See $ZrBr_2(c)$ table for details.

Vaporization Data

Tb is the temperature at which the Gibbs energy change approaches zero for the process $ZrBr_2(\ell) \rightarrow ZrBr_2(g)$. The difference between ΔHf° for $ZrBr_2(\ell)$ and $ZrBr_2(g)$ at Tb is ΔHv°.

Bond Distance: Zr-Br = [2.47] Å

Bond Angle: Br-Zr-Br = [180°]

$\sigma = [2]$

Rotational Constant: $B_0 = [0.01729]$ cm^{-1}

Heat of Formation

The heat of formation, $\Delta Hf^\circ_{298}(ZrBr_2, g) = -41.7$ kcal/mol, is derived from the estimated $\Delta Hr^\circ_{298} = 243.5 \pm 10$ kcal/mol for $ZrBr_2(g) \rightarrow Zr(g) + 2Br(g)$. The value of ΔHr°_{298} is twice the average bond dissociation energy, $D^\circ_{298}(Zr\text{-}Br_2) = 121.75$ kcal/mol, which is calculated from the relation $D^\circ_{298}(Zr\text{-}Br_2)/D^\circ_{298}(Ti\text{-}Br_2) = D^\circ_{298}(Zr\text{-}Br_4)/D^\circ_{298}(Ti\text{-}Br_4)$. The average bond dissociation energies, $D^\circ_{298}(Zr\text{-}Br_4) = 102.2$ kcal/mol, $D^\circ_{298}(Ti\text{-}Br_4) = 87.9$ kcal/mol and $D^\circ_{298}(Ti\text{-}Br_2) = 104.6$ kcal/mol, are all calculated from JANAF ΔHf°_{298} for $ZrBr_4(g)$, $TiBr_4(g)$, $TiBr_2(g)$, Zr(g), Ti(g) and Br(g).

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that the transition metal dihalides are generally linear (1, 2, 3, 4, 5) even though a few fluorides are bent (6). The bond distance is assumed to be the same as that in $ZrBr_4(g)$ which was estimated as 2.47 Å by Godnev et al. (7). The moment of inertia is 161.8979 × 10^{-39} g cm^2.

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 1.2 millidyne/Å and the bending force constant 0.06 millidyne/Å. These values are derived from force constants of transition metal dihalides listed by Brewer, Somayajulu and Brackett (8). The electronic levels and quantum weights are estimated to be the same as those of gaseous $TiCl_2$ (9).

Bond Distance: P-O = 1.41 ± 0.07 Å P-Br = 2.06 ± 0.03 Å

Bond Angle: Br-P-Br = 108° ± 3° $\sigma = 3$

Product of the Moments of Inertia: $I_AI_BI_C = 2.2602 \times 10^{-112}$ g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ of $POBr_3(g)$ was calculated from the heat of formation of the crystal and the heat of sublimation. The heat of sublimation was obtained by combining the ΔH_v and an estimated ΔH_m. The heat of formation of the crystal was derived from the heats observed for the reaction: $POBr_3(c) + (n+3)H_2O(l) \rightarrow [H_3PO_4+3HBr]$ in $nH_2O(l)$. The data used in these calculations may be summarized as follows:

Data	Source
$\Delta H^\circ_{f\ 298.15}$(water solutions)$H_3PO_4$	Obtained graphically from W. S. Holmes, Trans. Faraday Soc. 58, 1916 (1962).
$\Delta H^\circ_{f\ 298.15}$(water solutions)HBr	Obtained graphically from, "Selected Values of Chemical Thermodynamic Properties," Natl. Bur. Stds., Circular 500.
$\Delta H^\circ_{f\ 298.15}$(liquid)$H_2O$ = -68.3174 kcal. mole^{-1}	"Selected Values of Chemical Thermodynamic Properties," National Bureau of Standards Circular 500.
$\Delta H^\circ_{f\ 298.15}$(crystal)$POBr_3$ = -109.1 kcal. mole^{-1}	Recalculated from Heats observed by T. Charnley and H. A. Skinner, J. Chem. Soc. 450 (1953).
$\Delta H_{m\ 298.15}$ = [3.7] kcal. mole^{-1}	Estimated from comparison with $POCl_3$.
$\Delta H_{v\ 298.15}$ = [12.1] kcal. mole^{-1}	Estimated from the ΔH_v at T_b (10.6 kcal. mole^{-1} at 464.9°K). ΔH_v was calculated from a least squares treatment of the v.p. data of M. Van Driel, Rec. Trav. Chim. 61, 748 (1942).

Heat Capacity and Entropy.

The molecular constants used were calculated from electron diffraction measurements by J. H. Secrist and L. O. Brockway, J. Am. Chem. Soc. 66, 1941 (1944). The calculated moments are $I_A = I_B = 8.68174 \times 10^{-38}$ g. cm.^{2} and $I_C = 1.474471 \times 10^{-37}$ g. cm.^{2}

From the Raman spectra of $POBr_3$ the vibrational frequencies were measured and assigned by H. Gerding and M. van Driel, Rec. trav. Chim. 61, 419 (1942). The Raman spectra was studied and the vibrational frequencies were listed by M. L. Delwaulle and F. Francois, Compt. Rend. 220, 817 (1945). The frequencies may also be found in Compt. Rend. 222, 550 (1946) and J. Chim. Phys. 46, 87 (1949) by Delwaulle and Francois.

Dec. 31, 1963

PHOSPHORUS TRIBROMIDE (PBr_3) (IDEAL GAS) MOL. WT. = 270.723

Point Group C_{3v}

$S^\circ_{298.15}$ = 83.206 cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = [1]

$\Delta H^\circ_{f\ 0}$ = -25.3 ± 1.5 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -30.7 ± 1.5 kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$	ω, cm.$^{-1}$
392 (1)	392.2 (2)
161.3 (1)	115.7 (2)

Bond Distance: P-Br = 2.20 ± 0.03 Å

Bond Angle: Br-P-Br = 106° ± 3°

$\sigma = 3$

Product of the Moments of Inertia: $I_AI_BI_C$ = 1.1897 X 10^{-111} g.^{3} cm.^{6}

Heat of Formation.

The heat of formation of PBr_3 gas from white (α) phosphorus, -34.9 kcal. mole^{-1}, was obtained by T. Charnley and H. A. Skinner, J. Chem. Soc. 450 (1953). This was changed from white (α) to the red (V) phosphorus reference state to give the value used in this table (-30.7 kcal. mole^{-1}). To obtain their value (-34.9 kcal. mole^{-1}), Charnley and Skinner measured the heat of formation of the liquid, and combined it and their estimate of the liquid enthalpy with the heat of vaporization (9.5 kcal. mole^{-1}) calculated by M. Van Driel and H. Gerding, Rec. Trav. Chem. 60, 943 (1941). For the liquid heat of formation Charnley and Skinner observed the ΔH°_r = -67.2 ± 0.6 kcal. mole^{-1} for $PBr_3(l) + (n+3)H_2O(l) \rightarrow [H_3PO_3 + 3HBr]$ in $nH_2O(l)$. Van Driel and Gerding measured the vapor pressure over $PBr_3(l)$ and calculated the heat of vaporization with the aid of a modified Clapeyron equation. The uncertainties on the heats of formation are estimates.

Heat Capacity and Entropy.

Q. Williams and W. Gordy, Phys. Rev. 79, 225 (1950) have reported moments of inertia from the microwave spectrum of PBr_3. From this data D. H. Whiffen in "Tables of Interatomic Distances and Configuration in Molecules and Ions", Scientific Editor, L. E. Sutton, Special Publication No. 11, The Chemical Society (London) 1958, has calculated the selected molecular constants. From these constants the principal moments of inertia were calculated as $I_A = I_B$ = 8.5214 X 10^{-38} g. cm.^{2} and I_C = 1.6383 X 10^{-37} g. cm.^{2}

M. Lister and L. E. Sutton, Trans. Faraday Soc. 37, 393 (1941) have reported P-Br = 2.23 ± 0.04 Å and the angle P-Br-P = 100° ± 2°. S. M. Swingle has measured P-Br = 2.18 ± 0.03 Å and the angle P-Br-P = 101.5° ± 1.5°. The work of Swingle was reported in a private communication from L. Pauling and V. Schomaker, California Institute of Technology to P. W. Allen and L. E. Sutton, Acta. Cryst. 3, 46 (1950). Swingle's data as well as that of Lister and Sutton was obtained by electron diffraction. The 106° angle was selected since 101.5° and 100° give imaginary force constants with the ranges allowed for the type A, 392 cm.$^{-1}$ frequency and the form of the potential function assumed by P. W. Davis and R. A. Oetjen, J. Molecular Spec. 2, 253 (1958).

The vibrational frequencies were measured and assigned in the infrared by Davis and Oetjen. Raman measurements and assignments by J. Cabannes and A. Rausset, Ann. Phys. (Paris) 19, 229 (1933) were also listed by M. L. Delwaulle, Compt. Rend. 222, 1391 (1946) and Compt. Rend. 224, 389 (1947). The Raman assignments were as follows: type A, 380 cm.$^{-1}$ and 162 cm.$^{-1}$ and type E, 400 cm.$^{-1}$ and 116 cm.$^{-1}$.

Thiophosphoryl Bromide ($PSBr_3$)

Bond Distance: P-Br = 2.13 ± 0.03 Å P-S = 1.89 ± 0.06 Å

Bond Angle: Br-P-Br = 106° ± 3° σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = 1.8780 \times 10^{-111}$ g.^{3} cm.^{6}

Heat of Formation.

The $\Delta H^\circ_{f\,298.15}$ of $PSBr_3(g)$ was calculated from the $\Delta H^\circ_{f\,298.15}$ of $POBr_3(g)$ and estimated strengths for P-S and P-O bonds.

The difference in the P-S and P-O bond strengths was assumed to be the same for $POF_3 - PSF_3$ and $POBr_3 - PSBr_3$. For the P-S bond strength in PSF_3, C. B. Henderson and R. S. Scheffee, "Survey of Thermochemical Data," January 1960, Atlantic Research Corp., Alexandria, Virginia, estimated 91 kcal., from a consideration of unpublished data. The P-O bond was estimated to be 115 kcal. by E. Neale and L. T. D. Williams, J. Chem. Soc. 2485 (1955) and E. Neale, L. T. D. Williams, and V. T. Moores, J. Chem. Soc., 422 (1956).

The $\Delta H^\circ_{f\,298.15}$ of $POBr_3(g)$, [-93] kcal. mole^{-1}, was taken from the March 31, 1963, JANAF Table. The $\Delta H^\circ_{f\,298.15}$ of O(g) and S(g) were taken from June 30, 1962, and March 31, 1961, JANAF Tables.

Heat Capacity and Entropy.

The molecular constants were determined from electron diffraction data by J. H. Secrist and L. O. Brockway, J. Am. Chem. Soc. 66, 1941 (1944). The principal moments of inertia calculated from these constants were $I_A = I_B = 1.105941 \times 10^{-37}$ g. cm.^{2}, and $I_C = 1.535429 \times 10^{-37}$ g. cm.^{2}

The vibrational frequencies obtained from the Raman spectra of $PSBr_3$ were reported by M. L. Delwaulle and F. Francois, Compt. Rend. 224, 1422 (1947).

Dec. 31, 1961; June 30, 1964; June 30, 1968

TITANIUM TRIBROMIDE ($TiBr_3$) (CRYSTAL) GFW = 287.627

ΔHf°_0 = -127.0 ± 2.0 kcal/mol

$S^\circ_{298.15}$ = 42.2 ± 0.8 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -131.5 ± 2.0 kcal/mol

Tt = 179.9°K

ΔHt° = 0 kcal/mol

Ts = 1067.2°K

ΔHs° = 33.165 kcal/mol

Heat of Formation

The heat of formation of $TiBr_3(c)$ is based on the vapor pressure data reported by Hall and Blocher (1) for the process $1/2Hg_2Br_2(c) + TiBr_3(c) = TiBr_4(g) + Hg(\ell)$ over the temperature range 430 to 546°K. Second and third law analyses of these data give values for the heat of reaction of 24.2 ± 0.3 and 24.4 kcal/mol, respectively, for seventy three points, with ten points rejected due to failure of a statistical test. The third law drift in the data is calculated as 0.6 ± 0.6eu. The third law value of 24.4 kcal/mol is combined with the JANAF heats of formation of $TiBr_4(g)$ and $Hg_2Br_2(c)$ to obtain the adopted heat of formation.

Heat Capacity and Entropy

The heat capacity and entropy of $TiBr_3(c)$ have been measured over the temperature range 51° to 800°K by King et al. (2). Heat capacities above 800°K are estimated from graphical extrapolation. The value of S°_{298} is derived from these data, based on S°_{51} = 8.60 eu. The value of S°_{51} is estimated from a Debye-Einstein extrapolation of the measured heat capacities, the equation being $C_p = D(70.0/T) + E(120/T) + 2E(306/T)$. It is assumed that all electronic entropy is contained within the measured and extrapolated heat capacities.

Transition Data

A second order transition at 179.9°K was observed by King et al. (2). The heat capacity at this temperature is in excess of 56.1 gibbs/mol. King et al. measured the value of $H^\circ_{188} - H^\circ_{160}$ as 0.773 kcal/mol.

Heat of Sublimation

The heat of sublimation is claculated from the heats of formation of $TiBr_3(c)$ and $TiBr_3(g)$ at the sublimation temperature. The sublimation temperature is taken as the point at which ΔGr = 0 for the process $TiBr_3(c) = TiBr_3(g)$.

Bond Distance: Ti-Br = [2.4] Å

Bond Angle: Br-Ti-Br = [100°] σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = [1.70 \times 10^{-111}]\ g^3\ cm^6$

Heat of Formation

The heat of formation of $TiBr_3$(g) is calculated from the heat of sublimation of $TiBr_3$(c). A tentative equation for the vapor pressure of $TiBr_3$(c) was reported by Hall and Blocher (1). Second and third law analyses of the equation over the temperature range 700° to 900°K give values of ΔHs°_{298} of 45.2 and 41.9 kcal/mol, respectively, with a third law drift of -4.2 eu. The chosen value of ΔHf°_{298} is based on the third law ΔHs°_{298}.

Heat Capacity and Entropy

The interatomic distance is estimated from those of $TiCl_4$, $TiCl_3$ and $TiBr_4$. The pyramidal bond angle is estimated by asssuming that $TiBr_3$(g) is similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 9.76 \times 10^{-38}$ g cm^2 and $I_C = 1.78$ g cm^2. The vibraional frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} (2).

Mar. 31, 1962; June 30, 1964

ZIRCONIUM TRIBROMIDE ($ZrBr_3$) (CRYSTAL) MOL. WT. = 330.968

$\Delta H_f^\circ{}_0$ = [-147] kcal. mole^{-1}

$S^\circ{}_{298.15}$ = [41.12] cal. mole^{-1} deg.$^{-1}$

$\Delta H_f^\circ{}_{298.15}$ = [-152] kcal. mole^{-1}

T_s = [1100]°K.

$\Delta H_s^\circ{}_{298.15}$ = [49] kcal. mole^{-1}

Heat of Formation.

E. M. Larsen and J. J. Leddy, J. Am. Chem. Soc. 78, 5983 (1956), studied the reaction $Zr(c) + 3ZrBr_4(g) = 4ZrBr_3(c)$ in the temperature range 473 to 973°K. and pressure range 5 to 15 atm. They present a plot of the fractional reaction, for a series of temperatures, as a function of the reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The free energy function change for this reaction was calculated at 100° intervals from 500 to 1100°K. At each temperature, the equilibrium constant was assumed to be 1, and $\Delta H_{r\ 298}$ accordingly calculated. These values and the heat of formation of $ZrBr_4(g)$ [see $ZrBr_4$ table] were used to compute a series of values for the standard heat of formation of $ZrBr_3(c)$. The following table gives representative values at four temperatures.

T(°K.)	K_p	$\Delta H_r^\circ{}_{298}$	$\Delta H_f^\circ{}_{298.15}$ [$ZrBr_3(c)$]
500	1	-70.26 kcal. mole^{-1}	-132.8 kcal. mole^{-1}
700	1	-96.48 kcal. mole^{-1}	-139.3 kcal. mole^{-1}
900	1	-121.75 kcal. mole^{-1}	-145.6 kcal. mole^{-1}
1100	1	-146.28 kcal. mole^{-1}	-151.8 kcal. mole^{-1}

If one assumes an initial pressure of from 5 to 10 atm. for $ZrBr_4$ and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of $ZrBr_4$ to attain a value of 1 atm. and hence an equilibrium constant of 1. The data of Larsen and Leddy indicate about 82% reaction at 973°K. It was assumed that around 1100°K. the equilibrium constant attains a value of 1 giving -152 kcal. mole^{-1} for the heat of formation of $ZrBr_3(c)$ at 298.15°K. The limits of error were taken to be ±16 kcal. mole^{-1} which corresponds to a ±500° temperature spread in the above table.

A second law calculation of their data was carried out but the results are of doubtful value in view of the uncertainty in the attainment of equilibrium at the lower temperatures.

Heat Capacity and Entropy.

The heat capacity was estimated in the same manner as for $ZrBr_4(c)$ [see $ZrBr_4(c)$ table]. The values for Θ_D and Θ_E were taken to be the same as those estimated for $ZrBr_4(c)$. The internal contribution was obtained from the estimated $ZrBr_3$ vibrational frequencies and the anharmonicity factor "a" was taken to be 2.5×10^{-3}. The specific heat above 300°K. was obtained by graphical extrapolation.

It was assumed, in the above estimation, that the crystalline lattice is made up of $ZrBr_3$ molecules. However, E. Holze [see R. F. Rolsten, "Iodide Metals and Metal Iodides", John Wiley & Sons, Inc., New York, 1961, page 46] concluded that crystalline ZrI_3 was composed of a chain lattice of $(Zr_2I_6)_n$ units. A chain lattice of $(Zr_2Br_6)_n$ units is probably a better representation of the solid state structure of $ZrBr_3$. Until more quantitative data becomes available, however, it is felt that the above analysis gives a fair approximation to the heat capacity of $ZrBr_3$.

Temperature of Disproportionation.

As detailed in the "Heat of Formation" section, this was assumed to be 1100 ± 500°K.

Liquid Phase.

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data.

The heat of sublimation at 298.15°K. was obtained from the difference in the heats of formation of the gas and solid at 298.15°K. The sublimation point was obtained from the free energy crossover between gas and solid.

Heat of Formation.

The heats of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides were computed from data issued in these tables. The zirconium-halide bond energy, taken as 1/4 of this heat of formation, was found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it was found that the bond energy of the trichloride was around 7 kcal. mole^{-1} greater than that for titanium tetrachloride. This amount was added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, was found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium was determined from this curve and their estimated bond distances.

For zirconium tribromide, the heat of formation from the gaseous atoms was -329 kcal. mole^{-1} and from the elements in their standard state, -103 kcal. mole^{-1}.

Heat Capacity and Entropy.

The measured internuclear distances for the tribromides of P, As, and Sb were plotted as a function of the atomic weight of these atoms and a smooth curve was drawn through the points. The internuclear distance for $ZrBr_3$ was taken from this plot. The bond angle was assumed to be intermediate between the bond angles of $AsBr_3$ and $SbBr_3$; it was taken to be 98°. The individual moments of inertia are: $I_A = I_B = 101.408 \times 10^{-39}$ gm. cm.^{2}, I_C = 172.669 gm. cm.^{2}.

The measured vibrational frequencies for the tribromides of phosphorus, arsenic, and antimony were plotted as a function of internuclear distance. Smooth curves through these points were obtained for ω_1, ω_2, and ω_4; these curves and the estimated $ZrBr_3$ bond distance were used to obtain correlation values of ω_1, ω_2, and ω_4 for $ZrBr_3$. Force constants, assuming a valence force field and a Br-Zr-Br angle of 98°, were derived from the above values for ω_1 and ω_2. These force constants were then used to derive values for ω_3 and ω_4. By a process of successive approximation, a set of force constants was obtained which gave frequencies in good agreement with the three correlation values. The three correlation frequencies and the derived frequency were used in this table.

Sept. 30, 1966

IRON DIBROMIDE, DIMERIC (Fe_2Br_4) (IDEAL GAS) GFW = 431.330

Point Group [D_{2h}]

ΔHf°_0 = [-54.6 ± 2] kcal/mol

$S^\circ_{298.15}$ = [123.3] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = [-60.5 ± 2] kcal/mol

Electronic Levels and Quantum Weights

ϵ_1, cm^{-1}	g_1

Bond Distance: Fe-Br = [2.24] Å

Bond Angles: $Fe\text{-}Br_{bridge}\text{-}Fe$ = [90]° $Br_{bridge}\text{-}Fe\text{-}Br_{bridge}$ = [90]°

$Br\text{-}Fe\text{-}Br_{bridge}$ = [135]° σ = [4]

Product of the Moments of Inertia: $I_AI_BI_C = [1.4498 \times 10^{-110}]\ g^3\ cm^6$

Heat of Formation.

The chemical equilibria, 622-665°K, for the reaction $Fe_2Br_4(g) = 2\ FeBr_2(g)$ were studied by R. F. Porter and R. C. Schoonmaker, J. Phys. Chem. 63, 626 (1959), using a mass spectrometer. Based on the reported partial pressures for the two species, the enthalpy change ($\Delta Hr^\circ_{298.15}$) for the reaction was evaluated by both the second and third law methods to be 40.36 ± 2.0 and 40.75 ± 0.2 kcal/mol, respectively. Using the third law ΔHr° value and $\Delta Hf^\circ_{298.15}$ ($FeBr_2$,g) = -9.9 ± 0.5 kcal/mol, the heat of formation ($\Delta Hf^\circ_{298.15}$) for $Fe_2Br_4(g)$ was calculated as -60.5 ± 2.0 kcal/mol and was adopted.

Heat Capacity and Entropy.

The molecular structure is assumed to be planar. The two Fe atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two Br atoms. The two remaining Br atoms are situated outside the square on a straight line joining the two Fe atoms. The Fe-Br bond distance was estimated to be the same as that in the $FeBr_2(g)$ molecule. The first six vibrational frequencies were estimated by comparison with those for $K_2Br_2(g)$ calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The last three degenerate frequencies were assigned arbitrarily in order to give good second and third law agreement for the heats of dissociation of dimer to monomer. The order of the frequencies listed above is arbitrary and not related to their species types.

The electronic levels and quantum weights were estimated by comparison with those for $FeBr_2(g)$. The three principal moments of inertia are: $I_A = 6.6576 \times 10^{-38}$, $I_B = 4.3456 \times 10^{-37}$ and $I_C = 5.0113 \times 10^{-37}\ g\ cm^2$.

Lead Tetrabromide ($PbBr_4$)

Dec. 31, 1961; June 30, 1964; June 30, 1968

TITANIUM TETRABROMIDE ($TiBr_4$) (CRYSTAL) GFW = 367.536

ΔHf°_0 = -141.7 ± 1.1 kcal/mol

$S^\circ_{298.15}$ = 58.2 ± 1.6 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -147.7 ± 1.0 kcal/mol

Tm = 311.4°K

ΔHm° = 3.08 kcal/mol

Heat of Formation

The heat of formation, ΔHf°_{298}, of $TiBr_4(c)$ has been determined calorimetrically by several investigators as follows.

Investigators	Reaction	$\Delta Hf^\circ_{298.15}$, kcal/mol
Nelson, Johnson and Prosen (1)	$Ti(c) + 2Br_2(g) = TiBr_4(c)$	-147.3 ± 1.1
Johnson, Gilliland and Prosen (2)	$TiCl_4(\ell) + 2Br_2(\ell) = TiBr_4(c) + 2Cl_2(g)$	-147.6 ± 1.3
Schlafer and Schmidtke (3)	$Ti(c) + 2Br_2(\ell) = TiBr_4(c)$	-147.7 ± 0.3
Gross, Hayman and Levi (4)	$Ti(c) + 2Br_2(\ell) = TiBr_4(c)$	-148.1 ± 0.3

The chosen value of ΔHf°_{298} is the average of these determinations. The value from the work of Nelson et al. (1) is obtained from their heat of reaction and the JANAF value for the heat of vaporization of bromine. The value obtained from Johnson et al. (2) is a combination of their heat of reaction and the JANAF value for the heat of formation of $TiCl_4(\ell)$.

Heat Capacity and Entropy

The heat capacity of $TiBr_4(c)$ has been measured over the temperature range 51° to 298°K by King et al. (5). They reported a value of 42.74 eu for $S^\circ_{298} - S^\circ_{51}$ based on their measurements. The value of S°_{51} is estimated as 15.46 eu. King et al. (5) reported an estimate of 14.75 ± 1.60 for the same quantity. The former estimate is used so that the values of ΔHs°_{298} obtained by both second and third law methods are in agreement. See $TiBr_4(g)$ table for details. The value of $H^\circ_{51} - H^\circ_0$ is estimated as 0.372 kcal/mol. This estimate is based on a Debye-Einstein extrapolation of the measured heat capacity with vibrational contributions removed.

Melting Data

The melting temperature and heat of melting were reported by King et al. (5).

TITANIUM TETRABROMIDE ($TiBr_4$) (LIQUID) GFW = 367.536

$S°_{298.15}$ = 67.918 ± 1.6 gibbs/mol

$\Delta Hf°_{298.15}$ = -144.681 ± 1.0 kcal/mol

Tm = 311.4°K

ΔHm° = 3.08 kcal/mol

Tb = 504.1°K

ΔHv° = 10.80 kcal/mol

Heat of Formation

The heat of formation of $TiBr_4(\ell)$ is calculated from the heat of melting, $\Delta Hm°_{311.4}$, the heat of formation of $TiBr_4(c)$, and the values of $H°_{311.4} - H°_{298.15}$ for both crystal and liquid.

Heat Capacity and Entropy

King et al, (1) reported the heat capacity of $TiBr_4(\ell)$ between the melting point and normal boiling point, The entropy, $S°_{298}$, of $TiBr_4(\ell)$ is calculated from $\Delta Sm°_{311.4}$, the values of $S°_{311.4} - S°_{298.15}$ of both crystal and liquid and the value of $S°_{298.15}$ of $TiBr_4(c)$.

Melting Data

The melting temperature and heat of melting were reported by King et al. (1).

Vaporization Data

The boiling temperature, Tb, is taken as the point at which Kp = 1 for the reaction $TiBr_4(\ell) = TiBr_4(g)$. The heat of vaporization is calculated as the difference between ΔHf° of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for $TiBr_4(g)$.

Heat of Formation

The heat of formation of $TiBr_4(g)$ is calculated from those of $TiBr_4(c)$ and $TiBr_4(\ell)$ and the heats of reaction for the processes (A) $TiBr_4(c) = TiBr_4(g)$ and (B) $TiBr_4(\ell) = TiBr_4(g)$. Second and third law analyses of the vapor pressure data for these processes yield the following results. The first four investigations employed the spoon gauge method, the last investigation being a manometric determination.

Source	Reaction	No. Pts.	Range T°K	$\Delta Hr°_{299}$, kcal/mol Second law	Third	Drift, eu	$\Delta Hf°_{298.15}$** kcal/mol
Boni, 1966 (1)	A	13	275 - 311	16.4 ± 0.2	16.19	-0.6 ± 0.5	-131.5
Funaki et al., 1961 (2)	B	14	385 - 493	12.2 ± 0.3	12.92	1.6 ± 0.3	-131.8
Seki, 1941 (3)	A	12	286 - 306	15.4 ± 0.5	15.90	1.6 ± 1.6	-131.8
Hall et al., 1958 (4)	B	89*	341 - 499	13.2 ± 0.1	13.14	-0.1 ± 0.1	-131.5
Keavney & Smith, 1960 (5)	A	14	287 - 310	16.1 ± 0.3	16.14	0.2 ± 0.8	-131.6

* Four points rejected due to failure of a statistical test.

** Calculation beased on third law $\Delta Hr°_{298}$.

The adopted value of 131.5 kcal/mol is that obtained from the data of Hall et al. (4),whose third law drift was adjusted to zero by changing the entropy of the crystal within its uncertainty.

Heat Capacity and Entropy

The interatomic distance was reported by Lister and Sutton (6). The tetrahedral configuration is confirmed by spectroscopic studies (7,8). The individual moments of inertia are $I_A = I_B = I_C = 1.89 \times 10^{-37}$ g cm^2.

The vibrational frequencies have been reported by Delwaulle and Francois (7) and by Miller and Carlson (8). These values are based primarily on the Raman and infrared spectra of $TiBr_4(\ell)$, the value of ν_3 being the only frequency measured for $TiBr_4(g)$.

The electronic spectra of $TiBr_4$ in solution have been measured by Dijkgraaf (9). Di Sipio et al. (10) have reported the near ultraviolet spectra of $TiBr_4(g)$. Both of these studies indicate that $TiBr_4$ has no low lying electronic levels which would contribute significantly to the entropy.

Mar. 31, 1962; Mar. 31, 1964

ZIRCONIUM TETRABROMIDE ($ZrBr_4$) (CRYSTAL) MOL. WT. = 410.884

$S^\circ_{298.15}$ = [53.70] cal. deg.$^{-1}$ mole^{-1}

T_m = 723°K.

T_s = 630°K.

$\Delta H_f^\circ{}_0$ = [-175.3] ± 0.8 kcal. mole^{-1}

$\Delta H_f^\circ{}_{298.15}$ = -181.6 ± 0.6 kcal. mole^{-1}

$\Delta H_s^\circ{}_{298.15}$ = 28.0 ± 1.0 kcal. mole^{-1}

Heat of Formation.

A. G. Turnbull, J. Phys. Chem. 65, 1652 (1961), measured the heat effect accompanying the following reactions:

(1) $ZrBr_4(s) + 4NaOH(aq.) = ZrO_2(hyd.) + 4NaBr(aq.) + 2H_2O$

(2) $ZrBr_4(s) + 2H_2O = ZrOOH^+_{(aq.)} + 4Br^-_{(aq.)} + 3H^+_{(aq.)}$

Turnbull also measured the chlorine analogue of the above reactions. He used the measured heat of formation of zirconium tetrachloride, reported by Gross, Hyman and Levi [see $ZrCl_4$ table], to calculate the heats of formation of ZrO_2(hyd.) and $ZrOOH^+$(aq.). The heat of formation of solid zirconium tetrabromide from reaction (1) was -182.2 ± 0.7 kcal. mole^{-1} and from reaction (2) was -181.0 ± 0.6 kcal. mole^{-1}. An average of the two was taken to represent the heat of formation of the tetrabromide.

Heat Capacity and Entropy.

The heat capacity from 0 to 300°K. was calculated by means of the relationship $C_p = C_{VT}(\Theta_D^{3^\circ} = 85°K.) + C_{VR}(\Theta_E^{3^\circ} = 155°K.) + C_{Vi} + a^2C_V{}^2T$, where C_{VT} represents the hindered translational, C_{VR} the librational, and C_{Vi} the internal vibrational contributions to the heat capacity of the solid. $C_V = C_{VT} + C_{VR} + C_{Vi}$ represents the constant volume heat capacity to which $a^2C_V{}^2T$, the anharmonic contribution, is added to convert to a heat capacity at constant pressure. The internal contribution, C_{Vi}, was obtained from the estimated vibrational frequencies [see gas table]. The values for Θ_D and Θ_E were obtained from an elaborate correlation with the corresponding values for $ZrCl_4$ [see $ZrCl_4$ crystal table]. C_p was computed using a number of values for the constant term "a". The value, a = 2.5 X 10^{-3}, was chosen from a consideration of the sublimation calculations [see below]. The heat capacity above 300°K. was obtained by a graphical extrapolation.

Melting Point.

This was reported by O. Rahlfs and W. Fischer, Z. anorg. allgem. Chem. 211, 349 (1933).

Sublimation Data.

Vapor pressure measurements have been reported by Rahlfs and Fischer (loc. cit.) and by H. L. Schlafer and H. Skoludek, Z. Elektrochem. 66, 367 (1962). The heat of sublimation results, for two values of "a", are given in the following table.

Reference	"a"	$\Delta H_{s(298)}$ [3rd Law]	$\Delta H_{s(298)}$ [2nd Law]	
			A	B
Schlafer	3.0 X 10^{-3}	27.43	28.82	28.82
Schlafer	2.5 X 10^{-3}	27.73	28.68	28.68
Rahlfs	3.0 X 10^{-3}	27.52	28.35	28.15
Rahlfs	2.5 X 10^{-3}	27.85	28.19	27.99

All heat values are in kcal. mole^{-1}. Two sets of second law heat values are given; set "A" was obtained from the slope reported by the authors and set "B" from a least squares fit performed at The Dow Thermal Laboratory. Various high temperature extrapolations were carried out for a particular value of "a" but only insignificant changes in the heat of sublimation resulted. The data of Schlafer and Skoludek showed a considerable temperature dependent third law heat of sublimation at 298°K. when "a" was taken as 3.0 X 10^{-3}, and a moderate temperature dependence when "a" was taken as 2.5 X 10^{-3}. The data of Rahlfs and Fischer showed a very slight temperature dependence for a = 3.0 X 10^{-3} and no temperature dependence for a = 2.5 X 10^{-3}.

In both sets of data there are large differences between 2nd and 3rd law values for a = 3.0 X 10^{-3}, good 2nd and 3rd law agreement for the data of Rahlfs and Fischer and a = 2.5 X 10^{-3}, and only fair agreement for the data of Schlafer and Skoludek and a = 2.5 X 10^{-3}. Extrapolation of the data of Schlafer and Skoludek for a = 2.0 X 10^{-3} indicated a continuing temperature dependent third law heat of sublimation and disagreement between 2nd and 3rd law values. The heat of sublimation was taken as the average of the third law and two second law values calculated from the data of Rahlfs and Fischer using "a" = 2.5 X 10^{-3}. The results of this analysis should not be considered conclusive since all of the data is estimated.

The sublimation point reported by Rahlfs and Fischer (loc. cit.) was 630°K., that calculated from the data of Schlafer and Skoludek was 624°K. and that obtained from the free energy crossover between solid and gas was 630°K. The sublimation point was taken as 630°K.

Since the sublimation point is lower than the melting point, the liquid phase is thermodynamically unstable under ordinary conditions.

Calculated from the heats of formation and sublimation for the crystal at 298.15°K. (see crystal table for details).

Heat Capacity and Entropy.

The interatomic distance was obtained from an involved correlation of the interatomic distances and covalent radii of the tetrahalides of Pb, Si, Ti, Ge, and Sn. I. N. Godnev, A. M. Aleksandrovskaya, and I. V. Regina, Optics and Spectroscopy 7, 172 (1959), estimated the interatomic distance and report 2.47 Å as the Zr-Br distance. The bond angle was taken to be the tetrahedral angle. The three principal moments of inertia are: $I_A = I_B = I_C$ = 2.1237 X 10^{-37} gm. cm.^{2}.

The fundamental vibrational frequencies are all estimated. The product of ω_1 and internuclear distance for the tetrabromides of Si, Ti, Ge, Sn, and Pb was found to be nearly constant. Utilizing the estimated Zr-Br distance, a value of 218 cm.$^{-1}$ was obtained for ω_1. A plot of ω_1 and ω_2 versus internuclear distance for these molecules gave nearly linear smooth curves. Values of ω_1 and ω_2 obtained from these plots were 216 cm.$^{-1}$ and 58 cm.$^{-1}$ respectively. These values for ω_1 and ω_2 were used in a valence force field calculation to derive values for ω_3 and ω_4. Central and valence force field calculations, using estimated force constants were carried out but the results proved to be inconsistent. Therefore, ω_1 was taken as the average of the two empirically derived values, ω_2 as its empirically derived value, and ω_3 and ω_4 as those derived from the empirical values and the valence force field calculation. Godnev, Aleksandrovskaya, and Regina (loc. cit.) estimated the vibrational frequencies; they obtained ω_1 = 224 cm.$^{-1}$, ω_2 = 65 cm.$^{-1}$, ω_3 = 309 cm.$^{-1}$, and ω_4 = 78 cm.$^{-1}$.

TUNGSTEN PENTABROMIDE (WBr_5)   (CRYSTAL)   GFW = 583.395

ΔHf_0° = Unknown

$S^\circ_{298.15}$ = [65 ± 5] gibbs/mol $\Delta Hf^\circ_{298.15}$ = -74.5 ± 3 kcal/mol

Tm = 559° ±10°K ΔHm° = 4.10 kcal/mol

Heat of Formation

S. A. Shchukarev and G. A. Kokovin (1) have measured calorimetrically the heat of reaction ΔHr°_{298} = -187.475 ± 0.9 kcal/mol for $WBr_5(c) + 1/2Br_2(\ell) + 8NaOH(77.4H_2O) \rightarrow Na_2WO_4(c) + 6NaBr(c) + 4H_2O(\ell)$. This leads to $\Delta Hf^\circ_{298}(WBr_5, c)$ = -74.5 ± 3 kcal/mol, using $\Delta Hf^\circ_{298}(NaOH \cdot 77.4H_2O)$ = -112.348 kcal/mol (2), $\Delta Hf^\circ_{298}(NaWO_4, c)$ = -369.2 kcal/mol (3), $\Delta Hf^\circ_{298}(NaBr, c)$ = -86.38 kcal/mol (4) and $\Delta Hf^\circ_{298}(H_2O, \ell)$ = -68.315 kcal/mol (5).

Heat Capacity and Entropy

Cp_{300} = 6.2 gibbs/g-atom and Cp_{559} = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. Ll. Evans (6). Between 300°K and 559°K, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, S°_{298} = 65 eu, is estimated from that of $WCl_5(c)$ (7) and the entropy difference between bromides and chlorides. The latter is estimated to be 13 eu based on an extrapolation to pentavalent compounds of the entropy values of bromides and chlorides given by W. M. Latimer (9). Both WBr_5 and WCl_5 are paramagnetic with an effective moment of about 1.1 Bohr magnetons as indicated by B. N. Figgis and J. L. Lewis, "Progress in Inorg. Chem.," Vol. 6, page 121, Interscience Publishers, New York, 1964.

Melting Data

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin (8) have found the melting point, 559°K, by the thermographic method and 568°K by the tensimetric method. The value of 559°K is adopted in the tabulation.

The heat of melting is calculated from the difference between the heats of sublimation and vaporization at the melting point. The heats are both calculated from a second law analysis of the vapor pressure data reported by Shchukarev et al. (8), who gave the uncorrected heat of fusion, 5 kcal/mol. This value, when corrected for ΔCp of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

TUNGSTEN PENTABROMIDE (WBr_5) (LIQUID) GFW = 583.395

$S°_{298.15}$ = [70.113] gibbs/mol $\Delta Hf°_{298.15}$ =[-71.236] kcal/mol

Tm = 559° ± 10°K   ΔHm° = 4.10 kcal/mol

Tb = 633.5°K   ΔHv° = 19.48 kcal/mol

Heat of Formation

The heat of formation, $\Delta Hf°_{298}(WBr_5, \ell)$ = -71.236 kcal/mol, is calculated from that of WBr_5(c) by adding the heat of melting and the difference between $H°_{559} - H°_{298}$ for the crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed to be a constant, 7.25 gibbs/g-atom.

The entropy, $S°_{298}$ = 70.113 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data

See WBr_5(c) table (June 30, 1967) for details.

Vaporization Data

Tb is calculated as the temperature at which the Gibbs energy of reaction $WBr_5(\ell) \rightarrow WBr_5(g)$ approaches zero. The difference between the heats of formation for liquid and gas at the boiling point is ΔHv°.

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin, Zh. Neorg. Khim. 4, 2185 (1959), derived the boiling point 665°K and the heat of vaporization 14.5 ± 0.5 kcal/mol from vapor pressure data. Our second law values, corrected for ΔCp, are Tb = 666°K and ΔHv° = 13.8 kcal/mol.' The adopted values are significantly different because the second law value of ΔSv is not adopted in the table.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of $MoCl_5$ determined by electron diffraction (1). The bond distance is estimated to be the same as that in $WBr_6(g)$. The three principal moments of inertia are $I_A = I_B = 267.5 \times 10^{-39}$ and $I_C = 229.3 \times 10^{-39}$ g cm^2.

All vibrational frequencies are estimated from those of $WCl_5(g)$ (2), using the average value of $\nu(WBr_5)/\nu(WCl_5) = 0.62$ for modes which are independent of the central atom and 0.68 for modes involving the central atom. These average values of 0.62 and 0.68 are obtained from the ratios of corresponding vibrational frequencies of $ReX_6^=$, $SnX_6^=$ and $PtX_6^=$ summarized by H. Siebert (3) and K. Nakamoto (4).

The electronic levels and quantum weights are estimated to be the same as those in $WCl_5(g)$ (2).

TUNGSTEN HEXABROMIDE (WBr_6) (CRYSTAL) GFW = 663.304

ΔHf_0° = Unknown

$S^\circ_{298.15}$ = [75 ± 5] gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -82.0 ± 3 kcal/mol

Tm = 582°K

ΔHm° = Unknown

Heat of Formation

S. A. Shchukarev and G. A. Kokovin (1) have measured calorimetrically the heat of reaction ΔHr°_{298} = -180.0 ± 0.8 kcal/mol for $WBr_6(c) + 8NaOH(77.4H_2O) \rightarrow Na_2WO_4(c) + 6NaBr(c) + 4H_2O(\ell)$. This leads to $\Delta Hf^\circ_{298}(WBr_6, c)$ = -82.0 ± 3 kcal/mol, using $\Delta Hf^\circ_{298}(NaOH{\cdot}77.4H_2O)$ = -112.348 kcal/mol (2), $\Delta Hf^\circ_{298}(Na_2WO_4, c)$ = -369.2 kcal/mol (3), $\Delta Hf^\circ_{298}(NaBr, c)$ = -86.38 kcal/mol (4) and $\Delta Hf^\circ_{298}(H_2O, \ell)$ = -68.315 kcal/mol (5).

Heat Capacity and Entropy

Cp_{300} = 6.2 gibbs/g-atom and Cp_{582} = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. Ll. Evans (6). Between 300° and 582°K, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, $S^\circ_{298}(WBr_6, c)$ = 75 eu, is estimated by assuming $S^\circ_{298}(WBr_6) = S^\circ_{298}(WCl_6) + 6[S^\circ_{298}(Br^-) - S^\circ_{298}(Cl^-)]$. The value, $S^\circ_{298}(WCl_6, c)$ = 57 eu, is obtained from the JANAF $WCl_6(\alpha)$ table (Dec. 31, 1966); and the value, $S^\circ_{298}(Br^-) - S^\circ_{298}(Cl^-)$ = 3 gibbs/mol, is obtained from the average entropy values for Br^- and Cl^- ions given by W. M. Latimer (7) and K. K. Kelley (8).

Melting Data

S. A. Shchukarev, G. I. Novikov and G. A. Kokovin (9) have found the melting point, 582°K, under 50 atm pressure of $Br_2(g)$ by the thermographic method. The heat of fusion is unknown.

[250] (3)	[70] (3)

Bond Distance: W-Br = [2.40] Å

Bond Angle: Br-W-Br = [90°] σ = [24]

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.857] x 10^{-110} g^3 cm^6

Heat of Formation

The heat of formation, $\Delta Hf°_{298}(WBr_6, g)$ = -58.1 kcal/mol, is calculated from that of the crystal plus the estimated heat of sublimation $\Delta Hs°_{298}$ = 23.9 kcal/mol for $WBr_6(c) \rightarrow WBr_6(g)$. The value of $\Delta Hs°_{298}$ is assumed to be the same as that for $WCl_6(c) \rightarrow WCl_6(g)$. See WCl_6 table (Dec. 31, 1966) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be an octahedron similar to those of $WF_6(g)$, and $WCl_6(g)$ determined by electron diffraction. The bond distance is estimated to be 2.40 Å by assuming $r_{W-Br} = r_{W-Cl} + (r_{Na-Br} - r_{Na-Cl})$. The bond distances,W-Cl, Na-Br and Na-Cl,are given in JANAF WCl(g) and NaBr(g) and NaCl(g) tables, as 2.26 Å, 2.50 Å and 2.36 Å, respectively. The three principal moments of inertia are: $I_A = I_B = I_C = 305.7 \times 10^{-39}$ g cm^2.

All vibrational frequencies are estimated from those of $WCl_6(g)$ (1), using the average value of $\nu(WBr_6)/\nu(WCl_6)$ = 0.62 for modes which are independent of the central atom and 0.68 for modes involving the central atom. These average values of 0.62 and 0.68 are obtained from the ratios of corresponding vibrational frequencies of $ReX_6^=$, $SnX_6^=$ and $PtX_6^=$ summarized by H. Siebert (2), and K. Nakamoto (3).

CARBON (C) (REFERENCE STATE - GRAPHITE) MOL. WT. = 12.011

$\Delta H^\circ_{f0} = 0$

$\Delta H^\circ_{f\ 298.15} = 0$

$\Delta H^\circ_{S\ 298.15} = 170.89 \pm 0.5$ kcal. mole^{-1}

$\Delta S^\circ_{298.15} = 1.359$ cal. deg.$^{-1}$ mole^{-1}

Heat of Formation

Zero by definition.

Heat Capacity and Extrapolation

The low temperature C_p measurements of P. H. Keesom and N. Pearlman (1° to 4°K. and 10° to 20°K.), Phys. Rev. 99, 1119 (1955), and of W. DeSorbo and G. E. Nichols (1° to 20°K.), The Phys. and Chem. of Solids 6, 352 (1958), were joined smoothly with the C_p measurements of W. DeSorbo and W. W. Tyler (13° to 300°K.), J. Chem. Phys. 21, 1660 (1953). C_p values above 300°K were taken from National Bureau of Standards Report 6928, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element Compounds", July, 1960. Heat capacity values above 1000°K were adjusted to give smooth results. Above 4000°K. the C_p values are estimated.

S°_{15} and H°_{15} were calculated to be 0.00265 cal. deg.$^{-1}$ mole^{-1} and 0.03982 cal. mole^{-1} respectively from smooth C_p values using Weddle's rule.

CARBON, MONATOMIC (C) (IDEAL GAS) AT. WT. = 12.011

ΔH°_{f0} = 169.58 ± 0.45 kcal. mole^{-1}

Ground State Configuration $^3P_0$

$\Delta H^\circ_{f\ 298.15}$ = 170.89 ± 0.45 kcal. mole^{-1}

$S^\circ_{298.15}$ = 37.76 ± 0.01 cal. deg.$^{-1}$ mole^{-1}

Electronic Levels and Multiplicities

ϵ_i cm.$^{-1}$	g_i	ϵ_i cm.$^{-1}$	g_i
0	1	60,360	9
16.4	3	61,982	3
43.5	5	64,090	15
10,194	5	70,000	34
21,648	1	75,000	99
33,735	5	85,000	401

Heat of Formation

The ΔH°_{f0} is given by the following cycle at 0°K.

(I)	$C(c) + 1/2\ O_2(g) = CO(g)$	-27.1995 kcal. mole^{-1}
(II)	$CO(g) = C(g) + O(g)$	255.764
(III)	$O(g) = 1/2\ O_2(g)$	-58.989

For details concerning (I), (II), and (III) see the CO(g) and O_2(g) sheets. A definitive review of the heat of sublimation of carbon is given by L. Brewer and A. W. Searcy, Ann. Rev. Phys. Chem. 7, 259 (1956).

Heat Capacities and Entropies

The electronic energy levels are those listed by C. E. Moore, Nat. Bur. Standards (U. S.) Circ. 467, (1949). Levels above 60,000 cm.$^{-1}$ have been averaged.

Heat of Formation.

The heat of formation was calculated from the equation: $C(g) + e^- \rightarrow C^-(g)$ with the JANAF auxiliary value for C(g); using an electron affinity = 1.25 e.v. (28.83 kcal/mole) obtained from M. Seman and L. M. Branscomb, Phys. Rev. 125, 1602 (1962). Other values for the electron affinity are: 1.17 e.v. reported by E. Clementi and A. D. McLean, Phys. Rev. 133, A419 (1964); 1.12 e.v. reported by E. Clementi, A. D. McLean, D. L. Raimondi and M. Yoshimine, Phys. Rev. 133, A1274 (1964); and 1.24 e.v. reported by B. Edlen, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, U. S. National Bureau of Standards Circular 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case nitrogen. The electronic levels above 1 X 10^5 cm^{-1} were omitted because their contribution is negligible below 6000°K. The $H^\circ-H^\circ_{298}$ value at 0°K. is -1.481 kcal/mole.

r_e = [1.77] Å

Heat of Formation.

$\Delta H^\circ_{f\ 0}$ was calculated from D_0, 83.0 kcal. mole^{-1}, estimated by J. S. Gordon, Astrosystems International, Livingston, N. J., private communication, June 6, 1963. $\Delta H^\circ_{f\ 298.15}$ was then calculated. P. Zeeman, Can. J. Phys. 32, 9 (1954) reported a D_0 = 1.6 ± 0.2 e.v., 36.9 kcal. mole^{-1}, for a molecule that was apparently AlC(g). However, H. Wooley, Nat'l Bur. Std. Report No. 6928, July 1, 1960, surmised that this D_0 and the reported molecular constants were for the $Al_2(g)$ molecule. His judgment was accepted.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit.

BORON CARBIDE (BC) (IDEAL GAS) MOL. WT. = 22.831

Ground State Configuration [$^2\Pi$]

$\Delta H^\circ_{f\ 0} = 196 \pm 10$ kcal. mole^{-1}

$S^\circ_{298.15} = [49.822]$ cal. deg.$^{-1}$ mole^{-1}

$\Delta H^\circ_{f\ 298.15} = 198 \pm 10$ kcal. mole^{-1}

$\omega_e = [1350]$ cm.$^{-1}$

$\omega_e x_e = [12.0]$ cm.$^{-1}$

$B_e = [1.555]$ cm.$^{-1}$

$\alpha_e = [0.018]$ cm.$^{-1}$

$\sigma = 1$

Heat of Formation.

The heat of formation at 298.15°K. was calculated from $\Delta H^\circ_0 = 105 \pm 10$ kcal. mole^{-1} for the reaction BC(g) = B(g) + C(g) reported by G. Verhaegen, F. E. Stafford, M. Ackerman, and J. Drowart, Nature, 193, 1280 (1962).

Heat Capacity and Entropy.

All spectroscopic constants were obtained from J. S. Gordon, Astrosystems, International, West Caldwell, New Jersey, private communication, November 2, 1962.

Dec. 31, 1960; June 30, 1963; Sept. 30, 1965; Dec. 31, 1965

TETRABORON MONOCARBIDE (B_4C) (CRYSTAL) MOL. WT. = 55.25515

$S^\circ_{298.15}$ = 6.483 ± 0.03 cal. deg.$^{-1}$ mole^{-1}

T_m = 2743 ± 20 °K.

$\Delta H^\circ_{f\ 0}$ = -9.2 ± 2.4 kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = -9.3 ± 2.4 kcal. mole^{-1}

ΔH°_m = [25] kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was calculated from $\Delta H^\circ_{r\ 298.15}$ = -683.3 ± 2.2 kcal. mole^{-1} for the reaction $B_4C(c) + 4O_2(g) \rightarrow 2B_2O_3(amorph) + CO_2(g)$ measured by D. Smith, A. S. Dworkin and E. R. Van Artsdalen, J. Am. Chem. Soc. 77, 2654-6 (1955) and the heat of formation for B_2O_3(amorph) (Dec. 31, 1964) and for CO_2(g) (March 31, 1961) in JANAF Tables.

Heat Capacity and Entropy.

The low temperature heat capacities, 54-294°K., were taken from K. K. Kelley, J. Am. Chem. Soc. 63, 1137 (1941). Above 298°K., C_p was calculated using the equation $C_p = 22.99 + 5.40 \times 10^{-3}T - 10.72 \times 10^5 T^{-2}$ obtained from the enthalpy data in the range 298 to 1726°K. reported by E. G. King, Ind. Eng. Chem. 41, 1298 (1949). The values from the two sources join smoothly at 298°K. The $S^\circ_{298.15}$ was calculated based on the low temperature heat capacities measured by K. K. Kelley, loc. cit., using $S^\circ_{53.1}$ = 0.047 cal. deg.$^{-1}$ mole^{-1}.

Melting Data.

T_m was determined by Dolloff, WADD Tech. Rept. 60-143, 1960 and ΔH°_m was estimated.

Dec. 31, 1960; June 30, 1963; Dec. 31, 1965

TETRABORON MONOCARBIDE (B_4C) (LIQUID) MOL. WT. = 55.25515

$S^\circ_{298.15}$ = 16.592 cal. deg.$^{-1}$ mole^{-1}

T_m = 2743 ± 20°K.

$\Delta H^\circ_{f\ 298.15}$ = 18.1 ± 2.5 kcal. mole^{-1}

ΔH°_m = [25] kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was obtained from $\Delta H^\circ_{f\ 298.15}(c)$ by adding ΔH°_m and the difference between $H^\circ_{T_m}-H^\circ_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 1750°K. The heat capacity below 1750°K. was obtained from the heat capacity of the crystal. Above 1750°K. the heat capacity was assumed constant and estimated as 32.50 cal. deg.$^{-1}$ mole^{-1} or 6.5 cal. deg.$^{-1}$ per g-atom.

The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See $B_4C(c)$ table.

Dec. 31, 1960; Mar. 31, 1962; June 30, 1963

DIBERYLLIUM MONOCARBIDE (Be_2C) (CRYSTAL) MOL. WT. = 30.037

$\Delta H_{f\ 0}^\circ$ = Unknown

$S^\circ_{298.15}$ = [3.9 ± 1.0] cal. deg.$^{-1}$ mole^{-1}

$\Delta H_{f\ 298.15}^\circ$ = 21.7 ± 2.5 kcal. mole^{-1}

T_m = [2400]°K.

ΔH_m° = [18] kcal. mole^{-1}

Heat of Formation.

The selected $\Delta H_{f\ 298.15}^\circ$ was calculated by the 3rd law method using vapor pressures reported by B. D. Pollock, J. Phys. Chem. 63, 587 (1959). Pressures for the reaction $Be_2C(c) \rightarrow 2Be(g) + C_{(graphite)}$ were measured by Pollock in the temperature range 1430-1669°K. by Knudsen technique. Vapor pressure data for this decomposition reaction have also been reported by J. Baboin, French Patents 1.193.790 (1959), J. Quirk, Reactor Handbook 3, 98 (1955) and F. Muratov and A. Novoselova, Dokl. Akad. Nauk SSSR 129, 334 (1959). The calculated $\Delta H_{f\ 298.15}^\circ$ values are summarized as follows:

Calc. Method	Number of Pressures	T, °K.	$\Delta H_{r\ 298.15}^\circ$ kcal. mole^{-1}	$\Delta H_{f\ 298.15}^\circ$ kcal. mole^{-1}	References
3rd law	14	1430-1669	89.117	-21.7	B. D. Pollock
2nd law	14	1430-1669	90.8	-25.1	Least squares fit of Pollock's v.p. to the equation: log P (atm.) = 6.946-19,593/T
3rd law	6	1673-1953	71.411	+13.7	F. Muratov and A. Novoselova
3rd law	8	1900-2600	81.278	- 6.1	J. Quirk
3rd law	8	1600-2300	96.266	-36.0	J. Baboin

H. L. Schick, D. F. Anthrop, P. L. Hanst, R. E. Dreikorn, and M. B. Panish, "Thermodynamics of Certain Refractory Compounds, Part II", 1 March 1963 to 31 May 1963 have listed the measured vapor pressures. The vapor pressures reported by J. Baboin (loc. cit.) used in the 3rd law calculation were those listed by H. L. Schick, et al.

Heat Capacity and Entropy.

The heat capacity values, from 298.15 to 1200°K., were derived from the mean C_p data measured by J. J. Neely, E. Teeter, Jr., and J. B. Trice, J. Am. Ceramic Soc. 33, 363 (1950). Neely, et al., estimated an overall error of 15% in their mean heat capacity data. The powdered Be_2C material which was used analyzed 80 to 74% Be_2C. The impurities were mainly oxide and nitride of Be. No corrections were made for the effect of these impurities.

From 1200-2400°K. the C_p was extrapolated so as to approach the value, 22 cal. deg.$^{-1}$ mole^{-1} calculated from O. H. Krikorian, "Estimation of High-Temperature Heat Capacities of Carbides," University of California, UCRL 6785, February 6, 1962. The $S^\circ_{298.15}$, 3.9 cal. deg.$^{-1}$ mole^{-1}, was estimated by Krikorian (loc. cit.).

Melting Data.

H. L. Schick, et al., (loc. cit.) have summarized the available melting data i.e.: Y. Oishi and Y. Hamona, Osaka Kogyo Gijutsu Shikenjo Kiho 8, 89 (1957) have reported decomposition upon heating as low as 1873°K. L. Brewer, L. Bromley, P. Gilles, and N. Lofgren, "The Chemistry and Metallurgy of Miscellaneous Materials," in "Thermodynamics", McGraw-Hill, New York (1950) and I. S. Gaev, AEC TR 3036 Transl. from Zh. Neorg. Khim. 1, 196 (1956) reported melting or dissociation between 2373° and 2423°K.

The melting point is assumed to be 2400°K. as estimated by T. B. Douglas and A. C. Victor, National Bureau of Standards Preliminary Report 6645, 1 January 1960 and H. L. Schick, et al. (loc. cit.). From the estimated melting point, 2400°K., and an estimated 2.5 cal. g. atom^{-1} deg.$^{-1}$ for the entropy of melting, the heat of melting was calculated.

Dec. 31, 1960; Mar. 31, 1962; June 30, 1963

DIBERYLLIUM MONOCARBIDE (Be_2C) (LIQUID) MOL. WT. = 30.037

$S^\circ_{298.15}$ = [11.345] cal. deg.$^{-1}$ mole^{-1}

T_m = [2400]°K.

$\Delta H^\circ_{f\ 298.15}$ = [3.798 ± 10] kcal. mole^{-1}

ΔH°_m = [18] kcal. mole^{-1}

Heat of Formation.

The $\Delta H^\circ_{f\ 298.15}$ was calculated from the heat of formation of the crystal and the estimated heat of melting.

Heat Capacity and Entropy.

The heat capacity was assumed constant and equal to the heat capacity of the solid Be_2C at the estimated melting point.

Melting Data.

The National Bureau of Standards Report 6645, January, 1960, states that Be_2C seems to decompose easily only at temperatures above its reported melting point. For this reason they extended their Be_2C table into the liquid region. For detailed melting data see the Be_2C (c) table.

CARBON MONOBROMIDE (CBr)   (IDEAL GAS)   GFW = 91.92015

Ground State Configuration $^2\Pi$

$S^\circ_{298.15}$ = [55.8] gibbs/mol

ΔHf°_0 = 123 ± 15 kcal/mol

$\Delta Hf^\circ_{298.15}$ = 122 ± 15 kcal/mol

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	2
465	2
33163	2
33218	2
[40000]	[2]

ω_e = [736] cm^{-1} $\omega_e x_e$ = [4.0] cm^{-1} σ = 1

B_e = 0.4890 cm^{-1} α_e = [0.0036] cm^{-1} r_e = 1.8170 Å

Heat of Formation

Dixon and Kroto (1) have observed predissociation of CBr(g) which indicates that the dissociation energy (D°_0) is less than 94.7 kcal/mol. They evaluated the kinetic data of Simons and Yarwood (2), obtaining a value of D°_0 = 97 ± 5 kcal/mol, based on the heat of formation of bromoform and the dissociation energy of HBr, and concluded that the true value of D°_0 is very close to the upper limit of 94.7 kcal/mol. Comparisons of C-X bond energies of CX_4 and CX compounds, however, indicate that this value is too high to be consistent with other carbon halides. Therefore the value of D°_0 adopted is 75 ± 15 kcal/mol. The corresponding ΔHf°_{298} for CBr(g) is 122 ± 15 kcal/mol.

Heat Capacity and Entropy

The rotational structure of the near UV spectra of CBr(g) has been investigated by Dixon and Kroto (1) in the 3000 Å region. They assigned the above doublet electronic levels to the ground ($^2\Pi$) and first excited ($^2\Delta$) states and reported a value of B_0 = 0.4872 ± 0.0003 cm^{-1} for the ground state. An additional electronic level ($^2\Sigma$) is expected to be close to the first excited state by analogy with CF(g) and CCl(g).

The fundamental vibrational frequency ω_e is estimated from Guggenheimer's relation for single bonded molecules (3). The anharmonic vibrational term $\omega_e x_e$ is estimated by assuming $\omega_e x_e = \omega_e^2/(4D_0 + 2\omega_e)$. The value of α_e is calculated from the Morse potential function. The rotational constant B_e is calculated from $B_e = B_0 + \alpha_e/2$. The bond distance is calculated from B_e.

BROMOTRIFLUOROMETHANE ($CBrF_3$) (IDEAL GAS) GFW = 148.91535

Point Group C_{3v}

$\Delta Hf^\circ_0 = -152.2 \pm 0.7$ kcal/mol

$S^\circ_{298.15} = 71.155 \pm 0.12$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -155.1 \pm 0.7$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
1086 (1)	1206 (2)
761 (1)	549 (2)
348 (1)	300 (2)

Bond Distance: C-F = 1.328 Å C-Br = 1.909 Å

Bond Angle: F-C-F = 108.6 ± 1° F-C-Br = 110.33° $\sigma = 3$

Product of the Moments of Inertia: $I_AI_BI_C = 2.3403 \times 10^{-113}$ g^3 cm^6

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Coomber and Whittle (2, 3, 4) have determined equilibrium data for $CClF_3(g) + BrCl(g) = CBrF_3(g) + Cl_2(g)$ and for $CF_3X(g) + Br_2(g) = CF_3Br(g) + BrX(g)$ where X = H, Cl, and CF_3. Equilibrium data for $CF_3I(g) + BrI(g) = CBrF_3(g) + I_2(g)$ were obtained by Lord et al. (5). These data link $CBrF_3$ with C_2F_6, CHF_3, $CClF_3$ and CF_3I.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Sharbaugh et al. (6), Bowen (7), and Anderson (8) and from microwave data by Sheridan and Gordy (9). The adopted parameters are an average of those reported by (8, 9). Infrared spectra of the gas were observed by several investigators (10, 11, 12) and Raman spectra of the liquid were obtained by Edgell and May (12). The vibrational assignments of (11, 12) are in close agreement. These assignments are adopted but preference is given to frequencies observed for the gas. The value for ν_6 is taken as 300 cm^{-1} which is between the values of 305 and 297 ± 3 cm^{-1} derived from Raman spectra and IR (combination and overtone) spectra, respectively.

The thermodynamic functions of this table are essentially the same as those calculated by (11). Uncertainty in the entropy is estimated to vary from 0.12 to 0.5 gibbs/mol over the range from 300 to 1000°K. Uncertainty in ν_6 and neglect of anharmonicity are the major sources of error. Discussions of the magnitude of anharmonic effects appear on the tables for $CClF_3(g)$ and $CF_4(g)$. The principal moments of inertia are $I_A = 14.68 \times 10^{-39}$ and $I_B = I_C = 39.93 \times 10^{-39}$ g cm^2.

CYANOGEN BROMIDE (BrCN) (IDEAL GAS) GFW = 105.92685

Point Group $C_{\infty v}$

$\Delta Hf_0^\circ = 46.1 \pm 1.5$ kcal/mol

$S^\circ_{298.15} = 59.33 \pm 0.01$ gibbs/mol

$\Delta Hf^\circ_{298.15} = 44.5 \pm 1.5$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	
575	(1)
342.5	(2)
2200	(1)

Bond Distance: C-Br = 1.789 Å C-N = 1.158 Å

Bond Angle: Br-C-N = 180° $\sigma = 1$

Rotational Constants: $B_0 = 0.13705$ $D_0 = 2.929 \times 10^{-8}$ cm^{-1}

Spectroscopic constants used in calculating corrections to rigid-rotator-harmonic oscillator approximation (cm^{-1}).

$\alpha_1 = 5.17 \times 10^{-4}$ $x_{11} = [-3.0]$ $x_{12} = [-4.0]$

$\alpha_2 = -3.84 \times 10^{-4}$ $x_{22} = -0.86$ $x_{23} = -6.19$

$\alpha_3 = 6.77 \times 10^{-4}$ $x_{33} = [-5.0]$ $x_{13} = [-3.0]$

$g_{22} = 1.14$

Heat of Formation

The heat of formation is calculated from ΔHf°_{298}(BrCN, c) = 33.58 kcal/mol (1) and ΔHs°_{298} = 10.92 ± 0.1 kcal/mol. This latter is obtained from an analysis of the vapor pressure data of Lord and Woolf (2) and Baxter et al. (3).

The heat of formation of the crystal is calculated from ΔHr°_{298} = -56.0 kcal/mol obtained by Lord and Woolf (2) for the reaction

$$BrCN(c) + 2NaOH(56\ H_2O) = NaCNO(2800\ H_2O) + NaBr(2800\ H_2O) + H_2O(\ell).$$

The auxiliary data used were $\Delta Hf^\circ_{298}(NaOH\cdot 56\ H_2O)$ = -112.26 kcal/mol (1, 4), $\Delta Hf(NaCNO\cdot 2800\ H_2O)$ = -92.25 kcal/mol (1, 4) and $\Delta Hf^\circ_{298}(NaBr\cdot 2800\ H_2O)$ = -70.54 kcal/mol (1, 4). The uncertainty in the final value reflects the uncertainty in $\Delta Hf(NaCNO\cdot 2800\ H_2O)$ which was determined by Lord and Woolf (2) to be -93.6 kcal/mol in excess $NaOH\cdot 56\ H_2O$.

Heat Capacity and Entropy

J. S. Gordon (5) used the constants given above to calculate the adopted table, using the method of Pennington and Kobe (6) for anharmonicity, vibration rotation interaction, and centrifugal stretching corrections.

The bond lengths and angle were reported by Tyler and Sheridan (7).

Heat of Formation.

The heat of formation, ΔH_f° 298.15, was calculated and reported by F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and I. Jaffe, "Selected Values of Chemical Thermodynamic Properties", National Bureau of Standards Circular 500, 1952.

Heat Capacity and Entropy.

The molecular constants, bond distance, and bond angle were determined by electron diffraction by C. Finbak, O. Hassel, and B. Ottar, Arch. Math. Naturv B44, No. 13 (1941) and C. Finbak, O. Hassel, and O. Olaussen, Tidsskr. Kjemi Bergv. 3, 13 (1943). The constants reported by C. Finbak, et al., in 1943 were selected. These constants are listed in, "Tables of Interatomic Distances and Configuration In Molecules and Ions," Special Publication No. 11, The Chemical Society (London), 1958. The principal moments of inertia calculated from these constants were $I_A = I_B = I_C$ = 1.3343 X 10^{-37} g. cm.^{2}

The vibrational frequencies used were assigned by A. G. Meister, S. E. Rosser, and F. F. Cleveland, J. Chem. Phys. 18, 346 (1950). They measured the infrared and Raman spectrum, considered the previous literature, calculated force constants and made most probable value assignments for the frequencies. A more recent paper by B. Moszynska and J. P. Mathieu, Compt. Rend 256, 2820 (1963) made assignments from Raman and Infrared spectra which agreed with all of Meister, et al.'s assignments except ν_2 which they found was 126 cm.$^{-1}$ rather than 122 cm.$^{-1}$.

CARBON MONOCHLORIDE (CCl) (IDEAL GAS) GFW = 47.46415

ΔHf°_0 = 119.1 ± 5 kcal/mol

$S^\circ_{298.15}$ = 53.63 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 120 ± 5 kcal/mol

Electronic Levels and Quantum Weights

State	ε_i, cm^{-1}	g_i
$X^2\Pi$	0	2
	134.92	2
$^4\Sigma$	[20000]	4
$A^2\Delta$	36004	4

ω_e = 876.4 cm^{-1} $\omega_e x_e$ = 6.15 cm^{-1} σ = 1

B_e = 0.69666 cm^{-1} α_e = [0.0066] cm^{-1} r_e = 1.642 Å

Heat of Formation

The data of Miller and Palmer (1) provide a value of D_{C-Cl} = 80 ± 5 kcal/mol, which appears to be reasonably substantiated. They studied the chemiluminescence from flames of $CHCl_3$ and CCl_4 burning in potassium vapor. These flames exhibit C_2 Swan band radiation with major departures from vibrational and rotational equilibrium. The spectra are interpreted as due to the reaction $C + CCl \rightarrow C_2^* + Cl$ where the carbon atom is either ^3D ground state or ^1D first excited state. The separation between the ground and first excited state of the carbon atom is matched closely by the difference in preferential population of the excited C_2 levels. The assumption is made that all the exothermicity of the reaction is retained as vibrational excitation of the C_2, thus the populated levels are measures of the heat of reaction. In this manner we obtain a heat of reaction of 67 ± 2.5 kcal for the reaction $C + CCl \rightarrow C_2 + Cl$ which, using JANAF auxiliary data, gives $\Delta Hf^\circ(CCl, g)$ = 124 ± 2.5 kcal/mol; however, this represents the initial state of the CCl which in the flame is presumed to have about 4 kcal of vibrational energy at roughly 2000°K. Thus, we obtain $\Delta Hf^\circ_{298}(CCl, g)$ = 120 ± 5 kcal/mol, which is adopted.

The heat of formation can also be estimated from the dissociation energy calculated from the linear Birge-Sponer extrapolation of the ground state vibrational constants. This yields D_0 = 89 kcal or ΔHf°_{298} = 111 kcal/mol. There are several indications that this dissociation energy is probably a maximum value, for example, Hildenbrand (5) has applied an ionic-covalent correction to the linear extrapolation which gives D°_0 = 72 kcal. We would expect this heat of formation to be a minimum value. A real minimum for the dissociation energy can be obtained from the knowledge that the first vibrational level of the $^2\Delta$ state is occupied and so the dissociation energy of this state must be greater than 850 cm^{-1}. This yields a minimum dissociation energy of the ground state of 76 kcal, assuming the dissociation products are $C(^1\Delta)$ and $Cl(^2P)$, and $\Delta Hf^\circ_{298}(CCl, g)$ = 124 kcal/mol which is the maximum value of the heat of formation.

Heat Capacity and Entropy

The rotational and electronic constants are those of Verma and Mulliken (2). The vibrational constants are those derived by Ovcharenko et al. (3) from the data of Gordon and King (4). The anharmonicities listed by Verma and Mulliken are not used, since these are based only on the 0,0 and 0,1 transitions. The $^4\Sigma$ level is estimated by analogy with CF(g). The value for α_e was obtained from the other constants assuming a Morse potential function.

Moments of inertia: $I_A = [7.480 \times 10^{-39}]$g cm.^{2} $I_B = [16.008 \times 10^{-39}]$g. cm.^{2} $I_C = [23.31 \times 10^{-39}]$g cm.^{2}

$\sigma = 1$

Heat of Formation

The heats of formation of $COCl_2$ and COF_2 have been averaged to obtain that of COClF.

Heat Capacity and Entropy

The molecular constants are from R. J. Lovell, C. V. Stephenson, and E. A. Jones, J. Chem. Phys. 22, 1953 (1954).

Chlorotrifluoromethane ($CClF_3$)

CHLOROTRIFLUOROMETHANE ($CClF_3$) (IDEAL GAS) GFW = 104.45935

Point Group C_{3v}

ΔHf°_0 = -168.0 ± 0.8 kcal/mol

$S^\circ_{298.15}$ = 68.174 ± 0.1 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -169.2 ± 0.8 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
1106 (1)	1217 (2)
782 (1)	560 (2)
474 (1)	350 (2)

Bond Distance: C-F = 1.328 Å C-Cl = 1.751 Å

Bond Angle: F-C-F = 108.6 ± 0.5° F-C-Cl = 110.33° σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = 9.4425 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Coomber and Whittle (2) have determined equilibrium data for $CClF_3(g) + BrX(g) = CBrF_3(g) + ClX(g)$ where X = Cl and Br. Lord et al. (3) studied the analogous equilibria $CF_3I(g) + ClI(g) = CClF_3(g) + I_2(g)$. These data link $CClF_3$ with $CBrF_3$ and CF_3I.

Other data which were omitted from the adjustment include those of Baibuz (4, 5), Mears (6), Kolesov (7), Kirkbride (8), and von Wartenberg (9). Baibuz (4, 5) derived ΔHf° = -166.2 ± 2.2 kcal/mol by applying the method of explosion in a spherical bomb to mixtures of H_2, O_2 and $CClF_3$. By comparison with similar data for CF_4 and CCl_4, we estimate the bias in Baibuz' value to be about +2 kcal/mol. Mears (6) gave a preliminary report of values of ΔHr at 300°C for reactions involving HF, HCl and CCl_nF_{4-n} (n = 1, 2, 3, 4). We derive ΔHf° = -172 and -173 kcal/mol from two different combinations of reactions; however, no detailed account of the data has been published. The other authors (7, 8, 9) measured ΔHr for reaction of $CClF_3$ with an alkali metal (Na or K) to form amorphous carbon and mixtures of the fluoride and chloride. Discrepancies of many kcal/mol exist in these studies, presumably due to inadequate characterization of the thermochemical reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Bowen (10) and Bartell (11). Results from Bartell are adopted. These parameters are consistent with the microwave data of Coles (12). Principal moments of inertia are $I_A = 14.68 \times 10^{-39}$ and $I_B = I_C = 25.37 \times 10^{-39}\ g\ cm^2$. Vibrational assignments are based on the work of Claassen (13) and the gas-phase Raman spectra observed by Holzer and Moser (14).

The largest uncertainty in Cp° and S° probably results from the neglect of anharmonicity. Barho (15) and Albright (16) have given estimates for the anharmonic contributions. These vary from 0.1 to 0.3 gibbs/mol in both Cp° and S° over the range from 300 to 1000°K, respectively. Somewhat larger contributions are possible based on the anharmonic functions calculated by McBride (17) for $CF_4(g)$. We estimate the overall uncertainty in the entropy of this JANAF table to be 0.1 eu at 300°K and 0.4 eu at 1000°K. Cp° is consistent with Cv° measured at 300°K by the wire-ribbon method (18).

Dec. 31, 1960; June 30, 1961; June 30, 1966

CYANOGEN CHLORIDE (ClCN) (IDEAL GAS) GFW = 61.47085

Point Group $C_{\infty v}$

ΔHf°_0 = 32.8 kcal/mol

$S^\circ_{298.15}$ = 56.459 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 32.97 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm $^{-1}$
714.52 (1)
378.3 (2)
2215.5 (1)

Bond Distance: Cl-C = 1.631 Å C-N = 1.162 Å

Bond Angle: Cl-C-N = 180°

σ = 1

Rotational constants: B_o = 0.19817 cm.$^{-1}$ D_o = 5.503 X 10^{-8} cm $^{-1}$

Spectroscopic constants used in calculating corrections to rigid rotator-harmonic oscillator approximation (cm $^{-1}$):

α_1 = 8.25 X 10^{-4} x_{11} = [-4] x_{12} = [-6.8] g_{22} = 0.95

α_2 = -5.46 X 10^{-4} x_{22} = -0.65 x_{23} = -7.236

α_3 = 1.06 X 10^{-3} x_{33} = [-7] x_{13} = -2.8

Heat of Formation.

The heat of formation was taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties" NBS Technical Note 270-1, Washington, 1965.

Heat Capacity and Entropy.

J. S. Gordon, Astrosystems International Inc., Fairfield, N. J., (private communication, Feb., 1966), has used the constants listed above to calculate C from 298.15 to 6000°K using the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The constants B_o and D_o were taken from C. A. Burrus and W. Gordy, Phys. Rev. 101, 599 (1956); ω_1, α_1, α_3, x_{22}, x_{23}, x_{13} and g_{22} were obtained from W. J. Lafferty, D. R. Lide and R. A. Toth, J. Chem. Phys. 43, 2063 (1965); α_2 has been taken from C. H. Townes, A. N. Holden and F. R. Merritt, Phys. Rev. 74, 1113 (1948); and x_{11}, x_{33} and x_{12} were estimated by Gordon, loc. cit. The bond distances and bond angle were taken from Lafferty et al., loc. cit.

Dec. 31, 1965

CARBONYL MONOCHLORIDE (COCl) (IDEAL GAS) MOL. WT. = 63.46355

Point Group C_s

$S^\circ_{298.15}$ = [64] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 2

$\Delta H^\circ_{f\ 0}$ = [-15 ± 10] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-15 ± 10] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
570 (1)
281 (1)
1880 (1)

Bond Distance: C-Cl = [1.75] Å C-O = [1.17]Å

Bond Angle: Cl-C-O = [120] ° σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [1.27603 x 10^{-115}] g.^{3} cm.^{6}

Heat of Formation.

The enthalpy change (ΔH_r°) for the reaction $COCl_2(g) = CO(g) + 2Cl(g)$ is calculated to be 82 kcal. mole^{-1}, which is the sum of two bond energies, i.e. D(Cl-COCl) + D(Cl-CO). By comparison with the values, D(H_3C-COCH_3)/D(H_3C-CO) = 72/18 = 4.0 for $CH_3COCH_3(g)$ and D(H_3C-COCl)/D(Cl-CO) = 4.3 for $CH_3COCl(g)$, the ratio of D(Cl-COCl)/D(Cl-CO) is estimated to be 4.0 for $COCl_2(g)$. Hence the enthalpy change for the reaction $COCl_2(g) = COCl(g) + Cl(g)$ is calculated as 82 x (4/5) = 65.6 kcal. mole^{-1}. Using the ΔH_r° value obtained, the heat of formation for COCl(g) is derived to be -15 ± 10 kcal. mole-1.

Heat Capacity and Entropy.

The vibrational frequencies were reported by M. E. Jacox and D. E. Milligan, J. Chem. Phys. 43, 866 (1965). The bond distances and angle were estimated by Jacox and Milligan, loc. cit. Due to the presence of one unpaired electron on C atom, the ground state quantum weight is calculated to be 2. The three principal moments of inertia are: I_A = 1.29987 x 10^{-38}, I_B = 7.1580 x 10^{-40}, and I_C = 1.37145 x 10^{-38} g. cm.^{2}

Mar. 31, 1965; Dec. 31, 1968

CARBON DICHLORIDE (CCl_2) (IDEAL GAS) GFW = 82.91715

Point Group C_{2v}

ΔHf°_0 = 56.7 ± 5 kcal/mol

$S^\circ_{298.15}$ = 63.4 ± 0.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 57.0 ± 5 kcal/mol

Ground State Quantum Weight = 1

Electronic Levels and Quantum Weights

ϵ_i, cm^{-1}	g_i
0	1
[4000]	[3]
[17500]	[1]

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
721 (1)
[350] (1)
748 (1)

Bond Distance: C-Cl = [1.76] Å

Bond Angle: Cl-C-Cl = [100 ± 10°]

σ = 2

Product of Moments of Inertia: $I_AI_BI_C$ = [1.1017] x 10^{-114} g^3cm^6

Heat of Formation

Shapiro and Lossing (1) have measured mass-spectrometrically the appearance potentials 12.2 and 14.7 eV for the processes $CHCl_3(g) + e^- \rightarrow CCl_2^+(g) + HCl(g) + 2e^-$ and $C_2Cl_4(g) + e^- \rightarrow CCl_2^+(g) + CCl_2(g) + 2e^-$, respectively. The difference in these two processes gives ΔHr° = 2.5 eV (57.65 kcal/mol) for the reaction $C_2Cl_4(g) + HCl(g) \rightarrow CCl_2(g) + CHCl_3(g)$ which leads to ΔHf°_{298} (CCl_2, g) = 57.32 kcal/mol, using JANAF ΔHf°_{298} = -2.97, -22.063 and -24.7 kcal/mol for $C_2Cl_4(g)$, HCl(g) and $CHCl_3(g)$, respectively. Since the authors claimed that the experimental error was probably 5 kcal/mol, the value, 57 ± 5 kcal/mol, is adopted for the heat of formation.

Heat Capacity and Entropy

Milligan and Jacox (2) have found two stretching fundamentals (721 and 748 cm^{-1}) for the CCl_2 radical in the infrared and ultraviolet spectra by matrix-isolation, and proposed a bent molecular structure (the valence angle = 100 ± 10°) with a ground singlet state which was based on the analogy with the electronic absorption spectrum of CF_2. L. Andrews (3) has confirmed all these observations in his infrared spectrometric studies of dichlorocarbene in solid argon, and made vibrational assignment to the fundamentals and also eliminated the possibility of a linear molecular structure for CCl_2. The bending frequency (350 cm^{-1}) is estimated by the valence force method (4), using the same ratio of bending over stretching force constants from $CF_2(g)$ (5). The bond distance is estimated to be the same as that of $CCl_4(g)$ measured by Bartell et al (6). The three principal moments of inertia are $I_A = 2.1828 \times 10^{-39}$, $I_B = 21.4013 \times 10^{-39}$, and $I_C = 23.5840 \times 10^{-39}$ g cm^2.

The triplet low lying electronic level of 4000 cm^{-1} is estimated by analogy with that of $CF_2(g)$. The other level of 17,500 cm^{-1} is also estimated based on a weak band appearing between 4400 and 5600 Å in the spectra of CCl_2 observed by Milligan and Jacox (2).

Product of the Moments of Inertia: $I_AI_BI_C = 2.5841 \times 10^{-113}\ g^3cm^{-6}$

Heat of Formation

Mears and Stahl (1) investigated several heats of reaction involving CF_4, CF_3Cl, CF_2Cl_2, $CFCl_3$, CCl_4, HF and HCl. Using JANAF values for all compounds except CF_2Cl_2 and $CFCl_3$ we obtain the following observations:

1. $\Delta Hf_{298}(CCl_3F, g) = -70.12 \pm 1.1$ kcal/mol
2. $\Delta Hf_{298}(CCl_2F_2, g) = -116.53 \pm 1.5$ kcal/mol
3. $\Delta Hf_{298}(CCl_2F_2, g) - \Delta Hf_{298}(CCl_3F, g) = -49.39 \pm 1.0$ kcal/mol
4. $\Delta Hf_{298}(CCl_2F_2, g) - 2\Delta Hf_{298}(CCl_3F, g) = 20.34 \pm 1.0$ kcal/mol
5. $\Delta Hf_{298}(CCl_3F, g) - 2\Delta Hf_{298}(CCl_2F_2, g) = 165.47 \pm 1.0$ kcal/mol

The sum of the squares of the deviations is smallest when $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -117.5$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_3F, g) = -69$ kcal/mol, and all the values are within their uncertainty ranges.

Petersen and Pitzer (8) obtained an approximate equilibrium constant for the reaction $2CClF_3(g) + CCl_4(g) = 3CCl_2F_2(g)$ of log $K_{400} = -3.0$. This on 3rd law reduction gives $\Delta Hr^\circ_{298} = 7.64$ kcal and with $\Delta Hf^\circ_{298}(CClF_3, g) = -169.2$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_4, g) = -22.94$ kcal/mol this yields $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -117.9$ kcal/mol.

Kirkbride and Davidson (2) investigated the reaction of potassium with the chlorofluoromethanes and obtained $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -115.1 \pm 2$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_3F, g) = -72.9 \pm 4$ kcal/mol after correction with JANAF auxiliary data. Wartenberg and Schiefer (3) investigated the same reaction and we obtain, after correction with JANAF auxiliary data, $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -112.7$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_3F, g) = -63.1$ kcal/mol. Kolesov et al. (4) have reported analogous data for the reaction with sodium which, after correction with JANAF auxiliary data, yields $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -114.4 \pm 3.5$ kcal/mol.

We adopt the values calculated above from Mears and Stahl (1), since they have a high degree of internal consistency and also lead to a realistic progression in the heats of atomization in going from CF_4 to CCl_4. With the adopted heats of formation, the successive replacement of F by Cl changes the atomization heats by 43.8, 41.6, 38.5 and 36.0 kcal.

Heat Capacity and Entropy

Claassen (5) chose the frequencies given above from his own gas-phase Raman measurements and the infrared values of earlier investigators. The values are in good agreement with the assignment of Plyler and Benedict (6). Masi (9) has measured the gas phase heat capacities at 243, 273, 318 and 363°K, within this range our adopted heat capacities are from .3 to .7% high. The entropies agree to within 0.05% and further adjustment to obtain better fits was not considered necessary. The molecular structure was determined from the microwave measurements of Long et al. (7). The individual moments of inertia were: $I_A = 31.929 \times 10^{-39}\ g\ cm^2$, $I_B = 21.216 \times 10^{-39}\ g\ cm^2$, and $I_C = 38.148 \times 10^{-39}\ g\ cm^2$.

	Cl-Cl	2.884 ± 0.001
	C-Cl	1.746 ± 0.004
	Cl-C-Cl angle	111.3 ± 0.1°

Moments of inertia: $I_A = 1.0690 \times 10^{-38}$ g. cm.² $I_B = 2.4489 \times 10^{-38}$ $I_C = 3.5291 \times 10^{-38}$ $\sigma = 2$

Heat of Formation

J. Thomsen, Thermochemische Untersuchungen, Barth, Leipzig, 1882, Vol. 2, p. 361, reports the heat of alkaline hydrolysis of $COCl_2$, from which $\Delta H^\circ_{f\ 298.15}$ is calculated to be -54.4 ± 0.3 kcal. mole⁻¹. From the heat of combustion of $COCl_2$ in O_2 and H_2, reported by Thomsen, op. cit., p. 363, $\Delta H^\circ_{f\ 298.15}$ is calculated to be -51.73 ± 0.43 kcal. mole⁻¹. M. Bodenstein and H. Plaut, Z. Phys. Chem. 110, 399 (1924), J. A. Christiansen, ibid. 103, 99 (1923), and M. Bodenstein and G. Dunant, ibid. 61, 437 (1908), report 10 values of K_p from 647° to 876°K for the reaction $CO + Cl_2 \rightleftarrows COCl_2$. These yield -25.91 ± 0.04 kcal. for $\Delta H^\circ_{r\ 298.15}$, whence $\Delta H^\circ_{f\ 298.15}$ for $COCl_2$ is -52.33 ± 0.62 kcal. mole⁻¹. The average of the 3 foregoing values of $\Delta H^\circ_{f\ 298.15}$, weighted for the uncertainties, is adopted here. Values calculated from the degree of dissociation of $COCl_2$ from 374° to 778°K, reported by R. H. Atkinson, C. T. Heycock, and W. J. Pope, J. Chem. Soc. 117, 1410 (1920), range from -47.06 to -53.11 kcal. mole⁻¹ and are ignored.

Heat Capacity and Entropy

The vibrational frequencies were assigned by E. Catalano and K. S. Pitzer, J. Am. Chem. Soc. 80, 1054 (1958), on the basis of their own infra-red spectra and other data. The molecular dimensions listed above were deduced from microwave spectra by G. W. Robinson, J. Chem. Phys. 21, 1741 (1953), and are confirmed by electron-diffraction values compiled by P. W. Allen and L. E. Sutton, Acta Cryst. 3, 46 (1950). The moments of inertia are weighted for the isotopes and were calculated from Robinson's dimensions by W. F. Giauque and J. B. Ott, J. Am. Chem. Soc., 82, 2689 (1960). Giauque and Ott, loc. cit., determined $S^\circ_{298.15}$ experimentally to be 67.81 cal. deg.⁻¹ mole⁻¹, with which the value calculated here agrees.

TRICHLOROMETHYL (CCl_3) (IDEAL GAS) GFW = 118.37015

Point Group D_{3h}

ΔHf°_0 = 19.15 ± 2 kcal/mol

$S^\circ_{298.15}$ = 70.92 ± 1.5 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = 19 ± 2 kcal/mol

Ground State Quantum Weight = 2

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
[450] (1)
[460] (1)
898 (2)
[240] (2)

Bond Distance: C-Cl = [1.74] Å

Bond Angle: Cl-C-Cl = [120°]

σ = 6

Product of the Moments of Inertia: $I_AI_BI_C$ = [3.8215 x 10^{-113}] g^3 cm^6.

Heat of Formation

Benson (1) has reanalysed the kinetic data of Sullivan and Davidson (2) for the reaction $Br_2(g) + CHCl_3(g) = HBr(g) + CBrCl_3(g)$ and has obtained from it the heat of the initial step, $Br(g) + CHCl_3(g) \rightarrow CCl_3(g) + HBr(g)$, as 8.2 ± 1 kcal/mol. Substituting this value and $\Delta Hf^\circ_{298}(Br)$ = 26.74 kcal/mol, $\Delta Hf^\circ_{298}(CHCl_3)$ = -24.66 kcal/mol and $\Delta Hf^\circ_{298}(HBr)$ = -8.71 kcal/mol, we obtain $\Delta Hf^\circ_{298}(CCl_3, g)$ = 19 ± 2 kcal/mol, which is adopted here.

Heat Capacity and Entropy

Walsh (3) has predicted that CCl_3 is non-planar on the basis of his orbital correlation diagram. Andrews (4) indicates that his matrix infrared observations of the symmetric and antisymmetric stretches are consistent with a non-planar C_{3v} structure and a near tetrahedral angle. The antisymmetric stretch has been confirmed by Current and Burdett (5). They rationalize the absence of the symmetric stretch and claim support of the C_{3v} structure. Rogers et al. (6) have made a thorough search for the symmetric stretch and did not find it in the region where it was reported by Andrews (4). Thus, they conclude that since only the antisymmetric stretch has been confirmed, the possibility of a planar D_{3h} molecule cannot be excluded. Magat et al. (7) have observed the NMR spectrum of trapped CCl_3 and find it consistent with a planar molecule. The absence of the symmetric stretch strongly implies a planar configuration, and we adopt such a configuration until more definitive proof of the non-planarity can be obtained. The remaining vibrational frequencies are estimated by comparison with those of BCl_3. The bond length was estimated as 1.74 Å by Andrews (4) from a correlation with related molecules. The individual moments of inertia are $I_A = I_B = 2.6734 \times 10^{-38}$ g cm^2 and I_C = 5.3468 x 10^{-38} g cm^2.

349.5 (1)	241 (2)
535.3 (1)	398 (2)
1085 (1)	847 (2)

Bond Distance: C-Cl = 1.76 Å C-F = 1.33 Å

Bond Angle: Cl-C-Cl = 109°40' F-C-Cl = 109°28' σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = 5.73499 \times 10^{-113}\ g^3cm^{-6}$

Heat of Formation

Mears and Stahl (1) investigated several heats of reaction involving CF_4, CF_3Cl, CF_2Cl_2, $CFCl_3$, CCl_4, HF and HCl. Using JANAF values for all compounds except CF_2Cl_2 and $CFCl_3$, we obtain the following observations:

1. $\Delta Hf_{298}(CCl_3F, g) = -70.12 \pm 1.1$ kcal/mol
2. $\Delta Hf_{298}(CCl_2F_2, g) = -116.53 \pm 1.5$ kcal/mol
3. $\Delta Hf_{298}(CCl_2F_2, g) - \Delta Hf_{298}(CCl_3F, g) = -49.39 \pm 1.0$ kcal/mol
4. $\Delta Hf_{298}(CCl_2F_2, g) - 2\Delta Hf_{298}(CCl_3F, g) = 20.34 \pm 1.0$ kcal/mol
5. $\Delta Hf_{298}(CCl_3F, g) - 2\Delta Hf_{298}(CCl_2F_2, g) = 165.47 \pm 1.0$ kcal/mol

The sum of the squares of the deviations is smallest when $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -117.5$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_3F, g) = -69$ kcal/mol, and all the values are within their uncertainty ranges.

Petersen and Pitzer (9) obtained an approximate equilibrium constant for the reaction $CClF_3(g) + 2CCl_4(g) = 3CCl_3F(g)$ of $\log K_{400} = -4.5$. This on 3rd law reduction gives $\Delta Hr^\circ_{298} = 10.56$ kcal and with $\Delta Hf^\circ_{298}(CClF_3, g) = -169.2$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_4, g) = -22.94$ kcal/mol this yields $\Delta Hf^\circ_{298}(CCl_3F, g) = -68.2$ kcal/mol.

Kirkbride and Davidson (2) investigated the reaction of potassium with the chlorofluoromethanes and obtained $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -115.1 \pm 2$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_3F, g) = -72.9 \pm 4$ kcal/mol after correction with JANAF auxiliary data. Wartenberg and Schiefer (3) investigated the same reaction and we obtain, after correction with JANAF auxiliary data, $\Delta Hf^\circ_{298}(CCl_2F_2, g) = -112.7$ kcal/mol and $\Delta Hf^\circ_{298}(CCl_3F, g) = -63.1$ kcal/mol. Baibuz (4) has reported $\Delta Hf^\circ_{298}(CCl_3F, g) = -66.4 \pm 2.1$ from heat of explosion measurements. A correlation of his other results would indicate that this value is not negative enough, possibly by as much as 3 kcal.

We adopt the values calculated above from Mears and Stahl (1), since they have a high degree of internal consistency and also lead to a realistic progression in the heats of atomization in going from CF_4 to CCl_4. With the adopted heats of formation, the successive replacement of F by Cl changes the atomization heats by 43.8, 41.6, 38.5 and 36.0 kcal.

Heat Capacity and Entropy

Claassen (5) chose the frequencies given above from his own gas phase Raman measurements and the infrared values of earlier investigators. The values are in good agreement with the assignment of Plyler and Benedict (6), and the matrix studies of King (7). The molecular structure was determined from the microwave measurements of Long et al. (8). The individual moments of inertia were: $I_A = I_C = 34.301 \times 10^{-39}\ g\ cm^2$ and $I_B = 48.744 \times 10^{-39}\ g\ cm^2$.

CARBON TETRACHLORIDE (CCl_4) (IDEAL GAS) GFW = 153.82315

Point Group T_d $\Delta Hf_0^\circ = -22.42 \pm 0.5$ kcal/mol

$S_{298.15}^\circ = 74.02 \pm 0.01$ gibbs/mol $\Delta Hf_{298.15}^\circ = -22.94 \pm 0.5$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}
458 (1)
218 (2)
776 (3)
314 (3)

Bond Distance: C-Cl = 1.760 Å

Bond Angle: Cl-C-Cl = 109.47° $\sigma = 12$

Product of the Moments of Inertia: $I_AI_BI_C = 1.14972 \times 10^{-112}\ g^3cm^6$

Heat of Formation

Hu and Sinke (1) have measured the heat of combustion of $CCl_4(\ell)$ in the rotating platinum bomb calorimeter, using As_2O_3 solution as the reducing agent. They reported $\Delta Hc_{298}^\circ = -86.02$ kcal/mol for $CCl_4(\ell) + 2H_2O(\ell) \rightarrow CO_2(g) + 4HCl(600H_2O, aq)$ which leads to $\Delta Hf_{298}^\circ (CCl_4, \ell) = -30.69$ kcal/mol, using $\Delta Hf_{298}^\circ = -94.051$, -39.823 and -68.315 kcal/mol for $CO_2(g)$, $HCl(600H_2O, aq)$ and $H_2O(\ell)$, respectively (2). The standard deviation of five combustion runs was ±0.074 kcal/mol. Employing the heat of vaporization of $CCl_4(\ell)$ at 298°K as 7.75 kcal/mol (3), we obtain $\Delta Hf_{298}^\circ (CCl_4, g) = -22.94$ kcal/mol which is adopted in the tabulation.

L. Smith et al. (5), based on the combustion data of E. Eftring (4), re-evaluated the heat of combustion of carbon tetrachloride at 18.7°C as $\Delta E_c^\circ/M = -567.5$ cal/g for $CCl_4(\ell) + 2H_2O(\ell) \rightarrow CO_2(g) + 4HCl(600H_2O)$. This value needs to be further corrected for a change in the heat of oxidation of As_2O_3 (6) and calculated to 25°C to give $\Delta E_{c298}^\circ = -88.105$ kcal/mol, $\Delta Hc_{298}^\circ = -87.513$ kcal/mol, $\Delta Hf_{298}^\circ(CCl_4, \ell) = -29.20$ kcal/mol and $\Delta Hf_{298}^\circ(CCl_4, g) = -21.45$ kcal/mol.

C. A. Neugebauer (7) has measured the heat of reaction of CCl_4 with Mg in presence of hydrogen in the stationary bomb calorimeter and then derived the heat of formation, $\Delta Hf_{298}^\circ (CCl_4, \ell) = -32.3 \pm 2$ kcal/mol which yields $\Delta Hf_{298}^\circ (CCl_4, g) = -24.55 \pm 2$ kcal/mol. V. F. Baibuz (8), using an explosion technique, obtained $\Delta Hf_{298}^\circ (CCl_4, g) = -24.6 \pm 1.9$ kcal/mol. Bodenstein and Gunther (9) have measured calorimetrically $\Delta H_{r293}^\circ = -62.57 \pm 0.35$ kcal/mole for $CCl_4(g) + 2H_2(g) \rightarrow C(c) + 4HCl(g)$. They calibrated their calorimeter by means of the reaction $H_2(g) + Cl_2(g) \rightarrow 2HCl(g)$ for which they took $\Delta H_{293}^\circ = -44$ kcal/mol. Their data have been re-evaluated to give $\Delta Hf_{298}^\circ (CCl_4, g) = -25.68$ kcal/mol, but no correction is applied for the heat of formation of carbon which was not the reference state "graphite" formed in the reaction. Domalski and Armstrong (10) reviewed several cases of active carbon formed in similar reactions and quoted a heat of formation of carbon from +1.9 to +3.95 kcal/mol. If this correction is applied to the data of Bodenstein, their heat of formation of $CCl_4(g)$ should be 2 to 4 kcal/mol less negative than -25.68 kcal/mol.

Heat Capacity and Entropy

Bartell, Brockway and Schwendeman (11) have measured the bond distance as 1.760 ± 0.004 Å by the electron diffraction measurement. The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (12) in which they are essentially the same as those frequencies determined from Raman and infrared spectra by Classen (13). The three principal moments of inertia are $I_A = I_B = I_C = 48.627 \times 10^{-39}\ g\ cm^2$.

Heat of Formation

M. Farber et al. (1) have studied the weight change of graphite in CF_4 at high temperatures. Our reanalysis of their data uses the equilibrium constants for CF_4, CF_3 and CF_2 from the JANAF Tables (2); the only other C-F species considered is assumed to be CF. This treatment yields negative values for the CF pressure except at the highest temperature, where 3rd law analysis of the equilibrium constant yields ΔHf°_{298}(CF, g) = 59.4 kcal/mol. Farber et al. also investigated mass-spectrometrically the vapor species present at equilibrium and followed the intensities of CF^+ and F^+. From a second law treatment of the intensities they report ΔHf°_{2300}(CF, g) = 62.0 kcal/mol, or ΔHf°_{298}(CF, g) = 64 kcal/mol.

Porter et al. (3) have investigated the A-X band system under high dispersion. From an analytical extrapolation of the 10 observed levels they reported a dissociation energy of 126.9 ± 2.9 kcal/mol, which yields ΔHf°_{298}(CF, g) = 61.9 ± 2.9 kcal/mol.

The predissociation limit of CF(g) has been reported by Thrush and Zwolenik (4) as $\leq$132 kcal/mol; Kuzyakov and Tatievsky (5) determined the same quantity as $\leq$133 kcal/mol. These results yield ΔHf°_{298}(CF, g) $\geq$ 56 kcal/mol. Thrush and Zwolenik (4) also report a predissociation limit for the reaction $CF_2 \rightarrow CF + F$ which is $\leq$120 kcal/mol. This value has now been shown to be erroneous (see the CF_2(g) table for details).

Modica (6) has studied the equilibrium $CF_2 \rightarrow CF + F$ in a shock tube in the range 2680° to 3400°K. Since functions for CF_2, CF and F are well established, the data were analyzed using 2nd and 3rd law treatments. The 2nd law analysis gives ΔHr°_{298} = 107.2 ± 7.6 kcal/mol, in agreement with the value reported by Modica. The 3rd law analysis yields ΔHr°_{298} = 134.9 ± 7.2 kcal/mol and a drift of 9.7 ± 2.5 eu. The excessive drift indicates that the reported equilibrium constants do not represent the stated reaction.

Andrews and Barrow (7) report a dissociation energy of 114 kcal from an extrapolation of four B state levels. This extrapolation is considered unreliable by Porter et al. (3) since this state is formed from an avoided crossing and is likely to be perturbed.

The adopted value of ΔHf°_{298}(CF, g) is 61 ± 2 kcal/mol, which is within the uncertainties and ranges of the acceptable investigations.

Heat Capacity and Entropy

The vibrational and rotational constants are from Porter et al. (3); the higher electronic levels are those reported by Andrews and Barrow (7), except that the B state is now considered to be $^2\Sigma$. The estimated level at 25000 cm^{-1} is proposed in order to explain the low bond dissociation energy of C_2F_2, by analogy with the reasoning used by Simons (8) for C_2F_4. This level would be a $^4\Sigma$ level and could correlate with the ground state atoms.

σ = 1

Heat of Formation

Davis and Okabe (1) have determined the dissociation energy of FCN to F(g) and CN(g) by measuring the threshold energies of incident photon radiation to produce $B^2\Sigma^+$ CN which is monitored by its fluorescence. The dissociation energy determined by this technique is ≤ 111 kcal/mol with an uncertainty of about 1 kcal in the determination of the limit.

Dibeler and Liston (2) have reported a dissociation energy of ≤ 115.6 kcal/mol from the threshold of the CN^+ ion as determined by photoionization.

We adopt a median value of 113.1 ± 2.5 kcal/mol which leads to ΔHf°_{298}(FCN, g) = 8.6 ± 4 kcal/mol with auxiliary JANAF values for F(g) and CN(g).

Heat Capacity and Entropy

The molecular structure and bond lengths and angle were determined using microwave spectroscopy by Tyler and Sheridan (3). The vibrational frequencies were reported by Aynsley et. al. (4) from the infra-red spectrum, except for the bending frequency which is estimated from the values for ClCN, BrCN and ICN, by comparison of bending force constants. The reasonable limits for this value as calculated from generous limits on the bending force constant are 405-450 cm^{-1}.

Dec. 31, 1965

CARBONYL MONOFLUORIDE (COF) (IDEAL GAS) MOL. WT. = 47.00895

Point Group C_s

$S^\circ_{298.15}$ = [59] cal. deg.$^{-1}$ mole^{-1}

Ground State Quantum Weight = 2

$\Delta H^\circ_{f\ 0}$ = [-41 ± 15] kcal. mole^{-1}

$\Delta H^\circ_{f\ 298.15}$ = [-41 ± 15] kcal. mole^{-1}

Vibrational Frequencies and Degeneracies

ω, cm.$^{-1}$
1018 (1)
626 (1)
1855 (1)

Bond Distance: C-F = [1.34] Å C-O = [1.18] Å

Bond Angle: F-C-O = [135] °

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = [2.1986 x 10^{-116}] g.^{3} cm.^{6}

Heat of Formation.

The enthalpy change (ΔH°_r) for the reaction $COF_2(g) = CO(g) + 2F(g)$ was calculated as 160.5 kcal. mole^{-1}. By analogy with D(Cl-COCl)/D(Cl-CO), the value of D(F-COF)/D(F-CO) was taken to be 4. Based on ΔH°_r = 160.5 x (4/5) = 128.4 kcal. mole^{-1} for the reaction $COF_2(g) = COF(g) + F(g)$, the heat of formation for COF(g) was derived as -41 ± 15 kcal. mole^{-1}.

Heat Capacity and Entropy.

The vibrational frequencies were reported by D. E. Milligan, M. E. Jacox, A. M. Bass, J. J. Comeford and D. E. Mann, J. Chem. Phys. 42, 3187 (1965). The bond distances and angle were estimated by comparison with those for HFCO (g). Due to the presence of one unpaired electron on C atom, the ground state quantum weight is calculated to be 2. The three principal moments of inertia are: I_A = 7.8757 x 10^{-39}, I_B = 3.3980 x 10^{-40}, and I_C = 8.2155 x 10^{-39} g. cm.^{2}

Carbon Difluoride (CF_2)

(Ideal Gas) GFW = 50.00795

Heat of Formation

Thrush and Zwolenik (1) reported a predissociation limit for $CF_2 \rightarrow CF + F$; however, Marsigny et al. (2) have since observed in emission the assumed predissociated level, and others above it, which invalidates the reported limit.

Walter et al. (3) have obtained the photoionization threshold at 0°K for onset of the reaction $C_2F_4 + e^- \rightarrow CF_2^+ + CF_2 + 2e^-$, as 14.63 ± 0.04 eV (337.37 kcal). The ionization potential of CF_2 has been reported as 11.7 eV (4), 11.8 ± 0.3 eV (5) and 11.86 ± 0.1 eV (6). Since these values were obtained by electron impact methods, there may be excess energy involved. Thus, adopting the lowest value as 11.7 ± 0.2 eV, we obtain $\Delta Hf°_{298}(CF_2, g)$ = -44.4 ± 2.5 kcal/mol (7). All previous electron impact methods are considered superseded by this photoionization result.

Modica and LaGraff (8) determined equilibrium constants for the reaction (A) $C_2F_4 \rightarrow 2CF_2$ by use of a shock tube to achieve high temperatures and ultra violet absorption to detect the CF_2 concentration. Carlson (9) has studied the same reaction using a similar technique, and also Zmbov et al. (5) have investigated this equilibrium in a mass spectrometer. A 2nd and 3rd law analysis of all three sets of data is given below, along with our recalculated equilibrium data of Farber et al. (10) for the reaction (B) $C + 2F \rightarrow CF_2$ from weight loss experiments in the system $C + CF_4$.

Kinetic methods were used by Edwards and Small (11) to study the equilibrium (C) $CHF_2Cl(g) \rightleftarrows CF_2(g) + HCl(g)$. They analysed their data by assuming that the only other equilibrium occurring was $2CF_2(g) \rightleftarrows C_2F_4(g)$, and fit their kinetic data by trial and error. In this manner they obtained activation energies of the forward and back reaction (C) of 55.79 ± 0.49 and 6.21 ± 3.0 kcal, thus ΔE_a = 49.6 ± 3.0 and ΔH_{900} = 51.4 ± 3 kcal, which yields $\Delta Hf_{298}(CF_2)$ = -42 ± 4 kcal/mol (7). They also obtained the activation energy of reaction (A) as 70.36 ± 1.3 kcal. Dalby (12) has reported the activation energy of the reverse of (A) as 1.2 ± 0.2 kcal, thus, ΔE_a = 69.2 ± 1.3 and ΔH_{900} = 71.0 ± 1.3 kcal, which yields $\Delta Hf_{298}(CF_2)$ = -42.6 ± 1.0 kcal/mol (7). Gozzo and Patrick (13) also investigated the kinetics of reaction C and obtained activation energies of 51.4 ± 2.5 and 14.4 ± 5 kcal, the latter value being corrected for the activation energy of CF_2 recombination (12). Thus, we obtain ΔE_a = 37 ± 7 and ΔH_{1000} = 39 ± 7 kcal, which yields $\Delta Hf_{298}(CF_2)$ = -54 ± 9 kcal/mol (7).

Modica and LaGraff (14) investigated the kinetics of CHF_3 decomposition by a mass spectrometer coupled to a shock tube. They investigated the pressure dependence of the rate and concluded that at the high pressure limit E_o = 58.4 ± 2.2 kcal. Taking this value as $\Delta H°_0$ for the reaction (D) $CHF_3(g) \rightarrow CF_2(g) + HF(g)$, we obtain $\Delta Hf_{298}(CF_2)$ = -41.3 ± 2.5 kcal/mol (7). However, any activation energy of the reverse reaction (D) will make this value more negative. Since values of the reverse activation energy of analogous reaction (C) range from 6.2 to 14.4 kcal, it appears likely that reverse reaction (D) will have a significant activation energy; thus, $\Delta Hf_{298}(CF_2)$ < -41.3 ± 2.5 kcal. Tschiukow-Roux (15) has investigated the same reaction in a shock tube, but was unable to obtain sufficient variation of rate with pressure to calculate the high pressure limit.

Reference and Reaction	Points	Range °K	ΔHr_{298}, kcal/mol 2nd law	3rd law	Drift eu	**$\Delta Hf_{298}(CF_2, g)$ kcal/mol

*Points omitted due to failure of a statistical test **Calculated from the 3rd law heat of reaction.

A median value of $\Delta Hf_{298}(CF_2, g)$ covering the area of maximum probability is adopted as -43.5 ± 1.5 kcal/mol.

Heat Capacity and Entropy

The structure of CF_2 has been reported by Powell and Lide (16) from microwave measurements and has been confirmed by Mathews (17) from the fine structure of the 2500Å absorption band. Mathews also reported ω_2, and Herr and Pimentel (18) reported ω_3, both from gas phase studies. Milligan et al. (19) have observed all three vibrations in matrix-isolated CF_2 as 1222, 668 and 1102 cm^{-1}. The electronic levels are from Mathews (17) with the triplet level estimated by Simons (20) to explain the low C=C bond energy of 70 kcal in C_2F_4. The individual moments of inertia are $I_A = 0.9512 \times 10^{-39}\ g\ cm^2$, $I_B = 6.7020 \times 10^{-39}\ g\ cm^2$, and $I_C = 7.6532 \times 10^{-39}\ g\ cm^2$.

CARBONYL FLUORIDE (COF_2) (IDEAL GAS) GFW = 66.0074

Point Group C_{2v}

$S^\circ_{298.15}$ = 61.85 ± 0.02 gibbs/mol

Ground State Quantum Weight = 1

ΔHf°_0 = -152.0 ± 0.4 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -152.7 ± 0.4 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
965 (1)	1249 (1)
1928 (1)	584 (1)
626 (1)	774 (1)

Bond Distances: C-F = 1.312 Å C-O = 1.174 Å

Bond Angles: F-C-F = 108° F-C-O = 126° 1'

σ = 2

Product of the Moments of Inertia: $I_AI_BI_C = 7.243 \times 10^{-115}\ g^3\ cm^6$

Heat of Formation

Ruff and Li (1) measured equilibrium constants for the reaction

$$2COF_2(g) \rightleftarrows CO_2(g) + CF_4(g)$$

in the temperature range 573-1273°K. These equilibrium data were recently analyzed by Stull, Westrum, and Sinke (2). Their third law analysis of the data clearly indicates that the three low temperature points are in error and should not be used in calculating ΔHr_{298}. They reported, ΔHr_{298} = -12 ± 3 kcal/mol, based upon an average of the five high temperature points. Combining this result with the heat of formation of carbon dioxide and carbon tetrafluoride (3), we derive,

$$\Delta Hf^\circ_{298}(CF_2O, g) = -152.5 \pm 3.3 \text{ kcal/mol.}$$

Wartenberg and Riteris (4) measured the heat of hydrolysis of CF_2O. They reported, ΔHr = -26.7 ± 0.2 kcal/mol, for the reaction

$$COF_2(g) + H_2O(\ell) \rightarrow CO_2(g) + 2HF\cdot 300\ H_2O.$$

Combining this result with heat of formation data for carbon dioxide and HF($\Delta Hf^\circ_{298}(HF\cdot 300\ H_2O)$ = -76.84 kcal/mol (5)), we derive,

$$\Delta Hf^\circ_{298}(CF_2O, g) = -152.7 \pm 0.4 \text{ kcal/mol.}$$

Armstrong, Coyle, and Krieger (6) measured the heats of combustion of CH_4 in O_2-F_2 mixtures and found $\Delta Hf^\circ_{298}(CF_2O, g)$ = -154.8 kcal/mol. The value calculated from Wartenberg's data is adopted here.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Hopper et al. (7) and are in good agreement with the results of Lovell et al. (8) and Nielsen et al. (9). The molecular constants are from the microwave studies of Laurie et al. (10) and are in reasonable agreement with the electron-diffraction work of Brown and Livingston (11). Individual moments of inertia calculated from the rotational constants of Laurie et al. (10) are $I_A = 7.105 \times 10^{-39}$ g cm^2, $I_B = 7.144 \times 10^{-39}$ g cm^2, and $I_C = 14.27 \times 10^{-39}$ g cm^2.

Point Group C_{3v}

$S°_{298.15}$ = 63.329 ± 1.0 gibbs/mol

Ground State Quantum Weight = 2

$\Delta Hf°_0$ = -111.7 ± 1.0 kcal/mol

$\Delta Hf°_{298.15}$ = -112.4 ± 1.0 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
1090 (1)	1259 (2)
701 (1)	[500] (2)

Bond Distance: C-F = [1.33] Å

Bond Angle: F-C-F = [112°]

σ = 3

Product of the Moments of Inertia: $I_AI_BI_C$ = [9.608×10^{-115}] g^3 cm^6

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Kinetic data provide the most consistent paths to ΔHf° of $CF_3(g)$. Forward and reverse activation energies for the reactions $CHF_3(g) + X(g) \rightarrow CF_3(g) + HX(g)$ have been reported for X = Cl by Coomber (2), for X = Br by Amphlett (3), and for X = I by Goy (4). Increases of about 0.3 kcal/mol in the reverse activation energies for X = Cl and Br were proposed by Arthur (5) on the basis of additional data. Combining these values and reducing to 298.15°K, we get ΔHr° = 2.93 ± 0.7 (X = Cl), 18.89 ± 0.7 (X = Br), and 35.5 ± 3 kcal/mol (X = I). Coomber (2) reviewed data for the analogous reactions with X = CH_3 and CD_3; these yield ΔHr° = 0.6 ± 2 kcal/mol at 298.15°K for X = CH_3. Activation energies have also been reported (6) for $CF_3I(g) + I(g) \rightarrow CF_3(g) + I_2(g)$ from which we derive the average value ΔHr° = 17.1 ± 2 kcal/mol. The data of Tschuikow-Roux (7) for $C_2F_6(g) \rightarrow 2CF_3(g)$, recalculated as suggested by Coomber (8) but with JANAF functions, yield ΔHr° = 97.6 ± 6 kcal/mol. Differences between the calculated and observed values of ΔHr° are all less than half of the uncertainties assigned to the observed values.

The thorough discussion of photoionization data by Noutary (9) emphasized that CF_3^+ is formed with large amounts of excess energy both during ionization of CF_3 and during fragmentation of other fluorides. The amount of excess energy varies with the parent molecule. This may also be involved in electron-impact studies and could account for some of the discrepancies in bond-dissociation energies derived from appearance potentials and ionization potentials. Such data have been summarized by Coomber (10). Ionization data were omitted from the simultaneous adjustment due to uncertainty in the amounts of excess energy.

Also omitted was the mass-spectrometric study of $3C_2F_4(g) \rightarrow 4CF_3(g) + 2C(graphite)$ by Ehlert (11) which gave ΔHf° = -102 ± 3 kcal/mol. The discrepancy of 10 kcal/mol suggests that the data may not represent equilibrium for the above reaction. This reaction was one of many which resulted from heating MnF_3 in an effusion cell made of graphite.

Heat Capacity and Entropy

The bond length is assumed to be 1.33 Å by comparison with the molecules CF_3X, and the bond angle is estimated from molecular-orbital calculations of Morokuma (12) and Pople and coworkers (13). The nonplanar structure is consistent with electron-spin-resonance spectra (14) of CF_3 in krypton and xenon matrices, with infrared spectra of CF_3 in various matrices (15) and in the gaseous phase (16), and with photoionization spectra (17). The observed vibrational fundamentals of Carlson (16) are confirmed by the matrix spectra of Milligan (15). The latter estimated ν_4 to be in the range of 500 to 600 cm^{-1}. We choose the lower value by comparison with CF_3H, SiF_3H and SiF_3 (18).

The uncertainty in ν_4 corresponds to an uncertainty in the entropy of 0.4 eu at 300°K and 0.7 eu at 1000°K. Coomber (2) and Amphlett (19) used kinetic data to derive entropies of 63.2 eu at 350°K and 71.5 eu at 600°K. The calculated entropies from this table are higher by 2.0 and 1.7 eu, respectively. These differences are only slightly larger than our estimate of the uncertainty in the kinetic results. We estimate the overall uncertainty in the calculated entropies as 1.0 eu at 298°K and 1.6 eu at 1000°K.

Point Group C_{3v}

ΔHf°_0 = -139.4 ± 0.8 kcal/mol

$S^\circ_{298.15}$ = 73.498 ± 0.15 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -140.8 ± 0.8 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
1074 (1)	1185 (2)
742 (1)	539 (2)
284 (1)	260 (2)

Bond Distance: C-F = 1.332 Å C-I = 2.130 Å

Bond Angle: F-C-F = 108.3 ± 1° F-C-I = 110.62° σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = 4.4095 \times 10^{-113}$ g^3 cm^6

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Lord, Goy and Pritchard (2, 3) report equilibrium data for the reactions $CF_3X(g) + I_2(g) = CF_3I(g) + XI(g)$ where X = H, Cl, and Br. In addition to these prime links, there is a weak link to CF_3 through kinetic studies of $CF_3I(g) + I(g) \rightarrow CF_3(g) + I_2(g)$. Data for this reaction (3, 12) yield the average value ΔHr° = 17.1 ± 2 kcal/mol at 298.15°K.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction studies by Bowen (4), Anderson (5), and Wong and Schomaker (6). Differences among the data are small. The results of Anderson are adopted since they are intermediate between the others. Microwave data (7) are consistent with the adopted parameters. Infrared spectra of the gas were observed by several investigators (8, 9, 10) and Raman spectra of the liquid were obtained by Edgell and May (10). The vibrational assignments of (9, 10) are in close agreement. These assignments are adopted but preference is given to frequencies observed for the gas. In particular, ν_6 is taken as 260 cm^{-1} (from overtone and combination bands of the gas) rather than 265 cm^{-1} (from the Raman spectra of the liquid). The approximate values of ν_2, ν_3 and ν_6 have been confirmed by analysis (11) of absorption spectra in the UV.

The thermodynamic functions of this table are essentially the same as those calculated by (9). Uncertainty in the entropy is estimated to vary from 0.15 to 0.6 gibbs/mol over the range from 300 to 1000°K. Uncertainty in ν_6 and neglect of anharmonicity are the major sources of error. Discussions of the magnitude of anharmonic effects appear on the tables for $CClF_3(g)$ and $CF_4(g)$. The principal moments of inertia are $I_A = 14.71 \times 10^{-39}$ and $I_B = I_C = 54.75 \times 10^{-39}$ g cm^2.

CARBON TETRAFLUORIDE (CF_4) (IDEAL GAS) GFW = 88.00475

Point Group T_d

$S^\circ_{298.15}$ = 62.454 ± 0.06 gibbs/mol

Ground State Quantum Weight = 1

ΔHf°_0 = -221.61 ± 0.3 kcal/mol

$\Delta Hf^\circ_{298.15}$ = -223.04 ± 0.3 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
908.5 (1)	1283.0 (3)
435.0 (2)	631.5 (3)

Bond Distance: C-F = 1.320 Å

Bond Angle: F-C-F = 109.47° σ = 12

Product of the Moments of Inertia: $I_AI_BI_C = 3.1489 \times 10^{-114}\ g^3\ cm^6$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of HF(g), HF(50 H_2O) and five closely related fluorides. Adjustment of 23 selected observations relating the 7 variables gives the following heats of formation in kcal/mol at 298.15°K: HF(g), -65.14 ± 0.2; HF(50 H_2O), -76.78 ± 0.1; NaF(c), -137.52 ± 0.2; BF_3(g), -271.42 ± 0.4; CF_4(g), -223.04 ± 0.3; NF_3(g), -31.43 ± 0.3; and C_2F_4(polymer), -198.2 ± 0.7. The ± values are estimates of the overall uncertainty including systematic error. Further details of the simultaneous adjustment are given in (1).

The selected value is essentially the same as that obtained by Greenberg and Hubbard (2) in their thorough calorimetric study of the combustion in fluorine of natural and synthetic graphite. Their result is confirmed by the data of Domalski and Armstrong (3) for combustion of graphite-Teflon mixtures. Reliable data (1) also link CF_4(g) with HF(n H_2O), NF_3(g) and C_2F_4(polymer). Armstrong (4, 3) critically reviewed the more uncertain data which were omitted from the adjustment.

Heat Capacity and Entropy

The fundamental vibrations are those observed in the gas-phase Raman spectra by Monostori and Weber (5) and the gas-phase infrared spectra by Maki et al. (6) and Chalmers and McKean (7). The frequencies are essentially the same as those selected by Shimanouchi (8) who also lists earlier spectral studies. Electron-diffraction studies of the gas were reported by Thornton (9) and Hoffman and Livingston (10). The adopted bond length is the average of these two results which differ by only 0.006 Å. The principal moments of inertia are $I_A = I_B = I_C = 14.657 \times 10^{-39}\ g\ cm^2$.

The most significant uncertainty in the calculated thermodynamic functions is due to neglect of anharmonic contributions. Estimates for these contributions were given by Barho (11) and Albright et al. (12), and functions calculated with anharmonic terms were given by McBride et al. (13). Differences between McBride and this JANAF table vary from 0.1 to 0.75 gibbs/mol in Cp° and 0.05 to 0.49 gibbs/mol in S° over the range from 300 to 1000°K. Measurements (14) of C_v(303-473°K) suggest that anharmonic contributions are significant, but the data are not sufficiently accurate to test the calculations of McBride (13). Heat capacity data (15) for the condensed phases were reviewed by Kelley and King (16) who derived $S^\circ_{298.15}$ = 62.8 ± 0.5 gibbs/mol for CF_4(g).

TRIFLUOROMETHYL HYPOFLUORITE (CF_4O) (IDEAL GAS) GFW = 104.004

Point Group C_s

$\Delta Hf^\circ_0 = -181.9 \pm 3$ kcal/mol

$S^\circ_{298.15} = 77.06 \pm 0.7$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -182.8 \pm 3$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
1294.4 (1)	679.0 (1)	1223.2 (1)
1262.5 (1)	584.1 (1)	607.5 (1)
947.3 (1)	433.7 (1)	250.0 (1)
882.1 (1)	227.5 (1)	internal rotation

Bond Distances: C-F = [1.33] Å F-O = [1.42] Å C-O = [1.43] Å

Bond Angles: C-O-F = [103.2°] F-C-F = [109.5°]

σ = 1

Product of Moments of Inertia: $I_AI_BI_C = 1.138 \times 10^{-113}\ g^3\ cm^6$

Heat of Formation

Porter and Cady (1) measured equilibrium constants for the reaction

$$CF_3OF(g) \rightleftarrows COF_2(g) + F_2(g)$$

in the temperature range 630-750°K. Equilibrium constants were also determined with excess fluorine added to the system. Second and third law analyses of these data yield the following heats of reaction:

	ΔH°_{298} 2nd law	ΔH°_{298} 3rd law	Drift
	kcal/mol		gibbs/mol
Set 1	27.65 ± 0.2	30.10	3.6 ± 0.3
Set added fluorine	25.11 ± 0.3	30.09	7.2 ± 0.5

The third law analyses indicate significant trends within each set of equilibrium data. If the entire error is assigned to the free energy functions, then the drifts in the third law analysis imply that the free energy functions for CF_3OF should be increased by 3.6 or 7.2 gibbs/mol. However, the real error in these free energy functions is probably no larger than 1 gibbs/mol in the temperature range of the experimental data. Apparently, the equilibrium reaction investigated by Porter and Cady (1) was affected by side reactions possibly involving perfluorodimethyl peroxide. However, since the only other approach to the heat of formation of CF_3OF involves bond energies, we adopt the third law value, $\Delta Hr^\circ = 30.1$ kcal/mol, and derive $\Delta Hf^\circ_{298}(CF_3OF, g) = -182.8 \pm 3$ kcal/mol with $\Delta Hf^\circ_{298}(COF_2, g) = -152.7 \pm 0.4$ kcal/mol (2).

Czarnowski et al. (3) recently determined the O-F bond energy in CF_3OF from kinetic studies on the thermal decomposition of CF_3OF in the presence of SO_3. They reported the value D(O-F) = 43.5 ± 0.5 kcal/mol. Combining this result with the following data,

$\Delta Hf^\circ_{298}(C, g) = 170.89 \pm 0.45$ kcal/mol (4)
$\Delta Hf^\circ_{298}(F, g) = 18.86 \pm 0.40$ kcal/mol (5)
$\Delta Hf^\circ_{298}(O, g) = 59.559 \pm 0.03$ kcal/mol (6)
Do(C-F) = 117.4 kcal/mol (from $\Delta Hf^\circ_{298}(CF_4, g) = -223.04 \pm 0.3$ kcal/mol (7))
Do(C-O) = 84 kcal/mol (8)

we derive $\Delta Hf^\circ_{298}(CF_3OF, g) = -173.8$ kcal/mol.

The value determined from Porter and Cady's equilibrium data is adopted here. $H^\circ_0-H^\circ_{298}$ is determined to be -4.086 kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared and Raman studies of Wilt and Jones (9) and are in reasonable agreement with nine of the twelve expected fundamentals observed by Lagemann et al. (10). Bond lengths and angles are estimated quantities chosen by Wilt and Jones (9). Individual moments of inertia calculated from these estimated molecular constants are $I_A = 14.723 \times 10^{-39}\ g\ cm^2$, $I_B = 27.796 \times 10^{-39}\ g\ cm^2$, and $I_C = 27.801 \times 10^{-39}\ g\ cm^2$. The contributions of hindered internal rotation to the thermodynamic properties of CF_3OF are from the tables of Pitzer and Gwinn (11). The reduced moment of inertia, I_r, and the potential barrier, V_o, are from the work of Wilt and Jones (9) and are:

$I_r = 2.939 \times 10^{-39}\ g\ cm^2$
$V_o = 1130$ cal/mol ($\nu_{12} = 56\ cm^{-1}$)

$\sigma = 1$

$B_e = 14.455$ cm^{-1}

$\alpha_e = 0.5339$ cm^{-1}

$r_e = 1.1198$ Å

Heat of Formation

G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950, reanalyzed the rotational predissociation reported by T. Shidei, Japan J. Phys. 11, 23 (1936), and concluded that $D°_0$ = 80.0 kcal/mol (3.47 eV). This yields $\Delta Hf°_{298.15}$(CH, g) = 142.0 kcal/mol and is the adopted value.

R. G. Brewer and F. L. Kester, J. Chem. Phys. 40, 812 (1964), have confirmed the value as 142 ± 5 kcal/mol, from an equilibrium study of the temperature variation of the intensity of the $^2\Delta \rightarrow {}^2\Pi$ emission band.

M. Linevsky, J. Chem. Phys. 47, 3485 (1967), determined the concentration of CH radicals in equilibrium with 1 atm. of hydrogen gas, by application of a high resolution spectro-photographic technique to three electronic transitions in absorbtion. A third law analysis, using the present functions, of 27 determinations in the temperature range 3065 - 3155°K yielded $\Delta Hf°_{298}$(CH, g) = 142.01 ± 1.28 kcal/mol with a negligible drift. This value is in excellent agreement with the spectroscopic predissociation value.

Heat Capacity and Entropy

The vibrational and rotational constants and electronic levels are from Herzberg, loc. cit., with the exception of the estimated $^4\Sigma$ level. All the constants have been adjusted to the normal isotopic abundances for both carbon and hydrogen. The $^4\Sigma$ level is estimated from the ab initio calculations of A. C. Hurley, Proc. Roy. Soc. (London), 249A, 402 (1959), which include electron correlation effects. Earlier LCAO calculations had predicted the $^4\Sigma$ level to be the ground state, but J. Higuchi, J. Chem. Phys. 22, 1339 (1954), used LCAO-SCF calculations and obtained the $^4\Sigma$ level at 800 cm^{-1}. M. Krauss and J. F. Wehner, J. Chem. Phys. 29, 1287 (1958), using essentially the same technique as Hurley, obtained $^4\Sigma$ at 3000 cm^{-1}.

Bond Distance: C-H = 1.12 Å C-Cl = 1.689 Å

Bond Angle: H-C-Cl = 103.4° σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 3.9877 \times 10^{-117}\ g^3\ cm^6$

Heat of Formation

The heat of formation can be estimated as the average of those of the CH_2 and CCl_2 radicals, which gives ΔHf°_{298}(CHCl, g) = 74.5 ± 15 kcal/mol. A better value for the heat of formation can be obtained by considering the reactions CHCl → CH + Cl and CHCl → CCl + H. When ΔHf°_{298}(CCl, g) = 74.5 kcal/mol is substituted into the above equations it gives D_{C-Cl} = 96 kcal and D_{C-H} = 98 kcal. Although these values are not unreasonable the D_{C-H} value appears to be too high compared to that in CFH. Thus, we adopt ΔHf°_{298}(CHCl, g) = 80 kcal/mol which gives D_{C-Cl} = 91 kcal and D_{C-H} = 92 kcal.

Heat Capacity and Entropy

The structure and electronic levels of the molecule have been established by Merer and Travis (1) from an analysis of the rotational structure of the visible absorption bands. The estimated triplet state is based on the electronic levels of CCl_2 and CH_2 as given in these tables. The vibrational levels are from Jacox and Milligan (2) who investigated the infrared spectrum of matrix-isolated CHCl, and also estimated the missing frequency.

The individual moments of inertia are $I_A = 4.6455 \times 10^{-39}$ g cm^2, $I_B = 1.780 \times 10^{-40}$ g cm^2, and $I_C = 4.8235 \times 10^{-39}$ g cm^2.

Dec. 31, 1960; Sept. 30, 1961; Sept. 30, 1964; June 30, 1970

CHLORODIFLUOROMETHANE ($CHClF_2$) (IDEAL GAS) GFW = 86.4689

Point Group C_s

ΔHf_0° = -113.6 ± 3 kcal/mol

$S_{298.15}^\circ$ = 67.126 ± 0.2 gibbs/mol

$\Delta Hf_{298.15}^\circ$ = -115.1 ± 3 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
3024 (1)	812 (1)	1350 (1)
1312 (1)	598 (1)	1108 (1)
836 (1)	417 (1)	400 (1)

Bond Distance: C-H = 1.09 Å C-Cl = 1.74 Å C-F = 1.35 Å

Bond Angle: H-C-Cl = 107° Cl-C-F = 110.5° F-C-F = 107°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 3.43433 \times 10^{-114}\ g^3\ cm^6$.

Heat of Formation

Edwards and Small (1) determined a single equilibrium constant at 600°C for the reaction $2CHClF_2(g) \rightarrow C_2F_4(g) + 2HCl(g)$. The value was not obtained directly but was obtained by extrapolation to eliminate the effects of side reactions. The equilibrium constant was used with JANAF free energy functions (2) to obtain ΔHr_{298}° = 28.75 kcal, which yields ΔHf_{298}° ($CHClF_2$, g) = -115.1 kcal/mol. An uncertainty of ±3 kcal/mol corresponds to an uncertainty of about ±500% in the equilibrium constant.

Heat Capacity and Entropy

The gas phase vibrational frequencies have been observed in the Raman by Holzer and Moser (3); they do not see anything in the 1350 cm^{-1} region as reported in the liquid by Glockler and Edgell (4). Plyler and Benedict (5) in their assignment replaced an 831 cm^{-1} frequency by 1178 cm^{-1}. We essentially adopt Glockler and Edgell's assignment with updated gas phase values for the observed frequencies. The microwave spectrum has been analysed by McLay and Mann (6) and Beeson et al. (7), who derive bond lengths and angles in excellent agreement with each other. The values given by Beeson et al. are adopted here.

Neilson and White (8) have measured the low temperature heat capacity and heat of vaporization and have reported an entropy in the gas phase at 232.5°K of 63.919 ± 0.28 gibbs/mol. This compares with 63.959 gibbs/mol calculated from our adopted functions.

The individual moments of inertia are $I_A = 8.203 \times 10^{-39}\ g\ cm^2$, $I_B = 17.402 \times 10^{-39}\ g\ cm^2$ and $I_C = 24.060 \times 10^{-39}\ g\ cm^2$.

Bond Distance: C-H = 1.09 Å C-Cl = 1.75 Å C-F = 1.367 Å

Bond Angle: Cl-C-Cl = 112°12' F-C-Cl = 109° H-C-Cl = 109°45' σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = 1.11593 x 10^{-113} g^3 cm^6.

Heat of Formation

The change in heat of atomization by successive replacement of F by Cl in the CF_4 to CCl_4 series follows a regular pattern (see CCl_2F_2 table). A similar pattern is to be expected in the CHF_3 to $CHCl_3$ series. The first replacement of the series is, in fact, 4 kcal higher than the mean versus 3.8 kcal higher in the CF_4-CCl_4 series. Thus, we have selected the atomization energy of the second and third replacements to continue this pattern. In this manner we have selected the atomization energy of $CHCl_2F$ as 367.4 kcal which corresponds to $\Delta Hf^\circ_{298}(CHCl_2F, g)$ = -67.7 kcal/mol. With this adopted value, the successive replacement of F by Cl changes the heat of atomization by 41.4, 37.3 and 33.0 kcal.

Heat Capacity and Entropy

Holzer (1) has reported the gas phase Raman spectrum which is in excellent agreement with the assignments of Plyler and Benedict (2). The only discrepancy is in ν_7, which Plyler and Benedict assign at 1242 cm^{-1}, and Holzer (1) does not report a band in this region. Holzer does, however, report a band at 728 cm^{-1} which has not been reported in the earlier liquid studies. There is strong evidence from correlations with $CHCl_3$ and CHF_3 that two frequencies should occur between 1220 and 1376 cm^{-1}. On this basis we adopt the assignment of Plyler and Benedict for ν_7, while accepting the gas phase values of Holzer for the other frequencies. The extra band at 728 cm^{-1} is not used. It is probable that the bands at 741 and 728 cm^{-1} are due to Fermi resonance of ν_4 with $2\nu_9$; the unperturbed level would lie at 735 cm^{-1}. The symmetry classes of ν_4 and $2\nu_9$ are identical and thus Fermi resonance is allowed.

McLay (3) has reported the molecular structure from his microwave investigations. The individual principal moments of inertia are I_A = 12.053 x 10^{-39} g cm^2, I_B = 25.684 x 10^{-39} g cm^2 and I_C = 36.047 x 10^{-39} g cm^2.

CHLOROFORM ($CHCl_3$) (IDEAL GAS) GFW = 119.3781

$CHCl_3$

Point Group C_{3v}

ΔHf°_0 = -23.49 ± 0.3 kcal/mol

$S^\circ_{298.15}$ = 70.628 ± 0.01 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -24.66 ± 0.3 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
3034 (1)	1220 (2)
680 (1)	774 (2)
363 (1)	261 (2)

Bond Distances: C-H = 1.100Å C-Cl = 1.758Å

Bond Angles: Cl-C-Cl = 111°18' H-C-Cl = 107°34' σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = 3.2811 \times 10^{-113}\ g^3cm^6$

Heat of Formation

Hu and Sinke (1) have measured the heat of combustion of $CHCl_3(\ell)$ in the rotating bomb calorimeter, using As_2O_3 solution as the reducing agent. The reported ΔHc°_{298} = -113.10 kcal/mol for $CHCl_3(\ell) + 0.5O_2 + H_2O(\ell) \rightarrow CO_2(g) + 3HCl(600H_2O, aq)$ which leads to $\Delta Hf^\circ_{298}(CHCl_3, \ell)$ = -32.10 kcal/mol, using ΔHf°_{298} = -94.051, -39.823, -68.315 kcal/mol for $CO_2(g)$, $HCl(600H_2O, aq)$ and $H_2O(\ell)$, respectively (2). The standard deviation of six combustion runs was 0.09 kcal/mol. Employing the heat of vaporization of chloroform at 298°K as 7.44 kcal/mol (3), we obtain ΔHf°_{298} ($CHCl_3$, g) = -24.66 kcal/mol which is adopted in the tabulation.

L. Smith et al. (4), based on the combustion data of E. Eftring (5), re-evaluated the heat of combustion of chloroform at 18.7°C as $\Delta E^\circ_c/M$ = -947.7 cal/g for $CHCl_3(\ell) + 0.5O_2(g) + H_2O(\ell) \rightarrow CO_2(g) + 3HCl(600H_2O, aq)$. This value needs to be further corrected for a change in the heat of oxidation of As_2O_3 (6) and calculated to 25°C to give ΔHc°_{298} = -113.44 kcal/mol, $\Delta Hf^\circ_{298}(CHCl_3, \ell)$ = -31.76 kcal/mol and $\Delta Hf^\circ_{298}(CHCl_3, g)$ = -24.32 kcal/mol.

Heat Capacity and Entropy

The assigned fundamental vibrational freqencies are obtained from Shimanouchi's selection (7), based on infrared and Raman spectra measured by Nielsen and Ward (8), Madigan and Cleveland (9), Gibian and McKinney (10) and Stanevich and Yaroslavskii (11).

The bond distances and angles were obtained from the microwave spectra by Jen and Lide (12). The three principal moments of inertia are $I_A = I_B = 25.719 \times 10^{-39}$ and $I_C = 49.603 \times 10^{-39}\ g\ cm^2$.

1182 (1)

Bond Distance: C-H = 1.121 Å C-F = 1.314 Å

Bond Angle: H-C-F = 101.6°

σ = 1

Product of the Moments of Inertia: $I_AI_BI_C = 1.0217 \times 10^{-117}$ g^3 cm^6

Heat of Formation

The heat of formation can be estimated as the average of those of the CH_2 and CF_2 radicals, which gives $\Delta Hf^\circ_{298}(CHF, g)$ = 25 ± 20 kcal/mol. A better value for the heat of formation can be obtained by considering the bond energies $CHF \rightarrow CH + F$ and $CHF \rightarrow CF + H$. When $\Delta Hf^\circ_{298}(CHF, g)$ = 25 kcal/mol is substituted into the above equations it gives D_{C-F} = 136 kcal and D_{C-H} = 86 kcal. These are not unreasonable values but are probably close to the upper and lower limits respectively. A value of $\Delta Hf^\circ_{298}(CHF, g)$ = 30 kcal/mol gives D_{C-F} = 131 kcal and D_{C-H} = 81 kcal which are more probable since both fall within the bounds of normal bond strengths. The strongest established C-F bond is 135 kcal in CF_3 and the weakest established C-H bond is 80 kcal in CH. We adopt $\Delta Hf^\circ_{298}(CHF, g)$ = 30 ± 7 kcal/mol.

Heat Capacity and Entropy

The structure and electronic levels of the molecule have been established by Merer and Travis (1) from an analysis of the rotational structure of the visible absorption bands. The estimated triplet state is based on the electronic levels of CF_2 and CH_2 as given in these tables. The vibrational levels are from Merer and Travis (1) and Jacox and Milligan (2), the latter investigated the infrared spectrum of matrix-isolated HCF and also estimated the missing frequency.

The individual moments of inertia are $I_A = 2.2979 \times 10^{-39}$ g cm^2, $I_B = 1.795 \times 10^{-40}$ g cm^2, and $I_C = 2.4774 \times 10^{-39}$ g cm^2.

1836.9 (1)	662.5 (1)
1342.5 (1)	[1030] (1)

Bond Lengths and Angles

C-F = 1.31 ± 0.02 Å C-O = 1.183 ± 0.003 A C-H = 1.10 ± 0.02 A

∡ FCO = 122.7 ± 0.05° ∡ HCF = 108 ± 3° ∡ HCO = 129 ± 3°

Moments of Inertia

$I_A = 0.92052 \times 10^{-39}$ g. cm.^{2} $I_B = 7.13510 \times 10^{-39}$ g. cm.^{2} $\sigma = 1$

$I_C = 8.07064 \times 10^{-39}$ g. cm.^{2}

Heat of Formation

ΔH_r for III was estimated to be the average of the ΔH_r's of I and II.

(I) $CH_2O(g) = CO(g) + 2H(g)$ 106 kcal.

(II) $CF_2O(g) = CO(g) + 2F(g)$ 162 kcal.

(III) $CHFO(g) = CO(g) + F(g) + H(g)$ [134] kcal.

The auxiliary $\Delta H_{f\ 298.15}$ of CH_2O = -28, H = 52, F = 19, CO = -26, CF_2O = -150 kcal. mole^{-1} was used. See the respective sheets for details. The estimated heat of formation is consistent with the instability of CHFO(g) at room temperature.

Heat Capacities and Entropies

The molecular structural parameters were obtained by O. H. LeBlanc, V. W. Laurie and W. D. Gwinn, J. Chem. Phys. 33, 598 (1960), from combining the results of microwave measurements with those of electron diffraction determined by M. E. Jones, K. Hedberg, and V. Schomaker, J. Am. Chem. Soc. 77, 5278 (1955). Agreement within the assigned uncertainties was obtained by R. F. Stratton and A. H. Nielsen, J. Mol. Spect. 4, 373 (1960), on the basis of infrared measurements.

Five of the fundamentals were observed by Stratton and Nielsen, loc. cit. in agreement with those obtained by H. W. Morgan, P. A. Staats and J. H. Goldstein, J. Chem. Phys. 25, 337 (1956). The estimated frequency was based upon the observed value of 857.4 cm.$^{-1}$ for the fundamental in the infrared spectrum of the deuterated compound and the application of the Teller-Redlich isotope rule.

Dec. 31, 1960; Dec. 31, 1963; June 30, 1969

Point Group C_{3v}

ΔHf°_0 = -164.9 ± 0.8 kcal/mol

$S^\circ_{298.15}$ = 62.032 ± 0.08 gibbs/mol

$\Delta Hf^\circ_{298.15}$ = -166.6 ± 0.8 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
3035 (1)	1376 (2)
1137 (1)	1152 (2)
700 (1)	508 (2)

Bond Distance: C-F = 1.333 Å C-H = 1.098 Å

Bond Angle: F-C-F = 108.6 ± 0.5° F-C-H = 110.33° σ = 3

Product of the Moments of Inertia: $I_AI_BI_C = 9.7204 \times 10^{-115}\ g^3\ cm^6$

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF_3, CF_3X (X = H, Cl, Br, I, CF_3) and C_2F_4. Details of the input data and the adjustment are given in (1). Trifluoromethane is linked to HF(21.5 H_2O) by calorimetric data, to $CBrF_3(g)$ and $CF_3I(g)$ by equilibrium data, and to $CF_3(g)$ by kinetic data. Neugebauer (2) reported calorimetric data for $CHF_3(g) + 0.5\ O_2(g) + H_2O(\ell) \to CO_2(g) + 3\ HF(21.5\ H_2O)$, where $CF_4(g)$ was also formed in a competing reaction. Recalculation of the original data with $\Delta Hf^\circ_{298.15}(CF_4, g) = -223.0$ kcal/mol yields the mean value of $\Delta Hr^\circ_{298.15} = -90.35 \pm 0.7$ kcal/mol, but the individual values of ΔHr° show a disturbing trend with the amount of competing reaction. Possible causes for the trend include corrosion and error in the analysis of the reaction products. Calibration was done in the presence of HF in an attempt to eliminate the heat due to corrosion. Because of this unexplained trend, we increase the uncertainty to ± 1.0 kcal/mol. Goy (3) and Coomber (4) determined equilibrium data for $CHF_3(g) + X_2(g) = CF_3X(g) + HX(g)$ where X = I and Br. Kinetic data pertinent to CHF_3 are noted on the table for $CF_3(g)$.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Thornton (5) and from microwave data by Ghosh (6). The results are in close agreement and average values are adopted. Vibrational frequencies are from the assignment of Long (7) who reviewed the spectral data and gave force-constant calculations. Preference has been given to the gas-phase spectra, particularly the Raman data of Claassen (8). Shimanouchi (9) assigned ν_2 = 1117 rather than 1137 cm^{-1}, but he apparently did not consider the gas-phase data of (8, 10). Principal moments of inertia are $I_A = 14.786 \times 10^{-39}$ and $I_B = I_C = 8.108 \times 10^{-39}\ g\ cm^2$.

Valentine (11) used low-temperature calorimetric data to derive the ideal gas entropy at the normal boiling point of 190.97°K. The experimental value of 57.18 gibbs/mol is in good agreement with 57.216 gibbs/mol obtained from this table. Schwing (12) measured C_v for CHF_3 vapor (25-100°C) and confirmed that the vibrational assignment is adequate. Uncertainty in Cp° and S° increases at higher temperatures due to neglect of anharmonicity in the calculations. Discussions of anharmonic contributions are given on the tables for $CF_4(g)$ and $CClF_3(g)$. The error probably does not exceed 0.3 gibbs/mol in S° at 1000°K. Cp° is consistent with Cv° measured at 300°K by the wire-ribbon method (13).

713.5 (2)
3311.5 (1)

Bond Distances: C-H = 1.066 Å C-N = 1.153 Å
Bond Angle: H-C-N = 180°
Rotational Constant: B_0 = 1.4782 cm^{-1}

σ = 1

Spectroscopic constants used in calculating corrections to the rigid-rotator harmonic oscillator approximation (cm^{-1}):

$\alpha_1 = 10.10 \times 10^{-3}$ $-x_{11} = 7.07$ $-x_{12} = 2.53$

$\alpha_2 = -3.61 \times 10^{-3}$ $-x_{22} = 2.65$ $-x_{23} = 19.01$

$\alpha_3 = 10.42 \times 10^{-3}$ $-x_{33} = 52.49$ $-x_{13} = 10.44$

$g_{22} = 5.16$

Heat of Formation

The value adopted is from reference 1. The data of Thomsen (2) who measured both C_2N_2 and HCN and Berthelot (3) were used in conjunction with the well established value for C_2N_2 to derive the adopted value (4).

Badger (5) studied the equilibrium $NH_3(g) + C(c) = HCN(g) + H_2(g)$ from both sides; we obtain a 3rd law $\Delta Hr°_{298}$ = 46 ± 0.9 kcal and a 2nd law $\Delta Hr°_{298}$ = 34.5 ± 19 kcal, the 3rd law drift is 14 ± 24 eu. The 3rd law value leads to $\Delta Hf°_{298}$(HCN, g) = 35 ± 1 kcal/mol.

Horiuchi et al. (6) studied the equilibrium $2\ CO(g) + NH_3(g) = HCN(g) + CO_2(g) + H_2(g)$. We obtain $\Delta Hr°_{298}$ = 1.1 ± 0.5 kcal from a 3rd law analysis with a drift of -2 ± 3 eu, and a 2nd law value of 2.9 ± 2.6 kcal. The 3rd law value leads to $\Delta Hf°_{298}$(HCN, g) = 31.35 ± 0.6 kcal/mol. The two sets of equilibrium data are self-consistent but disagree with each other and the direct combustions. We adopt an uncertainty of 2.0 kcal/mol to draw attention to this unsatisfactory situation.

Heat Capacity and Entropy

McBride et al. (7) used the constants listed above to calculate the adopted table which includes first and second corrections for anharmonicity, vibration-rotation interaction and centrifugal stretching. The bond lengths and molecular constants are those listed by Rank et al. (8). A more extensive set of anharmonic constants has recently been determined by Nakagawa and Morino (9), they are in generally good agreement with the values used.

Product of Moments of Inertia = $I_AI_BI_C$ = 4.73 X 10^{-118} g.^{3} cm.^{6} σ = 1

Heat of Formation

Calculated from ΔH_0 = 75.1 ± 2.3 kcal. for the reaction $H_2CO(g) \rightarrow HCO(g) + H(g)$, reported by J. C. D. Brand and R. T. Reed, J. Chem. Soc. 2386 (1957).

Heat Capacity and Entropy

The vibrational levels and multiplicities are from G. E. Ewing, W. E. Thompson, and G. C. Pimentel, J. Chem. Phys. 32, 927 (1960), while the ground state multiplicity and structural data are from G. Herzberg and D. A. Ramsay, Proc. Roy. Soc. A233, 34 (1955).

Bond Distance: C-H = [1.029] Å C-O = [1.090] Å

Bond Angle: H-C-O = [180°] σ = [1]

Rotational Constant: B_o = [1.56015] cm^{-1}

Heat of Formation.

The selected heat of formation, ΔHf°_0 (HCO^+, g) = 203 kcal/mol was obtained from electron impact studies on cis-and trans-HCOOH by F. M. Field and J. L. Franklin, "Electron Impact Phenomena," Academic Press, New York, 1957. A higher value, ΔHf°_0 = 220 kcal/mol has also been reported from appearance potential measurements on CH_3CHO by J. R. Majer, C. R. Patrick and J. C. Robb, Trans. Faraday Soc. 57, 14 (1961). Generally, errors in the heat of formation derived from electron impact studies are such as to cause the quantities to be high because of unaccounted excitations or residual kinetic energy in the fragments; therefore, the value of 203 kcal/mol is preferable, assuming the same reliability of the experiments.

Heat Capacity and Entropy.

Since the molecule HCO^+(g) has the same number of valence electrons as HCN(g), a linear molecular configuration is assumed for HCO^+(g) in the tabulation. The bond distances H-C and C-O were estimated by comparison with those in similar molecules by D. G. Clifton, J. Chem. Phys. 41, 3656 (1964). The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants of Clifton. The principal moment of inertia is 1.7941 X 10^{-39} g cm^2.

Spectroscopic constants used in calculating corrections to the rigid-rotator harmonic oscillator model (cm^{-1}):

$\alpha_1 = 3.4 \times 10^{-3}$ $-x_{11} = [3.7]$ $-x_{12} = [1.9]$

$\alpha_2 = -3.4 \times 10^{-4}$ $-x_{22} = [2.4]$ $-x_{23} = [18.0]$

$\alpha_3 = 3.1 \times 10^{-3}$ $-x_{23} = [51.0]$ $-x_{13} = [8.0]$

Bond Distances: C-H = 1.0667 Å C-P = 1.5421 Å

Bond Angle: H-C-P = 180° $\sigma = 1$

Rotational Constant: B_0 = 0.66633 cm^{-1}

Heat of Formation

The bonding in HCP and HCN is very similar, as evidenced by the bond lengths and vibrational frequencies. We assume that the C-H bond strength is thus the same in these two molecules. For the reaction HCN → H + CN we derive ΔHr = 123.8 kcal from ΔHf°_{298}(HCN) = 32.3, ΔHf°_{298}(H) = 52.1 and ΔHf°_{298}(CN) = 104 kcal/mol. Applying this to the reaction HCP → H + CP, we obtain ΔHf°_{298}(HCP, g) = 40 ± 15 kcal/mol, from ΔHf°_{298}(CP) = 111.7 kcal/mol.

Heat Capacity and Entropy

The molecular configuration was first reported by Gier (1), and later the bond lengths were determined by Tyler (2) using microwave spectroscopy. The vibrational frequencies and electronic levels were obtained from an analysis of the ultraviolet spectrum by Johns et al. (3). Since the first excited state is above 24000 cm^{-1} and the first nonlinear state at 34,000 cm^{-1}, there is negligible error introduced by assuming ground state molecular constants for all excited states. The anharmonic constants were estimated from those of HCN by Gordon (4) and the adopted table includes these corrections and the electronic contributions.

Heat of Formation

Chupka and Livshitz (1) have recently obtained the photoionization threshold for the production of CH_2^+ from CH_3 as 15.09 ± 0.03 eV. In conjunction with the spectroscopic ionization potential determined by Herzberg (2), they report $D_0(CH_2\text{-}H)$ = 4.694 ± 0.033 eV (108.25 ± 0.77 kcal). Use of $\Delta Hf^\circ_0(CH_3, g)$ = 35.62 kcal/mol from these tables yields $\Delta Hf^\circ_0(CH_2, g)$ = 92.25 ± 1.0 kcal/mol, which is adopted.

Chupka (3) and Dibeler et al. (4) have determined the photoionization threshold for the production of CH_2^+ from CH_4. If the latter value is corrected for rotational energy effects as suggested by Chupka the two values are identical and yield $\Delta Hf^\circ_0(CH_2, g)$ = 94.6 kcal/mol. However, Chupka indicates that this is a maximum value since the process of H_2 elimination is likely to occur with excess energy in the products at the threshold. Chupka et al. (14) have obtained the appearance threshold of CH_2^+ from $C_2H_4(g)$ by photoionization and obtain a maximum value of $\Delta Hf^\circ_0(CH_2, g)$ = 95.5 kcal/mol.

Dibeler and Liston (5) have also reported the photoionization threshold for the process $CH_3CN \rightarrow CH_2^+ + HCN$ as 14.94 eV (344.55 kcal). Using auxiliary data from (2) and (13) we obtain $\Delta Hf^\circ_0(CH_2, g)$ = 95 kcal/mol, however the above process is also likely to occur with excess energy and so this is a maximum value.

The older electron impact data of Langer et al. (6) contained several inconsistencies with presently accepted values and was reanalysed by Prophet (7) to give $\Delta Hf^\circ_{298}(CH_2, g)$ = 95 ± 5 kcal/mol. Chupka et al. (8) have also reported a heat of formation, from chemical equilibria measured in a mass spectrometer, as 86.8 ± 6 kcal/mol.

Heat Capacity and Entropy

The ground state configuration, bond length and angle are from Herzberg (9). The excited electronic states are from the calculations of Goldberg and Riter (10) who have tried to allow for correlation energy effects in the different states. The separation between the a^1A_1 and b^1B_1 states is established as 7100 cm^{-1}. The degenerate bending frequency was listed as a possible fundamental of CH_2 by Milligan and Pimentel (11). There is considerable uncertainty that it is in fact the ground state bending frequency, excited state bending frequencies of 1353 and 557 cm^{-1} have been reported. The symmetric stretch was estimated to be that listed by Herzberg (12) for a bent molecule. The asymmetric stretch was estimated using the valence force field approximation.

The uncertainty in the entropy reflects the possible errors in the vibrational frequencies and the uncertain position of the low lying electronic levels and their varying geometries.

Bond Distance: C-H = 1.078 Å C-Cl = 1.759 Å C-F = 1.378 Å

Bond Angle: H-C-H = 111°54' F-C-Cl = 110° H-C-Cl = 109°06' σ = 1

Product of the Moments of Inertia: $I_AI_BI_C$ = 4.8154 x 10^{-115} g^3 cm^6

Heat of Formation

The change in heat of atomization by successive replacement of F by Cl, in the CF_4 to CCl_4 series and CHF_3 to $CHCl_3$ series, follows a regular pattern (see CCl_2F_2 and $CHCl_2F$ tables). We make the assumption that this same regular variation occurs also in the CH_2F_2 to CH_2Cl_2 series. Thus, the difference between the atomization energies of CH_2F_2 and CH_2Cl_2 is divided into two unequal parts which fall into the pattern established in the CF_4 and CHF_3 sequences. We adopt a heat of atomization of 385.5 kcal which corresponds to a $\Delta Hf^\circ_{298}(CH_2ClF, g)$ = -62.6 kcal/mol. The changes, in kcal, in the heat of atomization by successive replacement of F by Cl are tabulated, below for all three series.

CF_4		
43.8		
CF_3Cl	CHF_3	
41.6	41.4	
CF_2Cl_2	CHF_2Cl	CH_2F_2
38.5	37.3	35.0
$CFCl_3$	$CHFCl_2$	CH_2FCl
36.0	33.0	29.7
CCl_4	$CHCl_3$	CH_2Cl_2

Heat Capacity and Entropy

Plyler and Benedict (1) assigned the vibrational frequencies from the infrared and Raman data for the liquid. The molecular structure was obtained from the microwave measurements of Muller (2). The individual moments of inertia are I_A = 2.008 x 10^{-39} g cm^2, I_B = 16.241 x 10^{-39} g cm^2, and I_C = 14.766 x 10^{-39} g cm^2.

DICHLOROMETHANE (CH_2Cl_2) (IDEAL GAS) GFW = 84.9331

Point Group C_{2v}

$\Delta Hf^\circ_0 = -21.19 \pm 0.3$ kcal/mol

$S^\circ_{298.15} = 64.574 \pm 0.01$ gibbs/mol

$\Delta Hf^\circ_{298.15} = -22.83 \pm 0.3$ kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}	ω, cm^{-1}
2999 (1)	282 (1)	898 (1)
1467 (1)	1153 (1)	1268 (1)
717 (1)	3040 (1)	758 (1)

Bond Distances: C-H = 1.068Å C-Cl = 1.7724Å

Bond Angles: H-C-H = 112° Cl-C-Cl = 111.8° $\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 1.8686 \times 10^{-114}\ g^3cm^6$.

Heat of Formation

Hu and Sinke (1) have measured the heat of combustion of $CH_2Cl_2(\ell)$ in the rotating bomb calorimeter, using As_2O_3 solution as the reducing agent. They reported $\Delta Hc^\circ_{298} = -144.00$ kcal/mole for $CH_2Cl_2(\ell) + O_2(g) \rightarrow CO_2(g) + 2HCl(600H_2O, aq)$ which leads to $\Delta Hf^\circ_{298}(CH_2Cl_2, \ell) = -29.70$ kcal/mol, using $\Delta Hf^\circ_{298} = -94.051$ and -39.823 kcal/mol for $CO_2(g)$ and $HCl(600H_2O, aq)$, respectively (2). The standard deviation of five combustion runs was 0.12 kcal/mol. Employing the heat of vaporization of $CH_2Cl_2(\ell)$ at 298°K as 6.87 kcal/mol (3), we obtain $\Delta Hf^\circ_{298}(CH_2Cl_2, g) = -22.83$ kcal/mol which is adopted in the tabulation.

L. Smith et al. (4), based on the combustion data of E. Eftring (5), re-evaluated the heat of combustion of dichloromethane at 18.7°C as $\Delta E^\circ_c/M = -1701.4$ cal/g for $CH_2Cl_2(\ell) + O_2(g) \rightarrow CO_2(g) + 2HCl(600H_2O, aq)$. This value needs to be further corrected for a change in the heat of oxidation of As_2O_3 (6) and calculated to 25°C to give $\Delta E^\circ_{c298} = \Delta Hc^\circ_{298} = -144.89$ kcal/mol, $\Delta Hf^\circ_{298}(CH_2Cl_2, \ell) = -28.80$ kcal/mol and $\Delta Hf^\circ_{298}(CH_2Cl_2, g) = -21.93$ kcal/mol.

J. Lacher et al. (7) have measured the heat of hydrogenation of dichloromethane to methane and hydrogen chloride at 250°C as -40.07 kcal/mol. Correction to 298°K gives $\Delta Hf^\circ_{298}(CH_2Cl_2, g) = -23.05$ kcal/mol which is in good agreement with the value adopted.

Heat Capacity and Entropy

The bond distances and angles have been determined from the microwave spectra by R. J. Myers and W. D. Gwinn (8). The three principal moments of inertia are $I_A = 2.630 \times 10^{-39}$, $I_B = 2.5623 \times 10^{-38}$ and $I_C = 2.7727 \times 10^{-38}$ g cm^2.

The assigned fundamental vibrational frequencies are obtained from Shimanouchi's selection (9), based on infrared and Raman spectra by Shimanouchi and Syzuki (10), **Palma** et al. (11), and **Welsh** et al. (12).

2949 (1)	529 (1)	1176 (1)
1508 (1)	1262 (1)	1435 (1)
1116 (1)	3013 (1)	1090 (1)

Bond Distances: C-F = 1.358 ± 0.001 Å C-H = 1.092 ± 0.003 Å

Bond Angles: F-C-F = 108° 17' ± 6' H-C-H = 111° 52' ± 25' $\sigma = 2$

Product of the Moments of Inertia: $I_AI_BI_C = 1.2272 \times 10^{-115}$ g^3 cm^6

Heat of Formation

Neugebauer and Margrave (1) measured the enthalpy of combustion of CH_2F_2. Their result for the combustion reaction

$$CH_2F_2(g) + O_2(g) \rightarrow CO_2(g) + 2HF\cdot 21.5\ H_2O$$

was ΔH_{298} = -139.84 ± 0.22 kcal/mole. Using $\Delta Hf^\circ_{298}(HF\cdot 21.5\ H_2O)$ = -76.75 ± 0.1 kcal/mol (2), obtained with dilution data compiled by Parker (3), we derive,

$$\Delta Hf^\circ_{298}(CH_2F_2,\ g) = -107.7 \pm 0.4\ \text{kcal/mol},$$

from Margrave's data.

Heat Capacity and Entropy

The vibrational frequencies are average values from the infrared studies of Stewart and Nielsen (4) and Plyler and Benedict (5). Individual moments of inertia are calculated from the rotational constants reported by Lide (6) with the result $I_A = 1.7082 \times 10^{-39}$ g cm^2, $I_B = 7.9160 \times 10^{-39}$ g cm^2, and $I_C = 9.0754 \times 10^{-39}$ g cm^2. The molecular structure data are from the microwave studies of Lide (6) and are in excellent agreement with electron-diffraction studies of Brockway, Thornton, and Bartell whose results are reported in the Annual Review of Physical Chemistry (7).
